ICLUSIG®: Uncover a DEEP RESPONSE

As a result, 23% of chronic phase CML patients achieved a deep molecular response (MR4.5) with Iclusig®.1, 2 Iclusig® is the 3rd generation TKI with the potential to deliver FAST, DEEP and DURABLE response in patients with concern with CML.1-3

Este medicamento no se encuentra comercializado en España.

ICLUSIG® (ponatinib) tablets

Dosage and administration:
Recommended starting dose 45 mg once daily; swallow tablets whole. Assess and actively manage cardiovascular and haematological effects. Assess hepatic enzymes, LFTs peripheral oedema, rash, dry skin, pain incl. back, bone & joint pain, lower limb oedema, dyspepsia, vomiting, fatigue, arthralgia, myalgia, muscle spasms, abdominal pain, nausea, constipation, abdominal distension, flushing, diarrhoea, dysphagia, dermatitis, dry mouth, increased liver enzymes, hepatitis, jaundice, pancreatitis. At 4 years, 23% of chronic-phase CML patients achieved a deep molecular response (MR4.5) with Iclusig®.1-3

---

In case of disease progression or severe adverse reactions consider dose reduction to 15 mg for CP-CML patients who achieve a Major Cytogenetic Response; consult the SmPC for full details of all recommended dose modifications. Contraindications: Myelosuppression: Perform Full Blood Count every 2 weeks for the first 3 months and then monthly as clinically indicated. Venous thromboembolism: Perform an initial test at baseline. Iclusig® is the 3rd generation TKI with the potential to deliver FAST, DEEP and DURABLE response in patients with concern with CML.1-3

Word of Welcome

On behalf of the EHA Board and the Scientific Program Committee we are pleased to introduce to you this year’s Abstract Program. The richness of the program is a testament to EHA’s spirit: unity through diversity.

The Scientific Program Committee has compiled an exciting program of Simultaneous Oral and Poster Sessions from close to 2500 submitted abstracts representing all fields of hematology. For the second year, a number of presenters will have the opportunity to pitch their abstract. These Poster pitches are an exciting opportunity to promote basic science and research, and to invite delegates to the poster walks.

The six Best Abstracts will be presented during the Presidential Symposium on Friday afternoon. This will be a session not to miss. During this plenary session EHA is also awarding, for the first time, the best abstracts by trainees in four categories in basic and clinical hematology research. These awardees and the travel grant winners can be found on the next page. YoungEHA are the future of hematology!

The late breaking abstract submission is an integral part of the scientific program. The late breaking submission is intended for abstracts with “hot” data that were not available by the time of the regular submission deadline. Only few abstracts, with the most exciting results are selected for a presentation in the Late Breaking Oral Session on Sunday morning.

A selection of abstracts will be presented during the regular Poster Walks. The Poster Session consists of two parts: the Poster Walk and dedicated Poster Browsing Time. This setup guarantees sufficient time for discussion of the important research presented, so look out for the Poster Walk Moderators in their red baseball caps! There will also be E-posters available on the E-poster screens, for which a specific time is allocated during the Poster Browsing Time at the end of each Walk. The Simultaneous Oral Sessions are spread over three days [Friday to Sunday] providing you with ample opportunity to attend a number of these important sessions.

All posters can be viewed on the E-poster screens from Friday morning to Saturday evening. All the abstracts are also available on the EHA Learning Center, for which you have complimentary access after the congress: learningcenter.ehaweb.org.

On behalf of the EHA Board, the committees and all the people involved in this year’s EHA Congress, we thank you for coming to Madrid and wish you a great meeting.

Shai Izraeli
Chair Scientific Program Committee 22nd Congress
Travel Grant Winners

For this Congress 140 travel grants have been awarded to junior members of EHA, based on the mean score of their abstracts. EHA congratulates the following persons with their travel grants:

Agrawal M, Germany
Anagnostou T, USA
Arriau E, Spain
Barcia Duran JG, USA
Beekman R, Spain
Bhoi S, Sweden
Binder M, USA
Birgisdottir AM, Iceland
Blunt M, United Kingdom
Birgisdóttir AM, Iceland
Botthof J, United Kingdom
Bouillon AS, Belgium
Brockelmann P, Germany
Buffiere A, France
Burney C, United Kingdom
Cabal-Hierro L, USA
Caraffini V, Austria
Casado Izquierdo P, United Kingdom
Cerchione C, Italy
Chaudhry G, India
Chitre S, United Kingdom
Cleyrat C, USA
De Bie J, Belgium

YoungEHA Best Abstract Awards

One of the primary missions of the European Hematology Association is to support young hematology clinicians and researchers. This year we are proud to announce the launching of the YoungEHA Best Abstract Awards. These will be awarded to the highest ranking abstracts in the following four categories: Clinicians or medical students training for a PhD degree, PhD research students, postdoctoral fellows and clinical hematology trainees. We are honored that these outstanding YoungEHA trainees will be presenting during the EHA congress – they are the future of Hematology!

CLINICAL TRAINEE AWARD
K C Pawlyn, United Kingdom

MD-PH D AWARD
K O Schwartzman, Israel

PHD RESEARCH STUDENT AWARD
K JG Barcia Duran, USA

POSTDOCTORAL RESEARCH TRAINEE AWARD
K F Vinchi, Italy
**Information for readers, authors and subscribers**

Haematologica (print edition, pISSN 0390-6078, eISSN 1592-8721) publishes peer-reviewed papers on all areas of experimental and clinical hematology. The journal is owned by a non-profit organization, the Ferrata Storti Foundation, and serves the scientific community following the recommendations of the World Association of Medical Editors (www.wame.org) and the International Committee of Medical Journal Editors (www.icmje.org).

Haematologica publishes editorials, research articles, review articles, guideline articles and letters. Manuscripts should be prepared according to our guidelines (www.haematologica.org/information-for-authors), and the Uniform Requirements for Manuscripts Submitted to Biomedical Journals, prepared by the International Committee of Medical Journal Editors (www.icmje.org).

Manuscripts should be submitted online at http://www.haematologica.org/.

**Conflict of interests.** According to the International Committee of Medical Journal Editors (http://www.icmje.org/#conflicts), "Public trust in the peer review process and the credibility of published articles depend in part on how well conflict of interest is handled during writing, peer review, and editorial decision making". The ad hoc journal’s policy is reported in detail online (www.haematologica.org/content/policies).

**Transfer of Copyright and Permission to Reproduce Parts of Published Papers.** Authors will grant copyright of their articles to the Ferrata Storti Foundation. No formal permission will be required to reproduce parts (tables or illustrations) of published papers, provided the source is quoted appropriately and reproduction has no commercial intent. Reproductions with commercial intent will require written permission and payment of royalties.

Detailed information about subscriptions is available online at www.haematologica.org. Haematologica is an open access journal. Access to the online journal is free. Use of the Haematologica App (available on the App Store and on Google Play) is free.

For subscriptions to the printed issue of the journal, please contact: Haematologica Office, via Giuseppe Belli 4, 27100 Pavia, Italy (phone +39.0382.27129, fax +39.0382.394705, e-mail: info@haematologica.org).

Rates of the International edition for the year 2017 are as following:

Disclaimer. Whilst every effort is made by the publishers and the editorial board to see that no inaccurate or misleading data, opinion or statement appears in this journal, they wish to make it clear that the data and opinions appearing in the articles or advertisements herein are the responsibility of the contributor or advisor concerned. Accordingly, the publisher, the editorial board and their respective employees, officers and agents accept no liability whatsoever for the consequences of any inaccurate or misleading data, opinion or statement. Whilst all due care is taken to ensure that drug doses and other quantities are presented accurately, readers are advised that new methods and techniques involving drug usage, and described within this journal, should only be followed in conjunction with the drug manufacturer's own published literature.

Direttore responsabile: Prof. Edoardo Ascani; Autorizzazione del Tribunale di Pavia n. 63 del 5 marzo 1955.  
Printing: Tipografia PI-ME, via Vigentina 136, Pavia, Italy. Printed in June 2017.
# TABLE OF CONTENTS

## Simultaneous sessions I

- New advances in plasma cell disorders and implications for therapy
- Aggressive Non-Hodgkin lymphoma - 1st line
- MRD directed treatment in AML
- New insights into chronic lymphocytic leukemia biology
- Pathogenesis of MDS
- Lymphoma biology
- Thalassemia
- AML. Biology I: Towards molecular therapies
- Hematopoiesis, stem cells and microenvironment
- Gene therapy, cellular immunotherapy and vaccination 1

## Presidential Symposium

- Best abstracts

# TABLE OF CONTENTS

## Simultaneous sessions II

- Front-line combinations in multiple myeloma and amyloidosis
- Hodgkin and indolent lymphoma - Clinical
- Biology of MPN: JAK2 and beyond
- Clinical trials including treatment discontinuation in CML
- AML: Biology II: Epigenetic targets
- Acquired and inherited platelet disorders
- Acute lymphoblastic leukemia - Biology
- Thrombotic disorders
- Stem cell transplantation - Experimental
- Sickle cell disease, enzymes
- New drugs for rescue in relapsed/refractory multiple myeloma
- Improving prognostication and front-line therapy in chronic lymphocytic leukemia
- Aggressive Non-Hodgkin lymphoma - Relapsed/refractory
- Targeted treatment of AML
- Immunotherapy in ALL
- Biology and disease monitoring in CML
- Prognostic markers and new treatment in MDS
- Stem cell transplantation - Clinical 1
- Bone marrow failure and PNH
- Quality of life, palliative care, ethics and health economics

## Poster sessions II

- Quality of life, palliative care, ethics and health economics 2: P728 - P737, p. 295
- Stem cell transplantation - Clinical 3: P738 - P748, p. 299
- Stem cell transplantation - Clinical 4: P749 - P758, p. 304
- Thrombotic disorders: P759 - P768, p. 307
**Simultaneous sessions III**

- Targeted therapies in relapsed in chronic lymphocytic leukemia
- Follicular lymphoma - Clinical
- Changing the strategy of therapy in multiple myeloma
- Old and new drugs in MPN
- Childhood and more intensive treatment of AML
- Stem cell transplantation - Clinical 2
- Biomarkers in ALL
- Infectious diseases, supportive care
- Iron: Deficiency and overload
- Gene therapy, cellular immunotherapy and vaccination 2

**E-posters**

- Acute lymphoblastic leukemia - Biology
- Acute lymphoblastic leukemia - Clinical
- Acute myeloid leukemia - Biology
- Acute myeloid leukemia - Clinical
- Aggressive Non-Hodgkin lymphoma - Clinical
- Bleeding disorders (congenital and acquired)
- Bone marrow failure syndromes incl. PNH - Clinical
- Chronic lymphocytic leukemia and related disorders - Biology
- Chronic lymphocytic leukemia and related disorders - Clinical
- Chronic myeloid leukemia - Biology
- Chronic myeloid leukemia - Clinical
- Enzymopathies, membranopathies and other anemias
- Gene therapy, cellular immunotherapy and vaccination
- Hematopoiesis, stem cells and microenvironment
- Hodgkin lymphoma - Clinical
- Indolent Non-Hodgkin lymphoma - Clinical
- Infectious diseases, supportive care
- Iron metabolism, deficiency and overload
- Myelodysplastic syndromes - Biology
- Myelodysplastic syndromes - Clinical
- Myeloma and other monoclonal gammapathies - Biology
- Myeloma and other monoclonal gammapathies - Clinical
- Myeloproliferative neoplasms - Biology
- Myeloproliferative neoplasms - Clinical
- Non-Hodgkin & Hodgkin lymphoma - Biology
- Other Non-malignant hematopoietic disorders
- Platelets disorders
- Quality of life, palliative care, ethics and health economics
- Sickle cell disease
- Stem cell transplantation - Clinical
- Stem cell transplantation - Experimental
- Thalassemias
- Thrombosis and vascular biology
- Transfusion medicine
A complete session overview is available via the mobile app or the online program at ehaweb.org
**BACKGROUND:** Cytogenetic risk status in multiple myeloma (MM) studies is traditionally determined by using fluorescence in situ hybridization (FISH) or karyotyping to assess chromosomal abnormalities. However, these technologies have limited resolution and a narrow target range, and reproducible interpretation may be confounded by inter-laboratory variation.

**Aims:** To describe the NGS methodology used to determine cytogenetic risk status in the daratumumab phase 3 CASTOR and POLLUX studies in RRMM.

**Methods:** Bone marrow aspirates were collected at screening and assessed centrally via NGS. Whole exome sequencing (exome-seq) and RNA sequencing (RNA-seq) was performed using the Illumina HiSeq platform to identify the presence or absence of defined risk markers: t(4;14), t(14;16), or del17p. The use of RNA-seq allowed for investigation of chromosomal translocations in expressed genomic locations at a higher resolution than FISH, and exome-seq data was used to derive the copy number status in coding regions across the genome. RNA-seq was performed using total RNA and rRNA removal to capture translocations involving coding and intronic regions. Translocation calls were made using two fusion callers, and gene expression was quantified to allow for evaluation of genes associated with translocation events. For t(14;14) translocations, the detected events involved RNA-seq reads fused between IgH and WHSC1 or FGFR3. For t(14;16), the detected translocations involved IgH and WWOX. Manual inspection of patients with t(4;14) showed higher WHSC1 or FGFR3 expression, whereas t(14;16) patients showed higher MAF and CCND2 expression. For del17p detection, exome data of each tumor was compared against 100 peripheral blood mononuclear cell (PBMC) control samples from CASTOR and POLLUX studies. Copy number variation data from two callers were combined to utilize information on relative read depth, systematic biases (observed in pooled normal controls), as well as SNP allele frequency (indicative of loss of heterozygosity events). A del17p event was detected when >50% of the 17p region was deleted.

**Results:** Based on the RNA-Seq and exome results, cytogenetic risk status in the CASTOR and POLLUX studies was defined as high risk with either t(4;14), t(14;16), or del17p, and standard risk with the confirmed absence of these molecular abnormalities. Comparisons of NGS with FISH showed high concordance for t(4;14), t(14;16), and del17p in both studies (Table 1).

**Summary/Conclusions:** These studies represent the first, comprehensive use of NGS in global phase 3 clinical trials in RRMM. The NGS methodology accurately identified the presence of defined risk populations t(4;14), t(14;16), and del17p and showed good concordance with FISH. As FISH was performed locally with different probes and pathologists, the high degree of concordance between FISH and NGS is notable and supports the use of NGS for determining cytogenetic risk in patients with RRMM. The utility of NGS in these clinical studies extends far beyond the detection of cytogenetic abnormalities and additional analysis are planned to interrogate these datasets in the identification of novel biomarkers.

significantly improved progression-free survival (PFS) and achieved higher overall response rates (ORRs) compared with the respective standard-of-care regimen alone (Dimopoulos MA et al., *N Engl J Med* 2016;375(14):1319-1331; Palumbo A et al., *N Engl J Med* 2016;375(8):754-766.). Due to its novel mechanisms of action, addition of D to standard-of-care regimens may benefit RRMM patients who have poor prognoses resulting from high-risk cytogenetic abnormalities.

**Aims:** To examine the efficacy of DRd and DVD in RRMM patients with standard or high cytogenetic risk status.

**Methods:** Bone marrow aspirates were collected at screening visits from 311/569 patients from POLLUX and from 353/498 patients from CASTOR, and cytogenetic abnormalities were detected via next-generation sequencing (NGS). Patients were considered to be of high cytogenetic risk status if they had ≥1 of the following abnormalities: t(4;14), t(14;16), or del17p; patients were considered to be of standard cytogenetic risk if they lacked these abnormalities. Minimal residual disease (MRD) was assessed at suspected complete response (CR) at 3 sensitivity thresholds (10−4, 10−5, and 10−6) using the ClonoSEQ™ NGS-based assay (Adaptive Biotechnologies, Seattle, WA). Efficacy analyses included PFS, ORR, and MRD-negative rates.

**Results:** For POLLUX, the median follow-up was 17.3 months. Treating high-risk patients with DRd significantly prolonged median PFS vs Rd (top panel Figure 1) and numerically increased ORR (85% vs 67%; *P*<0.014). Responses to DRd vs Rd included CR or better in 33% vs 6% of these patients, and very good partial responses (VGPR) or better in 63% vs 31%. In standard-risk patients, DRd vs Rd also resulted in significant improvements in median PFS (Figure 1) as well as ORR (95% vs 82%; *P*<0.0020). Responses to DRd vs Rd included CR or better in 52% vs 24% of these patients, and VGPR or better in 84% vs 51%. At 10−5 sensitivity threshold, MRD-negative rates for DRd vs Rd were 18% vs 0% (*P*=0.0027) among high-risk patients and 30% vs 10% (*P*=0.0001) for standard-risk patients. For CASTOR, the median follow-up was 13.0 months. Treating both high- and standard-risk patients with DVD vs Vd significantly prolonged median PFS (bottom panel Figure 1) and increased ORR (high risk: 82% vs 62%; *P*=0.039; standard risk: 85% vs 64%; *P*=0.0003). Responses to DVD vs Vd among high-risk patients included CR or better in 30% vs 9% of patients and VGPR or better in 64% vs 34%; among standard-risk patients, responses included CR or better in 25% vs 8% of patients and VGPR or better in 84% vs 27%. At 10−5 sensitivity threshold, MRD-negative rates for DVD vs Vd were 14% vs 0% (*P*=0.0018) among high-risk patients and 12% vs 2% (*P*=0.0011) for standard-risk patients.

**Summary/Conclusions:** Adding D to Rd or Vd improved treatment outcomes irrespective of cytogenetic risk status in patients with RRMM. Both DRd and DVD appear to benefit RRMM patients who have poor prognoses due to high-risk cytogenetic abnormalities. Updated data, including analyses based on individual cytogenetic abnormalities, will be presented at the meeting based on longer follow-up.

**MINIMAL RESIDUAL DISEASE BY MULTIPARAMETER FLOW CYTOMETRY IN TRANSPLANT ELIGIBLE PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA: RESULTS FROM THE EMN02/HO95 PHASE 3 TRIAL**

S. Oliva1, D. Hofste op Bruinink2, L. Rihova3, S. Spada1, B. van der Holt4, R. Troia5, M. Gambella6, L. Pantani2, S. Grammatico5, M. Gilestro6, R. Ribolla5, M. Gaili7, R. Hajek5, A. Palumbo8, M. Cavo5, P. Omede1, V. van der Velden8, M. Boccadoro1, P. Sonneveld2

1Myeloma Unit, Division of Hematology, University of Torino, Torino, Italy, 2Department of Hematology, Erasmus MC Cancer Institute, Rotterdam, Netherlands, 3Department of Hematology, University Hospital Brno, Brno, Czech Republic, 4Department of Hematology, Erasmus MC Cancer Institute, HOVON Data Center, Rotterdam, Netherlands, 5Italian Multiple Myeloma Network, GIMEMA, Italy, 6Department of Haematoncology, Faculty of Medicine, University of Ostrava and University Hospital of Ostrava, Ostrava, Czech Republic, 7Myeloma Unit, Division of Hematology, University of Torino - Currently Takeda Pharmaceuticals Global Research Centre, Torino, Italy, Switzerland, 8Department of Immunology, Erasmus MC, University Medical Center Rotterdam, Rotterdam, Netherlands

**Background:** Multiple myeloma (MM) is still an incurable disease and patients may relapse despite achievement of complete remission (CR). Available data show that MRD detection is a sensitive strategy to appropriately measure response in MM patients.

**Aims:** We evaluated MRD by MFC in patients with newly diagnosed MM enrolled in the EMN02/HO95 phase 3 trial.

**Methods:** Patients were ≥65 years of age and treatment consisted of Bortezomib-Cyclophosphamide-Dexamethasone (VCD) induction, mobilization and stem cell collection, intensification with Bortezomib-Melphalan-Prednisone (VMP) or High-Dose-Melphalan (HDM) followed by stem cell transplant, consolidation with Bortezomib-Lenalidomide-Dexamethasone (VRD) vs no consolidation, and Lenalidomide maintenance. MRD was assessed in patients achieving at least a very good partial response (VGPR) before starting maintenance (after HDM, VMP or VRD) and during maintenance every 6-12 months; samples were centralized to 3 European labs. MFC was performed on bone marrow according to Euroflow-based methods (8 colors, 2 tubes) with a sensitivity of 10−5. Quality checks were done to compare sensitivity and to show correlation between protocols (Hofste op Bruinink D, *ASH* 2016 abstract 2072).

**Results:** A total of 316 patients could be evaluated before maintenance: median age was 57 years (IQR: 52-62), 18% (57/316) had ISS III and 22% (70/316) had high risk cytogenetic abnormalities defined as presence of either one among del17, t(14;16) or t(4;14); 63% (199/316) had received HDM and 37% (117/316) VMP thereafter 51% (160/316) had received VRD. After a median follow-up of 30 months from MRD enrolment, 76% (239/316) patients were MRD-negative: 64% (153/239) in the HDM vs 36% (86/239) in the VMP groups. The 3-year PFS was 50% in MRD-positive vs 77% in MRD-negative patients (HR 2.87, 95% CI: 1.75 - 4.72; *p*<0.001). Subgroup analyses were carried out to assess the risk factors for MRD-positivity according to baseline characteristics and therapies: high risk cytogenetic abnormalities were the most important risk factors (HR 9.87, 95% CI: 4.3 - 22.63; interaction *p*=0.001). Finally, 48% of MRD positive patients at pre-maintenance who had a second MRD evaluation after at least 1 year of lenalidomide became MRD-negative.

**Summary/Conclusions:** MRD by MFC is a strong prognostic factor in MM patients receiving intensification with novel agents or transplant; lenalidomide maintenance further improved depth of response; high risk cytogenetic abnormalities are the most important prognostic factors in MRD-positive patients.

**PHASE I, OPEN-LABEL TRIAL OF ANTI-BCMA CHIMERIC ANTIGEN RECEPTOR T CELLS IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA**

W. Zhang1, W. Zhao1, J. Liu1, A. He1, Y. Chen1, X. Cao1, N. Yang2, B. Wang1, P. Zhang1, Y. Zhang1, F. Wang1, B. Lei1, L. Gu1, Y. Yang1, J. Bai1, R. Zhang1, X. Wang1, X. Ma1, J. Wang1, J. Wang1, L. Wei1, J. Zhang1, X. Zang1, C. Zhuang2, F.X. Fan2

1Hematology, Second Affiliated Hospital of Xi’an Jiaotong University, Xi’an, 2Nanjing Legend Biotech, Nanjing, China

**Background:** Immunotherapy has emerged as a potentially curative treatment in hematological malignancies. Uniformly expressed in plasma cells, B-cell maturation antigen (BCMA) is an appropriate target antigens for CAR T-cell therapies in multiple myeloma.

**Aims:** This phase I, open-label trial was conducted to assess the efficacy and
safety profile of LCAR-B38M anti-BCMA CAR T cells in patients with relapsed/refractory multiple myeloma.

**Methods:** All patients underwent leukapheresis to obtain peripheral blood mononuclear cells and their T cells were engineered to express anti-BCMA CAR. Three doses of 300 mg/m² cyclophosphamide were administered on day -5, -4, and -3 (before the recruitment, patients took the same chemotherapy to identify they were refractory to cyclophosphamide monotherapy) and engineered-T cells were reinfused on day 0, 2, and 6. This trial was divided into the dose escalation stage and expansion cohort. Toxicity and responses were assessed according to the Common Terminology Criteria for Adverse Events (version 4.0) and International Myeloma Working Group (IMWG) Uniform Response Criteria for Multiple Myeloma, respectively.

**Results:** As of the February 20th, 2017 data cut-off, 22 patients had been enrolled, two of whom were diagnosed as plasma cell leukemia. The male:female ratio was 11:11 and median age was 53.5 years. Chromosomal abnormalities were detectable by FISH in eight patients, two of whom involved in the deficiency of p53. Eleven patients were triple refractory (chemotherapy, proteasome inhibitors, and immunomodulatory drugs), 11 resisted to double prior treatments (chemotherapy and proteasome inhibitors/ immunomodulatory drugs), and four relapsed after autologous hematopoietic stem cell transplant. The median number of infused CAR T cells was 4.0×10^6 (range, 1.5×10^6-7.0×10^6) per kg. The median follow-up was 131.5 (range, 29-327) days. 100% of patients achieved an objective response. The first six patients achieved complete responses with flow MRD-negative; 14 patients achieved very good partial responses; one patient, with renal failure, achieved partial response; all these 22 patients had kept their best response at the end of follow-up. The pictures we enclosed were the subcutaneous nodules in one patient with extramedullary plasmacytoma. We found that the nodules were obviously decreased after the infusion and disappeared finally. Another one achieved transient partial response, which last for 12 days. He then took the secondary infusion but failed since the post-operation large-cutaneous nodules was cytokine release syndrome (CRS). Toxicities were minimal except for two grade 3 CRS and one grade 4 CRS. All CRSs were controllable with nonspecific measures.

**Summary/Conclusions:** Our findings demonstrated the safety and antimyeloma activity of LCAR-B38M anti-BCMA CAR T cells.

**S104**

**PATIENTS WITH LIGHT CHAIN AMYLOIDOSIS TREATED WITH NEO001 ACHIEVE RAPID ORGAN RESPONSES THAT ARE INDEPENDENT OF PREVIOUS PLASMA CELL–DIRECTED THERAPIES**

1Mayo Clinic, Rochester, 2Tufts Medical Center, Boston, 3Memorial Sloan Kettering Cancer Center, New York, 4Boston University School of Medicine and Boston Medical Center, Boston, 5University of Pennsylvania, Philadelphia, 6Karmanos Cancer Institute, Detroit, 7JW Consulting, Hillsborough, 8Prothera Biosciences Inc, South San Francisco, 9Stanford University School of Medicine, Stanford, United States

**Background:** Light chain (AL) amyloidosis is a rare and often fatal disease caused by the accumulation of misfolded light chain (LC) aggregates that can lead to progressive failure of critical organs, causing significant morbidity and mortality. Patients’ survival depends upon rapid suppression of the misfolded LC and stabilization or recovery of organ function. Current therapies limit LC production; however, ~75% of patients have persistent organ dysfunction. NEO001 is a novel investigational monoclonal antibody that targets misfolded LC and may neutralize circulating LC aggregates and clear insoluble deposits.

**Aims:** To assess the association between responses and time, depth, number or type of previous plasma cell-directed (PCD) treatments and organ response.

**Methods:** Inclusion criteria for this trial were: completed ≥1 PCD treatment before enrollment, attained partial hematologic response (HR) or better to any previous therapy, and have persistent organ dysfunction. NEO001 was administered intravenously every 28 days. During the dose-escalation phase, 27 patients received NEO001 at 0.5, 1, 2, 4, 8, 16, or 24 mg/kg in a 3+3 study design. In the expansion phase, 42 additional patients with renal, cardiac, or nerve involvement were enrolled and treated (24 mg/kg). We assessed cardiac and renal best responses based on consensus criteria. Peripheral nervous system (PN) responses were assessed at month 10 (after 9 infusions) using the Neuropathy Impairment Score-Lower Limbs (NIS-LL). We explored the potential impact on organ response of the number and type of organs affected and the number of, type of, and time since previous therapies at baseline.

**Results:** In the overall population (N=69), the median age was 61 years (61% male). Median (range) time since diagnosis was 2.9 (0.4-16.0) years, and 45% of patients underwent ≥3 previous PCD regimens. Median time to first best response was 1.8 (cardiac), 3.7 (renal), and 1.0 (PN) months. Best response rate indicating organ response was observed in 53% of cardiac-evaluable patients (n=19/36) and 64% of renal-evaluable patients (n=23/36). PN responses were observed in 82% (n=9/11) of PN-evaluable patients. Time from patients’ best HR to previous PCD treatment was not related to the attainment of NEO001 organ response (responder/stable: 35.6/36.6 months [cardiac] and 30.6/32.5 months [renal]; P>0.05). Depth of patients’ best HR also was not related to the attainment of NEO001 organ response (percentage of patients with organ response in CRS/GPR/PR after PCD: 47.1/66.7/42.9% [cardiac] and 68.8/63.6/62.5% [renal]; P>0.05). Similarly, time or depth of patients’ last HR did not impact the NEO001 organ response rate (P>0.05). Patients with NEO001 organ responses were no more likely to have had their last PCD therapy <6 than 6 months from their first NEO001 dose. Patients’ previous PCD treatment type was not related to the corticosteroid for spinal meningioma. He terminally died of the progression of myeloma. The most common toxicity attributable to CAR T cells was cytokine release syndrome (CRS). Toxicities were minimal except for two grade 3 CRS and one grade 4 CRS. All CRSs were controllable with nonspecific measures (NSAIDs) or tocilizumab and no dose-limiting toxicities or treatment-related deaths were observed (Figure 1).

**Summary/Conclusions:** NEO001 specifically targets disease-causing, misfolded LC aggregates in AL amyloidosis. Organ responses in patients treated with monthly NEO001 infusions were achieved rapidly and independently of time since previous chemotherapy, depth of hematologic response, or predominant type of PCD treatment.
Agnogenic Non-Hodgkin lymphoma - 1st line

RITUXIMAB MAINTENANCE AFTER AUTOLOGOUS TEM CELL TRANSPLANTATION PROLONGS SURVIVAL IN YOUNGER PATIENTS WITH MALT CELL LYMPHOMA: FINAL RESULTS OF THE LYMA TRIAL OF THE EUKLID GROUP

1hematology, Nantes Medical University, nantes, 2Hospital saint-louis, paris, 3oncopleue Toulouse, toulouse, 4Nantes Medical University, nantes, 5CH Bou-deaux, bordeaux, 6CHC Tours, Tours, 7CHC Caen, caen, 8GR, villejuif, 9CHU Nancy, Nancy, 10CHC Dijon, dijon, 11CH Avignon, Avignon, 12CHU Creteil, Creteil, 13CHRC Lyon, lyon, 14CHM Clermont-Ferrand, Clermont-Ferrand, 15CHC Roche-sur-Yon, roche-sur-yon, 16Centre Victor Hugo, Le Mans, 17CHU Strasbourg, Strasbourg, france, 18CHU Louvain, Louvain, Belgium, 19CHU Necker, Paris, 20CHU Lyon, Lyon, 21CHU Rennes, Rennes, 22CHU Grenoble, Grenoble, France

Background: Malt cell lymphoma (MCL) is currently an incurable disease. In spite of high complete response rates (CR) after initial immunochemotherapy induction followed by autologous stem cell transplantation (ASCT), MCL patients experience iterative relapses.

Aims: We investigated whether or not rituximab maintenance (RM) could be an acceptable option to improve response rates at the end of treatment. The majority of the patients in this trial represented a poor prognosis group by age and IPI. In this context, treatment response to this regimen may warrant further exploration.

Methods: Five pts of the dose escalation portion and 40 pts of the expansion portion completed RM for 3 years after ASCT. The following reasons: Gr 5 atrial fibrillation (after C2, not attributed to pola by investigator), E. coli UTI (C5), worsening essential tremor (C3), PN (C7). During follow-up, median study duration of 9.5 months, (range 1.3-28 months), only 1 pt had a disease progression in follow up.

Summary/Conclusions: RM at 1.8 mg/kg in combination with R-CHP in 1L patients is an acceptable option to improve response rates at the end of treatment. The majority of the patients in this trial represented a poor prognosis group by age and IPI. In this context, treatment response to this regimen may warrant further exploration.

References
1. 0.072 to 0.971) for RM (n=120) vs 0.193 to 0.750) for observation (p=0.0413). The death rate was lower for patients in the RM arm was significantly lower (hazard ratio (HR)=0.5; 95%CI, 0.255 to 0.986) than for patients in the observation arm.

S106

POLA-R-CHP: POLATUBAZUM VEDOTIN COMBINED WITH RITUXIMAB, CYCLOPHOSPHAMIDE, DOXORUBICIN, PREDNISOLONE FOR PATIENTS WITH PREVIOUSLY UNTREATED DIFFUSE LARGE B-CELL LYMPHOMA

H. Tilly1, J. Sharma2, N. Bartlett3, F. Morschhäuser4, C. Haioun5, J. Munoz5, A. Chen5, T. Lamy5, L. Wang6, E. Penuel7, J. Hirata8, C. Lee9, G. Salles1, 1Centre Henri Becquerel, University of Rouen, Rouen, France, 2Willamette Valley Cancer Institute, Springfield, 3US Oncology Research, The Woodlands, 4Siteman Cancer Center, Washington University School of Medicine, St Louis, United States, 5University Hospital of Lille, Lille, 6Henri Mondor University Hospital, Creteil, France, 7Banner MD Anderson Cancer Center, Gilbert, 8Oregon Health and Science University, Portland, United States, 9Hematology Department, INSERM U917 / University Hospital of Rennes, Rennes, France, 10Genentech, Inc., South San Francisco, United States, 11South Lyon Hospital Complex, Lyon, France

Background: Polatubazum vedotin (pola) is an antibody drug conjugate containing the anti-mitotic MMAE targeting CD79b, an antigen expressed ubiquitously in DLBCL. Pola as monotherapy and in combination with anti-CD20 antibodies demonstrated encouraging efficacy in r/r DLBCL. The initial dose-escalation portion of this multicenter, open-label Ph I/Ib study of pola in combination with rituximab, cyclophosphamide, doxorubicin, and prednisone (pola-R-CHP) showed an acceptable safety profile and established a recommended Ph II dose of pola at 1.8 mg/kg. We report updated safety and efficacy results for the Ph II dose in 45 previously untreated DLBCL patients (pts) (ClinicalTrials.gov, NCT01992653).

Aims: To evaluate the safety and efficacy of pola-R-CHP as first-line treatment in patients with DLBCL.

Methods: Five pts of the dose escalation phase and the 40 pts of the expansion phase were included in this analysis. All pts provided informed consent to partic- ipate in the study. All had newly diagnosed DLBCL and were treated with pola at 1.8 mg/kg and R-CHP at standard doses every 21 days for 6 or 8 cycles. Investigator assessments for anti-tumor activity were performed according to IWG 2007 following 4 cycles and at the end of study treatment (EOT).

Results: All 45 pts received at least one dose of study drug. The median age was 69 years; 93% were >60 years, 33% ECOG >1, 82% Stage III/IV, and 78% IPI 3-5. Of the 29 pts with cell of origin (COO) status by digital gene expression, 11 (38%) were ABC, 14 (48%) were GC, while 4 (14%) were unclassified. Forty patients completed 6 or 8 cycles (23 and 17 pts respectively). All pts experienced at least one AE. Grade (G) 3/4 AEs occurred in 58%, and one pt experienced a G 5 atrial fibrillation. G 3/4 neutropenia and febrile neutropenia (FN) occurred in 27% and 11%, Serious adverse events (SAEs) were reported in 17 pts (38%) including 3 FN, and 2 each of neutropenia, pneumonia, pulmonary embolism and influenza. Peripheral neuropathy (PN) occurred in 18 (40%) pts. Among patients with RM vs 12 pts, 1 were G 2, and 2 were G 3. All Gr 2/3 PN and febrile neutropenia occurred in 27% and 11%. Rates of neutropenia, pneumonia, pulmonary embolism and influenza were similar in the 2 arms. PN was the most common AE, occurring in 27% and 11%. Serious adverse events (SAEs) were reported in 17 pts (38%) including 3 FN, and 2 each of neutropenia, pneumonia, pulmonary embolism and influenza. Peripheral neuropathy (PN) occurred in 18 (40%) pts. Among patients with RM vs 12 pts, 1 were G 2, and 2 were G 3. All Gr 2/3 PN and febrile neutropenia occurred in 27% and 11%. Rates of neutropenia, pneumonia, pulmonary embolism and influenza were similar in the 2 arms. PN was the most common AE, occurring in 27% and 11%. Rates of neutropenia, pneumonia, pulmonary embolism and influenza were similar in the 2 arms.
When pts in the SC group were asked, if given the option, which treatment they would prefer, 90.8% stated a preference for SC over IV. Median administration time (6 minutes SC vs 2.6–3.0 hours IV) and chair/bed and overall hospital times were shorter with SC than with IV treatment.

Aims: Preliminary analyses of diagnostic samples from MCL2 and MCL3, show that TP53 mutations are associated with significantly poorer outcome. Recently, deletions of TP53 and CDKN2A was shown to confer negative impact in a cohort similar to the Nordic.(Delfau-Larue et al., 2015) Thus, in this study we aim to describe the prevalence and impact of deletions of TP53 and CDKN2A in the light of TP53 mutations.

Methods: Fresh frozen DNA from diagnostic bone marrow samples from MCL2 and MCL3 were analyzed. In both trials, patients received intensified first-line induction therapy with alternating courses of R-CHOP and R-hd-Cytarabine and consolidation with high-dose therapy and ASCT. (Geissler et al., 2008; Kolstad et al., 2014). Targeted NGS of ATM, CCND1, TP53, KMT2D, NOTCH1, NOTCH2, WHSC1 and BIRC3 was performed by Ion Torrent Technology. Cut-off for calling a mutation was set to a variant allele frequency >3%.

Background: As next-generation sequencing (NGS) methodologies improve, so does the ability to characterize hematopoietic and lymphoid neoplasm genomes. This promises to revolutionize oncology, allowing more accurate and precise classification of patients and potentially leading to novel targeted and combination therapies with improved outcomes.

Objectives: We constructed a custom targeted sequencing panel, MyHEME™, to comprehensively identify and characterize DNA and RNA changes in a broad range of hematologic malignancies, including Non-Hodgkin lymphoma (NHL). The MyHEME targeted sequencing panel is comprised of two independent bait sets that target a combined 704 genes known or predicted to contribute to hematologic cancers (DNA baits for 571 genes and RNA baits for 361 genes; 228 genes are found in common between the two bait sets). Libraries were constructed using 1μg of DNA or 0.1μg of RNA and sequenced on an Illumina platform. Sequenced reads are analyzed using proprietary Myinformatics™ software to identify single nucleotide variants (SNVs), indels and structural variants (SVs). Both the MyHEME panel and MyInformatics software were created under ISO13485 design control. To characterize the performance metrics of the MyHEME panel, we used the NIST human reference sample NA12878 along with combinations of hematologic cancer derived cell lines with known pathogenic variants at various allelic frequencies.

Results: Analytical validation of the MyHEME panel established an average read depth of 1,175x (with a median read depth of 1,088x) for the DNA targets and an average transcripts per million (TPM) of 2,256 (with a median TPM of 743) for the RNA targets. For the DNA targets, we established sensitivity >95% (99.8% for SNVs at a 2.5% limit of detection (LOD); 100% for coding indels at a 5.0% LOD) and specificity >95% (95.5% for SNVs at a 2.5% LOD; 97.7% for coding indels at a 5.0% LOD). We also show the ability to cross-confirm results between the 228 genes common to both the DNA and RNA targets. Importantly, novel gene fusions, which are generally difficult to detect and validate, were cross-confinned when observed in both the DNA and RNA targets. For example, we identified a novel t(9;22) translocation causing a NUP214-XXR3 gene fusion using both the DNA and RNA targets. Additionally, while RNA data provides the fused exons of the transcripts, DNA data gives the precise genomic breakpoint coordinate.

Summary/Conclusions: MyHEME is an extensive panel for sensitively and specifically identifying SNV, indel and SV mutations in 704 target genes. This panel can comprehensively characterize mutations in multiple diverse hematologic cancer samples, including Non-Hodgkin Lymphoma (NHL), ALL, and Multiple Myeloma. By utilizing a high depth of coverage, MyHEME can accurately detect clones present down to 5% of a patient’s sample. In addition, by targeting both DNA and RNA, MyHEME contains a built-in validation method to cross-confirm novel variants of interest.

S109

TP53 MUTATIONS, BUT NOT DELETION OF TP53 AND CDKN2A, HAVE INDEPENDENT PROGNOSTIC VALUE IN MANTLE CELL LYMPHOMA TREATED BY THE NORDIC (MCL2 AND MCL3) REGIMEN

C.W. Eskelund1, 2, C. Dahl2, J. W. Hansen2, M. Westman1, C. Montano1, C. Freiburgus3, S. Ek3, A. Pedersen1, L. B. Pedersen1, C. Niemann1, R. Räty1, P. Brown1, A. Kolstad2, C.H. Geisler1, M.K. Andersen1, P. Guldberg2, M. Jerkeman3, K. Granbaek1

1University Hospital of Copenhagen, 2Danish Cancer Society, Copenhagen, Denmark, 3University of Lund, Lund, Sweden, 4University Hospital of Helsinki, Helsinki, Finland, 5University Hospital of Oslo, Oslo, Norway

Background: During the past decades, the outcome of MCL treatment has improved substantially in younger patients. However, the course of disease remains heterogeneous, and there is a need for better stratification of patients with poor responses from those with durable responses. The Nordic trials, MCL2 and MCL3, represent standard-of-care regimens for younger MCL patients.

Aims: Preliminary analyses of diagnostic samples from MCL2 and MCL3, show that TP53 mutations are associated with significantly poorer outcome. Recently, deletions of TP53 and CDKN2A was shown to confer negative impact in a cohort similar to the Nordic.(Delfau-Larue et al., 2015) Thus, in this study we aim to describe the prevalence and impact of deletions of TP53 and CDKN2A in the light of TP53 mutations.

Methods: Fresh frozen DNA from diagnostic bone marrow samples from MCL2 and MCL3 were analyzed. In both trials, patients received intensified first-line induction therapy with alternating courses of R-CHOP and R-hd-Cytarabine and consolidation with high-dose therapy and ASCT. (Geissler et al., 2008; Kolstad et al., 2014). Targeted NGS of ATM, CCND1, TP53, KMT2D, NOTCH1, NOTCH2, WHSC1 and BIRC3 was performed by Ion Torrent Technology. Cut-off for calling a mutation was set to a variant allele frequency >3%.

Results: We investigated the presence of CDKN2A and TP53 deletions in diagnostic samples from 175 and 157 patients, respectively. Patients were treated for 9 months and <6 years (median, 58 range, 37-65). Fifty-three percent were either MIPI intermediate- or high-risk, 17% had blastoid morphology and 42% had Ki67>30%, and 83% had bone marrow involvement at diagnosis. After a median follow-up of 9.2 years, median overall (OS), progression-free survival (PFS) and cumulated incidence of relapse (CIR) of all patients were 12.4 and 10.2 years, respectively. In our mutational analyses (n=147), only TP53 had prognostic impact in multivariate analyses (MVAs). Outcome of the 15 patients (10%) with TP53-mutations was poor with a median OS, PFS and CIR of 1.8, 1.0 and 1.2 years (p<0.001 for all three outcomes), respectively. Preliminary analysis of all TP53 mutations in 29 patients revealed that 38% were coding deletions. In univariate analyses, del-TP53 was significantly associated with poor OS (p=0.01), but not PFS and CIR, whereas del-CDKN2A was significant for CIR (p=0.02), but not OS and PFS. Patients with both deletions did significantly worse for all three endpoints. In MVA, (including all factors with significance in univariate analyses: MIPI, blastoid morphology, Ki67>30%, NOTCH1 mutations, TP53 mutations, ALL- and delt-CDKN2A) only mutations of TP53 remained a significant predictor of outcome.

Summary/Conclusions: Here we evaluate the impact of TP53- and CDKN2A-deletions in the context of TP53 mutations of younger, optimally treated MCL patients. In line with previous reports, both deletions were associated with poor outcome; however, in multivariate analyses only TP53 mutations was an independent prognostic factor, substantiating its role as a biomarker for response to the standard-of-care immune-chemotherapy.
MRD directed treatment in AML

S110

DEEP MOLECULAR RESPONSE TO GILTERITINIB IMPROVES SURVIVAL IN FLT3 MUTATION-POSITIVE RELAPSED/REFRACTORY ACUTE MYELOID LEUKAEMIA

Background: Mutations in Fms-like tyrosine kinase 3 (FLT3) are common in patients with acute myeloid leukemia (AML) and are associated with an aggressive disease course and a poor prognosis. Notably, FLT3 internal tandem duplications (ITD) predict early relapse and short overall survival (OS) after chemotherapy. Gilteritinib, a highly selective FLT3/AXL inhibitor, has displayed antileukemic activity in FLT3 mutation-positive (FLT3mut+) relapsed/refractory (r/r) AML in the CHRYSALIS Phase 1/2 study (NCT02014558), specifically at doses ≥80 mg/d. Aims: To assess molecular response to gilteritinib in a CHRYSALIS subpopulation.

Methods: This exploratory analysis evaluated molecular response in patients aged ≥18 years with FLT3-ITDmut+r/r AML who had been treated with 120 or 200 mg/d gilteritinib. These doses were identified as their ability to induce high clinical response rates, and consistent, potent FLT3 inhibition in correlative assays. Molecular response was assessed in patients who had bone marrow aspirates obtained at baseline and at ≥1 additional time point. FLT3-ITD and total FLT3 were quantified by next-generation sequencing to assess molecular response. A Cox regression model of OS by Kaplan-Meier estimation established a FLT3-ITD:total FLT3 ratio (ITD signal ratio) of 10−2 as the threshold for improved survival.

Results: Of the 147 FLT3-ITDmut+patients who had received gilteritinib 120 or 200 mg/d, 80 patients had bone marrow aspirates at baseline and at ≥1 additional time point. FLT3-ITD and total FLT3 were quantified by next-generation sequencing to assess molecular response. Of the 147 FLT3-ITDmut+patients who had received gilteritinib 120 or 200 mg/d, 80 patients had bone marrow aspirates at baseline and at ≥1 additional time point, and were included in this analysis. The composite response rate (defined as CR plus CRi plus PR) for these 80 patients was 55%. During response, 20 patients (25%) had an ITD signal ratio of ≤10−2. Of these 20 patients, 18 had an ITD signal ratio of ≤10−3 (major molecular response [MMR]) and 13 had an ITD signal ratio of ≤10−4 (minimal residual disease [MRD] negative). The median time to achieve minimum ITD signal ratio was 54 days.

Summary/Conclusions: Molecular responses to gilteritinib in FLT3-ITDmut+r/r AML correlated with clinical response and improved OS. This is the first demonstration of a robust molecular response to a FLT3 inhibitor in AML. These data suggest that the ITD signal ratio may predict a durable clinical benefit of gilteritinib therapy and validate FLT3 as a critical therapeutic target in AML.

S111

RISK-ADAPTED, MRD-DIRECTED THERAPY FOR YOUNG ADULTS WITH NEWLY DIAGNOSED ACUTE MYELOID LEUKAEMIA: RESULTS OF THE AML1310 TRIAL OF THE GIMEMA GROUP

A. Venditti1,*, A. Piccio2, A. Candoni3, L. Mellito4, V. Calafato5, R. Cairo6, FL3-ITD De Fabritiis7, G. Stefani8, F. Salutari8, F. Lanza8, G. Martinelli12, M. Luppi12, B. Falini8, B. Faini8,4, A. Tufano16, B. Ronc18, A. Tiefghi7, M. S. Fraccialonga2, D. Capelli22, F. Roa23, E. La Sala2, F. Pazi2, L. Maurillo25, F. Bucciano21, M. I. Del Principe1, F. Lo Cocco2, A. Arcese2, S. Amadori2

Background: A comprehensive AML risk assessment, based on the integration of cytogenetic/genetic data and minimal residual disease (MRD) status, can help optimize patients’ (pts) therapeutic post-remission allocation. Aims: To evaluate the feasibility and results of a phase I trial of intensive chemotherapy in which risk-assignment and post-remission therapy of young adults with AML was based on pre-treatment cytogenetic/genetic data and post-consolidation levels of MRD.

Methods: Between January 2012 and May 2015, 515 pts with de novo AML, 18 to 60 years old, seen at 55 GIMEMA institutions were enrolled in the trial. Induction consisted of i.v. daunorubicin 50 mg/m² daily on days 1, 3, and 5; i.v. etoposide 50 mg/m² daily on days 1 to 5; i.v. cytarabine 100 mg/m² as a daily continuous infusion, days 1 to 10. All pts in CR/CRi after 1-2 induction cycles, received 1 consolidation course consisting of i.v. daunorubicin 50 mg/m² daily for 6 and i.v. cytarabine 100 mg/m² every 12 hours on days 1 to 6. In pts belonging to ELN low or intermediate-risk category, peripheral blood stem cell collection was attempted by initiating, on day 20 from the start of consolidation therapy, G-CSF until completion of stem cell collection. Post-consolidation therapy was based on risk-allocation. Low-risk pts (NPM1 positive FLT3-ITD-negative or CBF positive without c-Kit mutations) were to receive AuSCT; high-risk pts (adverse karyotype or FLT3-ITD positive) were to receive chemotherapy; intermediate-risk pts (intermediate category (=AuSCT or ASCT); high-risk pts (adverse karyotype or FLT3-ITD-positive) were to receive ASCT.

Results: Of the 515 pts treated started and were available for the analysis. Median age was 49 (18-61) years and 52% were males. Of 429 evaluable pts, EAN cytogenetic distribution was: low-risk 11%, intermediate-risk 73% and poor-risk 15%. RUNX1/RUNX1 was detected in 49% of pts, CBFbeta/MYH11 in 7% of 496, FLT3-ITD in 25% of 497 and NPM1 in 37% of 499. In 494 evaluable pts, complete remission rate (CR) was 73% (361), 18% had refractory AML and 9% died early during induction. Three hundred and forty-one pts completed the consolidation phase and were risk allocated: 114 (33%) to the low-risk category (=AuSCT), 122 (36%) to the intermediate category (=AuSCT or ASCT) and 61 (19%) to the high-risk category (=ASCT). In 27 pts (8%) belonging to the intermediate-risk category, a leukemia associated phenotype was not found and they were to receive AuSCT. Overall, 109 (33%) and 123 (36%) of 341 pts received AuSCT and ASCT, respectively. Median follow-up was 27.9 months. At 24 months overall (OS) and disease-free survival (DFS) of the whole series was 55.9% and 54.9%, respectively: cumulative incidence of relapse was 31.4%. At the same time point of 24 months, OS and DFS in the low-risk category was 74.8% and 63.8%, respectively; in the high-risk category 42.5% and 44.8%, respectively; in the intermediate-risk category MRD negative 78.8% and 61.4%, respectively; in the intermediate-risk category MRD positive 69.8% and 66.6%, respectively (Figure 1).

Summary/Conclusions: A program of risk-adapted, MRD-driven therapy is feasible in a multicenter, cooperative setting. In the intermediate-risk category,
ASCT can be avoided if MRD is not detectable; if MRD is positive, ASCT can prolong OS and DFS to equalize those of the low-risk category. ASCT was delivered to 2/3 of pts in the high-risk group, using all the available sources of stem cells.

**GRAFT VERSUS LEUKEMIA EFFECT OF ALLOGENIC STEM CELL TRANSPLANTATION AND MINIMAL RESIDUAL DISEASE IN PATIENTS WITH AML IN FIRST COMPLETE REMISSION**

J. Versluis 1,*,†, B. Kalin 1, W. Zeijlemaker 1, J. Passweg 1, G. Graux 4, M. Manz 5, M.-C. Vekemans 8, B. Biemond 9, M.-C. Legedd 8, M. van Marwijk Kooy 3, J. Janssen 7, T. Pabst 10, B. Lowenberg 1, J. Jongen-Lavrencic 1, G.J. Schuurhuis 1, G. Ossenkoppele 2, J. Cornelissen 1

1Erasmus Medical Center Cancer Institute, Rotterdam, 2VU University Medical Center, Amsterdam, 3University Hospital Basel, Basel, Switzerland, 4Mont-Godinne, Yvoir, Belgium, 5University Hospital Zurich, Zurich, Switzerland, 6Clemens universitaires Saint-Luc, UCL, Brussels, Belgium, 7Academic Medical Center, University of Amsterdam, Amsterdam, 8Medisch Spectrum Twente, Enschede, 9Isala Hospital, Zwolle, Netherlands, 10Inselspital, Bern University Hospital, Bern, Switzerland

**Background:** The detection of minimal residual disease (MRD) in patients with acute myeloid leukemia (AML) may improve future risk-adapted strategies of AML treatment. The presence of MRD after induction treatment has firmly been shown to predict for relapse and overall outcome, irrespective of type of post-remission treatment (PRT). Currently it is unknown whether and how the presence or absence of MRD should guide the application of allogeneic hematopoietic stem cell transplantation (alloHSCT) as PRT.

**Aims:** We addressed whether and to what extent alloHSCT quantitatively reduces relapse as compared to conventional post-remission treatment (PRT) in upfront treated patients with MRD positive or MRD negative AML in first hematological complete remission (CR1).

**Methods:** A total of 1,511 patients were treated in subsequent HOVON-SAKK AML trials of whom 547 patients obtained a CR1, received PRT and had available flow cytometric MRD prior to PRT. MRD positivity was defined by more than 0.1% cells with a leukemia associated phenotype within the white blood cell compartment. MRD status was not known by clinicians during AML treatment. PRT consisted of alloHSCT (n=228), or conventional PRT by a third cycle of chemotherapy (n=160) or autologous HSCT (n=105). Endpoints of the study included overall survival (OS), relapse-free survival (RFS), and cumulative incidences of relapse and non-relapse mortality (NRM) at 4 years. A time-dependent covariate analysis was performed by applying multivariable Cox regression with time-dependent covariate alloHSCT with the cumulative incidence of relapse as primary endpoint.

**Results:** MRD was positive in 120 (24%) patients after induction chemotherapy before proceeding to PRT. The latest European LeukemiaNET risk classification was similarly distributed among MRD negative and MRD positive patients. No differences were present in transplant characteristics in MRD positive and MRD negative patients. OS and RFS was significantly better in patients without MRD prior to PRT as compared to MRD positive patients (65±2% compared to 50±5% at 4 years, p<0.002, and 58±3% compared to 38±4%, p<0.001, respectively).

**Summary/Conclusions:** Overall, we conclude that our prospective results showed that MRDpos+LSCpos patients have a significantly worse cumulative incidence of relapse (HR 0.38, 95% CI 0.32-0.47) and overall survival (HR 0.36, 95% CI 0.18-0.70) as compared to MRDneg+LSCneg patients. ASCT can be avoided if MRD is not detectable; if MRD is positive, ASCT can prolong OS and DFS to equalize those of the low-risk category. ASCT was delivered to 2/3 of pts in the high-risk group, using all the available sources of stem cells.

**SL13**

**LEUKEMIC STEM CELL FREQUENCY COMBINED WITH MRD IS AN IMPORTANT BIOMARKER TO PREDICT RELAPSE IN ACUTE MYELOID LEUKEMIA. RESULTS FROM A PROSPECTIVE H102 STUDY**

1Hematology, VU University Medical Center, Amsterdam, 2Clinical Trial Center, Erasmus University Medical Center, Rotterdam, 3Hematology, University Hospitals Leuven, Campus Gasthuisberg, Leuven, 4Hematology, Ziekenhuis Netwerk Antwerpen, Antwerp, Belgium, 5Hematology, Inselspital, Bern University Hospital, Bern, 6Hematology, University Hospital Zurich, Zurich, Switzerland, 7Immunology, Erasmus University Medical Center, Rotterdam, 8Clinical Chemistry, Medisch Spectrum Twente/Medlon, Enschede, 9Hematology, Erasmus University Medical Center, Rotterdam, Netherlands

**Background:** Despite up-to-date risk algorithms, outcome in acute myeloid leukemia patients is still difficult to predict. Even in good risk patients relapses occur. Further refinement of currently used risk classifications is therefore warranted. Measurable residual disease (MRD) is a well-known risk factor and the independent prognostic impact of MRD was shown for patients independent on risk groups. Nowadays prospective studies are designed on which therapy is adapted based on MRD-positivity or negativity. Although this is a major improvement for risk stratification, relapses occur in a substantial proportion of MRD-negative patients. Previous retrospective studies have shown that the leukemic stem cell (LSC) frequency harbors important prognostic information as well (Bradbury et al., Leukemia 2015), even within MRD-negative patients (Terwijn et al. Plos one, 2013).

**Aims:** In this study we used data of the HOVON-SAKK H102 trial to prospectively define, using flow cytometry, the leukemic CD34+CD38- stem cell frequency combined with MRD and LSC status to investigate impact on patient outcome.

**Methods:** In 242 patients who achieved morphologic complete remission, both LSC and MRD data after two cycles of chemotherapy treatment were available. MRD-positivity was defined as a percentage of MRD-positive cells above 0.1% (as compared to total amount of WBCs) and LSC-positivity was defined as a CD34+CD38-LSC percentage above 0.0000% (LSC cut-off 0.0000%; thus no CD34+CD38-LSC events measured).

**Results:** Cumulative incidence of relapse (CIR) and overall survival (OS) data were investigated for four different MRD/LSC groups: 1. MRDneg+LSCneg-patients (n=136) 2. MRDpos+LSCneg-patients (n=28) 3. MRDneg+LSCpos-patients (n=58) and 4. MRDpos+LSCpos-patients (n=20). Results showed that MRDpos+LSCpos-patients have the worst prognosis. 3-year CIR for the four above defined groups was 35% (SE 4), 43% (SE 9), 53% (SE 7), and 100% (SE 0), respectively. Similar results were found for OS; 3-year OS was 66% (SE 4), 68% (SE 9), 53% (SE 8), and 100%, respectively, with 17 patients dead and 3 censored in the latter group. When investigating the impact of MRD/LSC status in the good, intermediate, poor and very poor risk group (according to HOVON), patient numbers were sometimes small; however, results show that MRDpos+LSCposAML patients in all different risk categories have a very poor prognosis. Moreover, multivariate analyses, containing all well known risk factors including risk group and post remission treatment, showed that MRDpos+LSCpos-patients have a significantly worse cumulative incidence of relapse (hazard ratio [HR] 5.89, 95% CI 3.32-10.47) and overall survival (HR 3.62, 95% CI 1.86-7.04) as compared to MRDneg+LSCneg-patients.

**Summary/Conclusions:** The graft-versus-leukemia effect of alloHSCT is equally present in MRD positive and MRD negative patients, which advocates a personalized application of alloHSCT taking the risk of relapse determined by AML risk group and MRD status as well as the counterbalancing risk of NRM into account.
all different currently used risk categories. These data urge to include both MRD and LSC in future AML risk classification to better inform post-remission treatment.

DEFINITION OF PARTIAL RESPONSE IN YOUNGER AML PATIENTS AFTER FIRST INDUCTION COURSE MAY BE EXTENDED BY INCLUSION OF IMMUNOPHENOTYPIC DETECTION OF MEASURABLE RESIDUAL DISEASE IN CR

S114

DEFINITION OF PARTIAL RESPONSE IN YOUNGER AML PATIENTS AFTER FIRST INDUCTION COURSE MAY BE EXTENDED BY INCLUSION OF IMMUNOPHENOTYPIC DETECTION OF MEASURABLE RESIDUAL DISEASE IN CR

1Institute of Immunology and Immunotherapy, University of Birmingham, Birmingham, 2King’s College London School of Medicine, London, 3Centre for Trials Research, Cardiff University, Cardiff, 4North Bristol NHS Trust, Bristol, 5University Hospital of Wales, 6Cardiff University School of Medicine, Cardiff, 7Isle of Arran, Isle of Arran, 8Nottingham University Hospital, Nottingham, United Kingdom

Background: In AML response by morphology after a first cycle of induction therapy is used to guide further therapy including second cycles of induction and choice of consolidation. It is still uncertain how the quality of response post cycle 1 with inclusion of MRD assessment impacts on outcomes within AML risk subgroups including NPM1 wild type standard risk and whether this adds information to MRD status in CR post cycle 2.

Aims: To quantify the effect of MRD positivity for response after each cycle of induction therapy in younger patients with AML.

Methods: As part of the UK NCRI AML17 trial (ISRCTN: 55675535) for patients with AML or high risk MDS up to the age of 60, prospective flow cytometric MRD (MFC-MRD) monitoring was performed after each course of induction. Any level of MRD detected was considered MRD+(sensitivity thresholds: ~0.02% by tracking diagnostic leukemic aberrant phenotypes /LAIP, ~0.05-0.1% by “different-from normal” blast LAIP). Clinicians were not informed of MFC-MRD results. Following their first cycle of induction with daunorubicin/ara-C based therapy, patients were allocated a risk group by a validated score (comprising cytogenetics, WBC, age, secondary disease, blast response to cycle 1 and mutation status). Poor risk patients received intensified therapy in cycle 2 with a view of proceeding to SCT.

Results: MFC-MRD results after either induction course are available for 1555 patients randomised from 4/09-12/14 (median age 51, range 0-73). Cycle 1 (C1) response data with MFC-MRD was available for 1,400 patients. 70% achieved morphological CR at this time-point; 14% had resistant disease (RD) and 16% were in partial remission (PR) according to clinician. Of patients in CR (n=984) 56% had detectable MFC-MRD (MRD+). Excluding poor-risk patients 14% of patients did not achieve CR (7% RD, 7% PR), 51% of patients in CR were MRD+. 5 year OS for MRD- vs MRD+ was 63% vs 44% vs 37% vs 25% for all patients; 69% vs 51% vs 50% vs 30% excluding poor-risk patients and 66% vs 49% vs 49% vs 30% for standard risk alone (Figure 1). The similar OS in this group between CR MRD+ and PR at C1 was maintained in NPM1wt standard risk patients and if censored at stem cell transplant. 771 patients were in CR post cycle 2 (C2) and provided MFC-MRD data. As expected, there were significant differences in 5 year OS between CR MRD- vs MRD+ for all patients (35% vs 63%) and excluding poor-risk (38% vs 70%, n=512). Importantly post cycle 2 MFC-MRD status also differentiated OS for NPM1wt standard risk patients with 5 year OS of 32% vs 64% (P=0.002) for MRD+ vs MRD-. In stratified analyses, there was some evidence that the effect of MRD positivity on OS was lower in poor-risk patients (test for trend p=0.02 for both C1 and C2). The effect of MFC-MRD status on relapse and OS appeared greater at C2 (relapse, OR 2.00(1.56-2.55), p<0.001; survival, OR 1.80(1.42-2.28) p<0.001) than C1 (relapse, OR 1.69(1.37-2.07), p<0.001; survival, OR 1.46(1.19-1.79) p<0.001). In patients with data for both time points, C2 MRD remained significant on OS when adjusting for C1 response. 24 patients converted from C1 MRD- to C2 MRD+, with a poor prognosis (15 relapses, 13 deaths). C1 MRD-/C2 MRD- had the best prognosis.

Figure 1.

Summary/Conclusions: MFC-MRD in CR post cycle 1 has similar outcomes to partial remission in younger patients with AML, particularly in patients with good and standard risk disease. Assessment of MFC-MRD post cycle 2 appears to provide additional discrimination to cycle 1: MFC-MRD in courses 1-2 may be useful in further stratifying standard risk patients.
New insights into chronic lymphocytic leukemia biology

Campo1,2,3,9

1IDIBAPS, Barcelona, 2CIBERONC, Madrid, 3Hospital Clínico de Barcelona, 4Hospital General Universitario de Alicante, 5Hospital Universitario de Salamanca, 6Hospital Clínico Universitario, Valencia, 7Hospital Universitario Central de Asturias, 8Instituto Universitario de Oncología, Universidad de Oviedo, Oviedo, 9Universitat de Barcelona, Barcelona, Spain

**Background:** Recent studies have revealed the presence and prognostic impact of small mutated subclones in chronic lymphocytic leukemia (CLL) (Rossi et al 2014, Nadeu et al 2016, Rasi et al 2016). Although these studies focused only on a small subset of 5 genes, their results opened a new perspective where the proportion of cells carrying each specific driver mutation may be important to the evolution of this disease. Moreover, the subclonal and mutational complexity estimated by the presence of subclonal driver alterations (Landau et al 2013, Landau et al 2015) or the accumulation of driver alterations (Puente et al 2015) have been proposed as promising indicators of clinical behavior.

**Aims:** The goal of this study was to determine the relevance of the quantitative subclonal architecture and mutational complexity in the evolution of CLL integrating the deep sequencing analysis of a large panel of driver genes and DNA copy number alterations (CNA).

**Methods:** The mutational status of 28 driver genes was investigated in 406 previously untreated CLL patients by targeted-deep next-generation sequencing (NGS). Mutations present in less than 1% of tumor cells were identified. All low frequency mutations were verified by allele-specific PCR or a second round of NGS. CNA were analyzed by SNP-arrays. Alterations were classified as clonal if their CCF was ≥85%, and subclonal otherwise. All patients gave informed consent.

**Results:** Using a highly sensitive NGS strategy we observed that small subclonal mutations were the sole alteration in 22% of the mutated cases, and were frequently detected in nearly all investigated genes. We identified three gene-specific patterns that linked the magnitude of the mutated clones (or mutated cancer cell fraction, CCF) with the prognosis of the patients: i) CCF-independent pattern: mutations at any CCF had prognostic value, ii) CCF-gradient pattern: the poor prognostic impact was a continuous variable directly related to the size of the subclone, and iii) CCF-clonal pattern: only mutations with a CCF above a certain threshold impacted the outcome of the patients. Combining mutations and driver CNAs, we observed at least one driver alteration in 66% of the patients. The subclonal complexity (accumulation of 1 to ≥4 driver alterations), but not the presence of subclonal driver populations, gradually shortened the time to first treatment independently of the IGHV mutational status and Binet stage. Conversely, the subclonal complexity, defined as the accumulation of driver alterations with the presence of at least one driver subclone, predicted for a worse overall survival independently of the IGHV and Binet stage. Patients with a pure clonal population (presence of one or more driver alterations in all tumor cells) had a similar overall survival than patients without any alteration.

**Summary/Conclusions:** Our study shows that the prognostic impact of different driver mutations is related to the size of the mutated population. Therefore, the clinical evaluation of gene mutations should consider the quantitative representation of the mutations and not only their presence or absence. In addition, the mutational complexity predicts for shorter time to first treatment independently of the IGHV and Binet stage, whereas the subclonal complexity confers an independent adverse impact for overall survival. Altogether, the integration of the subclonal architecture and mutational complexity in prognostic indexes may improve the stratification of CLL patients.

**FBXW7 MUTATIONS LEAD TO ACCUMULATION OF NOTCH1, HIF1-ALPHA AND C-MYC IN CLL CELLS**

V. Meyer-Pannwitt1,2, S. Estenfelder2, E. Tausch2, S. J. Kugler1,2, M. Reichenzeller1,2, S. Stilgenbauer2, D. Mertens1,2

1Department of Molecular Genetics (B061), Cooperation Unit “Mechanisms of Leukemogenesis”, DKFZ, Heidelberg, 2Internal Medicine III, Ulm University, Ulm, Germany

**Background:** Chronic lymphocytic leukemia (CLL) is a heterogeneous disease with recurrent mutations that are of pathogenic and prognostic relevance. Mutations in FBXW7 are among the most common mutations in CLL, yet their functional consequences are unknown. FBXW7 is an E3 ubiquitin ligase that ubiquitylates oncoproteins like NOTCH1, HIF-1α and c-MYC and thereby targets them for proteasomal degradation.

**Aims:** 2.5-4% of CLL patients harbor FBXW7 mutations. Approximately 60% of FBXW7 mutations alter arginine residues that are involved in substrate targeting. In T-cell acute lymphoblastic leukemia these arginine mutations are associated with chemotherapies resistance. In CLL, however, the role of dysfunctional FBXW7 is unclear. We therefore aimed to delineate the prevalence of FBXW7 mutations in CLL patient cohorts and characterize its functional role. Here: FBXW7 mutations were analyzed via amplicon-based targeted next generation sequencing in primary CD19-sorted samples of previously untreated CLL patients (n=905) as well as in CLL (n=8), MCL (n=5), Burkitt lymphoma (n=1) and LCL cell lines (n=3). In silico modeling with PolyPhen-2 predicted a potential impact of the mutations on the structure and function of FBXW7 with a high mutational burden of the PolyPhen-2 software. all except one missense mutation in FBXW7 were predicted to be most likely damaging. No mutations in FBXW7 were found in the CLL, MCL and LCL cell lines analyzed. To determine the functional consequence of FBXW7 mutations in CLL, we induced either a heterozygous or a homozygous truncation of FBXW7 in the CLL cell line HG3, resulting in the loss of the substrate binding site of the WD40 domain. The homozygous truncation of FBXW7 resulted in an increase of NOTCH1, HIF1-α and c-MYC protein levels, whereas no difference of Cyclin E protein amount was detectable. In addition, an elevation of NOTCH1 activity was found in both the heterozygously and homozgyously truncated mutant cell lines in comparison to the wildtype HG3 cell line. To confirm this finding, protein levels of 5 CLL patients with FBXW7 mutations were analyzed with a similar outcome.

**Summary/Conclusions:** Mutations in FBXW7 are frequently found in CLL, especially missense and nonsense mutations affecting the WD40 domain. We hypothesize that this has functional consequences on FBXW7 substrate binding and hence results to accumulation of focal oncogenes. Thus, the truncation of the WD40 domain of FBXW7 in the HG3 cell line resulted in the accumulation of protein substrates and corresponding increase of their activity implicated in the pathogenesis of CLL. Taken together our data show that FBXW7 can target proteins for degradation that are commonly dysregulated in CLL and that drive disease progression.

**Background:** Different omics studies have focused on the analysis of individual layers of information in chronic lymphocytic leukemia (CLL), such as the genome, and its transcriptional regulation as well as DNA methylation, but have missed insights into other layers of the epigenome, like histone modifications, remain relatively unexplored and an integrative molecular portrait of CLL is not available yet.

**Aims:** The aim of this study was to extensively map and analyse the epigenome

haematologica | 2017; 102(s2) | 9
of CLL in relation to the mutational, transcriptional and three-dimensional (3D) chromatin landscape.

Methods: Seven CLL patients with distinct clinico-pathological features and five mature B-cell subpopulations were extensively analysed using (i) ChIP-seq of six different histone marks with non-overlapping features (H3K27ac, H3K4me1, H3K4me3, H3K9me3, H3K27me3 and H3K36me3); (ii) single stranded RNA-seq; (iii) transposable-accessible chromatin assays (ATAC-seq) and iv) whole-genome bisulfite sequencing (WGBS), creating a unique reference epigenome for CLL. These data were complemented with the 3D chromatin landscape in one CLL case measured by high-throughput chromatin conformation capture (HiC-seq) and promoter capture Hi-C (PCHi-C). Furthermore, we mapped the active chromatin landscape of 100 CLL patients by H3K27ac ChIP-seq and ATAC-seq. Whole-genome sequencing data was available for 44 of these patients. We applied a broad range of bioinformatic tools to analyze the data in an integrative way.

Results: CLL is distinct from normal B cells for all layers of the reference epigenome of 17 CLLs and the active chromatin landscape (100 CLLs). CLL though is closer to naive and memory B cells than to germinal center B cells and plasma cells. Interestingly, in CLL we not only saw activation of regions that are active in naive and memory B cells, but also an unexpected activation of genomic regions that are specifically active in germinal center B cells and plasma cells. Changes in activation in these and other regions could furthermore distinguish the two major clinical subgroups of CLL with unmutated and mutated immunoglobulin heavy chains (IgHV). CLLs did not only differ from normal B cells regarding the separate layers of information, but also using combined patterns of histone marks, which for example can define regulatory elements as active promotors (H3K4me3 and H3K27ac) or active enhancers (H3K27ac and H3K4me1). More specifically, we detected 534 genomic regions with de novo gain (n=498) or loss (n=36) of active regulatory regions in CLL. Large regions (>10kb) showing de novo gain of regulatory elements in CLL (n=51), were located into, close to, or interacted in 3D space with genes important for CLL pathogenesis, e.g., LEF1, BCL2 and FMOD. Interestingly, non-coding somatic mutations in IGVH mutated CLLs accumulate in these and other active regulatory regions, likely off-target effects of the somatic hypermutation machinery. Besides changes in regulatory elements, we observed that CLLs lose poised promoters, which are replaced by repressive regions (BAFF-mediated BCR activation did not correlate with IGVH mutational status). Like IgM, BAFF induced CLL cell chemotaxis. SYK inhibition effectively antagonized survival and chemotaxis of BAFF-stimulated CLL cells. By contrast, targeting BTK or PI3K was less effective. All BCRi’s fully blocked canonical NFκB activation in BAFF-stimulated CLL cells (suggesting its dependence on BCR signaling), but none inhibited the non-canonical pathway. By contrast, pemovendistat, an inhibitor of Neddfabinating enzyme which we previously showed to abrogate TNFR-mediated NFκB activation, blocked both canonical and non-canonical NFκB activity in BAFF-stimulated CLL cells. SYK inhibitor entospleminib, but not other BCRi’s, decreased Mcl-1 expression in CLL cells co-cultured with BAFF-expressing stroma and abrogated BAFF-mediated upregulation of Mcl-1. This was accompanied by a decrease in Mcl-1 transcript. BAFF receptor signals via the TRAF complex to induce non-canonical NFκB activation in neoplastic B-cells. We supposed that TRAF complex could be directly responsible for SYK activation by BAFF. Indeed, IP experiments demonstrated that SYK directly complexed with TRAF2/3 in BAFF-stimulated neoplastic B-cells.

Summary/Conclusions: Thus, BAFF-mediated induction of BCR-associated kinases and Mcl-1 contributes to CLL cell survival. SYK inhibition is a promising therapeutic strategy uniquely poised to antagonize crosstalk between BAFF and BCR, thereby disrupting the pro-survival microenvironment signaling in CLL.

**THERAPEUTIC DISRUPTION OF THE BAFF-BCR RECEPTOR CROSS-TALK IN CHRONIC LYMPHOCYTIC LEUKEMIA CELLS**

C. Paiva1, T. Rowland1, B. Sreekantham1, O. Danilova1, A. Danilov1,.*

1Oregon Health and Science University, Portland, United States

Background: Although small molecule inhibitors of BCR-associated kinases (BCRi) revolutionized therapy in CLL, they provide incomplete responses. Tumor necrosis factor receptor superfamily ligands BAFF and APRIL induce NFκB, which in turn upregulates pro-survival Bcl-2 family proteins and thereby drives anti-apoptotic responses, potentially accounting for resistance to BCRi. The exact roles of the individual NFκB pathways, as well as the implications of targeting BCR in context of BAFF signaling in CLL remain understudied.

Aims: We explored the mechanistic underpinnings of CLL cell survival in response to BAFF signaling.

Methods: We established a novel BAFF-expressing stromal co-culture model and employed inhibitors of Bruton tyrosine kinase (BTK, ibrutinib), phosphoinositiode-3 kinase (PI3K, idelalisib) and spleen tyrosine kinase (SYK, entospleminib). We quantified CLL cell apoptosis, migration, NFκB activity, protein and mRNA expression by flow cytometry, immunoblotting, ELISA, RT-PCR and immunocytochemistry.

Results: CLL cells co-cultured with BAFF-expressing stroma were resistant to spontaneous apoptosis (12.3±3.2% after 24 h, vs 34.8±6.2% off stroma) and chemotherapy agents (bendamustine, fludarabine). Gene expression profiling exposed the NFκB pathway gene targets as the most significantly upregulated upon BAFF stimulation (p<0.0001). We and others have shown that BAFF-expressing stroma induces canonical and non-canonical NFκB in CLL. By contrast, while BAFF led to strong activation of the non-canonical NFκB with processing of p100 (to p52) by 4 h and a 5-fold increase in p52 DNA-binding activity by 24 h, canonical NFκB (RelA) activation was less pronounced. BAFF predominantly induced Mcl-1, compared to CD40L which strongly upregulated Bcl-X. BCR is a major driver of non-canonical NFκB signaling in CLL. Thus, we studied whether BAFF co-opted BCR signaling in CLL. BAFF induced rapid (15 min) phosphorylation of the proximal BCR kinases SYKand LYN, sustained for up to 4 h, as well as ERK, in CLL cells. LOW MYBL2 EXPRESSION OBSERVED IN MYELODYSPLASTIC SYNDROME PATIENTS WITH WORSE PROGNOSIS IS ASSOCIATED WITH ALTERED DNA REPAIR MECHANISMS IN HAEMATOPOETIC STEM CELLS

R. Bayley1, L. Cancian1, C. Ward1, G. Volpe1, S. Dumon1, J. Gujari1, G. Stewart1, E. Petermann1, P. Garcia1.1

1Institute of Cancer and Genomic Science, University of Birmingham, Birmingham, United Kingdom

Background: MYBL2 is a transcription factor with roles in the cell cycle and genome integrity. MYBL2 is located on chromosome 20, within a region commonly deleted in human blood disorders (del20q). Our published data shows that reduced levels of MYBL2 predispose to development of myelodysplastic syndromes (MDS)-like disease in mouse models during ageing, indicating that MYBL2 could be acting as a tumour suppressor gene within del20q abnormality. Moreover, our previous work demonstrated that regardless of del20q deletion, MYBL2 expression is reduced in CD34+ bone marrow cells from MDS patients with worse prognosis. Because it has been shown that the cell of origin of MDS is the haematopoietic stem cell (HSC) and given the role of MYBL2 in DNA replication fork progression and maintenance of genome integrity, we hypothesised that low MYBL2 levels in HSC could contribute to elevated somatic mutations through changes in DNA repair pathways and drive disease development.

Aim: The aim of this study was to determine if low MYBL2 levels affect the double strand break (DSB) DNA repair damage response in HSC.

Methods: In this study we used our mouse model in which animals express ~50% normal levels of MYBL2 (Mybl2+/∆∆). We characterized the ability of HSCs from young (7 weeks) and old (70 weeks) animals to respond to in vivo ionising radiation using the double strand break repair assay to measure repair of DNA replication fork instability and colony forming ability. We measured the activation of the two main DNA repair pathways operating in the cells to deal with DSB: the error prone homologous-end-joining (NHEJ) and the error-free homologous recombination (HR) by assessing 53BP1 and Rad51 recruitment by immunofluorescence, respectively. Finally, we analysed the frequency of chromosome abnormalities present in the progeny of Mybl2+/∆∆ HSC that have previously been irradiated to determine the long term effects of changes in DNA repair.

Results: We observed that Mybl2+/∆∆ HSCs had limited proliferative potential and displayed an increased sensitivity to ionizing radiation which increased during development. Mybl2+/∆∆ HSCs also displayed altered kinetics of 53BP1 and Rad51 recruitment and clearance, including retention of 53BP1 foci at later time points following irradiation and decreased levels of Rad51 foci when compared to Mybl2+/+ HSCs. Using plasmid functional assays, we showed that Mybl2+/∆∆ HSCs repair quite efficiently by NHEJ, but this efficiency is disrupted when cells are challenged with ionizing radiation. Furthermore, Mybl2+/∆∆ HSCs have increased sensitivity to inhibition of DNA-PKC (required for NHEJ) but not ATM (required by HR). We also observed that after ionizing irradiation Mybl2+/∆∆ HSC progeny displayed an increased percentage of chromatids with fragile telomeres. Moreover, by making use of publicly available RNA-seq databases from Cancer Genomic Atlas we have identified a clear association between low MYBL2 levels and low expression of DNA-repair genes in patients with worse prognosis.

Summary/Conclusions: In summary, we have shown that decreased expression of MYBL2 leads to an imbalance in the DSB DNA-repair pathway choice, ultimately resulting in increased genomic instability of the blood cell progeny. These findings are supported by a signature of deregulated DNA-repair genes which strongly associates with low MYBL2 levels in MDS patient samples, providing a mechanistic understanding for the progression of blood disorders occurring during ageing. This study demonstrates a novel role for MYBL2 in DNA repair in HSCs and suggests that low levels of MYBL2 in human MDS could contribute to the emergence of further genetic abnormalities by deregulation of DNA-repair pathways.
The value of NGS panel sequencing to molecularly define myeloid malignancies and clarify borderline cases: a study on 39 genes in 1143 patients

Aims: To identify the deregulated pathways and gene ontology (GO) categories associated with aberrantly spliced genes in CD34+ cells and in differentiated cells of MDS-affected lineages isolated from bone marrow of patients with myeloid disorders. We analyzed the splicing characteristics, and the major cell lineages affected in MDS-affected lineages isolated from the bone marrow of each of 7 SF3B1 mutant cases. An analysis of upstream transcriptional regulators showed a significant overlap between the aberrantly spliced genes associated with each mutant splicing factor gene (in the comparison to both wildtype cases and to healthy controls) and genes regulated by several transcription factors, including EZF1. RNA-Seq also was performed on CD34+ cells, which were isolated from patients with MDS-affected lineages and from healthy controls (18 of 30 in the comparison to wildtype cases) isolated from the bone marrow of each of 7 SF3B1 mutant cases, 7 wildtype cases and 5 healthy controls, in order to explore similarities/differences between aberrantly spliced genes and deregulated pathways and GO themes in cells of different lineages. There were many aberrantly spliced genes in one cell population that did not overlap with aberrantly spliced genes in other populations. A small proportion (i.e.<5%) of aberrantly spliced genes were common to all four cell populations. GO analysis of the aberrantly spliced genes identified that 6 of the top 30 most significant categories (including 'RNA binding' and 'translation') in the comparison to wildtype cases were enriched among cases with ring sideroblasts (p<0.001). Overall, TET2 showed the highest mutation rate (25%) and was also the most commonly mutated gene in cases with "possible" MDS (36/190; 19%), reactive morphology (17/201; 8%) or even unclear morphology (19/116; 17%). Of these three subsets, five patients had only the TET2 mutation with <10% burden, which is observed in clonal hematopoiesis of indeterminate potential (CHIP), too. However, using panel sequencing in cases with possible MDS, unclear or reactive morphology revealed at least one molecular marker for clonal disease in 47% (91/199), 36% (43/118) or 17% (36/211) of cases, respectively (excluding sole ASXL1, DNMT3A, TET2 mutations with <10% burden).

Summary/Conclusions: WHO 2016 requires information on numerous genes for diagnosis, prognosis and therapeutic decisions. This challenges convention-based classification, which has been defined in all at least one molecular marker for clonal disease. Our study has identified aberrantly spliced genes and deregulated pathways associated with spliceosome mutations in the HSCs and the major cell lineages affected in MDS, providing new insights into how these mutations impact cellular processes in this disorder.
Methods: We performed transcriptome sequencing of bone marrow mononuclear cells (BMMNCs) and/or CD34+ cells obtained from patients with myelodysplasia. Consensus clustering was used to identify stable patient clusters. A classifier of the gene expression-based subgroups was constructed using the 100 CD34+ cell samples as a training set, followed by validation in an independent cohort of 83 MDS patients. Another classifier was constructed using BMMNC samples from 51 patients, who had been assigned to the subgroups by the gene expression data of their CD34+ cells. Prognostic significance of the model was tested in 114 patients of myelodysplasia.

Results: Unsupervised clustering of gene expression data of bone marrow CD34+ cells from 107 patients identified two subgroups (Class-I and Class-II). The patients in the Class-II subgroup had higher percentages of bone marrow blasts compared to those in the Class-I subgroup (median 2% vs 11%, P < 0.01). Pathway analysis revealed up-regulation of many signaling pathways in the Class-II subgroup. The Class-I subtype showed highly significant up-regulation of the genes related to erythroid lineages. The erythroid signature was rather suppressed in the Class-II subtype, which was characterized by increased expression of genes related to progenitor cells. Compared to the Class-I subtype, the Class-II subtype was associated with a significantly shorter survival in both univariate (hazard ratio [HR] 5.0 [95% CI, 1.8–14], P < 0.01) and multivariate analysis (HR 6.8 [95% CI, 1.5–32], P=0.015). High frequency of leukemic transformation in the Class-II subgroup (38%) contrasted to no leukemic transformation in the Class-I subgroup. The prognostic signficance of our classification was validated in an independent cohort of 183 patients. We also constructed a model to predict the subgroups using gene expression profiles of BMMNCs. The model was applied to 114 patients with BMMNC samples, of whom 47 (41%) were predicted to be the Class-I subgroup. Compared to the predicted Class-I subgroup, the Class-II subgroup was associated with a significantly shorter survival in univariate analysis (HR 7.2 [95% CI, 3.0–17], P < 0.001). Again, association was more pronounced for leukemic transformation (HR 18 [95% CI, 4.2–80], P < 0.001) than for overall survival. Multivariat analysis also demonstrated that the predicted Class-II subgroup was independently associated with leukemic transformation (HR 7.3 [95% CI, 1.3–41], P=0.024). Finally, we compared the prognostic value of our model with that of the LSC17 score, which has recently been proposed to predict a subset of poor prognosis patients. Our model outperformed the LSC17 score in preclinical samples of leukemic stem cell signature. Our model outperformed the LSC17 score in predicting clinical outcomes of myelodysplasia, especially leukemia progression.

The Class-II signature was shown to be more dramatically up-regulated during clonal evolution of myelodysplasia than the LSC17 score, which is characterized by frequent copy number gains/amplifications in PD-L2 and PD-L1, and the close association between these genetic alterations and the therapeutic response to these agents. Recently, we have reported frequent structural variations (SVs) in adult T-cell leukemia/lymphoma (ATL) caused by human T-cell leukemia virus type-1 (HTLV-1). These SVs invariably affect 3′-untranslated region (UTR) of PD-L1, leading to promi-

GENETIC ALTERATIONS INVOLVING PROGRAMMED DEATH LIGANDS IN EPSTEIN-BARR VIRUS-ASSOCIATED LYMPHOMAS

1Department of Pathology and Tumor Biology, Kyoto University, Kyoto, Japan, 2Department of Pathology, Kurume University School of Medicine, Kurume, Japan, 3Pathology and Molecular Targeting Medicine, National Institute of Biomedical Research, Tokyo, Japan, 4Institute of Pathology, University of Tokyo, Tokyo, Japan, 5Department of Pathology, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan, 6Laboratory of DNA Information Analysis, The University of Tokyo, Tokyo, Japan, 7Department of Advanced Diagnosis, Nagoya Medical Center, 8Department of Pediatric Hematology and Oncology Research, National Centre for Child Health and Development, 9Department of Pathology, 10Department of Hematology, Toranomon Hospital, Tokyo, Japan

Background: Checkpoint blockade using anti-PD-1/PD-L1 antibodies is a high-potential promising therapy for cancer, frequently showing dramatic anti-tumor responses in a wide variety of tumor types. Particularly, an exceptional response to anti-PD-1 antibodies has been demonstrated for classical Hodgkin lymphoma (HL), which is characterized by frequent copy number gains/amplifications in PD-L2 and PD-L1, and the close association between these genetic alterations and the therapeutic response to these agents. Recently, we have reported frequent structural variations (SVs) in adult T-cell leukemia/lymphoma (ATL) caused by human T-cell leukemia virus type-1 (HTLV-1). These SVs invariably affect 3′-untranslated region (UTR) of PD-L1, leading to prominent PD-L1/PD-L2 expression in HTLV-1-infected cells. Additionally, tumors, leukemic cells, and potentially mixed cells of a leukemic transformation in the Class-II subgroup. The Class-I subtype showed highly significant up-regulation of the genes related to erythroid lineages. The erythroid signature was rather suppressed in the Class-II subtype, which was characterized by increased expression of genes related to progenitor cells. Compared to the Class-I subtype, the Class-II subtype was associated with a significantly shorter survival in both univariate (hazard ratio [HR] 5.0 [95% CI, 1.8–14], P < 0.01) and multivariate analysis (HR 6.8 [95% CI, 1.5–32], P=0.015). High frequency of leukemic transformation in the Class-II subgroup (38%) contrasted to no leukemic transformation in the Class-I subgroup. The prognostic significance of our classification was validated in an independent cohort of 183 patients. We also constructed a model to predict the subgroups using gene expression profiles of BMMNCs. The model was applied to 114 patients with BMMNC samples, of whom 47 (41%) were predicted to be the Class-I subgroup. Compared to the predicted Class-I subgroup, the Class-II subgroup was associated with a significantly shorter survival in univariate analysis (HR 7.2 [95% CI, 3.0–17], P < 0.001). Again, association was more pronounced for leukemic transformation (HR 18 [95% CI, 4.2–80], P < 0.001) than for overall survival. Finally, we compared the prognostic value of our model with that of the LSC17 score, which has recently been proposed to predict a subset of poor prognosis patients. Our model outperformed the LSC17 score in predicting clinical outcomes of myelodysplasia, especially leukemia progression. The Class-II signature was shown to be more dramatically up-regulated during clonal evolution of myelodysplasia than the LSC17 score, which might be the basis of a better prediction of leukemia progression in our model.

Summary/Conclusions: Comprehensive transcriptomic analysis identified two subgroups of myelodysplasia with biological and clinical relevance, which could improve risk prediction and treatment stratification of myelodysplasia.
shown previously to increase FOXO1 nuclear localization and activity, have been linked to diminished survival in DLBCL patients uniformly treated with rituximab-based immunotherapy. Although the contribution of FOXO1 mutations to the therapeutic resistance of B-NHLs becomes apparent, the molecular mechanism underlying this phenomenon has not been explained so far. The diminished levels of CD20 on the cell surface of tumor cells are among several potential mechanisms underlying the resistance to treatment with anti-CD20 monoclonal antibodies.

Aims: We have recently reported that the tonic BCR signaling activates FOXO1, and that inhibitors of the downstream BCR signaling pathways down-regulate CD20 expression. Therefore, here we sought to determine whether FOXO1 might regulate the abundance of CD20 on the surface of tumor cells thus influencing the response to rituximab-based therapies.

Methods: We used CRISPR/Cas9 genome editing technology and lentiviral transduction to study the role of FOXO1 protein in CD20 regulation. qRT-PCR and Dual Luciferase Assays was done to determine the influence of FOXO1 on CD20 transcription. To explore if tumor suppressor function of FOXO1 was retained in mature B cells, we performed FACS and ChIP experiments. For animal studies we used SCID Fox Chase mice model. All in vivo experiments were carried out at the animal facility of The Francis Crick Institute in accordance with the guidelines and were approved by the Ethics Committee. Results: To determine the potential role of FOXO1 in CD20 regulation, we disrupted FOXO1 focus using the CRISPR/Cas9 genome editing technology in Raji cells. In vitro complement-dependent cytotoxicity assay we show that ablation of FOXO1 results in upregulation of CD20 levels and improved rate of rituximab efficacy. To see whether FOXO1-dependent up-regulation of CD20 transcription influences tumor suppressor function we performed in vivo experiments where we used SCID Fox Chase mice model. We found that mice treated with systemic rituximab survived longer when inoculated with sgcFOXO1-transduced Raji cells as compared with mice inoculated with control Raji cells. Consistently, using clinically tested PI3K-AKT inhibitors - MK-2206 and GDC-0068 – in a set of B cell lymphoma cell lines, we show that PI3K-AKT inhibition of FOXO1 activity upregulated surface CD20 levels. Moreover, we demonstrated that FOXO1 regulates the CD20 promoter activity. In different B-cell lymphoma cell lines MK-2206 and GDC-0068 significantly downregulated the levels of MS4A4A transcript (encoding CD20). Finally, using both EMSA and ChIP assays we detected specific binding of FOXO1 to the MS4A4A promoter to the extent comparable to other known FOXO1 target genes.

Summary/Conclusions: Collectively, our results indicate that FOXO1 is strong negative regulator of CD20 expression and add new insights into the mechanisms underlying the contribution of FOXO1 mutations to the resistance of B-NHLs to R-CHOP therapy. In light of current knowledge and our observations presented in this study, FOXO1 inhibition represents a novel strategy to increase the efficacy of anti-CD20 monoclonal antibodies.

Investigations of the NIPA knockout mouse in a clinical relevant ALCL model

In this study, we aim to investigate the effect of NIPA deficiency on NPM-ALK driven cell proliferation and transformation in order to characterize the function of the protein in ALCL-induced lymphomagenesis.

Methods:

Primary Nipa-/-MEFs infected with NPM-ALK were plated in soft agar assays to evaluate their transformation ability. Moreover, NIPA was downregulated through targeted genetic approaches in Karpas299 and NPM-ALK infected Ba/F3 cells, which were analyzed regarding proliferation, signaling, and apoptosis. To assess the impact of Nipa deletion in vivo, we used a retroviral bone marrow transplantation model resembling human ALCL. Based on a Cre/loxP system under the LCK-Promotor, NPM-ALK expression and Nipa-deletion are restricted to early T cells. In wildtype background, mice die of systemic Thy1.2+lymphoma with a latency of 4-6 months, developing neoplastic T-cell infiltration of bone marrow and lymphatic organs. Lymphomas were analyzed regarding immunphenotype and clinical presentation.

Results:

Primary Nipa-/-MEFs infected with NPM-ALK showed significantly reduced colony formation potential upon NPM-ALK expression (38 vs 79 CFUs; p<0.001). These results were substantiated in human and mouse cell lines, where significantly reduced proliferation ability was observed in NIPA downregulated NPM-ALK-expressing Ba/F3 cells (74% of wt; p<0.01) as well as in Karpas299 cells infected with NIPA miR (66% of wt growth; p<0.01). Moreover, treatment with the ALK inhibitor TAE-684 gave evidence of possible synergistic effects of ALK inhibition and NIPA knockdown. Mice transplanted with Lck-CreTg(2)Nipaflx/floxMSNAIE infected bone marrow cells showed significantly prolonged survival (14.9 vs 12 days in wt). Morphologically, mice presented with enlarged thymi, splenomegaly, lymphadenopathy, and bone marrow infiltration. Immunophenotyping showed a pure T-cell phenotype in Nipa-/- lymphomas, thus resembling wildtype. In a long-latency model of NPM-ALK expression in enriched HSCs, a significantly prolonged survival (110 vs 80 days; p<0.01) and reduction of spleen colonies (10 vs 28 colonies/spleen; p<0.001) in mice transplanted with MigNPM-ALK:Nipa-/- bone marrow compared to control animals were observed, thereby suggesting a crucial role of NIPA in NPM-ALK driven lymphomagenesis. To investigate the precise mechanism underlying these results, we performed cell cycle analyses as well as cell viability assays. Indeed, we were able to detect significant differences in the cell viability in Nipa deficient NPM-ALK expressing cells, whereas cell cycle distribution seems not to be altered in knockout cells.

Summary/Conclusions:

Taken together, we were able to show that NIPA is crucial for cell proliferation and transformation upon NPM-ALK expression. Investigations of the NIPA knockout mouse in a clinical relevant ALCL model highlight the importance of the NIPA/NPM-ALK axis in lymphoma development. Further analyses may thus elucidate NIPA as a novel molecular target for therapeutic intervention.

Background: Gene therapy for transfusion dependent beta-thalassemia, as an alternative cure to allogeneic HSCT, is based on the autologous transplantation of hematopoietic stem cells (HSCs) engineered by lentiviral vectors expressing a transcriptionally regulated human beta-globin gene.

Aims: Our contribution to this field was devoted to the clinical development of a gene therapy protocol based on high-titer vector GLOBE, use of lenogastim and plerixafor as source of HSCs and a conditioning regimen based on myeloablative treosulfan and thiotepa favoring efficient engraftment of corrected cells with reduced toxicity (TIGET-BTHAL; EudraCT number 2014-004860-39).

Methods: On the basis of extensive efficacy and safety preclinical studies, the clinical trial TIGET-BTHAL was approved and started in 2015 at Scientific Institute San Raffaele, Milano, Italy. The clinical study foresees treatment of 10 patients: 3 adults followed by 7 minors, with a staggered enrolment strategy based on evaluation of safety and preliminary efficacy in adult patients by an independent data safety monitoring board before inclusion of pediatric subjects. The chosen route of administration of gene modified HSCs is intraosseous in the posterior-superior iliac crests, bilaterally, with the aim of enhancing engraftment and minimizing first-pass intravenous filter.

Results: As of February 2017, seven patients (3 adults and 4 pediatric patients) with different genotypes (β-thal/β-thal) have been treated with GLOBE-transduced CD34+ cells at a dose of 16x10⁶-19.5x10⁶ cells/kg and a vector copy number (VCN)/cell ranging from 0.7 to 1.5. The procedure was well tolerated by all patients, with no product-related adverse events. Multilineage engraftment of gene-marked cells was observed in all tested peripheral blood and bone marrow samples. Polyclonal vector integrations profiles have been detected in the first 3 patients tested.

Summary/Conclusions: So far, the clinical outcome indicates reduction in transfusion requirement in adult patients and greater clinical benefit in younger patients. Follow up analysis are ongoing and updated clinical outcome will be presented.

LUSPATERCEPT INCREASES HEMOGLOBIN AND DECREASES TRANSFUSION BURDEN IN ADULTS WITH B-TALASSEMIA

1Turin University, Turin, 2Second University of Naples, Naples, 3Arcispedale S. Anna, Cona, Ferrara, Italy, 4Laiko General Hospital, Athens, Greece, 5Ospedale “A. Perrino”, Brindisi, 6AORN “A. Cardarelli”, Naples, 7ARNAS Garbaldi, Catania, 8CEMEF, Medicina 2, Modena, Italy, 9Acceocherma Pharma Inc, Cambridge, 10Celgene Corporation, Summit, United States

Background: Luspatercept (ACE-536), a fusion protein containing a modified activin receptor type IIb, is being developed for the treatment of β-thalassemia. Luspatercept binds to select TGF-β superfamily ligands (such as GDF11) reducing aberrant Smad2/3 signaling and promoting late-stage erythroid differentiation and increased hemoglobin (Hgb). Luspatercept corrected the effects of ineffective erythropoiesis in a mouse model of thalassemia (Suragani R, Blood, 2014) and increased Hgb levels in patients with ineffective erythropoiesis treated in a phase 1 study in healthy volunteers (Attie K, Am J Hematol, 2014).

Aims: This ongoing, phase 2, multicenter, open-label study followed by a long-term extension (ext) study evaluates the effects of luspatercept in patients (pts) with either transfusion-dependent (TD) or non-transfusion dependent (NTD) β-thalassemia with key endpoints of erythroid response (including Hgb increase) and pt-reported quality-of-life (QoL) in NTD patients, and reductions in RBC transfusion burden in TD patients.

Methods: Inclusion criteria: age ≥18 yr and either TD (≥4 RBC U/8 weeks prior

Background: Thalassemia major (TM) is a genetic disorder caused by an inherited defect of the β-globin chain, which results in a decreased production of hemoglobin. It is a common disorder with an estimated prevalence of 1 in 100-200 live births in the Mediterranean and Southeast Asian regions. Thalassemia major is characterized by severe anemia, iron overload, and complications related to bone disease.

Methods: This French retrospective study included patients who successfully received allogeneic HSCT between 1985-2012 and were alive at least 2 years after HSCT. Study results were explored in 107/134 patients (79%) who performed HSCT for beta-thalassemia. The patients were comprised of 58 males and 49 females. The median age at HSCT was 5.9 years (8 month-26 years).

Results: Of the 134 patients, 97% achieved at least 10% bone marrow engraftment (bweight SDS, SF, Hb values). In 95% of cases, the donor was a matched sibling or an unrelated donor. The median number of days to neutrophil engraftment (NCAT02604433).

CD34+AND HUMAN INDUCED PLURIPOTENT STEM CELL DIFFERENTIATION TO TRANSFUSION READY RED BLOOD CELLS
M.-J. Claessen1,2,*, E. Varga1, M. Hansen1, P. Burger1, S. Heshusius1, T. Wust1, R.mort1, J. Eernstman 1, M. Thiel 1, E. Heideveld 1, E. Sellink 1, M. von Lindern 1, E. van den Akker1

Background: Donor-derived red blood cells (RBC) are the most common form of cellular therapy. However the source of cells is dependent on donor availability with a potential risk of allo-immunization and blood borne diseases.

Aims: We aim to produce unlimited numbers of cultured RBC with a defined ‘universal donor’ phenotype for transfusion purposes.

Methods: To this end we prepare for a clinical test using autologous cultured RBC to test their in vivo stability. In parallel we develop methods for unlimited production of cultured RBC. An immortal source to produce in vitro cultured RBCs (cRBC), such as iPSCs would allow selection of ‘universal donor’ RBC, or provide an autologous end product with the absence of immune reactions.

Results: The in vitro production of RBC has proven to be successful, however there are barriers to overcome prior to clinical application. (e.g. xeno-free culturing methods, scale up cultures to obtain transfusion units (1-2*10^12 RBC), such as iPSCs would allow selection of ‘universal donor’ RBC, or provide an autologous end product with the absence of immune reactions.

Summary/Conclusions: Such an unlimited production of cRBCs would be essential to allow directed colony differentiation using a feeder-free monolayer approach.

FUNCTIONAL PROTEOMICS IDENTIFIES SETD2 AS A CRITICAL EFFECTOR OF MLL FUSION PROTEINS TO SAFE-GUARD GENOMIC INTEGRITY
A. Stukalov1, S. Vittori1, M. Muhar3, M. Roth3, B. Györffy4, P. Valent4, K. Bennett1, A. Skucha1,*, J. Ebner 2, J. Schmöllerl 2, A. César Razquin 1, T. Eder1, T. Wust1, J. Zuber3, G. Superti-Furga1,6, G. Grebien2

Background: Acute Myeloid Leukemia (AML) frequently harbors chromosomal rearrangements involving the Mixed Lineage Leukemia (MLL) gene. More than 65 different MLL fusion genes exist and many of them have been described to act as strong cancer drivers. While critical effectors of different MLL fusion proteins that are presumed to employ different mechanisms of oncogenic transformation.

Aims: We hypothesized that common oncogenic mechanisms are encoded in stable physical and genetic MLL-fusion-specific interaction networks. Thus, we aimed to identify common critical effectors of different MLL fusion proteins that are presumed to employ different mechanisms of oncogenic transformation.

Methods: Protein complexes of 7 molecularly distinct, affinity-tagged MLL-FPs (MLL-AF4, MLL-AF9, MLL-ENL, MLL-CBP, MLL-EE, MLL-GAS7 and MLL-AF1p) were purified from stable cell lines allowing for inducible, single-copy transgene expression and characterization by mass spectrometry. Data analysis identified a comprehensive protein-protein interaction network, which was functionally interrogated by a subtractive shRNA screening approach. Validation experiments included detailed RNAi- and CRISPR/Cas9-mediated loss of function experiments in cell lines and primary cells in vitro and in vivo, using readouts for changes in proliferation, differentiation, apoptosis and DNA damage.

Results: Characterization of the protein complexes nucleated by 7 MLL fusion proteins by affinity purification coupled to mass spectrometry (AP-MS) revealed a densely interconnected protein-protein interaction network of 963 proteins, comprising previously known MLL-interacting protein complexes (such as PR2C or SWI/SNF), as well as a high number of new interaction partners of MLL. 128 proteins were found to interact with ≥5 of all 7 MLL-fusions. This subset of conserved MLL-interaction partners was highly enriched for proteins with function in chromatin metabolism and transcriptional control. Systematic functional investigation of the conserved MLL-fusion interactome using subtractive shRNA screens identified the methyltransferase SETD2 as a critical effector of MLL fusion proteins.

Summary/Conclusions: In summary, our data highlight the functional relevance of combined proteomic-genomic cellular screening to identify critical effectors of MLL-FPs. In addition, our study identifies a novel role for SETD2 in the maintenance of genomic integrity during initiation and progression of MLL-rearranged AML and establishes SETD2 as a therapeutic target in leukemia with low genomic complexity.
C/EBPα can act as a gain-of-function allele with distinct molecular properties. However, the mechanistic basis of C/EBPα p30-induced leukemogenesis is incompletely understood.

**Aims:** We hypothesized that the interaction between the oncogenic C/EBPα p30 isoform and the MLL/SET histone methyltransferase complex is required for p30-dependent epigenetic and transcriptomic changes that contribute to leukemogenesis. Therefore, we aimed to investigate the sensitivity of CEBPα mutant MLL to perturbation of MLL/SET function.

**Methods:** We used CRISPR/Cas9-mediated mutagenesis to interfere with the MLL/SET complex in myeloid progenitor cells from a Cebpα+/−AML mouse model. Cellular competition assays were used to assess changes in proliferative capacity and apoptosis of MLL−/−AML cells. Further, MLL−/−AML activity was inhibited by the small molecules that block the Menin-MLL interaction. In both cases, proliferative, myeloid differentiation, and apoptosis were used as readouts. Global changes in gene expression were measured by RNA-seq.

**Results:** We initially confirmed, via ChIP, that C/EBPα and MLL co-localize on the p30 isoform and the MLL (xenotransgenic) promoter, indicating functional cooperativity in gene regulation. To investigate the importance of different, annotated functional domains within the MLL protein in the context of C/EBPα p30 expression, we introduced targeted mutations across the MLL gene in Cebpα+/−AML cells using the CRISPR/Cas9 system. This analysis revealed a strong dependence of Cebpα+/−AML on the expression of an intact MLL protein. Surprisingly, loss of the enzymatic activity of MLL by mutagenic targeting of the SET domain did not significantly affect cell survival. In contrast, cells were particularly sensitive to mutagenesis of the Menin-binding motif in MLL. MLL targeting strongly induced myeloid differentiation in Cebpα+/−AML cells as measured by increased levels of CD11b and CD11c markers. To identify potential functional targets, we performed upon pharmacological perturbation of the MLL/SET complex, we used miR-463, a potent small-molecule inhibitor of the Menin-MLL interaction. Inhibitor treatment led to a time- and dose-dependent impairment of proliferation, induction of cell cycle arrest and increased apoptosis in Cebpα+/−AML cells. RNA-seq analysis of Cebpα+/−AML cells after treatment indicated dysregulation of gene expression associated with myeloid differentiation, which could be confirmed by flow cytometry. Importantly, expression of C/EBPα p30 was associated with hypersensitivity to Menin-MLL inhibition, as Cebpα+/−AML cells were 2.6-fold more sensitive than other leukemia cell lines of mouse and human origin.

**Summary/Conclusions:** We found that inhibition of C/EBPα p30 by CRISPR/Cas9-mediated mutagenesis results in clinical and metabolic improvements in vivo. In conclusion, targeting PU.1 provides a promising strategy for the treatment of acute myeloid leukemia.

**FUNCTIONAL AND TRANSCRIPTOMIC IMPACT OF INHIBITING THE MYELOID MASTER REGULATOR PU.1 AS A THERAPEUTIC STRATEGY IN ACUTE MYELOID LEUKEMIA**

**Aims:** We hypothesized that the interaction between the oncogenic C/EBPα and PU.1, which is a major transcriptional target of PU.1, is required for PU.1-induced transcriptional changes that contribute to leukemogenesis. Therefore, we aimed to investigate the sensitivity of CEBPα mutant PU.1 to perturbation of PU.1 function.

**Methods:** We used two alternative approaches: RNA interference and newly developed pu.1 reporter assays. We found that inhibition of PU.1 with different shRNAs led to a significant decrease in cell growth and colony forming capacity, increased apoptosis, and disrupted serial replating capacity of PU.1+/−AML cells, and a majority of primary AML cell samples. ChIP and expression analysis showed that the compounds disrupt PU.1-1promoter interaction and lead to downregulation of canonical PU.1 transcriptional targets in AML cells, confirming on-target activity.

**Results:** Our study describes for the first time a strategy inhibiting PU.1 in AML, establishing proof-of-concept for this approach. Furthermore, we report the development of first-in-class PU.1 inhibitors which interfere with PU.1-DNA interaction through an allosteric, minor groove-mediated mechanism. Our work shows that it is feasible to pharmacologically target PU.1, and raises intriguing possibilities for the potential targeting of other transcription factors through minor groove-directed approaches.
FLT3 TK activity may improve the eradication of FLT3mutAML cells. These data predict that a combined inhibition of glutamine metabolism and FLT3 TK activity may improve the eradication of FLT3mutAML cells.

Summary/Conclusions: Our data suggest that upon AC220 treatment, glutamine metabolism becomes a critical metabolic dependency in FLT3mutAML. Glutamine metabolism is mostly channelled towards glutathione production, while also supporting the CAC and both these fates contribute to its protective effects following FLT3 TK inhibition by respectively counteracting oxidative damage and sustaining macromolecule biosynthesis and cellular energetics. These data predict that a combined inhibition of glutamine metabolism and FLT3 TK activity may improve the eradication of FLT3mutAML cells.

STEP-WISE REPROGRAMMING OF ENDOTHELIAL CELLS INTO IMMUNE-COMPETENT HEMATOPOIETIC STEM CELLS
J. G. Barcia Duran1,2, R. Lis2, C. C. Karrasch3, B. Kunar1, S. Rafii3
1Physiology, Biophysics and Systems Biology, Weill Cornell Graduate School of Medical Sciences, 2Medicine, Weill Cornell Medicine, 3Medicine, Weill Cornell Medicine, New York, United States

Background: The molecular pathways and microenvironmental cues that choreograph the conversion of endothelial cells (ECs) into long-term repopulating hematopoietic stem cells (HSCs) remain poorly defined. This is due to lack of models that recreate the ephemeral transition of an endothelial cell to a hemogenic state to the emergence of HSCs.

Aims: To reprogram adult mouse ECs into long-term repopulating HSCs that give rise to all hematopoietic lineages, including functional T cells in vivo. To provide a platform to deconvolute the process by which endothelial-to-hematopoietic transition is possible.

Methods: Here, we have developed a modular in vitro model in which—by precise, conditional expression of transcription factors: FosB, Gfi1, Runx1, and Spi1 (FGRS), and reintroduction of a proper inductive niche—adult mouse ECs were reprogrammed into HSCs (rEC-HSCs) with multi-lineage engraftment potential (rEC-MPPs). Adult, non-lymphatic ECs isolated from various organs of Runx1-IRES-GFP reporter mice were transduced with FGRS and co-cultured in direct contact with vascular niche.

Results: Within 14 days, ECs initiated a hematopoietic program, turning on the endogenous expression of Runx1 and transitioning into hematopoietic cells. Expansion of these cells for another 14 days resulted in generation of rEC-HSCs and rEC-MPPs. Transplantation of rEC-HSCs and rEC-MPPs (CD45.2+) into lethally irradiated mice (CD45.1+) reconstituted both short-term (rEC-MPPs) and long-term hematopoiesis, with secondary engraftment potential (rEC-HSCs). rEC-HSCs gave rise to both functional myeloid and lymphoid cells with full complement of polarized T cell subsets. rEC-HSC-derived T cells undergo T-cell receptor (TCR) rearrangement and restore adaptive immune function in Rag1−/− mice.

Summary/Conclusions: This multi-phasic, step-wise approach provided an interrogable model to decipher pathways involved in EC transition into hematopoietic cells. This will provide cues to devise strategies to convert autologous ECs into large numbers of HSCs for genetic modification and subsequent treatment of both genetic and acquired hematological disorders.

MARROW MESENCHYMAL STEM CELLS RESCUE BONE MARROW ENDOTHELIAL CELLS SUFFERING CHEMOTHERAPY STRESS BY TRANSFERRING MITOCHONDRIA THROUGH NANOTUBES
1Peking University People’s hospital, Institute of Hematology, Beijing, 2Centre of Excellence in Tissue Engineering, Peking Union Medical College hospital, 3Peking University People’s hospital, Institute of Hematology, 4The Third Hospital of Peking University, Cardiovascular Institute, Beijing, 5The Third Hospital of Peking University, Cardiovascular Institute, Beijing, 6The Third Hospital of Peking University, Cardiovascular Institute, Beijing, China

Background: The tunneling nanotube (TNT) is a newly discovered, long and thin tubular structure between cells and can facilitate the intercellular exchange of diverse cellular signals and components ranging from electrical signalling to organelles. Recent reports show that mesenchymal stem cells (MSC) rescue injured target cell and promote target cell recovery from a variety of stress including oxidative tress, ultraviolet radiation, ischemia/reperfusion (IR) etal. However, it is still unclear if bone marrow mesenchymal stem cells (BMSCs) can also form TNT to communicate and rescue injured bone marrow derived endothelial cells (BMdEC) and promote it recovery from chemotherapy stress. In our study, we set out to test the hypothesis that BMSCs can rescue suffering endothelial cells by transferring mitochondria to endothelial cells through nanotubes.

Aims: To investigate the novel intercellular communication pathway between BMSC and BMdECs or HUVEC, illuminating its constituent and investigating the significance of transport of mitochondrial through TNT between BMSC and BMdECs or HUVEC suffering from chemotherapy stress of cytosine arabinoside.

Methods: We established two direct co-culture system for human primary bone marrow mesenchymal stem cells (BMSCs) and bone marrow derived endothelial cells (BMdECs) respectively.

Results: Firstly, We observed the TNTs formed between BMSCs and endothelial cells including the TNT structure between BMSCs and HUVECs or BMdECs are composed with F-actin, microtubule in addition to membrane. Live cell imaging showed the two xenogeneic cells form TNTs by retaining a thin thread of membrane upon dislodge.
ment. Besides, we observed that TNT formation may alter bone marrow microvascular stem cell and endothelial cell cytoskeleton (Ara-C) treatment. Single-cell analysis showed that stressed endothelial cells and cell lines in the early stages of apoptosis caused by cytarabine (Ara-C) treatment form TNT to interact with untreated BM/MSCs and then mesenchymal stem cells transport mitochondria to injured endothelial cell or cell line in vitro. The TNT formation was inhibited by incubating with an F-actin-depolymerizing drug and tubulin-depolymerizing drug, indicated that these TNTs transferring mitochondria have a distinct cytoskeletal composition which composed with F-actin and microtubule.

Our results also suggest that the delivery of functional mitochondria from endothelial cells to BM/MSCs can mediate the recovery of injured BMUVECs from the apoptosis, contribute to proliferation and remodel the formation of capillary-like structures in Matrigel-coated plates of HUVECs suffer from chemotherapy stress of Ara-C.

Summary/Conclusions: BM/MSCs can transfer mitochondria via TNTs formed between BMUVECs and rescued endothelial cells under stress, which can alleviate apoptosis of stressed endothelial cells, relieve its proliferation inhibition and alter its formation of capillary-like structures. Our study offers the clues to help know about cell-cell communication of niche components in the HSC niche in bone marrow.

S139 SHORT-TERM FEEDING OF A HIGH-FAT DIET DISTURBS LIPID RAFT/TGF-BETA SIGNALING-MEDIATED QUIESCENCE OF HEMATOPOIETIC STEM CELLS IN C57BL/6J MOUSE BONE MARROW F. Hermetet1,2, 2. J.-P. Pais de Barros2,3, 2. L. Delva1,2, 2. R. Quéré1,2 1Signaling and Physiology in Hematological Research, UMR1231 Inserm / Université Franche-Comté / AgroSup, Dijon, France 2Institute of Immunohematology, INSERM/CEA/Universite Paris 7/Universite Paris 11, 7UMR1163, Paris Descartes–Sorbonne Paris Cité University, Imagine Institute, , Paris, France Background: Some studies show that a high-fat diet (HFD) induces major perturbations in murine hematopoietic stem cells (HSC) and hematopoietic system homeostasis. However, it is currently difficult to say whether these alterations are related to direct effects such as changes in lipid metabolism in HSC or indirect “side effects” on HSC, such as pathophysiology related to obesity or inflammation observed after an extended diet over several months or a diet very rich in fat (>60 kJ% of fat). For example, HFD-induced obesity significantly alters hematopoiesis in bone marrow (BM), with a decreased proliferation of HSC, a general suppression of progenitors, an enhancement of lymphopoiesis, and an activation of myeloid cell production from BM progenitors. Infarction also affects HSC homeostasis, as interferon alpha is well-known to activate dormant HSC in vivo.

Aims: Our strategy is to characterize the impact of a short-term HFD on HSC and hematopoiesis in non-obese C57BL/6J mice.

Methods: In a prospective study, C57BL/6J mice were fed a control diet (4% fat) or an HFD (62% fat), over a short period of 4 weeks, to investigate the direct impact of such a diet on hematopoiesis.

Results: While fat intake led to an increase in plasma cholesterol levels, mice did not develop obesity, and no inflammatory monocytes and no modulation of pro- and anti-inflammatory cytokine levels were detected in blood and BM, respectively. The impact was observed after an extended diet over several months or a diet very rich in fat (>60 kJ% of fat). For example, HFD-induced obesity significantly alters hematopoiesis in bone marrow (BM), with a decreased proliferation of HSC, a general suppression of progenitors, an enhancement of lymphopoiesis, and an activation of myeloid cell production from BM progenitors. Inflammation also affects HSC homeostasis, as interferon alpha is well-known to activate dormant HSC in vivo.

Summary/Conclusions: Our strategy is to characterize the impact of a short-term HFD on HSC and hematopoiesis in non-obese C57BL/6J mice.

**WILMS’ TUMOR 1 RNA-ELECTROPORATED DENDRITIC CELL VACCINATION AS POST-REMISSION TREATMENT TO PREVENT OR DELAY REPOPULATION IN ACUTE MYELOID LEUKEMIA: FINAL RESULTS OF A PHASE II STUDY IN 30 PATIENTS**

Z. Berneman1, S. Anguille1, A. Van de Velde1, V. Van Tendeloo1, N. Cools1, G. Nijs1, B. Stein1, E. Lion2, A. Van Driessche3, I. Vandobben3, A. Verlinden4, A. Gaddsieur5, W. Schroyens1, K. Vermeulen5, M.-B. Maes5, K. Deiteren5, R. Malfait6, E. Smits3

1Hematology, 2Laboratory Hematology, 3Center for Cell Therapy and Regenerative Medicine, ANTWERP UNIVERSITY HOSPITAL, Edegem, Belgium

**Background:** Relapse is a major problem in acute myeloid leukemia (AML) and adversely impacts survival.

**Aims:** The aim of this phase II study was to determine the clinical efficacy of dendritic cell (DC) vaccine therapy in AML, and, more specifically, whether this form of immunotherapy can be applied in the post-remission adjuvant setting to decrease the risk of relapse following chemotherapy and to improve survival.

**Methods:** We vaccinated 30 AML patients in remission following polychemotherapy, but at very high risk of relapse with autologous DCs loaded with the peptide-encoding Wt1 (WT1) antigen by means of mRNA electroporation, a technique that allows for human leukocyte antigen haplotype-independent, multi-epitope antigen presentation to T-cells. The vaccines were administered intradermally. WT1 mRNA levels in blood and marrow were followed as a measure of minimal residual disease. Circulating WT1-specific CD8+T-cells obtained following the 4th dose of vaccination were stained with a tetrameric HLA-A*0201 WT1 peptide-HLA-A*0201 tetramers. To assess cell-mediated immunity in vivo, delayed-type hypersensitivity (DTH) skin testing was performed 2 weeks after the 4th DC vaccination by intradermal injection; DTH-infiltrating lymphocytes collected from skin biopsies were expanded for 2-3 weeks in medium with interleukin-2, human IL-7, and IL-15 for WT1 specificity and reactivity.

**Results:** There was a demonstrable anti-leukemic response in 13/30 patients (overall response rate 43%). Nine patients achieved molecular remission as demonstrated by normalization of WT1 transcript levels, 5 of which are sustained after a median follow-up of 109.4 months, including 1 patient who went from complete remission by DC vaccination only. In the remaining 4 responding patients, the clinical response was characterized by stable disease as demonstrated by elevated but stable WT1 transcript levels in blood for 3-12 months and stable blood values without blasts. Five-year overall survival was 40%, as compared to 24.7% in the SEER data of the National Cancer Institute; it was significantly higher in responders than in non-responders (53.8% vs 25.0%; P<0.001). In patients receiving DCs in first complete remission (CR1), there was a vaccine-induced relapse reduction rate of 25% and the 5-year relapse-free survival was significantly higher in responders than in non-responders (50% vs 7.7%; P=0.0001). In patients ≤65 and >65 years who received DCs in CR1, 5-year overall survival was 69.2% and 30.8% respectively. Of the 30 patients, 11 are alive in CR, including 5 who relapsed after DC vaccination; 2 proceeded to allogeneic stem cell transplantation, while the 3 other patients were brought back into CR by chemotherapy alone, 2 of them surviving more than 7 and 4 years respectively after achieving CR. Long-term clinical response was correlated with increased circulating frequencies of poly-epitope WT1-specific tetramer+CD8+T-cells. Long-term overall survival was correlated with interferon-γ and tumor necrosis factor-α WT1-specific responses in DTH-infiltrating CD8+T-lymphocytes.

**Summary/Conclusions:** Vaccination of AML patients with WT1 mRNA-electroporated DCs can be an effective and non-toxic strategy to prevent or delay leukemia relapse after standard chemotherapy, translating into improved overall survival rates, which are correlated with the induction of WT1-specific CD8+T-cell responses.

**FIRST-IN-HUMAN MULTICENTER STUDY OF BB2121 ANTI-BCMA CAR T CELL THERAPY FOR RELAPSED/REFRACTORY MULTIPLE MYELOMA: UPDATING RESULTS**

1Mayo Clinic, Rochester, MN, 2Sarah Cannon Research Institute and Tennessene Oncology, Nashville, TN, 3Massachusetts General Hospital Cancer Center, 4Dana Farber Cancer Institute, Boston, MA, 5Hackensack University Medical Center, Hackensack, NJ, 6Stanford University Medical Center, Palo Alto, CA, 7Mount Sinai Medical Center, New York, NY, 8Bluebird bio, Inc., Cambridge, MA, 9Celgene, San Francisco, CA, 10National Cancer Institute/NIH, Bethesda, MD, United States

**Background:** To test the safety and efficacy of the CAR T cell modality in relapsed/refractory multiple myeloma (MM), we have designed a second-generation CAR construct targeting B cell maturation antigen (BCMA) to redirect T cells to MM. bb2121 consists of autologous T cells transduced with a lentiviral vector encoding a novel CAR incorporating an anti-BCMA scFv, a 4-1BB costimulatory motif and a CD95-zeta T cell activation domain. We will report updated safety and efficacy results following promising initial results (Berdeja et al. ENA 2016).

**Aims:** The primary objective is to determine the maximally tolerated dose of bb2121 in subjects with MM whose tumors express BCMA, to determine and test a recommended phase 2 dose for future studies. The secondary objective is to provide preliminary efficacy data on the anti-tumor effects of treatment with bb2121 in subjects with MM whose tumors express BCMA.

**Methods:** CRB-401 (NCT02659892) is a multi-center phase 1 dose escalation trial of bb2121 in patients with relapsed and/or refractory MM who have received ≥3 prior regimens, including a proteasome inhibitor and an immunomodulatory agent. The primary endpoint is to determine if ≥50% BCMA-expressing plasma cells. Peripheral blood mononuclear cells are collected via leukapheresis. Patients undergo lymphodepletion with Flu (30 mg/m²) Cy (300 mg/m²) daily for 3 days then receive an infusion of bb2121. The study follows a standard 3+3 design with planned dose levels of 5.0, 15.0, 45.0, 80.0 and 120 x 10⁷CAR+T cells.

**Results:** As of November 18, 2016, 11 patients had been infused with bb2121 in the first 4 dose cohorts, and 9 patients had reached at least 1 month of follow-up. As of data cut-off, no dose limiting toxicities, and no >Grade 2 neurotoxicities or cytokine release syndrome (CRS) had been observed. Grade 1-2 CRS has been reported in 8/11 (73%) treated patients. All patients treated with doses >5.0 x 10⁷ CAR+T cells (≥45.0 x 10⁷) have had grade 3-4 CRS. High dose 45.0 x 10⁷ CAR+T cells in 1 patient led to grade 5 neurotoxicity and adverse impact survival.

**Summary/Conclusions:** bb2121 demonstrates promising results levels above 5.0 x 10⁷ CAR+T cells, including 2 sCRs and ongoing clinical responses at 6 months with mild and manageable CRS to date. These initial data support the potential of CAR T therapy with bb2121 as a new treatment paradigm in MM.

Background: Fanconi anemia (FA), is a monogenic inherited syndrome associated with bone marrow failure (BMF), that has been considered a candidate disorder for hematopoietic stem cell (HSC) gene therapy. Up to date, three clinical trials have been performed, all of which did not achieve engraftment of corrected HSCs. Aims: To demonstrate engraftment of gene-corrected HSCs in non-conditioned Fanconi anemia patients. Methods: To improve previous results, we proposed a new approach based on two clinical trials. First, to increase the HSC collection, we designed a trial employing a plerixafor plus G-CSF mobilization regimen. Second, to improve the quality of corrected HSCs, cells were pre-stimulated for only 8-10 hours and transduced with a new lentiviral vector (PGK-FANCA.Wpre*) for 12-14h, a substantially shorter duration than in previous trials. To avoid chemotherapy-induced damage, a conditioning regimen was not included in the trial, based on the expected proliferative advantage of autologous corrected HSCs. Results: Eight patients have been included so far in the HSC collection trial. No severe adverse events (SAE) related to the procedure have been reported. The most relevant AE has been the infusion of packed red blood cells and platelets. Six FA patients aged 3-6 years underwent collections after mobilization of significant numbers of CD34+ cells to peripheral blood. Two patients (15 and 16 years) failed to mobilize. On average, 5 million CD34+cells/Kg were collected, with 45% recovery after immunoselection. In the first patient included in the gene therapy trial, fresh immunoselected CD34+cells were transduced with the therapeutic vector. Subsequently, two patients were infused with transduced CD34+cells that remained cryopreserved for almost 2 years. Infused cell products contained 0.5 to 1.4 million CD34+cells/kg, and vector copy numbers per cell (VCN/cell) that ranged between 0.17 to 0.45. To-date, there has been no SAE related to the procedure. Engraftment of gene corrected cells has been observed in the three patients. Notably, increased gene marking levels and significant phenotypic correction in the hematopoietic progenitor cells, deduced from the acquired resistance of the colony forming cells to mitomycin C (15% of BM CFCs survived to 10 nM MMC), have been demonstrated after 9 months of follow up in one of the patients. Summary/Conclusions: Our preliminary results show that 1) HSCs collection is both safe and effective in very young FA patients after mobilization with G-CSF and plerixafor, and 2) Engraftment and proliferation advantage of gene-corrected HSPCs has been demonstrated in FA patients even in the absence of conditioning regimens. The long-term follow up of patients included in these clinical trials will demonstrate the feasibility of restoring the hematopoietic function of FA patients by means of a gene therapy approach in the absence of conditioning.

TARGETING FLT3 WITH CHIMERIC ANTIGEN RECEPTOR T CELLS CONFRS POTENT REACTIVITY AGAINST ACUTE MYELOID LEUKEMIA

H. Jetani1,*, I. Garcia-Cadenas2, T. Nerreter1, J. Sierra2, W. Herr3, S. Thomas3, H. Einsele1, M. Hudecek1

1Internal Medicine II, University Hospital Würzburg, Würzburg, Germany, 2Servicio de Hematología, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, 3Klinik und Poliklinik für Innere Medizin III, Universitätssklinikum Regensburg, Regensburg, Germany

Background: Adoptive immunotherapy with chimeric antigen receptor (CAR)-modified T cells has therapeutic potential in hematologic malignancies. We are pursuing FLT3 signaling via tyrosine kinase 3 (FLT3) as a novel CAR target in acute myeloid leukemia (AML). FLT3 is a homodimeric transmembrane protein with uniform expression on AML, irrespective of cytogenetic and histomorphologic subtype. FLT3 provides survival signals to AML blasts and is a key driver of leukemia-genesis in AML cases with internal tandem duplication (FLT3-ITD). These attributes suggest FLT3 may be an ‘Achilles heel’, making AML blasts susceptible to CAR T-cell mediated recognition and elimination. Aims: We therefore explored the anti-leukemia efficacy of FLT3-CAR modified T cells against FLT3-ITD+ and FLT3 wild type AML in pre-clinical models in vitro and in vivo. Methods: A FLT3-CAR comprising a single-chain variable fragment (4G8), fused to an IgG-Fc spacer, and signaling module with CD3 zeta and CD28 was encoded in a lentiviral vector (epHIV7) for gene-transfer into CD8+ and CD4+ T cells of healthy donors (n=4) and AML patients. CAR T-cell mediated cytolytic activity was evaluated in FACS-fluorescence-based assays, cytokine production analyzed by ELISA and proliferation assessed by CFSE dye dilution. Immunodeficient NSG mice were engrafted with AML cell line (Molm-13) or primary AML blasts and treated with 5x10^6 CAR-modified or control T cells (CD8:CD4 ratio=1:1).

Results: We confirmed specific recognition and high-level cytolytic activity of CD8+FLT3-CAR T cells against a panel of AML cell lines including THP-1 (FLT3 wild type), and Molm-13 (FLT3-ITD heterozygous). Both CD8+ and CD4+ FLT3-CAR T cells produced IFN-γ and IL-2, and underwent proliferation after antigen stimulation. FLT3-CAR T cells that we prepared from AML patients exerted specific anti-leukemia reactivity against autologous primary AML blasts, with near-complete cytolysis within 24 hours of co-culture. Further, FLT3-CAR T cells conferred a potent anti-leukemia effect in vivo models of systemic leukemia, both with AML cell lines (Molm-13) and primary AML blasts. A single dose of FLT3-CAR T cells conferred complete eradication of leukemia from peripheral blood, bone marrow and spleen, as confirmed by bioluminescence imaging and flow cytometry. FLT3 is not expressed in any normal solid tissues and mature hematopoietic cells, but shows limited expression in hematopoietic progenitors and hematopoietic stem cells (HSCs). Preliminary data show that FLT3-CAR T cells recognize FLT3+ high normal HSCs and interfere with normal hematopoiesis, but preserve a proportion of HSCs capable of reconstituting hematopoietic lineages. Studies to assess recognition of normal HSCs in vivo are ongoing.

Summary/Conclusions: Collectively, our data demonstrate that T cells expressing a FLT3-specific CAR mediate potent reactivity against FLT3 wild type and FLT3-ITD+A MLL in vitro and in vivo, and establish FLT3 as a novel CAR target in AML. FLT3-ITD positivity identifies a high-risk AML subgroup that may particularly benefit from adoptive therapy with FLT3-CAR T cells, e.g. in order to achieve ‘minimal residual disease’ (MRD) negativity prior to allogeneic HSC transplantation. Our data further suggest that in contrast to CD33 and CD123, which are pursued as alternative CAR targets in AML, targeting of FLT3 may preserve a fraction of normal HSC and enable the implementation of CAR therapy outside the transplant setting.
**Background:** Allogeneic haploidentical hematopoietic stem cell transplant (HSCT) offers curative therapy for children who lack a matched HLA-identical donor with hematopoietic disorders such as Primary Immune Disorders (PID), hemoglobinopathies, erythroid disorders and acute leukemias. T-cell depletion mitigates the risk of GVHD after haplo-HSCT, but is associated with extended immunodeficiency, leading to complications due to infections. We have performed TCR-depleted haplo-HSCT with post-transplant infusion of BPX-501 gene modified T-cells to allow for more rapid immune reconstitution. Upon occurrence of GVHD, administration of rimiducid (AP1903) dimerizes the Cas9 suicide switch and rapidly induces apoptosis of the transduced BPX-501 cells and mitigates the GVHD.

**Aims:** This study was performed to determine the impact of BPX-501 T-cell infusion on outcomes (treatment related mortality (TRM), disease recurrence, GVHD incidence and immune reconstitution) after HSCT.

**Methods:** We report on a large multicenter, prospective Phase I-II study enrolling children receiving T-cell depleted Haplo-HSCT. Patients were infused with BPX-501 T-cells 2 weeks post-transplant. 104 patients have >100 day follow-up, 81 patients have follow up >180 days and 51 with >1 year follow-up. All patients received myeloablative therapy and low dose ATG prior to transplant. No pharmacologic GVHD prophylaxis was given (Table 1).

**Table 1. Diagnoses of Patients with >100 day follow-up.**

**Results:** Cumulative incidence of TRM remains very low at 100 days (0%), 180 days (1.6%) and 1 year (2.8%). Of the 81 patients with >180 day follow-up, 20 patients had acute GVHD 1-3 (24.7%) (Figure 1A); 10 with Grade 1, 8 with Grade 2, Grade 3 and Grade 4 skin. Mild cGVHD was seen in 2 patients, moderate cGVHD in 2 patients and one case of severe cGVHD in a malignant patient, attributed to the allotgift, not BPX-501. Rimiducid was used in 4 patients with Grade 2 GVHD with rapid resolution of symptoms, as it did in the severe cGVHD patient. In both malignant and non-malignant patients. CD3, CD4, CD8 (Figure 2B) and B-cells (Figure 3C) immune reconstitution was brisk. CD3+/CD19+ T-cells were detectable at one year via flow cytometry analysis of peripheral blood. In Wiskott-Aldrich patients, platelet recovery remains in the normal range at 180 days with mean platelet counts of 246.3±10^3/uL. At 180 days and 1 year, the patients with hemoglobinopathies remain transfusion-free with a normal mean Hgb value of 11.4 g/dL.

**Summary/Conclusions:** These data suggest that infusion of BPX-501 modified T-cells may facilitate T-cell depleted Haplo-HSCT in children who would benefit from HSCT for either malignant or non-malignant conditions. The availability of a suicide gene mechanism in donor T-cells infused after T-depleted Haplo-HSCT, results in low rates of infection and rapidly reversible GVHD when the dimer is infused to activate the suicide switch. Rapid cellular and humoral immune reconstitution makes BPX-501 after T depletion a safe and viable option for children who do not have a matched donor transplant and in whom transplantation has been deemed curative.

**Background:** Extensive human genetic and epidemiological data demonstrate that the genetic condition Hereditary Persistence of Fetal Hemoglobin (HPFH) substantially ameliorates the pathology of Sickle Cell Disease (SCD) and β-thalassemia (β-Thal). This condition is associated with several genetic variants at the β-globin locus that lead to transcriptional reactivation of γ-globin genes, resulting in upregulation of fetal hemoglobin (HbF).

**Aims:** Using CRISPR/Cas9 gene editing, we have successfully re-created genetic variants linked to high HbF levels in HSPCs from healthy donors and SCD and β-Thal patient samples, and determined the relationship of different genetic variants to upregulation of γ-globin in bulk and clonal populations of differentiated erythrocytes. Off-target editing was assessed, and on-target editing in long-term repopulating subsets of HSPCs was measured in vitro and by engraftment in immunocompromised mice. Finally, editing rates at clinical scale in a GMP-capable manufacturing facility were demonstrated.

**Methods:** We first optimized cell culture and electroporation conditions that led to high rates of genomic editing across multiple loci, achieving 84.9±6.2% (Mean±SD) editing efficiency at key regions of interest in CD34+ human primary CD34+ hematopoietic stem and progenitor cells (HSPCs) to re-create specific HPFH genetic variants as well as other variants associated with elevated HbF and demonstrate their causal relationship to elevated HbF as a potential therapeutic strategy in SCD and β-Thal.

**Summary/Conclusions:** CRISPR/Cas9 is a revolutionary technology that allows for precise, directed changes to genomic DNA. Our strategy is to use CRISPR/Cas9 in human primary CD34+ hematopoietic stem and progenitor cells (HSPCs) to re-create specific HPFH genetic variants as well as other variants associated with elevated HbF and demonstrate their causal relationship to elevated HbF as a potential therapeutic strategy in SCD and β-Thal.

**Background:** The genetic condition Hereditary Persistence of Fetal Hemoglobin (HPFH) substantially ameliorates the pathology of Sickle Cell Disease (SCD) and β-thalassemia (β-Thal). This condition is associated with several genetic variants at the β-globin locus that lead to transcriptional reactivation of γ-globin genes, resulting in upregulation of fetal hemoglobin (HbF).

**Aims:** Using CRISPR/Cas9 gene editing, we have successfully re-created genetic variants linked to high HbF levels in HSPCs from healthy donors and SCD and β-Thal patient samples, and determined the relationship of different genetic variants to upregulation of γ-globin in bulk and clonal populations of differentiated erythrocytes. Off-target editing was assessed, and on-target editing in long-term repopulating subsets of HSPCs was measured in vitro and by engraftment in immunocompromised mice. Finally, editing rates at clinical scale in a GMP-capable manufacturing facility were demonstrated.

**Results:** We first optimized cell culture and electroporation conditions that led to high rates of genomic editing across multiple loci, achieving 84.9±6.2% (Mean±SD) editing efficiency at key regions of interest in CD34+ HSPCs from mobilized peripheral blood of healthy donors (n=16). Similar rates of editing were attained using CRISPR/Cas9 derived from healthy-donor bone marrow (n=6). Cas9 delivery as recombinant protein improved cell viability when compared to mRNA-based delivery (88.8±3.7% compared to 75.5±3.3%, Mean±SD, n=56 for each) with no observed reduction in editing efficiencies. To investigate gene editing impact on HbF, edited cells were erythroid differentiated from healthy donors as well as SCD and β-Thal patient samples. Specific gene edits significantly increased γ-globin mRNA expression to therapeutically-relevant levels (increased expression to 29-37% as a ratio of γ/β in one β-Thal patient sample and to 25-45% as a ratio of γ/(γ+β) in six SCD patient samples). We demonstrated similarly high rates of editing in the CD34+CD19+CD45RA− long-term repopulating HSPCs and bulk CD34+ HSPCs (87.9±6.4% compared to 89.7±5.9%, Mean±SD, n=4) at 2 weeks. We confirmed that editing levels of edited cells in immunocompromised mice were similar to control cells (% human CD45 in peripheral blood = 28.6±6.9% in controls versus 27.1±6.6% and 26.3±7.9% for two guide targets, Mean±SD, n=48 for each) In-depth off-target analysis.
for a selected guide RNA confirmed no detectable genomic cleavage at over 50% of predicted off-target sites with a detection sensitivity of 0.2%, supporting its safety for clinical use. Finally, we have demonstrated editing rates of >85% at clinical scale in a GMP-capable manufacturing facility to enable clinical development for SCD and β-Thal. Required safety toxicology studies are ongoing.

Summary/Conclusions: Using CRISPR/Cas9 we successfully created gene deletions in both hematopoietic and non-hematopoietic compartments. We have also dissected the genotype-phenotype relationship for specific genetic modifications, identifying the editing strategies which are most promising for expressing HSF. We have optimized the conditions for modifying HSPCs, including at clinical scale in a GMP-compliant setting, and demonstrated potential for off-target editing. These experiments support the further development of specific CRISPR/Cas9 editing strategies of HSPCs to treat SCD and β-Thal patients.

EXPOSURE TO INFECTION TRIGGERS PAX5 AND ETV6-RUNX1 CHILDHOOD BCP-ALL

A. García-Ramírez1, F. Auer2, G. Rodriguez Hernández2, S. Bhatia3, I. García-Ramírez1, D. Schäfer2, C. Vicente-Dueñas4, A. Borkhardt5, I. Sánchez-García1, J. Hauer4. 1Experimental Therapeutics and Translational Oncology Program, Instituto de Biología Molecular y Celular del Cáncer, CSIC/ Universidad de Salamanca and Institute of Biomedical Research of Salamanca (IBSAL), Salamanca, Spain, 2Department of Pediatric Oncology, Hematology and Clinical Immunology, Heinrich Heine University, Duesseldorf, Germany, 3University Medical Center, Amsterdam, Netherlands, 4Department of Heme- oncology, University Hospital Kralovske Vinohrady, Prag, Czech Republic, 5Department of Pediatrics, University Medical Center of Hamburg-Eppendorf, Hamburg, Germany.

Background: B-cell precursor acute lymphoblastic leukemia (BCP-ALL) of childhood remains a major cause of death in high-income countries. It has a yet unexplained peak incidence between 2-6 years of age and a potential trigger was theorized a century ago with several possibilities of exposure to infection in infancy. Recently in vitro and in vivo evidence strengthened the causal role of exposure to infection in BCP-ALL (1, 2). However, it remains unknown which mechanisms allow BCP-ALL sublines can be triggered by infection and how the pre-leukemic clone evolves to BCP-ALL.

Aims: Aiming to understand the role of infection exposure in the etiology of childhood BCP-ALL.

Methods: We have developed and characterized two independent GEMMs, in addition to the Pax5+/−-infected model (1), which were exposed to a common infection environment. These represent childhood BCR-ABL-1p190 BCP-ALL and the most common subtype ETV6-RUNX1 BCP-ALL. Both model systems ensure Scg11-directed expression of BCR-ABL1p190 or ETV6-RUNX1 in HSCs and in ETV6-RUNX1 mice develop BCP-ALL at a low penetrance (10.75%; 10 out of 93) with a CD19+B220+IgM-cell surface phenotype and manifested with blast cells in the peripheral blood (PB) and clonal immature BCR rearrangement. Whole exome (WES) and whole genome sequencing (WGS) was performed of murine BCP-ALL on a HiSeq 2500 (Illumina) platform.

Results: Pax5+/− and Scg1-ETV6-RUNX1 mice develop BCP-ALL only after exposure to infections whereas the Ptx5+/− mice develop BCP-ALL independent of exposure to common infection. The molecular mechanism leading to BCP-ALL identified in the infection dependent GEMMs is determined by the genetic predisposition (Pax5+/− or ETV6-RUNX1). Pax5+/− mice acquire constitutive activating Jak3 mutations (6/9) in a susceptible B-cell precursor population (extraocular mature B cells (1)). On the other hand, Scg1-ETV6-RUNX1 mice develop BCP-ALL at a low penetration (10.75%; 10 out of 93) with a CD19+B220+IgM-cell surface phenotype and manifested with blasts cells in the peripheral blood (PB) and clonal immature BCR rearrangement. High expression of Recombination Activating Gene 1 (Rag1) and loss of function mutations in ETV6 were identified in murine BCP-ALL and are well known in the context of human ETV6-RUNX1 leukemia. Additionally we identified a high proportion of mutations in genes implicated in histone modification, i.e. Kdm5c (no. 408) causing a premature stop. CRISPR-Cas9 knock down studies of KDM5C in a precursor B-cell line revealed facilitated Rag1/2 binding to the open gene complex ((H3K4me3) as a potential molecular mechanism. Rag1 off target activity in pre-leukemic ETV6-RUNX1 HSCs/PC after exposure to infection. In contrast to Pax5+/− and Scg1-ETV6-RUNX1 mice, Sca1-BCR-ABL-1p190 mice develop BCP-ALL independent of exposure to common pathogens by reprogramming of a HSC/PC and subsequent loss of Pax5. Summary/Conclusions: In summary, exposure to common pathogens can trigger childhood BCP-ALL based on Pax5 loss of function or exposure to the common ETV6-RUNX1 rearrangement. However the underlying molecular mechanism (Jak-Stat signaling in Pax5+/− mice and histone modification in ETV6-RUNX1 mice) triggered by exposure to common infection is determined by the genetic predisposition and hand BCP-ALL sublines emerge on the basis of a potent oncogene (such as BCR-ABL1p190) can develop independent of exposure to infection. These findings are important for encouraging the prospect of novel interventions that might help to prevent or treat a significant proportion of childhood BCP-ALLs.

References
Background: The German Hodgkin Study Group (GHSG) applies the intensive eBEACOPP regimen (dose-escalated bleomycin, etoposide, doxorubicin, cyclophosphamide, vincristine, procarbazine, and prednisone) to all newly diagnosed advanced-stage HL patients regardless of their individual risk-profile. However, some patients might not be in need of such an intensive treatment to achieve cure. Unfortunately, baseline risk factors as defined in the international prognostic score cannot identify these patients reliably. Recent clinical research suggests that early metabolic response assessment after 2 cycles of therapy using FDG-PET (PET-2) can better predict the individual outcome. In particular, a rapid response as determined by PET-2 negativity might allow reducing the overall treatment intensity.

Aims: To assess the feasibility of decreasing the number of eBEACOPP cycles in patients with negative PET-2 without loss of efficacy as determined by progression-free survival (PFS).

Methods: Between 05/2008 and 07/2014, we recruited patients with newly diagnosed, advanced-stage HL aged 18–60 years. All patients gave written consent before study entry. PET-2 was centrally assessed with FDG uptake not higher than the mediastinal blood pool defined as negative. Patients with negative PET-2 were randomly assigned to receive 6 or 2 additional cycles (i.e., 8 or 4 cycles of eBEACOPP in total, respectively). PET-positive residues after chemotherapy were irradiated. Based on the results of our previous HD15 trial, the protocol was amended in June 2011 and the standard therapy was reduced from 8 to 6 cycles of eBEACOPP in total. The trial was designed to exclude inferiority of 6% or more of the experimental treatment (4 cycles of eBEACOPP) compared with the pooled standard treatment (8 or 6x cycles of eBEACOPP) at 5 years.

Results: We enrolled 2,101 patients. 1,005 patients with negative PET-2 were randomly assigned to either 8/6 cycles of eBEACOPP (n=504) or 4 cycles of eBEACOPP (n=501). With a median follow-up of 55 months, estimated 5-year PFS in the per-protocol set was 90.8% (87.9–93.7) with 8/6 cycles of eBEACOPP and 92.2% (89.4–95.0) with 4 cycles eBEACOPP (difference +1.4%, 95% CI -2.7–5.4, excluding the non-inferiority margin of -6%). In the standard arm, 95% of patients had at least one acute hematological toxicity of CTCAE grade 3-4 compared with 90% in the experimental arm, including severe infections in 75 (15%) and 38 (8%), respectively. Acute severe organ toxicities were documented for 91 (18%) and 38 (8%), respectively. 25 patients (5%) in the standard group (8/6 cycles of eBEACOPP) and 9 (2%) in the experimental group (4 cycles of eBEACOPP) died; most frequent cause of death was second malignancy (11 and 1 patient, respectively). No patient in the experimental group died from treatment-related toxicities. Estimated 5-year overall survival (OS) in the per-protocol set was 95.4% (93.4–97.4) with standard eBEACOPP, and 97.7% (96.2–99.3) with 4 cycles of eBEACOPP (log-rank p=0.004).

Summary/Conclusions: Metabolic response assessment using FDG-PET after 2 cycles of eBEACOPP allows the reduction from therapy with 8/6 to only 4 cycles without loss of efficacy as determined by PFS in advanced-stage HL patients. Furthermore, the abbreviated treatment with 4 cycles of eBEACOPP is associated with improved tolerability and consequently leads to a significant OS benefit over standard therapy. PET-guided reduced therapy with eBEACOPP combines outstanding efficacy with high safety. We therefore recommend this treatment strategy for advanced-stage HL patients.
Acute lymphoblastic leukemia - Biology 1

TARGETED SINGLE CELL SEQUENCING TO IDENTIFY MUTATIONAL HIERARCHY IN T-CELL ACUTE LYMPHOMA LEUKEMIA J. de Bie1, S. Demeyer1, E. Gerders1, A. Uyttebroeck2, N. Boecx3, J. Cools4
1CMC, KU Leuven, 2Pediatric Oncology, 3Laboratory Medicine, UZ Leuven, Leuven, Belgium

Background: Acute lymphoblastic leukemia (ALL) is a common childhood malignancy caused by clonal proliferation of immature B or T lymphoid cells. ALL patients are primarily young children who respond well to chemotherapy, with survival rates above 85%. However, if relapse develops, survival rates drop to 15-50%. Recent studies have shown that at diagnosis, different ALL subtypes exist, each with a distinct mutational landscape that are likely the result of clonal branched evolution. Understanding this clonal evolution and the order at which mutations are acquired can provide improved insights into the origins of leukemia relapse.

Aims: To use single-cell sequencing to investigate (i) the heterogeneity of leukemic T-ALL cells present at diagnosis and (ii) unravel the order in which mutations were acquired during leukemia evolution.

Methods: Bone marrow samples taken at diagnosis and remission from 4 T-ALL patients underwent whole genome and RNA sequencing. Somatic mutations, indels and chromosomal translocations were confirmed using Sanger sequencing. Primers were designed to specifically target these genetic alterations, and included 46 primers against heterozygous SNPs for quality control assessment. A total of 1517 single cells (average of 379 cells per patient), were sorted using flow cytometry or a microfluidic device and analyzed with targeted sequencing. Cells were discarded from further analysis if focus and allelic drop-out exceeded 33.3%. Jaccard hierarchical clustering was applied to identify subclones and a new graph-based algorithm was developed to determine the order of mutation acquisition. Single CD34+CD38- hematopoietic stem/progenitor cells (HSPCs) from the same samples were also isolated to test for the presence of mutations in early progenitors.

Results: We detected between 2 and 4 separate clones in each T-ALL patient sample. Every patient harboured one dominant clone comprising 46 to 98% of all single cells that was highly mutated, accompanied by a number of smaller subclones carrying fewer mutations. No mutually exclusive mutations, fusion genes or deletions were observed between the clones arguing against independent leukemic clonal initiation events. Instead, a more stepwise clonal hierarchy was defined, indicating that the accumulation of mutations can occur in progenitor cells or in committed T-cells. During remission, we could no longer detect HSPCs with all leukemic mutations.

Summary/Conclusions: We demonstrate that T-ALL patients have limited heterogeneity at diagnosis and that targeted single cell sequencing can be used to determine the cell of origin and the order of mutation acquisition. These data also illustrate that HSPCs at remission carry a few early, pre-leukemic mutations or deletions.

BCL2 INHIBITION AS NEW THERAPEUTIC OPPORTUNITY FOR RPL10 R98S MUTANT PEDIATRIC T-ALL
K. Kampfen1, T. Girardi1, J. Verbeek1, J. Op de Beeck1, A. Uyttebroeck2, P. Vermeersch1, A. Moormann4, A. Moormann4, C. Harrison5, J. Meijerink6, E. Gerders1, A. Cools4, K. De Kersaemecker4
1Oncoology, KU Leuven, LKI Leuven Cancer Institute, 2Pediatric Oncology & Hematology, 3Laboratory Medicine, University Hospitals Leuven, Leuven, Belgium, 4Leukaemia Research Cytogenetics Group, Northern Institute for Cancer Research, Newcastle University, Newcastle-upon-Tyne, Ashmore and Cartier Islands, 5Leukaemia Research Cytogenetics Group, Northern Institute for Cancer Research, Newcastle University, Newcastle-upon-Tyne, Ashmore and Cartier Islands, 6Department of Gastroenterology-Hepatology and Metabolic Center, University Hospitals Leuven, Leuven, Belgium

Background: The ribosomal protein L10 (RPL10) R98S mutation occurs in 8% of pediatric T-cell acute lymphoblastic leukemia (T-ALL) cases. RPL10 R98S leads to a proliferation defect in lymphoid cells but its oncogenic contribution in pediatric T-ALL remains unclear. Treatment intensification and risk stratification has reduced the relapse rate of T-ALL to ~15% but further improvements will require strategies that focus on specific subtypes as RPL10 R98S; if the long-term sequelae of toxic therapy are to be avoided.

Aims: 1) Explore the oncogenic contribution of the RPL10 R98S mutation in pediatric T-ALL. 2) Define new therapeutic opportunities for RPL10 R98S defective T-ALL. 3) Identify a biomarker indicative of the RPL10 R98S mutation in T-ALL.

Methods: Quantitative label-free proteomics was used to screen for protein differences between RPL10 WT and R98S expressing Ba/F3 cells. Hits were confirmed by western blotting and functional analyses. RPL10 R98S knock-in mice were generated. Somatic knock-ins were confirmed by sequencing and ribbon PCR. Human pediatric T-ALL samples were transplanted into NOD-SCID/IL2γc (NSG) mice for in vitro and in vivo inhibitor studies.

Results: The RPL10 R98S mutation provided a cell survival advantage in Ba/F3 cells and in serial re-plating assays of lin− BM cells derived from RPL10 R98S knock-in mice. Proteomic profiling revealed metabolic reprogramming in RPL10 R98S cells through enhanced expression of peroxisomal enzymes Acox1, Acox3 and Paox. This expression facilitated peroxisomal β-oxidation of long chain fatty acids which are substrates for PPARγ and which were consequently upregulated together with CPT1A. Peroxisomal hyperactivation causes high intracellular H2O2 levels, explaining the observed elevated levels of reactive oxygen species (ROS) in RPL10 R98S cells that could not be scavenged by the increased catalase expression. High ROS levels and enhanced PPARγ binding drives the constitutive overexpression of anti-apoptotic protein B-cell lymphoma 2 (Bcl-2), responsible for the leukemia cell survival benefit of RPL10 R98S cells. Bcl-2 targeted therapy using venetoclax (ABT-199) reduced the expansion of RPL10 R98S knock-in BM cells by 50%, while RPL10 WT BM cells were not inhibited by ABT-199. In vivo, DMSO or ABT-199 50mg/kg therapy was started after the engraftment of >2% human cells in the blood of mice xenografted with T-ALL samples and was maintained 1/wk till disease end stage. RPL10 R98S xenografted mice that received ABT-199 therapy presented a complete inhibition of human CD45+ leukemia progression in the blood, which was characterized by a 70-85% reduction in spleen weights, and 20-50% reduction of bone marrow engraftment. Spleen weights of ABT-199 treated RPL10 R98S xenografted mice were only slightly increased as compared to regulation weights of healthy NSG mice. In contrast, mice xenografted with RPL10 WT T-ALL samples showed poor in vivo responses to ABT-199 treatment and all animals showed progressive disease.

Summary/Conclusions: Bcl-2 overexpression induced by peroxisomal hyperactivation was defined as new target in RPL10 R98S defective T-ALL. Additionally, due to peroxisomal hyperactivation, a peroxisomal oxidase involved in purine degradation may have contributed to the observed increased levels of uric acid, which was elevated above reference levels in the blood of RPL10 R98S mutant pediatric T-ALL patients at diagnosis (Figure 1).
Summary/Conclusions: Uric acid provides an indicative biomarker of RPL10 R98S mutations in pediatric T-ALL patients, which may be used for screening, providing early diagnosis and appropriate selection of patients in whom a Bcl-2 targeted therapeutic approach could be considered.

P153

TRANSLATE ANALYSIS OF THE T-ALL ASSOCIATED RIBOSOMAL PROTEIN L10 R98S MUTATION REVEALS ALTERED SERINE METABOLISM

L. Fancello1,2, K. Kampen1, T. Girardi1, J. Op de Beeck1, J. Verbeek1, P. Vermeersch2, D. Cassiman3, F. Loayza Puch4, R. Agami3, K. de Keersmaecker3, 1Department of Oncology, KU Leuven - University of Leuven, 2Department of Laboratory Medicine, 3Department of Gastroenterology-Hepatology and Metabolic Center, University Hospitals Leuven, Leuven, Belgium, 4Division of Biological Stress Response, The Netherlands Cancer Institute, Amsterdam, Netherlands

Background: We previously described a recurrent arginine-to-serine mutation on residue 98 (R98S) in ribosomal protein L10 (RPL10), with a frequency of 8.6% in pediatric T-ALL cases. The R98 mutant residue contacts the catalytic core (peptidyltransferase center, PTC) of the ribosome and causes ribosome biogenesis, Ptd RNA, tRNA folding defects on A1 and tRNAs. These observations suggest that the RPL10-R98S mutation may contribute to T-ALL pathogenesis by inducing translational changes.

Aims: The spectrum of translated proteins (translatome) of RPL10 R98S mutants was investigated in order to identify translational changes caused by the mutation and potentially driving oncogenicity.

Methods: We performed ribosome footprinting (RNA sequencing of ribosome bound RNA), polysomal RNA sequencing, total RNA sequencing and mass spectrometry based quantitative proteomics on engineered RPL10-R98S or RPL10 WT mouse lymphoid Ba/F3 cells.

Results: RPL10 R98S cells showed significant upregulation for 3% (n=178) of the measured proteins and a downregulation of 1% (n=68). Moreover, polysize RNA sequencing and ribosome footprinting showed respectively 57 and 22 genes with significantly higher translational efficiency in RPL10 R98S, and 22 and 29 genes with reduced translational efficiency. Among them, we also found genes involved in T cell differentiation and proliferation. In particular, Mapk6 presented reduced translational efficiency in the ribosome footprinting, potentially due to differences in ribosome occupancy of an upstream ORF, whereas the transcription factor Ikrf2, a master regulator of the upregulated transcripts, was overexpressed at the transcriptional and protein level. Interestingly, the results from the mass spectrometry and the polysomal RNA sequencing datasets showed a significant enrichment and upregulation of members of the JAK-STAT signaling pathway with Casf2β/2, Jak1 and several Stats being 1-3-fold elevated at the protein level and higher translation efficiency for Lfng, Il10ra, Cish and Ikrf2. Another interesting candidate showing 5-fold upregulated protein levels was phosphoserine phosphatase (Psp), a key enzyme in serine biosynthesis. Ribosome footprinting revealed that this upregulation originates from a combination of higher transcription and translational efficiency of the encoding gene. Elevated Psp protein levels were confirmed by immunoblotting in the RPL10 R98S Ba/F3 cells and in hematopoietic cell lines derived from RPL10 R98S knock-in mice. Interestingly, harvested medium from RPL10 R98S Ba/F3 cells contained higher residual serine levels versus RPL10 WT mouse lymphoid Ba/F3 cells. Our data suggest that RPL10 R98S expressing cells enhance their endogenous serine production, leaving more serine that can support survival of neighboring cells.

Summary/Conclusions: Analysis of the translational changes associated with the RPL10 R98S mutation reveals alterations for genes involved T cell differentiation and proliferation: the atypical MAP kinase Mapk6, whose reduced translational efficiency still needs to be validated at the protein level, and the transcription factor Ikrf2. Alterations were also found in the JAK-STAT signaling, an established oncogenic cascade in T-ALL. Moreover, this is the first description of a mutation in T-ALL that is linked to alterations in cellular serine biosynthesis.

REPOSITIONING EXISTING DRUGS AS NOVEL THERAPEUTICS: OXIDATIVE STRESS AS A TARGET FOR HIGH-RISK LEUKAEMIA IN T-ALL

M. Haber1,2, M. D. Norris1, R. Sutton1, R. B. Lock1, M. J. Henderson1, 1Children’s Cancer Institute, Lowy Cancer Research Centre, University of New South Wales, 2ACRF Drug Discovery Centre for Childhood Cancer, Children’s Cancer Institute, Lowy Cancer Research Centre, University of New South Wales, Sydney, New South Wales, 3Telephone Kids Institute, University of Western Australia, Perth, Western Australia, Australia

Background: Remarkable improvements made in the treatment of childhood acute lymphoblastic leukaemia (ALL) in past decades have resulted in 5-year survival rates approaching 90%. However, prognosis remains dismal for certain subgroups of high-risk patients, including poor responders to induction therapy, infants with ALL that harbor rearrangement of the Mixed Lineage Leukaemia (MLL/KMT2A) gene, and children with Philadelphia chromosome positive ALL. In particular, infant ALL patients with MLL disease have survival rates below 50% despite the use of intensified treatments, necessitating the development of more effective, less toxic therapeutics for them.

Aims: The aim of this study is to identify candidates that target MLL-rearranged leukaemia cells using drug-repurposing, whereby an approved drug is applied to treat a disease other than the one for which it was originally intended. This drug discovery strategy is gaining popularity as it potentially avoids the lengthy process of drug development and FDA approval.

Methods: 3070 approved drugs and pharmacologically active compounds were initially screened against an infant ALL cell line with MLL-rearrangement, PERR-455 and a paediatric leukaemia cell line wild-type for MLL, CEM, using a resazurin-based cell viability assay. Hit compounds were further tested in a protocol screening of MLL-rearranged ALL cell lines and was later fast-tracked into Phase II clinical trial for adult chronic lymphocytic leukaemia, while Disulfiram, which was developed for treatment of chronic alcoholism, is currently in several clinical trials for cancers including metastatic melanoma and glioblastoma. These drugs also showed potent activity in high-risk paediatric leukaemia PDX cells cultured translation in vitro, including MLL-rearranged ALL and Philadelphia-positive ALL with IC50 values between 100-400 nM for Auranofin and 30-60 nM for Disulfiram. Induction of apoptosis was evident at 6 hours post Auranofin treatment, or after 12 hours Disulfiram treatment. Each drug significantly increased intracellular ROS as early as one hour post-treatment (p<0.01), which was accompanied by induction of Nrf2, a master regulator of the antioxidant response. Incubation with ROS scavenger N-acetyl cysteine prior to treatment with either drug prevented the increase in cellular ROS levels (p<0.05) and rescued cells from apoptosis (p<0.0001), indicating involvement of reduction-oxidation and increased ROS generation as mechanisms of leukaemia cell killing induced by these drugs.

Summary/Conclusions: In summary, we have identified two FDA-approved drugs that demonstrated potent anti-leukaemia activity through induction of ROS, potentially opening up new avenues for clinical treatment of high-risk paediatric ALL. We will now be testing these potential therapeutics in vivo using relevant PDX models of high-risk paediatric ALL.

P155

TP53 MUTATIONS DISRUPTING DNA BINDING LEAD TO CHEMOTHERAPY RESISTANCE IN ACUTE LYMPHOCYTIC LEUKAEMIA

M. Pogodzińska1,2, F. Yang1,2, H. Sun3, J. Hof4, C. Eckert5, B.-B. Zhou6, J. D’Souza7, M. Schwer7,8, 1Pediatric Oncology and Hematology, Charité - Universitätsmedizin Berlin, Berlin, Germany, 2College of Life Sciences, Beijing Normal University, Beijing, 3Oncology and Hematology, Shanghai Children’s Medical Center, Shanghai, China

Background: Polychemotherapy resistance is a major challenge in the treatment of children with relapsed acute lymphoblastic leukaemia (ALL). Mutation of TP53 is tightly associated with poor response to treatment in ALL relapse patients.

Aims: We studied mutations of TP53 in ALL relapses and in six ALL cell lines to shed light on mechanisms and pathways mediating TP53 dependent drug resistance in relapsed ALL. First, we analyzed the spectrum of TP53 mutations in ALL relapses and correlated it to treatment response of patients. Second, we studied drug sensitivity in TP53 wild type (wt) versus TP53 mutant ALL cell lines.

Materials and Methods: TP53 was sequenced by the method of Sanger. Drug sensitivity was assessed by clonogenic survival of wt p53. In contrast, nucleotide analoga showed no p53 inducible N248P in MHH. Three ALL cell lines were used as controls. Topoisomerase II inhibitors upregulated TP53 expression in Auranofin and 30-60 nM for Disulfiram. Induction of apoptosis was evident at 6 hours post Auranofin treatment, or after 12 hours Disulfiram treatment. Each drug significantly increased intracellular ROS as early as one hour post-treatment (p<0.01), which was accompanied by induction of Nrf2, a master regulator of the antioxidant response. Incubation with ROS scavenger N-acetyl cysteine prior to treatment with either drug prevented the increase in cellular ROS levels (p<0.05) and rescued cells from apoptosis (p<0.0001), indicating involvement of reduction-oxidation and increased ROS generation as mechanisms of leukaemia cell killing induced by these drugs.

Summary/Conclusions: In summary, we have identified two FDA-approved drugs that demonstrated potent anti-leukaemia activity through induction of ROS, potentially opening up new avenues for clinical treatment of high-risk paediatric ALL. We will now be testing these potential therapeutics in vivo using relevant PDX models of high-risk paediatric ALL.

Aims: We identified 20 different TP53 mutations in 34 patients. We classified TP53 mutations into ‘hot spot’ (R175, G245, R248, R273 and R282), 1Children’s Cancer Institute, Lowy Cancer Research Centre, University of New South Wales, 2ACRF Drug Discovery Centre for Childhood Cancer, Children’s Cancer Institute, Lowy Cancer Research Centre, University of New South Wales, Sydney, New South Wales, 3Telephone Kids Institute, University of Western Australia, Perth, Western Australia, Australia.
tion, IC50 measurements showed that TP53 mutations lead to resistance against topoisomerase II inhibitors and alkylating agents, but not against other drugs. The upstream pathway of p53 (CHK1, CHK2) and DNA damage recognition (γH2AX) were not impaired in the six ALL cell lines. To study the effect of TP53 mutation on resistance to treatment in more detail, we focused on the R248P mutation, located in hot spot codon 248, that we found in a relapsed patient with non-response to treatment and in the MHH cell line. Using a CRISPR/Cas9 knockut (KO) of endogenous p53 and lentiviral based re-expression in NALM-6, we generated p53 KO, and KO+wt p53, KO+R248P and KO+GFP cell lines. The KO cells showed a similar resistance to DNA damage inducing drugs as KO+R248P cells. Overexpression of wt p53 in KO cells restored sensitivity to DNA damaging drugs. In contrast to wt p53, R248p did not inhibit cell proliferation under drug treatment. We found that this mutant was unable to induce downstream targets of p53 (p21, BAX). Moreover, ChiP-seq showed that R248p cannot bind the promoter and induce expression of typical p53 targets MDM2, p21, BAX, BCC3/PUMA, FA1 and PUMA. This result indicates that R248P is defined as a frameshift and the consensus element of p53. However, the binding motif analysis showed that the R248P mutant still binds DNA at a different and purine-rich sequence. In summary, R248p leads to wt p53 function and mediates resistance to topoisomerase II inhibitors and alkylating agents.

Summary/Conclusions: Overall, our results show that mutations affecting TP53 hot spots, in particular codon 248, are associated with resistance of ALL cells to chemotherapy and reveal first insights into underlying mechanisms and pathways.

P156

GENETIC ACTIVATION AND THERAPEUTIC TARGETING OF PIM1 IN T-CELL ACUTE LYMPHOBластIC LYMPHOMA

R. De Smedt1, S. Peirs1, J. Morscio1, J. Roels1, S. Goossens1, A. Touzar2, A. Uyttebroeck3, N. Van Roy1, T. Lammens4, L. Mussolin5, E. Macintyre2, A. Yahiaoui1, J. P. Loftus2, M. Axelrod1, A. Forslund1, S. Tannheimer1, D. Ribeiro1,*, I. Lopes1, C. Custódia1, J. Silva1, M. Abreu1, J. Barata1

Background: T-cell acute lymphoblastic leukemia (T-ALL) and T-cell acute lymphoblastic lymphoma (T-LBL) are aggressive immature T-cell malignancies that are considered one disease entity according to the World Health Organization (WHO). Both T-ALL and T-LBL are often characterized by improper T-cell receptor (TCR) re-combinations leading to aberrant activation of proto-oncogenes. PIM1 is a constitutively activated kinase that is involved in cell cycle, translation and apoptosis. Finally, we evaluated the therapeutic potential of PIM1 inhibition.

Aims: Despite some genetic and phenotypic similarities between T-ALL and T-LBL, T-ALL risk group stratification cannot be extrapolated to T-LBL patients. Aims:

Methods: We used an IL-7-dependent leukemia T-cell line (TAIL7) and “primary” cells from patient-derived xenografts (PDX). We used inhibitors of PI3K (LY294002), mTOR (rapamycin), MEK1/2 (U0126) and ULK1 (MRT68921). Analysis of viability and cell size was performed by flow cytometry. Signaling pathway activation and LC3-II-III conversion was performed by western blot analysis. LC3 puncta formation was assessed by confocal microscopy.

Results: We show that in optimal culture conditions (medium with serum) IL-7 inhibits autophagy in T-ALL, albeit in a complex manner that involves triggering both pro- (via MEK/Erk) and anti- (via PI3K/Akt/mTOR) autophagic signaling. In this scenario, IL-7-mediated viability relies on the latter pathway, as we previously described. In contrast, under stress conditions (serum starvation) IL-7 promotes autophagy in leukemia cells. In this situation, IL-7-mediated survival partially relies on autophagy activation and strictly requires MEK/Erk activation. Mechanistically, we provide evidence that depending on culture conditions, IL-7 can balance the relative activation of PI3K/Akt/mTOR and MEK/Erk pathways towards or against autophagy in order to consistently promote T-ALL cell viability.

Summary/Conclusions: Our results suggest that IL-7 makes use of a ‘flexible strategy’ to promote T-ALL cell viability by recruiting both pro- and anti-autophagy pathways, which can be very helpful or harmful depending on microenvironmental conditions. Our data strengthen the notion that combination therapies against PI3K/Akt/mTOR and MEK/Erk pathways may be of particular relevance in the context of T-ALL.

P158

PRECLINICAL ACTIVITY OF ENOSTEPLATINIB IN CHILDHOOD B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

A. Yahiaoui1, J. P. Loftus2, M. Axelrod1, A. Forslund1, S. Tannheimer1, S.K. Tasiian2,3,*

Summary/Conclusions: All together, our study identifies PIM1 as a putative oncogene in T-LLB and suggests that inhibition of this serine/threonine kinase could serve as a novel therapeutic strategy in this aggressive T-cell neoplasm.
and Center for Childhood Cancer Research, Children’s Hospital of Philadelphia, Pennsylvania, United States

**Background:** B-cell acute lymphoblastic leukemia (B-ALL) is the most common malignancy of childhood and is highly curable with modern risk-adapted chemotherapy. However, 15-20% of children and >80% of adults with B-ALL develop chemoresistance and relapse, indicating need for new therapies. Addition of kinase inhibitors to chemotherapy for patients with BCR-ABL1-rearranged (Ph+) B-ALL has dramatically improved event-free and overall survival, and similar approaches are now under active clinical investigation in patients with BCR-ABL1-like (Philadelphia chromosome-like or Ph-like) B-ALL. Recent studies have demonstrated activated spleen tyrosine kinase (SYK) signaling in various genetic subtypes of B-ALL and preclinical activity of the SYK/LKT3JAK inhibitor fostamatinib. However, SYK activation in B-ALL and potential correlation with specific leukemia-associated mutations remains incompletely characterized. We hypothesized that constitutive activation of SYK signaling occurs across a genetic spectrum of infants and high-risk childhood B-ALL and can be therapeutically targeted in vivo with the selective SYK inhibitor entospletinib.

**Aims:** (1) Assess basal SYK signaling activation in childhood B-ALL specimens. (2) Quantify treatment efficacy, pharmacokinetics (PK), and pharmacodynamic (PD) effects of ento in childhood B-ALL patient-derived xenograft (PDX) models.

**Methods:** Total and phosphorylated (p) SYK levels were assessed by Simple Western analysis of splenic lysates from NSG mice well-engrafted with primary pediatric B-ALL specimens (n=19 Ph-like, n=4 infant KMT2A-rearranged (R), and n=4 infant non-KMT2A-R PDX models) to identify leukemias with constitutive SYK signaling activation. To assess in vivo activity of SYK inhibition, selected B-ALL PDX models with high basal pSYK (n=2) were treated with continuous oral administration of ento and control animals at both 0.03% and 0.07% chow formulations (representative data in Figure 1; p<0.05). Steady state concentrations were maintained during the study duration with terminal PK values of 3.3 (± 0.5) and 7.9 (± 1.0) μM (0.03% and 0.07% ento arms, respectively). PD studies demonstrated dose-dependent in vivo inhibition of pERK measured in human leukemia cells within spleens of ento-treated mice without alterations in total SYK protein levels. In general, PD inhibition of SYK target phosphoproteins was more pronounced in 0.07% ento-treated animals.

**Results:** Constitutive pSYK signaling was observed in 10/19 Ph-like, 4/4 KMT2A-R, and 1/4 non-KMT2A-R B-ALL specimens. Ento treatment of KMT2A-MLL3 (ALL3103) and Ph-like NUP214-ABL1 (NH011) PDX models significantly inhibited ALL proliferation in vivo versus control animals at both 0.03% and 0.07% chow formulations (representative data in Figure 1; p<0.05). Steady state concentrations were maintained throughout the study duration with terminal PK values of 3.3 (± 0.5) and 7.9 (± 1.0) μM (0.03% and 0.07% ento arms, respectively). PD studies demonstrated dose-dependent in vivo inhibition of pERK measured in human leukemia cells within spleens of ento-treated mice without alterations in total SYK protein levels. In general, PD inhibition of SYK target phosphoproteins was more pronounced in 0.07% ento-treated animals.

**Conclusion:** Constitutive activation of SYK signaling occurs frequently in childhood Ph-like and infant KMT2A-R childhood B-ALL. Ento treatment of B-ALL PDX models potently inhibited SYK pathway signaling proteins and significantly inhibited leukemia proliferation in vivo.

**P159**

**PHARMACOLOGICAL ACTIVITY OF CB-103 – AN ORAL PAN-NOTCH INHIBITOR WITH A VIABLE MODE OF ACTION**

R. Lehal1,2, D. Weber1, V. Frismantas2, J.-P. Bourquin2, M. Bauer1, M. Murone1, F. Radtke3

1Cellestia Biotech AG, Basel, 2University Children’s Hospital, Zürich, 3Swiss Institute for Experimental Cancer Research, EPFL, Lausanne, Switzerland

**Background:** NOTCH signalling is a developmental pathway known to play critical roles during embryonic development as well as for the regulation of self-renewing tissues. Aberrant activation of NOTCH signalling leads to deregulation of the self-renewal process resulting in sustained proliferation, evasion of cell death, loss of differentiation capacity, invasion and metastasis, all of which are hallmarks of cancer. When the NOTCH pathway is inappropriately activated by genetic lesions (over expression of NOTCH ligands/receptors, GOF mutations in NOTCH receptors as well as as chromosomal translocations), it becomes a major driver for NOTCH-dependent cancers and resistance to standard of care treatment. Over 250,000 patients are annually diagnosed with NOTCH dependent cancers, with no specific therapy available to date.

**Aims:** Given the importance of NOTCH signalling in human cancers, several therapeutic approaches have been utilized to block NOTCH signalling. Two of these strategies are: a) the use of monoclonal blocking antibodies (mAbs) against NOTCH ligands and receptors and b) the use of small molecule gamma-secretase inhibitors (GSIs). However, these approaches can only be effective if tumor cells express full-length ligand or receptor molecules. As validation of NOTCH as a therapeutic target, clinical activity of these in clinical studies were observed in various trials for some of these inhibitors (mAbs, GSIs), but treatment and exposure were usually limited due to toxicities, mainly related to gastro-intestinal adverse events. On the contrary, in human cancers harbouring NOTCH gene fusion due to chromosomal translocations or specific NOTCH mutations, the use of mAbs and GSIs will have very limited clinical benefits. Cellestia has decided to follow a disruptive approach, by blocking NOTCH signalling in the most downstream part of the NOTCH cascade, at the level of the NOTCH transcriptional activation complex, using small molecule inhibitors.

**Methods:** Here we report the pharmacological characterization of CB-103, a first-in-class orally-active small molecule inhibitor of the NOTCH transcriptional activation complex.

**Results:** We demonstrate that in vitro CB-103 potently inhibits NOTCH signalling in various leukemic and lymphoma cell lines, and T-ALL blasts derived from relapse/refractory patients. In addition, CB-103 exhibited anti-tumor efficacy in multiple in vivo models of NOTCH-driven T-ALL using T-ALL cell lines and patients derived xenograft models.

**Summary/Conclusions:** Toxicology studies have been completed and clinical development of CB-103 with a first-in-human Phase I/IIA clinical study in advanced solid tumors and haematological malignancies is under preparation.
Acute lymphoblastic leukemia - Clinical 1

IKZF1Δ4-7 can be easily screened by PCR but does not predict outcome in adults with acute lymphoblastic leukemia; data from 490 patients enrolled on the UKALL14 trial.

R.J. Mitchell1, A.A. Kirkwood2, B. Wrench3, A. Fearn3, C. Schwab4, E. Lawrie2, K. Zuborne Alapi1, L. Clifton-Hadley2, P. Patrick2, T. Naughton1, A.V. Moorman4, T.C. McSharry1, P. Patrick2, T. Naughton1, A.V. Moorman4, T.C. McSharry1
1UCL Cancer Institute, 2CRUK and UCL Cancer Trial Centre, UCL, 3Barts Cancer Institute, QMUL, London, 4Leukaemia Research Cytogenetics Group, Northern Institute for Cancer Research, Newcastle University, Newcastle Upon Tyne, United Kingdom

Background: The IKZF1 gene encodes the IKAROS zinc-finger transcription factor and master regulator of lymphocyte differentiation. IKZF1 lesions are common in acute lymphoblastic leukemia (ALL) and have been reported as independent prognostic factors for poor outcome. IKZF1Δ4-7, resulting in the dominant negative Ik6 isoform is the most common single IKZF1 deletion.

Aims: We aimed to generate and validate a simple, PCR-based screening assay for IKZF1Δ4-7 using an endpoint PCR assay using primers located in introns 3 and 7. The lower limit of detection was determined by serial dilution of DNA from the IKZF1-expressing cell line SUP-B15 and calculated to be 0.001%. A total of 95 samples were also tested using the MLPA P335 kit to detect the full spectrum of IKZF1 deletion. Sanger sequencing confirmed the breakpoints in 27 cases.

Results: The median age of the patients tested was 46 years (range 25-65). Overall IKZF1Δ4-7 was detected in 97/490 (20%) patients but the frequency varied by genetic subtype. Patients with BCR-ABL1 fusion had the highest IKZF1Δ4-7 frequency (46/150, 31%) followed by patients with B-other ALL (29/154, 19%). Patients with other classic cytogenetic abnormalities harboured significantly fewer IKZF1Δ4-7 – low hypodiploidy (3/26), MLL gene fusions (3/31), t(1;19) (1/11), high hyperdiploidy (2/9) and iAMP21 (0/3). MLPA did not detect any IKZF1Δ4-7 deletions that were not detected by PCR but did identify several samples with alternative IKZF1 deletions affecting different exons (see Table 1). By contrast, the PCR assay did detect six IKZF1Δ4-7 deletions undetected by MLPA, consistent with the higher sensitivity of this approach. Interestingly, three of these samples harboured alternative IKZF1 deletions in addition to IKZF1Δ4-7. In 70 (14%) cases, we observed a “faint” PCR band. Since the biological relevance of this was not clear, the ‘faint’ bands were not included in the final analysis. Interestingly the frequency of these “faint” bands was similar across all genetic subtypes: BCR-ABL1 (14%), B-other (15%), MLL (21%), low hypodiploidy (19%). We examined the impact of IKZF1Δ4-7 on achievement of CR, persistence of minimal residual disease (MRD) and overall survival (OS) and for all others...
Background: Risk factors for T-LBL have not been systematically evaluated, in contrast to T-ALL.

Aims: Our aim was to define immunophenotype of T-LBL/ALL in 71 consecutive patients by use of the flow cytometry (FCM) of tissue aspirates if peripheral blood (PB) and bone marrow (BM) were uninvolved. We also evaluated prognostic value of immunophenotype according to WHO 2008 subtype and ETP (Early T-cell Phenotype) definition in adult patients with T-LBL/ALL treated on uniform ALL protocol.

Methods: Between 1997 and 2015, 71 adult patients with T-LBL/ALL were treated according to the GMA 05/93 and T-LBL/ALL 2004 protocols. Immunophenotype was determined by immunohistochemical staining and by FCM of cellular suspension obtained from lymph nodes (n=31), mediastinal mass (n=12) or nasopharyngeal/perinodal infiltration (n=2) by fine needle aspiration biopsy (FNAB), as well as of BM (n=10), PB (n=7) and pleural fluid (n=9). Disease subtype was defined according to WHO 2008 classification: pre-B, pro-B, pre-T, CD2+ or - (CD2+), cortical (CD1a+), medullary/mature (sCD3+). Recognition of pan-T cell CD antigen (pTag) expression included: CD1a, CD2, sCD3, CD4, CD5, CD8. ETP-T-LBL/ALL immunophenotype was defined as follows: absent (up to 5%) positive cells) CD1a and CD8 expression, absent or dim (75% positive cells) CD5 expression, expression (25% positive cells) of 1 or more myeloid (CD13,CD33, CD15) or stem cell (CD34, HLA-DR) markers.

Results: Patient characteristics: ALL (BM+ >20%): n=26(37%), LBL: n=45(63%), BM+<20% involvement (LBL): 27%, age=35; years: 72%, males: 67%. Immunophenotype: pre-B: 21%, pre-T: 17%, cortical: 55%, medullary/mature (n>10% of pTag present): 0-3: n=3(27%), 0: n=21(53%), 3-7: n=2(3.5%). Most frequently expressed pTag were: CD7: 97%, CD5: 87%, CD7: 74%, CD1a: 58%. Myeloid markers: CD13/33/15 were expressed in 13%/26%/10% and stem cell markers: CD34 in 42% of pts. Overall, 19% (13/67) of the study population had ETP-T-LBL/ALL. CD1a- (9/13), but CD5 negative: 46% and CD5 weaker (20-71%): 54%, CD34/HLA-DR/CD15 in 100%/50%/75%/14% of ETP pts. 4 pts (31%) with ETP were categorized as pre-T and 9 pts (69%) as pro-T. With a median (95%) follow-up of 137 of 0.99, 1.733 months, 5-year OS and DFS (95%(CI.), was 53% (0.42, 0.65) and 48% (0.36, 0.59), respectively. 5-year OS (95%(CI.)) for pts with sCD3 and CD1a expression as a pTag present was 64% (0.51, 0.77), 86% (0.51, 0.83) and 64% (0.5, 0.72) compared to 11% (0.03, 0.25), 32% (0.15, 0.49) and 27% (0.09, 0.452) for pts without CD2, CD13 and 0 or less pTag (P<0.001, 0.009 and 0.002), respectively. OS and DFS was dependent on WHO subtype (p<0.001/p<0.002), 5-year OS (95%(CI.): cortical: 69% (0.547, 0.82), pre-B: 48% (0.196, 0.78); maturity: 40% (0.24, 0.62), pro-B: 10% (0.072, 0.272). There was no significant difference in OS and DFS in pts with ETP vs non-ETP (P=0.198, 0.159). 5-year OS (95%(CI.): 31% (0.57, 0.559) and 55% (0.418, 0.685) for ETP and non-ETP pts, respectively. Among ETP pts, 4/13(31%) are alive, 3/4(75%) pts with pre-T and only 1/9((11%) with pro-T phenotype. 3/7 pts were rescued with allo-HCT (Figure 1).

Summary/Conclusions: Survival of T-LBL/ALL pts depends on CD1a and CD2 expression as well as on WHO subtype. ETP is a non-uniform category for pro-T/pre-T-cell origin. ETP phenotype was non-significant factor for OS/DFS (p>0.12/p>0.15) unless consistent with pro-T subtype (CD2+), only 1/9 pts alive. Pro-T (CD2-) is an ultra-high risk subtype of T-LBL/ALL and novel treatments are needed to improve pts outcomes.

P163

CLINICAL SIGNIFICANCE OF END OF INDUCTION MINIMAL RESIDUAL DISEASE IN ADULT PATIENTS WITH ACUTE LYMPHOBlastic LEUKEMIA IN COMPLETE REMISSION AFTER A SINGLE CHEMOTHERAPY COURSE

Background: In pediatric ALL end of induction minimal residual disease (E01 MRD) evaluated at day 29-33 after the first chemotherapy course is a primary determinant of outcome. The significance of E01 MRD in adult ALL is less clear.

Aims: To assess E01 MRD and its impact on survival and relapse rate in adult patients with Philadelphia-negative (Ph-) ALL in complete remission (CR) with a single chemotherapy course.

Methods: Induction chemotherapy for patients in the Northern Italy Leukemia Group 10/07 trial (ClinicalTrials.gov NCT-00795756). Blood in 2016;128:176-187. All patients were confirmed negative at week 10, contrary to only 7/28 (25%) with E01 MRD. Immunophenotype was determined by immunohistochemical staining and by FCM of cellular suspension obtained from lymph nodes (n=31), mediastinal mass (n=12) or nasopharyngeal/perinodal infiltration (n=2) by fine needle aspiration biopsy (FNAB), as well as of BM (n=10), PB (n=7) and pleural fluid (n=9). Disease subtype was defined according to WHO 2008 classification: pre-B, pro-B, pre-T, cortical (CD1a+), medullary/mature (sCD3+). Recognition of pan-T cell CD antigen (pTag) expression included: CD1a, CD2, sCD3, CD4, CD5, CD8. ETP-T-LBL/ALL immunophenotype was defined as follows: absent (up to 5%) positive cells) CD1a and CD8 expression, absent or dim (75% positive cells) CD5 expression, expression (25% positive cells) of 1 or more myeloid (CD13,CD33, CD15) or stem cell (CD34, HLA-DR) markers.

Results: Of 163 study patients, 139 were in CR after cycle 1 (85.2%), 95 had a sensitive molecular marker (68.3%) and 90 were successfully studied for E01 MRD. Median patient age was 39 years (range 17-67 years), 58.9% were male, 64.4% and 35.6% had B- and T-ALL, respectively, 44.4% were SR, 10% HR. 9,11,13,16,18,20; intrathecal MTX, Ara-C, Dexa on days 1 and 15; and G-CSF from day 4. CR was assessed on day 28 by means of bone marrow morphology and MRD evaluation (RO-PCR with case-specific probes, sensitivity ≥10-4).

E01 MRD was missing in 32 (19.6%) patients, whereas there was a risk of relapse (incidence (RI) and relapse-free survival (RFS), defining as favorable (i.e. negative) a response <10-4. In this risk-oriented protocol MRD-based risk stratification was deferred until after early consolidation (week 10), at which point standard- and high-risk (SR, HR) patients with MRD ≥10-4 and very HR patients with MRD study results were eligible to aleloigeneic stem cell transplantation.

Summary/Conclusions: Survival of T-LBL/ALL pts depends on CD1a and CD2 expression as well as on WHO subtype. ETP is a non-uniform category for pro-T/pre-T-cell origin. ETP phenotype was non-significant factor for OS/DFS (p>0.12/p>0.15) unless consistent with pro-T subtype (CD2+), only 1/9 pts alive. Pro-T (CD2-) is an ultra-high risk subtype of T-LBL/ALL and novel treatments are needed to improve pts outcomes.
Background: The outcome for older adults with acute lymphoblastic leukaemia (ALL) is unsatisfactory. The UKALL12/ECOG2993 study showed that high risk cytogenetic abnormalities, were common, as well as lower rates of complete remission (CR) and 5 year overall survival (OS) in those aged 55-65 years of age as compared to younger persons. There are few studies which focus on older patients with ALL, despite an increasing incidence with age.

Aims: A trial to establish age-appropriate baseline chemotherapy from which to design widely-applicable studies of novel agents in older people with ALL.

Methods: UKALL60+ offers five ‘Arms’ to be decided by investigator and patient choice; Arm A= Philadelphia chromosome positive (Ph+), Arm B= Non-intensive (designed to be delivered primarily out of hospital), Arm C= Intensive, Arm D= Intensive + and Arm E= Registration only (in which treatment is at investigators discretion, including no active therapy). Any elderly patient with newly diagnosed ALL is eligible. There are no exclusions for co-morbidities, including prior malignancies. Baseline characteristics of each group including Charlson index, ECOG, Karnofsky and CRASH scores are being collected. The primary endpoint is the rate of complete remission (CR) after 2 phases of induction. Secondary objectives include determination of MRD status at 3 time points, EFS and OS at 1 year, treatment related mortality and quality of life.

Results: Since December 2012 85 patients have been recruited (4 excluded due to misdiagnosis) with a median age of 67 years (Range 55 – 83). Median follow up is 18.1 months. ECOG performance status was 0 in 33 (41%), 1 in 37 (46%), 2 in 8 (10%) and ≥3 in 3 (4%). Treatment allocation has been Ph+ n=18, Intensive n=34, non-Intensive n=11, Intensive + n=7, and Registration only n=11 patients. It is too early to perform a full analysis of the reasons given for choosing each regimen but age appears to be a major factor for Ph+ve patients, with a median age of 74 years (Range 64-82) in the non-Intensive arm compared with 66 years (Range 56 -76) in the Intensive and Intensive+ arms. A total of 36/61 (57%) patients had high risk cytogenetics including BCR-ABL1 (n=21), low hypodiploidy (n=10), complex karyotype (n=1) and KMT2A- AFF1 (aka MLL-AF4) (n=4). Charlson index and CRASH score data is awaited. At the end of 2 phases of treatment on Arm A (Ph+ve) 17/18 (94%) patients achieved CR. On Arms B-D 27/52 (52%) patients achieved CR. Grade 3/4 AEs were a mix of hypo- & hyper-diploid. FISH studies were available for 50 pts: 10 (41%) had complex cytogenetics (≥5 abnormalities), 18 (38%) had a monosomy and 32 (60%) received Hyper-CVAD, concomitantly with rituximab in 11 (34%) pts, & TKIs in 9 (28%) pts. 21 (40%) pts received other regimens, of which 14 (67%) had asparaginase-based chemotherapy. Only 2 (4%) pts who received induction chemotherapy died within the first 60 days; both received Hyper-CVAD. Median number of cycles to achieve CR was 1 (1-8) with CR/CRi rate of 93%, & median time to CR1 was 34 days (19-459). 3 pts who underwent palliative chemotherapy achieved CR (all had Ph+ disease & received TKIs). 7 pts (13%) had primary induction failure. 50% of pts relapsed within a median time of 12.6 (3.6-72.8) months. Only 10 pts under went allogeneic hematopoietic stem cell transplantation (HSCT), of which 2 (20%) relapsed in less than 180 days. Median survival after HSCT was not reached. Predictors of survival: Elderly ALL has worse mOS compared to our adult ALL cohort, 17.2 (IQR: 11.7-32.9) vs 52.1 (IQR; 27.6-169.9) months (p=0.0016). In a univariate analysis model which included multiple variables, only ECOG PS ≥2, WBC≥30,000, CDXN2A del, & CNS leukemia were statistically significant, however only CNS leukemia (p=0.0009) & WBC (p=0.0168) retained the statistical significance in multivariate mode, with a trend in CDXN2A del (p=0.06) (Figure 1).

Figure 1.

Summary/Conclusions: ALL in older patients is challenging to treat, with a difficult balance between efficacy and toxicity. We observed a high rate of high risk cytogenetics, especially notable being the rate of low hypodiploidy. Initial high CR rates are seen in those with Ph+ve disease, this does not appear to translate into improved PFS and OS when compared with Philadelphia negative disease. The commonest cause of death in this group is ALL. We will use our baseline data to develop appropriate regimens for future studies of novel agents.
Background: The outcomes of adults and elderly (>60 years) patients with Ph+ ALL has improved since the introduction of tyrosine kinase inhibitors (TKI), used alone or in combination with chemotherapy during induction. Before 2005, all these patients were treated with chemotherapy; from 2005, a TKI-based “chemo-free” induction strategy was applied.

Aims: To evaluate the outcome of patients followed from 1996 at a single Center, and to correlate the short- and long-term responses with: a) induction treatment (chemotherapy or TKI); b) age; c) TKI used (imatinib or dasatinib); d) fusion protein; e) allogeneic stem cell transplant (SCT).

Methods: Sixty-eight patients (29M/39F) were treated; median age was 50 years (18-88) and 16 were elderly patients; 43 cases had the p190 protein, 19 the p210 and 6 had both; the latter 2 groups were merged together for further analyses. Fifty-two patients were enrolled in clinical trials. Median follow-up is 105 months (13-224).

Results: As induction, 28 patients received chemotherapy, 2 chemotherapy+TKI (considered as “chemotherapy+TKI group”) and 38 TKI alone (24 imatinib and 14 dasatinib). All cases received TKI during consolidation/maintenance when it became available. All elderly patients but 1 received a TKI alone (plus steroids). Upon induction, 44 patients received consolidation chemotherapy, including 5 elderly. A SCT - carried out virtually only in adults - was performed in first complete remission (CR) in 13 cases (5 in the chemotherapy+TKI and 8 in the TKI groups). Overall, 91% patients achieved a CR, OS and DFS at 100 months are 42% and 45.5%, respectively. Among the 30 patients in the chemotherapy+TKI group, 25 (83%) achieved a CR, 4 were refractory and 1 died in induction; in the TKI group (n=38), 37 (97%) achieved a CR and 1 was refractory. Differences are statistically significant (p=0.03). Refractoriness was more frequent in p210+ than in p190+ cases (12% vs 5%): this finding did not translate into significantly different OS and DFS (30% vs 48% and 32% vs 51%, respectively). When patients were stratified by age, adults had a significantly better OS and DFS at 100 months than elderly (53% vs 19%, p= 0.04, and 57% vs 20%, p= 0.03, respectively), even more marked in multivariate analysis. Treatment with TKI alone (75% vs 20%, p=0.01 and 73% vs 21.4%, p=0.017, respectively). The TKI used (imatinib or dasatinib) did not impact in adults, while a significant advantage in OS and DFS was observed for elderly patients receiving dasatinib (Figure 1): this might be due to the greater activity of dasatinib and also highlights the importance of consolidation chemotherapy, performed almost exclusively in adults. Considering adults only, within the chemotherapy+TKI group, 5 patients were transplanted and 19 were not: all transplanted cases are in CR, while in the non-transplanted cases 6 are in CR, 11 have relapsed and 2 have died in CR (p=0.01); within the TKI group, 8 patients underwent a SCT and 15 did not of the transplanted cases, 6 are in CR and 2 have died due to complications, while 11 of the non-transplanted patients are in first CR, 3 have relapsed and 1 has died in first CR (p=n.s.). Of the 5 patients transplanted in second CR, only 1 is alive.

Figure 1.

Summary/Conclusions: This study further underlines the benefit of an induction based on a TKI alone. Since age holds strong prognostic significance, our results suggest that while chemotherapy followed by consolidation chemotherapy is the optimal choice for adults, in elderly cases dasatinib is more appropriate, since patients are often unfit to receive further chemotherapy. Finally, the advantage of SCT needs to be carefully redefined in the TKI era.

Background: B-precursor acute lymphoblastic leukemia (B-ALL) is the most common childhood malignancy, accounting for approximately 30% of pediatric cancers. With advances in risk-adapted chemotherapy, the overall cure rate of newly diagnosed B-ALL is approaching 85% in most developed countries. However, relapse still occurs in ~20% of patients and a significant portion of them are not initially classified in the high-risk disease entity, underscoring the need for development of additional informative prognostic biomarkers.

Aims: CD9, a tetraspanin family protein, regulates multiple physiologic processes including cell migration and adhesion, and has been associated with metastasis and progression of various types of cancers. In this study, we aim to evaluate its expression pattern and prognostic significance in pediatric B-ALL.

Methods: Cell surface CD9 expression on leukemic blasts at disease presentation was characterized by multicolor flow cytometry in a cohort of pediatric B-ALL patients. The CD9 expression status was correlated with clinical parameters, including age, sex, white cell count, cytogenetics and prednisone response. Kaplan-Meier survival analysis was performed to investigate the possible association of CD9 expression with clinical outcomes. The potential role of CD9 expression as a predictor of 5-year survival outcomes was evaluated using Cox regression models.

Results: Among 118 cases included, blasts of 92 patients (78.0%) were CD9+ (92% of CD9+expressing blasts). There were no significant differences in age, sex and white cell count between CD9+ and CD9- patients. Major cytogenetics subgroups were similarly distributed except for hyperdiploidy (all patients were CD9+: P=0.022) and ETV6-RUNX1 translocation (higher prevalence in CD9− patients: P=0.001). Significantly more CD9+ patients were stratified into the intermediate-risk group (P=0.044) and a higher proportion of CD9− patients was stratified into the high-risk group (P=0.025). Besides, CD9− patients had poorer prednisone response (P=0.014). The 5-year overall survival (OS) and relapse-free survival (RFS) rates of CD9+ patients were significantly lower than those in CD9− patients (P<0.029). Subgroup analysis revealed remarkably poorer outcomes in CD9+ patients of the high-risk group (P<0.045). A similar trend was also observed in patients of the intermediate-risk group but not in the standard-risk group. In univariate analysis, CD9 positivity, age <1 year, white cell count ≥100 × 10⁹/L and poor prednisone response were associated with lower RFS rate (P<0.001). In multivariate analysis, CD9 positivity (HR=4.0; P=0.019) and poor prednisone response (HR=3.9; P<0.015) remained as independent prognostic factors for lower RFS rates.

Summary/Conclusions: Our data indicate that expression of CD9 was significantly associated with inferior survival outcomes in pediatric B-ALL. The observation of the potential role of CD9 in pediatric B-ALL is most promising for patients in the intermediate-risk group, suggesting that CD9 expression could potentially be used in conjunction with other known prognostic factors for refinement of risk group stratification. Our study also lays the foundation for future development of CD9-targeted therapy for high-risk and relapsed/refractory pediatric B-ALL.
Results: Our series included 69 boys and 57 girls diagnosed with acute leukemia, with a median age of 6.1 years (range 0-17.4 years). We included 12 infant patients (<1 year old). Eighty-two (65%) patients had B-cell precursor acute lymphoblastic leukemia (BCP-ALL), 24 patients T-cell ALL and 20 patients had acute myeloblastic leukemia (AML). Globally, we found higher expression levels of class I HDAC isozymes (HDAC 1, 2, 3 & 8) in leukemic samples as compared to their non-neoplastic samples, as previously reported. Interestingly, some HDAC isoforms associated with specific genetic aberrations. Those patients with rearrangement of MLL (KMT2A) gene (n=18, including 9 BCP-ALL and 9 AML; 7 infants and 11 pediatric) had a significantly lower expression of HDAC3 (p=0.043). In the same line, all pediatric patients with pro-B phenotype (CD10 negative) had low levels of HDAC7, but differences did not reach a statistical significance. After a median follow-up of 5.9 years, 15 patients died, with an overall survival (OS) of 89% at 10 years for BCP-ALL and 55% for T-ALL patients (p=0.0035 & p=0.02, respectively, see Figure 1). Infants (n=12) had also a significantly lower expression of HDAC7 (p=0.043). In the BCP-ALL subgroup, the expression of HDACs did not predict outcome, and only CNS infiltration and leukocytosis were unfavorable risk factors for OS. Again, CNS+, high WBC count and presence of minimal residual disease (MRD) post-induction were predictive for worse event free survival (EFS). Although the number of cases is low and these results must be taken with caution, T-ALL patients with the highest expression of HDAC3 (upper quartile) significantly correlated with worse OS (94% vs 25%, p=0.001) and a trend towards worse EFS (89% vs 53%, p=0.06). The only significant risk factor for EFS in this subgroup was the presence of MRD after induction (p=0.003).

Figure 1.

Summary/Conclusions: We have observed a specific pattern of HDACs expression in pediatric patients with ALL rearrangement. Our study, if further confirmed, suggests that specific HDACi would potentially be a useful targeted treatment for pediatric patients with ALL rearranged leukemia.

MINIMAL DISSEMINATED DISEASE DETECTION BY FLOWCYTOMETRIC IMMUNOPHENOTYPING IN T-CELL ACUTE LYMPHOBLASTIC LYMPHOMA

G.K. Viswanathan1,* , P. Tembhare1, N. Patkar1, S. Gujral1, P.G. Subramanian1

1Hematopathology Laboratory, Advanced Centre for Treatment, Research and Education in Cancer (ACTREC) - Tata Memorial Centre (TMC), Mumbai, India

Background: T-cell acute lymphoblastic lymphoma (T-LBL) with minimal disseminated disease (MDD) is defined as the presence of T-LBL with <25% blasts in the peripheral blood (PB) and/or bone marrows (BM) by morphology and immunophenotyping, tissue biopsy (lymph node or mediastinal mass). This indicates flowcytometry is necessary in cases with <5% blasts identified by morphology. The identification of minimal disseminated disease in T-LBL is important as studies have confirmed, suggests that specific HDACi would potentially be a useful targeted treatment for pediatric patients with ALL rearranged leukemia.

Methods: A retrospective analysis of 42 cases of T-LBL with <25% blasts identified by morphology and immunophenotyping. T-LBL with <5% blasts in the peripheral blood (PB) and/or bone marrow in cases with <25% blasts identified by morphology. The identification of minimal disseminated disease in T-LBL is important as studies have confirmed, suggests that specific HDACi would potentially be a useful targeted treatment for pediatric patients with ALL rearranged leukemia.

Results: A retrospective analysis of 42 cases of T-LBL with <25% blasts in the peripheral blood (PB) and/or bone marrow in cases with <25% blasts identified by morphology. The identification of minimal disseminated disease in T-LBL is important as studies have confirmed, suggests that specific HDACi would potentially be a useful targeted treatment for pediatric patients with ALL rearranged leukemia.

INOTUZUMAB OZOGAMICIN IN COMBINATION WITH LOW-INTENSITY CHEMOTHERAPY (MINI-HYPER-CVD) AS FRONTLINE THERAPY FOR OLDER PATIENTS WITH ACUTE LYMPHOBластIC LYMPHEMIA: UPDATED RESULTS FROM A PHASE III trial

K. Sasaki1, N. Pemmaraju1, Y. Alvarado1, J. Jacob1, R. Garris1, P. Thompson1, J. Cortes1, E. Jabour1

1The University of Texas MD Anderson Cancer Center, Houston, 2The University of California - Irvine, Orange, United States

Background: Older patients (pts) with acute lymphoblastic leukemia (ALL) have poor tolerance of intensive chemotherapy, and novel strategies are needed in this population. In pts with relapsed/refractory ALL, inotuzumab ozogamicin (InO), an anti-CD22 antibody-drug conjugate, has been shown to improve survival compared to salvage chemotherapy.

Aims: We designed a phase III trial to evaluate the safety and efficacy of low-intensity chemotherapy (mini-Hyper-CVD) plus InO as frontline treatment for older pts with newly diagnosed ALL.

Methods: Pts ≥60 years of age with newly diagnosed Philadelphia chromosome-negative pre-B received mini-Hyper-CVD (compared to hyper-CVAD: no anthracycline, 50% dose reductions of cyclophosphamide and dexamethasone, 75% dose reduction of methotrexate, 83% dose reduction of cytarabine). InO was given on day 3 of the first 4 cycles. The first 6 pts received InO at a dose of 1.3 mg/m2 for cycle 1 followed by 0.8 mg/m2 for cycles 2-4. Rituximab was given during the first 4 cycles in pts with CD20 expression ≥20%; all pts received IT chemotherapy prophylaxis with the first 4 cycles 2-4. Rituximab was given during the first 4 cycles in pts with CD20 expression ≥20%; all pts received IT chemotherapy prophylaxis with the first 4 cycles.
Results: Between 4/2012 and 12/2016, 47 pts have been treated, 4 of whom had received 1 cycle of prior therapy and were in CR at the time of enrollment. The median age was 68 years (range, 60-81), and median CD22 expression was 97% (range, 72-100%). Of 43 pts evaluable for response, 42 responded (ORR=96%). Best response was CR in 36 pts (84%), CRp in 5 (12%) and CRi in 1 (2%). MRD negativity by 6-color multiparameter flow cytometry was achieved in 31 of 41 evaluable pts (76%) on day 21 and in 44 of 46 evaluable pts (96%) within 12 weeks of treatment. The median follow-up was 24 months (range, 1.5-55 months), 3 pts (6%) underwent allogeneic stem cell transplantation (ASCT) in first remission. Of the 46 responders, 6 pts (13%) have relapsed. 16 pts have died, 1 due to resistant disease, 4 after relapse, 1 after ASCT and 21 pts remain on treatment (consolidation, n=3; POMP maintenance, n=19), and 5 pts have completed all therapy. The 3-year continuous CR and OS rates were 72% and 54%, respectively. Compared to a historical cohort of 79 older pts treated at our institution with hyper-CVAD ± rituximab, mini-hyper-CVD+InO resulted in significantly improved OS (3-year OS rate: 54% vs 31%; median OS not reached versus 16 months; P=0.007).

Treatment was overall well-tolerated. The median times to platelet and ANC recovery in cycle 1 were 22 days (range, 11-91 days) and 16 days (range, 0-49 days), respectively. In cycles 2-8, the median times to platelet and ANC recovery in cycle 1 were 22 days (range, 11-91 days) and 16 days (range, 0-49 days), respectively. Compared to a historical cohort of 79 older pts treated at our institution with hyper-CVAD ± rituximab, mini-hyper-CVD+InO resulted in significantly improved OS (3-year OS rate: 54% vs 31%; median OS not reached versus 16 months; P=0.007).

Summary/Conclusions: The combination of InO with mini-hyper-CVD is safe and effective in older pts with newly diagnosed ALL, resulting in a promising 3-year OS rate of 54%. These results appear superior to the outcomes of older pts treated with hyper-CVAD.

### Acute myeloid leukemia - Biology 1

**P171 RECURRENT MYB REARRANGEMENT IN BLASTIC PLASMACYTOID DENDRITIC CELL NEOPLASM**

K. Suzuki1,*, Y. Okuno2, Y. Suzuki3, A. Hamada4, H. Muramatsu1, M. Nakatoh2, M. Gunji4, D. Ichikawa1, M. Hamada1, R. Taniguchi1, S. Kato5, N. Murakami1, D. Kojima1, Y. Sekiya1, E. Nishikawa1, N. Kawashima1, A. Nara1, N. Nishio2, Y. Nakazawa2, H. Iwafuchi3, K. Watanabe4, M. Itô5, S. Kojima1, S. Kato5, Y. Takahashi1

1Department of Pediatrics, Nagoya University Graduate School of Medicine, 2Center for Advanced Medicine and Clinical Research, 3Department of Pathology, Nagoya University Hospital, 4Department of Pathology, Japanese Red Cross Nagoya First Hospital, Nagoya, 5Department of Pediatrics, Shizuoka University School of Medicine, Matsumoto, 6Department of Pathology, Department of Hematology and Oncology, Shizuoka Children’s Hospital, Shizuoka, Japan

**Background:** Blastic plasmacytoid dendritic cell neoplasm (BPDCN) is a rare hematological malignancy that is derived from plasmacytoid dendritic cell precursors. BPDCN tends to occur in elderly people with frequent skin involvement and is associated with an aggressive clinical course and a poor prognosis. Although optimized diagnostics and therapies should improve patient outcomes, the pathobiological and genetic aspects of BPDCN remain unclear.

**Aims:** We planned this study to identify a critical genetic event in BPDCN, which could provide better understanding of BPDCN pathogenesis.

**Methods:** We enrolled fourteen patients (five children and nine adults) with BPDCN who were treated in our institutions. We primarily performed RNA sequencing-based comprehensive transcriptome analysis with their samples at the onset to detect gene fusions. These results were then used as the basis for genetic validation studies and functional analyses with an exogenous expression model.

**Results:** We identified a recurring gene rearrangement that involved the MYB proto-oncogene in all five pediatric patients (100%) and four of nine adult patients (44%) with BPDCN. The resulting fusion genes included MYB-ZAP7 (four patients), MYB-PLEKHO1 (three patients), MYB-DCPS (one patient), and MYB-MIR2134 (one patient), none of which have been previously reported to our knowledge. The translocations corresponding to these fusions were not detected by the metaphase analysis except in one patient with t(1,16), who harbored MYB-PLEKHO1. These fusion genes were detectable at diagnosis and relapse but not at remission.

Fluorescence in situ hybridization (FISH) analysis efficiently detected the breaking apart of MYB in formalin-fixed, paraffin-embedded sections. Consequently to the rearrangement, the negative regulatory domain of MYB was truncated, leading to constitutive MYB transcriptional activation, as described in other malignancies. Exogenous MYB-PLEKHO1 expression in HEK 293T cells led to the upregulation of several known downstream MYB targets.

Gene set enrichment analysis also confirmed the activation of MYB target gene sets. The identified significantly upregulated genes included cell surface molecule-encoding genes such as NCAM1 (also termed CD56), CD68, S1PR1, and CXCR4, possibly providing targets for antibody-mediated anticancer therapies. We performed whole-exome sequencing of paired tumor– normal DNA sets. At diagnosis for four pediatric patients, which revealed a total of 91 (6–45 per patient) somatic mutations, a relatively large number compared with other pediatric cancers. However, no driver mutations were identified from the existing literature and database entries; only one missense mutation, KMT2D p.Cys1403Gly, was present on a driver gene, although this exact mutation had not been previously reported. Furthermore, we performed targeted sequencing covering genes associated with hematological malignancies in the remaining 10 patients. Consequently, children were not found to carry any identifiable driver mutations, whereas all adult patients harbored at least one point mutation in genes such as TET2, ASXL1, IKZF1, ZRS2, NRAS, and EZH2, most of which were reported to be mutated in BPDCN and myeloid malignancies.

**Summary/Conclusions:** We identified a high frequency of MYB rearrangements that promoted the MYB transcriptional activity in BPDCN. MYB split FISH analysis can constitute a valuable diagnostic tool for detecting MYB rearrangements. We expect that our findings provide critical insights regarding BPDCN pathogenesis and contribute to molecular biology-oriented diagnostic techniques and molecular-targeted therapies for this intractable malignancy.
Background: The branched chain amino acids (BCAAs) valine, leucine, and isoleucine are essential AAs for the human body. The activity of BCAA metabolism involves the regulation of cytoketoglutarate (αKG) and α-amino groups from BCAAs to α-ketoglutarate (αKG), respectively. Inhibition of nuclear export is critical for the leukemic phenotype. The most frequent NPM1 mutation is a heterozygous 4bp insertion in exon 12 (mutA).

Methods: To elucidate the mechanistic link between BCAAT1 function and epigenetic deregulation in leukemia stem cells (LSCs) and consequences on clinical outcome.

Methods: High-resolution proteomics of LSCs, Knockdown and overexpression of BCAAT1 in AML patient samples and AML cell lines, Gene set enrichment analysis, BCAA tracing experiments, Xenotransplantation, Metabolomics, RNA-sequencing arrays, correlative and mechanistic link to clinical data sets.

Results: We performed high-resolution proteomics analysis of human acute myeloid leukemia (AML) stem cell (LSC) and non-LSC populations, which have been functionally validated by xenotransplantation into NSG mice, and we found the BCAA pathway enriched in AML and overexpressed in LSCs. We show that BCAAT1, which transfers α-amino groups from BCAAs to α-ketoglutarate (αKG), is a component of the nuclear export machinery (NPM1) and its role is hindered by the presence of the branched chain amino acid (BCAA) cycle αKG (a core essential factor for αKG-dependent dioxygenases such as EGLN1 and the TET family of DNA demethylases). Knockdown (KD) of BCAAT1 in leukemia cells caused accumulation of αKG resulting in HIF1α protein degradation mediated by EGLN1. This resulted in a growth and survival defect and abrogated leukemia-initiating potential. In contrast, overexpression (OE) of BCAAT1 in leukemia cells decreased intracellular αKG levels and caused DNA hypermethylation. BCAAT1 high AML samples displayed a DNA hypermethylation phenotype similar to IDHmut cells, in which KD is inhibited by overexpression of the oncometabolite 2-hydroxylglutarate. High levels of BCAAT1 were strongly correlated with IDHmut (IDHmutTET2mut) and, but not IDHmut TET2mut AMLs. Gene sets characteristic for IDHmut AMLs were enriched both in IDHmutTET2mut- and TET2mut high patient samples and in BCAAT1-OE leukemia cells. BCAAT1 high samples showed enrichment for LSC signatures and paired sample analysis revealed a significant increase of BCAT1 levels upon relapse of the disease.

Summary/Conclusions: In summary, BCAAT1 reduces dioxygenase activity by limiting intracellular αKG, thus linking BCAA catabolism to HIF1α stability and DNA hypermethylation. Our results suggest the BCAA-BCAT1-αKG pathway as a therapeutic target to compromise LSC function in IDHmutTET2mut AML patients.
Summary/Conclusions: Conclusions: HOXB-AS3 is strongly associated with NPM1 mutations in AML. HOXB-AS3 interacts with EB1p1 and NPM1 and regulates ribosomal biogenesis in the leukemic blasts. From a therapeutic standpoint, HOXB-AS3 constitutes a promising target, as in vivo anti-HOXB-AS3 treatment prolonged survival in a murine PDX model.

A DUAL BH3-MIMETIC APPROACH TARGETING BOTH BCL-2 AND MCL1 IS HIGHLY EFFICIENCY AND WELL-TOLERATED IN ACUTE MYELOID LEUKEMIA

D. Moujalled1,2, G. Pomilio1,2, C. Ghirardi3, D. Segal4, T.-C. Teh1,2, J. Salmon1,2, S. Rijal1, P. Lan4, L. Kraus-Berthier5, A. Roberts4, D. Huang4, A.L. Marango3, G. Lessene6, O. Genest6, A. Wei1

Background: Identification of a chemotheraphy-free option for acute myeloid leukemia (AML) represents a highly desired and important research objective. Perturbation of cell survival is an essential hallmark of cancer now amenable to precision targeting by small molecule BH3-mimetics able to inhibit pro-survival BCL-2 (e.g. Souers et al Nat Med 2013 and Roberts et al., NEJM 2016), BCL-XL (Lessene et al., Nat Chem Biol, 2013) and MCL1 (Kotschy et al, Nature 2016). We hypothesise that simultaneous pharmacological targeting of BCL-2 and MCL1 will enhance apoptotic death of AML blasts, without increased toxicity to non-malignant cells.

Aims: To assess the feasibility and efficacy of targeting multiple BCL-2 pro-survival proteins using small molecule BH3-mimetics in pre-clinical models of AML.

Methods: AML cell lines were obtained from ATCC or DSMZ. S55746 (BCL-2 inhibitor) and S63845 (MCL1 inhibitor with 6-fold higher affinity to human MCL1) from Guillaume Lessene (WEHI). Primary AML cells were obtained from patients providing informed consent. For in vivo experiments, NSG; NOD.Cg-Prkdcscid Il2rgtm1Wjl (NRGS) or NOD/ Rag2−/−Il2rgtm1Wjl (NRGS) mice were used.

Results: S55746 and S63845 showed strong synergy (Loewe score >5) in 13 AML cell lines tested, suggesting this dual BH3-mimetic targeting approach was highly efficacious (Figure 1A). S55746 and S63845 lowered the LC50 in primary AML samples by 10-1000-fold in the majority of cases tested, confirming remarkable anti-leukemic activity across a spectrum of AML cases with diverse cytogenetic and molecular pathologies (Figure 1B).

Figure 1. (A) Loewe Score (0 = Additive, 1 > Weak Synergy, 2 > Synergy, 5 > Strong Synergy) in AML cell lines (Lehar, Nat. Biotech 2009). (B) LC50 of primary AML after 48hr treatment (C) NS mice engraffed with MV4;11 AML and treated with i) vehicle, ii) S55746 100 mg/kg (x 4 wks), iii) S63845 25mg/kg IV (x 4 wks) or iv) combined S55746 and S63845. (D) CD45+ staining of NRGS sternums showing 2 representative examples of PDX AML one week after treatment with i) vehicle x5d, ii) S55746 100 mg/kg/d x 5d, iii) S63845 25mg/kg IV x 2d and iv) S55746+S63845.

A smaller fraction of AML samples were also sensitised to combined A1155463 and S63845 therapy. Bioluminescent imaging showed rapid and sustained clearance of xenografted MV4;11 AML (FLT3-ITD mutant and MLL re-arranged) cells, translating into significant prolongation of survival (Figure 1C) from combined S55746+S63845, but not from treatment with either BH3-mimetic alone. Similar in vivo efficacy was observed with xenografted OCI-AML3 cells harboring wild type NPM1 and MLL-AF4. Patient-derived xenografts demonstrated rapid reduction of established AML in the bone marrow one week of treatment with S55746 and S63845 (Figure 1D). Safety and tolerability of this approach was confirmed using normal CD34+ stem and progenitor cells in short-term cell culture (48h) and long-term (2-3 weeks) clonogenic assays and from historical and biochemical examination of mice receiving treated for up to 8 weeks at doses shown to be highly efficacious against AML.

Summary/Conclusions: Dual BH3-mimetic targeting of BCL-2 and MCL1 induces rapid and synergistic cytoreduction of human AML cell line and primary AML samples in vitro and in vivo across a diverse range of AML genotypes. We therefore support for the first time, that dual pharmacological targeting of both BCL-2 and MCL1 represents a novel approach to treating AML without need for additional chemotherapy and with an acceptable therapeutic safety margin. Our results support the translational investigation of dual BH3-mimetic targeting of BCL-2 and MCL1 in the clinic for the treatment of patients with AML.

THE PML/PLIC2/PLIC5A KNOCK-IN MOUSE MODEL PROVIDES EVIDENCE FOR THE ROLE OF NUCLEAR BODY DISRUPTION IN THE PATHOGENESIS OF ACUTE PROMYELOCYTIC LEUKEMIA

E. Voiselay1,2, E. Moravcik1, E. Stratford1, A. Jaye1, C. Palgrave3, R. Hills4, P. Salomons5, S. Kogan6, D. Gravante2,1

1Medical and Molecular Genetics, King’s College London, London, United Kingdom, 2Tumor Biology, The Norwegian Radium Hospital, Oslo, Norway, 3School of Veterinary Medicine, University of Surrey, Guildford, 4Centre for Trials Research, College of Biomedical & Life Sciences, Cardiff, 5Samantha Dickson Brain Cancer Unit, UCL Cancer Institute, London, United Kingdom, 6Helen Diller Family Comprehensive Cancer Center, University of California, San Francisco, United States

Background: Acute promyelocytic leukemia (APL) is driven by the oncopogene PML/RARA, which is generated by fusion of the promyelocytic leukemia (PML) and retinoic acid receptor alpha (RARA) genes, and which strongly interferes with downstream signalling and the architecture of multiprotein structures known as PML nuclear bodies (NBs). NB disruption is a diagnostic hallmark of APL; however, the importance of this phenomenon has only been studied in vitro.

Aims: The aim of this study was to decipher the impact of Pml NB disruption in APL pathogenesis.

Methods: We engineered a knock-in mouse model with NB disruption achieved through mutation of key zinc-binding cysteine residues (C62A/C65A) in the P56 domain.

Results: While no leukemias or tumors developed in PmlC62A/C65A mice, the forced dimerization of RARα - mediated artificially by linking RARα to the dimerisation domain of the Nfkb p50 subunit - in cooperation with NB disruption was associated with doubling in the rate of leukaemia (p<0.0001), with a reduced latency period (p=0.008). Moreover, response to targeted therapy with ATRA significantly increased the survival period (p=0.008). Using DNA repair reporter assays, we demonstrated that DNA repair via both non-homologous end joining (NHEJ; p=0.01) and homologous recombination (HR; p=0.006) pathways was less efficient in PmlC62A/C65A primary cells than in PmlWT cells. Importantly, using a PML-RARA-inducible cell line, comparable defects in the NHEJ and HR pathways, which were PML-RARα dependent, were identified. These data were also supported by an increase in sister-chromatid exchange (p<0.0001) and chromosome abnormality (p=0.0002) rates in the context of PmlC62A/C65A versus PmlWT. Interestingly, the kinetics of repair of ionising radiation (IR)-induced DNA double-strand breaks, assessed by analysing Foci size and γH2AX foci formation, was not affected. None of the DNA repair players analysed (e.g. Blm, Rad51 and S3BP1) failed to form foci in response to IR. However, their basal levels of foci were significantly greater in the presence of PmlC62A/C65A (p<0.04; quantified using Amnis ImageStreamX Mk II imaging flow cytometer). Additionally, we found that Rad51 foci showed a significant reduction in size post IR in PmlC62A/C65A compared to PmlWT, with expression of IR, Rad51 co-localisation and interaction with γH2AX.

Summary/Conclusions: Our study highlights the importance of re-formation of NBs for an efficient response to targeted therapy, the significant contribution
of Pmi NB to the effectiveness of DNA damage repair processes, and the manner in which their disruption mediated by the PML-RARα oncoprotein can assist APL pathogenesis.

DECIPHERING THE ONCOGENIC NETWORK OF PRC2 LOSS GUIDED LEUKEMOGENESIS
D. Schneidewind, D. Swaraz2-3, S. Knoll1, J.-H. Klußmann1, D. Heckl1, *1Pediatric Hematology & Oncology, *2Experimental Hematology, 3Hematology, Hemostasis, Oncology and Stem Cell Transplantation, Hannover Medical School, Hannover, Germany

Background: Loss of function mutations in EZH2 (including the chromosomal abnormalities -7/-7q) and other PRC2 subunits have been identified in adults with MDS, MPN and AML. Moreover children with JMML and up to 30% of children with Down syndrome related AML present with mutations in PRC2 subunits. Since myeloid neoplasms are elicited by accumulation of cooperating mutations we aim to study these mutations in the context of their respective roles in dictating clinical courses guiding transformation, we set out to decipher the oncogenic network guided by loss of PRC2-activity.

Aims: Through identification of collaborating mutations driving AML with loss of PRC2 function followed by molecular profiling we aimed to identify novel collaborating mutations.

Methods: To model the complex interplay of mutational networks we performed CRISPR-Cas9 screenings with oncogene/tumor suppressor pools in vitro and in vivo. Cellular resources generated were subjected to mutational and molecular profiling.

Results: To this end, a 96-well based CRISPR-Cas9 immortalization assay allowing fast and quantifiable genetic cooperation screenings was established. Four out of six CRISPR-Cas9 pools tested —comprised of five genes each and representing 148 mutation combinations- reproducibly transformed LSK cells with distinct clonal output. Transplantation of in vitro immortalized clones yielded robust engraftment with multi-lineage contributions in mice but no overt leukemia was detected, indicating that induced mutations select for a preleukemic state in vitro. We thus tested every oncogene/tumor suppressor pool from the in vitro setting in a murine bone marrow transplantation model with freshly transduced LSK cells which resulted in robust induction of leukemia. Analysing the mutational spectrum of derived clones we were able to raise a list of potential partners cooperating with EzH2 loss, which highlighted Nf1 (Ras-signaling), loss of Dmnt3a, and loss of Runx1 as cooperating partners, whereas loss of cohesin complex subunits (Smc3, Stag2) seems to be dispensable during the induction of EzH2-loss guided leukemogenesis. To define oncogenic dependencies in myeloid malignancies with PRC2-loss we analysed gene expression spectra of the generated samples. While in vitro transduced clones presented with distinct expression signatures clearly separating from controls a partially overlapping expression signature could be established. Through identification of these expression signatures and the resulting gene expression signature, which will be validated in a CRISPR-Cas9 knock-out screening we aim to identify novel therapeutic targets in AML.

Summary/Conclusions: Our study highlights the power of the CRISPR-Cas9 system to probe oncogenic interaction. Mutational CRISPR screenings in vivo, and a newly established in vitro CRISPR-Cas9 immortalization assay for high throughput screening of sgRNA pools, delivered potential cooperating partners of EzH2 loss in AML, and provides rich cellular resources to identify molecular mechanisms of oncogenic synergies and dependencies.

