Abstract

In this short paper we study the existence of positive and negative semidefinite solutions of the algebraic Riccati equation corresponding to linear quadratic problems with an indefinite cost functional. An important role is played by certain two-variable polynomial matrices associated with the algebraic Riccati equation. We characterize all unmixed solutions in terms of the Pick matrices associated with these two-variable polynomial matrices. As a corollary it turns out that the signatures of the extremal solutions are determined by the signatures of particular Pick matrices.

1 Introduction

Let $A \in \mathbb{R}^{n \times n}$ and $B \in \mathbb{R}^{n \times m}$ be such that $(A, B)$ is a controllable pair. Let $Q \in \mathbb{R}^{n \times n}$ be symmetric and let $R \in \mathbb{R}^{m \times m}$ be nonsingular. Finally, let $S \in \mathbb{R}^{m \times n}$. The quadratic equation

$$A^T K + KA + Q - (KB + S^T) R^{-1} (B^T K + S) = 0 \quad (1)$$

in the unknown $n \times n$ matrix $K$ is called the (continuous-time) algebraic Riccati equation, in the following called simply the ARE. Since its introduction in control theory at the beginning of the sixties, the ARE has been studied extensively because of its prominent role in linear quadratic optimal control and filtering, $H_2$-optimal control, differential games, and stochastic filtering and control (see [7] for a discussion on the ARE and its applications and an overview of the existing literature).

In this communication we formulate reasonably simple necessary and sufficient conditions for the existence of at least one real positive semidefinite solution, or of at least one real negative semidefinite solution to the ARE. Some partial results regarding the solution to such problem were obtained in [7, 7, 7, 7, 7]; for an overview of such results and of their relation with the classical problem of the existence of nonnegative storage functions for dissipative systems, we refer to [7].

The necessary and sufficient condition presented in this communication is based on the signs of certain constant $n \times n$ matrices which in the following will be called the Pick matrices associated with the ARE; such matrices are constructed in a straightforward way from the parameters appearing in the ARE. It turns out that a real symmetric positive semidefinite solution of the ARE (1) exists if and only if (i) the ARE has at least one real symmetric solution; and (ii) a suitable Pick matrix is negative semidefinite (likewise, the existence of at least one negative semidefinite solution depends on the positive semidefiniteness of a suitable Pick matrix).

In the process of establishing such conditions we obtain a number of intermediate results, among which a new characterization of all unmixed real symmetric solutions of the ARE, and a new characterization of its supremal and infimal real symmetric solutions. Such characterizations are all given in terms of the Pick matrices associated with the ARE.

A few words on notation: in this communication we
adopt the usual symbols $\mathbb{R}$ and $\mathbb{C}$ in order to denote the set of real and complex numbers, respectively. The open and closed right half-planes of $\mathbb{C}$ are denoted respectively by $\mathbb{C}_+^\text{R}$ and $\mathbb{C}_+^\text{C}$. Given $\lambda \in \mathbb{C}$, its complex conjugate is denoted by $\bar{\lambda}$. The space of $m \times n$ real, respectively complex, vectors is denoted by $\mathbb{R}^{m \times n}$, respectively $\mathbb{C}^{m \times n}$, and the space of $m \times n$ real, respectively complex, matrices, by $\mathbb{R}^{m \times n}$, respectively $\mathbb{C}^{m \times n}$. If $A \in \mathbb{R}^{m \times n}$, then $A^T \in \mathbb{R}^{n \times m}$ denotes its transpose, and if $A \in \mathbb{C}^{m \times n}$, then $A^* \in \mathbb{C}^{m \times n}$ denotes its conjugate transpose $A^T$. The ring of polynomials with real coefficients in the indeterminate $\xi$ is denoted by $\mathbb{R}[\xi]$; analogously, the ring of two-variable polynomial matrices with real coefficients in the indeterminates $\zeta$ and $\eta$ is denoted by $\mathbb{R}[\zeta, \eta]$. The space of all $n \times m$ polynomial matrices in the indeterminates $\zeta$ and $\eta$ is denoted by $\mathbb{R}^{n \times m}[\zeta, \eta]$, and that consisting of all $n \times m$ polynomial matrices in the indeterminates $\xi$ is denoted by $\mathbb{R}^{n \times m}[\xi]$, and that consisting of all $n \times m$ polynomial matrices in the indeterminates $\zeta$ and $\eta$ is denoted by $\mathbb{R}[\zeta, \eta]$.

