mg and 35 mg) dosing was evaluated. Pharmacokinetics (PK), pharmacodynamics (PD), and safety were monitored, as well as an assessment of efficacy. Clinical response was assessed by standard criteria. Potency and specificity for SYK and JAK pathway inhibition were measured in whole blood assays by monitoring signaling responses following ligation of the BCR and receptors for IL-4. Serum markers of inflammation, minimal residual disease (MRD) and apoptosis in CLL patients were also measured.

**Results:** A phase 2 study was initiated in May 2016 to enroll up to 40 patients in each of three cohorts; 1) relapsed/refractory CLL/SLL, 2) relapsed/refractory indolent NHL, and 3) relapsed DLBCL, MCL and transformed FL. As of March 1, 2017, 37 patients have been enrolled, 17 with CLL/SLL, 15 with indolent NHL (10 FL, 4 MZL, 1 WM), and 5 with aggressive NHL (3 DLBCL, 1 MCL, 1 tFL). Median patient age is 70 years (range, 51-93). The median number of prior therapies is 3 (range 1–7). 11 patients had prior BTK or PI3K inhibitor therapy. The safety profile has been similar to what was seen in the Phase 1 study. However, 3 patients at 35 mg BID achieved higher than expected drug concentrations and had SAEs (2 grade 5 infections, 1 grade 3 pancreatitis). The starting dose was reduced to 30 mg BID and a PK monitoring and dose reduction strategy has been implemented. To date, this has resulted in a better safety profile without PK outliers. The most common AEs of any grade have been diarrhea (27%), fatigue (27%) and nausea (24%). Grade 3+ AEs occurring in more than one patient are infection (5 patients), abdominal pain (3 patients) and hypertension (3 patients). As seen in phase 1, significant inhibition of SYK and JAK signaling pathways in peripheral blood is observed. Evidence for tumor cell mobilization to peripheral blood in CLL/SLL is consistently observed following one week of therapy. PRs have been seen in all 3 cohorts including 10 of 13 (77%) CLL/SLL and 3 of 6 (50%) FL patients evaluated. Of these 13 PRs, 12 are still on drug with 4 patients in response for greater than 6 months. In addition, PRs have been seen in patients who relapsed on ibrutinib (FL patient, 8+ months) and venetoclax (SLL patient, 7+ months) therapy. As demonstrated preclinically, we have seen evidence of apoptosis (Annexin V+ B-cells) in 6 CLL patients. 5 of these patients had a PR at the end of the 2nd cycle (Figure 1).

**Summary/Conclusions:** Cerdulatinib demonstrates clinical activity in heavily pretreated patients with CLL/B-cell NHL and is generally well tolerated. Clinical response was assessed by standard criteria. Potency and specificity for SYK and JAK pathway inhibition were measured in whole blood assays by monitoring signaling responses following ligation of the BCR and receptors for IL-4. Serum markers of inflammation, minimal residual disease (MRD) and apoptosis in CLL patients were also measured.

**Results:** A phase 2 study was initiated in May 2016 to enroll up to 40 patients in each of three cohorts; 1) relapsed/refractory CLL/SLL, 2) relapsed/refractory indolent NHL, and 3) relapsed DLBCL, MCL and transformed FL. As of March 1, 2017, 37 patients have been enrolled, 17 with CLL/SLL, 15 with indolent NHL (10 FL, 4 MZL, 1 WM), and 5 with aggressive NHL (3 DLBCL, 1 MCL, 1 tFL). Median patient age is 70 years (range, 51-93). The median number of prior therapies is 3 (range 1–7). 11 patients had prior BTK or PI3K inhibitor therapy. The safety profile has been similar to what was seen in the Phase 1 study. However, 3 patients at 35 mg BID achieved higher than expected drug concentrations and had SAEs (2 grade 5 infections, 1 grade 3 pancreatitis). The starting dose was reduced to 30 mg BID and a PK monitoring and dose reduction strategy has been implemented. To date, this has resulted in a better safety profile without PK outliers. The most common AEs of any grade have been diarrhea (27%), fatigue (27%) and nausea (24%). Grade 3+ AEs occurring in more than one patient are infection (5 patients), abdominal pain (3 patients) and hypertension (3 patients). As demonstrated preclinically, we have seen evidence of apoptosis (Annexin V+ B-cells) in 6 CLL patients. 5 of these patients had a PR at the end of the 2nd cycle (Figure 1).

**Summary/Conclusions:** Cerdulatinib demonstrates clinical activity in heavily pretreated patients with CLL/B-cell NHL and is generally well tolerated. Consistent activity is seen in patients with CLL and FL. Accrual is proceeding; updates will be presented.
and IRC PET evaluation. Comparison of PFS based on CT-response and re-analysis of PET scans applying the now recommended 5-point scale for PET response assessment will be presented. Pooled analyses of these and data from other studies with longer follow-up may determine PET response as a reliable early surrogate for PFS and OS, providing a platform for study of response-adapted therapy.

Hoffmann-La Roche Ltd, Basel, Switzerland, 11The University of Manchester and The Christie NHS Foundation Trust, Manchester Academic Health Science Centre, Manchester, United Kingdom, 12Department of Haematology, National Cancer Center Hospital, Tokyo, Japan, 13Pharma Development Safety and Risk Management, 14Pharma Development Biometrics Biostatistics, F. Hoffmann-La Roche Ltd, Basel, Switzerland, 15Department of Haematology, Kings College Hospital, London, United Kingdom

Background: The Phase III GALLIUM study (NCT01332968) showed that obinutuzumab (GA101; G) significantly prolonged PFS in previously untreated FL pts relative to rituximab (R) when combined with chemotherapy (chemo; CHOP, CVP or bendamustine [B]). Grade 3–5 and serious AEs were more common with G-chemo.

Aims: To explore outcomes by immunochemotherapy regimen.

Methods: Pts were aged ≥18 yrs with documented, previously untreated FL (grades 1–3a), advanced disease (stage III/IV or stage II with tumor diameter ≥7cm), ECOG PS 0–2, and requiring treatment according to GELF criteria. Chemo regimen was allocated by center. Pts were randomized 1:1 (stratified by chemo, FLIPI-1 group and geographic region) to R 375mg/m² on day (D) 1 of each cycle (C) or G 1000mg on D1, 8 and 15 of C1 and D1 of C2–8, for 6 or 8 cycles depending on chemo. Pts with CR or PR at EOI (per Cheson 2007) continued to receive R or G every 2 months for 2 yrs or until progression. The cut-off date for this analysis was September 10 2016. All pts gave informed consent.

Results: 1202 FL pts were randomized. Baseline characteristics were generally similar across chemo groups, although B and CVP pts had relatively more comorbidities, e.g. GI and vascular disorders, than CHOP pts. After 41.1 months’ median follow-up, investigator (INV)-assessed PFS remained superior for G-chemo relative to R-chemo (HR, 0.68; 95% CI 0.54–0.87; p=0.0016) with consistent HRs across chemo groups (Figure 1). HRs for secondary time-to-event endpoints were supportive of the primary analysis. Difference in frequency of grade 3–5 AEs between arms was highest with CHOP and CVP (Table 1). Rates of second neoplasms and grade 3–5 infections were similar in G and R arms for CHOP and CVP but not for B. In all chemo groups, SAEs were more frequent with G than R, and AEs causing treatment discontinuation and fatal AEs were similar. Reductions in T-cell counts were more pronounced and prolonged in the B group than CHOP or CVP groups.

Figure 1.

Table 1. Safety summary (number (%) of FL pts* with ≥1 AE).

Summary/Conclusions: In treatment-naive FL pts, PFS was superior with G-chemo relative to R-chemo with consistent effects across chemo regimens. Some differences were seen in safety profiles between chemo regimens, but comparisons may be confounded by the lack of randomization.

S776
Efficacy and Safety of Copanlisib in Patients with Relapsed/Refractory Follicular Lymphoma: A Subset Analysis of the Chronos-1 Study

Summary/Conclusions: In treatment-naive FL pts, PFS was superior with G-chemo relative to R-chemo with consistent effects across chemo regimens. Some differences were seen in safety profiles between chemo regimens, but comparisons may be confounded by the lack of randomization.
Background: Follicular lymphoma (FL) is the most common indolent non-Hodgkin lymphoma (NHL) subtype, yet treatment options in the relapsed/refractory setting are limited. Copanlisib is a potent and selective pan-class I PI3K inhibitor with predominant activity against the δ- and α-isoforms. Aim: We report results from the FL subset of a large phase II study in indolent NHL patients (NCT01660451, part B).

Methods: Patients with histologically confirmed indolent indolent FL (grade 1-3a) relapsed/refractory to ≥2 prior lines of treatment were treated with copanlisib (60 mg IV infusion) administered on days 1, 8 and 15 of a 28-day cycle until disease progression or unacceptable toxicity. The primary endpoint was objective response rate (ORR) as assessed by independent radiology review according to the response criteria for lymphoma (Cheson et al, JCO 20:579, 2007). Secondary endpoints included progression-free survival (PFS) and duration of response (DOR), safety and tolerability.

Results: A total of 141 patients with iNHL were treated in the phase II study, including 104 patients with FL. The FL subset was characterized as: 52% male, 83% white, median age 62 yrs, 62% ECOG 0, 63% refractory to last chemotherapy or combination, and 46 (44.2%) with partial response. Stable disease was observed in 35 (33.7%) patients and progression of disease as best response in 2 patients. The median duration of response was 370 days (range 0-687), with 43 responders censored at data cut-off. Median duration of treatment was 22 weeks (range 1-105). 33 (32%) patients remained on treatment. Per investigator assessment, 87 of 96 evaluable patients (91%) had some degree of tumor shrinkage as best response, and 58/96 (60%) had >50% tumor shrinkage (Figure 1). For all patients in the phase II study, the most common treatment-emergent AEs occurring in >25% of patients included (all grade/grade 3+): diarrhea (34%/5%), reduced neutrophil count (30%/24%), fatigue (30%/24%), and fever (25%/4%). Hyperglycemia (50%/41%) and hypertension (30%/24%) were transient. The incidence of pneumonitis (8%/1.4%), hepatic enzymeopathy (AST 28%/1.4%; ALT 23%/1.4%), opportunistic infection (1.4%) and colitis (0.7%) were low. Six deaths were observed, 3 of which were attributed to copanlisib: one lung infection, one respiratory failure, and one thromboembolic event.

Summary/Conclusions: Copanlisib was highly active as a single agent in heavily pretreated relapsed/refractory FL patients and resulted in responses in the majority of patients with a median duration of response of 370 days. Toxicities were manageable, with a low incidence of severe AEs associated with other PI3K inhibitors, especially hepatic enzymeopathy, opportunistic infections, and colitis.
Background: Between March 2000 and May 2005 a multicenter randomized trial comparing frontline use of CHOP-R vs R-HDS with autograft has been performed on 134 Follicular Lymphoma (FL) patients, selected for age less than 60 yrs. and poor prognostic features according to age-adjusted IPI (2-3) and IIL-score (3 or greater). Results at 4-yr follow-up were previously published (Ladetto M et al, Blood 2008), showing superior disease control with R-HDS without any survival advantage.

Aims: We have recently performed a long term update and the results at a median follow-up of 13 yrs are here presented.

Methods: The long-term outcome has been updated for 119 out of the original 134 randomized patients (56 CHOP-R and 63 R-HDS arms). Main features of the updated patients included: median age 51 yrs. (22-60), M/F ratio 68/51, aIPI 2-3 90%, high LDH 43%, bulky disease 60%, B-symptoms 46%, BM involvement 86%; no significant differences were observed in clinical presentation between the two arms, as previously reported. Treatment schedule consisted of: i. CHOP-R arm: 6 courses of cyclophosphamide/doxorubicin/vincristine/prednisone followed by 4-weekly rituximab courses; ii. experimental R-HDS arm: rituximab with high-dose sequential chemotherapy followed by autografting. The analysis was intention to treat with event-free survival as the primary endpoint. Minimal residual disease (MRD) was evaluated post treatment in 56 patients with a bcl-2/IgH MBR or mcr translocation confirmed at diagnosis by nested PCR. The trial was registered at www.clinicaltrials.gov, no. NCT00435955. The long-term outcome has been updated in January 2017 by 27 out of 30 participating Centers, on 119 patients (88% of the whole series).

Results: Complete remission (CR) was achieved by 86 (72%) patients, including 32 (57%) with CHOP-R and 54 (85%) with R-HDS (p <.001); Molecular Remission (MR) was achieved in 37 out of 56 (66%) evaluable patients. At a median follow-up of 13 yrs., 74 patients (63%) are alive. Overall, 22 patients died for lymphoma progression (13 CHOP-R, 9 R-HDS), 12 died for secondary malignancy (3 in the CHOP-R, 9 in the R-HDS arms), 11 patients died for other causes, including four early toxic deaths. The overall survival (OS) for the whole series is 63% at 13 yrs, as shown in Figure 1A. No significant differences in the long-term OS were observed between the two arms, with 13-yr survival of 65% and 61% for CHOP-R and R-HDS, respectively (p=0.51). At 13 years, the event free survival is 35%, whereas the disease-free survival (DFS) is of 53%, as shown in Figure 1B. Response to induction therapy had a major impact on the OS, with 13 yr survival of 75% for patients achieving CR vs 33% for those with less than CR (p <.001). Similarly, Molecular Remission (MR) achievement was associated with prolonged OS, with 13 yr survival of 81% for patients in MR on BM cells, and of 47% for those with positive MRD (p=.02) (Figure 1C).

Summary/Conclusions: i. poor risk FL may have a prolonged survival, with 63% of patients alive at 13 yrs.; ii. no survival differences between CHOP-R and R-HDS can be detected even at 13 yrs of follow-up; iii. achieving CR is still crucial for the long-term survival; iv. the MRD analysis has a prognostic impact not only on progression-free but also on OS; v. lymphoma progression remains the major cause of death, while secondary neoplasms represent the second cause of treatment failure; vi. a subgroup of advanced-stage FL may experience a prolonged DFS lasting at least 13 yrs; this raises the issue of the potential curability of FL.
Changing the strategy of therapy in multiple myeloma

**S779**

**PHASE II TRIAL OF COMBINATION OF ELOTUXUMAB, LENALIDOMIDE, AND DEXAMETHASONE IN HIGH-RISK SMOLDERING MULTIPLE MYELOMA**

I. Oshotobi1, A. Cadal1, P. Henrick1, A. Savelli2, J. Cappuccio1

I. Oshotobi, Dana-Farber Cancer Institute, Boston, MA, United States

**Methods:** Patients enrolled on study met eligibility for high-risk SMM based on the newly defined criteria proposed by Rajkumar et al, Blood 2014. Patients who had failed prior therapy were eligible. Patients were then to proceed on maintenance therapy with the combination of elotuzumab, lenalidomide, and dexamethasone for 2 years. Maintenance therapy was then to be continued for 3 years.

**Results:** Of the 64 enrolled patients, 40 continued on study treatment without disease progression for 47.0 months (median duration of follow-up). The overall response rate (ORR) was 86% (61 complete responses (CR), 18 very good partial responses (vgPR), and 15 partial responses (PR)). Median progression-free survival (PFS) was not reached. Median duration of response (DOR) was 25.7 months. Median overall survival (OS) was not reached for patients with NDMM.

**Summary/Conclusions:** The combination of elotuzumab, lenalidomide, and dexamethasone in patients with high-risk smoldering multiple myeloma (SMM) is feasible and active in patients with NDMM, with weekly and twice-weekly ixazomib dosing having been investigated. The study is ongoing.

**TWICE-WEEKLY IXAZOMIB PLUS LENALIDOMIDE-DEXAMETHASONE IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA: LONG-TERM FOLLOW-UP DATA FOR PATIENTS WHO DID NOT UNDERGO STEM CELL TRANSPLANTATION**

J. Berdeja1, M. Liedtke1, A. Charé2, S. Smith3, D. Lebovic3, N. Raje4, E. Liao5, X. Zhang1, D. Berg1, R. Baz1

1Dana-Farber Cancer Institute, Boston, MA, United States

**Background:** Among other novel agents that have been tested in newly diagnosed multiple myeloma (NDMM) patients (San Miguel et al, N Engl J Med 2008, Durie et al, Lancet 2017). Data from two phase 1/2 studies indicate that the combination of ixazomib plus lenalidomide-dexamethasone (IRd) is feasible and active in patients with NDMM, with weekly and twice-weekly ixazomib dosing having been investigated (Kumar et al, Lancet Oncol 2014). In the Phase 2 study (NCT01383928), 204 patients were randomized to receive either ixazomib plus Rd or Rd alone. The median progression-free survival (PFS) for patients who received maintenance therapy was 29.4 months. Median overall survival (OS) was not estimable; 2-year Kaplan-Meier estimate for OS was 92%. A total of 78% of patients who had grade ≥3 treatment-related adverse events (AEs); the most common treatment-related grade ≥3 AEs and serious AEs are shown in the Table 1. After completing induction therapy with IRd, 18 patients went on to receive maintenance with single-agent ixazomib on a twice-weekly dosing schedule. Patients who went on to maintenance received a median (range) of 31.5 (17–75) treatment cycles. Among the patients who received maintenance therapy, the ORR (PR + VGPR + CR) was 94%, the complete response and very good partial response (CR + VGPR) was 86%, and the CR rate was 44%. Two (11%) patients improved their responses during maintenance therapy, and 1 VGPR and 1 VGPR to stringent CR (sCR). Of the 39 patients who received maintenance therapy, 31 had a median follow-up of 13.9 (range 11.0–22.2) months. Median OS was not reached.

**Methods:** Patients with NDMM who received twice-weekly ixazomib (1.6 mg/kg) and lenalidomide (25 mg) received 3 cycles of induction (days 1, 4, 8, 12, and 15) followed by 2 cycles of consolidation (days 1, 4, 8, 12, and 15). Maintenance therapy consisted of twice-weekly oral ixazomib (1.6 mg/kg) and lenalidomide (25 mg) for 2 years. Patients who continued to respond at last were allowed to remain on maintenance therapy with the combination of elotuzumab, lenalidomide, and dexamethasone for 2 years. Maintenance therapy was then to be continued for 3 years.

**Results:** Of the 27 patients who received the combination of elotuzumab, lenalidomide, and dexamethasone (IRd) in the Phase 2 trial, 19 patients (70%) went on to receive maintenance. The median OS was 29.4 months. Median DOR was 25.7 months. Median PFS was not reached. Median OS was not reached for patients with NDMM. The study is ongoing.

**Summary/Conclusions:** The combination of elotuzumab, lenalidomide, and dexamethasone in patients with high-risk smoldering multiple myeloma (SMM) is feasible and active in patients with NDMM, with weekly and twice-weekly ixazomib dosing having been investigated. The study is ongoing. The combination of elotuzumab, lenalidomide, and dexamethasone is active in patients with NDMM, with weekly and twice-weekly ixazomib dosing having been investigated. The study is ongoing.
**Summary/Conclusions:** In patients with NDMM, twice-weekly ixazomib plus Rd resulted in excess adverse response rates in patients who did not receive a SCT and who received maintenance therapy. The responses were deep and durable, with long PFS and a high 2-year OS estimate. The majority of AEs had an onset during induction, and the incidence of AEs during maintenance was infrequent.

**Background:** Multiple myeloma is characterized by osteolytic bone disease, with up to 80% of pts presenting with detectable lesions. Myeloma bone disease is mediated by osteoclast activating factors such as RANKL, increasing the risk of skeletal-related events (SREs) and impacting morbidity and mortality. DMB, a human monoclonal antibody that targets and binds to RANKL, can be administered subcutaneously (SC) to pts regardless of renal function. **Aims:** This study evaluates the efficacy and safety of DMB compared with Za in newly diagnosed myeloma pts. **Methods:** Adult pts were randomized 1:1 to DMB 120mg SC Q4W or Za 4mg IV (adjusted) Q4W along with anti-myeloma therapy. Key stratification factors included type of first-line therapy (novel or non-novel) and previous SRE. Pts with renal insufficiency were excluded if baseline creatinine clearance (CrCl)<30mL/min. The primary endpoint was non-inferiority of DMB to Za with respect to time to first on-study SRE. Secondary endpoints included superiority of DMB for time to first on-study SRE and first- and subsequent on-study SRE, and overall survival (OS). Progression-free survival (PFS) was an exploratory endpoint. Safety was also assessed. **Results:** A total of 1718 pts were randomized, 859 to each arm. Baseline demographic and disease characteristics were balanced, with 66.0% of DMB and 67.2% of Za pts reporting prior SRE history; CrCl≤60mL/min was reported in 67.2% of Za pts and 66.0% of DMB pts. **Figure 1**

**Figure 1.**

**Summary/Conclusions:** DMB demonstrated non-inferiority to Za in delaying time to first on-study SRE in myeloma pts, meeting the primary endpoint of the study. A landmark analysis at 15 m for time to first SRE demonstrated a HR(95%CI)=0.81(0.66,0.99), P=0.039 (Figure 1) between DMB and Za. OS was similar between DMB and Za (HR[95%CI]=0.90[0.70,1.16], P=0.41), with fewer deaths with DMB (121[14.1%]) than Za (129[15.0%]). PFS yielded a HR(95%CI)=0.82(0.68,0.99), descriptive P=0.036, with median times of 46.0m (95%CI:34.3,57.8) for DMB and 35.3m (95%CI:30.19,52.9) for Za. The most common TEAes(>20%) for DMB were diarrhea and nausea. The rates of SAEs (DMB,ZA [%];46.0,47.3), hypocalcemia (16.9,12.4; serious:0.9,0.2), and positively adjudicated ONJ (4.1,2.8) were comparable to known safety profiles. Fewer DMB pts (%) compared with Za pts had AEs potentially related to renal toxicity (10.0,17.1;P<0.001), most notably in pts with baseline CrCl<60mL/min (12.9,20.4). TEAes led to IP discontinuation in 12.2% of pts (12.9,11.5).
Background: Pembrolizumab (pembro) is a humanized, highly selective, high-affinity IgG4/κ antibody that blocks the interaction between programmed death-1 (PD-1) and its ligands PD-L1 and PD-L2, activating tumor immunity. Pembrolizumab plus lenalidomide (len) and low-dose dexamethasone (dex) may provide synergistic antitumor activity in relapsed/refractory multiple myeloma (RRMM). Biomarkers indicative of response, pharmacodynamic activity, and/or mechanism of action to combination therapies are also needed.

Aims: To determine the maximum tolerated dose (MTD) and safety and tolerability of pembrolizumab plus len and low-dose dex in patients with RRMM. Additionally PD-L1 and PD-L2 expression in bone marrow (BM), immune profiles in circulating lymphocytes, and gene expression in blood were evaluated.

Methods: This open-label, phase 1 KEYNOTE-023 (NCT02036502) study of pembrolizumab plus len and low-dose dex enrolled patients with RRMM previously treated with ≥2 prior therapies, including both a proteasome inhibitor and an immunomodulatory drug. Patients received pembrolizumab 200 mg IV every 2 weeks (Q2W), len 25 mg orally on days 1-21, and dex 40 mg orally weekly on each 28-day cycle. Primary end points were safety and determination of the MTD. Ongoing follow-up was focused on maintaining hematocrit (HCT) level ≥45%. Response assessment was performed at weeks 8 and 28. Immuno-oncology Biomarker Analysis (IBA) was performed at screening, or before the first dose of study drug. Absolute and/or relative numbers of circulating lymphocytes (by flow cytometry [FC]) and gene expression profile (GEP) (by Neoan) were evaluated in predose; cycle 1, day 1 (C1D1); and cycle 2, day 1 (C2D1) blood samples.

Results: MTD was determined as pembrolizumab 200 mg IV Q2W plus len 25 mg and dex 40 mg. Median (range) age was 61 years (46-77); median (range) number of prior lines of therapy was 4 (1-10); 38 (75%) patients were len-refractory, and 27 (53%) were double-refractory. Most common grade ≥3 treatment-related adverse events (TRAEs) were neutropenia (33%), thrombocytopenia (18%), and anemia (12%). Two patients (4%) died because of TRAEs (hepatic failure, ischemic stroke). Immune-related adverse events occurred in 5 (10%) patients. No pneumonitis was reported. ORR was assessed by IMWG 2006. Exploratory biomarker analyses included analysis of PD-L1 and PD-L2 on CD3+CD138+ cells in BM aspirate samples obtained at screening, or before the first dose of study drug. Absolute and/or relative numbers of circulating lymphocytes (by flow cytometry [FC]) and gene expression profile (GEP) (by Neoan) were evaluated in predose; cycle 1, day 1 (C1D1); and cycle 2, day 1 (C2D1) blood samples.

Old and new drugs in MPN

RUXOLITINIB FOR THE TREATMENT OF INADEQUATELY CONTROLLED POLYCYTHEMIA VERA WITHOUT SPLITENOMEGALY: 80-WEEK FOLLOW-UP FROM THE RESPONSE-2 TRIAL

Background: Polycythemia vera (PV) is characterized by hyperproliferation of erythroid/myeloid/megakaryocytic components in the bone marrow, cardiovascular complications, and high symptom burden. Treatment (Tx) in patients (pts) with PV is indicated by increasing hematocrit (HCT) levels (HCT ≥45%). Ruxolitinib (RUX) is a JAK1/2 inhibitor that reduces HCT, erythrocytosis, and symptom burden. The RESPONSE-2 trial evaluated the efficacy and safety of RUX vs best available therapy (BAT) in hydroxyurea (HU)-resistant/intolerant pts with PV ≥18 years without splenomegaly and with phlebotomy (PT) requirement to control HCT. At week (wk) 28 (primary analysis), HCT control was reported in 46/74 pts in the RUX arm vs 14/75 pts in the BAT arm. The aim of this preplanned analysis of RESPONSE-2 was to evaluate the duration of efficacy and safety of RUX vs BAT, after all pts reached wk 80 into the study or discontinued the study.

Methods: Pts were randomized 1:1 to RUX 10 mg twice daily or BAT. Primary end point was the proportion of pts who achieved HCT control at wk 28 (absence of PT eligibility [HCT >45], ie, ≥3 percentage points from baseline, or HCT <48%) from wk 8 to 28, with ≥1 pt eligible for HCT at wk 0 to 8. Key secondary end point was the proportion of pts who achieved complete hematologic remission at wk 28 (CHR: HCT <45%, WBC ≤10 ×10^9/L, platelet count ≤450 ×10^9/L). In a post hoc analysis, pts ≥65 years of age were included. The analysis was performed on all pts with ≥1 pt-week of exposure (primary analysis) or ≥4 pt-weeks of exposure (post hoc). The post hoc analysis was performed per-protocol (n=75) and as intention to treat (n=109) analyses.

Results: Baseline demographics were comparable among RUX (N=74) and BAT (N=75) arms. At baseline (wk 0) 28/32 pts (87%) in the BAT arm and 25/32 pts (78%) in the RUX arm were still receiving Tx; while 5 pts discontinued Tx (adverse events [AEs]=3 pts, physician’s decision/patient withdrew consent=1 pt, each). In BAT arm, 58 pts crossed over to RUX (crossover data to be included in presentation) with remaining pts either ongoing follow-up (fu; n=59) or having discontinued Tx (completed fu per protocol, n=7; death, n=1; other reasons, n=4). Median exposure was 28.4 wk in the BAT arm and 28 wk in the RUX arm. At wk 80, durable HCT control was achieved in 35 pts (47%) in RUX vs 2 pts (3%) in BAT arm. Of those who achieved a HCT response at wk 28, Kaplan-Meier estimate of maintaining response up to wk 80 was 78.3% in the RUX arm. Durable CHR was achieved in 18 pts (24%) in RUX vs 2 pts (3%) in the BAT arm. Total number of pts was higher in the RUX arm vs BAT arm (Figure 1). At wk 80, 45% of pts randomized to RUX continued to achieve ≥25% of reduction in the MPN-SAF TSS. At wk 80, mean percentage change from baseline in JAK2V617F allele burden was −9.7% in the RUX (n=65) vs +0.3% in the BAT arm (n=3). AEs observed were consistent with those generally reported with RUX (primarily grade ≥3). Most common AEs (all Grades) were headache (16.9%), arthralgia (9.1), and pruritus (9.1) in the RUX arm vs pruritus (37.5%), headache (16.9), and thrombocytopenia (15.0) in the BAT arm. Rate of thromboembolic events (Standardized MedDRA Query, exposure-adjusted) was RUX (1.5) vs BAT arm (1.9). No pts in the RUX arm had disease progression or ≥2 pts in the BAT arm. No deaths were reported in the RUX arm vs 3 pts in the BAT arm (septic shock/disease progression/study indication=1 pt, each).

Summary/Conclusions: RUX provided durable HCT control, durable CHR, reduction in PT requirement, improved symptom burden, and was generally well tolerated with <90% of pts still receiving Tx at wk 80. This modest reduction in allele burden over time. Findings from both RESPONSE studies suggest RUX could be considered as a standard of care for second-line Tx in this inadequately controlled pt population with PV.
PHASE 3 RANDOMIZED TRIAL OF MOMELOTINIB VERSUS RUXOLITINIB IN JAK INHIBITOR NAIVE PATIENTS WITH MYELOFIBROSIS: RESULTS OF THE SIMPLIFY-1 STUDY
1Stanford University Medical Center, Stanford, United States, 2Saint-Louis Hospital (APHP) and Paris Diderrt University, Paris, France, 3Monash University, Melbourne, Australia, 4University Hospitals Leuven, Leuven, Belgium, 5Kaposi Mor Teaching Hospital, Kapovar, Hungary, 6Medical University of Gdansk, Gdansk, Poland, 7Guy’s and St. Thomas’ NHS Foundation Trust, London, United Kingdom, 8University of Miyazaki, Miyazaki, Japan, 9Emory University School of Medicine, Atlanta, 10Gilead Sciences, Inc., Foster City, United States, 11Hospital Clinic, University of Barcelona, Barcelona, Spain, 12Mayo Clinic Cancer Center, Scottsdale, United States

Background: Momelotinib (MMB), an investigational oral JAK inhibitor (JAKI), has been shown in early trials to reduce spleen volume, improve disease associated symptoms and improve red blood cell (RBC) transfusion requirements in patients with myelofibrosis (MF).

Aims: To test the non-inferiority of MMB vs ruxolitinib (RUX) in splenic volume reduction and symptom amelioration, and superiority in transfusion response, in JAKI naive patients with primary myelofibrosis, and post-polycythemia vera or post-essential thrombocythemia myelofibrosis.

Methods: Eligibility included primary myelofibrosis or post-polycythemia vera/essential thrombocythemia myelofibrosis; International Prognostic Scoring System (IPSS) high risk, intermediate-2 risk, or intermediate-1 risk associated with symptomatic splenomegaly; palpable spleen ≥5cm; and no Grade ≥2 peripheral neuropathy. Informed consent was obtained. Stratification was by transfusion dependence and platelets (<100K, 100K-200K, and >200K/μl). Patients were randomized 1:1 to 24 weeks of MMB 200 mg QD or BAT. Assessments included spleen volume by MRI, and patient-reported symptoms using a daily eDiary of modified MPN-SAF Total Symptom Score (TSS). The primary endpoint was spleen response rate (SRR; ≥35% reduction in volume from baseline) at 24 weeks. Secondary endpoints, evaluated sequentially, were rates of TSS response (TSS RR; ≥50% reduction from baseline), RBC transfusion, RBC transfusion independence (TI) and RBC transfusion dependence (TD).

Results: 73 of 104 (70%) and 40 of 52 (77%) patients receiving MMB or BAT, respectively, completed the 24 week randomized treatment phase. BAT for all 144 patients included ruxolitinib, and 27% of patients were on ruxolitinib in combination with other drugs. Efficacy results are in Table 1. The most common treatment-emergent adverse events in MMB patients were diarrhea (33%), asthenia (19%), nausea (19%), and cough (17%), and in BAT patients, asthenia (21%), fatigue (19%), anemia (15%), diarrhea (15%), and abdominal pain (15%); the most common Grade ≥3 adverse events in MMB patients were anemia (13%) and thrombocytopenia (7%), and in BAT patients, anemia (13%), thrombocytopenia (6%) and abdominal pain (6%). Treatment emergent peripheral neuropathy occurred in 11 (11%) of MMB (1 Grade 3) and in no BAT patients; MMB was discontinued in 3 patients due to neuropathy.

Summary/Conclusions: In previously ruxolitinib-treated patients with myelofibrosis, 24 weeks of momelotinib was not superior to best available therapy for splenic response, but significantly better in improving disease related symptoms and transfusion independence. NCT02101268.

S787

MOLECULAR RESPONSE TO HYDROXYUREA AND ROPEGINTERFERON ALFA-2B IN THE PROUD-PV RANDOMIZED PHASE 3 TRIAL

J.-J. Klidjian1,2,3,4,5, B. Cassinat4,5, J. Soret-Duphy6, E. Verger7, L. Roy6, J. Rey6, N. Masliah6, B.Grohmann-Isy7, C. Klaed7, H. Gisslinger6

1Clinical Investigations Center, Hopital Saint-Louis, 4INSERM UMR5131, 5Paris Diderot University, 6Hopital Saint-Louis, Paris, 7Hopital Henri Mondor, Creteil, France, 8Nanogen, Marseille, 9AOP Orphan Pharmaceuticals AG, 10Medical University of Vienna, Vienna, France

Background: Interferon alfa (IFNa) has been successfully used to treat myeloproliferative neoplasms (MPN) for many years and several phase 2 studies have indicated recently shown high rates of hematological and molecular responses assessed by the quantification of mutant JAK2 allele burden (%JAK2V617F) in peripheral blood. However, direct in vivo studies investigating the impact of IFNa treatment on proliferation of bone marrow (BM) normal and malignant hematopoietic progenitors are lacking.

Aims: To report the findings of a randomized controlled phase III trial (PROUD-PV) comparing the novel, long-acting Rogepinginterferon alfa-2b (AOP2014) with hydroxyurea (HU) in polycythemia vera (PV) patients (pts) to assess correlation between evolution of %JAK2V617F in peripheral blood and the impact of therapy on malignant clones by functional assays testing mutant BM hematopoietic progenitors in the French study population.

Methods: Randomized, controlled, multicenter phase 3 trial comparing efficacy, safety and tolerability of hydroxyurea and Rogepinterferon Alfa-2b in PV pts (NCT01949805). The primary endpoint was non-inferiority of AOP2014 vs HU at 12 months (mos) of therapy in terms of complete hematological response (CHR) according to ELN criteria and normal spleen size. As an important secondary endpoint the treatment of %JAK2V617F was assessed as rate of complete and partial molecular response (CPMR) according to modified ELN criteria. In the group of pts enrolled in France, we could study BM progenitors clonogenic potential by cultures with or without Erythropoietin (EPO) at baseline and after 12 months of therapy. The presence of colonies without EPO, namely Endogenous Erythroid Colonies (EECs) is a hallmark of PV. After 14 days, erythroid colonies were enumerated and picked for molecular analyses.

Results: A total of 257 pts were randomized in 13 European countries including 13 pts in France. Non-inferiority of AOP2014 versus HU regarding CHR could be demonstrated in the whole study population (43.1 vs 45.6%). In the subgroup of French pts (54% males, mean age 55 years) CHR at 12 mos was 40% in pts receiving AOP2014 (n=5) and and 50%, in those receiving HU (n=8). %JAK2V617F at baseline in the AOP2014 and HU arms were 39.4% and 46.2% at baseline, 24.0 (95% CI, 16.7-31.3) and 35.6 (95% CI, 28.1-43.0) at 12 mos. Complete remission was achieved at 12 mos, but PPR was observed in 40% and 25% of pts in AOP2014 and HU arms (p>ns), respectively. BM progenitors could be studied in 10/13 French pts, 3 treated with AOP2014 and 7 with HU. AOP2014 treatment induced an important decrease of the proportion of EECs (median decrease of 64%) between samples collected at baseline and after 12 months of therapy compared to HU (median decrease 25%). In addition, clonal architecture studies showed that the % of JAK2V617F mutant colonies before and after treatment profoundly decreased in all AOP2014-treated patients while wild type JAK2K colonies decreased from 86% at baseline to 46% at 12 mos. Among HU-treated pts, only 1 experienced a decrease in the % of mutated colonies while mean ratio of mutant vs wild type JAK2 colonies didn’t significantly decrease (from 87% at baseline to 79% after 12 mos).

Summary/Conclusions: In this phase 3 trial comparing Rogepinginterferon alfa-2b versus HU, we found a different impact of both drugs on hematopoietic cells. Although both treatment induced a decrease of JAK2K mutant allele burden at 12 mos in peripheral blood, BM clonogenic assays suggest that AOP2014 is able to specifically target JAK2K mutant progenitors, an effect not seen in HU treated pts. Such targeted impact of AOP2014 may account for the strikingly different kinetics in allele burden reduction and suggests that sustained long-term molecular response may only be achieved with IFNa based treatment.

S788

POOLED SURVIVAL ANALYSIS OF MIDOSTAURIN CLINICAL STUDY DATA (D2201+A2213) IN PATIENTS WITH ADVANCED SYSTEMIC MASTOCYTOSIS COMPARED WITH HISTORICAL CONTROLS

1University Medical Centre Mannheim, Mannheim, Germany, 2University Medical Center Groningen, Groningen, Netherlands, 3University of New Mexico, Albuquerque, 4Brigham and Women’s Hospital, 5Dana-Farber Cancer Institute, Boston, United States, 6University of Paris Descartes, Imagine Institute, Paris, France, 7The Ohio State University Comprehensive Cancer Center, Columbus, 8University of Pennsylvania, Philadelphia, 9Memorial Sloan Kettering Cancer Center, New York, 10Novartis Pharmaceuticals Corporation, East Hanover, United States, 11Novartis Pharma SAS, Rueil-Malmaison, France, 12Novartis Pharma AG, Basel, Switzerland, 13University of Cologne, University of Cologne, Cologne, 14Ludwig Maximilians University Munich, Munich, Germany, 15Medical University of Vienna, Vienna, Austria, 16Stanford University School of Medicine, Stanford, United States

Background: AdvSM (ie, aggressive SM [ASM], SM with an associated hematologic neoplasms [SM-AHN], and mast cell leukemia [MCL]) comprises rare hematologic neoplasms with a poor prognosis. KIT D816V mutations occur in a majority of patients with advSM. Midostaurin is a multitargeted kinase inhibitor that blocks wild-type and D816V-mutated KIT. Two single-arm phase 2 studies (D2201+A2213) evaluated the safety and efficacy of midostaurin in a large, international, multicenter study. Overall, 60% and 69% of patients in D2201 and A2213, respectively, achieved the primary endpoint of partial or complete normalization of SM-related organ damage.

Aims: We compared pooled data from these studies with data from a patient registry to determine the effects of midostaurin on overall survival (OS).

Methods: Data from the midostaurin studies, in which patients received midostaurin 100 mg twice daily until progression or toxicity, were pooled. Historical control data were obtained from a contemporary patient registry based at University Medical Centre Mannheim, Germany. Although the primary analysis did not include matching for patient selection, subgroups analyses, and mulivariate analyses were performed to assess whether baseline characteristics affected OS and estimated HR. Propensity scoring was used for supportive analyses to match the patients in the registry. Patients were evaluated for OS based on time from diagnosis to death; patients in the pooled analysis with known dates of diagnosis were included in the primary analysis. A sensitivity analysis to compensate for potential bias in patient selection was conducted using the start date of last treatment to death.

Results: The primary analysis of OS in patients with advSM included 89 patients from the midostaurin pooled analysis for whom the date of diagnosis was available (77% of the entire pooled cohort) and all 46 patients from the German registry who had not been treated with midostaurin. SM subtypes among patients from the pooled analysis and registry were similar: 66% of patients in the pooled cohort and 63% in the registry had an AHN (Table 1).KIT D816 mutations were present in 82% of patients in the pooled analysis and 96% in the registry. More patients in the registry (67%) vs the pooled analysis (42%) were aged >65 y. Median follow-up (time from diagnosis to data cutoff for the analyses) was similar for the 2 patient groups: registry, 54.9 (range, 1.9-150.4) mo and midostaurin, 53.6 (range, 31.6-215) mo. Patients in the midostaurin pooled analysis had a clinically relevant improvement in OS vs historical controls (HR=0.62 [95% CI, 0.39-0.98]; P=0.0204; Figure 1). Median OS was 42.8 (95% CI, 31.0-53.9) mo in the pooled analysis vs 24.0 (95% CI, 13.0-39.5) mo in the registry. Multivariate Cox regression analysis after adjusting for covariates was consistent with the primary analysis: HR=0.51 (95% CI, 0.30-0.88); P=0.0147. Data using propensity score for matched pairs (n=44) were also consistent (HR=0.381 [95% CI, 0.169-0.960]; P=0.101). Subgroup analyses of OS showed HR in favor of midostaurin for all subgroups analyzed (HR from the multivariate analysis=0.38 [95% CI, 0.22-0.65]; P=0.0004).

Table 1.
Background: Approximately 10% of the children with Down syndrome are diagnosed with transient myeloproliferative disorder (TMD) within the first days of life. Previous studies have shown that TMD patients face an around 20% risk of early death and a 20% to 30% risk to develop myeloid leukemia during the first 4 years of life (ML-DS).

Aims: The aim of the AML-BFM TMD Prevention 2007 trial was to analyze the outcome of patients diagnosed with TMD and to evaluate whether the application of a low-dose cytarabine treatment can prevent the progression to ML-DS.

Methods: The AML-BFM TMD Prevention 2007 trial is a multi-center, non-randomized, historically controlled study. Patients with TMD were prospectively enrolled. They received a low-dose cytarabine treatment (1.5 mg/kg i.v./s.c. daily) for one week respectively if they met the following criteria: TMD-related symptoms (e.g. hyperleucocytosis, hepatopathy) at diagnosis, MRD-positivity (FACS≥10−4 or qPCR≥10−4) eight weeks after diagnosis. Patients could receive cytarabine-treatment up to three weeks in case of failure to respond to the cytarabine-treatment (morphologic detection of blasts between week four and eight after diagnosis and/or MRD-positivity after treatment in week ten after diagnosis).

Results: Here we report a cohort of 108 patients (male: 60, female:48) diagnosed with TMD. The median age at diagnosis was 4 days. As common in children with Down syndrome, many of the patients presented with comorbidities (cardiac defects: 68%, other malformations: 15%); 36% were delivered preterm. 45 patients received low-dose cytarabine treatment, 57 patients did not receive this treatment. Overall, patients in this trial do not show a significantly better event-free survival (EFS; 72±4% vs 63±4%, p=0.15) and overall survival (OS; 91±3% vs 85±3%, p=0.15) than the historic control group (n=146). The cumulative incidence (CI) of death was lower, (8±3% vs 15±3%) albeit not significantly (p=0.09). The CI of ML-DS was also similar (19±4% vs 22±4%, p=0.88).

Patients that presented with TMD-related clinical symptoms (n=43; symptoms: hyperleucocytosis [WBC>100,000], hepatopathy, ascites, hydrops fetalis) had a tendency for a better EFS (59±8% vs 44±8%, p=0.097), OS (80±6% vs 67±7%, p=0.10) and CI of death (20±7% vs 33±7%, p=0.10) than patients with those symptoms in the historic control group (n=45). For the progression to ML-DS there is no significant difference between the two groups (21±7% vs 23±7%, p=0.91). For patients that do not show any of the TMD-related symptoms (n=58), no significant differences were observed regarding EFS (81±5% vs 71±5%, p=0.27), OS (98±3% vs 93±3%, p=0.16) and CI of ML-DS (19±6% vs 22±4%, p=0.95) compared to patients without these symptoms in the historic control (n=101).

Summary/Conclusions: The consequent treatment with low-dose cytarabine of symptomatic patients results in a trend towards reduced CI of death as compared to the historic control. However, progression to ML-DS remains to be a threat suggesting that the treatment with low-dose chemotherapy does not seem to prevent the development of subsequent leukemia in TMD-patients. Therefore, a general preventive chemotherapeutic treatment of children diagnosed with TMD cannot be recommended. However, children with TMD-related symptoms should receive low-dose cytarabine to reduce disease-related mortality.

Childhood and more intensive treatment of AML

LOW-DOSE CYTARABINE TREATMENT IN CHILDREN WITH DOWN SYNDROME AND TRANSIENT MYELOPROLIFERATIVE DISORDER TO PREVENT ML-DS: AML-BFM TMD PREVENTION 2007 STUDY

M. Flasinski1, K. Scheibke1, M. Zimmermann1, K. Reinhardt2, D. Reinhardt2, C. von Neuhoff4, J.-H. Kußmann1

1Department of Paediatric Haematology and Oncology, Hannover Medical School, Hannover, 2Pediatric Oncology and Hematology, Pediatrics III, University Hospital of Essen, Essen, Germany

Background: Approximately 10% of the children with Down syndrome are diagnosed with transient myeloproliferative disorder (TMD) within the first days of life. Previous studies have shown that TMD patients face around a 20% risk of early death and a 20% to 30% risk to develop myeloid leukemia during the first 4 years of life (ML-DS).

Aims: The aim of the AML-BFM TMD Prevention 2007 trial was to analyze the outcome of patients diagnosed with TMD and to evaluate whether the application of a low-dose cytarabine treatment can prevent the progression to ML-DS.

Methods: The AML-BFM TMD Prevention 2007 trial is a multi-center, non-randomized, historically controlled study. Patients with TMD were prospectively enrolled. They received a low-dose cytarabine treatment (1.5 mg/kg i.v./s.c. daily) for one week respectively if they met the following criteria: TMD-related symptoms (e.g. hyperleucocytosis, hepatopathy) at diagnosis, MRD-positivity (FACS≥10−4 or qPCR≥10−4) eight weeks after diagnosis. Patients could receive cytarabine-treatment up to three weeks in case of failure to respond to the cytarabine-treatment (morphologic detection of blasts between week four and eight after diagnosis and/or MRD-positivity after treatment in week ten after diagnosis).

Results: Here we report a cohort of 108 patients (male: 60, female:48) diagnosed with TMD. The median age at diagnosis was 4 days. As common in children with Down syndrome, many of the patients presented with comorbidities (cardiac defects: 68%, other malformations: 15%); 36% were delivered preterm. 45 patients received low-dose cytarabine treatment, 57 patients did not receive this treatment. Overall, patients in this trial do not show a significantly better event-free survival (EFS; 72±4% vs 63±4%, p=0.15) and overall survival (OS; 91±3% vs 85±3%, p=0.15) than the historic control group (n=146). The cumulative incidence (CI) of death was lower, (8±3% vs 15±3%) albeit not significantly (p=0.09). The CI of ML-DS was also similar (19±4% vs 22±4%, p=0.88).

Patients that presented with TMD-related clinical symptoms (n=43; symptoms: hyperleucocytosis [WBC>100,000], hepatopathy, ascites, hydrops fetalis) had a tendency for a better EFS (59±8% vs 44±8%, p=0.097), OS (80±6% vs 67±7%, p=0.10) and CI of death (20±7% vs 33±7%, p=0.10) than patients with those symptoms in the historic control group (n=45). For the progression to ML-DS there is no significant difference between the two groups (21±7% vs 23±7%, p=0.91). For patients that do not show any of the TMD-related symptoms (n=58), no significant differences were observed regarding EFS (81±5% vs 71±5%, p=0.27), OS (98±3% vs 93±3%, p=0.16) and CI of ML-DS (19±6% vs 22±4%, p=0.95) compared to patients without these symptoms in the historic control (n=101).

Summary/Conclusions: The consequent treatment with low-dose cytarabine of symptomatic patients results in a trend towards reduced CI of death as compared to the historic control. However, progression to ML-DS remains to be a threat suggesting that the treatment with low-dose chemotherapy does not seem to prevent the development of subsequent leukemia in TMD-patients. Therefore, a general preventive chemotherapeutic treatment of children diagnosed with TMD cannot be recommended. However, children with TMD-related symptoms should receive low-dose cytarabine to reduce disease-related mortality.
Background: AML is a heterogeneous disease based on genetic characteristics with impact on prognosis. So, it becomes necessary to treat patients according to risk-adapted therapies.

Aims: To analyze the results of intensive induction and post-remission treatment in 868 patients with the novo AML enrolled into the CETLAM-03 trial between 2003 and 2012 with a prolonged follow-up (results reported at 10 years).

Methods: Patients received bolus days 1 or 2 induction chemotherapy courses of IDICE-G (idarubicin, intermediate cytarabine (IDC), VP-16 and priming with G-CSF) followed by mitoxantrone and IDC as consolidation therapy. Further treatment was assigned according to the CETLAM risk groups as follows: Favorable risk (FR), defined as favorable cytogenetics according to MRC; autologous stem cell transplantation (ASCT); or allo-SCT if leukocyte index [LI=leucocytes x (BM blasts/100)] ≥20 or high dose cytarabine (HDAC) (one course) if LI <20. Intermediate risk (IR), defined as patients in CR after a single induction course, <50x10E9/l white blood cells at diagnosis, normal karyotype and absence of FLT3-ITD internal tandem duplication (FT3-ITDwt) and no MLL rearrangement: ASCT. Adverse risk (AR), patients not included in FR or IR: CR or ASCT or allo-SCT as first line treatment (allo-SCT) depending on donor availability (HLA-identical sibling or unrelated donor if high risk of relapse).

Results: There were 868 patients. Median age was 53 years old (16-70). According to MRC cytogenetics, available in 802 patients, 99 belonged to the favorable (12%), 581 (73%) to the intermediate and 122 (15%) to the adverse groups. 66 patients with no metaphases. FT3-ITD was present in 128 patients with normal karyotype (36%). Four patients died before treatment and 864 patients received induction therapy. 77% of patients achieved a CR (88% with a single course), 11% were refractory and 12% died during induction. CR rate was comparable between normal (CR = 91% in NPM1 mutation without FLT3-ITD, 77% in intermediate cytogenetic and no mutations, 74% if FT3-ITD, 70% in adverse cytogenetics and 62% if monosomal karyotype was present (p<0.001). The multivariate analysis showed that mutational status (adverse cytogenetics, FLT3-ITD and absence of NPM1 mutation) had an adverse impact on CR achievement. Separately serial immunophenotypic quantitation of leukaemic stem/progenitor cells (LSC) was performed in 44 patients.

The RAVVA trial randomized 259 adults with AML (n=217) and MDS (n=42) to receive AZA monotherapy (AZA (75 mg/m²) x 7 days every 28 days) or AZA combined with VOR (300 mg orally per day) for a minimum of 6 cycles. Next generation sequencing was performed on 42 genes commonly mutated in AML and MDS in 250 patients treated on the RAVVA trial and correlated with response. Separately serial immunophenotypic quantitation of leukemic stem/progenitor cells (LSC) was performed in 44 patients.

S972
SORAFENIB MAINTENANCE IN FLT3-ITD MUTATED ACUTE MYELOID LEUKAEMIA AFTER ALLOGENEIC STEM CELL TRANSPLANT
S. Ahmed1, R. Saibia1, G. Rondon1, A. Alousi1, Q. Bashiri2, S. Ciurea3, G. Al-Atrash1, K. Patel1, A. Olson1, D. Marin1, K. Rezvani1, P. Kebriaei1, U. Popat1, E. Shapall1, R. Champlin1, B. Gral1
1Stem cell transplant and cellular therapy, 2Hematopathology, University of Texas, MD Anderson Cancer Center, Houston, United States

Background: The fms-like tyrosine kinase 3 internal tandem duplication (FLT3-ITD) mutation is a genetic alteration found in approximately 30% of patients with acute myeloid leukemia (AML). Although autologous transplantation with AZA achieves remission rates similar to those with FLT3-ITD wildtype status with induction chemotherapy regimens; patients with FLT3-ITD have significantly shorter remission durations and increased rates of relapse. Even though allogeneic SCT improves outcomes, patients still have higher rates of relapse compared to patients requiring non-progression. Sorafenib(SFB) is a TKI with activity against RAF, VEGF and FLT3-ITD and its use as maintenance therapy after allogeneic SCT has been shown as a promising approach to decrease relapse. Several studies report that SFB maintenance post SCT provides durable complete responses; however, there are also descriptions of sorafenib post SCT triggering acute GVHD, cytokopenia, rash and thrombocytopenia.

Aims: To assess the outcomes, including progression free survival (PFS) and overall survival (OS), in patients with FLT3-ITD mutated AML who receive SFB maintenance after allogeneic SCT.

Methods: We analyzed adult patients (age<18) with a diagnosis of FLT3-ITD mutated AML leukemia (acquired SCT between 2010-2016), who achieved remission after induction therapy with AZA, followed by a minimal disease state and transplantation. All patients had FLT3-ITD mutation that underwent ASCT during study period, we identified 13 cases (maintenance) and 26 controls (no maintenance). Median follow-up of survivors were 12 months and 30 months for maintenance and control group respectively. Disease and transplant

S971
MOLECULAR PREDICTORS OF RESPONSE TO AZACITIDINE THERAPY: THE RESULTS OF THE UK TRIALS ACCELERATION PROGRAMME RAVVA STUDY
C. Craddock1,*, L. Quek2, A. Houlton3, P. Ferguson4, E. Gbdji3, C. Roberts5, M. Metzner2, K. Wheatley6, S. Siddique6, S. Pillai7, M. Dennis8, J. Cavenagh9, SFB initiation for cases and the same time point after SCT for their matched controls. Absract No 1065). The mean number of mutations per patient in the 250 geno-typed patients was 3.4. The presence of mutations in CDKN2A (p=0.0001), IDH1 (p=0.004) and TP53 (p=0.003), NPM1 (p=0.037) and FLT3-ITD (p=0.04) was associated with survival. No mutations were associated with FLT3-ITD or FLT3 mutations adjusted for all clinical variables mutations in CDKN2A, IDH1 and FLT3 remained predictive of decreased OS. No mutations were associated with FLT3-ITD or FLT3 mutations adjusted for all clinical variables mutations in CDKN2A, IDH1 and FLT3 remained predictive of decreased OS. No mutations were associated with FLT3-ITD or FLT3 mutations adjusted for all clinical variables mutations in CDKN2A, IDH1 and FLT3 remained predictive of decreased OS.
characteristics were comparable between groups as presented in Figure 1. Patients were classified by the European Leukemia Net (ELN) classification and 23% in both groups were categorized as adverse risk while 77% were intermediate risk. All patients received myeloablative conditioning and diseases status at SCT was first/second complete remission (CR1/2) with or without count recovery (CRn) in 69% while it was active disease in 31%. PFS at 24 months post SCT was 82% in the maintenance and 45% in control groups HS: 0.3; 95% CI (0.1-1.3) p=0.1. Overall survival at 24 months was also higher in SFB cases as 100% compared with 60% in control group p=0.035. Only, 2 patients relapsed post SCT on SFB maintenance, one with new TP53 mutation at relapse, and other received only <30 days of SFB. However, more than half the patients had disease progression within the control period. The most commonly administered dose was 400 mg daily (5 patients) for 28 days cycle; only 2 patients tolerated higher doses and 6 patients received SFB as 300mg daily or less. There were delays in subsequent cycles in 10 of 12 patients, and the most common reasons for delays included cytopenias, liver function test abnormalities, and fatigue.

Figure 1.

Summary/Conclusions: Sorafenib maintenance is safe and can produce long term durable remissions after allogeneic stem cell transplant in a high risk population with FLT3-ITD mutated AML.

S793

A PHASE 1B STUDY OF THE COMBINATION OF VADASTUXIMAB TALIRINE AND 7+3 INDUCTION THERAPY FOR PATIENTS WITH NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA

1Baylor University Medical Center, Dallas, TX, 2Gehr Family Center for Leukemia Research - City of Hope, Duarte, CA, 3Ohio State University Comprehensive Cancer Center, Columbus, OH, 4Colorado Blood Cancer Institute, Denver, CO, 5Cleveland Clinic, Cleveland, OH, 6Massachusetts General Hospital, Boston, MA, 7John Theurer Cancer Center, Hackensack, NJ, 8Fred Hutchinson Cancer Research Center, Seattle, WA, 9Loyola University Medical Center, Maywood, IL, 10Karmanos Cancer Institute, Detroit, MI, 11Sarah Cannon Research Institute, Nashville, TN, 12University of Washington Medical Center, Seattle, WA, 13MD Anderson Cancer Center, Houston, TX, 14Seattle Genetics, Inc., Bothell, WA, 15University of Alabama-Birmingham, Birmingham, AL, United States

Background: For patients <65 yrs with newly diagnosed AML, standard induction treatment is continuous infusion of cytarabine for 7 days and an anthracycline for 3 days (7+3). Although a high percentage of patients achieve a CR by morphologic criteria, some requiring a 2nd induction, many are resistant to treatment or achieve a morphologic CR with evidence of minimal residual disease (MRD). Vadastuximab talirine (SGN-CD33A; 33A) is a CD33-directed antibody conjugated to 2 molecules of a pyrrolobenzodiazepine dimer. Combining 33A with 7+3 could result in enhanced and deeper (MRD negative) remissions, resulting in reduced relapse rates and improved OS.

Aims: This phase 1b study (NCT02326584) evaluated the safety and antileukemic activity of escalating doses of 33A on 2 schedules: split dose (D1 and 4) or single dose (D1) with 7+3 induction therapy (cytarabine 100 mg/m² and daunorubicin 60 mg/m²).

Methods: AML patients must be eligible for induction therapy. Response assessments occur on D15 and 28. Second induction and post-remission therapies were per investigator choice and did not include additional 33A. MRD was assessed centrally by bone marrow exam by a multiparametric flow at D15 and D28.

Results: Split-dose cohort: 42 patients (median age 45.5 yrs [range, 18-65]) were treated with 33A on D1 and 4 (10+10 [n=4] or 20+10 [n=38] mcg/kg) with 7+3. Most patients had intermediate (50%) or adverse (36%) cytogenetic risk. 19% had secondary AML. 2 patients had hematologic DLTs (lack of recovery of platelets [25K] and/or ANC [500] by D42) and 20+10 mcg/kg was determined to be MTD. The median time to count recovery from D1 of therapy in patients who achieved CR/CRI was 4.1 wks for ANC (≥1K) and 5.9 wks for platelets (≥100K) in patients who achieved CR/CRI. Patients had intermediate (48%) or adverse (36%) cytogenetic risk. 16% had secondary AML. The median time to count recovery from D1 of therapy was 4.1 wks for ANC (≥1K) and 5.9 wks for platelets (≥100K) in patients who achieved CR/CRI. Four patients had hematologic DLTs, 1 at 30 and 3 at 40 mcg/kg. Non-hematologic TEAEs were consistent with those seen in the D1 and 4 schedule. Of the 24 EE patients, best responses included 12 CR (50%), 6 CRi (25%), and 3 mLFS (13%) with a CRc rate of 75%, achieved in 1st cycle. Of the evaluable patients with blast clearance, 89% (17/19) achieved MRD negative status. Across schedules (N=67), the CRc rate was 76%; 79% (44/56) of evaluable patients with blast clearance achieved MRD negativity. The CRc rate at the 40 mcg/kg dose level was 91% (10/11); all 11 patients had blast clearance and 90% (9/10) of evaluable patients achieved MRD negative status. The median time to count recovery from D1 of therapy was 4.1 wks for ANC (≥1K) and 5.9 wks for platelets (≥100K) in patients who achieved CR/CRI. Four patients had hematologic DLTs, 1 at 30 and 3 at 40 mcg/kg. Non-hematologic TEAEs were consistent with those seen in the D1 and 4 schedule. Of the 24 EE patients, best responses included 12 CR (50%), 6 CRi (25%), and 3 mLFS (13%) with a CRc rate of 75%, achieved in 1st cycle. Of the evaluable patients with blast clearance, 89% (17/19) achieved MRD negative status. Across schedules (N=67), the CRc rate was 76%; 79% (44/56) of evaluable patients with blast clearance achieved MRD negativity. The CRc rate at the 40 mcg/kg dose level was 91% (10/11); all 11 patients had blast clearance and 90% (9/10) of evaluable patients achieved MRD negative status. The CRc rate at the 40 mcg/kg dose level was 91% (10/11); all 11 patients had blast clearance and 90% (9/10) of evaluable patients achieved MRD negative status. The CRc rate at the 40 mcg/kg dose level was 91% (10/11); all 11 patients had blast clearance and 90% (9/10) of evaluable patients achieved MRD negative status.

Summary/Conclusions: S33A can be safely combined with 7+3 with acceptable count recovery in this population at the doses and schedules studied. Extramedullary AEs, including hepatotoxicity, and induction mortality rates were similar to reported rates for 7+3 alone in this AML population. A high remission rate with the 1st induction cycle was observed, the majority of which were MRD negative.
**21-COLOR FLOW CYTOMETRY REVEALS IMMUNOPHENOTYPES ASSOCIATED WITH RESPONSE IN ACUTE GRAFT-VERSUS-HOST DISEASE PATIENTS TREATED WITH THE JANUS KINASE INHIBITOR INCB039110**

**Background:** Although ~50% of aGVHD patients respond to steroids, no consensus second-line treatment exists. Recent preclinical models, retrospective studies, and this prospective trial have demonstrated safety and efficacy of JAK inhibitors (e.g. ruxolitinib, INCB039110) in steroid-refractory aGVHD.

**Aims:** Here, we present 21-marker FACS analysis of blood from patients enrolled in a prospective, randomized, parallel-cohort, open-label phase 1 trial of the potent and selective JAK1 inhibitor INCB039110 for aGVHD (NCT02614612). Preliminary results were previously presented at ASH 2016 (Schroeder et al).

**Methods:** Patients (n=30) were >18 years old undergoing first alloHSCT from any source with steroid-refractory or treatment-naive grades IIb-IVD aGVHD, randomized 1:1 to 200 or 300 mg oral daily INCB039110 combined with corticosteroids. Peripheral blood, obtained at treatment days 7, 14, 28, 56, 100, and 180, was analyzed by 21-color FACS quantifying >30 cell types, including B, CD4+ and CD8+ T, myeloid, monocyte-derived suppressor cells (MDSCs), natural killer cells (NKs), and monocytic and plasmacytoid dendritic cells (DCs). Patients were stratified by treatment response (e.g. complete response (CR), partial response (PR), mixed response (MR)).

**Results:** During INCB039110 treatment, overall B, T, and myeloid proportions did not correlate with response. However, the CR group increased native KCs (CD3-CD20-CD4-HLA-DR-CDS6+), mDCs (CD3-CD20-CD14-HLA-DR+CD11c+), and memory CD4+ T cells (CD3+CD4+CD45RA-). Among CD4+ memory cells, the CR group showed significant or trend-toward-significant increases in Th1 (CXC5-CR6-CR10-CR3+), Th2 (CXR5-CR5-CR6+CCR4+CCR3-CR10-), Th17 (CXC5-CR5-CR6-CR10-CR3+), and Th22 (CXC5-CR5-CR6+CCR4+CCR3-CR10+). Tregs (CD4+CD25+CD127+) trended toward a ~2-fold increase in the CR group. Within the monocyte subgroup (CD3-CD20-CD14+), the CR group skewed toward classical monocytes (HLADR+CD16+) (64.7% vs 36.0%, CR vs PR/MR, p=0.0078) and away from MDSCs (HLADR-CD16+) (30.0% vs 58.4%, CR vs PR/MR, p=0.0139) during treatment. Interestingly, the NK-to-MDSC ratio was a sensitive and specific predictor of CR vs all other responses, finding consistent for both CD16+ and CD16- NK cells (Fig. 1 a, b). Before treatment, decreased native CD8+ T cells (CD45RA+CCR7+) predicted CR versus PR/MR (12.6% vs 32.3% of CD8+ cells, CR vs PR/MR, p=0.0047) with a similar trend toward decreased naive CD4+ T cells (13% vs 24.4% of CD4+ cells, CR vs PR/MR, p=0.0749). While naive T cells did not correlate with pre-treatment aGVHD grade, grades III-IV aGVHD demonstrated increased Th2 cells (CD45RA-CXCR5-CR6-CR10+) and activated CD8+ cells (CD38+HLADR+) as compared to grade II aGVHD. Further correlation with serum cytokines, JAK-STAT signaling, and pharmacology will be available at time of presentation.

**Summary/Conclusions:** Decreased pre-treatment native T cells may predict better outcomes in INCB039110-treated aGVHD. During treatment, increased DCs, NKs, and memory T cell subsets correlated with better response. Surprisingly, increased MDSCs associated with poorer response, suggesting MDSC expansion during persistent inflammation. The NK-to-MDSC ratio may be an important clinical marker to track treatment progress. Finally, this study establishes a novel FACS-based 21-marker immunophenotyping method with superior throughput, sample preservation, and flexibility as compared to cytometry time of flight (CyTOF) methods.

**INCB039110 DISEASE PATIENTS TREATED WITH THE JANUS KINASE INHIBITOR ASSOCIATED WITH RESPONSE IN ACUTE GRAFT-VERSUS-HOST DISEASE**

Z. Peric1,2, M. Durakovic1,2 L. Desnica1, V. Rezo Vranjes3, I. Marekovic3, R. Serventi-Severini1 J. Bilinski3 G. Basaki1 V. Vhowa1

1Hematology, University Hospital Centre Zagreb, 2School of Medicine, University of Zagreb, 3Department of Microbiology, University Hospital Centre Zagreb, Zagreb, Croatia, 4Hematology, Medical University of Warsaw, Warsaw, Poland

**Background:** Research has recently highlighted the importance of healthy gut microbiota in the prevention of graft-versus-host disease (GVHD). Gut decontamination and the use of broad-spectrum antibiotics have led to the loss of natural microbiota diversity and the overgrowth of opportunistic pathogens with emerging antimicrobial resistance. However, the role of multi-drug resistant by MRSA and MRGNB in development of grade III-IV, patients were colonized with more than one MDR pathogen. The cumulative incidence (CI) of severe (grade III-IV) acute GVHD was significantly higher in patients colonized with MDR-GNB (27%, 95% CI, 19-39%) than in non-colonized patients (14%, 95% CI, 7-23%) (p=0.04). Moreover, MDR-GNB colonized patients had significantly more gas troenteritis (GI) GVHD CI as opposed to non-colonized patients (28% (95% CI, 20-41%) vs 14% (95% CI, 7-23%), p=0.02) and more acute GVHD-related mortality (16% (95%CI, 9-26%) vs 7% (95%CI, 3-15%), p<0.10). A substantial and independent role of gut colonization with MDR-GNB on the development of acute GVHD was confirmed by multivariate analysis using time-dependent covariate functions for high risk disease, myeloablative conditioning, peripheral blood stem cells, unrelated donor (hazard ratio 2.14; 95%CI, 0.99-4.68, P=0.05), older age (hazard ratio 2.15; 95%CI, 1.00-4.59, P=0.04) and MDR-GNB gut colonization (hazard ratio 2.26;95%CI, 1.05-4.83, P=0.03).

**Summary/Conclusions:** In summary, this report shows a significant role of MDR-GNB in the pathogenesis of severe acute GVHD. To our knowledge, we are the first to show that gut colonization with MDR-GNB represents an independent risk factor for GI GVHD. With growing resistance and lack of efficient antibiotics, decolonization strategies as fecal microbiota transplantation become an attractive strategy for restoration of healthy gut flora and prevention of severe acute GVHD.

**IMPACT OF HLA DISPARITY ON OUTCOME IN HLA-HAPLOIDENTICAL BONE MARROW TRANSPLANTATION FOLLOWED BY HIGH DOSE POST-TRANSPLANT CYCLOPHOSPHAMIDE**

L. Giannoni1,2 A.M. Raiola1 N. Sacchi2 L. Garbarino2 A. Dominietto1 L. Giannoni1,2 A.M. Raiola1 N. Sacchi2 L. Garbarino2 A. Dominietto1

1Hematology, IRCCS AOU San Martino IST, 2IBMDR, Ospedali Galliera, Genova, Italy.

**Background:** By definition ‘haplo-identical’ donors share genotypically 4/8 anti-
gens with recipients. However, causal phenotypical homozygosity in the non-
shared haplotypes made the real degree of disparity less than 4/8 in a few donor/recipient pairs.

Aims: Since 2010, patients who lacked a HLA-identical donor have been trans-
planted from a haploidentical donor in our two Italian institutions. In this large series of patients we aim to verify the real degree of antigen disparity between donor/recipient pairs and whether it impacts on transplantation outcomes.

Methods: All haploplants performed in two Italian institutions from August 2010 to July 2016 (n = 318) were included. All patients received a myeloablative regimen (MA) followed by unmanipulated bone marrow and high dose post-
transplant cyclophosphamide (PT-CY), combined with cyclosporine and mycophenolate. Donors and recipients were typed, until 2015, using DNA method (SSO and SBT) for HLA A, B, C, DRB1. DQ and DP at a high reso-
lution level, as defined by EFL standards and by NGS at allelic level in 2016 for the same loci. When applicable (72.3% of patients) members of the immediate family where typed to definitively establish HLA genotype and haplotype identity. Differences in HLA mismatching were calculated using HVG direction and graft rejection rate according to the degree of HLA mismatches in the HVG direction.

Results: Median age of patients was 48 years (17-74). Diagnoses included acute myeloid leukemia (130), acute lymphoblastic leukemia (64), lymphoid and myeloid leukaemia (43), myelodysplastic syndrome (33). 144 patients (45%) were transplanted in advanced phase of disease. With a median follow up of 562 days (range 6-
2241 days), 2-year OS was 55.7%. Considering the proportion of “true” hap-
loidentical D/R pairs, 231 out of 318 (72%) couples showed 4/8 mismatches at HL A and HLA DRB1 loci. Neither OS nor NRM showed significant correlation with the degree of overall mismatches at 2 years (0-2 mismatches: 54.2% vs 3-4 mismatches: 58.8%, p = 0.08 and 0-2 vs 3-4: 19.1%, p = 0.93, respectively).

Summary/Conclusions: In this series, about one third of haploidentical donor/recipient pairs differ for less than 4/8 HLA antigens. Furthermore, in the setting of a MA conditioning with PT-CY the real degree of HLA mismatch observed had no impact on OS, NRM, CI of Relapse and acute and chronic GVHD.

Marqués de Valdecilla, Santander, Spain, 16Hematology, Erasmus MC Cancer Institute, Rotterdam, Netherlands, 17Transplantation and Therapy Research, University of Freiburg, Spain, 18Stem Cell Medical Center, Tel-Hashomer, Israel
Background: High-risk acute myeloid leukemia (AML) is mainly defined by the presence of determined poor-risk cytogenetic abnormalities and is a stan-
dard indication for allogeneic stem cell transplantation (SCT). Nevertheless, high-risk AML is a very heterogeneous group including several abnormalities with different levels of prognostic impact. Deletion 5q or monosomy 5 (-5q-) has been part of the high-risk group of AML for many years. SCT seems to improve their survival but the autologous impacts of other high-risk cytogenetic features on survival have never been thoroughly studied.

Aims: To evaluate the role of SCT in -5q- AML with additional cytogenetic abnormalities such as complex karyotype (CK), monosomal karyotype (MK), monosomy 7 (-7), or 17p abnormalities (abn(17p)).

Methods: Patients who lacked a HLA-identical donor (UD) were included in the analysis. Peripheral blood was used as a source of stem cells in 62% of the patients. Conditioning regimen was myeloablative in all cases (the median TBI dose was 12Gy); 1346 patients were treated with CYTBI while 152 patients with Vep/TBI. Patients in the Vep/TBI group were younger (median 28 y. vs 30 y., p = 0.04), treated more in recent period (median year of HCT: 2009 vs 2007, p = 0.009) and treated more frequently in CR1 (87% vs 78%, p = 0.01).

Results: In a univariate analysis, as compared to CYTBI, the use of Vep/TBI was associated with significantly reduced incidence of relapse (17% vs 30% at 5 years, p = 0.007), increased rate of leukemia-free survival (LFS, 60% vs 50%, p = 0.04) as well as improved “GVHD and relapse-free survival” (GRFS, 43% vs 33%, p = 0.04). No significant effect could be observed in terms of the incidence of non-relapse mortality, acute or chronic GVHD. In a multivariate model the use of Vep/TBI was associated with reduced risk of relapse (HR=0.62, p=0.04) while the effect on other study end-points was no longer significant. Among other factors, recipient age (HR=1.17 per every 10 years, p<0.0001), year of alloHCT (HR=0.97 per every year), p=0.01) and disease stage (HR=2.14 for CR2, p<0.0001) had significant influence on the risk of treatment failure, either relapse or non-relapse mortality. The risk of relapse was additionally increased for sibing vs unrelated donor transplants (HR=1.47, p=0.01) and donorrecipient gender combination other than female/male (HR=1.26, p=0.04).

Summary/Conclusions: Conditioning regimen based on etoposide combined with TBI appears more effective than the cyclophosphamide TBI combination for adult patients with Ph-negative ALL treated with alloHCT. Further, prospective studies are needed to confirm our observation and potentially discriminate subgroup of patients who are most likely to benefit from the use of etoposide.
27%. The main cause of death was disease-related. In multivariate analysis, active disease correlated strongly with worse OS, LFS and NRM. The other factors influencing outcomes were UD with increased NRM, and age with decreased OS and LFS. Based on the frequencies of the different additional cytogenetic abnormalities, we identified 4 groups within our cohort. Group 1 (None) included 47 pts with -5/5q- but no MK, CK, or abn(17p) (N=90). Group 3 (MK) included 169 pts with -5/5q- and CK but no MK or abn(17p) (N=90). Group 3 (MK) included 169 pts with -5/5q- and CK but no MK or abn(17p). Finally, group 4 (17p) included pts with -5/5q- and abn(17p) (N=193). The 4 groups were quite similar in term of characteristics. The 2-year probability of LFS was 39% for group 1, 25% for group 2, 20% for group 3 and only 13% for group 4 (p<0.001). OS decreased also significantly from group 1 to group 4 (p<0.001). NRM was similar across the groups. In multivariate analysis, factors associated with worse OS and LFS were active disease, age, MK and abn(17p). The corresponding 2-year probability of GvHD and relapse-free survival was 27% for group 1, 17% for group 2, 14% for group 3 and 7% for group 4 (Figure 1).

Summary/Conclusions: SCT in -5/5q-AML provides a durable response for approximately 20% of pts. Active disease at time of transplantation was the most powerful predictor of an inferior outcome. The presence of -5/5q- without CK, MK or abn(17p) was associated with a significant better survival and the addition of MK or abn(17p) translated into worse outcomes. We confirmed the deleterious effect of the combination of -5/5q- and abn(17p) on SCT outcome. Future efforts should be focused on this subgroup in order to improve their outcome.
Background: the outcome of Ph+ acute lymphoblastic leukemia (Ph+ ALL) has drastically improved since the introduction of tyrosine kinase inhibitors (TKI). At present however, well-defined prognostic markers, beyond the monitoring of minimal residual disease (MRD) during follow-up and to a lesser extent IKZF1 deletions, are lacking.

Aims: To identify genomic lesions of prognostic value, we evaluated copy number aberrations (CNA) by SNP arrays, confirmed them by multiplex ligation-dependent probe amplification (MLPA) and we set up a droplet digital PCR (ddPCR) assays for additional lesions. Furthermore, we correlated the lesions identified with MRD monitoring, outcome and biological features, including reports of the differential use of type of fusion protein (p190 or p210). Finally, in a subset of patients gene expression profiling (GEP) was carried out.

Methods: Genomic DNA of 116 newly diagnosed adult Ph+ ALL patients enrolled in 4 consecutive GIEMMA trials, namely 021B1, 09B4, 1205 and 1509, was evaluated. All the trials were based on an induction with steroids and TKI, the first 2 with imatinib and the remaining with dasatinib. For CNA, the Cytoscan HD Arrays (Affymetrix, Santa Clara, CA) were used. The lesions were confirmed by MLPA on all samples using the Mala SNP MLPA P335-A3 ALL-IKZF1 kit (MRC-Holland, Amsterdam, The Netherlands), ddPCR was used to validate lesions targeting MEF2C. In 42 cases, GEP experiments were performed using the HGU133 Plus 2.0 gene chips (Affymetrix, Santa Clara, CA).

Results: We found a similar load and type of lesions across the 4 trials, one of which included elderly. The majority of lesions targeted IKZF1 (84%), PAX5 (36%) and CDKN2A/B (32%). In our cohort, IKZF1 deletions alone did not affect complete molecular response (CMR) achievement or relapse-free survival, whereas patients harboring CDKN2A/B and PAX5 deletions had a significant inferior outcome (p=0.004, p=0.003 respectively). In line with this, a worse DFS was observed for the so-called “IKZF1 plus” cases, i.e. concomitant deletions of IKZF1 and CDKN2A/B and/or PAX5 (46% vs 24% at 36 months, p=0.005). MLPA confirmed the incidence of these deletions and allowed the study of IKZF1 isoforms. Among IKZF1 deleted cases, patients carrying the Δ4-7 isoform (25%) had a worse DFS (p=0.02) than patients harboring other IKZF1 isoforms. Importantly, SNP arrays highlighted novel genomic lesions targeting MEF2C in 13% of cases, which were associated to the achievement of a CMR (p=0.05) and had a significant impact on DFS (62% vs 32% at 36 months, p=0.02). The association with CMR was not affected by the trial (p=0.76) or the TKI used (p=0.57). This result was confirmed by ddPCR. Unsupervised hierarchical clustering of GEP experiments identified 3 subgroups: the first comprised mainly patients who reached a CMR, the second one the patients who had IKZF1 alone, and the last one comprised “IKZF1+MEF2C” patients. GEP analysis showed an overexpression of genes involved in cell communication and protein modification process in PAX5 deleted cases, suggesting that these genes could be contributing factors in BCR/ABL1-driven leukemogenesis.

Summary/Conclusions: In adult Ph+ ALL, IKZF1 deletions have a prognostic impact and could be considered among other lesions. Among IKZF1 deletions, only the Δ4-7 deletion has a deleterious effect. MEF2C lesions carry prognostic implications, being significantly associated with a better prognosis. This study paves the way to design a prognostic model for adult Ph+ ALL that includes these findings and more conventional features, in order to better stratify patients at diagnosis and to further optimize treatment.
Background: Reduced intensity conditioned allogeneic haematopoietic stem cell transplant (RICalloHCT) enables HCT to be performed in older patients. The UK NCRI UKALL14 study of adult acute lymphoblastic leukaemia (ALL) considers patients ≥41 years “high risk” and recommends a RICalloHCT where there are high quality donors. Other “high risk” factors are high WBC at presentation, t(9;22), t(4;11), hypodiploidy/near triploidy, complex karyotype and positive minimal residual disease (MRD) after completing induction therapy. The presence of MRD at this time-point predicts poor outcome after conventional chemotherapy. There is evidence that myeloablative alloHCT can overcome this risk, but the benefit of RICalloHCT is uncertain.

Aims: To determine whether RICalloHCT mitigates the high relapse risk predicted by MRD positivity after induction therapy.

Methods: Protocol treatment: patients receive a steroid pre-phase before 2 cycles of induction chemotherapy. At the end of induction, patients are assigned subsequent therapy on the basis of risk. All patients over 41 years are allocated RICalloHCT, conditioned with fludarabine, melphalan and alemtuzumab. Post HCT, escalating doses of donor lymphocyte infusions were given for T-cell mixed chimerism +/- MRD persistence or relapse. MRD assessment: BCR/ABL1 or Ig/TCR MRD was assessed and analysed per EuroMRD guidelines. MRD is negative (undetectable with an assay quantitative range of 1x10^-4 or less), positive (≥1x10^-4), positive outside quantitative range (POQR)(<1x10^-4) or indeterminate (undetectable but assay quantitative range ≥5x10^-4). Patients with indeterminate MRD were excluded from this analysis.

Results: There are 736 patients randomised to date, of whom 184 received a RICalloHCT, of these, 115 had analysable MRD. The following Table 1 shows patient characteristics.

At 2 years post transplant, overall survival (OS) was 63.1% in the 115 patients with evaluable MRD and 62.7% in the 184 patients receiving RICalloHCT; event free survival (EFS) was 55.2% and 55.9% respectively. By contrast, in the 38 of 115 patients with positive MRD after induction, OS and EFS were 40.6% and 28.4% respectively. Twenty eight of the 115 patients relapsed, with a 2 year actuarial relapse risk of 31.5% (22.2-43.5). We assessed the association of the following factors; age, sex, immunophenotype, presenting WBC, BCR/ABL1, other cytogenetics, post-induction MRD and donor type with the risk of relapse. Among this population of high risk patients, post-induction MRD was the only independent prognostic factor for relapse (univariable HR: 3.82 (1.59-9.16), p = 0.001 (see Figure 1) and multivariable HR: 4.14 (1.61-10.65), p = 0.003). The relapse rate of the MRD+ patients was 57.2% at 2 years post HCT.

Summary/Conclusions: The 2-year OS of 62.5% in UKALL14 participants over 41 years old after RICalloHCT is greater than would be expected with chemotherapy alone. However, MRD positivity after induction is associated with significantly lower OS, EFS and a higher risk of relapse, which is not abrogated by RICalloHCT.

Figure 1.
Summary/Conclusions: We showed that Blin responders have significantly higher TRB repertoire diversity at scr compared to persisters and that the repertoire expansion during Blin treatment is sharper in responders. Other repertoire characteristics did not differ significantly between groups. Further studies on larger patient cohorts are necessary in order to elucidate whether the response to treatment can be predicted by repertoire diversity at scr.

Amplicon NGS is a useful tool for monitoring of T-cell repertoire. Development, standardization, and validation of TRB primer sets is in progress within Euro-Clonality-NGS Consortium.

DISCONTINUING ANTIBACTERIAL THERAPY AFTER APYREXIA AND CLINICAL STABILITY REGARDLESS OF NEUTROPHIL COUNT IN FEBRIL NEUTROPENIA IS SAFE AND REDUCES EXPOSITION TO ANTIBIOTICS (HOWLONG RANDOMIZED TRIAL)

I. Espigado1,*, M. Aguilar-Guisado2, A. Martín-Peña2, C. Gudío3, J. Falantes1, L. Vazquez1, I. Montero1, M.L. Martino1, R. Parody1, J. Gonzalez-Campos1, S. Garzon2, C. Calderon-Cabrera1, P. Barba5, N. Rodriguez-Torres3, M. Rivira7, J.A. Perez-Simon1, J.M. Cisneros-Herreros2

1Unidad Clínica de Hematología, 2Unidad Clínica de Enfermedades Infecciosas, Microbiología y Medicina Preventiva, Instituto de Biomedicina de Sevilla (IBiS), Hospital Universitario Virgen del Rocío/CSIC/Universidad de Sevilla, Sevilla, 3Servicio de Enfermedades Infecciosas, Hospital de Bellvitge, Barcelona, 4Servicio de Hematología, Hospital Clínico de Salamanca, Salamanca, 5Servicio de Hematología, Hospital de Jerez de la Frontera, Jerez, 6Servicio de Hematología, Hospital Universitario Vall Hebron, 7Servicio de Hematología, Hospital Clinic, Barcelona, Spain

Background: In neutropenic patients with unexplained fever the classical approach is maintaining the empirical antibacterial therapy (EAT) until neutrophil recovery. This strategy may result in unnecessarily prolonged EAT favoring bacterial resistance, organ toxicity and damage to microbiota. Nevertheless, the available scientific evidence supporting the alternative approach of stopping EAT before neutrophile recovery is moderate.

