A finite-dimensional Port-Hamiltonian formulation for the dynamics of smooth open channel flows is presented. A numerical scheme based on this formulation is developed for both the linear and nonlinear shallow water equations. The scheme is verified against exact solutions and has the advantage of conservation of mass and energy to the discrete level.

1. Introduction

Port based network modeling of complex lumped parameter physical systems naturally leads to a generalized Hamiltonian formulation of the dynamics. It results in a class of open dynamical systems called "Port-Hamiltonian" systems [1] that are defined using a power conserving interconnection structure called the Dirac structure, the Hamiltonian and dissipative elements. Such a generalized Hamiltonian formulation, called the "Port-Hamiltonian" formulation, has been successfully extended to classes of distributed parameter systems by introducing an infinite-dimensional Dirac structure based on Stokes' theorem. The key aspect of this formulation is that it allows a non-zero energy flow into the spatial domain through its boundary using the Dirac structure, whereas the standard Hamiltonian formulation assumes a zero energy flow through the boundary using the Poisson structure [2]. The Port-Hamiltonian formulation is also effectively used towards control design by using energy shaping methods. The technique relies on constructing a Lyapunov function by using the energy function of the system together with the conserved quantities called Casimirs [3].

The Port-Hamiltonian formulation [4] can be directly applied to model infinite-dimensional fluid dynamical systems containing all its physical conservation laws such as mass, momentum and energy (Hamiltonian). But for practical purposes, it is crucial to approximate these infinite-dimensional systems by a finite-dimensional system such that it is again a Port-Hamiltonian system cf., [5]. The finite-dimensional approximation then conserves most of the physical quantities of its infinite-dimensional counterpart and better captures the physics of the fluid dynamical system. To devise such a numerical scheme based on the finite-dimensional Port-Hamiltonian formulation, we choose a particular example of fluid flows, namely open channel flows. Preliminary works on such formulations are found in [6–8].

The one-dimensional shallow water equations governing open channel flows are the depth averaged approximations of the two-dimensional Navier–Stokes equations. They are a direct consequence of the conservation of mass and momentum and obey the conservation of energy for smooth flows but dissipate energy for non-smooth flows in the form of bores and hydraulic jumps. Many numerical methods exist for these equations such as finite volume methods [9,10] and discontinuous Galerkin finite element methods [11–13]. These numerical methods follow mass and momentum laws of balance, but they may not follow energy balance even in the smooth regions of a flow. Hence, we propose the use of the framework of Port-Hamiltonian systems which follows an energy balance law. Such a framework has implications towards the meteorological and oceanographic studies on geophysical flows, where the numerical schemes that conserve the energy are of great importance (for example following [14–16]).

A new numerical scheme based on a finite-dimensional Port-Hamiltonian formulation for the dynamics of shallow open
channel water flow is the aim of the present paper. A shallow
water channel with topography is first modeled as an infinite-
dimensional Port-Hamiltonian system defined with respect to a
Stokes–Dirac structure. Consequently, the system obeys a power
conserving property, which is naturally equivalent to the energy
balance, expressed in terms of power port variables called flows
and efforts of the fluid dynamical system. For shallow water system, the
flows are the rate of change of water depth and velocity, the
efforts are the discharge and Bernoulli’s function, and the shallow
water equations are a direct consequence of the relation between
flows and efforts captured by the Stokes–Dirac structure.

To model the shallow water canal as a finite-dimensional Port-
Hamiltonian system, we tessellate the spatial domain with finite
elements and approximate the flow variables with cell averages
and effort variables with continuous piecewise linear polynomials.
Such a choice of different approximation spaces for flows and
efforts ensures the compatibility of the flow–effort relation in the
Stokes–Dirac structure which are ordinary differential equations.
Further, the continuity of efforts ensures the conservation of
flow quantities. Consequently, each finite element will be a
finite-dimensional Port-Hamiltonian system satisfying a power
conserving property per finite element. We then enforce a discrete
energy balance in the system by summing up the power conserving
relation of all the finite elements. This effectively gives rise to
an algebraic relation between the efforts and the corresponding
discrete co-energy variables. Thus, the finite-dimensional Port-
Hamiltonian system for a shallow water channel consists of a
system of differential–algebraic equations.

The ordinary differential equations arising from the Port-
Hamiltonian formulation are further discretized in time using an
implicit mid-point time discretization. This time discretization
is a second-order symplectic method and well-suited for a
Hamiltonian system. After time discretization, the ODEs are
transformed into nonlinear algebraic equations which are then
solved by integrating them in pseudo-time using a five stage
Runge–Kutta scheme until a steady state is reached in pseudo-
time [11]. The numerical scheme is verified against several
idealized exact solutions to show that it is first-order accurate and
accurately conserves the energy.