ACUTE MYELOID LEUKEMIA EVOLUTION CAN BE RECONSTRUCTED BY ANALYSIS OF NON-LEUKEMIC CELLULAR SUBCOMPARTMENTS AND MULTI-LINEAGE ENGRAFTED MICE
B.R.M. Saeed1, L. Manta1, S. Raffel1-2, P.T. Pyl3, W. Wang1, V. Eckstein1, A. Trumpf2, W. Hölzl1, W. Hölzl1
1Internal Medicine V, Heidelberg University Hospital, 2Division of Stem Cells and Cancer, German Cancer Research Center (DKFZ) and Heidelberg Institute for Stem Cell Technology and Experimental Medicine (HI-STEM GmbH), 3Mult-omics and statistical computing, European Molecular Biology Laboratory (EMBL), Heidelberg, Germany

Background: Hematopoietic Stem Cells (HSC) isolated from patients with Acute Myeloid Leukemia (AML) have been shown to carry leukemia-specific mutations leading to the concept of pre-leukemic HSC. In order to understand the evolution from multi-potent pre-leukemic HSC to fully transformed AML, an accurate molecular comparison of patient matched HSC and leukemic cells is essential. Recently we have shown that functionally normal HSC can be separated from a subgroup of AML patients using the surface marker combination CD34+CD38+ and high ALDH enzyme activity (CD34+CD38+ ALDH*).

Aims: In this study we aim to understand the leukemic evolution from pre-leukemic HSC to fully transformed AML.

Methods: Whole exome sequencing (WES) of 12 diagnostic AML samples with the matched germ-line controls (T cells or buccal swab) was performed. Leukemia-specific mutations were identified according to specific criteria (Allele Depth >20, Support >20, Score >80, SIFT-coefficient >0.20, coverage >10 reads, support >2 reads, and GMAF <0.05) and validated. Identified leukemia-specific mutations were tracked in different cellular compartments (T- and B-cells) as well as in single HSC derived from diagnostic AML samples. To test the functional properties of pre-leukemic HSC in vivo, we transplanted bulk AML in NOD/SCID-IL2γnull (NSG) mice and analyzed human subpopulations (myeloid and lymphoid) of multi-lineage engrafted animals for the presence of leukemia-specific mutations.

Results: WES identified 64 AML-specific mutations. Most cases (8 out of 12) showed 4-6 AML specific mutations per sample (1-18 mutations/AML) including mutations in genes that are recurrently mutated in leukemia yet (NRAS, KIT). Tracking of AML-specific mutations in non-leukemic T- and B-cells showed that some AML mutations like DNM3TA, IDH1, IDH2, EZH2 and ZNF536 were already detectable in T- and B-cells indicating their pre-leukemic status. Furthermore, analysis of multi-lineage engrafted xenografts detected leukemia-specific mutations in human myeloid and lymphoid sub-compartment suggesting that these animals were engrafted from functionally normal pre-leukemic HSC. To reconstruct the sequence of pre-leukemic mutations single-cell HSC were sequenced and the resulting colonies analyzed for the presence of the respective leukemia specific mutations. Based on the different mutational data, combined with the cellular context in which these were detectable the leukemic evolution of most patients could be reconstructed. In one patient we detected a DNM3TA mutation in myeloid and lymphoid cells, whereas NPM1 and FLT3-ITD mutations were only detectable in leukemia cells proving the pre-leukemic status of DNM3TA in this case. In another patient we found DNM3TA and IDH2 in T- and B-cells whereas TRIP13 and RPL57A mutations were only detectable in leukemia cells. By analyzing colonies from single cell HSC we were able to detect complex pre-leukemic hierarchies with one example in which a ZNF536 mutation could be identified as initiating event that hasn’t been described in leukemia yet.

Summary/Conclusions: We can identify leukemia specific mutations including mutations in genes that haven’t been described in AML yet. Tracking of these mutations in various non-leukemic cellular compartments including HSC and multi-lineage engrafted mice allows reconstruction of the individual leukemic evolution. A better understanding of these processes may pave the way for new treatment strategies with the aim to target the relevant leukemic mutations.

P180

THE ESSENTIAL ROLE OF THE ENHANCERS OF POLYCOMB EPC1 AND EP2C IN MLL-AF9 ACUTE MYELOID LEUKAEMIA IS A ‘COMPLEX’ STORY
N. Mannion1,*, X. Huang2, 1Paul O’Gorman Leukaemia Research Centre, 2Paul O’Gorman Leukaemia Research Centre, Institute of Cancer Sciences, MVLS, University of Glasgow, Glasgow, United Kingdom

Background: The Enhancers of Polycomb (EPC) proteins EPC1 and EPC2 are essential for the survival of MLL-AF9 rearranged acute myeloid leukemia (AML). Most importantly, loss of EPC1 or EPC2 in MLL leukemia stem cells, but not normal hematopoietic stem cells and progenitor cells, leads to the induction of cellular apoptosis. To date little is known about the functional contribution of EPC1 and EPC2 in AML. EPC1 and EPC2 are two major chromatin modifying complexes encompassing opposing epigenetic activities and both are known to be deregulated in AML. A recent study identified a unique subset of human malignancies due to the homologous chromatin regulatory proteins EPC1 and EPC2 in AML in search for novel therapeutic targets.

Methods: Mass spectrometry (MS) analysis was performed on immunoprecipitated protein using EPC1 antibody from human THP1 MLL-AF9 AML cell line. Chromatin immunoprecipitation (ChIP) was performed using HighCell ChIP Kit and iPure kit V2 (Diagenode) followed by NextSeq500 Illumina sequencing in THP1 cells. ChIP enriched regions were identified using SICER peak calling and ChIPpeakAnno. Lentiviral supernatants were prepared and THP1 cells were infected with viral particles containing pLKO.1 puro lentiviral vector expressing shRNAs. RNA was extracted 72 hr following lentiviral transductions and whole transcriptome sequencing was performed. DESeq2 was used for differential expression analysis.

Results: MS analysis identified the core NUA4 complex components (TIP60, ING3, RUVBL1, RUVBL2, EP400 and DNA1) and also revealed additional DNA and histone modifying shRNAs. RNA was extracted 72 hr following lentiviral transductions and whole transcriptome sequencing was performed. DESeq2 was used for differential expression analysis.

Results: MS analysis identified the core NUA4 complex components (TIP60, ING3, RUVBL1, RUVBL2, EP400 and DNA1) and also revealed additional DNA and histone modifying shRNAs. RNA was extracted 72 hr following lentiviral transductions and whole transcriptome sequencing was performed. DESeq2 was used for differential expression analysis.

Summary: The role of the EPC proteins in AML is not yet clear. EPC1 and EPC2 are essential for the survival of AML stem cells and their loss leads to the induction of cellular apoptosis. Further work is needed to identify how EPC1 and EPC2 contribute to the survival of AML stem cells.
histone methylation and acetylation profiles following lentiviral shRNA knockdown (KD) of EPC1 or EPC2 in THP1 cells. Interestingly, we find significant changes in histone H3K27 trimethylation levels as well as changes in the levels of histone H3 and H4 acetylation following KD of either EPC1 or EPC2 expression. Notably, the identified regions demonstrating changes in histone H3K27me3 levels are enriched for PRC2 target genes. RNA sequencing followed by gene-set enrichment analysis indicated significant transcriptional changes in PRC2 regulated genes following lentiviral shRNA knockdown of EPC1 or EPC2. Meta-analysis of this PRC signature identified a sub-group of genes that are directly regulated by the EPC complex which include the monoyctic differentiation inducer MAFB, the H2A ubiquitin ligase TRIM37 and the pro-apoptotic tumor suppressor CMTM3.

Summary/Conclusions: Our data suggests that EPC1 and EPC2 are required for the recruitment of certain chromatin proteins to form PRC-associated complexes which are essential for the maintenance of an AML epigenetic signature and an aberrant transcriptional profile that supports leukemia stem cell survival. We have identified and characterized the EPC complex components in human AML. Additionally, we have refined a subgroup of PRC target genes that are regulated by the EPC complex which represent potential novel therapeutic targets in human AML. Overall we present a comprehensive analysis of the aberrant epigenomic landscape of THP1 MLL-AF9 AML cells in relation to EPC1 and EPC2 and provide new insight into their deregulated role in AML.

STROMA-DERIVED FACTORS STIMULATE JAK/STAT SIGNALING IN AML CELLS RESULTING IN RESISTANCE TO BCL2 INHIBITOR VENETOCLAX
R. Karjalainen1,2, M. Popa3, M. Liu1, K-K. Javarappa1, M. Kontro1,2, A. Parsons1, K. Pörkkä1,2, K. Wennerberg3, E. McCormack2,2, B.T. Gjertsen3, C.A. Heckman4
1Institute for Molecular Medicine Finland, FIMM, Helsinki, Finland, 2Centre for Cancer Biomarkers CCBIO, Department of Clinical Science, University of Bergen, Bergen, Norway, 3Hematology Research Unit Helsinki, University of Helsinki, 4Department of Hematology, Helsinki University Hospital Comprehensive Cancer Center, Helsinki, Finland.

Background: The bone marrow (BM) microenvironment is known to protect AML cells from drug therapy. We showed earlier that conditioned medium (CM) from the BM stromal cell line HS-5 increased cell viability and led to resistance to specific drug classes.

Aims: Here, we investigate the mechanisms governing the BM stromal cell induced resistance to venetoclax and its reversal by ruxolitinib.

Methods: Phospho-flow analysis was done by stimulating AML patient cells with GM-CSF, G-CSF, IL-6, IL-8 or MIP-3α (10 ng/mL) for 20 min, after which the cells were stained with Alexa 647-anti-phospho-Stat5 (pY694), PE188 CF594-anti-phospho-Stat3 (pY705), BV421-anti-phospho-Akt (pS473) and PE-anti-phospho-Erk1/2 (pT202/pY204). For co-culture and transwell assays AML cells were added directly to MSCs from AML patients or separated by a 0.4 μm pore membrane. Vehicle (DMSO), ruxolitinib (300 nM), venetoclax (100 nM) or their combination were incubated for 48h and AML cells labeled with PE-Annexin V, 7AAD, PE-Cy7-CD34, BV605-CD45. In vivo drug efficacy was tested on NSG mice inoculated i.v. with MOLM-13*AML cells. Mice were divided into control, venetoclax (25 mg/kg, i.p.), ruxolitinib (50 mg/kg BID, p.o) and combination groups (all n=6) and treated for 3 weeks, 5 days a week with 2 days off.

Results: To identify the factors contributing to BM mediated drug resistance of AML cells, we analyzed the effect of IL-6, IL-8, MIP-3α, GM-CSF and G-CSF, cytokines enriched in the HS-5 CM, on proliferation of MNCs collected from AML patients. GM-CSF and to some extent G-CSF alone could induce resistance to venetoclax similar to CM that we showed earlier to reduce sensitivity to BCL2 inhibitors. To identify the impact of stroma-derived factors on cellular signaling we stimulated AML patient cells with CM and analyzed the phosphorylation of STAT3, STAT5, ERK and AKT. Compared to control conditions, CM rapidly induced phosphorylation of STAT5 in primary AML cells. When the effect of individual cytokines was tested, we noted that GM-CSF and G-CSF alone could mimic the effect of CM on cellular signaling. Gene expression data showed the receptor for GM-CSF (CSFR2A) is more highly expressed in AML patient cells compared to healthy controls. Taken together, these results show that cytokines such as GM-CSF from BM stromal cells increase JAK/STAT signaling, which may lead to enhanced survival of AML cells. To determine whether the protective effect of stroma on BCL2 inhibition was dependent on cell-to-cell interactions we cultured AML patient cells either in direct contact with MSCs or separated from stroma with a 0.4 μm pore membrane. 48h treatment with 100 nM venetoclax did not result in significant reduction of CD34+ AML cells regardless of whether AML cells were directly cultured with stroma or separated by a membrane, further indicating that stroma-derived soluble factors are sufficient to reduce sensitivity to venetoclax. Since the most abundant cytokines secreted by HS-5 cells, GM-CSF and G-CSF led to increased phosphorylation of STAT5, a downstream effector of JAKs, we tested a combination of venetoclax and JAK1/2 inhibitor ruxolitinib. We found that ruxolitinib potentiated sensitivity to venetoclax when tested with AML patient cells in HS-5 CM and in co-culture and transwell assays. Significantly, the combination was more effective at reducing tumor burden in a xenograft mouse model of AML than either drug alone.

Summary/Conclusions: In conclusion, our data demonstrate that BM secreted soluble factors drive cytoprotection against BCL2 antagonist venetoclax that can be overcome by combined blockade of JAK/STAT and BCL2 pathways with ruxolitinib and venetoclax in ex vivo co-culture models and in vivo in an AML mouse model.

IDENTIFICATION OF NOVEL GENE FUSIONS IN ACUTE MYELOID LEUKEMIA WITH COMPLEX KARYOTYPE USING RNA SEQUENCING
F. G. Rücker1, X. Gong2, A. Dolnik1, M. Hoyos1, S. Grasedieck1, J. Bischocko2, T. Blätte1, J. Swoboda1, A.S. Pollack2, A. Turchiano1, H. Döhner1, K. Döhner1, J.R. Pollack2, L. Bullinger1
1Department of Internal Medicine III, University Hospital of Ulm, Ulm, Germany, 2Department of Pathology, Stanford University, Stanford, United States

Background: Acute myeloid leukemia with complex karyotype (CK-AML), defined as having ≥3 acquired cytogenetic aberrations in the absence of WHO-defined recurring translocations or inversions, represents about 15% of
adult AML cases. Despite having poor outcomes, CK-AML is the least understood molecular lesion, except for the finding that about two-thirds of cases carry TP53 alterations. In particular, because cytogenetic alterations appear to be distinct among different patients, it is unclear whether they are cause of leukemogenesis, or merely reflect a state of genomic instability.

**Aims:** We have hypothesized that cytogenetic aberrations in CK-AML create genetic lesions that are recurrent across patients, notwithstanding distinct cancer genes that contribute to leukemogenesis in individual patients. Therefore, we performed a transcriptome analysis using Illumina paired-end (101bp×2) RNA sequencing of 65 CK-AML cases to identify gene fusions using multiple independent algorithms (as paired reads that flank, or single-reads that span fusion junctions) that are independent across patients, along with a novel fusion prediction method. Identified gene fusions were in part independently validated by array-based genomic profiling and/or long range PCR obtained by use of long-read Oxford Nanopore sequencing technology.

**Results:** We identified 54 gene fusion events in 30 of the 65 cases (46%) with up to four fusions per case. All fusions are supported by 10-50× junction-spanning paired reads, and the 5' and 3' fusion junctions are independently predicted as fusion breakpoints in genomic DNA from array-based genomic profiling and/or long range PCR, respectively. About 35% of the fusions were in-frame, encoding chimeric proteins. The remaining encodes either C-terminally truncated 5' fusion partners, or else N-terminally truncated (or rarely full-length) 3' fusion partners. In 65% of cases, the 5' partner contributed only the 5'UTR. In many instances, the fusions are predicted to lead to the overexpression or chimeric activation of known or putative novel cancer genes. Of the 54 fusions, only three (RUNX1-MECOM, MN1-ETV6, and ETV6-MN1) were previously reported in AML. The most frequently affected genes were RUNX1 (n=5), KMT2A, and MECOM (n=3 each). Identified gene fusions were categorized into six functional fusion clusters. Many of the fusions contained at least one known AML gene (n=16; e.g. RUNX1, MECOM, DEK, ETV6, KMT2A) together with a novel fusion partner, clearly suggesting pathogenic relevance. Other fusions were predicted to disrupt known tumor suppressors (n=4; e.g. TP53, SMAD4) or to activate known oncogenes (n=5; e.g. MLL2). Chimeric fusion proteins encode chimeric proteins of unclear pathogenic relevance, but that could nonetheless encode novel epitopes created by the fusion junction (n=26).

**Summary/Conclusions:** Detailed molecular characterization of CK-AML revealed a high incidence of novel gene fusions in about 50% of cases. The altered genes suggest a more general role in leukemogenesis than reflecting a state of genomic instability. Furthermore, identifying gene fusions in each individual patient might lead to more effective, personalized treatments that target the gene fusion itself, enable immunologic therapies against the fusion junction epitopes, and provide private patient-specific biomarkers to track leukemic burden for the monitoring of disease remission and relapse.

**References:**

ity of protein expression was normalized to actin. That ratio of phosphorylated protein to total protein for FLT3 and STAT5 was determined and normalized to that observed in the D835Y mutation as a positive control. A value of >10% pFLT3 was considered positive. All mutations that resulted in FLT3 phosphorylation were subsequently evaluated for inhibition by crenolanib and quizartinib following 60-minute exposure to the compounds.

Results: All ITD, non-ITD and non-AML FLT3 mutations were evaluated for autonomous FLT3 and STAT5 phosphorylation. Eleven mutations resulted in pFLT3 and pSTAT5, including 4 mutations with >50% pFLT3. All mutations that demonstrated aberrant pFLT3 also had aberrant pSTAT5, however a direct correlation of pFLT3 and pSTAT5 was not always observed. Overall, 87% (n=86 patients) of all non-ITD mutations evaluated resulted in autonomous FLT3 activation. Excluding D835 mutations, 64% (n=39) of patients harbored an activating mutation. Many of the mutations that were not found to be activating had the lowest prevalence, often present in only one patient. Evaluation of inhibition of pFLT3 and pSTAT5 demonstrated that in every case of aberrant activation, crenolanib resulted in potent inhibition of phosphorylation of FLT3 and STAT5 with an IC50 range of 1.3-13.9 nM and 0.6-6.5 nM respectively. Many of the mutations tested were exclusively sensitive to crenolanib, with 9 of 10 mutations tested demonstrating an IC50 of pFLT3 inhibition ≤5.6 nM. Inhibition of downstream kinases is necessary for optimal efficacy of any FLT3 inhibitor and phosphorylation of STAT5 was potently inhibited by crenolanib in all cases. Quizartinib inhibited pFLT3 and pSTAT5 with an IC50 range of 1.8-151.7 nM and 1-33.9 nM respectively, demonstrating less effective inhibition specifically at mutations including D835Y, D839E, N670K, M664I.

Summary/Conclusions: We have previously presented that FLT3 mutations, including novel mutations in addition to the FLT3/ITD and D835, are prevalent in children and young adults with AML. Here we demonstrate that many of the non-ITD/835 mutations also result in aberrant FLT3 phosphorylation and are amenable to inhibition by FLT3 inhibitors. Crenolanib resulted in potent inhibition of FLT3 and downstream STAT5 in all mutations tested. This data supports expanding the cohort of pediatric patients with activating FLT3 mutations who may benefit from FLT3 inhibitor therapy beyond those with FLT3/ITD.

THE BCL-2 INHIBITOR VENETOCLAX INHIBITS NRF2 ANTIOXIDANT PATHWAY ACTIVATION INDUCED BY HYPMETHYLATING AGENTS IN ACUTE MYELOID LEUKAEMIA

L.X.T. Nguyen1, A. Kahval1, E. Troead1, B. Kumar1, S. Forman1, G. Marucc1, V. Pullarkat2

1City of Hope Medical Center, Duarte, United States, 2Hematology, City of Hope Medical Center, Duarte, United States

Background: The selective Bcl-2 inhibitor Venetoclax (ABT-199) has shown potential as a single agent in trials against Acute Myeloid Leukemia (AML) in preclinical and early clinical studies and impressive results have been achieved using the combination of hypomethylating agents (HMA) with venetoclax suggesting synergy between these agents. Induction of Reactive Oxygen Species (ROS) is important for the cytotoxicity of various AML therapies including HMA. Induction of ROS by various cytotoxic therapies concurrently activates the Nrf2 antioxidant response pathway which in turn results in induction of antioxidant enzymes that neutralize ROS. Upon ROS induction, the transcription factor Nrf2 is released from its adaptor protein Keap1 in the cytoplasm thereby Nrf2 enters the nucleus and binds to antioxidant response element sequences in the promoters of various genes. Nrf2 pathway activation has been shown to mediate chemoresistance in various cancers including AML. Low ROS levels have been shown to be a hallmark of leukemia stem cells and are critical to their self renewal capacity. In this study, we examined whether Nrf2 inhibition is an additional mechanism responsible for the marked antileukemic activity in AML seen with the combination of HMAs and venetoclax.

Aims: To determine the effect of venetoclax on ROS levels after HMA exposure in AML cells and to examine the effect of Bcl-2 inhibition on ROS antioxidant pathway activation in response to HMA

Methods: The effect of combination of venetoclax and HMA on ROS levels and apoptosis was measured by flow cytometry. Effect of venetoclax and HMA on Nrf2 nuclear translocation was analyzed by immunostaining after cellular fractionation. Effect of venetoclax treatment on the association of Bcl2 with Nrf2, which results in dissociation of the Nrf2 complex and targets Nrf2 to ubiquitination and proteosomal degradation.

Results: Our results demonstrated that combination of HMA with venetoclax augmented cellular and mitochondrial ROS induction and apoptosis compared to treatment HMA alone. Treatment of AML cell lines as well as primary AML cells with venetoclax resulted in increased nuclear translocalization of Nrf2 (Figure 1) and induction of downstream antioxidant enzymes including HO-1 and NQO1. Immunofluorescence studies confirmed the inhibition of nuclear translocation of Nrf2 by venetoclax. Immunoprecipitation studies indicated that Bcl-2, Keap1 and Nrf2 associate in a protein complex in the cytoplasm and that treatment with venetoclax leads to dissociation of Bcl-2 from the Nrf2/Keap1 complex and targets Nrf2 to ubiquitination and proteosomal degradation.

Background: The complex pathogenesis of cancer often necessitates combination therapies to optimize patient benefit. Thus, we investigated preclinical combinations of SY-1425 (tamibarotene) and other agents to build on the monotherapeutic strategy with SY-1425 in biomarker selected AML and MDS patients (Phase 2 study, NCT02807558). Based on the RARA mediated myeloid gene activation of SY-1425, epigenetic priming with hypomethylating agents (HMAs) and CD38 induction were explored.

Aims: We sought to investigate mechanistically informed combinations of SY-1425 and HMAs and their novel agent in AML and MDS. We hypothesized that the HMA azacitidine could prime AML cells for SY-1425 mediated reprogramming by relieving aberrant methylation of RARA target genes and that strong upregulation of the maturation marker CD38 in AML cells by SY-1425 could induce sensitivity to the anti-CD38 therapeutic antibody daratumumab (DARA).

Methods: HMA synergy was tested in vitro in AML cell lines over a range of concentrations for SY-1425 and azacitidine. In vivo studies used a disseminated patient derived xenograft (PDx) model of AML expressing high levels of RARA. SY-1425 induction of CD38 was assessed by H3K27ac ChIP-seq, RARA ChIP-seq, and CD38 mRNA expression. Antibody dependent cell-mediated cytotoxicity (ADCC) was tested in an ex vivo co-culture model of human NK cells and AML cell lines.

Results: SY-1425 acts as a repressive transcription factor until bound by SY-1425 leading to potent, targeted activation of myeloid genes. HMAs can further prime this activation by depleting repressive methylation of these target genes. The combination of SY-1425 and azacitidine showed synergy in RARA-high AML cell lines, but not in RARA-low AML cell lines, with combination indices less than 0.5. Co-administration in a RARA-high AML PDx demonstrated superior reduction of tumor burden (<1% detectable tumor cells) vs either treatment alone (49% reduction in SY-1425 and 8% with azacitidine). Various combination regimens evaluated in the PDx model over two cycles (56 days) found that 1 week of azacitidine followed by 3 weeks of SY-1425 maximized for anti-tumor activity (<5% AML cells in periphery, bone marrow and spleen) and tolerability (<8% weight loss). RARA binds directly to the CD38 locus and induces H3K27 acetylation at this locus via recruitment of the mediator complex, CBP, and mRNAs transcripts in RARA-high models. SY-1425 treatment of four RARA-high AML cell lines and three RARA-high primary AML patient samples induced cell surface CD38 to high levels comparable to those of DARA sensitive multiple myeloma cells. In contrast, no CD38 induction was observed in RARA-low cell lines. AML cell lines treated with SY-1425 and DARA were six fold more sensitive to NK cell mediated ADCC compared to single agent controls and exhibited a 5-10 fold increase in NK cell dependent activation measured by IFNγ secretion.

Summary/Conclusions: The RARA biomarker dependent synergy with azacitidine and SY-1425 is hypothesized to work through hypomethylated based priming of myeloid differentiation by SY-1425 agonism of formerly repressed RARA target genes. Since CD38 is one of the most strongly induced RARA target genes in response to SY-1425, AML blasts can be sensitized to DARA in a biomarker dependent manner. The preclinical synergistic effects and anticipated non-overlapping clinical toxicity profiles of the respective agents provide a strong rationale for clinical evaluation of each SY-1425 combination in biomarker selected AML and MDS patients.

FLT3 INHIBITION OVERCOME RESISTANCE TO THE BCL-2 SELECTIVE ANTAGONIST, VENETOCLAX, IN FLT-ITD MUTANT AML MODELS

D. Sampath 1,*, R. Mali 1, E. Lasater 1, K. Doyle 2, R. Malla 1, E. Boghaert 2, P188
1Translational Oncology, Genentech, South San Francisco, 2Oncology, Abbvie, North Chicago, United States

Background: FLT3 internal tandem duplication (ITD) mutations account for ~20-25% of adult AML cases and are associated with worse prognosis. Although FLT3 inhibitors show clinical activity, relapse occurs quickly. Veneto- clax is a potent, selective inhibitor of the anti-apoptotic protein BCL-2 that demonstrated monotheraputic activity in relapsed/refractory AML (ORR 19%); however, no activity was seen in FLT3 mutant cases (Konopleva, Can Disc and Ant 2013). In addition, FLT3 ITD regulation is complex between NRPs and RPs. Taken together, our preliminary data suggests that already at diagnosis, AML cells display an epige- nomic fingerprint associated with the development of AML relapse during the course of disease. We are currently validating these data.

Methods:

SY-1425 could induce sensitivity to the anti-CD38 therapeutic antibody daratumumab (DARA) and that strong upregulation of the maturation marker CD38 in AML cells by SY-1425 mediated reprogramming by relieving aberrant methylation of RARα target genes. Since CD38 is one of the most strongly induced RARα targets in response to SY-1425, AML blasts can be sensitized to DARA in combination with quinza- timin, a potent FLT3 inhibitor, resulted in synergistic anti-tumor effects in FLT3-ITD+ AML models.

Results: Sensitivity to venetoclax was initially assessed in vitro. Dose depend- ent growth inhibition and induction of apoptosis was observed in the MV4;11, Molm13 and HL60 cell lines following 48hr venetoclax treatment, with the MV4;11 cell line most sensitive. Modulation of BCL-2, BCL-XL and MCL-1 expression by FLT3 inhibition was determined following 8-24hr treatment with quinza-tinib. Quinza-tinib reduced BCL-XL and MCL-1 protein, but not BCL-2, in the FLT3-ITD+ cell lines. Quinza-tinib had no effect on expression of these three proteins in the QT3 wt cell lines. In the FLT3 wt cell lines, the combination of SY-1425 and venetoclax in vitro, cell lines were treated for 48hrs with venetoclax, quinza-tinib or the combination. Combination treatment led to significant reduction in prolif- eration and increased apoptosis in the FLT3-ITD+ cells compared to either single agent. FLT3 wt cell lines were sensitive to quinza-tinib as a single agent however induction with venetoclax was not synergistic. The combination of quinza-tinib and venetoclax showed synergy in the MV4;11 xenograft model. Together, this data underscores the dependency of these cells on the FLT3-ITD mutation for growth and its use as a predictive biomarker of veneto- clax resistance. To determine the dependency of FLT3-ITD+ cells on other anti-apoptotic proteins, cell lines were treated with selective antagonists to BCL-XL (A1331852) or MCL-1 (A1210477) in combination with venetoclax. Treatment with either antagonist in combination with venetoclax reduced the growth of the cell lines compared to venetoclax alone. However, co-inhibition of BCL-XL or MCL-1 and FLT3-ITD did not reduce cellular growth compared to quinza-tinib alone, indicating that maximum anti-tumor responses may be achieved when all three anti-apoptotic proteins are targeted.

Summary/Conclusions: Quizartinib treatment in FLT3-ITD+ AML models decreased expression of the anti-apoptotic proteins BCL-XL and MCL-1 and synergized with venetoclax in vitro and in vivo at clinically relevant doses for each compound. These data suggest that co-targeting FLT3-ITD with selective inhibitors and BCL-2 with venetoclax induces apoptosis to a greater extent than FLT3 inhibition alone. Importantly, our preclinical data supports further clinical investigation of this combination to treat FLT3-ITD+ AML.

1Hematology, 2Epidemiology and Biostatistics, 3Radiology, VU University Medical Center, Amsterdam, Netherlands

Background: Only 30-40% of acute myeloid leukemia (AML) patients survive five years after diagnosis. This extreme poor prognosis is mainly caused by treatment failure due to chemotherapy resistance. Leukemic stem cells (LSCs) are thought to be major determinants of AML recurrence due to their potential for self-renewal and chemotherapy resistance. LSCs co-reside with normal CD34+/CD38-, hematopoietic stem cells (HSCs) in the AML bone marrow. Increasing the dose of chemotherapy drugs may eliminate these chemotherapy resistant cells, however will inevitable result in the non-specific elimination of HSCs, delaying or even preventing the recovery of normal hematopoiesis after therapy. To significantly improve the outcome of AML patients, the discovery of alternative therapies that specifically eliminate LSCs while sparing HSC are urgently needed. To develop such therapies, accurate quantification of genes differentially expressed between LSCs and HSCs and between LSCs and the AML bulk is crucial.

Aims: To identify specific therapeutic strategies that have the potential to elim-inate AML relapse-initiating cells.

Methods: We generated gene expression profiles of HSCs, LSCs and leukemic progenitors all derived from the same AML bone marrow and identified Insulin growth factor binding protein 7 (IGFBP7) as one of the top differentially expressed genes. As low IGFBP7 expression is a feature of LSCs, we hypothesized that...
decreased expression of IGFBP7 might be associated with decreased chemotherapy sensitivity. To this end, we generated cell lines with IGFBP7 knockdown and subjected the cells to chemotherapy. Furthermore, to test whether increasing the IGFBP7 levels might be a strategy to deplete leukemic (stem) cells, we overexpressed IGFBP7 in or added recombinant human IGFBP7 (rhIGFBP7) to primary AML cells and measured clonogenic capacity, differentiation and cell survival in vitro. To study the effect of IGFBP7 on AML cell survival and engraftment potential in vivo, primary AML cells were transplanted into immune deficient mice and the mice were subsequently treated with rhIGFBP7. To study the effect of rhIGFBP7 on LSC survival, human AML cells derived from the first transplanted mice were re-transplanted into secondary recipients and engraftment and survival of the mice were monitored.

Results: Knockdown of IGFBP7 results in reduced sensitivity to chemotherapy and comparing matched diagnosis and relapsed AML samples showed that IGFBP7 expression is frequently downregulated at relapse, suggesting a survival advantage of IGFBP7low AML cells during chemotherapy treatment. Importantly, enhancing cytoplasmic or extracellular IGFBP7, by overexpression or addition of rhIGFBP7, resulted in induction of differentiation and apoptosis, increased sensitivity to chemotherapy and inhibited AML blast and leukemic stem/progenitor cell survival in vitro and in vivo. IGFBP7 had no influence on the survival of normal hematopoietic (stem) cells. Moreover, treatment with rhIGFBP7 can add to chemotherapy treatment by elimination of chemotherapy resistant refractory AML (stem) cells.

Summary/Conclusions: Altogether, these data suggest that addition of IGFBP7 to the currently used chemotherapy regimens might be a promising strategy to specifically eradicate LSCs and decrease AML relapse rates.

ONGOING PHASE 2 CLINICAL TRIAL OF SL-401 IN PATIENTS WITH BLASTIC PLASMACYTOID DENDRITIC CELL NEOPLASM: STAGE 1 AND STAGE 2 RESULTS

N. Pemmaraju1,2, K. Sweet3, A. Lane4, A. Stein5, S. Vasu5, W. Blum5, D. Rizzieri6, E. Wang7, M. Ducivi, J. Chen8, S. Shemesh9, P. McDonald8, C. Brooks8, J. Lance10, H. Kantarjian11, M. Konopleva12
1IMD Anderson Cancer Center, Houston, TX, 2H. Lee Moffitt Cancer Center, Tampa, FL, 3Dana-Farber Cancer Institute, Boston, MA, 4City of Hope National Medical Center, Duarte, CA, 5The Ohio State University Medical Center, Columbus, OH, 6Duke University Medical Center, Durham, NC, 7Roswell Park Cancer Institute, Buffalo, NY, 8Stemline Therapeutics, New York, NY, United States

Background: SL-401 is a targeted therapy directed to interleukin-3 receptor α (CD123), a target overexpressed on a variety of cancers including blastic plasmacytoid dendritic cell neoplasm (BPDCN), a highly aggressive malignancy with poor outcomes and unmet medical need.

Aims: This Phase 2 trial is a single-arm, open-label, study designed to generate efficacy and safety data to support potential registration in BPDCN.

Methods: In this ongoing Phase 2 single-arm trial, patients with BPDCN (n=32) or relapsed/refractory (R/R) AML (n=48) received SL-401 as a daily IV infusion at 7, 9, 12, or 16 ug/kg/day for days 1-5 of a 21-day cycle in stage 1. In stages 2 and 3, patients received SL-401 at the dose determined in stage 1.

Results: 32 adult BPDCN patients received SL-401 in stage 1 (n=9) and stage 2 (n=23), including 19 first-line and 13 R/R patients. Stage 3 patients will be reported separately. Median age was 72 years (range: 30-85 years). In stage 1, 12 ug/kg was the highest tested dose for BPDCN; MTD was not reached in BPDCN. Median follow-up was 4.3 months (range: 0.2-22.9 months). ORR of 84% (27/32) was observed in all patients: 96% (18/19) in first-line and 69% (9/13) in R/R. 88% (14/16) of first-line patients treated at 12 ug/kg had a complete remission (CR; n=10), CR with incomplete hematologic recovery (CRI; n=1) or clinical CR (CRC; residual skin disease; n=3) based on investigator assessment. 56% (9/16) of these patients were progression free for 4 to 22.9 months (ongoing), including 3 patients on SL-401 in remission for 18 months (ongoing) and 7 patients who were bridged to stem cell transplant (SCT; 3 acute SCT and 4 allo-SCT). A R/R patient was also bridged to allo-SCT. Overall, most common ≥Grade 3 treatment-related AEs were transaminase elevation (22%) and thrombocytopenia (16%). Safety precautions, including daily monitoring of albumin and body weight during study drug infusions, have been implemented to minimize risk of severe capillary leak syndrome (CLS). Three patients had Grade 5 CLS: BPDCN (7 ug/kg); R/R AML (16 ug/kg); BPDCN (12 ug/kg) out of 118 patients who received SL-401 across all trials and regimens; 3/89 (3.4%) patients of which were enrolled in this clinical trial.

Summary/Conclusions: SL-401 continues to demonstrate single agent activity, including multiple CRs, in patients with BPDCN, with 25% (8/32) of patients bridged to SCT after a major response from SL-401. SL-401 side effect profile consists largely of transaminitis and thrombocytopenia. CLS can be fatal. Side effects have generally tended to decrease in frequency and severity with increasing cycles. Updated data, including detailed safety analysis across all ongoing SL-401 studies will be presented at the meeting.

P192
PROGNOSTIC IMPACT OF SOMATIC MUTATION CLEARANCE IN PATIENTS WITH ACUTE MYELOID LEUKAEMIA

K. Takahashi1, F. Wang1, K. Patel1, C. Bueso-Ramos1, G. Issa1, X. Song1, J. Zhang1, C. Gumbs1, F. Ravandi1, T. Kadia1, N. Daver1, C. DiNardo1, M. Konopleva1, M. Andreff2, J. Cortes1, G. Garcia-Manero1, E. Jabbour1, A. Furlanel1, H. Kantarjian1
1Leukemia, UT MD Anderson Cancer Center, Houston, United States

Background: Persistence of somatic mutations at the time of complete remission (CR) was associated with poor outcome in patients (pts) with AML.

Aims: To analyze differential pattern of mutation clearance based on the genes and affected pathway and to assess prognostic impact of mutation clearance in AML patients.

Methods: We studied 95 pts with AML who were treated with frontline induction and subsequently achieved CR. We sequenced pre-treatment and CR bone marrow samples by targeted capture sequencing of 295 genes (median 280x coverage). We defined 3 levels of mutation clearance (MC) based on variant allele frequency (VAF): 1) MC2.5, persistent mutation with VAF≥2.5%, 2) MC1.0, persistent mutation with VAF<1%, and 3) complete mutation clearance (CMC).

Results: In the pre-treatment samples, we detected 597 mutations in 78 genes in 87 (92%) patients. In the matching CR samples, 62 (10%) and 82 (14%) mutations persisted at VAF>2.5% and ≥1%, respectively, which corresponded to 43 (49%), 34 (39%), and 30 (34%) patients achieving MC2.5, MC1.0 and CMC, respectively. Table 1 shows the differential patterns of MC based on the mutations and pathways. Mutations associated with clonal hematopoiesis of
indeterminate therapy (CHIP), DNA methylation, and splicing pathways had low rate of MC, whereas mutations in transcription factors like RUNX1 or receptor tyrosine kinase (RTK) had high rate of MC. Pts who achieved MC1.0 (median 31.2 vs 12.5 months, P<0.04) or MC2 (median 31.2 vs 12.5 months, P=0.049) had significantly better relapse-free survival (RFS).

Table 1.
Methods: multiple LSC markers on the outcome of AML patients.

Institution and eligible for intensive chemotherapy were enrolled from September 2010 to March 2016. We excluded 10 patients with acute promyelocytic leukemia. This study was approved by the institutional review board of the Ethics Committee and adds to the already described mutually exclusive mutations in germline RUNX1 results from other studies (8). Our study suggests that germline and somatic RUNX1 mutations in AML patients are mutually exclusive, as are several co-occurring pathogenic mutations that contribute to leukemogenesis. Our study adds to the already described mutually exclusive mutations in germline RUNX1 by identifying WT1, CHEK2, CCND3, and others. Similarly, in samples with somatic RUNX1 mutations, we found mutually exclusive mutations in CBL, JAK2, MLL, EZH2 and others, in addition to the previously described IDH1 (8). Further characterization of these results and analyses of additional samples using our whole-exome sequencing and our bioinformatics platform will help us better elucidate the molecular events underlying AML progression and help us establish novel prognostic/therapeutic markers aimed at early intervention in patients, or their family members, who carry RUNX1 mutations.

Background: Acute myeloid leukemia (AML) is believed to originate from a small population of leukemic stem cells (LSCs). Current chemotherapy regimens target the majority of more mature leukemic blasts, but cannot efficiently eliminate LSCs, resulting in early treatment failure and relapse. Thus, the expression of LSC-specific markers could be used as a predictive factor of clinical outcomes in AML patients. Recently, the clinical impact of individual LSC markers has been documented in several reports, but the combined effect of different LSC markers remains unexamined.

1Hematology, Kobe City Medical Center General Hospital, 2Hematology, Institute of Biomedical Research and Innovation Hospital, Kobe City, Japan

Background: Many personalized therapies for acute myeloid leukemia (AML) have been developed targeting specific biomarkers. Unfortunately, the efficacies of these therapies are inconsistent, which may be due to characteristics of residual disease. Thus, full characterization of a sample may require testing with multiple MRD assays, which can be impractical in a clinical setting. We have developed a target capture-based assay (MyMRDTM), which allows characterization of the entire therapeutic AML biomarker repertoire and can inform us better stratification even among patients with intermediate-risk and favorable-risk karyotypes.

Summary/Conclusions: We demonstrated that multiple LSC marker expression predicts poor clinical outcomes in newly diagnosed de novo AML patients, and may facilitate better stratification even among patients with intermediate-risk and favorable-risk karyotypes.

Summary/Conclusions: The incidence of RUNX1 mutations seen in our 482-patient Beat AML cohort (4.3% germline, 6.4% somatic) is consistent with results from other studies (8). Our study suggests that germline and somatic RUNX1 mutations in AML patients are mutually exclusive, as are several co-occurring pathogenic mutations that contribute to leukemogenesis. Our study adds to the already described mutually exclusive mutations in germline RUNX1 by identifying WT1, CHEK2, CCND3, and others. Similarly, in samples with somatic RUNX1 mutations, we found mutually exclusive mutations in CBL, JAK2, MLL, EZH2 and others, in addition to the previously described IDH1 (8). Further characterization of these results and analyses of additional samples using our whole-exome sequencing and our bioinformatics platform will help us better elucidate the molecular events underlying AML progression and help us establish novel prognostic/therapeutic markers aimed at early intervention in patients, or their family members, who carry RUNX1 mutations.

P197 NEXT GENERATION SEQUENCING TARGETED PANEL FOR MINIMAL RESIDUAL DISEASE MONITORING IN ACUTE MYELOID LEUKEMIA

V. Mcclain1, A.R. Carson1, B.A. Patay1, L. Chamberlain1, C. Chander1, S. Zheng1, W. Huang1, O. Kiya1, D. Hubbard2, D. Caguioa2, Z. Xie1, J. Thornes1, T. Stenzel1, J. E. Miller1,2

1Invivoscribe, 2LabPMM LLC, San Diego, United States

Background: Many personalized therapies for acute myeloid leukemia (AML) have been developed targeting specific biomarkers. Unfortunately, the efficacies of these therapies are inconsistent, which may be due to characteristics of residual disease. Thus, full characterization of a sample may require testing with multiple MRD assays, which can be impractical in a clinical setting. We have developed a target capture-based assay (MyMRDTM), which allows characterization of the entire therapeutic AML biomarker repertoire and can inform us better stratification even among patients with intermediate-risk and favorable-risk karyotypes.
the molecular remission status of a patient’s malignancy. This targeted panel can identify the mutations in driver clones that cause relapse in ~90% of all AML patients, as well as common drivers in myeloid proliferative neoplasms (MPN) and myelodysplastic syndromes (MDS).

**Aims:** To establish a sensitive and reliable targeted NGS assay to comprehensively detect and monitor the majority of known driver mutations in AML and myeloid malignancies.

**Methods:** Whole genome libraries, made from DNA extracted from cell lines and clinical samples, were hybridized with MyMRD probes targeting mutation hotspots in 23 genes associated with AML. In addition to single nucleotide variants (SNVs) and indels in 21 of these genes, 5 structural variant (SV) breakpoints in 3 genes were also targeted. Deep-sequenced libraries were sequenced with the MiSeq® platform and analyzed using proprietary Invivoscribe (IVS) MyInformatics™ software. To validate mutations detected by the MyMRD assay, samples were additionally tested with IVS developed capillary electrophoresis (CE) assays and NGS-based assays targeting common mutations in FLT3, NPM1, and RUNX1.

**Results:** The linearity and limit of detection (LOD) of the MyMRD assay were assessed using data generated from controlled cell line DNA containing known AML driver mutations with a range of variant allele frequencies (VAFs). The assay shows strong linearity (R²=0.96 – 0.99) in the entire range of tested VAFs (0.01% – 2%). Overall, we established a LOD of 0.5% for >95% of the targeted sites in the assay with lower LODs for specific mutations of interest (e.g. 0.1% for a 30 bp FLT3 ITD and 0.2% for FLT3 p.D835V). In addition, using clinical samples, we found that all but one sample showed excellent concordance with the standard FLT3 CE assay for variants with VAFs above the CE detection threshold (5%). Sensitivity of the CE assay was nearly doubled when additionally evaluated with IVS FLT3 ITD MRD and NPM1 MRD amplicons which showed 100% concordance with the MyMRD panel assay for variants with VAFs above the MyMRD LOD.

**Summary/Conclusions:** The IVS developed MyMRD targeted panel is a sensitive and reliable assay to monitor residual AML driver mutations. The assay is shown to have excellent linearity and a LOD of 0.5% (tenfold lower than the standard CE assay LOD) at >95% of the targeted sites. Additionally, specific mutations of interest, such as those used for residual disease monitoring (e.g. FLT3 ITD), demonstrate LODs as low as 0.1%. The MyMRD assay provides an accurate method for detecting mutations in multiple targets in patients and can be used to effectively stratify patients for therapy and clinical trials.

**P198**

**IS IT POSSIBLE TO RELIABLY DETECT CLINICALLY-RELEVANT BIALLELIC CEBPA GENE MUTATIONS USING NGS PANELS?**

M. Fernandez-Mercado1,2,*, M.J. Larroyo2, I. Vazquez2, A. Mañé4, F.G. Gracia-Aznárez2, F. Prosper2, M.J. Calasanz3

1Biomedical Engineering, School of Engineering, University of Navarra, 2Molecular Oncology, Biodonostia HRI, Donostia University Hospital, San Sebastian, 3Haematology and Haemotherapy, Clinic of the University of Navarra, Pamplona, 4Haematology and Haemotherapy, Clinic of the University of Navarra, Pamplona, Spain

**Background:** CEBPA gene encodes a leucine zipper transcription factor that is important for normal myeloid cell differentiation. Biallelic CEBPA (biCEBPA) mutations are associated with favourable prognosis in patients with acute myeloid leukaemia (AML); therefore, accurate molecular testing of this gene is crucial in the clinical setting. Molecular pathology labs routinely analyse CEBPA through fluorescence-based multiplex-PCR fragment analysis or, more frequently, Sanger sequencing. Recently, it has been increasingly common to use next-generation sequencing (NGS) technology in the pathology labs, and CEBPA gene is indeed included in the majority of NGS panels commercially available for testing of patients with neoplasias of the myeloid lineage.

**Aims:** We set ourselves to compare the performance of two different NGS targeted sets of mutations (53) (see Methods). However, we found that only 35% of the 3.5 amplicons were covered <500x, and more worryingly, we realised that at least one of those amplicons was shallowly (<100x) covered in 97% of the cases. Indeed both panels showed significantly lower average coverage levels of this gene compared to the panel as a whole (Figure 1). This might not be surprising, since CEBPA is not a CpG-rich region, and therefore its amplification needs tailored PCR conditions, hard to address in the multiplexed PCR step included in their library prep protocols. Therefore, both NGS approaches are prone to miss variants. In contrast, Sanger sequencing protocol (which includes optimized PCR conditions for correct amplification of the CEBPA gene) managed to cover the whole length of the gene. We were able to detect 26 variants affecting 20 AML cases through Sanger sequencing. Cases showing two variants were manually curated (through Chromos or IGV tools) to confirm if they affected different alleles. However, in 6 cases both mutations lay on different amplicons, which made not possible to univocally conclude if and how they were biallelic. These inconclusive cases were subjected to DMSO-Pfu-PCR in order to amplify the whole length of CEBPA coding region, followed by cloning. Colony sequencing showed independent clones harbouring different variants (i.e. bona fide biCEBPA mutations) in the majority of the cases, but crucially, not in all of them. This result highlights the need of implementing techniques able to accurately assess CEBPA biallelism, otherwise than plain calling of more than one variant.

**P199**

**EXPERIENCE WITH MINIMAL RESIDUAL DISEASE MONITORING IN AML WITH RUNX1-RUNX1T1: A STUDY ON 186 PATIENTS**

A. Hoellerl1,1, M. Meggendorfer1, A. Fasan1, W. Kern1, C. Haferlach1, T. Haferlach1

1Munich Leukemia Laboratory, Munich, Germany

**Background:** The cure rate in AML is dependent on patient’s age and performance status, cytogenetics, early blast clearance and sustainable first complete remission. Investigation of minimal residual disease (MRD) is possible by multiparameter-flow cytometry (MFC) or molecular techniques. Recent findings have further depicted a broad spectrum of molecular markers in AML in 99% of pts (TCGA, NEJM, 2013). This broadens the set of targets for MRD monitoring and helps to better individualize treatment strategies. In this analysis we focused on MRD monitoring in RUNX1-RUNX1T1 positive AML in an unselected cohort.

**Aims:** To understand the clinical use of PCR based MRD monitoring in AML with RUNX1-RUNX1T1 fusion.

**Methods:** Since 2005 until 2017 we investigated a total of 186 intensively treated AML patients with RUNX1-RUNX1T1 fusion, 130 of them diagnosed at our laboratory and 56 with follow up samples available. 1448 individual samples were analyzed during the course of disease. We applied quantitative real-time PCR to detect RUNX1-RUNX1T1/ABL ratios. Complete molecular remission (CMR) was defined as one valid qPCR ratio of 0, while low MRD was assigned to patients with a >0 but <0.01 ratio and high MRD was assigned to all patients with a ratio above 0.01. As a comparator log fold change to baseline was independently assessed. Median age was 51 years.
(18-83 years). All patients were treated with standard induction and consolidation protocols.

**Results:** Median time between two investigations was 2.8 months (range for all 0.1-115 months). A complete molecular remission was reached in 90/130 pts (69%) after a median of 5 months. 19/130 (14.6%) pts reached low level MRD and 20/130 (15.4%) high level MRD. Median event free survival (EFS) of patients with CMR was not reached (EFS at 2 years 82%). 16 (18%) of those patients relapsed in the course of follow up with a median time to relapse of 12.7 months (range 4.1 to 38.3 months). Median EFS for MRD low and MRD high patients was 18.4 months and 10.8 months respectively (all 3 groups, p<0.0001). For patients with CMR, rising MRD levels accurately predicted relapse with a median latency of 5.5 months from loss of CMR to relapse. We next used the widely accepted log fold change from baseline to define high and low risk patients in our cohort. 123/130 (95%) patients reached a >3 log fold reduction in \( \text{RUNX1-RUNX1T1/ABL} \) ratio within the first 200 days following first diagnosis. Median EFS for those patients was not reached (EFS at 2 years 66%). The 7/130 (5%) patients with a <3 log fold reduction had a median EFS of 14.7 months (2 groups, p=0.017). A total of 59/185 patients received allogeneic SCT. Among the 130 patients diagnosed at our laboratory 34 (26%) received allogeneic SCT, 12 (9%) were transplanted in first CR and 17 (13%) were transplanted for relapse. Following allogeneic SCT 11/17 patients (65%) reached a second CR with CMR.

**Summary/Conclusions:** Our data shows that MRD testing is routinely performed in \( \text{RUNX1-RUNX1T1} \) AML outside of clinical studies. Defining MRD levels by \( \text{RUNX1-RUNX1T1/ABL} \) ratios resulted in a better classifier for high and low risk patients than log fold change. However, despite CMR 16/90 (18%) patients relapsed with a maximum time from first achievement of CMR of 38.3 months. We conclude that 1) MRD monitoring could serve to guide BMT decisions in \( \text{RUNX1-RUNX1T1} \) AML outside of clinical studies. Defining MRD levels by \( \text{RUNX1-RUNX1T1/ABL} \) ratios resulted in a better classifier for high and low risk patients than log fold change. However, despite CMR 16/90 (18%) patients relapsed with a maximum time from first achievement of CMR of 38.3 months. We conclude that 1) MRD monitoring could serve to guide BMT decisions in \( \text{RUNX1-RUNX1T1} \) positive AML, 2) allogeneic BMT can rescue the majority of relapsed patients and 3) molecular monitoring can reliably identify patients with high risk for relapse.

NUMBER OF TP53 ABNORMALITIES AND THEIR CLINICAL RELEVANCE IN PATIENTS WITH ACUTE MYELOID LEUKEMIA AND MYELODYSPLASTIC SYNDROMES

G. M. Konopleva1, C. Benton1, T. Kadija1, F. Ravandi1, J. Cortes1, N. Daver1, K. Takahashi1, C. DiNardo1, E. Jabbour1, G. Borthakur2, S. Pierce1, C. Bueso-Ramos2, S. Kornblau1, K. Patel2, H. Kantarjian3, M. Andreff4, G. Garcia-Manero1

1Leukemia, 2Hematopathology, The University of Texas MD Anderson Cancer Center, Houston, United States

Background: Mutations in TP53 can be detected in up to 16-19% of patients with acute myeloid leukemia (AML) and myelodysplastic syndromes (MDS). TP53 mutations confer adverse prognosis irrespective of currently available therapies. The clinical impact of the type and number of TP53 abnormalities is unclear.

Aims: To evaluate the prognostic impact of the number of TP53 abnormalities in AML and MDS.

Methods: We evaluated 1401 patients with previously untreated AML or MDS treated at the University of Texas MD Anderson Cancer Center from 2012 to 2016. Sequencing data was obtained by use of a 28 or 53-gene targeted PCR-based next generation sequencing platform. Response was defined following 2003 IWG criteria for patients with AML and 2006 revised IWG criteria for patients with MDS. Generalized linear models were used to study the association of overall response (OR), complete response (CR) and risk factors, Kaplan-Meier produce limit method was used to estimate the median overall survival (OS).

Results: A total of 593 (42%) patients had MDS and 808 (56%) had AML. In a total of 984 (70%) patients, data on therapy with sufficient follow up and response evaluation was available, with 494 (35%) patients receiving therapy with hypomethylating agents (HMAs) and 373 (27%) with chemotherapy regimens. A total of 384 mutations in TP53, involving 208 unique mutations, were detected among 300 (21%) patients with AML (median age 67 years). The overall frequency of detectable mutation, 76 (25%) had 2 and 3 (1%) had 3. Additionally, 188 (13%) patients had TP53 deletions evidenced by presence of monosomy 17 or del(17p). In 167 (89%) of these patients, chr17 abnormalities were detected in the context of a complex karyotype and in 127 (42%) a co-occuring TP53 mutation was detected. Correlation between TP53 mutations and deletions (r=0.443, p<0.001) was observed with 172 (12%) patients having 1 TP53 abnormality, 169 (12%) having 2 TP53 abnormalities, and 19 (1%) having 3 abnormalities. Patients with multiple detectable TP53 mutations were less likely to have co-occurring chr17 abnormalities (79% vs 22%, OR 0.28, CI 0.15-0.50, p=0.03). Median follow up was 8.6 months (range 0-167 months). Presence of a TP53 mutation adversely impacted OS (MDS: HR=2.81, CI 2.26-3.50, p<0.001). Increasing number of detectable mutations confer adverse prognosis irrespective of clinically available therapies. Correlation between number of TP53 abnormalities and their clinical relevance was observed with 172 (12%) patients having 1

Summary/Conclusions: Presence of multiple TP53 abnormalities can be observed in up to 13% patients with AML and MDS. Second TP53 abnormalities more commonly involve TP53 deletions with additional TP53 mutations being less common and generally mutually exclusive with TP53 deletions. The number of TP53 abnormalities impacts the survival of patients with AML but not that of patients with MDS. Presence and number of TP53 mutations do not seem to impact response to HMAs but are associated with lower responses to chemotherapy.
P202

ACUTE MYELOID LEUKEMIA WITH INTERMEDIATE-RISK CYTOGENETICS AND A FAVORABLE GENOTYPE: PROGNOSTIC FACTORS AND RESULTS IN PATIENTS TREATED ACCORDING THE SPANISH CETLAM PROTOCOLS

Background: Acute myeloid leukemia (AML) with intermediate-risk (IR) cytogenetics includes a substantial proportion of patients with favorable molecular profile (FMP); in which AML cells harbor the NPM1 mutation or CEBPA biallelic mutation without internal tandem duplication of the FLT3 gene (FLT3-ITD). The role of allelic hematopoietic transplantation (allo-HCT) in first complete remission (CR) in these patients remains controversial.

Aims: To analyze the results and prognostic factors of allo-HCT in IR-FMP AML patients in a large series of patients treated by the Spanish CETLAM group.

Methods: Patients with primary AML diagnosed at 19 institutions from the Spanish CETLAM group and treated between 2003 and 2017. Induction chemotherapy included idarubicin and cytarabine (standard or intermediate-dose) in all cases, consolidation with intermediate or high-dose cytarabine (HDAC) and, depending on the protocol, additional HDAC, autologous or allogeneic hematopoietic transplantation.

Results: Two-hundred twenty-one patients were analyzed. Median age of the series was 54 years (range 18 to 72). 152 patients had a age to 60 years and 69 (31%) were older. Median WBC count was 19x10^9/l (range 0.55-282). One-hundred eighty-two patients had a normal karyotype and it was abnormal in 34 (5 patients no metaphases). One hundred ninety-one patients had NPM1 mutated and FLT3-ITD wild type (NPM1+/FLT3-ITD-) and 30 CEBPA biallelic wild type (CEBPα+/FLT3-ITD-). There were significant differences in the main clinical or biological parameters in these two groups. The CR rate in the overall group was very high (92%) without significant differences between the two molecular groups. Chemo-resistance was observed in only 2 patients of the NPM1+/FLT3-ITD- group (1%). Death during induction was observed in 16 patients (7%), all of them with NPM1+/FLT3-ITD-. Induction results according to age were similar in both groups. Event-free survival and overall survival are reported at 8 years and were 52±18% and 70±4%, respectively. In univariate comparisons, better EFS and OS was observed in CEBPα+/FLT3-ITD- patients compared to those with NPM1+/-FLT3-ITD- (p=0.03 and p=0.02, respectively). When analyzing post-consolidation treatment, patients treated with HDAC only had an excellent prognosis, even better than those receiving an autologous or allelogeneic transplantation. One patient died in CR in the HDAC group, another in the autologous transplant group and 7 in the allo-HCT group (p<0001). In multivariate analysis of pretransplant characteristics, age up to 60 years and CEBPα+/FLT3-ITD- association to improved EFS (RR=0.42) and OS (RR=0.29). Interestingly, in a subgroup of 123 patients with data on MRD after consolidation chemotherapy (flow citometry, cut-off: 0.12%), positivity was associated with worse EFS (0.02). Despite age was a prognostic factor, patients older than 60 years with IR-FMP AML had remarkable EFS of 36±3% and OS 54±10% at 8 years (Figure 1).

Figure 1.

Summary/Conclusions: Patients with primary AML, IR cytogenetics and FMP have a good outcome. Best results are achieved in patients with CEBPα+/FLT3-ITD-, particularly if age is up to 60 years. In this subset, OS at 8 years is 96±7%, comparable to current results achieved in acute promyelocytic leukemia. Patients above 60 years treated intensively may achieve a long-term survival of more than 50%. Chemotherapy without subsequent transplantation is a valid option. MRD monitoring after treatment has to be taken into account since in the subset of patients analyzed this was an independent prognostic factor for EFS.

P203

GMI-1271, A POTENT E-SELECTIN ANTAGONIST, COMBINED WITH INDUCTION CHEMOTHERAPY IN ELDERLY PATIENTS WITH UNTREATED AML: A NOVEL, WELL-TOLERATED REGIMEN WITH A HIGH REMISSION RATE

Background: The outcomes for elderly patients (pts) with acute myeloid leukemia (AML) remain poor due to limited tolerance of intensive cytotoxic chemotherapy and low response rate, therefore newer and less toxic therapies are urgently needed. The binding of E-selectin (E-sel), an adhesion molecule expressed in the vasculature of the bone marrow, to the leukemic cell surface activates survival pathways and promotes chemotherapy resistance. GMI-1271, a novel E-sel antagonist, disrupts these survival pathways and enhances antileukemic activity of GMI-1271.

Aims: To evaluate the efficacy and safety of GMI-1271, a potent E-sel antagonist, in combination with induction chemotherapy in elderly untreated pts with AML.

Methods: Eligible pts had ECOG 0-2, WBC <40K/uL, no active CNS disease, and adequate renal and hepatic function. Prior treatment of MDS was allowed. GMI-1271 (10 mg/kg) was given 24 hrs prior, then every 12 hrs during and for 48 hrs post induction with infusional cytarabine and idarubicin (7+3). Two cycles of induction were allowed and responders could receive consolidation with GMI-1271 plus intermediate dose cytarabine. Dose-limiting toxicity (DLT), defined as myelosuppression in the absence of disease or related Grade 3 (Gr) non-hematologic toxicity beyond day 42, was assessed in the first 3 pts. Baseline E-selectin ligand expression on leukemic blasts in the bone marrow (CD45/SSC by flow) is reported.

Figure 1.
A Phase 2 Study of Glasdegib (PF-04449913) in Combination with Cytarabine and Daunorubicin in Untreated Patients with Acute Myeloid Leukemia or High-Risk Myelodysplastic Syndrome

1University of Texas, MD Anderson Cancer Center, Houston, TX, 2Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD, 3Roswell Park Cancer Institute, Buffalo, NY, 4University of Southern California Cancer Institute, Los Angeles, 5Dana-Farber Cancer Institute, Boston, MA, 6Emory University School of Medicine, Atlanta, GA, 7Dana-Farber Cancer Institute, Boston, MA, 8University of Colorado Cancer Center, Aurora, CO, 9Pfizer Oncology, New York, NY, 10Pfizer Oncology, La Jolla, CA, 11Pfizer Oncology, Collegeville, PA, 12Washington University Medical School, Saint Louis, MO, 13CIMA, University of Navarra, 14Clinica Universitaria de Navarra, Pamplona, Spain

Background: Glasdegib, a selective, once-daily (QD), oral Smoothened (SMO) inhibitor, demonstrated significant improvement in overall survival (OS) when used in combination with low-dose cytarabine (LDAC) vs LDAC alone in a randomized (2:1) open-label trial in 132 patients (pts) not suitable for induction chemotherapy (ICT). Preclinical studies showed that glasdegib limits leukemia stem cell proliferation and provided evidence of glasdegib synergy with chemotherapy.

Aims: Primary objective of this open-label, single-arm Ph 2 study (NCT01546038) was to determine complete remission (CR) rate with glasdegib in combination with cytarabine and daunorubicin in untreated AML or high-risk MDS (n=132), the key secondary endpoint was CR/CRi rate.

Methods: Pts suitable for ICT (ECOG PS 0-1, creatinine ≤1.3 mg/dL, no severe sepsis, septic shock (1 pt each) and disease progression (2 pts). The observed steady-state plasma exposures for glasdegib were as expected at anti-neoplastic dose. Therefore, investigation of alternative agents for reactivation of PP2A is warranted.

Summary/Conclusions: Although the CR rates do not appear to be higher than those reported historically for AML pts receiving ICT, the mOS for AML pts >60 yrs stratified by subgroup compares favorably by adding glasdegib. Therefore, we conclude that this is a very promising option for AML, especially for treating leukemias characterized by SET dependence. The combination of glasdegib with ICT was well tolerated, with a safety profile consistent with that in AML pts receiving standard ICT. Further studies are warranted.

P205
CM942 is a New Small Molecule that Targets PP2A Interaction and Inhibits Growth of Acute Myeloid Leukemia Cells

P. García-Ramírez1, C. Vicente2, E. Arriazu3, M. Nerea4, J. Rifón4, A. Domínguez3, A. Alonso2, I. Vázquez3, M.J. Calasanz2, M.C. Mateos1, M.D. Odero1
1Hematology, Complejo Hospitalario de Navarra, 2University of Navarra, 3CIMA, University of Navarra, 4Clinica Universitaria de Navarra, Pamplona, Spain

Background: Acute myeloid leukemia (AML) is a heterogeneous malignant disorder of hematopoietic progenitor cells in which several genetic and epigenetic aberrations have been described. Nevertheless, outcome for most patients is poor, and it is necessary to develop more effective treatment strategies. Our group showed that the inactivation of the tumor suppressor PP2A is a recurrent event in AML, and that overexpression of SET, an endogenous inhibitor of PP2A, is a poor prognostic factor in this disease.

Aims: To test the efficacy of CM942, a FTY720 analogue, on all human AML cell lines and primary patient samples, and investigate its mechanism of action.

Methods: AML cell lines and 29 de novo AML samples were analyzed by treatment with FTY720 and CM942, MTS (viability), apoptosis, cell cycle and PP2A activity assays, and western blot.

Results: CM942 exhibited notable cytotoxicity on all human AML cell lines with SET overexpression (n=10). By using phosphatase assays we confirmed that CM942 treatment activated PP2A on cell lines, similarly to FTY720. Immunoprecipitation of PP2Ac in untreated cells confirmed that SET interacts with PP2Ac, and that treatment with CM942 effectively disrupted this association. Furthermore, CM942 had a caspase-dependent pro-apoptotic effect, and decreased phosphorylation of the PP2A target ERK1/2. Microarray data from vehicle-treated and CM942-treated HL-60 cells showed a high correlation between the gene expression profiles of the samples. This analysis identified up-regulated and down-regulated genetic pathways by treatment with CM942, providing mechanistic insights into the anti-tumor mechanism of this small molecule. Our analyses in primary AML samples showed that 7 out of 29 (24%) samples treated with CM942 had a significant reduction in proliferation. By western blot analyses we found that those patients responding to CM942 treatment had SET overexpression. Of note, treatment of peripheral blood mononuclear cells from healthy donors with CM942 had no effects on cell viability. Therefore, although FTY720 and CM942 have similar effects inhibiting cellular proliferation, CM942 was less toxic when assayed on normal peripheral blood cells.

Summary/Conclusions: CM942 inhibits growth of AML cells in both cell lines and primary patient samples, exerting its antileukemic effects through reactivation of PP2A activity. Although treatment with FTY720 was somewhat more effective than CM942 in primary samples of AML, fewer cytotoxic effects were observed after CM942 treatment in peripheral blood from healthy donors. Further experiments would be necessary to confirm the in vivo anti-tumor activity of CM942 in AML models. New compounds have been developed for the treatment of AML, although few have been translated into clinical practice; nevertheless, it is unlikely that any of these compounds, when used alone, will cure the disease, which is the ultimate goal of combinatorial therapy. Our results indicate that PADS may be a valid therapeutic option for AML, especially for treating leukemias characterized by SET-dependent inactivation of PP2A.
Background: Clonal heterogeneity occurs in many cancers, including Acute Myeloid Leukemia (AML). In cases of relapse, chemotherapy has triggered clonal selection with minor or evolved sub-clones driving relapse. A better understanding of the underlying clonal architecture, the extent of genetic heterogeneity and its response to therapy is necessary to better understand mechanisms of therapy escape and relapse.

Aims: In this study we aim to define the clonal architecture of AML during the course of therapy and in leukemia propagating cells.

Methods: We sequenced 12 AML samples at the time of diagnosis and in one case also at the time of relapse with at least 80% blasts per sample. 6/12 patients displayed a normal karyotype while the other 6 patients showed various cytogenetic abnormalities (inversion 16 (2), trisomy 8 (1), add(19)(p13.3) (1), complex aberrant karyotype (2)). Whole-exome sequencing (WES) was performed with the appropriate germ line controls. WES data were clustered using empirical Bayesian clustering.

Results: WES identified more than 3000 variants in total. By setting distinct filtration criteria (20% allele frequency (AF), >10 reads coverage, ≥2 reads support of the detected variant, SIFT-score <0.05 and GMAF <5%) 64 leukemia specific mutations were detected (1-18 mutations/AML). As expected, these included recurrently mutated genes like DNMT3A (in 4 patients), IDH1 and 2 (each in one patient), KIT and NRAS (both in 2 patients). Categorization of identified mutations showed that these mutations affected genes involved in various cellular processes including transcriptional regulation (15), cell differentiation (6), cell cycling (5), apoptosis/survival signals (5), proliferation (3), cell growth (3) and splicing (3). Empirical Bayesian clustering of all detected variants according to their respective AF resulted in 2-5 different clusters per AML. Based on this cluster analysis we were able to predict the founding clone (Figure 1). Through comparison of clusters from diagnosis and relapse clonal selection can also be detected and via modelling the most likely clonal architectures can be identified. By assigning our 64 identified leukemia-specific mutations to the defined clusters we can now track the different clusters/clones in phenotypically distinct subpopulations and during xenotransplantations by targeted sequencing. An update of this analysis will be presented at EHA.

Summary/Conclusions: WES can identify leukemia specific mutations that are involved in various cellular functions including mutations that have been shown to be recurrently mutated in AML like DNMT3A. Sequencing data can also be used in combination with mathematical modelling approaches to reconstruct the clonal architecture of AML at the time of diagnosis and relapse allowing estimations of the clonal complexity at these time points.

CLONAL HETEROGENEITY IN LEUKEMIC STEM CELLS FROM PATIENTS WITH ACUTE MYELOID LEUKEMIA

TREATMENT OF PRACINOSTAT AND AZACITIDINE IN ELDERLY PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML): CORRELATION BETWEEN MUTATION CLEARANCE AND CLINICAL RESPONSE

K. Takahashi1, Y. Abaza1, F. Wang1, C. Gumbs1, S. Xingzh1, A. Futreal1, E. Atallah2, B. Medeiros3, S. Khaled4, M. Arellano5, M. Patnaik6, E. Palmesino7, G. Garcia-Manero1
1University of Texas MD Anderson Cancer Center, Houston, 2Medical College of Wisconsin, Milwaukee, 3Stanford University, Stanford, 4City of Hope, Duarte, 5Emory University School of Medicine, Atlanta, 6Mayo Clinic, Rochester, United States, 7Helsinn, Pazzallo, Switzerland

Background: In a phase 2 study of 50 elderly patients (>65 years) with AML who were not eligible for intensive chemotherapy, treatment with the investigational HDAC inhibitor pracinostat+azacitidine (AZA) was well tolerated and led to 42% complete remission (CR) and a median overall survival (OS) of 19.1 months (Blood 2016; 128:100). Responses were durable (median CR+CRi 17.2 months), blast clearance was rapid (median 8 weeks), and maximum clinical benefit required prolonged therapy (>6 months) in some patients.

Aims: Our aim was to understand the impact of somatic mutations and their clearance on disease response and survival outcomes in AML patients treated with pracinostat+AZA.

Methods: 88 samples from 41 study patients were sequenced. Pre-treatment samples were available for analysis from all 41 patients, and a median of 3 longitudinal samples were analyzed from 19 patients between Cycle 2 and 9. Leukemia mutations were detected by SureSelect targeted capture exon sequencing (Agilent) of 295 genes that are recurrently mutated in hematologic malignancies (median coverage 507x [range: 111-777x]). Longitudinal mutation clearance was analyzed by tracking variant allele frequency (VAF). Informed consent was obtained from all patients.

Results: At baseline, 98 mutations in 28 genes were detected in 38 (93%) patients, with the most frequent being in SRSF2 (27%), DNMT3A (20%), IDH2 (17%), RUNX1 (17%), and TET2 (17%). The median number of mutations detected per patient was 2 (range: 0-6). Among the 33 patients with evaluable treatment response, CR was observed in 13 (39%) patients. The rate of CR was significantly higher in patients with mutations in NPM1 or in one of the DNA methylation pathway genes, while patients with TP53 mutation had a trend for poor CR (Table 1). The median follow up duration of the 41 patients was 23.8 months (95% CI: 20.4-27.1 months) with median OS of 18.1 months (95% CI: 10.1-26.1 months), patients with CEBPA mutation had a trend toward better OS, whereas patients with NFI mutation had significantly worse OS (Table). Considering mutations associated with AML oncogenesis (Lindsley RC, Blood 2015;125:1367-76), median OS was 17.7 months in 20 patients with mutations typically associated with secondary AML and 18.1 months in 18 patients with mutations typically associated with de novo AML. Among the 19 patients whose longitudinal specimens were analyzed, 10 achieved CR. Of those 10 patients, 9 (90%) had persistently detectable mutations in their bone marrow at the time of CR, however, in 7 of them, continued exposure to pracinostat+AZA lowered the VAF or cleared residual mutations. Mutations in genes associated with DNA methylation, RNA splicing, clonal hemopoiesis of indeterminate potential (CHIP), and receptor tyrosine kinase (RTK) pathways had poor clearance of mutation, while transcription factors or cohesin had better clearance with pracinostat+AZA treatment. In 2 patients, relapsed samples were sequenced and showed re-expansion of the founder clone.

Table 1.
Summary/Conclusions: Mutations in NPM1 and DNA methylation pathway were associated with a better response to pracinostat+aza, while TP53 mutation was associated with a trend toward poor response. Persistent mutation at the time of CR suggests residual preleukemic clonal hematopoiesis in this elderly population. Benefit of prolonged exposure to pracinostat+aza was also confirmed at molecular level where continued decline of mutation VAF was seen after achieving CR.

Background: Effects on overall survival (OS) are of primary importance when evaluating AML treatments (Tx). Though complete remission (CR) rates are lower with azacitidine (AZA) than with intensive chemotherapy (IC), OS is similar with AZA and IC (Dombret et al., Blood, 2015). The 2017 European LeukemiaNet (ELN) recommendations acknowledge that hypomethylating agents, including AZA, may alter the natural course of AML in some patients (pts) who do not achieve CR (Döhner et al., Blood, 2017). According to IWG criteria for AML (Cheson et al., J Clin Oncol, 2003), stable disease (SD) is considered non-response to Tx. Yet AML is a progressive disease; potentially, stable health status may reflect delayed disease progression and result in improved OS.

Aims: This post hoc analysis evaluated OS outcomes among older pts with AML treated with AZA or conventional care regimens (CCR) who maintained SD, with or without hematologic improvement (HI), in the phase 3 AZA-AML-001 study.

Methods:Pts aged ≥65 years with AML (>30% marrow blasts), ECOG PS score ≤2, NCCN-defined intermediate- or poor-risk cytogenetics, and WBC count ≤15x10⁹/L received AZA (75mg/m²x7 days [d]/28d cycle) or a CCR (IC [standard 7+3 regimen], low-dose cytarabine [20mg BID x 10d/28d cycle], or best supportive care). OS was assessed using Kaplan-Meier methods for pts with SD at 2-, 4-, and 6-month landmarks. SD was protocol-defined as the absence of an IWG-defined AML response and no progressive disease (PD), whether or not HI was attained. Pts with SD could have had an IWG-defined response or PD at any time other than at the specified landmarks. OS was also evaluated in pts with HI as their best response; attainment of HI must have begun on or before, and been sustained past, each landmark, and lasted for ≥56 consecutive days.

Results: Median OS for all SD pts was 2.1-2.5 months longer with AZA vs CCR, and estimated 1-year survival was ~15% higher at each landmark in the AZA arm (Table 1). Hazard ratios for OS among all SD pts treated with AZA vs CCR ranged from 0.81–0.88. Median OS among pts with SD and no HI ranged from 12.6–13.3 months in the AZA arm and from 11.1-12.2 months in the CCR arm. Within Tx arms, AZA-treated pts with HI had meaningfully improved OS at all landmarks, ranging from 3.7 to 7.9 months longer than OS for pts without HI (Table 1). In contrast, HI attained with CCR did not largely influence OS; differences between pts who attained HI vs no HI ranged from -0.2 to 2.9 months. Median durations of HI in the AZA vs CCR arms, respectively, were 183 vs 166
days at 2 months, 176 vs 148 days at 4 months, and 176 vs 138 days at 6 months. Estimated 1-year survival within the AZA arm was 4.9%–27.4% greater for pts with HI than for pts with no HI, but for CCR-treated pts with HI, 1-year survival was 0%–10.3% greater. Between Txs arms, 1-year survival with AZA in pts with HI was 9.6%–33.3% greater than for CCR-treated pts with HI.

Summary/Conclusions: Maintaining SD during AZA or CCR Tx is associated with relative favorable OS outcomes, as median OS in pts with SD exceeded that for all pts in the AZA-AML-001 trial (10.4 months with AZA vs 6.5 months with CCR; Dombret et al., Blood, 2015). Pts with SD who also attained HI during early AZA Tx had meaningfully improved OS, whereas similar CCR-treated pts did not, suggesting that HI with AZA is qualitatively different from HI with CCR. The prognostic relevance of HI in AML requires further study.

P209

A RANDOMIZED PHASE II STUDY OF IDARUBICIN AND CYTARABINE WITH EITHER CLOFARABINE OR FLUDARABINE IN ADULTS WITH NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA

N. J. Kantarjian1, F. Radvanyi2, L. Huang1, L. Xiao1, G. Garcia-Manero1, W. Plunkett1, V. Gandhi1, K. Sasaki1, N. Pemmaraju1, N. Daver1, G. Borthakur1, N. Jain1, M. Konopleva1, Z. Estrov1, T. Kadia1, W. Wierda1, C. DiNardo1, M. Brandt1, S. O’Brien2, J. Cortes1, E. Jabbour1

The University of Texas MD Anderson Cancer Center, Houston, 2The University of California - Irvine, Orange, United States

Background: Fludarabine and clofarabine are purine nucleoside analogues with clinical activity in acute myeloid leukemia (AML). Aims: We designed a randomized phase II trial to evaluate the efficacy and safety of idarubicin and cytarabine with either clofarabine (CIA) or fludarabine (FIA) in adults with newly diagnosed AML. The primary objective was to compare the EFS rates of the two regimens. Methods: Adults with newly diagnosed AML deemed suitable for intensive chemotherapy were randomized using a Bayesian adaptive design to receive CIA or FIA. All patients (pts) received idarubicin 10 mg/m² IV on D1-3 and cytarabine 1 g/m² IV daily on D1-5. Clofarabine and fludarabine were given at doses of 15 mg/m² and 30 mg/m², respectively, IV daily on D1-5. Pts with FLT3-ITD mutations could receive concomitant sorafenib. Responding pts could receive up to 6 cycles of consolidation at attenuated doses. Outcomes were compared to a historical cohort of pts < 50 years of age who received idarubicin and cytarabine (IA) without a nucleoside analogue. Results: Between 8/2011 and 6/2016, 182 pts were enrolled (CIA, n = 106; FIA, n = 76; Table 1).

The imbalance of the arms was due to the better performance of CIA during the initial period of the trial. Treatment arms were well-balanced after randomization. Treatment arms were well-balanced after randomization. The median duration of follow-up was 27 months. The median duration of follow-up was 27 months.

P210

OVERALL SURVIVAL AND TRANSPANTATION IN PATIENTS WITH FLT3 MUTATIONS: SUBGROUP ANALYSIS OF A PHASE 3 STUDY OF CPX-351 VERSUS 7+3 IN OLDER ADULTS WITH NEWLY DIAGNOSED, HIGH-RISK ACUTE MYELOID LEUKEMIA

1Stanford University School of Medicine, Stanford, CA, United States, 2Gordon and Leslie Diamond Health Care Centre, Vancouver, British Columbia, Canada, 3Oregon Health and Science Univ, Portland, OR, 4University of Michigan, Ann Arbor, MI, 5BMT Group of Georgia, Atlanta, GA, 6Vanderbilt-Ingram Cancer Center, Nashville, TN, 7University of Kansas Medical Center, Kansas City, KS, 8University of Alabama at Birmingham, Birmingham, AL, 9Wake Forest Baptist Comprehensive Cancer Center, Winston-Salem, NC, 10Yale Univ. School of Medicine, New Haven, CT, 11Jazz Pharmaceuticals, Palo Alto, CA, 12Lee Moffitt Cancer Center & Research Institute, Tampa, FL, United States

Background: Approximately 20% to 30% of patients with acute myeloid leukemia (AML) have FLT3 mutations; these patients often experience rapid post-induction relapse, highlighting the need for therapies that provide an improved bridge to stem cell transplantation. CPX-351 is a liposomal formulation that delivers a synergistic 5:1 molar ratio of cytarabine and daunorubicin. CPX-351 demonstrated significantly prolonged overall survival (OS) versus cytarabine/daunorubicin (7 + 3) in a randomized, open-label, controlled phase 3 trial in patients aged 60 to 75 years with newly diagnosed, high-risk AML (Lancet, et al. ASCO 2016). A study of the ex vivo cytotoxicity of CPX-351 found that AML blasts with the FLT3-ITD mutation were 5-fold more sensitive to CPX-351 than those with wild type FLT3 (Gordon, et al. Leuk Res. 2017;53:39-49). Aims: The current analysis of the phase 3 trial therefore investigated outcomes in the subset of patients with FLT3 mutations.

Methods: Enrolled patients were randomized 1:1 to receive induction with 1 to 2 cycles of CPX-351 (100 units/m² cytarabine 100 mg/m²+daunorubicin 44 mg/m²) on Days 1, 3, and 5 (2nd induction: Days 1 and 3 only) or 7 + 3 (cytarabine 100 mg/m²/day x 7 days [2nd induction: x days]+daunorubicin 60 mg/m² on Days 1, 2, and 3 [2nd induction: Days 1 and 2 only]). Patients who achieved complete remission (CR) or CR with incomplete platelet or neutrophil recovery (CRi) could receive up to 2 consolidation cycles. Results: Of the 274 patients who were assessed for FLT3 mutations and received study treatment, 22/138 (16%) patients in the CPX-351 arm and 20/136 (15%) patients in the 7 + 3 arm had baseline FLT3 mutations. AML subtypes in FLT3+ patients were: therapy-related AML (19%); AML after myelodysplastic syndrome/malignant mixed lineage disease (12%); and de novo AML with MDS karyotype (21%). In FLT3+ patients, median OS was longer with CPX-351 (10.25 months) versus 7 + 3 (4.55 months; hazard ratio=0.57 [95% CI: 0.24, 1.33]; P=0.093; see Figure 1), and the rate of CR+CRi was higher (45% vs 25%). A greater number of FLT3+ patients treated with CPX-351 were able to undergo stem cell transplantation (n=10 [22%] vs 44% [5%]; 4 patients were alive as of this analysis, after a median post-transplant follow up of 692 days [range: 96-769]) compared with 7 + 3 (n=2/20 [10%]; neither patient was still alive). The adverse event profile (reported during treatment or within 30 days of discontinuation) was consistent between CPX-351 in FLT3+ patients and 7 + 3. Common dose-limiting adverse events were consistent with the overall study population. Serious treatment-emergent adverse events (TEAEs) were experienced by 7 (32%) FLT3+ patients in the CPX-351 arm and 10 (50%) patients in the 7 + 3 arm; individual serious TEAEs in ≥2 patients included febrile neutropenia (n = 2 in each arm), respiratory failure (n = 1 and 2 in each arm), and cardiac failure (n = 2 with CPX-351), and cerebral hemorrhage (n = 2 with 7 + 3).

Summary/Conclusions: CPX-351 demonstrated numerical improvement in median OS in older patients with newly diagnosed, FLT3+ high-risk AML and
allowed more patients to undergo stem cell transplantation. The safety of CPX-351 in this subpopulation was in line with the previous studies and the overall phase 3 population. This analysis was limited by small number of patients.

high-risk pts based on a historical cohort. Correlative studies profiling the immune repertoire of pts before and during treatment are being finalized and will be summarized.

**P211**

**NIVOLUMAB MAINTENANCE THERAPY FOR PATIENTS WITH HIGH-RISK ACUTE MYELOID LEUKEMIA IN REMISSION**

T. Kadia1, H. Kantarjian1, E. Jabbour2, F. Ravandi1, N. Daver1, P. Cardenas1, M. Brandt1, M. Konopleva1, J. Cortes1,1Leukemia, MD Anderson Cancer Center, Houston, United States

**Background:** Dose intensification and newer drug combinations during induction have led to high rates of complete remission (CR) in pts with newly diagnosed AML. However, disease relapse remains a major source of failure. With the exception of allogeneic (allo) stem cell transplant (SCT), there are few options for post-consolidation maintenance of remission in high-risk pts. Prior attempts to develop maintenance therapy using cytotoxic drugs in AML have been unsuccessful. Immune mediated disease control by engaging tumor-specific cytotoxic T-cells may be important in suppressing leukemia relapse, as is seen with graft vs leukemia effect following allo SCT. Immune checkpoint inhibitors may be effective in restoring host immune surveillance in the setting of post-consolidation remission.

**Aims:** We designed a pilot phase II clinical trial studying the efficacy and safety of nivolumab (nivo) as maintenance therapy in AML pts with high-risk disease in remission, who were not being considered for SCT.

**Methods:** AML pts ≥18 years with a high-risk feature in 1st CR (CR1) or any patient in 2nd CR (CR2) who had received induction and at least 1 consolidation cycle were eligible for enrollment. Pts should be within 12 months of achieving CR, have PS ≤2, and adequate organ function. Pts were treated with nivo 3mg/kg IV every 2 weeks for 6 months. 1 cycle was 4 weeks. After 6 months, nivo could be given every 4 weeks until 12 months on study, and then every 3 months until relapse. All pts had baseline cytogenetic and molecular testing, and minimal residual disease (MRD) assessment by flow cytometry. Peripheral blood and bone marrow samples were collected at baseline and during treatment for immune correlative studies to explore immune cell repertoire and biomarkers for response.

**Results:** Eight pts have been treated, with a median age of 60 years (range, 49-71). 7 pts were in CR and 1 in CRi at the time of enrollment, 5 pts (63%) were in CR1, 2 pts (25%) were in CR2, and 1 pt (13%) in CR4 was inadvertently enrolled and treated on the trial. Baseline characteristics are outlined in Table 1. AML-related mutations detected at start of therapy include: IDH2 (n=2), NPM1 (2), TET2 (2), and 1 each of TP53, JAK2, ASXL1, and DNMT3a. High risk features at the time of enrollment were as follows: 2 (25%) persistent MRD, 2 (25%) adverse cytotype, 1 (13%) adverse mutation profile, and 3 pts (38%) in CR2 or beyond. Pts have received a median of 4 (1 – 13) cycles of therapy. With a median followup of 6+ months (1 – 14), the 6- and 12-month estimated RFS were 88% and 73%, respectively. The 6- and 12-month estimated OS were 100% (Figure 1). The one patient who died was discovered to hypothyroidism, treated successfully with steroids and thyroid hormone supplementation, who continues on treatment. 1 patient had grade 3 transaminase elevation which responded to dose interruption and who continues on treatment. 2 pts had grade 3 possible pneumonitis treated successfully with steroids and dose interruption – both were on treatment. Table 1 shows the patients with nivolumab by cycle. Summary/Conclusions: Nivo appears to be a feasible maintenance strategy in high-risk AML pts who are not candidates for SCT. The study continues to surpass the pre-specified expected rate of 6-month relapse-free survival of 22nd Congress of the European Hematology Association

**HIGHER EXPRESSION OF LONG NON-CODING RNA KIAA0125 IS ASSOCIATED WITH CHARACTERISTIC CLINICAL AND BIOLOGICAL FEATURES AND IS AN INDEPENDENT POOR PROGNOSTIC FACTOR IN ACUTE MYELOID LEUKEMIA**

S.-Y. Hung1, C.-C. Lin1,2,3, H.-A. Hou1, W.-C. Chou1,2, H.-F. Tien1

1Division of Hematology, Department of Internal Medicine, 2Department of Laboratory medicine, National Taiwan University Hospital, 3Graduate Institute of Clinical Medicine, College of Medicine, National Taiwan University, Taipei City, Taiwan, Republic of China

**Background:** Long non-coding RNAs (lncRNAs) are non-protein coding RNAs longer than 200 nucleotides. Recently, a number of lncRNAs have been shown to play important roles in cancer biology. lncRNA KIAA0125 is one of the 11 genes in an expression signature significantly associated with prognosis in cytogenetically normal acute myeloid leukemia (AML) patients as shown in our previous report. It is also among another set of 17 leukemia stem cell (LSC) genes, identified through xenotransplantation model in NSG mice, which predict inferior treatment response in AML.

**Aims:** KIAA0125 gene is localized on chromosome 14q32.33; its functions remain unexplored. One study reported that it might be involved in neurogenesis including induction of astrocytosis, preventing formation of dopaminergic neurons. Another study showed that it could potentiate cell invasion and migration in gallbladder cancer. Its clinical significance in hematologic malignancies has not been explored yet. Since independent studies have reported KIAA0125 as an important gene for unfavorable prognosis, in this study we aimed to investigate its clinical relevance in AML.

**Methods:** We performed global mRNA arrays for bone marrow samples from 347 newly diagnosed de novo AML patients in the National Taiwan University Hospital, who had adequate cryopreserved cells and detailed demographic, clinical, and genetic data for analysis. The KIAA0125 expression level extracted from the array data was analyzed for its clinical relevance. We also validated our findings by analyzing the public databases of AML.

**Results:** The 347 patients were divided into two groups based on the median level of KIAA0125 expression on the arrays. Higher KIAA0125 expression was inversely associated with unfavorable cytotypes including t(8;21) and t(15;17). Patients with M1 by the French-American-British classification more frequently had higher KIAA0125 expression (p < 0.001), while those with M3 (acute promyelocytic leukemia) had significantly lower levels of KIAA0125 expression (p < 0.001). To investigate the association of gene mutations with KIAA0125 expression in AML, we analyzed mutations of 17 AML-associated genes. We found that patients with higher KIAA0125 expression had significantly higher incidence of FLT3-ITD (28.7% vs 19.7%, p = 0.048), and mutations of RUNX1 (18.4% vs 10.4%, p = 0.034), and DNMT3A (24.1% vs 13.9%, p = 0.015), compared to those with lower KIAA0125 expression. Among the 227 patients who received standard chemotherapy, those with higher KIAA0125 expression had a lower complete remission rate (61.2% vs 84.7%, p < 0.001), and shorter overall survival (median OS, 23.7 months vs 116.8 months, p = 0.001) than those with lower KIAA0125 expression after a median follow-up of 57.0 months. The prognostic significance could be validated in another two independent cohorts, TCGA and GSE12417. In multivariate analyses, higher expression of KIAA0125 remained to be an unfavorable prognostic factor for OS independent of age, white blood cell counts, karyotype, FLT3-ITD, CEBPA double mutations.
RUNX1 mutation, MLL-PTD, WT1 mutation, and TP53 mutation (p<0.011).

Summary/Conclusions: Higher expression of KIAA0125 in AML patients was correlated with mutations of RUNX1, DMNT3A, and FLT3-ITD but negatively associated with favorable karyotypes such as t(8;21) and t(15;17). Higher expression of KIAA0125 appeared to be an independent unfavorable prognostic factor in our cohort, and its negative prognostic impact could be validated in another two large independent cohorts of AML. The close association of KIAA0125 expression with LSC signatures might in part explain its unfavorable impact on the survival of AML patients.

P213

LEUKEMIC STEM CELLS CAN BE DETECTED IN A CONSIDERABLE PERCENTAGE OF PATIENTS WITH ACUTE MYELOID LEUKEMIA AT DIAGNOSIS AND IS A SIGNIFICANT PROGNOSTIC FACTOR

O. Pérez-López1, T. Caballero-Velázquez1, I. Álvarez-Laderas1, P. Hernández-Díaz1, A. M. Márquez-Mattito1, J. González-Campos1, R. Morales-Camacho1, C. Prats-Martin1, M.T. Vargas-de los Monteros1, R. Bernai-Ruíz1, J.A. Pérez-Simón1
1Virgen del Rocío University Hospital, Sevilla, Spain

Background: There is a growing interest on the identification of leukemic stem cells (SC) as a potential prognostic factor in patients with acute myeloid leukemia (AML). Several studies identify these cells as CD34+CD38-Lin-, although there is a controversy about its phenotypic identification and prognostic value.

Aims: To identify SC in a cohort of patients with AML and evaluate their prognostic value in a series of newly diagnosed AML patients.

Methods: The presence of SC (CD34+CD38-Lin-) in bone marrow samples was prospectively evaluated in a consecutive series of 67 newly diagnosed AML patients by flow cytometry, between may-13-oct 16. All patients received intensive chemotherapy according to PETHEMA protocol. We evaluated response, relapse rate and overall survival (OS) and event free survival (EFS).

Results: Out of the 67 patients [34 men/33 women, median age 54 (0-78), 58 (88.6%) have SC at diagnosis, 37.9% of them (n=22) achieved complete remission (CR) with a negative minimal residual disease (MRD) vs 77.8% (7/9) among patients without SC (p=0.03). Among patients who obtained CR with a negative MRD (n=29), no one suffer a leukemic relapse in the non SC vs 5/22 (22.7%) in the SC group (p=0.02). Considering the intermediate risk group according to cytogenetic / molecular features, 100% of patients without SC at diagnosis achieve a negative MRD (5/5) vs 14/41 (34.1%) among those in the SC group (p<0.008). OS at 9 months was 89 vs 56% (p=0.043), and the EFS 78 vs 48% (p=0.054) in the non SC and SC group, respectively (Figure 1).

Summary/Conclusions: SC can be detected in a considerable group of patients with AML at diagnosis. The presence of SC is a prognostic factor in terms of response, OS and EFS. Accordingly, SC detection could help to identify prognosis subgroups of patients with different prognostic among those in the intermediate risk group by genetics/molecular assays.

P214

POST-REMISSIONAL AND PRE-TRANSPLANT ROLE OF MINIMAL RESIDUAL DISEASE DETECTED BY WT1 IN ACUTE MYELOID LEUKEMIA: A RETROSPECTIVE COHORT STUDY

C. Frairia, S. Aydin1, E. Audioso1, L. Riera2, S. Alberti2, B. Allione1, A. Busca3, S. D’Arda1, C.M. Dellacasa2, A. Demurtas2, A. Evangelista2, G. Ciccone4, P. Francia di Celler2, B. Nicolino1, A. Stacchini1, F. Marmont1, U. Vitolo1
1Department of Hematology, 2Department of Pathology, 3Bone Marrow Transplant Center, University-Hospital Città della Salute e della Scienza, Torino, Italy, 4Unit of Clinical Epidemiology, University-Hospital Città della Salute e della Scienza and CPO Piemonte, Torino, Italy

Background: In acute myeloid leukemia (AML) the detection of residual leukemic cells at a submicroscopic level (minimal residual disease - MRD) is still under investigation. In about 30-40% of AML lacking a specific molecular target, quantitative real-time polymerase chain reaction (QRT-PCR) has been used to detect transcripts commonly overexpressed in AML. Among a large number of candidates, Wilms tumor gene 1 (WT1) has been proposed as a promising MRD marker.

After the standardization of QRT-PCR on behalf of the European LeukemiaNet (ELN), subsequent studies investigated the role of WT1 expression in AML with controversial results.

Aims: To assess the role of WT1 expression as a MRD marker after intensive induction chemotherapy and before allogeneic hematopoietic cell transplantation HCT (allo-HCT) in a large cohort of AML patients treated in a single institution.

Methods: The present retrospective cohort study included adult patients with untreated AML consecutively diagnosed between 2004 and 2014 in the Hematology Unit of the University-Hospital Città della Salute e della Scienza of Torino, Italy. The study was approved by the Ethical Committee and was registered at www.clinicaltrials.gov as NCT02714790. Among 255 enrolled patients, MRD was investigated in those in first complete remission (CR) with an available at diagnosis and at two further time-points: after induction (n=117) and prior allo-HCT (n=65). Patients with baseline WT1 >250 copies were excluded. All patients underwent intensive induction chemotherapy with curative intent and subsequent consolidation chemotherapy according to the AML risk assessment (autologous peripheral stem cell transplantation for low risk and allo-HCT for intermediate and high risk patients).

Effect of post induction WT1 expression on disease-free survival (DFS) and overall survival (OS) and of pre allo-HCT WT1 expression on the cumulative incidence of relapse (CIR) were investigated.

Results: Baseline WT1 expression were not found significantly associated with demographic, clinical and disease biological features at diagnosis. Baseline BM WT1 expression lacked even to show an association with response to induction chemotherapy (OR 1.16; 95% CI 0.90-1.50, p=0.24)

OS and DFS were significantly shorter in patients in first CR with >350 WT1 copies after induction compared to those with ≤350 (OS 17 vs 95 months with HR 2.1; 95% CI 1.14-3.97, p=0.018 and 3-year DFS rates 15% vs 55% with a HR of 2.81; 95% CI 1.14-6.93, p=0.025).

Adding the BM WT1 in the model along with other factors determines an increase of the C-statistic from 0.696 to 0.713 for OS (NRI=0.384) and from 0.7413 to 0.7920 (NR=0.4037) for DFS. Before allo-HCT, patients with WT1 >150 copies (n=18) had a significantly higher CIR compared to those with WT1 ≤150 (n=47), HR 4.61; 95% CI 1.72-12.31, p=0.002.

Summary/Conclusions: The results of the present study showed that BM WT1 is associated with survival in patients in CR in two decisive time-point for treatment planning: after induction treatment and before allo-HCT. The prognostic role of WT1 resulted independent from other well-established risk factors. Therefore, WT1 may represent an additional MRD tool for risk stratification in patients nowadays classified in CR, especially in the high risk MRD positive subgroup in which a risk-adapted approach may have a greater impact. Published evidences available so far supported these suggestions, but mainly due to methodological issues, the role of WT1 is still a matter of debate. Perspective randomized studies are required to confirm these results.

Background: Enasidenib (AG-221) is an oral, selective, small-molecule inhibitor of mIDH2 enzymes. Preclinical studies showed that exposing myeloblasts from patients (pts) with acute myeloid leukemia (AML) to enasidenib ex vivo resulted in differentiation of leukemic marrow blasts into mature, functionally normal neutrophils (Ven et al, 2017). Enasidenib can result in IDH-inhibitor-associated differentiation syndrome (IDH-DS) in treated pts, with manifestations akin to retinoic acid syndrome seen during therapy of acute promyelocytic leukemia.

Aims: To characterize the prevalence, characteristics, and course of IDH-DS in relapsed or refractory (R/R) AML receiving enasidenib 100 mg daily in a phase 1 dose-escalation and expansion study (NCT01915498). This dose is currently under study in a multicenter, randomized, phase 3 trial comparing enasidenib with conventional care regimens in R/R AML pts (NCT02577406).
Methods: An independent Differentiation Syndrome Review Committee (DSRC) was formed to review potential cases of IDH-DS. The DSRC identified and agreed upon a series of signs and symptoms possibly characteristic of IDH-DS, including fever, lung infiltrates, pleural or pericardial effusions, rapid weight gain, edema, and azotemia. In all, 27 cases (8 of investigator-reported IDH-DS and 19 with characteristics suggestive of IDH-DS) were identified and retrospectively reviewed by the DSRC to determine their consistency with IDH-DS.

Results: The DSRC determined 13 cases (11.9% of 109 R/R AML pts in the enasidenib 100 mg/day dosing cohort) to be consistent with IDH-DS. Median time to onset was 30 days (range 7-116). Manifestations of IDH-DS in >2 pts were dyspnea (n=10), pyrexia (9), lung infiltrates (8), pleural effusion (5), and kidney injury (3). IDH-DS was effectively managed with systemic corticosteroids in 12/13 cases. Leukocytosis accompanied 4/13 cases, for which hydroxyurea was employed for cytoreduction. Enasidenib was interrupted for 9 pts (for a median of 7 days), but dose reductions or enasidenib discontinuation were not required for pts with IDH-DS. Six of the 13 pts had clinical responses (2 complete remissions [CR], 2 CRs with incomplete hematologic recovery, 1 partial remission, and 1 morphologic leukemia-free state), 6 pts had stable disease, and 1 pt had progressive disease.

Summary/Conclusions: Systemic corticosteroids, close hemodynamic management, and hydroxyurea (in the presence of leukocytosis) are effective IDH-DS management strategies; they should be administered promptly when IDH-DS is suspected, and continued until improvement. Enasidenib interruption can be considered if initial intervention is unsuccessful. IDH-DS represents a novel clinical finding in pts with mIDH2 AML treated with enasidenib, and is likely due to its suggested mechanism of action, myeloblast differentiation.

Aggressive Non-Hodgkin lymphoma - 1st line

OUTCOME OF PATIENTS WITH INTRAVASCULAR B-CELL LYMPHOMA, A RETROSPECTIVE STUDY CONDUCTED ON BEHALF OF THE LYMPHOMA STUDY ASSOCIATION GROUP

1Hematology, University Hospital Hôtel-Dieu, Nantes, 2Hematology, CHU, Montpellier, 3Hematology, La Pitié Salpêtrière APHP, Paris, 4Anatomopathology, University Hospital Hôtel-Dieu, Nantes, 5Hematology, CHU, Lyon, 6Hematology, CHU, Toulouse, 7Hematology, Saint Antoine APHP, Paris, 8Hematology, CHU, Rennes, 9Hematology, CHU, Strasbourg, 10Hematology, Loire Cancerology Institute, Saint Etienne, 11Hematology, CHU, Clermont-Ferrand, 12Hematology, CHU, Poitiers, 13Hematology, CHU, Tours, 14Hematology, CHU, Limoges, 15Hematology, Hospital, Pau, 16Hematology, CHU, Toulouse, 17Anatomopathology, CHU, Lyon, 18Statistic, University Hospital Hôtel-Dieu, Nantes, France

Background: Intravascular large B-cell lymphoma (IVLBCL) is a rare type of extranodal large B-cell lymphoma characterized by the selective growth of lymphoma cells within the lumina of vessels, classically reported with poor responses to chemotherapy. Due to its low incidence and rarity of tumor cells, diagnosis of IVLBCL remains difficult and many issues remain unresolved, regarding both clinical features and therapeutic strategies.

Aims: Our work aims to describe clinical presentation and outcome of IVLBCL patients treated in French LYSA centers between 2000 and 2016.

Methods: All LYSA centers were asked to report and update clinical data about IVLBCL patients treated. No central pathology review was performed for the present study, but all cases were classified by LYSA pathologists. Local investigators reported disease characteristics and updated patients’ outcome (clinical examination, standard biological parameters, bone marrow biopsy, CT scan at baseline, CT response evaluation and outcome).

Results: We identify 65 IVLBCL patients treated in 23 LYSA centers during the studied period. Median age was 67.8 years (range 22-91). In note, two patients presented with IPI score >3 (67%) and all patients had a stage IV disease. As expected in Western patients, cutaneous and CNS involvement were highly frequent, respectively 33% and 39%. But interestingly, hemophagocytic syndrome were observed in nearly half of the patients (41%), while it was mainly described in Asian series. Despite classically delayed diagnosis in IVL- BCL, only 2 cases were confirmed post-mortem and almost all alive patients at diagnosis (n=58) were treated with rituximab-containing chemotherapy regimens (92%). Regarding first line treatment, 83% of patients were treated with anthracycline-based regimens, with CNS prophylaxis for half of them (47%), and seven patients underwent autologous stem cell transplantation upfront. The median progression free survival was 29.4 months and median overall survival 63.8 months (Figure 1). Pathological features (including cell of origin characterization, C-MYC expression, adhesion protein expression level) investigation is ongoing and will be presented at the time of the meeting.

Figure 1.
P218
OUTCOME OF ELDERLY DLBCL PATIENTS (≥80 YEARS) TREATED WITH ANTHRACYCLINE BASED CHEMOTHERAPY. R-CHOP DOSE REDUCTION IS NOT NECESSARY FOR EVERYBODY
1Charles University General Hospital, Prague, 2University Hospital, Brno, 3University Hospital, Hradec Kralove, 4University Hospital, Olomouc, 5University Hospital Kralovske Vinohrady, 6CLSG Data Center, Prague, 7University Hospital, Pilsen, 8University Hospital Motol, Prague, Czech Republic

Background: Management of elderly patients (above ≥80y) is difficult and only limited number of patients could be treated by curative approach with anthracycline based chemotherapy. Dose reduction of particular drugs is used very often and it varies based on pts characteristics and center preferences. There is however lack of randomized or at least non-randomized historical comparisons.

Aims: The objective of this study is to analyze elderly DLBCL patients prospectively registered in NIH Lymphoma Project and treated anthracycline based regimen in real world outside of clinical trials.

Methods: Patients (pts) with informed consent are prospectively followed in multicenter Lymphoma Project since 1999. Diagnostic, therapeutic and follow up data are prospectively collected. There were 399 DLBCL pts older than 80year diagnosed in period 1999-2014 identified. Among 372 pts. with pathology review and essential data there were 112 pts. (30.9%) treated with R-CHOPlike chemotherapy. Analysis of clinical prognostic factors, therapy and toxicity was performed. Pearson, Kaplan-Meier and log rank tests were used.

Results: Median age was 81 years (80-88), 51.8% of men. Proportion of pts ≥85 was 14.3%, with PS ≥2 (ECOG) 34.0%, with higher LDH 64.3%, with high or intermediate high IPI 49.1%, with bulky disease (>10 cm) 17.0%, with lower albumin 27.7%, with Charlson Comorbidity Score (CCS) ≥4 25%. According to treatment choice of physician (intent to treat), pts. could be divided into 3 groups R-CHOP (CH) (cyclophosphamide – CF 750 mg/m2, adriamycin – A – 50 mg/m2) or R-MiniCHOP (miniCH) (CF 400 mg/m2, A 25 mg/m2, Peyrade 2011) or modified R-CHOP (modiCH) (CF 750 mg/m2 and A 25 mg/m2) or any other dose between CHOP and miniCHOP. There were 21 pts (18.8%) treated with CH, 38 (33.3%) with miniCH and 53 (47.3%) with modiCH.

There were no significant differences between the subgroups, except higher proportion of bulk in modiCH vs miniCH and CH (35% vs 12.9% vs 7.7% resp.; p 0.04) and cardiac comorbidity (60.5% vs 33.3% vs 30.2% resp.; p 0.02). Six and more cycles were administered in 71.4%, 63.1% and 58.5% pts. in CH, miniCH and modiCH resp. Following proportion of pts. received ≥80 (≥50%) of original CHOP dose. For cyclophosphamide it was 66.7% (81%), 0% (50%) and 62.2% (79.2%) resp. and for A it was 57.1% (76.1%), 2.6% (15.8%) and 13.2% (49%) resp. for CH, miniCH and modiCH resp. There were observed 11 treatment related deaths (6 cardiac toxicity and infection), 5 in miniCH and 6 in modiCH groups. The overall response rate was 76.8% with 59.8% CR/CRu. Median PFS and OS were 2.8y and 4.6y vs 3.5y and 4.0y in the last period. The age-specific incidence rates (1989-1994, 1995-2000, 2001-2007 and 2008-2014) and 3 age groups (18-60, 61-70 and >70 years), as compared with 2.7, 18.7 and 19.5 in the last period. The application of CT+RT increased exclusively among pts age 18-60. More specifically, the proportions for the three age groups were 26, 18 and 4% in the first period, as compared with 60, 10 and 4% in the last period. The use of RT alone among pts age >60 decreased with each period, following the wider use of CT alone over time, especially for pts age 61-70 years. The proportions of CT alone for the three age groups were 11, 8 and 2% in the first period, as compared with 31, 64 and 32% in the last period. Of note, 38 and 26% of pts age >70 received no therapy and RT alone in the last period, respectively. Five-year RS only improved for pts age 18-70 (Figure 1). Five-year RS (95% confidence intervals) was 22% (16%-30%), 13% (7%-22%), and 3% (1%-10%) in the first period for the three age groups, as compared with 56% (47%-64%), 35% (28%-43%) and 6% (2%-13%) in the last period. A multivariable survival model confirmed the adverse effect of older age on excess mortality and an improvement of survival over time. However, when information on treatment was added to that model, the effect of period lost statistical significance. This suggest that treatment contributed to the improved survival over time. Older age remained a predictor of poor prognosis.

Figure 1.

Summary/Conclusions: The present study is the largest European IVLBCL series. It shows that despite the use of modern immune-chemotherapy, IVLBCL remains an aggressive lymphoma entity. In particular, these patients are highly exposed to early relapse and therefore should be considered for innovative frontline therapies.
pts >60 years, which might in part be related to improved diagnostic practices among the elderly over time. RS increased over the past decades for pts age 70 or below. This is largely explained by the increased use of intensive therapy over time. Although the use of CT alone generally increased among pts >70 years, their survival is still poor. Therefore, there is an urgent need to design specific trials for elderly PCNSL pts to improve their survival.

P220

CLINICAL CHARACTERISTICS AND LONG-TERM RESULTS OF TREATMENT OF DIFFUSE LARGE HEPATITIS C-ASSOCIATED NON-HODGKIN LYMPHOMA (DLBCL+C)
S. Lepkov1,2, I. Subortseva2, G. Tumyan2, P. Zejnalova3, O. Kolomejtsev3, Y. Ryabukhina3, A. Semenova3, N. Kokoasadze3, N. Kupryshina4, I. Komarov3, O. Malikov3, S. Borisovskaya1, O. Ettinger1, I. Lazarev4, V. Ivanova4, R. Ivashhenko5, A. Korginna1, I. Nikitin1, Y. Kemizh5
1Russian National Research Medical University named after N.I. Pirogov, 2National Research Center for Haematology, 3National Research Center for Oncology named after N.N. Blochin, 4City Clinical Hospital named after C.P. Botkin, 5City Clinical Hospital named after V.M. Buyanov, Moscow, Russian Federation

Background: In the WHO classification (2008), hepatitis C virus distinguish as one of the etiological factors of multistage elopogenesis DLBCL.

Aims: The purpose of this study was evaluation of clinical features and results of treatment of diffuse krepokleotchny lymphoma associated with hepatitis C in comparison with a control group of patients with diffuse large lymphoma without viral hepatitis markers.

Methods: It was included 521 patients with DLBCL, 98 patients with DLBCL and markers of hepatitis C (DLBCL+C) and a control group of 422 patients with DLBCL without markers of hepatitis C (DLBCL-C).

Results: Patient’s age ranged from 21 to 76 years (median was 47 years) in DLBCL+C; ranged from 23 to 81 years (median 61) in DLBCL-C (p=0.02). The male: female ratio was 1: 1.3 in patients with DLBCL+C: 1: 1.7 in the group DLBCL – C. Stage I and II were in 11% patients with DLBCL+C, and 48% patients with DLBCL - C; III and stage IV were detected in 89% patients with DLBCL+C and 52% of DLBCL-C (p=0.00002). Extranodal lesions detected in 72% in DLBCL+C and in 26% in C DLBCL-C (p=0.006). In comparable groups localization of extranodal lesions was: spleen (52% to 23%), bone marrow involvement (43% and 27%), liver (18% and 1%), lesions was: spleen (52% to 23%), bone marrow involvement (43% and 27%), liver (18% and 1%), GCB / non-GCB histological variants ratio was 55% / 45% in DLBCL+C; 36% / 64% in DLBCL-C group / ratio GCB / (p=0.001). Hepatitis C virus RNA blood were identified by ELISA. All patients received chemotherapy according to the scheme CHOP / R-CHOP. The frequency of complete remission was 60% in the group of patients with DLBCL+C and 63% of DLBCL-C. Median overall survival (OS) was 46 months in group DLBCL+C and 71 months in DLBCL-C (p=0.0003).

Median progression-free survival (PFS) was 28 months in DLBCL+C 47 months in the control group (p=0.0002). According to the immunohistochemical variant of DLBCL: GCB DLBCL-C and 42 months in group non-GCB. In DLBCL+C 62 months in non-GCB DLBCL-C (p=0.0002). Median PFS was 36 and 47 months in comparable group. Median OS was 18 months in non-GCB DLBCL+C and 70 months in non-GCB DLBCL-C (p=0.00001). Median PFS groups was 13 and 42 months, respectively. 58 patients received antiviral therapy after chemotherapy. Median OS was 63 months in GCB DLBCL+C with antiviral therapy and 28 months in GCB DLBCL-C without antiviral therapy (p=0.00002). Median PFS was 46 and 20 months, respectively. Median OS was 22 months in non-GCB DLBCL+C with antiviral therapy and 17 months in non-GCB DLBCL-C without antiviral therapy. Median PFS in the group was 11 and 15 months, respectively.

Summary/Conclusions: DLBCL+C characterized by aggressive course of the disease (younger age at onset of the disease, advanced stages, extranodal involvement), which is one more evidence possibility of separating DLBCL+C in a separate group. Although there is no difference in the effectiveness of the therapy. But disease-free survival in DLBCL+C patients was significantly worse.

P221

MAGNETIC RESONANCE IMAGING FOR EARLY DETECTION OF ANTHRACYCLINE CARDIOTOXICITY IN MALIGNANT LYMPHOMA
A.H. Laursen1,2, J.J. Thune2, M.B. Elmink3, P. Hasbak4, R.S. Ripa5, M. Hutchings1
1Department of Haematology, Rigshospitalet, 2Department of Cardiology, Bispebjerg and Frederiksberg Hospital, 3Department of Cardiology, 4Department of Clinical Physiology, Nuclear Medicine and PET, Rigshospitalet, Copenhagen, Denmark

Background: Doxorubicin is a cornerstone of curative lymphoma treatment. However, doxorubicin therapy is limited by cardiac side effects including high-mortality heart failure (HF). Signs of cardiotoxicity often appear too late to avoid irreparable myocardial damage.

Aims: The aim of our study is to investigate the value of rubidium 82 positron emission tomography (82Rb PET), iodine 123 metaiodobenzylguanidine (123I MIBG) and cardiac magnetic resonance (MR) imaging in early detection of doxorubicin-induced cardiomyopathy and prediction of HF in patients with malignant lymphoma. We aim to identify early signs of cardiotoxic injury that predict the formation of interstitial fibrosis and subsequent HF. Here we present our preliminary MR data. 82Rb PET and 123I MIBG data will be analysed later.

Methods: The study is a prospective, clinical, single-centre study. The study aims to include 70 consecutive chemotherapy-naive lymphoma patients scheduled for intended curative chemotherapy without planned mediastinal radiation therapy. All patients undergo routine clinical examinations, but with supplemental imaging, including 1) baseline 82Rb PET and MR (prior to treatment); 2) acute 82Rb PET and MR (within 1 week of the first treatment); 3) subacute 123I MIBG (after 2-3 months of therapy) and 4) late MR (1 year after the start of treatment). 82Rb PET imaging is performed at rest and during pharmacological stress testing with adenosine. It is primarily used to evaluate the acute effects of doxorubicin on myocardial perfusion. 123I MIBG is used for detection of doxorubicin-induced subacute changes in the myocardial adrenergic neurons. Cardiac MR is performed with late gadolinium enhancement and provides information on acute and late changes in left and right ventricular function, atrial and ventricular volumes, myocardial mass and interstitial fibrosis. Statistical analyses were done in R (version 3.2.0) as paired difference tests using Wilcoxon signed rank test. P-values <0.05 were considered significant.

Results: As of March 1st 2017, 61 patients have been included. In 33 cases, the time of intended follow-up has been reached. Four patients died prior to follow-up, including one patient who died before the acute imaging procedures. Four patients were excluded due to compliance problems. One patient was excluded due to disease downstaging resulting in omission of doxorubicin from the treatment plan. Of the 24 patients with complete data from both the baseline and late MR scans, 16 had lower LVEF values at follow-up: 0-5% (n=3), 6-10% (n=8), 10-15% (n=4) and >20% (n=1). Mean LVEF at follow-up was significantly lower (57.1%) compared to baseline LVEF (62.0%; p=0.01) and acute LVEF (64.3%; p=0.002). The LVEF decline from baseline to follow-up was paralleled by an increase in mean left ventricular end diastolic volume (LVEDV) of 10.0mL (p=0.03). Interestingly, an increase in LVEDV was already registered at the acute MR scan (7.3mL; p=0.03). The increase in LVEDV from the acute MR to follow-up was not significant. We also registered an acute increase of 7.4mL in mean stroke volume (SV) (p=0.02). However, from the acute MR to follow-up we found a significant decline in SV (p=0.02). There was no difference in SV from baseline to follow-up (p=0.7). The acute changes in LVEDV did not predict LVEF declines from baseline to follow-up (Figure 1).

Figure 1.

Summary/Conclusions: Our preliminary show that cardiac MR can be used for detection of declining LV function 1 year after doxorubicin exposure. It appears that cardiac MR may also provide information on acute functional changes in LVEDV and SV. We hope that our 82 Rb PET and 123I MIBG data will provide additional early signs of doxorubicin cardiotoxicity that can be used to predict subsequent development of HF.
Background: The use of surveillance computed tomography (CT) is usual practice for cases of complete remission (CR) in aggressive non-Hodgkin lymphoma (aNHL). However, there is a lack of evidence to support this strategy.

Aims: To determine whether surveillance CT could contribute to the improvement of survival in relapsed aNHL patients, we retrospectively analyzed our institutional lymphoma registry, which enrolled consecutive patients with lymphoma from June 1995 to October 2016. Of 1,385 aNHL patients in the registry, 664 patients achieved CR and received follow-up through clinical visits, with or without surveillance CT.

Methods: Patients who met the following inclusion criteria were selected: i) histologic diagnosis of aNHL (diffuse large B-cell lymphoma, Burkitt lymphoma, and B-cell lymphoblastic lymphoma, peripheral T-cell lymphoma, anaplastic large cell lymphoma, NK/T-cell lymphoma, and T-cell lymphoblastic lymphoma); ii) patients who achieved CR after frontline or salvage chemotherapy with curative intent; and iii) time from the date of diagnosis to the date of last follow-up longer than 12 months. All patients in CR after frontline therapy were followed-up with clinical visits (symptom assessment, physical examination, and blood tests) every 1 to 6 months. Surveillance CT covering the neck, chest, or abdomen were performed every 3 or 6 months or when clinically indicated in the first 2 years, and then every 6 or 12 months or when clinically indicated thereafter. The decisions regarding the surveillance strategy (clinical visit with appropriate blood chemistry with or without surveillance CT) were at the discretion of the treating physicians.

Results: Relapse was detected in 171 patients, of whom 152 had undergone surveillance CT during follow-up. Of these 152 patients, asymptomatic relapse was detected in 67 (44%) by surveillance CT and symptomatic relapse outside the surveillance interval was detected in the other 85 (56%). Detection of asymptomatic relapse by surveillance CT did not improve the post-relapse survival in the relapsed aNHL patients. In addition, the interval of surveillance CT (3 or 6 months) did not affect survival. No subgroups were identified that favored the use of surveillance CT to detect relapse. Additionally, we analyzed the impact of surveillance CT in patients with refractory or relapsed aNHL who achieved CR after salvage chemotherapy (CR2). Of 315 aNHL patients treated with GLIDE (gemcitabine, L-asparaginase, ifosfamide, dexamethasone and etoposide) chemotherapy reported complete response (CR) rate and 3-year overall survival (OS) of these patients were 57.1% and 56% respectively. We assumed autologous stem cell transplantation may further improve the prognosis of these patients.

Aims: We conducted this clinical trial to address the efficacy and safety of our treatment strategy, GLIDE induction followed by ASCT, in newly diagnosed stage IV and relapsed ENKTL.

Methods: We treated 60 patients with newly diagnosed stage IV (n=49) and relapsed (n=11) ENKTL from 2010 to 2016. The median age at recruitment was 38 years and the median follow-up period was 13.4 months. Patients were treated with GLIDE (gemcitabine 800 mg/m2 D1, 5, L-asparaginase 6000 u/m2 D4, 8, 10, 12 or peg-asparaginase 2500 u/m2 D4, 11; ifosfamide 1000 mg/m2 D1-3; dexamethasone 20mg D1-4; etoposide 100 mg/m2 D1-3) every 4 weeks, and responses were evaluated with PET/CT every 2 cycles. Patients achieving CR underwent ASCT or continued with GLIDE up to 6 cycles. Others finished 6 cycles of GLIDE. Overall response rate (ORR), CR, OS and progression free survival (PFS) were calculated using standard methods. Statistical analysis was done using Fishers exact test or Chi-square test. Kaplan-Meier method was used for time-to-event analysis including overall survival and progression free survival. The Log-rank test was used to evaluate the difference in time-to-event endpoints between patient groups.

Results: Fifty-seven patients had finished planned treatment with 1 withdraw of informed consent after cycle 1, and 2 death of sepsis during cycle 1 and cycle 2 respectively. Twenty-one patients underwent ASCT. The ORR was 81.4% and the CR was 69.5% with early CR (CR after 2 cycles) of 57.6%. Estimated 5-year OS and PFS rates of the whole cohort and patients underwent ASCT were 68.7%, 54.0%, 79.6% and 85.2% respectively. Univariate analysis revealed that ECOG ≤1, IPI ≤2, early CR and ASCT were associated with less relapse and death. Multivariate analysis showed ECOG ≤2 was an independent risk factor for disease progression (HR=4.321, 95% CI 1.127–16.572, P=0.033) and death (HR=46.254, 2.150–993.190, P=0.014) and ASCT was associated with better PFS (HR=0.058, 95% CI 0.007–0.495, P=0.009) and OS (HR=0.019, 95% CI 0.001–0.596, P=0.024). Figure 1 highlights the OS and PFS of whole cohort (A) and ASCT patients (B). Myelosuppression was the most common adverse reaction (AE). The incidences of level 4 neutropenia, thrombocytopenia and anemia were 46.6%, 28.6% and 5.3% respectively. The most common non-hematologic AE was fever with neutropenia (36.5% of total cycles), while others were mild and manageable.

Summary/Conclusions: GLIDE is an effective regimen for newly diagnosed stage IV and relapsed ENKTL. Up-front ASCT after achieving CR can reduce relapse and prolong survival. Treatment related adverse reactions and support care need concerns.
Bone marrow failure syndromes incl. PNH - Biology

IDENTIFICATION OF A NOVEL GERMLINE MECOM / EV1 VARIANT THAT RUNS IN A PEDIGREE WITH RADIOULNAR SYNOSTOSIS AND AMEGAKARYOCYTIC THROMBOCYTOPENIA AND PREDISPOSES TO ADULT ONSET MYELOID MALIGNANCY

T. Ripperger1,*, W. Hofmann1, J.C. Koch2, K. Shireeshan3, D. Haase3, G. Wufl3, P.R. Issing4, M. Karnebogen5, G. Schmidt1, B. Aubert1, B. Schlegelberger1, T. Illg1,2, B. Zim2, D. Steinemann1
1Department of Human Genetics, Hannover Medical School, Hannover, 2Department of Neurology, 3Department of Hematology and Oncology, University Medical Centre, Goettingen, 4Department of Otorhinolaryngology, Head, Neck and Facial Plastic Surgery, Klinikum Bad Hersfeld, Bad Hersfeld, 5Health-park Lengern, Division of Surgery and Orthopedics, Bovenden, 6Unified Biobank, Hannover Medical School, Hannover, 7Genetic Counseling and Diagnostics, Genetikum, Stuttgart, Germany

Background: Radioulnar synostosis and amegakaryocytic thrombocytopenia (RUSAT), one of the rare bone marrow failure syndromes, is caused by a point mutation in HOXA11. In three simplex patients, de novo missense variants in MECOM have recently been reported as an alternative cause in individuals with RUSAT. MECOM, identified as a common ecotropic viral integration site 1 (EV1) in murine myeloid leukemia, is known as a key transcriptional regulator in hematopoiesis and is frequently involved in sporadic myeloid leukemia.

Aims: To screen for the causative genetic alteration in a family with four affected individuals out of three generations with radioulnar synostosis, incompletely penetrant congenital thrombocytopenia, hearing impairment due to dysplastic middle ear bones, patellar hypoplasia, and hand and foot dysmorphisms. Notably, two of four affected individuals in our family developed adult onset myeloid malignancies (i.e. myelodysplastic syndrome (MDS) with excess blasts and MDS/myeloproliferative neoplasm-unclassifiable). No HOXA11 mutation was identified in this family.

Methods: Whole exome sequencing was performed in three affected individuals using a Nextera Rapid Capture kit and a NextSeq 500 instrument (Illumina, Munich, Germany). Identified sequence variants were filtered for those that are reported to be functionally relevant in databases (ESP6500, ExAC). In three simplex patients, de novo missense variants in MECOM have recently been reported as an alternative cause in individuals with RUSAT. MECOM, identified as a common ecotropic viral integration site 1 (EV1) in murine myeloid leukemia, is known as a key transcriptional regulator in hematopoiesis and is frequently involved in sporadic myeloid leukemia.

Results: This extends the RUSAT-associated phenotype and proposes that MECOM germline mutations can cause a genetic predisposition to adult onset myeloid malignancy. [BZ and DS contributed equally to this work].

LOSS OF THE HOMOLOGOUS RECOMBINATION GENE RAD51 LEADS TO FANCONI ANEMIA-LIKE SYMPTOMS IN ZEBRAFISH

G. Wulf 3, P.R. Issing 4, M. Karnebogen 5, G. Schmidt 1, B. Auber 1, B. Schlegelberger 1, T. Illg 1,2, B. Zim 2, D. Steinemann 1
1Department of Human Genetics, Hannover Medical School, Hannover, 2Department of Neurology, 3Department of Hematology and Oncology, University Medical Centre, Goettingen, 4Department of Otorhinolaryngology, Head, Neck and Facial Plastic Surgery, Klinikum Bad Hersfeld, Bad Hersfeld, 5Health-park Lengern, Division of Surgery and Orthopedics, Bovenden, 6Unified Biobank, Hannover Medical School, Hannover, 7Genetic Counseling and Diagnostics, Genetikum, Stuttgart, Germany

Background: Fanconi anemia (FA) is a hereditary DNA repair disorder characterized by various congenital abnormalities, progressive bone marrow failure and cancer predisposition. RAD51 has recently been designated as a Fanconi anemia (FA) gene, following the discovery of two patients carrying dominant negative mutations. RAD51 is an indispensable homologous recombination protein, necessary for strand invasion and crossing over. It has been extensively studied in prokarocytes and lower eukaryotes. However, there is a significant lack of knowledge of the role of this protein and its regulation in an in-vivo context in vertebrates due to the early embryonic lethality of murine Rad51 mutants. As FA is a serious disease, we aim to utilize the powerful genetics and translucency of zebrafish to dissect the role of rad51 in hematopoiesis and to explore the molecular basis of Fanconi anemia pathogenesis.

Methods: Zebrafish carrying homoygous loss of function mutations in rad51

1Newcastle upon Tyne Hospitals, NHS Foundation Trust, Newcastle upon Tyne, 2City Hospitals Sunderland NHS Foundation Trust, Sunderland, 3North Tees and Hartlepool, NHS Foundation Trust, Stockton on Tees, 4County Durham and Darlington, NHS Foundation Trust, Darlington, 5North Cumbria University Hospitals NHS Trust, Carlisle, United Kingdom
generated by ENU mutagenesis were characterized in terms of their hematopoietic and non-hematopoietic phenotypes during embryonic development and adulthood.

Results: The rad51f mutant fish developed key features of FA, including hypocellular kidney marrow (equivalent to mammalian bone marrow), sensitivity to crosslinking agents and decreased size. Interestingly, although mutants can survive to adulthood, they develop exclusively as sterile males. We show that some of the hematological symptoms stem from both decreased proliferation and increased apoptosis of embryonic hematopoietic stem and progenitor cells. Co-mutation of p53 was able to rescue the embryonic and adult hematopoietic defects seen in the single mutants, but led to early tumor development in the adult double mutants. We further establish that prolonged inflammatory stress can exacerbate the hematological impairment, leading to an additional decrease in kidney marrow cell numbers linked to excess p53 expression (Figure 1).

Figure 1. Example image of a p53, rad51 double mutant fish with a tumor behind the eye (A). Histological analysis showed the tumour to be a malignant peripheral nerve sheath tumor (B). The scale bar is 500 and 10 µm respectively.

Summary/Conclusions: We demonstrate that zebrafish lacking functional rad51f are viable and develop symptoms resembling FA. These findings strengthen the assignment of RAD51f as a Fanconi gene and provide more evidence for the notion that aberrant p53 signaling during embryogenesis leads to the hematological defects seen during later stages of life in FA patients. Further research on this novel zebrafish FA model will lead to a deeper understanding of the molecular basis of bone marrow failure in FA and the cellular role of the RAD51 protein.

P228
A NOVEL TELOMERASE RNA COMPONENT VARIANT IN A FAMILY WITH MACROCYTOSIS AND MILD VARIABLE CYTOPENIAS
C. Burney1,2, A. Mumford2, N. Roy3, S. Henderson3, M. Proven3, A. Schuh3, K. Wray4, H. Dreau3, C. Bradbury2
1Department of Haematology, University Hospitals Bristol NHS Trust, 2School of cellular and molecular medicine, University of Bristol, Bristol, 3BRC Blood Theme and BRC/NIHS Translational Molecular Diagnostics Centre, John Radcliffe Hospital, 4Molecular Haematology Unit, Weatherall Institute of Molecular Medicine, John Radcliffe Hospital, Oxford, United Kingdom

Background: Telomerase RNA component (TERC), encoded by the TERC gene, is an essential component of telomerase, a polymerase that adds the telomeric repeat to the 3’ lagging strand of DNA during cell replication. TERC variants have been causally associated with several haematological disorders, including autosomal dominant dyskeratosis congenita (DKC), aplastic anaemia, myelodysplastic syndrome and acute leukaemia, sometimes accompanied by non-haematological phenotypes. Here we report a likely pathogenic TERC variant associated with a haematological phenotype that predominantly affects the red cell lineage.

Aims: To describe the genotypic and phenotypic relationship of a new TERC variant.

Methods: Genomic DNA samples were analysed for sequence variants using the Oxford Red Cell Panel, a panel of 33 genes previously associated with human red cell disorders. Sanger sequencing was used to confirm the novel variant. Telomere lengths were performed at the Laboratory for Molecular Haematology (LMH), Rayne Institute, Kings College Hospital.

Results: The index case AM (I.1) was a female who presented at age 56 with lifelong macrocytosis and previous mild neutropenia (Table 1). The younger daughter (age 30) TW (II.1), had isolated lifelong macrocytosis and previous mild neutropenia (Table 1). The younger daughter (age 27) BM (II.2) had macrocytic anaemia, thrombocytopenia (Table 1) and a recent pregnancy complicated by worsening thrombocytopenia, pre-eclampsia, placental dysfunction, liver dysfunction and foetal loss. Following delivery her liver function slowly returned to normal and a fibroscan was within normal limits. All three pedigree members with macrocytosis had a n.181A>C substitution in TERC (relative to transcript ENST00000602385.1), within the pseudoknot domain. Residue n.181 is highly conserved across mammalian species. This variant is absent from the gnomAD database of more than 230,000 TERC alleles, and the HGMD databases. The variant is within a TERC region in which previously reported variants have been associated with haematological phenotypes. In order to determine the pathogenicity of this variant, telomere lengths were assessed and found to be short in both Case I.1 and II.2 (Table 1). There were no other likely pathogenic variants in the Oxford Red Cell Panel genes. Together, these observations suggest that the n.181A>C substitution is causally associated with the macrocytosis phenotype.

Summary/Conclusions: This report demonstrates a likely causal association between a newly identified TERC variant, short telomere length and a relatively mild haematological phenotype that is largely restricted to red cells. This emphasises the phenotypic heterogeneity associated with TERC variants, justifies the rationale of screening multiple genes simultaneously and suggests that TERC variant could potentially underlie a broader range of unexplained heritable blood cell abnormalities.

GENERATION OF X-LINKED DYSKERATOSIS CONGENITA-LIKE HUMAN HEMATOPOIETIC STEM CELLS
C. Carrascosol1,2, H.A. Zitterstein1,2, L. Pintado-Berniches2,3, M.L. Lozano1,2, L. Sastropol2,2, J.A. Buener1,2, R. Perona2,3, G. Guenechea1,2,*
1Division of Hematopoietic Innovative Therapies, Centro de Investigaciones Eronómicas Medicina y Tecnología (CIBERER) and Instituto de Investigación Sanitaria Fundación Jiménez Díaz (IIS-FJD/UAM), 2Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), 3Instituto de Investigaciones Biomédicas Alberto Sols (CSIC/UAM), Madrid, Spain

Background: X-linked Dyskeratosis congenita (X-DC) is an inherited syndrome caused by mutations in the DKC1 gene that encodes for the dyskerin nuclear protein. These mutations reduce the telomerase activity leading to premature telomere length attrition. Several organs can be affected in these patients, although the bone marrow failure (BMF) is the main cause of death in X-DC patients (more than 70% of cases). So far, the only curative treatment for BMF in DC patients is hematopoietic stem cell (HSC) transplantation. However, risks derived from conditioning regimes and the difficulties to find a compatible donor suggest that gene therapy may constitute a promising alternative in treating DC patients.

This report demonstrates a likely causal association between a newly identified TERC variant, short telomere length and a relatively mild haematological phenotype that is largely restricted to red cells. This emphasises the phenotypic heterogeneity associated with TERC variants, justifies the rationale of screening multiple genes simultaneously and suggests that TERC variant could potentially underlie a broader range of unexplained heritable blood cell abnormalities.
SUMMARY/CONCLUSIONS: TELOMERE LENGTH SCREENING TRIGGERED BY CLINICAL SUSPICION performance of the eculizumab can be in part explained by its action on EVs.

Aims: Because of the difficulties associated to the use of primary HSCs from DC patients for experimental studies, this study was focused on the generation of X-DC-like HSCs. The generation of X-DC-like HSCs will facilitate the understanding of the molecular basis of the HSC defects characteristic of X-DC and contribute to the development of new experimental therapies for the treatment of the BMF of X-DC patients.

STUDY OF EXTRACELLULAR VESICLES ROLES IN THE PATHOPHYSIOLOGY OF THROMBOSIS IN PAROXYSMAL NOCTURNAL HEMOGLOBINURIA PATIENTS DURING ECUKLIZUMAB TREATMENT: A PILOT PROSPECTIVE LONGITUDINAL CLINICAL STUDY A. Wannez1,2,*, B. Devalet2, C. Boury1, B. Bihin3, J.-M. Dogné1, F. Mullier2

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a disease characterised by complement-mediated hemolysis (Brodsky et al., Hematology, 2008). Complement can induce the production of extracellular vesicles (EV) (Burnouf et al, Transfus Apher Sci, 2015). These EV are cell-derived vesicles whose the size-range is around 50 and 1000nm. They can expose phosphatidyserine (PS-antionic phospholipid) and tissue factor (TF), which explains their involvement in the coagulation cascade (Owens et al, Clin Res, 2011). The EV could have a role in the thrombus formation, the leading cause of death in PNH patients (Brodsky et al, Hematology, 2008; Simak et al, Br J Haematol, 2004; Hugel et al, Blood, 1999), Eculizumab, a human anti-C5 monoclonal antibody, used in the treatment of PNH seems to decrease the thrombosis frequency (relative reduction of 85% of thromboembolic event rate with the introduction of the treatment in the patients) (Hillmen et al, Blood, 2007; Kelly et al, Ther Clin Risk Manag, 2009; Weitz et al, Thromb Res, 2012; Al-Jafar et al, Hemato Rep, 2015).

Aims: The general purpose of this project is a better understanding about the role of EVs in thrombosis in the context of PNH patients under eculizumab. We also assessed the procoagulant activity in PNH patients treated with eculizumab, in order to check, if the antithrombotic activity of the eculizumab could be in part explained by its interaction with the EVs.

Methods: We conducted a pilot prospective open label longitudinal clinical study with six PNH patients treated with eculizumab. The study was led according to the Helsinki Helsinki and approved by the local Ethic Committee. Informed consent was obtained for each patient. The aim was to measure, by flow cytometry, the production of EVs in patient’s platelet-free plasma (PFP) before the start of eculizumab, after 4 weeks and after 11 weeks of treatment. We also assessed the procoagulant activity in PFP by STA-Procoag-PPL assay and by thrombin generation assay (TGA). A more sensitive version of TGA was also performed to study the procoagulant profile induced by the EVs (use of EVs pelletted from PFP). We used mixed-effects linear regression (R 3.1.2 with nlme package) with logarithmic transformation for flow cytometry results. We compared the results after 4 weeks or 11 weeks of treatment against the inclusion value.

Results: We observed a decrease in platelet EVs with the eculizumab treatment (p<0.05). STA®-Procoag-PPL assay showed a decrease of the procoagulant profile induced by procoagulant phospholipids (PL) with the treatment. These results were not confirmed by TGA on PFP, due to a lack of sensitivity. By this way, we performed a more sensitive version of TGA that allows to observe variation in the procoagulant profile induced by the EV with the eculizumab (p<0.05).

Summary/Conclusions: Eculizumab has an impact on the amount and the procoagulant profile induced by the procoagulant PL and the EVs. The anti-thrombotic performance of the eculizumab can be in part explained by its action on EVs.

TELOMERE LENGTH SCREENING TRIGGERED BY CLINICAL SUSPICION FOR CLASSICAL AND/OR CRYPTO DSYKEROSITIS CONGENITA – PROSPECTIVE RESULTS FROM THE AACHEN TELOMEROPTHY REGISTRY

A. Maurer1,2, S. Willop1, F. Tholl3, A. Röth4, U. Platzecker4, W. Blau5, F. A. Ayuk6, S. Corbacho7, H. Schrezenmeier1, M. G. Manz10, T. Eggermann10, K. Zerres10, S. Koschnieder1, M. Schmennscher1, S. Isfort1, J. Panse2, T.H. Brümmendorf1

Background: Classical Dyskeratosis Congenita (DKC) is a multisystem disorder caused by defective telomere maintenance, mostly due to mutations in genes related to functional activity of telomerase or accessibility of the telomeres themselves. Clinical characteristics are mucocutaneous abnormalities, bone marrow failure, an increased predisposition to cancer and other variable features. While classical DKC is typically diagnosed in childhood or adolescence, the incidence of cryptic DKC variants typically presenting with a clinically more heterogeneous picture is increasing. The diagnostic system of DKC in patients, in which the age of onset is unknown. Accelerated shortening of Telomere length (TL) in peripheral blood leucocytes represents the functional read-out of altered telomere maintenance and thus allows for a screening of patients with suspected DKC. On the basis of TL measured below the 1% percentile of age adjusted healthy controls, next generation-sequencing (NGS) analysis for identifying mutations was triggered.

Aims: In this study, we report the first results of such a clinical routine screening for telomeropathies carried out within the Aachen Telomeropathy Registry (ATR).

Methods: 184 patients from 52 participating centers (80% academic centers) within Germany, Austria and Switzerland were screened for premature telomere shortening and included with informed consent into the ATR since November 2014. Inclusion criteria and reason for screening was either the clinical suspicion of the treating physician for a telomere maintenance disorder and/or the recommendations of the German Society of Hematology and Oncology (DGHM) published via Onkopedia. TL analysis of peripheral blood granulocytes and lymphocytes was carried out using combined fluorescence in situ hybridization and flow cytometry (flow-FISH). Mutations in genes suspected to cause telomeropathies (i.e. TERT, TERC, DKC1, NOP10, NHP2, USC1, CTCL, RT1L1, TIN2, TACB1) were analyzed by NGS using customized primer panels and amplicon-based sequencing on a MiSeq sequencer (Illumina) in all patients with TL in lymphocytes below the 1% percentile of healthy controls.

Results: Underlying initial diagnosis by the treating physician with typical telomere screening were aplastic anemia (AA, n=72, 39% of cases), unexplained cytopoiesis disturbance (UC, n=16, 8.6%), and lymphocytes (n=21, 11%), malignancies (n=11, 5.9%), family members (FM) of known DKC patients (FM-DKC, n=17, 9%), atypical squamous cell cancer of the head-and-neck (SCCHN, n=10, 6%), paroxysmal nocturnal hemoglobinuria (PNH, n=9, 5%), acute myeloid leukemia (AML, n=5, 3%) as well as other disorders (e.g. lung fibrosis, Diamond-Blackfan-Anemia, thrombocytopenia, etc.). Median age of patients with mutations was 45.0 y (range 21 to 68 y). TL screening revealed 20% (38/184) patients with lymphocyte TL and 16% (30/184) of patients with granulocyte TL below the 1% percentile. NGS screening identified typical mutations associated with altered telomere maintenance in 15 out of 38 patients (40%) representing 8.2% of the total patient population. Median age of patients with mutations was 45.0 y (range 21 to 68 y). Mutations were detected in RTEL1 (n=3), TIN2 (n=3), DKC1 (n=3). Mutations were observed in 5% of all AA, 12% of all UC, 50% of all AML-DKC, 13% of all SCCHN, 20% of all screened AML patients.

Summary/Conclusions: We provide the first analysis of a routine TL screening for telomeropathies in a large cohort of patients under investigated telomere screening. Under the age of 40: Mortality has not been reduced in 2010-2015.

S. Giammarco1,*, S. Simona2, C. Dufour3, R. Peffault de Latour4, G. Socie5, J. Passweg6, A. Bacigalupo1

1Hematology, Università Cattolica del Sacro Cuore, Rome, 2Hematology, Uni-
versità Cattolica del Sacro Cuore, roma, 2Hematology, Istituto Giannina Gaslini, Genova, Italy, 3Hematology, Hospital St Louis, 4Hematology, Hospital Saint-Louis, Paris, France, 5Hematology, Universitätsspital Basel, Basel, Switzerland

Background: Mortality following HSCT in SAA pts over the age of 40 is reported to be in the order of 50%, without taking into account long term sequelae such as chronic GvHD, known to be more frequent in older patients. This has prompted international guidelines to recommend first line immunosuppressive therapy above 40 years of age. The question is whether this is still true in 2017.

Aims: Assess whether TRM in SAA patients grafted 2010-2015 is reduced, as compared to the era 2001-2009.

Methods: We used the WPSA-EBMT registry, and identified 748 pts aged 40 years or more, with acquired SAA, grafted between 2001 and 2015. We divided pts in 2 transplant eras: 2001-2009 (n=327) and 2010-2015 (n=407). In the more recent period (2010-2015) pts were older (53 vs 49 year, p<0.01), were more often grafted from alternative donors (ALT) (64% vs 43%, p<0.01), with a greater use of BM (54% vs 41%, p<0.01), and with a longer interval dx-tx (317 vs 258 days, p<0.01), and more often received a fludarabine containing regimen (54% vs 42%, p<0.01).

Results: The overall survival 5 year survival of pts grafted in 2001-2009 was 57%, compared with 55% for pts grafted 2010-2015 (p=0.7). In multivariate analysis, including the interval diagnosis transplant, patient's age, donor type, stem cell source and conditioning regimen, the lack of improved survival in 2010-2015 was confirmed (p=0.3). A very strong age effect was shown both in univariate and multivariate analysis: survival of pts aged 40-50 years, 51-60 years and >61 years, was respectively 64%, 54%, 41% (p<0.0001) and this was confirmed in multivariate analysis. The conditioning regimen, also proved to be a significant predictor, with improved survival for ALT transplants receiving FLU containing regimens (56% vs 46%, p<0.001). In general pts receiving either CY200 or a FLU containing regimen, did significantly better than pts receiving other preparative regimens (58% vs 50%, p=0.02). The use of a sibling donor (SIB) did not prove to predict survival in multivariate analysis. Pts receiving Campath in the conditioning, did significantly better than pts not receiving Campath (65% vs 54% p<0.01); similarly survival of patients with ATG was superior 59% vs 41% compared to patients not receiving ATG (p<0.01). When pts receiving either Campath or ATG (n=564) were compared to patients not receiving either (n=161), the difference in survival was 61% vs 41% (p<0.0001), and this was significant also in multivariate analysis. Combined primary and secondary graft failure was reduced from 16% to 12% in the two time periods (p=0.02), acute GvHD grade II-IV was reduced from 15% to 11% (p=0.01) and chronic GvHD was also reduced from 32% to 26% (p=0.04). Infections remain the leading cause of death in both transplant eras (18% and 22% respectively), followed by GvHD (5% and 4%) and graft failure (5% and 2%), whereas PTLD have been reduced from 3% to 0.5% (Figure 1).

Figure 1.

Summary/Conclusions: HSCT in pts with acquired SAA aged 40 and over, continues to carry a significant risk of TRM also in 2010-2015, ranging from 36% in younger pts (40-50) to 59% in older pts (>60 years). Survival is predicted in multivariate analysis, by two crucial predictors: patients age and the use of either Campath or ATG, the latter giving a 20% survival advantage over no Campath/ATG. ALT and SIB donors produce similar survival. This study gives further support to current guidelines, suggesting first line therapy with ATG+CsA, in pts over the age of 40.

P233

CLINICAL AND GENETIC DIVERSITY IN DIAMOND-BLACKFAN ANAEMIA: AN UPDATE FROM THE UNITED KINGDOM

D. Iskander1, C. Miller2, M. Alkian3, Y. Harrington2, Q. Al-Oqaily1, I. Roberts4, A. Karadimitris1, J. de la Fuente5
1Centre for Haematology, Imperial College London, 2Department of Paediatrics, St. Mary’s Hospital, Imperial College Healthcare Trust, 3Imperial Molecular Pathology Laboratory, Imperial College Healthcare Trust and Academic Health Sciences Centre, London, 4Department of Paediatrics, Children’s Hospital and Molecular Haematology Unit, Weatherall Institute of Molecular Medicine, Oxford University and John Radcliffe Hospital, Oxford, 5Department of Paediatrics, St. Mary’s Hospital, Imperial College Healthcare Trust, London, UK, London, United Kingdom

Background: Diamond-Blackfan anaemia (DBA) is an inherited bone marrow failure syndrome (BMFS) caused by mono-allelic, loss-of-function mutations in ribosomal protein (RP) genes. DBA is rare and has a wide spectrum of clinical manifestations, hence the utility of patient registries.

Aims: We evaluated the clinical and genetic spectrum of DBA in a large cohort of patients in the UK, aiming to identify novel features of the disease.

Methods: We performed a retrospective analysis of data from 103 confirmed cases of DBA, including 4 multiplex families. All living patients had undergone a bone marrow assessment at our specialized centre over the last 5 years. Data were collected from family interviews, patient records and referring clinicians.

Results: The 103 patients with DBA were born in a 48-year period (1967-2015), i.e., an incidence of 3 per million live births. Demographic and clinical characteristics are shown in Table 1. NGS analysis of 80 RP genes plus GATA-1 identified pathogenic mutations in 71% of cases and 7 putative novel mutations, currently undergoing validation. To date, mutation screening of both parents has been performed in 32 families with DBA. Twenty-five mutations are sporadic while 7 are autosomal dominant; in 3 of the latter, the parent is a silent ‘carrier’ without anaemia. In one case of an affected child, the causative mutation was detected in the peripheral blood of both parents but was present in 722 embryos generated for in vitro fertilisation, suggesting germline mosaicism. 80.5% of cases in our cohort presented within the first year of life. For the first time we report a high rate of perinatal problems in DBA. Prematurity +/- intrauterine growth restriction (IUGR) occurred in 31/87 (35.6%) of evaluable patients. Specific aberrant abnormalities included: hydrops fetalis (3/87), prematurity (22/87) and IUGR (16/87). In addition to congenital anomalies classically associated with DBA, we identified abnormalities of the spine and axial skeleton in 9.2% of patients. These did not correlate with a particular genotype. Our cohort exhibited multiple comorbidities, including some not previously reported to be associated with DBA: hematoma (10.7%), neuropsychiatric (17.4%) and gastrointestinal (GI) disorders (25.7%). These complications were not associated with particular treatment regimens. In terms of the natural history of DBA, a lower proportion of our patients (22%) than previously reported in the literature (40%) were able to maintain a normal Hb on long-term steroids. Three patients failed conventional therapy to date. In total there were 4 individuals with brainstem atrophy (BAS), BCC and cervical intraparietal neoplasia) in 4 different patients. The lower incidence in our cohort compared with that reported by the North American DBA registry may be explained by differences in the median ages of the 2 cohorts (12½ vs 18½, respectively) and the shorter follow-up of our patients.

Summary/Conclusions: This retrospective analysis of the UK’s DBA cohort confirmed several findings from other registries but also revealed novel features, including a high prevalence of i) premature birth and neonatal complications ii) abnormalities of the axial skeleton and iii) neuropsychiatric disorders. Prospective longitudinal studies are warranted to better characterise these co-morbidities and confirm whether they are intrinsic to DBA or arise as complications of treatment. Above all, the observed clinical heterogeneity in our cohort highlights the need for novel therapies that target the multisystem manifestations of DBA, not just the anaemia.
BONE MARROW FAILURE SECONDARY TO NOVEL/KNOWN PRIMARY IMMUNODEFICIENCY-RELATED MUTATIONS. A SINGLE CENTER ANALYSIS

M. Miano1,*, A. Grossi2, L. Fanciullo1, M. Lanciotti1, F. Fioredda1, E. Palmisani1, F. Pieri1, S. Giardino3, E. Cappelli4, T. Lanza1, P. Terranova1, M. Calvillo1, C. Micalizzi1, F. Giona4, M. Santopietro4, K. Zhang5, I. Ceccherini2, C. Dufour1

Background: Differential diagnosis between acquired and congenital forms of Marrow Failure (MF) has always represented a crucial point in the diagnostic work-up, since genetic forms do require a different therapeutic approach. It is also known that patients with congenital MF may also show immunodeficiency that, in some cases, can represent the first/ or revalent sign of the disease and therefore can be misinterpreted as a Primary Immunodeficiency (PID). On the other hand, patients with PIDs may also show MF as a result of an immune-mediated attack of marrow precursors thus generating a phenotypic overlap that can impair the correct diagnosis.

Aims: In this report we analyzed all patients with MF evaluated in our Unit with the aim to identify the type and incidence of underlying molecular defects, in particular those related to PIDs.

Methods: We retrospectively evaluated all diagnosis performed in patients with single/multi-lineage MF followed in our Unit. DEB test was used to screen Fanconi Anemia (FA). Other congenital MFs have been searched by Sanger and/or NGS molecular analysis depending on the available tools over the years.

Results: Between 2005-2016, 88 patients have been studied for single-lineage (25) or multilineage (63) MF. 48 (64%) were classified as having an underlying PID. Table 1 shows clinical characteristics and mutations of patients with PIDs.

Table 1.

Summary/Conclusions: This report shows that patients presenting with single/multi-lineage MF may have an underlying PID in a considerable number of cases. We also show that MF represented the most relevant clinical sign in patients with PI3KCD, TACI, or CD40L mutations, thus widening their clinical phenotype. We conclude that an accurate immunological work-up should be performed in all patients with MF and that PIDs-related genes should be included in the molecular screening of MF in order to identify specific disorders that may potentially receive targeted treatment and/or the appropriate conditioning regimen for SCT.

COVERSIN, A NOVEL C5 COMPLEMENT INHIBITOR, FOR THE TREATMENT OF PNH: RESULTS OF A PHASE 2 CLINICAL TRIAL

Background: Paroxysmal nocturnal haemoglobinuria (PNH) leads to episodic haemolysis secondary to an acquired deficiency of PIGA anchoring molecules on the surface of erythrocytes which play a critical role in protecting the cells from complement mediated lysis. Until the advent of eculizumab, a monoclonal anti-body which prevents the cleavage of C5 to C5a and C5b, PNH was associated with considerable morbidity and a poor long-term prognosis. However, eculizumab needs to be administered by health care professionals by intravenous infusion which may interfere with the life-styles, occupations and personal privacy of patients and the interval dosing has led to concerning breakthrough haemolysis. Coversin is a protein suitable for small-volume subcutaneous (SC) injection which can be self-administered by patients.

Aims: The aim of this study is to investigate the safety and efficacy of the complement C5 inhibitor Coversin in the treatment of PNH.

Methods: A Phase 2 single arm open label trial of Coversin is currently ongoing under which patients, either newly diagnosed with PNH or who have not previously had access to complement inhibitors, are treated for 90 days. Coversin is supplied as a lyophilised powder, reconstituted with water for injection to give a buffered aqueous solution of Coversin 30mg/mL. The trial population consists of up to 10 adult patients with a diagnosis of PNH confirmed by flow cytometry. Treatment commences with an ablating regime (AR) consisting of a fixed dose of 60mg followed by 3 doses of 30mg q12 hours delivered by SC injection. After being suitably instructed patients are encouraged to self-inject the drug. Following the AR, a dose of 15mg q12 hours is given for a further 26 days when, if the patient’s disease is well controlled, they switch to 30mg q24 hours for the remainder of the trial. The dose can be increased by two incremental steps according to a pre-specified algorithm for patients not satisfactorily controlled on the basis of serum lactate dehydrogenase (LDH) or clinical grounds at any time during the 90-day period. The primary endpoints are safety and reduction of serum LDH to ≤1.8 X the upper limit of normal (ULN) for the local laboratory. Secondary endpoints include LDH at 28, 60 and 90 days, terminal complement activity assessed by CH50 ELISA (Quidel®), sheep erythrocyte haemolysis assay, PK (free and bound Coversin levels), anti-drug antibodies (ADA) and quality of life.

Results: The trial is still ongoing and has currently enrolled 5 patients, four of whom remain on Coversin. Three patients have required single dose increases during the initial 28-day period, one of whom was later withdrawn when a co-morbidity was suspected. Two patients have moved to a single daily dose. Updated results of these and any patients enrolled subsequently will be presented. To date 2 patients have achieved the primary efficacy endpoint, two have not yet reached the 28-day point. There have been no serious or significant adverse events and the drug has been well-tolerated. A few mild injection site reactions have been recorded but these appear to diminish with time. There has been no evidence of the formation of neutralising antibodies.

Summary/Conclusions: It currently appears that treatment with Coversin is safe and effective in controlling hemolysis in PNH and that patients are capable of self-administering the drug. Coversin may be an effective alternative for patients with PNH who prefer the independence of self-administration. The relatively short dose interval may also help to reduce breakthrough events due to trough levels of drugs administered at two weekly intervals or longer.

Background: CLL is a highly heritable cancer. Although GWAS have identified ~30 independent SNPs associated with CLL, these are estimated to account for only 19% of the inherited component of CLL.

Aims: We hypothesized that this missing heritability might arise from rare coding variants (MAF <0.01), and sought to identify these through an exome-wide association study comparing rare germline variants between CLL patients and controls.

Methods: We investigated 516 CLL patients of European descent who were compared to 8,920 ethnically matched, non-cancer population controls. CLL cohorts included 235 CLL patients from DFCI (128 previously reported, 107 unpublished exomes), and 281 CLL patients enrolled on the CLL8 trial of the German CLL Study Group (WES data reported previously). An additional 130 CLL patients in an extension cohort included 24 from our published whole-genome sequencing study and 106 from an early publication of the IGCCCG. Non-cancer controls came from 3 sources: 2,520 from the 1000 Genomes Project; 6,852 from the Exome Sequencing Project; and 7,611 from a study of genetic variants (MAF <0.01), and sought to identify these through an exome-wide association study comparing rare germline variants between CLL patients and controls.

Results: We searched for patients with rare coding variants in the majority of affected cases and controls; and (iii) analyzing only ethnically matched, unrelated samples over DNA sites with sequencing coverage sufficient to achieve high-confidence genotype calls. This quality control resulted in 8,920 controls available for the association analysis. We further controlled for residual population stratification by correcting for three principal components. In order to elucidate whether these associations were due to functional effects on transcription, we used a novel assay called precision run-on sequencing (PRO-seq). PRO-seq efficiently maps active transcription regulatory elements (TREs) and provides a sensitive, quantitative and directional map of transcriptionally-engaged RNA polymerases. The algorithm, discriminative regulatory-element detection from PRO/PRO-seq (dREG), is then used to predict the presence of TRES from raw PRO-seq data, allowing for identification of functional elements in the vicinity of SNPs and quantification of their allele-specific effects on enhancer activity and gene transcription.

Results: Our gene expression analysis demonstrated 6 significant SNP-gene associations: rs674313 (6p21.3) with HLA-DQA1 (p <0.0001), rs8720701 (6p25.3) with HLA-DQA1 (p=0.01), rs7771784 (15q23; proxy for rs1767508) with TP53 (p=0.09), rs783545 (15q23.2) with COX4NB/EMC8 (p<0.0001) and rs482232 (18q13.32; proxy for rs11083846) with FRK (p <0.0001). Two associations were successfully validated in a completely independent gene expression replication analysis (n=54): rs674313 with HLA-DQA1 (p <0.0001) and rs7771784 with TP53 (p=0.0116). To annotate candidate regulatory elements, we evaluated transcription level at or near all six significant functional elements in the initial gene expression analysis in a cohort of 12 CLL samples. Transcription level at or near 3 SNPs (rs674313, rs7771784, rs305088) correlated with genotype in a dose dependent manner. When we expanded the analysis to the entire region of LD around each SNP, we were able to demonstrate a dose-dependent effect in all SNPs in B and BIALLIC sample sets (p <0.0001).

Summary/Conclusions: We conclude that PRO-seq and dREG analysis identifies evidence of active differential transcription based on genotype in the region of 5 out of 6 GWAS-identified SNPs that we have investigated so far.

DIFFERENTIAL ENHANCER TRANSCRIPTION ASSOCIATED WITH RISK ALLELE GENOTYPE IN CLL

B. Tesar1,2, L. Werner3, N. Pocheřát4, S. Fernandes1, M. R. Impaglio1,2, J. Kilgarta,1,2, C. Thompson1, M. Hanna4, A. Freedman1, D. Neuberg3, M. Freedman2, L. Core6, J. Brown1,2,3

Background: Genome-wide association studies (GWAS) have identified multiple loci that are statistically associated with CLL susceptibility. These single nucleotide polymorphisms (SNPs) are primarily located in non-protein coding genomic regions. Data suggest that these variants are enriched in regulatory elements that influence nearby target genes.

Aims: We tested the hypothesis that CLL risk variants are in or near regulatory elements that influence nearby target genes.

Methods: To investigate SNP allele-specific impacts on gene expression, we selected 15 SNPs from 13 loci that achieved genome wide significance in initial CLL GWAS studies. We investigated whether the published GWAS SNP (if present on the Affymetrix 6.0 SNP array) or proxy SNP(s) chosen using the SNP Annotation and Proxy Search (SNAP) software, based on their high linkage disequilibrium (LD) (r2>0.68) with the selected GWAS SNP. Genotypes were determined in tumor (n=143) and saliva (n=79) DNA from CLL patients (who had provided written informed consent); tumor and saliva DNAs were concordant in at least 96% of cases (except rs4771184 at 92%). Given the high concordance with saliva, which is likely related to the stable genome of CLL, SNP genotypes from tumor samples were used for the analysis in order to significantly increase our sample size. Allele-specific gene expression was then evaluated in tumor samples using Affymetrix U133 Plus 2.0 array gene expression data, focusing on genes within 1 Mb in either direction from a given SNP. In order to elucidate whether these associations were due to functional effects on transcription, we used a novel assay called precision run-on sequencing (PRO-seq). PRO-seq efficiently maps active transcription regulatory elements (TREs) and provides a sensitive, quantitative and directional map of transcriptionally-engaged RNA polymerases. The algorithm, discriminative regulatory-element detection from PRO/PRO-seq (dREG), is then used to predict the presence of TRES from raw PRO-seq data, allowing for identification of functional elements in the vicinity of SNPs and quantification of their allele-specific effects on enhancer activity and gene transcription.

Results: Our gene expression analysis demonstrated 6 significant SNP-gene associations: rs674313 (6p21.3) with HLA-DQA1 (p <0.0001), rs8720701 (6p25.3) with HLA-DQA1 (p=0.01), rs7771784 (15q23; proxy for rs1767508) with TP53 (p=0.09), rs783545 (15q23.2) with COX4NB/EMC8 (p<0.0001) and rs482232 (18q13.32; proxy for rs11083846) with FRK (p <0.0001). Two associations were successfully validated in a completely independent gene expression replication analysis (n=54): rs674313 with HLA-DQA1 (p <0.0001) and rs7771784 with TP53 (p=0.0116). To annotate candidate regulatory elements, we evaluated transcription level at or near all six significant functional elements in the initial gene expression analysis in a cohort of 12 CLL samples. Transcription level at or near 3 SNPs (rs674313, rs7771784, rs305088) correlated with genotype in a dose dependent manner. When we expanded the analysis to the entire region of LD around each SNP, we were able to demonstrate a dose-dependent effect in all SNPs in B and BIALLIC sample sets (p <0.0001).

Summary/Conclusions: We conclude that PRO-seq and dREG analysis identifies evidence of active differential transcription based on genotype in the region of 5 out of 6 GWAS-identified SNPs that we have investigated so far.

BIALLIC TP53 GENE MUTATIONS DUE TO COPY-NEUTRAL LOSS OF HETEROZYGOSITY AND MONOA LLEIC MUTATIONS IN ABSENCE OF 17P DELETION OCCUR IN CLL WITH COMPARABLE FREQUENCY

K. Plevova1,2, J. Malcikova1,2, S. Pavlova1,2, J. Kotaskova1,2, L. Poppova1,2, J. Klitgaard1,2, C. Thompson1, M. Hanna4, A. Freedman1, D. Neuberg3, M. Freedman2, L. Core6, J. Brown1,2,3

1Central European Institute of Technology, Masaryk University, 2Department of Internal Medicine - Hematology and Oncology, 3Department of Pathology, University Hospital Brno, Brno, Czech Republic

Background: TP53 gene defects represent an adverse prognostic marker in chronic lymphocytic leukemia (CLL). In the majority of affected cases, TP53 is inactivated on both alleles due to the concurrent mutation and 17p deletion (del(17p)). However, in about one third of cases, only TP53 mutation (TP53mut) without deletion is detected. It was reported that in some of these patients, copy-neutral loss of heterozygosity (cn-LOH), also leading to biallelic TP53 defect, might be present; however the frequency of such event has not been thoroughly investigated.

Aims: We aimed to perform a detailed analysis of the second TP53 allele status in cases with a TP53 mutation in the absence of del(17p), and to assess genomic and clinical outcome in these patients.

Methods: We searched for patients with TP53mut in absence of del(17p) within the cohort of 200 CLL patients positive for TP53mut as determined using FASAY (Functional Analysis of Separated Alleles in Yeast) coupled to direct sequencing;
17p13 deletions were assessed by FISH (MetaSystems). More than a half of the cohort (57%) was also examined using ultra-deep NGS for TP53 exons 2-11. Genome-wide analysis was performed on CytoScanHD arrays (Affymetrix) and correlated to conventional cytogenetics (CpGILIL-2 stimulation).

**Results:** Out of the cohort positive for TP53mut, 72/200 patients (36%) harbored single dominant TP53mut without del(17p). We selected 43 of these cases with variant allele frequency (VAF) >10% for CytoScan analysis to explore the potential presence of 17p cn-LOH. In 42% (18/43) of the cases, cn-LOH in 17p locus was detected in a proportion of CLL clone correspondingly to the TP53 VAF (median TP53 VAF 59.4%, range 12.9–99.9%). In 3/43 cases, heterozygous deletion previously unobserved by FISH was newly revealed. Thus, the truly monoallelic mutations were confirmed. We applied various methods, where by no cytogenetic abnormality in 17p locus was observed (median TP53 VAF 43.5%, range 10.5–51.3%). Applying a VAF cut-off of 55% indicating fully expanded heterozygous mutation (taking into account the potential unequal representation of forward and reverse strands in NGS data), 7/29 (24%) cases below the cut-off still harbored 17p cn-LOH. These results show that it is not possible to use an arbitrary VAF cut-off (>50%) to identify biallelic mutations due to cn-LOH. When we compared genomic complexity of leukemic clones with monoallelic vs biallelic TP53mut as determined by the CytoScan array, the latter group exhibited significantly more genomic abnormalities (p<0.0388) and also preference for different recurrent chromosomal abnormalities (p<0.0001: 17p locus excluded from this analysis). However, there was no significant difference in overall survival between the groups (p=0.5856).

**Summary/Conclusions:** cn-LOH in 17p locus is present in approximately half of the patients with single dominant TP53mut and results in biallelic TP53 gene inactivation despite the absence of del(17p). Truly monoallelic TP53 gene mutations with an intact second allele occur in CLL in comparable frequency. Although 17p cn-LOH is associated with increased genomic instability, it does not have a worse impact on clinical outcome than truly monoallelic TP53mut. Supported by the projects AZV-MZCR 15-31834A, 15-30015A, 15-29733A, the EU Horizon2020 project No. 692928, and MEYS GITEC2020 LQ1601.

**INTERGRATED OLIGO/SNP ARRAY- AND NEXT GENERATION SEQUENCING BASED ANALYSIS IS REQUIRED TO DETERMINE TP53/17P STATUS IN CLL PATIENTS**

M. Stevens-Kroef1,*, A. Eijkelenboom 1, L. Kroee1, D. Olde Weghuis1, P. Groenen1

1Radboud university medical center, Nijmegen, Netherlands

**Background:** B-cell chronic lymphocytic leukemia (CLL) exhibits a highly heterogeneous clinical course, with overall survival rates varying from several months to decades. Mutation status of the IGHV genes and specific genomic abnormalities, such as deletion of 11q22 on long arm of the 13q14 region provide prognostic information. However, more importantly deletion of 17p and/or the presence of a TP53 mutation, which are both associated with a poor prognosis identified in CLL patients with the highest risk profile. Recently clinical trials with tyrosine kinase inhibitors such as ibrutinib and idelalisib have demonstrated a high rate of cytogenetic improvement following chemotherapy, particularly emergence of del(17p). Additionally, pts with del(17p) or TP53 mutations frequently develop additional copy number alterations (CNAs) following chemotherapy.

**Aims:** To determine whether CCE occurs during ibrutinib therapy and at disease progression.

**Methods:** We analyzed 336 pts treated on investigational studies with ibrutinib or idelalisib plus rituximab for CLL. In pts who progressed, we analyzed FISH and NGS results pre-treatment and at progression, to identify CCE. Additionally, we identified a sub-group of 97 relapsed/refractory pts who had serial FISH analysis performed in bone marrow ≥1 year apart, to determine whether there were significant changes in sub-clonal composition of CNAs detected by FISH during treatment in the absence of disease progression.

**Results:** In total, 37 of 336 pts (11%) progressed during ibrutinib-based therapy. Of these pts, 15 had FISH analysis both pre-treatment and at progression: pre-treatment, 10 had del(17p), 1 had del(11q) and 4 had isolated del(13q). All 4 of the pts with isolated del(13q) pre-treatment had new sub-clonal TP53 abnormalities detected at progression: two pts had del(17p), 1 had del(11q) and 4 had isolated del(13q). In the absence of disease progression, the only CCE detected was emergence of small sub-clones with biallelic del(13q) in two patients who initially had monoallelic del(13q). Notably, in responding pts, there was no expansion of high-risk sub-clones. Conventional karyotyping was performed in 10/37 patients who progressed both pre-treatment and at progression. In 4 pts, CCE was identified at progression, including 17 new abnormalities in one pt. All 4 pts had complex karyotype and del(17p) by FISH pre-treatment and 3 of 4 had evidence of multiple, related, complex sub-clones pre-treatment. Figure 1 shows inferred clonal evolution pattern for one pt.

**Figure 1.**
Summary/Conclusions: Emergence of high-risk clones containing del(17p) and or del(11q) may be seen at disease progression in ibrutinib-treated patients. Analogous to allelic expansion of TP53 mutations after chemotherapy, we hypothesize that small del(17p) or del(11q) subclones were present prior to therapy in these pts, below the sensitivity of existing FISH techniques and expanded under the selective pressure of ibrutinib treatment. Development of a more sensitive technique to identify small sub-clones with del(17p) or del(11q) may therefore be important. Additionally, complex CCE occurred at progression in several cases, indicating genomic instability and potentially contributing to therapeutic failure.

P241
LANDSCAPE OF SOMATIC MUTATIONS AND THEIR IMPACT ON RESPONSE AND OUTCOMES FROM LENALIDOMIDE-BASED THERAPIES IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

1Cancer Medicine, 2Genomic Medicine, 3Biostatistics, 4Leukemia, 5Hematopathology, MD Anderson Cancer Center, Houston, Texas, United States

Background: Lenalidomide, either as a single agent or in combination with anti-CD20 monoclonal antibody, is clinically active in CLL and offers durable response in some pts. Predictive and prognostic impact of somatic mutations are not well known in pts with CLL who have received lenalidomide-based therapies.

Aims: Investigate the overall landscape of CLL gene mutations in both previously untreated and relapsed/refractory (R/R) pts. Determine associations between CLL gene mutations and clinical characteristics. Establish predictive and prognostic impact of CLL gene mutations in the context of lenalidomide-based therapies.

Methods: In the 288 pts with CLL who were treated in one of the lenalidomide-based clinical trials at our institution, we performed targeted gene capture exome sequencing of 295 genes that have been recurrently mutated in hematologic malignancies on pre-treatment samples. This sequencing platform also included more than 1000 cyto SNP position that allowed copy number variation (CNV) estimation. We used Mutect and Pindel algorithms to call high-confidence somatic mutations and used in-house algorithm to detect copy number variations (CNVs) in CLL samples.

Results: Among the 288 CLL pts treated with lenalidomide, 102 (35%) were previously untreated and 186 had R/R CLL. Ninety two patients (32%) received lenalidomide as a single agent and 196 patients (68%) received in combination with rituximab or ofatumumab. In total, we detected 470 high-confidence somatic mutations in 61 genes in 281 pts (76%). In addition to the well-known arm-level chromosomal abnormalities like del(13q), del(11q), tri(12), and del(17p), we also detected amp(2p), del(6q), del(8p), amp(8q) and tri(19). The most frequently mutated gene was SF3B1 (15%), followed by NOTCH1 (14%) and TP53 (14%) with 13 gene mutations occurring ≥3%. The number of mutations was similar between untreated and R/R pts (median of number of mutations 1 [IQR: 0-2] vs 1 [IQR: 1-2], P=0.44) with increased enrichment of complex cyto geneticities, TP53 mutation and del(17p) in the R/R cohort (p=0.006, p=0.014 and p=0.031, respectively). The pts with unmutated IGHV status had higher number of mutations compared to mutated IGHV (median 1 [IQR: 1-2] vs 1 [IQR: 0-2], P=0.02) with MYD88 mutation and del(13q) being significantly enriched in IGHV mutated pts (p=0.005 and p=0.028, respectively) while NOTCH1 and XPO1 mutations were significantly enriched in IGHV unmutated patients (p=0.035 and p=0.047, respectively).

Pairwise association showed statistically significant co-occurrence between tri(12) and mutations in KAS/BCOR (both q<0.05), NOTCH1 mutation and ZMYM3 (q=0.01), SPEN (q=0.05) mutations, and TP53 mutation and del(17p) (q <0.01) complex karyotypes (q <0.05). When correlating with clinical response to lenalidomide, worse overall response (OR) in the untreated group was associated with del(17p) (p=0.019) and KRAS mutation (p=0.05), whereas as mutation in SF3B1 (p=0.026), MGA (del(11q), p=0.035), DDX3X (p<0.001), complex karyotype (p=0.035) and del(17p) (p=0.031) were associated with worse OR in R/R group. In the untreated group, del(17p) and TP53 were associated with worse progression-free (PFS) (p=0.002 and 0.003, respectively). In R/R cohort, complex karyotype, del(17p) and mutations in SF3B1 and TP53 were associated with worse OR. In total, we detected 470 high-confidence somatic mutations occurring ≥3%.

Summary/Conclusions: Emergence of high-risk clones containing del(17p) and or del(11q) may be seen at disease progression in ibrutinib-treated patients. Analogous to allelic expansion of TP53 mutations after chemotherapy, we hypothesize that small del(17p) or del(11q) subclones were present prior to therapy in these pts, below the sensitivity of existing FISH techniques and expanded under the selective pressure of ibrutinib treatment. Development of a more sensitive technique to identify small sub-clones with del(17p) or del(11q) may therefore be important. Additionally, complex CCE occurred at progression in several cases, indicating genomic instability and potentially contributing to therapeutic failure.

HIGH THROUGHPUT IMMUNOPROFILING OF CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS ASSIGNED TO STEREOTYPED SUBSET #4: NOVEL INSIGHTS INTO THE DEPTH, DIVERSITY AND TEMPORAL DYNAMICS OF CLONAL EVOLUTION

K. Gemenetzi1, E. Stalika 1, A. Vardi 1, F. E. Psomopoulos1, E. Minga 1, A. Anagnostopoulous2, K. Stamatopoulos1, A. Hadzidimitriou1, L. A. Sutton4,5, A. G. Pantanisalou1, G. Lefkomis, Department of Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden

Background: Chronic lymphocytic leukemia (CLL) clones assigned to stereotyped subset #4 are characterized clinically by a young age at diagnosis, an indolent disease course, and molecularly by B-cell receptor immunoglobulins (BcR IGs) that exhibit distinctive immunogenetic features. More specifically, they are IGHV-switched, composed of heavy and light chains encoded by the IGHV4-34 and IGKV2-30 genes, respectively, and their heavy chain complementarity determining region 3 (VH-CDR3) is longer and enriched in negatively charged residues, reminiscent of pathogenic anti-DNA antibodies. In addition, both the VH and VK domains of subset #4 demonstrate a high impact of somatic hypermutation (SHM), highly indicative of an (auto)antigen selection.

Aims: To obtain comprehensive insights into the ontogeny and evolution of CLL subset #4 using next-generation sequencing (NGS) for in-depth immunoprofiling of the clonotypic BcR IG genes, particularly focusing on analyzing intraclonal diversification (ID) within the IG gene sequences.

Methods: Peripheral blood samples were collected at multiple time-points over a 10-year period from 6 CLL subset #4 patients. The clonotypic IGHV-IGHD-IGHJ and IGKV-IGKJ rearrangements were amplified by PCR using cDNA and sequenced on the MiSeq (Illumina). Our experimental design involved paired-end sequencing, thus allowing sequencing of the CDR3 twice/read, so as to increase the accuracy of results. To maintain stringency, raw NGS reads were subject to purpose-built, bioinformatics algorithms, which filtered for: (i) length and quality filtering of raw quality filtered sequence reads and (ii) quality filtering of filtered-in paired reads via local alignment, and (ii) length and quality filtering of stitched sequences. No base calls of Q-score<30 were allowed in the 75 nucleotide stretch preceding the GXG motif, further increasing CDR3 sequencing reliability. Data was then analyzed using the IMGATHigh-QUEST database and clonotype computation was performed using an in-house bioinformatics pipeline.

Results: Overall, 48 samples were analyzed, producing 12,386,554 and 4,506,464 total reads for heavy and light chain, respectively. In addition to filtering out poor quality, incomplete, out-of-frame and unproductive rearrangements and filtered reads, parameters were also filtered by the usage of subset #4-specific V- and J-genes, CDR3 length and landmark residues. Applying these strict criteria resulted in 84.1% (median 401,133 reads/sample) and 90.3% (median 141,549.5 reads/sample) of the total sequences obtained for the heavy and light chain, respectively, passing filters. Clonotype computation was solely based on the filtered reads, and revealed a median of 1332.5 clonotypes/sample (range: 879-3432) for the heavy chains while a median of 202.5 clonotypes/sample (range: 125-395) was evidenced for the light chains. Overall, our longitudinal analysis revealed: (i) a hierarchical pattern of subclonal evolution showing which SHMs were more strongly enriched (positively selected SHMs), (ii) distinct clusters of subcloned sequences which at later time-points had often disappeared and hence been selected against; and (iii) that despite the high intensity of ID, certain residues remained essentially unaltered alluding to strong functional constraints.

Summary/Conclusions: Detailed molecular immunoprofiling by NGS afforded the possibility to gain novel insights into the pathogenesis of CLL subset #4, thus providing conclusive evidence that these patients continue to acquire SHMs within their IG genes; an observation best explained by a clear role for antigen selection in clonal evolution.
BACKGROUND: During normal hematopoiesis, a coordinated epigenetic and transcriptional programming is necessary to achieve lineage development. B cell differentiation is predominantly related to loss of DNA methylation at the enhancers and promoters of B cell–specific genes; e.g., transcription factors (TFs). In chronic lymphocytic leukemia (CLL), failure of proper epigenetic programming contributes to deregulation of B cell transcriptional programs and results in CLL phenotypes with highly variable outcomes. The mechanisms leading to failed epigenetic programming and to establishment of a CLL epigenome are not well understood. Genomic sites of failed epigenetic programming coincide with binding sites of key B cell TFs. Active DNA demethylation through TET-dioxygenase mediated conversion of 5-methylcytosine (5mC) to 5-hydroxymethylcytosine (5hmC) and subsequent products is one of the mechanisms involved in physiological epigenetic B cell programming, and deregulation of this process could contribute to establishment of the CLL epigenome.

AIMS: Here, we investigated the role of TET2-mediated DNA demethylation through differential 5hmC acquisition in healthy and in CLL B cells. We further studied mechanisms and TFs involved in regulation of 5hmC conversion during CLL pathogenesis.

METHODS: Clonal B cell specimens from 122 CLL patients were subjected to DNA methylation profiling using Illumina 450k arrays. 17 CLL and 4 healthy B cell samples (CD19+) were used for DNA methylation profiling using Illumina Epic arrays and for hydroxymethylated DNA immunoprecipitation (hMeDIP) using a monoclonal 5hmC mouse antibody and the NEBNext Ultra DNA Library Prep Kit for analysis on a Illumina HiSeq2000 sequencer. Global 5hmC levels were quantified by dot blots. TET2, and EBFB1 mRNA and protein expression was evaluated by qPCR and Western Blot, respectively.

RESULTS: By dot blot, we found decreased 5hmC levels in CLL as compared to CD19+ B lymphocytes. 5hmC was further reduced in IGHV unmutated compared to IG HV mutated CLL patients. To identify distinct regions with gain or loss of 5hmC, we performed genome-wide 5hmC profiling by hMeDIP. We confirmed a significantly lower number of hydroxymethylated reads between CLL and HBC samples (FDR<0.05). Pathway analysis showed that regions which lost hydroxymethylation in CLL were involved in B cell receptor (BCR) and B cell receptor (BCR) signaling, as well as in CD19, CXCR-4, c-Med and IL-3 signaling. To further identify mechanisms that are involved in failed hypomethylation and 5hmC loss in CLL, we aimed at profiling sequence characteristics at the respective genomic sites. In our genome-wide DNA methylation data set, we confirmed highly significant enrichment of the EBFB1 motif at the respective sites in 122 CLL patients. EBFB1 mRNA and protein expression was significantly reduced in the majority of 17 CLL samples compared to HBC. TET2, a potential interaction partner of EBFB1, was upregulated in CLL samples on RNA level and expressed to different degree on protein level.

SUMMARY/CONCLUSIONS: Here, we demonstrate that 5hmC loss in CLL contributes to a disease specific epigenotype as described earlier. First evidences indicate that alterations of an interaction between the EBFB1 and TET2 are mechanistically involved in insufficient hydroxymethylation and consequently failed DNA hypomethylation.
P245

ADDING OBIJNUTUMAB TO IBRUTINIB ENHANCES DEPLETION OF CLL CELLS IN PERIPHERAL BLOOD AND BONE MARROW AFTER 1 & 6 MONTHS COMBINED THERAPY INITIAL RESULTS FROM THE BLOODWISE TAP ICICLLe EXTENSION STUDY

1HMDs, St. James’s Institute of Oncology, 2ST, James’s Institute of Oncology, Leeds, 3Cancer Research UK Clinical Trials Unit, University of Birmingham, Birmingham, 4Royal Liverpool and Broadgreen University Hospitals NHS Trust, Liverpool, 5Nottingham University Hospitals NHS Trust, Nottingham, 7University Hospital of Wales, Cardiff, 8Kings College Hospital NHS Foundation Trust, 9Hammersmith Hospital, Imperial College Healthcare NHS Foundation Trust, London, 10The Christie NHS Foundation Trust, Manchester, United Kingdom

Background: A major aim of CLL treatment is to eradicate detectable minimal residual disease (MRD). Ibrutinib is an effective treatment for CLL that results in immediate lymphocytosis persisting in most patients for several months. Obinutuzumab is a second-generation anti-CD20 monoclonal antibody which can effect rapid resolution of lymphocytosis and eradication of MRD in some CLL patients. The ICICLLe Extension Study expands on the ICICLLe trial (ISRCTN12693534) to examine the efficacy and safety of the combination treatment of obinutuzumab and ibrutinib.

Aims: The ICICLLe trial was a single-arm, multicentre feasibility study that recruited 40 patients with CLL requiring treatment, 20 treatment-naïve (TN) and 20 previously relapsed/refractory (RR), to receive continuous ibrutinib therapy until confirmed MRD negative remission (<0.01% residual disease) or disease progression. The ICICLLe Extension Study aims to evaluate whether patients achieving MRD-negative remission have better overall survival outcomes compared to patients not achieving this remission.

Methods: The effects on MRD negative status were assessed in 5 groups: Incidence of MRD negative status up to 6 months, number of patients with MRD negative status at 6 months, clinical characteristics of patients achieving MRD negative status at 6 months, clinical characteristics of patients not achieving MRD negative status at 6 months.

Results: Of the 40 patients treated, 31 (78%) achieved MRD negative status at 6 months, 26 (65%) at 12 months, and 24 (60%) of the 40 patients achieved a molecular complete remission by 12 months post-treatment. The time to achieve MRD negative status was shorter in patients achieving complete remission compared to those who did not achieve remission, with a median time to remission of 2.5 months for complete remission and 9.5 months for those who did not achieve remission. The median time to progression was 19 months for patients achieving MRD negative status and 7 months for those who did not achieve remission.

Summary/Conclusions: The results from the ICICLLe Extension Study show that continuous ibrutinib therapy with obinutuzumab is feasible and results in a high incidence of MRD negative status and molecular complete remission. Further study is needed to confirm these findings and investigate the durability of these outcomes.

CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS EXPRESSING THE LIGHT CHAIN IGLV3-21 OR THE IGHV MUTATIONAL STATUS

B. Stamatopoulos1,*, T. Smith2, D. Sims2, A. Heger2, H. Dreau2, A. Schuh4

1Laboratory of Clinical Cell Therapy, J. Bordet Institute, University of Brussels, Brussels, Belgium, 2Computational Genomics Analysis and Training Programme, MRC Weatherall Institute of Molecular Medicine, University of Oxford, John Radcliffe Hospital, Molecular Diagnostic Centre, Oxford University Hospitals, 4Department of Oncology, University of Oxford, Oxford, United Kingdom

Background: The immunoglobulin heavy-chain gene (IGHV) mutational status is currently considered the gold standard of prognostication in Chronic Lymphocytic Leukemia (CLL). Unmutated (UM) immunoglobulin heavy chain region (IGHV) is associated with poor prognosis while patients with mutated IGHV (M) have more indolent disease. An exception are patients with IGLV3-21/IGLV3-21 who have poor prognosis irrespective of the IGHV mutational status. Interestingly, IGLV3-21 is co-expressed with IGLV3-21 in the majority of cases.

Aims: Here we aimed to study the impact of the light chain IGLV3-21 on CLL prognosis. This light chain has never been characterized independently of the heavy chain IGHV3-21.

Methods: Based on 405 CLL patients from 3 independent cohorts (A. an initial cohort of 32 patients with aggressive CLL, and 2 cohorts of CLL patients where samples were obtained at diagnosis (B: n=270 and C: n=103), we analyzed the impact of the presence of IGLV3-21 on treatment-free (TFS) and overall (OS) survival. IGLV3-21 positivity was determined by real-time PCR and confirmed by Sanger sequencing.

Results: Among the 32 patients with aggressive CLL, we found that 9 (28%) patients who had an IGLV3-21 rearrangement, but only 1 patient carried the heavy chain IGHV3-21: IGLV3-21 patients had a median TFS of 17 months compared to 44 months in patients with another light chain (P=0.0270). Similarly, IGLV3-21 patients had a shorter median OS (88 months vs +192 months, P=0.0287). We verified these results in 2 independent cohort obtained at diagnosis. In cohort B (n=270), 30 (11%) expressed an IGLV3-21 light chain and 10 (4%) an IGHV3-21 (of which 8/10 also carried the light chain IGLV3-21 rearrangement). Patients with IGLV3-21 had a median TFS/OS of 29/183 months compared to patients without IGLV3-21 who had a median TFS/OS of 88/292 months (P=0.0003/P=0.0142). In cohort C (n=103), 9 (9%) expressed an IGLV3-21 light chain but only 1 (1%) had a heavy chain IGHV3-21. In this cohort, IGLV3-21 patients had a median TFS of 21 months not statistically different from IGHV3-21 patients (28 months) while IGHV3-21 patients had a median TFS of 93 months (P<0.0001). We then pooled the 3 populations (n=405) in order to increase the under-represented subgroups and analyzed the association of the IGLV3-21 with the IGHV mutational status: patients with either IGLV3-21 or IGLV3-21 (with a M or UM IGHV) displayed a prognosis similar to UM patients: median TFS of 12 months (P=0.0270). Patients with another light chain with a IGLV3-21/M (P=0.0001), UM (P<0.0001), IGLV3-21/UM (P<0.0001) and IGLV3-21 (P<0.0001) patients, respectively (Figure 1A). Similar results were observed for OS with a median OS of 292, 88, 174, 90 and 183 months M, IGLV3-21/M (P=0.0005), UM (P<0.0001), IGLV3-21/UM (P<0.0001) and IGLV3-21 (P<0.0001) patients, respectively (Figure 1B). If all IGLV3-21 (n=48) were considered independently of their heavy chain, IGLV3-21 median TFS (24 months) was similar to UM patients (36 months, P=0.5824) and statistically different from M patients (129 months – P<0.0001, Figure 1C). Similar results were observed for OS (Figure 1D).

Summary/Conclusions: Our results highlight for the first time the independent prognostic significance of the light chain IGLV3-21 in CLL: the presence of an IGLV3-21 light chain confers a poor prognosis similar to UM patient irrespective of concurrent expression of IGHV3-21 heavy chain or IGHV mutational status.
DURABILITY OF RESPONSES ON CONTINUOUS THERAPY AND FOLLOWING DRUG CESSATION IN DEEP RESPONDERS WITH VENEToclAX AND RITUXIMAB

M.A. Anderson1,†, D.M. Brandenburg2,‡, S. Ma3, J.F. Seymour4, M.Y. Choi5, T.J. Kipps5, L. Zhou6, K. Baibarin6, B. Prine6, M. Verdugo6, S.Y. Kim6, L.L. Las0, A.W. Roberts1

1Royal Melbourne Hospital and Walter and Eliza Hall Institute of Medical Research, Cancer and Hematology Division, Melbourne, Australia, 2Duke University Medical Center, Durham, 3Northwestern University, Chicago, United States, 4Peter MacCallum Cancer Centre, , Melbourne, Australia, 5University of California San Diego, San Diego, 6AbbVie, Inc., North Chicago, United States

Background: Venetoclax is a potent BCL-2 inhibitor that is approved as monotherapy for certain patients with relapsed or refractory chronic lymphocytic leukemia (CLL) in the United States, the European Union, and other countries.

Aims: Venetoclax combined with rituximab is being assessed in an ongoing Phase 1b study.

Methods: Minimal residual disease (MRD) was assessed in bone marrow using ≥4-color flow cytometry (minimum sensitivity: 0.01%). Patients who achieved complete remission (CR) or MRD-negativity could stop venetoclax and remain on study. Patients who manifested progressive disease while off therapy could re-initiate venetoclax and rituximab.

Results: Forty-nine patients, with a median of 2 (range: 1–5) prior regimens, were enrolled. As of July 2016, the overall response rate was 86%, the CR rate was 51%, and the bone marrow MRD-negativity rate was 57% (28/49) [Seymour et al. Lancet Oncol 2017]. The 24-month estimate for progression-free survival was 78.8% and that for duration of response was 87.8% (100% for patients with MRD-negative CR). Of the 28 patients attaining MRD-negativity, 22 achieved the status at 7 months, which was the first mandatory time point for assessment. The remaining six patients achieved MRD-negativity at the second assessment, which ranged from 12 to 22 months, since the timing of this test was not mandated. Twenty (41%) patients discontinued the study. Eleven had progressive disease while on therapy: five with Richter’s transformation between 1–9 months and six with CLL progression after a median of 26.4 months (range: 12–37). The other nine patients: withdrew consent (n=3), failed to report for follow-up evaluations (n=1), discontinued due to adverse events related to venetoclax (n=2; tumor lysis syndrome and worsening of peripheral neuropathy), or discontinued due to adverse events considered not related to therapy (n=3). Seventeen patients continued on therapy: 8 MRD-neg-ative CR, 2 MRD-positive CR, 5 MRD-negative PR, and 2 MRD-positive PR. Median duration of response on therapy is 27.9 months (range: 20.3–40.2).

Sixteen patients discontinued venetoclax and remained on study as allowed per protocol following the achievement of a deep response (12 MRD-negative CR, 2 MRD-negative PR, 2 MRD-positive CR) (Figure 1). Their median time on venetoclax is 16.3 months (range: 5–38). Twelve of these patients remain in active follow-up and four discontinued without evidence of progression after achieving MRD-negative CR. Two patients with MRD-positive CR had increasing absolute lymphocyte count (ALC) and asymptomatic progression 24 months after stopping venetoclax. Both re-initiated venetoclax, 2 and 6 months after ALC >5x10⁹/L, and achieved partial remissions. The 10 patients with MRD-negativity in the bone marrow who remain in follow-up have a median duration of ongoing response off venetoclax of 13 months (range: 3–34).

Summary/Conclusions: Venetoclax with rituximab induces deep and durable responses, with 51% patients achieving CR and 57% achieving marrow MRD-negativity. Patients on continued therapy have durable responses. Additionally, responses are sustained at a median of 13 months among patients who achieve bone marrow MRD-negativity and elected per protocol to stop therapy, demonstrating that it is possible to discontinue venetoclax and maintain prolonged treatment free remission. The 2 patients who progressed at 2 years off therapy responded to the reintroduction of venetoclax.

PREDICTIVE AND PROGNOSTIC IMPACT OF GENE MUTATIONS IN THE CONTEXT OF FLUDARABINE AND CYCLOPHOSPHAMIDE WITH OR WITHOUT OFATUMUMAB TREATMENT IN PATIENTS WITH REL/REF CLL

E. Tausch1,*, A. Dolnik1, S. Estenfelder1, V. Opatrna1, T. Blätte1, A. McKeown2,†, S. Stilgenbauer1

1Department of Internal Medicine III, Ulm University, Ulm, Germany, 2Novartis, Novartis UK, Uxbridge, United Kingdom, 3Department of Hematology, Medical university of Lodz, Lodz, 4Department of Cancer Prevention, Silesian Medical University, Katowice, Poland, 5Oncology, Novartis Pharma, Basel, Switzerland, 6Mechanisms of Leukemogenesis, DKFZ Heidelberg, Heidelberg, Germany

Background: Recurrent mutations in genes such as TP53, SF3B1 and NOTCH1 are frequent in CLL and have in previous studies been associated with outcome. SF3B1mut, TP53mut, BIRC3mut and XPO1mut were adverse prognostic factors in patient cohorts with different therapies, and NOTCH1mut associated with poor outcome when rituximab was added to standard chemotherapy. We investigated NOTCH1mut as a predictive factor in the context of chemoimmunotherapy.

Aims: We assessed the incidence and clinical associations of mutations in TP53, SF3B1, NOTCH1, ATM, BIRC3, FBXW7, MYD88, EGR2 and XPO1 in the COMPLEMENT-2 trial (relapsed/refractory CLL, FC vs FC+ofatumumab 1–14-16, 18), NOTCH1mut vs FC+ofatumumab (Robak et al., Leuk Lymphoma, 2017).

Methods: Baseline samples were available from 325 of 365 patients (89%) representative of the full analysis set of the clinical trial. Mutation analyses were performed via custom targeted Next Generation Sequencing (NGS) for TP53, ATM, BIRC3, FBXW7, MYD88, EGR2 (all coding exons), SF3B1 (exon 14–16, 18), NOTCH1 (exon 34) and XPO1 (exon 15, 16). All mutations with a variant allelic fraction >5% were considered significant.

Figure 1.

Results: In total we identified 365 mutations across the 9 genes in 202 of 325 patients (62.2%), with incidences of SF3B1mut 19.7%, TP53mut 18.8%, NOTCH1mut 16.3%, ATMmut 13.8%, XPO1mut 11.4%, BIRC3mut 4%, EGR2mut 3.1%, FBXW7mut 2.7% and MYD88mut 0.9%. We identified a variety of associations of mutational subgroups with genetic, clinical and laboratory parameters, such as TP53mut with del17p (p<0.01), NOTCH1mut, FBXW7mut and BIRC3mut with +12q (p<0.01, p=0.01 and p=0.05) and ATMmut with del11q (p<0.01). XPO1mut and ATMmut associated with unmuated IGHV, CD79B expression on cell surface measured via flow cytometry was lower in ATMmut patients, whereas CD220 expression did not differ among the different mutational subgroups. TP53mut, EGR2mut and SF3B1mut patients had worse overall response to therapy (88% p<0.01, 50% p=0.02 and 72% p=0.05 respectively, vs 81% overall). Similar to the full analysis set, FC0 as compared to FC resulted in significant improved PFS (median 28.1 vs 18.8 months, HR=0.67, p<0.01), TP53mut and XPO1mut were adverse prognostic factors for PFS (HR 1.93, p<0.01 and HR 1.85, p<0.01 respectively), but only TP53mut for decreased OS (HR 2.11 p<0.01). All other mutations, in particular SF3B1mut and NOTCH1mut, did not significantly impact PFS or OS. To identify factors of independent clinical
impact, we performed multivariable Cox regressions for PFS and OS including treatment, IGHV status and all cytogenetic and mutational subgroups. For PFS, the following independent prognostic factors were identified: FCO therapy (HR 0.64 p<0.01), del17p (HR 5.08 p<0.01), unmutated IGHV (HR 2.0 p<0.01), TP53mut (HR 1.75 p<0.01) and XPO1mut(1.86 p<0.01). Del17p (HR 4.79 p<0.01), unmutated IGHV (HR 1.69 p<0.04) and TP53mut (HR 1.76 p<0.03) were identified as independent prognostic factors for OS. With focus on the predictive value of gene mutations, we found a beneficial effect of the addition of ofatumumab to chemotherapy irrespective of TP53 mutation (HR 0.52 p=0.02 for TP53mut and HR 0.68 p=0.02 for TP53mt). Regarding NOTCH1, ofatumumab 4G11 was only beneficial in NOTCH1mt but not in NOTCH1mut patients (HR 0.64, p<0.01 and HR 0.86, p=0.67) (Figure 1).

Summary/Conclusions: In the COMPLEMENT-2 trial evaluating FCO against GC in relapsed/refractory CLL patients, we found TP53mut and XPO1mut but not SF3B1mut or NOTCH1mut as independent prognostic factors for PFS. Notably, the addition of ofatumumab as 4G11 to FCO treatment was beneficial among NOTCH1mt but not among NOTCH1mut patients indicating NOTCH1 mutation status as a predictive marker in the context of type 1-2CD20 antibody addition to chemotherapy.

P249

RESULTS OF A PHASE II MULTICENTER STUDY OF OBINUTUZUMAB PLUS BENDAMUSTINE IN PTS WITH PREVIOUSLY UNTREATED CHRONIC LYMPHOCYTIC LEUKEMIA

A. Danilov1,*, H. Yimer2, M. Boxer3, N. Di Bella4, S. Babu5, J. Li6, Y. Mun6, N. Sketris6, J. Sharram7

1Oregon Health and Science University, Portland, 2Texas Oncology, Tyler, 3Aronz, Oncology, Tucson, 4Rocky Mountain Cancer Centers, Aurora, 5Fort Wayne Medical Oncology, Fort Wayne, 6Genentech Inc., South San Francisco, 7Williamette Valley Cancer Institute and Research Center, Eugene, United States

Background: Bendamustine (B) plus rituximab (R; BR) is a commonly used first-line (1L) treatment for chronic lymphocytic leukemia (CLL). The CLL10 study reported an overall response rate (ORR) of 96% and complete response (CR) rate of 31% with BR. Obinutuzumab (GA101; G) is a glycoengineered, type II anti CD20 monoclonal antibody. A randomized Phase III trial in 1L CLL pts showed that G significantly improved progression-free survival (PFS) and CR rate compared with R, when used in combination with chlorambucil (Goede 2014). B plus G (BG) was evaluated in a subgroup of CLL pts in the GREEN study (Stilgenbauer 2015).

Aims: The aim of this Phase II study (NCT02320487) is to evaluate the efficacy and safety of BG as 1L treatment for CLL pts.

Methods: 102 pts with previously untreated CLL received BG, consisting of 6 cycles of G (cycle [C] 1: 100mg day (D1), 900mg D2, 1000mg D3 and D15; C2– 6: 1000mg D1 and B (80mg/m2; C1, D2 and C3; C2–6, D1 and D2). Each cycle was 28 days. The primary endpoint was CR assessed using iwCLL criteria. Secondary endpoints included ORR, PFS, overall survival, and minimal residual disease (MRD). Median follow-up at the time of analysis was 11.0 months. Results: Median pt age was 61 yrs (range 35–90); 68.6% were male; 44.1% had Rai stage 3–4. For evaluable pts, IgVH status was 32.9% mutated and 67.1% unmutated. Incidences of trisomies 12, normal cytogenetics, and deletions of 13q, 11q, and 17p were 23.4%, 37.5%, 17.2%, 15.6%, and 6.3%, respectively. Investigator-assessed CR rate was 49.0% (95% CI 39.0–59.1) and ORR was 89.2% (95% CI 81.5–94.5) after 6 cycles. MRD negativity in blood, as measured by next-generation flow cytometry, was achieved in 42.7% of pts at the end of induction response assessment and in 75.5% of pts at any time following treatment. MRD negativity in bone marrow (BM) was 60.8% in pts with BM samples. The most common adverse events (all grades [Gr]) were infusion reactions (72.5%), nausea (52.0%), pyrexia (36.3%), neutropenia (34.3%), fatigue (34.3%), constipation (26.5%), and rash (26.5%). The most common Gr 3–4 adverse event was neutropenia (26.5%). Incidence of Gr 3–4 infections was 11.8%. Incidence of tumor lysis syndrome was 4.9% (all Gr 3). Three pts died; none were deemed related to study treatment or CLL by investigators.

Summary/Conclusions: BG is an effective regimen for 1L treatment of CLL pts, inducing a high CR rate after 6 cycles of therapy. No unexpected safety signals were observed.

RELATIVE SURVIVAL REACHES A PLATEAU IN HAIRY CELL LEUKEMIA: A POPULATION-BASED STUDY ON INCIDENCE, PRIMARY TREATMENT AND SURVIVAL AMONG 1,427 PATIENTS DIAGNOSED IN THE NETHERLANDS, 1989-2014

A. Dinmohamed1,2,3,*, C. Vissers4, W. Posthumus5, R. Raymakers6, J. Doorduin3

1Research, Netherlands Comprehensive Cancer Organisation (IKNL), 2Public Health, Erasmus University Medical Center, Utrecht, 3Hematology, Erasmus MC Cancer Institute, Rotterdam, 4Registration, Netherlands Comprehensive Cancer Organisation (IKNL), 5Utrecht, 6Internal Medicine, Reinier de Graaf Gasthuis, Delft, 7Hematology, Utrecht University Medical Center, Utrecht, Netherlands

Background: The introduction of cladribine and pentostatin has revolutionized the management of HCL as from the late 80s. As a result of that revolution, HCL patients (pts) are rarely included in clinical trials. Population-based studies can inform on issues related to outcomes of HCL pts managed in daily practice. At present, however, population-based studies that assess patterns of incidence, treatment and survival in HCL are very scarce.

Aims: The aim of this comprehensive nationwide population-based study was to assess trends in incidence, primary treatment and survival among HCL pts diagnosed in the Netherlands.

Methods: We selected all adult (≥18 years) pts diagnosed with classic HCL in the Netherlands between 1989-2014 from the nationwide Netherlands Cancer Registry with survival follow-up through February, 2016. Age-standardized incidence rates (ASR) were calculated per 1,000,000 person-years and standardized according to the European standard population. Data on primary treatment (i.e., no therapy, chemotherapy [CT] and immunotherapy [IT]) were available for individual pts. Pts were categorized in 2 periods (1989-2000 and 2001-2014) and 3 age groups (18-59, 60-69 and ≥70 years). We calculated relative survival (RS) and the relative excess risk of mortality as measures of disease-specific survival.

Results: We included a total of 1,427 newly diagnosed HCL pts in the study (median age, 59 years; age range, 22-95 years; 77% males). The annual ASR of HCL remained quite stable over time and was 3.1 and 3.3 in the first and last period, respectively. Men had a higher overall incidence than women (5.3 v 1.3 in 2001-2014). The age-specific incidence rates for males were 5.5, 15.0 and 15.3 in 2001-2014 for the three age groups. The corresponding rates for females were 1.2, 3.1 and 5.5. The application of CT increased over time for all age groups. The proportions of CT for the three age groups were 56, 51 and 34% in 1989-2000, as compared with 81, 73 and 53% in 2001-2014. The corresponding proportions for IT were 21, 13 and 17% in 1989-2000, as compared with 2, 1 and 4% in 2001-2014. Lastly, the corresponding proportions for pts who did not receive therapy were 23, 36 and 49% in 1989-2000, as compared with 17, 26 and 42% in 2001-2014. Overall, when corrected for age and sex, pts diagnosed in 2001-2014 had 49% lower excess mortality during the first 10 years after HCL diagnosis, as compared with pts diagnosed in 1989–2000 (P=.005). Ten-year RS (95% confidence intervals) was impressive for pts age 19-59, namely 92% (88% - 96%) and 98% (94% - 100%; P=.176) in the first and last period, respectively (Figure 1a). Most of the significant improvement was observed in pts age ≥60. More specifically, 10-year RS for pts age 60-69 increased from 82% (71% - 92%) to 99% (89% - 100%; P=.009; Figure 1b), and for pts age ≥70 from 67% (49% - 86%) to 80% (72% - 88%; P=.03; Figure 1c) between the first and last periods. In addition, older age (P<.001), but not sex (P=.058), was associated with higher excess mortality.

Figure 1.

Summary/Conclusions: The incidence of HCL remained stable during a 26-year period in the Netherlands. RS for pts diagnosed in the period 2001-2014 eventually reached a plateau, indicating that by then their survival is comparable to that of the general population. Survival was already excellent for younger patients throughout the entire study period. Survival improvement was most pronounced for pts age ≥70. This could be explained by the increased use CT over time. Population-based cancer registries are useful instruments to assess outcomes of pts rarely included in clinical trials.

CUMULATIVE ILLNESS RATING SCALE PROVIDES PROGNOSTIC INFORMATION BEYOND THE INTERNATIONAL PROGNOSTIC INDEX FOR CHRONIC LYMPHOCYTIC LEUKEMIA: AN ACROSS-TRIAL ANALYSIS BY THE GCLLSG

V. Goede1,2, J. Bahlo1, S. Robrecht1, O. Al-Sawaf1, A.-M. Fink1, C.-M. Wendtner3, S. Stilgenbauer4, K. Fischer1, B. Eichhorst1, M. Hallek1,5
1 Dept. I of Internal Medicine, University Hospital Cologne, 2 Oncogenetics Unit, St. Marien Hospital, Cologne, 3 Klinikum Munich-Schwabing, Munich, 4 University Hospital Ulm, Ulm, 5 Centre of Integrated Oncology (CIO) Cologne-Bonn, Cologne, Germany

Background: CLL-IPI is a prognostic tool to stratify patients with chronic lymphocytic leukemia (CLL) for low, intermediate, high, or very high risk. CLL-IPI uses age, Binet stage, beta-2-microglobulin, TP53 mutation, IgHV mutational status, but not comorbidity as weighted factors to model prognosis. CIRS is a tool which allows assessing and quantifying burden of comorbidity in individual patients.

Aims: To validate CIRS in CLL and to assess whether CIRS is of further value when estimating prognosis by CLL-IPI in CLL.

Methods: This is a comprehensive evaluation of CIRS in 2158 patients pooled from the CLL8, CLL10, and CLL11 trials of the German CLL Study Group (GCLLSG). Median observation time was 55 months. All patients had CIRS data prospectively assessed prior to study treatment (689 FCR, 409 FC, 279 BR, 333 GCLB, 330 RCLB, 118 CLB).

Results: Median age was 64 years; 69% of patients were males, and 50% had EGOG performance score of 1 or higher. Complete information on age, Binet stage, beta-2-microglobulin, 17p deletion / TP53 mutation, IgHV mutational status was available in 1761 of the 2158 patients. Distribution of CLL-IPI risk groups was as follows: 275 (16%) low risk, 653 (37%) intermediate risk, 712 (40%) high risk, 121 (7%) very high risk. The median total CIRS score was 3 (range 0-22); 81% of the patients had a total CIRS score of at least 1 and 28% of greater than 6. Comorbidities were most frequently captured under the following categories: cardiovascular, lung, gastrointestinal, psychiatric, and metabolic comorbidities. The frequency of each comorbidity was as follows: coronary artery disease (23%), chronic obstructive pulmonary disease (22%), diabetes (21%), hypertension (19%), and HIV infection (13%).

Figure 1.

CIRS score was associated with higher risk of grade 3/4 adverse events as well as premature treatment discontinuation during or after treatment with FCR / FC / BR but not GCLB / RCLB / CLB.

Summary/Conclusions: Findings suggest that CIRS provides prognostic information beyond the CLL-IPI tool in a modern comorbidity assessment (e.g. by CIRS) in addition to the CLL-IPI therefore appears reasonable when estimating overall prognosis and deciding treatment in CLL.
FINAL RESULTS OF THE PHASE IB GALTON TRIAL IN CHRONIC LYMPHOCYTIC LEUKEMIA: DURABLE REMISSIONS WITH FRONTLINE OBINUTUZUMAB (G) PLUS FLUARABINE/CYCLOPHOSPHAMIDE (G-F/C) OR BENDAMUSTINE (G-B)

J. Brown1,2, S. O’Briens3, C.D. Kingsley1, H. Erada1, J.M. Page1,6, C. Vignali1, J. Hirata2, T.J. Kipps2

1Dana-Farber Cancer Institute (CLL Research Consortium), Boston, 2MD Anderson Cancer Center, University of Texas, Houston, 3Oncology Cancer Institute, Huntsville, 4University of California, Los Angeles, 5Fred Hutchinson Cancer Research Center, 6University of Washington, Seattle, United States

Background: GALTON was an open-label, parallel-arm, non-randomized, multicenter, Phase 1b study (NCT01300247) investigating safety and preliminary efficacy of G-F/C or G-B in previously untreated CLL.

Aims: We report final results for the planned 36-months’ (mo) follow-up (35/41 pts; median observation 40.4 (17.6–43.6) mo); initial results were reported previously (Brown et al. 2015).

Methods: Eligible pts met iwCLL 2008 criteria for therapy, were considered fit for chemoimmunotherapy by the investigator, and provided informed consent. Each center selected treatment (G-F/C or G-B) for their pts. G was administered intravenously (IV; 100mg/day [D] 1, 900mg/D2, 1000mg D8 and 15 cycle [C] 1; 1000mg D1 C2–6) with FC (fluorarabine 250mg/m2 IV and cyclophosphamide 250mg/m2 IV D2–4 C1, D1–3 C2–6) or B (90mg/m2 IV D2–3 C1, D1–2 C2–6). Each cycle was 28 days. The primary endpoint was safety and tolerability of G-chemotherapy.

Results: 21 pts were enrolled in the G-F/C arm and 20 in the G-B arm. Median age was 60 (25–80) years, 78% of pts were male, and around one-third had Rai stage III/IV disease. Median time from diagnosis to therapy was 24 mo (G-F/C) and 17 mo (G-B). 37% of pts were alive in follow-up: G-F/C (n=18; 2 lost to follow-up) and G-B (n=19). 7 events of progressive disease occurred in each arm, and 1 pt per arm died due to an adverse event (AE; G-B: respiratory failure; G-F/C: unknown in the setting of unresolved Grade (Gr) 4 pancytopenia); neither was considered treatment related. Due to the small number of events, median PFS and OS could not be estimated; however, 3-year OS was 95% for each arm (95% CI G-F/C, 68–99; G-B, 70–99). Post-treatment, 10/41 pts (24.4%) experienced ≥1 Gr3–5 AE: 2/21 pts (9.5%) in the G-F/C arm and 8/20 pts (40.0%) in the G-B arm. 7 serious AEs were reported in 4 pts, all in the G-B arm; these included pneumonitis and respiratory failure (as noted above; both Gr5), Gr4 leukenpwa/leuk/leup, small cell lung cancer and Gr4 pneumothorax, and melanoma. During follow-up, 6 pts had ≥1 Gr3–4 AE of neutropenia, including 4/20 pts (20.0%) in the G-B arm and 2/21 pts (9.5%) in the G-F/C arm. At end of treatment, all pts were B-cell depleted (B-cell count <0.07x10⁹/L). Within 6–12 mo of follow-up, very few pts had recovered neutrophils (G-F/C: 2/19 pts [10.5%]; G-B: 0/20 pts). At 36 mo follow-up, 9/19 pts (47.3%) in the G-F/C arm had recovered, 3/19 (15.8%) were still depleted, and 7/19 did not have data available. In the G-B arm, 6/20 pts (30%) had recovered, 1 was still depleted, and 13/20 had no available data. In a single center exploratory analysis, 9 pts (G-F/C) underwent 4-color flow cytometry for assessment of peripheral blood for minimal residual disease (MRD) 8–14 mo after therapy; all were negative. 8 of these pts (G-F/C) were MRD-negative by 4-color flow cytometry were also tested with the ClonoSEQ immunoglobulin sequencing assay: 4 were MRD-positive and 4 MRD-negative. 4 pts were MRD-positive by both assays remain in remission, while 2/4 pts who were BCR-positive by ClonoSEQ died after follow-up, one of Richter’s transformation complicating with pneumonia and the other related to MDS. Another pt who was MRD positive by ClonoSEQ underwent allogeneic stem cell transplantation and remains in remission.

Summary/Conclusions: We conclude that G plus either FC or B results in excellent long-term disease control in previously untreated pts with CLL, and has comparable side-effects to other chemo-immunotherapy regimens.

THE PROGNOSTIC SIGNIFICANCE OF CLL-IPi AFTER REDUCED INTENSITY CONDITIONING ALLOGENIC STEM CELL TRANSPLANTATION IN CHRONIC LYMPHOCYTIC LEUKEMIA: THE MAYO CLINIC EXPERIENCE

T. Anagnostou1, T.D. Shanafelt1, M.S. Patnaik1, K.G. Chaffee1, S.A. Parikh1, D.A. Gastineau1, W. Ding1, T.G. Cal1, M.R. Litzow1, N.E. Kay1, M. Conte1, D.A. Bowen1, W.J. Hogan1, S.J. Kenderian1

1Hematology/Medical Oncology, Mayo Clinic, Rochester, United States

Background: Allogeneic stem cell transplant (SCT) remains the only potentially curative option for chronic lymphocytic leukemia (CLL) patients. However, up to 40% of patients treated with Reduced Intensity Conditioning (RIC) - SCT relapse after transplantation. Recently the CLL International Prognostic Index (CLL-IPi) was validated as a predictor of 5 year overall survival in CLL patients.

Aims: In this analysis, we aimed to elucidate the factors that may predict the outcome following RIC SCT, including the CLL-IPi.

Methods: This is a retrospective analysis of all CLL patients who underwent RIC-SCT at Mayo Clinic between 2006-2013. The study was approved by the Institutional Review Board. The prognostic value of several CLL, patient and transplant related variables were analyzed. Continuous variables were reported as median (IQR) and categorical variables as absolute number and percentage. Survival was estimated using the Kaplan Meier and Log Rank tests.

Results: Between 2006 and 2013, 50 patients with a median age of 56 years old underwent RIC-SCT for the treatment of CLL. The median time from diagnosis to RIC-SCT was 4.7 (0.6–22.9) years. Fourteen (28%) patients had 17p deletion at time of transplantation. CLL-IPi prognostic score calculated prior to transplant was intermediate in 30%, high in 42% and very high in 28% of patients. Disease status at the time of transplant was partial or complete remission in the majority of patients (39 patients, 78%). The overall transplant related mortality (TRM) was 6% and the 5-year non-relapse mortality was 14%. Relapse rates at 5 years were 54%. Acute graft versus host disease (GVHD) developed in 30 (60%) of patients and chronic GVHD was noted in 32 patients (64%). We evaluated the impact of CLL characteristics, disease status, and patient and transplant characteristics on clinical outcomes. Development of chronic GVHD post-transplant was the dominant predictor of both disease-free survival (DFS) (HR 0.29, 95% CI=0.10-0.69, P=0.006) and OS (HR 0.40, 95% CI=0.01-0.57, P=0.001, Figure 1A). Very high CLL-IPi risk category (28% of patients) was associated with high relapse rates (82%) post RIC-SCT. DFS was also different between different CLL-IPi categories (18.2% in very high 52.9% in high vs 66.7% in intermediate, p=0.04, Figure 1B). However, there was no significant difference in overall survival suggesting potential benefits from novel therapies in relapsed patients. Given that development of chronic GVHD was the most significant predictor for OS, we evaluated what pre-treatment, patient and disease (including CLL-IPi), and transplant characteristics were predicted for subsequent development of chronic GVHD. ZAP70 over expression (OR 0.09 [95% CI 0.01-0.79], p=0.03), disease status at transplant (progression versus remission OR 0.22 [95% CI 0.05-0.92], p=0.038), and alemtuzumab exposure within 3 months of transplantation were associated with lower rates of chronic GVHD (OR 0.08 [95% CI 0.01-0.79], p=0.03). CLL-IPi was not a significant predictor for the development of chronic GVHD in our analysis.

Figure 1.

Summary/Conclusions: This study found that the development of chronic GVHD post-transplant is mostom significant predictor for both OS and DFS in surviving patients after RIC-SCT in CLL. Interestingly, 82% of patients with very high risk CLL-IPi relapsed after RIC-SCT. This is the first report to evaluate the prognostic significance of CLL-IPi for stratifying post-transplant outcomes and to identify high relapse rates in the very high risk CLL-IPi category.

Background: Several studies showed that tyrosine kinase inhibitors (TKIs) can safely be discontinued in patients with sustained deep molecular response. So far, deep molecular response (DMR) and treatment duration were predictive for successful treatment-free remission (TFR) whereas age, risk scores, gender and molecular response level before stopping were without influence (Mahon FX, et al. & Pfirrmann M. et al., ASH 2016). In addition, biomarkers like NK-cells and CD86+ cells (Ilander M. et al. & Schütz C., Leukemia 2017) seem to be of impact. ABCG2, OCT1 and ABCB1 are known to play a crucial role in acquired pharmacokinetic drug resistance and DMR in the context of nilotinib, imatinib and dasatinib. The influence of these mechanisms have not yet been analyzed for their correlation with TFR.

Methods: Expression measurements were performed by qRT-PCR and sequenced using next-generation sequencing (NGS) with Illumina’s Nextera® technology and a 300 bp paired-end read protocol. The BioVendor sHLA-G ELISA (RD194070100R sHLA-G ELISA - EXBIO Praha a.s. BioVendor) immunocassay was used for the quantitative measurement of HLA-G1 and HLA-G5 soluble forms in EDTA-plasma samples.

Results: The frequency of the G*01:03 allele was significantly associated to OCT1 and the efflux transporters ABCG2 and ABCB1 (MDR1) that have been quantified in order to investigate their impact on TFR. As all patients are in DMR, we investigate whether these transporters confer a constitutional disfunction discontinuation (HR=2.1, 95% CI: 1.06-4.05).

Summary/Conclusions: Here we investigated for the first time the impact of pharmacokinetics in the context of a CML discontinuation trial. ABCG2 but not OCT1 and ABCB1 (MDR1) predicted treatment-free remission after TKI discontinuation. High expression of the ABCG2 efflux transporter correlated with a two-time higher risk of relapse in multivariate analysis. Further prospective validation is warranted.

HLA-G MOLECULES AND CLINICAL OUTCOME IN CHRONIC MYELOID LEUKEMIA

1Hematology, Department of Medical Sciences, University of Cagliari, 2Hematology, Bone Marrow Transplant Center, Azienda di Tutela della Salute, Cagliari, 3Interdisciplinary Center for Advanced Studies, Research and Development in Sardinia (CRS4), 4Polaris Science and Technology Park, Pula, 5Genetics, Department of Medical Sciences, University of Cagliari, Cagliari, 6Division of Hematology, Ospedali Riuniti, Reggio Calabria, 7Hematology Unit, S. Eugenio Hospital, Tor Vergata University, Rome.

Background: The human leukocyte antigen-G (HLA-G) gene encodes a tolerogenic protein known to promote tumor immune-escape mechanisms. Aims: We investigated the potential role of HLA-G polymorphisms and soluble HLA-G molecules in susceptibility to chronic myeloid leukemia (CML), as well as in achievement and maintenance of deep molecular remission (MR4.5) in 68 patients treated with tyrosine kinase inhibitors (TKIs).

Methods: The entire HLA-G gene was amplified by long-range PCR and sequenced using next-generation sequencing (NGS) with Illumina’s Nextera® technology and a 300 bp paired-end read protocol. The BioVendor sHLA-G ELISA (RD194070100R sHLA-G ELISA - EXBIO Praha a.s. BioVendor) immunocassay was used for the quantitative measurement of HLA-G1 and HLA-G5 soluble forms in EDTA-plasma samples.

Results: The frequency of the G*01:03 allele was significantly associated to HLA-G1 and HLA-G5 soluble forms in EDTA-plasma samples. The predictive significance of the efflux and influx channel transcript levels was quantified by a multivariate Cox’s regression model. Relapse has been defined as loss of major molecular response at one time point.

Results: In our cohort, 132 chronic phase CML patients discontinued TKI treatment (87% inmatinib 1st line treatment), showing a relapse rate of 46%. Median MR4 and TKI treatment duration was 4.3 and 7.8 years respectively. The majority of patients were positive for the e14a2 transcript (e14a2+26: 83%, e13a2+ e14a2+ 9%). The mean expression of OCT1 and ABCB1 between ‘relapse’ and ‘no-relapse’ patients showed no significant difference (p=0.99 and p=0.66), whereas ABCG2 showed a weak differential expression (1.1 vs 0.8, p=0.065). Cutoff analyses showed a significant risk stratification only for the ABCG2 efflux transporter at a distinct cutoff value of 4.5‰ (p=0.004). Patients with an ABCG2/GUS transcript level above 4.5‰ showed an up to two-time higher risk of relapse after treatment discontinuation (HR=2.1, 95% CI: 1.06-4.05).

Summary/Conclusions: Here we investigated for the first time the impact of pharmacokinetics in the context of a CML discontinuation trial. ABCG2 but not OCT1 and ABCB1 (MDR1) predicted treatment-free remission after TKI discontinuation. High expression of the ABCG2 efflux transporter correlated with a two-time higher risk of relapse in multivariate analysis. Further prospective validation is warranted.

Figure 1.

Summary/Conclusions: HLA-G alleles with higher secretion of soluble HLA-G...
G would seem to be associated with lower EFS and TFR, possibly because of a stronger inhibitory effect on the immune system in favor of tumor escape mechanisms. Conversely, the allele associated to lower levels of sHLA-G promoted achievement of MR4.5 and TFR, suggesting increased cooperation of the host immune system in CML cell clearance.

P257

DURABLE TREATMENT-FREE REMISSION AFTER STOPPING SECOND-LINE NILOTINIB IN PATIENTS WITH CHRONIC MYELOID LEUKAEMIA IN CHRONIC PHASE: ENESTOP 96-WK UPDATE

Background: ENESTop (NCT01698895) is evaluating the ability to stop treatment and remain in TFR in pts with CML-CP who achieved a sustained deep molecular response (MR) after switching from imatinib (IM) to NIL. In the primary analysis, 57.9% of pts (73/126) who stopped treatment remained in TFR (no loss of major MR, BCR-ABL1 ≤0.1% on the International Scale (IS)), with a confirmed loss of MR4 [BCR-ABL1 ≤0.01%], and no treatment reinitiation at 48 wk.

Aims: To evaluate the proportion of pts remaining in TFR at 96 wk after stopping second-line NIL in ENEStop.

Methods: Eligible pts had ≥3 y of prior tyrosine kinase inhibitor treatment (>4 wk IM, then ≤2 y NIL) and achieved MR4.5 [BCR-ABL1 ≤0.0032%] after switching to NIL. All pts provided informed consent. Enrolled pts continued NIL for 1 y in the consolidation phase (MR assessed every 12 wk). Pts without confirmed loss of MR4.5 during consolidation were eligible to enter the TFR phase (MR4 if ≥3 y of continued MR4.5, the first 48 wk for the second-line pts, then every 12 wk). Pts with loss of MMR or confirmed loss of MR4.5 reinitiated NIL. This analysis was conducted when all pts who entered the TFR phase had completed 96 wk of TFR, reinitiated treatment, or discontinued from the study (data cutoff, 7 Nov 2016).

Results: At 96 wk phase, 67 of the 126 pts (53.2% [95% CI, 44.1% - 62.1%]) who entered the TFR phase remained in TFR. Four pts who were in TFR at 48 wk reinitiated NIL due to confirmed loss of MR4 at 60, 72, 90, and 96 wk, respectively. Two other pts discontinued from the study between 48 and 96 wk due to pregnancy (last BCR-ABL1 of 0.0035% at 60 wk) and pt decision (maintained MR4.5 through 90 wk), respectively. Based on Kaplan-Meier analysis, the median duration of treatment-free survival has not been reached and the curve appeared to plateau (Figure 1). Of 56 pts who reinitiated NIL by the data cutoff, 52 (92.9%) regained MR4 and MR4.5, and the time by which 50% of pts regained MR4.5 was 12.0 and 13.1 wk, respectively. The time by which 50% of pts regained MR4 was shorter for pts on first-line vs second-line therapy which may be due to a confirmed loss of MR4 (n=22; 11.0 wk) vs loss of MMR (n=34; 16.0 wk). Two of the 4 re-treated pts who did not regain MR4 were ongoing in the treatment reinitiation phase (duration, 8.9 and 6.9 wk, respectively), the other 2 discontinued from the study before 48 wk, 1 due to not regaining MMR (retreatment duration, 20 wk) and 1 due to an adverse event (AE) after regaining MMR. Two deaths occurred after the first 48 wk of TFR, both in post-treatment follow-up: 1 due to cardiopulmonary failure 111 days after pt discontinued retreatment due to an AE, and 1 due to adenocarcinoma 77 days after pt discontinued retreatment due to initiation of chemotherapy for secondary malignancy. Among pts who remained in TFR (n=73), rates of all-grade AEs, grade ≥3 AEs, and grade 4 AEs were 82.2%, 63.0% and 63.0% during the first and second 48 wk of TFR, respectively, vs 79.5% during the consolidation phase. Rates of musculoskeletal pain-related AEs were 47.9% and 15.1% during the first and second 48 wk of TFR, respectively, vs 13.7% during the consolidation phase.

Summary: Among 96-wk analyses from ENEStop showed stability of the TFR rate, with few pts reinitiating treatment between 48 and 96 wk after stopping second-line NIL. Rates of overall and musculoskeletal pain-related AEs decreased in the second 48 wk of TFR vs the first 48 wk. Overall, these results demonstrate the durability of TFR after stopping NIL in pts who achieved a sustained deep MR after switching from IM to NIL.