Aims: To investigate if a clinical approach (based on apyrexia and clinical recovery) is better than and as safe as the standard criteria (recovery from neutropenia) to decide the discontinuation of EAT.

Methods: After local Ethical Committee approval, a randomized, controlled, multicenter, open-labeled phase IV clinical trial was performed (EudraCT: 2011-005152-34). Study period: May-2012 to May-2016. Inclusion criteria: a) Adult patients (>18 years); b) Hematologic malignancy or autologous or allogeneic hematopoietic stem cell transplantation (SCT) recipients; c) High risk febrile neutropenia (FN) d) Informed consent signed. Exclusion criteria: etiological diagnosis of FN. Patients were randomized 72 hours after fever onset to: 1. Experimental group (EG): EAT discontinuation if a) apyrexia ≥72 h, plus b) clinical recovery ≥72 h (independently of neutrophil count) or 2. Control group (CG): EAT discontinuation if a) apyrexia ≥72 h, plus b) clinical recovery ≥72 h, plus c) >0.5x10⁶/L neutrophils. Follow-up: 28 days from EAT. Primary (efficacy) end-point was number of EAT-free days. Secondary (safety) end-points were days with fever, and crude mortality.

Results: One hundred and fifty seven patients were included (EG 78 and CG 79). There were no differences in baseline characteristics or clinical presentation between groups. The most frequent underlying conditions were induction/re-induction chemotherapy for acute leukemia (n=42, 26.7%), autologous SCT (n=42, 45.8%), and allogeneic hematopoietic stem cell transplantation (SCT) recipients; c) High risk febrile neutropenia (FN) d) Informed consent signed. Exclusion criteria: etiological diagnosis of FN. Patients were randomized 72 hours after fever onset to: 1. Experimental group (EG): EAT discontinuation if a) apyrexia ≥72 h, plus b) clinical recovery ≥72 h (independently of neutrophil count) or 2. Control group (CG): EAT discontinuation if a) apyrexia ≥72 h, plus b) clinical recovery ≥72 h, plus c) >0.5x10⁶/L neutrophils. Follow-up: 28 days from EAT. Primary (efficacy) end-point was number of EAT-free days. Secondary (safety) end-points were total days of fever and crude mortality.

CONJUGATED PNEUMOCOCCAL VACCINE TRIGGERS A BETTER IMMUNE RESPONSE THAN POLYSACCHARIDE PNEUMOCOCCAL VACCINE IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA: A RANDOMIZED STUDY BY THE SWEDISH CLL GROUP

1Section of Haematology, Institution of Medical Sciences, Upsala, 2Department of Medical Sciences, Oerebro University Hospital, Oerebro, 3Falun Hospital, Falun, 4Institute of Clinical Sciences, Faculty of Medicine, Lund University Hospital, Lund, 5Hematology and Coagulation Section, Sahlgrenska University Hospital, Goeteborg, 6Eskilstuna Hospital, Eskilstuna, 7Karlstad Hospital, Karlstad, 8Section of haematology, Institution of Medical Sciences, Upsala, 9Department of Medicine, Unit of Hematology, Karolinska Institute and University Hospital, Huddinge, Sweden

Background: Patients with CLL have an increased risk for infection and Streptococcus pneumoniae is one of the most common pathogens with high morbidity. Patients with CLL are known to respond poorly to the traditionally used polysaccharide vaccines. Conjugation of polysaccharide to protein carriers renders a thymus-dependent, memory-inducing and more immunogenic vaccine. In patients with CLL, there is no consensus on a recommendation for pneumococcal vaccination, due to a lack of comparative studies.

Aims: To determine if patients with untreated chronic lymphocytic leukemia (CLL) benefit from vaccination with a 13-valent conjugated pneumococcal vaccine (PCV13), Prevenar13® compared with a 23-valent capsular polysaccharide vaccine (PPSV23), Pneumovax® in terms of immune response.

Methods: 128 treatment naïve CLL patients from eight hematology clinics in Sweden were randomized to vaccination with PCV13 (n=63) or PPSV23 (n=65) after stratification by IgG levels and CLL clinical stage (Rai). Blood samples for evaluation of immune response were obtained at baseline, at one and at six months after vaccination. Analyses for each of the 12 pneumococcal serotypes common for PCV13 and PPSV23 were performed by opsonophagocytosis assay (OPA) and enzyme-linked immunosorbent assay (ELISA).

Results: PCV13 elicited a superior immune response than PPSV23 in 10/12 serotypes one month after vaccination and in 5/12 serotypes six months after vaccination, measured as OPA geometric mean titers (GMTs). Geometric mean concentrations of serotype-specific IgG antibodies elicited by PCV13 as measured by ELISA, were higher than those elicited by PPSV23 in half of the common serotypes, both after one and six months. The proportion of patients with good response (defined as response in 8 of 12 common serotypes according to predefined response criteria) was higher in PCV13 recipients than in PPSV23 recipients after one month (40% vs 22%, P=0.034) as well as after six months (33% vs 17%, P=0.041). Never did PPSV23 trigger a better immune response for any of the serotypes, than PCV13, regardless of analysis. For two of the serotypes, OPA GMTs were lower than the six months than at the one-month follow up. Negative predictive factors for vaccination response were hypogammaglobulinemia and long disease duration. Both vaccines were well tolerated.

Summary/Conclusions: In patients with previously untreated CLL, the efficacy of an immune response is significantly higher for PCV13 than for PPSV23 for many serotypes common for the two vaccines. PCV13 should be considered as a part in vaccination programs against Streptococcus pneumoniae for these patients and administered as possible during the course of the disease.

S806

INFECTION-RELATED MORTALITY AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION: AGE, CMV AND PRE-TRANSPLANT LEVELS OF IGA/IGM PREDICT IRM IN A NEW CLINICO-BIOLOGICAL SCORING SYSTEM

A. Forcina1, 2, P. Rancicà3, V. Marasović3, R. Greco1, M.T. Lupo Stanghellini1, M. Carrabba1, M. Marcacci1, C. Di Serio2, M. Bernardi1, J. Peccatori1, C. Corti1, M. Svensson6, I. Nilsson7, L. Rombo6, H. Cherif8, E. Kimby9

1IRCCS San Raffaele Scientific Institute, 2Vita-Salute San Raffaele University, Milan, Italy

Background: Infection-related mortality (IRM) is a major challenge after allogeneic hematopoietic stem cell transplantation (allo-HSCT). Aims: The aim of this study was to develop a scoring system predicting IRM based exclusively on pre-transplant data.

Methods: A total of 589 adult patients receiving allo-HSCT were studied (Jan 2009-Dec 2011). A total of 273 set of patients (n=273, Jan 2012-May 2015) the ROC curve analysis defined the optimal cut-offs predicting 100-day IRM for continuous data. All clinical and biochemical variables were challenged in a multivariate analysis and a 3-tiered weighted score was elaborated and tested firstly in a retrospective validation set (n=219, Jan 2009-Dec 2011) and then in a prospective validation set (n=97, Jun 2016-Nov 2016).

Results: Median follow-up was 43 months (range 1-85). Acute leukemia was the main indication to transplant, accounting for 60% (n=356) of patients. The majority of the patients received an alternative-donor transplant (44% a HLA-haploidentical, 37% a matched unrelated donor). Forty-seven percent (n=277) of patients had advanced diseases. Multivariate analysis revealed age >60 yrs (P=0.003), CMV host/donor serostatus different from negative/negative (P<0.001) and pre-transplant levels of IgA <1.11 g/L (P=0.004) and IgM <0.305 g/L (P=0.028) as the only independent predictors of increased IRM. Noticeably, these associations were independent from disease type or status, donor type, intensity of conditioning, in vivo T or B-cell depletion or from previous colonization by multidrug-resistant bacteria. According to the proposed IRM score, patients were divided into 3 classes: low (<10.17 points), intermediate (10.17-11.11 points) or high-risk (>11.11 points). In the training set, 100-day and 2-yrs IRM were 5% (95% CI 2-10) and 9% (95% CI 4-16) for low-risk, 11% (95% CI 5-18) and 23% (95% CI 14-33) for intermediate-risk, and 16% (95% CI 16-37) and 41% (95% CI 28-53) for high-risk patients, respectively (P=0.001). In the retrospective validation set, 100-day and 2-yrs IRM were 7% (95% CI 3-14) and 14% (95% CI 2-28) for low-risk, 17% (95% CI 10-26) and 23% (95% CI 15-33) for intermediate, and 28% (95% CI 15-42) and 33% (95% CI 19-44) for high-risk patients, respectively (P=0.044), with a c-index of 0.608 (Figure 1). In the prospective validation set, only 100-day IRM was calculated due to a shorter follow-up, being of 0%, 3% (95% CI 0-13) and of 14% (95% CI 3-33) for low, intermediate and high-risk patients (P=0.003). Additionally, in both training and retrospective validation sets (n=492), the 2-yrs OS was different among the 3 groups being 59% (95%CI 52-67), 50% (95% CI 43-59) and 37% (95% CI 29-48) for low, intermediate and high-risk groups, respectively (P=0.0001). In the prospective validation set, only 100-day OS was evaluated, being of 95% (95% CI 88-100), 91% (95% CI 82-100) and 80% (95% CI 65-100), respectively (P<0.001). Out of a total of 129 infection-related deaths, 94/129 (73%) were attributed to bacteria, 22/129 (17%) to viruses, 11/129 (8%) to fungi and 2/129 (2%) to parasites.

Figure 1.

Summary/Conclusions: This new clinic-biological score based on age, CMV serostatus and levels of IgA and IgM, may contribute to the prompt identification of patients at higher risk of fatal infections prior to allo-HSCT, thus promoting post-transplant personalized intensive active surveillance strategies and immune-intervention approaches to improve the overall outcome of transplant. A multicentric Italian study in currently on the way for the external validation of these results.

LETTERMOVIR FOR PREVENTION OF CYTOMEGALOVIRUS INFECTION IN ADULT CMV-SEROPPOSITE RECIPIENTS OF ALLOGENIC HEMATOPOIETIC CELL TRANSPLANTATION

R. Duarte1, 2, F. Marty2, P. Ljungman3, R. Chemaly4, J. Maertens5, D. Snymann6, E. Blumberg7, H. Einsele8, M. Boecch9, V. Teal10, H. Wan11, N. Kartsonis11, R. Leavit11, C. Badshah11

1BMT Programme & Myeloid Leukemia Division, Hospital Universitario Puerta del Hierro, Barcelona, Spain, 2Division of Infectious Diseases, Dana-Farber Cancer Institute , Boston, United States, 3Hematology, Karolinska University Hospital , Stockholm, Sweden, 4Department of Infectious Diseases, Infect Control & Employee Health , UT MD Anderson Cancer Center , Houston, United States, 5Hematology, Universiteite Ziekenhuizen , Leuven, Belgium, 6Medicine, The University of Texas Southwestern Medical School of Medicine at the University of Pennsylvania , Philadelphia, United States, 7Internal Medicine, Universitätsklinikum Würzburg , Wuerzburg, Germany, 8Vaccine and Infectious Diseases Division, Fred Hutchinson Cancer Research Center , Seattle, 9Late Development Statistics, 10Global Clinical Development - Oncology & Infectious Diseases Division, Fred Hutchinson Cancer Research Center , Seattle, 10Late Development Statistics, 11Global Clinical Development - Oncology & Infectious Diseases Division, Fred Hutchinson Cancer Research Center , Seattle.

Background: CMV remains a common complication of HCT, yet no antiviral drug suitable for prophylaxis is available in HCT. Letermovir is a first-in-class drug
that inhibits the CMV terminase complex. A dose-escalation phase 2 trial showed that LET prophylaxis for up to 12 weeks post-HCT was effective with a safety profile similar to placebo.

**Aims:** To compare LET prophylaxis to placebo for the prevention of clinically significant CMV infection (CS-CMV), defined as CMV disease or CMV viremia leading to preemptive treatment (PET) in a Phase III randomized, double-blind, placebo-controlled trial.

**Methods:** CMV seropositive HCT recipients 18 years or older who had undetectable plasma CMV DNA within 5 days of randomization were eligible (full eligibility at clinicaltrials.gov, NCT02137772). Subjects had to start treatment by Day+28 post-HCT. Subjects were randomized 2:1 to receive LET or placebo PO, 9% through Week 14 (Day +100) post-HCT, stratified by study site and high or low CMV disease risk. LET was dosed at 480 mg/d (or 240 mg/d if on cyclosporine due to drug-drug interaction). Subjects were assessed weekly through Week 14, biweekly through Week 24, and every other month through Week 48 after HCT. Plasma obtained at each visit was assayed for CMV DNA in a central laboratory. Subjects who developed CS-CMV discontinued study drug and received anti-CMV treatment. Local CMV assay results could be used to start PET. The primary endpoint was the stratum-adjusted proportion of subjects with CS-CMV through Week 24 post-HCT among subjects with undetectable CMV DNA at randomization; subjects who discontinued the study for any reason or with missing data at Week 24 were considered failures. All adverse events (AEs) were analyzed through 14 days after the last dose of study drug.

**Results:** From June 2014 to March 2016, 565 randomized subjects received study treatment; 31% were at high CMV disease risk. 50% subjects received myeloablative conditioning, 35% received ATG. Donors included 14% mismatched unrelated, 13% haploidential and 4% cord blood. Study arms were balanced. Subjects began study drug a median of 9 days post-HCT, 37% had engrafted prior to start. Of 495 treated subjects with undetectable CMV DNA at randomization, fewer subjects developed CS-CMV or were considered failures in the LET arm (122/325, 38%) compared to placebo (103/170, 61%; p<0.0001) by Week 24 post-HCT. Figure 1 shows the time to CS-CMV analysis. The most common AEs (LET, placebo) were GVHD (39%, 39%), diarrhea (26%, 25%), and nausea (27%, 23%). More frequent vomiting (19%, 14%), edema (15%, 9%), atrial arrhythmias (10%, 5%), and ALT levels >5xULN (4%, 2%) was noted in LET-treated subjects; no increased myelotoxicity or nephrotoxicity was observed. The Week 24 all-cause mortality was 10% for LET recipients and 15% for placebo recipients.

**Summary/Conclusions:** Letermovir prophylaxis was effective in reducing clinically significant CMV infection, was overall well tolerated, and provides a new approach to CMV prevention after HCT.

### S808

**EFFICACY AND SAFETY OF DEFIBROTIDE TO TREAT HEPATIC VENO-OCCCLUSIVE DISEASE/SINUSOIDAL OBSTRUCTION SYNDROME POST-CHEMOTHERAPY: A POST HOC ANALYSIS OF FINAL DATA OF AN EXPANDED-ACCESS PROTOCOL**

N. Kernan1, P. Richardson2*, S. Grupp3, J. Antin4, Y. Messinger5, W. Liang6, R. Ryan7, R. Hume8, W. Tappe9, R. Soiffer10

1Pediatric Bone Marrow Transplantation Service, Memorial Sloan Kettering Cancer Center, New York, 2Jerome Lipper Multiple Myeloma Center, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, 3Pediatric Oncology, The Children’s Hospital of Philadelphia, Philadelphia, 4Stem Cell/Bone Marrow Transplantation Program, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, 5Children’s Hospitals and Clinics of Minnesota, Minneapolis, 6Jazz Pharmaceuticals, Inc., Palo Alto, 7Center for Stem Cell Transplantation, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, United States

**Background:** Hepatic VOD/SOS, which may be unpredictable and potentially life-threatening, is typically considered a complication of hematopoietic stem cell transplantation (HSCT), and VOD/SOS with multi-organ dysfunction (MOD) may be associated with >80% mortality. Defibrotide is approved to treat severe hepatic VOD/SOS post-HSCT in the European Union and to treat hepatic VOD/SOS with renal or pulmonary dysfunction post-HSCT in the United States. However, VOD/SOS can occur after chemotherapy without HSCT.

**Aims:** To perform a post hoc analysis of final data on safety and response to defibrotide in patients developing VOD/SOS after primary chemotherapy without HSCT.

**Methods:** In an expanded-access protocol for patients with VOD/SOS post-HSCT or chemotherapy, with or without MOD (renal and/or pulmonary dysfunction), defibrotide 25 mg/kg/d (4 divided doses of 6.25 mg/kg) was given a recommended ≥21 days after patients provided informed consent. Post-chemotherapy subgroup survival was analyzed post hoc from the day defibrotide was started (days 0–30 after start of chemotherapy) for 70 days (because follow-up data were collected for 100 days post-chemotherapy).

**Results:** Of 1154 VOD/SOS patients receiving defibrotide, 137 (12%) developed VOD/SOS post-chemotherapy without HSCT. Among the 82 patients (38 with MOD) treated with DF by day 30 after start of chemotherapy, median age was 7.5 years (range, 0–68 years) and 66 (81%) were pediatric patients (<16 years of age). Among pediatric patients, 15% were age 0-23 months, 74% were 2-11 years and 11% were 12-16 years. Most common primary diseases were acute lymphocytic leukemia (51%), acute myeloid leukemia (13%), and neuroblastoma (6%). Kaplan-Meier estimated survival at Day +70 was 74% overall (95% CI, 63–82%; 86% (49–79%) in patients with MOD and 81% (66–90%) in patients without MOD. By age subgroup, Kaplan-Meier estimated survival at Day +70 was 80% (95% CI, 68–88%) in pediatric patients (Figure 1) and 50% (95% CI, 25–71%) in adults. Adverse events (AEs) were reported in 54/82 patients (66%). Hemorrhagic AEs ≥2% were pulmonary (6%), epistaxis or mouth (4%), and hematochezia (2%). There were 22 (27%) patients with AEs assessed as being at least possibly related to defibrotide, the most common (≥2%) were pulmonary or mouth hemorrhage (4% each) and hematochezia, nausea, encephalopathy, epistaxis, or hypotension (2% each). Related AEs led to discontinuation in 6 patients and were associated with 1 death (pulmonary hemorrhage, hypotension).

**Summary/Conclusions:** The 74% survival rate at Day +70 in patients with VOD/SOS receiving defibrotide within 30 days of starting chemotherapy (81% in patients ≤16 years) is clinically encouraging. Of note is the 66% survival rate in patients with MOD. The defibrotide safety profile was consistent with that previously reported in the overall population of this expanded-access protocol. Background: GPX4 is a selenoprotein belonging to the family of the glutathione peroxidases, a class of enzymes involved in cellular defence against oxidative stress. This enzyme is essential for life since it is the only peroxidase able to use lipid peroxides as substrate. Mice constitutively lacking GPX4 die at embryonic days 3.5 by the occurrence of tissue-specific ablation in neurons and T-cells causing neurodegeneration and impaired immune response. Recent studies have identified GPX4 as the main regulator of ferroptosis, an iron-dependent ROS-mediated form of nonapoptotic cell death. Erythrocytes are highly specialized cells that utilize a large amount of iron to bind and deliver oxygen to all tissues. Being constantly exposed to oxygen, erythroid cells need to continuously fight against oxidative stress by expressing a variety of antioxidant enzymes, including GPX4. Iron availability for erythropoiesis depends on systemic iron levels which are regulated via the hepcidin/ferroportin regulatory system. Hepcidin binding to the iron exporter ferroportin reduces systemic iron export regulating body iron levels. In hypoxic conditions the erythroid hormone ErFe suppresses hepcidin synthesis to provide iron for the elevated erythropoietic demand.

Aims: The aim of this study is to identify how the lack of GPX4 in the hematological compartment affects iron homeostasis.

Methods: Lethally irradiated C57BL/6 female mice were reconstituted with bone marrow cells from Gpx4fl/fl; Rosa26-CreERT2 or Gpx4wt/wt; Rosa26-CreERT2 and allowed to recover for 8 to 10 weeks. GPX4 deletion in the hematopoietic system was induced by feeding tamoxifen citrate for 3 weeks and blood and organs were drawn at 3 and 6 weeks after terminating the tamoxifen-containing diet. Erythroid cells have been analysed in FACS. Serum iron levels have been assessed using a colorimetric assay. All animal experiments were approved by the institutional guidelines and conducted in compliance with institutional guidelines.

Results: Compared to Gpx4wt/wt;CreERT2 controls, Gpx4fl/fl;CreERT2 transplanted mice lacking GPX4 in the haematological compartment show a decrease in the number of red blood cells, haemoglobin and haematocrit. Reticulocyte and EPO measurement revealed a strong increase in this population, suggesting that the erythropoiesis could be due to a block in the reticulocyte maturation. Reticulocyte FACS characterization revealed a shift towards a more immature population while tissue electron microscopy analysis showed an accumulation of unphagocytosed vesicles containing remnants of mitochondria. Analysis of the spleen revealed extramedullary erythropoiesis. The anaemia and the erythropoiesis trigger a hypoxic signature hallmarkned by an increase in circulating EPO and increased ErFe expression. However, both hepatic mRNA analysis and circulating protein measurement failed to show alteration in hepcidin production. Analysis of the liver showed an increase in non-heme iron content and in the lipid peroxidation causing an elevated mRNA and protein expression of heme oxygenase 1. Hepatic ferritin and ferroportin are also increased as a consequence of the increased iron content.

Summary/Conclusions: Our data show for the first time that the presence of GPX4 in the haematological compartment is essential for the proper hepcidin down-regulation upon ErFe stimulation. This finding opens new insights in the mechanism that regulate hepcidin during hypoxia.

IDENTIFICATION OF GUANOSINE 5′-DIPHOSPHATE AS POTENTIAL IRON MOBILIZER: PREVENTING THE HEPCIDIN-FERROPORTIN INTERACTION AND MODULATING INFLAMMATORY RESPONSES INSTIGATED BY INTERLEUKIN-6/STAT-3 PATHWAY

S. Angmo1,*, N. K. Singh2

1Food science and Nanobioscience, 2National Agri Food biotechnology, Mohali, India

Background: Anemia of inflammation (AI) is one of the most common manifestations of iron deficiency in the patients with inflammatory conditions. AI is responsible for hypoferremia, with consequent iron-restricted erythropoiesis with high level of hepcidin, which stimulate the internalization of ferroportin (FPN) transporter. Therefore, inhibiting hepcidin-mediated FPN degradation can be an important strategy to ameliorate AI.

Aims: To increase iron bioavailability we selected a Novel compound against hepcidin action through natural compound libraries that might provide a new alternative approach to increase iron absorption for prevention of hepcidin-mediated FPN internalization and to ameliorate turbine-induced anemic state with different insilico, invitro and invivo studies.

Methods: To find a systemic approach involving in silico, in vitro and in vivo studies was employed to identify hepcidin inhibiting agents. To identify a potent hepcidin-binding agent, natural compounds were screened using molecular docking and dynamics simulations and further investigated on cell lines (GFP-FPN, Caco-2, HepG2) using flow cytometry and western blotting. Normal or turpenline induced anemic mice were used in the associated studies.

Results: The virtual screening via molecular modelling showed that GDP as a potent hepcidin-binding agent as shown in the (Figure 1A). In vitro studies revealed that GDP significantly increased ferroportin stabilization in GFP-FPN cell lines (Figure 1C) and in vivo results showed that co-administration of GDP and ferrous sulphate (FeSO4) significantly improved the turbine-induced anemic state with increase in haemoglobin level (Figure 1B).

Figure 1.

Summary/Conclusions: AI is a normocytic anemia, common among patients with chronic infection and inflammatory disorders. We found that GDP molecule have higher contribution to the stability of hepcidin-GDP complex and thus blocks its interaction with FPN. The results support the novel hypothesis that GDP along with iron supplement regimen can overcome the binding of hepcidin from interaction with FPN that would be an effective treatment for AI.

UNRAVELING THE MOLECULAR PATHOGENESIS OF INEFFECTIVE ERYTHROPOIESIS IN CONGENITAL DYSERYTHROPOIESIS ANEMIA TYPE II: A LITERATURE REVIEW AND PROSPECTIVE EVALUATION OF RAP-011 TREATMENT

G. De Rosa1,*, I. Andolfo1, F. Manna1, A. Gambale1, R. Marra1, B. E. Rosato1, A. Iolascon1, R. Russo1

1Molecular Medicine and Medical Biotechnology, CEINGE - Biotechnologie Avanzate, Naples, Italy

Background: Congenital Dyserythropoietic Anemias (CDAs) are subtypes of bone marrow failure syndromes, hallmarkled by ineffective erythropoiesis. The most common form is CDA type II (CDAII), showing moderate/severe anemia, relative reticulocytopenia, jaundice, and iron overload. It is inherited as autosomal recessive disorder to loss of function mutations in SEC23B gene. More than 300 CDAII cases and 80 causative mutationshave been described so far. Despite this high allelic heterogeneity, two variants, R14W and E109K, represent more than 50% of the mutational events. To date, treatments for CDAII patients consist of supportive therapy, such as erythrocyte transfusions, or bone marrow transplantation or splenectomy in transfusion-dependent cases. Recently, members of TGF-β superfamily have been studied as potential regulators of erythropoiesis, especially the growth differentiation factor 11 (GDF11). Through the binding of specific receptors, GDF11 leads to an inhibited late-stage erythropoiesis. Indeed, two GDF11 inhibitors, ACE-011 and ACE-536, have been associated with improvements of haematological parameters. Studies with the mouse counterpart of ACE-011, RAP-011, on mouse model of β-thalassemia showed increased differentiation of erythroid cells, improvement of anemic condition and reduced iron overload in treated mice.

Background: Anemia of inflammation (AI) is one of the most common manifestations of iron deficiency in the patients with inflammatory conditions. AI is responsible for hypoferremia, with consequent iron-restricted erythropoiesis with high level of hepcidin, which stimulate the internalization of ferroportin (FPN) transporter. Therefore, inhibiting hepcidin-mediated FPN degradation can be an important strategy to ameliorate AI.

Aims: To increase iron bioavailability we selected a Novel compound against hepcidin action through natural compound libraries that might provide a new alternative approach to increase iron absorption for prevention of hepcidin-mediated FPN internalization and to ameliorate turbine-induced anemic state with different insilico, invitro and invivo studies.

Methods: To find a systemic approach involving in silico, in vitro and in vivo studies was employed to identify hepcidin inhibiting agents. To identify a potent hepcidin-binding agent, natural compounds were screened using molecular docking and dynamics simulations and further investigated on cell lines (GFP-FPN, Caco-2, HepG2) using flow cytometry and western blotting. Normal or turpenline induced anemic mice were used in the associated studies.

Results: The virtual screening via molecular modelling showed that GDP as a potent hepcidin-binding agent as shown in the (Figure 1A). In vitro studies revealed that GDP significantly increased ferroportin stabilization in GFP-FPN cell lines (Figure 1C) and in vivo results showed that co-administration of GDP and ferrous sulphate (FeSO4) significantly improved the turbine-induced anemic state with increase in haemoglobin level (Figure 1B).

Figure 1.

Summary/Conclusions: AI is a normocytic anemia, common among patients with chronic infection and inflammatory disorders. We found that GDP molecule have higher contribution to the stability of hepcidin-GDP complex and thus blocks its interaction with FPN. The results support the novel hypothesis that GDP along with iron supplement regimen can overcome the binding of hepcidin from interaction with FPN that would be an effective treatment for AI.
Aims: The main aim of our study is to assess the effects of RAP-011 on different cellular mediators of ESA response. Methods: We measured circulating GDF11 levels in CD34+ cells and healthy controls (HC) by western blot (WB). To assess the effectiveness of RAP-011 (provided by Celgene Corporation) in vitro, we established two different cellular models of CDAII: (i) K562 cells stably silencerfied SEC23B by Sh-CTR and (ii) K562 cells stably overexpressing SEC23B and the two variants, R14W and E109K. In vitro treatment has been performed at 0, 3, and 6 days of erythroid differentiation by hemin+GDF11 in presence or absence of RAP-011 in K562 cells stably silenced for SEC23B. Results: WB and subsequent densitometric analysis showed an increase of GDF11 in SEC23B silenced K562 cells from 18 to 36% (p=0.02). Stable silencing of SEC23B in K562 cells led to the establishment of two different clones, Sh-70 and Sh-74, showing amarkeddecrease of SEC23Bexpression compared to Sh-CTR (85-90% and 60-65%, respectively). At 3 and 6 days of K562 erythroid differentiation by hemin, we observed an increase of pSMAD2 in GDF11-treated cells compared to non-treated clones; interestingly, a reduction of pSMAD2 in RAP-011+GDF11-treated cells was observed.

Summary/Conclusions: We firstly demonstrated the increased levels of GDF11 in CD34+ cells, which is a more relevant marker of ESA’s effect on the production of red blood cells within the bone marrow and have shown to have a high level of sensitivity (AUC=0.87). We also confirmed the previous results obtained by the in vivo treatment of K562 stably overexpressing SEC23B-WT, SEC23B-R14W and -E109K.

S812 INTRAVENOUS IRON VERSUS ORAL IRON VERSUS NO IRON WITH OR WITHOUT ERYTHROPOIESISSTIMULATING AGENTS FOR CANCER PATIENTS WITH ANAEMIA: A SYSTEMATIC REVIEW AND NETWORK META-ANALYSIS

A. Weigl1*, N. Köhler1, I. Monsef1, J. Bohlius2, I. Becker3, K. Kuhr3, N. Skoetz1
1Cologne, Germany, 2Institute of Social and Preventive Medicine, University of Cologne, Cologne, Germany, 3Institute of Medical Statistics, Informatics and Epidemiology, University Hospital Cologne, Cologne, Germany

Background: A widely prevalent complication in patients suffering from cancer is the deficiency of haemoglobin-containing red blood cells, referred to as anaemia. While many patients develop anaemia due to an involvement of malignant bone marrow cells, others suffer from so-called chemotherapy/radiotherapy induced anaemia. Erythropoiesis-stimulating agents (ESAs) stimulate the production of red blood cells within the bone marrow and have shown to increase Ha levels in anaemic patients. Uncertainties remain regarding the effect of iron supplementation on the fatal consequences of ESA-treatment.

Aims: The aims of this systematic review and network meta-analysis are to evaluate the effects of iron on the treatment of disease-related as well as therapy induced anaemia in cancer patients.

Methods: Based on an a-priori Cochrane protocol, we developed sensitive search strategies for Cochrane Central Register of Controlled Trials (CENTRAL), MEDLINE, databases of ongoing trials and conference proceedings (search date 12/2016). We included only randomized controlled trials (RCTs) including anaemic patients of any age with solid and/or haematological malignancy undergoing chemotherapy, radiotherapy or no anti-cancer therapy. We excluded studies including anaemic cancer-patients as a result of surgery or anaemia related as well as therapy induced anaemia in cancer patients.

Results: We identified a total number of 105 eligible studies, including 25.722 extracted data and assessed quality of trials. The primary outcome was on-therapy mortality and risk for thromboembolic events, there is no evidence that iron supplementation alters these risks. However, addition of iron to ESA does further decrease the need for RBC-transfusions compared to ESA alone. Further investigation, with regards to iron type and route of administration may yield further distinct results.

Summary/Conclusions: While our analyses show that ESA use increases mortality and risk for thromboembolic events, there is no evidence that iron supplementation alters these risks. However, addition of iron to ESA does further decrease the need for RBC-transfusions compared to ESA alone. Further investigation, with regards to iron type and route of administration may yield further distinct results.
Our findings have potential implications, on one side, for hemolytic diseases, where RBC hemolysis and elevated circulating heme might promote a detrimental chronic inflammatory state, and, on the other one, for infectious diseases, where free heme and iron, released upon cell damage, might boost inflammation and enhance resistance to infections. Conversely, accelerated RBC clearance, by suppressing macrophage pro-inflammatory response, is rather expected to promote infections in transfused individuals.

Gene therapy, cellular immunotherapy and vaccination 2

A PHASE 3 STUDY TO EVALUATE SAFETY AND EFFICACY OF LENTIGLOBIN GENE THERAPY FOR TRANSFUSION-DEPENDENT B-THALASSEMIA IN PATIENTS WITH NON-β0/β0 GENOTYPES: THE NORTHSTAR-2 (HGB-207) TRIAL

1UCSF Benioff Children’s Hospital and Research Center, Oakland, 2Lurie Children’s Hospital , Chicago, United States, 3Ramathibodi Hospital, Bangkok, Thailand, 4Children’s Hospital of Philadelphia , Philadelphia, United States, 5IRCNS Ospedale Pediatrico Bambino Gesù, Rome, Italy, 6University College London Hospital, London, United Kingdom, 7Medizinische Hochschule Hannover , Hannover , Germany, 8Great Ormond Street Hospital, London, United Kingdom, 9Hôpital d’enfants de La Timone, Marseille, France, 10General Hospital of Thessaloniki, Thessaloniki, Greece, 11bluebird bio, Cambridge, United States

Background: Standard treatment for transfusion-dependent β-thalassemia (TDT) includes regular red blood cell (RBC) transfusions and management of iron overload. Successful allogeneic hematopoietic cell transplantation (HCT) can eliminate RBC transfusions and, eventually, chelation. However, due to transplant-related risks such as graft-versus-host disease (GVHD), as well as donor constraints, HCT is rarely an option for TDT patients. By transferring a functioning copy of the β-globin (HBB) gene into hematopoietic stem cells (CD34+ cells) and re-infusing the modified cells, gene therapy may be an alternative one-time treatment available to all patients with TDT, without risks of GVHD. LentiGlobin gene therapy is an investigational treatment consisting of autologous CD34+ cells transduced with the BB305 lentiviral vector. The Northstar (HGB-204) phase 1/2 clinical study of LentiGlobin gene therapy for TDT included 18 patients who received LentiGlobin drug product (DP). As of September 2016, all patients in Northstar with non-β0/β0 genotypes and at least 12 months of follow-up stopped transfusions (median total hemoglobin [Hb] 11.2 [range 9.4–12.2] g/dL) and there was >60% reduction in transfusions in patients with a β0/β0 genotype. The safety profile was consistent with autologous HCT. In this initial study, the average number of therapeutic gene copies per CD34+ cell in the DP (i.e. DP vector copy number per diploid genome or DP VCN; median 0.7, range 0.3 to 1.5) correlated with peripheral HbA1C (genetically engineered hemoglobin) expression at 6 months (ASH, 2016). In an effort to optimize the proportion of patients able to discontinue blood transfusions to achieve “transfusion independence” in all patients and increase unsupported Hb levels after treatment, the manufacturing process for LentiGlobin DP was modified to increase the DP VCN and the proportion of genetically modified cells. Northstar-2 (HGB-207) is a recently initiated phase 3 study using this new manufacturing process in patients with TDT and a non-β0/β0 genotype.

Aims: To evaluate safety and efficacy of autologous HCT with LentiGlobin DP in patients with TDT and a non-β0/β0 genotype.

Methods: After providing informed consent, patients 12 to 50 years of age (N=15) will have CD34+ cells collected via mobilization and apheresis. After individualized DP manufacture and satisfaction of release criteria, the patient will receive myeloablative conditioning with single-agent busulfan (starting dose 32 mg/kg/day for 4 days, with target AUC 4500 [range 4000–5000] µM*min) followed by infusion of LentiGlobin DP. Patients will be followed for engraftment, safety and efficacy endpoints for 2 years after infusion; patients will then have the option to enroll in a 13-year follow-up study. The primary endpoint is the proportion of patients who achieve transfusion independence after DP infusion, defined as total Hb ≥9g/dL without RBC transfusions for a continuous period of ≥12 months. Secondary endpoints include time to neutrophil engraftment, adverse events, and biological parameters including VCN in peripheral blood and levels of HbA1C over time.

Results: As of March 1, 2017, two 20-year-old females with β0/β0 genotypes have been treated with LentiGlobin DP in the Northstar-2 trial. The DP VCN was 2.9 and 2.4 copies per diploid genome, respectively. Outcomes in all evaluable patients will be presented.

Summary/Conclusions: Results from the Northstar-2 study will provide data on safety and demonstrate the extent to which an increase in LentiGlobin DP VCN yields normalization of total Hb and consistently achieves transfusion independence in patients with TDT of non-β0/β0 genotypes. Optimizing DP VCN has the potential to improve outcomes across all TDT genotypes treated by investigational LentiGlobin gene therapy.

S815

CIS IS A POTENT CHECKPOINT IN NK CELL ANTI-LEUKEMIA IMMUNITY

N. Huntington1,*, N. Huntington

1Molecular Immunology, Walter and Eliza Hall, Parkville, Australia

Background: The detection of leukemia by natural killer (NK) cells is controlled
by the integration of signals from activating and inhibitory ligands and from cytokines such as IL-15.

Aims: We set out to identify the negative regulators of NK cell function in order to understand why immunogenic tumours and leukaemia can evade or overcome NK cell detection and killing.

Methods: We used a multidisciplinary approach including RNAseq, Mass Spectrometry, functional biology, kinase enrichment and activity assays, NK cell in vitro analysis, biochemistry and de novo/experimental tumor/leukemia in vivo models.

Results: We identified cytokine-inducible SH2-containing protein (Cis, encoded by Cish) as a critical negative regulator of IL-15 signaling in NK cells. Cis was rapidly induced in NK cells in response to IL-15, and deletion of Cis rendered NK cells hypersensitive to IL-15, as evidenced by enhanced proliferation, survival, IFN-gamma production and cytotoxicity toward tumors. This was associated with increased JAK-STAT signaling in NK cells in which Cis was deleted. Correspondingly, Cis interacted with the tyrosine kinase JAK1, inhibiting its enzymatic activity and resulting in a profound functional ablation. Cis−/− mice are resistant to leukaemia in vivo, and this was independent of MHC-I expression.

Summary/Conclusions: Our data uncover a potent intracellular checkpoint in NK cell-mediated tumor immunity and suggest possibilities for new cancer immunotherapies directed at blocking Cis function.

S816

GENERATION OF MEMORY STEM T CELLS MODIFIED WITH A NOVEL OPTIMIZED CD30-SPECIFIC CHIMERIC ANTIGEN RECEPTOR FOR THE TREATMENT OF CD30+ T-CELL MALIGNANCIES

L. Escrivá-García1, C. Alvarez-Fernández1, J. Wegner2, J. Rydzek3, M. Tellez-Gabriel4, J. Sierra1, H. Einsele2, J. Briones1, M. Hudecek2

1Hematology Service, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, 2Universitätsklinikum Würzburg, Medizinische Klinik und Poliklinik II, Würzburg, Germany

Background: Peripheral T-cell lymphomas (PTCL) represent the most aggressive form among non-Hodgkin lymphomas with a very poor prognosis (5-year survival of 30%), demanding innovative novel treatment strategies. Adoptive immunotherapy with chimeric antigen receptor (CAR) engineered T cells has demonstrated its therapeutic potential in advanced hematological malignancies. However, its application to PTCL remains a formidable challenge mainly due to a lack of truly tumor-specific antigens that are not expressed on normal T cells. Anaplastic large T-cell lymphomas (ALCL) and several other subtypes of PTCL express CD30, which is expressed by activated normal T cells but no other healthy tissues. Indeed, brentuximab vedotin, an anti-CD30 antibody-drug conjugate, has shown some clinical efficacy in PTCL and ALCL patients although duration of responses is short in the majority of cases. Here, we developed a refined anti-CD30-CAR T-cell approach to target CD30+ PTCL as a potential novel therapeutic strategy. We selected a novel targeting domain that is unaffected by soluble CD30 protein to prevent blockade of the CD30-CAR in vivo. Moreover, we optimized the therapy by using memory stem T cells (TSCM) to promote engraftment and persistence of CD30-CAR T cells after transfer, and we have included an EGFFr depletion marker as a safety feature.

Aims: We evaluated the antitumor effect of memory stem T cells (TSCM) genetically modified with a novel CD30-specific CAR that recognizes a membrane-proximal epitope in the CD30 molecule in a CD30+ T-cell lymphoma model.

Methods: A second generation CD30-41BBz-EGFRz CAR was generated using a scFv that recognizes a tumor-cell membrane-proximal epitope of CD30 protein (Nagata S et al. Clin Cancer Res, 2002). Naive T cells from healthy donors were activated with anti-CD3/CD28 beads in presence of IL-7, IL-15 and IL-21 during 10 days to obtain a TSCM-enriched population (Alvarez G et al. J Transl Med, 2016); on day 2 of culture, cells were transduced with a third-generation lentiviral vector encoding the CD30-CAR. The anaplastic large T-cell lymphoma cell line Karpas 299 was used as tumor model. Cytotoxicity assay was performed at 4 hours at 10:1, 5:1, 1:1 and 1:5 effector/target (E/T) ratios, and the tumor cell death was determined by flow cytometry. Cytokines (IFNγ and IL-2) were analysed at 24 hours in a 5:1 E/T ratio culture using Luminex technology.

Results: TSCM were the most prevalent T-cell subset at day 10 of culture, representing 84 ± 3% of total cells, and the CD30-CAR expression in these cells was 76.9 ± 1.0% in CD4+ TSCM and 77.3 ± 2.0% in CD8+ TSCM. Although CD30 protein was detected in a fraction of activated T cells in culture (CD4+ T cells: 32.4 ± 2.1%; CD8+ T cells: 59 ± 4.3%), lentiviral transduction of TSCM with our CAR did not compromise their ex vivo expansion (CD4+ CD30-CAR TSCM: 96.0 ± 3.2 fold expansion; CD8+ CD30-CAR TSCM: 109.0 ± 4.2 fold expansion). CD30+ CD30-CAR TSCM conferred specific cytolic activity and lysed Karpas 299 cells (tumor cell death 1:1 ratio: 92.6 ± 2.4% vs. 0.0% with untransduced TSCM <p>0.001), while control CD30+ target cells (Raji) were not recognized. In addition, CD30-CAR TSCM secreted IFNγ and IL-2 after stimulation with Karpas 299 cells (IFNγ: 126.6 ± 18.12 pg/ml vs 5.03 ± 0.16 pg/ml with control targets, p<0.002; IL-2: 20.47 ± 2.3 pg/ml vs 4.06 ± 0.24 pg/ml, p<0.002).

Summary/Conclusions: Collectively, our data demonstrate the potential to generate CD30-CAR T cells with enhanced functional attributes against CD30+ PTCL. TSCM cells can be efficiently transduced and ex vivo expanded with a novel CD30-CAR and confer potent antitumor efficacy against CD30+ PTCL in vitro. Our findings suggest the potential to improve outcome of patients with CD30+ PTCL through adoptive therapy with CD30-CAR modified T cells.

MESENCHYMAL STROMAL CELLS FOR THE TREATMENT OF STEROID-RESISTANT ACUTE GRAFT VERSUS HOST DISEASE: FACTORS INFLUENCING CLINICAL RESPONSES

A. Galleu1, S. Deplano2, R. Szydlo3, A. Bradshaw2, R. Wynn4, D. Marks5, D. Richardson6, K. Orchardi6, E. Kanfer6, E. Tholouis6, M. Saïfi6, P. Sivaprasakasam6, S. Lawson7, A. Bloos8, A. Pagliuca9, J. Snowden10, A. Vora11, B. Kishore12, H. Hunter13, J. Apperley2,3, F. Dazzi3

1Division of Cancer Studies, King’s College London, 2Imperial College Healthcare NHS Trust, 3Imperial College London, London, 4Central Manchester University Hospital, Manchester, 5University Hospitals Bristol, Bristol, 6University Hospital Southampton, Southampton, 7Birmingham Women’s and Children’s Hospitals, Birmingham, 8The Christie NHS Foundation Trust, Manchester, 9King’s College Hospital NHS Trust, London, 10Royal Hallamshire Hospital, 11Sheffield Children’s Hospital, Sheffield, 12Heart of England NHS Foundation Trust, Birmingham, 13Plymouth Hospitals NHS Trust, Plymouth, 14King’s College London, London, United Kingdom

Background: The immunosuppressive activity of mesenchymal stromal cell (MSC) has been extensively tested for the treatment of steroid-resistant acute graft versus host disease (aGvHD). However, the factors affecting clinical responses are poorly understood.

Aims: We assessed the impact of MSC treatment on clinical outcomes and investigate factors influencing the response to MSC.

Methods: Data collected from a cohort of 60 patients treated with MSC between May 2008 and December 2014 in the UK were analyzed. Clinical grade MSC were generated from bone marrow aspirates collected from the iliac crest of healthy donors and expanded using platelet lysate. All patients received MSC for the treatment of steroid-resistant aGvHD, defined as failure to respond to high-dose steroids (2mg/Kg methyl-prednisolone) after 6 days. Informed consent was obtained from all patients in accordance with the local ethics committee requirements. Clinical responses to MSC were assessed 1 week after MSC infusion. Patients were defined as: a) Responders when an improvement of at least 50% in at least one organ affected by aGvHD was observed, or b) Non-Responders if they had stable or progressive disease.

Results: Patient characteristics are summarized in Table 1.

Table 1.

| Table 1 |
ing to the first dose, failed to respond to the second one. When we evaluated potential factors for response, organ involvement, age at transplant and the cumulative dose of MSC infused were found statistically significant. Response rate was 67% among patients with involvement of gut, skin or both, but only 22% among those with involvement of the liver (alone or in combination with skin and/or gut). Patients younger than 20 years fared better, with 88% of them responding. Conversely, only 30% and 42% of those aged 20-50 years or older than 50 responded, respectively. Lastly, higher cumulative MSC dose (>3.0x10^6/Kg) was associated with a response in 76%, while none of those receiving less than 1.5x10^6/Kg responded. All 3 factors remained significant in multivariate logistic regression analysis. Patient gender, pre-MSC therapy, interval from transplant or aGvHD diagnosis to MSC treatment and grade of aGvHD did not affect response. The impact of achieving a response 1 week after MSC had a profound impact on the overall survival at 18 months accounting for 59% in responders and 17% in non-responders (log-rank test, \( p < .001 \)).

**Summary/Conclusions:** In our cohort of patients, MSC treatment was safe and well tolerated. We conclude that the presence of a response at one week highly impacted on the survival of patients with an otherwise very poor prognosis. Importantly, younger age at the transplant, absence of liver aGvHD involvement and use of higher MSC doses were strong predictors of a response.

CARD9 CONTROLS DECTIN-1-INDUCED T-CELL CYTOTOXICITY AND TUMOR GROWTH IN MICE

T. Haas1,*, S. Heidegger1, H. Poeck1, J. Ruland2

1Klinik und Poliklinik für Innere Medizin III, 2Institut für Klinische Chemie und Pathobiochemie, Klinikum rechts der Isar, TU München, München, Germany

**Background:** Activation of the C-type lectin receptor Dectin-1 by beta-glucans triggers multiple signals within dendritic cells (DCs) that result in activation of innate immunity. While these mechanisms can potently prime CD8+ cytotoxic T cell (CTL) responses without additional adjuvants, the Dectin-1 effector pathways that control CTL induction remain unclear.

**Aims:** Aims of this study were: To define details of the intracellular signalling pathway responsible for cross-priming of a CTL response after activation of the C-type lectin receptor Dectin-1. To analyze whether identified signalling molecules were indispensable for antitumor immunity. To analyze whether NK cells played a role in antitumor immunity after Dectin-1-mediated CTL induction.

**Methods:** We used *in vitro* coculture between DCs (wildtype vs gene deficient) and CD8 T cells to define signalling components of Dectin-1 induced CTL cross-priming. We used WT and gene-deficient mice to define the signalling pathway of Dectin-1 induced CTL crosspriming in vivo and to test the role of this pathway for antitumor immunity by challenging mice with B16-Ova tumor cells intravenously, with or without depletion of CD8 T cells or NK cells, respectively.

**Results:** Here we demonstrate that Dectin-1-induced CTL cross-priming in mice does not require inflammasome activation but strictly depends on the adapter protein Card9 *in vitro*. In vivo, Dectin-1-mediated Card9 activation after vaccination drives both expansion and activation of antigen-specific CTLs, resulting in long-lasting CTL responses which are sufficient to protect mice from tumor challenge. This Dectin-1-induced antitumor immune response was independent of natural killer (NK) cell function and completely abrogated in Card9-deficient mice. Thus, our results demonstrate that Dectin-1-triggered Card9 signaling but not inflammasome activation can potently cross-prime antigen specific CTLs, suggesting that this pathway would be a candidate for immunotherapy and vaccine development (Figure 1).

**Summary/Conclusions:** We identify Card9 as central regulator of Dectin-1-induced cross-priming of cytotoxic T cells (CTLs) in mice. These antigen specific CTLs mediate potent antitumor immunity independent of inflammasome activity and NK cells. This pathway is a candidate for immunotherapy and vaccine development.

PRECLINICAL COMBINATION OF AN NOVEL IRE1 RNASE INHIBITOR MCK-8866 AND TYROSINE KINASE INHIBITION ACTS SYNERGISTIC IN ACUTE LYMPHOBLASTIC LEUKEMIA

M. Vieri1,*, A. Salimi1, J.B. Patterson2, A. Samali3, E. Chevet4, T.H. Brümmendorf1, I. Appelmann1, B. Kharabi1
1Hematology, Oncology, Hemostaseology and Stem Cell Transplantation, University Hospital RWTH Aachen, Aachen, Germany, 2KampKind Corporation, Valencia, United States, 3Department of Biochemistry, National University of Ireland, Galway, Ireland, 4Centre de Lutte Contre le Cancer Eugène Marquis, Université Rennes 1, Rennes, France

Background: The role of the unfolded Protein Response (UPR) in BCR-ABL+ ALL cells has been extensively studied, proving the importance of cytoplasmic and nuclear events promoting cell survival. However, a therapeutic strategy involving UPR inhibition has not been considered as a viable option. We identified a strategy that may lead to the development of a novel drug for BCR-ABL+ ALL.

Aims: In this study we aim to identify a potential synergistic effect of simultaneous pharmacological inhibition of IRE1 and BCR-ABL in pre-B cells.

Methods: To study the link between IRE1-XBP1 axis of UPR and BCR-ABL, we utilized both pharmacological and genetic approaches. 1) We tested the effect on proliferation and viability of pharmacological IRE1 inhibition (using MCK-8866) alone and in combination with Tyrosine Kinase Inhibitors (TKI) using Imatinib or Nilotinib on BCR-ABL+ human ALL cell lines, SUP-B15 and TOM-1. The cell lines were also co-cultured with immortalized tertMSCs to test the chemo-protective effect of bone marrow stromal cells (BMSCs) on leukemia cells. 2) We tested whether genetic knock-down of XBP1 could sensitize cells towards the effect of Imatinib and Nilotinib. To this end, primary murine pre-B cells from conditional XBP1fl/+mice were transduced with BCR-ABL1 construct and with either inducible cre or empty vector.

Results: IRE1 inhibitor MCK-8866 (MCK) in combination with either Imatinib (IM) or Nilotinib (NL) showed enhanced capacity to arrest proliferation and to induce cell death in both BCR-ABL+ ALL cell lines compared to single treatments, after 3 days incubation (Viable SUP-B15: MCK 50 µM 94.9±0.1%, IM 10 µM 78.4±0.4%, Combination 17.0±1.4%; MCK 30 µM 94.1±0.7%, NL 5 µM 64.2±0.6%, Combination 20.0±0.8%. TOM-1: MCK 30 µM 85.0±0.9%, IM 10 µM 89.9±0.4%, Combination 17.6±0.7%. MCK 30 µM 94.6±0.1%, NL 5 µM 71.0±0.9%, Combination 30.6±3.6%). Using RNA sequencing for both genotypes and genotypes, we confirmed a striking synergistic effect. Successively, to exclude any possible off-target effect at the basis of the observed synergism, we used a genetic approach to block IRE1-XBP1 signaling in vitro. B-cell precursors from Xbp1fl/+ mice, instead of Xbp1fl/fl, were used in order to warrant a basal signal of XBP1, present during pharmacological inhibition. After transductions with BCR-ABL1, and either cre or the empty vector, we could observe that heterozygous deletion of Xbp1, induced by 4OHT, significantly increased TKI-induced cell death, after 3 days incubation (4OHT 1µM: 47.5%±13.0%, IM 1µM: 70.8±1.7%, IM+4OHT: 18.3±2.7%, NL 0.5µM: 65.2±0.3%, IM+4OHT: 14.5±0.9%). Finally, we showed whether the tested drugs combination were still effective in presence of BMSCs. It’s known that BMSCs are a critical component to escape TKI-induced cell death in Ph+ leukemia and that IRE1-XBP1 is responsible for chemoresistance in many different cancer types, although this role has never been confirmed in BCR-ABL+ cells. To shed light on this aspect we co-cultured either SUP-B15 or TOM-1 cells with tertMSCs, and while the stroma was capable to block Nilotinib-induced cell death, after 5 days incubation (in SUP-B15, NL 5 µM in standard culture 28.7±1.9%, NL 5 µM in co-culture 74.9±0.1%; in TOM-1, 29.1±2.8 vs 78.7±0.2%), this protective activity was partially abrogated upon treatment with IRE1 inhibitor. On the other hand, MSCs were not able to reverse IM effect on cell viability.

Summary/Conclusions: Overall, our data demonstrate that simultaneous inhibition of BCR-ABL1 and IRE1 branch of UPR exerts a potent effect in vitro, by acting synergistically on BCR-ABL+ ALL cells. This provides basis for a clinical application of a combined targeted therapy.

E820
HIGH-THROUGHPUT COPY NUMBER PROFILING IN PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA USING MULTIPLE LIGATION-DEPENDENT PROBE AMPLIFICATION IN COMBINATION WITH NEXT-GENERATION SEQUENCING

D. Alpar1,*, P.A. Kiraly1, A. Benard2, I. Haltrich3, H. Piko4, K. de Groot4, J. Schouten1, S. Savola2, C. Bodo1
1MTA-SE Lendulet Molecular Oncohematology Research Group, 1st Department of Pathology and Experimental Cancer Research, Semmelweis University, Budapest, Hungary, 2MRC-Holland, Amsterdam, Netherlands, 3rd Department of Pediatrics, Semmelweis University, 4th Department of Molecular Genetics and Diagnostics, National Center of Public Health, Budapest, Hungary

Background: Development, progression and resistance of pediatric acute lymphoblastic leukemia (pALL) are widely associated with recurrent copy number abnormalities (CNAs). Multiplex ligation-dependent probe amplification (MLPA) is an established technique to screen CNAs, thus providing valuable information for risk assessment in pALL. However, the number of simultaneously analyzable genomic loci is limited to 55-60.

Aims: To introduce and test a high-throughput, high-resolution and comprehensive disease-relevant CNA profiling approach applicable to all subtypes of pALL.

Methods: A new digitalMLPA (dMLPA) technique has been developed which combines the advantages of MLPA and next-generation sequencing (NGS), massively improving the number of genomic targets that can be analyzed for their copy number in a single reaction. Bone marrow samples from 58 patients with pALL were analyzed using this novel assay targeting ~470 genomic loci. CNAs in pre-B and pre-T ALL, respectively, followed by CDKN2A/B, PAX5, RB1, VPREB1, MLT13, CD200/BLA, TBL1XR1, IKZF1, CASP8AP2, PTPN, RUNX1, BTG1, TP53, IKB2, EZH2, NF1, NR3C2, RAG2 and the PAR region were analyzed for copy number changes. Results were compared to conventional MLPA, cytogenetic and FISH data.

Results: CNAs directly indicating structural or whole chromosome aberrations or indirectly referring to gene fusions were detected in 93% of patients, in 44/48 pre-B ALL and 10/10 pre-T ALL cases. Among patients with CNAs, recurrent aberrations specifically affecting putative driver genes varied between 0 and 11 patients, including: TP53 (17:1), BCR-ABL1 (19:0), TP63 (4:0), CASP8AP2 (5:0), IKZF2 (1:0), CDKN2A (3:0), CDKN2B (2:0), PTPN11 (2:0), IKB2 (1:0), TP53 (1:0), RB1 (1:0), PTEN (1:0), MLLT3 (1:0), TBL1XR1 (1:0), IKB2 (1:0), and IKB2 (1:0). Overall, our data demonstrate that simultaneous inhibition of both BCR-ABL1 and IRE1 significantly improves cellular efficacy and confidence as compared to conventional MLPA and enabled a more patient-specific characterization of CNAs, as revealed by 15 different deletion patterns across 23 samples harboring del(6p). In addition to genomic lesions specifically influencing putative or proven driver or relevant genes, 24 structural (134 whole chromosome aberrations were detected genome-wide which was strongly facilitated by the inclusion of ~200 digital karyotyping probes covering each chromosome arm.

Summary/Conclusions: A novel NGS-based method has successfully been introduced for high-resolution profiling of CNAs in pALL. dMLPA is a robust, fast and cost-effective technique; its input DNA requirement (20ng) is similar to those of other low-input NGS protocols and lower than the requirement for MLPA. Due to its targeted approach, data analysis is computationally less demanding as compared to most NGS methods. The number of genomic sites analyzed in dMLPA (i) allowed the detection of subclonal aberrations with an improved efficacy and confidence as compared to conventional MLPA and (ii) enabled a more patient-specific characterization of CNAs, e.g. by revealing 15 different deletion patterns across 23 samples harboring del(6p). In addition to genomic lesions specifically influencing putative or proven driver or relevant genes, 24 structural (134 whole chromosome aberrations were detected genome-wide which was strongly facilitated by the inclusion of ~200 digital karyotyping probes covering each chromosome arm.

CRITICAL ROLE FOR NOTCH SIGNALLING IN B-CELL PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA (B-ALL) DRUG RESPONSE

P. Takam Kamga1,*, G. Dal Collo1, M. Midolo1, A. Adamo1, A. Gatti1, R. Caruso1, M. Bonifacio1, M. Krampera1
1Medicine, University of Verona, Verona, Italy

Background: B-cell precursor acute lymphoblastic leukemia (B-ALL) is the leading cause of cancer-related death in children and young adults. There is still a need of more efficient therapies for the subset of refractory patients. Our group has previously shown that Notch-3 and Notch-4 promote human B-ALL cell survival in presence of stromal cell support. However, the prognosis value of Notch signalling as well as its contribution to the pathogenesis of B-ALL is still a matter of debate.

Aims: In this study we used B-ALL cell lines and samples from new diagnosed B-ALL patients to analyse the contribution of Notch signalling to B-ALL pathogenesis in terms of prognosis, proliferation survival and drug response in vitro and in mice xenograft models of B-ALL.

Methods: B-ALL cell lines were obtained from ATCC, while B-ALL primary cells were obtained from bone marrow or peripheral blood of 30 B-ALL patients. Flow cytometry and western immunoblotting were used to study the expression of Notch receptors and ligands. Drugs used were Cytarabine (Ara-C), Dexamethasone (Dex), and Notch modulators including anti-Notch blocking antibodies, gamma secretase inhibitors (GSIs), and Notch transcription factor inhibitor (SAHM1). Mouse xenograft model of B-ALL were obtained by injecting the B-ALL line RS4;11 in
NOD/Shi-scid/lL-2Rnull mice (NOG). Cell viability was evaluated by Annexin-V/PI and MTT assay; proliferation was assessed through CFSE dilution.

Results: Western blot and flow cytometric analysis showed that B-ALL cell lines as well as primary blast cells displayed the same Notch expression pattern consistent in low expression levels of Notch2 and Jagged1, high expression levels of Notch1, Notch3, Notch4, Jagged2, DLL3 and DLL4. Notably, in primary blast cells deriving from patients, the expression of Notch3, Notch4, Jagged2, DLL3 and DLL4 was significantly higher in the cases refractory to treatment as compared to patients achieving complete remission, thus suggesting that Notch signalling could be involved in the response to chemotherapy. In line with this hypothesis, we found that the treatment in vitro of B-ALL cell lines with Ara-C or Doxo up-regulated the expression of Notch receptors. This down regulation was also observed in human CD19+ blast cells isolated from bone marrow of recipient mice treated with Ara-C compared to cells isolated from not treated mice. In addition, Notch inhibitors significantly improved in vitro the cytotoxicity of Ara-C and Doxo towards B-ALL cells. Finally, we evaluated the administration to mice of a pan Notch inhibitor, i.e. the GSI XII, significantly lowered the CD19+ leukaemic burden in the bone marrow of recipient mice, potentiating anti leukemic effect of Ara-C.

Summary/Conclusions: In this study we used both in vitro and in vivo assays to highlight the prognostic value of Notch expression in B-ALL, as well as its critical role in B-ALL cell survival and response to chemotherapy. We also demonstrated that Notch inhibitors were able to improve Ara-C-mediated reduction of blast cells in bone marrow, revealing that Notch signalling is a possible therapeutic strategy to eradicate minimal residual disease in B-ALL.

E822
REGULATION OF NOTCH AND WNT SIGNALING PATHWAYS BY NRARP IN T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA
I. Pinto1, M. L. Oliveira1, J. T. Barata1, R. Fragoso1,*, 1JBarata Lab, Instituto de Medicina Molecular, Lisboa, Portugal

Background: T-cell acute lymphoblastic leukemia (T-ALL) is an aggressive hematological malignancy. Although the outcome of T-ALL patients has improved over recent years, the poor prognosis of patients with resistant or relapsed disease is still a major concern. Even though NOTCH is a known driver in T-ALL, its inhibition cannot be efficiently achieved with the drugs currently available, due to their weak therapeutic effects and severe toxicity. We have shown that loss of mir-181ab1 blocks Notch-induced T-ALL development partly by de-repressing the expression of NRARP (NOTCH regulated ankyrin repeat protein) a negative regulator of NOTCH signaling. Importantly, NRARP overexpression in human hematopoietic stem cells impairs T-cell development suggesting that de-regulation of NRARP expression can contribute to the pathogenesis of T-ALL.

Aims: To investigate the role of NRARP in human T-ALL cell growth and survival and its therapeutic potential in T-ALL.

Methods: mRNA and protein expression were determined by real time-PCR and western blot analyses. In vitro functional evaluation of NRARP in T-ALL cell lines was performed by flow cytometry analysis of proliferation and viability upon NRARP overexpression using lentiviruses.

Results: We started by characterizing NRARP expression in human T-ALL cell lines and compared it with the expression of NRARP in normal human thymocytes. We found that NRARP protein levels are significantly increased in T-ALL cells. This result, although consistent with the fact that NRARP is a transcriptional target of NOTCH, suggests that NRARP is not sufficient to block NOTCH oncogenic signals. To test this hypothesis, we overexpressed NRARP in human T-ALL cell lines. Curiously, NRARP overexpression blocks the expansion of the T-ALL cell lines that display NOTCH1-activating mutations but promotes the expansion of the T-ALL cells without NOTCH1 mutations. Although in both cell types (WT and NOTCH1-mutated) NRARP overexpression blocks NOTCH signaling, in NOTCH1-WT T-ALL cells we observe an increase in c-Myc expression. Consistent with these results, NOTCH1-WT NRARP overexpressing cells are more sensitive to QOJ, a small-molecule bromodomain inhibitor that targets c-Myc. NRARP is known to positively regulate LEPF, a DNA binding transcription factor acting downstream of WNT. Thus we sought to investigate the impact of NRARP on NOTCH1 signaling pathway. Very interestingly, our results show that in NOTCH1-mutant cells NRARP overexpression results in the down-regulation of the WNT signaling pathway while in NOTCH1-WT T-ALL cells results in its up-regulation.

Summary/Conclusions: Taken together our results suggest that NRARP may play a dual role in T-ALL pathogenesis, regulating both NOTCH and WNT pathways, with opposite functional effects on leukemia cells depending on NOTCH mutational status and signaling levels. This dual role may have important biological and therapeutic implications.

E823
ETV6/RUNX1-LIKE ACUTE LYMPHOBLASTIC LEUKEMIA: A NOVEL B-CELL PRECURSOR LEUKEMIA SUBTYPE IDENTIFIED BY THE CD27/CD44 IMMUNOPHENOTYPE
M. Zaliova1,2,3, M. Kotrova1,2,3, S. Bresolin4, J. Stuchi1,2, J. Stary1,2, O. Hrusak1,2,3, G. te Kronnie4, J. Trka1,2,3, J. Zuna1,2,3, M. Vasková1,2, 1Department of Paediatric Haematology and Oncology, 2Second Faculty of Medicine, Charles University, 3University Hospital Motol, 4CLIP - Childhood Leukaemia Investigation Prague, Prague, Czech Republic, 5Department of Women’s and Children’s Health, University of Padova, Padova, Italy

Background: We have shown previously that ETV6/RUNX1-positive acute lymphoblastic leukemia (ALL) is distinguishable from other ALL subtypes by CD27pos/CD44low/neg immunophenotype. During diagnostic immunophenotyping of 573 childhood B-cell precursor ALL (B-ALL), we identified eight cases with this immunophenotype among ‘B-other ALL’ (B-ALL cases negative for hyperdiploidy, ETV6/RUNX1, TCF3/PBX1 and BCR/ABL1 fusion genes and KMT2A-rearrangements).

Aims: We aimed to characterize their genetic and biological background, to reveal to what extent they resemble ETV6/RUNX1-positive ALL and to elucidate whether they belong to the recently described ETV6/RUNX1-like ALL (Liljebjörn et al., Nature Communications 2016).

Methods: We utilized microarrays to study the gene expression profile (GEP) and biological similarity of the B-ALL subtypes. Five ETV6/RUNX1-positive and five hyperdiploid ALL cases were analyzed using microarrays in parallel to seven CD27pos/CD44low B-other cases that were classified as ETV6/RUNX1-like ALL. We identified multiple regions of acquired copy number aberrations (CNA) unparental disomies (5 to 27 per case) and point mutations (10 to 41 per case) in all 7 cases and 3 in-frame fusions transcribed each in one patient. The most important findings are summarized in Figure 1. All 5 ETV6/RUNX1-like cases harbored a deletion of the ETV6 gene, resulting in an in-frame ETV6/BORC5 fusion in one of them. The deletion of ARP2P21 was found in 3 cases, and the deletions of PAX5, ATP10A, BTG1 and the gain of RUNX1 were found in 2 cases each. The ARP2P21 deletions displayed a strikingly uniform character and were highly enriched in ETV6/RUNX1-like ALL. Using WES and RNAseq, no recurrently mutated gene and no in-frame fusions were found, respectively, except for the ETV6/BORC5. Integrating data from all platforms, we identified IKZF1 as another recurrently affected gene; a deletion, a nonsense mutation and an IKZF1-involving out-of-frame fusion were found in one case. The other cases with available material. Microarray data from all 17 B-ALL cases were combined with data from an independent Italian cohort of 291 BCP-ALL cases (including ETV6/RUNX1-positive, BCR/ABL1-positive, TCF3/PBX1-positive, KMT2A-rearranged, hyperdiploid and B-other ALL cases) whose specimens were analyzed using the same microarray. To study the genomic background, we performed comprehensive profiling using single nucleotide polymorphism (SNP) arrays and whole exome and whole transcriptome sequencing (WES and RNAseq).

Results: In the hierarchical clustering based on GEP all five ETV6/RUNX1-positive cases and 5 of 7 CD27pos/CD44low B-other cases clustered within the ETV6/RUNX1-positive cluster. These B-other cases were thus classified as ETV6/RUNX1-like ALL. We identified multiple regions of acquired copy number aberrations (CNA) unparental disomies (5 to 27 per case) and point mutations (10 to 41 per case) in all 7 cases and 3 in-frame fusions transcribed each in one patient. The most important findings are summarized in Figure 1. All 5 ETV6/RUNX1-like cases harbored a deletion of the ETV6 gene, resulting in an in-frame ETV6/BORC5 fusion in one of them. The deletion of ARP2P21 was found in 3 cases, and the deletions of PAX5, ATP10A, BTG1 and the gain of RUNX1 were found in 2 cases each. The ARP2P21 deletions displayed a strikingly uniform character and were highly enriched in ETV6/RUNX1-like ALL. Using WES and RNAseq, no recurrently mutated gene and no in-frame fusions were found, respectively, except for the ETV6/BORC5. Integrating data from all platforms, we identified IKZF1 as another recurrently affected gene; a deletion, a nonsense mutation and an IKZF1-involving out-of-frame fusion were found in one case. The other cases with available material. Microarray data from all 17 B-ALL cases were combined with data from an independent Italian cohort of 291 BCP-ALL cases (including ETV6/RUNX1-positive, BCR/ABL1-positive, TCF3/PBX1-positive, KMT2A-rearranged, hyperdiploid and B-other ALL cases) whose specimens were analyzed using the same microarray. To study the genomic background, we performed comprehensive profiling using single nucleotide polymorphism (SNP) arrays and whole exome and whole transcriptome sequencing (WES and RNAseq).

Summary/Conclusions: We showed that similarly to ETV6/RUNX1-positive ALL, ETV6/RUNX1-like ALL is also associated with CD27pos/CD44low/neg immunophenotype. We identified deletion of ARP2P21 to contribute to the specific genomic profile of ETV6/RUNX1-like ALL in addition to lesions of ETV6

Figure 1.
and KZF1. In conjunction with the single published study, our study establishes the ETV6 lesion as the only common genetic aberration and thus the most likely key driver of ETV6/RUNX1-like ALL.

GENETIC ALTERATIONS IN CHILDREN WITH T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA IN TAIWAN
1Mackay Children's Hospital and Mackay Medical College, Taipei, 2Chang Gung Memorial Hospital and Chang Gung University, 3Chang Gung Memorial Hospital, Taoyuan, Taiwan, Republic of China

Background: The leukemogenesis of T-cell acute lymphoblastic leukemia (T-ALL) involves multistep processes of genetic alterations. Aims: We aimed to determine the genetic alterations including common fusion transcripts, overexpression of T-cell transcription factor oncogenes and deletion or mutations of targeted genes in pediatric T-ALL in Taiwan as well as their impact on outcomes in those treated with TPOAG-2002 protocol. Methods: Between 1995 and 2015, bone marrow samples from 102 children (<18 years old) consecutively diagnosed with T-ALL were examined. SIL-TAL1, MLL-ENL, and CALM-AF1/20 transcripts were detected by RT-PCR assays. RTPCR with TaqMan assays were used to measure the expression of HOX11, TAL1, and NYLI oncogenes expressed as normalized copy number (NCT) to ABL internal control gene. TAL1 overexpression was defined as NCT > the lowest level of SIL-TAL1 positive patients. Overexpression of HOX11 and TAL1 was defined as NCT > the upper limit of the 95% confidence interval control genes. Mutations of NOTCH1, FBXW7, PHF6, JAK1, JAK2, RUNX1, WT1, NRAS, and KRAS genes were analyzed by PCR-based assays followed by direct sequencing. P16 deletion was determined by PCR or multiplex ligation probe amplification (MLPA), PTEN and PHF6 mutations, MYB duplication and NUP214-ABL1 deletion. Results: The frequency of SIL-TAL1 fusion transcript was 16.2%, MLL-rearranged 5.1%, CALM-AF1/20 1.0%, and no NUP214-ABL1. The frequency of NOTCH1 mutations was 46.9%, FBXW7 13.0%, RUNX1 5.2%, JAK1 6.3%, NRAS 6.2%, KRAS 2.1%, and no JAK1 or JAK2 mutations. P16 deletion was present in 56.2%, PTEN in 11.1%, PHF6 deletion/mutation in 13.4%, and MYB duplication in 4.8%. Overexpression of TAL1 was present in 26.4%. 62% of patients were positive for HOX11. The correlation among the genetic alterations showed that NYLI overexpression occurred more frequently in P16 wild-type compared with P16 deleted patients (P<0.003) and absence of SIL-TAL1 transcript was significantly associated with NYLI overexpression (P<0.018). A comparison of outcomes was made according to the status of each genetic abnormality. NOTCH1 mutations conferred a favorable overall survival (OS) (P=0.025), PHF6 deletion/mutation conferred an inferior OS (P=0.030). PTEN deletion was associated with shorter relapse-free survival (RFS) (P=0.0001) and OS (P=0.0001). Status of other gene mutations, deletion or duplication did not influence the RFS or OS. TAL1 overexpression predicted a higher risk of relapse (37% vs 21%, P=0.006), an inferior RFS (P=0.002) and OS (P=0.025) whereas HOX11 or NYLI overexpression had no prognostic impact. Multivariable analysis, NCT1 muta-tions, and clinical characteristics achieved significant influence for an independent predictor of OS (HR 0.167, P=0.112), PHF6 deletion/mutation was an independent unfavorable predictor for OS (HR 4.596, P=0.006), and PTEN deletion was an independent predictor for both RFS (HR 29.493, P=0.007) and OS (HR 15.830, P=0.003). TAL1 overexpression was an independent risk factor for both RFS (HR 9.639, P=0.014) and OS (HR 2.701, P=0.047).

Summary/Conclusions: The present study showed that NYLI overexpression was negatively associated with SIL-TAL1 or P16 deletion. PHF6 deletion/mutation, PTEN deletion, and TAL1 overexpression were the independent predictors of adverse outcomes. COMPUTATIONAL METHODS TO FIND NEW THERAPEUTIC TARGETS IN ALL, SYSTEMATICAL IDENTIFICATION OF ESSENTIAL GENES
L. Ekdahl1,*, M. Pertesi1, A. Palm1, L. Järvstråt1, E. Johnsson1, U. Gullberg1, A.-K. Wihlborg1, B. Nilsson1
1Division of Hematology and Transfusion Medicine, Lund University, Lund, Sweden

Background: Deletion of chromosomal material is a hallmark of cancer genomes. While these lesions primarily target tumour suppressor genes, neighbouring genes are frequently deleted in parallel. Loss of chromatin insufficiency of a neighboring gene that is essential for the survival of the cancer cells may constitute potential therapeutic targets in that the cancer cells may be selectively sensitive to further suppression of the function of that gene. Identifying such vulnerabilities is one of the current challenges in cancer genomics. We show that vulnerabilities in cancer cells can be identified by applying pattern recognition techniques to a copy-number dataset. This approach will identify genomic regions with potential essential genes. Genes in these regions can be evaluated downstream by genome editing techniques to find novel targets for treatments. Using pattern recognition techniques to find essential genes is straightforward, easily applied and non-time-consuming method compared to genome wide experimental approaches.

Aims: Develop a computational framework to find regions with potential essential genes from copy-number data, with a primary focus on hematological malignancies and in particular ALL.

Methods: Our computational framework first selected regions of the tumour genome with heterozygous, but not homozygous, deletion. In sections flanking these regions we scanned for linear increases in homozygous deletion frequency. Genes near the start of these increases that have more than one case with homozygous deletion are discarded. Remaining genes were scored by calculating a line of best fit using the least square method towards the nearby peak in homozygous deletion. We sorted the results by settings cut-offs for the slope, amplitude and correlation coefficient of the linear regression line. Genes with the highest scores were then manually evaluated by comparing to known mean copy-number loss dependence score from other data-sets, by graphical visualisation and by investigation of their known function. The framework we analysed contains copy-numbers from tumour samples matched to normal blood samples or normal tissue from the same donor. To validate the essentiality of genes in the discovered regions we used pooled CRISPR/Cas9 editing in ALL cells with and without a deletion of the driving tumour suppressor.

Results: Our framework identified several regions with potential essential genes around well-known tumour suppressors. The strongest signals in the data set were located around the tumour suppressor CDKN2A. Downstream analysis with pooled CRISPR/Cas9 editing in ALL cells with and without a CDKN2A deletion provided evidence for the essentiality of several genes in the identified region, including one gene that was essential only in CDKN2A-deleted cells.

Summary/Conclusions: In conclusion, we explored a computational approach to identify regions with essential genes in copy-number datasets. Application of our approach to real data showed several regions with essential gene candidates around well-known tumour suppressors, indicating the framework works. Downstream genome-editing experiments in model cell-lines provided further evidence for the essentiality of some genes found in such identified regions. While we cannot yet draw conclusions on whether some of these genes are viable therapeutic targets it allows for informed guesses on limited sets of genes for further focused analysis in hematological cell-lines.

TARGETING ANTIOXIDANT ENZYMES FOR THE TREATMENT OF B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA
K. Fidytk1,*, K. Szczygiel1, A. Pastorczyk2, A. Graczyk-Jarzynka1, E. Patkowska1, K. Fidyt1,*, K. Szczygiel1, A. Pastorczak2, A. Graczyk-Jarzynka1, E. Patkowska1, K. Fidyt1,*, K. Szczygiel1, A. Pastorczak2, A. Graczyk-Jarzynka1, E. Patkowska1
1Department of Immunology, Medical University of Warsaw, Warsaw, 2Department of Pediatrics, Oncology, Hematology and Diabetology, Medical University of Lodz, Lodz, 3Department of Hematology, Institute of Hematology and Transfusion Medicine, Warsaw, Poland

Background: B-cell acute lymphoblastic leukemia (B-ALL) is a genetically heterogeneous disease characterized by abnormal expansion of B cell precursors and is mainly affecting children and adolescents. The backbone of the treatment is chemotherapy providing high cure rates in pediatric ALL (> 85%) but much worse treatment response and even lethal outcome in adults (ponse 50%). Patients who relapse develop refractory, chemotherapy resistant disease and remain a clinical challenge. Growing body of evidence suggests that disturbance of redox homeostasis is a promising anticancer approach. Due to high metabolic demands and proliferation rate cancer cells elevate their antioxidative capacity to overcome excessive ROS production and depend on these antioxidant interventions for their survival. One of the oxidative stress protectors are peroxiredoxins (PRDXs) that next to thioredoxins (TXNs) belong to the TXN-family and are the key components of TXN antioxidant system. PRDXs are enzymes involved in scavenging peroxides. TXNs are responsible for cysteine-thiol disulfide exchange in numerous protein substrates.

Aims: To investigate the potential of targeting the TXN antioxidant enzymes as a novel pro-oxidative strategy in B-ALL treatment.

Methods: We have used three different cell lines representing distinct cytogenic subgroups of B-ALL: BV-173 (BCR-ABL), SEMK-2 (MLL-AF4) and NALM-6 (t(12;21)). ROS levels were measured using Quant-ROS, RNA and protein levels of TXN-family enzymes were measured by quantitative PCR and immunoblotting, respectively. Downregulation of PRDX1 was established by a novel CRISPR/Cas9 gene editing system. We have employed lenti-
CRISPR v2 plasmid to produce lentiviral vectors encoding PRDX1-specific sgRNA and Cas-9 and used them to generate BV-173 cells with PRDX1 genomic deletion. Proliferation rate was evaluated by trypan blue exclusion method. Cytostatic/cytotoxic effects of TXN-family enzymes inhibitors, such as adenanthin (ADE), auranothin (AUR) and SK053 were assessed by MTT viability assay and by detection of propidium iodide-positive cells in flow cytometry.

Figure 1.

Results: We have found that B-ALL cell lines exhibit significantly higher levels of ROS as compared to normal B cells isolated from human tonsils (Fig.1A). In accordance with this observation, our analysis of TXN antioxidant enzymes gene expression in B-ALL cell lines showed their upregulation (Fig.1B). Analysis of deposited data revealed that PRDX1 expression level is the highest in B-ALL among the other types of leukemia (Fig.1C). Moreover, we have observed elevated expression of PRDX1 in malignant lymphoblasts derived from pediatric patients at both RNA and protein levels. Genomic deletion of PRDX1 in BV-173 cells leads to suppression of their proliferation rate, comparing to parental cells and cells transduced with mammalian non-targeting sgRNA. These results allow us to suspect that PRDX1 may play growth-supporting role in these cells. Targeting TXN-family enzymes was also performed with the use of various small molecule inhibitors. Both B-ALL cell lines and primary cells are sensitive to PRDX and TXN inhibitors, which reduce cell viability in dose-dependent manner.

Summary/Conclusions: All the above results suggest that targeting TXN antioxidant system may exert desirable anticancer effects in the treatment of B-ALL. Inhibitors of TXN-family enzymes can be considered as putative agents to use in combination with classical drugs and improve existing therapeutic approaches. Further studies are underway.

Background: The IGF2 mRNA binding protein 1 (IGF2BP1, other aliases IMP-1 (IMP1), CRD-BP (CRDBP), ZBP-1 (ZBP1), and VICKZ1) belongs to a family of regulatory RNA-binding proteins with an oncotelic expression pattern. IGF2BP1 has also been identified to be exclusively specific for ETV6/RUNX1-positive acute lymphoblastic leukemia (ALL) but biological significance of IGF2BP1 overexpression has not been thoroughly investigated to date (Andersson, Olofsson et al. 2005; Stokšus, Gineikiene et al. 2011). We have recently contributed by reporting that ETV6/RUNX1 transcript is a target of RNA-binding protein IGF2BP1 in t(12;21)(p13;q22)-positive ALL, suggesting a role of IGF2BP1 in ETV6/RUNX1-mediated leukemogenic events (Stokšus, Vaitkevičienė et al. 2016).

Aims: To define the biological significance of IGF2BP1 overexpression in t(12;21)(p13;q22) ETV6/RUNX1-positive ALL.

Methods: In this study we have used stable sublines with downregulated IGF2BP1 from our previously published study (Stokšus, Vaitkevičiene et al. 2016). Dynamics of viable cell population was assessed by flow cytometry using 7-AAD staining (BD Biosciences) following 72 hrs culture in complete medium. An EdU flow assay (Thermo Fisher Scientific, TFS) was used to assay DNA replication in proliferating cells. Spontaneous and doxorubicin (Doxo), staurosporine (STS), and STAT3 selective inhibitor S3I-201 (all from Santa Cruz Biotechnology) induced cell death rates were determined by Annexin V (TFS) and 7-AAD staining. All samples were analyzed on Accuri C6 cytometer (Accuri Cytometers) using CFlow Plus and FCS Express software (De Novo Software). IGF2BP1, ETV6/RUNX1, and STAT3 RT-qPCR was performed previously (Stokšus, Gineikiene et al. 2011). Statistical analyses performed using GraphPad Prism software (GraphPad Software).

Results: Downregulation of IGF2BP1 by 2-fold have rendered into approximately 2-fold lower population growth rate, increasing levels of spontaneous cell death in dynamics, and modest yet statistically significant attenuation of cell cycle progression (35.13% vs 40.40%, p<0.0001). Data from treatment with 50 nM of Doxo, 250 nM of STS suggest that IGF2BP1 downregulation has no effect on pharmacological effectiveness of these drugs. In contrast, IGF2BP1-downregulated cells are more sensitive to pharmacological inhibition of STAT3 even upon treatment with suboptimal 25 µM concentration of S3I-201. Lastly, we have probed if STAT3 transcript levels could be sustained by IGF2BP1 protein as in agreement with previously reported (Stohr, Kohn et al. 2012) and our unpublished insights from anti-IGF2BP1 RNA immunoprecipitation datasets. Correlation analysis of RT-qPCR data have confirmed these assumptions as downregulation of IGF2BP1 expression have resulted in a decrease of ETV6/RUNX1 mRNA (r2=0.8253, p<0.001, slope 0.9459) and also STAT3 transcript levels (r2=0.7709, p=0.002, slope 0.6436). These data suggest that STAT3 transcript is also a potentially regulated by RNA-binding protein IGF2BP1 in t(12;21)(p13;q22)-positive ALL model cells (Fig 1).

Figure 1.

