Since plasma lipoproteins contain both protein and phospholipid components, either may be involved in processes such as atherosclerosis. In this study the identification of plasma lipoprotein-associated phospholipids, which is essential for understanding these processes at the molecular level, are performed. LC-ESI/MS, LC-ESI-MS/MS and High Performance Thin Layer Chromatography (HPTLC) analysis of different lipoprotein fractions collected from pooled plasma revealed the presence of phosphatidylethanolamine (PE), phosphatidylinositol (PI), and sphingomyelin (SM) only on lipoproteins and phosphatidylcholine (PC), Lyso-PC on both lipoproteins and plasma lipoprotein free fraction (PLFF). Cardiolipin, phosphatidylglycerol (PG) and Phosphatidylserine (PS) were observed neither in the lipoprotein fractions nor in PLFF. All three approaches led to the same results regarding phospholipids occurrence in plasma lipoproteins and PLFF. A high abundancy of PE and SM was observed in VLDL and LDL fractions respectively. This study provides for the first time the knowledge about the phospholipid composition of all defined plasma lipoproteins.

Despite major advances in the aetiology, prevention and treatment of cardiovascular disease, and in particular atherosclerosis, it remains the leading cause of mortality and morbidity in Western countries. Atherosclerosis results from the interaction between genetic and environmental factors modulating the functions of various cell types and inflammatory molecules within the arterial wall. Extensive epidemiological studies have shown that lipoproteins play a major role in atherosclerosis of which LDL cholesterol levels are directly related to the risk of coronary artery disease and HDL cholesterol levels are inversely related to this risk. Despite lipid cholesterol modification therapies such as LDL-lowering treatments, cardiovascular events still occur. In addition, compared to plasma cholesterol measurements, much less attention has been given to the relationship between phospholipids and atherosclerosis.

Lipoproteins are different in phospholipid composition and (apolipo) protein contents. Moreover, the apolipoproteins play an important role in lipoprotein stability, binding, and catabolism. In addition, plasma phospholipids transfer protein (PLTP) mediates the transfer of phospholipids from VLDL and LDL to HDL and is able to modulate HDL size and composition and may also be involved in HDL cellular-mediated efflux of phospholipids and cholesterol. The presence of abnormal phospholipids was also shown in patients with essential hypertension. In addition, it was recently shown that the phospholipid composition of HDL plays an important role in SR-BI- and ABCA1-mediated cholesterol efflux3,4,14. Yancey et al.15 also demonstrated that Phosphatidylcholine (PC) enrichment of HDL increase the efflux, whereas sphingomyelin decrease the influx of HDL cholesterol. Other studies suggest that the phospholipid composition of HDL could be a key determinant in a variety of other processes, including the inhibition of adhesion molecules,15-18 the efflux of cholesterol from Fu5AH cells to human serum19 and in its anti-inflammatory and anti-oxidant properties20,21.

It is also recently suggested that hemodialysis therapy in patients with chronic renal failure play an important role in dyslipidemic profile of these patients by modification of lipid and phospholipids composition concentrations22. Furthermore, it has been recently reported that the concentrations of phospholipid composition are clearly different in acute phase HDL compared to normal HDL23.

The phospholipid content is one of the factors, which have been suggested to contribute to the closer lateral molecular packing in LDL. The phospholipid composition in surface of lipoprotein particles influences the binding of apo A–I and that is the reason why apo A–I is absent in LDL particles in vivo. The impairment of PC biosynthesis led to the inhibition of VLDL secretion, resulting in the changing of nascent VLDL phospholipids
In addition, VLDL stimulates the contact pathway of blood coagulation via the exposure of phosphatidylethanolamine. Navab et al. have recently shown that oral phospholipid 1,2-dimyristoyl-sn-glycero-3-phosphocholine (DMPC) in the drinking water of apoE-deficient mice results in an increase of plasma HDL cholesterol levels, an improvement in HDL function, and a marked reduction in atherosclerosis. Moreover, numerous studies have shown that phospholipid administration leads to the reduction of atherosclerotic development in vivo.

