The Mystery of TFP

Nicholas Oulton

Centre for Macroeconomics, London School of Economics and National Institute of Economic and Social Research
Email: n.oulton@lse.ac.uk

GGDC 25th Anniversary Conference, June 28-30, 2017
Causes of (measured) aggregate TFP growth

1. Technical and scientific progress (including improvements in management techniques).
2. Learning effects, either learning by doing or learning from others, or more broadly externalities; economies of scale.
3. Reallocation of inputs towards more (or less) productive uses, either at the firm or the industry level.
4. Measurement error, e.g.
   – if increases in the quality of human or physical capital are wrongly ignored
   – or if output is mis-measured
   – or when some types of asset (such as intangibles) are wrongly omitted.

Solow (REcStats 1957); Hulten (2001)
Causes of (measured) aggregate TFP growth

1. Technical and scientific progress (including improvements in management techniques).
2. Learning effects, either learning by doing or learning from others, or more broadly externalities; economies of scale.
3. Reallocation of inputs towards more (or less) productive uses, either at the firm or the industry level.
4. Measurement error, e.g.
   – if increases in the quality of human or physical capital are wrongly ignored
   – or if output is mis-measured
   – or when some types of asset (such as intangibles) are wrongly omitted.

5. Shifts in the structure of output and demand leading to changes in the aggregate growth rate of TFP and hence of aggregate labour productivity. These shifts could be favourable or unfavourable.

Baumol (AER, 1967); Oulton (OEP, 2001)
Questions considered in this presentation

• Has structural change been favourable or unfavourable to growth?
• Is capital mis-measured?
• Is the true elasticity of output with respect to capital (the capital elasticity) higher than capital’s share? If so, TFP growth is overstated.
• Does TFP growth cause capital growth?
• Is TFP growth persistent?
Data

• Source: EU KLEMS (www.euklems.net).
• 18 countries with data on TFP growth.
• 10 industry groups collectively making up the market (business) sector.
• So imputed rent of home-owners, health, education and government excluded (25% of GDP).

O’Mahony and Timmer (EJ, 2009)

Shares are unweighted means across 18 countries and time.
Why industry data from EU KLEMS?

• The industry data is consistent with the national accounts of each country.

• In EU KLEMS labour and capital are measured in a detailed and consistent way. Labour is measured by hours worked broken down by education, age and sex. Capital, measured by the PIM, is broken down into 7 types (3 ICT and 4 non-ICT).

• In micro data labour and capital are often crudely measured, e.g. heads not hours for labour and no breakdown by type. Capital is often measured by book value, with no breakdown by type.
Structural change

In all countries, resources have been shifting towards industries with lower than average TFP growth (Finance) or even negative TFP growth (Business services). But TFP growth in the market sector generally shows no long run tendency to decline.

How is this possible?
Value added share of Manufacturing (D) in market sector GDP

Mean TFP growth rates, % p.a., by country

D. Manufacturing

K (exc. 70). Renting and business activities
Growth of TFP in the market sector (A-K), % p.a.

Source: EU KLEMS.
Note: Trend growth rate is that of HP-smoothed TFP level. Dashed lines denote country means of actual TFP growth rate.
Baumol’s (AER, 1967) cost disease model

• Suppose output grows at the same rate in all industries but some industries (e.g. services) have lower TFP growth than others (e.g. manufacturing). Then resources shift to slow-productivity-growth services and overall TFP (and LP growth) slows down.

• But this argument is couched in terms of final services (private or public). What about intermediate services? (Oulton, OEP, 2001).
Aggregate and industry TFP growth

Aggregate (top down) measure of TFP growth:

\[ \mu := \hat{V} - \alpha \hat{K} - (1 - \alpha) \hat{L} \]

\( V \) : real value added (GDP); \( \mu \) : TFP growth

Aggregate and industry TFP growth

Top down measure of aggregate TFP growth:
\[
\mu := \hat{V} - \alpha \hat{K} - (1 - \alpha) \hat{L} \quad V: \text{real value added (GDP)}; \quad \mu: \text{TFP growth}
\]
Bottom up measure of aggregate TFP growth is

a Domar-weighted sum (not average) of industry TFP growth rates:
\[
\mu = \sum_{i=1}^{N} d_i \mu_{GO}^i
\]
where \( d_i := \left[ \frac{GO_i}{GDP} \right] \), the Domar weights
and
\[
\mu_{GO}^i := \hat{Y}_i - \sum_{k=1}^{C} \alpha_{ik} \hat{K}_{ik} - \sum_{l=1}^{D} \beta_{il} \hat{L}_{il} - \sum_{j=1}^{N} m_{ij} \hat{M}_{ij}
\]

Simple algebra shows that top down and bottom up measures are identically equal.

