Chapter 1

Global properties of integrable Hamiltonian systems

1.1 Problem setting and summary of the results

We continue the study by Duistermaat [27] and Nguyen [89] of global properties of Lagrangian bundles, i.e. symplectic $n$-torus bundles with Lagrangian fibres, as these occur in integrable Hamiltonian systems. The main interest is in obstructions to triviality and classification. We review the geometrical setting of the problem and give a summary of the results. Details will be dealt with in sections 1.2 and 1.3 and in the appendices.

1.1.1 Setting of the problem

Let $(M, \sigma)$ be a connected $2n$-dimensional symplectic manifold, that is, $M$ is a smooth manifold and $\sigma$ is a closed 2-form on $M$ such that the $2n$-form

$$\sigma \wedge \cdots \wedge \sigma$$

is nowhere zero. Let $B$ be a connected $n$-dimensional smooth manifold, and call a locally trivial bundle $f : M \to B$ a Lagrangian bundle if $df$ has maximal rank everywhere on $M$ and the fibres of $f$ are compact connected Lagrangian submanifolds of $M$, that is, for any $p \in M$ and any $X, Y \in T_p F_p$, where $F_p = f^{-1}(f(p))$,

$$\sigma(X, Y) = 0.$$

Obstructions to global triviality of Lagrangian bundles were studied in [27, 89]. In this work we give new proofs and elucidate certain aspects of the results of [27]. In particular, we stress the role of the integer affine structure, the definition of which follows, and explain in more detail the symplectic classification of Lagrangian bundles with a given integer affine structure.

1.1.2 Motivation and terminology

Lagrangian bundles arise naturally in the study of integrable Hamiltonian systems, as we show now. Recall [1, 2] that the phase space of a conservative mechanical system is a symplectic
manifold \((M, \sigma)\), and the dynamics in the system is given by a function
\[
H : M \to \mathbb{R},
\]
called the Hamiltonian, which defines a vector field \(X_H\) on \(M\) such that
\[
dH = -\sigma(X_H, -).
\]
The vector field \(X_H\) is called the Hamiltonian vector field associated to \(H\), and we note that the time \(t\) map \(X_{H,t}\) of \(X_H\) preserves the symplectic form in the sense that
\[
X^*_t\sigma = \sigma.
\]
Such a Hamiltonian dynamical system is denoted by \((M, \sigma, H)\). Let \(F\) be a function on \(M\) with \(X_H(F) = dF(X_H) = 0\). We call such a function a first integral of \(X_H\), or of \(H\). From the definition of the Hamiltonian vector field \(X_H\) which also applies to \(X_F\) it follows that
\[
\sigma(X_F, X_H) = 0,
\]
which is usually expressed by saying that \(F\) and \(H\) are in involution. The vector field \(X_F\) defines a symmetry of the system \((M, \sigma, H)\), that is, for any time \(t\)
\[
X^*_{F,t}\sigma = \sigma \quad \text{and} \quad H \circ X_{F,t} = H,
\]
where, as before, \(X_{F,t}\) denotes the time \(t\) map of \(X_F\). Recall [1] that a Hamiltonian system is called integrable if there are \(n\) functions \(F_1, \ldots, F_n = H\) on \(M\), such that \(dF_1, \ldots, dF_n\) are linearly independent everywhere on \(M\) except on a set of points of measure zero, and \(F_1, \ldots, F_n\) are pairwise in involution.

Now let \(f : M \to B\) be a Lagrangian bundle, and \(h : B \to \mathbb{R}\) be a smooth function. We can consider the function \(H = h \circ f\) as the Hamiltonian on \(M\). Then for any \(h' : B \to \mathbb{R}\) the function \(h' \circ f\) is a first integral of \(h \circ f\), and \(h \circ f\) is a first integral of \(h' \circ f\). All first integrals obtained in such a way are in involution. Notice that, whenever it will cause no confusion, in what follows we will use the same symbol for a function \(h\) and the corresponding function \(h \circ f\) on \(M\). Locally on \(B\) one can choose \(n\) functions \(h_1, \ldots, h_n\) such that \(dh_1, \ldots, dh_n\) are linearly independent, thus the bundle \(f : M \to B\) admits locally \(n\) first integrals \(h_1, \ldots, h_n\), where \(h_n = H\).

**Example 1.1.1 (The spherical pendulum)** [22, 27] The spherical pendulum has an associated Lagrangian bundle. To see that first recall that the spherical pendulum consists of a unit mass particle moving on the surface of the unit sphere \(S^2 \subset \mathbb{R}^3\) under a uniform vertical gravitational force. Thus the configuration space of the spherical pendulum is \(S^2\), and the phase space is the cotangent bundle \(T^*S^2\) with canonical 2-form \(\sigma\). The Hamiltonian \(H\) of the pendulum is the sum of the kinetic and the potential energy of the particle. The system is invariant under the rotation with respect to the vertical axis in \(\mathbb{R}^3\), and the corresponding first integral is the angular momentum \(J\). The map \((J, H)\) has maximal rank almost everywhere on \(T^*S^2\), and compactness of fibres of \((J, H)\) follows from compactness of level sets of the Hamiltonian \(H\). Removing from \(T^*S^2\) fibres containing the points where \(dJ\) and \(dH\) are linearly dependent, one obtains a Lagrangian bundle, the fibres of which are 2-tori.

If there is no danger of confusion, in what follows we refer to the bundle \(f : M \to B\) by its total space \(M\).
1.1.3 Preliminaries on geometry of Lagrangian bundles

We recall the setting of local and global geometry of Lagrangian bundles and introduce the notion of integer affine structure as this plays a fundamental role in our considerations.

The local geometry of Lagrangian bundles

The local geometry of Lagrangian bundles was studied in [2, 3, 6, 27, 55] and is described by the Liouville-Arnold theorem, which states that for each $p \in M$ there exists an open neighborhood $O \subset M$ of the fibre $F_p = f^{-1}(f(p))$ and local action-angle coordinates $(x, \varphi) = (x_1, \ldots, x_n, \varphi_1, \ldots, \varphi_n)$ on $O$ such that $(x, \varphi)$ is symplectic, that is,

$$\sigma = \sum_{i=1}^{n} d\varphi_i \wedge dx_i,$$

where the functions $\varphi_i$ take values in $\mathbb{R}/\mathbb{Z}$, and the functions $x_i$ factor through $f$ to smooth local coordinate functions on $B$. The existence of action-angle coordinates implies that $f : M \to B$ locally is a principal torus bundle (see Appendix B or [10, 49, 77]). The action of the torus in $M$ is induced by a natural action of fibres of $T^*B$ on fibres of $M$, which can be defined independent of the coordinates, and with respect to our present action-angle coordinates $(x, \varphi)$ has the following form.

For each $b \in B$ an element $\sum_{i=1}^{n} \alpha_i dx_i(b)$ in $T^*_B B$, regarded as an additive group, acts on $f^{-1}(b)$ by sending the point with coordinates $(\bar{\varphi}_1, \ldots, \bar{\varphi}_n)$ to the point with coordinates $(\bar{\varphi}_1 + \alpha_1, \ldots, \bar{\varphi}_n + \alpha_n)$. The kernel $P_b$ of the action is a discrete subgroup of $T^*_B B$ generated by $dx_1(b), \ldots, dx_n(b)$. The set $P = \bigcup_{b \in B} P_b$ is a subset of $T^*B$, and the projection $P \to B$ is a locally trivial bundle with fibre $\mathbb{Z}^n$, called the bundle of period lattices. By abuse of language we will call the bundle $g : P \to B$ the period lattice [27]. For each $b \in B$ the $n$-torus $T^*_b B/P_b$ acts freely and transitively on $f^{-1}(b)$, and for $b' \in B$ near $b$ there is a canonical isomorphism between the tori $T^*_b B/P_b$ and $T^*_b B/P_{b'}$. Thus locally there is a smooth torus action, and $f : M \to B$ is a principal $n$-torus bundle locally.

We note that the canonical symplectic structure on $T^*B$ induces a symplectic structure on the set

$$T^*B/P = \bigcup_{b \in B} T^*_b B/P_b,$$

making the projection $T^*B/P \to B$ another Lagrangian bundle. The Liouville-Arnold theorem implies that the bundles $f : M \to B$ and $T^*B/P \to B$ are locally isomorphic; globally this need not be the case. In fact, the set of all possible Lagrangian bundles with base $B$ and period lattice $P$ is classified, up to symplectic bundle isomorphisms, by their Lagrange classes, see Section 1.1.3.

Transformations between local action-angle coordinates have to preserve the period lattice, which makes them very rigid. If $(\tilde{x}, \tilde{\varphi})$ is another system of action-angle coordinates then in the common domain of $x$ and $\tilde{x}$ the differentials $(dx_1, \ldots, dx_n)$ and $(d\tilde{x}_1, \ldots, d\tilde{x}_n)$ generate the same period lattice. This means that $(dx_1, \ldots, dx_n)$ and $(d\tilde{x}_1, \ldots, d\tilde{x}_n)$ are related by a matrix in $GL(n, \mathbb{Z})$, the group of invertible $(n \times n)$ matrices with integer coefficients, and
the same is true for \((x_1, \ldots, x_n)\) and \((\tilde{x}_1, \ldots, \tilde{x}_n)\) up to a translation. A transformation in \(\mathbb{R}^n\), which can be obtained as a composition of an element in \(\mathbb{GL}(n, \mathbb{Z})\) and a translation, is called an \textit{integer affine transformation}, and the group of such transformations is denoted by \(\mathbb{R}^n \rtimes \mathbb{GL}(n, \mathbb{Z})\), where \(\rtimes\) stands for the \textit{semi-direct product} \([74]\). We see that the base manifold \(B\) necessarily has an \textit{integer affine structure}, meaning that it admits an atlas such that the transformations between charts are integer affine transformations.

**Global properties of Lagrangian bundles**

Global properties of Lagrangian bundles were studied in \([27, 89]\). Obstructions to triviality of Lagrangian bundles, monodromy and the Lagrange class were introduced in \([27]\). Briefly, they are defined as follows.

**Monodromy**

Monodromy is an invariant for the period lattices \(P\) and the obstruction to the period lattice being trivial, i.e. to the existence of an isomorphism \(P \to B \times \mathbb{Z}^n\), and the obstruction to the Lagrangian bundle being a principal torus bundle globally. On the one hand, this means that if the monodromy of \(P\) is non-trivial, then the Lagrangian bundle \(M\) is not a principal bundle globally and is certainly non-trivial; on the other hand, if the monodromy is trivial, the Lagrangian bundle \(M\) is a principal torus bundle globally, but it still need not be trivial.

More precisely, if the monodromy is zero, then the period lattice \(P \to B\) is trivial in the sense that there is a basis \(\alpha_1, \ldots, \alpha_n\) of \(P_b\) depending smoothly on \(b \in B\). Then for each \(b, b' \in B\) there is a canonical isomorphism between the groups \(T^*_b B/P_b\) and \(T^*_b B/P_{b'}\). Then a smooth action of \(\mathbb{T}^n\) can be defined globally, and \(f : M \to B\) is globally a principal torus bundle. The lack of triviality of \(P \to B\) is described by the monodromy map

\[
H : \pi_1(B, b_0) \to \text{Aut } P_{b_0} \cong \mathbb{GL}(n, \mathbb{Z}),
\]

where \(b_0 \in B\) is fixed, and \(\mathbb{GL}(n, \mathbb{Z})\) is the group of automorphisms of \(\mathbb{Z}^n\). The lattice \(P\) has unique path-lifting, as in the case of covering spaces \([40, 57, 58]\), and the map \(H\) is defined using this property. Namely, for each closed loop \(\gamma\) based at the point \(b_0 \in B\) the image \(H([\gamma])\) is the automorphism of \(P_{b_0}\) which maps the initial point of any lift \(\tilde{\gamma}\) of \(\gamma\) to its terminal point.

We say that period lattices \(P \to B\) and \(P' \to B\) with monodromy maps \(H\) and \(H'\) respectively have the same monodromy if there exists a group isomorphism

\[
I : P_{b_0} \to P'_{b_0},
\]

such that \(H' = IHI^{-1}\). The monodromy map is a complete invariant of period lattices in the sense that if \(P \to B\) and \(P' \to B\) have the same monodromy, then there exists a diffeomorphism

\[
\Phi : P \to P'
\]

commuting with projections on \(B\), and such that \(\Phi|P_{b_0} = I\). However, the existence of such a diffeomorphism \(\Phi : P \to P'\) need not imply that there is a diffeomorphism \(\phi : B \to B\) such that \(\phi_* P' = P\).
Example 1.1.2 (Integer affine structures on the circle) Consider the circle $S^1 = \mathbb{R}/\mathbb{Z}$ with a coordinate $\bar{x} \in \mathbb{R}/\mathbb{Z}$, denote by $\pi : T^*S^1 \rightarrow S^1$ the projection and let $(x, y)$ be standard symplectic coordinates on $T^*S^1$ such that $x = \bar{x} \circ \pi$. Define period lattices $P$ and $P'$ by

$$P = \{(x, y) \in T^*S^1 \mid y \in \mathbb{Z}\} \quad \text{and} \quad P' = \{(x, y) \in T^*S^1 \mid y \in \frac{1}{2}\mathbb{Z}\}.$$

The length of $S^1$ measured by action coordinates in $T^*S^1/P$ and $T^*S^1/P'$ is 1 and 2 respectively, so these integer affine structures are non-equivalent, that is, there is no diffeomorphism $\phi : S^1 \rightarrow S^1$ such that $\phi^*P' = P$. Also the symplectic areas of $T^*S^1/P$ and $T^*S^1/P'$ are 1 and $\frac{1}{2}$ respectively.