2. Infinite-dimensional Port-Hamiltonian formulation

The Port-Hamiltonian formulation of fluid dynamical sys-
tems [4,17] is an extension of the Hamiltonian formulation in-
corporating non-zero flow through boundaries. Here, we present
the Port-Hamiltonian formulation for open channel or canal water
flows in one dimension.

2.1. Shallow water model

The dynamics of flow through an open channel of length L is
governed by the shallow water equations which in one dimension read as
\[ \partial_t h + \partial_x Q = 0 \quad \text{and} \quad \partial_t u + \partial_x B = 0 \quad \text{on } [0, L] \] (1)
with \( h(t, x) \) the water depth, \( u(t, x) \) the depth averaged velocity, \( Q = hu \) the flow discharge, \( B = u^2/2 + g(h + b) \) the Bernoulli func-
tion and \( b(x) \) the channel bed height measured from a fixed refer-
ence level. The shallow water equations (1) are completed together
with the initial conditions \( h(0, x) = h_0(x) \) and \( u(0, x) = u_0(x) \), and
inflow, outflow, solid wall or periodic boundary conditions at \( x = 0 \)
and \( x = L \). The total hydraulic energy (or Hamiltonian) in the open
channel is
\[ \mathcal{H} := \int_0^L \left( \frac{1}{2} (hu^2 + g(h + b)^2) - gb^2 \right) dx. \] (2)

2.2. Preliminaries of differential geometry

The Port-Hamiltonian formulation is convenient in a differen-
tial geometric framework. For the one-dimensional shallow water
model, we introduce the differential zero and one forms in one di-
mension. By definition, zero forms are functions that can be evalu-
ated at any point on the domain and one forms are objects with
a one-dimensional distribution that cannot be evaluated at a given
point but can be integrated over any one-dimensional path of the
domain. Now, the following operators relate zero and one forms in
one dimension:

1. Exterior derivative. Consider a zero form or function \( f(x) \in \mathbb{R} \) and a one form \( g \) defined as \( g := (df/\partial x)dx \) which in
coordinate-free language is given as \( g = df \), where \( d(\cdot) \) is called
the exterior derivative transforming the zero form to one form.
2. Hodge star operator. Consider a function \( f(x) \in \mathbb{R} \) which by it-
self is a zero form and its one form \( df \). The Hodge star operator
\( * (\cdot) \) in one dimension is defined as \( * f \) \( \text{dx} := f \) and \( * f \) \( \text{dx} \) transforming a zero form to a one form and vice versa.
3. Wedge product. Given a zero form \( f \) and one form \( g \), the wedge
product \( f \wedge g \) is defined as \( f \wedge g := fg \) which is again a one form.

For more general definitions of these operators in \( n \) dimensions, we refer to [18]. Further, we denote the set of zero forms as \( W^0(\Omega) \) and
the set of one forms as \( W^1(\Omega) \).

2.3. Stokes’ Dirac structure

The Port-Hamiltonian formulation is based on the concept of a
Dirac structure which is a geometric object formalizing the power
conserving interconnections [1].

Definition 1. Let \( V \) be a linear space (possibly infinite-dimen-
sional). There exists on \( V \times V^* \) the canonically defined symmetric
bilinear form
\[ \langle \langle f_1, e_1 \rangle \rangle \ducible \langle e_1 | f_1 \rangle \] (3)
with \( f_i \in V \) and \( e_i \in V^* \). \( \langle \langle \cdot , \cdot \rangle \rangle \) denoting the duality product
between \( V \) and its dual subspace \( V^* \). A constant Dirac structure on
\( V \) is a linear subspace \( D \subset V \times V^* \) such that
\[ D = D^\perp, \] (4)
where \( \perp \) denotes the orthogonal complement with respect to the
bilinear form \( \langle \langle \cdot , \cdot \rangle \rangle \).

Let now \( (f, e) \in D \) \( D^\perp \). Then as an immediate consequence of
(3),
\[ 0 = \langle \langle f, e \rangle \rangle \ducible \langle (f | e) \rangle \] (2 | 1).
Thus for all \( (f, e) \in D \) we have \( (e | f) = 0 \), expressing power
conservation with respect to the dual power variables \( f \in V \) and
\( e \in V^* \).

