**Abstract**

The molecular structures of the three main haemolytic compounds (Fj1, Fj2 and Fj3) isolated from the ichthyotoxic microalgal species *Fibrocapsa japonica* have been investigated by NMR, LC–ESI–MS, ESI–MS–MS, IR, GC–MS and GC–HRMS methods. They are polyunsaturated fatty acids which we identified as: 6,9,12,15-octadecatetraenoic acid (OTA, C\(_{18}:4\)\(\text{v}3\)), 5,8,11,14,17-eicosapentaenoic acid (EPA, C\(_{20}:5\)\(\text{v}3\)) and 5,8,11,14-eicosatetraenoic acid (arachidonic acid AA, C\(_{20}:4\)\(\text{v}6\)). The identity of the latter two was confirmed on the basis of commercial standards (C\(_{20}:5\)\(\text{v}3\) and C\(_{20}:4\)\(\text{v}6\)). Both displayed the same spectroscopic and chromatographic characteristics as Fj2 and Fj3 and had a similar strong haemolytic effect. We propose that when *F. japonica* cells accumulate in fish gills during blooms these compounds could be the cause of ichthyotoxicity.

1. **Introduction**

In the class Raphidophytes, the species *Fibrocapsa japonica*, *Heterosigma akashiwo* and *Chattonella* spp. have been reported to produce red-tide blooms that induce mass mortality of cultured fish in Southeast Asian coastal waters (Toriumi and Takano, 1973; Nakamura and Watanabe, 1983). The species *F. japonica* has caused significant damage to coastal fisheries in Japan (Toriumi and Takano, 1973; Yoshimatsu, 1987; Montani et al., 1995). From the beginning of the 1990s *F. japonica* has been observed in European coastal waters (Billard, 1992; Vrieling et al., 1995; Rademaker et al., 1998). Both molecular and physiological data on *F. japonica* strains suggest a recent range expansion of this species (Kooistra et al., 2001; De Boer et al., 2002).

The mechanism behind the toxicity of *F. japonica* is still under debate. Oda and co-workers (1997) showed the production of reactive oxygen species by a Japanese *F. japonica* strain that could damage fish gills. Polyether neurotoxins were found in a European strain (W420) and identified as brevetoxins on the basis of their chromatographic behaviour in HPLC (Khan et al., 1996), and brevetoxins were also recently detected using a competitive ELISA technique in American strains (Bridgers et al., 2002).
From the crude extract of *F. japonica* from the German coast (CCRGu, C13, Culture Collection, University of Groningen, The Netherlands) that did not contain components in the size class of brevetoxins (LC–MS), we purified three compounds with pronounced haemolytic activity (Fu et al., 2002). The elucidation of the structures of these three purified compounds is described in the present communication.

2. Materials and methods

2.1. NMR experiments

The dried haemolytic compounds Fj1 (1.6 mg), Fj2 (2.0 mg) and Fj3 (1.2 mg), obtained by ELA-guided HPLC purification (Fu et al., 2002), were dissolved in methanol-d₄ and NMR spectra were recorded from these solutions on an AVANCE 500 NMR spectrometer (Bruker) (¹H 500.1 MHz, ¹³C 125.8 MHz). The measurements were carried out at 300 K. The chemical shifts are reported on the δ-scale in ppm and were referred to the internal standard, signals of non-deuterated methanol (¹H: 3.30 ppm) or signals of deuterated methanol (¹³C: 49.00 ppm). Coupling constants *J* are given in Hz. Assignment of the signals was done according to the ¹H and ¹³C-NMR spectra.

2.2. LC–ESI–MS and ESI–MS–MS experiments

Fj1, Fj2 and Fj3 were diluted in 80% acetonitrile (gradient grade from Merck, made with UV-treated deionised water), and several drops of ammonium hydroxide solution (0.25% NH₄OH in acetonitrile) were added. The HPLC-system consisted of two Perkin Elmer series 200 micro LC pumps, a Perkin Elmer series 200 autosampler, a pre-column and an analytical column (Alltima, £m, C18, 150 x 2.1 mm²). The flow rate was 0.2 ml/min, with an injection volume of 50 µl.

