Chapter 5

Differential epitope recognition in the immunodominant staphylococcal antigen A of *Staphylococcus aureus* by IgGs from mice and men

*Accepted for publication in Scientific Reports*
Abstract

The immunodominant staphylococcal antigen A (IsaA) is a potential target for active or passive immunization against the important human pathogen *Staphylococcus aureus*. Consistent with this view, monoclonal antibodies against IsaA were previously shown to be protective against *S. aureus* infections in mouse models. Further, patients with the genetic blistering disease epidermolysis bullosa (EB) displayed high IsaA-specific IgG levels that are potentially protective. Yet, mice actively immunized with IsaA were not protected against *S. aureus* infection. The present study was aimed at explaining these differences in IsaA-specific immune responses. By epitope mapping, we show that the protective human monoclonal antibody (humAb) 1D9 recognizes a conserved 62-residue N-terminal domain of IsaA. The same region of IsaA is recognized by potentially protective IgGs in EB patient sera. Further, we show by immunofluorescence microscopy that this N-terminal IsaA domain is exposed on the *S. aureus* cell surface. In contrast to the protective humAb 1D9 and IgGs from EB patients, the non-protective IgGs from mice immunized with IsaA were shown to predominantly bind the C-terminal domain of IsaA. Altogether, these observations focus attention on the N-terminal region of IsaA as a potential target for immunization against *S. aureus*. 
Introduction

\textit{Staphylococcus aureus} can cause a wide variety of diseases and has a strong tendency of developing resistance against multiple antibiotics. Methicillin-Resistant \textit{S. aureus} (MRSA)- associated infections are becoming increasingly harder to treat. Therefore, a renewed focus on the development of alternative means of treatment has arisen. Whereas many infectious diseases are nowadays controlled through vaccination, \textit{S. aureus} immunity has proven hard to achieve with vaccines \cite{1-4}. As an alternative to the active immunization against \textit{S. aureus} with vaccines, passive immunization with monoclonal antibodies specifically targeting \textit{S. aureus} is currently explored \cite{5-10}.

Invariantly expressed cell surface-exposed proteins are attractive potential targets for immunization, due to their high accessibility to the human immune system \cite{11}. This focused attention on the immunodominant \textit{S. aureus} antigen A (IsaA). The IsaA protein was first described in the year 2000 as an antigen recognized by IgGs from patients with sepsis caused by MRSA \cite{12}. Subsequent, proteomic analyses of the \textit{S. aureus} exoproteome revealed that the IsaA protein was invariantly produced by all investigated isolates of this pathogen \cite{13,14}. More specifically, IsaA is a non-covalently cell wall attached protein that is both exposed to the cell surface and secreted \cite{12,15,16}. The IsaA protein has a putative soluble lytic transglycosylase domain at the C-terminus, indicating a role in peptidoglycan turnover and cell wall hydrolysis \cite{16,17}. Interestingly, this C-terminal active site domain is exposed to the staphylococcal cell surface while the precise localization of the N-terminal domain was so far not known \cite{11,17}. Further, IsaA was localized to the septal region of dividing cells, suggesting its involvement in cell growth, separation and survival \cite{15}. In addition to its potential role in cell division, IsaA was shown to be involved in biofilm formation \cite{16,18,19}.

The immunodominant nature of IsaA was confirmed by different studies showing that both IgG1 and IgG4 against this protein are present in sera from a wide range of healthy human individuals and patients \cite{12,20-23}. Interestingly, healthy \textit{S. aureus} carriers showed significantly higher IgG levels against IsaA than non-carriers \cite{21}. Furthermore, patients with the genetic blistering disease epidermolysis bullosa (EB), who are highly colonized with \textit{S. aureus}, displayed very high IgG responses against IsaA \cite{22}. Since the skin barrier of EB patients provides only limited protection against \textit{S. aureus}, the latter finding suggested that the anti-IsaA antibodies could be protective against serious \textit{S. aureus} infections. In turn, these findings indicated that IsaA could be a suitable target for passive immunization. This view is supported by passive immunization experiments in animal studies. Firstly, a murine monoclonal antibody (mAb) targeting IsaA was shown to be protective in mouse models of catheter-related \textit{S. aureus} infection \cite{6}, and a humanized form of this mAb mediated bacterial killing in blood samples from high risk patients \cite{7}. In another study, we showed that a fully human monoclonal antibody (humAb) against IsaA (designated 1D9) improved the survival of mice challenged with a clinical \textit{S. aureus} isolate \cite{5}.

