Teaching sterile skills in anaesthesia
Is providing context helpful for robust skill acquisition?

Fokie Cnossen¹, Katja Paul¹, Roelof Lettinga² & Götz Wietasch²

Epidural anaesthesia

- Pan relief method during childbirth and during and after operations
- As it is an invasive technique, it carries the risk of contamination
- Residents basically learn the procedure in the clinic
- Even after 4 years of training, residents still make sterility errors (Friedman et al., 2008)
- Sterility is a complex concept
- Sterility is not visible

Present training is not optimal

- Medical skills should be flexible and robust (Cnossen, 2015)
- Flexible: applicable outside context in which it was learned
- Robust: resistant to stress and workload
- Present training of complex procedures often focuses on the order of the steps of the procedure
- This makes learning vulnerable
  - steps may be forgotten and skipped
  - steps may be performed in the wrong order
- In practice there is no fixed order of steps
  - different procedures have different steps, equipment, medication
  - not all steps have to be performed in a strict order
  - in practice, every supervisor has their own preferred order and method
- Focus on the steps in the procedure during learning
  - does not lead to flexibility in the skill
  - what if a step cannot be performed
- does not lead to robustness of the skill
  - in stress situation memory errors can happen

Different approach: focus on the context

- Taatgen, Huss, Dickison & Anderson (2005) showed that in teaching flexible cognitive skills teaching materials should draw attention to
  - the pre-conditions of actions (knowing when)
  - the post-conditions of actions (knowing the effects of actions in the environment)
- They found that Boeing pilots were more flexible and the skill was more robust after learning with a focus on these environmental cues
- learners can then rely on environmental cues rather than keeping track of all the executed steps in their mind
- We applied this approach to training preparing and executing epidural anesthesia

Main results

- Contrary to expectation the context condition did not result in robust skill
- This stands in contrast to Taatgen et al’s study
- Context condition even resulted in more sterility errors than the list condition

Why?

- Environmental cues
  - In epidural anaesthesia procedure, there are also many environmental cues in list condition (e.g. syringes filled or empty)
  - Boeing pilots used complicated system with low usability, so possibly profitied more from context
- Memory load
  - Context condition possibly imposed larger memory load on participants
  - The known advantages of the context method were at least partly offset by the disadvantages of this high memory load

Sterility

- Apparently, sterility errors are difficult to prevent, even though we explicitly noted which steps of the procedures were sterile or not
- The participants in the experiment were probably unfamiliar with the concept of sterility
- Sterility is a complex concept
  - it is not obvious for example that crossing a sterile workspace with (unsterile) bare underarms is not sterile

Discussion

- Complex medical skills involve many steps and induce a high memory load to learn them
- Providing context when teaching a procedure may therefore not necessarily lead to better skill acquisition than learning the steps
- but the resulting skill may be more flexible and robust after context-learning
- Further research is needed to test whether it may be advantageous to first study the steps in a procedure until all steps are remembered before performing the skill
- separating studying the declarative knowledge from training the procedural skill
- we can then also test the flexibility and robustness of the skill
- Further research is needed to test whether teaching sterility concepts separately from the procedure itself is needed

Method

- 37 medical students participated in simulation study
- Skill: preparation of epidural anaesthesia
  - 24 steps
  - 10-15 minutes

Procedure

- Video instruction of procedure
- Studying description of steps on paper
  - non-sterile actions were written in red
  - sterile actions were written in green
- 15 minutes practice with materials and instruction sheets
- Test: perform the procedure with an “non-sterile nurse”

Instructions

- List condition
  - 24 steps in chronological, strict, order
- Context condition
  - steps arranged in sets
  - order within set was not important
  - photographs
  - pre-conditions of a set of actions (“before”)
  - post-condition (“after”)
  - description of the actions to be performed within the set

context condition

- 13. Geef de gele sticker aan de 2
- 12. Grote bakje, voor roze Chloorhexidine,
- 10. Naalden in blauwe bak
- 9. Trek de handschoenen aan
- 8. Trek de steriele jas aan
- 7. Desinfecteer je handen
- 6. Klaarzetten

Sterility errors

- 10-15 minutes preparation of epidural anesthesia
- Sterility is not visible
- Sterility errors

REFERENCES

present training is not optimal

- Medical skills should be flexible and robust (Cnossen, 2015)
- Flexible: applicable outside context in which it was learned
- Robust: resistant to stress and workload
- Present training of complex procedures often focuses on the order of the steps of the procedure
- This makes learning vulnerable
  - steps may be forgotten and skipped
  - steps may be performed in the wrong order
- In practice there is no fixed order of steps
  - different procedures have different steps, equipment, medication
  - not all steps have to be performed in a strict order
  - in practice, every supervisor has their own preferred order and method
- Focus on the steps in the procedure during learning
  - does not lead to flexibility in the skill
  - what if a step cannot be performed
- does not lead to robustness of the skill
  - in stress situation memory errors can happen

conclusions & recommendations

- Complex medical skills involve many steps and induce a high memory load to learn them
- Providing context when teaching a procedure may therefore not necessarily lead to better skill acquisition than learning the steps
- but the resulting skill may be more flexible and robust after context-learning
- Further research is needed to test whether it may be advantageous to first study the steps in a procedure until all steps are remembered before performing the skill
- separating studying the declarative knowledge from training the procedural skill
- we can then also test the flexibility and robustness of the skill
- Further research is needed to test whether teaching sterility concepts separately from the procedure itself is needed