Based on above-mentioned evidence, plasma lipoproteins contain both protein and phospholipid components, either of which may be involved in the atherosclerosis, inflammation, lipid metabolism, and haemostatic processes. Thus, the plasma lipoprotein functions can be manipulated by protein or phospholipids compositions. After genomics and proteomics, many analytical techniques have been developed and used to elucidate the human lipidome. A lipidomics approach may be a reliable way to analyze the lipid composition in biological fluids, such as human plasma lipoproteins. A reliable analysis of phospholipid molecules, “lipidomics”, in the context of genomics and proteomics is an essential step to understanding cellular physiology and pathology and consequently, lipid biology has become a major research target of the post-genomic revolution and systems biology.

In our previous study, we have characterized proteins associated with HDL. In this study, liquid chromatography-electrospray ionization/mass spectrometry (LC-ESI-MS) and tandem MS were performed to identify the phospholipids composition of the major lipoprotein classes. ESI allows for large, non-volatile molecules to be analyzed directly from the liquid phase. The analysis of main phospholipids composition of lipoproteins is needed to gain additional insight into in vivo functions of lipoprotein-phospholipids content both in normal and pathological states.

Results
Characterization of lipoproteins. High performance gel-permeation chromatography (HPGC). To investigate whether one-step ultracentrifugation provided lipoprotein fractions of acceptable purity, the collected lipoprotein fractions were subjected to HPGC (figure 1). The HDL fraction obtained by ultracentrifugation resulted in a single peak with a retention time of approximately 51 min (figure 1D).

Figure 1 | Panel A shows the major human plasma lipoprotein fractions after one-step salt gradient ultracentrifugation. Panel B shows Cholesterol profiles of major plasma lipoprotein fractions separated by High Performance Gel-Permeation Chromatography (HPGC). Lipoprotein fractions obtained by one-step ultracentrifugation were subjected to size-exclusion chromatography as described in Material and Methods. Panel (A) CM fraction, Panel (B) VLDL fraction, panel (C) LDL fraction, panel (D) HDL fraction, panel E: Plasma lipoproteins free fraction and panel F: standard cholesterol.
HPGC elution of a commercial HDL lipoprotein standard revealed identical elution patterns, which confirmed that the fraction contained only HDL (figure 1F). VLDL and LDL fractions isolated by the same method yielded peaks eluting at approximately 28 min and 40 min, respectively (figure 1B and C). Same retention times were found when commercial LDL and VLDL lipoprotein standards were analyzed by HPGC, confirming the identity of the peaks (figure 1F). However, the intermediate-density lipoprotein (IDL) peak was also detected in the VLDL fraction. No peaks were detected in the plasma lipoprotein free fraction (figure 1E). The IDL fraction obtained by a combination of ultracentrifugation and HPGS yielded a peak eluting at approximately 35 min (figure 2). Although the IDL fraction contains LDL, the fraction was very highly enriched in IDL. The subject of CM fraction to HPGC resulted in a single peak with a retention time of 28 min which is similar to elution peak of VLDL and HDL (figure 1A). Although both CM and VLDL fractions yielded a peak eluting at 28 min, the IDL peak was not observed in CM fraction. Nepholometry and Western blot analysis of apolipoproteins. Nepholometry was performed to further investigate the results obtained by HPGC concerning the purity of the isolated lipoprotein fractions collected by ultracentrifugation. Nepholometric analysis revealed the presence of apo A-I in the HDL fraction (approximately 1.1 g/l), but not in the VLDL, IDL and LDL or plasma lipoprotein free fractions. In addition, no cross-contamination of apo B was observed in the HDL or PLFF fractions while it was found to be abundant in the CM (0.52 g/l), VLDL (approximately 0.7 g/l), IDL (0.7 g/l) and LDL (1.2 g/l) fractions. Western blotting with anti-apo B antibodies confirmed the results obtained by HPGC and nepholometry (figure 3). As depicted in figure 3, anti-apo B antibodies showed the presence of an intense band of about 550 kDa corresponding to full length apo B100 in VLDL, IDL and LDL fractions, but not in HDL and PLFF fractions. This indicated that the one-step ultracentrifugation protocol resulted in a purification of the major lipoprotein fractions (and a combination of ultra and HPGC for IDL purification) without contamination with other lipoproteins. Identification of plasma lipoprotein phospholipids composition. Liquid Chromatography-ElectroSpray Ionization-Mass Spectrometry (LC-ESI-MS). LC-ESI-MS analysis in the negative and positive mode led to the identification of different phospholipids associated with lipoproteins. All samples were run twice in positive ion and negative ion modes, allowing the detection of the predominant positive and/or negative ions of each class of phospholipids. Although we did not observe CL, PG and PS in all lipoprotein fractions as well as PLFF (table 1, supplement) the PI (figure 1 A–D, supplement) and SM negative ions of each class of phospholipids. Although we did not observe CL, PG and PS in all lipoprotein fractions as well as PLFF (table 1, supplement) the PI (figure 1 A–D, supplement) and SM were only detected in the plasma lipoprotein fractions (figure 2 A–D).
The PC, Lyso-PC and PE were also detected in all fractions (table 1, supplement). However, PE was not measured in PLFF fraction, using LC-ESI-MS approach (see Materials and Methods; ESI-MS paragraph). Also, CM was not analyzed by LC-ESI-MS strategy.