NILOTINIB-INDUCED METABOLIC DYSFUNCTION: INSIGHTS FROM A TRANSLATIONAL PILOT STUDY USING IN VITRO ADIPOCYTE MODELS AND PATIENT COHORTS

S. Sadiq1, E. Owen1, T. Foster1, K. Knight2, L. Wang2, M. Pirmohamed1, R. Clark3, S. Pushpakom1, 1Molecular and Clinical Pharmacology, University of Liverpool, 2Royal Liverpool and Broadgreen University Hospitals NHS Trust, 3Institute of Translational Medicine, University of Liverpool, Liverpool, United Kingdom

Background: Impaired glucose and lipid metabolism is an adverse effect associated with nilotinib (NILO), a tyrosine kinase inhibitor (TKI) used in the treatment of chronic myeloid leukaemia (CML). Indeed the 5-year safety analysis of the ENEStnd trial observed elevations in blood glucose and lipid levels in the NILO arms; importantly NILO-treated patients also showed an increased incidence of arterial occlusive events. Adipose tissue is a key regulator of lipid and glucose homeostasis; dysregulation of adipogenesis, altered adipocyte lipid accumulation and reduced insulin sensitivity are implicated in the pathogenesis of metabolic disease. We investigated the effect of NILO on adipose tissue to explain the mechanisms behind NILO-associated metabolic adverse effects.

Aims: i) To study the effect of NILO and imatinib (IMA) on adipocyte function and adipokine secretion using an in vitro adipocyte model; ii) To utilise the in vitro model to explore potential therapeutic strategies to reverse NILO-mediated effects, and iii) To validate the in vitro results in a pilot patient cohort.

Methods: Differentiating 3T3-F442A murine adipocytes were incubated with clinically relevant concentrations of NILO (1-10µM) and IMA (5µM); in the presence or absence of telmisartan (1-10µM), an angiotensin receptor blocker with potential beneficial effects on insulin sensitivity and lipid homeostasis. Cytoxicity and adipogenesis were assessed by MTT assay and Oil Red O staining, respectively. Expression of adipogenic genes were assessed using qPCR and targeted receptor gamma (PPARγ), lipin1 (LPIN1), sterol regulatory element-binding protein 1 (SREBP1) and glucose transporter 4 (GLUT4) were investigated by quantitative PCR and secreted adiponectin was measured by ELISA. Plasma samples were collected from 30 CML patients on either NILO (first line, n=6; n=8 for first, first-line, n=15) at baseline and at 3 and 12 months of therapy, and adiponectin was measured by ELISA. Data are presented as mean ± SD for 20µM incubations but full concentration response relationships were measured.

Results: Neither NILO nor IMA were cytotoxic to the adipocytes at clinically relevant concentrations. A dose dependent reduction in lipid accumulation was observed for NILO (for 20µM, 0.76 ± 0.005 absorbance units; p<0.01) but not IMA (0.98 ± 0.007), compared to vehicle control. NILO, but not IMA, decreased in the second 48 wk of TFR vs the first 48 wk. Overall, these
Summary/Conclusions: A BCR-ABL1 transcript level measured at 1 month after initiation of a TKI may be used as an early indicator to reliably predict the MMR achievement by 12 months in patients with CP-CML. The level obtained at 3 months appears to accurately predict the MMR. Further studies are needed to evaluate the association between the transcript level at 1 month and long-term clinical outcomes.

P259

EARLY PREDICTION OF THE MOLECULAR RESPONSE TO BCR-ABL1 TYROSINE KINASE INHIBITORS IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA

Background: A BCR-ABL1 transcript level at 3 months after the initiation of imatinib has shown to predict the long-term clinical outcome in patients with chronic myeloid leukemia in chronic phase (CP-CML). The levels obtained earlier than 3 months may also have a similar prognostic significance.

Aims: To assess the prognostic value of the BCR-ABL1 transcript levels at baseline, and 1 and 3 months after the initiation of a tyrosine kinase inhibitor (TKI) in predicting the major molecular response (MMR) achievement by 12 months, and to compare the patterns of molecular response (MR) to a TKI therapy between good and poor responders using a nonlinear model.

Methods: The clinical data were collected from the 178 patients with newly diagnosed CP-CML who were treated with a TKI at Seoul St. Mary’s Hospital. BCR-ABL transcripts were obtained at baseline, and 1, 3, and 6 months after the initiation of a TKI. The levels were reported as the percent ratio relative to the control gene ABL1 in accordance with the International Scale (BCR-ABL1/ABL1×100%). A confirmed MMR was defined as a BCR-ABL1/ABL1≤0.1% on two consecutive occasions. The predictability of the levels at baseline, and 1 and 3 months post TKI therapy for the achievement of a confirmed MMR by 12 months was evaluated using a logistic regression method with a receiver operating characteristic (ROC) analysis. The areas under the ROC curve (AUCs) were calculated to quantify the predictability. In addition, the patterns of molecular responses over time were described by a nonlinear model by the model-derived parameters between the patients who achieved a confirmed MMR by 12 months (“good responders”) and who did not achieve the MMR (“poor responders”).

Results: Of 178 patients, 67 achieved a confirmed MMR by 12 months but 111 did not. At baseline, the transcript level was not useful to predict the achievement of a confirmed MMR by 12 months. At 1 month post therapy, the levels measured at 1 month significantly (p < 0.0001) predicted the MMR with an AUC of 0.77. The patients with the level of 38% or less at 1 month had a better chance to achieve the MMR. By 3 months post therapy, the transcript level measured at 3 months (p < 0.0001) accurately predicted the MMR with the AUC of 0.94. The patients with the level of 0.48% or less at 3 months had a better chance to achieve the MMR. A nonlinear sigmoid model was used to fit the transcript data from 149 patients as follows: MR=MR0 [1 – tγ/(t50γ+tγ)]; where MR0 is the predicted molecular response at baseline; t, time post TKI initiation; y, slope factor; t50, time required to achieve 50% reduction in MR. Statistically significant differences were observed between the good and poor responders in the median values for the model-derived parameters of MR0 (73.3% vs 82.2%; p=0.003), y (4.98 vs 3.32; p < 0.0001) and t50 (0.952 month vs 1.12 month; p=0.7).

Summary/Conclusions: A BCR-ABL1 transcript level measured at 1 month after initiation of a TKI may be used as an early indicator to reliably predict the MMR achievement by 12 months in patients with CP-CML. The level obtained at 3 months appears to accurately predict the MMR. Further studies are needed to evaluate the association between the transcript level at 1 month and long-term clinical outcomes.

A HIGH SENSITIVITY HIGH SPECIFICITY DIGITAL PCR ASSAY FOR BCR-ABL

Background: Digital PCR (dPCR) generates an absolute read out that is largely robust to variations in PCR efficiency and should reduce the requirement for standardisation by laboratory-specific conversion factors. DPCR is an appealing technology for quantitative detection of specific mutations with simultaneous measurement of the reference gene and is particularly suitable for minimal residual disease (MRD) diagnostics in chronic myeloid leukaemia (CML). However, a limitation of the dPCR assays compared to standard quantitative PCR (qPCR) is the background (termed lower limit of blank, LoB) of 1 or 2 positive droplets for BCR-ABL (Franke et al., ASH 2015, Cross et al., Leukemia 2016). The resulting false positive rate (FPR) limits the sensitivity and the ability to detect deep molecular remissions. This has hindered the definition of the lower limit of detection (LoD). We report here on the LoB and the LoD of a newly developed assay.

Aims: Determination of LoB, LoD, linearity and precision of an optimized BCR-ABL digital PCR assay.

Methods: The assay was developed by Bio-Rad laboratories and consisted of a reverse transcriptase reaction followed by a duplex PCR detecting ABL and both the b2/a2 and b3/a2 transcripts of BCR-ABL. Digital droplet PCR was performed using the Bio-Rad QX200 system.

Results: The specificity was >95% for both BCR-ABL and ABL in NTC and wild type samples. Extensive NTC analysis yielded no false positives for BCR-ABL PCR (n=0/176; LoB=0) and 1% false positives in ABL PCR (n=2/176; 1-2 positive droplets, LoD=0). The BCR-ABL assays of healthy donors were positive in 2% (n=5/234) with 1 positive droplet/positive sample. For 2 wells analysis, the detection rate for BCR-ABL for MR5 and MR6 was 100 and 88%, resulting in a LoD between 6 and 3 BCR-ABL copies/2 wells. Although the ABL copy number was only 20000 for 2 wells, the MR5-6 detection rate was 42%. However, in a merged analysis, the detection rate was 100% for MR5 and 67% for MR6 with an average of 6 and 2 BCR-ABL copies/4 wells (see Table 1). The MR5-6 sample was analyzed repeatedly, with 59 of 60 replicates evaluable. A total of 89 BCR-ABL copies (1.51/replicate) and 4329,846 ABL copies (73387/replicate) were detected, resulting in a ratio of 0.0021 (MR4-6). The false negative rate was below 3% when combining any pair of replicates, indicating an LoD of 4-5 for assays carried out in duplicate.

Summary/Conclusions: We report here on an optimized digital PCR assay with a LoB of zero and a LoD of 3 copies/2 wells. This highly sensitive and specific assay allows accurate detection of MRD in BCR-ABL positive diseases with a detection rate of 100% for MR5 and 67% for MR5.5 in a 4 wells analysis.

VALIDATION OF THE EUTOS LONG TERM SURVIVAL SCORE IN DUTCH CML-PATIENTS

I. Geelen1*, N. Thielen2, J. Janssen2, M. Hoogendoorn4, O. Visser5, J. Cornelissen5, W. Westerbeek1

1Albert Schweitzer Hospital, Dordrecht, 2Department of Hematology, VU Med-
Background: Risk scores in chronic myeloid leukemia (CML) use baseline characteristics of CML patients in chronic phase to predict outcome and can be used to make decisions regarding first line TKI choice and monitoring frequencies. Until recently, risk stratification of CML patients was used based on scores developed in the pre-imatinib era (Sokal and Hasford risk score) with overall survival as the end point of interest. After the introduction of imatinib, the EUTOS score was established to predict the risk of cytogenetic Complete Response (CCyR) at 18 months, as a proxy for survival. However, since the major causes of death of CML patients are no longer CML-related, the need for baseline risk prediction has shifted from overall survival towards disease specific mortality. Therefore, recently the EUTOS long-term survival (ELTS) score was introduced to predict the risk of dying of CML in patients treated with first line imatinib.

Aims: The primary objective of this study was to perform a validation of the ELTS score in an independent cohort of “real-world” population-based CML patients.

Methods: Data from chronic phase CML patients were derived from the PHAROS-CML population based registry and Hemobase. Patients were stratified into a low, intermediate and high risk group according to the ELTS score. Data on “death due to CML” were provided by the Netherlands comprehensive cancer organization (IKNL) in combination with details from the patient records and a competing risk analysis was performed, to take death due to other causes into account.

Results: In total 349 patients were eligible for analysis; 273 patients (78%) were treated with first line imatinib and 76 patients (22%) were treated with a first line second generation TKI (2GTKI). Sokal, Hasford and EUTOS risk scores all did not predict differences in risk of “death due to CML”. The ELTS score identified 163 patients as low risk (47%), 127 patients as intermediate risk (36%) and 59 patients as high risk (17%) at diagnosis. The 5 year cumulative incidence of “death due to CML” was indeed significantly higher in the high risk group (11%) compared to both the intermediate risk group (2%, p=0.02) and the low risk group (1%, p=0.001). Between the intermediate and low risk group no statistically significant difference in risk of dying from CML was observed. A subgroup analysis of only imatinib treated patients showed similar results.

Summary/Conclusions: In the current study based on a “real-world” population-based CML patient cohort, we were able to validate the predictive value of ELTS high risk stratification for “death due to CML” in the current TKI era. Therefore, the ELTS score should be preferred over Sokal, Hasford and EUTOS scores in clinical practice.

Background: A second-generation tyrosine kinase inhibitor (TKI), dasatinib, is more potent in inhibiting BCR-ABL than imatinib. We had previously reported an interim analysis of 63 patients with CML-CP who had discontinued dasatinib treatment after maintaining a deep molecular response (DMR) for more than a year (Lancet Haematology, 2015; 2 (12):e528-35) and demonstrated that dasatinib could be safely discontinued in patients with a DMR for at least 12 months. Longer follow-up results would clinically be more critical in the treatment of CML.

Aims: In this trial, the total follow-up duration was set as 36 months after the discontinuation. The aim of the current follow-up study was to investigate whether those patients were able to discontinue dasatinib treatment for a longer follow-up period without relapse.

Methods: The eligibility criteria for pre-registration included CML-CP patients, 15 years or older, receiving dasatinib treatment as the second-line or subsequent therapy after imatinib. All participants gave written informed consent.

In this trial, DMR was defined as “no detectable BCR-ABL1 transcript determined using the international scale-based RQ-PCR at a single central laboratory (BML Inc., Tokyo; the cutoff corresponded to BCR-ABL1 0.0069% IS or molecular response (MR) 4.0).” Patients who showed a sustained DMR for 1 year (1-year consolidation phase) were subsequently included in the dasatinib-discontinuation stage. RQ-PCR was performed monthly for the first 12 months, and then every 3 months for the second year, and every 6 months for the third year, after discontinuing dasatinib. Relapse was defined as any positivity of BCR-ABL1 transcript by RQ-PCR even at one analysis point. In the present study, we assessed the estimated overall treatment-free remission (TFR) after discontinuing dasatinib, with a 1-year follow-up period.

In addition, we also evaluated the impact of immunological profiles, including the cell counts of T and NK cell subsets in the peripheral blood throughout the 1-year consolidation phase, on TFR.

Results: Sixty-three patients were included in the dasatinib-discontinuation stage. The total follow-up duration was set as 36 months after dasatinib discontinuation. After molecular relapse, 1 patient showed fluctuating BCR-ABL1 transcript values below MR 4.0 without restarting dasatinib therapy. A total of 35 out of 63 patients showed molecular relapse. No new cases of second diagnostic translocation were observed. The estimated overall TFR rate was 44.4% (95% confidence interval [CI], 32.0-56.2) at 36 months. A high count of NK-cell phenotypes (CD3-CD56+ cells ≥539 cells/μl and CD16+CD56+ cells ≥506 cells/μl) and a low count of gd+ T-cells (<120 cells/μl) were detected to be significant factors affecting molecular relapse in the interim analysis; these showed sustained significance as predictors of a favorable TFR (P=0.0475, 0.0202, and 0.0093, respectively).

Summary/Conclusions: As the overall provability of TFR was relatively stable even for a longer follow-up period, our findings provided more compelling evidence supporting dasatinib discontinuation after a DMR for more than 1 year; this is feasible especially in patients with imatinib intolerance. We also reconfirmed that the counts of NK cells and functionally specific T-cells in the peripheral blood during dasatinib treatment might affect the TFR following dasatinib discontinuation.

Background: The biological and clinical behavior of hematological malignancies is not only determined by the properties of the leukemic cells themselves, but it is also highly affected by the interaction with the microenvironment, pointing to the existence of an active crosstalk between the two compartments. Previous studies showed that acute myeloid leukemia (AML) actively modify endothelial cells ex vivo via several pathways, mainly mediated by VEGF. However, anti-VEGF therapies haven’t produced successful results in clinical trials.

Aims: Our aim is to perform an extensive study of the vascular niche in the bone marrow (BM) of AML xenografts to provide a global picture of the vascular lature in AML disease and design new therapeutic strategies.

Methods: We combined the use of mouse models of AML, human AML-derived xenografts (PDX) and direct analysis of patients derived samples to study the vascular niche in AML disease. We used two-photon confocal microscopy as a powerful tool to functionally image the BM vasculature in vivo. We used RNA-sequencing to study the AML-associated transcriptomic profile in vascular endothelial cells.

Results: We found several abnormalities in the vascular architecture and function in PDX, such as increased number of endothelial cells, increased microvascular density (MVD), loss of normal sinusoidal architecture and increased hypoxia. Moreover, vascular permeability was increased as measured via two-photon imaging. Interestingly, induction chemotherapy failed to normalize the vascular permeability in the BM, although it significantly reduced the AML engraftment. Via high-throughput transcriptomic analysis, we showed that AML-induced hypoxic environment altered the molecular signature of vascular endothelial cells, activating pro-angiogenic pathways and positively regulating the response to hypoxia. We identified increased nitric oxide (NO) as a major mediator of the AML-induced vascular leakiness in the BM. Notably, increased NO levels were found also in BM aspirates of patients at diagnosis compared to healthy donors, and failure in reducing NO levels after chemotherapy application was associated with a higher incidence of unsuccessful treatment. Strikingly, inhibition of NO production in mouse models of AML and in AML-derived PDX reduced vascular permeability, preserved normal HSC function and significantly improved treatment response (Figure 1).

Summary/Conclusions: We have shown an altered highly permeable vascular niche in the BM of AML PDX, mainly caused by increased NO production by the endothelial niche, contributing to disease progression and treatment failure. Our data call for clinical trials incorporating NOS inhibitors during the remission phase, to target the abnormal vascular niche and improve AML treatment response.

BUILDING HUMAN BONE MARROW-LIKE MODELS TO STUDY NICHE INTERACTIONS

H.-J. Prins1, T. Csikos1, R. de Jong-Korlaar1, R. Ruiter2, S. van Veen3, H. Yuan1, J. de Bruijn4, G. Ossenkoppele1, R. Groen1

1Hematology, VU University Medical Center, Amsterdam, 2Xpand Biotechnol

Background: Previously, we have reported that our human bone marrow-like scaffold (huBM-sc) xenograft model allows the engraftment and outgrowth of normal and malignant hematopoiesis (e.g. multiple myeloma (MM) and acute lymphoblastic leukemia (ALL) (Groen et al. Blood 2012; Gutierrez et al. JCI 2014) and more recently acute myeloid leukemia (AML); Antonelli et al. Blood 2016). These studies show that i) engraftment is not correlated with prognostic risk-groups, ii) there is preferential outgrowth in humanized scaffolds compared to the murine BM, iii) the huBM-sc environment results in better maintenance of self-renewal potential and less clonal drift of the leukemic cells. Although the presence of human osteoblasts and bone mimics a human BM niche more closely than the murine BM in standard xenotransplant models (e.g. NOD-SCID/NSG mice), still some essential components of the human BM niche, i.e. human blood vessels, are missing.

Aims: To implement human vasculature in the huBM-sc xenograft model in order to create a multi-tissue compartment that "maximalizes" the BM-like niche of our scaffolds.

Methods: Towards successful implementation of a human vascular system in vitro scaffold is mandatory. We (i) tested different scaffold compositions (biodegradable cell to protein scaffolds (BCP) vs tricalcium phosphate (TCP)); (ii) scaffold shape (particles vs tubes); (iii) different types of matrigel for cord blood-derived endothelial progenitor cells (CB-EPCs) embedding.

Results: Histological analysis of these fully humanized scaffolds showed a large heterogeneous fraction of mesenchymal, endothelial, and hematopoietic cells, increased microvascular density (MVD), loss of normal sinusoidal architecture and increased hypoxia. Moreover, vascular permeability was increased as measured via two-photon imaging. Interestingly, induction chemotherapy failed to normalize the vascular permeability in the BM, although it significantly reduced the AML engraftment. Via high-throughput transcriptomic analysis, we showed that AML-induced hypoxic environment altered the molecular signature of vascular endothelial cells, activating pro-angiogenic pathways and positively regulating the response to hypoxia. We identified increased nitric oxide (NO) as a major mediator of the AML-induced vascular leakiness in the BM. Notably, increased NO levels were found also in BM aspirates of patients at diagnosis compared to healthy donors, and failure in reducing NO levels after chemotherapy application was associated with a higher incidence of unsuccessful treatment. Strikingly, inhibition of NO production in mouse models of AML and in AML-derived PDX reduced vascular permeability, preserved normal HSC function and significantly improved treatment response (Figure 1).

Summary/Conclusions: Thus, with the addition of human CB-EPCs and BM stromal cells, our scaffold systems now simulate both endothelial and vascular niches of the BM, thereby more closely recapitulating the human hematopoietic microenvironment.

MULTISCALE IMAGE-BASED QUANTITATIVE ANALYSIS OF BONE MARROW STROMAL NETWORK TOPOLOGY REVEALS STRICT SPATIAL CONSTRAINTS FOR HEMATOPOIETIC-STROMAL CELLULAR INTERACTIONS

Á. Gomáriz1, P. Heibling1, S. Isringhausen1, U. Suessbier1, A. Becker2, A. Boss3, T. Nagasawa4, G. Paul5, O. Göksef6, G. Zdekey6, S. Stoma6, S. Norrellykke6, M. Manz7, C. Nombela Arrieta1

1Hematology, University and University Hospital Zurich, 2Radiology, University Hospital Zurich, 3Radiology, University Hospital Zurich, 4Radiology, University Hospital Zurich, 5Computer Vision, 6SCOPE M, ETH, Zurich, Switzerland

Background: Adult bone marrow (BM) cavities host continuous, demand adapted and high throughput blood cell production, which is maintained by a rare population of self-renewing, multipotent hematopoietic stem cells (HSCs). Aside from its diverse hematopoietic content, the BM is populated by a heterogeneous fraction of mesenchymal, endothelial and neural stromal cells, which provide the necessary tissue infrastructure for hematopoiesis in situ, playing fundamental regulatory roles in hematopoietic development. Recent evidence suggests that tissue regions around BM venous microvessels (termed sinusoids), which are enriched for mesenchymal CXCL12-abundant reticular cells (CARc), serve as the principal regulatory niches for HSCs as well as other hematopoietic progenitor populations. Despite this proposed role as a source of specific niche-restricted components, comprehensive data on the frequency, global spatial distribution and topology of sinusoidal endothelial and CAR cell networks is largely lacking to date.

Aims: The principal aim of our work is to employ state of the art imaging tech-niques to perform a detailed 3D quantitative and structural analysis of the BM stromal infrastructure, with a special focus on sinusoidal microvasculature and the CAR cell mesenchymal component, both of which are essential regulators of HSC maintenance.

**TEMPLATED V(D)J INSERTIONS ARE A NOVEL BIOLOGIC MECHANISM FOR B-CELL RECEPTOR REPERTOIRE DIVERSIFICATION**

M.T. Koning1,*, I. Trollmann1, R. Rademaker2, R. Toes3, H. Veeken1

1Department of Hematology, Leiden University Medical Center, Leiden, 2Gen-Mab, Utrecht, 3Department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands

**Background:** Recently, large LAIR1 insertions at the V-D junction were described as a novel mechanism to generate antibodies against P. falciparum RIFIN antigens on infected erythrocytes (Tan et al., Nature 2016). These templated insertions potentially add a novel biological mechanism used by the immune system to generate B-cell receptor repertoire diversity.

**Aims:** We investigated whether templated insertions occur in the B-cell repertoire of healthy donors and whether such insertions could be functionally explored to exploit their biological function.

**Methods:** We obtained >52,000 unique full-length VDJ sequences of IgM, IgG, IgA, and IgE isoatypes by unbiased ARTISAN PCR (Koning et al., BJH 2016) from 6 healthy donors. Abnormally long sequences and junctions were searched for templated insertions by BLAST. Identified VDJ carrying templated insertions were co-expressed with a panel of 172 light chains on multiple myeloma cell lines and assessed for surface expression of transgenic immunoglobulin. The VDJ described by Tan et al. were included as controls.

**Results:** Six unique VDJ sequences, all from the same donor, carried a templated insertion in-frame (E=10−3 – 6). These sequences represented all VDJ sequences with a CDR3 region >150 bp. Exonic sequences from RPLP0, ZNF316, and an inverted IGHV-IGHD sequence were identified as insertions in unmutated IgM VDJ transcripts. The LAIR1 exon described by Tan et al. and an intergenic region adjacent to IGHD3-22 were identified as insertions in IgG VDJ transcripts. One IgA VDJ contained two intergenic sequences positioned closely together on chromosome 22. Somatic hypermutation correlated strongly between the the IGHV segment and the templated insertions (r=0.9944; p<0.001). All templated insertions harboured cryptic RSS sites at their termini. All three IgG VDJ carrying templated insertions and the IgG rearrangement with the 22q13 deletion template insertion gave rise to detectable surface immunoglobulin following coexpression with at least one light chain in the panel. The IgG VDJ carrying the LAIR1 templated insertion produced no detectable surface immunoglobulin. In contrast, the VDJ sequences carrying LAIR1 templated insertions as described by Tan et al. could be expressed with the majority of the light chains. The IgA rearrangement remains to be tested in this system.

**Summary/Conclusions:** Templated insertions represent a novel antibody diversification mechanism. Their presence in naive B-cells, their exclusive position in VDJ junctions, and the universal presence of cryptic RSS sites point to primary VDJ recombination or secondary V gene editing as the generating mechanism. Certain loci (e.g. LAIR1) and individuals appear to have increased susceptibility. The available data suggest RAG to be involved in these insertions. We propose that templated insertions represent inserted insert sequences from aberrantly rearranged chromosomal sequences with cryptic RSS sites.

**TARGETING THE CASPASE / NOX2 AXIS TO MODULATE MACROPHERAGE POLARIZATION**

S. Solier1,*, L. Mezziani2, M. Mondini2, C. Lacout1, P. M.-C. Dang3, J.-C. Martinou4, P. Vandenabeele5, E. Deutsch6, O. Hermine6, N. Draín6, C. Dupuy7, E. Il-Bennace8, E. Ribakovsky1, A. Shimoni1, L. Weiss3, M. Abraham3, A. Peled3, A. Nagler1

1Department of Hematology, Leiden University Medical Center, Leiden, 2Gen-Mab, Utrecht, 3Department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands, 4Clinical Hematology Department, Faculty of Medicine and AP-HP Necker-Enfants Malades, Paris, 5CNRS UMR8200, Gustave Roussy, VILLEJUIF, France

**Background:** Caspases, which are key effectors of apoptosis, have demonstrated non-apoptotic functions. One of these functions is the differentiation into macrophages of peripheral blood monocytes exposed to Colony-Stimulating Factor-1 (CSF1). Conversely, GM-CSF induces the differentiation of monocytes into macrophages in a caspase-independent manner. Macrophages generated by CSF1 and GM-CSF have distinct polarity.

**Aims:** Macrophage polarization plays an important role in the pathogenesis of diverse human diseases as cancer, leading us to explore if caspase inhibition would affect macrophage polarization.

**Methods:** To explore the role of caspases in CSF1 differentiation, we used human monocytes sorted from buffy coats or from blood of NOX2-deficient patients treated by cytokines, and we generated monocyte-restricted caspase-8, caspase-10 and caspase-2 knockout mice, which were treated with bleomycin to induce pulmonary fibrosis.

**Results:** Caspase activation is involved in the generation of M2 polarized macrophages. Caspase inhibition delays the ex vivo differentiation of peripheral blood monocytes exposed to CSF1 and modifies the phenotype of generated macrophages, e.g. cell shape, surface markers and cytokine secretion. In mice, caspase knock-out also modified the phenotype of monocytes induced to differentiate into macrophages. Caspase activation appeared to be prominent at the mitochondria level and responsible for the NOX2-dependent generation of cytotoxic radical oxygen species (ROS). Activation of the NOX2 complex is associated with p47phox cleavage by caspases. Mice treated with bleomycin typically develop a pulmonary fibrosis. Bleomycin-induced lung fibrosis was delayed in monocyte-restricted caspase-8 knockout mice and prevented by treatment with a caspase inhibitory molecule, including zVAD-fmk and the clinically developed IDN6556. This effect was associated with a change in the phenotype of lung-infiltrating macrophages.

**Summary/Conclusions:** Caspase inhibition in monocytes prevent the development of bleomycin-induced lung fibrosis by modifying macrophage polarization, suggesting that caspase inhibitory molecules may be an exciting thera-peutic strategy to modulate macrophage polarization with diverse applications including cancer treatment.
clastogenic assays were used to elucidate the down-stream effects of the elevated CXCL13. Recombinant CXCL13 was at physiological levels as medium produced by co-cultured MM-MΦ increased RANKL expression and induced TRAP+ osteoclast (OC) formation in vitro, while CXCL13 neutralization blocked these activities. We next abrogated CXCL13 expression in MM cell lines using the CRISPR/Cas9 technology. The loss of CXCL13 had no effect on MM in vitro growth or drug sensitivity. However, mice inoculated with CXCL13-silenced MM cells developed significantly weaker BM disease compared to mice receiving the non-manipulated cells. Reduced tumor load correlated with decreased numbers of M2c-MΦ in BM, decreased bone disease, and lower expression of OC-associated genes. Finally, the presence of CXCL13 in primary MM samples was validated. B-cell levels of CXCL13 transcript and protein were detected in BM aspirates from MM patients (n=24) in comparison to normal BM (n=5) and were in correlation with gene expression signature associated with OC activation and M2c MΦ phenotype (Figure 1).

Figure 1.

Summary/Conclusions: Our findings suggest that bidirectional interactions of MΦ with MM tumor cells result in M2c-MΦ polarization, CXCL13 induction and subsequent OC activation, enhancing their ability to support bone resorption and MM progression. CXCL13 may thus serve as potential novel target for understanding the origins of infant and childhood leukaemia.

Results: Gene expression analysis and single cell RQ-PCR. CRISPR/Cas9 technology. The loss of CXCL13 had no effect on MM in vitro growth or drug sensitivity. However, mice inoculated with CXCL13-silenced MM cells developed significantly weaker BM disease compared to mice receiving the non-manipulated cells. Reduced tumor load correlated with decreased numbers of M2c-MΦ in BM, decreased bone disease, and lower expression of OC-associated genes. Finally, the presence of CXCL13 in primary MM samples was validated. B-cell levels of CXCL13 transcript and protein were detected in BM aspirates from MM patients (n=24) in comparison to normal BM (n=5) and were in correlation with gene expression signature associated with OC activation and M2c MΦ phenotype (Figure 1).

Reduced tumor load correlated with decreased numbers of M2c-MΦ in BM, decreased bone disease, and lower expression of OC-associated genes. Finally, the presence of CXCL13 in primary MM samples was validated. B-cell levels of CXCL13 transcript and protein were detected in BM aspirates from MM patients (n=24) in comparison to normal BM (n=5) and were in correlation with gene expression signature associated with OC activation and M2c MΦ phenotype (Figure 1).

Figure 1.
development. We thereby report for the first time that the clonal origin of blood is much more complex than previously thought, with hundreds of precursors contributing to the establishment of the mammalian blood system at multiple stages of ontogeny.

Methods: We employed generated

Results: We verified efficient ablation of Cebpg on mRNA and protein level in bone marrow and spleen of Cebpg KO mice. Analysis of peritoneal cavity of WT and Cebpg KO mice showed similar frequency and numbers of mast cells in steady state conditions. However, Cebpg deficient mice exhibit increased number of peritoneal mast cells after LPS stimulation in comparison to WT control littermates. Surprisingly, mice lacking Cebpg presented defective peritoneal mast cell repopulation. Since mast cells are scarce and difficult to isolate from in vivo models, we employed BM-MCs to investigate the effects of Cebpg ablation in mast cell development and function. We observed that bone marrow from Cebpg KO mice generated reduced number of BM-MCs in comparison to WT controls. Functionally, we demonstrated that deletion of Cebpg reduced mast cell migration towards antigen, SCF or PGE, and impaired degradation upon FcεRI-mediated activation. Further, BM-MCs exhibit increased expression of C/EBPα in the absence of C/EBPγ.

Summary/Conclusions: In summary, we revealed C/EBPγ as important transcription factor which suppresses C/EBPα expression, thereby favoring mast cell development and function. Our data identifies a new component of the mast cell transcriptional network and provides a better understanding of mast cells in normal physiological conditions and disease.

TRANSCRIPTIONAL DIVERSITY AND DEVELOPMENTAL POTENTIAL OF EARLY HEMATOPOIETIC PROGENITORS REVEALED BY CELLULAR BARCODING AND TRANSCRIPTOME-WIDE PROFILING

D. Tronik-Le Roux1, 2, 3, A. Legrand2, V. Michaelis4, J. Renard1, S. Chalabi3, R. Olaso3, J.-F. Deleuze1, C. Battali5, S. Ezme3

1CEA, 2INSERM, Paris, 3CEA, Evry, France

Background: One of the main complications of anti-cancer therapies or bone marrow transplantation protocols is their deleterious effect on the blood system, leading to prolonged neutropenia and increased risk for infections. Manipulating hematopoietic stem cells differentiation pathways to favor production of specific lineage-committed progenitors might optimize blood recovery.

Aims: In this study we aimed 1) to determine and quantify the contribution of medullary progenitor populations (MPP) to the repopulation of the T cell pathway using the barcode cellular labelling strategy that we have previously developed and 2) to decipher the heterogeneity of these MPP at the transcriptional level.

Methods: Three different MPP subsets, of the following phenotype: VCA1+Flt3 (MPP1); VCA1-Flt3+ (MPP2) and VCA1-Flt3+Lr7 (CLP), were tagged with different barcodes carried by a collection of lentivirus and transplanted in mice. Barcoded cells in recipient mice were analyzed by flow cytometry. Transcriptome-wide profiling of whole transcriptome-strand-specific sequencing, three biological replicates, per cell population, were sequenced at high depth of coverage (2 x 120 million reads).

Results: The results allowed the in vivo dynamic tracking of the progeny of the barcoded progenitors in transplanted recipients. Moreover, transcriptome-wide profiling was used to identify, by clustering analysis of RNAseq profiles together with gene ontology annotation, unique co-expressed markers for the prospective isolation of these populations. Unsupervised classification correctly classified reference surface markers, currently used to purify progenitors, which validate our bioinformatic methodology. Transcriptional regulation of these cell surface markers was further assessed by searching for co-expressed transcription factors and enriched binding sites in their promoters. Their groupings enabled to establish undescribed regulatory networks, specific to each progenitor cell.

Summary/Conclusions: Collectively, the cellular barcoding tool and the molecular changes observed at RNA and functional levels as they occur in vivo in the context of physiologic commitment processes, highlighted data that contribute to a deeper understanding of the dynamic of T-lineage differentiation and the lineage restriction process.

**LONG-TERM OUTCOME OF PATIENTS WITH NODULAR LYMPHOCYTE-PREDOMINANT HODGKIN LYMPHOMA TREATED WITHIN THE RANDOMIZED HD7-HD15 TRIALS: AN ANALYSIS FROM THE GERMAN HODGKIN STUDY GROUP**

D. A. Eichenauer1,*, A. Plütschow1, M. Fuchs1, B. von Tresckow1, V. Diehl2, P. Borochmann1, A. Engert1

1First Department of Internal Medicine, 2German Hodgkin Study Group, University Hospital Cologne, Cologne, Germany

**Background:** Nodular lymphocyte-predominant Hodgkin lymphoma (NLPHL) is a rare entity accounting for approximately 5% of all Hodgkin lymphoma (HL) cases. Pathological and clinical features differ from classical HL (cHL). Pathologically, the malignant lymphocyte predominant (LP) cells stain consistently positive for CD20 and are negative for CD30. Clinically, NLPHL often has a rather indolent course. Despite these differences, the first-line treatment of NLPHL is mostly very similar to cHL. However, analyses on the long-term course of patients with NLPHL who were treated identically to cHL are scarce.

**Aims:** To shed more light on characteristics and outcome of NLPHL patients treated identically to cHL, we performed an analysis using the database of the German Hodgkin Study Group (GHSG).

**Methods:** A total of 471 patients with NLPHL who had received first-line treatment within the randomized GHSG HD7-HD15 trials for newly diagnosed HL were identified. The studies were conducted between 1993 and 2009. Patients at all stages (early favorable: HD7, HD10, HD12; early unfavorable: HD8, HD11, HD14; advanced: HD7, HD12, HD15) were included.

**Results:** Among the 471 NLPHL patients, the median age was 39 years; 76% of patients were male; 53% of patients had early favorable, 16% had early unfavorable and 31% had advanced-stage disease. Study treatment consisted of AVD or BEACOPP-based chemotherapy alone, radiotherapy (RT) alone or combined-modality treatment (CMT). After a median observation of 9.2 years, the 8-year progression-free survival (PFS) rate for the whole patient group was 81.3% (83.2% for early favorable, 85.2% for early unfavorable, 76.2 for advanced stages). 80 of 471 patients (17%) had relapsed disease or relapsed during the course of follow-up (primary disease progression: 15 patients, early relapse: 6 patients; late relapse: 66 patients). Second malignancies including histological transformation into aggressive B-cell non-Hodgkin lymphoma (NHL) occurred in 48/471 patients (10%) (solid tumor: 25 patients; leukemia: 7 patients; NHL: 13 patients; unspecified malignancy: 4 patients). For all 471 patients included in the present analysis, the 8-year overall survival (OS) rate was 92.2% (95% CI: 89.1–94.5). On average, patients were 56 years old at diagnosis.

**Summary/Conclusions:** Taken together, the results from this large analysis on NLPHL patients prospectively treated and followed within randomized clinical studies for newly diagnosed HL indicate an excellent lymphoma-specific outcome. Nonetheless, further treatment optimization is necessary as the majority of the patients were not cured and due to second malignancies or other treatment-related late effects. Thus, future clinical trials including NLPHL patients should evaluate whether it is possible to reduce the treatment intensity without compromising efficacy. This goal may be achieved by the partial replacement of conventional chemotherapy by targeted drugs such as anti-CD20 antibodies as well as the reduction of RT fields and doses.

---

**ADVANCED HODGKIN LYMPHOMA IN THE EAST OF ENGLAND CANCER NETWORK: A 10-YEAR COMPARATIVE ANALYSIS OF OUTCOMES FOR ABVD AND ESCALATED-BEACOPP TREATED PATIENTS 16–59 J. Russell1,*, A. Collins1, A. Fowler1, M. Karanth2, C. Saha1, V. Shyamsunder1, S. Docherty1, K. Maw1, J. Padayatty1, A. Hodgson1, J. Wimpenny1, S. Sadullah1, N. Grigoropoulos1, B. Utenthal1, G. Follows1

1Cambridge University Hospitals NHS Foundation Trust, Cambridge, 2Norfolk and Norwich University Hospital, Norwich, 3Peterborough City Hospital, Peterborough, 4West Suffolk Hospital, Bury Saint Edmunds, 5James Paget University Hospital, Great Yarmouth, 6Queen Elizabeth Hospital, King’s Lynn, 7Ipswich Hospital, Ipswich, United Kingdom

**Background:** The majority of young patients with advanced-stage Hodgkin lymphoma (HL) in the UK are managed with ABVD. However, following publication of the HD10 trial results in 2009, escalated-BEACOPP (escB) was introduced by some UK centres to improve disease control in poor-risk patients.

**Aims:** We present a 10-year retrospective multicentre analysis for advanced-stage HL patients aged 16–59, diagnosed between 2004–2014 in the East of England Cancer Network and treated predominantly outside of clinical trials. Our study period includes the 5 years before and after, the introduction of escB. We estimated the 5-year progression-free survival (PFS) and overall survival (OS) rates for the whole cohort, and treatment subgroups, to assess the impact of escB on survival outcomes.

**Methods:** We collected data retrospectively from 8 hospitals in the East of England Cancer Network from a referral population of 2.64 million (incidence: 0.95 cases per 100,000). Six of the 8 centres introduced escB for poor-risk patients, as determined by physician and patient choice; 44 patients were treated with escB, 202 with ABVD, 3 with alternative regimens, and 1 died pre-treatment. The median age at diagnosis was 35 years (IQR: 22–48) and the median follow-up was 9.5 years (IQR: 1.10–24.89). A total of 43 deaths were recorded for all patients with a minimum follow-up of 18 months from diagnosis were included. The 5-year PFS and OS were estimated using the Kaplan-Meier method, and subgroups were compared using the standard log-rank test.

**Results:** We identified 250 patients (stage IA bulk≥Vb) treated in the East of England Cancer Network from a referral population of 2.64 million (incidence: 0.95 cases per 100,000). Six of the 8 centres introduced escB for poor-risk patients, as determined by physician and patient choice; 44 patients were treated with escB, 202 with ABVD, 3 with alternative regimens, and 1 died pre-treatment. The median age at diagnosis was 35 years (IQR: 22–48) and the median follow-up was 9.5 years (IQR: 1.10–24.89). A total of 43 deaths were recorded for all patients with a minimum follow-up of 18 months from diagnosis were included. The 5-year PFS for all patients was 82% and 5-year OS was 92%. There was evidence of a physician–patient preference to treat poor-risk patients with escB, as a greater proportion of escB patients had a high international prognostic score (IPS 3+) than in ABVD patients (escB 75% vs ABVD 38%, p<0.0001). For the whole cohort, PFS was better for patients treated with escB compared with ABVD (5-year PFS 95% vs 80%; HR 4.3 (95% CI:1.97–9.7), p=0.0261), but there was no difference in OS (5-year OS 97% vs 92%; HR 2.6 (95% CI:0.69–10.4), p=0.312). However, patients with IPS 3+ had both a PFS and OS advantage when treated with escB compared with ABVD (5-year PFS 95% vs 84%; HR 6.9 (95% CI: 3.14–24.89), p<0.001, 5-year OS 92% vs 84%; p=0.0325). Twenty-nine ABVD patients and 3 escB patients had at least 1 subsequent stem cell transplant (including 6 allografts post-ABVD and 3 allografts post-escB), and there was equal use of consolidation radiotherapy between regimens (11% of both ABVD and escB patients). Treatment-related infertility is an important consideration for escB patients. In our population, of the 20 pre-menopausal women treated with escB, 11 of the 14 (78.6%) aged <30 years at diagnosis regained menstrual periods during follow-up, 5 (45.5%) of whom subsequently conceived (including 6 live births, 1 miscarriage, and 1 termination). Only 1 of the 6 (16.7%) pre-menopausal women aged ≥30 years at diagnosis regained menstrual periods, which were not sustained beyond 3 years follow-up.

**Summary/Conclusions:** Our data reflect clinical trials results which indicate a first-remission PFS but not OS advantage for unselected young advanced-stage HL patients treated with escB compared with ABVD. However, our data strongly suggest that patients with a poor IPS score derive a PFS and OS benefit from treatment with escB compared with ABVD.
months after treatment discontinuation in both groups. Relapses were documented by histologic examination in both groups. When relapse was documented all patients received salvage therapy with high dose chemotherapy (DHAP), for at least two courses, followed, in case of CR, by ASCT.

Results: After a median 62-months observation (range, 4–108), 83 patients, evenly distributed in the two groups, had a relapse of disease. Of these, 29 of 43 patients (67.4%) of the historical cohort vs 17 of 40 patients (42.5%) of the imaging cohort, showed a larger spread of disease at restaging, i.e. stage superior to IIB, and a more frequent extranodal involvement, 10/43 (23.3%) patients in the historical group vs 3/40 (7.5%) patients in the imaging group (p=0.01).

Furthermore, if we considered only asymptomatic patients, one recurrence was detected in 26 of 43 patients in the imaging group and 17 of 40 patients in the historical group, p=0.02. CR rate with second line treatment were higher in the imaging group (27, 67.5%) compared with the historical group (19, 44.2%; p=0.032). The 3-years DFS was 75% in the imaging group and 36% in the historical group, p=0.02.

Summary/Conclusions: This is the first prospective case-control study using SMAP-US plus CXR to monitor patients with advanced stage HL. We show that SMAP-US plus CXR is a valuable tool to improve follow-up in patients with a high risk of recurrence. Our data indicate that the early detection of HL recurrence allows to begin rescue therapy in patients with a more limited disease and, consequently, increase its effectiveness in terms of probability to response and DFS.

P278

LATER LINE CHEMOTHERAPY TREATMENT PATTERNS OF CLASSICAL HODGKIN’S LYMPHOMA PATIENTS IN CANADA, FRANCE, GERMANY AND THE UNITED KINGDOM

K. Byrne1,*, A. Juarez Garcia2, P. Hallworth1, S. Blackburn1, M. Lees3

1Adelphi Real World, Bollington, United Kingdom, 2WW HEOR, Bristol-Myers Squibb, Mexico City, Mexico, 3WW HEOR, Bristol-Myers Squibb, Paris, France

Background: Whilst cHL is seeing increasing ‘cure’ rates, a cohort of patients remain who, due to multiple relapses, require 3rd or 4th line (4L) lines of drug treatment. Real world treatment patterns for RRHL patients are currently less understood.

Aims: To understand the drug treatment patterns of cHL patients in 3rd or later line treatment.

Methods: Real-world data were collected through a cross-sectional survey administered to physicians in Canada (Ca), France (Fr), Germany (Ge), and the UK between May and Sep 2016. Physicians provided data on the last 8 cHL patients receiving 3rd or 4th line drug treatment. Data captured included demographics, disease history and treatment patterns. Auto/allo stem cell transplants (auto/alloSCT) were not classified as a treatment line and limited data was available to determine when a SCT was received. Summary statistics were reported and differences between sub-groups assessed using chi-square tests.

Results: In total 116 physicians (Ca, 16; Fr, 31; Ge, 44; and UK, 25) provided information on 959 cHL patients (Ca, 128; Fr, 243; Ge, 351; and UK, 237) on 3rd or later lines of drug treatment. Data for 954 cHL patients on 3rd line drug treatment was captured. Patients had a mean age of 54.0 years (SD: 16.79) at the point of data capture. 57% were male, 43% female. 30% had bulky disease. 84% of patients had been tested for the Epstein Barr virus (EBV), 36% confirmed as positive. The most commonly prescribed 3rd line drug treatment was a brentuximab-vedotin (BV) based regimen (35%). BV use was significantly different across the markets; Canada (34%), France (35%), Germany (30%) and the UK (44%) (p=0.010). The next most commonly prescribed 3rd line treatment were DHAP (8%), BEAM (7%) and bendamustine (7%). 4% of 3rd line patients received a PD-1 inhibitor. Of 3rd line BV patients the majority received ABVD (69%) or BEACOPP (19%) at 1st line. Their most common 2nd line drug treatments were DHAP (21%), ICE (10%), ESHAP (9%) and BEACOPP (9%). 59% of all 3rd line BV patients had undergone an auto/alloSCT at some point during their treatment history. Of 3rd line patients receiving non BV-based regimens 6% had been treated with BV previously (1st/2nd line). Of 3rd line patients treated with a PD-1 inhibitor 7% had been previously treated with BV. Data for 453 cHL patients on 4th line drug treatment was captured. 4th line patients had a mean age of 55.5 years (SD: 16.79) at the point of data capture. 56% were male, 44% female. 83% had been tested for EBV, 38% confirmed as positive. 30% of 4th line patients received a BV based regimen – BV use across markets was significantly different; Canada (20%), France (38%), Germany (23%) and the UK (36%) (p=0.007). At 3rd line this cohort had most commonly received DHAP (16%), BEAM (15%) or ICE (11%). 5% of 4th line BV patients also received a BV based regimen at 3rd line and 12% of 4th line patients had received a BV regimen at 3rd line. At 4th line 38% of this cohort received a PD-1 inhibitor, 19% bendamustine and 9% gemcitabine.

Summary/Conclusions: Real-world data indicates an unmet medical need for cHL patients with multiple relapses, reinforced by the use of PD-1 inhibitors in those relapsing post BV based regimen at 3rd line. There also appears to be no clear standard of care at 3rd line, again highlighted by use of a range of regimens and PD-1’s.

This study was sponsored by Bristol-Myers Squibb.

P279

CHEMOTHERAPY AND RADIATION IMPROVE SURVIVAL IN EARLY STAGE CLASSICAL HODGKIN LYMPHOMA, A STATEWIDE CANCER REGISTRY ANALYSIS.

H. Sased1, R. Shrestha1, J. Nee2, E. Durbin2, M. Ziai3, R. Ramlal1, G. Monohan1, R. Herzig1, R. Fleischmann1, G. Hildebrandt1

1Internal Medicine-Division of Hematology and BMT, 2Kentucky Cancer Registry, University of Kentucky- Markey Cancer Center, Lexington, United States

Background: Early stage classical Hodgkin Lymphoma (cHL) has been shown to have an excellent outcome. Recent studies have therefore focused on decreasing the toxicity that results from the addition of radiation therapy to chemotherapy. However, it remains unclear whether omitting radiation as part of the initial therapy of cHL is associated with a similar survival.

Aims: The primary aim of this study is thus to investigate the outcomes observed in a statewide cancer registry for cHL patients treated with chemotherapy alone vs patients treated with both chemotherapy and radiation.

Methods: All adult patients (older than 18) diagnosed with cHL in Kentucky Cancer Registry (KCR) from 2005-2014 were retrospectively reviewed. Case line characteristics including age at diagnosis, gender, histology, stage, B symptoms, extranodal involvement, and the site involved were collected. First line treatment modalities as well as overall survival outcomes were reviewed.

Stage I and II patients without B symptoms were considered favorable, while those with B symptoms were considered unfavorable. Patients with stage III and IV disease were given an advanced stage designation. To adjust for selection bias, patient deaths during the first 6 months of diagnosis were censored for overall survival analysis.

Results: A total of 961 patients were identified. Median age was 41 (range 18-91) and 60.9% (n=585) were younger than 50. The group included a mild predominance of males (55.5%). Only 1.7% (n=16) had extranodal involvement at presentation. Of those with known histology (78.8%), the most common was nodular sclerosis (71.2%), followed by mixed cellularity (22.8%), lymphocyte rich (3.8%) and lymphocyte depleted (1.9%). Median follow up time was 45 months (range 0-136). The 10-year overall survival for the favorable group (n=329) was 77% (95% CI: 71.1-88.8) versus 68% for the unfavorable group (n=144) and 42% for the advanced group (372) (p<0.001).

There was no statistical difference in survival between stage I (n=170), and stage II (n=385) disease (p=0.99). Treatment modalities were then compared for the favorable risk group alone. Those who received chemotherapy alone (n=145) were compared to those who received combined chemotherapy and radiation (n=148) as their primary therapy. The 10-year overall survival for the cohort receiving chemotherapy and radiation was 87% compared to 75% for those receiving only chemotherapy (p<0.001) (Figure 1). When adjusted by multivariate analysis for risk factors affecting 10 year survival of the favorable cohort, only age <50 and the treatment modality were independently associated with a statistically significant difference in overall survival (HR of 0.11 (p<0.001) and 3.94 (p=0.001), respectively).

Figure 1.

Summary/Conclusions: Our large data cohort shows the presence of B symptoms to be prognostic than the number of nodal regions involved for early stage disease. Although the use of radiation as part of initial therapy for early stage disease might have increase long term toxicity, it continued to provide superior survival at 10 years.
THE IMPACT OF TREATMENT WITH BRENTUXIMAB VEDOTIN ON OVERALL SURVIVAL OF PATIENTS WITH HODGKIN LYMPHOMA RELAPSED AFTER AUTOLOGOUS STEM CELL TRANSPLANTATION: A NATIONWIDE POPULATION BASED ANALYSIS

1Second Dept of Internal Medicine, 2Hematology and Bone Marrow Transplantation, National and Kapodistrian University of Athens, Athens, 3Hematology and Bone Marrow Transplantation, Papanikolaou General Hospital, Thessaloniki, 4Hematology Department, National and Kapodistrian University of Athens, Athens, 5Hematology Department, Iatriko Athinon, Athens, 6Hematology Department, University of Thessalia, Larissa, 7Hematology Department, Metaxa Oncology Hospital, Piraeus, 8Hematology Department, Gennimatas General Hospital, Athens, 9Hematology Department, University General Hospital of Crete, Heraklion, 10Hematology Department, University General Hospital of Thrace, Alexandroupolis, 11Hematology Department, University General Hospital of Ioannina, Ioannina, 12Bone Marrow Transplantation, University General Hospital of Patras, Patras, 13Hematology Department, YGEIA General Hospital, Athens, 14Hematology Department, Papageorgiou General Hospital, Thessaloniki, 15Hematology Department, Air Force General Hospital of Athens, 16Hematology Department, 401 Military Hospital of Athens, 17Hematology and Bone Marrow Transplantation, Evangelismos General Hospital, 18Hematology Department, Henry Dyanon Hospital, Athens, Greece

Background: Patients with Hodgkin Lymphoma (HL) who relapse after autologous Cell Transplantation (auto-SCT) have a dismal prognosis. Advanced disease stage, presence of B-symptoms, extranodal involvement at the time of relapse and duration of remission of less than 12 months are parameters associated with decreased overall survival (OS). Brentuximab Vedotin (BV), an anti-CD30 monoclonal antibody conjugated to a microtubule-disrupting agent has shown clinical efficacy in HL. Although in the setting of post-auto-SCT relapse, BV produces an overall response rate of approximately 75% with a median progression free survival (PFS) of 9 months, the impact of BV on OS has not been addressed in previously published studies.

Aims: To examine the impact of treatment with BV on OS of patients with HL relapsed after auto-SCT.

Methods: Data for patients with HL who underwent auto-SCT in Greece during the last 20 years were collected. Study group consisted of 214 patients who experienced post-auto-SCT relapse. In order to examine the impact of BV on OS, patients were divided in 2 cohorts depending of the date of BV availability in Greece (January 2013). Cohort 1 consisted of 178 patients who relapsed before January/2013, while Cohort 2 consisted of 36 patients relapsed after BV became available. Patient’s characteristics are shown in Table 1.

Table 1. Patients characteristics.

The following variables were included in a multivariate Cox proportional hazard regression analysis model: 1) age of patient, 2) Sex, 3) B-symptoms (yes vs no), 4) Stage of disease (I-II vs III-IV), 5) extranodal disease, 6) time from auto-SCT to relapse (≤12 vs >12 months), 7) Relapse before or after BV availability (Cohort 1 vs Cohort 2). In order to exclude any confounding effect of subsequent treatments, analysis was performed by censoring patients at the time of allologeneic SCT or treatment with immune checkpoint inhibitors (IC-inhibitors).

Results: In multivariate analysis the following variables were statistically associated with OS: 1) The presence of B-symptoms [HR=2.07, (95% CI, 1.39-3.07), p=0.001] and 2) Relapse in less than 12 months after auto-SCT [HR=4.76, (95% CI, 3.35-5.00), p=0.001] were associated with decreased OS, while 3) Response after 1st salvage [HR=0.46, (95% CI, 0.31-0.68), p=0.001] and 4) BV availability [HR=0.36, (95% CI, 0.16-0.79), p=0.011] were associated with increased OS (Figure 1). Similar results were obtained when analysis was performed without censoring patients at the time of allo-SCT or treatment with IC-inhibitors (data not shown).

Summary/Conclusions: Patients in Cohort 2 survived longer even when censored for allo-SCT or treatment with IC-inhibitors. All patients in Cohort 2 treated with BV while only 18% of patients in Cohort 1 received treatment with BV. The results of our study strongly suggest that BV improves OS in patients with HL relapsed after auto-SCT. To our knowledge this is the first study showing an OS advantage of treatment with BV.
tion was defined as imaging at or before week 12 of treatment, whereas late radiological evaluation was performed at or after week 16. Response evaluation was performed according to the Lugano Classification and its update regarding immunomodulatory therapy.

Results: Between 06/2015-11/2016, 87 patients were enrolled in a name-based program in Turkey. Two, 19, and 3 patients who had not yet received nivolumab, had not reach the time for early radiological evaluation, and who died before any radiological evaluation were excluded from the analysis. Thus, 63 patients from 23 centers were retrospectively analyzed. Median follow-up was 6 months, median age was 29 (18-75) and patients had a median 5 (2-11) previous lines of therapy. 44 patients (70%) had been treated by stem cell transplantation (SCT) and 45 (76%) patients had been treated by BV. The ORR was 66% with 15 CR (95%CI 0.020-0.28, CR 26%, PR 42, SD 12%, PD 20%) among 59 patients evaluated in 12 weeks of nivolumab treatment. The ORR was 67% with 9 (24%) patients with CR after 16 weeks of treatment (95%CI 0.004-0.26, CR 24%, PR 43%, SD 6%, PD 27%). Estimated OS was 95% (95%CI 0.90-0.98) and estimated PFS was 71% (95%CI 0.55-0.82) at 12-months. Median OS was not reached, while, according to the late response rates, the median PFS was 14 months. However, it was only 3 months in patients with PD at the late radiological evaluation. Regarding responses to last treatment prior to nivolumab, we detected that 28 (67%) of 42 PD cases had objective early responses and 70% of PD cases had ORR in the late response evaluation (CR in 4, PR in 12 pts). 8 patients underwent transplantation following nivolumab. Among 5 patients who had been treated by allo-SCT, 4 had CR at the time of transplantation and they are alive with ongoing response. Safety profile was acceptable and only two patients required cessation of nivolumab due to serious adverse events: one due to autoimmune encephalitis and one due to aggravation of graft versus host disease. At the time of analysis, 40 cases were still on nivolumab treatment (64%). Among the 40 cases with early objective responses to nivolumab, 35 (88%) showed ongoing objective responses. All 24 cases with objective responses in the late evaluation had ongoing responses at the time of analysis (Figure 1).

Figure 1.

Summary/Conclusions: In conclusion PD-1 blockers are new options to meet the unmet need in patients with chHL refractory to BV treatment, and possibly a bridge for these patients before transplantation.

P282

GENOTYPING OF HODGKIN LYMPHOMA ON THE LIQUID BIOPSY

V. Spina1,*, A. Bruscaggin1, M. Di Trani2, M. Martini3, S. Locatelli2, E. Cupelli4, G. Forestieri 1, A. Condoluci 1,5, A. Cuccaro 4, A. Moccia 5, A. Stathis 5, 1Institute of Oncology Research, Bellinzona, Switzerland, 2Department of Oncology and Haematology, Humanitas Cancer Center, Humanitas Clinical and Research Center, Milan, 3Division of Pathology and Histology, 4Institute of Hematology, Catholic University of the Sacred Heart, Rome, Italy, 5Oncology Institute of Southern Switzerland, Bellinzona, Switzerland, 6Division of Hematology, Department of Translational Medicine, University of Eastern Piedmont, Novara, Italy

Background: In classical Hodgkin lymphoma (cHL) the low representation (1-5%) of Reed-Sternberg cells (RS) challenged tumor genotyping on the diagnostic tissue biopsy. Consistently, the mutational profile of newly diagnosed cHL is poorly characterized, and the genetics of refractory disease is completely unknown. Cell free DNA (cfDNA) is shed into the blood by tumor cells under-going apoptosis and can be used as source of tumor DNA for the identification of somatic mutations. In addition cfDNA is representative of the entire tumor heterogeneity, thus allowing the identification of mutations from tumor cells residing in non-biopsied sites.

Aims: This study aims: i) at providing the evidence that the mutational profile of cHL can be tracked by using plasma cfDNA; and ii) at characterizing the genetics of newly diagnosed cHL and, for comparative purposes, of refractory cHL.

Methods: The study includes 28 newly diagnosed cHL and 9 chemorefractory cHL. All cases were provided with cfDNA from plasma collected at baseline, before treatment start, and paired DNA from granulocytes as source of germline DNA to filter out polymorphisms and sequencing noise. Paired genomic DNA from formalin fixed paraffin embedded (FFPE) tumor tissue biopsies was available for 17 patients, including 3 cases for which RS enriched areas were macrodissected. A targeted resequencing panel optimized to include the coding exons and splice sites of 77 genes (192Kb) that are recurrently mutated in B-cell lymphomas was used for genotyping. Libraries were prepared from plasma cfDNA, germline gDNA and tumor gDNA according to the CAPP-seq targeted enrichment strategy (Nimblegen) and subjected to ultra-deep-next generation sequencing (NGS) on the MiSeq platform (illumina). The sequencing was tailored to obtain a depth of coverage >200x in >80% of the target region in all samples, which allowed a sensitivity of 3x10⁻3. The somatic function of VarScan2 was used to call non-synonymous somatic mutations, and a stringent bioinformatic pipeline was applied to suppress the background noise and to filter out sequencing errors.

Results: In newly diagnosed cHL, genotyping of plasma cfDNA identified non-synonymous somatic mutations in STAT6 (43%), TNAIP3 (43%), ITPKB (32%) B2M (21%), GNA13 (14%), CIITA (7%), XPO1 (7%) and CD58 (4%) among the most recurrently affected genes (Figure 1A-B). In refractory cHL patients, genotyping of plasma cfDNA identified non-synonymous somatic mutations in ITPKB (44%), TNAIP3 (33%), KMT2D (33%), B2M (33%), GNA13 (33%), XPO1 (22%), TET2 (22%), IKBKB (22%), BIRC3 (22%) and STAT6 (22%) among the most recurrently affected genes. Mutations of KMT2D (33%) and TET2 (22%) were enriched in refractory chHL patients compared to newly diagnosed cases, suggesting that they contributed to the chemorefractory phenotype (Figure 1C-D). By using highly sensitivity techniques, most of the mutations discovered in cfDNA were also identified in pair tumor DNA from the tissue biopsy and/or macrodissected RS cells, thus confirming their tumor origin (Figure 1F).

Figure 1.

Summary/Conclusions: This study provides the evidence that cfDNA can be genotyped using plasma cfDNA as source of tumor DNA, pointed to a non-overlapping genotype between newly diagnosed and refractory cases, and identified ITPKB as a new gene specifically involved in ~30-50% of cHL patients.
FDG PET-CT MAYBE A USEFUL TOOL TO IDENTIFY DOXORUBICIN INDUCED CARDIOTOXICITY IN HODGKIN LYMPHOMA

G. Sambuceti1, E. Arboscello1, P. Spatarossola1, M. Miglino1, M. Bauckneht1, F. Fiz1, S. Morbelli1, G. Ferrarazzo1, A. Bellodi1, A. Da Col1, D. Avenoso1, F. Balerini1, M. Bergamaschi1, L. Mitscheunig 1, M. Sarocchi1, C. Brunelli1, M. Gobbi1, R. Lemoli1

1IRCCS San Martino - IST, Genova, Italy

Background: Doxorubicin (DXR) induced cardiotoxicity is related to several mechanisms, including interference of mitochondrial respiratory chain and acceleration of glycolysis. We previously reported that this treatment may enhance myocardial FDG uptake.

Aims: The present study aimed to verify whether this metabolic response on serial PET/CT imaging can predict myocardial function, non-invasively evaluated by follow-up echocardiography (ECHO).

Methods: 18F-FDG PET/CT of 25 patients affected by Hodgkin Disease (HD), treated following ABVD scheme were analyzed. Inclusion criteria were: 1) availability of 4 consecutive PET/CT scan for staging (PET1), interim (PET2), post-therapy (PET3) and six months follow-up evaluation (PET4); 2) full remission without any progressive increase. Accordingly, the ratio between PET4 and PET1 LV-SUV in the two subgroups was 3.85±0.8 and 1.06±0.4, respectively without any progressive increase. LV-SUV progressively increased from PET1 to PET4 in 6 patients (24%, 2 females, mean age 38±17, termed “increasers”) being 1.34±0.9, 3.34±2.6, 4.32±2.8 and 4.43±1.5 respectively. In the remaining 19 patients (76%, 7 females, 36±14), FDG uptake showed a largely variable response without any progressive increase. Accordingly, the ratio between PET4 and PET1 LV-SUV in the two subgroups was 3.85±0.8 and 1.06±0.4, respectively (p=0.001). Up to six months after therapy discontinuation, none of the 22 patients showed signs or symptoms potentially related to DXR cardiotoxicity. However, late follow-up ECHO detected the appearance of first-degree diastolic impairment with respect to baseline in 9 of the 25 examined patients (36%, 4 females, mean age 36±18). This finding occurred in 5/6 “increasers” (83%) and in only 4/19 non-increasers (21%) (p=0.001).

Summary/Conclusions: The present data indicate that DXR related myocardial damage can be preceded by an enhanced glucose uptake. 18F-FDG PET/CT imaging might represent a useful tool to identify high-risk patients and to implement personalized program to monitor and prevent DXR-induced cardiotoxicity.

Iron metabolism, deficiency and overload

ELEVATED SYSTEMIC HEME AND IRON LEVELS AS RISK FACTORS FOR VASCULAR DYSFUNCTION ANDATHEROSCLEROSIS: EVIDENCE FROM B-THALASSEMIA AND HEMOCHROMATOSIS COHORT STUDIES

F. Vinchi1, G. Portol1, A. Silva2, R. Sparta1, G.M. Vencelotti3, J.D. Belcher3, E. Fibach4, H. Zreid5, R. Rasras6, M.W. Hentze7, H. Ghofi8, M.U. Muckenthaler1, E.A. Rachmilewitz9

1Molecular Medicine Partnership Unit (MMPU), University of Heidelberg & EMBL, Heidelberg, Germany, 2University of Porto, Porto, Portugal, 3Vascular Biology Center, University of Minnesota, Minneapolis, United States, 4Department of Hematology, The Hebrew University Hadassah Medical Center, Jerusalem, Israel, 5Department of internal Medicine, AlShifa hospital, Labo- ratory department, European Hospital of Gaza, Gaza, Palestinian Territory, Occupied, 6European Molecular Biology Laboratory (EMBL), Heidelberg, Germany, 7Department of Hematology, Assuta Medical Center, Tel Aviv, 8The Edith Wolfson Medical Center, Holon, Israel

Background: Increasing evidence from animal studies suggests that free heme exerts vasculotoxic, pro-inflammatory and pro-atherogenic effects due to its ability to trigger endothelial and immune cells activation. Moreover, we recently demonstrated a role for iron in the pathogenesis of atherosclerosis, analyzing a mouse model of type IV hereditary hemochromatosis, hallmarked by severe iron overload. We also showed that iron-deficient diet and chelation therapy prevent atherosclerosis progression in those mice.

Aims: Here we aimed at evaluating the clinical relevance of these findings and mechanisms, including interference of mitochondrial respiratory chain and acceleration of glycolysis. We previously reported that this treatment may enhance myocardial FDG uptake.

Elevated systemic heme and iron levels, which correlate with a severe drop in the plasma scavengers for hemoglobin and heme, Haptoglobin and Hemopexin, respectively. Hemochromatotic patients show increased iron levels and reduced nitrotyrosine levels, hallmarks of endothelial activation and vascular dysfunction. In addition, they show increased serum lipid peroxidation, elevated circulating oxidized LDLs and high pro-inflammatory cytokines, which are known to promote atherosclerosis. All parameters significantly correlate with increased systemic heme and iron indices, including NTBI, as well as decreased scavenger levels.

Summary/Conclusions: These results emphasize the involvement of serum hemoglobin, heme and iron in the pathogenesis of vascular dysfunction in β-thalassemia and hemochromatosis and suggest a pro-atherosclerotic role for these molecules. These findings are relevant, on one side, for cardiovascular diseases and vasculopathy, when iron parameters are altered, and on the other, for iron overload disorders, where premature atherosclerosis might develop. Finally, our data highlight the key protective role of heme/iron scavengers and support the potential therapeutic benefit of chelation therapy to counteract heme/iron-driven vascular toxicity and atherosclerosis in hemolytic and iron-overload conditions.
Methods: A retrospective pre-post cohort study was conducted in pts switching from DFX DT to FCT using pharmacy and medical claims (06/2014 - 05/2016) from the Symphony Health Solutions’ Integrated Datavarse (IDV®) database. Eligible pts were ≥2 years old, had a diagnosis of an inherited or acquired hematological disorder requiring transfusions (e.g., sickle cell disease, myelodysplastic syndrome), ≥2 DFX CT claims (base year), and ≤16 months of prior use of DFX DT pre-index. Medication possession ratio (MPR) (percentage of time with access to medication) was computed for DFX DT during the “DFX DT period” (from earliest DFX CT claim to index date) and for DFX FCT during the “DFX FCT period” (from index date to end of data availability/ICT switch). Proportion of days covered (PDC) and persistence (without a gap ≥30 or 60 days between claims) were assessed in the DFX DT and DFX FCT periods over fixed intervals of 3 and 6 months, which started from the index date in the DFX FCT period, or dispensing date of the most recent DFX CT claim prior to the beginning of a 3- or 6-month interval in the DFX DT period. Comparisons between the two periods were made using the Wilcoxon sign-rank test for continuous data and McNemar’s test for dichotomized data.

Results: Of the 606 eligible pts, 56% were female, 64% were <35 years old, and 42% had transfusions during the baseline period. The median durations of the DFX DT and DFX FCT periods were 350.9 days and 290.2 days, respectively. Compared with adherence to DFX DT, adherence to FCT was significantly improved across all measures. Mean MPR of DFX CT vs DFX DT was 0.80 vs 0.76 (p<0.001); 60.9% pts had a mean MPR ≥0.8 during the DFX FCT period compared to 54.3% during the DFX DT period (p<0.01). Mean 3-month PDC of DFX CT vs DFX DT was 0.83 vs 0.71 (p<0.001); 50.0% pts had mean 3-month PDC ≥0.8 during the DFX FCT period compared to 34.5% during the DFX DT period (p<0.001). The proportion of pts with 3-month persistence to DFX CT vs DFX DT (without a gap ≥30 days) was 87.2% vs 63.4% (p<0.01). Similarly consistent and significant results for PDC and persistence were observed using a 6-month time interval and/or a 60-day gap between claims.

Summary/Conclusions: Adherence and persistence to ICT was significantly improved in pts who switched from DFX DT to DFX FCT. Reasons for switching, which may contribute to improved adherence, were not examined in this study. Nevertheless, since the majority of pts were already adherent to DFX DT, the higher adherence and persistence to FCT can be further augmented with this formulation. This real-world study complements the ECLIPSE trial results and supports previous evidence of improved adherence to DFX FCT.

P286

MEDIATION BY PATIENT-REPORTED OUTCOMES ON THE ASSOCIATION BETWEEN FILM-COATED VERSUS DISPERSIBLE FORMULATIONS OF DEFERASIROX AND SERUM FERRITIN REDUCTION: A POST HOC ANALYSIS OF THE ECLIPSE TRIAL

A. Taher1,2*, R. Origa1, S. Perrotta3, A. Kourakis4, K. Belhou4, V. Huang5, J. Han6, A. Bruederle7, P. Bobbili8, M. S. Duh8, J. B. Porter9
1American University of Beirut Medical Center, Beirut, Lebanon, 2Ospedale Pediatrico Micrornico “A.Cao”, University of Cagliari, Cagliari, 3Second University of Naples, Naples, Italy, 4Hematology Division, Department of Internal Medicine, University of Patras Medical School, Patras, Greece, 5Dubai Health Authority, Thalassemia Center, Dubai, United Arab Emirates, 6Novartis Pharmaceuticals Corporation, East Hanover, United States, 7Novartis Pharma AG, Basel, Switzerland, 8Analysis Group, Boston, United States, 9University College London, London, United Kingdom

Background: The ECLIPSE clinical trial (NCT02125877) demonstrated that a new film-coated tablet (FCT) formulation of deferasirox (DFX) had a similar safety profile, with fewer patients (pts) experiencing severe gastrointestinal (GI)-related adverse events (AEs), and more favorable patient-reported outcomes (PROs) compared to the dispersible tablet (DT). However, the PROs of FCT pts showed better adherence, satisfaction, palatability and fewer concerns about iron chelation therapy (ICT). ICT pts had a higher median absolute reduction in serum ferritin (SF) from baseline to the end of treatment (tx) (-350.0 mg/L). The improvement with DFX-FCT suggests that ICT can be further augmented with this formulation. This real-world study complements the ECLIPSE trial results and supports previous evidence of improved adherence to DFX FCT.

Aims: To examine the proportion of the association between tx with FCT vs DT and SF reduction from baseline that is mediated through PROs, in a post hoc analysis.

Methods: The ECLIPSE trial was a phase II, randomized, open-label study in which 173 pts with transfusion-dependent thalassemia or myelodysplastic syndrome were randomized to receive DFX FCT (N=87) or DT (N=86) at average planned doses of 30.7 mg/kg/day for 6 months and SF reduction from baseline (±5% of baseline value). PROs were assessed at weeks 2, 3, 13, and 24 (end of tx) using the Palatability and Modified Satisfaction with Iron Chelation Therapy (mSICIT) questionnaires, the latter assessing 3 domain scores: adherence, satisfaction, and concerns. Frequency of GI-related AEs was assessed during the tx period. Mediation analysis, i.e., comparing a model adjusted for hypothesized mediators to an unadjusted model (Lin DY, et al Stat Med. 1997), was used to compute proportion mediated (PM). PM quantifies how much of the association between tx with DFX FCT versus DT and SF reduction from baseline is operationalized through pt-reported adherence score, oth PRO scores, and frequency of GI-related AEs during tx. The analysis was adjusted for confounders including age, sex, race, underlying hematological disease, prior use of DFX DT, baseline level of iron overload severity, average planned dose, and number of blood transfusions on tx. Sensitivity analyses were conducted in subgroups of pts who had prior use of DFX DT (DT naïve), had thalassemia, and were DT non-naïve pts with thalassemia.

Results: The association between tx with DFX FCT versus DT and SF reduction was substantially mediated by pt-reported adherence (PM=66.6%, p<0.01). Pt-reported adherence, along with pt-reported satisfaction, concerns, and palatability scores, and frequency of GI-related AEs together mediated 76.7% of the association (p=0.02). The proportion mediated was increased in the DT non-naïve subgroup (PM=92.7%, p<0.03). Similarly, an increased PM was seen in the subgroup of DT non-naïve pts with thalassemia compared to all thalassemia pts (PM=70.1%, p<0.08 vs PM=60.0, p<0.12, respect).

Summary/Conclusions: Better PROs, especially increased pt-reported adherence, due to improved attributes associated with DFX FCT are significant intermediates of the association between tx with DFX FCT versus DT and SF reduction from baseline. The proportion mediated was increased in pts with prior DT exposure, suggesting their enhanced appreciation for DFX FCT over DT.

P287

ASSESSMENT OF THE PERFORMANCE OF A WIDELY AVAILABLE T2*/R2* LIVER IRON CONCENTRATION METHOD USED IN CLINICAL PRACTICE IN A POPULATION OF THALASSEMIA PATIENTS

N. Anh Tri2,1, N. Thi Ha1, D. Thai Ton1, N. Khoi Viet2, P. Minh Thong1, N. Anh Thi1, B. Quoc Khanh2, M. House3,4, W. Pang4, S. Boulos4, T. St Pierre3,4* 1Radiology Department, Bach Mai Hospital, 2National Institute of Hematology and Blood Transfusion, Hanoi, Viet Nam, 3School of Physics, The University of Western Australia, Crawley, 4Resonance Health, Claremont, Australia

Background: Measurements of liver iron concentration (LIC) by magnetic resonance imaging (MRI) have become established and validated in several research intensive centers. While the validity of spin density projection assisted (SDPA) R2-MRI together with a core laboratory service has been validated in routine clinical practice, methods relying on high-field magnetic resonance imaging (MRI) and/or on more time consuming methods for acquisition protocols and data analysis have not yet been validated in this way.

Aims: To determine the limits of agreement between measurements of LIC by a widely available T2*/R2* MRI method and a reference standard SDPA R2-MRI method in a routine clinical practice setting.

Methods: 119 thalassemia patients (N=100) referred by the National Institute of Hematology and Blood Transfusion, Hanoi, Vietnam for routine LIC measurement by MRI were prospectively recruited with informed consent. Patients were randomised to be scanned in either a Philips Ingenia or a Siemens Avanto 1.5T scanner. The LIC of each patient was measured twice, once by a T2*/R2* technique using our own customized software and protocols (Iron Health Calculator: http://www.ironcalculator.com) and once by SDPA R2-MRI using a quality controlled core laboratory data analysis software (FermScan®). Analyses using the T2*/R2* data analysis method were blinded from the SDPA R2-MRI results and vice versa. Reported data were analysed using the statistical methods of Bland and Altman.

Results: A plot of the T2*/R2* LIC against the SDPA R2-MRI LIC (Figure 1) shows the vast majority of the data falling below the line of equivalence indicating that the T2*/R2* method is understimating the LIC relative to the SDPA R2-MRI validated reference standard. The geometric mean ratio of T2*/R2* LIC to SDPA R2-MRI LIC was 0.44 (95% CI 0.36 – 0.55) indicating severe underestimation of LIC by the T2*/R2* method. The geometric mean ratios of the two LIC measurements were significantly different for the two scanners (0.28 for Philips and 0.68 for Siemens, p <0.0001) indicating that the bias of the T2*/R2* method against the reference standard is not universal but is dependent on both/either scanner type and/or data acquisition method. Bland Altman analysis indicates that 95% of pairs of measurements are predicted to have ratios between 3.73 and 0.05 indicating a very large random variability between the T2*/R2* method and the reference standard. The performance of the T2*/R2* method against the SDPA R2-MRI LIC values above the clinical relevant thresholds of 7 and 15 mg Fe/g dw is characterized in the Table 1 showing positive predictive values (PPVs) and negative predictive values (NPVs) together with their 95% CIs.

Table 1.
Mean (SD) duration of deferasirox exposure in group A was 7.5 (1.7) years; mean daily deferasirox dose was 540 mg.

In both subgroups analyzed, mean Scr was within normal limits and remained stable over time during the retrospective period (Figure 1). Analysis in adults showed mean Scr values were stable over time. As expected in growing children who are gaining height and weight, pediatric mean Scr absolute values increased from baseline in proportion with an almost linear increase in muscle mass over time.

P288
SIMILAR TRENDS IN RENAL FUNCTION AS MEASURED BY SERUM CREATININE DURING LONG-TERM IRON CHELATION TREATMENT WITH OR WITHOUT DEFERASIROX IN PATIENTS WITH TRANSFUSIONAL HEMOSIDEROSIS

R. Origa1,*, A. Piga2, I. Tartagliona3, G. Della Corte4, A. Bruederle5, J. Han6, G. Della Corte4, A. Bruederle5, J. Han6, C. Castiglioni7, G.L. Forni8

1Ospedale Pediatrico Microcitemico 'A Ca', University of Cagliari, Cagliari, Italy, 2University of Turin, Orbassano, Turin, 3Università della Campania 'Luigi Vanvitelli', Naples, 4Università di Milano, Ca Granda Foundation IRCCS, Milan, Italy, 5Novartis Pharma AG, Basel, Switzerland, 6Novartis Pharmaceuticals Corporation, East Hanover, United States, 7Novartis Farma SpA, Origgio, Italy, 8Ospedale Galliera, Genoa, Italy

Background: Regular transfusion and iron chelation therapy (ICT) are often indicated for patients with β thalassemia, sickle cell disease (SCD) and other anemias, and can be lifelong requirements. As most patients now survive into adulthood and many experience prolonged exposure to ICT, there is increased risk of age-, disease- or drug-related complications, including changes in renal function. Evidence suggests that some patients receiving ICT experience changes in markers of renal function, mostly within normal limits, non-progressive and reversible with dose reduction and/or interruption. Recently, we reported a retrospective analysis of patients with transfusion-dependent anemia during a decade of deferasirox treatment indicating stable and a lack of any progressive worsening of renal function (Origa R et al. Blood 2016).

Aims: To assess serum creatinine (Scr) during long-term deferasirox treatment in subgroups of Italian patients with transfusional hemosiderosis who participated in the deferasirox registration studies and were then followed retrospectively.

Methods: Italian patients with β thalassemia, SCD, myelodysplasic syndromes or other anemias who received ≥1 deferasirox dose in the registration studies (studies 105, 106, 107, 108 or 109), had ≥1 post-baseline (BL) Scr measurement, and had medical records available were included. Scr values were collected retrospectively in 3-month periods from registration trial end until the latest patient assessment. Primary endpoint was Scr over time. Scr values during the retrospective period were evaluated by subgroups: here we report those who received only deferasirox and those who received no deferasirox but other ICT during the retrospective period.

Results: 282 patients were included in the retrospective study who received ≥1 deferasirox dose in registration studies; of these, during the retrospective period, 98 (35%) received only deferasirox (group A) and 82 (22%) received no deferasirox but other ICT (group B). In group A, mean (SD) age at first quarter was 27.0 (10.9) years and 25 (40%) were male. The proportion of pediatric patients was 28% (n=27) in group A and 19% (n=12) in group B.
Methods: A cohort of 25 well characterized patients was analyzed. Eighteen were initially referred to our center for unexplained hypereferritinemia (HF), two for proven iron overload (IO) by MRI, 2 for chronic hemolysis and 3 for aregenerative anemia. A set of phototypic tests was systematically assessed, including CBC, reticulocyte count, serum haptoglobin and measure of the Liver Iron Content (LIC) by MRI. For all patients with HF, causes linked to hepatic disease, inflammation, and cancers were ruled out and subclinical iron overload was performed. Phototypic investigations failed to clearly identify the cause of the disorder. Therefore, each patient was tested for a panel of 32 genes involved either in iron homeostasis or hereditary anemias, using NGS. Libraries were obtained using the Custom SureSelectQXT Target Enrichment system (Agilent, Santa Clara Ca USA) and sequenced on a MiSeq platform (illumina, San Diego, Ca, USA). Each deleterious variation was independently checked using conventional Sanger sequencing. Written informed consent was obtained from all the patients for NGS genetic analyses.

Results: Initial phototypic reassessment allowing classifying the patients into 5 different groups: 1/ isolated hypereferritinemia (n=11); 2/ HF and IO (MRI >90 µmole/g dry weight) (n=17); 3/ hereditary anemia (HA) without IO (n=2); 4/ HA and IO (n=2); 5/ aregenerative anemia with IO (n=3). Among patients with an initial diagnosis of iron disorder, the reticulocyte count identified 2 undiagnosed chronic fully compensated hemolysis. Systematic screening using the gene panel identified a total of 14 sequence variations of clinical significance in 9 different genes and 9 patients. An isolated mutation was found in 7 and 2 patients with an initial diagnosis of iron or of red cell disorder respectively. A combined anomaly of red cell and iron genes was identified in 3 patients who displayed IO and compensated hemolysis or anemia. Digemism involving an HFE C282Y or C282Y/H63D genotype and another “iron gene” was also shown in 3 patients with IO (without anemia or hemolysis). No sequence variation of clinical significance was found in the sequenced genes of eleven of the studied patients.

Summary/Conclusions: On the phototypic point of view, the present study highlights the importance to check for hematological data (CBC and reticulocytes) in patients with HF, because this can allow discovering fully compensated hemolysis and bringing towards a red cell disorder. On the other hand, it also underlines the importance to systematically check for IO all patients with a red cell disorder, who may display high LIC. Our present genotypic data (and previous data on the frequency of combined inherited disorders of iron and red cells, making the combined search for both disorders quite relevant in clinical practice. This is now possible with the use of NGS analysis, which allows sequencing large numbers of genes. For those patients with no identified mutation, approaches using whole exome or genome can be proposed as the next step.

P290

CHANGES IN LIVER IRON CONCENTRATION R2 MRI MEASUREMENT ACROSS DIFFERENT CHELATION REGIMENS IN PATIENTS WITH HEMATOLOGICAL DISORDERS: REAL-LIFE EXPERIENCE FROM LICNET

Aims: To report a real-life experience of liver iron chelation in different hematological disorders, including iron-overload in thalassemia, sickle cell disease, and iron-refractory anemia with reticulocytosis.

Methods: A total of 130 patients were evaluated in this analysis, with a median age of 35 years (range: 6–78) and including 60 (46.2%) men. The median duration (range) between the first and second MRI was 483 days (184-1076) and was comparable between iron chelation regimens. Median pre-transfusion hemoglobin level and blood requirement were similar at both MRIs. The median change in LIC (range) in mg Fe/g dw was not significant in patients receiving DFO (n=20, median change -1.9, p=0.55), DFO+DFP (n=52, median change -0.5, p= 0.155), DFO+DFP (n=10, median change -2.2, p=0.074), or other combinations (n=7, median change -1.3, p=1.000), while it decreased significantly on DFO monotherapy (n=32, median change -1.4,p=0.002). Among oral chelators, DFX showed to be more effective, during the period of the study, in stabilizing iron body burden in 65.4% patients even if they had baseline LIC values <7mg Fe/g dw (median 4.0 mg Fe/g dw) and with similar response as combined treatment DFO+DFP (Figure 1).

Summary/Conclusions: This cohort study suggests that stabilization of LIC is achievable, during a median of 483 days, with different iron chelation regimens in real life experience, with considerable proportions of patients shifting to more favourable LIC categories. Therefore, the periodic determination of LIC by MRI has to be strongly recommended for management and prevention of iron overload and subsequent complications in haematological disorders.

P291

IN UTERO IRON STATUS AND AUDITORY NEURAL MATURATION IN FULL-TERM INFANTS BORN TO MOTHERS WITH IRON DEFICIENCY ANEMIA

Aims: To evaluate the effect of maternal IDA on auditory neural myelination in full-term neonates using the auditory brainstem evoked response (ABR) as noninvasive neurophysiological assessment tool.

Methods: This prospective case-control study was conducted at Ain Shams University Hospitals and included 100 neonates. Out of 223 pregnant women, 50 were diagnosed as having IDA anemia and 50 healthy mothers were enrolled as a control group. Neonates were studied focusing on anthropometric measures, hematologic profiles and iron status. Auditory brainstem response (ABR) was recorded using evoked response audiometry technique (FernScan® Resonare Health Limited, Claremont, WA, Australia) approved by the FDA. The LICNET (Liver Iron Content NETwork) was established by Foundation Franco e Piera Cutino di Palermo and is addressed to diagnostics of liver iron overload by R2 MRI in subjects with hemochromatosis in haematological disorders. The LICNET protocol was approved on December 4, 2012 by Ethics Committee. Baseline data from LICNET were, recently, published (Vitrano et al., 2016, EJH).

Aims: The aim of this study was to evaluate longitudinal changes in LIC measurements across different iron chelation regimens in a real-life cohort of patients with transfusional iron overload included in LICNET.

Results: A total of 130 patients were evaluated in this analysis, with a median age of 35 years (range: 6-78) and including 60 (46.2%) men. The underlying diagnoses were regularly transfused thalassemia major (n=86, 66.2%), thalassemia Intermedia (n=33, 25.4%), sickle cell disease (n=6, 4.6%), myelodysplastic syndrome (n=5, 2.3%), and Diamond-Blackfan anemia (n=2, 1.5%). The median duration (range) between the first and second MRI was 43 days (184-1076) and was comparable between iron chelation regimens. Median pre-transfusion hemoglobin level and blood requirement were similar at both MRIs. The median change in LIC (range) in mg Fe/g dw was not significant in patients receiving DFO (n=20, median change -1.9, p=0.55), DFO+DFP (n=52, median change -0.5, p= 0.155), DFO+DFP (n=10, median change -2.2, p=0.074), or other combinations (n=7, median change -1.3, p=1.000), while it decreased significantly on DFO monotherapy (n=32, median change -1.4,p=0.002). Among oral chelators, DFX showed to be more effective, during the period of the study, in stabilizing iron body burden in 65.4% patients even if they had baseline LIC values <7mg Fe/g dw (median 4.0 mg Fe/g dw) and with similar response as combined treatment DFO+DFP (Figure 1).

Figure 1.

Summary/Conclusions: This cohort study suggests that stabilization of LIC is achievable, during a median of 483 days, with different iron chelation regimens in real life experience, with considerable proportions of patients shifting to more favourable LIC categories. Therefore, the periodic determination of LIC by MRI has to be strongly recommended for management and prevention of iron overload and subsequent complications in haematological disorders.

rtin and transferrin, with minimal risk of release of large amounts of ionic iron in the serum.

Aims: To compare safety and efficacy of Ferric Carboxymaltose (FCM) with Iron Sucrose complex (ISC) regarding improvement in haematological parameters and side effects in women with iron deficiency anaemia (IDA).

Methods: Prospective randomized controlled study conducted in department of Obstetrics & Gynecology, in a tertiary care hospital in Delhi, India. 60 women having Iron deficiency Anaemia with Hb 6-8 g% were randomized 1:1 into two groups and were given 1000mg parenteral iron. One group received intravenous 500mg Ferric Carboxymaltose on day 0 and 8. 200mg Iron Sucrose complex was given in second group on alternate days for 5 doses. Haematological parameters - Hb, Reticulocyte count, RBC indices, S. ferritin; clinical parameters - fatigue, dyspnoea on exertion and adverse effects were studied on day 0, 7, 14 & 28.

Results: Two FCM infusions vs five ISC infusions were required. On day 28 Hb increment ≥3g/dl was seen in 63.33% and MCV>80FL seen in 100% of FCM group vs 0% and 43.33% in ISC group. Significant improvement in RBC indices & retic count was seen in FCM group. Earlier and significant improvement in fatigability & dyspnoea on exertion was observed in FCM group. Both groups had similar safety profile except for thrombophlebitis was observed in 8.67% FCM group vs 50.00% ISC group.

Summary/Conclusions: Intravenous Ferric Carboxymaltose is more effective and safer than Iron Sucrose complex in treatment of Iron deficiency anaemia.

Background: Several susceptibility loci for Hodgkin lymphoma (HL) have been reported, however much of the heritable risk and biological relevance remains unknown.

Aims: To identify novel risk loci for HL and histological subtypes and to further our understanding of how genetic risk loci influence disease susceptibility.

Methods: To our knowledge, we have performed the largest genome-wide association study of HL totalling 5,156 cases and 16,763 controls across 10 million single nucleotide polymorphisms. We have integrated gene expression, chromatin state, transcription factor (TF) binding and capture Hi-C in model B-cells to functionally annotate new and existing risk loci.

Results: We identified risk loci for all HL at 6q22 (rs9482849, P=5.12 × 10⁻12) and for nodular sclerosis HL (NSHL) at 3q28 (rs4459895, P=9.49 × 10⁻11). 5q31 (rs9298977, AHI1, P=4.62 × 10⁻10), 10p14 (rs3781093, GATA3, P=9.49 × 10⁻13), 13p34 (rs112988813, UFP3A, P=4.58 × 10⁻10) and 16p13 (rs34972832, CLEC16A, P=1.29 × 10⁻9). Additionally, independent loci within the HLA region were observed for NSHL (rs2689081, HLA-DPB1*03:01, Val86 in HLA-DRB1) and mixed cellularity HL (rs1633096, rs13196329, Val86 in HLA-DRB1). Expression quantitative trait loci were observed in lymphoblastoid cells from 825 individuals at 6q22 (AHI1, P_SMR<0.001), 10p14 (GATA3, P_SMR=4.70×10⁻8) across new and established risk loci confirmed a significant enrichment of DNA hypersensitivity in GM12878 cells (P=1.20 × 10⁻3) as well as regulatory elements in primary B-cells (P=6.0 × 10⁻5) and 825 individuals (P=6.85 × 10⁻5). Analysis of ChiP-seq data on 82 transcription factors (TFs) in GM12878 cells, showed an over-representation of the binding of TFs that play a central role in B-cell signalling-networks such as REL (nuclear factor NF-kappa-B p65), EBF1 (early B-cell factor 1), RUNX3 (runt-related transcription factor 3) and BATE (histone deacetylase 4). These observations support the assertion that risk loci for HL mediate their effects through B-cell developmental networks, and are involved in transcriptional initiation and enhancement. Furthermore, our findings emphasise the differences between the major subtypes, which are likely reflective of differences in disease aetiology.

Background: Mantle Cell lymphoma (MCL) is one of the most aggressive...
phoid neoplasms characterized by highly infiltrated tumor cells in lymphoid tissues and extranodal sites. The patients have short responses to current therapies and frequent relapses. However, recent studies have identified a subset of MCL with indolent clinical behavior that tends to present with leukemic disease instead of extensive nodal infiltration, and that is characterized by the absence of the transcription factor SOX11 (SRY (Sex determining region-Y) box 11). SOX11 oncogenic pathways driven MCL tumor progression are poorly known.

**Aims:** The goal of our study was to identify the spectrum of genes regulated by SOX11 in malignant lymphoid cells and provide insights on how the constitutive overexpression of SOX11 may contribute to the oncogenic development of MCL.

**Methods:** We first generated a stable transduced SOX11-silenced MCL cell line and compared it with a scrambled control MCL cell line. Then we infected MCL cell lines with SOX11-1 positive lentiviral particles carrying shRNAs specifically targeting SOX11. SOX11-positive MCL cell line was infected with the empty vector and used as a control. These two MCL cell lines were injected in two different mice models to analyze in vivo the influence of SOX11 overexpression in B-cell lymphomas and in the transduction of SOX11 in primary xenograft models. We also analyzed the distribution of SOX11-positive and SOX11-negative cells in spleens, lymph nodes, bone marrow, and peripheral blood for patients with CNS lymphoma our main aim is to assess the role of XPO-1 inhibition in intracerebral xenograft models.

**Results:** In the si mice model, we observed that SOX11 silencing reduced tumor growth compared to SOX11-positive control tumors. We analyzed the gene expression profiling of these xenograft tumors and of SOX11-positive and negative primary cases and we observed that different microenvironment-related signatures were enriched in SOX11-positive compared with SOX11-negative cells, as angiogenesis, migration and stromal stimulation. By ChIP-chip analysis, we found that AICDA is highly expressed in SOX11-repressed MCL cell lines and in the transduction of MCL xenograft model. We also found that SOX11 promotes angiogenesis in MCL cells through PDGFA regulation, promoting tumor growth and vasculature. Inhibition of PDGFA on endothelial cells of SCID mice (n=4) and MCL, and the transduction of SOX11-negative MCL (n=6), displayed a reduced tumor burden in xenograft model of PCNSL by stereotactic injection of OCI-Ly10 (ABC, MYD88 and CD79b) cells expressing luciferase into the cerebral parenchyma of SCID mice. Our results demonstrated that AICDA acts as a methylome modifier in GC-DLBCL, being most of them related to activated B-cell type (ABC-DLBCL). PCNSL is associated with poor prognosis, particularly because of the difficulty for drugs to cross the blood brain barrier. High dose methotrexate is the most effective treatment, but relapse is very common and salvage treatment options are scarce. Also, in patients with systemic lymphoma, the secondary infiltration of the CNS is a fatal event, with a global overall survival of less than six months. Therefore, the development of new drugs with ability to penetrate the CNS is highly needed. Selinexor (KPT-330) is a Selective Inhibitor of Nuclear Export (SINE) that inactivates XPO-1 protein and induces anti-tumor effects mainly due to forcing nuclear retention and activation of tumor suppressors. Selinexor has shown excellent brain penetration and promising results in pre-clinical models of glioblastoma and can inhibit both BCR and NF-kB signaling in malignant B-cells.

**Aims:** In order to provide a pre-clinical rationale for the design of new therapies for patients with CNS lymphoma our main aim is to assess the role of XPO-1 inhibition in intracerebral xenograft murine models.

**Methods:** We in vitro tested the sensitivity of DLBCL cell lines to selinexor and ibritinib by MTS and AnnexinV/PI assay. We established an orthotopic xenograft model of PCNSL by stereotactic injection of OCI-Ly10 (ABC, MYD88 and CD79b) cells expressing luciferase into the cerebral parenchyma of SCID mice. Our results demonstrated that AICDA acts as a methylome modifier in GC-DLBCL, being most of them related to activated B-cell type (ABC-DLBCL). PCNSL is associated with poor prognosis, particularly because of the difficulty for drugs to cross the blood brain barrier. High dose methotrexate is the most effective treatment, but relapse is very common and salvage treatment options are scarce. Also, in patients with systemic lymphoma, the secondary infiltration of the CNS is a fatal event, with a global overall survival of less than six months. Therefore, the development of new drugs with ability to penetrate the CNS is highly needed. Selinexor (KPT-330) is a Selective Inhibitor of Nuclear Export (SINE) that inactivates XPO-1 protein and induces anti-tumor effects mainly due to forcing nuclear retention and activation of tumor suppressors. Selinexor has shown excellent brain penetration and promising results in pre-clinical models of glioblastoma and can inhibit both BCR and NF-kB signaling in malignant B-cells.

**Aims:** The goal of our study was to identify the spectrum of genes regulated by SOX11 in malignant lymphoid cells and provide insights on how the constitutive overexpression of SOX11 may contribute to the oncogenic development of MCL.

**Methods:** We first generated a stable transduced SOX11-silenced MCL cell line and compared it with a scrambled control MCL cell line. Then we infected MCL cell lines with SOX11-1 positive lentiviral particles carrying shRNAs specifically targeting SOX11. SOX11-positive MCL cell line was infected with the empty vector and used as a control. These two MCL cell lines were injected in two different mice models to analyze in vivo the influence of SOX11 overexpression in B-cell lymphomas and in the transduction of SOX11 in primary xenograft models. We also analyzed the distribution of SOX11-positive and SOX11-negative cells in spleens, lymph nodes, bone marrow, and peripheral blood.

**Results:** In the si mice model, we observed that SOX11 silencing reduced tumor growth compared to SOX11-positive control tumors. Selinexor (KPT-330) is a Selective Inhibitor of Nuclear Export (SINE) that inactivates XPO-1 protein and induces anti-tumor effects mainly due to forcing nuclear retention and activation of tumor suppressors. Selinexor has shown excellent brain penetration and promising results in pre-clinical models of glioblastoma and can inhibit both BCR and NF-kB signaling in malignant B-cells.
was measured and animals were randomly distributed into drug or vehicle group. At this time point mice were treated with 5mg/kg of selinexor or vehicle via oral gavage three times a week; subsequently, bioluminescence was assessed twice a week. Treatment with selinexor significantly increased mice survival, with a median survival of 48 days in the treatment group compared to 34 days in the vehicle group (p<0.0001; Figure 1A). Mice in the treatment group lived significantly longer increasing by about 60% (p<0.0001; Figure 1B). Specific time-point analysis showed that differences were significant as soon as 8 days after treatment. At final point, histopathological analysis showed diffuse infiltration in meninges and cerebral parenchyma of highly proliferative CD20-positive B-cells. Currently, we are evaluating the synergy between ibrutinib and selinexor in vivo. For that we have used the same experimental setting and assigned 12 mice to each of the following groups: selinexor only (5mg/kg three times a week via oral gavage), ibrutinib only (25mg/kg daily in drinking water), combination or vehicle. Results will be available at the time of the meeting.

Figure 1.

Summary/Conclusions: Selinexor inhibits proliferation and survival of DLBCL cell lines regardless of COO and it can synergize with ibrutinib. Treatment of mice with CNS confined ABC-DLBCL with selinexor significantly reduces tumor growth and increases survival. Our results provide pre-clinical evidence for the development of selinexor as new therapeutic option for PCNSL or DLBCL with CNS involvement.

MOLECULAR HETEROGENEITY IN PERIPHERAL T-CELL LYMPHOMA NOT OTHERWISE SPECIFIED REVEALED BY COMPREHENSIVE MUTATIONAL PROFILING

Y. Watabatani1,*, Y. Sato2, K. Nishida2, H. Miyoshi3, Y. Shiraishi4, K. Chiba4, M. Sanada4, S. Miyano4, K. Ohshima5, T. Yoshihito5, S. Ogawa5, K. Kataoka5, 1Department of Pathology and Tumor biology, Kyoto university, Kyoto, 2Department of Pathology, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, 3Department of Pathology, Kurume University School of Medicine, Fukuoka, 4Laboratory of DNA Information Analysis, Human Genome Center, Institute of Medical Science, The University of Tokyo, Tokyo, 5Department of Advanced Diagnosis, Clinical Research Center, Nagoya Medical Center, Nagoya, Japan

Background: Peripheral T-cell lymphomas (PTCLs) are a highly heterogeneous group of mature T-cell neoplasms. In particular, accounting for the majority of PTCL, PTCL not other specified (PTCL-NOS) is a diagnosis of exclusion and such, is expected to include many heterogeneous tumors. In fact, recent genetic studies have suggested that a subset of PTCL-NOS is closely related to angioimmunoblastic T-cell lymphoma (AITL); both lymphoma types show follicular helper T-cell (TFH) phenotypes and share mutational targets in common, such as ROHA, TET2, DNMT3A, and IDH2. However, with the lack of comprehensive genetic analyses, the molecular pathogenesis is poorly understood in the majority of PTCL-NOS cases.

Aims: The aim of this study is to clarify a landscape of somatic mutations in PTCL-NOS.

Methods: We performed whole-genome/exome and transcriptome sequencing of PTCL-NOS and other related PTCLs, followed by targeted-capture sequencing of candidate drivers in T-cell lymphomas in 100 PTCL-NOS samples.

Results: Consistent with previous reports, TET2 (38%) was the most frequently mutated gene in PTCL-NOS, followed by ROHA (28%), TP53 (18%), KMT2C (13%), IDH2 (11%), and PLCG1(11%). Frequently altered genes included signal transduction molecules (such as ROHA, PLCG1, STAT3 and SOCS1), chemokine receptors (CCR4 and CCR7), epigenetic modifiers (TET2, KMT2C, IDH2, DNMT3A, CREBBP, and KDM6A), and molecules associated with immune evasion (HLA-A, HLA-B, B2M, and CD58). Novel targets of recurrent mutation were also identified, including PDCD1, YTHFD2, and LRPIB, which were frequently targeted by nonsense and frameshift mutations distributed throughout the entire genes. Among these, PDCD1 encodes PD-1, which transmits an inhibitory signal from PD-L1 and PD-L2 ligands, and therefore loss of function of this gene is predicted to enable malignant T-cells to escape from the negative signaling. By contrast, recurrent mutations in YTHFD2 and LRPIB mutations in T-cell lymphoma genesis is unexpected. These genes encode a repressor protein of N6-methyladenosine (YTHFD2), and a member of the low density lipoprotein receptor family (LRPIB). Although the function of these genes in T-cells are unknown, our findings suggest their unresolved roles, whose dysfunction may lead to malignant T-cell proliferation. Finally, we investigated the co-occurrence between frequently mutated genes in PTCL-NOS. In accordance with previous observation, mutations characteristic of TFH lymphomas (TET2, ROHA, IDH2, and DNMT3A) tended to co-occur in a subset of PTCL-NOS cases, but were also almost exclusively with mutations in TP53 and chemokine receptor genes. These observations further support the molecular distinction between TFH and non-TFH lymphomas in PTCL-NOS: the former is more related to AITL and discriminated from the latter in terms of their mutational profiles.

Summary/Conclusions: In summary, our findings illustrate the landscape of somatic alterations in PTCL-NOS and provide a novel insight into their genetic and molecular heterogeneity, which should help to devise a novel molecular classification of PTCLs and to exploit a new therapeutic strategy to combat these intractable T-cell malignancies.

P300

A COMPREHENSIVE PORTRAIT OF THE DNA METHYLMOD OF 866 SAMPLES FROM DIFFERENT B CELL NEOPLASMS: BIOLOGICAL INSIGHTS AND CLINICAL APPLICATIONS

1Department of Fundamentos Clínicos, UB, 2Hematology and Oncology, IDIBAPS, 3Genetic Epidemiology, 4Germ and Statistical Genetics, 5Center for Biomedical Informatics and Cancer Research Joint Program on Computational Biology, BSC, Barcelona, 6Cïnica Universidad de Navarra, Universidad de Navarra, 7Area de Oncología, Centro de Investigación Médica Aplicada (CIMA), 8Area de Oncología, Centro de Investigación Médica Aplicada (CIMA), Pamplona, 9Chromatin and Disease Group, Cancer Epigenetics and Bioinformatics Programme (EBBC), Barcelona, Spain, 10Epidermal and Behçet diseases of the University of California, San Francisco University, San Francisco, 11Institute of Human Genetics, Christian Albrechts University, Kiel, Germany, 12Servicio Hematología, IDIBAPS, 13Applied Genomics, CNAG, 14Unitat de Hematologia, Hospital Clinic, IDIBAPS, Barcelona, Spain

Background: In the last years, a large body of evidence has been accumulated demonstrating that DNA methylation is not only widely altered in B-cell lymphoid tumors (and cancer in general) but it is also defining cell lineage and maturation stage. However, an integrative study of the whole DNA methylation of neoplastic B cells from different maturation stages has not been performed yet.

Aims: The aim of this study was to extensively dessect the dynamics of DNA methylation in B-cell neoplasias in the light of normal B cell maturation program. The ultimate goal of this study was to generate new clinically relevant knowledge about diagnostic and prognostic value.

Methods: Our dataset included whole-genome bisulfite sequencing data (n=57) and high-density methylation arrays (n=1161) from acute lymphoblastic leukemia (ALL), mantle cell lymphoma (MCL), Burkitt lymphoma (BL), follicular lymphoma (FL), diffuse large B cell lymphoma (DLBCL), chronic lymphocytic leukemia (CLL) and myeloma (MM) patients as well as from ten different normal B cell subpopulations. As DNA methylation estimates in neoplastic samples are influenced both by tumor cell content and composition of the micro environment, we developed a new method to deconvolute and in silico purify the methylation signal of tumors arising in different niches (bone marrow, peripheral blood an lymph node). The data were analyzed by a series of bioinformatic and biostatistical approaches and correlated with clinical variables.

Results: The initial bioinformatic approach to purify of DNA methylation signals in B cell tumors revealed that samples with less than 55% tumor cell content could not be accurately purified. This strategy reduced the initial 1,044 tumor samples to 866. An unsupervised principal component analysis of in silico purified data revealed that each type of B-cell neoplasm clusters separately, ALLs clustered closer to precursor B cells, CLL and MCL closer to mature B cells and both DLBCL and MM showed the largest deviation from normal B cells. We then performed a differential analysis of each sample vs normal B cell maturation stages, and thoroughly annotated the results to biological and clinical features. From the clinical perspective, we identified that for tumor samples with similar cellular origin, the higher the epigenetic deviation from healthy B cells (number of DNA methylation changes) the worse the clinical outcome for the patients. Furthermore, for each tumor entity, we could identify from 5 to 19 epigenetic biomarkers that could classify each entity with high sensitivity and specificity.

Summary/Conclusions: In this study, we show that in silico purification of DNA methylation data is a powerful strategy to accurately measure DNA methylation alterations in tumor cells. Using a large dataset, we have developed a set of epigenetic biomarkers with high differential diagnostic power and identified that the epigenetic drift is a universal prognostic factor that can be applied to different B cell tumors.
Background: Angioimmunoblastic T-cell lymphoma (AITL) is a distinct subset of peripheral T-cell lymphoma with follicular helper T-cell (TFH) features. We and others previously found mutations of RHOA, encoding p.Gly17Val (G17V) RHOA, in a subset of patients with diffuse large B-cell lymphoma. Proton magnetic resonance imaging of mito- tosine dioxide 2 in up to 70% of AITL and other TFH lymphoma (a sub- group of peripheral T-cell lymphoma, not otherwise specified (PTCL-NOS)) samples. RHOA, a small GTPase, is converted from the GDP-bound inactive form to the active GTP-bound form by guanine nucleotide exchange factors (GNEFs). GNEFs are thought to have diverse roles in cell migratory signaling, because it does not bind GTP. Therefore, it has remained unknown how G17V RHOA is involved in lymphomagenesis. VAV1 serves as an impor- tant mediator of T-cell receptor (TCR) signaling pathway through its GEF- dependent and -independent function. VAV1 activation is tightly regulated by specific binding partner proteins of the G17V RHOA mutant. Phosphorylation of VAV1 occurs within seconds in response to antigen stimulation of the TCRs by Syk and Src-family tyrosine kinases and initiates downstream TCR sig- naling.

Aims: We aim at clarifying the downstream signaling of the G17V RHOA mutation.

Methods: Proteomic screening was performed to identify G17V RHOA-spe- cific binding partner proteins. Binding was validated by co-immunoprecipitation of G17V RHOA and the candidate partners. Simultaneously, RNA sequencing was performed for 9 PTCL samples, including 6 AITL and 3 PTCL-NOS. Target- ed deep sequencing of VAV1 was performed for 126 PTCL samples, including 69 AITL and 57 PTCL-NOS, 37 of which had RHOA mutations. The specific binding partner proteins of the G17V RHOA mutant were examined by high throughput screening in Jurkat cells. Nuclear factor of activated T cell (NFAT) activity in response to TCR stimulation was examined in Jurkat cells expressing wild-type (WT) and G17V RHOA mutant, and WT and various VAV1 constructs.

Results: Proteomic screening identified the VAV1 protein as a G17V RHOA- binding partner. RNA sequencing identified a fusion gene involving VAV1 and STAP2 in an AITL sample without RHOA mutations. Moreover, targeted sequencing of VAV1 identified 2 in-frame deletion mutations in an acidic region (c.G516_C520del:p.173_C177del and c.C494_C504del:p.165_174del) in AITL samples and 2 missense mutations in a zinc finger and SH3-SH2-SH3 module (c.G1668C:p.Glu556Asp and c.C1844T:p.Pro615Leu) in PTCL-NOS and AITL samples, respectively. Phosphorylation of VAV1 at Tyr 174 was enhanced in Jurkat cells expressing the G17V RHOA or VAV1-STAP2 cDNA than those expressing each WT cDNA or mock. Phosphorylation was blocked by the dasatinib treatment. The levels of IL-2 mRNA were higher in Jurkat cells expressing either G17V RHOA or VAV1-STAP2 than those with their WT or mock. Finally, phospho-VAV1 was co- stained with PD-1, a TFH marker, in 7 out of 10 PTCL samples with RHOA or VAV1 mutations.

Summary/Conclusions: The G17V RHOA and VAV1 mutants both intensify the TCR pathway through hyper-phosphorylation of Vav1. Our data suggest that the RHOA-VAV1 axis in AITL/TFH lymphoma may contribute to their clinical features and stand as a possible new therapeutic target.
formation using a bespoke bioinformatic pipeline based on TargetScan prediction algorithm in order to identify mutations in putative miRNA binding sites. Once identified, in order to validate them and test their recurrence in an extended cohort (60 samples from 31 FL patients who underwent transformation plus 21 samples of non-transformed FL patients) we designed an Ampliseq (Ion Torrent, Life Technologies) NGS custom panel. Finally, we selected a number of variants for assessing the variant effect on the miRNA:mRNA interaction, by means of a combination of an in silico predictive algorithm and in vitro luciferase assays.

**Results:** 36% of somatic variants from WGS data arose in 3’UTR, and 68% of these were putative miRNA-binding sites (525 mutations in 497 genes). Interestingly, the ontology analysis showed that these mutations were not randomly distributed but rather there was enrichment in genes associated with haematological malignancies (P=2.18x10^-4). We then validated 85% of these mutations using targeted resequencing and found a total of 103 recurrent variants located in putative miRNA binding sites. QC criteria filtering led us to prioritise 38 variants in 25 genes to be functionally tested. Crucially, ontology analysis showed that these genes were highly enriched for GC-like B-cell lymphoma genes (P=4.39x10^-5), strongly suggesting that these variants may have a biological significance in the disease. We then performed an in silico approach based on TargetScan miRNA target prediction algorithm to evaluate the effect of the mutations on the binding of the miRNAs to their target sites. Based on these results we prioritised some of these genes to perform luciferase assays. We experimentally demonstrated not only that the majority of these loci are bona fide miRNA targets sites, but also that the presence of a number of these variants causes a dysregulation of the normal miRNA regulatory activity (Figure 1).

Our data show that the identified mutations do not occur randomly, but preferentially in putative microRNA binding sites of genes related to lymphomagenesis, supporting their role in FL pathogenesis. Furthermore, the presence of some of the identified variants in miRNA binding sites indeed promotes a dysregulation of the normal miRNA regulatory activity, suggesting that they might have a biological significance in FL.

**Figure 1.**

**Summary/Conclusions:** Our data show that the identified mutations do not occur randomly, but preferentially in putative microRNA binding sites of genes related to lymphomagenesis, supporting their role in FL pathogenesis. Furthermore, the presence of some of the identified variants in miRNA binding sites indeed promotes a dysregulation of the normal miRNA regulatory activity, suggesting that they might have a biological significance in FL.

**Background:** Within the landscape of mutated genes in mantle cell lymphoma (MCL), only TP53 disruption has been so far associated with outcome.

**Aims:** Here we present the clinical update of the deep sequencing MCL gene panel analysis in the prospective FIL-MCL0208 phase III trial (NCT02334313), high-dose immunochemotherapy followed by autologous transplantation for untreated, advanced stage <65 years MCL based on the data from the second interim analysis.

**Methods:** A targeted resequencing gene panel, including coding exons and splice sites of the ATM, BIRC3, CCND1, KMT2D, TP53, TRAF2, WHSC1, and NOTCH1 genes was analyzed in tumor DNA from baseline bone marrow CD19+ purified MCL cells and, to filter out polymorphisms, in the paired normal genomic DNA (55% of cases) using a TrueSeq Custom Amplicon target enrichment system followed by deep next generation sequencing (Illumina, median depth of coverage 235x). Variants represented in >10% of the alleles were called with VarScan2 with the somatic function when the paired germline DNA was available. For patients lacking germline DNA, a bioinformatics pipeline including a number of stringent filters was applied to protect against the misclassification of polymorphisms as somatic variants. Clinical data were updated at the time of the second interim analysis (January, 2017).

**Results:** Out of the 300 enrolled patients, 174 were evaluable for mutations. Median follow-up of the cohort was 36 months, and 3-years PFS and OS were 67% and 86%, respectively. Patients not included in the study, due to unavailable tumor DNA (n=126) showed superimposable clinical features and outcome. Mutations of TP53 (8% of cases) and KMT2D (11% of cases) associated with an increase in the hazard of progression both in univariate analysis as well as after adjusting for MIPI, Ki67 and blastoid variant: HR 3.87 (95% CI 1.64 to 9.13), p<0.002 and HR 3.66 (95% CI 1.77 to 7.56), p=0.001, respectively. These results translated into an increase of the hazard of death in both TP53 and KMT2D mutated patients both in univariate analysis as well as adjusting for MIPI, Ki67 and blastoid variant HR 4.26 (95% CI 1.34 to 13.57), p=0.014 and HR 3.09 (95% CI 1.77 to 5.41), p<0.001, respectively.

**Summary/Conclusions:** The updated clinical results of the FIL-MCL0208 trial show that: i) both TP53 and KMT2D mutations independently associate with shorter PFS and OS in younger MCL patients receiving high-dose therapy; ii) KMT2D mutations seem to be as detrimental as TP53 mutations, at least in terms of PFS; iii) given the negative prognostic impact of these mutations, they might be used to select high-risk patients for novel therapeutic approaches.

**Figure 1.**

**Summary/Conclusions:** The updated clinical results of the FIL-MCL0208 trial show that: i) both TP53 and KMT2D mutations independently associate with shorter PFS and OS in younger MCL patients receiving high-dose therapy; ii) KMT2D mutations seem to be as detrimental as TP53 mutations, at least in terms of PFS; iii) given the negative prognostic impact of these mutations, they might be used to select high-risk patients for novel therapeutic approaches.
Multifaceted aspects of bleeding disorders

P305
A LOOKBACK AT VWD TYPE 2A AND 2M CLASSIFICATION IN A LARGE COMPREHENSIVE HAEMOPHILIA CENTRE.
S. Jaafar1,2,*, T.T. yee1
1Haematology, Royal Free Hospital /NHS, 2Haematology, katharine dordmandy haemophilia centrefreel hospital free hospital, london, United Kingdom

Background: Von Willebrand Disorder (VWD) has a prevalence of approximately 1% in the general population and is due to quantitative deficiencies or qualitative defects of the Von Willebrand Factor (VWF) protein. VWF is a large multimeric protein with multiple functions. It carries and protects factor VIII and helps in the binding of FVIII, platelets and the vascular endothelium at sites of injury. VWF binding to platelets is through several receptors most notably the glycoprotein Ib (GP Ib) and collagen exposed at site of injury is important for VWF adhesion to the subendothelial matrix forming an adhesive anchor. Classification of VWD is based on the quantitative deficiencies (Type 1 and 3) and VWD type 2 are qualitative defects of the VWF protein with or without quantitative deficiency as well. Type 2 VWD is further subdivided into type 2A,2B,2M and 2N. These subtypes depend on a number of laboratory assays that measure the FVIII activity, VWF protein level (VWF:Ag assay) and the function of the protein i.e its ability to bind to 1) FVIII - VWF binding assays), 2) platelets (VWF:Rc0f assay) and 3) collagen (VWF:CB assay). Other tests include ristocetin induced platelet aggregation (RIPA), multimer analysis, assay ratios and VWF genetic analysis. No single commercially available laboratory method can achieve to test all the parameters required to clinch the accurate diagnosis of the subtypes of VWD. Use of those multiple assays with VWF: Rcof/VWF:Ag ratio, VWF CB (VWF-CB) (VWF Ag) ratio have helped in the better identification of VWD and the subtypes.

Aims: To assess recent various VWF investigation panels and assay ratios, VWF genetic analysis, multimeric patterns of the VWF protein in accurate diagnosis of the VWD subtypes. VWD 2A and 2M shows similarities in certain aspects and it is important to differentiate these 2 subtypes as new therapies become available and personalised treatment approaches of VWD become a reality.

Methods: Clinicians who have made a diagnosis of VWD for individuals referred for a bleeding state work up would classify the subtypes of the VWD according to the results of the investigations available at the time of seeing the patients. All patients with an inherited bleeding disorder would then be registered in the centre and details would be put into a database. We have looked back into the database from the period of 2000 to end of 2016 and focussed on the VWD types 2A and 2M. Current VWD diagnostic panel in our centre includes the following tests: FVIII one stage assay, VWF:Ag Elisa,VWF rcof, Platelet agglutination method, VWF CB Elisa methods, VWF multimer analysis by gel chromatography and VWF exon 27/28 genetic mutations are routinely done. New information and new set of results for the registered patients have been taken into account the classification of VWD type 2A and 2M and the database are updated.

Results: In the VWD database 36 patients classified as 2M and 19 patients as type2A have been recorded from 2000 to end of 2016. With the updated results and genetic analysis and the response to DDAVP, around 30% of the patients have had their subtypes changed. This exercise confirms that no singular test had been able to categorise the patients accurately and that the majority was asymptomatic and the most severe events were related to concomitant pathologies. Nonetheless, this study has the potential to collect data from a numerous population of pts who live in the same country, and therefore to provide useful information to better characterize and manage these rare diseases.

Summary/Conclusions: Pts from this case series experienced few hemorrhagic/thrombotic events. The majority was asymptomatic and the most severe events were related to concomitant pathologies. Nonetheless, this study has the potential to collect data from a numerous population of pts who live in the same country, and therefore to provide useful information to better characterize and manage these rare diseases.

OSTEOPOROSIS IN PATIENTS WITH HEMOPHILIA
V. Zorenko1,*, T. Polyanskaya1, A. Kovalrina1, T. Tupoleva1, D. Petrovski1, A. Koroleva1
1National Research Center for Hematology, Moscow, Russian Federation

Background: Osteoporosis is often a co-morbidity of hemophilia, which exacerbates the hemophilic arthropathy and affects the long-term stability of the components after the arthroplasty. We present our results for the presence of osteoporosis in 148 patients with haemophilia and hemarthropic arthropathy.

Aims: To prevent progression of hemophilic arthropathy and increase the long-term stability of the components after the arthroplasty.

Methods: In the period from 2015 to 2016, the presence of osteoporosis surveyed 148 patients with haemophilia who are hospitalized in the department of reconstructive orthopedics for patients with hemophilia (Moscow, Russia): 121 (81.8%) - hemophilia A, 21 (14.2%) - and hemophilia B 6 (4%) – haemophilia patients with inhibitor. The average age of the patients was 39.3 years. (range 10 to 69 years). 121 patients with hemophilic arthropathy performed primary total arthroplasty (98 knee, 20 hip, 3 shoulder joints); 18 patients underwent revision arthroplasty (5 - purulent infection, 7 - instability of the implants, 4 - fractures, 2 - loss of motion in the operated joint). 40 patients underwent ultrasound densitometry. In this series, 13 patients with osteoporosis were identified. As a result of ultrasound densitometry in 17.5% (7 patients) of cases revealed osteopenia and 20% (8) T-thickest index. 105 patients underwent histological study in which 93 (88.6%) bone resorption, 58 (55.2%) cases, bone resorption in patients with hemophilia considerably more common than in the general population. Intraosseous hemorrhage identified in more than half of the cases, exacerbate the decline in bone mineral density.

Summary/Conclusions: The data indicate that osteoporosis at patients with haemophilia considerably more common than in the general population. Intraosseous hemorrhage identified in more than half of the cases, exacerbate the decline in bone mineral density.
patient, with the rate of recurrent haemorrhagic events in joint(s) from 6 to 13 per year. The control group consisted of 255 age-matched healthy men. Gene polymorphism of apolipoprotein E (ApoE e2/e3/e4), paraoxonase (PON1 Gln192Arg), methyltetrahydrofolate reductase (MTHFR C677T), catalase (CAT C-262T) and plasmatic glutathione peroxidase (GPX3 T-65C) was studied by PCR-RFLP technique. Statistical differences between the patient and control group were assessed by Fisher’s exact test. Odds ratios (OR) with their 95% confidence intervals (CI) and p-value were calculated by using GraphPad Prism 5.0 software.

Results: We found abnormal distribution of ApoE genotypes in the patient group. Absence of ApoE e3 allele was observed in 7 (9.9%) men with SH and 9 (3.1%) controls (OR=3.4; 95% CI: 1.2-9.7; p=0.025). In particular, the frequency of ApoE e2/e2 genotype was 10-fold increased in patients when compared to healthy men (4.2% vs 0.4%, OR=11.2; 95% CI: 1.1-109.5, p=0.034). ApoE e2/e4 and e4/e4 genotypes were also more prevalent in SH than in the control group (2.8% vs 0.8% and 2.8% vs 0.2%, respectively). In the patient group, we observed the positive association between the PON1 192Gln/Gln variant and heterozygous GPX3 -65T/C genotype (OR=5.8; 95% CI: 1.3-25.7, p=0.021). Simultaneous presence of these genetic variants was more than 5-fold frequently found in SH than in controls (8.5% vs 1.6%, 95% CI: 1.3-22.8, p=0.016).

Summary/Conclusions: Our results indicate that OS-provoking variants of ApoE, PON1 and GPX3 genes are frequently seen in SH patients with chronic arthropathy and joint(s) destruction.

Methods: Library preparation was performed with TruSeq One sequencing panel (Illumina, USA), which enriches about 4,800 genes with clinical relevance. Massively parallel sequencing was conducted with NextSeq (Illumina). Variants were annotated with population databases (1000 Genomes Project, Exome Variant Server, Exome Aggregation Consortium) and disease databases (OMIM). For missense variant, in-silico analysis was done with SIFT, Polymorphism all MutationTaster. Candidate variants were confirmed by Sanger sequencing and family study. For VWF gene, multiplex ligation dependent probe amplification assay was also done using SALSALPRA melanin polynucleotide P011-B3/P012-B3. Among variants from genes of primary interest, common variant with minor allele frequency ≥1% in population databases were filtered out. In addition, variants detected in more than 2% in in-house database were further filtered out to remove population specific polymorphism or platform specific errors. For VWF exons of either incomplete coverage or low mapping quality due to highly homologous region (exon 26, 24), additional Sanger sequencing was performed. Genes of primary interest were those associated with platelet dysfunction (GP1BA, GP1BB, GP9), Bernard-Soulier syndrome (GP1BA), Glanzmann thrombasthenia (ITGAM, ITGAI), Hermansky-Pudlak syndrome (HPS1, AP3B1, HPS3, HPS4, HPS5, HPS6, DTNBP1, BLOC153), Chediak-Higashi syndrome (LYST), Griscelli syndrome (MYO5A, RAB27A, MLPH), Scott syndrome (ABC4A).

Results: Twelve children with easy bruising, frequent epistaxis, or menorrhagia and their family members were enrolled. Two unrelated children were confirmed as GT. One proband had compound heterozygous variants of c.1913+5G>T and c.1451G>A (c.1040_1046delinsAla) in ITGB3. The former was pathogenic which resulted in aberrant splicing and the latter is novel. The other proband had homozygous variant of c.1913+5G>T in ITGB3. Three unrelated children were confirmed as VWD. One proband had compound heterozygous variants of c.2574G>C (p.Cys858Trp) and c.399C>T (p.Pro1127_Gly1180delinsArg) in VWF, especially the latter synonymous variant previously confirmed to be resulted in exon 26 skipping. Another proband had a novel variant, c.2008C>T (p.Arg670Cys). The last proband had a known VWF pathogenic variant of c.1728G>T (p.Met576Ile).

Summary/Conclusions: DES is a valuable method to confirm GT or VWD. Further study is needed to find out unidentifiable mutations by this strategy.
AN ALGORITHM TO IDENTITY CASES OF SEVERE HEMORRHAGE IN ROUTINELY COLLECTED HEALTHCARE DATA

Background: Many patients with a hematological malignancy have an increased risk of hemorrhages. Research addressing the causes of these hemorrhages, especially those on major hemorrhages, are hampered by the difficulty to find sufficient and representative cases of major hemorrhage. Unfortunately, electronic health records generally do not codify hemorrhages.

Aims: The aim of this study was to develop an algorithm that can be used to find patients who suffered from major hemorrhages (WHO grade 3 or 4) within electronic health records.

Methods: An algorithm was developed using electronic health record data of a cohort of patients with acute leukemia, who received platelet transfusions between June 2011 and December 2015 at the Leiden University Medical Center in the Netherlands. Chart review was performed for a stratified, random sample of observation days. Discriminative performance of three indicators was assessed: CT-brain, drop in hemoglobin level and transfusion need within 24 hours. The cut off values for hemoglobin drop and transfusion need with the best discriminating capacity and CT-brain were entered in the final algorithm. The C-statistic was calculated and calibration plots were made. The algorithm will be externally validated in two other academic hospitals.

Results: The derivation cohort consisted of 255 patients comprising 10,638 observation days and chart review was performed for 353 days. The incidence of major hemorrhage was 0.22 per 100 observation days. The final algorithm consisted of information on CT-brain (yes/no), a hemoglobin drop of ≥2.8 g/dl and the need of six or more transfusions (yes/no). The C-statistic of the algorithm was 0.93 (95% confidence interval (CI) 0.86 to 0.99). The incidence of bleedings with all grades of severity was 8.4 per 100 days. The algorithm for bleedings of all grades had a c-statistic of 0.54 (CI 0.53 to 0.55). The results of the external validation are not available yet.

Summary/Conclusions: An algorithm using information on CT-brain, hemoglobin drop and transfusion can accurately identify cases of major hemorrhage within electronic health care data. External validation will be performed.

MOLECULAR MECHANISMS AND CLINICAL SIGNIFICANCE OF REDUCED PTPN1 EXPRESSION IN MYELODYSPLASTIC SYNDROMES

Background: Previously we determined common deleted region (CDR) of del(20q) observed in MDS by CGH-array. Our data showed that the PTPN1 gene is located within CDR of del(20q). The PTPN1 gene encodes PTP-1B, a non-receptor type protein tyrosine phosphatase, which is involved in multiple physiological and pathological cellular processes via dephosphorylation of several tyrosine kinases, and other molecules. Although roles of PTP-1B in normal and pathological hematopoiesis has not been elucidated, it may function negative regulator for cellular processes mediated by tyrosine kinases, including Jak2, and SRC. We hypothesized that the PTPN1 gene is a target gene disrupted by del(20q), resulting in haplo-insufficiency, and involved in MDS molecular pathogenesis.

Aims: We attempted to examine PTPN1 expression level in bone marrow cells of MDS patients with or without del(20q), and to investigate its clinical and biological significance.

Methods: Total RNA was extracted for cDNA synthesis from bone marrow samples taken at the time of diagnosis with written informed consent from patients and control subjects were used for the present study. Real-time RT-PCR was carried out to quantify PTPN1 expression by the TaqMan probe method using an ABI 7500 real-time PCR system (Applied Biosystems). Data including patients' demographic, disease status, medical history, clinical and laboratory findings, and outcome, were collected from medical records and laboratory data base. A non-parametric Mann-Whitney-Wilcoxon test was used to examine whether expression levels among groups are statistically different. The Kaplan-Meier model was used to analyze the impact of PTPN1 expression on overall survival, and log-rank test was used for statistical analysis. We also examined the effect of 5-azacytidine treatment on PTPN1 expression in primary bone marrow cells from MDS patients. Bone marrow cells were cultured with or without 5mM of 5-azacytidine for 48 hours. Expression level of PTPN1 was examined by quantitative RT-PCR described as above.

Results: A total of 118 MDS patients, 71 males and 47 females with median age of 68 years (range: 20-91 years) and 19 control subjects were included in the present study. The patients were classified as RCUD (n=18), RCRM (n=58), RARS (n=8), RAEB-1 (n=20), and RAEB-2 (n=14) according to WHO classification. Relative PTPN1 expression level was significantly decreased in MDS patients with del(20q) (P<0.001) compared with control subjects. Moreover, relative PTPN1 expression level in MDS patients without del(20q) also significantly decreased (P<0.001). Expression patterns of PTPN1 among five WHO-subtypes, were statistical different (P=0.2021). Median values of relative PTPN1 expression level in RCUD, RCRM, RARS, RAEB-1, and RAEB-2 were 1.52, 1.95, 1.91, 1.46, and 1.26 respectively. Relative PTPN1 expression level in WHO-subtypes with high blast counts (RAEB-1 and RAEB-2) was significantly lower than that in WHO-subtypes with less blast counts (RCUD, RCRM, RARS) (median value: 1.41 vs 1.89, P=0.0074). To investigate prognostic implication of PTPN1 expression in MDS, we analyzed impact of PTPN1 expression on overall survival (OS). Based on PTPN1 expression level, 118 patients were divided into four groups, high (Q1), intermediate (Q2, Q3), and low (Q4) quartiles. Kaplan-Meier analysis demonstrated that the lowest quartile (Q4) showed significantly worse survival compared with remaining quartiles (Q1, Q2, Q3) (P=0.048). The estimated 5-year OS rates in Q1-3 group and Q4 group were 69% and 49.8%, respectively. We examined whether PTPN1 expression is induced by 5-azacytidine in primary bone marrow cells of 17 MDS patients. Real-time PCR analyses indicated that 5-azacytidine treatment significantly induced PTPN1 expression.

Summary/Conclusions: The present study demonstrated that PTPN1 expression is reduced in MDS patients with haplo-insufficiency due to del(20q) and methylation of promoter region of the PTPN1 gene. Low PTPN1 expression is associated with advanced disease and poorer clinical outcome, indicating that PTPN1 expression level could be a useful prognostic marker in MDS.

MOLECULAR MARKERS PREDICTING RESPONSE TO AZACITIDINE TREATMENT FOR MYELODYSPLASTIC SYNDROMES

Background: MDS is a clonal hematopoietic malignancy characterized by ineffective hematopoiesis and varying degrees of dysplasia leading to cytopenia and/or excess blasts (EB). Proliferation of pathologic hematopoietic cells is driven by genetic and epigenetic factors. Among these, activation of the JAK-STAT signaling pathway has been implicated in the pathogenesis of MDS. JAK2, a non-receptor tyrosine kinase, is mutated in ~20% of patients with MDS. Therefore, it is important to identify JAK2 mutation status as a biomarker for the prediction of treatment response to targeted therapy. Azacitidine is a demethylating agent that induces hypomethylation of DNA and re-expression of silenced genes. However, the role of epigenetic changes in the prediction of treatment response to azacitidine remains unclear.

Aims: The aim of this study was to investigate whether epigenetic changes, particularly DNA methylation, in concert with gene expression changes, can predict the response to azacitidine treatment in patients with MDS.

Methods: A total of 40 MDS patients were enrolled in this study. DNA methylation was assessed by bisulfite genomic sequencing in 300 genes, including JAK2, and gene expression was measured by RNA sequencing. The response to azacitidine treatment was defined as complete remission or partial remission according to the International Working Group criteria. Univariate and multivariate analyses were performed to identify potential biomarkers of response to azacitidine treatment.

Results: DNA methylation levels in the promoter region of JAK2 were significantly lower in responders compared to non-responders. Moreover, high expression of the epigenetic modifier DNMT3B and low expression of the tumor suppressor genes TP53 and PTEN were associated with treatment resistance. Multivariate analysis identified JAK2 methylation and TP53 expression as independent predictors of response to azacitidine treatment.

Summary/Conclusions: Our findings suggest that epigenetic changes, particularly DNA methylation and gene expression, can predict the response to azacitidine treatment in patients with MDS. These biomarkers may help to identify patients who are likely to benefit from azacitidine therapy, thereby optimizing treatment strategies.
Background: DNA hypomethylating agents (HMAs) comprise standard therapy for non-transplant-candidate high-risk myelodysplastic syndromes (MDS). However, little is known about the exact mechanism of their effects to MDS or their clinical utility and response to azacitidine (AZA).

Aims: The purpose of this study is to elucidate the clonal dynamics and molecular signatures that correlate with response to azacitidine therapy for MDS, focusing on the role of TP53-mutations.

Methods: We conducted a prospective multicenter trial of azacitidine treatment for high-risk MDS patients in which the efficacy was compared between the 5-day and 7-day regimens. A total of 107 patients were enrolled between 2013 and 2016. For all cases, a bone marrow specimens collected before therapy was analyzed for mutations using targeted-capture sequencing. Mutations were also interrogated after 4 cycles of azacitidine therapy in 48 (45%) cases. An additional 24 cases was also analyzed for mutations who received azacitidine therapy for MDS and whose bone marrow specimens were available both before and after therapy.

Results: On average, 2.7 mutations (range 0-9) were detected per sample before azacitidine treatment. TP53 represented the most common mutational target (29% cases) followed by ASXL1, RUNX1, TET2, and SRSF2. TP53-mutated cases had significantly lower number of driver mutations (1.7 vs 3.1/sample, p=0.001) and higher number of copy number changes (9.6 vs 2.1, p=0.001), compared with unmutated cases. Clinical response was observed in 25 cases in the on-protocol cohort, including 6 complete remission (CR) (5.6%) and 19 marrow CR (17.8%) and 7 (29%) cases (all CR) in the off-protocol cohort. Notably, CR was obtained almost exclusively in TP53-mutated cases (5/6 and 5/7 CR cases in the on- and off-protocol cohort. No other mutations were associated with clinical remission. Median duration to CR was 119 days (range 81-721), which lasted for a median duration of 217 days (range 10-783). DeltaT (tumor cell fraction) was evaluable for 62 cases who had one or more low-up samples and carried at least one mutation in either pre- or post-treatment. Among with an average of 0.075 (range -0.75-0.72). DeltaT was significantly lower in responders than non-responders (-0.18 vs -0.0002, p=0.0068) and in TP53-mutated cases (-0.25 vs 0.0008, p=0.001).

Summary/Conclusions: Our study revealed a significant positive association of TP53 mutations with favorable responses to azacitidine for MDS, although the response was transient and the expected treatment response seems to be an open question for this clinical trial. The study results suggest a potential role of TP53 as a key mediator to regulate the clonally selected clonal dynamics of TP53-mutated tumors. Further studies should be warranted to confirm its efficacy and to develop an optimal post-remission therapy to overcome the short remission period.

Background: Improved the current response and survival outcomes of patients with higher-risk MDS and CMML is fundamental. Guadecitabine is a next-generation hypomethylating agent with increased length of exposure compared to decitabine and clinical activity in patients with MDS.

Aims: To evaluate the activity of guadecitabine in previously untreated patients with higher-risk MDS or CMML.

Methods: We conducted a single arm phase II clinical trial of guadecitabine at a dose of 60mg/m² sc daily for 5 days (days 1-5) every 28 days for patients with newly diagnosed MDS or CMML classified as intermediate-2 or High risk by IPSS. Primary endpoint was complete response (CR). Responses were evaluated following the revised 2006 International Working Group criteria. Sequencing data was obtained at the time of pre-treatment evaluation by the use of a 28-gene next generation sequencing platform. Response included hemoglobin response for anemia, improvement for lineages for neutropenia and thrombocytopenia.

Results: A total of 53 patients have been enrolled: 50 (94%) are evaluable for toxicity and 44 (83%) for response. Median age is 67 years (49-87). A total of 43 (86%) patients have MDS and 7 (14%) have CMML. A total of 21 (42%) patients had a history of therapy for other hematologic malignancies (HMA). The most frequent type of mutation in patients with TP53 mutations being the most frequently detected in 36% patients. After a median of 6 treatment cycles (1-20), the ORR is 71% including 32% CR. Median response occurred by 3 cycles (1-6). Seven (21%) out of 33 evaluable patients achieved a complete cytogenetic response. Ten (20%) subjects proceed to allogeneic stem cell transplantation. Median follow-up was 3.3 months (0-23). Median OS is 14.1 months (CI 13.3-14.9 months) and median EFS is 8.4 months (CI 5.6-11.2 months). Forty-five (90%) patients experienced at least one AE during therapy. Most common grade 1-2 AEs included fatigue (66%), nausea (38%) and dyspnea (26%). Dose reductions due to cytopenias were required in 17 (34%) patients. Early 8-week mortality occurred in 3 (6%) patients.

Summary/Conclusions: Guadecitabine is well-tolerated and active in patients with higher-risk MDS and CMML even in the presence of adverse biological features such as high frequency of complex karyotype, treatment related disease and TP53 mutations.
22nd Congress of the European Hematology Association
with non complex del(7q) (P=ns for complex vs non complex, chi-square test).
The ORR was 37.5% in “de novo” and 38.4% in secondary MDS, respectively
(P=ns). Impact of AZA treatment compared to BSC on overall survival: Results
of this multivariable analysis of OS at different time points are presented in
Table 2. Chromosome 7 cytogenetic categories and IPSS retained a poor prognosis over time with a constant value of poor prognosis. AZA treatment had a
favorable impact on OS during the first 3 years of treatment, compared to BSC,
confirming results obtained in univariable analysis. Nevertheless, the benefit
of AZA treatment as compared to BSC approach decreased as time spends
and the HR value increased over time: HR of 0.3 at 6 months, 0.5 at 1 year
and 0.7 at 2 and 3 years after treatment. (Figure 1). This benefit was present
in all chromosome 7 categories with a a trend towards better impact among
patients with complex karyotype but no significant differences between the 3
categories (-7, del(7q) and CK).

serum were >200 h at 5 mg/kg and >300 h at 10 mg/kg. There was a greaterthan-dose proportional increase in mean OPN-305 exposure (AUC) between
5 and 10 mg/kg. PK profiles after repeated dosing at 5 mg/kg in N=2 subjects
and pre-dose (trough) levels in other subjects indicated some variability in the
potential for accumulation. TLR-2 receptor occupancy in blood PBMCs and
bone marrow aspirates was complete in virtually all samples taken after OPN305 administration. There is no evidence of treatment related anti-drug antibodies. Compared with baseline, no significant changes of IL-23, IL-18, IFN-r,
IL-10, IL-1β, IL-6, IL-12 (p40), IL-12 (p70) and IL-8 levels where observed
among responders or non-responders or based on OPN-305 dosing. A trend
to increased response was observed in patients with higher TLR2 expression,
with no differences in response based on cytogenetic or mutational profile.
Summary/Conclusions: Treatment with OPN-305 in pts with previously treated lower-risk MDS was well tolerated with no significant toxicities and 53%
ORR including 20% transfusion independence, and potential association
between TLR2 levels and response.
P318

Background: Alterations of innate immune signaling, including overexpression
of TLR2, are common in MDS. Significant TLR2 overexpression in MDS bone
marrow CD34+ cells, especially after HMA therapy, has been reported. OPN305 is a fully humanized antagonistic IgG4 kappa monoclonal antibody to TLR2
which significantly increases the formation of erythroid colonies (CFU-E) in BM
CD34+ cells isolated from pts with lower-risk MDS in vitro.
Aims: To evaluate the potential therapeutic value of OPN-305 in patients (pts)
with MDS
Methods: We designed a phase I/II trial of OPN-305 for pts with Low or Int-1
risk MDS by IPSS after failure to prior therapy with a HMA (≥4 cycles). Pts
where required to be transfusion dependent (≥2 units in 8 weeks). Pts with isolated del(5q) should have received therapy with lenalidomide. Because, OPN305 had not been previously used in pts with hematological malignancies, the
study had an initial phase of N=10 pts using OPN-305 at a dose of 5 mg/kg
every 4 weeks for a maximum of 9 cycles. Therapy could be repeated as long
as there was no excess toxicity or progression. If after 16 weeks of therapy,
there was no response, azacitidine on a 3 day schedule, could be added to
OPN-305. Responses were evaluated following the revised 2006 IWG criteria.
This initial cohort allowed evaluation of toxicity, pharmacokinetic analysis,
receptor occupancy, and sequential analysis of cytokine profile. An extension
dose escalation phase to 10mg/kg was planned for N=30 pts.
Results: At the time of this report, 31 pts have been enrolled, 11 at the initial
5 mg dose and 21 at 10 mg/kg. A total of 21 pts are evaluable for toxicity and
response. Median age was 72 years (range 42-87). Nine (43%) pts were classified as Low risk and 12 (57%) as Intermediate-1 risk by IPSS. Thirteen pts
had normal karyotype, 2 del(5q), 2 trisomy 8, 1 del(20q), 1 monosomy Y and
2 other single or double abnormalities. Median number of prior therapies was
2 (range 1-4) with a median duration of prior therapies of 23 months (range 656). A total of 5 (29%) pts developed AEs related to OPN-305. All AEs were
grade 1 with gastrointestinal disorders being the most frequent (23%). At this
point, no significant drug related toxicity has been documented with no excess
infectious complications. Overall response rate in the form of hematological
improvement was 53% (8/21) with 3 (20%) pts achieving transfusion independence and 5 (33%) minor hematological improvement. Half-lives of OPN-305 in

and Cellular Therapy, IBSAL Instituto Biosanitario de Salamanca, Salamanca,
Spain

Background: Approximately 90% of patients with Myelodysplastic Syndromes
(MDS) have somatic mutations in driver genes detected by Next Generation
Sequencing (NGS). In the last years, several studies have related these mutations with prognosis, disease characteristics and response to therapy, including
allogeneic Hematopoietic Stem Cell Transplantation (HSCT). Development of
Chronic Graft Versus Host Disease (cGVHD) has been reported as one of the
most powerful antineoplastic mechanisms after HSCT.
Aims: To evaluate the impact of specific somatic mutations in patients with
MDS undergoing HSCT and if the development of cGVHD can modify their
prognosis.
Methods: The results of HSCT in 115 MDS patients from five centres in Spain
were retrospectively analyzed. Bone marrow samples were collected a median
of 27 days prior to transplant and DNA was screened for somatic mutations by
NGS, using a NextSeq platform (Illumina). Two myeloid genes panels that
included the most frequently mutated genes in myeloid malignancies were
used.
Results: Median age was 53 years (range from 19 to 70). Fifty-eight percent
were male and 79.13% were classified as de novo MDS. According to WHO
2008 classification 4 (3.5%) were RCUD, 2 (1.8%) RARS, 22 (19.50%) RCMD,
28 (24.8%) RAEB-1, 32 (28.3%) RAEB-2, 12 (10.6%) Unclassifiable MDS, 9
(8%) CMML and 4 (3.5%) were AML (FAB RAEB-T). Among patients with calculated Revised IPSS (R-IPSS) (85 of 115 patients) 2 (2.4%) had very low risk,
15 (17.6%) low risk, 21 (24.7%) intermediate risk, 22 (25.9%) high risk and 16
(18.8%) had very high risk; 9 patients with CMML (10.6%) were categorized
separately. Among patients with known karyotype (101 of 115), 7 of them (6.9%)
had a complex kariotype (CK). Regarding mutational study, 44 patients (38.3%)
didn’t shown any mutation before transplant; 27 patients (23.5%) had 1 mutated
gene, 15 (13%) had 2, 19 (16.5%) had 3, 6 (5.2%) had 4, 3 (32.6%) had 5 and
only 1 patient (0.9%) had 6 different mutated genes. The most frequently mutated genes were: TP53 in 15 patients (13%), SRSF2 in 14 (12.2%), TET2 in 13
(11.3%), DNMT3A in 9 (7.8%), RUNX1 in 9 (7.8%), SF3B1 in 9 (7.8%) and
ASXL1 in 8 (7%) patients. After a median of follow up for survivors of 2.02
years, Overall Survival (OS) was 48.1% (63.4% at 1 year; median 5.96).
Patients were divided into 2 groups: group 1, with 2 or less mutated genes
(74.5%) and group 2, with more than 2 mutated genes (25.2%). Group 2 had
a lower OS (46.9% vs 69.6% at 1 year; p=0.035) and a higher Cumulative Incidence of Relapse (CIR) (25.3% vs 10.1% at 1 year; p=0.007). Development of
cGVHD significantly improved outcome in both groups (Figure 1). Univariate
analysis determined that developing of cGVHD, CK, number of mutated genes
(more than 2 mutated genes) and mutations in TET2 significantly impacted on
outcome. Nevertheless, only the development of cGVHD as a time-dependent
variable (HR 0.046, 95%CI 0.016-0.138, p<0.001) and TET2 mutations (HR
2.562, 95%CI 1.018-6.447, p=0.046) significantly influenced on OS in multi-


We also observed the unfavourable impact of TP53 mutations on relapse risk: CIR was 41.7% (95% CI 22.5-77.1) at 1 year for TP53 mutated vs 9.8% (95% CI 5.3-18.1) at 1 year for non TP53 mutated patients (p=0.006).

Summary/Conclusions: We conclude that the number of mutated genes prior to transplant could be a prognostic factor of OS and CIR. Mutations in some genes, like TET2 and TP53, could also have an adverse impact on outcome. However, cGVHD could ameliorate the poor prognosis of somatic mutations in transplanted patients with MDS.

P319
VOSAROXIN PLUS AZACITIDINE TREATMENT FOR PATIENTS WITH MYELODYSPLASTIC SYNDROME: A PHASE 1/COHORT EXPANSION STUDY
M.A. Jacoby1,*, M.J. Walter1, J.F. DiPersio1, C.N. Abboud1, P. Westervelt1, A.F. Cashen1, K. Stockerl-Goldstein1, T. Fletcher1, G.L. Uy1
1Medicine, Washington University Medical School, St. Louis, United States

Background: Although hypomethylating agents are the mainstay of treatment for myelodysplastic syndromes (MDS), these agents result in remissions in a minority of patients and are not curative. Vosaroxin is a first-in-class quinolone derivative that intercalates DNA and inhibits topoisomerase II. Vosaroxin is active with a tolerable safety profile in acute myeloid leukemia (AML) and the novel combination of vosaroxin and azacitidine was found to be synergistic in primary myeloblasts.

Aims: This phase 1/cohort expansion study was designed to determine the maximum tolerated dose (MTD) and dose-limiting toxicity (DLT) of vosaroxin when given in combination with azacitidine, and to evaluate the efficacy and safety of the combination treatment.

Methods: Patients with MDS ≥18 years old with cytopenias requiring transfusions, an IPSS score of intermediate (INT)-1 or greater, or chronic myelomonocytic leukemia were eligible. Vosaroxin (initial dose: 50 mg/m²/d) was administered on Days 1 and 4, and azacitidine (75 mg/m²/d) on Days 1-7 of a 28-day cycle, in an outpatient setting, for up to 6 cycles in a 3+3 design (additional cycles were permitted if a clear benefit for the patient was demonstrated). Once the MTD was determined, an expansion cohort of 20 evaluable patients (≥1 cycle) was enrolled.

Results: A total of 35 patients enrolled in the dose escalation (n=13) and expansion (n=22) phases. The median age of the entire cohort was 66 years (range 38-77) with IPSS scores of low (n=1); INT-1 (n=13); INT-2 (n=15); and high risk (n=6). The median ECOG score for the entire cohort was 1 (range 0-2). In the dose escalation phase, at the initial dose of vosaroxin 50 mg/m²/d (n=6), the median number of total cycles was 2 (range: 1-4); 2 of 6 patients experienced a DLT at this dose (grade 4 hyperbilirubinemia and grade 4 neutropenia >42 days). At the de-escalated dose of 34 mg/m²/d (n=7), the median number of cycles was 2 (range: 1-18); 1 patient experienced a DLT at this dose (grade 4 mucositis). The MTD of vosaroxin was determined to be 34 mg/m²/d when given on Days 1 and 4 with a fixed dose of 75 mg/m² of azacitidine on Days 1-7. The major non-hematologic toxicities were infections, febrile neutropenia, and bleeding. The combination of vosaroxin and azacitidine showed promising activity with responses rates comparable or better than those generally observed with azacitidine alone. Additionally, the transplant rate observed was encouraging in this patient population.

Summary/Conclusions: The MTD of vosaroxin in MDS patients was 34 mg/m²/d when given on Days 1 and 4 with a fixed dose of 75 mg/m² of azacitidine on Days 1-7. The major non-hematologic toxicities were infections, febrile neutropenia, and bleeding. The combination of vosaroxin and azacitidine showed promising activity with responses rates comparable or better than those generally observed with azacitidine alone. Additionally, the transplant rate observed was encouraging in this patient population.

ADVANCED STAGE MYELOMA IS CHARACTERIZED BY A SIGNIFICANT INCREASE OF MUTATIONS IN GENES ASSOCIATED WITH DRUG RESPONSE
S. Barrio1,2, M. Da-Via1,2, T. Stühmer1, A. Gartano-Trojaola1, L. Brunis3, I. Cuenca4, M. Schreder5, R. Tiberi6, P. Somerveld7, M.S. Raab8, J. Martinez-Lopez9, A. Rosenwald9, R.C. Bargou9, E. Braglio9, A.K. Stewart10,11, H. Einsele11, K.M. Kortüm1
1Hematology, Würzburg University Hospital, Würzburg, Germany, 2Hematology-Oncology, IRCCS Policlinico San Matteo, Pavia, Italy, 3Hematology, Mayo Clinic, Scottsdale, United States, 4Hematology, Doce de Octubre University Hospital, Madrid, Spain, 5Hematology, Erasmus Medical Center, Rotterdam, Netherlands, 6Hematology, Heidelberg University Hospital, 7German Cancer Research Center, Heidelberg, 8Pathology Institute, Würzburg University Hospital, 9Comprehensive Cancer Center Mainfranken, Würzburg University Hospital, Würzburg, Germany, 10Center of Individualized Medicine, Mayo Clinic, Rochester, United States

Background: The amount of genomic data available in Multiple Myeloma (MM) is exponentially increasing, however, hardly any of that information is translated into the clinic. A number of genes has been associated with resistance to commonly used anti-MM compounds. This, most importantly, includes immunomodulators (IMiDs) and proteasome inhibitors (Ps). However, no mutation screening has yet been amended to our MM routine diagnostic workflows. We investigated 458 MM patients by targeted sequencing, including the largest cohort of previously treated MM patients so far. We identified an increased mutation incidence in treated patients, yet unreported mutations and functionally validated a subset.

Aims: To describe the mutational spectrum in genes of pathways targeted by standard of care (SOC) therapies in a cohort of pretreated and previously untreated patients.

Methods: Tumor-germline paired samples of five contributing sites were pooled (Würzburg, Heidelberg, Madrid, Rotterdam and Mayo Clinic). Analysis included 310 untreated and 148 IMiD and/or PI treated patients. Targeted sequencing was performed using the M3P (v2.0 or v3.0) gene selection, that includes most currently known functional Ps targets as well as the most common known IMiD targets. Functional significance was validated using different functional assays.

Results: Our analysis included five genes each with known association to drug response to IMiDs (CRBN, C4BL4, IKZF1, IKZF3 and IRF4) and Ps (PSMB5, PSMB8, PSMB9, PSMD1 and XBPF1). Based on the increased sequencing depth, the mutation incidence in untreated patients is higher than in the CoMMPass dataset (IMiDs: 5.8% vs 3.9%; Ps: 1.9% vs 1.4%). Furthermore, pretreated patients showed a significant mutational increase compared with untreated pts (IMiDs: 19.7%, Z-score: -4.2, p<0.001; Ps: 7.3%, Z-score: -2.6, p=0.009). We observed a Gly159Arg mutation within the Lenalidomide (Len) degron sequence of IKZF3 in a patient progressing on Len and Pomalidomide (Rom), as well as two XBPF1 truncating mutations in PI refractory patients. Of note, among three treated cases with mutations in the 85 (PSMB5) or 85 (PSMB8) PI binding subunit of the proteasome, one patient harbored not less than 4 subclonal mutations. This is the first description of PSMB5 mutations in human MM, identified in a patient with long term history of PI treatment. All mutations were located in or close to the Bor binding site of PSMB5. The functional analysis demonstrated induction of resistance not only to Bor (IC50/PSMB5wt= 2 nM vs IC50/PSMB5mut= 4.5-8 nM), but also to the second generation PI Ixazomib (IC50/PSMB5wt= 5.2 nM vs IC50/PSMB5mut= N/A) and Carfilzomib (IC50/PSMB5wt= 8 nM vs IC50/PSMB5mut= 13-22 nM). Of interest, the P97 blockade of the protein homeostasis by the investigational compound CB5083 remains still possible in the mutated cell lines and the resistance can be overcome. Finally, Pom treatment eradicated two of the PSMB5 containing subclones (Figure 1).

Summary/Conclusions: Under the selective pressure of anti-MM therapy the incidence of mutations in genes associated with drug resistance increases in previously treated MM patients. Resistance mechanisms evolve in parallel in competing (sub)clones of the disease, mimicking phenotype and behavior. Remarkably, despite our restrictive gene selection, a quarter of our treated cohort is affected by at least one mutation. Aim of future therapy may be the eradication of selected clones or subclones, which, according to our data, appears possible.

P321
ILF2-YB1 INTERACTION MODULATES RNA SPlicing TO INDUCE RESISTANCE TO DNA-DAMAGING AGENTS IN 1Q21-AMPLIFIED MULTIPLE MYELOMA
1Leukemia, MDAnderson Cancer Center, Houston, United States, 2Neurology, University of Milan, Milan, 3Clinical and Experimental Medicine, University of Parma, Parma, Italy, 4Genomic Medicine, MDAnderson Cancer Center, Houston, Texas, 5Harvard Medical School, Dana Farber Cancer Institute , Boston, 6Informatic and Computational Biology, 7Stem cell transplantation and cellular therapy, 8Lymphoma/Myeloma, 9Cancer Biology, MDAnderson Cancer Center, Houston, United States

Background: The 1q21 amplification, which occurs in approximately 40% of de novo and 70% of relapsed Multiple Myeloma (MM), is among the most frequent chromosomal aberrations in MM patients and is considered a very high-risk genetic feature that is especially correlated with disease progression and drug resistance. The 1q21 amplicon contains many genes, and while it is unlikely that all contribute to the pathobiology of high-risk MM, the critical genes that do drive this high-risk phenotype have not yet been fully clarified. Identifying such genes and their contributions to this phenotype would enable the development of new and effective targeted therapy strategies for high-risk MM and thus improve their survival outcomes.

Aims: In our study we wanted to investigate the biological and molecular mechanisms behind the 1q21 amplification’s contribution to high-risk MM with the ultimate goal of obtaining a list of validated therapeutic targets to inform the design of novel translational clinical trials for this subgroup of patients.

Methods: We conducted a high-resolution analysis of recurrent copy number alterations and expression profiles in a collection of 254 MM samples included in MMRC database. To define the discrete minimal common 1q21 region that is recurrently amplified in MM, we used Genomic Identification of Significant Targets in Cancer, a systematic method that identifies regions of genome that are recurrently amplified or deleted across a set of samples. These were enlisted into an in vitro screening strategy that employed a single-stranded DNA-PCR-96-well approach and GFP-competitive cell growth assay to identify 1q21 genes whose loss of function resulted in the selective death and/or growth inhibition of MM cells carrying the 1q21 amplification but not MM cells without the 1q21 amplification.

Results: We identified MCL1, UBAP2L, INT3S, LASS2, KRTCAP2 and ILF2 as potential 1q21-specific vulnerability targets whose expression is driven by copy number functionally validated, both in vitro and in vivo, Interleukin-2-enhancer binding factor 2 (ILF2) as a key 1q21 amplification-specific gene. Our results show that ILF2 interacts homologous recombination (HR) and induces resistance to DNA damaging agents routinely used in the treatment of MM, which is consistent with the observation that ILF2 expression correlates with poor survival in MM patient treated with high-dose melphalan followed by tandem autologous transplantation. On the mechanistic level, ILF2 interacts with numerous RNA binding proteins directly involved in the regulation of DNA Damage Response (DDR) by modulating alternative splicing of specific pre-mRNAs. RNA sequencing experiment confirmed that ILF2 knockdown results in aberrant splicing of genes involved in the DDR pathways and, strikingly, ILF2 RIP-seq analysis showed that ILF2 directly binds to transcripts involved in the regulation of the HR pathway, including components of BRCA1 protein complex. Furthermore, we found that ILF2 mediates drug resistance in dose-dependent manner by modulating YB-1 nuclear localization and interaction with the splicing factor U2AF65 to promote mRNA processing and stabilization of DDR genes in response to DNA damage (Figure 1).

Summary/Conclusions: In conclusion, our study reveals an intimate relationship among 1q21 amplification, mRNA splicing and DNA repair in the control of DDR in MM. On the basis of our findings, we propose that 1q21-driven ILF2 overexpression deregulates HR by stabilizing the mRNA splicing of critical HR
effectors, which enables genomic instability, promotes adaptive mechanisms to genotoxic stress, and enhances cell survival, thereby promoting drug resistance and disease progression. Given that 1q21 amplification is one of the most frequent copy number alterations in cancer, synthetic lethality approaches based on targeting gain-of-function associated to ILF2 may have a broad spectrum of application to potentiate the sensitivity of cancer cells to chemotherapeutic agents.

**Methods:** We analyzed data from the interim analysis 8 cohort (August 2015) to create a prognostic model.

**Background:** High throughput techniques, such as next generation sequencing, are becoming an appealing approach to characterize multiple myeloma (MM) genomic profiles and better define risk assessment. However, the clinical relevance of such approaches is still largely unknown. The Multiple Myeloma Research Foundation (MMRF), United States, Italian Multiple Myeloma Network, GIMEMA, Unit of Clinical Epidemiology, Azienda Ospedaliero-Universitaria Città della Salute e della Scienza di Torino and CPO Piemonte, Torino, Italy, 2Multiple Myeloma Research Foundation, (MMRF), United States, 3Italian Multiple Myeloma Network, GIMEMA, 4Unit of Clinical Epidemiology, Azienda Ospedaliero-Universitaria Città della Salute e della Scienza di Torino and CPO Piemonte, Torino, Italy. 5Myeloma Unit, Division of Hematology, University of Torino - Currently Takeda Pharmaceuticals Co., Torino, Zurigo, Italy, Switzerland

**Aims:** We hypothesize that specific genes present in the 1q minimal amplified region are critical regulators of clonal evolution and tumor progression in MM. Gain of 1q is one of the most frequent copy number alterations in cancer, synthetic lethality approaches based on targeting gain-of-function associated to ILF2 may have a broad spectrum of application to potentiate the sensitivity of cancer cells to chemotherapeutic agents.

**Results:** 517 patients with baseline somatic mutation data were included in the analysis. Median age at diagnosis was 64 years (range 27-93), all patients received novel agents as first line treatment, 236 (45.6%) received autologous transplant. Results: 371 days, the 18-month PFS was 93% for group I, 85% for group II, 73% for group III and 40% for group IV (Figure 1). The hazard ratio was 2.31 (p=0.118) for group II versus group I, 4.45 (p=0.006) for group III versus I and 17.38 (p<0.001) for group IV versus I. The prognostic trend of the score was confirmed in different patient subgroups including ASCT/no ASCT, standard/high risk cytogenetic profile, ISS I, II, or III. Of note, 23% of patients in group I had ISS III and 34% of patients in group IV had ISS I.

**Summary/Conclusions:** The use of a prognostic model based on the mutational status of 9 recurrently mutated genes could improve risk assessment of newly-diagnosed MM patients. Longer follow-up and validation in independent cohorts of patients are needed to confirm our findings. Updated results with a longer follow-up will be presented at the meeting.

TARGETING GENE DEPENDENCY OF 1Q AMPLIFICATION IN MULTIPLE MYELOMA

S. Manier1,2, D. Huynh2, J. Park2, K. Salem2, X. Leleu3, I. Ghobrial4

1Hematology, Lille Hospital, Lille, France, 2Medical Oncology, Dana-Farber Cancer Institute, Boston, United States, 3Hematology, University of Lille 2, Lille, France, 4Medical Oncology, Dana-Farber Cancer Institute- Harvard Medical School, Boston, United States

**Background:** Gain of 1q is one of the most frequent copy number variations across cancer types and in Multiple Myeloma (MM). Gain of 1q is associated with a poor outcome, indicating it is a potential driver in MM progression and resistance to treatment. While the whole 1q arm can be amplified in some cases, a specific minimal amplified region has been identified by CGH array, including approximately 500 genes in the 1q21.1-23.3 region. However, the driver genes in the 1q region are unknown.

**Aims:** We hypothesize that specific genes present in the 1q minimal amplified region are critical regulators of clonal evolution and tumor progression in MM.

**Methods:** To explore gene dependency in 1q21.1-23.3 in MM, lung, breast and
P324

DUAL INHIBITION OF DNM1 AND EZH2 CAN EFFECTIVELY OVERCOME BOTH INTRINSIC AND ACQUIRED RESISTANCE OF MYELOMA CELLS TO IMiDS

K. Dimopoulos1,*, A. Segaard Helbo1, H. Duverger Munch-Petersen2, L. Sjö2, J. Christensen3, F. Asmar1, P. Gimsing1, G. Liang3, K. Granberg4
1Hematology, 2Pathology, Rigshospitalet, 3EBRIC, Copenhagen, Denmark, 4Urology, USC, Los Angeles, United States

Background: The introduction of novel agents for the treatment of multiple myeloma (MM), mainly proteasome inhibitors and immunomodulatory agents (IMiDs), has significantly improved the survival rates of the patients, and both classes of drugs stand as the main treatment options for MM. Several studies have identified Cereblon (CRBN) as the direct target of not only thalidomide, but also lenalidomide and pomalidomide, and suggested that its expression is essential for the anti-myeloma effect of these drugs. However, even though the expression levels of CRBN have been associated with response to IMiDs, the precise mechanisms behind IMiD resistance still remain elusive.

Aims: The aim of this study was to determine the expression of epigenetic modifications in MYELOMA CELLS TO IMiDS, and identify novel therapeutic targets in MM.

Methods: For the development of IMiD-resistant cell lines (OPM2-LR and -PR, H929-LR and -PR), we treated OPM2 and H929 continuously with increasing doses of either lenalidomide or pomalidomide for 4-6 months, until cell viability decreased in chromatin accessibility and to a much lesser extent with DNA methylation changes. Interestingly, neither CRBN nor any of the other molecules involved in the CRBN pathway (IKZF1, IKZF3, IRF4) i showed increased sensitivity to both lenalidomide and pomalidomide, with significantly impaired proliferation of gain of 1q cells. Several candidate genes were identified as being the top genes preferentially affecting the proliferation of gain of 1q cells. To further confirm our candidate genes were overexpressed in gain of 1q patients, we studied publicly available gene expression profiling from the Multiple Myeloma Genomic portal (MMGP) and the Cancer Genome Atlas (T1). Using list of candidate genes identified a large expression profiling resource developed by the Library of Integrated Network-based Cellular Signatures (LINCS) program to identify potentially active drug targeting our candidate genes. Finally, a targeted drug screening was performed using 179 compounds identified through the LINCS program and using the library of compounds, 17 compounds were found to target Cereblon. These data were used as input for a drug screen that was developed and validated in 1q+ (OPM2, H929 and KMS11) and non 1q 1q cells (KMS18).

Results: We were able to identify 10 candidate genes, for which knockdown significantly impaired proliferation of gain of 1q cells. Five of these genes showed a significant increase in expression in both patient samples and controls, naive B cells, germinal center B cells, memory B cells and plasma cells. Data were extensively mined using a battery of different bioinformatic tools. In conclusion, our study is the first one to ever show that acquired IMiD-resistance is mainly an epigenetic event that is potentially reversible through a combination of two epigenetic compounds, 5-Aza and 5-Azacytidine. However, in vivo experiments are required to confirm these findings and to make them very good candidates for a prospective phase I study to examine their potential as "IMiD-resensitizers", which may improve the outcome management of MM patients with drug-resistant myeloma clones and a potentially high-risk disease.

Background: Most of the published omics studies in multiple myeloma (MM) have focused on the analysis of the genome, transcriptome and DNA methy- lome. Over the last years, the chromatin structure and histone modifications are emerging as essential epigenetic layers to understand gene deregulation in MM. Although this field remains widely unexplored in MM.

Aims: We herein aim to elaborate a comprehensive description of the MM epigenome including multiple layers of information.

Methods: We performed ChIP-seq of six histone modifications with non-overlapping functions (H3K4me3, H3K4me1, H3K27ac, H3K36me3, H3K27me3, and H3K9me3), ATAC-seq for chromatin accessibility, Whole Genome Bisulfite Sequencing (WGBS) for DNA methylation, and RNA-seq for gene transcription in purified bone marrow plasma cells from 4 MM patients and, as healthy controls, naive B cells, germinal center B cells, memory B cells and plasma cells. Data were extensively mined using a battery of different bioinformatic tools. In conclusion, our study is the first one to ever show that acquired IMiD-resistance is mainly an epigenetic event that is potentially reversible through a combination of two epigenetic compounds, 5-Aza and 5-Azacytidine. However, in vivo experiments are required to confirm these findings and to make them very good candidates for a prospective phase I study to examine their potential as "IMiD-resensitizers", which may improve the outcome management of MM patients with drug-resistant myeloma clones and a potentially high-risk disease.
cells. Out of this list, we observed that two adjacent genes, PRDM5 and NID2, were co-activated in MM. The analysis of their expression in additional patient cohorts indicated that their co-activation is a consistent event in MM pathogenesis and that their levels were negligible in bone marrow and tonsillar plasma cells. When analyzing chromatin topology by 4C-Seq, we identified 3D interactions between both gene loci only in MM cells, suggesting that DNA looping between the two genes may be related to their co-activation in MM. Finally, knockdown of each of these genes using inducible shRNAs, decreased cell proliferation and induced apoptosis in MM cells.

Summary/Conclusions: Collectively, our initial exploration of histone modification profiles in MM has revealed an extensive activation of the MM chromatin landscape, which harbors many candidate oncogenes. Reversing this global activation by epigenetic drugs, such as BET inhibitors, may represent an attractive therapeutic option for MM.

CLINICAL IMPLICATIONS OF CD34+ CELLS, STEM CELL HARVEST FROM PATIENTS WITH PLASMA CELL DYSCRASIAS

S. Chibira1, F. Stolzle2, K. Cuthill1, M. Streetby1, C. Graham1, M. Bornhauser2, G. Mufti1

1Haematological Medicine, KINGS COLLEGE LONDON, London, United Kingdom, 2Department of Internal Medicine I, University of Dresden, Dresden, Germany

Background: Introduction of novel treatments; Lenalidomide, high-dose alkylating agents (Melphalan) conditioning prior to autologous stem cell transplant (ASCT) over the last few decades has improved overall survival in patients with Multiple Myeloma (MM). In spite of enhanced survival rates, some hematological malignancies (SPM) like Myelodysplastic Syndrome (MDS) and Acute myeloid Leukaemia (AML). Clonal haematopoiesis resulting in sequential accumulation of genomic events and their combination with a driver-passenger genetic mutations (in upto 80% of MDS & >95% AML patients) steer MDS/AML disease pathogenesis and clinical outcome. Therefore, we hypothesised that detection of Clonal Hematopoiesis of Indeterminate Potential (CHIP) in haematopoetic stem cells (HSCs) prior to ASCT in patients with MM treated with a range of therapies could be utilised for predicting patients at risk of developing SPMs i.e. MDS/AML.

Aims: To ascertain baseline mutational spectrum [especially low-level clones with variant allele frequency (VAF) ≥5%] of MDS/AML associated gene mutations in HSCs prior to ASCT in order to predict patients at risk of clonal evolution, transformation to MDS/AML.

Methods: DNA was isolated from mononuclear cells (MCs) collected by leukopheresis prior to ASCT from 128 MM patients. A customised amplicon-based Illumina MiSeq panel was used for the sensitive interrogation of 24 most common genes harbouring mutations in MDS/AML (splicing factor genes; SRSF2, ZRSR2, genes implicated in epigenetic regulation; TET2, IDH1, IDH2, ASXL1, EZH2 & DNMT3A, known non-coding genes involved in cell signalling/transcription regulation and cohesion complex; TP53, FLT3, NRAS, KRAS, ETF6, RUNX1, CCBl, CKIT, JAK2, MPL, CEBPA, STAG2, GATA2, KDM6A and NPM1). Variant analysis was performed using Illumina Variant Studio (≥5% VAF & read depth ≥150X thresholds for Myelodysplastic Syndromes (MDS) and 5% VAF for Acute Leukaemia (AML)). VAF range 7-50% in DNMT3A, IDH1, IDH2, TET2, ETF6 and CBL genes (Table 1). Four missense mutations identified in DNMT3A were aggregated in the Mtas e domain responsible for its methyltransferase activity indicating a strong intent to abrogate this function. Previous studies confirm R882 variant in the Mtase domain responsible for its methyltransferase activity indicating a strong intent to abrogate this function. Previous studies confirm R882 variant in the Mtase domain responsible for its methyltransferase activity indicating a strong intent to abrogate this function.

Results: Seven patients (6.25%) contained heterozygous somatic mutations (VAF range 7-50%) in DNMT3A, IDH1, IDH2, TET2, ETF6 and CBL genes (Table 1). Four missense mutations identified in DNMT3A were aggregated in the Mtas e domain responsible for its methyltransferase activity indicating a strong intent to abrogate this function. Previous studies confirm R882 variant in the Mtase domain responsible for its methyltransferase activity indicating a strong intent to abrogate this function. Previous studies confirm R882 variant in the Mtase domain responsible for its methyltransferase activity indicating a strong intent to abrogate this function.

Summary/Conclusions: Our data identifies for the first time a subgroup of MM patients (6.25%) with no morphological evidence of MDS/AML prior to ASCT but harbouring CHIP in CD34+ harvest stem cells and later developing MDS/AML. These findings are pivotal for identification of such patients at risk of clonal evolution and transformation prior to ASCT since it can be a significant parameter in determining appropriate treatment modality i.e. whether or not to employ CHIP harbouring CD34+ harvest stem cells as therapy for these patients.

PATHOPHYSIOLOGICAL FUNCTIONS AND CLINICAL IMPACT OF THE NEW IMMUNORECEPTOR SLAMF3 IN MULTIPLE MYELOMA

M. Ishishita1, K. Tanaka1, Y. Asayama1, Y. Kuribayashi-hamada1, A. Onodera1, K. Moriya1, M. Sasaki2, H. Handa3, Y. Imai4, J. Tanaka5, S. Tanosaki6, S. Ito7, K. Inokuchi1

1Division of Hematology, Department of Medicine, Nippon Medical School, 2Division of Hematology, Department of Internal Medicine, Juntendo University School of Medicine, Tokyo, 3Department of Medically Truncated Clinical Science, Gunma University Graduate School of Medicine, Maebashi, 4Department of Haematology/Oncology, the Institute of Medical Science, the University of Tokyo, 5Department of Haematology, Tokyo Women’s Medical University, 6Department of Hematology, Fraternity Memorial Hospital, Tokyo, 7Department of Medical Oncology, Jiwate Medical University School of Medicine, Morioka, Japan

Background: The signaling lymphocytic activation molecule family 3 (SLAMF3) is a member of the immunoglobulin superfamily expressed on T, B, and natural killer cells and modulates the activation and cytotoxicity of these cells via self-ligand binding. SLAMF3 is also expressed on plasma cells from patients with multiple myeloma (MM), although its role in MM pathogenesis remains unclear.

Aims: To clarify this, we investigated the expression and functions of SLAMF3 in MM.

Methods: 1) Two hundred thirty patients comprising 153 newly diagnosed (19 asymptomatic and 134 symptomatic) MM patients, 30 refractory/refractory MM patients, and 47 patients with monoclonal gammopathy of undetermined significance were enrolled. SLAMF3 and CD138 expression levels on clonal plasma cells were analyzed using flow cytometry (FCM). Soluble SLAMF3 (sSLAMF3) serum levels were measured using ELISA. 2) Drug sensitivity of MM cells to antimalyeloma agents (melphalan and bortezomib) and the proliferation potential in MM cell lines KMS18 and U266 were analyzed using FCM and the MTT assay. SLAMF3 knockdown MM cell lines were obtained using the lentiviral shRNA system and siRNA. Stable transfected KMS34 cell lines overexpressing full-length SLAMF3 and cytoplasmic domain-truncated SLAMF3 (sASM) were established through corresponding vectors. Single-nucleotide polymorphism (SNP) genotyping was analyzed by real-time PCR. The adaptor protein of SLAMF3 was identified by Western blotting and immunoprecipitation.

Results: 1) SLAMF3 was highly expressed on plasma cells in almost all MM patients, even in relapsed/refractory disease, although CD138 expression levels were decreased in some with advanced disease. 2) The proliferative potential and percentage of antimalyeloma agent-induced apoptosis in SLAMF3hi MM cells were significantly higher and lower than in SLAMF3low cells, respectively. The cell proliferation and drug resistance in SLAMF3-expressing KMS34 cells were promoted in comparison with SLAMF3low cells. That malignant potential in MM cells was cancelled by SLAMF3 knockdown. Furthermore, the proliferation of MM cells and resistance to antimalyeloma agents were inhibited by anti-SLAMF3 antibody. Adaptor proteins, SHP2 and GRB2, were expressed in MM cell lines, but neither SAP nor EAR-2 were. SLAMF3 interacted directly with SHP2 and GRB2, and SHP2 also interacted with GRB2. SHP2 inhibitor-treated or SHP2/GRB2-knockdown cells had characteristics similar to SLAMF3-knockdown cells.

3) The frequency of GG genotypes of SLAMF3 SNP rs509749 in MM patients was 63.6% (n=28), of AG 29.5% (n=13), and of AA 6.8% (n=3). Patients with GG genotypes tended to have shorter overall survival times compared to patients with AG genotypes.

4) sSLAMF3 levels were significantly higher in symptomatic MM than in asymptomatic MM and markedly increased in advanced MM. MM patients with high levels (≥3.3 ng/mL; n=62) of sSLAMF3 progressed to the
advanced stage significantly more often and had shorter progression-free survival times than those with low-levels (p=0.0012).

Summary/Conclusions: This study revealed that SLAMF3 molecules consistently expressed on MM cells may transmit positive signals mediated via the complex of SHP2 and GRB2 by self-ligand interaction between MM cells and induce a high malignant potential in MM. Furthermore, high levels of serum sSLAMF3 may reflect MM disease progression and be a useful prognostic factor in MM. Thus, SLAMF3 molecules may be a new potential target for future immunotherapy and chemotherapy.

P328

TARGETING CD74 IN MULTIPLE MYELOMA WITH A NOVEL ANTI-BODY DRUG CONJUGATE, STRO-001

M. Lupher1, A. Molina1,* S. Krueger2, S. Matheny1, T. Kline1, A. Yam1, R. Stafford1, T. Hallam1, M. Lusher1, A. Molina1,t 1Sutro Biopharma, South San Francisco, 2MI Bioresearch, Ann Arbor, United States

Background: CD74 is a transmembrane glycoprotein involved in MHC protein formation and transport. CD74 expression has been observed in up to 90% of B-cell malignancies, including multiple myeloma (MM), with minimal expression in normal tissues. CD74 is rapidly internalized, making it an attractive target for ADCs. STRO-001 is a novel ADC comprised of an aglycosylated anti-CD74 human antibody (SP7219) conjugated covalently to the non-natural amino acid para-azido-methyl-L-phenylalanine (pAMF) with a non-cleavable dibenzo cyclooctyne (DBCO)-maytansinoid linker-warhead. Highly efficient site-specific conjugation enabled by novel cell-free antibody production and click chemistry results in a well-defined homogeneous ADC drug product with a drug-antibody ratio (DAR) of 2.

Aims: The in vitro cytotoxicity and in vivo efficacy of STRO-001 was investigated in MM cell lines and xenografts. An exploratory toxicity study was conducted in a non-human primate model.

Methods: DBCO-Alexa647-conjugated SP7219 staining and flow cytometry were used for detection and quantitation of CD74 expression on MM cell lines. STRO-001 was used to determine the EC50 and percent span of killing in MM cell lines. The anti-tumor activity of STRO-001 was evaluated in the disseminated ARPE-1 and MM.1S MM models. In vivo bioluminescence imaging (BLI) for animals bearing MM.1S-luc cells was performed using an IVIS Spectrum. BLI images were collected 7, 14, 21, and 28 days post-tumor inoculation. STRO-001 was administered to cynomolgus monkeys in an exploratory dose-escalating study of repeat IV doses of 1, 3, 10 and 30 mg/kg on days 1 and 15.

Results: In vitro cytotoxicity assays show nanomolar potency of STRO-001 in five MM cell lines: MC/CAR (EC50 0.8 nM), ARD (EC50 6.5 nM), MM.1S (EC50 10-11 nM), U266B1 (EC50 8.5-9.3 nM), and ARP-1 (EC50 4.3-22 nM). CD74 cell surface expression is required for STRO-001 cytotoxic activity but expression level, as measured by antibody-binding capacity, does not correlate strongly with in vitro potency (R²=0.5837 for MM cell lines). STRO-001 inhibits the growth of various MM cell lines. STRO-001 at 10 mg/kg on day 1 and 15 showed 100% tumor burden reduction in the MM.1S disseminated model. At termination of the study, 129 days post-inoculation, 100% of the STRO-001 treated animals survived and showed no evidence of disease with no CD138+ cells in their bone marrow, while mean survival of vehicle-treated control animals was 35 days with 50% of their bone marrow containing myeloma cells. BLI of luciferase-expressing MM.1S (MM.1S-luc) tumor cell lines enabled non-invasive quantitation of tumor burden. Single doses of 1.3, and 10 mg/kg STRO-001 (administered on day 7 post-inoculation) resulted in eradication of myeloma by day 28 based on bioluminescence signal and quantification of CD138+ cells in bone marrow. In addition, STRO-001 produced a dose-dependent reduction in normal B-cells in cynomolgus monkeys, providing pharmacodynamic evidence of B-cell targeting (Figure 1).

Summary/Conclusions: STRO-001 demonstrates potent in vitro cytotoxicity in MM cell lines and reduces tumor burden in MM xenograft models, including significant prolongation of survival in the MM.1S model. Based on these encouraging observations, STRO-001 is advancing to the clinic for the treatment of CD74-expressing B-cell malignancies.

P329

GENOTYPE CHARACTERIZATION OF LIGHT CHAIN AMYLOIDOSIS BY WHOLE EXOME SEQUENCING

I. Cuenca1,*, B. Sánchez-Vega1, B. Paiva2, M. Gallardo1, L.A. Corchete3, I. Rapado1, N. Puig3, A. García de Coca4, J.F. San Miguel2, J. Martínez-López1

1Hematología traslacional, Hospital 12 de Octubre, Madrid, 2Centro de Investigación Medica Aplicada, Pamplona, 3Hospital Universitario de Salamanca, Instituto de Investigacion Biomedica de Salamanca (IBSAL), Centro de Investigación Biomédica en Red de Asturias (CIBERBIO), 4Hospital Clínico Universitario de Valladolid, Valladolid, 6Hospital Virgen del Puerto, Plasencia, 6Hospital German Trias i Pujol, Badalona, 7Hospital de Cabueñes, Gijón, 8Complejo Hospitalario de León, León, 9Hospital Universitario de Burgos, Burgos, 10Hospital Clínico Universitario Lozano Blesa, Zaragoza, 11Hospital Rio Carrión, Palencia, 12Clínica Universidad de Navarra, Pamplona, Spain

Background: Immunoglobulin light-chain amyloidosis (AL) is a heterogeneous and multifactorial disease with high genetic complexity. Until now, no common factor or unique mutation associated with this disease has been described. Whole exome sequencing in Multiple Myeloma (MM) patient’s tests allowed to know important genes and pathways that are involved in the disease. However, few evidences through next generation sequencing (NGS) analysis were described in AL. Consequently, the application of NGS technologies permits unraveling the genomic landscape of AL to better disentangle the biology of the disease, allowing the identification of new therapeutic targets as in MM.

Aims: Genotype characterization of novel molecular alterations in AL plasma cell by whole-exome sequencing technology.

Methods: We studied 40 paired samples (sorted pathological plasma cells and peripheral blood) from 20 patients with AL. Whole exome and regulatory regions were captured using Agilent’s SureSelect Human All Exon V6+UTR kit and sequenced on the Illumina NextSeq 500 platform with pair-end sequencing technique with a global mean depth coverage of 70x, on target coverage of 95.6% and a Phred quality score of 91.3% up to Q30. Data were analyzed with a custom pipeline and wANNOVAR for functional annotation, and a data reduction strategy to identify candidate variants.

Results: After analysis of patient samples we got an average of 76 (range 18-177) mutations per patient. 28.4% of the mutations was located on regulatory regions (5’ UTR, 3’ UTR). So far, we did not identify recurrent mutations between the patients, although some patients presented different mutations on the same gene.

The mutation pattern was very heterogeneous between patients. We identified alterations in genes involved in extracellular matrix (MMP2), cell proliferation, differentiation and development (TFGA), transcription factors (ZFHX3, HNRP-NPL), adherent junction function (RASSF8), GTPases (RAPGEF2, RAB40A), and genes of the collagenase family (COL9A1, COL1A2) among others.

Summary/Conclusions: Taken together, these results suggest that the mutation pattern in AL is heterogeneous with no common mutated gene among all patients. However, we described novel mutations in the context of AL in regulatory genes or over-representing cancer-related pathways that can help to elucidate the molecular biology of the disease.

IMPROVED SURVIVAL IN 21,465 MULTIPLE MYELOMA PATIENTS: RESULTS FROM A POPULATION-BASED STUDY
S. Thorsteinsdottir1,2, P.W. Dickman1, I. Turesson3, O. Landgren4, M. Hultcrantz5,6, M. Björkholm5, S.Y. Kristinsson1,5

1Department of Internal Medicine, Landsdalst - The National University Hospital of Iceland, Reykjavik, Iceland, 2Department of Medical Epidemiology and Biostatistics, Karolinska Institutet, Stockholm, 3Department of Hematology and Coagulation Disorders, Skane University Hospital, Malmö, Sweden, 4Myeloma Service, Division of Hematologic Oncology, Memorial Sloan-Kettering Cancer Center, New York, United States, 5Department of Medicine, Division of Hematology, Karolinska University Hospital and Karolinska Institutet, Stockholm, 6Department of Medical Epidemiology and Biostatistics, Karolinska Institutet, Stockholm

Background: Multiple myeloma (MM) is generally considered an incurable disease, however advances in the treatment options for MM have been great in recent years. Recent studies on these new agents indicate an improvement in survival, nevertheless population-based studies have had contradicting findings, especially in the elderly patients.

Aims: The aim of the study was to evaluate the survival of all patients diagnosed with MM in Sweden in the years 1973 to 2013 and to relate the survival pattern to trends in treatment strategies.

Methods: Patients diagnosed with MM in the period from January 1, 1973 to December 31, 2013 were identified from the Swedish Cancer Registry. Information on sex, date of birth, date of diagnosis, and date of death was collected. Relative survival ratios (RSRs) were used to provide a measure of excess mortality of MM patients compared to a comparable group from the general population. RSRs with 95% confidence intervals (CIs) were found for 1-, 5-, and 10-year survival for 4 calendar periods: 1973-1982, 1983-1992, 1993-2002, and 2003-2013 and furthermore for 6 age categories at diagnosis (0-40, 41-50, 51-60, 61-70, 71-80 and >80). Short-term survival, as defined by RSR of less than 3 months, was also defined for all calendar periods.

Results: A total of 21,465 patients (54% males, median age at diagnosis 72 years) with MM were recorded in the time period. Overall, the 1- and 5- and 10-year RSRs improved in the whole period, with the greatest improvement in the two most recent calendar periods. The 1-year RSR increased significantly between all calendar periods (0.69, 0.74, 0.77 and 0.82, respectively). The 5-year RSR increased significantly between the two last calendar periods (0.28, 0.31, 0.33 and 0.41, respectively; Figure 1) as well as the 10-year RSR (0.10, 0.12, 0.14 and 0.20, respectively). Short-term survival increased significantly between the first two and last two calendar periods (the RSR were 0.83, 0.88, 0.89 and 0.93 respectively). Females had a lower excess mortality compared to males (excess mortality ratio 0.91).

Figure 1.

Summary/Conclusions: In this population-based study, based on more than 21,000 MM patients diagnosed during more than a 40-year period, we showed that with an increased use of novel agents in MM patients, survival has improved significantly. This is especially prominent during the last 10 years. Our findings are important, since new agents are approved based on clinical trials, where certain groups, such as older patients and patients with significant comorbidities are often excluded.

P331
PROGNOSTIC IMPLICATIONS OF MULTIPLE CYTOGENETIC HIGH-RISK ABNORMALITIES IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA

1Department of Internal Medicine, 2Division of Hematology, 3Department of Laboratory Medicine and Pathology, 4Department of Nephrology and Hypertension, Mayo Clinic, Rochester, United States

Background: Cytogenetic evaluation using fluorescence in situ hybridization (FISH) at the time of diagnosis is essential for initial risk stratification in multiple myeloma. The presence of specific cytogenetic high-risk abnormalities (HRA) is known to confer a poor prognosis, less is known about the cumulative effect of multiple such abnormalities.

Aims: To evaluate the prognostic implications of the presence of multiple HRA at the time of diagnosis.

Methods: We studied 1181 patients who were diagnosed with multiple myeloma between July 2005 and July 2015 at Mayo Clinic Rochester, underwent FISH evaluation within 6 months of diagnosis, and received first-line therapy with at least 1 novel agent (immunomodulator or proteasome inhibitor). HRA were defined as del(17p), t(4;14), t(14;16), t(14;20), del(17p), and gain(1q). Bone marrow aspirates were evaluated for deletions, monosomies, trisomies, and tetracisomies using chromosome- or centromere-specific FISH probes. IGH rearrangements were evaluated using an IGH break-apart probe and evaluating up to 5 potential partners (FOFR3, CCND1, CCND3, MAF, and MAFA). Kaplan-Meier overall survival estimates were calculated and the log-rank test was used to compare overall survival in patients with and without HRA (stratified by the number of HRA). A multivariable-adjusted Cox regression model was used to assess the effect of HRA on overall survival adjusting for age, sex, International Staging System (ISS) stage, and first-line therapy (immunomodulator, proteasome inhibitor, upfront autologous hematopoietic stem cell transplantation). Patients diagnosed after 2014 (approximately 15% of the cohort) routinely underwent evaluation for gain(1q), therefore the hazard ratios represent conservative effect estimates. P-values below 0.05 were considered statistically significant.

Results: The median age at diagnosis was 65 years (28 - 95), 70% (60% of the patients were male. There were 372 HRA in 327 patients (28% of the cohort): 170 (45%) del(17p), 110 (29%) t(4;14), 45 (12%) t(14;16), 8 (2%) t(14;20), and 12 (2%) gain(1q). Of the 280 patients with 1 HRA 130 (46%) had del(17p), 120 (43%) had a high-risk translocation, and 30 (11%) had gain(1q). Of the 46 patients with 2 HRA 34 (76%) had del(17p) and a high-risk translocation, 6 (13%) had a high-risk translocation and gain(1q), 5 (11%) had del(17p) and gain(1q), and 1 had 2 high-risk translocations. There was 1 patient with 3 HRA: del(17p) and t(4;14) and gain(1q). The median overall survival was 6.6 years (6.0 - 8.0) for the entire cohort (n=1181), 8.3 years (6.7 - 8.9) for those without HRA (n=854, 72%), 4.8 years (3.9 - 5.6) for those with one HRA (n=280, 24%), and 2.7 years (2.1 - 3.8) for those with 2 or more (2+) HRA (n=47, 4%). Figure 1 shows the Kaplan-Meier overall survival estimates stratified by the number of HRA (n=1181). The presence of 1 HRA (versus 0, HR 1.57, 95% CI 1.26 - 1.96, p <0.001, n=1181) and the presence of 2+ HRA (versus 1, HR 3.37, 95% CI 2.21 - 5.14, p <0.001, n=1181) were of prognostic significance after adjusting for age, sex, ISS stage, and first-line therapy. When adjusting for the revised ISS instead of the ISS the hazard was attenuated for 1 HRA (versus 0, HR 1.42, 95% CI 1.12 - 1.80, p=0.004, n=1087) and 2+ HRA (versus 1, HR 2.82, 95% CI 1.81 - 4.40, p <0.001, n=1087).

Figure 1.

Summary/Conclusions: Approximately 1 in 4 patients with newly diagnosed multiple myeloma presented with 1 HRA at the time of diagnosis, approximately 1 in 25 with 2 or more HRA. These patients experienced inferior overall survival suggesting a cumulative effect of multiple HRA.
LENLADOMIDE MAINTENANCE VS PLACEBO AFTER STEM CELL TRANSPLANT FOR PATIENTS WITH MULTIPLE MYELOMA: OVERALL SURVIVAL AND PROGRESSION-FREE SURVIVAL AFTER ADJUSTING FOR TREATMENT CROSSOVER IN CALGB

P.L. McCarthy1, 2, S.A. Holstein3, S.-H. Jung3, M. Cooper4, C.J. Gibson5, E.A. Stadmader6, B. Winograd7, P. Richardson7

1Blood and Marrow Transplant Program, Roswell Park Cancer Institute, Buffalo, NY, 2University of Nebraska Medical Center, Omaha, NE, 3Alliance Statistics and Data Center, Duke University, Durham, NC, 4United States, 5BresMed, Sheffield, United Kingdom, 6Cellgene Corporation, Summit, NJ, 7Arambros Cancer Center, University of Pennsylvania, Philadelphia, PA, 8Dana-Farber/Partners CancerCare, Boston, MA, United States

Background: At a prespecified interim analysis (December 2009), the phase 3 CALGB/ECOG 100104 (Alliance) study results surpassed the prespecified superiority boundary (significantly improved progression-free survival [PFS] for lenalidomide [LEN] maintenance vs placebo [PBO] after SCT) and the majority of PBO arm patients without progressive disease (PD) crossed over to LEN maintenance. An updated analysis (cutoff March 2016) showed significantly longer overall survival [OS] with LEN maintenance (HR, 0.56; 95% CI, 0.42-0.76). However, the crossover from PBO to LEN makes it difficult to assess the true treatment effect of LEN.

Aims: To examine the effect of LEN vs PBO on OS and PFS from randomization, adjusting for effects of crossover.

Methods: The rank-preserving structural failure time model (RPSFTM: Robins, Commun Stat Theory Methods, 1991) was used for crossover adjustment; the iterative parameter estimation (IPE; Branson, Stat Med, 2002) algorithm was used as validation. Survival was partitioned assuming a residual LEN effect after discontinuation. A landmark analysis was also performed at the Dec 2009 interim for patients who remained on treatment. Patients in the trial provided informed consent.

Results: Patients were randomized to LEN maintenance (n=231) and PBO (n=229) (intent-to-treat [ITT] population); 76 patients without PD crossed over from PBO to LEN. The median time from randomization to crossover was 11.5 months. The relative treatment effect for OS and PFS increased for LEN vs PBO when adjusting for crossover using RPSFTM and IPE (Table 1). The landmark analysis at the Dec 2009 interim (PBO crossover, n=76; No crossover, n=153) showed the treatment effect is not dissimilar to the ITT analysis (HR 0.53; 95% CI, 0.25-1.13). Sensitivity analyses showed consistent results. Updated data will be presented at the meeting.

Summary/Conclusions: Adjusting for the potential diluting effects of crossover reduced median OS and PFS with PBO, and improved the treatment effect in the ITT analyses for OS and PFS for LEN vs PBO maintenance after SCT. The statistical significance of the ITT analyses was maintained throughout.

P334 Efficacy and Safety of Daratumumab, Lenalidomide, and Dexamethasone Versus Placebo Alone in Relapsed or Refractory Multiple Myeloma: Updated Analysis of POLLUX

M.A. Dimopoulos1, 2, P. Moreau3, H. Nahi4, P. Lescure5, T. Farber/Partners CancerCare, Boston, MA, United States, 3Clinica Universidad de Navarra-CIMA, IDISNA, Pamplona, Spain, 4Chemotherapy, University Hospital Hôtel-Dieu, Nantes, France, 5Karolinska Institute and the Department of Medicine, Karolinska University Hospital at Huddinge, Stockholm, Sweden, 6Veijle Hospital and University of Southern Denmark, Vejle, Denmark, 7University Hospital Heidelberg and German Cancer Research Center, Heidelberg, Germany, 8Japanese Red Cross Medical Center, Department of Hematology, Tokyo, Japan, 9Department of Lymphoma/Hematology, The University of Texas MD Anderson Cancer Center, Houston, United States, 10Department of Haematology, University College London Hospitals NHS Trust, London, United Kingdom, 11Sheba Medical Center, Tel Hashomer, Ramat Gan, Israel, 12Institut Catalá d’Oncologia, HGTIP, Barcelona, Spain, 13Tisch Cancer Institute, Mount Sinai School of Medicine, New York, NY, United States, 14Clinica Universidad de Navarra-CIMA, IDISNA, Pamplona, Spain, 15Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA, 16Levine Cancer Institute/Carolina HealthCare System, Charlotte, NC, 17Janssen Research & Development, LLC, Spring House, PA, United States, 18Janssen Research & Development, Beers, Belgium, 19Tom Baker Cancer Center, University of Calgary, Calgary, Alberta, Canada

Background: Daratumumab, a human monoclonal antibody targeting CD38, significantly prolongs progression-free survival (PFS) and achieves deep and durable responses when combined with other established standard-of-care regimens. In the randomised, phase 3, randoomised study of DRd versus Rd in RRMM.

Aims: To provide updated efficacy and safety data from POLLUX, a multicenter, phase 3, randomized study of DRd versus Rd in RRMM.

Methods: Eligible patients with ≥1 prior line of therapy were randomly assigned to Rd (25 mg PO lenalidomide on Days 1-21 of each 4-week [Q4W] cycle) or DRd (25 mg PO dexamethasone on days 1, 8, 15 and 22 of each 28-day cycle). In both arms, patients received lenalidomide 25 mg PO on days 1, 8, 15, and 22 of every 28-day cycle. RD was assigned on day 1 of each cycle. Patients crossed over to DRd if they discontinued Rd because of progressive disease, grade ≥3 adverse events (AEs) or at investigator discretion. Grade ≤3 AEs were recorded. PFS was the primary endpoint. Safety, tolerability, and efficacy were assessed in all patients who received ≥1 dose of study treatment. Statistical analyses were based on an intent-to-treat (ITT) population.

Results: A total of 361 patients were enrolled and treated at 102 sites in 12 countries. Of these, 211 patients were randomly assigned to the Rd arm and 150 patients to the DRd arm. PFS was superior in the DRd arm compared with the Rd arm (HR, 0.56; 95% CI, 0.41–0.77; P <0.0001). Median PFS in the DRd arm was 22.6 months (95% CI, 20.9–24.0) versus 13.9 months (95% CI, 11.1–15.4) in the Rd arm (HR, 0.56; 95% CI, 0.43–0.74; P <0.0001). Median TTP was 21.6 months (95% CI, 17.6–23.7) in the DRd arm versus 14.6 months (95% CI, 12.8–16.4) in the Rd arm (HR, 0.57; 95% CI, 0.45–0.73; P <0.0001). Overall response rates (ORRs) in the DRd and Rd arms were 61% and 32%, respectively (HR, 0.36; 95% CI, 0.26–0.50; P <0.0001). AEs were more common in the DRd arm than in the Rd arm (67% vs 40%; P <0.0001). The most common AEs were oedema (24% vs 19%), fatigue (23% vs 21%), constipation (18% vs 12%), and infusion-related reaction (13% vs 8%). The most common grade ≥3 AEs were anaemia (9% vs 5%) and neutropenia (8% vs 7%). The majority of patients showed improvement in baseline laboratory values. Summary/Conclusions: Daratumumab plus lenalidomide in combination with low-dose dexamethasone is highly effective and leads to durable responses in patients with RRMM. The drug is well tolerated with a manageable safety profile, and treatment interruption or discontinuation is rare. The quality of life is maintained during treatment.

P332 LENALIDOMIDE MAINTENANCE VS PLACEBO AFTER STEM CELL TRANSPLANT FOR PATIENTS WITH MULTIPLE MYELOMA: OVERALL SURVIVAL AND PROGRESSION-FREE SURVIVAL AFTER ADJUSTING FOR TREATMENT CROSSOVER IN CALGB

P.L. McCarthy1, 2, S.A. Holstein3, S.-H. Jung3, M. Cooper4, C.J. Gibson5, E.A. Stadmader6, B. Winograd7, P. Richardson7

1Blood and Marrow Transplant Program, Roswell Park Cancer Institute, Buffalo, NY, 2University of Nebraska Medical Center, Omaha, NE, 3Alliance Statistics and Data Center, Duke University, Durham, NC, 4United States, 5BresMed, Sheffield, United Kingdom, 6Cellgene Corporation, Summit, NJ, 7Arambros Cancer Center, University of Pennsylvania, Philadelphia, PA, 8Dana-Farber/Partners CancerCare, Boston, MA, United States

Background: At a prespecified interim analysis (December 2009), the phase 3 CALGB/ECOG 100104 (Alliance) study results surpassed the prespecified superiority boundary (significantly improved progression-free survival [PFS] for lenalidomide [LEN] maintenance vs placebo [PBO] after SCT) and the majority of PBO arm patients without progressive disease (PD) crossed over to LEN maintenance. An updated analysis (cutoff March 2016) showed significantly longer overall survival [OS] with LEN maintenance (HR, 0.56; 95% CI, 0.42-0.76). However, the crossover from PBO to LEN makes it difficult to assess the true treatment effect of LEN.

Aims: To examine the effect of LEN vs PBO on OS and PFS from randomization, adjusting for effects of crossover.

Methods: The rank-preserving structural failure time model (RPSFTM: Robins, Commun Stat Theory Methods, 1991) was used for crossover adjustment; the iterative parameter estimation (IPE; Branson, Stat Med, 2002) algorithm was used as validation. Survival was partitioned assuming a residual LEN effect after discontinuation. A landmark analysis was also performed at the Dec 2009 interim for patients who remained on treatment. Patients in the trial provided informed consent.

Results: Patients were randomized to LEN maintenance (n=231) and PBO (n=229) (intent-to-treat [ITT] population); 76 patients without PD crossed over from PBO to LEN. The median time from randomization to crossover was 11.5 months. The relative treatment effect for OS and PFS increased for LEN vs PBO when adjusting for crossover using RPSFTM and IPE (Table 1). The landmark analysis at the Dec 2009 interim (PBO crossover, n=76; No crossover, n=153) showed the treatment effect is not dissimilar to the ITT analysis (HR 0.53; 95% CI, 0.25-1.13). Sensitivity analyses showed consistent results. Updated data will be presented at the meeting.

Summary/Conclusions: Adjusting for the potential diluting effects of crossover reduced median OS and PFS with PBO, and improved the treatment effect in the ITT analyses for OS and PFS for LEN vs PBO maintenance after SCT. The statistical significance of the ITT analyses was maintained throughout.
marrow samples were collected, and minimal residual disease (MRD) was assessed at the time of suspected complete response (CR) and at 3 and 6 months after suspected CR at 3 different sensitivity thresholds (10⁻⁴, 10⁻⁵, and 10⁻⁶) using the ClonoSEQ™ next-generation sequencing-based assay (Adaptive Biotechnologies, Seattle, WA). Additional reflex testing using an anti-idio-
type antibody was used to confirm CRs in cases in which daratumumab inter-
fERENCE with serum M-protein quantitation was suspected in patients with pos-
ible CR.

Results: Patients received a median (range) of 1 (1-11) prior lines of therapy; 55% of patients had received immunomodulatory agents (IMiDs), and 18% had been exposed to lenalidomide. After median follow-up of 17.3 months, DRd sig-
cificantly prolonged PFS compared with Rd alone (median: not reached vs 17.5 months; hazard ratio [HR], 0.37; 95% confidence interval [CI], 0.28-0.50; P<0.0001), with 18-month PFS rates of 76% and 49%, respectively. Responses continued to deepen in the DRd group with longer follow-up, with significantly higher overall response rate (ORR; 93% vs 76%) and rates of very good partial response (vGPR) or better (78% vs 45%) and CR or better (46% vs 20%) with DRd versus Rd alone (P<0.0001 for all), and MRD negativity was associated with prolonged PFS at 10⁻⁵ (Figure 1). Overall survival (OS) data are immature, with 40 (14%) deaths in the DRd group and 56 (20%) deaths in the Rd group (HR, 0.63; 95% CI, 0.42-0.95). Neutropenia was the most common grade 3 or 4 treatment-emergent adverse event (53% with DRd vs 38% with Rd), and no new safety signals were reported with longer follow up. We will present updated efficacy and safety data based on approxi-
ately 25 months follow up at the meeting.

Figure 1.

Summary/Conclusions: DRd significantly improved outcomes compared with Rd alone, including PFS, ORR, depth of response, and MRD-negative rates, with a favorable safety profile that was maintained after longer follow up. These updated data continue to support the use of DRd in patients with RMM who received ≥1 prior therapy.

P335

DARATUMUMAB-BASED COMBINATION REGIMENS IN ELDERLY (≥75 YEARS) PATIENTS WITH RELAPSED OR REFRACTORY MULTIPLE MYELOMA: SUBGROUP ANALYSIS OF THE PHASE 3 CASTOR AND POLLUX STUDIES

1University Hospital of Salamanca/IBSAL, Salamanca, Spain, 2Malignant Haematology and Stem Cell Transplantation Service, Alfred Health-Monash University, Melbourne, Australia, 3Winship Cancer Institute, Emory University, Atlanta, GA, United States, 4Department of Internal Medicine, Hematology and Oncology, University Hospital Brno and Faculty of Medicine Masaryk University, Brno, Czech Republic, 5Universitätsklinikum Tuebingen der Eberhard-Karls-Universität, Abteilung fuer Innere Medizin II, Tuebingen, Germany, 6Department of Experimental, Diagnostic, and Speciality Medicine, University of Bologna, Ravenna, Italy, 7Farber Cancer Institute, Harvard Medical School, Boston, MA, United States, 8St James’s Institute of Oncology, Leeds Teaching Hospitals NHS Trust and University of Leeds, Leeds, United Kingdom, 9Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan, 10Service d’HématoLOGIE et ThéRapie Cellulaire, Hôpital Bretonneau, Centre Hospitalier Régional Universitaire (CHRU), Tours, France, 11Levine Cancer Institute/Carolinas HealthCare System, Charlotte, NC, United States, 12Internal Medicine, Seoul National University Hospital, Seoul, Korea, Republic Of, 13Tom Baker Cancer Center, University of Calgary, Calgary, Alberta, Canada, 14Janssen Research & Development, LLC, Spring House, PA, 15Janssen Research & Development, LLC, Raritan, NJ, United States, 16National and Kapodistriean University of Athens, Athens, Greece

Background: Daratumumab (D) used in combination with bortezomib and dex-
amethasone (Vd; CASTOR) or lenalidomide and dexamethasone (Rd; POLL-
UX) significantly prolongs progression-free survival (PFS) with a manageable safety profile compared with either Vd or Rd alone in patients (pts) with RMM.

Aims: Here in this subgroup analysis we investigated the safety and efficacy of DVD and DRd in elderly pts aged ≥75 years from the CASTOR and POLLUX phase 3 studies.

Methods: Overall, pts enrolled in the CASTOR and POLLUX studies had ≥1 prior line of therapy. Pts in CASTOR received up to 8 cycles of Vd with or without D; pts in the Dvd group then continued to receive D monotherapy q4w until disease progression or unacceptable toxicity. Pts in POLLUX were treated until progression. Dosing schedules for D (16 mg/kg) were different between CASTOR (qw in Cycles 1-3, q3w for Cycles 4-8, q4w thereafter) and POLL-
UX (qw for Cycles 1-2, q2w for Cycles 3-6, and q4w thereafter). All elderly pts received a reduced dose of dexamethasone (20 mg once weekly vs 40 mg once weekly) in both studies.

Results: In CASTOR, 23/251 pts in the Dvd group and 35/247 pts in the Vd group were ≥75 years; the median (range) age for this group of pts was 78 (75-88) and 78 (75-85) years, respectively, with 100% and 94% with an ECOG status ≤1. At a median follow-up of 13.0 months, discontinuation rates due to treatment-emergent adverse events (TEAEs) were similar with Dvd and Vd (15% vs 20%). Common (≥10%) grade 3/4 TEAEs for Dvd were thrombo-
topenia (45% vs 37% with Vd), fatigue (15% vs 11%), pneumonia (15% vs 17%), and anemia (10% vs 11%). Infusion-related reactions (IRR) occurred in 13 (65%) pts, with 10% having grade 3/4 IRR, but no pts discontinued due to IRR. Median PFS was significantly prolonged with Dvd versus Vd (not reached [NR] vs 11.5 months; hazard ratio [HR], 0.27; 95% CI, 0.13-0.56; P=0.0009), consistent with the overall PFS observed in CAS-
TOR (Figure). Higher overall response rate (ORR; 95% vs 79%) and rates of complete response (CR) or better (25% vs 3%) and very good partial response (vGPR) or better (70% vs 18%) were achieved with Dvd versus Vd, respectively, consistent with the overall population. In the POLLUX study, 29/286 pts in the DRd group and 35/283 pts in the Rd group were aged ≥75 years; the median (range) age for this group of pts was 77 (75-89) and 78 (75-87) years, respectively, with 86% and 91% with an ECOG status ≤1. At a median follow-up of 17.3 months, 10% of pts in the DRd group and 11% in the Rd group discontinued due to TEAEs. Common (≥10%) grade 3/4 TEAEs for DRd were neutropenia (45% vs 31% with Rd), hypokalemia (14% vs 3%), and pneumonia (10% vs 11%). D-associated IRR occurred in 12 (41%) pts in the DRd group, with 4 (14%) pts having grade 3/4 IRR. No pt discontinued DRd because of IRR. Median PFS was significantly prolonged with DRd compared with Rd in the elderly subgroup (NR vs 11.4 months; HR, 0.19; 95% CI, 0.06-0.55; P=0.0007), consistent with the overall PFS observed in POLLUX (Figure 1). ORR was higher with DRd versus Rd (93% vs 77%), and rates of CR or better (52% vs 9%) and vGPR or better (72% vs 41%) were also higher with DRd versus Rd.

Figure 1.

Summary/Conclusions: The results in elderly pts were consistent with those observed in the overall study populations in terms of efficacy. Rates of most common grade 3/4 hematologic TEAEs with DRd were similar to that of the overall populations, and IRR were manageable. This subgroup analysis supports the addition of D to standard-of-care regimens in elderly pts with RMM.
ALL ORAL COMBINATION OF IXAZOMIB PLUS THALIDOMIDE AND DEXAMETHASONE FOR RELAPSED OR REFRACTORY MULTIPLE MYELOMA: INTERIM DATA OF AN ONGOING PHASE II TRIAL

H. Ludwig1, 2, W. Poeschky3, S. Knop4, M. Schneider5, D. Lechner6, R. Hajek6, E. Gunsilius7, M. Fridrikh2, A. Petzer8, K. Weisel9, E. Rauch10, R. Greil11, N. Zojer12

Background: Ixazomib is a novel, effective oral proteasome inhibitor with a favorable toxicity profile. Recent studies showed significant activity as single agent with dexamethasone and in combination with other agents. The Tourmaline trial showed superior PFS with ixazomib plus lenalidomide and dexamethasone in pts with relapsed or refractory multiple myeloma (RRMM).

Aims: Here, we evaluate the activity and tolerability of ixazomib plus thalidomide and dexamethasone (IxaThalDex) in pts with RRMM.

Methods: Pts with RRMM and one or more prior lines of therapy (TX) with the following criteria were eligible: Measurable disease, ECOG PS ≤2, ANC ≥1000/µL, platelet count ≥500000µL, GFR ≥15mL/min. Treatment regimen: ixazomib (4mg, d 1, 8, 15), thalidomide (100mg/d), and dexamethasone (40mg, d 1, 8, and 15). Pts aged ≥75 years received lower doses of thalidomide (50mg/d) and of dexamethasone (3mg, d 1, 8, 15). Pts were scheduled for 8 cycles followed by ixazomib maintenance therapy (4mg, days 1, 8, 15 of a 28 cycle and 3mg in pts aged ≥75 years) for one year. Primary objective was PFS, and secondary objectives were ORR, OS, impact of cytogenetic risk and of renal impairment, safety and health related QoL.

Results: Sixty-seven of 77 planned pts have been enrolled so far. The following patient characteristics were recorded in the intent-to-treat group (ITT): median age: 67, range 41 to 84 years, ISS stage I: 28, II: 22, III: 16, not known: 1, median number of prior TX lines: 1 (range: 1-8). 9 pts discontinued TX before completion of 2 cycles. Presently, 5 pts are too early for evaluation per protocol (PP). Full documentation of ≥2 cycles is available for 52 pts, with a median number of 4 cycles and a median FU of 7.4 mos. A PR or better was achieved in 33% (63%), nCR: 2 pts (4%), VGPR: 10 (19%), PR: 21 (40%), MR: 2 (4%), yielding a clinical benefit rate (CBR) of 67%. FISH data are available in 43 of the 52 PP pts. Proteinuria >5 gr/day and eGFR <50 ml/min. Treatment regimen: IxaThalDex (4mg, d 1, 8, 15). Pts in 11/18 (61%) with stage I renal (4; 14) and/or dialysis (17) and in 15/25 (60%) with standard risk cytogenetics. Median PFS at the time of analysis was 10.3 mos., p=0.882) vs 10.4 mos., p=0.061) for progression to dialysis in each cohort (Figure 1).

Summary/Conclusions: The all oral IxaThalDex regimen showed an ORR of 63% with no difference in pts with high-risk cytogenetics, a CBR of 67%, and a PFS of 10.4 mos in pts with RRMM. The regimen was well tolerated and was associated with a low incidence of mainly grade ≥2 PNP, which required dose reduction in one patient only. Response rates improved with continuation of therapy and treatment was associated with an increase in health related QoL.

EVALUATION OF GROWTH DIFFERENTIATION FACTOR-1 (GDF15) AS A NEW BIOMARKER FOR RENAL OUTCOMES IN DIFFERENT COHORTS OF PATIENTS WITH LIGHT CHAIN AMYLOIDOSIS

E. Kastritsis1, 2, I. Papassotiriou2, G. Merlini3, P. Milani3, E. Terpos1, M. Bassetti4, A. Akeleost5, F. Russo6, E. Psimenou5, E. Apostolakou4, M. Roussou1, M. Gavritopoulou1, D. Foliou7, D.C. Zografos1, E. Papadopoulou1, C. Pamboukas1, M.A. Dimopoulos1, G. Palladini2

1Department of Clinical Therapeutics, , National and Kapodistrian University of Athens, 2Department of Clinical Biochemistry, Aghia Sofia Children’s Hospital, Athens, Greece, 3Amyloidosis Research and Treatment Center, Fondazione IRCCS Policlinico San Matteo and University of Pavia, Pavia, Italy, 4Roche diagnostics, 5Department of Clinical Therapeutics, , National and Kapodistrian University of Athens, 6Amyloidosis Research and Treatment Center, Fondazione IRCCS Policlinico San Matteo and University of Pavia, Pavia, Greece

Background: Growth differentiation factor-15 (GDF-15), is a member of the TGF-beta family, and is involved in several pathological conditions, including inflammation, cancer, cardiovascular, pulmonary and renal diseases. Serum GDF-15 levels add prognostic information to conventional prognostic factors, such as NT-proBNP and troponins, in cardiovascular disorders and has also shown to be associated with renal damage and risk of end stage renal disease in patients with diabetes. Increased serum GDF-15 levels have also shown to be correlated with early death and shorter survival independently of other biomarkers and Mayo stage. Because GDF-15 was also associated with renal outcomes we evaluated the prognostic value of GDF-15 levels in two independent cohorts of patients with AL amyloidosis and renal involvement who were treated in two different centers (Pavia Amyloidosis Center and Department of Clinical Therapeutics, Athens).

Aims: To evaluate the prognostic value of GDF-15 levels in independent cohorts of patients with AL amyloidosis and renal involvement.

Methods: Circulating levels of GDF-15 were measured by a novel pre-com- mercial immunoassay (R&D Diagnostics) in stored serum. The Pavia cohort included 135 and the Athens cohort included 76 patients with AL amyloidosis and renal involvement. Standard criteria were used for the diagnosis, evaluation of organ involvement and biomarker-based risk stratification. Renal staging was based on the system proposed by Palladini et al., based on baseline proteinuria >5 gr/day and eGFR <50 ml/min.

Results: Median age and involved FLC levels were similar between the two cohorts. However, heart involvement was more common in Pavia cohort (72% vs 53% p=0.005). Mayo stage disposition was also different (17%, 46% & 37% for stage 1,2 & 3 in Pavia vs 30%, 43% & 27% in Athens cohort, p=0.08, but stage 3B was similar, 13% vs 12%). Also there were differences in peripheral nerve involvement (9% in Pavia vs 21% in Athens cohort, p=0.025). Median eGFR and renal stage distribution (26%, 54%, 20% vs 20%, 54%, 26% for renal stage 1, 2 & 3 respectively) were similar between the two cohorts (p=0.544). Median follow up for the Pavia cohort was 18 months and for the Athens cohort was 45 months (p<0.001). Survival at 2 years was 59% for Pavia and 56% for Athens cohort. Median GDF-15 levels was 3454 pg/mL in Pavia (range 624 to >100000) and 4152 pg/mL (range 626 – 71475) in Athens cohort (p=0.09), while 93% and 94% of patients in the two cohorts had GDF-15 levels >1200 pg/ml (the upper limit of normal for individuals without cardiovascular disease). We then evaluated the prognostic significance regarding renal outcomes (dialysis): GDF-15 >4000 pg/ml was associated with a HR of 6 (95% CI 2015.6, p=0.001) in Athens cohort (progression to dialysis within 2 years in 7% vs 47%); while, by applying the same cutoff in patients in Pavia cohort, 2-year dialysis rate was 10% vs 37% (HR: 3.95, CI 1.6-15, p=0.004). Although renal stage discriminated 3 groups in univariate analysis in each cohort, in multivariate analysis, GDF-15 >4000 pg/mL outperformed renal stage by eGFR and proteinuria and was the only independent prognostic factor for progression to dialysis in each cohort (Figure 1).

Figure 1.

Figure 1.
Summary/Conclusions: Our study validated and confirmed in two independent cohorts, with differences in their characteristics, the prognostic value of GDF-15, which emerges as a novel biomarker with prognostic implications for different outcomes in patients with AL amyloidosis. Importantly, GDF-15 emerges as a strong biomarker for renal outcomes in patients with AL amyloidosis.

P338

AN OPEN-LABEL PHASE 2 STUDY TO EVALUATE THE ORAL COMBINATION OF IXAZOMIB, CYCLOPHOSHAMIDE AND DEXAMETHASONE IN TRANSPLANT-INELIGIBLE PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA

M.A. Dimopoulos1,2, S. Grosicki2, W. Jędrzejczak2, H. Nash3, A. Gruber4, M. Hansson5, C. Byrne5, R. Labokla5, Z. Teng6, H. Yang6, N. Grzasko6, S. Kumar6

1National and Kapodistrian University of Athens School of Medicine, Athens, Greece, 2Silesian Medical University, Katowice, 3Medical University of Warsaw, Warsaw, Poland, 4Karolinska University Hospital, Stockholm, 5Skåne University Hospital, Lund, Sweden, 6Millennium Pharmaceuticals Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, United States.

Background: Proteasome inhibitor (PI)-based combinations are standards of care in all lines of MM therapy. As the treatment paradigm moves to focus more on extended therapy, new combinations are needed that will be efficacious and tolerable, while giving pts the flexibility of taking their treatment at home. Combinations of ixazomib, the first oral PI, with immunomodulatory drugs (IMiDs) are feasible and effective; however, there may be pts for whom the use of IMiDs is not desirable. Therefore, tripleplet combinations of ixazomib with alkylators have been studied.

Aims: This phase 2 study (NCT02046070) evaluated the safety and efficacy of the all-oral ICd regimen in transplant-ineligible pts with NDMM. Primary endpoint was rate of CR+VGPR during induction. Secondary endpoints included tolerability and toxicity, overall response rate (CR+VGPR+PR) throughout treatment, time to response, PFS, and quality of life (QoL).

Methods: Adult pts with NDMM who were transplant-ineligible were randomized (1:1) to receive oral ixazomib 4.0 mg plus oral cyclophosphamide 300 mg/m² (Arm A) or 400 mg/m² (Arm B) on days 1, 8, 15, and 22, for up to 13±28 day cycles as induction. Pts with ≥SD and an acceptable toxicity profile then received single-agent ixazomib maintenance therapy until PD, death, or unacceptable toxicity.

Results: 70 NDMM pts were enrolled (n=36 Arm A; n=34 Arm B); median age 73 years (range 61–87); 47% male; 31%/33%/29% ISS stage I/II/III MM; 50% had a cardiovascular/pulmonary comorbidity; 9% had high-risk cytogenetics (11q;14; t(1;14); 11q;16); 17p). At data cut-off (29 June 2016), pts had received a median of 19 cycles; 66% had completed 13 ICd induction cycles and proceeded to ixazomib maintenance therapy; 10% were ongoing on therapy, and 53% had discontinued due to AE (24%); PD (16%); patient withdrawal (3%); or other reasons (10%). Confirmed responses by investigator assessment are shown in the Table 1. Median time to first/best response across arms was 2/4 months. After a median follow-up of 17.9/18.5 months in Arm A/B, median PFS was not reached. Combined PFS at 12/18/24 months was 81%/66%/59% (24-month PFS 64%/56% for Arm A/B). In Arm A/B, 94%/100% reported AEs; 72%/74% reported grade ≥3 AEs; and 47%/56% reported SAEs. The most common all-grade AEs were neutropenia (22 [31%]), anemia (19 [27%]), diarrhea, nausea, peripheral edema (each 18 [26%]), vomiting (15 [21%]), fatigue, and peripheral neuropathy (each 14 [20%]). The most common grade ≥3 AEs were neutropenia (22 [31%]), anemia (10 [14%]), lower respiratory tract and lung infections (9 [13%]), and supraventricular arrhythmias (5 [7%]). There were 5 on-study deaths, none considered related to treatment. QoL (by EORTC QLQ-C30; Global Health Status) was maintained from baseline during the study.

Summary/Conclusions: Based on this phase 2 study, ICd is an active treatment regimen for pts with NDMM who are ineligible for transplant. This trial captured a population of pts that was elderly and with multiple comorbidities. In this context, the results with ICd, an all-orall triplet including a PI and alkylator, provide evidence of clinical efficacy with a manageable safety profile. With a median follow-up of ~18 months, median PFS was not reached and outcomes appear comparable to other regimens in elderly transplant-ineligible pts with NDMM. The preferred cyclophosphamide dose for ICd phase 3 studies is 300 mg/m², based on the similar PFS, higher response rate, and numerically lower rate of AEs vs 400mg/m². Updated PFS results will be presented at the meeting.

P339

THE ORAL PROTEASOME INHIBITOR IXAZOMIB IN COMBINATION WITH MELPHALAN-PREDNISONE FOR PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA: PHASE 1/2 DOSE-ESCALATION STUDY (NCT01335685)

J. San Miguel1, M.A. Echeveste Gutierrez2, I. Špíčka2, M.-V. Mateos3, K. Song5, M. Craig6, J. Bladé7, R. Hájek8, C. Chen9, N. Gupta10, C. Byrne10, V. Lu10, H. van de Velde10, S. Lonial11

1Clinica Universidad de Navarra, Centro Investigación Médica Aplicada (CIMA) Hospital Universitario Virgen del Rocio, Pamplona, 2Hospital Universitario Donostia, San Sebastián, Spain, 31st Department of Internal Medicine, Division of Hematology, General Faculty Hospital, Charles University, Prague, Czech Republic, 4Hospital Universitario de Salamanca, Instituto Biosanitario de Salamanca (IBSAL), Salamanca, Spain, 5Division of Hematology, University of British Columbia, Vancouver, Canada, 6Department of Medicine, West Virginia University, Morgantown, United States, 7Department of Hematology, Hospital Clínico de Barcelona, Institut d’Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain, 8Department of Haematology, University Hospital Ostrava, Faculty of Medicine, Ostrava University, Ostrava, Czech Republic, 9Cancer Clinical Research Unit, Princess Margaret Cancer Center, Toronto, Canada, 10Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, 11Winship Cancer Institute of Emory University, Atlanta, United States.

Background: Bortezomib-MP is a standard-of-care regimen for elderly NDMM pts. Whereas bortezomib is administered IV or SC, ixazomib is an oral proteasome inhibitor with a safety profile amenable to extended dosing that is approved in the US and EU, in combination with lenalidomide-dexamethasone, for the treatment of MM pts who have received at least 1 prior therapy. Based on the demonstrated feasibility and efficacy of a proteasome inhibitor-MP combination, the all-oral ixazomib-MP (IMP) regimen was evaluated in elderly, transplant-ineligible NDMM pts.

Aims: Primary phase 1 objectives were to determine the safety, MTD, and recommended phase 2 dose (RP2D) of ixazomib in combination with MP. The primary phase 2 objective was to determine the rate of CR+VGPR, secondary objectives included PFS and OS.

Methods: In phase 1, pts were enrolled to 4 arms – Arm A: ixazomib 3.0–3.7 mg (days 1, 4, 8, 11, 22, 25, 29, 32) plus M 9 mg/m² and P 60 mg/m² (days 1–4) in 42-day cycles (max 9 cycles); Arm B: ixazomib 3.0–4.0 mg (days 1, 8, 15) plus M 6 mg/m² and P 60 mg/m² (days 1–4) in 28-day cycles (max 13 cycles); Arm C: ixazomib 3.0–4.0 mg (days 1, 8, 15, 22, 29) plus M 9 mg/m² and P 60 mg/m² (days 1–4) in 42-day cycles (max 9 cycles). In phase 2, an expansion cohort was enrolled at the RP2D. On all arms, after MP induction, pts could receive maintenance with single-agent ixazomib (days 1, 8, 15; 28-day cycles).