The Stokes–Dirac structure for the shallow water equations is
defined as follows. The spatial domain \( \Omega \subset \mathbb{R} \) is represented by
a one-dimensional manifold with point boundaries. We associate
the energy variables water depth \( h(t, x) \) and velocity \( u(t, x) \), with
the zero forms \( \delta h dx \in W^0(\Omega) \), respectively \( \delta u dx \in W^0(\Omega) \); and
co-energy variables, Bernoulli function \( B \) and discharge \( Q \), with zero
forms as \( (B, Q) \in V^0(\Omega) \) in which
\[ V^1(\Omega) := W^1(\Omega) \times W^1(\Omega) \] (5)
and
\[ V^0(\Omega) := W^0(\Omega) \times W^0(\Omega) \]
where \( W^0(\Omega) \) and \( W^1(\Omega) \) are the space of zero and one forms, re-
spectively. Now, the rate of energy variables, i.e., \( f_h := -\partial_x(h \delta h) \)
and \( f_u := -\partial_x(u \delta u) \), are called flows; and the co-energy variables,
i.e., $e_n := \delta_n \mathcal{H} = B$ and $e_u := \delta_u \mathcal{H} = Q$, are called efforts. Furthermore, the values of the Bernoulli function $B$ and the discharge $Q$ evaluated at the boundaries would constitute the flow and effort variables at the boundary as $f_b = B|_{\partial \Omega} \in W^2(\partial \Omega)$ and $e_b = -Q|_{\partial \Omega} \in W^0(\partial \Omega)$ with $W^0(\partial \Omega)$ the space of zero forms on the boundary.

Consider the linear space of flow variables $\mathcal{F} = V^1(\Omega) \times W^0(\partial \Omega)$ and effort variables $\mathcal{E} = W^0(\Omega) \times W^0(\partial \Omega)$ together with the bilinear form

$$
\left\langle (f_1^b, f_1^e, e_1^b, e_1^e), (f_2^b, f_2^e, e_2^b, e_2^e) \right\rangle = \int_\Omega \left( e_1^b \wedge f_2^b + e_2^b \wedge f_1^b + e_1^e \wedge f_2^e + e_2^e \wedge f_1^e \right) + \int_{\partial \Omega} (e_1^b \wedge f_2^b + e_2^b \wedge f_1^b),
$$

(6)

where $f_b := -(\partial h/\partial t) dx$, $f_e := -(\partial u/\partial t) dx$, $f_b := B|_{\partial \Omega}$, $e_b := B$, $e_u := Q$, $e_b := -Q|_{\partial \Omega}$, $(f_1^b, f_1^e, f_2^b, f_2^e)$ is the flow, $(e_1^b, e_1^e, e_2^b, e_2^e)$ are the efforts and $i = 1$ or 2. It has been shown in [4] that $\mathcal{D} \subset \mathcal{F} \times \mathcal{E}$ defined as

$$
\mathcal{D} := \{(f, e) \in \mathcal{F} \times \mathcal{E} | f_b = de_u, f_e = de_u, f_b = e_u|_{\partial \Omega}, e_b = -e_u|_{\partial \Omega}\}
$$

(7)

is a Stokes–Dirac structure, i.e., $\mathcal{D} = \mathcal{D}^\perp$, with respect to the bilinear form $\langle \cdot, \cdot \rangle$ defined in (6) and thus defines an infinite-dimensional Port–Hamiltonian system. The flow–effort relation in (7) is a direct consequence of the shallow water equations (1).

2.4. Power conserving property and energy balance

The Stokes–Dirac structure is always associated with a power conserving property stated as

$$
\int_\Omega (e_b \wedge f_b + e_u \wedge f_u) + \int_{\partial \Omega} e_b \wedge f_u = 0.
$$

(8)

Substituting the definitions of $f_b, f_u, e_b, e_u$ and $e_b$ in (8), we get

$$
\int_\Omega \left( \delta e_u \wedge f_u + Q \delta u \wedge f_u \right) + \int_{\partial \Omega} B Q = 0.
$$

(9)

Manipulating the first term in (9), the energy balance equation arises as follows

$$
\frac{d \mathcal{E}}{dt} = (B Q)|_{x=1} - (B Q)|_{x=0} = 0.
$$

(10)

3. Finite-dimensional Port–Hamiltonian formulation

A finite-dimensional Port–Hamiltonian formulation is obtained by approximating the flows and efforts such that they are compatible with the Stokes–Dirac structure and satisfy both the power conserving property and the energy balance equation.