Summary/Conclusions: We provide evidence that IGF2BP1 promotes survival of t(12;21)(p13;q22)-positive ALL model cells through cell cycle progression and preventing spontaneous cell death. Potentiation of ETV6/RUNX1®STAT3 signaling axis is one of the possible mechanisms responsible for this phenotype as IGF2BP1 maintains appropriate levels of primarily ETV6/RUNX1 and also STAT3 mRNAs. Further studies are clearly warranted to further delineate the role of IGF2BP1 in t(12;21)(p13;q22)-positive ALL (Stokšus, Eidukaitė et al. 2016).

6-MERCAPTOPURINE PROMOTES ENERGETIC FAILURE IN LEUKEMIC T-CELL LINE JURKAT

A. Fernandez Ramos1,2,*, C. Marchetti-Laurent1,2, V. Poindessous1,2, A. Parnis1,2,3,4, S. Antonio2,3, P. Laurent-Puig1,2,4, S. Bortoli2,3, M.-A. Loriot1,2,4, N. Pallet1,2,4
1INSERM UMRS-1147, 2Université Paris Descartes, 3INSERM UMR-S 1124, 4Assistance Publique-Hôpitaux de Paris, Hôpital Européen Georges Pompidou, Paris, France

Background: 6-Mercaptopurine (6-MP) is a thiopurine drug with antiproliferative effects by blocking purine synthesis. 6-MP is largely prescribed for the treatment of childhood acute lymphoblastic leukemia (ALL). Recent evidence
suggest that 6-MP inhibits the phosphatidylinositol 3 kinase (PI3K)/ mammalian target of Rapamycin (mTOR) signaling pathway and modulates the transcriptional activity of hypoxia inducible factor 1α (HIF-1α). As mTOR and HIF-1α are key mediators of metabolic reprogramming in cancer and normal T cells, we hypothesized that 6-MP can impact cellular metabolic remodeling through its action on nucleotide synthesis. Metabolic reprogramming fosters glycolysis, glutaminolysis and nucleotide synthesis to sustain cell proliferation and proliferation, a key feature of cancer cells. This metabolic switch is regulated by metabolic checkpoints, including mTOR, AMP-activated protein kinase (AMPK) and the oncogenes Myc and HIF-1α.

**Aims:** Our objective is to study the impact of the antiproliferative molecule 6-mercaptopurine (SM) on the remitting T-cell leukemia cells metabolic reprogramming.

**Methods:** In vitro experiments were performed in a Jurkat T cell line. Cells were incubated with 6-MP from 6h to 72h. We used RT-PCR, Western Blot, glucose uptake and glycolytic and glutaminolytic flux to evaluate the metabolic effects of 6-MP.

**Results:** Our results showed that 6-MP reduces ATP content as early as after 2 hours of treatment and this decrease is maintained up to 72 hours. As AMPK is an energetic sensor activated with low ATP content, we studied AMPK activation after 6-MP treatment. We observed that 6-MP treatment activates AMPK after 6 and 48 hours of treatment. Moreover, 6-MP significantly modifies the transcriptional activity of hypoxia inducible factor 1α. Genes implicated in glycolysis, glutaminolysis and nucleotide synthesis after 24, 48 and 72 hours of treatment. In addition, 6-MP inhibits the expression of the metabolic checkpoints mTOR, HIF-1α and Myc after 24, 48 and 72 hours of treatment. 6-MP also decreases glucose and glutamine oxidation after 48 hours of treatment by 60% and 35%, respectively, suggesting that 6-MP inhibited TCA (tricarboxylic acid cycle) and OXPHOS (oxidative phosphorylation). The production of lactate, a marker of aerobic glycolysis, is significantly decreased by 30% after 6-MP treatment for 48 hours, meaning that aerobic glycolysis is also inhibited. However, 6-MP has no effect on glucose uptake or on glucose transporters (Glut1 or Glut3, SLC2A1 or SLC2A3). In addition, our original approach to better understand the cellular effects of 6-MP treatment.

**Conclusion:** In conclusion, our findings offer new insights on the cellular effects of 6-MP treatment by promoting an early energetic stress that influence proliferation and raise apoptosis in leukemia T cells. Interestingly, the inhibition of the metabolic checkpoints (mTOR, HIF-1α, Myc) and the diminution of glycolytic and glutaminolytic fluxes by 6-MP treatment provide an original approach to better understand the cellular effects of 6-MP treatment.

**GENETIC ABERRATIONS IN ADULT ACUTE LYMPHOBLASTIC LEUKEMIA AND THEIR IMPACT ON CLINICAL OUTCOME**

K. Takahashi1,*, F. Wang2, K. Patel2, C. Bueso-Ramos2, X. Song2, J. Zhang2, C. Gumbs2, L. Latazas2, S. Tippen2, T. Kadia2, F. Ravandi1, G. Garcia-Manero1, N. Short1, N. Jain1, M. Konopleva1, H. Kantarjian1, A. Futreal1, E. Jabbour1

**1Leukemia, 2UT MD Anderson Cancer Center, Houston, United States**

**Background:** Genetic alterations have prognostic impact on pediatric patients with B cell acute lymphoblastic leukemia (B-ALL). Genomic landscape and its impact on clinical outcome is less understood in adults with B-ALL.

**Aims:** To describe the landscape of genomic aberrations and analyze the correlation with clinical characteristics and prognostic impact in adults with B-ALL.

**Methods:** We assessed bone marrow specimens from 64 consecutive adults with a median age of 51 years (range 18 to 80) with previously untreated B-ALL between 2012 and 2015. The cohort included 23 Philadelphia chromosome (ph)-positive and 41 Ph-negative B-ALL. Sixty patients (94%) were treated with Hyper-CVAD (hyperfractionated cyclophosphamide, vincristine, doxorubicin, dexamethasone) and prednisolone (prednisone 16 mg/m², dexamethasone alternating with high-dose methotrexate and cytarabine)-based regimen; 23 of them received additional tyrosine kinase inhibitor for Ph-positive disease (dasatinib [N=4] or pontinib [N=19]). Four patients (6%) were treated with augmented BFM (Berlin-Frankfurt-Munster) regimen. Genomic DNA extracts were sequenced by targeted capture exome sequencing of 295 genes that are recurrently mutated in hematologic malignancies (median 280x coverage). The panel comprised a minimum of 25 markers, and 25 markers and 320Mb for CN-LOH.

**Results:** Among the 64 patients, we detected 70 point mutations in 40 genes in 38 patients (54%). Ph-positive ALL had significantly less point mutations than Ph-negative ALL (median number of mutations/patient 0 [range: 0-2] versus 1 [range: 0-4]; P=0.002). The most frequently mutated genes were TPS5 (17%) followed by MLLT3 (10%), AK2 (6%), NRAS (6%), NFI (5%), RUNX1 (5%), and TET2 (5%). TP53 mutations were strongly associated with Ph-negative B-ALL (P=0.004) and low hypothyroidism (P=0.009). Recurrent CNVs involved loss/deletion in genes such as PAX5 (38%), TCF3 (38%), IKZF1 (31%), CDKN2A/2B (31%), BTLA (25%), CD200 (22%), ETV6 (22%), RBL (20%), MIR15a/16-1 (15%), EG14 (14%), and MLLT3 (11%), whereas gain/amplification was detected in NRASC2 (18%), ERG (15%), RUNX1 (15%), and LEF1 (14%). MLLT3 loss/deletion was specific to Ph-negative ALL (0% for Ph-positive versus 17% for Ph-negative, P=0.036) and MIR15a/16-1 loss/deletion had non-statistically significant association with Ph- ALL (4% versus 22% respectively, P=0.08). In this cohort, 78% and 100% of the Ph-negative and Ph-positive ALL achieved complete remission, respectively. None of the point mutations or CNVs were associated with differential response to therapy. Survival analysis was stratified by Ph status. Complex karyotype had trend toward worse event-free survival (EFS) (median EFS 3.6 months versus 26.3 months, P=0.06) in Ph-negative ALL. None of the point mutations or CNVs were associated with EFS/overall survival (OS) in Ph-negative ALL. Notably, TP53 mutation nor low hypothyroidism did not affect EFS/OS in the current cohort. In Ph-positive ALL, IKZF1 deletion/loss was associated with a trend toward worse EFS (median EFS 3.6 months versus 21.3 months, P=0.07) but it did not affect OS.

**Summary/Conclusions:** Genetic analysis highlights the molecular heterogeneity of adult B-ALL. Adult B-ALL is frequently associated with CNVs and point mutations are less frequent. Prognostic impact of genetic alteration in adult B-ALL appears to be limited except for IKZF1 deletion/loss, which may predict worse EFS in Ph-positive B-ALL.

J. ribera2, J. Carreras Leukaemia Research Institute, 2Universitat Autònoma de Barcelona, 3Catalan Institute of Oncology at Germans Trias i Pujol Hospital, Badalona, 4Catalan Institute of Oncology at Josep Trueta Hospital, Girona, 5Catalan Institute of Oncology at Duran i Reynals Hospital, Hospitalat de Llo- bregat, 6Catalan Institute of Oncology at Joan XXIII Hospital, Tarragona, 7Mutua de Terrassa, Terrassa, 9Doce de Octubre Hospital, Madrid, 10Clinic Hospital of Valencia, Valencia, 11Josep Carreras Leukaemia Research Institute, 12Hospital Clinic, Institut d’Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), 13University of Barcelona, 14Sant Pau Hospital, Barcelona, 15Reina Sofia University Hospital, Cordoba, Spain

**Background:** The survival rate of relapsed adult acute lymphoblastic leukemia (ALL) is around 10%.

**Aims:** We looked for recurrent Copy Number Alterations (CNA) in relapsed adult B cell progenitor ALL (BCP-ALL) to shed light into the molecular mechanisms of relapse.

**Methods:** BM or PB samples with at least 30% of blasts from 31 adult BCP-ALL patients at 1st relapse and, of them, 21 paired diagnosis and relapse samples were analysed by MLPA (MRC-Holland, The Netherlands). 19 out of these 21 paired samples were analysed by SNP array with CytoScan HD chips (Affymetrix, Santa Clara, California, USA). CNV analysis was performed for all genes and encompassed a minimum of 25 markers, and 25 markers and 320Mb for CN-LOH.

**Table 1:**
Results: With a median follow up of 12.43 [2.4;3.0] months, the median OS of the 31 patients at first relapse was 7.9 months. [2.4;13.5]. The OS of patients at first relapse was significantly lower in those having more than 3 CNA by MLPA (median s3 CNA 9.7 months [0-20.9] vs median s3 CNA 4.2 months (0.6-7.8), p=0.042). CDKN2A/B deletion was the most common CNA observed at relapse (16/31, 52%) and most of these deletions were homozygous (12/16, 75%). ORR of patients harboring CDKN2A/B deletions was more frequent at relapse (from 8 heterozygous CDKN2A/B deleted patients at diagnosis, 7 became homozygous at relapse, p=0.070). SNP arrays detected 554 CNA (409 DEL, 125-DUP and 20 LOH) in 34 samples of 19 patients. At diagnosis (n=16 patients) the mean number of CNA was 12.5 (9.6 DEL, 2.3 DUP and 0.4 LOH); while at 2nd relapse (n=13 patients) was 17.8 CNA (12.6 DEL, 4.2 DUP and 1 LOH) and in second relapse (n=5 patients) was 21 CNA (14.6 DEL, 6.4 DUP and 0.4 LOH) (p=0.007). All matched diagnosis and first relapse samples (available for 10 patients) showed common CNA. In 6/10 cases some of CNA were retained from diagnosis while others were acquired or lost at relapse (suggesting different biological rationale in their acquisition). Finally, the most retained or acquired CNA at diagnosis were 9p, 11q, 12p, 22q and 7p deletions and 1q, 8q, 17q, 21+ and 20+ duplications. The tumor suppressor genes such as TP53, FOXO1, FOXO3 or RB1 were detected in 3 patients.

Summary/Conclusions: BCP-ALL has a high genetic heterogeneity at relapse, with most of the genetic alterations playing important roles for disease progression. This heterogeneity points out the need for search of personalized treatments depending on their molecular features. Finally, we propose that the Instituto de Salud Carlos III, Ministerio de Economía y Competitividad, Spain, Red Temática de Investigación Cooperativa en Cáncer (RTICC, FEDER) (RD12/0036/0044); Sociedad Española Hematología y Hemoterapia; 2014 SGR226 (GRE) Generalitat de Catalunya; Fundació Internacional Josep Carreras, Celgene Spain and “la Caixa” Foundation.

IGF1/IRS PHARMACOLOGICAL INHIBITION REDUCES CELL PROLIFERATION AND MIGRATION IN ACUTE LYMPHOBластIC LEUKEMIA CELLS

A.P.N. Rodrigues Alves1, J. Machado-Neto1, R. Scopim-Ribeiro1, J.C. Fernandes1, A.A. Fenerich1, F.B. Da Silva1, P.S. Scheucher1, B.P. Simões1, E.M. Rego1, A.J. Ridley2, F. Traina1

1Internal Medicine, University of Sao Paulo at Ribeirão Preto Medical School, Ribeirão Preto, Brazil. 2Randall Division of Cell and Molecular Biophysics, King’s College London, London, United Kingdom

Background: A recurrent clinical complication of the acute lymphoblastic leukemia (ALL) is the infiltration of lymphoblast into central nervous system. The IGF1/IGFR signaling pathway is initiated through binding of the ligand (IGF1) to its transmembrane receptor (IGFR1), and the subsequent activation of its substrates, IRS1 and IRS2, which transmit mitogenic and antiapoptotic signals, mainly through the modulation of the PI3K/AKT/mTOR and MAPK signaling pathways. These signaling pathways play an important function in cell proliferation, survival and migration of leukemia cells. We have previously noticed that NT157 (IRS1/2 pharmacological inhibitor) significantly decreased cell viability and induced apoptosis in T-ALL (Jurkat and MOLT-4), and in B-ALL (Namalwa and Raji) cell lines and in primary ALL cells (T-ALL [n=2] and B-ALL [n=2]), although did not presented citotoxicity in peripheral blood mononuclear cells (PBMC) from healthy donors. In addition, NT157 was able to induce the p21 (CDKN1A) expression, which is a cell cycle arrest-related gene. We also observed that OSI-906 (IGF1/IGFR pharmacological inhibitor) significantly reduced cell viability, but did not induce apoptosis in ALL cell lines tested, and did not modulate viability and apoptosis of primary ALL cells and normal PBMC. The molecular mechanism by which leukemia cells break the blood-brain barrier, allowing the infiltration of the central nervous system and causing serious complications is not well understood.

Aims: We herein aimed to investigate the impact of the pharmacological IGF1/IR and IRS1/2 inhibition on cell proliferation and migration in ALL cells.

Methods: T-ALL Jurkat and B-ALL Namalwa were used. Cell lines were treated or not with NT157 at 0.2, 0.4, 0.8, 1.6 and 3.2 µM, or with OSI-906 at 0.5, 5, 10, 20 and 40 µM for 24 and 48 hours. After drug exposure, cell lines were evaluated for cell proliferation (Ki67 assay), migration (Time-Lapse microscopy analysis) and cell adhesion (using human umbilical vein endothelial cells HUVEC monoclonal). Statistical analyses were performed by the ANOVA. Value p <0.05 was considered statistically significant.

Results: In ALL cells, NT157 strongly reduces cell proliferation in a dose-dependent manner (p<0.05) after 24 hours of treatment. OSI-906 was not able to reduce cell proliferation in these cell lines. The 24 hours treatment with 10µM OSI-906 decreased accumulated distance (µm) and velocity (µm/min), while 0.4µM NT157 reduces only the accumulated distance of Jurkat cells under migration assay into fibronectin monolayer, after being filmed by time-lapse microscopy for 3 hours; the images were captured every 1.5 minutes. Although there is a trend for reduction, cell adhesion between Jurkat and Namalwa leukemia cells and the human endothelial cell monolayer was not significantly modulated by treatment with both inhibitors.

Summary/Conclusions: The reduction in cell proliferation found during IGF1/IRS pharmacological inhibition reaffirms the important role of these proteins on malignant phenotype of ALL cells. Migration analysis indicated that NT157 and OSI-906 are potential inhibitors of transendothelial migration in ALL cell lines and contribute with new perspectives on the participation of the IGF1/IRS1 pathway in the break of the blood-brain barrier.

LEUKEMIA-PROVAGATING CELLS DEMONSTRATED DISTINCTIVE GENE EXPRESSION PROFILES COMPARED WITH THE OTHER CELL FRACTIONS IN PATIENTS WITH DE NOVO PHILADELPHIA CHROMOSOME-POSITIVE PH+ALL

H.-Y. Zhao1, Y. Song1,2, X.-N. Cao1, Y.-Z. Qin1, Y.-Y. Lai1, H. Jiang1, Q. Jiang1, Y. Kong1, X.-J. Huang1, 1Peking University People’s Hospital, Peking University Institute of Hematology, 2Peking-Tsinghua Center for Life Sciences, Academy for Advanced Interdisciplinary Studies, Peking University, Beijing, China

Background: Relapse remains one of the major obstacles in Philadelphia chmosome-positive acute lymphoblastic leukemia (Ph+ALL) even after allogeneic hematopoietic stem cell transplantation (allo-HSCT). Relapse of Ph+ALL may be associated with the persistence of leukemia propagating cells (LPCs), which are defined by their ability to initiate human leukemia and self-renew in immunocompromised mice. In acute myeloid leukemia, higher LPCs frequencies and a gene expression profile typical of LPCs at diagnosis are predictive of unfavorable clinical outcome. Here, we aimed to explore how relapse LPCs were enriched in the CD34+CD38−CD58− fraction using a xenograft assay. Moreover, our cohort study indicate that the LPCs phenotype at diagnosis is an independent risk factor for relapse in Ph+ALL. However, little is known about the differential gene expression profiles between LPCs and the other cell fractions in de novo Ph+ALL patients.

Aims: To identify the potential molecular basis of LPCs-mediated relapse, the gene expression profiles of the sorted LPCs and other cell fractions from patients with de novo Ph+ALL were compared.

Methods: Twenty patients with de novo Ph+ALL were enrolled for this study at Peking University Institute of Hematology from 2015 to 2018. The LPCs (CD34+CD38−CD58−) and other cell fractions (including CD34+CD38+CD58+, CD34+CD38+CD58+ and CD34+CD38+CD58−) were sorted from the bone marrow mononuclear cells of de novo Ph+ALL patients (N=3) using a FACs Aria II. Differential expression analysis between LPCs and the other cell fractions were performed using RNA sequencing (RNA-Seq) and the DESeq package (1.10.1), Gene Ontology (GO) enrichment analysis and Kyoto Encyclopedia of Genes and Genomes (KEGG) analysis. RNA-Seq results were partially validated by a TaqMan-based real-time quantitative polymerase chain reaction (qRT-PCR) technique. Moreover, cell cycle status was compared between LPCs and other cell fractions in de novo Ph+ALL patients (N=20) by flow cytometry.

Results: 1021 genes (301 up-regulated and 720 down-regulated), 1245 genes (354 up-regulated and 891 down-regulated) and 1228 genes (248 up-regulated and 980 down-regulated) were differentially expressed between LPCs, and Other Cell1 (patient No 1), and Other Cell3 (patient No 2), and LPCs, and Other Cell2, (patient No 3), respectively. Most of differential expression of genes (DEGs) are related to the regulation of cell cycle and metabolism. GO analysis identified enriched terms of biological functions in DEGs including ATP binding process, ribonucleotide binding process, nucleoside binding process, DNA replication process, primary metabolic process, etc. KEGG analysis showed significantly enriched signaling pathways involved in DEGs including cell cycle, DNA replication, nucleotide metabolic pathways, biosynthesis of amino acids, glutathione metabolism, p53 signaling pathway, etc. Consistent with RNA-Seq results, mRNA levels of the cell cycle-related genes, such as CDK4 and H2AX, were significantly lower in LPCs fractions than those in other cell fractions. Moreover, the frequencies of quiescent cells in LPCs were significantly higher than those in other cell fractions.

Summary/Conclusions: Distinctive gene expression profiles and cluster, which are mostly related to the regulation of cell cycle and metabolism, were demonstrated between LPCs and the other cell fractions in patients with de novo Ph+ALL. Therefore, our data indicate that it would be of value to develop LPCs biomarkers to contribute to personalized leukemia therapy and the need to identify therapeutic targets directed toward LPCs in Ph+ALL.
Acute lymphoblastic leukemia - Clinical

E835
HOSPITALIZATION FOR PATIENTS IN THE U.S. AND EU TREATED WITH INOTUZUMAB OZOGAMICIN VS STANDARD OF CARE FOR RELAPSED/REFRACTORY ACUTE LYMPHOBластIC LEUKEMIA IN A GLOBAL PHASE 3 TRIAL

Y. Su1, I. Van Oostrum2, E. Vandendriess1, V. Welch1, F.R. Loberiza1

1Pfizer Inc, New York, United States, 2Ingress-health Netherlands, Rotterdam, Netherlands

Background: Inotuzumab Ozogamicin (InO), an anti-CD22 antibody-calicheamicin conjugate, with its once a week one-hour infusion schedule, has demonstrated lower hospital utilization, in association with a clinically meaningful improvement in overall survival, high rate of complete remission, favorable patient-reported outcomes (PRO), and generally manageable safety profile versus standard of care (SOC, intensive chemotherapy) for relapsed/refractory acute lymphoblastic leukemia (R/R ALL) in the phase 3 INO-VATE trial.

Aims: This study aims to determine the region-specific hospitalization days per patient in the INO-VATE trial.

Methods: Patients receiving study treatment (safety population) and recruited from the US and EU were included in the analyses. The total number of days hospitalized for each patient was calculated. Hospital days prior to randomization and those after the end of study treatment were excluded. Due to different durations of treatment for InO and SOC (median 1 vs 3 cycles), calculations were reported for cycle 1 treatment period (randomization to end of cycle 1) and for the entire treatment period (all cycles - randomization to end of treatment).

Results: A total of 264 patients from the safety population of the phase 3 INO-VATE trial were available for the analyses. 149 were from the US, and 115 from 11 of the EU countries. The percentage of patients requiring hospitalization was lower for InO compared to SOC (Table). The median and mean hospitalization days were shorter for patients in the InO arm compared to the SOC arm across both regions. The difference between the two treatment arms appears to be greater in the US compared to the EU. Hospitalizations in the US appear to be shorter than in the EU, particularly for patients receiving InO.

Table 1. Hospitalizations in R/R ALL patients from the INO-VATE trial.

Summary/Conclusions: InO treatment in R/R ALL is associated with less hospitalization across both the US and EU compared to SOC, consistent with InO’s better efficacy, tolerability, PRO and dosing schedule. The finding that US has lower hospitalization than the EU might be explained by different patient care practices in the two regions. Given that hospitalization is the biggest cost driver in cancer care, the data suggest both EU and US could benefit from cost-savings of less hospitalization with InO treatment.

E836
NON-INTERMITTENT BUT NON-INTERRUPTIVE TREATMENT WITH FEWER ALLO-HSCT IS EFFECTIVE STRATEGY FOR ADULT PH-NEGATIVE B-CELL PRECURSOR (BCP-) ALL: OUTCOME OF THE RUSSIAN PROSPECTIVE MULTICENTER ALL-2009 STUDY

E. Parovichnikova1, V. Troitskaya2, A. Sokolov2, O. Gavrilina2, S. Bondarenko3, O. Baranova4, Z. Akhmerzueva2, G. Kliassova2, L. Kuzmina1, E. Gribanova2, G. Baskhaeva2, I. Piskunova2, T. Obukhova6, M. Rusinov7, S. Kulikov1, V. Savchenko1

1BMT department, 2Haematology department, National Research Center for Hematology, Moscow, 3BMT department, Raisa Gorbacheva Memorial Research Institute for Pediatric Oncology, Hematology and Transplantation, St. Petersburg, 4Haematology department, N.N. Blokhin Russian Cancer Research Center, 5Scientifc clinical laboratory of clinical bacteriology, mycology and antibiotic therapy, 6Cytogenetics laboratory, 7Department of biostatistics, National Research Center for Hematology, Moscow, Russian Federation

Background: As Ph-negative-BCP-ALL in adults remains less favorable in prognosis than T-ALL, and by expert opinion needs intensive protocols with high portion of allo-HSCT, the results of treatment based on the different approaches are escalating but non-interruptive treatment with low numbers of allo-HSCT may be of interest and can provide new insights to the common view.

Aims: to evaluate survival data and risk groups in Ph-neg-BCP-ALL pts in the RALL-study.

Summary/Conclusions: InO treatment in R/R ALL is associated with less hospitalization across both the US and EU compared to SOC, consistent with InO’s better efficacy, tolerability, PRO and dosing schedule. The finding that US has lower hospitalization than the EU might be explained by different patient care practices in the two regions. Given that hospitalization is the biggest cost driver in cancer care, the data suggest both EU and US could benefit from cost-savings of less hospitalization with InO treatment.
Methods: The ALL-2009 (NCT01193933) was initiated in Apr 2009. The treatment plan was identical for all risk groups with allo-HSCT indicated only for very high-risk BCP-ALL (t(4;11), t(1;19); WBC >100). Since Apr 2009 till Dec 2016, 329 Ph-negative ALL pts (m.age 28 y (15-55), f/m 147/182) were recruited. Phenotype was unknown in 6 pts, biophenotypic AL was diagnosed in 1 (2%), T-ALL/LBL in 36.7% (n=125), BCP-ALL in 51.9% (n=194). Among BCP-ALL there were 54 early pre-B ALL (72.8%), 101 common ALL (52%), 39 pre-B ALL (20.2%). In BCP-ALL pts m.age was 27 y (15-54), f/m 99/95, initial WBC >9140 FMO (0.4-8990), LDH 901 IU (31-13059), CNS leukemia in 17 pts (8.7%), mediastinal mass in 3 (1.5%), splenomegaly in 111 (57.2%). Standard cyto- genetics was documented in 124 pts (64%), 11% had no mitosis, so information is avail- able in 58.2% (n=112). 43.4% of BCP-ALL (n=49/113) pts had normal karyotype (NK); 7.9% (n=9) and 1.8% (n=2) had t(4;11) and t(1;19) respectively; other abnormalities were detected in 53 (46.9%), including p53 (3.2%), +8 (6.3%), complex karyotype (7.9%), high hyperdiploidy (16%), del(1p) (22.2%, etc. 9 BCP- ALL patients (n=47) were not qualified by the risk in the data-base: 68.1% (n=126) were attributed to the high risk (HR) group (WBC >30; EGG, BI, LDH>2N; late CR, t(4;11)-pos). The analysis was performed in Feb 2017. 191 pts were available for induction outcomes, DFS and relapse probability (RP), and all pts – for overall survival (OS).

Results: CR rate in 191 pts was 87.4% (n=167); induction death occurred in 8.9% (n=17); resistance was registered (7.9% (n=9). Late responders constituted 13.6% (n=26). Death in CR on chemotherapy was 6.3% (n=12) and 1 death after alloHSCT. All-HSCT was performed in 13 (6 – matched related donor, 7 MUD) of 176 patients who survived induction (7.4%), 11 of them – in 1CR. Totally 59 pts (34.9%) had relapsed. At 7y OS for the whole cohort consti- tuted – 54,3%, DFS – 56.5%, RP – 35,4%. In a multivariate analysis for BCP- ALL HR group (age >27y, WBC>75*109/l, t(4;11)).

Summary/Conclusions: Our data demonstrate that non-intensive but non- interruptive treatment with fewer allo-HSCTs is rather effective in adult BCP- ALL producing more than 50% OS at 7 years, though the RP is high. In our study among common risk factors only age, initial WBC and t(4;11) remained the most valuable markers of poorer prognosis, while immunophenotype, time to CR, CNS involvement, and other cyto- genetic markers did not matter. So RALL protocol without intensive highly myelosuppressive consolidation courses and high portion of autologous HSCT, may become an alternative and reproducible approach for adult Ph-negative ALL.

E837

POST-INDUCTION MINIMAL RESIDUAL DISEASE RESPONSE DETERMINED BY MULTICOLOR FLOW CYTOMETRY IS A POWERFUL INDICATOR OF EVENT-FREE-SURVIVAL IN THE CHILDHOOD T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

P. Tembhare1,*, G. Chatterjee1, I. Sanyal1, P. Devre1, S. Ghogale1, N. Patkar1, G. Narula1, B. Arora2, N. Deshpande1, Y. Badrinath1, S. Gujral1, S. Banawali1, P. Subramanian1

1Hematopathology Laboratory, Tata Memorial Centre, Mumbai, Navi Mumbai, India
2Medical Oncology (Paediatrics), Tata Memorial Centre, Mumbai, Mumbai, India

Background: Minimal residual disease (MRD) is a powerful predictor of event- free survival in acute leukemia including T-cell acute lymphoblastic leukemia (T-ALL). Due to lower incidence of T-ALL MRD studies are limited and restricted to a small cohort of patients. Moreover, flowcytometry based MRD (FC-MRD) studies in T-ALL are very few. AIEOP-BFM group showed that late (Day-78) MRD response determines overall risk-of-relapse and event-free survival (EFS) using RQ-PCR. However, a larger study by COG (Brent Wood et al, 2016) demonstrated 7y OS=79%, DFS=71%, RP=23% in the standard risk (SR) group (age >27y, WBC >75*109/l, t(4;11)-pos). The analysis was performed in Feb 2017. 191 pts were available for induction outcomes, DFS and relapse probability (RP), and all pts – for overall survival (OS).

Methods: We studied post-induction (Day-35) MRD (PI-MRD) & post-consol- idation (Day-78) MRD (PC-MRD) in bone marrow samples from 100 patients of T-ALL treated under modified MCP-841 protocol between 2014 & 2016. In T-ALL with early-thymic-precursor (ETP) immunophenotype, patients received dexamethasone in place of prednisolone. MRD was performed using 10-color FC-MRD assay on Navios flow-cytometer (Beckman Coulter, BC) and MRD analysis was performed with Kaluza software v-1.3 (BC). Any detectable level of MRD (≥20 events) was defined as MRD-positive. Events included relapse & disease-related deaths. Statistical analysis was performed using SPSS v.16.

Results: The median age of patients was 11.5 years (range 2–16 y; M:4–6). Based on the immunophenotypic criteria, 13 patients were diagnosed as ETPLL & remaining 87 as non-ETPLL type. PI-MRD was positive in 58/100 (58%) with the median level of 0.23% (range, 0.002% to 6%). PC-MRD was not performed in 71.4% (30/42) of Ph-negative & 1.2% (6/58) Ph-MRD- positive patients. PC-MRD was available in 64 patients (30/42 of PI-MRD-neg- ative & 6/58 of PI-MRD-positive). PC-MRD was positive in 28% (18/64) (median, 0.2% & range, 0.009% to 4%). PI-MRD positivity was significantly high in ETPLL as compared to non-ETPLL (93% vs 53%; p=0.01). Median follow-up of all patients was 14 months (3-38 months). Patients were categorized MRD standard-risk (MRD-SR) if PI-MRD was negative and MRD high-risk (MRD-HR) if PI-MRD was positive with any level. Thus, 42% were categorized as MRD-SR & 58% as MRD-HR. Twenty patients relapsed & of them, six died (2 were ETPLL & 18 non-ETPLL; 3 MRDSR & 17 MRD-HR) within 26 months. Median EFS of MRD-HR patients was significantly inferior as compared to MRD-SR (26 months vs did not reach; & 70.67% vs 92.86%; p=0.0017) (Kaplan-Mayer curve shown in Figure 1). Interestingly, there was no difference in EFS for PI-MRD <0.01% vs >0.01%, suggesting any level of PI-MRD positive indicated inferior EFS. Furthermore, the PC-MRD response was not found to be significant over PI-MRD (P-value=0.17). ETP vs non-ETP status was also not found to be associated with EFS (P-value=0.85).

Figure 1.

Summary/Conclusions: We concluded that 10-color FC-based post-induction MRD response is a powerful indicator of EFS in childhood T-ALL. The frequency of PI-MRD positivity was significantly high in ETPLL indicating a lower tumor clearance rate. There was no difference in the EFS based on the level of PI- MRD-positivity indicating even a low level (<0.01%) PI-MRD is important in risk-stratification of childhood-TALL.

E838

SMAC MIMETICS - A NOVEL THERAPEUTIC APPROACH IN CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA

M. Meyer1,*, J. Zinggrebe1, L.-H. Meyer1, K.-M. Debatin1

1Department of Pediatrics and Adolescent Medicine, University Medical Center, Ulm, Germany

Background: Pediatric acute lymphoblastic leukemia (ALL) is one of the most common malignancies in childhood. Survival rates have increased enormously over the past decades, but the prognosis for patients with relapsed ALL or ALL after alloHSCT is rather poor. Thus, novel therapeutic options are urgently required. The family of inhibitor of apoptosis proteins (IAPs) has been shown to play an important role in the prevention of cell death, and to mediate gene activation important for cell survival. Many of the cellular processes regulated by IAPs are deregulated in cancer. Thus, IAPs represent a promising target in anticancer therapy. IAP antagonists, also known as SMAC Mimetics (SMs), were developed to counteract IAPs function. SMs have been shown to induce cell death in a number of different cancer entities, amongst them B cell precursor (BCP)-ALL. In BCP-ALL, SM-induced cell death was...
**Background:** Acute lymphoblastic leukemia (ALL) exhibits a bimodal age distribution with 60% of cases occurring in children and adolescents (<20 y) and 25% in older adults (>45 y; http://seer.cancer.gov/csr/1975_2013/). As many as 20% of children relapse after initial therapy, with subsequent poor clinical outcomes (Front Oncol 2014;4:63). Promising results were observed with KTE-C19, an anti-CD19 chimeric antigen receptor (CAR) T cell therapy, in B cell malignancies, including refractory, aggressive non-Hodgkin's lymphoma in the ZUMA-1 trial (Blood 2016;128:LBA-6). Here, we present updated results from the phase 1/2 trial of KTE-C19, a phase 1/2 trial of KTE-C19 in pediatric and adolescent patients with relapsed/refractory relapsed/refractory acute lymphoblastic leukemia.

**Aims:** The aim of the phase 1 study is to evaluate the safety of KTE-C19 in pediatric and adolescent patients with R/R ALL. Methods: Pediatric and adolescent patients (aged 2-21 y) with high burden R/R ALL (>25% marrow blasts), adequate renal, hepatic, pulmonary and cardiac function received 2×10^6 CAR T cells/kg after low-dose conditioning chemotherapy consisting of cyclophosphamide (900mg/m² once) and fludarabine (25mg/m²/d for 3 days) (CyFlu). The primary endpoint is the overall response rate of 1 phase 1 trial. The secondary endpoints include efficacy outcomes and biomarker assessments.

**Results:** As of 19 Jan 2017, 5 patients have enrolled and 4 have been treated with KTE-C19 at 2×10^6 CAR T cell/kg. KTE-C19 was successfully manufactured in a centralized, streamlined 6-8-day process for all patients across a wide range of baseline absolute lymphocyte counts (0.21–1.0×10^9/L), except in 1 patient who had disease progression with white blood cells 150,000/µL at apheresis and <0.2% T cells in the apheresis collection. All 4 treated patients had high disease burden with a median marrow lymphoblast content of 57%.
(range, 41–99%). All 4 patients received bridging chemotherapy during the manufacturing period before conditioning chemotherapy and KTE-C19. No patient experienced a dose-limiting toxicity. One patient had a grade 5 adverse event of disseminated mucormycosis which was not related to KTE-C19. Cytokine release syndrome was reported in all 4 patients (all ≤ grade 3); neurologic events were reported in 1 patient (grade 3). All cytokine release syndrome events resolved with tocilizumab, corticosteroids, and/or nilotinib plus other supportive care with a median duration of 8.5 days (range, 4–16 days). Minimal residual disease-negative remission was observed in all 4 patients. One patient received stem cell transplant post-remission, which is allowed per protocol at investigator discretion. Peak expansion of CAR T cells occurred 1–2 weeks post-KTE-C19 infusion. Updated data with additional patients, different dose of KTE-C19, earlier tocilizumab use, and biomarkers will be presented.

Summary/Conclusions: KTE-C19 after low-dose CyFlu has been tolerable and appears safe for further analysis in pediatric and adolescent patients with R/R ALL. No toxicities were observed with KTE-C19 at the 2×10^6 cells/kg dose in patients despite high leukemic burden. All patients receiving KTE-C19 achieved a minimal residual disease-negative remission. Based on these results, ZUMA-4 continues to enroll (NCT02625480).

**COMPARISON OF 8-COLOR FLOW CYTOMETRY AND PCR-BASED METHODS IN MEASUREMENT OF MINIMAL RESIDUAL DISEASE IN ADULT ACUTE LYMPHOBLASTIC LEUKEMIA**

S. Hrabovsky1,2,*, F. Folber1,2, J. Horacek3,4, O. Stehlikova1, H. Jelinkova1, C. Salek1,2, M. Dubek1,2,7

1Department of Internal Medicine, Hematology and Oncology, University Hospital Brno, 2Faculty of Medicine, Masaryk University, Brno, 34th Department of Internal Medicine – Hematology, University Hospital and Charles University, Faculty of Medicine Hradec Králové, 4Department of Military Internal Medicine and Hygiene, University of Defence, Faculty of Military Health Sciences, Hradec Králové, 5Institute of Hematology and Blood Transfusion, 6First Faculty of Medicine, Charles University, Prague, 7Central European Institute of Technology, Brno, Czech Republic

Background: The presence of minimal residual disease (MRD) is the most important prognostic factor in adult acute lymphoblastic leukemia (ALL). MRD monitoring is routine performed by flow cytometry (FCM) and real-time quantitative polymerase chain reaction methods (RT-PCR).

Aims: We conducted a retrospective analysis comparing these MRD measurement methods in ALL patients treated in three Czech hematology/oncology centers within the CELL group (Czech Leukemia Study Group for Life).

Methods: Adult patients (age 18-55) with both Ph-negative and positive ALL were enrolled in the study, all treated consecutively between 2008 and 2016 according to a pediatric-inspired CELL ALL protocol. Samples for MRD evaluation were acquired from bone marrow on day 26 of induction (D26) and in the 11th week of treatment before the first consolidation (W11). We divided RT-PCR MRD positive and negative groups using three different cut-off values and analyzed them separately: 1) 1.0×10^{-3}, 2) 1.0×10^{-4}, 3) every RT-PCR positive result considered MRD positive even below 1.0×10^{-4}. Cut-off value 1.0×10^{-3} was used for FCM MRD. Results were statistically analyzed by the Kaplan-Meier method and log-rank (Cox-Mantel) test.

Results: Total number of 103 patients was evaluated. Nine of them (8.7%) did not reach a hematological remission on D26 were excluded from the study. The 5-year event-free survival of the final cohort was 76.7% for FCM (N=73) and RT-PCR of immunoglobulin heavy chain (IGH, N=62) or T-cell receptor (TCR, N=3) clonal rearrangements and BCR-ABL (N=24), MLL-AF4 (N=4) and E2A-PBX1 (N=1) fusion genes.

**QUALITY-ADJUSTED LIFE YEARS (QALY) FOR INOTUZUMAB OZOGAMICIN VS STANDARD OF CARE FOR RELAPSED/REFRACTORY ACUTE LYMPHOBlastic LEUKEMIA (R/R ALL)**

I. van Oostrum1,*, Y. Su2, B. Hegg1, T. Wilke3, A. Smith4, F.R. Loberiza2

1InnoCure, Amstelveen, Netherlands, 2Ingress Health, New York, United States, 3Ingress-healt Germany, Wismar, Germany, 4Pfizer, Ltd, Walton Oaks, United Kingdom

Background: Inotuzumab Ozogamicin (ino), an anti-CD22 antibody-calicheamicin conjugate, has demonstrated superior clinical activity versus standard of care (SOC; intensive chemotherapy), including clinically meaningful improvement in overall survival (OS), high rates of complete remission (CR) and potentially curative hematopoietic stem cell transplantation (HSCT), and favorable patient-reported outcomes for R/R ALL in the phase 3 INO-VATE trial. Quality of life (QoL) is an important consideration for R/R ALL patients in both short- and long-term survival.

Aims: This study aimed to estimate mean overall survival adjusted for QoL (QALY) for patients treated with inO vs SOC.

Methods: A Markov model was developed with five health states - No CR, CR, post-HSCT, progression, and death. Lengths and transition probabilities between health states and mortality rates were based on the InO-VATE trial. These rates were extrapolated to a lifetime horizon using parametric survival curves fitted to available OS data, and published literature for survival beyond available data. Utilities (QoL valuations) for each health state were based on the patient-reported EQ-5D scores collected in the InO-VATE trial and a literature review for health states not captured in the trial. Disutilities from adverse events experienced during and after treatments, including adverse events as a result of subsequent HSCT such as veno-occlusive disease (VOD), were taken into account in overall QoL. Outcomes were discounted at 1.5% and half-cycle corrected.

Results: The estimated mean LY and QALY in each health state for InO and SOC and their differences are shown in Table. Most gains in LY and QALY for InO over SOC were from Post-HSCT. These gains are greater in the InO arm and potentially curative hematopoietic stem cell transplantation (HSCT), and favoring the patient-reported-outcomes for R/R ALL in the phase 3 INO-VATE trial. Quality of life (QoL) is an important consideration for R/R ALL patients in both short- and long-term survival.

Summary/Conclusions: This analysis taking into account both quantity and quality of life estimates shows that InO offers an average of nearly 2 years of QALY compared to SOC in R/R ALL. Based on higher CR and HSCT rates, “tail-of-the-curve” survival gains, and better QoL. This can help inform patients, physicians and payers in decision making.

**A COST-EFFECTIVE, HIGH SENSITIVITY 10-COLOR SINGLE TUBE FLOW-CYTOMETRY BASED B-CLL PRECURSOR ACUTE LYMPHOBLastic LEUKEMIA MINIMAL RESIDUAL DISEASE (MRD) ASSAY WITH STUDY OF ARTIFACTS AND MIMICS**

G. Chatterjee1,*, D. Dhaliwal1, S. Ghogale1, B. Yajamanam1, N. Deshpande1, 2

1Department of Internal Medicine, Hematology and Oncology, University Hospital Brno, 2Faculty of Medicine Hradec Kralove, 3Institute of Hematology and Blood Transfusion, 4Department of Military Internal Medicine, Faculty of Medicine Hradec Králové, 5Ingress-healt Germany, Wismar, Germany, 6Pfizer, Ltd, Walton Oaks, United Kingdom

Background: Minimal residual disease (MRD) detection is important in adult acute lymphoblastic leukemia (ALL), but RQ-PCR is not the assessment method for all patients due to non-applicable RQ-PCR target or applied RQ-PCR criteria.

Methods with strongest sensitivity for OS prediction on D26 were RQ-PCR with 1.0×10^{-3} cut-off (4-year OS: 76.6% vs 48.8%; median OS: not reached vs 39.1 months; p<0.012) and FCM (4-year OS: 78.3% vs 30.3%; median OS: not reached vs 27.4 months; p<0.016). The most sensitive method in W11 was RQ-PCR with every positive result considered MRD positive (4-year OS: 79.6% vs 53.1%; median OS: not reached vs 46.5 months; p<0.013). Flow cytometry and PCR with other cut-offs were not sufficiently sensitive. The sub-analysis of Ph-negative patients has shown the same results for RQ-PCR (p<0.01).

Summary/Conclusions: Our analysis has shown both RQ-PCR and FCM to be suitable methods for MRD assessment on D26 of induction in adult ALL patients receiving an intensive treatment. Furthermore it seems convenient to take any RQ-PCR positivity (even below 1.0×10^{-3}) into account in W11 and later stages of treatment. FCM can be used for MRD assessment on D26, but it is not sufficiently sensitive in later stages of treatment. We suggest using RQ-PCR as a method of choice for MRD assessment in adult ALL while retaining FCM as a backup method for patients without applicable RQ-PCR target or when faster MRD evaluation is needed.

Supported by MUNI/A/1106/2016 grant of Masaryk University, Czech Republic and the Czech Leukemia Study Group for Life.

1Hematopathology, Tata Memorial Hospital, Mumbai, Mumbai, India

Background: Minimal residual disease (MRD) has been proven to be the most important indicator of relapse in BC-PALL. Recently, flow-cytometry based MRD has been shown to achieve a sensitivity of <10-5 using a standardised panel with high number of event acquisition. However, high-sensitivity BMRD analysis is based on experience and acquisition of high number of events also includes other rare BM cellular elements and artifacts. We present a study of the cost-effective high-sensitivity 10-color single tube FC-MRD assay in BC-PALL along with description of rare BM cellular elements and artifacts causing interference in analysis.

Aims: 1. To study the applicability and sensitivity of a 10-color high event single tube FC-MRD assay for BC-PALL; 2. To document the rare BM cellular elements and artifacts causing interference in high-sensitivity FC-MRD assay for BC-PALL and describe their immunophenotypic features.

Methods: We studied 230 BC-PALL MRD samples. FC-immunophenotyping was performed on Navios flow-cytometer using bulk-lysis-and-stain method and data was analyzed with Kaluza-software. MRD was monitored using 10-color single tube FC-MRD assay including CD45, CD10, CD19, CD20, CD34, CD33, CD56, CD98, CD123 and CD25/COD73 with an additional 4-color nuclear dye (SYTO13) tube. Samples with cluster of ≥20 and ≥2 leukemia associated phenotypes (LAIPs) were called MRD-positive. High number of events were acquired for MRD-assay (1.5 to 6 million). To evaluate the applicability of assay, number of LAIPs were determined in diagnostic and MRD samples. In addition, the frequency and antigen expression pattern of mimics and artifacts were studied.

Results: We studied 230 BC-PALL MRD samples. High number of events was acquired for MRD-assay with median-events 3427000 (range, 1678000 to 6052800). We determined the limit of detection (LOD=10 events) by performing dilution assay. MRD was positive in 107 (46.5%) samples with median of 0.135% and range of 0.0003% to 48.3%. We categorized positive MRD results into samples with MRD <0.001%, 0.001- <0.01%, 0.01- <0.1%, 0.1- <1% and >1% and they were respectively 1.74%, 10.43%, 13.48%, 5.65% and 10.00%. Furthermore, in 24 samples with MRD-positive ≥0.1% and >1.5 million acquired-events, the results were compared between time-gated initial 500000-events and all events acquired. Sixteen samples among these were found to be negative in initial 500000-events and eight in initial 1000000-events highlighting the importance of acquisition of >1.5 million cells. Further, we categorized rare cellular events and artifacts in the following way: 1) CD34+ mature B cells; 2) CD10+ mature B cells; 3) CD73+ mesenchymal stem cells and endothelial cells; 4) CD123+ CD19+ 7PD precursors; 5) CD86+ CD58+B cell precursors (BPC); 6) CD19+ NK cells (Table 1). We also described their immunophenotypic features highlighting the differentiating features from MRD and B cell precursors (Figure 1).

Summary/Conclusions: We established a cost-effective 10 color single tube FC-MRD assay with high sensitivity of least 1 in 105 and applicability in >97% BC-PALL MRD samples. We also described the frequency and extent of different cellular events and artifacts that can interfere with high-sensitivity BC-PALL FC-MRD analysis. The knowledge regarding presence and antigen expression pattern of these cellular events and artifacts are critical to avoid potential false positive results.

SPECKLE TRACKING ECHOCARDIOGRAPHY IN PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA: A PRELIMINARY STUDY

M. Belloni1,*, G. Biddeg1, G. Bordini2, E. Varotto1, M. Pillon1, G. Geranio2, G. Bassoi1, B. Buldini2, A. Todesco1, B. Castaldi1, M.C. Puthi2
1Clinic of Pediatric Hemato-Oncology - Department of Woman and Child Health, 2Pediatric Cardiology Unit - Department of Woman and Child Health, University of Padua, Padova, Italy

Background: Children with acute lymphoblastic leukemia (ALL) are at risk for late-onset anthracycline-related cardiotoxicity. Left ventricular Global Longitudinal Strain (GLS) by Speckle Tracking Echocardiography has been recently used to identify preclinical late-onset heart failure in both adult and pediatric ALL patients. Nonetheless, efficient strategies for the early diagnosis and management of cardiac toxicity during chemotherapy are still not defined.

Aims: We prospectively studied LV function in ALL patients treated at our Centre, according to AIEOP-BMF ALL 2009 protocol, measuring both GLS and M-Mode Left Ventricular Ejection Fraction (LVEF).

Methods: Out of 42 consecutively examined ALL patients (pts), 32 (76%) underwent prospective follow-up (Table). At basal evaluation, 19 pts had Hb<9 g/dl, 7 pts had fever, 7 pts had hyperleukocytosis, 2 had BMI>25. The influence of these factors on cardiovascular parameters could not be evaluated due to low numbers. Echocardiography was performed with Vivid E9 ultrasound system (GE Medical System) and M5Sc probes at the following time points (TP): diagnosis (TP0), after induction phase (anthracycline cumulative dose 120mg/m2, TP120), at the end of anthracycline exposure (TP240 in standard risk-SR-pts; TP320 in high risk-HR-pts). HR pts underwent intermediate controls before each re-exposure (TP150, TP210, TP270). GLS values>−0.1% (or GLS drop between basal and LVEF value) and LVEF values<55% (or LVEF drop >10% from basal value) were considered as abnormal. Statistical analysis was performed using Student's t-test.

Table 1.

<table>
<thead>

</table>

Results: Basal evaluation was performed on 26 SR and 16 HR pts. Three SR pts with severe anemia (<7g/dl) and BMI=25 showed altered GLS at TP0. At the succeeding evaluation, 2 patients recovered, while one obese adolescent confirmed GLS and LVEF alterations. Follow-up after induction therapy (TP120) was performed on 10 SR pts and on 11 HR pts: GLS was altered in 3/10 SR pts (30%) and in 7/11 HR pts (63.6%). Two SR pts showed alterations in both GLS and LVEF values, while one child had isolated GLS impairment. Out of the 7 HR pts, one had both GLS and LVEF impairment and 3 worsened in GLS and LVEF values, while one child had isolated GLS impairment. Out of 42 patients, 32 (76%) underwent late-onset heart failure in both adult and pediatric ALL patients. Nonetheless, efficient strategies for the early diagnosis and management of cardiac toxicity during chemotherapy are still not defined.

Figure 1.

Summary/Conclusions: We established a cost-effective 10 color single tube FC-MRD assay with high sensitivity of least 1 in 105 and applicability in >97% BC-PALL MRD samples. We also described the frequency and extent of different cellular events and artifacts that can interfere with high-sensitivity BC-PALL FC-MRD analysis. The knowledge regarding presence and antigen expression pattern of these cellular events and artifacts are critical to avoid potential false positive results.
with b-blockers, as they could limit arrhythmogenic toxicity by their heart rate-lowering activity and antioxidant effect. All the 8 patients subsequently improved in both GLS and LVEF values, despite the occurrence of one episode of mild hypotension in 2 patients.

Summary/Conclusions: All children, even if exposed to low doses of arrhythmogenic toxicology, show early signs of LV impairment. Overt drop in LVEF, when present, mostly follow GLS alterations. Alterations seem more frequent in HR pts, possibly due to the higher burden of both leukemia itself and HR treatment. Further studies on wider series are needed to confirm the relevance of the early diagnosis of LV preclinical dysfunction in pediatric ALL patients.

Methods: Rearranged products from within the TRG and TRB locus were generated by PCR using proprietary multiplex master mixes with consensus primers targeting all TRG and TRB V and J exons families, synthesized with MiSeq specific adapter and individual barcode ID sequences. The PCR products were purified, quantified and pooled into equimolar library. The final library was sequenced on the MiSeq. The sequencing data FASTAQ output file was analyzed using Invivoscribe’s LymphoTrack® software. The software generated frequency distributions for the top 200 rearranged sequences, identified the DNA sequences, generated V-J assignments and V-J usage. Cell line DNA known TRG and TRB V-J rearrangements was tested for the analytical performance. DNA from different clinical sample type (FFPE, PB, and BM) was used to assess the clinical performance.

Results: This NGS assay was able to correctly detect all known TRB and TRG rearrangements from cell line DNA. The on-target reads per sample were 90% - 100%. Excellent linearity (R2>0.90), sensitivity of 2.5% for clonality, and reproducibility (<20% CV) were demonstrated with serial dilutions of contrived cell line DNA. The clinical performance of the LymphoTrack® TRG + TRB NGS assays was evaluated on different clinical samples that have also been tested using the PCR-CE TRG and TRB assays. Assessment of clonality using the LymphoTrack® MiSeq and PCR-CE assays for TRG and TRB demonstrated good concordance.

Summary/Conclusions: This combo NGS assay provides a fast, simple, and accurate method to detect clonality. In combination with the LymphoTrack software, the TRG + TRB MiSeq assay can identify clonal TRG and TRB V-(D)-J rearrangements and the specific V-(D)-J region DNA sequences required to track clones in follow-up testing. Excellent concordance comparing clonality with specific rearrangements was demonstrated between LymphoTrack® MiSeq and PCR-CE method.

Methods: Detection of clonality in clinical specimens from suspected B-cell malignancies using comprehensive IGH lymphotrack® MiSeq® and PGM® assays Y. Huang1, K. Hutt1, J. Panganiban1, A. Jacobsen1, N. Wong1, D. Duong1, R. Bob2, S.A. Pileri3, L. Bernard3, E. Gerbino3, T. Stenzel1, J.E. Miller1

1Invivoscribe Technologies, San Diego, United States, 2Department of Pediatrics, Korea University Guro Hospital, Korea University An聖on Medical Centre, Cha University, Seoul, Republic Of Korea

Background: NUDT15 polymorphism has been recently identified as a determinant of thiopurine intolerance. 6-thioguanine nucleotides (6-TGN) is monitored to prevent hematopoietic toxicity in acute lymphoblastic leukemia (ALL).

Methods: Genotyping of NUDT15 was performed in 258 children with ALL who were registered in Samsung Medical Center. According to NUDT15 diplotypes, patients were classified into low risk (LR, wild-type), intermediate risk (IR, heterozygous variant), or high risk (HR, homozygous or compound heterozygous variant).

Results: A total of 182 were finally included after 76 patients were excluded for TPMT variation or lack of information during maintenance therapy; LR (n=131), IR (n=46), and HR (n=5).

Summary/Conclusions: Patients with NUDT15 variants encountered significant thiopurine intolerance even with low level of 6-TGN. This concurs with the existing hypothesis that NUDT15 protein may prevent incorporation of thiopurine active metabolites into DNA. Therefore 6-TGN monitoring is not useful to predict hematopoietic toxicity for patients with NUDT15 variant.
Summary/Conclusions: Comprehensive IGH Assays have been developed for both MiSeq and PGM platforms. These assays identify clonal IGH V-J rearrangements and provide the clonal DNA sequences of the tumor-specific clonotypes required to perform follow up testing to detect residual disease. Combining FR1, FR2 and FR3 improved the overall clonality detection rate to 96%. Both NGS-based IGH assays have demonstrated excellent concordance in detecting clonality regardless of whether clonality was determined using a PCR-CE method or with assays formatted for the MiSeq and PGM platforms.

E848

CORRELATION BETWEEN A 10-COLOR FLOW CYTOMETRIC MINIMAL RESIDUAL DISEASE (MRD) ANALYSIS AND MOLECULAR MRD IN ADULT ACUTE LYMPHOPROLIFERATIVE LEUKEMIA

J. Singh1,*, M. Gorniak1, G. Grigoriadis1,2, D. Westerman3, M. McBean3, N. Venn4, R. Sutton4, S. Morgan 1, S. Fleming1,2

1Laboratory Haematology, Alfred Pathology, 2Clinical Haematology, Monash Health, 3Pathology, Peter MacCallum Cancer Centre at the Victorian Comprehensive Cancer Centre, Melbourne, 4Children’s Cancer Institute, Lowy Cancer Research Centre, UNSW, Sydney, Australia

Background: Minimal residual disease (MRD) monitoring in Acute Lymphoblastic Leukemia (ALL) is an accepted standard of care in both adult and pediatric patients as one of the strongest predictive factors for disease outcome and as a stratification tool for treatment intensification and allogeneic stem cell transplant. The currently accepted standard of molecular monitoring with either immunoglobulin heavy or kappa chain (IG) or T-cell receptor (TCR) quantitative PCR (qPCR) in Philadelphia negative ALL allows for sensitive monitoring of MRD, but requires a high degree of expertise, and factors such as cost and turnaround time may limit generalized applicability of this technique. Flow cytometric MRD monitoring is utilized in many centers, with increased sensitivity seen with implementation of multi-parameter flow cytometry at 8-colours or more.

Aims: We sought to compare a 10-color flow cytometry assay for detecting MRD in B-ALL with standard molecular monitoring.

Methods: To facilitate rapid identification of MRD in patients with B-ALL, we developed a 10-colour single tube flow cytometry assay utilizing CD19, CD22, CD20, CD38, CD58, CD13/33, CD66c, CD10, CD45 and CD34 as markers. These markers were selected to provide at least two targets for identification of B-lineage cells, and to include the most frequently aberrant markers in precursor B-lineage ALL. Samples were subject to bulk ammonium chloride lysis to maximize cell yields with a target of 1 x 10^6 events. Once normal maturation patterns were established, patient samples were analyzed in parallel to standard of care molecular monitoring with either IG/TCR qPCR in Philadelphia negative (Ph-) disease and BCR-ABL qRT-PCR in Philadelphia positive (Ph+) disease. Statistical correlation was performed in Graphpad Prism version 7.0 for linear regression and calculation of correlation co-efficient.

Figure 1.

Results: 33 samples at different time points from 13 patients were analyzed by flow cytometry. 9 samples from 9 patients were taken at diagnosis. Whilst an informative MRD phenotype was identified by flow cytometry in all 9 patients, a molecular assay was not able to be developed in one patient due to lack of an identifiable marker. 24 samples from 13 patients were tested for MRD by flow cytometry. The median lower limit of detection was 0.0078% (range 0.0016% to 0.028%) with a median lower limit of quantification of 0.018% (range 0.002% to 0.07%). A sensitivity of <0.01% was attained in 21 of 24 samples (88%). 20 samples from 11 patients were tested concurrently for MRD by both molecular and flow cytometry methods. 11 samples were in Ph- disease and 9 were in Ph+ disease. MRD was detected by both molecular and flow cytometry in 11 samples and not detected by both methods in 8 samples. In one sample, MRD was detected only by molecular at an unequivatable level. There was a strong correlation co-efficient between molecular and flow cytometric MRD analysis (R²=0.905, p<0.001). Correlation was strong with both IG/TCR based molecular analysis (R²=0.949, p<0.001) and BCR-ABL based molecular assays (R²=0.993, p<0.001).

Summary/Conclusions: 10-color flow cytometric minimal residual disease analysis with bulk lysis attains a high degree of sensitivity in minimal residual disease determination in precursor B-lineage Acute Lymphoblastic Leukemia. There was a strong correlation with molecular MRD monitoring for both quantification of MRD and determination of MRD negative status. Flow cytometric methods may also permit MRD monitoring in patients where a suitable molecular assay cannot be developed.

HYPOGLYCEMIC EVENTS DURING TREATMENT OF PEDIATRIC ACUTE LYMPHOPROLIFERATIVE LEUKEMIA: OBSERVATIONS FROM TRIAL AIEOP-BFM ALL 2009

D. Blackmann1,*, J. Allen1, N. Bodmer2, E. Zapotocka3, D. Barbaric4, M. Schrappe1, S. Vieth1, M. Zimmermann5, A. Möricke1

1Department of Pediatrics, University Medical Center Schleswig-Holstein, Campus Kiel, Kiel, Germany, 2Pediatric Oncology and Hematology, Universität, Kinderspital Zürich, Zürich, Switzerland, 3Department of Pediatric Hematology and Oncology, Motol University Hospital, Prague, Czech Republic, 4Centre for Childhood Cancer and Blood Disorders, Sydney Children's Hospital, Sydney, Australia, 5Pediatric Hematology/Oncology, Medical School Hannover, Hannover, Germany

Background: Hypoglycemia has been reported as a rare side effect in children and adolescents treated for acute lymphoblastic leukemia (ALL). It has been associated to purine nucleoside analogues (PNA), but potential relationship with asparaginase has also been described. Despite these reports, clinicians' awareness of this risk seems to be limited.

Aims: Descriptive evaluation of symptomatic hypoglycemic events during ALL treatment.

Methods: Hypoglycemic events were analyzed among 3293 patients treated in the trial AIEOP-BFM ALL 2009 in four of the participating countries (Germany, Switzerland, Czech Republic, and Australia) between 06/2010 and 08/2016. PNA were administered during induction-consolidation, the second part of the intensification phase (reinduction-consolidation) and during maintenance (MT). Pegylated asparaginase (PEG-ASP) was given in induction-consolidation phase of reintensification, as well as high-risk blocks. Additionally, the benefit of intensified PEG-ASP was tested during induction-consolidation in the high-risk group, and during reinduction-consolidation/MT in the medium-risk group. Adverse events were generally captured in a targeted approach by means of defined events assessed as clinically relevant, not including hypoglycemia. Thus, data collection of these events was based on proactive reporting by the investigators. For analysis, clinical severity of the events was retrospectively graded according to patients' capacity of action and reaction.

Results: In total, 28 hypoglycemic events were reported in 26 of the 3293 patients. 25 events in 23 patients were described as symptomatic, to which further analysis was restricted (22 precursor B- and one T-ALL; 8 standard-risk, 12 medium-risk, and 3 high-risk). Age of patients ranged between 1.7 and 15.5 years at occurrence of symptomatic hypoglycemia. Balanced ratio between both sexes can be observed (13 male, 10 female), median age was essentially similar (male 3.2 y, female 4.1 y). Hypoglycemic events occurred in induction treatment (n=1), induction-consolidation (n=8), reinduction-consolidation (n=4; one in standard reinduction, 3 in reinduction with intensified PEG-ASP treatment), high-risk block (n=1), and in MT (n=11; 4 events during standard MT, 6 events during MT with intensified PEG-ASP treatment, and one event 4 weeks after last PEG-ASP during MT). Seven events were reported with mild symptoms, 6 patients showed moderate symptoms, and in 12 events patients showed severe symptoms (loss of consciousness, seizure-like).

Summary/Conclusions: In accordance with previous reports, hypoglycemic events accumulated in PNA containing treatment phases, but not exclusively. Considering that 324 patients of the total cohort were treated with intensified PEG-ASP in reinduction-consolidation/MT, an additive effect of PEG-ASP and PNA regarding a hypoglycemic metabolic condition may be assumed although a similar effect was not seen in induction-consolidation with intensified PEG-ASP. However, numbers are small and reporting bias of the present data is probable, as hypoglycemic events were not captured systematically. Investigators' attention to adverse reactions and proactive reporting might be higher.
in experimental arms as well as in case of preceding hypoglycemic events in other patients of the respective trial center. Despite these analytical limitations, our data suggest that hypoglycemia during ALL treatment is a relevant and probably underestimated clinical problem. Further investigation including possible identification of predisposing metabolic conditions is required to avoid harm to patients by this preventable complication.

NUDT15 VARIANT IN KOREAN CHILDREN WITH ACUTE LYMPHOBlastic LEUKEMIA
1Pediatrics, Yeungnam University, College of Medicine, 2Pediatrics, Daegu Fatima Hospital, 3Pediatrics, Kyungpook National University College of Medicine and Dongsan Medical Center, 4Laboratory Medicine, Keimyung University School of Medicine, 5Laboratory Medicine, Yeungnam University College of Medicine, Daegu, Korea, Republic of Korea

Background: Acute lymphoblastic leukemia (ALL) is the most prevalent pediatric cancer with cure rates approaching 90% with current therapy. Patient with ALL require long-term maintenance therapy. The combination of weekly methotrexate and daily 6-mercaptopurine (6-MP) is used for the backbone of ALL maintenance regimens. Genetic polymorphism in thiopurine methyltransferase (TPMP) is well known to affect the 6-MP tolerance. However prevalence of non-functional variant of TPMP is rare in Far East. Recently, a study has identified a variant of the NUDT15 gene associated with intolerance of 6-MP.

Aims: We examined the association between NUDT15 polymorphism and clinical data of Korean pediatric ALL.

Methods: NUDT15 genotyping and collection of clinical data was performed for 74 Korean pediatric ALL patients from two different hospital. For NUDT15 genotyping, DNA was extracted from whole blood/or bone marrow sample and Sanger sequencing was performed for exon 1 and 3 of NUDT15 gene. 6-MP dose intensity, defined as the ratio of prescribed 6-MP dose over protocol planned dose.

Results: We found two kinds of variants, c.55_G6insG/G6TGC(c869320776) in exon 1 from 8 patients and c.415C>T(rs116852322) in exon 3 from 14 patients. Of them, 7 patients had both variants and all variants were heterozygote. Patients could be divided to four distinct groups according to combinations of genotype (Table 1). 6-MP dose intensity in wild type was higher than three other genotypes during maintenance therapy (p=0.003) (Fig 1). The number of hospitalized days in wild type is smaller compared to other three genotypes (p=0.017). Frequency of febrile neutropenia, hepatotoxicity, cumulative days of antibiotics use and overall survival did not significantly differ by NUDT15 genotype.

Table 1. Treatment outcome of children with acute lymphoblastic leukemia according to NUDT15 genotypes.

TREATMENT OUTCOME OF ACUTE LYMPHOBlastic LEUKEMIA IN KOREAN ADOLESCENTS AND YOUNG ADULTS
1Center for Pediatric Oncology, 2National Cancer Control Institute, 3Hematology Oncology Clinic, National Cancer Center, Goyang-si, Gyeonggi-do, Korea

Background: The outcome of acute lymphoblastic leukemia (ALL) has markedly improved for last centuries, but the improvement was mainly observed in children under 10 years old. In contrast, the treatment outcomes of ALL in adolescents and young adults (AYA) still lag behind those of younger children.

Aims: We conducted this study to investigate the treatment outcome of AYA ALL in Korea, and to define any patterns of care related to the treatment outcome of AYA ALL.

Methods: Clinical data of 10-29 years old ALL patients diagnosed between 2002 and 2010 were extracted from Korean national health insurance service. Data about patients’ diagnosis, age, gender, mainly treated department (internal medicine vs pediatrics), usage data of medications (L-asparaginase, 6-mercaptopurine, vincristine, prednisolone or dexamethasone), hematopoietic stem cell transplantation (HSCT), radiotherapy, survival, and follow-up duration were collected. Patients who were treated with steroid over 2 weeks, and L-asparaginase at least once in initial 2 months were considered to be treated as pediatric protocol, and those who did not fulfill this criteria were considered to be treated as adult protocol.

Results: Total 1,223 ALL AYA patients were diagnosed between the 2002 and 2010, and excluding those who never treated, 1,208 patients underwent ALL treatment. Among them, 665 (55%) patients were treated with pediatric protocol, and the other 543 (45%) patients were treated with adult protocol. Radiotherapy was done in 278 (41.8%) and 186 (34.3%) in each group, and HSCT was done in 205 patients (30.8%) and 216 patients (39.8%) in each group, respectively. Pediatric protocol group showed significantly better overall survival compared to adult protocol group in total age (65% vs 43%, P<0.0001), 10-15 year old (76% vs 57%, P<0.0001), and 20-24 year old patients (51% vs 31%, P=0.0116). In univiable analysis, patient age (younger), treatment protocol (pediatric), L-Asparaginase, 6-mercaptopurine, and steroid over 2weeks in initial 2 months were associated with better overall survival (P<0.0001 for each).

Summary/Conclusions: The overall survival rates in Korean AYA ALL were comparable with previous studies done at other countries. Patients treated with pediatric protocol tended to result better overall survival rate when compared to patients treated with adult protocol. Radiotherapy and early HSCT were widely used in the 2000s, and further study is needed to follow up the recent trend of treatment, and outcome as a result.

E853
AUTOLOGOUS TRANSPLANTATION AS TIME-DEPENDENT FACTOR FOR SURVIVAL OF PATIENTS WITH T-CELL ACUTE LYMPHOBlastic LEUKEMIA: STUDY DATA AND SIMULATION MODEL
S. Kulikov1, M. Rusinov1, A. Kulikovskiy1, E. Parvinshtikova2
1Biostatistics, 2Hematological Oncology and BMT, National Research Center for Hematology, Moscow, Russian Federation

Background: The role of autologous hematopoietic stem cells transplantation (aHSCT) for patients with T-cell ALL is still being discussed. The recent Russian study of ALL shows the promising effect of aHSCT but there is a skepticism as the study was not randomized. The possible bias was referred to the "time selection" factor.

Aims: It's need to prove that time selection can not explain the magnitude of the effect of aHSCT on patient's survival.

Methods: We have developed SAS macros time-depended graphical and analytic procedures for time dependent factors: Land Mark (LM) methods, Mantel-Bay test, Cox regression model (CM) and also a base for simulation all end points and study events like remission, transplantation, relapse and death are well approximated by a mixture of exponent distributions. Non-constant (dropping) hazard assumption as most possible source of biases was tested on our simulation model in different situations. Real data multicenter study of ALL was used to fit simulation model parameters. Russian ALL study group held a prospective multicenter trial RALL-2009 in the treatment of PH-negative adult ALL patients based on non-intensive but non-interruptive treatment (NCT01193933). The therapy was unified for all PH-negative ALL pts, but in T-cell ALL/LBL autologous hematopoietic stem cell transplantation (auto-HSCT) after non-myeloblastic BEAM conditioning was scheduled as intense intensification (+3-4 mo of CR) followed by prolonged 2 years maintenance. From Jan 2009 till Jul 2016, 30 centers enrolled 107 T-ALL/LBL pts. Median age was 28 years (15-54 y), 34 f / 73 m; early T-cell (TIIi) phenotype was verified in 56
(52.3%), mature (T-IV) - in 10 (0.9%), thymic (TII, CD1a+) ALL - in 41 pts (38.3%). T-lymphoblastic lymphoma (T-IVL ≤ 25% b/m blasts) was diagnosed in 22 pts (20.5%). Autologous HSCT was performed in 35, allogeneic in 7 pts.

Results: The survival analysis of real data shows 4-fold dropping hazard rate. The effect of aHSCT was confirmed by LM analysis. Mantel-Bay test - PMB = 0.004, Cox model output: 1/HR = 15.9, P = 0.008. Simulation model for remission consists of 3 fractions: early (α = 10%, t = 0.05 m, δ = 0.2 m), normal (α = 57%, t = 0.28 m, δ = 1 m) and late remission (α = 33%, t = 1.31 m, δ = 2.2 m), for survival consists of 2 fractions: short life (α = 59%, t = 22 m), long life (α = 41%, t = 600 m). The first simulation experiment was performed in preposition that transplantation has no effect (HR = 1). To exclude the random effect the sample size was N = 4000, Mantel-Bay and Cox model show significant (PM = 0.50, PCM = 0.50, HR = 0.93) but LM plot demonstrates recognizable bias in transplanted patient group (Fig. 3). The second experiment supposed that the existed effect of aHSCT (HR = 0.5), N = 500, Mantel-Bay and Cox model would show significance, but hazard ratio was underestimated (PM = 0.03, PCM = 0.03, HR = 0.05). Most experiments were done for repeated simulation, which demonstrated a very good agreement of Mantel-Bay and Cox methods and their robustness.

Figure 1.

Summary/Conclusions: The effect of autologous HSCT in T-cell ALL was confirmed by usual analysis and by simulation experiments. It was shown that potential bias caused by no constant hazard rate cannot explain the magnitude of HSCT effect demonstrated on real data. LM plot could express small bias. Mantel-Bay and Cox model are robust against violation of constant hazard assumption and give very concordant outputs. Cox model underestimated the effect of time-depending factor in case of dropping hazard. Simulations model is a good instrument for testing tests in situations of deviation from theoretical assumptions.

E854

INDUCTION WITH TYROSINE KINASE INHIBITORS, CONSOLIDATION WITH FLUDARABINE, ARA-C AND DAUNOXOME FOLLOWED BY ALLOGENEIC STEM CELL TRANSPLANT IS AN EFFECTIVE AND FEASIBLE STRATEGY FOR PH+ ALL PATIENTS

N. Di Felice1*, P. Minetto1, F. Guolo1, M. Clavio1, N. Bisso1, G. Pastorini1, D. Guardo1, M. Gambella1, A. Bellodi2, E. Arboscello2, N. Colombo1, F. Ballerini1, M. Miglino1, R.M. Lemo1, M. Gobbi1

1Clinic of Hematology, Department of Internal Medicine (DIMI), University of Genoa, 2Clinic of Internal Medicine III, Department of Internal Medicine (DIMI), University of Genoa, IRCCS AOI San Martino-IST, Genova, Italy

Background: The prognosis of Philadelphia positive (Ph+) acute lymphoblastic leukemia (ALL) patients has improved since the introduction of tyrosine kinase inhibitors (TKI). Following TKIs treatment almost all patients rapidly achieve complete hematologic remission (CR). However, only a minority of patients obtain complete molecular response and most of all will eventually relapse without further treatment. On the other hand, the concomitant combination of TKIs to conventional chemotherapy regimens greatly increases complete molecular responses, but at the price of significant toxicities and high rates of deaths due to toxicity.

Aims: We present here the preliminary results of a sequential therapeutic strategy starting with TKI (Dasatinib) as single agent induction until CR is achieved. Fludarabine (Flu), Cytarabine (Ara-C), Lymphosarcoma Daunorubine (DNX), FLAD regimen and Dasatinib were given as consolidation therapy, in order to maximize efficacy and reduce toxicity. Allogeneic stem cell transplantation (HSCT) was planned for all patients in MRD negative CR.

Methods: Dasatinib was given in association with steroids at the dosage of 140mg id/le until the achievement of CR. FLAD regimen consisted of a three days administration of Flu 30mg/sqm followed by Ara-C 2000mg/sqm and DNX 100mg/sqm. Dasatinib was administered again from the end of chemotherapy and G-CSF was given to all patients starting from day 4 until complete hematological recovery. FLAD was administered for up to two cycles. Minimal residual disease (MRD) was evaluated in all patients after each FLAD either by multicolor flow cytometry (MFC), RQ-PCR for VDJ rearrangements, and RQ-PCR for BCR/ABL.

Results: From January 2008 to December 2016, 8 Ph+ ALL at diagnosis (medi- an age 52 years) have been enrolled in this protocol. The median follow-up was 27 months. All patients received 70 days induction with Dasatinib + Steroids and achieved CR with complete hematological recovery. In all patients but one, however, BCR/ABL was still positive both on day 33 and on day 70. Therefore, we found MFC MRD positive on day 33 (one on day 70 also), whereas five patients achieved MFC MRD negativity on day 33. After the first FLAD course all patients achieved MFC MRD negativity, with four patients achieving also negativity for VDJ rearrangements and BCR/ABL transcript. FLAD was very well tolerated, with a median ANC and platelet recovery of 7.5 and 4 days, respectively. No patient experienced relapse so far and 4 patients proceeded to HSCT. Two patients are currently waiting for transplant. Overall, 6 patients are alive and in MRD negative CR at the time of analysis. One patient died at day +289 after SCT due to non-relapse mortality and one has died after the first FLAD course in molecular CR because of an unrelated event.

Summary/Conclusions: This therapeutic strategy proved to be well tolerated and extremely effective for Ph+ ALL patients. Administering FLAD in patients who had already achieved complete hematological response with Dasatinib + steroids allowed us to reduce the period of neutropenia and thrombocytopenia compared to what is reported after combined TKI and chemotherapy treatment given at diagnosis. Most patients underwent HSCT in molecular CR.

E855

BONE MARROW MRD EVALUATION ON DAY 7 OF STEROID TREATMENT OF MODIFIED ST JUDE TOTAL XV THERAPY IN STANDARD/LOW RISK PATIENTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA

S. Aytac1*, M. cetin1, I. Yaman Bajin1, I. Altan1, S. unal1, B. kuskonmaz1, D. uckan1, F. gumruk1

Pediatric Hematology, Hacettepe University, Ankara, Turkey

Background: In the recent years it was clearley shown that levels of minimal residual disease (MRD) studied by flowcytometry during treatment reflect the overall response to the chemotherapy and give a chance to individualize treatment and improved outcome.

Aims: To determine the clinical significance of MRD on day 7 of initial steroid treatment in patients with childhood ALL we analyzed data from 173 patients treated with modified St Jude Total XV therapy between 1 January 2008 and 31 December 2015.

Methods: According to our previous successfull fulls with high dose methylprednisolone (HDMXP) we add 7 days of HDMXP to the modified St Jude Total XV as an initial treatment and randomized patients at doses of 10mg/kg/d or 20mg/kg/d HDMXP: not exceeding at maximum 1000mg methylprednisolone. After the end of 7th day of steroid concomitant chemotherapy was given and the doses were tapered gradually to 5mg/kg/d and 10mg/kg/d in each group respectively. By the 3rd week of treatment steroid dose was tapered to 2mg/kg/d in both groups and continued with this dose till the end of 3rd week of induction phase. MRD levels were studied at the 15th, 22nd and 42nd days of induction according to the protocol. However we also analyse steroid response rate by the peripheral smear on day 7. Moreover, patients were asked to obtain simultaneously optional bone marrow aspiration after getting informed consents to show whether there will be any concordance with the steroid response and/or whether it can give any idea of the outcome.

Results: Steroid response rate on day 7 by peripheral smear was 91% (n=158) for the whole group. However simultaneously bone marrow MRD measurement was done in 22 of the 173 patients.There were 13 female and 9 male patient with a median initial WBC count of 6400/mm3 (110-55300/mm^3),all were Calla+ pre B cell ALL (17 low risk ALL, 6 standart risk and 1 high risk ALL),all were in complete remission and all except one is alive at the time of the analysis. There were 10 patients receiving 10mg/kg/d HDMXP and 12 patients were in the group of 20mg/kg/d HDMXP. MRD levels were not statistically different on day 7 between these two groups. Furthermore all patients except 2(one in each group) were steroid responsive by means of peripheral absolute blast count <1000/mm^3. Bone marrow MRD on day 15th and 42nd there were no statistically significant difference in each group(P>0.05) Although some of those patients in each group have high levels of MRD on day 7, interestingly they all were steroid responsive.

Summary/Conclusions: Our preliminary results suggest to think that MRD level on day 7 in a small group of low/standart ALL patients may not predict outcome.
and clinical outcomes of the patients were analyzed. Lymphoblastic leukemia (ALL, n=46) were enrolled in this study. Expression of JL1 antigen is expressed on tumor cells of T, B, and myeloid lineage in >80% of acute leukemia patients, and its expression is limited in normal multipotent hematopoietic cells. The antigen is not expressed on mature peripheral blood lymphocytes (LyBP) in over 99% of healthy people. JL1 is a novel epitope of CD43, which is known to be specifically expressed on lymphoblastic leukemia (LLyBP). The antigen is expressed on tumor cells in >80% of pediatric acute lymphoblastic leukemia (ALL) patients and to assess their correlation with baseline characteristics and prognostic factors.

Aims: The aim of this study was to evaluate baseline levels of cytokines, cytotoxic receptors and adhesion molecules in newly diagnosed acute lymphoblastic leukemia (ALL) patients and to assess their correlation with baseline characteristics and prognostic factors.

Methods: A total of 30 newly diagnosed ALL patients (median age 46, range 22–75 years, 20 males) were included in this study. We evaluated serum levels of 31 analytes were correlated with baseline characteristics and prognostic factors, such as the number of baseline analyte levels and inferior PFS or OS were found. In newly diagnosed ALL patients, we found statistically significant correlations between sTN-Fr-1 and sTNFR-2 (r=0.805; p<0.0001), IL-1α and IL-4 (r=0.700; p=0.008), sTNF-β and VEGF (r=0.664; p=0.012). Furthermore, we found significant positive correlations between IL-7 and antithrombin III (r=0.758; p=0.075). These findings demonstrated that anti-JL1 antibody might be used in childhood acute leukemia patient showing JL1 expression.

Results: Positive JL1 expression was observed in 16 (64.0%) patients with AML, and 27 (58.7%) with ALL. In AML patients, positive JL1 group showed higher expression than negative JL1 group in CD 14 (P=0.043), CD7 (P=0.026), CD56 (P=0.016) and lower expression in CD65 (P=0.05). With regard to ALL patients, CD 20 (P=0.002) and CD22 (P=0.005) expressions were significantly higher in JL1 positive group than JL1 negative group. Positivity of JL1 expression did not show significant difference between B-lineage vs. T-lineage ALL (P=0.671). Positivity of JL1 expression was not significantly associated with overall survival in 71 patients with newly diagnosed childhood acute leukemia (P=0.570).

Summary/Conclusions: 60.5% of childhood acute leukemia displayed positive JL1 expression. This finding is similar to 61.2% of JL1 expression in adult AML and 57.9% of expression in adult ALL reported previously. The JL1 expression was significantly associated with some immunophenotypic features, but was not significantly associated with clinical outcome. These findings demonstrates that anti-JL1 antibody might be used in childhood acute leukemia patient showing JL1 expression.

JL1 ANTIGEN EXPRESSION OF LEUKEMIC CELLS IN CHILDHOOD ACUTE LEUKEMIA

E. You1, S. Kim2, C.-J. Park1, S. Jang1, Y.-U. Cho1, C.H. Yoon1, K.-N. Koh1, H.J. Im3, J.J. Seo3

1Department of Laboratory Medicine, Asan Medical Center, University of Ulsan College of Medicine, 2Department of Pediatrics, Asan Medical Center Children’s Hospital, University of Ulsan College of Medicine, Seoul, Korea, Republic Of

Background: JL1 is a novel epitope of CD43, which is known to be specifically expressed depending on the differentiation stages of hematopoietic cells. JL1 antigen is expressed on tumor cells of T, B, and myeloid lineage in >80% of acute leukemia patients, and its expression is limited in normal multipotent hematopoietic cells. The antigen is not expressed on mature peripheral blood cells or other normal tissues. Thus, the clinical phase 1 test of a therapeutic agent for leukemia targeting JL1 is being conducted, and when anti-JL1 antibody was combined with a toxic substance, its therapeutic effect was found earlier in preclinical trials.

Aims: This study aims to examine JL1 expression of leukemic cells in childhood acute leukemia.

Methods: Between December 2014 and January 2016, a total of 71 patients younger than 21 years with acute myeloid leukemia (AML, n=25), and acute lymphoblastic leukemia (ALL, n=46) were enrolled in this study. Expression of JL1 was assessed using a commercially available kit (Bio-Rad, CA USA) based flow cytometry, and an expression of 20% or above was defined as positive JL1 expression. Pathological and immunophenotypic characteristics, and clinical outcomes of the patients were analyzed.

Results: Median duration of PON therapy was 3 months (5 days-30 months+). Out of the 19 pts who received PON for ≥ 4 weeks, 5 pts failed to reach CR, 14 (73.7%) reached or maintained it. Molecular response was not reported uniformly. During induction by PON, 5 grade 3-4 events occurred in 4 pts (1 pulmonary infection; 1 acute renal failure; 1 pancreatitis; 1 hepatitis; 1 venous trombo-embolic event; no arterial occlusive event). Post-induction therapy consisted in PON-based therapy in most pts. HSCT was performed in 5 pts. Out of 13 pts in CR on PON, 1 pt died in CR from acute lymphoblastic leukaemia relapse at 8 months, and 11 pts ultimately experienced bone marrow relapse, all of them within 6 months after PON initiation, except 2 who relapsed at 13 and 27 months after HSCT. Two patients are alive in CR at 14 and 30 months, respectively.

