Abstract

The notion of a maximally nondensely defined symmetric operator or relation is introduced and characterized. The selfadjoint extensions (including the generalized Friedrichs extension) of a class of maximally nondensely defined symmetric operators are described. The description is given by means of the theory of ordinary boundary triplets and exhibits the extensions as infinite-dimensional perturbations of a certain selfadjoint operator extension of the symmetric operator.

doi:10.1016/j.indag.2012.08.007
decomposition $\mathfrak{H} = \mathfrak{H}_1 \oplus \mathfrak{H}_2$ with $\mathfrak{H}_1 = \text{dom } S$ and $\dim \mathfrak{H}_2 > 0$, and

$$S f_1 = S_{11} f_1 \oplus S_{21} f_1, \quad S_{j1} \in B(\mathfrak{H}_1, \mathfrak{H}_j), \quad j = 1, 2, \quad f_1 \in \mathfrak{H}_1.$$  \hspace{1cm} (1.1)

Referring to this formula let the matrix

$$\widetilde{A} \overset{\text{df}}{=} \begin{pmatrix} S_{11} & S_{21}^g \\ S_{21} & S_{22} \end{pmatrix},$$  \hspace{1cm} (1.2)

corresponding to the decomposition $\mathfrak{H} = \mathfrak{H}_1 \oplus \mathfrak{H}_2$, be an arbitrary bounded selfadjoint operator extension of $S$. Of course $S$ will also have unbounded selfadjoint operator extensions and, in fact, $S$ will have selfadjoint extensions, which are relations, i.e., multivalued linear mappings. The following result may serve as a starting point to approach the main topics of the paper; cf. [21, Proposition 5.1] and [12, Proposition 3.5] for an inverted form. Here and elsewhere the language of boundary triplets will be used freely; cf. [11,12].

**Proposition 1.1.** Let $S$ be a closed bounded symmetric operator as in (1.1) and (1.2). Then the following statements hold:

(i) $S$ has equal defect numbers $(d, d)$, $d = \dim \mathfrak{H}_2 \leq \infty$;

(ii) the adjoint $S^*$ of $S$ in $\mathfrak{H}$ is the relation given by

$$S^* = \{ \widehat{f} = (f, \tilde{A} f + h); \quad f \in \mathfrak{H}_1, \quad h \in \mathfrak{H}_2 \};$$

(iii) a boundary triplet for $S^*$ is given by $\Pi = \{ \mathfrak{H}_2, \Gamma_0, \Gamma_1 \}$, where

$$\Gamma_0 \widehat{f} = -h, \quad \Gamma_1 \widehat{f} = f_2; \quad f = f_1 \oplus f_2 \in \mathfrak{H}_1, \quad \widehat{f} = (f, \tilde{A} f + h) \in S^*;$$

(iv) the corresponding $\gamma$-field $\gamma$ is given by $\gamma(\lambda) = (\tilde{A} - \lambda)^{-1} \upharpoonright \mathfrak{H}_2$ and the Weyl function $M$ is given by

$$M(\lambda) = P_2(\tilde{A} - \lambda)^{-1} \upharpoonright \mathfrak{H}_2 = \left( S_{22} - \lambda - S_{21}(S_{11} - \lambda)^{-1}S_{21}^g \right)^{-1},$$

where $P_2$ stands for the orthogonal projection onto $\mathfrak{H}_2$;

(v) the selfadjoint extensions $A_\Theta = \ker(\Gamma_0 + \Theta \Gamma_1)$ of $S$ in $\mathfrak{H}$ are in one-to-one correspondence with the selfadjoint relations $\Theta$ in $\mathfrak{H}_2$ via

$$A_\Theta = \begin{pmatrix} S_{11} & S_{21}^g \\ S_{21} & S_{22} + \Theta \end{pmatrix},$$

and their resolvents, with $\lambda \in \rho(A_\Theta) \cap \rho(\tilde{A})$, are connected by

$$(A_\Theta - \lambda)^{-1} = (\tilde{A} - \lambda)^{-1} - \gamma(\lambda)(M(\lambda) + \Theta^{-1})^{-1}\gamma(\tilde{A})^*.$$
where $P_2$ stands for the orthogonal projection onto $\mathcal{N}$. This formula implies that the defect subspaces of the bounded nondensely defined symmetric operator $S$ admit the following property

$$\ker(S^* - \lambda) \cap \overline{\text{dom} S} = \{0\} \quad \text{for all } \lambda \in \mathbb{C} \setminus \mathbb{R}. \quad (1.3)$$

The present paper deals with the general class of symmetric, not necessarily closed, relations $S$ in a Hilbert space $\mathcal{H}$ satisfying (1.3). Such relations will be called \textit{maximally nondensely defined}; cf. Definition 3.3. The property (1.3) holds precisely when the componentwise sum

$$S_\infty = S \hat{\oplus} ([0] \times \text{mul} S^*) \quad (1.4)$$

is an essentially selfadjoint extension of $S$; see Proposition 3.10. Thus the closure of $S_\infty$ is a selfadjoint extension of $S$ in $\mathcal{H}$. In particular, this means that $S$ has equal defect numbers and clearly, if $S$ is not itself essentially selfadjoint, then by taking closures in (1.4) one concludes that $\text{mul} S^* \neq \text{mul} S**$. Consequently, the defect numbers $(d, d)$ are nonzero as $d = \dim(\text{mul} S^* \ominus \text{mul} S**)$; see Lemma 3.2. The extension $S_\infty$ is selfadjoint if and only if

$$\text{dom } S = \overline{\text{dom } S} \cap \overline{\text{dom } S^*} \quad (1.5)$$

a condition, which has appeared earlier in [8]. Various characterizations for symmetric relations satisfying (1.4) or (1.5) will be established; cf. Propositions 3.10 and 3.11.

One of the aims of the paper is to present an extension of Proposition 1.1 which will now be sketched; cf. Theorem 5.1 and Corollary 5.2. Let $S$ be a closed symmetric operator, which satisfies (1.5) so that it is maximally nondensely defined, and let $\tilde{A}$ be some selfadjoint operator extension of $S$, which is transversal to $S_\infty$ (there always exist such extensions $\tilde{A}$ of $S$). Then the selfadjoint extensions $A_\Theta$ of $S$ are in one-to-one correspondence with the selfadjoint relations $\Theta$ in $\mathcal{H}$ via the perturbation formula

$$A_\Theta = \tilde{A} + G\Theta G^* P_2. \quad (1.6)$$

where $G$ is a bounded and boundedly invertible operator from the Hilbert space $\mathcal{H}$ onto $\text{mul } S^*$; see Theorem 5.3. The formula (1.6) admits essentially the same simplicity as the block formula in Proposition 1.1. In general, when $S$ is not closed and bounded, one cannot rewrite the perturbation formula (1.6) as a block form; see Example 5.6. However, such a block formula is still possible for unbounded symmetric operators, which are partially bounded; see Sections 4 and 5.3. Notice also that in (1.6) the operator extensions of $S$ are parameterized by operators $\Theta$ in $\mathcal{H}$, i.e., by bounded or unbounded (range) \textit{perturbations} of the selfadjoint operator $\tilde{A}$. On the other hand, the purely multivalued selfadjoint relation $\{0\} \times \mathcal{H}$ in $\mathcal{H}$ corresponds to the selfadjoint extension $S_\infty$ in (1.4). In fact, $S_\infty$ is the only selfadjoint extension of $S$ whose domain is contained in $\overline{\text{dom } S}$ and, hence, it coincides with the so-called generalized Friedrich extension of $S$; cf. [20]. If $S$ is semibounded then $S_\infty$ coincides with the standard Friedrichs extension; cf. [8]. Perturbation formulas as in (1.6) often occur in concrete applications; see [1,3,9,10,15,13,25].

One may view the underlying symmetric operator $S$ as a domain restriction of any of its selfadjoint operator extensions $A_\Theta$ in (1.6). A completely formal reasoning leads to analogous results for range restrictions $S$ of a selfadjoint operator $\tilde{A}$. All the selfadjoint extensions of $S$ can again be described by means of an ordinary boundary triplet which is constructed in Proposition 5.11, which gives rise to an explicit domain perturbation formula for all selfadjoint extensions of $S$ analogous to (1.6). Such results find applications in problems involving ordinary and partial differential equations; see [1,14,17,28]. A typical case of this situation occurs for
symmetric densely defined operators, for which \( \lambda = 0 \) is a point of regular type (\( \text{ran} \, S \) is closed, \( S^{-1} \) is bounded), or if for instance there is a selfadjoint extension of \( S \) with discrete spectrum. Roughly speaking all what is needed to derive such results is to pass to the formal inverse \( S^{-1} \), which in turn becomes (the graph of) a maximally nondensely defined symmetric relation, and then describe the inverses \( A^{-1}_\Theta \) of the selfadjoint extensions \( A_\Theta \) of \( S \) as the range perturbation of \( S^{-1} \) as in (1.6).

The contents of the paper are as follows. In Section 2 some preliminary results concerning range perturbations and ordinary boundary triplets are presented; see [16] for linear relations and [12,17] for ordinary boundary triplets. The class of maximally nondensely defined symmetric relations is investigated in Section 3 and continued further in Section 4 under the additional assumption that \( S \) is partially bounded. The extension theory of maximally nondensely defined symmetric relations is presented in Section 5 with a construction of suitable boundary triplets for \( S^* \) yielding in particular the (range) perturbation formula as in (1.6). In that section also connections to block matrix formulas are given covering the known special case of bounded symmetric operators. Finally, the translation to the perturbations on the side of domains is shortly described.

2. Preliminaries

2.1. Some facts about linear relations

Let \( S \) be a, not necessarily closed, linear relation in a Hilbert space \( \mathcal{H} \), with inner product \( \langle \cdot, \cdot \rangle \), so that \( \mathcal{H} = \overline{\text{dom} \, S^*} \oplus \text{mul} \, S^{**} \). The so-called (orthogonal) operator part of \( A \) is defined by

\[
S_{\text{op}} \overset{\text{df}}{=} \{ (f, f') \in S; f' \in \overline{\text{dom}} \, S^* \}. \tag{2.1}
\]

Let \( Q \) stand for the orthogonal projection from \( \mathcal{H} \) onto \( \overline{\text{dom}} \, S^* \). Then \( S \) admits a so-called canonical decomposition into the (operator wise) sum of its regular and singular parts \( S = S_{\text{reg}} + S_{\text{sing}} \) which are defined as follows:

\[
S_{\text{reg}} \overset{\text{df}}{=} QS = \{ (f, Qf') \in S; (f, f') \in S \}, \tag{2.2}
\]

\[
S_{\text{sing}} \overset{\text{df}}{=} (I - Q)S = \{ (f, (I - Q)f') \in S; (f, f') \in S \}; \tag{2.3}
\]

see [23]. By definition \( \text{dom} \, S_{\text{reg}} = \text{dom} \, S_{\text{sing}} = \text{dom} \, S \) and, moreover, the regular part \( S_{\text{reg}} \) is a regular, i.e. closable, operator and the singular part \( S_{\text{sing}} \) is a singular relation, i.e. \( \text{ran} \, S_{\text{sing}} \subset \text{mul} \, S_{\text{sing}}^{**} \).

Then (2.1) and (2.2) show that \( S_{\text{op}} \subset S_{\text{reg}} \), which implies that as a restriction of a closable operator, the operator part of \( S \) is also closable. For further properties of this and some other related decompositions of linear relations the reader is referred to the papers [23,16].

Let \( S \) be a, not necessarily closed, symmetric linear relation in a Hilbert space \( \mathcal{H} \), so that \( S \subset S^* \), or equivalently, \( (f', f) \in \mathbb{R} \). The closure \( S^{**} \) is also symmetric with the same adjoint \( S^* \), thus \( S \subset S^{**} \subset S^* \). For a symmetric relation \( S \) one has

\[
\text{ran} \, (S - \lambda) \cap \text{mul} \, S^* = \text{mul} \, S, \quad \lambda \in \mathbb{C} \setminus \mathbb{R}. \tag{2.4}
\]

To see this, it suffices to show that the left-hand side is contained in the right-hand side. Let \( h \in \text{ran} \, (S - \lambda) \cap \text{mul} \, S^* \), then \( h = f' - \lambda f \) for some \( (f, f') \in S \); hence \( (f', f) = \lambda (f, f) \), which leads to \( f = 0 \) and \( h = f' \in \text{mul} \, S \).
The \textit{defect subspaces} of $S$ are defined by $\mathcal{N}_\lambda(S^*) = (\text{ran } (S - \lambda))^\perp = \ker(S^* - \lambda)$. The \textit{defect numbers} of $S$ are defined by $\dim \ker(S^* - \lambda) \leq \infty$ and are constant for $\lambda \in \mathbb{C}^+$ and for $\lambda \in \mathbb{C}^-$. The following notation is used:

\[ \mathcal{N}_\lambda(S^*) \overset{df}{=} \{ f_\lambda \overset{df}{=} (f_\lambda, \lambda f_\lambda) ; f_\lambda \in \mathcal{N}_\lambda(S^*) \}, \quad \lambda \in \mathbb{C}. \]  

(2.5)

The adjoint $S^*$ has the following componentwise sum decomposition

\[ S^* = S^{**} \oplus \mathcal{N}_\lambda(S^*) \oplus \mathcal{N}_{\bar{\lambda}}(S^*), \quad \lambda \in \mathbb{C} \setminus \mathbb{R} \]  

due to von Neumann. Observe that $\mathcal{H} = \text{dom } S^* \oplus \text{mul } S^{**}$ and decompose the closed symmetric relation $S^{**}$ accordingly:

\[ S^{**} = (S^{**})_{\text{op}} \oplus ([0] \oplus \text{mul } S^{**}), \]  

(2.7)

where the orthogonal operator part $(S^{**})_{\text{op}} = Q S^{**} = S^{**}_{\text{reg}}$ is as in (2.1), (2.2); for more details on such decompositions see also [16]. Taking adjoints one obtains

\[ S^* = ((S^{**})_{\text{op}})^* \oplus ([0] \oplus \text{mul } S^{**}), \]

which leads in particular to

\[ \ker(S^* - \lambda) = \ker(((S^{**})_{\text{op}})^* - \lambda), \quad \lambda \in \mathbb{C}. \]  

(2.8)

\[ \text{mul } S^* \ominus \text{mul } S^{**} = \text{mul } ((S^{**})_{\text{op}})^*. \]  

(2.9)

Thus the deficiency indices of $S$ in $\mathcal{H}$ are equal to the ones of its operator part $(S^{**})_{\text{op}}$ in the subspace $\mathcal{H} \ominus \text{mul } S^{**}$.

2.2. Range perturbations of linear relations

Recall that for closed subspaces $\mathcal{M}$ and $\mathcal{N}$ of a Hilbert space $\mathcal{H}$ the sum $\mathcal{M} + \mathcal{N}$ is closed if and only if $\mathcal{M} \perp + \mathcal{N} \perp$ is closed; see [24, IV, Theorem 4.8]. The following lemma is a weakening of a known result; cf. [12,16].

\textbf{Lemma 2.1.} Let $\mathcal{M}$ be a linear, not necessarily closed, subspace, let $\mathcal{N}$ be a closed linear subspace of a Hilbert space $\mathcal{H}$, and let $P$ be the orthogonal projection from $\mathcal{H}$ onto $\mathcal{N} \perp$. Then

(i) $\mathcal{M} + \mathcal{N}$ is closed if and only if $P \mathcal{M}$ is closed;

(ii) $\mathcal{M} + \mathcal{N} = \mathcal{H}$ if and only if $P \mathcal{M} = \mathcal{N} \perp$;

(iii) $\ker(P \mid \mathcal{M}) = \mathcal{M} \cap \mathcal{N}$.