Preliminary experiments showed fibrocapsins to easily lose protons. Mass spectrometry was therefore performed in the negative ion detection mode for which a post-column base condition (0.25% NH₄OH in acetonitrile) was supplied at 100 µl/min with a syringe pump (Harvard Apparatus 22) which was also connected to the MS system. The MS system used was a PE SCIEX API 3000 triple quadrupole LC–MS–MS mass spectrometer equipped with a pneumatically assisted electrospray ionisation interface. The ionisation voltage was set to −4.5 kV. Nitrogen was employed as both nebulizing gas and drying gas (heated to 450 °C, 2 bar, 2 l/min). Ion detection was performed in negative mode under the energy condition (OR = −15 V, RNG = −150 V). The scan data were acquired with a 0.1 u step width and 0.1 ms dwell time.

Three pure compounds, fibrocapsin 1, 2 and 3, were injected directly into an API 3000 triple quadrupole MS–MS mass spectrometer with a syringe infusion pump (Harvard Apparatus 22) at 10 µl/min. Ion detection was performed in the negative ion mode under the energy conditions OR = −41 V and RNG = −130 V. The [M–H]⁺ precursor masses 275.1 (Fj1), 301.3 (Fj2) and 303.4 (Fj3) were selected separately. ESI–MS–MS spectra were acquired with nitrogen as the collision gas. All scan data were acquired with 0.1 u step width and 2 ms dwell time.

2.3. IR experiments

Three haemolytic compounds Fj1, Fj2 and Fj3 were each dissolved in 100% methanol (HPLC grade from Merck). Several drops of solutions were taken and dripped on the sodium chloride plate, which was then air dried. The plate was measured in the IR spectrometer (ATI Mattson Genesis Series FTIR™).

2.4. GC–MS and GC–HRMS experiments

The haemolytic compounds Fj1 (170 µg), Fj2 (250 µg) and Fj3 (140 µg) dissolved separately in 200 µl CH₂Cl₂, were treated ultrasonically for 15 min. Hundred microlitres Fj1, 70 µl Fj2 and 100 µl Fj3 were then incubated with 50 µl N-methyl-N-trimethylsilyltrifluoroacetamide solution (MSTFA, CS-Chromatographie Service GmbH) for 1 h at 80 °C.

GC–MS analyses of the volatised TMS-fibrocapsins were performed on a HP 5890 Series II GC (Avondale, PA) coupled with a Finnigan MAT SSQ 710B mass spectrometer (San Jose, CA). The GC was equipped with a KAS 3 injector (Gerstel) and a J&W Scientific DB-5HT 15m capillary column (0.25 mm, 0.25 µm film thickness) with helium as the carrier gas. The samples were injected at an oven temperature of 60 °C. After 1 min the temperature was programmed to raise to 300 °C at 3 °C/min and kept for 50 min at this temperature.

GC–HRMS analyses applied a Finnigan MAT 95 Q mass spectrometer with ICIS 8.2.1, ICL 10.0 software. The GC equipment was similar to that described above, helium was also used here as carrier gas, but with an HP-1MS column (60 m x 0.25 mm ID, 0.25 µm film thickness). The samples were injected also at an oven temperature of 60 °C. After 2 min, the temperature was raised to 150 °C at a 10 °C/min rate and then to 300 °C at a 4 °C/min and kept there for 10 min.
3.3. Physical and spectroscopic data of Fj1

Fj1 was obtained as colourless oil: UV $\lambda_{\text{max}}$ (HPLC-DAD) 210 nm; LC−ESI−MS (negative mode) $m/z$ [M−H]$^-$ 275, [M+HCOO]$^- 321, [2M−H]$^-$ 551; ESI−MS−MS (negative mode) $m/z$ [M−2H]$^-$ 138, [M−3H]$^-$ 89, 156, 192, 228. 