Summary/Conclusions: Our series of resistant pts is comparable to the PACE study population by initial characteristics and high frequency of BCR-ABL mutations. CR was achieved in most pts, suggesting the role of PON as a bridge-agent for leukemia targeting JL1 is being conducted, and when anti-JL1 anti-
IMATINIB VS. DASATINIB FOR OUTCOMES AFTER ALLOGENEIC STEM-CELL TRANSPLANTATION FOR PATIENTS WITH PH+ ACUTE LYMPHOBLASTIC LEUKEMIA

A. Shigematsu1, S. Ota1, H. Goto2, K. Minnauchi3, J. Sugita2, D. Hashimoto2, M. Obara1, T. Endo1, M. Inamur1, T. Teshima2, N. Kobayashi1

22nd Congress of the European Hematology Association

Background: The survival of the patients with Philadelphia chromosome positive acute lymphoblastic leukemia (Ph+ALL) who received allogeneic stem cell transplant (allo-HSCT) has improved over the development of tyrosine kinase inhibitors (TKIs). Currently, Imatinib (IMA) and Dasatinib (DAS) are widely used for the treatment for Ph+ALL. However, there has been no data comparing the outcomes between the patients who received allo-HSCT and the two distinctive TKIs respectively.

Aims: We conducted a retrospective analysis for comparing the two TKIs for the outcome after allo-HSCT.

Methods: Clinical data of patients were retrospectively collected from Hokkaido University Hospital and Sapporo Hokuyu Hospital. The patients’ eligibility were as follows: diagnosed as Ph+ALL, aged more than 16 years, and received allo-HSCT between 1990 and 2016 and first time for SCT.

Results: Sixty-six patients were eligible for the study. Fifty-six out of the 66 were administered TKIs (TKI group) and the remaining ten who developed Ph+ALL in the early course were treated without TKIs (non-TKI group). Overall survival was not different between the two groups. Of the 56 patients in the TKI group, 39 received IMA (IMA-pts), and the remaining 17 received DAS (DAS-pts). Compared with DAS-pts, IMA-pts received allo-HSCT in relatively older years of age, more frequent myeloablative conditioning regimen, and cyclosporine-containing, not tacrolimus-, regimen for GVHD prophylaxis more frequently. Overall survival did not differ between the two groups when we performed univariate analysis. However, by multivariate analysis using Cox regression model for adjusting confounding factors, including, overall survival was superior for IMA-pts [Hazard ratio; 0.32 (0.11-0.94), P=0.04]. Incidences of transplant-related mortality and relapse were not different between the groups, even though relapse rate tended to be increased in DAS-pts [IMA; 16.1%, DAS; 47.1%, Gray P=0.2).

Summary/Conclusions: Our analysis suggests that overall survival may be superior for the Ph+ALL patients treated with allo-SCT and IMA compared with those with DAS. There are some limitations for our analysis due to retrospective fashion and relatively small number of the patients analyzed. Therefore, prospective study comparing survival of the Ph+ALL patients treated with the two distinctive TKIs before HSCT is needed.

IS OLDER AGE AN EXCLUSION CRITERION FOR ALLOGENEIC HEMATOPOIETIC STEM-CELL TRANSPLANTATION IN PATIENTS WITH PHILADELPHIA-POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA?

O. Gavrilina1,*, E. Parovichnikova1, V. Troitskaya1, I. Galtseva1, L. Kuzmina1, S. Bondarenko3, V. Lapin1, T. Obukhova5, A. Sudarikov6, K. Zarubina1, S. Kulikov5, M. Rusanov7, V. Savchenko1
1Chemotherapy and BMT, 2Bone marrow transplantation, National Research center for hematology, Moscow, 3BMT, Institute of the Pediatric Hematology and Transplantology, Saint-Petersburg, 4Hematology, Regional hospital, Yaroslavl, 5Cytogenetic, 6Molecular hematology, 7Statistic, National Research Center for Hematology, Moscow, Russian Federation

Background: Philadelphia-positive acute lymphoblastic leukemia (Ph+ ALL) is diagnosed more often in older than in younger patients. This type of the acute lymphoblastic leukemia is characterized by very aggressive course of the disease. All clinical recommendations for such conditions indicate allogeneic bone marrow transplantation (allo-BMT) after achieving complete remission. The addition of tyrosine kinase inhibitors (TKI) to chemotherapy has dramatically improved the long-term outcome in Ph+ acute lymphoblastic leukemia patients. Nevertheless whether to administer chemotherapy at all and if yes – how intensive it should be, is still the matter of debate. We have conducted two consecutive trials in Ph+ ALL aiming to evaluate the efficacy of more and less intensive chemotherapy approaches in combination with constant non-stop 600 mg Ima-tinib. All patients in both protocols with suitable donors underwent hematopoietic stem-cell transplantation (HSCT).

Aims: To analyze the effectiveness of RALL–2009+TKI and RALL–2012+TKI protocols in Ph+ ALL patients with or without HSCT. To analyze the efficacy of treatment with or without transplantation regarding the patient’s age.

Methods: From 2010 January to 2017 January, 35 new Ph+ALL cases were diagnosed in 3 centers of the RALL–group. From 2010 to 2012, 12 Ph+ ALL pts were treated according to RALL–2009 protocol (ClinicalTrials.gov; NCT00333993) with concurrent administration of Imatinib. This protocol includes 8 cytostatic drugs and no intervals between treatment phases. Since 2012 till now 23 pts were included in ongoing RALL–2012 protocol, based mainly on 600 mg Imatinib with prednisolone, VNCR, L-asp, followed by 6-MP and MTX. Both protocols suggested the shift to Dasatinib (100-140mg) after non-achievement of MolCR on day 70 of treatment. MolCR was stated if bcr/abl chimeric transcript was <0.01% by PCR with 10-4 sensitivity. All patients were considered as candidates for allogeneic HSCT if HLA-identical donor was available. 13 pts (37%) underwent allo-HSCT as the first-line therapy: 1 autologous, 5 matched related and 7 matched unrelated.

Results: MolCR on day 70 was achieved in 36% and 59% in RALL–2009 (n=4) and RALL–2012 (n=13) respectively. Death on therapy (within 2 months of induction/consolidation) was registered in 2 cases on less intensive RALL–2012 protocol and 2 cases on RALL–2009. Hematological CR was achieved in 30 (85.7%) of 35 pts (except four early deaths and 2 refractory cases). There was one autologous HSCT in MolCR on the first protocol. Allo–HSCT was carried out in 5 of RALL–2009 protocol pts and in 9 of RALL–2012. The major issue was the non-relapsed mortality after unrelated allo–HSCT in 3 older pts (49, 56 and 59 years old) who were included in RALL–2012 (aGVHD and severe infections, at a median +4 months after HSCT and more than 12 months of CR duration).

The 5y overall survival (OS) and relapse-free survival (RFS) for all 35 pts constituted 54.6% and 40.4% respectively. The long-term outcome on both protocols was similar: OS – 62.8% vs 49.4% (p=0.6), RFS – 55.7% vs 45% (p=0.7), respectively. In order to evaluate the impact of allogeneic HSCT we performed a comparison of transplanted and non-transplanted patients by a landmark analysis. The land mark was chosen as the median time from CR to allo-HSCT – 4.3 mo (3-16 mo). So, the 5y OS from landmark was 53.3% for non-transplanted patients and from day of HSCT - 65.6% in transplanted (p=0.18), and RFS was 25% vs 62.5 (p=0.19), respectively. OS for older pts (>45 y) was 40% vs 25% in transplanted vs non-transplanted group of the pts, and RFS was 25% vs 66.6%, respectively. OS in younger (45y) pts was 83.3% vs 58.9% for transplanted vs non-transplanted pts, EFS was 77.1 vs 21.4%, respectively.

Summary/Conclusions: The results very pessimistic in older (>45 years) patients who received HSCT. The contrary was observed in younger adult patients with very good results after HSCT – OS was 83.3% and EFS 77.1%. We conclude that patients aged>45y should continue chemotherapy without allogeneic HSCT or may be we could apply autologous HSCT for that group of the patients.

TARGETABLE BLINATUMOMAB + TYROSINE KINASE INHIBITORS TREATMENT IN RELAPSED/REFRACTORY ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS: CLINICAL EFFECTIVENESS AND PERIPHERAL LYMPHOCYTES SUBPOPULATIONS KINETICS

A. Sokolov1,*, E. Parovichnikova1, V. Troitskaya1, I. Galtseva1, L. Kuzmina1, J. Davidova1, N. Kapranov1, I. Lukyanova1, T. Lobanova1, K. Zarubina1, E. Usikova1, V. Savchenko1, V. Savchenko2
1National Research Center for Hematology of the Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation, 2Chemotherapy of hematologoses and bone marrow depression and bone marrow transplantation, National Research Center for Hematology of the Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation

Background: Blinatumomab is a bispecific monoclonal anti-CD3/CD19 antibody which has clinical activity in relapsed/refractory Ph-positive acute lymphoblastic leukemia (ALL) as monotherapy. Combination of Blinatumomab with
tyrosine kinase inhibitors (TKI) is the promising approach in treating Ph-positive ALL. Some other rearrangements like IKZF1 in Ph-like ALL, FLT3 and JAK2 in Ph-negative ALL are the potential targets to some TKIs.

Aims: To demonstrate effectiveness and toxicity profile of Blinatumomab+TKI treatment. To evaluate peripheral blood lymphocytes subpopulations kinetics during blinatumomab treatment.

Methods: From October 2015 to February 2017 10 patients (pts) aged from 24 to 42 (median 31), 7 female and 3 male, with relapsed/refractory ALL were treated in our center. The diagnosis was relapsed ALL in 8 pts (7 – overt hematological, 1 – cytogenetic relapse) and persistent/increasing minimal residual disease of ALL in 2 pts. All pts had strong CD19 positive. 8 pts was diagnosed as Ph-positive ALL (p190), 1 – Ph-like ALL (IKZF1 rearranged), 1- FLT3+ ALL. Two pts has T315I ABL mutation. In all pts blinatamobabel continuous infusion + TKI therapy was started. Blinatumomab dose during 1st week of 1st cycle was 9 mcg/day, 28 mcg – subsequent three weeks. Blinatumomab dose in subsequent 4-weeks cycles was 28 mcg/day. 7 pts were treated with TKI Dasatinib, 1 – Bosutinib (Dasatinib/Nilotinib intolerant), 1 – Ponatinib (T315I), 1 – Sorafenib (FLT3+). ATRA was added to Dasatinib in 1 pt with IKZF1 rearranged Ph-positive ALL. 1 pt received 1 cycle of 4 weeks blinatumomab, 1 pt – 2 cycles, 6 pts -4 cycles, 2 pts – 5 cycles. TKIs were administered continuously in all pts. T-helper, T cytotoxic, T-regulatory and NK cells were measured by flow cytometry in every week during all cycles of blinatumomab treatment.

Results: No one pt has neurological toxicity of any grade. All pts has significant decrease of normal IgG level and all of them received intravenous human normal immunoglobulin replacement. Palmar-plantar eruption was noted in one pt on sorafenib completely resolved after temporarily TKI discontinuation. Diarrhea in 1 pt on dasatinib/nilotinib completely resolved on bosutinib. 8 pts achieved molecular remission (MoCR), one pt – cytogenetic remission and one pt with T315I progressed to overt hematological relapse. T-helper and T-regulatory lymphocytes subpopulations were on or below of lower limit of normal range. T-cytotoxic and NK subpopulations gradually returned into normal range (Fig. 1). AlloBMT was performed in 4 pts. Three pts are awaiting alloBMT and three are continuing Blinatumomab + TKI treatment.

Summary/Conclusions: Lowering toxicity in non-chemotherapy treatment has its significance in such a heavily pretreated patients with relapsed ALL. The treatment has high MoCR rate and low toxicity profile. Treatment effectiveness correlated with T-helper and T-regulatory subpopulations exhaustion. T-cytotoxic and NK cells subpopulations restoring also correlated with clinical effectiveness.

Figure 1.

Methods: From October 2015 to February 2017 10 patients (pts) aged from 24 to 42 (median 31), 7 female and 3 male, with relapsed/refractory ALL were treated in our center. NOVEL CRLF2 MUTATIONS AND CLINICAL SIGNIFICANCE IN ADULT ACUTE LYMPHOBLASTIC LEUKEMIA

Z. Ge1,2, Y. Gu2,3, Q. Han2,3, X.-L. Zhou2,3, B.-A. Chen1,2, J.-Y. Li3, C. Song2,4,*

1Pediatric Oncology Department, 2Hematology Lab, P.&A. Kyriakou, ATHENS, Greece

Results: During this period, a total number of 353 patients with childhood ALL were treated in our Department, according to BFM protocols. Recurrence occurred in 86 patients (24.4%, 56 male - 30 female - median age: 4.83 years), within 3 to 184 months from initial diagnosis. Very very late recurrence was noted in 3.1% of our relapses (8 male - 3 female) at 53, 72, 83, 84, 108, 112, 116, 120 and 184 months from initial diagnosis. In 9 patients recurrence involved the bone marrow, in 1 both bone marrow and central nervous system (CNS) and in 1 only the testicles. Two children had received allogeneic BMT from a matched related donor in first complete remission (CR1) and they had a bone marrow relapse 4 and 5 years later, respectively. The mean WBC, Hb, Blasts and PLT values at diagnosis were 29260/mm3, 5.6g/dl, 21360/mm3 and 18000/mm3, respectively. All of them were B-cell ALL except for 1 who had CD33 and CD13 co-expression. Regarding the immunophenotypical profile of the disease at recurrence, it remained almost identical to the initial. Regarding cytogenetic characteristics of the patients at diagnosis, 3 of them had high hyperdiploidy, one del(6)(q12), one BCR-ABL fusion and one 47,X,Y+13(9), idio- del(12p)(q13?); none del(12p). In ALL, the disease at recurrence, the cytogenetic profile remained identical at recurrence, while in 1, trisomia 13 was not detected and another had heterozygous absence of IKZF1, PAIX5, EBF1, CDKN2A and CDKN2B genes. On Day 8, nine of 11 patients were Prednisone Good Responders. On Day 15, nine children had bone marrow m1, one m2 and one m3, and on Day 33 only one had m2. Two patients were classified as low risk, 6 as intermediate risk and 3 as high risk. Second remission (CR2) was achieved in 9 children with very very late recurrence. The other 2 died from disease progression. Six of nine patients are still alive and well 6, 8, 10, 10, 11 and 20 years after initial diagnosis. One patient of 9 died from secondary recurrence and the last two had a second allogeneic BMT and died due to severe infection, 2 and 11 months following BMT. Interestingly, 3 out of 5 patients who finally died, had the very very late recurrence (10, 10 and 15 years after initial diagnosis) and had been treated with adult type protocols.

Summary/Conclusions: The rate of very very late B-cell ALL recurrence was only 12.8% of all recurrences. The prognosis is worse in patients, older than 18 years, treated with adult type protocols.
was lower than that of non-mutation (8.53×10^9/L vs 28.9×10^9/L, P=0.032). The positive rate of Ph chromosome in patients with R186S was lower than that without the mutant (10.0% vs 31.8%, P=0.018). In addition, the incidence of splenomegaly in patients with R186S and P224 L mutants was lower than that in non-mutant patients (0.0% vs 29.5%, P=0.026; 0.0% vs 29.7%, P=0.034, respectively). The B-ALL patients with L86I mutant had myeloid antigen expression, high white blood cell count (248.4×10^9/L) and low platelet count (10×10^9/L), and relapsed in two months after the first induction chemotherapy; and the overall survival was only 2 months. The patient with W255C mutation did not achieve complete remission (CR) with the first induction chemotherapy.

Summary/Conclusions: Six novel CRLF2 genetic mutations were identified in adult ALL patients and may associate with clinical outcome, such as CRLF2 R186S indicating favorable, while L86I and W255C indicating poor outcome. Our data indicated that the CRLF2 mutations may be new prognostic markers and play an important role on oncogenesis in ALL.

Background: Recently, comprehensive genetic profiling of pediatric and adult core-binding factor (CBF) AML revealed a variety of cooperating events in a cohort of 85 t(8;21) AML patients (Faber et al. Nat Genet 2016). These mutations comprised alterations in genes encoding for proteins in tyrosine kinase (TK) signaling, epigenetic regulation (ER), and in the cohesin complex (CC).

Aims: To validate and to further extend our recent findings by comprehensive characterization of the mutational landscape of t(8;21) positive AML using a high-throughput targeted sequencing (HTS) approach.

Methods: The HTS panel comprised the entire coding region of 244 genes that are involved in hematological malignancies. Pretreatment blood (n=23) or bone marrow specimens (n=72) of 95 additional adult t(8;21) positive AML patients (pts) (median age: 51 yrs, range 18-72 yrs) were analyzed. 92/95 pts were enrolled in one of seven prospective AMLSG treatment trials. Libraries (total probe size: 1.359 Mbp) were prepared using SureSelectXT custom solutions (Agilent). Paired-end sequencing was carried out on a HiSeq 2000 (Illumina). The variant allele frequency (VAF) cutoff for reporting mutations was set at ≥0.05.

Results: The median coverage per pt was 900x. Mutations were detected with an average of 5.1 (SD: ±2.6) per pt with 99% of all pts harboring at least 1 mutation and 87% ≥ 3 mutations. Consistent with previous studies, mutations in TK signaling pathways were common events: KIT mutations were found in 22/95 pts (23%) followed by mutations affecting NRAS (16/95; 17%), FLT3 (11/95; 12%; point mutations only), and KRAS (4/95; 4%). A significant enrichment of mutations was also observed in genes involved in epigenetic regulation, ASXL1 (15/95; 16%), ASXL2 (12/95; 13%), KDM6A (11/95; 12%), CREBBP (8/95; 8%), SRCAP (8/95; 8%), EZH2 (7/95; 7%), SETD2 (5/95; 5%), TET2 (12/95; 13%) and DNMT3A (5/95; 5%), highlighting their contribution in altering the epigenetic state of this leukemia subtype. Moreover, mutations affecting members of the CC were found with a high frequency: RAD21 (13/95; 14%), SMC1A (5/95; 5%), STAG2 (3/95; 3%), and SMC3 (2/95; 2%). Of note, mutations in CC genes were almost mutually exclusive. We also identified additional mutations in previously detected cooperating genes such as mutations clustering in exon 2 of the ZBTB7A gene (15/95; 16%), encoding for a transcription factor involved in hematopoietic lineage fate. Recurrent mutations were also observed in CCL22 (9/95; 9%), that plays an important role in regulation of hematopoietic cell proliferation, as well as DDX15 (6/95; 6%) being involved in spliceosome function and ribosome biogenesis. With respect to the clonal architecture we found that the median VAF in genes belonging to ER and CC (0.30; range 0.03-0.91; 0.31, range 0.05-0.73, respectively) was higher than in genes associated with TK signaling (0.19, range 0.05-0.53). These data suggest that alterations affecting the epigenetic state and differentiation occur earlier than those in signaling during t(8;21) leukemogenesis.

Summary/Conclusions: Using a comprehensive, deep sequencing approach we could further characterize the mutational landscape of t(8;21) positive AML. Here, mutation clusters in genes involved in TK signaling, ER and CC were confirmed as well as novel CBF-associated gene mutations that play an essential role in regulation of hematopoietic cell proliferation and differentiation. Further analyses in terms of sample size extension as well as correlation of findings with clinical parameters are ongoing.
Background: Mixed Lineage Leukemia’s (MLL’s) are characterised cytogenetically by reciprocal translocations of the MLL gene and clinically by unfavourable outcomes. Evidence indicating that MLL leukemia’s are resistant to apoptosis encourages the identification of novel drug targets.

Aims: Using cord blood (CB) CD34+ cells (control) and CB CD34+ cells expressing MLL-AF9, we sought to determine the potential role of BTK in the development and progression of MLL+ leukemia. We further aimed to uncover possible downstream target/s of BTK, improving the therapeutic efficacy of the drugs used.

Methods: Experiments were performed using control and MA9.3 cells and leukemia blasts from 3 AML (MLL+) patients. Signalling events were evaluated by immunoblotting, p65 mediated BTK expression was determined by promoter assays. Cells were treated with specific inhibitors of BTK (Ibrutinib (IBI): 0.25, 0.5, 1.0 and 2μM) in combination with Daunorubicin (DAU 5nM) or RAC (NSC 23766 (NSC): 5, 10, and 20μM) for 48 hrs and cell viability was assessed using Annexin V/Sytox-Blue based flow cytometric analysis.

Results: In the context of a therapeutic target in MLL+ AML, we examined the whole cell lysates (WCL) from control cells, two clones of CB expressing MA9 (MA9.3 and .6) and leukemia blasts from the 3 AML patients. Activated BTK (pY223) was detectable in both the clones of MA9 and MLL+AML samples. Interestingly, the cells demonstrated activation of p65 (pS536) but not in control cells. To address if activated p65 could potentially drive BTK expression, we performed BTK promoter assays with reporter construct and empty vector. MA9.3 cells electroporated with test construct demonstrated significantly higher transcriptional activity. At the protein level, p65 inhibitor treatment (MG132 or Bay 11-7082) reduced total BTK expression, indicated down-regulated p65 upstream of BTK in the context of MA9.3 treatment. Treatment of control and MA9.3 cells with various concentrations of IBR for 48 hrs induced a dose-dependent reduction of cell viability (Annexin V and Sytox blue negative). We further sought to determine if the use of IBR in combination with Daunorubicin would further sensitize MA9.3 cells. The apoptotic rate of the cells in combination treatment was significantly higher than that of cells treated with IBR or DAU alone. The coefficient of drug interaction (CDI) values indicated that IBR-DAU combination synergistically reduced cell viability (CDI > 1.0-antagonistic; < 1.0 synergistic and = 1 additive effect). Recent studies suggested that RAC-GTPase signaling may also represent a target in AML, particularly in the context of FLT3-ITD (Longo 2009 and B Mizukawa et al., Blood 2011). This intrigued us to test if BTK is possibly upstream of RAC. We measured activation of the GTPase RAC via active RAC pull down assay. Interestingly, treatment with IBR/DAU significantly reduced RAC activation, positioning BTK upstream of RAC in line with observations reported earlier. We further observed that MA9.3 cells are responsive to RAC inhibitor, NSC. This effect of NSC on cell viability was further potentiated in combination with IBR (0.5μM). CDI values once again indicated that the drugs together have a synergistic effect on reducing the cell viability.

Summary/Conclusions: Taken together, our data support a biological link between NFkB, BTK and RAC pathways in the modulation of cell survival in MLL-rearranged AML cells. Abruptly active p65 drives the expression of BTK and contributes to the progression of the AML. Combination treatment using IBR-DAU and IBR-NSC might be a promising therapeutic strategy, minimizing high drug dose-related side effects but increasing the therapeutic efficacy.

SECRETION OF SOLUBLE FACTORS BY AML CELLS INFLUENCE CD3/CD3 BITE® ANTIBODY MEDIATED CYTOTOXICITY AND T-CELL PROLIFERATION

M. Costanzí1,2, K. Krupka1,2, R. Kischel3, P. Kuefer3, T. Köhnik1,2, K. Spiekermann4,5, W. Hiddeßen4,5, M. Subkiewicz4,5 and W. Wernitz4,5
1Laboratory for Translational Cancer Immunology - Gene Center, 2Department of Internal Medicine III, Hospital of the Ludwig-Maximilians-University (LMU) Munich, 3AMGEN Research GmbH, Munich, 4German Cancer Consortium (DKTK) and German Cancer Research Center (DKFZ), Heidelberg, Germany

Background: In our previous work, we showed that the CD3/CD3 BITE® antibody construct (AMG 330) is able to recruit autologous, residual T cells and induce cytotoxicity against primary AML cells ex vivo. However, as described previously (Musasi et al, Blood 2013) primary AML cells are able to secrete soluble factors, which might not only influence T-cell proliferation but also negatively affect AMG 330 mediated cytotoxicity.

Aims: In this study we characterized the influence of soluble factors secreted by primary AML cells on AMG 330 mediated cytotoxicity.

Methods: We used plasma samples (from heparinized serum tubes or after density gradient centrifugation) from newly diagnosed and relapsed AML patients in AMG 330 cocultures of healthy donor (HD) T cells and AML cell lines. In flow cytometry based experiments we determined the influence of AML plasma in comparison to fetal calf serum (FCS, heat inactivated) on AMG 330 mediated cytotoxicity and T-cell proliferation. In transwell experiments using primary AML cells physically separated from AMG 330 cocultures, we evaluated if AML cells are the source of soluble factor secretion.

Results: The influence of AML plasma from bone marrow (BM) of AML patients on AMG 330 mediated cytotoxicity and T-cell proliferation was heterogeneous: In 15/30 samples, AMG 330 mediated cytotoxicity was significantly reduced compared to cultures containing FCS (mean% specific lysis FCS vs BM: 72.8 ± 26.8). There was an associated reduction in T-cell proliferation (mean% proliferation FCS vs BM: 27.7 ± 9.5%). The degree of immunosuppression could not be correlated to percentage of bone marrow blasts. Interestingly, the effect was not observed in AML plasma samples from peripheral blood (PB) (mean% specific lysis FCS vs PB: 84.7 ± 83.5%, proliferation FCS vs PB 32.2 ± 15.9%). In the remaining 15 samples, plasma from AML BM influenced AMG 330 mediated T-cell function was observed (mean% specific lysis FCS vs BM: 82.1 ± 78.3%; proliferation FCS vs BM: 25.7 ± 26.8). In control cultures plasma from AML patients in complete remission (CR) or from HD BM was used which did not negatively impact AMG 330 mediated cytotoxicity (mean% specific lysis FCS vs CR: 76.5 ± 69.2%; FCS vs PB: 76.1 ± 76.2%), proliferation (FCS vs CR: 76.5 ± 68.2%; FCS vs HD: 58.9 ± 65.4%). To further explore the influence of soluble factors from primary AML cells, we performed transwell experiments. Primary AML cells were cultured in the previously described long term culture system (Krupka et al., Leukemia 2016) and HD T cells were added. In all MOLM 13 cells were placed in transwell devices (3μm). In analogy to our findings with AML BM plasma, we observed a strong reduction in AMG 330 mediated cytotoxicity and T-cell proliferation in 7/14 experiments (mean% specific lysis control vs AML: 95.0 vs 70.8%; proliferation control vs AML: 78.6 vs 26.8).

1Klinik für Innere Medizin III, Universitätsklinikum Ulm, Ulm, 2Medizinische Klinik und Poliklinik, Universitätsklinikum Hamburg, Hamburg, 3Klinik für Innere Medizin II, Universitätsklinikum Tübingen, Tübingen, 4Klinik für Hämatologie und Medizinische Onkologie, Universitätsklinikum Göttingen, Göttingen, 5Klinik für Hämatologie, Onkologie und Klinische Immunologie, Universitätsklinikum Düsseldorf, Düsseldorf, 6Klinik für Innere Medizin I, Universitätsklinikum Freiburg, Freiburg, 7Klinik für Hämatologie, Hämatoonkologie, Onkologie und Stammzelltransplantation, Medizinische Hochschule Hannover, Hannover, 8Department of Medicine and Comprehensive Cancer Research Center, University of Chicago, Chicago, IL, United States, 9Nationales Centrum für Tumorerkranckungen (NCT), Universität Heidelberg, Heidelberg, Germany. 10Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA, United States

Background: Internal tandem duplications (ITD) in the receptor tyrosine kinase FLT3 occur in about 22% of patients (pts) with acute myeloid leukemia (AML) and confer a poor prognosis depending on the mutational load. Treatment options for FLT3-ITD carry a high risk of resistance and the role of a multi-targeted TKI (midostaurin; 6 pts in the AMLSG16-10 (NCT01477606) or CALGB 10603 (RATIFY, NCT00651261) trial in paired samples obtained at diagnosis (Dx), complete remission (CR) and relapse (Rel), by whole exome sequencing (WES).

Methods: WES was performed in 17 FLT3-ITD pts using the Nextera Rapid Capture Exome kit (illumina) for library preparation followed by sequencing on an Illumina HiSeq2000. 6 pts were treated in the RATIFY trial receiving either midostaurin or placebo combined with intensive chemotherapy during induction and 11 pts were treated in the AMLSG16-10 trial. In the former treatment with midostaurin combined with intensive chemotherapy during induction and consolidation followed by a one-year maintenance therapy with midostaurin; 4 pts in the AMLSG16-10 trial received alemtuzumab, hematopoietic cell transplantation. The presence of FLT3 and NPM1 mutations (mut) and the allelic ratio (AR) of FLT3-ITD were analyzed according to standard protocols.

Results: The median AR of FLT3-ITD was 0.51 (0.10-18.94) and 0.54 (0.07-26.31) at Dx and Rel, respectively. Loss of FLT3-ITD was observed in 5 pts; changes of the ITD clone at Rel occurred in 7 pts. Of those, 5 pts had a change of the original ITD and 1 pt gained an additional ITD clone at Rel. 3 pts had a D835V FLT3-TKDmut that was lost at Rel. 6 pts had a NPM1mut that persisted at Rel in all pts. Using WES, 301 mut (226 missense, 24 nonsense, 41 indels, 6 splice sites, 4 unique) were identified. The average coverage was 125 (186-67) among all samples. 131 (43%) mut were present at both time points (Dx and Rel). 40 mut were found only at Dx, 73 (24%) mut were detected only at Rel and 14 mut with 10 mut only at Dx. Besides FLT3-ITD, the average number of mut per sample (Dx or Rel) was 13. Mut were most frequently observed in genes related to signaling (23%), transcription (20%), DNA methylation (9%), chromatin remodeling (9%), components of the mTOR switch under stromal influence. These observations suggest that resistance to targeted therapies in vivo in part may derive from changes that AML cells induce in the microenvironment.

E869

MICROENVIRONMENT SECRETED PROTEINS MEDIATE RESISTANCE TO TARGETED THERAPY IN PRIMARY AML CELLS

A. Doka1, J. Gribben1, P. Cutillas1

1Haematology-Oncology, Barts Cancer Institute, London, United Kingdom

Background: The bone marrow stromal microenvironment (BMSM) plays an important role in the pathophysiology of acute myeloid leukemia (AML). This is demonstrated by primary AML blasts dependence on stromal conditioned media to survive long-term in culture. Although some of the components of the stromal secretome (the totally secreted proteins by biological cells) that augment AML survival are known, the precise molecular mechanisms of the stromal-blast interactions are not fully defined.

Aims: (i) identify proteins secreted by bone marrow stromal cells that mediate AML cell survival; (ii) investigate global changes in signaling pathways activity induced by stromal factors in primary AML; (iii) Validate the functional significance of these interactions through targeted inhibition of BMSM activated signaling pathways.

Methods: We used primary AML cells and established cell lines. Four different human AML lines were grown individually or in co-culture with a mouse bone marrow stromal line (MS-5). The resulting conditioned medium from these experiments (4 AML lines alone, 4 AML lines + MS-5, MS-5 alone) was purified to obtain the secretome (in triplicate). Proteins in these secretomes were quantified using Liquid Chromatography Tandem Mass Spectrometry (LC-MS/MS). Peptide sequence searches against both mouse and human proteomes allowed for discrimination between the mouse stromal and human AML proteins. Guava EasyCye Flow Cytometry was used to measure the viability and proliferation of these cell populations, assessing the capability of the identified factors above on primary AML cells (n=6) as well as the effects of kinase inhibitors (midostaurin, trametinib, tofacitinib and Midostaurin over 72hrs with and without stromal conditioned media (n=10). Label-free LC-MS/MS based phosphoproteomics quantified >5,000 phosphorylation sites in primary AML patient cells treated with identified stromal factors individually and combined in triplicate. Commercial (MASCOT) and in-house (PESCAL, KSEA) software were utilized to identify and quantify proteins, determine kinase activities and interpret intracellular signaling.

Results: Initially by comparing secretomes of the four AML lines (on their own or in MS-5 co-culture) we identified 520 bone marrow stromal proteins and 293 AML blast proteins. From these, six stromal proteins were selected (including collagen, a secreted extracellular matrix protein [CTGF] and bone morphogenic protein-1 [BMP-1]) based on their ability to effect growth and likely signalling capacity in AML cells. These six proteins were used in varying combinations to determine their effect on growth of primary AML cells from patients (n=6). We also analysed the phosphoproteomes of primary AML cells displaying the maximal effects on growth in response to the six factors above to determine the underlying biological mechanisms. These studies have shown that several different pathways are activated as a result of secretome treatment including mTOR and MAPK. Primary AML cells were sensitive to targeted inhibition of these pathways. However, the inclusion of stromal secreted factors to the same AML cells could induce sensitivity to another kinase inhibitor and insensitivity towards the previously effective inhibitor.

Summary/Conclusions: This proteomic approach has allowed identification of a panel of key proteins (including 10-A11, CTGF, BMP-1) secreted by the stromal cells that modulate cell signalling and cell fate in AML blasts. Using a multi-targeted approach to screen secreted stromal factors we were able to dissect the factor specific effects on AML signalling. Subsequent survival assays and targeted inhibition studies demonstrate that despite heterogeneity in patient response to these factors, activity in key signalling pathways such as mTOR and mTOR switch under stromal influence. These observations suggest that resistance to targeted therapies in vivo in part may derive from changes that AML cells induce in the microenvironment.

University of Chicago, Chicago, IL, United States, 1National Centre for Tobacco Control, University of Heidelberg, Heidelberg, Germany, 10Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA, United States

Background: Internal tandem duplications (ITD) and mutations (mut) in the tyrosine kinase domain (TKD) of the receptor tyrosine kinase FLT3 occur in about 25% of acute myeloid leukemia (AML) patients (pts). FLT3-ITD is associated with an unfavorable prognosis in particular in pts with a high allelic mutant to wildtype ratio (AR>0.5) as well as localization of the ITD in the beta1-sheet of the receptor. FLT3is targetable by tyrosine kinase inhibitors (TKI) and the combination of chemotherapy with the TKI midostaurin has been recently investigated within the CALGB 10603 RATIFY trial and is still under investigation within the AMLSG 16-10 trial.

Aims: To study the FLT3mut status at the time of diagnosis (Dx), refractory disease (RD) and relapse (Rel) in AML pts treated within the CALGB 10603 RATIFY trial and AMLSG 16-10 (NCT01477606) trial with regard to AR-FLT3-ITD and FLT3-ITDmut, loss of FLT3-ITD and FLT3-TKDmut and change of ITD clones (ITD insertion site, length, number of clones).

Methods: FLT3-ITD and FLT3-TKDmut were detected using Genescan-based fragment-length analysis according to standard protocols. In the randomized phase-III RATIFY study, FLT3mut pts were treated with induction (daunorubicin/ cytarabine) and consolidation (high-dose cytarabine) and maintenance therapy in FLT3-ITD positive pts.

Results: In total, 83 pts were analyzed, of which 33 were treated in the RATIFY and 50 within the AMLSG 16-10 trial. 36 pts had RD and 47 pts had relapsed. FLT3-ITDwas present at diagnosis in all pts treated in the AMLSG 16-10 trial; one pt had an additional FLT3-TKDmut. Pts entering the RATIFY trial either had either a FLT3-ITDmut (n=22), as FLT3-ITDmut (n=2), or both (n=2). The median AR of FLT3-TKDmut at Dx was 0.82 (0.27-2.66) and the majority of pts showed loss of FLT3-TKDmut at RD or Rel (n=9/12; 75%). In relapsed pts, loss of FLT3-ITD occurred in 14 (36%) pts. There was no significant difference between the median FLT3-ITD AR at Dx [0.62 (0.10-18.94)] and Rel [0.65 (0.07-38.75); p=0.98]. A switch of the ITD clone was found in 14 (36%) pts at Rel, with switch of the ITD insertion site or length in 8 (21%) pts. 8/14 pts with change of the ITD clone at Rel had multiple ITD clones at Dx. For 35 FLT3-ITDPositive pts with refractory AML, FLT3-ITD loss was observed in 17 (49%) pts. The median AR of FLT3-ITD was significantly lower at the time of RD [0.29 (0.05-2.37)] compared to Dx [0.62 (0.05-8.91); p=0.02]. The ITD clone changed in 5 (14%) pts with RD. In pts with shift of the ITD clone at Rd (n=5) or Rel (n=14), no significant difference of the median ITD length was observed (p=0.84).

Summary/Conclusions: Comparing the FLT3-ITD status at Dx, at the time of RD or Rel, we found a lower median AR of FLT3-ITD in pts at RD compared to Dx, whereas no significant change of AR was observed at Rel. In addition, loss of FLT3-ITD was observed in 49% of pts at RD and in 36% of pts at Rel. These findings suggest that the FLT3-ITD clone can be targeted in a significant number of pts and other clones might mediate resistance to treatment. We also observed a switch of the ITD clone in about 20% of pts with Rel, indicating the preeminence of ITD clones in the context of resistance to treatment. Despite the small number of TKD mutations in our study, it was remarkable that most of the TKDs (75%) were lost at the time of RD or Rel.

E872

COOPERATION OF MLL-PTD WITH DNMT3A OR RUNX1 MUTATIONS IN AML LEUKEMOGENESIS

H.-W. Kao1, R. Bera2, Y.-J. Huang2, J.-F. Fu2, D.-C. Liang3, L.Y. Shih3
1Chang Gung Memorial Hospital and Chang Gung University, 2Chang Gung Memorial Hospital, Taoyuan, 3Mackay Memorial Hospital, Taipei, Taiwan, Republic of China

Background: Our previous study showed that DNMT3A or RUNX1 mutations were frequently coexisted in the MLL-PTD AML patients (Oncoarget 2015). We aimed to investigate the role of coexisted DNMT3A or RUNX1 mutations in leukemogenesis of MLL-PTD AML.

Methods: After lentiviral-mediated over-expression of RUNX1 or DNMT3A mutants in MLL-PTD mouse bone marrow (BM) cells or human MLL-PTD AML cells, colony formation, cell proliferation, differentiation and apoptosis assays were carried out. Interaction of RUNX1, HIF-1α, and MLL-PTD were evaluated by co-immunoprecipitation assay. Differential gene sets and protein expression, histone modifying protein expression, and enrichment of histone 4 acetylation (H4Ac) were assessed by RT-qPCR, Western blot, and ChIP-qPCR, respectively. For BM transplantation assays in mice, MLL-PTD BM cells over-expressing DNMT3A-Wild type (WT) mutants and empty vector (EV) control were injected into C57BL/6 mice via tail vein.

Results: We observed that MLL-PTD BM cells with RUNX1 mutants lacking C-terminal WWRPY sequence (H377SxK and V435fsX376) had increased self-renewal, proliferation, increased HIF-1α and its downstream gene expression. In addition, the interaction of HIF-1α and MLL-PTD was disrupted in the cells transduced with C-terminal truncated RUNX1 mutants or RUNX1 shRNA. Compared with those expressing DNMT3A mutants, over-expression of DNMT3A-Wt reduced cell growth, colony formation and self-renewal activities of EOL-1 and MLL-PTD BM cells. All DNMT3A mutants impaired Nαbulyrate-induced differentiation, but only R82H mutant impaired ATRA-induced differentiation in vitro. DNMT3A mutations were associated mostly with up-regulation of homeobox B (HOXB) genes. The expressions of BCL2, AREG, PRKCA, PRKN were all up-regulated and MCL1 was significantly down-regulated in the DNMT3A-mutant cells compared to those of DNMT3A-Wt. Cells with DNMT3A- mutants showed regulation of H4Ac enrichment at the HOXB and HOXC12 promoter regions compared to the control cells or the cells with DNMT3A-Wt. DNA methylation microarray analysis identified both hypo- and hypermethylation features in different regions throughout the genome of DNMT3A-mutant-transduced EOL-1 cells. Up-regulated genes including HLX and HBEF1 were hypermethylated in the EOL-1 cells transduced with DNMT3A mutants. In vivo study showed that white blood cells including neutrophils, lymphocytes and monocytes increased significantly (P<0.03) in the DNMT3A-mutants mice compared to EV or WT-mice at 10 months post-BM transplantation.

Summary/Conclusions: The present study showed that both RUNX1 and DNMT3A mutants dysregulated self-renewal, proliferation and apoptosis in the mouse MLL-PTD BM cells. Disruption of MLL-PTD-RUNX1-HIF-1α complex in the RUNX1-mutant and aberrant methylation in the DNMT3A-mutant cells might play an important role in AML pathogenesis. Our results showed that cooperatively RUNX1 or DNMT3A mutations had impact on leukemogenesis of MLL-PTD AML.

AML BLASTS INDUCE A SENESCENT PHENOTYPE IN THE BM-MSC

E. Forde1, 2A. Abdul-Aziz1, T. Mehta2, F. Di Palmara2, C. Ingham2, M. Lawes2, K. Bowles1, S. Rushworth1
1Norwich Medical School, University of East Anglia, 2Earlham Institute, 3Department of Trauma and Orthopaedic Surgery, NNUH, 4Department of Haematology, Norfolk and Norwich University Hospital NHS Trust, Norwich, United Kingdom

Background: Acute myeloid leukaemia (AML) is a heterogeneous clonal disorder that arises from the haematopoietic myeloid progenitor cells within the
bone marrow microenvironment (BMM). Survival of patients with AML is presently poor; two-thirds of younger adults, and 90% of older adults die of their disease. Even in patients who achieve remission with chemotherapy, relapse is common and occurs from minimal residual disease sequestered in protective niches in the BMM. Reciprocal interactions between that of the AML and bone marrow mesenchymal stromal cells (BM-MSC) are central to the survival and propagation of blasts therein. The microenvironment promotes quiescence in malignant cells as well as the activation of anti-apoptotic and pro-survival pathways.

**Aims:** To investigate how BM-MSC are programmed by AML to generate a pro-tumoural environment.

**Methods:** Primary AML and BM-MSC were isolated from the pelvis of AML patients following informed consent and under approval from the UK National Research Ethics Service (LREC/07/H0310/146). Low input RNASeq of 10 AML BM-MSC and 10 healthy BM-MSC (taken from the pelvis of patients undergoing elective hip replacement surgery) was performed following CD271 Magnetic Cell Isolation Kit (Miltenyi Biotech). AML blasts cultured in co-culture with confluent primary BM-MSC for 48 hours (h), 72h and 168h. Real-time PCR was used to verify the RNA sequencing data and Western Blot analysis to confirm protein expression. Lentivirus mediated knockdown was used to target gene expression in the BM-MSC. Senescence was assayed by β-Galactosidase staining.

**Results:** From the RNA sequencing data carried out to compare 10 healthy and 10 AML BM-MSC show that 1125 genes were differentially expressed, with 924 down-regulated in AML derived BM-MSC and 201 up-regulated. From this analysis, we found that CDKN1A (p21) is up-regulated in BM-MSC from AML patients (7.406 logFC) compared to BM-MSC from patients with normal bone marrow (2.636 logFC). p21 mRNA expression was confirmed by RT-PCR in AML BM-MSC compared to normal BM-MSC. In-vitro experimentation showed that p21 mRNA and protein expression is increased in BM-MSC when co-cultured with primary AML. Furthermore, we show that AML increased senescence β-Galactosidase staining in BM-MSC and that p21 knockdown in BM-MSC reversed the senescence phenotype. Finally, primary AML cultured on p21 knockdown BM-MSC had reduced survival compared to control BM-MSC.

**Summary/Conclusions:** We have identified that AML induces a senescent BM-MSC niche via the p21 mediated pathway which in turn promotes survival and proliferation of AML. Silencing of p21 within the BM-MSC reduces AML survival. In identifying this novel microenvironment feedback loop in AML we highlight a potential new target for future AML therapies.
a preferential engraftment in the presence of FLT3-ITD mutation (9 of 18). Furthermore, we found that the mutational fraction of 3 out of 4 patients harbouring a FLT3-ITD mutation enriched for this mutation in the primary PDX and then remained stable in subsequent xenotransplants. Similarly, eight PDX with respective primary AML were analysed by next-generation sequencing (NGS) of 27 AML relevant genes. We found stable variant allele fractions (VAF) among the primary and serial PDX bone marrows and spleens for 50 mutations (6% in healthy pre-treated ALL patients, reasons for resistance have not been determined. In contrast to classical T-cell activation, BiTE® antibody construct mediated T-cell activation relies solely on binding to the CD3ε chain of the T-cell receptor (TCR) complex. Resolving the exact mechanism of BiTE® antibody construct mediated T-cell activation is a prerequisite for our understanding of mechanisms of resistance. Aims: In the present study we characterized the role of costimulation on intracellular signalling in CD33/CD7 BiTE® antibody construct (AMG 330)-mediated T-cell activation.

Methods: We generated a murine cell line stably expressing human CD33 and devoid of human costimulatory molecules (B33). In in vitro cocultures, cytokicity against B33 cells and the AML cell line MOLM-13 was evaluated by flow cytometry, Activation of downstream signalling pathways was assessed by a phospho-flow cytometry protocol for T-cell recruiting antibodies. Results: Coculture of B33 cells with CD3+ healthy donor T cells (n=4) resulted in AMG 330 mediated mean cytokicity of 58.3%. In contrast, MOLM-13 cells were completely lysed (% specific lysis relative to control B33 vs MOLM-13: 58.3±32.9 vs 99.9±0.1, n=4), despite comparable CD33 expression levels (CD33 medium fluorescence intensity (MFI) ratio: B33 116.1 vs MOLM-13 67.6). However, with the addition of an antiCD3/antiCD28 antibody construct, mean% cytokicity against B33 cells could be restored (% specific lysis AMG 330 vs anti-CD3/anti-CD28: 1.4±1.2 and 3.0±1.0 respectively, n=3). At lower E:T ratios (1:4) the additional costimulatory signal also increased AMG 330 mediated mean% pAkt and pErk (mean% phosphorylated (p)Akt and pErk 7.9 and 7.6, vs 1.7±1.9 and 3.5±2.0, respectively, n=3) (% specific lysis AMG 330 vs anti-CD3/anti-CD28: 65.1±19.7 vs 80.7±16.1, n=3). We next analysed intracellular Akt and Erk phosphorylation levels of T cells after stimulation with AMG 330 or a control BiTE® antibody construct (cBiTE®) and MOLM-13 cells in the absence of antiCD3/antiCD28 antibodies semi-de novo. In the presence of target cells, AMG 330 induced significantly lower Akt and Erk phosphorylation (mean% phosphorylated (p)Akt and pErk 7.9 and 7.6, n=3-5) compared to crosslinked CD3/CD28 antibodies (mean% pAkt and pErk 43.0 and 34.6). However, the combination of AMG 330 and CD28 increased the amount of phosphorylated proteins (mean% pAkt and pErk 11.6 and 11.1), but not to the level achieved by CD3/CD28 stimulation. In the absence of target cells, no Akt phosphorylation was observed upon incubation with AMG 330, suggesting a highly target cell dependent T-cell activation (mean% pAkt with vs without target cells: 0.8 vs 7.9).

Summary/Conclusions: Our data support the hypothesis that costimulation influences the susceptibility of target cells to lysis by T-cell recruiting antibody constructs. Currently, we are validating our results in a larger cohort using T cells from healthy donors and patients with AML. Furthermore, we will analyse the phosphorylation pattern within different T cell subsets and upon knock out of different CD3+ subsets. Our results will contribute to the understanding of BiTE® mediated activation of T cells, which is a prerequisite for clinical responses.

ESTABLISHING SINGLE CELL WHOLE EXOME SEQUENCING ANALYSIS AS A DISCOVERY TOOL IN NPM1/FLT3-POSITIVE PEDIATRIC ACUTE MYELOID LEUKAEMIA

C. Walter1,2, C. Pozzorini2, R. Geffers3,2, H. Hanenberg1, Z. Xu2, N. von Neuhoff1, D. Reinhardt1

1Department of Pediatrics III, University Children’s Hospital Essen, Essen, Germany, 2Sophia Genetics, St. Sulpice, Switzerland, 3Helmholtz-Zentrum für Infektionsforschung GmbH, Braunschweig, Germany

Background: AML is a rare hematological disorder in children and adolescents caused by distinct genetic aberrations, which are relevant for leukemogenesis, prognosis and therapy. Although major players in the molecular landscape and clonal evolution of AML have been identified in adults, it remains a major technical challenge to genetically characterize the few leukemic stem cells (LSCs) cells against a noisy background of AML blasts and normal hematopoietic cells. Aims: The aim of this study was to establish a simple workflow for reliable whole exome sequencing (WES) of single pediatric patients with AML, where often limited research material is available.

Methods: For three pediatric AML patients with mutations in the genes NPM1 and/or FLT3, we performed single cell sorting for CD34+ CD38- AML blasts by FACS and subsequently whole genome amplification (WGA) using the REPLiG single cell DNA amplification kit (Qiagen). The amplified single cell DNA and additional DNA of the corresponding bulk bone marrow was analysed by exome sequencing (WES). Bulk DNA was additionally evaluated by an amplicon-based sequencing approach targeting 54 genes (TruSight Myeloid Panel, Illumina) associated with myeloid malignancies.

Results: The analysis revealed that the median read coverage obtained in the WES of the five DNAs amplified from the single CD34+ CD38- cells and in the corresponding bulk DNAs from the bone marrow of all three patients was comparable for three out of the five single cells. For three amplified single cell genomes, between 92 and 98% of all reads could be mapped to the human genome, however the median coverage for the two failed single cells was 0. For validation of the WGA quality from single LSC DNA, data from 50 out of 54 genes genes analyzed by both sequencing approaches, WES and TSM Panel, were available for all three patients. The majority of variants detected in the WES bulk data could consistently be found at a comparable variant frequency in the TSM panel data. The variant frequencies in the single cell data from WES were more variable and more variants could not be detected in the TSM panel data derived from bulk DNA. We were able to detect n=79 (66%) out of n=121 somatic variants (SNVs, InDels) present in the patients’ AML blasts with three sequencing approaches. WES readily identified n=103 (85.1%) and n=93 (78.9%) of all variants in the bulk and single cell DNA, respectively. Only n=4 (3.3%) variants were not detected by WES at all. We were able to retrace the NPM1 and FLT3 mutations for each of the three patients in the targeted sequencing approach. However the NPM1 mutations and one FLT3 ITD could not reliably be called in the WES approach due to insufficient coverage.

Summary/Conclusions: In summary, WES of amplified single cell DNA is an excellent discovery tool also in pediatric AML for detecting unique changes in potential LSCs that should be validated by targeted sequencing approach with sufficient read counts for finding of rare events.

Background: Myeloid sarcoma (MS) is a subgroup of acute myeloid leukemia (AML), where leukemic cells invade non-hematopoietic tissues and form solid tumors. It may occur as isolated event or simultaneously with leukemic infiltration of the bone marrow (BM). Loss of RAF kinase inhibitor protein (RKIP), a negative regulator of RAS signaling, has recently been described as a frequent event in AML and to be functionally involved in leukemogenesis. Although RKIP has been shown to inhibit the formation of metastases in solid tumors previously, its role in the development of MS is currently unknown.

Aims: In this study, we aimed to delineate the role of the metastasis-suppressor RKIP in the development of MS.

Methods: RKIP protein and mRNA expression was evaluated in formalin-fixed paraffin-embedded biopsies of MS and BM by immunohistochemistry and quantitative real-time PCR (qPCR). Sequence analysis of MS biopsies defined as MS and BM carried out using next generation sequencing approach. WES of amplified single cell DNA was more variable and more variants could not be detected in the TSM panel data derived from bulk DNA. We were able to detect n=79 (66%) out of n=121 somatic variants (SNVs, InDels) present in the patients’ AML blasts with three sequencing approaches. WES readily identified n=103 (85.1%) and n=93 (78.9%) of all variants in the bulk and single cell DNA, respectively. Only n=4 (3.3%) variants were not detected by WES at all. We were able to retrace the NPM1 and FLT3 mutations for each of the three patients in the targeted sequencing approach. However the NPM1 mutations and one FLT3 ITD could not reliably be called in the WES approach due to insufficient coverage.

Results: This study comprised 14 patients with MS (MS-group) and 14 patients with AML without any evidence of extramedullary involvement (BM-group). Of the 14 cases within the MS-group, MS occurred as isolated event in three cases and concomitantly with systemic AML in eleven cases. Both groups were assessed in this matched and clinical as well as laboratory values were comparable between them. Most importantly, however, when we measured the protein expression of RKIP in leukemic tissues of these patients (MS biopsies in the MS-group and leukemic BM biopsies in the BM-AML group), we observed a
significant increase of specimens exhibiting loss of RKIP expression in the MS-group (7/14 vs 1/14, P=0.0329). Interestingly, RKIP loss in MS specimens of cases with concomitant systemic AML was also present in the corresponding leukemic BM samples, thereby excluding a geographical clonal heterogeneity during MS formation in respect to RKIP expression. We then analyzed RKIP mRNA levels by qPCR and observed that RKIP loss correlated with decreased expression (mean of MS group vs non MS group, P=0.041). To gain more insight into the molecular landscape of MS patients with and without RKIP loss, we performed NGS of 39 genes that are recurrently mutated in AML. Interestingly, five out of six (83%) MS patients with RKIP loss demonstrated mutation(s) affecting the RAS-pathway, suggesting a potential functional synergism between these events. Consequently, we performed in vitro overexpression and knockdown of RKIP in the RAS-mutated THP-1 AML cell line and subsequently studied these cells in functional migration and invasion assays. Importantly, RKIP knockdown increased both migration and invasion, thereby indicating a role of RKIP in the development of this condition.

INHIBITING MIR-10A OVERCOMES CYTARABINE-RESISTANCE IN ACUTE MYELOID LEUKAEMIA

T.T. Vu1, K. Wang1, F. Stütz2, G. Ehringer2, T. Mollenky, D. Ma3

1Haematology, Vincent's Hospital, Sydney, Australia, 2Medical Clinic and Policlinic I, University Hospital ‘Carl Gustav Carus’, Dresden, Germany

Background: Chemoresistance is the principle cause of treatment failure in acute myeloid leukaemia (AML) despite a promising response to induction chemotherapy. Emerging evidence suggest the roles of autophagy, a self-eating process contributing to chemoresistance of leukaemia cells. We previously demonstrated that miR-10a, highly expressed in a subgroup of AML harboring Nucleophosmin1 mutations, promotes cell survival by inhibiting non-canonical cell death pathway, suggesting its function in autophagy and thus chemoresistance in AML.

Aims: We aim to demonstrate evidence that miR-10a, a regulator of autophagy, plays important roles in chemoresistance in acute myeloid leukaemia.

Methods: Apoptosis and proliferation in miR-10a inhibited and overexpressed leukaemia cells after cytarabine treatment was measured by Annexin V binding and MTT assay. Autophagy was measured by monitoring the levels of LC3II/LC3I proteins, autophagy-related proteins via Western Blotting and monodansyl-cavardine (MDC) staining (flow cytometry).

Results: First, we observed a decreased expression of miR-10a in the leukaemia cells after the exposure to stress induced by serum starvation. Overexpressing miR-10a in miR-10a low MV4-11 cells decreased apoptosis induced by nutrient starvation and resulted in the resistance to cytarabine. In contrast, its inhibition in OCI-AML3 cells, which express high miR-10a constitutively, resulted in the induction of apoptosis and increased chemosensitivity towards cytarabine. miR-10a was shown to directly downregulate key members of the p53-mediated tumour suppressor gene network, including the CDKN1A (p21) inhibitor Transcription Factor AP2-gamma (TFAP2C). The inhibition of either miR-10a itself or CDKN1A by siRNA treatment inhibited autophagy induced by serum starvation, treatment with autophagy inducer,mg132 or p35 stabiliser, Nutlin3a.

Summary/Conclusions: The data suggests miR-10a as an important regulator of autophagy and a potential therapeutic target in AML.

E881

BY AN MCL-1-DEPENDENT MECHANISM, ALVOCIDIB POTENTIATES THE ACTIVITY OF CYTARABINE AND MIOTOXANTRONE WHEN ADMINISTERED IN A TIME SEQUENTIAL REGIMEN IN AML

H. Haws1, M. Livingston1, W. Kim1, R. Mangelsen1, A. Siddiqui-Jain1, P. Peterson1, C. Whatcott1, S. Weitman1, D. Bears1, S. Warner1

1Discovery Biology, Toleram Pharmaceuticals, Inc., LEHI, United States

Background: Treatment with alvocidib has shown significant improvements in the complete remission rates in newly diagnosed acute myeloid leukaemia (AML) patients when administered before cytarabine and mitoxantrone (ACM regimen) in a randomized Phase 2 study compared to 7+3. Although the mechanism of alvocidib action as a single agent is documented, the mechanism underlying synergy found in the ACM regimen is not fully understood. The ACM regimen was originally developed based on the perceived benefit of a time-sequence regimen starting with cell-cycle arrest (alvocidib), followed by release of the cells from arrest and inhibition of DNA replication (cytarabine/mitoxantrone) during S-phase. However, recent reports suggest that the transcriptional repression of key anti-apoptotic proteins (eg., MCL-1) mediated by alvocidib’s CKD9 inhibition, may contribute to the activity in the ACM regimen.

Aims: We hypothesized that MCL-1 transcriptional repression constitutes the primary mechanism for the synergism observed with the ACM treatment regimen.

Methods: Following treatment, cell viability and caspase activation, an indicator of apoptosis, were assessed using CellTiter-Glo and Caspase-Glo assays, according to manufacturer protocol. mRNA levels were assessed using RT-PCR. Protein levels were assessed using standard immunoblotting technique.

Results: In this study, we demonstrate that treatment with alvocidib, followed by treatment with cytarabine and mitoxantrone, synergized in vitro and correlated with the downregulation of MCL-1 protein and mRNA expression. Indeed, the ACM regimen resulted in a 2.4 or 3.4-fold increase in caspase activity relative to any single agent within the combination in MV4-11 or OCI-AML3 cells, respectively. As has been previously reported, we also observed that increased activity of cytarabine in alvocidib-treated cells corresponded with progression into the S-phase of the cell cycle, following the washout of alvocidib. However, this observation accounted for only a small portion of the inhibition of cell proliferation. This was further confirmed by the observation that CDK4/6 (cell cycle) specific inhibitors, such as palbociclib, did not show synergistic increases in caspase activity following treatment in the same setting. In various AML cell lines treated with MCL-1 siRNA, followed by cytarabine and mitoxantrone treatment, we also observed a synergistic increase in the inhibition of cell proliferation.

Summary/Conclusions: Considering our earlier work showing that MCL-1 dependence predicts AML patient response to the ACM regimen, we propose that MCL-1 repression is the primary mechanism of alvocidib’s clinical activity. As MCL-1 also confers resistance to cytarabine, the current study provides additional rationale for the inclusion of alvocidib in the treatment of AML, and in the ACM regimen specifically. Taken together, this data suggests that the ACM regimen may be an effective regimen in treating patients with high-risk AML because of alvocidib’s inhibition MCL-1.

DYSREGULATION IN KEY REGULATOR GENES OF AUTOPHAGY AS A MECHANISM OF THERAPY RESISTANCE AND POOR PROGNOSIS IN ACUTE MYELOID LEUKAEMIA (AML): RESULTS FROM MICROARRAY ANALYSIS ON 148 PATIENTS

M.C. Fontana1,2, G. Marconi1, C. Papayannidis2, G. Simionetti2, A. Padella2, E. Ottaviani2, A. Ferrari2, E. Franchini2, N. Testoni2, C. Baldazzi3, S. Lo Monaco2, S. Paolini2, M.C. Abbenante2, J. Nanni2, L. Bertinetti2, G. Martelli2

1Department of Experimental, Diagnostic and Specialty Medicine, 2University of Bologna, Bologna, Italy

Background: To date, there are no clear evidences if autophagy can lead to therapy resistance or favor apoptosis in cancer. Autophagy can function as a pro-apoptotic mechanism, or can improve stresses survival clearing damaged mitochondria and proteins accumulation. Levels and activity of pro-apoptotic and anti-apoptotic proteins, particularly BCL-2 and p53, high levels of CAMP, and a complex made by PINK/PARK could play as fulcrum of this yin and yang effect of autophagy.

Aims: Our study aims to define the role of PI3P pathways in AML, and to establish if autophagy could reduce the patients’ chance to respond to induction, and to worsen OS.

Methods: We analyzed 148 consecutively newly diagnosed non M3 AML patients treated with induction chemotherapy regimens containing at least one dose of anthracycline. We screened all patients for TP53, FLT3, NPM1 mutations. In all
patients, we perform Microarray-based High-Throughput Technology with Affymetrix SNP array 6.0 or Cytoscan HD. Survival data were collected prospectively from the time of diagnosis, with a median follow-up of 18 months. Survival analysis was performed with Kaplan Meyer method using log rank test. Univariate and multivariate regression and Cox Hazard Ratio (HR) model was performed. Correlation between variables was assessed with Fisher’s exact test. Results: Autophagy alteration (gene group 1: M238; gene group 2: M16) had 14 and 2 pairs with significant expression, respectively. CEBPA (gene 911: U1K7R17; BECN1; ATG14; AMBRA1; UVRAG; ATG9A; ATG9B; PIK3C3; PIK3R4) were related to lower Complete Remission rate (CR%) after induction in univariate (p<0.001) and multivariable regression with age, karyotype, secondary AML, TP53 mutation (p<0.01). Autophagy alteration showed to confer worse OS (p<0.001) and was significantly associated with complex karyotype and TP53 mutation (p<0.001). We detected significant differences in terms of survival independently both in Copy Number (CN) Gain and CN Loss in group 1 genes (p<0.001). Furthermore, we investigated genes in AMPK pathway (2: S6EN1; PRKAA1 CHR 3; PRKAB1; PRKAA1 CHR 1; PRKAG1 CHR11; PRKAG1 CHR11): and other genes that could contribute to a switch from a physiological role of autophagy to a resiliency mechanism (group 3: CCND1; BCL2; PINK1; PARK2; TP53; MDM1; MDM4): alterations in those genes were shown to confer worse OS (p<0.001 in both groups). Alteration in group 2 and group 3 were related to lower CR% after induction (p<0.001 in both groups). Whole Exome Sequencing on 56 patients in our set did not found any significant mutation in genes we analyzed with the exception of TP53.

Summary/Conclusions: Our work investigates for the first time with a genomic approach the role of autophagy in AML. We found that both CN gain and CN loss in autophagy key regulator genes are associated with poor prognosis and therapy resistance. A CN loss in autophagy could enhance proliferation and block apoptosis, a CN gain could give cell resiliency, favoring cytokopten turnover, damaged mitochondria elimination, and neutralizing oxidative damages. Further functional studies will be necessary in order to confirm these results.

Background: MSI is the addition or loss of bases within repetitive DNA sequences located in microsatellites (MS) found in DNA repair. MSI is most often observed in endometrial and colorectal carcinomas, and pts with MSI-positive (MSi) solid tumors have shown promising responses to therapy with immune checkpoint inhibitors. MSI’s existence in AML has been examined in several studies, but the results are equivocal, with some reporting a total absence of MSI and others finding as many as 20% of AML pts to be MSI+. These studies tested for MSI using polymerase chain reaction (PCR) analysis was performed with Kaplan Meyer method using log rank test. Univariable and multivariable regression and Cox Hazard Ratio (HR) model was performed. Correlation between variables was assessed with Fisher’s exact test. Results: Autophagy alteration (gene group 1: M238; gene group 2: M16) had 14 and 2 pairs with significant expression, respectively. CEBPA (gene 911: U1K7R17; BECN1; ATG14; AMBRA1; UVRAG; ATG9A; ATG9B; PIK3C3; PIK3R4) were related to lower Complete Remission rate (CR%) after induction in univariate (p<0.001) and multivariable regression with age, karyotype, secondary AML, TP53 mutation (p<0.01). E884
SY-1425, A POTENT AND SELECTIVE RARA AGONIST, REPROGRAMS AML CELLS FOR DIFFERENTIATION ALONG DISTINCT LINEAGES, UNCOVERING PD MARKERS FOR CLINICAL STUDIES
M. Mckeown1,2, C. Fiore2, K. Austgen2, E. Lee3, D. Smith2, M.L. Eaton2, A. Volker3, C. Murphy3, K. Stephens3, C. Fritz5, T. Lodde6, E. di Tomaso1, E. Olson7, 1Translational Medicine, 2Biology, 3Clinical, Syros Pharmaceuticals, Cambridge, United States

Background: SY-1425 (famibartotene) is a potent and selective agonist of the retinoic acid receptor alpha (RARA) transduction factor (TF), currently in a bio- pharmaceutical development pipeline. A subset of AML and MDS has been found to have RARalpha pathway activation characterized by a large enhancer at the RARA locus (RARA-high) and/or upregulation of IRF8, a TF associated with RARA signaling, forming the basis of a new PD-sensitive tumor identification.

Aims: We sought to understand how SY-1425 agonism of RARalpha acts to promote maturation and halt proliferation of AML blasts locked into an immature cell state by the cancer circuity. This characterization could further inform clinical pharmacodynamics markers.

Methods: We analyzed the epigenomic and transcriptional landscape of 66 non-APL AML patients and normal primary myeloid cells by RNA-seq and ChIP-seq for the enhancer marker H3K27ac. AML cell lines were profiled by RNA-seq, ChIP-seq for H3K27ac and RARalpha, and ATAC-seq with or without SY-1425 treatment. Cell surface marker changes were assessed by flow cytometry. Results: A subgroup of the patient samples was defined by an SE driving RARA, which co-occurred with SEs driving FOS and JUNB, or IRF8, FOS and JUNB form the AP-1 heterodimeric TF known to promote an immature cell state and the interferon regulatory factor 8 (IRF8) pathway has been implicated in AML pathogenesis. Previously reported crosstalk between INF and retinoic acid signaling was supported by the strong induction of interferon gene sets by SY-1425 in IRF8-high AML models. We found that each AML cell line had distinct compositions of lineage factors consistent with cancer initiation from different stages of myeloid development. SY-1425 induced maturation features associated with monocyctic, macrophage, dendritic, and granulocytic cell types. While AML has a broad and diversified and IRF8 and granulocytic differentiation, we found that RARalpha/IRF8-high AML could follow multiple differentiation paths depending on the initial state of the AML model, necessitating different marker panels to capture full cell typing. Functional validation confirmed surface marker changes consistent with RARalpha/IRF8-high AML. We observed epigenetic alterations including ID11b, CD11c, CD66b, and CD38 upregulation. We integrated epigenetic data, DNA accessibility, and SY-1425 response to understand RARalpha perturbation to cell circuity. Enhancer elements directly bound by RARalpha were associated with greater response to SY-1425 as was enhancers bound by other TFs involved in myeloid differentiation. The accessibility of RARalpha and IRF8 motifs were increased and their associated TFs were upregulated. The target genes of known immu- norepressive state drivers, such as RUNX1 and CEBP, were downregulated. Importantly, the FOS/JUN circuit, identified as a component of the oncogenic RARalpha circuit in patient samples, was found to be suppressed.

Results: Genomic and functional analysis identified RARalpha and associated cell state TFs play a critical role in the differentiation of AML. SY-1425 perturb- ation of this circuity leads to differentiation toward multiple potential lineage paths depending on the initial state of the cancer. These pharmacodynamic changes can be assessed clinically and combined with common AML/MDS markers to assess disease burden and develop therapeutic strategies for t-AML. Finally, because it has been proposed that t-AML might be more prone to clinical and preclinical data to inform current and future clinical studies.

E885
GENETIC CHARACTERIZATION OF A LARGE GROUP OF CBESA MUTATED AML PATIENTS AND THE EFFECT OF TET2 AND GATA2 MUTATIONS ON OUTCOME
N.P. Konstandin1,2, F. Pastore1, A. Dufour1, K.H. Metzeler1,2,3, M. Rothenberg-
Background: Mutations in the CEBPA gene are detected in about 10% of patients (pts) with cytogenetically normal (CN) acute myeloid leukemia (AML). CEBPA mutations can either be biallelic (bi) or monoallelic (mo). Only pts with bi-CEBPA mutations have favorable outcomes when compared to other CN-AML pts. bi-CEBPA mutations are rarely associated with other prognostic mutations like internal tandem duplications (ITD) or mutations in the tyrosine kinase domain (TKD) of the FLT3 gene or mutations in NPM1. There is a specific association of bi-CEBPA mutations with mutations in the transcription factor GATA2.

Aims: In this study we aimed to characterize the mutational spectrum of CN-AML pts with mo- and bi-CEBPA mutations. We further analyzed the effect of TET2 and GATA2 mutations on outcome in pts with bi-CEBPA mutations.

Methods: Targeted amplicon resequencing (Agilent Haloplex, target region: 63kb) was used to analyze 42 target genes or hotspots known to be mutated in CN-AML or other hematologic neoplasms.

Results: In 48 bi-CEBPA and 32 mo-CEBPA we found mutations in 20 and 26 different genes respectively. Mo-CEBPA pts showed significantly more additional mutations compared to bi-CEBPA pts (mean: 3.9±1.7 vs 2.2±1.5; p<0.001). We also compared the mutational profile of mo- and bi-CEBPA pts with a collection of 106 CN-AML pts. bi-CEBPA pts had a higher occurrence of CN-ITD (21.6%) vs a lower occurrence of CN-ITD (11.4%) in mo-CEBPA pts. bi-CEBPA mutations were significantly more frequent in bi-CEBPA pts (21.2%) vs mo-CEBPA pts (12.5%; p<0.001). FLT3-ITD1/TKD2 mutation frequency in bi-CEBPA significantly differed from mo-CEBPA (p=0.002) and wt-CEBPA (p=0.004). There was a significant difference in the frequency of FLT3-ITD in bi-CEBPA (20.8%) vs wt-CEBPA (4.5%) and mo-CEBPA (0.0%) but not in comparison to mo-CEBPA (43.8%). IDH2 was found mutated only in wt-CEBPA (21.6%) and mo-CEBPA (18.8%). In 48.5% of wt-CEBPA pts DNMT3A was mutated, this significantly differs from bi-CEBPA pts (14.3%; p<0.001) but not from mo-CEBPA patients (28.1%). CSF3R was frequently mutated only in bi-CEBPA (10.4%) but not in mo-CEBPA (0.35%; p<0.001) or mo-CEBPA (3.1%; ns). STA2G was associated with mo-CEBPA (25%), while STAG2 mutations were significantly less frequent in bi-CEBPA (6.3%; p<0.001) and wt-CEBPA pts (6.27%; p=0.002). TET2 mutations had a negative prognostic impact on overall survival (OS) in bi-CEBPA pts, but not in mo-CEBPA pts or in wt-CEBPA pts (p=0.033). CEBPA mutations were significantly worse in bi-CEBPA pts with a TET2 mutation, but relieve a poor outcome (RFS) and cumulative incidence of relapse (CIR) was not different depending on TET2 mutational status. In bi-CEBPA pts we also evaluated the clinical impact of GATA2 mutations. For 30 of 48 bi-CEBPA pts survival data was available, 15 of these pts were GATA2mut and 15 were GATA2wt. We observed a significant difference with respect to RFS (p=0.216), OS (p=0.479) and CIR (p=0.059). In a combined analysis, the GATA2mut and TET2wt genotype was associated with a lower relapse risk and a trend towards a higher RFS compared to the GATA2wt and TET2wt genotype.

Summary/Conclusions: bi-CEBPA, mo-CEBPA or wt-CEBPA pts show a distinct profile of co-occurring mutations that might explain the biological differences between these groups. TET2 mutations were found in 40% of all CEBPA mutated pts and might have a prognostic impact in bi-CEBPA pts.
found 150 mutations in 31 genes, in 73 out of the 91 patients included (a median of 1 mutation per patient (range: 0-5) with a mean read depth of 10360x. Eighteen patients remained wild-type for all analyzed genes (Figure 1). Only one of this patients suffered relapse (5%). In the global series, no single mutation or functional category showed an association with clinical variables or prognostic impact in terms of overall survival or relapse free survival (RFS). There were no differences in the mean number of mutations per patient in each risk APL group (p=0.05). Patients who lack mutations belonged to the intermediate (13/48, 27%) and low risk (4/28, 14%) groups, except for only one patient (1/15, 6%) in high-risk group. FLT3 was the most frequently affected gene in high risk APL subgroup (10 out of 15): 8 patients carried an FLT3-ITD mutation and 2 patients had amino acid substitutions at codon 832. Seven patients assigned to intermediate-risk relapsed (7/38, 18%). All but one carried mutations that have been reported as unfavorable in AML (FLT3, PTEN, ASXL1, CUX1 and WT1). By contrast, patients who remain in complete remission in this group, lack mutations with a greater frequency (12/31, 39%). Finally, within the low-risk group 3 patients suffered relapse (3/27, 11.5%) and all of them presented missense mutations in the Ras domain of NRAS at diagnosis (p Ser65Arg & p.Gln61Arg). Therefore, we could identify a small subgroup of patients at a very high risk of relapse (RFS at 5 years, 25% vs 100%, p<0.001).

Summary/Conclusions: In summary, the present study shows that the mutation status of NRAS and FLT3 genes could be used as genetic markers for prognosis in APL, especially in the intermediate and low-risk groups, allowing a more accurate patient risk classification. Our data suggests the need to search for new mutations required for progression in APL, in order to benefit from a change in post-remission therapy.

ANALYSIS OF THE PD-1/PD-L1 AXIS POINTS TO ASSOCIATION OF UNFAVORABLE RECURRENT MUTATIONS WITH PD-L1 EXPRESSION IN AML

K. Giannopoulos1,2,*, M. Zajac1, J. Zaleska1, A. Dolnik3, A. Siwiec4, O. Jankowska-AML

Unfavorable recurrent mutations with PD-L1 expression in AML patients shed new light on the complex regulation of PD-1/PD-L1 axis during development of this disease.

Methods: We performed analysis of TP53, CD274 and miR-34a expression in 197 AML patients available from The Cancer Genome Atlas (TCGA) database. Moreover, we assessed mRNA expression of PDCD1 in independent cohort of 54 AML, 62 MDS and 8 s-AML patients using qRT-PCR method. For miRNA analysis, CD33+ cells from 29 AML patients were isolated and CD33+ miRNA expression was analyzed.

Results: We observed significant differences in PD-L1 expression in groups of 54 AML, 62 MDS and 8 s-AML patients compared to HVs. TCGA data analysis showed that high expression of PD-L1 was associated with nearly fivefold lower risk of disease (OR=4.93, p=0.009). We observed significant differences in OS in AML patients in case of presence of certain genotypes of PD-1.16. Genotype AA was associated with higher risk of shorter OS compared to the rest of the genotypes (58 vs 333 days, HR=35; p<0.001).

Summary/Conclusions: Our analyses indicate that p53 might specifically modulate the tumor immune response by regulating PD-L1 via miR-34a which directly binds to the PD-L1 3’ UTR and blocks its expression. Moreover, we observed significant differences in PD-L1 expression level regarding to PD-1.15 polymorphism. Moreover, analysis of a PD-1.13 polymorphism in HVs and MDS groups revealed that genotype GG was associated with nearly fivefold lower risk of disease (OR=4.93, p=0.009). We observed significant differences in OS in AML patients in case of presence of certain genotypes of PD-1.16. Genotype AA was associated with higher risk of shorter OS compared to the rest of the genotypes (58 vs 333 days, HR=35; p<0.001).

DISSECTING THE DYNAMICS OF SINGLE-TUMOR-CELL-LINEAGEs THAT UNDERPIN RELAPSE OF AML

F. Caiado1, D. Maia-Silva1, C. Refolet1, R. Faria1, B. Silva-Santos1, H. Norell1,*

1Instituto de Medicina Molecular, Faculdade de Medicina, Universidade de Lisboa, Lisbon, Portugal

Background: Cancers kill primarily via disease recurrences after transient treatment responses. The emergence of therapy-resistant tumor escape variants is fueled by intra-tumor heterogeneity, underpinned by interference and Darwinian evolution across continuously developing sub-clones in the residual tumor. Several non-genetic factors add significant variation, on top of the divergent fitness provided by the often complex landscape, resulting intratumor heterogeneity, which is associated with extremely heterogenous and dynamic tumor cell population that can drive disease under many conditions. The relapse of human acute myeloid leukemia (AML) is a prime clinical example of how evolving sub-clonal dynamics can frequently drive treatment-resistant cancer recurrence after initially potent therapy.

Aims: We aimed to understand how single-lineage interference is regulated in AML in response to standard and emerging treatments - and clarify how this impacts the development of therapy resistance. Specifically, we aimed to dissect if relapse from each drug regimen was driven by predetermined or stochastically selected sub-lineages and determine the functional impact of such differences.

Methods: We dissected the intra-tumor population dynamics of relapsing AML, beyond the genetic level, by performing single-cell lineage-tracing through cellular barcoding technology (lentivirus-integrated non-coding DNA-tags). We

MRD ANALYSIS BY NEXT-GENERATION SEQUENCING APPROACH FOR ACUTE MYELOID LEUKEMIA FOLLOW-UP
E. Onchea De La Fuente1,2,*, I. Rapado2,*, T. Cedena1,2, M. Llops3, Y. Ruiz-Heredia1, J. A. Garcia Velas1, Perez Oteyza5, Figuera6, F. J. Peñalver1, E. Barragan8, M. Gallardo1,2, J. Martinez-Lopez1,2, R. Ayala1,2
1Hospital Clinico San Carlos, Madrid, Spain; 2Genetic Laboratory, Hospital Clinico San Carlos, Madrid, Spain; 3Haematology Unit, Vall d’Hebron, Barcelona, Spain; 4Hospital Universitario La Fe, Valencia, Spain; 5Hospital Universitario de Getafe, Madrid, Spain; 6Hospital Universitario HM Sanchinarro, Madrid, Spain; 7Hospital de la Princesa, 8Hospital Universitario Fundación Alcorcón, Madrid, Spain.

Background: Sensitive detection of molecular marker of minimal residual disease (MRD) in acute myeloid leukemia (AML) could improve prognostication of a possible relapse during the remission. Traditional methods for measuring minimal residual disease (MRD) in AML, such as real-time PCR and multiparametric flow cytometry (MFC) are associated with high technical complexity, low applicability and laborious standardization. However, some patients who achieve a negative MRD become to relapse and several MRD-positive patients have a long survival, which indicates that the sensitivity and specificity of traditional techniques are not enough to detect the residual disease. Aims: To detect minimal residual disease in AML follow-up sample using high-throughput sequencing as a standard and accurate technique.

Methods: We studied 54 gDNA bone marrow follow-up samples (27 after induction, 10 after first consolidation, 17 after second consolidation) from 30 AML patients treated according to PHEMA AML clinical protocols and with DNA sample at diagnosis. All patients had achieve CR at the moment of MRD assessment. We developed a custom-targeted sequencing panel of 32 genes (ion Torrent Proton System-Thermo Fisher) for mutation (SNV and/or InDels) detection at diagnosis sample. From the 32 genes, we use specific primers to amplify the specific region of the four most frequent alterations at diagnosis (Samples at follow-up: FLT3n-ITD n=2, NPM1n=46, IDH2 n=9 or IDH1 n=7). We analysed and detected at diagnosis and at follow-up (after induction, first consolidation or second consolidation), and sequenced with high-throughput approach. We achieve a technical sensibility around 10-4 for point mutations and 10-5 for Indels mutations according to specificities and sensitivity calibration curves.

Results: We analysed the results of assessing MRD by NGS, and the presence or absence of MRD was established at a cut-off level of 0.0017 (between 10-4 and 10-5) with ROC curve with a sensitivity of 0.5 for DFS and 0.571 for OS, and a specificity of 0.92 for DFS and 0.897 for OS; thereby all result above this level was considered as MRD positive. DFS (Disease Free Survival) and OS (Overall Survival) rates in this group were 29.9% and 24.1%, respectively; positive MRD sample was independent marker associated with shorter DFS (p=0.002, HR=0.33, 95% CI:1.60-33.51) and OS (p=0.002, HR=8.33, 95% CI:1.87-37.15) (see figure 1). These results support the usefulness of MRD evaluation in patients with AML by NGS in the context of molecular biology studies.

Figure 1.

Summary/Conclusions: High-throughput NGS is a technique with the capacity to measure, identify and classified MRD levels. In fact, NGS MRD evaluation has a better DFS and OS prediction than other traditional methods. Implementation of NGS technique on MRD detection could help to anticipate to disease progression.

THE ROLE OF MYELOID-DERIVED SUPPRESSOR CELLS-LIKE BLASTS WHICH SUPPRESS T CELL PROLIFERATION IN LEUKEMIC CELL GROWTH
S. Y. Hyun1,*, J. I. Lee1, E. J. Na1, J.-W. Cheong2
1Internal Medicine, Yonsei University Wonju College of Medicine, Wonju, Korea; 2Internal Medicine, Yonsei University College of Medicine, Seoul, Korea, Republic Of

Background: Myeloid-derived suppressor cells have an ability to suppress T-cell function and have been known to facilitate tumor growth. We elucidated the immune suppressive function of leukemic blasts which resembled MDSC phenotype and their role in the growth of leukemic cells.

Aims: We elucidated the immune suppressive function of leukemic blasts which resembled MDSC phenotype and their role in the growth of leukemic cells.

Methods: CD11b+CD33+HLA-DR blast (MDSC like blast) were isolated using flow-cytometry from bone marrow mononuclear cells of primary acute myeloid leukemia (AML) patient samples. CD14, CD15, Arg1 and iNOS expression were checked by flow-cytometry to identify the phenotype of MDSC like blast. To evaluate the ability of MDSC like blasts to suppress T cell proliferation, CD8+ T cells from healthy donor and MDSC like blasts were co-cultured with the ratio of 1:1 without/with phorboxomaglutinin A10g/mL. T-cell proliferation was measured by carboxyfluoreescin diacetate succinimidyl ester dilution assay after 3 days of culture. Then, various leukemic cell lines were co-cultured with jurkat T cells and/or MDSC like blasts at leukemic cell line:jurkat T cell: MDSC like blast ratio of 4:4:1. The effect of jurkat T cells and MDSC like blasts on the proliferation of leukemic cells was assessed by the CCK-8 assay after 1 and 3 days of culture.

Results: MDSCs like blast can be divided into two subtypes, monocyte like subgroup expressing CD14 and granulocytic subgroup expressing CD15, and CD14 expression was more frequent than CD15 (67.5% vs 39.3%). MDSC-like blasts showed higher expression of Arg1 (77.1% vs 38.5%, P<0.001) and iNOS (33.0% vs 11.1%, P<0.0001) compared to non-MDSC-like blasts. CD8+ T cell proliferation induced by PHA was significantly suppressed when co-cultured with MDSC-like blasts compared to without them. Among the various leukemic cell lines, the proliferation of NB4 cells were significantly suppressed when co-cultured with jurkat T cells on day 3 (NB4 23.4%±6.26% of control, NB4+jurkat 12.62±3.92%, P<0.01). The decreased proliferation of NB4 cells was partially recovered after 3 days of co-culture with MDSC-like blasts (NB4+jurkat 12.62±3.92%, NB4+jurkat+MDSC like blast 18.71±6.19, P=0.022).

