Asynchronous Implementation of Distributed Coordination Algorithms: Conditions Using Partially Scrambling and Essentially Cyclic Matrices

Yao Chen, Member, IEEE, Weiguo Xia, Member, IEEE, Ming Cao, Senior Member, IEEE and Jinhu Lü, Fellow, IEEE

Abstract—Given a distributed coordination algorithm (DCA) for agents coupled by a network, which can be characterized by a stochastic matrix, we say that the DCA can be asynchronously implemented if the consensus property is preserved when the agents are activated to update their states according to their own clocks. This paper focuses on two central problems in asynchronous implementation of DCA: which class of DCA can be asynchronously implemented, and which other cannot. We identify two types of stochastic matrices, called partially scrambling and essentially cyclic matrices, for which we prove that DCA associated with a partially scrambling matrix can be asynchronously implemented, and there exists at least one asynchronous implementation sequence which fails to realize consensus for DCA associated with an essentially cyclic matrix.

Index Terms—Distributed coordination algorithm, asynchronous implementation, partially scrambling matrix, essentially cyclic matrix.

I. INTRODUCTION

Distributed coordination algorithms (DCA) belong to a typical class of algorithms which gives rise to emerging collective behavior in complex systems through local interactions [13], [19]. Using such an algorithm, each agent updates its state through averaging those of its neighbors, making the states of all agents converge to some identical value, called consensus [4], [17], [15], [30]. Due to the special distributed converging property of DCA, it can be used not only in solving practical engineering problems, such as distributed gradient-descent for large-scale convex optimization problems [16], but also for explaining interesting social phenomena, such as opinion formation in social networks [9].

The convergence of DCA relates closely to the convergence of products of stochastic matrices [6], [7], [20]-[23], [25]-[28], [29], the analysis of which is difficult since the commonly used smooth Lyapunov function cannot be easily found [18]. An effective method for the analysis of DCA is evaluating the ergodic coefficient of the corresponding matrix products [10], [20], [21], [25], based on which many interesting results have been reported [1], [2], [12], [22], [23]. It should be noted that the constructed ergodic coefficients for DCA are generally non-smooth, the magnitude of which has strong connection with the structure of the corresponding graphs describing how the agents are coupled together. Based on this observation, the graphical approach, rather than the algebraic approach, usually plays a critical role in the analysis of DCA [4], [27]. Specifically, all the existing results only focus on some specific types of matrices, since the analysis on products of general stochastic matrices is much harder [24] and in fact is an open problem in the field of DCA. In this paper, we will use the graphical approach to study the asynchronous implementation of DCA with some special graphical structures.

The asynchronous implementation of DCA means that the state updating of each agent follows an independent clock, and it has been proved that asynchronous updating of states also guarantees consensus if self-loops are preserved in the graph [3]. However, for general DCA without self-loops in the graph, the dynamics of asynchronous implementation are rather complicated, and an important fact is that asynchronous updating may not lead to consensus even if the corresponding synchronous updating does [26]. Based on this observation, an interesting question for DCA is what type of DCA reaches consensus when implemented asynchronously. As a step towards answering this question, Xia and Cao proved that any asynchronous updating achieves consensus if the associated graph is neighbor-shared [26] (i.e., the associated stochastic matrix is scrambling), where by a neighbor-shared graph it is meant that any two nodes in the graph share a common neighbor [4]. For a further step, it is natural to ask: can we find a larger set of graphs in which any associated DCA guarantees consensus for any asynchronous implementation? Besides this problem, this paper also tries to address the corresponding inverse question: what kind of DCA cannot be asynchronously implemented in the sense that there always exists an asynchronous implementation for the given DCA which cannot lead to consensus? In this paper, we will report two sets of stochastic matrices that have been constructed for the first time, giving answers to the above two questions.

The rest of the paper is organized as follows: Section II formulates the asynchronous implementation problem; Section III proposes a set of stochastic matrices, called partially scrambling matrices, and proves that any partially scrambling matrix can be asynchronously implemented; Section IV gives...
a set of stochastic matrices, called essentially cyclic matrices, and proves that each essentially cyclic matrix cannot be asynchronously implemented; Section V presents some examples and corollaries; Section VI concludes this paper.

II. PROBLEM FORMULATION

Any stochastic matrix $A \in \mathbb{R}^{N \times N}$ can be described by a graph $G(A) = (V, E)$, where $V = \{1, 2, \ldots, N\}$ is the set of nodes and $E$ is the set of edges: $(i, j) \in E$ if and only if $a_{ij} > 0$. Given a set $S \subseteq V$, $G_S$ is defined as the induced subgraph of $G$ over $S$.

A directed path in $G(A)$ is a sequence of distinct nodes $i_1, \ldots, i_k$ such that $(i_s, i_{s+1}) \in E$ for $1 \leq s \leq k - 1$. $G(A)$ is rooted if it contains a node, called a root, that has a directed path to every other node. If $G(A)$ is rooted, we define root$(A)$ as the set of all the roots of $G(A)$. Specifically, we define the following function $N(\cdot, \cdot)$ for any stochastic matrix:

$$N(A, S) = \{ j : a_{ij} > 0, i \in S \},$$

where $A \in \mathbb{R}^{N \times N}$ is stochastic and $S$ is a subset of $V$.

Stochastic matrices can be used to describe the distributed coordination algorithm in the form

$$x_{k+1} = Ax_k, \quad k \geq 1,$$

where $x_k \in \mathbb{R}^N$ and $A \in \mathbb{R}^{N \times N}$ is a stochastic matrix. If $A$ is SIA (i.e., stochastic, indecomposable, and aperiodic) [25], then for any $x_1 \in \mathbb{R}^N$, there exists $\xi \in \mathbb{R}^N$ such that $\lim_{k \to \infty} x_k = \xi$, where $1 \in \mathbb{R}^N$ is the all-one vector [3].