Chern and Lagrange classes

The Lagrange class can be seen as measuring the difference between the bundles $f : M \rightarrow B$ and $T^*B/P \rightarrow B$. First we restrict to the case where the monodromy is trivial, which means that the monodromy map $H$ is trivial in the sense that it maps each homotopy class of loops in $B$ to the identity of $\text{GL}(n, \mathbb{Z})$. In this case $f : M \rightarrow B$ is a principal $\mathbb{T}^n$-bundle. Such bundles, but without symplectic structure, are classified by their Chern classes. In the case $n = 1$ the classification is given by the classical theory (Appendix B) with the Chern class taking values in the singular cohomology $H^2(B, \mathbb{Z})$; for $n > 1$ a similar invariant is introduced in the cohomology with coefficients in $\mathbb{Z}^n$. The fact that Lagrangian bundles are $n$-torus bundles with symplectic structure complicates the problem in two ways. First, a given $\mathbb{T}^n$-bundle may or may not admit a symplectic form so as to make the bundle Lagrangian; second, if a $\mathbb{T}^n$-bundle admits a symplectic form, this form is not unique. If $\sigma$ and $\sigma'$ are two such symplectic forms on $M$, then the corresponding bundles are isomorphic if there is a diffeomorphism $\Phi : M \rightarrow M$ such that $\Phi^*\sigma = \sigma$ and $f = f \circ \Phi$. It turns out that Lagrangian bundles up to isomorphisms are described by the Lagrange characteristic class in the first cohomology group of $B$ with coefficients in the sheaf of closed sections of the principal bundle $T^*B/P$ (see Appendix C on preliminaries on sheaf cohomology). This group is related through an exact sequence with cohomology groups of $B$ with integer and real coefficients. If the monodromy is not trivial, the same argument remains true, only instead of cohomology with coefficients in $\mathbb{Z}^n$ the Chern class is an element of the cohomology with coefficients in a sheaf of sections in the period lattice $P \rightarrow B$. This is also called the cohomology with twisted coefficients (see [10] for a simple example). The bundle $T^*B/P$ is a locally principal bundle, and the Lagrange class is an element in the cohomology with coefficients in the sheaf of sections of the locally principal bundle $T^*B/P$.

1.1.4 Summary of the results

The present work continues the study of obstructions to triviality of Lagrangian bundles by Duistermaat [27] and Nguyen [89], providing new geometric proofs and clarifying subtle aspects of the theory. The Lagrange class classifies Lagrangian bundles with fixed integer affine structure. Monodromy is related to the integer affine structure but does not describe the latter completely, as Example 1.1.2 shows. Asking for a complete classification of integer affine structures makes no sense, since this would be similar to asking for a classification of open sets in $\mathbb{R}^n$ up to translation. The problem of classification of Lagrangian bundles can be solved only partially, namely, one can classify period lattices by monodromy, and classify Lagrangian bundles with fixed integer affine structures by the Lagrange class. The role of an
integer affine structure is somewhat latent in \([27, 89]\), and is stressed in this work. We also give a systematic geometric treatment of the classification of Lagrangian bundles with fixed integer affine structure by the Chern and the Lagrange classes.

### 1.1.5 Historical comments

The study of the local geometry of Lagrangian bundles started in the 19-th century with the work of Liouville [54], and the first geometric formulation of the problem and a geometric proof of the Liouville-Arnold theorem were given in the 20-th century by Arnold and Avez [3]. Certain assumptions of Arnold and Avez [3] were later relaxed by Markus and Meyer [55] and by Jost [50]. Some authors also mention the works by Mineur which appeared earlier than Arnold and Avez [3] but remained unknown to a wider audience (see Miranda and Nguyen [63] for a discussion). Other proofs of the Liouville-Arnold theorem can be found in Duistermaat [27], Bates and Śniatycki [6], Audin [5], Abraham and Marsden [1], and others.

Global properties of Lagrangian bundles were studied by Duistermaat in [27], who introduced monodromy and the Lagrange class as obstructions to triviality of Lagrangian bundles. The term ‘Lagrangian class’ (we choose the name ‘Lagrange class’ by analogy with ‘Chern class’) was introduced by Nguyen [89] who elucidated certain aspects of [27] and extended the theory to Lagrangian bundles with singularities. The first example of a Lagrangian bundle with non-trivial monodromy, the spherical pendulum, was found by Cushman and first mentioned by Duistermaat [27]. The interest in global properties of Lagrangian bundles increased after Cushman and Duistermaat [19], and later Child [16], Cushman and Sadovskii [23] discovered that monodromy explains certain phenomena in joint spectra of atoms. Examples of classical and quantum systems with non-trivial monodromy were found by Cushman and Bates [22], Bates [7], Giacobbe, Cushman and Sadovskii [39], Efstathiou [28] and many others. Vù Ngọc [85], Matveev [59] and Nguyen [88] proved that monodromy in 2-dimensional Lagrangian bundles is related to the presence of focus-focus singularities, and systems exhibiting such phenomena as fractional monodromy and bidromy were discovered in Nekhoroshev, Sadovskii and Zhilinskii [64], Sadovskii and Zhilinskii [72]. The work by Miranda and Nguyen [63], Giaccobe [38], Vù Ngọc [86] is devoted to semi-local classification of integrable Hamiltonian systems near singular fibres, and the papers by Nekhoroshev, Sadovskii and Zhilinskii [65], Efstathiou, Cushman and Sadovskii [30] investigate fractional monodromy.

### 1.2 The Liouville-Arnold integrability theorem revisited

In this section we give a geometric proof of the Liouville-Arnold theorem and establish the existence of the integer affine structure on the base space of a Lagrangian bundle, a precise definition of which we give below. We recall that we assume the base manifold \(B\) and fibres of the Lagrangian bundle to be (pathwise) connected [40].

**Definition 1.2.1 (Lagrangian bundle)** Let \((M, \sigma)\) be a connected \(2n\)-dimensional symplectic manifold, and \(B\) be a connected \(n\)-dimensional smooth manifold. Then a surjective map \(f : M \rightarrow B\) is called a Lagrangian bundle if it has the following properties:

1. \(df\) has maximal rank everywhere on \(M\).

2. Fibres of \(f\) are connected compact Lagrangian submanifolds of \(M\).
Definition 1.2.1 does not require apriori that a Lagrangian bundle is locally trivial (see Appendix B on bundles). We prove local triviality in Section 1.2.1.

**Theorem 1.1 (Liouville-Arnold) [27]** Let \( f : M \to B \) be a Lagrangian bundle and \( b \in B \). Then there exists an open neighborhood \( V \subset B \) of \( b \) and coordinates \( (I_1, \ldots, I_n, \varphi_1, \ldots, \varphi_n) \) on \( f^{-1}(V) \) such that:

1. Each \( I_j \) factors through \( B \), that is: there exist functions \( x_j \) on \( B \) such that \( I_j = x_j \circ f \), and \( dx_1, \ldots, dx_n \) are linearly independent.
2. Each \( \varphi_j \) takes values in \( \mathbb{T}^1 = \mathbb{R}/\mathbb{Z} \),
3. The coordinates \( (I, \varphi) \) are symplectic, that is
   \[
   \sigma|_{f^{-1}(V)} = \sum_{j=1}^{n} d\varphi_j \wedge dI_j. \quad (1.2.1)
   \]
4. The coordinates \( I \) are unique up to an integer affine transformation in \( \mathbb{R}^n \rtimes GL(n, \mathbb{Z}) \).
5. Given \( I \), the coordinates \( \varphi \) are determined by the choice of a Lagrangian submanifold on which all \( \varphi_i \) are zero.

The coordinates \( (I, \varphi) \) are called *action-angle* coordinates. The Lagrangian submanifold in item 5 plays the role of the ‘zero section’ in the bundle \( M \), and action-angle coordinates \( (I, \varphi) \) play the role of local trivializations of a Lagrangian bundle, making it locally a principal \( n \)-torus bundle. Our proof of Theorem 1.1 is based on the idea of Duistermaat [27] to use the natural fibrewise action of \( T^*B \) on \( M \) to construct local trivializations and is given in section 1.2.2.

### 1.2.1 Local topological triviality of Lagrangian bundles

We show that a Lagrangian bundle \( f : M \to B \) (Definition 1.2.1) is locally topologically trivial with smooth trivializations. Denote by \( F_b = f^{-1}(b) \) the fibre at \( b \in B \).

**Proposition 1.2.1 (Local triviality of Lagrangian bundles)** A Lagrangian bundle \( f : M \to B \) is locally trivial, that is, for each \( b \in B \) there exists an open neighborhood \( V \subset B \) and a diffeomorphism

\[
\phi_V : f^{-1}(V) \to V \times F_b \quad (1.2.2)
\]

commuting with projections on \( V \).

**Proof.** Since \( F_b \) is compact, it has a tubular neighborhood \( \mathcal{W} \) in \( M \) [47] with a smooth retraction map

\[
r : \mathcal{W} \to F_b,
\]

that is, \( r|_{F_b} = \text{id} \). We show that the map

\[
(f, r) : \mathcal{W} \to f(\mathcal{W}) \times F_b : p \mapsto (f(p), r(p)),
\]

is a local trivialization of \( f \) over \( \mathcal{W} \).
which makes the following diagram commutative,

\[
\begin{array}{ccc}
W & \xrightarrow{(f,r)} & f(W) \times F_b \\
\downarrow f & & \downarrow \text{pr}_1 \\
W & \xrightarrow{id} & f(W)
\end{array}
\]

is a diffeomorphism near \(F_b\). Indeed, since \(df\) has maximal rank everywhere on \(M\) and \(r|F_b = \text{id}\), \(d(f,r)\) has maximal rank on \(F_b\), by the Inverse Function theorem \([1]\) \((f,r)\) is a local diffeomorphism near each point of \(F_b\). This means that each \(p \in F_b\) has an open neighborhood \(O_p \subset W\) such that \((f,r)|O_p\) is a diffeomorphism. Then \((f,r)\) has maximal rank on \(\mathcal{O} = \bigcup_{p \in F_b} O_p\), and to prove that it is a diffeomorphism near \(F_b\) we only have to show that \((f,r)\) is injective on a neighborhood \(W \subset \mathcal{O}\). This is the content of the following lemma.

**Lemma 1.2.1 (Trivializing neighborhood of \(F_b\))** There exists an open neighborhood \(W \subset \mathcal{O}\) of \(F_b\) such that the restricted map \((f,r)|W\) is injective.

**Proof.** Suppose there is no such neighborhood, and consider a decreasing sequence \(\{W_j\}_{j \in \mathbb{N}}\) of relatively compact neighborhoods of \(F_b\) such that

\[
\bigcap_j W_j = F_b.
\]

Then there exist sequences of points \(p_j, p'_j \in W_j\) such that

\[
p_j \neq p'_j \quad \text{and} \quad (f,r)(p_j) = (f,r)(p'_j).
\]

(1.2.3)

Passing to a subsequence, we may assume that both \(p_j\) and \(p'_j\) converge to \(p\) and \(p'\) respectively, then by continuity \((f,r)(p_j)\) converges to \((f,r)(p) = (f,r)(p') \in F_b\). Since \((f,r)\) is injective on \(F_b\) this implies \(p = p'\). Fix an open neighborhood \(O_p\) of \(p\) such that \((f,r)|O_p\) is a diffeomorphism. Then there exists a number \(j \in \mathbb{N}\) such that \(p_j, p'_j \in O_p\), so \(p_j \neq p'_j\) implies \((f,r)(p_j) \neq (f,r)(p'_j)\) which contradicts (1.2.3). This means that there exists a neighborhood \(W\) of \(F_b\) such that \((f,r)|W\) is injective.

\[\square\]

Returning to the proof of Proposition 1.2.1 we now choose a neighborhood \(V \subset B\) of \(b\) such that \(f^{-1}(V) \subset W\). Then the restriction

\[
\phi_V = (f,r) : f^{-1}(V) \to V \times F_b
\]

is a local trivialization of \(f : M \to B\).

\[\square\]

It should be noted that Proposition 1.2.1 is just the Ehresmann theorem \([34]\).

### 1.2.2 Proof of the Liouville-Arnold theorem

In this section we prove the Liouville-Arnold theorem 1.1, using the natural action of fibres of \(T^*B\) on fibres of \(M\), as it was described in Section 1.1.3.
**Action of fibres of $T^*B$ on fibres of $M$**

To construct the action of fibres of $T^*B$ on fibres of $M$, for each $b \in B$ we will define the map

$$s_b : T^*_b B \to \text{Diff}(F_b),$$

where $F_b = f^{-1}(b)$, such that

$$s_b(\alpha + \beta) = s_b(\alpha) \circ s_b(\beta).$$

Then $T^*_b B$, regarded as an additive group, acts on $F_b$ by diffeomorphisms

$$T^*_b B \times F_b \to F_b : (\alpha, p) \mapsto s_b(\alpha)(p),$$

and the action is transitive but not free. We study the isotropy group $P_b$ of the action, identify the fibre $F_b$ with the $n$-torus $T^*_b B/P_b$ and show that there is a free smooth action of the $n$-torus on a small neighborhood of $F_b$.

**Definition of the action**

Fix a point $b \in B$. To obtain the map $s_b$ we first define the map

$$S_b : T^*_b B \to \mathcal{X}(F_b), \quad (1.2.4)$$

where $\mathcal{X}(F_b)$ denotes the set of vector fields on the fibre $F_b$, and obtain $s_b$ by taking the time 1 map of a vector field $S_b(-)$ in (1.2.4). To define $S_b(\alpha)$ for $\alpha \in T^*_b B$ choose a smooth function $h : B \to \mathbb{R}$ such that $dh(b) = \alpha$, and set

$$S_b(\alpha) = X_{ho f}|F_b, \quad (1.2.5)$$

where $X_{ho f}$ is the Hamiltonian vector field associated to the function $h \circ f$ on $M$ by

$$\sigma(X_{ho f}, -) = -d(h \circ f)(-), \quad (1.2.6)$$

and $X_{ho f}|F_b$ denotes the restriction of the vector field to the fibre $F_b$. The following lemma shows that the map $S_b$ is well-defined, i.e. the vector field $S_b(\alpha)$ is tangent to the fibre $F_b$, and $S_b(\alpha)$ does not depend on the choices made in the definition.