We denote the set $\mathbb{Q}^d$ of all polynomials $\mathbb{Q}^d$ with $\mathbb{Q}$-DFs allows to develop a calculus that has applications in stability theory, optimal control, and $H_\infty$-control (see [7], [11], and [13]). We restrict attention to a couple of concepts that are used extensively in this communication. The first one is the map $\mathcal{Q}_g : \mathbb{R}^{2\times 2} \rightarrow \mathbb{R}^{2\times 2}$ defined by

$$\mathcal{Q}_g(\xi, \eta) := \Phi(-\xi, \eta).$$

Observe that for every $\Phi \in \mathbb{R}^{2\times 2} \rightarrow \mathbb{R}^{2\times 2}$, $\mathcal{Q}_g$ is para-hermitian, i.e., $\mathcal{Q}_g = (\mathcal{Q}_g)^\text{c}$. Another notion used in this paper is that of derivative of a QDF. Given a QDF $Q_\Phi$ we define its derivative as the QDF $\frac{d}{dw}Q_\Phi$ defined by $(\frac{d}{dw}Q_\Phi)(w) := \frac{d}{dw}(Q_\Phi(w))$. $Q_\Phi$ is called the derivative of $Q_\Phi$ if $\frac{d}{dw}Q_\Phi = Q_\Phi$. In terms of the two-variable polynomial matrices associated with the QDF's, this relationship is expressed equivalently as $(\zeta + \eta)(\Phi(\zeta, \eta)) = \Phi(\zeta, \eta)$.

In this communication we also use integrals of QDF's. In order to make sure that the integrals exist, we assume that the trajectories on which the QDF acts are of compact support, that is, they belong to $\mathcal{D}(\mathbb{R}^d)$. Given a QDF $Q_\Phi$, we define its integral as the functional from $\mathcal{D}(\mathbb{R}^d)$ to $\mathbb{R}$ acting as $\int Q_\Phi(w) = \int Q_\Phi(w)dw$. We call a QDF $Q_\Phi$ average nonnegative, if $\int Q_\Phi \geq 0$, i.e., $\int Q_\Phi(w) \geq 0$ for all $w \in \mathcal{D}(\mathbb{R}^d)$. A QDF can be tested for average nonnegativity by analyzing the behavior of the para-Hermitian matrix $\mathcal{Q}_g$ on the imaginary axis. Indeed, it is proven in [7] that $\int Q_\Phi \geq 0 \iff \mathcal{Q}_g(i\omega) \geq 0 \forall \omega \in \mathbb{R}$.

2 Quadratic differential forms

In this communication we use extensively the concepts and tools developed in the behavioral context; the reader is referred to the textbook [7] or the paper [11] for a thorough exposition. Among such concepts the most widely used in this communication is that of quadratic differential form introduced in [7], which we now review.