Given a stochastic matrix $A = (a_{ij})_{i,j=1}^N$, let $a_k \in \mathbb{R}^{1 \times N}$ $(k = 1, 2, \ldots, N)$ denote its $k$th row. Define the following matrix

$$A_k = (e_1, \ldots, e_{k-1}, a_k^T, e_{k+1}, \ldots, e_N)^T,$$

where $e_k \in \mathbb{R}^N$ is the unit vector with the $k$th entry being 1. Since matrix $A$ is stochastic, one can verify that $A_k$ $(k = 1, 2, \ldots, N)$ is also stochastic. The matrix $A_k$ is called the asynchronous implementation of $A$ on the $k$th node.

Given a stochastic matrix $A \in \mathbb{R}^{N \times N}$, a sequence of matrices $\{A_{\sigma(k)}\}_{k=1}^\infty$ $(\sigma(k) \in V)$ is called an asynchronous implementation sequence of matrix $A$ if $\bigcup_{k=1}^\infty \{\sigma(k)\} = V$ for all $j \geq 1$. An asynchronous implementation sequence $\{A_{\sigma(k)}\}_{k=1}^\infty$ of matrix $A$ is said to realize consensus if for any initial condition $x_1 \in \mathbb{R}^N$, it holds

$$\lim_{k \to \infty} x_k = \lim_{k \to \infty} A_{\sigma(1)} \cdots A_{\sigma(k)} x_1 = \xi.$$

III. SET OF MATRICES WHICH CAN BE ASYNCHRONOUSLY IMPLEMENTED

In what follows, we will introduce the concepts of the absorbing set and partially scrambling matrix first.

For any stochastic matrix $A = (a_{ij})_{i,j=1}^N$, a set $S \subseteq V$ is called absorbing with respect to $A$ if

a) $G(A)$ is rooted and $S \cap \text{root}(A) \neq \emptyset$;

b) For any $i \in S$, $N(A, i) \cap S \neq \emptyset$.

Based on the above definition, one knows that if $G(A)$ is rooted, then $V$ is absorbing with respect to $A$. Specifically, if $a_{kk} > 0$ and $k \in \text{root}(A)$, then the singleton $\{k\}$ is absorbing with respect to $A$.

A matrix $A = (a_{ij})_{i,j=1}^N$ is called partially scrambling if for any $i, j \in V$ $(i \neq j)$, there exists $k$ such that $a_{ik} a_{jk} > 0$. According to [8], one knows that $G(A)$ is rooted for any

$$A = \begin{pmatrix} 0 & 0.5 & 0.5 \\ 1 & 0 & 0 \\ 0.5 & 0.5 & 0 \end{pmatrix},$$

whose graph $G(A)$ is given in Fig. 1. One can easily verify that $A$ is partially scrambling by letting $\nu = 3$ and $\mathcal{I} = \{1, 2\}$.
Fig. 1. An example of partially scrambling graph: the set \( \mathcal{I} = \{1, 2\} \) is absorbing, \( \nu = 3 \) shares a common neighbor with each node of \( \mathcal{I} \).

Let \( \mathcal{Q}_{ps} \) be the set of partially scrambling matrices and we will show that \( \mathcal{Q}_{ps} \) is larger than \( \mathcal{Q}_s \).

**Proposition 4:** \( \mathcal{Q}_s \subseteq \mathcal{Q}_{ps} \).

**Proof:** For any \( A \in \mathcal{Q}_s \), since any scrambling matrix is rooted [8], one can choose \( \nu \in \text{root}(A) \). Furthermore, \( \nu \) is absorbing with respect to \( A \) since \( \mathcal{G}(A) \) is rooted. For any \( i \in \mathcal{V} \), since \( A \) is scrambling, there exists \( k \in \mathcal{V} \) such that \( \alpha_{ik} > 0 \). Hence, the two conditions of partially scrambling matrices are both satisfied and \( A \in \mathcal{Q}_{ps} \). \( \Box \)

The main result of this section is given as follows:

**Theorem 1:** Given any matrix \( A \in \mathcal{Q}_{ps} \), any asynchronous implementation sequence of matrix \( A \) realizes consensus.

The proof of Theorem 1 relies on the following Proposition 5 and Lemma 1-5. In Proposition 5 and Lemma 1-5, we assume that \( A \in \mathcal{Q}_{ps}, \{ \mathcal{A}_k \}_{k=1}^\infty \) is an asynchronous implementation sequence of \( A \), \( q \) is the constant given in the definition of an asynchronous implementation sequence, \( \mathcal{I} \) is an absorbing set of \( \mathcal{V} \) with respect to \( A \), and \( \nu \in \text{root}(A) \).

The basic idea of the proof of Theorem 1 can be summarized as follows: At first, we divide the asynchronous implementation sequence \( A_{T,1} = A_{\sigma(T)}A_{\sigma(T-1)} \cdots A_{\sigma(1)} \) into two parts for some large \( T \), one is \( A_{T:(r+1)} = A_{\sigma(r+1)}A_{\sigma(r+1-1)} \cdots A_{\sigma(1)} \), and the other is \( A_{\sigma(r+1)}A_{\sigma(r+1-1)} \cdots A_{\sigma(1)} \); Second, we show that for any two vertices \( i \) and \( j \), the function \( \mathcal{N}'(A_{T:(r+1)},:) \) makes \( i \) accessed by \( \nu \), and \( j \) accessed by one of the nodes in \( \mathcal{I} \) (Lemma 3); Third, we show that for any \( k' \in \mathcal{I} \), \( \mathcal{N}'(A_{r},\nu) \) and \( \mathcal{N}'(A_{r},k') \) share a common element (Lemma 4); At last, we combine the above two steps and demonstrate that \( \mathcal{N}(A_{T,1},i) \) and \( \mathcal{N}(A_{T,1},j) \) share a common neighbor (Lemma 5), which implies that \( A_{T,1} \) is scrambling (Proposition 2) and the convergence to consensus can be obtained via Proposition 1.