**Lemma 1.2.2 (S_b is well-defined)** The map

$$S_b : T^*_b B \to \mathcal{X}(F_b) : \alpha \mapsto X_{ho f}|F_b$$

is well-defined, that is, given $\alpha \in T^*_b B$:

1. For any choice of a function $h : B \to \mathbb{R}$ such that $dh(b) = \alpha$, the Hamiltonian vector field $X_{ho f}$ is tangent to fibres of $M$.
2. The restriction $X_{ho f}|F_b$ depends only on $\alpha$, and not on the choice of the function $h$. 

9
Proof. To prove the first item notice that for any vector field $Y$ on $F_b$ we have

$$d(h \circ f)(Y) = -\sigma(X_{ho f}, Y) = 0,$$

which implies that at each $p \in M$ we have $X_{ho f}(p) \in T_{F_b} F_b^\sigma$, where $T_{F_b} F_b^\sigma$ denotes the skew-orthogonal complement of $T_{F_b} F_b$ (Appendix A). Since fibres of $M$ are Lagrangian, $T_{F_b} F_b^\sigma = T_{F_b} F_b$, so $X_{ho f}$ is tangent to fibres of $M$. The fact that the restriction $X_{ho f}|_{F_b}$ depends only on $\alpha \in T^*_b B$ follows from the fact that the restriction of the 1-form $d(h \circ f)$ to $F_b$ depends only on $\alpha$ (see (1.2.6)). \Box

Remark 1.2.1 (Involutivity of first integrals) For any two functions $h, h' : B \to \mathbb{R}$ we have by Lemma 1.2.2

$$\{h' \circ f, h \circ f\} = \sigma(X_{h' \circ f}, X_{h \circ f}) = 0, \quad (1.2.7)$$

i.e. the functions $h \circ f$ and $h' \circ f$ are in involution. This means that any two functions on $M$ which factor through $B$ are first integrals of each other (see Section 2.1 for the definition of the first integral).

We also show that $S_b$ is linear, and the image of $S_b$ in $\mathcal{X}(F_b)$ consists of vector fields with commuting flows, i.e. [66, 77]

$$[S_b(\alpha), S_b(\beta)] = 0.$$

This is the content of the following lemma.

Lemma 1.2.3 (Linearity of $S_b$) The map

$$S_b : T^*_b B \to \mathcal{X}(F_b) : \alpha \mapsto X_{ho f}|_{F_b}$$

has the following properties:

1. $S_b$ is linear,
2. If $\alpha$ is non-zero, then $S_b(\alpha)$ is nowhere zero on $F_b$,
3. For any $\alpha, \beta \in T^*_b B$

$$[S_b(\alpha), S_b(\beta)] = 0, \quad (1.2.8)$$

so the flows of $S_b(\alpha)$ and $S_b(\beta)$ commute.

Proof. The items 1 and 2 follow from bilinearity of the symplectic form $\sigma$ and the definition (1.2.6) of the vector field $X_{ho f}$. To prove the third item, let $\beta \in T^*_b B$ and let $h' : B \to \mathbb{R}$ be such that $dh'(b) = \beta$. Then by the properties of the Poisson bracket $\{,\}$ (Appendix A) and Remark 1.2.1 we have

$$[S_b(\alpha), S_b(\beta)] = [X_{ho f}|_{F_b}, X_{h' \circ f}|_{F_b}] = X_{\{h \circ f, h' \circ f\}|_{F_b}} = 0.$$ \Box
Taking the time 1 map \( (S_b(-))_1 \) of the vector field in (1.2.4) we obtain the map

\[ s_b : T^*_b B \to \text{Diff}(F_b) : \alpha \mapsto (S_b(\alpha))_1. \tag{1.2.9} \]

The fibre \( F_b \) is compact, so any vector field \( S_b(\alpha) \) is complete and the time 1 map \( (S_b(\alpha))_1 \) is defined for any \( \alpha \). To show that \( s_b \) defines an action of \( T^*_b B \) as an additive group we will prove that for any \( \alpha, \beta \in T^*_b B \)

\[ s_b(\alpha + \beta) = s_b(\alpha) \circ s_b(\beta), \tag{1.2.10} \]

in the following lemma.

**Lemma 1.2.4 (Additivity of \( T^*_b B \)-action)** For any \( \alpha, \beta \in T^*_b B \) we have

\[ s_b(\alpha + \beta) = s_b(\alpha) \circ s_b(\beta), \tag{1.2.10} \]

where \( s_b : T^*_b B \to \text{Diff}(F_b) \) is given by (1.2.9).

**Proof.** By Lemma 1.2.3 for any \( \alpha, \beta \in T^*_b B \) the flows of \( S_b(\alpha) \) and \( S_b(\beta) \) commute, so (1.2.10) holds (see [66]).

By Lemma 1.2.4 each element \( \alpha \in T^*_b B \) acts on \( F_b \) by the diffeomorphism \( s_b(\alpha) \), i.e. there is a map

\[ T^*_b B \times F_b \to F_b : (\alpha, p) \mapsto s_b(\alpha)(p). \]

**Terminology 1.2.1 (Action of \( T^*_b B \) on \( F_b \))** The map \( s_b \) is the action of \( T^*_b B \) on \( F_b \), and \( s_b(-)(p) \) is the map from \( T^*_b B \) to \( F_b \), determined by \( p \in F_b \); by Lemma 1.2.5 this map is surjective.

By the hypothesis fibres of \( M \) are connected, which implies that the action \( s_b \) is transitive. This is the content of the following lemma.

**Lemma 1.2.5 (Transitivity of \( T^*_b B \)-action)** The action \( s_b \) is transitive, that is, for any \( p, p' \in F_b \) there exists an element \( \alpha \in T^*_b B \) such that

\[ s_b(\alpha)(p) = p'. \]

**Proof.** Fix \( p \in F_b \), then the derivative of the map

\[ s_b(-) : T^*_b B \to F_b \tag{1.2.11} \]

has maximal rank, so \( s_b(-)(p) \) is a local diffeomorphism. This implies that the orbit of the action through \( p \), i.e. the image of (1.2.11) in \( F_b \), is open in \( F_b \). Suppose the action \( s_b \) is not transitive, then \( F_b \) is a union of two or more disjoint orbits which are open sets in \( F_b \). This contradicts the assumption that \( F_b \) is connected \([1, 40]\), hence \( s_b \) is transitive.

\[ \square \]
Remark 1.2.2 (Smooth dependence on point in the base) We notice that the action \( s_b \) depends smoothly on the point \( b \) in the base space \( B \). In particular, and this will be of importance later in this section, the smooth action of fibres of \( T^*B \) can be defined on a small neighborhood of \( F_b \). Choose \( V \subset B \) open, \( b \in V \), such that both bundles \( M \) and \( T^*B \) are trivial when restricted to \( V \), and let \( z : V \to M \) be a smooth local section. Then define the map

\[
K : T^*(V) \to f^{-1}(V),
\]

where \( T^*(V) \) stands for the restriction \( T^*B|_V \), i.e. the set of all covectors with base point in \( V \subset B \), by

\[
K(b', \alpha) = s_b(\alpha)z(b'),
\]

where \((b', \alpha)\) denotes an element \( \alpha \in T^*_bB \). The map \( K \) has maximal rank and is a local diffeomorphism [1] near each \( \alpha \in T^*(V) \). We will use this map later in this section to construct local trivializations of the bundle \( M \).

The isotropy subgroup of the action

Since the fibre \( F_b \) is compact, and the cotangent space \( T^*_bB \) is not compact, the action \( s_b \) is not free. The isotropy group of the action is the subgroup

\[
P_b = \{ \alpha \in T^*_bB \mid s_b(\alpha)(p) = p \}.
\]

Since the action \( s_b \) is transitive and commutative, the isotropy group \( P_b \) does not depend on the point \( p \in F_b \) [2]. The following lemma proves that \( P_b \) is a lattice in \( T^*_bB \), i.e. \( P_b \) is a discrete subgroup of \( T^*_bB \) isomorphic to \( \mathbb{Z}^n \).

Lemma 1.2.6 (Isotropy subgroup) The isotropy subgroup \( P_b \subset T^*_bB \) is a lattice in \( T^*_bB \), that is, there exist linearly independent elements \( \gamma_1, \ldots, \gamma_n \in T^*_bB \) such that

\[
P_b = \{ \ell_1 \gamma_1 + \cdots + \ell_k \gamma_n \mid \ell_j \in \mathbb{Z} \}. \tag{1.2.12}
\]

Proof. For each \( p \in F_b \) the map \( s_b(-)(p) \) is a local diffeomorphism at each point in \( T^*_bB \), hence each \( \alpha \in P_b \) has an open neighborhood in \( T^*_bB \) which contains no other point of \( P_b \), i.e. \( P_b \) is a discrete subgroup of \( T^*_bB \). It follows [2, 6] that there exists \( k \leq n \) linearly independent elements \( \gamma_1, \ldots, \gamma_k \in T^*_bB \) such that for each \( \alpha \in P_b \)

\[
\alpha = \sum_{i=1}^{k} \ell_i \gamma_i, \quad \text{where} \quad \ell_j \in \mathbb{Z}.
\]

Dividing by \( P_b \) we obtain a diffeomorphism

\[
s_b(-)(p) : T^*_bB/P_b \to F_b,
\]

denoted by the same symbol as the similar map of \( T^*_bB \). Since \( F_b \) is compact, the quotient \( T^*_bB/P_b \) must be compact. This implies that \( k = n \), i.e. \( P_b \) is generated by \( n \) elements.

\[ \square \]
Remark 1.2.3 (Identification of isotropy group with $\mathbb{Z}^n$) The isomorphism between the lattice $P_b$ and $\mathbb{Z}^n$ is determined by the choice of a basis $\gamma_1, \ldots, \gamma_n$ of the lattice. Such a basis is not unique, and any two bases of $P_b$ are related by a linear transformation in $\text{GL}(n, \mathbb{Z})$.

The action of the quotient $T_b^* B / P_b$ on $F_b$, given by

$$T_b^* B / P_b \times F_b \to F_b : ([\alpha], p) \mapsto s_b(\alpha)(p),$$

is transitive and free. The map

$$s_p = s_b(-)(p) : T_b^* B / P_b \to F_b$$

is a diffeomorphism, depending on the choice of the point $p \in F_b$.

Terminology 1.2.2 (Action of $T_b^* B / P_b$ on $F_b$) As for $T_b^* B$, we denote by $s_b$ the action of $T_b^* B / P_b$ on $F_b$. We also call the maps $s_b(-)(p)$ given by (1.2.13) preferred identifications of $T_b^* B / P_b$ with $F_b$.

The quotient $T_b^* B / P_b$ is isomorphic to $\mathbb{T}^n$, and the fibre $F_b$ can also be identified with $\mathbb{T}^n$, which is done in the following lemma.

Lemma 1.2.7 (Identification of the quotient with the standard torus) Given a basis $\gamma = (\gamma_1, \ldots, \gamma_n)$ in $P_b$, there is a corresponding group isomorphism

$$\gamma^* : T_b^* B / P_b \to \mathbb{T}^n.$$  (1.2.14)

Proof. The choice of a basis $\gamma_1, \ldots, \gamma_n$ of $P_b$ determines the isomorphism

$$\gamma^* = (\gamma_1^*, \ldots, \gamma_n^*) : T_b^* B \to \mathbb{R}^n,$$

where $\gamma_i^*$, $i = 1, \ldots, n$, stand for linear coordinates on $T_b^* B$ so that $\gamma^*_i(\gamma_j) = \delta_{ij}$, and which maps $P_b$ onto the subgroup $\mathbb{Z}^n \subset \mathbb{R}^n$. Dividing by the lattice $P_b$ we obtain the identification

$$\gamma^* : T_b^* B / P_b \to \mathbb{T}^n,$$  (1.2.15)

of the fibre $T_b^* B / P_b$ with the standard $n$-torus, which we again denote by $\gamma^*$.

Terminology 1.2.3 (Identification of fibres of $M$ with standard tori) Given a point $p \in F_b$ and an isomorphism $\gamma^*$ (1.2.14), there is an isomorphism

$$\gamma^* \circ s_p^{-1} : F_b \to \mathbb{T}^n,$$  (1.2.16)

which we call the preferred diffeomorphism between $F_b$ and $\mathbb{T}^n$. 

13
Definition 1.2.2 (Integer affine structure) An integer affine structure on a manifold $F$ is given by an atlas, i.e. a collection of local charts covering $F$, such that the transition maps between these charts are transformations in the semi-direct product $\mathbb{R}^n \rtimes \text{GL}(n, \mathbb{Z})$. We call the transformations in $\mathbb{R}^n \rtimes \text{GL}(n, \mathbb{Z})$ integer affine transformations. Let $F$ and $F'$ be manifolds with integer affine structures. A diffeomorphism $g : F \to F'$ preserves the integer affine structure if for any $p \in F$ and any integer affine chart $(V, \psi)$ on $F'$ such that $g(p) \in V$, there exists an integer affine chart $(U, \phi) \subset F$ with $p \in U$ such that $\psi \circ g \circ \phi^{-1} \in \mathbb{R}^n \rtimes \text{GL}(n, \mathbb{Z})$ and the same holds for its inverse. In this case integer affine structures on $F$ and $F'$ are called isomorphic.

Remark 1.2.4 (Integer affine structure on fibres of Lagrangian bundles) The preferred diffeomorphisms (1.2.16) are determined up to an integer affine transformation, where an element in $\text{GL}(n, \mathbb{Z})$ corresponds to the choice of a basis in the lattice $P_b$ (Remark 1.2.3), and a translation in $\mathbb{R}^n$ corresponds to the choice of a point $p \in F_b$. This means that the preferred diffeomorphisms give the fibre $F_b$ an integer affine structure.