\textbf{Proof.} Since $\mathcal{N}$ is closed, the Hilbert space $\mathcal{H}$ allows the orthogonal decomposition $\mathcal{H} = \mathcal{N} \oplus \mathcal{N} \perp$. Now it is straightforward to check the following identity:

\[ \mathcal{M} + \mathcal{N} = P \mathcal{M} \oplus \mathcal{N}. \]

This implies immediately the statements in (i)–(ii). Statement (iii) is clear. \qed

In the sequel also the following closely related fact is needed.

\textbf{Lemma 2.2.} Let $\mathcal{M}$ and $\mathcal{N}$ be linear, not necessarily closed, subspaces of a Hilbert space $\mathcal{H}$, and let $P$ be the orthogonal projection from $\mathcal{H}$ onto the closed subspace $\mathcal{N} \perp$. Then $\mathcal{M} + \mathcal{N}$ is dense in $\mathcal{H}$ if and only if $P \mathcal{M}$ is dense in $\mathcal{N} \perp$. 

Proof. Observe the following inclusions:
\[ \mathcal{M} + \mathcal{N} \subset \mathcal{M} + \text{clos} \mathcal{N} = P \mathcal{M} \oplus \text{clos} \mathcal{N} \subset \text{clos} (\mathcal{M} + \mathcal{N}). \]
Hence \( \text{clos} (P \mathcal{M}) \oplus \text{clos} \mathcal{N} = \text{clos} (\mathcal{M} + \mathcal{N}) \), which implies the claim. \( \square \)

For the calculus of linear relations in a Hilbert space, involving adjoints and componentwise sums, see for instance [11,16].

Lemma 2.3. Let \( S \) and \( T \) be closed linear relations from a Hilbert space \( \mathcal{H} \) to a Hilbert space \( \mathcal{K} \). Then the following statements are equivalent:

(i) \( S \perp T \) is a closed relation from \( \mathcal{H} \) to \( \mathcal{K} \);
(ii) \( S^* \perp T^* \) is a closed relation from \( \mathcal{K} \) to \( \mathcal{H} \).

Proposition 2.4. Let \( T \) be a relation from a Hilbert space \( \mathcal{H} \) to a Hilbert space \( \mathcal{K} \), let \( \mathcal{L} \) be a closed linear subspace in \( \mathcal{K} \), and let \( P_{\mathcal{L}} \) be the orthogonal projection from \( \mathcal{K} \) onto \( \mathcal{L} \). Then the following statements are equivalent:

(i) \( T^{**} \perp (\{0\} \times \mathcal{L}) \) is closed in \( \mathcal{H} \times \mathcal{K} \);
(ii) \( \text{dom} T^* + \mathcal{L}^\perp \) is closed in \( \mathcal{K} \);
(iii) \( \text{dom} T^* + \mathcal{L}^\perp = (\text{mul} T^{**} \cap \mathcal{L})^\perp \);
(iv) \( P_{\mathcal{L}}(\text{dom} T^*) \) is closed in \( \mathcal{K} \).

Moreover, if \( \text{mul} T^{**} + \mathcal{L} \) is closed in \( \mathcal{K} \) or, equivalently, if \( \overline{\text{dom} T^* + \mathcal{L}^\perp} \) is closed in \( \mathcal{K} \), then each of the statements (i)–(iv) is equivalent to each of the following statements:

(v) \( \overline{\text{dom} T^*} \subset \text{dom} T^* + \mathcal{L}^\perp \);
(vi) \( P_{\mathcal{L}}(\overline{\text{dom} T^*}) = P_{\mathcal{L}}(\text{dom} T^*) \).

In particular, if \( T \) is a closable operator from \( \mathcal{H} \) to \( \mathcal{K} \), i.e., if \( \text{mul} T^{**} = \{0\} \), then the statements (v) and (vi) reduce to:

(vii) \( \text{dom} T^* + \mathcal{L}^\perp = \mathcal{K} \);
(viii) \( P_{\mathcal{L}}(\overline{\text{dom} T^*}) = \mathcal{L} \),

respectively.

Proof. (i) \( \Leftrightarrow \) (ii) The assumption that \( T^{**} \perp (\{0\} \times \mathcal{L}) \) is a closed subspace in \( \mathcal{H} \times \mathcal{K} \) is equivalent, via Lemma 2.3, to the closedness of the subspace
\[ T^* \perp (\mathcal{L}^\perp \times \mathcal{H}) = (\text{dom} T^* + \mathcal{L}^\perp) \times \mathcal{H}, \]
which is closed precisely when \( \text{dom} T^* + \mathcal{L}^\perp \) is closed.

(ii) \( \Leftrightarrow \) (iii) Observe that \( \text{mul} T^{**} = (\text{dom} T^*)^\perp \), which implies that
\[ (\text{dom} T^* + \mathcal{L}^\perp)^\perp = \text{mul} T^{**} \cap \mathcal{L}, \]

since \( \mathcal{L} \) is closed. Therefore,
\[ \text{clos} (\text{dom} T^* + \mathcal{L}^\perp) = (\text{mul} T^{**} \cap \mathcal{L})^\perp, \]
which shows that \( \text{dom} T^* + \mathcal{L}^\perp \) is closed if and only if (iii) is satisfied.

(ii) \( \Leftrightarrow \) (iv) Apply Lemma 2.1 with \( \mathcal{M} = \text{dom} T^*, \mathcal{N} = \mathcal{L}^\perp \), and \( P = P_{\mathcal{L}} \).

Next observe that the subspace \( \text{mul} T^{**} + \mathcal{L} \) is closed if and only if the subspace \( (\text{mul} T^{**})^\perp + \mathcal{L}^\perp = \text{dom} T^* + \mathcal{L}^\perp \) is closed, and that in this case
\[ (\text{mul} T^{**} \cap \mathcal{L})^\perp = \overline{\text{dom} T^* + \mathcal{L}^\perp}. \]
(iii) ⇔ (v) When \( \text{mul} T^{**} + \mathcal{L} \) is closed, it follows from (2.11) that the condition \( \text{dom} T^* + \mathcal{L} = (\text{mul} T^{**} \cap \mathcal{L})^\perp \) can be rewritten as
\[
\text{dom} T^* + \mathcal{L} = \overline{\text{dom} T^* + \mathcal{L}^\perp},
\]
which is equivalent to
\[
\overline{\text{dom} T^*} \subset \text{dom} T^* + \mathcal{L}^\perp.
\]

(v) \( \Rightarrow \) (vi) It is clear that in general \( P_2(\text{dom} T^*) \subset P_2(\overline{\text{dom} T^*}) \). The reverse inclusion follows directly from (v) as \( \overline{\text{dom} T^*} \subset \text{dom} T^* + \mathcal{L}^\perp \). Hence (vi) holds.

(vi) \( \Rightarrow \) (v) Let \( f \in \overline{\text{dom} T^*}. \) Then there exists \( h \in \text{dom} T^* \) such that \( f - h \in \mathcal{L}^\perp \) and \( f = h + (f - h) \in \text{dom} T^* + \mathcal{L}^\perp \). Hence (v) holds.

Finally observe that if \( T \) is a closable operator, then \( (\text{dom} T^*)^\perp = \text{mul} T^{**} = \{0\} \). Hence, in this case \( \text{mul} T^{**} + \mathcal{L} = \mathcal{L} \) is closed and furthermore \( \overline{\text{dom} T^*} = \mathcal{L} \). Therefore the statements (v) and (vi) clearly reduce to the statements (vii) and (viii), respectively. \( \square \)

**Remark 2.5.** In [12, Definition 2.1] a linear relation \( T \) satisfying the property stated in (i) of Proposition 2.4 has been called \( \mathcal{L} \)-regular; in [12, Proposition 2.5] the equivalence of (i) and (iv) in Proposition 2.4 has been also proved.

### 2.3. Ordinary boundary triplets

Let \( S \) be a closed symmetric relation in a Hilbert space \( \mathcal{H} \). If the defect numbers are equal, then \( S \) has selfadjoint extensions in the Hilbert space \( \mathcal{H} \). Let \( A_0 \) and \( A_1 \) be selfadjoint extensions of \( S \); they are called disjoint with respect to \( S \) if \( A_0 \cap A_1 = S \) and transversal with respect to \( S \) if \( A_0 \cap A_1 = S^* \); see [12, Definition 1.7]. Some further definitions and facts which can be found in [12] are now given.

**Definition 2.6 ([12]).** Let \( S \) be a symmetric relation in a Hilbert space \( \mathcal{H} \) with equal deficiency indices and let \( S^* \) be its adjoint. Then the triplet \( \Pi = (\mathcal{H}, \Gamma_0, \Gamma_1) \), where \( \mathcal{H} \) is a Hilbert space and \( \Gamma \overset{\text{df}}{=} (\Gamma_0, \Gamma_1) \) is a linear single-valued surjection of \( S^* \) onto \( \mathcal{H} = \mathcal{H} \times \mathcal{H} \), is said to be an ordinary boundary triplet for \( S^* \) if the abstract Green’s identity
\[
(\langle f', g \rangle, \gamma)_{S} - (\langle f, g' \rangle, \gamma)_{S} = (\langle \Gamma_1 \hat{f}, \Gamma_0 \hat{g} \rangle_{\mathcal{H}} - (\langle \Gamma_0 \hat{f}, \Gamma_1 \hat{g} \rangle_{\mathcal{H}}), \quad (2.12)
\]
holds for all \( \hat{f} = (f, f'), \hat{g} = (g, g') \in S^* \). If \( S \) is closed one may think of \( (\mathcal{H}, \Gamma_0, \Gamma_1) \) as the ordinary boundary triplet of \( S \) itself.

If \( (\mathcal{H}, \Gamma_0, \Gamma_1) \) is a boundary triplet for \( S^* \), then \( \dim \mathcal{H} = n_\pm(S) \). Moreover, \( S = \ker \Gamma \subset \ker \Gamma_0 \cap \ker \Gamma_1 \) and the relations \( A_0 \) and \( A_1 \) defined by
\[
A_0 \overset{\text{df}}{=} \ker \Gamma_0, \quad A_1 \overset{\text{df}}{=} \ker \Gamma_1, \quad (2.13)
\]
are selfadjoint extensions of \( S \) and they are transversal with respect to \( S \). Conversely, for any two selfadjoint extensions \( A_0 \) and \( A_1 \) of \( S \) which are transversal with respect to \( S \), there exists a boundary triplet \( (\mathcal{H}, \Gamma_0, \Gamma_1) \) for \( S^* \) such that (2.13) holds. In particular, a boundary triplet is not unique if the defect numbers of \( S \) are not equal to zero.

Boundary triplets are particularly convenient for the parameterization and description of the intermediate extensions \( \mathcal{H} \) of \( S \), i.e., the extensions \( \mathcal{H} \) of \( S \) which satisfy \( S \subset \mathcal{H} \subset S^* \). More
precisely, the mapping
\[ \Theta \mapsto A_\Theta \overset{\text{df}}{=} \{ \hat{f} \in S^*; \Gamma \hat{f} \in \Theta \} = \ker(\Gamma_1 - \Theta \Gamma_0) \] (2.14)
establishes a bijective correspondence between the closed relations \( \Theta \) in \( \mathcal{H} \) and the closed intermediate extensions \( A_\Theta \) of \( S \). Furthermore, it can be shown that
\[ A_{\Theta^*} = (A_\Theta)^*. \] (2.15)
In particular, a closed extension \( A_\Theta \) of \( S \) is symmetric or selfadjoint if and only if the relation \( \Theta \) is symmetric or selfadjoint, respectively. A specific symmetric subspace in \( \mathcal{H} \), which is called in [12, p. 141] a forbidden manifold, is defined as follows:
\[ F_{\Pi} \overset{\text{df}}{=} \Gamma \{ \{0\} \times \text{mul } S^* \}. \] (2.16)
Note that the symmetric extension of \( S \) corresponding to \( F_{\Pi} \) in (2.14) is given by
\[ S_{\infty} \overset{\text{df}}{=} A_{F_{\Pi}} = S + \{ \{0\} \times \text{mul } S^* \}; \]this extension has an important role in later sections. Finally recall that the intermediate extensions in (2.14) have the following properties (see [12, Proposition 1.4]):
\[ A_\Theta \cap A_0 = S \quad \text{(disjoint)} \iff \Theta \text{ operator,} \] (2.17)
and
\[ A_\Theta + A_0 = S^* \quad \text{(transversal)} \iff \Theta \text{ bounded operator.} \] (2.18)

**Definition 2.7** ([12]). Let \((\mathcal{H}, \Gamma_0, \Gamma_1)\) be a boundary triplet for \( S^* \) with \( A_0 = \ker \Gamma_0 \). The \( \Gamma^\prime \)-field \( \gamma \) is defined by (see (2.5))
\[ \gamma(\lambda) = \{(\Gamma_0 \hat{f}_\lambda, \Gamma_1 \hat{f}_\lambda); \hat{f}_\lambda \in \hat{\mathfrak{N}}_\lambda(S^*)\}, \quad \lambda \in \rho(A_0), \] (2.19)
and the Weyl function \( M \) is defined by
\[ M(\lambda) = \{(\Gamma_0 \hat{f}_\lambda, \Gamma_1 \hat{f}_\lambda); \hat{f}_\lambda \in \hat{\mathfrak{N}}_\lambda(S^*)\}, \quad \lambda \in \rho(A_0). \] (2.20)
Denote by \( \Pi_1 \) the orthogonal projection in \( \mathfrak{H} \oplus \mathfrak{H} \) onto the first component. Observe that the restriction \( \Gamma_0 \upharpoonright \hat{\mathfrak{N}}_\lambda(S^*) \) of the mapping \( \Gamma_0 \) to \( \hat{\mathfrak{N}}_\lambda(S^*) \) is a bijective mapping onto \( \mathcal{H} \). Hence, \( \gamma(\lambda) \) is the graph of a bounded linear operator from \( \mathcal{H} \) to \( \hat{\mathfrak{N}}_\lambda(S^*) \) and \( M \) is a \( \mathcal{B}(\mathcal{H}) \)-valued function, given by
\[ \gamma(\lambda) = \Pi_1(\Gamma_0 \upharpoonright \hat{\mathfrak{N}}_\lambda(S^*))^{-1}, \quad M(\lambda) = \Pi_1(\Gamma_0 \upharpoonright \hat{\mathfrak{N}}_\lambda(S^*))^{-1}, \quad \lambda \in \rho(A_0). \]
For all \( \lambda, \mu \in \rho(A_0) \) the \( \Gamma^\prime \)-field \( \gamma \) satisfies the identity
\[ \gamma(\lambda) = (I + (\lambda - \mu)(A_0 - \lambda)^{-1})\gamma(\mu), \] (2.21)
which, in particular, shows that \( \gamma \) is holomorphic on \( \rho(A_0) \). The Weyl function \( M \) and the \( \Gamma^\prime \)-field \( \gamma \) are related via the identity
\[ \frac{M(\lambda) - M(\mu)^*}{\lambda - \bar{\mu}} = \gamma(\mu)^* \gamma(\lambda), \quad \lambda, \mu \in \rho(A_0). \] (2.22)
Since \( \gamma(\lambda) \) is injective and maps \( \mathcal{H} \) onto \( \mathcal{N}_1(S^*) \), (2.22) shows that \( \Im M(\lambda) \) is boundedly invertible. By means of \( M \) the identity (2.14) can be rewritten as

\[
(A_0 - \lambda)^{-1} = (A_0 - \lambda)^{-1} - \gamma(\lambda) (M(\lambda) - \Theta)^{-1} \gamma(\lambda)^* .
\]

(2.23)

The class \( \mathbf{N}_0(\mathcal{H}) \) is introduced as the collection of all Nevanlinna functions \( M \), which satisfy

\[
sup_{y > 0} y \langle \Im M(iy)h, h \rangle < \infty ,
\]

(2.24)

for all \( h \in \mathcal{H} \); cf. [20]. In this case there exists a selfadjoint operator \( E \in \mathcal{B}(\mathcal{H}) \) such that

\[
\lim_{\lambda \to \infty} M(\lambda)h = Eh, \quad h \in \mathcal{H}.
\]

It is well-known that for any Nevanlinna function \( M \) there exists an operator \( B \in \mathcal{B}(\mathcal{H}) \) such that

\[
\lim_{\lambda \to \infty} \frac{M(\lambda)h}{\lambda} = Bh, \quad h \in \mathcal{H}.
\]

If \( B \) is boundedly invertible then

\[
s - \lim_{y \to \infty} iyM(iy)^{-1} = B^{-1} .
\]

(2.25)

A Nevanlinna function is said to be uniformly strict, when \( 0 \in \rho(\Im M(\lambda)) \) for all \( \lambda \in \mathbb{C} \setminus \mathbb{R} \); in this case also \( -M(\lambda)^{-1} \) belongs to \( \mathbf{N}(\mathcal{H}) \) and is uniformly strict. The boundedness of the limit value in (2.25) shows that the function \( -M(\lambda)^{-1} \) belongs to the subclass \( \mathbf{N}_0(\mathcal{H}) \).