In many modeling and control problems for linear systems it is necessary to study quadratic functional of the system variables and their derivatives. An efficient representation for such quadratic functional is by means of two-variable polynomial matrices as follows. Let $\Phi \in \mathbb{R}^{n \times n}[\zeta, \eta]$; then $\Phi$ can be written in the form $\Phi(\zeta, \eta) = \sum_{h,k=0}^{N} \Phi_{h,k} \zeta^h \eta^k$, where $\Phi_{h,k} \in \mathbb{R}^{n \times n}$ and $N$ is an integer. The two-variable polynomial matrix $\Phi$ induces a bilinear form from $\mathcal{C}^{\infty}(\mathbb{R}, \mathbb{R}^n) \times \mathcal{C}^{\infty}(\mathbb{R}, \mathbb{R}^n)$ to $\mathcal{C}^{\infty}(\mathbb{R}, \mathbb{R})$ defined as $\mathcal{L}(w_1, w_2) := \sum_{h,k=0}^{N} \Phi_{h,k} \frac{d}{dw_1} \frac{d}{dw_2}$. If $\Phi$ is a symmetric two-variable polynomial matrix, i.e. if $q_1 = q_2$ and $\Phi_{h,k} = \Phi_{k,h}$ for all $h, k$, then it induces also a quadratic functional $Q_\Phi$ from $\mathcal{C}^{\infty}(\mathbb{R}, \mathbb{R}^d)$ to $\mathcal{C}^{\infty}(\mathbb{R}, \mathbb{R})$ defined by $Q_\Phi(w) := \mathcal{L}(w, w)$. We will call $Q_\Phi$ the quadratic differential form (in the following abbreviated with QDF) associated with $\Phi$. We denote the set of all symmetric $q \times q$ two-variable polynomial matrices by $\mathbb{R}_\Phi^{q \times q}[\zeta, \eta]$.

The association of two-variable polynomial matrices with QDF's allows to develop a calculus that has applications in stability theory, optimal control, and $H_\infty$-control (see [7], [11], and [13]). We restrict attention to a couple of concepts that are used extensively in this communication. The first one is the map $\partial : \mathbb{R}^{2\times 2} \rightarrow \mathbb{R}^{2\times 2}$ defined by $\partial(\xi, \eta) := \Phi(-\xi, \eta)$.
Moreover, there exists a one-one relation between storage functions $\Psi$ and dissipation functions $\Delta$ for $\Phi$, defined by $\frac{d}{dt}Q_\Phi = Q_\Phi - Q_\Delta$ or, equivalently, $(\zeta + \eta)\Psi(\zeta, \eta) = \Phi(\zeta, \eta) - \Delta(\zeta, \eta)$.

Since storage functions measure the energy stored inside a system, it is to be expected that they are related to the memory, to the state, of the system. Using the concept of state map introduced in [?], one can formalize such intuition as follows (for a proof see [?]).

**Proposition 2** Let $B$ be represented by $w = M(I\hat{A})l$, and let $X \in \mathbb{R}^{n \times d}[\xi]$ induce a state map for $B$. Let $P$ be a symmetric $q \times q$ matrix, and define the two-variable polynomial matrix $\Phi(\zeta, \eta) = M^T(\zeta)PM(\eta)$. Let $Q_\Phi$ be a storage function for $Q_\Phi$. Then $Q_\Psi$ is a quadratic function of the state, i.e. there exists a symmetric $n \times n$ matrix $K$ such that $Q_\Psi(l) = |X(I\hat{A})l|^2$ for all $l \in \mathbb{C}^{\infty}(\mathbb{R}, \mathbb{R}^d)$, equivalently, $\Psi(\zeta, \eta) = X^T(\zeta)KX(\eta)$.

Given an average nonnegative QDF, in general there exist an infinite number of storage functions; however, they all lie between two extremal storage functions (see [?], Theorem 5.7):

**Proposition 3** Let $\int Q_\Phi \geq 0$. Then there exist storage functions $\Psi_-$ and $\Psi_+$ such that any other storage function $\Psi$ for $\Phi$ satisfies $\Psi_- \leq \Psi \leq \Psi_+$.