Smooth local torus action on fibres of $M$

We prove that the isotropy group $P_b$ smoothly depends on a point $b \in B$, which implies that the quotient $T_b^* B / P_b$ also smoothly depends on $b$. This implies that locally there is a smooth action of fibres of $T^* B / P$ on $M$. We prove these facts in the rest of this section.

Choose a small open neighborhood $V \subset B$ of $b$ and a smooth local section $z : V \to M$, so that (Remark 1.2.2) there is a local diffeomorphism

$$K : T^*(V) \to f^{-1}(V) : (b', \alpha) \mapsto s_b(\alpha)(z(b')),$$

determined by $z$. For each $b' \in V$ the lattice $P_{b'}$ is the preimage of the point $z(b')$. Consider the set

$$P = \bigcup_{b \in B} P_b,$$

and denote by $g = \pi|P$ the restriction of $\pi : T^* B \to B$ to $P$. We call the bundle $g : P \to B$ the period lattice. The restriction $P|V$, for which in what follows we write $P(V)$, is the preimage of $z(V)$ under the local diffeomorphism $K$. It follows that $P$ is a closed smooth $n$-dimensional submanifold of $T^* B$ and the map $g$ is a local diffeomorphism [1]. Moreover, it turns out that $g : P \to B$ is a locally trivial bundle with fibre $\mathbb{Z}^n$ (Appendix B.1), as is proven in the following lemma.

Lemma 1.2.8 (Local triviality of $P$) The projection $g : P \to B$ is a locally trivial bundle with fibre $\mathbb{Z}^n$, that is, for $b \in B$ there exists an open neighborhood $V \subset B$ and a homeomorphism

$$\psi_V : V \times \mathbb{Z}^n \to P(V),$$

(1.2.17)

commuting with projections on $V$.

Proof. Let $\gamma_1, \ldots, \gamma_n$ be a basis of $P_b$, and $s_1, \ldots, s_n$ be the sections of $P$ through $\gamma_1, \ldots, \gamma_n$ respectively. We can find an open neighborhood $V$ of $b$ such that for each $s_i, i = 1, \ldots, n$, the restriction $g|s_i(V)$ is a diffeomorphism, and such that for $b' \in V$ the elements $s_1(b'), \ldots, s_n(b')$
are linearly independent. Then for any integral linear combination \( s = \sum_{i=1}^{n} \ell_i s_i, \ell_i \in \mathbb{Z} \), the restriction \( g|s(V) \) is also a diffeomorphism. Define the map (1.2.17) by

\[
\psi_V(b', \ell) = \ell_1 s_1(b') + \cdots + \ell_n s_n(b'), \quad \ell = (\ell_1, \ldots, \ell_n) \in \mathbb{Z}^n.
\]

This map is injective since the sections \( s_1, \ldots, s_n \) are linearly independent. We next prove that \( \psi_V \) is surjective, i.e. \( s_1, \ldots, s_n \) is a basis of sections in \( P(V) \). Assume that there exists \( \beta \in P(V) \) which is not in the image of \( \psi_V \). The elements \( s_i(g(\beta)), i = 1, \ldots, n, \) are in the lattice \( P_{g(\beta)} \) and form a basis in \( T_{g(\beta)}B \) over \( \mathbb{R} \). Without loss of generality we may assume that \( \beta \) is not an integral multiple of any other element in \( P \). Then there exists a basis \( (\beta_1, \ldots, \beta_n = \beta) \) of \( P_{g(\beta)} \) [2], and

\[
s_i(g(\beta)) = \sum_{j=1}^{n} m_{ij} \beta_j, \quad \text{where} \quad m_{ij} \in \mathbb{Z}.
\]

The matrix \( (m_{ij}) \) is invertible over \( \mathbb{R} \) and its inverse has rational coefficients by the Cramer rule. Therefore,

\[
\beta = \sum_{i=1}^{n} \lambda_i s_i(g(\beta)), \quad \text{where} \quad \lambda_i \in \mathbb{Q},
\]

and, since \( \beta \) is not in the image of \( \psi_V \), not all \( \lambda_i \) are integers. Choose a continuous curve \( c : [0, 1] \to V \) such that \( c(0) = g(\beta) \) and \( c(1) = b \). On a small neighborhood of \( c(0) \) we can lift the curve \( c(t) \) to a continuous curve \( \tilde{c}(t) \) in \( P \) through \( \beta \) by a local section, so

\[
\tilde{c}(t) = \sum_{i=1}^{n} \lambda_i(t) s_i(c(t)).
\]

We note that, as before, \( \lambda_i(t) \) have to be rational and continuous in \( t \). This means that the \( \lambda_i(t) \) are independent of \( t \). From this it follows that the local lift \( \tilde{c}(t) \subset P \) can be extended over the whole interval \([0, 1]\). This implies that

\[
\tilde{c}(1) = \sum_{i=1}^{n} \lambda_i s_i(b) = \sum_{i=1}^{n} \lambda_i \gamma_i \in P_b,
\]

which is a contradiction. It follows that \( \psi_V \) is surjective. Thus \( \psi_V \) is a homeomorphism.

\[\square\]

**Remark 1.2.5 (Unique path-lifting)** It follows from Lemma 1.2.8 that, like covering spaces [40, 58], the period lattice \( g : P \to B \) has unique path-lifting, i.e., given a continuous curve \( c(t) \) in the base \( B \) and a point \( \alpha \in P_{c(0)} \) there is a unique continuous curve \( \tilde{c}(t) \) in \( P \) such that \( \tilde{c}(0) = \alpha \) and \( g \circ \tilde{c} = c \).

Now, both \( T^*(V) \) and \( P(V) \) are trivial, i.e. there are local bundle isomorphisms

\[
V \times \mathbb{R}^n \to T^*(V), \quad \text{and} \quad V \times \mathbb{Z}^n \to P(V),
\]

and it follows that there is a diffeomorphism

\[
T^*(V)/P(V) \to V \times \mathbb{T}^n,
\]

where \( T^*(V)/P(V) \) stands for the restriction \( T^*B/P|V \). This means that \( T^*B/P \) is a smooth manifold and \( \tau : T^*B/P \to B \) is a locally trivial bundle with fibre \( \mathbb{T}^n \). Fibres of the bundle \( T^*B/P \) are groups acting on fibres of the bundle \( M \) with the same base and, since \( T^*B/P \) is locally trivial, the action of fibres of \( T^*B/P \) on fibres of \( M \) is locally smooth.
Terminology 1.2.4 (Locally principal bundles $T^*B/P$ and $M$) Recall (Appendix B) that a bundle $\pi : E \to B$ is called a principal bundle with group $G$ if there is a fibre-preserving, smooth and free action of $G$ on $E$, which is transitive on fibres. In our case a local identification of fibres in $T^*B/P$ is induced by the identification of fibres in the period lattice $P$, which by continuity is unique. This means that there is a smooth local action of the $n$-torus $T^n b$ on $T^*B/P$ and $M$ near $T^n b$ and $F_b$ respectively, so $T^*B/P$ and $M$ locally are principal bundles.

The map $K : T^*(V) \to f^{-1}(V)$ defined in Remark 1.2.2 factors on $V$ to a diffeomorphism

$$K : T^*(V)/P(V) \to f^{-1}(V)$$

which we denote by the same symbol and which, as the map in Remark 1.2.2, is determined by the choice of a local section $z : V \to M$.

Terminology 1.2.5 (Smooth local trivializations of $M$) The maps $K$ can be viewed as local bundle isomorphisms between $T^*B/P$ and $M$, which are in one-to-one correspondence with smooth local sections $z : V \to M$. There is a similar situation in principal circle bundles (Appendix B): a local trivialization of a principal circle bundle $\pi : S \to B$ can be regarded as a local isomorphism between $S$ and the trivial bundle $B \times T^1 \to B$, and the trivializations are in one-to-one correspondence with local sections in $S$. By analogy we call $K$ or $z$ smooth local trivializations of the Lagrangian bundle $f : M \to B$.

Terminology 1.2.6 (Transition maps of smooth trivializations of $M$) In a Lagrangian bundle $f : M \to B$ let $V$ be a simply connected neighborhood of $b$ (such a neighborhood always exists, see Appendix C.3 or [45]), and let $z, z' : V \to M$ be smooth local section with corresponding trivializations. Then there exists a differential 1-form $\beta$ on $V$ determined up to a local section in $P(V)$ such that for each $b' \in V$

$$z'(b') = s_{b'}(\beta(b'))(z(b')).$$

Thus, like in a principal circle bundle (Appendix B), the difference between two trivializations of $M$ is determined by a local section in the bundle $T^*B/P$ of groups, acting on fibres of $M$, i.e. such sections occurs as transition maps of $M$. This resemblance to principal bundles will be used in Section 1.3 to define obstructions to triviality of Lagrangian bundles.

Local symplectic identification of $T^*B/P$ and $M$

In this section we will show that local trivializations

$$K : T^*(V)/P(V) \to f^{-1}(V) \quad (1.2.18)$$

constructed in Section 1.2.2, can be chosen to be symplectic. For that we have to prove that the quotient manifold $T^*B/P$ is symplectic. This is achieved in the following sequence of steps: we show that the smooth map

$$K : T^*(V) \to f^{-1}(V),$$

constructed in Remark 1.2.2 in Section 1.2.2, is symplectic if and only if the section $z : V \to M$, which determines the map, is Lagrangian. The necessity is straightforward: if $K$
is symplectic, then it has to map the Lagrangian zero section \( V \subset T^*(V) \) onto a Lagrangian submanifold of \( M \); hence \( K \) can only be symplectic if the section \( z : V \to M \) is Lagrangian. We will show that \( z \) being Lagrangian is sufficient for \( K \) to be symplectic. Then the preimage \( P(V) \) of the Lagrangian section \( z(V) \) under \( K \) is a Lagrangian submanifold of \( T^*B \). It will then follow that the quotient \( T^*B/P \) by the Lagrangian period lattice \( P \) has the induced symplectic structure from \( T^*B \), and the trivialization (1.2.18) is symplectic if and only if \( z : V \to M \) is Lagrangian.

Recall the construction of \( K \) for a given \( z \) from Remark 1.2.2 in Section 1.2.2, only now take \( z \) Lagrangian. For this choose local coordinates \((x_1, \ldots, x_n)\) on \( B \). Then \( dx_1, \ldots, dx_n \) are linearly independent, and for each \( b \) in the coordinate neighborhood the frame \( dx_1(b), \ldots, dx_n(b) \) is a basis of \( T^*_bB \). The functions \( a_j = x_j \circ f \) are pairwise in involution (section 1.2.2 Remark 1.2.1), so by the Darboux theorem (Appendix A) there exist local functions \( \eta = (\eta_1, \ldots, \eta_n) \) on \( M \) (not unique) such that the coordinate system \((a, \eta)\) is symplectic, i.e.

\[
\sigma = \sum_{i=1}^n d\eta_i \wedge da_i.
\]

Now choose a local ‘zero section’ \( z : V \to M \) in such a way that

\[
z(V) = \{\eta = 0\}.
\]

Such a section \( z \) is Lagrangian (Appendix A), and for each \( dx_i, i = 1, \ldots, n, \) on \( V \) we have

\[
\frac{\partial}{\partial \eta_i} \bigg|_{F_b} = S_b(dx_i(b)),
\]

where \( S_b : T^*_bB \to \mathcal{X}(F_b) \) is defined in Section 1.2.2. As before, the map \( K \) is given by

\[
K : T^*(V) \to f^{-1}(V) : (b, \alpha) \mapsto s_b(\alpha)(z(b)),
\]

where \( s_b(\alpha) = (S_b(\alpha))_1 \) is the time 1 map (section 1.2.2).

**Remark 1.2.6 (Expression of \( K \) in local coordinates)** We obtain the expression for \( K \) in local coordinates near the zero section \( V \subset T^*(V) \). We can do this only locally since the coordinates \((a, \eta)\) are local. By (1.2.19) and the definition of the map \( s_b \) (Section 1.2.2) we have for \( b \in V \) and small \( \lambda_i, i = 1, \ldots, n, \)

\[
s_b \left( \sum_{i=1}^n \lambda_i dx_i \right)(a_1, \ldots, a_n, 0, \ldots, 0) = (a_1, \ldots, a_n, \lambda_1, \ldots, \lambda_n).
\]

Let \((x, y)\) be canonical symplectic coordinates on \( T^*(V) \) (Appendix A), and recall that in these coordinates we have

\[
y_j \left( \sum_{i=1}^n \lambda_i dx_i \right) = \lambda_j, \quad j = 1, \ldots, n.
\]

Then (1.2.20) yields that near the zero section \( V \subset T^*(V) \) the map \( K \) is expressed in local coordinates by

\[
a_i \circ K = x_i, \quad \eta_i \circ K = y_i,
\]

which implies that, if \( z \) is Lagrangian, \( K \) preserves the symplectic structure at the points near the zero section in \( T^*(V) \).
The following lemma shows that \( z \) being Lagrangian is sufficient for \( K \) to be symplectic.

**Lemma 1.2.9 (Symplectic maps between \( T^*B \) and \( M \))** Provided \( z : V \to M \) is a Lagrangian section, the map

\[
K : T^*(V) \to f^{-1}(V) : (b, \alpha) \mapsto s_b(\alpha)(z(b)),
\]

where \( s_b : T^*_bB \to \text{Diff}(F_b) \) is given by (1.2.9), is symplectic.