3. Maximally nondensely defined symmetric relations

3.1. Orthogonal projections of nondensely defined symmetric relations

Let \( S \) be a symmetric relation in a Hilbert space \( \mathfrak{H} \) and assume it is nondensely defined so that \( \text{mul} \ S^* \) is nontrivial. The Hilbert space \( \mathfrak{H} \) admits the orthogonal decomposition \( \mathfrak{H} = \mathfrak{H}_1 \oplus \mathfrak{H}_2 \) with \( \mathfrak{H}_1 = \overline{\text{dom} \ S} \) and \( \mathfrak{H}_2 = \text{mul} \ S^* \). Note that \( \mathfrak{H}_1 \subset \overline{\text{dom} \ S^*} \). Let \( P \) denote the orthogonal projection from \( \mathfrak{H}_1 \) onto \( \text{mul} \ S^* \). Note that \( \text{mul} \ S^{**} \subset \text{mul} \ S^* \) so that \( (\text{mul} \ S^*)^\perp \subset (\text{mul} \ S^{**})^\perp \).

Define the linear relations

\[
S_1 = (I - P)S \quad \text{and} \quad S_2 = PS \quad \text{in} \ \mathfrak{H}
\]

by

\[
S_1 = \{(f, (I - P)f'); (f, f') \in S\}, \quad S_2 = \{(f, Pf'); (f, f') \in S\} .
\]

(3.1)

It is clear that \( \text{dom} \ S_1 = \text{dom} \ S \subset \mathfrak{H}_1 \), \( \text{ran} \ S_1 \subset \overline{\text{dom} \ S} = \mathfrak{H}_1 \), and that \( S_1 \) is a symmetric operator in \( \mathfrak{H} \). Moreover,

\[
S_1^* = S^*(I - P), \quad S_1^{**} = (S^*(I - P))^* \subset (I - P)S^{**} .
\]

Note that \( \text{mul} \ S^* = \ker(I - P) \subset \text{dom} \ S_1^* \). Likewise it is clear that \( \text{dom} \ S_2 = \text{dom} \ S \subset \mathfrak{H}_1 \), \( \text{ran} \ S_2 \subset \text{mul} \ S^* = \mathfrak{H}_2 \), and that \( S_2 \) is a relation in \( \mathfrak{H} \) with \( \text{mul} \ S_2 = \text{mul} \ S \). Moreover,

\[
S_2^* = S^*P, \quad S_2^{**} = (S^*P)^* \subset PS^{**} .
\]

Note that \( \overline{\text{dom} \ S} = \ker P \subset \text{dom} \ S_2^* \), which implies that

\[
\overline{\text{dom} \ S_2^*} = \overline{\text{dom} \ S} = \mathfrak{H}_1 \ominus \text{mul} \ S^{**} = \overline{\text{dom} \ S} \oplus (\text{mul} \ S^* \ominus \text{mul} \ S^{**}), \tag{3.2}
\]

in particular, \( \text{mul} \ S_2^{**} = \text{mul} \ S^{**} \).
In some sense $S_1$ and $S_2$ resemble the regular and singular parts of the relation $S$. However it will be useful to consider them in spaces related to the decomposition $S = S_1 \oplus S_2$. The relation $S_1$ is a linear subspace of the product $S_1 \times S_1$. However, the inclusions $\text{dom} \ S_1 \subset S_1$, $\text{ran} \ S_1 \subset S_1$ show that $S_1$ may also be considered as a linear subspace of the product $S_1 \times S_1$; therefore define

$$S_{11} = S_1 \cap (S_1 \times S_1),$$

in other words $S_{11}$ as a graph is the same as $S_1$ but considered in the product space $S_1 \times S_1$, rather than in the product space $S \times S$. Clearly $S_{11}$ is a symmetric relation in $S_1$ with $\text{dom} \ S_{11} = \text{dom} \ S$; hence $S_{11}$ is densely defined and closable in $S_1$. Observe that

$$(S_{11})^* = S^* \cap (S_1 \times S_1),$$

so that $S_{11}^* \subset S^*$. The relation $S_2$ is a linear subspace of the product $S_2 \times S$. However, the inclusions $\text{dom} \ S_2 \subset S_1$, $\text{ran} \ S_2 \subset S_2$ show that $S_2$ may also be considered as a linear subspace of the product $S_2 \times S_2$; therefore define

$$S_{21} = S_2 \cap (S_1 \times S_2),$$

in other words $S_{21}$ as a graph is the same as $S_2$ but considered in the product space $S_1 \times S_2$, rather than in the product space $S \times S$. Clearly $\text{dom} \ S_{21} = \text{dom} \ S$, so that the relation $S_{11}$ is densely defined in $S_1$. Observe that

$$(S_{21})^* = S^* \cap (S_2 \times S_2),$$

so that $S_{21}^* \subset S^*$. The adjoints in (3.4) and (3.6) of $S_{11}$ and $S_{21}$ have been taken with respect to the spaces $S_1 \times S_1$ and $S_1 \times S_2$, respectively. This convention will be used in the rest of the paper; in fact, the notations $S_{ij}$ and $S_{ij}^*$, $i, j = 1, 2$, will stand for $(S_{ij})^*$ and $(S_{ij})^{**}$, respectively. The next lemma can be derived from [22]; see also [30,27]. Observe that if the multi-valued relation $S$ is not symmetric, then the following matrix representation fails to hold in general.

**Lemma 3.1.** Let $S$ be a symmetric relation in the Hilbert space $S$. Then $S$ admits the following block representation as a multi-valued column operator from $S_1$ to $S_1 \oplus S_2$ with entries $S_{11}$ and $S_{21}$ defined in (3.3), (3.5):

$$S = \begin{pmatrix} S_{11} \\ S_{21} \end{pmatrix}.$$

Moreover, the adjoint $S^*$ is a, not necessarily densely defined, operator from $S_1 \oplus S_2$ to $S_1$ such that

$$S^* \supset \begin{pmatrix} S_{11}^* & S_{21}^* \end{pmatrix}, \quad S^{**} \subset \begin{pmatrix} S_{11}^* & S_{21}^* \end{pmatrix}^* = \begin{pmatrix} S_{11}^{**} \\ S_{21}^{**} \end{pmatrix}.$$

Conversely, if $S_{11}$ is a symmetric operator in $S_1$ and $S_{21}$ is a linear relation from $S_1 \oplus S_2$ such that $\text{dom} \ S_{11} \cap \text{dom} \ S_{21}$ is dense in $S_1$, then $S$ defined by (3.7) is a symmetric relation in $S$ with a dense domain in $S_1$.

**Proof.** Clearly the inclusion “$\subset$” in (3.7) holds for an arbitrary (not necessarily symmetric) relation $S$. Since $S$ is symmetric, $\text{mul} \ S \subset \text{mul} \ S^* = S_1 \oplus \text{dom} \ S = S_2$ and hence $\text{mul} \ S = \text{mul} \ S_2$; this implies that the inclusion “$\supset$” in (3.7) is also satisfied. The formulas in (3.8) follow from (3.7) using the general result on block relations in [22, Proposition 2.1].

The converse statement can be checked in a straightforward manner. □
In particular, Lemma 3.1 implies that $S$ is closable if and only if $S_{21}$ is closable and that $\text{mul } S^{**} = \text{mul } S^{*}$ or, equivalently,

$$\text{dom } S_{21}^* = \text{mul } S^* \ominus \text{mul } S^{**} = \overline{\text{dom } S^*} \ominus \mathcal{F}_1. \quad (3.9)$$

If the adjoint of $S$ is calculated in $\mathcal{F}_1$ then it is given by $S^* \hat{+} (\{0\} \times \text{mul } S^*)$, where $S^*$ is the adjoint as in Lemma 3.1.

The defect subspaces of the densely defined symmetric operator $S_{11}$ in $\mathcal{F}_1$ are said to be the semidefect subspaces of the original symmetric relation $S$ in $\mathcal{F}_1$: they are denoted by

$$\mathfrak{N}_\lambda(S_{11}^*) = \text{ker}(S_{11}^* - \lambda) = \mathcal{F}_1 \ominus \overline{\text{ran}(S_{11} - \tilde{\lambda})}, \quad \lambda \in \mathbb{C} \setminus \mathbb{R}. \quad (3.10)$$

The dimensions of the semidefect subspaces of $S$, i.e. the defect numbers of $S_{11}$ in $\mathcal{F}_1$, are called the semidefect numbers of $S$; see [2,31, Section 1.5]. To formulate the next lemma denote by $P_\lambda$ the orthogonal projection from $\mathcal{F}_1$ onto $\text{ker}(S^* - \lambda)$, so that $\text{ker } P_\lambda = \overline{\text{ran}(S - \lambda)}$.

**Lemma 3.2.** Let $S$ be a symmetric relation in a Hilbert space $\mathcal{F}_1$. Then

$$\mathfrak{N}_\lambda(S_{11}^*) = \mathfrak{N}_\lambda(S^*) \cap \overline{\text{dom } S}, \quad \lambda \in \mathbb{C} \setminus \mathbb{R}, \quad (3.11)$$

and moreover,

$$P_\lambda(\mathfrak{N}_\lambda(S_{11}^*) \oplus \text{mul } S^*) = \mathfrak{N}_\lambda(S^*), \quad (3.12)$$

$$\text{ker}(P_\lambda(\mathfrak{N}_\lambda(S_{11}^*) \oplus \text{mul } S^*)) = \text{mul } S^{**}. \quad (3.13)$$

In particular,

$$\dim \mathfrak{N}_\lambda(S^*) = \dim \mathfrak{N}_\lambda(S_{11}^*) + \dim(\text{mul } S^* \ominus \text{mul } S^{**}), \quad \lambda \in \mathbb{C} \setminus \mathbb{R}. \quad \text{Proof.}$$

The identity (3.11) follows directly from (3.4). It follows from (3.10) that

$$\overline{\text{ran}(S_{11} - \tilde{\lambda})} \oplus \mathfrak{N}_\lambda(S_{11}^*) \oplus \text{mul } S^* = \mathcal{F}_1. \quad (3.14)$$

Observe that $S_1 = (I - P)S$ leads to

$$\text{ran}(S_{11} - \tilde{\lambda}) \subset \text{ran}(S - \tilde{\lambda}) + \text{mul } S^*. \quad (3.15)$$

Hence a combination of (3.14) and (3.15) gives

$$\overline{\text{ran}(S - \tilde{\lambda})} + (\mathfrak{N}_\lambda(S_{11}^*) \oplus \text{mul } S^*) = \mathcal{F}_1,$$

which leads to (3.12). Finally apply (2.4) with $S^{**}$ to obtain (3.13). \hfill \square

It follows from Lemma 3.2 that for a nondensely defined symmetric relation $S$ there are two extreme cases. The one extreme case occurs when $\mathfrak{N}_\lambda(S_{11}^*) = \{0\}$ or, equivalently, when $S_{11}$ is essentially selfadjoint in $\mathcal{F}_1$. Since this case has an important role in the present paper, the following definition is introduced.

**Definition 3.3.** A symmetric, not necessarily closed, relation $S$ is said to be maximally nondensely defined if the semidefect numbers of $S$ are equal to $(0, 0)$, or equivalently, if the following equality holds:

$$\mathfrak{N}_\lambda(S^*) \cap \overline{\text{dom } S} = \{0\}, \quad \lambda \in \mathbb{C} \setminus \mathbb{R}.$$
The other extreme case occurs when \( \mathcal{M}_\lambda(S^{**}) = \mathcal{M}_\lambda(S^*) \) or, equivalently, when \( \mathcal{M}_\lambda(S^*) \subset \overline{\text{dom} \ S} \). For the sake of completeness this last case will be described in the rest of the present subsection.

Lemma 3.4. Let \( S \) be a symmetric relation in a Hilbert space \( \mathfrak{H} \). Then the following statements are equivalent:

(i) \( \mathcal{M}_\lambda(S^*) \subset \overline{\text{dom} \ S} \) for some (equivalently for every) \( \lambda \in \mathbb{C} \setminus \mathbb{R} \);

(ii) \( \text{mul } S^{**} = \text{mul } S^* \);

(iii) \( \text{mul } S_{21}^{**} = \text{mul } S^* \) or, equivalently, \( S_{21} \) is singular.

If the relation \( S \) is a closable operator, then (ii) is equivalent to

(iv) \( \text{dom } S \) is dense in \( \mathfrak{H} \).

If the relation \( S \) is closed, then each of (i), (ii), or (iii) is equivalent to

(v) \( S = \text{dom } S \) S_{\text{op}} \oplus ([0] \oplus \text{mul } S^*) \).

Proof. (i) \( \iff \) (ii) In view of (3.11) one has

\[
\mathcal{M}_\lambda(S^*) \subset \overline{\text{dom} \ S} \iff \mathcal{M}_\lambda(S_{11}^{**}) = \mathcal{M}_\lambda(S^*), \quad \lambda \in \mathbb{C} \setminus \mathbb{R}.
\]

In this case it follows from

\[
\mathfrak{H} = \overline{\text{ran} \ (S_{11} - \lambda)} \oplus \mathcal{M}_\lambda(S_{11}^{**}) \oplus \text{mul } S^* = \overline{\text{ran} \ (S - \lambda)} \oplus \mathcal{M}_\lambda(S^*)
\]

that

\[
\overline{\text{ran} \ (S_{11} - \lambda)} \oplus \text{mul } S^* = \overline{\text{ran} \ (S - \lambda)}
\]

and hence

\[
\text{mul } S^* \subset \overline{\text{ran} \ (S - \lambda)} \subset \overline{\text{ran} \ (S^{**} - \lambda)} = \text{ran} \ (S^{**} - \lambda),
\]

which combined with (2.4) shows that \( \text{mul } S^* \subset \text{mul } S^{**} \), i.e., \( \text{mul } S^* = \text{mul } S^{**} \).

Conversely, observe that (3.11) and (2.4) imply that

\[
\mathcal{M}_\lambda(S_{11}^{**}) = P_\lambda(\mathcal{M}_\lambda(S_{11}^{**})) = P_\lambda(\mathcal{M}_\lambda(S_{11}^{**}) \oplus \text{mul } S^{**}).
\]

Hence, if \( \text{mul } S^* = \text{mul } S^{**} \), then (3.12) implies that

\[
\mathcal{M}_\lambda(S_{11}^{**}) = P_\lambda(\mathcal{M}_\lambda(S_{11}^{**}) \oplus \text{mul } S^*) = \mathcal{M}_\lambda(S^*),
\]

which with (3.11) shows that \( \mathcal{M}_\lambda(S^*) \subset \overline{\text{dom} \ S} \).

(ii) \( \iff \) (iii) Since \( \text{mul } S_{21}^{**} = \text{mul } S^* \), this means that (ii) is equivalent to \( \text{mul } S_{21}^{**} = \text{mul } S^* \).