In the following we call $Q_{\Psi_-}$ the smallest and $Q_{\Psi_+}$ the largest storage function of $Q_\Phi$. Under additional assumptions on $\Phi$, $Q_{\Psi_-}$ and $Q_{\Psi_+}$ can be computed as follows:

**Proposition 4** Let $\Phi(\zeta, \eta) \in \mathbb{R}^{2 \times 2}[\xi]$. Assume $\det(\Phi) \neq 0$ and $\partial \Phi(\omega) \geq 0$ for all $\omega \in \mathbb{R}$. Then the smallest and the largest storage functions $\Psi_-$ and $\Psi_+$ of $\Phi$ can be constructed as follows: let $H$ and $A$ be semi-Hurwitz, respectively semi-anti-Hurwitz, polynomial spectral factors of $\Phi_i$ (i.e. $\Phi_i = H^*H = A^*A$ with all the roots of $\det(H)$ in $\mathbb{C}_-$ and all roots of $\det(A)$ in $\mathbb{C}_+$). Then

$$\Psi_+(\zeta, \eta) = \frac{\Phi(\zeta, \eta) - A^T(\zeta)A(\eta)}{\zeta + \eta}$$
$$\Psi_-(\zeta, \eta) = \frac{\Phi(\zeta, \eta) - H^T(\zeta)H(\eta)}{\zeta + \eta}.$$

It also turns out that if $P$ is para-hermitian, and if $P(\omega) > 0$ for all $\omega \in \mathbb{R}$, then for every factorization of the scalar polynomial $\det(P)$ as $\det(P) = f^*f$, where $f$ and $f^*$ are coprime, there exists $F \in \mathbb{R}^{n \times m}[\xi]$ such that $P = F^*F$ and $\det(F) = f$.

We finally introduce the Pick matrices associated with average nonnegative quadratic differential forms. We consider a two-variable symmetric polynomial matrix $\Phi(\zeta, \eta) \in \mathbb{R}^{2 \times 2}[\xi]$, and we assume that $\partial \Phi(\omega) > 0$ for all $\omega \in \mathbb{R}$. We introduce Pick matrices in the special case that the singularities of $\partial \Phi$ are semi-simple, i.e. every singularity $\lambda$ of $\partial \Phi$ has the property that its multiplicity as a root of $\det(\partial \Phi)$ is equal to the rank deficiency of $\partial \Phi(\lambda)$ at $\lambda$. (The definition of Pick matrices in the general case is notionally more involved and is not considered in this communication. However, the results presented here hold also in the general case.)

**Definition 6** Let $f \in \mathbb{R}[\xi]$ be such that $\det(\partial \Phi) = f^*f$ and $f$ and $f^*$ are coprime. Let $\lambda_1, \lambda_2, \ldots, \lambda_n$ be the roots of $f$. We adopt the convention that if the multiplicity of $\lambda_i$ as a root of $\det(\partial \Phi)$ is $m_i$, then $\lambda_i$ appears in this list $m_i$ times. (It is easy to see that, $\partial \Phi$ being para-hermitian, all the other singularities of $\partial \Phi$ are $-\lambda_1, -\lambda_2, \ldots, -\lambda_n$, i.e. the roots of $f^*$.) Now for $i = 1, 2, \ldots, n$, let $v_i \in \mathbb{C}^n$ be such that $\partial \Phi(\lambda_i)v_i = 0$, and such that the $v_i$'s associated to the same roots of $\det(\partial \Phi)$ are linearly independent. The Pick matrix associated with $f$ is the matrix $T_f$ whose $(i, j)$-th element is $\sqrt{\Phi(\lambda_i, \lambda_j)v_j}$.

Note that $T_f = T_f^* \in \mathbb{C}^{n \times n}$, where $2n$ is the degree of $\det(\partial \Phi)$.

### 4 The ARE and storage functions

In this section we study the connection between the existence of real symmetric solutions of the ARE, and average nonnegativity of a given QDF associated with the ARE.