Intriguingly, several immunization studies in animals also revealed high immune responses against IsaA \cite{24-27}. Nonetheless, no protection against \textit{S. aureus} infection was observed in these immunized animals. This raised the question why certain monoclonal antibodies against IsaA, such as 1D9, are at least partially protective against \textit{S. aureus} infection, while high anti-IsaA IgG levels raised by animal immunization were not protective. The present study was aimed at explaining this difference by assessing the IsaA epitopes recognized by the apparently protective and non-protective antibodies. Briefly, the results show that potentially protective antibodies recognize a different epitope in IsaA than the non-protective antibodies.
**Materials and Methods**

**Bioinformatics**

BLAST searches were performed with default search parameters (Program BLASTP 2.3.0+, 28,29; word size 6; expect value 10; hitlist size 1000; gapcosts 11,1; matrix BLOSUM62; filter string F; genetic code 1; window size 40; threshold 21; composition-based stats 2) against the NCBI Protein Reference Sequences Database (refseq_protein; posted date: December 7, 2015 10:23 AM). Pfam sequence searches (http://pfam.xfam.org/search) were performed with default options: use E-value 1.0 cut-off 30. Multiple sequence alignments were performed using COBALT 31 with default parameters (alignment parameters: gap penalties -11,-1; end-gap penalties -5,-1; CDD Parameters: Use RPS BLAST on; Blast E-value 0.003; find conserved columns and recompute on; query clustering parameters: use query clusters on; word size 4; max cluster distance 0.8; alphabet regular). Visualizations of HMM logos (representing both sequence alignments and profile hidden Markov models) were obtained using Skylign (http://skylign.org, 32) with the following parameters: alphabet: AA; letter height: information content above background; alignment processing: HMM - remove mostly-empty columns. Predicted protein masses (kDa) and isoelectric points (pI) were obtained using the Expasy compute pl/Mw tool (web.expasy.org/compute_pi/). Data from Western blots were quantified by ImageJ software (available via http://rsbweb.nih.gov/ij/).

**Bacterial strains and growth conditions**

Bacterial strains and plasmids that were used in this study are listed in Table 1. Staphylococcal strains were grown at 37°C, 250 rpm in Tryptone Soy Broth (TSB; Oxoid, Hampshire, UK). *L. lactis* strains were grown at 30°C in M17 broth (Oxoid Limited) or on M17 plates with 1.5 % agar and 0.5% glucose (w/v), supplemented with chloramphenicol (5µg/ml) for plasmid selection. For in vivo studies the *S. aureus* clinical isolate P 14 was grown in Brain Heart Infusion broth (BHI; Becton Dickinson, Breda, The Netherlands).

**Construction of expression plasmids for the production of IsaA and its derivatives**

PCR primers for the construction of IsaA protein-expressing plasmids are shown in Supplementary Table 1. DNA was isolated with the Genelute bacterial genomic DNA kit (Sigma-Aldrich, Zwijndrecht, The Netherlands). PCR was performed with the Phusion Hot Start II polymerase (Thermo Fisher Scientific, Wilmington, Delaware USA) using genomic DNA of *S. aureus* NCTC8325 as a template as described before 36. The PCR fragments purified using the High Pure PCR purification kit (Analytic Jena, Jena, Germany) were clef with BamHI and NotI restriction enzymes (New England Biolabs, Ipswich, USA) and ligated to BamHI/NotI-linearized vector DNA using T4 DNA Ligase (New England Biolabs). Of note, PCR products obtained with primer combinations including a reverse primer with a stop codon (F1/R2) were inserted into plasmids pNG4110, and PCR products obtained with reverse primers lacking a stop codon (F1/R1) were inserted into plasmid pNG4210. The resulting plasmids were transferred to electrocompetent *L. lactis* PA1001 as described before 38. All plasmids were verified by sequencing (Eurofins MWG Operon, Ebersberg, Germany).

**HumAb production and labeling**

The humAb 1D9 directed against *S. aureus* IsaA was produced as described before 5. Briefly, Expi293 cells were transiently transfected with plasmids encoding the H and K fragments of 1D9 (Expi293 Expression System, Life Technologies). Secreted 1D9 antibodies were isolated from the cell
culture medium by Protein A column purification (HiTrap Protein A HP, GE Lifesciences) followed by desalting (HiTrap Desalting, GE Lifesciences) according to the manufacturer’s protocol. F(ab')2 nanobodies derived from 1D9 were produced using the FragIT kit (Genovis, Sweden) following the manufacturer’s protocol. The complete 1D9 antibody or the respective F(ab')2 nanobodies were labeled with IRDye 800CW (LI-COR Biosciences, Bad Homburg, Germany) by incubation with 20µg of this dye per mg of protein in PBS (pH 8.5, 2 h, room temperature). The labeled antibodies were isolated and desalted as described above, and they were stored in the dark at 4°C.