3.1. Preliminaries

The flow domain $\Omega := [0, L]$ is tessellated with finite elements $K_k = [x_j, x_{j+1}]$, where $x_j$ and $x_{j+1}$ are the spatial coordinates of its nodes as shown in Fig. 1. On each finite element $K_k$, the one forms corresponding to the water depth and velocity field are approximated as

$$
\tilde{h}(t, x) dx = \tilde{h}_k(t) \psi \quad \text{and} \quad \tilde{u}(t, x) dx = \tilde{u}_k(t) \psi;
$$

(11)

where $\psi := dx$ is the one form with $* \psi = 1$, $h_k(t)$ is the mean water depth and $u_k(t)$ is the mean velocity of the fluid in the finite element $K_k$. Subsequently, the approximation of flows is directly given as

$$
\tilde{f}_b(t, x) = -\partial_t \tilde{h}_k \quad \text{and} \quad \tilde{f}_e(t, x) = -\partial_t \tilde{u}_k \psi.
$$

(12)

As a consequence, the flows are piecewise constant per finite element $K_k$ and discontinuous across the nodes in the domain.

To satisfy the energy balance and mass conservation, the efforts $e_b = B$ and $e_u = Q$ are approximated with linear polynomials per element $K_k$ such that they are continuous across each node. The approximation of efforts in each finite element $K_k$ is therefore given as

$$
\tilde{e}_b(t, x) = \tilde{B}(t, x) \psi(t, x) + \tilde{B}_{j+1}(t) \psi_{j+1}(x) \quad \text{and} \quad \tilde{e}_u(t, x) = \tilde{Q}(t, x) \psi(t, x) + \tilde{Q}_{j+1}(t) \psi_{j+1}(x),
$$

(13)

where $\psi(t, x) := (x_{j+1} - x_j)/(x_{j+1} - x_j)$ is a shape function, $\tilde{B}(t)$ and $\tilde{B}_{j+1}(t)$ are nodal values of the Bernoulli function $B$, and $\tilde{Q}(t)$ and $\tilde{Q}_{j+1}(t)$ are nodal values of the discharge $Q$. Finally, the approximation of boundary variables $f_b$ and $e_b$ on each boundary of the finite element $K_k$ becomes

$$
\tilde{f}_b = \tilde{B}_{j+1}(t) \quad \text{and} \quad \tilde{e}_b = \tilde{Q}_{j+1}.
$$

(14)

3.2. Discretization of the Stokes–Dirac structure

The discrete Port–Hamiltonian formulation starts by substituting the approximations of flows (12) and efforts (13) per finite element $K_k$ in the flow–effort relations of the Stokes–Dirac structure (7) to get

$$
-\partial_t \tilde{h}_k \psi = \tilde{Q}_k \delta \phi_j + \tilde{Q}_{j+1} \delta \phi_{j+1} \quad \text{and} \quad -\partial_t \tilde{u}_k \psi = \tilde{B}_k \delta \phi_j + \tilde{B}_{j+1} \delta \phi_{j+1}.
$$

(15)

The choice of approximation of flows with piecewise constants and efforts with piecewise linear polynomial is made such that the flow–effort relation (15) is non-degenerate. Integrating (15) over the finite element $K_k$, the evolution of flows in terms of efforts per finite element emerge as

$$
\frac{d \tilde{h}_k}{dt} = \frac{1}{\Delta x_k} \left( \tilde{Q}_k - \tilde{Q}_{j+1} \right) \quad \text{and} \quad \frac{d \tilde{u}_k}{dt} = \frac{1}{\Delta x_k} \left( \tilde{B}_k - \tilde{B}_{j+1} \right),
$$

(16)

with $\Delta x_k = x_{j+1} - x_j$. The flow and effort approximations together with the boundary effort variables (14) automatically satisfy the power conserving property per finite element as follows

$$
\int_{x_k} \left( \partial_t \tilde{h}_k \psi + \partial_t \tilde{u}_k \psi \right) + \int_{\partial x_k} \partial_t \tilde{h}_k \psi = \frac{\Delta x_k}{2} \left( \tilde{B}_{j+1} + \tilde{B}_j \right) \frac{d \tilde{u}_k}{dt} - \frac{\Delta x_k}{2} \left( \tilde{Q}_{j+1} + \tilde{Q}_j \right) \frac{d \tilde{h}_k}{dt} - \Delta x_k \left( \tilde{B}_{j+1} \tilde{Q}_j - \tilde{B}_j \tilde{Q}_{j+1} \right) = 0.
$$

(17)

The power conserving property (17) is deduced by using (12)–(14) in (8) and substituting (16). Having obtained a discretization for the Stokes–Dirac structure, it now remains to discretize the Hamiltonian and satisfy energy balance.