**Proof.** By Remark 1.2.6 \( K \) is symplectic at points near the zero section in \( T^*(V) \). It follows that \( K \) is symplectic everywhere on \( T^*(V) \). To see this for \( \alpha \in T^*_B \) choose \( h : B \to \mathbb{R} \) such that \( dh = \alpha \). The function \( h \circ \pi \) depends only on a point in the base, and the Hamiltonian vector field \( X_{h \circ \pi} \) is tangent to fibres of \( T^*(V) \). Moreover,

\[
(X_{h \circ \pi})_1(b, 0) = (b, \alpha),
\]

where \( (X_{h \circ \pi})_1 \) denotes the time one map. Recall from the definition of \( K \) (Section 1.2.2) that

\[
K(b, \alpha) = (S_b(\alpha))(z(b)) = (X_{h \circ \pi})_1(z(b)),
\]

so the following diagram is commutative.

\[
\begin{array}{ccc}
(b, \alpha) \in T^*(V) & \overset{K}{\longrightarrow} & K(b, \alpha) \in f^{-1}(V) \\
(X_{h \circ \pi})_1 \uparrow \ & & \uparrow (X_{h \circ \pi})_1 \\
(b, 0) \in T^*(V) & \overset{K}{\longrightarrow} & z(b) \in f^{-1}(V)
\end{array}
\]

Since \( K \) is symplectic near the points of the zero section in \( T^*(V) \), and the flows of the Hamiltonian vector fields \( X_{h \circ \pi} \) and \( X_{h \circ f} \) preserve the symplectic form, \( K \) is symplectic near \( \alpha \) and hence everywhere on \( T^*(V) \).

\[\square\]

We use the properties of \( K \) to prove that the period lattice \( P \) is a Lagrangian submanifold of \( T^*B \), and the quotient \( T^*B/P \) is a symplectic manifold.

**Lemma 1.2.10 (Induced symplectic structure)** The following holds:

1. The period lattice \( P \) is a Lagrangian submanifold of \( T^*B \).

2. The fibrewise quotient \( T^*B/P \) by the period lattice \( P \) has an induced symplectic structure, making the projection \( T^*B \to T^*B/P \) a symplectic map.

**Proof.**

1. Let \( z : V \to M \) be a Lagrangian section, and \( K : T^*(V) \to f^{-1}(V) \) be the corresponding map. Then \( P(V) \) is a preimage of \( z(V) \) under \( K \). Since \( z(V) \) is Lagrangian, and \( K \) is symplectic, \( P(V) \) is a Lagrangian submanifold.
2. Let \( \alpha \in T^*B/P \), and let \( O \subset T^*B/P \) be a trivializing neighborhood of \( [\alpha] \) in the bundle \( q : T^*B \to T^*B/P \), such that \( \tau(O) = V \). Choose a local section \( m : O \to T^*B \) and define the symplectic form \( \omega' \) on \( T^*B/P \) by

\[
\omega' = m^*\omega,
\]

where \( \omega \) is the canonical form on \( T^*B \). This definition does not depend on the choice of \( m \) by the following argument. Let \( m' : O \to T^*B \) be another section, then \( m \) and \( m' \) differ by a Lagrangian section \( \gamma : V \to P \). Then by Lemma A.0.1 in Appendix A we have

\[
m^*\omega = m'^* (\omega + d\gamma) = m'^*\omega.
\]

This proves that \( T^*B/P \) has a well-defined symplectic structure induced from \( T^*B \).

\[\square\]

The following corollary is immediate.

**Corollary 1.2.1 (Local symplectomorphism K)** Provided \( z : V \to M \) is a Lagrangian section, the corresponding trivialization

\[
K : T^*(V)/P(V) \to f^{-1}(V) : (b, [\alpha]) \mapsto s_b(\alpha)(z(b)),
\]

where \( s_b : T^*_b B \to \text{Diff}(F_b) \) is given by (1.2.9), is symplectic.

**Terminology 1.2.7 (Local symplectic trivializations of \( M \))** We call a local Lagrangian section \( z : V \to M \) and the corresponding symplectic diffeomorphism \( K \) a **local symplectic trivialization** of \( M \) (compare to Terminology 1.2.5).

**Terminology 1.2.8 (Transition maps of symplectic trivializations of \( M \))** Recall (Section 1.2.2 Terminology 1.2.6) that transition maps between smooth trivializations of \( M \) are given by smooth local sections in the bundle \( \tau : T^*B/P \to B \). In the case of symplectic trivializations of \( M \) such sections have to be Lagrangian. To see that let \( z \) and \( z' \) be local Lagrangian sections of \( M \), and let \( K \) be the trivialization defined by \( z \). Then \( K^{-1}(z'(V)) \) is locally the image of a closed section \( \beta : V \to T^*B \) under the quotient map \( T^*B \to T^*B/P \), and hence is a Lagrangian section in \( T^*B/P \) (Lemma 1.2.10). We will often say a ‘closed section of \( T^*B/P \)’ meaning a Lagrangian section of \( T^*B/P \). Such sections occur as transition maps of symplectic trivializations of \( M \).

**Adapted coordinates on \( B \) and action coordinates on \( M \) and the freedom in their construction**

In this section we prove the existence of an integer affine structure on the base \( B \), i.e. we show that \( B \) admits a system of local charts \( (V, x) \) such that the transition maps between the charts are transformations in \( \mathbb{R}^n \times \text{GL}(n, \mathbb{Z}) \). The coordinates \( x \) will be called **adapted** coordinates.

Recall from section 1.2.2 that the cotangent bundle \( T^*B \) contains the period lattice \( P \) which is a locally trivial \( \mathbb{Z}^n \)-bundle (Lemma 1.2.8 section 1.2.2). Let \( \alpha_1, \ldots, \alpha_n \) be a local basis of sections in the period lattice. The sections \( \alpha_i \) are locally defined differential 1-forms on \( B \),
the Poincaré lemma there exist local functions \( x_1, \ldots, x_n \), such that \( dx_i = \alpha_i \), \( i = 1, \ldots, n \) (such a neighborhood always exists, see Appendix C.3 or [45]). By taking \( V \) even smaller, if necessary, we can arrange that \( x_1, \ldots, x_n \) are coordinates on \( V \).

**Terminology 1.2.9 (Adapted coordinates)** Local coordinates \( x_1, \ldots, x_n \) on \( B \), such that the differentials \( dx_1, \ldots, dx_n \) are a local basis of sections in the period lattice \( P \), are called the adapted coordinates.

By Remark 1.2.4 in section 1.2.2, if \( x \) and \( x' \) are two choices of adapted coordinates on \( V \), then at each \( b \in V \) the bases \( dx_1(b), \ldots, dx_n(b) \) and \( dx'_1(b), \ldots, dx'_n(b) \) are related by a linear transformation \( A \in \text{GL}(n, \mathbb{Z}) \). Since the sections \( dx_i \) are smooth and the group \( \text{GL}(n, \mathbb{Z}) \) is discrete, this transformation is locally constant on \( V \). This determines the transition maps between \( x \) and \( x' \) up to a translation of the origin, and the latter can be moved by a vector \( \xi \in \mathbb{R}^n \). Therefore,

\[
x' = Ax + \xi, \quad (\xi, A) \in \mathbb{R}^n \times \text{GL}(n, \mathbb{Z}),
\]

and adapted coordinates give \( B \) an integer affine structure (section 1.1.3).

As in Section 1.2.2, we can define the functions \( I_i = x_i \circ f \), \( i = 1, \ldots, n \) on \( M \), called the action coordinates. It follows that for any two choices \( I \) and \( I' \) of action coordinates we have

\[
I' = AI + \xi, \quad (\xi, A) \in \mathbb{R}^n \times \text{GL}(n, \mathbb{Z}),
\]

i.e. the functions \( I \) are determined up to the same integer affine transformation in \( \mathbb{R}^n \times \text{GL}(n, \mathbb{Z}) \) as the corresponding adapted coordinates.

**Angle coordinates and the freedom of their construction**

To finish the proof of the Liouville-Arnold theorem we only have to obtain angle coordinates \( \varphi = (\varphi_1, \ldots, \varphi_n) \) and determine the freedom of their construction. For that let \( x = (x_1, \ldots, x_n) \) be adapted coordinates on \( B \), as obtained in section 1.2.2, and let \( (x, y) \) be the corresponding canonical symplectic coordinates on \( T^*(V) \) (Appendix A), i.e. consider the isomorphism

\[
(x, y) : T^*(V) \to U \times \mathbb{R}^n,
\]

where \( U = x(V) \subset \mathbb{R}^n \) is open. The image of the period lattice \( P \) under this isomorphism is the subset \( U \times \mathbb{Z}^n \subset U \times \mathbb{R}^n \), and the induced coordinates on the quotient \( T^*B/P \) are

\[
(x, y) : T^*(V)/P(V) \to U \times \mathbb{T}^n,
\]

where \( y_i \), \( i = 1, \ldots, n \), take values in \( \mathbb{T}^1 \). The composition of \( (x, y) \) with the inverse of a local symplectic trivialization \( K : T^*(V)/P(V) \to f^{-1}(V) \), determined by the choice of a local Lagrangian section \( z : V \to M \), provides us with local symplectic coordinates

\[
(I, \varphi) = (x, y) \circ K^{-1} : f^{-1}(V) \to U \times \mathbb{T}^n,
\]

such that the functions \( I = (I_1, \ldots, I_n) \) factor through \( B \), and the functions \( \varphi = (\varphi_1, \ldots, \varphi_n) \) take values in \( \mathbb{T}^1 \). These coordinates are called action-angle coordinates.

To determine the freedom in the construction of action-angle coordinates, notice that, given the adapted coordinates \( x = (x_1, \ldots, x_n) \), the coordinate system \( (x, y) \) on \( T^*(V) \) is completely determined (Appendix A), and the only freedom in the construction of the angle coordinates \( \varphi = (\varphi_1, \ldots, \varphi_n) \) is to choose a ‘zero section’ \( z : V \to M \).

This finishes our proof of the Liouville-Arnold theorem 1.1.
1.3 Complete invariants of Lagrangian bundles

In this section we consider obstructions to triviality of Lagrangian bundles, as introduced by Duistermaat [27]. We review the theory of obstructions to triviality of Lagrangian bundles. A Lagrangian bundle \( f : M \to B \) is trivial if it is isomorphic to a trivial principal symplectic \( n \)-torus bundle, and the obstructions to its triviality are the following.

In Section 1.3.1 we consider the monodromy, which, as was already explained in Section 1.1.3, is a complete invariant of period lattices \( P \) and an obstruction to the Lagrangian bundle being a principal bundle. Notice (Section 1.1.3 Example 1.1.2), that if two period lattices \( P \) and \( P' \) are isomorphic, this does not imply that they define isomorphic integer affine structures on the base manifold \( B \) (Section 1.2.2 Definition 1.2.2), so if two Lagrangian bundles \( M \) and \( M' \) have the same monodromy, their lattices \( P \) and \( P' \) are isomorphic, but may not be the same or even not related by a diffeomorphism in \( B \), i.e. there may be no diffeomorphism \( \phi : B \to B \) such that \( \phi^* P' = P \). Next we fix the integer affine structure on the base manifold \( B \), and study Lagrangian bundles \( f : M \to B \) with the corresponding period lattice \( P \). We are interested in a more general question than obstructions to triviality: given two Lagrangian bundles \( f : M \to B \) and \( f' : M' \to B \) with fixed integer affine structure, when are these bundles isomorphic (see Section 1.3.2 for the definition of isomorphism of Lagrangian bundles)? In Section 1.3.2 we show that two such Lagrangian bundles are smoothly isomorphic if and only if they have the same Chern class, and they are symplectically isomorphic if and only if they have the same Lagrange class. So a Lagrangian bundle with trivial monodromy is trivial if its Lagrange class is zero, which means that the bundle admits a global Lagrangian section or a global trivialization. In Section 1.3.2 we elaborate on the relation between the Chern and the Lagrange classes of Lagrangian bundles.

1.3.1 Monodromy

In this section we introduce monodromy. The symplectic structure does not play any role in the considerations of this section, for this reason we consider the general case, namely, locally trivial \( \mathbb{Z}^n \)-bundles \( g : P \to B \) over a connected base space \( B \). We introduce a complete invariant of such bundles, called monodromy. Notice that, given \( B \), not every \( \mathbb{Z}^n \)-bundle \( P \) over \( B \) can be realized as a period lattice in \( T^* B \); for example, if \( T^* B \) is non-trivial, the period lattice can only be non-trivial. We show that the monodromy can be seen as an obstruction to triviality of Lagrangian bundles.

Monodromy of \( \mathbb{Z}^n \)-bundles

Like covering spaces, the bundle \( P \) has unique path-lifting (Section 1.2.2 Remark 1.2.5), and the classification of \( \mathbb{Z}^n \)-bundles is analogous to that of covering spaces. For this reason in our treatment of monodromy we will be brief and omit proofs, referring to [40, 58].

Using the property of unique path-lifting, given \( b \in B \) we define the homomorphism

\[
H : \pi_1(B, b) \to \text{Aut}(P_b)
\]

of the fundamental group \( \pi_1(B, b) \) into the group \( \text{Aut}(P_b) \cong \mathbb{GL}(n, \mathbb{Z}) \), as follows. Choose a closed curve \( c : [0, 1] \to B \) which represents the equivalence class \( [c] \in \pi_1(B, b) \), and for each \( \alpha \in P_b \) denote by \( c_{\alpha} \) the unique lift of \( c \) with the starting point \( c_{\alpha}(0) = \alpha \). Then define

\[
H([c])(\alpha) = c_{\alpha}(1).
\]
The homomorphism (1.3.22) is called the \textit{monodromy homomorphism} or just the \textit{monodromy}.

For a proof that $H([c])$ does not depend on the choice of a representative in $[c]$ and is an automorphism of $P_b$ we refer to [40, 58].

We notice that the homomorphism $H$ is independent of the point $b$ in the following sense. Let $b' \in B$ and denote by $H'$ the monodromy homomorphism at $b'$. Since $B$ is connected, the fundamental groups $\pi_1(B,b)$ and $\pi_1(B,b')$ are isomorphic [40, 58], and, due to the unique path-lifting of $P$, there exists a group isomorphism

\[
\mathcal{C} : P_b \to P_{b'}
\]
such that $H' \circ \mathcal{C} = \mathcal{C} \circ H$. The following theorem states that the monodromy is a complete invariant of $\mathbb{Z}^n$-bundles $P$.