Domar (EJ, 1961); Hulten, RES, 1978; Jorgenson et al. (1987); Gabaix, Econometrica, 2011.
Aggregate and industry TFP growth, cont.

Alternatively, we can use the value added concept of TFP growth:

\[ \mu_{i}^{VA} := \hat{V}_{i} - \sum_{k=1}^{C} \alpha_{ik}^{VA} \hat{K}_{ik} - \sum_{l=1}^{D} \beta_{il}^{VA} \hat{L}_{il} \]

Simple algebra shows that:

\[ \mu_{i}^{VA} = \left[ \frac{GO_{i}}{VA_{i}} \right] \mu_{i}^{GO} \]

Hence we get the alternative aggregation scheme:

\[ \mu = \sum_{i=1}^{N} v_{i} \mu_{i}^{VA} \quad \text{where} \quad v_{i} : \text{value added share of ith industry in GDP} \]
Implications of Domar aggregation

\[ \mu = \sum_{i=1}^{N} d_i \mu_i^{GO} \]

1. The Domar weights do not sum to 1 (generally the sum is between 2 and 3).
2. One Domar weight can increase without any other weight necessarily decreasing.
3. For given TFP growth rates, a rise in the Domar weight for the ith industry will raise the aggregate TFP growth rate, provided TFP growth in the ith industry is positive.
4. A shift in resources from high TFP growth to low (but positive) TFP growth industries can raise, not lower, the aggregate TFP growth rate.
Simple two-sector model

- Closed economy, two sectors: Cars and Business services (BuS)
- Car industry makes only final sales.
- Business services makes only intermediate sales (to the car industry).
- Cars uses K, L, and BuS as inputs.
- BuS uses only K and L as inputs.
Growth accounting in the simple two-sector model

\[ \mu = d_{Cars} \cdot \mu_{Cars}^{GO} + d_{Bus} \cdot \mu_{Bus}^{GO} \quad \mu_{Cars}^{GO} > 0, \quad \mu_{Bus}^{GO} > 0 \]

where

\[ d_{Cars} = \frac{GO_{Cars}}{GDP} = \frac{\text{Final sales of cars}}{GDP} = 1 \]

and

\[ d_{Bus} = \frac{GO_{Bus}}{GDP} = \frac{\text{Intermediate sales to Cars}}{GDP} = \frac{GO_{Cars} - VA_{Cars}}{GO_{Cars}} = 1 - \frac{VA_{Cars}}{GO_{Cars}} \]
Increased outsourcing as a source of growth

Suppose there is increasing outsourcing by the car industry, i.e. GO/VA is rising in cars.

Then $d_{BuS}$ is rising even though $d_{Cars}$ is constant. I.e. the sum of the Domar weights increases.

So for given (gross output) TFP growth in Cars and Business services, aggregate $\mu$ rises.

And this is true even if TFP growth in BuS is lower than in Cars.

(Using the value added concept, TFP growth is rising in cars, constant in BuS, and rising overall since contribution of Cars is constant).
In summary ...

Domar weight on BuS can rise, with everything else on RHS constant. So $\mu$ rises.

\[ \uparrow \quad \mu = (d_{Cars}^\text{GO}) \ast \mu_{Cars} + (d_{Bus}^\text{GO}) \ast \mu_{BuS} \quad \uparrow \quad \mu_{BuS}^\text{GO} > 0 \]

Baumol (AER, 1967); Oulton (OEP, 2001); Baumol in Krueger (JEP, 2001)
Intuition

As long as TFP growth in Business services is positive, the price of providing these services is falling relative to the price in the Car industry of providing them in-house. If demand for Business services is elastic then their share in total costs of the car industry will rise.

In practice, Business services includes some very sophisticated and high-tech products (design, accountancy, legal, management, computer, etc).
## Changes in Domar weights between first year and last year

But now there’s a problem ...

Mean TFP growth rates, % p.a., by country

D. Manufacturing

K (exc. 70). Renting and business activities
Calculating the effect on TFP

• TFP growth in Business services is negative ---very implausible. Good price indices are lacking.
• So set it equal to mean TFP growth rate in the market sector in each country in each year. Adjust the TFP growth rates of other industries so that average is unchanged. (Conservative assumption: aggregate TFP growth rate is correct, offsetting errors at industry level).
• Now calculate what TFP growth in the market sector would have been if the Domar weights had been constant at
  ➢ (a) those of the beginning of the sample period or
  ➢ (b) those of the end of the sample period.
• The difference [(b) minus (a)] is the effect of structural change.