The Hamiltonian (or energy) is discretized in each finite element $K_k$ as

$$
\tilde{\mathcal{H}}_k := \int_{x_k} \frac{1}{2} \left( \tilde{h} \tilde{u}^2 + g(\tilde{h} + \tilde{b})^2 - g \tilde{b}^2 \right) dx
$$

$$
= \frac{\Delta x_k}{2} \left( \tilde{h} \tilde{u}_k^2 + g(\tilde{h} + \tilde{b}_k)^2 - g \tilde{b}_k^2 \right);
$$

(18)

where $\tilde{h}(x) := \tilde{h}_k * \psi$ is the approximated bed height. The co-energy variables of the discretized Hamiltonian $\tilde{\mathcal{H}}_k$ are then
defined as
\[ \hat{b}_k := \frac{\partial \hat{E}_k}{\partial h_k} = \left( \frac{1}{2} k e_k^2 + g(h_k + \hat{b}_k) \right) \Delta x_k \quad \text{and} \]
\[ \hat{q}_k := \frac{\partial \hat{E}_k}{\partial u_k} = (h_k u_k) \Delta x_k. \]  
(19)

We now enforce the following energy balance
\[ \sum_{k=1}^{N} \left( \frac{d\hat{E}_k}{dt} + \hat{b}_{k+1} \hat{q}_{k+1} - \hat{b}_k \hat{q}_k \right) = 0 \]  
(20)

by equating the discretized effort variables to the co-energy variables at the interior nodes as
\[ (\hat{b}_j, \hat{q}_j) = \left( \alpha_j \hat{b}_{j-1} + \beta_j \hat{b}_j, \beta_j \hat{q}_{j-1} + \alpha_j \hat{q}_j \right) \]
for \( j = 2, \ldots, N; \)
(21)

and at the boundary nodes as
\[ (\hat{b}_1, \hat{q}_1) = (\hat{b}_{N+1}, \hat{q}_{N+1}) \]  
(22)

with \( \alpha_j + \beta_j = 1, \alpha_j \in \mathbb{R} \) an arbitrary value for any \( j = 2, \ldots, N; \) \( \hat{q}_0 \) and \( \hat{q}_N \) are the given inflow or outflow discharges at \( x = 0 \) and \( x = L \), respectively. For a solid wall boundary, the inflow or outflow discharge is simply set to zero and for periodic boundaries, the boundary efforts are determined by making the two boundary nodes as a single interior node to obtain
\[ \hat{b}_1 = \hat{b}_{N+1} = \alpha_1 \hat{b}_1 + \beta_1 \hat{b}_N \quad \text{and} \]
\[ \hat{q}_1 = \hat{q}_{N+1} = \beta_1 \hat{q}_1 + \alpha_1 \hat{q}_N \]
with \( \alpha_1 + \beta_1 = 1 \) and \( \alpha_1 \) an arbitrary value. The flow–effort relations (16) together with Eqs. (21)–(23) constitute the discretized dynamics of the shallow water equations.

**Remark 1.** To determine the efforts at each node \( j \) using (21), there exist several choices for \( \alpha_j \) or \( \beta_j \) and can be arbitrarily chosen. In all the test cases, we made a simple choice of \( \alpha_j = \beta_j = 1/2 \).

### 3.3. Discrete conservation properties

**Proposition 1.** The Port-Hamiltonian discretization (16), (21) and (23) satisfies the mass and energy balance as follows
\[ \frac{dM}{dt} + \hat{Q}_{N+1} - \hat{Q}_1 = 0 \quad \text{and} \quad \frac{dE}{dt} + \hat{b}_{N+1} \hat{Q}_{N+1} - \hat{b}_1 \hat{Q}_1 = 0 \]  
(24)

where \( M := \sum_{k=1}^{N} \hat{h}_k \Delta x_k \) is the total mass and \( E := \sum_{k=1}^{N} \hat{E}_k \) the total energy.

**Proof.** The proof of mass balance is straightforward; evaluating the time derivative on total mass \( M \) using (16):
\[ \frac{dM}{dt} = \sum_{k=1}^{N} \frac{dh_k}{dt} \Delta x_k = \sum_{k=1}^{N} \left( \hat{q}_k - \hat{q}_{k+1} \right) = -(\hat{Q}_{N+1} - \hat{Q}_1). \]  
(25)

To prove the energy balance, we first evaluate the time derivative on total energy \( E \) using (16) to find
\[ \frac{dE}{dt} = \sum_{k=1}^{N} \frac{d\hat{E}_k}{dt} = \sum_{k=1}^{N} \left( \hat{b}_k \frac{d\hat{h}_k}{dt} + \hat{q}_k \frac{d\hat{u}_k}{dt} \right) \Delta x_k \]
\[ = \sum_{k=1}^{N} \left( \hat{b}_k (\hat{q}_k - \hat{q}_{k+1}) + \hat{q}_k (\hat{b}_k - \hat{b}_{k+1}) \right). \]  
(26)