**Proposition 5:** [11] For any \( k \geq 1 \) and \( S \subset \mathcal{V} \), it holds

\[
\mathcal{N}(A_{\sigma(k+1)}A_{\sigma(k)},S) = \mathcal{N}(A_{\sigma(k)},\mathcal{N}(A_{\sigma(k+1)},S)).
\]

**Lemma 1:** If \( j \in \mathcal{I} \), then for any \( T \geq 1 \), we have

\[
\mathcal{N}(A_{\sigma(T)}A_{\sigma(T-1)} \cdots A_{\sigma(1)},j) \bigcap \mathcal{I} \neq \emptyset.
\]

**Proof:** According to the definition of \( \mathcal{I} \), one knows that for any \( \sigma(k) \in \mathcal{V} \) and \( i \in \mathcal{I} \), \( \mathcal{N}(A_{\sigma(k)},i) \bigcap \mathcal{I} \neq \emptyset \). Applying Proposition 5 on \( \mathcal{N}(:,j) \) we arrive at the conclusion. \( \Box \)

**Lemma 2:** For any \( i, j \in \mathcal{V} \), if

\[
\mathcal{N}(A_{\sigma(T)}A_{\sigma(T-1)} \cdots A_{\sigma(1)},i) \bigcap \mathcal{N}(A_{\sigma(T)}A_{\sigma(T-1)} \cdots A_{\sigma(1)},j) \neq \emptyset,
\]

for some \( r \geq 0 \) and \( T \geq r + 1 \), then

\[
\mathcal{N}(A_{\sigma(T)}A_{\sigma(T-1)} \cdots A_{\sigma(1)},i) \bigcap \mathcal{N}(A_{\sigma(T)}A_{\sigma(T-1)} \cdots A_{\sigma(1)},j) \neq \emptyset.
\]

**Proof:** It follows directly from Proposition 5. \( \Box \)

**Lemma 3:** Given \( T \geq 2Nq + 2 \), for any \( i, j \in \mathcal{V} \), there exists \( r \) which satisfies \( T - r \leq 2Nq + 1 \) and

\[
\nu \in \mathcal{N}(A_{\sigma(T)}A_{\sigma(T-1)} \cdots A_{\sigma(1)},i), \mathcal{N}(A_{\sigma(T)}A_{\sigma(T-1)} \cdots A_{\sigma(1)},j) \bigcap \mathcal{I} \neq \emptyset.
\]

**Proof:** Since \( \mathcal{I} \) is an absorbing set, \( \mathcal{I} \bigcap \text{root}(A) \neq \emptyset \). Letting \( j \in \mathcal{I} \bigcap \text{root}(A) \), there exists a directed path from \( j \) to \( j \) in \( \mathcal{G}(A) \) denoted by \( j \rightarrow j \rightarrow \cdots 

Letting \( j \in \mathcal{I} \bigcap \text{root}(A) \), there exists a directed path from \( j \) to \( j \) in \( \mathcal{G}(A) \) denoted by \( j \rightarrow j \rightarrow \cdots \rightarrow j \), where \( m \leq N \).

Denote

\[
t(0) = \max \{ k: \sigma(k) = j, 1 \leq k \leq T\},
\]

\[
t(1) = \max \{ k: \sigma(k) = j, 1 \leq k < t(0)\},
\]

\[
\vdots
\]

\[
t(m-1) = \max \{ k: \sigma(k) = j, m-1, 1 \leq k < t(m-2)\},
\]

from which one obtains

\[
j_1 \in \mathcal{N}(A_{\sigma(T)}A_{\sigma(T-1)} \cdots A_{\sigma(1)},j),
\]

\[
j_2 \in \mathcal{N}(A_{\sigma(t(0)+1)}A_{\sigma(t(0)+2)} \cdots A_{\sigma(t(1))},j_1),
\]

\[
\vdots
\]

\[
j_m \in \mathcal{N}(A_{\sigma(t(m-2)+1)}A_{\sigma(t(m-2)+2)} \cdots A_{\sigma(t(m-1)+1)},j_m).
\]

According to Proposition 5, one derives that \( j \in \mathcal{N}(A_{\sigma(T)}A_{\sigma(T-1)} \cdots A_{\sigma(t(m-1)+1)},j) \) and \( j \in \mathcal{I} \). According to the absorbing property of \( \mathcal{I} \), for any \( k \leq t(m-1) \), we know that

\[
\mathcal{N}(A_{\sigma(T)}A_{\sigma(T-1)} \cdots A_{\sigma(1)},j) \bigcap \mathcal{I} \neq \emptyset.
\]

Specifically, from the property that \( \bigcup_{j=k+1}^{q+1} A_{\sigma(j)} = \mathcal{V} \) (\( k \geq 0 \)), one knows

\[
T - t(0) \leq q,
\]

\[
t(i) - t(i+1) \leq q, \text{ for } 0 \leq i \leq m - 2,
\]

and hence \( T - t(m-1) \leq mq \leq Nq \).

Consider another path \( i_p \rightarrow i_{p-1} \rightarrow \cdots \rightarrow i_1 \) in \( \mathcal{G}(A) \), where \( i_p = \nu, p \leq N \), and

\[
i_t \in \mathcal{N}(A_{\sigma(T)}A_{\sigma(T-1)} \cdots A_{\sigma(t(m-1)+1)},\nu),
\]

for which the fact that \( \nu \in \text{root}(A) \) guarantees the existence of such a path. Similar to the above deductions, one can find some \( d \leq Nq \) such that

\[
\nu \in \mathcal{N}(A_{\sigma(t(m-1)+1)}A_{\sigma(t(m-1)+2)} \cdots A_{\sigma(t(m-1)+d)},i_1).
\]

Combining (4) and (5) together leads to

\[
\nu \in \mathcal{N}(A_{\sigma(T)}A_{\sigma(T-1)} \cdots A_{\sigma(t(m-1)+d)},\nu).
\]

Let \( r = t(m-1) + d - 1 \), and one knows

\[
T - r = (T - t(m-1)) + t(m-1) - r \leq Nq + d + 1 \leq 2Nq + 1.
\]

Combining (3) and (6), the proof is hence completed. \( \Box \)