LC-ESI tandem MS (LC-ESI-MS/MS). LC-ESI-MS/MS was applied to further examine the observed phospholipid profile in the major lipoprotein fractions and PLFF obtained by LC-ESI-MS analysis.

LC-ESI-MS/MS strategy revealed the presence of PE (figure 4 A–E), PI (figure 5 A–E) and SM (figure 6 A–E) in all lipoprotein fractions but not in PLFF. The occurrence of PC and Lyso-PC were shown in all lipoprotein fractions and PLFF (figure 7 A–E and figure 8 A–E respectively), using LC-ESI-MS/MS. Although traces of SM were found in PLFF fraction, it could have resulted from very small traces of VHDL fraction and not vice versa. Furthermore, the CL, PG, and PS were also not detected in all fractions, applying this strategy. Although CL, PG, and PS were not observed in all fractions, lipoprotein fractions and PLFF obtained by LC-ESI-MS/MS strategy corresponded with the LC-ESI-MS profiles of the same fractions. The global intensity of each analyzed phospholipid in the different fractions was shown in table 1.

Discussion
To shed light in the role of lipoproteins in patho-physiologic processes it is essential to elucidate the make-up of the lipoprotein particles, i.e. its phospholipid and protein composition. Since recent...
clinical studies have stressed the atheroprotective and proatherogenic role of HDL and LDL respectively, further studies of these particles have become even more crucial. In this study, as first step, we applied a LC-ESI/MS and LC-ESI-MS/MS strategy to lipoprotein fractions to identify lipoprotein-associated phospholipids. Due to its high sensitivity, selectivity and specificity, LC-ESI-MS/MS is without parallel the most sophisticated technique for assessing the lipid composition of biological samples such as the phospholipid content of plasma lipoproteins. Lipoproteins were isolated from human pooled plasmas and the quality of purity of collected lipoproteins (VLDL, IDL, LDL and HDLs) was determined using three independent techniques: HPGC, nephelometry and Western blotting. Furthermore, it is basically impossible to separate chylomicrones from VLDL to collect the pure VLDL or CM due to the continuum of VLDL and CM sizes by ultracentrifugation and HPGC. Although CM and VLDL fraction could be contaminated with each other, the first fraction was rich in CM and the second one rich in VLDL. However, we did not observe any specific differences between the fraction rich in CM and VLDL fraction with respect to phospholipid composition.

Nephelometric analysis exhibited that apo A–I (the major constituent of HDL) was only observed in the HDL fractions, whereas apo B (the major constituent of CM, VLDL, IDL and LDL) was not. Furthermore, cholesterol analysis, protein analysis and elution behaviour of ultracentrifugation isolated VLDL, IDL (extra purified steps by HPGC), LDL, HDL and PLFF confirmed the purity of the fractions. Finally, Western blot analysis revealed the absence of apo B in the isolated HDL fractions and the presence of apo B in the isolated CM, VLDL, IDL and LDL fractions. These results confirm the utility of our strategy to collect lipoprotein fractions from plasma that was not contaminated with other lipoproteins, although CM and VLDL fractions could be contaminated with each other.