**Theorem 1.2 (Monodromy theorem)** Let $B$ be a connected manifold and $\pi_1(B,b)$ be the fundamental group of $B$ with base point $b$. Let $g : P \to B$ and $g' : P' \to B$ be $\mathbb{Z}^n$-bundles, and denote by $H$ and $H'$ the monodromy homomorphisms associated to $P$ and $P'$ respectively. Then $P$ and $P'$ are isomorphic, i.e. there exists a diffeomorphism

\[
\Phi : P \to P',
\]
commuting with the projection maps $g$ and $g'$, if and only if there exists a group isomorphism

\[
\mathcal{I} : P_b \to P'_b
\]
such that the following diagram commutes for each $[c] \in \pi_1(B,b)$,

\[
\begin{array}{ccc}
P_b & \xrightarrow{\mathcal{I}} & P'_b \\
\downarrow H([c]) & & \downarrow H'([c]) \\
P_b & \xrightarrow{\mathcal{I}} & P'_b
\end{array}
\]  \hspace{1cm} (1.3.23)

i.e. we have $\Phi|_{P_b} = \mathcal{I}$.

Moreover, for any group morphism $H$ (1.3.22) there is a corresponding $\mathbb{Z}^n$-bundle. These statements are proved by standard methods of theory of covering spaces [40, 58].

**Monodromy of period lattices**

Recall (Section 1.2.2) that the period lattice $P$ is a locally trivial $\mathbb{Z}^n$-subbundle of $T^*B$, so the above applies to $P$. The monodromy homomorphism $H$, defined by (1.3.22), is trivial, if its image is the identity in $\text{Aut}(P_b)$. The lattice $P$ is trivial, if there exists a diffeomorphism $P \to B \times \mathbb{Z}^n$ commuting with obvious projections. By Theorem 1.2 the period lattice $P$ is trivial if and only if the monodromy homomorphism $H$ is trivial. If $P$ is trivial, the bundle $T^*B$ is trivial, and it follows that also the quotient bundle $T^*B/P$ is trivial as well, i.e. there exists an isomorphism $T^*B/P \to B \times \mathbb{T}^n$. Recall (Section 1.2.2) that fibres of $T^*B/P$ act freely and transitively on fibres of the corresponding Lagrangian bundle $f : M \to B$. If $T^*B/P$ is trivial, for each $b,b' \in B$ there is a canonical isomorphism between the fibres $T_b^*B/P_b$ and $T_{b'}^*B/P_{b'}$, and there is the smooth action of the $n$-torus $\mathbb{T}^n$ on $M$. This means that if the period lattice $P$ is trivial, then the Lagrangian bundle $M$ is a principal torus bundle which, however, needs not be trivial, as we show later in Section 1.3.2. If the monodromy is non-trivial, the bundle $M$ is not a principal bundle and is certainly non-trivial. In this sense the monodromy is the obstruction to $M$ being a principal bundle.
Furthermore, if we regard $M$ usual sense, that is, if it is diffeomorphic to the product to the standard notion of local triviality only if the quotient bundle $T^1.2.6)$. It should be stressed here that we adopt a modified notion of local triviality; it reduces and the transition maps of the trivializations are defined by local sections in $T^1.2.7), and transition maps of the trivializations are symplectic and are determined by local one-to-one correspondence with local sections in $T^1.2.8).$

1. Let $B = \mathbb{S}^2$. Since $\mathbb{S}^2$ is simply connected, the monodromy map has to be trivial, and also the period lattice $P \subset T^*\mathbb{S}^2$ must be trivial. But this is not possible, since $T^*\mathbb{S}^2$ is non-trivial (Hairy Ball Theorem, [77]). Thus there is no Lagrangian bundle over $\mathbb{S}^2$.

2. Let $B = \mathbb{S}^3$. The tangent bundle $T\mathbb{S}^3$, and hence the cotangent bundle $T^*\mathbb{S}^3$, is trivial. However, as we show now, there is no integer affine structure on $\mathbb{S}^3$ (and no period lattice over $\mathbb{S}^3$). Indeed, suppose such a period lattice $P \subset T^*\mathbb{S}^3$ exists. Since $\mathbb{S}^3$ is simply connected, the monodromy is trivial and hence $P$ is a product, i.e. $P \cong \mathbb{S}^3 \times \mathbb{Z}^3$. So we can take a global non-zero section $\alpha$ in $P$. Because $P$ is Lagrangian, the 1-form $\alpha$ is closed. Since the de Rham cohomology $H^1_{dR}(\mathbb{S}^3)$ is trivial [10], $\alpha$ is exact and there exists a smooth function $f : \mathbb{S}^3 \rightarrow \mathbb{R}$ with $df = \alpha$. But this leads to a contradiction: since $\mathbb{S}^3$ is compact, $f$ must have a maximum on $\mathbb{S}^3$. Then $df$ vanishes at the maximum point, while $\alpha$ is nowhere zero.

1.3.2 The Chern and the Lagrange classes of a Lagrangian bundle

In this section we introduce the classification of Lagrangian bundles with fixed integer affine structure on the base manifold $B$ by the Lagrange class. This means that the period lattice $P$ and the quotient bundle $T^*B/P$ are fixed. Since we are going to deal with different kinds of bundles, first we review the terminology.

Recall (Section 1.2.2) that a Lagrangian bundle $f : M \rightarrow B$ is a locally trivial $n$-torus bundle, although the fibres of $M$ do not have a group structure. The quotient bundle $\tau : T^*B/P \rightarrow B$ is a locally trivial (Lagrangian) bundle whose fibres are torus groups, acting on the corresponding fibres of $f : M \rightarrow B$. The action of fibres of $T^*B/P$ on fibres of $M$ is free, transitive and smooth. Local identification of fibres in $T^*B/P$ is induced from the identification of fibres in the period lattice $P$, so it is unique. This means that locally on $M$ (and $T^*B/P$) there is a smooth fibre-preserving and free action of an $n$-torus, and $M$ (and also $T^*B/P$) locally is a principal bundle (Section 1.2.2 Terminology 1.2.4).

We can treat both $M$ and $T^*B/P$ as general locally principal $n$-torus bundles. Then (local) trivializations of $M$ are local bundle isomorphisms of $T^*B/P$ to $M$. These trivializations are in one-to-one correspondence with local sections $z : V \rightarrow M$ (Section 1.2.2 Terminology 1.2.5), and the transition maps of the trivializations are defined by local sections in $T^*B/P$ (Section 1.2.6). It should be stressed here that we adopt a modified notion of local triviality; it reduces to the standard notion of local triviality only if the quotient bundle $T^*B/P$ is trivial in the usual sense, that is, if it is diffeomorphic to the product $B \times \mathbb{T}^n$ (see also Terminology 1.3.1). Furthermore, if we regard $M$ and $T^*B/P$ as symplectic $n$-torus bundles, then local symplectic trivializations of $M$ are local symplectic bundle isomorphisms of $T^*B/P$ to $M$, which are in one-to-one correspondence with local Lagrangian sections in $M$ (Section 1.2.2 Terminology 1.2.7), and transition maps of the trivializations are symplectic and are determined by local closed sections in $T^*B/P$ (Section 1.2.2 Terminology 1.2.8).

Recall from Appendix B, that $f : M \rightarrow B$ and $f' : M' \rightarrow B$ with fixed $P$ and, therefore, fixed $T^*B/P$ are isomorphic as general locally principal torus bundles, if there exists a
diffeomorphism $\Psi : M \to M'$ such that the following diagram commutes

$$
\begin{array}{ccc}
M & \xrightarrow{\Psi} & M' \\
\downarrow{f} & & \downarrow{f'} \\
B & & 
\end{array}
$$

and $\Psi$ commutes with the action of tori in $T^*B/P$ on $M$. We say that Lagrangian bundles $f : M \to B$ and $f : M' \to B$ are isomorphic if they are isomorphic as general locally principal $n$-torus bundles. Two Lagrangian bundles $f : M \to B$ and $f : M' \to B$ are symplectically isomorphic if there is such a diffeomorphism $\Psi$, which also preserves the symplectic structure, i.e. such that $\Psi^*\sigma' = \sigma$, where $\sigma$ and $\sigma'$ are the symplectic forms on $M$ and $M'$ respectively. Note that $\tau : T^*B/P \to B$ can be also seen as a Lagrangian bundle whose fibres have a group structure. The bundle $T^*B/P$ has a global zero Lagrangian section, so we say that $T^*B/P$ has a global trivialization (in the extended sense, see Terminology 1.3.1 below).

**Terminology 1.3.1 (Triviality of a Lagrangian bundle)** We say that a Lagrangian bundle $f : M \to B$ admits a global trivialization if it admits a global section. In this case $\tau : T^*B/P \to B$ and $f : M \to B$ are isomorphic as general locally principal $n$-torus bundles. We say that the bundle $M$ admits a global symplectic trivialization if it admits a global Lagrangian section. In this case $T^*B/P$ and $M$ are symplectically isomorphic.

We will define the Chern class of a general locally principal torus bundle, and show that it is a complete invariant of such bundles, which means at least that if two general $n$-torus bundles are not isomorphic, their Chern classes should be different. The notion of a complete invariant will be made more precise in Section 1.3.2. We also note that the Chern class can be seen as the obstruction to a general torus bundle to admit a global section, i.e. a general torus bundle may admit a global section only if its Chern class is trivial. For Lagrangian bundles this means that the Chern class is the obstruction to the Lagrangian bundle being topologically trivial in the sense of Terminology 1.3.1.

Similarly, we will define the Lagrange class of a Lagrangian bundle, and show that it is a complete invariant of Lagrangian bundles with fixed integer affine structure and the obstruction to a Lagrangian bundle to admit a global Lagrangian section. Then in the sense of Terminology 1.3.1 the Lagrange class is the obstruction to a Lagrangian bundle $M$ being symplectically isomorphic to the bundle $T^*B/P$ and the bundle $M$ being trivial in that sense.

Notice that each symplectic $n$-torus bundle can be seen as a general torus bundle by forgetting the symplectic structure on $M$; however, not every general $n$-torus bundle admits a symplectic structure, as will be shown in Section 1.3.2. Thus for a symplectic torus bundle one can define both the Lagrange and the Chern class, although in this case the Chern class is not a complete invariant, which means that not every Chern class can be realized as the Chern class of a Lagrangian bundle, and bundles, which are not symplectically isomorphic, may have the same Chern class. We will clarify the relation between the Chern and the Lagrange classes. In particular, we will point out conditions on a manifold $B$ under which any $n$-torus bundle over $B$ admits a symplectic structure; we will also show that if an $n$-torus bundle admits a symplectic structure, this structure is never unique, and often is not unique up to a symplectic bundle isomorphism.
The Chern class of a general \( n \)-torus bundle and the Lagrange class of a Lagrangian bundle

In this section we develop the classification of locally principal general \( n \)-torus bundles by the Chern class, and the classification of Lagrangian bundles by the Lagrange class. We do this first for a fixed good cover \( \mathcal{V} \) of \( B \), and then show that the results do not depend on the choice of the good cover \( \mathcal{V} \) (see Appendix B.2).

The Chern class of a general \( n \)-torus bundle

We start with the classification of locally principal general \( n \)-torus bundles. Let \( \pi : R \rightarrow B \) be a locally trivial vector bundle over \( B \) with fibre \( \mathbb{R}^n \) and \( g : P \rightarrow B \) be a locally trivial \( \mathbb{Z}^n \)-subbundle of \( R \). Then the fibrewise quotient \( \tau : T = R/P \rightarrow B \) is a locally trivial \( n \)-torus bundle whose fibre is a group. Let \( f : M \rightarrow B \) be an \( n \)-torus bundle, i.e. fibres of \( M \) are diffeomorphic to \( \mathbb{T}^n \) but do not have a group structure. We assume that there is a free and transitive action of fibres of \( T \) on fibres of \( M \), given by

\[ G_b : T_b \times F_b \rightarrow F_b, \]

where \( F_b = f^{-1}(b) \) and \( T_b = \tau^{-1}(b) \). Note, that locally there is the canonical identification of fibres in \( T \), which is induced by the identification of fibres in \( P \). This means that the smooth action of \( T_b \) is defined on a neighborhood of each \( F_b \), and locally \( M \) is a principal bundle. If \( T \) is trivial, the action of \( T_b \) is smooth on the whole of \( M \), and \( M \) is a principal bundle. We fix the bundles \( R \) and \( P \), and look for invariants classifying general locally principal \( n \)-torus bundles.

To define a complete invariant of general locally principal \( n \)-torus bundles we will use the same approach as for principal circle bundles (Appendix B). As in the case of principal circle bundles, trivializations of \( M \) are determined by the choice of local ‘zero’ sections, and the difference between trivializations is determined by a local section in the bundle of groups \( T \) whose fibres act on fibres of \( M \) (Section 1.2.2 Terminology 1.2.6).

Recall (Appendix C.3, [45]) that a good cover \( \mathcal{V} \) of \( B \) is a locally finite open cover such that all sets of \( \mathcal{V} \) and all finite intersections of sets of \( \mathcal{V} \) are contractible. Any good cover is a trivializing cover of any bundle, e.g. \( M, R, P \) etc. For each \( V_i \in \mathcal{V} \) let \( z_i : V_i \rightarrow M \) be a local section determining a trivialization of \( M \) whose fibres act on fibres of \( M \) (Section 1.2.2 Terminology 1.2.6).

For each \( b \in V_i \cap V_j \) determine a local section

\[ \alpha_{ij} : V_i \cap V_j \rightarrow T(V_i \cap V_j), \]

called the transition map of \( M \), such that for each \( b \in V_i \)

\[ G_b(\alpha_{ij}(b), z_j(b)) = z_i(b). \]

The transition maps are alternating,

\[ \alpha_{ij} = -\alpha_{ji}, \]

and satisfy the cocycle condition,

\[ \alpha_{ij} + \alpha_{jk} = \alpha_{ik}. \]
Denote by $\tilde{T}^n$ the sheaf of sections of the bundle $T$. As in the case of principal circle bundles, (1.3.25) implies that the 1-cochain

$$\alpha : (ij) \mapsto \alpha_{ij} \in C^1(\mathcal{V}, \tilde{T}^n)$$

is a 1-cocycle. The cohomology class

$$[\alpha] \in H^1(\mathcal{V}, \tilde{T}^n)$$

is called the Chern class of the $n$-torus bundle $M$. The proof of the following results is analogous to the proofs of Lemma B.2.1 and Theorem B.1 in Appendix B.

