Enantioselective synthesis of natural products containing tertiary alcohols and contributions to a total synthesis of phorbasin B

Wu, Zhongtao

Publication date: 2015

Citation for published version (APA):
In this chapter, a novel asymmetric synthesis of dihydrofurans and cyclopentenols is described. Copper-catalyzed 1,2-addition of Grignard reagents to enones, combined with Sonogashira coupling/cyclization or ring-closing metathesis, provided two different kinds of dihydrofurans with medium to high enantioselectivities.

Parts of this chapter have been published:

2.1 Introduction

Functionalized chiral five-membered cyclic ethers, e.g. dihydro- and tetrahydrofuran derivatives, are ubiquitous structural units in natural products.\(^1\) Also due to their wide-spread applications,\(^2\) for example, as probe molecules for chemical reactions,\(^3\) in complex pharmaceuticals, and in commodity chemicals,\(^2\) the synthesis of compounds containing chiral (dihydro)furans has been intensively studied.\(^1,4\)

The asymmetric synthesis of five-membered ring ethers in which the oxygen is connected to a tertiary or quaternary stereocenter is of particular importance. Ring closing by face-selective attack of an oxygen nucleophile to an alkene is most commonly used. In this process, the alkene is activated either by Lewis acids including protonation,\(^6\) via allylic substitution,\(^7\) or conjugate addition\(^8\) or alternatively via ring-opening of the corresponding epoxide\(^9\) or haluronium ion.\(^10\)

Alternatively, asymmetric ring-closing olefin metathesis has been applied.\(^11\)

For cyclic ether formation using the alternative approach, e.g. alkylation of a chiral tertiary alcohol followed by ring-closing, literature is particularly scarce. This is easily explained by the limited examples of effective methods for the enantioselective synthesis of the latter.

2.2 Strategies for chiral cyclic ether formation

Recently, our group reported on the use of a copper/Josiphos-type catalyst system to accomplish the enantioselective 1,2-addition of Grignard reagents to \(\alpha,\beta\)-unsaturated ketones (Scheme 1).\(^{12}\) This leads to chiral enantioenriched tertiary allylic alcohols.\(^{13}\)

We realized that upon subsequent alkylation on oxygen to the corresponding ethers, and together with suitable ring-closing reactions, this strategy will provide a useful method for the synthesis of chiral five-membered cyclic ethers. As the quaternary stereocenter formed is obviously not prone to racemization and not involved in the ring-closing reaction, the latter process should not lead to erosion of ee. As an additional task, we planned to unambiguously establish the absolute configuration of the tertiary alcohols and ethers formed in this way, as reliable data on these compounds are practically absent.

Scheme 1. Asymmetric Cu-catalyzed 1,2-addition of Grignard reagents to enones
Based on the product of the enantioselective 1,2-Grignard addition reaction, several approaches for ring-closure were selected (Scheme 2). In case the substituent X is bromide, it had already been shown that Sonogashira reaction readily leads to the corresponding enyne.\[^{12c}\] Base-induced intramolecular hydro-alkoxylation following a literature procedures\[^{14}\] leads then directly to substituted dihydrofurans (route A).

![Scheme 2. Strategies for chiral cyclic ether formation](image)

Upon allylation of the hydroxy group in the addition product, formally 1,6-dienes are formed. These should be very suitable substrates for ring-closing olefin metathesis, leading to chiral dihydrofurans with a double bond at the 3,4-position (route B). In turn, these out-of-conjugation alkenes can be further functionalized to provide highly substituted tetrahydrofurans.