**Lemma 4:** Given an absorbing set \( \mathcal{I} \) and any \( k' \in \mathcal{I} \), if \( r \geq q(N + q) + 1 \), there exists \( k'' \in \mathcal{V} \) such that

\[
k'' \in \mathcal{N}(A_{\sigma(T)}A_{\sigma(T-1)} \cdots A_{\sigma(1)},\nu) \bigcap \mathcal{N}(A_{\sigma(T)}A_{\sigma(T-1)} \cdots A_{\sigma(1)},k') \neq \emptyset.
\]
Proof: Since $r \geq q(N + q) + 1 \geq q$, one can define
\[
\begin{align*}
t_v &= \max\{k : \sigma(k) = \nu, 1 \leq k \leq r\}, \\
t_{k^*} &= \max\{k : \sigma(k) = k^*, 1 \leq k \leq r\},
\end{align*}
\]
and the property of asynchronous implementation sequence guarantees that $r - t_v \leq q - 1$ and $r - t_{k^*} \leq q - 1$.

We make the following discussions:
**CASE a):** $t_{k^*} = t_v$.
In this case, one knows $k^* = \nu$, the result holds naturally.

**CASE b):** $t_{k^*} > t_v$.
Denote
\[
\begin{align*}
s_1 &= \{k^*\}, \\
s_1' &= \{k : \sigma(k) \in s_1, t_v < k \leq r\}, \\
t^{(1)} &= \max s_1', \text{ if } s_1' \neq \emptyset, \\
k_1 &= \sigma(t^{(1)}),
\end{align*}
\]
where $k_1$ also satisfies $k_1 = k^*$.

Furthermore, for any $p \geq 2$, we construct the following iterative formulas:
\[
\begin{align*}
s_p &= \mathcal{N}(\sigma(t_p^{(p-2)}) \cdots \sigma(t_p^{(2)}), k_p-1) \cap I, \\
s_p' &= \{k : \sigma(k) \in s_p, t_v < k < t_p^{(p-1)}\}, \\
t^{(p)} &= \max s_p', \text{ if } s_p' \neq \emptyset, \\
k_p &= \sigma(t^{(p)}),
\end{align*}
\]
where $t^{(0)} = r + 1$.

Since $t_v < t_p^{(p-1)}$, one knows the condition of $t_v < k < t_p^{(p-1)}$ will not be satisfied after several times of iteration, and hence there exists $p$ such that $s_p = \emptyset$.

Denote $m = \min\{p : s_p = \emptyset\}$, and then the above iterations imply that
\[
\begin{align*}
k_2 &\in \mathcal{N}(\sigma(t_2^{(0)}) \cdots \sigma(t_2^{(1)}), k_1) \cap I, \\
k_3 &\in \mathcal{N}(\sigma(t_3^{(1)}) \cdots \sigma(t_3^{(2)}), k_2) \cap I, \\
&\vdots \\
k_{m-1} &\in \mathcal{N}(\sigma(t_{m-2}^{(m-3)}) \cdots \sigma(t_{m-2}^{(m-2)}), k_{m-2}) \cap I, \\
\emptyset &\neq \mathcal{N}(\sigma(t_{m-2}^{(m-3)}) \cdots \sigma(t_{m-2}^{(m-1)}), k_{m-1}) \cap I.
\end{align*}
\]

Consider the pair of indices $k_{m-1}$ and $\nu$, due to the fact that $k_{m-1} \in I$, there exists $k^* \in I$ such that $a_{k_{m-1}, k^*} > 0$ and hence $k^* \in \mathcal{N}(A, k_{m-1}) \cap \mathcal{N}(A, \nu) \cap I$, which leads to
\[
\begin{align*}
k^* &\in \mathcal{N}(\sigma(t_{m-2}^{(m-2)}) \cdots \sigma(t_{m-2}^{(m-1)}), k_{m-1}) \cap I, \\
k^* &\in \mathcal{N}(\sigma(t_{m-2}^{(m-1)}) \cdots \sigma(t_{m-1}), \nu) \cap I.
\end{align*}
\]
If $k^* \neq \nu$, due to the fact that $s_m' = \emptyset$, one further knows
\[
k^* \in \mathcal{N}(\sigma(t_{m-2}^{(m-1)}), k_{m-1}) \cap I,
\]
which indicates
\[
k^* \in \mathcal{N}(\sigma(t_{m-2}^{(m-1)}), k_{m-1}) \cap I.
\]

Therefore,
\[
k^* \in \mathcal{N}(\sigma(t_{m-2}^{(m-1)}), \nu) \cap \mathcal{N}(\sigma(t_{m-2}^{(m-1)}), k_1) \cap I.
\]

According to Lemma 2 and using the absorbing property of $I$, one derives that there exists $k''$ such that
\[
k'' \in \mathcal{N}(\sigma(r) \cdots \sigma(t_{m-2}^{(m-1)}), \nu) \cap \mathcal{N}(\sigma(r) \cdots \sigma(t_{m-2}^{(m-1)}), k_1) \cap I,
\]
which in view of $k_1 = k'$ completes the discussion.

If $k^* = \nu$, one derives $\nu \in \mathcal{N}(\sigma(t_{m-2}^{(m-1)}), k_{m-1})$, which indicates $\nu \in \mathcal{N}(\sigma(r) \cdots \sigma(t_{m-2}^{(m-1)}), k_1)$. Since $\nu \in \mathcal{N}(\sigma(r) \cdots \sigma(t_{m-2}^{(m-1)}), \nu)$, there also exists $k''$ such that
\[
k'' \in \mathcal{N}(\sigma(r) \cdots \sigma(t_{m-2}^{(m-1)}), \nu) \cap \mathcal{N}(\sigma(r) \cdots \sigma(t_{m-2}^{(m-1)}), k_1).
\]

**CASE c):** $t_{k^*} < t_v$.
Since $\nu \in \text{root}(A)$, one can find a cycle from $\nu$ to $\nu$ with length $l (l \leq N)$, repeating this cycle for $(\frac{l}{2}) + 1$ times generates a cycle with length $l = l(\frac{l}{2}) + 1 > q$. Specifically, the length of the merged cycle also satisfies $l \leq (\frac{l}{2}) + 1 \leq N + q$.