366 | haematologica | 2017; 102(s2)
SUMMARY/CONCLUSIONS: CD11b+CD33+HLA-DR- MDSC-like blasts subpopulation which expressed the INOS and Arg1 existed in AML, and showed ability to suppress the T cell proliferation. MDSC-like blasts partially restored the suppressed leukemic cell growth of NB4 cells by jurkat cells. MDSC-like blasts might play a certain role in immune-escape mechanism of AML.

GENERALIZATION OF NEW CELLULAR MODELS FOR THE STUDY OF PEDIATRIC NON DOWN SYNDROME ACUTE MEGAKARYOBLASTIC LEUKEMIA BASED ON HUMAN PLURIPOTENT STEM CELLS

J. Domingo-Reinés1,  , F. González-Pozas1, L. Morales-Cacho1, M. Vogel-Gonzalez1, G. Rodríguez-Real1, J. Olmedo-Pelayo1, R. M. Montes1, V. Ayllón1, V. Ramos-Meja2, 1Genyo, Granada, Spain

Background: Acute megakaryoblastic leukemia (AMKL) is a rare and complex type of Acute Myeloid Leukemia (AML), more frequent in children than in adults, characterized by the accumulation of immature megakaryoblasts and thrombocytopenia. Paediatric AMKLs are classified in Down Syndrome AMKL (DS-AMKL) with a good prognosis; and AMKL non-related to Down Syndrome (non-DS-AMKL), a more aggressive disease with a mortality rate close to 80%. There is a limited amount of research done on infant non-DS AMKL, due to its low preincidence and early human hematopoiesis, we postulate that they preserve their pluripotency and could serve as platforms to mimic human embryonic hematopoietic development. In this project, we aim to human hPSCs expressing non-DS AMKL-associated fusion oncomers as cellular models for this leukemia, to study the molecular and cellular pathways involved in the development of pediatric non-DS-AMKL

Methods: Generation of human models of non-DS AMKL using hPSCs: 1. Generation of hPSCs with the oncogenic fusion proteins RBM15-MKL1, CBFA2T3-GLIS2 and NUP98-JARID1 using transduction with lentiviral vectors. 2. Generation of hPSCs with the chromosomal translocations t(1;22) and t(1;12), that generate the fusion proteins RBM15-MKL1 and NUP98-JARID1 respectively, and the inversion of chromosome 16, that originates the fusion protein CBFA2T3-GLIS2. 

Aims: It is essential to establish new human models to provide enough biological material for functional and molecular studies. As the genetic alterations that drive infant leukemia occur in the developing fetus, we propose that human embryonic stem cells (hPSCs) are ideal models to study non-DS AMKL, as these cells allow us to mimic human embryonic hematopoietic development. In this project, we aim to use human hPSCs expressing non-DS AMKL-associated fusion oncomers as cellular models for this leukemia, to study the molecular and cellular pathways involved in the development of pediatric non-DS-AMKL.

Summary/Conclusions: These models will serve as platforms to discover and understanding the cellular and molecular alterations caused by these oncomers, and their impact in the generation of hematopoietic cells during development. With this information we will have a better understanding of the origin and development of paediatric non-DS AMKL, so we will be able to design new therapeutic approaches for these children.

CHARACTERIZATION OF HEMATOLOGIC MALIGNANCIES WITH ANCHORED MULTIPLEX PCR AND NEXT-GENERATION SEQUENCING

L. Aouini, M. Beasap, A. Berlim1, J. Haines1, D. Fugere1, L. Griffin1, K. Trifilo1, N. Manco1, H. Wang1, R. Ryan2, M. Hussain3, B. Kudlow2, 1ArcherDX, Boulder, CO, 2Massachusetts General Hospital, Boston, MA, 3Moffitt Cancer Center, Tampa, FL, United States

Background: Hematologic malignancies can be driven by a diversity of mutation types, including single nucleotide variants, copy number variants, gene fusions, insertions and deletions and changes in gene expression profiles. However, comprehensive detection of these mutation types is challenging, as specific assays are required to detect each mutation type. Next-generation sequencing (NGS) enables comprehensive detection of all mutation types from whole genomes and transcriptomes. However, low detection sensitivity, high input requirements and high costs render these approaches impractical for routine detection of mutations from clinical sample types. Anchored Multiplex PCR (AMP™) is a target enrichment strategy for NGS that uses molecular barcoded (MBC) adapters and unidirectional gene-specific primers (GSPs) for amplification.

Aims: Our goal was to develop AMP-based NGS assays to simultaneously detect multiple mutation types from DNA and RNA, as well as relative gene expression of several models and common hematologic malignancies. In particular, we sought to develop methods to detect novel fusion genes, internal tandem duplications (ITDs) and mutations in CEBPα.

Methods: We developed AMP-based Archer™ VariantPlex™ and FusionPlex™ assays to enable NGS-based detection of mutations from DNA and RNA, respectively. Open-ended amplification enables detection of novel gene fusions with FusionPlex and complex mutation types such as ITDs with VariantPlex assays. MBC adapters ligated to RNA and DNA fragments prior to amplification enable relative gene expression and CNA analysis.

Results: We show instances of gene fusion detection from open-ended amplification of AXL-RUNX1, RUNX1-TAL1 and AML1-RUNX1 in acute myeloid leukemia and high expression levels relevant in hematologic malignancies. Importantly, AMP enables identification of known and novel gene fusions at nucleotide resolution, detection of ITDs and characterization of relative gene expression levels and CNAs.

Background: Mutations of ASXL1 are considered early founder events in AML and leukemogenesis. They are included in the definition of the “chromatin-splice-some” genomic class of AML and among the high risk genetic prognosticators in the 2017 ELN recommendations.

Aims: We aimed to study the frequency of ASXL1 mutations in a cohort of newly diagnosed AML patients and to look for correlations with conventional cytogenetic findings and baseline characteristics.

Methods: Three hundred and sixty AML patients diagnosed between 2005 and 2014 were studied. Conventional cytogenetic analysis was performed on unstimulated bone marrow cells cultured for 24 and 48 hours. Molecular analysis of ASXL1 exon 12 mutations was performed by PCR and subsequent direct sequencing in diagnostic bone marrow or peripheral blood samples.

Results: Median age of the whole cohort was 63 years (11-95) and 56% of patients were male. Eighty two patients (22.8%) had secondary AML (sec-AML) with prior diseases being MDS (63), CMML (4), PV/ET (9), MF (2) and CML (4). Karyotypic analysis was successful in 352 (97.7%) AML samples of which 104 (29.4%) exhibited clonal karyotypic abnormalities. ASXL1 mutations were detected in 52 patients (14.4%). The most common mutation was c.1934dupG in 44/52 (84.6%). ASXL1 mutated patients were significantly older with median age 72 vs 61.5 years in the unmutated (p=0.0001). Three of 61 patients (4.9%) aged ≥60, 10/97 aged 41-60 (10.3%) and 39/198 aged ≥60 (19.7%) were mutated. Avs. 11.5% vs 16.8%, p=0.07). ASXL1 mutations were significantly more frequent among cases with trisomy 8 (25% vs 12.8%, p=0.02) and patients with chromosome 11 abnormalities (23.7% vs 13.7%, p=0.01). None of the 12 patients with inv(16)(t(16;16)) was mutated while 2/16 (12.5%) of those with t(8;21) had ASXL1

haematologica | 2017;102(s2) | 367
mutations. Moreover, ASXL1 mutations were detected in 3 of 12 patients with aberrations detected (25%), 2/9 (22%) with trisomy 13, 2/11 (18%) with t(6;9) and only 1 of 22 patients with t(15;17). Multivariate logistic regression suggested that independent predictors of the presence of ASXL1 mutations were older age (OR 1.43 per decade, 95% CI 1.13-1.79), chromosome 11 aberrations (OR 2.69, 95% CI 1.09-6.63), and sec-AML (OR 4.44, 95% CI 2.3-8.57), whereas t(7;17) or -5/del5q predicted for lower frequency (OR 0.32, 95% CI 0.13-0.75).

Summary/Conclusions: Our results support the association of ASXL1 mutations in AML with advancing age and sec-AML. Association with trisomy 8 did not retain significance in multivariate analysis. Chromosome 11 aberrations emerged as cyto-independend predictor. Despite the strong link with secondary AML (majority of cases post MDS), our data show inverse relationship with -7/del(7q) or -5/del5q. In addition, ASXL1 mutations were not positively associated with MDS-related cytogenetic abnormalities, complex or monosomal karyotypes.

A COMPREHENSIVE DNA TEST FOR THE DETECTION OF TRANSLOCATIONS IN ACUTE LEUKEMIA

E. Van Den Berg-De Ruiter1,*, M.Z. Alimohamed1, L.F. Johansson1,2, E.N. de Boer1, E. Splinter3, P. Klous3, A.G. Bosga1, M. van Min3, A.B. Mulder4, E. Vellenga5, R.J. Sinke1, R.H. Sijmons1, B. Sikkema-Raddatz1

1Genetics, 2Genetic Coordination Center, UMCG, Groningen, 3Cergentis B.V., Utrecht, 4Laboratory Medicine, 5Hematology, UMCG, Groningen, Netherlands

Background: Patients with acute leukemias carry a wide range of chromosomal abnormalities, which affect their prognosis and treatment options. Currently, over 500 different translocations are reported to be involved in the disease progression. Traditional methods to detect chromosomal abnormalities involve a combination of techniques such as karyotyping, FISH, array and RT-PCR. However, these methods are laborious and at times inadequate. Targeted Locus Amplification (TLA), a new targeted next generation sequencing technology can overcome these shortcomings. It is based on proximity ligation (crosslinking) of DNA and outward oriented probes for enrichment and can therefore identify chromosomal translocation partners regardless of their identities.

Aims: Here we present a TLA multiplex panel in combination with next generation sequencing as a first tier screening tool in detecting translocations in acute leukemias.

Methods: A multiplex TLA panel was designed using primer sets covering known break-point regions of the 17 most frequently reported genes involved in acute leukemia’s. TLA was performed on five different cell lines carrying translocations detectable by our panel. t(12;21), t(16;11), t(11;19)(8;13), t(6;9), t(17;19). Various combinations of cell line mixtures in multiple dilution series were used to determine the specificity and sensitivity of the panel, and to set sample quality thresholds during analysis. Samples were processed using standard TLA protocol (de Vree et al, 2014). Targets were enriched by PCR amplification with the multiplex panel and subjected for sequencing on Illumina Nextseq 500. To facilitate an easy analysis workflow a semi-automated data analysis was developed. This includes a quality control step, labelling samples with no coverages at the anchor regions after filtering at more than half the number of target regions as failed. These were not interpreted. Only peaks outside other anchor regions were considered as false positive peaks. Peaks present in other anchor regions were interpreted as possible artefacts and labelled as needing extra confirmation. In these series until now, up to 10% aberrant cells were detected with no false positives as no translocations other than expected for cell lines were detected. Bone marrows of 36 patients suspected of chromosomal translocation were taken for routine diagnostic karyotyping (Karyotyping, FISH and or RT-PCR) and TLA. Sample analysis was performed randomized and blinded. TLA outcome was then compared with results from routine genetic testing.

Results: From a total of 36 patients three samples did not meet the required sample quality for further analysis. In the remaining 33 patients our TLA multiplex panel confirmed the presence of translocations on 16 samples. This includes a cryptic translocation involving the ETV6-RUNX1 fusion gene, t(12;21)(p13;q22) in five pediatric ALL samples, not detected with karyotyping but RT-PCR confirming the TLA findings. In fifteen samples no translocation was detected. In 15% samples t(6;9) was the only translocation detected in a patient with myelodysplastic syndrome. TLA testing was not performed due to insufficient sequence reads on the partner chromosome. In addition, in one sample one translocation partner was also missed, located in the telomeric region of the chromosome and therefore resulting to nonspecific mapping of the sequence reads. An additional finding, involving a three way translocation t(12;22;11), missed by cytogenetics was detected by our panel. Two new findings have yet to be confirmed with FISH.

Summary/Conclusions: Our TLA panel showed concordant results for 29 out of the 33 successful sequenced samples. No false positives were found, while an additional translocation was detected. Our panel is able to detect (cryptic) translocations without prior knowledge of the fusion partner. Therefore, the TLA multiplex panel is suited as a first tier screening tool in acute leukemia. A prospective study, comparing the diagnostic yield of the TLA panel with current tests, can establish whether the TLA panel is applicable as a routine procedure.

E898
ALTERATIONS IN NECROTOPSIS PATHWAY AFFECT PROGNOSIS OF PATIENTS WITH ACUTE MYELOID LEUKEMIA

S. Lo Monaco1,*, G. Marconi1, M.C. Fontana1, C. Papayannidis1, E. Ottaviani1, E. Franchini1, A. Ferrari1, A. Padella1, G. Simonetti1, S. Paolini1, G. Martinelli1

1University of Bologna, Bologna, Italy

Background: Necroptosis is a type of necrotic cell death involving several genes transcription and activation of molecular mechanisms as death receptors, interferon, toll-like receptors, intracellular RNA and DNA sensors. The process is leading by the family of receptor-interacting protein kinase (RIPK3, RIPK2, RIPK1) and the MLKL substrate. Losses of RIPK3 or MLKL, as well as deficiency in apoptosis, could allow tumor cells to escape the immune-mediated cells death (ICD).

Aims: We want to investigate the role of necroptosis deficiency in correlation with chemotherapy resistance and its impact as prognostic factor in AML.

Methods: We performed SNP Arrays (Cytoscan HD and SNP 6.0, Affymetrix) on a cohort of 300 non-M3 AML patients at diagnosis and we analyzed the Overall Survival (OS) of our patients with deficiency on necroptosis pathways. Survival was analyzed with Kaplan-Mayer method and Log-Rank test. We further analyze the relevance of different prognostic factors by the use of COX-Hazard Ratio statistical analysis.

Results: We found that 18 patients presented a loss of RIPK1 or MLKL (nobody presented losses in RIPK3/RIPK2) and 13/18 is younger than 65 years old. The Overall Survival (OS) of patients with alterations in these genes is significantly lower than control group, with a median OS of 3 month vs 6 month respectively (p<0.001). With Fisher Exact Test we further demonstrate that copy number loss of RIPK1 or MLKL are associated to loss of TP53 or FANCA genes, complex karyotype and advanced age. COX-Hazard Ratio model with RIMK1 or MLKL loss, BRCA1 loss, TP53 mutation, FANCA loss, secondary disease and diagnosis karyotype considered as categorical variable show that necroptosis deficiency (HR 1.98. CI 95% 1.04-3.78) TP53 mutation, and secondary AML are independent negative prognostic factors in an optimal model.

Summary/Conclusions: Our study shows that losses in necroptosis pathways are an uncommon alteration in AML, prevalent in old population. Moreover, we hypothesize that the loss of genes involved in necroptosis could be a real mechanism of tumor immune-escape and could be a rational to select patients that high probability to be resistant at chemotherapy promoting ICD mechanism.

NGS ANALYSIS AND IMPACT OF VARIANT ALLELIC FREQUENCY AT RELAPSE AND REFRACTORY STATUS IN AML PATIENTS

E. Onecha De La Fuente1,2, I. Rapado1,2, M. Llops3, Y. Ruiz-Heredia1,2, T. Cedena1,2, E. Barragan3,4, M. Gallardo1,2, J. Martinez Lopez1,2, R. Ayala1,2

1Hematologia traslacional, Hospital 12 de Octubre, 2Haematological Malignancies Clinical Research Unit, CNIO, Madrid, 3Instituto de Investigación Sanitaria La Fe, 4Clinical Pathology Service, Hospital Universitari i Politècnic La Fe, Valencia, Spain

Background: A high number of patients with acute myeloid leukemia (AML) present resistance at treatment, which is associated with clonal persistence or evolution. The generation of high-depth sequencing data allowed to quantify variant allelic frequencies (VAF) and permitting estimation of the size of tumor clonal populations in each AML sample, and to perform an estimation of clonal evolution at relapse or refractory case according to diagnostic.

Aims: To evaluate the predictive impact of the fluctuation Variant Allelic Frequency in resistance to treatment cases in AML.

Results: Mutations in signalling pathway (EPOR, FLT3, JAK2, KIT, LNK or/and MPL) show VAF trend decreases. No correlation was found between VAF and% blasts, nor did VAF fluctuation with blasts fluctuation.

Summary/Conclusions: These results show VAF increases of specific mutations as RUNX1 correlates with primary refractoriness status. Furthermore, the variable frequency signalling pathway (EPOR, FLT3, JAK2, KIT, LNK or/and MPL) play a critical role in resistance status, increasing variant allelic frequencies of mutations in relapse and decreasing in refractoriness.

PRECLINICAL EVIDENCE THAT TRAMETINIB ENHANCES THE RESPONSE TO TYROSINE KINASE INHIBITORS IN ACUTE MYELOID LEUKEMIA

M.L. Morales1, M. Linares1, A. Arenas1, I. Zagorac2, R. Ayala3, N. Castro1, I. Rapado1, M. Quintela-Fandino2, J. Martinez-Lopez1

1Servicio de Hematologia, Hospital Universitario 12 de Octubre, 2Unidad de Proteómica, Centro Nacional de Investigaciones Oncológicas, Madrid, Spain

Background: Acute Myeloid Leukemia (AML) is the most common type of acute leukemia in adults and the second in children in whom overall survival is less than 35% and 60% respectively. Activating mutations of FLT3 are now recognized as the most common molecular abnormality in this disease, and the poor prognosis of patients harboring these mutations renders FLT3 an obvious therapeutic target. Although different tyrosine kinase inhibitors (TKI) have been used for this purpose, their ability to extend progression-free and overall survival is limited by drug resistance. This strategy could be improved by rationally combining TKIs with other agents. In this work, we have explored bone marrow samples from a FLT3-AML patient before and after TKI treatment by phosphoproteomics and observed enhanced activity of Ras-Raf-MEK-ERK1/2 pathway as a possible mechanism for TKI resistance.

Aims: To validate the role of ERK1/2 during TKI resistance in vitro and ex vivo and to search suitable combinations that allow overcome/avoid resistances in preclinical models of the disease.

Methods: Resistance mechanisms were studied in vitro in MOLM13 (FLT3WT/WT) after generating resistance by two different methods: by subculturing with increasing doses of sorafenib or by treating them with high doses of sorafenib, and recollecting alive proliferative (resistant) cells after CFDA and Annexin labeling. Phosphoproteomic analyses were carried out by LC-MSMS after IMAC enrichment or by western blot techniques. Drug sensitivity assays with trametinib (MEK inhibitor) and three TKIs (sorafenib, pazopanib, midostaurin) were read after 48 hours or 72 hours of treatment in vitro or ex vivo respectively. The efficacy of the combinational treatments was characterized by the cell viability assay using WST8, and analyzed with Graphpad Prism software. Synergy effects were measured with CalcuSoft software.

Results: As it is presented in figure 1, ERK1/2 pathway was more activated after TKI treatment in the FLT3-AML patient during sorafenib-resistance development. The same fact was confirmed in MOLM13 sorafenib-resistant culture and in living proliferative cells recollected after sorafenib treatment. Different doses of trametinib, sorafenib, pazopanib and midostaurin in monotherapy were tested in MOLM13 cell line determining their IC50 values. Synergy effects of combining trametinib with the three TKIs were analyzed with CalcuSoft software and normalized isobolograms were represented. All combinations showed CI values less than 0.5 (CI<0.5). The inhibition levels of four pathways (PI3K, STAT5, ERK1/2 and MAPK14) implicated in TKIs resistance were studied by western blot and the combination of midostaurin plus trametinib was the only one that inhibited all of them. Trametinib efficacy in the MOLM13 sorafenib-resistant culture was evaluated and confirmed that remained effective. Trametinib plus midostaurin combination was tested in OCI AML-3 cell line (FLT3WT/WT) showing high efficacy and strong synergy (CI<0.5) too. Finally, we have assayed these drugs ex vivo in three AML samples showing the same effectiveness as in vitro, with IC50 values ranging from 0.2µM to 0.9 µM for midostaurin and 3 nM to 29 nM for trametinib and CI values less than 0.5.

Summary/Conclusions: In conclusion, we provide preclinical evidence that combining a TKI, especially midostaurin, with a MEKI, such as trametinib, is a rational and efficacious treatment regimen for AML. As trametinib has previously shown good results when combined with pazopanib in clinical trials for other kind of tumors, we expect similar results in AML.
IDENTIFICATION OF NOVEL THERAPEUTIC DRUGS IN DISTINCT PEDIATRIC AML SUBTYPES BY TARGETING EPIGENETIC REGULATORS

C. Wiggers 1, 2, *, D. Lelieveld 3, D. Egan 3, M. Bartels 3
1Pharmaceutical Screening Core, Cell Biology, University Medical Center Utrecht, Utrecht, Netherlands
22nd Congress of the European Hematology Association

Background: Treatment protocols for pediatric acute myeloid leukemia (AML) are chemotheraphy-based, including high-dose cytarabine. While >90% of patients reach clinical remission, there is still a high relapse rate of ~30%, with overall survival rates of 60-70%. Therefore, better risk-classification at diagnosis and alternative treatment strategies are warranted. There is increasing evidence that epigenetic deregulation is involved in the initiation and progression of cancers, including AML. Epigenetic processes are required for hematopoiesis and epigenetic regulators are frequently translocated (MLL) or mutated (EZH2) in AML. Following this, deregulated epigenetic pathways could be used for targeted therapy and provide an alternative approach to improve pediatric AML therapy.

Aims: To identify new therapeutic drugs in pediatric AML by using an 80-compound screen containing inhibitors of epigenetic regulators, including histone writers (which deposit post-translational modifications (PTMs) on histones), readers (binding of PTMs) and erasers (removal of PTMs).

Methods: Cell lines used in this study are THP-1 (t(9;11)), Kasumi-1 (t(8;21)) and CMK (Down’s syndrome with GATA1 mutation), reflecting distinct pediatric AML entities and a differential response to treatment with cytarabine. Cells were treated for 72hrs followed by analysis of cell viability and apoptosis based on Hoechst, DragQ and Calcein Green staining. The effect of three candidate compounds were further investigated in triplicates at several concentrations for their effect on cell viability (Annexin V/FITC staining), cell cycle, morphology, and cell death in normal myeloid precursor cells derived from blood donors, normal cord blood, and pediatric AML patient cells representing distinct AML subtypes.

Results: From the 80 epigenetic compounds tested in THP-1, Kasumi-1 and CMK cells, we observed significant effects following treatment with the HDAC 4/5 inhibitor LMK235, the pan-HDAC inhibitor NSC3852, and the pan-bromodomain inhibitor Bromosporine. Dose-response curves showed differential cytotoxicity of the compounds and suggested LMK235 as most effective. Cell proliferation was inhibited by LMK235 at an IC50 of 0.1μM, 0.13μM and 0.425μM in Kasumi-1, CMK-1 and THP-1, resp. While inhibition by LMK235 resulted in an immediate response of apoptosis, Bromosporine-treated cells retained in G1 between 48 and 96 h, and, interestingly, LMK235 treatment resulted in an increase of cells in S-phase and G2/M. Among the differential effects of the compounds in the cell lines, we also observed differences in sensitivity. In line with previous studies, THP-1 cells were more resistant, illustrated by a 10-fold increase in concentration required for NSC3852-induced apoptosis. Interestingly, upon treatment with LMK235, Kasumi-1 and CMK cells showed a similar response, while Kasumi-1 cells were significantly more sensitive to NSC3852-induced effects. These data are currently validated in pediatric AML patient cells.

Summary/Conclusions: Treatment of three distinct pediatric AML cell lines with the epigenetic compounds LMK235, NSC3852 and Bromosporine resulted in cell lineage-specific and compound specific effects, including cell cycle regulation and induction of apoptosis. Our data suggests a potential role for epigenetic compounds, with specificity for molecular subtypes, in the treatment of clinically and biologically distinct pediatric AML subtypes.

ALVOCIDIB SYNERGIZES WITH CYTARABINE AND DAUNORUBICIN (7+3) IN PRECLINICAL MODELS OF ACUTE MYELOID LEUKEMIA

W. Kim1, H. Haws1, R. Mangelson1, P. Peterson1, C. Whatcott1, *, A. Siddiqui-Jain1, B.T. Gjertsen1, 2, 3
1Centre for Cancer Biomarkers (CCBIO), University of Bergen, 2Department of Biomedical Laboratory Sciences and Chemical Engineering, Bergen University College, 3Department of Internal Medicine, Haematology Section, Haukeland University Hospital, 4Department of Clinical Science, Leukemia Research Group, University of Bergen, Bergen, Norway

Background: Interferon alpha (IFNa) monotherapy is effective in selected myeloid neoplasias and is proposed to act through mechanisms that may be additive to the action of valproic acid (VPA), a histone deacetylase (HDAC) class I and IIa inhibitor with effect in approximately 20% of acute myeloid leukemia (AML) patients. Normal myeloid drugs are found to have direct anti-cancer effects targeting apoptosis, differentiation and proliferation, as well as indirect effects targeting the immune system. Aims: As several IFNa formulations are commercially available, we wished to explore the differences between two such drugs, recombinant IFNa-2b and human IFNa-Le, in relevance to AML treatment.

Methods: Flow cytometry and Hoechst staining was used to investigate apoptotic potential of the IFNa therapeutics, whilst phospho-flow cytometry and difference gel electrophoresis in combination with mass spectrometry unraveled IFNa signaling pathways. For in vivo efficacy analyses two orthotopic rodent models were implanted with leukemic cells and treated with VPA, IFNa-Le or both drugs.

Results: To investigate the anti-leukemic effects of IFNas we combined the two therapeutics with VPA in vitro using the human MOLM-13 cell line (wild type for FLT3 ITD and TP53). Results showed that IFNa-Le was more effective compared to IFNa-2b in inducing apoptosis, whilst both drugs were ineffective in combination with VPA. Investigating IFNa signaling pathways using phospho-specific flow cytometry we found IFNa-2b and IFNa-Le to have an identical stimulation profile in MOLM-13 cells, except from p-STAT5 Y691 that was higher expressed by IFNa-2b. The phospho-proteome was further explored using difference gel electrophoresis (DIGE) and mass spectrometric analyses to find a potential explanation to the difference in apoptosis-inducing effects between the two drugs. Here we found protein folding (LCP1, HSPA8, TCP1, CCT6A), cell stress (AKR1B1, HSP90AB1) and cell death (PKM2, PARK7, HSPA5, ANXA5, PRDX2) to be differently regulated between IFNa-2b and IFNa-Le, and also identified the presence of a dose-dependent effect of protein expression by IFNa-2b and IFNa-Le. Further, we investigated the potential synergetic anti-leukemic effects of VPA and IFNa-Le in vivo using a MOLM-13Luc+immunodeficient NOD/Scid IL2 g-/- orthotopic xenograft mouse model, and the expression of key anti-apoptotic proteins via CDK9/ RNA polymerase II, including MCL-1. With this understanding, we reasoned that alvocidib would enhance the activity of the 7+3 regimen.

Aims: These studies sought to interrogate the preclinical activity of alvocidib in the context of the 7+3 regimen in models for AML.

Methods: CellTiter-Glo and Caspase-Glo was used for all cell viability and apoptotic analyses, respectively, in the 7+3 model. Following manufacturer’s protocol. We used RT-PCR to measure mRNA expression of MCL-1 and other markers in response to drug treatment. Protein levels were interrogated using standard immunoblotting techniques. To determine the efficacy of an alvocidib/7+3 combination on tumor growth in vivo, we performed a MV4-11 xenograft mouse model. Using flow cytometry we found IFNa-2b and IFNa-Le to have an identical stimulation profile in MOLM-13 cells, except from p-STAT5 Y691 that was higher expressed by IFNa-2b. The phospho-proteome was further explored using difference gel electrophoresis in combination with mass spectrometry unraveled IFNa signaling pathways. For in vivo efficacy analyses two orthotopic rodent models were implanted with leukemic cells and treated with VPA, IFNa-Le or both drugs.

Results: Single agent IC50 values of alvocidib, cytarabine, and daunorubicin range in AML cell lines from 2.2 nM to as high as 567 nM in viability assays. In apoptosis (Caspase-Glo) assays, however, we observed modest induction with single agent cytarabine, and good induction with single agent daunorubicin or alvocidib. In the combination setting, we observed a strong synergy with more than two-fold enhanced induction of apoptosis in some treatment groups. As has been previously described, we report here too that alvocidib treatment reduced the expression of MCL-1 protein and mRNA in a time and concentration-dependent fashion in AML cells. We observed this in the 7+3 treatment as well. In an MV4-11 xenograft model, we observed 21.1 and 48.5% tumor growth inhibition (%TGI) following single agent treatment of daunorubicin or cytarabine, respectively. 1.25mg/kg alvocidib yielded 60.0% TGI. The combination of alvocidib, cytarabine, and daunorubicin, however, resulted in tumor regression, yielding a 116.2% TGI.

Conclusions: These results provide a clear rationale for a clinical study directly comparing the triple combination to 7+3 alone. Taken together, our results suggest that a combination of alvocidib, cytarabine, and daunorubicin might be a potential clinical regimen in treating frontline AML, offering patients additional treatment options in treating their disease.
immunocompetent brown Norwegian myeloid leukemia (BNML) syngeneic rat model. VPA mono-treatment increased survival from a median of 34 days to 38 days in the MOLM-13\textsuperscript{ace} mouse model, and from 21 days to 50 days in the BNML rat model. Additionally, the IFNα-Le (0.8x10\textsuperscript{6} IU/kg) and VPA (400mg/kg) combination treatment indicated a tendency to increased survival in the BNML model. However, IFNα-Le monotherapy (1x10\textsuperscript{6} IU/kg) decreased survival in the MOLM-13\textsuperscript{ace} model.

Brazma\textsuperscript{2}, R. Dunn\textsuperscript{2}, C. Grace\textsuperscript{2}, E. Nacheva\textsuperscript{2,3}

\textsuperscript{1}Biosciences Laboratory, IRCCS, Istituto Scientifico Romagno!lo per lo Studio e la Cura dei Tumori (IRST), Meldola, \textsuperscript{2}Department of Hematology and Oncological Sciences, I, and A. Seragoni, Bologna, \textsuperscript{3}Hematology Unit, IRCCS, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST), Meldola, \textsuperscript{4}Department of Medical Sciences, University of Ferrara-Arcispedale Sant’Anna, Ferrara, Italy, \textsuperscript{5}Celleceutix Corporation, Beverly, United States

Background: Acute Myeloid Leukemia (AML) is a heterogeneous disorder defined by clonal expansion of immature myeloid cells that infiltrate bone marrow and other tissues. AML therapeutic strategies remain unchanged since 1970 and the majority of patients often eventually relapse and die due to disease progression. Tumor protein p53 transcription factor is a key regulator of several cellular pathways, such as cell cycle, apoptosis and angiogenesis. It is mutated in 8-14% of AML cases and its mutations are commonly associated with a complex karyotype. Kevetrin is a new molecule compound, proposed by Celleceutix, with the ability to target both wild type and mutant p53 tumors.

Aims: The aim of this project is to explore cellular and molecular alterations induced by Kevetrin, focusing on its role in the p53 pathway.

Methods: Kevetrin was kindly provided by Celleceutix, dissolved and stored at 4°C in sterile water in a 600 μg/ml stock solution, and diluted in medium immediately before use [concentration range in use 15-60μg/ml]. Cell lines, MOLM-13 and KASUMI-1, were cultured in RPMI 1640 supplemented with 20% heat inactivated fetal bovine serum, 2mM L-glutamine, 100 U/ml penicillin and 100 μg/ml streptomycin. After 24 and 48 h of treatment MTS, Annexin-V, TUNEL, JC-1 and Active Caspase-3 assays were performed according to manufacturer’s instructions. Proteins were separated by polyacrylamide gel electrophoresis and transferred to 0.2 μm polyvinylidene fluoride membranes. Quantitative analysis was performed with Quantity One software. Statistical analysis was carried out using the paired and unpaired two-tailed Student’s t tests. p values <0.05 were considered as significant.

Results: Our data indicate that Kevetrin exposure induces cell growth arrest, a great drop of mitochondrial membrane potential and a remarkable increment of Caspase-3 cleaved form, features that contribute to apoptotic cell death in the two cell lines. Cellular changes can be associated with a dose and time-dependent effect in the TP53 mutated cell line (KASUMI-1) but not in the wild type one (MOLM-13), in which we can observe an activity only after 48 h at the higher concentration. Regarding molecular alterations in KASUMI-1 we found a great p53 down-regulation, probably due to Hsp90 reduction, resulting in a less marked formation of the Hsp90-p53 oncogenic complex. We also found a down-regulated p53 active form (Ser15), a reduced expression of p53 targets, p21 and PUMA, and a down-regulation of SIRT-3, that cannot exert its inhibitory activity on p53. The MOLM-13 cell line showed a great p53 reduction, probably related to SIRT-3 up-regulation and Hsp90 down-regulation. Regarding p53 active form, we noticed slight variations in protein expression, suggesting a physiological response of the protein to cellular damage. In accordance with p53 activity, we observed a great drop of mitochondrial membrane potential and a remarkable increment of SIRT-3, that cannot exert its inhibitory effect on p53. The MOLM-13 cell line showed a great p53 reduction, probably associated with a drug resistance mechanism; in contrast, PUMA protein was highly down-regulated, suggesting a p53-independent mechanism of action or a feedback regulation of the apoptotic process, after Caspase-3 activation (Figure 1). In order to better understand drug’s mechanism of action we are performing gene expression profiling after 48h of treatment with Kevetrin 60μg/ml.

Summary/Conclusions: IFNα does not add beneficial effects to VPA treatment in the two in vivo orthotopic models tested, possibly due to immune constitution and tumor load.

E905

CLEARANCE OF ‘DRIVER-COSMIC’ MUTATIONS POST CR1 WITH OPERATING RUNX1-L5ES IS UNLIKELY TO CONTRIBUTE TOWARDS DISEASE PROGRESSION IN AML

L. Rai\textsuperscript{1,7}, T. Boneva\textsuperscript{2}, D. Brazma\textsuperscript{2}, R. Dunn\textsuperscript{2}, C. Grace\textsuperscript{2}, E. Nacheva\textsuperscript{2,3}

\textsuperscript{1}Onco-Cytogenomics, \textsuperscript{2}OncoGenomics, HSL Analytics LLP, \textsuperscript{3}Cancer Research Institute, UCL, LONDON, United Kingdom

Background: Clinical significance of gene variants in AML is well established (Papaemmanuil E et al, NEJM 2016) and is increasingly being implemented into routine diagnostic algorithms. Although 80% of patients achieve morphological remission after induction chemotherapy, long-term relapse free survival is a meagre 50% (Walter RB et al, JCO 2010. Monitoring of disease kinetics, is therefore, very critical.

Aims: To study the kinetics of gene variants post-induction chemotherapy in AML patients.

Methods: 130 follow-up samples from 45 de novo AML patients [median age-60 yr & median FU period- 18.6 mo] were screened for gene variants using TruSight Myeloid panel (Illumina CA) covering 54 genes with relevance in myeloid diseases. Gene variants at Variant allele frequency (VAF) of ≥10% at diagnosis and VAF of ≥15% during follow-up; both with target coverage of ≥300 reads were considered. Bone marrow (BM) or peripheral blood (PB) was obtained at presentation (BM-44; PB-1) and follow-up (BM-130). Gene variants in 95 samples from 40 MDS patients were also evaluated for progression to secondary AML. Public databases-Catalogue of Somatic Mutations In Cancer (COSMIC), dbSNP and 1000 genome (≥2%) were used to classify gene variants as either Drivers (D), variants of unknown significance (VUS) and germline polymorphisms (SNP). P-value was generated with 2-tailed Fisher Exact (GraphPad Software, Inc, USA).

Results: Of 45 AML patients 19 achieved complete morphological remission (CR), 21 had a relapse and 5 had refractory disease with a median of 4 mutations/patient in each subgroup. Driver mutation was identified in 38 patients; 82% of who had persistence until clinical end-point. While 17 of 18 relapse patients retained a driver only 9 of 15 patients in remission retained it (Table 1). 8 of the 9 patients had a ‘driver with COSMIC and SNP’ (D-C/S) reference that persisted, while all ‘driver with COSMIC only’ (D-C) disappeared post-induction. This suggests that drivers with both COSMIC and SNP reference may not always contribute towards disease progression. We also found that D-C mutations persist in 85.7% of relapse patients compared to only 11% of patients in remission (P-value: 0.001). Additionally, D-C mutations were retained in all 13 relapse patients with intermediate risk cytogenetics while complete clearance was observed in all 6 patients who were in sustained remission (P-value: 0.001). Further investigation of genes with D-C/S mutation in the remission cohort (8x) revealed that 4 patients had persistent DNM73A-25457242, 1 had DNM73A-25457243, 2 had RUNX1-36259324/L5ES and 1 had CBL-119149011. As DNM73A mutations are considered to occur in pre-leukemic
stem cells contributing to clonal haematopoiesis (Askush et al, Nature 2014; Genovese et al, NEJM 2014); this led us to study the distribution of RUNX1 gene variants in an additional 119 AML diagnostic samples. 34 patients (21%) harboured RUNX1 mutation, of which 5 had RUNX1_L56S that were often associated with D-C mutations (4 of 5 cases). Finally, we evaluated kinetics of D-C in 40 MDS cases of which 34 had chronic MDS and 6 had secondary AML (sAML). No significant difference was observed in the number of patients with persistent D-C mutation in the 2 subgroups (chronic MDS: 16 of 19 (84.2%); sAML: 5 of 5 (100%); P-value: 1.000).

Summary/Conclusions: Clearance of ‘Driver-COSMIC only’ mutations while RUNX1_L56S persists is unlikely to contribute towards disease progression in AML.

Summary/Conclusions: Our prognostic score based on simple and usual data: FLT3 status, cytogenic, ECOG and percentage blast decrease found distinct groups with statistically different outcomes. Basically, the higher is the score, the worst is the OS. This new score is a valuable, simple and useful score for the therapeutic salvage management of AML patients presenting early relapse and primary refractory.
PRELIMINARY RESULTS FROM A PHASE 1 STUDY EXAMINING THE NOVEL BCL-2 INHIBITOR S55746/BCL201 AS SINGLE AGENT IN PATIENTS WITH ACUTE MYELOID LEUKEMIA OR HIGH RISK MYELODYSPlastic SYNDROME

A. Wei1, A. Bajel2, N. Boiselay3, I. Kloos4, C. Delifer4, S. Banquet4, X. Thomas5, N. Vey6
1Department of Clinical Haematology, The Alfred Hospital and Monash University, 2Department of Haematology & Bone Marrow Transplantation, The Royal Melbourne Hospital, Melbourne, Australia, 3Department of Haematology, Hôpital Saint Louis, Paris, 4Servier, Suresnes, 5Department of Hematology, Centre Hospitalier Lyon Sud, Lyon, 6Department of Hematology, Institut Paoli-Calmettes, Marseille, France

Background: Novel and effective therapeutic options for patients (pts) with advanced acute myeloid leukemia (AML) and myelodysplastic syndrome (MDS) are limited. Targeting the prosurvival molecule BCL-2 is clinically efficacious in various hematological malignancies. S55746/BCL201 is a novel, selective and potent inhibitor of BCL-2, with demonstrated antileukemic activity in preclinical models.

Aims: To evaluate the safety, recommended phase 2 dose (RP2D), pharmacokinetic (PK), pharmacodynamic (PD) and preliminary activity of S55746/BCL201 in patients with AML (relapsed/refractory (R/R) or >65 years until for intensive chemotherapy (IC)), or MDS failing prior therapies.

Methods: A phase I study (EUDRACT 2014-002559-24, NCT02920541) is underway to investigate S55746/BCL201 as a single agent in 5 European and Australian centers. S55746/BCL201 was initially administered in fasting conditions, once daily (21-day cycles), until disease progression, unacceptable toxicity, or investigator’s or patient’s decision. Pts giving informed consent received S55746/BCL201 at escalating dose levels according to a modified continual reassessment method for dose allocation.

Results: As of 23 February 2017, 34 pts have received S55746/BCL201 at doses ranging from 100 to 1300mg/day (median time on treatment: 43 days, range 1 to >374), 28 pts were R/R AML, 2 pts were elderly AML unfit for IC, and 4 pts had MDS failing prior therapies. Median age was 70 years (range 19-80), median of prior therapies 2 (range 0-6), median WBC 3.0 G/L (range 0-30). Among the AML cohort, European LeukemiaNet risk (Döhner 2010) was adverse in 53%, intermediate-I in 20%, and intermediate-II in 27%. Among the MDS cohort, 4 pts had MDS failing prior therapies. Median age was 70 years (range 19-80), median number of prior therapies 2 (range 0-6), ECOG ≤2, and median WBC 3.0 G/L (range 0-30). Among the AML cohort, European LeukemiaNet risk (Döhner 2010) was adverse in 53%, intermediate-I in 20%, and intermediate-II in 17%. Preliminary PK results in fasting pts showed that exposure increased linearly but with some inter-individual variability. Most common (≥20% of pts) non-hematological adverse events (AEs), all grades, included diarrhea (27%), hypokalemia (27%), nausea (21%), and vomiting (21%). The most frequent grade ≥3 AEs were hematological (anemia (35%), thrombocytopenia (32%), febrile neutropenia (21%), and neutropenia (16%)), hypokalemia (18%), and sepsis (15%). Of 12 pts (38%) with AEs possibly related to study drug, the most frequent were diarrhea (3 pts), muscle spasms, thrombocytopenia, and anemia (2 pts each). One 74-year-old pt had grade 5 cardiac failure considered drug-related after 6 cycles of treatment (900mg). Non-related fatal AEs were reported (2 pts each). One 74-year-old pt had grade 5 cardiac failure considered drug-related after 6 cycles of treatment (900mg). Non-related fatal AEs were reported (2 pts each). One 74-year-old pt had grade 5 cardiac failure considered drug-related after 6 cycles of treatment (900mg). Non-related fatal AEs were reported (2 pts each). One 74-year-old pt had grade 5 cardiac failure considered drug-related after 6 cycles of treatment (900mg). Non-related fatal AEs were reported (2 pts each).

Summary/Conclusions: Initial findings suggest that S55746/BCL201 has acceptable tolerability and clinical activity in advanced AML and MDS. Based on non-compartmental pharmacokinetic food interaction results from another study, demonstrating that S55746/BCL201 Cmax and AUC increased about 6-fold with food, dose escalation has started in patients with drug intake during a meal.

DISSECTING THE CLINICAL HETEROGENEITY OF NUCLEOPHOSMIN-1 (NPM1) MUTATED ADULT ACUTE MYELOID LEUKEMIA: THE CONTRIBUTION OF FLOW-CYTOMETRIC DETERMINATION OF MINIMAL RESIDUAL DISEASE

E. Buccisano1,*, L. Maurillo1, M.I. Del Principe1, A. Di Veroli2, E. De Bellis2, L. Cicioni3, M. Divona3, T. Ottone3, S. Lavorgna3, V. Rossi4, A. Zizzari4, M.A. Imo Consalvo2, D. Fraboni1, C. Conti1, G. De Poeta1, M.T. Voso1, W. Arcese1, F. Lo Coco1, A. Venditti1
1Biomedicine and Prevention, University Tor Vergata, Rome, Italy

Background: Acute Myeloid Leukemia (AML) with mutations of the gene encoding Nucleophosmin-1 (NPM1) identifies a subgroup of patients with favorable prognosis according to the 2008 WHO classification. However, recent evidences (Papaemmanuel, NEJM 2016) suggest that the coexistence of additional gene mutations (e.g. DNM3TA, IDH1, IDH2R1408, and TET2) may determine an inferior clinical outcome as compared to favorable risk AML and precludes a reliable outcome prediction. The presence of minimal residual disease (MRD), as determined by quantization of NPM1 mutated transcripts, provides powerful prognostic information independent of other risk factors (Ivey, NEJM 2016).

Aims: The aim of our study was to investigate if detection of NPM1 by multi-parametric flow cytometry (MFC) might represent an alternative tool to discriminate different prognosis within the NPM1 mutated AML group, in a setting where an extensive gene profiling at diagnosis or a quantitative determination of NPM1 transcripts in remission would not be available.

Methods: We analyzed a series of 69 AML patients with NPM1 mutations; all the patients were in complete remission (CR) after intensive induction cycle of EORTC-GIMEMA protocols. The frequency of NPM1 mutated cases was not different among patients below (48/142, 34%) or above (21/61, 34%) the age of 60 years, respectively. Twenty out of 65 patients (31%) carried a concomitant FLT3-ITD mutation; 51/66 (77%) NPM1 mutated cases had a normal diploid karyotype. Upon full hematological recovery after consolidation cycle, counting, by MFC, ≥3.5×10^9 (0.03%) residual leukemic cells (RLCs) in the bone marrow (BM) was regarded as a condition of MRD positivity.

Results: Among NPM1 mutated patients, the rate of MRD negative CR was significantly lower (5/69, 7%) as compared to NPM1 WT ones (39/134, 29%), respectively (p<0.001). Although there was not a statistically significant difference, probably due to the low numbers, NMRD negative/NPM1 mutant patients had a lower Cumulative Incidence of Relapse (CIR) as compared to MRD negative/NPM1 WT ones (25% vs 60%). Also we evaluated the impact of autologous (AuSCT) or allogeneic (ASCT) transplantation on the outcome of MRD positive/NPM1 WT patients. The overall survival (OS) was significantly higher for patients submitted to ASCT (n=14) as compared to those (n=15) submitted to AuSCT (93% vs 33%, p<0.011). This was confirmed even after excluding from the analysis FLT3-ITD+patients. When all the meaningful clinical variables were challenged in multivariate analysis (MRD, type of transplant, age >60 yrs, karyotype), the type of transplant (ASCT vs AuSCT) was the only variable that significantly influenced OS and DFS (p=0.001 and 0.003, respectively).

Summary/Conclusions: In conclusion, although both quantitative RT-PCR represents the gold standard, MFC determination of MRD also confirms that the quality of remission is critical to discriminate patients with a different outcome among NPM1 mutant patients. In fact, these patients have a low chance to become MFC MRD negative and in a situation of MRD positivity, a very poor outcome can be substantially improved only by a timely use of an allogeneic procedure.

EXPRESSION OF IMMUNE CHECKPOINT MOLECULES (PD-1, PD-L1, PD-L2) ON BONE MARROW T CELLS IN ACUTE MYELOID LEUKEMIA

1Department of Laboratory Medicine, Asan Medical Center, University of Ulsan College of Medicine, 2Department of Pediatrics, Asan Medical Center Children’s Hospital, University of Ulsan College of Medicine, 3Department of Hematology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic Of

Background: Immune checkpoints constitute a mechanism by which tumors escape from the host immune system and involve the programmed death-1 (PD-1) receptor and its ligands, PD-L1 and PD-L2. In a tumor microenvironment, the expression of PD-1, an inhibitory receptor on the surface of T cells, can lead to dysfunction of antitumor effector cells. Recently, investigators have detected overexpression of PD-1 for patients with acute myeloid leukemia (AML) who experienced relapse following allogeneic stem cell transplantation

Figure 1.
Aims: The authors evaluated patients with AML to determine expression levels of checkpoint molecules (PD-1, PD-L1, and PD-L2) according to diagnosis and treatments (chemotherapy [CTx] and SCT). The purpose of this study was to identify optimal candidates for checkpoint blockade therapy for AML.

Methods: Bone marrow (BM) samples were obtained from 195 AML patients in different stages of the disease. Samples were stratified by time since diagnosis (n=69) and treatment response (complete remission [CR] after CTx, n=30; persistence after CTx, n=29; relapse after CTx, n=7; normocellular marrow with trilineage regeneration [NMTR] after SCT, n=19; persistence after SCT, n=18; and relapse after SCT, n=23) BM samples also were collected from 23 patients with no evidence of hematologic malignancies (control group). Flow cytometric analysis of PD-1 expression on T cells and PD-L1/PD-L2 expression on leukemic cells was performed by means of a FACSCanto II system (Becton-Dickinson, Sunnyvale, CA, USA).

Results: There were no differences in levels of PD-1 expression on CD8+ and CD4+ T cells at time of AML diagnosis, compared with controls. However, PD-1 expression levels on CD4+ T cells were significantly correlated with time since diagnosis. For patients at time of diagnosis, PD-1 expression on CD8+ and CD4+ T cells was significantly different compared with patients who experienced relapse after SCT (P=0.025 and P<0.0001), and NMTR after SCT (P<0.0001 and P<0.0001). In contrast, no difference in PD-1 expression was observed between patients at time of diagnosis and patients after CTx (Figure 1). For CD4+ T cells, a significant difference was found between SCT and CTx groups, and PD-1 expression levels of groups that experienced relapse (P<0.0001) or persistence (P<0.0001) after SCT were significantly higher than those of patients in the CTx groups. PD-1 and PD-2 expression on leukemic cells at time of diagnosis was higher in secondary AML transformed from myelodysplastic syndrome than in de novo AML (P<0.0001 and P=0.039). Although PD-L1 and PD-L2 expression levels for patients at time of AML diagnosis did not differ from groups that experienced relapse or persistence after SCT, PD-L1 and PD-L2 levels for diagnosed patients did differ from those of patients who experienced persistence after CTx (P=0.038 and P=0.023).

Summary/Conclusions: Our study shows that HIV status has no prognostic impact on AL patient’s outcome. HIV patient with acute leukemia should thus be included in clinical trials to improve and standardize their therapeutic management.

E911

TEN-DAY DECITABINE AS INDUCTION THERAPY FOR OLDER PATIENTS WITH ACUTE MYELOID LEUKEMIA FIT FOR INTENSIVE CHEMOTHERAPY

C. Zhou1, H. Wei1, D. Lin1, Y. Wang1, B. Liu1, K. Liu1, B. Gong1, Y. Li1, G. Zhang1, S. Qiu1, R. Gu1, S. Wei1, X. Gong1, Y. Mi1, J. Wang1.*
Background: Currently, there is no consensus regarding optimal treatment for older patients with acute myeloid leukemia (AML). Decitabine for 5 consecutive days produced a complete remission (CR) rate of 17.8% in older patients with newly diagnosed acute myeloid leukemia (AML) treated with standard of care (SOC) chemotherapy, in pts with AML who receive indoximod in combination with 7+3 remission induction consisting of cytarabine (100mg/m^2/day for 7 days) and mitoxantrone. The overall response rate (OS) of AML was 20.7 months. One-year and two-year OS rates were 71.4% and 44.4%, respectively. Patients who responded to treatment had significantly longer OS than non-responders.

Summary/Conclusions: This indicates that the 10-day decitabine regimen may be an optimal management for older AML patients who are in intermediate or adverse cytogenetic risk group and fit for chemotherapy.

E912 INDOXIMOD IN COMBINATION WITH IDARUBICIN AND CYTARABINE FOR UPFRONT TREATMENT OF PATIENTS WITH NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA (AML): PHASE 1 REPORT
A. Emadi1,2,3,*, N.G. Holtzman1,2, M. Imran1, F. El Chaer1, M. Koka4, Z. Singh4, A. Shahlaee5, E. A. Sausville 1,2,3, J. Law 1,2, S. T. Lee 1,2, A. Banerjee 1,2, A. Rapoport1,2, M. R. Baer1,2, V. H. Duong1,2, D. H. Munn4, M. Loken2, E. Kennedy5, N. Vahanian5, C. Link6
1University of Maryland Greenebaum Comprehensive Cancer Center, 2Medicine, 3Pharmacology, 4Pathology, University of Maryland, Baltimore, 5Institute of Hematology and Blood Diseases Hospital, Chinese Academy of Sciences, 6Link Genetics Co., Ames, United States

Background: AML cells can acquire immune evasion and tolerance through overexpression of the IDO (indoleamine 2,3-dioxygenase), which exerts immunomodulatory effects through tryptophan (Trp) catabolism and kynurenine production. By degrading Trp, IDO shifts the balance from a Trp-rich environment, which encourages T-cell proliferation and activation, to a Trp-poor environment. The common non-hematologic toxicities were febrile neutropenia and infections. Median overall survival (OS) of all patients was 20.7 months. One-year and two-year OS rates were 71.4% and 44.4%, respectively. Patients who responded to treatment had significantly longer OS than non-responders.

Summary/Conclusions: This indicates that the 10-day decitabine regimen may be an optimal management for older AML patients who are in intermediate or adverse cytogenetic risk group and fit for chemotherapy.

E913 PHASE III STUDY OF MEK INHIBITOR (MEK-162; BINEMITIN) IN PATIENTS WITH RELAPSED AND/OR REFRACTORY MYELOID MALIGNANCIES
K. Nadv1,2, T. Kadia1, G. Borthakur1, K. Takahashi1, P. Bose1, N. Daver1, Y. Alvarado1, M. Ohanian1, C. DiNardo1, E. Jabbour1, G. Garcia-Manero1, H. Kantarjian1, A. Patel1, F. Ravandi1
1Department of Leukemia, UTMD Anderson Cancer Center, Houston, United States

Background: Activation of the mitogen-activated protein kinase (MAPK) signaling (RAS/RAF/ERK/ERK pathway) promotes growth and inhibits apoptosis of hematopoietic cells. Inhibition of MEK/MEK/MAPK pathway has shown antiproliferative effects in acute myeloid leukemia (AML) and myelodysplasia (MDS). MEK-162 is an oral, potent, selective allosteric, ATP-competitive inhibitor of MEK1 and 2. Aims: To study the efficacy and safety of MEK-162 in patients with advanced myeloid malignancies.

Methods: Patients with relapsed/refractory AML, not candidates for intensive chemotherapy, and patients with high risk myelodysplastic syndrome (MDS) who were resistant/intolerant to standard treatment including stem cell transplant were treated with MEK-162 twice daily every 28 days. Patients in the expansion phase had to be RAS mutated. The primary endpoint was overall response rate (ORR) of 40% after 1 cycle of therapy. Survival was estimated using the Kaplan-Meier method. Safety analysis included all patients who had received at least 1 dose of MEK-162. MEK-162 dose escalation followed a 3+3 design; phase 2 had 45mg twice daily was the first indecisive dose for expansion phase.

Results: Sixteen patients were treated (escalation=7; expansion=9): 14 AML and 2 MDS. Median age was 62 years (31-85); 56% were female; 94% had a performance status of 1-2. Median number of prior therapies was 4 (1-6); 3/16 (19%) patients had complex karyotype. 11/16 (69%) patients were RAS mutated. 12/16 patients completed a minimum of 1 cycle of MEK-162 therapy and were evaluable for response (3 at 30mg and 7 at 45mg dose). ORR was 10% (CRI in 1/10 patients). Median number of cycles administered were 2 (1-4). Median duration on therapy was 1.1 months (0.1-3.4). Median overall survival is 3.2 months (0.3-7.6). Common G3/4 toxicity included neutropenia (56%), fatigue (13%), nausea/vomiting (15%) and electrolyte abnormalities (19%). No dose limiting toxicity was reported.

Summary/Conclusions: MEK-162 shows a tolerable safety profile with an ORR of 10%. The study is currently on-going. Additional studies involving combination of MEK-162 with RAF and PI3 kinase inhibitors are ongoing.

E914 HAPLOIDENTICAL TRANSPLANTATION IS SAFE AND EFFECTIVE FOR OLDER PATIENTS WITH AML/MDS

1Stem Cell Transplantation, The University of Texas MD Anderson Cancer Center, Houston, 2Thomas Jefferson University, Philadelphia, 3Leukemia, The University of Texas MD Anderson Cancer Center, Houston, United States

Background: Acute myeloid leukemia (AML) is more common in the older population. Haploidentical stem cell transplantation (haploSCT) is a potentially curative therapy.
ative treatment option for patients with AML and allows transplantation for patients without an HLA matched donor. Recently, the use of post-transplant cyclophosphamide-based (PTCy) GVHD prophylaxis has improved outcomes of haploSCT; however, outcomes of haploSCT in older patients remain unclear.

Aims: Here we evaluated outcomes of older patients with AML/MDS who underwent haploSCT.

Methods: We retrospectively analyzed outcomes of all 43 patients ≥55 years with AML/MDS who underwent a haploSCT at our institution after year 2009. All patients were treated with fludarabine-melphalan (FM)-based conditioning regimen (melphalan 100 or 140mg/m²) plus thiotepa 5mg/kg or 2GyTBI. Characteristics of these patients are presented in Table 1.

Results: Median age was 61 years (range 55-69), 22 patients (51%) were in CR1/2, 16 patients (37%) had poor-risk cytogenetics, and median HCT-CI was 73%. Donors were children in 35 (81%) or siblings 10 (19%) patients.

Figure 1.

The probability of achieving MFC-MRD negativity at TP2 was only influenced by ELN risk group (p < 0.05). In the whole cohort, 2 years OS was 60.2% (median not reached). Multivariate Cox-Proportional Hazard model showed that MFC-MRD >0.1% at TP2 was the strongest predictor of higher risk of death, whereas MFC-MRD <0.025 at TP1 was the strongest predictor of long survival (Figure 1c). Thirty-five patients carried NPM1-mutation. Two-years OS for NPM1-mut patients showing more or less than 3.5 log transcript reduction at TP1 was 94, respectively (p = 0.039); 2 years OS for patients achieving NPM1-MRD negativity at TP2 was 90.5% vs 42.9% (p = 0.003). MFC MRD analysis in the NPM1-mut cohort led to results comparable with the whole cohort. Multivariate analysis showed that NPM1-MRD at TP1 was the strongest predictor for OS in this group.

Summary/Conclusions: Our data show that MRD assessment at different time-point reduction retains a strong prognostic impact in AML and that different cut-offs at different time-points can give different and useful prognostic information that may drive post-induction therapy. MFC MRD evaluation at TP2 with 0.1% cut-off is the most useful for patients risk stratification. However, the evaluation of MFC-MRD at TP1 with 0.025% cut-off can early identify a group of patients with a significantly low risk of relapse. At the same TP, MFC and WT1 MRD integration allows a better risk stratification. MFC MRD is accurate also in NPM1-mut patients; however, in this cohort NPM1-based MRD evaluation is the most accurate predictor of prognosis.

E915

OPTIMIZATION OF MINIMAL RESIDUAL DISEASE EVALUATION IN ACUTE MYELOID LEUKEMIA TO DRIVE POST INDUCTION THERAPY

P. Minetto1,*, F. Guolo1, M. Clavio1, M. Miglino1, A. Kunkl2, N. Colombo1, E. Fantini1, G. Fugazzola1, D. Guardo1, S. Matarrese1, F. Ballerini1, C. Di Grazia3, A.M. Raita2, A. Bacigalupo3, R.M. Lemoli1, M. Gobbi1

1Clinic of Hematology, Department of Internal Medicine (DIMI), University of Genoa, 2Service of Flow Cytometry, Department of Pathology, 3Division of Hematology and Bone Marrow transplantation, IRCCS AOI San Martino-IST, Genoa, Italy

Background: Among Acute Myeloid Leukemia (AML) patients achieving hematological complete remission (CR) the persistence of detectable disease assessed with highly sensitive techniques as Multicolor-Flow-Cytometry (MFC) or PCR-based molecular analysis retains a negative prognostic value. However, a consensus on the most informative time-points (TP) and sensitivity cut-offs for MRD assessment has not been reached.

Aims: The aim of the present study was the evaluation of the prognostic impact of MFC and molecular MRD assessment by identifying TP, MFC positivity cut-off values and molecular MRD markers with the highest prognostic impact.

Methods: One hundred and ten consecutive AML patients treated in our center between 2004 and 2014 were retrospectively analyzed. As previously described, all patients had received a fludarabine-containing induction. Median age was 47 years (range 18-65). Median follow up was 59 months. Three different MRD-TP have been considered: TP1, after induction I; TP2, after induction II; TP3, after consolidation therapy for patients who did not undergo hematopoietic stem cells transplantation (HSCT). For patients who underwent HSCT, TP3 coincided with pre-transplant MRD evaluation. MFC-MRD evaluation had been performed through 4-colour MFC analysis (and 5-colour from 2011). To define the MFC-MRD positivity cut-off values, were considered: of 2.5x10^-13 residuum leukemic cells (>0.025%) or a threshold of 1 x 10^-3 residual leukemic cells (>0.1%). For patients carrying NPM1-gene mutation NPM1 expression levels at TP1, TP2, TP3 (NPM-MRD) were analyzed. A reduction >3.5 log of NPM1 transcript at TP1 was considered optimal as per our published experience. For patients presenting WT1 over-expression at diagnosis WT1-MRD was evaluated at TP1, considering WT1 negativity with a cut-off of WT1 copies/10^4 ABL lower than 250.

Results: CR rate after induction I and II was 82.7 and 85.5%, respectively. The percentage of MFC-MRD negativity was 94.1% and 91.5% at TP1 and TP2, respectively. The probability of achieving MFC-MRD negativity at TP2 was only influenced by ELN risk group (p < 0.05). In the whole cohort, 2 years OS was 60.2% (median not reached). Multivariate Cox-Proportional Hazard model showed that MFC-MRD >0.1% at TP2 was the strongest predictor of higher risk of death, whereas MFC-MRD <0.025 at TP1 was the strongest predictor of long survival (Figure 1a-c). However, patients with MFC-MRD >0.025 at TP1 displayed a heterogeneous outcome. In this subgroup WT1-MRD at TP1 was able to identify patients with the higher risk of death (Figure 1c). Thirty-five patients carried NPM1-mutation. Two-years OS for NPM1-mut patients showing more or less than 3.5 log transcript reduction at TP1 was 94, respectively (p = 0.039); 2 years OS for patients achieving NPM1-MRD negativity at TP2 was 90.5% vs 42.9% (p = 0.003). MFC MRD analysis in the NPM1-mut cohort led to results comparable with the whole cohort. Multivariate analysis showed that NPM1-MRD at TP1 was the strongest predictor for OS in this group.

Figure 1.

Summary/Conclusions: Our data show that MRD assessment at different time-point reduction retains a strong prognostic impact in AML and that different cut-offs at different time-points can give different and useful prognostic information that may drive post-induction therapy. MFC MRD evaluation at TP2 with 0.1% cut-off is the most useful for patients risk stratification. However, the evaluation of MFC-MRD at TP1 with 0.025% cut-off can early identify a group of patients with a significantly low risk of relapse. At the same TP, MFC and WT1 MRD integration allows a better risk stratification. MFC MRD is accurate also in NPM1-mut patients; however, in this cohort NPM1-based MRD evaluation is the most accurate predictor of prognosis.
Background: Hematopoietic recovery is considered to be associated with the number of multipotent hematopoietic stem cells in the bone marrow, as observed in functional assays involving stem cell transplantation. However, there is little evidence related to hematopoietic recovery in non-transplantation settings, which is accomplished by endogenous hematopoietic cells. A recent study suggested that progenitors are the main contributors during this steady-state hematopoiesis, which differs from exogenous transplantation. And our previous data revealed that, CD34+CD38+CD117+HLA-DR+CD13+CD33+ cells (P cells), a kind of progenitor cell, is significantly decreased in patients with delayed neutrophil recovery after chemotherapy compared with that without delayed count recovery.

Aims: To further examine a potential impact of P cells percentage on hematopoietic recovery.

Methods: The data of 223 patients diagnosed with de novo AML was analyzed retrospectively. All these patients enrolled in our previously published prospective randomized controlled trial AML 2010-01 (201002024). We reviewed the data from bone marrow flowcytometry before the first and second course of consolidation therapy, in which the CD34+CD38+CD117+HLA-DR+CD13+CD33+ pro- genitor cell percentage in the bone marrow was analyzed. Platelet recovery time and time of neutropenia were counted for the evaluation of hematopoietic recovery ability after chemotherapy.

Results: We found that less P cell percentage was significantly associated with prolonged neutrophilia recovery time after the first and second courses of consolidation chemotherapy (p=0.001; p=0.028, respectively). We also observed similar results regarding platelet recovery time after the first course of consolidation chemotherapy (p=0.001). Univariate analysis showed that P cell percentage, rather than gender, age, WHO classification and cytogenetic subgroup, were associated with neutrophilia recovery after chemotherapy.

Summary/Conclusions: Our results indicate that CD34+CD38+CD117+HLA-DR+CD13+CD33+ cells before each course of chemotherapy is associated with chemotherapy and hematopoietic reconstitution capacity independently. These findings may help better understand endogenous hematopoietic reconstitution and modify future chemotherapy regimens based on progenitor cell percentages.

E918

MICRORNAS (MIRs) IN HIGH RISK PEDIATRIC ACUTE MYELOID LEUKEMIA (AML) AS PREDICTION TOOLS FOR RELAPSE INCIDENCE AND RISK STRATIFICATION AFTER REJECTION OF ALLOLOGENIC STEM CELL TRANSPLANTATION

P.P. Leoncini1,*, P. Vitullo1, G. Nigita2, D. Veneziano2, P. Fadda3, V. Tocco1, M. Pigazzi2, G. Basso4, R. Rota1, A. Bertaina1
1Oncohematology, Bambino Gesù Children Hospital, Roma, Italy, 2Medical Genetics, 3Genomic Shared Resources, Ohio State University, Columbus (OH), United States, 4Oncohematology-Pediatrics, University of Padova, Padova, Italy

Background: Despite recent progresses made in the treatment of acute myeloid leukemia (AML) (AML) of childhood, the cure rates of high-risk subtypes remain low. Indeed, patients harboring FLT3-ITD mutations or 11q23 translocations (MLL rearrangements) are still characterized by a poor prognosis, mainly due to leukemia recurrence. Since microRNA (miRs) are small RNA molecules controlling normal hematopoiesis whose deregulation is fundamental in leukemia’s pathogenesis, a possible role as predictors of relapse should be considered.

Aims: Our purpose is to identify, at time of diagnosis, significant miRs signatures able to predict the risk of relapse for patients with high-risk AML, such as FLT3-ITD and MLL mutated. Moreover, these signatures would help us in identifying new molecules for novel targeted therapy and to deeply characterize different deregulated pathways among FLT3-ITD and MLL rearranged patients. Method: A total of 20 AML bone marrow (BM) derived samples collected either at diagnosis (ND) and at relapse (RL) together with 8 healthy controls (HCs) were studied. Informed consent has been obtained from either ND and RL samples, revealing 301 miRs that maintained their deregulation in the 2 subgroups, while 113 and 85 were uniquely found in ND and HCs and RL vs HCs, respectively. Remarkably, miR-34a-5p (P<0.0001) was the recurrent and most statistically significant upregulated miR in both ND and RL samples. Moreover, upregulated miR-10a-5p and miR-99a-5p (P<0.0001), and downregulated miR-5p (P<0.0001) were the most statistically significant miRs in the FLT3-ITD and MLL-rearranged sets respectively, underlying putting unique elements distinguishing the two clinical subsets.

Summary/Conclusions: Our results suggest the presence of different microRNA signatures in pediatric AML carrying FLT3-ITD and 11q23 translocations [t(9;11) and (10;11)]. The identifications of new targets linked to this miRs would be useful in further studies focused on finding novel targeted based therapy. Interestingly, miR-34a-5p was recurrently found upregulated either in ND and RL groups, but not in the comparative analysis between ND vs RL, suggesting a potential involvement in the mechanisms at the base of both onset and relapse in these subtypes of high-risk AML.
E919
MRD-DRIVEN CHOICE OF CONSOLIDATION AND MODULATION OF INDUCTION AND CONSOLIDATION INTENSITY RESULTED IN A SIGNIFICANTLY IMPROVED OUTCOME OF YOUNGER AML PATIENTS IN THE LAST THREE YEARS
M. Clavio1,*, F. Guolo1, P. Minetto1, M. Miglino1, F. Ballerini1, D. Guardo1, E. Coviello1, R.M. Lemoli1, M. Gobbi1
1Clinic of Hematology, Department of Internal Medicine (DiMI), University of Genoa, IRCCS OAU San Martino-IST, Genova, Italy

Background: In the last decades no effective new drugs have been introduced and AML induction therapy is still based on an anthracycline and cytarabine. The MRC group has, however, reported a progressive increase of cure rates in younger patients. Our group has recently showed that the outcome can be improved by a fludarabine-containing induction (FLAI5, with fludarabine administration in first course only), followed by a risk-adapted consolidation.

Aims: The aim of the present study was to evaluate if the disease free survival (DFS) and the overall survival (OS) of younger (<65 years) AML patient treated in our center had shown any modification in four consecutive periods of treatment (< 2008; 2008-2010; 2011-2013; 2014-2016) and to recognize factors possibly leading to this result.

Methods: We reviewed the outcome of 145 consecutive AML patients aged 65 or less and uniformly treated according to the above mentioned strategy. Minimal residual disease (MRD) evaluation was performed by flow cytometry (MFC), assessment of WT1 expression levels and, where applicable, evaluation of recurrent abnormalities such as NPM1 mutation. Results: The cohorts of patients treated in the four periods had a comparable age and risk distribution. Notably, although the median follow up of the 4 cohorts of patients is different, patients treated in the last 3 years showed a significant improvement in DFS (Fig 1), in comparison with previously treated patients. When we reviewed our experience, we found that some changes we introduced in the therapeutic management, possibly contributed to improve outcome. Beside classical risk factors, the time from hematological recovery after the first induction (induction 1) and the start of the second induction course (induction 2) proved to be significantly related to DFS and OS probability. An interval shorter than 15 days resulted in significantly higher toxicity, whereas a time longer than 28 days was associated with an increased relapse probability. Patients being treated in the last three years had a median time from recovery after induction 1 to start of induction 2 of 17 days, compared to 22 days in the other cohorts (p<0.05). Furthermore, after 2013, MRD information after induction 1 was added as a prognostic factor and ELN low and intermediate risk patient with negative MRD after induction 1 were no more scheduled for early allogeneic stem cell transplant (HSCT), but received an higher dose of Ara-C in each of the three consolidation cycles (12g/sqm cumulative dose vs 8g/sqm). Among 8 intermediate risk patients who were MFC MRD negative post FLAI5 and did not proceed to HSCT in first complete remission (CR1), only one relapsed whereas among 5 intermediate risk patients who underwent HSCT in CR1 because of MRD positivity no relapses have been observed. Starting from 2014, patient in CR1 not scheduled for HSCT who showed MRD recurrence underwent salvage therapy before overt hematologic relapse, followed by HSCT consolidation. MRD-directed therapy allowed all treated patients to achieve MRD negative remission before HSCT. Finally, the improved outcome may be associated with a reduced incidence of invasive fungal infections (IFI) due to the introduction of prophylaxis with posaconazole. The lower rate of IFI contributed to the reduction in the delay between chemotherapy courses.

Summary/Conclusions: Our experience shows that, even without the contribution of new drugs, more appropriate utilization of HSCT, tailored on early MRD assessment, MRD directed salvage therapy and posaconazole prophylaxis of IFI led to a relevant improvement of outcome.

Background: Treatment of acute myeloid leukemia(AML) in the elderly, unfit patients is a challenge for clinical hematologists. Therapeutic management in these patients is characterized by shorter survival times and numerous complications including early deaths. A standard treatment of low dose cytarabine (LD-AraC) or using hypomethylating therapy is not satisfying enough. Polish Adult Leukemia Group’s (PALG) studies showed, that addition of cladribine to daunorubicine and cytarabine increases the complete remission rate and improves overall survival in younger patients with AML. We also proved effectiveness of cladribine combined with high dose AraC and mitoxantron in relapsed and refractory AML (1, 2). Cladribine, enhances the concentration of Ara-CTP, an active metabolite of Ara-C in leukemic cells (3). Recent data indicate that cladribine has also hypomethylating properties.

Aims: The aim of our study was to evaluate the efficacy and toxicity of cladribine in combination with LD-AraC in older AML patients.

Methods: Patients with newly diagnosed AML (excluding APL), older than 60 years, unfit for standard induction chemotherapy, were enrolled to our study. The patients were given two cycles of cladribine 5mg/m2 i.v. on days 1-5 and low-dose cytarabine 40mg/m2 s.c. daily for 7 days in days 1-10 every 28 days for the remaining cycles of cladribine 5mg/m2 i.v on days 1-2 with LD-AraC (40mg/m2 s.c. 1-10 days). Responding patients were treated with a prolonged maintenance consisting of LD-AraC (40mg/m2 1-10 day). The treatment was continued until progression.

Results: Twenty-four patients have been enrolled with median age 70 years (range 62-84). In our cohort 20 patients had newly diagnosed AML, 3 secondary and 1 therapy related AML. Cytogenetic risk: good risk 5 patients, intermediate 12, poor risk 3 patients, 4 patients were unclassified. The overall response rate (CR+PR) was 84%. 13 out of 24 (54%) patients achieved complete remission (CR) and 7 (30%) achieved partial remission. Time median number of cycles to obtain CR was 2 (range 1-3). 16% of patients do not responded to treatment. The regimen was well tolerated without 4-week and 8-week mortality. The main reason of death was: heart failure (n=2), renal failure (n=1) and progressive disease (n=4). We didn’t observe grade 3 and 4 nonhematologic adverse events. With a median time of follow-up 14 months, the median overall survival was 12 months.

Summary/Conclusions: The combination of cladribine plus low dose AraC is effective and well tolerated regimen in elderly AML patients unfit for standard chemotherapy.

Background: The use of large scale hybridization panels in early stages of clinical trials for novel therapies elicits a plethora of information for targeted biomarkers. However, as therapeutic targets are further characterized large panels generate an overly broad set of data, compromising sensitivity in the selected biomarker subset. Therefore, once biomarker targets are identified, the use of smaller hybridization panels can facilitate specific variant detection by analyzing specific genomic regions of interest with greater sensitivity than larger gene panels and PCR-based assays. Modifications of laboratory methods for small scale panels allow for the maintenance of high analytic quality with finely targeted panels. Our small panels (~10kb) focus on 1-4 genes, allowing for high-multiplexing of samples on sequencers, and reduced costs/processing times without compromising accuracy. Small panels (~10kb) are currently limited to the specific genomic regions of interest with greater sensitivity than larger gene panels and PCR-based assays. Modifications of laboratory methods for small scale panels allow for the maintenance of high analytic quality with finely targeted panels. Our small panels (~10kb) focus on 1-4 genes, allowing for high-multiplexing of samples on sequencers, and reduced costs/processing times without compromising accuracy.

Methods: Two separate next generation sequencing-target capture assays were developed with bioinformatics software under ISO13485 design control. The panel contained 3 genes, including fms related tyrosine kinase 3 (FLT3); the second covers only CD274 (PD-L1). Libraries were made, hybridized with biotin, and sequenced using the Illumina MiSeqDx. Validation was carried out by spiking in fixed amounts of mutant DNA into wild type DNA to establish the linearity and sensitivity of the assays. Sequencing libraries were generated by conventional PCR with primers from both panels. Sequencing data was analyzed using proprietary software developed by InvivoScribe. Eight AML clinical samples were cross validated for FLT3 mutations by this small panel, amplicon based NGS assay, and capillary electrophoresis (CE) assay.
Results: DNA from 24 cell lines was assessed using both panels, confirming variants previously detected using other methods. A validation was run on the 3-genene panel using a series of contived samples generated from cell lines containing between 0.5% and 25% variant allele frequencies for expected variants. Initial validation indicates that these small panel assays can detect mutations down to 0.5% variant allele frequencies. Assay linearity for FLT3/TKD detection from 0.25% to 12.5% or for FLT3/ITD detection from 0.5% to 25% is excellent (R² = 0.996 and 0.998, respectively). Average sequencing coverage was high, ranging from 5.26x to 7.68x. Comparison of FLT3 analysis of the small panel to amplicon based NGS assay and CE, FLT3-ITD showed complete concordance in clinical samples - and showed a strong linear relationship between the 2 methodologies. It showed the potential to greatly assist in understanding the molecular backgrounds of responders, super-responders, and non-responders, information which can help improve patient outcomes. Developing these assays with bioinformatics using the international ISO13485 design control standards makes them suitable for regulatory approval worldwide.

MOLECULAR GENETIC TESTING PATTERNS FOR PATIENTS WITH NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA (AML) ENROLLED IN THE CONNECT® MDS/AML DISEASE REGISTRY

D. Pollyea1, 2, T. George3, K. Foucau4, H. Erba1, 2, M. Thompson5, G. Robozo6, D. Landau1, J. Page1, K. Seiter8, C. Cogle9, M. Nifenecker10, A. Swern10, P. Kiselev10, M. Sugre10
1University of Colorado Cancer Center, Aurora, 2University of New Mexico, Albuquerque, 3University of Alabama at Birmingham, Birmingham, 4Aurora Research Institute, Aurora Health Care, Milwaukee, 5Weill Cornell College of Medicine, New York, 6University of Florida Health Cancer Center-Orlando Health, Orlando, 7Swedish Cancer Institute, Seattle, 8New York Medical College, Valhalla, 9University of Florida, Gainesville, 10Celgene Corporation, Summit, United States

Background: Recurrent mutations in AML-associated genes have prognostic value and may help guide treatment decisions. Molecular genetic testing patterns for AML in clinical practice are largely unknown. Previous results of the CONNECT MDS/AML Disease Registry (George et al. ASH 2016; abstract 3548) showed suboptimal adherence to the WHO 2008 recommendations for AML diagnosis in a cohort of patients with newly diagnosed AML in clinical practice.

Aims: To report a detailed analysis of patterns of molecular genetic testing in patients with newly diagnosed AML in community and academic settings.

Methods: The CONNECT MDS/AML Disease Registry (NCT01688801) is a US prospective, observational cohort study of patients with newly diagnosed AML (≥55 years) or myelodysplastic syndrome (MDS). All clinical decisions are made by the treating clinicians. Data are collected, using an electronic data capture system, at screening, enrollment, and approximately quarterly throughout the duration of the patient’s participation in the registry. All patients provided informed consent. Enrollment is ongoing. The current analysis evaluated the percentage of patients with AML who had undergone molecular genetic testing recommended by NCCN guidelines (NPM1, FLT3-ITD, CEBPA, IDH1, IDH2, DNMT3A, and KIT). Chi-square tests evaluated effects of several variables on likelihood of molecular genetic testing.

Results: Between 12 Dec 2013 and 8 Dec 2016 (data cutoff), 259 patients with AML were enrolled at 86 sites. Molecular genetic testing was reported in 67% (173/259) of patients. Likelihood of testing varied, respectively, for academica vs community settings (76% [70/92] vs 62% [103/167], P = .018), normal vs abnormal karyotype (77% [79/102] vs 59% [79/133], P = .006), age <65 vs ≥65 (83% [85/103] vs 65% [80/123], P = .003), and white blood cell (WBC) count ≥20 × 10⁹/L vs <20 × 10⁹/L (81% [83/103] vs 74% [90/122], P = .025). In patients who had undergone molecular genetic testing (n=173), the mutations tested varied substantially. All of the NCCN-recommended molecular genetic tests were reported in 9% (15/167) of patients, corresponding 8% (670/8412) of patients with normal karyotype. Of the seven NCCN-recommended tests, NPM1 (77%) and FLT3-ITD (76%) were most often reported and DNMT3A least often (16%).

Summary/Conclusions: Early data from the CONNECT MDS/AML Disease Registry reveal that despite molecular testing reported in 67% of patients with newly diagnosed AML, a majority did not receive guideline-recommended testing. This prospective registry is uniquely positioned to capture changes in testing patterns as guidelines are established.

E924
PHASE 1, OPEN-LABEL, RANDOMIZED STUDY TO EVALUATE THE EFFECT OF CYTOCHROME P450 (CYP) 3A4 INHIBITION ON THE PHARMACOKINETICS (PK) AND SAFETY OF QUIZARTINIB (Q) AND ITS ACTIVE METABOLITE, AC886

J. Li1,*, M. Kankam2, D. Treme1, G. Gammon3
1Daichi Sankyo, San Diego, CA, 2Vince & Associates, Overland Park, KA, Formerly Daichi Sankyo, San Diego, CA, United States

Background: Q is a potent, selective FMS-like tyrosine kinase 3 (FLT3) inhibitor currently being investigated in Phase 3 studies in AML patients (pt) with FLT3 internal tandem duplication (ITD) mutations. Early studies showed concentration (c) and area under the concentration-time curve (AUC) post-dose reductions in FLT3 positive pts; however, the identification of Q as the active metabolite, AC886, was a significant predictor of the QTC prolonging effect(Levis, et al. ASH 2016). Q and AC886 are both primarily metabolized by CYP3A4. Because CYP3A4 inhibiting drugs are frequently required in the...
course of AML treatment, a drug interaction study was performed to assess PK when Q is co-administered with CYP3A4 inhibitors. **Aims:** The primary aim was to determine the effect of ketoconazole (K), a strong CYP3A4 inhibitor, and fluconazole (F), a moderate CYP3A4 inhibitor, on PK of Q and AC886. The secondary aim was to assess the tolerability and safety of Q co-administered with K or F.

**Methods:** This was an open-label, randomized, parallel-group study. Healthy subjects (HS) aged 18–55 years (who provided informed consent were randomized 1:1:1 to receive K 200mg twice daily (BID), F 200mg BID, or placebo (P) BID on Days(D) 1-28. A single 30mg dose of Q was administered to all HS on D8. Plasma Q and AC886 conc were measured D8-28, using a validated liquid chromatography–tandem mass spectrometry method. PK parameters were determined using noncompartmental analysis. steady-state (SS) drug conc, following repeated once daily dosing, were predicted using non-parametric superposition. An analysis of variance (ANOVA) was performed to assess the CYP3A4 inhibitory effect of K and F on the PK.

**Results:** 93 HSs were enrolled (31 per arm). Inhibitors Q received Q. 75% were male, median age 32 yr (18-53). Relative to Q+P, co-administration of Q+K or Q+F increased the geometric mean (GeoMean) C_max of Q by 17% and 11%, and GeoMean AUC_0-24 by 94% and 20%, respectively (Table 1 below). The GeoMean C_max and AUC_0-24 of AC886 were decreased by 60% and 15%, respectively, for Q+K, and were increased by 3% and 14%, respectively, for Q+F. Apparent clearance (CL/F) of Q was 50% lower and t_1/2 of Q and AC886 were 46% and 96% longer, respectively in Q+K vs Q+P. CL/F of Q was 17% lower and t_1/2 of Q and AC886 were 10% and 28% longer, respectively, in Q+F vs Q+P. AC886 is a minor component in circulation relative to Q (approximately 25%). An increase of 86% in simulated SS Q C_max and GeoMean AUC_0-24 was observed following repeat daily dosing of 30mg Q+K vs Q+P, while a modest decrease in AC886 exposure (<20%) was predicted. The most common (≥5%) adverse events were headache (7.5%) and diarrhea (5.4%), with the majority being Grade 1/2. There were no clinically significant hematology, clinical chemistry, QTC, or vital sign observations, and no deaths or serious adverse events.