Employing butenylmagnesium bromide in the asymmetric addition reaction gives a direct access to 1,6-dienes as well (route C). Although the enantioselectivity of the addition reaction in this particular case is less satisfactory (the reaction requires branched Grignard reagents to reach excellent ee values), we wanted to pursue this approach, as subsequent ringclosure via olefin metathesis leads to chiral allylic cyclopentenols. Formally, these originate from addition of a carbon nucleophile to cyclopentenone,\[^{15}\] but this reaction in an enantioelective fashion is not known. Alternatively, 1-methyl-2-cyclopentenol has been prepared from linalool using ring-closing metathesis.\[^{16}\]

**2.3 Results and Discussion**

The study commenced with the preparation of the enantioenriched tertiary allylic alcohols via catalytic asymmetric addition of Grignard reagents to the corresponding enones. These α-bromo enones 1, in turn, are readily obtained by aldol condensation of benzaldehyde and the appropriate ketone, followed by dibromination/HBr elimination.\[^{17}\]
Upon treatment of the α-bromo enones 1a and 1b with isobutylmagnesium bromide in the presence of CuBr•SMe2 (5 mol%) and \((S, R_{Fe})-L\) (6 mol%) in methyl tert-butyl ether (MTBE) at –78 °C, the desired chiral tertiary alcohols 2a and b were obtained in good yields and good to excellent enantioselectivities (Table 1).\[12\] In addition, 1a was used in the addition of (2-ethyl)butylmagnesium bromide and cyclohexylmethylmagnesium bromide leading to the corresponding alcohols. As expected, the reactions could be performed on gram scale without deterioration in yield or ee except for 2d, in which a longer reaction time led to a slightly lower ee.

With the products 2 in hand, the Sonogashira reactions, as part of route A, were carried out using 5 mol% Pd(PPh3)2Cl2 and 10 mol% CuI as the catalysts in Et3N. The corresponding enynes 3a-3d were isolated in high yields (Table 2).\[18\] Subsequent treatment with tBuOK in DMSO for 1 h at 60 ºC afforded the desired cyclized products 4a-d in good yields.\[14a\] It has been shown that 3-benzylidene-2,3-dihydrofurans are strongly fluorescent compounds.\[19\]

Synthesis of the 2,5-dihydrofurans 7, via route B, also started from the chiral tertiary alcohols 2. Debromination with tBuLi in dry Et2O at –78 ºC for 0.5 h,\[20\] followed by aqueous work up, yielded the desired products 5a-c in good isolated yields (Table 3). Alkylation of the hydroxyl groups in 5 turned out to be surprisingly difficult and substituents other than allyl could not be introduced. Under optimized conditions, comprising the use of 1.5 eq allyl bromide, 1.5 eq NaH and 3.0 eq HMPA in refluxing dry THF,\[21\] 6a-c were however prepared in high to excellent yield. Remarkably, 2d refused to react under all conditions, presumable due to steric hindrance.

Compounds 6a-c were subsequently transformed into the corresponding 2,5-dihydrofurans 7a-c by treatment with 5 mol% Hoveyda-Grubbs second generation catalyst in dichloromethane (Table 3). The reactions went fully selective to complete conversion and the high yields are probably only reduced because of the volatility of the products.

For the synthesis of cyclopentenols according to route C, butenylmagnesium bromide was added to 1a and its α-methyl (instead of α-bromo) analogue 1c (Scheme 3). Enantioselectivities were modest, as expected. Subsequent debromination of 2e, following the procedure described earlier gave 5e in 83% isolated yield. Subsequent ring-closing metathesis resulted in 1-methyl-2-cyclopentenol 8a, in 40% yield, the moderate yield being solely due to its extreme volatility. Ring-closing of its congener 2f gave 8b in high yield.

Scheme 3. Synthesis of 2-cyclopenten-1-ols 8

In order to determine the absolute configuration of this class of tertiary alcohols and ethers, we decided to prepare the corresponding α-hydroxy acids 9a-b from 2a-b and 2g (Table 4). This would lead to known, well-described compounds and in itself, this approach might serve as an alternative route to chiral enantioenriched α,α-disubstituted acids which are important building blocks in natural product synthesis and normally prepared from chiral pool precursors. Hydroxy acid 9a and 9b were obtained from 2a and 2b in good yield by ozonolysis in acetone. The sign of their optical rotation, in comparison with the literature data, showed unambiguously that the (S,RFe) enantiomer of ligand L produces the opposite stereochemistry for R1 = Me than for R1 = Ph, though both products are assigned the R configuration due to application of the CIP-rules. In the case of 2g, ozonolysis was followed by a bromoform reaction which provided 9b in low yield. For this substrate holds that the (S,RFe) enantiomer of L provides the same stereochemistry as for 2b (in both cases R1
is Ph), although the product (that is, the product of the 1,2 addition reaction, not the compound in Table 4) is designated S due to the CIP-rules.\[23\]

