Chapter 1

Recent advances in the catalytic asymmetric synthesis of \( \beta \)-amino acids

This chapter describes the progress in catalytic asymmetric synthesis of \( \beta \)-amino acids covering the literature since 2002. The chapter is structured into three parts: 1) transition metal catalysis, 2) organocatalysis and 3) biocatalysis. The respective paragraphs are subdivided into the most important synthetic methods, such as hydrogenation, the Mannich reaction and conjugate additions.
1.1 Introduction

β-Amino acids are key structural elements of peptides, peptidomimetics and other natural products. In addition, they are essential chiral building blocks for the synthesis of pharmaceuticals. Furthermore, β-amino acids are precursors for β-lactams which are potentially biologically active and of interest as antibiotics. Some β-amino acids show interesting pharmacological properties by themselves, but most are valuable intermediates in routes to novel molecules with biological and pharmacological activity. β-Peptides have secondary structures comparable to their α-amino acid analogues. β-Amino acids are subdivided into β2-, β3- and β2,3-amino acids depending on the position of the side chain at the 3-aminocarboxylic acid core (figure 1.1). Additionally, cyclic amino acids have the amino and ester moiety as substituents or the amino group is integrated into the heterocyclic structure, such as β-proline.

![Figure 1.1. General structure of β-amino acids.](image)

Until recently, methods for the synthesis of β-amino acids relied predominantly on classical resolution, stoichiometric use of chiral auxiliaries or homologation of α-amino acids. Much of the work related to asymmetric synthesis of β-amino acids before 2002 has been reviewed by Sibi, and summarized in the book Enantioselective synthesis of β-amino acids edited by Juaristi and Soloshonok in 2005. Seebach and coworkers described recently the preparation of β2-amino acids for β-peptide synthesis. Therefore, this chapter is focussed on catalytic asymmetric synthesis using transition metals, organocatalyst and biocatalysts covering the literature since 2002. Methods using chiral auxiliaries and kinetic resolution (biocatalysis) are not discussed herein.

1.2 Transition metal catalysis

Various transition metals and chiral ligands have been used for the synthesis of β-amino acids. The most frequently employed methods are catalytic asymmetric hydrogenation, conjugate addition of carbon- and nitrogen nucleophiles to α,β-unsaturated systems and the Mannich reaction.

1.2.1 Hydrogenation

The enantioselective hydrogenation of β-substituted-β-(amino)acrylates has been extensively discussed (scheme 1.01). Therefore, this part concerning catalytic asymmetric hydrogenation is kept relatively brief, focussing on key contributions since 2002. The geometrical isomers of the β-(amino)-acrylates show different reactivity and
selectivity in metal-catalyzed hydrogenations: (E)-isomers generally lead to higher enantioselectivities, and (Z)-isomers frequently react faster, although the enantioselectivity is sometimes lower.

![Scheme 1.01. Rhodium catalyzed hydrogenation of (E)- and (Z)- \( \beta \)-dehydroamino acid derivatives.](image)

The first example of an asymmetric hydrogenation of \( N \)-acyl-\( \beta \)-(amino)acrylates was published in 1991 by Noyori and coworkers using Ru(O\( \text{2CCH}_3 \))\(_2\) and (\( R \))-Binap, providing >90% ee.\(^{11} \) Their advances in Ru- and Rh-catalyzed homogeneous hydrogenations have since then become a standard procedure for the synthesis of \( \beta \)-amino acids, using a variety of chiral bidentate and monodentate phosphorous ligands.\(^{10-12} \) An important breakthrough by Hsiao and coworkers was the use of chiral ferrocenylphosphine ligand 1.003 in the hydrogenation of (Z)-enamine esters with an unprotected amine group in trifluoroethanol (TFE) as solvent to yield the corresponding amino esters with excellent ee (up to 97%) (scheme 1.02).\(^{13} \) This represents the first example of a high yielding enantioselective hydrogenation of unprotected \( \beta \)-enamine esters without the use of a directing protecting group.

![Scheme 1.02. Rhodium-ferrocenylphosphine catalyzed hydrogenation of unprotected enamines.](image)

TangPhos 1.006 was employed in the synthesis of \( N \)-aryl-\( \beta \)-amino acids by Zhang and coworkers.\(^{14} \) Starting from (Z)-enamines, the products were obtained with up to 96% ee using Rh-1.006 in TFE (scheme 1.03).

![Scheme 1.03. Rhodium-Tangphos catalyzed hydrogenation of (Z)-enamines.](image)
The Rh-catalyzed enantioselective hydrogenation of \((E)\)- and \((Z)\)-\(\beta\)-acylamino acrylates using BDPMI \(1.009\) gave under mild conditions ee’s of 97% and 92%, respectively (scheme 1.04).

\]

Scheme 1.07. Rhodium-bisphosphine catalyzed hydrogenation of (E)-enamines using bisphosphine ligands.

Using (S)-C3-TunaPhos 1.021 as ligand in a ruthenium catalyzed reaction, Zhang and coworkers synthesized cispentacin with excellent ee (up to 99%) (scheme 1.08).\textsuperscript{20} In the same reaction, TangPhos 1.006 and Me-DuPhos 1.015 gave cispentacin derivative 1.020 with significantly lower enantiomeric excess.

Monodentate ligands such as phosphites and other phosphorous ligands can also result in high enantioselectivities in Rh-catalyzed hydrogenations.\textsuperscript{21} Phosphite-based ligands with a carbohydrate moiety have been applied in the Rh-catalyzed homogeneous hydrogenation. β\textsuperscript{2}-Amino acid derivatives are formed with up to 99% ee when phthalimide protected acrylates are hydrogenated using carbohydrate-phosphite 1.024 (scheme 1.09).\textsuperscript{22}

\end{align*}
\]

Scheme 1.10. Rh-phosphite catalyzed hydrogenation of acrylates.

The use of monodentate phosphoramidite ligands in the rhodium-catalyzed hydrogenation of (E)/(Z)-β-dehydroamino acids has been described by Feringa, Minnaard, de Vries and coworkers (scheme 1.11).10,24 Ligand 1.031 leads to β-amino acid precursors with excellent enantioselectivities for (E)-substrates, while a slight modification in the amine backbone of the ligand leads to very good enantioselectivities in the hydrogenation of (Z)-substrates.

\[
\text{R}_1\text{NHAc} + \text{Rh(COD)BF}_4 (1.0 \text{ mol%}) + 1.031 \text{ or } 1.032 (2.0 \text{ mol%}) \rightarrow \text{R}_1\text{NHAc} + \text{CO}_2\text{R}
\]

\end{align*}
\]

Scheme 1.11. Rh-phosphoramidite catalyzed hydrogenation of (E)- and (Z)-enamines.

The mixed ligand approach has been employed in the hydrogenation catalyzed by rhodium-phosphoramidite complexes in order to further enhance the enantioselectivity (scheme 1.12).10,24,25 Hereby, three different catalysts are in equilibrium with one another, namely the two homo-complexes Rh-L\text{A}L\text{A} and Rh-L\text{B}L\text{B} and the hetero combination L\text{A}L\text{B}. Enhanced enantioselectivities are observed when Rh-L\text{A}L\text{B} is more active and more selective than each of the hetero combinations.26 Chiral phosphoramidite 1.035 in combination with achiral tris-o-tolyl-phosphine was used for

\]

Scheme 1.13. Ir-phosphoramidite catalyzed asymmetric hydrogenation.

As demonstrated previously\(^{10}\) and discussed in the preceding paragraphs, the hydrogenation of $\beta$-dehydroamino acids represents an important tool for the synthesis of $\beta$-amino acids. High enantioselectivities have been achieved starting from both (\(E\))- or (\(Z\))-enamines.

1.2.2 Mannich reaction

The Mannich reaction is an important C-C-bond forming reaction involving the addition of metal enolates of carbonyl compounds to imines.\(^{28,29}\) The versatility and potential of the Mannich reaction to form $\beta$-amino carbonyl compounds has made it an important method to synthesize $\beta$-amino acids. Recently, several successful examples of catalytic asymmetric Mannich reactions have been developed.\(^{28}\) Earlier work relied on the stoichiometric use of chiral auxiliaries.