If \( S \) is a closable operator, then \( \text{mul } S^{**} = \{0\} \), and condition (ii) means that \( \text{mul } S^* = \{0\} \),

which is equivalent with (iv). If \( S \) is closed, then (ii) \( \iff \) (v) follows from (2.7). \( \square \)

Example 3.5. The condition \( \mathcal{M}_\lambda(S^*) \subset \overline{\text{dom} \ S} \) may be satisfied without \( S \) being densely defined. Let \( S_{21} \) be a singular operator in a Hilbert space of the form \( \mathfrak{H}_1 \oplus \mathfrak{H}_2 \) with \( \mathfrak{H}_1 = \overline{\text{dom} \ S_1} \) and \( \mathfrak{H}_2 = \overline{\text{ran} \ S_2} \neq \{0\} \); such an operator is easily constructed from any singular operator in a, necessarily infinite-dimensional, Hilbert space \( \mathfrak{H} \); cf. [16]. Let \( S_{11} \) be a bounded selfadjoint operator acting in \( \mathfrak{H}_1 \). Then \( S \) defined by (3.7) is a symmetric operator in \( \mathfrak{H} \) with \( \overline{\text{dom} \ S} = \overline{\text{dom} \ S_{21}} \) and \( \text{mul } S^{**} = \text{mul } S_{21}^{**} = \mathfrak{H}_2 = (\overline{\text{dom} \ S})^\perp \). Hence by Lemma 3.4 \( \mathcal{M}_\lambda(S^*) \subset \overline{\text{dom} \ S} \) for all \( \lambda \in \mathbb{C} \setminus \mathbb{R} \), while the operator \( S \) is not densely defined in \( \mathfrak{H} \).
Remark 3.6. Example 3.5 shows that the condition $N_{\lambda}(S^*) \subset \overline{\text{dom}} \ S$, $\lambda \in \mathbb{C} \setminus \mathbb{R}$, does not imply that $S$ is densely defined in $H$ when $S$ is not closed.

Notice also that in Lemma 3.4(i) it suffices to consider the inclusion $N_{\lambda}(S^*) \subset \overline{\text{dom}} \ S$ for one point $\lambda \in \mathbb{C} \setminus \mathbb{R}$. If one knows in addition that $N_{\lambda}(S^*) \subset \overline{\text{dom}} \ S$ and $N_{\bar{\lambda}}(S^*) \subset \overline{\text{dom}} \ S$ for some $\lambda \in \mathbb{C} \setminus \mathbb{R}$, then from the first von Neumann’s formula one concludes that $\overline{\text{dom}} \ S^* \subset \overline{\text{dom}} \ S$. Since $S$ is closable if and only if $S^*$ is densely defined, it follows that $S$, together with $S^*$, is densely defined; hence using two points one obtains a more direct proof for item (iv) in Lemma 3.4 via von Neumann’s formula.

3.2. Some characterizations of symmetric relations

Let $S$ be a symmetric relation in a Hilbert space $\mathcal{H}$ and assume it is nondensely defined so that $\text{mul} \ S^*$ is nontrivial. Then the relation $S_{\infty}$ defined by the forbidden manifold (see (2.16))

$$S_{\infty} = S \overset{\wedge}{\oplus} ([0] \times \text{mul} \ S^*), \quad (3.16)$$

is a symmetric extension of $S$:

$$S \subset S_{\infty} \subset (S_{\infty})^* \subset S^*. \quad (3.17)$$

Observe that the operatorwise sum $S_1 + S_2$ is a symmetric extension of $S$, which is contained in $S_{\infty}$. It follows from $\text{mul} \ S \subset \text{mul} \ S^*$ that $\text{mul} \ S_{\infty} = \text{mul} \ S^*$. Clearly, $S \subset \text{clos} \, S = S^{**}$ and, since $(\text{dom} \, S^{**})^\perp = \text{mul} \ S^*$, it is easy to see that the following inclusions hold:

$$S_{\infty} \subset (S^{**})_{\infty} \subset \text{clos} \, (S_{\infty}) = \text{clos} \, (S^{**})_{\infty}. \quad (3.18)$$

Observe that

$$\text{ran} \, (S_{\infty} - \lambda) = \text{ran} \, (S - \lambda) + \text{mul} \ S^*, \quad \lambda \in \mathbb{C}. \quad (3.19)$$

Due to (2.4) the sum in (3.19) is direct for $\lambda \in \mathbb{C} \setminus \mathbb{R}$ if and only if $S$ is an operator. The operator $S_{11}$ in (3.3) and the relation $S_{\infty}$ in (3.16) are related by

$$S_{\infty} = S_{11} \overset{\wedge}{\oplus} ([0] \times \text{mul} \ S^*), \quad (3.20)$$

where $[0] \times \text{mul} \ S^*$ is a selfadjoint relation in the Hilbert space $\text{mul} \ S^*$. The next lemma describes $S_{\infty}$, its adjoint, and its closure; cf. [16].

Lemma 3.7. Let $S$ be a symmetric relation in a Hilbert space $\mathcal{H}$. Then

$$S_{\infty} = \{(f, f') \in S^*; f \in \text{dom} \, S\}, \quad (3.21)$$

$$(S_{\infty})^* = \{(f, f') \in S^*; f \in \overline{\text{dom}} \, S\}, \quad (3.22)$$

and

$$(S_{\infty})^{**} = \{(f, f') \in S^*; f \in \text{dom} \, S_{11}^{**}\}. \quad (3.23)$$

Proof. The formulas (3.21) and (3.22) can be found in [16,8]. To prove (3.23), observe that the orthogonal sum decomposition in (3.20) implies that

$$(S_{\infty})^{**} = S_{11}^{**} \overset{\wedge}{\oplus} ([0] \times \text{mul} \ S^*). \quad (3.24)$$

In particular, $S_{11}^{**} \subset (S_{\infty})^{**} \subset S^*$. Now it is easy to check that the formula (3.24) is equivalent to the formula (3.23). $\Box$
Note that \((S_\infty)^* = ((S^{**})_\infty)^*\); see (3.18). Since \(S\) is symmetric, Lemma 3.7 implies that \(\overline{\text{dom}} (S_\infty)^* = \overline{\text{dom}} S\) and, hence, \(\text{mul} \text{ clos} (S_\infty) = \text{mul} S^* = \text{mul} S_\infty\).

**Lemma 3.8.** Let \(S\) be a symmetric relation in a Hilbert space \(\mathfrak{H}\). Then the following statements are equivalent:

(i) \(S_\infty\) is closed;
(ii) \(S_{11}\) in (3.1) is a closed operator in \(\overline{\text{dom}} S\);
(iii) \(\text{ran} (S - \lambda) + \text{mul} S^*\) is closed for some (and hence for all) \(\lambda\) in \(\mathbb{C} \setminus \mathbb{R}\);
(iv) \(\text{dom} S = \text{dom} S^{**}\) and \(\overline{\text{dom}} S^* = \text{dom} S^* + \overline{\text{dom}} S\).

If the symmetric relation \(S\) is closed, then each of the statements (i)–(iv) is also equivalent to the following statement:

(v) \(P_\lambda\) \(\text{mul} S^*\) is a closed subspace of \(\text{ker} (S^* - \lambda)\) for some (and hence for all) \(\lambda\) in \(\mathbb{C} \setminus \mathbb{R}\).

**Proof.** (i) \(\Leftrightarrow\) (ii) This equivalence follows from (3.20).

(i) \(\Leftrightarrow\) (iii) The symmetric relation \(S_\infty\) is closed if and only if \(\text{ran} (S_\infty - \lambda)\) is closed for some (and hence for all) \(\lambda\) in \(\mathbb{C} \setminus \mathbb{R}\). Then recall the identity in (3.19).

(i) \(\Rightarrow\) (iv) Since \(S_\infty\) is closed, one has \(S_\infty = (S^{**})_\infty\); see (3.18). This shows that \(\text{dom} S = \text{dom} S^{**}\). Next apply Proposition 2.4 with \(T = S^{**}\) and \(\mathcal{L} = \text{mul} S^*\). Since \(S\) is symmetric, it follows that \(\text{mul} S^{**} \subset \text{mul} S^*\), so that \(\text{mul} S^{**} + \mathcal{L} = \mathcal{L}\) is closed. By Proposition 2.4 the relation \((S^{**})_\infty\) in (3.16) is closed if and only if

\[
\overline{\text{dom}} S^* \subset \text{dom} S^* + (\text{mul} S^*)^\perp = \text{dom} S^* + \overline{\text{dom}} S.
\]

Since the right-hand side is clearly contained in \(\overline{\text{dom}} S^*\), this shows that (iv) holds.

(iv) \(\Rightarrow\) (i) If \(\overline{\text{dom}} S^* = \text{dom} S^* + \overline{\text{dom}} S\) then Proposition 2.4 shows that \((S^{**})_\infty\) is closed. On the other hand, \(\text{mul} S \subset \text{mul} S^{**} \subset \text{mul} S^*\) and hence the equality \(\text{dom} S = \text{dom} S^{**}\) implies the equality \(S_\infty = (S^{**})_\infty\) and, thus, (i) is satisfied.

Now assume in addition that \(S\) is closed. Then equivalently \(\text{ran} (S - \lambda), \lambda \in \mathbb{C} \setminus \mathbb{R}\), is closed.

(iii) \(\Leftrightarrow\) (v) Apply Lemma 2.1 to the closed subspaces \(\mathfrak{M} = \text{mul} S^*\) and \(\mathfrak{N} = \text{ran} (S - \lambda)\). Note that \(\mathfrak{N}^\perp = \text{ker} (S^* - \lambda) = \text{ran} P_\lambda\). Hence, by Lemma 2.1(i)

\[
\text{ran} (S - \lambda) + \text{mul} S^*, \quad \lambda \in \mathbb{C} \setminus \mathbb{R},
\]

is closed if and only if \(P_\lambda\) \(\text{mul} S^*\) is closed. \(\square\)

**Remark 3.9.** In the case that \(S\) is a closed operator the equivalence of (ii) and (v) in Lemma 3.8 is also proved, for instance, in [2, Theorem 1.5.4] and in fact it goes back to M.A. Krasnoselskii [26]. The equivalence of (i) and (ii) has been also proved e.g. in [12, Proposition 2.5]. Some further equivalent conditions, based on the rigged Hilbert space generated by \(S^*\) can be found in [2, Theorem 2.4.1]. In [29] (see also [2,12]) a symmetric operator \(S\) is said to be **regular**, if the subspaces \(P_\lambda\) \(\text{mul} S^*, \lambda \in \mathbb{C} \setminus \mathbb{R}\), are closed; in the opposite case \(S\) is said to be **singular**. In the present paper the terms regular and singular refer to a more general terminology which appears in connection with general linear operators and relations in Hilbert spaces, cf. Section 2; for further details see [16] and the references therein. Finally, observe that in [2, Section 2.4] the term **O-operator** stands for a closed symmetric operator whose semidefect numbers are equal to \((0, 0)\), instead of the present expression “\(S\) is maximally nondensely defined” that appears in Definition 3.3.
The next result gives several criteria for $S$ to be maximally nondensely defined in $\mathfrak{H}$.

**Proposition 3.10.** Let $S$ be a symmetric relation in a Hilbert space $\mathfrak{H}$. Then the following statements are equivalent:

(i) $S$ is maximally nondensely defined in $\mathfrak{H}$;

(ii) $S_{11}$ in (3.1) is an essentially selfadjoint operator in $\overline{\text{dom}}
S$, i.e., the semidefect indices of $S$ are equal to $(0,0)$;

(iii) $S_{\infty}$ is essentially selfadjoint;

(iv) ran ($S - \lambda$) + mul $S^*$ is dense in $\mathfrak{H}$ for some (and hence for all) $\lambda$ in $\mathbb{C}^+$ and for some (and hence for all) $\lambda$ in $\mathbb{C}^-$;

(v) $\text{dom } S_{11}^{**} = \overline{\text{dom}}
S \cap \text{dom } S^*$;

(vi) $P_\lambda \text{mul } S^*$ is dense in $\ker(S^* - \lambda)$ for some (and hence for all) $\lambda$ in $\mathbb{C}^+$ and for some (and hence for all) $\lambda$ in $\mathbb{C}^-$.

**Proof.** (i) $\iff$ (ii) This follows from Lemma 3.2.

(ii) $\iff$ (iii) This equivalence follows directly from (3.24).

(iii) $\iff$ (iv) This equivalence follows from (3.19).

(ii) $\iff$ (v) By Lemma 3.7 the equality $(S_{\infty})^{**} = (S_{\infty})^*$ can be rewritten as $\text{dom } S_{11}^{**} = \overline{\text{dom}}
S \cap \text{dom } S^*$, since $\text{dom } S_{11}^{**} \subset \text{dom } S^*$, cf. (3.24).

(iv) $\iff$ (vi) Consider the subspaces $\mathfrak{M} = \text{mul } S^*$ and $\mathfrak{N} = \text{ran } (S - \tilde{\lambda})$ with $\lambda \in \mathbb{C} \setminus \mathbb{R}$. By Lemma 2.2 the sum $\text{ran } (S - \tilde{\lambda}) + \text{mul } S^*$ is dense in $\mathfrak{M}$ if and only if $P_\lambda \text{mul } S^*$ is dense in $\mathfrak{N} \bot = \ker(S^* - \lambda)$. □

By combining Lemma 3.8 and Proposition 3.10, one obtains the following characterizations for $S_{\infty}$ to be selfadjoint. The equivalence of the statements (i) and (iv) goes back to [8].

**Proposition 3.11.** Let $S$ be a symmetric relation in a Hilbert space $\mathfrak{H}$. Then the following statements are equivalent:

(i) $S_{\infty}$ is selfadjoint;

(ii) $S_{11}$ in (3.1) is a selfadjoint operator in $\overline{\text{dom}}
S$;

(iii) ran ($S - \lambda$) + mul $S^*$ is dense in $\mathfrak{H}$ for some (and hence for all) $\lambda$ in $\mathbb{C}^+$ and for some (and hence for all) $\lambda$ in $\mathbb{C}^-$;

(iv) $\text{dom } S = \overline{\text{dom}}
S \cap \text{dom } S^*$;

(v) $S$ is maximally nondensely defined in $\mathfrak{H}$ and in addition $\text{dom } S = \text{dom } S^{**} \cap \overline{\text{dom}}
S^*$.

If the symmetric relation $S$ is closed, then each of the statements (i)--(iv) is also equivalent to the following statement:

(vi) $P_\lambda \text{mul } S^* = \ker(S^* - \lambda)$ for some (and hence for all) $\lambda$ in $\mathbb{C}^+$ and for some (and hence for all) $\lambda$ in $\mathbb{C}^-$.

**Proof.** The equivalence of (i), (ii), (iii), (v), and (vi) is obtained from Lemma 3.8 and Proposition 3.10. The equivalence (i) $\iff$ (iv) follows from Lemma 3.7. □

### 3.3. Characterizations via intermediate extensions

The following theorem gives necessary and sufficient conditions for $S_{\infty}$ to be selfadjoint by means of a symmetric extension $T$ of $S$ which is transversal to $S_{\infty}$.
Theorem 3.12. Let $S$ be a closed symmetric relation in a Hilbert space $\mathcal{H}$. Then the following statements are equivalent:

(i) $S_\infty$ is selfadjoint;

(ii) there exists a closed symmetric extension $T$ of $S$ such that

$$S^* = T \uparrow \uplus S_\infty;$$

(iii) there exists a closed symmetric extension $T$ of $S$ such that

$$S^* = T \uparrow (\{0\} \times \text{mul} S^*);$$

(iv) there exists a closed symmetric extension $T$ of $S$ such that

$$\text{dom } S^* \subset \text{dom } T;$$

(v) there exists a closed symmetric extension $T$ of $S$ such that

$$\ker (S^* - \lambda) \subset \text{dom } T, \quad \ker (S^* - \bar{\lambda}) \subset \text{dom } T,$$

for some $\lambda \in \mathbb{C} \setminus \mathbb{R}$.