**Protein expression, purification and detection of IsaA and its subdomains**

The production and isolation of IsaA-His6 from *E. coli* BL21DE3 (pET24d::*isaA::his6*) was performed as described previously. Expression of IsaA and its derivatives in *L. lactis* PA1001 was
induced with nisin (3 ng/ml, Sigma-Aldrich, St. Luis, MO) at an Optical Density at 600 nm (OD$_{600}$) of ~0.5. After continued overnight incubation at 30ºC, cells were separated from the growth medium by centrifugation. Protein samples from both fractions were prepared as described before 36. All proteins obtained were analyzed by LDS-PAGE (NuPAGE gels, Life Technologies), and visualized either by protein staining (Simply Blue$^\text{TM}$ Safe Staining, Life Technologies) or by Western blotting on nitrocellulose membranes (Protran nitrocellulose transfer paper, Whatman, Germany). Immunodetection of particular proteins was achieved with the following antibodies or sera: mouse anti-His tag (Life Technologies), rabbit anti-IsaA (kindly provided by N. Sakata 15), sera from mice immunized with IsaA, rabbit anti-SceD (kindly provided by S. Foster 16) or the IRDye 800CW-labeled 1D9 anti-IsaA humAb 5. The binding of unlabeled antibodies was visualized with fluorescently labeled goat anti-human, goat anti-mouse or donkey anti-rabbit IRDye 800 CW-labeled secondary antibodies (LI-COR Biosciences, Lincoln, NE, USA), using the Odyssey Infrared Imaging System (LI-COR Biosciences).

Cell wall extraction and binding experiments

Crude cell wall extracts were obtained from overnight cultures of S. aureus MA12 ΔisaA or S. aureus Newman ΔspaΔsbi. To this end, cell pellets were resuspended in demineralized water with 0.1 µm glass beads (Biospec Products, Bartlesville, USA) and disrupted in a Precellys 24 homogenizer (Bertin Technologies, France), followed by centrifugation at 4000 rpm for 6 min. Recovered supernatants were centrifuged for 15 min at 14000 rpm and pellets containing crude cell wall extracts were resuspended in demineralized water and stored at 4 ºC. Non-covalently bound cell wall proteins were extracted from S. aureus Newman ΔspaΔsbi cells by a 10 min incubation with 1 M KSCN as described previously 35.

Growth medium fractions of overnight nisin-induced cultures expressing IsaA protein fragments were precipitated with 10% TCA. The resulting protein pellets were resuspended in 4-fold diluted phosphate buffered saline with 0.1% Tween 20 (PBS-T), and proteins were analyzed by LDS-PAGE. For rebinding experiments, crude cell wall extracts were incubated with IsaA protein fragments (obtained as described above) at room temperature for 10 min and, thereafter, the binding of the IsaA fragments was assessed by LDS-PAGE and Western blotting.

Near Infrared Microscopy

Aliquots of 1 ml of bacterial cultures (OD$_{600}$ of 1) in TSB were collected, washed twice with PBS, and resuspended in 1 ml of PBS. Next, ~10$^{10}$ cells thus obtained were incubated with 0.65 mg/ml IRDye 800CW-labeled 1D9 or 1D9 F(ab')$_2$ for 1 h at room temperature. After washing 3 times with PBS, cells were spotted on poly-L-lysine-coated glass slides (Sigma Aldrich) and inspected using a Leica DM5500B epifluorescence microscope equipped with an 800 nm filter block. Images were captured with a Leica DFC365FX camera using a 63x objective (Leica Microsystems BV, The Netherlands).

Epitope mapping with peptide arrays

To determine which epitopes of S. aureus IsaA were recognized by the investigated anti-IsaA IgGs, libraries of linear 15-mer IsaA-specific peptides were synthesized with an overlap on a solid support (Pepsan), as previously described 39,40. Next, the peptide libraries were probed with heat-inactivated mouse sera, humAb 1D9, or rabbit anti-IsaA in a dilution of 1:1000. Bound IsaA-specific antibodies were detected with a secondary HRP-conjugated antibody (Southern Biotech, Birmingham, USA) and
2,2'-azino-bis(3-ethylbenzothiazoline-6-sulphonic acid) (Sigma-Aldrich). A charge-coupled device camera was used to record the absorbance at 405 nm.