Sodeoka and coworkers published in 2005 the addition of $\beta$-ketoesters to various imines catalyzed by a chiral cationic palladium complex (scheme 1.14).\(^{30}\) The catalysts derived from SegPhos \(1.040\) and Binap \(1.041\) were investigated. Two stereogenic centers are created in this reaction; high diastereomeric ratios (up to 95:5) are obtained, along with
excellent ee’s (up to 99%). Next to the p-methoxyphenyl (PMP) protecting group, Boc and tosyl protecting groups for the imine could be employed. Moreover, the three component coupling, using p-anisidine, α-aldehyde esters and cyclic β-keto esters, gave the product with up to 99% ee and a dr of 95:5.

Diethylzinc and bridged-Binol 1.046 form in situ the active catalyst that has been used by Shibasaki and coworkers in the anti-selective Mannich reaction of hydroxyketone 1.043 with N-Dpp imines 1.042 (scheme 1.15).31 The anti-Mannich products 1.044 are obtained with high diastereomeric ratio and high enantiomeric excess from imines with aromatic, heteroaromatic and cyclopropyl-groups. The β-amino ketone was transformed into the corresponding β-amino ester by Baeyer-Villiger oxidation.
Shibasaki and coworkers also used the bridged-binol complex 1.046 with In(III) that catalyzes the addition of \(N\)-(2-hydroxyacetyl)pyrrole 1.048 to various imines 1.047 (scheme 1.16). The diastereomeric ratio depends on the imine used. In general, the \textit{syn}-adducts were obtained with good \(dr\) and high \(ee\) with alkenyl and phenyl substituted imines and the \textit{anti}-adducts with a moderate diastereomeric ratio and high enantiomeric excess using \(-\text{o-aryl}\)-substituted imines. The \(N\)-acyl-pyrrole group was transformed under basic conditions to the corresponding ethylester to give \textit{syn-\(\alpha\)}-hydroxy-\(\beta\)-amino esters 1.050.
Moreover, La(III)-iPr-pybox 1.055 was studied by Shibasaki and coworkers in the direct asymmetric Mannich reaction of trichloromethyl ketones 1.052 and pyridyl- or thienylsulfonyl-protected imines 1.051 (scheme 1.17).\textsuperscript{33} The \textit{syn}-isomers were preferentially formed with high ee (>99%) using the thienylsulfonyl protecting group. Aliphatic, aromatic and heteroaromatic imines were employed as substrates. The product 1.053 was transformed into the $\text{N}$-Boc-protected $\beta^2$-amino ester 1.054 using esterification under basic conditions and subsequent Boc-protection of the amino group.

The same group investigated the homonuclear Ni$_2$-Schiff base complex 1.060 for the synthesis of tetrasubstituted \textit{anti}-$\alpha,\beta$-diamino acids (scheme 1.18).\textsuperscript{34} Boc-protected aromatic and aliphatic imines 1.056 gave with nitro-acetate 1.057 the corresponding adducts 1.058 with high $dr$’s (up to 97:3) and high ee’s (up to 99%). Using NaBH$_4$/NiCl$_2$, the nitro group was reduced to give the $\alpha,\beta$-diamino ester 1.059.
The Jørgensen group developed Cu-phosphino-oxazoline complex \textbf{1.064} that catalyzes the asymmetric Mannich reaction of glycine derivatives \textbf{1.061} and imines \textbf{1.062} (scheme 1.19).\textsuperscript{35} Preferentially, \textit{syn}-adducts were formed with high diastereomeric- and enantiomeric excess using aromatic and aliphatic imines as substrates. The highest selectivities in the synthesis of the \textit{\alpha,\beta}-diamino ester derivatives \textbf{1.063} were obtained with CuClO\textsubscript{4} as metal salt in the presence of molecular sieves.

Furthermore, the group of Kobayashi investigated copper salts in the direct three-component Mannich reaction producing protected \textit{\alpha,\beta}-diamino esters using Me-Duphos \textbf{1.015} as ligand (scheme 1.20).\textsuperscript{36} Simple aromatic and enolizable aliphatic aldehydes \textbf{1.065}, secondary amines \textbf{1.066} and glycine derivatives \textbf{1.061} are used as starting materials in this reaction. (\textit{R,R})-Me-Duphos leads to a 1:1 mixture of \textit{syn/anti} diastereomers with 75\% and 77\% \textit{ee}, respectively.

In the asymmetric Mannich type reaction of \(N\)-acylimino esters 1.068 and silyl enol ethers 1.069, Kobayashi and coworkers have studied copper-diamine complexes 1.071 as catalysts (scheme 1.21).\(^{37}\) The Mannich adducts were obtained in high yields with high ee’s. In the reactions of \(\alpha\)-substituted silyl enol ethers (\(X = \alpha\)-methyl or benzyloxy), the desired syn-adducts were obtained again with high enantio- and diastereomeric excess. When CuClO\(_4\)-(\(S\))-xylyl-Binap was used as a catalyst system in the addition of tert-butyllithio-trimethylsiloxy-propene and \(N\)-benzoylimino esters, the syn-adduct was obtained with high diastereo- and enantioselectivity starting from (\(Z\))-enolates, and the anti-adduct starting from (\(E\))-enolates.\(^{37}\)

Scheme 1.21. Cu-catalyzed addition of silylenol ethers to \(N\)-acylimino esters.

The same group studied also the iron(II)-complex of 3,3’-I2Binol complex 1.075 in the asymmetric Mannich-reaction (scheme 1.22).\(^{38}\) The reaction of \(\alpha\)-dimethyl silyl enoethers 1.073 with protected aromatic imines 1.072 provided the adducts 1.074 with good ee’s (up to 84%).
Chapter 1: Recent advances in the catalytic asymmetric synthesis of β-amino acids

Kobayashi and coworkers also used chiral catalysts based on Binol and Zr(IV) in the Mannich reaction.\textsuperscript{39} In the synthesis of α-methyl-β-amino acid derivatives by condensation of (E)-silyl ketene acetals 1.078 with aldimines, the chiral zirconium catalyst 1.079 prepared from Zr(O\textsubscript{t}Bu)\textsubscript{4}, 6,6′-dipentafluoroethyl-1,1′-bi-2-naphthol and N-methylimidazole (NMI) was used (scheme 1.23a).\textsuperscript{39a,40} Aromatic and aliphatic imines were employed as substrates, giving the anti-adducts in good yields with high diastereomeric and enantiomeric excess. The products were transformed into α-methyl-β-amino esters by transesterification of the Mannich adduct followed by deprotection of the amino group via a sequence involving methylation of the phenolic OH-group and deprotection using AgNO\textsubscript{3} in the presence of excess (NH\textsubscript{4})\textsubscript{2}S\textsubscript{2}O\textsubscript{8}. This chiral air-stable zirconium catalyst as a mixture with powdered molecular sieves (ZrMS-1.079) could be stored for 53 d under air without loss of activity, and be recycled for a second catalytic cycle.\textsuperscript{39b} The enantioselectivity was enhanced in the presence of molecular sieves; from the (E)-silyl enol ether 1.078 the syn-adduct is formed, while from the (Z)-silyl enol ether the anti-adduct is obtained, both in good yield with high dr and ee (scheme 1.23a).
Further optimization studies identified bridged-bis-Binol 1.080 and ligand 1.081 as the best ligands, but the enantioselectivity could not be further increased (scheme 1.23b). When they were applied in the Zr-catalyzed reactions, the Mannich adducts 1.076 of various aromatic imines were provided in high yield with up to 94% ee. In conclusion, chiral Lewis acids are useful catalysts for the asymmetric Mannich reaction to produce \(\beta\)-amino acid derivatives. Many combinations of metals, such as Cu(I), Cu(II), Fe(II), In(III), La(III), Ni(II), Zr(IV), and various ligands as source of the chiral information have been developed. The Mannich reactions discussed here (see also paragraph 1.3.1 for organocatalysts) represent highly stereoselective and frequently atom-economic methods for the synthesis of chiral \(\beta^2\) and \(\beta^{2,3}\)-amino acid derivatives and diamino acids.