Let the merged cycle be $i_j = \nu \rightarrow i_{j-1} \rightarrow i_{j-2} \cdots \rightarrow i_0 = \nu$. Similar to the techniques in the proof of Lemma 3, one can find $1 < r' \leq r$ such that
\[
\nu \in \mathcal{N}(\sigma(r) \cdots \sigma(t_{m-2}^{(m-1)}), \nu),
\]
where $q < r - r' \leq q(N + q)$.

Based on the definition of $r'$, one further defines
\[
t_{k^*} = \max\{k : \sigma(k) = \nu, 1 \leq k \leq r'\},
\]
then $t_{k^*} \leq r' < r - q < r - q + 1 \leq t_{k^*}$. The remaining proof is similar to that of CASE b) and hence omitted.

Summarize the above three cases, the proof is hence completed.

Lemma 5: For any $i, j \in V$, if $T \geq (3N + q)q + 2$, then
\[
\begin{align*}
\mathcal{N}(\sigma(T) \cdots \sigma(i), i) &\subseteq \mathcal{N}(\sigma(T) \cdots \sigma(i), j) \\
\mathcal{N}(\sigma(T) \cdots \sigma(i), j) &\neq \emptyset.
\end{align*}
\]

Proof: According to Lemma 3, one can find some $k' \in V$ and $\nu$ which satisfies $T - r \leq 2Nq + 1$ such that
\[
\nu \in \mathcal{N}(\sigma(T) \cdots \sigma(i), j) \\
k' \in \mathcal{N}(\sigma(T) \cdots \sigma(i), j) \cap I \neq \emptyset.
\]

Since $T \geq (3N + q)q + 2$, one knows $r \geq (N + q)q + 1$. According to Lemma 4, one further derives
\[
\begin{align*}
\mathcal{N}(\sigma(T) \cdots \sigma(i), \nu) &\subseteq \mathcal{N}(\sigma(T) \cdots \sigma(i), j) \\
\mathcal{N}(\sigma(T) \cdots \sigma(i), \nu) &\neq \emptyset.
\end{align*}
\]

Summarizing the above two facts leads to the completion of the proof.

Based on the above lemmas, we are ready to present the proof of the main theorem.

Proof of Theorem 1: Given a sequence of implemention matrices $\{A(\sigma(k))\}_{k=1}^\infty$, denote
\[
Q_k = A(\sigma(kT)) \cdots A(\sigma((k-1)T + 2)) \cdot A(\sigma((k-1)T + 1)),
\]
if $r \leq q(N + q)$, the existence of $r'$ may not be guaranteed.
where $T = (3N + q)q + 2$.

According to Lemma 5 and Proposition 2, one knows that $Q_k$ is scrambling and hence $\tau(Q_k) \leq 1 - \alpha^T$, where $\alpha$ is the minimal positive entry of $A$. Since $\prod_{k=1}^{\infty} A_{\sigma(k)} = \prod_{k=1}^{\infty} Q_k$ and $\tau(\prod_{k=1}^{\infty} Q_k) \leq \prod_{k=1}^{\infty} \tau(Q_k)$, we arrive at the conclusion. \hfill \Box

IV. SET OF MATRICES WHICH CANNOT BE ASYNCHRONOUSLY IMPLEMENTED

To facilitate the description of the following problem, given a graph $G = (\mathcal{V}, \mathcal{E})$ and a set $S \subseteq \mathcal{V}$, we define the two functions

$$\partial^-(S) = \{k : (i, k) \in \mathcal{E}, i \in S, k \notin S\},$$

$$\partial^+(S) = \{k : (k, i) \in \mathcal{E}, i \in S, k \notin S\}.$$

Given a graph $G = (\mathcal{V}, \mathcal{E})$, let $\{V_i\}_{i=1}^{r}$ be a partition of $\mathcal{V}$:

$$\bigcup_{i=1}^{r} V_i = \mathcal{V}$$

and $V_i \cap V_{i'} = \emptyset$ for $i_1 \neq i_2$. The reduced graph of $G$ with respect to $\{V_i\}_{i=1}^{r}$ is defined by $\tilde{G} = (\tilde{\mathcal{V}}, \tilde{\mathcal{E}})$, where $\tilde{\mathcal{V}} = \{1, 2, \cdots, r\}$ and $(i, j) \in \tilde{\mathcal{E}}$ if and only if there is a link from a node in $V_i$ to a node in $V_j$.

A graph $G = (\mathcal{V}, \mathcal{E})$ is called a directed acyclic graph (DAG) if $G$ contains no cycle. Based on this definition, one knows that a DAG may not be rooted.

A stochastic matrix $A = (a_{ij})_{i,j=1}^{N}$ is called essentially cyclic if there exists a partition $\{V_i\}_{i=1}^{r}$ of $\mathcal{V}$ with $r \geq 3$ such that:

a) The subgraph $\tilde{G}_{V_1}$ is a DAG;

b) The reduced graph with respect to $\{V_i\}_{i=1}^{r}$ is a directed cycle.

The above definition of essentially cyclic matrices is inspired by the definition of periodic matrices [21]: a stochastic matrix $A = (a_{ij})_{i,j=1}^{N}$ is called periodic if there exists an equivalent partition $\{V_i\}_{i=1}^{r}$ of $\mathcal{V}$ which makes the corresponding reduced graph a directed cycle, and makes each subgraph $\tilde{G}_{V_i}$ a null graph.

Given any connected graph $G$, one can decompose it into several strongly connected components with the corresponding reduced graph being a DAG [14]; such a property is exactly opposite to the decomposition of an essentially cyclic graph, in which each decomposed component contains no cycle but the reduced graph is cyclic.