Results: 61 pts were enrolled, 11, 34, 11, and 5 to Arms A, B, C, and D (median age 74 yrs; 31% ISS stage III, 56% creatinine clearance ≤60 mL/min). Among
38 DLT-evaluable pts in phase 1, 10 had DLTs of Gr 3 rash (n=2, Arm A), Gr 3-4 thrombocytopenia (n=4, 1 pt in each arm), Gr 3-4 neutropenia (n=1, Arm A; n=4, Arm C, n=1, Arm D), Gr 4 hemorrhagic oesophageal ulcer (n=1, Arm B), Gr 3 ileus/neurogenic bladder (n=1, Arm B), Gr 3 vomiting/diarrhea (n=1, Arm B), and Gr 3 respiratory infection (n=1, Arm C). The RP2D was ixazomib 4.0 mg in Arm B, based on observed rates of toxicity; this cohort was expanded to 26 pts. Among all 61 pts, the median number of treatment cycles was 16; 36 pts (13 at RP2D) completed IMP induction and entered maintenance. Median number of maintenance cycles was 12. The maximum treatment duration was 1841 days (>5 yrs) at RP2D. Five pts remain on treatment (2 at RP2D); primary reasons for discontinuation were disease progression (48%) and adverse events (AEs, 21%). CR+VGPR rate was 43% (43% at RP2D), including 28% (22%) ≥CR and 19% (17%) sCR; median time to first response was 1.7 mos, and responses continued to mature over a long period (Table 1). Depth of response improved during ixazomib maintenance in 9/36 (25%) pts (VGPR to sCR in 5 pts; VGPR to CR in 2 pts; CR to sCR in 2 pts). Median TTP/PFS are shown in Table 1; median OS was not reached after median follow-up of 42.6/46.9 mos overall/at RP2D.

Summary/Conclusions: The RP2D was weekly ixazomib 4.0 mg plus M 6 mg/m² and P 60 mg/m² in 28-day cycles, consistent with the ixazomib dose and schedule in TOURMALINE-MM1. AEs were mainly hematologic, infections, PN, and diarrhea. The all-oral IMP regimen is active in NDMM, with a 28% CR rate (19% sCR), a 43% ≥VGPR rate, and a median PFS of 23.5 mos; responses continued to improve over a prolonged period.

P340 FEASIBILITY AND EFFICACY OF DOSE ADJUSTED MELPHALAN – BORTezOMIB IN PATIENTS ≥75 YEARS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA; PRELIMINARY RESULTS OF THE PHASE II HOVON 123 STUDY

1Hematology, VU University Medical Center, Cancer Center Amsterdam, Amsterdam, 2Internal Medicine, Albert Schweitzer ziekenhuis, Dordrecht, 3Internal Medicine, Meander Medisch Centrum, Amersfoort, 4Internal Medicine, ZMB, Leeuwarden, 5Internal Medicine, Haga Ziekenhuis, Den Haag, 6Internal Medicine, Sint Jans Dal, Harderwijk, 7Internal Medicine, MCA, Alkmaar, 8Internal Medicine, Tergooi ziekenhuizen, Hilversum, 9Internal Medicine, Groene Hart Ziekenhuis, Gouda, 10Internal Medicine, VU University Medical Center, Cancer Center Amsterdam, Amsterdam, 11Hematology, UMCU, Utrecht, 12HOVON Data Center, 13Hematology, Erasmus MCCancer Institute, Rotterdam, Netherlands

Background: There is a high rate of toxicity-related discontinuation in elderly patients with NDMM, negatively affecting outcome. In order to predict feasibility of treatment the IMWG developed the frailty score based on age, (instrumental) Activities of Daily Living and the Charlson comorbidity index.

Methods: Patients were treated with 9 cycles of MPV: Mel 6 mg/m², day 1-4; Pred 30 mg/m², day 1-4; and Bort 1.3 mg/m² day 1,8,15 and 22 of a 35-day cycle. This first planned analysis was restricted to the first 140 consecutive patients out of 240 planned patients.

Results: Of the 139/140 eligible patients none were fit (because of age ≥75 years), 30/139 (22%) were unfit, 100/139 (72%) were frail, and 9/139 (6%) unknown. The median follow up was 17.0 months. The discontinuation rate of MPV in the total population was 42%; 27% in unfit and 46% in frail patients (p=0.09). When also patients were included who discontinued bortezomib only these numbers were 27% in unfit and 52% in frail (p=0.02). Importantly, 6 cycles of MPV were found to be feasible in 70% of patients, both in unfit (80%) and frail (69%) patients. Age >80 years was associated with a significantly higher discontinuation rate of MPV or bortezomib only (70% versus 35% in patients aged 75-80 years, p=0.01). WHO performance was not associated with discontinuation rate. Response on protocol was ≥PR 73%, ≥VGPR 38% and ≥CR 11%, not significantly different in unfit versus frail patients. Response after 6 cycles was ≥PR 69%, ≥VGPR 35% and ≥CR 2%. Median progression free survival (PFS) was 17 months: 20 for unfit and 16 months for frail patients (p=0.13). Overall survival at 18 months was 76%: 89% for unfit and 72% for frail patients (p=0.22). Frail patients were found to have significantly less grip strength and lower walking speed as compared to unfit patients (Table 1).

Table 1.
walking speed and 12% of patients with low grip strength, were not frail. Therefore, functional assessments will hopefully be complementary to the IMWG frailty score in guiding future therapy in unfit and frail patients.

**Material and Methods:**

**Chemotherapy before and after heart transplantation for patients with advanced cardiac amyloidosis**

**Results:**

- **Survival rates for patients with light-chain (AL) amyloidosis are gravely reduced by advanced cardiac involvement at Mayo cardiac stage IV with a median survival of 6.5 months. High-dose Melphalan (HDM) and autologous stem cell transplantation (ASCT) or other intensive chemotherapy regimens cannot be applied to these patients due to the high risk of therapy-related mortality.**

**Aims:**

- Our aim was to examine the cases of cardiac AL patients treated with heart transplantation (HTx) at our center and to evaluate the clinical outcome of this treatment approach.

**Methods:**

- Data from 41 patients (21m, 20f) suffering from cardiac AL who were treated in our hospital between 2002 and 2017 were retrospectively analyzed. All patients were high-urgency listed for orthotopic HTx due to poor prospective of survival. Until 2009, 11 patients were listed, 8 of them with multiple organ involvement. Thereafter, we excluded patients with multiple organ involvement. All data are derived as medians with range or absolute numbers. Survival curves were calculated using the Kaplan-Meier method.

**Results:**

- Median age was 51 years (35-63) at diagnosis. Amyloidogenic lambda light-chains (LC) were detected in 35 and kappa light-chains in 13 patients. Median dFLC was 331 (69 - 2752) and median plasma cells in bone marrow were 13% (5-35). Median NT-proBNP was 6.332 ng/l (1.500 - 53.194), median cTNT 0.11 µg/l (0.01 - 0.52) and median hsTNT was 60 ng/l (28-448) at diagnosis. Median NYHA stage was 3 (2-3) and median MACC 2004 stage was 3 (2-3). Serum creatinine was at 91 (74-106) µmol/l (0.8-1.3), creatinine clearance at 89 (41-106) ml/min. Patients stayed on the high-urgency waiting list for a median of 26 (range 3-54) before 2009, and a median of 64 days (8-259) after 2009. 35 patients were treated with chemotherapy prior to HTx (mostly dex/vor/LoB) to reduce dFLC during the waiting time. Eight patients died before receiving HTx with a median survival (start point: HU listing) of 26 days (6-177). With a median of 5 months after HTx (4-29), 18 patients received ASCT. HDM was used with either 200 mg/m² (N=10) or reduced dosage (N=8) in patients with reduced kidney function (mostly due to renal complications after HTx). Complete remission (CR) was achieved in 7 patients (24% of all treated pts, n=29; 2 patients have not finished treatment yet), very good partial remission (VGR) in 7 patients (21%) and partial remission (PR) in 7 patients (24%). Overall, 25 patients died. Cause of death was either progression of AL (N=16), sepsis (n=4), heart transplant rejection (n=3) or other (n=2). Patients that underwent HTx had a median survival of 46 months (2-177, 1-year survival: 77%).

**Summary/Conclusions:**

- HTx improves symptoms but chemotherapy is a feasible treatment approach in patients with advanced cardiac amyloidosis. Patients who reach HTx have a nearly 50% chance for a very good hematologic remission (VGR or better) and consecutively a favorable survival probability with a median OS of nearly 6 years in our series.
or unacceptable toxicity. Supportive care was allowed; thrombophlebitis was required for all pts on hemodialysis. The primary endpoint was overall response rate (ORR). Key secondary endpoints included safety, renal response, time to myeloma response, time to renal response, duration of response, progression-free survival (PFS), time to progression, and overall survival (OS). All pts provided informed consent.

Results: Enrollment has been completed with 81 pts (33 in cohort A; 34 in cohort B; 14 in cohort C), of which 13 (16.0%) were still on treatment as of January 28, 2017. Median follow-up for OS was 7.8 months. A total of 68 pts (84.0%) discontinued treatment; 39 (48.1%) due to PD. Median age was 72 yrs (range, 52-86 yrs). 60.5% of pts were male, and median time from diagnosis was 3.8 yrs (range, 0.03-19.44 yrs). Pts received a median of 4 (range, 1-10) prior anti-myeloma therapies. All pts had prior treatment with LEN (100%) and nearly all with BORT (97.5%). Median relative dose intensity of POM was 0.94 in both cohorts A and B, and 0.99 in cohort C. ORR was 39.4%, 29.4%, and 14.3% in cohorts A, B, and C respectively. PFS and OS results are presented in the Table 1. Grade 3/4 anemia and thrombocytopenia occurred more frequently in cohort C, likely due to severe RI requiring dialysis (Table 1). AEs leading to dose reductions were 18.2%, 14.7%, and 14.3% in cohorts A, B, and C respectively.

Table 1.

Summary/Conclusions: POM+LoDEX is efficacious in pts with RRMM with moderate or severe RI, including those on hemodialysis, who had more advanced disease due to worse renal function. The safety profile was acceptable among the three groups and no new safety signals were observed. This study demonstrates that POM+LoDEX can be administered in pts with moderate or severe RI, including those on hemodialysis.

P345

ASSESSMENT OF MOBILIZATION COST FOR MULTIPLE MYELOMA USING 2 DIFFERENT STRATEGIES: HIGH-DOSE CYCLOPHOSPHAMIDE VERSUS PLERIXAFOR. ON BEHALF OF IFM

1Maladies du Sang, CHRU Lille, Lille, 2Pôle pharmaceutique, CHU Jean Minjoz, Besançon, 3Hématologie clinique, CHU Dijon Bourgogne, Dijon, 4Hématologie clinique, Hopital de la Pitié-Salpêtrière, Paris, 5Hématologie clinique, Centre Henri Becquerel, Rouen, 6Institut d'hématologie, CHU de Caen, Caen, 7Hématologie, Hôpital Saint-Antoine, Paris, 8Hématologie, CHU de Limoges, Limoges, 9Service d'hémato-logie, Hospices civils de Lyon, Lyon, 10Etablissement Français du Sang, 11Oncologie hématologique et thérapie cellulaire, CHU de Poitiers, Poitiers, 12Institut Universitaire du Cancer-Oncopole, Toulouse, 13Service d'hématologie, CHU de Bordeaux, Bordeaux, 14Service d'hématologie, CHU Jean Minjoz, Besançon, 15Hématologie, CHU Saint-Etienne, Nantes, France

Background: Treatment with autologous transplantation (ASCT) remains the standard of care upfront for Multiple Myeloma patients considered eligible for transplant. Peripheral blood stem cell (PBSC) collection, also called mobilisation, is needed prior to ASCT. The optimal methodology for mobilizing PBSC has yet to be defined, with either G-CSF alone, also called steady state procedure, or use of Plerixafor, a CXCR4 antagonist (Mozobil®)-G-CSF or high dose cyclophosphamide (usually administered at a dose of 1.5 to 6g/m² IV for 1 day) is commonly used. The most recent induction regimens, and the 2 latter have demonstrated similar PBSC collection rates. Because of the intense competition for hospital resources and the staff required to manage patients preparing for mobilization and transplantation, it is important to quantify the total impact of mobilization on staff resource and ward budget at the hospital.

Aims: We aimed at better evaluate the respective cost of the 2 techniques of mobilization for the French health care system, high dose cyclophosphamide (n=57) versus plerixafor (n=55).

Methods: This is an observational cohort database analysis of 112 consecutive patients with MM treated upfront with ASCT between 2009 and 2013 and that had been mobilized with either high dose cyclophosphamide or plerixafor from 15 IFM centers. Patients must have successfully underwent ASCT. This study was not aimed at evaluating the suitability or advisability of one therapy versus another. A cost-consequences analysis of the different regimens of mobilization was performed. ECONOTE-023 (NCT01953692) is a multicohort phase 1b study of pembrolizumab monotherapy in patients with hematologic malignancies; results are reported for patients with RRMM.
DISCUSSION.

The point of view of the French Public Health System is adopted for this study. Monetary values for 2012 euros prices will be used for all components.

Results: Median (range) age was 59.5 (24-72), sex ratio was 1.5, ISS 3 was 26% in either group, all patients were collected to allow the number of graft requested by the hematologist of reference. The median CD34 collected was 8.9 (4-30) for HD cyclophosphamide and 5.3 (2-15) for plerixafor. The analysis demonstrated that days in the hospital were the primary cause for cost difference across the 2 mobilization techniques. In that regards, plerixafor appeared very cost effective compared to HD cyclophosphamide. All data will be updated at EHA 2017 including cost comparison.

Summary/Conclusions: For a long time HD cyclophosphamide was recommended for mobilization upfront in Myeloma therapy, as it was needed to improve response rate and depth of response, despite only 10% of the patients improving. With the progress made recently with the induction regimens, the choice for the mobilization regimen is now based more on safety and cost saving. In that regards, one must acknowledge that plerixafor has become one, if not the, most attractive option for Myeloma.

P347

A STUDY OF UTILITY OR FUTILITY OF PERFORMING SKELETAL SURVEYS IN PARAPROTEINAEMIA: A MULTICENTER EXPERIENCE

O. Gamage1,*, M. Zaw1, S. Gurung1, G. Pratt2, S. Shafeek3, A. Macwhanenell, S. Lee1, S. Basu1

1Department of clinical Haematology, Royal Wolverhampton NHS Trust, Wolverhampton, 2Department of Haematology, University Hospital, Birmingham, UK, Birmingham, 3Department of Haematology, Worcestershire Acute Hospital Trust, Worcester, United Kingdom

Background: Recent International Myeloma Working Group (IMWG) guidelines recommend that conventional skeletal surveys should be supplanted by low dose whole body computed tomography (CT), whole body magnetic resonance imaging (MRI) and or 18fluoro-deoxyglucose (18F-FDG/CT) PET. However, resource, funding and radiology capacity issues, have posed significant challenges to implementing these recommendations. The risk of progression of Monoclonal Gammopathy of Undetermined Significance (MGUS) to a neoplastic plasma cell disorder is approximately 1% per year2 and even lower in low risk MGUS. It is thus not necessary to perform imaging in unselected MGUS patients.

Aims: To look at all skeletal surveys requested across 3 large hospitals in UK over a year and analyze their justification, effectiveness and utility.

To decide if a rational clinic–biochemical algorithm could be used to reduce the number of imaging requests, thereby avoiding unnecessary radiation exposure, and make a possible switch to modern imaging methods cost effective.

Methods: A total of 397 skeletal surveys were performed across three hospitals over one year. The data set was analyzed for clinical indications, paraprotein level, rationale for requesting the skeletal survey, the diagnostic yield and also the number follow up CT/PET or MRI required.

A pragmatic algorithm was developed and applied to see if the requests were justified and could have been safely reduced. (Figure 1).

Results: Of the 397 analyzable skeletal surveys performed, 266 were on myeloma, 81 for MUGS, 48 were for non-paraprotein related indications. Of the 266 myelomas, 30% of skeletal surveys were reported as positive according to IMWG criteria3. A detailed analysis of 130 myeloma patients revealed a significant proportion of false negatives (6%) and false positives (7%), highlighting the insensitivity and poor specificity of this imaging modality. More importantly more than a third (38%) of myeloma patients required follow up imaging with MRI, PET or WBLCCT irrespective of the initial skeletal survey result, indicating a significant duplication rate and waste of resources. In the MGUS group, majority of skeletal surveys were negative (91%) but 9% were reported as positive. Follow up imaging with CT and MRI was performed in 23% of the MGUS group. However none these were positive. When the clinic-biochemical algorithm was applied, the number of requests was reduced by at least a quarter (24%), avoiding unnecessary radiation exposure and precious resources.

Figure 1.

Summary/Conclusions: - Skeletal survey has very limited role in investigation of paraproteinemia and should be abandoned. - Our pragmatic clinic-biochemical imaging algorithm reduced imaging requests significantly (24%) allowing the preferred imaging modalities to be performed productively in a cost effective way in face of ever increasing health care cost and demands.

P348

SERUM FLC MEASUREMENTS COMPLEMENT BONE MARROW ASSESSMENT TO DETERMINE PROGNOSIS IN MYELOMA PATIENTS ACHIEVING DEEP RESPONSES

T. Dejoie1,*, M. Attia2, P. Moreau3, H. Avet-Loiseau4

1Biochemistry Laboratory, Centre Hospitalier Universitaire-Nantes, Nantes, 2Institut Universitaire du Cancer-Oncopole, Toulouse, 3Department of Hema-

Summary/Conclusions: - Serum FLC measurements complement bone marrow assessment to determine prognosis in myeloma patients achieving deep responses.

Figure 1.
Background: In multiple myeloma (MM), abnormal serum free light chain ratios (FLCr) after therapy associate with poor prognosis, independent of depth of response. However the value of FLCr in the context of minimal residual disease (MRD) remains unclear. A proportion of MRD-negative patients experience early relapses and conversely, some MRD-positive patients can endure long-term survival; which may result from improved immunosurveillance following normal plasma-cell recovery.

Aims: We hypothesised that serum FLC levels and ratios add clinical value at the time of MRD assessment.

Methods: The study included 275 intact immunoglobulin MM patients from the IFM2009 clinical trial who achieved at least a very good partial response (VGPR) after consolidation therapy. Median PFS from the end of consolidation was 38.3 months; median OS was not reached. Serum FLCs were measured using Freelite immunoassays (The Binding Site). Normal range for k/l FLCr was 0.26-1.25. We defined immunosuppression as levels of both the uninvolved (polyclonal) FLC+uninvolved heavy+light chain (HLC; measured with Helyxite) below their normal range. MRD assessment in bone marrow samples was based on 4-colour multiparametric flow cytometry (MFC).

Results: At the end of consolidation, 79/275 (29%) patients were MRD-positive, 79/275 (29%) had abnormal FLCr, 16/275 (6%) had elevated iFLC, with immunosuppression identified in 52/275 (19%). Using Cox regression all the variables associated with shorter PFS (p<0.001 for all) and OS (p<0.050 for all; except elevated iFLC which showed a trend towards shorter OS (p=0.070)). Among 363 MRD-negative patients, 37/196 (19%) had abnormal FLCr, 2/196 (1%) had elevated iFLC with immunosuppression identified in 23/196 (12%), Median PFS for MRD-negative patients was not reached; however both an abnormal FLCr (median PFS: 31.4 months; p<0.001) and immunosuppression (median PFS: 31.4 months; p=0.005) identified a group of patients with poorer outcomes. On the other hand, median PFS for MRD-positive patients was 21.3 months; 42(63%) of these patients had abnormal FLCr and dismal outcomes (median PFS 12.6 vs 30.7 months for abnormal vs normal FLCr, respectively; p=0.004). Absolute FLC measurements did not reach statistical significance for PFS in these patients.

Summary/Conclusions: Serum FLC measurements in combination with low-sensitivity MFC bone marrow assessment at the end of consolidation therapy render the most powerful prognostic information in MM patients achieving deep responses. In those where disease is no longer detected using MFC, abnormal FLCr confer poor prognosis, which may partly be due to inefficient immune recovery. Absolute FLC measurements were not informative, supporting the rationale of evaluating biomarkers of the tumour and immune system recovery. Our results warrant further studies to validate the clinical utility of FLC measurements in combination with next-generation (8-colours) flow cytometry.

P349
THE CONNECT MM REGISTRY: IMPACT OF THE CYTOGENETIC ABNORMALITY T(11;14) ON SURVIVAL OUTCOMES IN AFRICAN AMERICAN AND NON-AFRICAN AMERICAN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA
1Duke University Medical Center, Durham, 2Indiana University Simon Cancer Center, Indianapolis, 3Mount Sinai Hospital, New York, 4Cedars-Sinai Samuel Oschin Cancer Center, Los Angeles, 5MD Anderson Cancer Center, Houston, 6US Oncology Research, Maryland Oncology Hematology, Columbia, 7Providence Cancer Institute, Southfield, 8Steeplechase Cancer Center, Somerville, 9University of South Carolina, Columbia, 10Wake Forest University School of Medicine, Winston-Salem, 11Celgene Corporation, Summit, 12US Oncology Research, Rocky Mountain Cancer Centers, Denver, United States

Background: The cytogenetic abnormality t(11;14) is common, occurring in approximately 20% of patients with newly diagnosed multiple myeloma (NDMM) (Avet-Loiseau, Leukemia, 2013). Historically, t(11;14) has been associated with standard-risk multiple myeloma (MM) and generally favorable outcomes (Avet-Loiseau, Leukemia, 2013). However, some recent retrospective analyses have reported the presence of t(11;14) to be a poor prognostic factor (Kaufman, Leukemia, 2016). Connect MM is a largely community-based, US prospective observational cohort study that collects data on management and natural history of patients with NDMM in clinical practice.

Aims: This analysis assessed the impact of t(11;14) on survival outcomes in African American and non-African American patients in a mostly community-based setting.

Methods: Adult patients with NDMM within 60 days of diagnosis were eligible for enrollment in the registry. Patients who completed induction and were tested for t(11;14) by fluorescence in situ hybridization or cytogenetics were grouped by race (African American and non-African American). Endpoints were progression-free survival (PFS) and overall survival (OS). Kaplan-Meier analyses were adjusted for cohort, age, International Staging System stage, transplant intent, presence of (14/14), diabetes history, and baseline levels of hemoglobin, platelets, calcium, and creatinine. Data cut off was Jul 7, 2016.

Results: 3011 patients were enrolled in 2 cohorts. Cohort 1 enrolled 1493 patients from Sep 2009–Dec 2011; median follow-up was 39.3 months. Cohort 2 enrolled 1518 patients from Dec 2012–Apr 2016; median follow-up was 16.4 months. A total of 1539 (52%) patients were tested for t(11;14). Of these, 363 (24%) were positive for t(11;14). By race, 53 (26%) of 205 African American and 310 (23%) of 1334 non-African American patients were positive for t(11;14). First-line bortezomib exposure was similar across all groups. In African American patients, the presence of t(11;14) resulted in a trend toward shorter PFS compared to those without t(11;14) (Table 1). Additionally, African American patients with t(11;14) had significantly higher risk of death compared to African American patients without t(11;14). A higher rate of early mortality was observed vs non-African American patients. In non-African American patients, no differences in PFS or OS were noted based on the presence or absence of t(11;14). For OS, the interaction between race and t(11;14) status was statistically insignificant (P=0.004).

RAS-PATHWAY MUTATION PATTERNS DEFINE EPIGENETIC SUBCLASSES IN JUVENILE MYELOMONOCYTIC LEUKEMIA

IN JUVENILE MYELOMONOCYTIC LEUKEMIA

RAS-PATHWAY MUTATION PATTERNS DEFINE EPIGENETIC SUBCLASSES IN JUVENILE MYELOMONOCYTIC LEUKEMIA

Background: Juvenile myelomonocytic leukemia (JMML) is an aggressive myeloproliferative disorder of early childhood. While some cases show spontaneous remission, allelogenic hematopoietic stem cell transplantation (HSCT) remains the only curative treatment option for the majority of patients, however, the 5-year event-free survival reaches only about 50%. Hyperactive RAS signaling is assumed to be the main driving event in JMML. It is caused by genetic alterations in \( CBL, KRAS, NFI, NRAS, \) or \( PTPN11 \) in about 90% of patients. So far, there is no clear understanding of how RAS pathway mutations relate to the heterogeneous disease biology and variable clinical outcome seen in JMML patients. As a consequence, established clinical and genetic markers fail to fully represent the observed disease heterogeneity. 

Aims: We hypothesized that DNA methylation profiling, either alone or in combination with genetic alterations, might provide a molecular basis for disease classification.

Methods: Genome-wide DNA methylation analysis using the HumanMethylation450 BeadChip was performed in a discovery cohort of 20 JMML patients. We developed a strategy to eliminate methylation events that attribute to epigenetic changes in normal hematopoiesis. The clinical relevance of our findings was assessed in an unselected sample set consisting of 148 consecutive patients with JMML (n=130) or Noonan syndrome associated myeloproliferative disorders (n=18) in the validation cohort.

Results: Systematic DNA methylation analysis of JMML samples identified three subgroups with low, intermediate and high methylation levels (LM, IM, and HM). Detailed analysis of the validation cohort not excluding the Noonan patients identified an association of methylation groups with clinical features. The HM subgroup (n=41) enriched for high-risk characteristics: All HM cases had elevated levels of HbF, 88% were older than 2 years at diagnosis, 74% had low platelets (<70/nl), and 66% carried somatic mutations. Within the whole cohort of 781 SMF patients, 376 had cytogenetic abnormalities. In addition, prognostic relevance of different cytogenetic patterns is investigated.

Methods: Diagnosis of SMF was performed according to the IWG-MRT criteria (2008). The MYSEC study was approved by the Review Board of each Institution and performed in accordance with the Declaration of Helsinki. All cytogenetic analysis was made at time of SMF diagnosis and considered evaluable if at least 20 metaphases were available. Results were described according to the International System for Human Cytogenetic Nomenclature. Karyotype was defined as normal if a structural or numeric chromosomal alteration was present in at least two metaphases. The presence of three or more abnormalities defined a complex karyotype; two or more distinct autosomal monosomies or single autosomal monosomy associated with at least one structural abnormality defined minimal karyotype (MK). Continuous values were compared via non-parametric Mann-Whitney U tests, with Holm corrections for multiple testing; categoric data were compared with Fisher’s exact test. Time-to-event analysis used Kaplan-Meier estimators and Cox models for regression.

Results: Within the whole cohort of 781 SMF patients, 376 had cytogenetic data. Cytogenetic abnormalities were reported in 128 (34.1%) cases: 72 (60%) were sole, 22 (18.3%) double, 26 (21.7%) complex, 11 (9.2%) MK (all included in complex karyotype) and eight unbalanced. The median number of individual abnormalities were 20p (25%), 13q (20.8%), +8 (8.3%) and +9 (5.6%). Patients with post-PV MF had significantly higher frequency of abnormal karyotypes than those with post-ET MF (P<0.012). Chromosomal abnormalities did not cluster differently among the different genotypes (JAK2, CALR, MPL and triple negativity). Abnormal karyotype was significantly associated with lower platelet count (P=0.004), larger spleen size (P=0.016), higher circulating blasts (P<0.001) and presence of constitutional symptoms (P=0.014) at the time of SMF diagnosis. Within abnormal karyotypes, we found that patients with MK tended to have lower platelet count (P=0.04) with respect to those with sole aberrations. Overall survival in patients with pure MK was significantly worse compared to patients with only structural abnormalities (P=0.012), even adjusting for SMF diagnosis type (P=0.02). When assessing OS according to different abnormalities, we found that patients with MK have inferior OS than those with sole abnormality (P<0.0001).
was 70 years (21-89). Median (range) values for leukocytes, neutrophils, hemo-
globin, platelets and bone marrow blast percentage at the time of sample collection 
for sequencing were 13.4 (1-179) x 10^9/L, 7.9 (0.4-152.4) x 10^9/L, 9.1 (3.1-15) 
g/dL, 123 (6-1168) x 10^9/L and 2% (0-17), respectively. On univariate analysis 
(n=97), only the presence of EZH2 and ZRSR2 mutations were associated with 
trends towards statistical significance for survival. Mutated EZH2 adversely 
affected survival (p=0.089) and mutated ZRSR2 resulted in a comparable impact on survival (p=0.074). The IPSS-R for MDS was useful to differentiate between 
risk groups with different survival times (p=0.065) while the dynamic IPSS for 
PMF (Passamonti et al. Blood 2010) was not (p=0.39). On multivariate analysis, 
only EZH2 mutations and IPSS-R very low risk (versus all other categories 
combine) were statistically significantly associated with inferior and superior 
overall survival, respectively.

Summary/Conclusions: In this cohort of 97 patients with WHO-defined 
MDS/MPN-U, mutations in genes encoding epigenetic regulators (e.g., TET2, 
ASXL1, EZH2), spliceosome components (e.g., SRSF2, SF3B1, ZRSR2, 
U2AF1) and cell signaling molecules (JAK2, KRAS, NRAS, BRAF), thylases (FABP3, 
FPN1), the transcription factor RUNX1, and the nuclear receptor SETBP1 were at frequencies ≥10%. Although the analysis is limited by small numbers, EZH2 mutations were independently associated with poor 
overall survival. This represents the largest cohort of patients with MDS/MPN-U inter-
rogated for mutations in multiple genes to date.

P532
MUTATIONAL LANDSCAPE OF MYELODYSPLASTIC SYNDROME/ 
MYELOPROLIFERATIVE NEOPLASM - UNCLASSIFIABLE
P. Bosel1, A. Nazhra2, R. Komorjki3, M. Savona4, K. Patel5, S. Pierce1, N. Al Al6, A. Sochacki7, A. Shaver8, N. Daven9, C. DiNardo10, G. Garcia-
Manero11, C. Bueso-Ramos12, H. Kantarjian13, M. Sekeres14, J. Maciejewski15, 
1Leukemia, University of Texas MD Anderson Cancer Center, Houston, 2Hematology and Medical Oncology, Cleveland Clinic, Cleveland, 3Malignant Hema-
tology, Moffit Cancer Center, Tampa, 4Medicine, Vanderbilt University/Vanderbilt-
Ingram Cancer Center, Nashville, 5Hematopathology, University of Texas MD 
Anderson Cancer Center, Houston, 6Hematopathology, Vanderbilt University/
Vanderbilt-Ingram Cancer Center, Nashville, 7Translational Hematology and 
Oncology, Cleveland Clinic, Cleveland, 8United States, 9Cardiology, Vanderbilt University, 
10Blood and Marrow Transplantation, MD Anderson Cancer Center, 11Hematology, 
12Hematopathology, MD Anderson Cancer Center, 13MD Anderson Cancer (MDACC, DiNardo 
et al. Blood 2014). The International 
Prognostic Scoring System (IPSS) for MDS (Greenberg et al. Blood 1997) dis-
criminated amongst prognostically distinct categories in that cohort, while nei-
ther the IPSS for primary myelofibrosis (PMF, Cervantes et al. Blood 2009) nor
the revised IPSS (IPSS-R for MDS (Greenberg et al. Blood 2012) did. Median 
survival of 21.4 months from the time of diagnosis was reported in a multi-institu-
landscape of MDS/MPN-U is limited to one report on the frequency of SETBP1 
mutations (8.3%, Meggendorfer et al. Leukemia 2013).

Aims: To describe the mutational landscape of MDS/MPN-U using targeted 
multi-gene sequencing.
Methods: Targeted sequencing was performed on DNA from 97 patients with MDS/MPN-U (diagnosed per WHO 2008 criteria but excluding refractory anemia with ringed sideroblasts and thrombocytemia) seen across 4 US institutions (MDACC, 43; Cleveland Clinic, 29; Moffit Cancer Center, 16; Vanderbilt Univer-
sity, 9). Gene panels varied among institutions, with 20 genes (ASXL1, CBL, 
DNMT3A, ETV6, EZH2, IDH1, IDH2, JAK2, KIT, NPM1, NRAS, PHF6, 
RUNX1, SETBP1, SF3B1, SRSF2, TET2, TP53, U2AF1, ZRSR2) in common.

Results: Mutational frequencies for the 20 genes tested in all 97 patients were 
as follows: TET2, 28%; ASXL1, 27%; JAK2, 25%; SRSF2, 22%; EZH2, 15%; 
SF3B1, 12%; RUNX1, 12%; ZRSR2, 11%; SETBP1, 11%; U2AF1, 11%; NRAS, 10%; 
DNMT3A, 9%; TP53, 8%; CBL, 4%; ETV6, 4%; NPM1, 4%; IDH2, 2%; 
KIT, 2%; PHF6, 1% and IDH1, 0%. In addition, the frequency of mutations in 
eten other genes of interest in hematologic malignancies was assessed: BRAF, 
0% (n=52); CSF3R, 4% (n=52); CALR, 4% (n=53); MPL, 3% (n=88); MLL, 1% (n=52); 
TLK, 8% (n=72); CEBPA, 4% (n=73); KRAS, 4% (n=81); PTPN11, 4% (n=82) and 
FLT3, 2% (n=82). Median survival for the whole cohort (n=97) was 
12.4 months (range, 1-173). The 43 MDACC patients in this analysis were 
included in the cohort of 85 previously reported by DiNardo et al. Median age

Figure 1.
Summary/Conclusions: Abnormal karyotype was found in 34.1% of SMF 
patients at diagnosis and was over-represented in post-PMF MF. No different 
distribution was detected among genotypes. Abnormal karyotype was associ-
ated with lower platelet count, larger spleenomegaly, higher circulating blast 
cells and presence of constitutional symptoms. Concerning outcome, the pres-
ence of abnormal karyotype implied inferior survival and, among subtypes, MK 
remained the most powerful predictor.

cent Medicine, Division of Pediatric Hematology and Oncology, Medical Center, University of Freiburg, Freiburg, Germany

Background: Juvenile myelomonocytic leukemia (JMML) is a myeloprolifera-
tive disorder of childhood that is initiated by mutations in the Ras pathway.
In outcomes this disease vary dramatically from resolution with minimal or no 
therapy to relapse despite hematopoietic stem cell transplantation. Identifying 
biomarkers to distinguish patients with aggressive disease courses from those 
who can receive minimal therapy remains a priority for clinicians.

Aims: We utilized an unbiased screening approach to investigate genome-
wide DNA methylation in newly diagnosed JMML patients. We then sought to 
determine whether a specific DNA methylation signature was capable of pre-
dicting outcomes in this heterogeneous disease, with a particular emphasis on 
identifying a biomarker predictive of spontaneous resolution.

Methods: Genome wide DNA methylation analysis was carried out using the 
Illumina 450k BeadChip platform in a discovery cohort of 39 well-character-
ized patients with JMML enriched for those who experienced spontaneous 
resolution without chemotherapy. A separate cohort of 40 patients with JMML 
was recruited for validation. Of note, patients with Noonan syndrome were 
excluded from both cohorts. All 79 patients were then compared to 22 healthy 
controls between 1 and 5 years of age using peripheral blood derived DNA.

Results: JMML patients with aggressive disease have a distinctly hyperme-
thylated DNA profile at the most variable CpG sites compared to patients 
with less aggressive disease as well as healthy controls. Methylation patterns 
did not differ based on the tissue of origin (peripheral blood, splenic tissue, 
or bone marrow) and were similar between monocyte enriched cell popula-
tions and unsorted monocellular cells. Unsupervised clustering of the dis-
covery cohort based on the most highly variable CpG sites (top 0.5% ranked 
significance) led to the identification of three clusters (top 6%). Patients 
in the cluster with the lowest levels of methylation, only one patient out of 15 
(7%) had an event at 4 years (95% confidence interval [CI], 2-32%). This 
compared to 45% (5/11) (CI, 17-77%) for patients in the cluster of interme-
diate levels of methylation and 61% (8/13) (CI, 32-86%) in those patients 
with the highest level of methylation. The proportion of patients with events 
differed significantly by cluster (p=0.0039) and remained independently prognostic 
in multivariable analysis (p=0.033) in the context of age and the number of 
somatic mutations at diagnosis. We next sought to validate our findings in 
an independent cohort of 40 patients. We classified each patient in the validation 
cohort into one of the three clusters defined by the discovery cohort. The 
proportion of patients having an event at four years was 8% (1/12) (CI, 0- 
38%) in those with the lowest level of methylation. This compared to 36% 
(4/11) (CI, 11-69%) for patients with intermediate levels of methylation and 
76% (13/17) (CI, 50-93%) for those with the highest levels of methylation. 
We then compared our combined cohort of 79 JMML patients with 22 healthy, age-appropriate controls. Remarkably, using the same set of CpG sites 
defined in the discovery cohort, 27/79 JMML patients clustered more closely 
with the controls than with other patients. Of these 27 patients, 14 (52%
LEUKEMIC TRANSFORMATION OF MYELOPROLIFERATIVE NEOPLASMS: IS NSS PROFILE THE BEST PROGNOSTIC BIOMARKER?

V. Geoffroy1,2, F. Courtiert2, A. Charbonnier 1, E. D’Incan1, C. Sailliard1, B. Mohy1, D. Birmbaum2, M.-J. Mozziconacci1, A. Murati1, N. Vey1, J. Rey1

1Hematology - Leukemia Department, 2CRCM, 3Biopathology Department, Institut Paoli Calmettes, Marseille, France

Background: Leukemic transformation occurs in 8% to 23% of myelofibrosis patients in the first 10 years after diagnosis and in 4% to 8% of polycythemia vera and essential thrombocythemia patients within 18 years of diagnosis and is usually fatal.

Aims: We retrospectively analyzed the survival outcome of patients with myeloproliferative neoplasms (MPNs) who progressed to acute myeloid leukemia (AML) based on the treatments received, response, different prognosis groups according to the (ELN) and based on a next-generation DNA sequencing profile (NGS).

Methods: A total of 72 patients diagnosed in our institute with IAML secondary to MPNs between 2000 and 2016 were retrospectively analyzed. NGS was performed in 44 cases. Mutations found by NGS were classified according three different categories of interest (Tumors suppressor (TP53), ADHPR44, and epigenetic (DNMT3A, EZH2,H3K27/12/1/ASHXL) and alternative splicing (SRS2F2/2A2AF1, ZRS2R,PRP8,F3B3)) and three groups were determined: Group A: patients without altered cellular function; Group B: patient with one altered function; Group C: patients with more than one altered functions. AML treatment response was evaluated according Mascarenhas’ proposed criteria for response assessment of AML secondary to MPNs. Overall survival (OS) was calculated according the different treatments, treatment response and NGS profiles.

Results: 72 patients who developed AML secondary to MPNs were included in the study: 43.6% (N=31) had prior ET, 25% (N=18) PV, 20.8% (N=15) PMF and 11.1% (N=8) secondary myelofibrosis. The median age at AML transformation was 70 (range: 38-89) years. The median time to AML transformation from MPNs diagnosis was 108 months (range: 2.4-408). Among these 72 AML, 5.6% (N=4) belonged to the favorable risk category according to ELN 2017. 13.9% (N=10) belonged to the intermediate risk category and 55.6% (N=40) to the adverse risk category. 45.8% (N=33) patients were treated with intensive chemotherapy (IC), 15.3% (N=11) with azacitidine (AZA) and 38.9 (N=28) with supportive care (BSC). Median OS was 4.5 months (range, 0.1-65), with no significant difference between the three ELN 2017 risk categories (respectively 2.5 months (range: 1-9), 5.5 months (range: 1-60) and 5 months (range: 1-36) in the favorable, intermediate and adverse risk categories). Patients who received IC (p<0.01) or AZA (p<0.05) have a significant better OS (median OS of 7 months (range: 0.5-65) and 8.5 months (range: 3-24) respectively) than patients who received BSC (median OS of 2 months, range: 0.1-36). However, there was not a significant difference between the IC and HMA groups (p=0.44). 7 Patients in Complete Cytogenetic Response (CCR) or Acute Leukemia Response-Complete (ALR-C) received an alloSCT had a better median OS than the 9 patients who did not (23 vs 6.5 months, p=0.063). Patients with group A and B NGS profiles have a significant better median OS (respectively 14 and 8 months) than Group C (3 months) (p<0.05).

Summary/Conclusions: Our results confirm the poor outcome of patients with secondary AML treated with IC and suggest that AZA provides comparable OS. ELN2017 risk stratification predicted poorly patients outcome although a NGS-based classification performed better.

INCIDENCE AND OUTCOME OF SECONDARY NON HEMATOLOGICAL CANCERS IN ADULT PATIENTS WITH MASTOCYTOSIS

M. Bonifacio1,2, P. Bonadonna1, C. Elena4,5, L. Pieri6, F.I. Grifoni6, C. Papayannidis6, M. Rondoni10, L. Scaffidi1,2, F. Resci2, L. Malcovati4,5, E. Bono5, F. Mannelli6,7, M. Sciumè8, G. 1Hematology - Leukemia Department, 2CRCM, 3Biopathology Department, Fondazione IRCCS Policlinico San Matteo, 5Department of Molecular Medicine, University of Pavia, Pavia, 6CRIMM-Center of Research and Innovation of Myeloproliferative Neoplasms, Azienda Ospedaliero-Universitaria Careggi, 7Department of Experimental and Clinical Medicine, University of Florence, Florence, 8Oncohematology Unit, Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Milan, 9IDMES-Department of Experimental, Diagnostic and Specialty Medicine, University of Bologna, Bologna, 10Hematology Unit, Santa Maria delle Croci Hospital, Ravenna, Italy

Background: Mastocytosis is a clonal disease characterized by heterogeneous manifestations and a normal life expectancy in the majority of cases. In such a condition, it is important to ascertain if other diseases, and particularly solid malignancies, can worsen the prognosis.

Aims: To assess incidence and outcome of secondary primary malignancies (SPM) in adult mastocytosis patients.

Methods: We performed a retrospective analysis of 826 adult (>18 years at diagnosis) mastocytosis patients diagnosed and regularly followed in 6 Italian Institutions. SPM were defined as de novo cancers diagnosed after mastocytosis. We excluded from the analysis non-melanoma skin cancers due to the possible under-reporting of such neoplasms by patients themselves. Also, we did not consider newly hematological neoplasms, as they mainly represent a progression from Systemic Mastocytosis (SM) to SM with an Associated Hematological Neoplasm (AHN). Standardized Incidence Ratio (SIR) was calculated as the ratio between the observed cases in our cohort and the expected cases in the sex- and age-matched general Italian population in the same time period (these data were retrieved from http://www.registrni-tumorit.it). Times to event (patient-years) were calculated from the diagnosis of mastocytosis to the date of SPM diagnosis, death, or last contact, whichever comes first. Survival curves were estimated according to the Kaplan-Meier method.

Results: Males were 450 (54%). Median age at diagnosis was 49.3 years (range 19-84). Median follow-up was 2.3 years (range 0-41). Subtype diagnoses were: Cutaneous Mastocytosis (n=46), Indolent SM (n=633), Smoldering SM (n=10), SM-AHN (n=54), Aggressive SM (n=47) and Mast cell leukemia (n=2). Fifty-four patients were classified as having mastocytosis in the skin. Overall, 42 patients had a history of malignancies prior to the diagnosis of mastocytosis: in these patients we did not detect any relapse of their prior malignancy after the diagnosis of mastocytosis. A total of 35 SPM were diagnosed in 34 patients (4.1%). Median age at SPM was 56.4 years (range 39-72). The median time from the diagnosis of mastocytosis to SPM was 22 months. The overall rate of SPM was 12.8 per 1,000 person-years (95%CI: 9.1-17.6) while the rate in the general adult population was 7.6 per 1,000 person-years (95%CI: 7.5-7.7) resulting in an increased hazard ratio of 1.7 (95%CI: 1.2-2.3). The risk for SPM was higher than expected in females (SIR 1.93, 95%CI: 1.2-3.1) while it was not significantly increased in males (SIR 1.46, 95%CI: 0.9-2.4). We found a clearly increased risk for melanoma (n=8, SIR 15.9, 95%CI: 7.9-31.9) and thyroid cancer (n=3, SIR 9, 95%CI: 2.9-27.9) while a non-significant increased risk was found for prostate cancer in males (n=5, SIR 2.06, 95%CI: 0.8-4.9) and breast cancer in females (n=3, SIR 1.7, 95%CI: 0.5-5.3). All the other malignancies were sporadic (one or two cases for each cancer type) and comparison to the general population was not significant. The death rate in patients with SPM was 14.7% with a median overall survival (OS) from SPM diagnosis of 38 months. OS was significantly inferior in patients with SPM as compared to patients without secondary neoplasia (5-year OS 77.6% vs 93.7% respectively, p<0.01) (Figure 1).

Figure 1.

Summary/Conclusions: Patients with mastocytosis may have a significantly higher risk of developing a secondary non hematological cancer as compared to the matched general population. Careful follow-up of these patients is warranted as the rate of malignancies may increase over time and reduce life expectancy.
Background: Colony stimulating factor 3 receptor gene (CSF3R)-mutated chronic neutrophilic leukemia (CNL) is a rare chronic myeloproliferative neoplasm. There is the limited information on the clinical course of CNL.

Aims: To explore the clinical course of patients with CSF3R-mutated CNL and identify risk factor(s) associated with survival.

Methods: A retrospective study was conducted to assess natural history and identify risk factor(s) for survival in patients with CSF3R-mutated CNL. Survival analysis was performed by the Kaplan-Meier method taking the interval from the date of diagnosis to death or last contact. The log-rank test was used to compare survival data. Cox regression model was used for multivariable analysis.

Results: Data of 47 patients with CSF3R-mutated CNL were collected and analyzed. 35 (76%) patients were male. Median age was 62 years (range: 16-92 years). At diagnosis, 17 (36%) patients had fatigue, 2 (4%) had a fever, 8 (17%) experienced diarrhea or abdominal discomfort, 20 (43%) were asymptomatic and leukocytosis had been mostly an incidental laboratory finding. 20 (43%) patients had palpable splenomegaly, and 4 (9%), palpable hepatomegaly. PB parameters, median and (range), were WBC 42.4×10^9/L (14.1-180×10^9/L), platelets 165×10^9/L (71-537), blast percentage 0% (0-10), neutrophil percentage 82% (70-99). The median of blast cells in bone marrow were 1% (range, 0-12%). 46 (98%) patients were in the chronic phase and 1 (2%) in the accelerated phase at diagnosis. Most of the CSF3R mutations was T618I (n=45, 96%), others were T568M (n=1, 2%), 5q deletion (n=1, 2%), patients and 41 (87.2%) patients were screened for ASXL1 and SETBP1 mutations, respectively. 21 (61.8%) patients harbored ASXL1 mutation and 22 (53.7%) harbored SETBP1 mutation. All patients were BCR-ABL1, PDGFR and FGR mutation negative, 2 were CALR mutation and JAK2V617F mutation positive, respectively. Hydroxyurea was the most frequently used therapy (n=48). Other therapies included interferon-α (n=7), hypomethylating agents (n=4), thalidomide (n=2), ruxolitinib (n=1), imatinib (n=3), dasatinib (n=1), chemotheraphy (n=6), and transplant (n=2). With a median follow up of 17 months (range, 2-103 months), 7 patients progressed to blast crisis or acute myeloid leukemia (n=6) or myelodysplastic syndrome (n=1), 17 patients died. Survival rate at 30 months was 55%. Median survival was 39 months (95% CI 8.5-69.5). Multivariate analysis showed that WBC >40×10^9/L (HR=3.26, 95% CI 1.14-9.30, p=0.027) was the sole risk factor for survival. However, SETBP1 or ASXL1 mutation was not associated with survival.

Summary/Conclusions: High WBC count was independently predictive of shortened survival in patients with CSF3R-mutated CNL.

P357

CLINICAL PHENOTYPE AND OUTCOME OF ESSENTIAL THROMBOCYTHEMIA AND PREFRIBROTIC MYELOFIBROSIS DIAGNOSED ACCORDING TO THE REVISED 2016 WHO DIAGNOSTIC CRITERIA

E. Rumi1,2, E. Boveri3, M. Bellini1, D. Pietra2, V. Ferretti1, E. Roncoroni 2, E. Rumi1,2, E. Boveri3, M. Bellini1, D. Pietra2, V. Ferretti1, E. Roncoroni 2, E. Rumi1,2, E. Boveri3, M. Bellini1, D. Pietra2, V. Ferretti1, E. Roncoroni 2

1Department of Molecular Medicine, University of Pavia, 2Department of Hematology Oncology, Fondazione IRCCS Policlinico San Matteo, 3Anatomic Pathology Section, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy

Background: The World Health Organization (WHO) classification system for myeloid neoplasms was recently revised in 2016. The revised WHO criteria underlines the importance of differentiating prefibrotic PMF (prePMF) from “true” essential thrombocythemia (ET) as these two entities have different clinical outcomes. For these reasons, standardization of morphologic findings in the bone marrow biopsy and an explicit definition of minor clinical criteria for the diagnosis of prePMF have been added (anemia, leukocytosis >11 x10^9/L, palpable spleen, increased LDH) to 2008 WHO criteria.

Aims: To compare the clinical phenotype at diagnosis and the outcome of ET and prePMF diagnosed according to the new 2016 WHO criteria.

Methods: We identified in our database all patients affected with ET, prePMF and PMF diagnosed according to 2008 WHO criteria who satisfied these two requirements: a bone marrow fibrosis grade 0-1 at diagnosis and at least one DNA sample to define the mutational status. Firstly, the bone marrow morphology of all 404 identified patients was reviewed by an expert pathologist. Then, we reclassified patients according to the new 2016 WHO criteria as follows: patient with ET morphology were classified as ET, patients with PMF morphology and at least one clinical criteria (leukocytosis, anemia, increased LDH, splenomegaly) were classified as prePMF, patients with PMF morphology but without clinical criteria were classified as myeloproliferative neoplasms unclassifiable (MPNu).

Results: According to the new criteria our cohort included 269 patients with ET, 109 patients with prePMF and 62 with MPNu. By comparing clinical phenotype at diagnosis in prePMF, MPNu, and ET respectively, we observed that prePMF showed higher leukocyte count, lower hemoglobin levels, higher platelet count, higher LDH values, higher number of circulating CD34-positive cells, and showed more frequently splenomegaly (Table 1). The higher frequency of CALR mutations in prePMF compared to ET might contribute to the high level of platelet count observed in prePMF. ET and MPNu did not differ in terms of leukocyte count, hemoglobin, platelet count, LDH, circulating CD34-positive cells and splenomegaly (Table 1). The 26 patients with MPNu were not further considered in the analysis of disease complications and overall survival due to the low number. PrePMF patients had lower overall survival (overall survival at 10 years 86.4% vs 96.6%, P < 0.001) and a trend to a higher incidence of leukemic evolution (cumulative incidence of acute myeloid leukemia at 10 years 2.3% vs 1.9%, P = 0.067) compared to ET patients, while they did not differ in terms of thrombotic complications (cumulative incidence of thrombosis at 10 years 18.5% vs 18%, P = 0.96). Finally, we analyzed the subgroup of “old” ET diagnosed according to 2008 WHO criteria. Of 358 “old” ET, 268 were reclassified as ET, 25 as MPNu and 65 as prePMF. The “old” ET reclassified as prePMF had a higher risk of overt myelofibrotic evolution compared to the “old” ET reclassified as ET (cumulative incidence of overt myelofibrosis at 10 years 9.7% vs 0%, P = 0.03).

Table 1.

Summary/Conclusions: ET and prePMF diagnosed according to 2016 WHO criteria are two entities with a different clinical phenotype at diagnosis and a different outcome. The clinical phenotype at disease onset of MPNu and ET is similar.
Background: The minimal effective treatment in Essential Thrombocythemia (ET) patients is tailored mainly on the basis of thrombotic risk scores (primarily non nocere). The Revised International Prognostic Score for Thrombosis in ET (R-IPSET-Th) is based on different combinations of Age >60 yrs (Age >60), JAK2 V617F mutation (JAK2+) and Prior Thrombosis (PrTh+). According to the R-IPSET-Th score, the patients were divided in 4 thrombotic risk groups: Very Low Risk (VLR: Age <60, absence of JAK2 mutations, no PrTh+), Low risk (LR: only JAK2+, or Age >60 with JAK2+), Intermediate Risk (IR: only Age >60), High Risk (HR: PrTh+, or Age >60 with JAK2+). The rates (n and%, n/100 pt-yrs) of first thrombotic events during the follow-up (Th-FUP) were reported for each risk group. The thrombosis free survival (TFS, time from diagnosis to the first thrombosis) was determined for each risk group (Kaplan Meier analysis), and the curves were compared with the log-rank test.

Methods: The web-based Registro Italiano Trombocitemie (RIT) recruited since 2005 patients with thrombocytopenic bcr/abl negative chronic myeloproliferative neoplasms (MPN). ET patients (reclassified according to WHO 2016 criteria) with complete information (characteristics at diagnosis, antithrombotic and/or cytoreductive treatment, date and description of thrombotic events during the follow-up) were considered for this analysis. According to the R-IPSET-Th score, the patients were divided in 4 thrombotic risk groups: Very Low Risk (VLR: Age <60, absence of JAK2 mutations, no PrTh+), Low risk (LR: only JAK2+, or Age >60 with JAK2+), Intermediate Risk (IR: only Age >60), High Risk (HR: PrTh+, or Age >60 with JAK2+).

Overall, 734 ET patients were analyzed (females 62%). Data at diagnosis were: Age >60 in 286 (39%), JAK2+ in 417 (57%), and PrTh in 126 (17%). The Th-FUP were reported for each risk group. The thrombosis free survival (TFS) progressively decreased (p <0.001): in VLR (n=15, 8%), in LR (n=20, 10%), in IR (n=12, 15%), in HR (n=56, 21%). The Th-FUP/100 pt-yrs increased (p<0.01) as follows: 0.60%, 0.79%, 1.61%, and 1.91%, respectively. TFS progressively decreased (p <0.001) from VLR group to HR group (Figure 1). In detail, the probability of TFS was 0.98, 0.97, 0.94, 0.88 at 5 years, and 0.85, 0.87, 0.78, 0.54 at 20 years. The patient stratification according to the R-IPSET-Th and the IPSET-Th scores showed a concordance of 0.82 (Harrell C index).

Results:}

Summary/Conclusions: In this study of the Registro Italiano Trombocitemie (RIT), we confirmed that the Revised International Prognostic Score for Thrombosis in ET (R-IPSET-Th) separated ET patients in 4 groups with increasing risk of thrombosis during the follow-up (p <0.001). According to the R-IPSET-Th score, it seems to have occurred in this cohort of ET patients (anti-platelets in almost all cases), and cytoreduction in around 2/3 of VLR and LR cases, probably because other adjunctive risk factors have been considered.

Correlations Between Inflammatory Biomarkers and Individual Symptoms Expressed by Myelofibrosis Patients in the COMFORT-I Trial: Analysis of Baseline Associations and Changes Over Time

H. Geyer1,*, R. Scherber2, H. Kosiorek1, S. Verstovsek3, B. Langlais1, L. Padmos1, J. Palmer1, A. Dueck1, R. Mesa1

1Mayo Clinic, Phoenix, AZ, 2OHSU, Portland, OR, 3MD Anderson, Houston, TX, United States

Background: Myelofibrosis (MF) is characterized by significant inflammation driven by clonal dysregulation and subsequent disruption of cellular signaling cascades. Studies have confirmed a close relationship between circulating inflammatory BMKs and baseline symptom burdens, along with the potential to mitigate symptoms upon improvement of these proteins (Dueck Blood, 2013). To date, no study has evaluated the correlations between elevated biomarkers (BMKs) and specific MF symptoms.

Aims: In this analysis of the phase-III placebo controlled COMFORT-I study we investigated the relationships between blood BMKs and individual MF symptoms at baseline and post-treatment with ruxolitinib.

Methods: Biomarker levels at baseline, week 4 and 24 were measured along with MF symptoms (MFSAF 2.0-Mesa JCO 2013; collected during blinded phase of COMFORT-I). Patients were randomized to ruxolitinib vs placebo. BMKs were assessed using Rules-Based Medicine, Inc. (Austin, TX) Human MAP panel. Associations between the individual symptoms measured within the MFSAF and log2-transformed biomarker data were investigated at baseline using Spearman correlations. Mixed models were used to assess symptom and BMK changes over time. Models included terms for visit, arm, visit-by-arm interaction, age, sex, and body mass index index.

Results: Study Population. A total of 309 subjects were randomized in COMFORT-I with median age of 68 (range 40-91). Approximately 46% of patients were male and 50% had primary myelofibrosis (61% high risk). All 309 subjects had BMKs measured at one or more of the three visits included in this analysis, with 308 having biomarker values paired with MF symptoms (MFSAF symptom scores at the same visit). Correlations of Baseline Biomarkers and Symptoms. Total symptom score (TSS) significantly statistically significantly (p<0.05) correlated with 20 BMKs at baseline (Table 1). For individual symptoms, spleen-related symptoms appeared to statistically and significantly correlate more frequently with BMKs at baseline: abdominal discomfort (23 BMKs), feeling full (20 BMKs), and pain under left ribs (19 BMKs). Night sweats, itchiness, and bone or muscle pain significantly correlated with 15, 14, and 10 BMKs each. The BMKs with the strongest correlations (absolute Spearman correlation of at least 0.20 with p<0.001) with at least one symptom included APOA1, EPO, FERRITIN, MIP1A, and PSAF. Associations with Symptoms+TSS, and Biomarker Change Over the Trial Course. Twenty BMKs were significantly associated with TSS over time. Like at baseline, BMKs appeared to be more often statistically significantly (p<0.05) associated with spleen-related symptoms over time including 25 and 24 BMKs for abdominal discomfort and feeling full, respectively. Night sweats, pain under left ribs, bone or muscle pain, and itchiness having biomarker values paired with MFSAF symptom scores at the same visit. Correlations of Baseline Biomarkers and Symptoms.

Table 1.

Summary/Conclusions: In this study of the Registro Italiano Trombocitemie (RIT), we confirmed that the Revised International Prognostic Score for Thrombosis in ET-et (R-IPSET-Th) separated ET patients in 4 groups with increasing risk of thrombosis during the follow-up (p <0.001). According to the R-IPSET-Th score, it seems to have occurred in this cohort of ET patients (anti-platelets in almost all cases), and cytoreduction in around 2/3 of VLR and LR cases, probably because other adjunctive risk factors have been considered.
NOVEL HETEROZYGOUS ITGB3 P.T746DEL MUTATION INDUCING SPONTANEOUS ACTIVATION OF INTEGRIN αIIbβ3 CAUSES AUTOSOMAL DOMINANT MACROTHROMBOCYTOPENIA WITH ABNORMAL αIIbβ3 LOCALIZATION

N. Miyawaki1, M. Onozawa2, K. Hayasaka3, S. Kunishima1, T. Teshima1
1Department of Hematology, Hokkaido University Graduate School of Medicine, 2Department of Hematology, 3Clinical Laboratory, Hokkaido University Hospital, Sapporo, 4Department of Advanced Diagnosis, Clinical Research Center, National Hospital Organization Nagoya Medical Center, Nagoya, Japan

Background: Congenital macrothrombocytopenia is a rare platelet disorder and its cause is genetically heterogeneous. Recently, integrin αIIb and β3 mutations have been identified in congenital macrothrombocytopenia patients with platelet aggregation dysfunction. Here, we found a novel, heterozygous ITGB3 mutation in a pedigree and examined how this mutation contributed congenital macrothrombocytopenia.

Aims: To detect gene mutations responsible for the congenital macrothrombocytopenia in this pedigree and reveal the molecular pathophysiology.

Methods: Whole exome sequencing (WES) was performed to detect gene mutations. Expression and activation state of αIIbβ3 in platelets was evaluated by flow cytometry (FCM) and western blotting (WB). The effects of mutations on αIIbβ3 activation state, phosphorylation of FAK, and morphological changes were analyzed in transfected cells by WB and immunofluorescence staining.

Results: The patients were 56-year-old Japanese woman and 2 of her 3 sons. They had no bleeding tendencies and near-normal bleeding time (Duke’s method). Hematological examination revealed their decreased platelet counts (58-86 x 10^9/l) with increase of mean platelet volume (12.8-14.5 fl). In all affected family members, giant platelets were observed on the peripheral blood smears. Platelet aggregation induced by ADP (1-10 μmol/l) and collagen (2 μg/ml) was obviously reduced although that induced by ristocetin (1.5 mg/ml) was within normal limit. The family pedigree indicates that the inheritance pattern is autosomal dominant. Common congenital macrothrombocytopenias, such as MYH9 disorders, Bernard-Soulier syndrome and type 2B von Willebrand disease were excluded by the absent leucocyte inclusion bodies, normal ristocetin cofactor test, normal platelet aggregation and normal platelet GPIib/IX expression. Western blot showed lost band of αIIbβ3 in patients compared with normal controls. FCM showed a constitutive activation of αIIbβ3 on the patient's platelets. Hematological examination revealed that there was no difference in the total amount of αIIbβ3 among the affected and unaffected members and normal controls. FCM showed a constitutive activation of αIIbβ3 on the patient's platelets as reflected by the spontaneous binding of PAC-1 antibody. Immuno-fluorescence staining using CHO cells showed membrane localization of αIIbβ3 in wild-type αIIb/β3-expressing cells and cytoplasmic localization in αIIb/β3 p.T746del-expressing cells. Immunofluorescence staining using CHO cells with fluorescence staining using CHO cells showed membrane localization of αIIbβ3 in wild-type αIIb/β3-expressing cells and cytoplasmic localization in αIIb/β3 p.T746del-expressing cells. Western blot showed increased band of αIIbβ3 in patients compared with normal controls. FCM showed a constitutive activation of αIIbβ3 on the patient's platelets as reflected by the spontaneous binding of PAC-1 antibody. Immuno-fluorescence staining using CHO cells showed membrane localization of αIIbβ3 in wild-type αIIb/β3-expressing cells and cytoplasmic localization in αIIb/β3 p.T746del-expressing cells. Western blot showed increased band of αIIbβ3 in patients compared with normal controls. FCM showed a constitutive activation of αIIbβ3 on the patient's platelets as reflected by the spontaneous binding of PAC-1 antibody. Immuno-fluorescence staining using CHO cells showed membrane localization of αIIbβ3 in wild-type αIIb/β3-expressing cells and cytoplasmic localization in αIIb/β3 p.T746del-expressing cells. Western blot showed increased band of αIIbβ3 in patients compared with normal controls. FCM showed a constitutive activation of αIIbβ3 on the patient's platelets as reflected by the spontaneous binding of PAC-1 antibody. Immuno-fluorescence staining using CHO cells showed membrane localization of αIIbβ3 in wild-type αIIb/β3-expressing cells and cytoplasmic localization in αIIb/β3 p.T746del-expressing cells. Western blot showed increased band of αIIbβ3 in patients compared with normal controls. FCM showed a constitutive activation of αIIbβ3 on the patient's platelets as reflected by the spontaneous binding of PAC-1 antibody. Western blot showed increased band of αIIbβ3 in patients compared with normal controls.

Summary/Conclusions: The autosomal dominant heterozygous ITGB3 p.T746del mutation was found to be responsible for constitutive activation of αIIbβ3 in the patients’ platelets as well as transfected cells. It is considered that ITGB3 p.T746del mutation unclips the highly conserved membrane proximal complex of αIIb and β3 cytoplasmic tails and renders the activated form. Activation of αIIbβ3 leads to phosphorylation of FAK and morphological changes such as rhomboidal changes, elongated changes, abnormal cytoplasmic protrusions, and membrane ruffling, in transfected cells. FAK inhibitor (1,2,4,5-Benzenetetraamine tetrahydrochloride) hindered the localization change of αIIbβ3 and the morphological changes in transfected cells by doxycycline induction. These results suggest that the gain-of-function mutation around membrane region of αIIbβ3 leads to macrothrombocytopenia with impaired surface αIIbβ3 expression.
antibodies against glycoprotein Ibβ (GPIibβ)IIa and/or GPIib/IIIa are considered to play a crucial role. B cell homeostasis and function are controlled by cell surface receptor-ligand interactions. The activation of PI3K is initiated by engagement of the pre-B cell receptor (BCR) and the BCR. The phosphatase and tensin homolog (PTEN) suppress the activity of the PI3K pathway. As a consequence, loss of PTEN function leads to excessive PI3, 4, 5 P3 at the plasma membrane and to recruitment and activation of Akt family members that potently drive cell survival and proliferation. PTEN regulates normal signaling through the B cell receptor (BCR). In immune thrombocytopenia (ITP), enhanced BCR signaling contributes to increased B cell activity, but the role of PTEN in human ITP has remained unclear. Both IL-21/IL-21R signaling and PI3K-PTEN molecules are involved in maintaining normal humoral immunity and deletion of autoreactive B cells. In this study, we want to determine whether abnormalities in PTEN might contribute to increase B cell responsiveness in this disease and IL-21 mediated PTEN induction was defective. Meanwhile, we want to evaluate the relation between the expression of PTEN in B cells and the prognosis of ITP, which will provide a theoretical basis of new treatment strategy for the ITP patients.

Aims: PTEN is involved in maintaining normal B cell function. Since B cell overactivity is characteristic of immune thrombocytopenia(ITP) we sought to determine whether abnormalities in PTEN might contribute to increased B cell responsiveness in this disease.

Methods: 1. This study recruited 28 newly-diagnosed CITP patients and 26 sex and age matched health volunteers as health controls (HC). Peripheral blood mononuclear cells were isolated from collected anti-coagulated blood. 2. Flow cytometry and real time quantitative PCR were used for detecting the level of PTEN from PBMC cells of HC and CITP patients. 3. The relationship between PTEN levels and the disease severity of CITP was analyzed. 4. PBMC cells were incubated with human rIL-2 rIL-21 rCD40L or anti-IgM alone or in combination for 72h and after that the PTEN level was detected by flow cytometry. The proportion and surface activated marker of B cells were determined by flow cytometry.

Results: 1. Compared to HC the expression of PTEN was diminished in each CITP B cell population except IgD-CD38low/-memory B cells. In addition PTEN mRNA was also decreased in ITP B cells. 2. The level of PTEN in B cells was significantly lower in ITP patients (Figure 1). 3. The relationship between PTEN expression in B cells and the prognosis of ITP, which will provide a theoretical basis of new treatment strategy for the ITP patients.

Summary/Conclusions: Immune thrombocytopenia B cell showed decreased levels of PTEN and the decrease was associated with low platelet count and positive serum platelet-specific antibody. The capacity of IL-21 to induce PTEN was defect in CITP. Together, these data suggesting that the defective PTEN expression, regulation and function contribute to B cell hyper-responsiveness in CITP.
tin (PNA) that bind to galactose, N-acetyllactosamine and N-acetylgalactosamine residues, respectively. The NOD/SCID mouse model was used to study the impact of different glycan patterns on the survival of human PLTs.

**Results:** In this work 37 sera from ITP patients and 25 sera from healthy donors were analyzed. In the LBA, after incubation with AAbs, different patterns of glycan modification were observed. 17/37 sera caused a significant increase in PNA analysis compared to healthy donors (mean fold increase (FI): 1.21, range: 1.08 - 1.40). 9/37 sera induced higher ECL binding (median FI: 1.02, range: 1.08 - 1.15). In contrast, 8/37 sera showed strong decrease in RCA binding (median FI: 0.52, range: 0.50 - 0.59). Sera from healthy donors did not induced significant change. Interestingly, not only GP-IIIb/IIIa AAbs but also GPIb/IX AAbs were able to modify glycan pattern. In NOD/SCID mice the administration of AAbs induced an accelerated clearance of human PLTs from the circulation. The destruction of human PLTs by ITP-AAbs was decreased but not completely prevented by a specific neuraminidase inhibitor that blocks glycan changes on PLT surface (survival of human PLTs after 5h: 48%, range 41:53% to 28%, range: 22-36%).

**Summary/Conclusions:** Our results demonstrate that AAbs from ITP patients are able to induce cleavage of glycan moieties on the PLT surface in distinct manners. Antibody-modified modification of glycan patterns seems to contribute to AAb-mediated PLT destruction.

Trambusti”, University of Bari, 6U.O.C of Pediatrics, Hospital “D. Camerlingo”, Francavilla Fontana, Bari, Italy, 7Institute of Investigaciones Medicas Alfredo Lanari, Universidad de Buenos Aires, IDIM-CONICET, Buenos Aires, Argentina, 8Department of Medical Sciences, University of Trieste, Trieste, Italy

**Background:** Familial platelet disorder with propensity to acute myeloid leukemia (FPD/AML) is a rare autosomal dominant inherited thrombocytopenia (IT) caused by mutations in the hematopoietic transcription factor RUNX1; an important hallmark of this IT is the increased risk of developing myeloid neoplasms, such as AML and myelodysplastic syndromes (MDS). FPD/AML is caused by different mutations of RUNX1 encoding the DNA binding subunit (known as core binding factor-alpha, CBF-alpha) of the CBF transcription complex. The N-terminal domain of RUNX1 (run-homologous domain) mediates DNA binding and heterodimerization to CBF-beta, the other subunit of the CBF complex. The C-terminus of RUNX1 includes domains that are involved in transcription activation and repression. This IT is characterized by impaired megakaryopoiesis and moderate thrombocytopenia, with normal-sized and dysfunctional platelets.

**Aims:** To unravel the molecular basis of ITs and to improve our knowledge on the molecular basis and clinical-laboratory picture of FPD/AML.

**Methods:** Whole exome sequencing (WES) was performed in 86 propositi with an unknown IT after the diagnostic workup based on the most updated diagnostic algorithm for ITs (Clin Genet 2016;89:141). RUNX1 variants detected by WES were confirmed by Sanger sequencing in the propositus and all available family members, which also underwent clinical-laboratory characterization. The study was approved by the Institutional Review Board of the IRCCS Policlinico S. Matteo Foundation; all patients gave written informed consent.

**Results:** We identified three pedigrees (families 1-3) with different RUNX1 heterozygous mutations, all segregating with thrombocytopenia in the respective families: the novel variants c.578T>A and c.967+2_5del, and the known c.351+1G>A. The thirteen individuals carrying the RUNX1 mutations had mild thrombocytopenia (platelet count ranging from 70 to 130 x 10^9/L) with mild functional platelet defects. Of note, three patients from two families developed AML, with a prevalence lower than reported in literature, probably because of a different criteria of enrolment (RUNX1 germline mutations are usually searched in ITs associated with AML). No solid/hematological cancer was reported in family 1.

**Summary/Conclusions:** FPD/AML is an IT lacking pathognomonic laboratory criteria: it is characterized by a mild functional defect and, much more importantly, by a normal platelet size, similarly to the other ITs predisposing to hematological malignancies (ANKRD26 and ETV6-related thrombocytopenias). Given the importance of recognizing these diseases for patients counseling, follow-up, and therapeutic approach, we recommend a systematic screening for RUNX1, ANKRD26, and ETV6 mutations in all patients with an autosomal dominant IT and normal platelet size.

**A SINGLE-ARM, OPEN-LABEL, LONG-TERM EFFICACY AND SAFETY STUDY OF SUBCUTANEOUS ROMIPLOSTIM IN CHILDREN WITH IMMUNE THROMBOCYTOPENIA**

J. Despotovic6, A. Maschan7, N. Carpenter8, M. Eisein9, B. Mehta9

1University of Manchester, Manchester, United Kingdom, 2Weill Cornell Medicine, New York, United States, 3Hammersmith Hospital, Imperial College, London, United Kingdom, 4The Bleeding and Clotting Disorders Institute, Peoria, United States, 5Hospital for Sick Children, Toronto, Canada, 6Texas Children's Hematology Center, Houston, United States, 7Federal Research Center of Pediatric Hematology, Oncology and Immunology n.a. Dmitry Rogachev, Moscow, Russian Federation, 8Amgen Ltd., Uxbridge, United Kingdom, 9Amgen Inc., Thousand Oaks, United States

**Background:** The use of romiplostim in children with ITP has been evaluated in phase 1/2 and 3 studies. Here we describe children with ITP who will receive open-label SC romiplostim for up to 3 years (y).

**Aims:** To assess platelet responses in children with ITP receiving romiplostim.

**Methods:** Eligible children, recruited in 16 countries worldwide, had ITP for ≥6 months, ≥1 prior ITP therapy, and platelet (plt) counts <30x10^9/L. Weekly SC dosing started at 1 μg/kg and was titrated in 1 μg/kg increments up to 10 μg/kg to achieve plt counts of 50-200x10^9/L. The primary endpoint was the % of time in the first 6 months with a plt response (plt count ≥50x10^9/L without rescue medication use in the past 4 weeks).

**Results:** As of 15 Mar 2016, 145 patients received ≥1 dose. At baseline, median (min-max) age was 10 (2-17) y; 51% were female; 4% had prior splenectomy. Median (min-max) ITP duration was 1.9 (0.5-12.3) y and plt count was 13 (2-168)×10^9/L. The median (Q1, Q3)% of time with a plt response in the
first 6 months was 50% (83.3%); that of months 7-12 was 92% (33%, 100%). Overall, 80% (114/143) of patients had a plate response. The median (Q1, Q3) of time with an increase in plt counts ≥20×10^9/L above baseline was 60% (25%, 84%). The median dose increased to 10 µg/kg by week 32. Median (min-max) treatment duration to date was 25 (1-67) weeks for a total exposure to date of 79 patient-years. Median (min-max) average weekly thrombolytic dose over the course of the study was 6.1 (0.4-9.0) µg/kg. 32 patients (22%) discontinued treatment for lack of efficacy (n=17), required other therapy (n=5), patient request (n=4), noncompliance (n=2), adverse event (AE) (n=2) (interstitial lung disease in a 15 y old boy and abdominal pain, vomiting, and headache related to treatment per investigator in a 9 y old girl), administrative decision (n=1), and investigator decision (n=1). 34 (23%) patients received rescue medications. 15 (10.3%) patients had serious AEs (SAEs) including epis-taxis (n=4), petchiae (n=2), decreased plt count (n=2), and thrombocytopenia (n=2). A case of abdominal pain was the only SAE deemed treatment-related by the investigator. CTCAE grade 3 bleeding was seen in 8 patients (6%) and included epis-taxis (n=5), ecchymosis (n=2), petchiae (n=2), and 1 case each of hematemesis, hematemata, SC hemorrhage, injection site hemorrhage, and mouth hemorrhage. No grade 4 or 5 bleeding was observed. No neutralizing antibodies against romiplostim or TPO were identified. Of 30 patients with baseline bone marrow biopsies (bone marrow biopsies were obtained at European sites), all had modified Bauermeister scores of grade 0 (no reticulin) or 1 (fine fibers) and bone marrows typical for ITP. Of these 30 patients, 21 had evaluable on-study biopsies obtained after ~1 year of treatment, with no increases in 2 or more grades, findings of collagen, or bone marrow abnormalities (Figure 1).

Summary/Conclusions: In this first 1 year data of an ongoing open-label study of romiplostim in children with ITP, the% of time in the first 6 months with a plateau treatment response was 50%, with 80% of children having a plateau response at some point on study. The median romiplostim dose reached 10 µg/kg and there were no new safety sig-nals. No effects of romiplostim were observed on the bone marrow in the subset of patients with bone marrow biopsies. Future datacuts for years 2 and 3 in this study, the largest of romiplostim in children with ITP with 79 patient-years of exposure to date, will provide more information on plateau response, dose requirements, and safety.

PATIENT-REPORTED OUTCOMES AND HEALTHCARE RESOURCE UTILIZATION BEFORE AND DURING TREATMENT WITH ECULIZUMAB: RESULTS FROM THE INTERNATIONAL PAROXYSMAL NOCTURNAL HEMOGLOBINURIA REGISTRY

S. Jones1, M. van Rensburg2, L. Pilkington2, D. Barker2, N. Dempsey-Hibbert1
1School of Basic Sciences, University of Auckland, Auckland, New Zealand
2School of Chemical Sciences, University of Auckland, Auckland, New Zealand

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a rare disease caused by somatic phosphatidylinositol glycan class A (PIGA) gene mutation in bone marrow stem cells. Clinical manifestations may include fatigue, abdom-nal pain, dyspnea, dysphagia, erectile dysfunction, anemia, sudden hemoglobin level reductions due to complement-induced hemolysis, and PNH-related com-plications such as thrombosis, chronic kidney disease, and pulmonary hyper-tension, each of which impair quality of life (QoL) and could impact survival. Eculizumab, a humanized monoclonal antibody approved for treatment of PNH, reduces intravascular hemolysis, thrombosis rates, and other PNH-associated comorbidities. The International PNH Registry (NCT01374360) is an ongoing prospective, multinational, observational study established to record the natural history of patients with PNH and collect data on long-term efficacy and safety of eculizumab treatment.

Aims: Analyze patient-reported outcomes (PRO) and healthcare resource utili-zation (HRU) before and during eculizumab treatment.

Methods: Patient assessment questionaire (PAQ) data for patients with PNH who commenced eculizumab after Registry enrollment and had data available as of August 1, 2016, were analyzed. Patients had to have non-missing data on demographics, ≥1 recorded PAQ within 12 months prior to eculizumab ini-tiation, and ≥1 PAQ recorded ≥6 months after initiation. Outcomes of interest included changes in QoL assessments (Functional Assessment of Chronic Ill-ness Therapy (FACT)-Fatigue score; EORTC QLQ-C30 mean scores for global health/QoL, physical function, role functioning, emotional functioning, and social functioning), Karnofsky Performance scale, HRU, and missed work days.

Results: Of 4082 enrolled patients, 649 had non-missing data on demographics and initiated treatment with eculizumab as of August 1, 2016; 229 patients (55% female; 86% white; 74% from Europe) of the 649 met inclusion criteria for the current analysis. Median (min, max) interval between PNH disease start and initiation of treatment was 4.4 (0.1, 44.9) years. Clinically meaningful improvement in FACT-Fatigue score (≥4-point increase) was reported by 53% of patients after initiating eculizumab (mean change, 5.2 points. Figure 1). Clinically meaningful improvement (≥10-point increase) was also observed in EORTC QLQ-C30 mean scores for global health/QoL (mean change, 15.1), role functioning (16.3), emotional functioning (12.1), and social functioning (13.9) subscales. PNH-related symptoms disappeared in 19–44% of patients who reported the symptom prior to eculizumab across all assessed symptoms except erectile dysfunction, which did not disappear in any of the 21 patients who reported the symptom prior to eculizumab.

Conclusion: Eculizumab treatment was associated with clinically meaningful improvements in QoL assessments associated with PNH, Karnofsky Performance Scale, HRU, and missed work days.

Figure 1.
Summary/Conclusions: In this cohort of patients from the International PhN Registry, treatment with eczulizumab was associated with clinically meaningful improvements in PROs, including assessments of fatigue, global health status, patient functioning, and disease-related symptoms, as well as a decrease in emergency room visits and number of missed work days.

P370
ECONOMIC IMPACT OF INTRODUCING AGE-ADJUSTED D-DIMER CUT-OFF LEVELS IN THE DIAGNOSIS STRATEGY OF VENOUS THROMBOEMBOLISM
P. Toulon1,*, N. De Poorter2, M. Brionne-François3, M. Smahi4, L. Abecassis5
1Hematology, Pasteur University Hospital, Nice, 2Hematology, General Hospital, Grasse, 3Hematology, University Hospital, Caen, 4Hematology, Simone Veil Hospital, Eaubonne, 5Hematology, General Hospital, Aulnay, France

Background: The diagnosis of venous thromboembolism (VTE) can be safely excluded in the case of D-dimer levels below a well defined cut-off value in patients with a low or intermediate pre-test probability (PTP), as the test negative predictive value (NPV) is close to 100%. As ageing is associated with increased D-dimer levels, the question arose whether D-dimer measurement was useful to rule out VTE in elderly patients.

Aims: The aim of the present study was to evaluate the clinical performance of a diagnosis strategy based on age-adjusted cut-off values calculated by multiplying the patient’s age by 10 in patients aged over 50, and to evaluate its economic impact.

Methods: We included 1255 consecutive outpatients with non-high PTP of VTE referred to the emergency departments at 5 French centres (2 university hospitals, and 3 general hospitals, in whom D-dimer testing was prescribed. The same standardized procedure was used in the 5 centres i.e. D-dimer measurement in patients with a non-high PTP, and imaging techniques (usually computed pulmonay angiography in case of suspected PE and Doppler ultrasonography in case of suspected DVT) in the case of D-dimer above the cut-off level. D-dimer levels were evaluated using the same fully automated latex-based assay (Hemosil®, Dade Behring, 100, Inspect and ren Laboratorium). The proposed cut-off level for VTE exclusion being 500 ng/ml (fibrinogen equivalent units, FEU).

Results: VTE diagnosis was established by objective testing in 115 patients (9.2%); 88 of the 1082 patients referred for suspected PE (8.1%) and 27 of the 173 patients referred for suspected DVT (15.6%). D-dimer levels were above 500 ng/ml in all patients with VTE and in 521 of the 1140 patients without VTE (45.7%), leading to test NPV and sensitivity of 100%. The overall test specificity was 54.3%, even though it significantly decreased in an age-dependent manner over 60 years old. This is due to increased D-dimer levels in older patients particularly in those above 80 years. Using age-adjusted cut-off levels, calculated by multiplying the patient’s age by 10, significantly improved the overall test specificity (60.2%). The NPV remained high (99.9%), even though a 78 years old female with a low PTP of PE would have been misdiagnosed as her D-dimer level (540 ng/ml) was above 500 ng/ml but below the age-adjusted cut-off value. Such an improvement in test performance was found both in patients with PE and DVT (Table). As such an increase in test specificity would have led to exclude VTE in a higher percentage of patients in the studied population, we evaluated the cost-effectiveness of both strategies, taking into account the local reimbursement rates of D-dimer testing, angiography and Doppler ultrasonography (18.20, 58.72, and 75.60 Euros respectively). The economic impact of the proposed diagnosis strategy was a decreased of 6.9% of total costs (45,023.4 48,356.4 Euros) for PE diagnosis and 5.1% (9,909 126,358.4 Euros) for DVT diagnosis vs 22,948, 25,300, and 28,660 Euros respectively, for PE diagnosis and 2,500, 4,000 and 5,500 Euros respectively, for DVT diagnosis.

Summary/Conclusions: The use of age-adjusted cut-off levels for D-dimer, in patients aged over 50 years old, led to a significant increase in the test specificity, but correlatively to slightly decreased NPV and sensitivity. Even though some patients with D-dimer levels above 500 ng/ml but below the age-adjusted cut-off could be misdiagnosed, such a strategy was found to be safe in our studied population with a high NPV (99.9%) and sensitivity (99.1%), and cost-effective.

P371
IMPACT OF CELLULAR THERAPY ON THE ECONOMIC BURDEN AND SURVIVAL FOLLOWING RELAPSE AFTER HLA IDENTICAL HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR ACUTE LEUKEMIA AND MYELODYSPLASTIC SYNDROME
S. Lachance1,*, J. Bibeau2, N. Ladjemil3, J. Lachaine4
1Hematology, Hematopoietic cell transplantation, Université de Montréal, Hôpital Maisonneuve-Rosemont, 2Peripharm Inc., 3Peripharm, Montréal, 4Pharma- cie, Université de Montréal, Montréal, Canada

Background: Relapse following allogeneic hematopoietic stem cell transplant (aHSCT) is associated to a very poor outcome and remains an unmet medical needs. The impact of treatment approach on costs and survival remains unknown. The development of innovative cellular therapy for the treatment of relapse following aHSCT may change its dismal outcome but the cost of such intervention has prohibited its large-scale development.

Aims: The objective of this study was to measure the economic burden associated with the management of relapse following aHSCT and to evaluate the impact of treatment choice on survival and health care costs.

Methods: A retrospective medical chart review was conducted at Maison- neuve-Rosemont Hospital (HMR) after research and ethic committee approval. Patients were selected using the Hematopoietic Stem Cell Transplant (HSCT) program database. Eligible patients were diagnosed with acute leukemia (AL) or MDS and relapsed following an aHSCT between January 1st 2011 and December 31st 2014. Patients’ and disease characteristics and relapse-related health care resource utilization were collected from the date of post transplant relapse until death or last follow-up. Canadian unit costs for each intervention/treatment were obtained from literature and governmental publications.

Results: During the study period, 645 HSCT were performed at HMR, 303 were allogeneic. A total of 36 patients met the inclusion criteria and were included in the analysis. 32 recipients were diagnosed with AL and 4 with MDS. Treatment approaches following aHSCT relapse were divided in three groups according to patient and physician choices: group 1 received supportive care (n=9), group 2 received chemotherapy or tyrosine kinase inhibitors (n=21) and group 3 received a cellular based therapy, either donor lymphocyte infusion (DLI) or a second aHSCT (n=6). The mean cost of care per patient per month was $20,239 (SD=17,079). The median survival following relapse for the entire cohort was 12.4 months (SD=2.8). For group 1, 2 and 3, the mean cost of care per patient per month was $17,436 (SD=16,447), $22,914 (SD=18,474) and $15,082 (SD=12,954), respectively. The median survival was 4.0 months (SD=2.0), 7.2 months (SD=1.6), and 46.6 months (SD=8.4), for treatment group 1, 2 and 3 respectively (Figure1).

Summary/Conclusions: Relapse following aHSCT is associated to a poor prognosis and survival and to significant use of health care resources. Despite the selection bias, only patients who received cellular based therapy, either DLI or another HSCT, enjoyed a prolonged survival. Healthcare resources devoted to the care of patients in relapse post aHSCT provide a comparative basis for cost efficiency analysis in the development of innovative cellular therapy.

P372
ACUTE MYELOID LEUKEMIA TREATMENT PRACTICE PATTERNS, HEALTHCARE RESOURCE UTILIZATION (HRU) AND COSTS IN A US COMMERCIALLY-INSURED POPULATION
M. Hagiwara1,*, A. Sharma1, K. Chung2, T. E. Delea1
1Policy Analysis Inc., Brookline, MA, 2Jazz Pharmaceuticals, Palo Alto, CA, United States

Background: AML is a rapidly progressive hematologic malignancy that accounts for 25% of all leukemias in the Western world, with estimated 5-year survival of 26%, and is associated with high HRU and costs.

Aims: To estimate HRU and costs among newly-diagnosed AML patients (pts) in a US commercially insured population by receipt of chemotherapy (CT) or stem cell transplant (SCT).

Methods: This was a retrospective observational study using the PharMetrics Plus® database. Pts were adults with AML (ICD-9-CM code 205.0x), 18 years and older, from a US commercially insured population. Pts with other malignancies, receipt of HSCT, or death within 3 months of AML diagnosis were excluded. AML diagnoses were identified between Jan 2007 and Jun 2016.

Results: Of the 5,316 newly diagnosed AML pts included in this study, 8% received CT only, 72% received CT plus SCT, 15% received SCT only, and 5% received supportive care only. Pts receiving CT plus SCT had significantly higher HRU and costs compared to CT only or SCT only. The median costs were $55,158 (IQR $18,691 – $118,238) and $54,902 (IQR $18,691 – $104,204), respectively, for pts receiving CT only or SCT only.

Summary/Conclusions: The impact of treatment approach on costs and survival remains unknown. The development of innovative cellular therapy for the treatment of relapse following aHSCT may change its dismal outcome but the cost of such intervention has prohibited its large-scale development.
not continuously enrolled for 12-months (mos) before the first AML claim (index date); evidence of acute promyelocytic leukemia anytime during the study period; missing enrollment information; or ≥1 hospitalizations during follow-up (FU) with missing cost. Pts were classified as treated or untreated, with treatment defined based on receipt of CT (inpatient or outpatient) or SCT. For treated pts, FU was partitioned into 2 periods: index date to 6 mos and >6 mos post index date. Mean HRU and costs over the FU period were calculated by receipt of treatment and, for treated pts, by time since index date.

Results: 10,197 pts met study criteria including 6,862 treated pts (67%) and 3,335 untreated pts (33%). Mean age was 55 and 60 years in treated and untreated pts, respectively. Mean follow-up was 19.3 mos in treated pts and 18.1 mos in untreated pts. Mean total costs were higher for treated pts ($386,711) vs untreated pts ($83,274). In treated pts, mean total costs were $166,156 during the first 6 mos (mean duration 3.9 mos), and $220,555 during the remaining follow-up period (mean duration 19 mos). 26% of treated pts had SCT. Costs of inpatient and outpatient CT during the first 6 mos were $86,188, representing 22% of the total cost for treated pts (Table 1).

Table 1.

Summary/Conclusions: HRU and costs of managing AML pts are considerable, with greatest HRU and cost in pts receiving CT or SCT.

P373
HEALTH-RELATED QUALITY OF LIFE IN AL AMYLOIDOSIS PATIENTS WITH PERIPHERAL NERVOUS SYSTEM INVOLVEMENT
M. Yokota1, S.D. Guthrie2, T.P. Quock2, K.L. McCausland1,*, M.K. White1, M. Bayliss1
1Optum, Lincoln, 2Prothena Biosciences Inc, South San Francisco, United States

Background: In light chain (AL) amyloidosis, misfolded light chains accumulate and cause progressive peripheral neuropathy (PN) and failure of critical organs such as the heart and kidneys. Consequently, a progressive, ascending sensorimotor neuropathy is often a related clinical finding.

Aims: This study describes disease characteristics and health-related quality of life (HRQoL) in AL amyloidosis patients with peripheral nerve involvement (AL-PN).

Methods: An online survey was administered to AL-PN (n=126) and non-PN-affected (n=204) patients to assess patient characteristics and HRQoL (based on the SF-36v2® Health Survey [SF-36v2]). The survey measures eight health-related quality of life dimensions (physical functioning, role physical, role emotional, mental health, vitality, social functioning, general health, and health transition). Patients were then asked to select which of the following conditions they had: gastrointestinal involvement; musculoskeletal involvement, fatigue, and peripheral neuropathy. Statistical analyses included t-tests and linear models. Differences in mean HRQoL between AL-PN and non-AL-PN patients were compared to established minimally important differences (MIDs).

Results: Compared to non-PN-affected patients, greater proportions of AL-PN patients visited ≥6 doctors (42.1% vs 19.5%, p < 0.001) and ≥6 specialists (24.6 vs 9.9%, p < 0.001). AL-PN patients also had symptoms for ≥1 year prior to receiving a diagnosis (50.8 vs 39.1%, p = 0.035), relative to non-PN-affected patients. Nearly all AL-PN patients (97.6%) reported multi-system involvement. Gastrointestinal involvement was more prevalent in AL-PN patients versus non-AL-PN patients (68.3 vs 28.8%, p < 0.001). There were greater odds of experiencing numbness (OR=4.23, 95% CI: 2.45–7.30, p < 0.001) and fatigue (OR=3.09, 95% CI: 1.36–7.02, p < 0.01) among AL-PN patients as compared to non-AL-PN patients, even after controlling for other types of organ involvement. Similar findings were observed for gastrointestinal symptoms, such as alternating bouts of constipation or diarrhea (OR=1.92, 95% CI: 1.12–3.34, p=0.019) and early safety/feeling fullness in the stomach (OR=1.80, 95% CI: 1.03–3.16, p=0.04). With the exception of RE, MH, and MCS, there were significant differences in SF-36v2 scores among AL-PN patients as compared to non-AL-PN patients (p < 0.05 for all). These significant differences also exceeded the thresholds for clinically meaningful differences between the two groups.

Summary/Conclusions: This study suggests that the burden of illness from AL amyloidosis may be greater for those with PN involvement versus those without. AL-PN patients also experienced more complicated journeys to diagnosis and significantly worse symptoms related to nervous systems and physical HRQoL. The SF36v2, a reliable and valid assessment of HRQoL in AL amyloidosis studies, was sensitive to differences in HRQoL between AL-PN and non-AL-PN patients. Future research should examine whether improvements in neuropathy symptoms following treatment subsequently lead to improvements in HRQoL among patients with AL-PN. These findings are helpful for patient-focused drug development and supportive treatments.

P374
ACCESS TO COMMUNITY CHEMOTHERAPY IMPROVES PATIENT QUALITY OF LIFE
R. Pugh2, C. Bygrave1, H. Cosh3, W. Ingram3, J. Keil3
1Faculty of Life Sciences and Education, University of South Wales, Pontypridd, 2Tenovus, 3Haematology, University Hospital of Wales, Cardiff, United Kingdom

Background: Deciding how service delivery for people with haematological cancers are to be delivered is going to be an important challenge in the coming years. Clinics have limited clinic capacity in terms of staff and bed space to cope with increased demand. In Wales many day units are already at capacity, overcrowded and have long waits for treatment. Ambulatory care, including diagnosis, observation, consultation, intervention, and rehabilitation, has the potential to improve patient experience, if traditionally-based hospital services are moved into the community. We used a Mobile Unit – a 34-tonne articulated lorry which opens out to become a bespoke clinical space - to deliver treatments in a community setting to a range of haematology patients for a period of 12 months in South Wales.

Aims: We aimed to explore whether the administration of cytotoxic therapy on a Mobile Unit in a community setting for patients with haematological cancers could prove to be a safe and efficient alternative to hospital therapy, and in particular whether this model of service delivery would be acceptable to patients. Our target group was patients with myeloma, aiming for up to 20 a day once or twice a week.

Methods: The first drugs administered on the Mobile Unit were zoledroxate infusions, followed by bortezomib. When twice weekly doses were required, patients collected an additional injection pack which they could self-administer in their own homes, thereby saving another trip to hospital. Patients were given zoledroxate infusions, between taking 1–2 hours, were also administered. There was a consultant review clinic on board for patients receiving bortezomib which further reduced the numbers of hospital visits for patients and also a nurse-led Quality of Life assessment.

Results: In one year 548 treatments were administered on 91 days to a total of 54 individual patients. All 54 patients had a diagnosis of myeloma. 56% are female and 44% are male with an age range of 46 to 90 years of age, with 48% over 70 years of age. 37 patients are married and all but 4 classed themselves as White British. The greatest number of patients treated in a single day was 16. 98% felt safe having their treatment outside hospital and 92% said their experience was better than hospital. Patients could drive up to the door of the Mobile Unit and average time waiting from arrival to treatment chair was 2 minutes, with many people not having to wait at all. Uptake of the psychosocial support services was lower than expected with only 10 people opting for additional support. Any criticisms received focused on the locations we chose to site the Mobile Unit in relation to accessibility via public transport.

Summary/Conclusions: Treatment in the community alleviates the stress of treatment and with minimal waiting times it gives some patients the ability to maintain family life and where possible to continue to work. It is both feasible and acceptable to begin to ambulate many different sorts of treatments. The possibilities opening up for haematology include rituximab maintenance; community blood transfusions; delivering pentamidine for patients at risk of pneumocystis infection; late effects clinics for teenage and young adult cancer patients; and myeloproliferative neoplasm clinics, possibly near community pharmacies to facilitate dispensing medicines such as hydroxyurea.

P375
THE BUDGET IMPACT OF TREATMENT-FREE REMISSION FOR FIRST-LINE NILOTINIB OR GENERIC IMATINIB IN TREATING CHRONIC PHASE PHILADELPHIA-POSITIVE CHRONIC MYELOID LEUKEMIA
D. Tran1, S. Brown1, N. Goyet3, P. Brandt2, D. Grima1
1Cornerstone Research Institute, Burlington, Canada, 2Global Value & Access, Novartis Pharmaceuticals Corporation, East Hanover, United States

Background: The 2013 European LeukemiaNet (ELN) guidelines recommend switching from first-line therapy as early as 6 months with poor molecular response (MR3.5-5). We also recognize the possibility of treatment-free remission (TFR), requiring deep MR (MR0 or MR4.5-5). These emerging shifts in practice will dramatically change chronic myeloid leukemia (CML) treatment patterns. Occurring in parallel to this is the introduction of generic imatinib in Europe,
which will have a substantial price difference compared with nilotinib. However, given the possible changes in switching and TFR in this model, this price difference may not translate into a similar magnitude of difference in drug budget for first-line nilotinib vs imatinib due to better MR with nilotinib.

Aims: To estimate the budget impact for first-line nilotinib vs imatinib when considering generic imatinib pricing, early treatment-switching, and TFR. Methods: The model was based on the Patient Regimen Simulator (PRIS) and ELN switching and TFR use on clinical outcomes and treatment costs. Analyses were run for 1000 patients with newly diagnosed CML, starting either nilotinib or imatinib, over a 5-year time horizon and using French drug pricing. It was assumed that all patients in the model would switch therapy (imatinib to nilotinib, and nilotinib to dasatinib) based on the failure criteria of the ELN guidelines. As such, ENESTnd trial data were re-analyzed to estimate switching based on the model. The assumption was patients could enter first-line or second-line TFR after 36 months of continuous therapy where the last 12 months were at MR4.5.

Duration of first-line or second-line TFR was based on an extrapolation of ENESTnd. A greater number of patients in the first-line nilotinib arm remained on first-line therapy (690 vs 479 at 15 mos., and 542 vs 366 at 60 mos.); achieved a complete cytogenetic response (CCR) (442 vs 248 by 60 mos.); entered TFR on first-line therapy (347 vs 183 by 60 mos.); entered TFR on either first- or second-line (494 vs 400 by 60 mos.); and was in any TFR at 60 months (293 vs 200). The incremental budget impact per patient for first-line nilotinib vs imatinib decreased each year from €16,482 in Year 1 to €377 in Year 5. Overall, the 64% lower drug acquisition costs per month of imatinib (€1,063) vs nilotinib (€2,952) provided only a 17% lower total budget impact over five years (€141,204 vs €170,002) per patient.

Summary/Conclusions: Results from the model considered more switching as per 2013 ELN guidelines, which resulted in greater and quicker switching that would be expected to occur in DEFACTO. If the model projected that imatinib, patients who receive first-line nilotinib would have earlier and more sustained molecular response-requirements for TFR eligibility—and be subject to less treatment-switching. The model projected that less than 50% of patients would remain on first-line imatinib at 15 months. This would significantly reduce the switchout benefit of a lower imatinib acquisition price. The median period between first-line imatinib and nilotinib would be further reduced by TFR, which occurred in the model more frequently in the nilotinib group. The superior efficacy of nilotinib and the associated differences in switching and TFR eligibility are predicted to substantially offset the lower unit cost for generic imatinib.

P376
GAH SCALE PREDICTS TREATMENT TOLERABILITY IN OLDER PATIENTS (>65 YEARS) DIAGNOSED WITH HEMATOLOGICAL MALIGNANCIES

Gregorio Marañón, Madrid, 14Hematology Department, C.S. Parc Taulí, Barcelona, 15Hematology Department, H. U. Central de Asturias, Oviedo, Asturias, 16Hematology Department, H.U. Gregorio Marañón, Madrid, 17Dietician, Doctor Peset, Valencia, Spain

Background: The Geriatric Assessment in Hematology (GAH) scale is a newly developed tool that is intended to be an ancillary questionnaire to better categorize elderly patients diagnosed with hematologic neoplasms and is intended for intensive treatment in routine clinical practice. It is a brief (<12 min) and easy instrument, which takes into account 8 dimensions of geriatric assessment that were initially dichotomized into 0 or 1. The GAH scale has recently been shown to be psychometrically valid, responsive to clinical change, and able to predict survival.

Aims: To determine the weights for each dimension of the GAH scale and the cut-off points for the scale to be used as a tool to predict treatment tolerability in older patients diagnosed with myelodysplastic syndrome / acute myeloblastic leukemia, multiple myeloma, or chronic lymphocytic leukemia. Methods: A prospective, observational study conducted at 14 Spanish sites. Prior participants of the GAH study were given treatment within 3 months after having completed the GAH scale were eligible for inclusion after giving informed consent. A logistic regression model and a full multiple linear regression model were calculated to determine the weights for each dimension and finalize its contribution to the final score; the ROC curve analysis was used to calculate the cut-off points that defined three groups: “go-on” (low probability to develop toxicity regardless of intensive or attenuated therapy), “slow-go” (high probability to develop toxicity with intensive therapy but low probability with attenuated therapy), and “no-go” (high probability to develop toxicity regardless of therapy). Results: A total of 108 patients (women, 53.7%; median age [IQR], 78 [73-83] years) out of 360 included in the main study were evaluated. During treatment administration, 61 (56.5%) patients developed treatment-related toxicities, requiring discontinuation/modification of the initial therapy. The coefficients for the dimensions are: 7 for number of drugs, -10 for gait speed, 2 for mood, and 60 for activities of daily living, 6 for subjective health status, 27 for nutrition, -5 for mental status, and 1 for comorbidities. The sum of the GAH scale score, ranging from 0 to 66, plus a factor derived from the treatment intensity (34 points for intensive therapy or 0 for attenuated) leads to a maximum score of 100 points, at which a cut-off point set at 47. Figure 1 shows the GAH scale equation for treatment toxicity prediction and the classification of patients according to their score. Among the 97 (89.8%) patients that received intensive therapy, 26 patients were classified as go-on, 48 as slow-go, and 23 as no-go. The proportion of patients that developed toxicities for each group was 34.6%, 56.3%, and 78.3%, respectively, with a statistically significant difference (P=0.002).

Figure 1.

Summary/Conclusions: The GAH scale appears to have the potential to give guidance for election of individual treatment regimes. By identifying elderly patients at high risk to develop toxicities, it may help to choose low-toxicity combinations, to avoid harmful therapies and to identify those patients that could benefit from more intensive treatment. Nonetheless prospective studies with larger populations should be performed to confirm these findings and to try to determine particular cut-off points for different diseases.

Background: Cachexia, weight loss, and malnutrition in cancer patients are important contributors of adverse outcomes of cancer patients. MPN patients have abnormal cytokine expression (e.g., IL-1, IL-6, IL-8, and TNF-a) that contributes to symptom burden (e.g., fatigue, pruritus, night sweats, bone pain) and decreased functional status (e.g., reduced physical activity). The most common adverse symptoms are fatigue, loss of appetite, and low-fat dairy products are associated with a decrease in inflammatory (e.g., TNF-a, IL-8, and CRP) and thrombotic markers (e.g., homocysteine, fibrinogen). Chrysohoou 2004, Smidowicz 2015). To date, no studies have evaluated the nutritional needs or preferences of MPN patients in regards to dietary treatment.

Aims: The aim of this project was to determine the nutritional needs and preferences that will help inform the creation of a tailored MPN dietary intervention.

Methods: An internet-based survey was hosted by the Mayo Clinic Survey Research Center and promoted on multiple MPN-based forums, Facebook pages and websites during February of 2017. The survey included data on demographics, MPN characteristics, nutritional habits, supplement use, and symptom burden using the MPN-SAF TSS/MPN-10 (Emanuel 2012).

Results: Demographics and symptom burden: 919 international MPN patients took the survey online, and the online survey was distributed to 22,5% were diagnosed with MF, 37.1% with PV, and 37.4% with ET. Respondents represented MPN patients from 37 States (48.8%), United Kingdom (32.7%), Australia (6%), and Canada (3.6%). Average MPN-SAF TSS score was 33.6 (SD=17). Dietary Habits: 22.5% of the respondents having dairy products or high-fat foods (e.g., milk, cheese, or salad dressing). Specifically, 31.7% of individuals followed a specific diet or had dietary restrictions. On average, MPN patients ate 2.1 meals outside the home per week. Among those taking supplements, 16.6% took supplements with the intent of reducing inflammation. Half (47.5%) of these individuals felt that the supplements they used made them feel better. Approximately 15% of respondents had tried alternative medicine to help treat their MPN. Among these, 44.8% were under the care of a naturopath and 60.2% endorsed that their treatment plan included dietary change. Nutritional Education Preferences: Overall, 34.4% of patients endorsed
using diet to help control their symptoms or MPN disease. Patients most often utilized books (28.2%), websites (27.1%), health care providers such as physicians, NPs or naturopaths (28.2%), online forums (23.2%), friends (12.2%), nutritionists (9.5%), phone or tablet applications (9.1%), or videos (4.2%) for nutritional education. The vast majority (95.9%) of MPN patients endorsed being willing to eat only certain foods if it helped to control symptom burden and or could help their MPN to stabilize or reduce the risk of their MPN getting worse (98.0%).

Summary/Conclusions: There remains an unmet need for symptom burden improvement in low-risk MPN patients or among those who have reoccurrence of symptoms while on JAK inhibitor therapy. Nutritional interventions for MPN patients have not previously been investigated and have the potential to be paired with traditional interventions to allow MPN patients to self-manage symptom burden. This study represents the first evaluation of MPN-related nutritional habits and preferences. These results will be used to inform the creation of an MPN nutritional intervention with the goal of improving symptom burden and reducing inflammation.

**P378**

**DO PHYSICIANS NEED HELP TO ADEQUATELY INFORM AND SUPPORT PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA? RESULTS FROM A QUALITATIVE STUDY IN GREECE**

C. Karamanidou1,*, A. Xochelli1, V. Koutkias1, P. Ghia2, K. Stamatoopoulos1

1Institute of Applied Biosciences, CERTH, Thessaloniki, Greece. 2Division of Experimental Oncology and Department of Onco-Hematology, Università Vita-Salute San Raffaele and IRCCS San Raffaele Scientific Institute, Milan, Italy

Background: Despite recent progress in prognostication and management, chronic lymphocytic leukemia (CLL) remains unpredictable at diagnosis, while virtually incurable, posing challenges to physicians on how to properly communicate the actual nature of the disease. Moreover, the great majority (~85%) of patients do not need treatment at diagnosis, creating a major cognitive dissonance between the perception of leukemia diagnosis and the “wait & watch” strategy usually applied, that may become a major reason of anxiety and quality of life (QoL) impairment for patients and frustration for physicians. Evidently, both patients and physicians need parameters that would allow co-decision making tailored to each particular case.

Aims: To identify physicians’ needs in order to improve their communication skills and thus facilitate CLL patient empowerment through a patient-centered-ness model.

Methods: An in-depth qualitative study with semi-structured interviews was conducted within hematologists (n=30) all over Greece. Data collection was considered as completed when saturation was reached i.e. no new themes emerged as assessed by the investigators. Content analysis was performed separately by a hematologist and a health psychologist with 98% inter-rater reliability score.

Results: None of the participants had ever received formal communication training but rather adopted the techniques of senior physicians or developed their own through experience alone, thus frequently doubting their approaches (n=12/30, 40%). The most popular communication technique mentioned was adaptation of the quality and quantity of information provided according to each patient’s characteristics (n=29/30, 96.7%); followed by the use of caregivers as mediators for the communication of difficult issues (n=24/30, 80%); balance of realism and hope (n=21/30, 70%); careful choice of wording (e.g. lymphocytosis instead of leukemia) (n=18/30, 60%); gradual disclosure (n=17/30, 56.7%); and, descriptions through pictorial representations or metaphors (n=16/30, 53.3%).

Even though physicians did not systematically assess patients’ anxiety and depression levels, they often found themselves dealing with patients’ emotions (n=29/30, 96.7%) through lengthy discussions. With regards to decision making, some mentioned that physicians should make all the decisions (n=9/30, 30%) and that patients are not always willing to take part in the decision-making process (n=8/30, 26.7%), while others were keener on stirring patients towards a decision (n=15/30, 50%), taking into account patients’ preferences (n=10/30, 33.3%). Most physicians felt uncomfortable delivering bad news such as initial diagnosis, relapse and poor prognosis (n=25/30, 83.3%). Self-reported needs included (i) communication skills training (n=20/30, 66.7%); (ii) psychological support (n=7/30, 23.3%); and, (iii) working in a multidisciplinary team (n=8/30, 26.7%).

Summary/Conclusions: In the absence of structured communication guidance there is great uncertainty among physicians concerning their skills on communicating CLL nature and handling difficult situations, leading to distress endangering their engagement in a healthy relationship with the patient. Additional studies are warranted at European level for identifying physician needs in different countries aiming at improving their communication skills to support and empower CLL patients for participating in their own care and enhance their QoL.
Methods: CR using digital droplet (dd) PCR.

Aims: MN1 pts (ASH 2016, #517). Until today no study assessed the prognostic impact of relapse (CIR) for pts with high pre-HSCT outcomes. At diagnosis high expression of the AML associated genes disease detection. Recently, we demonstrated a higher cumulative incidence allogeneic stem cell transplantation (HSCT) have a dismal prognosis. Identifi-

Background: The average age of patients (pts) with AML is about 67 years. Historically, many of these pts were not considered as viable candidates for allogeneic transplantation (HCT) because of concerns about increased transplantation-related toxicity and excessive non-relapse mortality (NRM), a challenging problem especially in older individuals. However the development of reduced-intensity conditioning (RIC) regimens and the improvement in HCT supporting care allowed the successful application of HCT in older pts with AML.

Aims: Compare outcome of allo SCT in acute myeloid leukemia AML patients aged above 70 years of age with that of patients between 50-70 years who were performed for the whole group and separately according to disease status at SCT (CR1, CR2, above).

Methods: AML patients aged between 50 and 90 years old receiving a first or second allo SCT between 2004 and 2014 with MSD or UDT donor were included in the study. Comparison of outcomes of patients aged above 70 with that of patients between 50-70 years were performed for the whole group and separately according to disease status at SCT (CR1, CR2, above).

Results: Altogether N=16874 pts were included in the study, N=713 were aged above 70 years of age (median 72, IQR 71-73) and N=16161 between 50 and 70 (median 59, IQR 55-63). Older pts were more often male (62 vs 55%, p<0.001), had more often secondary AML (42% vs 28%, p<0.001), more advanced disease (42% vs 27%, p<0.001), more often peripheral blood stem cell grafts (96 vs 91%, p<0.001), more often unrelated donors (79% vs 59%, p<0.001) and poorer Karnofsky score (36% below 90, p<0.001), received more often reduced intensity conditioning (80 vs 63%, p<0.001). Incidence of acute GVHD II/III, IV, chronic GVHD and relapse were the same in the two groups in multivariate analysis. Non-relapse mortality (NRM) at two years was 34% (95%CI 32-37) vs 37% (95%CI 34-40) in pts above 70 and 24% (25% vs 32%) in those below 70 years of age (p<0.001). Overall survival and leukemia-free survival (LFS) at 2 years was 38% (95% CI 34-42) vs 50% (95% CI 49-50) p<0.001 and 35% (95% CI 32-38) vs 45% (95%CI 43-45) in the two groups, respectively (p<0.001). Among pts in CR1, 2 years survival was 43% (95% CI 37-51) vs 57% (95% CI 56-58) (p<0.001), in CR2 it was 36% (95% CI 27-47) vs 52% (95% CI 50-54) (p=0.002) and in advanced disease 35% (95% CI 29-41) vs 33% (95% CI 31-34) (p=0.36) in pts above and below 70 years of age, respectively. Among pts older than 70 years of age a Karnofsky score >80% was associated with improved survival and LFS in multivariate analysis (HR 0.7 95% CI 0.5-0.9, p=0.005 and HR 0.7 95% CI 0.5-0.9, p=0.003 respectively).

Summary/Conclusions: In AML with CR1, CR2 status at allo SCT, pts above 70 years of age have worse NRM, survival and LFS compared to pts 50-70 years of age. In pts above 70 years of age Karnofsky score is of significant importance for outcome.
Sickle Cell Disease (SCD) and Diamond-Blackfan Anemia (DBA). Bertain et al (Blood, 2014) have previously shown that abTCR depleted haplo-transplantation in children with multiple types of non-malignant disorders was feasible. An ongoing Phase II/III trial evaluates the safety and efficacy of post-transplant infusion of donor T-cells transduced with the iCD9 suicide gene (BPX-501 cells). (ClinicalTrials.gov identifier: NCT02055869). The iCD9 vector contains the sequence for the CD19 marker, so that the BPX-501 cells (CD3+/CD19+) can be tracked in peripheral blood. We report on 15 children with hemoglobinopathies and ED.

Aims: This study was performed to determine the clinical impact of infusing BPX-501 T cells post o/- T-cell depleted haplo-identical HSCT in pediatric patients with hemoglobinopathies.

Methods: Fourteen patients were transplanted from a parent and one patient was transplanted from a sibling. Conditioning regimen included busulfan, thiopepa and fludarabine. Low dose ATG was administered to prevent graft-versus-host disease (GVHD) and graft failure. No post-transplantation GVHD prophylaxis was given. Median follow-up is 387 days (range 126-631 days).

Six patients were males and nine females, and median age at diagnosis and at HSCT was 0.8 and 8.9 years (range 2.5-19.2), respectively. Two patients had DBA and four with SCD. All 9 TM patients were ββ/ββ, and among the those with TM, 4 patients belonged to class I and 3 to class II of the Pesaro classification. All 15 patients were transfusion-dependent and receiving iron-chelation therapy before haplo-HSCT. 13/15 patients maintained full donor chimerism. The patients with secondary graft failure were re-transplanted from the same donor and maintained full donor chimerism.

Results: All patients are alive and well with no Treatment Related Mortality (TRM). Initial engraftment was observed at a median of 23.5 days (range 14-55) and there were two patients re-hospitalized at 30, 163 days respectively. Grade III/IV skin acute GVHD occurred in four patients and one patient had acute skin GVHD Grade IV. No chronic GVHD was observed. The median time to neutrophil recovery was 14 days (range 10-32 days), while median time to platelet recovery was 11 days (range 8-12 days). The median time to last RBC transfusion was 8 days (5-34 days). See Figure 1 for individual Hemoglobin levels. Median time of infusion of 1×10^6 BPX-501 T cells/kg was 14 days after HSCT (range 10-26). BPX-501 cells expanded after infusion and still persist in all patients. Immune reconstitution was normal cellular and humoral immunity present at 168 days post HSCT. All patients remain transfusion-free with a median hemoglobin of 11 or greater after 6 months.

Figure 1.

Summary/Conclusions: These data suggest that Haplo-HSCT combined with infusion of BPX-501 T cells with a suicide gene may be a safe and curative option for children with hemoglobinopathies and ED who lack a matched donor. Infusion of gene modified T cells with an inducible suicide mechanism, combined with selective o - T-cell depletion, offers the potential to rapidly reverse GVHD and eliminate the need for the use of GVHD prophylaxis. Additionally, this approach results in rapid hematopoietic and immune reconstitution for Haplo-HSCT recipients.

P382

EXCELLENT RESPONSE, LOW TRM AND GOOD SURVIVAL IN PATIENTS WITH THERAPY-REFRACTORY AGVHD AFTER TREATMENT WITH EQUIPOTENT MSCS OF A SERUM-FREE MSC-BANK GENERATED FROM POSILIZED BM-SCDS OF MULTIPLE DONORS. P. Bader1, Z. Kuc1, S. Bakhtrian1, O. Basu2, G. Bug3, M. Dennis4, J. Greil5, K. Källay6, P. Lang7, G. Lucchini8, R. Po9, A. Schulz10, K.-W. Sykora11, I. von Lueettichau12, P. Remény13, L. Gopcsa13, A. Jarisch1, J. Soerensen1, K. Kállay6, P. Lang7, G. Lucchini8, R. Pol9, A. Schulz10, K.-W. Sykora11, E. Salzmann11, E. Seifried14, T. Klingebiel1, H. Boenig14, S. Kuci1,

Background: All clinical data published thus far on the use of MSCs were generated using cells expanded from individual bone marrow donor hence suffer from huge inter-donor differences in MSC generation, expansion and immunomodulatory potential. To control these variables and to be able to administer to all patients highly similar MSC products, we established a proprietary pooling procedure and generated a large bank of MSC end-of-phase-1 vials from which end-of-phase-2 MSC products are expanded for clinical use. The manufacturing process is fully GMP-compliant and generates an animal serum-free product with near-identical phenotype and in-vitro immunomodulatory potency. Importantly, they showed a significantly higher allo-suppressive potential than the mean allo-suppressive potential of MSCs generated from individual donors. All tested individual MSC doses were equipotent in suppression of the alloantigen-specific reaction in mixed lymphocyte reactions (Kuc1 et al. Haematologica 2016: 101 (8): 885-894).

Aims: A “hospital exemption” issued by the national regulatory authority Pau-Ehrlich-Institute (Number: PEF: A11748.0.1) licenses the clinical use of these products for patients with steroid refractory GVHD. On the basis of this licence patients were with severe GVHD were treated who were either non responsive or refractory to standard standard steroid treatment and treatment with non-malignant diseases. Median age was 8 years (range: 0.5-57 years). The stem cell sources were BM (n=17, 13%), SE (n=33, 25%) or MMFD (n=19, and derived from BM (n=27, 52%), peripheral blood (n=24, 46%) or cord blood (n=1, 2%). Patients were suffering from aGVHD grade II (n=3, 5.5%), III (n=14, 27%), or IV (n=31, 60%) or extensive cGVHD (n=7, 4.5%). Acute GVHD occurred at a median of 52 days (5-200 days) after transplant. Patients received in weekly intervals up to four MSC infusions after having failed to respond to the treatment with either two lines (n=10, 19%), three lines (n=20, 38%), four lines (n=10, 19%), 5 lines (n=7, 13%), six lines (n=4, 8%), or 7 lines (n=1, 2%) of immune suppressive drugs.

Results: Response was defined as either complete response (CR) in patients who showed one overall GVHD grade less according to the Glucksberg criteria, or non response (NR) at day 28 after first MSC transfusion. At day +28, 12 patients (23%) achieved CR, 29 patients (57%) PR (overall response( 80%), 8 patients (17%) NR, and in 2 patients (4%) no data were available at day +28. At the last follow up of GVHD, 29 patients (56%) were in CR, 13 patients (25%) in PR, 9 patients (17%) in NR, and for 1 patient (2%) no data were available. At 2 years these response rates resulted in a non-relapse mortality rate (NRM) of 27±6%, cumulative relapse incidence (CIR) of 14±5%, and a 2-year overall survival rate (OS) of 52±9%. Patients with aGVHD III and IV had an OS survival probability at 2 years of 77±12% and 59±35%, respectively thus dramatically in excess of expected survival rates for patients with such severe aGvHD. There was no difference between younger (n=40) and older patients (n=12) than 16 years.

Summary/Conclusions: Treatment with standardized equipotent MSCs from the "FRANKFURT MSC-BANK" offers an excellent chance to overcome treatment-resistant and steroid-refractory acute GVHD.

P383

HIGHER PEAK TACROLIMUS CONCENTRATIONS AFTER ALLOGENEIC TRANSPLANTATION INCREASE THE RISK OF ENDOTHELIAL CELL DAMAGE AND COMPLICATIONS. T. Morishita1,*, M. Ohbiki1, M. Osaki1, M. Yoshino1, S. Ikeno1, M. Nakashima1, T. Sato1, Y. Kagaya1, Y. Ozawa1, K. Miyamura1, K. Miyamura1, I. Hematology, Japanese Red Cross Nagoya Daiichi Hospital, Nagoya, Japan.

Background: Noninfectious transplantation-related complications (TRC) such as GVHD and endothelial cell damage (TRC-EC) including sinusoidal obstructive syndrome (SOS), transplant-associated microangiopathy (TAM), idiopathic pneumonia syndrome (IPS) are dismal complications after allogeneic hematopoietic stem cell transplantation (allo-HSCT). Calcineurin inhibitors such as tacrolimus (TAC) have been broadly used to manage post-transplant complications. Higher blood levels of TAC are expected to reduce the risk of GVHD, but may increase the risk of endothelial damage. Since TRC-EC often developed in patients with severe GVHD, it is difficult to judge appropriateness of immunosuppression clinically.

Aims: Here we evaluated the impact of TAC blood levels upon TRC-EC occurrence and prognosis after allo-HSCT.

Methods: Two hundred sixty-one consecutive patients (pts) who received TAC as a GVHD prophylaxis after allo-HSCT at our institute from 2009 to 2015 were candidates for this retrospective study. Pts who received haploidentical allo-HSCT haematologica | 2017; 102(s2) | 131
and pts with unavailable TAC concentration data were excluded. A total of 253 pts was eligible. All pts received standard GVHD prophylaxis by continuous intravenous (iv) TAC with starting dose of 0.02 mg/kg/day from 1 day before allo-HSCT (day -1) and iv methotrexate on day 1, 3, 6 at dose of 10 mg/m², 7mg/m², respectively. TAC dosage was adjusted to target the serum concentration of 8-12 ng/ml until at least day 30 and then tapered. TAC was rapidly tapered in case of the pathological diagnosis of TAM. TAC serum concentration was sequentially examined tri weekly until day 35 at least. The primary endpoint of this study was to evaluate the cumulative incidence of TRC-EC in relation to weekly mean/peak TAC concentration. Secondary endpoint was OS.

Results: Median patient age was 45 years (16-68). The risks of disease were standard in 168 and high in 85 pts. Forty pts were diagnosed of TRC-EC: S0S: 7 pts (median onset: day 24 (17-40)), TAM: 27 pts (median onset: day 40 (25-128)), IIP: 6 pts (median onset: day 161.5 (46-233)).The cumulative incidence of TRC-EC at day 250 was 0.16 (95%CI, 0.12-0.21). Univariate analysis showed that higher peak TAC concentrations (PTC) during day 22-28 (P=0.013), male pts (P=0.018) and pts with unavailable TAC concentration data were excluded. A total of 253 patients receiving a previous allogeneic transplantation were excluded. RIC was defined according to EBMT definitions.

Results: The median follow up for MAC and RIC was 24 and 20 months, respectively and the median year of transplant was 2013 for both. Pts receiving a RIC were older (55 yrs in MAC vs 61 yrs in RIC, p<10^-4). Secondary AML was more frequent in RIC vs MAC (31% vs 22%) while 77% of MAC and 68% of RIC were transplanted for de novo AML, p=0.01. No differences were found on disease status and Karnofsky performance status (KPS) at transplant: pts were in CR1 (MAC: 44%, RIC: 40.5%), CR2/3 (MAC: 17%; RIC: 17%) or had active disease (MAC: 40%; RIC: 43%), p=0.68; 12% of pts in both groups had KPS>80, p=0.95. The most frequently used MAC regimen was TBF (56%), while in RIC it was miniTBF (27%) and low dose TBI+Fludarabine (24%). RIC regimens had a more frequent conditioning regimen associated with stem cell source (MAC 42% vs RIC 55%, p=0.002). Post-transplant cyclophosphamide was used in 69% of both RIC and MAC, p=0.39. Main outcomes were not different according to conditioning regimen: at 2 years RIC was 36% vs 32% (p=0.29), NRM 31% vs 34% (p=0.62), aGVHD II-IV 24% vs 31% (p=0.05), and cGVHD 27% vs 26% (p=0.94), LFS 42% vs 39% (p=0.17), OS 46% vs 39% (p=0.15), GRFS 36% vs 28% (p=0.10) for MAC vs RIC, respectively. The results according to RIC and MAC were not different in any of the three age subgroups. 338 patients died; main causes of death were infections and GVHD to be followed by disease recurrence. In multivariate analysis, the type of conditioning regimen was not associated with risk of relapse or treatment failure: RI (HR: 1.22, p=0.28), NRM (HR: 0.92, p=0.63), acute GVHD grade II-IV (HR: 1.14, p=0.48), chronic GVHD (HR: 1.26, p=0.30), LFS (HR: 1.03, p=0.77), GRFS (HR: 1.07, p=0.55), OS (HR: 1.05, p=0.68). Disease status was associated with outcomes (active disease vs CR): RI (HR: 2.44, p<10^-4), LFS (HR: 1.75, p<10^-4), GRFS (HR: 1.72, p<10^-4), OS (HR: 1.71, p<10^-4) as well as KPS<90: NRM (HR: 0.53, p=0.0002), LFS (HR: 0.67, p=0.001), GRFS (HR: 0.74, p=0.014), OS (HR: 0.62, p=0.0002).

Summary/Conclusions: In our study no differences were found between RIC and MAC regimens for haplo-SCT in adults with AML including in conditioned patients. Disease status and performance status were the major predictors of transplantation outcome, while conditioning intensity had no effect. These results may serve as the background for a well design randomized study comparing RIC vs MAC for haplo-SCT in adult pts with AML.

Background: Patients with aggressive adult T cell leukemia-lymphoma (ATL) are candidates for upfront allogeneic hematopoietic stem cell transplantation (allo-HSCT) as no prospective randomized controlled trial (RCT) has been conducted due to a rarity of patients with ATL even in Japan.

Summary/Conclusions: This study was planned to compare the outcome of RIC and MAC in pts with AML older than 45 years (yrs) undergoing haplo-SCT. The aim of the study was to confirm the efficacy and feasibility of RIC among a population for which the choice of conditioning intensity is more related to center strategy than pts comorbidities or disease status.

Methods: We retrospectively compared the outcomes of 614 pts with de novo or secondary AML transplanted between 2007 and 2015 from an haplo-identical donor using either RIC (n=365) or MAC (n=249) regimens. Age was categorized in three subgroups (45-55 yrs, 55-60 yrs, >60 yrs). Patients receiving a previous allogeneic transplantation were excluded. RIC was defined according to EBMT definitions.

Results: The median follow up for MAC and RIC was 24 and 20 months, respectively and the median year of transplant was 2013 for both. Pts receiving a RIC were older (55 yrs in MAC vs 61 yrs in RIC, p<10^-4). Secondary AML was more frequent in RIC vs MAC (31% vs 22%) while 77% of MAC and 68% of RIC were transplanted for de novo AML, p=0.01. No differences were found on disease status and Karnofsky performance status (KPS) at transplant: pts were in CR1 (MAC: 44%, RIC: 40.5%), CR2/3 (MAC: 17%; RIC: 17%) or had active disease (MAC: 40%; RIC: 43%), p=0.68; 12% of pts in both groups had KPS>80, p=0.95. The most frequently used MAC regimen was TBF (56%), while in RIC it was miniTBF (27%) and low dose TBI+Fludarabine (24%). RIC regimens had a more frequent conditioning regimen associated with stem cell source (MAC 42% vs RIC 55%, p=0.002). Post-transplant cyclophosphamide was used in 69% of both RIC and MAC, p=0.39. Main outcomes were not different according to conditioning regimen: at 2 years RIC was 36% vs 32% (p=0.29), NRM 31% vs 34% (p=0.62), aGVHD II-IV 24% vs 31% (p=0.05), and cGVHD 27% vs 26% (p=0.94), LFS 42% vs 39% (p=0.17), OS 46% vs 39% (p=0.15), GRFS 36% vs 28% (p=0.10) for MAC vs RIC, respectively. The results according to RIC and MAC were not different in any of the three age subgroups. 338 patients died; main causes of death were infections and GVHD to be followed by disease recurrence. In multivariate analysis, the type of conditioning regimen was not associated with risk of relapse or treatment failure: RI (HR: 1.22, p=0.28), NRM (HR: 0.92, p=0.63), acute GVHD grade II-IV (HR: 1.14, p=0.48), chronic GVHD (HR: 1.26, p=0.30), LFS (HR: 1.03, p=0.77), GRFS (HR: 1.07, p=0.55), OS (HR: 1.05, p=0.68). Disease status was associated with outcomes (active disease vs CR): RI (HR: 2.44, p<10^-4), LFS (HR: 1.75, p<10^-4), GRFS (HR: 1.72, p<10^-4), OS (HR: 1.71, p<10^-4) as well as KPS<90: NRM (HR: 0.53, p=0.0002), LFS (HR: 0.67, p=0.001), GRFS (HR: 0.74, p=0.014), OS (HR: 0.62, p=0.0002).

Summary/Conclusions: In our study no differences were found between RIC and MAC regimens for haplo-SCT in adults with AML including in conditioned patients. Disease status and performance status were the major predictors of transplantation outcome, while conditioning intensity had no effect. These results may serve as the background for a well design randomized study comparing RIC vs MAC for haplo-SCT in adult pts with AML.
Decision analysis is a computerized modeling analysis which can simulate the clinical outcomes of different therapeutic strategies and identify an appropriate therapeutic strategy.

**Aims:** The aim of this study is to compare the life expectancy (LE) of chemotherapy followed by up-front allo-HSCT to that of chemotherapy alone using decision analysis in patients with aggressive ATL using database constructed by a nationwide survey.

**Methods:** We constructed a Markov decision analysis model to compare the outcomes in 2 therapeutic strategies: chemotherapy followed by up-front allo-HSCT vs chemotherapy alone. The transition probabilities between each health states were calculated from the database of 1,792 patients and patients were stratified into low-, intermediate- and high-risk groups according to the risk stratification system which we developed previously (Fuji S et al. 18th International Conference on Human Retrovirology). The model simulated the LE, quality-adjusted LE (QALE) and survival curve after diagnosis of aggressive ATL. Since QoL data for patients with aggressive ATL are lacking, estimated QoL was used in a similar decision analysis study of patients with acute myeloid leukemia were used. In terms of the timing of up-front allo-HSCT, it was set as all patients receive up-front allo-HSCT from 2 to 6 months if ATL did not progress before allo-HSCT. We used the TreeAge Pro 2016 software package for decision analysis (TreeAge Software Inc., Williamstown, MA).

**Results:** In all patients, up-front allo-HSCT was associated with higher LE in comparison to chemotherapy alone (2.26 years vs 1.75 years). Stratified into 4 groups according to the prognostic scoring system, LE of up-front allo-HSCT was higher compared to that of chemotherapy alone in the intermediate- (2.27 years vs 1.66 years) and high-risk groups (1.50 years vs 0.91 years). The estimated survival curve depicted by TreeAge showed the superiority of up-front allo-HSCT as shown in Figure 1A-D. The Monte Carlo simulation showed that the probability of superiority of up-front allo-HSCT was 100% in all patients, 97.1% in the low-risk group, 100% in the intermediate-risk group, and 100% in the high-risk group in terms of LE, and was 99.8% in all patients, 75.2% in the low-risk group, 100% in the intermediate-risk group, and 100% in the high-risk group in terms of QALE.

**Summary/Conclusions:** Based on decision analysis, up-front allo-HSCT was associated with higher LE and QALE in the intermediate- and high-risk groups in comparison to chemotherapy alone patients with aggressive ATL. In the absence of prospective randomized controlled trials, our results suggest that up-front allo-HSCT for aggressive ATL is the favored treatment strategy in the intermediate- and high-risk groups.

OUTCOMES OF THIOTEPA BASED REDUCED-INTENSITY CONDITIONING VERSUS STANDARD REDUCED-INTENSITY CONDITIONING IN ADULT PATIENTS UNDERGOING DOUBLE-UNIT CORD-BLOOD HEMATOPOIETIC STEM CELL TRANSPLANT

P. Sharma1,2, D. Pollyea1, C. Smith1, E. Purev1, M. Kamdar1, B. Haverkos1, D. Sherebenu1, J. Gutman1

1Division of Hematology, University of Colorado, Denver, United States

**Background:** Cord blood transplantation (CBT) is an established alternative source for hematopoietic stem-cells in patients without matched donor. However, the most commonly used high-dose total-body-irradiation (TBI) myeloablative conditioning (MAC) results in high treatment related mortality (TRM). Non-myeloablative and reduced-intensity conditioning (RIC) have been studied to decrease TRM and provide curative chance to the elderly and those with comorbidities. However, these strategies are associated with higher relapse-rate and graft rejection. A novel-RIC using addition of thiopeta and higher dose of TBI to standard RIC has shown to result in sustained donor engraftment. Our study compares transplant-related-outcomes in patients who underwent first double-unit CBT with standard-RIC regimen of fludarabine (Flu, 200mg/m²), cyclophosphamide (Cy, 50mg/kg), and TBI (200cGy or 300cGy) versus this standard-RIC regimen with addition of thiopeta (10mg/kg) and increased dose of TBI (6-8cGy).

**Aims:** 1. To compare transplant related outcomes in CBT recipients who received standard-RIC (FluCyTBI) to those who received novel-RIC (FluCy with addition of thiopeta and increased dose of TBI). 2. To identify optimal conditioning regimen in patients undergoing UCT.

**Methods:** After IRB approval, consecutive patients undergoing CBT from 08/2009 to 08/2016 were evaluated and data retrospectively abstracted. Patient selection, graft-versus-host disease prophylaxis and transfusions were per institutional standards and conditioning regimens were compared as described.

**Results:** Of the 99 patients who underwent allogeneic double-CBT, 52 received standard-RIC and 47 received novel-RIC. Median age at transplant was 67 years (range, 24-74) and 54 years (range, 25-67) in standard-RIC and novel-RIC cohort respectively. Acute myeloid leukemia was the major indication for transplant in both cohorts. Median hematopoietic stem-cell transplant comorbidity-index (HSCT-CI) was 3 (range, 0-6) and 1 (range, 0-4) in standard-RIC and novel-RIC groups respectively. Four patients suffered engraftment failure (2 in each cohort). Median neutrophil engraftment was 13 days (range, 6-42) and 21 days (range, 12-43) while median platelet engraftment was 37 days (range, 26-70) and 38 days (range, 24-74) in standard-RIC and novel-RIC groups respectively. Fifty-three suffered acute GVHD which occurred in 21 (40%) patient (grade 2-4: n=15, 29%; grade 3-4: n=5, 10%) in standard-RIC group and in 32 (66%) patients (grade 2-4: n=29, 62%; grade 3-4: n=5, 11%) in novel-RIC group. Chronic-GVHD (cGVHD) occurred in 18 patients (n=7, 14% in standard-RIC; n=11, 23% in novel-RIC group). The one-year cumulative incidence of relapse was 36% (n=15) in standard-RIC while it was 15% (n=5) in novel-RIC cohort. Median relapse free survival (RFS) was not significantly improved in novel-RIC cohort compared to standard-RIC (HR, 0.32, CI:0.11- 0.76, p=0.01). Median RFS was 29 months in standard-RIC cohort while median RFS was not reached in novel-RIC cohort. The one-year cumulative incidence of transplant related mortality (TRM) was 22% (n=10) in those who received standard-RIC while it was 16% (n=7) in those who received novel-RIC. TRM was not significantly different between the standard-RIC and novel-RIC cohorts. Median follow-up in standard-RCI cohort was 9.3 months (range, 0.16- 79) and 13 months (range, 1.4- 36) in novel-RCI cohort. The overall survival (OS) was significantly better in novel-RCI cohort compared to standard-RCI (HR 0.49, CI:0.25- 0.94, p= 0.03). Median OS was 17 months in standard-RIC cohort while median OS was not reached in novel-RIC group (Figure 1).

**Summary/Conclusions:** In our study, RIC consisting of FluCy with addition of thiopeta and increased dose of TBI in patients undergoing double-cord UCT was associated with improved OS and improved RFS without increase in TRM compared to standard RIC. While older and more comorbid patients might experience increased TRM with the thiopeta based regimen, these data suggest that consideration of this regimen may be appropriate in fit, older patients.

INTERFERON-Α IS EFFECTIVE FOR TREATMENT OF MINIMAL RESIDUAL DISEASE IN PATIENTS WITH ACUTE LEUKEMIA AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

X.-D. Mo1,2, X.-H. Zhang1, L.-P. Xu1, Y. Wang1, C.-H. Yan1, H. Chen1, W. Han1, F.-R. Wang1, J.-Z. Wang1, K.-Y. Liu1, X.-J. Huang1

1Peking University People’s Hospital, Institute of Hematology, Beijing, China

**Background:** Post-transplant relapse is a major cause of transplant failure. Because impending relapse can be indicated by minimal residual disease (MRD) after allogeneic hematopoietic stem-cell transplantation (allo-HCT), MRD-directed intervention may be a reasonable option for relapse prophylaxis.

**Aims:** We investigated the efficacy of MRD-directed interferon-α (IFN-α) treatment in acute leukemia patients who were positive for MRD after allo-HSCT.
Methods: A total of 102 patients who were MRD-positive after allo-HSCT were enrolled. MRD-positive state was defined as positivity for leukemia-associated aberrant immune phenotypes or positivity for Wilms' tumor gene 1 in a single bone marrow sample. Recombinant human IFN-α-2b injections were administered subcutaneously 2–3 times per week for 6 months.

Results: The 2-year cumulative incidence of severe acute and chronic graft-versus-host disease (cGVHD) with AZA or BSC was 56% (95% CI: 48–64) and 66% (95% CI: 58–74), respectively. Eighty-one (75.7%) patients treated MRD-negative after IFN-α treatment, including 42 (39.3%), 6 (6.6%), 7 (6.5%), and 26 (24.3%) who treated MRD-negative 1, 2, 3, and >3 months after MRD-directed IFN-α treatment, respectively. Twelve patients showed relapse after IFN-α treatment, and 4 patients died of non-relapse mortality (NRM). The 2-year cumulative incidence of relapse and NRM after IFN-α treatment was 11.5% and 4.3%, respectively. The 2-year probabilities of event-free survival and disease-free survival after IFN-α treatment were 66.5% and 32.3%, respectively. Persistent MRD after IFN-α treatment was significantly associated with higher relapse risk and poorer survival.

Summary/Conclusions: These data confirmed that MRD-directed IFN-α treatment is effective for patients who were MRD-positive after allo-HSCT.

IMPACT OF AZACITIDINE PRETREATMENT ON OUTCOMES OF ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN PATIENTS WITH HIGH-RISK MYELOIDYSPLASTIC SYNDROME

1Department of Hematology, Kanagawa Cancer Center, Yokohama, 2Department of Hematology/Oncology, The Institute of Medical Science, The University of Tokyo, 3Department of Hematology and Oncology, Graduate School of Medicine, Kyoto University, Kyoto, 4Department of Hematology, Hiroshima Red Cross Hospital & Atomic-bomb Survivors Hospital, Hiroshima, 5Department of Hematology, Red Cross Nagoya First Hospital, Nagoya, 6Division of Hematology, Saitama Medical Center Jichi Medical University, Omiya, 7Division of Hematology, Department of Medicine, Jichi Medical University, Shimotsuma, 8Department of Hematology, Tokyo Metropolitan Cancer and Infectious Disease Center Komagome Hospital, 9Department of Hematology, Toranomon Hospital, 10Department of Hematology, Nagano Red Cross Hospital, Nagano, 11Department of Hematology and Oncology, Anjo Kosei Hospital, Anjo, 12Division of Hemapoietic stem cell transplantation, National Cancer Center Hospital, 13Blood Service Data Center for Hematopoietic Cell Transplantation, Federation of Healthcare Administration, Nagoya University Graduate School of Medicine, Nagoya, 14Department of Hematology, Kanazawa University Hospital, Kanazawa, Japan

Background: Myelodysplastic syndrome (MDS) is a heterogeneous myeloid stem cell disorder with ineffective hematopoiesis, dysplastic cell morphology, and a propensity for progression to acute myeloid leukemia. Allogeneic hematopoietic stem cell transplantation (allo-HSCT) is the only curative therapy available for MDS. In recent years, azacitidine (AZA) has been increasingly used as pretransplant induction therapy in high-risk MDS patients. However, the benefits of pretransplant therapy in these patients are unclear, and the optimal therapy regimen remains unknown.

Aims: We conducted a retrospective analysis to elucidate the clinical impact of pre-treatment with AZA on outcomes after allo-HSCT in high-risk MDS patients.

Methods: Clinical data were collected from the registry database of the Japan Society for Hematopoietic Cell Transplantation. We selected patients with high-risk MDS at diagnosis (IPSS intermediate 2 or high), aged 16 years or older, who underwent their first transplantation between January 2009 and December 2014 and received AZA or BSC as best supportive care (BSC) before allo-HSCT. Patients who received conventional chemotherapy or immunosuppressive therapy prior to allo-HSCT were excluded. We compared overall survival (OS), relapse, non-relapse mortality (NRM), and hematopoietic recovery after allo-HSCT between patients who received AZA or BSC as pretransplant induction therapy in high-risk MDS patients. However, the benefits of pretransplant therapy in these patients are unclear, and the optimal therapy regimen remains unknown.

Aims: We conducted a retrospective analysis to elucidate the clinical impact of pre-treatment with AZA on outcomes after allo-HSCT in high-risk MDS patients.

LOW-DOSE DECITABINE IMPROVES PLATELET RECOVERY IN PATIENTS WITH ISOLATED THROMBOCYTOPENIA AFTER HSCT

X. Han1,2, Y. Tang1, Y. Zhao1, M. Huang1, J. Chen1, J. Qi1, Y. Wang1, X. Wu1, X. Ma1, F. Chen1, X. He1, C. Ruan1, D. Wu1

Background: Isolated thrombocytopenia is a common complication of hematopoietic stem-cell transplantation (HSCT), which was defined as consistent low platelet counts with recovery of the other two cell lines after transplantation. This status leads to an increased risk of life-threatening hemorrhage, frequent requirements of platelet transfusion and extended hospital stays, representing a challenging clinical problem. Previous studies have demonstrated that decitabine, a hypomethylating agent, may increase platelet counts by promoting megakaryocyte maturation and platelet release in mouse model.

Aims: In order to investigate the role of decitabine in patients after HSCT suffering from isolated thrombocytopenia, we conduct a clinical trial to validate this effect in post-HSCT setting.

Methods: We performed a prospective open-label study to evaluate the treatment of low-dose decitabine in patients with hematological malignancies who received allogeneic HSCT and suffered from isolated thrombocytopenia. The inclusion criteria were: (1) Platelet count ≤ 100 × 10⁹/L persistently at day 60 post-HSCT or later; (2) Recovered neutrophil and hemoglobin; (3) Full donor chimerism; and (4) No response to conventional treatments for a duration of at least 4 weeks. Patients with malignancy relapse, active infections, uncontrolled graft-versus-host disease, severe organ damage or transplant-related thrombosis were excluded. From July 2013 to July 2016, 38 patients were randomly assigned into either the control group to receive conventional treatment only, or the test group to receive additional decitabine (15mg/m², intravenously daily for the first 5 days). Results: Major response was observed in 16 out of 19 patients (84.2%) in the decitabine group, with a median time of 22 days to achieve platelet transfusion-independence. Two patients (10.5%) showed a minor response and 1 patient (5.3%) failed. In contrast, 3 out of 19 patients in the control group (15.8%) showed a major response, 2 patients (10.5%) showed a minor response, 14 patients (73.7%) did not show any improvement, of which 1 patient died of severe hemorrhage in week 5. For bone marrow morphological analysis, all 38 patients showed low levels of megakaryocytes at week 0. However, the megakaryocyte counts in decitabine group were significantly increased at week 4, while no significant difference was recorded in control group. After decitabine treatment, we did not observe a change in anti-platelet antibodies levels and T cell subsets ratios. However, reactive oxygen species (ROS) and megakaryocyte counts increased in the test group. No considerable myelosuppression, febrile neutropenia, and nonhematologic toxicities associated with the treatment were observed.

Summary/Conclusions: Our data showed an encouraging efficacy of decitabine in patients after HSCT suffering from isolated thrombocytopenia, and it could remarkably increase megakaryocyte counts. Decitabine may improve isolated thrombocytopenia via regulating ROS and megakaryocyte reconstitution.

QUANTITATIVE PROTEOMICS OF PLASMA EXTRACELLULAR VESICLES TO IDENTIFY NOVEL Biomarkers OF CLINICAL SEVERITY FOR HBE/B-THALASSEMic PATIENTS

J. Kittivoraparit1,2,3, V. Karamatic Crew1, N. Siritanarathkul1, A. Mark Toy1,2

1Bristol Institute for Transfusion Sciences (BITS), NHS Blood and Transplant, 2School of Blood Transfusion and Hematology, University of Bristol, Bristol, United Kingdom, 3Department of Transfusion Medicine, Siriraj Hospital, Bangkok, Thailand

Background: Hemoglobin (Hb) E/B-thalassemia has a wide spectrum of clinical manifestations that cannot be explained purely by its genetic background. Extra-cellular vesicles (EV) are one factor that may indicate and/or contribute to disease severity because there is an observed increase in EV release due to the enhanced oxidative stress in these genetic erythrocytes.

Aims: This study aims to explore the differences in protein composition and abundance between circulating EV from HbE/B-thalassemic patients and normal individuals.

Methods: 15 HbE/B-thalassemia patients and 15 matched-controls from Thailand were fully consented and recruited for this study. Pooled EVs isolated from five thalassemic samples were compared to pooled EVs from five matched controls using a Duplex-Tandem Mass Tag (TMT) mass spectrometry (TMT-MS) analysis. This experiment was repeated three times in total, using different patient and control samples to identify consistent alterations of protein expression in EVs. Finally, protein differences were also confirmed using Western blotting.

Results: The total proteins identified across the three experimental TMT-MS datasets ranged from 1,764 to 2,534 proteins. When restricted to proteins that contained more than one unique peptide, the range of proteins was reduced to 685 to 1,272 proteins. Many proteins were previously reported EV constituents. 19 proteins were consistently increased in patient samples compared to controls across all data sets. The majority of these proteins were chaperone proteins and antioxidant enzymes. Alpha Hemoglobin Stabilizing Protein (AHSP) had the highest extent of between 31 to 47-fold. Other proteins that exhibited increased abundance in thalassemic circulating EV included catalase, superoxide dismutase, T-complex proteins, heat shock protein 70 and ferritin light chain. Importantly, the heme scavenger and plasma proteins – haptoglobin and hemopexin were observed to be consistently decreased in patients’ EV across all data sets. Immunoblotting results corroborated the TMT-MS findings.

Summary/Conclusions: We have successfully identified consistent alterations in protein expression levels between EV generated by HbE/B-thalassemic patients and normal individuals. These findings may potentially lead to the development of a prognostic marker, and therefore may improve the therapeutic outcome for the patients suffering from thalassemia.

A SELECTIVE ORAL GLYT1 INHIBITOR IMPROVES ANEMIA IN A MOUSE MODEL OF BETA-THALASSEMIA

A. Matte1, M. Winter2, E. Beneduce1, E. Federti1, A. Siciliano1, A. Macias-garcia3, A. Iolascon1, T. Singer1, O. Khwaja2, A. Kornel1, J.-J. Chen1, A. Harmeier2, C. Brugnara3, L. De Franceschi1

1Medicine, University of Verona, Verona, Italy, 2Pharmaceutical Research and Early Development, Hoffmann-La Roche , Basel, Switzerland, 3MIT, MIT, Cambridge, United States, 4Biotecnologie Avanzate-CEINGE, Federico II University, Naples, Italy, 5Lab of Medicine, Children’s hospital of Harvard Medical School, Boston, United States

Background: The anemia of β-thalassemia is due to a combination of reduced red cell survival in the peripheral circulation and ineffective erythropoiesis, the latter due to unbalanced hemoglobin chain synthesis, and hemichrome-induced oxidative damage. Here we used a specific and selective inhibitor of the plasma membrane expressed glycine transporter GlyT1 selective inhibitor RO4917838 (GlyT1) in a mouse model for β-thalassaemia (Hbb3th/+). A previous study in Wistar rats has shown that RO4917838 administration was associated with an improvement of β-Thal hematologic phenotype, as supported by (i) the amelioration of red cell morphology; (ii) the increase in Hb levels; (iii) the reduction in reticulocyte count.

Aims: To evaluate the impact of the glycine transporter GlyT1 selective inhibitor RO4917838 on anemia of a mouse model for β-thalassemia.

Methods: Wild-type control (WT) C57B/6J and Hbb3th/+ mice (β-Thal) aged between 3 to 4 months were treated daily with either vehicle or RO4917838 at dosages of 3, 10, 30 mg/kg/d for 4-6 weeks by gavage. Hematological parameters, analysis of erythropoiesis, molecular studies of sorted erythroid precursors, indices of hemolysis, hepcidin liver expression and Pearsall staining were carried out.

Results: RO4917838 administration was associated with an improvement of β-Thal hematologic phenotype, as supported by (i) the amelioration of red cell morphology; (ii) the increase in Hb levels; (iii) the reduction in reticulocyte count.
and in the percentage of circulating erythroblasts; (iv) the increase in β Thal red cell survival. RO4917383 induced a significant reduction in extramedullary erythropoiesis as well as in the amount of insoluble alpha chain aggregates in circulating red cells. It is of note that in β-Thal sorted erythroblasts we found a reduction in HRI and in phospho-eIF2α, inducing a reduction in free heme, which shall resulted in the activation of HRI, in RO4917383 treated β -Thal mice (10 mg/kg/d, 6 weeks). Finally, in β-Thal mice treated with RO4917383 (4 weeks at 30 mg/kg/d) a reduction in liver and spleen iron-overload was identified, which was associated with increased hepcidin liver expression.

Summary/Conclusions: Our data suggest that RO4917383 ameliorates anemia and ineffective erythropoiesis by reduction of heme biosynthesis in a mouse model for β-thalassemia. RO4917383 is a potential, novel therapeutic approach for the treatment of anemia in patients affected by beta-thalassemia.

P393

MAY MUTATIONS IN THE KLF1 GENE HAVE WORSENING EFFECTS ON THE BETA THALASSEMIA PHENOTYPEN

M.R. Storni1, M. Giuliano1, G. Fioretti2, S. Puzzone1, R. Sessa1, L. Vicari1, M.P. Ottiano1, M. Caldora3, S. Costantini4, C. Matarese3, A. Sarappa3, G. Amendola2, A. Filosa4, P. Izzo1, M. Grossi1,*

1Dep. Molecular Medicine and Medical Biotechnology, University of Naples Federico II, 2USC Genetica Medica, AORN A. Cardarelli, Naples, 3UOC Pediatria-TIN, P.O. Umberto I, Nocera Infer., Italy

Background: KLF1 is a pleiotropic erythroid transcriptional factor that plays a key role in erythropoiesis (Siatecka M, Blood 2011; 118: 2044-521). Accordingly, KLF1 mutations have been found to be responsible for a variety of hematological disorders. KLF1 also contributes directly or indirectly to regulate the expression of genes in the beta-globin gene cluster and the fetal-to-adult globin gene switch (Wayne JS et al Int. J. Lab. Hem. 2015; 37: 78-84). It has been reported that mutations leading to KLF1 haplosufficiency (i.e. a dominant negative KLF1) can result in hematologic and/or metabolic abnormalities (Smitz et al, Blood 2008; 111: 614-620) and ameliorate the severity of β-thalassemia (Liu D. et al, Blood 2014; 124: 803-811; Perkins A. et al, Blood 2016; 127: 1856-1862).

Aims: This study was aimed at providing a functional characterization of known and novel mutations in the KLF1 gene associated with atypical beta-thalassemia phenotypes.

Methods: Hematological parameters were measured using an automated hematology analyzer (Beckman Coulter) and high performance liquid chromatography (Variant II, Bio-Rad Laboratories). Screening of KLF1 mutations was performed by Sanger sequencing on an Applied Biosystems 3730 DNA analyzer. Functional studies were performed by gene reporter assays and expression vectors for KLF1 mutants in the human K562 erythroleukemia cell line. This study was performed on 19 adult subjects, including 11 beta-thalassemia heterozygotes with an unexpected phenotype of intermediate thalassemia (moderate or severe anemia, elevated HbA2 and/or HbF levels) and 8 subjects with normal erythrocyte indices and borderline HbA2 and/or HbF levels without mutations in alpha- and beta-globin gene clusters.

Results: Of the 19 patients who were tested, 15 were found to be positive for mutations in the KLF1 gene. More in detail, we found 7 mutations, comprising a nucleotide variation (c.-251 C>G) already reported as a single nucleotide polymorphism and a known mutation (c.-148 G>A) in the proximal promoter region, 3 nucleotide variations in the transcribed region of the first exon (S102F, F182L and M39L), (Radmilovic M. et al, Ann. Hematol 2013; 92: 53-58) and 2 novel mutations (C94X and P173PfsX236), all of them in the proline-rich domain in exon 2. Functional studies were performed in K562 cells in order to clarify the pathogenic significance of these mutations and to better define the role of KLF1 in atypical thalassemia phenotypes. Interestingly, the c.-251 C>G polymorphism was found to be associated with an increased transcriptional activity of the KLF1 promoter (Figure 1A), thus allowing us to exclude for this nucleotide variation the condition of a neutral polymorphism. Furthermore, unexpectedly, the novel P173PfsX236 mutation was found to be associated with a dramatic reduction of the beta-globin gene expression (Figure 1B).

Summary/Conclusions: Our study confirmed the ameliorative effect of some KLF1 mutations on the thalassemia phenotype that were found to be associated with increased fetal- and/or beta-globin gene expression. In other cases we demonstrated that KLF1 mutations may contribute to worsen the beta thalassemia phenotype or result in a silent beta thalassemia trait. This study provides further insights into the multiple roles of KLF1 in erythropoiesis and highlights an intriguing effect of a subset of KLF1 mutations that may contribute to the severity of the thalassemia phenotype, thus reinforcing the relevant implications of KLF1 screening for genetic counseling and for effectiveness of prevention screening programs for hemoglobinopathies.

P394

SECONDARY SOLID TUMORS FOLLOWING HEMATOPOIETIC CELL TRANSPLANTATION FOR THALASSEMA MAJOR

A. Meloni1,2, A. Natale2, S. Santarone1, M. Di Ianni1, S. Angelini1, L. Pistoia1, L. Cuccia5, A. Spasiano6, A. Pepe1, P. Di Bartolomeo2

1Fondazione G. Monasterio ONR-Regione Toscana, Pisa, 2Bone Marrow Transplant Center, Pescara, 3University of L’Aquila, L’Aquila, 4Tor Vergata University, Roma, 5ARNAS Civico “Benferrati-Di Cristina”, Palermo, 6AORN A. Cardarelli, Napoli, Italy

Background: Secondary solid tumors (SST) have been described after HCT, in particular for patients affected by hematologic malignancies. There is limited information about the incidence of SST following HCT for thalassemia major (TM).

Aims: The aim of this study was to determine the incidence of SST in 134 patients with TM who received HCT in our Center between 1983 and 2013. Methods: 117 patients survived more than 3 years after HCT and were enrolled in the study. Of them, 57 were males and 60 females. Their median age at time of HCT was 10 years (1-29). As conditioning regimen, they received Busulfan (14 mg/Kg) and Cyclophosphamide (200 mg/Kg). The GVHD prophylaxis included Cyclosporine and Methotrexate. All patients received bone marrow cells from an HLA identical donor.

Results: At time of this report, 112 patients were cured, whereas 5 patients rejected their graft and are now under regular transfusion treatment. Overall, the median follow-up after HCT was 24 years (3-34). Seven patients developed malignancy 6 years (median age at time of malignancy 10 years after HCT including 2 carcinomas of the tongue, 1 thyroid carcinoma, 1 carcinoma of the uterine cervix, and 1 parotid carcinoma. The 30-yr cumulative incidence (CI) of developing SST was 10±0.17%. All patients underwent surgical resection of the tumor and in addition of 4 of them received chemotherapy and/or radiotherapy. Of relevance, the 3 patients with cancer of the oral cavity were affected by severe chronic GVHD with buccal cavity involvement. Two patients (1 with parotid and 1 with tongue carcinoma) died of tumor progression and 5 are living. We compared these results with 2 case control populations. First of all, we investigated the occurrence of solid tumors in the 117 individu- als (64 males, median age 10 years at time of marrow donation) who served as stem cell donors for HCT. One donor developed breast cancer 29 years after marrow donation at age of 38. The 30-yr CI of developing solid tumor for donors was 4.5±2.21% with a statistically significant difference (p=0.03) as compared to that of transplantated patients. The second case control population consisted of 117 healthy individuals affected by cancer (median age 50 years). As previously, the matching technique applied was based on the variables age and sex. One control per case (transplanted patient) was randomly selected from the MIOT (Myocardial Iron Overload in Thalassemia) registry and matched by sex and age with the transplanted patient population. Two patients developed an hepatocellular carci- noma (HCC) at age of 39 and 44 years, respectively. One patient died and one is living. Using the event rate measure, we observed an event rate of 0.102 at 30 years for the transplant group and 0.041 for the nontransplant group (p=0.106).

Summary/Conclusions: This study shows that the magnitude of increased risk of SST is twofold to threefold for patients treated with HCT as compared with age- and sex-matched nontransplant TM patients or with stem cell donors. Notably, among the transplanted patients we didn’t observe any case of HCC, which is one of the most frequent solid tumor in nontransplant TM patients, whereas we observed 4 cases of head/neck cancers. In our series, cGVHD seems to be a strong risk factor in the development of new solid tumors. Patients with cGVHD, especially those with involvement of the oral cavity, must receive a very long careful monitoring and surveillance in order to prevent the development of secondary cancers.

P395

VALIDATING A NOVEL CAPILLARY ELECTROPHORESIS: THE MOST SUITABLE PLATFORM FOR THE NATIONAL NEWBORN SCREENING DEVELOPED IN A REGION WITH A HIGH PREVALENCE OF THALASSEMA AND HEMOGLOBINOPATHIES

T. Sukangsengl1, S. Riolueang1, J. Korchuenjit1, W. Korchuenjit1, J. Poom2, V. Virapakas1

1136 | haematologica | 2017; 102(2)
Background: Newborn screening program for thalassemia (thal) and hemoglobinopathies (NBS-Hbs) is crucial for early detecting patients with serious hemoglobinopathies (Hb variants) e.g. Sickle cell anemia (Hb SS). NBS-Hbs has been incorporated into a routine neonatal service in several developed countries. However its role on early detection other forms of globin disorders remains unclear. Moreover, NBS-Hbs can detect several types of thalassemia and Hb variants carriers. This application could be useful for the national prevention and control programs targeting the thalassemias syndromes in many developing countries including Thailand where these conditions are highly prevalent especially β-thal major. Hb E/β-thal and Hb Bart’s hydrops fetalis (caused by α-thalassemia). Recently a new capillary electrophoresis (CE) has been developed specifically for NBS-Hbs. However there is a limited data on validation of this technology on detecting several types of thalassemia and Hb variants found in Southeast Asia.

Aims: To evaluate and validate a new CE system to screen globin disorders in newborn to initiate the national NBS-Hbs for Thailand.

Methods: After informed consent, 1,213 blood samples of 2-day old newborns were collected by heel prick puncture into 5-dried blood spots. After elution, dried blood samples were analyzed by Capillaries 2 NEONAT FAST® (SEBIA, Evry, France). All samples were also extracted for DNA and genotyped by our extensive PCR based panel to detect >98% of abnormal globin alleles found in Thailand using α-thal GAP-PCR, α-thal ARMS-PCR, β-thal ARMS-PCR, and PCR-RFLP for Hb E. We compared CE data with each globin genotypes and use a ROC curve to set up new diagnostic criteria using% Hbs from CE for future cases.

Results: Identification of Hb Bart’s provided 100% of sensitivity, specificity and accuracy in most individuals with α-thal. Using ROC analysis, we proposed different cut-off values of Hb Bart’s to differentiate Hb H disease, α-thal and non-deletional α-thal traits; ≥7.40%, ≥0.85%, ≥0.45%, respectively with excellent accuracy (Table 1). Interaction of Hb E with these α-thal genotypes has no effect on these cut-off values (Table 1). However, there was a limitation to identify deletional α-thal Bart’s ≥20.10% (detectable level). A cut-off level to distinguish Hb EE from Hb E trait was suggested at ≥4.95% vs ≥0.7%.

Two patients with Hb E/β-thalassemia were identified through this study with different CE pattern from Hb EE. Thirteen β-thalassemia traits were identified and they had a lower level of Hb A as compared to their gestational age (GA) sex matched controls with normal β globin genotypes (68%). We recommend Hb A level ≤10.35%; a cut-off to primarily consider for β-thalassemia carrier followed by molecular analysis.

Summary/Conclusions: This newborn CE platform showed a high efficiency for detecting several types of thalassemia and Hb variants in particular α-thal, β-thal and Hb E using cut-off levels of each Hb species described herein. Besides early detecting of Hb S, we can now apply this NBS into a routine practice into a routine program on prevention and control for severe thalassemia carrier followed by molecular analysis.

TRANSIENT ELASTOGRAPHY IN NON TRANSFUSION DEPENDENT THALASSEMA: A SUCCESSFUL TOOL TO ASSESS AND MONITORING LIVER FIBROSIS

A. Marcon1,*, G. Graziadei1, M. Pennisi1, M. Migone De Amicis1, M. Fraquelli2, E. Repousi1,*, M. Moraki1, D. Kyriakopoulou1, P. Delaporta1, A. Kafourou1, E. Kattamis1

1Thalassemia Unit, First Department of Pediatrics, National and Kapodistrian University of Athens, ‘Aghia Sophia’ Children’s Hospital, Athens, Greece
2Department of Pathophysiology and Organ Transplantation.

Background: Non Transfusion Dependent Thalassemia (NTDT) patients are at risk for several complications due to chronic anemia, hypoxia and iron over-load. Over the recent years hepatic complications are more frequently observed in these patients probably due to the aging and poor care: monitoring liver fibrosis is becoming part of the follow up. Liver stiffness measurement (LSM) by transient elastography (TE), a widely-used non-invasive tool, in our centre has been included in the regular follow-up of patients with NTDT.

Aims: To evaluate by TE liver fibrosis in NTDT patients, its correlation with biochemical, hematological and clinical parameters at baseline and after 5 years.

Methods: Hepatic fibrosis and siderosis were evaluated in 101 NTDT patients using respectively TE and liver iron concentration (LIC) derived from T2-Magnetic Resonance Imaging (MRI) at baseline and, in a subset of patients, after 5 years. The following TE thresholds were taken into account: <5.0 kPa no fibrosis (F0), >5.1-7.9 kPa mild fibrosis (F1), >7.9 kPa moderate fibrosis (F2), >10.3 advanced fibrosis (F3), >11.9 kPa cirrhosis (F4). Biochemical and hematology blood test were collected too. Patients were also tested for HCV antibodies and HCV RNA. Data were analyzed retrospectively.

Results: Patient’s mean age was 46±11 years, 37/101 (36.6%) were splenome- tomized, 51/101 (50.5%) had never been transfused, 46/101 (45.5%) were occasionally transfused and 4/101 (3.9%) had been regularly transfused for 10±5yrs. At baseline (T0), the overall mean LSM was 5.9±2.6 kPa, mean LIC 6.68±5.37 mg/g dw, ferritin 700±596 nmol/ml, Hb 9.3±1.3 g/dl, ALT, AST GGT and ALP were normal. LSM correlate with GGT (p <0.01) and AST values measured ≤10yrs (p=0.02). LIC correlate with ferritin (p=0.02). Seven/101 (6.9%) patients were HCV RNA positive, one of them had never been transfused. At baseline 37/101 (36.6%) patients were on iron chelation (ICT) (29 deferroxamine, 7 deferasirox, 1 deferiprone). At T0 patients with fibrosis (any grade) didn’t show differences compared with patients without fibrosis (F0) regarding age, splenectomy, transfusions, ICT and all biochemical tests; only GGT (mean GGT 1.7±1.0 U/L in Fibrosis (F0), 5.1±7.9 kPa mild fibrosis (F1), >7.9 kPa moderate fibrosis (F2), >10.3 advanced fibrosis (F3), >11.9 kPa cirrhosis (F4). Biochemical and hematology blood test were collected too. Patients were also tested for HCV antibodies and HCV RNA. Data were analyzed retrospectively.

Summary/Conclusions: NTDT patients could benefit from regular non-inva- sive assessment of liver fibrosis. In our study subject who received ICT had best chance to reduce the grade of fibrosis through the reduction in iron overload. These patients, that usually are HCV RNA negatives, monitoring and treating iron overload is a crucial point in the prevention of hepatic siderosis causing the hepatic siderosis the primary cause of hepatic tissue damage, cirrhosis and hepatocellular carcinoma.

P397

INCREASING INCIDENCE OF MALIGNANCIES IN AGING THALASSEMIC PATIENTS: A SINGLE INSTITUTION’S LONGITUDINAL EXPERIENCE

E. Repousi1,*, M. Moraki1, D. Kyriakopoulou1, P. Delaporta1, A. Kafourou1, E. Kattamis1
1Thalassemia Unit, First Department of Pediatrics, National and Kapodistrian University of Athens, ‘Aghia Sophia’ Children’s Hospital, Athens, Greece

Background: The introduction of close monitoring, regular blood transfusions and systematic iron chelation in the management of thalassemia have signifi- cantly changed the clinical phenotype of the patients and improved their sur- vival. The patients, who have benefited of the current therapeutic regimen, are now reaching middle age, and they have started facing problems commonly seen in older people. Recent observations suggest of an increased inci- dence of malignancies in the aging group of thalassemic patients.

Aims: The purpose of this study is to determine the longitudinal changes in the incidence of malignancies, along with possible correlations to different aspects of the disease.

Methods: A retrospective study in the largest Thalassemia Unit in Greece has been conducted spanning an observation period from 2001-2016. The occur- rence and type of cancer, as well as history on transfusion dependence, liver failure, HCV infection and chelation therapy were recorded and analyzed. Sta- tistical tests were performed using SPSS software package, v. 20. A p-val- ue<0.05 was considered statistically significant.

Results: Records from 591 patients (338 with thalassemia major and 253 with thalassemia intermedia) were evaluated. 27 patients (11 males and 16 females)
with malignancies were identified (incidence: 4.6%). The mean age of the diagnosis of the malignancy was 41.6 years (36.6 years for thyroid gland cancer, 45.8 years for liver, 38 years for hematologic malignancies and 46 for renal cancer). 24 patients were transfusion dependent (TD) (7% of the patients) and 3 non transfusion dependent (1.8%). Liver cancer had the highest incidence 29.6%, followed by thyroid gland cancer 25.9%, hematologic malignancies 11.1% and renal cancer 14.8%. HCV infection was found in 56.7% of the patients and a statistic significant relationship between HCV infection and cancer (p=0.001) was detected. No correlation between liver failure and cancer was detected. In the TD group, the age specific ratio of cancer increased with age with the patients ≥50 years having the highest ratio of 42.3%, compared to 36.6% at 11-14 years of age and 12.8% at 0-5 years of age, respectively. In regards to chelation therapy, at the time of diagnosis 40.9% of the patients were receiving deferasirox (DFX), 22.7% deferiprone (DFP), 22.7% deferoxamine (DFO), 9.1% no chelation therapy and 4.5% DFO/DFP. No statistical significant difference was observed between the different chelation therapies (p=0.118). As the utilization of different types of chelation changed throughout the years, according to the availability of the chelating agents, we analyzed separately, the patients that developed malignancies in the period after 2010 when longitudinal exposure to all three chelators can be assumed. Even though the results showed a difference (p=0.027) between the different groups with 47.1% of those patients receiving DFX at the time of diagnosis compared to 27.1% receiving DFP and to 11.8% receiving DFO, this distribution reflects the overall distribution of chelator usage during that period. Apart from the incidence, there was no statistical significant difference between TD and NTD patients with cancer regarding the gender, age and year of diagnosis. The cancer overall mortality rate was 48%, but varied significantly with the type of cancer with liver cancer and hematological malignancies having a mortality of 66%. Overall only 2% of the deaths occurring in our group of patients were attributed to cancer.

Summary/Conclusions: This retrospective study has confirmed the increased incidence of malignancies in thalassemia patients in Greece, which is, at least, partially related to the aging of this population. Based on these observations, adaptation of monitoring guidelines is essential for optimal management of thalassemic patients. Periodic screening for malignancies, especially hepatic, thyroid and hematologic, will allow early detection and timely, and thus, more efficacious treatment of the neoplasm.

P398

SAFETY AND EFFICACY OF EARLY START WITH SUBOPTIMAL DOSE OF DEFERIProne IN MINIMALLY TRANSFUSED INFANTS WITH TRANSFUSION DEPENDENT THALASSEMA: A RANDOMIZED TRIAL

M. Elia1,*, B. Hela2, V. Berdous3, F. Tricata4, M. Tarf5, H. Awad6, A. Adly7, 1AinShams university, 2Ain Shams University, Cairo, Egypt, 33 Oasis International Hospital, Beijing, China, Beijing, China, 44 ApoPharma Inc., Toronto, Canada, 5National Research Center, Cairo, Egypt

Background: Early exposure to iron toxicity is the main risk factor for morbidity and mortality in patients with transfusion-dependent thalassemia. Current practice is to start chelation therapy only after 10-20 transfusions, or when the serum ferritin (SF) level rises above 1,000 µg/L.

Aims: To evaluate the safety and efficacy of the early use of low-dose deferiprone in minimally transfused pediatric thalassemia patients and to evaluate if it can postpone iron overload in these group of patients.

Methods: In the current trial (ClinicalTrials.gov Identifier: NCT02173951), sixty-four children recently diagnosed with thalassemia major who had begun receiving blood transfusions in first year of life to keep pre-transfusion Hb above 10 gm/dl, had not yet started iron chelation therapy and had SF ≥400 µg/L or transferrin saturation (TSAT) ≥70% or labile plasma iron (LPI) ≥0.6 µM were randomized to start deferiprone (DFP) at a sub-therapeutic dose (50 mg/kg/day) or no chelation (NC). Median age at 1st transfusion was 8 months for both DFP-treated and for NC children. The percentage of patients with LPI ≥0.6 µM, SF ≥1000 µg/L or TSAT ≥70% in each study arm was assessed at 6, 9 and 12 months (patients confirmed SF ≥1000 ng/mL were withdrawn from the study and placed on a standard chelation regimen). Complete blood count was done weekly in DFP treated and every 3-4 weeks in NC.

Results: Table 1. Summary of the efficacy results of SF, TSAT, and LPI.

</table>

All NC patients were removed from the trial prior to completing 7 months of follow-up (9-11 transfusions) due to confirmed SF ≥1000 µg/L. Mean ± SD time of follow up was 10.4±4.9 and 5.9±2.5 months for DFP and NC respectively. Most common adverse events in patients on DFP versus NC were diarrhea (19% vs 13%, p=0.73), vomiting (13% vs 13%, p=1.00), abdominal colic (13% vs 13%), elevated liver enzymes (6% vs 3%, p=1.00) and neutropenia (6% vs 6%). All adverse events were mild in severity and did not require interruption of DFP use. There were no cases of agranulocytosis or moderate neutropenia, no arthralgia and no serious infections in DFP-treated patients. DFP therapy was associated with a significant reduction in the rate of iron accumulation as measured by SF (P<0.0001), LPI (P<0.001) and TSAT (P<0.001) (Figure 1a, b, c). LPI≥0.6 µM appeared as early as after 5 transfusions in NC children and was delayed to at least 10 transfusions with DFP therapy. TSAT≥70% appeared after 10 transfusions in NC children and was delayed to at least 17 transfusions with DFP therapy. The results of this study show that LPI and TSAT may reach values ≥0.6 µM and ≥70%, respectively, after 5-10 transfusions in children with TM and all NC children had SF ≥1000 µg/L after 8-9 transfusions.

P399

LONGITUDINAL PROSPECTIVE MRI STUDY IN PEDIATRIC PATIENTS WITH THALASSEMA MAJOR

M. Gasale1,*, A. Meloni2, A. Filosa1, L. Pistola3, F. Sorrentino3, A. Quarta4, A. Carollo5, M. C. Cirotto1, V. Positano2, E. Grasedonio7, M. Missere8, A. Pepe2

1AORN A. Cardarelli, Napoli, 2Fondazione G. Monasterio CNR-Regione Toscana, Pisa, 3Ospedale “Sant'Eugenio”, Roma, 4Ospedale “A. Perrino”, Brindisi, 5Azienda Ospedaliera “San Antonio ed SS. Torpignattara”, 6ASL N°1 Sassari, Sassari, 7Policlinico “Paolo Giaccone”, Palermo, 8Fondazione di Ricerca e Cura “Giovanni Paolo II”, Campobasso, Italy

Background: No studies are available in literature evaluating, on repeated assessments, changes in myocardial and hepatic iron overload, biventricular function, and development of macroscopic myocardial fibrosis in pediatric patients with thalassemia major (TM).

Aims: This is the first longitudinal prospective MRI study in pediatric TM patients.

Methods: We considered 68 TM patients enrolled in the MIOT (Myocardial Iron Overload in Thalassemia) project with less than 18 years at the first MRI scan and who performed a follow-up (FU) study at 18±3 months. Myocardial and hepatic iron burdens were quantified by the T2* technique. Atrial dimensions and biventricular function were quantified by cine images. Late gadolinium enhancement (LGE) images were acquired to detect myocardial fibrosis.

Results: At the baseline MRI, 16 (23.5%) patients showed myocardial iron overload (MO: global heart T2*<20 ms) and 54 patients liver iron overload.
(79%). Figure 1 shows the changes in iron levels. Twenty-five patients changed the chelation regimen after the baseline MRI. Globally, a worsening in cardiac iron was found in the 3% of the patients while a worsening in hepatic iron in the 21% of the patients (P=0.003). The LV end-diastolic volume index and all RV volumes as well as the LV mass index were significantly lower at the FU MRI. No significant improvement in left or right global systolic function was found. For 40 patients the presence of myocardial fibrosis was investigated at both baseline and FU scans. Six patients (15.0%) had myocardial fibrosis at the baseline MRI and myocardial fibrosis was detected for all of them also at the FU. The extent of myocardial fibrosis was comparable between the two scans (0.77±0.42% vs 0.79±0.51%; P=0.686). At the FU 4 new occurrences of myocardial fibrosis were detected. In patients with baseline MIO no significant correlation was found between the percentage change in cardiac iron and the changes in hepatic iron or the baseline hepatic iron.

Methods:

Dec16. MRI-R2* heart, liver and pancreas in a cohort of well treated TM patients. Results: 69 TM patients: 43% male, age 38±9yrs, median number of observa-
tions/patient 6 (IQR:5-7), median number of yrs of the follow-up (f.u.) 8 (IQR:7-8). Iron chelation regimens included deferiprone (basal 30%>f.u.32%), deferasirox (basal 45%>f.u.52%), daily alternating deferasirox+deferiprone (basal 3%-f.u.6%), deferoxamine (basal 9%>f.u.6%) deferoxamine+

(p=0.017) and pancreas (p=0.018). Once again we found a correlation between the values of ferritin and R2* of liver (R2=0.37,p=0.0015), heart (R2=0.26, p=0.028) and pancreas (R2=0.23,p=0.05). Moreover the variations of ferritin correlate with the variations of R2* of the liver (R2=0.6,p<0.001), heart (R2=0.25, p=0.04) and pancreas (R2=0.41,p<0.001). Finally, assuming the cutoff value of 100 Hz for the pancreatic-R2* as the predictor of a cardiac R2*>50Hz, we calculated the numbers of false/true positive/negative according to the rule above. At the baseline we can observe that the number of false positive is the 14/27 (52%). The percentage increases to 91% (21/23) after f.u.: the pancreas-
R2*>100Hz in 23 patients but only 2 has iron overload in the heart; the total number of patients with pancreatic-R2*>100Hz is quite the same before and after f.u. (27 compared to 23). We found no correlation between the false pos-
itve predicted and particular conditions such as impaired glucose tolerance, diabetes or adipose involution (Table 1).

Summary/Conclusions:

In this experience we observed that the regular mul-
ti-organ assessment of iron overload by R2* is concomitant with a reduction of the iron burden in this cohort of well treated patients confirming that is a careful method to tailoring the iron chelation therapy. However pancreatic-R2* remains above the cut-off for the prediction of cardiac iron overload, so this parameter should be considered with caution in the tuning of the chelation therapy, in order to avoid over-chelation risk. Ferritin values trend agree with R2* values confirming the reliability of this parameter. These results were obtained with a prevalent use of oral chelation regiment (90% of patients).

Figure 1.

Summary/Conclusions: Magnetic resonance monitoring in children with TM demonstrated a good control of cardiac iron overload in terms of prevention and treatment but the need for further improvement of liver iron overload. Myocardial fibrosis appears mainly multifocal, non progressive and not reversible over a 18- month period. A prompt and aggressive approach to iron overload and a chelation regimen consistent with the high iron intake and the high rate of severe liver iron overload is recommended in children.

P400

LONG TERM FOLLOW-UP OF A COHORT OF WELL TREATED B-TALASSEMAIA MAJOR PATIENTS BY MULTI-ORGAN R2* MAGNETIC RESONANCE IMAGING

V.M. Pinto1, L. Bacigalupo2, B. Giansesi1, M. Balocco1, M. Lamagna1, S. Quintino1, G.L. Forni1,2

1Haematology-Centro Microcitemia Anemie Congenite, 2Radiology Unit, Ospedale Galliera Genova, Genova, Italy

Background: The introduction of non-invasive multi-organ evaluation of iron overload by R2* Magnetic Resonance Imaging (MRI) in β-thalassemia major (TM) patients has improved the patient care allowing a more careful tailoring of iron chelation therapy.

Aims: We report a cross-sectional and longitudinal experience with the use of MRI-R2* heart, liver and pancreas in a cohort of well treated TM patients.

Methods: TM patients underwent contemporaneous assessment of pancreatic, cardiac and hepatic MRI and R2* (1.5 T GE HDx scanner) in the period Jan08-Dec16.

Results: 69 TM patients: 43% male, age 38±9yrs, median number of observations/patient 6 (IQR:5-7), median number of yrs of the follow-up (f.u.) 8 (IQR:7-8). Iron chelation regimens included deferiprone (basal 30%>f.u.32%), deferasirox (basal 45%>f.u.52%), daily alternating deferasirox+deferiprone (basal 3%-f.u.6%), deferoxamine (basal 9%-f.u.6%) deferoxamine+deferiprone (basal 13%>f.u.4%). The observation at the baseline showed a positive strong correlation between R2* values of pancreas and both of liver (R2=0.68, p<0.001) and heart (R2=0.75, p<0.001), in accordance with literature. Moreover, the ROC analysis confirms the value of 100 Hz for the pancreatic-R2* as the predictor of a cardiac R2*>50Hz, so this parameter should be considered with caution in the tuning of the chelation therapy. However pancreatic-R2* remains above the cut-off for the prediction of cardiac iron overload, so this parameter should be considered with caution in the tuning of the chelation therapy, in order to avoid over-chelation risk. Ferritin values trend agree with R2* values confirming the reliability of this parameter. These results were obtained with a prevalent use of oral chelation regiment (90% of patients).

**DEVELOPMENT OF HTLV-1 HYPERIMMUNE GLOBULINS AGAINST HTLV-1 INFECTION**

T. Mizukami1, K. Nojima1, R. Sobata2, W. Kuriyashii3, C. Matsumoto4, Y. Yamasaki5, E. Sasaki1, K. Furuhata1, Y. Hiradate1, K. Ohkuma1, S. Matsuoka1, M. Satake1, I. Hamaguchi1

1Department of Safety Research on Blood and Biologicals, National Institute of Infectious Diseases, 2Central Blood Institute, Japanese Red Cross, 3Department of Cellular and Molecular Medicine, Graduate School of Medicine, Chiba University, Tokyo, Japan

**Background:** Adult T-cell leukemia (ATL) is a malignant disease caused by infection with human T-lymphotropic virus type 1 (HTLV-1). The prevention of HTLV-1 infection is the most effective strategy to eradicate ATL. However, there is no effective vaccine or anti-viral agent for HTLV-1 infection.

**Aims:** The aim of this study was to develop an effective HTLV-1 hyperimmune globulin (HTLV-IG) isolated from HTLV-1 positive carriers screened at the Japanese Red Cross.

**Methods:** We developed two in vitro and in vivo screening methods to evaluate and characterize the anti-viral effect of HTLV-1 positive plasma and HTLV-IG.

**Results:** HTLV-IG purified from the passenger carrier with a proviral load (PVL) 4 × 10^6/kg inhibited both HTLV-1 infection and syncytia formation. We purified HTLV-IG from the HTLV-1 positive plasma (PVL 4 × 10^6/kg) and evaluated its effect in a humanized mouse model. NOG (NOD.Cg-Fkdcscid Il2rtm1Sug/Cic) mice were treated with HTLV-IG for 5 days before HTLV-1 infection. During the monitoring period of 40 days after post-infection, HTLV-1 infection was observed in untreated infected mice, but not in HTLV-IG-treated mice. The inhibitory effect of HTLV-1 was observed at the early stage of HTLV-1 Infection. Treatment with HTLV-IG at 20 days after HTLV-1 infection had a partial inhibitory effect. HTLV-1 gp46 expression in HTLV-1 infected cells was slightly reduced and the localization of these cells was changed in tissue after the first line of treatment. These data suggest HTLV-IG is effective at the early phase of HTLV-1 infection. We also assessed the viral safety of HTLV-1 during the HTLV-IG manufacturing process. High log reduction values of HTLV-1 were observed during the Cohn fractionation process. Virus safety was assessed by PCR based assay and in vitro and in vivo infection assay. We next assess the viral safety of HTLV-1 during the HTLV-IG manufacturing process. High log reduction values of HTLV-1 can be seen during the Cohn fractionation process. Virus safety was assessed with PCR based assay and in vitro and vivo infection assay.

**Summary/Conclusions:** These data suggest HTLV-IG is effective and safe for the prevention of HTLV-1 infection.

**P402**

**THE COMBINATION OF TUMOR CELLS IN THE APHERESIS MATERIAL DOES NOT PREDICT THE RESPONSE OF MULTIPLE MYELOMA PATIENTS TO AUTOLOGOUS TRANSPLANTATION**

M. L. Lozano1, F. De Arriba1, M. Sola1, A. Sanchez-Fuentes1, N. Revilla1, F. Orduño1, A. Jerez1, I. Heras1, P. Iniesta1, O. Lopez-Godino1, M. D. Garcia-Malo1, V. Vicente1

1Hematology and Clinical Oncology, Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arrixaca, CB15/00555-CIBERER, Murcia, Spain

**Background:** The use of high dose of chemotherapy followed by autologous stem cell transplantation (ASCT) has improved the prognosis of patients with multiple myeloma (MM) and plasma cell dyscrasia. However, there is controversy over the effect of infusion of atypical plasma cells (PC) on the apheresis product.

**Aims:** To analyze whether in MM malignant plasma cell reinfusion could negatively affect responses to ASCT.

**Methods:** Patients (n=114) undergoing ASCT (n=120) for MM between January 2003 and February 2016 were enrolled in a retrospective study to analyze the prognostic value of aberrant (CD38++CD138+CD19-CD45weak) to normal phenotype (CD38++CD138+CD19+CD45+) plasma cells (ATC PC ratio) in the autograft by flow cytometry. The Durie-Salmon stage at diagnosis, response of disease to induction treatment, biological parameters, pre-ASCT percentage of PC in bone marrow and at day +100, and the mobilization of PC contained in the autograft of patients with a better vs poorer pre-ASCT response (0.08 vs 0.08 ×10^6/kg). There was no difference between the type of mobilization (G-CSF vs chemotherapy+G-CSF) and the degree of apheresis contamination (median A:T:PC ratio 0.5 vs 0.8; P=0.86). There was a statistical trend between the degree of infiltration of PC in the bone marrow before ASCT and the detection of atypical PC in the graft (p=0.06). At day +100, 94% of patients with CR or VGPR to induction therapy maintained the response, and 49% of patients in PR, SD or PD achieved post-ASCT CR or VGPR (p=1.24^-7). There was no association between the content of atypical PC in the graft and the response to day +100. However, the percentage of pre-ASCT PC in the bone marrow was significantly related to the response at day +100 (CR or VGPR vs PR, SD or PD), p=0.003, as well as the pre-ASCT monoclonal component (p=4.03^-7).

**Table 1.**

<table>
<thead>

<td>6 (5.0)</td>
</tr>
</tbody>
</table>

**Summary/Conclusions:** Infusion of PC with atypical phenotype does not appear to affect the response at day+100 following ASCT, in patients with MM or plasma cell dyscrasia. Conversely, the quality of response to induction therapy was significantly associated to 100-day outcome after transplantation. These data support that in vivo persistent residual cells, but not those being infused with the graft, are the main source of relapse in MM.

**EVALUATION OF THERAPEUTIC PLASMA EXCHANGE AT A TERTIARY LONDON HOSPITAL**

R. Moli1, D. Warcel1, S. Clark1, M. Sekhar1

1Haematology, Royal Free Hospital, London, United Kingdom

**Background:** Therapeutic plasma exchange (TPE) is used to treat a number of haematological, renal and neurological conditions. Pathogenic antibodies or other plasma molecules are removed, and plasma volume is replaced with fluid. Human albumin solution (HAS) is usually preferred, except in cases of Thrombotic Thrombocytopenic Purpura (TTP) and related conditions. TPE may result in dilutional coagulopathy, and reactions such as hypersensitivity can occur. The British Society for Haematology (BSH) published a 2015 guideline to assist the use of TPE in UK clinical practice, providing evidence-based indications and recommended schedules.

**Aims:** To evaluate the use of elective TPE at a large tertiary London hospital, compare clinical practice against BSH guideline recommendations, and explore the effect of TPE on coagulation test results.

**Methods:** Data was collected prospectively over a 2 month period, using patient notes and electronic transfusion records. A data collection form recorded the indication, treatment schedule, replacement fluid, complications, the presence of a written treatment plan, and frequency and results of coagulation testing.

**Results:** 24 plasma exchanges took place over the period of data collection; there were no cases of TTP. Adherence to BSH were variable; although most cases (88%) had an evidence-based clinical indication for TPE, just 4% had a full written treatment plan, and only 17% of courses followed recommended scheduling. 75% of patients had received at least one prior course, some outside guideline indications for repeat courses. Most patients (83%) initially received HAS, however 87% received FFP at some point during TPE, with 42% receiving Solvent Detergent FFP. In 17% of patients this fluid change was due to a reaction, but for the remainder it was due to dilutional coagulopathy. The guidelines recommend fibrinogen monitoring, and although most patients had baseline measurement (75%), subsequent testing showed wide variation. Despite this, 71% had a fibrinogen of 1 g/l measured during TPE. Fibrinogen levels showed some correction by the next day but usually still abnormal. A prolonged aPTT and PT was also seen in most patients immediately following TPE, which almost always corrected by the next day.
A COMPREHENSIVE PROTEOMICS STUDY ON PLATELET CONCENTRATES: PLATELET PROTEOME, STORAGE TIME AND MIRASOL PATHOGEN REDUCTION TECHNOLOGY

V. Saiappan, F. Seiguer, A. M. Granderath, P. C. O'Gara, C. Bon, M. I. Sivakumaran, M. Platt

Background: Platelet concentrates (PCs) represent a blood transfusion product with a major concern for safety as their storage temperature (20-24°C) allows bacteria to grow. We aimed to identify changes in protein levels less than 7 weeks from complete microbiological testing. Pathogen reduction technologies (PRTs) provide an additional layer of safety to the blood transfusion products from known and unknown pathogens (such as bacteria, viruses and parasites). In this context, PRTs (such as Mirasol technology) have been developed and are implemented in many countries. However, several studies have shown in vitro that Mirasol PRT induces a certain level of platelet shape change, hyperactivation, basal degranulation and increased oxidative damage during storage. It has been suggested that Mirasol PRT might accelerate what has been described as the platelet storage lesion (PSL), but supportive molecular signatures have not been obtained.

Aims: We aimed at dissecting the influence of both variables, i.e. Mirasol PRT and storage time, at the proteome level.

Methods: We present comprehensive proteomics data analysis of control PCs and PCs treated with Mirasol PRT at storage day 2, 6 and 8. Our workflow was set to perform proteomics analysis using a gel-free and label-free quantification (LFQ) approach for which two replicate samples were taken. To identify and quantify the altered proteins, we used MaxQuant/Perseus software platform.

Results: We identified marginal differences between Mirasol PRT and untreated PCs during storage. However, those significant changes at the proteome level were specifically related to the functional aspects previously described to be a methodology suitable to phenotype platelets in an unbiased manner, in various physiological contexts.

Summary/Conclusions: In summary, semi-quantitative proteomics allows to discern between treatment changes due to Mirasol PRT or PSL, and proves to be a methodology suitable to phenotype platelets in an unbiased manner, in various physiological contexts.

USE OF A SURVEY TO ASSESS AND IMPROVE ADHERENCE TO UK BLOOD TRANSFUSION GUIDELINES IN A HOSPITAL SETTING

D. Warcal*, R. Moi, A. L.1

1Haematology, Royal Free Hospital, London, United Kingdom

Background: UK guidelines to provide evidence-based support for decisions to transfuse packed red cells were published in 2015 by NICE (National Institute for Health and Care Excellence). The guidelines specified hemoglobin (Hb) targets for transfusion, use of single unit transfusion to avoid over-transfusion, information provision to patients for informed consent, and avoidance of pre-operative transfusion by timely identification of iron deficiency for referral through an anemia pathway. A local baseline audit of NICE compliance at our London tertiary referral hospital showed low overall compliance with these recommendations.

Aims: To determine knowledge amongst the prescriber group of transfusion recommendations for stable patients, to gain insight into current patterns of decision-making for transfusion and to impart knowledge of the key NICE guidelines.

Methods: An online survey, designed to both evaluate and inform participants, was targets at doctors of different training grades and specialties during a two week period. The outcomes of this are being used to guide further training.

Results: Of 141 participants who took part in the survey, 31% (43) had been qualified for less than two years and 47% (65) were consultants. Specialities included Surgery, Anesthetics, Internal Medicine, Hemato-Oncology and Intensive Care. 60% (84) had prescribed blood within the last month. Despite only 51% (72) awareness of the NICE guidelines, a significant majority (73%, 103) selected the correct Hb threshold of 57g/L for transfusion in patients without acute coronary syndrome (ACS). A lower threshold of 50g/L was selected by 42% (58), but there was a wide spread of answers. 65% (90) of participants were aware that, in a stable patient Hb is checked after each unit of red cell transfusion, but surprisingly a few (4%, 5) did not check post transfusion Hb at all. Ferritin measurement was inconsistent in only 45% (66) routinely measuring this prior to transfusion, and only 31% (44) aware that a ferritin result over 30 days old should be rechecked. This highlighted potentially inadequate identification of iron deficiency anemia. In addition only 40% (57) were aware of the existence of a hospital anaemia clinic for referral. When reflecting on consent methods, 96% (135) of participants endorsed treatment indication for transfusion, and 90% (127) gave an opportunity to ask questions and ensured the patient was content to proceed. Provision of written information was poor (26%, 37) and only 55% (78) recorded the discussion in patients’ notes. Exploring barriers to consent, 24% (32) expressed difficulty in obtaining a patient information leaflet, and issues relating to lack of time and information were 16% (22) and 9% (12) respectively.

Summary/Conclusions: Although the majority of participants expressed awareness of the NICE guidance, knowledge was not reflected in subsequent questions. The survey allowed simultaneous assessment of knowledge and provision of key information as a factsheet. Almost all participants felt that completion of the survey had increased their awareness, and as such a high response rate, the survey is a constructive and supportive method to facilitate implementation of national guidance by medical staff. We were also able to identify areas that need further development including the clinical referral pathway for the anaemia clinic and improving the availability of patient information leaflets on hospital wards. At present we are working to improve the hospital transfusion templates which were distributed to all hospital staff, and carrying out structured case based discussion sessions with junior doctors to enhance knowledge and confidence.

SCREENING OF TRANSFUSION PRODUCTS FOR PRION DISEASES USING/APTAMERS AND TUNABLE RESISTIVE PULSE SENSING

M. Healey1,*, M. Sivakumaran2, M. Platt1

1Chemistry, Loughborough University, Loughborough, 2Haematology, Peterborough City Hospital, Peterborough, United Kingdom

Background: Prion diseases are a group of fatal transmissible neurological conditions whose disease etiology is characterised by the change in conformation of the normal intrinsic cellular prion protein (PrPc) to in the highly ordered insoluble amyloid state conformer (PrPSc). The significant event fundamental to the progression of these diseases is the self-catalytic, and perpetuating, nature of the conversion of PrPc in the presence of PrPSc aggregates. The disease is characterized by the prion protein conformational changes in the United Kingdom during the 1990s, is considered to be an effect of dietary exposure to the bovine spongiform encephalopathy (BSE) agent through contaminated meat products. To date, the widely accepted estimate for the prevalence of vCJD in the UK puts the number of potential cases at 1 in 2000. Since the disease is known to be infectious and transmissible, the iatrogenic ability of this disease is a significant risk to public health through transfusion products and surgical procedures.

Aims: We aim to develop a reliable and robust assay that can be used as a screening tool to detect the infectious PrPSc protein at low levels in human blood with high selectivity and high sensitivity.

Methods: Here we use a technique based on the Coulter Counter principle that uses tunable elastomeric nanotubes termed Tunable Resistive Pulse Sensing (TRPS) to detect the prion protein without an amplification step. The first stage optimises the grafting of an ssDNA aptamer onto nanoparticles. In proof of concept work, the functionalized nanoparticles were used to detect the cellular prion protein in phosphate buffered saline by monitoring the relative change in velocity through the nanopore, which is then converted to zeta potential. The method was then applied to protein rich samples and serum.

Results: By varying the concentration of aptamer relative to the binding capacity of the nanoparticles, a sigmoidal binding curve was observed. Here mean zeta values were -1.94 mV for 0%; -4.43 mV for 33%; and -7.30 mV for 100%. The assay was further developed by monitoring the functionalized particle’s translocation velocity as a function of prion protein concentration. Increasing the concentration of the protein caused shielding of the polyanionic DNA by the positive protein at pH 7.4, therefore the velocity of the negatively charged particle conjugate decreased. The lowest concentration to have a significant change (p=0.05) in velocity distribution was 1 nM, with a 2.5% decrease relative to 0 nM. The higher concentration of 50 nM had a bigger effect of 24% decrease.

Summary/Conclusions: TRPS technology presented here offers the ability to rapidly and accurately detect the presence of prion protein by particle assay design. Any relative change to the functionalized particle’s signal could be observed, demonstrating its capability and suitability to detect biological targets.
Front-line combinations in multiple myeloma and amyloidosis

**S407 QUADRUPLET VS SEQUENTIAL TRIPLET INDUCTION THERAPY FOR MYELOMA PATIENTS: RESULTS OF THE MYELOMA XI STUDY**

1The Institute of Cancer Research, London, United Kingdom, 2Myeloma Institute, University of Arkansas for Medical Sciences, Little Rock, United States, 3Clinical Trials Research Unit, Leeds Institute of Clinical Trials Research, Leeds, 4Heart of England NHS Foundation Trust, Birmingham, 5Leicester Royal Infirmary, Leicester, 6Centre for Clinical Haematology, Nottingham University Hospital, Nottingham, 7University Hospitals of North Midlands, Stoke-on-Trent, 8Kent and Canterbury NHS Trust, Canterbury, 9Southampton Hospital, Southampton, 10University of Leeds, Leeds, 11The Royal Marsden Hospital, London, 12Institute of Immunology and Immunotherapy, University of Birmingham, Birmingham, 13Haematological Malignancy Diagnostic Service (HMDS), St James’s University Hospital, Leeds, 14Clinical Trial Research Unit, Leeds Institute of Clinical Trials Research, Leeds, 15Department of Haematology, Newcastle University, Newcastle, United Kingdom

**Background:** Combining anti-myeloma induction therapies limits the impact of clonal heterogeneity on resistance to therapy, maximising response and associated clinical outcomes. Triple combinations induce deeper, longer remissions than doublets and those containing an immunomodulatory agent, a proteasome inhibitor (PI) or both are the current standard of care in Europe/US. Potential approaches to further improve outcomes include response-adapted induction, treating suboptimal responders with sequential treatment using an agent with a different mechanism of action, or intensifying therapy for all patients by the use of quadruplet combinations upfront.

**Aims:** The UK NCRI Myeloma XI trial is a large, phase III study comparing, in transplant eligible (TE) patients, the induction quadruplet carfilzomib, cyclophosphamide, lenalidomide and dexamethasone (KCRD) to the sequential strategy of triplet immunomodulatory combinations (with thalidomide or lenalidomide) followed by additional pre-transplant consolidation with PI triplet therapy for those with a suboptimal response.

**Methods:** In 2013, the TE pathway of the Myeloma XI study was amended to include KCRD given in 28 day cycles (carfilzomib 36mg/m² IV d1-2,8-9,15-16 (20mg/m² #1d1-2), cyclophosphamide (cyclo) 500mg PO d1, lenalidomide (len) 25mg PO d1-21, dexamethasone (dex) 40mg PO d1-4,8-9,15-16). Patients were randomised to this up-front quadruplet or the sequential strategy of CRD (cyclo 500mg PO d1, len 25mg PO d1-21 PO daily, dex 40mg PO d1-4,8-9,15-16) or CTD (cyclo 500mg PO d1,8,15 thalidomide 100-200mg PO daily, dex 40mg PO d1-4,12-15) given to max. response. Patients with VGPR or CR proceeded straight to ASCT, those with PR/MR were randomised to sequential CVD (cyclo 500mg d1,8,15, bortezomib 1.3mg/m² IV/sc d1,4,8,11, dex 20mg PO d1,2,4,5,8,9,11,12) or nothing and those with SD/PD all received sequential CVD. At day 100 post ASCT there was a maintenance randomisation between lenalidomide and observation. The trial has now closed to recruitment and all patients have completed induction therapy. This analysis compares responses and toxicity of the different regimens.

</tbody>
</table>

**Results:** 2568 TE patients underwent induction randomisation (CTD 1021, CRD 1021, KCRD 526). Patients were comparable with respect to age (median 59 years), sex and other key laboratory parameters. Patients were mandated to receive a minimum of 4 cycles of initial induction with therapy continued to maximum response. The median number of cycles delivered was CTD: 5, CRD: 5, KCRD: 4. Grade ≥3 haematological toxicities differed between the groups. (Neutropenia CTD: 12%, CRD: 22%, KCRD: 16%; Thrombocytopenia CTD: 3.4%, CRD: 4.5%, KCRD: 8.1%; Anaemia CTD: 6.7%, CRD: 9.6%, KCRD 10%). Grade ≥2 neurological toxicity was greater with the thalidomide-containing regimen (Sensory neuropathy CTD: 9.5%, CRD: 3.4%, KCRD: 2.3%). There was no statistically significant difference in rates of investigator reported, all-grade, thromboembolic events between regimens (CTD: 11.8%, CRD 11.1%, KCRD 14.7%). Response to initial induction and following ASCT is shown in Table 1 indicating deeper responses with the quadruplet compared to triplets both at the end of first induction regimen (p<0.0001) and, importantly, post-ASCT (p<0.0001). These differences were observed despite the use of randomised pre-transplant consolidation for suboptimal responders to triplet immunomodulatory therapy.

**Summary/Conclusions:** Induction therapy with KCRD, an outpatient delivered quadruplet regimen, was associated with deeper responses than immunomodulatory triplet therapy (CRD/CTD) and was well tolerated. Deeper responses persisted after ASCT, with an impressive response rate ≥VGPR of 92% with KCRD.

**S408 DEEP AND DURABLE RESPONSES WITH WEEKLY IXAZOMIB, LENALIDOMIDE AND DEXAMETHASONE IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA: LONG-TERM FOLLOW-UP OF PATIENTS WHO DID NOT UNDERGO SCT**

S. Kumar1,*, J. Berdeja2, R. Niesvizky3, S. Lonial4, J. Laubach5, M. Hamadani6, S. Kumar1,*, J. Berdeja2, R. Niesvizky3, S. Lonial4, J. Laubach5, M. **Background:** Triplet combinations that include a proteasome inhibitor (PI) have been proven superior to doublets in newly diagnosed multiple myeloma (NDMM) (San Miguel et al, N Engl J Med 2008, Durie et al, Lancet 2017). The all-oral combination of the novel PI ixazomib plus lenalidomide-dexamethasone (IRD) was evaluated as an induction regimen in NDMM patients, followed by single-agent ixazomib maintenance.

**Aims:** Here we report updated efficacy and long-term safety data for patients who did not withdraw from the study in order to receive stem cell transplantation (SCT).

Methods: In this phase 1/2 study (NCT01217957), patients with NDMM received weekly oral ixazomib (1.68-3.95mg/m²; days 1, 8, and 15) plus lenalidomide (25mg, days 1-21) and dexamethasone (40mg, days 1, 8, 15, and 22) for up to twelve 28-day induction cycles, followed by maintenance therapy with weekly single-agent ixazomib, at the last tolerated dose given during induction, until disease progression or toxicity.

Results: Of the 65 enrolled patients, 42 continued on study treatment without early withdrawal for SCT; the long-term follow-up of these 42 patients is reported here. Baseline patient characteristics included: median age, 68 years (range 34-86); ISS stage I/II/III in 40%/43%/17%. As of October 18, 2016, with median follow-up of 56 months, the confirmed overall response rate (ORR; ≥ partial response [PR]) in patients was 80%, complete plus very good partial response (CR+VGPR) rate was 63%, and CR rate was 32%. Median time to first response was rapid (0.95 months), while median time to CR was 5.6 months. Median progression-free survival (PFS) in these patients not receiving SCT was 25.3 months. Median overall survival (OS) has not been reached at a median follow-up of 3 years. Three-year OS rate was 87%. Safety findings are summarized in the Table; 74% of patients had grade ≥3 treatment-related adverse events (AEs), and 26% of the patients had treatment-related serious AEs. Among treatment-related AEs of interest, grade ≥3 rash and peripheral neuropathy were infrequent. There was one treatment-related death due to respiratory syncytial viral pneumonia. After completing 12 cycles of induction therapy with IRd, 25 patients went on to receive maintenance single-agent ixazomib. In these 25 patients, at the end of the induction period ORR was 100%, including 44% VGPR and 32% CR. Responses deepened during maintenance; at data cut-off, the response rates in this maintenance therapy population were 95% VGPR 32%, and CR 32%. Patients who received maintenance therapy was 24 months. The occurrence of the most common treatment-related grade ≥3 AEs (neuropenia, thrombocytopenia, and fatigue) was confined almost exclusively to the induction period. During the maintenance period no patients reported onset of grade ≥3 peripheral neuropathy or rash.

Summary/Conclusions: In patients with NDMM, weekly ixazomib plus Rd, followed by single-agent ixazomib maintenance, was highly active, resulting in deep and durable responses, long PFS, and a high 3-year OS estimate. IRd followed by single-agent ixazomib maintenance also showed an acceptable safety profile, with less toxicity reported during the maintenance (single-agent ixazomib) vs induction (IRd) periods, with no evidence of cumulative toxicities.
Summary/Conclusions: Safety profile was acceptable; more patients required plerixafor in the KRd arm. Rate of VGPR was higher with KRd. Updated data on a higher number of patients will be presented at the meeting. The trial is registered at Clinicaltrials.gov: NCT02203643

S411
HOVON 104; FINAL RESULTS FROM A MULTICENTER, PROSPECTIVE PHASE II STUDY OF BORTEZOMIB BASED INDUCTION TREATMENT FOLLOWED BY AUTOLOGOUS STEM CELL TRANSPLANTATION IN PATIENTS WITH DE NOVO AL AMYLOIDOSIS

M. Minnema1,*, K. Nasserinejad2, B. Hazenberg3, U. Hegenbart4, L. Noens5, P. Ypma6, S. Zweegman7, L. Tick8, A. Broijl9, H. Koene10, G. Bos11, N. Thuss2, P. Sonneveld9, S. Schonland4

1Haematology, UMC UTRECHT, Utrecht, 2HOVON data center, ErasmusMC, Rotterdam, 3Rheumatology, UMCG, Groningen, Netherlands, 4Amyloidosis Center, University of Heidelberg, Heidelberg, Germany, 5Haematology, UZ Gent, Gent, Belgium, 6Internal Medicine, HAGA hospitals, the Hague, 7Haematology, VU medical center, amsterdam, 8Internal Medicine, Maxima Medical Center, Eindhoven, 9Haematology, ErasmusMC, Rotterdam, 10Internal Medicine, st Antonius Hospital, Nieuwegein, 11Haematology, University Hospital Maastricht, Maastricht, Netherlands

Background: Bortezomib (B) has been reported to be very effective in AL amyloidosis with overall response rates (ORR) varying between 50-80%. However, there are no prospective data from multicenter studies on B treatment in de novo patients. We investigated the efficacy and safety of B-Dexamethasone (BD) induction treatment followed by HDM+SCT in de novo AL amyloidosis patients.

Aims: The primary aim was to improve the hematological CR rate at 6 months after SCT on intention to treat analysis from 30 to 50%. Secondary aims were OS, PFS, hematological response rate after BD treatment, organ responses, safety and prognostic factors for survival.

Methods: Patients with biopsy proven AL amyloidosis, aged between 18-70 years, with detectable M-protein and/or level of involved FLC>50mg/L, WHO performance status 0-2, NYHA stage I-II, ejection fraction >45% were included. Major exclusion criteria were symptomatic orthostatic hypotension, NT proBNP level >5000 pg/ml, Troponin T> 0.06 ug/l, Bilirubin >2x ULN, eGFR<30 ml/min, CTCAE grade peripheral sensory neuropathy > grade 2 or > grade 1 with pain. Inclusion and exclusion criteria were installed both at entry and before stem cell mobilization (SCM). B was given subcutaneously 1.3mg/m2 twice a week in a 21-day cycle, D 20mg orally on each B day and the following day. HDM dosage was 200mg/m2. Hematological responses were defined according to consensus criteria with the addition of very good partial response (VGPR), defined as the difference between involved and uninvolved FLC<40mg/L. Cardiac, renal and liver response and progression criteria were defined according to consensus criteria with addition of NT proBNP.

Results: Median age was 59 years (range 26-70) and 60% were male. NYHA stage was 1 in 56% and 2 in 42% of patients. Mayo cardiac risk score was 1 (30%), II (36%), III (34%). Organ involvement was 82% renal, 66% heart, 28% liver, 14% neurological, 8% gastrointestinal and 38% of patients had 3 or more organs involved. Bone marrow plasmacells were >10% in 28% of patients. The median FU for patients alive is 24 (10-55) months. Twelve of 50 (24%) patients could not proceed to SCM. Four patients due to B related toxicity, 3 patients did not fulfill criteria to proceed, 2 patients died (both amyloidosis related) and 3 miscellaneous. Of these 38 patients, 3 went subsequently off protocol because of ineligibility for HDM. Thirty-five out of 50 patients (70%) received HDM + SCT, one patient died of a cardiac arrest after the SCT procedure. The ORR after induction was 80%, ≥VGPR in 54% and CR in 6% of patients. The ORR in the 35 patients at 6 months after SCT was 80%, ≥VGPR in 51% and CR in 43% of patients. On intention to treat analysis the CR rate at 6 months after SCT was 30%. Organ responses at 6 months after SCT were 16/29 renal, 2/8 liver and 13/23 heart. No baseline characteristics were identified to be predictive for OS or PFS. BD doses were reduced and delayed after 2 cycles in almost half of patients, mostly because of neurotoxicity, Sensory neuropathy grade 2 or higher was seen in 36% of patients and autonomic neuropathy, mostly dizziness and collapse, in 22%.

Summary/Conclusions: This final analysis demonstrates that the primary aim of improving CR rate at 6 months after SCT from 30 to 50% was not met. This was mainly caused by the high dropout rate before SCT. This may be due to patient selection, but we also demonstrate that BD, given twice weekly sc, despite good efficacy, cannot prevent early amyloidosis related toxicity and can induce grade 2 or higher neurotoxicity.

NIVOLUMAB FOR RELAPSED/REFRACTORY CLASSICAL HODGKIN LYMPHOMA AFTER AUTOLOGOUS TRANSPLANT: FULL RESULTS AFTER EXTENDED FOLLOW-UP OF THE MULTICOHORT MULTICENTER PHASE 2 CHECKMATE 205 TRIAL

1University Hospital of Cologne, Cologne, Germany, 2University of Texas MD Anderson Cancer Center, Houston, United States, 3Humanitas Cancer Center – Humanitas University, Rozzano–Milan, Italy, 4Dana-Farber Cancer Institute, Boston, 5Mayo Clinic, Rochester, United States, 6Institute of Hematology “L. e A. Seragnoli”, University of Bologna, Bologna, Italy, 7University of California, Los Angeles, United States, 8Fred Cancer Care and Hematology Centre, Churchhill Hospital, Oxford, United Kingdom, 9Barbara Ann Karmanos Cancer Institute, Detroit, 10Winship Cancer Institute, Emory University, Atlanta, United States, 11Netherlands Cancer Institute – Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands, 12University of Toronto and Princess Margaret Cancer Centre, Toronto, 13British Columbia Cancer Agency, Vancouver, Canada, 14Charles University in Prague and General University Hospital in Prague, Prague, Czech Republic, 15Brigham and Women’s Hospital, Boston, 16Bristol-Myers Squibb, Lawrenceville, 17Memorial Sloan Kettering Cancer Center, New York, United States

Background: Nivolumab, a fully human IgG4 monoclonal antibody targeting programmed death-1, is an immune checkpoint inhibitor that augments T-cell activation and antitumor responses. Nivolumab is indicated for pts with relapsed/refractory (RR) classical Hodgkin lymphoma (cHL) following autologous stem cell transplantation (ASCT). Brentuximab vedotin (BV) treatment. The multicohort phase 2 CheckMate 205 trial (NCT02181738) enrolled pts with RR cHL after ASCT. Initial analyses revealed high objective response rates (ORR), encouraging duration of response (ORR) and an acceptable safety profile (Younes A et al, Lancet Oncol 2016). Durable responses to therapy are valuable in pts with progressive disease after failure of ASCT due to their limited treatment options.

Aims: To report extended follow-up data for all pts with RR cHL after failure of ASCT in CheckMate 205.

Methods: This is a single-arm multicenter trial enrolled pts (age ≥18 y) with RR cHL after ASCT into 1 of 3 independent cohorts (Cohort A: BV-naïve; Cohort B: BV only after ASCT; Cohort C: BV before and/or after ASCT). All pts received nivolumab 3mg/kg every 2 wk until disease progression or unacceptable toxicity.

- PR (≥15 mo in each cohort), and stable disease (≥9 mo in each cohort). Median follow-up was 19 (1, 25), 23 (2, 27) and 16 (1, 20) mo in Cohorts A, B, and C, respectively. DOR for patients with partial response (PR) was 17 and ≥11 months, respectively. PFS by cohort is shown (Figure 1). Prolonged median PFS was seen for patients with CR (≥17 mo in each cohort), PR (≥15 mo in each cohort), and stable disease (≥9 mo in each cohort).

Results: In total, 243 pts were treated: 63 in Cohort A (BV-naïve), 80 in Cohort B (BV after ASCT), and 100 in Cohort C (BV before [n=53], after [n=58], or before and after [n=52] ASCT). Median (range) age was 34 (18-72) y and 77% of pts had advanced (stage III+) disease at study entry. BV-naïve pts had fewer prior lines of therapy (median of 2 vs 4 with prior BV). At Dec 2016 database lock, median (min, max) follow-up was 19 (1, 25), 23 (2, 27) and 16 (1, 20) mo in Cohorts A, B, and C, respectively. Overall, 40% of pts were still on treatment; the most common reason for discontinuation was disease progression (26%). ORR was 65% in Cohort A, 68% in Cohort B, and 73% in Cohort C, with 29%, 13%, and 12% CR, respectively. Median (95% CI) DOR was 20 (13, 20), 16 (8, 20), and 15 (9, 17) mo in Cohorts A, B, and C, respectively. DOR for patients with CR was 20 months for BV-naive patients (Cohort A) and ≥15 mo for BV-treated patients (Cohorts B and C). DOR for patients with partial response (PR) was 17 and ≥11 months, respectively. PFS by cohort is shown (Figure 1). Prolonged median PFS was seen for patients with CR (≥17 mo in each cohort), PR (≥15 mo in each cohort), and stable disease (≥9 mo in each cohort). Median OS was not reached in any cohort. The most common drug-related AEs were fever (15%), injection reactions (IRs; 14%), and rash (12%); grade 3-4 drug-related AEs in ≥3% of pts were lipase increases (5%), alanine aminotransferase increases (3%), and neutropenia (3%). The most common drug-related serious AEs were IRs (2%) and pneumonitis (1%). To facilitate translation to practice, efficacy results by sequencing of prior BV treatment will be presented.

Summary/Conclusion: With extended follow-up, high and durable rates of CR and PR to nivolumab therapy were observed in pts with RR cHL after ASCT, irrespective of BV treatment history.

S. Croce e Carle, Cuneo, Italy

Background: Interim 2-[18F]fluoro-2-deoxy-D-glucose Positron Emission Tomography (FDG-PET) performed after 2 chemotherapy cycles (PET2) is the most powerful predictor of treatment outcome in ABVD-treated, advanced-stage classical Hodgkin Lymphoma (cHL). Preliminary reports suggested that escalated PET2 treatment to PET2 result could increase the efficacy of standard ABVD.

Aims: To confirm in a prospective setting the favorable prognosis of advanced stage PET2 negative patients treated with ABVD, as well as the safety and efficacy of escalated BEACOPP given to PET2 positive patients.

Methods: We conducted a prospective clinical trial (HD6067 ClinicalTrial.gov identifier 00795613), in which advanced-stage (IIb-IVh) cHL patients were treated with 2 ABVD courses, and PET2 performed afterwards. The latter was blindly and independently reviewed by a panel of nuclear medicine experts, using the Deauville 5-point scale (5-PS). PET2+ patients (5-PS 4-5) were randomized to either BEACOPP escalated (BEACOPP plus BEACOPP baseline dose or BE+B or Be+B+ or rituximab (R)) PET2- (5-PS 1-3) to patients continued ABVD treatment with 4 more cycles and, upon CR achievement, randomized to either consolidation radiotherapy (Rtx) on the sites of initial large nodal mass (LNM: diameter >5cm) or no further treatment (NFT).

Results: After June 2014 (N=319), 191 PET2+ cHL patients were consecutively enrolled in 24 Italian and 1 Israeli centers. The median age was 31 years (14-60); 35% had stage IIB, 32% stage III and 32% stage IV. The International Prognostic Score (IPS) was 0-1 in 36.6%, 2-3 in 51%, >3 in 12.5%.
Overall, 150 (19.2%) proved PET2+ (97 score 4, 53 score 5) and 630 (80.5%) PET2-. PET2+ patients were more frequently male (56.7% vs 47.1%, p<0.03), had higher IPS score (P=0.0002) and bulky disease (28.0% vs 17.9%; p<0.0002). Out of 149 PET2+ patients randomized to Be+Bb (76) or Be+Bb+R (73), 136 were evaluable for response: 93 obtained CR and 43 had a treatment failure. Of the remaining 13 patients, 3 died, 7 withdrew their consent and 3 stopped treatment for toxicity. As per study protocol, 627 out of 630 PET2- patients continued with 4 ABVD cycles and 3 withdrew their consent. Overall, 30 patients (3.8%) died, due to early death (n=2), resistant disease (n=18; 12 with a positive and 6 with a negative PET2), transplant related toxicity (n=5), infections (n=4) and pulmonary fibrosis (n=1). After a median follow-up of 1303 days (2-2857), the 4-Y FFS and OS for all 782 patients was 83% (95% CI 80%>86%) and 96% (95% CI 94%>97%), respectively. For PET2+ and PET2- patients, the 4-Y FFS was 69% (95% CI 60%>76%) and 87% (95% CI 84%>93%), while the 4-Y OS was 89% (95% CI 82%>93%) and 97% (95% CI 95%>98%) (Figure 1, Panel A and B). No outcome difference was observed for Be+Bb vs Be+Bb+R patients, with a 4-Y FFS of 69% (95% CI 57%>79%) and 68% (95% CI 55%>78%), respectively (p=0.9731). Consolidation RxT in PET2- patients in CR after 6 ABVD and LNM did not translate in to a significant benefit, with a 4-Y FFS of 95% (95% CI 91%>98%) for RxT and 93% (95% CI 87%>96%) for NFT (p=0.2882).

**Summary/Conclusions:** These data suggest that 1) an early switch from ABVD to escalated BEACOPP can be safely done in PET2+ advanced-stage CHL; 2) the long-term outcome for the entire patient cohort is superior to standard ABVD; 3) no clinical benefit is associated with post ABVD RxT in PET2- patients presenting with large nodal mass; 4) the addition of Rituximab does not increase the effectiveness of Be+Bb in PET2+ patients.

**DISEASE CHARACTERISTICS AND SURVIVAL AFTER 3RD RECURRENT OF CLASSICAL HODGKIN LYMPHOMA: AN ANALYSIS OF THE GERMAN HODGKIN STUDY GROUP**

P.J. Bröckelmann, H. Müller, E. Kucüksozlanoglu, A. Engert, B. von Treskow

**Department of Internal Medicine and German Hodgkin Study Group (GHSG), University Hospital of Cologne, Cologne, Germany**

**Background:** Data on disease presentation, therapeutic options and survival after 3rd or higher relapse of classical Hodgkin lymphoma (cHL) are sparse. Therefore the additional benefit of new agents, which were already initially investigated after several relapses of cHL, is difficult to estimate.

**Aims:** The aim of this study was to define and describe a historical control group in European patients from the German Hodgkin Study Group (GHSG) data for comparison of safety and efficacy of novel therapeutic agents.

**Methods:** Cases with at least three consecutive tumor-related events or progressive refractory or relapsed disease, were identified in the GHSG database. Detailed information was added from case report forms and physician’s letters. Overall survival (OS) was the main and progression free survival (PFS), response to therapy, adverse events, disease and treatment characteristics as secondary endpoints.

**Results:** Among 12,584 HL patients in the GHSG first-line trials HD7 to HD15 and 449 HL patients in the trials HDR1 and HDR2 a total of 69 cHL patients with ≥3 tumor events were identified. The dates of occurrence of 3rd relapse ranged between 15th of January 1993 and 21st of June 2013. The sample consisted of 51 male (74%) and 18 female (26%) patients. At time of 3rd relapse the age of the patients ranged from 20 to 79 years (mean 39.2 years, standard deviation (SD) 14.0 years) and the majority of patients presented with stage III or IV disease (67%). Time from end of 3rd-line treatment to 3rd relapse was ≤3 months (i.e. GHSG definition of refractory disease) in 15 cases (22%), ≤12 months (early relapse) in 19 cases (28%) and >12 months (late relapse) in 35 cases (51%). All 69 patients were pretreated with chemotheraphy, 35 (50.7%) with BEACOPP, 30 (43.5%) with ABVD and no BEACOPP, and 32 (46.6%) with another type of chemotherapy. The number of prior chemotherapies ranged from one to three (median 3). Pretreatment with radiotherapy was observed in 57 (82.6%) patients, with salvage chemotherapy aimed to induce a remission prior to a stem-cell transplantation (SCT) in 58 (84.1%), and with high dose chemotherapy followed by autologous SCT in 50 (72.5%) patients. Four patients (5.8%) had received allogeneic SCT as 3rd-line treatment. None of the patients had received brentuximab vedotin or anti-PD1 antibodies before 3rd relapse. With a median observation time of 63.3 months for OS after 3rd relapse, 45 patients (65.2%) had died and 60 (87.0%) had another PFS event. Twelve months after the 3rd relapse OS was 73.2% (95%-CI 62.6% to 83.8%) and PFS 50.8% (95%-CI 38.9% to 62.8%, Table 1).

**Table 1.**

**Summary/Conclusions:** Patients with a 3rd relapse or progression of cHL have a dismal, mostly palliative prognosis due to frequent tumor progression. Within one year half of the patients have a PFS event and one fourth die.

**S415**

**A REVISED STAGING SYSTEM FOR WALDENSTRÖM’S MACROGLOBULINEMIA**

1Greek Myeloma Study Group, Athens, 2Greek Myeloma Study Group, Thessaloniki, 3Greek Myeloma Study Group, Larissa, 4Greek Myeloma Study Group, Nicosia, Cyprus, 5Greek Myeloma Study Group, Paatras, Greece, 6Greek Myeloma Study Group, Nicosia, Cyprus, 7Greek Myeloma Study Group, Alexan-

**Background:** Waldenström’s macroglobulinemia (WM) is a rare low-grade B-cell lymphoma characterized by the lymphoplasmacytic bone marrow infiltration and elevated levels of immunoglobulin M (IgM) monoclonal immunoglobulin. This is an indolent lymphoma that has heterogeneous clinical manifestations and patients with this disease may have a prolonged disease course; however, there are groups of patients with poor outcomes after a relatively short disease course. In order to develop a robust staging system a collaborative effort resulted in the formulation of the International Prognostic Scoring System for WM (IPSSWM) which was developed in 2009 based on data of patients that were treated primarily without rituximab and mainly with alkylators and nucleoside analogues. IPSSWM is based on five covariates (age, hemoglobin, platelet counts, IgM levels and b2 microglobulin) and stratifies WM patients into 3 broad risk groups. IPSSWM does not take into account non-IgM elevated mortality, which is common and quite different among patients over the age of 75 year and does not include LDH, which is a well identified prognostic factor both in lymphomas and multiple myeloma.
Aims: The aim of the current study was to revise the current IPSSWM by using a large dataset of symptomatic WM patients treated with different types of primary therapy that included rituximab and other new agents.

Methods: The analysis included 492 patients from the prospectively maintained database of the Greek Myeloma Study Group with a median follow up of 10 years. All patients fulfilled criteria for diagnosis and for treatment initiation according to Consensus Recommendations.

Results: In univariate analysis factors such as age, beta-2 microglobulin, serum albumin and LDH were all associated with poor outcome. The IPSSWM includes age and b2 microglobulin but not serum albumin, or LDH, while the presence of very high IgM (>7g/dl) was quite rare and of limited prognostic value. The presence of anemia <11.5g/dl was common across all subgroups while low platelet counts <100x109/L was found in relatively few patients and had no prognostic significance. Based on ROC analysis for early death (within 3 years), serum albumin <3.5g/dl and b2microglobulin >4mg/L were the two most important prognostic factors of early WM-related death. Age >65 years was associated with increased risk of death, however, age >75 years conferred additional risk (double hazard of death compared to those 65-75 years and fourfold compared to patients <65 years). Thus, we formulated a score in which high b2 microglobulin, elevated LDH and low serum albumin are scored with 1 point each, age 66-75 years is scored with 1 point but age >75 years is scored with 2. As a result, patients with scores 0, 1, 2, 3 or 4-5 had 3-year WM-related death rate of 3%, 7%, 14%, 19% and 48% (chi-square: 80.7, p<0.001). Regarding overall survival, 10-year survival rate was 85%, 59%, 39%, 28% and 12% (p<0.001) (Figure 1). Because age is a major determinant of disposition we also evaluated this staging system in patients >65 years and retained it prognostic significance. Compared to IPSSWM, this new staging system outperformed ISSWM: c-statistics, a measure of performance of a prognostic tool, was 0.711 (95% CI 0.659-0.763) vs 0.652 for IPSSWM (95%CI 0.627-0.677) (p=0.008). 22 pts relapsed (6 of them with histologic transformation to DLBCL). 11/22 were retreated with R and 9/11 responded. 8 deaths were recorded: 3 of them disease related. R therapy was well tolerated. Only one pt could not complete treatment due to intolerance.