1.2.3 Conjugate addition

The catalytic asymmetric conjugate addition when applied in the synthesis of \(\beta\)-amino acids can be achieved in two ways: 1) addition of carbon nucleophiles, such as organometallic reagents, cyanide or Michael donors, and 2) nitrogen nucleophiles, such as aromatic amines, hydroxylamines, and carbamates. 41

1.2.3.1 Carbon nucleophiles

The conjugate addition of carbon nucleophiles to \(\alpha,\beta\)-unsaturated compounds is an important C-C-bond formation reaction. This transformation shows a broad scope due to the large variety of acceptors (\(\alpha,\beta\)-unsaturated aldehydes, esters, ketones, phosphonates, sulfones, thioesters and nitroalkenes) and nucleophiles (organometallic reagents, Michael donors, other carbanions). 43 In particular, nitro-olefins are versatile acceptors for the synthesis of \(\beta\)-amino acids.

Organozinc species have been successfully applied in copper-catalyzed 1,4-additions to form chiral \(\beta\)-substituted esters and enones. The use of phosphoramidite ligands derived from 2,2’-binaphthol resulted in a breakthrough providing catalysts that show high activity and excellent chemo- and regio-selectivity. The groups of Sewald44, Wendisch45 and Feringa46 have successfully used 3-nitropropenoates or acetal substituted nitropropenoates as acceptors and bisalkyl zinc reagents as nucleophiles to synthesize \(\beta\)-amino acid precursors. 47 In 2002, Sewald and coworkers reported the addition of diethyl zinc to methyl-3-nitropropenoate 1.082 catalyzed by a Cu-phosphoramidite 1.085 complex (scheme 1.24a). 44 Adduct 1.083 was obtained with 92% ee, and the nitro group could easily be reduced by catalytic transfer hydrogenation using ammonium formate. The amino group was N-Boc protected and subsequent ester hydrolysis gave N-Boc-\(\beta^2\)-amino acid 1.084.
Chapter 1: Recent advances in the catalytic asymmetric synthesis of β-amino acids

Around the same time, Wendisch and coworkers reported the addition of bisalkyl zinc reagents to nitropropanoate 1.082 using phosphoramidite 1.087 as chiral ligand (scheme 1.24b). In MeO\textsubscript{t}Bu as solvent, the adduct was obtained in high yield with up to 85% ee using diethyl zinc as nucleophile. Furthermore, phosphoramidite 1.087 was employed in the Michael addition of trimethyl aluminium to nitroolefin 1.082 (scheme 1.25). At low temperature in ether as solvent, enantioselectivities up to 92% were obtained.

Excellent enantioselectivities (up to 98%) were obtained by Feringa and coworkers in the addition of dialkyl zinc reagents to acetal-substituted nitropropenoates (scheme 1.26). The adducts of Et\textsubscript{2}Zn, Me\textsubscript{2}Zn and Bu\textsubscript{2}Zn were obtained with high yields and high ee’s. The corresponding N-Boc protected β\textsuperscript{2}-amino acids were formed via Raney-Nickel reduction of the nitroalkane, followed by Boc-protection of the amine group and oxidation of the acetal under acidic conditions to the corresponding carboxylic acid 1.091.
Recently, carboxylic acid derivatives that have all carbon quaternary stereocenters have been synthesized through copper catalyzed asymmetric conjugate addition of dialkyl zinc reagents to 2-aryl acrylates 1.092 (scheme 1.27).\textsuperscript{49} Fillion and coworkers tested phosphoramidite ligand 1.087 to obtain the adducts in high yields with up to 94\% ee. \beta-Amino acid derivative 1.094 was synthesized through deprotection of adduct 1.093, followed by a Curtius rearrangement of the succinic acid derivative.

Trost and coworkers reported a heterodinuclear asymmetric chiral catalyst 1.099 comprising Mg and Zn and a chiral proline-derived ligand for the addition of \(\alpha\)-hydroxyketones to \(\beta\)-substituted nitroalkenes 1.096 (scheme 1.28).\textsuperscript{50} As substrates aromatic, aliphatic and alkynyl-\(\beta\)-substituted nitroalkenes and phenyl- and furyl-hydroxyketones were employed leading to up to 92\% ee and good diastereoselectivities in favor of the anti-products. Reduction of the nitro group and of the ketone to the corresponding amino-diol, followed by Boc-protection and oxidative cleavage of the diol gave the corresponding \(\beta\)-amino acid 1.098.
Chapter 1: Recent advances in the catalytic asymmetric synthesis of \( \beta \)-amino acids

An enantioselective rhodium catalyzed enolate protonation method for the synthesis of \( \beta \)-amino acids was reported by Sibi and coworkers (scheme 1.29). A complex prepared from Rh(acac)(ethylene)\(_2\) and difluoroPhos catalyzed the conjugate addition of aryl boronic acids to \( \beta \)-acylates. Enantioselective protonation of the oxa-\( \pi \)-allyl-rhodium intermediate resulted in good yields with high enantioselectivities (\( ee \) up to 91%) using one equivalent of phthalimide as proton source.

Jacobsen and coworkers reported the enantioselective conjugate addition of cyanide to \( \alpha,\beta \)-unsaturated imides using aluminium salen catalyst (scheme 1.30). The adducts were obtained with up to 98% \( ee \) in high yields and were transformed into \( \beta \)-amino acids by basic hydrolysis of the imide to the corresponding carboxylic acid, followed by Curtius rearrangement with diphenylphosphoryl azide (dppa) and hydrolysis of the nitrile group to the corresponding carboxylic acid under acidic conditions.
The addition of dialkyl zinc and aluminium reagents as well as α-ketoesters to α,β-unsaturated nitro alkenes represent valuable methods to synthesize β-aminonitro acid precursors with high enantioselectivities. Some methods can also be applied in the construction of all carbon quaternary stereocenters. Moreover, cyanide could be used in the addition to α,β-unsaturated imides to yield β-amino acids after three subsequent transformations. Furthermore, a rhodium-catalyzed addition of aryl boronic acids followed by enantioselective protonation gave optically active β-amino acid derivatives.

1.2.3.2 Nitrogen nucleophiles

Conjugate addition of amine nucleophiles to α,β-unsaturated carboxylic acid derivatives is one of the most attractive and atom-economic methods for the synthesis of β-amino acids. In the past, mostly chiral Michael acceptors or chiral amines have been used for diastereoselective conjugate additions. Recently, several groups have reported significant progress towards catalytic asymmetric versions of conjugate additions of amines.

For the enantioselective addition of primary aromatic amines to α,β-unsaturated oxazolidinones 1.107, Hii and coworkers investigated cationic palladium-Binap complex 1.109 (scheme 1.31a). Using aniline and crotonyl-oxazolidinone, the adducts were obtained in good yield with ee’s up to 93%. However, when the substrate incorporated longer aliphatic chains than methyl, i.e. ethyl and propyl, a significantly lower ee was observed.
A similar cationic palladium complex 1.112 was tested in the addition of aromatic amines to N-alkenoylcarbamates (scheme 1.31b).\textsuperscript{55} High enantioselectivities and high yields were achieved using various aliphatic substrates (R = Me, Et, Pr). The products were converted to N-aryl-\(\beta\)-amino acids by hydrolysis of the imide under basic conditions. Moreover, the authors compared isolated and \textit{in situ} formed complexes, and the obtained results being comparable.\textsuperscript{56}

Also, Sodeoka and coworkers employed a cationic catalyst derived from Binap, which was used in its dimeric form 1.114 (scheme 1.32).\textsuperscript{57} Aromatic amines substituted with electron donating or withdrawing groups gave the adducts in high yield with high \(ee\)'s (up to 97\%).
The Jørgensen group investigated Ni(II)-bisoxazoline catalyst 1.116 in the addition of secondary aromatic amines to oxazolidinones 1.107 (scheme 1.33). Various β-substituted aliphatic α,β-unsaturated oxazolidinones were used resulting in the amine adducts 1.115 in good yields and ee’s up to 96%.

Scheme 1.33. Ni-catalyzed addition of aromatic amines to α,β-unsaturated imides.

Iodo(binaphtholate)samarium complex 1.117 has been used in the addition of aromatic amines to N-alkenoyloxazolidinones (scheme 1.34). Substrates with aromatic substituents and p-anisidine as nucleophile resulted in the adducts 1.113 with ee’s (up to 76%), but only low ee’s were reached using oxazolidinones with aliphatic substituents.