### 2.4 Conclusions

In summary, we have developed a novel approach for the enantioselective synthesis of chiral dihydrofurans with a tertiary oxygen-containing stereocenter and of tertiary cyclopentenols. Based on the catalytic asymmetric 1,2-addition of Grignard reagents, combined with a Sonogashira coupling/cyclization approach, or an alkylation followed by ring-closing metathesis, different kinds of dihydrofurans were prepared efficiently. With their absolute stereochemistry being established, the obtained compounds are versatile building blocks both for natural product synthesis and pharmaceuticals.

### 2.5 Experimental Section

General remarks: $^1$H NMR (400 MHz) and $^{13}$C NMR (100 MHz) spectra were recorded with CDCl$_3$ as solvent. Chemical shifts were determined relative to the residual solvent peaks (CHCl$_3$, $\delta$ = 7.26 ppm for $^1$H NMR, $\delta$ = 77.0 ppm for $^{13}$C NMR). The following abbreviations are used to indicate signal multiplicity: s, singlet; d, doublet; t, triplet; q, quartet; qi, quintet; m, multiplet; br, broad. Enantiomeric excesses were determined by chiral HPLC in comparison with racemic products. Racemic products were obtained by the same procedure as used for the enantioselective 1,2-addition, but omitting the ligand and CuBr•SMe$_2$ (5 mol%) and
only using Grignard reagent (1.2 eq) at 0 °C in Et₂O. Regioselectivities were determined by ¹H NMR. Optical rotations were measured with a 10 cm cell (c given in g/100 mL) at 20 °C. Thin-layer chromatography (TLC) was performed on TLC Silica gel. Flash chromatography was performed on silica gel. Mass spectra were obtained from high resolution (ESI+ or APCI+) mass spectrometer. Copper salt was purchased and used without further purification. All starting materials, Copper salt, ligand (S, RFe-L), and tBuMgBr (2 M in Et₂O) were purchased and used without further purification. All Grignard reagents were prepared from the corresponding alkyl bromides and Mg activated with I₂ in Et₂O.

For the stereochemistry of α-bromo enones 1, to our surprise, we could not find a rigorous proof of the stereochemistry of the so-obtained bromo enones in literature, despite the fact that these compounds have been reported several times. In this study the stereochemistry is determined unambiguously a posteriori. Upon catalytic asymmetric 1,2-addition using the bromo enones as substrate, the products are identical to the corresponding products obtained in the uncatalyzed addition with the same Grignard reagent, used to prepare the racemic reference material, so isomerisation during the Grignard addition can be excluded. After debromination of the resulting tertiary alcohols with tBuLi (vide infra), ¹H-NMR clearly shows the presence of an E-carbon-carbon double bond. This determines the stereochemistry of the starting bromo enones being as shown.

1a-c: Starting materials were prepared following literature procedures[17].

**General procedure for the preparation of α-brominated enones:** To a suspension of oxone (100 mmol) in dichloromethane (250 mL) and water (50 mL) was added portion-wise sodium bromide (100 mmol) over 10 min at 0 °C, and the resulting mixture was stirred for an additional 30 min. Then the enone (50 mmol) was added over 20 min and stirred overnight, allowing the reaction to warm to room temperature. The mixture was poured into water and extracted with dichloromethane. The combined organic phases were washed with water, dried over Na₂SO₄, filtered and concentrated in vacuo. The residue was dissolved in dry dichloromethane (100 mL) and the solution was treated with dry triethylamine (60 mmol) added dropwise via syringe over 10 min under nitrogen. After the addition was complete, the mixture was left stirring under nitrogen at room temperature for an additional 16 h. Then the mixture was washed with HCl (aq, 2 M) and brine, dried over Na₂SO₄, filtered and evaporated in vacuo. The residue was purified by column chromatography on silica gel (pentane/EtOAc = 60 : 1) to afford the α-bromo-enone as a light yellow oil.
Catalytic asymmetric synthesis of dihydrofurans and cyclopentenols with quaternary stereocenters