TFP growth in Business services set equal to market sector average in each country. Other sectors adjusted to keep market sector average the same.
Results

• 11 out of 18 countries show a positive effect of structural change. And the average boost to growth for these 11 was 0.17% per year.
• The actual TFP growth rate amongst these 11 was 1.4% per year, so the boost is significant.
• 7 countries show a negative effect.
Conclusions

• The shift to Business services has had a positive effect on TFP growth in all countries (+0.08% per year).
• Overall, structural change has been positive in 11/18 countries.
• So the positive effect of Business services was offset by negative effects in 7/18 countries.
• These conclusions rely on upwardly adjusting TFP growth rates in Business services to the market sector average.
• This highlights the need for better measurement of industry output.
• Similar considerations apply to Finance.
THE END
Questions considered in this paper

• Is the empirical evidence on TFP consistent with the causes that theory considers important?
• How important is each source of TFP growth, particularly the fifth?
The Domar sum

\[ d_i = \frac{GO_i}{GDP} = \left[ \frac{GO_i}{VA_i} \right] \left[ \frac{VA_i}{GDP} \right] \]

\[ \sum_{i=1}^{N} d_i = \sum_{i=1}^{N} \left[ \frac{GO_i}{VA_i} \right] \left[ \frac{VA_i}{GDP} \right] \]

So the Domar sum is a weighted average of the degree of outsourcing (GO/VA) in the economy.
Source: EU KLEMS. Note: Domar weights are for market sector GDP. Dashed lines denote country means.
Outsourcing in sectors D, E, F, G, H and I: unweighted cross-country means of GO/VA ratio

Source: EU KLEMS.
Persistence of TFP

- TFP growth is positively serially correlated at the aggregate (market sector) level but not at the industry level. This is a problem for theories which ascribe TFP growth to innovation: innovations take time to spread.
(Lack of) persistence in TFP growth
Dependent variable is TFP growth

Country and year dummies included; sector dummies included in 10 sectors regression. OLS estimates with robust standard errors. *** significant at 1% level.
Persistent of TFP

- TFP growth is positively serially correlated at the aggregate (market sector) level but not at the industry level. This is a problem for theories which ascribe TFP growth to innovation: innovations take time to spread.
- Explanation: there are errors in the measurement of industry nominal value added which cancel out in the aggregate.
Errors-in-variables model

g_{ijt} : Measured TFP growth in \( j \)-th sector of \( i \)-th country in year \( t \)

\( \tilde{g}_{ijt} \) : True TFP growth

\( \eta_{ijt} \) : Measurement error

\( \nu_{ijt} \) : Value added share

1. \( \tilde{g}_{ijt} = \beta \tilde{g}_{ijt-1} + Controls + \tilde{\epsilon}_{ijt} \) (Hypothesis)

2. \( g_{ijt} = \tilde{g}_{ijt} + \eta_{ijt}, \text{ } E\eta_{ijt} \eta_{ijt-s} = 0 \) (Measurement error)

3. \( \sum_{i=1}^{N} \nu_{ijt} \eta_{ijt} = 0 \) (Errors cancel out in aggregate)

4. \( g_{it}^{MS} = \sum_{j=1}^{N} \nu_{ijt} g_{ijt} \) (Aggregation to MS level)
Then the regression equation

\[ g_{ijt} = \beta g_{ij,t-1} + Controls + \varepsilon_{ijt} \]

has the classic errors-in-variables form: the independent variable is correlated with the error term, so the estimate of beta is biased towards zero.

But there is no such bias if we run the regression at the aggregate (market sector) level:

\[ g^{MS}_{it} = \beta g^{MS}_{i,t-1} + Controls + \varepsilon^{MS}_{it} \]
Where do the errors come from?

• The growth of industry value added is much more volatile than the growth of industry input (K and L).

• If the national accounts on the income/output side are balanced year-by-year using a control total from the expenditure side, this could lead to errors in industry-level nominal value added.

• Conclusion: TFP is probably persistent at the sector level too.
Mismeasurement of capital

• Mismeasurement of quality change
• Missing assets
• Increasing variety
Mismeasurement of quality change in capital goods

At the aggregate level this may not matter much in large, rich countries. Reason:

1. GDP growth:
   \[ \hat{Y} = w_C \hat{Y}_C + w_I \hat{Y}_I \]
   \[ w_C (w_I) : \text{shares of } C (I) \text{ in GDP} \]

2. Aggregate TFP growth:
   \[ \mu = w_C \hat{Y}_C + w_I \hat{Y}_I - \alpha \hat{K} - (1 - \alpha) \hat{L} \]

3. Error in capital measurement:
   \[ e = \hat{K} - \hat{K} \]
   \[ \hat{K} : \text{true growth rate of } K \]

4. Then assuming \( \hat{Y}_I = \hat{K} \), TFP error = \( (w_I - \alpha)e < 0 \) if \( e > 0 \) and \( \alpha > w_I \)

But at industry level or in an open economy importing high-tech capital goods, the error could be larger