**Summary/Conclusions:** Co-administration of Q with K or F was well tolerated and safe. Overall, there was an approximate 2-fold increase in Q exposure when Q was co-administered with K, which is considered clinically significant. The increase in Q exposure when Q was co-administered with F was within 20% and is not considered clinically relevant. Given the relationship between Q conc and QTC prolongation, these results support reducing Q doses by approximately one-half when taken concomitantly with a strong CYP3A4 inhibitor. No dose reduction is needed when Q is co-administered with a moderate or weak CYP3A4 inhibitor. This approach has been implemented in two ongoing Phase 3 trials of Q in FLT3-ITD mutated AML.

**Table 1.**

**E926**

**CLINICAL OUTCOMES OF CHILDHOOD ACUTE MEGAKARYOBLASTIC LEUKEMIA: THE CHILDREN CANCER HOSPITAL EGYPT 57357 EXPERIENCE**

**Aims:** To evaluate the prognostic significance of various cytogenetic abnormalities and minimal residual disease (MRD) by flow cytometry after induction I and correlate them with clinical outcomes of patients with acute megakaryoblastic leukemia.

**Methods:** We retrospectively analyzed the data of 80 non-Down syndrome patients diagnosed with M7 AML treated at CCHE between January 2007 through December 2016. Three treatment protocols were used.

**Results:** The median age at diagnosis was 1.7 years (range 0.2-15). The median time to diagnosis was 1 month. The overall (OS), event free survival (EFS) and cumulative incidence of relapse at 2 years were 53.4%, 42.9% and 28.4% respectively. Sixty one patients had abnormal cytogenetic abnormalities including Trisomy 19 (n=20), 13q (n=3), Trisomy 8 (n=12), Complex karyotype (n=28), t(1;22) (n=12), MLL gene rearrangement (n=9), Trisomy 21 (n=24) but none of these had an impact on outcomes. Out of the 80 patients 56 were in complete remission post induction I. Two hundred patients had M7-0.1% after induction I. In the univariate analysis patients with MRD <0.1% post induction I had a better OS and EFS with a lower cumulative incidence of relapse however these findings did not reach a statistical significance.

**Summary/Conclusions:** Acute megakaryoblastic leukemia in non-Down syndrome patients have poor outcomes irrespective of any cytogenetic abnormalities. Future direction to determining tumor biology based on molecular pathways in this disease is being considered.

**E927**

**IDENTIFICATION OF RESISTANCE ASSOCIATED CPG METHYLATION CHANGES IN ACUTE MYELOID LEUKEMIA PATIENTS UNDERGOING INDUCTION CHEMOTHERAPY**

C. Niederwieser1, C. Rohde1, H. Serve2, W. Berdel3, G. Ehringer4, S. Göllner4, L. Müller1, C. Müller-Tidow1
**Background:** Acute myeloid leukemia (AML) is a heterogeneous disease associated with epigenetic alterations that can be targeted with demethylating agents to induce CR in a subgroup of patients. However, there are currently no predictive markers that reliably distinguish responder from non-responder patients. In this analysis we assessed DNA methylation changes in a group of refractory patients with AML treated either with the hypomethylating agent azacitidine followed by intensive chemotherapy or with intensive chemotherapy alone in order to identify the alterations and genes involved.

**Aims:** The exploration of whole genome methylation changes of azacitidine and chemotherapy treatment in refractory patients with AML guides treatment refinement.

**Methods:** Patients from the AML-AZA trial of the Study Alliance Leukemia were randomized to receive either azacitidine followed by chemotherapy or chemotherapy alone. Cells were harvested at baseline and 15 days after chemotherapy from 16 of the 105 patients receiving the combination and from four of the 109 patients randomized to receive chemotherapy only. Genome-wide DNA methylation was analysed using a 450K Illumina array (Illumina, San Diego, USA). With a signature derived by differential blasts within diagnosis to day 15, patients with a reduction of blasts clustered together by methylation of all the selected CpG sites, as did those with an increase of blasts on both day 0 and day 15, whereas unsorted samples or day 0 and day 15 frequently clustered together as well. This led us to refine blast independent analyses. We excluded methylation changes correlating with the percentage of blasts (p=0.14, exploratory regression among blast change and median methylation change change day 0 to day 15, each), since these are likely to reflect the increased lymphocyte counts seen in some of our unsorted samples used for analysis. Motifs most strongly impacted by methylation changes were detected using the Homer software (Salk institute, San Diego, USA). Methylation changes were compared between the two groups to identify the changes associated with the use of azacitidine prior to chemotherapy.

**Results:** In the Azacitidine plus Chemotherapy treated group, a total of 389 differentially methylated regions (DMRs), most of which were single CpGs, were identified, 176 of which were hypermethylated and 213 hypomethylated. The most highly represented hypermethylated loci were INS1M (p=1e-17, 6.25% of 176 DMRs), KLF13 (p=1e-14, 7.95%), HIC2 (p=1e-11, 5.11%), while those most commonly hypomethylated were ARID1 (p=1e-15, 2.82% of 213 DMR's), MYB (p=1e-14, 3.76%) and STAT1 (p=1e-14, 1.88%). The chemotherapy alone group yielded 7181 DMRs, 5752 of which were hypermethylated and 1429 hypomethylated. The genes most commonly hypermethylated in these patients were EHF (ETS) (p=1e-226, 32.79% of 5752), CEBPE (p=1e-90, 10.34%), and Jun-AP1 (p=1e-4S, 6.10%), while those most commonly hypomethylated were RUNX1 (p=1e-24, 28.34% of 1429 DMRs), TCFF4 (p=1e-21, 8.40%) and SMAD3 (p=1e-17, 1.05%).

A median overall survival did not differ between the two treatment groups, with 153 days for chemotherapy and 143 days for azacitidine plus chemotherapy patients.

**Summary/Conclusions:** Methylation changes associated with azacitidine and chemotherapy in refractory patients were particularly found in genes previously associated with cancer and AML. DNA hypermethylation was more common after chemotherapy alone. This finding suggests that DNA hypermethylation of specific loci may be associated with therapy resistance. Hence, the methylation levels were detected from the most resistant cells. Of note, upon Azacitidine treatment more hypomethylated loci were observed. This potentially indicates DNA hypomethylation in vivo.

---

**E928 OVER-EXPRESSION OF ZEB2-AS1 LncRNA PREDICTS POOR OUTCOMES IN PATIENTS WITH ACUTE MYELOID LEUKEMIA**

X. Shi,1,2, J. Li,1, M. Ma,1, L. Wen,1, Q. Wang,1, H. Yao,1, C. Ruam,1, D. Wu,1,2, S. Chen1

1The First Affiliated Hospital of Soochow University, Jiangsu University of Hematology, 2Institute of Blood and Marrow Transplantation, Collaborative Innovation Center of Hematology, Soochow University, Suzhou, China

**Background:** Acute myeloid leukemia (AML) is a fatal hematopoietic malignancy with poor clinical outcomes characterized by blasts infiltrated in tissues.

**Aims:** To determine whether the antisense lncRNA namely ZEB2-AS1 would be associated with clinical outcomes, we assessed its expression in retrospectively collected paired samples of 10 of 16 AML patients.

**Methods:** Relative quantitative real-time PCR analysis was employed for detecting levels of ZEB2-AS1. SYBR Green RT-PCR was performed, followed by obtaining relative threshold cycle normalized to reference GAPDH gene. Cell migration, invasion, proliferation and apoptosis tests were used to analyze biological phenotypes of AML cells after knocking down ZEB2-AS1 lncRNA by small interfering RNAs.

**Results:** Results showed that expression of ZEB2-AS1 lncRNA was prominently high and closely correlated with adverse clinical outcomes in AML patients, based on either modified MRC or ELN risk stratification system. Univariate analyses indicated that patients with higher expression of ZEB2-AS1 lncRNA had significant shorter 3-year overall survival (OS) (0% vs 68.2%, p=0.036) and disease-free survival (DFS) (25.0% vs 69.8%, p=0.039). In addition, patients with higher expression of ZEB2-AS1 lncRNA had significant lower complete remission (CR) rate in response to induction chemotherapy (75.0% vs 27.3%, p=0.031). In patients with low levels of ZEB2-AS1 lncRNA, patients treated by allogeneic hematopoietic stem cell transplantation had significant longer OS (3-year OS, 75.8% vs 28.6%, p=0.037) and DFS (3-year DFS, 81.8% vs 26.6%, p=0.049) compared to that of chemotherapy.

**Summary/Conclusions:** Moreover, knockdown of ZEB2-AS1 lncRNA could effectively inhibit invasion and migration in AML cells, which was closely associated with down-regulation of ZEB2 and up-regulation of E-cadherin. Collectively, although independent prognostic value for survivals was not rigorously determined, ZEB2-AS1 lncRNA may serve as candidate to improve conventional risk stratification system and contribute to evaluating therapeutic responses. Furthermore, ZEB2-AS1 lncRNA could potentially be a therapeutic target to treat AML.
SALVAGE TREATMENT FOR ADVANCED ACUTE MYELOID LEUKEMIA

DECITABINE COMBINED WITH HAAG REGIMEN IS AN EFFECTIVE

Aims: To evaluate the clinical efficacy and safety of decitabine (DAC) in combination with HAAG regimen (HDAc, Ara-C), doxorubicin (Acla) and recombinant human granulocyte colony stimulating factor (G-CSF) for advanced patients with AML.

Methods: Thirty-six patients with advanced AML receiving DAC combined with HAAG chemotherapy in our center from December 2012 to August 2015 were enrolled in this study. Eighteen of them were refractory or relapsed AML, and another 18 patients were those who didn’t achieve CR after a course of induction chemotherapy. The therapeutic responses, side effects and long-time survival were retrospectively analyzed.

Results: After a course of treatment, the rate of CR and partial response (PR) was 58.3% (21/36) and 22.2% (8/36) respectively, while the overall response rate (ORR) was 80.6% (29/36) in the cohort. For the patients with refractory or relapse AML, CR was 61.0% (11/18), PR was 22.2% (4/18), and ORR was 83.3% (15/18). While for the other not getting CR after a course of induction chemotherapy, CR was 55.6% (10/18), PR was 22.2% (4/18), and ORR was 77.8% (14/18). Grade 4 hematological toxicities were observed in all patients, and 72.2% cases experienced infection. And all non hematological side effects were mild and well-tolerated. With a median follow-up of 7.5 (0.5-33.3) months, the 1-year overall survival (OS) rate was 43.3%, 24.2% for the refractory or relapsed AML patients, and 61.6% for those not achieving CR after a course of induction chemotherapy. The difference was significantly (P<0.01).

Summary/Conclusions: DAC combined with HAAG regimen is safe and effective salvage treatment for advanced stage AML patients.

E930

PROGNOSTIC IMPACT OF IDH1 AND IDH2 MUTATIONS IN LOW AND INTERMEDIATE RISK AML: A MULTICENTER RETROSPECTIVE STUDY

Background: Mutations in the isocitrate dehydrogenase 1 and 2 (IDH1 and IDH2) genes are common in acute myeloid leukemia (AML) but, although investigated in several studies, their prognostic significance still remains controversial.

Aims: To evaluate the prevalence and prognostic impact of IDH1 and IDH2 mutations in adult AML patients with low and intermediate-1 and 2 risk (European LeukemiaNet ELN 2010).

Methods: We retrospectively evaluated IDH1 and IDH2 mutations in 99 low and intermediate risk patients with new diagnosed AML who underwent intensive induction chemotherapy in three Italian centers.

Results: Median age for all patients was 60 years. IDH mutations were detected in 25% of our patients. 7% were IDH1 R132, 16% were IDH2 R140 and 2% R172. Median WBC count was 12.66±10^9/L in IDH wild-type, and 24.71±10^9/L in IDH mutated. Absolute neutrophil count was 3.1±10^9/L in IDH wild-type and 0.8±10^9/L in IDH mutated, and the difference was statistically significant (p=0.001). Median bone marrow blasts, platelets count, and LDH did not differ significantly. Cytogenetic risk group according to ELN 2010 showed favorable risk in 31.4%, and intermediate (I) and II risk in 68.6%. In favorable risk group IDH mutated patients were 12%, and 13% in the intermediate risk group. IDH expression was significantly correlated neither with NPM1 mutation nor with FLT3 mutation. There were no significant differences between induction therapy in IDH mutated patients (overall 3+7 “like” regimens in 57 patients, FLAi like regimens in 42). There were not significant differences in CR rate after induction therapy, OS and PFS between IDH mutated and unmutated patients. Median OS was 595 days in IDH mutated and 467 in IDH wild-type (p=0.07). Median DFS was 319 days in IDH mutated and 406 days in unmutated (p=0.157). We further analyzed the impact of IDH mutation in different cytogenetic risk groups: OS and PFS were not significantly different between mutated and unmutated low cytogenetic risk patients. In intermediate I and II risk patients OS was significantly different (177 days in IDH mutated vs 406 days in IDH wild type, p=0.002), but OS was not. We then evaluated patients with normal karyotype and mutated NPM1. IDH mutations had no impact on OS and PFS.

Summary/Conclusions: In this multicenter retrospective study we found that lower absolute neutrophil count at diagnosis is significantly correlated with IDH mutation as already confirmed by other groups. In terms of prognosis we only demonstrated an advantage in DFS for unmutated intermediate risk patients, suggesting a negative prognostic impact of the mutations which need to be confirmed in further studies.

E931

DECITABINE COMBINED WITH HAAG REGIMEN IS AN EFFECTIVE SALVAGE TREATMENT FOR ADVANCED ACUTE MYELOID LEUKEMIA

Methods: We conducted a nationwide population-based cohort study and included all AML patients >25 years diagnosed in Denmark between 2000-2014 (follow-up ended Feb 2016). We compared chance of intensive chemotherapy, complete remission (CR) and chance of alloHSCT in CR1 by treatment-related mortality and marital status. Cox regression (HRs) were used to compare survival in acute myeloid leukemia (AML) patients using individualized socioeconomic and clinical data from Statistics Denmark and The Danish National Acute Leukemia Registry.

Figure 1.

Results: Median age for all patients was 60 years. IDH mutations were detected in 25% of our patients. 7% were IDH1 R132, 16% were IDH2 R140 and 2% R172. Median WBC count was 12.66±10^9/L in IDH wild-type, and 24.71±10^9/L in IDH mutated. Absolute neutrophil count was 3.1±10^9/L in IDH wild-type and 0.8±10^9/L in IDH mutated, and the difference was statistically significant (p=0.001). Median bone marrow blasts, platelets count, and LDH did not differ significantly. Cytogenetic risk group according to ELN 2010 showed favorable risk in 31.4%, and intermediate (I) and II risk in 68.6%. In favorable risk group IDH mutated patients were 12%, and 13% in the intermediate risk group. IDH expression was significantly correlated neither with NPM1 mutation nor with FLT3 mutation. There were no significant differences between induction therapy in IDH mutated patients (overall 3+7 “like” regimens in 57 patients, FLAi like regimens in 42). There were not significant differences in CR rate after induction therapy, OS and PFS between IDH mutated and unmutated patients. Median OS was 595 days in IDH mutated and 467 in IDH wild-type (p=0.07). Median DFS was 319 days in IDH mutated and 406 days in unmutated (p=0.157). We further analyzed the impact of IDH mutation in different cytogenetic risk groups: OS and PFS were not significantly different between mutated and unmutated low cytogenetic risk patients. In intermediate I and II risk patients OS was significantly different (177 days in IDH mutated vs 406 days in IDH wild type, p=0.002), but OS was not. We then evaluated patients with normal karyotype and mutated NPM1. IDH mutations had no impact on OS and PFS.

Summary/Conclusions: In this multicenter retrospective study we found that lower absolute neutrophil count at diagnosis is significantly correlated with IDH mutation as already confirmed by other groups. In terms of prognosis we only demonstrated an advantage in DFS for unmutated intermediate risk patients, suggesting a negative prognostic impact of the mutations which need to be confirmed in further studies.

E932

LESS-INTENSIVE TREATMENT LEADS TO DECREASED SURVIVAL IN UNMARRIED ACUTE MYELOID LEUKEMIA PATIENTS AND PATIENTS LIVING ALONE. A DANISH NATIONAL POPULATION-BASED COHORT STUDY

Background: Marital status has been found to affect leukemia survival. Still, lack of individual-level socioeconomic data, cohabitation status, and treatment information prevented further investigation of underlying mechanisms. As treatment is changing towards outpatient-care, effects of social support may become even more important.

Aims: We investigated whether and how cohabitation and marital status affect chance of intensive remission-induction chemotherapy and allogeneic stem cell transplantation (HSCT), treatment response, and survival in acute myeloid leukemia (AML) patients using individualized socioeconomic and clinical data from Statistics Denmark and The Danish National Acute Leukemia Registry.

Methods: We conducted a nationwide population-based cohort study and included all AML patients >25 years diagnosed in Denmark between 2000-2014 (follow-up ended Feb 2016). We compared chance of intensive chemotherapy, complete remission (CR) and chance of alloHSCT in CR1 by treatment-related mortality and marital status. Cox regression (HRs) were used to compare survival in acute myeloid leukemia (AML) patients using individualized socioeconomic and clinical data from Statistics Denmark and The Danish National Acute Leukemia Registry.
markers. Results were given overall and stratified by age (<60/≥60 years) and sex. Kaplan Meier curves and Cox regression (Hazard ratios; HRs) was used to compare survival by cohabitation (living with someone, living alone) and marital status (married, divorced, widowed, unmarried).

Results: The study included 3243 AML patients. Patients living with someone (n=2056) were younger, more likely to be married, male, to be working, and to have a higher education than patients living alone. Comorbidity, white blood cell count, lactate dehydrogenase, and blast counts did not differ between groups, however patients living with someone tended to have better performance status at time of diagnosis. Patients living with someone were more likely to receive intensive chemotherapy than patients living alone when aged 60 years or older (41.2% versus 22.8%, adjusted OR 0.81 (CI=0.46-0.81)). In patients <60 years, never-married patients were less likely to receive intensive therapy (adjusted OR 0.43 (CI=0.19-0.99)) than married patients. In patients <70 years achieving CR, the chance of allogHCT was reduced when living alone (11.8%, adjusted OR 0.47 (CI=0.28-0.78), versus 19.0% in patients living with someone). In 4/13 patients who did not achieve complete remission, the chance was also reduced (7.6%, adjusted OR 0.38 (CI=0.20-0.74)) compared to married patients (19.3%). Crude survival by cohabitation is shown in Figure 1. Overall survival was inferior in patients >60 years living alone (adjusted HR 1.21 (CI=1.09-1.33)) and unmarried patients (never-married: adjusted HR 1.29 (CI=1.06-1.57), divorced/widowed: adjusted HR 1.11 (CI=1.00-1.23)) compared to married patients. In contrast, cohabitation and marital status did not affect treatment response (living with someone: CR 70.6%, living alone: CR 72.8%) or overall survival (adjusted HR 1.08 (CI=0.81-1.23)) in intensive therapy patients only.

Summary/Conclusions: Our study results indicate, that the effect of cohabitation and marital status on outcome, especially in patients >60 years, is explained by social support rather than by differences in income and occupation. Patients living alone do not present with more advanced disease or higher comorbidity burden than patients living with someone. Still, patients living alone and never-married patients are less likely to receive intensive chemotherapy after overall survival. Increased focus on what drives treatment decisions in patients lacking social support is important to improve survival in these patients.

E933

TREATMENT OF MOLECULAR RELAPSE IN ACUTE MYELOID LEUKEMIA WITH MUTATED NPM1 REDUCES TOXICITY OF SALVAGE TREATMENT AND IMPROVES DISEASE CLEARANCE

F. Guolo1, P. Minetto1, M. Clavio1, D. Guardo1, E. Covelli1, N. Colombo1, F. Ballerini1, M. Miglino1, R.M. Lemoli1, M. Gobbi1

1Clinic of Hematology, Department of Internal Medicine (DIMI), University of Genoa, IRCCS AOU San Martino-IST, Genova, Italy

Background: Acute Myeloid Leukemia with mutated NPM1 (NPM-AML) is characterized by a favorable prognosis. Most patients achieve hematological complete remission (CR) and are not considered eligible for an early allogeneic stem cell transplantation (SCT). Nonetheless, the importance of minimal residual disease (MRD) monitoring in NPM-AML is well recognized but no data are currently available on MRD-directed therapy in this AML subset. Since 2004 we have prospectively evaluated NPM1 MRD at precise time points to evaluate salvage therapy.

Aims: To investigate the amount and clearance of MRD reduction and LAIP changes in de novo AML during chemotherapy and compare the results with clinical outcomes.

Methods: In a clinical prospective study since March 2016 till February 2017 50 patients (pts) de novo AML (f/m 32/18 m. age 44 (17-85)) were included. 14 pts by this moment completed basic chemotherapy (ChT) courses: 7+3x 2 induction and 2 consolidation. Among them favorable cytogenetics was in 4pts (t(16;21)-1, 16q22-1, t(8;21)-2pts), intermediate-7 (6-with normal caryotype, 1-t(17;22), poor-3 (complex karyotype-2, 11q23-1p3). Bone marrow samples were studied in standardized panel with most common antibodies by 6-color MFC (BD FACSCTo II, USA) before the treatment, after 1st and 2nd courses of induction and after 2nd consolidation. Any amount of MRD >0 was assumed as MRD positivity. Besides MRD status we also assessed LAIP changes in patients with CMR after 2nd ChT.

Results: Leukemia associated immunophenotype (LAIP) was detected in all monitored patients at the diagnosis. Molecular markers were detected in 28.5% (2pts-with NPM1+FLT3+CEBPA+, 1-wt FLT3+, 1-NPM1+). 2 pts had resistant AML after 2 courses (DR). 3 pts out of 7 with complete morphological remission (CMR) after 1st course had MRD positivity (0.03%, 0.16%, 8.3%), and these pts became MRD-negative after 2nd course. CMR was achieved after 2nd course in 5 more pts and MRD positivity was detected in 3 pts (0.033%, 0.523 and 3.9%) with intermediate cytogenetic risk. By the end of 4th course 11 pts stayed in CMR and we diagnosed 1 morphological relapse (patient with MRD negativity and CMR after 2nd ChT). Two early relapses were also detected: both with persistent MRD during all period of ChT and CMR after the second ChT. All pts with MRD-negative status after first course are alive and in CMR (8 months from diagnosis). While monitoring, LAIP changes were distinguished in 7 pts. One from two with resistant AML lost CD65, another one acquired CD11b. 5 pts were in CR after 2nd ChT and during ChT one of them gained CD56 and CD13, 2nd lost CD65 and CD11b, 3rd — gained CD56, 4th gained CD11b after 2nd ChT, the last one didn’t change LAIP. We detected relapse in 3 pts from this group and one — with increasing MRD after 4th course and cytopenic syndrome. We may suggest that LAIP changes during ChT reflect selection of more chemoresistant leukemia clone, followed by subsequent relapse.

Summary/Conclusions: The most favorable group consisted of MRD negative pts after 1st course. LAIP changes are common in pts with less favorable prognosis.

LENALIDOMIDE MAINTENANCE IN PATIENTS WITH HIGH RISK ACUTE MYELOID LEUKEMIA

T. Kadla1, J. Cortes1, F. Ravandi1, N. Daver1, E. Jabbour1, A. Ferrajoli1, N. Pemmaraju1, K. Naqvi1, S. Pelletier1, M. Brandt1, Z. Estrov1, H. Kantarjian1

1Leukemia, MD Anderson Cancer Center, Houston, United States

Madrid, Spain, June 22 – 25, 2017 | haematologica | 2017; 102(s2) | 383

Figure 1.

Summary/Conclusions: Despite the good overall prognosis, a significant proportion of NPM-AML patients will relapse. Our preliminary data strongly support the feasibility and efficacy of MRD-directed therapy in NPM-AML. This strategy reduces the toxicity related to re-induction and increases the proportion of patients achieving a MRD negative CR.

E934

MINIMAL RESIDUAL DISEASE AND LAIP CHANGES BY FLOW CYTOMETRY IN DE NOVO ACUTE MYELOID LEUKEMIA DURING CHEMOTHERAPY AND CLINICAL OUTCOMES

T. Lobanova1, I. Galtseva1, Y. Davydova1, N. Kapranov1, V. Troitskaya1, E. Parovichnikova1

1Hematological Oncology and BMT, National Research Center for Hematology, Moscow, Russian Federation

Background: Minimal residual disease (MRD) detection by multicolor flow cytometry (MFC) in acute myeloid leukemia (AML) is widely explored by different researchers and it is an additional independent factor in clinical outcomes. The prognostic value of leukemia associated immunophenotype (LAIP) changes in not explored enough.

Aims: To investigate the amount and clearance of MRD reduction and LAIP changes in de novo AML during chemotherapy and compare the results with clinical outcomes.

Methods: In a clinical prospective study since March 2016 till February 2017 50 patients (pts) de novo AML (f/m 32/18 m. age 44 (17-85)) were included. 14 pts by this moment completed basic chemotherapy (ChT) courses: 7+3x 2 induction and 2 consolidation. Among them favorable cytogenetics was in 4pts (t(16;21)-1, 16q22-1, t(8;21)-2pts), intermediate-7 (6-with normal caryotype, 1-t(17;22), ppoor-3 (complex karyotype-2, 11q23-1p3). Bone marrow samples were studied in standardized panel with most common antibodies by 6-color MFC (BD FACSCTo II, USA) before the treatment, after 1st and 2nd courses of induction and after 2nd consolidation. Any amount of MRD >0 was assumed as MRD positivity. Besides MRD status we also assessed LAIP changes in patients with CMR after 2nd ChT.

Results: Leukemia associated immunophenotype (LAIP) was detected in all monitored patients at the diagnosis. Molecular markers were detected in 28.5% (2pts-with NPM1+FLT3+CEBPA+, 1-wt FLT3+, 1-NPM1+). 2 pts had resistant AML after 2 courses (DR). 3 pts out of 7 with complete morphological remission (CMR) after 1st course had MRD positivity (0.03%, 0.16%, 8.3%), and these pts became MRD-negative after 2nd course. CMR was achieved after 2nd course in 5 more pts and MRD positivity was detected in 3 pts (0.033%, 0.523 and 3.9%) with intermediate cytogenetic risk. By the end of 4th course 11 pts stayed in CMR and we diagnosed 1 morphological relapse (patient with MRD negativity and CMR after 2nd ChT). Two early relapses were also detected: both with persistent MRD during all period of ChT and CMR after the second ChT. All pts with MRD-negative status after first course are alive and in CMR (8 months from diagnosis). While monitoring, LAIP changes were distinguished in 7 pts. One from two with resistant AML lost CD65, another one acquired CD11b. 5 pts were in CR after 2nd ChT and during ChT one of them gained CD56 and CD13, 2nd lost CD65 and CD11b, 3rd — gained CD56, 4th gained CD11b after 2nd ChT, the last one didn’t change LAIP. We detected relapse in 3 pts from this group and one — with increasing MRD after 4th course and cytopenic syndrome. We may suggest that LAIP changes during ChT reflect selection of more chemoresistant leukemia clone, followed by subsequent relapse.

Summary/Conclusions: The most favorable group consisted of MRD negative pts after 1st course. LAIP changes are common in pts with less favorable prognosis.
Background: New drug combinations and higher intensity therapy have led to significant improvements in complete remission (CR) rates for patients with acute myeloid leukemia (AML). However, relapsed disease remains a major source of failure. With the exception of allogeneic stem cell transplant (SCT), there are few options for post-consolidation maintenance of remission in high-risk patients. NK cells as part of the immune microenvironment are important mediators of immune surveillance in AML. Lenalidomide has demonstrated single-agent activity in AML and enhances NK cell activity and immune synapse formation in leukemia.

Aims: We designed a phase II clinical trial studying the efficacy of lenalidomide as maintenance therapy in AML patients with high-risk disease in remission, who were not being considered for SCT.

Methods: AML patients ≥18 years with a high-risk feature in 1st CR (CR1) or any patient in 2nd CR (CR2) who had received induction and at least 1 consolidation cycle were eligible for enrollment. Patients should be within 12 months of achieving CR, have PS ≤3, adequate kidney/liver function, ANC >0.5 and platelets ≥30. Patients were treated continuously with lenalidomide 10mg PO daily on D1-28 of a 28 day cycle for up to 24 cycles. All pts had baseline cytogenetic and molecular testing, and minimal residual disease (MRD) assessment by flow cytometry. After cycle 1, stepwise dose escalations were allowed to 20mg daily in pts who were tolerating their dose and have presence of minimal residual or morphologically detectable disease.

Figure 1. A total of 14 patients have been enrolled with a median age of 57.5 years (range, 23-67). All pts were in CR at the time of enrollment, with 12 pts (86%) in CR1 and 2 (14%) in CR2. Baseline pt characteristics are outlined in Table 1. AML-related mutations detected at start of therapy include: CEBPA (n=5), FLT3 (3), IDH2 (2), NRAS (2), DNMT3a (2), and 1 each of JAK2, TET2, and EZH2. High risk features at the time of enrollment were as follows (some are overlapping): S (36%) with history of prior myeloid neoplasm or therapy related AML, 4 (29%) persistent MRD, 4 (29%) adverse mutational profile, 2 (14%) adverse karyotype, 1 (7%) primary refractory disease, and 2 (14%) CR2 status. Patients have received a median of 9 cycles (1-24) cycles of therapy. With a median followup of 19+ months (8.5-39), the 6- and 12-month estimated RFS were 100% and 69%, respectively. The 6- and 12-month estimated OS were 100% and 90%, respectively (Figure 1). The regimen was well tolerated. Cytopenias were mild and managed with dose adjustments. The most common grade 3 (no grade 4 toxicity) non-heme toxicities were 1 each of rash, fatigue, cough, and nausea, vomiting, and stroke.

Summary/Conclusions: Lenalidomide is a safe and feasible maintenance strategy in high-risk AML patients who are not candidates for SCT. The study continues to surpass the pre-specified expected rate of relapse-free survival of high-risk patients based on a historical cohort. Studies evaluating dynamics of MRD on study are ongoing.

E936

POSTREMISSION THERAPY FOR AML WITH INTERMEDIATE RISK CYTOGENETICS IN FIRST COMPLETE REMISSION

J. Vydra1,*, C. Šálek 1, J. Schwarz 1, P. Četkovský 1, P. Žák 2, J. Novák 3, V. Petečuková3, J. Mayer4, Z. Ráčil4

Background: Postremission therapy of AML with intermediate risk cytogenetics in first CR is based on chemotherapy with high dose cytarabine (HIDAC) or hematopoietic cell transplantation (HCT). Evidence from single trials with regards to optimal postremission therapy has been inconclusive, metaanalyses suggest a survival benefit of allogeneic HCT in first CR, except for patients with mutation of NPM1 without concomitant FLT3/ITD.

Aims: We analyzed retrospectively data from patients with AML with intermediate risk cytogenetics in CR1 with the aim to determine rates of completion of postremission therapy, rates and risk factors for early relapse and non relapse mortality (NRM), overall survival (OS) and relapse free survival (RFS) according to postremission treatment and describe causes of and risk factors for treatment failure.

Methods: Data on 304 patients in CR1 treated with curative intent between 2007 and 2016 in four centers participating in Czech Leukemia Study Group for Life were analyzed. All patients signed informed consent with data collection, analysis and publication. Cox regression was used to determine risk factors for OS and RFS, using time dependent covariates for postremission therapy. Age, WBC count, number of induction cycles, NPM1 mutation, FLT3/ITD, performance status, BMI, previous malignancy and extramedullary disease were included in models. Postremission therapy was completed after HCT or after three cycles of HIDAC without HCT in patients ≤60 years or two cycles of intermediate dose cytarabine (IDAC) in patients>60 years. Competing risk cumulative incidence estimates were calculated for NRM and relapse. Early relapse and NRM were defined as relapse/NRM before completion of postremission therapy.

Results: Median age was 52(18-74) years. Median follow up time was 481(31-3384) days. Early relapse rate (RR) and NRM were 11.0% and 5.29%, respectively. Median OS after early relapse was only 128 days. Presence of FLT3/ITD mutation and high body mass index were associated with increased risk of early relapse on univariate analysis (HR 14.88, 95%CI 3.24-68.43 and 2.34, 95%CI 1.3-4.2, respectively). Age increased risk of early NRM (HR 5.13, 95%CI 1.5-17.58 for age 55-35 years). 76% of patients completed therapy: 42% received allogeneic HCT in CR1, 21% completed three cycles of HIDAC and 13% completed two cycles of IDAC. 3-year OS and RFS of the whole cohort were 53.68% and 40.26%, respectively. OS was 67% in a group of patients who completed HCT, 34% in IDAC group and 64% in HCT group (p=0.28469). Cumulative incidence of NRM and RR 3 years after completion of therapy were 23% and 20% after HCT, 7.13% and 51% after HIDAC and 16.8% and 66.4% after IDAC, respectively, differences among groups were significant (p=0.001947 and p<0.00001). HCT reduced the risk of relapse in comparison to chemotherapy (HR 0.51, 95%CI 0.3-0.85). RFS was adversely influenced by concomitant FLT3 ITD/NPM1 mutation (HR 2.17, 95%CI 1.06-4.45). Increasing age had negative effect on OS (HR 1.65, 95%CI 1.13-2.42 for age 55:35 years). After HCT, HLA mismatch and TBI based myeloablative conditioning were associated with increased NRM (HR 6.32 (95%CI 1.89-21.14) and 6 (95%CI 1.86-19.2), respectively) in comparison to transplantation from HLA matched donors and busulphan based myeloablative conditioning.

Summary/Conclusions: The majority of patients within intermediate cytogenetic group in our analysis received allogeneic HCT. Patients who relapsed before completion of treatment had dismal outcome with very short OS. Allogeneic HCT decreased risk of relapse but led to increased NRM, reducing positive effect of HCT on OS. Risk of NRM was increased after TBI based myeloablative conditioning and after HCT in mismatched unrelated donors.

LONG TERM FOLLOW UP OF PATIENTS OVER 60 YEARS TREATED WITH INTENSIVE CHEMOTHERAPY FOR ACUTE MYELOID LEUKEMIA AND MYELODYSPLASTIC SYNDROMES…

Background: More and more data on patients over the age of 60 years treated with intensive chemotherapy are emerging, however, long term data with patient outcomes after therapy and follow up 2-5 years are lacking. In 2007, we published a single center study on patients over the age of 60 years, suffering from acute myeloid leukemia (AML) or high risk myelodysplastic syndrome (MDS), treated with intensive chemotherapy (Knipp et al. Cancer 2007, 110:345-52). We now present long term follow up data of these patients, the first patient being treated in 1991, meaning 25 years after publication of the initial study.

Aims: To characterize the longterm outcome of elderly AML and high risk MDS patients treated with intensive chemotherapy after the usual 2-5 year follow up period.

Methods: We treated 160 patients aged 60 years or more suffering from high risk MDS and AML with intensive chemotherapy regimen between 1991 and 2004. None of the patients underwent allogeneic stem cell transplantation afterwards. We now performed a follow up of the surviving patients 10 years after publication of the initial study.

Results: In the initial study median survival from the start of induction therapy was 9.5 months (10 days to 157 months), with the median survival from diagnosis of 14 months (1 day to 157 months). At publication of the study in the year 2007, 20 patients were still alive, 18 of them presented with a low risk karyotype. 13 of these patients were in complete remission and 7 patients had relapsed. Since then 11 of the 13 patients who were in CR relapsed and died of their leukemia. One patient died of other causes and only one patient is still alive and well, currently at the age of 84. This patient initially presented with a normal karyotype, too. As a result the rate of long term survivors 5 years after treatment is 5.6% only.

Summary/Conclusions: Long term follow up data of elderly patients treated for AML and MDS with intensive chemotherapy is scarce. Our data show, that induction chemotherapy not followed by allogeneic stem cell transplantation does not result in a meaningful improvement of outcome. In addition, morbidity and lack of quality of life has to be taken into account. More data and studies on this subject are urgently needed in an aging population. In our population of 160 treated patients, 158 died of their leukemia, only one patient died of another cause and only one single patient is still alive and well over a decade later.

FLAG-IDA FOR RELAPSED/REFRACTORY ACUTE MYELOID LEUKAEMA: A SINGLE CENTRE 5-YEAR STUDY

C. Agbuduwe1, C. Follwos1, J. Craig1, B. Utenthal1, C. Crawley1, P. Krishnamurthy1
1Haematology, Cambridge University Hospitals NHS Trust, Cambridge, United Kingdom

Background: The treatment of relapsed/refractory Acute Myeloid Leukaemia (AML) remains a formidable challenge as the therapeutic options are limited. The regimen most commonly used in this setting, FLAG-ida (Fludarabine, cytarabine, G-CSF and idarubicin) is considered more toxic than standard Daunorubicin plus Cytarabine (DA) regimen, often associated with prolonged periods of bone marrow suppression and predisposition to severe infections.

Aims: In this study, we present a single tertiary centre experience in the use of this regimen with a view to identifying predictive factors for survival following FLAG-ida chemotherapy. The secondary aim of this project was to assess the efficacy and safety profile of the routine clinical setting.

Methods: We conducted a retrospective chart review of patients treated with FLAG-ida chemotherapy regimen for relapsed or refractory acute myeloid leukaemia (including secondary AML) between 2011 and 2016 in a large tertiary hospital. Patients treated with FLAG-ida as first line therapy were excluded.

Results: Fifty-four patients met the criteria for inclusion in this study. The median age of the patients was 53 (10-69) years. Eighteen percent (18%) received FLAG-ida for primary refractory AML while the remainder were treated having relapsed after at least 1 previous regimen. The median time to relapse was 15 months. Complete remission was achieved in 70% of patients and 81% of these patients proceeded to have an allogeneic stem cell transplant. The median overall survival following FLAG-ida chemotherapy was 16 months with 1-year and 2-year survival rates of 59% and 46% respectively. Approximately 6% therapy-related mortality was observed. The median overall survival in patients with early relapse (<12 months) was significantly shorter than those with late relapse (>12 months): 6 months and 20 months respectively (log-rank test p value: 0.04) (Figure 1). Complete remission rates were similar between relapsed and primary refractory AML patients.

Figure 1.

Summary/Conclusions: FLAG-ida is an effective salvage regimen in patients with refractory or relapsed AML allowing the achievement of complete remission in the majority of cases. In this single-centre cohort, early relapse, within 12 months, from first line therapy was associated with an inferior survival following salvage therapy with FLAG-ida.

E939

A MULTICENTER, RETROSPECTIVE ANALYSIS OF ELDERLY PATIENTS WITH ACUTE MYELOID LEUKEMIA WHO WERE TREATED WITH DECITABINE

1Hematology-Oncology, Chung-Ang university Hospital, 2Hematology-Oncology, Samsung Medical Center, Sungkyunkwan University School of Medicine, 3Hematology-Oncology, Kangnam Sacred-Heart Hospital, Hallym University Medical Center, Seoul, 4Hematology-Oncology, Hanyang University Gumi Hospital, Gumi, 5Hematology-Oncology, University College of Medicine, Cheonan, 6Hematology-Oncology, Hallym University Medical Center, Hallym University College of Medicine, Anyang, 7Hematology-Oncology, Hanyang University College of Medicine, 8Hematology-Oncology, VHS Medical Center, Seoul, Korea, Republic Of

Background: While acute myeloid leukemia (AML) is the disease of the elderly, treatment options has been limited for elderly patients. Decitabine is widely accepted as the treatment options for them. However, the efficacy has yet been evaluated in Asian population where difference of clinical manifestation or cytogentic had been noted.

Aims: In the current study, we conducted a multicenter, retrospective analysis on elderly AML patients from 8 tertiary institutes in Korea who were treated with decitabine in order to confirm whether the clinical outcomes of this agent are also acceptable in this population, and to provide further understanding of the disease nature of AML arisen in elderly patients.

Methods: Patients diagnosed with AML from 2013 to 2016 were included in the analysis. The inclusion criteria were as follows: (1) 65 or older patients with newly diagnosed, histologically confirmed AML (myeloid blast ≥20% either in the bone marrow or peripheral blood); (2) Treated with decitabine in a schedule of 20mg/m2 for five days every 4 weeks in patients. The primary end-point of the study was OS. We compared our data to the data from another Korean retrospective analysis, in which elderly patients with AML were treated with decitabine in order to confirm whether the clinical outcomes of this agent are also acceptable in this population, and to provide further understanding of the disease nature of AML arisen in elderly patients.

Results: A total of 80 patients were eligible for the analysis. The median age of patients was 74 years (range, 64 to 86 years) and 49 patients (61.3%) were male. Regarding the risk group, 6 (7.5%), 49 (61.2%), and 25 (31.3%) cases were classified as favorable, intermediate, and poor risk group, respectively. The patients had received median 3 (range 1-27) cycles of treatment and the median OS for all patients was 10.2 months. The median OS durations according to the cytogenic risk group are as follows: 12.4 months (95% CI 11.4-13.4) for favorable risk group (N=6), 13.6 months (95% CI 8.7-18.5) for intermediate risk group (N=49), and 5.5 months (95% CI 1.4-9.6) for poor risk group (N=25) (p<0.01). And when we categorized our cohort into two groups, that is, ECOG-PS 0-2 vs. ECOG-PS 3 & 4, those with good performance status demonstrated improved survival (11.5 months (95% CI 6.6-16.4) vs 4.4 months (95% CI 2.4-6.4), p=0.04). The OS curves according to prognostic factors are provided in figure 1. Next, we compared our data to another Korean retrospective analysis dealing with elderly AML patients who were treated with either best supportive care or intensive treatment. Although in our analysis more patients with poor performance status and elderly patients, it seems that outcomes of decitabine treatment are fairly better than that of best supportive care (OS 3 months) and comparable to intensive chemotherapy (12.1 months).
E940

DRUG-DRUG INTERACTION POTENTIAL OF GILTERITINIB IN HEALTHY SUBJECTS AND PATIENTS WITH RELAPSED/REFRACTORY ACUTE MYELOID LEUKEMIA

Aims: To evaluate drug-drug interaction potential with gilteritinib in healthy subjects and patients with relapsed/refractory (R/R) AML.

Methods: The effects of CYP3A4 inhibitors (itraconazole [ITZ] and fluconazole [FLZ]), as well as a CYP3A4 inducer (rifampin [RIF]), on the gilteritinib pharmacokinetic (PK) profile were assessed in an open-label, parallel-group study conducted in 81 healthy subjects. Gilteritinib was administered as a single 10mg dose alone on Day 6, or in combination with 200mg ITZ administered twice daily on Day 1 and once daily on Days 2–28, or in combination with once daily 400mg FLZ on Day 1 and 200mg FLZ on Days 2–28. When given concomitantly with ITZ or FLZ, gilteritinib was administered on Day 6. In an additional cohort, RIF 600mg was administered on Days 1–21 and gilteritinib was administered as a single 20-mg dose on Day 8. Additionally, the potential inhibitory effects of gilteritinib on the PK profile of a CYP3A4 substrate (midazolam) were assessed in a cohort of patients with R/R AML (n=9) in the Phase 1/2 CHRYSLIS study (NCT02014458). Patients received oral gilteritinib (300mg/d) and single oral midazolam (2mg) doses. Gilteritinib was administered on Cycle 1 Day 1 and continued once daily in 28-day cycles; midazolam was administered on Day-1 and Cycle 1 Day 15. Furthermore, in patients with R/R AML, gilteritinib trough concentration data for patients on strong (eg, voriconazole or posaconazole) or moderate (eg, ITZ or FLZ) CYP3A inhibitors were compared with those for patients not using CYP3A4 inhibitors.

Results: In healthy subjects, gilteritinib exposure (expressed as C_max and AUC24) was higher (2.2-fold increase) in subjects who were coadministered gilteritinib with a strong CYP3A4 inhibitor (ITZ) than in subjects who were administered gilteritinib alone. Coadministration of gilteritinib with RIF, a strong CYP3A4 inducer, resulted in an approximate 70% decrease in gilteritinib exposure in healthy adult subjects (Figure 1). In patients with R/R AML, midazolam exposure was approximately 10% higher when administered with gilteritinib compared to midazolam alone as reflected by the geometric mean ratio and 90% confidence intervals of midazolam C_max (111.64%; 69.54%–179.25%) and AUC24 (109.46%; 49.82%–240.48%). Additionally, a 2-fold increase in gilteritinib exposure was observed in patients who were taking concomitant medications that were moderate or strong CYP3A4 inhibitors relative to patients who did not use a CYP3A4 inhibitor. The increased exposure in these patients, however, did not translate to differences in the incidence of drug-related safety events when compared across groups.

Summary/Conclusions: These data suggest limiting concomitant use of strong CYP3A4 inducers, such as rifampin, with gilteritinib. Furthermore, these data suggest coadministration of CYP3A substrates with gilteritinib is unrestricted. A comprehensive review of safety data in patients with R/R AML did not suggest that dose adjustment is warranted when gilteritinib is coadministered with strong CYP3A4 inhibitors. Although concomitant use of gilteritinib with strong CYP3A inhibitors (eg, ITZ or FLZ) may be permissible, precaution is warranted.

E941

A FLUDARABINE-BASED ACUTE MYELOID LEUKEMIA INDUCTION IS WELL TOLERATED UP TO 75Y OF AGE ALLOWS EARLY CONSOLIDATION AND LONG TERM SURVIVAL. A SINGLE CENTRE EXPERIENCE OF 136 CONSECUTIVE PATIENTS

Aims: We report a single center, real life experience of unselected 136 consecutive AML patients treated since 2002 in our center with Fludarabine, Aracytin, Idarubicin and or Etoposide: FLAIE up to 65ys or FLAI up to 75ys.

Methods: Patients were treated with the FLAIE or FLAI regimen followed by Idarubicin plus Aracytin as 2 step induction. Exclusion criteria for treatment were: acute promyelocytic leukemia, poor performance status and severe comorbidity. Post remission treatment included up to three cycles of high dose AraCy, autologous (Auto) or allogeneic (Allo) stem cell transplantation according to cytogenetic and molecular risk stratification (CMR, Döhner Blood 2010 PMID 19880497) aiming for a curative strategy for all our AML patients.

Results: Median age at diagnosis was 55ys (18-75ys), median follow up was 18 months (range 3-172 months), 75% of patients (102/136) had de novo AML with strong (34/136) had strong, mostly from myelodisplastic syndrome, 19% of patients (26/136) had good CMR risk disease, 45% of patients (61/136) had intermediate risk and 36% of patients (50/136) had high risk disease. Complete remission (CR) rate was 68% and was comparable to the majority of pub-
lished trial data, considering the proportion of high CMR risk (36%) and leukemia of secondary origin (25%) and the relatively high median age: 36% of patients (49/136) were above the 60s old age limit of most AML protocols. In multivariate analysis CR rate was significantly affected by age below 50ys: p=0.011; good/intermediate CMR risk: p=0.011 and de novo AML: p=0.008. The induction death rate was 4% in line or slightly lower than published results, showing that this therapeutic strategy was well tolerated to low SOX4 expression. The median overall survival was 9 months and factors significantly affecting OS were age below 50ys p<0.001; de novo AML p=0.003; good/intermediate CMR risk p<0.002; intensive consolidation with Allo or Auto transplant p<0.001 compared to chemotherapy alone. The mean probability of Leukemia free survival (LFS) was 88 months (median not reached). Patients above 50ys had a worse survival than patients younger than 50. The median OS and LFS rates were 16.4 and 23.4 months respectively, this compares favorably with many published results. Chen Medicine 2016 PMID: 27472687 reported a median OS of 10.3 months in a large cohort of patients of similar age treated with intensive induction. Moreover we did not found a significant difference between the 50-59ys and 60-75ys age groups: median OS was 20.8 and 14 months (p=0.12) and median LFS was 15.9 and 23.6 months (p=0.71) respectively. Summary/Conclusions: In our real life experience the FLAIE/FLAI regimen combined with intensive consolidation demonstrated good long term results both in terms of OS and LFS in patients younger than 50ys, this regimen was also well tolerated to the patients with low SOX4 expression, because the low OS and LFS efficacy may be related to the high toxicity of intensive induction regimens and the nature of poor risk prognostic factors.

E942  
OVEREXPRESSION OF SOX4 CORRELATES WITH POOR PROGNOSIS OF ACUTE MYELOID LEUKEMIA  
C.-Y. Hu1, H.-A. Hou2, C.-Y. Chen2, H.-F. Tien2, L.-L. Lin1  
1Clinical Laboratory Sciences And Medical Biotechnology, National Taiwan University, 2Department of Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan, Republic of China  
Background: The SOX4 belongs to the SOX (Sry-related high-mobility group box) family and has been characterized as a transcription factor. Over the past decade, multiple functions of SOX4 have been unveiled, and the protein is now known to play important roles in embryonic development, cell fate decision, and cellular differentiation. Overexpression and amplification of SOX4 have been implicated in various cancers and are correlated with poor prognosis. In mouse models, previous studies demonstrated that the upregulation of SOX4 can be induced by and then cooperate with the aberrant expression of AML1-ETO, NUP98-DDX10, and PML-RARα; the overexpression of HOXA9, CREB, and Evi1, and the haplosufficiency of PU.1 to trigger leukemogenesis. Furthermore, a previous study that employed retroviral transduction of SOX4 and bone marrow transplantation techniques revealed that increased SOX4 expression may cooperate with the deregulation of Mef2c expression to induce myeloid leukemia in recipient mice. Sox4 gene was also reported to be a direct target of C/EBPα. C/EBPα is known to inhibit the self-renewal of leukemic cells and to restore cellular differentiation. The overexpression of SOX4 that results from C/EBPα inactivation contributes to the development of a type of leukemia that is characterized by a distinct leukemia-initiating cell (LIC) phenotype. This work further indicated that Sox4 is a key oncogenic target and critical mediator of C/EBPα mutants in acute myeloid leukemia (AML), which suggests a potential novel therapeutic approach to the treatment of this disease. However, the clinical implications of SOX4 expression and its role of AML leukemogenesis are not well understood.  
Aims: To evaluate the relationship between bone marrow (BM) SOX4 expression and clinicopathological parameters of de novo AML and to evaluate the prognostic value of SOX4 expression for AML patients.  
Methods: From Mar 2009 to Dec 2011, a total number of 112 adult AML patients were enrolled in this study. This study was approved by the Institutional Review Board (IRB) of the National Taiwan University Hospital (NTUH) and written informed consent was obtained from all participants in accordance with the Declaration of Helsinki. Immunocytochemical staining was used to assess SOX4 expression in bone marrow leukemic cells. All statistical analyses performed for this study involved two-tailed Student’s t tests, Mann-Whitney U test, and Chi-square test and the software used for multivariate analysis with Cox proportional hazards regression models. Kaplan-Meier estimation techniques were used to plot survival curves and log-rank tests.  
Results: We divided AML patients into two groups according to the intensity and extent of SOX4 expression as follows: low expression group (score 0-2, n=33) and high expression group (score 3, n=50), respectively. The variance of clinical manifestations of AML did not show significant differences in terms of SOX4 expression. However, AML patients with low SOX4 expression tended to have favorable-risk cytogenetic (P=0.0866). We did not observe significant differences between the high and low expression groups in terms of age, gender, hemograms, NPM1 mutation and FLT3/ITD. Additionally, of the 112 AML patients that underwent conventional intensive induction chemotherapy, 85 (75.9%) achieved complete remission (CR), and the high and low expression groups showed similar probabilities of achieving first CR (36/50, 72% vs 49/62, 79%, P=0.3219). However, high SOX4 expression were associated with increased risk of relapse compared to low SOX4 expression (19/36, 52% vs 13/49, 26.5%, P=0.028). Furthermore, with a median follow-up period of 46.7 months (range: 0.7 to 79.0 months), SOX4 expression was associated with overall survival (OS) and disease-free survival (DFS) in all patients with de novo AML (P=0.006 and P=0.013, respectively), patients with non-M3 subtypes (P<0.001 and P=0.001, respectively), patients with intermediate-risk cytogenetics, (P=0.001 and P=0.005 respectively), or even in those with normal karyotype profile (P=0.022 and P=0.111, respectively). In multivariate analysis, high SOX4 expression was found to be an independent poor prognostic factor of OS (HR 1.924, 95% CI 1.020-3.628, P=0.043) irrespective of age, WBC count or FLT3/ITD status. For the 62 patients that we conducted using an on-line data cohort retrieved from PrognoScan (a database for meta-analysis of the prognostic value of genes; http://www.abren.net/ PrognoScan) revealed similar findings.

Summary/Conclusions: In the current study, we found that AML patients with low BM SOX4 expression had higher remission rates and longer overall survival than those with high SOX4 expression, regardless of age, WBC count at diagnosis, karyotype profile and NPM1/FLT3-ITD status. Our results also reveal that SOX4 is an independent prognostic factor of AML. In conclusion, we reveal that BM SOX4 expression could serve as an informative new biomarker for the clinical prognosis of AML patients.

AN OPEN-LABEL, MULTICENTER, PROSPECTIVE, RANDOMIZED STUDY OF RECOMBINANT HUMAN THROMBOPOIETIN AS AN ADJUNCT AFTER INTENSIVE CONSOLIDATION CHEMOTHERAPY IN ACUTE MYELOID LEUKEMIA  
X.-H. Sul1, Y. Ll1, X. Wang2  
1Hematology department of Shandong provincial hospital affiliated to Shandong University, 2Hematology department of Shandong provincial hospital affiliated to Shandong University, Shandong University school of medicine, Jinan, China  
Background: Thrombocytopenia is a common problem in the management of patients with acute myeloid leukemia (AML) receiving induction and consolidation therapy. AML patients with platelet count of less than 20×109/L might have a high risk of bleeding complications and had to take dose modifications instead of intensive chemotherapy leading to increased disease-free survival and overall survival. Platelet transfusions have a short therapeutic effect and are associated with all types of transfusion reactions. Recombinant human thrombopoietin (rhTPO) has been shown to improve the megakaryocyte and platelet development in solid tumor patients and immune thrombocytopenia (ITP) patients refractory to the conventional corticosteroids. We conducted this study to determine the availability of rhTPO in the platelet recovery after intensive consolidation chemotherapy with AML patients.  
Aims: The aims of this study were to identify the effectiveness and safety of rhTPO in supportive care in patients with AML receiving consolidation chemotherapy.  
Methods: Patients: Patients were eligible if they were 15-70 years of age who achieved complete remission after one course of IA induction therapy, and had platelet counts of less than 50×109/L after induction therapy, with an Eastern Cooperative Oncology Group (ECOG) performance status of 0-3. Patients with AML M3 (acute promyelocytic leukemia) and AML M7 (acute myelomonocytic leukemia) were excluded from the study. All patients provided written informed consent according to protocol guidelines approved by the institutional review boards at their individual institutions. Study design: Patients received consolidation chemotherapy with DA, MA and intermediate-dose arabinosylcytosine (ARA-C), et al. When the platelet count was less than or equal to 50×109/L, patients in study group received 15000U/day of rhTPO (trade name: TIPOA) administration subcutaneously and patients in control group did not receive rhTPO therapy. The administration of rhTPO continued until the platelet count was more than 100×109/L or for the maximum of 21 days. Stanford University Baseline characteristics: There were no significant differences between samples test and chi-square test. Other statistical data analyses were performed using the two-tailed Student’s t test and were represented as means±SD of values. All differences were considered to be statistically significant when the P value was less than 0.05.  
Results: rhTPO did not result in hematologic effect was observed in the main characteristics between study group (n=49) and control group (n=36), including age, gender and other baseline characteristics. No patient withdrew. Platelet transfusion and time required for platelet recovery were shown in Table 1. Platelet transfusions: The mean number and days of platelet transfusions for the patients in the study group were significantly lower than those in the control group. There were no significant differences of statistic status between the patients. Platelet recovery: 1. rhTPO might reduce the duration of platelet count less than or equal to 20×109/L and 30×109/L after chemotherapy. 2. rhTPO could increase the maxim
mal and minimal platelet count after chemotherapy. 3. rhTPO might shorten the days of platelet count recover to at least 20×10^9/l from its nadir. The incidence of side effects were similar in both groups of the study.

Summary/Conclusions: rhTPO, administered as dose of 1500u/day when platelet count less than or equal to 50×10^9/l, might improve the recovery of thrombocytopenia of patients with acute myeloid leukemia in CR after consolidation chemotherapy. While there was no significant difference between study group and control group, there was a decreasing trend of platelet transusion number and shorter time required for platelet transfusion for patients in study group.

TREATMENT-ASSOCIATED SURVIVAL RATES IN OLDER PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML): A SYSTEMATIC LITERATURE REVIEW

J. Bell1, A. Galaznik2, R. Huelin3, M. Stokes4, D. Faller5, R. Fram6
1Global Outcomes Research, 2Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, 3Meta Research, Evidera Inc., Waltham, United States, 4Retrospective Observational Studies, Evidera Inc., Dorval, Quebec, Canada, 5Oncoology Clinical Research, 6Takeda Oncology, Cambridge, United States

Background: AML patients ≥60 years old are more likely to experience complications following intensive induction chemotherapy and are at higher risk of unfavorable outcomes compared with younger patients. Information regarding optimal treatment approaches for older AML patients is limited.

Aims: Summarize outcomes associated with therapies among older AML patients, with a focus on treatment patterns and overall survival (OS) as reported in the literature.

Methods: Searches were conducted in Medline and Embase (Jan 2014–May 2016) and supplemented by conference abstracts (2015–2016). Eligibility included studies in English reporting on treatment regimens and outcomes associated with older AML patients or subgroups thereof, and conducted in the US, EU 5 (United Kingdom, Germany, France, Spain, Italy), or Japan. Only studies enrolling ≥50 patients were included.

Results: Twelve studies (in 19 publications) reporting on OS among older AML patients were included. Participants in most studies were newly diagnosed with AML; ages ranged from 60 to 93 years. Five non-comparative studies examining the effects of various treatment modalities were identified. Median OS in studies examining azacitidine (AZA) ranged from 10 to 12 months, whereas in studies examining induction chemotherapy or reduced intensity conditioning-hematopoietic stem cell transplantation, the median OS ranged from 6.85 months (95% CI: 3.7–13.5) to 16.4 months (95% CI: 12.6–24.6), respectively. Six comparative observational studies assessed the efficacy of different treatment regimens. Intensive chemotherapy (IC) was generally associated with longer median OS compared to other regimens. In one study, median OS for patients receiving IC, lower-intensity therapy (low dose cytarabine [LD-AraC]- (AZA, decitabine), or best supportive care (BSC) was 12.4 months (95% CI: 8.5–17.4), 11.5 months (95% CI: 9.2–13.9), and 2.6 months (95% CI: 1.9–3.1), with 3-year OS rates at 27%, 17% and 6% (p<0.0001), respectively. Another study assessed the efficacy of LD-AraC relative to IC, hypomethylating agents (HMA), and BSC. Patients appeared to have longer OS when receiving IC compared to LD-AraC (median OS: 12.4 vs 9.6 months; 3-year OS: 27% vs 12%; p=0.07), and those receiving LD-AraC compared to BSC had significantly improved OS (median: 9.6 vs 3.4 months; p<0.001). In this same study, while OS was longer with HMA than LD-AraC, this difference was not significant (median OS 16.1 vs 9.6 months; 3-year OS 22% vs 12%, respectively; p=0.1). Two studies assessed the efficacy of AZA vs moderate-IC, LD-AraC, or palliative therapy, alone or in combination. AZA had a significantly better survival rate vs LD-AraC in poor prognosis patients (p=0.015). Furthermore, 1-year survival was higher for AZA-treated patients (67.8%) compared to those not treated with AZA (36.9%) (p=0.004). The efficacy of AZA relative to other conventional care regimens (CCRs) including BSC, LD-AraC, or standard IC was also examined in a randomized clinical trial (n=488). Median OS at 1-year was significantly higher for AZA relative to CCR (10.4 vs 6.5 months). Results also showed that 1-year median OS was higher with AZA than CCR in all cytogenetic risk groups, normal risk (14.1 vs 10.0), intermediate risk (13.0 vs 10.1), and high risk (6.4 vs 3.2), respectively.

Table 1.

| Summary/Conclusions: | E945 SYSTEMATIC REVIEW OF HEALTH STATE UTILITY VALUES FOR ECONOMIC EVALUATION OF ACUTE MYELOID LEUKEMIA A. Foryythe1, V. Bal 2, M. Dolph 3, S. Patel 4, G. Tremblay5 1Purple Squirrel Economics, New York, 2Novartis Pharma, East Hanover, United States, 3Purple Squirrel Economics, Montreal, Canada, 4Novartis Pharmaceuticals UK Limited, Surrey, United Kingdom, 5Purple Squirrel Economics, Quebec city, Canada  

Background: Cost-utility analyses undertaken to inform decision making regarding acute myeloid leukemia (AML) require a set of health state utility values (HSUVs) so that the time AML patients spend in different health states can be aggregated into quality-adjusted life-years (QALY). 

Aims: This study reviews AML-related HSUVs that could be used in economic evaluation and assesses their advantages and disadvantages with respect to valuation methods used and AML clinical pathways.

Methods: Embase, MEDLINE, Cochrane database, and conference abstracts (ASCO, ESMO and ASH) were systematically searched from Jan 2000 through Nov 2016 for relevant studies that reported quality of life (QOL) and HSUV in AML. Identified relevant EORTC Quality of Life Core Questionnaire QLQ-C30 values were mapped to HUV using previously published algorithm by Crott et al. 2010, HSUV for induction, consolidation, cryoablation (CR), relapse, stem cell therapy (SCT) treatment, SCT recovery and CR post SCT were identified.

Results: Ten relevant studies were identified. Six were cost effectiveness analyses utilizing HSUVs for calculation of Quality Adjusted Life years (QALY), one effectiveness analysis (incremental QALY). Two OOL studies reporting specific AML utilities (either collected or mapped from QLQ-C30). An additional study reported QOL for patients undergoing SCT. Since no study reported HSUV for relapse, values from study of secondary AML patients who failed prior treatment for Myelodysplastic Syndrome, were used. Where multiple HSUVs were available, prioritized clinical trial (n=488). Median OS at 1-year was significantly higher for AZA relative to CCR (10.4 vs 6.5 months). Results also showed that 1-year median OS was higher with AZA than CCR in all cytogenetic risk groups, normal risk (14.1 vs 10.0), intermediate risk (13.0 vs 10.1), and high risk (6.4 vs 3.2), respectively.

Summary/Conclusions: Among older AML patients, IC tended to be associated with improved OS compared with other CCRs. However, evidence from this review indicates that AZA could be an alternative treatment option for older AML patients, whether fit or unfit for IC.
Summary/Conclusions: This interim analysis of the use of decitabine in real life showed a superimposable OS to controlled international clinical trials. Safety profile was acceptable considering setting of pts and incidence of important comorbidities. Despite a similar OS, the comparison between our data and Cashen study (56 vs 55 pts) showed in our cohort, a poorer rate of CR+CRi+CRu, probably due to different impact of the second generation hypomethylating agent therapy. WBC >10000/µL as well as high cytogenetic risk. This apparent contradiction supports the idea that in elderly pts recovery of peripheral blood cells counts (PR+hematological improvement) is probably the most important factor influencing OS (Ferrara, Hemat 2016).

1Hematology Unit, University of Siena, Siena, 2Unit of Oncoematologia con autotrasfusione, Azienda Ospedaliera S.Maria, Terrin, 3Unit of Hematology, USL6, Livorno, 4Hematology Unit and Bone Marrow Transplant Unit Ospedale Cardi-nale G. Panico, Tricase, 5Unit of Hematology, USL11, Empoli, 6Unit of Hematol-ogy, Azienda Ospedaliera Careggi, Firenze, 7Unit of Hematology, AUSL della Romagna, Ravenna, 8Hematology Unit, Ospedale Mazzone, Ascoli Piceno, 9Hematology Unit, Ospedale Infermi, AUSL Romagna, Rimini, 10Hematology Unit, University of Pisa, Pisa, Italy

Background: Acute Myeloid Leukemia (AML) has a higher incidence among the elderly population. Older patients (pts) with AML have a worse prognosis and limited treatment options. Hypomethylating agent decitabine was recently approved by FDA and EMEA as first line treatment in AML pts older than 65 yrs and unfit to receive standard cytotoxic chemotherapy. Decitabine showed to be superior to supportive care or low dose cytarabine in controlled randomized clinical studies (Kantarjian, JCO 2012; Cashen, JCO 2010).

Aims: In July 2016 we approved a retrospective and prospective multicentric observational study to investigate efficacy and tolerability of decitabine at the approved schedule of 20mg/m² daily for 5 days of a 4-week cycle in real life (DEA65 study). The primary objective was the assessment of overall survival (OS). Secondary objectives were evaluation of adverse events (AEs) and response rate: complete remission (CR), CR with incomplete platelets or white cells (WBCs) count recovery (CRi), partial remission (PR) and hematological improvement with transfusion independence. We here present an interim analysis of the first 56 pts enrolled.

Methods: AML pts older than 65 yrs treated in first line with decitabine were enrolled in the study. At diagnosis and during follow-up, cytogenetic and molecular assessment was performed by each center according to local guidelines for AML management in elderly pts.

Results: Biologic and clinical data of 56 pts, with a median age of 73 yrs (range 65-90 yrs) are reported. Thirty-one patients (55.3%) had a secondary AML and 13/31 (42%) were progressed MDS previously treated with 5-azacitidine. Median WBCs count was 3050/µL (range 770-131500/µL) with 13/36 (23%) pts with WBCs>10000/µL. Cytogenetic analysis was performed in 52/56 pts, and in 24/43 (43%) molecular analysis including FLT3 and NPM1 mutations was performed. According to prognostic stratification, 50% of pts had a high risk, 34% an intermediate risk, 9% a low risk AML and in 4/56 (7%) pts risk was unknown. Median OS was 9,5 months (range 4-19) and 4 months (range 1-15) in responder vs non responder pts. Table 1 shows response rate according to pts characteristics. At present time 18/22 alive pts are still on treatment with decitabine. Regarding toxicity, 23/36 (41%) pts manifested a grade ≥3 AEs although severe comorbidities (cardiovascular and metabolic) pre-existed in 14/23 (60,9%). A total of 35 hospitalization episodes due to toxicity were recorded and 10/56 pts (17,8%) died due to serious AEs. Overall the most common non-hematologic AEs were pneumonia and fever.

Table 1.

Summary/Conclusions: This interim analysis of the use of decitabine in real life showed a superimposable OS to controlled international clinical trials. Safety profile was acceptable considering setting of pts and incidence of important comorbidities. Despite a similar OS, the comparison between our data and Cashen study (56 vs 55 pts) showed in our cohort, a poorer rate of CR+CRi+CRu, probably due to different impact of the second generation hypomethylating agent therapy. WBC >10000/µL as well as high cytogenetic risk. This apparent contradiction supports the idea that in elderly pts recovery of peripheral blood cells counts (PR+hematological improvement) is probably the most important factor influencing OS (Ferrara, Hemat 2016).

ASPARAGINASE ERWINIA CHRYSAENTHEMI EFFECTIVELY DEPLETES PLASMA GLUTAMINE, HAS CLINICAL ACTIVITY, AND IS WELL TOLERATED IN ADULT PATIENTS WITH RELAPSED OR REFRACTORY ACUTE MYELOID LEUKEMIA
A. Edami1,2,3, E.T. Stroyle1, R.G. Lapidus1,2, L.J. Feng2,4,5, M. Lee1, M.G. Blitzer4, B.A. Carter-Cooper1, D. Sewell1,2, I. Van Der Merwe1, M. Imran1, S.L. Yu1, H. Li1, P.C. Amrein6, V.H. Duong1,2, E.A. Saussville1,2, A.T. Fathi6, Z. Singh6, M.R. Baer1, S.M. Bentzen1,7
1University of Maryland Greenebaum Comprehensive Cancer Center, 2Medi-cine, 3Pharmacology, 4Pediatrics, 5Pathology, University of Maryland, Balti-more, 6Massachusetts General Hospital Harvard Medical School, Boston, 7Epi-demiology and Public Health, University of Maryland, Baltimore, United States

Background: Asparaginase-induced glutamine (Gln) depletion demonstrates anti-leukemic activity in preclinical studies of AML. We hypothesized that adminis-tration of asparaginase Erwinia chrysanthemi (Erwinaze) would lead to effective plasma Gln reduction and may be a feasible therapeutic approach for AML, because myeloblasts may be addicted to Gln.

Aims: The primary aim was to determine the dose of Erwinaze inducing plasma Gln levels ≤120μmol/L, with an acceptable safety profile, 48 hours (h) after the first intravenous (IV) dose and before each subsequent dose administered thrice weekly for 2 weeks in patients (pts) with relapsed or refractory (RR) AML.

Methods: This was a phase 1, single-arm, pharmacokinetic investigator-initi-ated trial (NCT02283190, funded by Jazz Pharmaceuticals), with a 3+3 design with dose de-escalation/escalation rules that incorporate both safety and biochemical activity (nadir plasma Gln levels) of Erwinaze. There was no intrapatient dose adjustment. For safety, a 3rd cohort of three pts was to be added if 2 of 6 pts in the 1st and 2nd cohorts experience a dose limiting toxicity (DLT) at a certain dose level. If ≥3 of 9 patients experienced DLT, the trial was to be terminated. To evaluate Gln reduction ability of Erwinaze, the dose could be increased based on 48h trough plasma Gln in cohorts of 3, 6, or 9 pts per dose level. Correlational studies measured plasma Gln, glutamate (Glu) and asparagine (Asn) levels, plasma asparaginase activity and plasma and urine 2-hydroxylglutarate (2-HG) levels.

Results: Five pts were enrolled on study. Enrollment was then halted due to Erwinaze supply manufacturing complexities. Median age was 69 (range 20- 83) years, 4 were male, 2 had prior MDS or CMLM, 3 had high risk abnormal karyotype, 3 had isocitrate dehydrogenase (2 IDH1, 1 IDH2) mutations, and 3 had been treated with ≥2 lines of prior treatment. Erwinaze was administered IV (25,000 U/m², dose level 0) for 6 doses MWF for 2 weeks to all pts. No DLT was observed. Anemia and electrolyte abnormalities were the most common adverse events. Plasma asparaginase activity 20.1 IU/mL was achieved in all pts at 48h trough, but in 3 pts it decreased to zero on day 8 (72h trough). Median trough plasma Gln, Asn and peak Glu levels (μmol/L) at 28 were 27.6 (range <12.5-227), 0 (range 0-0), and 704 (range 474-754), respectively. Asn remained undetectable for the entire 2 weeks. Gln levels increased significantly on day 8 (72h trough) compared to day 5, p<0.001. Four of 5 pts (80%, lower limit of 1-sided 95% CI: 34%) achieved at least one nadir Gln value <120 μmol/L. The fold reduction (FR) in Gln level at 3 days, relative to baseline, was 0.16 (p=0.031 for achieving partial remission (PR) and one achieved hematologic improvement (HI) after 6 doses of single agent Erwinaze. Both pts had plasma Gln levels <85 μmol/L on days 5, 10 and 12. Off study, after completion of Erwinaze, they have been treated with azacitidine. Both pts are still alive in complete remission (CR) and CR with incomplete count recovery (CRi) 13.3 and 13.4 months after the on-study date. Plasma and urine 2-HG levels did not change significantly. The 3 pts with IDH mutations tended to have higher plasma 2-HG levels (p=0.10).

Figure 1.
Summary/Conclusions: To the best of our knowledge, this is the first clinical report demonstrating that an asparaginase product is capable of not only decreasing plasma Gln level to ≤120μmol/L but also depleting it to undetectable (i.e. <12.5μmol/L) levels in pts with AML. Two of 5 patients with R/R AML had clinical responses and are alive in remission. Given clinical activity of asparaginase in AML, we are to investigate mechanistically-designed asparaginase combination therapies.

E948

PROGNOSTIC SIGNIFICANCE OF SOX2, SOX3, SOX11, SOX14 AND SOX18 GENE EXPRESSION IN DE NOVO ACUTE MYELOID LEUKEMIA (AML) PATIENTS

N. Tosić1, M. Virijević2, I. Petrović3, N. Kovacevic Grujicic3, S. Davidovic3, N. Stuljacizic Vukovic2, S. Pavlovic1, M. Stavrović2

1Laboratory for Molecular Biomedicine, Institute of Molecular Genetics and Genetic Engineering, University of Belgrade, Serbia, 2Clinic of Hematology Clinical Centre of Serbia, University of Belgrade Faculty of Medicine, 3Laboratory for Human Molecular Genetics, Institute of Molecular Genetics and Genetic Engineering, University of Belgrade, Serbia

Background: Members of the SOX (SRY-related high mobility group (HMG) box) gene family encode a group of transcriptional factors with important functions in embryonic development. Also, SOX genes are aberrantly expressed in different types of cancer. However, their role in hematological malignancies, especially in acute myeloid leukemia (AML), remains elusive.

Aims: The aim of this study was to investigate the expression level of SOX2, SOX3, SOX11, SOX14 and SOX18 genes in de novo AML patients, and to evaluate their potential as prognostic markers.

Methods: Fresh bone marrow (BM) samples were collected from 50 non-APL AML patients at diagnosis (27 male, 23 female, median age 52.5 years, range 22-73) and from 8 healthy donors. Relative quantification analysis of SOX genes expression level was performed by RQ-PCR methodology, with GAPDH gene as endogenous control, and using comparative ddCt method with healthy controls as calibrator.

Results: The median expression level of SOX2, SOX3, SOX11, SOX14 and SOX18 in AML patients was 0.46 (0.01-226.13), 0.81 (0.01-1210.00), 0.35 (0.01-177.29), 0.98 (0.02-469.51) and 3.53 (0.18-332.00), respectively. This was not significantly different from the levels detected in healthy controls where the median expression levels were 1.01 (0.32-2.54), 1.00 (0.45-5.73), 1.00 (0.19-2.83), 1.04 (0.38-2.38) and 1.00 (0.48-12.29), respectively. As a cut-off value above which the patients were considered to be positive for SOX2/3/11/14/18 gene expression we used median expression level of each SOX gene in healthy controls + 2SD. The percentage of patients who were positive for the expression of the studied genes ranged from 14% (SOX2* and SOX11*), 20% (SOX3* and SOX18*) to 28% (SOX14*). A significant association with the presence of FLT3-ITD and NPM1 mutations was detected in all but SOX14 patients. The same result was found concerning association with higher leukocyte count. There were no significant associations with any other presenting clinical parameters. As for the impact that SOX gene expression positive status had on the analyzed genes had on the prognosis and outcome of the disease, we detected higher relapse rate in SOX14* patients (p=0.045). Significantly shorter disease-free-survival (DFS) was detected among SOX2*, SOX11* and SOX18* patients (p<0.001; p=0.001; p=0.017, respectively). Although all of the SOX* patients had shorter overall survival (OS) time compared to SOX0 patients, the most prominent influence has been detected for the SOX2* patients (p=0.034).

Summary/Conclusions: This is the first study focused on examining the expression level of SOX2/3/11/14/18 in AML patients. We have found that these genes are seldom overexpressed among patients in comparison with normal BM. However, in some patients, the expression of these genes is highly increased, and associated with a negative prognostic factors such as the presence of FLT3-ITD mutations and higher leukocyte count. Also, increased expression of these genes has been clearly associated with shorter DFS and OS. This exact function of these genes in the pathogenesis of AML is not yet known, our preliminary results show that their overexpression can have prominent prognostic significance in AML patients and therefore should be the subject of further investigation.

ACUTE ANTHRACYCLINE INDUCED CARDIOTOXICITY IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

O. Pasvolsky1, O. morelli2, U. rosovski2, M. vatrul1, O. wolachi1, I. amitai1, I. vaxman1, R. ratzon1, M. yeshurun1, Z. lakshibvili1, R. kornowski1, P. raanani1

1Beilinson Hospital, Petach Tikva, Israel

Background: Chemotherapeutic agents are associated with a wide range of cardiotoxic adverse effects. Anthracyclines and related drugs are some of the most implicated agents, with a well-recognized potential for the development of cardiomyopathy and heart failure. Chronic anthracycline induced cardiotoxicity can lead to cardiomyopathy, which may develop several years after treatment. Acute and subacute anthracycline induced cardiotoxicity is considered relatively uncommon, described mostly in patients treated for solid tumors or lymphomas. While anthracycline based regimens have been used to induce remission in newly diagnosed patients with acute myeloid leukemia (AML) for more than four decades, relatively little is known about the acute cardiotoxic effect of anthracyclines in this setting. Since many of these patients were candidates for hematopoietic stem cell transplantation (HSCT), an intensive intervention usually reserved for fit patients, even transient decrease in cardiac function might render them ineligible for this intervention, or might increase their transplant related morbidity.

Aims: To study the short-term outcomes of anthracycline exposure on cardiac function in patients with AML who are candidates for allogeneic HSCT. Because current AML-induction regimens use anthracyclines (most commonly daunorubicin) at a relatively high dose between 45 and 90mg/m²/day for three consecutive days, we hypothesized that the incidence of post-induction cardiac injury in patients with AML might be high.

Methods: The medical records of 55 consecutive patients who had received induction chemotherapy and had undergone HSCT in our medical center were reviewed. Patients included in the study were those with echocardiographic data both prior to and post induction therapy. Median age at diagnosis was 59 years (range: 19-73) and 49% were males. Approximately half of the patients had de novo AML (N=29, 53%). 26 patients (47%) had either therapy related AML or AML secondary to a previous hematological disorder. Induction treatment included 7 days of cytarabine at a dose of 100mg/m²/day and 3 days of daunorubicin at a dose of 45mg/m²/day (N=2, 3.6%), 60mg/m²/day (N=34, 61.8%), or 60mg/m²/day (N=15, 27.3%).

Results: Selected patient characteristics are summarized in Table1. Post-induction echocardiogram studies demonstrated a significant cardiac deterioration in left ventricular ejection fraction (EF) (defined as 10% or more absolute decrease from baseline EF) in 25.5% of the patients (N=14). Higher doses (90mg/m²/day) of anthracyclines were associated with a stronger decrease in EF. So, the odds ratio for cardiac function deterioration (odds ratio: 4.1, 95%, confidence Interval: 1.06 to 15.7).

Patients with cardiovascular risk factors and male patients tended to develop cardiotoxicity at higher rates, whereas age, white blood cell counts at diagnosis and AML type (de novo vs. secondary) had no impact on cardiotoxicity. The decrease in cardiac function was temporary in 10.9% of the patients (N=6) with subsequent normalization of left ventricular EF in those patients.

Summary/Conclusions: The use of daunorubicin at a dose of 60mg/m²/day or less is associated with significantly lower rates of acute cardiotoxicity. Our findings should be taken into consideration when choosing the anthracycline dose, particularly in male patients with cardiovascular risk factors who are candidates for HSCT.
AN INTEGER WEIGHTED GENOMIC MUTATION SCORING (IWGMS) USING THE TRUSIGHT MYELOID SEQUENCING PANEL SHOWS HIGHER MORBIDITY AND MORTALITY IN PATIENTS WITH INTERMEDIATE RISK ACUTE MYELOID LEUKEMIA - A RETROSPECTIVE STUDY

1Internal Medicine, Houston Methodist Hospital, Weill Cornell Medical College, New York, United States
2Laboratory and Genomic Medicine, Houston Methodist Hospital, Houston, Texas, United States
3Hematology, Houston Methodist Cancer Center, 4Baylor Miraca Genetics Laboratories, Baylor College of Medicine, Houston, United States

Background: AML is currently classified by European LeukemiaNet into favorable, unfavorable, and intermediate prognosis based on cytogenetic aberrations. Although favorable and unfavorable categories have good prognostic values, the intermediate category encompasses the majority of patients and offers unclear prognosis. The development of Cancer Genome Atlas (TCGA) opens new windows for the incorporation of next generation sequencing (NGS) into cytogenetics to enhance prognostic risk stratification. However, few studies explore the combination of cytogenetics and NGS in prognostic predictions.

Aims: Here we have developed a system of Integer Weights for the Genomic Mutation Score (IWGMS) for a quantifiable stratification of the prognostic risks associated with a combination of cytogenetic aberrations and genomic mutations. Our next step is validating the scoring system through its application to data obtained from other institutions.

Methods: Patient data from Houston Methodist Hospital was queried from the Methodist Environment for Translational Enhancement and Outcomes Research (METEOR), a clinical data warehouse that integrates research databases and national registries. The diagnosis of AML was queried along with patient demographics, cytogenetics, NGS and OS. The resultant patients were divided into three categories based on their MRC cytogenetic risk groups. The intermediate cytogenetic group encompassed the majority of patients and offers unclear prognosis. We thus hypothesize the IWGMS scoring system can be utilized to divide the intermediate cytogenetic group into higher and lower mortality subgroups. In the intermediate cytogenetic group, high IWGMS score (>3) was considered significant as a poor prognostic factor. Statistical analysis was done using Chi-Square, Mann Whitney U test and multivariate logistic regression analysis. Data from other institutions will be analyzed in a similar fashion for the confirmatory portion of the project.

Results: A hundred of the 1200 AML patients met the criteria for having both cytogenetic and NGS data availability. The two-year mortality rates were 43%, 52%, and 51% respectively for the favorable, intermediate, and poor cytogenetic groups. In the intermediate cytogenetic group, high IWGMS score (>3) was associated with higher mortality when compared to low IWGMS score (80% vs 44%, p=0.045, Fig 1). A look at the gene mutation distribution in the intermediate cytogenetic risk group also showed a general correlation between known favorable gene mutations with low IWGMS scores and unfavorable ones with high IWGMS scores. We thus hypothesize the IWGMS scoring system can be utilized to divide the intermediate cytogenetic and low and higher mortality subgroups based on a combination of cytogenetic and genetic mutations. We expect similar results with data from other institutions.

Figure 1.

Summary/Conclusions: Most studies in current literature focuses on the individual contributions of cytogenetic aberrations or genetic mutations to risk stratification and treatments risk stratification and treatment response. However, prognosis varies widely in the heterogeneous, intermediate cytogenetic class, where 60% of the AML patients belong. We propose a systematic approach that integrates cytogenetic and genetic mutations in stratifying prognostic outcomes with a focus on the intermediate cytogenetics group. The ability to differentiate in this specific group opens great potentials for targeted therapies and improving outcomes.

SUCCESSFUL IDENTIFICATION OF SPECIFIC AMINO ACID-DEPENDENCE IN ADULT T-CELL LEUKEMIA / LYMPHOMA (ATL) AND PRECLINICAL APPLICATION FOR NEW THERAPY

J. Vassallo3, C. Silvia Passos Lima1, M. Boudier4,2, S. Yamazaki2, K. Shimizu2, K. Uchimaru4, A. Topi4, H. Nakachuki1,6
1Division of Stem Cell Therapy, 2Department of Laboratory Medicine, Research Hospital, 3Project Division of Advanced Regenerative Medicine, The Institute of Medical Science, The University of Tokyo, 4Laboratory of Tumor Cell Biology, The University of Tokyo, 5Department of Hematology and Oncology, Research Hospital, The Institute of Medical Science, The University of Tokyo, Tokyo, Japan, 6Institute for Stem Cell Biology and Regenerative Medicine, Stanford University, California, United States

Background: Adult T-cell leukemia / lymphoma (ATL) is highly aggressive malignancy caused by human T-cell leukemia virus type 1 (HTLV-1). As leukemia/lymphoma cells are often resistant to combination chemotherapy and recent antibody therapy, new strategies should be developed. Our laboratory recently found that proliferation and survival of hematopoietic stem cells are critically dependent on the amino acid valine (Science, 2016).