**Immunization of mice with IsaA**

Specified pathogen-free female BALB/cBYJ mice were obtained from Charles River (Saint-Germain-sur-l’Arbresle, France). Mice were treated and selected as described previously. Purified IsaA-His\(_6\) was emulsified 1:1 with TiterMax Gold adjuvant (Sigma-Aldrich). Mice were immunized subcutaneously in the flank with 100 μL formulated vaccine on days -28, -21, and -14 (25 μg of antigen). Control mice received 100 μL PBS emulsified with adjuvant. At day -1, blood was withdrawn from the tail artery. Sera were examined by ELISA using ELISA plates (Greiner Bio-One B.V, Alphen aan den Rijn, the Netherlands), coating, blocking, hybridization and detection procedures as described previously. Immunized mice (n = 6 immunized mice, n = 11 placebo-immunized mice) were challenged on day 0 by intravenous inoculation of 100 μL of S. aureus isolate P (3 × 10\(^5\) CFU) as described previously. Discomfort and animal survival rate over 14 days after infection were monitored. For discomfort score, clinical signs of illness in each mouse were evaluated at least twice daily as described before.

**Ethics statements**

Blood donations from EB patients were collected under the approval of the medical ethics committee of the University Medical Center Groningen (approval no. NL27471,042,09) upon written informed patient consent, and with adherence to the Helsinki Guidelines. The required written informed consent was obtained from all EB patients and healthy volunteers included in the present studies. All animal experiments were performed in accordance with the rules laid down in the Dutch Animal Experimentation Act and the EU Animal Directive 2010/63/EU (permit number: EMC2694).

**Results**

**IsaA contains 2 conserved domains**

As a first approach towards the identification of antigenic epitopes in IsaA, we performed a bioinformatics analysis of the domain structure of this protein. Inspection of the amino acid sequence of IsaA using Pfam only showed the presence of the known soluble lytic transglycosylase domain (SLT, pfam01464) in the C-terminus (Fig. 1B). Subsequent BLASTP searches against the NCBI Protein Reference Sequences Database using the N-terminus of IsaA (residues 30-145) revealed another conserved domain ranging from residues 30 to 84. A following Position-Specific iterated BLAST search with this region of IsaA showed that this domain is exclusively present in the N-termini of 391 proteins, primarily the IsaA and SceD proteins from S. aureus and other staphylococcal species (Fig. 1A and Supplemental Fig. 1). In what follows, we refer to this N-terminal conserved domain as the NCD domain of IsaA.
**S. aureus IsaA epitope recognition**

**Figure 1. Schematic representation of IsaA subdomains, their separate expression and immunodetection**

(A) The N-terminal conserved domain (NCD) of IsaA (residues 30-84) as identified by BLASTP searches with the N-terminal region of IsaA (residues 30-145; see also Supplementary Fig. 1). (B) The mature IsaA, its N-terminal (IsaA-N, IsaA-N1, IsaA-N2) or C-terminal (IsaA-C, IsaA-C1, IsaA-C2) fragments were expressed in *L. lactis* PA1001 and secreted as N-terminal or C-terminal His-tag fusions using the lactococcal signal peptide of Usp45 (spu). The C-terminal part of IsaA contains a soluble lytic transglycosylase (SLT) domain (pfam01464). In the schematic representations of the expression vectors pNG4110 and pNG4210, used to produce IsaA or its subdomains, the positions of the cleavage sites for the restriction enzymes *BamHI* (*B*) and *NotI* (*N*), and the N-terminal or C-terminal His-tags (*h6*) are indicated. Molecular weights (kDa) of IsaA and its subdomains and their isoelectric points (pI) are indicated. sp, IsaA signal peptide; *, stop codon provided within the expression vectors pNG4110 and pNG4210. (C) LDS-PAGE analysis of growth medium fractions of nisin-induced *L. lactis* cultures producing the C-terminally His-tagged IsaA protein or IsaA fragments. The His-tagged proteins are visualized either by Simply Blue gel-staining, or by Western blotting with the humAb 1D9-800CW, the polyclonal α-IsaA rabbit antibodies, or α-His-tag antibodies. Molecular weights (kDa) of the standard proteins are indicated on the left.
Figure 2. Cell-associated and secreted forms of IsaA and SceD

(A) *S. aureus* MA12, *S. aureus* MA12 Δ*isaA* and *S. aureus* Newman Δ*spaΔsbi* were grown overnight. Subsequently, cells (C) were separated from the growth medium (M) by centrifugation and proteins in the respective fractions were separated by LDS-PAGE. In addition, non-covalently cell wall-associated proteins (W) were extracted from *S. aureus* Newman Δ*spaΔsbi* and separated by LDS-PAGE. The presence of IsaA was subsequently visualized by Western blotting using humAb 1D9-800CW, hum Ab 1D9 F(ab')2-800CW or the polyclonal rabbit antibody α-IsaA. Molecular weights (kDa) of marker proteins are shown on the left and the positions of Protein A, Sbi and IsaA are indicated on the right. (B) Cellular (C) and secreted proteins in the growth medium (M) of the clinical *S. aureus* isolates D, E, F, G and H were separated by LDS-PAGE and detected by Western blotting using an α-SceD polyclonal antibody. Molecular weights (kDa) of marker proteins are shown on the left and the positions of protein A and SceD are indicated on the right.