Based on the definition of essentially cyclic matrices, one knows that

**Proposition 6:** Any SIP (stochastic, indecomposable, and periodic) matrix is essentially cyclic.

Furthermore, since the equivalent partition satisfies $r \geq 3$, any cycle in the corresponding graph of an essentially cyclic matrix has length greater than 3, which leads to the following proposition.

**Proposition 7:** Given a stochastic matrix $A$, if $\tilde{G}(A)$ contains $K_2$ as a subgraph$^3$, then $A$ is not essentially cyclic.

We use $\mathcal{Q}_{ec}$ to denote the set of essentially cyclic matrices. As shown in Fig. 2, the given graph is essential cyclic if we set $V_1 = \{1\}$, $V_2 = \{2\}$, and $V_3 = \{3, 4\}$, and then all the items

$^3K_n$ is the fully connected graph with $n$ nodes.
the corresponding graph containing $r$ DAGs, we use the corresponding asynchronous implementation sequences constructed in Lemma 7 for $r$ times, and then we obtain an asynchronous implementation sequence of matrix $A$ by combining these $r$ asynchronous implementation sequences; Third, we show that by suitably reordering these $r$ asynchronous implementation sequences the conditions of Lemma 6 will be satisfied, which leads to non-consensus.

**Lemma 6**: Given a stochastic matrix $A \subseteq \mathbb{R}^{N \times N}$, if there exists $V_1, V_2 \subseteq V, V_1 \cap V_2 = \emptyset$ such that

$$N(A, V_1) \subseteq V_2, \quad N(A, V_2) \subseteq V_1,$$

then matrix $A$ is not SIA.

**Proof**: By reordering the indices of $V$, matrix $A$ can be written as

$$A = \begin{pmatrix}
0 & A_{12} & 0 \\
A_{21} & 0 & 0 \\
\times & \times & \times
\end{pmatrix},$$

where each ‘$\times$’ means a block matrix with appropriate dimensions. The structure of $A$ implies for any $k \geq 1$, there holds

$$A^{2k} = \begin{pmatrix}
0 & 0 & 0 \\
0 & 0 & 0 \\
\times & \times & \times
\end{pmatrix}, \quad A^{2k+1} = \begin{pmatrix}
0 & 0 & 0 \\
0 & 0 & 0 \\
\times & \times & \times
\end{pmatrix}.$$

Hence for a sufficiently large $k$, any column of $A^k$ cannot be completely positive, which indicates $A$ is not SIA. \hfill $\Box$

The following Lemma 7 defines an ordering function $f(\cdot)$ on a DAG, which is critical for the consequent Lemma 8.

**Lemma 7**: There exists a topological ordering $f(k)$ associated with each node $k$ of a DAG $\mathcal{G} = (V, E)$, i.e., if $(i, j)$ is an edge of $\mathcal{G}$, then $f(i) > f(j)$.

**Proof**: We define the following function $f(\cdot)$ associated with each node of $V$:

1. Set $k := 1, G_1 = G$;
2. Set $V_k = \{j : \text{the out degree of } j \text{ in } G_k \text{ is zero}\}$;
3. Set $f(j) = k$ for each $j \in V_k$;
4. Set $G_{k+1}$ be the subgraph of $\mathcal{G}$ with node set $V/\{V_i\}_{i=1}^k$;
5. If $G_{k+1}$ is not null, set $k := k + 1$ and go to step 2.

One can verify that the above function $f(\cdot)$ is a topological ordering of $\mathcal{G}$. \hfill $\Box$

**Lemma 8**: Given a stochastic matrix $A \in \mathbb{R}^{N \times N}$ and a set $S \subseteq V$. If $\partial^+(S) \neq \emptyset$ and the subgraph $\mathcal{G}_S$ contains no cycle, then there exists an asynchronous realization sequence $A_{\sigma(k)}(k = 1, 2, \cdots, s)$ such that

$$N(A_{\sigma(s)}A_{\sigma(s-1)} \cdots A_{\sigma(1)}, S) = \partial^+(S),$$

where $s = |S|$ and $\bigcup_{k=1}^s \sigma(k) = S$.

**Proof**: For the set of nodes $S$, since $\mathcal{G}_S$ is a DAG, there exists a topological ordering $f(k)$ for each node $k$ of $S$. Based on the ordering function $f(\cdot)$ in Lemma 7, we define a sequence $\{k_i\}_{i=1}^s$ which satisfies $\bigcup_{k=1}^s \{i_k\} = S$ and $f(i_1) \leq f(i_2) \leq \cdots \leq f(i_s)$. Then, we will show that

$$N(A_iA_{i_2} \cdots A_{i_s}, S) \subseteq \partial^+(I).$$

For these nodes $i_1, i_2, \cdots, i_s$, without loss of generality, suppose that

$$f(i_1) = f(i_2) = \cdots = f(i_k) \neq f(i_{k+1}),$$

$$f(i_{k+1}) = f(i_{k+2}) = \cdots = f(i_l) \neq f(i_{l+1}),$$

$$f(i_{l+1}) = f(i_{l+2}) = \cdots = f(i_s) \neq f(i_{s+1}),$$

$$f(i_{s+1}) = f(i_{s+2}) = \cdots = f(i_{s+1}),$$

where $k + 1 = s$ and set $k_0 = 1$.

For nodes $i_1, i_2, \cdots, i_k$, according to the definition of $f(\cdot)$ in Lemma 7, there is no direct connections among them, and hence the implementations $A_{i_1}, A_{i_2}, \cdots, A_{i_k}$ are independent and these implementation maps the nodes from $i_1, i_2, \cdots, k$ to $i_{k+1}, i_{k+2}, \cdots, i_2$, which leads to

$$N(A_{i_1}A_{i_{k+1}}, A_{i_k+1} \cdots A_{i_k}, S) = \{i_{k+1}, i_{k+2}, \cdots, i_k\}.$$ Similarly, it holds

$$N(A_{i_{k+1}}A_{i_{k+2}} \cdots A_{i_k}, S) = \{i_{k+2}, i_{k+3}, \cdots, i_k\},$$

$$N(A_{i_{k+2}}A_{i_{k+3}} \cdots A_{i_k}, S) = \{i_{k+3}, i_{k+4}, \cdots, i_k\},$$

$$N(A_{i_k}, A_{i_{k+1}} \cdots A_{i_k}, S) = \partial^+(I).$$

Using the conductivity of the function $N(\cdot, \cdot)$, one derives that $N(A_{i_1}A_{i_2} \cdots A_{i_s}, S) \subseteq \partial^+(I)$. Set $\sigma(k) = i_{s-k+1}$ and this completes the proof. \hfill $\Box$

Based on the above three lemmas, one obtains the proof of Theorem 2.