If a closed symmetric extension $T$ of $S$ satisfies one of (3.25), (3.26), (3.27), or (3.28), then it automatically satisfies the other three of them. Any such closed symmetric relation $T$ is automatically selfadjoint with \text{mul} $T = \text{mul} S$; and the selfadjoint extensions $T$ and $S_\infty$ are transversal with respect to $S : S^* = T \uparrow \uplus S_\infty$.

Proof. (i) $\Rightarrow$ (ii) In fact there exists a selfadjoint extension $T$ of $S$, which is transversal to $S_\infty$; cf. [12].

(ii) $\Leftrightarrow$ (iii) This equivalence is obvious.

(iii) $\Rightarrow$ (iv) The identity (3.26) implies that $\text{dom } S^* = \text{dom } T$.

(iv) $\Rightarrow$ (iii) Observe that $T \uparrow (\{0\} \times \text{mul} S^*) \subset S^*$ for any symmetric extension $T$ of $S$. For the converse inclusion, let $\{f, f'\} \in S^*$. Then $f \in \text{dom } S^* = \text{dom } T$, and there exists an element $h \in \mathcal{H}$ such that $\{f, h\} \in T \subset S^*$. Hence $\{0, f' - f\} = \{f, f'\} - \{f, h\} \in S^*$, which shows that $\{f, f'\} \in T \uparrow (\{0\} \times \text{mul} S^*)$. Therefore $S^* \subset T \uparrow (\{0\} \times \text{mul} S^*)$ and (iii) follows.

(iii) $\Rightarrow$ (i) Since $S$ is closed the identity (3.26) implies the identity

$$S = T^* \cap (\overline{\text{dom } S \uplus \mathcal{F}}).$$

Now let $\{f, f'\} \in (S_\infty)^*$, so that by Lemma 3.7 $\{f, f'\} \in S^*$ and $f \in \overline{\text{dom } S}$. By assumption $f \in \text{dom } T \subset \text{dom } T^*$ and it follows from (3.29) that $f \in \text{dom } S$. Hence $\{f, f'\} \in S_\infty$ by Lemma 3.7. Therefore $S_\infty$ is selfadjoint.

(iv) $\Leftrightarrow$ (v) If (3.27) holds, then certainly (3.28) holds for all $\lambda \in \mathbb{C} \setminus \mathbb{R}$, since $\ker (S^* - \lambda) \subset \text{dom } S^*$ for all $\lambda \in \mathbb{C} \setminus \mathbb{R}$. Conversely, assume that (3.28) holds for $\lambda \in \mathbb{C} \setminus \mathbb{R}$. Recall von Neumann’s decomposition (2.6) of $S^*$, which shows that (with $S$ being closed)

$$\text{dom } S^* \subset \text{dom } S + \ker (S^* - \lambda) + \ker (S^* - \bar{\lambda}).$$

Now $\text{dom } S \subset \text{dom } T$ since $T$ is an extension of $S$. Hence (3.27) follows.

The proof of the equivalence of (ii), (iii), (iv), (v), has already shown that if a closed symmetric extension $T$ of $S$ satisfies one of the four conditions (3.25), (3.26), (3.27), or (3.28), it automatically satisfies the other three conditions too.

Finally, let $T$ be a closed symmetric extension of $S$ which satisfies (3.25), (3.26), (3.27), or (3.28). In fact, assume that $T$ satisfies (3.27). Then $\text{dom } T = \text{dom } T^* = \text{dom } S^*$, and it follows that $\text{mul } T = \text{mul } T^*$, since $T$ is closed. If $\{f, f'\} \in T^*$, then $f \in \text{dom } T^* = \text{dom } T$.
and there exists an element \( h \) such that \( \{ f, h \} \in T \subset T^* \). Hence \( \{ 0, f' - h \} \in T^* \) or \( f' - h \in \text{mul} \ T^* = \text{mul} \ T \), which implies that \( \{ f, f' \} = \{ f, h \} + \{ 0, f' - h \} \in T \). Therefore \( T \) is selfadjoint and \( \text{mul} \ T = (\text{dom} \ T^*)^\perp = (\text{dom} \ S^*)^\perp = \text{mul} \ S \). \( \square \)

**Corollary 3.13.** Let \( S \) be a closed symmetric relation in a Hilbert space \( \mathcal{H} \). Assume that \( S_\infty \) is selfadjoint and that \( T \) is a selfadjoint extension of \( S \) such that \( T \) and \( S_\infty \) are transversal with respect to \( S \). Then

\[
\mathcal{N}_\lambda(S^*) = \{(T - \lambda)^{-1} \varphi; \varphi \in \text{mul} \ S^* \}, \quad \lambda \in \mathbb{C} \setminus \mathbb{R}.
\]  

(3.30)

**Proof.** Let \((f, \lambda f) \in S^* \). Then it follows from (3.26) that

\[
(f, \lambda f) = (h, h') + (0, \varphi), \quad (h, h') \in T, \quad \varphi \in \text{mul} \ S^*.
\]

Therefore, one obtains \((h, h') = (f, \lambda f - \varphi) \in T \) and \((f, -\varphi) \in T - \lambda \), which leads to

\[
f = -(T - \lambda)^{-1} \varphi.\]

This shows \( \mathcal{N}_\lambda(S^*) \subset (T - \lambda)^{-1} \text{mul} \ S^* \).

Conversely, if \( f = -(T - \lambda)^{-1} \varphi \) with \( \varphi \in \text{mul} \ S^* \), then

\[
(f, -\varphi + \lambda f) = -(T - \lambda)^{-1} \varphi, \quad -\varphi - \lambda(T - \lambda)^{-1} \varphi \in T,
\]

so that by (3.26)

\[
(f, \lambda f) = (f, -\varphi + \lambda f) + (0, \varphi) \in T \oplus (\{ 0 \} \times \text{mul} \ S^*) = S^*.
\]

This shows \( \{(T - \lambda)^{-1} \varphi; \varphi \in \text{mul} \ S^* \} \subset \mathcal{N}_\lambda(S^*) \). \( \square \)

The next theorem contains a further characterization for \( S_\infty \) to be selfadjoint which involves only properties of the domain of some symmetric extension \( T \) of \( S \); it can be also seen as a weakening of the criterion (vi) in Proposition 3.11.

**Theorem 3.14.** Let \( S \) be a closed symmetric relation in a Hilbert space \( \mathcal{H} \). Then \( S_\infty \) is selfadjoint if and only if there is a closed symmetric extension \( T \) of \( S \) satisfying the following properties:

(i) \( \text{dom} \ T = \overline{\text{dom} \ S} \);
(ii) \( \text{dom} \ S = \overline{\text{dom} \ S \cap \text{dom} \ T^*} \);
(iii) \( \text{P}(\text{dom} \ T^*) = \overline{\text{P}(\overline{\text{dom} \ T^*})} \).

In this case \( T \) is selfadjoint and transversal to \( S_\infty : T \oplus S_\infty = S^* \). Moreover, if \( S_\infty \) is selfadjoint then every selfadjoint extension \( T \) of \( S \) such that \( T \oplus S_\infty = S^* \) admits the properties (i)–(iii).

In particular, if \( S \) is a closed symmetric operator, then \( S_\infty \) is selfadjoint if and only if there exists a closed symmetric operator extension \( T \) of \( S \) such that

(iv) \( \overline{\text{dom} \ T} = \mathcal{H} \);
(v) \( \text{dom} \ S = \overline{\text{dom} \ S \cap \text{dom} \ T^*} \);
(vi) \( \text{P}(\overline{\text{dom} \ T^*}) = \text{mul} \ S^* \).

**Proof.** \((\Rightarrow)\) Assume that \( S_\infty \) is selfadjoint; then there exists a selfadjoint extension \( T \) of \( S \) such that \( S^* = T \oplus S_\infty \); cf. Theorem 3.12. Moreover, by Theorem 3.12 \( \text{mul} \ T = \text{mul} \ S \), so that \( \overline{\text{dom} \ T} = \overline{\text{dom} \ S^*} \) and (i) follows. Taking adjoints in (3.26) leads to \( S = T \cap (\text{dom} \ S \times \mathcal{H}) \), which gives (ii). Since the right-hand side of (3.26) is closed and \( \text{mul} \ T + \text{mul} \ S^* = \text{mul} \ S^* \) is closed, it follows from Proposition 2.4 that \( \text{P}(\overline{\text{dom} \ T}) = \overline{\text{P}(\overline{\text{dom} \ T})} \), which is (iii).

\((\Leftarrow)\) Let \( T \) be a closed symmetric extension of \( S \), so that \( S \subset T \subset T^* \subset S^* \) and assume that (i), (ii), and (iii) are satisfied. Introduce the linear relation

\[
H = T \oplus (\{ 0 \} \times \text{mul} \ S^*).
\]
Clearly \( S \subset H \subset S^* \) and \( \text{mul } T + \text{mul } S^* = \text{mul } S^* \). By condition (iii) and Proposition 2.4 it follows that \( H \) is closed. Furthermore, observe that

\[ H^* = T^* \cap (\text{dom } S \times \mathcal{H}) = \overline{S}^\perp ([0] \times \text{mul } T^*), \]

where the last identity follows from the assumption (ii). Now by the assumption (i) \( \text{mul } T^* = \text{mul } S \) and, therefore, \( H^* = S \) or, equivalently, \( S^* = H \). Hence, the assumptions (i)–(iii) imply that \( S^* = H = T \updownarrow ([0] \times \text{mul } S^*) \), which by part (iii) of Theorem 3.12 means that \( S^\infty \) is selfadjoint and, furthermore, by the same theorem \( T \) is necessarily selfadjoint and satisfies \( S^* = T \updownarrow S^\infty \).

As to the last statement observe that, if \( S \) is a closed operator, then \( S^* \) is densely defined and, therefore, the statements (i)–(iii) reduce to the statements (iv)–(vi), respectively. \( \Box \)

**Corollary 3.15.** Let \( S \) be a closed symmetric relation in a Hilbert space \( \mathcal{H} \). Then \( S^\infty \) is selfadjoint if and only if there is a selfadjoint extension \( T \) of \( S \) satisfying the following properties:

(i) \( \text{dom } S = \overline{\text{dom } S} \cap \text{dom } T \);
(ii) \( P(\text{dom } T) = \text{mul } S^* \ominus \text{mul } S^{**} \).

**Proof.** (\( \Rightarrow \)) By Theorem 3.14 there exists a selfadjoint extension \( T \) of \( S \) with the properties (i)–(iii) stated therein. In particular, (i) and (iii) in Theorem 3.14 combined with (3.9) show that \( P(\text{dom } T) = P(\overline{\text{dom } S^*}) = \text{mul } S^* \ominus \text{mul } S^{**} \).

(\( \Leftarrow \)) Let \( T \) be a selfadjoint extension of \( S \) with the properties (i) and (ii). Here (ii) means that \( P(\text{dom } T) = P(\overline{\text{dom } S^*}) \) and hence \( P(\text{dom } T) = P(\overline{\text{dom } T}) \) holds. Since \( \ker P = \overline{\text{dom } S} \subset \text{dom } T \subset \overline{\text{dom } S^*} \), the equality \( P(\text{dom } T) = P(\overline{\text{dom } S^*}) \) implies that \( \overline{\text{dom } T} = \overline{\text{dom } S^*} \). To complete the proof it remains to apply Theorem 3.14. \( \Box \)

### 4. Partially bounded symmetric relations

Let \( S \) be a non-densely defined symmetric relation in a Hilbert space \( \mathcal{H} \). Then \( \mathcal{H} \) admits the orthogonal decomposition \( \mathcal{H} = \mathcal{H}_1 \oplus \mathcal{H}_2 = \overline{\text{dom } S} \oplus \text{mul } S^* \). Recall from Section 3.1 the definitions of \( S_{11} \) as a densely defined operator in \( \mathcal{H}_1 \) and of \( S_{21} \) as a densely defined relation from \( \mathcal{H}_1 \) to \( \mathcal{H}_2 \), which satisfy \( S_{11}^* \subset S^* \) and \( S_{12}^* \subset S^* \). Observe that the corresponding inclusions fail to hold for the linear relations \( S_1 = (I - P)S \) and \( S_2 = PS \) in \( \mathcal{H} \), since \( \text{mul } S^* \subset \text{dom } S_{11}^* = \text{dom } S^*(I - P) \) and \( \text{dom } S \subset \text{dom } S_{21}^* = \text{dom } S^*P \), but in general \( \text{mul } S^* \not\subset \text{dom } S_{11}^* \) and \( \overline{\text{dom } S} \not\subset \text{dom } S^* \). This motivates the following definition.

**Definition 4.1.** A symmetric, not necessarily closed, relation \( S \) in a Hilbert space \( \mathcal{H} \) is said to be inner or outer bounded if the closure of \( S_{11} \) or \( S_{21} \), respectively, has a closed domain. Moreover, \( S \) is said to be partially bounded if it is inner or outer bounded.

Partially bounded symmetric relations can be characterized as follows.

**Proposition 4.2.** Let \( S \) be a symmetric relation in a Hilbert space \( \mathcal{H} \). Then the following statements are equivalent:

(i) \( S \) is inner bounded, i.e., \( \text{dom } S_{11}^{**} \) is closed;
(ii) \( S_{11} \) is a bounded symmetric operator in \( \overline{\text{dom } S} \);
(iii) \( \text{dom } S \subset \text{dom } S^* \);
(iv) \( S^\infty \), as well as \( (S^{**})^\infty \), is essentially selfadjoint and their closure \( (S^\infty)^* = (S^\infty)^{**} \) has a closed domain.
Moreover the following statements are equivalent:

(v) $S$ is outer bounded, i.e., $\text{dom } S^{**}_{11}$ is closed;

(vi) $\text{mul } S^* \ominus \text{mul } S^{**} \subset \text{dom } S^*$.

**Proof.** (i) $\iff$ (ii) Since $S_{11}$ as a densely defined symmetric operator is closable and $S_{11}$ is bounded if and only if $S^{**}_{11}$ is bounded, this equivalence follows from the closed graph theorem.

(ii) $\Rightarrow$ (iii) If $S_{11}$ is bounded, then $S^{**}_{11}$ is bounded with a closed domain. Observe that $S_{11} \subset S^{**}_{11} \subset S^*$, see (3.8), which implies that $S^{**}_{11} \subset S^*$. Therefore, $\text{dom } S = \overline{\text{dom } S_{11}} = \overline{\text{dom } S^{**}_{11}} \subset \text{dom } S^*$.

(iii) $\Rightarrow$ (iv) By Lemma 3.1 one has

$$(S^{**})_{11} \subset S^{**}_{11},$$

and hence the assumption $\overline{\text{dom } S \subset \text{dom } S^*}$ implies that $S^{**}_{11}$ is bounded. Hence, $(S^{**})_{11}$ is also bounded and consequently

$$\text{dom } (S^{**})_{11} = \text{dom } S_{11} = \overline{\text{dom } S} = \overline{\text{dom } S \cap \text{dom } S^*},$$

which according to Proposition 3.10 means that $S_{\infty}$ and $(S^{**})_{\infty}$ are essentially selfadjoint. On the other hand, (3.24) implies that $\text{dom } (S_{\infty})^{**} = \text{dom } S_{11}^{**} = \text{dom } S$ is closed.

(iv) $\Rightarrow$ (i) This follows from the equality $\text{dom } (S_{\infty})^{**} = \text{dom } S_{11}^{**}$; see (3.24).

(v) $\Rightarrow$ (vi) If $\text{dom } S^{**}_{21}$ is closed then, equivalently, $\text{dom } S^{*}_{21}$ is closed. Hence, (3.8) and (3.9) imply that $\text{dom } S^{**}_{21} = \text{mul } S^* \ominus \text{mul } S^{**} \subset \text{dom } S^*$.