(Z)-3-Bromo-4-phenyl-3-buten-2-one (1a). 1a: yield 60%. $^1$H NMR (400 MHz, CDCl$_3$) $\delta$ 8.03 (s, 1 H), 7.87–7.85 (m, 2 H), 7.44–7.43 (m, 3 H), 2.59 (s, 3 H);

(E)-3-Bromo-4-phenyl-3-buten-2-one (S1). S1: yield 14%. $^1$H NMR (400 MHz, CDCl$_3$) $\delta$ 7.35–7.34 (m, 3 H), 7.33 (s, 1 H), 7.27–7.34 (m, 2 H), 2.27 (s, 3 H).

(Z)-2-Bromo-1,3-diphenyl-2-propen-1-one (1b). 1c: yield 78%. $^1$H NMR (400 MHz, CDCl$_3$) $\delta$ 7.86–7.80 (m, 4 H), 7.70 (s, 1 H), 7.62–7.58 (m, 1 H), 7.49 (t, $J$ = 7.6 Hz, 2 H), 7.45–7.42 (m, 3 H). (E)-2-Bromo-1,3-diphenyl-2-propen-1-one (S2). S2: yield 7%. $^1$H NMR (400 MHz, CDCl$_3$) $\delta$ 8.01–7.97 (m, 2 H), 7.57–7.53 (m, 1 H), 7.45–7.40 (m, 2 H), 7.38 (s, 1 H), 7.19–7.16 (m, 5 H).

General procedure for the copper-catalysed 1,2-addition of Grignard reagents: A Schlenk tube equipped with septum and stirring bar was charged with CuBr·SMe$_2$ (11.3 mg, 0.055 mmol, 5 mol%) and ligand (S, R$_{Fe}$)-L (39.2 mg, 0.066 mmol, 6 mol%). Under nitrogen, dry tBuOMe (8 mL) was added and the solution was stirred at room temperature for 15 min. Then the corresponding enone (1.10 mmol, in 5 mL tBuOMe) was added and the resulting solution was cooled to –78 °C. The corresponding Grignard reagent (1.32 mmol, 1.2 eq in Et$_2$O) was diluted with tBuOMe (2 mL) and added to the reaction mixture over 3 h. The mixture was left to stir overnight at –78 °C. The reaction was quenched by the addition of MeOH and saturated aqueous NH$_4$Cl and the mixture was warmed to room temperature, diluted with Et$_2$O and the layers were separated. The aqueous layer was extracted with Et$_2$O and the combined organic phases were dried over anhydrous Na$_2$SO$_4$, filtered and evaporated in vacuo. The residue was purified by column chromatography on silica gel (pentane/Et$_2$O = 20 : 1) to afford alcohol 2.

$\alpha$-hydroxy acids 9: 9a-b and S9c were prepared from 2a-b and 2g following the literature procedure,$^{[24]}$ and S9c afforded 9b following the procedure of literature.$^{[23c]}$ The absolute configurations of 9a-b were based on specific rotations reported in literatures.$^{[23a, 23b]}$

To a stirred solution of 2 (0.28 mmol) in acetone (7 mL) at −78 °C a stream of ozone was bubbled until a blue color persisted in the solution. Subsequently, nitrogen was bubbled through the solution until the blue color had disappeared. Dimethyl sulfide (0.5 mL) and water (1 mL) were added and the mixture was allowed to stir at room temperature for 1 h. The solvent was evaporated and the residue was extracted with ether.