LC-ESI/MS analysis resulted in the identification of sphingomyelin, PE, PI, PC and Lyso-PC in all lipoprotein fractions. However, we did not observe PG, PS and CL in plasma lipoprotein and lipoprotein free fractions. This could be due to the presence of only very low amounts of these phospholipids (below the detection limit of the LC-ESI-MS technique) and phospholipids and lipoprotein free fractions under normal conditions in plasma. The very low abundances of these phospholipids were also mentioned by Deguchi et al.39. Also, PG constitutes 2% of the total plasma phospholipids as shown by Schwars et al.40 and was confirmed by Uran et al.41. Since plasma divided in 9 fractions in this study, the concentration of PG (2%) will be also divided in these 9 fractions. That could be the reason why PG was not detected in our samples.

LC-ESI-MS/MS was used as a complementary technique to improve selectivity and consequently the signal/noise ratio of the

Figure 5 | High-performance liquid chromatography electrospray ionization tandem mass spectrometry analysis of plasma lipoproteins and plasma lipoprotein free fraction. We did not observe any adducts ions like Na or K. positive scan [M + H]+. Characteristic part of the parent-scan for phosphatidylinositol (PI) in the corresponding retention time window. ‘36:2’ specifies the composition of the protonated molecular ion as a species with 36 C-atoms in total in the acyl-chains with 2 unsaturated bonds in total; other assignments are analogous. (A) CM fraction, (B) VLDL fraction, (C) IDL fraction, (D) LDL fraction, (E) HDL fraction and (F) PLFF fraction.
preselected compound classes; overall it lowers limit of detections (LOD). By using the MS/MS mode (classes of) compounds can easily be identified, filtering out the interference of all those compounds that do not meet the MS/MS conditions. LC-ESI-MS/MS approach led to the identification of the same phospholipids as we identified in the different fractions when we used LC-ESI-MS, Indicating that LC-ESI-MS/MS confirms the results obtained by LC-ESI-MS.

It is intriguing to note that PE, PI and SM were only observed in plasma lipoproteins and not in PLFF. This finding confirmed the specificity of our utility to identify lipoprotein-associated phospholipids. Furthermore, on searching the literature, we were unable to find any study in which the plasma lipoprotein free fractions were used as control for plasma lipoproteins. In addition, HPTLC was used as an alternative method to support and confirm the results obtained by MS and tandem MS approach regarding phospholipids composition of the major plasma lipoproteins. Three independent strategies led to the identification of a similar lipoprotein-associated phospholipid pattern, indicating a high confidence in the obtained results. Interestingly, the molecular profile appeared to be conserved between the different lipoproteins even though the concentrations of the lipid classes show slight differences except for PC species 38:2, 38:4 and 40:6 in CM fraction. These three PC species were only detected in CM fraction and were complete absent in other fractions.

Although LC-ESI-MS and LC-ESI-MS/MS were applied as qualitative approach, HPTLC was used as semi-quantitative in this study. MS and tandem MS were used as qualitative approach, because of three points: 1- the use of different internal standard for each plasma lipoprotein fraction, 2; the use of different internal standard for each main phospholipid and lipid species and 3; the combination of step 1 and 2 increase the complexity of samples and in turn the use of many different internal standards hampered to obtain correct quantification. This complexity was also described by Uran et al. However, Uran et al. have shown a limit detection of 0.1–5 ng for blood-associated phospholipids. For this reason, HPTLC was used as semi-quantitative approach in this study and not MS approach.

Numerous studies show that low HDL-C can be considered as an independent risk factor of atherosclerosis even when LDL-C is low. In addition, it is also well studied that increased HDL-C reduces the risk for cardiovascular disease. Although there are many available strategies to increase the HDL-C, the present available therapies with the current drugs have a limited effect because of low efficacy and severe side effects of these drugs. An alternative therapy for the increase of the HDL-C levels is PI therapy via diet as shown recently by Burgess et al. and the others. Burgess et al. have shown that PI stimulates cholesterol reverse transport via an increased efflux from peripheral tissues to HDL and in turn the transport of cholesterol.
from HDL to the liver, bile, and faeces for clearance or removing. They have also demonstrated that when PI is taken orally during two weeks therapy leads on the one side the increase of apo-AI concentrations and on the other side the decrease of plasma triglyceride levels. Our results revealed that PI is only present on plasma lipoproteins, and this may increases the specificity of therapy with PI via diet to affect the lipoprotein composition levels. Although the mechanism study of PI effect on lipoprotein is beyond our study, the PI therapy via diet is very simple and performable without major and severe side effects.