(vi) $\Rightarrow$ (v) The adjoint of $S_2 = P S$ in $\mathcal{H}$ satisfies $\overline{\text{dom } S \subset \text{dom } S^*}$ and hence it follows from $\text{mul } S^* \ominus \text{mul } S^{**} \subset \text{dom } S^*$ and the formula (3.2) that

$$\overline{\text{dom } S_2} = \overline{\text{dom } S \oplus (\text{mul } S^* \ominus \text{mul } S^{**})} \subset \text{dom } S^* P = \text{dom } S_2^*.$$ 

Hence, $\text{dom } S_2^*$ and, therefore, also $\text{dom } S^{**}_{21}$ is closed or, equivalently, $\text{dom } S^{**}_{21}$ is closed, i.e., $S$ is outer bounded. \qed

Some further characterizations for $S$ to be inner bounded may be obtained by combining Proposition 4.2 with Proposition 3.10.

The next proposition gives a characterization for $S$ to be inner bounded and $(S^{**})_{\infty}$ to be selfadjoint.

**Proposition 4.3.** Let $S$ be a symmetric relation in a Hilbert space $\mathcal{H}$. Then the following statements are equivalent:

(i) $S$ is inner bounded and $(S^{**})_{\infty}$ is selfadjoint;

(ii) $(S^{**})_{\infty}$ is selfadjoint with a closed domain and $\text{mul } S^* \ominus \text{mul } S^{**} \subset \text{dom } S^*$;

(iii) $\text{dom } S^{**}$ is closed or, equivalently, $\text{dom } S^*$ is closed;

(iv) $S$ is inner and outer bounded.

In particular, a closable symmetric relation $S$ is inner and outer bounded if and only if $S$ is a bounded symmetric operator.

**Proof.** (i) $\Rightarrow$ (ii) If $S$ is inner bounded, then by Proposition 4.2 $\overline{\text{dom } S \subset \text{dom } S^*}$ and hence $\overline{\text{dom } S \cap \text{dom } S^*} = \overline{\text{dom } S}$. Since $(S^{**})_{\infty}$ is selfadjoint, it follows from Proposition 3.11 that

$$\overline{\text{dom } (S^{**})_{\infty}} = \overline{\text{dom } S^{**}} \subset \overline{\text{dom } S} = \text{dom } S.$$
Hence \( \text{dom } S^{**} \) and, thus, also \( \text{dom } S^* \) is closed. The inclusion \( \text{mul } S^* \ominus \text{mul } S^{**} \subseteq \text{dom } S^* \) is now obtained from (3.2).

(ii) \( \Rightarrow \) (iii) This implication is clear from \( \text{dom } (S^{**})_\infty = \text{dom } S^{**} \).

(iii) \( \Rightarrow \) (iv) If \( \text{dom } S^{**} \) is closed then it is clear from Lemma 3.1 that \( \text{dom } S^{**}_{21} = \text{dom } S^{**}_{11} = \text{dom } S^{**} = \overline{\text{dom } S} \), so that \( S \) is inner and outer bounded.

(iv) \( \Rightarrow \) (i) If \( S \) is inner bounded, then by Proposition 4.2 \( \overline{\text{dom } S} \subseteq \text{dom } S^* \) and \( \overline{\text{dom } S} \cap \text{dom } S^* = \overline{\text{dom } S} \). Since \( S \) is outer bounded, Proposition 4.2 shows that \( \text{mul } S^* \ominus \text{mul } S^{**} \subseteq \text{dom } S^* \). Now (3.2) shows that \( \overline{\text{dom } S^*} \subseteq \text{dom } S^* \), i.e. \( \text{dom } S^* \) is closed, and thus \( \text{dom } S^{**} = \overline{\text{dom } S} = \overline{\text{dom } S} \cap \text{dom } S^* \). Hence \((S^{**})_\infty \) is selfadjoint by Proposition 4.2. \( \square \)

As to the last statement in Proposition 4.3 observe, that if \( S \) is inner and outer bounded, but not closable, then \( \text{mul } S^{**} = \text{mul } S^*_{22} \) is non-trivial.

The situation that \( S \) is outer bounded and, in addition, maximally nondensely defined can be characterized as follows.

**Proposition 4.4.** Let \( S \) be a symmetric relation in a Hilbert space \( \mathcal{H} \). Then the following statements are equivalent:

(i) \( S \) is outer bounded and \((S^{**})_\infty \) is selfadjoint;
(ii) \( \text{dom } S^* = \text{dom } S^{**} \oplus (\text{mul } S^* \ominus \text{mul } S^{**}) \).

Moreover, the following statements are equivalent:

(iii) \( S \) is outer bounded and \( S_\infty \) is selfadjoint;
(iv) \( \text{dom } S^* = \text{dom } S \oplus (\text{mul } S^* \ominus \text{mul } S^{**}) \).

**Proof.** (i) \( \Rightarrow \) (ii) By Proposition 4.2 \( \text{mul } S^* \ominus \text{mul } S^{**} \subseteq \text{dom } S^* \), and hence

\[
\text{dom } S^{**} \oplus (\text{mul } S^* \ominus \text{mul } S^{**}) \subseteq \text{dom } S^*.
\]

As to the reverse inclusion let \( f \in \text{dom } S^* \) and use (3.2) to decompose \( f \) as \( f = g + h \) with

\[
g \in \overline{\text{dom } S}, \quad h \in \text{mul } S^* \ominus \text{mul } S^{**}.
\]

This implies that \( g = f - h \in \text{dom } S^* \). Since by assumption \( g \in \overline{\text{dom } S} \), it follows from the identity \( \text{dom } S^{**} = \overline{\text{dom } S} \cap \text{dom } S^* \) in Proposition 3.11 that \( g \in \text{dom } S^{**} \).

(ii) \( \Rightarrow \) (i) If \( \text{dom } S^* = \text{dom } S^{**} \oplus (\text{mul } S^* \ominus \text{mul } S^{**}) \) then it follows from Proposition 4.2 that \( S \) is outer bounded. Moreover, from the form of \( \text{dom } S^* \) it is clear that \( \text{dom } S^* \cap \overline{\text{dom } S} = \text{dom } S^{**} \). Hence, by Proposition 3.11 \((S^{**})_\infty \) is selfadjoint.

For the proof of the equivalence of (iii) and (iv) it suffices to replace \( \text{dom } S^{**} \) by \( \text{dom } S \) in the above arguments. \( \square \)

This section is finished with some decomposition result for partially bounded symmetric relations. Recall from (3.2) that the closure of \( \text{dom } S^* \) has the following orthogonal decomposition:

\[
\overline{\text{dom } S^*} = \overline{\text{dom } S} \oplus (\text{mul } S^* \ominus \text{mul } S^{**}). \tag{4.1}
\]

If \( S \) is partially bounded then by Proposition 4.2 either the closed subspace \( \overline{\text{dom } S} \) or the closed subspace \( \text{mul } S^* \ominus \text{mul } S^{**} \) belongs to \( \text{dom } S^* \). This means that with a partially bounded \( S \) the decomposition of \( \overline{\text{dom } S^*} \) in (4.1) induces also a decomposition for \( \text{dom } S^* \) itself (as in this case one of the components in (4.1) is a closed subspace of \( \text{dom } S^* \)). This yields the following block formula for the adjoint relation \( S^* \) itself; cf. [22, Proposition 2.1 (iii)] and [27, Proposition 4.5] for a special case.
Proposition 4.5. Let $S$ be a symmetric relation in a Hilbert space $\mathcal{H}$ and let $S$ be decomposed with respect to the decomposition $\mathcal{H} = \mathcal{H}_1 \oplus \mathcal{H}_2 = \text{dom } S \oplus \text{mul } S^*$ as in Lemma 3.1. If $S$ is partially bounded, then the inclusions in (3.8) hold as equalities:

$$S^* = \begin{pmatrix} S_{11}^* & S_{21}^* \end{pmatrix}, \quad S^{**} = \begin{pmatrix} S_{11}^{**} & S_{21}^{**} \end{pmatrix},$$

(4.2)

where $S : \mathcal{H}_1 \to \mathcal{H}_2$ and the adjoint $S^*$ of $S$ is considered as a relation from $\mathcal{H}_2$ to $\mathcal{H}_1$. If $S$ and its adjoint $S^*$ are considered as relations in $\mathcal{H}$, then the formula for $S^*$ takes the following equivalent form:

$$S^* = \left\{ \left( \begin{pmatrix} f_1 \\ f_2 \end{pmatrix}, \left( S_{11}^* f_1 + S_{21}^* f_2 \right) \right) ; \ f_1 \in \text{dom } S_{11}^*, \ f_2 \in \text{dom } S_{21}^*, \ \varphi \in \text{mul } S^* \right\}.$$

(4.3)

Proof. In view of Lemma 3.1 to prove the stated formula for $S^*$, it suffices to show the inclusion “$\subset$”. Consider $S^*$ as a linear relation from $\mathcal{H}_2 = \mathcal{H}_1 \oplus \mathcal{H}_2$ to $\mathcal{H}_1 = \text{dom } S$ and let $h = h_1 \oplus h_2 \in \mathcal{H}_1 \oplus \mathcal{H}_2$, let $k \in \mathcal{H}_1$, and assume that $(h, k) \in S^*$. This means that for all $(f, g) \in S$ with $g = g_1 \oplus g_2 = S_{11} f \oplus g_2$ and $(f, g_2) \in S_{21}$ one has

$$\langle S_{11} f, h_1 \rangle + \langle g_2, h_2 \rangle = \langle f, k \rangle.$$

(4.4)

If $S$ is inner bounded, then it follows from Proposition 4.2 that $\text{dom } S_{11}^*$ is closed, and hence $h_1 \in \text{dom } S_{11}^* = \mathcal{H}_1$. In this case (4.4) can be rewritten as

$$\langle g_2, h_2 \rangle = \langle f, k - S_{11}^* h_1 \rangle, \quad (f, g_2) \in S_{21},$$

(4.5)

which means that $(h_2, k') \triangleq (h, k - S_{11}^* h_1) \in S_{21}^*$, i.e., $(h, k) = (h_1, S_{11}^* h_1) + (h_2, k') \in (S_{11}^* S_{21}^*)$, which proves the inclusion $S^* \subset (S_{11}^* S_{21}^*)$ in (4.2).

If $S$ is outer bounded, then it follows from Proposition 4.2 that $\text{dom } S_{21}^*$ is closed, i.e., $\text{dom } S_{21}^* = \text{mul } S^* \ominus \text{mul } S^{**}$, and hence (3.2) implies that $h_2 \in \text{dom } S^* \cap \text{mul } S^* = \text{dom } S_{21}^*$, i.e., $(h_2, k') \in S_{21}^*$ for some $k' \in \mathcal{H}_2 = \text{mul } S^*$. Therefore, $(g_2, h_2) = (f, k')$ which implies that (4.4) can now be rewritten as

$$\langle S_{11} f, h_1 \rangle = \langle f, k - k' \rangle, \quad f \in \text{dom } S_{11} = \text{dom } S.$$

(4.6)

This means that $(h, k - k') \in S_{11}^*$, i.e., $S_{11}^* h_1 = k - k'$ and hence $(h, k) = (h, S_{11}^* h_1 + k') \in (S_{11}^* S_{21}^*)$, which again proves the inclusion $S^* \subset (S_{11}^* S_{21}^*)$ in (4.2).

The formula for the closure $S^{**}$ follows from the equality $S^* = (S_{11}^* S_{21}^*)$ by taking adjoints on both sides; see [22, Proposition 2.1 (ii)].

If $S$ and $S^*$ are considered as relations in $\mathcal{H}$ then $S$ is non-densely defined and, thus, $\text{mul } S^* = (\text{dom } S)^\perp = \mathcal{H}_2$ is nontrivial. This together with the formula for $S^*$ in (4.2) implies the formula in (4.3). $\square$

The next example shows that if $S$ is not partially bounded then the adjoint $S^*$ (in particular the domain $\text{dom } S^*$) of a (even maximally) non-densely defined symmetric operator $S$ is not decomposable as in Proposition 4.5.

Example 4.6. Consider an unbounded $2 \times 1$ block (matrix) operator $S$ in a Hilbert space $\mathcal{H}_1 \times \mathcal{H}_2$, of the form

$$S = \begin{pmatrix} A \\ A \end{pmatrix},$$
where \( A \) is an unbounded selfadjoint operator in \( \mathcal{H} \). Then \( S \) is a symmetric operator in \( \mathcal{H} \times \mathcal{H} \) and since \( S_{11} = A \) is selfadjoint, \( S \) is maximally nondensely defined with \( \text{mul} \ S^* = \{0\} \times \mathcal{H} \); cf. Proposition 3.10. Now consider \( S \) as a densely defined operator from \( \mathcal{H} \) to \( \mathcal{H} \times \mathcal{H} \). Since \( S \) is closed and \( S_{11} = S_{21} = A = A^*, \) Lemma 3.1 shows that

\[
S^* \supset (A^* \ A^*) = (A \ A), \quad S^{**} \subset (A^* \ A^*)^* = (A^{**})^* = S.
\]

In particular, \( S \) is closed and \( S^* = \text{clos} (A \ A) \). However, here the row operator \( \text{clos} (A \ A) \) is not closed, and \( S^* \) does not admit a representation with a block formula as in (4.2). In fact, a straightforward calculation using the definition of the adjoint shows that \( S^*, \) considered as an operator from \( \mathcal{H} \times \mathcal{H} \) to \( \mathcal{H}^* \), is given by

\[
S^* = \left\{ \left( \begin{pmatrix} f & h \end{pmatrix}, Ah \right) : h \in \text{dom} A, \ f \in \mathcal{H} \right\}.
\] (4.7)

Clearly, the vectors \( (f, -f) \in \mathcal{H} \times \mathcal{H}, f \in \mathcal{H}, \) belong to \( \text{ker} S^* \); however \( (f, -f) \in \text{dom} (A \ A) \) if and only if \( f \in \text{dom} A \). Therefore, the equality \( S^* = (A \ A) \) holds if and only if \( A \) is bounded.

Example 4.6 shows that even in the case that \( S_{\infty} \) is selfadjoint, \( S^* \) or its domain \( \text{dom} S^* \) need not be decomposable as in Proposition 4.5. However, in the case that \( S_{\infty} \) is selfadjoint one can select a transversal selfadjoint extension \( \widetilde{A} \), in which case \( S^* = \widetilde{A} \oplus S_{\infty} \) and construct a boundary triplet for \( S \) in an explicit manner. Such a boundary triplet will be constructed in the next section by extending some earlier formulas for boundary triplets known in the bounded case and in the case of finite defect numbers.

5. Boundary triplets for a class of maximally nondensely defined symmetric operators

5.1. Extensions for a class of maximally nondensely defined operators

Let \( S \) be a maximally nondensely defined operator in a Hilbert space \( \mathcal{H} \) with \( S_{\infty} \) selfadjoint. Then there exists a selfadjoint operator extension \( \widetilde{A} \) of \( S \), which is transversal to \( S_{\infty} \), in which case

\[
S^* = \widetilde{A} \oplus \{0\} \times \text{mul} \ S^*,
\] (5.1)

and the eigenspace \( \mathcal{N}_\lambda (S^*), \lambda \in \mathbb{C} \setminus \mathbb{R}, \) is parameterized as follows:

\[
\mathcal{N}_\lambda (S^*) = \{ (\widetilde{A} - \lambda)^{-1} \varphi; \varphi \in \text{mul} \ S^* \};
\] (5.2)

see Theorem 3.12 and Corollary 3.13. Hence, \( (f_\lambda, \lambda f_\lambda) \in \mathcal{N}_\lambda (S^*) \) with \( \lambda \in \mathbb{C} \setminus \mathbb{R} \) has the following unique decomposition as in (5.1):

\[
(f_\lambda, \lambda f_\lambda) = ((\widetilde{A} - \lambda)^{-1} \varphi, \varphi + \lambda(\widetilde{A} - \lambda)^{-1} \varphi) + (0, -\varphi), \quad \varphi \in \text{mul} \ S^*.
\] (5.3)

Let \( \mathcal{H} \) be a Hilbert space and let \( G \) be a bounded and boundedly invertible operator from \( \mathcal{H} \) onto \( \text{mul} \ S^* \), so that

\[
G \in \mathcal{B}(\mathcal{H}, \text{mul} \ S^*), \quad G^{-1} \in \mathcal{B}(\text{mul} \ S^*, \mathcal{H}).
\] (5.4)

Recall that the orthogonal projection onto \( \text{mul} \ S^* \) is denoted by \( P \).