Rearranging the summation over elements in (26) into a summation over nodes and substituting the efforts determined in (21)–(23), we further find
\[ \frac{dE}{dt} = (\hat{b}_1 \hat{Q}_1 + \hat{q}_1 \hat{Q}_1) - (\hat{b}_{N+1} \hat{Q}_{N+1} + \hat{q}_N \hat{Q}_{N+1}) \]
\[ + \sum_{k=2}^{N} \left( (\hat{b}_k - \hat{b}_{k-1}) \hat{q}_k + (\hat{q}_k - \hat{q}_{k-1}) \hat{b}_k \right) \]
\[ = (\hat{b}_1 \hat{Q}_0 + \hat{q}_1 \hat{Q}_1) - (\hat{b}_N \hat{Q}_N + \hat{q}_N \hat{Q}_{N+1}) \]
\[ + \sum_{k=2}^{N} (\hat{b}_k \hat{Q}_k - \hat{b}_{k-1} \hat{Q}_{k-1}) \]
\[ = (\hat{b}_1 \hat{Q}_0 - \hat{b}_N \hat{Q}_N) = (\hat{b}_1 \hat{Q}_1 - \hat{b}_{N+1} \hat{Q}_{N+1}) \]  
(27)

for a given inflow or outflow boundary conditions. For periodic and solid wall boundaries, we find \( \frac{dE}{dt} = 0 \). \( \square \)

### 3.4. Time discretization

The Port-Hamiltonian discretization (16) and (21)–(23) takes the following form:
\[ \frac{dy}{dt} = F(t, y); \]  
(28)

with \( y = (\hat{h}_1, \hat{u}_1, \ldots, \hat{h}_N, \hat{u}_N)^T \) the unknown flow variables and \( F(t, y) \) the nonlinear right hand side obtained after substituting efforts (21)–(23) and co-energy variables (19) into the RHS of (16).

To integrate the ordinary differential equations (28) in time, we employ an implicit mid-point time discretization to get
\[ L(t^n, y^n, t^{n-1}, y^{n-1}) :\]
\[ = y^n - y^{n-1} - \Delta t F \left( (t^n + t^{n-1})/2, (y^n + y^{n-1})/2 \right) = 0, \]  
(29)

where \( L(t^n, y^n, t^{n-1}, y^{n-1}) \) represents the nonlinear algebraic equations. The implicit mid-point scheme is a second-order symplectic method [19] that is well-suited for Hamiltonian systems and leads to a stable numerical integration in time. The nonlinear equations (29) are solved by augmenting them with pseudo-time derivatives as
\[ \Delta x \cdot \frac{dy}{dt} = -\frac{1}{\Delta t} L(t^n, y^n, t^{n-1}, y^{n-1}) \]  
(30)

with \( \Delta x = (\Delta x_1, \Delta x_2, \ldots, \Delta x_N, \Delta x_N)^T, \Delta t = t^n - t^{n-1} \) the time step and integrating in pseudo-time using a five-stage Runge–Kutta integration scheme [11] until it reaches the steady state in pseudo-time. The five-stage Runge–Kutta scheme is
\[ \left( 1 + \alpha_s \right) y_s = y^0 + \alpha_s \lambda_s (y^{n-1} - L(t^n, y^n, t^{n-1}, y^{n-1})); \]  
(31)

where \( s = 1–5 \) are the Runge–Kutta stages, \( \alpha_s = \{0.0791451, 0.163551, 0.283663, 0.5, 1.0\} \) the Runge–Kutta coefficients, and \( \lambda \) is chosen globally for all \( k = 1, \ldots, N \) the pseudo-time step \( \Delta t = CFL_{\Delta x} \Delta x_k / (\hat{u}_k + \sqrt{gh_k}) \) is chosen locally for each \( k \) and \( CFL_{\Delta t} = 1.0 \) and \( CFL_{\Delta t} = 0.9 \) are the Courant–Friedrichs–Lewy (CFL) numbers for \( \Delta t \) and \( \Delta x \), respectively.
4. Numerical examples

4.1. Burgers’ equation

On a flat bed, the one-dimensional nonlinear shallow water equations take the form of Burgers’ equation \( \partial_t q + \partial_x qq = 0 \), when one of its Riemann invariants is constant as \( u + 2\sqrt{gh} = c \) with \( q(x, t) = c - 3\sqrt{gh} \). An explicit exact solution is then constructed as

\[
h(x, t) = (q(x, t) - c)^2 / (9 g) \quad \text{and} \quad u(x, t) = (c - 2q(x, t)) / 3
\]

with \( q(x, t) = q_0(x') \) and \( x = x' + q_0(x')t \), where \( q(x, 0) = q_0(x) \) is the initial condition. Now for any given initial condition \( q_0(x) \) with \( dq_0/dx < 0 \) somewhere, wave breaking occurs at time \( t_b = -1/\min(dq_0/dx) \).