**IsaA is non-covalently bound to the staphylococcal cell wall**

To investigate the subcellular localization of IsaA, several experiments were performed. Fractionation and subsequent Western blotting analyses of *S. aureus* MA12, MA12Δ*isaA* and Newman Δ*spaΔsbi* showed that IsaA is both retained in the cell fraction and released into the culture medium (Fig. 2A). Furthermore, extraction of non-covalently cell wall-bound proteins from *S. aureus* Newman Δ*spaΔsbi* cells with KSCN resulted in the release of IsaA from the cells (Fig. 2A, lane labelled W). As KSCN is a chaotrope, the release of IsaA from the cells implies that this protein is associated with the cell wall through non-covalent cell wall interactions based on hydrogen bonds, van der Waals forces, or hydrophobic interactions (Fig. 2A). In contrast to IsaA, the IsaA parologue SceD is mostly secreted into the growth medium by clinical *S. aureus* isolates that produce this protein (Fig. 2B). Of note, the full size 1D9-800CW antibody also binds to the IgG binding proteins Spa (protein A) and Sbi whereas, as expected, 1D9 F(ab')2-800CW nanobodies do not bind to these proteins since they lack the Fc moiety needed for Spa- and Sbi-binding (Fig. 2A). Consistent with the Western blotting data,
fluorescence microscopy showed that 1D9 F(ab)\textsubscript{2}-800CW binds to whole cells of the wild-type \textit{S. aureus} MA12 strain, but not to cells of \textit{S. aureus} MA12 Δ\textit{isaA} (Fig. 3).

![Figure 3. Exposure of IsaA on the \textit{S. aureus} cell surface](image)

Phase contrast (left panels) and near-infrared fluorescence (right panels) microscopic images of overnight cultured \textit{S. aureus} cells treated with 1D9 F(ab)\textsubscript{2}-800CW. Top panels, \textit{S. aureus} MA12 Δ\textit{isaA} cells; bottom panels wild-type (wt) \textit{S. aureus} MA12 cells.

To further investigate the potential of IsaA for cell wall binding, the mature protein and its N- and C-terminal fragments were expressed in \textit{L. lactis} using vectors pNG4110 and pNG4210 as schematically represented in Figure 1B. Specifically, this resulted in the nisin-inducible production of: the N-terminal conserved domain (N; residues 30-145), the N-terminal sub-domains N1 (residues 30-91) and N2 (residues 92-145), the C-terminal domain with the SLT active site domain, (C; residues 146-233), and the C-terminal fragments C1 (residues 146-189) and C2 (residues 190-233). These fragments were expressed either with a C-terminal His-tag or with an N-terminal His-tag. Further, all His-tagged fragments were attached to an N-terminal signal peptide, allowing their facile purification from the growth medium of \textit{L. lactis} (Fig. 1C, simply blue staining panel and Western blot panel with α-His-tag antibodies). Of note, for unknown reasons the N and N2 fragments of IsaA had a lower mobility on LDS-PAGE than expected based on their molecular weight. Analysis of the cell and growth medium fractions of the \textit{L. lactis} cultures expressing the different fragments or the full-size IsaA protein showed that mature IsaA and the N, N1 and C fragments can be detected both in the cell and growth medium fractions (Fig. 4A). The localization of these fragments was not affected by the presence of the His-tag at the N- or C-termini. In case of the N1 fragments most of the protein was present in the cell fraction, suggesting that this IsaA moiety is of particular relevance for cell association. Conversely, relatively low amounts of the C fragment were localized to the cell fraction.
Importantly, the N2, C1 and C2 fragments were exclusively detected in the growth medium fraction, suggesting that they have no important role in cell association (Fig. 4A).

Figure 4. Cell wall association of IsaA-derived protein fragments
(A) IsaA, its N-terminal (IsaA-N, IsaA-N1, IsaA-N2) and C-terminal (IsaA-C, IsaA-C1, IsaA-C2) fragments were expressed in *L. lactis* PA1001 with the Usp45 signal peptide for export from the cytoplasm and an N-terminal (←) or C-terminal (→) His-tag (see Fig. 1B). Next, cells (C) were separated from the growth medium (M) by centrifugation and the presence of full-size IsaA or its fragments in the respective fractions was analyzed by Western blotting using α-IsaA polyclonal rabbit antibodies. (B) The rebinding potential of secreted IsaA or IsaA-derived fragments to the *S. aureus* cell wall was assessed using full-size IsaA or IsaA-derived fragments (as described in A) and crude cell wall extracts from *S. aureus* MA12 Δ*isaA* as described in the Materials and Methods section. Upon incubation for 10 min, the cell walls were pelleted by centrifugation and proteins in the pelleted cell wall (W) and supernatant (S) fractions were analyzed by LDS-PAGE and Simply blue staining (upper panels) or Western blotting using α-IsaA polyclonal rabbit antibodies (lower panels). (C) As a control, IsaA was incubated without the crude cell wall extract from *S. aureus* MA12 Δ*isaA* and upon incubation centrifuged. Pellet and supernatant fractions were processed as described in B. The molecular weights (kDa) of marker proteins are indicated on the left.