Scheme 1.34. Sm-catalyzed addition of aromatic amines to oxazolidinones.

Besides aromatic amines, hydroxylamines have been widely used in catalytic enantioselective conjugate additions. Sibi and coworkers used Mg-bisoxazoline complex 1.120 in the addition of O-benzylhydroxyl amine to oxazolidinones 1.118 (scheme 1.35a). However, only moderate enantioselectivities (up to 81%) were observed with high catalyst loadings of 30 mol%. The stereophysical outcome of this transformation depends on the temperature, i.e. at 0°C or room temperature the configuration reversed compared to the reaction at –60°C, and the ee was in general lower. β2-Amino esters were synthesized upon hydrolysis of the imide to the corresponding methyl ester.
Chapter 1: Recent advances in the catalytic asymmetric synthesis of $\beta$-amino acids

The addition of $N$-benzylhydroxyl amines to $\alpha,\beta$-disubstituted imide 1.121 catalyzed by bisoxazoline ligand 1.120 and Mg(NTf$_2$)$_2$ lead to the formation of isoxazolidinones 1.122 (scheme 1.35b). The $\textit{anti}$-adducts were obtained in high yields with high diastereo- and enantiomeric excess. Upon hydrogenolysis, the $\beta^{2,3}$-amino esters 1.123 were obtained in high yield.

Shibasaki and coworkers studied heterobimetallic catalysts 1.127 and 1.128 in the enantioselective aza-Michael addition of methoxylamine (scheme 1.36). Heterobimetallic catalysts are often combinations of rare earth metals and alkali metals. For instance, they show a cooperative effect of the two mutual centers, i.e. a Lewis acid to activate the electrophiles and a Brønsted base to deprotonate the nucleophiles to form activated metal nucleophiles. Herein, Lewis acid-Lewis acid cooperative catalysis is employed using Li as alkali metal and Y or Dy as rare earth metal. Both Li and the rare earth metal are activating the $\alpha,\beta$-unsaturated compound and control the orientation of the amine. Drierite (CaSO$_4$) was added as desiccant because traces of water decreased the rate of the reaction. Molecular sieves could not be used due to the absorption of methoxylamine. Mechanistic studies revealed that the ionic radius of the rare earth metals plays a major role. The enantiomeric excess of the adducts reaches up to 96%. The $N$-acylpyrrole group of 1.125 was easily transformed into the corresponding methyl ester. After hydrogenolysis of the hydroxylamine, $\beta^3$-amino esters 1.126 were obtained.

Sc(OTf)₃/i-Pr-pybox complex 1.131 has been used for the enantioselective addition of O-benzylhydroxylamine to α,β-unsaturated 3-acyloxazolidinones (scheme 1.37).⁶⁴ The adduct 1.129 was obtained in good yield with high ee's (up to 91%); using crotonoyloxazolidinone as substrate, N-benzyloxyamide 1.130 was also formed in 23% yield with 81% ee next to 77% of 1.129.

\[ \text{RE (rare earth metal)} = \text{Dy M=Li} \]

Scheme 1.37. Sc-catalyzed addition of benzylhydroxylamine to oxazolidinones.

Palomo and coworkers investigated Cu(II)-bisoxazoline 1.135 for the addition of carbamates to α-hydroxy-enones (scheme 1.38).⁶⁵ Benzyl-, butyl, methyl and ethyl carbamate were successfully added to aliphatic and aromatic α-hydroxy-enones 1.132 providing the adducts in high yield with high ee. The α-hydroxy ketone was oxidatively cleaved using NaIO₄ to yield the corresponding β⁺-amino acid 1.134.
Chapter 1: Recent advances in the catalytic asymmetric synthesis of β-amino acids

Aromatic amines, hydroxylamines and carbamates were successfully added to α,β-unsaturated carbonyl compounds using Lewis acids as catalyst. However, all methods described here and in the older literature\(^4\) use activated carbonyl compounds as acceptors. Simple carboxylic esters were not yet successfully employed to give β-amino esters via highly enantioselective conjugate additions.

### 1.2.4 Miscellaneous

Several reactions to form β-amino acids in an enantioselective manner which do not fit in the above described categories are discussed herein.

In 2007, an asymmetric Friedel-Crafts alkylation of 2-methoxyfuran with nitroalkenes was described (scheme 1.39).\(^6\) A diphenylamine-tethered bisoxazoline 1.140-Zn(II) complex was used to add methoxyfuran 1.136 to aromatic nitroolefins 1.137 with ee\(^\prime\)s up to 96%. The furan-ring was subsequently oxidatively cleaved and the intermediate treated with diazomethane to form the β-nitro ester 1.138 which could be further transformed into the corresponding β\(^2\)-amino acids.

Sodeoka and coworkers have tested chiral cationic dimeric palladium catalysts for the α-fluorination of β-ketoesters with \(N\)-fluorobenzenesulfonamide (NFSI) (scheme 1.40).\(^6\) Catalyst 1.144 derived from DTBM-SegPhos gave excellent enantioselectivities up to 94%. The products were converted to β-amino esters using a sequence involving...
Ph₃SiH/TFA for the diastereoselective \( (dr >95:5) \) reduction of the ketone to the corresponding anti-fluoro-alcohol or Ph₃SiH/TBAF for the reduction to the syn-fluoro-alcohol. Both diastereomers were subsequently transformed into the respective azides using the Mitsunobu reaction, followed by reduction and in situ Boc-protection to give the α-fluoromethyl-β-amino esters.

β²-amino acids were also synthesized by rhodium-catalyzed C-H insertion of aromatic diazoacetates 1.146 into N-Boc-N-benzyl-N-methylamine (scheme 1.41). Benzylamine 1.145 is the optimal substrate for the insertion of various aromatic, heteroaromatic and alkenyl diazoacetates which proceeds with up to 96% ee.

Walsh and coworkers have developed a multi-step procedure for the synthesis of γ-unsaturated β²-amino acid derivatives with high ee (scheme 1.42). First, an enantioselective vinylzinc addition to aldehydes yields allylic alcohol 1.150, followed by
Overman’s [3,3]-sigmatropic imidate rearrangement to yield 1.151 by a one-pot deprotection-oxidation sequence. The vinylzinc reagents were generated in situ via hydroboration of terminal alkyne 1.149 with dicyclohexylborane and transmetalation of the vinylborane with diethylzinc. Ligand 1.153 catalyzes the addition of the vinylzinc reagent to aromatic and aliphatic aldehydes in high yield with excellent ee’s (up to 99%). Then, the trichloroacetimidate was synthesized using trichloracetonitrile in DBU and heated to reflux yielding the rearranged product 1.151. One-pot deprotection of the trityl alcohol and oxidation of the free hydroxy-group using chromium trioxide in sulfuric acid gave the N-protected amino acid 1.152.

Scheme 1.42. Enantioselective addition of vinylzinc reagents to aldehydes as a key step for the synthesis of β-amino acids.

Ru-salen catalyst 1.157 was tested in an enantioselective cyclopropanation in order to prepare β-cyclopropane amino acids (scheme 1.43). The cyclopropanation of styrene with ethyl diazoacetate 1.154 proceeded with good diastereo- and enantioselectivity. For the synthesis of trans-cyclopropyl β-amino acid derivatives, the phenyl ring was oxidatively cleaved giving the free carboxylic acid which was used in a subsequent Curtius rearrangement. The resulting isocyanate was converted into N-Boc-protected amino ester 1.156.
Johnson and coworkers developed an asymmetric cyanation/1,2-Brook-rearrangement/C-acylation reaction sequence for the synthesis of β-amino-α-hydroxy-α-phenyl amino acid derivatives (scheme 1.44). Using cyanoformate 1.158, acylsilane 1.159 and 15 mol% of salen-aluminium complex 1.162, high enantioselectivities in the formation of 1.160 were achieved. First, enantioselective cyanation of the acylsilane occurs, leading to a chiral metaloxide that undergoes a 1,2-Brook-rearrangement to give the product 1.160 upon reaction with a second molecule of the cyanoformate. The nitrile group was subsequently reduced to the free amine 1.161.