**Proof of Theorem 2**: The critical step of the proof is to find an algorithm which generates the asynchronous implementation sequence of $A$ which cannot lead to consensus.

For the reason of simplicity, suppose that $V$ can be partitioned equivalently into $r = 3$ components. The case of $r > 3$ can be proved similarly. Hence the reduced graph $\mathcal{G} = (V, E)$ satisfies $E = \{(1, 2), (2, 3), (3, 1)\}$. Without loss of generality, suppose $V_1 = \{1, 2, \cdots, s_1\}, V_2 = \{s_1 + 1, s_1 + 2, \cdots, s_2\}$, and $V_3 = \{s_2 + 1, s_2 + 2, \cdots, s_3\}$, where $s_3 = N$.

For the component $V_1$, based on the definition of essentially cyclic graph, one knows the subgraph $\mathcal{G}_{V_1}$ contains no cycle. According to Lemma 8, we can find a matrix $B_1 = A_{i_1}, A_{i_2}, \cdots, A_{i_1}$ such that $N(B_1, V_1) = \partial^+(V_1) \subseteq V_3$, where $\bigcup_{i=1}^{s_1} \{ik\} = V_1$.

Similarly, one can construct two matrices $B_2 = A_{i_3}A_{i_{1+2}} \cdots A_{i_2}$ and $B_3 = A_{i_3}A_{i_{2+2}} \cdots A_{i_3}$ such that $N(B_3, V_3) = \partial^+(V_3) \subseteq V_2, N(B_2, V_2) = \partial^+(V_2) \subseteq V_1$. \hfill (7)

According to the above equalities, one derives

$$N(B_1B_2B_3, V_1) \subseteq N(B_2B_3, V_3) = N(B_3, V_3) \subseteq V_2,$$

$$N(B_1B_2B_3, V_2) = N(B_2B_3, V_2) \subseteq N(B_3, V_1) \subseteq V_1,$$

$$N(B_1B_2B_3, V_3) = N(B_2B_3, V_3) = N(B_3, V_3) \subseteq V_2.$$ According to Lemma 6, the above three equations imply that the matrix $B_1B_2B_3$ is not SIA, and hence repetitive products of $B_1B_2B_3$ cannot reach consensus. \hfill $\Box$
V. DISCUSSIONS AND EXAMPLES

According to Theorem 1 and 2, one knows the two sets of matrices \( \mathcal{Q}_{ps} \) and \( \mathcal{Q}_{ec} \) do not intersect with each other. Denote \( \mathcal{Q}_{SIA} \) as the set of SIA matrices, and an interesting question is whether \( \mathcal{Q}_{ps} \) and \( \mathcal{Q}_{ec} \) are complementary in \( \mathcal{Q}_{SIA} \), which is answered in the following proposition.

Proposition 8: It holds \( \mathcal{Q}_{ps} \cup (\mathcal{Q}_{ec} \cap \mathcal{Q}_{SIA}) \subset \mathcal{Q}_{SIA} \).

Proof: Consider the matrix

\[
A = \begin{pmatrix}
0 & 1/2 & 0 & 0 & 1/2 \\
1 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 1 & 0
\end{pmatrix}
\]

and the corresponding graph \( G(A) \). One can easily check that \( A \in \mathcal{Q}_{SIA} \).

Since \( G(A) \) contains \( K_2 \) as a subgraph, then \( A \notin \mathcal{Q}_{ec} \) from Proposition 7.

In graph \( G(A) \), one finds that only node 1 and 3 share a common neighbor 2. If \( A \in \mathcal{Q}_{ps} \), then the absorbing set \( I \) can be set as \( I = \{1\} \) or \( I = \{3\} \). However, since neither node 1 nor node 3 contains a self-loop, \( \{1\} \) and \( \{3\} \) cannot be the absorbing sets, which is a contradiction and hence \( A \notin \mathcal{Q}_{ps} \).

Summarizing the above completes the proof. \( \square \)

In what follows, we will give some corollaries and examples of Theorem 1 and 2.

Corollary 1: Given a stochastic matrix \( A \in \mathbb{R}^{N \times N} \), if \( G(A) \) is rooted with the diagonal entry corresponding to a root is positive, then \( A \in \mathcal{Q}_{ps} \).

Proof: Set \( I = \{\nu\} \), where \( \nu \in \text{root}(A) \) with the corresponding diagonal entry of \( \nu \) is positive in \( A \). One can check that all the conditions of partially non-scrambling matrices are satisfied. \( \square \)

Corollary 2: Given a stochastic matrix \( A = (a_{ij})_{i,j=1}^{N,N} \in \mathbb{R}^{N \times N} \), if there exists \( I \subseteq V \) such that
a) For each \( i \in I \), it holds \( a_{ii} > 0 \);
b) For each \( j \in V/I \) and \( i \in V \), there exists \( k \in V \) such that \( a_{ik}a_{j,k} > 0 \);
c) \( G(A) \) is rooted,
then \( A \in \mathcal{Q}_{ps} \).

Proof: If the root \( \nu \) of \( G(A) \) belongs to \( I \), then \( A \in \mathcal{Q}_{ps} \) from Corollary 1. If the root of \( \nu \) of \( G(A) \) belongs to \( V/I \), then considering that set \( V \) is absorbing, \( A \) still belongs to \( \mathcal{Q}_{ps} \) from Theorem 1. \( \square \)

In the definition of asynchronous implementation in section II, each \( \sigma(k) \) is only an element of set \( V \), and in fact, \( \sigma(k) \) can be generalized to a subset of \( V \), which is called multiple asynchronous implementation defined below.