We associate with the ARE (1) the manifest variable $w = \text{col}(x, u)$ represented by $\frac{d}{dt}x = Ax + Bu$ (here $\text{col}(x, y) = (x^T, y^T)$). Such equation constitutes a kernel representation of the behavior $\mathcal{B} = \{\text{col}(x, u) \in C^\infty(\mathbb{R}, \mathbb{R}^n) \times C^\infty(\mathbb{R}, \mathbb{R}^m) | \frac{d}{dt}x = Ax + Bu \text{ is satisfied}\}$. Since by assumption the pair $(A, B)$ is controllable, $\mathcal{B}$ can also be represented in image form; one such representation can be computed as follows. Let $X \in \mathbb{R}^{n \times m}[\xi]$ and $U \in \mathbb{R}^{n \times m}[\xi]$ induce a right coprime factorization of the rational matrix $(X(I\hat{A})^T, U(I\hat{A})^T)$. Observe that any such $X$ yields a minimal state map $X(I\hat{A})$ for $\mathcal{B}$.

Given the matrices $Q = QT \in \mathbb{R}^{n \times n}$, $R = RT \in \mathbb{R}^{m \times m}$ and $S \in \mathbb{R}^{n \times n}$ appearing in the ARE, and the
polynomial matrices $X$ and $U$, we define the symmetric $m \times m$ two-variable polynomial matrix $\Phi$ by

$$
\Phi(\zeta, \eta) = 
\begin{pmatrix}
X(\zeta)^T & U(\zeta)^T
\end{pmatrix}
\begin{pmatrix}
Q & S^T
\end{pmatrix}
\begin{pmatrix}
X(\eta) & U(\eta)
\end{pmatrix}.
$$

(2)

Now assume $R > 0$. The next result connects the average nonnegativity of the QDF associated with (2) with the existence of real symmetric solutions to the ARE (1) and with the existence of storage functions for $Q_\Phi$ (see also Ch. 8 of [?], [?] and Ch. 5 of [?]).

**Theorem 7** Let $\Phi(\zeta, \eta)$ be defined by (2), where $X$ and $U$ are such that $X(\zeta)U(\zeta)^{-1}$ is a right coprime factorization of $(\xi I_n - A)^{-1}B$. Assume $R > 0$. Then the following statements are equivalent:

1. $\int Q_\Phi \geq 0$,
2. There exists a real symmetric solution to the ARE.

In fact, for every $K = K^T \in \mathbb{R}^{n \times n}$ the following conditions are equivalent:

(i) $-K$ satisfies the ARE,

(ii) $|X(\frac{\partial}{\partial \zeta})|_{K}$ is a storage function for $Q_\Phi$ with associated dissipation function $\Delta(\zeta, \eta) = F(\zeta)F(\eta)$, where $F(\zeta) := R^{-1/2}(-B^T K + S)X(\xi) + R^{1/2}U(\xi)$.

5 *Pick matrices and the ARE*

In this section we present the main result of this communication, namely necessary and sufficient conditions for the existence of sign-definite solutions of the ARE; such conditions are given in terms of the Pick matrices associated with the Hurwitz and anti-Hurwitz factorizations of $\det(\Phi)$, with $\Phi$ given by (2).

Since $\partial \Phi$ is para-hermitian, $\det(\partial \Phi)$ has even degree. Actually, it turns out that $\deg(\det(\partial \Phi)) = 2n$, with $n$ the dimension of $\Phi$ defined in section 4 (for a proof, see [?], Prop. 5.4.1). Assume now that $\int Q_\Phi > 0$, equivalently, $\partial \Phi(\omega) \geq 0$ for all $\omega \in \mathbb{R}$. According to Theorem 7, this is equivalent to the existence of a real symmetric solution of the ARE. Observe that every polynomial spectral factorization of $\Phi$ as $\partial \Phi = F^*F$ with $F \in \mathbb{R}^{m \times n}[\xi]$ yields a factorization of $\det(\Phi)$ as $\det(\Phi) = f^*f$, with $f = \det(F)$ and $\deg(f) = n$. Let $\mathcal{F}$ be the set of all polynomials of degree $n$, with positive highest degree coefficient, that can occur as the determinant of a polynomial spectral factor of $\Phi$.