We choose the initial condition as \( q_0(x) = \sin(\pi x) \) with \( x \in [0, 2] \), \( g = 1 \), \( c = 3 \) and use periodic boundary conditions as given in (23). In our numerical simulation, this smooth initial condition develops into a discontinuity at time \( t_b = 1/\pi \) as in the case of exact solution, see Fig. 2(a). Fig. 2(b) shows that the total discrete energy is conserved in time demonstrating the advantage of the Port-Hamiltonian based numerical scheme. We then compute the numerical errors in \( L^2 \) and \( L^\infty \) norms and the respective orders of accuracy for water depth \( h \) and velocity \( u \) at various instants of time on different mesh sizes, presented in Table 1. The order of accuracy in Table 1 clearly suggests that the numerical scheme is first-order accurate.

4.2. Flow over a bump

Analytical solutions for steady subcritical and supercritical flows over a given parabolic bump are given by Houghton and Kashara [20]. The parabolic bump is taken as

\[
b(x) = \begin{cases} 
1/2 & \text{if } |x - 5| \leq 2, \\
0 & \text{if } |x - 5| > 2
\end{cases}
\]

in a channel from \( x = 0 \) to \( x = 10 \). The steady subcritical solution is obtained by solving the following equation for \( h \) and \( u \) at any \( x \in [0, 10] \),

\[
u h = Q \quad \text{and} \quad u^2/2 + g(h + b) = B
\]

with \( Q = 1 \), \( B = 25.5 \) and \( g = 25 \) such that the Froude number \( F = u/\sqrt{gh} \ll 1 \). We initialize this steady exact solution in our numerical scheme and simulate until a steady state is numerically achieved with inflow \( (h_0, \bar{u}_0) = (\bar{h}_1, 1/\bar{h}_1) \) and outflow \( (h_1, \bar{u}_0) \) = \( (h_0, \bar{u}_n) \) boundary conditions (see Fig. 3). At steady state, the errors and order of accuracy of water depth \( h \) and velocity \( u \) presented in Table 2 again shows that the scheme is first-order accurate.

4.3. Linear harmonic waves

The one-dimensional linear shallow water equations are

\[
\partial_t \eta + \partial_x (Hu) = 0 \quad \text{and} \quad \partial_t u + \partial_x (g \eta) = 0, \quad x \in [0, L]
\]

with \( \eta \) the free surface wave elevation measured from the water surface at rest, \( H \) the water depth at rest and \( \mathcal{H} := \int_0^L (Hu^2 + g\eta^2)/2 dx \) the Hamiltonian. They satisfy a harmonic wave solution,

\[
\eta(x, t) = A \sin(kx + \omega t) \quad \text{and} \quad u(x, t) = -\frac{A\omega k}{\omega} \sin(kx + \omega t)
\]

with \( A \) the amplitude, \( k = 2\pi m/L \) the wavenumber, \( \omega \) the frequency, \( T = 2\pi/\omega \) the time period, \( L \) the length of the domain, \( \omega^2 = k^2 gH \) the dispersion relation, \( m \) any integer, and periodic boundary conditions. The Port-Hamiltonian scheme for linear shallow water equations is easily derived by treating \( h \) as \( \eta \) and defining \( B := gh_0 \) and \( Q := Hu \).

We first initialized the exact solution (36) in the numerical scheme for linear shallow water equations setting \( A = 0.01, L = 1, m = 1, g = 1 \) and \( H = 1 \) and used periodic boundary conditions as given in (23). Linear harmonic waves are then simulated for 50 time periods on grids of size 20, 40, 80 and 160 elements with time step \( \Delta t = T/32, T/64, T/128 \) and \( T/256 \), respectively. Subsequently, we display the plots of free surface perturbation \( \eta(t, x) \) at time \( t = 50T \) and the discrete energy w.r.t. time in Fig. 4. It is clearly observed that the discrete energy is conserved and consequently there is no dissipation in the amplitude of the waves even after 50 time periods. However, the numerical scheme displays a dispersion error in the simulated waves which decreases from coarse to fine grids. Further, to show that the scheme is first-order accurate, we present numerical errors and orders of accuracy in Table 3 at various time instants.