Multiple asynchronous implementation of DCA associated with a stochastic matrix \( A \) is defined as: for any sequence of matrices \( \{A_{\sigma(k)}\}_{k=1}^\infty \) which satisfies \( \sigma(k) \subseteq V \),

\[
\bigcup_{k=j}^{j+q-1} \sigma(k) = V \quad \text{for all } j \geq 1, \text{ it holds that}
\]

\[
\lim_{k \to \infty} A_{\sigma(k)} \cdots A_{\sigma(2)} A_{\sigma(1)} x_1 = \mu \xi,
\]

where \( x_1 \in \mathbb{R}^N \) and \( \xi \in \mathbb{R} \) is decided by \( x_1 \) and the sequence \( \{A_{\sigma(k)}\}_{k=1}^\infty \). The matrix \( A_{\sigma(k)} (\sigma(k) \subset V) \) is a direct generalization of \( A_{\sigma(k)} (\sigma(k) \in V) \) by preserving multiple rows \( \sigma(k) \) of \( A \) in \( A_{\sigma(k)} \).

Corollary 3: If \( A \in \mathcal{Q}_{ps} \), then any multiple asynchronous implementation of \( A \) guarantees consensus.

Proof: The proof of Corollary 3 requires a slight modification of Lemma 4, and we omit the details since the basic ideas of them are quite similar. \( \square \)

Since asynchronous implementation is a special case of multiple asynchronous implementation (let \( \sigma(k) = V \) for each \( k \geq 1 \)), one derives:

Corollary 4: If \( A \in \mathcal{Q}_{ps} \), then \( A \) is SIA.

Example 1: Given the two matrices

\[
A = \begin{pmatrix}
0 & 0 & 0 & \frac{1}{2} & \frac{1}{2} \\
0 & 0 & \frac{1}{2} & \frac{1}{2} & 0 \\
0 & \frac{1}{2} & 0 & \frac{1}{2} & 0 \\
0 & \frac{1}{2} & 0 & \frac{1}{2} & 0 \\
0 & 0 & 0 & 0 & 1
\end{pmatrix},
B = \begin{pmatrix}
0 & 0 & 0 & \frac{1}{2} & \frac{1}{2} \\
0 & 0 & \frac{1}{2} & \frac{1}{2} & 0 \\
0 & \frac{1}{2} & 0 & \frac{1}{2} & 0 \\
0 & \frac{1}{2} & 0 & \frac{1}{2} & 0 \\
0 & 0 & 0 & 0 & 1
\end{pmatrix},
\]

the connectivity of \( G(A) \) and \( G(B) \) can be easily verified; however \( A \) is not scrambling since the third and fourth rows do not have positive entries in the same column. \( B \) is neither scrambling due to the same reason. For matrix \( A \), set \( I = \{3, 4\} \) and \( \nu = 1 \), one can verify all the conditions of partially non-scrambling matrix are satisfied; for matrix \( B \), set \( I = \{1, 4\} \) and \( \nu = 2 \), the conditions of partially non-scrambling matrix are also satisfied. According to Theorem 1, one knows that both \( A \) and \( B \) can be asynchronously implemented.

In order to verify Theorem 1, we choose \( q = 8 \) and generate the indices \( \sigma(4k+1), \sigma(4k+3), \sigma(4k+2), \sigma(4k+1) \), for each \( k \geq 0 \) via the following procedure:

a) Set \( k := 0 \);
b) Set \( \sigma(4k+j) = j \) for each \( j = 1, 2, 3, 4 \);
c) Randomly choose two elements among \( \sigma(4k+4), \sigma(4k+3), \sigma(4k+2), \sigma(4k+1) \), and swap their positions;
d) Repeat c) for 5 times;
e) Set \( k := k + 1 \) and go to b).

The above procedure guarantees \( \bigcup_{j=1}^{j+q-1} \{\sigma(k)\} = V \) for each \( k \geq 1 \). Given two sets of random initial values, the corresponding asynchronous dynamics of \( x_k \) defined in (2) with respect to \( A \) and \( B \) are given in Fig. 4, and one can see both of them realize consensus.

Example 2: As shown in Fig. 5, the graph on the left is a cyclic graph with period 3. Then adding two edges within two clusters generates an aperiodic graph. One can check that all the conditions of Theorem 2 are satisfied, and then any
stochastic matrix associated with the graph on the right cannot be asynchronously implemented.

Given the following stochastic matrix

\[
A = \begin{pmatrix}
0 & 0 & 0 & 0 & 1 \\
0.5 & 0 & 0.5 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 \\
0 & 0 & 0.5 & 0 & 0 \\
\end{pmatrix},
\]  

(9)

whose graph \(\mathcal{G}(A)\) is on the right of Fig. 5. According to the proof of Theorem 2, one can construct the following periodic indices

\[
\sigma(k) = \begin{cases}
4, & \text{when } k \equiv 1 \pmod{5} \\
5, & \text{when } k \equiv 2 \pmod{5} \\
3, & \text{when } k \equiv 3 \pmod{5} \\
1, & \text{when } k \equiv 4 \pmod{5} \\
2, & \text{when } k \equiv 0 \pmod{5}.
\end{cases}
\]

Given a set of random initial values, the dynamics of \(x_k\) driven by the above \(\sigma(k)\) are given in Fig. 6, and one can see that such an implementation does not realize consensus.

VI. CONCLUSION

This paper has discussed two problems on asynchronous implementation of DCA: what type of stochastic matrices can be asynchronously implemented, and what type cannot. We have found two types of stochastic matrices, called partially scrambling and essentially cyclic matrices, based on which we have proved that any partially scrambling matrix can be asynchronously implemented, while any essentially cyclic matrix cannot. Since the identified two types of stochastic matrices are not complementary, our future research will focus on identifying the maximal subclass of SIA matrices in which any asynchronous implementation sequence of each realizes consensus.