Another novel finding in this study is also the presence of SM only on lipoproteins. Although SM plays a major role in the constitution of all lipoproteins, the physiological function of SM in plasma is not until recently clear. Papasani et al. have shown that SM inhibits the oxidation of lipoproteins. Furthermore, Rey et al. have shown in reconstituted high density lipoproteins studies that SM influences the structure of discoidal and spherical rHDL as well as it inhibits the LCAT reaction in discoidal rHDL. It has been recently suggested that presence of SM in the lipoprotein surface involved in lipoprotein lipase-mediated lipolysis, and that cholesterol enrichment in the lipoprotein surface does not affect lipolysis. Moreover, it has been reported that SM can be used as marker for the clearance of remnant-like particles. Also, Jiang et al. have suggested that plasma SM concentration is a risk factor for atherosclerotic process. Although the function of SM in lipoproteins remains to be fully clarified, the SM could be also considered as an alternative therapy and pharmacological intervention to affect lipoprotein levels. To our knowledge, the observed effects of PI and SM in plasma could be only possible via lipoproteins, since PI and SM were only present on lipoproteins (with high intensity of SM in LDL fraction) and not detected in plasma lipoprotein free fractions.

Next to other studies, our approach also revealed the presence of PE on lipoproteins. Recently, Agren et al. demonstrated that there is a selective secretion of PE and sphingomyelin molecular species during VLDL secretion when they compare the molecular species phospholipids content of VLDL with liver phospholipids composition. Furthermore, it has been recently shown that Prothrombinase enhancement through quantitative and qualitative changes appear to affect very low density lipoprotein in complex with C-reactive protein, and the qualitative changes appeared to be resulted from a deficiency of PE in VLDL from disseminated intravascular coagulation patients with the biphasic waveform. In addition, Phosphatidylethanolamine N-methyltransferase appears to be an essential component in the secretion of apoB100-containing

**Figure 7** | High-performance liquid chromatography electrospray ionization tandem mass spectrometry analysis of plasma lipoproteins and plasma lipoprotein free fraction. We did not observe any adducts ions like Na or K. positive scan [M + H]+. Characteristic part of the parent-scan for phosphatidylcholine (PC) in the corresponding retention time window. ‘34 : 2’ specifies the composition of the protonated molecular ion as a species with 34 C-atoms in total in the acyl-chains with 2 unsaturated bonds in total; other assignments are analogous. (A) CM fraction, (B) VLDL fraction, (C) IDL fraction, (D) LDL fraction, (E) HDL fraction and (F) PLFF fraction.
VLDLs. Since PE is only present in lipoproteins, (with highest abundancy in VLDL fraction) its physiological role could be only possible via lipoproteins.

LC-ESI/MS analysis further revealed the presence of PC and Lyso-PC on lipoproteins. Parthasarathy et al. have reported that 40% of the PC in LDL is converted to lyso-PC during oxidized modification. Also, the lyso-PC concentration is shown to be increased in atherosclerotic plaques in mice fed an atherogenic diet. Furthermore, Lyso-PC induces human coronary artery smooth muscle cells migration. In addition, Lyso-PC increased in atherogenic lipoproteins and atherosclerotic lesions, and has been shown to stimulate transcription of a variety of endothelial genes relevant to atherogenesis.

In summary, this study resulted in the identification of 5 phospholipids associated with lipoproteins of which PE, PI and SM were only present in lipoproteins. The role of these identified lipoprotein-associated phospholipids in atherothrombosis awaits further investigation and may provide new insights into the mechanism(s) of atherothrombotic diseases and the future pharmacological intervention.