$$
\mathcal{F} := \{ f \in \mathbb{R}[\xi] \mid f(\xi) = f_0 + f_1\xi + \cdots + f_n\xi^n,
\quad f_n > 0 \text{, and there exists } F \in \mathbb{R}^{m \times n}[\xi] \text{ such that } \partial \Phi = F^*F \text{ and } \det(F) = f \}. 
$$

(3)

Also, let $\mathcal{S}$ be the set of all real symmetric solutions of the ARE:

$$
\mathcal{S} := \{ K \in \mathbb{R}^{n \times n} \mid K = K^T \text{ and } K \text{ satisfies the ARE} \}.
$$

For any $K \in \mathcal{S}$, denote $A_K := A - BR^{-1}(B^T K + S)$ and let $x_{A_K}$ be the characteristic polynomial of $A_K$. The following result states that there is a one-one correspondence between $\mathcal{F}$ and $\mathcal{S}$.

**Theorem 8** $\mathcal{S} \neq \emptyset$ if and only if $\partial \Phi(\omega) \geq 0$ for all $\omega \in \mathbb{R}$. In that case there exists a bijection between $\mathcal{F}$ and $\mathcal{S}$. Such bijection $\text{Ric} : \mathcal{F} \rightarrow \mathcal{S}$ is defined as follows. For any $f \in \mathcal{F}$, let $F \in \mathbb{R}^{m \times m}[\xi]$ be such that $f = \det(F)$ and $\partial \Phi = F^*F$. Then define $\text{Ric}(f) = K$, where $K = K^T \in \mathbb{R}^{n \times n}$ is the unique solution of

$$
\frac{\Phi(\zeta, \eta) - F^*F(\xi)}{\zeta + \eta} = X^T(\zeta)(-K)X(\eta).
$$

(4)

For any $K \in \mathcal{S}$ we have $\partial \Phi = (F_K)^*F_K$, where $F_K(\xi) := R^{-1/2}(B^T K + S)X(\xi) + R^{1/2}U(\xi)$. Furthermore, for any $K \in \mathcal{S}$ we have $\det(F_K) = \sqrt{\det(R)} X_{A_K}$, whence $\det(\Phi) = \det(R) (X_{A_K})^* X_{A_K}$, and $K = \text{Ric}(\sqrt{\det(R)} X_{A_K})$.

If we strengthen the assumptions of Theorem 7 to include $\partial \Phi(\omega) > 0$ for all $\omega \in \mathbb{R}$, then the one-to-one correspondence between polynomials and the set of real symmetric solutions of the ARE can be made even more explicit. In order to illustrate such result we introduce $\mathcal{F}_{\text{cop}}$, the set of all real polynomials $f$ such that the determinant of $\partial \Phi$ admits a factorization $f^*f$ with $f$ and $f^*$ coprime:

$$
\mathcal{F}_{\text{cop}} = \{ f \in \mathbb{R}[\xi] \mid f(\xi) = f_0 + f_1\xi + \cdots + f_n\xi^n, f_n > 0, (f, f^*) \text{ coprime} \}
$$

and $\text{det}(\partial \Phi) = f^*f$.

It is easily seen that if $\partial \Phi(\omega) > 0$ for all $\omega \in \mathbb{R}$ then $\mathcal{F}_{\text{cop}} \neq \emptyset$ if and only if $\partial \Phi(\omega) > 0$ for all $\omega \in \mathbb{R}$. Hence it follows from Proposition 5, that $\mathcal{F}_{\text{cop}} \subset \mathcal{F}$. In the remainder of this section we assume that $\partial \Phi(\omega) > 0$ for all $\omega \in \mathbb{R}$.