As the above cell association analysis was performed with the heterologous organism *L. lactis*, a cell wall rebinding analysis was performed using crude cell wall preparations of *S. aureus* MA12 Δ*isaA* to verify the cell wall binding capabilities of IsaA. This approach is based on the notion that non-covalently cell wall-bound proteins that have been released into the growth medium can in principle rebind to the *S. aureus* cell wall. In these experiments, we focused on *S. aureus* cell wall rebinding of the full-size IsaA, or the N or C fragments of IsaA, as purified from the growth medium of *L. lactis*. Upon incubation with the cell wall preparations, the cell walls were pelleted and the presence of IsaA (fragments) in the pellet and supernatant fractions was assessed by Western blotting. As shown in Figure 4B, the full-size IsaA and the N fragment were capable of rebinding to the *S. aureus* cell wall, albeit that rebinding of the N fragment was less effective depending on the position of the His-tag. In contrast, the C fragment of IsaA did not rebind to the *S. aureus* cell wall. For control, the assay was
performed also in the absence of cell wall extract. As shown in Figure 4C, hardly any IsaA was pelleted in the absence of cell wall extract (simply blue panel), although a relatively small amount of pelleted IsaA was detectable by Western blotting (α-IsaA panel). The latter probably represents a small amount of aggregated IsaA or IsaA bound to the tube. Altogether, the present observations show that IsaA has a modular structure composed of a conserved N-terminal domain and an active site domain in the C-terminus. Both domains are involved in effective binding of full-size IsaA to the S. aureus cell wall, albeit that the N-terminal domain can also bind to the cell wall in absence of the C-terminal domain.

**HumAb 1D9 binds to the NCD domain of IsaA**

The potentially different functions of the N and C domains of IsaA in cell wall binding and transglycosylase activity raised the question, which epitope(s) in IsaA need(s) to be recognized for a protective antibody response? As a first approach to answer this question, we assessed the binding site of our humAb 1D9 in IsaA using the different fragments of this protein expressed in L. lactis. As demonstrated by Western blotting, humAb 1D9 labeled with IRDye800CW binds effectively to the IsaA fragments N and N1, but not to the fragments N2, C, C1 and C2 (Fig. 1C). This shows that the epitope recognized by 1D9 resides within the first 62 residues of the mature IsaA protein. By contrast, all tested fragments of IsaA were bound by the polyclonal antibodies (α-IsaA) raised in a rabbit 15 (Fig. 1C). To further narrow down the epitope recognized by 1D9, we applied the PepScan technology 39,40, where antibody binding to an array with linear 15-mer peptides representing the entire IsaA protein was tested. Unexpectedly, 1D9 did not bind to this array (not shown), while the polyclonal rabbit α-IsaA antibodies did bind to the array (Fig. 5). In fact, the profile of polyclonal α-IsaA binding to the peptide array mirrored the results obtained by Western blotting, where the N, N1, N2, C, C1 and C2 fragments of IsaA were all shown to bind the polyclonal antibodies (Fig. 1C). Taken together, these findings show that humAb 1D9 binds to an epitope within the conserved NCD domain of IsaA, and that this epitope is not represented in the array of linear 15-mer peptides. The latter finding suggests that 1D9 binding to IsaA relates to a feature with a particular secondary or tertiary structure.

![Figure 5. Antibody reactivity against IsaA epitopes measured by pepscan-ELISA](image-url)  
Bar chart with relative fluorescence signals as detected upon binding of α-IsaA polyclonal rabbit antibodies to 15-mer peptides with 14 residue overlap. The peptides are ordered on the x-axis according to the position of their N-terminal residue in the overall IsaA amino acid sequence. The relative positions of the IsaA fragments N1, N2, C1 and C2 are indicated. The y-axis shows the OD (in AU).
Distinction of IsaA epitopes recognized by human sera and sera from IsaA-immunized mice

