Abstract

The current thesis deals with the catalytic methane combustion in microreactors with wall-coated Pt/ γ -Al₂O₃ catalyst. The Pt/ γ -Al₂O₃ washcoat preparation, the single- and multi-layer catalytic coating systems, and the different designs of microreactor geometries were particularly investigated. Various aspects were thus addressed, including the preparation procedures of the catalyst coating (e.g., the binder properties, pH value, initial Al₂O₃ particle size), the optimization of different reaction conditions with single- and multi-layer coating systems (e.g., temperature, flow rate, O₂/CH₄ molar ratio, Pt loading and coating thickness), the effect of internal channel configurations in the microreactor (i.e., involving straight parallel channels, cavity, double serpentine channels, obstructed parallel channels, meshed circuit and vascular network) on the reaction performance.

The thesis starts with a comprehensive literature review on the catalytic methane combustion at low temperatures, including catalyst, mechanisms, reaction conditions and reactor designs. Then, the preparation procedures of Pt/ γ -Al₂O₃ washcoat catalyst have been studied in details, in order to improve its adhesion and uniformity on FeCrAlloy and stainless steel microreactors. A good adhesion could be obtained by using the slurry with 20 wt% γ -Al₂O₃ (particle size: 3 μ m), pH = 3.5, and 3 to 5 wt% polyvinyl alcohol (molecular weight of 57,000 - 186,000). Based on the above-mentioned optimized preparation, Pt/ γ -Al₂O₃ washcoat catalysts of various loadings were deposited inside the stainless-steel capillary microreactors and studied both in the single- and multi-layer catalytic coating systems. The influence of different operating conditions including the reaction temperature, total flow rate, molar ratio of O₂:CH₄, and the reproducibility of catalyst were tested. The results demonstrate that in general the methane conversion was improved

with the temperature rise, and presented the highest at an oxygen to methane molar ratio of ca.1.5. An obvious decrease in the methane conversion could be found over the multi-layer systems compared to their respective single-layer counterparts (if the Pt mass in the catalyst was kept equal), due to the more significant internal diffusion limitation in thicker coatings. Among all the tested microreactor geometries washcoated with Pt/ γ -Al₂O₃ catalyst, the highest methane conversion could be obtained in the double serpentine channel microreactor and the lowest presented in the mesh circuit microreactor, which can be explained based on the available coating surface area, flow distribution and residence time property. In order to achieve a desirable methane conversion in microreactors, a proper tuning of the catalytic coating properties (e.g., surface area, Pt loading and thickness), the residence time, the fluid distribution uniformity and other reaction parameters (e.g., temperature and oxygen to methane molar ratio) are required.