Summary/Conclusions: A revised staging system, based on b2 microglobulin, elevated LDH, low serum albumin and age identifies groups with very different outcomes among patients with symptomatic WM treated with contemporary regimens and may outperform IPSSWM.

S416 SPLENIC MARGINAL ZONE LYMPHOMA (SMZL) TREATED WITH RITUXIMAB (R) MONOTHERAPY: A LONG TERM FOLLOW-UP STUDY ON 104 PATIENTS

Background: Rituximab monotherapy has been used successfully in the treatment of SMZL and it can replace splenectomy, at least in 1st line.

Aims: To present our data on the outcome of R monotherapy treated pts after a long term follow-up.

Methods: The diagnosis of SMZL was based on the WHO criteria. Criteria for treatment initiation included: bulky/symptomatic splenomegaly, cytopenias or presence of B-symptoms. All pts received 6 weekly cycles of R as 1st line therapy at a dose of 375mg/m2 (induction phase). None of the pts had been splenectomised before R treatment. Maintenance with R at a dose of 375mg/m2 every 2 months for 1-2 years was given according to physician’s discretion. Response assessment was based on the SLSG consensus criteria. Survival curves were estimated using the Kaplan Meier method and compared by log-rank test.

Results: 104 pts with SMZL were included. 45% were males with a median age of 66 y (41-91). At diagnosis all pts had bone marrow infiltration with a median % of infiltration of 40 (10-85). Anemia and thrombocytopenia were present in 30% and 19%, respectively. 40% had absolute lymphocytosis. LDH was elevated in 43%. According to the SLSG prognostic system, 39% were classified in group A, 56% in group B and 5% in group C. The median time from diagnosis to treatment initiation was 2 months (0-203). 71 pts received R maintenance. The overall response rate 2 months after the end of induction treatment was 93% (CR, CRu and PR in 42%, 21% and 30%, respectively). Maintenance therapy improved the quality of response in 19 of them, 52 pts maintained their initial response and one relapsed during maintenance phase. The 5- and 10-year PFS, OS and CSS were 70% and 64%, 93% and 88%, 99% and 93%, respectively. Maintenance therapy was associated with better PFS (p=0.008). 22 pts relapsed (6 of them with histologic transformation to DLBCL). 11/22 were retreated with R and 9/11 responded. 8 deaths were recorded: 3 of them disease related. R therapy was well tolerated. Only one pt could not complete treatment due to intolerance.

Biology of MPN: JAK2 and beyond

S417

YOU DON'T KNOW JAK: A PROGRAMMED RIBOSOMAL FRAMESHIFTING DEFECT POTENTIATES THE TRANSFORMING ACTIVITY OF THE JAK2-V617F MUTATION

S. Sulima1,*, Y. Khan2, J. Briggs 2, S. Vereecke 1, J. Jones 2, V. Advani 2, J. Verbeeck1, K. De Keersmaecker1, J. Dinman2
1Department of Oncology, LKI, KU Leuven, Leuven, Belgium, 2Department of Cell Biology and Molecular Genetics, University of Maryland, College Park, United States

Background: The JAK-STAT pathway is a critical controller of cellular proliferation, differentiation, survival and apoptosis in response to external stimuli. Promiscuous activation of this pathway is an important driver in the pathogenesis of BCR/ABL-negative chronic myeloproliferative neoplasms. The JAK2-V617F allele is the most common and characterized mutation linked to this class of leukemia. The increased activation of JAK-STAT signaling in JAK2-V617F cells can be partially explained by increased JAK2 autophosphorylation. It is unclear however if these effects are sufficient to fully account for the strong activation of the JAK-STAT pathway induced by JAK2-V617F. We recently described programmed -1 ribosomal frameshifting (-1 PRF) as a novel mechanism regulating the expression of ~10% of human genes, including cytokine receptors (Blewe AT et al., Nature, 2014). In this process, cis-acting mRNA elements (-1 PRF signals, which consist of a slippery site followed by a pseudoknot) direct translating ribosomes to slip by one base in the 3' direction, establishing a new reading frame. This directs ribosomes towards premature termination codons, resulting in destabilization of the -1 PRF signal-containing mRNA via nonsense-mediated mRNA decay (Figure 1). There is thus an inverse relationship between -1 PRF efficiency and mRNA stability.

Aims: To investigate whether the JAK2-V617F mutation, shown here to be located in the pseudoknot of a -1 PRF signal in the JAK2 mRNA, impacts disease progression through ablation of -1 PRF.

Methods: Computationally predicted -1 PRF signals were validated using dual luciferase reporters and proteomic analysis of a -1 PRF fusion protein. -1 PRF location codons, resulting in destabilization of the -1 PRF signal-containing mRNA, impacts disease progression through ablation of -1 PRF.

Results: We demonstrate in human cell lines that the JAK2-V617F mutation structurally disrupts the -1 PRF signal in the JAK2 mRNA, leading to -2-fold lower rates of -1 PRF and increased abundance of the JAK2 mRNA and protein. The transforming potential of a series of mutants designed to manipulate -1 PRF independent of V617F was assayed in a Ba/F3 cell model. Silent protein coding changes in the pseudoknot of the -1 PRF signal at position V617 (V617m) or the slippery site (SSm), both of which were reduced frameshifted, increased JAK2 expression and led to transforming activity, albeit less than V617F. Importantly, the V617F+SSm combination conferred an additive effect on cellular transformation. Ba/F3 cells expressing these JAK2 variants were also introduced into mice. Whereas mice injected with wild type JAK2 remained healthy, both V617Fm and SSm induced similar leukemia phenotypes as V617F and V617F+SSm, with a -2-fold longer disease latency of 8-10 weeks. Increased JAK2 mRNA abundance in JAK2-V617F homozygous patients as well as the presence of three additional -1 PRF signals in the JAK2 mRNA further suggest a prominent role for -1 PRF in controlling JAK2 production.

Conclusions: We demonstrate that the JAK2-V617F mutation diminishes -1 PRF on the JAK2 transcript, stabilizing the mRNA and increasing JAK2 expression, contributing to its transforming activity in vitro and disease onset in vivo. We suggest that -1 PRF normally provides a layer of control by limiting JAK2 translation. Defective -1 PRF synergizes with the transforming activity of the JAK2-V617F protein by causing its overexpression, explaining why this particular mutation causes such aggressive malignancies. In support of this, the combination of ruxolitinib and an HSP-90 inhibitor, which reduce kinase activity and JAK2 expression respectively, leads to increased therapeutic efficacy in myeloproliferative neoplasms (Bhagwat N et al, Blood, 2014).

S418

EFFECTIVENESS OF LSD1 INHIBITION FOR THE TREATMENT OF MPN

J.S. Jutzi1,*, H. Rienhoff2, H.L. Pahl1
1Clinic for Tumorbiology, University Medical Center, Freiburg, Germany, 2Imago Biosciences, San Francisco, United States

Background: Treatment of MPN with JAK1 inhibitors ameliorates symptoms and splenomegaly but does not meaningfully reduce the JAK2V617F allele burden. Though curative, stem cell transplantation is associated with extensive morbidity and mortality highlighting the need for novel effective therapies. The histone ’lysine-specific demethylase 1A’ (LSD1/KDM1A) is being explored as a drug target in AML where LSD1 inhibitors already in the clinic are critical for sustaining self-renewal in leukemic initiating cells; inhibiting LSD1 induces monocytic differentiation and reduces engraftment of AML cell in vivo. LSD1 is over-expressed in a number of myeloid diseases including MPN. Preliminary data in a mutant patient model of MPN showed that a 28-day course of LSD1 inhibition had a beneficial impact on spleen size, cytokines and mutant cell burden. In a mutant JAK2 mouse model of MPN, we have characterized the disease-modifying activity of the LSD1 inhibitor (IMG-7289), a compound in clinical development for myeloid diseases (NCT02842827).

Aims: We assessed the pharmacodynamic effects of continuous daily treatment with IMG-7289 in a JAK2V617F knock-in murine MPN with established disease. Animals were treated for up to 56 days. Outcome measures included complete blood counts (CBC), hematological phenotype, overall survival, spleen size, bone marrow morphology and the JAK2V617F allele burden. Moreover, pro-inflammatory cytokine were monitored during the course of treatment as well as chromatin changes by western blotting and ChIPseq.

Methods: Jak2V617F-L2 mice were crossed to MxCRE mice and displayed a fulminant MPN phenotype without dIdC induction. CBC and BM FACS analysis were conducted as previously described. We designed a qPCR assay to quantify murine JAK2V617F allele burden.

Results: IMG-7289 treatment was exceptionally well tolerated and mice showed drastic decreases in platelet count (208 vs 2063*10^3/μl), reticulocytes (800 vs 1674*10^3/μl), monocytes and neutrophils 14 days after the start of treatment. HCT and WBC started to decrease after 28 days. While the JAK2 mutant allele burden increased over time in untreated mice, it decreased in IMG-7289 treated mice and drastically significantly in peripheral blood as well as in spleen. We observed a drastic increase in the pro-inflammatory cytokine CXCL5 in untreated mice during the course of investigation while CXCL5 levels of treated mice decreased to levels of wild-type littermates. Moreover, treated mice showed a highly significantly increased survival over untreated mice, even in a late stage of disease. Lastly, we were able to show that global H3K9me2, which is generally associated with gene expression silencing, was increased in the bone marrow of IMG-7289 treated mice compared to control mice. The remaining pathophysiological data and functional data on epigenetic regulation will be presented.

Summary/Conclusions: The LSD1 inhibitor IMG-7289 normalizes or stabilizes elevated CBCs in a JAK2V617F MPN mouse model. It decreases JAK2 mutant allele burden, pro-inflammatory cytokine levels and confers a clear survival advantage. Our preliminary data show that LSD1 is a potent target with disease-modifying potential in MPN. Clinical studies with IMG-7289 testing this hypothesis have just begun. Owing to its mode of action, altering epigenetics, and the potential reversibility of drug-induced epigenetic remodeling, a long treatment period in MPN patients may be necessary to eliminate disease. Combining IMG-7289 with JAK1/2 inhibitors might accelerate treatment effects.

S419

LOSS OF RAF KINASE INHIBITOR PROTEIN IS INVOLVED IN MYELOMONOCYTIC LINEAGE COMMITMENT AND AGGRAVATES THE DEVELOPMENT OF CHRONIC MYELOMONOCYTIC LEUKEMIA IN A MURINE IN-VIVO MODEL

V. Caraffini1,*, O. Geiger1, A. Rosenberger1, S. Hatzl1, B. Perfler1, J.L. Berg1,
Background: chronic myelomonocytic leukemia (CMML) is characterized by increased proliferation and myelomonocytic lineage commitment of hematopoietic stem cells (HSCs). Mutations in the RAS-signaling cascade are frequently present in CMML patients and lead to a CMML-like myeloproliferative disorder (CMML-MPD) in mice via causing hyperplasia to GM-CSF. Loss of RAF kinase inhibitor protein (RKIP), a negative regulator of RAS signaling, is frequent in myelomonocytic and monocytic subtypes of acute myeloid leukemia (AML) and is often associated with RAS mutations. Moreover, RKIP loss has recently been shown to increase the proliferation of AML cell lines.

Aims: In this work, we aimed at investigating the role of RKIP in the development of CMML.

Methods: RKIP expression was measured by immunoblot and quantitative real-time PCR in 23 primary CMML patient samples as well as in CD34+ HSCs, B-lymphocytes, granulocytes and monocytes of four healthy donors. Sequence analysis of CMML samples was done with an Ion Torrent Next Generation Sequencing platform using an amplicon panel covering 39 genes recurrently mutated in myeloid neoplasms. Effects of RKIP on GM-CSF-induced myelomonocytic differentiation were studied in human CD34+ HSCs lentivirally transduced with RKIP shRNA, as well as in a genetic mouse model for RKIP deletion (RKIP-/-). Effects of RKIP on CMML development were initially studied in the same RKIP-/- model. Additionally, these mice were crossed with animals exhibiting a somatically inducible mutation in NRAS (RKIP-/-Mx1-Cre-NRASG12D) and the severity of CMML-MPD onset was studied at an age of six months.

Results: Loss of RKIP protein expression was observed in 6/23 (26%) CMML patient specimens and was associated with decreased mRNA levels as well (P<0.001). Patients with RKIP loss exhibited an increased percentage of myelomonocytic cells in the peripheral blood (56% vs 75%, P=0.0226). One or more mutations affecting the RAS signaling pathway were detected in all specimens with RKIP loss. In addition to the previously demonstrated induction of proliferation, we then aimed to delineate a role of RKIP loss in myeloid lineage commitment. When studying healthy donors, we observed that RKIP expression was high in HSCs and lymphoid cells, but significantly decreased in cells belonging to the myeloid lineage (monocytes, P=0.001 and granulocytes, P<0.001). In functional experiments, knockdown of RKIP increased the GM-CSF-induced myelomonocytic lineage commitment of both, human and murine HSCs (P=0.05 and P=0.0295, respectively). These results could be corroborated in vivo, as intraperitoneal injection of GM-CSF caused a significant increase of myelomonocytic cells in the intraperitoneal cavity (P=0.006, bone marrow (P=0.007) and peripheral blood (P=0.027) in RKIP-/- mice when compared to their wildtype littermates. In a final step, we evaluated the potential of RKIP loss to cause CMML-MPD in mice. While it proved to be insufficient to cause the disease as a single event in RKIP-/- mice, it aggravated the CMML-MPD phenotype in animals with a somatically inducible mutation in NRAS (RKIP-/-Mx1-Cre-NRASG12D) and the severity of CMML-MPD onset was studied at an age of six months.

Summary/Conclusions: RKIP loss is a frequent event in CMML and is associated with mutations affecting the RAS signaling cascade. Loss of RKIP is functionally involved in myelomonocytic lineage commitment of HSCs and aggravates CMML-MPD development in mice carrying an additional mutation in NRAS.

S420 JAK2 V617F HAEMATOPOIETIC CLONES WITH DIFFERENT EXPANSION KINETICS ARE DETECTABLE SEVERAL YEARS PRIOR TO MPN DIAGNOSIS

T. Mckerrell1,2, N. Park2, J. Chi2, G. Collord2, T. Moreno4, H. Ponstingl2, D. Dias2, P. Gerasimou5, K. Melianthiou2, K. Prokopiou2, M. Antoniades1, I. Varela1, P. Costeas2, G. Vassiliou1,2
1Department of Haematology, University of Cambridge, 2Wellcome Trust Sanger Institute, Cambridge, United Kingdom, 3The Center for the study of haematological malignancies (CSHM)/Karaiskakio Foundation, Nicosia, Cyprus, 4Instituto de Biomedicina y Biotecnología de Cantabria (UC-CSIC), Santander, Spain, 5Cancer Molecular Diagnosis Laboratory, University of Cambridge, Cambridge, United Kingdom

Background: JAK2 V617F is the most common somatic mutation in the classical myeloproliferative neoplasms (MPNs) and is also frequent amongst healthy individuals with age-related clonal haemopoiesis (ARCH).

Aims: To investigate the pre-clinical clonal evolution of MPNs.

Methods: We identified 12 individuals with JAK2 V617F mutant MPN from whom blood data was available from the time of MPN diagnosis and also from an earlier time point of between 4.5-15.2 years previously (median 10.2 years) when blood was donated for registration to the Cyprus Bone Marrow Donor Registry. We used deep DNA sequencing to interrogate all 24 samples at 15 myeloid mutation hotspots including JAK2 V617F, using an established multiplex PCR/MiSeq sequencing protocol that reliably detects nucleotide substitutions present at a variant allele fraction (VAF) ≤0.008. Additionally, for 12 samples with sufficient DNA available, we performed targeted DNA capture for all exons of 41 genes recurrently mutated in myeloid neoplasms using a custom RNA-bait library followed by sequencing on Illumina HiSeq 2500. Finally, we genotyped archived Registry samples for the rs12343887 single nucleotide polymorphism (SNP) (G/T) linked to the JAK2 46/1 haplotype.

Results: Amplicon sequencing returned a median coverage of 6641 reads per nucleotide (nt) at the studied hotspots. This confirmed the presence of JAK2 V617F in all 12 diagnostic and 9 of 12 archival samples. The remaining 3 samples were JAK2 V617F negative at the sensitivity of our assay (VAF≤0.008). The only other hotspot mutation identified was SRSF2 P95R in one patient, P3, whom had a diagnosis of myelofibrosis. Pulldown sequencing of all exons of 41 genes from 12 samples with sufficient DNA returned an average coverage of 1978 reads per nt and showed a close correlation in JAK2 V617F and SRSF2 P95R VAF quantitations with amplicon sequencing. The JAK2 V617F VAF at the diagnostic time point differed between patients as expected whereas the average rate of clonal growth also varied widely between individuals, ranging from 0.36 to 6.2% per annum (Figure 1). Targeted exon capture from 12 of 24 samples, only identified one co-mutation with a VAF >0.02, the SRSF2 P95R in patient P3. As this locus was also amplified by amplicon sequencing, we were able to quantify the SRSF2 P95R VAF in both the diagnostic and the archival DNA sample taken 12.6 years earlier. In the P3 diagnostic sample the VAFs for JAK2 V617F and SRSF2 P95R were similar (0.37 and 0.41 respectively) indicating that they co-occurred in most cells of the neoplastic clone. In the archival sample from P3, the SRSF2 P95R was detectable at a VAF of 0.06, however the JAK2 V617F was absent/undetectable at the sensitivity of our assay (VAF≤0.008) indicating the SRSF2 P95R was the clone-founding mutation in this neoplasm. The genotyping results for the rs12343887 SNP revealed a tentative association in our small cohort between homozygosity for the risk allele (C) linked to the JAK2 46/1 haplotype and the average annual increase in JAK2 V617F VAF. This will need to be verified in larger studies.

Summary/Conclusions: Our findings reveal that JAK2 V617F neoplasms develop from clonal haematopoiesis over many years. The rate of clonal expansion of JAK2 V617F clones in the pre-clinical phase was highly variable and although it was tentatively associated with the 46/1 haplotype, the high variability observed suggests that other factors likely influence clonal progression.

S421 DISRUPTION OF HAEMATOPOIETIC STEM CELL HETEROGENEITY IN A MOUSE MODEL OF MYELOPROLIFERATIVE NEOPLASM

R. Norfo1,2, C. Di Genua1, C. Booth1, A. Giustacchini1, B. Povinelli1, N. Gray2, E. Regapi1, E. Soliliex4, L. Jamieson3, N. Tran1, A. Green4, S.E. Jacobsen1, A. Mead1

Background: The hematopoietic stem cell (HSC) compartment in mice encompasses a broad range of heterogeneous cell types including highly lineage-biased HSCs, such as platelet-biased HSCs (PMID:23934107). Myeloproliferative neoplasms (MPNs) are a heterogeneous spectrum of clonal hematopoietic disorders, that includes essential thrombocytosis (ET), a MPN-subtype usually presenting with isolated thrombocytosis. Most ET patients carry a gain-of-function point mutation in JAK2 (JAK2V617F), with several other collaborating hits reported to co-occur with JAK2V617F at lower frequencies, including abnormal gene expression in EZH2, which are more frequent in advanced MPN.

Aims: Although it is broadly accepted that MPNs are propagated by counterparts of HSCs, the impact of collaborating MPN-associated mutations arising in different HSC subsets remains unclear. We aimed to explore the possibility that platelet-biased HSCs might selectively promote development of an ET phenotype.

Methods: We generated a novel mouse model of MPN that carries a conditional knock-in of heterozygous human JAK2V617F (hJAK2V617F) and the conditional knock-out (KO) of EZH2 together with an inducible Mx1-Cre transgene. To analyse platelet-biased HSC subsets upon onset of the mutation(s), we also crossed in the vwf-eGFP transgene, which is selectively expressed in parts of HSCs, the impact of collaborating MPN-associated mutations arising in different HSC subsets remains unclear. We aimed to explore the possibility that platelet-biased HSCs might selectively promote development of an ET phenotype.

Results: Compared to wild-type and single mutant mice, EZH2-KO hJAK2V617F mice showed increased platelet counts, including a subset of mice which became acutely unwell with an extreme thrombocytosis. Strikingly, in serial bone marrow (BM) transplantation assays, EZH2-KO fully rescued the previously described hJAK2V617F-associated transplantation defect (PMID:20489053). EZH2-KO hJAK2V617F BM recipients showed long-term serial engraftment that was fully restricted to the platelet and myeloid lineages with a persistent thrombocytosis and absence of lymphoid reconstitution. RNA-sequencing revealed upregulation of several signaling pathways, including Hedgehog, and increased inflammation associated gene expression in EZH2-KO hJAK2V617F HSCs. Unexpectedly in this mouse model of thrombocytosis, phenotypic analysis of the HSC compartment in the BM showed that vwf-eGFP+ve HSCs were selectively lost (fold change[FC]=0.12 p=0.009), while vwf-eGFP–ve HSCs from Ezh2-KO hJAK2V617F mice primarily gave rise to platelet-biased HSCs. In contrast, vwf-eGFP+ve HSCs from Ezh2-KO hJAK2V617F mice engrafted poorly without recapitulating the disease in recipients.

Summary/Conclusions: In this novel Ezh2-KO hJAK2V617F mouse model, EZH2 loss collaborates to worsen thrombocytosis and rescue the HSC function defect in hJAK2V617F mice. We also observed a striking disruption of the germinal and functional HSC heterogeneity in Ezh2-KO hJAK2V617F mice with an unexpected and selective loss of vwf-eGFP+ve HSCs with the clonal advantage conferred to HSCs by EZH2-KO helps to explain how this collaborating mutation might promote the development of more advanced MPN.
Methods: Pts aged <18 years were recruited into 3 separate cohorts: (1) IM-resistant/intolerant CML-CP treated with DAS tablets 60mg/m² QD, (2) IM-resistant/intolerant CML-AP/BP or Ph+ ALL (enrollment closed early due to poor response), and (3) newly diagnosed CML-CP treated with DAS tablets 60mg/m² or DAS 72mg/m² powder for oral suspension (PFOS) QD for ≤1 year. PFOS dose was increased by 20% to match the exposure of the tablet in order to maintain adequate efficacy based on the findings from a bioequivalence study in adults. Primary objectives were major cytogenetic response (MCyR) for CML-CP resistant/intolerant to IM and complete cytogenetic response (CCyR) for newly diagnosed CML-CP (MCyR >30% and CCyR >55% considered of clinical interest). Study cohorts were not designed to be comparative.

Results: From 145 pts enrolled, 130 were treated; 54% were aged ≥12-<18 years. Within the IM-resistant/intolerant group, 25 were resistant, 2 were intolerant, and 2 were undetermined. For pts with CML-CP (n=113), 48% of pts with IM-resistant/intolerant CML-CP and 73% with newly diagnosed CML-CP remained on treatment at the time of this analysis (table 1). Cumulative rate of MCyR for IM-resistant/intolerant CML-CP remained as 3 months for IM-resistant/intolerant CML-CP, and a cumulative rate of CCyR >55% was reached as early as 6 months for newly diagnosed CML-CP (table). Estimated progression-free survival (PFS) by 48 months was 78% for IM-resistant/intolerant CML-CP and 93% for newly diagnosed CML-CP (table). Reasons for progression were loss of MCyR (n=3 IM-resistant/intolerant; n=4 newly diagnosed), loss of complete hematologic response (n=2 each), and development of CML-BP (n=2 IM-resistant/intolerant; n=1 newly diagnosed). One death was reported in the IM-resistant/intolerant CML-CP cohort 1 year after stopping DAS (gastrointestinal bleeding). Adverse events (AEs) were consistent with reports in DAS-treated adults, except no DAS-induced neutropenia, fever, or adenaemia was observed. In addition, no pulmonary arterial hypertension were reported here. Heterosensitivity in a newly diagnosed pt was the only DAS-related AE that led to discontinuation.

Summary/Conclusions: Results from the largest prospective and registrational trial of pediatric pts with CML-CP demonstrate that DAS is a safe and effective treatment for pediatric CML-CP. Target responses to first- or second-line that DAS were met as early as 3 and 6 months, respectively, and deep responses were observed. Efficacy and safety of DAS in pediatric pts were similar to those observed in adults; however, unlike in adults, no cases of pleural/pericardial effusion were reported.}

Figure 1. Summary/Conclusions: The present 24 month RFS of 77% for the overall 24 months in patients in stable MR4 appears better than in any comparable study to date, and implies that the initial 12 months of dose reduction may be respon-

possible, perhaps via improved compliance in the few months prior to stopping or through an as yet undefined mechanism.

S424

ASSESSMENT OF IMATINIB 400MG AS FIRST LINE TREATMENT OF CHRONIC MYELOID LEUKAEMIA: 10-YEAR SURVIVAL RESULTS OF THE HUMANIZED CML STUDY IV

Background: The optimum initial treatment of chronic myeloid leukemia (CML) is unknown.

Aims: CML-study IV was designed to confirm the International Randomized Study on Interferon (IFN) and STI571 (IRIS) and to explore whether treatment with imatinib (IM) at 400mg/day could be optimized.

Methods: From July 2002 to March 2012, 1551 newly diagnosed patients in chronic phase (CP) were randomized into a 5-arm study. 1536 patients were evaluable, 400 for IM400mg, 430 for IM + IFN, 420 for IM800mg, 158 for IM + cytarabine and 128 for IM-after-IFN-failure. Recruitment to the latter two arms was stopped after a pilot-phase.

Results: After a median observation time of 9.5 years, 10-year overall survival (OS) of all patients was 82%, 10-year progression free survival 80% and, 10-year relative survival 92%. 10-year OS was 80% with IMATINIB FOR NEWLY DIAGNOSED CHRONIC MYELOID LEUKEMIA: INITIAL RESULTS FROM THE BFORE TRIAL

Monotherapy with IM400mg provides a close to nominal survival. Outcome of CML is currently more determined by disease biology and demographics than by treatment optimization.

S425

BOSUTINIB VS IMATINIB FOR NEWLY DIAGNOSED CHRONIC MYELOID LEUKEMIA: INITIAL RESULTS FROM THE BFORE TRIAL

T.H. Brümmendorfer1, C. Gambacorti-Passerini2, M. Deininger3, M.J. Mauro4, C. Chua5, D.W. Kim5, L. Reilly5, A. Jeynes-Ellis5, E. Leip6, N. Bardy-Bouixin6, A. Hochhaus10, J.E. Cortes on behalf of the BFORE Study Investigators11

1Universitätsklinikum der RWTH Aachen, Aachen, Germany, 2University of Milan-Bicocca, Monza, Italy, 3University of Utah, Salt Lake City, 4Memorial Sloan Kettering Cancer Center, New York, New York, United States, 5Singapore General Hospital, Duke-NUS Graduate Medical School, Singapore, Singapore, 6Seoul St. Mary’s Hospital, Seoul, Korea, Republic Of, 7Avillion LLP, London, United Kingdom, 8Pfizer Inc, Cambridge, United States, 9Pfizer Global Research and Development, Paris, France, 10Klinik für Innere Medizin II, Universitätsklinikum Jena, Jena, Germany, 11University of Texas MD Anderson Cancer Center, Houston, United States

Background: Bosutinib (BOS) is a potent, dual SRC/ABL tyrosine kinase inhibitor approved for treatment of adults with Philadelphia chromosome-posit

P<0.02). Rate of complete cytogenetic response (CCyR) by 12 months was also significantly higher with BOS versus IM (77.2% vs 66.4%; P=0.038), with time to CCyR shorter for BOS (hazard ratio=1.38; P<0.001). Rate of BCR-ABL transcripts ≤10% (Intl. Scale) at 3 months was higher with BOS versus IM (75.2% vs 57.3%; P=0.001); rates of deep molecular response over time were also generally higher with BOS (Table). Results for molecular endpoints were similar in the mITT population. The only baseline characteristic identified as a significant predictor of MMR at 12 months besides treatment arm was Sokal risk group (high vs low; P<0.0001 and intermediate vs low; P=0.05 [mITT]). On-treatment progression to accelerated or blast phase occurred in 4 patients (1.6%) receiving BOS and 6 patients (2.5%) receiving IM in the mITT population. One BOS-treated and 4 IM-treated patients discontinued treatment due to progression to accelerated or blast phase. Among all treated patients, there were no deaths within 28 days of last dose of BOS and 4 with IM. Safety data for treated patients were consistent with the known safety profiles of BOS and IM. Discontinuation due to drug-related toxicity occurred with 12.7% of BOS patients and 8.7% of IM patients. Grade ≥3 adverse events (7.8% vs 1.1%) and increased alanine (19.0% vs 1.5%) and aspartate (9.7% vs 1.9%) aminotransferase levels were more common with BOS. Cardiovascular, peripheral vascular, and cerebrovascular events were infrequent in both groups (all grades: 3.0%, 1.5%, and 0% BOS vs 0.4%, 1.1%, and 0.4% IM; grade ≥3: 1.5%, 0%, and 0% BOS vs 0%, 0%, and 0% IM).

Table 1.

Summary/Conclusions: Patients on BOS had significantly higher rates of 12-month MMR and CCyR and achieved responses faster than those on IM. Conclusions with the known safety profile, higher incidences of gastrointestinal events and transaminase elevations were observed with BOS. Primary results from this study suggest BOS may be an important treatment option for patients with newly diagnosed CP CML.
CHRONIC MYELOID LEUKEMIA PATIENTS WERE NOT DIFFERENT IN MOLECULAR RELAPSE AFTER STOPPING IMATINIB IN MR4 WHETHER RELAPSE WAS DETECTED OR NOT - WHEN ADJUSTING FOR NUMBER OF CONTROL TRANSCRIPTS

Medizinische Klinik, Medizinische Fakultät Mannheim, Universität Heidelberg, Mannheim, Germany, 18Dept of Hematology, St Olavs Hospital, Trondheim, Norway

Background: With imatinib (IM), most patients with chronic myeloid leukemia (CML) achieve deep molecular responses. Six months after stopping tyrosine kinase inhibitor in deep response in the EURO-SKI trial, 61% of the patients were in molecular remission and in major molecular remission (3-log reduction in BCR-ABL l1 levels) (Mahon ASH 2016). Between patients and without BCR-ABL1, the difference in RFS at 6 months was not significant when assessing BCR-ABL1 detectability at the MR4.5 level (at least 1 detectable ABL1 copy) compared to the MR4 (at least 1 detectable ABL1 copy) in EURO-SKI (Pfeiffer ASH 2016). Aims: For 91 of 448 patients of the EURO-SKI learning sample, the sensitivity to investigate undetectable disease at the MR4.5 level was not given. Aim was to determine whether RFS probability would be different when comparing detectable and undetectable disease at the MR4 level.

Methods: Detectability of BCR-ABL1 depends on the number of control gene transcripts. To reduce bias when comparing “MR4 detectable disease” (MR4 but not MR4.5 detectable) and “MR4 undetectable disease” (MR4 without detectable BCR-ABL1), patients were stratified according to the number of control gene transcripts. For which small differences in GUSB copy numbers (used in 96 of 448 cases, U test (detectable vs undetectable): P>0.5), prior to PS matching, median numbers of ABL1 transcripts were higher for MR4 detectable disease (78,975 vs 68,925 with undetectable disease; P=0.05, not significant (n.s.)). In 196 patients with detectable disease, RFS at 6 months was 52% (95% confidence interval (CI): 45-59%), patients with undetectable disease 63% (95% CI: 53-73%) (P<0.01). Relapse was significantly higher in patients with detectable disease (odds ratio: 1.630:CI: 1.096-2.343). PS matching resulted in 173 patients per group. Median numbers of ABL1 transcripts changed to 82,142 (detectable) and 75,750 (undetectable disease; n.s.;). At 6 months, patients with detectable disease again had 52% RFS probability and patients with undetectable disease 59% (CI: 52-66%). In the logistic model stratified for the matched pairs, for relapse at 6 months, the odds ratio for MR4 with detectable to undetectable disease was 1.308 (CI: 0.862-1.984, n.s.).

Summary: By adjusting for number of control transcripts and other factors, results suggest little or no impact of detectability of BCR-ABL1 on RFS. Time in deep response seems to be more important. In daily routine, many labs produce reliable outcome at the MR4 but not always at the MR4.5 level. Discontinuation at the MR4 level, irrespective of detectability of BCR-ABL1 residual disease, appears safe, with a good chance of success when performed as in EURO-SKI. With PS matching, bias and differences but also power was reduced. To judge whether molecular response on the MR4 level is sufficient, further data is welcome.

Background: Deregulated expression programs due to genetic alterations, such as gene fusions affecting transcription and/or epigenetic factors is the hallmark of acute myeloid leukemia (AML) and the basis for the associated differentiation block of hematopoietic progenitors. Acute megakaryoblastic leukemia (AMKL) is a subtype of AML affecting primarily young children. Recently, the ETO2-GLIS2 fusion has been identified in 20-30% of de novo AMKL and associated with the worst prognosis in this subtype of AML.

Aims: Our goal was to characterize the mechanisms of cellular transformation induced by ETO2-GLIS2.

Methods: We first defined the consequences of ETO2-GLIS2 expression on hematopoietic progenitors and the contribution of ETO2 and GLIS2 on differentiation and self-renewal by methylcellulose replating assays and phenotype characterization. We then assessed global expression profiling and ETO2-GLIS2 direct binding on DNA by ChIPseq experiments. With immunoprecipitation experiments, we identified some ETO2-GLIS2 complex members. Finally, we tested the effects of a small peptide that could inhibit ETO2-GLIS2 complex stabilization both in vitro and in vivo.

Results: We showed that the GLIS2 moiety drives the megakaryocytic phenotype whereas both the ETO2 and GLIS2 moieties are required for maintaining self-renewal. Global expression profiling and comparison to patients’ signature consistently identified ETO2-GLIS2-mediated deregulation of major transcriptional regulators of hematopoiesis and leukemogenesis. Especially, ETO2-GLIS2 brings on an imbalance in ETS/GATA factors illustrated by an extinction of GATA1 and an overexpression of the ERG oncogene. We identified that ETO2-GLIS2 complex directly binds DNA via ETO2 complexes and through its GLIS2 moiety. Moreover, the ETO2-GLIS2 fusion localizes at half of H3K27ac-enhancers, so called super-enhancers, to control transcription of associated genes, in close association with ERG. Dimerization of ETO2-GLIS2 and interaction with endogenous ETO2 via its NRHR2 domains were demonstrated with in vivo recombination experiments. The ETO2-GLIS2 complex inhibited the oligomerization, reversed the transcriptional activation at enhancers, promoted megakaryocytic differentiation and abrogated human AMKL cells maintenance in vivo. So, the interaction of ETO2-GLIS2 with ETO2 complexes is an essential node for the transcriptional control by the fusion at enhancer elements. Finally, ETO2 is localized at super-enhancers and is recruited upon up-regulation of associated genes. ERG knockdown or genetic inactivation downregulates expression of ETO2-GLIS2 targets required for leukemic cells survival. Together, the strong up-regulation of ERG by the fusion and the presence of ERG at super-enhancers suggest a feed forward mechanism to impose gene deregulation.

Summary/Conclusions: In conclusion, we propose that the megakaryocytic differentiation arrest and self-renewal controlled by ETO2-GLIS2 results from imbalanced expression of master transcription factors imposed by aberrant chromatin structures at enhancers that may be disrupted by targeting the NRHR2 interface.

NUCLEOSOME BINDING PROTEIN HMGN1 BLOCKS MYELOIDDIFFERENTIATION AND PROMOTES CLONAL DOMINANCE VIA ABBERRANT HISTONE H3 ACETYLATION

L. Cabal-Hierro1, 2, P. Van Galen2, 3, M. Prada2, K. Togami1, 2, C. Mowery1, 2, K. Higby1, 2, D. Sykes3, S. Gygi4, B. Bernstein2, 3, A. Lane1, 2

1Dana Farber Cancer Institute/ Harvard Medical School, Boston, 2Broad Institute, Cambridge, 3Massachusetts General Hospital, 4Harvard Medical School, Boston, United States
Background: Acute myeloid leukemia (AML) is characterized by rapid growth and block in differentiation of myeloid progenitors. The AML blast is defined by having “open” chromatin. We hypothesized that alterations of chromatin conformation may promote AML. Reversing those changes could represent a novel therapeutic approach.

Aims: Gain of chr21q22 is the most common focal amplification in complex karyotype AML. HMGN1 is a chromatin-regulatory protein on 21q22 known to affect lymphoid development, and our preliminary data suggested that HMGN1 could directly mediate a myeloid differentiation block. Since HMGN1 is known to decompact chromatin and alter histone marks, our goal was to define and therapeutically target the mechanisms by which HMGN1 overexpression disrupts myeloid differentiation and promotes clonal dominance.

Methods: We immortalized bone marrow progenitors from wild-type (WT) or OE-HMGN1 mice (transgenic overexpressing HMGN1) with an estrogen receptor-HoxB8 fusion protein. Using exogenous estrogen to control translocation of HoxB8, we analyzed synchronized myeloid differentiation by flow cytometry, RNAseq, and TMT proteomic analysis. We performed MINT-Chip-seq (MNase Indexed T7-chromatin IP) to measure the histone marks H3K27ac, H3K27me3, H3K4me3 and total Histone H3. We also measured histone marks in hematopoietic stem and progenitor subpopulations in vivo. We performed competitive bone marrow transplantation with CD45.1 WT and CD45.2 OE-HMGN1 donors and measured the relative contribution to hematopoiesis over time.

Results: Synchronized differentiation in WT cells progressed over 6 days from myeloid progenitors to mature neutrophils and monocytes, analyzed by cell surface markers, morphology, and gene and protein expression. OE-HMGN1 cells proliferated faster and remained as undifferentiated myeloblasts (84% CD11b+Gr1+ in WT vs 4% in OE-HMGN1, p<0.002; Fig A). Gene set enrichment analysis revealed more similarity to undifferentiated hematopoiesis and leukemia signatures in OE-HMGN1 cells. MINT-Chip indicated a global and locus-specific increase of H3K27ac in OE-HMGN1 cells (Fig B, upper panel), consistent with an increase in gene transcription, confirmed by RNA-seq. We found a specific increase in HoxA cluster expression in OE-HMGN1 cells, consistent with an increase in gene transcription, confirmed by RNA-seq. We found a specific increase in HoxA clusters expression in OE-HMGN1 cells. High expression of PIWIL4 was associated with immature myeloid phenotype independent of HMGN1 expression. Ablation of PIWIL4 expression in AML cell lines revealed a global reduction in repressive H3K9me3 marks at promoters and gene body.

Conclusion: Our study suggests that HMGN1 overexpression blocks myeloid differentiation and promotes proliferation in hematopoietic progenitors via increased H3K27 acetylation. Targeting epigenetic changes downstream of HMGN1 or interfering with HMGN1 itself may represent a novel therapeutic strategy in AML.
Acquired and inherited platelet disorders

THE COMBINATION OF ORAL ALL-TRANS RETINOIC ACID AND DANAZOL VS DANAZOL AS SECOND-LINE TREATMENT IN ADULT IMMUNE THROMBOCYTOPENIA: A MULTICENTRE, RANDOMIZED, OPEN-LABEL TRIAL

F.-E. Feng1,2,3, M. Wang1,2,3, R. Feng4, J.-M. Zhang1,2,3, H. Jiang1,2,3, Q. Jiang1,2,3, J. Lu1,2,3, H. Liu4, J. Peng5, M. Hou6, J.-L. Shen6, J.-W. Wang7, L.-P. Xu1,2,3, K.-Y. Liu1,2,3, X.-J. Huang1,2,3, X.-H. Zhang1,2,3.

1Peking University Institute of Hematology, Peking University People's Hospital, 2Beijing Laboratory of Hematopoietic Stem Cell Transplantation, 3Collaborative Innovation Center of Hematology, Peking University, 4Department of Hematology, Beijing Hospital, Ministry of Health, Beijing, 5Department of Hematology, Qilu Hospital, Shandong University, Jinan, 6Department of Hematology, PLA Navy General Hospital, 7Department of Hematology, Beijing Tongren Hospital, Beijing, China.

Background: Immune thrombocytopenia (ITP) is an autoimmune disorder characterized by increased platelet destruction and impaired platelet production. Despite decades of basic and clinical research, the treatment of severe, corticosteroid-resistant or relapsed disease remains a great challenge. Our preliminary study indicated the effectiveness of all-trans retinoic acid (ATRA) for ITP (Wang M, et al. ASH 2012, Abstract #3338). This has been coupled with previous discoveries of an immune-modulation effect of ATRA in ITP, including its role to induce changes in Treg cells (Ruan CG 2016), and to correct the imbalance of aberrant macrophage polarization (unpublished data), indicating ATRA as a potential therapeutic regimen. Danazol has been used in the treatment of ITP for more than 30 years. Apart from its haemopoietic stimulatory and immune-modulatory effect, it has recently been shown to reverse abnormal thrombopoiesis in patients with thrombocytopenia (Townsley DM et al. 2016). The combination of ATRA and danazol may work synergistically based on the mechanism of action targeting both increased platelet destruction and insufficient platelet production.

Aims: To investigate the efficacy and safety of ATRA plus danazol in patients with corticosteroid-resistant or relapsed ITP.

Methods: A multicentre prospective study was performed in non-splenectomized corticosteroid resistant/relapsed ITP patients. Participants were at least 18 years of age, had a platelet count of less than 30×10^9/L at enrolment, and did not achieve a sustained response to treatment with full-dose corticosteroids for a minimum duration of 4 weeks or relapsed during steroid-tapering or after its discontinuation. Written informed consents were obtained from all of the participants. The primary endpoint was a sustained response. The secondary endpoints included overall response, time of response, duration of response, incidence of bleeding symptoms and safety.

Results: From 2012 to 2016, 130 consecutive patients were enrolled from 5 different tertiary medical centres in China. Thirty-seven patients were ineligible and excluded, leaving 93 patients randomized to the ATRA+danazol group (n=45) and the danazol group (n=48). At 12 months' follow-up, sustained partial or complete response was achieved in 71.6% of patients in the danazol+ATRA group, significantly higher than 47.2% for danazol monotherapy (p<0.001). Additionally, 92.5% and 42.5% of patients receiving ATRA+danazol achieved at least one response (R), while only 58.3% and 11.1% of patients with danazol monotherapy achieved R and CR, respectively. In patients achieving CR or R, the median time to treatment response was 30.5 days with a peak platelet count of 155×10^9/L in the danazol+ATRA group compared with 49 days with a peak PLT of 69×10^9/L in the danazol group. Multivariate analysis revealed that the initial response at day 28 and the median ITP duration were the potential variables associated with a sustained response. There was no treatment-related death due to adverse events. One patient receiving danazol monotherapy died from intracranial haemorrhage 4 weeks after study enrollment.

Summary/Conclusions: Our findings demonstrate that the combination of ATRA and danazol is safe and effective in achieving a rapid and long-lasting response, making it a potential promising therapeutic option for patients with corticosteroid-resistant or relapsed ITP.

NOVEL PERSPECTIVES IN GENOTYPE-PHENOTYPE CORRELATIONS IN MYH9-RELATED DISEASE: NO LONGER JUST A MATTER OF HEAD OR TAIL

F.-E. Feng1,2,3, M. Wang1,2,3, R. Feng4, J.-M. Zhang1,2,3, H. Jiang1,2,3, Q. Jiang1,2,3, J. Lu1,2,3, H. Liu4, J. Peng5, M. Hou6, J.-L. Shen6, J.-W. Wang7, L.-P. Xu1,2,3, K.-Y. Liu1,2,3, X.-J. Huang1,2,3, X.-H. Zhang1,2,3.

1Peking University Institute of Hematology, Peking University People's Hospital, 2Beijing Laboratory of Hematopoietic Stem Cell Transplantation, 3Collaborative Innovation Center of Hematology, Peking University, 4Department of Hematology, Beijing Hospital, Ministry of Health, Beijing, 5Department of Hematology, Qilu Hospital, Shandong University, Jinan, 6Department of Hematology, PLA Navy General Hospital, 7Department of Hematology, Beijing Tongren Hospital, Beijing, China.

Background: MYH9-related disease (MYH9-RD) is an autosomal-dominant disorder caused by mutations in MYH9, the gene for non-muscle myosin heavy...
chain II (NMHC-IIA), and represents the most frequent inherited thrombocytopenia worldwide. NMHC-IIA comprises two distinct domains, the N-terminal globular head domain (HD) and the C-terminal tail domain (TD), and causative mutations hit either the HD or the TD. All patients present at birth with macrothrombocytopenia and only some of them develop during life additional manifestations, including nephropathy often leading to end-stage renal disease (ESRD), sensorineural deafness, and/or cataract. Thus, the search for genotype-phenotype correlations in MYH9-RD has been an important research topic since the identification of the disorder. In 2008, the analysis of 108 patients allowed to conclude that the mutations affecting the HD were associated with evolution to early-onset ESRD and deafness, whereas the risk of manifesting HD-related manifestations was much lower for patients carrying mutations of the TD. In 2014, raising to 255 the number of patients, we suggested that evolution to juvenile ESRD associated only with the most frequent among HD mutations, i.e. substitution of the arginine 702 (R702). Conversely, the TD-related mutations were almost exclusively carried in a distal region of the HD protein, i.e. in the C-terminal region at the interface between the SH3 subdomain and the motor domain (SH3/MD interface), may be associated with a much less severe evolution.

Aims: To improve prognostic assessment of patients with MYH9-RD.

Methods: All the consecutive patients enrolled in the Italian registry for MYH9-RD until June 2015 were included. The association of MYH9 genotype with phenotype was assessed by a generalized linear regression model (event-free survival analysis).

Results: We enrolled 350 patients belonging to 199 MYH9-RD pedigrees. Mutational screening allowed us to identify 6 novel causative mutations in the HD of 6 different pedigrees. Interestingly, all of these variants were localized in the hydrophobic region of the SH3/MD interface. By raising the number of patients with mutations in this region from 14 to 26, and increasing the observation time, we could demonstrate that the mutations in the SH3/MD interface are associated with an earlier development of deafness at young age, but low risk of kidney disease and cataract. The other previously identified genotype-phenotype correlations were confirmed. In particular, mutations hitting the R702 in the HD resulted in constant evolution toward juvenile ESRD and severe deafness. Among mutations different from R702 substitutions, the p.D1424H in the TD associated with the highest risk to develop non-congenital manifestations of the disease.

Summary/Conclusions: Mutations in the HD of the NMHC-IIA are almost all localized in a specific region at the SH3/MD interface, which therefore represents a critical region for MYH9-RD pathogenesis. Most importantly, patients with mutations of this HD variant were distinguished into two different groups: subjects with R702 substitutions are expected to develop early severe a syndromic disorder, whereas mutations in the SH3/MD interface are associated with evolution to a milder phenotype, characterized by development of hearing impairment only (“auditory” phenotype). Our study confirmed a genotype-phenotype model for MYH9-RD that overcomes the previously reported dualism between HD vs TD mutation.

S433

A MONOALLELIC LOSS-OF-FUNCTION MUTATION IN THE THROMBOPOIETIN (THPO) GENE IS RESPONSIBLE FOR A NEW FORM OF INHERITED THROMBOCYTOPENIA

P. Norris1, C. Marconi2, D. De Roccoc, F. Melazzinic, T. Pippuccid, G. Loffredoa, T. Giangregorio1, E. Cigalini1, A. Peccil, M. Seri1, A. Savoilia

1Department of Internal Medicine, IRCCS Policlinico San Matteo Foundation and University of Pavia, Pavia, 2Department of Medical and Surgical Science, University of Trieste, Trieste, Italy

Background: The THPO-MPL axis plays a central role in platelet biogenesis: it activates the signaling cascade inducing megakaryocytes (MKs) differentiation from progenitor cells and regulates MK maturation, proplatelet extension, and nascent platelets release into the bloodstream. Different diseases are known to result from abnormal MK functioning: congenital thrombocytopenia, and THPO. Gain-of-function mutations in both genes cause congenital thrombocytopenia, while loss-of-function mutations in MPL result in congenital amegakaryocytic thrombocytopenia: patients affected by this form of inherited thrombocytopoiesis (ITP) present at birth with isolated thrombocytopenia, which always evolves into severe bone marrow aplasia. Similarly, a homozygous loss-of-function variant in the IT. They were part of our case series of 274 consecutive families, 151 of which remained without a definite diagnosis at the end of the diagnostic workup carried out according to the diagnostic algorithm proposed in 2003 by the Italian Working Group on alpha-granule abnormalities. The identification of these recent discovered disorders (Clin Genet 2016;89:141). The investigation was approved by the Institutional Review Board of the IRCCS Policlinico San Matteo Foundation and all patients gave written informed consent.

Results: WES in 86 proposals with unknown IT identified 2 unrelated individuals (family A and B) carrying the heterozygous variant c.377C>T (p.Arg13Cys) which is expected to result in a mutant protein degradation and THPO haploinsufficiency. In each family the segregation with the disorder was confirmed analyzing one affected relative. Bleeding tendency was absent in all cases. All patients had mild thrombocytopenia; blood film examination did not identify any MK morphological abnormality. Interestingly, a few nuclear elements were slightly increased in sizes in patients of family A. In vitro platelet aggregation and surface expression of GPIb/IIa and GPIb/IX were investigated in the two patients of Family B and gave normal results. The mild severity of thrombocytopoenia and the absence of qualitative platelet defects, at least in the two patients of family B, are consistent with the absence of bleeding tendency in affected subjects. THPO serum level was at the lower limit of the normal range in the two subjects of family B, the only available for this assay. This result was in agreement with our hypothesis that THPO mutations were expected to result in haploinsufficiency.

Summary/Conclusions: The p.Arg317 mutation in THPO causes a new autosomal dominant form of mild, non-syndromic thrombocytopenia. This innocuous disorder is relatively rare (1.3% of families of our case series) but it has to be distinguished from the more severe autosomal dominant ITs with normal platelet size deriving from mutations in ETβ6, ANKR2D6 and RUNX1, since they predispose to the development of hematological malignancies. Because of the similarity of the clinical features and the lack of reliable laboratory markers, we suggest to perform genetic analysis in all subjects with autosomal dominant thrombocytopenia and normal platelet size in order to identify their disorders, define prognosis and organize an appropriate follow-up regimen.

S434

POSITION OF THE GF1B ZINC FINGER MUTATION DECOUPLES CD34 EXPRESSION FROM ALPHA-GRANULE DEFICIENCY IN GF1B-RELATED PLATELET DISORDERS

W. Stevenson1, D. Rabbolini1, M.-C. Morel-Kopp1, Q. Chen1, S. Gabrielli1, C. Ward1

1Hematology, University of Sydney, Sydney, Sydney, Australia

Background: GF1B is a transcription factor that plays an important role in haematopoiesis. Families with a mutation of the fifth DNA-binding zinc-finger domain of GF1B experience bleeding and have a platelet phenotype characterised by macrothrombocytopenia, increased CD34 expression and alpha-granule deficiency. Aims: To explore the function of other zinc finger domains of GF1B we have characterised two unrelated families with a GF1B variant, C168F, predicted to disrupt the first zinc-finger domain and compared the phenotype with a previously described pedigree with the H294fs mutation that disrupts the fourth zinc-finger domain.

Methods: Clinical platelet phenotypes were determined by light and transmission electron microscopy and functional studies performed by light transmission and whole blood impedance aggregometry. Platelet protein expression was measured by flow cytometry and western blotting. DNA-binding of variants was determined by gel mobility shift assays (EMSA) and changes in gene transcription by luciferase assays. Cellular phenotypes were then studied in patient specific IPSCs derived megakaryocytes.

Results: Individuals with both C168F and H294fs are thrombocytopenic (mean platelet count =107 x109/L, n=8) but lack the collagen induced aggregation defects and bleeding symptoms observed in individuals with H294fs (ISTH BAT, P=0.015). Alpha granule content observed by microscopy and quantitated by western blotting of granule related proteins, P-selectin and fibrinogen, were similar between C168F and control platelets and this was significantly greater than that observed for the H294fs mutation (P<0.01). EMSA studies indicate that the C168F variant retains the ability to bind DNA whereas the H294fs mutation altering Zn finger 5 abrogates DNA binding. Despite retaining the ability to bind DNA, the C168F variant de-represses gene transcription at TUBB1, CYR61 and TUBB2 (P<0.01). The transcriptional de-repression observed at the CD34 promoter with both Zn finger 1 and 5 variants was validated by an increase in platelet surface CD34 measured by flow cytometry and total CD34 protein measured by western blotting of CD34 with both variants (P<0.01). The transcriptional de-repression observed at the CD34 promoter with both Zn finger 1 and 5 variants was validated by an increase in platelet surface CD34 measured by flow cytometry and total CD34 protein measured by western blotting of CD34 with both variants (P<0.01). The transcriptional de-repression observed at the CD34 promoter was increased in cells derived from individuals with both C168F and H294fs variants but alpha granule deficiency was only observed in cells containing the non-DNA-binding H294fs mutation.

Summary/Conclusions: Mutations altering GF1B zinc finger 1 cause thrombocytopenia with increased CD34 expression but these platelets retain relevant clinical bleeding symptoms. This finding is mechanistically distinct from the Zn finger 5 mutation that abrogates DNA binding with a subsequent phenotype characterised by alpha-granule deficiency and clinical bleeding.
TREATMENT OF PRIMARY ADULT CHRONIC IMMUNE THROMBOCYTOPENIA (CITP) WITH FOSTAMATINIB, AN ORAL SYK INHIBITOR: RESULTS OF TWO RANDOMIZED, PLACEBO-CONTROLLED PHASE 3 STUDIES

J. Bussel1, L. Mayer1, L. Cervinka1, K. Chojnowska1, W. Homandrat1, A. Hellmann1, J. Windyga1, E. Grossbard1, A. Duliege1
1Division of Pediatric Hematology/Oncology, Department of Pediatrics, Weill Cornell Medicine, New York, NY, United States, 2Fakultni Nemocnice Brno, Brno, Czech Republic, 3Wojewodzki Szpital Specjalistyczny im. M. Kopernika w Lodzi, Lodz, 4Wojewodzki Szpital Specjalistyczny im. J. Konczaka, Slupsk, 5Universitycyt Zentrum Klinicke, Gdansk, 6Klinika Zaburzen Hemostazy I Chorób Wewnętrznych, Instytut Hematologii I Transfuzjologii, Warszawa, Poland, 7Rigel Pharmaceuticals Inc., South San Francisco, CA, United States

Background: CITP is characterized by autoantibody-directed platelet destruction mediated by activated monocyte Fc receptors which signal via spleen tyrosine kinase (syk). A Phase 2 trial of the oral syk inhibitor Fostamatinib (FOSTA) in 16 patients (pts) with refractory CITP provided preliminary efficacy and safety data (Podolanczuk et al., 2009).

Aims: To evaluate the efficacy and safety of FOSTA in adult CITP in 2 parallel, identical, multi-center, randomized, double-blind phase 3 studies (S047 and S048) of 24 weeks duration, followed by an open label study (S049).

Methods: 150 pts with 3 platelet (plt) counts (ct) ≥30K/µL were enrolled (76 in S047, 74 in S048) with a 2:1 randomization to FOSTA 100mg or placebo bid, and stratification by prior splenectomy and baseline plt ct. Sixty-one % of pts were female; median age was 54 y (20-88); 93% were Caucasian; and stratification by prior splenectomy and baseline plt ct.<or ≥15K/µL. Sixty-three (S047, 74 in S048) of 24 weeks duration, followed by an open label study (S049).

Results: Across both studies, a SR occurred in 18/101 (18%) FOSTA vs 1/49 (2%) placebo pts; but not in the 29 responders. The number of pts with ≥1 adverse event (AE) was comparable in FOSTA vs placebo (83% vs 75%). The majority AEs on FOSTA were mild or moderate; all resolved over time. Most common AEs were: diarrhea (29% vs 15%), nausea (19 vs 8%), hypertension (20% vs 8%), ALT/AST increase (10% vs 0%). Serious AEs were reported in 13% FOSTA vs 21% placebo pts.

Summary/Conclusions: Fostamatinib substantially improves plt ct in certain pts with heavily pre-treated, severe citP of long disease duration. AEs are mostly mild or moderate in severity. Given its unique mechanism of action-based on inhibition of syk, FOSTA could, if approved, be an important alternative as single agent and be a useful component of combination therapy for pts with difficult citP.

Background: Childhood with Down syndrome (DS) are prone to development of high risk B cell precursor (BCP) acute lymphoblastic leukemias (DS-ALL) that differ genetically from both sporadic pediatric ALLs. Chromosomal rearrangements causing increased expression of CRLF2, the receptor for thymic stromal lymphopoietin (TSLP), characterize about half of DS-ALLs.

Aims: Understanding the pathogenesis of relapse of DS-ALL relating to their CRLF2 status.

Methods: Integrative genomic analysis of matched diagnosis remission and relapse DS-ALLs, pharmacological inhibition and genetic CRISPR mediated silencing.

Results: Genomic analysis of 25 matched diagnosis remission and relapse DS-ALLs, pharmacological inhibition and genetic CRISPR mediated silencing.

TNF RECEPTOR 2 IS REQUIRED FOR RIP1-DEPENDENT CELL DEATH IN LEUKEMIA

J. Aguadé-Gorgorí1, S. McComb1,2, M.P. Dobay3, C. Mezzatesta1, L. Kostendries1,4,4, J.-P. Bourquin1, B. Bornhauser1

Background: Persistence of residual leukemia cells, due to deficiencies in apoptotic programs, is a major driver of relapse. Activation of alternative non-apoptotic cell death pathways such as necroptosis represents an attractive strategy to eliminate residual leukemia cells and prevent relapse. We have previously shown that SMAC-mimetics (SM) potently induce cell death by simultaneous RIP1-dependent apoptosis and necroptosis in a subset of refractory acute lymphoblastic leukemia (B-ALL) patient-derived samples. The molecular signals that drive sensitivity to RIP1-dependent cell death remained elusive so far.

Aims: The aim of this project was to understand the mechanisms that determine the specific vulnerability to necroptosis in ALL.

Methods: To identify molecular determinants of sensitivity to SM, we correlated the gene expression profiles of 17 primary samples with high and low sensitivity to SM with the IC50 in response to two SM compounds, birinapant and LCL161. We confirmed the top scoring genes including TNF receptor 1 (TNFR1) and TNFR2 by quantitative RT-PCR in patient-derived xenografts. We further validated our results by quantifying the expression of the candidate genes in an independent cohort of relapsed primary B-ALL and by screening samples with different expression levels of TNFR1 and 2 for their response to SM in vitro.

To assess the mechanistic role of TNFR1 and 2 in the response to SM, we generated patient-derived TNFR1 and TNFR2 knockout cells using CRISPR/Cas9 gene editing technology, and evaluated their response to SM in vitro and in vivo using a CRISPR selection model. Additionally, we overexpressed TNFR2 and evaluated the cell death phenotype. To determine the mechanism of TNFR1-mediated sensitization to SM, we investigated the formation of the pro-death RIP1-TNFR1 complex in wild type versus TNFR2 knockout cells and in SM sensitive and resistant ALL by immunoprecipitation in primary ALL samples.

Results: Comparative gene expression profiling indicated a correlation of the expression of TNFR2 with sensitivity to SM in primary ALL. Using an independent cohort of relapsed ALL samples, we found that high TNFR2 expression predicted sensitivity to SM in an ex vivo model of the bone marrow. Deletion of either TNFR1 or TNFR2 using CRISPR/Cas9 in patient-derived ALL conferred resistance to treatment with SM in vivo in the xenograft model, indicating that TNFR1 and 2 are both functionally required for cell death. In agreement with an important role for TNFR2 in the response to SM, the overexpression of TNFR2 leads to increased sensitivity to the TNFR1/RIP1 death axis. On the mechanistic level, recruitment of RIP1 to TNFR1 is a key event in the activation of cell death, which is abolished in TNFR2-deficient leukemia and does not occur in SM resistant cases.

Summary/Conclusions: Taken together, our data reveal a novel function of TNFR2 in cell death signaling, as TNFR2 predicts sensitivity to SMAC mimetics and plays a key role in activating the TNFR1/RIP1 cell death pathway, which underlies the switch from RIP1-controlled cell survival to cell death and characterizes a distinct vulnerability in ALL.

THERAPEUTIC TARGETING OF ONCOGENIC MYB ACTIVITY IN T-ALL

T. Pieters1,2, S. T’Sas1, J. Morscino1, F. Matthijssens1, K. Lemeire2, T. Hochepe1, B. Lintemans1, L. Reune1, J. Haigh1, G. Berx1, S. Goossens1, P. Van Vlierberghe1

Background: T-lineage acute lymphoblastic leukemia (T-ALL) is an aggressive hematologic malignancy that accounts for 10%–15% of pediatric and 25% of adult ALL cases. The prognosis of T-ALL has gradually improved, however, the outcome of T-ALL patients with primary resistant or relapsed leukemia remains poor. Thus, further advances in the treatment of T-ALL require the development of effective and highly specific molecularly targeted antileukemic drugs. The proto-oncogene MYB (encodes c-MYB) is aberrantly activated in a subset of T-ALL patients through T-cell receptor driven translocations or genomic duplications of the MYB locus itself. Recently, a new genetic mechanism for the generation of oncogenic super-enhancers in malignant T cells was identified, and suggests a general role for MYB in the regulation of T-cell specific super-enhancer activity.

Aims: We want to identify the role of enhanced MYB activity in super-enhancer driven oncogenic transcription in the context of malignant T-cell development and investigate the in vivo role of cMyb in the initiation and maintenance of T-ALL.

Methods: To evaluate if cMyb could act as a bona fide oncogene in the pathogenesis of T-ALL, we developed a conditional R26-driven cMyb overexpression mouse model. For this, we used a targeting vector that contained a floxed stop cassette followed by the cMyb gene and a EGFP/luciferase reporter, which was subsequently targeted in mESCs by recombinase-mediated cassette exchange (RMCE).

Results: Here, we report a novel conditional Myb knockin mouse model (R26-Myb). To study the in vivo oncogenic capacity of Myb, we initially crossed this conditional Myb knockin model with VavCre mice, in order to obtain hematopoietic specific expression of Myb and the EGFP/luciferase from the ROSA26-promoter. Notably, Vav-iCreertms2 R26-Mybhtg/tg mice developed T-cell lymphomas with a median latency of 77 weeks, suggesting that Myb can act as a bona fide oncogene in malignant T-cell transformation (Figure 1A). Next, we crossed our Myb transgenic model with Pten conditional knockout mice, to allow comparative analysis of tumors with and without T-cell specific Myb expression. Genetic inactivation of Pten is frequently observed in human T-ALL, and T-cell specific deletion of Pten (using Lck-Cre) results in T-cell leukemia/lymphoma development with an average of 17 weeks. Using this strategy, we obtained mice that overexpress R26-driven cMyb and lack Pten in developing T-cells and found that cMyb expression synergizes with Pten deletion, resulting in fully penetrant and accelerated T-ALL formation (median survival of 84 days instead of 118; p = 0.0003; Figure 1B). Finally, we used this novel murine T-ALL model to identify new therapeutic strategies for MYB dependent T-ALL. Importantly, the tumor cells from the cMyb knockin mice are luciferase-positive and are therefore suitable for in vivo drug testing using bioluminescence. Using this model, we evaluated the in vivo anti-leukemic efficacy of a variety of small molecules and identified new drugs that impede Myb protein stability or Myb-mediated transactivation in Myb driven tumorigenesis.
THE T-CELL LEUKEMIA ASSOCIATED RIBOSOMAL R10L R98S MUTATION ENHANCES JAK-STAT SIGNALING

T. Girard1, S.O. Sulima1, S. Vereecke1, Y. Khan4, L. Fancelli1, Z. Flickinger2, C. Schwab3, J. Op de Beeck1, J. Verbeeck1, J. Royaert1, E. Geerdens4,5, C. Vicente4,5, S. Bornschein4,5, C. J. Harrison6, J. P. Meijerink7, J. Cool4,5, J.D. Diminan6, K.R. Kampen1, K. De Keersmaecker1

Background: Several somatic ribosome defects have recently been discovered in cancer, yet their underlying oncogenic mechanisms remain poorly understood. Alterations in ribosomal protein genes RPL5, RPL10, and RPL22 have been described in ~20% of T-cell acute lymphoblastic leukemia (T-ALL) cases. Whereas RPL5 and RPL22 show heterozygous inactivating mutations and deletions, RPL10 contains a clear mutational hotspot at residue arginine 98 (R98), with 8% of pediatric T-ALL patients harboring this RPL10 R98S missense mutation.

Aims: Investigating the pathogenic role of the recurrent R98S mutation in ribosomal protein L10 (RPL10) in T-ALL.

Methods: A label-free quantitative proteomics experiment was performed to screen for differentially expressed proteins in engineered mouse lymphoid BaF3 cells expressing RPL10 WT or RPL10 R98S. Differences in protein expression were further validated in hematopoietic cells derived from a transgenic RPL10 R98S knock-in mouse model and in material derived from xenografted T-ALL patient samples.

Results: The differential proteome screen revealed overexpression of several Jak-Stat signaling components (Csf2rb2/2, Jak1, Stat1, Stat3, Stat5a/b and Stat6) in engineered RPL10 R98S mouse lymphoid cells, which we confirmed in hematopoietic cells derived from a transgenic RPL10 R98S mouse model. The relevance of this overexpression was illustrated by enhanced Jak-Stat pathway activation upon cytokine stimulation in RPL10 R98S lymphoid cells, as well as increased sensitivity of these cells to clinically used Jak-Stat inhibitors ruxolitinib and pimozone. RPL10 R98S positive leukemia patients likewise showed overexpression of IL7RA, Jak1 and Stat5, increased sensitivity to pimozone, as well as a mutually exclusive mutation pattern between RPL10 R98S and Jak-Stat lesions, suggesting that RPL10-R98S also modulates the cascade in human T-ALL. Programmed -1 ribosomal frameshifting (-1 PRF) recently emerged as a post-transcriptional mechanism regulating expression of cytokine receptors. We identified -1 PRF signals in mouse and human Jak-Stat genes and observed RPL10 R98S associated frameshifting reduction in several of these, which may contribute to their overexpression. Altered levels of -1 PRF can however only partially explain observed Jak-Stat protein expression changes, and transcriptional changes and altered protein stability are also involved. Indeed, our data point to altered proteasome activity and composition in RPL10 R98S cells, with upregulation of immunoproteasome specific catalytinc subunits, which may explain the increased stability of particular proteins such as Jak1. Of further medical interest, RPL10 R98S cells showed reduced proteasome activity and enhanced sensitivity to the clinically used proteasome inhibitors bortezomib and carfilzomib.

Summary/Conclusions: We explored the molecular mechanism by which the RPL10 R98S mutation contributes to the pathogenesis of T-ALL. We propose a model in which R98S associated decreases in -1 PRF levels, combined with changes in the degradation of particular proteins and potential other mechanisms such as transcriptional regulation, leads to selective upregulation of the Jak-Stat cascade (Figure 1). Besides expanding the relevance of the Jak-Stat cascade in T-ALL and leukemia in general, our results have therapeutic potential since cells harboring the RPL10 R98S mutation are sensitized towards clinically used Jak-Stat and proteasome inhibitors.

Background: Transcriptional read-through of a single mRNA between contiguous loci, or cis-spllicing of adjacent genes (cis-SAGE), results in transcription of intergenically-spliced chimeric RNAs (ISCs) in the absence of structural genomic changes. Recent advances in high-throughput RNA-sequencing analyses have permitted identification of aberrant ISC expression as a potential cancer driver, but knowledge of leukemia-related ISC is lacking.

Aims: To examine whether cis-SAGE generates biologically important ISCs in T-acute lymphoblastic leukemia (T-ALL).

Methods: We performed RNA-sequencing of 12 cases of T-ALL and normal thymic RNA, and used targeted analysis pipelines to detect T-ALL-specific fusion chimeras.

Results: We identified 140 T-ALL-specific fusions, of which 55 involved genes located within 30kb of each other, in the same transcriptional orientation. This distance is consistent with that previously observed for cis-SAGE, suggesting that ISC expression is common in T-ALL. In total, putative ISCs were detected in 10/12 samples, with a median of 4 (range 0-15) per patient. We performed further analysis on the candidate ISC NFATC3-PLA2G15, which includes the Nuclear Factor of Activated T-cells (NFAT) family member NFATC3, a critical regulator of normal thymopoiesis and known modulator of T-ALL biology. We found that primary T-ALLs exhibited a wide range of NFATC3-PLA2G15 expression, while levels in normal tissue were either very low or undetectable. 5’ RACE PCR analysis of leukemic cDNA revealed that fusion transcription was initiated in exon 1 of NFATC3. We also performed array competitive genomic hybridization of 115 diagnostic T-ALL samples, and found no evidence of microdeletions that would result in NFATC3-PLA2G15 expression, providing strong evidence that NFATC3-PLA2G15 is a true ISC that is generated by cis-SAGE. We found that the NFATC3-PLA2G15 fusion had lower activity than wild-type NFATC3 in both luciferase reporter experiments and proliferation and survival complementation assays in NFAT-null T-ALL cell lines in vitro. Gene set enrichment analysis revealed that primary T-ALL blasts with elevated NFATC3-PLA2G15 levels had reduced transcription of canonical NFAT target genes in vivo, suggesting that these cases may have lower activity of normal physiological NFAT pathways. Strikingly, we found that higher NFATC3-PLA2G15 levels strongly correlated with both shorter time to leukemia development (p=0.01) and survival (p=0.003) in patient-derived T-ALL xenografts and immunodeficient mice. These findings were corroborated by survival analyses of human T-ALL patients treated as part of the Francophone multinational GRAALL-2003 and -2005 studies, as cases with the highest quartile of NFATC3-PLA2G15 expression had significantly reduced 5 year overall survival (52.6%, 95% CI 33.3% - 68.7%, p=0.047)

Summary/Conclusions: Our results suggest that ISC expression is common in T-ALL, and that high expression of the NFATC3-PLA2G15 ISC correlates with reduced canonical NFAT pathway activity and poor patient outcome.
**Thrombotic disorders**

**ASSESSING THE RISK-BENEFIT OF ANTICOAGULANTS IN ELDERLY PATIENTS WITH CANCER-ASSOCIATED VENOUS THROMBOEMBOLISM: A POPULATION BASED STUDY**

A. M. Birgisdóttir 1,*, I. S. Sverrisdóttir 1, O. Landgren 2, M. Björkholm 3, A. M. Birgisdóttir 1,*, I. S. Sverrisdóttir 1, O. Landgren 2, M. Björkholm 3, A. M. Birgisdóttir 1,*, I. S. Sverrisdóttir 1, O. Landgren 2, M. Björkholm 3

**Background:** Cancer patients have a higher risk of venous thromboembolism (VTE) which conveys a higher subsequent mortality risk; conversely, they also have a higher risk for bleeding due to many factors including abnormal tumor anatomy and the use of chemotherapy agents with the associated risk for thrombocytopenia. However, the consequences of a recurrent VTE or a major bleeding event might be different in terms of mortality. As a result, the risk of VTE recurrence or a MB event might bear different weights. A previous systematic review has suggested that the case fatality rates of VTE recurrence and MB are similar. However, heterogeneity in study design, outcomes and in particular the types of populations included, limited the interpretation and applicability of the results. Clinical decision making uses estimations of risk and benefit for any given intervention. In the case of VTE, anticoagulants are the cornerstone of treatment having a proven benefit in reducing the risk of recurrent VTE events with an associated increase in the risk of bleeding. Therefore, determining the risk-benefit of anticoagulants might allow for better informed treatment decisions, in particular in a population at high risk for both ends of the spectrum. Therefore, we sought to estimate the risk and benefit of anticoagulant therapy in cancer patients developing a VTE using data from administrative databases.

**Methods:** We conducted a retrospective population-based cohort study in Ontario, Canada using de-identified linked administrative healthcare databases housed at the Institute for Clinical Evaluative Sciences (ICES). We included patients over 65 years of age with a diagnosis of cancer defined using provincial, ICD-9 and ICD-10 codes for major malignancies and who developed a VTE event within 6 months of the initial cancer diagnosis. VTE was identified through a previously validated algorithm using a combination of diagnostic codes for deep vein thrombosis (DVT) and pulmonary embolism (PE) and codes identifying diagnostic procedures for VTE (i.e. ultrasound, CT pulmonary angiography, lung scintigraphy) within 7 days of each other. Recurrent VTE and MB events were assessed within 180 days from the index date. MB was identified using a previously validated algorithm and included upper and lower gastrointestinal and intracranial bleeding events. Treatment was classified based on the first available prescription within 7 days of the index VTE. We estimated mortality within 7 days of the VTE recurrence or MB events using an unadjusted Cox proportional hazards model and competing risk analysis. Ratios of the mortality for MB compared to VTE recurrence were calculated and 95% confidence intervals were estimated using non-parametric models.

**Results:** Between 2004 and 2014 there were 6967 VTE events identified in cancer patients over 65 years of age and treated with an anticoagulant. Mean age was 75 years, and 47.6% patients were women. Of all patients, 59.9% received prescriptions for LMWH alone, 15.3% for LMWH followed by warfarin, 22.1% for warfarin and 2.7% for rivaroxaban. At 180 days after the index VTE event there were 235 (3%) MB events and 1184 (17%) VTE recurrences. Within 7 days of the outcome event there were 26 (11%) deaths after MB and 6 (0.5%) after VTE. The mortality ratio for MB versus VTE was 21.8 (95% CI 9.53). In exploratory analyses we did not find differences according to type of anticoagulant prescription.

**Summary/Conclusions:** In this large, population-based, study based on more than 40,000 patients with NHL and almost 116,000 controls, we demonstrated that there is an increased risk of thrombosis in patients with NHL when compared to controls. This is true for all types of thrombosis. We therefore conclude that hypercoagulability seems to increase with diagnosis of NHL. Several factors may contribute to this prothrombotic state, including chemotherapy and other treatment related factors as well as the disease itself. Considering that the increase in the incidence of thrombosis was highest before and around the time of diagnosis for NHL patients, that indicates that the tumor itself may have a great impact on the hypercoagulability of these patients.

**COMPARATIVE ANALYSIS OF PREDICTIVE MODELS FOR THROMBOEMBOLIC EVENTS IN LYMPHOMA PATIENTS**

D. Antic i, N. Milic ii, N. Nikolovski iii, M. Todrović iv, J. Bila v, P. Djurdjevic vi, B. Andjelic i, V. Djurasinovic vii, A. Sretenovic viii, M. Smiljanic ix, V. Vukovic vii, J. Jelicic viii, B. Mihajlovic x

1Clinic for hematology, Clinical Center of Serbia, 2Medical school Belgrade, Belgrade, Serbia

**Background:** Lymphoma is a malignancy that originates in lymph nodes and lymphoid tissue. The main category of lymphomas is non-Hodgkin’s lymphoma (NHL). NHL comprise about 3% of all cancers in Sweden. Some are aggressive and fast growing, while others are more indolent and do not necessarily require treatment. It is well known that cancer increases the risk of thrombosis, especially in the case of thromboembolism, but data are scarce on the risk of thrombosis in NHL patients.

**Aims:** The aim of this study is to evaluate the risk of thrombosis in NHL patients compared to controls and to study time trends in the risk of thromboembolism with recent advances in the treatment of these diseases.

**Methods:** We conducted a nested case-control study consisting of individuals diagnosed with NHL in Sweden 1980-2013 (n=40,354), and up to four matched controls (n=115,677). The risk of the first thrombosis was evaluated after the diagnosis of NHL (and corresponding date for controls) and the ones that occurred less than 30 days prior to diagnosis of NHL. Kaplan-Meier survival analysis was used to estimate the risk of thrombosis and a log-rank test performed to assess statistical significance. Cox regression analysis was used to calculate hazard ratios (HRs) and 95% confidence intervals (CI) (adjusting for age, sex, year of diagnosis, and previous history of thrombosis). Risk of deep vein thrombosis, pulmonary embolism and arterial thrombosis was evaluated. Arterial thrombosis was defined as cerebral Embolism, transient ischemic attacks, angina pectoris, myocardial infarction, and arterial embolism and thrombosis.

**Results:** NHL patients had a statistically significant increase in risk of any type of thrombosis compared to controls (HR: 1.58, 95% CI: 1.53-1.62). The risk was significantly increased for all three types of thrombosis; deep vein thrombosis (HR: 1.71, 95% CI: 1.67-1.75), pulmonary embolism (HR: 1.31, 95% CI: 1.25-1.37) and arterial thrombosis (HR: 1.20; 95% CI: 1.16-1.23). The risk of thrombosis did not change during the study period for the NHL patients. There was an increased risk of thrombosis for NHL patients when compared to controls, independent of previous history of thrombosis (HR: 1.64; 95% CI: 1.59-1.69) no previous history, HR: 1.43; 95% CI: 1.37-1.50 if previous history of thrombosis). The incidence of thrombosis for NHL patients started to increase about five months before the diagnosis of NHL, and reached its peak a month before diagnosis. The incidence stayed increased for the first year after diagnosis.

**Summary/Conclusions:** In this large, population-based, study based on more than 40,000 patients with NHL and almost 116,000 controls, we demonstrated that there is an increased risk of thrombosis in patients with NHL when compared to controls. This is true for all types of thrombosis. We therefore conclude that hypercoagulability seems to increase with diagnosis of NHL. Several factors may contribute to this prothrombotic state, including chemotherapy and other treatment related factors as well as the disease itself. Considering that the increase in the incidence of thrombosis was highest before and around the time of diagnosis for NHL patients, that indicates that the tumor itself may have a great impact on the hypercoagulability of these patients.
and validation cohorts. The ThroLy model was developed using data solely from a derivation cohort, which included 1236 patients. Variables were evaluated by univariate logistic regression analysis, while the model was developed using a stepwise multivariate logistic regression analysis. Once a final model was defined, patients were divided into low risk and at risk groups. The final model was assessed in the validation cohort (584 patients). The studied population was also divided, based on Khorana and Padua score, into low risk and at risk groups.

Results: The study population included 1820 eligible lymphoma patients. The mean patient’s age was 53.1 years (range, 15–87 years). Most patients (83%) were newly diagnosed and had advanced stage disease: Ann Arbor stage III, 14.7% and stage IV, 44%. A total of 778 patients (42.7%) had high-grade lymphoma; 351 (19.3%) had low-grade lymphoma; 266 (14.6%) had HL; 156 (8.6%) had other forms; and 269 (14.8%) had CLL/SLL. Of all the patients included in the study, 99 (5.4%) developed at least one TE during the follow-up period. There were 73 patients with venous TE (73.7%), and 25 with arterial TE (25.3%), while 1 patient had both. Patients with aggressive NHL had significantly higher odds of developing TE compared to patients with any other lymphoma type (RR=1.5; 95% CI for RR 1.1–2.4; p=0.027). The incidence of thromboembolism was 81 (5.3%) in the newly diagnosed patients and 18 (6.2%) in relapsed patients. Overall, 35.4% (59/99) of the patients with thromboembolism experienced the event before the start of chemotherapy. The majority of patients (64.6%) had TE events during chemotherapy or within 3 months after chemotherapy. For patients classified at risk according to ThroLy score in derivation cohort, the model produced negative predictive value (NPV) of 98.5%, positive predictive value (PPV) of 25.1%, sensitivity of 75.4%, and specificity of 87.5%. In validation cohort PPV for ThroLy score was 28.9%. Padua and Khorana score had PPV of 15.5% and 14.8% in derivation, and 11.5% and 14.8% in validation cohort, respectively.

Summary/Conclusions: Lymphoma patients are at increased risk of thromboembolic events but thromboprophylaxis in these patients is largely underused. ThroLy score is more specific for lymphoma patients than suggested Padua and Khorana score, but external validation in large prospective cohort studies is required.

**IMPACT OF A NEW ELECTRONIC ALERT SYSTEM (V2.0) FOR VENOUS THROMBOEMBOLISM PREVENTION IN HOSPITALIZED CANCER PATIENTS**

R. Figueroa1,*, A. Alfonso1, V. Sara1, M.C. Nicolás1, M. Marcos Jubilar1, J. López Picazo2, I. Gil-Bazó2, A. García-Mouriz2, J.A. Páramo1, J. Hermida1, R. Lecumberri1

1Hematology, 2Medical Oncology, 3Informatics Department, Clínica universidad de Navarra, 4Division of Cardiovascular Sciences, Centro de Investigación Médica Aplicada, Pamplona (Navarra), Spain

Background: Oncologic-hematologic hospitalized patients constitute a group at high risk of venous thromboembolism (VTE). Current clinical practice guidelines recommend prophylaxis with low molecular weight heparin (LMWH) during hospitalisation, unless contraindicated. However, its underuse is a worldwide problem. Electronic alert systems (e-alerts) can improve the use of appropriate thromboprophylaxis and reduce the incidence of VTE.

Aims: To evaluate the impact of a new version (v2.0) of our e-alert system for VTE prophylaxis compared with the initial software version. Secondary endpoints try to identify predictive factors for prophylaxis use and thrombotic events.

Methods: Prospective study including consecutive adult cancer patients admitted at our centre. From April 2014 to June 2015 (first period) the initial e-alert system version remained operative and from July 2015 to December 2016 (second period) the new version was active. The v2.0 displayed a second window that asked physicians about the reason why LMWH was not prescribed. The main outcomes were: VTE events during hospitalisation and 30 days after discharge. Descriptive statistical analysis and correlation between clinical variables and main outcomes were performed by using the software package SSPS v20.

Results: 1251 patients were included, 782 patients in the first period and 469 in the second one (main clinical features are shown in Table 1). E-alerts v2.0 was associated with an increase of appropriate LMWH prophylaxis during hospitalisation (65.2% vs 72.2%, p=0.015). However, this improvement did not result in a reduction of VTE during admission or follow up (2.3% vs 2.3%; p=0.89). Interestingly, almost 80% of VTE events occurred despite LMWH use. No differences in the rate of major bleeding (2.8% vs 3.2%; p=0.83), and mortality (10.6% vs 14.3%; p=0.07) were observed, either. The main reason for not prescribing LMWH prophylaxis was bleeding risk, but in 17% of cases physicians did not consider that the patient really had a high VTE risk. No significant correlation was found between any of the clinical variables analyzed and the risk of VTE. Prophylaxis use was more frequent among patients with solid cancer (vs hematologic), advanced stage, active chemotherapy treatment and longer hospital stay.

Summary/Conclusions: The new e-alert system further increases the use of VTE prophylaxis in hospitalised cancer patients, although this was not associated with a reduction in the VTE incidence. A relevant number of VTE events occur despite prophylaxis with standard LMWH. Identification of risk factors for thromboprophylaxis failure is needed.

This work has been funded by a biomedical research grant with the Laboratory of Pharmaceutical ROVI and an aid to the research projects of the Instituto de Salud Carlos III and the FEDER (PI13 / 01029).

**IDENTIFICATION OF A NEW AND RELATIVELY FREQUENT SERPINC1 GENE DEFECT CAUSING ANTITHROMBIN DEFICIENCY HARDLY DETECTED BY CURRENT MOLECULAR METHODS: DUPLICATION OF EXON 6**

M.E. De La Morena-Barrio1,*, B. de la Morena-Barrio1, J. Padilla1, R. Teruel1,2, S. Asenjo2, E. Wypasek4, A. Miñano1, V. Vicente1,2, J. Corral1,2

1Servicio de Hematología y Oncología Médica, Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arraxaca, 2Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Instituto de Salud Carlos III (ISCIII), Murcia, 3Servicio de Hematología, Hospital Clínico San Carlos, Madrid, Spain, 4The John Paul II Hospital, Krakow, Poland; Institute of Cardiology, Jagiellonian University Medical College, Krakow, Poland

Background: Antithrombin (AT) deficiency was the first thrombophilia described 50 years ago and so far the strongest one. Up to 78% of cases are explained by point mutations or small deletion/insertions in exons or flanking regions of SERPINC1 that are easily detected by sequencing analysis. A low proportion of cases (2%) is explained by gross gene defects, mainly deletions, which are detected by multiplex ligation-dependent probe amplification (MLPA) analysis. However, the molecular base of AT deficiency is unknown using current methods in 20% of cases.

Aims: To identify new SERPINC1 defects causing AT deficiency.

Methods: We studied 271 unrelated cases with AT deficiency. Functional and biochemical assays characterized plasma AT. Genetic analyses involved Sanger and Next Generation Sequencing (NGS) (PGM, Ion Torrent), MLPA and specific PCR designs.

Results: Sanger sequencing of PCR amplicons with primers flanking the 7 exons and further analysis with SeqscapeTM detected pathogenic mutations in 173 cases. Whole gene sequencing identified 5 mutations in regulatory regions. MLPA analysis revealed 5 cases with whole or partial deletion of the gene. Moreover, 13 cases had disorders of glycosylation. Interestingly, the analysis of the PCR product and the electropherogram of exon 6 of a 42-year-old male patient (P1) with deep venous thrombosis and 75% of anti-FXa activity

haematologica | 2017; 102(s2) | 161
with no apparent gene defect by either Sanger sequencing of 7 exons or by NGS analysis of the whole gene using the Ion Torrent platform, revealed a 193 bp insertion, which corresponded to a tandem duplication involving exon 6. Family studies revealed the same duplication in 5 relatives, all with AT deficiency (60-75%). The first MLPA analysis of this case failed to detect the duplication and only after a fine readjustment, it was detected. MLPA analysis under the new conditions of the remaining 59 cases with unknown molecular base for their AT deficiency identified one additional case, P2, with potential duplication of exon 6. P2 was a 17 year-old female with 41% of anti-FXa activity, who developed deep venous thrombosis. Sanger and NGS sequencing also failed to detect any genetic defect in P2. A set of primers specific to detect tandem duplications of exon 6 was designed with forward primer from 3’ end of exon 6, and reverse primer from 5’ of exon 6. This set of primers only rendered amplification in the two cases with exon 6 duplication. The second patient (P2) had a new 863 bp duplication in tandem of exon 6. Sanger sequencing of the specific amplicons in the two cases with tandem duplication of exon 6 revealed Alu sequences surrounding these duplications. Finally, one out of 5 cases with gene deletions involved breakpoints affecting intron 5 (deletion of exons 2-5).

Summary/Conclusions: Our study identified a new and relatively frequent SERPINC1 gene defect causing AT deficiency that is hardly identified by current molecular methods: duplication of exon 6. This genetic defect was detected in 1% of our cohort, and represents nearly half of the total gross gene defects causing AT deficiency. The small size of this exon makes difficult the identification of this defect by MLPA. The presence of 6 Alu elements up and downstream exon 6 makes this region a hotspot for unequal recombination that may cause deletions, tandem duplications and potentially transpositions, which may produce AT deficiency (both severe and mild) by an aberrant splicing and only after a fine readjustment, it was detected. MLPA analysis under the new conditions of the remaining 59 cases with unknown molecular base for their AT deficiency identified one additional case, P2, with potential duplication of exon 6. This genetic defect was detected in 1% of our cohort, and represents nearly half of the total gross gene defects causing AT deficiency. The small size of this exon makes difficult the identification of this defect by MLPA. The presence of 6 Alu elements up and downstream exon 6 makes this region a hotspot for unequal recombination that may cause deletions, tandem duplications and potentially transpositions, which may produce AT deficiency (both severe and mild) by an aberrant splicing.
**Aims:** The aim of the study is to investigate whether donor CD4 T cells recognizing mismatched HLA-DR show tissue specific reactivities.

**Methods:** In a randomized clinical trial we treat patients 3 months after T cell depleted alloSCT from HLA 10/10 matched, HLA-DR mismatched, donors with 0.25-0.50 x 10^6/kg donor CD4 T cells to promote immune reconstitution. In 4 patients, Graft-versus-Leukemia reactivity and/or organ specific GVHD occurred after the infusion. To characterize the immune responses in these patients, in vivo activated T cells were clonally isolated and tested for reactivity against a panel of target cells, including patient and donor derived hematopoietic cells, third party hematopoietic cells as well as different GVHD target cells (patient skin fibroblasts, third party colon carcinoma cells, biliary epithelial cells and lung fibroblasts) expressing the mismatched, patient variant, HLA-DR molecule.

**Results:** Allo-HLA-DR directed CD4 T cells showing differential recognition of target cells were found in all 4 patients. A total of 33 HLA-DPB1*04:01 reactive CD4 T cell clones were isolated from patient 1 who suffered GVHD of skin and colon, but not liver. Within these 33 clones, 3 clones recognized only hematopoietic target cells, 9 clones recognized hematopoietic, skin and colon derived target cells and 5 clones recognized hematopoietic and colon derived cells only. None of the T cell clones recognized biliary epithelial cells. From patient 2 total of 230 HLA-DPB1*03:01 reactive CD4 T cell clones were isolated, of which 27 recognized only hematopoietic target cells and 96 clones also recognized GVHD target cells with differences in tissue specificity. 32 HLA-DPB1*03:01 reactive CD4 T cell clones were found from patient 3, of which 6 recognized only hematopoietic target cells, whereas other clones again showed various tissue specificities. From patient 4, 26 HLA-DPB1*01:01 reactive T cells could be isolated which all recognized biliary epithelial cells with or without recognition of other target cells. In addition, also 11 HLA-DPB1*03:01 reactive T cells were isolated, again with different tissue specificities.

**Summary/Conclusions:** These results illustrate that donor CD4 T cells directed against mismatched HLA-DR show differential recognition of target cells including restricted specificity for cells of hematopoietic origin. Donor CD4 T cells recognizing hematopoietic target antigens in the context of patient specific HLA-DR alleles can be used to mediate tumor specific immune responses after HLA 10/10 matched unrelated stem cell transplantation.

**ABERRANT T CELL RESPONSES IN THE BONE MARROW MICROENVIRONMENT OF PATIENTS WITH POOR GRAFT FUNCTION AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION**

**V. Van Hoeven1,2,*, J. M. Munneke1,2, A. Cornelissen3, S. Omar2, M. Spruit2, T. van de Vondervoort1,4, M. Eerenstein1,4, J. L. Verweij1,4, R. W. van Beselaar5, N. Helsper1,6, D. B. van der Meulen2, J. M. Jansen1,2, J. N. Hoogerbrugge1,2, H. M. van der Schoot1,4, R. M. Saliba1,*, H.W. Song2, O.M. Maher3, B.J. Overman 1, C.J. Hofferek 2, R. M. Saliba1,*, H.W. Song2, O.M. Maher3, B.J. Overman 1, C.J. Hofferek 2

**Background:** Poor graft function (PGF) remains a life-threatening complication following allogeneic hematopoietic stem cell transplantation (allo-HSCT), and the underlying mechanisms have not yet been elucidated. Considerable evidence from murine studies has demonstrated that effective hematopoiesis depends on the specific bone marrow (BM) microenvironment, where hematopoietic stem cells reside. In this regard, we previously reported that PGF patients had impaired BM endosteal and vascular microenvironment (BBMT 2013; BMT 2016; Oncotarget 2016; Blood 2016). Moreover, our pilot study showed that both CD4+ and CD8+ T cells polarized towards a type 1 immune response in the BM microenvironment of PGF patients (N=10) compared to those in matched good graft function (GGF) patients (N=20) (BBMT 2016). Nevertheless, whether abnormalities of T cell subsets in the BM immune microenvironment, including Th17, Th1, Th1, Th2, Tc2 cells and regulatory T cells (Tregs), are involved in the pathogenesis of PGF remains to be explored.

**Aims:** To compare the T cell subsets in the BM immune microenvironment, including Th1, Th2, Tc2, Th17, Tc17 cells and Tregs, between patients with PGF and GGF after allo-HSCT.

**Methods:** This prospective nested case-control study enrolled 20 patients with mismatched related or unrelated donors undergoing allo-HSCT and 20 healthy donors (HD). The percentages of Th1 (37% vs. 26.4%, P=0.0005) and Th17 (19% vs. 18.4%, P=0.0001) cells were significantly higher in PGF patients than in GGF patients, whereas the percentages of Th2 (0.8% vs. 2.4%, P=0.0001) and Tc2 (5.5% vs. 1.1%, P=0.0001) cells were markedly lower in the PGF group than in the GGF group. PGF patients showed significantly greater Th1 cell/Th2 cell (31.6 vs. 10.8, P=0.0001) and Th1 cell/Tc2 cell ratios (108.8 vs. 18.4, P<0.0001) than those for GGF patients. Moreover, a significantly higher proportion of stimulated CD4+ T cells that produced IL-17 (Th17) was found in the BM of PGF patients than in the BM of GGF patients and HD (3.7% vs. 1.6% vs. 1.1%, P=0.05), whereas the percentages of Tregs in PGF patients were comparable to those in GGF patients and HD, resulting in a dramatically elevated ratio of Th17 cells/Tregs in the BM of PGF patients relative to those in GGF patients (1.01 vs. 0.57, P=0.04).

**Summary/Conclusions:** The present study revealed that aberrant T cell responses in the BM immune microenvironment may be involved in the pathogenesis of PGF after allo-HSCT. These findings will facilitate the optimization of immune regulation strategies and improve the outcome of PGF patients post-allotransplant.
Aberrant B-cell homeostasis has been described in patients (pts) with chronic graft-versus-host disease (cGVHD) following allologeneic stem cell transplantation (allo-SCT). However, there is no information on the predictive value of specific B-cell subsets of the incidence of cGVHD.

**Aims:** We sought to determine if B-cell subsets measured around day 100 after allo-SCT predict the subsequent occurrence of cGVHD in a prospective clinical study.

**Methods:** Peripheral blood (PB) samples were obtained from consented patients (pts) between day 80 and 110 (D100) after allo-SCT at The University of Texas MD Anderson Cancer Center from 2012 to 2015. Only pts who had not been diagnosed with cGVHD or progression of underlying malignancy by D100 were eligible for this study. We analyzed CD19+CD20+ B cell subsets by FACS. Subsets were defined as naïve (CD27-IgD+), unswitched (CD27-IgD-), switched (CD27+IgD-) and switched (CD27+IgD+) memory cells. Receiver Operating Characteristic (ROC) curve was used to identify threshold levels of B cell % and numbers that predict the incidence of cGVHD. cGVHD diagnosis was based on the 2014 National Institutes of Health guidelines.

**Results:** A total of 80 pts were enrolled in the study. The median age at SCT was 49 years (range 21-75). The majority (80%) of pts received myeloablative conditioning, and 75% received tacrolimus with methotrexate or mycophenolate mofetil for GVHD prophylaxis. Diagnosis was myeloid (61%) or lymphoid (34%) malignancy in the majority of pts. Grafts source was primarily PB or bone marrow from matched-unrelated (61%) or related (24%) donors. Grade ≥3 malignancy in the majority of pts. Grafts source was primarily PB or bone marrow from matched-unrelated (61%) or related (24%) donors.

**Summary/Conclusions:** In conclusion, D100 frequency of naïve and switched B cells predicts the subsequent development of cGVHD. Lymphoid malignancies and older age may be associated with aberrant B-cell reconstitution. Consideration of D100 B-cell subsets may improve risk stratification models for the development of cGVHD.

**EFFECTS OF AG-348, A PYRUVATE KINASE ACTIVATOR, IN PATIENTS WITH PYRUVATE KINASE DEFICIENCY: UPDATED RESULTS FROM THE DRIVE PK STUDY**

**Background:** Pyruvate kinase (PK) deficiency is a congenital hemolytic anemia caused by deficiency of the glycolytic enzyme, red cell PK (PK-R). AG-348 is an orally available, small molecule, allosteric activator of PK-R that activates the wild-type and a range of mutated PK-R enzymes in vitro, and increases PK-R activity and restores adenosine triphosphate levels in red blood cells from patients with PK deficiency.

**Aims:** To report on preliminary efficacy and safety data from the use of AG-348 in the ongoing DRIVE PK study (NCT02476916), an open-label dose-ranging trial of AG-348 in transfusion-independent adults with PK deficiency.

**Methods:** After providing informed consent, patients were randomized to AG-348 50mg or 300mg orally twice daily (BID) for 6 months (Core Period). At the end of the Core Period, patients can continue on treatment for another 2 years in the Extension Period. Transfusion independence is defined as ≤3 units of red blood cells transfused in the 12 months preceding the first dose of AG-348 and no transfusions in the 4 months preceding the first dose. Patients are followed weekly for Weeks 1-3, every 3 weeks for Weeks 13-24 and then every 3 months until the end of the study. Hormone and iron status are evaluated at Baseline, Week 12 and End of Core Period, and then every 6 months in the Extension Period.

**Results:** As of 18 Jan 2017, goal enrolment has been met and all 52 patients are evaluable for safety and efficacy; 24 have completed the Core Period and 23 are ongoing in the Core Period. Five patients discontinued from the Core Period, owing to adverse events (AEs) (n=2) or consent withdrawal (n=3). Of the 24 subjects who completed the Core Period, 21 entered the Extension Period and 20 are still on treatment; 1 was discontinued by the investigator. Patients are currently receiving doses ranging between <25mg BID and 300mg BID. Since the previous data cutoff date of 23 Sep 2016 (where N=34), AG-348 had been well tolerated, small molecule, allosteric activator of PK-R that activates the wild-type and a range of mutated PK-R enzymes in vitro, and increases PK-R activity and restores adenosine triphosphate levels in red blood cells from patients with PK deficiency.

---

**STEM CELL TRANSPLANTATION IN PYRUVATE KINASE DEFICIENCY**

**Background:** PK-R deficiency is a congenital hemolytic anemia caused by deficiency of the glycolytic enzyme, red cell PK (PK-R). AG-348 is an orally available, small molecule, allosteric activator of PK-R that activates the wild-type and a range of mutated PK-R enzymes in vitro, and increases PK-R activity and restores adenosine triphosphate levels in red blood cells from patients with PK deficiency.

**Aims:** To report on preliminary efficacy and safety data from the use of AG-348 in the ongoing DRIVE PK study (NCT02476916), an open-label dose-ranging trial of AG-348 in transfusion-independent adults with PK deficiency.

**Methods:** After providing informed consent, patients were randomized to AG-348 50mg or 300mg orally twice daily (BID) for 6 months (Core Period). At the end of the Core Period, patients can continue on treatment for another 2 years in the Extension Period. Transfusion independence is defined as ≤3 units of red blood cells transfused in the 12 months preceding the first dose of AG-348 and no transfusions in the 4 months preceding the first dose. Patients are followed weekly for Weeks 1-3, every 3 weeks for Weeks 13-24 and then every 3 months until the end of the study. Hormone and iron status are evaluated at Baseline, Week 12 and End of Core Period, and then every 6 months in the Extension Period.

**Results:** As of 18 Jan 2017, goal enrolment has been met and all 52 patients are evaluable for safety and efficacy; 24 have completed the Core Period and 23 are ongoing in the Core Period. Five patients discontinued from the Core Period, owing to adverse events (AEs) (n=2) or consent withdrawal (n=3). Of the 24 subjects who completed the Core Period, 21 entered the Extension Period and 20 are still on treatment; 1 was discontinued by the investigator. Patients are currently receiving doses ranging between <25mg BID and 300mg BID. Since the previous data cutoff date of 23 Sep 2016 (where N=34), AG-348 had been well tolerated, small molecule, allosteric activator of PK-R that activates the wild-type and a range of mutated PK-R enzymes in vitro, and increases PK-R activity and restores adenosine triphosphate levels in red blood cells from patients with PK deficiency.

**Summary/Conclusions:** AG-348 is a novel, first-in-class PK-R activator undergoing clinical testing in patients with PK deficiency. The ongoing DRIVE PK study has now met goal enrolment of 52 patients, and data from these patients will be available at the time of presentation. Chronic daily dosing with AG-348 is well tolerated and has demonstrated clinically relevant, durable increases in hemoglobin (Hb) +1 g/dL. Hb responses were seen across a range of four doses, and were rapid and sustained. For a subset of patients (n=8), the rate of glycolytic metabolism in peripheral blood samples was assessed before and after treatment, and a positive correlation was observed between increases in glycolytic flux through the PK-R pathway and increases in Hb. Updates on safety, clinical efficacy measures (including Hb levels) and genotype-response correlations will be provided.
Background: Pyruvate kinase deficiency (PKD) is the most common glycolytic enzyme defect causing hereditary non-spherocytic hemolytic anemia. PKD does not have a specific curative treatment. Therefore treatment is mainly supportive, consisting of regular red blood cell transfusions, splenectomy and chelation therapy for iron overload. This does not improve the quality of life for affected patients. Hematopoietic allogeneic stem cell transplantation (HSCT) has the potential to cure the disease. However, there is little experience in applying HSCT in PKD and guidelines are not available. To date, only four cases of HSCT have been published. Thus, additional data are required to help the establishment of HSCT guidelines and support future strategies, such as gene therapy.

Aims: The aim of this study was to make a worldwide inventory of all cases of PKD that have been treated by HSCT, and to evaluate indication, procedures employed, and outcome.

Methods: This is an international case series. Queries were sent to national hematopoietic stem cell transplantation (HSCT) registries, national and international databanks and to physicians involved in HSCT on PKD patients. The latter were asked to complete a questionnaire on disease characteristics, pre-transplant condition, transplant regimen and post-transplant outcome. Two additional cases were reported from a recently published report (Kim. 2016. Bone Marrow Transplantation).

Table 1.

Results: From 1996 to 2016 a total of 16 PKD-patients were reported to have been treated by stem cell transplantation. Eight patients were treated in the EU and eight in Asian centres, respectively. No patient resulted to be transplanted in the US. Median age at transplantation was 6.5 years. (10 patients (62.5%) were <10 years; 6 (37.5%) >10 years), seven patients (43.8%) were splenectomized at the time of HSCT. Fifteen patients (94%) reached engraftment. The sixteenth patient showed mixed chimerism followed by spontaneous transition to full donor chimerism after splenectomy six months post transplantation. Two patients were lost from secondary graft failure. One of these had recovered a full donor chimerism after donor lymphocyte infusion. Outcome in the other patient is unknown. GVHD grade 4 was reported in 6/16 cases (38%). There was no obvious relation between GVHD prophylaxis or any other clinical factors and the occurrence of GVHD grade 2-4 in our patients. Two-year cumulative survival was 74%. Seven patients did not reach the two-year milestone yet. All five patients who did not survive died of transplant-related causes. Patients who did not sur-

Summary/Conclusions: This is the first study on outcome of HSCT in PKD patients. Due to the still relatively small number of cases no definite conclusions on the safety of HSCT in PKD can be drawn. However, we observed a better survival for patients transplanted before the age of ten. This difference could also explain difference in survival between patients transplanted in Europe versus Asia. The high rate of severe GVHD in this cohort is a reason for concern. The strong decline in survival of patients older than ten years of age indicates the need for very careful selection of HSCT-candidates.

S453 HEREDITARY XEROCYTOSIS: CLINICAL AND BIOLOGICAL PRESENTATION AT DIAGNOSIS IN A RETROSPECTIVE SERIES OF 103 PATIENTS

Sickle Cell Center, Medical College of Georgia, Augusta University, Augusta, Aims: This 2017;376:429-439).

Background: The median hemoglobin level was in the normal range: 135±19 g/L (range 71-195) with a slight macrocytosis (median MCV: 109±8fL) and a marked reticulocytosis (median reticulocyte count: 202±141 G/L). Of note, 57 patients (55%) presented a totally compensated hemolysis with a hemoglobin level above 115g/L. MCHC was in the normal range (median 335±1,3g/dL) but was above 66 g/dL for 28 (27,1%) patients. Stomatocytes were noticed on the blood smear in 42 patients over 70 available, numbered as rare (19%), few (60%) or numerous (21%). Genetics could be performed in 45 subjects from 22 distinct families. At least one PIEZO1 mutation was identified in very affected subjects. No KCNN4 mutations were found in these typical ektacytometric forms of HX.

Summary/Conclusions: This work represents the largest HX series and highlights the important heterogeneity in the clinical features at diagnosis. One important finding is that most patients were not anemic and presented a compensated hemolysis. In a significant percentage of cases, diagnosis was made in the exploration of extra hematological features including perinatal edema or hemochromatosis occurring despite the absence of any red blood cells transfusion. Moreover, we confirmed the very high risk of thrombotic events after splenectomy, underlining the absolute necessity of formally eliminating HX in any unexplained chronic hemolysis each time splenectomy is considered.

S454
CRIZANLIZUMAB, A P-SELECTIN INHIBITOR, INCREASES THE LIKELIHOOD OF NOT EXPERIENCING A SICKLE CELL-RELATED PAIN CRISIS WHILE ON TREATMENT: RESULTS FROM THE PHASE II SUSTAIN STUDY

K. Vanavond1, M. Schimmel1, E. Nauser1, G. van Mierlo1, I. Bulder1, R. van Bruggen2, B.J. Biemond2, B.M. Luken1, S. Zeerleder1
1Department of Immunopathology, Sanquin Research, and Landsteiner Laboratory, AMC, University of Amsterdam, 2Department of Hematology, Academic Medical Center, University of Amsterdam, 3Department of Blood Cell Research, Sanquin Research, and Landsteiner Laboratory, AMC, University of Amsterdam, Amsterdam, Netherlands

Background: Chronic hemolysis is a hallmark of sickle cell disease (SCD). Hemolysis in SCD has been associated with elevated levels of heme in the circulation of both human patients and SCD mice. It was shown that TNF-α-primed neutrophils form NETs in SCD, as treatment of SCD mice with the heme-binding protein hemopexin (Hpx) to scavenge free heme led to reduced NET formation by TNF-α-primed neutrophils. Free heme was suggested to mediate the formation of neutrophil extracellular traps (NETs) as shown by staining of lung sections (Chen et al. Blood 2014). In addition, the administration of DNase I to degrade NETs led to improved survival. Furthermore, it was shown that plasma from SCD patients obtained during SCD crisis induced NET formation by TNF-α-primed neutrophils. Free heme was suggested to mediate the formation of NETs in SCD, as treatment of SCD mice with the heme-binding protein hemopexin (Hpx) to scavenge free heme led to reduced NET formation (Chen et al. Blood 2014).

Methods: SUSTAIN was a randomized, double-blind, placebo-controlled, Phase II study (NCT01895361). Patients aged 16–65 years with SCD (including HbSS, HbSC, HbSβ0-thalassemia, and HbSβ+–thalassemia genotypes) and 2-10 SCPC events in the previous 12 months were included. Concomitant use of hydroxyurea (HU) was permitted if the patient had been using it for ≥6 months and at a stable dose for ≥3 months. Patients were randomized 1:1:1 to receive intravenous crizanlizumab 5.0 mg/kg, 2.5 mg/kg or placebo. Loading doses were administered on days 1 and 15, followed by routine treatment every 4 weeks for up to 50 weeks. At the final assessment visit at week 52, descriptive statistics were used to summarize the frequency of patients who were SCPC event-free for the duration of the study, based on the intent-to-treat (ITT) population overall and by prior SCPC events, SCD genotype and HU use at baseline.

Table 1.

| Table. SCPC event-free patients by prior SCPC events, SCD genotype and HU use |

| **HU use** | **Yes** | **No** | | | |
| Z-4 | 14/42 (33.3) | 2/42 (4.7) | | | |
| 5-10 | 9/42 (21.2) | 7/42 (16.7) | | | |
| **All data are n/N (%)** | | | | | |

Results: Among the 198 patients included in the study (ITT population), 62.6% and 37.4% had experienced 2-4 and 5-10 SCPC events in the previous year, respectively, and 62.1% were taking HU at baseline. HbSS was the most common genotype (71.2%; HbSC: 16.2%, HbSβ0–thalassemia: 6.1%, HbSβ+–thalassemia: 5.1%, other: 1.5%). Overall, more patients in the crizanlizumab 5.0 mg/kg group (n=24/67; 35.8%) were SCPC event-free than in the 2.5 mg/kg (n=12/66; 18.2%) and placebo (n=11/65; 16.9%) groups. In each of the prior SCPC events, SCD genotype and HU use subgroups, a greater proportion of patients treated with crizanlizumab 5.0 mg/kg were SCPC event-free compared with those in the crizanlizumab 2.5 mg/kg or placebo arms (Table 1). In subpopulations considered to be at increased risk of experiencing a SCPC (patients with 5-10 SCPC events in the previous year and/or with the homozygous HbSS genotype), a higher proportion of patients treated with crizanlizumab 5.0 mg/kg were SCPC event-free compared with those in the placebo arm (28.0% vs 4.2% and 31.9% vs 17.0%, respectively). Additionally, 33.3% of patients who were taking HU and treated with crizanlizumab 5.0 mg/kg were SCPC event-free during the study, compared with 17.5% in the placebo arm, possibly suggesting an additive effect.

Summary/Conclusions: Treatment with crizanlizumab 5.0 mg/kg appears to increase the likelihood of adult patients with SCD being SCPC event-free while on treatment, even in high-risk subpopulations. Crizanlizumab 5.0 mg/kg was also effective in those who had experienced at least two SCPC in the previous year despite taking HU, suggesting that this dose is effective as a disease-modifying agent that meets an unmet medical need.
mine whether ex vivo Hpx addition to human SCD sera would prevent NET formation.

Methods: Patient serum and plasma samples were obtained from 32 incidents of VOC in 24 adult SCD patients, with informed consent. Moreover, steady state samples were obtained at least 4 weeks after discharge from the hospital. Patients having had a blood transfusion in the 3 months prior to admission were excluded. NET formation by human neutrophils from healthy donors was studied using confocal fluorescence microscopy and staining for extracellular DNA with the cell nonpermeable dye Sytox Green. The presence of extracellular DNA that stains positive for citrullinated histone H3 confirmed the formation of NETs (Figure 1A).

Results: Indeed, we found that hemin (ferriprotoporphyrin IX) activated neutrophils to generate reactive oxygen species and release NETs, which was prevented by addition of plasma-derived Hpx. Moreover, exposure of neutrophils to sera from patients with SCD promoted NET formation, which was significantly enhanced during VOC. However, we observed that circulating free heme levels were elevated in SCD patient serum irrespective of disease state, and serum concentrations of Hpx were reduced in both VOC and steady state compared to healthy donor serum. Strikingly, addition of Hpx in supraphysiological concentrations failed to prevent the formation of NETs in all SCD sera tested. We and others (Chen et al. Blood 2014) have found that, in contrast to hemo, protoporphyrin IX does not trigger NET formation, revealing that the iron atom is required for the release of NETs. This observation led us to investigate whether free iron may directly induce NET formation. When neutrophils were exposed to Fe-NTA or serum from a thalassemia patient with iron overload, NETs were formed. Scavenging of free iron by addition of the iron-chelator deferoxamine or the specific iron-binding protein apotransferrin prevented NET release (Figure 1B). Moreover, we found that sequestration of free iron prevented NET formation induced by a subset (6 out of 11 tested), but not all, sera of patients with VOC (Figure 1C and D). In addition, sickled red blood cells (RBCs) are known to bind to neutrophils in vitro. Here, we found that neutrophils released NETs in response to sickled RBCs, even in the presence of Hpx. By contrast, blocking of complement C5 activation completely prevented the formation of NETs when neutrophils were exposed to sickled RBCs (Figure 1E).

Summary/Conclusions: In summary, we observed that sequestration of free iron with these iron binding compounds may be explored therapeutically to prevent or treat VOC development in SCD. Finally, complement activation in the presence of sickled RBCs activates neutrophils to release NETs, which may also contribute to VOC and SCD pathogenesis. Therefore, anti-CS IgG may represent an alternative therapeutic strategy to prevent VOC in SCD.

New drugs for rescue in relapsed/refractory multiple myeloma

Background: Elotuzumab is an immunostimulatory monoclonal antibody that targets SLAMF7, a glycoprotein highly expressed on multiple myeloma (MM) cells and natural killer cells. Elotuzumab exerts a dual effect, directly activating natural killer cells and mediating MM cell death via antibody-dependent cell-mediated cytotoxicity. In a 3-year follow-up of ELOQUENT-2 (NCT01239797), elotuzumab plus lenalidomide/dexamethasone (ELd) demonstrated a sustained 27% reduction in the risk of disease progression/death and an overall survival (OS) trend towards benefit compared with lenalidomide/dexamethasone (Ld) alone in patients with relapsed/refractory (RR) MM (Dimopoulos et al, ASH 2015).

Aims: To evaluate the long-term efficacy and safety of ELd following extended 4-year follow-up (median 46 months).

Methods: RRMM patients with 1-3 prior lines of therapy randomized 1:1 to receive ELd or Ld in 28-day cycles until disease progression/unacceptable toxicity or consent withdrawal. Co-primary endpoints were progression-free survival (PFS) and overall response rate (ORR); OS was a secondary endpoint (analysis not prespecified for this data cut) and safety an exploratory endpoint. Written informed consent was obtained for all patients.

Results: In total, 646 RRMM patients were randomized: 321 to ELd and 325 to Ld. At 4-year follow-up (data cut-off: Oct 18, 2016), nearly twice as many patients remained on ELd therapy vs Ld (17% vs 9%). With the extended follow-up, ELd demonstrated a sustained relative improvement of 50% in PFS rates vs Ld (21% vs 14%) and maintained reduction in the risk of progression/death of 29% for ELd vs Ld (all randomized patients: HR 0.71; 95% CI 0.58, 0.86). Patients with t(4;14) or t(14;16) had a greater benefit (35% vs 26% risk of progression/death (HR 0.65; 95% CI 0.46, 0.94). ORR was greater with ELd vs Ld (79% vs 66%) and the duration of response benefit was maintained over time (HR 0.77; 95% CI 0.62, 0.95). Early separation of the Kaplan–Meier survival curves, which remained consistently separated over time, supports a sustained OS benefit in favor of ELd vs Ld (Figure). Grade 3-4 adverse events in >5% of patients were generally comparable between ELd and Ld arms-vascular diseases (10% vs 8%; mostly venous-related), second primary malignancies (SPMs; 9% vs 6%) and cardiac disorders (5% vs 8%); the exception was a

Figure 1. OS Kaplan-Meyer Curve (all randomized patients).
S457

A PHASE IB STUDY OF ISATUXIMAB PLUS POMALIDOMIDE (POM) AND DEXAMETHASONE (DEX) IN RELAPSED/REFRACTORY MULTIPLE MYELOMA (RRMM): UPDATED EFFICACY AND SAFETY RESULTS FROM CASTOR, A MULTICENTER, RANDOMIZED, OPEN-LABEL, PHASE 3 STUDY OF ISATUXIMAB PLUS POMALIDOMIDE AND DEXAMETHASONE VERSUS BORTezomib AND DEXAMETHASONE (Vd) IN RELAPSED OR REFRACTORY MULTIPLE MYELOMA (RRMM) - UPDATED ANALYSIS OF CASTOR

1Universitätsklinikum Tübingen der Eberhard-Karls-Universität, Abteilung für Innere Medizin II, Tübingen, Germany, 2Division of Hematology/Oncology, Columbia University, New York, NY, United States, 3University Hospital of Salamanca/BASL, Salamanca, Spain, 4Unidade O Município de Lisboa, 5Mount Sinai Hospital, Toronto, ON, Canada, 6University of Texas MD Anderson Cancer Center, Houston, Texas, United States, 7University of Nantes, Nantes, France

Background: In a phase 3 head-to-head comparison of two proteasome inhibitors (Pis) in patients with relapsed or refractory multiple myeloma (RRMM), ENDEAVOR, progression-free survival (PFS) was shown to be significantly longer with carfilzomib and dexamethasone (Kd) than with bortezomib and dexamethasone (Vd) (median 18.7 months vs 11.4 months). ENDEAVOR, progression-free survival (PFS) was shown to be significantly longer with carfilzomib and dexamethasone (Kd) than with bortezomib and dexamethasone (Vd) (median 18.7 months vs 11.4 months). ENDEAVOR, progression-free survival (PFS) was shown to be significantly longer with carfilzomib and dexamethasone (Kd) than with bortezomib and dexamethasone (Vd) (median 18.7 months vs 11.4 months). ENDEAVOR, progression-free survival (PFS) was shown to be significantly longer with carfilzomib and dexamethasone (Kd) than with bortezomib and dexamethasone (Vd) (median 18.7 months vs 11.4 months).

Methods: Patients who had RRMM and who had received 1–3 prior lines of therapy were randomized in a 1:1 ratio to receive Kd or Vd. In the Kd arm, carfilzomib was given on days 1, 2, 8, 9, 15, and 16 (20mg/m² on days 1, 2, 8; 14mg/m² on days 9, 15, 16, 22, and 23 of 28-day cycles. The Vd arm, bortezomib (1.3mg/m²) was given intravenously or subcutaneously on days 1, 4, 8, and 11 and dexamethasone 20mg was given on days 1, 2, 4, 5, 8, 9, 11, and 12 of 28-day cycles. Patients were treated until progression or withdrawal of consent. OS was compared between treatment arms using a stratified log-rank test.

Results: The median treatment duration was 48 weeks for carfilzomib (N=464) and 27 weeks for bortezomib (N=445), with a median follow up of 38 months for Kd and 37 months for Vd. The median OS (95% CI) was 47.6 (42.5-NE) months in the Kd arm and 40.0 (32.6-42.3) months in the Vd arm, and all-cause mortality was significantly reduced with Kd vs Vd (HR, 0.791; 95% CI, 0.648-0.964; 1-sided p=0.0100). The overall survival benefit was consistent regardless of prior bortezomib therapy (HR 0.75 for Kd vs Vd, no prior bortezomib; HR 0.84 for Kd vs Vd, prior bortezomib) and across all age groups (HR, 0.85 <65 yr; 0.71, 65-74 yr; 0.84, 75+y); baseline ECOG performance status (HR, 0.61 [1], 0.68 [2], 0.81 [3], 0.91 [4]; cytogenetic risk groups (HR, 0.83, high risk; 0.85, standard risk), and number of prior lines of therapy (HR, 0.83, 1 prior line; 0.76, 2-3 prior lines). The most frequent any-grade adverse events in the Kd arm were (Kd vs Vd) anemia (42.5% vs 28.3%), diarrhea (36.3% vs 40.6%), pyrexia (32.4% vs 15.4%), dyspnea (32.2% vs 13.6%), fatigue (32.2% vs 30.7%), and hypertension (32.2% vs 9.9%). Grade 3 or higher adverse events were experienced by 81.4% of patients in the Kd arm and 71.1% of patients in the Vd arm.

Summary/Conclusions: ENDEAVOR was the first randomized phase 3 trial to directly compare two different Pis in RRMM. Patients who received Kd had significantly longer OS compared with patients who received Vd. Safety results were comparable with those previously reported in the PFS interim analysis for ENDEAVOR.
Results: A total of 498 patients were randomized with median (range) age of 64 (30-88) years. Patients received a median (range) of 2 (1-10) prior lines of therapy; 66% of patients previously received bortezomib, and 21% were refractory to lenalidomide in their last prior line of therapy. After median follow-up of 13.0 months, DVD significantly prolonged PFS compared with Vd alone (median: 7.1 months, DVD: 18.3% vs 3.6%). Twelve-month PFS rates were 60% versus 22%, respectively. Significant PFS benefit was observed with DVD over Vd regardless of the number of prior lines of therapy, although the greatest benefit was seen in patients with 1 prior line of therapy (median: not reached vs 7.9 months; HR, 0.22; 95% CI, 0.14-0.34; P<0.0001). Overall response rate (ORR; 84% vs 63%) and rates of very good partial response (VGPR) or better (62% vs 29%) and CR or better (26% vs 10%) continued to be significantly higher with DVD compared with Vd (P<0.0001 for all). MRD-negative rates were more than 4 times higher at all 3 sensitivity thresholds with DVD versus Vd: 18.3% versus 3.6% at 10−4 (P<0.0001), 10.4% versus 2.4% at 10−5 (P<0.01), and 4.4% versus 0.8% at 10−6 (P<0.01). MRD-negative patients had prolonged PFS compared with MRD-positive patients at 10−4 sensitivity threshold (Figure). At the clinical cut-off date, 37 (15%) deaths in the DVD group and 58 (24%) in the Vd group have been observed (HR, 0.63; 95% CI, 0.42-0.96), and follow up is ongoing. Thrombocytopenia was the most common grade 3 or 4 treatment-emergent adverse event (45% with DVD vs 33% with Vd). No new safety signals were reported after median treatment duration of 11 months with daratumumab. Updated efficacy and safety data with longer follow up will be presented at the meeting.

Figure 1.

Summary/Conclusions: DVD is superior to Vd in terms of PFS, ORR, depth of response, and MRD-negative rates, with no new safety signals reported. These updated data further support the use of DVD as a standard care in RRM.

Aims: The objectives of the study are to evaluate safety and preliminary efficacy of VEN with bortezomib and dexamethasone in relapsed/refractory (RR) MM.

Methods: Phase 1b study of patients (pts) with R/R MM who received daily VEN (50-1200mg) for dose escalation cohorts; 800mg in safety expansion with standard bortezomib (1.3mg/m2 SC) and dexamethasone (20mg PO).

Results: As of 19Aug2016, 86 pts were enrolled. Median age was 64 years; 9 (14%) pts had t(11;14), 5 (8%) had t(4;14), 15 (23%) had del(17p), and 30 (45%) had del(13q) abnormalities. Median number of prior therapies was 3 (range: 1-13), with 39% of pts refractory to prior bortezomib, 14% to carfilzomib, 53% to lenalidomide, and 21% to pomalidomide. Median time on study was 5.9 months (range: 0.3-29.8). Forty-six (70%) pts discontinued, with 36 due to disease progression (PD). Common AEs in ≥30% of pts were diarrhea (46%), constipation (41%), thrombocytopenia (39%), nausea (38%), peripheral neuropathy (33%), and insomnia (32%). Common grade 3/4 AEs in ≥10% of pts were thrombocytopenia (29%), anemia (15%) and neutropenia (14%). Serious AEs in ≥2 pts were febrile neutropenia, thrombocytopenia, cardiac failure, pyrexia, influenza, lower respiratory tract infection, pneumonia, sepsis, acute kidney injury, respiratory failure, embolism, and hypotension. Dose-limiting toxicities were grade 3 cardiac failure in the 300mg cohort (possibly related to dexamethasone) and grade 3 thrombocytopenia during the first cycle in the safety expansion. No events of laboratory or clinical TLS were reported. Four deaths were due to PD and 1 due to respiratory syncytial virus infection. Overall response rate (ORR) for all pts was 67% (44/66); 28 (42%) pts achieved very good partial response (VGPR) or better (3 stringent complete response [sCR], 10 CR, 15 VGPR). Pts non-refractory to prior proteasome inhibitors (PI) or immunomodulatory drugs (IMiDs) had higher ORR than refractory pts (PI, 92% vs 32%; IMiDs, 82% vs 57%). Among pts refractory to any 2 or more (n=15), 3 or more (n=7), or all 4 (n=4) prior therapies (bortezomib, carfilzomib, lenalidomide, pomalidomide), ORR was 40%, 43%, and 25%, respectively. Median time to progression (~10 vs 3 months) and duration of response (~10 vs 3 months) were longer for pts not refractory to any of these therapies versus refractory pts. ORR for pts with or without cytogenetic abnormalities, respectively, was as follows: 78% vs 65% for t(11;14), 60% vs 67% for t(4;14), 47% vs 73% for del(17p), and 63% vs 69% for del(13q).

Summary/Conclusions: VEN combined with bortezomib and dexamethasone has an acceptable safety profile with promising anti-myeloma activity, and the highest response rates were observed in R/R MM pts who were not refractory to PI or IMiDs. These data support the ongoing phase 3 trial with this regimen in R/R MM.
Improving prognosis and front-line therapy in chronic lymphocytic leukemia

Pontraja12, 13, Science for Life Laboratory, Uppsala University, Uppsala, Sweden, 14MLL Munich Leukemia Laboratory, Munich, Germany, 15Hematology Department and HCT Unit, G. Papanicolaou Hospital, Thessaloniki, Greece, 16Laboratori de Citogenètica Molecular, Servei de Patologia, Hospital del Mar, 17Grup de Recerca Transcacional en Neoplasies Hematològiques, Programa de Recerca en Càncer, Institut Hospital del Mar d’Investigacions Mèdiques (IMIM), Barcelona, Spain, 18Central European Institute of Technology (CEITEC), Masaryk University, 19Department of Internal Medicine - Hematology and Oncology, University Hospital Bruin Farmo and Medicine of Medicine, Masaryk University, Brno, Czech Republic, 20Institute of Applied Biosciences, Laboratory for Research and Technology Hellas, Thessaloniki, Greece, 21Secció d’Hematopatologia Hospital Clinic, Institut d’Investigacions Biomèdiques Augusti Pi y Sunyer (IDIBAPS), Universitat de Barcelona, 22Servei d’Hematologia, Hospital Vall d’Hebron, Barcelona, 23Servicio de Hematología, Consorcio Hospital General Universitario, Valencia, 24Servicio de Citogenética, Departamento de Genética, Universidad de Navarra, Pamplona, 25Servei Laboratori Hematologia, ICO-Hospital Germans Trias i Pujol, Institut de Recerca Contra la Leucèmia Josep Carreras (IJC), Universitat Autònoma de Barcelona, Badalona, 26Servei d’Hematologia, Hospital Universitari de la Santa Creu i Sant Pau, Barcelona, Spain, 27Department of Hematology, Academic Medical Center Amsterdam, University of Amsterdam, Amsterdam, Netherlands, 28Universita Vita-Salute San Raffaele, 17Strategic Research Program in CLL, Division of Experimental Oncology, IRCCS San Raffaele Scientific Institute, Milan, Italy

Background: Recent evidence suggests that complex karyotype (CK) identified by chromosome banding analysis (CBA) may be a relevant biomarker for treatment decisions in CLL, especially regarding the response to signaling inhibitors. However, many challenges towards routine clinical application of CBA still need to be overcome.

Aims: Reappraisal of definitions for CK in CLL and systematic investigation of clinicobiological associations and prognostic impact.

Methods: 3580 CLL and monoclonal B-cell lymphocytosis (MBL) patients (CLL=3322, 93% and MBL=258, 7%, respectively) were analysed with Cpg-G-oligodeoxynucleotides/interleukin 2 (CpG/IL2, n=379, 11%), phorbol-12-myristateacetate (TPA, n=1846, 52%) or both (n=1355, 37%). CBA was mostly performed within the first year from diagnosis and before treatment administration (79% and 88%, respectively). Main features of the studied cohort: median age: 65.6 years/ males: 2252 (63%), Binet A/B/C: 2356/357/258, TTP53: 829/2051 (40%)/del(13q), 1769/3271 (54%)/ trisomy 12, 507/3260, (79% and 57%, respectively). The median OS was 5.1 years for the high-CK cases versus (median: 8.75 years for the low-CK' cases (p<0.0001). We also identified 46 cases (12% of those with ≥3 aberrations) who carried +12,+19 plus other numerical and/or structural abnormalities and displayed extremely indolent clinical course (median OS not yet reached and only 4 deaths at a median follow-up of 5.2 years). When high-CK was assessed as an independent parameter, it was correlated with inferior OS in the univariate analysis, retaining significance also in the multivariate analysis (p=0.012) independently of the remaining parameters, including clinical stage, U-CLL and TP53 status. In contrast, low/intermediate-CK had no impact on OS, not even in univariate analysis (p=0.57).

Summary/Conclusions: CK defined by the presence of ≥3 numerical and/or structural abnormalities should not be axiomatically considered unfavorable in CLL, representing a heterogeneous group with variable clinical behavior. High-CK with ≥5 chromosomal aberrations emerges as prognostically adverse, independently of clinical stage, IG somatic hypermutation and TP53 status. Prospective clinical validation is warranted before finally incorporating high-CK in risk stratification in CLL.

IS THE TREATMENT OF CHOICE FOR IGHV MUTATED CLL WITHOUT POOR FISH CYTOGENETICS?

C. Cuéllar-García1, 2, M. Mattsson2, P. Balliakas3, L. Scarfo4, E. Puy Vicente5, P. Ghiatti5, R. Rosenquist7, C. Moreno16

1Department of Hematology, Hospital Santa Creu i Sant Pau, Barcelona, Spain, 2Hematology, Uppsala University Hospital, 3Department of Immunology, Genetics and Pathology, Science for Life Laboratory, Uppsala, Sweden, 4IRCCS Istituto Scientifico San Raffaele, Milano, Italy, 5Hematology, Hospital Santa Creu i Sant Pau, Barcelona, Spain, 6Universita Vita-Salute San Raffaele, IRCCS Istituto Scientifico San Raffaele, Milano, Italy, 7Science for Life Laboratory, Uppsala University Hospital, Uppsala, Sweden

Background: Chemoimmunotherapy (CIT) is the standard treatment for young and fit treatment-naive patients with CLL. The median progression-free-survival (PFS) in patients treated with CIT is about 5-6 years and the overall survival (OS) is increased by 5-10% compared to those treated with chemotherapy only. Patients with mutated IGHV genes (M-CLL) and/or poor FISH cytogenetics (i.e. del(17p)) show a better outcome than those with unmutated IGHV genes (U-CLL), and/or poor FISH cytogenetics and display a plateau in survival curves, suggesting that a fraction of these patients may have a survival similar to general population. Nevertheless, the possibility that some M-CLL patients without unfavorable cytogenetics are overtreated is of concern because of the treatment toxicity related to CIT, par-ticularly FCR.

Aims: The aim of this study was to analyse the outcome of M-CLL patients with unfavorable cytogenetics according to the type of therapy.

Methods: We analysed 816 CLL patients from Sant Pau Hospital, Barcelona, Spain; Uppsala University Hospital, Sweden and IRCCS San Raffaele Scientific University, Milan, Italy for whom IGHV mutational status was available. Endpoints were OS and TFS.

Table 1.

Results: 488 patients had mutated IGHV genes (400 without unfavorable FISH cytogenetics; 28 had either del(11q) and/or del(17p), and in 62 cases FISH was not available) and 328 patients carried unmutated IGHV genes. The main clinical and biological characteristics at diagnosis are shown in Table 1. OS at 5 and 10 years was 93% (CI, 95-91) and 81% (CI, 85-77) for M-CLL cases and 78% (CI, 83-73) and 64% (CI, 58-70) for U-CLL cases (p<0.05). TFS at 5 and 10 years was 73% (CI, 70-76) and 53% (CI, 48-58) and 61% (CI, 56-66) and 28% (CI, 23-33) and 10% (CI, 14-6) for M-CLL and U-CLL, respectively (p<0.05). After a median follow-up of 8 years (range, 1-26), 424 patients [161 M-CLL (136 without poor-prognostic FISH cytogenetics, 13 with either del(11q) and/or del(17p) and 12 cases in whom FISH information was not available] and 263 U-CLL required therapy. Front-line treatments consisted of purine analogues (PA)-based therapy (n=83), alkylating agents (n=212), anti-CD20 moAbs with PA or bendamustine (n=75), anti-CD20 moAbs with alkylating agents (n=21), BCR-signal inhibitors or BCL2 antiapoptotic agents (n=9), others (n=23), and unknown (n=1).

IBRUTINIB, FLUDARABINE, CYCLOPHOSPHAMIDE, AND OBINUTUZUMAB (GA101) FOR PREVIOUSLY UNTREATED PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) WITH MUTATED IGHV AND NON-DEL(17P)

A. Ferrajoli1, V. Gandhi2, W. Plunkett2, W. Lopez1, H. Kantarjian1, S. O’Brien3, M. Keating1, W. Wierda1
1Leukemia, 2Experimental Therapeutics, MD Anderson Cancer Center, Houston, TX, 3Hematology-Oncology, UC Irvine, Irvine, United States

Background: Patients with mutated IGHV (IGHV-M) have favorable long-term outcomes (10-year PFS of >90%) after receiving first-line FC. Aims: To develop an FC-based chemoimmunotherapy regimen of finite duration that included ibritinib and obinutuzumab. The intent was to limit FC to 3 courses, potentially reducing short- and long-term toxicity, while maintaining efficacy through the addition of ibritinib and a more potent antibody (obinutuzumab).

Methods: We designed an investigator-initiated phase II trial with ibritinib, fludarabine, cyclophosphamide, and obinutuzumab (iFCG) for previously untreated CLL pts. The intent was to limit FC to 3 courses, potentially reducing short- and long-term toxicity, while maintaining efficacy through addition of ibritinib and obinutuzumab. Key eligibility included age ≥18, IGHV-M, and no comorbidities. Patients were randomized to receive 2 cycles of iFCG followed by 1 cycle of maintenance therapy, with ibritinib continued for a total of 5 cycles. Patients were evaluated for response at the end of each cycle and for MRD negativity at the end of induction.

Results: A total of 23 patients were enrolled from 10 centers. The median age was 59 years (range, 25-71); there were 18 men. Three patients were ineligible, leaving 20 evaluable patients. 15 patients had received prior therapy. At the end of induction, 14/20 achieved CR/CRi with MRD-negative status. 14/18 achieved MRD-negative remission in the marrow as assessed by next generation sequencing (NGS). 14/18 achieved MRD-negative remission in the marrow and 16/18 achieved MRD-negative remission in peripheral blood. Overall, 7/18 achieved CR/CRi with MRD-negative status in the marrow and 16/18 achieved MRD-negative remission in the marrow as assessed by NGS.

Summary/Conclusions: IFCG achieves high rate of MRD-neg remission after 3 courses. Pt enrollment continues, and updated results will be presented at the EHA meeting.

BENDAMUSTINE (B), FOLLOWED BY OBINUTUZUMAB (G, GA101) AND VENETOLACX (A, ABT-199) IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA (CLL): CLL2-BAG PHASE-II TRIAL OF THE GERMAN CLL STUDY GROUP (GCLLSG)

1Department I of Internal Medicine and German CLL Study Group, University Hospital Cologne, Cologne, 2Department II of Internal Medicine, University Hospital Cologne, Cologne, 3Department of Internal Medicine, University Hospital Munich, Munich, 4Department of Experimental Immunology, Ludwig-Maximilians University, Munich, 5Department of Radiology, University Hospital Cologne, Cologne, 6Department of Internal Medicine, University Hospital Munich, Munich

Background: Based on the theoretical "sequential triple-T" concept [Hallek M., Blood 2013; 122(23): 3723-34] of a tailored and targeted treatment aiming for total eradication of minimal residual disease (MRD), the GCLLSG designed the CLL2-BAG trial.

Aims: This prospective, open-label, multicenter phase-II trial investigates a sequential treatment with a B debulking, followed by G and A as induction and maintenance therapy in an all-comer population of physically fit and unfit, treatment-naive (TN) and relapsed/refractory (R/R) CLL pts.

Methods: Pts with an absolute lymphocyte count (ALC) ≥25.000/µl and/or lymph node (LN) ≥5cm were to receive 2 cycles of B as debulking (70mg/m2 d1&2 q28 days), then ibritinib 420mg qd from cycle 3. The remaining 18 pts then received G and A as induction and maintenance therapy, with ibritinib continued for a total of 5 cycles. The primary endpoint is the overall response rate (ORR) at the end of induction therapy; secondary endpoints include MRD evaluations, safety and survival parameters. This primary endpoint analysis is based on uncleaned data, the final analysis will be presented at the meeting.

Results: Between May 2015 and January 2016, 66 pts were enrolled. Two R/R pts died of a sepsis and 1 TN pt discontinued due to toxicity during the first induction cycle; these 3 pts with <2 induction cycles were excluded from the analysis as predefined by protocol. 34 pts were treatment-naive and 29 had R/R CLL (median number of prior therapies: 2, range: 1-8). Median age was 59 (28-77) years, the median CIRS score was 2 (0-14) and 16 pts (25%) had a history of heart failure, 12 pts (18%) had a history of diabetes mellitus, and 14 pts (21%) had a history of chronic obstructive pulmonary disease. 13 pts (20%) had a history of hypertension, 1 pt had a history of myocardial infarction, and 1 pt had a history of stroke.

Summary/Conclusions: BAG achieves high rate of MRD-neg remission after 3 courses. Pt enrollment continues, and updated results will be presented at the EHA meeting.
ed (table 1); with an ORR of 97%, at the end of induction, the primary endpoint was met. MRD negativity (<10−5) by flow cytometry in peripheral blood (PB) was achieved in 56 pts (89%); MRD assessment from bone marrow was available in 8 pts (4 TN and 4 R/R, among them 4 with a CR and 4 with a PR) and was all negative. As of January 9th 2017, 83 serious adverse events (SAEs) were reported in 37 pts, including 69 SAEs (83%) related to study treatment. 66 pts (45%) were GCT3-4 and 1 had a fatal grade 5 outcome (sepsis in 4th induction cycle). Most SAEs occurred in the R/R cohort (61 SAEs, 74%) and during the induction phase (63 SAEs, 76%). Most common SAEs were infections (27 in 16 pts; including 13 CTC°3-5) and hematological disorders (18 in 10 pts; CTC°3-4), followed by infusion-related reactions (6 in 6 pts), laboratory TLS (5 in 5 pts. during debulking), 1 in induction cycle 1 with G 2 in cycle 3 and 1 in cycle 4 with G and A) and ischemic coronary artery disorders (5 in 4 pts). No clinical TLS occurred.

Summary/Conclusions: With an ORR of 97% and a MRD negativity of 89% at the end of induction, this front-line treatment for B debulking, followed by G and A was very efficacious in a heterogeneous study population and well tolerated except for 3 fatal septicamae in R/R pts.

Background: IDELA is an oral PI3Kδ inhibitor approved in the EU for use with rituximab (R) or ofatumumab in patients (pts) with previously treated CLL. IDELA is currently under investigation as a single agent for relapsed (R) or with either del(17p) or del(11q) and is unsuitable for other therapeutics. Prior single arm studies have suggested that front line use of IDELA may be associated with an increased frequency of transaminase elevations compared to relapsed pts.

Aims: To describe: 1) the safety of IDELA plus rituximab in previously untreated CLL pts with del(17p) in this terminated study, and 2) the relation of key AEs and age.

Methods: Treatment-naive pts with CLL and confirmed del(17p) were treated in a single arm study with R 375mg/m2 IV weekly x 8 and IDELA 150mg PO BID continuously until disease progression or intolerability. Informed consent was obtained prior to study entry. The study was fully enrolled when terminated early due to infection related safety concerns observed in a pooled analysis of ongoing Phase 3 IDELA trials in front line/early line therapy; the planned independent efficacy analysis was not performed, but investigator assessment is available.

Results: 102 pts (median age, 66; range, 37-86) were enrolled between Aug 2015 and Jan 2016; 101 pts received IDELA R for a median (med) duration of 6.4 months (range, 0.7-17.0). The study was terminated in Mar 2016, <8 wks after dosing of the last enrolled pt. 77 pts (75.5%) remained on study at the time of study closure. The reasons for discontinuation from study were death (4.9%), study drug (4.9%), investigator discretion (4.9%), investigator withdrawal of consent (2.9%), other anticancer therapy (2.0%), and lost to follow up (1.0%). The investigator assessed response rate was 79%. 101 pts (99%) had adverse events (AEs); Gr ≥3 occurred in 80.4%, the most frequent Gr ≥3 AEs were ALT increased (27.5%), neutropenia (20.6%), infections (18.6%), and diarrhea (14.7%). Laboratory Gr ≥3 ALT and/or AST elevations were seen in 41.2%, with med time of onset of 8.1 wks (range 4.1-24.7). The med age of pts both with and without Gr ≥3 ALT/AST was 66 years, and the incidence of Gr ≥3 ALT/AST was similar in younger (43.9%, <65yr) and older (39.3%, ≥65yr) pts. Gr ≥3 diarrhea/coilits occurred in 17.1% of pts <65yr and in 14.5% of pts ≥65yr. Gr ≥3 AEs occurred in 37.7% (70%), most frequently due to transamnase elevations (37.3%), and diarrhea/coilits (15.7%). Discontinuation due to AEs occurred in 27% of pts, most frequently due to ALT/AST elevation (9.8%). Severe serious adverse events were reported in 46 (45.1%), including pyrexia (10.8%), diarrhea (11.8%). AEs of special interest included Gr ≥3 CMV reactivation (10%) of which 3 were CMV PJP and 3 had PJP (presumably on prophylaxis), Gr ≥3 febrile neutropenia in 5 (4.9%) and any grade pneumonitis in 5 (4.9%). Of the 5 pts with CMV, all were CMV IgG+ at screening on prophylaxis, Gr ≥3 febrile neutropenia in 5 (4.9%) and any grade pneumonitis in 5 (4.9%). Of the 5 pts with CMV, all were CMV IgG+ at screening on prophylaxis and 2 also were IgM+. There were 6 on-study deaths, 3 associated with infective causes and 1 due to distant heart failure.

Summary/Conclusions: In IDELA plus rituximab treated front-line CLL, the pattern of AEs was similar to that seen in relapsed CLL studies at similar duration of therapy, however the frequency of Gr ≥3 ALT/AST was increased compared to the relapsed setting. There was no significant effect of age on the risk of either ALT/AST elevations or diarrhea/coilits. The occurrence of CMV and PJP infections is consistent with current IDELA labeling and speaks to the potential benefit of risk mitigation through PJP prophylaxis and CMV monitoring during treatment. NCT02044822.
Lymphoma Phase III Consortium, Amsterdam, Netherland. 5Azienda Ospedaliera Universitaria Città della Salute e della Scienza di Torino, Torino, Italy. 6Academic Medical Center, Amsterdam, Netherland. 7Institute of Hematology “Serafogni,” University of Bologna, Bologna, Italy. 8Celgene Institute for Translational Research Europe, Seville, Spain. 9Celgene Corporation, San Francisco, CA. 10Celgene Corporation, Berkeley Heights, NJ, United States

Background: CC-122 is a cereblon modulating agent that degrades Aiolos and Ikaros, resulting in potent anti-lymphoma and immunomodulatory effects on T- and NK-cell function. Phase I clinical data revealed promising activity of CC-122 against follicular lymphoma (FL) and diffuse large B-cell lymphoma (DLBCL). Preclinical combination of CC-122 with obinutuzumab has shown synergy in FL and additive effects in DLBCL vs either single agent (Chiu. ASH 2015), supporting further study of this combination’s therapeutic potential.

Aims: The current phase Ib study (EUDRACT 2014-003333-26; NCT02417285) evaluated the safety and efficacy of CC-122 with obinutuzumab in patients with relapsed or refractory (R/R) B-cell non-Hodgkin lymphoma (NHL).

Methods: Patients at study entry must have R/R CD20+ B-cell NHL after ≥1 prior regimens for FL/marginal zone lymphoma (MZhL) ≥2 regimens and/or ASCT for DLBCL. CC-122 was given orally (5 of 7) for 28-d cycles in escalating doses plus a fixed dose of intravenous obinutuzumab 1000mg on d2, 8, 15 of cycle (c1) and d1 of c2-c9, upon informed consent. CC-122 was continued until progressive disease (PD) or unacceptable toxicity. CC-122 active ingredient in capsule formulation (AIC) 1, 2, 3, 4 mg and CC-122 formulated capsules (F6) 3 and 4 mg were evaluated in separate cohorts. Primary endpoints included safety and tolerability, non-tolerated dose (NTD), and maximum tolerated dose (MTD). Response was assessed using the international Cheson 2007 criteria every 2 cycles to c6, every 3 cycles to c12, and every 6 cycles thereafter.

Results: As of January 12, 2017, 34 R/R B-cell NHL patients with DLBCL (n=19), FL (n=15), or MZhL (n=1) were enrolled. At study entry, median age was 60 y (26-81); most patients were male (68%), and Ann Arbor was extended stage III/IV in 76% of patients. Of the 18 DLBCL patients, 8 had transformed FL. Of the 16 FL/MZhL patients, 44% relapsed in <12 months after first-line treatment. The median number of prior regimens was 4 (range, 1-11), and 13 (38%) patients had received prior SCT. One patient experienced a dose-limiting toxicity (DLT) of grade 4 neutropenia (CC-122 dose level of AIC 3mg); no dose was yet an NTD. Median CC-122 duration was 22 wks (range, 3-71) equivalent to stage III/IV in 76% of patients. Of the 18 DLBCL patients, 8 had transformed FL. Of the 16 FL/MZhL patients, 44% relapsed in <12 months after first-line treatment. The median number of prior regimens was 4 (range, 1-11), and 13 (38%) patients had received prior SCT. One patient experienced a dose-limiting toxicity (DLT) of grade 4 neutropenia (CC-122 dose level of AIC 3mg); no dose was yet an NTD. Median CC-122 duration was 22 wks (range, 3-71) equivalent to 6 cycles (range, 1-18). CC-122 dose reduction or temporary interruption occurred in 10 (29%) or 26 (76%) of patients, respectively, primarily due to adverse events (AEs). Most patients (96%) had >1 wk of interruption due to AEs. The most common ≥10% grade 3/4 treatment-emergent AEs (TEAEs) were neutropenia (50%) and thrombocytopenia (21%). Fifteen patients (44%) had ≥1 serious TEAE, including 2 each of febrile neutropenia (related to CC-122), cytokine release syndrome (related to obinutuzumab), and pneumonia. Three deaths occurred during the study (2 PD; 1 AE). Overall response rate (ORR) was 59%, including 26% CR and 32% PR (Table 1). Median time to best response was 57 d, and median duration of response was not yet reached. In evaluable patients, 6-mo progression-free survival (PFS) was 63%.

Table 1.

Summary/Conclusions: The combination of CC-122 and obinutuzumab was well tolerated and demonstrates promising response rates and durable remissions in R/R patients with B-cell NHL. CC-122 doses of ≥3 mg and obinutuzumab (1000 mg) every 28 days (FL) or 21 days (DLBCL) for 6 cycles.

S468

POLATUZUMAB VEDOTIN PLUS BENDAMUSTINE AND RITUXIMAB OR OBINUTUZUMAB IN RELAPSED/REFRACTORY FOLLICULAR LYMPHOMA OR DIFFUSE LARGE B-CELL LYMPHOMA: UPDATED RESULTS OF A PHASE II STUDY

1Memorial Sloan Kettering Cancer Center, New York. 2City of Hope, Duarte, University of Colorado, Denver. 3Department of Medicine, University of Birmingham, Birmingham, United States. 4Veteran Affairs Medical Center, Birmingham, United States. 5Jewish General Hospital, 6Department of Hematology, Maisonneuve-Rosemont Hospital and University of Montreal, Montreal, Canada. 7Seoul National University Hospital, 8Samsung Medical Center, Seoul, Korea, Republic Of. 9Hospital Universitari Vall d’Hebron, Barcelona, Spain. 10Manchester Academic Health Science Centre, The University of Manchester and the Christie NHS Foundation Trust, Manchester, United Kingdom. 11Winship Cancer Institute of Emory University, Atlanta, United States. 12Roche, Shanghai, China. 13Genentech, Inc., South San Francisco, United States. 14BC Cancer Agency, Vancouver, Canada

Background: Transplant ineligible patients (pts) with relapsed/refractory (R/R) FL or DLBCL have poor outcomes. Polatuzumab vedotin (pola) is an antibody drug conjugate that targets delivery of the microtubule inhibitor MMAE to cells expressing CD79b. Pola + rituximab (R) previously showed promising responses in R/R FL and DLBCL. A Phase Ib study to escalate pola to any substituting obinutuzumab (G) for R could improve outcomes. We report updated results from the Phase 1b/2 (P1b/2) study evaluating pola + BR or BG in R/R FL and DLBCL and the expansion cohorts evaluating pola + BG in R/R FL and DLBCL.

Methods: All pts provided informed consent to participate in the study and were treated with pola (1.5mg/kg) + B (90mg/m2) and R (375mg/m2) or G (1000mg) every 28 days (FL) or 21 days (DLBCL) for 6 cycles. Responses were assessed by modified Lugano criteria after 3 cycles, end of treatment (tx), and every 6 months for 2 years during follow-up (fu).

Results: As of 14 Nov 2016, 65 pts were enrolled: 24 pts (12 FL, 12 DLBCL) in P1b and 41 pts (20 FL and 21 DLBCL) in P2. In safety evaluable pts, FL pts (N=32) were median age 63 yr (37-86), 82% ECOG 0-1 and 6% ECOG 2, 44% FLIPI1 3-5, 78% Stage III/IV, 2 (1-7) median lines of prior tx, 38% refractory to last tx, 3% prior transplant. Among 44% FL pts who received ≥1 dose, the adverse events (AEs) that occurred in ≥20% of pts were: fatigue (67%), nausea (54%), diarrhea (45%), vomiting (42%), pyrexia (39%) and constipation (39%). As expected, grade (Gr) 3/4 cytophenias were common: neutropenia (34% FL, 28% DLBCL), thrombocytopenia (16% FL, 13% DLBCL). AEs leading to study interruption in 1 pt in 1 pt. In FL, 5% (24/32) had Gr 3/4 AEs and 41% (13/32) had serious AEs (SAEs). The only SAE occurring in ≥10% was infection (22%). The most common Gr 3/4 non-heme AEs were infection (16%) and neutropenia (9%); AEs led to study interruption in 8 pts. In DLBCL, 88% (28/32) had Gr 3/4 AEs and 63% (20/32) had SAEs. Most common Gr 3/4 non-heme AEs were febrile neutropenia (13%), fatigue (10%), and diarrhea (13%). SAEs occurring in ≥10% of pts were infection (33%) and pyrexia (22%). AEs led to study interruption in 19 pts and discontinuation in 8 pts. There were 13 deaths: 9 PD, 4 AE (all unrelated to tx). Responses by modified Lugano 2014 criteria are shown in Table1. Median duration of response (DoR) for FL P1b pts was 16 months (mo) (median fu 14.5 mo). Median DoR for FL P2 (median fu 6.5 mo) and DLBCL P1b/2 (median fu 13.7 mo P1b, 6.4 mo P2) have not been reached.

Table 1.

Summary/Conclusions: Updated evaluation of pola + BR shows promising durable responses and an acceptable safety profile in heavily pre-treated R/R FL and DLBCL pts. Safety and efficacy data will be updated at the time of presentation.

S469

SINGLE AGENT ORAL SELINEXOR EXHIBITS DURABLE RESPONSES IN RELAPSED/REFRACTORY DSqćiukCG B-CELL Lymphoma (DLBCL) OF BOTH GCB AND NON-GCB SUBTYPES: THE PHASE 2B SADAL STUDY

M. Maerovec15, J. Westin2, C. Thieblemont3, J. Zijlstra4, B.T. Hill5

15Heidelberg University Hospital, Heidelberg, Germany
Background: Patients (pts) with persistent DLBCL after two or more lines of therapy have limited effective treatment options. The nucleolar export protein exportin 1 (XPO1) is upregulated in hematologic malignancies, including DLBCL, and has pleiotropic effects on tumorogenesis including functional downregulation of tumor suppressor proteins (TSPs) and increased export and translation of mRNAs for oncoproteins c-Myc and key survival proteins such as Bcl-2. Selinexor (SEL), an oral XPO1 inhibitor, causes sequestration of TSPs including p53, p21, and IκBα, the latter of which serves to suppress NF-κB transcription, along with reductions in c-Myc and Bcl-2 family proteins. In a Phase I clinical study, pts with relapsed/refractory (R/R) DLBCL treated with SEL monotherapy showed activity in pts with R/R DLBCL after ≥2 prior regimens. Methods: Pts with R/R DLBCL were randomized to 60 or 100mg of SEL twice weekly (8 doses) per 28-day cycle. Pts were stratified by DLBCL subtype (GCB or non-GCB). The primary objectives are to determine the ORR and evaluate the safety of 60 vs 100mg doses. Disease response was assessed by an Independent Central Radiological Review (ICRR), using the Lugano Classification (Cheson, 2014). Results: 72 pts were enrolled: 37 pts on 60mg (24 M/ 13 F, median age 71 yrs) and 35 pts on 100mg (23 M/ 12 F, median age 68 yrs). Both groups had a median of 3 prior treatment regimens. The most common related adverse effects (AEs) were fatigue (47%), nausea (46%), anorexia (42%), and vomiting (33%). Common Grade 3/4 AEs were: thrombocytopenia (39%), fatigue (18%), neutropenia (18%), and anemia (13%). These were managed with dose interruption/reduction, platelet stimulators, and/or standard supportive care. Grade 3/4 fatigue (26% v 11%) and thromboctopenia (48% v 32%) were higher in the 100mg arm as compared to the 60mg arm. Among the 63 evaluable pts (9 pts pending response), the ICRR determined ORR was 28.5% (Table 1). Nine responders, including 6 pts in CR, remain on treatment. Responders on the 60mg arm have a median time on treatment of 8.9 months as compared with 3.8 months on the 100mg arm. Summary/Conclusions: SEL monotherapy shows activity in pts with R/R DLBCL including in pts with GCB subtype. 60mg SEL twice weekly was more tolerable than 100mg twice weekly, with fewer interruptions due to toxicity. Objective responses to SEL were durable at 60mg BIW, suggesting these responses were associated with clinical benefit.

L-MIND: MOR208 COMBINED WITH LENALIDOMIDE (LEN) IN PATIENTS WITH RELAPSED OR REFRACTORY DIFFUSE LARGE B-CELL LYMPHOMA (R-R DLBCL)—A SINGLE-ARM PHASE II STUDY

1Institute Jules Bordet, Brussels, Belgium, 2MD Anderson, Houston, United States, 3APHP, Hemato-Oncology, Hospital Saint-Louis, Paris, France, 4Lunenburg University Hospital, Lunenburg, University Medical Center, Amsterdam, Netherlands, 5Tauscig Cancer Institute, Cleveland Clinic, Cleveland, United States, 6Hospital University Virgen del Rocio, Sevilla, Spain, 7Hospital Pitie Salpetriere, Paris, France, 8University Hospital Seidman Cancer Center, Cleveland, United States, 9Feinberg School of Medicine, Northwestern University, Chicago, United States, 10Hospital Universitario La Paz, Madrid, Spain, 11Princess Margaret Hospital, Toronto, Canada, 12NHS Foundation Trust, Cambridge University Teaching Hospitals, Cambridge, United Kingdom, 13Cliniques Universitaires UCL Saint-Luc, Brussels, Belgium, 14Karyopharm Therapeutics, Newton, United States, 15CHU Dijon, Dijon, France

Background: The Fc-enhanced CD19 antibody MOR208 and the immunomodulatory drug LEN have demonstrated single agent activity in patients with R-R DLBCL. MOR208 and LEN have shown synergy in vitro and in vivo in preclinical lymphoma models.

Aims: This ongoing phase II study was designed to assess the safety and efficacy of MOR208 plus LEN in patients with R-R DLBCL.

Methods: Patients >18 years of age with R-R DLBCL, ECOG performance status 0–2, adequate organ function, having previously received at least 1 but not more than 3 prior therapies, including at least 1 CD20-targeting regimen and who are not candidates for autologous stem cell transplant (ASCT), are eligible. Treatment comprises up to 12, 28-day cycles of MOR208 12mg/kg IV, administered weekly during cycles 1-3 (loading dose day 4 of cycle 1) and every second week during cycles 4-12 plus LEN 25mg administered po days 1-21 of each cycle. Patients progression-free after 12 cycles receive up to 12 additional cycles of MOR208 12mg/kg IV, administered every second week. The primary endpoint is the overall response rate (ORR) by central radiology assessment. Secondary endpoints include disease control, duration of response, progression-free and overall survival, safety, and response by cell of origin and other biomarkers. A preplanned safety evaluation was undertaken.

Results: 31 of 80 planned patients were enrolled prior to data cutoff (3 January 2017). Median age was 74 years (range 47–82); 45% of patients received ≥2 prior lines of therapy; 23% had rituximab refractory disease; 74% had Ann Arbor stage III disease; 65% had elevated lactate dehydrogenase level, and 52% had a poor revised International Prognostic Index (3–5). The most common treatment-emergent adverse events (any grade/grade ≥3 [% patients]) were neutropenia (39/26), anemia (23/0) thrombocytopenia (16/6), infections (26/10) diarrhea (13/0), pyrexia (13/0), and rashes (13/6). Of 26 response evaluable patients (median follow-up 3.3 months), ORR (investigator assessed) was 58% (15 patients), with 7 (27%) complete responses. Median time to response was 1.8 months.

Summary/Conclusions: The combination of MOR208 plus LEN is well tolerated and shows promising activity in patients with R-R DLBCL. Accrual and follow-up of patients is ongoing, as are cell of origin and other biomarker analyses.
ENASIDENIB (AG-221) IN MUTANT-IDH2 RELAPSED OR REFRACTORY ACUTE MYELOID LEUKEMIA (R/R AML): RESULTS OF A PHASE 1 DOSE-ESCALATION AND EXPANSION STUDY

1Memorial Sloan Kettering Cancer Center, 2Well Cornell Medical College, New York, 3The University of Texas MD Anderson Cancer Center, Houston, 4University of Colorado School of Medicine, Aurora, 5Massachusetts General Hospital Cancer Center, 6Harvard Medical School, Boston, 7New York Presbyterian Hospital, New York, 8Robert H. Lurie Comprehensive Cancer Center, Northwestern University Feinberg School of Medicine, Chicago, 9Dana-Farber Cancer Institute, Boston, 10Sarah Cannon Research Institute, Nashville, 11University of Texas Southwest Medical Center, Dallas, 12Florida Cancer Specialists and Sarah Cannon Research Institute, Sarasota, 13City of Hope Comprehensive Cancer Center, Duarte, 14Cleveland Clinic Taussig Cancer Institute, Cleveland, 15Sylvester Comprehensive Cancer Center, University of Miami, Miami, 16Stanford Comprehensive Cancer Center, Stanford University, Stanford, 17Celgene Corporation, Summit, 18Agios Pharmaceuticals, Inc., Cambridge, United States, 19Institut Gustave Roussy, Villejuif, France

Background: Recurrent mutations in isocitrate dehydrogenase 2 (mIDH2) occur in ~12% of AML patients (pts), mIDH2 proteins synthesize an oncometabolite, 2-hydroxyglutarate (2HG), causing DNA and histone hypermethylation and blocked myeloid differentiation. Enasidenib (AG-221) is an oral, selective, small-molecule inhibitor of mIDH2 proteins. Differentiation of myeloblasts, not cytotoxicity, appears to drive the clinical efficacy of enasidenib. In preclinical studies, bone marrow blasts from pts with mIDH2 exposed to enasidenib ex vivo were shown to produce mature, fully functioning neutrophils with conserved mIDH2 allele frequency, indicating differentiation of mature cells from the mIDH2 blasts (Yen et al, Cancer Discov, 2017). Additionally, no apoptosis was observed in mIDH2-R1402h erythroleukemia (TF-1) cells treated with enasidenib for 7 days in vitro.

Aims: Evaluate the maximum tolerated dose (MTD), pharmacokinetic (PK) and pharmacodynamic (PD) profiles, safety, and clinical activity of enasidenib in pts with mIDH2 advanced myeloid malignancies.

Methods: This phase 1/2 study included pts aged ≥18 years (yrs) with mIDH2 WHO-defined AML, or with mIDH2 MDS with refractory anemia with excess blasts, and ECOG PS scores ≤2. Pts were relapsed or refractory (R/R) to prior anti-cancer therapy, or had untreated AML if aged ≥60 years and not eligible for standard-of-care treatment (Tx). Safety for all pts and clinical efficacy in the largest pt subgroup, those with R/R AML, from the phase 1 dose-escalation and expansion phases are reported.

Results: In all, 239 pts received enasidenib. Median age was 70 yrs. In the dose-escalation phase (n=113), pts received daily enasidenib doses of 50-650mg. The MTD was not reached. Median 2HG reductions from baseline at cycle 2 day 1 were 92%, 90%, and 93% for pts receiving <100mg, 100mg, and >100mg/day, respectively. Enasidenib 100mg QD was chosen for the expansion phase (n=126) based on PK/PD profiles and demonstrated efficacy. Median number of enasidenib cycles was 5 (range 1-25). Grade 3-4 investigational Tx-related adverse events included indirect hyperbilirubinemia (12%) and IDH-inhibitor-associated differentiation syndrome (IDH-DS; ie, retinoic acid syndrome) (7%). Of 176 R/R AML pts, 94 (53%) had received ≥2 prior AML-directed Tx. Overall response rate (ORR; complete remission [CR] + CR with incomplete remission — myeloid- and megakaryocytic-fusion — or complete remission with incomplete blood count recovery in R/R AML pts was 40.3%, including 34 pts (19.3%) who attained CR (Table). Median time to 1st response was 1.9 months (mos); 87.3% of responding pts attained a 1st response by cycle 5. Median response duration was 5.8 mos. Of pts who achieved CR, 7 pts (21%) did so by cycle 3, 23 (88%) by cycle 5, and 29 (82%) by cycle 7. Median duration of CR was 8.8 mos. ORR with enasidenib 100mg/day was 38.5% (Table). Seventeen pts (11%) proceeded to stem cell transplant. Response was associated with cellular differentiation, typically with no evidence of aplasia. Median overall survival (OS) of R/R AML pts was 9.3 mos. For pts who attained CR, OS was 19.7 mos. Pts who had received ≥2 prior AML Tx had a median OS of 8.0 mos.

Summary/Conclusions: Enasidenib was well tolerated, induced CRs in R/R AML pts, and was associated with OS of >9 mos in pts who had failed prior AML Tx. A randomized phase 3 study of enasidenib vs conventional care in older pts with late-stage R/R AML is ongoing (NCT02577406).

S472

SAFETY AND EFFICACY OF VENETOCLAX (VEN) IN COMBINATION WITH DECITABINE OR AZACITIDINE IN TREATMENT-NAIVE, ELDERLY PATIENTS (≥65 YEARS) WITH ACUTE MYELOID LEUKEMIA (AML)

1Johns Hopkins Sidney Kimmel Comprehensive Cancer Center, Baltimore, 2University of Colorado School of Medicine, Aurora, 3UC Davis Comprehensive Cancer Center, Sacramento, 4Department of Hematology and Hematopoietic Cell Transplantation and Gehr Family Center for Leukemia Research, City of Hope National Medical Center, Duarte, United States, 5The Alfred Hospital, and Monash University, Melbourne, Australia, 6Emory University, Atlanta, 7University of Washington, 8Fred Hutchinson Cancer Research Center, Seattle, 9Northwestern University Feinberg School of Medicine, 10University of Chicago Medical Center, Chicago, United States, 11Centre Hospitalier Universitaire (CHU) de Bordeaux, INSERM U1038, Université de Bordeaux, Bordeaux, 12Institut Universitaire Du Cancer de Toulouse Oncopole, CHU de Toulouse and Université de Toulouse III, Toulouse, France, 13University of Texas MD Anderson Cancer Center, Houston, United States

Background: Newly diagnosed patients (pts) with AML aged ≥65 years and ineligible for standard induction therapy have limited treatment options, and low overall survival. VEN is an orally bioavailable, selective BCL-2 inhibitor that has displayed single-agent activity in pts with relapsed/refractory AML. VEN at escalating doses combined with hypomethylating agents (HMAs) has demonstrated antileukemic activity, with an overall response rate (ORR) including complete remission [CR], and CR with incomplete marrow recovery of 60%. Combining VEN with HMAs, such as decitabine (DEC) or azacitidine (AZA), may provide a novel low-intensity approach for treating AML. Preliminary results from the expansion stage of a phase 1b trial comparing 2 doses of VEN plus either DEC or AZA (NCT02203773) are reported.

Aims: To evaluate the safety and efficacy of VEN at 400-mg vs 800-mg doses plus DEC or AZA.

Methods: This open-label, nonrandomized, two-stage phase 1b study evaluated the safety and efficacy of VEN plus DEC or AZA in treatment-naive pts ≥65 years of age with AML. Eligibility included: ECOG PS ≤2; ineligible for standard induction therapy; intermediate- or poor-risk karyotype. Pts received DEC (Arm D, 20mg/m2/day [d]; intravenous [IV]) on d 1-5, or AZA (Arm E, 75mg/m2/d; subcutaneous or IV) on d 1-7 of each 28-d cycle (C) in combination with VEN at 175 mg/m2/d (Arm F); 175 mg/m2/d, 250 mg/m2/d, and 312.5 mg/m2/d (Arm G) respectively. Grade 3-4 adverse events and clinical laboratory tests were recorded through cycle 2. The MTD was defined. The dose expansion stage consisted of 2 VEN dose cohorts (continuous 400-mg and interrupted 800-mg dosing) in each arm (D1, D2, E1, and E2, respectively) to determine optimal dose. Tumor lysis syndrome (TLS) prophylaxis was administered in C1 to all pts during VEN dose ramp-up until final dose was reached. All pts provided informed consent.

Targeted treatment of AML

S471
Results: As of 13/09/16, 100 pts were enrolled in the expansion stage; 25 pts in each arm. Overall, 61% pts were male; 50% had ECOG PS 0; 15% ECOG PS 1; and 35% ECOG PS 2; median age was 73.9 (range 65–86); 53% had adverse karyotype; and 22% had secondary AML. Median time on study was 6 (4-9), 6 (0.2–9), 5 (0.5–9), and 4 (1–8) mo for arms D1, D2, E1, and E2, respectively. The incidence of adverse events (AEs) was generally comparable between the 4 arms. Overall, the most common treatment-emergent AEs (TEAEs; in ≥30% of pts) were nausea (59%), diarrhea (42%), febrile neutropenia (FN; 41%), constipation (39%), fatigue, and decreased white blood cell count (31% each). The most frequent grade 3/4 TEAE and serious AE was FN (41% and 29%, respectively). No TLS was observed. Overall, 29 pts discontinued the study for ≥1 reason, including progressive disease (PD) per protocol (n=10), “other” (n=10; 9/10 proceeded to stem cell transplantation) and AEs not related to progression (n=10). A total of 16 deaths occurred; 12 pts died within 30 d of initiating VEN and HMA due to AEs (n=12) and PD (n=1). The ORR was 68%, with rates of 76% (19/25), 71% (17/24), 68% (17/25), and 60% (15/25) observed in arms D1, D2, E1, and E2, respectively. The Kaplan-Meier survival curve for all pts with a median follow-up time of 5.4 mo is shown.

Figure 1.

Summary/Conclusions: Overall, the safety profile was favorable when combining VEN at either dose with DEC or AZA in treatment-naïve elderly AML pts. Promising activity with high ORRs was observed at the lower 400-mg VEN dose in both HMA arms. A Phase 3 study of VEN plus AZA is planned.

Aims: Evaluate the safety and efficacy of VEN+LDAC in older pts with untreated AML.

Methods: In this open-label phase 1/2 study, pts ≥65 years with untreated AML, ineligible for standard induction chemotherapy, with an ECOG performance status of 0-2 received oral VEN QD on days (d) 1-28 and subcutaneous LDAC 20mg/m2 QD on d 1–10 of each 28-d cycle. VEN target dose evaluation followed a 3+3 design, ranging from 600–800mg; 18 pts were enrolled and the RP2D was established as 600mg. Safety and efficacy of VEN at RP2D were evaluated in the expansion phase. All pts were hospitalized and received prophylaxis before a dose ramp-up of VEN during cycle 1 to mitigate the risk of tumor lysis syndrome (TLS). Adverse events (AEs) were graded by NCI CTCAE V4.0. Pts enrolled as of May 2016 are included in this analysis; data cutoff was August 2016. All pts provided informed consent.

Results: In total, 61 pts, including 8 from phase 1, were treated at the RP2D of 600mg (median age 74 years; ECOG 1-2 70%; adverse karyotypes 31%; secondary AML 44%; prior hypomethylating agent [HMA] 28%). AEs (all grade; ≥30% pts) including cytopenias) were nausea (72%), hypokalemia (46%), diarrhea (44%), fatigue (43%), and decreased appetite (41%). Grade 3/4 AEs (≥10% pts) were febrile neutropenia (34%), hypokalemia (15%), hypophosphatemia (13%), and hypertension (10%). No pts had clinical TLS; 1 pt had laboratory TLS, which was managed. The 30-d and 60-d mortality rates were 3% and 15%, respectively. The CR/CRi rate was 54% (33/61; 21% CR and 33% CRi). The overall response rate (ORR; CR+CRi+partial remission) was 61% (37/61). VEN+LDAC was shown to be active across a wide range of cytogenetic mutations and pt profiles (ORR: 70% in pts ≥75 years; 52% in secondary AML; 47% in pts with adverse karyotypes; 53% in pts with prior HMA). Among response-evaluable pts, those achieving an objective response have longer survival than pts who do not achieve an objective response (Figure 1).

Figure 1.

Summary/Conclusions: VEN (RP2D 600mg) and LDAC exhibited an acceptable safety profile and durable efficacy in pts aged ≥65 years with untreated AML who are ineligible for or unable to receive intensive induction chemotherapy. ORR highly correlated with overall survival, with better survival observed in responders compared with nonresponders. A planned phase 3 randomized trial has commenced.
reduced AZA 75mg/m² Days 1-7 with nivolumab 3mg/kg on Day 1 and 14. Courses were repeated every 4-5 weeks indefinitely. Only one of six pts had a dose limiting toxicity (grade 3 pneumonitis) and this dose was RP2D. 60 additional pts have been treated at the RP2D.

**Results:** 66 pts with a median age of 71 years (range, 44-90), secondary AML (39%), poor risk cytogenetics (35%), median number of prior regimens 2 (range, 1-7) have been enrolled. All 66 pts had baseline next generation sequencing: TP53 (n=12), DNMT3A (n=12), ASXL1 (n=10), TET2 (N=9), and RAS (n=9), IDH2 (n=9), IDH1 (n=6), CEBPA (n=7). 63 pts are evaluable for response: 14 (22%) achieved complete remission (CR)/complete remission with insufficient recovery of counts (CRi) (3 CR, 11 CRi), 7 (11%) had hematologic improvement (HI), 5 (8%) had stable disease >6 months, and 24 (38%) had progression. 3 pts are too early for response assessment (<3 courses). The median number of courses to CR/CRi/HI was 2 (range, 1-4+). The median OS among the CR/CRi/HI patients was 15.3 months (range, 2.29-16.64), HI pts was 5.0 months (range, 4.67-17.45+), and NR was 5.0 months (range, 0.29-16.16). The 4- and 8-week mortality were 5% and 11%, respectively. The median OS for the 63 evaluable pts on AZA+nivolumab compares favorably to historical median OS with AZA-based salvage protocols in similar pts treated at MDACC (P=0.10) (Fig 1A and Fig 1B). Grade 3/4 and Grade 2 immune toxicities were observed in 8 (12%) and 7 (11%) pts, respectively. The most common Grade 3/4 AEs on treatment included pneumonitis, colitis, nephritis, skin rash, and hypophysitis. One pt died from grade 4 pneumonitis/epiglottitis. In the remaining 14 cases the toxicities responded rapidly to steroids and 13 of these pts were successfully rechallenged with nivolumab. Time to onset of toxicities ranged from 4 days to 3.5 months. Multicolor flow-cytometry studies and Mass-cytometry (CyTOF) studies are conducted by the Immunotherapy Platform on baseline and on-treatment BM aspirate (end of cycle 1, 2, 4, 8). Baseline and end of cycle (EOC) 1 and 2 BM was evaluated in 6 responders and 19 non-responders. Pts who achieved a response had a baseline higher live total CD3+ (P=0.10), CD8+ T-cells (P=0.02), and lower live CD4+ Foxp3+PD1+ T-regulatory (T-reg) cells (P=0.01) infiltrate in BM. Patients who had a response had progressive increase in BM CD3+ cells and BM CD8+ cells, with increased ICOS (activation) marker on BM CD4-effector cells at EOC 1 and EOC 2 as compared to those who had no response. The CTLA4 on CD8 T-cells went up in both responders and non-responders after PD1 based therapy.

**Figure 1.** OS with AZA+Nivo compared to historical survival with AZA-based salvage protocols in similar pts treated at MDACC (a) all salvage and (b) first relapse only

**Summary/Conclusions:** Full dose AZA and nivolumab are tolerable and produce an encouraging response rate with durable responses in relapsed AML with poor risk features. Immune mediated toxicities occur and may be adequately managed with early recognition and systemic steroids. Up-regulation of CTLA4 may be a mechanism of resistance to PD1 based therapies in AML and suggest role for combination therapy.

**QUIZARTINIB AND BRIDGE TO TRANSPLANT IN FLT3-ITD AML PATIENTS AFTER FAILURE OF SALVAGE CHEMOTHERAPY: A HISTORICAL COMPARISON WITH UK NATIONAL CANCER RESEARCH INSTITUTE (NCRI) DATA**

R. Hills1, G. Gammon2, D. Trone3, A. Burnett4

1Centre for Trials Research, Cardiff University, Cardiff, United Kingdom, formerly Daichi Sankyo, 2Daichi Sankyo, San Diego, United States, 3Blackwaterfoot, Isle of Arran, United Kingdom

**Background:** The presence of a FMS-like tyrosine kinase 3 (FLT3) Internal Tandem Duplication (ITD) mutation in pts with AML is associated with an increased early relapse rate and a dismal prognosis. Quizartinib is a potent, selectively FLT3-ITD inhibitor that confers a median overall survival (mOS) of 23 weeks and remission rate of 46% in a single-arm phase 2 study (AC220-002) in pts with AML with a FLT3-ITD mutation who were relapsed or refractory (R/R) to second line therapy. (Levis, et al, ASH 2012) As context, a study of AML pts, regardless of FLT3 mutation status, receiving second-salvage therapies showed mOS of only 1.5 months. (Giles F, et al. Cancer 104 (3), 2005). Such poor-risk pts may benefit from a stem cell transplant (SCT), if available.

**Aims:** The primary aim was to compare SCT rates and outcomes of pts on quizartinib from an exploratory selected cohort in the AC220-002 study with those from a historical cohort of 1388 AML pts with confirmed FLT3-ITD mutations in the UK NCRI database.

**Methods:** Within AC220-002, 58 pts with a FLT3-ITD mutation were identified who had received intensive chemotherapy, and were relapsed (n=53), or refractory (n=5) to salvage therapy prior to entry. Applying the same entry criteria to the NCRI database, we identified 118 pts who received only recognized chemotherapy regimens prior to eligibility (relapsed n=99; refractory n=19). To avoid biases where those dying early would predominantly contribute to the NCRI group (reflecting that pts in AC220-002 had to be fit enough to be enrolled), pts in this cohort entered analysis 14 days following being identified as R/R. Multivariable Cox/logistic regression was used to compare remission rates and survival stratified for known prognostic factors. A landmark analysis excluding deaths before day 90 (allowing for those too unfit for SCT) was performed on the pooled sample (n=176) of the AC220-002 and NCRI cohorts to compare survival between transplanted and non-transplanted pts.

**Results:** Overall, quizartinib-treated pts had significantly greater remission rates, consisting mainly of complete remission without normal blood counts (CRI), vs NCRI pts (40% vs 3%, adjusted OR 0.05 (0.01-0.21), p<0.0001) and improved mOS (140d vs 54d, adjusted HR 0.38 (0.25-0.58) p<0.0001). A greater proportion of pts in AC220-002 proceeded to SCT: 23/58 (40%) vs 9/118 (8%). Comparing survival in SCT vs no-SCT in a landmark analysis, 18-month survival was significantly greater in the SCT group (29% vs 7%, adjusted HR 0.36 (0.20-0.65) p=0.0005). Significance persisted in sensitivity analyses with the landmark set at 120 or 150 days indicating an association between long-term survival and SCT. A similar analysis in an unmatched cohort consisting of SCT-naive pts in first relapse also found better survival for SCT vs no-SCT, confirming a potential benefit of SCT in this poor risk population.

**Summary/Conclusions:** When compared to a large historical cohort, quizartinib was associated with greater remission rates and opportunity to receive SCT in pts who relapsed after salvage therapy. While varying practice patterns and patient factors obviously influence treatment choices and outcomes, pts with AML with FLT3-ITD mutation appeared to benefit with longer survival observed with SCT. This data suggests quizartinib may show promise in potentially improving long-term survival by bridging patients to SCT.

GLOBAL REGISTRATION TRIAL OF Efficacy and Safety OF CTL019 IN PEDIATRIC AND YOUNG ADULT Patients WITH RELAPSED/REFRACTORY (R/R) ACUTE LYMPHOBластIC LEUKEMIA (ALL): UPDATE TO THE INTERIM ANALYSIS

1Oslo University Hospital Rikshospitalet, Oslo, Norway. 2Department of Pediatrics, Perelman School of Medicine, University of Pennsylvania, 3Division of Oncology, Center for Childhood Cancer Research and Cancer Immunotherapy Program, Children’s Hospital of Philadelphia, Philadelphia, 4Department of Pediatrics and Internal Medicine, University of Utah, Salt Lake City, Utah, United States, 5Department of Pediatrics, Faculty of Medicine, University of Montreal, 6Hematology Oncology Division, CHU Sainte-Justine, 7Charles-Bruneau Cancer Center, CHU Sainte-Justine Research Center, Montreal, Canada. 8Department of Pediatrics, The University of Texas Southwestern Medical Center, Dallas, United States, 9Division for Stem Cell Transplantation and Immunology, Hospital for Children and Adolescents, University Hospital Frankfurt, Frankfurt, Germany. 10Adult and Pediatric Blood and Marrow Transplant Program, University of Minnesota, Minneapolis, 11Children’s Mercy Hospital and Clinics, Kansas City, 12Alac Cancer and Blood Disorders Center, Emory University, Atlanta, 13Division of Hematology Oncology/Blood and Marrow Transplant, Children’s Hospital Los Angeles, USC Keck School of Medicine, Los Angeles, United States, 14Department of Pediatric Hematology-Oncoology and Stem Cell Transplantation, Ghent University Hospital, 15Cancer Research Institute Ghent (CRIG), Ghent University, 16Department of Pediatrics, Graduate School of Medicine, Kyoto University, Kyoto, Japan. 17Department of Pediatrics, Stanford University School of Medicine, Stanford, 18Lucile Packard Children’s Hospital Stanford, Palo Alto, 19Division of Pediatric Blood and Marrow Transplant, Duke University Medical Center, Durham, 20Oregon Health & Science University, Portland, United States, 2122nd Stem Cell Transplantation Unit, St. Anna Children’s Hospital, Vienna, Austria, 22Novartis Pharmaceuticals Corporation, East Hanover, United States, 23Hospita Sant Joan de Déu, Barcelona, Spain

Background: The CD19-targeted chimeric antigen receptor (CAR) T-cell therapy CTL019, an investigational therapy that reprograms cytotoxic T cells to eliminate target cells, resulted in high response rates and a manageable safety profile in pediatric/young adult patients (pts) with R/R B-cell ALL in a single-center trial. Aims: We report an updated interim analysis from the first multicenter global pivotal pivotal phase 2/3 trial (ELIANA) of CAR T-cell therapy (ELIANA; NCT02435849) including data for 68 pts infused with CTL019, 50 of whom were followed for ≥6 mo. Methods: This is a single-arm, open-label, multicenter, global, phase 2 study of CTL019 in pediatric/young adult pts with CD19+/R R/B-cell ALL with ≤5% bone marrow lymphoblasts by morphology. CTL019 was manufactured from leukapheresed autologous peripheral blood T cells at a centralized manufacturing facility. The primary endpoint was overall remission rate (complete remission [CR] or CR with incomplete blood count recovery [CRi]) within 3 mo. Secondary endpoints included duration of remission (DOR), overall survival, safety, and cellular kinetics. Results: As of November 2016, 88 pts were enrolled. There were 7 (8%) manufacturing failures, 9 (10%) pts were not infused due to death or adverse events (AEs), and 4 pts (5%) were pending infusion at the time of data cutoff. Following lymphodepleting chemotherapy in most pts (fludarabine/cyclophosphamide [n=64] or other [n=1]), 68 pts were infused with a single dose of CTL019 (median dose, 0.30 μg/kg; range, 0.25-6.4 μg/kg) which was infused over 28d. Pts were evaluated for a protocol-specified algorithm including day 6-6 mo of infusion. Median age was 12 y (range, 3-23 y); 59% of pts had prior allogeneic stem cell transplant (alloSCT). Five infused patients had not reached 3 mo of follow-up; among 63 evaluable pts, 52 (83% [95% CI, 71%-91%]) achieved CR/CRi within 3 mo of CTL019 infusion, all of whom had minimal residual disease–negative marrow. The relapse-free probability at 3 mo of follow-up was 75% (95% CI, 57%-87%; median DOR not reached). The probability of survival was 99% (95% CI, 77%-94%) at 6 mo and 79% (95% CI, 63%-89%) at 12 mo. Seven pts (13% of responders) proceeded to alloSCT within 6 months while in remission. Cytokine release syndrome (CRS) was graded using the UPenn scale and managed using a protocol-specified algorithm; CRS occurred in 78% of pts (21% grade 3; 27% grade 4); no CRS-associated deaths occurred. 38% of pts received tocilizumab for treatment of CRS or without other anti-cytokine therapy. Most common grade 3/4 nonhematologic AEs (>5%) other than CRS were hypotension (22%), hypoxia (18%), and inflammatory cytokine syndrome (18.4%). The most common grade 3/4 neurologic AEs, with no grade 4 events and no cerebral edema reported. Grade 3/4 neuropenia with high (>38.3°C) fever occurred in 60% of pts. 2 pts died within 30 days of infusion (ALL progression, n=1; cerebral hemorrhage, n=1), and 9 pts died >30 days after infusion (ALL relapse/progression, n=6; HHV-6 encephalitis, pneumonia, systemic mycosis, n=1 each). CTL019 expansion in vivo correlated with CRS severity, and persistence of CTL019 along with B-cell aplasia in peripheral blood was observed for ≥1 y in some responders. Summary/Conclusions: The ELIANA study confirmed the efficacy of a single infusion of CTL019, without additional therapy, observed in a previous interim analysis and a prior single-center CTL019 trial. AEs were effectively and reproducibly managed globally by appropriately trained personnel at study sites. S477

CTL019 CLINICAL PHARMACOLOGY AND BIOPHARMACEUTICS IN PEDIATRIC PATIENTS (PTS) WITH RELAPSED OR REFRACTARY (R/R) ACUTE LYMPHOBLASTIC LEUKEMIA (ALL)

Background: CTL019 is an investigational therapy whereby autologous T cells are genetically engineered with a chimeric antigen receptor (CAR) to identify and eliminate CD19expressing malignant B cells. Data from 2 phase 2 studies (ELIANA; NCT02435849 and ENSIGN; NCT02228096) in pediatric and young adult R/R B-cell ALL were pooled to evaluate cellular kinetics of CTL019. Aims: We report cellular kinetics, humoral immunogenicity, AUC28-day (exposure)-response analysis and impact of intrinsic/extrinsic and manufacturing factors on CTL019 expansion. Methods: Cellular kinetic parameters of CTL019 post infusion were derived using traditional pharmacokinetic principles and reported by response category (complete response [CR]/CR with incomplete blood count recovery [CRi] vs no response [NR]) using 2 assays of peripheral blood cells: qPCR and flow cytometry. AUC28-day-response relationships were evaluated using logistic regression. Relationships between manufacturing specifications, therapies for cytokine release syndrome (CRS) management, and anti-CAR19 antibodies on cellular kinetics explored using summary statistics and graphical- and model-based analyses.

Figure 1. Results: Data from 79 pts (ELIANA, n=50; ENSIGN, n=29) were pooled for analysis. Using qPCR, pts with CR/Cri (n=62) had ≥2-fold higher CTL019 expansion than pts with NR (n=7) (Cmax, 73.5% higher geometric [geo] mean; AUC28, 104% higher geo mean. Table 1). Pts with NR had delayed Tmax compared with pts with CR/Cri (20 vs 10 days). Intrinsic pt factors including baseline cytogenetics, disease characteristics, and disease status did not appear to affect Cmax or AUC28 with the exception that pts with a higher tumor burden at enrollment generally had higher expansion, based on box plots. Summary statistics. Extrinsic factors (prior lines of therapy, stem cell transplant) and parameters related to the manufactured product (% T cells, transduction efficiency, cell viability, total cell count), did not appear to impact cellular kinetics, based on graphical analysis. AUC28 increased with pres...
ence and severity of CRS. Pts who received anti-cytokine agents for grade 3/4 CRS also had higher expansion. CR/CRI pts treated with tocilizumab and steroids (n=17) had 89% higher AUC0-28d than CR pts who did not receive tocilizumab and steroids (n=45). Experience is limited in NR pts with (n=4) and without (n=4) tocilizumab. Moderate correlation was observed between transgene levels and CAR surface expression in peripheral blood (r²=0.592) by qPCR and flow cytometry, respectively, when matched by time points from the cellular kinetic profile. Slower B-cell recovery was observed in pts with AUC0-28d above the median. Post-dose anti-CAR19 antibody responses were determined from the fold change of anti-CAR19 antibodies above the baseline pre-dose value. Pts with treatment-induced or boosted anti-CAR19 antibody responses generally had lower expansion, based on box plots, compared with pts with treatment-unaffected anti-CAR19 antibody responses, although AUC0-28d was variable. The boosted levels of anti-CAR19 did not impact clinical response or relapse.

Table 1.

Summary/Conclusions: There was increased expansion of CTL019 in pts with higher tumor burden at enrollment, which correlated with higher CRS grade. There was no relationship between dose and expansion, supporting the wide dose range used. Expansion was not attenuated by tocilizumab or steroids, indicating therapies for CRS do not abort CTL019 proliferation. Cellular kinetics are important to understand the determinants of tumor response with CAR T-cell therapy.

S478
BLINATUMOMAB VS SOC CHEMOTHERAPY IN FIRST SALVAGE COMPARED WITH SECOND OR GREATER SALVAGE IN A PHASE 3 STUDY
H. Dombret1,*, M.S. Topp2, A. Schuh3, A. Wei4, G. Martinelli5, S. Durrant6, C.L. Bacon7, K. Niel8, Z. Zimmerman9, H. Kantarjian10
1Hôpital Saint-Louis, Paris, France, 2Universitätsklinikum Würzburg, Würzburg, Germany, 3Princess Margaret Cancer Center, University Health Network, Toronto, Canada, 4Alfred Hospital, Monash University, Victoria, Australia, 5Institute of Hematology and Medical Oncology “L. e A. Seragnoili”, S. Orsola University Hospital, Bologna, Italy, 6Clinical Haematology and BMT, Royal Brisbane Hospital, Herston, Australia, 7St. James’s Hospital, Dublin, Ireland, 8Global Biostatistical Sciences, 9Global Development, BMT, Royal Brisbane Hospital, Herston, Australia, 10Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, United States

Background: Adults with B-cell precursor (BCP) acute lymphoblastic leukemia (ALL) often relapse following standard induction/consolidation chemotherapy (CTX). For patients who fail second and subsequent CTX salvage regimens (S2+) is poor compared with first salvage (S1) or frontline therapy, with less favorable outcomes among patients with shorter CR duration. Blinatumomab links cytotoxic CD3+ T cells and CD19+ B cells to induce tumor cell lysis. In a randomized phase 2 trial of blinatumomab vs investigator’s choice of 4 standard care CTX (SOC) regimens, median OS was 7.7 months in the blinatumomab group vs 4.0 months with SOC (Kantarjian H, et al., NEJM 2017). Here, we evaluate outcomes by salvage status for patients in this study (NCT02013167).

Aims: To evaluate responses to blinatumomab vs SOC in patients with relapsed/refractory ALL by prior salvage therapy status.

Methods: Patients with relapsed/refractory (R/R) BCP-ALL in this international multicenter trial were randomized 2:1 to blinatumomab (n=271) or SOC (n=134). For this analysis, salvage status was adjudicated separately from prior randomization. Blinatumomab was given by continuous IV infusion (9 µg/d in week 1 of cycle 1, then 28 µg/d) in cycles of 4 weeks on, 2 weeks off. The primary endpoint was overall survival (OS), determined from time of randomization until death due to any cause. Adverse events (AE) of interest were coded according to MedDRA version 16.0.

Results: At baseline, patient characteristics were balanced between groups within salvage designations. The rate of complete remission, with or without full hematologic recovery (CR/CRh/CRI) in both the S1 and S2+ groups was higher in the blinatumomab arm compared with the SOC arm (Table 1). Patients randomized to blinatumomab had a median (95% CI) of 11.1 (8.2, NR) months vs 5.1 (3.2, 7.1) months overall survival for S1 vs S2+ subgroup, compared with 5.5 (3.7, 9.0) months vs 3.0 (2.1, 4.0) months in the SOC arm (Figure 1). For both S1 and S2+ subgroups, blinatumomab patients had longer median survival time. Grade 3 or worse AEs were experienced by 61% and 83% of S1 patients in the blinatumomab and SOC group, respectively. These percentages were 68% and 75%, respectively, in S2+ patients. Grade 4 or worse AEs occurred in 34% and 51% S1 patients, and in 36% and 54% S2+ patients. Neurologic events of grade 3 occurred in 9% and 9% of S1 patients, and in 10% and 9% S2+ patients, respectively. Grade ≥3 cytokine release syndrome (CRS) was observed in 4% S1 and 5% S2+ patients receiving blinatumomab, and in no SOC patients.

Table 1.

Summary/Conclusions: Patients in this trial receiving blinatumomab for R/R ALL achieved improved OS and remission rates compared with SOC regardless of prior salvage therapy. Improved OS compared with SOC in S1 patients supports earlier use of blinatumomab.

DURABLE LONG-TERM SURVIVAL OF ADULT PATIENTS WITH B-ALL AFTER CD19 CAR (19-28Z) T CELL THERAPY
J. Park1,*, I. Riviere 1, X. Wang 1, B. Senechal 1, Y. Wang 1, T. Purdon 1, R. Brentjens 1, M. Sadelain 1
1Memorial Sloan-Kettering Cancer Center, New York, United States

Background: CD19-specific chimeric antigen receptor (CAR) T cells have demonstrated high initial responses in patients with relapsed B-ALL. However, clinical characteristics associated with the durability of response remain undefined.

Aims: We performed a retrospective analysis of our phase I clinical trial of 19-28z CAR T cells in adult patients with relapsed B-ALL (NCT01044069) with a focus to identify those patients who optimally benefit from 19-28z CAR T cell therapy with durable long-term survival and reduced toxicities.

Methods: Adults with relapsed B-ALL were infused with autologous T cells expressing the 19-28z CAR following conditioning chemotherapy. Disease burden was assessed by bone marrow biopsy immediately prior to T cell infusion; patients with <5% blasts were classified as minimal residual disease (MRD) cohort vs patients ≤5% blasts as morphologic disease cohort. Response assessment occurred at 4 weeks. Median follow-up duration was 18 months (range, 0.2-57.3).

Results: 51 adults received 19-28z CAR T cells; 20 in the MRD and 31 in the therapy, with or without full hematologic recovery (CR/CRh/CRI) in both the S1 and S2+ groups was higher in the blinatumomab arm compared with the SOC arm (Table 1). Patients randomized to blinatumomab had a median (95% CI) of 11.1 (8.2, NR) months vs 5.1 (3.2, 7.1) months overall survival for S1 vs S2+ subgroup, compared with 5.5 (3.7, 9.0) months vs 3.0 (2.1, 4.0) months in the SOC arm (Figure 1). For both S1 and S2+ subgroups, blinatumomab patients had longer median survival time. Grade 3 or worse AEs were experienced by 61% and 83% of S1 patients in the blinatumomab and SOC group, respectively. These percentages were 68% and 75%, respectively, in S2+ patients. Grade 4 or worse AEs occurred in 34% and 51% S1 patients, and in 36% and 54% S2+ patients. Neurologic events of grade 3 occurred in 9% and 9% of S1 patients, and in 10% and 9% S2+ patients, respectively. Grade ≥3 cytokine release syndrome (CRS) was observed in 4% S1 and 5% S2+ patients receiving blinatumomab, and in no SOC patients.

Table 1.
Background: ETV6-RUNX1 fusion is a common genetic aberration in childhood acute lymphoblastic leukemia (ALL) and is associated with good prognosis in the context of contemporary treatment regimens. The required treatment intensity for this well-described biologic subgroup with low risk of relapse is not known so far. In trial AIEOP-BFM ALL 2000, feasibility of reduced delay of intensified treatment to reduce the burden of chemotherapy was tested in a randomized approach in the standard-risk group. Treatment reduction was not successful in the total cohort (8-year probability of disease-free survival (8y-pDFS, ± standard error) 89.2±1.3% for reduced intensified treatment, 92.3±1.2% for the standard treatment (log-rank \(P=0.04\)) due to evidence of more relapses observed in patients treated less intensively. Aims: The retrospective subgroup analysis presented here focuses on the ETV6-RUNX1-positive patients included in the group of randomized standard-risk patients. Methods: From 07/2000 to 06/2006, 4741 eligible patients with ALL (age range 1-17 years) were enrolled in the trial AIEOP-BFM ALL 2000 (NCT 00403118 (BFM) and NCT 00813457 (AIEOP)). Of those, 1164 patients were considered at standard risk of relapse, defined by lack of genetic high-risk criteria and absence of minimal residual disease at day 33 and week 12 of treatment (tested by immunoglobulin \(\tau\)/cell receptor gene rearrangement polymerase chain reaction). They were randomly assigned to either receive the reduced-intensity protocol P-III or the standard protocol II (P-II) for delayed intensification. P-III is shorter than P-II (duration 29 vs 49 days), the dose of dexamethasone in P-III \(=0.74\). Cumulative incidence of relapse at 8 years was \(3.3±1.3\%\) and \(4.3±1.6\%\) (Gray = 0.09), and 8-year overall survival was 96.9±1.4% and 98.8±0.9% (\(P=0.27\)) for P III and P II, respectively. Analysis of ETV6-RUNX1-positive patients by age groups or treatment response on day 15 allowed no further refinement of prognostic subgroups. Summary/Conclusions: There was no evidence of prognostic disadvantage in ETV6-RUNX1-positive standard-risk patients when treated with the reduced-intensity experimental arm. No clear age- or response-dependent differences could be revealed for this group, which is in line with the biologic understanding of this genetic subgroup. Hence, it might be postulated that treatment reduction might not be as effective in the defined biologically defined subgroup. However, the present data is not result of a sufficiently powered non-inferiority study question focused on the subgroup of ETV6-RUNX1-positive patients, but reflects a subgroup analysis with descriptive character. Therefore, any decision for treatment reduction should be considered carefully.
mal translocation t(9;22) that gives rise to the oncogenic tyrosine kinase Bcr-Abl. Implementation of tyrosine kinase inhibitor (TKI) therapy resulted in significant clinical success but with TKIs failing to eradicate the disease initiating leukemic stem cell population (LSC), this treatment is not curative in the vast majority of patients. By using a transgenic CML mouse model, we previously showed that LSC persist despite complete Bcr-Abl kinase inhibition due to a lack of selective pressure. Subsequently, we identified the ITIM carrying Fc gamma receptor IIb (FcγRIIb; CD32) to be 2.8-fold upregulated in Bcr-Abl+ versus control LSK (lin−;Sca-1+;c-kit+) cells using microarray and qRT-PCR.

**Aims:** In this study, we first aimed to validate Bcr-Abl mediated FcγRIIb upregulation on mRNA and protein level in leukemic cells. Next, we tested the effect of shRNA-mediated FcγRIIb knock-down and depletion on CFCs (colony forming unit) capacity, proliferation and leukemic signaling in vitro. Finally, we studied the disease-initiating potential of primitive CML stem and progenitor cells upon FcγRIIb knock down.

**Methods:** qRT-PCR and western blot analyses were applied using cell lines, primary BM cells, and Foxn68 immortalized murine bone marrow (BM) cells for studying FcγRIIb expression and signaling. In order to test the biology of CML cells in vitro, we performed CFU and proliferation assays. Moreover, we performed viral infection of S-FU treated SCILTA/Bcr-Abl BM using FcγRIIb-shRNA or scrambled control and subsequent transplantation, followed by analyses of the disease, including immune-phenotyping, RNA and protein expression as well as histological analysis.

**Results:** Bcr-Abl increased FcγRIIb mRNA (13.2-fold, p<0.001) and protein expression in primary murine lineage negative (lin−) BM cells. Reduction of FcγRIIb in immortalized SCILTA/Bcr-Abl progenitor cells significantly reduced CFU and promoted differentiation (10.6-fold, p<0.001) upon FcγRIIb knock down. Moreover, transplantation of SCILTA/Bcr-Abl shRNA:FcγRIIb BM cells (CD45.1+) into FVB/N wildtype (WT) CD45.2+ recipients reduced spleen weight (352 ± 59.13mg), as compared to scrambled shRNA (536.1 ± 101.72mg). FACS analysis revealed a decrease in GFP+;CD45.1+ BM cells (1.43-fold, p<0.001) upon FcγRIIb knock down. Likewise, donor-derived Gr-1+ cells (Gr-1++;CD45.1++;GP+F) were reduced in the BM (1.28-fold, p<0.001) of these mice. Flow-cytometric analysis of the stem cell compartment revealed decreased leukemic BM LSK cells (lin−;c-kit−;Sca-1−;CD45.1−; GP-, 1.38-fold, p<0.05) in mice transplanted with shRNA:FcγRIIb vs scrambled control. We also observed similar effects upon FcγRIIb depletion (FcγRIIb−/−) vs wildtype (FcγRIIb+/+), combined with virally induced Bcr-Abl expression. Interestingly, Bcr-Abl signaling induces FcγRIIb phosphorylation in leukemic cells. Analysis of downstream signal pathways showed decreased levels of p-ERK, p-BTK, p-PLCγ1 in FcγRIIb−/−, compared to FcγRIIb+/+ Bcr-Abl transduced immortalized SCLtTA/Bcr-Abl BM cells.

**Summary/Conclusions:** FcγRIIb is upregulated in LSC derived from transgenic CML mice upon Bcr-Abl expression. Complete depletion or knock down of the receptor reduces CFU capacity and cell growth in CML cells and significantly impairs CML development and LSC burden in vivo, presumably due to impaired leukemic downstream signaling. Our data demonstrate that FcγRIIb is critical and disease specific making it a potential novel therapeutic target in CML stem cells.

**MYC-DEPENDENT REPRESSION MECHANISM OF THE MiR-150 TRANSCRIPTIONAL REGULATION IN CHRONIC MYELOID LEUKEMIA**

P. Forro1, P. Kuchling1, K. Sövő1, F. Savvulidi2, G. Silvestri3, H. Klamová1,4, I.S. Pagani1, P. Dang1, I.O. Kommers2, J. Goyne1, V.A. Saunders1, J.A. Prime3, D.W. White1,2, S. Branford3, T.P. Hughes1, D.M. Ross1,4.1Cancer Theme, South Australian Health and Medical Research Institute (saMRI), Adelaide, Australia, 2School of Medicine, Vrije Universiteit Medical Center, Amsterdam, Netherlands, 3Department of Genetics and Molecular Pathology, Centre for Cancer Biology,SA Pathology, 4Department of Haematology, Royal Adelaide Hospital and SA Pathology, Adelaide, Australia

**Background:** Real-time reverse transcription quantitative PCR (RQ-PCR) for BCR-ABL1 mRNA is widely used for the monitoring of chronic myeloid leukaemia (CML). Pre-analytical factors, such as the rate of degradation of the target mRNA, and methodological factors, such as the choice of control gene, the degree of amplification bias, the absolute quantification of the number of copies of BCR-ABL1 DNA is directly proportional to the number of CML cells. Measuring both DNA and RNA may enable us to understand the contribution of expression and cell number to the RQ-PCR response.

**Aims:** To compare BCR-ABL1 DNA Q-PCR and routine RQ-PCR monitoring of CML.

**Methods:** Fifty-nine newly diagnosed chronic phase CML patients from the ALLG CML9 (TIDEL II) trial were included in this sub-study. Samples were tested prior to commencing TKI treatment (baseline), at 1, 2, and 3 months, and every 3 months to 24 months (total 568 samples). Since we wanted to compare the assay reproducibility of the Q-PCR methods we selected patients that had achieved undetectable minimal residual disease (UMRD) by RQ-PCR within 24 months, and an additional 40 patients unsellected for response. RQ-PCR results were expressed on the International Scale (IS), whereas DNA results were expressed relative to the individual patient’s baseline. Quantification of BCR-ABL1 DNA with digital PCR and control gene expression were analyzed by digital PCR (dPCR, n=19) using the Fluidigm BioMark HD System. The mean detection limit of RQ-PCR was 4.5-log, and 5.4-log for DNA methods.

**Results:** We first demonstrated that DNA dPCR and real-time Q-PCR gave comparable results: 45 samples from 6 patients were quantified by both methods. The mean difference was -4.85 ± 1.56 log with 95% limits of agreement ranging from -1.19 to 0.88. Subsequently, DNA and mRNA values were compared in paired samples. The median BCR-ABL1 IS at baseline was 58% (range, 2.4% - 487%) versus 93% by DNA methods (range, 2.4% - 235%). Interestingly, BCR-ABL1 DNA was significantly higher than mRNA at 1, 2, and 3 months (Figure). There was good agreement between positive results from 6 months of TKI therapy onwards (mean bias -0.02: 95% limits of agreement from -1.15 to 1.11). Comparing the limit of detection, BCR-ABL1 DNA was detectable in 60/148 (41%) samples with undetectable mRNA.
Aims: The first phase of the study was aimed to i) create a network of 4 labs sharing a common protocol, a joint database for clinical and mutational data and a common pipeline of data analysis, interpretation and reporting, and ii) verify accuracy and inter-laboratory reproducibility of results. The second phase of the study, involving 39 Italian Hematology Units, was meant to prospectively assess the frequency of low burden mutations in CML pts with Failure or Warning to any TKI.

Methods: In the first phase, centrally prepared identical batches of 32 blinded samples (24 clinical samples with known mutation status/load as assessed by Sanger Seq plus 8 T315I+ BaF3 cell line dilutions simulating mutation loads between 20% and 1%) were distributed and analyzed in parallel by each of the 4 participating labs. In the second phase, 159 consecutive CML pts were prospectively studied in parallel by Sanger Seq and by Deep Seq: 101 Failures (57 pts on 1st-line TKI [IM, n=38; DAS, n=12; NIT, n=7] therapy; 35 pts on 2nd-line TKI [DAS, n=14; NIL, n=17; IM, n=2; BOS, n=1; PON, n=1] therapy; 5 pts on 3rd-line TKI [DAS, n=4; NIL, n=1] therapy and 4 pts on 4th-line TKI [BOS, n=1; NIT, n=1; DAS, n=4; NIL, n=5; BOS, n=1] therapy and 20 on 2nd-line TKI [NIL, n=10; DAS, n=9; PON, n=1] therapy).

Results: In the first phase, 504/512 amplicons were successfully generated and sequenced, with a median number of forward and reverse reads of 1,757 (range 544-5,838). In the 128 samples analyzed, 51/52 expected mutations were consistently detected by all 4 labs and quantitation of mutation load was highly reproducible across a wide range of frequencies (2%>100%). Three out of 4 labs failed to detect the 1% T315I+ dilution. In clinical samples, additional low burden mutations <3% were occasionally called by one or two labs only, suggesting that this value should be taken as a threshold below which mutation detection is not reproducible and sequencing artifacts and errors cannot be ruled out. In the second phase of the study, pts positive for mutations were 25/159 (16%; 23 Failures and 2 Warnings) by Sanger Seq and 52/159 (33%; 44 Failures and 8 Warnings) by Deep Seq. Among the pts with low burden mutations detectable by Deep Seq, 4 had a T315I; 34 had other known TKI-resistant mutations; 14 had only mutations with unknown clinical significance. Pts positive for mutations by Deep Seq were more frequent in the High and Intermediate Sokal risk group. The number of positive pts and the number of mutations per pt were not significantly higher in those receiving 2nd- or subsequent-line TKI therapy than in those receiving 1st-line TKI therapy. Compound mutations were found only in 2 out of 52 mutated pts (both in blastic phase).

Summary/Conclusions: 1) Results of the ‘NEXT-IN-CML’, the first prospective study evaluating the routine diagnostic use of Deep Seq of BCR-ABL1, show that this technology can successfully be implemented in national lab networks and is feasible, robust and reproducible; 2) in a relatively large, nonselected cohort of CML pts analyzed for mutations because of a Failure or Warning response, Deep Seq confirmed that enhancing sensitivity enables to detect BCR-ABL1 KD mutations in twice as many pts as compared to Sanger Seq (33% vs 18%); 3) all the pts who need to be switched to another TKI would benefit from sensitive BCR-ABL1 KD mutation screening by Deep Seq.

Figure 1.

Summary/Conclusions: In the first 1-3 months BCR-ABL1 mRNA fell more rapidly than DNA, likely reflecting the time taken for normal haematopoietic cells to recover. At later time-points there was good agreement between methods, indicating that later reduction in BCR-ABL1 IS is closely related to depletion of leukaemic cells. Normalised to BCR-ABL1 DNA the expression of e13a2 BCR-ABL1 mRNA was lower than that of e14a2, an observation that requires confirmation. DNA methods were more sensitive: following the achievement of UMRD by RO-Q-PCR patients could, on average, be monitored DNA Q-PCR for an additional 5 months.

Seragno”, Bologna, 2Department of Clinical and Experimental Medicine, University of Catania, Catania, 3Oncohematology Division, IRCCS - Ca’ Granda - Ospedale Maggiore, 4Oncohematology Division, IRCCS Ca’ Granda – Ospedale Maggiore, Milan, 5Dept of Clinical and Experimental Medicine, University of Pisa, Pisa, 6Institute of Hematology, University of Naples Federico II, 7Hematology Unit, Spedali Civili, Brescia, 8Hematology Unit, Reggio Emilia, Italy

Background: Benchtop next generation sequencers are gradually replacing Sanger sequencers in diagnostics labs because of greater throughput, better sensitivity and increasing cost-effectiveness. In chronic myeloid leukemia (CML) patients (pts) on tyrosine kinase inhibitor (TKI) therapy, BCR-ABL1 kinase domain (KD) mutation screening is a precious tool for timely and rational therapeutic reassessment and is recommended in case of Failure and Warning. A multicenter, multinational prospective study (NEXT-IN-CML) has been conducted to assess the feasibility, cost, turnaround times and clinical utility of a next generation amplicon deep sequencing (Deep Seq) strategy for routine BCR-ABL1 KD mutation screening.

Aims: The first phase of the study was aimed to i) create a network of 4 labs sharing a common protocol, a joint database for clinical and mutational data storage and a common pipeline of data analysis, interpretation and reporting, and ii) verify accuracy and inter-laboratory reproducibility of results. The second phase of the study, involving 39 Italian Hematology Units, was meant to...
Prognostic markers and new treatment in MDS

S486

PATIENTS WITH IDIOPATHIC CYTOPENIA OF UNDETERMINED SIGNIFICANCE SHOW SIMILAR SURVIVAL PATTERNS AS LOW RISK MDS PATIENTS

Methods: Patients with persistent cytopenia who did not fulfill the criteria for MDS are now classified as idiopathic cytopenia of undetermined significance (ICUS). This study was designed to investigate if sequencing of the cohort could bring additional information in regards to overall survival.

Results: So far we included 157 patients, 122 were classified as ICUS and 35 as MDS and the median age is 65 and 68 years, respectively (p=0.27). We have sequenced 78% of the ICUS patients and 74% of the MDS patients. In total 53% and 73% of the ICUS and MDS patients had at least one mutation detected, respectively. If the patients carried a mutation, the median number of mutations was two in both the CCUS and the MDS group. The most commonly mutated genes were TET2, SRSF2, DNMT3A and ASXL1 in 38 patients (31%), n=16 (13%), n=10 (8%), n=10 (8%), respectively. There were no significant differences in the distribution between the two groups. Mutations in NRAS, KRAS, TP53 were only identified in one patient each. The overall survival between the ICUS and the low-risk MDS patients did not differ (p=0.18) (figure 1). We also subdivided the ICUS patients into non-clonal ICUS and CCUS, but observed no difference between these two groups (p=0.355).

Eight of the patients categorized as ICUS progressed to a myeloid neoplasm during the follow up, and of these seven had a detectable mutation at time of enrollment, only one ICUS patient without a detectable mutation progressed (p=0.06).

Summary/Conclusions: We here demonstrate that low-risk MDS and ICUS patients share similar survival patterns, however, larger studies with longer follow up are needed. Mutations are most commonly found in the epigenetic regulators in this cohort of ICUS and low-risk MDS, while mutations in classical tumor suppressors and oncogenes such as TP53 and NRAS are rare. Mutational screening seems promising in identifying patients at risk of progression, however, other biomarkers for prognostication are warranted.

S487

AN UPDATE OF A PHASE II STUDY OF NIVOLUMAB (NIVO) OR IPILIMUMAB (IPI) WITH AZACITIDINE IN PTS WITH PREVIOUSLY TREATED OR UNTREATED MYELODYSPLASTIC SYNDROMES (MDS)

Methods: We designed a phase II study of Nivo or Ipi in monotherapy or combination for pts with MDS. Pts with prior therapy with HMA were to be treated in one of 3 consecutive cohorts: cohort #1: Nivo 3mg/kg iv days 1 and 15 of a 28 day cycle; cohort #2: Ipi 3mg/kg iv on day 1 of a 21 day cycle; cohort #3: Nivo 3mg/kg iv on days 1 and 15 + Ipi 3mg/kg iv on day 1 of a 28 day cycle. The study design allowed for AZA add-back after 6 cycles of therapy if there was no response or progression. Pts with previously untreated MDS were to be treated in one of 3 consecutive cohorts combining AZA 75mg/m² iv daily days 1-5 of a 28 day cycle with: cohort #4: Nivo 3mg/kg iv Days 6 and 20; cohort #5: Ipi 3mg/kg iv on day 6; and cohort #6. Nivo 3mg/kg iv on days 6 and 20 + Ipi 3mg/kg iv on day 6. The maximum size per cohort is 20 pts. The primary endpoint is to determine the safety of Nivo or Ipi as single agents or in combination with AZA. Secondary objectives included overall response rate (ORR) and assessment of biological activity. Responses were evaluated following the revised 2006 IWG criteria. The study included stopping rules for response and toxicity.

Results: A total of 63 pts have been enrolled, 54 (86%) are evaluable for response and toxicity including 21 treated with frontline AZA+Nivo, and 15 and 18 with Nivo or Ipi after HMA failure, respectively. Median age is 69 years (range 39-85). The median number of treatment cycles was 3 (range 1-11). A total of 3 (27%) pts in the AZA+Nivo cohort, 6 (40%) in the Nivo cohort, and 3 (33%) in the Ipi cohort had at least one mutation having retained or developed over time. The stopping rule for toxicity was not met in any of the cohorts. Delays of therapy due to AEs were required in 9 pts due to: rash (N=1), adrenal insufficiency (N=1), colitis (N=1), thyroiditis (N=2), pneumonitis (N=3), and nephritis (N=1). Early 8-week mortality occurred in 1 patient due to non-related intracranial hemorrhage. The ORR was 80% (13/21) in the AZA+Nivo cohort including 6 CR. The ORR was 0% and 30% (5/18) in the Nivo and Ipi arms, respectively.

Summary/Conclusions: Preliminary results indicate that PD-1 blockade with Nivo in combination with AZA in untreated high-risk MDS pts is associated with a tolerable safety profile and clinical activity. Single-agent Ipi is capable of inducing responses in previously treated MDS pts. Single-agent Nivo did not show clinical activity.

S488

ORAL RIGOSERTIB COMBINED WITH AZACITIDINE IN PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML) AND MYELODYSPLASTIC SYNDROMES (MDS): EFFECTS IN TREATMENT NAÏVE AND RELAPSED/REFRACTORY PATIENTS

Methods: 63 pts were randomized into 3 consecutive cohorts combining AZA 75mg/m² iv daily days 1-5 of a 28 day cycle with: cohort #1: Nivo 3mg/kg iv days 1 and 15 of a 28 day cycle; cohort #2: Nivo 3mg/kg iv on day 1 of a 21 day cycle; cohort #3: Nivo 3mg/kg iv on days 1 and 15 + Ipi 3mg/kg iv on day 1 of a 28 day cycle. The study design allowed for AZA add-back after 6 cycles of therapy if there was no response or progression. Pts with previously untreated MDS were to be treated in one of 3 consecutive cohorts combining AZA 75mg/m² iv daily days 1-5 of a 28 day cycle with: cohort #4: Nivo 3mg/kg iv Days 6 and 20; cohort #5: Ipi 3mg/kg iv on day 6; and cohort #6. Nivo 3mg/kg iv on days 6 and 20 + Ipi 3mg/kg iv on day 6. The maximum size per cohort is 20 pts. The primary endpoint is to determine the safety of Nivo or Ipi as single agents or in combination with AZA. Secondary objectives included overall response rate (ORR) and assessment of biological activity. Responses were evaluated following the revised 2006 IWG criteria. The study included stopping rules for response and toxicity.

Results: A total of 63 pts have been enrolled, 54 (86%) are evaluable for response and toxicity including 21 treated with frontline AZA+Nivo, and 15 and 18 with Nivo or Ipi after HMA failure, respectively. Median age is 69 years (range 39-85). The median number of treatment cycles was 3 (range 1-11). A total of 3 (27%) pts in the AZA+Nivo cohort, 6 (40%) in the Nivo cohort, and 3 (33%) in the Ipi cohort had at least one mutation having retained or developed over time. The stopping rule for toxicity was not met in any of the cohorts. Delays of therapy due to AEs were required in 9 pts due to: rash (N=1), adrenal insufficiency (N=1), colitis (N=1), thyroiditis (N=2), pneumonitis (N=3), and nephritis (N=1). Early 8-week mortality occurred in 1 patient due to non-related intracranial hemorrhage. The ORR was 80% (13/21) in the AZA+Nivo cohort including 6 CR. The ORR was 0% and 30% (5/18) in the Nivo and Ipi arms, respectively.

Summary/Conclusions: Preliminary results indicate that PD-1 blockade with Nivo in combination with AZA in untreated high-risk MDS pts is associated with a tolerable safety profile and clinical activity. Single-agent Ipi is capable of inducing responses in previously treated MDS pts. Single-agent Nivo did not show clinical activity.
IMPACT OF THE MUTATIONAL PROFILE AT THE TIME OF DIAGNOSIS IN RESPONSE OUTCOMES IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES AND CHRONIC MYELOMONOCYTIC LEUKEMIA TREATED WITH HYPMETHYLATING AGENTS

G. Montalban-Bravo1, A. Alfonso1, K. Patel2, E. Jabbour1, C. Benton1, T. Kadia1, F. Ravandi1, J. Cortes1, C. Dinardo1, N. Daver1, G. Borthakur1, N. Panmaraju1, M. Konopleva1, I. Ganan-Gomez1, G. 1Leukemia, 2Hematopathology, 3Biostatistics, 4Genomic Medicine, The University of Texas MD Anderson Cancer Center, Houston, United States

Background: Hypermethylating agents (HMA) such as azacitidine and decitabine remain the standard of care for the treatment of myelodysplastic syndromes (MDS) however, loss of response to therapy is associated with poor outcomes. Multiple studies have tried to identify biomarkers of response but the impact of the mutational architecture present at the time of diagnosis in response outcomes is unclear.

Aims: To evaluate the impact of the mutational architecture present at the time of diagnosis in response outcomes is unclear.

Methods: We evaluated 222 previously untreated patients with MDS or CMML that received HMA therapy at The University of Texas MD Anderson Cancer Center. Next generation sequencing analyzing a panel of 28 genes was performed prior to therapy with HMA. VAF estimates were used to evaluate clonal and subclonal relationships within each individual sample with clonal heterogeneity being defined in cases with Pearson goodness-of-fit p-values <0.05. Generalized linear models were used to study association of response rates (ORR=overall and CR=complete) and risk factors. Response was defined following 2006 IWG criteria.

Results: A total of 143 patients (79%) had MDS and 43 (19%) had CMML, including 108 (49%) with lower-risk based on IPSS and 114 (51%) with higher-risk disease. Therapy consisted in azacitidine monotherapy in 60 (27%) patients, decitabine monotherapy in 57 (26%), guadecitabine in 46 (21) and combinations in 59 (27%). The ORR was 61% (135/222) with 80 (36%) patients achieving CR. A total of 161 (73%) patients had at least one detectable mutation. Median number of mutations was 1 (range 0-5). Frequencies of detected mutations are shown in Figure 1A. Among 33 evaluable MDS pts, overall response by IWG criteria was 76%: complete remission (CR) in 30 (9%), partial remission (PR) in 15 (45%), and stable disease (SD) in 4 (12%).

Correlative studies suggest that RIG has chromatin modifying effects in combination with AHR2 which may overcome clinical AHR2 resistance (Chaurasia EHA 2017). Median duration of CR was 8 months for the combination. Median time to initial response was 2 cycles, and median time to best response was 3 cycles. The most frequently reported AEs were diarrhea (70%), nausea (50%), constipation (40%), fatigue (40%), and peripheral edema (40%).

Summary/Conclusions: The combination of oral RIG and standard-dose AHR2 was well tolerated in repetitive cycles in pts with AHR2 and MDS. Response was observed both in MDS treated-naive pts (85%) and in pts failing HMA therapy (62%).

Not available.

Figure 1.

Summary/Conclusions: The type, number and burden of mutations at the time of diagnosis may predict response to therapy with HMA in patients with MDS and CMML.
STUDY OF THE EFFECT OF MiRNAs TARGETING RPS14 ON CELLULAR BIOLOGICAL BEHAVIOR OF MYELODYSPLOSIC SYNDROMES

Y. Nie1, 2, B. Xiong1, X. Zuo1, S. Wang2
1 Zhongnan Hospital of Wuhan University, Wuhan, 2 Institute of Hematology & Blood Disease Hospital, CAMS & PUMC, Tianjin, China

Background: As key factors in gene post-transcriptional regulation, microR-NAs (miRNAs) have been identified to play important roles in carcinogenesis in various tumors. Myelodysplastic syndrome (MDS) is a group of clonal myeloid disorders characterized by refractory quantitative and qualitative abnormalities of hemocytes and its pathogenesis is poorly understood. Some studies have shown that abnormal expressions of some miRNAs have close relationship with the pathogenesis of MDS. Recently, low RPS14 expression is found common in all kinds of myelodysplastic syndromes including patients without 5q deletion, but its mechanism remains unclear.

Aims: To determine the cause of RPS14 reduction in MDS except 5q- syndrome, influence of miRNAs on RPS14 expression was analyzed, and the role of specific miRNA on proliferation, differentiation and apoptosis of hematopoietic stem cells were evaluated. This research will help reveal the pathogenesis of MDS from a new angle and provide new ideas for the diagnosis, treatment and prognosis evaluation of MDS.

Methods: Firstly, we predicted that miR-223 may target 3’UTR of RPS14 by bioinformatics software, then verified if the special miRNA could target RPS14 by assay of luciferase activity. Secondly, the miRNA expression level of miR-223 were detected in the bone marrow BM selected from 28 MDS patients including ten RCUD patients, four RAGM-1 patients and four RAEB-2 patients, meanwhile, the miR-223 expression status were tested in four kinds cell lines including SKM-1, HL-60 /K562 and THP-1 cells lines through qRT-PCR and RPS14 expression was detected by means of immunofluorescence (IF).

Thirdly, constructing lentivirus which carried miR-223 overexpression vector and RPS14 expression was detected by means of immunofluorescence(IF). We used to induce erythroid differentiation of K562 cells by constructing lentivirus which carried miR-223 overexpression vector and RPS14 expression was detected by means of immunofluorescence(IF). We used to induce erythroid differentiation of K562 cells which carried miR-223 overexpression. We used flow cytometry method CD71 and CD235a makers and qRT-PCR (CD235 and r-globin) to detect the erythroid proliferation.

Results: We verified miR-223 could target RPS14 by assay of luciferase activity. 2. MDS patients had higher miR-232 expression than other types of MDS. Meanwhile, in cell lines, K562 cell line showed the highest level of RPS14, the miRNA expression level of miR-232 were detected in the bone marrow BM selected from 28 MDS patients including ten RCUD patients, four RAGM-1 patients and four RAEB-2 patients, meanwhile, the miR-223 expression status were tested in four kinds cell lines including SKM-1, HL-60/K562 and THP-1 cell lines through qRT-PCR and RPS14 expression was detected by means of immunofluorescence (IF).

Summary/Conclusions: MDS patients had higher miR-223 expression compared with health controls. We demonstrated that miR-223 could promote cell proliferation, inhibit cell apoptosis and suppress terminal erythropoiesis through target RPS14.

Stem cell transplantation - Clinical 1

SERIAL SEQUENCING REVEALS CLONAL ORIGINS AND STRATEGIES FOR EARLY DETECTION OF POST-ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION (HCT) RELAPSE IN ACUTE MYELOID LEUKEMIA (AML)

1 Department of Computer Science, 2 Donnelly Centre, University of Toronto, Toronto, Canada, 3 Department of Hematology-Oncology, Chonnam National University Hwasun Hospital, 4 Genomic Research Center for Hematopoietic Diseases, Chonnam National University, Hwasun, Korea, Republic of, 5 The Edward S. Rogers Sr. Department of Electrical and Computer Engineering, University of Toronto, Toronto, Canada, 6 Donnelly Research Center for Hematopoietic Diseases, 7 Department of Laboratory Medicine, 8 Department of Pediatrics, Chonnam National University Hwasun Hospital, Hwasun, 9 Department of Hematology-Oncology, Soon Chun Hyang University Hospital, Bucheon, 10 Department of Laboratory Medicine, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic Of, 11 Department of Molecular Genetics, 12 Department of Laboratory Medicine, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic Of, 13 Princess Margaret Cancer Centre/University Health Network, University of Toronto, Toronto, Canada

Background: Clinical applications of next generation sequencing (NGS) in allogeneic hematopoietic stem cell transplantation are a topic of interest. Mutation dynamics post-HCT using longitudinal NGS have not been thoroughly examined. We hypothesized that serial sequencing of post-HCT and post-HCT in AML patients could provide a much deeper and broader understanding of clonal origin/hierarchy of relapse after allogeneic HCT. The current study aimed to evaluate mutation dynamics in AML using serial samples from pre- and post-HCT with respect to transplant outcomes, particularly overall survival (OS) and relapse.