Feringa and coworkers developed the catalytic asymmetric allylic substitution of Grignard reagents using Taniaphos 1.166 as a chiral ligand and used this transformation as a key step in a new route to β2-amino acids (scheme 1.45). Allylic amine 1.163 was treated with methylimagnesium bromide in the presence of the chiral copper catalyst to give 1.164 in high yield with an 95% ee. The olefin was oxidatively cleaved with RuCl3-NaIO4, and the N-Boc-N-tosyl protected β-amino acid 1.165 was obtained in 79% yield.
Chapter 1: Recent advances in the catalytic asymmetric synthesis of β-amino acids

Moreover, the catalytic asymmetric allylic amination of allylic carbonates catalyzed by Ir-phosphoramidite 1.170 was used for the preparation of β3-amino acid derivatives (scheme 1.46). 73 N-Boc-N-acetylamine was employed as nucleophile giving the branched products with high regioselectivity (>99:1) and excellent ee (up to 99%). The product was in situ deacylated under basic conditions to give N-Boc-protected aliphatic and aromatic allylic amines. Hydroboration-oxidation and subsequent oxidation of the resulting alcohol gave the N-Boc-protected-β3-amino acid 1.169.

Jørgensen and coworkers employed the asymmetric Henry reaction to synthesize α-hydroxy-β3-amino acid esters (scheme 1.47). 74 Copper-bisoxazoline 1.174 complex was used to add nitromethane to aliphatic and aromatic α-ketoesters to give the adducts in good yield with high ee’s (up to 94%). Upon reduction of the nitro group, the corresponding β-amino acid esters 1.173 were obtained.
Enantioselective [3+2]-cycloadditions of nitrones and α,β-unsaturated 2-acyl imidazole 1.176 were used to synthesize β2,3-hydroxy-amino acid derivatives (scheme 1.48).75 Evans and coworkers employed Ce(IV)-bisoxazoline catalyst 1.179 to achieve the addition of aliphatic and aromatic nitrones 1.175 to 2-acyl imidazoles 1.176 in high yield with up to 99% ee with an endo:exo ratio >99:1. The isoxazolidines 1.177 were reductively cleaved using Pd(OH)$_2$/C and hydrogen to give β2,3-amino acid derivatives 1.178.

Chiral nucleophilic quinuclidine alkaloid derived catalyst 1.184 in combination with Ti(OiPr)$_4$ as Lewis acid has been employed in the asymmetric aza-Baylis-Hillman reaction (scheme 1.49).76 Starting from aromatic aldehydes, tosylamide and methyl acrylate, Adolfsson and coworkers studied catalyst 1.184 to obtain the Baylis-Hillman adducts 1.183 in good yield with moderate enantioselectivities.
Using bifunctional asymmetric catalyst 1.188, Lectka and coworkers synthesized β-lactams from acyl chlorides 1.185 and imine 1.186 (scheme 1.50). A combination of In(OTf)$_3$ and quinidine derivative 1.188 gave the syn-β-lactam 1.187 with high $dr$ (up to 98:2) and high ee (up to 98%).

![Scheme 1.50. In-quinidine catalyzed asymmetric formation of β-lactams.](image)

The catalytic asymmetric Sharpless aminohydroxylation and dihydroxylation of α,β-unsaturated carboxylic acid derivatives are important methods for the synthesis of α-hydroxy-β-amino acids which are key building blocks for the synthesis of Taxol analogues. α-Trifluoromethylisoserine 1.192 was synthesized by dihydroxylation from 2-(trifluoromethyl) acrylic ester 1.189, followed by treatment with Burgess reagent to give sulfamidate 1.191 which was hydrolyzed in acidic medium to give the β-amino acid with 90% ee (scheme 1.51a). The aminohydroxylation was used in the synthesis of polyhydroxylated β-amino acid constituents of microsclerodermic cyclic peptides (scheme 1.51b). γ-Alkoxy-(E)-alkene 1.193 was transformed into syn-β-amino-α-hydroxy ester 1.194 with 97% ee using (DHQD)$_2$PHAL as catalyst and tert-butylcarbamate as nucleophile.
There are many versatile catalytic enantioselective methods to synthesize $\beta_2$- or $\beta_3$-amino acids. Among the most frequently employed are those based on cycloadditions and Sharpless amino- and dihydroxylation. However, these methods are most often used for the synthesis of specific amino acids, for example as key step in natural product synthesis.

1.3 Organocatalysis

Asymmetric transformations promoted by small chiral organic molecules have become very useful among the recently developed methods for the synthesis of β-amino acids. Important catalysts used for this purpose are proline, proline-derived amines, chiral Brønsted acids, (thio)ureas, and cinchona alkaloids. In this paragraph Mannich reactions, conjugate additions and miscellaneous organocatalytic synthesis of β-amino acids are presented, covering the recent literature since 2002.

1.3.1 Mannich reaction

Organocatalytic Mannich reactions represent a direct entry into β-amino carbonyl compounds. Low-molecular weight synthetic molecules that have hydrogen-bond donor abilities and a secondary interaction side, such as aromatic, and acidic or basic functionalities, can catalyze a variety of C-C and C-heteroatom bond forming reactions with high enantioselectivity. Chiral Brønsted acids are an important class of organocatalysts. Hydrogen bonds are formed between the catalyst and the electrophile to activate it and to organize the transition state. Chiral Brønsted acids are classified into two categories: 1) neutral Brønsted acids, such as thiourea and Taddol derivatives which
are called hydrogen-bonding catalysts, and 2) stronger Brønsted acids, such as Binol derivatives and phosphoric acids.

Chiral phosphoric acid 1.197 derived from Binol gave high stereoinduction in the reaction of aromatic aldimines with silylenol ethers (scheme 1.52). High diastereoselectivities (dr up to 100:0) and high enantioselectivities (ee up to 96%) were achieved.

![Scheme 1.52. Mannich reaction catalyzed by a chiral Binol-derived phosphoric acid.](image)

Yamamoto and coworkers studied chiral Brønsted acid 1.201 which was proposed to activate imine 1.199 through hydrogen bonding (scheme 1.53a). An achiral Brønsted acid (R^3OH) protonates the amine moiety of the intermediate to give the adducts 1.198 with good ee (up to 78%).

Taddol-derived phosphoric acid 1.202 was also used to catalyze the addition of silylenol ethers 1.200 to aromatic aldimines with good yield and high ee’s (scheme 1.53b).

![Scheme 1.53. Brønsted acid catalyzed Mannich reactions for the synthesis of β-amino acids.](image)

The reaction of aromatic N-Boc-protected aldimines with nitroacetate 1.204 using amine catalyst 1.206 gave the products in good yield and high ee (up to 98%) (scheme 1.54).
Using tributyl tinhydride and AIBN, the nitro group was removed to provide the corresponding $\beta^3$-amino ester 1.205.

![Scheme 1.54. Mannich reaction catalyzed by a chiral amine.](image)

Phase transfer catalyst 1.209, developed by Shibasaki and coworkers, is effective in the addition of glycine-Schiff-base 1.207 to aromatic imines (scheme 1.55).$^{89}$ The glycine-Schiff-base is deprotonated by Cs$_2$CO$_3$, presumably at the interface between liquid and solid phase, where upon counterion exchange with 1.209 takes place, followed by the asymmetric C-C-bond formation. The Mannich adducts 1.208 were obtained with good diastereomeric- and enantiomeric excess.

![Scheme 1.55. Mannich reaction catalyzed by a chiral phase transfer catalyst.](image)

Jacobsen and coworkers studied thiourea 1.212 as catalyst in the Mannich reaction of silylenol ethers 1.210 with $N$-Boc-aldimines 1.203 (scheme 1.56).$^{90}$ Aromatic $\beta^3$-amino acid derivatives were obtained in high yields with up to 98% ee. Variation in the amine part of the catalyst, i.e. thiourea 1.213, gave comparable enantioselectivities for the Mannich reaction.$^{91}$
Chapter 1: Recent advances in the catalytic asymmetric synthesis of β-amino acids

Scheme 1.56. Thiourea catalyzed asymmetric Mannich reaction.