Aims: We here aimed to assess amino acid dependence of lymphoma and leukemic stem cells, and to establish a novel therapy by utilizing the differences in amino acid dependence between normal and leukemic stem cells.

Methods: First, primary ATL cells were sorted from samples of 7 typical acute-type ATL patients by 12-color flow cytometry, and serially passaged on stromal cells. Then passageable ATL cells from 3 patients were transduced with GFP-expressing lentivirus for tracking and counting by image cytometry. Using complete medium and twenty different culture media each lacking a single amino acid, we examined amino acid dependency of ATL cells. Amino acids vital for ATL cells were screened by co-culture with stromal cells. Effects of these media on normal lymphocytes of healthy volunteers were also examined. Finally, the effectiveness of amino acid restriction was evaluated in vivo by xenotransplantation of ATL cells into NOG mice. Mice were fed with different diets lacking specific amino acids at 6 weeks after transplantation, and sacrificed at 10 weeks for analysis of peripheral blood, organs, and lymphoma size.

Results: In vitro studies revealed that ATL cells have dependency on specific amino acids- cysteine, methionine, and valine. As 2-weeks restriction of the former two amino acids damaged stromal cells or normal lymphocytes, valine was picked up for further analysis. Proliferation of ATL cells was dramatically inhibited by valine restriction while the influence on normal cells was limited. Interestingly, valine restriction did not appear to affect the proliferative capacity of normal lymphocytes. Valine-depleted diet did not significantly reduce hemoglobin or platelet count, and there were no significant organ damages as far as examined macroscopically. Summary/Conclusions: We discovered that proliferation and survival of adult T-cell leukemia / lymphoma cells were dependent on valine. ATL cells could be eradicated by 4-weeks of valine in vitro. In-vivo model also showed that 4-weeks restriction of valine could dramatically reduce ATL tumor size. Valine-depleted diet did not significantly reduce hemoglobin or platelet count, and there were no significant organ damages as far as examined macroscopically.

Background: Angiogenesis (AG), with participation of the vascular endothelial growth factor (VEGF) and its receptor (VEGFR2), plays a key role in clinical features and outcome of patients with diffuse large B cell lymphoma (DLBCL).

The ability to induce AG is variable in humans, once that VEGF and VEGFR2 genes have several single nucleotide polymorphisms (SNPs) described with distinct proteins production. The wild-type alleles of VEGF -2578 C/A (rs999447) -2489 C/T (rs10922930) -1177 G/C (rs1570360), -534G/C (rs2010963), -460C/T (rs833081), 936C/T (rs3025039), and VEGFR2 -2710G/A (7667289) and -604T/C (rs2071559) SNPs determine higher production, transcriptional activity or binding efficiency of VEGF/VEGFR2.

Aggressive Non-Hodgkin lymphoma - Clinical

VEGF AND VEGFR2 POLYMORPHISMS ARE INVOLVED IN AGGRESSIVENESS AND PROGNOSIS OF DIFFUSE LARGE B-CELL LYMPHOMA

A. Borsarelli Carvalho Bnto1, M. Torresan Delamain2, C. Antonio de Souza2, J. Vassallo2, C. Silvia Passos Lima1
1Department of Internal Medicine, 2Haematology and Haemotherapy Centre, 3Laboratory of Molecular and Investigative Pathology, University of Campinas, Campinas, Brazil

Background: Angiogenesis (AG), with participation of the vascular endothelial growth factor (VEGF) and its receptor (VEGFR2), plays a key role in clinical features and outcome of patients with diffuse large B cell lymphoma (DLBCL).

The ability to induce AG is variable in humans, once that VEGF and VEGFR2 genes have several single nucleotide polymorphisms (SNPs) described with distinct proteins production. The wild-type alleles of VEGF -2578 C/A (rs999447) -2489 C/T (rs10922930) -1177 G/C (rs1570360), -534G/C (rs2010963), -460C/T (rs833081), 936C/T (rs3025039), and VEGFR2 -2710G/A (7667289) and -604T/C (rs2071559) SNPs determine higher production, transcriptional activity or binding efficiency of VEGF/VEGFR2.

Madrid, Spain, June 22 – 25, 2017

haematologica | 2017; 102(s2) | 391
Aims: Since the roles of these SNPs in clinical aspects, response to therapy and prognosis of DLBCL treated with R-CHOP- are still unknown, these were the aims of the present study.

Methods: Our analysis included 168 consecutive DLBCL patients at diagnosis seen at University Hospital from July 2009 to September 2014. Genotypes were identified in DNA of peripheral blood by real-time polymerase chain reaction using a Taqman SNP Genotyping Assay. Replicates were performed in 10% of the reactions, achieving 100% of concordance. Chi-Square test, Fish er’s Exact test, and multivariate analysis, using the logistic regression model, served to assess associations between genotypes and clinical aspects. Kaplan-Meier analysis was used to evaluate the effect of clinical features and genotypes on the cumulative incidence of event free survival (EFS) and overall survival (OS). EFS and OS were calculated from the date of diagnosis to first event date (relapse, progression or death by disease) or last seen date and death by any cause or last seen date, respectively. Cox proportional hazard regression was used to evaluate the effects of clinical features and genotypes of the above mentioned SNPs on PFS and OS, and the results of analysis were presented as hazard ratios (HRs) with their corresponding 95% confidence intervals (CIs). First, these associations were examined using univariate Cox proportional hazards regression. In a second step, all variables with P<0.10 were included in a multivariate Cox regression. All reported P values were two-sided, and P<0.05 was considered to indicate statistical significance.

Results: Concerning clinical features, the frequency of the wild-type VEGF -1154G allele and VEGF-634G genotype were more common in stage III or IV patients. The wild-type VEGF -604GG genotype was more common in high intermediate and high international prognostic index (IPI) patients. Concerning response rate, patients with the wild-type VEGF 936CC genotype was associated with higher complete response (CR). These patients had 2.65 more chances of achieving CR to therapy than others. The median follow-up time of 168 DLBCL patients enrolled in the study was 43 months (range: 1-105). The estimated probabilities of 60-months EFS and OS were 58.8% and 66.0%, respectively. At 60 months of follow-up, patients with the variant VEGF 1154A and 936 T alleles had 1.52 and 1.52 more chances of presenting disease relapse or progression, and 1.47 and 1.60 more chances of evolving to death in univariate analysis, respectively. After correction with other classical prognostic factors in DLBCL (IPI and GCB subtype), only the VEGF 1154 A/G SNP was associated with FFS and OS: patients with the variant VEGF 1154 A allele had 1.88 and 1.83 more chances of having an event.

Summary: Our data present, for the first time, preliminary evidence that inherited abnormalities in AG pathway, related to the wild-type VEGF -1154A allele and VEGF-634G genotype and VEGF-604G allele, influence critical features, response to R-CHOP and outcome of DLBCL patients.

E954

THE PROGNOSTIC SIGNIFICANCE OF CD11b+CX3CR1+ MONOCYTES IN PATIENTS WITH NEWLY DIAGNOSED DIFFUSE LARGE B-CELL LYMPHOMA

1Internal Medicine, Chonbuk National University Hospital, Jeonju, 2Internal Medicine, Catholic University of Korea, Seoul, 3Mckusick-Nathans Institute of Genetic Medicine, Johns Hopkins University School of Medicine, Baltimore, Korea, Republic Of

Background: Interest in the role of myeloid-lineage cells, including monocytes and their precursors, has been increasing in prognosis of lymphoma. It has been shown that the circulating monocyte count at the time of diagnosis shows prognostic significance in diffuse large B-cell lymphoma (DLBCL), suggesting the role of specific subset of monocyte in prognosis of DLBCL. Recent studies suggest CD11b+ monocytes expressing CX3CR1 promote angiogenesis and suppress anti-tumor immunity through the interaction with fractalkine (CX3CL1), the only ligand for CX3CR1. However, limited data is available regarding the prognostic significance of CD11b+CX3CR1+ monocytes in DLBCL patients.

Aims: The study investigates the prognostic significance of peripheral blood (PB)- and bone marrow (BM)- CD11b+CX3CR1+ monocytes on progression-free survival (PFS) and overall survival (OS) in newly diagnosed DLBCL patients.

Methods: This is a retrospective multicenter study including patients older than 17 years, with a BMB and a PET/CT performed simultaneously as part of the routine pre-therapy staging for newly diagnosed DLBCL. Patients who had not received either chemotherapy or corticosteroids and no concomitant malignancy was known to be present at the time of both procedures. Only patients treated with R-CHOP as first line therapeutic strategy were included. Only variable was the obtained result in univariate analysis was included in the multivariate Cox regression for outcome predictors.

Results: A total of 271 DLBCL patients were initially identified; we excluded: 31 patients who received low intensity chemotherapy regimens (R-COP, Mini-CHOP-R, monotherapy with steroids) due to advanced age, comorbidities or detectable BM involvement; and DLBCL patients enrolled in clinical trials including standard regimens plus new agents (Bortezomib, Lenalidomide, Ibrutinib) or non-standard regimens (R-CHOP/14, Da-EPOCH-R, MACOP-B, Mega-CHOP, Hyper-CVAD). In the homogeneously treated R-CHOP(21)/205 DLBCL patients subset, the median age at diagnosis was 61 y.o. (range: 18-85), with a balanced gender distribution (51% female). Twenty-three of these patients (12.7%) had BMi on BM, whereas 43 (21%) had BMi according to PET/CT finding. Fifty-three patients (25.9%) had BMi according to either BM or PET/CT. Concordant BMi by means of both techniques was present in 16 (7.8%) patients. With a median follow-up of 25 months (15-47 months, p25-p75), 50 patients (24.4%) progressed or relapsed and 41 (20%) died. The 3-year estimated progression-free survival (PFS) and overall survival (OS) were 70%, and 78%, respectively. By univariate analysis, factors associated with a shorter PFS, with a <0.10, were: female gender, IPI3, abnormally elevated B2-microglobulin levels, PET/CT-BM(+) and BMi-BM(+) (+). In multivariate analysis only two factors were independent predictors of shorter PFS: VEGFR2 E954-634GG genotype and CD11b+CX3CR1+ monocytes. These patients had 2.65 more chances of achieving CR to therapy than others. The median follow-up time of 168 DLBCL patients enrolled in the study was 43 months (range: 1-105). The estimated probabilities of 60-months EFS and OS were 58.8% and 66.0%, respectively. At 60 months of follow-up, patients with the variant VEGF 1154A and 936 T alleles had 1.52 and 1.52 more chances of presenting disease relapse or progression, and 1.47 and 1.60 more chances of evolving to death in univariate analysis, respectively. After correction with other classical prognostic factors in DLBCL (IPI and GCB subtype), only the VEGF 1154 A/G SNP was associated with FFS and OS: patients with the variant VEGF 1154 A allele had 1.88 and 1.83 more chances of having an event.

Summary/Conclusions: In our DLBCL cohort, treated with a uniform first-line chemotherapy regimen, BMi by BM complemented IPI in predicting those patients with a higher risk for relapse or progression, while IPI defined a subset of patients with a worse survival. In this cohort, BMi by PET/CT could not independently predict a shorter PFS and/or OS.
27.7 months (IQR, 14.6-46.1), low PB-CD11b+CX3CR1+ cell group had significantly better PFS (3-year, 77.1% vs 58.7%; P=0.006) and OS (3-year, 86.6% vs 58.4%; P=0.004) than high PB group. No significant survival differences were observed between high and low BM-CD11b+CX3CR1+ cell groups. Uni-variable analyses demonstrated that age, ECOG performance status, B symptoms, extranodal involvement, NCCN-IPI, and PB-CD11b+CX3CR1+ cell group were significantly associated with OS. However, high risk NCCN-IPI was an only independent prognostic factor for reduced OS (hazard ratio, 4.41; 95% confidence interval, 1.17-16.59) in the multivariate analysis. In subgroup analysis according to the NCCN-IPI, 3-year OS of high PB-CD11b+CX3CR1+ monocytes was significantly inferior to that of low group (34.0% vs 77.9%; P=0.026) in IN-B-NHL, but not for high risk NCCN-IPI. In contrast, PB-CD11b+CX3CR1+ monocytes failed to predict OS (3-year, 91.7% vs 96.7%; P=0.878) in the low to low-intermediate risk NCCN-IPI subgroup.

Summary/Conclusions: Our study represents PB-CD11b+CX3CR1+ monocytes can be used in differentiating patients with high risk for early death and are associated with risk stratification by the NCCN-IPI, possibility of potential therapeutic target in DLBCL.

E955

RARE NON-HODGKIN LYMPHOMAS (R-NHLS) IN CHILDREN: THE AIEOP EXPERIENCE

G. Biddeo1, M. Nizzero2, E. Carraro3, L. Mussolin4, D. Massano5, L. Lo Nigro6, S. Buffardi7, A. Garaventa8, P. Farruggia8, R. De Santis9, N. Santoro9, R. Mura9, A. Tondo10, A. Saia11, M. Pignone12, F. Spreficco13, M.C. Putti14, E.S. D’Amore15, M. Pilone16

1C1. Clinic of Pediatric Hematology-Oncology, Department of Women’s and Children’s Health, Azienda Ospedaliero-Universitaria Meyer Children Hospital, Firenze, 2Department of Paediatrics, Ospedale San Gerardo, University of Milano-Bicocca, Fondazione MBBM, Monza, 3Department of Paediatric Haematology-Oncology, Regina Margherita Children’s Hospital, Torino, 4Pediatric Oncology Unit, Fondazione IRCCS Istituto Nazionale Tumori, Milano, 5C. Clinic of Pediatric Hematology-Oncology, Department of Women’s and Children’s Health, Padova, 6Institute of Pathology, San Bartolo Hospital, Vicenza, Italy

Background: Clinical management of pediatric rare non-Hodgkin lymphomas (r-NHL) is unclear.

Aims: To characterize children with r-NHLS in AIEOP centers. Performing a retrospective analysis of r-NHLS AIEOP case records, describing main epidemiological, clinical and histopathological parameters. To review the histopathological case records according to WHO 2008 classification. Evaluation of treatment response - chemotherapy or wait and see (W&S) in terms of overall survival (OS) and of complete remission (CR), relapse and resistance cases, secondary neoplasias and deaths.

Methods: Data from the AIEOP database were collected between 1997 and 2015. Results: The incidence of r-NHL in AIEOP registry was 6.5% (67 pts). Forty-eight were male and 19 female, median age was 11 years (0.3-21 years), classification according to St. Jude stage was: stage I n=36; II n=13; III n=11; IV n=7. Bone marrow (BM) involvement was diagnosed in 7 cases; central nervous system (CNS) in one case. Patients who presented LDH >500 UI were 18. B-NHLS accounted for approximately 49% (33 pts) of the entire population analyzed. PB-CD11b+CX3CR1+ monocytes were under 40% (27 pts), the remaining 11% (7 pts) of the population under study being categorized as “others” (other than those deriving from B or T/NK-cells). The most common histological subtypes were: follicular lymphoma (FL) amongst B-NHLSs; peripheral T-cell lymphoma (PTCL) n.o.s.; mycosis fungoides (MF); subcutaneous panniculitis T-cell lymphoma (SPTCL) and lymphomatoid papulosis (LP) amongst T-NHLSs; histiocytic sarcoma (HS) amongst “others” category. A similar proportion for both B and T/NK NHL underwent either W&S approach only or active treatment (AT): 45% and 55% were W&S and AT approach, respectively. Patients in “others” category were almost actively treated (71%). Therapy was based on AIEOP B-, T/NK-NHLS and ALC protocol, CHOP or CHOP and/or immunotherapy. Surgical resection has been performed in case of localized disease B-NHLSs only, followed by a W&S strategy, with 3-year OS and EFS were 76.5% and 60.9%, respectively. 3(5)/4110 patients with auto-HSCT, 3 year overall survival (OS) and disease-free survival (EFS) were 76.5% and 60.9%, respectively. (3)5/4110 patients with allo-HSCT, 3 year EFS and OS of allo-HSCT were 61.7% and 58.9%, respectively. (3)4/365 patients with CR1 status before auto-HSCT, 3 year OS and EFS were 87.3% and 68.7%, respectively. 20/56 patients with non-CR1 status before auto-HSCT, 3 year OS and EFS were 60.6% and 40.2%, respectively. The OS and EFS of the two groups were significantly different (P=0.001). (5)45/110 cases were young and high-risk patients (age<60 years, IPI score ≥3). 25/54 cases treated with allo-HSCT, the 3 year OS and EFS were 62.8% and 60.8%, 20/56 cases treated with auto-HSCT, the 3 year OS and EFS were 47.8% and 36.9%. The OS and EFS of the two groups were also significantly different (P=0.001).

Summary/Conclusions: HSCT can improve the efficacy of T cell lymphoma. Auto-HSCT in first complete remission (CR1) enables T-NHL patients with
greater benefit. Allo-HSCT can cure some T-NHL patients, which can be considered for the treatment of young and high-risk T-NHL patients.

**E957**

**SHORT COURSE OF R-HYPERCVAD/MTX/ARA-C FOLLOWED BY ASCT AS FIRST-LINE THERAPY IN MANTLE CELL LYMPHOMA PATIENTS PROLONGS PROGRESSION FREE SURVIVAL TO MORE THAN 9 YEARS.**

**SINGLE CELL EXPERIENCE**

M. Andrés-Campos1,2, S. Mercadal1, E. Domingo Domench1, V. Pareades Henao1, C. Aguilara Gomez1, A. Oliveras Ramos1, E. de la Band1, F. Clermont1, R. Parody Porras1, A. Fernandez de Sevilla1,2, A. Sureda1, E. Gonzalez Barca1,4, D. Department of Hematology, Institut Català d’Oncologia Hospitalat, IDIBELL, Barcelona, 2CIBER de Enfermedades Raras, CIBERER, ICSIII, Zaragoza, 3Pathology Department, Hospital Universitario de Bellvitge, IDIBELL, 4Department of Clinical Sciences, University of Barcelona, Barcelona, Spain

**Background:** Mantle cell lymphoma (MCL) is considered an incurable disease with an historical median overall survival around 3-4 years with short progression free survival (PFS) periods. Regimens that include high dose cytarabine and consolidation with autologous stem cell transplant (ASCT) have become standard therapy for fit patients. The median PFS reported after 4-6 cycles HyperCVAD followed by ASCT consolidation is 4.5 years (Ahmadi et al, BMT 2012). Nevertheless, toxicity is high and many patients cannot obtain stem cells for transplant. In this setting, some groups use 6-8 cycles R-HyperCVAD without ASCT consolidation, achieving the same median PFS of 4.6 years (Romaguera et al, Br J Hematol 2010). Based on this we have reviewed our experience using a short course of HyperCVAD followed by transplant consolidation.

**Aims:** To analyze our experience treating fit patients with MCL in first line with a short course of 2 cycles of R-HyperCVAD followed by consolidation with ASCT.

**Methods:** from January 2002 to August 2016, the patients diagnosed with MCL treated in first line with a short course of 2 cycles of R-HyperCVAD and ASCT were included in this retrospective analysis. International working group response assessment criteria were used, PFS was calculated from the date of start therapy until date of relapse/progression or last contact.

**Results:** During the study period 85 MCL patients were registered: 7 (8.2%) did not receive immediate therapy, 44 (52.4%) were not eligible for intensive therapy due to comorbidities or age and 33 (39.3%) were treated with R-HyperCVAD. Clinical characteristics at diagnosis of these 33 patients were: M/F ratio: 26/7 (78.8%/21.2%), median age: 63 y.o (limits: 40-73), ECOG 0-1: 26 (86.7%), Ann Arbor stage III-IV 28/31 (90.3%), MIPI score: low risk: 17 (56.7%), high risk: 8 (26.7%). Thirty (90.9%) patients completed the 2 cycles of R-HyperCVAD. Reasons for discontinuation were: 2 deaths for sepsis and 1 CNS progression. Intention to treat response rate was: CR 26 (78.8%), PR 2, (6.0%), progressive disease 3 (9.0%), not evaluable 2 (6.0%). Among the 28 patients in CR / PR considered eligible for consolidation with ASCT, 8 patients were not transplanted: 4 (14.3%) had harvest failure (all before plerixafor availability), 2 had persistent toxicity (prolonged neutropenia and severe mucositis) and were not considered for ASCT, 1 rejected, 1 unknown cause. Conditioning regimen was BEAM/LACE in 18 (90.0%) patients and cyclophosphamide-TBI in 2 (10%). One patient died 10 days after infusion for sepsis. With a median follow-up of 35 months (1-131) months, the median PFS was 22.6 (95%CI:21.2-23.9) months (11.4 years) for the whole group, 11.4 (47.3-180.7) months (9.4 years) for the transplanted patients vs 21.1 (3.1-38.9) months (1.8 years) for the not transplanted group. The median OS was 123 (31.9-214.1) months, median OS was not reached for transplanted group vs 31.0 (7.5-54.6) months for not transplanted.

**Summary/Conclusions:** A short course of R-HyperCVAD achieves a very high remission rate in fit patients with MCL. Stem cells could not be obtained in a small proportion of patients, all of them before the use of plerixafor. Two thirds of the patients could complete the planned therapy with ASCT consolidation, and those patients have an excellent outcome, with a PFS of more than 9 years.

**E958**

**THE FREQUENCY OF INCIDENTAL MALIGNANCIES DETECTED BY PET/CT SCANS IN PATIENTS WITH LYMPHOMA AND THE ASSOCIATED CLINICAL IMPLICATIONS**

J. Falconer1,2, G. Kidston-Gerber2, E. Wegner2

1Haematology, Concord Repatriation General Hospital, 2Haematology, The Prince of Wales Hospital, Sydney, Australia

**Background:** PET/CT imaging has a well-established role in the investigation of lymphoid malignancies. Given the widespread clinical applications, unexpected findings are occasionally identified. Whilst there is substantial information pertaining to additional primary cancers identified on PET/CT in patients with solid organ malignancy, there is a relative paucity of data in patients with lymphoma.

**Aims:** The primary aim was to identify the frequency of incidental second malignancies identified by PET/CT in patients with lymphoma. Qualitative data related to histological diagnosis and staging, interruptions or obstacles to lymphoma therapy, therapy for the second malignancy and the overall impact upon prognosis were also reviewed.

**Methods:** A total of 550 PET/CT images were performed in 298 patients at The Prince of Wales Hospital, Sydney Australia between January 2013 – March 2016. Patients with both Hodgkin’s and Non-Hodgkin’s lymphoma, with PET/CT imaging performed for all medicare-approved indications were included. All PET/CT reports suggestive of an incidental second malignancy prompted further review of electronic medical records, MOSAIC cancer database and paper medical records. Where a clear diagnosis of second malignancy was confirmed, information regarding histological findings and staging, as well as the implications of this diagnosis related to treatment of the underlying lymphoma and impact on overall prognosis was collected.

**Results:** 510 PET/CT scans in 259 patients had confirmed diagnoses of lymphoma. Patients aged 17 to 96 were included in the study, with a median age of 63 years. Of the 259 patients included (M=155; F =104), 55 patients had a diagnosis of Hodgkin’s lymphoma and 204 patients a diagnosis of Non-Hodgkin’s lymphoma. A total of 33 out of 259 patients with a diagnosis of malignant lymphoma had PET/CT findings suspicious for an underlying second malignancy (12.7%). Of the 33 patients, 19 underwent further invasive investigation, with a total of 8 patients having a biopsy proven histological diagnosis of a second malignancy (3.1%). Qualitative information was gathered regarding the patients who did not have further investigation.

**Summary/Conclusions:** The frequency of incidental malignancies detected by PET/CT imaging in patients with lymphoma was found to be comparable to other similar international retrospective studies. The majority of incidental second malignancies were early stage and gastrointestinal in origin. Further retrospective as well as prospective data may assist in the establishment of guidelines, to address a standardized diagnostic approach to investigating incidental lesions discovered on PET/CT imaging that are suggestive of a second malignancy.

**CLINICAL IMPACT OF KARYOTYPIC EVOLUTION ON THE PROGNOSIS OF DIFFUSE LARGE B CELL LYMPHOMA**

Y. Mizuno1, T. Kobayashi1, N. Ushimaru1, H. Kawata2, H. Uchiyama1, Y. Chinen1, Y. Shimura1, S. Honike1, J. Kuroda1

1Hematology, Kyoto Prefectural University of Medicine, 2Hematology, Japanese Red Cross Kyoto Daini Hospital, 3Hematology, Japanese Red Cross Kyoto Daiichi Hospital, Kyoto, Japan

**Background:** The acquisition of additional chromosomal abnormalities are generally accompanied by the emergence of therapeutic resistance and eventually lead to poor treatment outcomes. However, the actual clinical impact of karyotypic evolution on prognosis differs depending on the type of hematologic malignancy. Although several prognostic indexes, including the International Prognostic Index (IPI), revised IPI (R-IPI), National Comprehensive Cancer Network (NCCN)-IPI, and Kyoto Prognostic Index (KPI) which we have developed (Kobayashi T. Blood Cancer J 2016), have the determinants for prognosis, little is known concerning the prognostic impact of karyotypic evolution in diffuse large B cell lymphoma (DLBCL), the most prevalent subtype of non-Hodgkin lymphoma.

**Aims:** We in this study investigated the clinical impact of karyotypic evolution on the treatment outcome of DLBCL.

**Methods:** We retrospectively reviewed the medical records of 465 DLBCL patients who were diagnosed and treated with either rituximab, cyclophosphamide, doxorubicin, vincristine, and prednisolone (R-CHOP) or with a R-CHOP-like regimen at three independent institutes in Kyoto, Japan, between January 2006 and April 2014. We analyzed the relationship between the number of subclones and prognosis utilizing the Kaplan-Meier curve and Cox proportional hazards regression analysis. We also utilized Fisher’s exact test to investigate the correlation between the number of subclones and the conventional prognostic indexes, i.e. R-IPI, NCCN-IPI, and KPI. This study was conducted in accordance with the ethical principles of the Declaration of Helsinki.

**Figure 1.**

Summary/Conclusions: A short course of R-HyperCVAD achieves a very high remission rate in fit patients with MCL. Stem cells could not be obtained in a small proportion of patients, all of them before the use of plerixafor. Two thirds of the patients could complete the planned therapy with ASCT consolidation, and those patients have an excellent outcome, with a PFS of more than 9 years.
and was approved by the institutional review boards of all participating institutes.

Results: Among the 465 DLBCL cases, karyotypic analyses by G-banding were performed on biopsied tumor specimens before the start of treatment in 181 patients. Among the 181 patients, metaphase spreads were available for G-banding in 120 patients. Neither overall survival (OS) nor progression free survival (PFS) was statistically significantly different between the patients with available metaphase and no available metaphase spreads. Based on the result of G-banding, we next divided the 120 patients with available metaphase spreads into two groups, i.e., patients with karyotypic abnormalities accompanies by ≥2 subclones and patients with 0-1 subclones. We found that the presence of ≥2 subclones was significantly associated with poor OS (3 year OS rates of patients with ≥2 subclones and 0-1 subclones were 67.6% and 82.8%, respectively (p=0.035), and tended to associate with a shorter PFS. Among the 120 patients with available metaphase spreads, the R-IPI-defined high-risk patients and IPI-defined high-risk patients were significantly more frequent in the group of patients with ≥2 subclones. Ages and genders were not significantly different between patients with ≥2 and with 1-2 subclones.

Summary/Conclusions: DLBCL is a cytogenetically and molecularly heterogeneous disease entity. No specific chromosomal abnormality has been associated with the shorter survival, except double or triple hit lymphomas. However, in this study, it was possible to divide DLBCLs into two groups based on karyotypic evolution, i.e., DLBCLs with 0-1 subclones and with ≥2 subclones, because the OS was the most markedly different between these two groups. In our study, more subclones were associated with poor prognosis, suggesting the significance of karyotypic evolution in DLBCL. In conclusion, our study suggests that more advanced cytogenetic clonal evolution underlies the development of high-risk disease feature in DLBCL.

EPSTEIN-BARR VIRUS LATENT MEMBRANE PROTEIN 1-MEDIATED OVEREXPRESSION OF MYC AND BCL2 CAN PREDICT POOR PROGNOSIS IN PATIENTS WITH EXTRANODAL NK/T-CELL LYMPHOMA, NASAL TYPE

J.-H. Wang1, X.-W. Bi2, Z.-J. Xia1, W.-Q. Jiang2, H.-Q. Huang2, L. Wang1

1Hematologic Oncology, 2medical oncology, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: Recently double-hit lymphoma or double protein expressor lymphoma has been identified as a distinct group of diffuse large B cell lymphoma with poor prognosis. However, the expression status, clinical and prognostic effect of combined overexpression of MYC and BCL2 in extranodal NK/T-cell lymphoma, nasal type (ENKTL) are not known.

Aims: This study aims to explore the clinical and prognostic effect of combined overexpression of MYC and BCL2 in ENKTL.

Methods: Paraffin-embedded lymphoma samples from 53 patients with newly diagnosed ENKTL were studied using immunohistochemistry for MYC and BCL2, and fluorescent in situ hybridization (FISH) for MYC and BCL2 were done on 5 tissue sections with highest percentages of both MYC and BCL2 positive lymphoma cells.

Results: The median percentage of MYC-positive lymphoma cells and BCL2-positive lymphoma cells were 20% (range, 5% >45%) and 70% (10% >95%), respectively. Using median scores as cutoffs, we assigned each patient an IHC double-hit score (DHS) that ranged from 0 to 2. Using this DHS, 15 patients (28.3%) had a DHS of 0, 24 patients (45.3%) had a DHS of 1, and the remaining 14 patients (26.4%) had a DHS of 2. FISH analysis was performed on 5 tissue sections with DHS of 2, and none of them had MYC or BCL2 rearrangement. The DHS was not associated with patients’ age, gender, disease stage, LDH level, B symptoms, performance status, or local tumor invasiveness. However,
patients with tumor localized in extranasal sites seemed to have higher expression of BCL2 and higher DHS than nasal lesions (P=0.014 and 0.042, respectively). In univariate survival analysis, either high expression of MYC or BCL2 was significantly correlated with inferior PFS and OS (P<0.05). According to the DHS, patients with ENKTL who could be divided into three significantly different risk groups for PFS and OS (3-year PFS rate for DHS of 0, 1, and 2 was 60%, 41%, and 21%, respectively, P=0.008; 3-year OS rate for DHS of 0, 1, and 2 was 79%, 49%, and 33%, respectively, P=0.015). In multivariate survival analysis, it was found that DHS was an independent prognostic factor for both PFS and OS (P=0.006 and 0.011, respectively).

Summary/Conclusions: Our study demonstrated that DHS can help identify patients with newly diagnosed ENKTL who are at a high risk for a poor clinical outcome, which needs to be validated in prospective clinical trials with patients treated uniformly.

E962

SOLUBLE INTERLEUKIN-2 RECEPTOR AS A PREDICTIVE MARKER FOR SPONTANEOUS REGRESSION OF OTHER IATROGENIC IMMUNODEFICIENCY-ASSOCIATED LYMPHOPROLIFERATIVE DISORDERS: A RETROSPECTIVE STUDY

1Department of Hematology and Clinical Immunology, Yokohama City University Graduate School of Medicine, 2Department of Hematology, Yokohama City University Medical Center, 3Clinical Laboratory Department, Yokohama City University Graduate School of Medicine, Yokohama, Japan

Background: Patients treated with immunosuppressive drugs (ISD) for autoimmune diseases are at an increased risk of developing other iatrogenic immunodeficiency-associated lymphoproliferative disorders (OI-LPD). Some patients with OI-LPD shows spontaneous regression after withdrawal of ISD, but some require chemotherapy. The factors that are associated with spontaneous regression and outcomes of chemotherapy remain uncertain.

Aims: The aims of our retrospective study are to assess the clinical factors that predict spontaneous regression of lymphoma after ISD withdrawal in patients with OI-LPD and to evaluate the outcomes of patients who underwent chemotherapy without spontaneous regression.

Methods: We collected data from all patients with autoimmune disease who were pathologically diagnosed with OI-LPD between January 2002 to October 2016 at Yokohama City University Hospital, and Yokohama City University Medical Center.

Results: The patients included 12 males and 28 females, with a median age at diagnosis of 65 years (range 30-81). Methotrexate (MTX) was administered to all patients at any point of the clinical course before OI-LPD. The median time from diagnosis of autoimmune disease to OI-LPD development, and the median duration of MTX administration were 12 months (range 1-168) and 89 months (range 4-297), respectively. The histological findings of OI-LPD were diffuse large B-cell lymphoma (DLBCL) in 26 patients, follicular lymphoma in 4, and LPD in 4. EBER in 1, MALT in 2, peripheral T cell lymphoma, not otherwise specified in 3.

Conclusions: Our study revealed that an sIL-2R level of ≥2,400 U/mL was significantly associated with spontaneous regression in patients with OI-LPD. Because CR rates with chemotherapy in patients without spontaneous regression are low, evaluation of sIL-2R in patients with OI-LPD may be useful for an early withdrawal of ISD, resulting in a higher chance of spontaneous regression.

E963

PROGRAMMED DEATH-1 PROTEIN EXPRESSION AND ITS RELATION WITH HISTOLOGICAL AND CLINICAL VARIABLES IN MYCOSIS FUNGOIDES

C. Vázquez1, S. Novelli2, A. Mozos1, P. García Muret3, A.C. Caballero2, J. Sierra2, J. Briñez4

1Pathology, 2Haematology, 3Dermatology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

Background: Mycosis fungoides (MF) is a T-cell malignancy with affinity for the skin. In early stages, treatment directed to the skin can induce long-lasting remissions. However, advanced stages are characterized by short-duration remissions and progressive disease. The programmed death cell surface protein-1 (PD-1) is expressed on activated T cells. Interactions between PD-1 and its ligands control the induction and maintenance of peripheral T-cell tolerance during the normal immune response. These interactions may also play a role in the immune evasion of tumors in which PD-1 ligand is overexpressed.

Aims: To described histologic characteristics and the proportion and intensity of PD1 expression by tumor cells, as well as the presence of PD1 positive lymphocytes in the epidermis in patients with MF. To identify histologic variables that might have an impact in clinical outcome.

Methods: Histologic preparations of 85 patients diagnosed with MF were evaluated. Survival analysis was performed with the Kaplan-Meier method. A univariate analysis was performed with clinical variables (stage and age) and anatomicopathological variables (i.e. intensity of the inflammatory inflam-
trate, epidermotropism, cellular atypia, tumor density, presence of folliculotro-
pism and phenotypic alterations) and the proportion and intensity of PD1 expres-
tion by tumor cells, the presence of PD-1 positive lymphocytes in the epidermis. Likewise, a Pearson correlation analysis was performed between the degree of atypia and the ratio of PD-1 expression, PD-1 intensity, and loss of CD7 expression in tumor cells. Statistical analysis was performed using the IBM SPSS Statistics version 21.0.

Results: The median follow-up was 125 months (range 6-450 months). Char-
acteristics of patients are in Table 1. The overall survival (OS) at 10 years was 81%. OS in the early stages was 85% vs.64% in advanced stages (p<0.05). The OS for patients <60 years was 85%, and 75% for patients ≥60 years (p=0.05). Regarding histologic findings, the degree of atypia was the only variable that had an impact in OS. (see Figure 1) The presence of atypia grade 1 had an OS of 88%, grade 2 of 75%, and grade+3 of 50% (p<0.05). We performed a correlation analysis between degree of atypia and the ratio of PD-1 expres-
sion, PD1 intensity, and loss of CD7 expression. A positive correlation was detected, however it was weak (r<0.5).

Summary/Conclusions: MF tumoral cells express PD-1 protein in a high pro-
portion of cases being a potential therapeutic target. Advanced disease, age ≥60 years and the degree of atypia of the tumoral infiltrate had an impact on survival. E964

CIRCULATING MICRORNAS AS BIOMARKERS IN DIFFUSE LARGE B-CELL LYMPHOMA: A PILOT PROSPECTIVE LONGITUDINAL CLINICAL STUDY

C. Bouvy1,2, A. Wannez3,2, C. Chatelain1, J.-M. Dogne1
1Department of Pharmacy, University of Namur, Namur, 2CHU UCL Namur, Université Catholique de Louvain, Yvoir, Belgium

Background: Diffuse large B-cell lymphoma (DLBCL) is highly heterogeneous in terms of phenotype and treatment response in patients. These characteristics make the treatment prognosis difficult to establish and hinder the use of new personalized treatments in clinical practice. In this context, there is currently a necessity to define new biomarkers enabling a better definition of DLBCL subtypes, prog-
osis evaluation and an overview of the resistance to chemotherapeutics. We decided here to focus on circulating microRNAs that are found in all biological fluids. Their accessibility makes them good candidates for biomarkers studies.

Aims: This research aims at studying microRNAs found in plasma from DLBCL patients and at investigating their potential as biomarkers of survival in these patients. For this purpose, a plasma biobank was created with samples from DLBCL patients at different times of their treatment. This follow-up of microRN-
As level during the course of treatment is particularly innovative in this study.

Methods: A plasma biobank from DLBCL patients was set up at the Centre Hospitalier Universitaire (CHU) UCL Namur Yvoir, Belgium (ethical agreement number B039201419613). Informed consents of all patients were obtained. In this way, blood samples from patients were taken before any treatment (C0), at the administration of the second and the fourth chemotherapeutic cure (C2) and (C4) and at the remission review (C5). In the case of an autograft, a sample was taken at the post-graft review (Cpg). The first step of this study was the selection of the microRNAs that will be quantified in all the samples of the biobank and that could potentially be used as biomarkers. To this end, a quantification of 377 microRNAs was performed by TaqMan® Low Density Array on the plasma samples of two selected DLBCL patients and one healthy donor with no history of cancer. These DLBCL patients were selected based on their highly different response to treatment. One of them obtained a complete remission after a R-
CHOP treatment, while the other presented a refractory disease to the same treatment. Thereafter, we determined some criteria to use in a scoring system to evaluate their potential as biomarkers. In this way, one point was given to a microRNA each time it meets the criteria enabling it to be defined as a potential diagnostic, prognostic and/or remission biomarker, biomarker of a disease pro-
gression, biomarker of an inherent resistance to treatment, and/or biomarker of an acquired resistance to treatment.

Results: On the 377 microRNAs quantified into the plasma of the 3 selected donors (2 DLBCL patients and 1 healthy donor), 81 microRNAs were detected. Three microRNAs obtained the highest score of 5 points: miR-197, miR-20a and miR-451. Four points were attributed to miR-122, miR-19b and miR-19a. Two additional microRNAs were also selected: let-7e, for its prognostic value at C0, C2 and C4 and miR-21, for its numerous citations in the literature.

Summary/Conclusions: miR-197, miR-20a, miR-451, miR-122, miR-19a, miR-
19b, let-7e and miR-21 have been selected in this study and are currently quan-
tified in the plasma of the entire biobank. Since then, 19 patients have been included in the study and the potential of these microRNAs as biomarker are statistically evaluated.

E965

COMBINED CHEMOTHERAPY PLUS RADIATION THERAPY IS MORE EFFECTIVE IN LIMITED-STAGE DIFFUSE LARGE B-CELL LYMPHOMA OF THE TONSIL

S.-N. Lim1,2
1Internal Medicine, Haeundae Paik Hospital, Busan, Korea, Republic Of
2Department of Medicine, College of Medicine, University of Ulsan, Busan, Korea

Background: Primary extranodal non-Hodgkin’s lymphomas of the head and neck account for 10-20% of all non-Hodgkin’s lymphomas. Primary tonsillar lymphoma accounts for less than 1% of head and neck malignancies, although the tonsil is the most common primary extranodal site of head and neck non-
Hodgkin’s lymphomas.

Aims: The purpose was to evaluate the prognostic factors and treatment out-
come of patients with diffuse large B-cell lymphoma (DLBCL) of the tonsil.

Methods: In all, 114 patients with DLBCL of the tonsil with stage I or stage II, treated at multicenter in Korea, from September 1995 to April 2011, were includ-
ed. The median age was 59 years and the majority of patients (61%) were male. Systemic symptoms were present in 6% of patients. International prognostic index (IPI) score was 0 in 54 patients (48%), 1 in 40 (35%), 2 in 14 (12%), and 3 (3%). Ten patients (8%) showed elevated level of lactate dehydrogenase (LDH). Treatment consisted of a combination of chemotherapy (CTx) and radio-
therapy (RTx) for 38 patients (34%) and 72 patients (65%) received CTx only. Among those receiving RTx, the median RTx dose was 39 Gy.

Results: After median follow-up of 32 months (range 0.4-106 months), event free survival (EFS) and overall survival (OS) were 25.9% and 42.5%, respec-
tively. Significant prognostic factors included: age (≥ 60 year-old vs <60 year-
old), LDH level (> upper normal limit and supper normal limit), IPI score (0-1 vs 2-3), and treatment (CTx plus RTx vs CTx only). On multivariate analysis, LDH level (hazard ratio [HR], 10.522; 95% confidence interval [CI], 2.548-43.449, p=0.001) and treatment (HR, 12.393; 95% CI 2.151-71.410) were independent prognostic factor of EFS and age (HR, 8.920; 95% CI 1.089-73.053, p=0.043), LDH (HR, 8.316; 95% CI 1.914-36.127, p=0.005), and treatment (HR, 8.943; 95% CI 1.089-73.425) retained statistical significance in OS.
Methods: Fourteen (4 female, 10 male) consecutive frail elderly patients (median age: 79 years; range 68-86 years) with a-B-NHL (11 DLBCL, 1 Burkitt NHL, 1 Burkitt-like NHL and 1 Mantle cell lymphoma) were enrolled in a phase II study with bendamustine 70mg/m² i.v. on days 1 and 2, rituximab 375mg/m² i.v. on day 1 and oral dexamethasone 20mg total dose on days 1-4 for four cycles. Frailty criteria were age >58 years, or age >70 years associated with 3 or more comorbidities or at least one grade 3-4 adverse event according to the cumulative illness rating scale (CIRS), as well as not self-sufficient or the presence of geriatric syndromes.

Results: Patients who showed complete (CR) or partial response (PR) after the fourth induction cycle of RD-BENDA started a consolidation course with four weekly doses of rituximab (375mg/m² i.v.) followed, in the case of persistence of CR or PR, by a maintenance treatment with monthly courses of lenalidomide (10mg/m², days 1-21). All patients performed G-CSF prophylaxis to avoid febrile neutropenia. Patients with progressive disease after RD-BENDA started maintenance therapy with monthly courses of full dose lenalidomide. PFS and OS were performed for the assessment of the response and overall survival after RD-BENDA induction course and after rituximab consolidation. After a median follow-up of 6 months (range 2-18), the overall response rate was 81%, with CR and PR of partial response rates of 63 (n=7) and 21% (n=2) respectively. Two patients died due to multiple organ failure and disease progression after 1 and 8 months from diagnosis, respectively. In our frail old, elderly patient cohort, the sequential treatment strategy was well-tolerated. After RD-BENDA cycles, grade II infectious disease was observed in 2/11 patients (18%) and DNA-CMV reactivation was detected in 2 other 2 additional patients (18%). However, 2 out of five patients who started maintenance lenalidomide discontinuation therapy experienced renal and hematological grade 3 toxicity. At the time of analysis, the estimated median 18-month progression free survival (PFS) and overall survival (OS) were 75 and 66%, respectively.

Summary/Conclusions: Our preliminary data show that sequential treatment with RD-BENDA followed by four weekly doses of rituximab and finally by lenalidomide maintenance is a feasible and safe therapy option in frail elderly a-B-NHL patients, but needs to be assessed in a larger subsequent trial.

E968

CLINICAL RELEVANCE OF SARCOPENIA IN DIFFUSE LARGE B-CELL LYMPHOMA - TWO ARE BETTER THAN ONE

S.-I. Go, J.-M. Park, G.-W. Lee

1Division of Hematology, Department of Internal Medicine, University Hospital Dubrava, Zagreb, 2Division of Hematology, Department of Internal Medicine, University Hospital Centre Rijeka, 3Division of Hematology, Department of Internal Medicine, University Hospital Merkur, Zagreb, 4Medical School, University of Osijek, Osijek, 5Division of Hematology, Department of Internal Medicine, University Hospital Centre Split, Split, 6KroHem, University of Zagreb, Zagreb, Croatia

Background: Sarcopenia is known to be associated with poor clinical outcome in patients with diffuse large B-cell lymphoma (DLBCL). There is no consensus concerning the optimal method to define sarcopenia in DLBCL.

Aims: In this study, given the uncertainty about the optimal SMI to define clinically meaningful sarcopenia in DLBCL, we compared the characteristics and clinical outcome between sarcopenic patients determined by L3 skeletal muscle index (L3-SMI) and those determined by pectoralis muscle SMI (PM-SMI) who were treated with standard front-line R-CHOP therapy. Furthermore, the synergistic role of L3- and PM-SMIs as prognostic markers was also investigated.

Methods: We retrospectively reviewed 193 DLBCL patients treated with rituximab plus cyclophosphamide, doxorubicin, vincristine, and prednisone (R-CHOP) therapy. Sarcopenia was classified by the region where the pretreatment skeletal muscle index (SMI) was measured.

Results: Both the sarcopenia-L3 and sarcopenia-pectoralis muscle (PM) groups had increased incidences of severe treatment-related toxicities and treatment discontinuation compared with the non-sarcopenia-L3 and non-sarcopenia-PM groups, respectively. The sarcopenia-L3 and non-sarcopenia-L3 groups had 5-year overall survival (OS) rates of 40.5% and 67.8% (p=0.001), respectively. The sarcopenia-PM and non-sarcopenia-PM groups had 5-year OS rates of 35.9% and 69.0% (p<0.001), respectively. When the sarcopenia-L3 alone and sarcopenia-PM alone groups were compared, there were no differences in baseline characteristics, treatment toxicity, or survival. In multivariate analysis, when compared with the non-sarcopenia-both group, OS was significantly worse in the sarcopenia-both group (HR, 2.480; 95% CI, 1.284-4.792; p=0.007), but not in patients with either sarcopenia-L3 alone or sarcopenia-PM alone (p=0.151).

Summary/Conclusions: L3- and PM-SMIs are equally useful to define sarcopenia, which is related to intolerance to R-CHOP therapy and to worse survival in patients with DLBCL. More prognostic information can be obtained when these two SMIs are combined to define sarcopenia.

E969

INTENSIFIED TREATMENT REGIMENS IMPROVE EVENT-FREE AND OVERALL SURVIVAL IN YOUNGER NEWLY DIAGNOSED HIGH-RISK PATIENTS WITH B-LARGE CELL LYMPHOMA: A REPORT FROM THE OBSERVATIONAL STUDY OF KROHEM

1Division of Hematology, Department of Internal Medicine, University Hospital Centre Zagreb, 2Division of Hematology, Department of Internal Medicine, University Hospital Dubrava, Zagreb, 3Division of Hematology, Department of Internal Medicine, University Hospital Centre Rijeka, 4Medical School, University of Rijeka, Rijeka, 5Division of Hematology, Department of Internal Medicine, University Hospital Merkur, Zagreb, 6Medical School, University of Osijek, Osijek, 7Division of Hematology, Department of Internal Medicine, University Hospital Centre Split, Split, 8KroHem, University of Zagreb, Zagreb, Croatia

Background: Standard therapy for newly diagnosed B-large cell lymphoma (B-LCL) is R-CHOP. Patients with high-risk disease have unsatisfactory outcomes. Non-randomized trials have suggested that intensified regimens, such as R-CHOEP14 and DA-R-EPOCH, improve treatment results in younger patients.

Aims: We performed this analysis to compare response rates, event-free (EFS) and overall survival (OS) rates of newly diagnosed patients with high-risk disease treated with R-CHOEP21 and more intensive regimens (R-CHOEP14 and DA-R-EPOCH).

Methods: Outcomes of B-LCL patients younger than 60 with aaIPI ≥2 treated at two different centres with R-CHOEP14 and DA-R-EPOCH were collected retrospectively from patient files and compared to outcomes of patients with same characteristics treated with R-CHOEP21 from the registry of KroHem, the Croatian Cooperative Group for Hematologic Diseases. All three regimens were administered according to standard guidelines for 6-8 cycles. Patients in PR or with initial bulky disease were irradiated after the end of systemic treatment. Twelve patients treated with DA-R-EPOCH were autografted in 1st remission.

Results: 54 patients were treated with R-CHOEP21, 40 with R-CHOEP14 and 22 with DA-R-EPOCH. R-CHOEP14 and DA-R-EPOCH treated patients did not differ in response rates, EFS and OS and were grouped together for further analysis. R-CHOEP treated patients had less frequently bulky disease (25% vs 49%, P=0.07) than more intensively treated patients; there was no difference in age, gender, stage, elevated LDH or PS ≥2. Patients receiving R-CHOEP had similar response rates as those receiving more intensive regimens (80% vs 85%, P=0.455), but inferior EFS (HR 2.12, 95% CI [1.04-4.2], P=0.028) and OS (HR 2.15, 95% CI [1.07-4.3], P=0.034) (Figure 1). 5-year EFS rates were 48% and 78% and 5-year OS rates 50% and 80% for R-CHOEP21- and more intensively treated patients, respectively. Differences in outcomes between R-CHOEP and intensified regimens remained significant in a multivariate Cox regression model adjusted for age, gender and presence of bulky disease (HR 2.45, 95% CI [1.11-5.4], P=0.026 for OS and HR 2.46, 95% CI [1.16-5.24], P=0.019 for EFS).

Figure 1.
SUBSTITUTING DOXORUBICIN WITH ETOPOSIDE IN R-CHOP RESULTS IN INCREASED DISEASE CONTROL, BUT AT THE COST OF INCREASED CARDIAC TOXICITY IN ELDERLY PATIENTS WITH LARGE B-CELL LYMPHOMA: SERBIAN EXPERIENCE

I. Aurer16, P. Roncevic1, L. Galunic-Bilic 4, M. Dobrenic 56, A. Ostojic 1, D. Dujmovic 6, I. Petkovic4, V. Nikolic5, Josa”, University of Belgrade, Belgrade, 4Clinic of Oncology, University Clinical Center Kragujevac, Kragujevac, Serbia

Aims: The aim of this study was to evaluate the impact of the substitution of doxorubicin in the R-CHOP regimen with etoposide on the efficacy and toxicity of the new regimen in elderly patients with large B-cell lymphoma (LBCL) who were treated with this regimen in the Clinical Center of Serbia and the University of Belgrade.

Methods: From 2011 to 2016, 171 patients with LBCL aged 70 years or older were treated with the R-CHOP regimen. The substitution of doxorubicin with etoposide was evaluated in terms of disease control and side effects.

Results: The overall response rate was 90.5%, with complete response in 47.3% and partial response in 43.2%. The median progression-free survival (PFS) was 15 months, and the median overall survival (OS) was 30 months. The rate of grade 3-4 toxicity was high, with cardiac toxicity in 12.9% of cases, neutropenia in 25%, and neuropathy in 12%.

Summary/Conclusions: The substitution of doxorubicin with etoposide in the R-CHOP regimen resulted in increased disease control but at the cost of increased cardiac toxicity. This highlights the importance of considering cardiac toxicity in the treatment of elderly patients with LBCL.
E972

POST-TRANSPLANT LYMPHOPROLIFERATIVE DISORDER: A SINGLE-CENTER CASE SERIES

C. De Miguel1, B. Navarro1, J. Martín2, P. Martín2, G. Anze3, A. Alarcón1, R. Forés1, C. Bellas2, J.R. Cabrera1

1Hematology, 2Pathology, Hospital Universitario Puerta de Hierro Majadahonda, Majadahonda, Spain

Background: Post-transplantation lymphoproliferative disease (PTLD) is a complication of both solid organ transplant (SOT) and haematopoietic cell transplant (HCT) and represent a very heterogeneous group.

Aims: The objective of this study is to evaluate the epidemiology, clinical features, characterization and therapeutic management of this disease.

Methods: We evaluated a total of 52 patients diagnosed between May 1995 and February 2017. We analyzed the following data: type of transplantation, immunosuppression time from transplantation to lymphoma diagnosis, clinical stage, response to treatment and survival. We classified them morphologically according to the WHO criteria (2016 revision), using immunohistochemical and molecular techniques and their relationship with the Epstein-Barr virus (EBV) by studying the expression of EBERs. We correlated clinical data with morphological, immunohistochemical and molecular results.

Results: Among the 52 patients, 31 were men (59.6%) and 21 women. PTLD after SOT were 45 (86.5%), of which 16 were after liver transplant (35.6%), 14 cardiac (31.1%), 9 pulmonary (20%), 4 renal (8.9%) and 2 double (cardiac-pulmonary and cardiac-renal) (4.4%). There were 7 PTLD after HCT, 2 identical HLA family donor, 2 unrelated donor, 2 dual umbilical cord blood and 1 autologous. Of the 52 PTLD, 48 were B lymphomas (92.3%), of which 26 were diffuse large B-cell lymphomas (DLBCL) (54.2%), 7 polymorphic (14.6%), 7 low-grade (14.6%), 4 Burkitt lymphomas (8.3%), 1 Hodgkin’s lymphoma (2.1%) and 2 non-classifiable. Other 4 PTLD were T lymphomas (8.7%), 2 anaplastic, 1 T/NK lymphoma, and 1 gamma/delta T lymphocytosis. 35/52 PTLD were EBV (+) (67.3%). The median time of immunosuppression was 123 months in renal transplant, 93 months in liver, 85.5 months in cardiac, 51 months in lung and 3 months in HCT. Histologically, it was 96 months in T lymphomas and 80 months in B lymphomas, being 51 months in EBV + and 124 months in EBV-. Fifty percent of Burkitt lymphomas were diagnosed after lung transplant, while 85% of low-grade lymphomas were diagnosed after liver transplant. Clinical stage was III/IV in 73% of the patients (38). Among the 52, 45 received treatment (86.5%), 37 with immunochemotherapy (82.2%) and 8 with Rituximab (17.9%). Three patients responded to reduction of immunosuppression (5.8%) and 3 did not receive any treatment for early death (5.8%). At the time of writing, 19 patients remain alive (36.5%) and 33 have died. The median survival of these patients was 19.5 months (0-198).

Summary/Conclusions: PTLD constitute a very heterogeneous group. Its appearance is much earlier in the HCT than in the SOT and, within this latter group, it is earlier after lung transplant and later after renal transplant. The most common type in our series is DLBCL. The majority are related to EBV, so post-transplant monitoring is essential, and its diagnosis is earlier than in EBV-. Most low-grade lymphomas appear post-liver transplant, either in relation to viral reactivation or autoimmune diseases. Survival is significantly lower than in other primary LPS. -AR-SA: We analyzed the following data: type of transplantation, immunosuppression used in both induction and maintenance, immunosuppression time from transplantation to lymphoma diagnosis, clinical stage, response to treatment and survival. We classified them morphologically according to the WHO criteria (2016 revision), using immunohistochemical and molecular techniques and their relationship with the Epstein-Barr virus (EBV) by studying the expression of EBERs. We correlated clinical data with morphological, immunohistochemical and molecular results.

E973

SURVIVAL OUTCOMES AFTER FIRST-LINE THERAPY IN DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL) USING A UNITED STATES (US) ELECTRONIC MEDICAL RECORD (EMR)-BASED COHORT

A. Galaznik1, J. Bell1, L. Hamilton2, A. Ogbonnaya2, A. Raju2, K. Hennenfent2, M. Eaddy2, Y. Shou1

1Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, 2Xcenda LLC, Palm Harbor, United States

Background: In the rituximab era, the recommended first-line therapy (1LT) in DLBCL patients who can tolerate combination therapy is rituximab combined with chemotherapy. For refractory/relapsed disease, high-dose chemotherapy with stem cell transplant, combination chemotherapy, or single-agent rituximab are considered. While the efficacy of rituximab has been shown in clinical trials, few studies have evaluated survival outcomes in patients seen in routine clinical care.

Aims: We evaluated survival outcomes in a US population of newly diagnosed DLBCL patients seen in routine clinical care.

Methods: In this retrospective study, adult patients ≥18 years old with newly diagnosed DLBCL who had received a first-line therapy (1LT) for DLBCL were identified from the Humedica, a large US electronic medical record database, between 01/01/08 and 07/31/15. DLBCL diagnosis was determined by the presence of ≥1 inpatient record or ≥2 outpatient records with DLBCL diagnosis codes; the first DLBCL record served as the index date. Following the index date, initiation of 1LT for DLBCL was required. For the assessment of the survival outcomes, patients were evaluated from the date of treatment initiation until death, loss to follow-up, or end of study (09/30/15).

Results: 1,436 newly diagnosed DLBCL patients who initiated 1LT met the patient selection criteria. 54.0% were male, and the mean age was 66.4 years (SD: 13.7) at baseline. 27.4% of patients had a Charlson Comorbidity Index of ≥2, and the most common comorbidities were diabetes (20.3%), chronic pulmonary disease (15.5%), and moderate to severe renal disease (9.5%). In 1LT, 92.1% of patients received combination therapy, with R-CHOP (63.5%) being the most common combination therapy. 7.9% of patients received monotherapy upfront, with rituximab (77.2%) being the most commonly used single agent. At 2 years following initiation of 1LT, the Kaplan-Meier OS and PFS were 79.2% and 67.3%, respectively. Median OS was not reached, and median PFS was 53.9 months (95% confidence interval: 45.2, 61.5). OS and PFS were also compared among patients receiving monotherapy vs combination therapy in unadjusted analysis. At 2 years, OS was 80.2% for patients receiving combination therapy vs 67.4% (P=0.0093) for patients receiving monotherapy. Also at 2 years, PFS was 68.3% for patients receiving combination therapy vs 55.1% (P=0.0051) for patients receiving monotherapy.

Summary/Conclusions: In this population of patients with newly diagnosed DLBCL receiving 1LT, survival outcomes at 2 years were significantly improved for patients treated with combination therapy vs monotherapy. Future analysis will explore the differences in clinical characteristics of patients treated with monotherapy vs combination therapy in the 1LT setting.

**AN EXPERIENCE WITH LONG ACTING FACTOR VII PROPHYLAXIS IN PAEDIATRIC AND YOUNG ADULT PATIENTS WITH HAEMOPHILIA A**

S. Verma1, A. Tripathi1,1, G. Suni1, N. Kumar1, R. Kushwaha1, A. Kumar2, P. Kumar1

1K G. Medical University Lucknow, Lucknow, India

**Background:** Hemophilia is an X linked inherited bleeding disorder. Recurrent Joint bleeds and muscle bleeds are the common manifestations leading to long term comorbidities in hemophilia. High dose factor prophylaxis has been proven to be very effective in preventing joint problems in western world. We look for a cost effective and feasible way for Indian patients in terms of reduced dose and frequency of factor infusion. Data on prophylaxis with low dose long acting factor infusion on twice weekly dosing schedule is limited.

**Aims:** To study the efficacy and safety of long acting factor VII (Eloctate) for tertiary prophylaxis in pediatric and young adult patients with moderate and severe haemophilia A.

**Methods:** Thirty eight patients with moderate and severe haemophilia A without inhibitors and age range from 1 to 25 years were included in this study. Patients were initially observed for 4 months during which they received therapeutic doses of long acting factor VII, ELOCTATE (Factor VII with Fc Fusion Protein) on episodic basis after clinical bleed. In next 4 months they received prophylactic ELOCTATE, given intravenously at doses of 20 unit/kg body weight on twice weekly schedule. Annual bleeding rates, school absenteeism, emergency visits and other aspects of quality of life and joint scores were compared during observation and prophylaxis period.

**Results:** Total number of bleeds during observation and prophylaxis period was 607 and 90 respectively. Annual bleeding rate was 47.9 during observation period and 7.1 during prophylaxis. There was 85.1% reduction in bleeding rates on prophylaxis. School/college absenteeism was 3.1 days/ month and 0.84 days/month during observation and prophylaxis respectively. Emergency visits were significantly more during observation. None of the patients developed inhibitors and two patients had superficial thrombophlebitis during prophylaxis. Quality of life assessment using KIDSCREEN QOL questionnaire showed moderate to marked improvement in quality of life domains during prophylaxis.

**Summary/Conclusions:** Low dose, twice a week, long acting factor VII prophylaxis can be a reasonable option for patients with haemophilia A in developing countries. It significantly reduces joint bleeds, school absenteeism, Joint scores significantly without risk of inhibitor formation and also improves all domains of quality of life.

### E976

**RETROSPECTIVE EVALUATION OF PHENOTYPE AND MANAGEMENT OF A-HYPO-FIBRINOGENEMIA IN A COHORT OF ITALIAN PATIENTS**

C. Saporito1, F. Massaro1, E. Bonchi2, G. Ferrara1, A. Ferrero1, A. Santoro2, S. Pasca3, G. Castaman4, P. Peyvandi5, R. Foà6, M.G. Mazzucco1

1Cellular Biotechnology and Hematology, Hematology Sapienza University, Rome, 2Oncohaematology Department, Haemostasis and Thrombosis Service, Pugliese-Ciaccio Hospital, Catanzaro, 3Center for Hemorhagic and Thrombotic Disease, University Hospital of Udine, 4Center for Bleeding Disorders, Careggi University Hospital, Florence, Florence, 5Angelo Bianchi Bonomi Hemophilia and Thrombosis Center, Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy

**Background:** Afibrinogenemia (AF) and hypo-fibrinogenemia (HF) patients (pts) experience hemorrhages or thromboses, and the clinical management can be difficult.

**Aims:** To obtain information on AF/HF clinical phenotype and management.

**Facts:** This is a spontaneous, retrospective, multicenter national study. Data are collected from clinical records.

**Results:** 2 AF and 12 HF pts have been enrolled (6M, 8F). Median follow-up: 39 months (1-553). Median fibrinogen activity/antigen level: 78mg/dL (0-150)/73mg/dL (0-140). Five pts experienced epistaxis, hematomas, ecchymoses, menometrorrhagia, intra-abdominal bleeding, gum hemorrhages. Fresh frozen plasma, fibrinogen concentrate (FC), cryoprecipitate, whole blood, tranexamic acid were administered in the majority of these events. One ischemic stroke, 1 lower limb arterial and 1 cerebral sinus thrombosis, 1concomitant aortic and inferior vena cava thrombosis occurred: 3 events during FC therapy, 1 during perioperative period. Heparin, low molecular weight heparin (LMWH), anti-platelet agents, fibrinolytic agents, warfarin were then administered. One gastrectomy, 1 lower limb amputation, 5 gynecological, 1 otorhinolaryngological and 1 plastic surgery were performed in 2AF and 3 HF pts: in AF patients 2 surgeries were performed after FC therapy, 3 in HF patients 2 surgeries were performed after perioperative treatment with LMWH. No visceral bleeding was observed after 2 surgeries performed without prophylaxis. Eight pregnancies were initiated in 3 HF women. Two spontaneous deliveries (SD) and 2 cesarian sections (CS) were performed; 4 abortions occurred. FC prophylaxis and LMWH were administered during pregnancy in 3 and 4 cases, respectively. One venous thrombosis, 2 hemorrhages, 1 DIC and 4 complicated pregnancies were recorded. FC was administered at delivery and LMWH during peripuerium, for the 2 CS. No complications at delivery occurred.

**Summary/Conclusions:** AF and severe HF pts experience severe hemorrhagic/thrombotic events. The intervening clinical situations are difficult to manage. Further large scale data collections are necessary in order to provide useful information to better characterize and manage patients suffering from these rare diseases.

### E975

**NOVEL MUTATIONS IN THAI CHILDREN WITH CONGENITAL FACTOR VII DEFICIENCY**

D. Sosothikul1,1, T. Puosongchai1, R. Ittiwut1, P. Komvilaisak2, C. Traivaree3

1Department of Pediatrics, Chulalongkorn University, Bangkok, Bangkok, 2Department of Pediatrics, Khon Kaen University, Khon Kaen, 3Department of Pediatrics, Phramongkutklao Hospital and College of Medicine, Bangkok, Thailand

**Background:** Congenital factor VII (FVII) deficiency is a rare autosomal recessive coagulation disorder resulted from mutations in the FVII gene (F7). The disease severity is not correlated with FVII levels but might be determined by molecular defects in F7.

**Aims:** To delineate the phenotypic and genotypic characteristics of patients with congenital FVII deficiency.

**Methods:** We described demographic data, clinical manifestations, and outcome of patients with congenital FVII deficiency. F7 mutation analysis was performed by PCR-direct sequencing.

**Results:** Of the ten patients diagnosed with FVII deficiency, five (50%) were males. The median age (range) at diagnosis was 19 days old (1-730). Consanguinity was found in 50% of the patients. Of the nine patients (90%) classified as severe, six patients presented with intracerebral hemorrhage within the first month of life, two presented with gastrointestinal bleeding and one presented with hemorrhaxis. There were eight different alterations identified. Four have been previously reported (c.1091G>A (p.R364Q), c.1238G>A (p.R413Q), c.1256C>T (p.T419M), and c.681G>T (IVS6+1T)). Four were novel (c.1192G>T (p.R391L), c.1318G>C (p.G437R), c.1192G>A (p.R391L), c.1318G>C (p.G437R), c.1192G>A (p.R391L), c.1318G>C (p.G437R), and c.1256C>T (p.T419M)) and associated with major bleeding especially during infancy.

**Summary/Conclusions:** This study reported Thai children with congenital FVII deficiency presented with life-threatening bleeding especially in the first year of life. Pathogenic including newly identified variants in the F7 gene were detected in all cases. Genetic counseling can be appropriately provided to reduce the risk of disease recurrence in the families at risk.

### E977

**RETROSPECTIVE REVIEW OF FOUR YEARS OF VON WILLEBRAND’S FACTORS AS SURGICAL PROPHYLAXIS IN VON WILLEBRAND’S DISEASE**

S. Bal1, M.K. Riaz1, D. Peters1, J. Palascak1, S. Girnius1

1Department of Hematology, University of Cincinnati Medical Center, Cincinnati, United States

**Background:** Von Willebrand disease (vWD) is the most common inherited bleeding disorder that manifests as easy bruising, mucocutaneous bleeding and excessive hemorrhage with invasive procedures. In 2007, Humate-P, a lyophilized concentrate of purified VWF and FVIII, was approved in the United States for treatment and prophylaxis. Current guidelines per National Heart, Lung, and Blood Institute (NHLBI) Expert Panel recommend 40-60 U/kg pre-operatively, followed by maintenance dose of 20-40 U/kg for 7-14 days for major surgery and 5 days for minor surgery. Here, we report a single-institution experience of a short course of Humate-P as surgical prophylaxis.

**Aims:** To assess if an abbreviated schedule of Humate-P given as perioperative-dose of 40 U/kg pre for 2 days and 40 U/kg post for 2 days is safe and effective as the standard therapeutic dose of 40-60 U/kg preoperative and 20-40 U/kg post for 4 days in patients with vWD undergoing scheduled surgical procedures and for 4 days (one dose pre-op and one post-op) for one off centre due to the abbreviated surgical procedures.

**Methods:** We retrospectively identified 202 patients with known diagnosis of vWD at our institution that underwent surgical procedures requiring prophylaxis between 2002-2017. Ninety elective surgical events occurred among these patients that required peri-operative prophylaxis with Humate-P. These patients were treated with peri-operative dose of 40 U/kg on D0-1 for extensive dental procedures and for D0-3 for minor and major surgery. The definition of bleeding risk was based on NHLBI guidelines.

**Results:** Eighteen (20%) were males and 72 (80%) were females. Type I vWD constituted 94.4% (85/90). 84.4% Caucasian patients, 8.8% African American, 1.1% South Asian. Twenty-nine (32.2%) procedures were categorized as major surgery, 62 (66.6%) were minor surgery and 2 (2%) uncomplicated dental procedures. Eighty-four (93.3%) achieved excellent hemostatic efficacy defined as clinical hemostasis within normal limits. Six (6.6%) surgeries had good hemostatic efficacy defined as slight oozing. Five (6%) patients required blood transfusions.
(1-3 units packed red blood cells). 100% excellent-good outcomes similar to longer factor replacement schedules were noted. No deaths or thromboembolic events were noted. One patient required re-admission for post-op hematoma following gynecologic procedure. Thirty-four (37.7%) patients were discharged either same day or after overnight observation. Von Willebrand factor (VWF) is necessary to form a platelet plug by recruiting Factor VIII and platelets to damaged vessel walls. We believe that four days is sufficient for the formation a stable platelet plug and further downstream hemostasis is presumably VWF-independent. Here, we demonstrate safety and efficacy of a two to four day regimen of Humate-P, with only one person requiring re-admission for a post-operative hematoma. Current guidelines for surgical prophylaxis of VWD are based on expert opinion and lack level 1 evidence. Prolonged exposure may place patients at risk for unnecessary side effects, including thromboembolism and protracted hospitalization, and also causes financial toxicity. One unit of Humate-P costs 1.2 USD, which translates to enormous cost savings. Cumulatively, we were able to save ~1.5 million USD in these 90 surgical events using our abbreviated schedule.

Summary/Conclusions: Perioperative dose of 40U/Kg for 2 days (one dose pre-op and one post op) for extensive dental procedures and for 4 days (one dose pre-op and for 3 days post-op) for minor and major surgical procedures are associated with excellent hematologic outcomes and significant cost savings. However, this is single institutional data with limited number of patients and there remains a need for further studies to better define the exact dosing and duration of surgical prophylaxis.

E978

AUDIT ON MANAGEMENT OF HIGH INTERNATIONAL NORMALIZED RATIO (INR) IN WARFARINISED INPATIENTS

H. Hendra1, V. Gorur1,*, W. Nagi2
1Haematology, Broomfield Hospital, Chelmsford, United Kingdom

Background: Warfarin is the commonest used oral anticoagulant with an effective antide. The British Committee for Standards in Haematology guidelines recommend administration of 25-50µg of four factor Prothrombin Complex Concentrate (PCC) and intravenous (IV) Vitamin K 5mg for patients with major bleeding, 1-3mg of Vitamin K intravenously for those with minor bleeding and 1-5mg of Vitamin K orally for patients with INR >8 and who have no signs of bleeding.

Aims: The aim of this audit was to compare our hospital’s performance against the above guidelines.

Methods: A total of 76 patients admitted between 01/08/2015-31/01/2016 were analysed retrospectively.

Results: There were 103 incidents with INR level 5-8 and 24 with INR >8 in these 76 inpatients. Bleeding was documented in 18/127 cases, which included 6 incidents of major and 12 incidents of minor bleeding. In major bleeding, warfarin was withheld and Vitamin K administered. However, 4/6 (66.7%) of these patients got a dose different to 5mg advocated. Also, PCC was prescribed in only 50% of these patients. While 9/12 (75%) patients with minor bleeding received Vitamin K, only 3 of these 9 patients received the recommended dose of 1-3mg IV. Vitamin K was unnecessarily given to 9/16 (56.2%) non-bleeders with an INR between 5-8. Additionally, the recommended dose and route of administration of Vitamin K 1-5mg PO was followed only in 7/16 (44%) of non-bleeders with INR >8.

Summary/Conclusions: Our audit highlighted that there is less than 100% compliance in the recommended dose and route of vitamin K administration. A flowchart containing the guidelines will be designed to improve the management of high INR. To increase the awareness of this issue, teaching sessions for junior doctors and nursing staff are planned. A re-audit will be conducted once these steps are in place.

E979

NOVEL AND RECURRENT F7 MUTATIONS IN KOREAN PATIENTS WITH COAGULATION FACTOR VII DEFICIENCY

H. Kim1,*, K.-Y. Yoo2, K.-O. Lee3, S.-H. Kim1, H.-J. Kim1
1Laboratory Medicine & Genetics, Samsung Medical Center, Sungkyunkwan University School of Medicine, Korea Hemophilia Foundation, 2Samsung biomedial Research Institute, Seoul, Korea, Republic Of

Background: Coagulation factor VII deficiency is one of rare hereditary bleeding disorders with relatively limited clinical and genetic data. Aims: This study aimed to characterize F7 gene mutational patterns of Korean patients with coagulation Factor VII deficiency including their clinical and laboratory variability.

Methods: F7 gene mutations of total 16 unrelated Korean patients with Factor VII deficiency were identified by direct sequencing analyses of all exons and flanking intronic sequences. Variants were assigned according to the recently released criteria of 2015 ACMG standards and guidelines.

Results: A total of 14 mutations (pathogenic or likely pathogenic) were detected including four novel mutations (Glu66Lys, c.681+3A>T, Glu66Alafs, Ile290del).

Six (38%) patients have 2 mutant alleles and three mutations were recurrently identified. The most frequent mutation detected in this study was Cys389Gly detected in 37% (11/30) patients, validating the data of our previous patient cohort.

Summary/Conclusions: Correlation of genetic data with coagulation laboratory and clinical findings suggested the presence of modifiers, which warrants further investigation in a larger cohort of patient for better clinical prediction and management in this rare bleeding disorder.

UTILITY OF CD157 IN A FLAER BASED SINGLE TUBE FIVE COLOR COMBINATION FOR SCREENING OF PAROXYSMAL NOCTURNAL HEMOGLOBINURIA CLONE.

K. Rahman1, *, R. Gupta1, S. Harankhedkar1, T. Gupta1, M. Sarkar1, S. Nityanand1 1Hematology, Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India

Background: Fluorescent Aerolysin (FLAER) based flow cytometric analysis of polymorphs and monocytes is the gold standard for the screening of paroxysmal nocturnal hemoglobinuria (PNH) clone. In recent years CD157 has been identified as a PNH marker which targets both polymorphs and monocytes. It can be used in a single tube five color combination to screen polymorphs and monocytes simultaneously.

Aims: The objective of this study was to analyse the utility and advantage of CD157 in the PNH screening along with its ability to replace CD24 and CD14.

Methods: Our routine protocol for PNH screening included single tube six color antibody cocktail in following combination: FLAER-AF488, CD24-PE, CD15-PerCP, CD55-PE-Cy5.5, CD14-PerCy7, CD64-APC, CD45-APC H7. We assessed the utility of single tube 5 color combination of FLAER-AF488, CD15-PE, CD15-PerCP, CD55-PE-Cy5.5, CD64-APC, CD45-APC H7 for PNH screening and compared the results with the routinely used 6 color panel. Laboratory cutoff for CD157 was defined by running 10 samples from healthy individuals. Sensitivity analysis was assessed in spiking experiments by diluting a PNH positive sample with large clone size in a serial 10 fold dilution. Inter assay and intra assay precision analysis was done by running samples in triplicates across different clone size range and calculating the coefficient of variance (CV). Correlation of PNH clone size obtained from CD24/CD14 and CD157 was assessed by analysing a total range and calculating the coefficeint of variance (CV). Correlation of PNH clone size obtained from CD24/CD14 and CD157 was assessed by analysing a total range and calculating the coefficeint of variance (CV). Correlation of PNH clone size obtained from CD24/CD14 and CD157 was assessed by analysing a total range and calculating the coefficeint of variance (CV). Correlation of PNH clone size obtained from CD24/CD14 and CD157 was assessed by analysing a total range and calculating the coefficeint of variance (CV).

Results: CD157 was sensitive at the level of 10^-2 and better. Frequency of cells with PNH phenotype in normal samples were found to be <0.002%. The CVs of intra-assay precision analysis ranged from 0.92% to 3.24% for granulocytes and 1.92% to 5.36% for monocytes. The PNH clone size obtained by CD157 based analysis was highly comparable to those obtained by CD24/CD14 based assay (R2=0.993). CD157 was found much better than CD24/CD14 in identifying the type II PNH clones. There was no false positive or false negative result. The cost of analysis was found to be approximately 15% lesser than the routinely used 6 color assay.

Summary/Conclusions: CD157 is a robust, reliable and potentially useful universal marker for PNH screening. Its inclusion in a single tube five color FLAER based panel is a cost effective approach which is ready to replace CD24/CD14 from routine PNH screening.

IMMUNOPHENOTYPIC DYSPLASTIC FEATURES IN PATIENTS WITH APLASTIC ANEMIA

Y. Davydova1, *, E. Parovichnikova1, I. Galtseva1, E. Mikhaylova1, N. Kapranov1, A. Kohn1, L. Kuzmaya1, V. Troitakaya1, Z. Fidarova1, T. Mosseva1, V. Savchenko1 1Federal State-Funded Institution National Research Center for Hematology of the Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation

Background: Multicolor flow cytometry (MFC) of bone marrow (BM) is a promising additional approach to the diagnosis of myelodysplastic syndromes (MDS). Aplastic anemia (AA) as MDS characterizes by cytopenias and dysplastic features in BM by morphology are absent. It is well known that up to 15% of AA transformed in MDS over time. It is possible to suggest that in some cases of AA immunophenotypic abnormalities can also be identified.

Aims: To study and compare the presence of dysplastic features by MFC in AA and MDS without excess of blasts.

Methods: The study included 14 patients with AA (8m, 6f, median age 33), 28 patients with MDS de novo without excess of blasts by morphology (13m, 15f, median age 59). MDS group included 3 patients with 5q-syndrome, 4 - RCUD, 3 - RARS, 18 - RCMD. 20 patients with cytopenias constituted the control group (4m, 16f, median age 42) due to B-12 deficiency anemia, iron-deficiency anemia, Fanconi anemia, hemolytic anemia, β-thalassemia, ITP, hepatitis C, multiple myeloma, Burkitt’s lymphoma. BM of 33 healthy donors was used as the reference values. MFC was performed according to International Leukemias and Myelodysplasias Study Group. The reference values were adopted for the reference values. MFC was performed according to International Leukemia and Myelodysplasias Study Group. The reference values were adopted for the reference values. MFC was performed according to International Leukemia and Myelodysplasias Study Group. The reference values were adopted for the reference values. MFC was performed according to International Leukemias and Myelodysplasias Study Group. The reference values were adopted for the reference values.

Results: Among MDS patients without excess of blasts assessment “B” and “C” scores were obtained in 78.6% (sensitivity). Increased proportion of CD34+ myeloblasts was in 35.7% of cases, increased CD56 and CD7 - in 42.9%. The most common abnormalities were: increased CD66 (53.8%), abnormal patterns (39.3%), low granularity (35.7%) in granulocytes; increased expression (21.4%) and abnormal patterns (28.6%) in monocytes. 64.3% (n=9) patients with AA (100%) were assessed as “A”, 21.4% (n=3) as “B” and 14.3% (n=2) as “C” with high concordance of “B” and “C” assessment. Increased expression of CD117 and expression of CD56 on CD34+ cells were seen. AA patients with “B” and “C” showed increased expression of CD66, CD64 and decrease CD10 expression on granulocytes. Abnormal patterns were less common than in MDS patients. The increased proportion and CD64 expression in monocytes were more frequent than in MDS patients. All patients not diagnosed with AA, MDS were assessed as “A” (specificity 100%). But some MFC abnormalities were found in them: abnormal expression of CD34 (35%) and CD45 (30%) on CD34+ myeloblasts, and increased CD64 expression (20%) on granulocytes (pic.).

Summary/Conclusions: Flow cytometry MDS study with Ogata/Wells scale has a high sensitivity and specificity. Immunophenotypic abnormalities characterizing dysplastic features can also be found in AA patients up to 35% of cases. Increased expression of CD56 on CD34+ myeloblasts, granulocytes and monocytes is commonly found in AA patients. Perhaps the appearance of MFC dysplastic features foreshadows the MDS-transformation of AA, but requires further prospective studies.

SURGICAL MANAGEMENT OF PATIENTS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA (PNH) – DATA FROM THE SPANISH PNH REGISTRY

S. De La Iglesia1, *, C. Notario McDonell2, A. Gayà Valls3, M.T. Cedena

1University of Navarra, Spain, 2Hospital Universitario-Complejo Asociado de Navarra, Spain, 3Hospital Universitario de Sant Pau, Barcelona, Spain

Background: Multicolor flow cytometry of bone marrow (MFC) is a promising additional approach to the diagnosis of myelodysplastic syndromes (MDS). Aplastic anemia (AA) as MDS characterizes by cytopenias and dysplastic features in BM by morphology are absent. It is well known that up to 15% of AA transformed in MDS over time. It is possible to suggest that in some cases of AA immunophenotypic abnormalities can also be identified.

Aims: To study and compare the presence of dysplastic features by MFC in AA and MDS without excess of blasts.

Aims: Here we report data on the clinical management and treatment results of patients with PNH undergoing surgery.

Methods: We collected data on 14 surgical interventions of 11 patients (8 males; age, 25-76 years). All patients had a high prevalence of PNH clone cells (55-99% in PMN) and were receiving eculizumab (ECU). Types of surgery were: 6 laparoscopic cholecystectomies, a transjugular intrahepatic portosystemic shunt, a distal splenoportal shunt, a laparoscopic Achilles allograft ligation, a gastrectomy, an emergency appendectomy, and 3 urologic interventions. Ten patients received ECU 900mg, while one (patient E, surgery 6) received 1200mg since he had developed hemolysis at a previous surgical intervention (surgery 5). In two cases (patient G, surgery 7; patient H surgery 11), an additional dose of ECU was administered before surgery. Patient H (surgery 11) had developed hemolysis at previous surgical interventions (surgeries 9 and 10). In most cases, either the date of the ECU dose was taken into account when scheduling surgery or the ECU dose was moved forward to coincide with the date of surgery. The time between the last ECU dose and surgery was normally one day (range, 1-8).

Results: In nine cases, transfusions were required due to hemorrhagic complications. Patient I (surgery 12) had a thrombotic event leading to acute myocardial infarction one week after surgery. Increased hemolysis was observed (increased LDH and/or presence of hemoglobinuria) in five cases (patients E, H, I and K; surgeries 5, 9, 10, 12 and 14) during the week following surgery. Two of these patients (patients E and H) later underwent additional surgery (surgery 7 and surgeries 10 and 11, respectively). The pre-surgical ECU dose was increased in surgery 6 (patient E) and an extra dose was administered in surgery 11 (patient H) and no hemolysis was observed. (See Table 1).

Table 1.

**EFFICACY OF ECULIZUMAB IN PAROXYSMAL NOCTURNAL HEMOGLOBINURIA (PNH) PATIENTS WITH OR WITHOUT APLASTIC ANEMIA:**

**Methods:** The prospective study of Korean PNH cohort includes 46 total patients, 12 (26%) were classified as having PNH/AA and 34 with classic PNH. Of 46 total patients, 12 (26%) were classified as having PNH/AA and 34 with classic PNH. There were no substantial differences in laboratory findings, transfusion requirement, or clinical outcomes between the two groups. Treatment with eculizumab induced a rapid inhibition of hemolysis. At the time of 6 month follow-up, LDH level decreased to near normal levels in all patients and this effect was maintained until 36 months follow-up regardless of concomitant AA. Mean hemoglobin level significantly increased from the first 6 months of eculizumab treatment to 3.5 months after the effect (hemoglobin above 10 g/dL) was sustained throughout 36 months in both groups. Transfusion-independence was achieved by 54.3% within the first 6 months of treatment and 86.4% by the last 36 months (83.3% in PNH/AA vs 87.5% in classic PNH). The mean number of RBC units transfused was significantly reduced from 8.5 units during the previous 6 months to 1.6 units for the first 6 months in total PNH patients (Fig.). There were no significant differences in clinical outcomes (ie, LDH and transfusion unit per every 6 months) with eculizumab between the two groups. All TE (n=19) patients in whom 6 received concomitant anticoagulation therapy were resolved on the eculizumab; one classic PNH patient had recurrence of TE at the same site after discontinuation of anticoagulation therapy while on eculizumab. Among 9 patients who had baseline eGFR less than 60 ml/min/1.73m², 5 patients (56%) showed improvement of eGFR during the eculizumab treatment and 4 patients stabilized eGFR.
Summary/Conclusions: Clinical outcomes with eculizumab were significantly improved compared with the baseline in patients with both PNH/AA and classic PNH. This study demonstrated that eculizumab has a beneficial role in the management of patients with PNH/AA, similar to that of classic PNH, by inhibiting hemolysis and reducing transfusion requirements, thus resulting in the improvement of clinical signs and symptoms.