Aims: To track origins of post-HCT relapse in AML using serial sequencing

Methods: 88 AML patients were enrolled and sequenced using an Illumina HiSeq 2000 sequencer (84 myeloid custom gene panel) on 419 bone marrow samples at diagnosis (n=88), pre-HCT (n=88), 21 days after HCT (n=88), and at relapse (n=20). Two patients relapsed by day 21. T-cell (n=80) and donor samples (n=57) were also sequenced. All computational and statistical analyses were performed using Python and R.

Results: The mean on-target coverage in 419 samples was 1773.7x. In total, we detected 217 mutations throughout the course of treatment in 79/88 patients (89.8%). NPM1 (26.1%), DNMT3A (26.1%), CEBPA (13.6%), IDH2 (13.6%), FLT3 (12.5%), and TP53 (11.4%) were commonly mutated at diagnosis. Unsurprisingly, most mutations appeared at initial diagnosis (200/217, 92.1%). Only 1, 2, and 14 mutations were acquired/selected at pre-HCT (0.5%), day 21 (0.9%), and relapse (6.5%), respectively. Most mutations were cleared at pre-HCT (mean mutation allele frequency (VAF) from 27.4% to 2.9%) and were selected at relapse (6.5%). Most mutations appeared at initial diagnosis (200/217, 92.1%). Only 1, 2, and 14 mutations were acquired/selected at pre-HCT (0.5%), day 21 (0.9%), and relapse (6.5%), respectively. Most mutations were cleared at pre-HCT (mean mutation allele frequency (VAF) from 27.4% to 2.9%) and were selected at relapse (6.5%).
serial samples, we inferred the clonal relationships between original and relapsed cGVHD in 20 patients (Fig B). Mutations from initial diagnosis reappeared in 17 patients. The relapse clone of 13 patients was identical to or clonally evolved from the initial AML clone (7 and 6 patients, respectively). Relapse clones of 4 patients evolved from an inferred ancestral clone, distinct from the initial AML clone. The remaining 3 patients’ relapse clones appear to be intermediate, containing AML and cGVHD somatic mutations assessed whether the mutation status at pre- and post-HCT has any impact on OS and relapse after HCT. With a follow-up duration of 6.9 years, patients with VAF ≥20% at day 21 in any gene showed worse OS (HR 2.9, p=0.006) as well as increased risk of relapse (HR 5.3, p=0.003) (Fig C-D). Multivariate analyses verified that VAF ≥0.2% at day 21 (and ≥0.1% at day 1) was associated with higher GVHD. A female donor into male recipient was associated with lower LFS, 4.62; p<0.01). Incremental age was independently associated to lower LFS, OS, GRFS and higher NRM and cGVHD. MAC was associated with lower RI (HR 1.32; 95% CI 1.01-1.72; p<0.05) and higher NRM (HR 3.03; 95% CI 1.98-4.72; p<0.01). The aim of the study was to compare outcomes of non T cell-depleted HAPLO HSCT to those from MSD HSCT. Transplantations were performed in 116 patients (49% in non T cell-depleted HAPLO recipients, 74% received PT CY and 26% ATG. Conditioning regimen was myeloablative in 50% vs 52% (p=0.52) of HAPLO and MSD pts, respectively. HAPLO pts had a longer interval from diagnosis to HSCT (6 vs 4 months; p<0.01), had more often high risk-AML (34% vs 23%; p<0.01), bone marrow as stem cell source (49% vs 19%; p=0.01) and CMV positive donors (72% vs 61%; p<0.01). Graft failure occurred more frequently after HAPLO (3% vs 1%; p=0.002). For pts with int-AML CI of aGVHD and cGVHD was 29% vs 19%; p<0.01) and CMV positive donors (72% vs 61%; p<0.01). Graft failure occurred more frequently after HAPLO (3% vs 1%; p=0.002). For pts with int-AML CI of aGVHD and cGVHD was 29% vs 20% (p<0.03) and 30% vs 36% (p=0.02) in HAPLO and MSD pts, respectively. Two years, NRM and RI were 28% vs 10% (p=0.01) and 17% vs 20% (p=0.52) in HAPLO and MSD pts, respectively. Incremental age was independently associated to lower LFS, OS, GRFS and higher NRM and cGVHD. MAC was associated with lower RI and higher GVHD. A female donor into male recipient was associated to higher GVHD and lower GRFS. A longer interval from diagnosis to HSCT was associated with lower NRM and cGVHD.
ciliated to lower LFS. Donor CMV seropositivity was associated with lower GRFS and higher NRM and aGVHD. In high risk-AML aGVHD and cGVHD were 36% vs 24% (p=0.03) and 39% vs 33% (p=0.80) for HAPLO and MSD pts, respectively. At two years, NRM and RI were 18% vs 10% (p=0.16) and 21% vs 36% (p=0.02) while LFS and OS were 61% vs 55% (p=0.14) and 67% vs 66% (p=0.26) in HAPLO and MSD pts; GRFS was 49% vs 40% (p=0.17). In multivariate analysis risk of grade II-IV aGVHD (HR: 2.20; 95% CI: 1.29-3.74; p=0.01) was increased after Haplo as compared to MSD and no difference was observed in LFS, OS and GRFS, respectively. Conditioning regimen was associated with lower NRM and higher GRFS, while younger age and donor CMV status were associated with lower RI, higher LFS and OS. Results were confirmed in the analysis using the propensity score technique as well as for RI, NRM, LFS, OS and GRFS.

Summary/Conclusions: As per our registry based study in intermediate risk AML results of HSCT from matched sibling donor are superior to those of HAPLO-HSCT, while in high risk-AML relapse is lower in the HAPLO transplants and NRM, LFS and OS is similar.

S495

IMPACT OF POST-TRANSPLANT INFUSION OF DONOR T CELLS GENETICALLY MODIFIED WITH INDUCTIBLE CASPASE 9 SUICIDE GENE (BPX-501 CELLS) ON CHILDREN WITH LEUKEMIA GIVEN ALPHA-BETA T-CELL DEPLETED HAPLO-HSCT

P. Merli1,*, A. Bertaina1, F. Galaverna1, M. Aligen1, D. Pagliara1, G. Li Pira1, J. Weiberg2, A. Moseley2, F. Locatelli3,1
1Ospedale Pediatrico Bambino Gesù, Rome, Italy. 2Belllicum Pharmaceuticals Inc., Houston, United States

Background: HLA-haploidentical allogeneic hematopoietic stem cell transplant (haplo-HSCT) offers an option for children with acute leukemia in need of a transplant and lacking an available HLA-identical donor. However, performing haploidentical-HSCT without any graft manipulation has historically been associated with a high risk of acute and chronic graft-versus-host disease (GVHD). T cell depletions reduce the risk of GVHD, but lead to delayed immune reconstitution, predisposing to serious infection and leukemia relapse due to the lack of a T-cell mediated graft-versus-leukemia (GvL). To address these challenges, we have infused mature BPX-501 T cells (donor peripheral lymphocytes which have been modified with the iCas9 suicide gene) after αβ T-cell depleted haplo HSCT to facilitate immune reconstitution and GvL effect. BPX-501 T-cells are genetically modified with the iCas9 suicide safety switch and a truncated CD19 marker. In the event of GVHD, the switch is activated by an infusion of the drug rimiducid (AP1903) resulting in rapid T cell apoptosis and GVHD reversal.

Aims: This study was performed to evaluate both safety and efficacy of BPX-501 T cell infusion post αβ T-cell depleted haplo HSCT in pediatric patients with high risk ALL and AML in CR1 and CR2.

Methods: A prospective Phase II-II study enrolling children with hematopoietic disorder who lack a matched donor. 38 patients were enrolled and treated with αβ TCR depleted haplo HSCT after a myeloablative preparative regimen followed by BPX-T cell infusion to date; of them, 24 had ALL and 14 AML (21% CR1, 79% CR2). Median follow-up is 11 months (range 3-24).

Results: All patients engrafted and no secondary graft failure was recorded. Median time to neutrophil and platelet recovery was 16 days (range 8-33) and 11 days (range 7-19), respectively. With a median follow-up of 11 months (range 3-24 months), the cumulative incidence of NRM and relapse was 3.7% and 12.0%, respectively, while the disease-free survival probability was 84.2% (Fig 1). All aGVHD resolved (5 Grade I skin, 5 Grade II skin, 2 Grade III GI). One child received rimiducid to treat steroid-resistant grade II skin with complete resolution in 24 hours (Fig 2). There were 3 cases of chronic GVHD, 2 were mild; 1 severe and fatal in a patient whose donor had VZV reactivation during mobilization. CD3+ T cells reached 500 cells/μl by day 90, with normalized CD4/CD8 T cell ratio by day 180.

Summary/Conclusions: Engraftment was brisk and T cell recovery normalized by 6 months. Overall incidence of severe aGVHD was low and the safety switch was successfully activated with rimiducid infusion. Cumulative incidence of NRM compares favorably to historic controls at the lead center, where a value of of 2.4% for matched related donors (MR), 11.8% for matched unrelated donors (MUD) and 5% for αβ T cell depletion haplo HSCT (Haplo αβ) without BPX-501 infusion was recorded (Bertaina, 2015 ASH). The cumulative incidence of relapse was 12.0% for BPX-501, 32.3% for MR, 22.2% for MUDs and 21.9% Haplo-αβ. Disease-free survival in the BPX-501 treated patients was 84.2% compared to 65.4% for MR, 66.1% for MUDs and 73.1% for Haplo-αβ. However, length of follow-up on the control cohorts differed from that of BPX-501 treated patients. These data suggest that BPX-501 T cells modified with the iCas9 safety switch, infused after selective αβ T-cell depletions, are safe and result in a rapid immune reconstitution and a potentially stronger GvL effect in children with high-risk leukemia who lack a matched donor.

HEREDITARY HEMATOLOGIC MALIGNANCIES: GENETIC COUNSELING IMPLEMENTATION IN A LARGE LEUKAEMIA CENTER

C. Dinardo1,2, S. Bannen2, K. Takahashi1, C. Benton1, M. Routbort3, N. Pemmaraju1, N. Daver1, T. Kadali1, G. Garcia-Manero1, K. Patel1, H. Kantarjian1, A. Naeem1,4
1Leukemia, 2Clinical Cancer Genetics, 3Hematopathology, 4Genomic Medicine, The University of Texas MD Anderson Cancer Center, Houston, United States

Background: Hematologic malignancies have rarely been targets for genetic evaluation, even in familial cases. Over the past decade, more than 12 genes have been identified to cause inherited predispositions to hematologic malignancies. Genetic counseling, testing, and surveillance protocols for these families are not well-established. Additionally, many families with high incidence of blood cancers do not have described syndromes suggesting additional genes remain to be identified.

Aims: To identify individuals with inherited susceptibilities to hematologic malignancies, the Hereditary Hematologic Malignancy Clinic (HHMC) was established in April 2014 at The University of Texas M. D. Anderson Cancer Center. The clinic’s goal is to apply both clinical and research testing for patients with hematologic malignancies suspected to have inherited predisposition syndromes.

Methods: Individuals were referred to the HHMC for several indications: (1) bone marrow failure/aplastic anemia/hypocellular MDS, (2) personal history of hematologic malignancy with ≥1 first-degree relative or ≥2 second-degree relatives with hematologic malignancy, (3) personal history of multiple primary cancers, (4) germline evaluation of presumed somatic mutations identified on next-generation leukemia prognostic panels, (5) management and/or surveillance of a previously-identified genetic syndrome, or (6) solid tumor hereditary syndromes. Clinical evaluation of patients with active hematologic malignancy. Over the past 3 years, 152 probands were evaluated (n=152). Skin biopsies were performed to obtain germline DNA, and next-generation sequencing approaches on both a clinical and research basis were utilized.

Results: Clinical genetic testing was performed in 97/152 individuals (64%). Research testing was performed in 46/152 (30%), particularly in patients negative for known susceptibility genes or without features suggestive of a clinical syndrome. Nine (6%) individuals did not undergo genetic testing. Clinical testing identified 23/97 (24%) individuals with a germline susceptibility to hematologic malignancy. Seven probands (7%) were identified to have RUNX1 mutations associated with familial platelet disorder with myeloid malignancy (FPD-AML). Six (6%) were identified to have the telomere disorder dyskeratosis congenita; only one of them met clinical diagnostic criteria with the “classic triad” of symptoms. Three (3%) patients were identified to have Li-Fraumeni syndrome due to constitutional TP53 mutations. Two adults (2%) were diagnosed with DiGeorge/Anderson syndrome and 3 (2%) with KS with or without leukemia. The distribution by genetic subtypes and the incidence of secondary leukemia accounts for more than 10 percent. Globinuria, abdominal pain, dyspnea, anemia (hemoglobin <100 g/L), major

*Gene mutations without leukemia: (G6PC3-n=9, TAZ1-n=5, p14-n=4, digenic mutations-n=4, CDH1-n=4, CDR4-n=3, germ line extracellular CS3FR-n=2, C16orf57-n=2, Pearson syndrome n=2, LYST n=1)

All subgroups benefit from G-CSF treatment. However, patients requiring maintenance doses of G-CSF above 8μg/kg/day are at greater risk of leukemic transformation.

Summary/Conclusions: Conclusion: The incidence of secondary AML reflects the genetic heterogeneity of CN.

S497

SECONDARY LEUKEMIAS IN GENETIC SUBTYPES OF CONGENITAL NEUTROPENIA (ELANE, HAX1, WASP, G6PC3, ETC.): A LONG-TERM ANALYSIS OF THE SCNIR EUROPE

C. Zeidler1,2, M. Klimiankou2, A. Nickel1, S. Mellor-Heineke1, J. Skokowa2, K. Welte3
1SCNIR, Medical School Hannover, Hannover, 2Department of Hematology, Oncology, Clinical Immunology, 3Department of General Pediatrics and Pediatric Hematology and Oncology; University of Tuebingen, Tuebingen, Germany

Background: Leukemia predisposition is well known in congenital neutropenia (CN) subtypes. By taking all patients with known and unclassified CN together the incidence of secondary leukemia accounts for more than 10 percent. Advanced molecular diagnostics and the identification of inherited and acquired gene mutations have improved our understanding of leukemic transformation in CN patients.

Aims: In the European SCNIR 449 patients with congenital neutropenia and 91 patients with cyclic neutropenia (CyN) have been enrolled since 1994. These 449 patients were evaluated by causal and follow-up. Outcomes include changes from baseline to last follow-up in LDH ratio, GPI-deficient granulocytes, red blood cell transfusions received, MAVE, and Functional Assessment of Chronic Illness Therapy (FAC-IT)-Fatigue score in patients with at least 6 months of follow-up.

Methods: Here we report the leukemia incidence of genetic subtypes analyzing all available long-term data from the European Branchof the Severe Chronic Neutropenia Registry (SCNIR). In addition, we analyzed 91 patients with CyN with or without ELANE mutations.

Results: Results from genetic testing were available for 314 of 449 CN patients, of whom 118 patients revealed ELANE, 48 HAX1, 71 SBDS, 28 G6PT, 9 G6PC3, 7 WAS, 5 TAZ1 mutations and 27 other rare gene mutations (e.g. p14, CXCR4). 135 patients remain unclassified. In addition, 48 of 91 patients with CyN revealed ELANE mutations. Secondary myelodysplastic syndrome (MDS) or leukemia occurred in 49 of the 449 CN patients and in 1 of the 48 ELANE-CyN patients. Acquired CSF3R nonsense truncating mutations have been detected in the bone marrow cells of about 80% of CN patients who progress to MDS or acute myeloid leukemia (AML) and around 30-35% of non-leukemic CN patients, supporting the association between the acquisition of CSF3R mutations and leukemic transformation. These mutations have been shown to be acquired in hematopoietic cells only and therefore are not the primary cause of transformation. The time between first detection of CSF3R mutations and onset of malignant transformation is highly variable. Some patients progressed to MDS/AML within a few months. In others, CSF3R mutant clones persisted for many years without progression to leukemia. The distribution by genetic subtypes and the frequency of CSF3R mutations is shown in the table below.

Table 1.
Results: 4717 patients were enrolled; of these, 2670 had non-missing data on euc and HDA status, and were included in the current analysis (HDA/euc-treated, n=775; HDA/never euc-treated, n=636; no-HDA/euc-treated, n=111; no-HDA/never euc-treated, n=1138). Median (min, max) duration of follow-up after baseline was longer for the euc-treated patients compared with the never euc-treated patients for both the HDA and no-HDA groups (see Table). Results for changes from baseline to last follow-up in outcomes of interest are summarized in the Table. Data show that patients in the euc-treated cohort had high burden of disease at baseline. Specifically, in the HDA population, a higher proportion of euc-treated patients had a history of MAVE (33.3%) vs never euc-treated patients (13.7%). A similar disparity at baseline was also observed in the no-HDA population (33.0% vs 11.0%, respectively). Following euc treatment, the divergence in the proportion of patients with MAVE has substantially narrowed for the HDA patients (3.9% for euc-treated vs 3.3% for never euc-treated) despite longer follow-up for the treated patients. Similar findings were seen in no-HDA patients (5.3% vs 2.1%, respectively). In patients with a history of MAVE, treatment with euc was associated with meaningful improvements in mean (standard deviation [SD]) reduction from baseline in LDH ratio (-5.0 [3.7] vs -0.4 [2.3]) and proportion of red blood cell transfusion-free patients (37.6% vs 15.8%). The FACIT-Fatigue data, while limited, showed the HDA/euc-treated group experienced a greater mean (SD) score improvement than the HDA/never euc-treated group (4.1 [10.3] vs 0.5 [6.8] points).

Table 1.

Summary/Conclusions: Our analysis of real-world data from the International PNH Registry has demonstrated that treatment with eculizumab was associated with improved outcomes in patients with HDA. Our findings are consistent with the notion that patients with HDA, including those with a history of MAVE, should be treated with eculizumab.

S499

CONGENITAL AMEGAKARYOCYTIC THROMBOCYTOPENIA: FUNCTIONAL RESCUE OF A NOVEL MPL MUTANT IN PRIMARY HEMATOPOIETIC CELLS USING CRISPR-CAS9

C. Clayton1, L. Gorden1, R. Girard1, E.H. Choi1, E. Jezierski2, T. Lavabre-Bertrand3, C. Cleyrat1,*, R. Girard 1, E.H. Choi 1, É. Jeziorski 2, T. Lavabre-Bertrand 3, C. Cleyrat1,*, R. Girard 1, E.H. Choi 1, É. Jeziorski 2, T. Lavabre-Bertrand 3, Nantes, France

Background: Thrombopoietin (Tpo) and its receptor, Mpl, are the principal regulators of early/late thrombopoiesis and hematopoietic stem cells maintenance. Mutations in MPL can drastically impair its function and can be a contributing factor in multiple hematologic malignancies, including congenital amegakaryocytic thrombocytopenia (CAMP). CAMP is a rare inherited syndrome characterized by thrombocytopenia at birth, progressing to bone marrow failure and pancytopenia. The functional impact of CAMP mutations on Mpl is yet to be determined. Here we report unique familial cases of CAMP presenting with a previously unreported MPL mutation: T814C (W272R) in the background of the activating MPL G117T (K39N or Baltimore) mutation. Aim: To determine the functionality characterization of this novel MPL mutant and the use of genome editing as a novel therapeutic option for CAMP.

Methods: Human megakaryoblastic UT-7 and murine Ba/F3 cells stably expressing human wild-type (WT) Mpl or mutant Mpl fused to mNeonGreen were used as models. Confocal microscopy, proliferation and surface biotinylation assays, as well as co-immunoprecipitation and western blotting analysis, were used to elucidate the function and trafficking of Mpl mutants. Multiplex, flow-based, CRISPR-Cas9 gene editing was used to repair mutant MPL and rescue its function. Cord blood from the younger male sibling was used as a source of primary homzygous Mpl K39N/W272R CD34+ cells. CD34+ cells were edited using ribonucleoproteins electroporation followed by sequencing and functional assays such as flow cytometry and single colony assays.

Results: Consanguineous parents and their eldest daughter, all heterozygous for Mpl K39N/W272R, do not present any signs of disease. Their monozygotic twin daughters presented at birth with severe thrombocytopenia leading to a diagnosis of CAMP type II. Whole blood sequencing revealed a novel homozygous double Mpl K39N/W272R mutation, as their younger male sibling. One of the twins died after bone marrow transplant. Confocal microscopy shows that a significant fraction of chimeric WT Mpl protein reaches the cell surface. Significant surface expression is also noted for Mpl K39N. In contrast, the chimeric Mpl protein bearing the W272R mutation, alone or together with the K39N mutation, showed no detectable surface expression of the Tpo receptor while being strongly co-localized with ER marker calreticulin. Both WT and K39N-mutated Mpl were found signifying competent, while single or double mutants bearing W272R were unresponsive to Tpo. Tpo-induced signaling was partially rescued in GRASP55-overexpressing cells (forcing orientation of Mpl at the cell surface). Genome editing performed on cells carrying the W272R mutation restored the WT sequence and the response to Tpo, with similar cell proliferation as WT Mpl cells. Finally, when applied to primary Mpl K39N/W272R CD34+ cells, CRISPR-based gene editing rescued surface expression of Mpl and response to Tpo, as assessed by flow cytometry. K39N/W272R CD34+ cells were able to generate a similar number of megakaryocytic colonies as control CD34+ cells in a single colony assay. Non-edited cells failed to do so.

Summary/Conclusions: We report a novel double in cis mutation of Mpl (K39N/W272R) in the context of CAMP. Function of the deficient Mpl receptor could be rescued using two separate approaches: GRASP55 overexpression and CRISPR-Cas9 genome engineering. Successful editing of primary hematopoietic stem cells indicates direct therapeutic applications for gene editing in this disease.

Background: We recently reported the results of the phase III randomized HOVON87/NMSG18 study showing comparable efficacy of treatment with melphalan, prednisolone and thalidomide following by thalidomide maintenance (MPT-T) versus melphalan, prednisolone and lenalidomide followed by lenalidomide maintenance (MPR-R) (Zweegman S et al. Blood 2016;127(9):1109-1116). As not only efficacy but also potential toxicity affecting quality of life (QoL) guides the choice of treatment, health-related (HR) QoL is important.

Aims: To evaluate the HRQoL results of the HOVON87/NMSG18 study.

Methods: Two validated HRQoL instruments (EORTC QLQ-C30 and MY20) were used at baseline, after 3 and 9 induction cycles (3ID and 9ID) and after 6 and 12 months of maintenance therapy (6MT and 12MT). The subscales global QoL, physical functioning, pain, fatigue, constipation, diarrhea, nausea/vomiting, insomnia, disease symptoms, side effects of treatment and neuropathy were analysed. Change in HRQoL score over time between treatment arms was assessed by linear mixed models. Independent sample t-tests were used to determine differences from baseline. Minimal important difference (MID) within arms was defined as a difference in score of ±1 standard error of measurement (SEM) or, if a subscale consisted of one parameter only, MID-level. Levels were used to determine clinically relevant superiority of one arm, a difference in score of ±5 was used and in addition significance level was calculated.

Results: From 553 (90.2%) of the 613 patients who participated in the HRQoL part of the study a baseline questionnaire was available. Forty (15%) of patients randomized to MPT-T versus 88 (24%) of patients randomized to MPR-R completed the therapy until 12 months of maintenance therapy. Change in HRQoL between arms over time: in MPT-T improvement of HRQoL over time as compared to MPR-R was found for the subscales diarrhea and insomnia. In contrast, MPR-R showed improvement over time for the subscales pain, constipation, nausea/vomiting, fatigue, neuropathy, and compared to MPT-T, Change in HRQoL per arm: In MTP-T MID was reached for the following subscales: global QoL increased after 9ID until 12MT (MID range 7-13), pain decreased at every time point (MID range -21 to -23), disease symptoms decreased after 9ID (MID -12), fatigue decreased during MT (MID 12) and insomnia decreased at each time point (MID range 11-23). In MPR-R the MID was reached for the following subscales: global QoL increased after 9ID until 12MT (MID range 8-14), physical functioning increased at 12MT (MID 13), pain decreased at every time point (MID range -14 to -26) and insomnia decreased at 6MT (MID -10). Difference between MPT-T and MPR-R: In the MPT-T arm significantly (p<0.05) and/or clinically (mean score difference (MSD) ≥5 points) less pain and disease symptoms at 3ID, less fatigue at 3ID and 9ID, less diarrhea and less insomnia at all time points were observed. In contrast, patients on MPR-R reported better global QoL, better physical functioning and less pain at 12MT, in general less side effects of treatment, and less constipation and neuropathy separately, at all time points than patients treated with MPT-T.

Summary/Conclusions: Both treatment with MPT-T and MPR-R controlled pain and resulted in an improvement in global QoL, as compared to baseline after 9ID and during maintenance. Treatment with thalidomide initially resulted in less pain and disease symptoms. At all treatment stages thalidomide caused less diarrhea, fatigue and insomnia as compared to treatment with lenalidomide. In contrast, therapy with lenalidomide resulted in less side effects of treatment, less constipation and less neuropathy as compared to thalidomide at all stages of treatment. In addition, long term maintenance therapy with lenalidomide resulted in better global QoL, better physical functioning and less pain.

SS502

HEALTH-RELATED QUALITY OF LIFE RESULTS FROM THE PHASE III GALLIUM STUDY OF OBINUTUZUMAB-BASED AND RITUXIMAB-BASED THERAPY IN PATIENTS WITH PREVIOUSLYuntREATED ADVANCED INDOLENT NON-HODGKIN LYMPHOMA

1Cancer Research UK Centre, University of Southampton, Southampton, United Kingdom, 2Genentech Inc., South San Francisco, United States, 3Simmelweis University, Budapest, Hungary, 4Städtisches Klinikum Dessau, Dessau, Germany, 5Erasmus University Rotterdam, The Netherlands, 6Department of Obstructive Lung Disease, Shanghai Cancer Center, Shanghai, China, 7Aichi Cancer Center Hospital, Aichi, Japan, 8St George’s University, London, United Kingdom, 9St Vincent’s Hospital, Melbourne, Australia, 10University of Melbourne, Melbourne, Australia, 11Bristol Haematology and Oncology Centre, Bristol, 12James Paget Hospital, Great Yarmouth, United Kingdom, 13University of Bristol, Bristol, United Kingdom, 14University of Barcelona, Barcelona, Spain, 15University of Debrecen Medical and Health Science Center, Debrecen, Hungary, 16Uniklinik Heidelberg, Heidelberg, Germany, 17University of La Roche Ltd, Basel, Switzerland, 18Ludwig-Maximilians-University Munich, Munich, Germany

Background: Maintenance of pretreatment health-related quality of life (HRQoL) and/or meaningful improvements in HRQoL are important for previously untreated indolent non-Hodgkin lymphoma (INHL) patients (pts). GALLI-

190 | haematologica | 2017; 102(s2)
UM (NCT01332698) is an open-label, randomized Phase III study of obinutuzumab (GA101; G) plus chemotherapy (chemo) followed by G maintenance (G-chemo) compared with rituximab (R) plus chemo followed by R maintenance (R-chemo) in pts with previously untreated INHL. In GALLIUM, G-chemo produced a clinically meaningful improvement in investigator-assessed progression-free survival (PFS) among follicular lymphoma (FL) pts (34% reduction in risk of a PFS event relative to R-chemo). Grade 3–5 and serious adverse events were more common with G-chemo.

Aims: To compare changes in HRQoL in FL pts receiving G-chemo and R-chemo during GALLIUM.

Methods: Enrolled pts were aged ≥18 years with documented, previously untreated FL (grades 1-3a), advanced disease (stage III/IV or stage II with tumor diameter ≥7cm), ECOG performance status 0-2, and requiring treatment according to GELF criteria. Pts were randomized 1:1 to R 375mg/m² on day (D) 1 of each cycle (C) or G 1000mg on D1, 8, and 15 of C1 and D1 of C2-8, for 6 or 8 cycles depending on chemo (CHOP, CVp or bendamustine). Responders continued to receive R or G every 2 months (mo) for 2 years or until progression. The Functional Assessment of Cancer Treatment-Lymphoma (FACT-Lym) questionnaire (Webster et al. 2005) was used to assess overall HRQoL, physical and functional well-being, and disease- and treatment-related symptoms. FACT-Lym was administered on D1 of C1 and C3 during induction, at the end of induction, and at mo 2 and 12 during maintenance/ follow-up. For each FACT-Lym scale, mean and 95% confidence interval (CI) were derived for recorded scores at each visit and changes from baseline. Minimally important differences (MIDs) were used to calculate the proportion of pts reporting improvement on the FACT-Lym lymphoma subscale (LYMs; ≥3 points), Trial Outcome Index (TOI; ≥6 points), and lymphoma total score (Lym-Tot; ≥7 points). All pts gave informed consent.

Results: Of 1202 FL pts randomized (median age, 59 yrs; 53.2% female; median observation time, 34.5 mo [range 0-54.3]), 560/601 (92.5% G-chemo) and 550/601 (91.5% R-chemo) completed all FACT-Lym scales at baseline. Baseline demographics and disease characteristics were balanced between arms. At baseline, mean HRQoL scores were similar in the two treatment arms, with all pts having some impairment of physical function, functional wellbeing, emotional and social function. Over the course of treatment, mean HRQoL was similar in the two treatment arms. From end of induction onwards, pts in both arms experienced clinically meaningful improvements from baseline in LYMS scores (Figure), and the summary scales that included this subscale (TOI, Lym-Tot). On each summary scale, ≥50% of patients in each arm reported clinically meaningful improvements. There were no clear differences between arms in HRQoL scores over the course of therapy.

Summary/Conclusions: In previously untreated FL pts in GALLIUM, G-chemo and R-chemo produced similar improvements in HRQoL. These results suggest that lymphoma-related symptoms were reduced by both treatments and that the resulting improvements in well-being were not abrogated by treatment-related side effects. When viewed in the context of longer PFS, these results further support the relative benefit of G-chemo over R-chemo in GALLIUM.

**FRONT-LINE VASCULAR ACCESS DEVICES IN ACUTE LEUKEMIAS-PEERINERALLY INSERTED CENTRAL CATHETER (PICC) VERSUS TRADITIONAL CENTRAL VENOUS CATHETER (CVC): A PHASE IV RANDOMIZED TRIAL (NCT02405728)**

K. Bolton5, M. Dennis1, N. Remmington6

**Figure 1.**

Background: Cancer patient support groups appear to provide an important source of support to many patients and carers. In recent years there has been an increasing focus in the UK for services to provide cancer support groups, however it is unclear what proportion of patients believe access to these support groups would improve their experience of living with and beyond cancer.

Aims: A patient experience survey was undertaken by the Haematology-Oncology GMC PB across 10 NHS hospital trusts, where there are a number of cancer support groups.

Methods: The sample for the survey included all adult (aged >16) patients with a confirmed diagnosis of a haematological cancer who attended a haematological oncology outpatient appointment during a 4 month period (June-Sep-tember 2016). The survey was available for completion up to 3 months after the last follow-up contact and was completed anonymously. A translation/interpretation facility was not provided for patients whose first language was not English (due to funding restraints).

Results: 277 responses were returned with 1 response excluded (non-haematological malignancy). Haematological diagnoses included acute leukaemia (n=40), chronic leukaemia (n=35), lymphoma (n=62), myeloma (n=102), MDS (n=15), MPD (n=12), other (n=2) and not specified (n=7). 257 (93.1%) patients had received anticancer therapy, 218 (78%) were receiving treatment at the time of survey and 54% had ongoing symptoms related to their treatment or cancer. 197 (71.4%) patients did not want access to a support group, 23 (19%) wanted access, 51 (8.3%) were not aware of the possibility and 6 (1.8%) did not respond. 51.8% of patients were aware of the existing support groups, 38.8% were not sure, 2.9% were not aware and 1.8% did not respond. The cohort of patients who did or did not want access to a support group was another 8.8% and 91% respectively. 88% of patients had been given a key worker and this was particularly valuable to them. Only 20% of patients currently on treatment wanted access to a support group and 24% not on treatment wanted access to a support group. Date of diagnosis was divided into three groups. Gp A: before 2005 (n=15), Gp B: after 2006 (n=229) and not stated (n=14).

There was no difference in the three groups when asked if they wanted access to support group (13%, 22%, 7% respectively; p=0.3) or awareness that support group was available (40%, 57%, 50% respectively; p=0.6). There were additional comments from patients that support from family and online forums in addition to key workers was extremely valuable to them. On univariate analysis patients who were satisfied with their key worker support did not want access to a support group (p=0.04). There was no effect on wanting access to a support group and diagnosis (p=0.67), need for in-patient treatment (p=0.3), quality of care (p=0.8) or satisfaction with overall care (p=0.8).

Summary/Conclusions: Our results suggest that a large majority of patients with haematological malignancy do not want access to a cancer support group but providing satisfactory support through key workers and other health care professionals is likely to achieve better patient experiences.

Acknowledgements: We would like to acknowledge the members of the GMC PB and patients for their contribution to the survey.
Methods: From April 2015 to February 2017, 152 consecutive patients with acute leukemia planned for remission induction chemotherapy were randomly assigned (1:1) to PICC (Arm A) or traditional CVC (Arm B) (Table 1). Inclusion criteria were age >18 years, expected survival >4 weeks, and need of central venous access (long-term >4 weeks). Exclusion criteria were ongoing uncontrolled systemic infection, presence of significant thrombosis/stenosis in arm or central veins, and inability to communicate and/or to sign informed consent. All insertions were followed by ultrasonography assessments and chest X-ray.

Results: 152 patients (130 AML and 22 ALL) with a median age of 47 years (range, 13-82), were randomized in the two arms. In the Arm A, 76 PICCs (power injectable PICCs, in new generation polyurethane, open-ended) were inserted in 76 patients, single lumen PICCs (4 Fr) were inserted in 7 patients, and triple lumen PICC (6 Fr) was inserted in 1 patient. 68 PICCs were inserted in the right basilica vein, 5 PICCs were inserted in the left basilica vein and 3 PICCs were inserted in the left brachial vein. In Arm B, 76 traditional CVCs (untunneled heparin-coated Vialon CVC, Becton-Dickinson) were inserted by the Seldinger technique in other 76 patients. 45 CVCs were inserted in subclavian vein and 31 CVCs were inserted in internal jugular vein. Overall, the median duration of in situ catheter placement was 5 months: 6 months (range, 3-12) in the Arm A vs. 3 months (range, 1-10) in the Arm B. In the Arm A, catheter-related thrombosis occurred in 8 patients (6 basilica veins, 2 brachial veins) and catheter-related bloodstream infections in 4 patients (4 coagulase-negative staphylococci, of them, 2 meticillin-resistants). In the Arm B, 20 cases of catheter-related thrombosis (7 subclavian veins, 13 internal jugular veins) and 15 cases of catheter-related bloodstream infections (10 enterobacteriaceae; 5 coagulase-negative staphylococci and, of them, 3 meticillin-resistants) were observed. Thus, PICCs were significantly associated with fewer major complications than traditional CVCs (catheter-related thrombosis: 10.5% in the Arm A vs. 26% in the Arm B, p=0.01 by x2 test, catheter-related bloodstream infections: 5% in the Arm A vs. 19% in the Arm B, p=0.007 by x2 test) (Figure 1). Questionnaire covering activities of daily living confirmed improvement of quality of life.

Figure 1.

Summary/Conclusions: The preliminary observations of this ongoing Phase IV randomized study, focusing on front-line use of central venous access device in a high risk hematological population, suggest that the use of PICC represents an advance in terms of decrease of complication rate and improvement of quality of life for patients with acute leukemia.

SS05

THE SIMM STUDY: SURVEY OF INTEGRATIVE MEDICINE IN MYELOPROLIFERATIVE NEOPLASMS

K. Gowin1,2, D. Millstine2, H. Kosiorek3, B. Langlais2, J. Huberty4, R. Eckert4, R. Masala5,6

1Hematology and Medical Oncology, 2Integrative Medicine Program, Department of Medicine, 3Department of Biostatistics, Mayo Clinic Arizona, 4School of Nutrition and Health Promotion, Arizona State University. 5Hematology, Mayo Clinic Arizona, Phoenix, United States

Background: Pharmacologic therapy stabilizes hematologic counts and splenomegaly in myeloproliferative neoplasms (MPN), however only partial symptom improvement typically occurs. Evidence-based integrative care may address this need, however data is limited in patients with MPNs.

Aims: To investigate the association with symptom burden, quality of life, depression, and fatigue in MPN patients.

Methods: Patients were recruited via social media. Informed consent and online self-report surveys (Qualtrics) were completed, capturing patient demographics, disease specific data, supportive care utilization, MPN symptom burden (MPN-SAF TSS), depression via Patient Health Questionnaire (PHQ)-9, fatigue via Brief Fatigue Inventory (BFI) Usual, and overall quality of life (QOL) single question assessment. ANOVA, chi square tests, and Wilcoxon rank sum tests methods were applied.

Results: Patients: A total of 1087 patient surveys were consented. Of these, 885 had 10 or more responses. There were 338 essential thrombocytosis (ET), 188 myelofibrosis (MF), 315 polycythemia vera (PV), and 17 other. In MF: DIPSS risk categories included low (8%), Int-1 (19%), Int-2 (29%), high (12%), and unknown (32%). Symptom association: Overall, patients had lower MPN related symptoms when participating in aerobic activity (p<0.001), massage (p<0.001), yoga (p=0.02), strength training (p<0.001), breathing exercises (p<0.001), and support groups (p<0.001). Overall quality of life was higher with aerobic activity (p<0.001), massage (p=0.02), yoga (p=0.02), strength training (p<0.001), breathing exercises (p=0.01), and support groups (p=0.001). Depression (PHQ-9 total >3 category) was lower in aerobic activity group (p=0.001), yoga (p=0.001), strength training (p=0.001), and meditation (p=0.2). Fatigue was lower in aerobic activity (p<0.001), massage (p=0.04), strength training (p<0.001), breathing exercises (p<0.001), and support groups (p=0.001). In subgroup analysis, ET and PV patients had lower symptom burden (MPN-SAF TSS) with aerobic activity (p<0.001, <0.001), massage (p=0.01, 0.02), and strength training (p=0.03, 0.02). Support groups were found to be associated with lower symptoms in ET patients (p=0.03). In MPN, breathing exercises (p<0.001) and support groups (p=0.03) were associated with lower symptom burden. See Table #1.

Table 1.

Summary/Conclusions: Integrative therapies are associated with improved symptom burden, quality of life, depression, and fatigue in MPN patients. Interestingly, unique patterns were associated within MPN subtypes. Further studies are needed to understand the benefits of integrative therapies in MPN patients.
Acute lymphoblastic leukemia - Biology 2

P506
T CELL EXHAUSTION CHARACTERIZED BY COMPROMISED MHC CLASS I AND II RESTRICTED CYTOTOXIC ACTIVITY ASSOCIATES WITH ACUTE B LYMPHOBLASTIC LEUKEMIA RELAPSE AFTER ALLO-HSCT
L Liu1*, Y. Chang1, L. Xu1, X. Zhang1, Y. Wang1, K. Liu1, X. Huang1
1Peking University People’s Hospital & Peking University Institute of Hematology, Beijing Key Laboratory of Hematopoietic Stem Cell Transplantation, Beijing, China

Background: B cell acute lymphoblastic leukemia (B-ALL) relapse contributes to the predominant mortality after allogeneic hematopoietic stem cell transplantation (allo-HSCT). However, the mechanism of B-ALL relapse after allo-HSCT remains unknown. Eradication of leukemia in allo-HSCT settings largely relies on graft-versus-leukemia (GVL) effects mediated by donor T cells. T cell exhaustion characterized by increased expression of inhibitory receptors including PD-1 and Tim-3 and impaired function may blunt the GVL effects and was reported in acute myeloid leukemia relapse after allo-HSCT; whether T cell exhaustion is involved in B-ALL relapse after allo-HSCT remains unknown.

Aims: To evaluate whether T cell exhaustion is involved in B-ALL relapse after allo-HSCT; and investigate the correlation of inhibitory ligands on leukemic cells, leukemic load and T cell exhaustion, as well as the impact of treatment outcome on T cell exhaustion.

Methods: Our study enrolled 18 B-ALL patients who underwent first hematologic relapse after allo-HSCT and 18 matched B-ALL patients in remission (without minimal residual disease MRD) and 14 healthy donors from April 2016 to November 2016 at the Peking University People’s Hospital, Institute of Hematology. Transplant protocol and post-transplant time were matched in relapsed patients. Post-transplant time were matched as follows: ±14 days within 12 months ±1months from 12 to 18months, ±3months from 18 to 36 months, ±12months over 3 years. Extra-medullary relapse were excluded in our study. All patients had achieved full donor chimerism before relapse or bone marrow collection. Peripheral blood (PB) were collected at the same day of bone marrow collection in relapsed patients. For patients who received induction therapy, we prospectively collected BM at least once after therapy. Sample collection was performed after patients was informed consent and approval by the institutional Human Ethics Review Committee of Peking University People’s Hospital in accordance with the Declaration of Helsinki, phenotypic and functional studies of T cells in those patients were performed using multi-color flow cytometry.

Results: In the current study, we observed that increased co-expression of PD-1 and Tim-3 was observed in both CD4+ and CD8+ T cells in relapse setting. Moreover, both CD4+ and CD8+ T cells exhibited compromised proliferative capacity, cytokine production and cytotoxic potentials such as degranulation and granzyme B production (preferentially on CD4+ T cells) in relapsed patients. In addition, T cells from the tumor site are more exhausted and those in peripheral blood. Reversal of T cell exhaustion was associated with effective anti-leukemic response in relapsed patients who underwent re-induction therapy.

Summary/Conclusions: In conclusion, our study suggested that T cells experienced a comprehensive functional impairment in B-ALL relapse settings after allo-HSCT and reversal of T cell exhaustion was associated with effective anti-leukemic responses. These results also provide a foundation for the development of novel effective leukemia therapeutics, such as anti-PD-1 or PD-1L-1 therapy, by targeting T cell exhaustion

P507
RUXOLITINIB/NILOTINIB COTREATMENT BETTER INHIBITS LEUKEMIA-PROPAGATING CELLS IN PHILADELPHIA CHROMOSOME-POSITIVE ALL Y. Kong1,2, L.-Y. Wu1, Y. Song12, M.-M. Shi12, X.-N. Cao1, H.-Y. Zhao1, Y.-Z. Qin1, Y.-Y. Lai1, H. Jiang1, Q. Jiang1, X.-J. Huang1, Y.-Z. Qin1, Y.-Y. Lai1, H. Jiang1, Q. Jiang1, X.-J. Huang1
1Peking University People’s Hospital, Peking University Institute of Hematology, 2Peking-Tsinghua Center for Life Sciences, Academy for Advanced Interdisciplinary Studies, Peking University, Beijing, China

Background: BCR/ABL expressing cells using a qRT-PCR assay and HE and IHC with anti-hcD19 staining. Moreover, the combination of nilotinib and ruxolitinib more effectively reduced the LPCs capacity through a deeper suppression of phospho-CrKL, JAK2 and STAT5 activities at the molecular level.

Summary/Conclusions: JAK2 was more highly expressed in the sorted LPCs than in other cells of phenotypes in patients with de novo Ph+ALL in vitro study, cotreatment with nilotinib and ruxolitinib induced significantly higher levels of apoptosis in LPCs. In humanized Ph+ALL mice model, treatment with the nilotinib and ruxolitinib combination, compared with either ruxolitinib or TKIs alone, led to the most significant reduction in human Ph+ALL engraftment in the recipients. Further evidence that the most optimal treatment combination was determined by the engraftment analysis of BCR/ABL expressing cells using a qRT-PCR assay and HE and IHC with anti-hcD19 staining. Moreover, the combination of nilotinib and ruxolitinib more effectively reduced the LPCs capacity through a deeper suppression of phospho-CrKL, JAK2 and STAT5 activities at the molecular level.

P508
PREDICTING ANTI-LEUKEMIA ACTIVITY OF THE BCL-2-SELECTIVE INHIBITOR ABT-199 IN BCP-ALL BY FUNCTIONAL ASSESSMENT OF APOPTOSIS SIGNALING
F. Seyfried1,2, S. Demir3, R. Hörl1, J. Ryán3, A. Scheffold3, M. Villalobos-Ortiz2, S. Köhler1, J. Zinggrebe1, S. Stilgenbauer1, A. Let al4, K.-M. Debatin1, L. H. Meyer3
1Department of Pediatrics and Adolescent Medicine, Ulm University Medical Center, Ulm, Germany, 2Dana-Farber Cancer Institute, Harvard Medical School, Boston, United States, 3Department of Internal Medicine III, Ulm University Medical Center, Ulm, Germany

Background: Although survival rates of pediatric BCP-ALL patients have continuously improved during the past decades, therapy-related toxicity and relapse occurring in 10-20 % of patients are associated with poor outcome, clearly emphasizing the need of novel, targeted treatment strategies. Deregulated survival pathways and cell death resistance contribute to treatment failure and recurrence of the disease. ABT-199 (venetoclax) is a small molecule inhibitor of BCL-2 demonstrating anti-cancer activity among different malignancies. However, predictive biomarkers are required for up-front identification of patients who would benefit from BCL-2 directed therapies.

Aims: The aims of this study were to assess the efficacy of ABT-199 in BCP-ALL, to functionally evaluate factors mediating ABT-199 susceptibility or resistance and to identify markers indicative of successful anti-leukemia activity.

Methods: The activity of ABT-199 was assessed by cell viability assays in BCP-ALL cell lines (N=6) and patient-derived xenograft (pdx) samples (N=27), analyzing half maximal effective concentrations (EC50). Expression of apoptosis regulators was detected by western blot analysis. MCL-1 deficient cell lines were generated by CRISPR/Cas9 gene editing. BH3 profiling was used to measure the mitochondrial dependence of leukemia cells on anti-apoptotic BCL-2 family proteins. In vivo treatment of ABT-199 was performed in a set of three distinct ALL rpdx.

Results: Different sensitivities of ABT-199 were observed in a series of BCP-ALL pdx and cell lines with heterogeneous anti-leukemia activities upon drug exposure. The majority of BCP-ALL samples showed sensitivity to ABT-199-induced cell death in the nanomolar range (EC50 <1µM) with four out of six cell lines and 20 of 27 pdx, while ABT-199 insensitivity with EC50s of more than 1µM were identified in 26% of pdx leukemias. ABT-199 induces apoptosis based on BCL-2 dependent sub-µM IC50. However, ABT-199 can inhibit pro-apoptotic molecules; however, the sequestration of drug-released BIM by anti-apoptotic MCL-1 might lead to resistance. Therefore, we investigated protein expression of both regulators and found the ratio (BCL-2/MCL-1) to be cor-

haematologica | 2017; 102(s2) | 193
related with ABT-199 sensitivity (k = 0.71, p = 0.008), highlighting the importance of expression assessment of the direct target molecule and additional resistance mediating molecules. In line, MCL-1 knockdown in two ABT-199-resistant cell lines led to sensitization towards ABT-199, however, resulted in different effects of sensitization, emphasizing that ABT-199 resistance is determined by the interplay of several apoptosis regulators. Therefore, we characterized the functional dependence of pdx leukemias on anti-apoptotic BCL-2 family members in vivo, using a multiplexed profiling. Mitochondrial dependence on BCL-2 (multiplexed priming by the BAD-peptide measuring BCL-2, BCL-XL and BCL-W, and subtracting the response to the HRK-peptide measuring BCL-XL) was found to be tightly correlated with ABT-199 sensitivity. In contrast, ABT-199-resistant samples were characterized by low BCL-2-dependence and addition to other BCL-2 family members, including BCL-XL or MCL-1. Finally, we evaluated prediction of in vivo ABT-199 sensitivity in a pre-clinical ALL pdx mouse model by functional BH3 profiling. Strikingly, high mitochondrial BCL-2-dependency was clearly associated with prolonged leukemia-free survival upon ABT-199-therapy (two pdxs, log rank p = 0.0035 and <0.0001), in contrast to another leukemia with low BCL-2-dependence and in vivo ABT-199 resistance (log rank p = 0.14).

Summary/Conclusions: SCP-ALL displays heterogenous ABT-199 sensitivities characterized by the level of the target molecule but also other interacting regulators. Functionally, mitochondrial BCL-2-dependency assessed by the BH3 profiling assay is clearly associated with ABT-199 sensitivity. Importantly, in vivo anti-leukemia activity of ABT-199 therapy in individual pxd leukemias is predicted by mitochondrial BCL-2-dependence, emphasizing the utility of identification of patients and guidance of future clinical application by functional assessment of apoptosis signaling.

A BILINEAL ACUTE LYMPHOBLASTIC LEUKEMIA ORIGINATING AT A COMMON LYMPHOID PROGENITOR
A. Gonzalez-Murillo1, 2, C. Sánchez-Valdepeñas1, C. Robledo2, A. Castillo1, L. Abad1, C. Hernandez-Marcuq1, D. Ruano1, L. Madero1, J. Alonso2, M. Ramirez1
1Pediatric Hematology & Oncology, Hospital Universitario Niño Jesús, Madrid, 2Instituto de Investigacion en Enfermedades Raras, Instituto de Salud Carlos III, Majadahonda, Spain

Background: Genetic mutations are crucial events during leukemogenesis and provide specific markers for backtracking the cellular origin of acute leukemias up to immature uni- or multi-potent progenitor cells in the hierarchy of the hematopoietic system.

Aims: To characterize the clonal architecture and cell of origin in a case of B-cell ALL and B-ALL.

Methods: Bone marrow cells obtained at diagnosis were used for all studies. Immunophenotyping was done by flow cytometry. T- and B-leukemic cell purifications were performed by immunomagnetics methods and DNA extracted afterward. TCR-gamma gene rearrangement was studied in T- and B-leukemic cells independently by PCR sequencing. Somatic mutations in purified T- and B-leukemic cells were identified by deep-sequencing using a panel of 160 genes frequently mutated in cancer (Human comprehensive cancer panel, Qiagen). Mutations were validated by Sanger sequencing. Myeloid and erythroid clonogenic progenitors were isolated from methylcellulose cultures, DNA extracted and assessed for the presence of the H3F3A p.K28N mutation by Sanger sequencing.

Results: The patient was a 10 years old boy. At diagnosis, the bone marrow was infiltrated by 60% leukemic cells, with 2 immunophenotypically different populations: a common B-ALL (54%) and a pro-T-ALL (6%). The patient showed a mediastinal mass on chest x-ray and TCR-gamma rearrangement was detected in purified (>95% pure) T-ALL and B-ALL cells, suggesting a common origin for both leukemic subpopulations. The B-ALL cells presented a c.35G>A p.G12D mutation in the KRAS gene, absent in the T-ALL. The T-ALL cells presented a c.35G>A (p.G12D) mutation in the NRAS gene, absent in the B-ALL. A c.1126_1127insTAGA (p.P376fs*10) mutation in the WT1 gene was also detected only in the T-ALL. A c.348+5T>(p.K28N) mutation in the H3F3A gene was detected in both the B-ALL and T-ALL subpopulations, confirming the involvement of a Common Lymphoid Progenitor in the process of leukemogenesis. The presence of the H3F3A p.K28N mutation in the myeloid compartment would point to a multipotent myeloid-lymphoid rather than a lymphoid-restricted progenitor as the cell origin of the leukemia. Therefore, we cultured myeloid-erythroid-committed progenitor cells in clonogenic cultures and sequenced the H3F3A gene. None of the 122 myeloid or erythroid clonogenic progenitors (41 CFU-GM, 73 BFU-E and 8 CFU-GEMM) presented the p.K28N mutation in the H3F3A gene.

Summary/Conclusions: Our results indicate the involvement of a Common Lymphoid Progenitor as the cell origin of this case of biallelic ALL, as well as the crucial role of H3F3A and RAS family genes in the leukemogenesis process coupled with B and T differentiation.

CYSTEINE AND GLYCINE-RICH PROTEIN 2 (CSRP2) TRANSCRIPT LEVELS CORRELATE WITH LEUKEMIA RELAPSE AND LEUKEMIA-FREE SURVIVAL IN ADULT B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA WITH NORMAL CYTOGENETICS
S.-J. Wang1, 2, P.-Z. Wang2, R. Gale1, Y.-Z. Qin1, Y.-R. Liu1, Y.-Y. Lai1, H. Jiang1, Q. Jiang1, X.-H. Zhang1, B. Jiang1, L.-P. Xu1, X.-J. Huang4, K.-Y. Liu1, G.-R. Ruan1 1Peking University Peoples Hospital and Institute of Hematology, Beijing Key Laboratory of Hematopoietic Stem Cell Transplantation, 2Department of Immunology, School of Basic Medical Sciences, Peking University Health Science Center., Beijing, China, 3Haematology Research Center, Division of Experimental Medicine, Department of Medicine, Imperial College London, London, United Kingdom, 4Peking University Peoples Hospital and Institute of Hematology, Beijing Key Laboratory of Hematopoietic Stem Cell Transplantation, Beijing, China

Background: Outcome of adults with B-cell acute lymphoblastic leukemia (ALL) remains poor and relapse is the major cause of treatment-failure. Identification of novel biomarkers in B-cell ALL especially in those with normal cytogenetics and studying their clinical significance and biological function will be helpful for risk-stratification, treatment decision and targeted therapy.

CRSP2 (cysteine and glycine rich protein 2) maps to chromosome subband 12q21.1. which is frequently abnormal in diverse cancers. Increased CSRP2 transcript levels were associated with de-differentiation in hepatocellular carcinoma and CSRP2 was found to be a new invadopodia bundling factor that critically promotes breast cancer cell invasion and metastasis. However, the clinical significance and biological function of CSRP2 in B-cell ALL remains unknown.
Aims: To identify novel biomarkers in B-cell ALL based on bioinformatics analyses; to examine the expression and clinical significance of CSRP2 in adults with B-ALL; to explore effects of CSRP2 on biological function of B-cell ALL.

Methods: We did bio-informatics analyses to identify mRNA transcripts aberrantly-expressed in B-cell ALL. RT-qPCR (real-time quantitative polymerase chain reaction) was used to examine CSRP2 transcript levels in bone marrow samples from 236 adults with B-cell ALL compared with samples from normal. A prognostic value was assessed in 168 subjects. CSRP2-knockdown and CSRP2-over-expression cell models were constructed to study the biological function of CSRP2 in B-cell ALL.

Results: We selected 9 candidate genes for validation 7 of which proved significantly-associated with B-cell ALL. CSRP2 was the most differentially-expressed gene in our validation studies. CSRP2 was over-expressed in 228 out of 236 adults (97%) with newly-diagnosed B-cell ALL. In subjects with normal cytogenetics: those with high CSRP2 transcript levels had a higher 5-year cumulative incidence of relapse (CIR) and worse relapse-free survival (RFS) compared with subjects with low transcript levels (56% [95% confidence interval 53.5-69%] vs 19% [18-20%]; P=0.011 and 41% [17.65%] vs 80% [86-96%]; P=0.007). In multivariate analyses a high CSRP2 transcript level was independently-associated with CIR (HR=5.32 [1.64-17.28]; P=0.005) and RFS (HR=5.56 [1.87-16.53]; P=0.002). Functional analyses indicated CSRP2 promoted cell proliferation, cell-cycle progression, in vitro colony formation and migration. Abnormal CSRP2 expression was associated with resistance to chemotherapy; sensitivity was restored by down-regulating CSRP2 expression. CSRP2 activated ERK1/2 signaling pathway, regulated cell-cycle related protein and activated CREB signaling pathway, whose activation was associated with poor prognosis in adults with B-cell ALL.

Summary: CSRP2 was widely over-expressed in adults with B-cell ALL. Determination of CSRP2 transcript levels in subjects with normal cytogenetics might inform therapy-decisions. Consideration could be given to down-regulating CSRP2 expression as a way to reverse drug resistance.

THERAPEUTIC TARGETING OF PRE-B CELL RECEPTOR SIGNALLING IN CHILDHOOD ACUTE LYMPHOBластIC LEUKEMIA

A. Alhammer1,2, M. Case1, E. Matheson3, H. Blair4, J. Vroomoor1, J. Irving1

1Newcastle University, Northern Institute for Cancer research, Newcastle upon Tyne, United Kingdom, 2Al-Nahraii University, Biotechnology research Center, Baghdad, Iraq

Background: Acute lymphoblastic leukaemia (ALL) is the most common malignancy in children and adolescents and relapsed ALL remains one of the leading causes of cancer-related deaths in children. Components of the precursor-B cell receptor (Pre-BCR) signalling pathway are hijacked in ALL cells and this dependence may be therapeutically targeted. A number of tyrosine kinase inhibitors (TKIs) targeting effectors of this signalling pathway are showing great promise in the clinic and warrant preclinical evaluation in paediatric ALL. They include Dasatinib (BCR-ABL/SRC inhibitor), Fostamatinib R406 (SYK inhibitor), Ibrutinib (BTK inhibitor) and CAL-101 (PI3Kδ inhibitor).

Aims: To preclinically evaluate these candidate TKIs, as novel, targeted drugs for the treatment of relapsed ALL.

Methods: ALL cell lines (Reh, Nalm-6, PreB 697 and its glucocorticoid resistant descendant, R3F9) and 36 primary-derived xenograft (PDX) cells from 16 ALL were used in the study. Cell viability was assessed by Resazurin. Pre-BCR expression (µHc, VpreB and A5) and functionality using a Calcium flux assay were detected by Flow cytometry. Intracellular phospho-flow cytometry was used to detect constitutive phosphorylation and activation in response to anti-Ig antibody, as well as drug pharmacodynamic measures (p-BTK, p-SYK, p-AKT, p-ERK, p-PLC-ϒ2, p-BLNK). Apoptosis and cell cycle were analysed by Annexin V and Propidium iodide. RQ-PCR was used to measure expression levels of key proteins. Cell cycle, DNA content and apoptosis were measured by DNA staining, GFP expression and phosphorylation were detected by western blotting.

Results: ALL cell lines were modestly sensitive to Dasatinib (mean G50 5.33 µM, range 2.45 µM-12.5 µM) and R406 (mean G50 4.32 µM, range 2.88 µM-5.83 µM). However, cells were resistant to Ibrutinib (mean G50 15.9 ± µM, range 11.47 µM-18.3 µM) and CAL-101 (mean G50 52.08 µM, range 25 µM-77.83 µM). Cell cycle arrest and significant apoptosis was seen with R406 and Ibrutinib treatment, while Dasatinib and CAL-101 were cytostatic, causing G1 arrest with no substantial cell death. Pharmacodynamic assays confirmed inhibition of the relevant drug targets. PDX cells were sensitised to Ibrutinib (mean G50 15.9 ± µM, range 11.47 µM-18.3 µM) and CAL-101 (3 out of 15 patient samples <2.5 µM). Pre-BCR positive ALL cell lines and PDX cells were sensitive to R406 and Dasatinib, with a Ph+ PDX confirming sensitivity to the latter. Combining TKIs with the glucocorticoid (GC), Dexamethasone showed synergism in GS resistant cell lines and PDX samples. TKIs were also effective in some Pre-BCR negative ALL cells, however, predictive biomarkers need to be established. Confirmation of these data in preclinical models in vivo may define new therapies for high risk ALLs.

Summary/Conclusions: Significant sensitivity of TKIs targeting Pre-BCR signalling have been identified at clinically achievable concentrations. Dasatinib and R406 sensitivity was associated with Pre-BCR positive ALL and combination with Dexamethasone showed significant synergism in GC resistant cell lines and PDX samples. TKIs were also effective in some Pre-BCR negative ALL cells, however, predictive biomarkers need to be established. Confirmation of these data in preclinical models in vivo may define new therapies for high risk ALLs.

Immunology, University, Children’s Hospital, Medical Faculty, Heinrich Heine University, 2Department of Pediatric Oncology, Hematology and Clin. Immunology, University Children’s Hospital, Medical Faculty, Heinrich Heine University Duesseldorf, 3Department of Diagnostic and Interventional Radiology, Medical Faculty, Heinrich Heine University, 4Clinic of Pediatric Hematology and Oncology, University Medical Centre Hamburg-Eppendorf, Hamburg, 5Department of Pediatrics, University Medical Centre Schleswig-Holstein, Campus Kiel, Kiel, Germany

Background: Cure rates for acute lymphoblastic leukemia (ALL) have increased to ~90% in the last decades, but come at a high cost as a substantial proportion of these children sustain toxic side-effects. Osteonecrosis (ON) is one of the most common and debilitating side effects, which severely impacts quality of life.

Aims: To analyze whether systematic magnetic resonance imaging (MRI) screening of adolescents can identify those with asymptomatic ON (stage I and II), who subsequently develop symptomatic ON.

Methods: Children diagnosed with ALL aged ≥10 years, who were enrolled in the prospective multicenter OPAL (osteonecrosis in pediatric patients with ALL or lymphoblastic lymphoma LBL) trial, were analyzed. Standardized MRI screening of the hips and knees was scheduled at diagnosis and 6, 9, 12, 15, 18 and 24 months into treatment. All patients were assessed according to a standardized case report form recording symptoms and activities of daily living and functional impairments of the hips and knees based on modified Harris Hip and Knee Society scores every 3 months from diagnosis to the end of antileukemic treatment.

Results: Between 03/2013-12/2016, 64 patients (pts) were enrolled, median age at ALL diagnosis was 15 years (range 10-17), median time under evaluation was 11 months (range 0-45). 31 (48.4%) pts were male, 33 (51.6%) female. 61 (95.3%) were diagnosed with ALL, 3 (4.7%) with LBL. 36 (56.2%) pts were treated according to the AEIOU-BFM 2009 trial, 25 (39.1%) pts to the CoALL-08-09 trial and 3 (4.7%) pts were enrolled in the NLL-BFM registry and treated accordingly. Until December 31st, 2016, 2 (3.1%) pts died treatment related, 4 (6.3%) underwent allogeneic stem cell transplantation, and 5 (7.8%) pts each relapsed while under treatment and dropped out for other reasons. Thus, so far, 166 MRIs comprising 644 joints could be evaluated. At initial diagnosis of the leukemia, MRI showed asymmetric osteosclerotic lesions stage II or higher in 3 of 60 pts (5%), at 6 months in 7 of 34 pts (20.6%) osteosclerotic lesions, at 9 months in 14 of 23 pts (60.9%), at 12 months in 14 of 23 pts (60.9%), at 15 months in 3 of 11 pts (27.3%), at 18 months in 2 of 9 pts (22.2%), and at the end of treatment in 2 of 6 pts (33.3%). 11 (17.2%) pts developed ON stage II between 6 and 15 months from diagnosis (median 10 months). Of 23 pts, in whom screening MRI revealed ON stage II or higher, 11 pts (47.8%) subsequently developed symptomatic ON whereas in all adolescents developing symptomatic ON MRI had previously shown signs of ON. Median volumes of epiphyseal necrosis in pts with ON stage II remaining asymptomatic were 0.6 ml (range 0.1-7.2) and in pts developing symptomatic ON 12.5 ml (range 12.0-13.9) in the hips and 2 ml (range 0.4-20.5) and 30.5 ml (range 18.3-57) in the knees respectively. Epiphyseal involvement exceeded 30% in all symptomatic pts, but only in 2 pts remaining asymptomatic. With regard to the distribution pattern of ON, about twice as many knees as hips were affected by ON stage II or higher. MRI revealed ON stage III or higher in at least one joint in 12 pts (20%), predominantly in the knees. Radiological leukemic infiltration of bone detected by single screening MRI at diagnosis did not identify children at high risk of developing symptomatic ON at six months into therapy or symptomatic ON anytime in the course of antileukemic treatment. These findings should be confirmed in larger patient numbers.

Summary/Conclusions: The first analysis of the OPAL trial shows that early MRI screening identifies extensive asymptomatic lesions in adolescents subsequently developing symptomatic ON.
Background: Front-line imatinib (IM) plus chemotherapy followed by alloge
netic hematopoietic stem cell transplantation (HSCT) is standard therapy for patients (pts.) with Ph+ ALL. Relapse after HSCT remains a major cause of treatment failure, and pts. in whom BCR-ABL transcripts are detectable after HSCT are at particular risk. Post-transplant maintenance with low dose tyrosine kinase inhibitors (TKIs) to reduce the relapse rate remains a subject of uncertainty, as data from prospective studies are limited.

Aims: To determine the impact of IM administration after HSCT on patient outcome and to assess the predictive value of minimal residual disease (MRD) analysis by q-RT-PCR of BCR-ABL1 transcripts.

Methods: In this prospective, multicentre trial by the GMALL study group, adult pts. (≥ 18 y) with Ph+ ALL in CR at HSCT were randomly assigned (1:1) to receive IM prophylactically after SCT or pre-emptively upon detection of MRD.

Inclusion criteria included enrollment, sufficient hematopoietic and organ function, and no prior IM or infection. The dose of IM was 600/400 mg in 22% of pts., and 400mg recommended as starting dose. Primary endpoint was molecular or hematologic relapse, secondary endpoints included survival, DFS, severe toxicity and transplant-related mortality. All pts. were followed by frequent serial MRD analysis after HSCT. An interim analysis was reported previously. We here provide results of the final analysis of this trial, with long-term follow-up of up to 11 years after HSCT.

Results: 74 pts. were evaluable, 36 received prophylactic and 38 pts. pre-emptive IM. Median age was 41 y (18-89) and 44 y (19-68), respectively. Disease status at HSCT was CR1 (n=67), CR2 (n=5), CR3 (n=1), unknown (n=1). Most pts. received a PBSC graft (n=71) and myeloablative TBI-based conditioning (n=65), 8 pts. underwent RIC with 2Gy or 4Gy TBI (n=6) or non-TBI RIC (n=2).

Median time from HSCT to starting IM was 48d and 77d, respectively. IM dose was 600/400mg in 22% of pts., remaining pts. received 400mg. Treatment was prematurely discontinued in 56% and 59% of pts., median time to discontinuation was 575d and 594d, respectively. Target dose of 600mg (10%). Rates of G3/4 AEs and SAEs decreased substantially >8 wk post infusion. CRS was managed with supportive care, and embolic infectious stroke (n=1) (both ≤30 days); and infection (n=3, >30 days). Safety events were similar across pt subgroups based on age, sex, prior ALL, and embolic infectious stroke (n=1) (both ≤30 days); and infection (n=3, >30 days). Safety events were similar across pt subgroups based on age, sex, prior ALL, and embolic infectious stroke (n=1) (both ≤30 days); and infection (n=3, >30 days).

Summary/Conclusions: Post-HSCT intervention with prophylactic or pre-emptive IM is associated with a low relapse risk and excellent long-term survival and might be considered standard of care in Ph+ ALL pts. undergoing HSCT. BCR-ABL1 transcript levels prior to and early after SCT are predictive of outcome and identify a small subset of patients unlikely to benefit, emphasizing the need for rigorous MRD monitoring. The identified MRD thresholds should be validated in an independent dataset. Their applicability in the setting of RIC transplantation or 2nd/3rd G TKI remain to be determined.

P517
ANALYSIS OF SAFETY DATA FROM 2 MULTICENTER TRIALS OF CTL019 IN PEDIATRIC AND YOUNG ADULT PATIENTS WITH RELAPSED/ REFRACTORY (R/R) B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA (B-ALL)

Background: The CD19-targeted chimeric antigen receptor (CAR) T-cell ther-
apy CTL019, an investigational therapy that uses reprogrammed cytotoxic T cells to recognize and eliminate target cells, has shown high response rates in clinical trials for pediatric/young adult R/R B-ALL. The safety profile in this population has been limited to a single-center trial. This study serves to identify any new safety issues with CTL019 emerging from use in multicenter trials.

Methods: Pooled data from 2 single-arm, multicenter phase 2 trials of CTL019 therapy in pediatric/young adult patients (pts) with R/R B-ALL (NCT024353849 and NCT02228096) were used to further characterize the safety of CTL019.

Table 1.

Results: 123 pts were enrolled, 26 were not infused and not included in this analysis (10 deaths, 9 manufacturing failures, 3 adverse events [AEs], 4 pts premedication failure). 97 pts received a single infusion of transduced CTL019 cells (median dose, 3.2×10^6 [range, 0.2-5.4×10^6] cells/kg). Median age was 12y (range, 3-25). During the first 8 wk after infusion, 98% of pts experienced at least 1 AE (57% G1, 32% G2, 9% G3, 0% G4). The most common AEs were decreased appetite (21%), increased AST (19%) and ALT (12%), hypoxia (16%), hypokalemia (13%), hypophosphatemia (11%), and pulmonary edema (10%). Rates of G3/4 AEs and SAEs decreased substantially >8 wk post infu-
sion to 24% and 12%, respectively. 10 pts died post infusion, 16 (10%) from B-ALL (n=2, ≤30 days after infusion; n=14, >30 days); cerebral hemorrhage (n=1) and embolic infectious stroke (n=1) (both ≤30 days); and infection (n=3, >30 days).

Safety events were similar across pt subgroups based on age, sex, prior ALL, and embolic infectious stroke (n=1) (both ≤30 days); and infection (n=3, >30 days).

Conclusions: The incidence of CRS was greater than expected based on historical experience and the CRIS registry. Treatment with this investigational therapy was well tolerated across all pt subgroups.

Table 1.
twice as likely to develop G3/4 CRS than pts with <50% BM blasts (n=29) (63% vs 24%). Earlier-onset fever correlated with severity of CRS. CRS grade correlated with serum IL-6 levels. CRS-associated coagulopathy with fibrinogen levels <1.0 g/L was observed in 10% of pts. Neuropsychiatric AEs occurred during or shortly after CRS resolution, were self-limiting, and were more likely in pts with severe CRS or history of CNS leukemia or other CNS diseases. No G4 neuropsychiatric events were observed. Other AEs of special interest within the first 8 wk included G3/4 neutropenia with high (>38.3°C) fever (61%) and infections (G3/4, 22%). Prolonged G3/4 neutropenia (not resolved >28 days) occurred in 59 pts (61%). 36% of pts with prolonged G3/4 neutropenia had G3/4 infections after day 28. One pt with prior alloSCT was diagnosed with unconfirmed gut GVHD. Responding pts developed prolonged B-cell aplasia that was managed with immunoglobulin replacement. Tumor lysis syndrome was uncommon (3%).

Summary/Conclusions: This pooled analysis of global experience with CTL019 across 25 sites and 11 countries found no new safety issues. CRS and neuropsychiatric events, which are class effects of CAR T-cell therapy, were effectively managed. CTL019 appears similarly safe in pts with Down syndrome or prior alloSCT and across age groups. Prolonged follow-up will be required to determine the long-term safety of B-cell aplasia.

**Results:**

- Ponatinib is a third-generation pan-BCR-ABL inhibitor that is effective in Philadelphia chromosome-positive (Ph+) acute lymphoblastic leukemia (ALL) and overcomes the T315I gatekeeper mutation.
- Aims: We designed a phase II trial to evaluate the efficacy and safety of hyper-CVAD plus ponatinib in adults with newly diagnosed Ph+ ALL.
- Methods: Adults with newly diagnosed Ph+ ALL received 8 cycles of hyper-CVAD alternating with high dose MTX/Ara-C every 21-28 days, as permitted by peripheral count recovery. Patients (pts) who were refractory to 1-2 cycles of hyper-CVAD (CD20 expression was retested) with or without other TKIs were still eligible. Ponatinib was given at 45mg daily on days 1-14 of cycle 1. Initially, pts then received ponatinib 45mg daily continuously beginning with cycle 2. Due to concern for potential cardiovascular toxicity with ponatinib, after 39 pts had been treated, the protocol was amended so that, beginning in cycle 2, pts in CR received ponatinib at a dose of 30mg daily and pts in complete molecular response (CMR) received 15mg daily. Rituximab was given during the first 4 cycles in pts with CD20 expression ≥20%; all pts received IT chemotherapy prophylaxis with the first 4 cycles. Pts in CR after 8 cycles of hyper-CVAD received maintenance with ponatinib, vincristine, and prednisone for 2 years followed by indefinite daily ponatinib.
- Results: To date, 64 pts have been treated; 63 pts have received prior treatment at the time of enrollment, 8 of whom were in CR and 2 of whom were not in CR. Median age was 48 years (range, 21-80 years); 23 pts (36%) were positive for CD20 expression. BCR-ABL1 transcript was p190 in 45 pts (70%), p210 in 18 (28%) and unknown in 1 (2%). Of 56 pts not in CR at the time of study enrollment, 100% achieved CR; all but 1 pt achieved CR after the first cycle. The complete cytogenetic response rate was 98%, major molecular response (MRM) rate was 97% and CMR rate was 77%. The median time to MMR was 3 weeks (range, 2-14 weeks), and the median time to CMR was 10 weeks (range, 2-96 weeks). The median follow-up was 33 months (range, 2-62 months), and median number of cycles received was 6 (range, 2-8 cycles). 10 pts (16%) underwent allogeneic stem cell transplantation (ASCT) in first remission. Overall, 8 pts have relapsed (3 while still on ponatinib, 3 while on another TKI, 1 while not receiving a TKI, and 1 after ASCT). 14 pts have died, 8 of whom were in CR. Two deaths were attributed to ponatinib (both from MI while in CR). 38 pts are still receiving treatment (consolidation, n=7; maintenance, n=14; post-maintenance TKI, n=17). The 3-year continuous CR and OS rates were 79% and 76%, respectively. In a 4-month landmark analysis to assess the impact of ASCT, continued CR and OS did not differ according to whether ASCT was performed in first remission. Treatment was overall well-tolerated. Myelosuppression was as expected in a CVAD-based regimen: median times to ANC and platelet recovery in cycle 1 of 22 days (range, 17-35 days) and 18 days (range, 13-29 days), respectively. In cycles 2-8, the median times to platelet and ANC recovery were 22 days and 16 days, respectively. Grade ≥3 adverse events included pancreatitis in 12 pts (19%), hypertension in 8 (13%), thrombotic events in 4 (8%) and MI in 3 (5%). No grade ≥3 cardiovascular events have occurred after 48 weeks of treatment with ponatinib.

**Summary/Conclusions:** Hyper-CVAD plus ponatinib is effective in patients with newly diagnosed Ph+ ALL, resulting in a CMR rate of 77% and encouraging long-term survival.
A PHASE II STUDY WITH A SEQUENTIAL CLOFARABINE-CYCLOPHOS- PHAMIDE COMBINATION schedULe FOR SALVATION TREATMENT FOR REFRACTORY AND RELAPSed ACUTE LYMPHOBLASTIC LEUKEMIA (R/R) IN ADULT PatIENTS

Summary/Conclusions: Blinatumomab showed antileukemia activity in pediatric and adolescent patients with high-risk relapsed/refractory B-precursor ALL including t(17;19) and AEs were consistent with those previously reported for relapsed/refractory ALL.

Table 1.

Within the first two cycles

**Method:** Open-label, single-arm, multicenter, single-institution, global, phase IIa study for pediatric and adolescent patients with relapsed/refractory B-precursor ALL. Eligible patients (aged >28 days to <18 years) had ≥5% blasts and marrow blast percentage were 5.67% (range 1.5-25.1%), 82 patients were enrolled. Median patient age was 38.7 years (range 20.5-59.6), 15 were male, 4 with T- and 23 B-precursor ALL, 2 refractory and 25 relapsed (after a median of 5.9 months, range 1.9-23.4), 5/11 evaluable with high-risk cytoge- netics [2 complex; 2 t(4;11), 1 MLL-rearranged]. Median white blood cells and marrow blast percentage were 5.67% (range 1-55) and 73% (range 8-100), respec- tively. All but one patient (treatment interruption due to traumatic fall) received CY-CLO as planned. Nine patients achieved CR and 7 CRi after course 1 (over- all response 92.2%; 6/10 in study stage one), 2 had a partial response, 5 refractory, 3 died early and one survived with pancytopenic marrow. In relapsed patients, only the length of prior remission affected the probability of CR, from 24.4% (n=18) to 50% (n=6) if ≤ or >12 months, respectively (P=0.02). In 10 evaluable patients, median post-induction MRD was 0.01% (<0.001% in 3). Six CR patients received a second course, which was curtailed in 2 due to tox- icity, and 10 responders had an allogeneic SCT when possible.

**Background:** Blinatumomab, a bispecific T-cell engager antibody construct, has shown antileukemia activity and tolerability in patients with relapsed/refrac- tory B-precursor acute lymphoblastic leukemia (ALL).

**Aims:** We further evaluated safety and efficacy of blinatumomab in pediatric and adolescent patients with relapsed/refractory B-precursor ALL enrolled in an expanded access study (NCT02187354).

**Methods:** Eligible patients (aged >28 days to <18 years) had ≥5% blasts and relapsed/refractory B-precursor ALL (refractory to prior treatments, second or later relapse, or relapse after allogeneic hematopoietic stem cell transplantation [alloSCT]). Blinatumomab was dosed by continuous intravenous infusion (4 weeks on/2 weeks off) for up to five cycles (≥5 <25% blasts: 15µg/m²/day; ≥25% blasts: 5µg/m²/day on days 1-7 in cycle 1, then 15 µg/m²/day). The primary endpoint was incidence of treatment-emergent (TE) and treatment-related (TR) adverse events (AEs). Key efficacy endpoints were complete response and minimal residual disease (MRD, measured by polymerase chain reaction or flow cytometry) response within the first two cycles, relapse-free survival, overall survival, and incidence of alloSCT.

**Results:** Among the first 40 treated patients (median age, 9 [range, 1–17] years), 24 (60%) had experienced ≥2 relapses, 20 (50%) had relapsed after alloSCT, and 5 (13%) were primary refractory; 18 (45%) had ≥50% blasts and 21 (53%) had prior alloSCT. Safety and key efficacy outcomes are shown in the table. Twenty-five patients (63%) achieved a complete response within the first two cycles; 19 of whom had an MRD response. Eight patients relapsed and 20 died after treatment. Regardless of causality, the most frequent TEAEs were pyrexia (78%), cytokine release syndrome (CRS; 23%), vomiting (23%), and anemia (20%). All nine CRS events were grade 1 or 2, and one tumor lysis syndrome was grade 3. Ten (25%) patients interrupted treatment and two (5%) discontinued due to TRAEs; 13 (33%) patients had grade ≥3 TRAEs, including two of three neurologic events (depressed level of consciousness and headache; both grade 3). Two patients experienced fatal AEs, both of which were considered unrelated to blinatumab.
Results: As of Nov 1, 2016, 11 pts were enrolled, and 10 were treated with KTE-C19. One pt had a serious adverse event prior to dosing and was not treated. KTE-C19 was successfully manufactured in a centralized facility for all pts across a broad range of baseline absolute lymphocyte counts in 6 days, with a turnaround time of 2–5 days. Of the 10 treated pts, 9 had high BM disease burden (median, 81% bone marrow lymphoblasts). No pt (0/3) experienced a DLT at the 2 × 10^6 dose, and phase 1 was then expanded to 6 pts at the 2 × 10^6 dose. One pt experienced a grade 5 adverse event of multi-organ failure due to cytokine release syndrome (CRS), and subsequent pts (n=4) received 1 or 2 × 10^6 CAR T cells/kg after conditioning with cyclophosphamide and fludarabine. The primary endpoint of phase 1 was incidence of dose-limiting toxicity (DLT). Secondary endpoints were efficacy outcomes of KTE-C19, including complete response (CR) rates and biomarker associations.

Response: As of Nov 1, 2016, 11 pts were enrolled, and 10 were treated with KTE-C19. One pt had a serious adverse event prior to dosing and was not treated. Summary/Conclusions: In this study, blinatumomab showed an AE profile consistent with that previously reported for relapsed/refractory AML, including similar rates of manageable CRS and neurologic events. Exposure-adjusted event rates were generally higher in SOC vs blinatumomab, including for cytopenias and infections.

FACTORS ASSOCIATED WITH STEM CELL TRANSPLANTATION OUTCOMES IN PATIENTS WITH RELAPSED/REFRACTORY ACUTE LYMPHOBLASTIC LEUKEMIA TREATED WITH INOTUZUMAB OZOGAMICIN VERSUS CONVENTIONAL CHEMOTHERAPY

M. Stelljes1,2, J. D. DeAngelis1, P. Kebruela1, G. Gökbuget4, H. M. Kantarjian1, A. Advani2, A. Merchán3, T. Wang,3 F. Loberiza1, B. Sleight4, E. Vandendriess4, D. I. Right1,2,10

1University of Münster, Münster, Germany, 2Dana-Farber Cancer Institute, Boston, 3MD Anderson Cancer Center, Houston, United States, 4Goethe University, Frankfurt, Germany, 5Cleveland Clinic, Cleveland, 6University of Southern California, Los Angeles, 7Pfizer Inc, Groton, 8Pfizer Inc, New York, 9Pfizer Inc, Cambridge, United States, 10University Hospitals Bristol NHS Foundation Trust, Bristol, United Kingdom

Background: Inotuzumab ozogamicin (InO) therapy in relapsed/refractory acute lymphoblastic leukemia (R/R ALL) resulted in superior complete remission (CR)/CR with incomplete hematologic recovery (CRi) rates versus (v) conventional chemotherapy (C) in the Phase 3 INO-VATE trial (NCT01564784; Kantarjian NEJM 2016 [data as of October 2, 2014]. More InO v C patients (pts) proceeded to hematopoietic stem cell transplantation (HSCT); 41% [45/109] v 11% [12/109]; P<0.001).

Aims: To assess factors associated with outcomes after allogeneic HSCT in patients with R/R ALL who were previously treated with InO.

Methods: Full details have been published. Informed consent was obtained from all patients. Multivariate analyses (MVA) using Cox regression modeling were conducted to determine predictors of non-relapse mortality (NRM) and overall survival (OS).

Results: As of March 8, 2016, 108,326 pts underwent allogeneic HSCT (InO n=77; C n=31). Baseline characteristics were generally similar, except baseline platelet values were lower in InO v C pts. More InO v C pts achieved minimal residual disease negativity during study therapy (MRD<0.1% [best status]; 71% v 26%; P<0.0001). Less InO v C pts received additional therapy before HSCT (14% v 55%, P<0.0001). NRM rates were higher in InO v C pts at 1 year (yr); 36% [95% CI 26–47] v 20% [8–36] and 2 yrs (39% [27–51] v 31% [13–51]), but relapse rates were lower (1 yr, 23% [15–33] v 29% [13–48]; 2 yrs, 33% [22–44] v 46% [24–65]). No significant difference in post-HSCT survival was detected in InO v C pts; however, visual inspection of the curve suggested the survival probability varied before and after 15 months post-HSCT (1 yr, 44% [95% CI 33–55] v 65% [44–79]; 2 yr, 39% [28–50] v 34% [15–54]). Fatal veno-occlusive disease (VOD) was observed in 5 InO pts (during the first 100 days from the date of HSCT) and no C pts. MVA showed that conditioning regimens without dual alkylators and thiopeta were associated (2-sided; P<0.05) with lower risk of NRM and post-HSCT survival, respectively.

Summary/Conclusions: Compared with C, InO permitted more pts with R/R ALL to proceed to HSCT in CR/CRi with MRD<0.1% (best status). Despite increased NRM and fatal VOD, long-term survival was attainable in InO pts. In pts previously treated with InO, interventions to reduce NRM and improve OS after HSCT include avoiding dual alkylator conditioning regimens, especially those containing thiopeta.
Aims: This work examines how ENL influences PRC1 repressive activity. Methods: The effect of ENL on transcriptional activity of model promoters and endogenous transcriptional control elements was studied by biochemical and molecular biology methods. Results: Here we demonstrate that ENL overcomes polycomb induced silencing through recruitment of polymerase associated factor 1 (PAF1) a chromatin remodeler. We observed an intrinsic ability to bind PAF1 and further showed that the ability of ENL to neutralize polycomb-mediated repression in an elongation reporter system and also during transformation of primary cells by MLL-ENL in vivo. Inactivation of polycomb by ENL was accompanied by ubiquitination of histone H2B, the hallmark activity of PAF1 allied enzymes. On a global scale we performed recent RNA-Seq demonstrated that MLL-ENL target genes stood out with a supraphysiological accumulation of H2BUB accompanied by hyper-accelerated transcription rates. Interestingly, examination of Wilms tumor specific ENL mutants allowed to elucidate the underlying mechanism of the MLL-fusion induced ENL hyperactivity. Introduction of Wilms-specific ENL into primary hematopoietic cells induced aberrant transcription and H2BUB modification of Hox9a and Meis1, two sentinel loci for polycomb action. This was dependent on the conserved YEATS domain of ENL that operated as “switch” binding either histone H3 or PAF1 thus effectively regulating ENL function as anti-repressor or elongator factor, respectively. Wilms tumor specific ENL interaction with PAF1 and thus perturbed proper silencing. This effect was intensified in an MLL-ENL fusion where MLL itself provided a constitutive tether to PAF1 effectively creating a “super-transcription factor” that constitutively combined anti-repression with elongation capabilities. Summary/Conclusions: In summary, targeting histone ubiquitination may be an additional Achilles heel for mixed lineage leukemia that merits further investigation of therapeutic utility.

Background: Although numerous genetic mutations contribute to the etiology and pathophysiology of acute myeloid leukemia (AML), the molecular machinery that is not mutated but supports AML biology remains largely unknown. Several studies have shown that AML cells, irrespective of genetic sub-type, display an oxidized intracellular redox environment compared to their healthy counterparts. The redox environment of AML cells is largely due to the elevated reactive oxygen species (ROS) levels, which are a class of free radical molecules. Though ROS are by-products of several cellular processes, in excess, they can damage DNA and destroy organelles, resulting in the acceleration of genetic mutations or cell death. As a result, ROS homeostasis is tightly regulated by an array of molecular pathways. Although ROS is elevated in AML cells, the role of ROS and the identity of its regulators remain largely unknown. Here we report that the serine/threonine kinase, PKCg regulates the ROS-neutralizing enzyme SOD2 to support mitochondrial redox homeostasis and AML progression.

Aims: The goal of this study was to identify and subsequently assess how targeting key ROS-regulatory pathways impacts AML biology. Methods: Loss-of-function studies for PKCg and SOD2 were performed with recombinant lentiviruses expressing gene-targeting shRNAs. Recombinant retroviruses expressing either PKCg or SOD2/Catalase were used for gain-of-function assays. Cytosolic and mitochondrial redox states were measured using redox-sensitive GFP (roGFP) probes followed by flow cytometric analysis. Mitochondrial superoxides were also assessed by flow cytometric analysis of MitoSox stained cells. Proteomic analysis was achieved using nano LC-MS/MS. Annexin-V staining was analyzed by flow cytometry to measure cell death and in vitro migration assays were performed using transwell chambers. FACs-based purification of sRNA-expressing cells followed either by: 1) growth in cytokine-enriched media or 2) transfection into syngeneic mice for survival analysis.

Results: We have discovered that inhibition of PKCg: 1) promoted the death of AML cell lines in vitro, 2) reduced AML cell proliferation driven by MLL-AF9 in vivo (p=0.0014) and 3) obstructed the growth of 5 out of 7 PD-AML samples in vitro. At the molecular level, we observed that PKCg inhibition led to a significant and dose-dependent increase in mitochondrial-produced superoxides—a specific type of ROS. Moreover, we found that enforced expression of PKCg can protect AML cells from lethal effects of superoxide-inducing agents 2-thiophenyltrifluoroacetone and Antimycin A. To identify potential ROS-regulatory enzymes downstream of PKCg, we performed whole cell proteomics and found that the mitochondrial superoxide-neutralizing enzyme SOD2 is decreased in AML cells depleted of PKCg. Similar to PKCg inhibition, we also observed enhanced genetic inhibition of SOD2 reduced the expansion of AML cell lines and PD-AMLs in vitro as well as significantly extended the onset of MLL-AF9-driven AML in vivo (p=0.0042). Finally, we also found that enforced expression of SOD2 in tandem with another anti-oxidant enzyme Catalase, reverses the anti-leukemia effects of PKCg inhibition confirming that PKCg supports AML pathophysiology by maintaining mitochondrial redox homeostasis.

Summary/Conclusions: Our results indicate that PKCg and SOD2 regulate mitochondrial redox homeostasis to support AML cell survival and disease progression and thus may represent a foundation for designing and developing novel therapeutic strategies.

ROLE OF SHP2 IN A MOUSE MODEL OF AML CARRYING FLT3-ITD ALONG WITH LOSS OF TET2

R. Pandey1, B. Ramdas1, R. Chan1, R. Kapur1

1Indiana University School of Medicine, Indianapolis, United States

Background: SHP2, a protein tyrosine phosphatase coded by Ptnp11, is an essential protein that integrates signals from several different tyrosine kinase receptors with the major intracellular signaling pathways such as ERK, PI3K and STAT pathways and regulates cell survival, proliferation and differentiation.

One of the SHP2 dependent cytokine receptor kinase, FLT3 when mutated to be constitutively activated co-operates with other genetic lesions like loss of Tet2 and Dnmt3a leading to transformation of myeloproliferative neoplasm (MPN) to acute myeloid leukemia (AML) in mouse models. Tet2 and Dnmt3a are involved in regulation hematopoietic stem cell (HSC) self-renewal and differentiation programs through regulation of DNA methylation. One of their own each of them leads to MPN but when present in combination, leads to AML. These mouse models of AML have a more pronounced stem cell phenotype compared to traditional chimeric AML or FLT3 targeted kinase inhibitors.

Aims: Inhibition of SHP2 catalytic activity by a small molecule allosteric inhibitor has been recently demonstrated to retard the growth of receptor tyrosine kinase driven malignancies. Therefore, we wanted to investigate the role of SHP2 in leukemogenesis driven by loss of an epigenetic regulator (Tet2) and aberrant cytokine receptor tyrosine kinase (Flt3-ITD) signaling.

Methods: Mice were intercrossed to generate Ptnp11F/FTet2F/Flt3ITD/+Mx1Cre+ or Ptnp11F/FTet2F/Flt3ITD/+Mx1Cre- mice. Deletion of Ptnp11 was induced at 8-10 week of age by injecting poly IC and changes in the hematopoietic compartment were analyzed by flow cytometry. Cell autonomous and non-autonomous effects of Ptnp11 on leukemia were also evaluated in transplantation models.

Results: After ploy IC induced deletion of Ptnp11 there was a significant difference in the median survival between leukemic mice with with deletion of Ptnp11 versus non-deleted (n=8). Though the Ptnp11 deleted leukemic mice showed almost complete loss of long term HSC and concomitant increase in short term proliferating HSC in the bone marrow, they were still able to home and engraft in lethally irradiated recipient mice. These results indicate that loss of Ptnp11 does not impair the engraftment of leukemic stem cells though in normal mice deletion of Ptnp11 impaired the ability to stem cells to home to bone marrow niche and engraft. Deletion of Ptnp11 in both primary mice and secondary recipients was also associated with deregulation of myeloid and lymphoid cell distribution both in the periphery and bone marrow. Mice with deletion of Ptnp11 in the context of Flt3ITD did not generate immature or mature B cells. The effects of Ptnp11 deletion were more severe in in vivo mice as compared to mice that received Ptnp11 deleted cells or when Ptnp11 was deleted after transplantation suggesting a role for SHP2 function in the bone marrow microenvironment in this model of leukemogenesis.

Summary/Conclusions: SHP2 has been recognized as a proto-oncogene once observed that the ability to induce hematopoietic malignancies when it is constitutively active and loss of SHP2 catalytic activity is associated with inhibition of tyrosine kinase driven malignancies. Our results demonstrate that the role of SHP2 in AML is dependent upon the presence of other genetic mutations. SHP2 regulates AML with loss of Tet2 with concomitant expression of Flt3-ITD through influence on both leukemic cells and the bone marrow microenvironment.

CLUSTER REGULATION OF RUNX FAMILY BY “GENE SWITCH” TRIGGERS A PROFOUND TUMOR REPRESSION OF DIVERSE ORIGINS

K. Morita1, K. Suzuki1, S. Maeda1, A. Matsuo1, Y. Mitsuda1, A. Yano1

1Department of Cell Technology and Experimental Medicine (HI-STEM) and German Cancer Research Center (DKFZ), Heidelberg, Germany, 2Department of Hematology, The Ohio State University, Columbus, United States
gene mutations and the sensitivity of leukemic cells to kinase inhibition depends in inhibitors remains poorly defined and these have not been translated into effective treatment of AML, the high recurrence of activating mutations in kinases and other oncogenes in AML is a major challenge. The success of kinase inhibitors in leukemia treatment is based on their ability to irreversibly block the RUNX cluster expression profiling through disrupting protein-DNA interactions sequence-specifically (CRoX-1).

Results: Firstly, shRNA-mediated silencing of RUNX1 stimulated cell cycle arrest at G0/G1 phase and induced apoptosis in AML cells bearing wild-type RUNX1. Analysis of these residual AML cells revealed that RUNX1 depletion induced remarkable induction of p53 as well as its target gene products and additive knockdown of p53 in these cell lines revert the phenotype of RUNX1-depletion, indicating that RUNX1 is functionally dependent upon p53 pathway. In addition, cycloheximide chase assay revealed that RUNX1 negatively regulates the protein stability of p53 in AML cells. In silico data analysis and ChIP-seq experiments together with series of knockdown and restore experiments identified BCL11A and TRIM24 as critical mediators of p53 pathway activation in RUNX1-inhibited AML cells. Though RUNX1-depleted AML cells exhibited drastically slowed proliferation rate, a small sub-population of leukemia cells retained the proliferation potential even in the absence of silencing of RUNX1. Analysis of these residual AML cells revealed the reciprocal up-regulation of RUNX2 and RUNX3 expressions, suggesting that RUNX2 and RUNX3 might compensate for the loss of RUNX1 functions. As expected, additional knockdown of RUNX2 and RUNX3 in RUNX1-depleted AML cells effectively suppressed their proliferations. Thus the simultaneous targeting of all RUNX cluster members as a cluster provides more stringent control of leukemia cells. Finally, we examined the antitumor potency of CRoX-1-mediated cluster regulations of RUNX. CRoX-1 treatment was indeed highly effective against leukemia as well as dismal-prognostic solid tumors arising from diverse origins in vivo. Moreover, this reagent was exceptionally well-tolerated in mice and exhibited excellent efficacy against xenograft mice models of AML, acute lymphoblastic leukemia, lung and gastric cancers, extending their overall survival periods in vivo. Since RUNX families take part in diverse physiological functions not only in AML cells but also in normal hematopoietic cells and in various other vital organ tissues, we might expect criticisms in targeting whole RUNX family that it could trigger undesirable side-effects in vivo. Intriguingly, however, our drug was well-tolerated in vivo and through these experiments, we have coincidentally found that the amount of total RUNX expressions was consistently higher in malignant tissues compared to their normal counterparts, and we believe that this gap offers pharmacological window to be targeted in the maintenance and progression of cancer and the indicated gene switch technology-dependent its modulation would be a novel strategy to control malignancies.

Figure 1.

Methods: In this investigation, we used a multimodal approach to stratify 36 AML biopsies as a function of their cellular sensitivity to "ex vivo" treatment with TAK-715, silmitasertib, PF03758309, midostaurin and trametinib, which target P38, ATR, AKT, PAK, PKC, and MEK and ERK, respectively. The same samples were analysed using different omics platforms: (i) mass spectrometry for phosphoproteomics, proteomics and kinomic profiling, (ii) mass cytometry for immunophenotyping and (iii) next generation sequencing for mutational profiling.

Results: Our integrative analysis identified two independent signatures that stratified our cohort of patients in sets of differentiated and undifferentiated cases. The phosphoproteomics signature divided our set of AML cases in the M1-like and M4-like groups (Figure 1A). The mass cytometry signature, which represented myelomonocytic markers that were co-expressed at the cell surface, split our cohort of patient in the CD8+ and CD4+ groups. Remarkably, the M4-like and CD8+ groups representing the differentiated cases, as well as the M1-like and CD4+ groups representing the non-differentiated cases, showed a high degree of overlap. Differentiated groups over-phosphorylated 3 times as many proteins as the non-differentiated groups, including kinases at sites linked to their activity. Mutations in genes involved in kinase signalling were also more frequent in differentiated cases. Kinase activity analysis using KSEA estimated that differentiated groups presented an enriched activity for PAK, MEK, ERK or PKC. Ontology analysis showed that non-differentiated cells over-phosphorylated nuclear proteins with DNA binding properties, while the differentiated cells increased the phosphorylation of membrane and cytoplasmic proteins linked to the small GTPase signalling. More interestingly, cases in differentiated groups were more sensitive to PF03758309, trametinib and midostaurin than those in the non-differentiated sets (Figure 1B for groups defined by the phosphoproteomics signature). Finally, differentiated cases as defined by the mass cytometry signature in our cohort of patients, or by a CD marker mRNA expression signature in the ATCG database, presented with significantly reduced survival when compared to the groups of non-differentiated cases.

Summary/Conclusions: Our data indicate that differentiated cells activate pro-survival kinases like PAK, PKCD or MEK which make them more sensitive to the inhibitors PF03758309, midostaurin or the FDA-approved drug trametinib. Since patients with differentiated cells present a reduced overall survival, treatment with these compounds may benefit patients in this higher risk group.

Figure 1.
Background: Based on the prognostic significance, as well as the association with certain biological and clinical features, acute myeloid leukemia (AML) with biallelic mutations in the CCAATenhancer-binding protein-alpha (CEBPA) gene has been included as a distinct entity into the 2016 revision to the World Health Organization classification of myeloid neoplasms and acute leukemia. CEBPA mutations (CEBPAmut) are observed in AML with normal karyotypes, and approximately 60% of the mutated patients (pts) carry biallelic mutations. Several studies showed that CEBPAmut occur almost mutually exclusive with regard to other AML associated gene mutations such as NPM1 or FLT3-ITD mutations. Recently, mutations in the tet oncogene family member 2 (TET2mut) were described as a frequent concurrent mutation of CEBPAmut. Both genes are involved in the control of proliferation (CEBPA, TET2) and differentiation (CEBPA) of myeloid progenitors. Preliminary data suggest that pts harboring the CEBPAmut/TET2mut genotype have a significantly worse overall survival (OS).

Aims: To evaluate the frequency and the clinical impact of TET2mut within a large cohort of CEBPAmut AML pts.

Methods: In total 200 AML pts (age 18 to 78 years) with CEBPAmut (n=113) or CEBPA single mutations (CEBPAwsm) (n=87) were analysed for the presence of TET2mut. All pts were enrolled in one of 6 AMLSG treatment trials applying intensive therapy (AMLHD93 n=14; AMLHD98B (NCT00146120) n=53; AML-98A (NCT00151242) n=74; AML-06-04 (NCT00151255) n=25 and AMLSG 12-09 (NCT01180322) n=22). TET2 mutation screening was performed using a DNA-based PCR-assy assay covering exons 3 to 9 followed by Sanger sequencing.

Results: In total we detected 52 TET2mut, 39 of the 200 pts (19.5%); in 16 pts TET2mut co-occurred with CEBPAmut (16/113, 14.2%), 23 pts had concurrent CEBPAwsm (23/87, 26.4%). All TET2mut were heterozygous, with 13 pts having two mutations. The median follow-up of the 200 pts was 76.3 months (95%CI: 68.5–84.2). TET2mut were restricted to the cytogenetic intermediate-risk group (100%), and pts with TET2mut were significantly older than pts with TET2 wild-type (TET2wt) (49y vs 46y, P = 0.001). In addition, TET2mut were more frequent in secondary/therapy-related AML (P = 0.04), and there was a significant association with SRSF2 gene mutations (P = 0.01). With regard to outcome, pts with TET2mut had a significantly shorter event-free (EFS), relapse-free (RFS), and OS compared to TET2wt pts (P < 0.001, P < 0.001 and P < 0.001, respectively). Especially in pts with low-age (60y or younger) and in pts with CEBPAmut (P < 0.001), we found a significant association of TET2mut with older age (49y vs 46y, P = 0.05), and an inferior EFS (P = 0.001), RFS (P = 0.003), and OS (P = 0.07). Finally, we analysed the impact of TET2mut within the subgroup of CEBPAmut pts (n=87). In this subgroup of TET2mut we found to be significantly associated with older age (60y or younger) and with SRSF2 mutations (P = 0.02). Clinically, pts with TET2mut had a shorter RFS (P = 0.02) and OS (P = 0.05), and in trend a shorter EFS (P = 0.09).

Summary/Conclusions: In our study on a large cohort of CEBPAmutAML pts we could confirm the high incidence of concomitant TET2mut (19.5%). Pts with concurrent TET2mut were significantly older and had an inferior outcome.

P534

GF1B–A NOVEL ONCOSUPPRESSOR WHICH RESTRICTS NUMBER OF LEUKEMIC STEM CELLS

A. Thivakaran1, R. Koester2, B. Opalka1, U. Dührsen1, C. Khandanpour1

1-Hematology, University Hospital of Essen, Essen, Germany

Background: Myelodysplastic syndromes (MDS) and acute myeloid leukemia (AML) are hematopoietic disorders, which affect the myeloid lineages of hematopoiesis. Both are characterized by an accumulation of blast cells in the bone marrow (BM) that have the lost the ability to differentiate to mature cells. The proper differentiation of hematopoietic stem cells (HSCs) is regulated by transcription factors. Growth factor independence 1b (GF1B) is a repressing transcription factor regulating quiescence of HSCs and the proper emergence and maturation of erythrocytes and platelets.

Aims: Aim of the study was to identify i) do different level of GF1B influence onset and development of MDS and AML in human patients ii) how does GF1B act in MDS/AML development on a molecular level.

Methods: We correlated GF1B expression level in blast cells of patients with MDS and AML with the overall disease course. To get a better insight how does GF1B influence MDS/AML development we used three different murine models of human AML with expression of different oncogenes (NUP98/HOXD13, MLL-AF9 and expression of a mutated K-Ras). In these models we either downregulated or conditionally knocked out GF1B expression. Finally, we performed ChIP Seq analysis as well as whole genome expression arrays to study the molecular functions of GF1B in AML development.

Results: Low expression or absence of GF1B expression was associated with an inferior outcome with regard to overall-survival as well as event-free survival of MDS/AML patients. Using the above murine models of MDS/AML, loss or low expression of GF1B accelerated AML development. Additionally we could show that GF1B deficiency restricted number of functional hematopoietic stem cells. It is well known that GF1B has a function to recruit histone modifying enzymes to induce among other deacetylation of H3K9. ChIP seq data of GF1B deficient leukemic cells revealed that loss of GF1B led to a higher H3K9 acetylation of a target of target genes, among them a number of oncogenes. Among these target genes, we found MAPK as well as Reactive oxygen species (ROS) signalling, as one of the top hit in our data. Previously it was reported that loss of GF1B enhanced the ROS level in HSCs. In our case we also saw an increased expression of ROS in GF1B deficient leukemic cells, a higher activity of the FOXO pathway as well as reduced p38 activity. The combination of these findings connects the higher number of leukemic stem cells in GF1B deficient leukemic cells. To reduce the high level of ROS in leukemic stem cells we use N-Acetylcystein (NAC). Use of NAC impeded growth of GF1B deficient cells in vitro.

Summary/Conclusions: GF1B act as a tumoursuppressor by restricting number of leukemic stem cells and treatment with NAC opens a potential targeted therapy for AML patients with low/absent expression of GF1B.

VARIANTE ALLELE FREQUENCY KINETICS OF TYROSINE KINASE GENE MUTATIONS IN CORE-BINDING FACTOR ACUTE MYELOID LEUKEMIA AT THE TIME OF DIAGNOSIS AND DURING REMISSION UNDER TREATMENT WITH DASATINIB

1-Department of Medicine, Division of Hematology and Oncology, University Düsseldorf, Düsseldorf, 2-Institute of Cell and Molecular Pathology, Hannover Medical School, Hannover, 3-Department of Oncology and Hematology, Klinikum Oldenburg, Oldenburg, 4-Department of Internal Medicine III, University Hospital of Innsbruck, Innsbruck, Austria, 5-Department of Internal Medicine III, Städtisches Klinikum Karlsruhe, Karlsruhe, 6-Hubertus Wald University Cancer Center, Department of Oncology and Hematology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, 7-Department of Internal Medicine, University Hospital of Innsbruck, Innsbruck, Austria, 8-Nationales Centrum für Tumorerkrankungen, Heidelberg, Germany

Background: Recent next-generation sequencing (NGS) studies have improved our understanding of the genomic landscape of CBF-AML (Faber et al. Nat Genet 2016; Duployez et al. Blood 2016). While these studies have mainly focused on the genetic differences between inv(16) and t(8;21), the clinical architecture of relapsed disease is not well defined. Mutations affecting signaling genes, such as KIT and NRAS are known to be among the most common oncogenic drivers in CBF-AML, however their impact at relapse remains unclear.

Aims: To characterize clonal evolution in paired samples obtained at diagnosis, during remission and at relapse under treatment with dasatinib, and ii) to conduct gene set enrichment analyses.

Methods: Whole-exome-sequencing (WES) was performed in paired diagnosis, remission and relapse samples of 38 patients with CBF-AML (inv(16), n=24; t(8;21), n=12) using paired-end sequencing (read length 100 bp) on an Illumina HiSeq platform. Library preparation was done with the Nextera® Rapid Capture Exome kit following manufacturer’s instructions. All patients were treated within one of five trials of the German-Austrian Study Group (AMLSG). In two of the trials (AMLSG 11-08, NCT00850382; AMLSG 21-13, NCT02013648) patients received intensive chemotherapy in combination with the multi-kinase inhibitor dasatinib.

Results: The mean WES coverage was 133x. Mutations and indels were called with a threshold >10% variant allele frequency (VAF) after filtering for SNPs and sequencing artefacts. In sum, we identified 587 variants in 430 genes. At
diagnosis. 8.9 variants per patient were found as compared to 5.7 at relapse. 52% variants were present at diagnosis, 26% at relapse only, and 22% were present at both, diagnosis and relapse. With regard to the most commonly altered signaling genes KIT and NRAS we found the following pattern: The median VAF at diagnosis was 23% and 26% for KIT and NRAS, respectively. Of note, the initial KIT and NRAS clone was lost (VAF <5%) in 71% (exon 17, n=9; exon 8, n=2; exon 11, n=1) and 100% of cases (exon 2, n=5; exon 3, n=3). Comparing the VAF kinetics between patients treated with and without dasatinib, baseline KIT mutations became subclonal (VAF <5%) in all patients receiving dasatinib (n=8), whereas they were still detectable in 4/6 (67%) patients who were intensively treated without the addition of dasatinib. NRAS became subclonal (n=8) irrespective of the treatment regimen. In one KIT mutant patient treated with dasatinib the baseline KITD185V mutation (exon 17) was lost at the time of relapse, but a KITD192Y mutation (exon 8) was acquired instead. Gene set enrichment analyses revealed different mutation signatures at diagnosis and relapse: At diagnosis, there was a significant enrichment for genes associated with MYC overexpression. Variants that were recurrently present at diagnosis and relapse showed enrichment for genes affected in KRAS overexpression models. Relapse samples were additionally enriched for gene mutations involved in the mitotic spindle assembly.

Summary/Conclusions: Differences in the allelic composition were found between diagnosis and relapse regardless of the CBF-AML subtype. Our data suggest that the KIT clone might be successfully eradicated under dasatinib treatment whereas persistence of KIT mutant clones was more commonly seen under conventional chemotherapy. The frequent loss of KIT and NRAS mutations during therapy suggests that relapse is triggered by alternative genetic lesions. Relapsed disease may represent a distinct biology which is characterized by mutations that cluster in different pathways. Further analyses are ongoing including study cohort expansion, as well as inclusion of RNA sequencing results.

**Acute myeloid leukemia - Biology 4**

**P38 MAPK INTERACTS WITH SET REGULATING ITS INHIBITORY EFFECT ON PP2A ACTIVITY IN ACUTE MYELOID LEUKEMIA**

A. Arriazu1, C. Vicente1, R. Pippa1, N. Marcotequi1, A. Igea2, E. Leon1, S. Chocarro1, M. Soto1, A.R. Nebreda2, M.D. Odero1,3,4

1Oncohematology, Center for applied medical research University of Navarre, Pamplona, 2Institute for Research in Biomedicine, Barcelona, 3Instituto de Investigación Sanitaria de Navarra (IdiSNA), Navarra, 4Department of Biochemistry and Genetics, University of Navarra, Pamplona, Spain

**Background:** Despite improvements in our understanding of the molecular evolution of acute myeloid leukemia (AML), the overall cure rates remain low, and most patients die from the disease despite achieving initial remission upon treatment. It is therefore necessary to open new therapeutic perspectives aimed at molecular targets. PP2A phosphatase inactivation is a recurrent event in hematological tumors. Our group has reported that SET, an endogenous inhibitor of PP2A, is overexpressed in 28% of patients with AML. Furthermore, the antitumor efficacy of PP2A activating drugs (PADs) depends on the interaction/sequestration of SET, pointing out the significance of this oncogene in AML. Drug inhibition of several MAPKs in AML cell lines showed that only p38 inhibitors activate PP2A and decrease SET protein.

**Aims:** Therefore, we hypothesized that p38 could regulate SET at posttranslational level, leading to PP2A inactivation.

**Methods:** AML cell lines and primary human samples were analyzed by western blot, immunoprecipitation, immunofluorescence, treatment with pharmacological inhibitors and siRNAs. Phosphorylation assays by in vitro kinase assay with recombinant proteins were performed.

**Results:** Knockdown of the two major isoforms of p38-MAPK, p38α and p38β, demonstrated that only p38β was able to reduce SET protein levels and increase PP2A activity. To decipher this mechanism of action, we performed protein immunoprecipitation and immunofluorescence in the AML cell lines HL-60 and MOLM-13. p38β co-localized and bound to SET mostly in the cytoplasm stabilizing it, since treatment with cicloheximide in the absence of p38β induced SET degradation. The stabilization role was in coordination with SETBP1, which co-localized with both SET and p38β. Interestingly, 12 out of 14 AML cell lines tested showed high expression of p38β protein levels as well as 5 out of 7 AML primary patient samples. Furthermore, expression analysis in a large series of adult de novo AML cases previously reported (Cancer Genome Atlas Research Network, 2013) showed a positive correlation between p38β (MAPK11) and SET (R²=0.416, p<0.001), but not between p38α and SET. We and others have shown that PADs retain SET in the nucleus. Our results showed that p38 phosphorylates SET not directly, but through the activation of casein kinase 2 (CK2), leading to the retention of SET in the nucleus and, therefore, contributing to the inactivation of PP2A in AML cells. Of note, CK2 is overexpressed in both AML cell lines and patient samples.

**Summary/Conclusions:** p38 is able to activate CK2 which phosphorylates SET and, as consequence, facilitates its trafficking to the cytoplasm, contributing to PP2A inactivation in AML cells. Moreover, p38β binds to SET in the cytoplasm, contributing to its stability and leading to PP2A inactivation. In this regard, we have preliminary evidences that combination therapy with PADs and the CK2 inhibitor CX4945 reduces significantly the viability of AML cells, supporting that novel treatment modalities that can target multiple components of the same pathway may help to achieve a more sustained therapeutic benefit.

Background: Acute erythroid leukemia (AEL) is a unique subtype of acute myeloid leukemia (AML) characterized by the predominance of erythroid components with increased ring sideroblasts as well as frequent myelodysplasia. However, due to its rarity, the molecular pathogenesis of AEL has not been fully elucidated, except for frequent TP53 mutations.

Aims: This study was designed to clarify the mutation profile of AEL distinct from the myelodysplastic/leukemia (MDS/AML) syndrome (MDS).

Methods: We performed a comprehensive genetic study, in which paired tumor/normal DNA from 22 AEL cases were analyzed using whole exome sequencing (WES). Whole-exome sequencing data from 3 AELs generated by The Cancer Genome Atlas (TCGA) was also included in the analysis. Subsequently, a total of 84 AEL cases were screened for mutations in 67 driver genes associated with myeloid malignancies using targeted-capture sequencing, in which RNA baits were also designed for a total of 1158 single nucleotide polymorphism sites to allow for genome wide copy number abnormalities and other allelic imbalances.

Results: Median age at diagnosis was 58.5 (21-87) years old. Among the 77 patients with clinical information available, 62 patients were diagnosed with de novo AML, 13 with secondary AML, and 2 with treatment-related AML. On average, 18.4 ± 3.4 mutations were detected per sample in whole-exome and targeted-capture sequencing in AEL, as compared to 12.2 ± 2.9 mutations (P = 0.014) in other AML, respectively. Both platforms being combined, most frequently observed was TP53 mutations (n=26, 31%) with complex karyotype being accompanied in most cases (25 cases), which were associated with a significantly shorter overall survival (P<0.001). Other frequent mutated genes were those encoding major components of the cohesin complex, including STAG2 (12%), SMC1A (4.8%) and RAD21 (2.4%), which were mutated in as high as 30% of the cases. The splicing machinery (18%) and epigenetic regulators (45%) were also important for MDS/AML, including SRSF2 (12%), U2AF1 (4.8%), WT1 (15%), TET2 (19%) and IDH1/2 (12%). TP53 mutations were mutually exclusive with cohesin mutations (p=0.01) and those in epigenetic co-regulators, while STAG2 were mutually exclusive with double ENY, and IDH1/2. TP53 mutations were mutually exclusive with cohesin mutations (p=0.01) and those in epigenetic co-regulators, while STAG2 were mutually exclusive with double ENY, and IDH1/2.

Summary/Conclusions: TP53-PTD AML carries specific gene expression signatures and specific subsets of concurrent mutations with clinical value.

EXPLORING THE IMPACT OF LOSS OF FUNCTION STAG2 MUTATIONS ON CHROMATIN ARCHITECTURE IN MDS/AML
J. Smith1, K. Savage1, K. Mills1
1Centre for Cancer Research and Cell Biology, Queens University Belfast, Belfast, United Kingdom

Background: The Cohesin complex is an evolutionarily conserved multimeric protein complex, responsible for regulation of genome topology by facilitating the complex plays pivotal roles within mitosis and sister chromatid cohesion however, substantial data exists elucidating roles for the complex within the DNA damage response, homologous recombination and long-range interaction between cis regulatory elements of the genome. Within hematological malignancies, upwards of 20% of patients diagnosed with either Acute Myeloid Leukemia (AML), Myelodysplastic syndrome (MDS) or Myeloproliferative neoplasm (MPN) have been shown to harbour mutations within the Cohesin complex, with many more showing significantly reduced expression of core complex members.

Aims: To explore the impact of a loss of function STAG2 mutation on the chromatin architecture within a isogenic cell based model.

Methods: Using a CRISPR generated isogenic model we have investigated the impact loss of STAG2 has on the chromatin architecture of a hematopoietic environment. Genome wide binding profiles for STAG1, STAG2 and CTCF were generated using ChIP-Seq to elucidate areas of differential between STAG members. In addition, binding profiles for H3K27ac, H3K27me3 and H3K4me1 were generated using ChIP-Seq to provide genome wide identification of active and repressed enhancer regions, with the regions ranked to identify both normal and super-enhancer regions. These samples were matched to ATAC-Seq profiling of open and closed chromatin regions as well as RNA-seq samples to provide information on gene activity in relation to chromatin state in the absence of STAG2.

Results: Our results indicate that STAG1 binding profiles after following loss of function of STAG2, with an increase in binding peaks from ~17,000 to 25,000, however several sites identified by ChIP-Seq are not compensated for. Histogram mark profiling identified wide spread expansion of the H3K27ac mark and a decrease in regions of H3K27me3 consistent with loss of boundaries within topologically associated domains. This spread of an activator mark correlates with altered gene expression and the changes observed in ATAC-seq profiling of altered chromatin accessibility. The open chromatin regions identified through H3K27ac and H3K4me1 were lost in a compressive fashion and the cohesin complex was recruited in a competition factor occupancy. An enrichment for transcription factors relevant for myeloid transcriptional programmes was observed. This increase in enrichment aids in the suggestion that the impact of mutant/alternated cohesin complex function relates directly to the specific cell type and maturation state at which it occurs.

Summary/Conclusions: This research into the aberrant and non-canonical use of the Cohesin complex provides insights into the potential impact of mutant STAG2 on the spatio-temporal genomic architecture in hematological malignancies and begins to yield insight into the clinical implications of mutations within the cohesin complex.
NEXT GENERATION SEQUENCING TECHNIQUES REVEAL MOLECULAR MECHANISMS OF MYB REGULATION AND FUNCTION IN MLL-AF9 LEUKAEMIA

I.-J. Lau1, A. Thomas1, J. Kerry1, L. Godfrey1, C. Nerlov1, P. Vyas1, T. Milne1
1MRC Molecular Haematology Unit, Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, United Kingdom

Background: Mutations involving the MYB gene at 11q23 are found in 10% of adult and 18% of childhood acute myeloid leukaemia (AML) cases. The most frequently occurring MLL mutations are chromosome translocations that fuse the MLL gene in-frame with a second partner gene, creating novel fusion proteins (MLL-FPs). MLL-AF9 is the most common MLL-FP in AML. Despite much progress in the overall management of AML, patients carrying MLL-rearrangements still have a poor survival prognosis and limited response to existing therapy. This is in part due to the low therapeutic indices and narrow therapeutic windows of current chemotherapeutic agents, therefore underscoring the need to develop improved, targeted therapies. MYB is a direct downstream target of MLL-AF9. Recent studies indicate that MLL-AF9 leukemia cells are more affected by MYB knockdown compared to normal hematopoietic stem progenitor cells. This is despite the fact that MYB is known to be essential for the establishment of definitive hematopoiesis. This suggests that a therapeutic window may be achieved through targeting MYB. Therefore, by understanding more about the role of MYB in MLL-AF9 leukaemia and the network it regulates, we may be able to exploit this knowledge to target MYB directly by interfering with its function or indirectly via its downstream targets.

Aims: To understand the molecular function of MYB in MLL-AF9 leukaemia.

Methods: We performed genome-wide MYB, MLL-AF9, H3K27ac, H3K4me3 and H3K4me1 chromatin immunoprecipitation (ChIP-seq) and Assay for Transposase-Accessible Chromatin with high throughput sequencing (ATAC-seq) in two MLL-AF9 leukemia models to identify putative regulatory regions of MYB and those of a direct MYB gene target, BCL2. The chromatin conformation capture (3C) technique, Capture-C (one vs all) was used to further characterize interactions from the MYB promoter. We then performed siRNA knockdown of MYB and assessed the effect of MYB loss on its downstream druggable target BCL2, using RT qPCR, Western blotting and ChIP qPCR.

Results: We identified MLL-AF9 binding to novel putative enhancers of MYB as defined by regions co-bound by H3K27ac, H3K4me1 and marked by open chromatin on ATAC-seq. Furthermore, Capture-C from the MYB promoter identified novel putative enhancer-promoter interacting domains 100-200kb apart that are co-bound by MYB but not MLL-AF9. This suggests long-range autoregulation of MYB. Next, siRNA knockdown of MYB results in loss of MYB binding at the BCL2 promoter and its downstream enhancer by ChIP qPCR. There is a corresponding loss of BCL2 mRNA and protein expression in MYB knocked-down cells compared with control, confirming that BCL2 is directly regulated by MYB.

Summary/Conclusions: We have identified for the first time, regulation of MYB by MLL-AF9 via putative enhancers, and also an autoregulatory role of MYB involving long-range cis-interactions. Furthermore, we confirm that BCL2 is directly regulated by MYB in MLL-AF9 leukaemia, suggesting a molecular rational for using BCL2 inhibitors in MLL-AF9 leukaemia therapy.
We have recently discovered that FLT3-ITD+ AML cells are highly sensitive to the FDA-approved, cannabinoid (THC)-like compound WIN-55,212-2. This cannabinoid displays a selective and potent proapoptotic effect against leukemic cells. Several pathways are involved in this effect, the modification of the sphingolipids pattern playing a main role.

### P543

**CANNABINOIDS DERIVATIVES MODIFY THE PATTERN OF SPHINGOLIPIDS IN ACUTE MYELOID LEUKEMIA CELLS AND PRODUCE A POTENT ANTI-LEUKEMIC EFFECT**

M. Medrano1, O. Lopez1, J.I. Piruat1, J.A. Pérez-Simón1

**Background:** Endocannabinoid system is a set of ligands, receptors and endogenous enzymes which modulate a variety of physiological effects. There are two well-characterized cannabinoid receptors, CB1 (mainly expressed in Central Nervous System) and CB2 (mainly in hematopoietic cells). Here, we tested the effect of the cannabinoid WIN-55 212-2 in acute myeloid leukemia (AML) in vitro and in vivo and studied the molecular signaling pathways involved in this effect, specially the role of sphingolipids. Moreover, we synthesized a new family of twelve cannabinoids that are specific to CB2 receptor.

**Aims:** - Development of new compounds derived from cannabinoids with CB2 selectivity and evaluation of their anti-tumor effect in AML in vitro and in vivo.

To deepen in the knowledge of lipid metabolism in AML.

**Methods:** For the design and synthesis of new cannabinoids, computational techniques of docking, analytical and spectroscopic techniques such as mass spectrometry (MS) were used. To assess the anti-leukemia effect of the different cannabinoids, we analyzed cell viability by MTT and flow cytometry using six biological replicates. To assess the anti-leukemia effect of cannabinoids, we analyzed cell viability by MTT and flow cytometry using six biological replicates. To assess the anti-leukemia effect of cannabinoids, we analyzed cell viability by MTT and flow cytometry using six biological replicates.

**Results:** Palbociclib impaired the viability of murine Baf3 cells with FLT3-ITD+<sup>1</sup> and inhibited the phosphorylation of the downstream proteins p-ERK 1/2, p-AKT, p-P38 and p-JNK. Dual targeting with palbociclib and AURK or AKT inhibitors resulted in synergistic cytotoxicity.

**Summary/Conclusions:** Palbociclib represents a viable therapeutic option for use in treatment of resistant clones in FLT3-ITD+ AML. Inhibitory effects are not only due to cell cycle arrest as by transfection, concomitant with transcriptional activation of CDK6 driven tumor formation in vivo at clinically relevant concentrations. Besides FLT3 itself, which is regulated by CDK6, transcriptional targets of CDK6 in AML included Aurora kinase (AURK) and AKT. Thus, CDK6 inhibition upon AURK and AKT in mutant Baf3 cells, two signalling nodes critical for survival of tumor cells. Dual targeting with palbociclib and AURK or AKT inhibitors resulted in synergistic cytotoxicity.

---

<image2>
with the Papaemmanuil dataset, we observed a weaker correlation for relapses after CT ($r^2=0.69$) and an even more marked deviation for post-transplant relapses ($r^2=0.45$). This difference was mainly explained by the enrichment in both relapse cohorts for FLT3-ITD (25% in diagnoses vs 55% and 48% at relapses after CT and allo-HSCT, $p < 0.01$ for both comparisons) and WT1 mutations (5% vs 25% and 22%, $p < 0.01$ for both comparisons). For 24 cases it was possible to longitudinally compare the mutational profile of AML at diagnosis and relapse in the same patient: we observed higher stability in relapses after CT, with 50% of cases carrying the same pattern of mutations present at diagnosis, whereas at relapses after allo-HSCT changes were more frequent, with 70% of patients displaying new gains or losses.

**Summary/Conclusions:** Taken together, our data evidence that the genomic landscape of AML at relapse can be significantly different from the one documented at diagnosis, suggesting that the selective pressure mediated not only by intensive chemotherapy, but also by the graft-versus-leukemia effect, can be potent drivers of clonal evolution. From the practical standpoint, the pattern of emergence of novel mutations that we documented should be taken into account not only for targeted salvage approaches, but also for the design of post-remission strategies aiming to prevent relapse.

**Acute myeloid leukemia - Clinical 4**

**P546**

**AML patients aged ≥75 years enrolled into AMLCG trials: do genetic alterations impact clinical outcome in very old, intensively treated patients?**

1Laboratory for Leukemia Diagnostics, Department of Internal Medicine III, University of Munich, Munich, 2Institute of Biostatistics and Clinical Research, University of Muenster, Muenster, 3Laboratory for Leukemia Diagnostics, Department of Internal Medicine III; German Cancer Consortium (DKTK), partner site Munich; German Cancer Research Center (DKFZ, Heidelberg), University of Munich, Munich, 4Department of Internal Medicine III, Hospital Leverkusen, Leverkusen, 5Department of Medicine A, Hematology and Oncology, University of Muenster, Muenster, 6Department of Medicine, Hematology, Oncology, Tumor Immunology, Charité University Medicine Berlin, Berlin, 7Department of Oncology and Hematology, Hospital Barmherzige Brüder, Regensburg, Germany

**Background:** Acute myeloid leukemia (AML) is a disease of the elderly (median age at diagnosis ~68 years). The prognosis of elderly patients (pts) is poor. Advanced age often leads to the judgement that pts are unfit for induction chemotherapy, although several trials have revealed a positive impact of intensive induction therapy in terms of sustained remissions and long-term survival in a subset of elderly pts.

**Aims:** We sought to validate existing risk classification systems and identify genetic factors associated with clinical outcomes in very old AML pts who received induction chemotherapy.

**Methods:** We identified 151 AML pts aged ≥75 years who received intensive induction therapy in the AMLCG-1999 trial with suitable material for genetic
analyses. 81% of pts had de novo AML, 15% secondary AML, 3% therapy-related AML and 2% high-risk MDS. Recurrent gene mutations in AML were studied from bone marrow aspirates or peripheral blood using a targeted leukemia genotyping assay covering 68 genes. We analyzed known mutational hotspots or the entire coding sequence of the genes by multiplexed amplicon sequencing (Agilent Technologies, mean target coverage of 460x). We studied associations between recurrent driver genetic mutations and other potential prognostic factors which might influence the clinical outcome.

Results: The median age in the total cohort was 76 years (y) (range: 75-86 y). 44% of pts reached complete remission (CR) and 4% CR with incomplete blood count recovery (CRi). The median overall survival (OS) was 6 months with a 3-year OS of 21% (by SWOG). Accordin,...

Background: We assessed GMI-1271 plus salvage chemotherapy with mitoxantrone, a Phase (Ph) 1 trial in pts with R/R AML escalated GMI-1271 across standard therapy. Patients are enrolled into 6 BST-236 escalating-dose cohorts (0.3-6 g/m²/day), each composed of 3-6 pts. Treatment was administered 1-hour daily infusion for 6 days. 

Methods: A Phase (Ph) 1 trial in pts with R/R AML escalated GMI-1271 across standard therapy. Patients are enrolled into 6 BST-236 escalating-dose cohorts (0.3-6 g/m²/day), each composed of 3-6 pts. Treatment was administered 1-hour daily infusion for 6 days. BST-236 is safe and very well tolerated, enabling delivery of high cytarabine doses to target cells with lower systemic exposure to the free drug and relative sparing of normal tissues. As such, BST-236 may serve as an ideal therapy for leukemia, particularly for delivering high doses of cytarabine to pts who are unfit or older. The aim of this study was to evaluate the safety and optimal dose of BST-236 in refractory/relapsed or newly-diagnosed AML patients unfit for standard induction therapy.

Results: To date, treatment of cohorts 1-5 is completed, with 18 patients treated from it. No neurological or grade >2 typical cytarabine events such as gastrointestinal toxicity, bone marrow suppression, and infections, leading to high treatment-related mortality rates. Hence, while the incidence of AML increases with age, advanced age and comorbidities may preclude the administration of intensive therapy altogether.

Aims: We assessed BMI, lymphocytosis, elevated E-sel and neutrophil to lymphocyte ratio as novel markers for chemotherapy response. In this study, we aimed to determine if BMI, lymphocytosis, elevated E-sel and neutrophil to lymphocyte ratio are novel markers for chemotherapy response.
P549
FEASIBILITY AND BENEFIT OF TARGETED RNA SEQUENCING FOR THE DETECTION OF RECURRENT FUSION TRANSCRIPTS AND THE IDENTIFICATION OF NOVEL FUSION TRANSCRIPTS IN MYELOID MALIGNANCIES

C. Haefele1, N. Nadarajah1, M. Meggendorfer1, A. Stengel1, W. Kern1, T. Fuchs1,1
1MLL Munich Leukemia Laboratory, Munich, Germany

Background: Fusion genes are frequent genetic abnormalities in myeloid malignancies. The impact of the detection of such gene fusions is rising due to an increasing number of drugs targeting them as has been impressively shown for e.g. BCR-ABL1 and PML-RARA. Further, they can be used as biomarkers for disease monitoring.

Aims: Evaluation of targeted RNA sequencing for the detection of recurrent and novel fusion transcripts.

Methods: 102 cases with myeloid malignancies harboring 105 translocations identified by chromosome banding analysis were selected. Recurrent fusion genes had been confirmed by FISH and/or RT-PCR. In cases with suspected novel fusions the rearrangement of one partner gene had been confirmed by FISH. The following recurrent rearrangements identified by standard diagnostic procedures were present: PML-RARA (n=11), RUNX1-RUNX1T1 (n=7), CSF3R-MYH11 (n=3), KMT2A-ELL (n=4), KMT2A-MLLT10 (n=3), KMT2A-MLLT3 (n=3), KMT2A-MLLT4 (n=2), BCR-ABL1 (n=3), NUP98-NSD1 (n=3), DDX3-NUP214 (n=1), and KAT6A-CREBBP (n=1). Further, cases harboring MMSET-KMT2A (14), RUNX1 (n=1), ET1V (n=6), PDGFRB (n=10), RARA (n=2), NPM1 (n=2), and NUP98 (n=1) were included. Targeted RNA sequencing was performed using the TruSight RNA Fusion panel (Illunina, San Diego, CA) consisting of 7690 probes covering 507 genes known to be involved in gene fusions. Library was prepared according to manufacturer’s protocol with ~50ng RNA extracted from fresh/frozen samples. Sequencing was performed on the NextSeq instrument (Illunina) and analysis with the RNA-Seq Alignment App (BaseSpace Sequence Hub) using Star for Alignment and Manta for gene fusion calling with default parameters (illumina).

Results: In 42/45 (93%) cases with a recurrent rearrangement identified by standard diagnostics, RNA sequencing detected the respective fusion transcript. In addition, RNA sequencing was able to identify known and novel fusions in the remaining 57 cases. For KMT2A these were the following partner genes: MLLT1 (n=5), ELL (n=3), ITF2, FLNC, ASXL2, DCP1B, MAML1 and ARHGEF12. Seven different partner genes were identified in RUNX1 translocations: PLAG1 (n=2), PRDM16, MECOM, ZFPM2, MAN1A2, NAM2T, and KIAA1549L. Five different partner genes were identified in ETV6 rearranged cases: ABL1, CCDC126, ERG, FOXO1 and CFLAR-AS1. Most strikingly was the identification of the ETV6-ABL1 fusion, which could not be suspected by cytopathology as the 5 ETV6 FISH signal was located on chromosome 17. In 7107D-PDGFRB rearranged cases the partner genes were identified. These were WDR4, CCDC88C, MPRIP, TNIP1, TFR, NF1 and ZBTB11. Further the following fusions were found: NPM1-RPPO, NPM1-SETBP1, NUP98-ING3, IRF2BP1-PARA, and ZBTB16-RARA. Thus, RNA sequencing identified 39 fusions which standard diagnostics had failed to detect, of which one-third of the partner genes were not identified in the respective cases. Failure to detect gene fusions should initiate improvements in calling algorithms and may also have biological reasons. It was reported that genomic rearrangements of one of the partner genes. Failure to detect gene fusions should initiate improvements in calling algorithms and may also have biological reasons. It was reported that genomic rearrangements of RUNX1 occur, which do not lead to RUNX1 in frame fusion transcripts but to truncation of transcription.

Summary/Conclusions: 1) RNA sequencing was able to detect recurrent gene fusions with high accuracy and to characterize rare gene fusions providing the basis for the design of RT-PCR based assays for monitoring MRD. 2) Targeted RNA sequencing may be a valuable tool in routine diagnostics for patients with rearrangements unresolved by standard techniques. 3) These findings may have consequences for targeted treatment approaches.

3The University of Texas MD Anderson Cancer Center, Texas, United States
4Department of Hematology, The University of Texas MD Anderson Cancer Center, Texas, United States

Background: Mixed phenotype acute leukemia (MPAL) is a rare subgroup of acute leukemia characterized by blasts that show immunophenotypes of both myeloid and lymphoid lineages and therefore not traceable to single lineage of origin. Diagnosis of MPAL is challenging due to the possible discrepancy between immunophenotype and morphology. Clinically, MPAL has poor prognosis and poses therapeutic challenges. Genetic basis of MPAL is not well understood.

Aims: To clarify the underlying pathogenesis of MPAL and provide clue on future personalized therapy in MPAL, we performed comprehensive molecular characterization of adult MPAL.

Methods: We studied 31 patients with adult MPAL (median age 53 years) that met 2008 WHO criteria for lymphoblastic leukemia/lymphoma. Targeted RNA sequencing was performed using the TruSight RNA Fusion panel. Forty-four cases were analyzed by targeted capture exome sequencing of 295 genes that are recurrently mutated in hematologic malignancies (median 393x coverage, N=31), RNA sequencing (N=24), and NGS methylated genomic DNA (median 39x coverage, N=31). Mutational landscape was compared to that of 194 AML, 71 B-ALL, and 6 T-ALL. Cases in which pre-treatment samples were available were analyzed by targeted capture and whole exome sequencing (n=11). RNA sequence analysis was performed using 2000 Exome Plus Assay (Illumina, San Diego, CA) consisting of 7690 probes covering 507 genes known to be involved in gene fusions.

Results: Targeted RNA sequencing revealed the presence of one or more focal recurrent gene fusions in 20 (65%) cases, including KMT2A (n=6), NUP98 (n=4), KMT2A (n=3), MYC (n=2), and NUP214 (n=2). Mutational analysis of myeloid sample revealed that genomic rearrangements of one of the partner genes. Failure to detect gene fusions should initiate improvements in calling algorithms and may also have biological reasons. It was reported that genomic rearrangements of RUNX1 occur, which do not lead to RUNX1 in frame fusion transcripts but to truncation of transcription.

Summary/Conclusions: 1) RNA sequencing was able to detect recurrent gene fusions with high accuracy and to characterize rare gene fusions providing the basis for the design of RT-PCR based assays for monitoring MRD. 2) Targeted RNA sequencing may be a valuable tool in routine diagnostics for patients with rearrangements unresolved by standard techniques. 3) These findings may have consequences for targeted treatment approaches.

P551
THE EFFECTS OF EARLY INTENSIFIED INDUCTION CHEMOTHERAPY IN ADULT PATIENTS WITH ACUTE MYELOID LEUKEMIA COMPARED TO STANDARD ANTHRACYCLINE PLUS CYTARABINE 3+7 CHEMOTHERAPY D.-H. Kwak1, H.-J. Yoon1, H.-J. Kim1, S.-S. Park1, S.-E. Lee1, B.-S. Cho1, K.-S. Eom1, Y.-J. Kim1, S. Lee1, J.-W. Lee1, W.-S. Min1

1Department of Hematology, Catholic Blood and Marrow Transplantation Center, Leukemia Research Institute, Seoul St. Mary’s Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic Of

Background: Standard induction chemotherapy for acute myeloid leukemia (AML) which consists of anthracycline for 3 days plus cytarabine for 7 days was first introduced in 1970’s and has been used for a long time. Several modification or intensification for this conventional regimen did not prove the effect for higher complete remission (CR) rate or lower relapse rate which led to superior overall survival (OS) rate.

Aims: We tried to find out possible benefit of early intensification of standard induction chemotherapy in adult AML patients.

Methods: The present study enrolled 1195 adult AML patients from 2002 to 2013. All patients were initially treated with idarubicin (12mg/m2) plus cytarabine (100mg/m2) plus daunorubicin (25mg/m2) induction chemotherapy (3+7), and among them, 731 (61.2%) patients received additional early augmentation using cytarabine 3 days (3+10, n=363) or anthracycline 2 days plus cytarabine 3 days (2+11, n=348). Outcome of 2 groups was compared, which was based on the follow-up BM blast counts on the 7th day of 3+7 chemotherapy. Totally 3+10 for blast counts 5%–20% and 5% for blast counts >20% (early intensified group). The rest 464 with blast counts < 5% finished with 3+7 regi-
men (standard group). Re-induction and consolidation therapy was performed according to a consistent strategy and post-consolidation therapy was mainly based on hematopoietic cell transplantation.

**Results:** Early intensified group was consisted of younger patients (median age, 37 years old [range 17-69] vs 45 years in 3+7 vs 43 years in 3+10 subgroup) and larger proportion of t(8;21) (n=102 [27.7%] vs 73 [15.7%] vs 3+10 [12.9%], P<0.001). Also, initial GM blast counts were higher in two intensified groups (73.3% in 3+10 and 70.1% in 3+10 compared to 3+7 subgroup. (66.8%, P<0.001). Early death rate at 8 weeks was higher in patients older than 55 years (10.8% vs 3.7%, P<0.001) especially when they were treated with intensified chemotheraphy (21.7% in 3+10 and 15.7% in 3+10 vs 6.3% in 3+7, P=0.038). CR rate after induction was higher in young patients especially in 3+10 subgroup (79.8%, P<0.001) and we also found that patients with favorable to intermediate-risk karyotype might benefit with intensified chemotherapy in the context of CR rate (79.7% vs 68.3%, P<0.001, although final CR rates became similar after re-induction. Next, we found that pre-CHT relapse was lower in patients younger than 55 years (4% vs 0%, P=0.002) and favorable to intermediate-risk group (8.9% vs 20.2%, P<0.001) after intensified induction. In young patients with favorable to intermediate-risk karyotype, intensified groups showed superior 5-year OS (55.0% vs 45.5%, P=0.010) and lower long-term relapse rate (32.2% vs 38.0%, P=0.094), but multivariate analysis revealed no effects for both OS and CR. In patients older than 55 years, intensified groups showed inferior 5-year OS (19.2% vs 22.8%, P=0.014) with higher early death rate (17.6% vs 6.3%, P=0.015), and multivariate analysis also showed intensified induction was related inferior OS (HR=1.89, 95%CI; 1.14-3.15, P=0.013).

### Summary/Conclusions:

Our data revealed that intensified induction chemotherapy was not influential for poor-risk karyotype, while higher post-induction CR rate and low pre-CRT relapse was shown in young patients with favorable to intermediate-risk karyotype although it was not influential for final OS and CR rate. In elderly patients, intensified induction chemotherapy was related with higher early death rate which finally showed poor OS.

### P552

**VARIANT FLT3 MUTATIONS CAN BE ERADICATED BY CYTARABINE/ANTHRACYCLINE/CRENOLANIB INDUCTION IN ADULT PATIENTS WITH NEWLY DIAGNOSED FLT3 (ITD/TKD) MUTANT AML**

E. Wang1, R. Stone2, R. Collins1, T. Agrawal2, V. Uny1, M. Tallman2

1Department of Medicine, Roswell Park Cancer Institute, Buffalo, 2Department of Medical Oncology, Dana-Farber Cancer Institution in additional 6 pts. Out of 29 newly diagnosed FLT3 mutant AML patients with full/partial FLT3 gene sequencing performed, 4 pts were found to have novel variant FLT3 mutations consisting of V491L, V592L, D593H, A680V, and N841IT/K (Table 1). The majority of these novel mutations were located at the JM, kinase domain 1 and the activation loop (kinase domain 2). The allele fractions of these FLT3 variants ranged as high as 29% (higher than that of FLT3-ITD in pt3), suggesting that some of these clones may have been potentially driving clinical leukemia progression in some pts. All 4 pts had NPM1 mutations, and two also had DNMT3A mutations. All 4 pts achieved CR with full count recovery (3/4 pts achieved CR after just one cycle of cytarabine/anthracycline/crenolanib induction). The pt with FLT3-D835Yand N841IT achieved CR after cytarabine/anthracycline/crenolanib induction and one cycle of HiDAC consolidation. All pts received FLT3-ve and have remained CR-3-ve out of 4 pts received 1-4 cycles of HiDAC consolidation follow by crenolanib maintenance. Only one pt underwent allo SCT. With a median follow up of 13 months, one pt relapsed (at 8.4-month following treatment). This 61F pt was found to have FLT3-ITD, D593H and i836del FLT3 abnormalities at the time of diagnosis. A full FoundationOne gene panel done at the time of relapse, showed no residual FLT3 mutant clones.

### Summary/Conclusions:

This abstract reports multiple novel variant FLT3 mutations in adult pts with newly diagnosed FLT3-ITD or FLT3-D835 mutant AML. The allelic burden of these FLT3 variant mutations can sometime be higher than that of FLT3-ITD. Detailed FLT3 analyses in this subset of pts suggests that crenolanib in combination with standard induction chemotherapy has the ability to eradicate variant FLT3 clones. All 4 pts treated with chemotherapy followed by crenolanib showed clearance of FLT3-ITD, TKD, as well as other novel variants. To achieve maximal clinical benefit, a potent pan-FLT3 inhibitor with the ability to inhibit ITD, D835, as well as other activating mutations maybe beneficial.

### P553

**PATIENTS WITH ACUTE MYELOID LEUKEMIA WHO HAVE MUTATIONS IN IDH1 OR IDH2 RESPOND WELL TO INDUCTION CHEMOTHERAPY WITH “7+3” DESPITE THE PRESENCE OF COMPLEX KARYOTYPE OR FLT3-ITD**

D. M. Gupta1,*, D. S. Devlin2, D. M. Tallman2, D. E. Stein2

1Mount Sinai Hospital, 2Memorial Sloan Kettering Cancer Center, New York, United States

**Background:** Mutations in isocitrate dehydrogenase isoforms 1 and 2 (IDH1/IDH2) occur in 8-12% of patients with acute myeloid leukemia (AML). Mutant IDH enzymes catalyze the conversion of alpha ketoglutarate to beta hydroxyglutarate. Increased concentrations of intracellular 2-HG lead to histone hypermethylation and a block in cellular differentiation and may also lead to suppression of homologous recombination. Previous studies of outcomes in patients with IDH mutation in AML have generally reported inferior survival compared to other patients with AML. More recently, a small single institution study suggested that patients with IDH mutation in AML could benefit from induction chemotherapy with the 7+3 regimen. However, this study did not consider the prevalence of complex karyotype and FLT3-ITD in patients with IDH mutation.

**Objective:** To evaluate the outcomes of newly diagnosed AML with IDH1 or IDH2 mutations who have undergone induction chemotherapy with “7+3” regimen.

**Methods:** We retrospectively reviewed the records of 115 patients with AML from the Memorial Sloan Kettering Cancer Center who initiated induction chemotherapy between 2001 and 2014. Patients with IDH1 or IDH2 mutations were identified. The primary endpoint was OS. Pre-treatment characteristics and outcomes were compared between patients with IDH mutation without complex karyotype or FLT3-ITD (‘‘IdH1/2+’’), patients with complex karyotype (‘‘K+’’), and patients with FLT3-ITD (‘‘ITD’’).

**Results:** A total of 26 patients with IDH1/2 mutations were identified. The median age of patients was 59 years (range 32-79). The majority of patients were male (62%) and had a high intergroup risk (69%). The most common type of IDH mutation was IDH2-R172K (77%). The most common cytogenetic abnormalities were +8 (23%) and t(8;21) (19%). The majority of patients (65%) received induction chemotherapy with “7+3.” The OS of patients with ‘‘IdH1/2+’’ was significantly better than patients with ‘‘K+’’ (P=0.019) and patients with ‘‘ITD’’ (P=0.03). The OS of patients with ‘‘IdH1/2+’’ was not significantly different from patients with ‘‘IdH1/2-’’ (P=0.16).

**Conclusion:** IDH mutation is an independent predictor of OS in newly diagnosed AML patients who have undergone induction chemotherapy with “7+3”. Patients with IDH mutation who are eligible for induction chemotherapy with “7+3” have a better OS compared to patients with complex karyotype and FLT3-ITD. This study supports the use of “7+3” in newly diagnosed patients with IDH mutation in AML.

**Summary/Conclusions:** This abstract reports multiple novel variant FLT3 mutations in adult pts with newly diagnosed FLT3-ITD or FLT3-D835 mutant AML. The allelic burden of these FLT3 variant mutations can sometime be higher than that of FLT3-ITD. Detailed FLT3 analyses in this subset of pts suggests that crenolanib in combination with standard induction chemotherapy has the ability to eradicate variant FLT3 clones. All 4 pts treated with chemotherapy followed by crenolanib showed clearance of FLT3-ITD, TKD, as well as other novel variants. To achieve maximal clinical benefit, a potent pan-FLT3 inhibitor with the ability to inhibit ITD, D835, as well as other activating mutations maybe beneficial.
Aims: To delineate the complete remission rate in AML patients with IDH1 or IDH2 mutations who receive standard 7+3 induction chemotherapy.

Methods: After receipt of IRB approval, an institutional database of genomic abnormalities in all patients with AML was queried for patients with IDH1 or IDH2 mutations between the years of 2010 and 2016. Pathology records of patients identified as having an IDH1/IDH2 mutation were reviewed to confirm the presence of an IDH mutation. After confirmation of IDH mutational status, all patients who received standard induction chemotherapy with 7+3 were included in this retrospective chart review.

Results: Between 2010 and 2016, 82 patients with IDH1/IDH2 mutations who had been treated with 7+3 induction chemotherapy were seen at MSKCC. Of these, 33 (40.2%) had IDH1 mutations and 49 (59.8%) had IDH2 mutations. Of those with IDH2 mutations IDH2 R140Q mutations were present in 34 (69.3%), and IDH2 R172K mutations were present in 15 (30.6%). The median age of all patients treated was 63. 56 patients (68%) had de novo AML, 16 (20%) had AML with myelodysplasia related changes, 5 (6%) had a known prior history of MDS and 5 (6%) had therapy related AML. Nearly half of the patients (49%) had karyotypic abnormalities. Of the 82 patients who received induction chemotherapy with 7+3, 51 achieved a complete remission (CR) after 1 cycle and 16 after 2 cycles for a CR rate of 82%. The strongest predictor of response to induction chemotherapy was the presence of an NPM1 mutation. There was a trend towards decreased response to induction chemotherapy in patients with a complex karyotype (p=0.079) that did not reach statistical significance. The presence of an IDH2 R172K mutation was predictive of non-response to one cycle of (7+3) of 7+3 but when two cycles of induction chemotherapy were given, response rates were equivalent to patients with R140Q mutations. Co-occurring mutations in FLT3 (ITD or TKD), DNMT3A or N-RAS were not predictive of responses to induction chemotherapy.

Summary/Conclusions: Induction chemotherapy with 7+3 leads to a robust CR rate of 82% in patients with AML that harbor IDH1 or IDH2 mutation. CR is not affected by FLT3 ITD or TKD, although those with IDH2 mutations required two cycles of chemotherapy to achieve a remission. Karyotypic abnormalities did not influence the response to induction chemotherapy, nor did the presence of co-occurring FLT3-ITD, FLT3-TKD or NRAS mutations. For AML patients with IDH mutations who are eligible for induction chemotherapy, 7+3 is a reasonable induction regimen regardless of the presence of FLT3 mutations, or karyotypic abnormalities.
However, the correlation is only valid for CYT-IDA while the PM Test is applied to up to 45 treatments. Any such treatment identified as sensitive means the PM Test can provide a valuable guideline to hematologists. This means the PM Test can suggest sensitive treatments for the vast majority of patients.

**Figure 1.**

Summary/Conclusions: We have developed a novel ex vivo PM test for induction treatment in AML patients to guide hematologists selecting the right treatment to achieve CR in individual patients leveraging up to 45 different validated chemotherapeutic regimes. Assuming a similar response rate for all these treatments, our test could estimate a net prediction for sensibility to AML treatment higher than 80% in 1st line. This PM Test will be evaluated in an interventional clinical trial on relapse/refractory patients that is expected to begin in the next few months in collaboration with the PETHEMA group from Spain.

RESPONSE-ADAPTED AZACITIDINE AND INDUCTION CHEMOTHERAPY IN PATIENTS >60 YEARS OLD WITH NEWLY DIAGNOSED AML ELIGIBLE FOR CHEMOTHERAPY: RESULTS OF THE DRKS00004519 STUDY OF THE EAST GERMAN STUDY GROUP

N. Jaekel1,2, K. Hubert1, R. Krahl1, M. Haenel3, G. Maschmeyer4, R. Herbst5, C. Jakob1, S. Schulze1, S.-Y. Wang1, M. Cross1, C. Kahl1, M. Was5, H. Sayer1, O. Brosteana1, O. Niedenwieser1, H.K. Al-Ali6
1Department of Hematology and Oncology, University Hospital of Leipzig, 2Department of Hematology and Oncology, University of Leipzig, Leipzig, 3Department of Hematology and Oncology, Klinikum Chemnitz, Chemnitz, 4Department of Hematology, Oncology and Palliative Care, Klinikum Ernst von Bergmann, Potsdam, 5Department of Hematology, Oncology and Palliative Care, Klinikum Magdeburg, Magdeburg, 6Department of Hematology and Oncology, University Hospital of Halle, Halle (Saale), 7Department of Hematology and Oncology, Helios Klinikum Erfurt, Erfurt, 8Clinical Trial Centre Leipzig, University of Leipzig, Leipzig, Germany

Background: AML treatment in elderly patients (pts) >60 years (y) with intensive chemotherapy (IC) or azacitidine (AZA) are not necessarily mutually exclusive. Aims: Results of the multicenter DRKS00004519 (RAS-AZIC) study of the East German Study Group (OSHO) which evaluated first-line treatment with AZA followed by response-based AZA or IC in pts >60y with AML are presented. Methods: pts >60y with newly diagnosed AML (n=112) were included. Recruitment was completed in May, 2016. In the phase 1 part, safety of upfront AZA (75mg/m²/day s.c) for 7 days followed by IC (mitoxantrone 10mg/m²/day on day (d) 1-3 and cytarabine 1g/m²/BID on d 1, 3, 5, 7) on d17 was established through a 3+3 design. In the multicenter phase II part (figure), upfront AZA was sequentially followed by AZA or IC based on d15 bone marrow (BM) blasts (<45 vs ≥45%) and CR/CRi on d56 which were both previously identified as early predictors for long-term response to AZA in AML (Ai-All et al. Leuk Lymph 2011). The primary endpoint was response (CR/CRi, and PR) and OS according to the International Working Group criteria. Based on the optimal two-stage design (Simon. Control Clin Trials 1989), protocol treatment was non-inferior to standard IC if, on an intention-to-treat basis, an OR of 61% was reached. Adverse events (AEs) were reported according to the NCI CTCAE 4.03. All pts gave written informed consent. Results: Median age was 70y (52% males), de novo AML was present in 65% of pts. Median BM blasts and WBC were 50% and 4.4x10⁹/L respectively. Genetic risk was high in 30%, intermediate in 55%, and favorable in 15%. FLT3 and NPM1 were mutated in 12% and 22% respectively. All pts received first-line AZA. Only lower baseline blasts correlated with blasts <45% on d15 (p=0.0005). Yet, 40% of pts with baseline blasts >50% reached this goal. Protocol assigned treatment on d15 was applied to 101 (90.2%) pts (54.5% continued with AZA; 46.5% received IC). Of 152 AML cycles given till d56, 33.6% were applied in an outpatient setting. Until d90, one IC cycle was needed in 77 (68.8%) pts. In the intention-to-treat cohort (n=43%/15%); PR (4.5%)

**Figure 1.**

Summary/Conclusions: We have developed a novel ex vivo PM test for induction treatment in AML patients to guide hematologists selecting the right treatment to achieve CR in individual patients leveraging up to 45 different validated chemotherapeutic regimes. Assuming a similar response rate for all these treatments, our test could estimate a net prediction for sensibility to AML treatment higher than 80% in 1st line. This PM Test will be evaluated in an interventional clinical trial on relapse/refractory patients that is expected to begin in the next few months in collaboration with the PETHEMA group from Spain.

OVERALL SURVIVAL WITH CPX-351 VERSUS 7+3 IN OLDER ADULTS WITH NEWLY DIAGNOSED, THERAPY-RELATED ACUTE MYELOID LEUKEMIA: SUBGROUP ANALYSIS OF A PHASE 3 STUDY

1H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL, 2Duke Comprehensive Cancer Center, Durham, NC, 3David Geffen School of Medicine/UCLA, Los Angeles, CA, 4Medical Univ. of South Carolina & Hollings Cancer Center, Charleston, SC, 5Monter Cancer Center, Northwell Health system, Lake Success, NY, 6BMT Group of Georgia, Atlanta, GA, 7Oregon Health and Science Univ, Portland, OR, 8Univ. of Alabama at Birmingham, Birmingham, AL, 9Washington Univ. School of Medicine, St. Louis, MO, 10Jazz Pharmaceuticals, Palo Alto, CA, 11MD Anderson Cancer Center, Houston, TX, United States

Background: Therapy-related acute myeloid leukemia (tAML) may occur as
a late complication of cytotoxic or radiation therapy and is associated with a poor prognosis. CPX-351 is a liposomal formulation that delivers a synergistic 5:1 molar ratio of cytarabine and daunorubicin. In a randomized, open-label, controlled phase 3 trial in patients aged 60 to 75 years with newly diagnosed, secondary AML (eg, tAML or AML after myelodysplastic syndrome), CPX-351 significantly improved overall survival (OS) versus cytarabine/daunorubicin (7+3).

**Aims:** The current analysis of this phase 3 study evaluated outcomes in the subgroup of patients with tAML.

**Methods:** Enrolled patients were randomized 1:1 to receive induction with 1 to 2 cycles of CPX-351 (100 units/m² [cytarabine 100mg/m² + daunorubicin 44mg/m²] on Days 1, 3, and 5 [2nd induction: Days 1 and 3 only]) or 7+3 (cytarabine 100mg/m²/day x 7 days [2nd induction: x 5 days] + daunorubicin 60mg/m² on Days 1, 2, and 3 [2nd induction: Days 1 and 2 only]). Patients who achieved complete remission (CR) or CR with incomplete platelet or neutrophil recovery (CRi) could receive up to 2 cycles of consolidation therapy. Note, the study was not powered for this subgroup analysis.

**Results:** A total of 304 patients were enrolled and received study treatment, including 62 (20%) patients with tAML (CPX-351 arm, n=30; 7+3 arm, n=32). Characteristics of tAML patients were similar between the CPX-351 and 7+3 arms: median age was 69.0 versus 67.5 years, and 47% versus 53% were male. Primary treatment in patients with tAML included prior non-anthracycline chemotherapy alone (26%), radiation alone (26%), non-anthracycline chemotherapy + radiation (32%), non-anthracycline + anthracycline chemotherapy (5%), and non-anthracycline + anthracycline chemotherapy + radiation (11%).

CPX-351 was associated with a significant OS benefit versus 7+3 in older tAML patients and numerically longer event-free survival and remission duration (Figure). Additionally, a greater proportion of tAML patients in the CPX-351 arm versus the 7+3 arm achieved CR+CRi (47% vs 36%, respectively; odds ratio=1.33 [95% CI: 0.47, 3.81]) and proceeded to stem cell transplantation (37% vs 27%; odds ratio=1.54 [95% CI: 0.53, 4.49]). Serious treatment-emergent adverse events (TEAEs) were reported for 18/30 (60%) of tAML patients in the CPX-351 arm and 12/32 (38%) of tAML patients in the 7+3 arm; the observed difference in serious TEAEs in this subgroup appeared to primarily be due to the incidence of febrile neutropenia (n=6/30 [20%] vs n=0/32 [0%]).

Three (10%) patients in the CPX-351 arm and 5 (16%) patients in the 7+3 arm experienced a TEAE that resulted in death during the treatment period; there was no pattern in the individual TEAEs that led to death.

**Figure 1.**

**Summary/Conclusions:** CPX-351 is associated with improved efficacy and a safety profile comparable to 7+3 in older patients with newly diagnosed tAML. Outcomes in the tAML subgroup mirrored the overall study population, indicating CPX-351 may represent a new therapeutic option for this difficult to treat population.

HYPERFERRITINEMIA IS AN INDEPENDENT POOR PROGNOSTIC FACTOR IN ACUTE MYELOID LEUKEMIA

S. Bertoli1,2,3,*, X. Thomas 4, E. Bérard 5,6, F. Vergez 2,3,7, S. Tavitian 1, R. Christian1,2,3

**Background:** The prognostic impact of ferritinemia has been studied in a variety of malignancies, including acute myeloid leukemia. Ferritin is a protein that is upregulated in response to tissue iron stores and inflammatory conditions. In a previous study, ferritin was found to be associated with an increased risk of relapse and death in patients with acute myeloid leukemia (AML).

**Methods:** In the current analysis of this phase 3 study evaluated outcomes in the tAML subgroup. Outcomes in the tAML subgroup mirrored the overall study population, indicating an improved efficacy and a safety profile comparable to 7+3 in older tAML patients and numerically longer event-free survival and remission duration (Figure). Additionally, a greater proportion of tAML patients in the CPX-351 arm versus the 7+3 arm achieved CR+CRi (47% vs 36%, respectively; odds ratio=1.33 [95% CI: 0.47, 3.81]) and proceeded to stem cell transplantation (37% vs 27%; odds ratio=1.54 [95% CI: 0.53, 4.49]).

Serious treatment-emergent adverse events (TEAEs) were reported for 18/30 (60%) of tAML patients in the CPX-351 arm and 12/32 (38%) of tAML patients in the 7+3 arm; the observed difference in serious TEAEs in this subgroup appeared to primarily be due to the incidence of febrile neutropenia (n=6/30 [20%] vs n=0/32 [0%]). Three (10%) patients in the CPX-351 arm and 5 (16%) patients in the 7+3 arm experienced a TEAE that resulted in death during the treatment period; there was no pattern in the individual TEAEs that led to death.

**Figure 1.**

**Summary/Conclusions:** In conclusion, hyperferritinemia is a prognostic marker independent from well-acknowledged factors, such as cytogenetics and molecular abnormalities. Ferritinemia should be included in AML diagnosis workup as it provides reproducible information on short and long-term outcome for AML patients of any subgroup. The putative link between hyperferritinemia, inflammation and chemoresistance should be investigated.

NGS ANALYSIS OF 474 BONE MARROW SAMPLES FROM 157 AML PATIENTS TREATED WITH AZACITIDINE–IMPACT OF AGE ON MUTATIONAL LOAD

L. Pleyer1,2,3,*, F.J. Gassner1,2, S. Burgstaller4, H. Wedler5, T.N. Hartmann1,2,3, B. Jansko1, D. Neureiter6, J. Thaler4, R. Greil1,2,3

**Background:** Next-generation sequencing (NGS) is a powerful tool for detecting mutations in cancer, including acute myeloid leukemia (AML). The impact of age on mutational load in AML patients treated with azacitidine is not well understood.

**Methods:** A total of 474 bone marrow samples from 157 AML patients treated with azacitidine were analyzed using NGS. The impact of age on mutational load was assessed using linear regression models.

**Results:** Age was found to have a significant impact on mutational load, with younger patients having a higher mutational load compared to older patients. The impact of age on mutational load persisted after adjusting for other factors, such as cytogenetic risk and prior treatment.

**Conclusion:** Age is an important factor in determining mutational load in AML patients treated with azacitidine. This finding may have implications for treatment strategies and patient selection.

**References:**

AML pts treated with azacitidine (AZA) has only been presented in abstract form thus far (Tang et al., ASH 2016). Data on the impact of age on mutational load in AML are scarce.

Aims: To assess the mutational landscape in elderly AML pts treated with AZA; specifically, whether age has an impact on mutational load.

Methods: We analysed 474 bone marrow FFPE specimens from 157 AML pts in the Austrian Registry of Hypomethylating Agents from two centres (Salzburg, Wels-Grieskirchen) using a 53-gene panel (all exons). NGS was performed by Qiagen. Minimum coverage: 1.500x. All mutations were checked against COSMIC-v79, ClinVar, ICGC, DoCM, dbSNP and Varsome databases. For comparison of categorical variables Chi-squared test was used, for comparison of means Student T-test was used.

Results: The rate of secondary (s)AML was significantly lower in pts <75 (n=85), vs ≥75 years (n=54) (60.6% vs 77.8%, P<0.001). There was no significant difference in the rate of adverse cytogenetics or monosomal karyotype before AZA treatment between pts < vs ≥75 years, respectively (data not shown). Mutational load (average number of mutated genes and mutations per pt) assessed at/before initiation of AZA, was significantly higher in pts <75 yrs vs ≥75 yrs (10.2 vs 8.6 mutated genes/patient; P=0.030 and 12.9 vs 10.5 mutations/patient; P=0.012, Figure 1A). This also held true when mutational load was assessed at any time point during the course of AML (including during/post-AZA treatment) (Figure 1B). In total, 139 pts had more than one marrow sample with NGS results. Analysis of paired samples revealed that mutational load was significantly higher during/post-AZA vs before AZA in both age groups (Figure 1C-D). In total, 60.4%, 15.8%, 8.6%, 3.6% and 11.5% of pts acquired 1, 2, 3, 4-13 additional mutations, respectively. No relevant differences between pts < vs ≥75 years were found (data not shown). When comparing the deltat of mutations before vs during/after AZA according to age group, no significant difference was found (Figure 1E).

Background: Monitoring minimal residual disease based on quantitative PCR represents an important risk stratification tool in acute myeloid leukemia (AML) and enables the prediction of impending relapse. Besides common fusion genes and mutated genes, Wilms tumor 1 (WT1) gene is widely used to follow de novo AML.

Aims: The aim of our study was to evaluate the relevance of WT1 expression for the prognosis of patients with AML in a real life population.

Methods: Bone marrow samples from 174 consecutive adult AML patients (18-85 years) were used for WT1 mRNA quantification. APL patients were excluded. Of 143 patients with WT1 overexpression at diagnosis, those treated with intensive induction chemotherapy and achieving haematological remission after the first cycle of therapy were included in the retrospective follow-up analysis (n=129).

Results: The extent of WT1 expression at diagnosis had no prognostic relevance. In contrast, achievement of low WT1 levels after induction chemotherapy was associated with a significant better overall (OS) and disease free survival (DFS) as compared to persistent high WT1 expression at hCR1 5 years OS 80% (95% CI 75.0-82.0) vs 69% (95% CI 60.7-73.9), DFS 90% (95% CI 86.7-91.0) vs 80% (95% CI 75.0-82.0), respectively (p<0.001). Additionally, compared with patients with a low WT1-reduction (<5 log) at hCR1, the relative risk of death was 0.32 (95% CI 0.1-0.7) in patients with intermediate WT1-reduction (5-8 log) and 0.15 (95% CI 0.00-0.5) in patients with high WT1-reduction (>8 log), after adjustment for age, ELN-risk group, and stem cell transplantation in CR1. The corresponding 5-year OS rates were 77.8% vs 84% (p=0.001) and 71% vs 89% (p<0.001), respectively. Even though numbers of patients were small (n=33), SCT at CR1 seems to overcome the adverse risk of persistent WT1 expression: DFS 5.3 years (0-12.9) for patients with SCT and 0.7 years (0-6.9) for patients without SCT (p=0.004).

Summary/Conclusions: Persisting WT1 expression in AML patients achieving a CR1 after induction chemotherapy is a strong, independent predictor for DFS and OS in patients with AML. Since 80–90% of AML patients exhibit WT1 overexpression at diagnosis, this marker is widely applicable for early risk re-evaluation and corresponding therapy adaptation.

P560 EVALUATION OF THE IMPACT OF SIGNAL RATIO ON OVERALL SURVIVAL IN FLT3-MUTATION-POSITIVE RELAPSED/REFRACTORY ACUTE MYELOID LEUKEMIA FOLLOWING ONCE-DAILY TREATMENT WITH GILTERITINIB

1John Hopkins University, Baltimore, 2Robert H. Lurie Comprehensive Cancer Center of Northwestern University, Chicago, 3University of Pennsylvania-Abramson Comprehensive Cancer Center, Philadelphia, PA, 4University of Texas Southwestern Medical Center, Dallas, TX, 5University of California-San Francisco, San Francisco, CA, 6Mayo Clinic, Rochester, MN, 7Astellas Pharma US Inc., Northbrook, IL, 8University of Chicago, Chicago, 9Weill Cornell Medical College, New York, NY, 10Vanderbilt-Ingram Cancer Center, Nashville, TN, 11Roswell Park Cancer Institute, Buffalo, NY, United States, 12Universitaetsklinik Giessen und Marburg, Marburg, Germany, 13Saragoni Institute of Hematology, Bologna, Italy

Background: Fms-like tyrosine kinase 3 (FLT3) internal tandem duplications (ITD) in acute myeloid leukemia (AML) are associated with early relapse and short survival, particularly in the context of high allelic burden. Patients with high FLT3-ITD signal ratio are particularly sensitive to FLT3 inhibitors but the clinical effects of allelic burden on survival have not been validated in trials of these drugs. Gilteritinib is a highly specific, potent FLT3/AXL inhibitor with demonstrated activity against both FLT3-ITD and tyrosine kinase domain (TKD) mutations. A recent Phase 1/2 study (CHRYSALIS; NCT02014558) demonstrated that FLT3 mutation-positive (FLT3mut+) patients with relapsed/refractory (R/R) AML treated with gilteritinib had high clinical response rates and prolonged overall survival (OS), especially at doses ≥80mg/d.

Aims: To evaluate the effect of FLT3-ITD and FLT3-TKD signal ratios on OS in AML patients who had received gilteritinib doses ≥80mg/d.

Methods: Signal ratios were assessed in adult FLT3mut+R/R AML pts who had received gilteritinib doses ≥80mg/d. Genomic DNA extraction and PCR with fluorescent primers were used to generate transcripts of FLT3 alleles containing ITD and TKD mutations. FLT3 alleles containing ITD mutations generating PCR products >330 bp in length were used to amplify the TKD region were used to amplify the target region and an EcoRV endonuclease was used to digest the PCR products >330 bp in length. Multiplex PCR products >330 bp in length were used in the PCR reactions and an EcoRV endonuclease was used to digest the PCR products >330 bp in length. Sequencing (The Cancer Genome Atlas Research Network, NEJM 2013; Merkelscheid1, A. Welter2,9,20,18,17,16,15,14,13,12,11,10,9,8,7,6,5,4,3,2,1, J. Altman2, A. Perl3, J. Cortes4, J. Hill5, R. Lurie Comprehensive Cancer Center of Northwestern University, Chicago, 3University of Pennsylvania-Abramson Comprehensive Cancer Center, Philadelphia, PA, 4University of Texas Southwestern Medical Center, Dallas, TX, 5University of California-San Francisco, San Francisco, CA, 6Mayo Clinic, Rochester, MN, 7Astellas Pharma US Inc., Northbrook, IL, 8University of Chicago, Chicago, 9Weill Cornell Medical College, New York, NY, 10Vanderbilt-Ingram Cancer Center, Nashville, TN, 11Roswell Park Cancer Institute, Buffalo, NY, United States, 12Universitätsklinik Giessen und Marburg, Marburg, Germany, 13Saragoni Institute of Hematology, Bologna, Italy

Background: Fms-like tyrosine kinase 3 (FLT3) internal tandem duplications (ITD) in acute myeloid leukemia (AML) are associated with early relapse and short survival, particularly in the context of high allelic burden. Patients with high FLT3-ITD signal ratio are particularly sensitive to FLT3 inhibitors but the clinical effects of allelic burden on survival have not been validated in trials of these drugs. Gilteritinib is a highly specific, potent FLT3/AXL inhibitor with demonstrated activity against both FLT3-ITD and tyrosine kinase domain (TKD) mutations. A recent Phase 1/2 study (CHRYSALIS; NCT02014558) demonstrated that FLT3 mutation-positive (FLT3mut+) patients with relapsed/refractory (R/R) AML treated with gilteritinib had high clinical response rates and prolonged overall survival (OS), especially at doses ≥80mg/d.

Aims: To evaluate the effect of FLT3-ITD and FLT3-TKD signal ratios on OS in AML patients who had received gilteritinib doses ≥80mg/d.
P561

CLINICAL OUTCOME OF HYPOCELLULAR AML AND AML WITH MEYELODYSPLASIA-RELATED CHANGE (MRC) COMPARED TO DE NOVO ADULT AML WITH NORMAL CELLULARITY AFTER HEMATOPOIETIC CELL TRANSPLANTATION

D.-H. Kwak1, J.-H. Yoon1, H.-J. Kim1, S.-S. Park1, S.-E. Lee1, B.-S. Cho1, K.-S. Eom1, Y.-J. Kim1, S. Lee1, J.-W. Lee1, W.-S. Min1

1Department of Hematology, Catholic Blood and Marrow Transplantation Center, Leukemia Research Institute, Seoul St. Mary’s Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic Of

Background: Hypocellular acute myeloid leukemia (hypo-AML) and AML with myelodysplasia-related change (AML-MRC) accounts for small proportion of adult AML. As the characteristics and outcomes are not well recognized.

Aims: We tried to analyze these specific groups and compared to normocellular AML.

Methods: After exclusion of secondary AML, therapy-related AML, and AML M3, we retrospectively analyzed 1593 AML cases between 2002 and 2013. We found 101 (6.3%) patients with hypo-AML and 164 (10.3%) patients with de novo AML-MRC. Hypo-AML was diagnosed with blast counts ≥20% within hypocellular (<20%) bone marrow (BM) and AML-MRC was identified with at least two biopsy specimens and age-related correction was considered. De novo AML-MRC was defined with multilineage dysplasia ≥10% for each lineage with blast counts ≥20% without history of antecedent hematologic disease. Patients (n=20) with both AML-MRC and hypo-AML were distributed in AML-MRC group.

Results: Patients with hypo-AML were older (p=0.001) and significantly presented lower leukocyte and PB/BM blast counts (p<0.001). Patients with AML-MRC were older and lower hemoglobin level with lower PB/BM blast counts (p=0.001) compared to normocellular de novo AML. In both groups, the risk of karyotype was poorer. In untreated group (n=207), hypo-AML showed longer survival outcome compared to normocellular de novo AML, and AML-MRC showed higher therapy-related mortality (TRM) rate. However, multivariate analysis showed that there were no significant differences between the three AML subgroups especially when the patients were treated with hematopoietic cell transplantation (HCT).

Figure 1.

Figure 2.

Summary/Conclusions: The long-term outcome of hypo-aML and AML-MRC were poorer than normocellular de novo AML, mainly due to older age and large proportion of adverse-risk karyotype which caused unavailable condition for HCT.

P562

INITIAL RESULTS FROM A FIRST-IN-HUMAN STUDY OF IMGN779, A CD33-TARGETING ANTIBODY-DRUG CONJUGATE (ADC) WITH NOVEL DNA ALKYLATING ACTIVITY, IN PATIENTS WITH RELAPSED OR REFRACTORY AML

J. Cortes1,*, D. DeAngelo2, E. Wang3, C. Arana-Yi4, P. Zweidler-McKay5, M. Munteanu2, C. Andreu-Vieyra6, H. Erba6, W. Blum7, E. Traer8

1MD Anderson Cancer Center, Houston, 2Dana-Farber Cancer Institute, Boston, 3Roswell Park Cancer Institute, Buffalo, 4University of New Mexico Cancer Center, Albuquerque, 5ImmunoGen, Inc., Waltham, 6University of Alabama at Birmingham, Birmingham, 7The Ohio State University, Columbus, 8Oregon Health and Science University, Portland, United States

Background: Acute myeloid leukemia (AML) accounts for the highest number of leukemia deaths in the United States annually. IMGN779 is an ADC that binds with high affinity and specificity to CD33, a validated therapeutic target in AML. IMGN779 comprises a humanized anti-CD33 antibody attached via a cleavable linker to the novel DNA-interacting payload DGN462. Once released when administered to patients with CD33+AML, Evaluation of the safety, tolerability, pharmacokinetics (PK), pharmacodynamics (PD), and preliminary antitumor activity of IMGN779 are secondary objectives.

Methods: Adult patients (≥18 years) with relapsed or refractory CD33+ AML (defined by ≥20% of AML blasts expressing CD33 by flow cytometry) were eligible for enrollment. Informed consent was obtained from all patients. Dose-escalation, which follows a standard 3+3 design, began with a starting dose of 0.02mg/kg. IMGN779 was administered intravenously once every 2 weeks on days 1 and 15 as part of a 28-day cycle. Adverse events (AEs) were evaluated using NCI-CTC v4.03.

Aims: This Phase I study is designed to establish the maximum tolerated dose (MTD) and determine the recommended phase 2 dose (RP2D) of IMGN779 when administered to patients with CD33+ AML. Evaluation of the safety, tolerability, pharmacokinetics (PK), pharmacodynamics (PD), and preliminary antitumor activity of IMGN779 are secondary objectives.

Results: As of February 2017, a total of 17 patients (9 female, 8 male) with a median age of 62 years have received IMGN779 treatment. Five dose levels have been completed, with escalation proceeding from 0.02–0.26mg/kg. AEs were as expected for this relapsed/refractory AML population including cytopenias and constitutional symptoms. No relationship between frequency or severity...
Summary/Conclusions: This is the first clinical experience of the next generation CD33-targeting ADC, IMGN779, in AML patients. No DLTs have been noted to date. AEs were generally consistent with the underlying disease. PK and PD are favorable and dose escalation is continuing.

Background: TGR-1202 is a next generation, once daily, PI3Kδ inhibitor, active in patients (pts) with rel/ref hematologic malignancies that has demonstrated a notably differentiated safety profile, including in long-term follow up (Burris, 2016). Ublituximab (UTX) is a novel glycoengineered mAb targeting a unique epitope on the CD20 antigen. Bendamustine (Benda) is an active chemotherapy agent in pts with lymphoma. The combination of UTX + TGR-1202 is tolerable and active in pts with rel/ref hematologic malignancies and is under Phase 3 testing for patients with CLL and Phase 2b testing for patients with DLBCL.

Aims: This Phase 1 trial evaluates the safety and efficacy of UTX + TGR-1202 + Benda in pts with advanced Diffuse Large B-cell Lymphoma (DLBCL) and Follicular Lymphoma (FL).

Methods: Eligible pts had rel/ref DLBCL or FL with an ECOG PS ≤2 w/o limit to number of prior therapies. ANC of >750 and Platelets >50,000 was permitted. Pts refractory to prior PI3Kδ, Benda, or anti-CD20 therapy were eligible. UTX was dosed on Days 1, 8, 15 of Cycle 1. Day 1 of Cycle 2-6, followed by Cycle 9 & 12. TGR-1202 was started at 800mg QD with a -1 dose reduction cohort at 600mg if not tolerated in ≥2/6 pts. Benda was dosed at 90mg/m2 on Days 1 & 2 of Cycles 1-6 only. Primary endpoints included safety and efficacy (Cheson 2007).

Results: Twenty-three pts were evaluable for safety: 15 diffuse large B-cell (DLBCL) and 8 follicular (FL). Med age 68 yo (range 31-81); 12 M/11 F; median prior treatment regimens=2 (range 1-6); 12 pts (52%) were refractory to their immediate prior treatment and to prior CD20 therapy, and 7 patients had progressed post-transplant. ECOG PS 0/1/2 (3/18/2). Initially 2/4 pts at 800mg TGR-1202 experienced AEs in Cycle 1 that led to treatment interruption (rash, neutropenia) thus the 600mg dose of TGR-1202 was explored. No additional Cycle 1 treatment delays were reported at the 600mg dose level, which was later expanded and the 800mg TGR-1202 dose is now being evaluated with stricter eligibility criteria to require an ANC of ≥1.0, and the use of growth factor support in cycle 1 is now encouraged. The most common AE’s included diarrhea (39%; G3/4 4%), decreased appetite (35%; G3/4 4%), nausea (30%; G3/4 4%), asthenia (26%; G3/4 4%) and neutropenia (22%). The only Grade 3/4 AE reported in >10% of pts was neutropenia (22%). Two pts had a TGR-1202 dose reduction. Nineteen pts (11 DLBCL/8 FL) were evaluable for efficacy: ORR amongst all pts was 79% (15/19) with 42% (8/19) achieving a complete response (CR), of which 5 were DLBCL and 3 FL. ORR in the respective groups as follows:

<table>
<thead>
<tr>
<th>Group</th>
<th>N</th>
<th>ORR (%)</th>
<th>CR (%)</th>
<th>PR (%)</th>
<th>SD (%)</th>

<td>95%</td>
<td>5 (45%)</td>
<td>4 (36%)</td>
<td>2 (18%)</td>
</tr>
</tbody>
</table>

Median follow-up time on study is 6 mos for all pts (range 1-14+ mos).

Summary/Conclusions: The combination of UTX, TGR-1202, and bendamustine has exhibited manageable toxicity with significant activity in advanced DLBCL and FL pts including an encouraging 42% CR rate (45% in DLBCL and 38% in FL). Enrollment continues at the 800mg TGR-1202 dose level with the use of growth factor prophylaxis. Safety and efficacy data for all pts will be updated at the meeting. Based upon the early activity of the triplet, future registration directed studies are being planned.

Background: Venetoclax (VEN) in patients with relapsed/refractory non-Hodgkin lymphoma (NHL) is a novel agent in pts with lymphoma. The combination of VEN + rituximab (RTX) + bendamustine is tolerable and active in pts w/ rel/ref NHL and is under Phase 3 testing.

Aims: To assess the activity and safety of VEN + RTX + benda in pts with rel/ref NHL.

Methods: A Phase 2 trial of VEN + RTX + bendamustine in pts with rel/ref NHL: Eligible pts had rel/ref indolent or aggressive NHL. Pts with a history of prior NHL were excluded. Pts ≥ 18 yrs, an ECOG PS of ≤2, and an absolute lymphocyte count (ALC) > 1,000/μl were eligible. Cycle 1 treatment delays were reported at the 600mg dose level, which was later expanded and the 800mg TGR-1202 dose is now being evaluated with stricter eligibility criteria to require an ANC of ≥1.0, and the use of growth factor support in cycle 1 is now encouraged. The most common AE’s included diarrhea (39%; G3/4 4%), decreased appetite (35%; G3/4 4%), nausea (30%; G3/4 4%), asthenia (26%; G3/4 4%) and neutropenia (22%). The only Grade 3/4 AE reported in >10% of pts was neutropenia (22%). Two pts had a TGR-1202 dose reduction. Nineteen pts (11 DLBCL/8 FL) were evaluable for efficacy: ORR amongst all pts was 79% (15/19) with 42% (8/19) achieving a complete response (CR), of which 5 were DLBCL and 3 FL. VENETOCLAX (VEN) IN PATIENTS WITH RELAPSED/REFRACTORY NON- HODGKIN LYMPHOMA (NHL)

1Dana-Farber Cancer Institute, Boston, United States, 2Royal Melbourne Hospital, Parkville VIC, 3Peter MacCallum Cancer Centre, East Melbourne VIC, 4University of Texas MD Anderson Cancer Center, Houston, 5University of Arizona Cancer center, Tucson, Australia, 6AbbVie, Inc., North Chicago, 7Memorial Sloan-Kettering Cancer Center, New York City, United States
Background: VEN is a selective orally bioavailable BCL-2 inhibitor. The dose-escalation Phase 1 study of VEN in 106 patients (pts) with relapsed/refractory NHL reported an ORR of 44%. Most pts had diffuse large B-cell/ follicular lymphoma.

Aims: We report on updated results in pts with less common NHL subtypes.

Methods: VEN was administered and continued until progressive disease (PD). Only acceptable toxicity, in dose cohorts ranging from 300-1200mg. Adverse events (AEs) were assessed by NCI-CTCAE v4.0 and response by 2007 Cheson IWG response criteria, utilizing CT scans beginning at wk 6.

Results: 35 of 106 pts had mantle cell lymphoma (MCL, n=28), marginal zone lymphoma (MZL, n=5) or Waldenström macroglobulinemia (WM, n=4). Most common grade 3/4 AEs were nausea (51%), diarrhea (49%) and fatigue (34%); grade 3/4 AEs in >10% of pts were neutropenia and anemia (17% each). Laboratory TLS was reported in a single pt (bulky MCL). MCL pts (median age: 72 years) had received a median of 3 (1-7) prior treatments (tx). Median time from start of prior tx to start of VEN was 13 mo (2-148) and time on treatment was 13 mo (0.2-493). ORR was 75%, 6 pts (21%) achieved CR and remain on study (DORs: 25-40 mo). One pt with a PR proceeded to elective allogeneic stem cell transplant and remained disease free at last protocol defined follow-up (24 mo after coming off study). Median PFS was 11 mo and DOR was 15 mo. MZL pts (median age: 63 years) had received a median of 4 (2-6) prior tx. Time from start of prior tx to start of VEN was 8, 14, 73 mo and time on VEN was 5, 1, 35 mo. One pt (6 prior tx) received VEN for <1 mo due to progressive cytopenias; 1 pt (4 prior tx) achieved a PR with VEN at wk 6 but had PD at wk 16; 1 pt (2 prior tx) achieved PR at wk 6 and is the only pt to remain on study (DOR: 32 mo). WM pts (median age: 67 years) had a median of 4 (3-5) prior tx. Time from start of prior tx to start of VEN was 5, 18, 33, 67 mo and time on VEN was 42, 17, 54, 20 mo. All pts achieved PR (at wks 6 [n=26], 16 and 36), with DORS of 11, 12, 38 and 50+ mo (latter is ongoing and remains on study).

Summary/Conclusions: VEN monotherapy has a tolerable safety profile in MCL, MZL and WM pts. ORR were high and most responses durable; median PFS and DOR suggest significant activity in MCL pts. Further investigation of VEN in each disease is indicated.

P565

WHOLE BODY DIFFUSION-WEIGHTED MAGNETIC RESONANCE IMAGING IS A GOOD PREDICTOR FOR TREATMENT OUTCOME AFTER ONE CYCLE OF IMMUNOCHEMOTHERAPY IN AGGRESSIVE LYMPHOMA

K. De Paepe 1, F. De Keyser 1, C.-A. Van Keerberghen 2, O. Gheysens 2, V. Vandecaveye 1

Methods: Forty-six patients with aggressive NHL (35 diffuse large B-cell lymphoma (DLBCL), 2 primary mediastinal B-cell lymphoma (BCL), 1 unclassifiable BCL, 1 Burkitt lymphoma, 4 Mantle cell lymphoma (MCL), 2 peripheral T-cell lymphoma (TCL) and 1 extranodal natural-killer TCL) were consecutively enrolled between 2011 and 2015. All patients had baseline and interim WB-DWI/MRI as an radiation-free imaging technique to predict treatment outcome in NHL after one cycle of ICT (2-3 weeks).

Results: Median follow-up time was 43 months (4-70 months). Thirty-three patients achieved complete remission (CR), 4 progressed and 9 had recurrent disease. Patients were non-responders according to WB-DWI/MRI in case of an ADCmean decrease for lymphoid tissue or less than 10% b1000 mean decrease in bone or a b1000mean increase of less than 6% in extranodal lesions. WB-DWI/MRI predicted DFS correctly in 45/46 (96%) [p<0.001; hazard ratio (HR): 0.24, 95% CI 0.05-1.15], and interim FDG-PET/CT was additive to baseline and interim scan (Δr). Statistical analysis consisted of Kaplan-Meier survival analysis univariate and multivariate Cox regression analysis with disease-free-survival (DFS) as outcome measure.

Summary/Conclusions: In the largest single-center, real-world experience of Ibrutinib (IBR) use in DLBCL, RT and FL patients consecutively treated with IBR. Data collected included patient demographics, stage, IPI, genetic characteristics, prior treatments, IBR dose and discontinuation reasons for discontinuation and response, PFS and OS were estimated using the Kaplan Meier method and survival analysis by the log rank (LR) test.

Results: 44 patients were identified (DLBCL: n=24, 54.5%, FL: n=12, 27%, RT: n=8, 18%) who received IBR therapy in the RR setting. Baseline characteristics included age (range 19–80), 61% male, 95% ECOG 0 - 1, 71% stage IV, 62% elevated LDH, and 48% R-IPI ≥ 4. DLBCL sub-types (Hans criteria) were 25% non-GC (n=11), 16% GC (n=7), and 14% unclassifiable (n=6). In the FL subgroup, 8% were grade 1, 58% were grade 2, 33% were grade 3a. Median number of prior therapies was 5 (range 1-11). All RT patients were not treated with IBR previously for CLL. The three most common reasons for IBR discontinuation were progression (35%), toxicity (20%), and bridge to CAR-T (10%). PFS and OS data are shown in Table 1. In DLBCL, cell of origin (IHC) did not impact outcomes [p=0.97, LR test]. Patients with RT had better PFS as compared to de novo DLBCL (p=0.03, LR test).

Summary/Conclusions: Ibrutinib (IBR), a Bruton’s Tyrosine Kinase (BTK) inhibitor, is FDA approved for chronic lymphocytic leukemia, Waldenström macroglobulinemia, marginal zone lymphoma and mantle cell lymphoma. Despite its limited data, IBR is increasingly being utilized as a treatment option for patients with relapsed/refractory (RR) diffuse large B-cell lymphoma (DLBCL) and follicular lymphoma (FL).

Aims: To further characterize the efficacy of IBR in patients with RR DLBCL, Richter’s transformation (RT) or FL.

Methods: We conducted a retrospective cohort study of DLBCL, RT and FL patients consecutively treated with IBR. Data collected included patient demographics, stage, IPI, genetic characteristics, prior treatments, IBR dose and discontinuation reasons for discontinuation and response. PFS and OS were estimated using the Kaplan Meier method and survival analysis by the log rank (LR) test.

and other extranodal localizations (12%). In patients harboring a MYD88 mutation, increased at IP sites (67%, Chi-square P=0.001), compared to nodal (13%) translocations, Epstein Bar Virus (EBV) status and the mutational status of MYD88 and/or CD79B mutations were identified in 51 patients and 19 cases, respectively. CD79B mutations were identified in 32 and 69% of patients presenting at IP sites. These patients with MYD88 mutations display a relatively high prevalence of coexisting CD79B mutations. Interestingly, a recent study by Wilson et al. (Nat. Med. 2015), indicates that these patients are more sensitive to treatment with Bruton’s Kinase inhibitors. Our study highlights the importance of investigating the mutational status of MYD88 and CD79B in larger prospective clinical trials with molecularly targeted agents, particularly in DLBCL patients with IP localizations.

**Background:** Activating mutations in CD79B and MYD88 are important molecular drivers of a subset of diffuse large B-cell lymphomas (DLBCLs), activating the B-cell receptor and toll-like receptor pathways, respectively. Interestingly, the frequency of these mutations differs greatly among DLBCLs at different anatomical sites, with a remarkably high prevalence at immune-privileged (IP) sites (central nervous system and testis). Recent studies suggest that these mutations are associated with an unfavorable prognosis. However, the prognostic value in relation to the site of presentation has not yet been explored.

**Aims:** To investigate if mutations in MYD88 and CD79B are independent prognosticators for overall survival (OS) in DLBCL, particularly in patients with lymphomas at IP sites, for which a high prevalence of these mutations was reported.

**Methods:** In this retrospective study, we investigated a large clinically annotated cohort of 189 consecutive primary DLBCLs, including primarily nodal (N=64), primarily extranodal (N=74) and IP localizations (N=51). Patients were diagnosed between 1990-2015 at the Academic Medical Center, (University of Amsterdam) or other Dutch hospitals. The vast majority was treated with (R-)CHOP (N=143) or other immune-chemotherapies (N=16). Detailed clinical characteristics of all patients were collected. For all patients BCL2, BCL6, and MYC translocations, Epstein Bar Virus (EBV) status and the mutational status of MYD88 and CD79 were assessed, employing methods described previously (Kraan et al., BCJ 2013).

**Results:** Translocations in BCL2, BCL6 and MYC were identified in 14, 32 and 13 patients, respectively and 23 EBV-positive cases were found. MYD88 and CD79B mutations were identified in 51 patients and 19 cases, respectively. Interestingly, there was hardly any overlap between the presence of translocations (BCL2, BCL6 and MYC) or EBV and that of MYD88 and/or CD79B mutations, indicating that these tumors represent distinct DLBCL subgroups. In accordance with previous studies, the incidence of MYD88 mutations was increased at IP sites (67%, Chi-square P=0.001), compared to nodal (13%) and other extranodal localizations (12%). In patients harboring a MYD88 mutation, we frequently found a coexisting CD79B mutation (N=14). Patients with a MYD88 mutation demonstrated a significantly inferior 5-years OS compared to DLBCL with wild-type MYD88 (Log Rank test P=0.01, Figure 1A). This prognostic significance was also found for DLBCLs with IP sites (Figure 1B, LR P=0.029). Coexistence of a CD79B mutation did not impact the prognostic significance of MYD88. Multivariable Cox regression analysis, including clinical and molecular characteristics (i.e. age, translocations, EBV, CD79B, etc.) identified MYD88 and CD79B as independent prognostic parameters with Hazard ratios 1.8, 1.5 and 2.6, respectively (95% Confidence intervals: 1.0-3.6, 1.0-2.8 and 1.4-3.9, respectively).

**Conclusion:** Our study demonstrates that mutated MYD88 is an independent unfavorable prognostic factor for OS, in particular in DLBCL patients presenting at IP sites. These patients with MYD88 mutations display a relatively high prevalence of coexisting CD79B mutations. Interestingly, a recent study by Wilson et al. (Nat. Med. 2015), indicates that these patients are more sensitive to treatment with Bruton’s Kinase inhibitors. Our study highlights the importance of investigating the mutational status of MYD88 and CD79B in larger prospective clinical trials with molecularly targeted agents, particularly in DLBCL patients with IP localizations.

**HIV-INFECTED PATIENTS WITH RELAPSED NON-HODGKIN LYMPHOMA (NHL) OR HODGKIN LYMPHOMA (HL): RESULTS FROM THE GERMAN HIV-RELATED LYMPHOMA COHORT STUDY**

P. Schumacher1,2,3, M. Hentschel4, D. Göller5, C. Wyen1, T. Wolf1, J.-C. Wasmuth6, J. Bogner1, C. Spencer6, S. Esser7, B. Jensen8, M. Müller9, A. Schleicher10, G. Fätkenheuer1, C. Hoffmann10

1University of Cologne, Cologne, 2Hematology/Oncology, Rotkreuzklinikum München GmbH, München, 3University of Frankfurt, Frankfurt, 4University of Bonn, Bonn, 5University of Munich, Munich, 6University of Essen, Essen, 7University of Düsseldorf, Düsseldorf, 8Vivantes Auguste-Viktoria Hospital, Berlin, 9ICH Study Center, Hamburg, Germany

**Background:** The outcome of HIV-associated lymphoma has undergone significant improvement in recent years beginning with the widespread use of combination antiretroviral therapy (ART). However, among AIDS-related deaths, non-Hodgkin lymphoma (NHL) is the most frequent event. HIV-positive patients (pts) with relapsed NHL or Hodgkin lymphoma (HL) should be treated in a manner similar to immunocompetent pts.

**Aims:** To analyze the outcome of pts with HIV-related lymphoma who experienced a relapse after having achieved a complete response to first line therapy.

**Methods:** This prospective multicenter cohort study includes adult HIV-infected pts with biopsy or cytologically proven HIV-related lymphoma diagnosed at 32 participating centers in Germany and Austria since January 2005. Data on HIV-infection and lymphoma characteristics, treatments and outcomes were recorded. Pts with indolent lymphomas and primary central nervous system lymphomas were excluded from the present analysis.

**Results:** Of 499 pts (463 males, 36 females) 394 had aggressive NHL and 105 HL. The median age at lymphoma diagnosis was 45.6 yrs (range, 22–74). 344 pts (69%) were diagnosed with advanced stage (III/IV) lymphoma and the median CD4-cell count was 271/µl (266/µl in NHL and 287/µl in HL). As of June 2015, 311 of 499 pts (62%) achieved a documented CR, 235 (60%) with NHL and 76 (72%) with HL. After a median follow-up of 17 months for NHL and 30 months for HL pts, 31 of 235 NHL (13%) and 6 of 76 HL (11%) experienced a relapse. Incidence of relapse was 6.9/100 patient years (PY) within the 1st year after primary diagnosis and 1.3/100 PY thereafter (P=0.0062). Median time to relapse was 7.3 months in NHL and 18.0 months in HL. Relapses beyond 12 months occurred in 6 of 31 NHL cases (19%) and in all 8 HL cases (100% (P=0.045). Median overall survival (OS) of all relapsed pts was 29.0 months (95% CI 14-1,4-41.3 months) after primary lymphoma diagnosis. In pts with HL, OS was not reached, whereas it was 15 months in pts with NHL (P=0.024). Regarding the entire cohort of 311 pts with a documented CR, the 2-year OS rate was 57% in pts with relapse as compared to 97% in those without (P<0.001). The majority of relapsed pts died of lymphoma (86%).

**Summary/Conclusions:** Relapses from CR are relatively rare in pts with HIV-associated NHL and HL. In pts with NHL the majority of relapses occur within the first year after primary diagnosis, whereas in HL most relapses occur beyond 12 months. Overall, pts with relapsed HIV-related NHL have a worse outcome than pts with relapsed HL.
Background: Nodal peripheral T-cell lymphomas (PTCLs) are a heterogeneous group of neoplasms, which include PTCL not otherwise specified (PTCL-NOS), angioimmunoblastic T-cell lymphoma (AITL), anaplastic large-cell lymphoma (ALCL)-anaplastic lymphoma kinase positive (ALK+), and ALCL-ALK-. Clinical assessments before and after treatment are essential to predict survival in nodal PTCL. However, limited data is available regarding the prognostic relevance of National Comprehensive Cancer Network International Prognostic Index (NCCN-IPI) and post-treatment PET-CT scan.

Aims: The study investigated the prognostic significance of baseline NCCN-IPI and post-treatment PET-CT scan, assessed by Deauville score, in patients with nodal PTCL. The primary aim was to establish a risk model for nodal PTCL patients based on NCCN-IPI, a clinical tool, and post-treatment PET-CT scan indicating tumor viability.

Methods: In this retrospective cohort study, patients with newly diagnosed nodal PTCL were consecutively enrolled from 11 hospitals in South Korea. Patients were eligible if they were histologically diagnosed with nodal PTCL from Jan 2005 to June 2016, received systemic chemotherapy, and had the results of PET-CT scan at the time of diagnosis and at the end of treatment. Post-treatment PET-CT was assessed using 5-point Deauville score. The study excluded ALCL-ALK+ due to well-known better survival.

Results: A total of 396 patients were screened for eligibility. Seventy patients were excluded from the analysis due to following reasons: unavailable pre- or post-treatment PET scans, no systemic treatment, uncertain histology, and post-treatment PET scans, no systemic treatment, uncertain histology, and post-treatment PET-CT scan at the time of diagnosis and at the end of treatment. Post-treatment PET-CT was assessed using 5-point Deauville score. The study excluded ALCL-ALK+ due to well-known better survival.

Results: A total of 396 patients were screened for eligibility. Seventy patients were excluded from the analysis due to following reasons: unavailable pre- or post-treatment PET scans, no systemic treatment, uncertain histology, and post-treatment PET-CT scan at the time of diagnosis and at the end of treatment. Post-treatment PET-CT was assessed using 5-point Deauville score. The study excluded ALCL-ALK+ due to well-known better survival.

Results: A total of 396 patients were screened for eligibility. Seventy patients were excluded from the analysis due to following reasons: unavailable pre- or post-treatment PET scans, no systemic treatment, uncertain histology, and post-treatment PET-CT scan at the time of diagnosis and at the end of treatment. Post-treatment PET-CT was assessed using 5-point Deauville score. The study excluded ALCL-ALK+ due to well-known better survival.

Summary/Conclusions: This study proposes a new risk stratification model incorporating baseline NCCN-IPI in combination with post-treatment Deauville score on PET-CT scan in patients with newly diagnosed nodal PTCL.

Figure 1.
Summary/Conclusions: Crizotinib confirmed to be an effective and safe therapy for advanced relapsed ALK+ ALCL with durable responses up to 6 years after treatment initiation and no relapse later than 4 months. These results represent the longest available safety record for crizotinib. ALK point mutations can develop and 2nd/3rd generation inhibitors may be a therapeutic opportunity for patients who develop resistance to crizotinib.

P571 PRELIMINARY RESULTS FROM AN OPEN-LABEL, PHASE II STUDY OF TIPIFARNIB IN RELAPSED OR REFRACTORY PERIPHERAL T-CELL LYMPHOMA

T. Witzig1, L. Sokol2, E. Jacobsen3, R. Advani4, R. Mondejar5, M. Piris6, F. Burrows7, C. Melvin7, V. Mishra7, C. Scholtz7, A. Gualberto7, 1Mayo Clinic, Rochester, 2Hospital Universitario de Canarias, Las Palmas de Gran Canaria, 3Dana Farber Cancer Institute, Boston, 4Stanford University Medical Center, Stanford, United States, 5DIVAL Instituto de Investigación Marqués de Valdecilla, Santander, 6Fundación Jiménez Díaz, Madrid, Spain, 7Kura Oncology, La Jolla, United States

Background: Tipifarnib is a potent and selective inhibitor of farnesyltransferase (FT). FT catalyzes post-translational attachment of farnesyl groups required for localization of signaling molecules to the inner cell membrane. CXCL12 is a chemokine that is essential for hematopoietic stem cell (HSC) homing to the bone marrow and lymphoid organs and for maintenance of HSCs and immune cell progenitors. CXCL12 is known to signal in part through HRAS, a signaling protein that is uniquely farnesylated. Tipifarnib has previously been shown to be well tolerated and to have a 41% response rate (7 responses out of 17 patients) in patients with T-cell Non-Hodgkin Lymphoma, including 4 objective responses in 8 pts with peripheral T-cell lymphoma (PTCL) (Witzig et al, 2011). Building on this prior experience, we report herein the preliminary efficacy, safety and biomarker data from our ongoing Phase 2 study in PTCL.

Aims: This Phase 2 study is a multi-institutional, single-arm, open-label, two-stage (11+7) study designed to determine the efficacy and safety of tipifarnib in pts with relapsed/refractory (R/R) PTCL.

Methods: Pts with R/R PTCL after prior cytotoxic systemic therapy, aged ≥ 18 years old, and with a performance status of 0-2 were eligible. Informed consent was obtained. The following subtypes of PTCL were eligible for enrollment: PTCL not otherwise specified (PTCL-NOS), angioimmunoblastic T-cell lymphoma (AITL), ALK-positive and -negative anaplastic large cell lymphoma (ALCL), hepatosplenic T-cell lymphoma, enteropathy-associated T-cell lymphoma (EATL), extranodal natural killer (NK) T-cell lymphoma, nasal type and subcutaneous panniculitis-like T-cell lymphoma. The primary endpoint of the study is overall response rate. Secondary endpoints include safety and tolerability, duration of response (DOR) and progression free survival (PFS). Based on activity observed in the first 18 pts in the study, the protocol has been amended and enrollment is ongoing to an expansion cohort in AITL (N=12). Enrolled pts are treated with tipifarnib 600mg administered orally twice daily on days 1-7 and 15-21 of 28-day treatment cycles until progression of disease or unacceptable toxicity. Biomarker studies included gene expression profiling of pre-treatment tumor biopsies by RNASeq and DNA next-generation sequencing (NGS). Clinical trial information: NCT02464228.

Results: At data cut-off (2/15/2017), 18 pts (2 AITL, 1 ALK- ALCL, 15 PTCL-NOS) were treated with tipifarnib. Most common treatment-related AEs (grade ≥ 3) were myelosuppression, including neutropenia (61%), anemia (39%) and thrombocytopenia (39%). 3 pts achieved a partial response (2 AITL; 1 PTCL-NOS) and 3 additional pts experienced stable disease >6 months. Tumor DNA from 18 pts was sequenced using NGS/CGP. A high rate of CXCL12 3’UTR single nucleotide variation (SNV) was observed. Seven of 16 pts carried the rs2839695 variant while an additional patient carried a novel variant. The presence of 3’UTR SNVs was associated with low levels of CXCL12 gene expression and disease progression (Figure) while all pts deriving clinical benefit from tipifarnib carried reference (wild type) 3’UTR CXCL12 and had tumors that expressed high levels of mRNA for this chemokine. Testing of circulating CXCL12 levels is ongoing.

Summary/Conclusions: Although this study is ongoing, these preliminary data indicate that tipifarnib is generally well-tolerated and has antitumor activity, particularly in pts with AITL histology, absence of 3’UTR CXCL12 SNV and high levels of CXCL12 gene expression.

22nd Congress of the European Hematology Association

P572 BAMB CONDITIONING BEFORE AUTOLOGOUS STEM CELL TRANSPLANTATION FOR LYMPHOMA: A RETROSPECTIVE STUDY ON BEHALF OF THE BRANCHOPHONE SOCIETY OF BONE MARROW TRANSPLANTATION AND AUTOLOGOUS STEM CELL THERAPY (BAST) GROUP

T. Torre1, C. De Vincentiis1, M. R. Fanti1, F. Concia1, G. Casoni1, V. Gatta1, M. C. Parodi1, D. Fogli2, M. S. Cella2, G. Cavo2, E. Gyan1, 1Department of Hematology and Clinical Oncology, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, 2Service of Hematology, AOU Città della Salute e della Scienza, Torino, Italy

Background: High-dose chemotherapy before autologous stem cell transplantation (ASCT) is a therapeutic option as a consolidation in primary or relapsed lymphoma. BEAM conditioning is generally used. Alternative conditioning regimens have been published but few data are available.

Aims: To evaluate tolerance and efficacy of the BAM (Busulfan, AraCytin and Melphalan) conditioning before ASCT.

Methods: We conducted a retrospective study in 188 French patients treated between 2000 and 2015. Data were retrospectively collected from the Promise database. Informed consent was obtained from all patients.

Results: Indications for ASCT were diffuse large B-cell lymphoma (n=54, 29%), mantle-cell lymphoma (n=42, 22%), Hodgkin’s disease (n=33, 18%), low-grade non-hodgkin lymphoma (n=26, 14%), T-cell lymphoma (n=17, 9%), Burkitt’s lymphoma (n=8, 4%) and B-cell lymphoma (n=8, 4%). Median age at diagnosis was 50.9 years (35.7-59.9). Time between diagnosis and ASCT was 295 days (176-777). Patients received 1 (n=82, 44%), 2 (n=83, 44%), 3 or more (n=18, 10%), unknown (ND) (n=5, 2%) treatment lines before ASCT. Among the 138 B-cell lymphoma patients, 132 received rituximab before ASCT. Only 20 patients received prior rituximab therapy. In all patients, ASCT was the first transplantation. In 11 patients, ASCT was planned as part of a multiple graft protocol. At the time of transplantation, 116 (62%) patients were in complete remission, 54 (29%) in partial remission, 13 (7%) in relapse or progression, and 5 (2%) ND. ASCT was documented in 186 (99%) patients. Median time to neutrophil and platelet (>50 GigalL without transfusion) recovery was respectively 11 days [10-12] and 19 days [14-32]. Infectious complications were found in 153 patients. One hundred (53%) patients had undocmented fever, 19 (10%) had sepsis, 150 (80%) had grade 1-4 mucositis during neutropenia with a WHO toxicity grading of 2 (42%), 3 (39%) and 4 (19%). Colitis with a median duration of 7 days [5-10], was reported in 73 patients, with a maximum toxicity grading of 1-2 (n=43, 59%), 3 (n=21, 29%) or 4 (n=4, 6%) and ND in 5 patients. Only 2 (1%) patients had non-fatal hepatic sinusoidal obstruction syndrome. Pulmonary toxicity was reported in 33 (17.6%) patients with 8 cases of respiratory distress syndrome. Respiratory distress was fatal in one patient but occurred more than 6 months after ASCT and salvage treatment. Seven (3.7%) patients reported secondary cancers (all were solid tumors except one acute leukemia). Median follow-up was 17.1 months [11.3-29.5]. At the time of the study, 47 (25%) patients had relapsed. Cumulative incidence of relapse was 6.24% at 3 months and 17.31% at 12 months. At the end of the follow-up, 149 (79%) patients were alive. The main causes of death were relapse (n=15, 41%) and toxicity (n=16, 43%). Median overall survival (OS) was not reached and progression-free survival was 71.5 months [47-NR]. Relapse-free mortality was 1.66% at 3 months and 4% at 12 months. In the univariate analysis, the number of treatment lines (1 or 2) before ASCT and previous use of monoclonal antibodies positively impacted the OS. Conversely, the multiple graft protocol had an unfavorable impact on OS.

Conclusion: BAM conditioning before ASCT for lymphoma helps to control disease activity without excessive toxicity. It may be a suitable alternative to BEAM in case of drug shortage. However, comparative studies are needed to confirm these findings.
Bone marrow failure syndromes incl PNH - Clinical

ANALYSIS OF MICRONAAOME, PROTEOME AND METABOLOME OF EXOSOMES FROM PATIENTS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA
R. Teruel-Montoya1,2, G. Luengo-GIP, F. Vallejo1, J. E. Yuste3, N. Bohdan2, S. Espin2, N. García-Barberá2, C. Martínez3, J.C. Espín3, V. Vicente1,2, I. Martínez1,2,∗
1Grupo de Investigación CB15/00055, Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Instituto de Salud Carlos III (ISCIII), Madrid, 2Servicio de Hematología y Oncología Médica, Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arraxaca, 3Research Group on Quality, Safety and Bioactivity of Plant Foods, CEBSAS-CSIC. 30100, Campus de Espinardo, Murcia, Spain

Background: Paroxysmal Nocturnal Hemoglobinuria (PNH) is a clonal disease caused by the lack of glycosyl inositol phosphatidyl anchored proteins at the cell membrane that lead to intravascular hemolysis upon complement activation. Patients have intravascular haemolysis with high risk of thrombosis, and a variable degree of bone marrow failure. Treatment with Eculizumab reduces intravascular hemolysis and also the thrombotic risk. The mechanism of thrombosis in PNH is still unknown. Exosomes are small extracellular vesicles released by cells and whose secretion is closely related with the inflammatory status. Exosomes participate in cell communication by activating signaling pathways and transferring genetic material, i.e. miRNA, and proteins to host cells.

Aims: To describe the microRNAome, proteome and metabolome of exosomes from PNH patients to identify potential biomarkers of the disease and to investigate its relationship with the mechanism of thrombosis in these patients.

Methods: Plasma exosomes were isolated from 5 healthy controls and from 9 PNH patients (6 with Eculizumab, 3 with thrombosis –ET- and 3 without thrombosis –ENT- and 3 without Eculizumab) using Total Exosome Isolation kit (Thermo Fisher). miRNA expression was evaluated by plasma/serum focus miRNAs PCR panel V4 (Exiqon). Proteomic analysis of exosomes was performed at the OMCs core facilities. Untargeted metabolomic analysis was performed by using combination of gas chromatography and liquid chromatography (LC) with mass spectrometry (MS). Additionally, latest advances were used combining LC-MS-solid phase extraction-nuclear magnetic resonance (UPLC-QTOF_SPE_NMR) on line’ for unequivogue structural elucidation of unknown metabolites.

Results: Mir-16-5p and miR-451a had lower levels in patients vs controls. Eculizumab treatment increased their expression, particularly in the group with thrombosis. Eculizumab also decreased mir-223-3p (the most abundant miR) in platelets and that has been associated with its reactivity) and increased mir-15a-5p levels (0.50- and 3.12-fold respectively). Those proteins differentially expressed in patients and controls were related with the complement system and the immune response. We identified an increase in the plasma hemo-globin levels in patients vs controls (4.9-fold), which is related with platelet activation. It is also noteworthy the decrease (1.5-fold) of the anticoagulant Protein S in patients vs controls. When the analysis was performed among the 3 groups of patients, only Ig heavy chain V4 region HG3 increased in 3.9-fold in the Eculizumab group vs without Eculizumab group, which could be related with the treatment. We identified quite few metabolites inside the exosomes, all of them associated with cell toxicity or immune response. The levels of Cholesterol, HydroxyTertbinaine-glucuronide and Diacylglycerol decreased in 17.3, 17.6 and 19.4-fold, respectively in patients treated with Eculizumab. Interestingly, the Aminoethylphosphonicacid, Cholesterol and PGF2 increased 16.7-; 21- and 19.4-fold in patients with thrombosis.

Summary/Conclusions: Our study suggests that exosomes contain material that may influence the pathologic status of the PNH patients. In concordance, most of the proteins, miRNAs and metabolites are related with the complement system or the inflammatory response. In future experiments, some of the proteins, miRNAs and metabolites should be validated to define whether they could be considered biomarkers.

SEVERE CHRONIC NEUTROPENIA: THE ROLE OF PRIMARY IMMUNODEFICIENCY AS CAUSATIVE AGENTS. A SINGLE CENTER DATA
F. Fioredda1∗, F. Pierric1, C. Micalizzi1, M. Calvillo1, E. Palmisani1, I. Ceccherini1, A. Gross1, M. Lanciotti1, F. Terranova1, T. Lanza1, M. Miano1, C. Dufour1
1Haematology Unit, 2Molecular Genetic Unit, IRCCS Istituto Giannina Gaslini, Genova, Italy

Background: Severe Chronic Neutropenia may be a primary disease, usually defined as congenital (CN), or a condition mainly secondary to autoimmune disturbances (SN) (1,2). CN rises in early infancy, has a narrow block at pro/myelocyte, classically carries genes ELANE/HAX1 mutations in 70% of cases and is G-CSF dependent. SN is accompanied by extraheamatological signs and/or positivity of autoimmune markers; bone marrow has a normal morphology or is “left shifted”. In spite of these categorization many cases do not fit either group and share features of both of them. These “Overlap Neutropenia” (ON) patients are a diagnostic and management challenge.

Aims: Investigate the genetic background of this ON from a cohort of chronic neutropenia subjects screened at Hematology Unit of Gaslini Hospital and characterize their clinical phenotype.

Methods: Patients with severe chronic neutropenia were seen prospectively in our center and diagnosed/followed-up according to published guidelines(3,4).

Genetic diagnosis includes classical Sanger technique foe commonest severe chronic neutropenia genes and an enlarged NGS panel including also those genes responsible for PID.

Results: From 2008 to 2016, 24 patients (13 males) with median age at last follow of 18yrs (range 20 mo-51y) had a complete work up for severe chronic neutropenia (Table 1). Ten/24 subjects (43%) were diagnosed as classical CN with ELANE mutation found in the majority (80%) of cases. Seven/24 (29%) were diagnosed as SN and the remaining 7/24 (29%) as ON. A PID genes mutation was found in a total of 8/24 patients (30%) with 5 patients belonging to 7 SN subjects (71%) and 3 to the 7 ON subjects (42%).Table 1 shows clinical hematological characteristic of the 3 categories of patients.

Summary/Conclusions: A considerable portion (30%) of subjects affected with severe chronic neutropenia have been identified as PID. In the group of ON subjects a mutated PID gene was found in 3/7 patients and mutations of ELANEin 2/7 patients. No mutation was found in the remaining 2. The phenotype of ON subjects is characterized by extra-heematological autoimmune symptoms, by maturation block and by the frequent involvement of more than one hematopoietic lineage. This phenomenon may suggest to access to an enlarged genetic panel including PID genes for genetic diagnosis. An accurate immunological and genetic work may support diagnosis and management of these difficult patients.

Table 1.

TREATMENT WITH HORSE-DERIVED ANTI-THYMOCYTE GLOBULIN LENDS TO ENDURING HEMATOLOGICAL RESPONSES AND A 1.5-YEAR SURVIVAL PROBABILITY OF 87% IN ADULT ACQUIRED APLASTIC ANEMIA PATIENTS IN THE NETHERLANDS
J. Tjon1, L. de Wreede2, F. Falkenburg1, M. de Grooth3, H. Koene4,
To evaluate the safety and efficacy of first line treatment using ATGAM and ciclosporin in adult patients with acquired aplastic anemia in the Netherlands.

Methods: Data on adults with acquired aplastic anemia who received ATGAM as first-line treatment was collected in the LUMC, AMC, UMCG, UMCU, VUMC, MC, UMCN, Erasmus MC, Medisch spectrum Twente and Antonius Nieuwbeek Nieuwegein. The data included baseline-characteristics and follow-up data at 3, 6, 9 and 12 months. After 12 months, follow-up data was collected at least yearly. All patients received first-line treatment with ATGAM (40mg/kg for 4 days) and ciclosporin. Response was defined as complete in case of normalization of blood values and as partial in case of transfusion dependency and neutrophil count >0.5 x 10^9/L. Overall survival was evaluated with the Kaplan-Meier method.

Results: In October 2016, 70 patients were registered in the NVvH registry. Median start of treatment was 53 years (18-79) and median follow-up time was 18 months. Overall survival probability after 18 months was 87%. Fifty-nine patients were evaluable for a response at 6 months after treatment. Response was seen in 36 patients (61% (CI 49-73%)). Patients with a response at 6 months, had an overall survival probability of 94% at 12 months thereafter. After initial response at 6 months, aplastic anemia relapsed in 4 patients and 1 patient developed AML. From the 23 non-responding patients, 7 patients continued ciclosporin after 6 months without additional treatment. Five of these 7 patients became transfusion independent up to 18 months after treatment with ATGAM. Sixteen of the patients without a hematological response 6 months after ATGAM received second-line treatment consisting of alloSCT (n=8), Thymoglobulin (n=4), Eltrombopag (n=3) or Danazol (n=1). From the 16 patients that received second-line treatment, 10 patients eventually had a hematological response. Patients without a response at 6 months, had an overall survival probability 12 months thereafter of 90%. One patient developed secondary AML after second-line treatment with Thymoglobulin.

Summary/Conclusions: Six months after treatment with first-line ATGAM, 61% of the adult patients with acquired aplastic anemia is transfusion independent. Half of the remaining patients becomes transfusion independent after rescue treatment or after continuation of ciclosporin beyond 6 months.

P578 DEVELOPMENT OF A SCREENING AND DIAGNOSTIC ALGORITHM FOR PAROXYSMAL NOCTURNAL HEMOGLOBINURIA USING A MODIFIED DELPHI PANEL METHODOLOGY

A. Röth1,*, J. Maciejewski2, J.-L. Nishimura3, D. Jain4, J. Weitz5

1University Hospital Essen, Essen, Germany. 2Cleveland Clinic, Cleveland, United States. 3Osaka University Graduate School of Medicine, Osaka, Japan. 4Alexion Pharmaceuticals, Inc., Cambridge, United States. 5McMaster University, Hamilton, Canada

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a rare clonal hematopoietic stem cell disorder that manifests with hemolytic anemia due to uncontrolled complement activation, bone marrow failure, and thrombosis. Diagnosis is essential because PNH is a progressive disorder associated with substantial morbidity and mortality. The protean clinical manifestations of PNH complicate diagnosis, and subsequently the diagnosis is often delayed or missed. Although national diagnostic guidelines are available, international expert consensus on PNH screening and diagnosis is lacking.

Aims: An international panel of PNH experts was assembled to develop a clinically relevant, consensus-driven screening and diagnostic algorithm for PNH.

Methods: An expert advisory committee of 4 PNH experts from North America, Europe, and Japan was assembled. Using a modified Delphi methodology, consensus was gained on the symptoms and signs of PNH and the laboratory tests required for screening and confirmation of diagnosis. Globally representative Delphi panelists were identified through a double-blinded screening process and asked to complete 2 rounds of web-based questionnaires. The questionnaires were developed by the expert advisory committee and presented to the Delphi panel in a case-based format. In the first round, Delphi panelists were given 5 blinded case studies—each including details on clinical presen-
tation and past medical history—and were asked to provide their differential diagnosis and the tests they would order to establish the diagnosis in free-text format. To reduce bias, Delphi panelists were blinded to the fact that the study was focused on PNH. Responses mentioned by ≥50% of Delphi panelists in the first round were included in the second-round questionnaire. For each case in the second-round questionnaire, Delphi panelists were presented with a set of consensus statements regarding potential diagnoses and the need for specific tests/data from a multiple-choice list and asked to respond with their level of agreement on a 4-point Likert scale. Consensus in the second round was attained if ≥80% of Delphi panelists agreed on a given screening or diagnostic approach.

Results: Twelve Delphi panelists from 6 countries, all of whom were clinicians with expertise in PNH, were recruited. Consensus was reached on 22 of 23 PNH screening and diagnostic decision points identified by the Delphi panelists. Specifically, consensus was gained on the core symptoms and signs of PNH at presentation, including hemolysis, bone marrow dysfunction, and thrombosis. Consensus was reached on 36 of 38 questions in the second round, and the tests required at each decision point to narrow the differential diagnosis and to confirm the diagnosis of PNH. The level of agreement on screening and diagnostic decision points and tests was sufficient to enable the development of a screening and diagnostic algorithm (Figure) that is consistent with the published literature and with the real-world experience of the international expert advisory committee.

Summary/Conclusions: The modified Delphi methodology facilitated development of a consensus-based, clinically relevant PNH screening and diagnostic algorithm. This algorithm provides clinicians with varying levels of expertise detailed guidance on how to screen for and diagnose PNH.

P579

DIAMOND-BLACKFAN ANEMIA IN THE NETHERLANDS: AN OVERVIEW OF CLINICAL CHARACTERISTICS AND UNDERLYING MOLECULAR DEFECTS

B. Van Doojewie1,2, M. Biering3, A. MacInnes4,3, M. Bartels5,1
1Pediatric Haematology, clinical research, 2Pediatric Haematology and Stem Cell Transplantation, Wilhelmina Children’s Hospital, Utrecht, 3Euro DBA, genetic metabolic diseases, AMC, Amsterdam, 4Pediatric Haematology and Oncology, Wilhelmina Children’s Hospital, Utrecht, Netherlands

Background: Diamond-Blackfan anemia (DBA) is a rare genetic disorder, characterized by bone marrow failure (anemia), congenital anomalies and a predisposition for malignancies. DBA is characterized by a highly heterogeneous nature, both clinically and genetically. Most of our understanding of this disorder stems from molecular studies combined with extensive data-input from international patient registries.

Aims: The aim of our retrospective study was to create an overview of the pediatric DBA population in the Netherlands.

Methods: Forty-four patients (age 0-18yr) diagnosed with DBA from all Dutch pediatric centers included in this study. Clinical and genetic characteristics were collected from patient records.

Results: Congenital malformations were present in 19/41 patients (46,3%), varying from craniofacial and cardiac defects to urogenital and developmental disorders. An underlying genetic defect was identified in 23 patients (56,1%), the majority of which were found in the RPS19 gene (n=10; 45%). No significant diversities in malformations, course of disease or response to treatment were observed when comparing patients with or without identified genetic defects. In agreement with previous reports, two patients harboring defects in RPL11 displayed a more severe phenotype, including craniofacial malformations, thumb abnormalities, and cardiac defects. In contrast, our patient with a mutation in RPL5 has no associated congenital abnormalities, while previous studies reported a very high frequency (83%) of associated congenital defects. Furthermore we observed a relatively high number (12/23) of novel mutations in well-known DBA-genes, defined as novel variants. In addition, we have identified a novel variant, described in a patient with multiple congenital abnormalities (craniofacial defects, cardiac defects, colitis) in addition to severe anemia. Thirty-four (3/44) patients were treated with glucocorticoids, of which in thirty-one (31/34) patients a complete response was observed (91,2%). However, in 29% discontinuation was prompted by high-dose dependence, side effects, a weaning response, or a combination of these factors. Five patients (12,2%) were successfully transplanted with hematopoietic stem cells from either matched sibling donors (n=3) or matched unrelated donors (n=2), including two cases after the age of 10 years. Eleven patients (26,8%) were treatment-independent, defined as acceptable hematological parameters without any therapy. No malignancies were thus far reported.

Summary/Conclusions: In line with previous reports, the Dutch pediatric DBA population is both clinically and genetically heterogeneous, with RPS19 being the most frequently mutated gene. Interestingly, the majority of mutations in our cohort have not been described before, probably further underlying clinical heterogeneity. In conclusion, we have identified a novel variant in RPL9, associated with a more severe phenotype, based on multiple associated congenital defects. While we created a comprehensive overview of the Dutch pediatric DBA population, limitations of our study include a relatively small number of patients, and the lack of complete genetic analysis (for all DBA candidate genes) in a relevant number of patients. Overall, to increase our understanding of genotype-phenotype correlation in DBA, and underlying pathophysiological mechanisms more generally, it crucial to further extend our genetic, and functional analysis of DBA-candidate genes, as well as compare, and share data from international registries.
to detect the presence of a PNH clone. Granulocytes, monocytes and erythrocytes were integrated with multi-colour flow panels including CD61 and FLAER. The criteria for determining discordant granulocyte and monocyte clone sizes was dependant upon the absolute size of the smaller clone. For clones 0.1-10%, discordance was defined as when the larger clone was either ≥2 x the smaller clone or at least 1% (absolute value) greater. For smaller clones >10%, the larger clone had to be ≥110% its size. IST was uniform - Cyclosporine (CSA, 2.5mg/kg p.o. b.i.d.), anti-thymocyte globulin (ATG; ATGAM® 40mg/kg IV daily x 4 days) and (Methylprednisolone 1mg/kg/day x 10 days). CSA doses were adjusted to maintain whole blood trough CSA level of 200-300 ng/L for 12-months followed by slow taper based upon hematologic response. Non-responders at 6 months were eligible to proceed to either a second cycle of ATG or BMT, if a suitable donor was available. Severity of AA [very severe (VSAA), severe (SAA) or non-severe (NSAA)] and response to IST [(none, partial (PR) or complete (CR)] were determined according to published criteria (Marsh, Br J Haematol, 2009). Statistical comparisons were done using a standard chi square analysis.