Deng and coworkers tested catalyst 1.223 with a thiourea and a quinine alkaloid moiety (scheme 1.57a). The thiourea-group is proposed to activate and direct the electrophilic imine, and the tertiary nitrogen of the quinine moiety activates the nucleophile. The products 1.215 resulting from the addition of malonates to N-Boc-protected aromatic aldimines were obtained in high yield with high ee (up to 99%). Upon hydrogenation, the benzyl ester was deprotected and subsequent decarboxylation provided the N-protected β-amino acid 1.216 in high yield. The same group also tested catalyst 1.223 for the Mannich reaction with in situ generated carbamate-protected imines 1.218 (scheme 1.57b). The Mannich adducts were obtained in high yield with up to 96% ee starting from α-amino sulfone 1.218, dibenzyl malonate 1.219, and catalyst 1.223.

Dixon and coworkers used a similar thiourea-cinchonine alkaloid catalyst 1.224 for the addition of malonates to N-Boc- and N-Cbz protected aldimines 1.221 (scheme 1.57c). The Mannich adducts of dimethyl malonate 1.220 and the protected aromatic aldimines 1.221 were obtained in high yield with up to 97% ee.
The asymmetric Mannich reaction of β-keto esters with imines catalyzed by cinchonine alkaloid 1.229 was reported by Schaus and coworkers (scheme 1.58a). Cinchonine 1.299 catalyzed the formation of the Mannich adducts with high diastereoselectivity (dr up to 20:1) and high enantioselectivity (ee up to 96%). Upon reduction with Zn(BH₄)₂ the syn-amino alcohol derivative 1.228 was obtained. The same catalyst was also tested in the addition to cyclic β-keto esters, providing high yield and high diastereo- and enantioselectivities (scheme 1.58b).
Chapter 1: Recent advances in the catalytic asymmetric synthesis of \( \beta \)-amino acids

![Scheme 1.58. Cinchonine catalyzed asymmetric Mannich reaction of cyclic and acyclic \( \beta \)-ketoesters.](image)

Jørgensen and coworkers investigated quinidine alkaloid derivative \( \text{1.235} \) in the reaction of \( \alpha \)-cyanoacetates \( \text{1.232} \) with \( \alpha \)-imido carboxylates \( \text{1.233} \) (scheme 1.59).\(^{97}\) Aromatic \( \alpha \)-cyanoacetates \( \text{1.232} \) gave the corresponding Mannich adducts \( \text{1.234} \) in high yield in a highly diastereo- and enantioselective transformation; the highest \( ee \) and \( dr \) were obtained starting from \( \alpha \)-cyano-\( \text{tert} \)-butyl-carboxylate.

![Scheme 1.59. Quinidine alkaloid catalyzed asymmetric Mannich reaction of \( \alpha \)-imido carboxylates and \( \alpha \)-cyanoacetates.](image)

Barbas III and coworkers studied the Mannich reaction of thioesters with \textit{in situ} generated \( N \)-Boc imines catalyzed by cinchona alkaloid \( \text{1.239} \) (scheme 1.60).\(^{98}\) However, the Mannich adduct was only obtained with moderate enantioselectivity.
Proline and proline derivatives are important catalysts for organocatalytic transformations. Proline acts hereby as a multifunctional catalyst. The amine group of proline condensates with the carbonyl group of the substrate to generate an enamine, the carboxylic acid functionality activates the electrophile via hydrogen-bonding in a highly ordered transition state. The H-donor functionality was found to be important to arrange the electrophile relative to the pyrrolidine ring and thus lowering the activation barrier for the C-C-bond formation by stabilizing charge build up in the transition state.

Barbas III and coworkers have used proline as catalyst in the addition of aliphatic aldehydes to PMP-protected \( \alpha \)-imido ethylesters (scheme 1.61). The \( \text{syn} \)-products were obtained with high dr's and ee's, and subsequently oxidized and cyclized to obtain \( \beta \)-lactam. When an aqueous medium, such as THF/H\(_2\)O (9:1), was used in this Mannich reaction, the \( \text{syn} \)-adduct was obtained with high diastereomeric excess (95:5) and high enantioselectivity (up to 99%).

Quaternary all carbon stereocenters were synthesized via a Mannich reaction using proline catalysis and \( \alpha \)-branched aldehydes (scheme 1.62). \( \alpha,\alpha \)-Disubstituted aldehydes were used as donor reagents in the addition to \( \alpha \)-imido ethylester to provide quaternary \( \beta \)-formyl substituted \( \alpha \)-amino acid derivatives in high yield with
excellent \(dr\)'s (up to 96:4 \(\text{syn:anti}\)) and high \(ee\)'s (up to 99\%, \(\text{syn}\)). The products were further converted to form spiro-lactams 1.247. However, high catalyst loadings (30 mol\%) were required.

Scheme 1.62. Proline catalyzed asymmetric Mannich reaction to form quaternary all carbon stereocenters.

An extension of the scope of the direct asymmetric Mannich reaction of unmodified aldehyde donors was reported in 2003 by Barbas III (scheme 1.63).\textsuperscript{103} Several substituted proline derivatives were investigated in the addition of aldehydes to \(\alpha\)-imino ethyl glyoxylate, revealing that proline gives the best diastereoselectivities for the formation of the \(\text{syn}\)-adduct with high enantioselectivity. However, (S)-2-methoxymethylpyrrolidine shows reversed diastereoselectivity, \textit{i.e.} that the \(\text{anti}\)-adduct is formed preferentially but with only moderate enantioselectivity. The effect of water on the Mannich reaction with preformed aromatic aldimines was also studied: the reaction tolerates a significant amount of water (up to 10\%) without affecting the enantioselectivity. For substituted aromatic amines (with electron withdrawing functional groups) a diastereomeric ratio (up to 91:9) for the \(\text{syn}\)-adduct is obtained. Furthermore, the authors describe the one-pot-three-component reaction of aliphatic aldehydes, \(p\)-anisidine and substituted aromatic aldehydes to give adducts with high diastereomeric ratio (up to 95:5) and high \(ee\) (up to 99\%) (scheme 1.63). Hayashi and coworkers also reported the three component Mannich reaction of aromatic and heteroaromatic aldehydes, \(p\)-anisidine and aliphatic aldehydes to give the \(\text{syn}\)-adducts with high diastereomeric ratio (up to 95:5) and high \(ee\) (scheme 1.63).\textsuperscript{104} The same three-component Mannich reaction has been described by Córdova and coworkers for the synthesis of \(\gamma\)-amino alcohols.\textsuperscript{105} Córdova investigated a broader aldehyde scope such as heteroaromatic, aliphatic aldehydes and ethyl glyoxylate which gave the corresponding Mannich adducts again with high \(\text{syn}\)-selectivity and high \(ee\)'s.\textsuperscript{106}
Chapter 1

Using glycol aldehydes as substrates, Córdova and coworkers describe an entry into the synthesis of protected amino-tetroses 1.253 (scheme 1.64a) and syn-α-hydroxy-β-amino acids 1.256 (scheme 1.64b). 107 However, high catalyst loadings of proline are necessary to achieve excellent enantioselectivities (ee up to 99%) and good diastereoselectivity. The diastereomeric ratio is in some cases up to 91:9 but for most substrates it does not exceed 80:20 (syn/anti). In 2008, the synthesis of α-hydroxy-β-amino acid derivatives was improved using higher catalyst loadings and preformed imines to yield higher enantioselectivities (ee up to 99%) (X=TBS and PG=Boc) and diastereoselectivities (dr up to 95:5) for the syn-adducts (scheme 1.64b). 108 The products were converted by oxidation to the corresponding β-amino acids.

List and coworkers reported excellent diastereoselectivities (dr up to 99:1) and enantioselectivities (ee up to 99%) towards the syn-adduct for the proline catalyzed addition of aldehydes to aromatic N-Boc-protected imines 1.254 (scheme 1.65a). 109 A scope of aliphatic, heteroaromatic and aromatic imines is described. Employing slightly different reaction conditions, Córdova and coworkers also reported this transformation.

Scheme 1.63. Proline-catalyzed asymmetric one-pot-three component Mannich reaction.

Scheme 1.64. Proline-catalyzed asymmetric synthesis of α-hydroxy-β-amino aldehydes.
For a variety of aliphatic and allylic aldehydes the syn-products were obtained in a highly diastereo- and enantioselective transformations.