Second, we initialized harmonic waves (36) in the Port-Hamiltonian scheme for nonlinear shallow water equations with \( h(t, x) = H + \eta(t, x) \) and simulated until the smooth initial linear waves break because of the nonlinearity. The effects of nonlinearity are demonstrated by comparing the space–time evolution of harmonic waves using linear and nonlinear schemes in Fig. 5.

4.4. Standing waves

The one-dimensional linear shallow water equations (35) also satisfy a standing wave solution,

\[
\eta(x, t) = A \cos(kx) \cos(\omega t) \quad \text{and} \quad u(x, t) = \left( \frac{Agk}{\omega} \right) \sin(kx) \sin(\omega t)
\]

with solid wall boundary conditions at \( x = 0 \) and \( x = L \). The standing wave solution (37) is initialized in the numerical scheme for linear shallow water equations setting \( A = 0.01, L = 1, m = 1, g = 1 \) and \( H = 1 \), and simulated by applying solid wall boundary conditions as \( (\bar{h}_0, \bar{u}_0) = (\bar{h}_1, -\bar{u}_1) \) and \( (\bar{h}_1, \bar{u}_0) = (\bar{h}_N, -\bar{u}_N) \). Comparison of the numerical solution of the standing wave against its exact solution after one time period and the discrete energy conservation in time is shown in Fig. 6(a) and (b). Numerical errors and the corresponding orders of accuracy tabulated in Table 4 infers that the scheme is first-order accurate.

4.5. Linearized wave maker

A linearized wave maker, applying a kinematic boundary condition \( u(x = 0, t) = Agk \sin(kL) \cos(\omega t) / \omega \) at one end of a wave basin \( x = 0 \) and a solid wall boundary condition at the other end \( x = L \), generates the following gravity wave field

\[
\eta(x, t) = A \cos(k(L - x)) \sin(\omega t) \quad \text{and} \quad u(x, t) = \left( \frac{Agk}{\omega} \right) \sin(k(L - x)) \cos(\omega t)
\]

satisfying the one-dimensional linear shallow water equations (35) with the dispersion relation \( \omega^2 = gk^2 \) and \( k = (2m + 1)\pi/2 \).

We initialize the exact solution (38) in our numerical scheme for the linear shallow water equations setting \( A = 0.01, L = 1, m = 2, g = 1 \) and \( H = 1 \) and numerically generate the waves by applying the time varying boundary conditions \( (\bar{h}_0, \bar{u}_0) = (0, Agk \sin(kL) \cos(\omega t) / \omega) \) at the wave maker and solid

Fig. 5. Numerical solution of harmonic waves using Port-Hamiltonian numerical scheme for linear (left) and nonlinear (right) shallow water equations on a grid of 80 elements. Exact and numerical solutions are marked as “∗ − ∗” and “o − o”, respectively. Observe on the left, numerical harmonic waves are in good agreement with the exact solution and on the right side, the wave steepens due to nonlinearity.

5. Conclusions

A finite-dimensional Port-Hamiltonian formulation for the nonlinear shallow water equations defined with respect to a Stokes–Dirac structure is presented. The key advantage of this formulation is that the physical properties of the infinite-dimensional model, such as mass and energy conservation, are

Fig. 7. Numerical solution of harmonic waves generated by a linear wave maker using Port-Hamiltonian numerical scheme for linear (left) and nonlinear (right) shallow water equations on a grid of 80 elements. Exact and numerical solutions are marked as “- - -” and “- • -”, respectively. Observe that the numerically generated wave profiles are in good agreement with the exact solutions.
directly translated into the finite-dimensional model. Thus, the finite-dimensional model of shallow water equations preserves discrete mass and energy in time. It is useful to extend the present formulation to the shallow water equations in two dimensions and capture its important physical properties such as the conservation of potential vorticity and enstrophy that are of great interest in oceanographic and meteorological studies.

The Port-Hamiltonian based numerical scheme for the shallow water equations is developed and verified against exact solutions. It makes use of a symplectic time integration scheme stemming from implicit mid-point time discretization. This gave the advantage of preserving the discrete energy in time and resulted in a stable numerical scheme that is first-order accurate for the leading order approximation of flow variables in space. However, the scheme is valid only for smooth open channel flows as the underlying governing equations are in the primitive form. For non-smooth flows, the conservative form of shallow water equations is required as they satisfy the jump conditions at the bores or hydraulic jumps with the correct energy dissipating conditions. This was beyond the scope of our present work.