Our previous mouse immunization study with an octavalent anti-S. aureus vaccine including IsaA showed that antibodies against IsaA were not protective. This previous conclusion was verified by immunizing mice with IsaA only, which showed that high IsaA-specific IgG titers did not protect mice against a challenge with the S. aureus isolate P (Supplementary Figs. 2 and 3). To determine whether the IsaA epitopes recognized by potentially protective IsaA-specific IgGs from six EB patients, and six non-protective IsaA-specific IgGs from immunized mice are similar or different, we employed a Western blotting approach. The results in Figure 6 show that all tested sera of mice and men contained IgGs recognizing the full-size IsaA and the IsaA fragment N. All sera from mice contained IgGs recognizing fragment C, whereas this was significantly less common for the sera from EB patients. None of the tested sera contained IgGs recognizing fragment C2, and only two of the tested mouse sera contained IgGs recognizing fragment C1. Intriguingly, a distinguishing feature of the EB patient sera was that, with exception of the EB patient serum 51, all contained significant levels of IgGs against the N1 fragment (between ~22 to 41% of the total signal). Overall, this suggests that the IsaA-specific IgGs of EB patients preferentially recognize the N1 fragment of IsaA, similar to the protective humAb 1D9, whereas the non-protective IsaA-specific IgGs of immunized mice preferentially recognize the C fragment of IsaA (Fig. 6).

Figure 6. Differential binding of human and murine IgGs to IsaA-derived fragments

Proteins in the growth medium fractions of L. lactis PA1001 producing the full-size IsaA or N-terminal (N, N1, N2) or C-terminal (C, C1, C2) fragments of IsaA were separated by LDS-PAGE. Next, a Western blotting analysis was performed using sera from EB patients (EB01, EB09, EB11, EB15, EB51 and EB55) or sera from the mice immunized with IsaA (M31, M32, M33, M34, M35 and M36). The molecular weights (kDa) of marker proteins are indicated on the left. The intensities of detected bands were assessed with ImageJ, and the relative intensity for each band is indicated below each blot as the percentage of the total intensity determined for full-size IsaA plus the N-terminal (N, N1, N2) and C-terminal (C, C1, C2) fragments.

Discussion

The aim of this study was to localize immunogenic epitopes in the IsaA protein of S. aureus and to correlate the recognition of these epitopes by particular IgGs to protection against S. aureus infection. The results show that potentially protective IsaA-specific human IgGs predominantly target a conserved N-terminal domain in IsaA, while non-protective IsaA-specific murine IgGs predominantly target the conserved C-terminal domain of IsaA.

Previous studies have shown that the C-terminal part of IsaA contains a soluble lytic transglycosylase (SLT) domain (Pfam 06737) that is conserved also in the SceD protein of S. aureus. This SLT domain is able to cleave peptidoglycan, and impacts on the clumping and separation of S. aureus cells.
contrast, a possible function of the N-terminal region of IsaA was so far not known. Of note, our present data show that this N-terminal region contains a domain (NCD) that is well conserved in the IsaA and SceD proteins of a wide range of *Staphylococcus* species. Using proteomics approaches, it was previously shown that IsaA and SceD both are non-covalently cell wall-bound proteins. As it is known that most peptidoglycan hydrolases are composed of a catalytic site domain and a cell wall binding domain, we hypothesized that the NCD domain could contribute to cell wall binding. Indeed, separate expression of the different regions of IsaA showed that the N-region, which includes the NCD domain, has affinity for cell walls of *S. aureus* and *L. lactis*. In contrast, the C-terminal region does apparently not bind cell walls by itself. Yet, the highest levels of cell wall binding were observed for the intact IsaA protein, indicating that both the N- and C-regions are involved in cell wall binding with a potentially more prominent contribution from the N-region. It should be noted, however, that a substantial portion of IsaA is secreted into the growth medium, and this is also the case for SceD. Consistent with the observed cell wall binding of IsaA, we did observe localization of this protein to the *S. aureus* cell surface using an immunofluorescence microscopy approach. Of note, this involved an IRDye 800CW-labeled F(ab)_2 fragment of the humAb 1D9, which binds to the N1 subdomain of IsaA. Together, these observations imply that the N-domain of IsaA is exposed on the *S. aureus* cell surface, where it is accessible to IgG.

Intriguingly, our present results show that sera of patients with the genetic blistering disease EB contain IgGs that predominantly target the N-domain of IsaA. Chronic wounds of these patients are heavily colonized with *S. aureus*, which was previously shown to elicit IgG levels against *S. aureus* proteins that were much higher than the IgG levels against the respective proteins in healthy volunteers. The highest IgG levels were detected against the IsaA protein, leading to the view that these IgGs could be protective against *S. aureus* infections. This view is supported by the fact that EB patients rarely suffer from invasive *S. aureus* infections despite the high-level colonization of their wounds, and by the observation that monoclonal antibodies against IsaA (i.e. 1D9 and UK-66) can be protective against *S. aureus* infection in mouse models. Of note, our present study also shows that the protective humAb 1D9 also recognizes the N-domain of IsaA. In contrast to our findings with the sera of EB patients, the immunization of mice with purified IsaA did not elicit the production of IgGs that protect against *S. aureus* infection. In this case, the IsaA-specific IgGs predominantly recognized the C-terminal region of IsaA as shown in our present study. Together, these observations imply that IgGs against the C-terminal region of IsaA do not effectively protect against *S. aureus* infection.