In 2008, the List group reported the proline catalyzed reaction of N-Boc-imines with acetaldehyde (scheme 1.66). The β-amino aldehydes are obtained with excellent ee (up to 99%), however, the yields are low (23-58%), and a high catalyst loading of proline (20 mol%) has to be employed.

Hayashi and coworkers conducted experimental studies towards the mechanism and compared the reactivity of aldmines to aldehydes employing NMR-spectroscopy and theoretical calculations using density functional theory (B3LYP/6-31G*). In the Mannich reaction of p-anisidine and two equivalents of benzaldehyde, the formed imine reacts seven times faster with the second equivalent of aldehyde than the aldehyde enol would react with itself (aldol reaction). The authors attribute their findings to the fact that a protonation of the basic nitrogen atom of the aldimine by the carboxylic acid group of proline is more favourable than protonation of the aldehyde.

Several alternative organocatalysts based on proline have been designed in recent years. Jørgensen and coworkers used TMS-protected catalyst in the Mannich reaction of PMP-protected α-imino ethylglyoxylate and aliphatic aldehydes (scheme 1.67a). This catalyst gives the anti-adducts with high dr’s and high ee’s. Direct asymmetric Mannich reactions of aliphatic aldehydes with α-imino ethylglyoxylate were also described by Córdova and coworkers using related catalyst giving the anti-adducts with good selectivity (scheme 1.67b).
Chapter 1

H₂O₂ → H₂O₂

Scheme 1.67. a) Mannich reaction of aldehydes catalyzed by proline derivatives by Jørgensen and b) by Córdova.

Hayashi and coworkers performed calculations using density functional theory (B3LYP) and experiments on the Mannich reaction with catalyst 1.261 and 1.262. The addition of acetaldehyde to N-Bz-, N-Boc- and N-Ts-protected aromatic imines revealed that in the presence of p-NO₂PhCO₂H as additive better yields and excellent enantioselectivities were obtained. Experimentially, N-Boc- and N-Bz protected imines were investigated; all reactions gave the anti-adducts in good yield with high enantioselectivity (up to 98%).

Moreover, pipecolic acid 1.264, the 6-ring analogue of proline, was used by Barbas III and coworkers in the addition of aliphatic aldehydes to α-imino ethylglyoxylate (scheme 1.68). The ee’s are high for both diastereomers (ee >99%), but the selectivity towards syn-adducts is usually low (dr up to 67:33).

Scheme 1.68. Mannich reaction catalyzed by pipecolic acid.

The enantioselective aminomethylation of aldehydes was investigated by Gellman and coworkers for the synthesis of β²-amino acid building blocks for peptide synthesis (scheme 1.69a). An iminium species was in situ generated by elimination of MeOH from aminal 1.268. Proline derivative 1.262 catalyzed the addition of aliphatic aldehydes to give the adducts in good yields with high ee’s (up to 92%). The β-amino aldehydes were in situ reduced to the corresponding alcohols. For the synthesis of β²-amino acids, the amino alcohol was recrystallized as hydrochloride salt to increase the ee, the protecting groups removed by hydrogenation followed by Boc-protection, and the alcohol oxidized to the corresponding carboxylic acid 1.268. Córdova and coworkers
screened further additives and found that LiBr increases the enantioselectivity (ee up to 98%) (scheme 1.69b). The corresponding β²-amino acid 1.268 was synthesized by deprotection of the benzyl-protecting group and reprotection using Boc₂O, followed by oxidation of the alcohol to the carboxylic acid providing N-Boc-β-amino acid 1.268 with an overall yield of 57%.

Scheme 1.69. a) Organocatalytic aminomethylation for the synthesis of β²-amino acids by Gellman and b) by Córdova.

In recent years, the organocatalyzed Mannich reaction has found widespread application in the synthesis of β-amino acids. Both, β²- and β³-amino acids are accessible with high diastereoselectivities towards syn- or anti-Mannich products depending on catalyst source and substrate. However, when proline or its derivatives are used as catalysts, in most cases high catalyst loadings of 20-30% are still needed to achieve a highly stereoselective transformation.

1.3.2 Conjugate addition

The addition of carbon and nitrogen nucleophiles to α,β-unsaturated compounds is an important organic transformation for the synthesis of pharmaceuticals and natural products. Organocatalytic C-N bond formations are especially important for the synthesis of β-amino acids via conjugate addition.

MacMillan and coworkers designed nitrogen nucleophile 1.270 that readily undergoes a conjugate addition to α,β-unsaturated aldehydes (scheme 1.70). In the presence of an imidazolidinone organocatalyst 1.273 (as TFA-adduct), benzyl tertbutyldimethylsiloxycarbamate 1.270 was added to aliphatic and benzyloxy-substituted α,β-unsaturated aldehydes 1.269. The nucleophile was designed to enhance the nucleophilicity through the N-O functionality via the α-effect while the carbamate moiety renders the amino aldehyde product effectively nonbasic (pKₐ ~ 9). The products 2.171 are obtained in high yield with up to 97% ee, and were subsequently oxidized to N-protected β²-amino acids 1.272.
Chapter 1

Following a similar approach, Córdova and coworkers reported that proline-derived chiral amine 1.262 catalyzes the conjugate addition of N-Cbz-methoxylamine 1.274 to α,β-unsaturated aldehydes (scheme 1.71a).120 The β-amino aldehydes were obtained in high yield with high enantiomeric excess (up to 99%). A subsequent oxidation of the aldehyde 1.274 to the corresponding carboxylic acid and deprotection of the amine provided β3-amino acids 1.276. When carbamate-protected hydroxylamines 1.277 were used as nucleophile, the cyclic 5-hydroxy-isoaxazolidinones 1.278 were obtained with high ee up to 98% (scheme 1.71b).121 They were subsequently cleaved by hydrogenolysis to give β3-amino acid 1.276 with high ee.

Proline derivative 1.261 has also been used for intramolecular aza-Michael addition (scheme 1.72).122 Piperidines and pyrrolidines were synthesized with up to 95% ee. The aldehydes were oxidized to the corresponding carboxylic acids, such as homopipeolic acid derivative 1.281.
Chapter 1: Recent advances in the catalytic asymmetric synthesis of β-amino acids

Scheme 1.72. Intramolecular organocatalytic aza-Michael addition.

Sibi and coworkers used thiourea catalyst 1.284 for the conjugate addition of O-substituted hydroxylamines to pyrazole crotonates 1.282 (scheme 1.73). Aliphatic α,β-unsaturated compounds gave high enantioselectivities but phenyl-substituted substrates gave the adducts with only moderate ee.

Scheme 1.73. Thiourea catalyzed aza-Michael addition of hydroxylamines.

Moreover, carbon-nucleophiles have been added to α,β-unsaturated substrates using organocatalysts. An illustrative example leading to β-amino acids pertains to the addition of malonates to α,β-unsaturated nitroalkenes catalyzed by thiourea 1.291 (scheme 1.74). The products 1.287 were obtained with high enantioselectivity. Subsequent Baeyer-Villiger oxidation gave the corresponding ester 1.288, and a subsequent reduction with DIBAL-H provided the diol 1.289, which was oxidatively cleaved. Finally, the nitro group was reduced to give the free amino acid 1.290.
The organocatalytic addition of amine nucleophiles to α,β-unsaturated carbonyl compounds proceeds generally with very high enantioselectivities. However, relatively high catalyst loadings of 20-30% are employed. A major challenge is to further optimize the organocatalyzed conjugate addition of nitrogen nucleophiles to α,β-unsaturated carbonyl compounds with regard to catalyst loading and substrate scope. This reaction represents a fast atom-economic entry towards the synthesis of β-amino acids; many synthetically useful Michael adducts might be made readily in enantiomerically pure form via conjugate additions.

1.3.3 Miscellaneous

Several other reaction types were used for the synthesis of β-amino acids using organocatalysts such as substituted proline derivatives, cinchona alkaloids, thioureas and N-heterocyclic carbenes.