**Theorem 5.1.** Let \( S \) be a closed maximally nondensely defined symmetric operator in a Hilbert space \( \mathcal{H} \) with \( S_{\infty} \) selfadjoint. Let \( \widetilde{A} \) be a selfadjoint operator extension of \( S \), which is transversal
to $S_\infty$, so that
\[ S^* = \{ \hat{f} = (f, \tilde{A} f + \varphi); f \in \text{dom} \tilde{A}, \varphi \in \text{mul} S^* \}. \tag{5.5} \]

Then $\Pi = \{ \mathcal{H}, \Gamma_0, \Gamma_1 \}$, where
\[ \Gamma_0 \hat{f} = G^* Pf, \quad \Gamma_1 \hat{f} = G^{-1} \varphi, \quad \hat{f} \in S^*, \tag{5.6} \]
is an ordinary boundary triplet for $S^*$ with
\[ \text{ker} \Gamma_0 = S_\infty \quad \text{and} \quad \text{ker} \Gamma_1 = \tilde{A}. \tag{5.7} \]

The corresponding $\Gamma$-field $\gamma$ and Weyl function $M$ are given by
\[
\gamma(\lambda) = (\tilde{A} - \lambda)^{-1}[G^* P(\tilde{A} - \lambda)^{-1} \upharpoonright \text{mul} S^*]^{-1},
\]
\[
M(\lambda) = -G^{-1}[P(\tilde{A} - \lambda)^{-1} \upharpoonright \text{mul} S^*]^{-1}G^*.
\tag{5.8}
\]

Moreover, $G^* G$ is boundedly invertible and
\[
\lim_{\lambda \to \infty} \frac{M(\lambda)}{\lambda} = (G^* G)^{-1}. \tag{5.9}
\]

**Proof.** Note that $\text{dom} \Gamma = S^*$ and that (5.5) is equivalent to (5.1); see Theorem 3.12. Choose typical elements $\hat{f} = (f, \tilde{A} f + \varphi), \hat{g} = (g, \tilde{A} g + \psi)$ in $S^*$ as in (5.5). Then (5.6) implies
\[
\langle \Gamma_1 \hat{f}, \Gamma_0 \hat{g} \rangle_{\mathcal{H}} - \langle \Gamma_0 \hat{f}, \Gamma_1 \hat{g} \rangle_{\mathcal{H}} = \langle G^{-1} \varphi, G^* Pg \rangle_{\mathcal{H}} - \langle G^* Pf, G^{-1} \psi \rangle_{\mathcal{H}}
\]
\[
= \langle \varphi, g \rangle - \langle f, \psi \rangle = \langle \tilde{A} f + \varphi, g \rangle - \langle f, \tilde{A} g + \psi \rangle,
\]
since $f, g \in \text{dom} \tilde{A}$. Therefore (2.12) is satisfied. Since the operator $\tilde{A}$ is transversal to $S_\infty$, it follows from Theorem 3.14 that $P(\text{dom} \tilde{A}) = \text{mul} S^*$. Consequently,
\[
\Gamma'(S^*) = G^* P(\text{dom} \tilde{A}) \times G^{-1}(\text{mul} S^*) = \mathcal{H} \times \mathcal{H},
\]
so that $\Gamma'$ is surjective. Hence (5.6) defines an ordinary boundary triplet for $S^*$.

To verify the first equality in (5.7), let $\hat{f} = (f, \tilde{A} f + \varphi) \in \text{ker} \Gamma_0$ with $f \in \text{dom} \tilde{A}$ and $\varphi \in \text{mul} S^*$. By definition $P f = 0$ or, equivalently, $f \in \text{dom} S$. Since dom $\tilde{A} = \text{dom} S^*$ one has $f \in \text{dom} S \cap \text{dom} S^*$, so that $f \in \text{dom} S$ by Proposition 3.11. This implies $\hat{f} \in S_\infty$. Therefore ker $\Gamma_0 \subset S_\infty$, and since both sides are selfadjoint, equality follows: ker $\Gamma_0 = S_\infty$. In order to verify the second equality in (5.7), let $\hat{f} = (f, \tilde{A} f + \varphi) \in \text{ker} \Gamma_1$ with $f \in \text{dom} \tilde{A}$ and $\varphi \in \text{mul} S^*$. By definition $\varphi = 0$, which shows $\hat{f} \in \tilde{A}$. Therefore ker $\Gamma_1 \subset \tilde{A}$, and since both sides are selfadjoint, equality follows: ker $\Gamma_1 = \tilde{A}$.

Let $\hat{f}_\lambda \in S^*$ then there exists $\varphi \in \text{mul} S^*$ such that (5.3) holds. It follows from (5.3), (5.5), and (5.6) that
\[
\Gamma_0 \hat{f}_\lambda = G^* Pf_\lambda = G^* P(\tilde{A} - \lambda)^{-1} \varphi, \quad \Gamma_1 \hat{f}_\lambda = -G^{-1} \varphi.
\]

Therefore, according to (2.19) and (2.20) one obtains
\[
\gamma(\lambda) = \{(G^* P(\tilde{A} - \lambda)^{-1} \varphi, (\tilde{A} - \lambda)^{-1} \varphi); \varphi \in \text{mul} S^* \},
\]
\[
M(\lambda) = \{(G^* P(\tilde{A} - \lambda)^{-1} \varphi, -G^{-1} \varphi); \varphi \in \text{mul} S^* \},
\]
which lead to (5.8). Finally (5.9) can be seen from the observation that
\[
\lim_{\lambda \to \infty} \lambda G^* P(\tilde{A} - \lambda)^{-1} \varphi = -G^* \varphi, \quad \varphi \in \text{mul} S^*. \tag{5.10}
\]
A boundary triplet \((\mathcal{H}, \Gamma_0, \Gamma_1')\) for \(S^*\) with Weyl function \(M\) and \(\Gamma^*\)-field \(\gamma\) gives rise to a transposed boundary triplet \((\mathcal{H}, -\Gamma_1, \Gamma_0')\) for \(S^*\) with Weyl function \(-M^{-1}\) and \((-\Gamma_1, \Gamma_0')\)-field \(-\gamma M^{-1}\).

**Corollary 5.2.** Let \(G\) be as in (5.4) and assume that the conditions of Theorem 5.1 are satisfied. Then, in terms of the decomposition (5.5), \(\Pi' = (\mathcal{H}, \Gamma_0', \Gamma_1')\) with

\[
\Gamma_0' \hat{f} = -G^{-1} \varphi, \quad \Gamma_1' \hat{f} = G^* P f, \quad \hat{f} \in S^*,
\]

is an ordinary boundary triplet for \(S^*\) with \(\ker \Gamma_0' = \tilde{\Lambda}\) and \(\ker \Gamma_1' = S_\infty\). The corresponding \(\Gamma^*\)-field \(\gamma'\) and Weyl function \(M'\) are given by

\[
g'(\lambda) = -(\tilde{\Lambda} - \lambda)^{-1} G, \quad M'(\lambda) = G^* P (\tilde{\Lambda} - \lambda)^{-1} G.
\]

Moreover, the following statements are equivalent:

\[
\lim_{\lambda \to \infty} \lambda M'(\lambda) = -G^* G.
\]

5.2. Extensions as perturbations

In the situation of Theorem 5.1 the intermediate extensions of \(S\) can be seen as perturbations of the selfadjoint extension \(\tilde{\Lambda}\). Let \(P\) be the orthogonal projection onto \(\text{mul} S^*\).

**Theorem 5.3.** Let \(S\) be a closed maximally nondensely defined symmetric operator in a Hilbert space \(\mathcal{H}\) with \(S_\infty\) selfadjoint, and assume that \(\Lambda\) is a selfadjoint operator extension of \(S\), which is transversal to \(S_\infty\). Then the closed intermediate extensions \(A_\Theta\) of \(S\) are in one-to-one correspondence with the closed relations \(\Theta\) in \(\mathcal{H}\), via

\[
A_\Theta = \tilde{\Lambda} + G \Theta G^* P.
\]

Moreover, the following statements are equivalent:

(i) \(A_\Theta\) is an operator perturbation of \(\tilde{\Lambda}\);
(ii) \(\Theta\) is an operator in \(\mathcal{H}\) or \((A_\Theta \cap S_\infty = S)\),

and the following statements are equivalent:

(iii) \(A_\Theta\) is a bounded operator perturbation of \(\tilde{\Lambda}\);
(iv) \(\Theta\) is a bounded operator in \(\mathcal{H}\) or \((A_\Theta \cap S_\infty = S^*)\).

**Proof.** In terms of the ordinary boundary triplet \(\Gamma^*\) in (5.6) all (closed) intermediate extensions \(A_\Theta\) of \(S\) are in one-to-one correspondence with the (closed) linear relations \(\Theta\) in \(\mathcal{H}\) via (2.14). For \(f = (f, \tilde{\Lambda} f + \varphi) \in S^*\) with \(f \in \text{dom} \tilde{\Lambda}, \varphi \in \text{mul} S^*\), it follows from (5.6) that

\[
\Gamma \hat{f} = (\Gamma_0' \hat{f}, \Gamma_1' \hat{f}) = (G^* P f, G^{-1} \varphi) \in \Theta \iff (f, \varphi) \in G \Theta G^* P.
\]

Hence, \(\hat{f} = (f, \tilde{\Lambda} f + \varphi) \in S^*\) belongs to \(A_\Theta\) if and only if \((f, \varphi) \in G \Theta G^* P\), or, equivalently, that \(\hat{f} = (f, \tilde{\Lambda} f + \varphi) \in \tilde{\Lambda} + G \Theta G^* P\). This proves (5.14). It is clear from (5.14) that

\[
\text{mul} A_\Theta = \text{mul} G \Theta G^* P = G(\text{mul} \Theta).
\]

Hence, \(A_\Theta\) is an operator extension of \(S\) if and only if \(\Theta\) is an operator in \(\mathcal{H}\). Moreover, since \(G^* \in B(\text{mul} S^*, \mathcal{H})\), the product \(G \Theta G^* P\) is bounded if and only if \(\Theta\) is a bounded operator in \(\mathcal{H}\). \(\square\)
Corollary 5.4. Let the intermediate extension $A_\Theta$ be given by (5.14). Then
\[(A_\Theta)^* = \tilde{A} + G\Theta^*G^*P.\]  
(5.16)

Proof. It has been shown that $A_\Theta$ in (2.14) is written as (5.14). However, the adjoint $(A_\Theta)^*$ of $A_\Theta$ in (2.14) satisfies (2.15). Therefore, $(A_\Theta)^*$ is a perturbation of $\tilde{A}$ as in (5.14) based on the parameter $\Theta^*$.

Proposition 5.5. Let the assumptions be as in Theorem 5.3. Then
\[\text{dom } A_\Theta = \{ f \in \text{dom } \tilde{A}; G^*Pf \in \text{dom } \Theta \}.\]  
(5.17)

Moreover, if $\Theta_1$ and $\Theta_2$ are closed relations in $\mathcal{H}$. Then
\[\text{dom } A_\Theta_1 \subset \text{dom } A_\Theta_2 \iff \text{dom } \Theta_1 \subset \text{dom } \Theta_2.\]  
(5.18)

Proof. The identity (5.17) follows from (5.14). Now consider the equivalence in (5.18).

$(\Rightarrow)$ Let $g \in \text{dom } \Theta_2$. Since $\tilde{A}$ and $S_\infty$ are transversal, it follows from Theorem 3.14 (iv) that there exists $f \in \text{dom } \tilde{A}$ such that $G^*Pf = g$. Hence, $f \in \text{dom } A_\Theta_1 \subset \text{dom } A_\Theta_2$ and now (5.17) shows that $g \in \text{dom } \Theta_2$.

$(\Leftarrow)$ This follows directly from (5.17).

Example 5.6. Consider the unbounded $2 \times 1$ block operator $S$ in Example 4.6. Define
\[\tilde{A} = \left\{ \begin{pmatrix} f \\ h-f \end{pmatrix}, \begin{pmatrix} Ah \\ A_h \end{pmatrix} : h \in \text{dom } A, \ f \in \mathcal{H} \right\}.\]

Then $\tilde{A}$ is clearly a symmetric operator extension of $S$ and it follows from the expression (4.7) that $\text{dom } \tilde{A} = \text{dom } S^\ast$. By Theorem 3.12 this means that $\tilde{A}$ is a selfadjoint extension of $S$ which is transversal to the selfadjoint extension $S_\infty$ of $S$, i.e., $\tilde{A} \perp S_\infty = S^\ast$.

Now one can apply Theorem 5.1 or Corollary 5.2 to construct an ordinary boundary triplet for $S^\ast$. For this purpose take $\mathcal{H} = \mathcal{H}_2 := \text{mul } S^\ast = \{0\} \times \mathcal{H}_1$; let $P_2 = P$ be the orthogonal projection onto $\mathcal{H}_2$, and let $G$ be the identity mapping on $\mathcal{H}_2$, so that $\Pi = \{\mathcal{H}, I_0, I_1\}$ takes the form
\[\begin{pmatrix} I_0f \\ I_1s \end{pmatrix} = \begin{pmatrix} h-f \\ \varphi \end{pmatrix}, \quad \tilde{f} = \begin{pmatrix} f \\ h-f \end{pmatrix}, \begin{pmatrix} Ah \\ A_h+\varphi \end{pmatrix} \in S^\ast, \ h \in \text{dom } A, \ f, \varphi \in \mathcal{H}_1.\]

An application of Theorem 5.3 shows that all closed intermediate extensions of $S$ have an expression as (domain) perturbations of $\tilde{A}$ of the form $A_\Theta = \tilde{A} + \Theta P_2$, where $\Theta$ is a closed relation in $\mathcal{H}_2$. In particular, all closed intermediate operator extensions of $S$ are parameterized by closed operators $\Theta$ in $\mathcal{H}_2$ via the formula
\[A_\Theta = \tilde{A} + \Theta P_2 = \left\{ \begin{pmatrix} f \\ h-f \end{pmatrix}, \begin{pmatrix} Ah \\ A_h + \Theta(h-f) \end{pmatrix} : h \in \text{dom } A, \ h-f \in \text{dom } \Theta \right\}.\]
Note that if $A$ is, in addition, assumed to be bounded, then $\Sigma^*$ admits the decomposition stated in Proposition 4.5 and the previous formula for $A_\Theta$ can be expressed in a block operator matrix form as follows:

$$A_\Theta = \tilde{A} + \Theta P_2 = \begin{pmatrix} A & A \\ A & A + \Theta \end{pmatrix}.$$ 

Finally, notice that as in Corollary 5.2 one obtains a transposed boundary triplet $\Pi'$ for $\Sigma^*$, whose $\Gamma$-field and Weyl function take the following simple forms:

$$\gamma'(\lambda) = (\tilde{A} - \lambda)^{-1} | \mathcal{H}_2, \quad M'(\lambda) = P_2 (\tilde{A} - \lambda)^{-1} | \mathcal{H}_2.$$ 

Only in the case that $A$ is bounded it is possible to rewrite these formulas for the $\Gamma$-field and Weyl function, as well as the corresponding functions in (5.8), by means of the blocks of $\tilde{A}$ or proper Schur complements.