A key question that remains to be answered is why does there appear to be a bias towards IgGs specific for the N-terminal region of IsaA in EB patient sera, and a bias towards IgGs specific for the C-terminal region in immunized mice? Our present studies show that the N-terminal region of IsaA is exposed on the cell surface of *S. aureus*, which might suggest that this domain is better exposed to the human immune system than the C-terminal region of IsaA. Yet, our previous proteomics study, where *S. aureus* cells were shaved with trypsin that was immobilized on agarose beads, clearly showed that also the C-terminus of IsaA is exposed to the *S. aureus* cell surface. This makes a differential exposure of the N- and C-terminal regions of IsaA on the *S. aureus* cell surface a less likely explanation for the observed differences in the IgG specificities from mice and men. An alternative explanation could be that the immunogenicity of the N- and C-terminal domains of IsaA is different, depending on whether the immune system is challenged with IsaA attached to the *S. aureus* cell surface or with soluble IsaA. Conceivably, such a difference could relate to conformational differences in the respective domains when they are associated with the cell or secreted into the growth medium.
Conclusion

Altogether, our present study shows that the immune responses to IsaA are very different in the investigated mouse and human sera. In particular, the results seem to suggest that IgGs against the N-terminal domain of IsaA are potentially protective against *S. aureus* infection. This focuses attention on the N-terminal region of IsaA as a potential component in a future vaccine against the important human pathogen *S. aureus*.

Acknowledgements

We thank the anonymous patients with EB from the Dutch Epidermolysis Bullosa Registry for blood donations, and Magda van der Kooi-Pol, José Duipmans and Marcel Jonkman for collecting the EB patient sera in a previous study. We thank Sjouke Piersma for his help in the Western data analysis, Simon Foster for providing anti-SceD antibodies, and N. Sakata for providing anti-IsaA polyclonal rabbit antibodies.

Funding Statement

This research was supported by the Top Institute Pharma projects T4-213 and T4-502. F.R.P. received a scholarship from CONACyT (169643) and was supported in parts by the Graduate School for Medical Sciences of the University of Groningen. The funders had no role in study design, data collection and analysis, decision to publish, or preparation of the manuscript.

Author’s Contributions

DGAMK, FRP, JWB, IAJMB-W, GB conceived and designed the experiments. DGAMK, FRP, HH, SvdB, JWB, CK, RCP performed the experiments. DGAMK, FRP, HH, JWB, JMvD, GB analyzed the data. DGAMK, FRP, SvdB, JWB, IAJMB-W, JMvD, GB contributed reagents, materials and analysis tools. DGAMK, FRP, JMvD, GB wrote the manuscript. All authors have reviewed and approved the final manuscript.
S. aureus IsaA epitope recognition

Supplementary Figures

Figure S1 - S3

Supplementary Figure 1. Conserved N-terminal domain of IsaA
Conservation of amino acid residues in the ‘N-terminal conserved domain’ (NCD) of IsaA was assessed by multiple alignment of 391 protein reference sequences with residues 30-84 of IsaA. The alignment shows the similarity of the NCDs of the IsaA and SceD proteins from different staphylococcal species. Residues identical to the consensus sequence are marked in dark blue; residues with a positive Blosum62 score compared to the consensus are marked in light blue. The protein sequence gi numbers and the respective amino acid regions (in parentheses) are indicated.

Supplementary Figure 2. IgG titers in sera of mice immunized with IsaA
Six mice were immunized subcutaneously with IsaA-His6 at days -28, -21 and -14 (25 μg), and 11 mice were placebo immunized following the same schedule. The IsaA-specific IgG titers on day -1 were assessed by ELISA. Each symbol represents a single mouse. The median values are indicated by a horizontal line.
Supplementary Figure 3. Survival of immunized mice with *S. aureus* isolate P bacteremia

Mice immunized with IsaA (▲, n = 6) or placebo-immunized mice (●, n = 11) were infected with the clinical *S. aureus* isolate P by intravenous injection of $3 \times 10^5$ colony-forming units (CFU). Subsequently, the infected mice were monitored for 14 days. No statistically significant difference in animal survival rates was observed (P > 0.05; log rank test).