For the products of 2a-b, the combined organic phases were extracted with 5% NaOH$_{aq}$, and the combined alkaline phases were acidified with 10% HCl. The resulted solution was extracted with ether. The combined organic phases were dried over MgSO$_4$ and evaporated to afford 9a-b as colorless crystals.

For the products of 2g, the combined organic phases were dried over MgSO$_4$ and concentrated in vacuo. The crude product was purified by column chromatography (pentane/Et$_2$O = 50 : 1) to afford S9c as a colorless oil.

(R)-2-Hydroxy-2,4-dimethyl-pentanoic acid (9a). yield 75%. $[\alpha]_{D}^{20} = -10.4$ (c 0.56, CHCl$_3$); $^1$H NMR (400 MHz, CDCl$_3$) δ 1.83 – 1.75 (m, 2 H), 1.69 – 1.66 (m, 1 H),
1.47 (s, 3 H), 0.96 (d, \( J = 5.2 \) Hz), 0.89 (d, \( J = 5.6 \) Hz); \(^{13}\)C NMR (100 MHz, CDCl\(_3\)) \( \delta \) 180.0, 72.0, 45.6, 24.9, 21.8, 21.7, 20.5.

(R)-2-Hydroxy-4-methyl-2-phenyl-pentanoic acid (9b). Yield 86%. \([\alpha]^{20}_D = -10.0 \) (c 1.16, CHCl\(_3\)), \([\alpha]^{20}_D = -72.4 \) (c 1.16, EtOH); \(^1\)H NMR (400 MHz, CDCl\(_3\)) \( \delta \) 7.29 - 7.27 (m, 2 H), 7.01 – 6.92 (m, 3 H), 1.81 – 1.68 (m, 2 H), 1.50 (s, 1 H), 0.61 (d, \( J = 8.0 \) Hz, 3 H), 0.56 (d, \( J = 4.0 \) Hz). The absolute configuration was based on specific rotation reported in the literature: 9b \([\alpha]^{22}_D = -16.7 \) (c 0.83, EtOH).

(R)-3-Hydroxy-5-methyl-3-phenyl-2-hexanone (S9c). Colorless oil (46 mg, 79%). \([\alpha]^{20}_D = -16.9 \) (c 0.43, CHCl\(_3\)); \(^1\)H NMR (400 MHz, CDCl\(_3\)) \( \delta \) 7.42-7.39 (m, 2 H), 7.30-7.26 (m, 2 H), 7.23-7.19 (m, 1 H), 4.46 (s, 1 H), 2.13-2.06 (m, 2 H), 2.04 (s, 3 H), 1.79-1.72 (m, 1 H), 0.90-0.85 (m, 6 H); \(^{13}\)C NMR (100 MHz, CDCl\(_3\)) \( \delta \) 209.9, 141.7, 128.5, 127.8, 126.1, 82.8, 44.9, 24.6, 24.2, 23.8, 23.7; HRMS (ESI) calcd. for C\(_{13}\)H\(_{17}\)O \([\text{M} – \text{OH}]^+\) 189.1274, found 189.1268.

To a solution of S9c (40 mg, 0.19 mmol) in dioxane (3 mL) was added NaOH (10 mL, 4 M). The resulting suspension was stirred vigorously at 0 \(^\circ\)C while bromine (0.030 mL, 0.57 mmol) was added slowly. The resulting mixture was stirred for another 5 min after the addition was finished. Then the mixture was washed with ether. The aqueous layer was acidified with 1 M HCl and extracted with ether. The combined organic phases were dried over MgSO\(_4\), filtered and concentrated in vacuo. The residue was further purified by chromatography on silica gel (EtOAc : pentane = 6 : 1/1\% AcOH) to afford 9b (8 mg, 20 \%) which showed to be identical to the ozonolysis product of 2b. \([\alpha]^{20}_D = -7.8 \) (c 0.25, CHCl\(_3\)).