**Lemma 1.3.1 (Independence of choice of local trivializations)** The Chern class of a general $n$-torus bundle $f : M \to B$ does not depend on the choice of local trivializations, that is, if $\{z_i\}$ and $\{z'_i\}$ are two choices of trivializations over a good cover $\mathcal{V}$ with transition maps $\alpha_{ij}$ and $\alpha'_{ij}$ respectively, then

$$[\alpha] = [\alpha'] \in H^1(\mathcal{V}, \tilde{T}^n).$$

**Theorem 1.3 (The Chern class is a complete invariant)** Let $\mathcal{V}$ be a good cover of a manifold $B$, and let $P$ (and hence $T$) be fixed. Then:

1. Each element $[\alpha] \in H^1(\mathcal{V}, \tilde{T}^n)$ is the Chern class of a general locally principal $n$-torus bundle $f : M \to B$.

2. Two general locally principal $n$-torus bundles $f : M \to B$ and $f' : M' \to B$ with Chern classes $[\alpha]$ and $[\alpha']$ respectively are isomorphic if and only if $[\alpha] = [\alpha']$.

3. The Chern class of $f : M \to B$ is zero if and only if $M$ admits a global trivialization, and so is isomorphic to $T = R/P$ (Terminology 1.3.1).

**Terminology 1.3.2 (Complete invariants)** By Theorem 1.3 each value of the Chern class corresponds to a general locally principal $n$-torus bundle, and the Chern class determines a general locally principal $n$-torus bundle up to an isomorphism. This means that the Chern class is a complete invariant of general locally principal $n$-torus bundles.

**Remark 1.3.2 (Chern class in cohomology with coefficients in $\mathbb{P}$)** Denote by $\mathbb{P}$ the sheaf of sections of $g : P \to B$. By Example C.3.3 in Appendix C.3 for every good cover $\mathcal{V}$ of $B$ there is an isomorphism

$$\delta : H^1(\mathcal{V}, \tilde{T}^n) \to H^2(\mathcal{V}, \mathbb{P}),$$

so also the cohomology class

$$\nu = \delta[\alpha] \in H^2(\mathcal{V}, \mathbb{P}) \quad (1.3.26)$$

is a complete invariant of general locally principal $n$-torus bundles. The cohomology class $\nu$ is also called the Chern class of $f : M \to B$. 

26
Remark 1.3.3 (Chern class of a general \( n \)-torus bundle with trivial \( P \)) If the bundle \( g : P \to B \) is trivial, then \( \tau : T \to B \) is a trivial principal \( n \)-torus bundle and \( f : M \to B \) is a principal \( n \)-torus bundle. Then \( P \) is isomorphic to the direct sum of \( n \) trivial \( \mathbb{Z} \)-bundles, which yields the following isomorphism on sheaf cohomology (Appendix C.3 Example C.3.2)
\[
H^2(\mathcal{V}, \mathbb{P}) \cong H^2(\mathcal{V}, \hat{\mathbb{Z}}) \oplus \cdots \oplus H^2(\mathcal{V}, \hat{\mathbb{Z}}),
\]
where \( \hat{\mathbb{Z}} \) is the sheaf of locally constant \( \mathbb{Z} \)-valued functions. In its turn, \( \tau : T \to B \) is isomorphic to the direct sum of \( n \) circle bundles \( \tau_i : S_i \to B \), \( i = 1, \ldots, n \), with the Chern classes \( c_i \in H^2(\mathcal{V}, \hat{\mathbb{Z}}) \). Thus the Chern class \( \nu \in H^1(\mathcal{V}, \mathbb{P}) \) of \( T \) is the \( n \)-tuple
\[
(c_1, \ldots, c_n) \in H^2(\mathcal{V}, \hat{\mathbb{Z}}) \oplus \cdots \oplus H^2(\mathcal{V}, \hat{\mathbb{Z}}).
\]

The Lagrange class of a Lagrangian bundle

By an argument, similar to the one used in section 1.3.2 we introduce the Lagrange class of Lagrangian bundles, only now local trivializations and transition maps, involved in the construction, are symplectic. Let \( f : M \to B \) be a Lagrangian bundle, then \( R = T^*B \), the period lattice \( g : P \to B \) is a \( \mathbb{Z}^n \)-subbundle of \( T^*B \), and the quotient bundle \( \tau : T^*B/P \to B \) plays the role of the bundle \( T \). The quotient bundle \( T^*B/P \) is a bundle of torus groups, whose fibres act freely and transitively on fibres of \( M \) by
\[
G_b : T_b^*B/P_b \times F_b \to F_b, \quad b \in B, \quad F_b = f^{-1}(b).
\]

We develop the classification of Lagrangian bundles \( f : M \to B \) with fixed integer affine structure on \( B \), hence with fixed period lattice \( P \) and the quotient bundle \( T^*B/P \).

Recall (Section 1.2.2 Terminology 1.2.7 and 1.2.8) that in a Lagrangian bundle local symplectic trivializations over open sets of a good cover \( \mathcal{V} \) are determined by local Lagrangian sections \( z_i : V_i \to M \), \( V_i \in \mathcal{V} \), and on each non-empty intersection \( V_i \cap V_j \) the difference between \( z_i \) and \( z_j \) defines a closed local section
\[
\alpha_{ij} : V_i \cap V_j \to T^*B/P,
\]
such that for all \( b \in V_i \cap V_j \)
\[
\mathcal{G}(\alpha_{ij}(b), z_j(b)) = z_i(b).
\]
Denote by \( \hat{\mathcal{Z}} \) the sheaf of closed sections of \( T^*B/P \). Then the assignment
\[
\alpha : (ij) \mapsto \alpha_{ij} \in C^1(\mathcal{V}, \hat{\mathcal{Z}})
\]
is a 1-cocycle with coefficients in \( \hat{\mathcal{Z}} \), and the cohomology class
\[
\lambda = [\alpha] \in H^1(\mathcal{V}, \hat{\mathcal{Z}})
\]
is called the Lagrange class of the Lagrangian bundle \( f : M \to B \). By exactly the same argument as in the case of general locally principal \( n \)-torus bundles (and for principal circle bundles, Appendix B.2 Lemma B.2.1) one can prove that the Lagrangian class \( \lambda \) is independent of the choice of local trivializations \( z_i \). There is the following classification theorem.

**Theorem 1.4 (The Lagrange class is a complete invariant)** Let \( \mathcal{V} \) be a good cover of a manifold \( B \) with given integer affine structure. Then:
1. Each element \([\alpha] \in H^1(\mathcal{V}, \hat{\mathcal{Z}})\) is the Lagrange class of a Lagrangian bundle \(f : M \to B\).

2. Two Lagrangian bundles \(f : M \to B\) and \(f' : M' \to B\) with the fixed integer affine structure on \(B\) and Lagrange classes \([\alpha]\) and \([\alpha']\) respectively are symplectically isomorphic if and only if \([\alpha] = [\alpha']\).

3. The Lagrange class of \(f : M \to B\) is zero if and only if \(M\) admits a global symplectic trivialization and is symplectically isomorphic to \(T^*B/P\) (Terminology 1.3.1).

Similarly to principal circle bundles (see Appendix B.2), cohomology groups \(H^q(\mathcal{V}, \mathcal{S})\), \(q \geq 1\), where \(\mathcal{S}\) may be the sheaf \(\hat{T}^n\) or \(\hat{\mathcal{Z}}\), is independent of the good cover \(\mathcal{V}\). Taking the direct limit of cohomology groups over all good covers of \(B\), one obtains an isomorphism \(H^q(\mathcal{V}, \mathcal{S}) \to H^q(B, \mathcal{S})\). The image of the cohomology class \([\alpha]\) under this isomorphism corresponds to the same bundle over \(B\) as \([\alpha]\). It follows that the Chern and the Lagrange class are independent of the good cover of \(B\). In what follows we consider the Chern and the Lagrange classes with values in the cohomology of the manifold \(B\).

**Relating Chern and Lagrange classes**

By forgetting the symplectic structure on \(M\), a Lagrangian bundle \(f : M \to B\) is also a general locally principal \(n\)-torus bundle, and one can define the Chern class for it. In this section we elaborate on the relation between the Chern and the Lagrange classes of a Lagrangian bundle. For background in sheaf theory we refer to Appendix C.3.

We will relate the Chern and the Lagrange classes by a diagram with exact rows which we construct now. Denote by \(\mathcal{Z}^1\) the sheaf of closed sections in \(T^*B\), and denote by \(\mathcal{P}\) the sheaf of (closed) sections in the period lattice \(P\). Then the following sequence is exact,

\[
0 \longrightarrow \mathcal{P} \xrightarrow{i} \mathcal{Z}^1 \xrightarrow{q} \hat{\mathcal{Z}} \longrightarrow 0,
\]

where \(i\) and \(q\) are the inclusion and the quotient sheaf homomorphisms respectively, and induces the corresponding long exact sequence of sheaf cohomology

\[
\cdots \longrightarrow H^1(B, \mathcal{P}) \longrightarrow H^1(B, \mathcal{Z}^1) \xrightarrow{i*} H^1(B, \hat{\mathcal{Z}}) \xrightarrow{\delta*} H^2(B, \mathcal{P}) \xrightarrow{q*} H^2(B, \mathcal{Z}^1) \longrightarrow \cdots
\]

(1.3.27)

The period lattice \(P\) can be seen as a smooth \(\mathbb{Z}^n\)-subbundle of \(T^*B\), and the symplectic bundle \(T^*B/P\) is also a smooth bundle of groups if one forgets the symplectic structure on \(T^*B/P\). Denoting by \(\Lambda\) the sheaf of smooth sections in \(T^*B/P\), and by \(\Lambda^1\) the sheaf of smooth sections in \(T^*B\), i.e. differential 1-forms, we obtain the following exact sequence of sheaves

\[
0 \longrightarrow \mathcal{P} \xrightarrow{i} \Lambda^1 \xrightarrow{q} \hat{\Lambda} \longrightarrow 0,
\]

which induces the corresponding long exact sequence on cohomology

\[
\cdots \longrightarrow H^1(B, \mathcal{P}) \longrightarrow H^1(B, \Lambda^1) = 0 \xrightarrow{i*} H^1(B, \hat{\Lambda}) \xrightarrow{\delta*} H^2(B, \mathcal{P}) \xrightarrow{q*} H^2(B, \Lambda^1) = 0 \longrightarrow \cdots
\]

(1.3.28)

where \(H^q(B, \Lambda)\) vanishes for \(q \geq 1\) since \(\Lambda\) is a fine sheaf (Appendix C.2 Example C.2.1). This implies that \(\delta*\) is an isomorphism. The inclusion homomorphisms of sheaves of closed sections into the sheaves of smooth sections

\[
C : \mathcal{Z}^1 \to \Lambda^1 \quad \text{and} \quad A : \hat{\mathcal{Z}} \to \hat{\Lambda}
\]

28
yield the following commutative diagram with exact rows,

\[
\cdots \longrightarrow H^1(B, P) \longrightarrow H^1(B, Z^1) \overset{i}{\longrightarrow} H^1(B, \hat{Z}) \overset{\delta_*}{\longrightarrow} H^2(B, P) \overset{q}{\longrightarrow} H^2(B, Z^1) \longrightarrow \cdots.
\]

\[
C_r \downarrow \quad A_r \downarrow \quad = \quad C_r
\]

\[
H^1(B, \Lambda^1) = 0 \longrightarrow H^1(B, \hat{\Lambda}) \overset{\delta_*}{\longrightarrow} H^2(B, P) \longrightarrow H^2(B, \Lambda^1) = 0
\]

By the de Rham theorem (Appendix C.3 Theorem C.1) we have the isomorphisms

\[
H^q(B, Z_1) \longrightarrow H^{q+1}\text{dR}(B), \quad q \geq 1,
\]

(1.3.30)

where \(H^{q+1}\text{dR}(B)\) denotes the de Rham cohomology of \(B\). Combining (1.3.29) with (1.3.30), we obtain the following commutative diagram with exact rows

\[
\cdots \longrightarrow H^1(B, P) \longrightarrow H^2_{\text{dR}}(B) \overset{Q}{\longrightarrow} H^1(B, \hat{Z}) \overset{\delta_*}{\longrightarrow} H^2(B, P) \overset{E}{\longrightarrow} H^3_{\text{dR}}(B) \longrightarrow \cdots
\]

\[
C_r \downarrow \quad A_r \downarrow \quad = \quad C_r
\]

\[
H^1(B, \Lambda^1) = 0 \longrightarrow H^1(B, \hat{\Lambda}) \overset{\delta_*}{\longrightarrow} H^2(B, P) \longrightarrow H^2(B, \Lambda^1) = 0
\]

(1.3.31)

Then

\[
\nu = \hat{\delta}_* \lambda \in H^2(B, P)
\]

is the Chern class of the Lagrangian bundle \(M\). Analyzing Diagram (1.3.31) we immediately draw the following conclusions.

**Remark 1.3.4 (Symplectic structure on \(n\)-torus bundles)**

1. The map \(\hat{\delta}_*\) might not be surjective, which implies that a general locally principal \(n\)-torus bundle over \(B\) might not admit a symplectic structure. Finding examples of this situation presents an interesting problem.

2. Since the rows in (1.3.31) are exact, if \(H^3_{\text{dR}}(B) = 0\) then we have

\[
\text{image } \hat{\delta}_* = \ker E = H^2(\mathcal{V}, P),
\]

i.e. in this case every general locally principal torus bundle over \(B\) admits a symplectic structure. In particular, this means that every general locally principal torus bundle over a 2-dimensional manifold can be made Lagrangian (see Example 1.3.1 of torus bundles over \(T^2\)).