**Remark 5.7.** In [2, Theorem 2.5.8] a formula to express all regular selfadjoint operator extensions of a regular symmetric $O$-operator $S$ (meaning that $S_{11}$ is selfadjoint as in Theorem 5.3) has been established by means of Hilbert space techniques; see Remark 3.9 for this terminology. The parameterization in [2] is given via $(+)$-selfadjoint and $(+)$-bounded operators on a ($(+)$-closed) subspace $\mathcal{H}$ satisfying $\mathcal{H} = \overline{\text{dom} S + \mathcal{H}}$ (cf. [2, Proposition 2.4.2]). The perturbation formula (5.14) is essentially simpler than the formula given in [2, Theorem 2.5.8]; in addition (5.14) parameterizes all intermediate (in particular all selfadjoint) extensions of $S$ in $\mathcal{H}$. Note that the formula (5.14) relies on an explicit construction of an ordinary boundary triplet for $\Sigma^*$ which was established in Theorem 5.1.

### 5.3. Matrix decompositions

Let $S$ be a closed symmetric operator in $\mathcal{H}$, let $P$ be the orthogonal projection from $\mathcal{H}$ onto $\text{mul} S^* = (\overline{\text{dom} S})^\perp$, and write $S$ in a block form with entries $S_{11}$ and $S_{21}$ as in Lemma 3.1. Assume in addition that the operator $S$ is partially bounded. Then by Proposition 4.5 also the adjoint $S^*$ of $S$ admits a block representation as in (4.2), (4.3). This makes it possible to specialize the earlier results in this section in this special case and derive proper block formulas for all intermediate extensions $A_\Theta$ of $S$.

If $S$ is a partially bounded closed symmetric operator, then by Proposition 4.5

$$S^* = \left\{ \begin{pmatrix} f_1 \\ S_{11} f_1 + S_{21}^* f_2 \end{pmatrix} \middle| f_j \in \text{dom} S_{1j}^*, \varphi \in \text{mul} S^*, j = 1, 2 \right\}.$$ 

(5.19)

To apply the results in this section it is now assumed that $S_{11}$ is selfadjoint. It follows from Proposition 4.3 that if $S$ is inner bounded, then it is necessarily also outer bounded. In other words, a partially bounded closed symmetric operator $S$, such that $S_{11}$ is selfadjoint, is always outer bounded. According to Proposition 4.4 this implies that $\text{dom} S^* = \text{dom} S \oplus \text{mul} S^*$, since here $\text{mul} S^{**} = \text{mul} S = \{0\}$. One is now ready to specialize the main results in this section for a partially bounded closed symmetric operator $S$.

Parallel to (5.19) the selfadjoint extension $S_\infty$ can be written as:

$$S_\infty = \left\{ \begin{pmatrix} f_1 \\ S_{11} f_1 \end{pmatrix} \middle| f_1 \in \text{dom} S_{11}, \varphi \in \text{mul} S^* \right\}.$$ 

(5.20)
Let $S_{22} \in \mathcal{B}(\text{mul} \ S^*)$ be selfadjoint. Then the extension $\tilde{A}$ defined by
\[
\tilde{A} = \left\{ \left( \begin{array}{c} f_1 \\ f_2 \end{array} \right), \left( \begin{array}{c} S_{11} f_1 + S_{21}^* f_2 \\ S_{21} f_1 + S_{22} f_2 \end{array} \right) : f_1 \in \text{dom} \ S_{11}, \ f_2 \in \text{mul} \ S^* \right\}
\]
(5.21)
is selfadjoint and it is an operator. Note that $(S_{21})^*$ restricted to dom $S_{11}$ is $S_{21}$. It is obvious from (5.20) and (5.21) that $S_{\infty}$ and $\tilde{A}$ are transversal with respect to $S$. The identity (5.5) involving $S^*$ and $\tilde{A}$ can be written in explicit form:
\[
S^* = \left\{ \left( \begin{array}{c} f_1 \\ f_2 \end{array} \right), \left( \begin{array}{c} S_{11} f_1 + S_{21}^* f_2 \\ S_{21} f_1 + S_{22} f_2 + \varphi \end{array} \right) : f_1 \in \text{dom} \ S_{11}, \ f_2, \varphi \in \text{mul} \ S^* \right\};
\]
(5.22)
cf. (5.19). Thus the ordinary boundary triplet for $S^*$ in (5.6) has the specific form:
\[
\Gamma_0 \hat{f} = f_2, \quad \Gamma_1 \hat{f} = \varphi, \quad \hat{f} \in S^*,
\]
(5.23)
with the identification of $H$ with mul $S^*$. Therefore the intermediate extensions $A_\Theta$ of $S$ are in one-to-one correspondence with the relations $\Theta$ in mul $S^*$ via
\[
A_\Theta = \left\{ \left( \begin{array}{c} f_1 \\ f_2 \end{array} \right), \left( \begin{array}{c} S_{11} f_1 + S_{21}^* f_2 \\ S_{21} f_1 + S_{22} f_2 + \varphi \end{array} \right) : f_1 \in \text{dom} \ S_{11}, \ \{f_2, \varphi\} \in \Theta \right\}.
\]
This last result is sometimes written in a formal way as
\[
A_\Theta = \begin{pmatrix} S_{11} & S_{21}^* \\ S_{21} & S_{22} + \Theta \end{pmatrix}.
\]
(5.24)
Since $\tilde{A}$ and $S_{\infty}$ are transversal with respect to $S$, an application of Corollary 3.13 shows that $f_\lambda \in \mathcal{M}_\lambda(S^*)$ if and only if there exists $\varphi \in \text{mul} \ S^*$ such that $f_\lambda = (\tilde{A} - \lambda)^{-1} \varphi$. In terms of the matrix decomposition in (5.21) one obtains
\[
P(\tilde{A} - \lambda)^{-1} \varphi = [S_{22} - \lambda - S_{21}(S_{11} - \lambda)^{-1} S_{12}]^{-1} \varphi, \ \ \ \varphi \in \text{mul} \ S^*.
\]
Hence the Weyl function $M$ associated with (5.22) is given by
\[
M(\lambda) = \{(S_{22} - \lambda - S_{21}(S_{11} - \lambda)^{-1} S_{12})^{-1} \varphi, -\varphi) : \varphi \in \text{mul} \ S^*\},
\]
(cf. (2.20) and (5.8), which leads to the representations
\[
M(\lambda) = -S_{22} + \lambda + S_{21}(S_{11} - \lambda)^{-1} S_{12}, \quad \lambda \in \mathbb{C} \setminus \mathbb{R},
\]
and
\[
-M(\lambda)^{-1} = [S_{22} - \lambda - S_{21}(S_{11} - \lambda)^{-1} S_{12}]^{-1}, \quad \lambda \in \mathbb{C} \setminus \mathbb{R}.
\]
Thus such functions are characteristic functions of colligations in the sense of [4,5]. The results in this section can be seen as extensions of the matrix representations for selfadjoint operator or relation extensions of symmetric contractions (bounded symmetric operators) in [12,21].

5.4. Generalized Friedrichs extensions

Under the conditions of Theorem 5.1 the identity (5.1) can also be written as $S^* = \tilde{A} \oplus Z$, where $Z = \{0\} \times \text{mul} \ S^*$, so that $Z$ is a closed linear subspace of $\mathfrak{H} \times \mathfrak{H}$. In that case $S = \tilde{A} \cap Z^*$, or in other words
\[
S = \{(f, \tilde{A} f) \in \tilde{A} ; \ f \perp \text{mul} \ S^*\}.
\]
Hence the closed symmetric operator $S$ is a domain restriction of the selfadjoint operator $\tilde{A}$; this kind of domain restriction was first systematically studied in [7].

**Lemma 5.8.** Under the conditions of Theorem 5.1 the selfadjoint extension $S_\infty$ of $S$ is characterized by the formula

$$S_\infty = \{ \hat{f} \in S^*; f \in \overline{\text{dom}} S \}. \quad (5.24)$$

In particular, $S_\infty$ is the only selfadjoint extension of $S$ whose domain is contained in $\overline{\text{dom}} S$.

**Proof.** Since $S_\infty$ is selfadjoint, the description of $S_\infty$ in (5.24) is obtained from Lemma 3.7. Now assume that $H$ is a selfadjoint extension of $S$ such that $\text{dom } H \subset \overline{\text{dom }} S$. Then it follows from Proposition 3.11 that $\text{dom } H \cap \overline{\text{dom }} S = \text{dom } S$ and this implies that $H \subset S_\infty$. Since $H$ and $S_\infty$ are selfadjoint, the equality $H = S_\infty$ follows. \(\square\)

The extension $S_\infty$ is called the generalized Friedrichs extension of $S$. Observe that if $S$ is semibounded then the Friedrichs extension $S_F$ of $S$ is characterized by

$$S_F = \{ \hat{f} \in S^*; f \in \mathfrak{S}_1+ \} \quad (5.25)$$

where $\mathfrak{S}_1+$ stands for the energy space obtained as a completion of $\text{dom } S$ with respect to the graph norm of $S$ on $\text{dom } S$; see [8]. In particular, $S_F$ is the only selfadjoint extension of $S$ whose domain is contained in $\mathfrak{S}_1+$. Since the topology on $\mathfrak{S}_1+$ is in general stronger than the original topology of $\mathfrak{S}_1$ on $\overline{\text{dom }} S$, one has a strict inclusion $\mathfrak{S}_1+ \subset \overline{\text{dom }} S$. Hence, in the case that $S$ is maximally nondensely defined, the characterization of $S_\infty$ in Lemma 5.8 is actually stronger than the usual characterization of the Friedrichs extension $S_F$ in (5.25). For the case of nonsemibounded symmetric relations with defect numbers $(1, 1)$, see also [20, 15]. The generalized Friedrichs extension can be characterized analytically. In fact, the limiting properties (5.9) and (5.13) are characteristic properties.

**Theorem 5.9.** Let $S$ be a (nondensely defined) closed symmetric operator with equal deficiency indices in the Hilbert space $\mathfrak{S}$. Let $\Pi = (\mathcal{H}, \Gamma_0, \Gamma_1)$ be an ordinary boundary triplet for $S^*$ with corresponding Weyl function $M$. Assume that

$$s - \lim_{\lambda \to \infty} \frac{M(\lambda)}{\lambda} \quad (5.26)$$

is boundedly invertible. Then $S_\infty$ is a selfadjoint extension of $S$ and $\ker \Gamma_0 = S_\infty$.

**Proof.** Let $B$ denote the limit in (5.26), then according to [12, Proposition 2.6, Corollary 2.6] the forbidden manifold $\mathcal{F}_\Gamma$ defined in (2.16) is given by

$$\mathcal{F}_\Gamma = \{0\} \times \text{ran } B^{1/2}.$$  

Since $B^{-1} \in \mathcal{B}(\mathcal{H})$, clearly $\mathcal{F}_\Gamma = \mathcal{H}$ and since $\{0\} \times \mathcal{H}$ is selfadjoint, $\mathcal{F}_\Gamma$ as its symmetric extension must coincide with $\{0\} \times \mathcal{H}$, i.e., $S_\infty = \Gamma^{-1}(\mathcal{F}_\Gamma) = \ker \Gamma_0$. \(\square\)

**Corollary 5.10.** Let $S$ be a (nondensely defined) closed symmetric operator with equal deficiency indices in the Hilbert space $\mathfrak{S}$. Let $\Pi = (\mathcal{H}, \Gamma_0, \Gamma_1)$ be an ordinary boundary triplet for $S^*$ with corresponding Weyl function $M$. Assume that $M \in \mathbb{N}_0$. Then $S_\infty$ is a selfadjoint extension of $S$ and $\ker \Gamma_0$ is transversal to $S_\infty$. 

5.5. A connection with graph perturbations

It should be noted that so far \( \tilde{A} \) is a selfadjoint operator and \( Z \) is the subspace of a particular form for which \( \tilde{A} + Z \) is closed. It is possible to consider selfadjoint relations and closed linear subspaces \( Z \) (not necessarily of the above form) for which \( \tilde{A} + Z \) is not closed, in which case more general boundary triplets have to be considered. These more general situations considered from a different point of view, will be treated elsewhere; see also [11].

Finally, it is pointed out that all the results in this paper concerning maximally nondensely defined symmetric relations can be transformed from the domain side to the range side by systematically inverting the graphs of \( S \) and \( S^* \). The analog of \( S_{\infty} \) in (3.16) is a symmetric extension of \( S \) defined by

\[
S_0 = \hat{S} + (\{0\} \times \ker S^*). \tag{5.27}
\]

As an example it is mentioned that \( S \) is selfadjoint if and only if

\[
\text{ran } S = \overline{\text{ran } S} \cap \text{ran } S^*; \tag{5.28}
\]

cf. Proposition 3.10. If in addition \( S \) is nonnegative, then the selfadjoint extension \( S_0 \) in (5.27) coincides with the Kreĭn–von Neumann extension of \( S \); see [8]. If \( S \) is not semibounded and \( S_0 \) is selfadjoint, then it defines a so-called generalized Kreĭn–von Neumann extension of \( S \); it admits similar (geometric and analytic) characterizations proved for \( S_{\infty} \) in this paper; in the case of defect numbers \((1, 1)\) such results for a more general class of nonsemibounded symmetric operators (containing the class of all semibounded symmetric operators \( S \) and its Kreĭn–von Neumann extension \( S_N \) ) have been established in [19] along the lines of [20,18] for the generalized Friedrichs extension. As an example it is mentioned that if (5.28) is satisfied, then \( S_0 \) is characterized by

\[
S_0 = \{ \hat{f} \in S^*; f' \in \overline{\text{ran } S} \},
\]

and, moreover, \( S_0 \) is the generalized Kreĭn–von Neumann extension \( S_N \) of \( S \), and it is the only selfadjoint extension of \( S \), whose range is contained in \( \overline{\text{ran } S} \). In the scalar case this is a special case of [19, Theorem 8.1]. Using the selfadjoint extension \( S_0 \) one can construct a boundary triplet as in Theorem 5.1 for the adjoint \( S^* \).

**Proposition 5.11.** Let \( S_0 \) and \( \tilde{A} \) be transversal selfadjoint extensions of \( S \), let \( G \) be a bounded and boundedly invertible operator from a Hilbert space \( \mathcal{H} \) onto \( \ker S^* \), and let \( P \) be the orthogonal projection from \( \overline{\text{ran } S} \) onto \( \ker S^* \). Then

\[
S^* = \{ \hat{f} = (\tilde{A}^{-1} f' + G \varphi, f'); f' \in \overline{\text{ran } \tilde{A}}, \varphi \in \mathcal{H} \}
\]

and define the operators \( \Gamma_0, \Gamma_1 : S^* \to \mathcal{H} \) by

\[
\Gamma_0 \hat{f} = \varphi, \quad \Gamma_1 \hat{f} = G^* Pf', \quad \hat{f} \in S^*.
\]

Then \( (\mathcal{H}, \Gamma_0, \Gamma_1) \) is an ordinary boundary triplet for \( S^* \). The corresponding \( \Gamma \)-field \( \gamma \) and Weyl function \( M \) are given by

\[
\gamma(\lambda) = (I - \lambda \tilde{A}^{-1})^{-1} G, \quad M(\lambda) = \lambda G^* P (I - \lambda \tilde{A}^{-1})^{-1} G, \quad \lambda \in \mathbb{C} \setminus \mathbb{R}.
\]

There is a characterization of the Weyl function in Proposition 5.11 analogous to Theorem 5.9 and Corollary 5.10; cf. [19] for the scalar case.
An analog of Proposition 5.11, involving more general unitary boundary triplets, can be found in [11, Proposition 7.41]; see also [11, Corollary 7.33]. Even in the nonnegative case the result in Proposition 5.11 is useful in various applications (allowing infinite defect numbers, like in the analysis of elliptic PDEs) when studying selfadjoint extensions of $S$ and their spectral properties; see e.g. [14, Chapters 12 and 13], [28, Section 2]. Note that the conditions in Proposition 5.11 are satisfied if, in particular, the symmetric operator $S$ has a bounded inverse (cf. Section 5.3) or $S$ is for instance semibounded with a positive lower bound.

Further results on range, domain, and general graph perturbations can be found in [6,9,10,15] and in [1,13,14,17,24,25].