GC−MS (70 eV) of Fj1-TMS: $m/z$ [M]$^+$ 348 ($C_{25}H_{38}O_2Si$, 73), 327 ($C_{24}H_{36}O_2Si$, 6), 305 ($C_{23}H_{34}O_2Si$, 0.07), 279 ($C_{22}H_{32}O_2Si$, 4), 264 ($C_{21}H_{29}O_2Si$, 1), 258 [M−OH−TMS, 0.01], 252 [(CH$_2$)$_2$−Si=O−CO−((CH$_2$)$_2$−(CH$_2$)$_2$)−CH$_2$], 229 [(CH$_2$)$_2$−(CH$_2$)$_2$−(CH$_2$)$_2$−(CH$_2$)−CH−CH], 216 [(CH$_2$)$_2$−(CH$_2$)$_2$−(CH$_2$)$_2$−(CH$_2$)−CH−CH], 201 [TMSO−CO−(CH$_2$)$_3$−CH$_2$, 3], 189 [(CH$_2$)$_2$−(CH$_2$)$_2$−(CH$_2$)$_2$−CH$_2$, 13], 175 [(CH$_2$)$_2$−(CH$_2$)$_2$−(CH$_2$)$_2$−CH−CH$_2$, 16], 161 [(CH$_2$)$_2$−(CH$_2$)$_2$−(CH$_2$)$_2$−CH−CH$_2$, 27], 149 [(CH$_2$)$_2$−(CH$_2$)$_2$−(CH$_2$)$_2$, 9], 147 [(CH$_2$)$_2$−(CH$_2$)$_2$−CH$_2$−CH−CH$_2$, 35], 145 [TMSO−CO−CH$_2$−CH$_2$, 30], 132 [TMSO−C(OH)=CH$_2$, 129 [(CH$_2$)$_2$−SiO−CO−CH−CH$_2$, 45], 120 [(CH$_2$)$_2$−CH−CH−CH−(CH$_2$)$_2$−CH$_2$, 45], 117 [(CH$_2$)$_2$−CH−CH−CH−(CH$_2$)$_2$−CH$_2$, 132 [TMSO−CO−CH$_2$−CH$_2$, 30], 132 [TMSO−C(OH)=CH$_2$, 129 [(CH$_2$)$_2$−SiO−CO−CH−CH$_2$, 45], 120 [(CH$_2$)$_2$−CH−CH−CH−(CH$_2$)$_2$−CH$_2$, 45], 117 [(CH$_2$)$_2$−CH−CH−CH−(CH$_2$)$_2$−CH$_2$, 3].

4. Results

3.3.1. Physical and spectroscopic data of Fj2

Fj2 was also obtained as colourless oil: UV $\lambda_{\text{max}}$ (HPLC-DAD) 210 nm; LC−ESI−MS (negative mode) $m/z$ [M−H]$^-$ 301, [M+HCOO]$^- 347, [2M−H]$^-$ 604; ESI−MS−MS (negative mode) $m/z$ [M−H]$^-$ 348, [M−2H]$^-$ 174, [M−3H]$^-$ 116, 142, 178. 

GC−MS (70 eV) of Fj2-TMS: $m/z$ [M]$^+$ 374 ($C_{25}H_{38}O_2Si$, 0.51), 359 ($C_{25}H_{34}O_2Si$, 1), 345 ($C_{25}H_{34}O_2Si$, 0.74), 331 ($C_{25}H_{32}O_2Si$, 0.51), 305 ($C_{25}H_{30}O_2Si$, 3).
The amount of material was too little to record 13C-NMR spectra. 

The above data prove the structural identity of Fj2 with the polyunsaturated fatty acid 5,8,11,14,17-eicosapentaenoic acid (C20:5ω3, Structure 2).