For instance, Lewis base 1.294 catalyzes the hydrosilylation of β-enamino esters (scheme 1.75). The aromatic, aliphatic or cyclic (Z)-enamino esters 1.292 were hydrosilylated using trichlorosilane to give the corresponding β1-amino esters 1.293 in high yield with high enantiomeric excess.
Chapter 1: Recent advances in the catalytic asymmetric synthesis of β-amino acids

List and coworkers studied the transfer hydrogenation of β-nitroalkenes catalyzed by thiourea 1.297 (scheme 1.76). The Hantzsch ester was used as hydrogen source, leading to β-amino acid precursors 1.296 with high enantiomeric excess when (E)-alkenes were used, and high ee of the opposite enantiomer starting from (Z)-alkenes.

![Scheme 1.76. Thiourea catalyzed conjugate reduction of nitroalkenes.](image)

An alternative approach to β-amino acids based on a dynamic kinetic resolution was applied in the reduction of enamines with trichlorosilane (scheme 1.77). α-Amino acid derived amide 1.301 was used in the reduction with trichlorosilane of imines 1.299 which are in equilibrium with the corresponding enamines 1.298. The syn-β2,3-amino esters 1.300 were isolated with high dr (>99:1) and high ee (90%).

![Scheme 1.77. Dynamic kinetic resolution of enamines towards β-amino acid derivatives.](image)

Thiourea catalyst 1.305 was studied by Berkessel and coworkers for the kinetic resolution of racemic oxazinones 1.302 (scheme 1.78). With up to 57% conversion, the chiral remaining oxazinones 1.302 were isolated with >99% ee and the ring-opened β1-amino ester 1.303 with 84% ee. When the reaction was driven to 25% conversion, the ring-opened product had 96% ee. Using hydrolytic workup, the N-benzoyl-β-amino acid 1.304 was isolated with 97% ee.
Córdova and coworkers reported that proline derivative 1.262 catalyzes the aziridination of α,β-unsaturated aldehydes (scheme 1.79). The α,β-aziridine aldehydes 1.307 were obtained in a highly enantioselective transformation (up to 99%), and were converted in one step into the corresponding Cbz-protected amino esters 1.308 in the presence of an in situ generated thiazolium catalyst 1.309.

A multistage, one-pot procedure was used for the synthesis of α,β-amino diesters (scheme 1.80a). A proposed mechanism involves dehalogenation of 1.310 catalyzed by benzoylquinine (BQ) 1.314 and stoichiometric amounts of proton sponge (PS) 1.315, resulting in the formation of imine 1.318 (scheme 1.80b). This reacts subsequently with enolate 1.317 derived from carboxylic acid chloride 1.310 via ketene 1.316. The obtained β-lactam 1.312 undergoes ring opening upon treatment with methanol to yield aspartic acid derivative 1.313. Moreover, in one step, β-lactams were synthesized from preformed imines 1.319 and acylchloride catalyzed by benzoylquinine 1.320 in the presence of stoichiometric amounts of base and 15-crown-5 (scheme 1.80c).
Chapter 1: Recent advances in the catalytic asymmetric synthesis of β-amino acids

Scheme 1.80. Multistage one-pot procedure for the synthesis of β-lactams catalyzed by benzoylquinine.

Jørgensen and coworkers used the [1,3]-sigmatropic rearrangement of O-allylic trichloroacetimidates 1.321 to synthesize N-protected β-amino esters 1.322 catalyzed by dihydroquinidine (DHQD)_2PHAL (scheme 1.81). The products of the rearrangement were obtained in good yield with ee (up to 92%).

Scheme 1.81. [1,3]-Sigmatropic rearrangement for the synthesis of β-amino esters.
Chiral nucleophilic quinidine catalyst 1.314 has been employed in the asymmetric aza-Baylis-Hillman reaction (scheme 1.82). Aromatic imine 1.323 and activated alkene 1.324, 1,1,3,3,3-hexafluoroisopropyl acrylate, were reacted to give the Baylis-Hillman adducts 1.325 in moderate yield with moderate enantiomeric excess (up to 73%). Subsequent hydrolysis and ring closure upon treatment with BOPCl 1.327 gave β-lactam 1.326.

N-Heterocyclic carbene 1.330 was shown to catalyze the addition of nitrosobenzene to α,β-unsaturated aldehydes via a reaction involving umpolung of 1.306. This transformation gives isoaxazolidinone intermediates which were hydrolyzed under acidic conditions to the corresponding methyl ester 1.329 (scheme 1.83).

In this section routes to β\(^2\)- and β\(^\text{L}\)-amino acids and β-lactames based on a variety of methods including (transfer)hydrogenation, aziridination, (dynamic) kinetic resolution, one-pot reactions of imines with enolates, 1,3-sigmatropic rearrangement, aza-Baylis-
Hillman reaction and umpolung of α,β-unsaturated aldehydes were discussed. In most cases, these reactions have limited scope so far to prepare specific β-amino acid precursors or β-lactams.

1.4 Biocatalytic routes

There are only few recent biocatalytic methods reported for the synthesis of β-amino acid apart from kinetic resolutions. The biocatalytic preparation of enantiopure β-amino acids has been reviewed in 2006, therefore, this part will focus on non-kinetic resolutions since 2006.

A β-transaminase from Mesorhizobium sp. LUK was cloned and characterized as a new biocatalyst for the synthesis of β-amino acids (scheme 1.84). However, only phenyl substituted β-ketoester 1.331 was screened as precursor in combination with a lipase from Candida rugosa which catalyzes the hydrolysis of 1.331 to β-keto acid 1.332 being the substrate for the transamination. Racemic β-alanine was used as nitrogen source and β-phenylalanine 1.335 was obtained after low conversion (20%) albeit with 99% ee.

![Scheme 1.84. Transaminase catalyzed synthesis of β-phenylalanine.](image)

Saccharomyces carlsbergensis old yellow enzyme was studied in the asymmetric bioreduction of β-nitroacrylates (scheme 1.85). NADPH was supplied by a co-factor regeneration system (glucose-6-phosphate/bakers yeast glucose-6-phosphate dehydrogenase). (Z)-Alkenes substituted in α-position to the carboxylate with ethyl-, propyl or iso-propyl groups were reduced with high conversion and high ee (up to 96%). Subsequent hydrogenation and acidic hydrolysis gave the corresponding β′-amino acids 1.337. The scope is limited to short aliphatic substituents (Me, Et, n-Pr, i-Pr)

Scheme 1.87. PAM catalyzed synthesis of β-amino acids form cinnamic acid derivatives.

Biocatalytic processes are a valuable addition to the organocatalytic and transition metal catalyzed methods for the synthesis of β-amino acids. Enantioselectivities are in general very high (>99%), but most enzymes have a small substrate scope so far. Additionally, in the reports discussed here, frequently the β-amino acids were not isolated, but only conversion was measured, and substantial work is required to make these methods applicable to synthetic organic chemistry.
1.5 Conclusion and outlook

The synthesis of \( \beta \)-amino acids remains a challenging target for organic chemists due to the importance of these building blocks as pharmaceuticals intermediates and peptidomimetics. In the past 15 years, tremendous progress has been made as shown in this review and preceeding overviews.\(^6\)\(^8\) Using many different methodologies, \( \beta^2 \)- and \( \beta^3 \)-amino acids with various substitution patterns are now available. Organocatalysis has played an important role in recent years in the field of catalytic asymmetric synthesis and quickly provided a useful method to prepare \( \beta \)-amino acids, especially transformations based on the Mannich reaction. However, in many cases high catalyst loadings have to be used, and reaction times are in some cases rather long. On the other hand, one of the more promising catalysts, \((S)\)-proline, is a naturally occurring amino acid, and therefore very cheap. Homogeneous catalysis using transition metals provided the most important methods in recent years to synthesize \( \beta \)-amino acids. Among them, the hydrogenation of enamines has been applied in industrial synthesis of \( \beta \)-amino acids because high turnover, high enantioselectivity and low catalyst loadings can be used. However, some transition metals are highly toxic and harmful for the environment. Therefore, biocatalysis would provide an important alternative, but up to now no enzymes are known that have a broad substrate scope in combinations with high turnover numbers. Most enzymatic methods rely on kinetic resolutions, which means that only 50% of the starting materials can be converted, unless a dynamic kinetic resolution protocol is used. Therefore, the catalytic asymmetric synthesis of \( \beta \)-amino acids starting from simple and cheap starting materials and using recyclable sustainable catalysts remains an important challenge for synthetic organic chemists.