3. A Lagrangian bundle \(M\) is trivial, i.e. symplectically isomorphic to \(T^n B/P\), if and only if it admits a global section \(z : B \to M\) such that \(z^* \sigma = \Theta\) is exact (see Lemma A.0.1 in Appendix A)

4. If \(H^2_{\text{dR}}(B) = H^3_{\text{dR}}(B) = 0\), then classifications by the Chern and the Lagrange classes coincide, i.e. all symplectic structures on a given general \(n\)-torus bundles are isomorphic (see Example 1.3.2 of torus bundles over the Klein bottle).

**Theorem 1.5 (Modification of symplectic structure on \(M\))** Let \(f : M \to B\) be a Lagrangian bundle with symplectic form \(\sigma\), and let \(\mathcal{V}\) be a good cover with trivializations \(z_i : V_i \to M\), transition maps \(\alpha_{ij}\) and Lagrange class

\[
\lambda = [\alpha] \in H^1(\mathcal{V}, \hat{Z}).
\]

Let \(\Theta\) be a closed differential 2-form on \(B\). Then the following holds:
1. The closed 2-form

\[ \sigma' = \sigma - f^*\Theta \] (1.3.32)

is non-degenerate and defines a symplectic structure on \( M \).

2. There exist trivializations \( z'_i : V_i \to M \) with transition maps \( \alpha'_{ij} \) and the Lagrange class \( \lambda' = [\alpha'] \in H^1(\mathcal{V}, \hat{\mathcal{Z}}) \) such that

\[ \lambda - \lambda' = Q[\Theta]. \]

Proof.

1. Let \((a, \eta)\) be local symplectic coordinates near \( p \in M \) such that the functions \( a_i \) factor through \( B \). Then at each \( p \in M \) the symplectic form \( \sigma \) defines a quadratic form on \( T_pM \), represented by the matrix

\[ \Sigma = \begin{pmatrix} 0 & -I \\ I & 0 \end{pmatrix}, \] (1.3.33)

where 0 is the \( n \times n \) zero matrix, and \( I \) is \( n \times n \) identity matrix. Similarly, \( \sigma' = \sigma - f^*\Theta \) defines a quadratic form represented by the matrix

\[ \Sigma' = \begin{pmatrix} 0 & -I \\ I & A \end{pmatrix}, \] (1.3.34)

where \( A \) is an \( n \times n \) matrix corresponding to \(-f_*\Theta\). We have \( \det \Sigma = \det \Sigma' \), so \( \sigma' \) is non-degenerate.

2. To construct trivializations \( z'_i \), denote by \( \mathcal{Z}^2 \) the sheaf of closed differential 2-forms on \( B \), and consider the following short exact sequence.

\[ 0 \to \mathcal{Z}^1 \xrightarrow{i} \Lambda^1 \xrightarrow{d} \mathcal{Z}^2 \to 0, \]

where, as before, \( \mathcal{Z}^1 \) and \( \Lambda^1 \) are sheaves of closed 1-forms and all 1-forms on \( B \) respectively, \( i \) is the inclusion sheaf homomorphism, and \( d \) is the sheaf homomorphism, induced by the exterior differentiation. Since the cover \( \mathcal{V} \) is good, the following sequence of cochain complexes is exact.

\[ \begin{align*}
0 & \longrightarrow C^0(\mathcal{V}, \mathcal{Z}^1) \xrightarrow{i} C^0(\mathcal{V}, \Lambda^1) \xrightarrow{d} C^0(\mathcal{V}, \mathcal{Z}^2) \longrightarrow 0 \\
0 & \longrightarrow C^1(\mathcal{V}, \mathcal{Z}^1) \xrightarrow{i} C^1(\mathcal{V}, \Lambda^1) \xrightarrow{d} C^1(\mathcal{V}, \mathcal{Z}^2) \longrightarrow 0 \\
& \quad \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \\
\end{align*} \]

We use this diagram to construct sections \( z'_i \). The global 2-form \( \Theta \) corresponds to a 0-cocycle in \( C^0(\mathcal{V}, \mathcal{Z}^2) \). Since the sheaf homomorphism \( d \) is surjective, there exists a 0-cochain \( \beta : i \mapsto \beta_i \in C^0(\mathcal{V}, \Lambda^1) \) such that for each \( V_i \)

\[ d\beta_i = \Theta|_{V_i}. \]

The sections \( d\beta_i \) agree on intersections, so

\[ d(\delta\beta)_{ij} = \delta(d\beta)_{ij} = d\beta_i - d\beta_j = 0. \]
Thus $\delta \beta$ is a 1-cochain with coefficients in $\mathbb{Z}$. Define the local section $z'_i : V_i \to f^{-1}(V_i)$ by

$$z'_i(b) = K(\beta_i(b)), \quad b \in V_i,$$

where $K : T^*B|V_i \to f^{-1}(V_i)$ is the symplectic map determined by the section $z_i$. Then $z'_i$ are Lagrangian with respect to $\sigma'$, indeed,

$$z'_i(\sigma - f^*\Theta) = \Theta|V_i - z_i'^* \circ f^*\Theta = \Theta|V_i - \Theta|V_i = 0.$$

Denote $\gamma_i = q(\beta_i)$, where $q : T^*B \to T^*B/P$. Then the sections $(\delta \gamma)_{ij}$ are closed (Section 1.2.2 Lemma 1.2.10), and $\delta \gamma$ is a 1-cocycle with coefficients in $\hat{\mathbb{Z}}$. Transition maps $\alpha'_{ij}$ of sections $z'_i$ satisfy

$$\alpha'_{ij} = \alpha_{ij} + (\delta \gamma)_{ij},$$

so, denoting $\lambda' = [\alpha']$ we obtain

$$\lambda - \lambda' = [\delta \gamma], \quad (1.3.35)$$

where by the construction $\delta \gamma = Q(\Theta)$. 

\[ \square \]

**Example 1.3.1 (Lagrangian bundles over the torus)** Let $B = \mathbb{T}^2$, then $H^3_{dR}(B) = 0$, and by the exactness of rows in diagram (1.3.31) the map $\tilde{\delta}$ is surjective. This means that any general locally principal $n$-torus bundle over $B$ admits a symplectic structure and so becomes Lagrangian. Let $(x_1, x_2)$ be coordinates modulo 1 on the base $B$, and $(x_1, x_2, \bar{y}_1, \bar{y}_2)$ be symplectic coordinates on $T^*B$ with the canonical form

$$\omega = 2 \sum_{i=1}^2 d\bar{y}_i \wedge dx_i.$$ 

Choose $\alpha_1, \alpha_2 \in \mathbb{R} \setminus \{0\}$, and consider the period lattice in $T^*\mathbb{T}^2$, given by

$$P_\alpha = \{ \bar{y}_i = \ell_i \alpha_i \mid \ell_i \in \mathbb{Z}, \ i = 1, 2 \}. \quad (1.3.36)$$

The lattice $P_\alpha$ is trivial, which means (section 1.3.1) that the bundle $T^*\mathbb{T}^2/P_\alpha$ is a trivial principal bundle, i.e. there is an isomorphism $T^*\mathbb{T}^2/P_\alpha \to \mathbb{T}^2 \times \mathbb{T}^2$, commuting with the action of $\mathbb{T}^2$. The bundle $T^*\mathbb{T}^2/P_\alpha$ with symplectic form $\omega$ induced from $T^*\mathbb{T}^2$, has a global Lagrangian zero section, i.e. it has both zero Chern and Lagrange classes (Terminology 1.3.1). We want to classify the Lagrangian bundles which can be obtained from this bundle by modifying the symplectic structure. For this we compute the kernel of the map $Q$ in the diagram (1.3.31). These Lagrangian bundles are then in one-to-one correspondence with $H^2_{dR}(\mathbb{T}^2)/\ker Q$.

To this end introduce the coordinates $(x, y) = (x_1, x_2, y_1, y_2)$ on the cotangent bundle $T^*\mathbb{T}^2$ such that $P_\alpha$ is mapped onto $\mathbb{T}^2 \times \mathbb{Z}^2 \subset \mathbb{T}^2 \times \mathbb{R}^2$, by

$$y_i = \frac{1}{\alpha_i} \bar{y}_i, \quad i = 1, 2.$$ 

Then $dy_i = \frac{1}{\alpha_i} d\bar{y}_i$, and

$$\omega = \sum_{i=1}^2 \alpha_i dy_i \wedge dx_i.$$ 

31
Note that \((x, y)\) are not symplectic with respect to \(\omega\). According to Theorem 1.5 the action of \(Q\) is such that for \([\Theta] \in H^2_{dR}(\mathbb{T}^2)\), \(Q[\Theta]\) can be represented by \(T^*\mathbb{T}^2/P_\alpha\) with symplectic form \(\omega + \pi^*\Theta\), where \(\Theta\) is a representative of \([\Theta]\) and \(\pi\) is the canonical projection in \(T^*\mathbb{T}^2/P_\alpha\).

We note that \(H^2_{dR}(\mathbb{T}^2) \cong \mathbb{R}\) and that we may assume that \(\Theta = \gamma dx_1 \wedge dx_2\), where \(\gamma \in \mathbb{R}\). In order to investigate for which \([\Theta]\) we get a Lagrangian bundle with Lagrange class zero, we have to find out whether there is a section \(z\) in \(T^*\mathbb{T}^2/P_\alpha\) for which \(z^*(\omega + \pi^*\Theta)\) is exact. The cohomology class of \(z^*(\omega + \pi^*\Theta)\) depends only on the homotopy class of \(z\). Up to homotopy, any section \(z\) is ‘linear’ in the sense that [36]

\[
z : (x_1, x_2) \mapsto (x, A(x^\top)),
\]

(1.3.37)

where

\[
A = \begin{pmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{pmatrix} \in \text{gl}(2, \mathbb{R}),
\]

and juxtaposition denotes matrix multiplication. We note that \(z\) is a global section if and only if \(A \in \text{gl}(2, \mathbb{Z})\). Setting \(a_{12} = n_1, a_{21} = n_2\), we compute the pullback

\[
z^*\sigma = z^*(\alpha_1 dy_1 \wedge dx_1 + \alpha_2 dy_2 \wedge dx_2) = \alpha_1 n_1 dx_2 \wedge dx_1 + \alpha_2 n_2 dx_1 \wedge dx_2 = (\alpha_2 n_2 - \alpha_1 n_1) dx_1 \wedge dx_2.
\]

So \([\Theta] = [\gamma dx_1 \wedge dx_2]\) is in the kernel of \(Q\) if and only if for some \(n_1, n_2 \in \mathbb{Z}\), \(\gamma = \alpha_2 n_2 - \alpha_1 n_1\), i.e. \(\gamma \in (\alpha_1, \alpha_2)\), where \((\alpha_1, \alpha_2)\) is an additive subgroup of \(\mathbb{R}\) with elements of the form \(\alpha_2 n_2 - \alpha_1 n_1, n_1, n_2 \in \mathbb{Z}\). So

\[\ker Q \cong (\alpha_1, \alpha_2)\Z\text{ and image } Q \cong \mathbb{R}/(\alpha_1, \alpha_2)\Z.\]

Thus for a fixed \(P_\alpha\), \(\alpha = (\alpha_1, \alpha_2)\), and zero Chern class the set of isomorphism classes of Lagrangian bundles over \(\mathbb{T}^2\) is in one-to-one correspondence with the set \(\mathbb{R}/(\alpha_1, \alpha_2)\Z\), and the Lagrange class of the bundle \((T^*\mathbb{T}^2/P_\alpha, \omega')\) with \(\omega' = \omega - f^*\Theta\) equals \(\lambda = Q([\Theta])\). Since \(Q\) is a homomorphism, the same holds for any Chern class (see Remark 1.3.5).

Remark 1.3.5 (Conclusions on Example 1.3.1) 1. The set of isomorphism classes of Lagrangian bundles over \(\mathbb{T}^2\) with fixed Chern class is in one-to-one correspondence with \(\mathbb{R}/(\alpha_1, \alpha_2)\Z\), where \((\alpha_1, \alpha_2)\) is an additive subgroup of \(\mathbb{R}^2\) with elements of the form \((\alpha_2 n_2 - \alpha_1 n_1), n_1, n_2 \in \mathbb{Z}\).

2. We note that if the ratio \(\alpha_1/\alpha_2\) is rational, the quotient \(\mathbb{R}/(\alpha_1, \alpha_2)\Z\) has the natural topology of the circle \(\mathbb{T}^1\), otherwise the topology is more complicated.

Example 1.3.2 (Lagrangian bundles over the Klein bottle) Let \((x, y)\) be standard coordinates on \(\mathbb{R}^2\). Under the identification

\[(x, y) \sim (x + 1, y) \quad \text{and then} \quad (x, y) \sim (1 - x, y + 1)\]

one obtains the Klein bottle. The integer affine structure on \(\mathbb{R}^2\) induces an integer affine structure on the Klein bottle \(\mathcal{K}\), and the period lattice \(P_\alpha\) in \(T^*\mathcal{K}\) can be defined similarly to Example 1.3.1, i.e. by (1.3.36). Recall [10] that \(H^2_{dR}(\mathcal{K}) = 0\) and, since \(\mathcal{K}\) is not orientable, \(H^3_{dR}(\mathcal{K}) = 0\). Then it follows from diagram (1.3.31) that the map \(\tilde{\delta}^*\) is an isomorphism, which implies that there is an isomorphism between the sets of Chern and Lagrange classes of bundles over \(\mathcal{K}\). In other words, all symplectic structures on a general locally principal torus bundle over \(\mathcal{K}\) are isomorphic.

This completes our treatment of global invariants of Lagrangian bundles. As we already mentioned in Section 2.1, non-trivial monodromy have been found in many examples of real-world integrable systems. It is interesting also to know possible mechanical interpretations of other parts of the theory, i.e. integer affine structure, the Chern and the Lagrange class.