3.3. Physical and spectroscopic data of Fj3

Fj3 was obtained as colourless oil, too: UV λmax (HPLC-DAD) 210 nm; LC–ESI–MS (negative mode) m/z [M–H]− 337.3864 (calculated for C20H36O2Si, 337.2851). 

The three haemolytic compounds isolated from a methanol extract of F. japonica were identified as polyunsaturated fatty acids (PUFAs). PUFAs, either present as free acids, phospholipids or glycolipids, are usually encountered in algal extracts and considered to be membrane components. Fatty acid composition can be used in taxonomic identification (species or genus specific PUFAs) and also serves as an indicator of food quality to herbivores according to the presence or absence of essential fatty acids. These compounds have also been investigated for their use as food additives in human nutrition (Wood et al., 1999) and their effects on various inflammatory and autoimmune diseases (Borlak and Welch, 1994; Simopoulos, 2002). Furthermore, the role of PUFAs in infant nutrition also has received considerable attention (cf. Koletzko and Rodriguez-Palmero, 1999).

Although essential for some herbivores, high concentrations of PUFAs have been reported to be toxic. Yasumoto et al. (1990) identified two haemolytic fractions during a massive fish kill in 1998, associated with a Gymnodinium aureolum bloom along the Norwegian coast. The fraction with the highest haemolytic activity against mouse blood cells corresponded to the free fatty acid octadecapentaenoic acid (18:5ω3). Okaichi (1989) reported that the highly unsaturated fatty acids 16:4 and 18:4 may be the primary causative substances in fish mortalities. Among the PUFAs, EPA (C20:5ω3) is one of the most harmful (Arzul et al., 1995; Jüttner et al., 2001; Takagi et al., 1984). It exhibits lethal toxicity to mice when injected intraperitoneally, it can cause diarrhea (Sajiki et al., 1993), it is haemolytic, and it is also highly depressive for the bioluminescence of Vibrio Fischeri (reported as Photobacterium phosphoreum, Arzul et al., 1998).

The major fatty acids found in the Raphidophytes are 16:0, 18:4ω3 and 20:5ω3 (Marshall et al., 2002b; Mostaert et al., 2009).
et al., 1998). *Heterosigma akashiwo* was reported to contain the haemolytic PUFA 18:5ω3 too (Bell et al., 1997), but 18:4ω3 and 20:5ω3 were dominant and no C20:4ω6 was detected. *Chattonella* spp. contained 18:5ω3 as trace while this component was absent in the two strains of *F. japonica* that Marshall and co-workers studied. EPA was present in a high amount in all the raphidophytes species studied (17–27%) (Marshall et al., 2002b).

Fig. 2. $^1$H-NMR and $^{13}$C-NMR spectra of EPA (C20:5ω3) and Fj2.

Fig. 3. 1H-NMR spectra of AA (C20:4ω6) and Fj3.

Fig. 4. Haemolytic effects of two standards (10 μg/ml each) after 24 h incubation (negative control: ELA buffer and human erythrocytes; positive control: ELA buffer and completely lysed human erythrocytes).
Jüttner (2001) proposed that the polyunsaturated fatty acids observed in algal extracts are in fact the first products of the lipoxygenase cascade that starts upon cell disruption. Lipids are rapidly hydrolysed to yield unsaturated fatty acids, which readily oxidise to hydroperoxy fatty acids that subsequently cleave into unsaturated aldehydes and α-oxo-fatty acids. The PUFAs could be part of a defence strategy that rapidly converts an essential cell constituent into a highly toxic grazer toxin. Perhaps the production of PUFAs and ROS (Oda et al., 1992) in a F. japonica bloom are an indication of such a defence system (Marshall et al., 2002a). Although we did not carry out any fish bioassay, we assume that fishes involved in a F. japonica bloom accumulate cells in their gills and thereby experience strong toxic effects that could be lethal even without neurotoxins being present.