Note that if $f \in \mathcal{F}_{\text{cop}}$ and $K = \text{Ric}(f)$ then according to Theorem 7, $f = \sqrt{\det(R)} X_{A_K}$, so $x_{A_K}$ and $(X_{A_K})^*$ are coprime, equivalently, $\sigma(A_K) \cap \sigma(-A_K) = \emptyset$. If a solution $K$ of the ARE satisfies this property, we call it *unmixed*. The set of all unmixed solutions of the ARE is denoted by $\mathcal{S}_{\text{unmix}}$. It follows immediately from Theorem 7 that $\text{Ric}$ defines a bijection between $\mathcal{F}_{\text{cop}}$ and $\mathcal{S}_{\text{unmix}}$, and we now show how to use the Pick matrix $T_f$ in order to compute, given an $f \in \mathcal{F}_{\text{cop}}$, the unmixed solution $K = \text{Ric}(f)$.
Theorem 9 Assume \( \partial \Phi(\omega) \geq 0 \) for all \( \omega \in \mathbb{R} \). Then \( \partial \Phi(\omega) > 0 \) for all \( \omega \in \mathbb{R} \) if and only if \( F_{\text{cop}} \neq \emptyset \). Assume that this holds. Then \( \text{Ric} : F_{\text{cop}} \rightarrow S_{\text{unn}} \) is a bijection. Now define the \( n \times n \) zero state matrix \( S_f \) associated with \( f \) as \( S_f := \begin{pmatrix} X(\lambda_1)v_1 & \cdots & X(\lambda_n)v_n \end{pmatrix} \), where the \( \lambda_i \)'s are the roots of \( \det(\partial \Phi) \) and the \( v_i \)'s are the associated directions, see section 3. Then for all \( f \in F_{\text{cop}} \) the zero state matrix \( S_f \) is non-singular. Furthermore, for any \( f \in F_{\text{cop}} \), the corresponding solution \( \text{Ric}(f) \) is non-singular.

We now turn to the problem of establishing necessary and sufficient conditions for the existence of sign-definite solutions to the ARE. Our main result in this direction is an immediate consequence of Theorem 9, and is based on the result of Theorem 3, namely that the largest (smallest) storage function for \( \Phi \) is associated with an anti-Hurwitz (Hurwitz) factorization of \( \partial \Phi \). Let \( K_- \) and \( K_+ \) be the smallest, respectively largest real symmetric solution of the ARE.

Corollary 10 (Main result) Let \( \Phi(\zeta, \eta) \) be defined as in (??). Assume that \( \partial \Phi(\omega) > 0 \) for all \( \omega \in \mathbb{R} \). Factor \( \det(\partial \Phi) = (f_A)^{-1}f_A = (f_H)^{-1}f_H \), where \( f_A \) and \( f_H \) have their roots in \( \mathbb{C}_+ \) and \( \mathbb{C}_- \), respectively. Then \( K_- = -(S_f^H)^{-1}T_f S_f^{-1} \) and \( K_+ = -(S_f^H)^{-1}T_f S_f^{-1} \).

Consequently, the ARE (1) has a negative semidefinite (negative definite) solution if and only if the Pick matrix \( T_f \) is positive semidefinite (respectively positive definite). It has a positive semidefinite (positive definite) solution if and only if the Pick matrix \( T_f \) is negative semidefinite (respectively negative definite).

6 Conclusions

In this communication we applied concepts and tools coming from the calculus of QDF's to the problem of formulating necessary and sufficient conditions for the existence of (semi-) definite solutions. The authors believe that such conditions are more easily verified than those already (see [?]). Indeed, the known conditions require to check an infinite number of matrices for positive semidefiniteness; moreover, the dimensions of the matrices involved in such check are not upper bounded. The condition illustrated in this communication requires instead to check the positive semidefiniteness of only one \( n \times n \) Hermitian matrix which is easily constructed from the parameters of the ARE.