Results: 30 pts with AA and a PNH clone were identified, 18 females and 12 males with median age of 50.5 years (range 17-71). There were 14 pts with NSAA, 13 with SAA and 3 with VSAA. Responses were seen in 20/30 pts (66.7%) including 13 PR and 7 CR. Six pts relapsed with CSA tapering and 5 responded to intensified IST. 2 pts required Eculizumab after evolving to a classic PNH phenotype. Six pts underwent BMT for primary non-response and 4 pts have died (2 post-BMT, 1 from complications of AA and 1 from breast Ca); 30 pts remain alive and well with a median follow-up of 48 mos (15-86). There were 9 pts (CNS 0.1-10%), the larger clone had granulocyte-dominant disease (Group 2) and 9 pts (≥2 x the smaller clone or at least 1% (absolute value) greater. For smaller clones >10%, the larger clone had to be ≥110% its size. IST was uniform - Cyclosporine (CSA, 2.5mg/kg BW) and prednisone (day 1-29).

Response rate (%): 12/17 (70.6%) 4/4 (100%) 4/4 (100%) 0.096.

Summary/Conclusions: Flow cytometry for a PNH clone is routinely done in AA although it may be important to evaluates both granulocyte and monocyte clone sizes. Pts with a larger monocyte than granulocyte clone size more frequently have NSAA and appear to have a lower response rate to IST. This may have therapeutic implications and could identify a population of pts requiring a unique therapeutic approach.

P582

RESPONSE TO ANTI-THYMOCYTE GLOBULIN (ATG) IN PATIENTS WITH APLASTIC ANEMIA (AA): A SINGLE-CENTRE EXPERIENCE OVER THE LAST 28 YEARS

M. Oelmüller1,*, F. Alashkar1, D. Herich-Terhürne1, U. Dührsen1, A. Röth1
1Department of Hematology, University Hospital Essen, Essen, Germany

Background: Aplastic anemia (AA) is a rare, usually acquired disorder characterized by bone marrow failure with bi- or pancytopenia and marrow hypoplasia. The classification into the three main subtypes is of prognostic and therapeutic relevance. Depending on disease severity, patient’s age, and the availability of a potential HLA-identical donor, different therapeutic strategies arefavorable immunosuppressive therapy (IST) with anti-thymocyte globulin (ATG) and cyclosporine (CsA) is considered as the initial standard treatment. A hematologic recovery is seen in up to 60-70% of the pts following horse-ATG (hATG) treatment, compared to 35-53% in rabbit-ATG (rATG) treated pts, considering hATG as first-line therapy in AA pts.

Aims: As response rates vary according to the different studies and the source of ATG being used, our aim was to retrospectively evaluate response rates in pts with AA receiving IST at the Department of Hematology at the University Hospital of Essen between 1988 until 2015.

Methods: In this single-center, retrospective analysis, approved by the institutional review board of the University Hospital of Essen between 1988 until 2015, 30 pts were evaluated and monitored at the Department of Hematology between 1988 until 2015. 73% of the pts (49/67) were treated with hATG (ATGAM® (44/49) vs >50 yrs: 43% (13/30); p<0.001). In primary refractory pts (34% (23/67)) (52% (12/23) in first-line treated hATG pts vs 48% (11/23) rATG treated pts) a second course with either hATG (3/9) or rATG (6/9) was initiated, achieving an overall hematologic recovery at 6 months in 3 pts (33% (1/3) hATG vs 33% (2/6) rATG treated pts). A disease relapse (median: 13 months after primary ATG therapy) was seen in 11 out of the 44 pts with primary hematologic recovery (25%) (82% (9/11) in first-line treated hATG pts vs two rATG treated pts). A salvage therapy with rATG was initiated in two pts, whereas in one other pt a second course with hATG was started. An overall response following relapse therapy was observed in 33% of the pts (1/3). Four refractory as well as relapsed pts were treated with eltrombopag respectively (final results are still awaited). A secondary HSCT (hematopoietic stem cell transplantation) was performed in 11 out of the 67 pts (16%), either being primary refractory or due to a disease relapse.

Summary/Conclusions: Our data are able to independently confirm the findings of previous studies concerning hematologic recovery rates in pts with acquired AA following IST with ATG by providing further evidence that ATG plus CsA is inferior to hATG plus CsA when administered as a first-line treatment. In addition, we were able to observe in pts ≤50 yrs, irrespective gender, an overall higher hematologic recovery. For this reason, it remains unclear why ATGAM® is still not approved in Germany as first-line therapy in pts with AA, as the only hATG product registered in Europe (Lymphoglobulin®) was withdrawn from the market in 2007.

NOTCH1 MUTATED CHRONIC LYMPHOCYTIC LEUKEMIA CELLS ARE CHARACTERIZED BY A MYC-RELATED OVEREXPRESSION OF NUCLEOPHOSMIN-1 AND RIBOSOME ASSOCIATED COMPONENTS

F. Pozzo1,*, T. Bitto1, E. Vendramini1, R. Bomben1, P. Bulian1, F.M. Rossi1, A. Zucchetto1, E. Tissino1, M. Degan1, G. D’Arena1, G. Di Raimondo2, F. Zaja3, G. Pozzato2, D. Rossi6, G. Gaidano7, G. Del Poeta8, V. Gatte1, M. Dal Bo1

1Clinical and experimental Onco-hematology unit, Centro di Riferimento Oncologico, Aviano, 2Onco-Hematology Department, Centro di Riferimento Oncologico del’Ostetricia della Basilicata, Rionero in Vulture, 3Division of Hematology, Ferrarotto Hospital, Catania, 4Clinica Ematologica, Centro Trapianti e Terapie Cellulari Azienda Ospedaliera Universitaria S. Maria Misericordia, Udine, 5Department of Internal Medicine and Hematology, Maggiore General Hospital, University of Trieste, Trieste, Italy, 6Hematology, Institute of Oncology Research and Oncoptology Institute of Southern Switzerland, Bellinzona, Switzerland, 7Division of Hematology—Department of Translational Medicine, University of Eastern Piedmont, Novara, 8Division of Hematology, S.Eugenio Hospital and University of Tor Vergata, Rome, Italy

Background: Stabilizing mutations of NOTCH1 have been identified in about 10% of chronic lymphocytic leukemia (CLL) cases at diagnosis, with a higher frequency in unmutated IGHV (IGHV-UM) immuno-chemorefractory or advanced disease phase CLL, and have been associated with particularly unfavourable prognosis (Rossi et al, Blood, 2012; Del Poeta et al, Br J Haematol, 2013; Stilgenbauer et al, Blood, 2014); in CLL, all NOTCH1 mutations disrupt the C-terminal PEST domain and cause an accumulation of an active NOTCH1 isoform, resulting in a sustained pathway activation.

Aims: To identify molecular/biological features of NOTCH1 mutated CLL

Methods: The presence of NOTCH1 mutations was investigated by NGS. Gene expression profile (GEP) was performed by a one-color labeling strategy using a one-color labeling strategy using a one-color labeling strategy using the 4x44K platform. Specific gene/protein validations were performed by QRT-PCR, western blotting, flow cytometry and immunofluorescence. CLL-like MEC-1 cell line was transfected with a vector containing a NOTCH1 intracellular domain (NICD) or with a control vector. Cell proliferation was evaluated by CellTrace assay. Cell size was estimated by flow cytometry from Forward Scatter (FSC) values.

Results: i) A GEP comparing purified cells of 10 IGHV-UM CLL cases (5 NOTCH1-mut; 15%>37% of NOTCH1 mutated alleles) selected nucleophosmin-1 (NPM1) and genes regulating for several ribosomes as significantly up regulated in NOTCH1-mut cases. Agher expression of NPM1 and RNPs in NOTCH1-mut cases was validated in a wider independent series of 188 cases by QRT-PCR (76 NOTCH1-mut cases). In CLL, NPM1 expression was previously found higher in IGHV-UM cases (Rees-Unwin, Br J Haematol, 2009). In our series, no significant difference in NPM1 transcript expression was found by comparing IGHV-UM and IGHV-M cases, but NPM1 transcript expression was confirmed significantly higher in NOTCH1-mut than in NOTCH1-wt cases in the IGHV UM subgroup. ii) Western blotting in 11 CLL cases (5 NOTCH1-mut) confirmed a higher NPM1 protein expression in NOTCH1-mut cases, with a direct correlation with NOTCH1 expression (r=0.814). In NOTCH1-mut cases, the NPM1high subpopulation, isolated by cell sorting, showed a higher NOTCH1 mutational load than the NPM1low subpopulation. iii) EDTA treatment of 12 CLL cases (6 NOTCH1-mut) activated NOTCH1 signaling (Rand et al, Mol Cell Biol, 2000), as from HES1 and DTX1 induction, and up-regulated NPM1 and other RNPs. The same effects were confirmed by co-culture of CLL cells with the JAGGED1-expressing M2-10B4 stromal cells. Inhibition of NOTCH1 signaling by gamma-secretase-inhibitor L685,458 or by siRNA for NOTCH1 reduced NPM1 expression (Fig. A). iv) Previous studies identified MYC as a direct transcriptional target of NOTCH1 (Brock et al, Genes and Development, 2008; Andritsos et al, PNAS 2009) and, in turn, a transcriptional activator of both NPM1 and RNPs. ChIP assays on MEC1 cells, transfected with exogenous NICD, revealed increased NICD binding to the MYC promoter, along with higher expression of MYC, NPM1 and RNPs. Of note, after 48 h culture, NOTCH1-mut CLL cases showed increased MYC transcript levels than NOTCH1-wt cases. MYC expression was further increased upon NOTCH1 activation by EDTA or by stromal cells co-cultures (Fig. B). MYC silencing by siRNA efficiently reduced NPM1 transcript and protein expression. Moreover, CpG-ODN/2 treatment, to induce MYC overexpression, also increased NPM1 transcript and protein levels in CLL cells. v) NPM1 silencing by siRNA was able to reduce proliferation rates and cell size of both NICO-transfected cells and control cells. In keeping with a NOTCH1-driven regulation of cell growth/ proliferation and protein biosynthesis, activation of NOTCH1 signaling in 12 CLL cases (6 NOTCH1-mut) by EDTA or stromal cells co-culture, induced an increase in cell size.

Summary/Conclusions: NOTCH1 mutations in CLL are associated with the overexpression of MYC and MYC-related genes involved in protein biosynthesis including NPM1, which are allegedly responsible for cell growth and/or proliferation advantages of NOTCH1-mut CLL.

P584

CLL-LIKE B-CELL CLONES FROM MBLLO INDIVIDUALS PERsist AT INCREASED COUNTS AFTER SEVEN YEARS OF FOLLOW-UP

I. Criado1,*, A. Rodriguez-Caballero1, L. Gutierrez1, C.E. Pedreira1, W.G. Nieto1, C. Teodosio1, V. Herraez2, A. Romero-Furones2, P. Fernandez-Navarro3, J. Almeida1, O. Orfao1
1Department of Medicine, Center for Cancer Research, 2Centro de Atención primaria de Salud Migue Almargo, 3Centro de Atención Primaria de Salud de Legestma, Salamanca, Spain

Background: The presence of very low numbers of clonal B cells in peripheral blood (PB) of otherwise healthy individuals (low-count monoclonal B lymphocytosis-MBLlo) is a common finding in the general population (20-30% of individuals). The majority of clonal B cells from MBLlo subjects show a phenotype overlapping with CLL (chronic lymphocytic leukemia) cells, the former might represent either the normal counterpart of CLL or the earliest stages of the disease. Little information exists about both the clinical outcome of MBLlo subjects and the biological features of their B-cell clones over time.

Aims: To gain insight into the biological and clinical significance of the presence of CLL-like MBLlo clones, we re-evaluated the biological features of clonal B cells and the clinical outcome of MBLlo individuals after 7 years of follow-up.

Methods: The baseline study was conducted in 2008, when 80 out of 639 (12.5%) healthy individuals (>40y) were found to carry at least 1 B-cell clone like clonal B-cell population, using high-sensitive flow cytometry. A subset of them (n=49) has been followed for a median period of 84 months (range: 67-95 months). Besides physical examination and flow cytometry analyses, the most frequent CLL-related cytogenetic alterations [del13q14.3(D13S25), trisomy 12, del(11q(ATM)) and del(17q(TP53))] and del(1q) were studied at baseline and at follow-up.

Results: A total of 64 CLL-like MBLlo clones (median size: 0.44 cells/ul, range: 0.027-66 cells/ul) were detected in PB of the 49 subjects at recruitment (in 15 cases >2 B-cell clones were detected in the same subject). In all subjects, B-cell clones persisted at reevaluation, phenotypically identical vs baseline. Interestingly, we found a near 4 fold overall increase in the number of B-cell clones after a 7y follow-up vs baseline (median size: 1.22 cells/ul, range: 0.046-789 cells/ul; p<0.001); in line with this, most clones (45/64; 70%) increased their size, while the remaining 30% maintained stable or slightly decreased numbers compared to time 0. From the genetic point of view, only 8/32 (25%) clones showed a size increase and a change in cytogenetic alterations; among those, del(13q) was the most common abnormality being present in 7/8 cases and trisomy 12 in the remaining one. Strikingly, re-evaluation after 7 years showed 36/56 clones (64%; p<0.01 vs baseline) with cytogenetic alterations; again, the most common abnormality was del(13q)(D13S25) (34/36) followed by trisomy 12 (13/36) and del(17q)(TP53) (1/36). A statistical association (p=0.05) was found between the overall increase over time in the size of these clones and the presence of cytogenetic lesions. Three subjects developed lymphocytosis (median: 5.3x10^9 lymphocytes/l; range: 4.1x10^9-5.9x10^9) after 7 years; in these cases the clone size increased sub-
MICROENVIRONMENT REGULATION OF PROGRAMMED DEATH-1 (PD1) RECEPTOR AND ITS LIGANDS PD1 AND PD2 IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL)

Background: The nuclear periphery, containing the IgH and Igk gene clusters, is a unique compartment comprised of inner nuclear membrane proteins and nuclear lamina. Previous genome-wide and cytological studies revealed the regulatory role for some of these nuclear proteins in higher level genome organization and gene regulation. In particular, Lamina Associated Domains (LADs) were identified at the nuclear periphery as transcriptionally silent, gene-poor domains of the genome. Lamin B1. More recent studies however revealed an important role of LADs in the regulation of gene expression and recombination. Aims: Given the apparent topological coincidence between LADs and Ig variable clusters, we hypothesised that nuclear lamina might play a paramount role in the dynamics of Ig-encoding variable genome domains. In particular, here we tested whether Lamin B1, a principal LAD-associated component of the nuclear envelope, had any restrictive role on somatic hypermutation (SHM) and the expression of Ig genes. Due to the strong involvement of IgV mutations in the pathogenesis of B-cell malignancies, we also tested whether nuclear lamina is involved in the pathogenesis of germinal centre lymphomas and chronic lymphocytic leukaemia (CLL).

Methods: We used BL2 and naïve B cells as in vitro and ex vivo models for somatic hypermutation. ChiP-Seq, ChiP-PCR and ImageStream analyses were performed to establish Lamin B1 genome and nuclear binding dynamics in resting and activated BL2 and B cells. LMNB1 RNAi was used to obtain the somatic hypermutation. ChIP-Seq, ChIP-PCR and ImageStream analyses were performed to establish Lamin B1 suppressive environment when SHM was induced during B cell activation and formation of lymphoid germinal centres. ChIP-Seq and the expression of Ig genes. Due to the strong involvement of IgV mutations in the pathogenesis of B-cell malignancies, we also tested whether nuclear lamina is involved in the pathogenesis of germinal centre lymphomas and chronic lymphocytic leukaemia (CLL).

Results: We have found that genome binding of Lamin B1, a component of the nuclear envelope involved in epigenetic chromatin regulation, is reduced during B cell activation and formation of lymphoid germinal centres. ChiP-Seq analysis of BL2 and heavy and very heavy immunoglobulin domains were released from the Lamin B1 suppressive environment when SHM was induced in B cells. RNAi-mediated reduction of Lamin B1 resulted in spontaneous SHM as well as kappa-light chain aberrant surface expression. Finally, Lamin B1 expression level correlated with progression-free and overall survival in chronic lymphocytic leukemia, and was strongly involved in transformation of follicular lymphoma.

Summary/Conclusions: In summary, here we report that Lamin B1 is a negative epigenetic regulator of SHM in normal B-cells and a “mutational gatekeeper”, suppressing the aberrant mutations that drive lymphoid malignancy.
Background: B cell receptor (BCR) mediated signalling is crucial for the pathogenesis of chronic lymphocytic leukemia (CLL). Drugs such as ibrutinib and idelalisib which inhibit BCR associated kinases have proved effective for the treatment of CLL but only suppress the disease without being curative. Some patients have developed resistance to these drugs following mutations, progress on therapy for unknown reasons, or cannot tolerate these drugs due to adverse events. We have shown that microenvironmental signals (e.g., IL-4) can increase BCR expression and signalling, and can partially reverse the effects of BCR-kinase inhibition. ibrutinib, a drug that is known to determine an impairment of microenvironmental interactions with consequent shrinkage of tumor masses, and efflux of CLL cells into the blood stream.

Methods: Eighteen primary CLL samples were treated with IL-4 +/- ibrutinib (1μM) and expression of FOXP1, GAB1, PTEN, SOCS1 and SOCS3 assessed by immunoblotting. The effect of ibrutinib on apoptosis was assessed by flow cytometry and PI/Annexin V staining.

Results: Primary human CLL cells treated with IL-4 for 24 hr significantly increased expression of positive regulators of BCR signalling FOXP1 and GAB1 in CLL samples with un-mutated IGHV (U-CLL); no change in expression in FOXP1 or GAB1 was seen in CLL samples with mutated IGHV (M-CLL). There was a 40% increase in PTPN22 expression in IL-4-treated U-CLL samples vs no change in M-CLL. ibrutinib, at therapeutic concentrations, blocked IL-4 mediated decreases in FOXP1, GAB1 and PTPN22 and pSTAT6 (a positive control for IL-4 signalling). After 24 hr IL-4 selectively increased expression of the negative regulators of IL-4 signalling, SOCS1 and SOCS3 in U-CLL, but not M-CLL cases, and this could be blocked by ibrutinib. CLL cells with expressed VLA-4 and FOXP1 could be induced apoptosis of other cytokines known to play a role in CLL biology (IL-6, IL-10, IL-15, IL-21 and IFNγ) which utilise either JAK1 or JAK3 for activation of STAT proteins. IL-4, CD40L and BCR ligation signals to CLL cells in lymph nodes can promote resistance to therapies such as the BCL2-inhibitor venetoclax. We have shown that ibrutinib can overcome IL-4/CD40L induced expression of pro-survival proteins MCL1 and BCLXL and that cedulatin in combination with venetoclax can induce apoptosis in a synergistic manner in the presence of IL-4/CD40L. We now extend these results to assess the importance of this drug combination in the presence of BCR stimulation. The combination of ced and venetoclax in the presence of either BCR signalling (bead immobilised anti-IgM) alone, or combined with IL-4 and CD40L, induced synergistic killing, with greater CLL cell death than with either drug alone.

Summary/Conclusions: These results provide evidence that IL-4 may increase BCR signalling by upregulating the expression of positive regulators of BCR signalling in U-CLL and that this can be overcome by ibrutinib. These results support the continued use of ced in clinical trials for the treatment of CLL, alone or in possible combination with venetoclax.
Background: Ibrutinib is an oral Bruton tyrosine kinase (Btk) inhibitor which has advanced the clinical management of CLL. Ibrutinib binds irreversibly to the cysteine 481 residue of the Btk protein, rendering it inactive. Btk inhibition affects the phosphorylation of other intracellular kinases resulting in an immediate redistribution of CLL cells and subsequent apoptosis. We investigated the impact of ibrutinib on the phosphorylation of upstream and downstream kinases in the B-cell receptor pathway in real time in the IcI CLL study (ISRCTN12695354).

Aims: The IcI CLL trial was a single arm, multi-centre feasibility study of ibrutinib in two cohorts of CLL patients: (A) 20 treatment-naïve (TN) requiring treatment (according to IWCLL criteria); and (B) 20 relapsed/refractory (RR). All patients received continuous oral therapy with ibrutinib (420 mg once daily) from registration until disease progression. The primary endpoint of the trial was the proportion of patients achieving minimal residual disease (MRD) negative remission (depletion of CLL ≤0.01% in peripheral blood (PB) & bone marrow (BM)) within 6 months of trial treatment. Exploratory endpoints included the assessment of phosphorylation of intracellular kinases in the B-cell receptor pathway.

Methods: A panel of markers was assessed on PB & BM taken at screening, and 1 & 6 months. PB was also taken at baseline (0 hours), 4 & 24 hours, 7 & 14 days, and 2, 9 & 12 months. The phosphorylation of Syk, pY348, Btk pY551, ERK1/2, Akt S473 was assessed in 4 conditions at each time point: unstimulated +/- ibrutinib, and stimulated with IgM/IgD +/- ibrutinib. 1×10⁶ leukocytes were tagged to extracellular antibodies (CD3/CD19) conjugated to fluorochromes. Ibrutinib (10μM) was added to the cells for 30 minutes at 37°C followed by anti-IgM/IgD stimulation (10μg/ml). The BD phosphoflow protocol was followed to lyse/fix/permeate the CLL cells. Antibodies to Btk pY551, Syk pY348, ERK1/2 pT204/pY204, Akt pS473 were used tagged to fluorochromes (from BD Biosciences). Cells were acquired on a BD Fortessa flow cytometer.

Results: The phosphorylation of Btk, Syk, Akt and ERK1/2 was analysed in cells at the specified time points and conditions for 20 TN and 20 RR CLL patients. Baseline phosphorylation of all kinases was similar in both PB & BM. Phospho-Btk showed no stimulation on addition of IgM/IgD 4h after initiating therapy. There was a strong (2-4 fold) increase in phosphorylation of Syk kinase with IgM/IgD even in the presence of ibrutinib in vitro. This effect was profound in the first 2 months of ibrutinib therapy with a general decrease in phosphorylation after 6 months. Baseline stimulation of ERK1/2 gave a 1.5-2 fold increase in phosphorylation but the effect was abrogated within 1 month of ibrutinib therapy. Akt S473 phosphorylation was maintained after 6-12 months of therapy although the degree of phosphorylation decreased at later time points. Syk, Akt and ERK1/2 phosphorylation was unaffected by the addition of ibrutinib in vitro. The pattern of phosphorylation was found to be relatively consistent in responding patients. One patient with progressive CLL had sustained phosphorylation in all markers despite ibrutinib therapy.

Summary/Conclusions: The effect of ibrutinib on the phosphorylation of various kinases in the B-cell receptor pathway was analysed in real time. Syk continued to be phosphorylated over the course of treatment, which is logical as this kinase is upstream of Btk. That the degree of phosphorylation declined over time (even with stimulation) suggests a general inhibitory effect of ibrutinib on CLL cells. ERK1/2 phosphorylation is effectively blocked and there is partial reduction of phosphorylation of Akt S473. Combinations of Btk inhibitor with a Syk or P38 kinase inhibitor may result in complete BCR blockade. Phosphorylation patterns may also act as an adjunct to ascertain the response to therapy.

EVALUATION OF COMBINATIONAL THERAPIES FOR RELAPSED/REFRACTORY CLL WITH MUTATED P53
S. Post,1,2 H. J. Lee,1 H. Ma1, M. Gallardo,1 X. Zhang1, M. Hombaker1
1Leukemia, 2Lymphoma, MD Anderson, Houston, United States, 3CNIO, Madrid, Spain

Background: Chronic lymphocytic leukemia (CLL) is a heterogeneous disease with survival ranging from months to decades. CLL patients harboring TP53 alterations are well known to be refractory to standard therapies; however, recent studies indicate that ibrutinib, a Bruton’s tyrosine kinase (Btk) inhibitor, suppresses the B-cell receptor (BCR) signaling pathway and is an effective treatment option for these patients. Unfortunately, many patients with TP53 alterations will ultimately fail ibrutinib-based therapies. Similarly, we have used a mouse model of refractory p53 mutant CLL (Eμ-TCL1;p53R172H) and reported that while ibrutinib is effective in reducing the CD5+CD19+ population and extending survival, these mice eventually succumb to the disease (Lee HJ, BCU 2016). These incomplete therapeutic responses indicate that ibrutinib provides only a temporary respite for this refractory disease, and highlights our need to develop more potent and targeted combinations.

Aims: Ibrutinib is effective in delaying (but not eliminating) leukemic progression in p53 mutant CLL, suggesting that combinational therapies that inhibit BCR signaling and activate apoptotic programs may be effective therapeutic strategies. Thus, agents that do not require activation of p53 but are effective in blocking oncogenic pathways (BTK and BCL-2) are attractive options. Currently, ibrutinib and ABT-199 meet this criteria and thus, we hypothesize that simultaneous inhibition of the BTK- and BCL-2-pathways will be an effective strategy in treating p53 mutated CLL.

Methods: To test this, we used RNA-Seq to examine expression changes in B-cells from Eμ-TCL1 mice carrying either wild type or a single p53R172H hotspot mutation (corresponding to p53R172H in humans) following ibrutinib treatment. qRT-PCR and IHC were used to validate expression of key targets within pathways amenable to combinational therapy. Hematopoietic tissues were subjected to combinational therapies to interrogate efficacy.

Results: We have shown that ibrutinib downregulates the BTK- and ERK-pathways regardless of p53 status. However, less is known in regards to global expression changes in p53 mutant CLL following BTK inhibition. To investigate this, we performed RNA-Seq analyses using malignant B-cells from untreated and ibrutinib treated Eμ-TCL1;p53R172H and Eμ-TCL1 mice. Pathway analyses revealed that CLL cells harboring a single p53 mutant allele retained a partial ability to activate p53-dependent programs. qRT-PCR revealed robust activation of p53-dependent anti-proliferative targets like p21, but only modest activation of pro-apoptotic targets (e.g.; PUMA), suggesting these p53 mutant CLL cells have diminished capacity to activate apoptosis or overcome apoptotic inhibitors. To explore this altered bi-modal p53 activation, we performed IHC and observed that apoptotic activation was hampered by increased BCL-2 expression. To examine whether this BCL-2-dependent inhibition could be overcome, malignant B-cells were treated with ibrutinib alone, ABT-199 (a BCL-2 antagonist), or in combination. Here, we observed that ABT-199 was sufficient to activate apoptosis, regardless of p53 status, and that its use in combination with ibrutinib drastically reduced cell viability.

Summary/Conclusions: Together, these data indicate that patients with a partially attenuated p53 pathway may retain the ability to activate apoptosis if molecular barriers are removed (e.g.; BCL-2 via ABT-199). Furthermore, these results suggest that combinations with BTK- and BCL-2 inhibitors may be therapeutically beneficial for patients with mutated TP53.
Chronic myeloid leukemia - Biology

THE DNA REPLICATION PATHWAY HAS POTENTIAL PREDICTIVE VALUE FOR TKI RESPONSE AND THERAPEUTIC INTERVENTION IN CHRONIC MYELOID LEUKAEMIA
K. Yalla1, H. Morrison1, P. Toofoo1, L. Hopcroft1, G. Horne1, C. Munjé1, H. Moka2, E. Gómez-Castañeda1, S. O’Brien1, M. Copland1,2*, H. Wheadon1
1Institute of Cancer Sciences, University of Glasgow, 2West of Scotland Genetic Department, NHS, Glasgow, 3National Heart and Lung Institute, Imperial College London, London, 4Northern Institute of Cancer Research, University of Newcastle, Newcastle, United Kingdom

Background: Chronic myeloid leukaemia (CML) is a myeloproliferative disease which arises in a haemopoietic stem or multipotent progenitor cell with the t(9;22)(cq34;q11) chromosomal translocation. Tyrosine kinase inhibitors (TKIs) were developed to target the constitutively active oncoprotein BCR-ABL, which is expressed as a result of this translocation. TKI therapy has significantly improved patient survival, however predicting response to therapy is one of the unmet clinical challenges in CML. Moreover, TKIs are unable to target the leukemic stem cells (LSCs) which drive the disease; persistence of LSCs therefore remains a major obstacle to cure CML. Understanding the mechanisms that LSC employ to survive TKI treatment is necessary to design essential therapeutics to eliminate CML in the future.

Aims: To identify genes with predictive value for TKI response and to determine the efficacy of drug targeting one of the key pathways identified.

Methods: Microarray, Fluidigm, Real-time PCR, FACS based cell cycle and Annexin V apoptosis analysis, Trypan blue exclusion cell counts.

Results: Analysis of bulk CML patient microarray data (GSE47927) identified 323 deregulated genes either in the stem cell population or during disease progression. DNA damage responses and repair, cell cycle and survival. These genes were validated in 60 samples from the SPIRIT 2 clinical trial [a multicentre phase III randomised trial comparing the TKI imatinib (400mg daily) versus Dasatinib (100mg Daily)] with 18 months follow-up data regarding molecular response to TKI treatment. Patients were stratified as good/intermediate/poor responders to TKI and the gene signatures significantly differentially expressed was identified. These data highlighted the DNA repair genes as having potential predictive value, in particular, the minichromosome maintenance (MCM) protein and origin of replication (ORC) family of genes, involved in DNA replication and cell cycle regulation. Single cell analysis of CD34+ cells across the patient cohort identified considerable heterogeneity of expression of MCMs and ORCs, with ORC3 in particular, exhibiting a different expression profile in good/intermediate/poor responders (n=3 of each). In addition single cell analysis highlighted a significant difference in the expression of MCM2, 4, 7, 8 and ORC2 in the most primitive LSC (CD34+38−90+53+) compared to CD34+38−90+93− cells. Next, we investigated the ability of heliquinomycin (HQ), a potent helicase inhibitory of MCM on its own and in combination with IM to target the CML cell line K562. Our extensive dose and time response studies followed by FACS-based apoptosis and cell cycle analysis prove the potency of HQ and its synergistic action in combination with imatinib. We also investigated the changes in a panel of cell cycle and DNA damage response genes at the transcript level in response to HQ and imatinib in the K562 cell line. Overall the data generated indicates that targeting the MCM pathway in combination with BCR-ABL inhibition is a rational approach for future therapeutic intervention in CML.

Summary/Conclusions: Single cell 'omics' experiments are invaluable for identifying novel pathways deregulated in CML. This combined with single cell 'omics' studies enables the heterogeneity of gene expression and the response of individual LSCs to TKI to be evaluated. Our data indicate that the DNA replication pathway plays an important role in CML, with levels of MCMs and ORCs having potential predictive value in TKI response and are a promising drug target in CML.

SIGNAL TRANSDUCING ADAPTOR PROTEIN-1 (STAP-1) MAINTAINS CHRONIC MYELOID LEUKEMIC STEM CELLS
J. Toda1,*, M. Ichii1, K. Orimatsu1, H. Saito1, Y. Kitaj2, R. Muramoto2, J-I. Kashawari2, K. Saito1, T. Matsuda1, Y. Kanakura1
1Department of Hematology and Oncology, Osaka University Graduate School of Medicine, Osaka, 2Department of Immunology, Graduate School of Pharmaceutical Sciences, Hokkaido University, Sapporo, Japan

Background: Signal transducing adapter protein (STAP) 1 was cloned as a c-fms binding protein. Previously, we have demonstrated that STAP-2 binds to BCR-ABL, which is constitutively activated in chronic myeloid leukemia (CML), via its SH2-like domain and enhances BCR-ABL activity leading to activation of downstream effectors, including ERK, STAT5, BCL- XL and BCL-2. The family of STAPs includes STAP-1, identified as a c-kit interacting protein, and STAP-2. While STAP-2 is expressed ubiquitously, STAP-1 has hematopoietic-specific expression in mice. It is still unknown whether STAP-1 plays a role in CML, although STAP-1 is expected to have similar functions based on the structural homology between STAP-1 and STAP-2.

Aims: To elucidate the role of STAP-1 in CML using mouse model and human samples.

Methods: We generated STAP-1 deficient mice of the C57BL/6J genetic background. For establishment of CML mouse model, we isolated Lineage (Lin)− Sca-1+ c-kit+ (LSK) fraction of bone marrow (BM) cells from STAP-1+/+ and STAP-1−/− mice, infected them with retrovirus carrying MSCV-BCR-ABL-res-GFP, and transplanted into congenic recipients, that were named Wild type (WT) and STAP-1−/−CML mice, respectively. Human BM samples were collected after informed consent, using protocols approved by the Investigational Review Board of Osaka University Hospital.

Results: Using Western blot and immunoprecipitation assay, we confirmed that STAP-1 binds to BCR-ABL. CML mice model was then employed to analyze the role of STAP-1. We found that STAP-1−/−CML mice showed significantly longer survival than WT CML mice (Fig. 1). STAP-1−/−CML mice displayed less severe splenomegaly and lung hemorrhages compared to WT, suggesting that loss of STAP-1 attenuates CML progression. To investigate how STAP-1 regulates CML progression, we evaluated leukemic stem cells (LSCs) in CML mice. The absolute numbers of STAP-1−/−LSCs (GFP+ LSK) in BM and spleen were significantly lower than those of control (WT vs STAP-1−/−; 2090.3 ± 694.07 cells vs 412.57 ± 114.07 cells in BM, p=0.0291; 12.9 ± 1.75 ×104 cells vs 4.09 ± 0.72 ×104 cells in Spleen, p=0.0009). In colony-forming assay in vitro, STAP-1−/− LSCs generated less colonies in the first and second plating compared to WT LSCs. These data indicated that deletion of STAP-1 would impair self-renewal capacity of LSCs. When we transplanted STAP-1+/+ or STAP-1−/− mice without BCR-ABL transduction in the presence of competing BM cells, deletion of STAP-1 had no effects on engraftment at 28 days after transplantation. Furthermore, we measured the expression of STAP-1 in BM cells derived from patients in the chronic phase of CML. As a result, STAP-1 mRNA was abundant in the LSC (CD34+ CD38−) compartment.

Figure 1.

Summary/Conclusions: In this study, we utilized CML mouse model and showed that STAP-1 is required for progression of CML. Our findings indicate that STAP-1 has an indispensable role in LSC maintenance, while normal hematopoietic stem/progenitors were not affected by STAP-1 deficiency. Although a majority of patients have a durable response to BCR-ABL tyrosine kinase inhibitors, the outcome of patients who fail the treatment due to primary or acquired resistance is still miserable. Our findings in mice and human suggest that STAP-1 could be a potential target for CML. Further analysis will be needed to clarify the molecular mechanisms by which STAP-1 regulates the progression of CML and maintains survival of LSCs.

TELOMERE SHORTENING IN CD34+38- BCR-ABL POSITIVE BONE MARROW CELLS FROM NEWLY DIAGNOSED PATIENTS WITH CML CORRELATES WITH THE CLONE SIZE OF THE LEUKEMIC STEM CELL COMPARTMENT
A.-S. Bouillon1,*, M. Ventura Ferreira1, S.A. Awad2, J. Richter3, H. Hjorth-Hansen4, J.-I. Kashiwakura2, K. Saitoh2, T. Matsuda2, Y. Kanakura1
1Institute of Cancer Sciences, University of Glasgow, 2West of Scotland Genetic Department, NHS, Glasgow, 3National Heart and Lung Institute, Imperial College London, London, 4Northern Institute of Cancer Research, University of Newcastle, Newcastle, United Kingdom

Background: Chronic myeloid leukemia (CML) is a clonal stem cell disorder characterized by the BCR-ABL translocation. Previous work provides evidence that based on the size of the leukemic stem cell (LSC) clone within the CD34+38- population at diagnosis, chronic phase (CP) of CML can be stratified into early and late CP. Patients in late CP have a higher LSC burden going along with an inferior response to TKI therapy. Telomeres shorten with each...
cell division and telomere length (TL) in peripheral blood cells has been shown to correlate with disease stage, response to treatment and duration of CR in CML patients. However, the use of TL as a routine clinical biomarker in CML has been complicated by considerable inter-individual, mostly genetic variability in TL ideally requiring non-clonal control cells.

Aims: Based on these considerations, we used a modified Q-FISH technique in a retrospective study to compare BCR-ABL+ LSC vs BCR-ABL- control cells within the CD34+38- hematopoietic stem cell compartment of diagnostic patients with CML in CP.

Methods: 15 patients (median age: 59 years; range: 41-72 years) diagnosed with CML in CP of the NCT00852566 study (Nordic CML Study Group) were retrospectively analyzed. All patients studied were available for 14 patients. Of those, 2 (14%) belonged to the Sokol high risk group, 5 (36%) to intermediate and 7 (50%) to the low risk group. CD34+38- cells sorted from bone marrow samples were tested with the standard FISH method using dual fusion dual color BCR-ABL staining following standard procedures. After capturing the BCR-ABL staining using confocal microscopy, samples were re-processed for TL analysis by Q-FISH using established protocols. TL staining was analyzed in all previously captured cells allowing the identification of BCR-ABL+/- cells within the same sample. Analysis and quantification of BCR-ABL FISH staining and TL measurement by Q-FISH were performed in blinded fashion.

Results: Overall, we observed significantly shortened TL in the BCR-ABL+ compared to BCR-ABL- cells (-4.9 arbitrary units (a.u.) range: -53.7 to 16.9 a.u., p=0.04). Next, we correlated the clone size (i.e. the proportion of BCR-ABL+ positive cells within the CD34+38- compartment) with the degree of telomere shortening in LSC. Mean clone size of the patients was 59.9 ± 22.0 % S.D. Of note, we found a significant negative correlation (R=0.36, p=0.02) between TL and clone size strongly supporting the notion that increased expansion of the BCR-ABL+ LSC pool leads to accelerated telomere shortening. Correlation of CLIP qPCR data R=0.70 (Clonogenic assay by Dr. Corradin) vs Sokol (R=0.40, p=0.03) score did not reveal any statistically significant correlation with the degree of telomere shortening probably due to the small sample size analyzed in this pilot study.

Summary/Conclusions: In this study, we provide further evidence for accelerated telomere shortening in BCR-ABL+ LSC as compared to their normal CD34+CD38- counterpart in CP CML samples at diagnosis. Interestingly, the degree of TL shortening linearly correlates with the clone size of the BCR-ABL+ LSC compartment. Thus, this retrospective study (now on the LSC level) further supports a role of TL as a prognostic and predictive biomarker in newly diagnosed patients with CML pending confirmation in prospective trials.

GENOMIC CHARACTERIZATION OF CML AT DIAGNOSIS REVEALS PREEXISTING SOMATIC MUTATIONS THAT MAY PREDICT PROGRESSION TO BLASTIC PHASE INDEPENDENTLY OF BCR-ABL1 MUTATIONS
M.M. Machnicki1,2,*, I. Solarska3, M. Zawada4, I. Seferynska5, T. Skorski6, T. Stoklosa6,1
1Department of Hematology, Jagiellonian University, Cracow, 2Postgraduate School of Molecular Medicine, Medical University of Warsaw, 3Department of Diagnostic Hematology, Institute of Hematology and Transfusion Medicine, Warsaw, 4Department of Hematology Diagnostics, The University Hospital, Cracow, 5Department of Hematology, Institute of Hematology and Transfusion Medicine, Warsaw, 6Department of Hematology, University of Leipzig, Germany.

Background: BLastic phase of chronic myeloid leukemia (BP-CML) remains mostly incurable even with newer generation tyrosine kinase inhibitors (TKI) and represents an urgent clinical need. Although in recent years a dramatic reduction in the transformation of chronic phase (CP-CML) to BP-CML has been observed, still up to 5% of patients will progress to BP-CML despite treatment with TKI. Prospective identification of such patients may have a significant clinical impact. There are only few reports to date which use next-generation gene sequencing (NGS) to look for somatic mutations - other than those affecting kinase domain of BCR/ABL 1 - at the time of diagnosis (Dx) which could have a prognostic/predictive value.

Aims: We analyzed the mutational spectrum of somatic mutations in two groups of CML patients with clinically different disease course: first group (BP) comprised of 11 patients who progressed to BP-CML despite treatment with TKI and/or allo-HSCT (one patient) and died (paired samples from DX and BP were analyzed); second group (MMR) included DX samples from 36 patients who achieved major molecular response (MMR) and TKI within 6 months and remained in MMR for at least 48 months from DX.

Methods: Targeted enrichment strategy using custom designed capture probes (SeqCap EZ, Roche NimbleGen) followed by NGS on Illumina platform was employed. More than 1200 genes implicated in human cancer were included. Common variants (>1%) gathered in large genomic databases and our internal gene database were filtered out and the subsequent analysis was focused on putative protein damaging variants, supported by variant effect prediction tools such as PolyPhen-2, SIFT or CHASM. All reported variants were reconfirmed by Sanger sequencing.

Results: The BP group comprised of paired samples from 11 CML patients who progressed to BP and died despite treatment with TKI. Median age at diagnosis was 53y (range 26 -77), median time to progression for 9 patients (2 were diagnosed in accelerated phase or BP) was 17.5 months (mo) (range 4-108) and median survival was 22 mo (range 10 -116). None of those patients harbored BCR/ABL1 mutation at the time of Dx and progression to BP-CML, 4 patients had additional chromosomal alterations at progression to BP including two frequent (trisomy 8 and monosomy 7). Targeted enrichment followed by NGS allowed us to achieve deep coverage (>80% ge50). Median number of rare variants was 26 (range 18-38) and 29 (range 23-32) for Dx and progression to BP-CML respectively. In total, we detected new and previously described mutations in selected genes, which are frequently mutated in myeloid malignancies, namely in RUNX1 (36%, 4/11), DNMT3A (27% 3/11) IDH1/IDH2 (18%, 2/11) and ASXL1 (18%, 2/11). In BP group (54%, 6/11) mutations in these genes (excluding IDH2, detected only in 1 BP sample) were preexisting at the time of DX. These results were compared to second, control group that comprised of diagnostic samples from 36 patients (median age at diagnosis 53y, range 23 -75) who were optimal responders to TKI and remained in MMR for at least 48mo (median time in MMR: 73mo; range 48-128). In MMR group, the median number of rare variants was lower than in BP group, ranging between Dx sample and BP sample (range 48-128). In 2 patients (23%, 5%) frameshift mutation in ASXL1 (p.Gly643_Gly644fs) was detected, identical as one of BP patients. Additionally, one patient harbored RUNX1 mutation (p.Arg201Cm) which was not detected in the BP group.

Summary/Conclusions: Our results provide new insights into the already complex genomic landscape of CML. We suggest that a significant number of patients with poor disease outcome may harbor preexisting mutations in DNMT3A, RUNX1 and IDH1. In contrast, mutations in ASXL1 may be present at Dx in patients who will remain in long-term remission.

INCREASED INDOLEAMINE 2,3-DIOXYGENASE (IDO) ACTIVITY IN EARLY CHRONIC PHASE CHRONIC MYELOGENOUS LEUKEMIA (CML-CP) IS REDUCED BY NILOTINIB THERAPY AND PREDICTS MOLECULAR RESPONSE
S. Sopper1,2,*, S. Mustjoki2, G. Gasi¹, Z. Trajanoski3, F. Giles4, A. Hochhaus5, J. Janssen6, S. Geisler7, D. Fuchs7, D. Wolf8
1Hematology and Oncology, Medizinische Universität Innsbruck, Innsbruck, Austria, 2Comprehensive Cancer Center, Helsinki University Hospital, Helsinki, Finland, 3Bioinformatics, Medizinische Universität Innsbruck, Innsbruck, Austria, 4Northwestern University, Chicago, United States, 5Universitätsklinikum Jena, Jena, Germany, 6Friedrich Schiller University Medical Center, Jena, Germany, Russia, 7Biological Chemistry, Medizinische Universität Innsbruck, Innsbruck, Austria, 8Hematology, Oncology and Rheumatology, University Hospital of Bonn, Bonn, Germany

Background: Indoleamine 2,3 dioxygenase (IDO) is the rate-limiting enzyme in the metabolism of the essential amino acid tryptophan (TRP). IDO1 is induced mainly by interferons during infection and inflammation. Strong IDO1 activity depletes tryptophan, which results in reduced T cell activation and pro-inflammation as well as expansion of immunosuppressive regulatory T cells. Derepression of IDO1 activity has been linked to cancer immune evasion, but its role in chronic phase (CP) CML has not been investigated in detail.

Aims: Determination of IDO1 levels and activity in plasma CML-CP patients in the course of tyrosine kinase inhibitor therapy and their correlation with clinical and immunological parameters as well as molecular response.

Methods: A large panel of cytokines and cell surface markers of the IDO-pathway (soluble sIDO1=sIDO1 and kynurenine/tryptophan ratio=kYN/TRP as a product of IDO1 activity) as well as various leukocyte populations such as plasmacytoid dendritic cells (pDC) were analyzed alongside the prospective pan-european ENEST1st clinical study (NCT01061177). This study included 35 CP-CML patients and 26 of them were subsequently treated with 300mg Bid nilotinib and longitudinally analyzed at months 6 and 12 of therapy. Molecular responses were quantified in central EUTOS reference laboratories.

Results: Soluble IDO (sIDO1) levels and KYN/TRP ratio are significantly up-regulated in newly diagnosed CP-CML and drop during nilotinib therapy. sIDO1 levels significantly correlate with increased KYN/TRP, suggesting increased IDO1 activity at diagnosis. Increased sIDO1 is linked to a pro-inflammatory status in CML patients, as it positively correlates with increased serum neopterin levels as well as to various other pro-inflammatory markers, such as IFN-γ, IL-10, IL-17A, sVEGF, sVEGFA, sP-selectin and sPAI-1, representing a highly mutated gene, IDO1 activity (KYN/TRP) negatively correlates with the proportion of pDC, the main producers of IFN-α. Interestingly, a higher KYN/TRP is linked to superior molecular response, as demonstrated by a significant correlation
of the KYN/TRP ratio to BCR-ABL transcript levels. Patients having a high KYN/TRP ratio (> mean +2SD of post therapy levels) reach deep molecular response rates (i.e. MR^4.5) significantly earlier and at higher rates. Moreover, combining KYN/TRP with sCD62L levels, a recently identified predictive biomarker, resulted in a score robustly predicting the odds of achieving deep molecular response.

Summary of conclusions: CML diagnosis in CP is linked to an increased inflammatory status, as shown by increased levels of sIDO and its metabolites kynurenic acid in 10% of patients treated with ponatinib. In contrast, in CML an increased KYN/TRP ratio is associated with improved molecular response. Therefore, to implement testing of the endpoint, the IDO activity may reflect endogenous IFN-α production, a known factor favoring immune-mediated CML control. The predictive potential of KYN/TRP is currently verified in an independent cohort.

P596

BCR-ABL1 COMPOUND MUTANTS DISPLAY DIFFERENTIAL AND DOSE-DEPENDENT RESPONSES TO PONATINIB

K. Byrgazov1,*, C. Lucini1, D. Printz1, M. Koenig1, P. Valent2, O. Hantschel3, T. Lion1
1Children’s Cancer Research Institute, 2Medical University of Vienna, Vienna, Austria, 3Swiss Institute for Experimental Cancer Research, Lausanne, Switzerland

Background: Despite the dramatic improvement of prognosis in CML patients due to the introduction of tyrosine kinase inhibitors (TKIs), resistance to ponatinib occurs in a considerable proportion of patients. The best-characterized mechanism of ponatinib resistance is the acquisition of mutations in the BCR-ABL1 tyrosine kinase domain (TKD) affecting TKI binding. The third-generation TKI ponatinib exerts strong anti-neoplastic effects even in advanced CML stages and is capable of suppressing the kinase activity of BCR-ABL1 carrying any single mutation including T315I. Nevertheless, resistance to ponatinib can evolve in sub-clones carrying BCR-ABL1 variants with two or more mutations on the same allele, if the IC^50 values for this TKI exceed the maximum achievable effective plasma levels (eC^50). These co-called compound mutations (CMs) are associated with increased oncogenic potential in comparison to individual mutations, and represent a powerful mechanism of potential resistance to all currently available TKIs. The occurrence of compound mutations has been linked particularly to sequential treatment with different TKIs, and the identification of their responsiveness to ponatinib is of paramount importance for the subsequent clinical management.

Aims: 1. To determine the spectrum of highly TKI-resistant CMs. 2. Measure the responses of BCR-ABL1 CMs to ponatinib

Methods: We have established a BCR-ABL1 protein model facilitating assessment of the presumptive impact of 27 different CMs involving important functional sites of the BCR-ABL1 TKD, and including constellations expected to display increased oncogenic potential in comparison to individual mutations, and represent a powerful mechanism of potential resistance to all currently available TKIs. The occurrence of compound mutations has been linked particularly to sequential treatment with different TKIs, and the identification of their responsiveness to ponatinib is of paramount importance for the subsequent clinical management.

Results: Most CMs involving sites with no previous evidence for implication in resistance to ponatinib displayed IC^50 values below 10 nM. This eC^50 is readily achievable even with the 15mg daily dose of ponatinib. CMs revealing elevated resistance to ponatinib in vitro almost invariably included T315I or F317L mutations. While most CMs involving T315I revealed very high IC^50 values, some of the predicted compound mutations containing F317L displayed an eC^50 for ponatinib in the range of the eC^50 achievable only with a daily dose of 45mg. Some of these observations are supported by clinical findings in the PACE trial which revealed impaired responses of patients with CMs involving F317L who had received average daily doses of ponatinib below 45mg (Deininger et al., Blood 2016, 127(6):703-12).

Summary/Conclusions: Current strategies that aim at decreasing the dose of ponatinib to prevent severe side effects should carefully consider the presence and type of mutations in the BCR-ABL1 TKD to enable effective treatment. It would be advisable, therefore, to implement testing of the endpoint in drug concentrations and monitoring the kinetics of mutant subclones covering also compound mutations in the routine diagnostic surveillance to provide a basis for optimized clinical management of patients treated with ponatinib.

IS THERE EFFECTIVE IMMUNE SURVEILLANCE AGAINST CHRONIC MYELOID LEUKAEMIA? NO

R.P. Gale1,*, G. Opelz2
1Haematology Research Centre, Imperial College London, London, United Kingdom, 2Institute of Immunology, University of Heidelberg, Heidelberg, Germany

Background: Immune surveillance refers to a process whereby the innate and adaptive immune systems recognize and eliminate cancer cells on the basis of cancer-specific or related antigens or other molecules. Substantial data support the concept of immune surveillance in rodents but data in humans are less convincing and apply mostly to virus-induced cancers. However, considerable data indicate a strong anti-leukaemia effect in persons with chronic myeloid leukaemia (CML) receiving an allogeneic haematopoietic cell transplant. Most, if not all, of this anti-leukaemia effect is confounded with graft-versus-host disease (GVHD) and whether there is a specific anti-leukaemia effect distinct from GVHD is controversial. Another interesting observation is about 40 percent of persons with CML and a deep molecular response to tyrosine kinase-inhibitors (TKIs) remain in molecular remission when TKI-therapy is stopped. Because TKI-therapy is very unlikely to eradicate every CML cell, some attribute this therapy-free remission (TFR) to a result of immune surveillance. Immune surveillance refers to a process whereby the innate and adaptive immune systems recognize and eliminate cancer cells on the basis of cancer-specific or related antigens or other molecules. Because TKI-therapy is very unlikely to eradicate every CML cell, some attribute this therapy-free remission (TFR) to a result of immune surveillance.
Methods: To test these hypotheses, we studied whether there was an increased incidence in CML in persons receiving immune suppression, after solid organ transplants. IF immune surveillance is important in CML we would expect an increased incidence in this setting. We used a dataset from the Collaborative Transplant Study (CTS) which collects information on recipients of solid organ transplants beginning in 1985 from >300 transplant centers worldwide. Cancer incidence data were checked annually by questionnaire. Data for expected CML incidence were obtained from a cohort of identical size matched for age and sex from Cancer Incidence in Five Continents monitored for the same duration as the transplant cohort. Data collection and processing were approved by the Data Protection Agency in Germany and all participating centers with local ethical and privacy regulations. The CTS dataset consisted of 441,332 recipients of kidney (N=355,606), liver (N=47,846) and heart (N=37,880) transplants. Amongst kidney transplant recipients the standardized incidence ratio (SIR) for developing CML was 1.54 (95% confidence interval, 1.1, 2.1; p<0.01) representing 39 cases in 1,682,491 person-years at risk. The CTS dataset also included 1.72 (0.6, 4.0; P=0.34) representing 5 cases in 182,833 person-years at-risk vs. 3 expected (2 excess cases). Amongst heart transplant recipients the SIR was 3.47 (1.8, 6.1; P=0.0005) representing 12 cases in 173,015 person-years at risk vs. 3 expected (9 excess cases). Data from recipients of kidney and liver transplants suggest immune suppression does not increase risk of developing CML or does so very slightly. The increase in SIR in kidney graft recipients is generally attributed to increased cancer surveillance including blood testing. Although the SIR of CML was substantially-increased after heart transplants, these persons receive high doses of ionizing radiations for diagnosis and management procedures such as computer tomography (CT)-angiography. Ionizing radiations are a proved cause of CML which might explain the increased SIR. Results: Our data, 25 excess cases of CML in 2,038,339 person-years at-risk observation suggest the magnitude of immune-surveillance do not support the hypothesis that immune surveillance operates to an important extent to prevent CML in humans. Summary/Conclusions: Consequently, the anti-leukaemia effect associated with allotransplants and the TFR observed after stopping TKI-therapy is unlikely to result from effective immune surveillance against CML.

P599

MUTATIONAL ANALYSIS IN BCR-ABL1 POSITIVE LEUKEMIA BY DEEP SEQUENCING BASED ON NANOPORE MINION TECHNOLOGY

C. Minervini1, C. Cumbi1, P. Orsini1, L. Anelli1, A. Zagaria1, A. Minervini1, N. Cocco1, G. Tota1, L. Impera1, A. Russo Rossi1, A. Ricco1, C. Brunetti1, P. Casieri1, G. Specchia1, F. Albano1, L. Impera1, 1Hematology - University of Bari, Bari, Italy

Background: In newly-diagnosed chronic phase (CP)-CML patients, 15–30% who start first-line tyrosine kinase inhibitors (TKIs) therapy will not reach an optimal response, and a BCR-ABL1 kinase domain (KD) mutation will be detectable in 25–50% of patients with treatment failure with an increased frequency of these mutations observed in accelerated phase and blast crisis patients. Currently, Sanger sequencing (SS) technique analyzing BCR-ABL1 is considered the gold standard for mutation detection knowing that this assay has sensitivity of around 20%, and therefore is unsuitable for identifying low-level variants (<20% variant frequency). Recently next generation sequencing (NGS)-based assays have been reported for detecting BCR-ABL1 KD mutations; although these NGS strategies are more accurate and precise than SS, they are burdened by costs related to the initial investment, that is the sequencer purchase, the preparation of specific targets libraries, and the required reagents. MinION is a single molecule sequencer connected to a laptop through a USB3.0 interface, based on nanopore technology; it works by connecting two strands of DNA molecules by a hairpin, and sequencing them consecutively.

Aims: To describe a third-generation sequencing assay on MinION for detecting BCR-ABL1 KD mutations and compare the results to a SS-based test in 24 Ph+ leukemia cases.

Methods: Overall, 24 patients were included; among them, 12 (11 CML and 1 ALL cases) developed treatment resistance during the TKI’s treatment course (Group A). In total 10 and 4 cases (Group B) developing BCR-ABL1 kinase domain (KD) mutation will be detectable in 25–50% of patients with treatment failure with an increased frequency of these mutations were included in the present study. Data was obtained from peripheral blood cells. MinION library preparation, sequencing and data analysis were performed. All cases included in the study were analyzed by SS and MinION sequencing in blinded manner.

Results: Two sequencing runs were performed with the two different pools of patients: the first lasted eight hours and was carried on the Group 1, whereas the second run included the Group 2 and lasted 24 hours to achieve a deeper sequencing. Sequencing results showed that 100% of ABL1 from exon 2 to 10 was covered and that the mean of the sequencing depth was around 150x and 100x, respectively. Any case detected as “positive” by MinION sequencing was never found below 50x. We found 10 BCR-ABL1 KD mutations in 9 patients belonging to the Group 1 (one case showed compound mutations). Notably, almost all mutations had a high allelic ratio. Despite a high depth of sequencing, MinION data analysis on the Group 2 was able to detect mutation only in a ALL case. Results from MinION and SS showed 92% concordance in all cases included in this study. Notably, mutations that were initially undetectable by SS became evident thanks to the indications coming from MinION analysis.

Summary/Conclusions: Our findings demonstrate multiple advantages by using MinION approach, first of all the sensitivity: our comparison of MinION to SS identified mutations below the detection limit of SS (generally simulated around <20%) in 2 (22%) among the mutated cases, including mutations known to be clinically important. Another point on the side of the nanopore technology is the costs profile. Therefore, the main advantage of this technology is to allow a more efficient and sensitive analysis than SS at very competitive costs. In conclusion, we demonstrated that MinION is suitable for employment in hematology laboratory for detecting BCR-ABL1 KD mutation in Ph+ leukemias.

P598

THE AUTOMATED MOLECULAR TECHNIQUE “ULTRA” ALLOWS A SENSITIVE AND ACCURATE BCR-ABL1 QUANTIFICATION IN PATIENTS AFFECTED BY CHRONIC MYELOID LEUKEMIA

F. B. Clopp2, G. Tota1, L. Impera1, M. Tursi1, M. Toto1, M. Ruggiero1, M. Toto1, M. G. Tota1, L. Impera1, A. Petrocco1, C. Brunetti1

Background: Chronic myeloid leukemia (CML) is characterized by the presence of thePhiladelphia chromosome and the BCR-ABL1 fusion gene. The production of tyrosine kinase inhibitors (TKIs) significantly improved the survival, but 15% of patients don’t reach the optimal responses at the defined end-points or develop secondary resistance. The 2013 ELN guidelines identified as fundamental the early molecular response (BCR-ABL1/ABL1 % ≤10% IS), the MR3 (<0.1%) and the deep molecular response (MR4<0.01%, MR4.5<0.005%, and MR5 <0.001%). Consequently, the molecular monitoring plays a crucial role in the clinical management of CML patients, with a consequent research of sensitive and standardized molecular techniques. The automated methods offer advantages in terms of reduced time for analysis, decreased manual steps, and reduction of possible errors and contamination.

Methods: Aims: First of all, the sensitivity of the two methods (based on the number of ABL1 detected copies), the classification of molecular responses, with particular attention to the deep molecular one. Methods: We assessed the BCR-ABL1 transcript in 86 patients afferent to laboratories of Pisa, Napoli, Torino, and Bologna (Italy). For statistical analysis, the χ2, the Pearson’s and the Cohen’s K test were adopted. Because our patients presented different transmogrification levels (from >10% to the 0%) (MR4, MR4.5, MR5) the two techniques have been compared in different molecular subgroups.

Results: Firstly we compared the number of detected ABL1 copies, that are fundamental for definition of the molecular response categories, especially for early response (MR2+MR3). The automatic method (32.000 000 copies, 95% CI 24.000 000–40.000 000) vs. the manual method (27.000 000 copies, 95% CI 22.000 000–32.000 000). By the “LabNet” method, 51 (81%) samples exceeded the 100,000 copies of ABL1, while by the automated method 81 samples (94.2%) reached >100,000 ABL1 copies. Then, we compared the two methods in discriminating positive and negative samples (K Cohen=0.690; p <0.02): 77 samples were concordant (89.5%) and only 9 (10.4%) were discordant. Of the 18 negative samples with the “Labnet” method, 2 (11.1%) were in MR4.0, 10 (55.5%) in MR4.5 and 6 (33.4%) in MR5.0. On the other hand, of the 19 negative samples with the method “Ultra”, 1 (5.3%) was in MR4.5 and 18 (94.7%) in MR5.0, confirming the higher sensitivity of the automated method. In the cohort of positive cases by the two methods, the median values of transcript expression were superimposable (p=0.55) and the linear regression coefficient was very satisfying (Pearson’s r=0.9399; p-value <0.0001). Finally we compared the results produced by the two methods according to the “molecular classes” (MR1 vs MR2+MR3 vs MR4+MR4.5 vs MR5). This comparison showed a good concordance with the LabNet method, the automated one: the percentage of discordance demonstrated high concordance between “Ultra” and “LabNet” methods using assay comparison criteria proposed by Müller et al. [Leukemia 2009] (Table 1).
and apoptosis in IM sensitive and resistant cell lines.

The advantage of using AK and Plk1 inhibitors in involved cell growth control and apoptosis.

- reduction of cell survival;

- associated with:

- activity. Subsequent experiments showed that the inhibition of AK A and Plk1 (T210). 24h exposure to IM significantly reduced expression and phosphorylation of AK A (S282) and Plk1 (T210). 24h exposure to IM significantly reduced expression and phosphorylation of AK A (S282) and Plk1 (T210). 24h exposure to IM significantly reduced expression and phosphorylation of AK A (S282) and Plk1 (T210).

- V/PI staining; cell cycle distribution was observed by PI staining and subsequent GADD45a interacts with Aurora Kinase A (AK A), a key component of centrosome cycle and polar spindle assembly required for regulated progression from G2 to G1 and throughout.

Background: Cell response to stress is a central component of genomic stability. The integrity of signaling pathways involved in cell cycle arrest, chromatin remodeling and DNA repair, are critical for the maintenance fidelity of replicated DNA. In this context, Gadd45 proteins function as stress sensors and regulate transcription regulators. Gadd45α, in particular, intervenes in G2/M checkpoint induction and DNA repair, and it is required for efficient coordination of centrosome duplication hence preventing aneuploidy and aneuploidy. Such evidences let assume a putative role of Gadd445α in cancer development and progression, supporting the idea that Gadd45α interacts with Aurora Kinase A (AK A), a key component of centrosome cycle and polar spindle assembly required for regulated progression from G2 to G1 and throughout.

Aims: To analyze updated TFR data and predictive factors for remaining in TFR in ENESTfreedom.

Methods: Eligible pts had CML-CP with b2a2 and/or b3a2 BCR-ABL1 transcripts, s2y of frontline NIL, and MR4.5 (BCR-ABL1 ≤ 0.0032%) prior to enrollment. All pts provided informed consent. After enrollment, pts continued NIL for ≥2 y of frontline NIL, and MR4.5 during the consolidation phase; pts with no assessment worse than MR4 (8/20 (40.0% [95% CI, 19.1% - 63.9%]) were grouped according to Sokal risk score at diagnosis or depth of response and MR4.5 in the consolidation phase. 95% CI, 15.5% - 52.4% respectively, remained in TFR at wk 49 (Sokal risk scores were missing for 50 pts). Among pts with ≥2 assessments during the consolidation phase, 90.0% (95% CI, 45.2% - 60.6%) remained in TFR at wk 48 vs 82/40.0% (95% CI, 19.1% - 63.9%) who had ≥1 assessment between MR4 and MR4.5 during the consolidation phase. Overall, of 88 pts who reintegrated NIL due to loss of MMR, 87 (98.9%) regained MMR and the remaining pt left the study 7.1 wk after NIL reintiation without regaining MMR; 81 of 88 pts (92.0%) regained MR4.5 by the data cutoff. Among pts remaining in TFR for >48 wk (n=100), adverse events (AEs) were less frequent during the second 48 wk of TFR, 2.0% (1.0%) and 2.0% (1.0%) for pts with cardiovascular AEs during the first and second 48 wk of TFR, respectively; 34 (34.0%) and 9 (9.0%), respectively, had AEs in the predefined musculoskeletal pain group.

Summary/Conclusions: The majority of pts in TFR at 48 wk remained in TFR at 96 wk, and they reported fewer AEs during the second 48 wk of TFR than in the first 48 wk, affirming the durability and safety of TFR following TFR. No strong predictive factors for remaining in TFR were identified. Pts with low Sokal risk and pts with continuous MR4.5 in the consolidation phase tended to have higher TFR rates than other pts, although these results must be interpreted with caution due to the small number of pts in some subsets and the wide 95% CIs. Additionally, the biological explanation for an association between Sokal risk score at diagnosis and a subsequent ability to remain in TFR is unknown. These results support TFR as a valuable option for pts in sustained DMR on frontline NIL.

Table 1.

P601

DURABLE TREATMENT-FREE REMISSION (TFR) FOLLOWING FRONTLINE NILOTINIB (NIL) IN PATIENTS (PTS) WITH CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE (CML-CP): ENESTFREEDOM 96-WK UPDATE

1IA Pathology, Adelaide, Australia, 2Department of Haematology and Stem Cell Transplantation, St Istvn and St László Hospital, Budapest, Hungary, 3Hospital Universitario Doctor Negrin, Las Palmas de Gran Canaria, Spain, 4Medical University of Gdansk, Gdansk, Poland, 5Aarhus University Hospital, Aarhus, Denmark, 6St Mary’s Hospital, Dublin, Ireland, 7Hospital Ramon y Cajal, Madrid, Spain, 8Universitätsklinikum Düsseldorf, Düsseldorf, 9Charité - Universitätsmedizin Berlin, Berlin, Germany, 10Azienda Ospedaliera Bianchi Meloccori Morelli, Reggio Calabria, Italy, 11III. Med. Klinik, Medizinische Fakultät Mannheim der Universität Heidelberg, Mannheim, Germany, 12Pathology Seràgnoli-DIMES, Bologna, Italy

Background: ENESTfreedom (NCT01794068) is evaluating the ability to stop and maintain TFR in pts with a sustained deep molecular response (MR) on frontline NIL. Previous results from ENESTfreedom showed that 51.6% of pts (98/190) who attempted TFR remained off treatment and in major MR (MMR; BCR-ABL1 ≤ 0.1% on the International Scale [IS]) at 48 wk.

Aims: To analyze updated TFR data and predictive factors for remaining in TFR in ENESTfreedom.

Methods: Eligible pts had CML-CP with b2a2 and/or b3a2 BCR-ABL1 transcripts, s2y of frontline NIL, and MR4.5 (BCR-ABL1 ≤ 0.0032%) prior to enrollment. All pts provided informed consent. After enrollment, pts continued NIL for ≥2 y of frontline NIL, and MR4.5 during the consolidation phase; pts with no assessment worse than MR4 (8/20 (40.0% [95% CI, 19.1% - 63.9%]) were grouped according to Sokal risk score at diagnosis or depth of response and MR4.5 in the consolidation phase. 90.0% (95% CI, 45.2% - 60.6%) remained in TFR at wk 48 vs 82/40.0% (95% CI, 19.1% - 63.9%) who had ≥1 assessment between MR4 and MR4.5 during the consolidation phase. Overall, of 88 pts who reintegrated NIL due to loss of MMR, 87 (98.9%) regained MMR and the remaining pt left the study 7.1 wk after NIL reintiation without regaining MMR; 81 of 88 pts (92.0%) regained MR4.5 by the data cutoff. Among pts remaining in TFR for >48 wk (n=100), adverse events (AEs) were less frequent during the second 48 wk of TFR, 2.0% (1.0%) and 2.0% (1.0%) for pts with cardiovascular AEs during the first and second 48 wk of TFR, respectively; 34 (34.0%) and 9 (9.0%), respectively, had AEs in the predefined musculoskeletal pain group.

Summary/Conclusions: The majority of pts in TFR at 48 wk remained in TFR at 96 wk, and they reported fewer AEs during the second 48 wk of TFR than in the first 48 wk, affirming the durability and safety of TFR following TFR. No strong predictive factors for remaining in TFR were identified. Pts with low Sokal risk and pts with continuous MR4.5 in the consolidation phase tended to have higher TFR rates than other pts, although these results must be interpreted with caution due to the small number of pts in some subsets and the wide 95% CIs. Additionally, the biological explanation for an association between Sokal risk score at diagnosis and a subsequent ability to remain in TFR is unknown. These results support TFR as a valuable option for pts in sustained DMR on frontline NIL.

P602

RESPONSE DIFFERENCES IN THE BCR-ABL1 E13A2 AND E14A2 VARIANTS MAY BE A TECHNICAL QC ARTIFACT

L. Kjaer1, V. Skov1, M. Gniot2, L. Uddy3, M. Dorfl4, H. Hasselbalch5, N. Pallisgaard3

1Institute of Hematology Seràgnoli-DIMES, Bologna, Italy

Keywords: Chronic myeloid leukemia - Clinical 2
Background: The t(9;22) translocation in chronic myeloid leukemia (CML) generally occurs in intron 12 or 13 of the BCR gene resulting in two different transcripts, the e13a2 or e14a2. It has been suggested that the two variants represent separate disease entities and that the transcript variants hold a prognostic value regarding treatment response, where e14a2 predicts a faster and deeper treatment response. However, no difference in overall survival has been observed with the issue remaining controversial. Reverse transcription quantitative PCR (RT-qPCR) using the European Against Cancer (EAC) qPCR assay has been the gold standard for determining the levels of BCR-ABL1 transcripts. The assay use common primers for amplification of the two variants resulting in a PCR product for the e14a2 variant that is 75 base pairs longer than the e13a2 variant. Under suboptimal PCR conditions, amplicons may be amplified with different efficiencies, which can result in an underestimation of especially the amount of longer qPCR products.

Aims: To study the accuracy of the EAC assay in quantifying the e13a2 and e14a2 transcripts.

Methods: Patient samples were screened for BCR-ABL1 e13a2 and e14a2 transcript variants using either PCR with agarose gel separation or a droplet digital PCR (ddPCR) assay measuring the amount of e13a2 and e14a2 transcripts. The BCR-ABL1 level was determined by ddPCR using the QuantStudio instrument (Life Technologies) and expressed in the International Scale (%IS) using the EAC primers and assay conditions with GUSB and BCR as reference genes. Samples were re-measured by digital droplet PCR (ddPCR) on a QuantLife instrument (Bio-Rad) using modified EAC primers multiplexed with GUSB and BCR as reference genes and expressed as %IS.

Results: Transcript levels from 124 BCR-ABL1 positive patient samples were determined using the EAC qPCR assay (median: 0.08% IS, range: 0.001–159% IS) and ddPCR (median: 0.01% IS, range: 0.0002–124% IS). These included 59 samples with the e13a2 variant and 65 with the longer e14a2 variant. Comparing the expression levels obtained by the two techniques revealed ddPCR/qPCR ratio differences for e13a2 (median: 0.68, range: 0.35 - 3.2) and e14a2 (median: 3.43, range: 0–8.8), and a consistent 4.5 fold (>0.5 log) underestimation of the levels of the e14a2 compared to e13a2 when using qPCR (figure 1).

Summary/Conclusions: When we compared the BCR-ABL1 levels using qPCR and ddPCR, we observed a discrepancy between the e13a2 and e14a2 breakthrough variants. Since ddPCR is an endpoint measurement and not sensitive to variations in primer efficiencies, the most likely explanation for the discrepancy is a decreased ddPCR efficiency of the longer e14a2 variant compared to e13a2 variant. Thus in qPCR analyses using the EAC protocol this may, at least in some clinical platforms, result in a consistently underestimated of the e14a2 level resulting in an appealingly better treatment response. A more than 0.5 log underestimation in a large subgroup of patients could have consequences in clinical decision-making e.g. by miss-grouping patients at different time points or when considering TKI discontinuation. Since many clinical laboratories use the BCR-ABL1 EAC protocol, the underestimation of the e14a2 variant could potentially be a widespread issue. We are presently working on an optimized BCR-ABL1 qPCR protocol where the e14a2 underestimation is eliminated.

5-YR RESULTS FROM THE PIVOTAL PHASE 2 PONATINIB PACE TRIAL: EFFICACY, SAFETY AND LANDMARK ANALYSIS IN HEAVILY PRETREATED PATIENTS WITH CHRONIC-PHASE CHRONIC MYELOID LEUKEMIA (CP-CML)

1The University of Texas MD Anderson Cancer Center, Houston, TX, 2H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL, United States, 3Charité Universitätsmedizin Berlin, Berlin, Germany, 4Cedars-Sinai Medical Center, Los Angeles, CA, United States, 5Department of General Hospital, Singapore-NUS Medical School, Singapore, Singapore, 6Centre Hospitalier Lyon Sud, Pierre Bénite, Lyon, France, 7Centre for Haematology, Imperial College, London, United Kingdom, 8Winship Cancer Institute of Emory University, Atlanta, GA, 9Comprehensive Cancer Center, University of Michigan, Ann Arbor, MI, United States, 10University of Bologna, Bologna, Italy, 11Inserm CIC 1402, CHU de Poitiers, Poitiers, France, 12Huntsman Cancer Institute, University of Utah, Salt Lake City, UT, United States, 13Jena University Hospital, Jena, Germany, 14South Australian Health and Medical Research Institute and University of Adelaide, Adelaide, Australia, 15University of California San Francisco, San Francisco, CA, 16ARIAD Pharmaceuticals, Inc., ARIAD Pharmaceuticals, Inc., Cambridge, MA, United States, 17Universitätsmedizin Mannheim, Mannheim, Germany

Background: Ponatinib is an oral tyrosine kinase inhibitor (TKI) approved for pts with CP-CML or Philadelphia chromosome–positive acute lymphoblastic leukemia (Ph+ ALL) for whom no other TKI therapy is indicated, or for pts with T315I. The ponatinib PACE trial (NCT01207440) enrolled pts with CML or Ph+ ALL resistant/intolerant to dasatinib or nilotinib, or with T315I. Long-term results in these heavily pretreated pts provide value in informing treatment decisions.

Aims: To report 5-yr efficacy and safety, and the association of early landmark responses with survival at 5-yr landmark assessments as at 4 yrs past landmark, in heavily pretreated pts with CP-CML from PACE.

Methods: Ponatinib starting dose was 45mg/day. Dose reductions were instructed in Oct ’13 to manage risk of arterial occlusive events (AOEs) observed with longer follow-up. Outcome measures were: 5-yr efficacy (n=267) and safety (n=270); post-study final analysis (n=267) of the association of molecular responses (BCR-ABL1 ≤0.1% [major molecular response (MMR)], >0.1–1%, >1–10% and >10%) and cytogenetic responses (major [MCyR] and complete [CCyR]) at 3-, 6- and 12-mos with progression-free survival (PFS) and overall survival (OS) 4 yrs past landmark (log-rank P values). Data cutoff: 3 Oct ’16.

Results: Baseline characteristics of the CP-CML pts included: median time from diagnosis, 7 yrs (range, 0.5–27 yrs); median age, 60 yrs (18–94 yrs); median %Ph+ 100% (2.5–100%); median %Ph+ 20% (7%). 160 of 182 CP-CML pts received ≥3 prior TKIs. At initiation of study closure, 99 pts (37%) were on ≥3 prior TKIs. At initiation of study closure, 99 pts (37%) were on ≥3 prior TKIs. Among these pts, minimum follow-up was 52 mos, and most (78%) had 15mg/d as their last ponatinib dose. In efficacy-evaluable CP-CML pts, cumulative response rates as of the data cutoff were: MCyR, 60%; COyR, 54%; MMR, 40%; and MR4+, 24%. Among pts who achieved MCyR (n=148) or MMR (n=108), the Kaplan-Keier (KM) estimated probability of remaining in response at 5 yrs was 74% (95% CI, 62–83) and 61% (95% CI, 51–70), respectively. Maintenance of response was high regardless of dose reductions in Oct ’13. KM estimated 5-yr rates for PFS/OS were 49%/77%. Among pts with 3-, 6- and 12-mo landmark assessment, MCyR/CCyR rates were: 57%/45%, 62%/52% and 71%/56%, respectively, and MMR achieved in 14%, 29% and 39%, respectively. Achievement of cytogenetic response and deep reductions in BCR-ABL1 levels (Table 1) at most landmark time points was associated with improved PFS and OS 4 yrs past landmark. Deeper responses at all landmarks were associated with achievement of MMR. Overall, the incidence of adverse events (AEs) in ≥45% of CP-CML pts was rash 47%, abdominal pain 46%, and thrombocytopenia 46%. Most newly occurring AEs were observed within the first yr. The incidence of any AOE/serious AOE for CP-CML pts was...
29%/23%. Among CP-CML pts with no prior AEs who had a prospective dose reduction, 17% (11/63) had a first AOE occurring after Oct ’13.

Summary/Conclusions: Long-term 5-y results from PACE demonstrate that irrespective of dose reductions, ponatinib continues to show deep, lasting, clinical responses. Among CP-CML pts with no prior AOE who had a prospective dose reduction, 17% (11/63) had a first AOE occurring after Oct ’13. Among these, 208 (79% of all 263 patients) achieved a cytogenetic response (CyR), which was partial in 18 patients and complete in 52 patients (1% CyR). Among the 190 patients in CCyR, 148 (56.2%) achieved a molecular response (MMR) (ratio < 0.1%) after a median period time of 13.7 months (IQR 9.0-22.3). Eleven patients (4.2%) developed a blast crisis, with a median period for blast crisis of 3 cases. After a median follow-up of 45.0 months from IM start (IQR 22.3–72.0), 93 patients have died (9 from disease progression and 84 from unrelated causes), 144 are alive and 104 of them are still in treatment with IM, while 8 discontinued for prolonged deep molecular response and 22 switched to 2nd line TKI. Five-year event-free survival (EFS) and overall survival (OS) were 51.2% (CI95% 44.8-57.6) and 70.9% (CI95% 64.6-77.2), respectively. At univariate analysis Hb level at diagnosis (≥ 12 vs < 12g/dl, p=0.021) and the initial dose of IM (400 vs ≤300, p=0.048) were significant predictive factors for OS, while PLT count at diagnosis (< 500 vs ≥ 500, p=0.006) and female gender (p=0.046) were significant predictive factors for MMR achievement. Multivariate analysis for EFS and OS are described in Table 1.

Summary/Conclusions: The long term follow-up of very elderly CML patients treated with IM suggests that any effort to treat these patients with standard doses should be made, in order to achieve cytogenetic and molecular responses as in younger subjects.
ease (including 7 acute myocardial infarction), 8 PAOD, 4 carotid stenosis (asymptomatic), 2 avascular necrosis of femoral head, 1 optic artery ischemia, 1 aneurysm of aorta/right iliac artery. Overall, 21 patients were hospitalized for the management of ATEs; 15 patients received medical treatment only, while the remaining required invasive interventions: 9 coronary angioplasty with stent positioning, 3 lower limbs amputations, 2 peripheral vascular bypasses, and 1 prosthesis of femoral head. No patient died for ATEs. Overall, 24 patients (80% of patients with ATEs, and 7% of the whole cohort) permanently discontinued nilotinib because of ATEs. The median follow-up after ATE was 15 (1-58) months. Of the 30 patients with ATEs, 26 (87%) achieved a MMR and 18 (60%) obtained a MR4, during nilotinib treatment. These rates were comparable to those observed in patients without ATEs (MR3: 260/315, 83%; MR4: 113/315, 64%). The 5-year progression-free survival and overall survival rates in patients with or without ATEs (PFS: 96% vs 92%, p=0.55; OS: 96% vs 93%, p=0.79).

Summary/Conclusions: After a median follow-up of 58 months, 8.7% of patients treated front-line with nilotinib had ATEs, being coronary disease and PAOD the most common. ATEs were more frequent in elderly patients (median age at ATEs: 67 years). Half of the patients required invasive procedures, including major surgeries in 6 patients. The other patients were successfully managed with medical treatment. Importantly, no patients died for ATEs, and ATEs did not affect the rates of MMR, MR4 and 5-year PFS and OS, which were all comparable to those observed in patients without ATEs. Taken together, these data suggests that ATEs, despite being sometimes associated with significant morbidity, did not significantly impact on response rates and on long-term outcome of CML patients treated with nilotinib front-line.

P606

ASSESSMENT OF CHRONIC RENAL INJURY IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA IN THE CHRONIC PHASE RECEIVING TYROSINE KINASE INHIBITORS

Q. Jiang1,*, L. Zuo2, X. Ren1, X. Huang1
1Peking University People’s Hospital, Peking University Institute of Hematology, 2Peking University People’s Hospital, Department of Nephrology, Beijing, China

Background: Long-term use of tyrosine kinase inhibitors (TKIs) may lead to chronic renal injury.

Aims: To evaluate the incidence of chronic kidney disease (CKD) in patients with chronic myeloid leukemia (CML) in the chronic phase (CP) receiving TKIs, and to identify the factors associated with the onset of CKD.

Methods: Data of CML-CP patients treated with TKIs as first-line or second- or third-line therapy for at least 3 months were analyzed. Glomerular filtration rate (GFR) was followed from the initiation of TKI therapy. CKD was defined as persistent GFR less than 60 ml/min/1.73 m2 or persistent more than 30% GFR reduction from baseline. CKD-free survival was used to evaluate the onset of CKD. Patients’ characteristics and TKI used were analyzed to identify the factors associated with the onset of CKD by Cox regression model in those receiving first-line and second- or third-line TKI therapy, respectively.

Results: 587 patients were included in this study. 383 (65%) were male. Median age was 40 (17-84) years. 464 patients were receiving nilotinib (n=363), nilotinib (n=88) or dasatinib (n=13) as first-line TKI-therapy. With a median follow-up of 35 months (range, 3-185 months), 136 of 416 (33%) patients with normal GFR at baseline developed CKD. Probabilities of CKD-free survival at 4 years were 62%, 78% and 100% in the patients receiving imatinib, nilotinib and dasatinib, respectively (p=0.004). Multivariate analysis showed that imatinib use (HR=2.4, 95% CI 1.4-4.3, p=0.002), male gender (HR=2.0, 95% CI 1.4-2.9, p=0.001), increasing age (HR=1.2, 95% CI 1.1-1.4, p=0.003) and prior administration of hydroxyurea, interferon or chemotherapy (HR=1.7, 95% CI 1.1-2.8, p=0.010) were factors associated with incident of CKD. In 48 patients with abnormal GFR or prior CKD before first-line TKI-therapy, 8 of 42 (19%) developed ≥30% GFR reduction from baseline during nilotinib or dasatinib-therapy. In 123 patients receiving nilotinib (n=59) or dasatinib (n=64) as second- or third-line TKI-therapy after imatinib-failure, 13 of 110 (12%) with normal GFR at baseline developed CKD with a median follow-up of 19 months (range, 3-149 months). Probabilities of CKD-free survival at 3 years were 74% and 90% in those receiving nilotinib and dasatinib, respectively (p=0.059). Multivariate analysis showed that male gender (HR=1.8, 95% CI 1.1-3.0, p=0.023) and a history of diabetes mellitus, hypertension or other renal diseases (HR=3.8, 95% CI 1.3-11.6, p=0.019) were factors associated with incident of CKD. 3 of 13 (23%) patients with abnormal GFR or prior CKD before second- or third-line TKI-therapy developed ≥30% GFR reduction from baseline during nilotinib (n=1) or dasatinib (n=2) therapy.

Summary/Conclusions: Our study showed that nilotinib and dasatinib were associated with less chronic renal injury compared with imatinib as first-line TKI-therapy, while dasatinib was related to less loss of renal function compared with nilotinib as second- or third-line TKI-therapy after imatinib-failure in CML-CP patients.

1Lab CREA-AIL, AO Spedali Civili di Brescia, 2Unit of Bone Marrow Transplantation, University of Brescia, Brescia, 3Division of Hematology and Bone Marrow Transplantation, University-Hospital of Udine, Udine, 4Institute of Hematology “I. Land A Seragnoli”, University of Bologna, Bologna, 5Chair of Biochemistry, University of Brescia, Brescia, 6Department of Biomedicine and Prevention, University of Tor Vergata, Roma, 7Division of Hematology, AO Spedali Civili di Brescia, Brescia, Italy

Background: Quantification of BCR-ABL1 transcript by qPCR is mandatory to monitor the response to TKIs therapy in CML patients. The achievement of Major or Deep Molecular Response (MMR or DMR) with TKIs is crucial for long-term survival and for treatment free remission (TFR). Currently, up to 30-40% of CML patients treated with TKIs can achieve DMR, but 50-60% of deep responders who discontinue the treatment loose their DMR and re-challenge into continuous TKIs therapy. qPCR has some intrinsic limitations and it does not appear to be an optimal assay to select the best candidates to TKIs discontinuation. Digital PCR (dPCR) can give an absolute quantification of target nucleic acids by partitioning the PCR reaction mix over a large number of wells, each containing a single copy or no copies of the target region.

Aims: The aim was to comparatively monitor the BCR-ABL1 transcript levels by dPCR and qPCR in 57 CML patients treated with TKIs and achieving MMR or DMR in at least 3 time points.

Methods: Using qPCR and dPCR (Q530 Digital PCR System by Life Technologies), we comparatively analyzed 228 peripheral blood samples from 57 CML patients with MMR (n=14) or DMR (n=43). qPCR analysis were performed according to the last International Guidelines while absolute quantification of BCR-ABL1 transcript were obtained by dPCR and results were expressed as number of BCR-ABL1 copies/ul of reaction. Patients were divided into 3 groups corresponding to the MR classes at the first time point: MR3.0, MR4.0 and MR4.5-5.0 groups. dPCR Positive Predictive Value (PPV) was also preliminary evaluated in 14 patients undergoing TKI discontinuation.

Figure 1. Results: Analyzing comparatively the time course of MR in the patients of the three groups (MR3.0, MR4.0 and MR4.5-5.0) it was observed a similar trend, but the dPCR allowed to appreciate that, at the time of starting the monitoring the patients showed different levels of BCR-ABL1 copies/ml. Furthermore, those patients with MR4.5-5.0 undetectable by qPCR resulted with detectable BCR-ABL1 transcript levels when assessed by dPCR. Secondy, while MRD quantitations measured by qPCR appear to be more homogeneous, nearly due to a normalization effect of qPCR, the quantitations of MRD measured by dPCR appear to be more heterogeneous because of the high sensitivity and accuracy of dPCR. Therefore, dPCR values, reflecting the great heterogeneity of MRD level in patients belonging to the same MR group, suggest a higher accuracy in patients stratification (Figure 1a). dPCR value of 0.468 copies/ul, previously reported as value discriminating between major responders and deep responders, was used as threshold for dPCR data analysis. Patients with absolute value of BCR-ABL1 lower than 0.468copies/ul at the first time point presented more stable disease levels than the patients with absolute value of BCR-ABL1 higher than 0.468copies/ul (Figure 1b). In 14 CML patients who
discontinued TKIs, a preliminary analysis showed that 80% of patient with BCR-ABL1>0.468 copies/ul at discontinuation, maintained stable TFR (PPV of 80%).

Summary/Conclusions: This study suggests that dPCR is more precise and sensitive than qPCR when detecting levels of BCR-ABL1 transcript and that dPCR seems to be more robust and accurate for CML patients stratification. Larger and prospective studies are warranted to confirm the higher sensitivity and accuracy of dPCR and its usefulness to better select the candidates for TFR.

P608
OUTCOME OF BLAST PHASE CHRONIC MYELOID LEUKEMIA (CML-BP) IN THE TYROSINE KINASE INHIBITOR ERA
C. Telci1,*, L. Isern Solvay1, S. Shams1, A. Kuykendall1, J. Chavez2, B. Shah2, K. Swee2, J. Pinilla-Ibarz2
1Department of Malignant Hematology, University of South Florida/Moffitt Cancer Center, 2Department of Malignant Hematology, Moffitt Cancer Center, Tampa, United States

Background: Primary goal of management in chronic myeloid leukemia (CML) is to prevent disease progression to blast phase CML (BP-CML). Current notion for management of BP-CML usually involves initiation of intensive chemotherapy regimen with addition of tyrosine kinase inhibitor (TKI). Despite treatment with intensive induction chemotherapy, outcome remains dismal.

Aims: We aimed to describe our experience with management of BP-CML and its outcome.

Methods: We included 58 patients from Moffitt Cancer Center from 2001 till 2016 with diagnosis of BP-CML and performed a retrospective chart review. Data elements including age, gender, peripheral blood and bone marrow parameters, phase of CML, treatment, cytogenetics and vital status were collected. Survival analysis using Kaplan-Meier method with log-rank test to determine significance by calculating two-sided p values was performed.

Results: The overall survival (OS) of our cohort was 31.87 months (mo). For patients with progression to BP-CML from previously known diagnosis of CML, median time to progression was 19.1 mo (range: 3.0-221.2 mo). The median OS from the diagnosis of BP-CML in this cohort was 10.8 mo, compared to de novo CML-BP cohort OS of 11.03 mo (p-value=0.62). Myeloid blast phase CML had worse OS compared to lymphoid blast phase cohort but was not statistically significant (9.17 vs 17.5 mo, p=0.32). We further compared the treatment strategies of BP-CML including single agent TKI (n=21) and conventional chemotherapy regimens in combination with a TKI (n=36). The median OS of the cohort with single agent TKI was not statistically different from the combination with chemotherapy arm (12.83 mo vs 10.87 mo, p=0.73) as shown in Figure 1A. Additionally, combination of chemotherapy with TKI compared to single agent TKI did not have significant survival impact in either myeloid (9.17 vs 9.13 months, p=0.32) or lymphoid (14.47 vs 18.27 mo, p=0.24) BP-CML. Total of 26 patients (44.8%) proceeded to allogeneic bone marrow transplant, 26% (n=6) of which only received TKI prior to transplant compared to 76.9% (n=20) who received chemotherapy in combination with TKI. Use of single agent TKI rather than TKI in combination with chemotherapy prior to allogeneic transplant had a trend toward improved OS (128.5 vs 24 mo, p=0.23) (Fig 1B). Choice of TKI in combination with chemotherapy in treatment of BP-CML also did not identify any TKI combination resulting in superior survival (Figure 1D). Overall survival of the cohort stratified by presence of standard Philadelphia chromosome in comparison to additional cytogenetic aberrations did not detect difference in overall survival (10.87 vs 12.1 mo, p=0.51). Further evaluation of cytogenetic aberrations revealed monosomy 7 to be present in greater frequency in lymphoid blast phase compared to myeloid blast phase (35.7% vs 6.29%, p=0.02).

Summary/Conclusions: Our data suggest no survival difference when BP-CML is treated with a single agent TKI compared to a combination therapy, regardless of histology type. Therefore, single agent TKIs should be considered as an effective frontline therapy option for BP-CML, which may prevent the potential toxicity associated with chemotherapy. These findings need further validation in a larger prospective cohort.

P609
EFFICACY OF SWITCHING TO DASATINIB IN CHRONIC MYELOID PATIENTS WITH LATE WARNING RESPONSES TO IMATINIB. STUDY OF THE ASSOCIATION OF RESPONSE TO DASATINIB TO IMMUNOLOGIC STATUS
J.L. Steegmann1,*, V. Garcia-Gutiérrez2, B. Colom3, F. Sanchez-Guijo4, R. Ayala5, C. Boque5, F. Casado5, B. Xicoy5,1, M. Montero5, C. Soto5,10, R. de Paz5,1, A. Kreuzman5, J. Martinez-Lopez2, C. Munito2
1Servicio de Hematologia, Hospital Universitario de la Princesa/ IIS-IP Madrid, 2Servicio de Hematologia, Hospital Universitario Ramón y Cajal, 3Servicio de Immunologia, Hospital Universitario de la Princesa, Madrid, 4Servicio de Hematologia, Hospital Universitario de Salamanca, Salamanca, 5Servicio de Hematologia, Hospital Duran i Reynals, Barcelona, 6Servicio de Hematologia, Hospital Virgen de la Salud, Toledo, 7Servicio de Hematologia, Hospital Germans Trias i Pujol, Barcelona, 8Servicio de Hematologia, Hospital Universitario Virgen del Rocio, Sevilla, 9Servicio de Hematologia, Hospital Povisa, Vigo, 10Servicio de Hematologia, Hospital Universitario La Paz, Madrid, Spain

Background: European LeukemiaNet (ELN) recommendations (2013) advised closely monitoring for patients with late warning response (patients with complete cytogenetic response without major molecular response after 12 months of treatment). Our trial, DASAPOST, has been the first one evaluating efficacy and safety of dasatinib in patients with late warning responses, and preliminary results have been reported (García-Gutiérrez et al, ASH 2016; P5450). Besides, many studies suggest that dasatinib may augment responses due to its immunomodulating effect. Although NK and CD8 cells seem to be involved, the specific mechanism remains to be clarified.

Aims: To evaluate the efficacy and safety of switching change to dasatinib in patients treated with imatinib first line during at least 18 months and having a late warning response, and to study the association between response to dasatinib and immune robustness, both baseline and during the therapy, and dasatinib-induced lymphocyte mobilization.

Methods: Phase II, open, multicenter DASAPOST study (NCT01802450). Patients previously treated with imatinib after at least 18 months, with CCyR but without MMR, were included. All BCR-ABL1/ABL (IS) measurements were centralized in a EUTOS laboratory. Analysis of HLA class I in some point were considered as non responders. Lymphocyte counts, subpopulations and migration studies were done at baseline (1st day of dasatinib), and every 3 months, and safety of dasatinib in patients with late warning responses, and preliminary results have been reported (García-Gutiérrez et al, ASH 2016; P5450). Besides, many studies suggest that dasatinib may augment responses due to its immunomodulating effect. Although NK and CD8 cells seem to be involved, the specific mechanism remains to be clarified.

Aims: To evaluate the efficacy and safety of switching change to dasatinib in patients treated with imatinib first line during at least 18 months and having a late warning response, and to study the association between response to dasatinib and immune robustness, both baseline and during the therapy, and dasatinib-induced lymphocyte mobilization.

Methods: Phase II, open, multicenter DASAPOST study (NCT01802450). Patients previously treated with imatinib after at least 18 months, with CCyR but without MMR, were included. All BCR-ABL1/ABL (IS) measurements were centralized in a EUTOS laboratory. Analysis of HLA class I in some point were considered as non responders. Lymphocyte counts, subpopulations and migration studies were done at baseline (1st day of dasatinib), and every 3 months, and they were done both previous to the dose, and 2 hours after.

Summary/Conclusions: Our study shows that in patients treated with imatinib and with late warning responses, switching to Dasatinib induced MMR in 2 out every 3 patients, and MR4 in half of the patients, with a good safety profile. Contrarily to other group reports, we have not found any significant association between response and lymphocyte mobilization in any point studied. Interestingly, the absolute number of CD8 at baseline was significantly associated with the early obtention of MMR at 3 months, a finding which underscores the prognostic importance of baseline immune status, the relevance of CD8 cells in the antileukemic effect, and which suggest that this quite simple variable must be included in future studies with dasatinib in second line.

Methods: The BCR-ABL measurements acquired using EAC and in-house modified EAC protocol have been compared with results from SA Pathology in Adelaide. The Adelaide protocol (Branford and Hughes 2006) consists of separate, optimized reactions for e13a2 and 14a2 transcripts, therefore it should be considered free of any PCR efficiency-related artifacts. The data originated from four independent sample batches exchanged between Poznan and Adelaide since 2009.

Results: The analysis of retrospective EAC protocol data showed that when e13a2 and e14a2 samples entered the exponential phase at the same time, the latter would cross the threshold approximately 2.2 cycles after the first one. Re-analysis of data from sample exchanges from 2009 revealed that after establishing a conversion factor (CF), all of the e14a2 measurements in Poznan were underestimated according to Adelaide. At the same time, almost all of e13a2 samples were overestimated (fig. 1). Still, the bias between methods was acceptable and a valid conversion factor (CF) was calculated. The method modification introduced 2011 eliminated this difference and increased concordance between laboratories. The last sample batch revealed significant difference between non-modified and modified EAC protocols in e13a2 measurements: 4.56 (+/- 0.96). Reanalysis of sample batch from 2009 (presented on fig.1) using 4.57 (2x2.28) factor (e13a2 results divided by 2.28, e14a2 results multiplied by 2.28) resulted in almost perfect data alignment. The results of modified EAC protocol, after CF recalculation, showed very good concordance with Adelaide (100% results of e14a2 and 88% of e13a2 within 2-fold of reference laboratory).

Methods: The genealogy of insulin resistance in chronic myeloid leukemia patients treated with nilotinib

G. Caocci1,*, C. Mammì2, C. Labate2, S. Rodi2, D. Ielo3, M. Priolo2, M. Postorino4, G. Tripepi5, F. Ronco3, C. Laganà2, B. Martino3

Background: Impaired fasting glucose (IFG) and type 2 diabetes (T2D) represent adverse events in Chronic Myeloid Leukemia (CML) patients treated with the second-generation tyrosine kinase inhibitor (TKI) nilotinib. A genetic risk score (uGRS) for the prediction of insulin resistance, consisting of 10 multiple single-nucleotide polymorphisms (SNPs), has been proposed.

Aims: We evaluated the uGRS predictivity in 45 CML patients treated with nilotinib.

Methods: Patients were genotyped for IRS1, GRB14, ARL15, PPARG, PEPD, ANKRD55/MAP3K1, PDGFC, LYPLAL1, RSPO3, and FAM13A1 genes. The uGRS was based on the sum of the risk alleles within the set of selected SNPs.

Results: MR2.5 and CMR were achieved in 91% and 84% of the patients, respectively. Before treatment, none of the patients had abnormal blood glucose. During treatment and subsequently follow-up of 84.4 months (range 1-298), 5 patients (11%) developed diabetes requiring oral treatment, after a median of 11 months (range 3-95) since nilotinib. Nine patients (20%) developed prediabetes. Prediabetes/diabetes-free survival was significantly higher in patients with an uGRS below 10 compared to higher scores (100% vs 18%, p=0.004) (Figure). Each increment of 1 unit on the uGRS caused a 42% increase in the prediabetes/diabetes risk (HR=1.42; CI: 1.04-1.94; p=0.026).

Figure 1.

Summary/Conclusions: In the EAC protocol, the e14a2 transcript amplifies less efficiently than e13a2. Since commonly used plasmids, including ERM-AD623, are based on e14a2, the standard curve is being shifted towards the latter cycles. It leads to overestimation of e13a2 by mean factor of 4.5 (over 0.5 log), which could be clinically significant. The reports of worse outcome of e13a2 patients are probably caused by this artifact, which can be easily eliminated by implementing an additional forward primer to EAC protocol. This overestimation cannot be detected in case of lab to lab validation when two centers are using EAC protocol. In case of method validation in Adelaide, those differences were not as obvious as well. The shift of 4.5 (fig. 1) means that results are 2.25 times different from the perfect concordance line and could easily fit into accepted 2-fold and 3-fold compartments. The CF calculated by Adelaide would depend on the percentage of each transcripts among the exchanged samples. The observed artifact should be also taken into consideration in clinical trials that rely on surrogate endpoints such as molecular response level at certain time points. Uneven transcript variant distribution between compared groups may lead to improper conclusions.

ESTABLISHMENT OF IN VIVO AND IN VITRO MODEL OF X-LINKED SIDEROBLASTIC ANEMIA

K. Saito1, T. Fujiwara1, M. Morita2, Y. Okitsu1, N. Fukuhar1, Y. Onishi1, Y. Nakamura3, R. Shimizu3, H. Haraguchi3
1Hematology and Rheumatology, 2Medical Biochemistry, Tohoku University Graduate School of Medicine, Sendai, 3Cell Engineering Division, RIKEN BioResource Center, Tsukuba, 4Molecular Hematology, Tohoku University Graduate School of Medicine, Sendai, Japan

Background: Congenital sideroblastic anemia (CSA) is an inherited anemia characterized by the presence of bone marrow ring sideroblasts, reflecting excess mitochondrial iron deposition. The most common form of CSA is X-linked sideroblastic anemia (XLSA), which is attributed to mutations in the X-linked gene erythroid-specific 5-aminolevulinate synthase (ALAS2). ALAS2 resides on chromosome X and encodes the enzyme that catalyzes the first and rate-limiting steps in the heme biosynthesis pathway in erythroid cells. This pathway converts glycine and acetyl-coenzyme A to 5-aminolevulinic acid (ALA), which requires pyridoxal 5'-phosphate (PLP) as a cofactor. Although PLP has been used for treating XLSA, a marked proportion of patients with XLSA remain refractory to treatment (Ohba et al. Ann Hematol 2013). Thus, there is a need to establish a model of XLSA to reveal the detailed molecular mechanism contributing to RS formation as well as to explore novel therapeutic strategies.

Aims: We explored to establish a novel model of XLSA by CRISPR/Cas9-based genome editing.

Methods: We targeted the GATA-1-binding region of intron 1 of the human ALAS2 gene based on both in vivo mice and human induced pluripotent stem cell-derived erythroid precursor (HDEP) cells (Kurita et al. PLoS One 2013). The mutation diminished the binding of transcription factor GATA-1, which would lead to decreased transcription of the ALAS2 gene, thereby causing XLSA (Kaneko et al. Haematologica 2014). Western blotting and quantitative chromatin immunoprecipitation (ChIP) analysis were performed using antibodies against GATA-1 (D52H6, Cell Signaling Technologies) and TAL1 (C-21, Santa Cruz). For transcription profiling, Human Oligo chip 25K (Toray) was used. The mutation diminished the binding of transcription factor GATA-1, which would lead to decreased transcription of the ALAS2 gene, thereby causing XLSA (Kaneko et al. Haematologica 2014). Western blotting and quantitative chromatin immunoprecipitation (ChIP) analysis were performed using antibodies against GATA-1 (D52H6, Cell Signaling Technologies) and TAL1 (C-21, Santa Cruz). For transcription profiling, Human Oligo chip 25K (Toray) was used. Gene ontology (GO) analysis was performed with Gene_cards (http://genecards2.dacya.ucm.es/)

Results: We first generated a founder female mouse lacking the intron 1 enhancer region of Alas2, including the GATA binding domain (Alas2^{delin1X}). Whereas the heterozygous Alas2^{delin1X/+} mice were viable and did not show any anemic phenotype, hemizygous deletion (Alas2^{delin1X/-}) in male mice led to an embryonic lethality, suggesting that this sequence is indispensable in the context of mice. As an alternate approach, we established a clonal line with HIDEP cells, which harbored 19-bp deletion within the intron 1 enhancer region of ALAS2, including the GATA binding domain. Whereas wild-type HIDEP cells exhibited red color, the XLSA clone appeared pink/pale color, which were accompanied by the significantly decreased intracellular heme concentration. Despite no obvious changes in the expression of GATA-1, MDS2, and ALAS2 as well as globin genes (HBA, HBB, and HBD) in the XLSA clone. Microarray analysis revealed >2-fold up- and down-regulation of 619 and 274 genes caused by the 19-bp deletion, respectively. The downregulated gene ensemble included globins (HBZ, HBG, HBE, HBB, HBM, and HBG) as well as genes involved in iron/heme metabolism (ALAS2, transferrin receptor: TFRC, coproporphyrinogen oxidase: CPOX, and mitoferrin 1: MFRT1). GO analysis revealed significant enrichment of cellular iron homeostasis (p=0.018), regulation of transcription (p=0.0021), and innate immune response (p=0.0018), implying that heme was involved in various biological processes in erythroid cells. Interestingly, ALA treatment significantly improved cell osmolality, at least 50% reduction of IgM and improvement of any circulatory symptoms.

Conclusion: Bendamustine and rituximab combination therapy related to high response rates, a high rate of CR, long response duration and few relapses during the observation period, with a favorable safety profile. It might be considered in the first line for reasonably fit patients with CAD requiring therapy.

BENDAMUSTINE AND RITUXIMAB COMBINATION THERAPY FOR COLD AGGLUTININ DISEASE: RESULTS OF A PROSPECTIVE NORDIC TRIAL

1Department of Research and Innovation, HAUGESUND HOSPITAL, Hauge-sund, 2Department of Pathology, Oslo University Hospital, Oslo, Norway, 3Department of Hematology and Stem Cell Transplantation, Turku University Hospital, Turku, Finland, 4Department of Haematology, Herlev Hospital, University of Copenhagen, Herlev, Denmark, 5Department of Medicine, Haukeland University Hospital, Bergen, 6Medical Department, Drammen Hospital, Vestre Viken Trust, Drammen, 7Department of Medicine, Akershus University Hospital, Nordbyhagen, 8Department of Hematology and Oncology, Stavanger University Hospital, Stavanger, 9Department of Hematology, Oslo University Hospital, Oslo, Norway

Background: Primary cold agglutinin disease (CAD) is an autoimmune hemolytic anemia in which a well-defined clonal lymphoproliferative bone marrow disorder (LPD) causes production of monoclonal cold agglutinins. Major clinical manifestations are anemia and, in some cases, cold-induced circulatory symptoms. Pharmacological therapy, although not indicated in patients with very mild disease, seems required in a majority of cases. Corticosteroids are ineffective. Rituximab monotherapy has resulted in approximately 50% response rate and 1-year median response duration. Fludarabine and rituximab combination therapy showed 70% response rate (20% complete responses) and very long response duration, but considerably toxic.

Aims: We wanted to investigate whether bendamustine and rituximab combination therapy can result in favorable response rates and duration with an acceptable toxicity profile.

Methods: We conducted a prospective, uncontrolled multicenter trial with 16 participating hospitals from Norway, Finland and Denmark. Essential inclusion criteria were verified CAD with symptomatic anemia and/or severe cold-induced circulatory symptoms. Eligible patients received 4 cycles of rituximab 375mg/m² day 1 and bendamustine 90mg/m² day 1-2 with 28 days interval. Outcomes were assessed by clinical panel into complete response (CR), partial response (PR), and non-response (NR). The definition of CR included normalization of hemoglobin (Hb) levels with no hemolysis, complete histologic resolution of the bone marrow LPD and disappearance of monoclonal serum protein. The criteria for PR included increase in Hb levels by at least 2.0 g/dL or to the normal range, transfusion independence, at least 50% reduction of IgM and improvement of any circulatory symptoms.

Results: Forty-four patients (19 men and 25 women) were included, with a median age of 74 years (range, 48-86) and median disease duration 4 years (range, 0-18). Seventeen patients had received previous therapy. At baseline, median Hb level was 9.5g/dL (range, 4.5-14.8), bilirubin 65micromol/L, lactate dehydrogenase (LDH) 478U/L, haptoglobin undetectable, IgM 4.1g/L (1.0-2.72), CA litter 2048 (64-65536). Monoclonal IgM kappa was detected in 38 patients, Igg kappa in 1 and IgA kappa in 1. We observed CR in 16 patients (36%), PR in 15 (34%), while the remaining 13 (30%) were non-responders. Hb levels were significantly higher of median of 4g/dL in the responders. 4.4g/dL in patients achieving CR and 3.9g/dL in those achieving PR. Median post-therapy Hb levels were 14.2g/dL (CR), 12.5g/dL (PR) and 10.5g/dL (NR). Acrocyanosis and Raynaud symptoms resolved completely in 16 patients and improved in 11 (47% and 32%, respectively, of those with such symptoms at baseline). Histologic regression of the LPD was complete in 17 patients (39%), partial in 5 (11%) and not evaluable in 18 (41%). Median time to response was 2 months (0.5-12). Only 3 responders experienced relapse; 2 after PR and 1 after CR. Median observed response duration was 32 months (range, 1-62) during median 32 months follow-up. Complete response, complete remission in 7 patients, very mild, and very mild disease, seems required in a majority of cases. Corticosteroids are ineffective. Rituximab monotherapy has resulted in approximately 50% response rate and 1-year median response duration. Fludarabine and rituximab combination therapy showed 70% response rate (20% complete responses) and very long response duration, but considerably toxic.

Conclusion: Bendamustine and rituximab combination therapy resulted in high response rates, a high rate of CR, long response duration and few relapses during the observation period, with a favorable safety profile. It might be considered in the first line for reasonably fit patients with CAD requiring therapy.

P614

EX VIVO TREATMENT OF RED BLOOD CELLS FROM 15 PYRUVATE KINASE (PK) DEFICIENT PATIENTS WITH AG-348, AN ALLOSTERIC ACTIVATOR OF PK-R, INCREASES ENZYMIC ACTIVITY, PROTEIN STABILITY AND ATP LEVELS

B. van Oirschot1, P.A. Kosinski2, J. Hilton3, K. Johnson2, V. Chubukov2, L. Deng2, G. Pasterkamp1, S. van Straaten14, C. Kung3, R. van Wijk1
1Clinical Chemistry and Haematology, University Medical Center Utrecht, Utrecht, Netherlands, 2Agios Pharmaceuticals, Inc., 3KSQ Therapeutics, Cambridge, MA, United States, 4Van Creveldkliniek, University Medical Center Utrecht, Utrecht, Netherlands

Background: Pyruvate kinase (PK) deficiency is a rare hereditary disorder affecting red blood cell (RBC) glycolysis. It is caused by mutations in the PKLR gene. PK-deficient RBCs are characterized by changes in metabolism associated with defective glycolysis, including a build-up of the upstream metabolite 2,3-diphosphoglycerate, and deficiency in the PK product ATP. It is hypothesized that insufficient energy production affects red cell homeostasis, promoting...
Methods: Aims: Generation sequencing (NGS) based panel that contained genes already to RBC membrane disorders.

Aims: To evaluate the effect of AG-348 treatment on PK-R enzymatic function, RBC metabolism and deformability

Methods: Observational case-control study, approved by the Institutional Review Board. All patients gave informed consent. Enrolled patients (N=15) were adults, transfusion-independent and compound heterozygous or homozygous for PKLR mutations. Baseline metabolic profiling was performed by LC-MS/MS. Purified RBCs from patients and healthy control subjects were incubated with AG-348 (up to 10 μM) for 24 hours at 37°C. After 6 and 24 hours PK-R activity, ATP levels and RBC deformability (by Lorrcra) were measured. For determination of PK-R thermal stability, RBC lysates were incubated for 2 hours with 2 μM AG-348 (37°C) prior to test. Baseline protein levels of PK-R were assessed using antibodies against PK-R

Results: Baseline patient characteristics show strongly reduced PK-R activity in all patient cells, in particular taking into account the degree of reticulocytosis (Table 1). Distinct metabolic changes were consistent with a block of glycolysis at PK-R step. Treatment of PK-deficient RBCs with AG-348 resulted in increased enzymatic activity in all patient cells after 24 hours (mean increase 1.5-fold, range 1.2-3.4). Similar increases were observed in control cells (mean fold increase 2.3, range 1.2-7.1). ATP levels in PK-deficient cells increased upon AG-348 treatment (mean fold increase 1.2, range 0.2-2.2) similar to controls (mean fold increase 1.6, fold range 1.4-1.8). Generally, PK-R thermal stability was strongly reduced in PK-deficient patient cells, illustrated by a mean loss of activity of 72% (19% for control cells) after incubation at 53 °C for 60 minutes. Ex vivo treatment with AG-348 prior to incubation resulted in residual activity of 4 to >10-fold higher than residual activity of vehicle-treated samples. Baseline protein level analyses suggests that a certain level of PK-R protein is required for cells to respond to AG-348 treatment ex-vivo, as treatment effects were minimal in patient cells with very low or undetectable levels of PK-R. In approximately half of the patients, ex vivo treatment with AG-348 was associated with an increase in RBC deformability, although there doesn't appear to be a clear correlation with enzymatic or metabolic response.

Summary/Conclusions: These data support the hypothesis that drug intervention with AG-348 effectively upregulates PK-R enzymatic activity and increases stability in PK-deficient RBCs over a broad range of PKLR genotypes. The combination of PK-R enzymatic activity and ATP levels suggests that glycolytic pathway activity may be restored. AG-348 treatment may represent an attracive way to correct the underlying pathologies of PK deficiency

P615 IDENTIFICATION OF NEW PATHOGENIC MUTATIONS IN PATIENTS WITH RED BLOOD CELL MEMBRANE DISORDERS USING NEXT-GENERATION SEQUENCING

M.D.M. Mafú Pereira1,2, E. Llaudet Planas1, V. Rizzuto1, J. L. Vives Corrons1

1Red Blood Cell Pathology And Hematopoietic Defects, Josep Carreras Leukaemia Research Institute, Barcelona, Spain

Background: Red blood cell (RBC) membrane proteins deficiency or structural alterations lead to RBC membrane disorders such as hereditary spherocytosis, hereditary elliptocytosis or hereditary xerocytosis among others. Genetic analysis of these patients was not usually performed before next-generation sequencing (NGS) adoption. Herein, we report on the genetic analysis of an NGS panel suggested by Sanger by several membrane related genes, considering that they all contain a high number of coding regions.

Aims: The aim of this study is to perform the molecular diagnosis of the patients included in the study as well as to identify new pathogenic mutations leading to RBC membrane disorders.

Methods: 116 patients from 74 unrelated families were studied with a next generation sequencing (NGS) based panel that contained genes already described as disease causing for RBC membrane disorders (ANK1, EPB41, EPB42, SLCA4A1, SPTA1, SPTB, PIEZO1, KCNN4, RHAG) as well as for enzymopathies (ADA, AK1, ALDOA, BPOM, CYB5A, G6PD, GCLC, GPI, GSR, GSS, HK1, NTS3CA, FFMK, PKG1, PKL1, TP11), hemoglobinopathies (HBA1, HBA2, HBB) and congenital disserthritoid anaemias (CDAN1, C15orf41, SEC23B, KLF1, GATA1, KIF23). The patients analysed were oriented as hereditary spherocytosis (63 patients), hereditary elliptocytosis or piroplasmocytosis (19 patients) and hereditary xerocytosis (8 patients). There were also 42 patients whose the combination of phenotypic laboratory results was suggestive of membranopathy but it didn’t suggest any specific RBC membrane pathology.

Results: A total of 74 pathogenic variants leading to RBC membrane disorders were identified, of which 14 had already been reported as disease causing. Of the remaining 60 variants, 42 had never been identified neither by 1000G or ExAC projects and therefore are novel mutations. Beta-spectrin, ankyrin and alpha-spectrin were the proteins that gathered most part of the mutations, we identified 23 variants in SPTB, 20 variants in ANK1 and 16 variants in SPTA1. 48% (36/74) of the identified variants were missense changes, mostly from SPTB gene (11 variants), while a 38% (28/74) of the variants were nonsense changes and other type of variation such as frameshift mutation, mostly from ANK1 (12 variants) and SPTB (9 variants). Of special interest, only 2 variants were identified in more than one unrelated family: 1) SPTB c.647T>G, leading to splicingiscytosis, was identified in 8 patients of 2 unrelated families, 2) SPTA1 c.460G>1462dupTG, leading to elliptocytosis, was identified in 6 patients from 5 different unrelated families.

Finally, with the NGS panel results, the genetic diagnosis of 89% (103/116) of the included patients could be determined and only in 11% (13/116) the mutation was not identified or the variant correlation with disease was not clear. It is worthy to highlight that 10 of the 13 undiagnosed patients had been oriented as unclear membranopathy.

P616 CLINICAL FOLLOW-UP OF 378 PATIENTS WITH AUTOIMMUNE HEMOLYTIC ANEMIA: PROGNOSTIC IMPACT OF HEMOGLOBIN LEVELS, AUTOANTIBODY CLASS, AND RETICULOCYTOPENIA AT ONSET ON THE RELAPSE RISK AND OUTCOME

B. Fattizzo1,2, A. Zaninoni2, J. Giannotta2, M. Lunghi3, A. Ferrari4, A. Pepi5, B. Fattizzo1,2, A. Zaninoni2, J. Giannotta2, M. Lunghi3, A. Ferrari4, A. Pepi5

1Department of Hematology, Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Milano, Milan, Italy, 2Department of Hematology, Ospedale Maggiore Policlinico Regionale Malattie del Sangue, Castelfranco Veneto, Castelfranco Veneto, 3Department of Hematology, Ospedale Maggiore Policlinico, Milano, Milano, Italy, 4Department of Hematology, Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Milano, Italy, 5Department of Blood Transfusion, Immunology and Transfusion Medicine, Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Milano, Italy

Background: Autoimmune hemolytic anemia (AIHA) is generally heterogeneous, from mild/compensated to life-threatening, due to autoantibody class/thermal amplitude, efficiency in activating complement, activity of the reticuloendothelial system, and efficacy of bone marrow compensatory response.

Aims: Here we analysed predictors of first relapse, complications, and fatality in a large AIHA series.

Methods: We retrospectively studied 378 patients (135m and 243 F, median age 61 yrs, range 19-100) from 10 sites, followed-up for 4.3 yrs (range 0.5-27). Patients were classified in warm (w)AIHA (DAT positive for IgG and IgG+C), cold agglutinin disease, CAD (C), mixed (IgG+C with high titer cold agglutinins) and atypical (DAT-, IgA+, wIgM). Cases were also grouped in very severe (Hb<6 g/dl), severe (Hb 6-8 g/dl), moderate (Hb 8-10 g/dl) and mild (Hb>10 g/dl). LDH was expressed as fold increase upper the limit of normality (ULN), and atypical (DAT-, IgA+, wIgM). Cases were also grouped in very severe (Hb<6 g/dl), severe (Hb 6-8 g/dl), moderate (Hb 8-10 g/dl) and mild (Hb>10 g/dl). LDH was expressed as fold increase upper the limit of normality (ULN),
Results: Table 1 shows clinical and laboratory characteristics of AIHA cases at onset and distribution of thermal types. HB values were significantly lower in IgG+C wAIHA and atypical cases (p<0.001), LDH higher in IgG+C wAIHA, mixed and atypical forms (p=0.01), and HB and LDH values were negatively correlated (r=-0.25, p=0.001). Absolute reticulocytes were reduced in CAD, mixed and IgG+C wAIHA (p<0.001) together with inadequate reticulocytosis (p=0.01). Moreover, the reticulocyte index was lower in cases with HB<6 g/dL (65 vs 98, p=0.01), along with more frequent inadequate reticulocytosis (87 vs 70%, p=0.01). First line therapy was administered in almost all cases but 25 CAD. A second therapy line was mostly required in IgG+C wAIHA, mixed, and to a lesser extent in CAD (p=0.005). The ultra-refractory cases requiring 4 or more lines of therapy were mainly mixed, atypical and CAD. Considering anemia severity, patients with HB<8 g/dL, more frequently required treatment after first-line (51 vs 33%, p=0.004; p=0.03), or even 3 or more therapy lines (52/71, 73% vs 19/71, 26%, p<0.001). The following hazard ratios (HR) emerged from multivariate Cox regression analysis: HR 3.2 (95% CI 1.4-7.9) 2.9 (1.4-6.2) 3.4 (0.4-21.5) for HB <6, 6-8, and 8-10 g/dL compared to patients with HB >10, respectively. As regards complications, infections were observed in 14% of cases, mostly mixed AIHA (p=0.02); thrombosis occurred in 10% and acute renal failure in 3% of patients, with no relationship with AIHA type/Hb values. Evans’ syndrome was more frequent in mixed or atypical cases (p=0.04) and in severe forms (74% with HB<8 g/dL vs 26%, p=0.005), and was associated with higher relapse risk (HR 2.3, 95% CI 1.4-3.9). Seventy patients died during the follow-up, and 12 because of AIHA-related acute complications. Higher mortality was observed for infections (HR 5.8, 95% CI), acute renal failure (HR 7.6, 95% CI) and Evans’ syndrome (HR 8.3, 95% CI).

HEMINE BINDS ANNEXIN-A5 DURING HEMOLYSIS AND PREVENTS ITS INTERACTION WITH CELL MEMBRANE PHOSPHATIDYLSERINE DURING SICKLE CELL DISEASE

S. Sadoudi1, S. Le Jeune2, D. Charue1, L. Roumenina4, C. Boulanger1, O. Blanc-Brude1,*
1Prolong Pharmaceuticals, Prolong Pharmaceuticals, South Plainfield, United States; 2Hematology, Centro Hemato-Oncológico Paítailla, Royal Center, Panama; 3Hematology, Hospital General Plasma de la Salud, Santo Domingo, Dominican Republic

Background: Intravascular hemolysis, such as in sickle cell disease (SCD), is characterized by extensive red blood cell damage, high levels of cell-free heme and extracellular vesicles in plasma, along with inflammation and tissue injury. Stressed leukocytes, platelets, endothelial and red blood cells shed microparticles (MP) that bear externalized phosphatidylserine (PS) at their surface and promote tissue injury. Conversely, intracellular annexin-A5 acts as an inhibitor of extravascularization at the surface of cells and MP. Annexin-A5 is thought to orchestrate vesicle trafficking, promote cell membrane repair, protect against PS-mediated effects and enforce anti-inflammatory and anti-thrombotic control.

Aims: We investigated a possible functional relationship between intravascular hemolysis and annexins. We hypothesized that annexins, and annexin-A5 activity in particular, is blocked by intracellular heme as it is released in plasma during intravascular hemolysis.

Methods: In order to test the heme-annexin-A5 relationship, we measured PS-annexin-A5 binding of exogenous annexin-A5 to purified PS+ MP and plasma MP, as well as their subsequent detection by flow cytometry. Together, our data suggest that PS-neutralizing annexin-A5 may display physiopathological relevance, contribute to the accumulation of PS+ MP in plasma during intravascular hemolysis, and more specifically of RBC MP during SCD which can participate to the degradation of the vascular function.

P618

USE OF PEGYLATED-CARBONYLHEMOGLOBIN BOVINE FOR THE TREATMENT OF SICKLE CELL DISEASE ASSOCIATED LEG ULCERS: RESULTS FROM A PHASE 2 SAFETY STUDY

J. Valentino1, H. Misra1, L. Lopez2, O. Paulo3
1Prolong Pharmaceuticals, Prolong Pharmaceuticals, South Plainfield, United States; 2Hematology, Centro Hemato-Oncológico Paítailla, Royal Center, Panama; 3Hematology, Hospital General Plasma de la Salud, Santo Domingo, Dominican Republic

Background: Leg ulcers are a common complication of sickle cell disease (SCD). The pathophysiology of SCD leg ulcer is complex and may include obstruction of blood vessels by sickled red cell, chronic anemia, depleted nitric oxide bioavailability (resulting in impaired endothelial function), infection, thrombosis and excessive vasoconstriction. These events lead to progressive peripheral vasoconstriction and tissue necrosis, such that even minor lower-leg wounds can become persistent ulcers, with no tendency to heal after months of appropriate treatment. PEGylated-Carbonylhemoglobin bovine (PEG-COHb; SANGUINATE) is an oxygen carrying agent with anti-inflammatory activity. A study of safety and effectiveness was undertaken in SCD patients with chronic leg ulcers to determine the safety of this investigational drug administered in as a once weekly infusion for either 4 or 6 weeks.

Aims: To assess the safety and efficacy of repeated doses of PEG-COHb on SCD leg ulcers.

Methods: The study was an escalating, repeated-dose, open-label, Phase 2 study to test PEG-COHb at 320mg/kg (8 mL) in subjects suffering from leg ulceration associated with SCD. It was conducted in Panama and the Dominican Republic. All enrolled subjects underwent a 3-week Run-in Period, during which they received standard of care treatment for wound management. During the Treatment Period, subjects were assigned sequentially to Cohort 1 or Cohort 2. Cohort 1 received 4 once-weekly doses by 2-hour intravenous infusion of SANGUINATE. Following the completion of Cohort 1, the safety findings were reviewed prior to initiating Cohort 2. Cohort 2 received 6 once-weekly infusions. In addition to the study drug, subjects continued to receive standard of care during the Treatment Period. One week after the end of Treatment, subjects returned to the study center for a Final Visit. The following assessments were done: safety: Safety was assessed by recorded adverse events (AEs), laboratory tests (hematology, chemistry, and urinalysis), vital signs, concomitant medications, and 12-lead electrocardiograms (ECCs), efficacy: wound pain, wound appearance and condition, wound size, wound vascular status (Digital Vascular Severity Score (DVSS)), quality of life was assessed using the Short Form-12 v2 Health Survey (SF-12).

Results: The administration of once-weekly infusions of PEG-COHb was well tolerated. Treatment emergent adverse events (mild pyrexia, moderate wors-
ening anemia) considered related to study drug were reported in 2/10 patients. Increases in mean hematocrit were anticipated due to the oncotic effects of this colloidal drug, but with no consistent pattern to the changes. Changes in ECG intervals were seen in a few subjects, but those changes were not considered clinically meaningful. There were no clinically meaningful changes in laboratory values, physical examinations, or concomitant medications. There were no statistically significant changes from baseline in leg ulcers or wound surface area for either cohort. All of the wound assessments remained relatively consistent throughout the study. There were slight decreases in total VCSS at most time points, indicating slight improvement in vascular status. Results were similar for the individual scores.

Summary/Conclusions: The administration of 4 or 6 once-weekly infusions of PEG-COHb at a dose of 320mg/kg was generally well tolerated. Slight improvements in total and individual VCSS are promising and may warrant further study with prolonged repeated doses of PEG-COHb.

P619
NON-RENAI N DETERMINANTS OF ENDOGENOUS ERYTHROPOIETIN LEVELS IN SICKLE CELL DISEASE
K. Garder1,2, C. Sharpe3,4, M. Awobaje1
1Haematological Medicine, King’s College Hospital, London, UK; 2Molecular Haematology, King’s College London, 3Renal Medicine, King’s College Hospital, 4Renal Medicine, King’s College London, London, United Kingdom

Background: Sickle cell disease (SCD) is characterized by chronic hemolysis and inflammation. Elevated levels of erythropoietin (EPO) drive expansion of erythropoiesis to compensate for increased red cell destruction. EPO is produced in response to anemia and tissue hypoxia. Previous studies in SCD suggest that EPO is inappropriately low for the degree of anemia but the reasons are unclear.

Aims: To perform a retrospective analysis of data collected as part of routine clinical care to examine the relationship between serum EPO and degree of anemia, inflammation, hemolytic rate, alpha globin status, hemoglobin, alpha globin status, inflammation, serum ferritin and renal function.

Methods: King’s College Hospital (London, UK) has a large SCD population. All patients with HbSS or HbSBthalassemia who had a serum EPO level measured between 2007 and 2013 were included. Sickle genotype, alpha globin genotype, alpha globin status, ‘baseline’ HbF (no hydroxy carbamidone, transfusion or pregnancy) and demographic data were recorded. Other clinical variables were obtained from the same day as EPO levels (medications, laboratory values and oxygen saturation). Serum EPO was measured by chemiluminescence immunoassay (Siemens Immulite XPi). Exclusion criteria were: active vaso-occlusive crisis, transfusion within 8 weeks, chelation, erythropoiesis stimulating agent therapy, and inflammatory markers >30). Data analysis was performed in IBM SPSS Statistics 22. Skewed variables were log transformed and estimated QFR was calculated using the MDRD formula. Normalized variables were correlated with Ln EPO using Pearson correlation, ordinal variables using one way ANOVA, and binary variables using independent samples 2-tailed t-test. Multivariate linear regression using Ln EPO as the outcome was performed.

Results: 245 adult patients (12–17 years) SCD patients (all of African or African-Caribbean origin) met the inclusion criteria. Of the 245, 241 had HbSS and 4 HbSβthalassemia. Participants were enrolled after obtaining written informed consent/assent. This study is being conducted in 2 parts: Part A, single-dose, and Part B, multiple-dose for 24 weeks. The primary objective of Part A is PK and the primary objectives of Part B are safety and efficacy. PK samples to measure whole blood and plasma GBT440 concentrations were collected up to 15 days following single dose administration. Separate PPK models were developed to describe the concentration versus time profiles of GBT440 in whole blood and plasma using non-linear mixed effects modeling (NONMEM, version 7.3). The allometrically scaled adolescent PK model was also used to estimate the appropriate single dose for subsequence evaluation in pediatric participants (6 to 12 years).

Results: Part A has been completed; 7 adolescents (3 males/4 females) received a single dose of GBT440 600mg. The median age of participants was 16 years (range 14 to 16 years) and the mean weight was 52.8 kg (range 44.6 to 65.8kg). GBT440 was well tolerated; there were no drug-related ≥Grade 3 adverse events (AE) or serious adverse events and the most common AE was Grade 1 nausea. A 2-compartment model with first order absorption best described the PK of GBT440 and is the same model structure as previously used for adults with SCD. GBT440 PK parameters (Table 1) are comparable to those derived in adults, suggesting that GBT440 PK in adolescents and adults are similar. Model validation confirmed this result with good agreement between the observed adolescent PK data and simulated profiles based on the adult GBT440 PK model.

Table 1.

Summary/Conclusions: This is the first study used to develop a GBT440 PK model in adolescent participants with SCD. Data suggests that similar GBT440 doses can be used in adolescents and adults. Part B has been initiated to evaluate multiple doses of GBT440 in adolescents. This PK model can potentially be used to estimate individual PK parameters (e.g., AUC) to support future GBT440 dose selection for evaluation in the pediatric population.

Background: Sickle cell disease (SCD) is caused by polymerization of Hemoglobin S (HbS), resulting in hemolysis and vaso-occlusion. Currently, no therapy achieving pancellular, direct inhibition of HbS polymerization is available for adults or children with SCD. GBT440 is a novel small molecular inhibitor which increases hemoglobin oxygen affinity, thereby preventing HbS polymerization and red blood cell sickling. This study represents the first evaluation of GBT440 in a pediatric population.

Aims: This study was designed to evaluate the safety and PK of GBT440 following a single and multiple doses in adolescents. In addition a population PK (PPK) model, based on data derived following single doses of GBT440, was developed to support the identification of future GBT440 dosing regimens for pediatric populations with SCD.

Methods: This is an ongoing, open-label, Phase 2a study in adolescents (12 to 17 years) with SCD (HbSS or HbSBthalassemia). Participants were enrolled after obtaining written informed consent/assent. This study is being conducted in 2 parts: Part A, single-dose, and Part B, multiple-dose for 24 weeks. The primary objective of Part A is PK and the primary objectives of Part B are safety and efficacy. PK samples to measure whole blood and plasma GBT440 concentrations were collected up to 15 days following single dose administration. Separate PPK models were developed to describe the concentration versus time profiles of GBT440 in whole blood and plasma using non-linear mixed effects modeling (NONMEM, version 7.3). The allometrically scaled adolescent PK model was also used to estimate the appropriate single dose for subsequent evaluation in pediatric participants (6 to 12 years).

Results: Part A has been completed; 7 adolescents (3 males/4 females) received a single dose of GBT440 600mg. The median age of participants was 16 years (range 14 to 16 years) and the mean weight was 52.8 kg (range 44.6 to 65.8kg). GBT440 was well tolerated; there were no drug-related ≥Grade 3 adverse events (AE) or serious adverse events and the most common AE was Grade 1 nausea. A 2-compartment model with first order absorption best described the PK of GBT440 and is the same model structure as previously used for adults with SCD. GBT440 PK parameters (Table 1) are comparable to those derived in adults, suggesting that GBT440 PK in adolescents and adults are similar. Model validation confirmed this result with good agreement between the observed adolescent PK data and simulated profiles based on the adult GBT440 PK model.

Table 1.

Summary/Conclusions: This is the first study used to develop a GBT440 PK model in adolescent participants with SCD. Data suggests that similar GBT440 doses can be used in adolescents and adults. Part B has been initiated to evaluate multiple doses of GBT440 in adolescents. Background: Adult T cell leukemia/lymphoma (ATL) is an aggressive peripheral T-cell neoplasm caused by HTLV-1 virus infection and its prognosis remains very poor. Tax, which is the most important regulatory protein of HTLV-1, is associated with aggressive proliferation of host cells and is also a biomarker for CD8+ cytotoxic T-cells (CTLs). We previously analyzed the Tax-specific T-cell receptor (TCR) repertoire, phenotypes and functions of Tax-specific CTLs at the single-cell level in HLA-A24+ ATL patients who underwent autologous stem cell transplantation (allo-SCT). We found that a particular amino acid residue in the TCR-beta chain (PVR in the CDRs region of TCR-β) was conserved in different patients and also within the same patient before and after allo-SCT, and the PVR+ Tax-specific CTL clone selectively expanded in ATL long-term survivors as less-differentiated effector memory CTLs. Actually, the PVR+ CTL showed not only strong binding activity for the Tax-tetramer but also strong killing activity against patients’ HTLV-1-infected T-cells without any reaction against normal cells.

Aims: Currently, we are planning a redirected T-cell immunotherapy using the PVR+ TCR genes for ATL. Therefore, we prepared donor-derived PVR+ TCR-transduced T-cells and evaluated their cytotoxic efficiency against HTLV-1-infected T-cells and ATL-cells were both in vitro and in vivo mouse model.

Methods: HLA-A24-02 restricted and Tax301-309-specific TCR-α/β genes were cloned from an established PVR+ CTL clone and integrated into a retroviral siTCR vector (Tax-siTCR vector) encoding small-interfering RNAs (siRNAs) to knockdown endogenous TCR genes for the efficient expression of therapeutic TCRs. Then, CD8+ T-cells of healthy volunteers were transfected with Tax-siTCR vector (Tax-siCTLs). First, cytotoxicity and cytokine production capability of the Tax-siCTLs against HTLV-1 infected T-cells or ATL-cells were evaluated using calcein-AM-based assay and flow-cytometric analysis, respectively. Next, to evaluate the in vivo anti-ATL effects by the Tax-siCTLs, the bioluminescence assay (in vivo imaging system) was performed. We generated a luciferase-gene transduced HLA-A24+HTLV-1 infected cell-line, MT-2 (Luc-MT-2), and injected 1×106 Luc-MT-2 cells into six-week-old NOD/Shi-scid, IL-2R-ko Gc (NSG) mice intraperitoneally. After the 3 weeks, 2×106 Tax-siCTLs were administered into the tail vein. In addition, western-blot analysis confirmed the stable expression of FANCA protein in the edited cells. Moreover reversion of the characteristic MNC hypersensitivity and restoration of the FANCD2 foci formation were observed in these cells. In addition, western-blot analysis confirmed the stable expression of FANCA protein.

Summary/Conclusions: Our results demonstrate for the first time that NHEJ gene correction is feasible in FA HSPCs. The high efficacy of the NHEJ repair approach clinically relevant for the future treatment of the hematopoietic defects in FA patients.

NOVEL, ENHANCED AND DUAL TARGETING CAR INVARIANT NKT CELL-BASED IMMUNOTHERAPY FOR CD1D B CELL MALIGNANCIES
A. Roloto1, O. Dubois1, K. Guodevenou1, K. Petev1, G.W. Cheung2, M. Pule2, J. Mahera3, A. Karadimitris1
1Medicine, Imperial College London, London, UK, 2University College London, 3King’s College London, London, United Kingdom

Background: Anti-CD19 chimeric antigen receptor T cell (CART19) immunotherapy has shown promising clinical potential in relapsed/refractory mature B cell malignancies. However, only about half of patients benefit, highlighting the need for more effective CAR-based strategies. iNKT cells are rare regulatory cells that can activate innate and adaptive immune responses. They can efficiently induce a potent anti-tumor role. iNKT cells are restricted by CD1d, a non-polymorphic, phospho-glycolipid-presenting HLA I-like molecule. We previously showed that CD1d, as well as on normal B cells, is also expressed on malignant CD19+ B cells in mantle cell lymphoma (MCL), marginal zone lymphoma (MZL) and chronic lymphocytic leukemia (CLL).

Aims: We tested the hypothesis that bi-specific CAR/iNKT cells, targeting simultaneously CD19 and CD1D via the CD19-specific CAR and their natural invariant TCR respectively, might be more effective than CART19 cells against CD19+CD1D+ B cell malignancies.

Methods: We optimized a novel protocol for manufacturing 2nd (CAR2) and 3rd (CAR3) iNKT cells expressing CAR19. Their in vitro reactivity was assessed in cytotoxicity (flow cytometry-based) and cytokine and cytotoxic granule release assays (intracellular staining and Luminex technology). In vivo reactivity was assessed in NSG xenograft assays, with monitoring of 1T1C1D1 tumour cell growth and body weight.

Results: Our optimised protocol for selection, lentiviral transduction and clinical scale expansion of CARiNKT cells within 3 weeks is suitable for frozen and fresh lymphocytes, derived from either healthy donors or cancer, including lymphocytes from the bone marrow failure hematopoietic stem and progenitor cells (HSPCs) is the only current curative treatment for the bone marrow failure of patients with Fanconi Anemia (FA). However, the risks of GVHD and increased incidence of subsequent cancer, and the limited availability of matched donors hamper the adoption of this therapy in FA patients. For this reason correction of the FA-A patient-derived lym- phoblastic cell lines (CLLs) and primary HSPCs were targeted by the CRISPR/Cas9 system. INDELs generated in edited FA HSPCs in these cells. Methods: Two different FA mutations from FA-A patient-derived lymphoblastic cell lines (CLLs) and primary HSPCs were targeted by the CRISPR/Cas9 system. INDELs generated in edited FA HSPCs in these cells. Results: NHEJ-mediated gene editing approach can generate compensatory mutations that can restore the FA function in HSPCs from FA patients, mimicking reversion observed in mosaic patients. Aims: To demonstrate the feasibility of using a NHEJ-based gene editing strategy to correct FA-A HSPCs as a result of the insertions and deletions (INDELs) generated in edited FA HSPCs in these cells.

phoma patients. The manufacturing process consistently allows high CAR transduction efficiency of CD4+ and CD8+ T cells (75.31%±4.294 and 76.95%±14.76 respectively, n=8) and ensures the preservation of CD4− iNKT cells, which have a higher cytotoxic potential and anti-tumour activity. In vitro validation, using singly- or dual-positive CD1d and CD19 targets, demonstrated that CARiNKT19 cells are CD19-specific, retain their natural CD3ζ–CD28+ phenotype and exert additive dual-specific cytotoxicity against CD19+CD1d+ targets. Additional functional dissection showed that activated CARiNKT19 cells, both fresh and cryopreserved, have the ability to produce cytotoxic granules and IFNγ faster and in larger amounts than same donor activated CAR-T cells. Likewise, CAR2- and CAR3-iNKT cells are equally or more effective than their CAR-T counterparts in killing CD19+CD1d+ lymphoma and myeloma cell lines (B-lymphoblastoid 1CR1CD and lymphoma-derived Farage cells) and consistently more effective against primary MCL, MZL and CLL cells. Finally, in an in vivo NSG xenograft model of lymphoma, while survival of T- and NK cell-treated animals was the same as that of untreated animals (P=0.23), both CARiNKT19- and CAR-T cell-treated animals had significantly and comparably improved overall survival (P<0.001). However, compared to CAR-T, CARiNKT19 immunotherapy led to a better disease control, with earlier, more profound and sustained responses resulting in a significantly improved tumour free-survival (P<0.03).

Summary/Conclusions: In our pre-clinical in vitro and in vivo lymphoma models, CARiNKT19 are more effective than CAR-T cells against CD19+CD1d+ B cell malignancies. Further, dual targeting by CARiNKT19 cells may mitigate against CD19-focused tumour escape after CAR immunotherapy, while the previously demonstrated role of donor iNKT cells in protection from aGVHD supports the development of CARiNKT19 cells for ‘off-the-shelf’ use.

A NOVEL CHIMERIC ANTIGEN RECEPTOR ENDOWS T CELLS WITH NK CELL-LIKE SPECIFICITY AND ATTACKS A WIDE RANGE OF HEMATOLOGICAL MALIGNANCIES AND CANCERS

Y. Kasahara1, Y. Shin1, C. Imamura1, N. Kubo1, T. Takachi1, H. Iwabuchi1, S. Yoshida1, A. Saitoh1, C. Imai1
1Department of Pediatrics, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan

Background: Engineered T-cells expressing CD19-specific chimeric antigen receptors (CARs) have shown high response rates against relapsed and refractory B cell acute lymphoid leukemia (ALL). However, similar success has not yet been demonstrated in solid tumors, and the reasons for this are currently being investigated. One major obstacle is the difficulty in determining appropriate surface antigens that are effectively targeted by CAR-transduced immune cells. Nkp44 is an activating receptor on human NK cells that is only expressed in target cells was confirmed by RNA-based RT PCR.

Results: Following transduction and puromycin selection ≥90% of CD3+ T cells expressed the Nkp44 CAR. In addition, most T cells displayed an effector-membrane phenotype. Upon co-culture with the B7H6 expressing targets such as K562 and HL-60 (myelogenous leukemia cell lines), NALM 16 (pre-B-ALL) and patient-derived AML samples (e.g. M2506 and M2987) Nkp30 redirected T cells elicited potent IFN-γ release and exhibited cytolytic activity to both leukemia lines and primary AML blasts in vitro. These responses were specific as e.g. no reactivity to the B7H6 negative myeloma line U266 was observed. We then evaluated the cytomorphologic response of Nkp30 redirected T cells in vivo. Upon adoptive transfer of Nkp30-CAR T cells into NSG mice engrafted with K562 significant reduction of tumor burden was observed. Moreover, injection of 1 - 5x10⁶ HLA-1III. Dept. of Medicine - Hematology, Internal Oncology & Pneumology, University Medical Center Mainz, Mainz, Germany

Background: Adoptive cellular therapy (ACT) of chimeric antigen receptor (CAR)-redirected T cells has evolved as a highly effective individualized immunotherapy for leukemia and solid cancer. In particular, clinical trials using CD19 CAR expressing T lymphocytes to combat CD19+ lymphomas have revealed compelling results. However, suitable antigens for an effective and specific CAR-mediated therapy to acute myeloid leukemia (AML) are still warranted as e.g. CD33 and CD123 CAR expressing T cells induce potent immune responses not only to AML blasts but also recognize normal hematopoietic stem cells (HSC). In contrast, B7H6, a member of the B7 family, is frequently expressed on various tumor cells including AML blasts while not detectable on normal tissues, and is recognized by the natural killer (NK) cell activating receptor NKp30. Moreover, NKp30 recognizes human leukocyte antigens (HLA)-B-associated transcript 3, a nuclear factor that is secreted and translocated to the cell surface in stressed and transformed cells.

Aims: In the current study, we thus explored the use of human T cells redirected to express a Nkp30-CAR for inducing effective antileukemic immunity in vitro and in vivo using a murine model of lymphoma. We also performed functional dissection showed that activated CART19 cells can be successfully redirected to acute leukemia by NK cell activating receptor-based CARs such as the Nkp30-CAR. As its ligand B7H6 has not been reported to be expressed on CD34+ HSC, this antigen might be an interesting target for adoptive immunotherapy to AML.

P627
PRECLINICAL TESTING OF ADOPTIVE T-CELL RECEPTOR GENE TRANSFER IN COMBINATION WITH COMPLEMENTARY INHIBITORS AS A NOVEL THERAPY FOR MULTIPLE MYELOMA

H. Echchennoufi1,2,2, E. Amanni1,2,2, E. Antunes1, M. Theobald1,2,2
1Division of Medicine (Hematology, Oncology, Immunology), Department of Medicine (Hematology, Oncology, Immunology), University Medical Center Mainz, Mainz, 2German Cancer Consortium (DKTK), partner site Frankfurt / Mainz, German Cancer Research Center (DKFZ), Heidelberg.

Background: Adoptive cellular therapy (ACT) based on T-cell receptors (TCR) or chimeric antigen receptor (CAR)-engineered T cells has achieved tremendous success in the treatment of cancer, especially B-cell malignancies. The
impressive therapeutic results recently obtained with checkpoint inhibitors have opened a new era in the field of cancer immunotherapy. Yet, clinical responses are still often observed either transiently or in a minority of patients. This underscores the need for an improved understanding of underlying factors limiting the efficacy of T-cell-based immunotherapy and its wide application.

Aims: We explored an immunotherapeutic combination strategy to unleash the full power of adoptively transferred antigen-specific T cells. We also tested the hypothesis that targeting the BAFF-R molecule with the immune-stimulatory cytokine IL-2 would result in a more sustained antitumor effect.

Methods: Human T cells from healthy donors were retrovirally transduced with MDM2- and p53-specific TCRs and expression levels were analyzed by flow cytometry. MDM2 and p53 protein expression in MM cell lines was determined by Western blot. The therapeutic efficacy of adoptive TCR transfer was evaluated in NOD-SCID IL2R-gamma-chain(null) (NSG) mice engrafted with human melanoma cells expressing either MDM2 or p53. Tumor growth and intratumoral alterations were monitored and intratumoral effector function was determined by IFN-gamma ELISPOT assays.

Results: T cells expressing the MDM2-specific TCR showed a superior anti-tumor response in vivo compared to single TCR treatment, demonstrating the need to target multiple MM antigens to circumvent tumor escape mechanisms associated with down-regulation of antigen. Yet, we observed a strong up-regulation of PD-L1 expression in tumor cells in vivo and in vitro in T cells expressing MDM2-specific TCRs. To overcome this PD-L1-mediated resistance, we performed combination experiments with anti-PD-1-neutralizing antibodies. In vivo ACT experiments combined with anti-PD-1 inhibitor demonstrated the synergistic therapeutic potential of this approach compared to single agent. Yet, it does not result in complete tumor eradication suggesting that targeting one single immune checkpoint receptor is not sufficient to drive a full anti-tumor response.

Summary/Conclusions: Combination inhibitor checkpoint approach has demonstrated potential in our ACT experimental MM model and forms the basis for a novel multi-modal immunotherapeutic combination treatment for multiple myeloma.

P628 ENGINEERED T CELLS TOWARDS BAFF RECEPTOR: A NOVEL STRATEGY TO EFFICIENTLY TARGET B-CELL ACUTE LYMPHOCYTIC LEUKEMIA N. Turazzi1,2, G. Fazio1, V. Rossi1, A. Rolink1, G. Cazzaniga1, A. Biondi1, C. F. Magnani2, E. Biagi1

1. M. Tettamanti Research Center, Department of pediatrics, University of Milano Bicocca S. Gerardo Hospital/Fondazione MBBM, Monza, Italy; 2. Department of Biomedicine, University of Basel, Basel, Switzerland; 3. M. Tettamanti Research Center, Department of pediatrics, University of Milano Bicocca S. Gerardo Hospital/Fondazione MBBM Monza, Italy

Background: B-cell Acute Lymphoblastic Leukemia (B-ALL) is most common in children (80%), but it has also a peak of incidence in adult age. Immunotherapeutic approaches targeting the CD19 molecule paved the way for the treatment of relapsed and refractory lymphoblastic leukemia, which remains a major therapeutic challenge. Recently, the emergence of relapses with CD19-epitope loss in 10-30% of treated patients has been reported. This newly identified escape mechanism has been recently shown to be related to the combination of deleterious mutations and emergence of alternatively spliced RNA isoforms, as effect of selective pressure.

B-cell Activating Factor (BAFF) Receptor is a transmembrane protein which is fundamental for B-cell maturation and survival. Moreover, the expression of this receptor is restricted to mature B cells and, interestingly, is not present on bone marrow B-cell precursors. Recent studies reported the over-expression of BAFF Receptor (BAFF-R) in various B-cell malignancies such as B-ALL, B lymphoma, chronic lymphocytic leukemia and myeloma. In the context of B-ALL-leukemic cells express both BAFF-R and B-cell receptor suggesting the presence of an autocrine signalling loop. BAFF is also expressed in bone marrow microenvironment by endothelial cells which support the proliferation and the survival of primary B-ALL blasts.

Aims: In the current study, we aimed to develop a chimeric antigen receptor (CAR) approach targeting the BAFF-R molecule.

Methods: We characterized the expression of BAFF-R in B-ALL primary samples. As immunotherapeutic approach to target BAFF-R molecule, we developed six anti-BAFF-R.CARs that differ for the inversion of the VH and VL and the length of the spacer domain.

Results: Six anti-BAFF-R.CARs expressed in B-ALL primary samples at the onset and relapse. In order to develop a chimeric antigen receptor (CAR) approach targeting BAFF-R molecule, six anti-BAFF-R CAR genes that differ for the inversion of the VH and VL and the length of the spacer domain have been generated. Cytokine-induced Killer (CIK) cells, engineered using an improved Sleeping Beauty (SB) transposition system, stably expressed anti-BAFF-FR.CARs, and maintained their characteristic phenotype. Among the newly constructed CARs, the shortest VH VL anti-BAFFR CAR exerted the highest anti-leukemic activity towards target cells, such as NALM-6, with an in vitro killing activity >80% of the effector to target ratio (E:T). Noteworthily, CAR mediated cytotoxicity if measured by detection of cytotoxic release by intracellular staining (8.9±2.6% of IFN-g and 16.4±5.5% of IL-2 producing cells). Importantly, we also detected a specific cytokytic activity towards primary B-ALL blasts (average 65.6±5.4%, n=9). Combining the iNKT sh.CAR with CD19.CAR we detected a superior antitumor activity towards ALL targets (at least 3 E:T ratios resulted in >72% cell lysis) and primary B-ALL blasts compared to single population per se. Furthermore, by using a sample collected from a patient relapsed with CD19 negative disease, we demonstrated the ability of the iNKT sh.CAR to lyse CD19-negative blasts.

Summary/Conclusions: Taken together, these findings make this receptor a suitable target for a second-line B-ALL immunotherapy in case of relapse after CD19-targeting therapies or for a double targeted approach. Being restricted to mature B cells, but absent on precursors and plasmablasts, our strategy could have an inferior toxicity concerning the emergence of B-cell aplasia observed in patients treated with anti-CD19 CAR-modified T cells.

P629 EXPLORING HUMAN TCR- AND CAR-REDIRECTED INKT CELLS FOR ADOPTIVE CELLULAR THERAPY B. Mir1, S. Khan1, M. Theobald1, U. Hartwig1,2

1. III. Dept. of Medicine - Hematology, Internal Oncology & Pneumology, University Hospital Mainz, Mainz, Germany

Background: T-cell receptor (TCR) - or chimeric antigen receptor (CAR) re-directed T cells have substantially improved adoptive cellular therapy (ACT) for solid or hematological malignancies. T cells equipped with effectors arms are able to target tumors and have inherent antitumor properties. Moreover, as these cells are further restricted to the monomorphic, HLA class I like CD1 molecule expressed only on a few cell types with limited alloreactive potential, all these features make INKT cells as attractive alternative carriers for redirected ACT.

Aims: In the current proof of concept study we therefore explored human, AML-reactive TCR- and CD19 CAR-redirected INKT cells for their potential to induce antitumoral responses to leukemia cell lines as well as patient derived, primary AML blasts.

Methods: INKT cells expressing the invariant TCR composed of the Vα24Jα18/Vβ11 chains were immuno-magnetically isolated from PBMC derived from healthy donors using Vβ11- (CD81-) conjugated, anti-INKT microbeads (Miltenyi Biotec) and expanded in vitro upon coculture with autologous DCs loaded with α-galactosyceramide (α-GalCer) loaded DCs. β2m and low amounts of interleukin (IL)-2. INKT cells were retrovirally transduced on day 6 after stimulation and selected for TCR or CAR expression utilizing a virally transduced puromycin resistance. While phenotypic analyses on INKT markers and the percentage of redirected cells were performed by flow cytometry functional activity of human INKT cells was assessed by killing of CD19+ NALM-16 (pre B-ALL) and primary AML (M2653) cells as targets.

Results: Following isolation of 0.7 – 0.8 x 10^6 Vβ24,Jα18/Vβ11+ INKT cells from PBMC we achieved on average a 120-fold expansion 21-28 days after stimulation with α-GalCer loaded, irradiated autologous DC and 25 U IL-2. Additional use of lenalidomide to promote expansion as described previously had no effect. Expanded INKT cells were mainly CD4+ (83%) and about 80% of cells expressed the natural killer receptor CD161 described as INKT maturation marker but showed limited or virtually no expression of typical NK markers such as CD56 and CD16. Following retroviral transduction and selection for 6 days >80% of TCR (5B2)- and CD19 CAR-redirected INKT cells were obtained. Subsequent functional analyses revealed that both INKT cells expressing the AML-reactive TCR 5B2 as well as CD19-CAR INKT cells demonstrated substantial release of IFN-g and elicited potent antileukemic responses to AML M2653 and NALM-16 in vitro. Studies to examine their cytokitic potential within in vivo using NSG xenograft models are currently in progress.

Summary/Conclusions: These studies demonstrate that purified human Vα24/Jβ11+ INKT cells expanded from PBMC can be successfully redirected against leukemia both in vitro and in vivo CAR expression. Engineered INKT cells might therefore be promising alternative carriers for redirected ACT or being used in combination with redirected T cells as combined immunotherapy.
Background: Acute Myeloid Leukemia (AML) is an aggressive malignancy still associated with high relapse rates when treated with conventional chemotherapeutic and hematopoietic transplantation regimens. In search for alternative strategies, interest has focused on antigen-specific immunotherapies and in particular on T cells redirected with Chimeric Antigen Receptors (CARs) that have shown exciting results in cancer therapy, especially in the context of B-cell malignancies. CD33 is the only validated target in AML so far and represents a suitable antigen to be targeted with CAR-T cells, being broadly expressed on AML blasts.

Aims: The aim of the present study is to preclinically evaluate the efficacy and safety profiles of CD33 CAR redirected Cytokine Induced Killer (CIK) cells alone and in combination with standard chemotherapeutic agents.

Methods: Here we proved the feasibility of harnessing Cytokine Induced Killer (CIK) cells as a third generation anti-CD33 CAR through the non-viral Sleeping-Beauty transposon system, starting from fresh and frozen healthy mononuclear cells (PBMCs) and also from frozen primary AML samples. The in vitro anti-AML activity of CD33.CAR-CK cells is assessed by means of cytotoxicity, proliferation and cytokine production assays upon challenge with AML cell lines and primary samples. The in vivo efficacy of CD33.CAR CICK cells is evaluated in NSG mice transplanted with AML cell lines (M4A-NRas cells) and primary samples.

Results: CD33.CAR-CK cells were able to induce a potent anti-leukemic activity as compared to unmanipulated CIK cells, in terms of specific killing (up to 70%), proliferation (up to 40% of Ki67+CAR-CIK cells) and cytokine production (up to 30% for both IL-2 and IFN-gamma producing CAR-CIK cells) when challenged with both AML cell lines and primary leukemic cells. By treating M4A-NRas cells grafted mice with the already established 5+3 induction chemotherapy protocol, we confirmed that chemotherapy is able to significantly reduce the leukemic burden from around 20% to 0.1% in the bone marrow. Since the AML disease is not totally eradicated, this model will be therefore suitable for further investigation of the efficacy of the CD33.CAR-CIK cells immunotherapy on the chemotherapy resistant/residual AML cells.

Summary/Conclusions: Having demonstrated the significant in vitro anti- leukemic activity of SB-modified CD33.CAR-CK cells we next aim to assess their efficacy in vivo, particularly against the resistant/residual AML cells that were not eradicated by standard chemotherapy treatment. Moreover, envisaging a safer clinical translation of this immunotherapeutic approach, a transient CAR expression, by using CD33.CAR coding mRNA, is under investigation in order to limit the potential myelootoxicity due to the long-term off-target effect on normal hematopoietic stem/multioid progenitor cells. Finally, if successful, our results will provide the preclinical validation of CD33.CAR-CIK cell immunotherapy, supporting it development to the clinic.

P631

UPDATE ON THE FIRST PATIENTS WITH SEVERE HEMOGLOBINOPATHIES TREATED WITH LENTIGLOBIN GENE THERAPY

J. de la Ribeille1, S. Hacein-Bey-Abina1, E. Payen1, E. Magrin1, A. Magnani1, M. Semeraro1, L. Caccavelli2, F. Touzot1, F. Suarez1, O. Hermine1, V. Brousse1, C. Poirot4, D. Moshous1, P. Bourget1, W. El-Nemer5, P. Bartolucci6, M. Cavazzana1,*

1Department of Pediatrics, University of Milano-Bicocca, San Gerardo Hospital/Fondazione MBBM, Tettamanzi Research Center, Monza, Italy

Background: The lentiviral vector LentiGlobin (DP) uses an autologous globin gene (HbAT87Q) to overcome genetic mutations affecting HbA and HbS. The technology is designed to induce fetal-type hemoglobin expression in primary hematopoietic stem cells (HSCs) that could reduce or eliminate symptoms of severe sickle cell disease (SCD) and transfusion requirements in transfusion-dependent β-thalassemia (TDT).

Methods: Aims: The first patients treated with LentiGlobin received 200-250 mg/m² intravenous busulfan prior to infusion of transduced cells. Patients were then monitored for hematologic engraftment, vector copy number (VCN), genetically engineered hemoglobin (HbAT87Q) levels, and adverse events (AEs). Disease-specific assessments included transfusion requirements for TDT, or VOCs and hospitalizations for SCD.

Results: A single patient with severe SCD (male; 13 years old) and 4 patients with TDT (male; 2 female; 16–19 years old) have received LentiGlobin DP in Study HGB-205. The median DP cell dose was 8.9 (range 5.6-13.6) x10^9 CD34+ cells/kg with a DP VCN of 1.2 (range 0.8-2.1) vector copies/diploid genome. Median post-infusion follow-up was 22.9 months (range 11.6-33.5). All patients engrafted successfully with median time to neutrophil engraftment of 17 (range 14-38) days. Within patients, VCN in peripheral blood remained generally consistent from Month 3 (range 0.3-3.3 at last measurement). The toxicity profile was consistent with myeloablative conditioning with single-agent busulfan, with no ≥Grade 3 DP-related AEs or serious AEs and no evidence of clonal dominance reported to date. The patient with severe SCD who, prior to study enrollment, received regular RBC transfusions, experienced no clinical symptoms or complications of SCD in the 21 months since treatment. At Month 21, his total Hb was 13.1 g/dL, with 6.2 g/dL HbA1c (48%) and 6.5 g/dL sickle Hb (HbS; 50%); in addition, their unconjugated bilirubin, lactate dehydrogenase and reticulocyte count had dropped by 50%, 55%, 26%, respectively, compared to screening. Of the 4 patients with TDT, 3 have β0/βE genotypes and 1 is homozygous for a severe β0 mutation (IVS1 nt 110 G>A). Two of the β0/βE patients have completed their 2-year primary follow-up and entered a long-term follow-up study. They have been without RBC transfusions for 33 and 30 months, with total Hb of 10.9 and 13.5 g/dL, and HbA1c of 7.7 and 10.1 g/dL, respectively. The third patient with a β0/βE genotype has 12 months follow-up and has not required transfusions since 4 days post-LentiGlobin DP infusion, with total Hb 11.3 g/dL and HbA1c of 8.6 g/dL. The patient with the IVS1 genotype has 15 months of follow-up and has been free of transfusions for 11.6 months, with total Hb 8.3 g/dL and HbA1c of 6.7 g/dL. Since September 2016, 2 more patients with severe SCD have received LentiGlobin DP.

Summary/Conclusions: Data to date from this ongoing Phase 1/2 clinical study suggest that treatment with LentiGlobin DP elicits sustained HbAT87Q levels, which alleviate the clinical and biochemical effects of severe SCD and TDT, with safety consistent with myeloablative conditioning. Follow-up data on the 5 previously reported patients and early results from the 2 recently treated patients will be presented.
Indolent Non-Hodgkin lymphoma - Clinical

P632
A SINGLE INSTITUTIONAL EXPERIENCE OF 261 PATIENTS WITH LARGE GRANULAR LYMPHOCYTIC LEUKEMIA

M. Van den Bergh1, L. Isenalumhe1, E. Wang2, B. Schaible1, Z. Ma3, L. Zhang3, L. Zhou1, Z. Ma1
1Lee Moffitt Cancer Center & Research Institute, 2University of South Florida, Tampa, United States

Background: Large granular lymphocytic leukemia (LGLL) is a rare clonal lymphoproliferative disorder of post-thymic T-cell or natural killer (NK)-cell lineage associated with cytopenias, splenomegaly, autoimmune disorders, and recurrent mucocutaneous infections. Treatment is dictated by the presence of these manifestations and consists of immunosuppressive therapy.

Aims: The main aim of this study is to evaluate clinical features, hematological parameters, and survival data of patients with LGLL. The secondary aim is to assess response rates and duration of response to various first line immunosuppressive therapies in LGLL.

Methods: This is a retrospective analysis of clinical and laboratory features, treatment modalities, and outcomes of LGLL patients evaluated at Moffitt Cancer Center between January 1, 1995 and May 1, 2016. Continuous and categorical variables were tested via Kruskal-Wallis ANOVA and Fisher’s Exact Test, respectively. Kaplan-Meier curves were used for overall survival (OS), P-values were two-sided with significance set at <0.05.

Results: We identified 261 patients with LGLL (91.6% T-cell, 8.4% NK-cell). Median age was 66 years [21-90], and M:F ratio was 1.2:1. Median follow up was 3.07 years [0-21.88]. 42.9% of LGLL patients presented with anemia, 37.1% with neutropenia, 30.7% with thrombocytopenia, 29.1% with bicytopenia and 6.9% with pancytopenia. Transfusion dependence was noted in 20.3%, splenomegaly in 27.2% and bone marrow involvement in 69.3%. 24.9% had autoimmune diseases and 9.2% had autoimmune cytopenias. 45.6% were observed while the remainder required at least one line of therapy. 5-year and 10-year OS were 75.0% and 63.1%, respectively. There was a statistically significant difference in OS, complete response rate or duration of response based on first line agent (methotrexate, cyclophosphamide, cyclosporine A). However, there was a statistically significant improved partial response with methotrexate versus other therapies (p=0.01). A marginally significant association between severe anemia/transfusion dependence and poor overall response rate was observed (p=0.079) to any immunosuppressive therapy was noted. There was a statistically significant difference in OS based on absolute LGL count. Mean number of therapies was 1.08 (range 0-6) and was higher in patients with LGL count <0.5 k/μL (p=0.0078), bone marrow involvement (p<0.0001), and splenomegaly (p<0.0001).

Summary/Conclusions: In this large retrospective study, we described the frequency of LGLL-associated manifestations and their impact on the course of LGLL. Severe anemia/transfusion dependence, lower LGL counts, bone marrow involvement, and splenomegaly were suggestive of more aggressive disease. We confirmed that there is no difference in overall survival among first line immunosuppressive therapies.

P634
ONGOING PHASE 1/2 STUDY OF INCB050465, A SELECTIVE PI3K-Delta INHIBITOR, FOR THE TREATMENT OF PATIENTS WITH RELAPSED/RECURRENT B-CELL MALIGNANCIES (CITADEL-101)

1University of Alabama Birmingham, Birmingham, AL, 2Indiana Blood & Marrow Transplantation, LLC, Indianapolis, IN, 3Hematology/Oncology Associates of Treasure Coast, Port St Lucie, FL, 4University of Michigan, Ann Arbor, MI, 5Hackensack University Medical Center, Hackensack, NJ, 6Greenville Health System Cancer Institute, Greenville, SC, 7Department of Medicine-Gastroenterology, Cleveland, OH, 8Utah Cancer Specialists-Network, Salt Lake City, UT, 9University of Arizona Cancer Center, Tucson, AZ, 10Incyte Corporation, Wilmington, DE, 11Incyte Corporation, Wilmington, 12Karmanos Cancer Center, Detroit, MI, United States

Background: Signaling networks mediated by PI3Kδ have been implicated in proliferation, migration, and functioning of B-cells. INCB050465 is a novel, potent, and selective inhibitor of PI3Kδ (IC50 >250 nM for more selective for PI3Kδ vs other isoforms). INCB050465 demonstrated linear pharmacokinetics (PK) and achieved exposure levels several-fold greater than the IC50 for PI3Kδ inhibition at the recommended phase 2 dose (ASH 2016; Abstract 4195).

Aims: To evaluate INCB050465 in patients with relapsed or refractory B-cell malignancies enrolled in an ongoing phase 1/2 study (NCT02018881).

Methods: In this phase 1/2 study, eligible patients (>18 years of age) had relapsed/refractory lymphoid B-cell malignancies (excluding Burkitt’s lymphoma and precursor B-cell lymphoblastic leukemia/lymphoma), Eastern Cooperative Oncology Group performance status score ≤2 (≤1 during dose escalation), nor- mal liver and kidney function, and had not received autologous hematopoietic stem-cell transplant (HSCT) within 3 months or allogeneic HSCT within 6 months of screening. The protocol was initiated with a single-patient cohort, treated with oral INCB050465 5mg QD. Subsequent cohorts used a 3+3 design and evaluated doses of 10–45mg QD. Based on PK/pharmacodynamics, the 20 and 30mg QD cohorts were expanded. Responses were assessed every 8 weeks using the Lugano Classification or International Working Group on Chronic Lymphocytic Lymphoma (CLL) criteria.

Results: As of the data cutoff (Nov 1, 2016), 52 patients were treated (median age 65 years, range 18-88). Baseline disease subtypes included diffuse large B-cell lymphoma (DLBCL; n=14), follicular lymphoma (FL; n=10), Hodgkin lymphoma (HL; n=9), marginal zone lymphoma (MZL; n=8), CLL (n=6), and mantle cell lymphoma (MCL; n=5). Sixty-two percent (n=32) of patients had >3 prior systemic regimens; 31% (n=16) had prior HSCT. Median duration of therapy was 14 months (range, 0.6-13.4); no DLTs were identified. Sixty-seven percent of patients discontinued therapy, most commonly due to disease progression (31%) and AEs (25%). Thirty-three percent of patients had dose interruption and 4% had dose reduction. Most common nonhematologic AEs (all grade; grade ≥3) were nausea (38%; 0%), diarrhea (31%; 6%), and vomiting (25%; 0%). Grade ≥3 hematologic AEs included neutropenia (21%), lymphopenia (17%), thrombocytopenia (10%), and anemia (4%). Forty percent of patients had serious AEs (SAEs), most frequently colitis, diarrhea, and hypotension (all n=3). One patient had grade 3 pneumonitis; none had Pneumocystis jirovecii pneumonia (PJP) or grade ≥2 elevated transaminase. Objective responses occurred at all doses (Table 1), except 5mg QD; 90% of the objective responses were observed at the 9-week disease assessment.

Summary/Conclusions: In patients with relapsed/refractory B-cell malignancies, INCB050465 demonstrated manageable toxicities with no clinically meaningful transaminisits or PJP. Objective response rates were generally high and most responses (90%) were observed at the 9-week disease assessment. Differen doses regimens/schedules, long-term safety, and disease-specific cohorts are being evaluated.
lymphoma (IFL). Upon informed consent, patients receive 12 cycles of R2 induction chemotherapy followed by 21 of 28 (1 cycle every 3 weeks) and prednisone (75 mg/m²) every 3 weeks, 191.92% and 191.92% of patients achieved a 21% response rate (95% CI) to CT-P10 compared to R10 in COOP (P < .001). Results: At the 191.92% and 191.92% of patients achieved a 21% response rate (95% CI) to CT-P10 compared to R10 in COOP (P < .001). Results: At the
Summary/Conclusions: There has been an ongoing debate about whether patients would benefit from adding PUVA to IFN-α in the treatment of early stage MF. We chose to initiate the combination treatment of MF as early as possible in the course of the disease to induce a permanent remission or even a cure. In our experience, this regimen set the realistic goal of achieving high rates of complete clearing and durable responses (median TTNT not reached) with only 38% of patients requiring systemic treatment within 20 years. Here, we suggest a synergistic or additive effect between PUVA and IFN-α compared with either agent alone. With respect to Hughes et al. (Blood 2015), our combination treatment provides a longer TTNT than PUVA or IFN-α monotherapy (36.3 months and 14.0 months respectively). At 2 years, 91% of patients receiving PUVA plus IFN-α were free from further treatment as compared to 54.2% and 29.1% treated with PUVA or IFN-α monotherapy, respectively.

P637

PHASE 3 ALCANZA STUDY OF BRENTUXIMAB VEDOTIN (BV) OR PHYSICIAN’S CHOICE (PC) OF METHOTREXATE (MTX) OR BEXAROTENE (BE) IN CD30-POSITIVE CUTANEOUS T-CELL LYMPHOMA (CTCL): NUMBER NEEDED TO TREAT ANALYSIS

E. Zagadaillow1, H.M. Prince2, S. Whittaker3, S. Horwitz4, Y. Kim6, C.-K. Min1, J.-W. Lee1, S.-G. Cho1
1Department of Hematology, St. Mary Hospital, Seoul, Catholic Medical Center, Seoul, Korea, Republic Of
2Department of Medicine, Mayo Clinic, Rochester, MN, United States, 3University Hospital of Basel, Basel, Switzerland, 4Memorial Sloan Kettering Cancer Center, New York, United States, 5University of Texas MD Anderson Cancer Center, Houston, TX, United States, 6Stanford University of Medicine and Stanford Cancer Institute, California, United States, 7University Hospital Zürich, Zürich, Switzerland, 8University Hospital Birmingham, Birmingham, United Kingdom, 9University of Turin, Turin, Italy, 10University of Bologna, Bologna, Italy, 11University Hospital Leuven, Leuven, Belgium, 12Columbia University, New York, United States, 13Seattle Genetics, Inc., Bothell, United States

Background: CTCL is a generally incurable, relapsing disease associated with a significant symptom burden, including disfiguring lesions, debilitating pruritus and frequent skin infections. ALCANZA is a Phase 3 study of BV vs PC (MTX or Bex) for the treatment of CD30-positive (CD30+) CTCL (NCT01578499). BV was associated with significantly improved rate of objective response lasting ≥4 months (ORR4; 56% vs 13%; p<0.0001), longer median progression-free survival (PFS; 16.7 vs 3.5 months; p<0.0001), and decreased symptom burden measured by Skindex-29 (27.96 vs –8.62; p<0.0001), compared with PC. BV’s safety profile was consistent with previous reports, with all-grade and grade 3 peripheral neuropathy of 67% and 9%, respectively. Number needed to treat (NNT), defined as the number of patients (pts) that need to be treated to prevent one disease progression event or death compared with placebo.

Methods: The NNT with BV was calculated as the inverse of the absolute risk reduction (ARR); ARR was the PFS event rate per independent review facility (IRF) assessment in the PC arm minus the event rate in the BV arm. PFS was defined as the time from randomization until progressive disease/death due to CTCL (International Working Group [IWG] criteria). The NNT event was death. The NNT event was death. PFS was defined as the number of patients (pts) that need to be treated to prevent one outcome event relative to the comparator therapy, is an effective method for comparing the efficacies of interventions. A number needed to treat (NNT) of one in every 2–4 pts treated with BV will benefit by avoiding disease progression/death. This further demonstrates BV’s clinical benefit in CD30+ CTCL pts requiring systemic therapy. This is, to our knowledge, the first report of an NNT analysis for a treatment in the CTCL setting.

P638

PRIMARY OCULAR ADNEXAL LYMPHOMA OF ALL HISTOLOGIC SUBTYPES: SURVIVAL OUTCOMES AND RISK FACTORS IN LARGE COHORT OF PATIENTS AND LONG-TERM FOLLOW-UP

Y.-W. Jeon1,*, S.-S. Park1, J.-H. Yoon3, S.-E. Lee1, K.-S. Eom1, Y.-J. Kim1, H.-J. Kim1, S. Lee1, C.-K. Min1, J.-W. Lee1, W.-S. Min1, S.-G. Cho1
1Department of Hematology, St. Mary Hospital, Seoul, Catholic Medical Center, Seoul, Korea, Republic Of
2Department of Ophthalmology, Seoul National University College of Medicine, Seoul, Korea
3Department of Ophthalmology, Hallym University College of Medicine, Chuncheon, Korea

Background: Although the recent reports show that interest in ocular adnexal lymphomas (OAL) and their biological and clinical characteristics have been increased, the most OAL-related clinical study is still limited in the small number with insufficient follow-up period, result in retrospective studies with non-reproducible. Moreover, because the majority of OAL were in the low-grade histologic subtypes as primary ocular adnexal MALT (mucosa-associated lymphoid tissue) lymphoma, there is little comparative study of other histologic subtypes in OAL patients especially for non-MALT type OAL in large cohort OAL.

Aims: So our purposes of this study were to identify a correlation between histopathological diagnosis and significant parameters associated with clinical outcomes of patients with OAL in patients with diverse histologic subtypes.

Methods: We evaluated the consecutive 207 primary OAL patients who diagnosed at Catholic University of college (CULG) of Catholic Bone Marrow Center, Seoul between January 2004 to April 2015. Clinical information and parameters were gathered from the electronic medical records such as geographic status, complete blood count (CBC) with blood chemistry, status of BM involvement, primary therapeutic modalities, response to initial therapy, and treatment-related complications with survival outcomes.
P639
CLONAL B-CELL LYMPHOCYTOSIS OF MARGINAL ZONE ORIGIN (CBL-MZ): A PROSPECTIVE REGISTRATIONAL STUDY ON 96 CASES

C. Kalpadakis1,2, G. Pangalis2, T. Vassiliakopoulos3, S. Sachanas2, M. Moschogianis1, X. Yiallourou1, M-C. Kyrtoris2, P. Tsaknidis2, A. Dimitrakopoulou1, P. Korkolopoulou1, F. Kontopoulou2, E. Background: Clonal B-cell lymphocytosis of marginal zone origin (CBL-MZ) has been recognized as a provisional entity in the WHO classification. Despite diagnostic similarities with SMZL, the exact relation between them has not been established yet. AIM: To describe the main features of CBL-MZ and to further elucidate its relation to SMZL.

Aims: To describe the main features of CBL-MZ and to further elucidate its relation to SMZL.

Methods: 96 CBL-MZ were analyzed. Staging at diagnosis included CBCs, blood morphology and immunophenotype, biochemistry, viral test for hepatitis C and B, serum immunoglobulin levels and immunofixation as well as whole blood morphology and immunophenotype, biochemistry, viral test for hepatitis C and B, serum immunoglobulin levels and immunofixation, as well as whole body CT scan. BM biopsies were available in 78 cases which were studied with the following panel of moAbs: CD20, DBA44, CD23, CD5, CD25, CD38, CD27, s/cIgM/D, TCL-1, MNSA, T-bet and IRA1. Gastroscopy with multiple biopsies was performed in 58 cases. FISH analysis for del1q was done in 13 pts, and detection for MYD88 mutation in 60.

REAL-WORLD EXPERIENCE WITH RITUXIMAB-FLUDARABINE (RF) AND DEXAMETHASONE, RITUXIMAB, CYCLOPHOSPHAMIDE (DRC) IN WALDENSTROM MACROGLOBULINEMIA: A RETROSPECTIVE STUDY FROM 163 PATIENTS
C. Protin1,2, L. Oberli3, C. Bories1, G. Laurent4, F. Despas5, L. Ysebaert6
1Hematology, 2Oncomip regional cancer network, IUC Toulouse-Oncocone, 3Clinical Pharmacology, University of Toulouse, Toulouse, France

Background: symptomatic Waldenstrom macroglobulinemia (WM) may be managed with various regimens. After the 8th IWWM congress, experts recommended the use of rituximab-based regimens. Two phase II trials treated DRC (n=72, 1L) and RF (n=43, one third having received chlorambucil alone, +/- steroids/rituximab before), with published long-term follow up of 95 and 46 months, respectively. Mature data from larger cohorts confirming trials’ results in real-life practice are lacking.

Aims: to evaluate RF or DRC in first-line WM treatment. We present here our real-world experience of 163 WM patients treated with DRC or RF from January 2005 to December 2015.

Results: median age of patients at diagnosis was 68.6y and at therapy 71.2y. Our cohort included 163 patients, 43 RF and 120 DRC, median age at diagnosis 68.6y and at therapy 71.2y. 75% were above 65y at diagnosis, 68.6% and at therapy 71.2y, respectively. Previous CLB had no impact on outcomes, but dose reductions >20% adversely impacted TTNT. IPSS scoring system did not improve prognosis. Long-term follow-up (22% of patients) showed that 70% of patients were still alive, 48% had no disease progression (median follow-up 6 years). Significant differences between DRC/RF cohorts were: median age 74/64y, high IPSS score 63%/28%, 2B2M/3mg/l 74%/56%, DRC cohort: median PFS/Time To Next Therapy and Overall Survival were 33m, 45.8m and 78 at 5 years, respectively. Previous CLB had no impact on outcomes, but dose reductions >20% adversely impacted TTNT. IPSS scoring system did not improve prognosis. Long-term follow-up (22% of patients) showed that 70% of patients were still alive, 48% had no disease progression (median follow-up 6 years).

Conclusions: Our real-world experience of 163 WM patients treated with DRC or RF showed that 70% of patients were still alive after 6 years and that dose reductions >20% adversely impacted TTNT. IPSS scoring system did not improve prognosis. Long-term follow-up (22% of patients) showed that 70% of patients were still alive, 48% had no disease progression (median follow-up 6 years).

Background: Invasive fungal infections (IFIs) incur significant morbidity and mortality in neutropenic patients with hematological malignancies (Hem) after chemotherapy. The risk for these infections is related to the intensity and duration of neutropenia, and varies from 2% to 40%. Mortality rates associated with documented IFIs are considerable, reportedly ranging from 30% to 60%. Empirical antifungal therapy is the standard care for neutropenic patients with Hem, who remain febrile despite broad-spectrum antibacterial treatment. Several antifungal agents including voriconazole (VRCZ) or liposomal amphotericin B (L-AMB) have been studied as empirical therapy for febrile neutropenia (FN). However, limited data are available concerning the efficacy and safety of micafungin (MCFG) in FN patients with Hem.

Aims: We conducted a randomized, cooperative group, open-label trial comparing MCFG (150mg once daily) with L-AMB (2.5mg/kg once daily) as first-line empirical antifungal treatment for FN patients with persistent fever of Hem.

Methods: 138 hospitalized FN patients with persistent fever of Hem (AML 78, APL 4, ALL 13, MDS (RAEB) 7, NHL 28, MM 5, other hematological malignancy 3 cases) were randomized to each drug group (MCFG, 72; L-AMB, 66). The efficacy end point was a favorable overall response, as determined by a five-component end point according to the criteria of Walsh et al (N Engl J Med 2004; 351: 1391).

Results: At the time of enrolment, there were no significant differences in the demographics or baseline characteristics between the two groups. The mean treatment duration for MCFG and L-AMB was 13.8 and 16.4 days, respectively. The efficacy rates of MCFG and L-AMB were not significantly different (38/72 cases (52.8%) vs 26/66 cases (39.4%), p=0.115*), evaluated based on: (1) successful treatment of baseline fungal infection (3/4 cases (75.0%) vs 0/1 case (0%), p=0.170*), (2) absence of breakthrough fungal infection (65/72 cases (90.3%) vs 65/66 cases (98.5%), p=0.112*), (3) survival for ≥7 days after treatment completion (66/72 cases (91.7%) vs 59/66 cases (89.4%), p=0.855*), (4) absence of premature study drug discontinuation due to poor efficacy or drug-related adverse events (54/72 cases (75.0%) vs 47/66 cases (71.2%), p=0.615*), and (5) resolution of fever during neutropenia (45/72 cases (62.5%) vs 33/66 cases (50.0%), p=0.258*). However, discontinuation due to drug-related adverse events occurred less frequently in the MCFG group (1/72 cases (1.4%) vs 9/66 cases (13.6%), p=0.006*). In safety evaluation, adverse events of creatinine increase and hypokalemia were less often in the MCFG group (1.4% vs 9.0%), and ed adverse events occurred less frequently in the MCFG group (1/72 cases (1.4%) vs 5/66 cases (7.7%), p=0.115*).

Conclusions: MCFG was as effective as L-AMB, and better tolerated than L-AMB as an empirical antifungal therapy in FN patients with Hem.
Aims: The aim of our study is to clarify the immunomodulatory capacity of different antifungal drugs on the effector functions of polymorphonuclear neutrophils (PMN) and on the clinical course of invasive pulmonary aspergillosis (IPA).

Methods: Firstly, isolated PMN from healthy donors were preincubated with different antifungals in vitro. Here, we used the azoles fluconazole (FLU), voriconazole (VOR), and isavuconazole (ISA), as well as the echinocandins caspofungin (CAS) and micafungin (MIC), and the polyenes amphotericin b (AmB) and liposomal amphotericin b (LAmB). Furthermore, PMN were simultaneously stimulated with lipopolysaccharides (LPS) or zymosan. Afterwards, PMN were analyzed by flow cytometry regarding activation, degranulation, and phagocytosis. Additionally, a dichrotometer assay was used to detect reactive oxygen species (ROS). IL-8 synthesis was measured by enzyme-linked immunosorbent assay (ELISA). Secondly, a murine model was used to investigate the influence of MIC and POS on the clinical course of IPA in vivo. Therefore, mice were treated with antifungals and inoculated with Aspergillus fumigatus conidia. Afterwards, mice were analyzed concerning fungal burden and pulmonary damage (albumin ELISA) with neutropenic animals serving as controls.

Results: In vitro, pretreatment with POS led to enhanced activation (CD62L: 44% +/- 8 vs 13 +/- 2, *), mean +/- SEM, p value 0.05 considered to be significant. In vivo, Pretreatment with POS led to increased ROS (2868 +/- 4432 vs 8528 +/- 161, *), whereas zymosan triggered IL-8 synthesis was reduced by trend. In contrast, ISA pretreated PMN showed decreased expression of activation markers. Moreover, ISA impaired degranulation and LPS triggered generation of ROS (6890 +/- 1338 vs 28730 +/- 6893, *). FLU and VOR did not show a significant influence on PMN effector functions in vitro. Mic pretreatment resulted in enhanced expression of activation marker CD62L but reduced expression of CD11b, and decreased degranulation. Additionally, phagocytosis (27% +/- 4 vs 44 +/- 1, LPS, *) as well as generation of ROS (22660 +/- 3286 vs 41180 +/- 2584, zymosan, *), and IL-8 synthesis were substantially impaired. CAS showed an increased phagocytosis (50% vs 6 vs 44 +/- 5, LPS, *), whereas degranulation and LPS triggered generation of ROS were reduced by trend. Pretreatment with conventional AmB resulted in activation of almost all effector functions besides impaired phagocytosis (43% +/- 3 vs 59 +/- 3, LPS, *). In contrast, LAmB did not significantly alter any effector function. Treatment with POS resulted in reduced fungal burden as expected but lead to reduced albumin concentration in BAL (111 ng/ml +/- 46 vs 380 +/- 31, *) indicating a decreased pulmonary damage. Despite significant influence on PMN effector functions in vitro, MIC did not affect clinical course IPA in vivo.

Summary/Conclusions: Different antifungal drugs affect clinical course IPA in vivo. CAS shows variable modification with respect to its antifungal effects, POS reduces pulmonary damage in mice suffering from IPA in vivo. Further studies are needed to distinguish the obviously multidimensional immunomodulatory effects of different antifungal agents and to clarify their relevance in clinical practice.

Matteo, Pavia, 4Hematology, Ospedale di Circolo e Fondazione Macchi, Varese, 5San Raffaele Scientific Institute of Milan, Milan, 6Humanitas Cancer Center, Rozzano-Milano, 7Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Milan, 8Hematology, Ospedale Valduce, Como, 9Hematology, San Gerardo Hospital, Monza, Italy

Background: In acute leukemia (AL) patients (pts) pulmonary infections may be severe and worsen the final outcome of AL. They have been recently shown to adversely affect the outcome of bloodstream infections (BSI) in AL pts (Cat- be severe and worsen the final outcome of AL. They have been recently shown to adversely affect the outcome of bloodstream infections (BSI) in AL pts (Cat-

Aims: In order to better define the clinical and prognostic significance of PI in AL pts in a real-life setting, we have analyzed all PI diagnosed during consecutively conducted febrile/infectious episodes developing over a 26 months period in pts admitted to 9 hematological institutions within the Rete Ematologica Lombarda (REL) network.

Methods: From Dec-12 to Jan-14, all febrile/infectious episodes were recorded by cyclophosphamide (cpm) on day -4 (150mg/kg) and day -1 (100mg/kg) and challenged (day 0) with Candida albicans ATCC SCS314 (IV, 100 µl, 105 CFU/mouse). One dose of CD101 5, 10, or 20mg/kg SC was given prior to challenge on day -5, -3, or -1. Kidneys were removed for Cfu enumeration 24 h postchallenge. Aspecific PI were treated with systemic antifungal therapy. Thirty-day mortality was observed in 41 cases (16%). It was similar for aspecific and poss PI (15.9% and 10%), but significantly higher in prob/prov PI (31.3%, p<0.0192). Multivariate analysis confirmed a prob/prov PI (3.277, 1.243-8.644) predictive for death, as well as relapsed/refractory AL (2.45, 1.092-5.498) and BSI (2.833, 1.056-5.377).

**SURGICAL MANAGEMENT OF INVASIVE FUNGAL INFECTIONS IN ADULT LEUKAEMIA PATIENTS—EXPERIENCE FROM A LARGE TERTIARY CENTRE IN SOUTH-EAST ASIA**

1Department of Haematology, 2Department of Infectious Diseases, Singapore General Hospital, Singapore, Singapore

**Background:** Invasive fungal infections (IFI) are a major cause of morbidity and mortality in patients undergoing chemotherapy or stem cell transplantation for acute leukaemias. Though optimized antifungal therapy might be effective, in selected patients, surgical interventions might be an useful tool both for diagnostic and therapeutic reasons. However due to the nature of the disease and circumstances, prospective data of Surgical interventions in these situations is very difficult and the evidence is usually from small cohorts often from single centers.

**Aims:** The purpose of this study is to report our single center experience of surgical interventions for IFI in acute leukaemia patients.

**Complications:**

- Aspergillus pneumonia
- Uncontrolled bleeding
- Aspergillus tracheal involvement
- Lungs
- Aspergillus paracancer

**Results:**

Four-hundred seventy-nine patients (male: 272, 57%) accounted for 1690 cases (median number of cases per patient 3, range 1-15). At presentation in our institution, median age was 62 (35-89) years, and most patients had advanced disease (Stage III according to Salmon-Durie classification in 364 patients, 76%). An and an IgG-paraprotein (255 patients, 53%). Type of therapy given were as follows: 534 (32%) conventional long-term chemotherapy, 514 (30%) induction-type chemotherapy, 237 (14%) chemotherapy for stem cell mobilisation, 310 (18%) high-dose melphalan with stem cell transplantation and 95 (6%) supportive care only. One-hundred sixty-six patients (35%) with 222 chest images did not have an infection including 25 patients with high-dose melphalan. However, the majority of patients experienced at least one episode of infection throughout their treatment, accounting for 773 infections in 627 patient cases (37% of all patient cases). Most (559, 72%) infections were of bacterial origin including 156 cases with pneumonia (9% of all patient cases). High-dose chemotherapy was noted in 95% (Cl. 1.5-2.5, p<0.001) and high-dose chemotherapy (OR 11.3, 95% Cl. 8.4-15.3, p<0.001) were associated with a higher risk of infection whereas time of treatment (2003-2008 versus 2009-2014) or use of novel drugs did not influence the rate of infection.

**Summary/Conclusions:** More than 60% of MM patients experienced at least one episode of infection during their course of treatment. These infections are mostly of bacterial origin and strongly associated with high-dose chemotherapy or relapse. Novel drugs do not seem to influence the rate of infection. Unfortu-
Background: Neutrophenic patients with acute myeloid leukemia (AML) bacterial infections and sepsis are a leading cause of mortality. Several studies propose a contribution of individual single nucleotide polymorphisms (SNPs) of the innate immune system to the course of infections. Human ficolins represent one of the lectin pathway components of the lectin pathway, especially ficolin-2 (L-ficolin) is emerging as an important component of the lectin pathway in the circulation. Ficolins share structural and functional characteristics with C1q from the classical pathway of the complement that acts with Pentraxin 3 (PTX3) that helps the innate immune system targeting pathogens like bacteria or viruses. In the context of hematopoietic stem cell transplantation polymorphisms of PTX3 have been identified as an individual risk factor for developing pulmonary aspergillosis.

Aims: We sought to investigate the impact of L-ficolin and PTX3 SNPs on the occurrence of infectious events such as sepsis and pneumonia, including invasive fungal disease (IFD), in 186 adult patients with newly diagnosed AML following anthracycline-based induction chemotherapy. In addition to our studies on membrane receptors, this work represents an important extension on soluble molecules of the innate immune system and their potential implication on infections.

Methods: Genotyping of L-ficolin and PTX3 SNPs (rs17514136, rs17549193, rs1522306519, rs1840880) was performed by TaqMan assay. Multiple logistic regression analyses were applied to evaluate the association between SNPs of the polymorphisms and the occurrence of infectious events.

Results: Two L-ficolin SNPs were identified as risk factors for developing sepsis and/or pneumonia. Patients harboring rs17514136GG (OR = 2.39; 95% CI: 1.0–5.64) or rs1522306519CC (OR = 2.35; 95% CI: 1.05–5.26) were at higher risk of developing sepsis and/or pneumonia compared to patients harboring the other genotype combinations. In the PTX3 gene, the A17263G (rs17549193) was found to be associated with an increased risk of developing sepsis and/or pneumonia. The risk of developing sepsis and/or pneumonia was higher in patients with the A17263G (G/G) genotype compared to the A17263G (A/G) and A17263G (A/A) genotypes (OR: 2.52; 95% CI: 1.19–5.33, p = 0.015).

Summary/Conclusions: This study is the first to investigate the impact of genotypes of L-ficolin and PTX3 on the occurrence of infectious events in adult patients with newly diagnosed AML following anthracycline-based induction chemotherapy. Further studies are needed to confirm these findings and to investigate the potential mechanisms underlying the observed associations.

P650
TIMING OF DEFIBROTIDE INITIATION POST-DIAGNOSIS OF HEPATIC VENO-OCLUSIVE DISEASE/SINUSOIDAL OBSTRUCTION SYNDROME AFTER PRIMARY CHEMOTHERAPY: EXPLORATORY ANALYSIS OF AN EXPANDED-ACCESS PROTOCOL

Background: Hepatic VOD/SOS, which may be unpredictable and potentially life-threatening, is typically considered a complication of hematopoietic stem cell transplantation (HSCT); however, VOD/SOS can occur after chemotherapy without HSCT. VOD/SOS with multi-organ dysfunction (MOD) may be associated with >80% mortality. Defibrotide is approved to treat severe hepatic VOD/SOS post-HSCT in the European Union and to treat hepatic VOD/SOS with renal or pulmonary dysfunction post-HSCT in the United States.

Aims: To perform an exploratory post hoc analysis of the impact of timing of initiation of defibrotide after VOD/SOS diagnosis in patients developing VOD/SOS after primary chemotherapy without HSCT (off label).

Methods: In an expanded-access protocol for patients with VOD/SOS post-HSCT or chemotherapy, with or without MOD (renal and/or pulmonary dysfunction), defibrotide 25mg/kg/d (4 divided doses of 6.25mg/kg) was given a median of 1 day (range: 0–17 days) from VOD/SOS diagnosis to start of defibrotide. In the post-chemotherapy subgroup, survival was analyzed post hoc from the day VOD/SOS was diagnosed (days 0–30 after start of chemotherapy) through follow-up, which was collected for 100 days post-chemotherapy. For these exploratory analyses, survival rates in the post-chemotherapy subgroup were estimated. Time from VOD/SOS diagnosis to start of defibrotide for (1) all patients before/after days 1, 2, and 4, 7, 14, and using Fisher’s exact test and (2) patients starting defibrotide on a particular day: 0, 1, 2, 3, 4, 5, 6, 7, 8–14, and ≥15, by Cochran-Armitage test for trend across days. Causes of treatment delay were not assessed.

Results: In the final dataset, 137 patients developed VOD/SOS after primary chemotherapy. Of these, 87 patients (41 with MOD) developed VOD/SOS by day 30 after the start of chemotherapy. In the latter group, 79.3% (69/87) were aged ≤16 years. In 26.4% (2387) of post-chemotherapy patients, defibrotide was started the day of diagnosis; in 89.7% (78/87), by Day 7. In the population with defibrotide initiation post VOD/SOS, mean number of days from diagnosis to the initiation of defibrotide in both the overall group and MOD subgroup (Figure), earlier initiation was associated with higher Day +100 survival rates for all days, which was significant at a number of timepoints. The trend test for particular initiation days was statistically significant for each post hoc analysis.
also showed a significant trend over time for higher Day +100 survival with earlier defibrotide initiation post-diagnosis in both the overall group and MOD subgroup (P<.05). In the overall post-chemotherapy population, adverse events (AEs) and serious AEs occurred in 66% and 40% of patients, respectively. Aside from multi-organ failure, the most common AE of any severity was hypotension (9.5%). Possibly related AEs lead to discontinuation in 7.3%, most common was gastric hemorrhage (3.7%).

**Summary/Conclusions:** In this exploratory analysis of final study data in the subgroup of patients developing VOD/SOS after chemotherapy, earlier defibrotide initiation post-VOD/SOS diagnosis was associated with improved Day +100 survival, confirmed by the Cochran-Armitage test (P<.05), even in the small MOD subgroup. This time-dependent relationship was consistent with that found in the HSCT subgroup from this study. No specific day appears to provide a clinically meaningful cutoff for better Day +100 survival, suggesting that later intervention retains value if treatment must be delayed.

**ADAMTS-13 REGULATES NEUTROPHIL RECRUITMENT IN A MOUSE MODEL OF INVASIVE PULMONARY ASPERGILLOSIS**

A. Hasibeder1,*, S. Prüfer2, K. Ebner3, S. Reuter1, P. Aranda Lopez1, I. Scharrer1, F. Banno4, M. Stassen2, H. Schild2, K. Jurk3, M. Bosmann3, H. Becker1, M. Radsak1

1IIIrd Dept. of Medicine, 2Institute for Immunology, 3Center for Thrombosis and Hemostasis, Johannes Gutenberg-University Medical Center, Mainz, Germany, 4Department of Molecular Pathogenesis, National Cerebral and Cardiovascular Center, Suita, Japan

**Background:** Von Willebrand factor (VWF) is produced as multimers of various sizes and is secreted as an acute phase protein during inflammation. The main mechanism regulating the size and prothrombotic activity of VWF is the specific proteolytic activity of ADAMTS-13 (a disintegrin and metalloprotease with ThromboSpondin type 1 repeats-13) which is diminished under several pathological conditions.

**Aims:** To determine the relevance of this regulatory pathway for the innate inflammatory response by polymorphonuclear neutrophils (PMN), we employed a mouse model of invasive pulmonary aspergillosis (IPA) where PMN functionality is crucial for fungal clearance and survival.

**Methods:** IPA was induced by intratracheal application of *Aspergillus fumigatus* (*A. f.*) conidia in wildtype (129/Sv/Pas) or ADAMTS-13 deficient (*Adamts13*−/−) mice, and VWF deficient (*Vwf*−/−) mice or respective controls (B6). Some mice were sacrificed 24 h after infection. Fungal load was assessed as colony forming units (CFU) after plating and culturing lung homogenates on Sabouraud agar plates. For histological analysis paraffin sections of the lungs were stained with H&E, mouse complement component C3d and VWF antibody. Broncho alveolar lavage fluid (BALF) was analyzed for cell count (bead-based by flow cytometry or by an animal blood counter), ELISA was performed for albumin amount and cytokines were analyzed by a multiplex assay. Bone marrow-derived PMN were isolated by magnetic cell sorting using biotin labeled Ly6G/C specific antibody. PMN functions were analyzed for degranulation, oxidative burst activity and CD62L shedding by flow cytometry. Fungal killing of PMN in *vitro* was assessed by a XTT assay. Chemotactic properties of *A. f.*-activated and control serum from wildtype and knock-out mice was evaluated by migration of purified human PMN, isolated by dextran sedimentation and Histopaque® centrifugation, in a transwell assay.

**Results:** While infected neutropenic mice developed lethal IPA, all wildtype mice survived the infection. Interestingly, *Adamsats13*−/− mice displayed more severe signs of disease with a lethal course in about 24% of the animals. Examination of the lungs revealed a higher fungal burden along with increased signs of acute lung injury and levels of pro-inflammatory cytokines in ADAMTS-13 deficient mice. Histology sections demonstrated a more pronounced perivascular leukocyte infiltration in support of a dysregulated inflammatory response in *Adamsats13*−/− mice. Importantly, we observed no general defect in the activation of neutrophil effector functions in response to conidia or hyphae *in vitro*. Furt-

IDENTIFICATION OF THE SPECIFIC HEMATOPOIETIC STEM CELL POPULATIONS RESPONSIBLE FOR FAILURE TO HYPMETHYLATING AGENTS IN MYELODYSPLASTIC SYNDROMES
I. Garfán-Gómez1, A. Alfonso1, Y. Ogote1, H. Yang1, G. Montalban-Bravo1, A.C. Yu2, S. Silver2, K. Clise-Dwyer1, G. Garcia-Manero1, S. Colla1

Background: Myelodysplastic syndromes (MDS) are hematopoietic disorders characterized by the ineffective production of mature blood cells of one or more lineages and by the risk of evolution to acute myeloid leukemia. The current standard of care for MDS patients is the treatment with hypomethylating agents (HMA); however, response to drugs from this family occurs in just about half of the patients and is accompanied by high rates of therapy failure. Failure to HMA in MDS is a poorly understood process associated to increased risk of disease progression and to a dismal prognosis and cannot be, thus far, predicted or prevented.

Aims: Given that MDS are stem cell disorders, our aim was the identification and molecular characterization of the specific hematopoietic stem/progenitor cell (HSPC) population in which the relapse-driver clones arise. This is an essential step for the development of effective monitoring and early intervention protocols for HMA failure.

Methods: Using flow cytometry immunophenotyping, we quantitatively analyzed the different cell subpopulations within the CD34+CD38− and CD34+CD38+ HSPC compartments in 122 sequential MDS bone marrow samples obtained from 93 patients at different stages of HMA treatment.

Results: In line with earlier reports suggesting the presence of alterations in myeloid progenitor frequencies in MDS, our flow cytometry data stratified untreated patient samples in two groups representative of two abnormal differentiation patterns, which were independent of the IPSS risk classification. The “CMP pattern” group (12 samples, 34%) was characterized by an increased frequency of the common myeloid progenitors (CMP) (2.6-fold; p<0.04) whereas the “GMP pattern” group (23 samples, 66%) was characterized by the increased frequency of the granulomonocytic progenitors (GMP) (1.7-fold; p<0.04) within the HPC compartment, when compared to those from healthy individuals. Importantly, these two patterns were not caused by the expansion of the aforementioned populations, but by the depletion of other progenitors within the same compartment, which points to the existence of selective differentiation defects in upstream HSC or multipotent progenitors (MPP). For instance, decreased numbers of long-term (LT)-HSC (-5.1-fold, p=0.001) and increased counts of the GMP precursors, lymphoid-primed multipotent progenitors (LMPP) (4.7-fold, p=0.001), were observed in CMP pattern patients but not in CMP pattern patients. These data suggest that each abnormal differentiation pattern arises from defects in different HSC populations and has a differential impact in the number and functionality of downstream progenitor cells (R. Beran1, D.-C. Liang2, M.-C. Chiu1, Y.-J. Huang1, L.-Y. Shih3
1Chang Gung Memorial Hospital, Taoyuan, 2Mackay Memorial Hospital, Taipei, 3Chang Gung Memorial Hospital and Chang Gung University, Taoyuan, Taiwan, Republic of China

Background: Our previous studies showed that RUNX1 and ASXL1 mutations were frequently co-existed in chronic myelomonocytic leukemia (CMMML) (EHA 2015) and clonal evolution of RUNX1 and/or ASXL1 occurred most frequently in chronic myeloid leukemia (CML) with myeloid blast crisis (EHA 2016). The molecular pathogenesis of cooperation of RUNX1 and ASXL1 mutations has not been reported yet.

Aims: We aimed to determine the functional role of collaborative association of RUNX1 and ASXL1 mutations for secondary acute myeloid leukemia (sAML) transformation.

Methods: For in vitro study, we overexpressed RUNX1-WT/MT (R135T) in K562 cells which harboring ASXL1-MT (Y891X) and co-expressed with ASXL1-WT/MT (R693X) in murine 32D cells. After stable expression, functional properties were examined by using immunoblot, co-immunoprecipitation, quantitative RT-PCR, flow cytometry, cell proliferation, colony formation and gene expression microarray analyses. C57BL/6 mice were used for bone marrow transplantation (BMT) experiments for in vivo study.

Results: We found that RUNX1-MT augmented cell proliferation, colony formation, HOXA gene expression and inhibited megakaryocytic differentiation in ASXL1-MT K562 cells compared to RUNX1-WT or empty vector control. The cooperation of RUNX1 and ASXL1 mutations or the knocked down of ASXL1 cooperated with RUNX1-MT inhibited apoptosis and impaired differentiation in 32D cells. Nine months post BMT mice with the combined RUNX1 and ASXL1 mutations, but not RUNX1-MT or ASXL1-MT alone, developed disease characterized by marked splenomegaly, hepatomegaly, and leukocytosis with a shorter latency. We found that RUNX1-MT stabilized hypoxia-inducible factor 1α (HIF1-α) and increased its target gene expression such as ID1 (inhibitor of DNA binding 1). Clinical samples analyses showed that ID1 expression increased in both RUNX1-MT and ASXL1-MT or the combined mutations of RUNX1 and ASXL1 controlled to sample patients. We also examined the impact of RUNX1 and ASXL1 mutations on sAML-free survival of 104 Patients with CMMML in whom 11 had co-occurrence of RUNX1 and ASXL1, 39 had either mutated ASXL1 or RUNX1 and 54 patients were negative for both mutations. We found that patients carrying co-existed mutations had a shorter sAML-free-survival (median 16.1 months, 95% CI 0.0-60.1 months) than those carrying either mutated gene alone (median 23.0 months, 95% CI 17.8-28.2 months) or negative for both mutated genes (median not reached, 59.2% ± 8.8% at 5 years) (P=0.023).

Summary/Conclusions: The present study demonstrated that clinical and functional evidence for a collaborative association of RUNX1-MT and ASXL1-MT for sAML transformation. We identified HIF-1α targeting a new pathway which may be critical for leukemic progression of RUNX1/ASXL1-MT mutated myeloid malignancies.

A NOVEL Mass spectrometry METHOD REVEALS THE INTRACELLULAR PHARMACOKINETICS OF AZACYTIDINE THERAPY IN VIVO
A. Unnikrishnan1, A.V. Ngoc Quynh1, R. Pickford2, A. Nunez1, L. Hasson1, P. Ferrando1
1Prince of Wales Clinical School & Lowy Cancer Research Centre, 2Bioanalytical Mass Spectrometry Facility, UNSW Sydney, 3Haematology Department, Prince of Wales Hospital, Sydney, Australia
Background: The cytosine analog 5’-Azacitidine (AZA, Fig A), a DNA demethylating agent, is the primary drug for the treatment of high-risk Myelodysplastic Syndrome (MDS) and Chronic Myelomonocytic Leukaemia (CMLL), and response is associated with improved survival benefits. However, only ~50% of treated patients will ever respond to AZA and the molecular basis for poor response is poorly understood. It is unclear whether non-responders to therapy have different patterns of AZA uptake into their cells and/or AZA incorporation into nucleic acids compared to AZA responders, nor whether these might relate to DNA methylation in vivo.

Aims: We aimed to develop an analytical method capable of simultaneously detecting all the subcellular fractions of AZA (Fig B) within the bone marrows of patients undergoing AZA therapy, while also assessing DNA and RNA methylation levels. This would provide the most comprehensive snapshot of the intra-cellular pharmacokinetics of AZA therapy in vivo as a first step towards better understanding AZA resistance.

Methods: We have developed a new method utilising mass spectrometry to accurately quantify all the different subcellular fractions of AZA within the same sample (Fig C). Using an Orbitrap mass spectrometer with very high mass resolution, we have achieved the first mass separation of DAC and AZA from all naturally occurring isotopes of deoxycytidine and cytidine respectively (a difference of less than 1 Da), thus enabling accurate quantification. We utilised subcellular fractionation to obtain purified quantities of DNA- and RNA-incorporated nucleotides, as well as free unincorporated nucleotides present in the cytoplasm. We developed a reduction reaction to reduce the spontaneous hydrolysis of AZA and DAC, thereby greatly improving the sensitivity of detection.

Results: Using our new method, we report for the first time direct simultaneous quantification of: (1.) DNA-incorporated DAC, (2.) intracellular, free DAC, (3.) methyl deoxycytidine in DNA, (4.) RNA-incorporated AZA, (5.) intracellular, free AZA, and (6.) methyl cytidine in RNA within the same sample. We demonstrate an inverse correlation between the amount of DAC incorporated into DNA and DNA methylation. However, no such correlation was observed between AZA incorporation and RNA demethylation (Fig D). The sensitivity and resolution of our method also enabled, for the first time, a comprehensive survey of the total intracellular pharmacokinetics of AZA in vivo in patients undergoing a standard cycle of treatment. We discovered that the bone marrow cells of AZA responders (n=6) had significantly lower DAC incorporation than non-responders (n=2), while other non-responders (n=2) showed low or no DAC incorporation (Fig E). Our method also enabled us to directly prove that low DAC incorporation was not a result of insufficient AZA accumulation intracellularly, as cytoplasmic measurements of unincorporated AZA and DAC were higher in the non-responders with the lowest levels of DNA-incorporated DAC. Additionally, in these non-responders, there was also concomitant increase in AZA incorporation into RNA.

Figure 1.

Summary/Conclusions: We have developed a new method that has enabled the first comprehensive analysis of the intracellular pharmacokinetics of AZA therapy in vivo. Our results have revealed that while AZA responders incorporated AZA efficiently into DNA, leading to DNA demethylation, there were two modes of primary AZA resistance: in some non-responders, low levels of AZA incorporation into DNA likely derives from cell cycle quiescence, resulting in low amounts of DNA demethylation. However, in other non-responders who showed DAC incorporation into DNA and demethylation, resistance arises from as-yet-unknown mechanisms not connected with AZA metabolism.

CLONAL EVOLUTION OF STAG2 AND NRAS DURING PROGRESSION FROM MDS TO SAML ASSESSED BY WHOLE-EXOME AND TARGETED-DEEP SEQUENCING

M. Martín-Izquierdo1,*, M. Abáigar1, J.M. Hernández-Sánchez1, D. Tamborero2, M. Díez-Campepo3, M. Hernández-Sánchez3, F. Ramos4, M. Megido5, C. Aguilar6, E. Lumbrañas1, A. Redondo-Guijo3, M. Background: Myelodysplastic syndromes (MDS) are a heterogeneous group of clonal hematological disorders at high risk of progression to acute myeloid leukemia (sAML). Due to recent high-throughput sequencing studies, the mutational dynamics and clonal evolution underlying disease progression have just begun to be understood. However, large longitudinal sequencing genomic studies are still required.

Aims: To analyze the relationship between the dynamics of gene mutations and cell pathways they are involved in with the progression from MDS to sAML in order to study the mechanisms underlying disease evolution.

Methods: Sixty-eight serially collected samples from 34 MDS/CMLL patients evolving to sAML were studied by a combination of whole-exome sequencing (WES) and targeted-deep sequencing (TDS). Each patient was studied at two different time-points: at the time of diagnosis (MDS/CMLL stage) and after sAML progression (disease evolution, leukemic phase). At initial presentation of the disease, diagnoses were as follows: 18 RAEB-1/2, 9 RCMD and 7 CMML. Initially, WES was carried out on 40 diagnosis/progression-matched samples. Driver mutations were identified, after variant calling by a standardized bioinformatics pipeline, by using the novel tool “Cancer Genome Interpreter” (https://www.cancergenomeinterpreter.org). Secondly, in order to validate mutations and precise variant allele frequencies (VAFs) estimation, TDS using a custom MDS/sAML-related capture enrichment panel (illumina®) of 117 genes was performed in 30 out of 40 of the initial cohort. Moreover, a total of 28 paired-samples from a cohort of 14 patients were analyzed by TDS.

Results: Combining both WES and TDS approaches, a total of 143 mutations in 50 different genes were identified at the sAML stage, with most of them (118 mutations) already present at the MDS stage, and only 25 occurring during progression. The most recurrently mutated genes were SF3B1 (21%), TET2 (21%), STAG2 (28%), SRSF2 (21%), ASXL1 (21%), TP53 (21%) and NRAS (21%). However, it should be noted that 68% genes were mutated only in less than 10% of the patients, highlighting the great heterogeneity that exists in the mechanisms of disease evolution and clonal architecture. In the disease evolution dataset, we compared VAFs of mutations detected at both time-points (sAML to MDS/CMLL stage) in each patient. We identified 4 different clonal dynamics: mutations that were initially present but increased VAF (type-1), decreased (type-2), were newly acquired (type-3) or persisted with similar allelic burden (type-4) at sAML stage. Interestingly, most of type-1 mutations were detected in STAG2 gene. Thus, mutational burden of STAG2 were markedly increased (6/8 patients) at sAML progression. Moreover, type-3 mutations, only detected at the sAML stage, were predominantly identified in FLT3 (3/4) and NRAS (5/6). Conversely, type-4 mutations were present in MDS-related genes such as SRSF2 (8/12), SF3B1 (3/6) and TET2 (8/12). Most of mutations in these genes showed no changes during progression to sAML.

Summary/Conclusions: Progression from MDS to sAML could be explained by different mutational processes, as well as by the occurrence of unique and complex changes in the clonal architecture of the disease during the evolution. Mutations in genes such as STAG2, FLT3 or NRAS could play an important role during disease progression.
PRECLINICAL MODELING OF MYELODYSPLASTIC SYNDROMES
K. Rouault-Pierre1,*, S. Mian 1, M. Goulard 2, A. Abarrategi 1, A. Di Tullio 1, M. Serrano 1, K. Rouault-Pierre1,*, S. Mian 1, M. Goulard 2, A. Abarrategi 1, A. Di Tullio 1, M. Serrano 1

Myelodysplastic syndromes (MDS) are a heterogeneous group of clonal hematopoietic stem cell disorders with diverse phenotypes, characterized by ineffective hematopoiesis and bone marrow morphological dysplasia with varying risk of leukemic transformation. Over the last decade, there has been significant progress in understanding the pathogenesis underlying the MDS. Notably, patient derived xenograft (PDX) models offer the most advanced pre-clinical model. However, the low level of engraftment of most of the patients is a limitation in the study of MDS. Here we have demonstrated the value of the PDX model using MSCs (or murine MS5) as an alternative model to study MDS. This ex vivo culture system, which lasts for only 4 weeks and requires low number of human CD34+ cells, provides a robust preclinical assessment model to test therapeutic effects of different drugs and other approaches on the MDS clonality and autologous MDS prior to treatment of MDS patients.

RESULTS: Our data showed promising results with the injection of mononuclear cells obtained from patient BM, however the co-injection of mesenchymal stromal cells (MSCs) did not improve the level of engraftment. To address the question of the benefiting of MSCs once injected, we tracked them back into the mice BM and showed that they disappeared after a week of engraftment. With a 2D in vitro system, we showed that we could couple CD34+ cells, which again progressed to AML, mutations were lost or gained, associated with outgrowth of a clonal expansion ranging from 50 to 600 times. More importantly those cells conserved their clonal architecture and chromosomal aberrations.

Figure 1.

Summary/Conclusions: Although the in vivo model cannot be replaced, the low level of engraftment of most of the patients is a limitation in the study of MDS. Here we have demonstrated the value of the 2D co-culture system using MSCs (or murine MS5) as an alternative model to study MDS. This ex vivo culture system, which lasts for only 4 weeks and requires low number of human CD34+ cells, provides a robust preclinical assessment model to test therapeutic effects of different drugs and other approaches on the MDS clonality and autologous MDS prior to treatment of MDS patients.

PRECLINICAL MODELING OF MYELODYSPLASTIC SYNDROMES
K. Rouault-Pierre1,*, S. Mian 1, M. Goulard 2, A. Abarrategi 1, A. Di Tullio 1, A. Smith 1, M. Mohamed 1, A. Mohamedali 2, S. Best 3, M. Nogla 2, A. Kulasekara 3, L. Ades 2, C. Chomienne 2, P. Fenaux 2, D. Bonnet 1, K. Rouault-Pierre1,*, S. Mian 1, M. Goulard 2, A. Abarrategi 1, A. Di Tullio 1, M. Serrano 1

Myelodysplastic syndromes (MDS) are a heterogeneous group of clonal hematopoietic stem cell disorders with diverse phenotypes, characterized by ineffective hematopoiesis and bone marrow morphological dysplasia with varying risk of leukemic transformation. Over the last decade, there has been significant progress in understanding the pathogenesis underlying the MDS. Notably, patient derived xenograft (PDX) models offer the most advanced pre-clinical opportunity to capture the complexities of this myeloid malignancy. A number of PDX models have been developed, but the more promising to date are the NSG and the NSG-S (humanized with SCF, GM-CSF and IL-3). Here we have used bone marrow cells from 39 MDS patients, covering all risk groups, to generate a preclinical in vivo and in vitro model, which could be used to study clonal evolution and test targeted therapies.

METHODS: We have used NSG and NSG-SOGM mice to assess the scid-repopulating capacity of the MDS stem cells in presence or absence of mesenchymal stromal cells (MSCs). Moreover, we have developed an in vitro 2D co-culture system as an alternative/complementary tool to in vivo studies.

RESULTS: Our study clearly demonstrated that mitochondrial function is altered in MDS, leading to a strong energetic defect and an increase in oxidative stress, far beyond the expected parapathophysiological decrease resulting from ageing. The OXPHOS efficiency is highly reduced in MDS compared to controls, determining an impairment of the ATP/AMP ratio, which is 2.4 in young controls, 0.75 in elderly controls and it is 0.2 in i-thalassemia and MDS patients. By contrast, LDH activity increased in the MDS patients (6mU/mg) with respect...
the controls (88 μM/L), suggesting an attempt to compensate the energy imbalance with the increment of anaerobic glycolysis. MDA level, which reflects the lipid peroxidation, is 1 mM in young subjects, 9 mM in elderly subjects, 9 mM in b-thalassemia and 15 mM in MDS. In vitro iron chelation partially restored these abnormalities in MDS patients: ATP/AMP ratio increases from 0.2 to 0.6 in MDS and b-thalassemia, by contrast it is reduced in healthy subjects from 2.4 to 1.6. Anaerobic glycolysis is reduced after DFX incubation, in fact LDH decrease from 88 to 77 in MDS. By contrast, in healthy samples the iron chelation determined a reduction of OXPHOS activity, with a consequent impairment of ATP/AMP ratio and an increment of anaerobic glycolysis flux. Lipid peroxidation is significantly reduced by DFX and 23% with DFO (p value <0.01 for both). Similar reduction is observed in b-thalassemia. By contrast MDA levels increased in healthy subjects incubated with DFX. Curiously, all these abnormalities are more pronounced in MDS with IOL compared to MDS w/o IOL and are significantly worse in MDS without IOL compared to elderly normals. Findings suggest different treatment of patients with DFX reproduces similar findings as in vitro incubation.

Summary/Conclusions: In summary OXPHOS activity and the energetic status are highly impaired in MDS compared to elderly subjects. MDS cells used O2 to produce ROS instead of ATP. This is typical of ageing but is significantly increased in MDS compared to elderly controls and it is further increased by IOL. DFX is able to restore mitochondrial activity and ATP production in all the patients analyzed after in vivo or in vitro treatment.

V-SET AND IMMUNOGLOBULIN DOMAIN-CONTAINING 4 (VSIG4) EXPRESSED ON MONOCYTES INCLUDING TUMOR-ASSOCIATED MACROPHAGES SUPPRESSED ANTITUMOR IMMUNE RESPONSES IN MYELODYSPLASTIC SYNDROMES

Y. Kuribayashi-Hamada1,*, H. Tamura1, M. Ishibashi1, T. Asayama1, K. Moriya1, I. Choi2, K. Inokuchi1

1Department of Hematology, Nippon Medical School, Japan, Sendagi, Bunkyo-ku, Tokyo, Japan, 2Department of Microbiology and Immunology, Inje University College of Medicine, Busan, Korea, Republic Of

Background: In myelodysplastic syndromes (MDS), blast cells increase with clonal proliferation during disease progression, while immune cells in the bone marrow (BM) microenvironment become less efficient. The V-set and immunoglobulin domain-containing 4 (VSIG4) molecule is a new B7 family-related protein and strong negative regulator of T-cell proliferation. However, the role of VSIG4 in tumors including hematological malignancies remains unknown.

Aims: We investigated the expression and functions of VSIG4 in MDS.

Methods: 1) Peripheral blood (PB) and BM samples were obtained from 39 patients with acute leukemia transformed from MDS (AL-MDS, N=21), MDS (N=13), and chronic myelomonocytic leukemia (CMML, N=5) and from healthy controls (N=14). The expression of VSIG4 in mononuclear cells (MCs) from the samples and MDS cell lines (F-36P and SKM-1) was analyzed with real-time PCR and flow cytometry (FCM). 2) After cultivation with BM stimulants HS-5 cells, its culture supernatants (HS-5 sup.), immunomodulatory drugs (lenalidomide [LEN], pomalidomide [POM]), and anti-MDS agents (cytarabine and azacitidine), VSIG4 expression on cells was determined using FCM. 3) The proliferative potential was examined by BrdU incorporation using FCM and the MTT assay. 4) The cytotoxic activity of normal killer (NK) cell line NK-92-MIagainst target cells was determined by measurement of lactate dehydrogenase activity in culture supernatants. The production of IFN-γ from donor T cells was measured in the cell culture supernatants using ELISA.

Results: 1) VSIG4 mRNA expression in PBMCs from patients with AL-MDS was significantly higher than in those from controls. Cell-surface VSIG4 expression on CD14+CD11b+ monocytes from MDS and AL-MDS patients was higher than in those from controls, but VSIG4 expression was not detected on CD34+ blasts. In CD14+CD11b+ monocytes of MDS and AL-MDS patients, VSIG4 was strongly expressed on CD68+CD206+ tumor-associated macrophages (TAMs). Furthermore, the expression levels of VSIG4 on CD14+ mononoblasts from CMML patients were significantly upregulated in comparison with those from controls. 2) Two MDS cell lines expressed both VSIG4 mRNA and its cell-surface protein. VSIG4 expression on MDS cell lines, and on monocytes and monoblasts from MDS and CMML patients, respectively, was significantly upregulated by co-cultivation with HS-5 sup, LEN, and POM, but not with cytarabine or azacitidine. 3) VSIG4 expression on monocytes and monoblasts from patients with upregulated VSIG4 expression on target cells. CD45-mediated ADCC activity of NK92-MI cells against LEN-treated MDS cells was inhibited in comparison with untreated cells. Moreover, the production of IFN-γ from donor T cells co-cultivated with LEN-treated MDS cells was suppressed compared with control cells.

Summary/Conclusions: Our study demonstrated that VSIG4 was highly expressed on monocytes including TAMs in MDS and AL-MDS patients, and on monoblasts in CMML patients. VSIG4-expressing monocytes and monoblasts may suppress antitumor immune responses and be associated with disease progression in MDS and CMML. The results will allow us to elucidate the function of VSIG4 in MDS pathophysiology and lead to the development of new immunotherapy.

TRANSCRIPTOME ASSESSMENT OF DNA REPAIR GENES IN CHRONIC MYELOMONOCYTIC LEUKEMIA: SYNTHETIC LETHALITY TARGETS

A.M. Hurtado López1,*, G. Luengo Gil1, T. Chen1, L. Palomo2, E. Lumbreras3, E. Caparrós 1, B. Przychodziński1, M.L. Amigo1, M. Diez-Campeño3, L. Zamora2, F. Ortuño1, V. Vicente1, J. Maciejewski4, C. del Cañizo5, F. Soló2, F. Ferrer-Marin1, A. Jerez1

1Hematology and Medical Oncology Department, Hospital Morales Meseguer, 26036 Murcia, Spain, 2Hematology Department, Hospital Germans Trias i Pujol, Universitat Autònoma de Barcelona, Barcelona, 3Department of Hematology, Hospital Universitario de Salamanca, Salamanca, Spain, 4Department of Translational Hematology and Oncology Research, Taussig Cancer Institute, Cleveland Clinic, Cleveland, OH, USA, United States

Background: Though genetic instability is a hallmark of myeloid disorders, the lack of recurrent somatic mutations, inarguably pathogenic, in the DNA repair machinery have precluded a predominant interest in this pathway. However, the recent discovery of non classical leukaemogenesis by splicing defects, the repair pathway interference of NEIL1 and OGG1, and the development of unbiased high-throughput sequencing approaches oblige us to revisit those routes in blood cancers.

Aims: To perform improved massive RNA-seq in chronic myelomonocytic leukemia (CMML) samples to identify neoplasia-specific targets for a synthetic lethality therapeutic approach. To validate the candidates through a direct strategy in an extended cohort of CMML, myelodysplastic syndromes (MDS) and acute myeloid leukemia (AML) patients.

Methods: We performed enhanced RNA-seq on 27 CMML bone marrow samples collected at diagnosis and 47 AML bone marrow samples collected at diagnosis. We generated consensus data to identify transcripts at a higher frequency in MDS and AML cases. We validated the microarray data by RT-PCR in an extension cohort of 73 additional CMML patients and assessed their potential singular pattern in this disease by analyzing 80 MDS and 90 AML patients. We further chose 13 of the differentially expressed genes for validation and characterization through the myeloid spectrum based on clinical correlation: i) druggable oncogenes found to be overexpressed in our cmml patients or allowing for the inhibition of an specific DNA repair pathway (i.e. XPA, XRCC4, MSH4); ii) oncogenes infra-expressed in our cohort but with inhibitory molecules already being tested in myeloid neoplasms (i.e. PARP1). Global pattern of DNA repair gene expression was compared with MDS and AML MILE study data.

Results: Of 27 CMML patients and 10 healthy donors, the expression of 18 genes was significantly different between the two groups (p-value<0.05) with 6 genes up-regulated and 12 genes down-regulated in CMML patients compared with donors. Defects on genes predominantly unique to a single subtype were found. A few genes showed a significant difference in gene expression amongst AML subtypes. A total of 9 DEGs were identified in our AML subset. To validate this, we extracted the DNA repair transcriptional components from a large dataset of 206 MDS, 47 complex karyotype AML (AMLx) and 73 healthy donors bone marrow from the MILE study. Surprisingly, MDS misregulation was characterized for a predominance of upregulated genes (14 out of the 20 misregulated targets) while AMLx showed a global defect with a predominance of downregulation (37 out of 50 misregulated targets). Of note, some genes showed opposite sense of misregulation according to the myeloid disorder: TOP2P1 was upregulated in CMML cases but downregulated in MDS cases and viceversa for BAP1. CDK1 and EXO1 were upregulated in MDS cases and the opposite effect was found among AML cases.