Methods

Materials. Human blood was drawn from overnight-fasted normal healthy volunteers after informed consent, by venipuncture into tubes containing sodium-citrate as anticoagulant. Subsequently, plasma was obtained by centrifugation at 1,000 x g for 15 minutes at 4 °C and used freshly or stored at –80 °C for further analysis. All experiments were performed in accordance with relevant guidelines and regulations and had the approval of the local Medical ethical committee (Academic Medical Center Amsterdam/ University Medical Center Groningen).

Lipoprotein isolation by salt-gradient ultracentrifugation. One-step ultracentrifugation was used according to Kleinfeld et al. with some modifications (omission of sucrose in the salt gradient, and use of a 103,000 x g centrifugation step) to obtain the major lipoprotein fractions (VLDL, IDL, LDL, and HDL) and HDL-2 and VHD as well as Plasma Lipoprotein Free Fraction (PLFF). In this study, all plasma lipoprotein fractions were analyzed except lipoprotein small a (LPa) that was due to very small amount of extracted lipid fraction. The collected lipoprotein fractions were concentrated by concentrator (Eppendorf) and were freshly used in the experiments and the rest stored for 10 days at 4 °C. Only for the isolation of chylomicrons (CM) we applied other approach.

CM isolation. 12 ml non-fasted plasma was spun in a SW41.14 rotor for 1 hour at 29000 rpm in a Beckman ultracentrifuge. The top 3 ml was collected and spun under the same conditions. The top approximately 2.5 ml was again eluted and spun under the same circumstances. Finally, the top 2 ml collected fraction (rich in CM) was subjected to one-step ultracentrifugation according to Kleinfeld et al. with some modifications. This strategy was taken to remove as much VLDL possible from the chylomicrons fraction. All ultra, HPGC and mass spectrometry experiments involved CM fraction were separately performed and analyzed.
High performance gel-permeation chromatography (HPGC), cholesterol analysis and protein analysis. The cholesterol profiles of the major lipoprotein types were determined applying HPGC\(^{32-36}\). 60 µl of lipoprotein fractions collected by ultracentrifugation was introduced to gel-permeation chromatography using a Superose 6 HR 10/30 column (Pharmacia Biotech, Uppsala, Sweden)\(^{32-35}\). Chromatographic profiles of commercially available plasma lipid standards (SKZL, Nijmegen, The Netherlands) served as a reference. To obtain a purified ultra IDL fraction, Ultra IDL fraction was repeatedly exposed to HPGC. The protein analysis was used for the ultra IDL fraction analysis. All conditions for the protein analysis of the ultra collected IDL fraction are the same as above-mentioned procedure meant for the cholesterol analysis.

Nephelometry. Apo A-1 and apo B content in the lipoprotein fractions were measured by immunonephelometric determination using a BN ProSpec nephelometer protein analyser (Dade Behring, Marburg, Germany) according to the manufacturer’s instructions for ECL. Plex Western Blotting System (GE Healthcare Biosciences). PageRuler prestained protein ladder (Fermentas, Germany) were run in parallel. The protein concentration of the lipoprotein fractions was determined by absorbance at 280 nm (an OD of 1 equals 1 mg/mL).

Lipoprotein and plasma lipoprotein free fraction associated Phospholipid extraction. The phospholipids from 200 µl of each plasma lipoprotein and lipoprotein free fractions (three independent Lipoprotein isolation by salt-gradient phase extraction (monophasic))\(^{58}\). Based on this monophasic approach, we assume that we did not lose any phospholipids in our plasma lipoprotein fractions.

Liquid Chromatography- ElectroSpray Ionization-MS (LC-ESI-MS). LC. The LC system consisted of an HP1100 series binary gradient pump, a vacuum degasser, a column temperature controller (all from Hewlett Packard, Wilmington, DE, USA) and a Gilson 231 XL autosampler (Gilson, Villers-le-Bel, France). 20 µl of sample was loaded onto an analytical LiChrosphere Si 60 column (250 x 2 mm, 5 µm particle size, Merck, Darmstadt, Germany) and the column temperature was maintained at 22 °C. This phospholipid extraction approach is a single-phase extraction (monophasic)\(^{38}\). Based on this monophasic approach, we assume that we did not lose any phospholipids in our plasma lipoprotein fractions.