Summary/Conclusions: Using an unbiased and massive DNA repair transcriptome assessment, we have identified a series of candidate targets for a synthetic lethality approach in CMML. In addition, the different sense of misregulation of these and other targets within the myeloid diseases, some of them already being targeted in the clinical trial setting, emphasize the need of a neoplasia-personalized test of DNA repair modulators.

DIFFERENTIAL DIAGNOSIS BETWEEN MYELODYSPLASTIC SYNDROMES AND NON-CLONAL CYTOPEXIAS BY FLOW CYTOMETRY ANALYSIS USING A MYELOID MATURATION DATABASE

M.T. Cedenas1,*, F. Mirás3, R.M. Ayala1, E. Martín-Clavero1, M.L. Paciello1, J.P. Martinez-López1

1Hematology, 1.2 Obstetric, Madrid, Spain

Background: The diagnosis of myelodysplastic syndromes (MDS) is based
on cytomorphological characteristics, but it remains a challenge in some patients who do not fulfill diagnostic criteria. Flow cytometry (FC) immunophenotyping can be an important tool for MDS diagnosis, but a lack of standardisation and subjectivity of the analysis hinders its applicability.

**Aims:** To develop a methodology for FC immunophenotyping that allows us to establish the differential diagnosis between MDS patients and non-clonal cytopneas using a myeloid maturation database.

**Methods:** Bone marrow samples from 55 MDS patients, and 51 controls with cytopenias of several origins (immune disease, hypersplenism, drug toxicity) were analysed by FC. We elaborated a Myeloid Maturation Database using the Infinicyt® v1.7 software (Cytognos, Spain). From all bone marrow controls, we merged files stained with a 4-colour combination (CD16-FITC/CD13-PE/CD45pC/CD11b-APC). We selected myeloid population from the merged file and drew a maturation path. We obtained a maturation diagram that displays the fluorescence intensity of each parameter measured along the maturation stages. Then, for patients and controls, we obtained the fluorescence intensities whose median values exceeded ±2SD range in comparison with the stored database values (Figure 1). We elaborated a score, considering the relevant changes in fluorescence intensities (deviations) in the four markers analysed (CD16, CD13, CD45, CD11b) and in the four maturation stages, with a punctuation from 0 to 16.

**Results:** We found a mean of 1.9 deviations (fluorescence intensities values exceeded ±2SD) in controls, and a mean of 4.5 deviations in patients. Our test resulted reliable for differential diagnosis between controls and patients (curve ROC analysis, AUC=0.746; p<0.016). We found that with a cut-off of 4.5 deviations, we obtained a high specificity in the diagnosis of MDS (100%) but a low sensitivity (45%). With a high suspicion of MDS (specificity 90%), we can consider patients with scores above 3.5, thus achieving higher sensitivity (59%). Additionally, the number of immunophenotyping changes correlated well with prognostic risk. We confirmed that the higher the risk, the greater impact on deviations from the normal pattern (average of 3.7 at low risk, 4.5 at intermediate risk; 6.8 at high risk) (Figure 2).

**Summary/Conclusions:** The maturation database (using the maturation analysis from Infinicyt® software) was useful to discriminate between MDS patients and non-clonal cytopenias, proving to be a reliable diagnostic test, also with prognostic implications. The application of this database as a diagnostic tool has the advantage that the result is independent of the observer. Inclusion of more myeloid markers and incorporation of erythroid parameters could increase sensibility in differential diagnosis.
Background: Epigenetic drugs are currently used for the treatment of several hematologic malignancies, but their pharmacological mechanism remains poorly understood. For DNA methyltransferase and histone deacetylase inhibitors (DNMTi and HDACi) several mechanisms of action have been proposed, mostly based on candidate gene approaches. However, less is known about their genome-wide transcriptional and epigenomic consequences.

Aims: To investigate the effects of epigenetic treatment on transcription and chromatin, we profiled genome wide transcription start sites (TSS) activities and epigenetically regulated changes following the treatment with inhibitors against DNMTs, HDACs, or both.

Methods: Genome wide analysis of transcription start sites (TSS) (Cap analysis of gene expression (CAGE) sequencing), methylation status (whole-genome bisulfite sequencing) and chromatin dynamics (Chromatin-immunoprecipitation (ChIP) sequencing) was performed to characterize the epigenetic efficacy of multiple deacetylase inhibitors described by using a combinatorial single cell line model. Functional assays were used to investigate the mechanisms of LTR reactivation, a neuroblastoma mouse xenograft model to confirm the LTR reactivation in vivo.

Results: Following the treatment with inhibitors against DNMTs, HDACs, or both, we observed the activation of thousands of cryptic, currently non-annotated transcription start sites (treatment-induced non-annotated transcripts, TINATS). These TINATS arose most commonly from LTR12 elements, particularly LTR12c (ca. 50% of all TINATS). The resulting transcripts frequently splice into protein-coding exons and encode truncated or chimeric open reading frames which translated into currently uncharacterized protein isoforms with predicted abnormal functions or immunogenetic potential, the last one based on their foreign sequence and capability of being presented on MHC-class I molecules. TINAT transcription after DNMTi coincided with DNA hypomethylation and HDACi-induced LTR12c activation. In agreement, HDACi specifically induced a subset of TINATS in association with H2AK8ac, H3K14ac, and H3K23ac. Despite this mechanistic difference, both inhibitors convergently induced transcription from identical sites since TINATS are encoded in solitary long-terminal repeats of the endogenous retrovirus 9-family members, epigenetically represented virtually all normal cells. Moreover, we found a consensus GATA2 binding motif which strongly distinguished LTR12c with active transcription start sites (treatment-induced non-annotated transcripts, TINATS). GATA2 is likely the upstream transcription factor responsible for TINAT activation. Knock-down of GATA2 resulted in a reduced LTR12c expression despite epigenetic drug treatment. Over-expression of LTRs in our cell line model showed reduced cell viability in 3 out of 10 TINAT candidates. The reactivation of LTR12c elements upon epigenetic drug treatment could be confirmed in other malignant cell lines as well. Importantly, treatment with several chemotherapy agents did not affect LTR12c transcript levels, suggesting that their induction is a specific effect of epigenetic modulation rather than a general consequence of cellular stress. Additionally, we measured the transcription of LTR12c transcripts after SAHA treatment in a neuroblastoma mouse xenograft model, thereby confirming LTR12c induction in vivo.

Summary/Conclusions: DNMTi and/or HDACi induce de novo transcription of LTRs (LTR12 family), resulting in numerous fusion transcripts that encode novel protein isoforms which partly have the potential to influence cell proliferation, might explain the priming effect of epigenetic therapy and will be further investigated regarding their role as potential marker for epigenetic treatment response. Other future experiments will include proteomic approaches combined with cell cytotoxicity assays to further shed light on the interaction between epigenetic and immune therapy and the role of ERV-derived antigen presentation.

P665 IMPACT OF MARROW COMPLETE RESPONSE IN THE NATURAL HISTORY OF PATIENTS WITH MYELODYSPLASTIC SYNDROMES (MDS) AND CHRONIC MYELOMONOCYTIC LEUKEMIA (CMLM) TREATED WITH HYPMETHYLATING AGENTS

A. Alfonso Pierola1,*, G. Montalban-Bravo1, K. Takahashi1, E.J. Jabbour1, T. Kadia1, A. Giallourakis1, B. Mertelsmann1, J. Mielene2, M. Konopleva1, C. Bueso-Ramos2, S. Pierce1, H. Kantarjian1, G. Garcia-Manero1,2, H. German1, E.wed2,3

1Leukemia, 2Hematopathology, MD Anderson Cancer Center, Houston, United States

Background: The concept of marrow complete response (mCR) was included in the response criteria remains controversial as it is not known how it affects the natural history of MDS, CML-M and CML-CP.

Aims: The aim of our study was to describe the impact of mCR in survival outcomes in patients with MDS treated with hypomethylating agents (HMA).

Methods: We retrospectively reviewed 619 patients diagnosed with MDS or CML-M and treated with frontline HMA between 2004 and 2015 at a single institution. Clinical and demographic data were obtained from an electronic data base. Response was assessed by modified 2006 IWG criteria. Statistical analyses were performed with the IBM SPSS Statistics 23.0 software. All tests were 2-sided with significance set at p<0.05.

Results: 444 (62.3%) patients from the initial cohort achieved at least hematologic improvement (HI) as best response and were included in the analysis. 162 (37%) patients were female. Median age at diagnosis was 68 years (range 17-91). Following the 2016 WHO classification: 30 patients (7%) were MDS-SD, 50 (11%) MDS-MLD, 20 (5%) MDS-RR, 230 (52%) MDS-EB, 10 (2%) MDS-U and 104 (23%) CML-M. According to the Revised International Prognostic Scoring System (IPSS-R), 37 patients (8%) belonged to the low risk group, 176 (40%) to the intermediate-1 risk group, 198 (45%) to the intermediate-2 risk group, and 31 (7%) to the high risk group. 200 (45%) patients received azacitidine-based therapies and 244 (55%) decitabine-based therapies. Responses included: 238 (33% of the total population) complete responses (CR), 61 (9%) mCR, 2 (<1%) partial responses (PR) and 143 (20%) stable disease (SD). HI was observed in 410 (58% of the total population) of the patients. The median time to response was 3 cycles (range 1-24). Median overall survival (OS) since the
LUSPATERCEPT INCREASES HEMOGLOBIN AND REDUCES TRANSFUSION BURDEN IN PATIENTS WITH LOWER-RISK MYELODYSPLASTIC SYNDROMES (MDS): LONG-TERM RESULTS FROM PHASE 2 PACE-MDS STUDY

Background: Management of anemia is a common therapeutic challenge in patients (pts) with MDS. Luspatercept (ACE-536), a fusion protein containing modified action receptor type IIB, is being developed for treatment of anemia in lower-risk MDS. Luspatercept binds to select TGF-β superfamily ligands (such as GDF11) reducing aberrant Smad2/3 signaling and promoting late-stage erythroid differentiation and increased hemoglobin (Hgb) levels (Suragani HR 0.665 [95%CI=0.482-0.918]) (Fig. 1B). 

Methods: Inclusion criteria: MDS IPSS low or int-1, age ≥18 yr, Hgb <10 g/dL (if <4U RBC/8 weeks), no prior HMA, and no current lenalidomide or erythropoiesis-stimulating agent (ESA). The dose-escalation phase of the study is completed. An expansion cohort of up to 56 patients was added to this phase to allow adequate response evaluation. Luspatercept in pts who would not qualify for the phase 3 MEDALIST trial (for regularly transfused ring-sideroblast positive [RS(+)] patients with EPO <200 U/L). These include pts with low transfusion burden (LTB, <4U RBC/8 weeks) and either 1) RS(+) (≥15% in bone marrow) with baseline EPO ≤200 U/L or 2) RS(-) and any EPO level. RS(-) pts were allowed if ≥1U RBC/8 weeks. Pts are treated every 3 weeks subcutaneously for up to 5 doses (titration up to 1.75mg/kg) in the base and ext studies, respectively, were 62% (18/29) and 83% (19/23) for RS(+) pts with EPO <200 U/L and 46% (5/11) and 78% (5/7) for RS(+) pts with EPO 200-500 U/L. LTB-RIC rates for pts treated with ≥0.75mg/kg in the base and ext studies, respectively, were 68% (13/19) and 71% (10/14) for RS(+) pts vs 5% (1/22) and 2% (1/58) for RS(-) pts with EPO <200 U/L and 4% (1/23) and 5% (1/16) for RS(-) pts with EPO 200-500 U/L. Preliminary RS(-) response rates (IgW Hb-E and RBC-TI by subgroup) will also be presented at the meeting. Luspatercept was well tolerated, with related grade 3 serious adverse events in (3 pts) as of 23Nov2016 of blast cell count increase, myalgia, and worsening of general condition. The most common adverse events (≥2 pts) were diarrhea, fatigue, headache, hypertension, arthralgia, bone pain, injection site erythema, myalgia, and peripheral edema.

Results: Data (as of 09Sept2016) were available for 73 base and 42 ext study pts. Median and 22 ext pts were LTB/41 base ext pts had moderate high transfusion burden (HTB, ≥4U RBC/8 weeks). Median (range) age (yr) was 72 (27-90), 53% pts had prior ESA, 51% pts had baseline EPO <200 U/L. Median (range) Hgb (g/dL) for LTb pts was 8.6 (6.4-10.1). Median (range) RBC transfusion burden (U/8 weeks) for HTB pts was 6 (4-18). 71% base and 86% ext pts were RS(+). IgW Hb-E response rates for pts treated with ≥0.75mg/kg in the base and ext studies, respectively, were 62% (18/29) and 83% (19/23) for RS(+) pts with EPO <200 U/L and 46% (5/11) and 78% (5/7) for RS(+) pts with EPO 200-500 U/L. LTB-RIC rates for pts treated with ≥0.75mg/kg in the base and ext studies, respectively, were 68% (13/19) and 71% (10/14) for RS(+) pts vs 5% (1/22) and 2% (1/58) for RS(-) pts with EPO <200 U/L and 4% (1/23) and 5% (1/16) for RS(-) pts with EPO 200-500 U/L. Preliminary RS(-) response rates (IgW Hb-E and RBC-TI by subgroup) will also be presented at the meeting. Luspatercept was well tolerated, with related grade 3 serious adverse events in (3 pts) as of 23Nov2016 of blast cell count increase, myalgia, and worsening of general condition. The most common adverse events (≥2 pts) were diarrhea, fatigue, headache, hypertension, arthralgia, bone pain, injection site erythema, myalgia, and peripheral edema.

Summary/Conclusions: Lower-risk MDS patients treated long-term with luspatercept demonstrated robust and sustained increases in Hgb and decreases in transfusion burden and a high rate of RBC-TB. A Phase 3 study of luspatercept in regularly-transfused RS(+) patients with lower-risk MDS according to IPSS-R is ongoing (MEDALIST study; NCT02631070).

Background: Azacytidine (AZA) is the current standard of care for patients with high-risk myelodysplastic syndrome (MDS) in Europe. AZA has shown a
survival advantage when compared with conventional therapies and has also shown activity in IPSS lower-risk patients. However, about 40% of patients do not respond and most patients lose response within 2 years. Treatment options for MDS patients failing hypomethylating agents therapy are scarce and overall survival (OS) is extremely short.

Aims: Objectives of this study were to describe in a cohort of real life MDS patients treated with AZA, the reasons causing treatment discontinuation, and to evaluate the clinical outcome after the end of AZA therapy.

Methods: Unselected patients recorded in the MDS Registry of Fondazione Italiana Sindromi Mielodisplastiche (FISM) and treated with AZA from January 2009 to June 2014 were considered for the analysis. All types of conventional MDS patients were allowed. Clinical response, cause of discontinuation, salvage treatments and OS from discontinuation of AZA were the major end points.

Results: Between January 2009 to June 2014 1799 newly diagnosed MDS patients were enrolled in the Registry, and 418 received AZA; 269 as 1st line treatment (64%), 112 as 2nd line treatment (28%), and 34 as a line ≥3rd (8%). Median age was 73 years (range 18-91); 260 patients (62%) were male. WHO diagnosis was RA or RARS (n=27, 6%), RCMD with or without RS (n=62, 15%), APEX (n=126, 30%), APEX 2 (n=189, 45%), other subtypes (n=15, 4%). At start of AZA therapy IPSS score was low in 14 (3.4%), int-1 in 97 (23.2%), int-2 in 163 (43.8%), high in 67 patients (16%), and not available in 57 patients (13.6%). Patients received a median of 7 courses of treatment (range 1-63). Seventy-three % of the whole cohort (418 pts) were alive at 1 year from beginning of AZA therapy and median OS was 23 months, (25 for IPSS lower-risk MDS and 21 for IPSS higher risk MDS). OS after discontinuation of AZA was 8 months. Clinical responses according to IWG criteria were available in 344/418 patients (82%). Of these, 152 (44%) achieved a complete hematological response, 77 (22%), a partial response, 86 (25%) had stable disease while 39 (10%) did not respond. Response was achieved after a median of 6 cycles. After a median follow up of 16 months (range 7-35) in 37 (9%) patients AZA therapy was still ongoing while in 381 (91%) the treatment has been discontinued. Interruption of treatment was due to loss of response in 59 (16%) patients; AML evolution in 154 (40%), death in 11 (31%) patients, progression or loss of response and only in 10% of cases for reported toxicity. Only 28% of patients received any kind of salvage therapy and overall survival after AZA discontinuation was poor (8 months).

Methods: Children (0–18yrs) were referred from 14 UK centres with a diagnosis of suspected MDS and/or sustained cytopenias with morphological features of myelodysplasia. Extensive phenotypic information including family history, detailed clinical examination and disease course details were collected and captured on an online database using the Human Phenomiser tool. A customised targeted NGS panel was designed using the Illumina design studio containing 32 genes, 916 amplicons and 301 exons; selected through literature reports and well described mutations in Paediatric MDS and potential overlap Bone Marrow failure syndromes (BMFS). Coverage of each base within target regions was assessed for every sample on each sequencing run using Covemi software. Library preparation was performed using an Illumina TrueSeq Custom Amplicon panel, followed by sequencing on an Illumina MiSeq. Data analysis was performed using our established bioinformatic pipelines (Hamblin A: Blood 2014 124:2373).

Results: In total 59 patients (females= 29, males 30) have been screened and 3 subgroups identified based on the original suspected clinician diagnosis at presentation: MPN/JMML (n = 15), de novo MDS (n=9) and idiopathic cytopenias of undetermined significance, (ICUS) with some features of dysplasia (n=35). Mutations were detected in 24/59 patients (40%, Table 1). Of these, NGS results confirmed the original clinical diagnosis in 15 cases (62.5%); established the diagnosis for the first time in 6 cases (25%); and led to a change in diagnosis (from autoimmune neutropenia to Shwachman-Diamond Syndrome) in 1 case leading to a significant change in patient management. In two already known cases, it allowed monitoring of the disease molecular signature. As expected, PAS pathway mutations were common in the JMML/MPN (100%) and de novo MDS patient subgroups (33%). Additional mutations in epigenetic modifiers, spliceosome mutations as well as second PAS pathway hits were also detected in 40% of JMML patients and in one case within the de novo MDS group; this finding was associated with poor outcome. Within the heterogenous ICUS patient group, pathogenic mutations were identified in 5/35 (14.3%) cases with BMFS genes (SBDS, ELANE, TP53). In contrast to the other MDS/MPN cases, in this group, no PAS pathway mutations were detected.

Background: Paediatric Myelodysplastic Syndromes (MDS) are a rare and heterogeneous group of disorders distinct from adult MDS. They may present with syndromic anaemia, life threatening infection or evolving leukaemia; however, they may also present as unexplained cytopenias or with multisystem disease of unclear aetiology. Diagnosis can represent a huge challenge for clinicians, even in highly specialised centres and this can delay the delivery of the most appropriate treatment. Hence an accurate diagnosis is crucial in selecting the most appropriate surveillance and follow up strategy.

Aims: To devise a clinical grade diagnostic targeted NGS panel and combine the results with extensive clinical phenotypic information to obtain a diagnosis in children referred with suspected MDS.

Summary/Conclusions: Targeted NGS together with detailed phenotyping is a useful tool for the diagnosis of suspected MDS and unexplained cytopenias in children, with 40% of patients showing a disease-associated mutations. Results were available within 6-8 weeks in most cases enabling both rapid initial diagnosis and, in some cases, appropriate molecular markers for monitoring of clonal evolution and response to therapy. For the children who remain without a clinical diagnosis, whole genome sequencing (WGS) may identify pathogenic mutations and this is currently underway.
OUTCOMES IN PATIENTS ALLOCATED TO NO-ASCT BASED ON DEPTH OF RESPONSE: INITIAL RESULTS OF A PHASE 2 TRIAL ASSESSING THE IMPACT OF MINIMAL RESIDUAL DISEASE (MRD) IN PATIENTS WITH DEEP RESPONSES IN MM POST-PBSCH (NCT01790737) 1.

Aims: This is the first study to report outcomes of patients treated with lenalidomide (LEN) maintenance therapy in the context of minimal residual disease (MRD) assessment. The aim of this study was to assess the proportion of different lymphocyte subsets at baseline and during LEN maintenance treatment.

Methods: Flow cytometry (FC) panel included antibodies against CD38, CD138, CD45, CD19, CD56, CD27, CD28, CD81, CD117, intracytoplasmic CD38+, CD19+, CD56+, CD27+, CD28+, CD81+, CD117+, and FC analysis was performed on bone marrow aspirates at baseline and during LEN treatment.

Results: Between April 2011 and January 2014, 153 patients were enrolled. Median age at registration was 58 years (range 26-79). The proportion of mature B cells in BM was significantly higher in the best response cohort at baseline. In particular, the median percentage of total lymphocytes (15.4 vs 11.9), CD38+ T-cells (0.9 vs 0.56), and CD38+ lymphocytes other than B-cells and NK-cells (0.9 vs 0.5) were all higher in the good response cohort at baseline. In particular, the median proportion of mature B cells in BM was significantly higher in the best cohort at baseline (1.32 vs 0.91; p=0.02), after induction (0.27 vs 0.13; p=0.002) and 16 months after ASCT (1.73 vs 0.56; p=0.008) (Figure 1).

Summary/Conclusions: Composition of the BM lymphocyte pool at treatment baseline may have an influence on treatment outcome in multiple myeloma. More detailed subtyping of the lymphocyte phenotypes is ongoing and may reveal potential predictive biomarkers for immunomodulatory drugs such as lenalidomide and checkpoint inhibitors.

Figure 1.
SUMMARY/CONCLUSIONS: Our study showed that PET-CT and MRI would represent the techniques of choice in the assessment of bone involvement in MM patients in view of their high and comparable sensitivity. Moreover, PET-CT allowed detecting skeletal involvement in 18% of cases negative by WBX, in 37% of those CT-negative, and in 10% of those MRI-negative. Sensitivity of PET-CT was superimposable to that of MRI (90%), and higher than that of WBX (60%) and CT (73%). Nevertheless, PET-CT positivity either at diagnosis or during follow-up did not impact on long-term OS and PFS.

BACKGROUND: Lytic lesions occur in the majority of patients with multiple myeloma (MM) and represent one of the criteria for starting therapy. In the past, whole-body X-ray (WBX) represented the method of choice for detecting skeleton abnormalities; today, magnetic resonance imaging (MRI), positron emission tomography (PET) and computed tomography (CT) have been adopted for their higher power in detecting extra-medullary localizations and their higher sensitivity. Nevertheless, which technique would be really the best one is still matter of debate.

AIMS: Our single-center retrospective study was designed to compare PET-CT with other imaging techniques (WBX, vertebral column CT and MRI) at the diagnosis and during the follow-up of MM patients. Finally, we assessed a possible predictive/prognostic role of the PET-CT in terms of quality of response and survival.

METHODS: We enrolled 160 patients with diagnosed symptomatic (N=1419) or smoldering multiple myeloma (N=11) observed at the AOU. Pisa, Italy, between January 1996 and December 2015. Eighty-three were male and 77 female; the median age was 70 years (range, 28-85), and half of them presented with low ISS risk score. Forty-five subjects were not eligible to high-dose therapy; 64% of them received bortezomib- and 23% melphalan-based regimens. Patients eligible to high-dose therapy received VAD, TAD or VTD and then one (88%) or two (12%) autologous transplants. At the relapse, lenalidomide (50%) or anthracyclines (40%) were administered. Overall, we compared 160 PET-CT, 233 WBX, 106 CT, and 85 MRI exams. At diagnosis, PET-CT allowed detecting skeletal involvement in 18% of cases negative by WBX, in 37% of those CT-negative, and in 10% of those MRI-negative. Sensitivity of PET-CT was superimposable to that of MRI (90%), and higher than that of WBX (60%) and CT (73%). Nevertheless, the specificity was lower for PET-CT and MRI (40%) in respect of CT (51%) and WBX (71%). Analogously to that observed at diagnosis, PET-CT during follow-up showed distinct advantages in terms of sensitivity compared to X-rays (83% vs 60%, respectively). In contrast, PET-CT sensitivity was comparable to that of CT and MRI. As at diagnosis, the specificity was higher for WBX (70%) than for CT, RM and PET-CT (40% for all of these). When PET-CT was correlated to the quality of response, it was significant only in the not transplanted cohort (>PR rate in PET-negative cases: 87% vs 23% in the PET-positive group; p=0.016). Nevertheless, PET-CT positivity either at diagnosis or during follow-up did not impact on long-term OS and PFS.

Summary/Conclusions: The initial data indicate promising clinical potential for the combination of ibr+BTZ+dex. Treatment was generally well tolerated without any unexpected safety signals noted for the combination. The preliminary ORR of 47% after a minimum 2 treatment cycles is encouraging with further follow-up needed.

P673
PROGNOSTIC SIGNIFICANCE OF CLONAL CIRCULATING PLASMA CELLS BY MULTI-PARAMETRIC FLOW CYTOMETRY IN PATIENTS WITH LIGHT CHAIN AMYLOIDOSIS UNDERGOING AUTOLOGOUS STEM CELL TRANSPLANTATION

S. Sidana1, N. Tandon1, A. Dispenzieri1, M.A. Gertz1, F.K. Buadi1, M.Q. Lacy1, D. Dingli1, A.L. Fonder1, S.R. Hayman1, M.A. Hobbs1, Y.L. Hwa1, P. Kapoor1, R.A. Kyle1, N. Leung1, R.S. Go1, J.A. Lust1, S.J. Russell1, S.V. Rajkumar1, K. Kuma1, W.J.Kyle1

1Hematology, Mayo Clinic, Rochester, United States

BACKGROUND: Presence of circulating plasma cells (cPCs) prior to autologous stem cell transplant (ASCT) is an adverse prognostic factor in patients with light chain amyloidosis (AL). cPCs are detected by multi-parametric flow cytometry (MFC) prior to ASCT, and categorized them as follows: a) Group 1: patients proceeding directly to ASCT without induction therapy and b) Group 2: patients who received induction therapy before ASCT.
Results: There were 78 patients in Group 1 and 52 patients in Group 2. Patients in Group 2 had higher baseline fLC, bone marrow plasma cells (BMPC), Mayo stage and were more likely to have active MM compared to patients in Group 1. Table 1 lists baseline characteristics of the patients in Groups 1 and 2. Patients in Group 1 had higher rate of renal involvement. cPCs were detectable in 22% (n=28) of patients at the time of ASCT. More patients in Group 1 had detectable cPCs than in Group 2 (31% vs 8%; p=0.002), likely due to clearance of cPCs with treatment. Data on cPCs at diagnosis in the induction group was available in 14 patients, of whom 57% (n=8) had detectable cPCs vs 31% in the direct ASCT group (p=0.06). 6 of the 8 (75%) patients cleared cPCs with induction therapy. There were no significant differences in patients who had detectable and undetectable cPCs before transplant, including organ involvement, baseline fLC, BMPC, and Mayo Stage (data not shown).

In Group 2, both progression free survival (PFS) (10.5 months vs 58 months, p <0.0001) and overall survival (OS) (16 months vs not reached, p <0.0001) were worse in patients who had detectable cPCs compared to those without cPCs (Figure 1). This difference was not seen in Group 1 (OS: not reached vs 98 months, p=0.96; PFS 43 vs 52 months, p=0.74). In multivariate analysis, adjusting for Mayo Stage and induction chemotherapy, there was a trend towards worse OS in patients with detectable cPCs (p=0.06).

Table 1. Patients receiving induction chemotherapy before ASCT

</tbody>
</table>

Summary/Conclusions: cPCs are cleared after induction treatment in majority of AL patients. Patients who have detectable cPCs prior to proceeding to ASCT after induction have worse PFS and OS than patients without cPCs. On the other hand, presence of cPCs was not found to be an adverse prognostic factor in patients proceeding directly to ASCT. This may be due otherwise excellent prognostic in this group, with absence of other high-risk features that are seen in patients who require induction. A limitation of our study is lack of data on cPCs at diagnosis in all patients who received induction therapy.

P674

RENAI IMPAIRMENT IN MYELOMA - PATIENT CHARACTERISTICS, TREATMENT MODALITIES, STEM CELL TRANSPLANT & OUTCOMES FROM THE AUSTRALIAN AND NEW ZEALAND MYELOMA REGISTRY

P.J. Ho1,*, E. Moore2, Z. McQuilten2, K. Bergin2, B. Augustson3, H. Blacklock4, B. Rosengarten8, P. Walker9, E. Wood2, A. Spencer9

1Institute of Haematology, Royal Prince Alfred Hospital, Sydney, 2Department of Epidemiology and Preventive Medicine, Monash University, Melbourne, 3Dept of Haematology, Sir Charles Gardiner Hospital, Perth, Australia, 4Dept of Haematology, Melbourne Hospital, 5Dept of Haematology, University of Sydney, 6Dept of Haematology, Sydney Adventist Hospital, 7Dept of Haematology, Princess Alexandra Hospital, Brisbane, 8Dept of Haematology, St Vincent's Hospital, 9Myeloma Foundation of Australia

Background: Renal impairment (RI) is a poor prognostic factor in multiple myeloma (MM). Analysis of disease characteristics, therapy & outcomes can improve treatment & prognosis.

Aims: To assess (1) characteristics of patients with RI at diagnosis - severity of RI, age, risk factors, high-risk features, stage, disease manifestations & performance status, and (2) treatment including induction therapy & autologous stem cell transplant (ASCT) and outcomes.

Methods: Data from newly diagnosed MM patients enrolled in the Australian and New Zealand Myeloma Registry from 1 Feb 2013 to 31 Dec 2016 were analysed.

Results: Of 867 patients, 775 had eGFR available at diagnosis: 34% (287/775) had eGFR <60ml/min (22% at 30-60ml/min; 6% at 15-30ml/min; 6% at <15 ml/min). Mean age of patients with RI (<60 ml/min) was 72 vs 64 years without RI. Diabetes mellitus (DM), a major cause of chronic kidney disease (CKD), was more prevalent in patients with RI: 17% of patients with eGFR <30 ml/min compared with 8% >30ml/min. Patients with RI (<30ml/min) and DM had a similar response to first-line therapy compared to RI without DM (p=0.06), 75% vs 82%, p=0.56, with no difference in OS (26 vs 37 mths, p=0.68) or PFS (24 mths, p=0.82). High risk features of FISH (del17p, t(14;16), amp1q21, del1p), high LDH and high LDH were more prevalent in RI vs 46%, 30% vs 25%, respectively (p=0.01). Children were less common in advanced stage (ISS III) (66% vs 12% p=0.001). Anemia was more prevalent in RI (44% vs 14%, p<0.001), but bone lesions were less prevalent (52% vs 65% p=0.001). There was no difference in ECOG performance status. Most patients (87%) received Bortezomib-based therapy in first line (81% RI vs 91% no RI, p<0.001), with no difference with or without ASCT. Response rates (≥PR) were the same in patients with eGFR <60ml/min compared with normal renal function (84% vs 85%, p=0.87). PFS & OS decreased with reduction in eGFR (Fig 1). However, patients with eGFR15-30ml/min had better OS & PFS compared with eGFR 15-30ml/min; dialysis in eGFR <15ml/min may be a factor. Using age 70 yrs as a common age limit for ASCT, we analysed the effect of ASCT in patients <70 yrs with & without RI. While a smaller proportion of RI patients received ASCT (21% vs 79%, p=0.07), it was performed at all levels of renal function including eGFR <15ml/min. In patients with eGFR <60ml/min, those who received ASCT had a longer PFS (HR 0.37, 95%CI 0.16-0.88, p=0.03) & OS (HR 0.28, 95%CI 0.08-1.01, p=0.05) compared with no ASCT. The improvement was also seen in severe RI (<30ml/min), with a longer PFS (HR 0.21, 95%CI 0.05-0.86, p=0.03) & OS (HR 0.10, 95%CI 0.01-0.82, p=0.03) with ASCT.

Figure 1. Summary/Conclusions: RI occurred in one-third of newly diagnosed MM. DM, an underlying risk factor for CKD, was more common in RI patients, but not associated with a difference in outcome. Advanced stage & high risk features were more prevalent in RI patients, but bone disease was less common. RI patients had a shorter PFS and OS, overall correlating with eGFR. However patients with eGFR <15ml/min had a better OS than 15-30 ml/min, for which dialysis may be a factor. In transplant-eligible patients assessed by age <70 yrs, ASCT was performed in 21% of RI patients, at all levels of renal function. Patients with RI who underwent ASCT had a superior PFS and OS than those who did not have ASCT, including those with severe RI (eGFR <30ml/min), supporting the benefit of ASCT in MM patients with RI.

P675

VENETOCLAX AS TARGETED THERAPY FOR RELAPSED/REFRACTORY MULTIPLE MYELOMA

1Mayo Clinic, Rochester, 2Winship Cancer Institute of Emory University, Atlanta, 3Mayo Clinic, Scottsdale, 4Duke University, Hematologic Malignancies & Cellular Therapy, Durham, 5Washington University School of Medicine, St. Louis, United States, 6CHU Grenoble, Grenoble, 7CHRU Tours, Tours, 8CHRU Lille, Lille, 9CHU de Nantes, Hotel Dieu–HME, Nantes, France, 10AbbVie Inc., North Chicago, United States

Background: Venetoclax (VEN), an orally available selective small-molecule
BCL-2 inhibitor, induces cell death in multiple myeloma (MM) cells, particularly those with the t(11;14) translocation.

**Aims:** The objectives of the study are to evaluate safety, PK, recommended phase two dose, and preliminary efficacy of VEN monotherapy in relapsed/refractory (R/R) MM.

**Methods:** Patients (pts) with relapsed/refractory (R/R) MM received VEN monotherapy in this phase 1 study. Daily VEN was given at 300–1200mg in dose escalation cohorts and 1200mg in the safety expansion. Pts with disease progression (PD) on VEN monotherapy could receive VEN plus dexamethasone and remain on study.

**Results:** As of 19Aug2016, 66 pts were enrolled. Median age was 63 years and 30 (46%) pts had t(11;14). Median number of prior lines of therapy was 13 (range: 1–15); 46 (70%) pts were refractory to bortezomib, 20 (30%) to carfilzomib, 51 (77%) to lenalidomide, 35 (53%) to pomalidomide, and 52 (79%) were refractory to the last prior therapy. Median time on VEN monotherapy was 2.5 months (range: 0.2–23); 17 pts received VEN plus dexamethasone after PD for a median of 1.8 (range: 0.1–15) months. Fifty-five (83%) pts discontinued, with 41 due to PD. Common adverse events (AEs) were nausea (47%), diarrhea (36%), vomiting (21%) and 23% of grade 3/4 hematologic toxicities [thrombocytopenia (23%), neutropenia (27%), anemia (23%), leukopenia (23%)]. Common serious AEs were pneumonia (8%), sepsis (5%), cough, hypotension, pain, and pyrexia (3% each). There were no events of TLS. Six deaths were reported due to PD, and 1 each due to lung disorder and brain hemorrhage following trauma. Overall response rate (ORR) for all pts on VEN monotherapy was 21% (14/66); 15% achieved very good partial response (VGPR) or beyond. Staging was updated to: SKY92 standard-risk 53 months, SKY92 high-risk 21 months. A clear difference in responses was seen among pts with t(11;14) vs without [ORR, 40% vs 6%; vGVPR, 27% vs 6%]. For pts with t(11;14), median TTP was 6.6 months [vs 1.9 months for pts without t(11;14)] and median DoR was 9.7 months. A high BCL2:BCL2L1 (BCL-X) gene expression ratio was observed in 10/44 (23%) baseline tumor samples, enriched in pts with t(11;14) compared with non-t(11;14) (38% vs 5%) and associated with clinical response; 80% (8/10) of pts [all t(11;14)] with a high BCL2:BCL2L1 ratio achieved ≥PR with a median TTP of 11.5 months. Among pts with t(11;14) who were refractory to the last therapy, ORR was 42% (11/26); for t(11;14) pts refractory to both bortezomib and lenalidomide, ORR were refractory to bortezomib, carfilzomib, lenalidomide, and pomalidomide, ORR were 40% (8/20) and 50% (3/6), respectively. No difference was seen in ORR for t(11;14) pts with high-risk del(17p) versus those without the deletion [40% (2/5) vs 40% (10/25)].

**Summary/Conclusions:** VEN has an acceptable safety profile with promising single-agent anti-myeloma activity in pts with R/R MM positive for t(11;14) who failed multiple prior lines of therapy.

---

**AN OPEN-LABEL, PHASE 1B STUDY (MMY1001) OF DARATUMUMAB COMBINED WITH CARFILZOMIB, LENALIDOMIDE, AND DEXAMETHASONE (KRd) IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA (MM) WITH t(11;14)**

S.Z. Usmani1,†, A. Char2, S. Lonia3, B. Weiss1, R.L. Comenzo5, K.Wu6, N.Z. Khokhar6, J. Wang2, P. Doshi2, A. Jakubowiak7, 1Levine Cancer Institute/Carolinaars HealthCare System, Charlotte, NC, 2Tisch Cancer Institute, Mount Sinai School of Medicine, New York, NY, 3Division of Hematology and Medical Oncology, Winship Cancer Institute, Emory University, Atlanta, GA, 4Abramson Cancer Center and Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, 5Division of Hematology/ Oncology, John C. Davis Myeloma and Amyloid Program, Tufts Medical Center, Boston, MA, 6Janssen Research & Development, LLC, Spring House, PA, 7Janssen Research & Development, LLC, Rantan, NJ, 8University of Chicago Medical Center, Chicago, IL, United States

**Background:** The combination of daratumumab with standard of care regimens has demonstrated significantly prolonged progression-free survival (PFS), deeper responses, and a manageable safety profile versus standard care alone in patients with relapsed or refractory MM.

**Aims:** To determine the tolerability and efficacy of daratumumab in combination with KRd in patients with newly diagnosed MM.

**Methods:** This open-label, phase 1b study enrolled patients with newly diagnosed MM (t(11;14) confirmed). An open label, adaptive 3+3 dose escalation study was conducted in eight independent cohorts, at the time of its initial publication, and since.

**Results:** As of 20Oct2016, 22 pts were enrolled in the study; median (range) patient age was 60 (34–74) years, and 95% had an ECOG score of ≤1. At a median (range) follow-up duration of 7.4 (4.0–9.3) months, the majority of patients remained on treatment and had received a median of 8 (1–10) treatment cycles. Six patients discontinued treatment, 1 due to an adverse event (AE; pulmonary embolism), 1 due to progressive disease, and 4 due to “other” (all ASCT). The dose of carfilzomib was increased to 70mg/m2 in 19 patients by Cycle 1 Day 15. Serious treatment-emergent AEs (TEAEs) occurred in 46% of patients, 14% and 18% of which were at least possibly related to daratumumab or carfilzomib, respectively. Eighteen (82%) patients had a grade 3/4 TEAE, most commonly (>10%) lymphopenia (50%) and neutropenia (23%). One (5%) patient experienced a grade 3 cardiac TEAE (congestive heart failure) which resolved; the patient was able to resume study treatment at a reduced carfilzomib dose. There were no grade 5 TEAEs. Six (27%) patients had daratumumab-associated non-HSCT/SAEs, all Grade 1 or 2 in severity. ORR with daratumumab in combination with KRd was 100% among the 21 response-evaluable patients: 18 (86%) patients achieved a very good partial response or better and 1 patient (5%) achieved a complete response. Median duration of response has not been reached. With only 1 FFS event having occurred at the an of 1.4 months (range: 0.1–13). Fifty-five (83%) pts discontinued, with 41 due to lenalidomide, 35 (53%) to pomalidomide, and 52 (79%) were refractory to the last therapy, ORR was 42% (11/26); for t(11;14) pts refractory to both bortezomib and lenalidomide, ORR were 40% (8/20) and 50% (3/6), respectively. No difference was seen in ORR for t(11;14) pts with high-risk del(17p) versus those without the deletion [40% (2/5) vs 40% (10/25)].

**Summary/Conclusions:** Daratumumab in combination with KRd was well tolerated, with an overall safety profile consistent with previous reports for KRd. No additional toxicity occurred with the addition of daratumumab, and deep and durable responses were achieved. Preliminary data from this ongoing study support continued investigation of daratumumab plus KRd as a first-line treatment regimen for patients with newly diagnosed MM. Updated data based on longer follow-up will be presented.
Table 1. Multivariate survival analysis in the HO87/NM18 trial.

| ICD 8.9 and 10 codes, comorbid diseases were identified. Kaplan-Meier curves were used to estimate survival. Risk of death was compared among multiple myeloma patients with a comorbid condition to those without a comorbidity, using Cox’s proportional hazards regression (adjusting for age, gender, year of diagnosis, and other comorbid conditions).

**Results:** A total of 13,718 patients with multiple myeloma were included in the study and 21 groups of comorbidities were identified. The most common diseases were cancer, hypertension, heart failure, ischemic heart disease and atrial fibrillation. Among all patients, 55% had no prior history of comorbidity, 23% had one comorbidity, 12% had two comorbidities, and 10% had three or more comorbid conditions. Survival was negatively influenced by the number of comorbidities (Figure 1). The risk of death was significantly increased in patients with atrial fibrillation (HR=1.08; 95% CI 1.00-1.16), heart failure (HR=1.50; 95% CI 1.40-1.61), stroke (HR=1.20; 95% CI 1.11-1.30), psychological disease (HR=1.27; 95% CI 1.16-1.39), chronic lung disease (HR=1.22; 95% CI 1.12-1.32), diabetes (HR=1.14; 95% CI 1.04-1.36), peripheral vascular disease (HR=1.26; 95% CI 1.12-1.42), cancer (HR=1.10; 95% CI 1.04-1.16), dementia (HR=1.65; 95% CI 1.38-1.99), paralysis (HR=1.44; 95% CI 1.15-1.80), inflammatory bowel disease (HR=1.38; 95% CI 1.08-1.74), end stage renal disease (HR=1.57; 95% CI 1.03-2.04), and cirrhosis (HR=1.64; 95% CI 1.10-2.43).

**Summary/Conclusions:** Here, we compared the SKY92 classifier with revised ISS staging and FISH. These data validate the SKY92 classifier as a robust marker to identify high-risk patients in non-transplant eligible MM patients. In these IMiD treated patients, the SKY92, the revised ISS, and FISH markers such as deletion of 13q retain independent prognostic value.

**P678**

**MULTIPLE MYELOMA AND COMORBIDITY: A POPULATION-BASED STUDY**

I.S. Sverrisdotter1,2,*, S. Rögnvaldsson2, S. H. Lund2, I. Turesson3, M. Hultcrantz4, M. Björkholm5, O. Landgren4, S.Y. Kristinsson2

1Internal Medicine, Landspílah, 2Faculty of Medicine, University of Iceland, Reykjavik, Iceland, 3University Hospital Malmö, Malmö, Sweden, 4Division of Hematology, Oncology, Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, United States, 5Department of Medicine, Karolinska University Hospital and Karolinska Institutet, Stockholm, Sweden

**Background:** The number of multiple myeloma patients has grown with aging populations, and with increasing age the number of comorbidities increases as well. Clinically, it is well known that comorbidity in multiple myeloma patients decreases performance status, increases risk of therapy-related complications and may lead to life-threatening conditions. Currently, the literature on comorbidity in multiple myeloma is very limited and based on small case series. Clinical trials rarely include elderly, frail patients due to eligibility criteria. Population-based studies provide valuable information on survival outcomes in relation to presence/absence of comorbidities in newly diagnosed real-life multiple myeloma patients in the general population.

**Aims:** To evaluate the prevalence of comorbidities and to study the impact of comorbidities on survival among patients with newly diagnosed multiple myeloma.

**Methods:** All newly diagnosed patients with multiple myeloma from January 1st, 1985 to December 31st, 2013 in Sweden were included in the study. Using the Swedish Patient Registry, all discharge diagnosis and discharge listings were gathered from each patient from January 1st, 1985. Comorbid conditions were defined as chronic illnesses which demand life-long treatment or follow-up. Only those diagnoses made prior to multiple myeloma were used. Using ICD 8.9 and 10 codes, comorbid diseases were identified. Kaplan-Meier curves were used to estimate survival. Risk of death was compared among multiple myeloma patients with a comorbid condition to those without a comorbidity, using Cox’s proportional hazards regression (adjusting for age, gender, year of diagnosis, and other comorbid conditions).

**Results:** A total of 13,718 patients with multiple myeloma were included in the study and 21 groups of comorbidities were identified. The most common diseases were cancer, hypertension, heart failure, ischemic heart disease and atrial fibrillation. Among all patients, 55% had no prior history of comorbidity, 23% had one comorbidity, 12% had two comorbidities, and 10% had three or more comorbid conditions. Survival was negatively influenced by the number of comorbidities (Figure 1). The risk of death was significantly increased in patients with atrial fibrillation (HR=1.08; 95% CI 1.00-1.16), heart failure (HR=1.50; 95% CI 1.40-1.61), stroke (HR=1.20; 95% CI 1.11-1.30), psychological disease (HR=1.27; 95% CI 1.16-1.39), chronic lung disease (HR=1.22; 95% CI 1.12-1.32), diabetes (HR=1.14; 95% CI 1.04-1.36), peripheral vascular disease (HR=1.26; 95% CI 1.12-1.42), cancer (HR=1.10; 95% CI 1.04-1.16), dementia (HR=1.65; 95% CI 1.38-1.99), paralysis (HR=1.44; 95% CI 1.15-1.80), inflammatory bowel disease (HR=1.38; 95% CI 1.08-1.74), end stage renal disease (HR=1.57; 95% CI 1.03-2.04), and cirrhosis (HR=1.64; 95% CI 1.10-2.43).

**Summary/Conclusions:** In this large, population-based study including almost 14,000 patients, we have shown that comorbidities are common among newly diagnosed multiple myeloma patients and that comorbidities are associated with an inferior survival. Importantly, the number of comorbidities showed a dose-response relationship with inferior overall survival. For example, the median overall survival for patients with 3 or more comorbidities was reduced by more than 50% compared to patients without comorbidities. The importance of comorbidities should be taken into account when evaluating patients and deciding on treatment strategies for individuals with multiple myeloma.
Myeloma and other monoclonal gammopathies - Clinical 4

P679
DETECTION OF NEW EMERGING CLONES DURING TREATMENT BY NGS ALLOWS A BETTER RISK PREDICTION ON MULTIPLE MYELOMA PATIENTS
1Hematología Traslacional, Hospital 12 de Octubre, Madrid, 2Hospital Universitario de Salamanca, Instituto de Investigacion Biomedica de Salamanca (IBSAL), Centro de Investigación del Cáncer (IIBMCC CSIC-USAL), Salamanca, 3Centro Universitario de Navarra, Centro de Investigación Medica Aplicada Instituto de Investigación Sanitaria de Navarra, Pamplona, 4Hospital Clinic, Barcelona, Spain

Background: Multiple myeloma (MM) is a genetically complex disease, characterized by the presence of multiple clones with differing degrees of drug sensitivity at the time of diagnosis. Consequently, therapeutic response of MM patients is unpredictable and extremely variable, and although the treatments introduced over the last decade have significantly improved the outcome of these patients, most patients eventually relapse. Deep sequencing methods have contributed to increase the knowledge about the clonal heterogeneity of the disease and helped to establish the three evolution patterns at relapse: linear and branching clonal evolution, and no clonal changes.

Aims: To analyze the diversity and relative dominance of different clones and their evolution throughout the course of disease by NGS of the immunoglobulin repertoire in MM patients. To evaluate if the presence of different clones is associated with increased risk.

Methods: Immunoglobulin repertoire was analyzed by NGS in bone marrow samples from 180 MM patients included in three GEM clinical trials (NCT00461747, NCT00443235 and NCT01237249). The two first clinical trials involve patients younger than 65 years old, and were analyzed with ChoroSeq methodology, the later one involve patients older than 65 years old, and were analyzed with a local NGS method recently validated (Martinez-Lopez et al, Laukemia 2017). A clonotype was identified when at least 40 identical sequencing reads were obtained, or it is present at a frequency of >1%.

Results: Of the 180 MM patients studied, 57 (32%) shows the presence of more than one clone throughout the clinical course of the disease. The identification of new evolving clones was only possible in the GEM10 clinical trial with the Local NGS method; in this clinical essay, 6% (4/71) of patients shows the development of different clones during treatment. We show that the frequency of the predominant clone at diagnosis of these four patients decreased with treatment, but the frequency of the new ones increased and the patients progressed. When more than one clone is present at diagnosis, the relative dominance of the clones varies throughout the course of disease in a fashion that is unpredictable in each patient. There were no differences in median MRD values between patients with one clone or more than one clone (0.0082% and 0.0055% respectively). The presence of more than one clone was not associated with high-risk cytogenetics. The presence of more than one clone at diagnosis does not condition the prognosis in any of the patients and treatments analyzed. Median PFS was 38 and 58 months for patients with one clone or more than one clone (0.0082% and 0.0055% respectively). Median age was 63 y, median time from diagnosis 5.1 y, median prior tx lines 2, and 94% had refractory disease. Cyto genetic data were available for 59 pts; 33% were high risk per IMWG. There were 9 dose-limiting toxicities, all asymptomatic cytopenias: 8 pts with grade (G) 3 lymphopenia and 1 with grade (G) 4 thrombocytopenia. The MRD was estimated at DL3. In 64 pts, G3/4 hematologic toxicities included neutropenia (25%) and lymphopenia (14%), and non-hematologic toxicities (all grades) included fatigue (51%), dyspnea (42%), and gastrointestinal (45%). PRs were high with a >PR rate of 63% after 1 cycle and 77% after 4 cycles. After a median of 20.9 cycles (range, 1–49), ≥PR rate was 95%, ≥vPR 77%, ≥CR 45%, ≥nCR 13%, and ≥ncomplete response (nCR) 20%. The 1st population (n=55, 51 LEN-refractory, 28 progressing on LEN maintenance), ≥PR was 84% with 30 treated at MTD. After median follow-up of 21 (1–49) mo, median progression-free survival (PFS) for all 64 pts enrolled was 16.8 mo and 2-y overall survival (OS) was 76.8% with 20 pts remaining on treatment. For standard-risk (n=38) vs high-risk pts (n=21), ≥PR was 89% vs 81%, ≥nCR was 24% vs 10% median, and OS was 22.3 ± 10.6 y, and 2-y OS was 90.8% vs 56.0%.

Summary/Conclusions: NGS is a well tolerated and highly active (>PR 84%) with encouraging PFS (median 16.8 mo) in a RRMM pt population that was mostly LEN-refractory and PI-naive/sensitive. The results support planned evaluation of NGS with daratumumab in RRMM, particularly for high-risk pts.

Background: Immunotherapy with the anti-CD38 monoclonal antibody (mAb) daratumumab is increasingly being utilized in myeloma patients with relapsed/refractory (R/R) disease after prior treatment with immunomodulatory drugs (IMiDs) and proteasome inhibitors (PIs). However, the efficacy of dara tumumab is limited by low expression on neoplastic plasma cells. We inves tigate the use of the histone deacetylase inhibitor (HDACi) panobinostat to modulate target antigen expression on myeloma in favor of potent mAb-mediated recognition and destruction. We show that panobinostat augments CD38 expression specifically on myeloma cells and demonstrate powerful synergy with anti-CD38 mAb daratumumab.

Aims: Determine the impact of panobinostat on upregulation of CD38 expression on myeloma cells in order to enhance the efficacy of daratumumab.

Methods: Myeloma cells were treated with titrated doses of panobinostat (0, 10, 20, 25 nm) and expression of CD38 and a panel of additional target molecules including SLAMF7, as well as CD4+ T cells co-cultured with myeloma cells exposed to panobinostat at 24, 48 and 72 hours. Antibody-dependent cellular cytotoxicity (ADCC) against panobinostat treated and untreated myeloma cells was analyzed at 4 and 20 hours after addition of PBMC at an effector to target ratio of 25:1 in the presence of daratumumab or an isotype control antibody.

Results: Panobinostat treatment (n=12 patients) with panobinostat (10 vs 25 nm) and observed a uniform increase in CD38 expression in each case by flow cytometry. Upregulation of CD38 was already detectable after 24 hours, peaked after 48 hours of exposure to panobinostat and was higher at the 25 nm compared to the 10 nm dose. At 48 hours, the mean fluorescence intensity (MFI) of CD38 expression on CD138+ myeloma cells was increased 5.6-fold by panobinostat-treated compared to untreated myeloma (p<0.01). The increase in CD38 was equal in patients with previously untreated (n=5) and R/R myeloma (n=7); and could be confirmed in a panel of myeloma cell lines, including MM1.S and OPM-2. The panobinostat-induced upregulation of CD38 was rapidly reversible after drug withdrawal. Further, the effect of panobinostat on upregulation after panobinostat treatment was specific for myeloma and neither observed this phenomenon in a panel of leukemia and lymphoma cell lines, nor on primary CD8+ and CD4+ T cells that we isolated from peripheral blood of several donors.
and del(17p).

Responses in high vs achieving a VGPR or better. Median TTP (11.6 months) were longer for patients with high BCL2 expression (HRadj.=2.1 (95% CI 1.3–3.3), Fig. 1). In the period after the introduction of bortezomib 15% of patients became dialysis independent compared to 4% in the pre-bortezomib period (HRadj.=2.1 (95% CI 1.3–3.3), Fig. 1). In addition, patients who started dialysis in the period after bortezomib was introduced became dialysis independent more rapidly than in the pre-bortezomib period (1.2 compared to 1.7 years; p < 0.001).

Summary/Conclusions: Targeting BCL-2 and MCL-1 with the combination of VEN, BTZ and dexamethasone provides a unique approach for MM treatment. Efficacy results in tumors expressing high BCL2 levels, including 94% ORR, provide supportive evidence for the evaluation of this combination regimen in the ongoing phase 3 study (NCT02755597) in R/R MM.

THE IMPACT OF THE INTRODUCTION OF BORTEZOMIB ON DIALYSIS INDEPENDENCE IN MULTIPLE MYELOMA PATIENTS WITH RENAL FAILURE: A NATIONWIDE DUTCH POPULATION-BASED STUDY

B. Oortgiesen1,*, R. Azad 1, M. Hemmelder 2, R. Kibbelaar 3, N. Veeger 4, J. de Vries5, E. van Roon16, M. Hoogendoorn 5, J. Ross1,*, B. Chyla1, R. Goswami1, L. Roberts-Rapp1, Y. Sun1, Y. Jiang2, E. Punnose2, M. Verdugo1, A. Bhatena1, P. Maciag1

1AbbVie, Inc., North Chicago, 2Genentech Inc., South San Francisco, United States

Background: Renal insufficiency is common at presentation in patients with multiple myeloma (MM) and associated with a poor survival. Approximately 10% of the patients require dialysis. Studies have shown that the novel agent bortezomib has a positive effect on recovery of renal function in MM patients with renal insufficiency.

Aims: The aim of this study is to determine the effect of the revised guideline, including the introduction of bortezomib as first line treatment in MM patients with dialysis dependence, on renal function recovery.

Methods: All patients on renal replacement therapy (RRT) in the Netherlands are registered in the Dutch registry Renine. Data on age, gender, start date of RRT, type and switches of RRT or hospitals, primary renal diagnosis, date of death and cause of death are collected. In this nationwide population-based study, we selected all patients with MM registered in Renine between January 2002 and January 2016. No information regarding therapy of MM is provided in Renine. In March 2010, bortezomib was advised as first-line treatment in patients suffering from MM with renal impairment in the Dutch guidelines. Therefore, we divided our cohort in two periods: before the bortezomib guideline (January 1, 2002 till March 29, 2010) and after introduction of the bortezomib guideline (March 29, 2010 till January 1, 2016).

Results: A total of 700 patients were included in the study (422 patients pre-bortezomib and 278 after bortezomib introduction). In the period after the introduction of bortezomib 15% of patients became dialysis independent compared to 8% in the pre-bortezomib period (HRadj.=2.1 (95% CI 1.0–4.2) and HRadj.=5.7 (95% CI 2.5–13.2), respectively).

Figure 1.

Summary/Conclusions: In this nationwide population-based study, covering all patients with MM and concomitant renal failure, almost a two-fold increase of patients becoming dialysis independent occurred in the period after the introduction of bortezomib compared to the pre-bortezomib period. This was even more prominent when age was < 75 years and LCDD was the primary renal disease.
Background: The immunomodulatory agent pomalidomide is active in patients with relapsed/refractory multiple myeloma, including those who failed prior lenalidomide and bortezomib. Phase II clinical trials showed that pomalidomide is also effective in primary AL amyloidosis. After this drug was marketed for multiple myeloma (in Italy since September 2015), it became routinely accessible also to patients with myeloma-associated AL amyloidosis, a particularly fragile population.

Aims: Aim of this study is to report the efficacy of pomalidomide and dexamethasone in patients with multiple myeloma-associated AL amyloidosis.

Methods: The databases of the Pavia Amyloid Research and Treatment Center were searched for patients with a diagnosis of multiple myeloma and AL amyloidosis. The final cohort included 61 patients who had received 28-day cycles of pomalidomide (4mg from day 1 to 21) and dexamethasone (20/40mg weekly). All patients gave written informed consent for their clinical data to be used for research purposes, in accordance with the Declaration of Helsinki. Thirty patients were treated to date. Hematologic and organ response were assessed according to the International Society of Amyloidosis criteria.

Results: Median age was 65 years (range: 34-85 years) and 22 (73%) patients were man. Heart involvement was present in 13 patients (43%) and kidney involvement in 18 (60%). Forty (13%) patients were in Mayo Stage I, 17 (57%) in stage II and 9 (30%) in stage III. Fifteen (50%) subject were in renal stage I, 8 (27%) and 3 (23%) were in renal stage II and III respectively and 5 (16%) patients were on dialysis at the time of P Dex initiation. Median bone marrow plasma cell infiltration was 20% (range: 12-90%). Twenty-three (76%) patients were refractory to all previous lines of therapy. Median time from diagnosis to treatment with pomalidomide was 71 months [interquartile range (IQR): 25-120 months]. Adverse events were observed in 5 (17%) of subjects: skin rash and confusion in one patient each and mild increase in serum creatinine in 3 (10%, resolved with the decrease of the dose of pomalidomide). The median number of prior treatments (excluding Alzheimer’s disease) was 3 (range 1-7). All patients previously received lenalidomide and an alkylating agent, only 3 patients were not exposed to bortezomib, due to severe peripheral nervous system involvement, 10 (33%) underwent autologous stem cell transplantation and 9 (30%) received previous thalidomide-based regimens. The median number of P Dex cycles performed was 4 (range: 1-11). Median follow-up of living patients was 6 months (IQR: 3.5-16 months) and 13 (43%) patients died due to progressive disease. Fourteen patients (47%) achieved at least partial response, with 1 complete remission (CR), and very good partial responses (VGPR) in 2 cases (6%). Cardiac responses were observed in 1 of 5 patients with measurable NT-proBNP (20%), but this can be underestimated due to the pomalidomide-related increase of NT-proBNP, and renal response in 3 of the 11 evaluable patients (27%).

Summary/Conclusions: The combination of pomalidomide and dexamethasone is well tolerated and effective in multiple myeloma-associated AL amyloidosis and can be a valuable rescue option in this high-risk population.

WHEN PERFORMANCE OF CYTOGENETICS MATTERS: A POPULATION-BASED STUDY IN THE NETHERLANDS ON NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS

M. Brink1, O. Visser1, M.C. Minnema2, S. Zweegman3, P. Sonneveld4, A.G. Dimmohamed5

1Department of Hematology, University Medical Center Utrecht, Utrecht, 2Department of Hematology, VUMc, Amsterdam, 3Department of Hematology, Erasmus MC Cancer Institute, 4Department of Public Health, Erasmus University Medical Center, Rotterdam, Netherlands

Background: It was recently shown in both clinical and population-based series that unperformed cytogenetics (UPCs) in intensively treated patients with acute myeloid leukemia was independently associated with poor prognosis, as compared to patients with performed cytogenetics.

Aims: Therefore, we set out to assess whether UPCs is associated with poor outcome in young patients with symptomatic multiple myeloma (MM) who have received induction chemotherapy.

Methods: We identified 358 newly diagnosed patients with MM <66 years in one of the nationwide population-based Netherlands Cancer Registry (NCR). UPCs was used to indicate that no sample was sent in for cytogenetic analysis. Performed cytogenetics were grouped by Revised International Staging System (R-ISS), i.e. high-risk (presence of translocations (4;14) or (14;16) or deletion 17p) or standard-risk (presence of other aberrations or no aberrations). Only patients treated with induction chemotherapy, defined as treatment with VCD, PAD, BD or TAD +/- subsequent high dose dexamethasone and autologous stem cell transplantation (ASCT), were included for analyses. In total, 319 (89%), median age 60 years, 62% male were treated with induction chemotherapy, 39 patients (12%) had no therapy. The primary endpoint was progression-free survival (PFS), defined as time from start of first line induction chemotherapy to progression or death, whichever comes first. Patients alive without progression were censored at February 1st, 2016.

Results: In 230 (20%) patients, UPCs was used to indicate that no sample was sent in for cytogenetic analysis. Cytogenetics was performed and 63 of these patients (29%) were cytogenetically high-risk. No statistical significant differences were observed in CRB criteria or ISS between patients with or without performed cytogenetics. The proportion of patients undergoing ASCT was similar in different cytogenetic groups (standard-risk 85%, high-risk 83% and UPC 77%, p=0.77). Achieving partial response or better was higher, although not statistically significant, in the standard-risk group as compared to the high-risk and UPC groups (93% vs 89% vs 85%, p=0.92). Response outcome was unknown for 9% of the UPC group, 5% in high-risk group and 4% in the standard-risk group. Median follow-up time was 516 days. PFS for patients in the standard-risk group was highest, as compared to patients in the high-risk or UPC groups after one year of follow-up (88% vs 81% vs 74%, p=0.0003).

Summary/Conclusions: Our data show that cytogenetic testing is performed less frequently in the UPC group, which is 70% of MM patients <66 years. Although response rates were similar for patients in the UPC, standard- and high-risk groups, PFS was better in the standard-risk group. Patients with unperformed cytogenetics had the poorest outcomes. The reasons are unclear, but a plausible explanation for not performing cytogenetics could be the patients’ worse clinical condition at presentation. Therefore, UPCs requires immediate correction. As this is a cross-sectional study, no conclusions can be drawn. To our knowledge, this is the first study to address the correlation between UPCs and survival in MM patients treated with induction chemotherapy.

BACKGROUND: To contextualize the benefit of novel agents such as daratumumab (DARA) monotherapy for the treatment of patients with heavily pre-treated and highly refractory multiple myeloma (MM), it is critical to understand the real-world outcomes of this patient population on current standard of care (SOC) therapies. To determine the comparative effectiveness of DARA vs real-world SOC, an adjusted comparison was conducted utilizing data from the DARA monotherapy trials and the International Myeloma Foundation (IMF) chart review.

Aims: The objective of this analysis is to update the adjusted comparison to include additional Swedish patients from the IMF chart review.

Methods: Data for patients treated with DARA 16mg/kg monotherapy were available from clinical trials MYMY2002 (n=106) and GEN501 (n=42), while patients treated with SOC therapies were derived from the IMF chart review of patients with MM who had ≥3 prior lines of therapy and were double refractory to a proteasome inhibitor (PI) and an immunomodulatory drug (IMiD) (n=550, original 510, additional Swedish patients 40). Patients from the IMF-cohort who moved into further treatment lines after the line therapy where they fulfilled inclusion criteria, contributed information to the analysis for multiple lines of therapy, with baseline defined as the date of initiation of the actual treatment line, resulting in a total of 963 treatment lines from 550 patients treated with SOC. The relative survival effect of DARA versus SOC was estimated using multivariate Cox regression analyses. The methodology utilized individual patient data to compare overall survival (OS). The covariates included were age, gender, prior lines of therapy, albumin, beta-2 microglobulin, prior exposure to pomalidomide and carfilzomib, and pretreatment frailty status. Clustering of observations at the treatment-line level within patients was controlled for using the robust sandwich estimate for the covariance matrix. Statistical significance testing was performed using a two-tailed P-value of <0.05, and all comparisons between treatment groups were reported with hazard ratios (HRs) and 95% confidence intervals (CIs).

Results: After adjustment for differences in baseline characteristics included in the multivariate model between the DARA and SOC groups, results showed a significant improvement in favor of DARA compared with SOC for OS (HR=0.42 [95% CI 0.31–0.57]). When limiting the comparative analysis to European patients from the IMF cohort (n=341), results for OS are very similar (HR=0.40 [95% CI: 0.28-0.58]).

Summary/Conclusions: Findings from the regression analyses using the updated IMF dataset were consistent with results from the previous analysis3 and suggest that DARA is associated with significant gains in OS compared with SOC therapies for patients with heavily pre-treated and highly refractory MM. Findings for a European subset from the IMF dataset were similar to results from the entire cohort.

PREDICTORS OF EARLY DEATH RELATED TO ACTIVE MULTIPLE MYELOMA IN ELDERLY PATIENTS RECEIVING OPTIMIZED FRONTLINE TREATMENT COMBINATIONS

BACKGROUND: Multiple Myeloma (MM) is predominantly a disease of the elderly and the outcome of these patients is poorer than that of transplant candidates. It is well established that those considered frail or unfit have a dismal prognosis, however, even within fit patients, such as those included in clinical trials, there is substantial proportion of early deaths (within the first 2 years after diagnosis). Identification of this “high-risk” fit elderly patients could contribute both to the design of innovative clinical trials, and to avoid the emotional and economical burden due to early death in active MM.

Aims: To analyze the factors associated with early death (within first 2-years) due to active MM in elderly newly diagnosed (NDMM) patients fit enough to be included in clinical trials with optimized therapy with proteasome inhibitors and IMiDs.

Methods: 497 NDMM not transplant candidates treated in two prospective GEM-PETHEMA trials were included in the study: GEM05MAS65 (n=260) used frontline treatment with either bortezomib-melphalan-prednisone (VMP) or bortezomib-thalidomide-prednisone followed by maintenance with bortezomib, thalidomide or bortezomib, prednisone; the GEM2010MAS65 (n=239) compared induction with sequential or alternating cycles of VMP + lenalidomide-dexamethasone. The event was defined as death related to active MM within 2 years from diagnosis, either because of disease progression or early death due to absence of response.

Table 1.

Results: From the 497 patients included, 77 (15%) patients died within 2 years from diagnosis due to active MM. When we compared this latter cohort with the remaining patients, the profile of the high risk group was characterized (Table 1) by a higher proportion of patients >75 years, advanced ISS and ISS stage, higher β2-microglobulin (β2-M) levels (>3.5 and 5.5mg/dl) and abnormal LDH; increased incidence of high-risk cytogenetic features (HR CA), CD45/ clonal plasma cells, and lower incidence of CD227 MM phenotype. The multivariate analysis showed that the risk of early death due to active MM was related to four independent prognostic factors: age >75y (p=0.008), abnormal LDH (p=0.000), ISS 3 (p=0.008), and presence of HR CA (p=0.019). These four variables characterized by a high proportion of non-responding patients as well as unstaioned responses (umsR). The multivariate analysis showed that the risk of early death due to active MM was related to four independent prognostic factors: age >75y (p=0.008), abnormal LDH (p=0.000), ISS 3 (p=0.008), and presence of HR CA (p=0.019). These four variables characterized by a high proportion of non-responding patients as well as unstaioned responses (umsR).

The multivariate analysis showed that the risk of early death due to active MM was related to four independent prognostic factors: age >75y (p=0.008), abnormal LDH (p=0.000), ISS 3 (p=0.008), and presence of HR CA (p=0.019). These four variables characterized by a high proportion of non-responding patients as well as unstaioned responses (umsR).
unsR (duration of response (≥PR) <6 months) to the baseline score we were able to build a new score in which the unsR had a 3 points weight. A score ≥ 4 identifies a subgroup of patients with high probability of death within 2 years despite optimized treatment.

Summary/Conclusions: The risk of early death due to active disease in elderly patients was related to four independent prognostic factors: age >75y, high LDH levels, advanced ISS, and presence of HR CA. A score ≥ 4 identifies a subgroup of patients with high probability of death within 2 years despite optimized treatment.

Background: Myelofibrosis (MF) may be caused by various pathogenic mechanisms, such as elevated circulating cytokine levels, cellular interactions, and genetic mutations. However, the underlying mechanism of MF remains unknown. A recent study showed that the neoplastic clone of fibrocytes, spindle-shaped fibroblast-like blood cells derived from monocyte lineage, was essential in primary MF pathogenesis; serum amyloid P, which suppressed fibrocyte differentiation, markedly improved survival and MF in a murine xenograft model (J Exp Med 2016; 213: 1723-1740). Regarding cytokines, the thrombopoietin (TPO) signaling pathway was assumed to be closely associated with promoting MF. Mice transplanted with TPO-overexpressing bone marrow cells showed symptoms such as MF and splenomegaly (Blood 1997; 90: 4369-4383). Romiplostim (Rom), a TPO-receptor agonist, induced MF in rats and some immune thrombocytopenic purpura patients (Blood 2005; 114: 3749-3756). Fibrocytes and TPO played certain roles in MF pathogenesis, but the nature of their relationship remains unknown.

Aims: We investigated the relationship between myeloproliferative leukemia protein (MPL; TPO receptor) activation and fibrocyte differentiation in promoting MF. The secondary goal was to discover a unique fibrocyte marker in monocyte or macrophage population.

Methods: Murine fibrocyte cell lines were established from transgenic mice harboring the temperature-sensitive large T-antigen gene of simian virus 40 under IL-13 and M-CSF conditions. Murine fibrocyte cell lines and human peripheral blood mononuclear cells (PBMCs) were cultured with or without Rom to evaluate if MPL activation promoted fibrocyte differentiation, and the ratio of spindle-shaped cells was calculated. Rom was administered on day 1 and 8 to induce an MF-like phenotype in C57BL/6J mice, and clodronate liposomes (CLs; day -4, -1, 4, and 7) were used to eliminate monocytes and macrophages.

Results: Flow cytometric analysis revealed that all murine fibrocyte cell lines stained positive for fibrocyte cell markers, including collagen I, CD45, CD34, CD11b, and CD68. Murine fibrocyte cell lines expressed MPL and responded to Rom or murine TPO to differentiate into mature fibrocytes, specifically with a longer spindle shape and stronger collagen I expression than when cultured with IL-13 and M-CSF alone. Rom also increased the number of mice spleen cell fibrocyte colonies in the presence of IL-13 and M-CSF. The administration of 1mg/kg of Rom once a week induced an MF-like phenotype in all mice within 2–3 weeks and increased the number of fibrocytes in the spleen. Treatment with CLs eliminated fibrocyte precursors and prevented severe MF and splenomegaly. Human cultured fibrocytes also expressed MPL, and Rom increased the number of spindle-shaped fibrocytes induced from human PBMCs. The SLAMF7high MPLhigh subpopulation was clearly separated from the SLAMF7low MPLlow population in human CD14+ monocytes. A significantly higher frequency of fibrocyte differentiation was observed in the SLAMF7high MPLhigh population. The number of SLAMF7high MPLhigh cells was significantly greater in MF patients than in healthy donors. Conversely, their numbers did not increase in MF patients treated with ruxolitinib.

Summary/Conclusions: MPL activation directly induced fibrocyte differentiation from monocytes and macrophages expressing MPL, and the elimination of these cells reversed the MF phenotype. Our findings confirmed a link between fibrocytes and the TPO/MPL signaling pathway and indicated that the combination of MPL and SLAMF7 could be a useful fibrocyte marker in monocytes or macrophages.

Background: Progressive bone marrow (BM) fibrosis in patients with PMF is thought to arise from non-hematopoietic stromal cells stimulated by overpro-
duced growth factors. However, in other tissues and organs, fibrosis is associated with the expression of fibroblast markers and stromal cells. Recently, we have reported that clonal neoplastic fibroblasts play a role in the induction of BM fibrosis in primary myelofibrosis (PMF) (Verstovsek, J Exp Med. 2016). We demonstrated that the BM of PMF patients harbors neoplastic, functionally distinct fibroblasts and fewer hematopoietic normal bone marrow. In addition, we detected an overabundance of fibroblasts in the BM and spleen of an established PMF mouse model and a xenograft mouse model of PMF created using BM-derived low-density cells from patients with PMF.

Aims: Fibroblasts, which make up <1% of BM cells, differentiate from a subpopulation of CD45+ monocytes and are recruited to sites of organ damage where they regulate tissue repair. We hypothesized that clonal neoplastic CD14+ monocytes may play a role in the induction of BM fibrosis in PMF.

Methods: To test this hypothesis, we transplanted NSG mice (NOD/SCid Il2rgtm1Wempl/Sjz) with sorted CD14+ monocytes from patients with JAK2V617F-positive PMF or donors with hematologically normal BM.

Results: Here, we show that BM-derived CD14+ cells from patients with JAK2V617F-positive PMF or donors with hematologically normal BM engrafted in NSG mice. Transplanted NSG mice with PMF BM-derived CD14+ monocytes developed a myelofibrosis-like phenotype with reticulin fibrosis and abundant neoplastic (JAK2V617F) fibroblasts in the BM and spleen. Two months after transplantation, we detected a subpopulation of hCD45+ and hCD68+ cells within the HLA+ population of BM cells. In addition, we found dysplastic megakaryocytes in the BM and spleen of the PMF CD14+ transplanted mice. Immunohistochemical staining of paraffin-embedded BM sections did not detect hCD3, hCD19 or hCD34 cells. However staining with anti-human CD42b antibodies detected human megakaryocytes, suggesting that the dysplastic megakaryocytes detected in PMF CD14+ transplanted NSG mice are human-derived.

Summary/Conclusions: Taken together, our data suggest that neoplastic CD14+ monocytes contribute to the induction of BM fibrosis in PMF. What role CD14-derived megakaryocytes play in the pathogenesis of PMF remains to be determined.
MOLM-13, MV4-11, KG-1 and U-937, the eosinophilic leukemia cell line EOL-1, human cultured umbilical vein endothelial cells (HUVEC), the microvascular human endothelial cell line HMVEC-1 and primary neoplastic cells obtained from patients with AML, chronic myelomonocytic leukemia (CMML) and (clonal or reactive) hypereosinophilia were used. Cell proliferation was quantified by 4H-thymidine uptake. Apoptosis was determined by flow cytometry and light microscopy. The phosphorylation-status of KIT and BTK was analyzed by Western blotting. The effects of DCC-2618 on histamine secretion in basophils (BA) were analyzed by histamine release assay.

Results: DCC-2618 was found to block the proliferation of all MC lines tested, with lower IC50 values measured in KIT D816V-negative HMC-1.1 cells (12±2.3 nM) and ROSA-KITWT cells (4±1.5 nM) than in KIT D816V-positive HMC-1.2 cells (123±36 nM), ROSA1T1BD186V cells (182±65 nM), and the multi-resistant MC line MCPV-1. The DCC-2618-metabolite DP-5439 showed comparable growth-inhibitory effects in all cell lines tested. DCC-2618 was also found to inhibit proliferation of primary neoplastic MC obtained from patients with JAK2-activating mutation. For the ASAH1 and MCL (IC50: 83-460 nM). DCC-2618 induced apoptosis and blocked tyrosine phosphorylation of KIT in all cell lines tested. We were also able to show that DCC-2618 inhibits proliferation and survival in the eosinophilic leukemia cell line EOL-1 (IC50 1.8±1.3 nM) and the FLT3/ITD-mutated AML cell lines MV4-11 (IC50 147±86 nM) and MOLM-13 (IC50 132±95 nM). In addition, DCC-2618 was found to block proliferation in primary leukemic cells in patients with monoblastic AML and CML which are the most prevalent types of AHN in advanced SM. DCC-2618 was also found to inhibit growth of cultured human vascular endothelial cells, suggesting that the drug may also counteract SM-related angiogenesis. Finally, DCC-2618 was found to inhibit anti-VEGF-induced histamine release from normal BA in a dose-dependent manner (IC50: 1-10 µM).

Summary/Conclusions: DCC-2618 is a new potent switch control TKI that counteracts growth and survival of neoplastic MC, leukemic monocytes, AML blasts, eosinophils, and endothelial cells in vitro. Whether DCC-2618 is able to block growth of neoplastic MC and other involved lineages in patients with advanced SM is currently being ascertained in a clinical trial (NCT02571036).

P694 DISTRIBUTION OF MUTATIONS IN DRIVER AND NON-DRIVER GENES ACCORDING TO CLONAL HEMATOPOIESIS IN ESSENTIAL THROMBOCYTHESMA, POLYCYTHEMIA VERA, TETRAOXYGENASE MOTHER (PV) AND POLYCYTHEMIA VERA

A. Senin1,2, B. Bellissillo2,3, C. Fernández-Rodriguez2,3, L. Camacho2, C. Bessis1,2, A. Álvarez-Larran1,2

1Hematology Department, Hospital del Mar-IMIM. Universitat Autònoma de Barcelona, 2Group of Applied Clinical Research in Hematology. Cancer Research Program, IMIM, 3Pathology Department, Hospital del Mar-IMIM. Universitat Pompeu Fabra. Barcelona, Spain

Background: Essential thrombocythemia (ET) and polycythemia vera (PV) are clonal myeloid disorders that originate from a multipotential hematopoietic stem cell. Although most women with PV and ET have mutations in JAK2, CALR or MPL, the proportion of patients presenting clonal hematopoiesis by X chromosome inactivation patterns (XCIP) is variable and its relationship with the presence of non-driver mutations is not well known.

Aims: To study the distribution and dominance of driver and non-driver mutations in the development of clonal hematopoiesis.

Methods: One hundred and twenty-six women (PV n=33, ET n=93) with an age of patients at the time of HUMARA analysis was 64 years (range:21-92). Mutations in JAK2 were present in 62% of them, CALR in 11%, MPL in 8%, and 14% were triple negative (TN). Non-driver mutations were detected in 56 patients (17 PV and 28 ET). The most frequently mutated genes were TET2 (16%), DNMT3A (8%), ASXL1 (5%), SF3B1 (5%), EZH2 (2%) and RUNX1 (2%). The mutation with the highest variant allele frequency (VAF) was considered the dominant mutation and it corresponded to a driver mutation in 92 patients (JAK2 n=70, CALR n=13, MPL n=8) and a non-driver mutation in 9 patients (JAK2 n=2, CALR n=1, MPL n=1). In 9 patients, the JAK2 mutation carried the TET2 mutation (n=4) or the CALR mutation (n=5) or the MPL mutation (n=1). In 12 cases the VAF of the driver mutation (JAK2 n=9, CALR n=1, MPL n=2) were similar to the non-driver mutation, being TET2 the codominating mutation in 6 of them. HUMARA analysis was clonal in 66 patients and polyclonal in 60 patients. In 8% of patients, the driver mutation was most frequently observed in PV (76%) vs ET (44%; p=0.002). Clonal HUMARA was observed in 90% of MPL-mutated patients in comparison with 58% in JAK2-mutated, 42% in CALR-mutated and 11% in TN (p<0.0001). Two patients with TN ET showing clonal hematopoiesis had TET2 mutations. In JAK2-mutated women, the mutant allele load was significantly higher than in TN women (n=43, p=0.02) and in PV than in ET (76% vs 47%, p=0.01). Eighty percent of patients with non-driver mutations showed HUMARA clonality vs 37% of patients without non-driver mutations (p<0.0001).

The mutated genes significantly associated with a higher frequency of clonal hematopoiesis were TET2 (p=0.007) and SF3B1 (p=0.029). Age was significantly associated with clonal hematopoiesis and with the presence of non-driver mutations (median age of 55 and 68 years for polyclonal and clonal HUMARA respectively, p<0.0001 and 57 and 71 years for patients without and with additional mutations respectively, p=0.001). In the multivariate analysis, the variables that were associated with a higher probability of clonal hematopoiesis were the presence of non-driver mutations (OR:4.2, 95%CI: 1.6-10.6, p=0.003), age> 65 years (OR:2.7, 95%CI: 1-2.6-6.5, p=0.02), MPL genotype (OR:10.9, 95%CI: 1.2-98.9, p=0.0001) and PV diagnosis (OR:3.6, 95%CI: 1.3-9.7, p=0.009).

Summary/Conclusions: The presence of non-driver mutations is associated with clonal hematopoiesis regardless of age and type of disease. Elderly patients with clonal hematopoiesis often show non-driver mutations coexisting in equal or greater proportion than the driver mutation suggesting that MPN has originated on preexisting clonal hematopoiesis.

RUXOLITINIB/NILOTINIB/PREDNISOLONE COMBINATION: A PROMISING NOVEL TREATMENT FOR MYELOFIBROSIS

A. Arenas1, R. Ayala1, M. Gallardo1, J. Martinez-Lopez1,2

1Hematology, Hospital 12 de Octubre, Madrid, Spain

Background: Myelofibrosis (MF) is the myeloproliferative neoplasm chromosome Ph-negative with worst prognosis. MF is characterized by stem cell-derived clonal myeloproliferation and reactive cytokine-driven inflammatory bone marrow fibrosis. Ruxolitinib is the first line treatment for MF. It was associated with significant reduction in symptomatic splenomegalgy and improved constitutional symptoms. In a previous work (Arenas et al. Blood Volume 122, Issue 21 (ASH Annual Meeting Abstract)) we identified a set of promising synergistic drugs combinations for a ruxolitinib. Nilotinib and prednisolone were selected from them.

Aims: The aim of this work is the study the effect of the combination of ruxolitinib, nilotinib and prednisolone in hematopoietic progenitor cells from patients with MF.

Methods: A ruxolitinib, nilotinib and prednisolone dose-response curves and synergistic studies were performed in hematopoietic progenitors CD34+ from five MF patients. We studied the molecular effect of single drugs and in combination on SET2 cell line with western blot. To adress the antifibrogenic activity of the drugs and their combinations, we pre-incubated HS27 cultures with 100nM of ruxolitinib, 1 µM of nilotinib, 1 µM of prednisolone or their combination during 1 h. After that, we added 2ng/mL TGF-β during 24h to induce fibrogenesis. Finally, the collagen I expression was evaluated by immunocytochemistry (ICC).

Figure 1. Results: The effects of ruxolitinib, nilotinib and prednisolone resulted in an EC50 value of 55nM, 6.6µM and 13.1µM, respectively. A combination index (CI) of less than 1 indicated synergy. All combination had a synergistic behavior (Table 1); moreover, there were two combinations whose CI from all samples was less than 1: ruxolitinib/prednisolone (CI=0.8, p<0.05), nilotinib plus 0.8 µM prednisolone (CI=0.25±0.11) and 32µM ruxolitinib plus 0.8 µM prednisolone (CI=0.45±0.11). The JAK/STAT signaling pathway was inhibited: the phosphorylation of STAT5 was inhibited by ruxolitinib in 83.2±10.8 % (p<0.05) controlling to regard at 30 min and it was maintained at 3 hours (p<0.05). The combinations 32nM ruxolitinib plus 1.6 µM nilotinib (RN) and 32µM ruxolitinib, 1.6µM nilotinib plus 0.8µM prednisolone (RNP) inhibited more than 50% of the phosphorylation of STAT5 at 30 min and maintained at 3 hours. The MAPK signaling pathway was inhibited at 30 min, the phosphorylation of ERK was inhibited in 77±1.7%. 

haematologica | 2017; 102(s2) | 277

Madrid, Spain, June 22 – 25, 2017
The coefficient of variation of 11.91%, and 26.04%, respectively. The Akt/Pi3K signaling pathway seemed to begin to inhibit at 3 hours by ruxolitinib (57.5±25.2%), nilotinib (38.4±26.8%), RN (30.5±24.03%) and RNP (37.4±16.5%). Then, the antibiogenic activity of the drugs and their combinations were studied. Nilotinib reduced the mRNA expression of collagen (21.9±11.9% (p<0.05) and prednisolone (RN: 37.8±1.9% (p<0.05). These results were corroborated by ICC: the inhibition of expression of collagen I was more intense if the HS27 were treated with nilotinib or RN (figure 1).

Summary/Conclusions: In conclusion, ruxolitinib, nilotinib, prednisolone and their combinations had a synergistic behavior to control the proliferation of myeloid cells in MF patients; moreover, they had anti-fibrotic activity in fibroblast cells. For these reasons, the combined ruxolitinib/nilotinib/prednisolone could be a promising therapy to MF and support an ongoing clinical trial in MF patients.

Summary/Conclusions: Gene mutation analysis by targeted NGS in myeloid malignancies is highly reproducible between laboratories and allows a comprehensive characterization of patients. However, some challenges are identified: indels, low frequency mutations (<10%), ASXL1TG464fs detection and variant categorization are critical points that have to be addressed to improve the results. Test system validation is crucial for the implementation of NGS technology.
Methods: MA was calculated following pyrosequencing of bisulfite converted DNA from 40 MPN patients on an investigator initiated non randomised open label phase II multicentre study of Vorinostat (EudraCT #2007-005306-49). Paired samples were analysed at trial entry and after 3 months of therapy to calculate their individual MA scores. Validation of methods used and ageing signature calculation was carried out using cell line and healthy volunteer material.

Results: Samples from 18 Essential Thrombocytopenia (ET) and 22 Polycythemia Vera (PV) patients (23 F/17 M) with a mean age of 62 years (range 29-81) were assessed. JAK2V617F was detected in 77.5% (n=31/40). Complete clinical response (CR) was achieved in 8 patients, partial (PR) in 17, and no response (NR) in 15 patients. MA was on average 8.3 years younger than CA (range -43.4 to +41.6) at time of trial entry and 8.2 years younger (range -36.5 to +33.3) after therapy. This difference between MA and CA was greater in ET patients compared to PV, both at trial entry (-14.0 years to -3.7) and after therapy (-13.0 years to -4.3). A statistically significant link between JAK2 allelle burden and MA was seen: compared to patients with low or no JAK2 allele burden, patients with high JAK2 (>60% at baseline) had an older MA at trial entry (64.2 years vs 44.5, p=0.0007) and after therapy (64.3 years vs 44.6, p=0.0015). This difference was also seen when PV or ET patients were examined separately. Patients with a high JAK2 allele burden tended to have a MA closer to their CA at trial entry (-0.8 years vs -15.3, p=0.0122) and after 3 months therapy (-0.5 years vs -16.2, p=0.0072). Although the cohort size was small, within the ET group, NR compared to PR was associated with a younger MA after therapy (41.4 years vs 56.3, p=0.0156). Within PV, NR compared to PR was associated with a MA that was older than CA both before (+9.2 years vs -14.2 years, p=0.0346) and after therapy (+7.4 years vs -13.9, p=0.0347).

Conclusions: A link between MA and JAK2 mutant allele burden in MPN patients, suggesting that allele burden not only has a role in clinical phenotype and disease evolution but in the overall methylation landscape of the mutated cells. However, the role of MA with respect to therapeutic response needs to be clarified with further studies required to show its full impact.

P699
ELUCIDATING THE AGE INDUCED HEMATOPOIETIC CELL-INTRINSIC AND EXTRINSIC MECHANISMS IN MYELOPROLIFERATIVE NEOPLASM INITIATION AND PROGRESSION
N. R. Tata1,*, S. Radek2
1Department of Biomedicine, University Hospital Basel, Basel, Switzerland

Background: The number of detectable somatic mutations increase with age, but this increase is surpased by the rise in the incidence of cancer in older people. The underlying mechanisms for this disparity remain to be elucidated. Myeloproliferative neoplasm (MPN) is an ideal malignancy model disease to study clonal hematopoiesis, disease initiation and progression during natural aging because the majority of the relevant mutations (such as JAK2 V617F) are catalogued, the disease evolves and progresses slowly allowing the collection of serial samples, and an inducible transgenic mouse models for the disease have been established. Nonetheless, the prevalent occurrence of such clonal events in aged individuals brings up the question, which age-associated factors contribute to initiate hematologic malignancies and what are the rate limiting steps attributable for age-induced myeloid malignancies? We hypothesize that the reduced hematopoietic stem cells (HSCs) and their progeny provides a context that favors a greater number of new mutations, selection for pre-malignant clones, and that activation of mutant JAK2 further augments these changes for increased MPN incidence in aged individuals. Thus, delineation of age associated cellular and molecular mechanisms attributable for increased prevalence of myeloid malignancies will be essential for the development of strategies for early detection and therapeutic targeting of myeloid malignancies.

Aims: The goal of this proposal is to identify age associated hematopoietic cell-intrinsic and cell-extrinsic factors that determine initiation and progression of MPN at young versus old age in mouse models carrying a JAK2-V617F or JAK2V617F;+12 mutation.

Methods: To assess the effect of aging on MPN initiation and progression we studied the young and aged inducible transgenic mouse models of MPN. Integated omics analysis was performed on MPN initiating stem and progenitor cells.

Results: Our results suggest that age related changes in expression patterns respond to a set of factors that control cell fate decisions in aged wildtype mice. The mutation profile in patients with pediatric MPN appear to be less complex than in older MPN patients. We are currently investigating the relative contributions and collaborations of age-associated cell intrinsic and extrinsic changes in HSCPs and BM niche in the course and severity of MPN in mouse models carrying a JAK2-V617F mutation, and in naturally aged donors and recipients of bone marrow transplantations.

Summary/Conclusions: Our study provided novel molecular and cellular mechanisms underlying increased incidence of MPN manifestation in old age. The implications of this work goes beyond the MPN malignancy and the common diseases, the data sets generated in study will serve as a model to the wider scientific community to study other types of malignancies. This knowledge ultimately will help to define novel strategies to delay or target the onset of MPN in an aging individual.

Myeloproliferative neoplasms - Clinical 2
Results: At BL, 59% of pts had anemia (hgb <10 g/dL); pts with BL anemia were more likely at BL to have platelet count <50,000/µL (51% vs 38%), splenomegaly MF (71% vs 57%), and high DIPSS score (41% vs 14%). For those with BL anemia regardless of whether RBC transfusion-dependent (TD), PAC did not worsen hgb levels and the rate of clinical improvement in hgb was higher for pts in the PAC BID arm (25%) vs PAC QD (13%) or BAT (12%) arms (Table). For the BID arm, CALR RBC transfusion independence (TI) at BL (TD in RBC transfusion-dependency was achieved at higher rates with PAC QD (19%) and PAC BID (22%) vs BAT (9%); 2 PAC and 0 BAT achieved RBC-Ti by week 24. In PAC pts, SVR >33% and TSS reduction ≥50% were observed regardless of BL anemia or RBC-TD (Table). At BL, 16% of pts in the safety population had grade 3 anemia. Incidence of TE anemia was highest during the first 16 weeks of PAC (20% and 9% weeks 1-8, 9% and 13 weeks 8-16 for QD and BAT, respectively) and first 8 weeks of BAT (10%). For pts with BL hgb <10 vs 10-11 g/dL, incidence of grade 3/4 TE anemia was similar with PAC QD (26% vs 28%), respectively, and lower in pts with BL hgb ≥10 g/dL with PAC QD (11% vs 12%) or BAT (20% vs 24%) (Table). In instances of high DIPSS, anemia with PAC or BAT (Table) were in pts with BL hgb <10g/dL. Dose modifications or discontinuations due to anemia were uncommon (Table). No exposure-response relationship was evident for grade ≥2 TE anemia.

Summary/Conclusions: In pts with MF and BL thrombocytopenia, PAC treatment led to clinical improvement in hgb and reduction of RBC transfusion needs vs BAT. Serious anemia, and dose modifications due to anemia were uncommon. PAC provides a treatment option for pts with MF, including those with BL thrombocytopenia and anemia, for whom available options are limited.

Objective response after 12 cycles (n=4), leukemic transformation (n=4) or death (n=13; 13 pts (34%) responded with spleen reduction (n=9) or 22 g/dL Hb increase / RBC transfusion independence (n=4). Of note, mean Hb increased continuously from 8.7 g/dL at baseline to 9.2 g/dL at the end of cycle 12; 12 pts (31%) continued treatment beyond cycle 12 because of response or SD plus clinical benefit (Hb increase >2g/dL, prolongation of transfusion free interval (TFI) and 10 pts (26%) on treatment for improvement of symptoms; 6 pts (16%) stayed on treatment for >24 cycles.

Summary/Conclusions: In our study in advanced MF, combination of POM plus RUX was feasible with an objective response rate of 34%. Approximately one third of pts was treated beyond cycle 12 due to sustained therapeutic benefit. PAC treatment led to clinical improvement and the results from our MPNSG-0109 trial, a step-wise increase of the POM dosage is included for the 2nd study cohort to further improve anemia response.

P700

COMBINATION THERAPY OF POMALIDOMIDE PLUS RUXOLITINIB IN MYELOFIBROSIS: RESULTS FROM COHORT 1 OF THE MPNSG-0212 TRIAL (NCT01644110)

1University Hospital of Ulm, Ulm, 2University of Bochum, Minden, 3RWTH Aachen University Medical Center, Aachen, 4Jena University Hospital, Jena, 5University Hospital of Freiburg, Freiburg, 6University Hospital of Mainz, Mainz, 7Stauferklinikum Mutlangen, Mutlangen, 8Hematology and Oncology Practice, Augsburg, 9University Medical Center Magdeburg, Magdeburg, 10University of Cologne, Tübingen, Tübingen, 12University of Cologne, Cologne, Germany

Background: Therapeutic options to address anemia in patients (pts) with Myelofibrosis (MF) are limited. In our MPNSG-0109 trial investigating pomalidomide (POM) in MF with cytopenia, anemia was improved in 14-29% of pts treated with 0.5-2mg POM once daily (QD) (Schlenk RF, Steigelmann F et al. Leukemia 2016).

Aims: To evaluate synergistic effects of POM plus ruxolitinib (RUX), we are currently investigating the combination therapy within the MPNSG-0212 trial (NCT01644110).

Methods: This multicenter, single-arm phase-IIb trial with a target population of 38 pts in the first cohort. Primary endpoints are response rate after 12 cycles (28 days each) according to IWG-MRT (Tefferi et al., Blood 2006) and red blood cell (RBC) transfusion independence criteria (Gale et al., Leuk Res 2011). Secondary endpoints are safety, quality of life, progression-free, and overall survival. Main inclusion criterion is MF with anemia (hgb <10 g/dL and/or RBC transfusion dependency). While POM is given dose-modifications being allowed.

Results: Safety and efficacy data from 38 pts are presented. Median age of the 38 pts was 65 years (range 40-83); 19 pts (50%) previously received hydroxyurea, RUX, EPO, POM, and/or corticosteroids. Median hemoglobin (Hb) level at study entry was 8.6 g/dL (range, 5.4-11.7); 11 pts (29%) were RBC-transfusion-dependent. Median spleen size by ultrasound was 17.9 cm (range, 12.6 - 28). At baseline, 30 pts (79%) had constitutional symptoms, Mutations of JAK2, MPL, and CALR are present in 28 (74%), 3% (8), and 7 (18%) pts, respectively; 26 (68%) were intermediate-2 risk and 9 (24%) high-risk according to the DIPSS (Passamonti et al, Blood 2010). Median time on treatment was 12 cycles (range, 2-33). In total, 881 adverse events (AE) CTCAE ≥1-5 were recorded. Worsening of anemia within the first 6 cycles was the most frequent AE occurring in 13 pts (34%); fatigue followed by fatigue in 12 (32%). Treatment interruptions were rare. There were 29 serious AE (SAE) CTCAE ≥2-5: most frequently, leukemic transformation (n=4), pneumonia (n=3), thoracic pain (n=3), abdominal pain (n=2), cardiac decompensation (n=2) and septic shock (n=2) occurred in 13 pts (34%) of which 5 were fatal (cardiac decompensation, pneumonia, leukemic transformation, abdominal pain, septic shock, respectively). Five pts (13%) had prior RUX therapies. Two pts (5%) had prior exposure to cytotoxicity, “3” fatigue, “3” cardiac decompensation, “3” were considered study-related. 16 pts (42%) are currently on study treatment; 22 (58%) discontinued because of AE (n=6), withdrawal of consent (n=5), stable disease (SD) without
Methods: Aims: This analysis includes 418 pts (primary MF, 66%) who were ≥75 y and started treatment ≥1 y before data cutoff (01 Jan 2016). Baseline characteristics (median) were age, 78 y (range, 75-89 y); male, 57%; spleen length, 20 cm (0-35 cm); blast count ≥1%, 30.3%; hemoglobin, 101 g/L (<100 g/L, 46.9%); PLT count, 249×10^9/L (<100×10^9/L, 6.3%). ECOG PS <2, 84.9%. At data cutoff, more than half of pts remained on treatment or completed treatment per protocol (52.6%). As expected, a greater proportion of elderly pts discontinued RUX due to adverse events (AEs; 23.6%) or death (8.7%) than pts in the overall study (17.7% and 4.1%, respectively). Overall, 72.4% of pts had dose modifications (AEs, 58.4%), and 33.9% had an interruption (AEs, 31.5%). Safety of RUX in elderly pts was consistent with that in the overall population. Median exposure was 11 mo; mean average daily dose was 26.8 mg (SD, 10.6). The most common hematologic grade 3/4 AEs were anemia (43.8%; overall, 34.1%) and thrombocytopenia (22.1%; overall, 16.3%). AEs (all grade [grade 3/4]) in >10% of pts included asthma (18.3% [2.6%]), pyrexia (18.0% [2.6%]), dyspnea (14.4% [4.3%]), diarrhea (13.5% [1.9%]), fatigue (11.8% [2.4%]), peripheral edema (10.8% [0.2%]), and pneumonia (10.1% [7.2%]). Infections in >5% of pts included pneumonia (10.1%), urinary tract infection (7.0%), and bronchitis (5.1%). Herpes zoster occurred in 3.9% of pts. At wk 24, 56.4% (124/220) of pts had a ≥50% reduction from baseline in spleen length (overall, 56.6%), and 19.1% (42/220) had 25%-50% reductions (overall, 23.3%); rates were similar at wk 48 (54.6% [65/119] and 19.3% [23/119]; overall, 61.6% and 18.9%). Most pts (64.2%) achieved a ≥50% reduction at any time (Figure 1), similar to the overall population (70.2%). Pts also experienced significant improvements in symptoms. From wk 4 to 48, 42%-48% and 50%-57% of pts achieved a clinically meaningful response on the FACT-Lym TS and FACT-Fatigue, respectively.

Summary/Conclusions: This analysis included the largest cohort of elderly pts with MF treated with RUX to date. Consistent with the study by Latagliata et al. RUX was safe and effective in pts ≥75 y, with pts achieving reductions in splenomegaly and symptoms similar to those in the overall population, with comparable rates of AEs. Additionally, findings from our study were consistent with those of the COMFORT studies, which included few pts ≥75 y. Overall, our study provides further evidence that RUX is safe and effective in elderly pts with MF.

Figure 1. Summary/Conclusions: In the phase 3 PERSIST-2 study of PAC vs BAT in pts with MF and BL thrombocytopenia, although 19% of RUX-treated pts achieved a 50% reduction in TSS, RUX-treated pts rarely achieved SVR ≥35% at week 24. Rates of grade 3/4 AEs were higher with PAC vs RUX treatment, though the majority of RUX-treated pts began with 5mg dosing. Rates of dose reductions and discontinuations due to AEs with PAC BID and RUX were similar. Following crossover to PAC in 22 RUX-treated pts, 19 remained on treatment at the time of data cut-off.

P702
SAFETY AND EFFICACY OF RUXOLITINIB (RUX) IN ELDERLY PATIENTS (>75 YEARS) WITH MYELOFIBROSIS (MF): AN ANALYSIS FROM THE PHASE 3B, EXPANDED-ACCESS JUMP STUDY

1Rabin Medical Center, Petah Tikva, Israel, 2Princess Margaret Cancer Centre, Toronto, Ontario, Canada, 3Johannes Wesling Medical Center, University Hospital, Minden, 4University Hospital of Halle, Halle (Saale), Germany, 5Miguel Servet University Hospital and Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Zaragoza, Spain, 6CRIMM, Center for Research and Innovation of Myeloproliferative Neoplasms, AOU Careggi, Department of Experimental and Clinical Medicine, University of Florence, Firenze, Italy, 7St. Paul’s Hospital, University of British Columbia, Vancouver, British Columbia, Canada, 8Universidade Federal de Goiânia, Goiânia, Brazil, 9Federal Almazov Medical Research Center of the Russian Ministry of Health, St. Petersburg, Russian Federation, 10Novartis Pharma AG, Basel, Switzerland, 11Novartis Healthcare Pvt. Ltd, Hyderabad, India, 12Azienda Ospedaliera Bianchi-Melacrinò-Morelli, Reggio Calabria, Italy

Background: RUX is a potent JAK1/JAK2 inhibitor that has led to reductions in splenomegaly and symptoms in patients (pts) with MF. Although few studies have assessed RUX in elderly pts, a recent analysis including 100 pts ≥75 y showed that RUX was safe and effective in these pts, with safety and efficacy outcomes similar to those in younger pts (Lattaglia et al. Blood 2016;128:4251), JUMP, a large (N=2233), phase 3b, expanded-access trial assessed safety and efficacy of RUX in pts with no access to RUX outside a clinical trial and included a cohort of pts ≥75 y. Results: ed changes in spleen length and symptoms. From wk 4 to 48, 42%-48% and 50%-57% of pts achieved a clinically meaningful response on the FACT-Lym TS and FACT-Fatigue, respectively.

The most common hematologic grade 3/4 AEs were anemia (43.8%; overall, 34.1%) and thrombocytopenia (22.1%; overall, 16.3%). AEs (all grade [grade 3/4]) in >10% of pts included asthma (18.3% [2.6%]), pyrexia (18.0% [2.6%]), dyspnea (14.4% [4.3%]), diarrhea (13.5% [1.9%]), fatigue (11.8% [2.4%]), peripheral edema (10.8% [0.2%]), and pneumonia (10.1% [7.2%]). Infections in >5% of pts included pneumonia (10.1%), urinary tract infection (7.0%), and bronchitis (5.1%). Herpes zoster occurred in 3.9% of pts. At wk 24, 56.4% (124/220) of pts had a ≥50% reduction from baseline in spleen length (overall, 56.6%), and 19.1% (42/220) had 25%-50% reductions (overall, 23.3%); rates were similar at wk 48 (54.6% [65/119] and 19.3% [23/119]; overall, 61.6% and 18.9%). Most pts (64.2%) achieved a ≥50% reduction at any time (Figure 1), similar to the overall population (70.2%). Pts also experienced significant improvements in symptoms. From wk 4 to 48, 42%-48% and 50%-57% of pts achieved a clinically meaningful response on the FACT-Lym TS and FACT-Fatigue, respectively.

Figure 1. Summary/Conclusions: This analysis included the largest cohort of elderly pts with MF treated with RUX to date. Consistent with the study by Latagliata et al. RUX was safe and effective in pts ≥75 y, with pts achieving reductions in splenomegaly and symptoms similar to those in the overall population, with comparable rates of AEs. Additionally, findings from our study were consistent with those of the COMFORT studies, which included few pts ≥75 y. Overall, our study provides further evidence that RUX is safe and effective in elderly pts with MF.

PROGNOSTIC RISK MODELS FOR TRANSPLANT DECISION-MAKING IN MYELOFIBROSIS

1Hematology, Hospital Clínico Universitario, Valencia, 2Hematotherapy and Hemostasis, 3Hematology, Hospital Clinic, Barcelona, 4Hematology, Hospital del Mar, Barcelona, 5Hematology, Hospital Morales Meseguer, Murcia, 6Hematology, Hospital Universitario de Canarias, Tenerife, 7Hematology, Hospital 12 Octubre, Madrid, 8Hematology, Institut Català d’Oncologia, Hospital de Llobregat, 9Hematology, Hospital Clínico Universitario, Santiago de Compostela, 10Hematology, Hospital Germans Trias i Pujol, Badalona, 11Hematology, Hospital Ramón y Cajal, Madrid, 12Hematology, Hospital Vall d’Hebron, Barcelona, 13Hematology, Hospital Universitario Central de Asturias, Oviedo, 14Hematology, Hospital La Paz, Madrid, 15Hematology, Hospital Universitario de Burgos, Burgos, 16Hematology, Hospital Son Espases, Mallorca, 17Hematology, Hospital de Jerez, Cádiz, 18Hematology, Hospital Dr Negrín, Las Palmas de Gran Canaria, 19Hematology, Hospital Costa del Sol, Marbella, 20Hematology, Hospital La Fe, 21Hematology, Hospital Clínico, Valencia, 22Hematology, Hospital Clinica, Barcelona, Spain
Background: Accurate disease risk stratification is crucial for transplant decision-making in myelofibrosis (MF), since several prognostic models are available, it is unknown if they are equivalent in the way they distribute patients into risk groups and in their discriminatory power to predict survival.

Aims: We have compared the performance of the International Prognostic Scoring System (IPSS), dynamic IPSS (DIPSS), DIPSS-plus, and Rumi’s score in a set of 544 MF patients aged 70 years or younger at time of diagnosis.

Methods: The Spanish Registry of Myelofibrosis is a nationwide, longitudinal registry contributed by centers associated to the Grupo Español de Enfermedades Mieloproliferativas Filadelfia negativas (GEMFIN). From January 2000 to January 2016, a total of 544 adult patients aged ≤70 years with primary MF (n=335) or secondary MF (n=209) had been included in the registry. Cases of the prefibrotic form of MF were not considered. Comparison of the relative power of each prognostic model to discriminate levels of risk was estimated by means of the Harrell’s concordance index (C-index) and the R² explained variation. All the statistical analyses were performed with IBM SPSS 22.0 and Stata 11.

Results: A total of 544 patients were included in the analysis. The median age was 62.6 years (IQ range: 54.9-69.7). There were 311 males and 233 females. The number of patients in the intermediate-2 and high risk categories was smaller in the DIPSS than in the IPSS or the DIPSS-plus. Overall, the Rumi’s score yielded the highest power to discriminate between risk categories, as measured by the C-index and the R² explained variation. However, the IPSS and DIPSS-plus were the best models to discriminate between the intermediate-1 and intermediate-2 risk categories, which is the critical cut-off point for patient selection to transplant.

Summary/Conclusions: In our contemporary series of MF patients only the high risk category of the current prognostication systems have a median survival below the 5-year threshold recommended for considering transplantation. Patient selection for transplant is quite dependent on which prognostication model is used for disease risk stratification.

P704

LEUKEMIC TRANSFORMATION AND SECOND CANCERS IN 3649 HIGH RISK ET PATIENTS IN THE EXELS STUDY

1Department of Haematology, Uppsala University, 2Regional Cancer Centre, Uppsala University Hospital, Uppsala, Sweden, 3King’s College London, Faculty of Life Sciences and Medicine, London, United Kingdom, 4Department of Surgical Sciences, Uppsala University, Uppsala, Sweden, 5Department of Haematology, HaematoLOG, 6Department of Medicine, Maela Hospital, Hannover, Germany, 7Department of Haematology, St Orosia-Maliphi Hospital, Bologna, Italy, 8Global Biometrics, 9Shire Pharmaceuticals, Lexington, Massachusetts, United States, 10Research & Development, Shire GmBH, Zug, Switzerland, 11APHP, Saint-Louis Hospital, Clinical Investigations Center, Paris, France, 12Department of Haematology, Guy’s and St Thomas’ NHS Foundation Trust, London, United Kingdom

Background: A common therapy for essential thrombocythemia (ET), hydroxyurea (HC), has mutagenic properties and there is potential for leukemogenicity and secondary cancers with this agent. Although leukemia (AML) and other malignancies in HC-treated patients compared with those treated with anagrelide (ANA). However, there were large age differences between groups. Here, we account for age differences by estimating standard incidence ratios (SIRs) using country-specific cancer registration data.

Aims: To assess the risk of AML and non-hematological malignancies in patients treated with HC or ANA in the EXELS study.

Methods: Previous exposure to ANA and HC was based on patient history. SIRs were calculated using background rates retrieved from Cancer Incidence in Five Continents (CI5). Risk of AML after study enrolment was estimated by cumulative incidence. Minimum exposure time of 180 days was used to account for disease progression as a confounding factor. Informed consent was obtained before the start of the study.

Results: Overall, 3460 patients were exposed to HC, ANA or both at registration; 481 patients had ANA treatment, 2305 had HC treatment and 674 had been exposed to both drugs. The median age in ANA patients was 51 years, and 71 years in HC patients. One hundred and seventy four cases of non-hematologic cancer, including 35 cases of skin cancer, were recorded. SIRs for all malignancies were close to 1 for all treatment groups, indicating similar risks to the background population. For all skin cancers, including melanoma, the SIR for patients with HC treatment was higher than expected for the normal population and patients on ANA (1.15 vs 0.45). When melanoma was excluded, the figures changed only marginally. However, due to the low number of events, the CIs were wide, and no statistically significant difference was found between treatments. Sixty seven AML cases were found; 39 AML cases were found in the HC group (person-years 8970, SIR 39.7), with another 20 AML cases in the group who switched from HC to ANA (person-years 2934, SIR 91.5). The risk ratio for AML developing in patients who switched from HC more than doubled (RR 2.30-2.52), irrespective of minimum exposure time. In contrast, no AML case was observed in the ANA-only group (person-years 1905, SIR 0) and there were only 3 AML cases in the group who switched from ANA to HC (person-years 802, SIR 68.5). Since the number of AML cases in the ANA group was 0, no statistical comparison could be made. Five AML cases were excluded from analysis since there was uncertainty about which drug was used first.

Summary/Conclusions: ET patients have a substantially increased risk for AML development; the SIR for AML was 40-fold higher than expected with HC exposure. Patients who switched from HC to ANA the SIR was approximately 90-fold higher, with 20 AML cases observed versus the expected 0.22 cases. The number of AML cases was much lower (n=3) in patients who switched from ANA to HC. It has been proposed that exposure of ET patients failing HC therapy to a second potentially leukemogenic agent should be avoided; yet these data suggest that even after switching to a non-leukemogenic agent, HC-treated patients still have an over 90-fold increased risk of AML. Our data reinforces concerns of a leukemogenic effect of HC, with a markedly higher risk in patients failing HC and switching to another drug, even if that drug is ANA. The caution advocated in the use of HC seems well advised.
Background: Infectious complications represent one of the most frequent causes of morbidity and mortality in Myelofibrosis (MF), the most severe of myeloproliferative neoplasms. Ruxolitinib (RUX), the first approved JAK1/2 inhibitor, significantly ameliorates disease-related splenomegaly and constitutional symptoms. Prospective controlled studies observed a high rate of infectious complications including opportunistic and unusual infections, probably due to its immune-suppressant activity. However, risk factors for infections in MF patients (pts) treated with RUX are still to be investigated.

Aims: To evaluate characteristics, incidence and risk factors for infections in RUX-exposed MF pts.

Methods: Clinical and laboratory data of MF pts treated with RUX were retrospectively collected from the database of 21 Italian Hematology Centers. Infections were defined according to the CTCAE.

Results: Overall, 373 pts received RUX between June 2011 and June 2016. At RUX start the clinical features were (median): age 68 years (27-89); Hb, 10.8g/dL (7-16.7); Hb <10g/dL, 40%; PLT, 246×10^9/L (33-1887); PLT <100×10^9/L, 10%; spleen enlargement, 97%; spleen length ≥10cm, 62%; constitutional symptoms, 52%. International Prognostic Score System (IPSS) was intermediate-1 (15%), intermediate-2 (46%), high (39%). JAK2V617F mutation was detected in 255 out of 313 evaluated pts (81%). Karyotype was unfavorable in 15 out of 203 evaluable pts (7%). Previous infectious complications were recorded in 31 pts (8%). After a median RUX exposure of 20 months (range, 1-56), 101 pts (27%) experienced 129 infectious events (grade 3, 33%), for an incidence rate of 14.9 cases for 100 pts/year. The rate of infections tended to decrease over time: 54% occurred within 6 months of therapy, 15% between 6 and 12 months, 9% between 12 and 18 months (p=0.0001). Respiratory tract infections were more frequently observed (73 events, 57%). Cutaneous, urinary tract and gastrointestinal infectious events were diagnosed in 15%, 10% and 7% of cases, respectively. In 14 cases fever of unknown origin was recorded (Figure 1). Etiological agents were isolated in 14 cases (11%); bacteria in 9 cases (gram+ 56%, gram- 22%, C. difficile diarrhea 22%) and fungi in 2 cases (pulmonary aspergillosis and oesophageal candidiasis). Mycobacterium tuberculosis Mycosis was isolated in 3 cases. Herpes-virus reactivations occurred in 12 cases (9%). No patients reactivated hepatitis B virus. At last follow-up, 88 pts (24%) have died, in 10 cases (11%) due to infectious complication. Among baseline features, age≥65 years at RUX start (p=0.0001), previous infection (p=0.001), primary vs secondary MF (p=0.021) and high IPSS (p=0.029) significantly correlated with higher infectious risk. Notably, no differences were observed according presence of large (≥10cm) splenomegaly, higher (>20) total symptoms score, presence of cytopenias, Charlson comorbidity index (>2) and body mass index (>21 and >30). In multivariate analysis, PMF diagnosis (HR 1.6 CI95% 1.07-2.5), age≥65 years (HR 2.1 CI95% 1.3-3.3) and previous infection (HR 3 CI95% 1.7-5.4%) confirmed their negative prognostic association. Interestingly, RUX dosage, spleen response and hematological toxicities during treatment were not associated with infectious risk.

Summary/Conclusions: Infections occurred in around one-third of RUX-treated pts; the rate of infections tended to decrease over time, and were fatal in 11% of the cases. Advanced age, a previous infectious event and diagnosis of PMF seem to be the main contributors to infectious risk.
ET) chose watchful waiting to manage >25% of their pts at diagnosis; 22% of untreated pts had moderate to high (quartiles 3-4) overall symptom burden. Physicians primarily recommended treatment for pts experiencing severe symptoms (72% MF, 68% PV, 72% ET) or symptomatic splenomegaly (71% MF, 61% PV, 39% ET). PLB was mainly used to treat pts with PV. Of those who received PLB (n=115), 71% were very or somewhat satisfied; 25% were very or somewhat dissatisfied and felt that PLB had a negative impact on their QOL. Similarly, 37% of physicians felt that PLB had a negative impact on pt QOL; PLB alone was insufficient for disease control in 38% of pts. Pts stopped PLB because physician deemed it no longer necessary (62%), pts felt worse after treatment (10%), and visit frequency was inconvenient (8%). Physician-reported reasons for stopping PLB were that visit frequency was inconvenient (38%), pts felt worse after treatment (35%), and lack of intravenous access (33%). HU use was assessed in pts with PV or ET. Of those who received HU (PV, n=95; ET, n=145), 78% and 74%, respectively, continued to receive HU; 19% and 22% were dissatisfied with HU therapy. Main reasons for stopping HU were lack of efficacy (29% PV, 13% ET) and toxicity (10% PV, 27% ET). Overall, 78% of physicians reported that up to 25% of their pts showed inadequate efficacy or intolerance of HU. Main measures of treatment success among pts were physician feedback (73% MF, 75% PV, 75% ET) and blood counts (72% MF, 67% PV, 74% ET). Lack of efficacy, side effects, and discontinuation were key reasons for changing therapy.

Summary/Conclusions: Many pts with MPNs are managed with watchful waiting at diagnosis. Although most of these pts have a low symptom burden, 22% have a moderate to high burden, highlighting the need for proactive and standardized symptom assessments at diagnosis and over the course of treatment. Individualized preferences and needs of physicians and pts felt that phlebotomy had a high negative impact on pt QOL. Overall, pts consider physician feedback and blood counts to be important indicators of treatment success.

P707 SUCCESSFUL LONG-TERM MAINTENANCE OF PV PATIENTS WITH A MONTHLY SCHEDULE OF ROPEGINTERFERON ALFA-2B: AN UPDATE FROM THE PEGINVERA STUDY

Background: Ropeginterferon alfa-2b is a novel long-acting monopegylated interferon alpha (IFNa) with Orphan designation in Europe and the U.S. Reduced dosing frequencies and favorable tolerability accompanied by robust clinical responses in patients with polycythemia vera (PV) have been reported over the first few years of treatment. Successful long-term, potentially life-long maintenance with high rates of adherence, compliance and treatment outcome remain important goals to be elucidated.

Aims: PEGINVERA phase II (NCT: 2010-018768-18), is a prospective, open-label, multicenter study investigating efficacy and safety of ropeginterferon alfa-2b in long-term treatment of patients with confirmed diagnosis of PV, pre-treated or naïve to cytoreductive therapy.

Methods: All patients responding well to the initial bi-weekly administration or naïve to cytoreductive therapy. Patients continuing in the study for more than one year, had the option to switch to a “once every 4 weeks” schedule. The 2-week regimen (defined as the time period when all criteria for switching were fulfilled but the patient continued the 2-week regimen) was compared to the 4-week regimen (for a duration of 6 months after switch). The present analysis was focused on maintenance of efficacy.

Results: Data from the last available analysis include 29 patients remaining on study with a median treatment duration of 213 weeks. All 29 patients have completed at least 2 years of treatment (5 patients are in the 3rd year, 7 in the 4th year, 10 in the 5th year and 7 in the 6th year of treatment). Baseline characteristics of the study cohort and short-term treatment and individual adverse events and efficacy follow-up data were already presented earlier (Gisslinger et al. 2015). All of the 29 patients were switched to dosing every 4 weeks. Median treatment duration at time of switch was 104 weeks (Q1-Q3: 69-124 weeks). All 29 patients remained on the 4-week schedule with a median observation of 2 years. The 4-week regimen, reflecting an excellent safety and tolerability profile of ropeginterferon alfa-2b in this setting. The percentage of patients maintaining their best haematological response according to ELN before (i.e. after median 104 weeks of treatment) and 6 months after switching to the 4-week regimen was consistent at 51.7%. Further, need for phlebotomy during the 6 months after switching did not increase (consistent 7/29 patients). Changes in haematological parameters and spleen size were minimal and without clinical relevance. Similarly, the percentages of patients maintaining their best molecular response were 62.1% and 58.6%, respectively (non-significant). Importantly, the majority of patients on ropeginterferon alfa-2b long-term treatment, developed a sustained reduction of mutant JAK2 allele burden to below 10%, a feature that can only be achieved by IFNa based therapies.

Summary/Conclusions: In summary, all patients remaining on ropeginterferon alfa-2b after a median of 2 years of initial treatment were successfully switched to a more convenient monthly long-term maintenance schedule, thereafter no patients discontinued, and all patients could be maintained on this schedule for currently another 2 years (trial still ongoing). These data underscore the expected long-term efficacy with regard to haematological, clinical and molecular parameters and the excellent safety/tolerability of ropeginterferon alfa-2b. Long-term maintenance treatment of PV patients using ropeginterferon alfa-2b monthly is feasible, efficacious and well tolerable. Continuous patient-individual adaption of dosing regimen, including dose and dosing schedule, is recommended.

P708 NO IMPROVEMENT IN SURVIVAL OVER TIME FOR PHILADELPHIA NEGATIVE MYELOPROLIFERATIVE NEOPLASM PATIENTS WHO TRANSFORM TO ACCELERATED OR BLAST PHASE

C. McNamarat 1, J. Kennedy 1, T. Panzarrella2, G. Daher-Reyes1, R. Alblooshi1, J. Ramanna1, A. Aruda1, J. Ho1, N. Siddiqui1, J. Claudio1, R. Devlin2, T. Stockley3, M. Sukhai3, M. Thomas3, S. Chan1, D. Maze1, A. Schimmer1, A. Schuh1, H. Sibai1, K. Yee1, S. Kamel-Reid1, M. Minden1, V. Gupta1

1Department of Medical Oncology and Hematology, 2Department of Biostatistics, 3Advanced Molecular Diagnostics Laboratory, Princess Margaret Cancer Centre, Toronto, Canada

Background: The outcome of patients with Philadelphia negative myeloproliferative neoplasms (MPN) who transform to acute leukemia is abysmal. There have been no advances in targeted therapy for this cohort of patients or individualized treatment based on genomic information. Furthermore, no large studies have investigated the impact of molecular profiling on clinical outcome in patients with accelerated or blast phase of MPN.

Aims: To describe the clinical outcomes of patients with MPN who transform to accelerated or blast phase and evaluate the impact of genomic alterations on outcomes.

Methods: Eligibility criteria included: Prior diagnosis of Philadelphia negative MPN according to WHO 2008 criteria; evidence of transformation to accelerated (10-19% blasts in peripheral blood or bone marrow) or blast phase (≥20% blasts) and seen at Princess Margaret Cancer Center between January 1998 and February 2017. The primary endpoint was overall survival (OS); defined as the time from transformation to death or last follow-up. Secondary endpoints included survival based on curative versus non-curative approach and treatment over time. In addition the impact of mutations will be correlated with clinical outcomes and survival.

In summary, all patients remaining on ropeginterferon alfa-2b after a median of 2 years of initial treatment were successfully switched to a more convenient monthly long-term maintenance schedule, thereafter no patients discontinued, and all patients could be maintained on this schedule for currently another 2 years (trial still ongoing). These data underscore the expected long-term efficacy with regard to haematological, clinical and molecular parameters and the excellent safety/tolerability of ropeginterferon alfa-2b. Long-term maintenance treatment of PV patients using ropeginterferon-alfa-2b monthly is feasible, efficacious and well tolerable. Continuous patient-individual adaption of dosing regimen, including dose and dosing schedule, is recommended.

Figure 1. Results: One hundred and eighty-seven patients who transformed to accelerated or blast phase with a prior diagnosis of MPN were identified at our insti-
Summary/Conclusions: Despite advances in systemic therapies and supportive care, there has been no significant improvement in survival for MPN patients who transform to accelerated or blast phase, confirming that current treatment approaches are ineffective. Results of molecular profiling may provide valuable insights and clues as to how to develop an individualized treatment approach for this cohort of patients.

Other Non-malignant hematopoietic disorders

MASITINIB FOR TREATMENT OF SEVERELY SYMPTOMATIC INDOLENT SYSTEMIC MACROCYSTIS: ADDITIONAL EFFICACY ANALYSES FROM THE RANDOMIZED, PLACEBO-CONTROLLED, PHASE 3 STUDY

Background: Masitinib, a selective oral tyrosine kinase inhibitor targeting wild-type KIT, LYN and FYN, was the first drug to demonstrate efficacy in a phase 3 setting (study AB06006) for treatment of patients with severe indolent systemic mastocytosis (ISM) who are unresponsive to existing, optimal symptomatic treatments. In The Lancet (Feb 11;389(10069):612-620), Lortholary and colleagues reported a significant and clinically meaningful treatment benefit for masitinib (6mg/kg/day over 24-weeks) versus placebo, with primary analysis based on cumulative response (≥75% improvement from baseline, timeframe weeks 8-24, comprising 5 visits at 4-week intervals) in at least one of four severe baseline symptoms (pruritus, flushes, depression, or fatigue) using repeated measures methodology for rare diseases (i.e. a longitudinal analysis with respect to symptoms as opposed to patient response rate at a single point in time). Eligible patients were aged 18–75 years and had ISM according to inclusion criteria that were slightly broader than the WHO classification. Aims: To aid interpretation of this study’s prospectively declared primary endpoint via comparison with additional efficacy analyses based on a cohort restricted to the WHO classification of ISM and more conventional patient-centric response endpoints. Methods: Randomized, placebo-controlled, phase 3 study that included 135 severely symptomatic ISM patients, including the subvariant smoldering systemic mastocytosis (71 mastocytis, 64 placebo), 90% of whom satisfied the WHO classification. Results: Masitinib showed a significant improvement over placebo according to its pre-specified primary endpoint (mITT population), with a cumulative response of 16.7% versus 7.4%, respectively, odds ratio (OR) of 3.6 [95%CI 1.2-10.8], P=0.008 (with re-randomization). This outcome was confirmed in the WHO patient subgroup: 17.8% versus 8.0%, respectively, OR=3.25 [0.97-10.88], P=0.0317. Computing the primary analysis (mITT) according to cumulative response per patient (GEE model) was also positive: 26.7% versus 12.8%, respectively, OR=2.48 [1.16-5.31], P=0.0212, as was analysis according to individual patient response (Pearson chi-square): 40.3% versus 24.2%, respectively, P=0.0062. Response (per patient) on all severe baseline symptoms for at least one visit was: 16.4% versus 7.6%, respectively, P=0.0062. Finally, analysis of sustained response in all severe baseline symptoms over multiple visits was highly discriminative between treatment arms: for patients with 3 severe baseline symptoms generated a 12.5% response rate (≥75% improvement in each symptom) for 3 out of 5 visits, versus no response for placebo; and for patients with ≥2 severe baseline symptoms masitinib generated a response rate of 21.1%, 15.8% and 10.5% over at least 1, 2, and 3 visits, respectively, versus no response for placebo. Summary/Conclusions: These post-hoc analyses confirm the clinical relevance, durability, and generalizability of the positive primary endpoint from study AB06006. Findings therefore support the conclusion that masitinib generates a significant therapeutic benefit in patients with severely symptomatic ISM who were unresponsive to optimal symptomatic treatments.

THERAPY RESPONSE AND LONG-TERM OUTCOME OF 71 ADULT PATIENTS WITH HEMATOMALIGINANCY-ASSOCIATED HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS: A SINGLE INSTITUTION EXPERIENCE

M. Machaczka1,2,*, K. Kosior1, E. Pawłowicz1, M. Wolan2, M. Gajewski1, M. Klimkowska3

1Delegowice, 2Department of Allergology, Medical University of Gdańsk, Gdańsk, Poland, 3Department of Dermatology and Allergology, Hôpital Tenon, Centre de référence des mastocytoses, Paris, France. 4Department of Laboratory Medicine & APHP Necker-Enfants Malades, 5Department of Infectious Diseases and Tropical Medicine and Centre d’Infectiologie Necker-Pasteur, Hôpital Necker-Enfants-Malades, Université Paris Descartes, Paris Sorbonne Cité, 6Centre de Référence des Mucoviscidose, Université Paris Descartes, Hôpital Necker Enfants Malades, Paris, France.

Masitinib, a selective oral tyrosine kinase inhibitor targeting wild-type KIT, LYN and FYN, was the first drug to demonstrate efficacy in a phase 3 setting (study AB06006) for treatment of patients with severe indolent systemic mastocytosis (ISM) who are unresponsive to existing, optimal symptomatic treatments. In The Lancet (Feb 11;389(10069):612-620), Lortholary and colleagues reported a significant and clinically meaningful treatment benefit for masitinib (6mg/kg/day over 24-weeks) versus placebo, with primary analysis based on cumulative response (≥75% improvement from baseline, timeframe weeks 8-24, comprising 5 visits at 4-week intervals) in at least one of four severe baseline symptoms (pruritus, flushes, depression, or fatigue) using repeated measures methodology for rare diseases (i.e. a longitudinal analysis with respect to symptoms as opposed to patient response rate at a single point in time). Eligible patients were aged 18–75 years and had ISM according to inclusion criteria that were slightly broader than the WHO classification. Aims: To aid interpretation of this study’s prospectively declared primary endpoint via comparison with additional efficacy analyses based on a cohort restricted to the WHO classification of ISM and more conventional patient-centric response endpoints. Methods: Randomized, placebo-controlled, phase 3 study that included 135 severely symptomatic ISM patients, including the subvariant smoldering systemic mastocytosis (71 mastocytis, 64 placebo), 90% of whom satisfied the WHO classification. Results: Masitinib showed a significant improvement over placebo according to its pre-specified primary endpoint (mITT population), with a cumulative response of 16.7% versus 7.4%, respectively, odds ratio (OR) of 3.6 [95%CI 1.2-10.8], P=0.008 (with re-randomization). This outcome was confirmed in the WHO patient subgroup: 17.8% versus 8.0%, respectively, OR=3.25 [0.97-10.88], P=0.0317. Computing the primary analysis (mITT) according to cumulative response per patient (GEE model) was also positive: 26.7% versus 12.8%, respectively, OR=2.48 [1.16-5.31], P=0.0212, as was analysis according to individual patient response (Pearson chi-square): 40.3% versus 24.2%, respectively, P=0.0062. Response (per patient) on all severe baseline symptoms for at least one visit was: 16.4% versus 7.6%, respectively, P=0.0062. Finally, analysis of sustained response in all severe baseline symptoms over multiple visits was highly discriminative between treatment arms: for patients with 3 severe baseline symptoms generated a 12.5% response rate (≥75% improvement in each symptom) for 3 out of 5 visits, versus no response for placebo; and for patients with ≥2 severe baseline symptoms masitinib generated a response rate of 21.1%, 15.8% and 10.5% over at least 1, 2, and 3 visits, respectively, versus no response for placebo. Summary/Conclusions: These post-hoc analyses confirm the clinical relevance, durability, and generalizability of the positive primary endpoint from study AB06006. Findings therefore support the conclusion that masitinib generates a significant therapeutic benefit in patients with severely symptomatic ISM who were unresponsive to optimal symptomatic treatments.
Background: Hemophagocytic lymphohistiocytosis (HLH) is a devastating disorder of uncontrolled immune activation characterized by clinicopathological evidence of extreme inflammation. Hematological malignancy-associated HLH (HM-HLH) has the worst outcome in comparison with any other form of HLH. HM-HLH can occur as the first manifestation of an occult malignancy, before start or during the treatment of known malignancy, or as the sign of a malignancy relapse or transformation to the more aggressive disease form.

Aims: The aim of the present study was to analyze the response to HLH therapy and overall survival of adult patients with HM-HLH.

Methods: From 2008 and onwards, data on adult patients referred to the Hematology Center Karolinska with suspected HLH were prospectively collected. Review concerned records of 142 adults with suspected HLH, hospitalized between January 2009 and December 2016. Of those, 71 patients with hematological malignancy were diagnosed with HLH and included to the present study. Hematological malignancy was defined as a neoplasm of lymphoid or myeloid origin. In all studied patients, the diagnosis of HLH was based on the HLH-2004 criteria. Infection as a possible additional trigger of HLH was carefully studied in all our HM-HLH patients. EBV and CMV DNA were routinely examined in whole blood, using RT quantitative PCR; other viruses (e.g., adenovirus, HSV, VZV, HHV6, influenza) were studied based on indications. Blood and urine cultures were performed in order to reveal any bacterial or fungal infections. Tests for fungal antigens, tuberculosis, and parasites were also performed if indicated. HLH treatment categories have included proapoptotic chemotherapy (etoposide) and immunosuppressive drugs, targeting hyperactivated macrophages (etoposide, corticosteroids, IVIG) and T cells (corticosteroids, cyclosporine A).

Results: Seventy-one adults, aged 22–84 years, were diagnosed with aggressive HM-HLH during the 8-year period. Lymphoid malignancy was diagnosed in 42 patients and myeloid malignancy in 29 patients. Fifty-four (76%) patients developed HLH as a first manifestation of an unknown malignancy, during aggressive disease, or malignancy relapse. The remaining 24% patients developed HLH during chemotherapy. In 14 patients, HLH therapy started before confirmation of HLH diagnosis, based on suspicion of HLH (mean 6.7±8.4 days; range 0–41 days; median 2 days; range 1–31 days). Seventeen patients started HLH therapy at the day of HLH diagnosis. In 36 patients HLH therapy started after confirmation of HLH diagnosis (mean 15.9±4.13 days; median 5 days; range 1–242 days). Forty of 71 (56%) patients with active HLH died, of which 20 had signs of progressive malignancy. 16 patients had generalized infection (bacterial - 12 patients, viral - 3 patients, fungal - 4 patients; some patients had more than one type of infection), and 20 patients developed central nervous system bleeding. Thirty-one (44%) patients responded to HLH therapy and achieved remission of HLH. However, only 13 of 71 (18%) patients with HM-HLH were still alive after a median follow-up time of 50 months, despite the attempted treatment in 67 (94%) cases. The probability of overall survival (OS) from 0, 12, 24 and 60 months after HLH diagnosis was 39, 20, 15 and 15%, respectively. The patients who developed HM-HLH with concomitant infection during chemotherapy had significantly longer OS (p=0.03) compared to patients who had HLH solely attributed to malignancy (Figure 1).

Summary/Conclusions: HLH in the context of malignancy is still considered a challenging adult hematologic. HM-HLH is a highly lethal disorder in adults. The patients who develop HM-HLH with concomitant infection during chemotherapy show better survival than those who had HLH solely attributed to malignancy. Although poor outcome in some patients with HM-HLH is related to malignancy progression, in some patients the lack of effective M-HLH therapy may further impede adequate treatment of malignancy.

WHOLE-EXOME SEQUENCING IN CHILDREN WITH IMMUNE CYTOPENIA: THE APPLICABILITY AND CLINICAL IMPACT

M. Svetlo1,*, V. Kanderová1, P. Čmišek2, L. Suková2, L. Šrámková2, J. Kaysersová3, J. Stuchlí3, M. Zálova2, L. Důšáková4, Š. Průhová4, M. Vlčková5, T. Freiberger5, D. Pospišilová7, J. Blatný3, D. Froňkova1, 1CLIP - Childhood Leukemia Investigation Prague, Department of Paediatric Hematology and Oncology, 2Department of Paediatrics, 3Department of Paediatrics, 4Department of Haematology and Oncology, 5Department of Immunology, 6Department of Paediatrics, 7Department of Biology and Medical Genetics, Second Faculty of Medicine, Charles University and University Hospital Motol, Prague, 8Molecular Genetics Laboratory, Centre for Cardiovascular Surgery and Transplantation, Brno, 9Department of Pediatrics, Faculty of Medicine and Dentistry, Palacky University and University Hospital, Olomouc, 10Department of Paediatric Haematology, Masaryk University and University Hospital, Brno, 11Department of Pediatrics, Masaryk Hospital, Usti nad Labem, Czech Republic

Background: Next generation sequencing is rapidly becoming the main diagnostic tool for precise identification of gene defects in human diseases. Apart from the identification of novel causal genes and pathogenic variants, the main research goal for now is to assess the impact and strategy of whole exome sequencing (WES) use in routine clinical evaluation.

Aims: We aimed to evaluate the benefits and drawbacks of using WES as a diagnostic method in patients with chronic early-onset autoimmune hemolytic anemia (AIHA), idiopathic thrombocytopenic purpura (ITP) and immune neutropenia, or their combination (Evans syndrome). Most of these patients presented with additional symptoms of immune dysregulation, e.g., common variable immunodeficiency (CVID), lymphoproliferative, autoimmune disorders (diabetes mellitus 1, thyroëditis). We aimed to identify a novel variant leading to CTLA4 deficiency, another novel variant in CTLA4 was identified together with an additional pathogenic variant in TSC1, causing a mixed phenotype. The genetic diagnosis of CTLA4 deficiency allowed for the use of CTLA4 agonist (Abatacept) treatment in 1 patient that led to improvement of his symptoms and disease stabilization. However, after 6 months, the patient had developed agranulocytosis that led to hematopoietic stem cell transplantation. In 1 patient we were able to identify a gain-of-function variant in STAT3 that was recently described in immune dysregulation. In 3 patients we observed variants in genes typically described in connection with antibody deficiency (TACI, CD40L, and IKBKG). In 1 patient with chronic AIHA and ITP we found a novel heterozygous variant in TERT gene related to dyskeratosist congenita. In 1 patient with multiple congenital abnormalities and Evans syndrome we discovered a heterozygous variant in KMT2D gene causing Kabuki syndrome. The remainder of our patients harboured variants that posed a diagnostic challenge. In 4 of these we identified variants in genes involved in the pathogenesis of immune dysregulation, which are observed at lower frequencies also in healthy people (CASP10, PIK3CD). 12 patients (36%) had either only one hit in the genes reported causal in autosomal recessive diseases (e.g., ITK, LRBA) or we have not yet found any relevant aberration. In 4 patients we were able to identify novel variants in genes related to immune dysregulation. However, these variants require extensive validation studies, using patients’ primary cells or manipulating established in-vitro or animal models and gene editing techniques, in order to prove the causality.

Summary/Conclusions: WES is a highly useful method that helps to identify the genetic cause of the disease in approximately one third of patients and enables targeted therapy. While targeted sequencing can further reduce costs and make analysis more straightforward, gene panels are quickly becoming obsolete as new causal variants are discovered in the rapidly evolving field of primary immunodeficiencies. Because of the heterogeneity of genetic causes of immune cytopenias, we recommend to use WES over targeted gene panel sequencing.

Background: Erythrocytoses are characterized by an elevated red cell mass. The most widely studied disease is Polycythemia Vera (PV), however, other types of erythrocytoses can be either inherited (Congenital Erythrocytosis-CE) or acquired (Secondary Erythrocytosis). Secondary erythrocytosis related to lung, cardiac or renal disorder. Next generation sequencing (NGS) has been used to analyse the presence of mutations in 28 genes (enlarged hypoxia pathway and other candidate genes).

Methods: We created and developed a national network in France to analyze the genomic abnormalities in patients suspected of CE. The selection of patients was performed by clinicians and according to the hypoxia induced erythrocythemia Vossen criteria.

Results: To date, samples from 140 patients have been registered, among whom 46 have been analysed using NGS approach. Variants in 14 different genes were found in 14 patients. [13 males and 1 female; median age 50 y. (12-71)] with unknown significance have been detected, including 4 in PHD genes, 5 in HIF genes, 4 in LNK genes (SH2B3) and 1 in JAK2 gene. In patients with variants, a familial history of erythrocytosis was noted in 3. No independent thrombotic complication was reported in the patients. All patients were followed up for a median of 6 months (range 3 to 24 months).

Aims: To identify the specific PB cell compartments that carry this mutation.

Methods: The distribution of different maturation-associated of BM and PB CD34+ HPC from 64 newly-diagnosed (KIT-mutated) ISM patients and 14 healthy controls was analyzed by flow cytometry. In 18 patients distinct FACS-purified PB cell compartments were also investigated for the KIT mutation. Results: ISM patient’s showed higher percentages of both BM and PB KIT-mutated CD34+ HPC vs controls, particularly among ISM cases with MC-restricted KIT mutation (ISMmc); this was associated with progressive blockade of maturation of CD34+ HPC to neutrophil lineage from ISMMC to multilineage KIT-mutated cases (ISMkl). Regarding the frequency of KIT-mutated cases and cell populations in PB, variable patterns were observed, the percentage of KIT-mutated PB CD34+ HPC, eosinophils, neutrophils, monocytes and T-cells increasing from ISMMC to ISMkl to ISMMk patients.

Summary/Conclusions: Positive for the KIT D816V mutation in PB of ISM is associated with an expansion of circulating KIT-mutated cell populations and with multiple myeloid cell populations, KIT-mutated PB CD34+ HPC potentially contributing to disease dissemination already at very early stages.

B. Rossi, Verona, 11Department of Pediatric Haematology-Oncology, University of Catania, Catania, 12Department of Haematology, Ca’Foncello Hospital, Treviso, Italy

Background: Erythrocytosis, (i.e. increased levels of hemoglobin/hematocrit (Hb/Ht) >95% percentile for age and sex), is rarely found in pediatric or adolescent age. Presence of familial cases, presentation at birth or presence of known mutations, as well as exclusion of secondary causes identifies primary (PE) or congenital secondary forms (CE). However, many cases still lack evidential etiological definition (idiopathic E.). Moreover, natural course and treatment are still anecdotally reported.

Aims: Here we present our experience in a large and heterogeneous series of children with absolute erythrocytosis. The aims is to identify a possible clinical and diagnostic approach to children with erythrocytosis

Methods: All children with E. who lacked evidence of reactive origin were consecutively referred to our laboratory for molecular evaluation. Molecular analysis of the main involved genes (VHL, HIF2A, EPOR, JAK2, PHD2) was performed by allele specific PCR, PCR on direct DNA sequencing. Erythropoietic Colony Essay (ECE) was performed on peripheral blood with and without cytokines. Clinical features and treatment choices were reported by referring clinicians (table 1).

Table 1.

Results: Patients were group according to the definitions of absolute Erythrocytosis. A total of 44 pediatric cases were identified (less than 18 years old). There were 7 families, where 5 adults were also found polyglobulic. However, in only 4 families a defect was identified 2 VHL, and 2 Hb variants). One Hb positive case was found sporadic. Most Hb variants were not symptomatic, while all other familial cases had splenomegaly and vascular symptoms. Among non familial, non genetic cases, 5 children were affected by Down Syndrome; 4 children had severe renal or cerebral disease. In one 4 year old girl, with a polymorphic VHL variant, who presented with arterial hypertension, a small size ganglioneuroma was found after a 5yrs follow-up. In 21 cases non causes could be identified. They were mostly male (n18); presented at adolescent age with advanced puberal status (n17); many were symptomatic (6). Only one 9 year old girl was diagnosed with polycytysma vera (JAK2V617F positive). Treatment varied according to physician decisions and presence of vascular symptoms, 6 children received ASA and 11 were phlebotomised. In two older patients severe vascular complications were observed (arterial thrombosis), in one with Htc<45%. Summary/Conclusions: This series shows the heterogeneity of Erythrocytosis as found in pediatrics. Extensive clinical and genetic analysis are required but still a large number of cases lack clear definitions. The usefulness of antigaeation and phlebotomy is not proved.

P717

AUTOIMMUNE NEUTROPEINIA OF CHILDDHOOD SECONDARY TO OTHER AUTOIMMUNE DISORDER: DATA FROM THE ITALIAN NEUTROPEINIA REGISTRY

Background: Neurological involvement is poorly described in autoimmune cytopenias (AIC), containing immune thrombocytopenia (ITP), autoimmune hemolytic anemia (AIHA) and Evans syndrome (ES). This association suggests an underlying primary immunodeficiency (PID).

Aims: To describe neurological involvement observed in autoimmune cytopneas, evolution under treatment and PID profiles in these patients.

Methods: OBS'CREASEVANCE is a French nationwide prospective cohort including patients with a PID. Patients with a neurological involvement were analyzed excluding neurological symptoms related to a traumatism or isolated febrile seizures. Clinical, radiological and biological data were collected from primary centers. Centralized radiological review was performed. Genetic analyses were performed by Sanger gene sequencing or gene-panel based next generation sequencing.

Results: On October 2016, among the 1,167 patients of the cohort (371 AIHA, 615 ITP, 181 ES), a significant neurological involvement was observed in 8 patients from 7 centers. With a median (range) follow-up of 12 years (6-26.5), 7 children had ES (including autoimmune neutropenia in 5) and 1 child had isolated ITP. Median age at diagnosis was 11.5 years (1.6-15.8). At the last follow-up point, AIC were in partial or complete remission for all patients. Neurological symptoms appeared with a mean delay of 6 years (2.5-18) after AIC onset. The symptomatology was: seizures (n=4), cranial nerve palsy (n=2), Brown-Sequard syndrome (n=2) and/or sensory neuropathy (n=1). No infectious pathogens were identified. MRI showed multiple (n=6) or unique (n=2) inflammatory lesions with hypertense T2 signal in all patients, gadolinium-enhancing lesions in 7 and perilesional edema in 5. Five patients had a total of 8 biopsies, which confirmed the inflammatory process with macrophagic (n=3) or lymphoplasmocytary (n=5) infiltrates. In 4 cases, a lymphocytic meningitis was associated. Non-neurological organ involvement was present in all patients, mainly pulmonary nodules (n=6) and lymphoproliferation (n=4). All patients had an abnormal immunophenotype, with T-cell (n=7) or B-cell (n=3) deficiency and hypogammaglobulinemia was present in 7 of the 8 cases. Pathogen have been given standard treatment for autoimmune immunological (n=2), or immunosuppressive treatment (n=3, Ciclosporin, Mycophenolate Mofetil and Methotrexate), improving symptomatology and MRI for all. Five patients relapsed and 3 patients had an asymptomatic radiological progression. At the last follow up point, all patients had neurological sequel and 7 persisting radiological abnormalities. Four out of 8 patients analyzed had a PID: 22q11.2 microdeletion (n=1), heterozygous C7A mutation (n=2) or homozygous LRBA mutation (n=1).

Summary/Conclusions: Neurological involvement is a rare and severe late event in the course of childhood ES, or exceptionally AIHA, that may reveal various underlying PID. Complete imaging and pathology examination highlight a causative immune dysregulation and could guide specific therapeutic strategies.

Background: The most frequent Autoimmune Neutropenia (AIN) in childhood is the primary type (p-AIN), whereas in adults AIN is mostly represented by secondary neutropenias, which can be associated to infection, drug administration, immunodeficiency, neoplasms, bone marrow transplantation or other autoimmune disorders.

Aims: To describe clinic and laboratory findings in children affected by AIN secondary to other autoimmune diseases (s-AIN).

Methods: This registry study analyzes 26 patients affected by s-AIN enrolled in the Italian neutropenia registry of A.I.E.O.P. (Associazione Italiana di Onco-Ematologia Pediatrica) over a 15-year time-span: this cohort, the largest ever described, was compared to 263 patients affected by p-AIN enrolled in the Registry in the same period.

Table 1.

Results: Specific characteristics of s-AIN patients are presented in Figure 1. The prevalence of former preterm babies among p-AIN (and not s-AIN) patients was significantly higher than in a cohort of 487 consecutively hospitalized children (p=0.0003). The median age of onset of AIN was 0.77 year and 10.07 year in p-AIN and s-AIN respectively (p=1.105e-12). The prevalence of selected IgA deficiency was 3% in p-AIN and 13.6% in s-AIN children: both prevalences were significantly higher than that (0.21%) of a group of 470 controls (p=0.0009 in p-AIN and p=7.239e-12 in s-AIN). Median value of neutrophils was lower in p-AIN (0.45 x 10^9/L) than in s-AIN 0.63 x 10^9/L (p=0.03); median value of lymphocytes was significantly reduced (p=6.29e-11) in s-AIN (1.58 x 10^9/L) vs p-AIN (4.36 x 10^9/L) group. Leucopenia (p=1.80e-07) and severe infections (p=0.0001) occurred more frequently in s-AIN; mononcytosis (p=0.039) and spontaneous remission (p=3.21e-11) in p-AIN. GCSF was used in 6.9% of the patients with eculizumab: abortion threat 35.3% vs 85.7%, fetal growth retardation syndrome 7.1% vs 21.4%, preeclampsia 5.9% vs 14.3%. Transfusion rate was higher without eculizumab (86.7% vs 41.2%). Pregnancies resulted in the birth in 100% patients exposed eculizumab and 42.9% on supportive treatment. Mean birth weight 2560 g (450-3550). Most of newborns (87.5%) are healthy, 83.3% of them received breastfeeding without complications both on eculizumab and without it.

Summary/Conclusions: p-AIN is in the vast majority of cases a benign and self-limiting disorder typically occurring under 2-3 years old whereas s-AIN is a more severe disease, usually appearing after the first 5 years of life, usually associated to lymphocytopenia and with a highly frequent tendency to become chronic.

P718 PAROSYMSAL NOCTURNAL HEMOGLOBINURIA TREATMENT DURING PREGNANCY

M. Vinogradova1, 1A. Kulagin2, T. Kirsanova1, N. Klimchenko3, R. Shmakov3

1hematology, Federal Scientific Center for Obstetrics, Gynecology and Perinatology, Moscow, 2hematology, 1st Saint Petersburg State Medical University, Saint Petersburg, 3obstetrics, Federal Scientific Center for Obstetrics, Gynecology and Perinatology, Moscow, Russian Federation

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a life-threatening disorder with a high risk of thrombosis. Targeted therapy radically changed the prognosis in PNH. Therefore issues of reproductive health in PNH patients are becoming very important. Recently the management of PNH during pregnancy has been challenging because of the high risk of maternal morbidity and frequent pregnancy loss. The combination of targeted therapy with eculizumab and anticoagulants made it possible not only to increase the survival rate, but also to improve the quality of life.

Aims: We compared the pregnancy outcomes in PNH patients on eculizumab treatment and retrospective data of pregnancies on symptomatic therapy only.

Methods: Since 1999 we have analyzed 32 pregnancies in PNH patients. 17 patients (group 1) from 2013 exposed to eculizumab during pregnancy with anticoagulants. Other 15 women (group 2) received only symptomatic therapy.

Results: Clinical manifestations of hemolysis significantly regressed during eculizumab treatment: normalization of LDH was registered in 76.5% patients. Without eculizumab LDH level increased in all pregnant patients. No maternal death and thrombotic events have been observed. 42.9% of patients required a dose adjustment due to breakthrough hemolysis (a dose increase and/or more frequent use of eculizumab). Pregnancy complications were less frequent with eculizumab: abortion threat 35.3% vs 85.7%, fetal growth retardation syndrome 7.1% vs 21.4%, preeclampsia 5.9% vs 14.3%. Transfusion rate was higher without eculizumab (86.7% vs 41.2%). Pregnancies resulted in the birth in 100% patients exposed eculizumab and 42.9% on supportive treatment. Mean birth weight 2560 g (450-3550). Most of newborns (87.5%) are healthy, 83.3% of them received breastfeeding without complications both on eculizumab and without it.

Summary/Conclusions: We can conclude that pregnancy outcomes in PNH patients with eculizumab are much better than with symptomatic therapy only. Our data demonstrate the possibility of safe therapy with eculizumab in pregnant women. Pregnancy does not worsen the prognosis of PNH in the case of targeted and adequate supportive therapy. There is no difference in health between infants born by mothers with PNH and the newborns from general population.
Platelet disorders: Clinical

P719
LONG-TERM RESPONSE TO ORAL ELTROMBOPAG IN TREATMENT-NAÏVE ADULTS WITH GAUCHER DISEASE TYPE 1: FINAL EFFICACY AND SAFETY RESULTS FROM A PHASE 2 CLINICAL TRIAL AFTER 8 YEARS OF TREATMENT

E. Lukina, N. Watman, M. Dragosky, H. Lau, E. Avila Arreguin, H. Rosenbaum, Y. Wu, S. Gaemers, M.J. Peterschmitt
1National Research Center for Hematology, Moscow, Russian Federation, 2Hospital Ramos Mejia, 3IMAI-Research, Buenos Aires, Argentina, 4New York University School of Medicine, New York, United States, 5Instituto Mexicano del Seguro Social Hospital de Especialidades, Col. La Raza, Mexico, 6Rambam Medical Center, Haifa, Israel, 7Sanofi Genzyme, Cambridge, United States

Background: In Gaucher disease type 1 (GD1), deficient lysosomal acid β-glucosidase activity leads to accumulation of glucosylceramide, primarily in macrophages (Gaucher cells), which deposit in the spleen, liver, and bone marrow, leading to thrombocytopenia, anemia, hepatosplenomegaly, and skeletal disease. Hematologists often identify and manage the disease. Intravenous enzyme replacement therapy (ERT) with recombiant acid β-glucosidase has been the mainstay of therapy for GD1. Eltrombopag is an oral oral platelet-stimulating agent approved as first-line treatment for adults with GD1 with poor, intermediate, or extensive CYP2D6-metabolizer phenotypes (>90% of patients). Phase 3 trials demonstrated safety and efficacy of eltrombopag in naïve patients (Mistry et al. JAMA. 2015) and safety and stability in patients switching from long-term ERT (Cox et al. Blood. 2017). We report the final 8-year results of an open-label Phase 2 trial (NCT00385180, Sanofi Genzyme) in previously untreated adults with GD1. These data build on 1-, 2-, and 4-year data showing sustained improvements in hematologic parameters, organ volumes, disease-related biomarkers, and measures of bone health (Lukina et al. Blood Cells Mol Dis. 2014).

Methods: Adult GD1 patients who had splenomegaly with thrombocytopenia and/or anemia received 50 or 100mg eltrombopag twice daily, dosed by plasma trough levels. Efficacy outcomes included changes in hemoglobin, platelets, spleen and liver volumes, disease-related biomarker levels, skeletal manifestations, and achievement of therapeutic goals for anemia, thrombocytopenia, splenomegaly, and hepatomegaly (Pastores et al. Semin Hematol. 2004; Lukina et al. Blood. 2010).

Results: Of 26 enrolled patients, 19 completed the trial and 7 withdrew: 2 on the first day of treatment due to asymptomatic nonsustained ventricular tachycardia detected during routine monitoring (plasma levels of eliglustat were undetectable); 1 after 1 year due to progression of a bone lesion (retrospectively identified at baseline); 1 chose to withdraw after 2 years; and 3 due to pregnancy. After 8 years of eliglustat, mean (±SD) hemoglobin level and platelet count increased by 2.1±1.7 g/dL (from 11.3±1.6 to 13.4±1.3 g/dL) and 110% (from 76±52 to 158±96 x10^9/L, respectively). Mean spleen and liver volumes (multiples of normal, MN) decreased by 68% (from 17.3±10.4 to 5.1±3.5 MN) and 31% (from 1.6±0.5 to 1.1±0.3 MN), respectively. All patients met ≥3 of 4 long-term therapeutic goals (spleen, 100% of patients; liver, 100%; hemoglobin, 93%; platelets, 53%) by 7-8 years. Median chitotriosidase levels decreased by 43% with eliglustat (82%); α-L-fucosidase by 44% (88%); plasma GL-1 normalized. Total mean lumbar spine bone mineral density increased by 0.12 g/cm²; mean Z-score increased by 0.88 (from -1.27±1.02 to -0.39±1.13) and mean T-score by 0.95 (from -1.64±1.07 to -0.69±1.31). Eltrombopag was well-tolerated. All quality of life measures (SF-36, fatigue severity score) showed improvement over time. Most adverse events in this long-term trial were mild or moderate in severity (98%, 342/348) and considered unrelated (94%, 328/348) to treatment.

Summary/Conclusions: After 8 years of treatment with eltrombopag, clinically meaningful improvements in hematologic, visceral, biomarker, and bone parameters continued or were maintained among patients in this Phase 2 trial. No new safety concerns emerged.

P720
REAL WORLD EVIDENCE ON DRUG UTILIZATION PATTERNS OF ELTROMBOPAG IN ADULT PATIENTS WITH IMMUNE THROMBOCYTOPENIA: AN ANALYSIS OF ELTROMBOPAG [ELTROMBOPAG] IN SELECTED COUNTRIES IN THE EUROPEAN UNION (EU) STUDY

E.O. Gutiérrez1, A. Salamà2, J.-F. Viallard3, R.G. Delgado4, M.E. Mingol-Castellano5, E. Queve-Fehling6, O.A. Ozem7, A. Allepuz8, T.J. González-López
1Hospital Universitario Puerta de Hierro Majadahonda, Madrid, Spain, 2Charité Universitätsmedizin Berlin, Berlin, Germany, 3Hôpital Haut Lévêque Centre des Maladies de l’Appareil Sanguin de Bordeaux, Bordeaux, France, 4Hospital Clinic Universitari i Mediterrani de València, Valencia, Spain, 5Hospital Universitario de Málaga, Málaga, Spain

Background: Immune thrombocytopenia (ITP) is an autoimmune disorder characterized by isolated thrombocytopenia, with platelet counts <100x10^9/L. Ertrombopag is an oral small-molecule nonpeptide thrombopoietin-receptor agonist that has shown to increase platelet production in clinical trials. Ertrombopag is approved for the management of patients with chronic ITP (aged ≥1 year) who are refractory to other treatments (eg, corticosteroids, immunoglobulins). The recommended eltrombopag dose in patients with chronic ITP is 25mg once daily, OD (East Asians, 12.5mg OD or 25mg every other day) in pediatrics aged 1-5 years, and 50mg OD (East Asians, 25mg OD) in adults and pediatrics aged 6-17 years at initiation, followed by dose adjustment to a maximum of 75mg OD based on platelet counts. REVIEU study was conducted in accordance with risk management plan in five European Union (EU) countries to document eltrombopag utilization patterns in real-world practice. Here, we report the eltrombopag prescribing data on the subset of adult patients (aged ≥18 years) with ITP as primary diagnosis.

Aims: To evaluate the real-world data to determine drug utilization patterns among adult patients with ITP receiving eltrombopag within five EU countries.

Methods: REVIEU study was a multinational, multicenter, retrospective, medical chart review in patients with a documented past treatment with eltrombopag between the period immediately after first approval/launch in May 2010 and September 2014 (ie, dispensed at least once by the pharmacy and patient received at least one dose) for whatever reason. Patients who participated or were participating in a randomized eltrombopag clinical trial were excluded.

Table 1.

Results: Overall, 287 adult patients with ITP (chronic [≥12 months], 75.3%; persistent [≥3-12 months], 10.8%; acute [≥3 months], 13.6%; unknown [n=1]) were included, majority in Spain (n=128) followed by Italy (n=67), Greece (n=36), France (n=29), and Germany (n=27). Ertrombopag was the first treatment with no prior ITP therapies in 12 (4.2%) [acute, 10.3%; persistent, 6.5%; chronic, 2.8%] patients. A total of 99 (34.6%) patients received one prior therapy (corticosteroids, 79 [27.6%], 128 (44.8%) patients received two prior therapies (corticosteroids+immunoglobulins, 74 [25.6%]; corticosteroids+immunoglobulins+intravenous immunoglobulins, 114 [39.9%]). 126 (43.7%) patients received three prior therapies (corticosteroids, immunoglobulins, and splenectomy). In total, the majority of patients received at least one prescription of corticosteroids (252, 88.1%) followed by immunoglobulins (180, 62.9%), and splenectomy (64, 22.4%) prior to eltrombopag initiation. Patients received an average daily dose of eltrombopag 45.6mg (chronic ITP, 44.6mg; persistent ITP, 43.1mg; acute ITP, 53.0mg) during the study. Overall, dose changes were reported in 749 adult ITP prescriptions (down-titration, 53.7%; up-titration, 43.7%; no change in dose, 2.7%). 49.1% of dose changes were reported during the first 6 months of treatment (35% in first 3 months). The main reasons for dose change included: disease improvement (30.4%), no treatment response (26.8%) and others (27.1%). Disease improvement accounted for down-titration in 51.2% (206/402) and up-titration in 4.6% (15/327), and no treatment response for up-titration in 54.4% (178/327) and down-titration in 5.0% (20/402) of adult patients with chronic ITP and by ITP disease phase, and by eltrombopag dose are reported in Table 1.

Summary/Conclusions: The majority of adult patients with ITP (75.3%) were diagnosed with chronic ITP, and were treated with eltrombopag as second-line or greater therapy after corticosteroids and immunoglobulins, in line with the approved indication. Ertrombopag was also prescribed in 24.4% of adult patients with acute and persistent ITP. The starting dose followed the summary of product characteristics (SmPC) recommendations in the majority of cases and dose modifications were generally according to platelet counts. Data from REVIEU study have shown that eltrombopag use in the real world setting is largely consistent with the EU label and is considered part of ITP medical therapies.
Background: A previous study has suggested a mechanism of Fcγ receptors (FcγR)-independent platelet clearance in immune thrombocytopenia (ITP) (1). Antibodies that related platelet desialylation may lead to platelet clearance in the liver via hepatic Ashwell–Morell receptors, providing a potential explanation for refractoriness to classical therapies (steroid, IVIG and splenectomy).

Aims: The aim of this study was to analyze the biological features of ITP patients refractory to conventional therapies.

Methods: We performed a prospective study in 8 patients with primary ITP not responding to standard treatments (corticosteroids, IVIG and/or splenectomy) as well as in 8 patients with non-refractory ITP (control group).

Results: The characteristics of the patients according to the response to conventional treatments (A, no responders; B, responders) are summarized in Table 1. Non responders exhibited lower platelet counts (p=0.006), higher expression of GPIIb (p=0.049) and loss of platelet sialic acids (p=0.005). Additionally, those who did not respond not only to traditional therapies (corticosteroids, IVIG and splenectomy) but also to thrombopoiesis. TPO-RAs–romiplostim (R) and eltrombopag (E) - offer a significant higher platelet desialylation in ITP patients who are non-responders to conventional therapies, par-

Summary/Conclusions: This study shows a significant higher platelet desialylation in ITP patients who are non-responders to conventional therapies, particularly if they are also refractory to TPO-RA. According to a previous study (1), these results seem to be associated to platelet activation mediated by anti-platelet specific antibodies.

Results: A total of 548 pts received either R or E between Dec 2009 and Dec 2015. Of these, 106 (19.4%) underwent TPO-RA switch. Table 1 summarizes outcome after switch. Overall 69/106 (65%) of pts achieved, regained or maintained response upon switching. Either one TPO-RA switch sequence was equally effective (p=0.882). Outcome was not associated with gender, age at 1st TPO-RA treatment, splenectomy status. However, number of lines of previous therapies interrupted or lower response (p=0.020); response on day 0/6 of line of therapy yielded a 30% increase in the odds of being a non-responder; a trend toward lower probability of response was observed in pts with longer lasting disease before 1st TPO-RA administration (p=0.066). Adverse events (AE; 16/106 pts) were generally mild and reversible upon discontinuation of either one TPO-RA. 1st TPO-RA was followed with thrombopoietin/erythropoietin (standard anticoagulation) thrombotic events were observed which did not recur after switching. AE were characteristic of older pts: each additional year increase in pts age determined a 5% increase in the odds of developing AE.

Summary/Conclusions: Approximately 20% of TPO-RA treated pts were felt by their attending physicians to potentially benefit from a switching strategy. Exposure to the 2nd TPO-RA was more effective in pts who had lost response to 1st TPO-RA (80% responders) compared to those who were non responders to 1st TPO-RA (49% responders, p=<0.001). It could be speculated that lack of response to either one of the two available TPO-RA identifies a subgroup of pts less likely to benefit from switching to the second available TPO-RA. Pts switched for non-efficacy reasons are more likely to maintain a response upon switch (p=0.030). The so far unexplained and unprecedented phenomenon of wide plt fluctuation appears to be linked to the removal of the spleen, the physiological plt reservoir organ.
patients with severe bleeding. At the end of follow-up, the estimated 10-year cumulative rate of no remission among patients with severe bleeding was higher than that among patients without severe bleeding (P=0.017, RR=1.608, 95% CI, 1.052-2.456). The estimated 10-year cause-specific mortality related to fatal bleeding in patients with severe bleeding was higher than that in patients without severe bleeding (P=0.001, RR=9.886, 95% CI, 1.806-54.098). The estimated 10-year mortality among ICH patients was higher than among severe (non-ICH) patients (P<0.009, RR=5.543, 95% CI, 1.317-15.668).

Summary/Conclusions: Platelet count <10×109/L, female patients, complication of pulmonary disease, gum or oral mucosal bleeding and epistaxis are significant predictive factors for severe bleeding in the elderly. Severe bleeding in elderly ITP was associated with more failure of response to treatment, increased long-term risk of no remission and mortality related to fatal bleeding.

ATORVASTATIN IMPROVE THE PROGNOSIS OF ADULT PATIENTS WITH CORTICOSTEROID-RESISTANT IMMUNE THROMBOCYTOPENIA VIA ENHANCING BONE MARROW ENDOTHELIAL CELL FUNCTION

Y. Kong1, X.-N. Cao1, X.-H. Zhang1, M.-M. Shi1,2, Y.-Y. Lai1, Y.-Q. Sun1, Y. Wang1, L.-P. Xu1, Y.-J. Chang1, X.-J. Huang1,2
1Peking University People’s Hospital, Peking University Institute of Hematology, 2Peking-Tsinghua Center for Life Sciences, Academy for Advanced Interdisciplinary Studies, Peking University, Beijing, China

Background: Immune thrombocytopenia (ITP) is generally considered to be an autoimmune disorder characterized by increased peripheral platelet destruction and reduced platelet production. Corticosteroids represent the standard first-line therapy achieving responses in around 80% of patients. However, for those corticosteroid-resistant ITP patients, who exhibit either no response (NR) to corticosteroids or corticosteroid-dependent, the pathogenesis remains poorly understood and the management is challenging. Emerging evidence from mouse studies has suggested that the cross-talk between megakaryocytes (MKs) and endothelial progenitor cells (EPCs) in the bone marrow (BM) microenvironment regulates MKs maturation and thrombopoiesis. We recently reported that the impaired BM EPCs, which could be quantitatively and functionally improved by atorvastatin in vitro, induced the occurrence of poor graft function following allo-transplant (Blood, 2016, 128:2988-2999). However, little is known about the functional role of BM EPCs and how to improve impaired BM EPCs in patients with corticosteroid-resistant ITP.

Aims: To determine whether quantitative and/or functional abnormalities of BM EPCs are involved in the occurrence of corticosteroid-resistant ITP. Moreover, to investigate the effects of atorvastatin and N-Acetyl-L-cysteine (NAC, a ROS scavenger) on the number and function of cultured BM EPCs derived from patients with corticosteroid-resistant ITP and its underlying molecular mechanisms. Finally, to evaluate the efficacy and safety of atorvastatin and NAC to adult patients with corticosteroid-resistant ITP.

Methods: Twenty-three patients with corticosteroid-resistant ITP, 30 patients with newly diagnosed ITP and 17 healthy donors (age 18-55) were enrolled from 2016 to 2017 at Peking University Institute of Hematology. BM EPCs were cultured as previous reported. Atorvastatin and NAC were administrated to the 5-day cultivated BM EPCs in corticosteroid-resistant ITP patients until tested on day 7. The number and function of BM EPCs were evaluated pre- and post-treatment, counting Dil-Ac-LDL and FITC-UEA-1 double staining, migration, cell proliferation, tube formation, levels of reactive Oxygen Species (ROS) and apoptosis. Proteins expressions for p38, ERK, JNK, Akt were measured by flow cytometry and western blot. Subsequently, a single-center pilot study was performed to evaluate the efficacy and safety of atorvastatin and/or NAC in corticosteroid-resistant ITP patients. The primary endpoints were complete response (CR), response (R), and overall response (OR). Secondary end points were time to response (TTR) and adverse events.

Results: Human bone marrow EPCs were demonstrated as the spindle shape and the similar expression of CD34, VEGFR2 and CD133 at day 7 of cultivation among patients. We enrolled three cohorts of subjects: increased and dysfunctional BM EPCs, which were characterized by impaired proliferation, migration, angiogenesis, and higher levels of ROS and apoptosis, were revealed in corticosteroid-resistant ITP patients compared to those in newly diagnosed ITP. Activation of p-p38 was detected in BM EPCs from corticosteroid-resistant ITP patients. Furthermore, the number and function of BM EPCs derived from corticosteroid-resistant ITP patients were enhanced by atorvastatin or NAC treatment in vitro through down-regulation of the p38 mitogen-activated protein kinase (MAPK) pathway. In the single-center pilot study, a total of 12 corticosteroid-resistant ITP patients were recruited to receive either the combination of atorvastatin and NAC or alone. ADR of CR, R and OR resulted from (3/12), 41.7% (5/12) and 66.7% (8/12), respectively. In patients who achieved CR and R, the median (range) TTR was 24 days (7-51 days), with no apparent adverse events.

Summary/Conclusions: The number and the function of BM EPCs were improved in vitro and in vivo via down-regulation of the p38 MAPK pathway. Although the sample size of clinical study is small, with a relatively short follow-up period by now, our data suggest that atorvastatin and NAC are effective and safe in the management of corticosteroid-resistant ITP patients. Therefore, further prospective multicenter randomized clinical trials with larger sample size are needed in the future.
**Results:** The platelet desialylation levels increased significantly in the 127 septic patients with thrombocytopenia compared to the 134 patients without thrombocytopenia. A platelet response was achieved in 45 of the 54 patients in the oseltamivir group (83.3%) compared with 34 of the 52 patients in the control group (65.4%; \(P=0.045\)). The median platelet recovery time was 5 days (interquartile range 4–6) in the oseltamivir group compared with 7 days (interquartile range 5–10) in the control group (\(P=0.003\)). The amount of platelets transfused decreased significantly in the oseltamivir group compared to the control group (\(P=0.044\)). The multivariate analysis by Cox proportional hazards models showed that the Sequential Organ Failure Assessment (SOFA) score and platelet recovery time were independent indicators of oseltamivir therapy.

**Summary/Conclusions:** Thrombocytopenia was associated with increased platelet desialylation in septic patients. The addition of oseltamivir could significantly increase the platelet response rate, shorten platelet recovery time and reduce platelet transfusion. Chinese Clinical Trial Registry, ChiCTR-IPR-16005542.

**Background:** Children with ITP for ≥6 months who completed a romiplostim phase 1/2 or phase 3 parent study could enroll in this open label long term extension study

**Aims:** To evaluate the safety and efficacy of long-term romiplostim in children with ITP.

**Methods:** Patients enrolled at 28 sites in the US, Canada, Spain, and Australia. All patients received SC romiplostim once weekly. The initial dose was the final dose from the parent study or 1 µg/kg for patients previously receiving placebo; dose was then adjusted from 1–10 µg/kg to target platelet counts of 50–200×10\(^9\)/L. Incidence of adverse events (AEs) was the primary endpoint.

**Results:** As of 24 Feb 2016, 66 patients entered this study; 65 received romiplostim for up to 6.2 years. At baseline, median (min–max) age was 11 (3–18) years; 56% were female; 61% were white, 14% African American, 14% Hispanic/Latino, 9% Asian, and 3% other; 9.1% had prior splenectomy. Median (min–max) baseline platelet count was 27.5 (2–458)×10\(^9\)/L. Median (min–max) treatment duration was 100 (5–321) weeks. Median (min–max) average weekly romiplostim dose was 4.8 (0.1–10.0) µg/kg, which included escalation to a stable dose. After ~week 200 (n ≤8 patients), the median dose was observed to fluctuate. All 65 patients received their doses per protocol >90% of the time; 18 patients missed ≥1 dose due to noncompliance for a total of 41 times. Reasons for discontinuing treatment (n=22, 33%) included consent with-

P728 IMPACT OF VENETOCLAX ON THE QUALITY OF LIFE OF CLL PATIENTS RELAPSED/REFRACTORY TO B-CELL RECEPTOR (BCR) SIGNALING PATHWAY INHIBITOR TREATMENT

W. Wierda1, K. Saijil, J. Potluri2, L. Noe3, R. Kamalakar4, J. Gdovin5, R. Humerickhouse6, M. Verdugo7

1The University of Texas MD Anderson Cancer Center, Houston, 2AbbVie Inc, North Chicago, United States

Background: The prognosis for patients with CLL after B-Cell Receptor inhibitor (BCR) failure is very poor. Patients with R/R CLL who discontinue and/or progress on BCRi treatment tend to have poor clinical outcomes. Venetoclax (VEN) is an oral BCL-2 inhibitor that has demonstrated deep and durable responses in relapsed/refractory (R/R) CLL patients.

Aims: To assess whether VEN has an impact on health related quality of life (HRQoL) among CLL patients R/R to BCRi treatment and receiving VEN monotherapy.

Methods: The study enrolled patients with CLL who had previously received treatment withibrutinib and/or idelalisib, have relapsed on treatment, or experienced progression after discontinuation of either agent. Patients are to receive VEN monotherapy for up to two years, or until discontinuation due to disease progression, unacceptable toxicity, or any other reason. Patient-reported HRQoL measures included the EORTC QLQ-C30 and EORTC QLQ-CLL16, which were assessed at Baseline (BL), Week 24, and every 12 weeks thereafter. A mean change from BL to each assessment through Week 48 are reported here. Clinical relevance was based on minimum important difference (MID) of values from BL to each assessment. A change of 5-10 points is considered a "small" change on the EORTC-QLQ-C30. The lower bound of 5 points was used for MID acceptance on both measures.

Results: In this interim analysis, HRQoL improvements from BL were observed early and were sustained throughout the 48 weeks in VEN treated patients in the EORTC-QLQ-C30 global health status and the role, social, and emotional functioning scales. Furthermore, early and sustained improvements in fatigue through week 48 were seen in both EORTC-QLQ-C30 and EORTC-QLQ-CLL16 (Table 1).

Summary/Conclusions: This interim analysis provides preliminary evidence that demonstrates CLL patients R/R to BCR inhibitors receiving VEN monotherapy experienced improvement in several key aspects of functioning and HRQoL. These results may be important to consider when making therapeutic choices in R/R CLL following relapse or progression on BCRi inhibitors.

P729 THE ROLE OF PSYCHOLOGICAL VARIABLES FOR TYROSINE KINASE INHIBITORS (TKI) DISCONTINUATION IN CHRONIC MYELOID LEUKEMIA (CML) PATIENTS: IMPLICATION FOR MEDICAL DECISION MAKING

S. Riva1,*, A. Cortelezzi2, I. Cutica1, E. Orlandi3, E. Chiara3, C. Bucelli2, A. Iurlo2, G. Pravettoni1

1The University of Texas MD Anderson Cancer Center, Houston, 2AbbVie Inc, North Chicago, United States

Background: The prognosis for patients with CML after B-Cell Receptor inhibitor (BCR) failure is very poor. Patients with R/R CML who discontinue and/or progress on BCR treatment tend to have poor clinical outcomes. Venetoclax (VEN) is an oral BCL-2 inhibitor that has demonstrated deep and durable responses in relapsed/refractory (R/R) CML patients.

Aims: To assess whether VEN has an impact on health related quality of life (HRQoL) among CML patients R/R to BCR treatment and receiving VEN monotherapy.

Methods: The study enrolled patients with CML who had previously received treatment withibrutinib and/or idelalisib, have relapsed on treatment, or experienced progression after discontinuation of either agent. Patients are to receive VEN monotherapy for up to two years, or until discontinuation due to disease progression, unacceptable toxicity, or any other reason. Patient-reported HRQoL measures included the EORTC QLQ-C30 and EORTC QLQ-CLL16, which were assessed at Baseline (BL), Week 24, and every 12 weeks thereafter. A mean change from BL to each assessment through Week 48 are reported here. Clinical relevance was based on minimum important difference (MID) of values from BL to each assessment. A change of 5-10 points is considered a "small" change on the EORTC-QLQ-C30. The lower bound of 5 points was used for MID acceptance on both measures.

Results: In this interim analysis, HRQoL improvements from BL were observed early and were sustained throughout the 48 weeks in VEN treated patients in the EORTC-QLQ-C30 global health status and the role, social, and emotional functioning scales. Furthermore, early and sustained improvements in fatigue through week 48 were seen in both EORTC-QLQ-C30 and EORTC-QLQ-CLL16 (Table 1).

Summary/Conclusions: This interim analysis provides preliminary evidence that demonstrates CML patients R/R to BCR inhibitors receiving VEN monotherapy experienced improvement in several key aspects of functioning and HRQoL. These results may be important to consider when making therapeutic choices in R/R CML following relapse or progression on BCRi inhibitors.

P730 BUDGET IMPACT ANALYSIS OF BIOSIMILAR RITUXIMAB (CT-P10) FOR THE TREATMENT OF CHRONIC LYMPHOCYTIC LEUKAEMIA IN THE 28 EU MEMBER STATES

F. Rencz1,2,*, L. Gulácsi1,2, P. Baji1,2, M. Pénzek1,2, V. Brodszky1,2

1Department of Health Economics, Corvinus University of Budapest, 2HTA Consulting Budapest, Budapest, Hungary

Background: In December 2016, the European Medicines Agency’s Committee for Medicinal Products for Human Use has recommended granting marketing authorization to biosimilar rituximab (CT-P10) in all indications of the reference product, including chronic lymphocytic leukaemia (CLL). Compared to the originator rituximab, significant price reductions are expected offering a more affordable treatment option for CLL patients across Europe.

Aims: To assess the budget impact of the introduction of CT-P10 into the treatment of CLL in the 28 EU member states. Moreover, we provide an estimation for the number of additional CLL patients that can be treated with CT-P10 from the cost savings.

Methods: A budget impact analysis was performed to evaluate the one-year cost outcomes under two scenarios with and without the availability of CT-P10. The budget impact was calculated as the difference in costs between the two scenarios. For the major European markets, five-year cost savings were also estimated. Market uptake of CT-P10 was assumed to be 30%. A third party payer’s perspective was adopted, and only drug costs were considered. Based on expert opinion, it was assumed that when CT-P10 is entering the market it will be at 50-70% of the official list price of originator rituximab in each country. Costs of administration and monitoring were not incorporated in the calculations, as it can be assumed that these are equal for the reference product and CT-P10. The initial number of patients treated with rituximab was estimated from IMS sales data on total annual consumption of originator rituximab in 2016. Other model parameters such as patients’ average body surface area and treatment rate of rituximab among CLL patients, were derived from the published literature. One-way sensitivity analysis was undertaken to test the robustness of model assumptions.

Results: Over a one year time horizon, the cumulative budget impact of adopting CT-P10 is estimated to be €17.80 million in the 28 EU member states (30% discount in drug prices compared to the originator rituximab). Countries responsible for the majority of the cost savings are Germany (€4.06 million), Italy (€3.15 million), France (€2.41 million), Spain (€1.50 million), the UK (€1.34 million), and Italy (€1.25 million). The budget impact per million patients treated is €12,000. The potential cost savings are in a direct correlation with the price and market uptake of CT-P10. Applying a 40% and 50% discount in drug prices compared to the originator rituximab, cost savings are projected to €23.73 and €29.67 million, from which further...
Background: Therapeutic advances in multiple myeloma (MM) mean that patients have extended periods of remission without need for active anti-myeloma therapy. This provides an opportunity to review how these patients are managed and design patient-centred healthcare systems. Remote monitoring systems have been implemented for other cancer patients in remission.

Aims: We aimed to explore patient needs during stable remission from MM and how remote monitoring contributes to acceptability of various methods of remote monitoring.

Methods: Patients with stable MM in a treatment-free interval selected from outpatient clinics at a tertiary centre completed a survey which explored the acceptability of various methods of remote monitoring. Subsequently semi-structured interviews were conducted by an independent researcher to investigate factors influencing this preference. Interviews were carried out until saturation of themes, transcribed verbatim and thematic analysis was performed using open coding by a doctor, physiotherapist and psychologist.

Results: 78 patients were surveyed; the most acceptable alternative was a telephone clinic (with doctor 77%, nurse 69%). 19 interviews were conducted exploring suitable options for remote monitoring (55% preferred a nurse-led telephone consultation (TC) replacing current face-to-face (FTF) consultations with a doctor. Median age was 61 years (range 46–76), and 9 were male. 18 patients were in 1st remission; 16 had most recently received high dose therapy and autograft, 3 had post autograft consolidation. The centre was not the local hospital for 18 patients interviewed. The majority were accepting of TC as an alternative to FTF clinics due to the burden of travel, associated cost and clinic waiting times. These affected patients’ physical and psychological well-being, with TC perceived as less burdensome. Patients acknowledged reduced needs during remission compared to treatment phase and felt TC would benefit redistribution of consultant time for patients on active therapy. Patient’s suggested this service change would be beneficial for healthcare resourcing rather than themselves personally. Interpretation of blood results by clinicians was regarded as central to monitoring disease, and for some who were unaware of clinical symptoms, the only way a relapse would be detected. General preference was for bloods to be done locally, leading to conclusion that results of blood tests for MM were usually how to monitor their own MM, hence valued the knowledge of their medical team. Doctors were perceived to have more expertise than nurses and this influenced preference. Interviews were carried out until saturation of themes, transcribed verbatim and thematic analysis was performed using open coding by a doctor, physiotherapist and psychologist.

Results: 78 patients were surveyed; the most acceptable alternative was a telephone clinic (with doctor 77%, nurse 69%). 19 interviews were conducted exploring suitable options for remote monitoring (55% preferred a nurse-led telephone consultation (TC) replacing current face-to-face (FTF) consultations with a doctor. for birth weight (large for gestational age) to control confounding. Cases with Down syndrome were excluded from the analyses.

**Results:** Overall, 13 cases (1.2%) and nine controls (0.3%) had a record indicating at least one CT examination. Of the relevant CT scans, 50% were performed on the head region and 41.3% the thorax region. The median age at CT scan was 8.12 years (7.46 years for cases and 10.9 years for controls). In a conditional logistic regression analysis adjusted for birth weight, a significantly increased leukemia risk (OR=4.75, 95% CI 1.55, 14.5) was found for any CT examination (one or more) at least two years prior to leukemia diagnosis. When comparing one CT examination and two or more CT examinations with no examinations the ORs were respectively 2.78 (95% CI 0.73, 10.5) and 16.9 (95% CI 1.81, 150).

**Summary/Conclusions:** In our preliminary analyses we observed a substantial increase in childhood leukemia risk related to pediatric CT scans. The risk estimates are materially higher than in two earlier studies and need to be interpreted with caution. We will seek to estimate radiation doses to the red bone marrow, based on limited data available on CT examinations (body part and examination type).

**HEALTHCARE RESOURCE UTILIZATION WITH IXAZOMIB OR PLACEBO PLUS LENALDIDOMIDE-DEXAMETHASONE IN THE RANDOMIZED, DOUBLE-BLIND, PHASE 3 TOURMALINE-MM1 STUDY IN RELAPSED/ REFRACTORY MULTIPLE MYELOMA (RRMM)**

**Background:** Treatment paradigms for RRMM have evolved in recent years with the approvals of multiple novel agents and evidence of benefits for using triplet vs doublet therapy and continuous treatment until progression. With more complex regimens and longer treatment duration, costs of treatment and healthcare resource utilization (HRU) are expected to increase, with IV agents having a greater impact on treatment burden than oral agents. The oral proteasome inhibitor ixazomib is approved in the US, EU, and multiple countries worldwide, in combination with lenalidomide-dexamethasone (Rd), for the treatment of RRMM patients (pts) following at least 1 prior therapy. Approval was based on the phase 3 TOURMALINE-MM1 study of ixazomib-Rd vs placebo-Rd, which demonstrated significantly improved progression-free survival (PFS; median 20.6 vs 14.7 months, HR 0.74) with ixazomib-Rd, with limited additional toxicity and no adverse impact on patient-reported quality of life (Gol et al, N Engl J Med 2016).

**Aims:** HRU was an exploratory endpoint of the TOURMALINE-MM1 trial. The aim of this analysis was to compare HRU with ixazomib-Rd vs placebo-Rd, incorporating all non-protocol additional medical care encounters such as inpatient and outpatient admissions and their duration, as well as time lost from work or other activities by pts and their caregivers.

**Methods:** 722 RRMM pts with 1-3 prior lines of therapy received ixazomib 4mg (n=360) or matching placebo (n=362) on days 1, 8, and 15, plus lenalidomide 25mg on days 1-21 and dexamethasone 40mg on days 1, 8, 15, and 22, in 28-day cycles until disease progression or unacceptable toxicity. The primary end-point was PFS. HRU was assessed on day 1 of each cycle prior to treatment and every 4/12 weeks during PFS/overall survival follow-up. After a median follow-up of ~23 months, pts had received a median of 17 (range 1-34) and 15 (1-34) cycles of ixazomib-Rd and placebo-Rd, respectively; HRU data are reported from this analysis time point.

**Table 1.**

**Table: Odds ratios and frequencies of CT scans**

**Methods:** We used nationwide, register-based case-control study design to investigate the role of CT imaging in the etiology of childhood leukemia. We identified all childhood (0-15 years) leukemia cases from 1990 to 2011 (N=10953) in Finland and randomly selected thrice as many controls (N=3279) from the Population Registry, individually matched by gender and year of birth. The cases were 81% (N=885) acute lymphoblastic leukemias and 13% (N=142) acute myeloid leukemias. We collected data on all pediatric CT scans from 1975 to 2011 from the databases of all five university hospitals in Finland and two large central hospitals. In total, we identified 46 CT scans to our subjects. We approximated that this approach covers 81% of all pediatric CT scans performed in Finland from 1975 to 2011. We used a two-year latency period to avoid reverse causation. Conditional logistic regression analyses were adjusted
Results: Overall, 152 (42%) pts on the ixazomib-Rd arm had 316 hospitalization events, compared to 156 (43%) pts (335 events) in the placebo-Rd arm. Exposure-adjusted hospitalization rates (0.530 and 0.564 per pt-year [ppy], respectively) and mean length of stay (10 and 10.8 days) were similar between the ixazomib-Rd and placebo-Rd arms (Table 1). Rates of outpatient visits were also similar between arms; 217 (60%) pts on the ixazomib-Rd arm had 197 (median 4) compared to 198 (55%) pts and 194 visits (median 5) on the placebo-Rd arm. Exposure-adjusted visit rates were 3.305 and 3.355 ppy, respectively (Table 1). On the ixazomib-Rd arm, 46 (13%) pts missed a total of 527 (median 7 days) of work or other activity, compared to 51 (14%) pts and 580 (median 8 days) on the placebo-Rd arm. Similarly, 16 (4%) pts caregivers missed 4128 (median 5 days) of work or other activity on the ixazomib-Rd arm, compared to 24 (7%) pts caregivers and 110 (median 4) days on the placebo-Rd arm.

Summary/Conclusions: The ixazomib-Rd triplet regimen did not add to the HRU burden compared to the placebo-Rd doublet, while prolonging PFS. The ixazomib-Rd triple was consistent with the limited additional toxicity burden and the reported lack of an adverse impact on QoL with ixazomib-Rd. In contrast to findings reported for injected agents (Armoiry et al, J Clin Pharm Ther 2011; Gaultney et al, J Clin Pharm Ther 2013; Baz et al, Support Care Cancer 2015), this all-oral triplet regimen did not increase time lost from work, caregiver burden, or the number of inpatient/outpatient visits.

P737
EFFECT OF IMPROVEMENTS IN SURVIVAL, POPULATION AGING AND IMWG’14 CRITERIA ON INCIDENCE AND PREVALENCE OF MULTIPLE MYELOMA
V. Martinez-Robles1,*, B. Ballina1, S. Cerda1, N. de las Heras1, M. Fuertes1, L. Villalobos1, J.A. Rodriguez-Garcia1, E. Fernando1
1Hematología, Complejo Asistencial Universitario de León, LEON, Spain
Background: There are some variables that can modify Multiple Myeloma incidence of New Diagnosed (NDMM) and prevalence over the time: Past decade shows a new demographic data in our society: the increment of expectancy of life and an excellent performance status. In the last years we have assisted to an amazing improvement in the management and expectancy of life of Multiple Myeloma (MM) patients. Recent changes in criteria recommendation by IMWG’14 to begin treatment in NDMM patients can increment its incidence. New expensive but very effective and well tolerated antilymoma (antiMM) agents are in the center of attention of Hematologic and Public Healthcare Systems. There are data of improvement of survival that can increment of prevalence.

Aims: We have analysed our data base and calculate incidence by sex, age and three 5-years periods of time at diagnosis and obtain tendencies to get ready for next decade of ageing people with best antilymoma agents. We have analysed prevalence of MM patients on last 7 years with cutoff date on 1st of November (2010 to 2016).

Methods: We retrospectively analysed the incidence of patients with new diagnostic of Multiple Myeloma (NDMM) from 1998 to 2012. (Fig.1). Then we divide the cohort in several groups: sex and age at diagnosis (3 groups: <65, 66-75 and 75+); and in four 5-year (quinquennium) period of time (1998-2002, 2003-07, 2008-12, 2013-NOV2016). (Fig. 2). We have calculated the incidence per 100000 inhab/year using census data of our Local Registry of Tumours of our Public Health Area. Characteristics of patients: n= 346. M/F: 206/140. Median age at diagnosis: 74 years (Range: 39-100).

Results: A) INCIDENCE RATES (see Table). In the past IMW (Roma-14#PO197) we reported incidence rates form 1998 to 2012. We observed a constant increase of Annual Average of incidence from 4.57 cases/100000 inhabitants/ year from the 1st period to 6.15 in the last. Adjusted by Age Incidence increase from 14 to 18.5 cases in the O65 group. From 2013 to Nov-2016 global and adjusted by age incidence remains similar to last years data with 80 new cases in the 4 year-period (5.9 cases for global population and 17.2 cases for over65 population). After IMWG’14 criteria to begin treatment in NDMM the incidence was similar to the last 7 years (2008-12 period) incidence with 37 NDMM cases (25 O65y group).

B) PREVALENCE RATES (PreVR).
• 2012. 77 pts alive. PreVR: 22.2 /100000 inhabit;
• 2014. 84 pts alive. PreVR: 24.4/100000 inhabit;
• 2016. 103 pts alive. PreVR: 30.3 /100000 inhabit.

Table 1.

Summary/Conclusions: Although we don’t observe substantial changes on incidence rates of NDMM, we have noted an important rise on prevalence rates of more than 40% from 2010 to 2016 (21.2 to 30.3 pts alive /100000 inhabit.) Several new antiMM drugs are available in the therapeutic arsenal and probably increases the prevalence rates.
Hematopoietic stem cell transplantation (HSCT) is a powerful tool in the treatment of hematologic malignancies, particularly in children with acute lymphoblastic leukemia (ALL) in first remission (iEMR). The decision to proceed with HSCT is based on several factors, including the patient's age, disease status, and the presence of risk factors. HSCT can be performed using autologous, allogeneic, or haploidentical donors, with each option having its own advantages and considerations.

In a recent study, 281 patients with ALL iEMR were included in the analysis. The patients were transplanted with allogeneic hematopoietic stem cell transplantation (HSCT) from 19 centers, members of the Italian Pediatric Onco-Hematology Association (AIEOP). The study aimed to evaluate the impact of different conditioning regimens on overall survival (OS) and the incidence of hepatic veno-occlusive disease (VOD) or sinusoidal obstruction syndrome (SOS), which are significant complications after HSCT.

Methods:
- Data were collected from 19 centers in Italy, members of the Italian Pediatric Onco-Hematology Association (AIEOP).
- Patients with ALL iEMR were included in the analysis.
- The study included 198 patients who underwent autologous HSCT (Auto HSCT) and 83 who underwent allogeneic HSCT (allo HSCT).
- Conditioning regimens included total body irradiation (TBI), fludarabine-based, busulfan-based, and cyclophosphamide-based regimens.
- The primary outcome was overall survival (OS) and the incidence of VOD or SOS.

Results:
- Overall survival (OS) for the entire cohort was 72%, with 5-year OS rates of 74% for the allo HSCT group and 69% for the auto HSCT group.
- The incidence of VOD/SOS was 11% in the allo HSCT group and 3% in the auto HSCT group.
- Patients who received a busulfan-based transplant had a lower risk of VOD/SOS compared to those who received a fludarabine-based transplant (HR 0.39, 95% CI 0.2-0.8).
- Age, site of relapse, length of first remission, HSCT type (Auto vs MFD), and receiving a busulfan-based transplant (TBI) were significant predictors of VOD/SOS.

Conclusion:
- The study highlights the importance of conditioning regimens in the prevention of VOD/SOS after HSCT.
- Busulfan-based conditioning regimens are associated with a lower risk of VOD/SOS compared to fludarabine-based regimens.
- Age, site of relapse, and length of first remission are significant predictors of VOD/SOS.

PAROXYSMAL NOCTURNAL HEMOGLOBINURIA-12

ALLO-HCT FOR PAROXYSMAL NOCTURNAL HEMOGLOBINURIA-12

**Background:**
Paroxysmal nocturnal hemoglobinuria (PNH) is a rare acquired clonal abnormality of hematopoietic stem cell leading to lack of phosphatidylinositol-4,5-bisphosphate 3-kinase C2 (PI3K-C2) activity. The disease is characterized by a complement-mediated intravascular hemolysis in the presence of a specific complement regulatory factor, leading to hemolytic anemia, microangiopathic hemolytic anemia, transfusion dependency, hemolytic crises, and thrombosis. The disease is caused by somatic mutation of the CYTL1 gene, which encodes a PIG-A enzyme (phosphatidylinositol glycan anchor biosynthesis class A) responsible for N-glycosylation of glycoproteins, necessary for proper cellular function. The main treatment for PNH is treprostinil, which reduces endothelial cell activation and improves hemodynamic features. However, this treatment is not curative, and there is a need for a curative option, such as allogeneic hematopoietic stem cell transplantation (allo-HCT).

**Aims:**
The aim of this study was to evaluate the safety and effectiveness of allo-HCT in PNH.

**Methods:**
We report 41 allo-HCTs: 37 from MUD and 4 from MRD performed for 5% with MUD group, 9324 (38.0%) were pediatric (aged <16 years; 5105 [53.7%] with MOD) and 169264 (64.0%) were adults (aged >16 years; 88169 [52.1%] with MOD). Kaplan-Meier estimated survival at Day +100 (Figure) was 52.8% (95% CI, 45.6%–58.7%) across all HSCT pts and 43.9% (95% CI, 35.4%–52.0%) for pts with MOD; for pediatric pts, this was 60.4% (95% CI, 49.4%–69.7%) overall and 45.4% (95% CI, 31.0%–58.6%) for pts with MOD; for adults, Day +100 survival was 48.7% (95% CI, 40.9%–56.0%) overall and 43.0% (95% CI, 32.5%–53.0%) for pts with MOD. Adverse events (AEs) occurred in 75.4% of the total group (80.6% with MOD); 70.5% of pediatric pts (76.6% with MOD); 78.1% of adults (83.0% with MOD). Treatment-related AEs (TRAEs) occurred in 20.8% overall (23.7% in those with MOD); 21.1% of pediatric pts (23.5% with MOD); 20.7% of adults (23.9% with MOD). The most common TRAEs (>3%) were epistaxis, pulmonary hemorrhage, gastrointestinal hemorrhage, and hematuria (each in <5% of pts). TRAEs leading to study discontinuation (n=25) or death (n=10), the most common was pulmonary hemorrhage.

**Results:**
All pts engrafted, median counts of granulocytes 0.5 G/l, platelets 50 G/l and Hb 10 g/dl were achieved on days 17.5(10-33), 16(9-39) and 19.5(11-34). Acute GVHD grade I and II was present in 16, 7 and 3 pt, limited and extensive chronic GVHD respectively in 11 and 3 pts. LDH decreased by 73%(5%-91%) in first 30 days indicating disappearance of hemolysis. 100% donor chimerism was achieved in all pts. In 1 patient donor chimerism decreased to 81% what was treated with donor lymphocytes infusion (DLI). 3 patients died, 1 previously hemolyzed pt died on day +102 due to nephrotoxicity complicating adenosine/CMV hemorrhagic cystitis, two other SAA patients with PNH clone<10% died on days +56 due to severe pulmonary infection and +114 due to aGVHD-III and multi organ failure. Complications in survivors were FVO (10 pts), CMV reactivation (13), VOD (1), neurotoxicity (1), acute graft-versus-host disease (1), hemolytic disease of the newborn (1) and mucositis (1) were present. Acute GVHD grade III was present in 17, 7, and 3 pt, limited and extensive chronic GVHD respectively in 11 and 3 pts. LDH were significantly lower compared to that of the MSD group (29 yrs, 31 yrs, and 39 yrs; P<0.01, and 44.6% and 33.3% vs. 89%; P<0.01, respectively). When we compared the incidence of transplant-related mortality (TRM) 10.7% vs 7.4% at 6 yrs; P=0.53) and overall survival rate (OS; 89.3% vs 92.5% at 6 yrs; P=0.52) between the WM-URD and the MSD groups, there were no significant differences. However, trends of higher TRM incidence (18.2% vs 7.4% at 6 yrs; P=0.05) and lower OS rate (81.8% vs 92.5% at 6 yrs; P=0.05) were observed between the PM-URD and the MSD groups. There was no primary graft failure in 38.6% of pts. Incidence of graft-versus-host disease of both grades in 0% vs 18.3%; P<0.01 and PM-URD (0% vs 18.3%; P=0.02) groups were significantly lower compared that of the MSD group. When we adjusted other clinical and transplant-related factors, which include age and IST failure, using multivariate
analysis, the OS rate of the WM-URD group was not significantly different (HR 1.45, 95% CI; 0.52-4.09; P=0.48), whereas that of the PM-URD group was significantly lower (HR 2.85, 95% CI; 1.01-8.02; P=0.04), compared to that of the MSD group.

Summary/Conclusions: Our study showed that there was no significant difference in OS rate between the WM-URD and the MSD groups. As high incidence of GVHD remains a problem in the former group, strategies to reduce it are needed in future protocols.

P743
HAPLOIDENTICAL ALLOGENEIC STEM CELL TRANSPLANTATION IN SEVERE THALASSEMIA PATIENTS
S. Hongkarn1,2, S. pakakasam1, U. anurathapan1, B. Andersson2
1Pediatrics, Ramathibodi hospital, Mahidol University, Bangkok, Thailand, 2Stem cell transplantation, MD Anderson Cancer Center, Houston, United States

Background: Thalassemia free survival after allogeneic stem cell transplantation (SCT) is about 80–90% with either matched related or unrelated donors. However, the probability of finding a HLA-compatible donor is less than 50%. We explored the use of a mismatched related ("Haplo") donor.

Aims: To evaluate the outcome of SCT with Haplo donors in severe thalassemia patients

Methods: All patients received two courses of pre-transplant immunosuppression therapy (PTIS) with fludarabine (Flu) 40mg/m2/d together with dexamethasone (Dxm) 25mg/m2 for 5 d to facilitate engraftment. After two courses of PTIS, a reduced-toxicity conditioning regimen of rabbit anti-thymocyte globulin (ATG) 10mg/kg on days SCT -12,-11,-10, Flu 35mg/m2 on days SCT -7,-6,-5,-4,-3,-2 and IV Busulfan (Bu) 130mg/m2 on days SCT -7,-6,-5,-4 was given followed by T-cell replete peripheral blood progenitor cells (PBPC). GVHD prophylaxis consisted of cyclophosphamide (Cy) 50mg/kg on days SCT -3 and -4 (Post-Cy), and on day SCT +5 tacrolimus or sirolimus was started together with a short course of mycophenolate moefetil.

Results: Fifty-one patients underwent haplo-SCT. Their median age was ten years (range, 2 to 28 years). Forty-nine patients engrafted with 100% donor chimerism. Two of five patients with high titers of donor-specific anti-HLA antibodies suffered primary graft failure. Median time to neutrophil engraftment was 14 days (range, 11 to 18 days). Eight patients developed mild to moderate, reversible veno-occlusive disease, while twelve patients developed acute GVHD grade II, that quickly responded to steroid therapy. Only seven patients developed limited chronic GVHD. Projected overall and event-free survival rates at two years are 95% and 94%, respectively. The median follow up time is 18 months (range;10 to 50 months).

Summary/Conclusions: This haplo-SCT protocol may yield excellent outcomes for thalassemia patients, and provide a treatment option for patients lacking a HLA-matched donor.

P744
AUGMENTATION OF FLUDARABINE AND BUSULFAN-BASED MYELOABLATIVE REGIMEN WITH THIOTEPA IMPROVES OUTCOMES WITH NO ADDITIONAL TOXICITY IN ALLOGENEIC STEM CELL TRANSPLANTATION FOR ACUTE MYELOID LEUKEMIA
V.S. Sheeh1, N. Boaz1, S. Grisariu1, B. Avni1, R. Or1, M. Shapira1
1Pediatrics, HADASSAH, Jerusalem, Israel

Background: Allogeneic stem-cell transplantation (HSCT, allo-SCT) is the most effective way to control leukemia relapse for patients with acute myeloid leukemia (AML). Busulfan and Cyclophosphamide (Bu/Cy), the current standard of care, in allogeneic transplant for acute myeloid leukemia (AML), is limited by increased treatment related mortality. Myeloablative doses of Busulfan (12-8mg/kg) with Fludarabine (186mg/m²) (Flu-Bu), has reduced toxicity, however with the limitation of increased relapses. We have tried to improve outcome of Flu-Bu regimen by augmentation with Thiotepa (10mg/kg). Here we compared outcomes of 45 such patients (getting augmented regimen, Flu-Bu with the addition of Thiotepa, (group 2), to 44 patients who received Fludarabine, Busulfan myeloablative reduced toxicity regimen (group 1), during the same period

Aims: The primary objective of the report was to compare the toxicity and incidence of relapse between the two regimens. Secondary objective was to compare overall survival (OS), and disease-free survival (DFS), the non-relapse mortality (NRM), engraftment kinetics, incidence of acute and chronic graft-versus-host disease (GVHD), and comparison between high and low-risk patients amongst the two groups.

Methods: 89 patients with AML were retrospectively analyzed. 44 patients were conditioned with Flu-Bu (group 1) and 45 patients augmented with Thiotepa (Flu-Bu-TT, group 2). The transplant conditioning regimen, (augmented myeloablative) consisted of 30mg/m² intravenous Fludarabine for 5 days (total dose 150mg/m²), for matched related donors or for 6 days (180mg/m²), for unrelated or mismatched donors, intravenous Busulfan (3.2mg/kg/day for 4 days, total dose 12.8mg/kg), and intravenous Thiotepa 5mg/kg for 2 days (10mg/kg). The conventional myeloablative regimen was identical, however without the addition of Thiotepa.

Results: Toxicities were comparable, with mucositis in 7 patients (15%) in group 1 and 8 patients (17%) in group 2, (p=1.0), severe sepsis in 4 (9%) in group 1 and 3 (6%) in group 2, (p=0.7), severe venoocclusive disease in 2% of group 1 and 4% of group 2, (p=1.0) and comparable non- relapse mortality (NRM). 5-year disease free survival (DFS) median follow up of 5 years, was significantly better in group 2, 38% for group 1, and 62% in group 2, (p=0.02) and 5-year overall survival showed trend towards benefit in group 2 (62% vs 42%, p=0.06), 14/30 (46%) patients in group 1 relapsed, as compared to 4/31 patients, (12%, p=0.005) in group 2, considering NRM as competing risk.

Figure 1.

Summary/Conclusions: In conclusion, the outcome of augmented regimen (DFS and OS) is superior Flu-Bu regime, mainly due to reduction in relapses, with comparable toxicities and could eventually replace Bu/Cy.

PROGNOSTIC TOOLS CAN PROVIDE PERSONALIZED OUTCOMES PREDICTION AFTER ALLOGENEIC HCT IN PATIENTS WITH HEMATOLOGIC MALIGNANCIES
C. Choi1,2, S. Devlin2, P. Hilden2, M. Maloy1, M. Horowitz3, J.D. Rizzo3, B. Logan3, P. Barbé3, R. O'Reilly5, S. Giralt1, M.-A. Perales1
1Adult Bone Marrow Transplant Service, Department of Medicine, 2Department of Biostatistics and Epidemiology, Memorial Sloan Kettering Cancer Center, New York, NY, 3Medical College of Wisconsin and Center for International Blood and Marrow Transplant Research, Milwaukee, WI, United States, 4Department of Hematology, Hospital Vall d’Hebrón, Universitat Autònoma de Barcelona, Barcelona, Spain, 5Bone Marrow Transplant Service, Department of Pediatrics, Memorial Sloan Kettering Cancer Center, New York, NY, United States

Background: Current prognostic indices for allogeneic HCT (alloHCT) outcomes often focus on a limited set of factors, be they patient characteristics, disease features, or transplant approaches. We sought to evaluate two comprehensive prognostic models in a large sample of patients undergoing alloHCT with CD34 selection (CD34 alloHCT).

Aims: To evaluate two comprehensive prognostic models: The first combining the Hematopoietic Cell Transplantation Comorbidity Index (HCT-CI) and Disease Risk Index (DRI); the second applying the Center for International Blood and Marrow Transplant Research (CIBMTR) One Year Survival Outcomes Calculator, which uses large-scale multicenter data reported to the CIBMTR to provide patient-specific predictions on survival 1 year after first alloHCT.

Methods: This retrospective analysis included adult recipients of first alloHCT with CD34+ selected PBSCs from 7/8 or 8/8 donors for AML, ALL, or MDS at a single center between 1/2000 and 12/2015. The Kaplan-Meier (KM) method estimated OS and RFS. The cumulative incidence method for competing risks estimated relapse and nonrelapse mortality. We evaluated univariate association between variables of interest and OS/RFS using the log-rank test. Cox regression models assessed the adjusted effect of covariates on OS/RFS. We then determined predicted 1 year OS for each patient using the CIBMTR Calculator. Patients were divided into groups based on predicted OS probability,
in intervals of 5% +/- 2% (e.g. 65 +/-2% probability of survival at 1 year). Corresponding observed 1 year OS was then estimated for each group by the KM method. A kernel smoother was used to visually display the average of observed 1 year survival estimates over the continuous range of predicted OS.

Results: 506 patients with AML (n=290), ALL (n=72), or MDS (n=144) were included. Of these, 470 patients (AML=263, MDS=141, ALL=66) had full data available for the CIBMTR Calculator. On univariate and multivariate analyses, DRI, HCT-CI, and age correlated with significant differences in OS/RFS, while donor HLA match correlated with a significant difference in OS. Stratifying patients based on a composite of DRI (low/intermediate vs high/very high) and HCT-CI (0-2 vs +3) revealed significant differences in OS/RFS between the 4 groups (Fig. 1). Compared with a reference group of patients with both low/intermediate DRI and low HCT-CI, those with high DRI and low HCT-CI were at greater risk of death (HR 2.30; 95% CI 1.39-3.81) and relapse or death (HR 2.50; 95% CI 1.55-4.05), more so than patients with a higher HCT-CI but still low/intermediate DRI (HR death 1.80; 95% CI 1.34-2.43; HR relapse/death 1.68; 95% CI 1.26-2.24). When comparing predicted and observed survival, KM estimates of 1 year OS fell within range of that predicted by the CIBMTR Calculator in almost all groups (Fig. 1). In one group, patients had lower observed 1 year OS than predicted (76%, 95% CI 62-93%, vs 85 +/- 2%, p=NS). In this group, 29/30 patients (97%) had intermediate or high DRI; 59% had poor prognostic ALL by NCCN criteria (n=12, 44%) or other adverse features such as minimal residual disease pre-HCT (n=4, 15%).

Summary/Conclusions: Based on a large cohort of patients who underwent CD34 alloHCT for acute leukemia or MDS, we demonstrate that DRI is a major determinant of outcome. The CIBMTR Survival Outcomes Calculator predicts 1 year prognosis with relative precision, though some disease-risk features not reflected in the Calculator may affect outcomes in patients with otherwise good prognosis. Taken together, these prognostic models can assist in predicting outcomes and identifying patients most likely to benefit from CD34 alloHCT. Furthermore, applying the CIBMTR calculator analysis in individual centers may help identify patients with worse outcomes than predicted and guide patient and/or HCT selection.

P747
THROMBOTIC MICROANGIOPATHY AFTER ALLOGENEIC STEM CELL TRANSPLANTATION: IS THERE A PROTECTIVE ROLE FOR URSODEOXYCHOLIC ACID?
1Clinical Hematology, H.Universitario Virgen del Rocío, Seville, 2Clinical Hematology, ICO-Duran i Reynals, Barcelona, 3Clinical Hematology, H.Universitario de Salamanca, Salamanca, 4Hematology, H.Universitario Virgen del Rocío, Seville, 5Hematology, H Santa Creu i Sant Pau, 6Hematology, H.Clinic, Barcelona, 7Hematology, H.Clinico, Valencia, 8Hematology, H.Universitario de Salamanca, Salamanca, 9Hematology, H.Santa Creu i Sant Pau, 10Hematology, Hospital Clinic, Barcelona, 11Hematology, H.Clinico, Valencia, Spain

Background: Thrombotic microangiopathy (TMA) after allogeneic stem cell transplantation (alloSCT) may be a severe complication associated with high mortality. Since there is no standard treatment it would be helpful to have efficacious prophylactic measures. Some data support the beneficial effect of ursodeoxycholic acid (UDA) in RIC alloSCT.

Aims: We retrospectively analysed a total of 671 patients undergoing to reduced intensity conditioning (RIC) alloSCT, comparing the occurrence of overall TMA according to the use or not of UDA.

Methods: Both uni and multivariate analysis were performed including patient and transplant related variables at the moment of transplant to analyse the risk of developing TMA.

Results: Cumulative incidence for overall TMA was 4.8 (3.4-6.6) at 1 month, 10.1 (7.9-12.5) at 100 days, and 12.7 (10.3-15.4) at 180 days (Fig. 1). On univariate analysis, TMA was more frequent in lymphoid malignancies, Fluorarabine-melphalan based conditioning, unrelated donor, mismatched donor, prophylaxis with sirolimus-tacrolimus (SRL/TKR), prior transplant and non-UDA patients. The probability of overall TMA at 180 days in UDA patients was 9.6% (95% CI: 5.9-14.3), versus 14.7% (95% CI: 11.7-18.1) in non-UDA patients. On multivariate analysis the risk factors which remained statistically significant were use of UDA (HR 0.54; 95% CI 0.38-0.77; p=0.001), non-uda prior transplant (HR 1.57; 95% CI 1.12-2.21; p=0.009) and aGVHD (HR 3.53; 95% CI 1.13-10.7; p=0.031).

Summary/Conclusions: The use of UDA decreases the risk of TMA after alloSCT regardless of type of immunophrophylaxis.
Results: Characteristics of patients are shown in Table 1. With a median follow up for patients alive of 39 months (3-222), the median estimated survival in months and the % at +1 year and +2 years was: 114 months, 70% and 62% overall survival (OS); 23 months, 57% and 49% event free survival (EFS); 6 months, 35% and 26% GRFS1; 11 months, 46% and 38% GRFS2. 147 (24%) and 218 (35%) hadn’t any event in GRFS1 and in GRFS2 respectively. In GRFS1, event incidence was: 90 (15%) for III-IV aGvHD, 170 (27%) for cGvHD, 152 (25%) for relapse and 57 (9%) for death; In GRFS2 was 90 (15%), 65 (11%), 174 (28%) and 65 (11%) respectively. Considering those patients with cGvHD as event in GRFS1, 105 of them hadn’t the event as cGvHD at the same time in GRFS2 (since they had cGvHD requiring systemic treatment but not severe cGvHD). For these patients, the alternative event in GRFS2 was: 72 without any event, 22 relapsed and 11 died. In the multivariate analysis, factors associated with better outcomes were: for GRFS1 diagnosis (p=0.04; benefit in NHL/HL/CLL p=0.02, HR 0.71; CML5% 0.53-0.95), >4 prior lines (p=0.03, HR 1.5, CML5% 1.04-2.04), early EBMT stage (p=0.001 with early as reference; intermediate p=0.002, HR 1.5, CML5% 1.2-1.9; advance p=0.001, 2.0, 1.5-2.6), in vivo T-cell depletion (p=0.02, 0.6, 0.39-0.92) and haploidential donor (p=0.04 with HLA identical as reference, no significance 1 or 2 mismatch [p=0.18], haploidential p=0.02, 0.43, 0.25-0.74). Only early EBMT disease stage maintained significance in GRFS2 (p=0.001 with early as reference; intermediate p=0.005, 1.5, 1.1-1.9; advance p=0.001, 1.9, 1.4-2.6).

Summary/Conclusions: In our study the percentage of the GRFS endpoint was similar to previously reported. Comparing both proposed definitions, the GRFS2 endpoint define a higher population of patients without any event; so that it is possible that the morbidity is misdiagnosed. The EBMT disease score was the factor with more impact in both; it is interesting to point that although the group is smaller, haploidential donor is associated with better GRFS1.

PT48
EFFECTIVITY AND SAFETY OF DEFIBROTIDE IN THE TREATMENT OF HEPATIC VENO-OCLUSIVE DISEASE/SINUSOIDAL OBSTRUCTION SYNDROME FOLLOWING HEMATOPOIETIC STEM CELL TRANSPLANTATION: FINAL SUBGROUP RESULTS

P. Richardson1, A. Smith2, B. Triplett3, N. Kernan4, S. Grupp5, J. Antin6, L. Lehmann7, S. Giralt8, W. Liang9, R. Hume9, W. Tappe9, R. Soiffer7
1Jerome Lipper Multiple Myeloma Center, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, 2Division of Pediatric Blood and Marrow Transplantation, University of Minnesota, Minneapolis, 3Bone Marrow Transplantation and Cellular Therapy, St. Jude Children’s Research Hospital, Memphis, 4Pediatric BMT Service, Memorial Sloan Kettering Cancer Center, New York, 5Pediatric Oncology, The Children’s Hospital of Philadelphia, Philadelphia, 6Stem Cell/Bone Marrow Transplantation Program, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, 7Center for Stem Cell Transplantation, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, 8Memorial Sloan-Kettering Cancer Institute, New York, 9Jazz Pharmaceuticals, Inc., Palo Alto, United States

Background: Hepatic veno-occlusive disease/sinusoidal obstruction syndrome (VOD/SOS) is a potentially life-threatening complication of conditioning regimens for hematopoietic stem cell transplant (HSCT) and may also occur following chemotherapy without HSCT. VOD/SOS with multi-organ dysfunction (MOD) may be associated with >80% mortality. Diagnosis has traditionally been based on the Baltimore criteria or modified Seattle criteria. Defibrotide is approved for treating severe hepatic VOD/SOS post-HSCT in the European Union and for treatment of hepatic VOD/SOS with renal/pulmonary dysfunction post-HSCT in the United States. The defibrotide expanded-access protocol was designed to provide access to defibrotide prior to its approval in the United States and to collect additional data on safety and efficacy in a broader patient population, including those with and without MOD, and following HSCT or chemotherapy without HSCT.

Aims: This is an analysis of defibrotide efficacy and safety in the subgroup of patients developing VOD/SOS following HSCT, using final data from the expanded-access protocol.

Methods: The original expanded-access protocol required VOD/SOS diagnosis by either criteria or biopsy post-HSCT, with evidence of MOD (27%) or pulmonary dysfunction). The study was amended to also include patients without MOD (off-label), with VOD/SOS per modified Seattle criteria, and/or with VOD/SOS following chemotherapy without HSCT (off-label). After patients provided informed consent, defibrotide treatment (25mg/kg/d in 4 divided doses of 6.25mg/kg) was recommended ≥21 days.

Results: This analysis of final data is based on 1000 patients enrolled from 2007–2016 who had confirmed VOD/SOS following HSCT and had received ≥1 dose of defibrotide. Of these patients, 512 (51.2%) had MOD. The median age was 14 years (range 0.10–77.0), with 570 patients (57.0%) aged ≤16 years, (29.3%) <1 year, (19.3%) >16 years; 430 patients (43.0%) had MOD. Among pediatric patients, 28.2% were aged <1–23 months, 52.5% aged 2–11 years, and 19.3% aged 12–16 years. Primary diseases in ≥10% of the overall HSCT group were acute lymphocytic leukemia (19.8%), acute myelogenous leukemia (26.1%), and neuroblastoma (10.5%). Kaplan-Meier estimated Day+100 survival was 58.8% (95% confidence interval [CI], 55.7%–61.9%) in the overall HSCT group (Figure), with rates of 49.5% (95% CI, 45.0%–53.8%) in patients with MOD and 68.9% (95% CI, 64.5%–72.9%) in patients without MOD. In patients aged ≥16 years, Kaplan-Meier estimated Day+100 survival was 67.9% (95% CI, 63.8%–71.6%) and 47.1% (95% CI, 42.3%–51.8%) in patients aged >16 years (Figure). In the overall HSCT population, 210 patients (21.0%) had ≥1 treatment-related adverse event (TRAE). TRAEs occurring in ≥2% of patients were pulmonary hemorrhage (4.6%), gastrointestinal hemorrhage (3.0%), epistaxis (2.3%), and hypotension (2.0%).

Figure 1. Summary/Conclusions: This final analysis of the defibrotide expanded-access protocol demonstrates favorable Day +100 survival (58.9%) in patients with confirmed VOD/SOS following HSCT, and 49.5% in those with MOD, a complication typically associated with dismal outcomes. Survival and safety findings, consistent with prior clinical trials, provide supportive evidence for the clinical utility of defibrotide for treatment of VOD/SOS in patients with and without MOD.

GENERATION OF IMMORTAL MURINE HEMATOPOIETIC STEM/PROGENITOR CELL LINES FROM TRANSGENIC MICE
E. Domá1, A. Höbl1, V. Sexl1
1Pharmacology und Toxikologie, Veterinärmedizinische Universität Wien, Wien, Austria

Background: Research on hematopoietic and leukemic stem cells (LSCs) is currently limited as these cells are infrequent and their immortalization is hardly achievable. Aim: We aimed to establish a long term ex vivo culture system that allows maintenance and expansion of LSK (lin- Sca-1-, c-kit+) cells.

Methods: We adapted a technique described by the L. Carlsson lab and transduced high-purity sorted murine LSKs with Lhx2, a LIM-homeobox transcription factor, which has been reported to facilitate ex vivo expansion of immature hematopoietic cells.

Results: Lhx2 expressing hematopoietic progenitor cell (HPC(LS)) lines require SCF (stem cell factor) and IL-6 and they can be maintained in a feeder-independent culture for more than 6 months. They preserve LSK markers despite continuous proliferation. HPC(LS) cells repopulate lethally irradiated mice and re-feeding the T cell-depleted secondary cell pool (H2Kd) long-term lines were established from a range of transgenic mice, underlining the overall applicability of this model. Using this system, we established LSC lines that express BCR/ABLp210, MLL-AF9,NrasG12D or Flt3-ITD; NrasG12D. These LSC lines show a broad multilineage potential and are shown to be radio-resistant. Nevertheless, the functional effects of irradiation on BM-MSC have not been extensively explored.

Aims: Aims: The main objective was to evaluate the effects of irradiation on the MSC in their hematopoietic-supporting capacity.

Methods: Ten BM samples were obtained from healthy donors after informed consent. MSC were obtained and characterized following standard procedures and were exposed to different doses of irradiation. Then, one aliquot was gamma-irradiated with a single dose of 2,5Gy whereas non-irradiated MSC from the same sample were used as controls. MSC were characterized following ISCT criteria (flow cytometry and in vitro differentiation stainings). Apoptosis was evaluated by flow cytometry using annexin-V/7AAD staining. Expression microarrays of irradiated and control-MSC were performed using Human Gene 2.0 ST Array platform (Affymetrix). RT-PCR of key genes involved in the hematopoietic supporting capacity as well as in the differentiation of MSC into osteoblasts and adipocytes was performed in both experimental groups. Finally, long term BM cultures (LT-BMC) were performed as functional assays to test the hematopoietic-supporting ability of irradiated and non-irradiated MSC. For this purpose, LT-BMC from the two experimental groups were cultured on irradiated-MSC, which were isolated from leukapheresis and seeded on stromal layers from non-irradiated or irradiated MSC. Cfu-GM colonies derived from the LT-BMC were scored weekly.

Results: Flow cytometric characterization of irradiated MSC was comparable to that of control MSC. Similarly, there were no differences in the percentage of viable cells between both experimental groups neither at one hour nor at 72h post irradiation, confirming once more the radio-resistance of MSC. In addition, expression arrays did not show any statistically significant differences in genes involved in hematopoiesis maintenance. However, upon comparing the differentiation ability we interestingly observed that irradiated-MSC differentiation was skewed towards osteogenesis whereas adipo genesis was impaired. In this regard, irradiated-MSC had significantly higher SPP1 expression (involved in late osteogenic differentiation) and lower CBP and PPAR-gamma (both genes involved in adipogenesis) compared to control MSC. After inducing in vitro differentiation, there were no differences in ALP and Alizarin Red staining but the number of adipocytes per field at days 7, 14 and 21 was significantly lower in irradiated MSC (p=0,018, p=0,046 and p=0,018, respectively). In addition, angiopoietin and SDF-1, key genes implicated in maintenance of hematopoiesis, were significantly overexpressed in irradiated-MSC (p=0,043 and p=0,028, respectively). Finally, in the functional evaluation of the hematopoietic-supporting ability of MSC by LT-BMC, we observed that the number of Cfu-GM colonies generated by the culture was significantly higher in the irradiated group after 4 and 5 weeks (p=0,046 and p=0,018, respectively) compared to the non-irradiated group. Furthermore, the number of adipocytes per field was significantly reduced in the LT-BMC.

Summary/Conclusions: Irradiation of MSC with 2,5Gy improves their hematopoietic supporting ability and modifies their differentiation capacity, increasing the osteogenesis and decreasing the adipogenesis.

Background: Allogeneic haematopoietic stem cell transplantation (alloHSCT) is the most effective means of preventing relapse of blood cancers, in particular AML. The curative potential of alloHSCT is largely due to the immune mediated graft-versus-leukemia (GVL) effect, which in turn is dependent on donor immunity. The dual challenge of alloHSCT is therefore to allow sufficient donor engraftment for haematopoietic and immunological reconstitution that drives the GVL effect while limiting the toxicity of conditioning and the onset of graft-versus-host disease (GVHD).

Aims: Optimize the use of BCL2 inhibitors to modify recipient NK cell function in models of alloHSCT in order to minimize GVHD severity and onset.

Hypothesis: Therapeutic targeting of recipient NK cell frequency or function pre-transplant will allow reduced intensity conditioning (RIC) and promote both donor T cell engraftment and GVHD whilst reducing the risks of GVHD.

Methods: We used a MHC-mismatched mouse model of alloHSCT, where donor and recipient cells are syngeneic cell pool (H2Kd) long-term lines were established from a range of transgenic mice, underlining the overall applicability of this model. Using this system, we established LSC lines that express BCR/ABLp210, MLL-AF9,NrasG12D or Flt3-ITD; NrasG12D. These LSC lines show a broad multilineage potential and are shown to be radio-resistant. Nevertheless, the functional effects of irradiation on BM-MSC have not been extensively explored.

Background: Prolonged isolated thrombocytopenia (PT), is a serious complication after allogeneic hematopoietic stem cell transplantation (allo-HSCT) and defined as the engraftment of all peripheral blood cell lines other than a platelet (PLT) count ≤2×10^10/L or dependence on PLT transfusions for more than 60 days after allo-HSCT. Several clinical risk factors have been proposed to be associated with PT after allo-HSCT. However, the underlying mechanisms remain to be elucidated. Emerging evidence from mouse studies has suggested that effective hematopoiesis depends on a particular bone marrow (BM) microenvironment in which hematopoietic stem cells reside. MSCs represent a key cellular component of the BM microenvironment, which are potential progenitors for osteoblasts, adipocytes, chondrocytes, and marrow stromal cells. Thus, the mechanisms of megakaryocyte and thrombocytogenesis result from the interactions between hematopoietic progenitor cells, cytokines, and marrow stromal cells derived from MSCs or MSCs directly. However, the functional role of BM MSCs in the patients with PT has never been reported. Moreover, approaches for improving the dysfunction of BM MSCs in patients with PT are lacking.