E985
DIAGNOSIS AND FOLLOW-UP OF THE CLONES OF PAROXYSMAL NOCTURNAL HEMOGLOBINURIA BY FLOW CYTOMETRY
S. Oukid1, S. Taoussi1, N. Rekab1, M.T. Abad1
1Hematology, EHS ELCC CAC, Bilda, Algeria

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a very rare chronic disease associated with a clonal expansion of one or several hematopoietic stem cells carrying acquired somatic mutations of PIG-A gene resulting in GPI-AP deficient blood cells and great susceptibility to complement mediated cell lysis. Diagnosis of PNH is of importance and flow cytometry (FC) is a required tool for this. We report 33 cases of PNH diagnosed and monitored by FC.

Aims: To show the interest of flow cytometry for the diagnosis and follow-up of PNH clones in some risky haemopathies.

Methods: A PNH clone has been researched in 234 patients since August 2009 in Saint-Petebsurg, Russian Federation.

Methods: A PNH clone has been researched in 234 patients since August 2009 in Saint-Petebsurg, Russian Federation.

Results: Out of 234 cases analyzed, 201 cases (85%) showed absence of PNH clone and 33 cases (14%) had a PNH clone. There are 14 women and 19 men; Sex ratio (M/F) = 1.35, mean age = 42.27 years (17-73). Among patients who should be screened for positive PNH clone we have bone marrow failure: 25 positive (21.9%) of 114 cases screened, hemolytic anemia with negative direct coombs test (DCT), meyoldysplasia (MDS), unexplained cytopenia and thrombosis. The search for the PNH clone by FC is based on the analysis of the following monoclonal antibodies: FLAER and CD59 on neutrophils, CD55 and CD45 on monocytes and CD59 with gating on Glycophrin A for red blood cells. We judged that the patient has a PNH clone when the deficiency is >50% on at least two markers highlighted on two different lines. FC surveillance is provided in the absence of a deficit or in case of the recovery or single-line deficit.

Summary/Conclusions: Thus, in patients with AA the decrease of NK-T cell level was observed along with recovery of hemopoiesis in all the subgroup variants. Previously we have shown that the decrease of NK-T cells accompanies the recovery of TNFα and IL-4. This pattern, taking into consideration our earlier obtained data, may be the evidence of the role of NK-T cells in regulation of balance Th1:Th2 and produced by them cytokines.

Summary/Conclusions: The role of NK-T cells in development of aplasia of AA is now broadly studied. Nevertheless, up to this moment, the features of balance of T lymphocyte subsets, and, especially NK-T cells during stable and prolonged remission are not characterized yet.

Aims: To evaluate the association of T-, B-, NK and NKT cells in AA patients with the duration of remission, its completeness, duration of period free of immunosuppressive therapy (IST) and the size of PNH-clone.

Methods: The studied group included 36 patients with AA in remission, reference group – 20 patients with primary diagnosed AA. Level of T-, B-, NK and NKT cells in peripheral blood (PB) and bone marrow (BM) was evaluated using 5-color flow cytometry (Beckman Coulter, FC-500).

Results: Group of AA patients in remission was divided into subgroups in four variants: 1) according to the remission duration (<12 months, 12-24 months, 24-36 months, >36 months); 2) completeness of remission (CR); 3) duration of IST-free period (<1 year, ≥1 year); 4) PNH-clone size (0.1-1%, 1-10%, >10%). Levels of T-, B- and NK cells in AA patients with remission varied broadly in different subgroups, but there were not revealed any clear trend in their dynamics in all assigned subgroups, except for NK-T cells. In primary AA patients the level of NKT cells in PB and BM exceeded normal level 1.8- and 2.2-fold, respectively. In patients with remission ≥36 months NK-T cell level decreased significantly; then, along with increase of remission duration (24-36 months), it normalised, and in patients with remission >36 months it significantly decreased both in PB and BM (data presented in table 1). In patients with PR, as compared with primary AA patients, NKT cells decreased 2.8- and 1.9-fold, respectively, and further in CR this tendency persisted. Duration of IST-free period less than 1 year and ≥1 year was also accompanied by a significant and stable decrease of NKT cells in PB and BM. It is known that PNH-clone presence is a favourable factor for treatment response. Therefore, in order to study the association of NK-T cell level in AA remission with the size of PNH-clone. In subgroup with small PNH-clone (0.1-1%) NK-T cell level was decreased as compared to primary AA patients, and it significantly decreased further along with growth of PNH-clone size.

E987
A NOVEL DUAL-REAGENT SINGLE TUBE FLOW CYTOMETRIC ASSAY TO SCREEN PAROXYSMAL NOCTURNAL HEMOGLOBINURIA
Bommannan1, M. S. Sachin, Ahluwalia1, B. Bose1, N. Varma1
1Hematology, Post Graduate Institute of Medical Education and Research, Chandigarh, India

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is an acquired hematopoietic stem cell disorder resulting from loss of membrane-bound glycosylphosphatidylinositol (GPI) anchor protein. The disease is characterized by heterogeneous clinical phenotypes including intravascular hemolysis, cytopenia(s), bone marrow hypoplasia and atypical site thrombosis. Screening guidelines recommend documentation of the lack of at least two PNH-related anti-gens on at least two cell lineages. Alexea fluor 488 conjugated fluorescent Aerolysin (FLAER-AF488) has become a mandatory component in FCN based PNH assays.

Aims: We have analyzed the feasibility of a novel dual-reagent assay for a single tube, single tube, direct coombs test for detecting PNH.

Methods: EDTA anti-coagulated peripheral blood of patients referred to department of Hematology with clinical suspicion of classical-PNH/ aplastic anaemia, was tested with a single tube panel of FLAER-AF488/CD33/APC. Simultaneously, the routine two tube flow cytometry assay (established sensitivity of 0.1%) for detection of PNH for TNFα and IL-4 was performed (21 cases). Inclusion of granulocytes and FLAER/CD33/CD14 for monocytes) was performed in the same sample. Each tube was run till a minimum of 50,000 granulocytes were acquired or till the tube ran dry. A cluster of at least 20 FLAER negative events was considered for reporting PNH-clone positivity in both granulocytes and monocytes. The granulocyte and monocyte PNH positivity and the respective clone sizes determined by both the strategies were compared.

Results: A total of 33 patients and 7 healthy controls were analyzed by both dual-reagent and conventional strategies. Among the thirty-three patients, twelve patients concurrently showed the presence of PNH clones by both methods. Thus, the presented strategy was more effective for reporting PNH-clone in granulocytes and monocytes by both strategies, indicating complete concordance at a sensitivity of 0.2% (Chi Square p<0.000). Of the PNH positive cases, the mean PNH clone sizes among the granulocytes by dual-reagent and conven-
tional methods were 3.79% (range, 0.2-18.2) and 3.60% (range, 0.1-28.8), respectively. The mean PNH clone sizes among the monocytes by dual-reagent and conventional methods were 7.30% (range 0.2-29.4) and 7.32% (range 0.1-28.8), respectively. There was no significant difference in the granulocyte and monocyte PNH clone sizes determined by both the methodologies (p>0.000). There were significant correlations between the granulocyte PNH clone sizes (Pearson’s r=0.993, p=0.000) and the monocyte PNH clone sizes (Pearson’s r=0.991, p=0.000) detected by both the analysis strategies.

Summary/Conclusions: This pilot study demonstrates the practical feasibility of a simple, cost-effective and widely applicable dual-reagent, single tube PNH-screening assay at a sensitivity of 0.2%. The study needs to recruit patients of various hematological disorders besides healthy controls, and although seems effective for analyzing classic and subclinical PNH, the strategy has to be further standardized to achieve a sensitivity of 0.01%.

**E988**

**TREATMENT OF REFRACTORY APLASTIC ANEMIA WITH ELTROMBOPIAG: EXPERIENCE OF A CENTER**

M. Gomes1, M.J. Teles2, F. Ferreira1, J.E. Guimarães1

1Clinical Hematology, 2Clinical Pathology, São João Hospital Centre, Porto, Portugal

**Background:** Ertrombopag, a thrombopoietin receptor agonist, was approved in 2008 for the treatment of immune thrombocytopenic purpura. More recently, benefits demonstrated in the proliferation and maintenance of hematopoietic stem and progenitor cells (HSTC) led to its use and approval in the treatment of severe aplastic anemia (AA) refractory to immunosuppressive therapy.

**Aims:** In this report, we evaluated response to ertrombopag in patients with refractory severe hematologic response of one or more hematopoietic lineage, independence of side effects occurred.

**Methods:** Retrospective analysis of six patients with a diagnosis of aplastic anemia and thrombocytopenia (platelet count ≤30,000/μl), refractory to immunosuppressive therapy and ineligible for allotransplant, treated with ertrombopag. Patients characteristics, response, clinical evolution and adverse effects were evaluated.

**Results:** Four patients were female and median age at diagnosis was 66 years (36-76). Previous treatments included horse antithymocyte globulin (1), cyclosporine (4), intravenous immunoglobulin (1), corticosteroids (4) and danazol (1). Treatment with ertrombopag was associated to cyclosporine in four patients; two cases had chronic renal failure and consequent contraindication to cyclosporine. The median duration of treatment with ertrombopag at the time of this analysis was 7 months (3-12). At 3 months, all patients had platelet counts >30,000/μl (median increase, 16,500/μl). Five patients improved hemoglobin levels (median increase, 2.2g/dL); 3 of them were previously dependent on red cell transfusions, and no longer needed transfusions. Four patients increased neutrophil counts (median increase, 1110/μl). All but one patient received a maximum dose of 150mg per day. Only one patient needed temporary discontinuation due to hepatic abnormalities, that were rapidly resolved. One other patient had mild elevation of liver enzyme levels. No other relevant side effects occurred.

**Summary/Conclusions:** Treatment with ertrombopag was associated with hematologic response of one or more hematopoietic lineage, independence of blood transfusions and improved quality of life of patients with refractory severe AA. Except for infrequent and reversible hepatic abnormalities, tolerability was excellent. Thus, ertrombopag might be used in situations where other measures have failed in patients who have no indication for allogeneic stem cell transplant. A caution, however, should be taken on the risk for clonal evolution that might be further standardized to achieve a sensitivity of 0.01%.

**E989**

**DECREASED EXPRESSION OF ADHESION MOLECULES IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) CELLS OF PATIENTS TREATED WITH IBRUTINIB**

A. Guarni1, M.S. De Propris1, L.L. Milani1, S. Intoppa1, S. Farano1, N. Peragine1, P. Marigioni1, M.C. Puzo1, F.R. Maurizi2, I. Del Giudice1, R. Foschi3

1Department of Cellular Biotechnologies and Hematology, 2Department of Molecular Medicine, Hematology, Sapienza University, Rome, Italy

**Background:** The B-cell receptor (BCR) pathway in CLL plays a well recognized role in the onset and progression of the disease and the resulting development of mechanism-driven drugs is revolutionizing the therapeutic management. Ibrutinib is a BTK inhibitor that plays an important role in the BCR pathway and induces several alterations in CLL cells.

**Aims:** The modulation of the expression of adhesion molecules on the surface of CLL cells from patients treated with ibrutinib has been evaluated to analyze the effect of treatment on the relationship between the microenvironment, that promotes cell survival and proliferation, and the leukemic cells with the consequent cell mobilization and increased drug exposure.

**Methods:** In a cohort of 101 CLL patients treated with ibrutinib (420mg/die) and rituximab (375mg/m²/week) in the GIMEMA CLL1114 trial, we evaluated, before and after 15 days of therapy, the surface expression on leukemic cells of several adhesion molecules. In detail, using 8 color antibody combinations (all from Becton Dickinson, BD, San José, CA) we evaluated the MIF expression (using the FACSCanto II, BD) of CD11a, CD18, CD38, CD40, CD43, CD44, CD49d, CD62L, CD69, CD80, CD81, CD154, CD184, CD185 on CD5/CD19+ leukemic cells.

**Results:** The number of CD5/CD19+ did not increase after 15 days of treatment (52.8±5.88 vs 53.4±5.10 x 10^9/L; p=0.36) probably because of the concomitant rituximab administration, which ‘masks’ the mobilization effect induced by ibrutinib. We observed a significant down-modulation of CD62L (461±435 vs 171±146; p<0.0001), a molecule (L-selectin) that has been reported as the key factor controlling the binding of CLL cells to the endothelial walls in vivo. CD69 expression resulted also significantly decreased (744±784 vs 438±716; p<0.0041), is expressed on CLL cells in the tissue microenvironment, both in the bone marrow and in lymph nodes. We observed the significant down-modulation of the expression of CD43 (3265±2282 vs 2515±1826; p<0.0063); this antigen is utilized in CLL for the detection of minimal residual disease (MRD) and does therefore not seem a reliable marker in patients treated with ibrutinib. On the contrary, CD81 expression, another antigen utilized for MRD detection, resulted unchanged after 15 days of treatment. CD185 expression was significantly decreased (1502±1327 vs 804±887; p<0.001), while we unexpectedly observed the up-modulation of CD16 (2244±2022 vs 3182±1877; p<0.0003); both antigens participate in the BTK signaling pathway. CD40, that interacts with the activated CD4+ T cells, resulted down-modulated (722±467 vs 395±262; p<0.0001). CD38 and CD49d, when expressed in >20% of the leukemic cells, resulted significantly increased (p<0.028 and p<0.021) down-modulated: both molecules have a role in the crosstalk between the leukemic cells and the microenvironment. No significant changes were detected in the expression of CD11a, CD18, CD44, CD60, CD86 and CD154.

**Summary/Conclusions:** Within an ancillary biologic study of the GIMEMA CLL1114 protocol we observed a significant down-modulation in the expression of several adhesion molecules on the surface of CLL cells of patients treated with ibrutinib. Since these molecules promote the binding of the leukemic cells with the microenvironment, these results help to elucidate the mobilization process of CLL cells from the different compartments observed with ibrutinib and support its progressive efficacy over time in controlling the disease. A follow-up clinical analysis will define a possible correlation between these findings and response to treatment.

**E990**

**CLL CELLS UNDERGO METABOLIC REPROGRAMMING AND UTILIZE FREE FATTY ACIDS AS THEIR PRIMARY ENERGY SOURCE**

1Hematology, Davidoff Cancer Center, Beilinson Campus, Petah Tikva, Israel, 2Department of Leukemia, The University of Texas, MD Anderson Cancer Center, 3Department of Leukemia, The University of Texas, MD Anderson Cancer Center, Houston, Texas, United States

**Background:** We previously demonstrated that CLL cells undergo metabolic reprogramming and utilize fatty acids as their primary energy source. This mechanism contributes to the progressive resistance to ibrutinib treatment and supports the maintenance of myeloid-like signature of the leukemic cells.

**Aims:** We aimed to validate the role of free fatty acids (FFA) in the metabolic reprogramming of CLL cells, and to elucidate the proteomic changes associated with this process.

**Methods:** We carried out a proteomic analysis of CLL cells, under normal medium condition (control) and in the presence of 5mM palmitate (a saturated FFA) as a source of FFA. Protein expression was analyzed by Tandem Mass Tag Protein Profiling (TMT) and identified by LC-MS/MS on a Orbitrap. We performed a differential analysis to identify proteins significantly changed by FFA supplementation. In addition, we assessed the expression of selected genes associated with metabolic reprogramming by qRT-PCR.

**Results:** We observed a significant downregulation of proteins involved in mitochondrial ATP production (complexes I, IV, V andsuccinate dehydrogenase) and upregulation of proteins involved in FFA metabolism and utilization, such as peroxisomal fatty acid CoA ligase and mitochondrial acyl-CoA synthetase. Moreover, we identified a signature of proteins involved in the immune-stimulatory pathway, indicating a shift toward a more aggressive phenotype. We also observed a downregulation of the B-cell receptor (BCR) pathway components, consistent with the impact of ibrutinib treatment. Finally, we found a correlation between the proteomic changes and the expression of genes involved in metabolic reprogramming, supporting the role of FFA in the modulation of the metabolic phenotype.

**Summary/Conclusions:** Our findings provide insights into the metabolic reprogramming of CLL cells and support the role of FFA in the progressive resistance to ibrutinib treatment. These results may pave the way for the development of new therapeutic strategies targeting the metabolic pathways in CLL cells.
Background: The gene expression profile of chronic lymphocytic leukemia (CLL) cells revealed a homogeneous phenotype related to memory B cells accompanied by an aberrant expression of several proteins. For example, lipoprotein lipase (LPL), typically expressed in adipocytes, is readily detected in CLL cells. However, unlike their normal counterparts which are resting cells, CLL cells do proliferate. What energy source CLL cells use and which metabolic pathway they recruit is currently unknown. Because the gene expression profile of CLL cells is skewed towards that of adipocytes, and because they proliferate at similar rates, we hypothesized that like adipocytes CLL cells utilize free fatty acids (FFA).

Aims: To determine whether CLL cells are capable of utilizing FFA for energy production. (B) Determine whether lipid metabolism in CLL is LPL dependent. (C) Determine why LPL is aberrantly expressed in CLL cells.

Methods: Peripheral blood (PB) and bone-marrow derived lymphocytes were obtained from previously untreated patients with CLL. Imaging of CLL cells was done by electron microscopy, and PB lymphocytes were stained for Oil red O. Confocal microscopy studies helped in determining the cellular localization of LPL. To study the capacity of CLL cells to utilize FFA we developed an assay that measured the oxygen concentration in the sera of cultured CLL cells prior to and after adding FFA. In addition we measured the oxygen consumption of CLL cells derived from ibrutinib-treated patients. We used immunoprecipitation (CHiP) and luciferase assays to study the binding of STAT3 to the LPL promoter.

Results: To study whether CLL cells are capable of utilizing FFA we cultured them and determined the concentration of cultured media-dissolved O2 (dO2) prior to and after adding FFA, assuming that if the cells oxidize the acid, dO2 levels will drop. Indeed, after 48 hours incubation with FFA dO2 levels were markedly reduced as compared with the dO2 levels in media of non-transfected cells. Indeed, dO2 levels in cultured CLL cells dropped to about 4% of the levels in media without FFA. Intriguingly, the levels of dO2 remained unchanged if CLL cells were incubated in the presence of FFA and ibrutinib. Similarly, the dO2 levels of CLL cells obtained from ibrutinib-treated patients remained constant, suggesting that ibrutinib disrupts the capacity of CLL cells to utilize FFA. Oil Red O staining of CLL bone marrow smears detected lipid deposits and electron microscopy confirmed the presence of lipid vacuoles in the cytoplasm of peripheral blood CLL cells but not in normal B cells, suggesting that like adipocytes, CLL cells store lipids in intracytoplasmic lipid vacuoles. Similar to adipocytes CLL cells express LPL which mediates the uptake of lipid particles into the cells and catalyze the hydrolysis of triglycerides into free fatty acids. Indeed, freshly isolated CLL cells expressed LPL in the cytoplasm and in the cytoplasm of CLL cells. Furthermore, using small interfering RNA (siRNA) we knock-downed LPL mRNA levels and found that LPL-siRNA reduced the capacity of CLL cells to utilize FFA, suggesting that the lipid metabolism in CLL is LPL dependent. Because STAT3 is constitutively active in CLL cells, and because the LPL gene harbors STAT3 binding sites, we sought to determine whether STAT3 activates the LPL gene. Indeed, transfection of luciferase reporter gene constructs driven by LPL promoter fragments into MM1 cells revealed that STAT3 activates the LPL promoter. In addition, CHiP confirmed the binding of STAT3 to the LPL promoter. Furthermore, transfection of CLL cells with STAT3-shRNA downregulated LPL transcripts and protein levels, confirming that STAT3 activates the LPL gene.

Summary/Conclusions: Our data suggest that CLL cells undergo metabolic reprogramming and use strategies normally utilized by adipocytes. This process is driven by constitutively activated STAT3 and is inhibited by ibrutinib.
ence or absence of IL-4. Most of the investigated samples in this series showed reduced surface FcγR expression and increased surface IgM expression after IL-4 treatment, but a few cases showed only reduced FcγR expression and no change in IgM expression. Interestingly, these samples also showed greater anti-IgM induced phosphorylation of SYK, PLCγ2, AKT and ERK, suggesting that downregulation of FcγR is the primary mechanism through which IL-4 regulates the BCR signaling capacity of CLL cells. FcγR is downregulated by IL-4 and shows reduced expression in LN CLL cells, which could represent a mechanism to allow CLL cells to respond more effectively to stimulation with antigen encountered in the appropriate context.

Summary/Conclusions: These data show that FcγR is a negative regulator of BCR signaling in CLL cells. Overexpression of FcγR could be at least in part responsible for the reduced BCR signaling capacity of PB CLL cells. FcγR is downregulated by IL-4 and shows reduced expression in LN CLL cells, which could represent a mechanism to allow CLL cells to respond more effectively to stimulation with antigen encountered in the appropriate context.

E994 TRANSCRIPTION FACTORS AND CHECKPOINT INHIBITORS EXPRESSION WITH AGE: MARKERS OF IMMUNOSENESCENCE?
L. Damg, K. Willard-Chalmers2, S. Garaud3, H. Duvillier1, J.-N. Lodewyckx2, C. Solinas2, C. Gu-Trantien2, B. Stamatiopoulos1, C. Sibille 3, D. Bron1, 1Clinical and Experimental Hematology, 2Molecular Immunology, 3Anatomopathology, INSTITUT JULES BORDET, ULB, Brussels, Belgium

Background: Aging is characterized by a progressive decline in immune surveillance that favors tumor development in older patients. One mechanism used by malignant cells to escape immune surveillance is the upregulation of immunomodulatory processes.

Methods: Peripheral blood mononuclear cells were isolated from whole blood using Lymphoprep (Stemcell Technologies) density gradient centrifugation. Lymphocyte subsets (CD19+, CD3+CD4+, CD3+CD8+) were isolated for subsequent molecular analyses using the MACS Technology (Miltenyi), with the purity of each lymphocyte subpopulation between 95%-99%. PD-1 (PDCD1), PD-L1 (CD274), IL-4, IFNG, BACH2, and PRDM1 mRNA transcripts were quantified using qRT-PCR. BACH2 and BLIMP1 (PRDM1) protein expression were examined by Western blotting.

Results: Blood samples were obtained from 60 healthy volunteers and 41 untreated B-cell lymphoproliferative leukemia (B-CLL) patients (median: 67y). Healthy donors (HD) between the ages of 20 to 90 years subdivided into <50 years (median: 36yo) and >50 years (median: 65yo). BACH2 mRNA expression in the HD groups is significantly down-regulated in CD4+, CD8+ T cells and CD19+ B cells from the older HD group (p<0.0012; 0.0045 and 0.0367, respectively). BACH2 expression was further reduced in CD4+, CD8+ T cells, and CD19+ B cells from CLL patients compared to HD well balanced for gender (p<0.01; <0.0001 and 0.0043). PRDM1 mRNA expression was inversely correlated with BACH2 in CD4+, CD8+ T cells and CD19+ B cells (r=0.61; 0.71 and 0.85, respectively). Curiously, PRDM1 was – as expected – significantly up-regulated in CD4+ and CD8+ T cells (p<0.0034; p<0.0017) from B-CLL patients but not in their leukemic B cells. Western blotting analysis demonstrated that BACH2 and BLIMP1 (PRDM1) protein expressions in the T and B cell subpopulations were significantly correlated with transcript expression. BACH2 and BLIMP1 protein expressions were both significantly correlated with BCR and PD-1 expression (r=0.87). We also observed that BACH2 down-regulation is correlated with increased IL-4 mRNA expression (r=0.67) but not IFNG in CD4+ T cells. These observations suggest that BACH2 down-regulation in CD4+ T cells could enhance the expression of effector memory-related genes, particularly Th2 such as IL-4 and PRDM1. CD4+ T cell mRNA expression was up-regulated in CD4+, CD8+ T cells (p=0.0153 and 0.0214) in the older HD group and also up-regulated in the T cells from B-CLL patients (p=0.0014 and 0.0023) when compared to age-matched HD population. High PD-1 mRNA expression was correlated with increased age in HD B cells (p=0.04) with a further increase detected in CD4+ T cells (p=0.001). We also observed an inverse correlation between BACH2 and PD-1 in CD4+, CD8+ T cells (r=0.62 and 0.68), and between BACH2 and PD-L1 in CD19+ B cells (r=0.66).

Summary/Conclusions: These data suggest that down-regulation of BACH2/PRDM1 and up-regulation of PD1/PD-L1 mRNA expression in major lymphocyte subsets from CLL patients and older healthy controls are significantly correlated with the aging immune cells and could be part of the immunosenescence process.

E995 T-CELL EXHAUSTED PHENOTYPE IS ENHANCED DURING DISEASE PROGRESSION IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL)
I. Jiménez1, S. Bobillo2, P. Abrissquetta2, C. Palacio2, J. Carabia1, M.J. Terol3, M. Crespo1, F. Bosch1
1Experimental Hematology, 2Hematology, Vall d’Hebron Institute of Oncology, Barcelona, Spain

Background: The different biological mechanisms leading the clinical progression of CLL from early stages are currently not fully elucidated. Different progression factors that contribute to a higher probability of progression, such as genetics, immunosenescence, and environment, cannot be easily identified and it is not able to identify an important proportion of patients that eventually progress. Clinical progression from early stages to an advanced CLL is associated with a certain reduced acquisition of molecular changes that are not able to explain the fifty percent of the CLL cases progressing. CLL cells are dependent on survival and proliferative signals from the microenvironment and are able to evade immune anti-tumoral responses using different mechanisms, which is a crucial feature for cancer development. T-cell dysfunction is one of the main sources of impaired anti-tumor immunity. In CLL, T cells show functional defects and have increased expression of the exhaustion markers PD1, CD244 and CD155 compared to T cells from healthy individuals. Taking this into account, we hypothesize that changes in the microenvironment, and particularly in T-cell exhaustion component, are contributing to the clinical progression of CLL.

Aims: In order to explore the role of the immune system in the progression of CLL we studied the immunophenotype of T cells from CLL patients using paired samples at diagnosis and progression.

Methods: A total of 14 CLL patients (median age, 69 years; median time to progression of 29.5 months) and 6 patients diagnosed with CLL that did not experience clinical progression during a median follow up of 34 months were included in the study. Multicolor flow cytometry was performed in matched samples at two time-points: diagnosis and progression before treatment or diagnosis and follow-up. We studied T-cell differentiation status based on CD45RA and CCR7 expression and the inhibitory receptors PD1, CD244, CD160, LA93, TIM3 and CTLA4. We also analyzed the expression of the transcription factors BACH2/PRDM1.

Results: We observed a significant increase in CD8+ absolute numbers (P=0.0107) and a significant decrease of the CD4:CD8 ratio (P=0.0012) with progression. T cells increased their effector memory (EM) CD45RA−CCR7− phenotype during progression (EM CD4+P=0.0353; EM CD8+P=0.0023), PD1 expression was significantly increased during progression in absolute numbers and in % of CD8+ T cells (P=0.0186) as well as in the PD1+ EM subset (EM PD1+CD4*; EM PD1+CD8* P=0.0024). Interestingly, we did not observe these changes in CLL patients that did not progress where the absolute numbers of cells expressing PD1 were either diminished or maintained during the follow-up, pointing out an important role of PD1 in regard to CLL progression. We observed that the percentage of CD8+ T cells expressing PD1 and CD160 were higher at the time of progression, especially for CD244 (P=0.0078). Moreover, the co-expression of these markers with PD1 was found on CD8+ T cells and its percentage was increased during progression (P=0.0078). Among the different subclusters, the EM and CD45RA+ (TEMRA) CD8+ T cells expressed the highest percentages of CD244 and CD160. We did not observe changes in LA93, TIM3 and CTLA4. T-bet and Eomes are essential to regulate T-cell differentiation and their expression has also been associated with a progenitor (T-bet+PD1+) or a terminal (Eomes+PD1−) exhausted phenotype in chronic viral infections. The percentage of CD8+ T cells expressing Eomes and PD1 was significantly increased during progression (P=0.0186 and P=0.0286, respectively) whereas T-bet expression was more stable.

Summary/Conclusions: T cells from patients with progressed CLL show a more severe exhausted phenotype compared to diagnosis, which is characterized by an effector memory subset with higher expression and co-expression of PD1, CD244 and CD160, as well as higher levels of the transcription factor Eomes, indicating that the terminal exhausted phenotype (EomeshiPD1hi) is predominant. These changes may contribute to the immune evasion that facilitates the progression and to the immunosuppressive scenario that dominates advanced CLL stages. Functional assays to explain why this T cell subset is enhanced during progression are currently ongoing.

E996 EARLY SPECIFIC INCREASED EXPRESSION OF SURFACE IGM BUT NOT OF OTHER ASSOCIATED MOLECULES APPEARS TO REFLECT ANTIGEN DICKENPONT AND IN CLL PATIENTS ON IBRUTINIB THERAPY
F. Forconi1,4, S. Drennan1, G. Chiiodin1, A. D’Avola1, P.W. Johnson3, L. Trentin2, G. Packham1, A.J. Steele3, F.K. Stevenson3, F. Conforzi1,4

Background: B cell receptor (BCR) signaling through surface IgM (sIgM) is key to the survival and proliferation of normal and chronic lymphocytic leukemia (CLL) cells, and can be targeted effectively by the BTK inhibitor ibrutinib. Chronic exposure of the BCR to (super)antigen leads to downmodulation of sIgM,
but not of slgD, levels and signaling capacity. This is evident in the circulating CLL B-cells which are characterized by variably reduced slgM levels/signaling. The variability influences outcome and cases with relatively higher slgM levels/signaling capacity, but not slgD, have more rapid progression, likely due to a larger proliferative component.

**Aims:** The aim of this study was to investigate the effect of ibrutinib in vivo on the clonal expansion and function of slgM and of other surface molecules associated with the BCR complex on the circulating CLL cells of patients during the early phases of therapy (first 3 months).

**Methods:** Peripheral blood mononuclear cells were collected from 12 CLL patients prior to (pre-) and at 1 week, 1 month and 3 months following commencement of single agent ibrutinib therapy. Expression of BCR-complex associated slgM, slgD, CD19 and other surface markers was assessed by flow cytometry. Signaling capacity following slgM stimulation was measured by immunoblotting. Following biotinylation of cell surface proteins, the N-glycosylation pattern of the µ chain was assessed by immunoblotting as a readout of slgM expression and function. Flow cytometric analysis was obtained from 7 patients (REC: H22/02/01).

**Results:** At week 1 of ibrutinib therapy, there was a dramatic increase in the expression of slgM on the circulating CLL cells (mean fold increase 1.6, P=0.001), while expression of slgD and CD19 remained constant. At this time point, increased slgM expression associated with full N-glycan maturation of slgM heavy-chain, indicative of recovery from antigen engagement at tissue sites. Also, the slgM levels correlated with increased anti-igM mediated SYK phosphorylation (r=0.64, P=0.03), to indicate functionality upstream of BTK. Sequential assessment at month 1 and 3 revealed that slgM levels were similar to that observed prior to therapy, with preserved upstream signaling ability. In marked contrast, the other BCR complex associated molecules slgD, CD19 and CD20 all reduced expression (P<0.001). Reduction of these markers was also accompanied by reduction of cell size and of other surface markers while overexpression of autophagy marker LC3B2 was documented.

**Summary/Conclusions:** Our data point to two major events dissociating slgM expression from other BCR-complex associated molecules. In the initial phase, the increased slgM expression and maturation, with no changes of other BCR-associated molecules, appears consequent to lack of antigen encounter, likely due to inhibition of chemokine-mediated entry to tissue sites. In the later phases the circulating CLL cells will suffer lack of tissue derived pro-survival stimuli. In their absence, CLL cells will reduce expression of several markers and cell size, possibly explained by autophagocytic mechanisms aiming to protect the circulating CLL cells from death unless ibrutinib therapy is withheld.

**ROLE OF THE COMBINATION MEK1/2 INHIBITOR BINIMETINIB AND AKT INHIBITOR MK2206 IN CLL**

S. Sandhu1,2,*, S. Mulligan2,3, G. Best2

1Acute Medical Unit, Royal Melbourne Hospital, Parkville, 2Northern Blood Research Centre, Kolling Institute of Medical Research, 3Haematology, Royal North Shore Hospital, St Leonards, Australia

**Background:** Clinical trials of ibrutinib andidelalisib demonstrate the efficacy of B-cell receptor-targeted therapies for CLL. We sought to investigate the efficacy of targeting both the BCR and the MAPK-ERK1/2 signaling pathways.

**Aims:** To evaluate the role of targeting the Ras-Raf-MEK1/2-ERK1/2 together with the PI3K-AKT pathways as a potential novel approach in treating chronic lymphocytic leukemia. In particular, assessing the efficacy of MEK1/2 inhibitor, binimetinib (MEK162), in combination with either a PI3K inhibitor, idelalisib or an AKT inhibitor, M2206.

**Methods:** All experiments conducted on primary CLL cells were co-cultured with CD40L-expressing stroma which mimics the support conferred by the tumour environment. Firstly, the effects of MK2206 and idelalisib at doses varying from 1 to 40µM were tested on primary CLL cells. Secondly, binimetinib and MK2206 were tested as single agents and in combination at 20µM against primary CLL cells. Thirdly, binimetinib at 20µM combined with varying doses of idelalisib on primary CLL cells. The mechanisms underlying the effects of binimetinib in combination with MK2206 in primary CLL cells were investigated by western blotting with changes in the expression of phosphorylated and total forms of AKT, MCL-1, and ERK1/2 assessed. Expression of B-actin was used as a loading control.

**Results:** MK2206 is effective against CLL cells co-cultured with stromal cells in a dose dependent manner. It was also observed that the primary CLL cells co-cultured with the CD40L-expressing stroma were significantly more sensitive to MK2206 than to idelalisib (Figure 1A). No cytotoxic effects of binimetinib...
were observed while the combination with MK2206 was significantly more effective than either alone, suggestive of synergy between the two drugs (Figure 1B). The analysis of binimetinib at 20μM with idelalisib failed to demonstrate any additive effects or suggestion of synergy between the two drugs (Figure 1C). Binimetinib treatment led to an increase in the activity of AKT and a decrease in ERK1/2 phosphorylation. MK2206 completely abrogated the activation of AKT and MCL-1 phosphorylation when combined with binimetinib (Figure 2A). Although we observed a reduction in AKT phosphorylation following idelalisib alone, it had no effect on the levels of AKT activity induced by binimetinib or the levels of phosphorylated MCL-1 protein. This result was irrespective of the dose of idelalisib used (Figure 2B). We explored the possibility that protein kinase C (PKC) may be involved in binimetinib-induced AKT phosphorylation. Using the pan-PKC inhibitor GF109203X (GFX), we demonstrated that inhibition of PKC significantly reduces binimetinib-induced phosphorylation of AKT with no effect on the activity of ERK1/2-MAPK (Figure 2C). These data suggest a role for PKC in the regulation of AKT activity in CLL cells.

Summary/Conclusions: The combination of binimetinib and MK2206 in vitro has been shown to be effective strategy to treat primary CLL cells. The western blot data reinforce that the increased activity observed in AKT activity in CLL cells following binimetinib treatment is independent of the idelalisib and totally abrogated by MK2206. This PIS kinase-independent regulation may be regulatively different and is likely to play a significant role. Dual inhibition of MAPK-ERK1/2 and AKT signaling may be effective at targeting the proliferative/drug-resistant compartment of CLL that resides in the tumour microenvironment.

TARGETING HIF-1α AND ITS REGULATORY PATHWAYS AS A STRATEGY TO HAMPER LEUKEMIA-MICROENVIRONMENT INTERACTIONS IN CHRONIC LYMPHOCYTIC LEUKEMIA

C. Vitale1,2, Y. Grigio1,2, M. D'Amore1, C. Ricci1, I. C. Saragaglio3, C. Salvetti1,2, C. Rigoni1, C. M. Musella1, M. D. Massaia1, M. Cosca1,2

1Hematology, A.O.U. Città della Salute e della Scienza di Torino, 2Department of Molecular Biotechnology and Health Sciences, 3Department of Oncology, University of Torino, Torino, Italy

Background: The CXCL12-CXCR4 axis has a fundamental role in the microenvironment-mediated protection of chronic lymphocytic leukemia (CLL) cells from spontaneous and drug-induced cell death. The binding of CXCL12 with CXCR4 activates multiple intracellular pathways, including RhoA- and Ras-dependent signaling. We have previously shown that co-culture with stromal cells (SC) induces in CLL cells the activation of RhoA/RhoA kinase and Ras/ERK1-2 signaling, the upregulation of Akt, and an increased activity of the transcription factor HIF-1α (Rigoni et al., Oncotarget 2015).

Aims: The purpose of this study was to identify new potential pharmacological targets involved in the CXCL12/CXCR4 axis in order to impair the protection exerted by SC towards spontaneous and fludarabine-induced apoptosis in CLL cells.

Methods: Peripheral blood was collected from 62 patients with CLL. In selected experiments, the M2-10B4 murine SC line and the HS-5 human SC line were used. Patient-derived bone marrow SC were generated from 12 patients with CLL. Where indicated, cell cultures were treated with recombinant CXCL12 (100 ng/ml), CXCR4 inhibitor AMD3100 (5 μg/ml), fludarabine (F-ara-A, 10 μM), simvastatin (1 μM), ERK1-2 kinase inhibitor PD98059 (10 μM), HF-1α inhibitor BAY89-2243 (1 μM), and P13K inhibitor idelalisib (10 μM). RhoA and Ras activities were evaluated by an ELISA based assay and by pull-down assay, respectively. ERK1-2, HIF-1α amount in whole cell extracts and in nuclear fraction, and HIF-1α phosphorylation were evaluated by Western Blot. RhoA kinase, Akt and HIF-1α activities were measured with specific immunoassay kits. CXCL12 was quantified by ELISA. Cell viability was determined by Annexin-V/propidium iodide immunostaining and flow cytometry analysis.

Results: The exposure of CLL cells to recombinant CXCL12 led to the activation of RhoA- and Ras-dependent signaling, and to the downstream upregulation of HIF-1α. The CXCR4 antagonist AMD3100 completely abrogated the positive regulation exerted by both CXCL12 and SC, thus unveiling the key role of the CXCL12/CXCR4 axis in the SC-induced modulation of these signaling pathways. The inhibition of Ras and RhoA activity by simvastatin, and the inhibition of ERK1-2 and HIF-1α by PD98059 and BAY87-2243 effectively blocked the SC-induced expression and activity of HIF-1α, significantly impairing the SC-mediated protection of CLL cells, both in absence and presence of fludarabine. Similar effects were observed by targeting the PI3K/Akt pathway with idelalisib. We then investigated whether targeting RhoA- and Ras-dependent signaling could modulate HIF-1α also at the SC level. Simvastatin and BAY87-2243 effectively inhibited HIF-1α expression both in SC lines and in patient-derived SC. Moreover, simvastatin significantly reduced the secretion of CXCL12, which is a known transcriptional target of HIF-1α.

Summary: Our data demonstrate that the targeting of HIF-1α and its regulatory pathways, both at the tumor cell and at the SC level is an appealing strategy to overcome the microenvironment-mediated protection to spontaneous and fludarabine-induced apoptosis in CLL cells.

Anna Hospital, Ferrara, 5Department Medical Sciences, University of Milan, Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Milan, Italy

Background: Chemomunotheraphy with fludarabine, cyclophosphamide and rituximab is the optimal front-line treatment for fit chronic lymphocytic leukemia (CLL) patients. IGHV mutations and FISH lesions are predictive marks of response and progression-free survival after FCR. Minimal residual disease (MRD) is the single best post-treatment predictor of long-term outcome after FCR, independent of biologic prognostic markers.

Aims: To explore whether conventional biologic markers (i.e. IGHV mutations, FISH lesions) and 7PS3, NOTCH1, BIRC3 and SF3B1 mutations can predict the obtaining of a MRD negativity after first-line treatment of CLL patients with FC and ofatumumab (FCO).

Methods: Eighty young (≤65 yrs) and fit CLL patients from 15 Italian centers were enrolled in the GIMEMA LLC0911 first-line trial and treated with 6 cycles of FCO. CLL diagnosis, treatment requirement and response were defined according to the 2008 IWCLL guidelines. MRD was evaluated in responding patients by 8-color flow cytometry in the peripheral blood (PB) and bone marrow (BM) 2 months after the end of induction (month +8), and every 6 months thereafter: flow negative cases were analyzed by RQ-PCR, according to the guidelines. The association between CLL biologic markers and MRD clearance after FCR was tested by Fisher’s exact test; logistic regression models were used to estimate the risk values in univariate and multivariate analyses.

Table 1.
17p was the consequence of an unbalanced translocation (n=167/240, 70%), abnormalities were found in the 195 patients. In the majority of cases, loss of the sole abnormality detected by K in 28/195 (14%) cases. A total of 240 17p+, 13 months and a median of 2 lines of treatment [1-10]. In 28/124 (23%) cases, years [33-88], 59% were Binet stage A, 28% B, 12% C.

OS and time to first treatment (TTFT) were calculated from diagnosis to death or first-line treatment, respectively, or last follow-up. The log-rank test was used to compare survival between groups.

Methods: A total of 195 CLL patients harboring a 17p deletion were included in this study. All the K were reviewed by the members of the study group.

Summary/Conclusions: Among the high risk group of 17p- CLL, i(17q) confines a shorter OS than the other 17p abnormalities. In addition, the gain8q aggravates the outcome as well as the presence of additional unbalanced translocations. These results confirm that patients with 17p- CLL have a variable clinical course and highlight the relevance of conventional karyotyping to identify the alterations that modulate the prognosis within these patients.

ISOCHROMOSOME 17q, UNBALANCED TRANSLocations AND 8q GAIN REPRESENT ADVERSE PROGNOSTIC FACTORS IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) WITH 17p DELETION. A GFCH STUDY

**E1002**

THE MICROENVIRONMENT REGulates THE EXPRESSION OF MiR-21 AND TUMOR SUPPRESSOR GENES Pten, Pias3 and Pcdh4 THROUGH ZAP-70 AND THE BCR SIGNALING PATHWAY. A Laboratory for Cytogenetics, Chromosomal abnormalities are present in about 80% of CLL. Among them, the loss of the short arm of chromosome 17 (17p-), unbalanced translocations, deletions, gains and isochromosomes. All these aberrations lead to the loss of one copy of the TP53 gene, the remaining allele being generally mutated. In addition, 17p- is frequently accompanied by genomic complexity. Patients with 17p- typically progress quickly and are refractory to most conventional therapies.

Aims: We evaluated if the type of chromosomal abnormality leading to 17p- and the additional aberrations could influence the prognosis.

Background: Chromosomal abnormalities are present in about 80% of CLL. Among them, the loss of the short arm of chromosome 17 (17p-), unbalanced translocations, deletions, gains and isochromosomes. All these aberrations lead to the loss of one copy of the TP53 gene, the remaining allele being generally mutated. In addition, 17p- is frequently accompanied by genomic complexity. Patients with 17p- typically progress quickly and are refractory to most conventional therapies.

Aims: We evaluated if the type of chromosomal abnormality leading to 17p- and the additional aberrations could influence the prognosis.

Methods: Peripheral blood mononuclear cells (PBMC) from 48 patients diagnosed with CLL were isolated by Ficoll-Paque Plus density gradient centrifugation. Ramos B-cells stably transfected with a vector encoding for ZAP-70 protein fused with Green fluorescent protein (GFP) or GFP only as a control were treated with Akt (LY294002), MAPK (PD98059) and STAT3 (US-124) inhibitors for 1 hour. BCR was stimulated with F(ab)2 anti-IgM. PBMC were co-cultured with bone marrow stromal cells with CD40L and CpG to mimic the microenvironment found in proliferation centers. After 48 hours CLL cells were harvested to analyze cell viability, cell proliferation and mRNA expression. Expression levels of primary miR-21, miR-21, PTEN, PDDC4 and PIA3S were measured by QRT-PCR.

Results: First, we observed that miR-21 expression was significantly higher in patients with high expression of ZAP-70. Subsequently, using stably transfected Ramos B-cells with ZAP-70 protein fused with Green fluorescent protein (GFP) or GFP only as a control we treated with Akt (LY294002), MAPK (PD98059) and STAT3 (US-124) inhibitors for 1 hour. BCR was stimulated with F(ab)2 anti-IgM. PBMC were co-cultured with bone marrow stromal cells with CD40L and CpG to mimic the microenvironment found in proliferation centers. After 48 hours CLL cells were harvested to analyze cell viability, cell proliferation and mRNA expression. Expression levels were measured using primary miR-21, miR-21, PTEN, PDDC4 and PIA3S were measured by QRT-PCR.

Results: First, we observed that miR-21 expression was significantly higher in patients with high expression of ZAP-70. Subsequently, using stably transfected Ramos B-cells with ZAP-70 protein fused with Green fluorescent protein (GFP) or GFP only as a control we treated with Akt (LY294002), MAPK (PD98059) and STAT3 (US-124) inhibitors for 1 hour. BCR was stimulated with F(ab)2 anti-IgM. PBMC were co-cultured with bone marrow stromal cells with CD40L and CpG to mimic the microenvironment found in proliferation centers. After 48 hours CLL cells were harvested to analyze cell viability, cell proliferation and mRNA expression. Expression levels were measured using primary miR-21, miR-21, PTEN, PDDC4 and PIA3S were measured by QRT-PCR.

Summary/Conclusions: Among the high risk group of 17p- CLL, i(17q) confines a shorter OS than the other 17p abnormalities. In addition, the gain8q aggravates the outcome as well as the presence of additional unbalanced translocations. These results confirm that patients with 17p- CLL have a variable clinical course and highlight the relevance of conventional karyotyping to identify the alterations that modulate the prognosis within these patients.
E1003 IMPACT OF RECURRENT MUTATIONS ON PROGRESSION-FREE SURVIVAL IN CLL PATIENTS TREATED WITH FRONT LINE RITUXIMAB-BASED REGIMENS

M. Hlozkova1,*, J. Malcikova1, N. Tom1, M. Borsky1, Y. Brychtova1, M. Doubek1, A. Panovska1, E. Diviskova1, M. Mraz1, S. Pospisilova1, J. Mayer1, M. Trbusek1
1University Hospital Brno and Faculty of Medicine, Masaryk University, Brno, Brno, Czech Republic

Background: Regimens consisting of rituximab and DNA-damaging drugs represent an important therapeutic option for patients with chronic lymphocytic leukemia (CLL). Up-to-date studies including clinical trials agreed upon the adverse outcome of TP53-defective patients that should be provided alternative treatment approaches. Additionally, mutations in NOTCH1 gene were connected with a lack of benefit from rituximab added to chemotherapy. A potential impact of other mutations commonly occurring in CLL patients remains less clear, namely regarding a role in relapse development.

Aims: (a) to assess impact of mutations in ATM, SF3B1, NOTCH1 and BIRC3 genes on progression-free survival (PFS) in CLL patients treated with front line rituximab-based regimens, and (b) to analyze clonal evolution of mutations in relapse.

Methods: We analyzed 53 CLL patients administered first line regimens FCR (fludarabine, cyclophosphamide, rituximab) or Q-FCR (FCR with reduced doses) or BR (bendamustine, rituximab); all harbored intact TP53 gene as assessed by FISH and the yeast functional analysis; 46/53 (87%) had unmutated IGHV. The next generation sequencing using MiSeq (Illumina) was done in 53 pre-therapy samples and 41 relapsed samples using three separate pan-els: ATM (exons 2-6; median coverage (MC) 6100), SF3B1/NOTCH1/BIRC3 (exons 14-16, part of 34, and 7-10, respectively, MC 11200), and TP53 (exons 2-11; MC 31500). Functional impact of ATM mutations was verified by SIFT and PolyPhen online tools. Only mutations present in >10% of reads were considered for the PFS analysis (log-rank (Mantel-Cox) test); the interval was calculated from therapy completion to clinical progression (as defined by the iwCLL recommendations).

Results: In the pre-treatment analysis, we identified 23 patients with one disrupted gene and 7 patients with two disrupted genes; the rest of the cohort analyzed consisted of 15 patients (37%) with three or more disrupted genes, followed by 6 patients (11%) with two disrupted genes; the rest of the cohort (43%) did not observe any mutations. In the pre-therapy analysis, we identified 23 patients with one disrupted gene, 10 patients with two disrupted genes, and 10 patients with three or more disrupted genes.

In the pre-therapy analysis, we identified 23 patients with one disrupted gene, 10 patients with two disrupted genes, and 10 patients with three or more disrupted genes.

Summary/Conclusions: Our pilot analysis with limited number of samples does not indicate an adverse impact of studied mutations in rituximab-based regimens.

E1004 BCR SIGNALLING PROFICIENT CHRONIC LYMPHOCYTIC LEUKAEMIA B CELLS ARE PRONE TO RITUXIMAB MEDIATED ELIMINATION IN VIVO

G. Pavlasova1,2,*, M. Borsky2, V. Sveda1,2, J. Cernak1,2, V. Seda1,2, J. Osickova1, Y. Brychtova1, M. Doubek2, S. Pospisilova1,2, J. Mayer1, M. Mraz1,2
1Molecular Medicine, CEITEC MU, 2Department of Internal Medicine - Hematology and Oncology, University Hospital Brno and Faculty of Medicine, Masaryk University, Brno, Czech Republic

Background: Anti-CD20 monoclonal antibody rituximab (RTX) has improved clinical outcome of patients with CD20-positive B-cell malignancies, including chronic lymphocytic leukaemia (CLL). However, despite the fact that RTX has been clinically used for 20 years, the exact mechanism of its action remains largely unclear.

Aims: The aim of this study was to determine susceptibility of CLL cells’ subpopulations to RTX.

Methods: Peripheral blood samples from CLL patients (N=17) were obtained and analysed before (day 0) and 24 hours (day 1) after RTX administration (375mg/m², single agent).

Results: It was described that CLL cells that interacted with stromal cells in vivo can be characterised by relatively weak cell-surface expression of chemokine receptor CXCR4 and high expression of activation marker CD55 on their surface. Furthermore, we showed that rituximab-sensitive cells had higher CD20 expression than CD20 resistant CLL cells (N=40; P=0.001). We analysed blood samples obtained from CLL patients treated with RTX as a single agent and indeed, we observed that RTX preferentially and nearly completely eliminates the CXCR4dimCD55high subpopulation after the first RTX dose (8.3% pre-RTX vs 2.1% post-RTX, P<0.0001). We further demonstrated that CXCR4 signaling proficiency of the CXCR4dimCD55high CLL subpopulation, since CD20 was proposed to play a role in BCR signalling. We observed that CXCR4dimCD55high CLL cells have higher immunoglobulin (IgM) expression (~2-fold, P<0.005) which was coupled with higher responsiveness to BCR crosslinking with anti-IgM (P=0.005). Moreover, CXCR4dimCD55high cells also have higher levels of CD19 (18, P=0.001), which is an important component of BCR complex that augments signal transduction. Furthermore, we demonstrated that CXCR4dimCD55high cells have higher phosphorylation of several proteins involved in PI3K/BCR/NFκB signalling pathway (P=0.05) compared to CXCR4dimCD55low cells obtained from the same patient. This led us to hypothesize that CXCR4 signaling proficiency is likely of physiological importance for PI3K/BCR signalling. Indeed, we observed significant reduction in phosphorylation of tyrosine-protein kinases associated with PI3K/BCR signalling after silencing of CD20 by siRNA in B cells.

Summary/Conclusions: We showed that CXCR4dimCD55high CLL subpopulation is more sensitive to RTX compared to peripheral blood of CLL patients has the highest surface levels of CD20 and is therefore preferentially and effectively eliminated by RTX. These CLL cells likely represent the most “aggressive” subclone of CLL cells since they have relatively high proliferative and BCR signalling capacity.

B cells we performed a co-immunoprecipitation assay, followed by Western blotting analysis, at steady state and after IgM (10µg/ml) stimulus. We also evaluated the interaction between c-Cbl and Lyn after treatment with 17-DMAg (500nM), a potent HSP90 inhibitor.

Results: We demonstrated that c-Cbl is overexpressed (p<0.001, Student's t test) in CLL B lymphocytes with respect to normal B cells. We found that in neoplastic B cells c-Cbl did not co-immunoprecipitate with Lyn neither after BCR trigger. We obtained similar results when we treated neoplastic B lymphocytes with 17-DMAg to dissociate the Lyn-Hsp90 complex: after 1h, 2h and 4h of treatment we immunoprecipitated Lyn demonstrating that neither before nor after IgM stimulation c-Cbl interacts with this kinase. These results support the hypothesis that c-Cbl is not involved in Lyn turnover. Data obtained from 10 independent experiments showed that in CLL neoplastic cells the phosphorylation on Y700 increased after 5' and 10' of IgM stimulus, highlighting the involvement of c-Cbl in BCR signaling.

Summary/Conclusions: These preliminary results prompt us to investigate the role of c-Cbl in the development of neoplastic clone. In CLL cells c-Cbl is overexpressed with respect to normal B cells, and upon BCR engagement it undergoes Y700 phosphorylation. However, c-Cbl is unable to stably interact with Lyn suggesting an altered c-Cbl function that contribute to affect cell homeostasis.

E1006 ACTIVATION OF SHP-1/PP2A PATHWAYS TRIGGERS APOPTOSIS IN CHRONIC LYMPHOCYTIC LEUKEMIA CELLS

F. Severin1,2, E. Tibiladi2, M.A. Pagano2, F. Frezzato1,2, V. Trimarco1,2, V. Martin1,2, F. Raggi2, L. Martinello1, M. Facco1,2, G. Zagotto1, G. Ribaudo1, V. Mencal1, L. Bordini1, A. Visentin1,2, F. Zonta2, G. Semenzato1,2, A.M. Brunati3, L. Trentin1,2.

Background: CLL B cells inability to reach programmed cell death is due to intrinsic defect and extrinsic factors. Among the intrinsic fault there is the misregulation of the phosphorylation pattern. Reversible protein phosphorylation is a fundamental post-translational modification by which virtually all cellular events are regulated. The crucial players involved in this dynamic process are protein kinases and protein phosphatases, which are placed at the different levels of cellular signaling. The Src Family Kinase (SFK) Lyn is a key factor in the dysregulation of survival and apoptotic pathways of malignant B cells in CLL. One of the effects of Lyn's action is the spatial and functional segregation of the tyrosine phosphatase SHP-1 into two pools, one beneath the plasma membrane in an active state promoting pro-survival signals, the other in the cytosol in an inhibited conformation and unable to counter the elevated level of cytosolic tyrosine phosphorylation.

Aims: Because CLL is characterized by a high level of Lyn-dependent tyrosine phosphorylation in the cytosol, we focused our attention on compounds capable of directly or indirectly driving the activation of SHP-1 which in turn could counter the action of Lyn and induce cell demise. The goal is to discover new therapeutic strategies to defeat a still incurable disease as CLL.

Methods: B cells were isolated from 37 CLL patients. Freshly isolated CLL cells incubated with increasing concentrations of nintedanib (0-24 µM) and MP07-66 (2,2-diethoxyethyl)[4-(4-hexylxoyl)phenyl][methyl]amine) for 24 and 48 hours with/without a layer of Mesenchymal Stromal Cells (MSCs). Caspase dependence was demonstrated using the pan-caspase inhibitor z-VADfmk. CLL B cells viability was tested by Flow Cytometer with Annexin V/PI test, SHP-1 and PPP2Ac expression and phosphorylation were evaluated by Western Blotting.

Results: We performed in vitro caspase activity assays on the cytosolic pool of SHP-1 in the presence of increasing concentrations of nintedanib, a receptor tyrosine kinase inhibitor recently shown to trigger SHP-1 activity. Nintedanib treatment could activate the phosphorylated (at Ser591), and inhibited, form of SHP-1 and to induce apoptosis, depending on the caspase activation, after 24h and 48h at marked level. Interestingly, we recently demonstrated that Ser591 phosphorylation of SHP-1 could be dephosphorylated by PP2A. In this scenario, the restoration of PP2A activity by a finkolimod analogue which devoid of immunosuppressive action, called MP07-66, and the subsequent dephosphorylation of PP2A substrates, was shown to trigger apoptosis, like nintedanib, in a caspase-dependent manner. Since our data suggest that the activation of either PP2A or SHP-1 is triggered by specific small molecules caused stimulate each other's activity, we treated CLL cells with nintedanib and MP07-66 together demonstrating an improved effect when used in combination.

Similar results, in all the conditions, were obtained in presence of a MSC layer, showing the capability of these treatments to counteract the protective action of tumor microenvironment.

Summary/Conclusions: In conclusion, our findings indicate that phosphatase activators may represent a new weapon against this form of leukemia. Overall, these data corroborate the hypothesis that the inhibition of PP2A is central to CLL cell viability and that its activation is facilitated by the supportive action of SHP-1, as demonstrated by the effect produced by the simultaneous use of the respective activators.

E1007 TARGETING NANOPARTICLES TO CHRONIC LYMPHOCYTIC LEUKAEMIA: EXPLOITING THE PROPERTIES OF CXCR4

C. McCallion1, A. Booth1, J. Adams3, K. Rees-Unwin3, A. Peters1, A. Plümen2, S. Webb1, J. Burthem3.
1School of Chemistry, University of Manchester, Manchester, 2School of Chemistry, University of Leeds, Leeds, 3Institute of Cancer Sciences, School of Pharmacy, University of Manchester, Manchester, United Kingdom

Background: Nanoparticle carriers of therapeutic agents (“drug delivery vehicles”) can be used to deliver drugs to specific cells through the incorporation of a “targeting ligand.” Targeting provides the therapeutic benefit of achieving high local drug concentrations while reducing off-target effects against other cells; the combined ligand/delivery vehicle system can also be manipulated to determine the uptake pathway or modulate biological effects. The CXCR4 chemokine-receptor is an attractive target for drug delivery vehicles. It is overexpressed in cancers including chronic lymphocytic leukaemia (CLL) (Doman ska et al., 2013) and binding to its ligand (CXCL12) may induce proliferation, survival or entry into protective cellular niches (Ganju et al., 1998). Targeted nanoparticles that can bind and antagonise CXCR4 could therefore allow specific drug delivery to cancer cells while simultaneously blocking CXCL12-induced chemoprotection.

Aims: A drug-design strategy was developed to synthesise and evaluate a novel CXCR4 targeting motif (BAT1) with structural similarity to Plerixafor, a CXCR4-antagonist in clinical use. A key design principle was to incorporate a polyethylene glycol (PEG) tether with a functional end-group to provide an attachment point for cargoes, particularly liposomes. The evaluation aim was to assess the effectiveness of BAT1 to deliver a chemotherapy cargo to CLL cells within an ex vivo culture system.

Methods: A three-step synthesis was used to generate BAT1 (Figure 1A); its structure and purity was confirmed using NMR, MS and HPLC. Bioactivity testing employed primary CLL lymphocytes. Assays evaluated: CXCR4 binding-affinity (flow cytometric competition assays), cell-binding characteristics (immunocytofluorescence) and blockade of CXCL12-induced signalling (immunoblot). Initial targeting assessment used a fluorescent label (Cy5) conjugated to the functional PEG tether. Cholesteryl chloroformate was then selected to conjugate BAT1 to PEGylated liposomes.

Results: The binding affinity of BAT1 (Figure 1B) was demonstrated using competition assays (CXCL12, anti-CXCR4 ab, and the bis(cyclam) drug Plerixafor). The studies confirmed BAT1 had high affinity for CXCR4 receptors expressed on primary CLL cells. Immunocytofluorescence comparison with its native ligand confirmed binding of BAT1 to the CLL cell surface, while immunoblotting demonstrated blocking of CXCL12-induced signalling (Figure 1C and 1D). The fluorescent moiety Cy5 was covalently linked to the PEG moiety as a test-cargo, demonstrating that binding affinity was retained in the presence of a cargo and that the drug competed for CXCR4 binding with related bis(cyclam) drugs. This work has been extended to attach BAT1 to liposomes, with present work focusing on optimising liposome characteristics for binding and uptake by CLL and the delivery of cytotoxic payload.

Figure 1.

Summary/Conclusions: A novel bis(cyclam) CXCR4 antagonist and targeting motif – BAT1 – has been synthesised. BAT1 demonstrates high affinity for the CXCR4 receptor, supporting targeted delivery to CLL cells. Receptor binding is associated with simultaneous blockade of CXCL12-mediated signal initiation and effect, and therefore biological modulation of target cell behaviour. BAT1.
is readily attached to liposomes through the PEG moiety, which will allow chemotherapy delivery using stealth-liposomes (Allen and Collins, 2013). Liposome size and composition will be used to drive pathway-specific uptake to different intracellular compartments. BAT1 therefore offers significant potential to enhance therapy in CLL.

THE ROLE OF THROMBOPOIETIN AS A TOOL OF IMMUNE MODULATION IN CHRONIC LYMPHOCYTIC LEUKEMIA
S. Ringelstein-Harle1,2,*, M. Fanadka2, N. A. Horowitz1, T. Kat1
1Department of Hematology and Bone Marrow Transplantation, Rambam Health Care Campus, 2Bruce Rappaport Faculty of Medicine, Technion, Israel Institute of Technology, Haifa, Israel

Background: Thrombopoietin (TPO) is the major regulator of platelet production, synthesized mainly by liver cells. The TPO receptor (TPO-R) is known to be expressed on platelets, megakaryocytes and CD34+ cells. It has been reported that patients with immune thrombocytopenic purpura, treated with TPO-R agonists, developed alterations in the T-cell repertoire and pattern of cytokine secretion from B- and T-cells. Thus, clinical activity of these agents could be attributed in part to immune modulation. In chronic lymphocytic leukemia (CLL), characterized by aberrant T-cell responses, high TPO serum levels coexist with low levels of TPO gene transcripts in the malignant cells. These observations could imply that TPO acts as an immune modulator in CLL.

Aims: The aim of the current study was to explore the role of TPO in T-cell modulation in CLL.

Methods: B-cells and CD4+ T-cells were isolated from peripheral blood mononuclear cells (PBMCs) of untreated CLL patients (Rai stages 0-IV) and healthy donors. CLL B-cells were activated with anti-CD45 and goat-anti-rabbit IgG antibodies, high-dose IL2 and TPO for 5 days. Percentage of cells retaining in G0 (non-proliferating pool) was assessed. CLL B-cells were activated with a TLR9 agonist (ODN) and TPO expression was assessed by Q-PCR.

Results: CD4+ T-cells of CLL patients expressed significantly higher levels of TPO-R (CD110) compared to T-cells of healthy donors, with a mean fluorescent intensity of 764±148 and 498±206, respectively (p<0.05; n=6). Stimulation of patients’ T-cells with TPO led to a 12% increase in the number of CD4+ T-cells (from 7.5%±5.4 to 8.5%±6.4; p<0.05; n=8), whereas pro- liferation of healthy donor T-cells remained unaffected by TPO (11.5%±5.7 and 11.4%±5.7 of G0 in p=NS; n=6). Additionally, TPO stimulation resulted in a 24% increase of Treg levels in patient T-cells (from 2.1%±1.7 to 2.6%±1.7%; p<0.01; n=8). However, the Treg levels were not altered in healthy donor T- cells subjected to TPO (0.74%±0.7 and 0.74%±0.8; p=NS; n=5), which is similar to their proliferation response to this growth factor. To determine whether CLL B-cells could be the TPO source in this disease, TPO mRNA expression in the malignant cells was assessed, demonstrating a baseline ct value of 721±296, which significantly increased to 1033±342 (p<0.05; n=6) upon ODN activation.

Summary/Conclusions: In the current study, TPO is found to affect immune properties of CLL patient T-cells, inhibiting their proliferation and increasing Treg levels. These effects have been observed in patient T-cells only, which could be partly explained by higher levels of TPO-R expression revealed on patient T-cells compared to healthy donor T-cells. The elevated TPO mRNA expression in CLL B-cells could point to them as one of the possible sources of this growth factor in patient serum. Activation of TPO-R may represent a novel mechanism of T-cell inhibition in CLL.

E1009
TREATMENT WITH BCR INHIBITORS INCREASES ROR1 EXPRESSION IN CLL CELLS
J. Kotaskova1,2,*, S. Pavlova1,2, K. Pleveova1, J. Malcikova1,2, O. Stehlikova1, L. Poppova1, H. Kockova1, M. Dubek2,3, V. Bryja4, S. Sposilovska1, O. Stehlikova1
1CMOBT, Department of Internal Medicine – Hematology and Oncology, University Hospital Brno and Faculty of Medicine, Masaryk University, 2Central European Institute of Technology (CEITEC), Masaryk University, 3Department of Internal Medicine – Hematology and Oncology, University Hospital Brno and Faculty of Medicine, Masaryk University, 4Institute of Experimental Biology, Faculty of Science, Masaryk University, Brno, Czech Republic

Background: Receptor Tyrosine Kinase-Like Orphan Receptor-1 (ROR1) expression on malignant B-cells is considered a promising target for therapy of CLL and other lymphoproliferative disorders. Recently published data suggest that combination of BCR inhibitor ibrutinib with ROR1 antibody cirtumumab can enhance treatment efficiency in CLL. Nevertheless, the variability in ROR1 expression in different stages of the disease using flow cytometry and qRT-PCR with focus on patients undergoing therapy; ii) analyze changes in ROR1 expression within individual patients during the disease course.

Methods: CLL cohort consisted of 96 CLL patients (152 samples): 23 patients with stable disease, 16 patients with active disease prior first therapy intervention, 6 patients during first therapy, 13 patients in progression before second line treatment, 3 patients in complete remission, 10 refractory patients, 9 patients treated with ibritinib before first therapy. ROR1 antigen changes in ROR1 expression we tested serial samples from 5 CLL patients (median follow up 76 months (66-131), median number of sampling points 12 (5-18)). For surface ROR1 protein analysis we used 8-colour flow cytometry (modified MRD protocol: CD45/CD3/CD19/CD5/CD81/CD79b/CD22/ROR1) in all samples. To quantify ROR1 mRNA expression changes within individual patients we performed qRT-PCR in serial CLL cells (>95% CD19+CD5+). CLL cells from samples in remission were separated immunomagnetically (Whole Blood Anti-ROR1 MicroBead Kit, Miltenyi Biotec).

Results: Using multicolour flow cytometry we confirmed ROR1 antigen/protein expression in CLL cells. We observed increased samples in patients treated with ibritinib, meanwhile 65,2% of patients with abnormal SPE exhibited at least one poor cytogenetic abnormalities such as del17p, del11q, del13q and trisomy 12 (assessed by standard cytotype, FISH analysis and QMPSF).

Summary/Conclusions: ROR1 antigen remains detectable on CLL cells during disease course even in complete remission. ROR1 mRNA levels are highly influenced by therapy administration especially in the case of treatment with Bcr inhibitors.

E1011
HSP70 EXPRESSION IS MODULATED BY ITS MASTER REGULATOR HSF1 VIA PI3K AND PI3KAKT/MTOR PATHWAYS IN CHRONIC LYMPHOCYTIC LEUKEMIA
M. Facco1,2, F. Piazza1,2, G. Basso3, G. Semenzato1,2, L. Trentin1,2,*, 1Department of Medicine, University of Padua, 2Venetian Institute of Molecular Medicine (VIMM), 3Department of Women’s and Children’s Health, University of Padua, Padova, Italy
Background: The search for molecules involved in apoptosis resistance/ increased survival of B cells from Chronic Lymphocytic Leukemia (CLL) is still ongoing since this disease remains not definitively understood. Very recently, we found that the Heat Shock Protein of 70KDa (HSP70), expressed in response to a wide variety of stress signals and allowing cells to survive to lethal conditions, was particularly overexpressed in neoplastic B cells from CLL. Moreover, the Heat Shock Factor 1 (HSF1), the major responsible for the transcription of HSP70, is itself overexpressed in CLL and strictly correlated to HSP70. In response to stress, HSF1 becomes phosphorylated, forms homotrimers, binds DNA and activates heat shock gene transcription. HSF1 is regulated by a fine balance of activatory/inhibitory phosphorylations mediated by kinases belonging to pathways triggered by RAS (i.e. PI3K/AKT and RAS/RAF/MEK/ERK). Aims: Since HSP70 is overexpressed in CLL neoplastic B cells and most of “HSF1-1-phosphorylating agents” belong to signalling pathways taking part from RAS, being the PI3K/AKT/mTOR and the RAS/MEK/ERK pathways, we are herein aimed at gaining information and dissecting this network in CLL B cells.
Methods: In a Reverse Phase Protein Array (RPPA) study, previously performed from 57 CLL patients and 11 healthy subjects, we evaluated the activation/expression of key signalling proteins. Herein, we focused on HSP70, AKT-Ser473, mTOR-Ser244, GSK3α/β-Ser21/9, CDK2, CREB, Ser133, MEK1/2-Tyr202/204, ERK1/2-Tyr202/204, NFκB-Ser536, p38MAPK-Thr180/Tyr182, SAPK-JNK-Thr183/Tyr185 and PDK1-Ser241. Cluster and separated analyses have been performed.
Results: We divided our patients in HSP70-high and HSP70-low considering as cut-off the value of the median of HSP70 expression levels calculated by RPPA and demonstrated that the examined proteins behave in a different way between patients expressing high or low levels of HSP70. HSP70-high patients present high AKT-Ser473, an inhibitor of GSK3α/β that, in the inhibited form, prevents HSF1 inhibition. By contrast, HSP70-low patients have high MEK1/2-Ser217/221 and ERK-Thr202/Tyr204, known to negatively regulate HSF1. Intriguingly, p38MAPK-Thr180/Tyr182 which has been described to both activate and inhibit HSF1 at different sites, is overexpressed in those patients presenting low levels of HSP70.
Summary/Conclusions: These data would suggest that, in CLL, HSP70 expression is regulated by the modulation of HSF1 activity through the activation of one or the other way triggered by RAS. In particular, an activation of the PI3K/AKT/mTOR pathway leads, as result, to a higher expression of HSP70 while an activation of the RAF/MEK/ERK signalling rather results in HSP70 down regulation. The dissection of signalling pathways connected to HSP70-HSF1 axis in CLL will contribute to define the biology and understand the pathogenesis of this disease.

E1012
THE INTERPLAY BETWEEN TH17 AND TREGS: A NEW IMMUNOSUPPRESSIVE INSIGHT IN CHRONIC LYMPHOCYTIC LEUKEMIA
S. De Mattes1,*, R. Napolitano1, A. Lucchesi2, D. Cancini2, A. Cuneo3, G.M. Rigoli2, E. Volta2, G. Musaraca2
1Bioscience Laboratory, 2Hematology Unit, IRCCS Istituto Scientifco Romagnolo per lo studio e la cura dei tumori (IRST), Meldola, 3Medical Sciences, University of Ferrara-Arcispedale Sant Anna, Ferrara, Italy
Background: Chronic lymphocytic leukemia (CLL) is the most frequent leukemia in the Western world and it is characterized by the clonal expansion of CD5 positive B cells. In CLL, different T cells dysfunctions have been described, probably related to the interaction with malignant B cells. TH17 and regulatory T cells (Tregs) are subpopulations of T lymphocytes which play a fundamental part in inflammatory response and immune tolerance. However, their role in the immunopathogenesis of CLL has not yet been fully clarified.
Aims: The aim of this study is to clarify the interplay between TH17 and Tregs in the pathogenesis of CLL.
Methods: After obtaining the patient’s informed consent, peripheral blood was collected from 30 untreated CLL patients and 30 age-matched healthy volunteers (HV). Cytokine production was evaluated before and after a 48 h culture of CD4+ T cells in complete medium with IL-6 (in), followed by a 5 h stimulation with PMA, ionomycin and Monensin (PIM), or with Anti-Tbet PE or anti-GATA-3 PE. Statistical analysis were carried out using the paired and unpaired two-tailed Student’s t-tests and confirmed with the non-parametric Wilcoxon signed-rank test.
Results: In CLL patients we observed a reduced production of IFN-γ and IL-4, respectively from TH1 and TH2 and an increase of IL-17A from TH17, compared to HV. All the observed differences were statistically significant. We also evaluated the ability of CD4+ T cells to secrete IL-17A, IL-10 or both. We reported a statistically significant increase in the frequency of CD4+ IL-17A-producing cells in CLL patients compared to HV, whereas the percentage of IL-17A+IL-10+ cells remained unchanged. In order to evaluate the functional effects of the observed alterations, we analyzed IFN-γ+CD4+ T cells-mediated response after stimulation with C. Albicans for 48 h, with or without depletion of IL-17A-secreting cells. The frequency of IFN-γ-producing T cells resulted statistically significant increased in patients than HV before IL-17A-secreting T cells depletion. Conversely, after IL-17A+ CD4+ T cells depletion, we didn’t observe significant differences in term of IFN-γ production. We also observed increased IL-23 plasma levels in patients compared to HV. In addition our data highlighted a significantly higher frequency of CD4+ CD25hiFOXP3+ Tregs (Tregs) in CLL samples, with a statistically significant increase in Tbet+ Tregs, RORγt+ Tregs and GATA-3+ Tregs subpopulations (Figure 1).

Figure 1.
Summary/Conclusions: Our results reported a down-regulation of IFN-γ and IL-4 producing T cells, associated to an increased frequency of Tregs and their subsets in CLL patients, probably trying to overcome the deficit of effector T cells. On the other hand, we observed a rise in IL-17A secreting T cells related to the increased IL-23 production by dendritic cells in order to restore TH17 pool, without changing the percentage of IL-17A+IL-10+ cells. These data support the idea of the protective function of TH17 that show an effector and not a regulatory T phenotype. Starting from these observations, this study could pave the way to further researches and applications in the comprehension of the biological and regulatory mechanisms of TH17 and Tregs, supporting the study of a pioneering antitumor therapy in CLL.

E1013
LOW EXPRESSION OF CD25 IN CHRONIC LYMPHOCYTIC LEUKEMIA
V. Vicente3, A. Jerez1
1Bioscience Laboratory, 2Hematology Unit, IRCCS Istituto Scientifco Romagnolo per lo studio e la cura dei tumori (IRST), Meldola, 3Medical Sciences, University of Ferrara-Arcispedale Sant Anna, Ferrara, Italy
Background: Recently, it has been shown that CDK6-mediated repression of CD25 is required for induction and maintenance of NOTCH1-induced T-cell acute lymphoblastic leukemia.
Aims: The aim of this study was to identify the NOTCH1 mutation status detected by deep sequencing in a cohort of 138 patients and to correlate it with the immunophenotypic profile and CD4 and CD64 expression.
Methods: We performed targeted NGS sequencing of blood samples, collected at diagnosis, from 138 CLL patients. We designed a TruSeq Custom Amplicon
containing 13 genes and covering 28,099 bases. Paired-end sequencing was performed with NGS using 454 platform in 147 CLL patients. The frequency of mutations was 16.3% in NOTCH1 mutated and non-mutated patients was 163 and 146 units, respectively (p=0.05). We measured CDK4 and CDK6 expression in the CD19+ sorted fraction RNA of 7 NOTCH1 mutated cases and 11 non mutated cases, without finding significant differences (0.26 vs 0.27 for CDK6, 0.025 vs 0.022 for CDK4; p>0.5 in both cases).

Summary/Conclusions: We found a significant inferior expression of CD25 when activating NOTCH1 mutations are present in CLL patients. The relationship found between these two variables, with an inverted direction to that found in physiological conditions, has also been shown in the setting of NOTCH1-mutated T acute lymphoblastic leukemia. In CLL cases, it seems to be independent of CDK4/6 expression, prompting further studies assessing CDK4 and CDK6 regulators.

**E1014**

**GENE MUTATIONS ANALYZED BY NEXT-GENERATION SEQUENCING ALLOW US TO DEFINE THE PROGNOSIS OF CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS WITH EARLY-STAGE DISEASE AND 13Q DELETION**

Aims: To analyze the presence of mutations of a panel of genes by NGS and prognostic markers would help to improve prognostication of CLL patients. Interestingly, gene mutations could help us to refine the prognosis in the group of CLL patients with 13q deletion and other prognostic markers associated with good prognosis.

Methods: Amplicon-based-NGS was performed using 454 platform in 147 CLL patients to evaluate the mutational status of 13 genes (TP53, NOTCH1, SF3B1, XPO1, FBXW7 and MYD88). Samples were obtained at diagnosis or before treatment in all cases. 70.1% were Binet A and 53% had 13q deletion (13q-).

Results: 1. NGS analysis showed that 37.4% of CLL patients (55/147) showed mutations in any of the analyzed genes. The frequency of mutations was 16.3% for NOTCH1, 10.2% for SF3B1, 6.8% for TP53, 4.8% for XPO1, 3.4% for FBXW7, and 1.4% for MYD88. The presence of mutations in any of these genes except to MYD88 (mutated CLL) was significantly associated with clinical progression (60.0% for mutated CLL vs. 38.2% for unmutated CLL; P=0.05). Interestingly, mutated CLL patients showed a shorter time to first treatment (TFT) than unmutated CLL patients (30 months vs. 88 months; P=0.006). By contrast, MYD88 mutations were detected in CLL with mutated IGHV and 13q-. Of note, 23.8% of the mutations had a mutational load of ≥15% and thus would not have been detected by capillary Sanger sequencing. CLLs with mutations in MYD88 had a shorter TFT than those without mutations (18 vs 88 months; P=0.018), and similar to CLL patients with mutations in ≥15% of cells (P=0.370). In addition, 14.5% of mutated CLL patients showed 2mutations. Patients with more than one mutation had a shorter TFT than CLL patients with one mutation (7 months vs 31 months). 3. In the group of CLL patients with 13q deletion (13q-), 32.8% of them showed mutations in any of the analyzed genes. Interestingly, CLL patients Binet A with mutations (except to MYD88) showed a shorter TFT than CLL patients without mutations (31 vs 131 months, P=0.001). Besides this, CLL with 13q- as the sole cytogenetic alteration and gene mutations had also a shorter TFT that unmaturated 13q- CLL patients (P=0.001).

Summary/Conclusions: 1) CLL patients with mutations in TP53, NOTCH1, SF3B1, XPO1 and FBXW7 show a worse prognosis than CLL patients without mutations. 2) Gene mutations in TP53, NOTCH1, SF3B1, XPO1 and FBXW7 in a low percentage of the cells are associated with a shorter TFT. 3) Among CLL patients with good prognostic characteristics (Binet A and 13q-), gene mutations help us to define the prognosis of the patients.

ASSOCIATION OF CpG-STIMULATED KARYOTYPE WITHTIME-TO-FIRST TREATMENT FOR CLL

1Bone Marrow Transplantation, Ospedale Pausilipon, Napoli, Italy, 2Leukemia, MD Anderson Cancer Center, Houston, United States, 3Ematologia, PO San Giuseppe Moscati, Avessa, Italy, 4Chao Family Comprehensive Cancer Center, California, United States

Background: Prognostic factors correlate with clinical outcomes, independent of treatment. B cell receptor (BCR) signaling pathway inhibitors can nullify the prognostic impact of some markers, such as IGHV mutation status. CpG-stimulated metaphase karyotype can identify clonal cytogenetic abnormalities in CLL that may not be seen with standard non-stimulated karyotype or by FISH. Complex cytogenetics, defined as 3 or more chromosome abnormalities in 2 or more metaphases was the highest-risk feature for shorter progression-free and overall survival in patients receiving ibrutinib for relapsed/refractory CLL. Complex karyotype is not uncommon among relapsed/refractory CLL cases, particularly those who previously received genotoxic chemotherapy.

Figure 1.

Aims: The aim of this study is to report the incidence and the impact of CpG-stimulated karyotype in the treatment of naive CLL.

Methods: We evaluated 501 treatment-naïve patients with CLL at MDACC between July 2013 and June 2016. CpG-stimulated metaphase karyotype of CLL cells from blood or bone marrow was performed by culture of mononuclear cells for 72 hrs in media containing CpG-865 (20ug/ml), phorbol 12-myristate 13-acetate (PMA; 0.04ug/ml) and Pokeweed mitogen (PWM; 0.1ug/ml). Banding and analyses were by standard laboratory procedures. Twenty metaphases were analyzed per culture and patients were categorized as having diploid karyotype, a single, 2 or 3 or more(complex) clonal chromosome abnormalities present in more than 1 metaphase by CpG-stimulated karyotype. The frequency and distribution of chromosome abnormalities with other prognostic factors and time-to-first treatment from diagnosis (TTFT) were analyzed (Table + Figure).

Results: The majority (69%) of patients had diploid cytogenetics. Higher-risk prognostic features such as del17p, del11q, unmutatedIGHV and ZAP70 expression were associated with presence of complex karyotype abnormalities. Shorter TTFT from diagnosis was associated with 1, 2, and complex clonal chromosome abnormalities compared to diploid karyotype (p<0.0001). A model was developed, which identified patient characteristics independently associated with shorter TTFT including: 1 or more clonal chromosome abnormality by CpG stimulated karyotype; unmutatedIGHV; 3 involved lymph node sites; and CD38 expression (>30%).

Summary/Conclusions: In conclusion, CpG-stimulated karyotype identified 1 or more clonal chromosome abnormalities in nearly a third of untreated patients and was a significant independent prognostic factor for TTFT. Models for TTFT may be useful in identifying patients at high-risk for needing treatment sooner and thereby useful for early intervention clinical trials.

E1017

COMPARISON OF THE CHRONIC LYMPHOCYTIC LEUKEMIA INTERNATIONAL PROGNOSTIC INDEX (CLL-IPI) WITH THE BARCELONA-BRNO PROGNOSTIC MODEL: ANALYSIS OF 1299 NEWLY DIAGNOSED CASES

1Hematology, Hospital Annunziata, Cosenza, Cosenza, Italy, 2Hematology, Mayo Clinic, Rochester, United States, 3Oncology, Oncology Institute of Southern Switzerland, Bellinzona, Switzerland, 4Hematology, Catholic University Hospital “A. Gemelli”, 5Hematology, Università La Sapienza, Rome, 6Hematology, Pugliese-Ciaccio Hospital, Catanzaro, 7Hematology, 7SS Molecular Diagnostics IRCSS S. Martino-IST, Genova, 8Hematology, Hospital Annunziata, Cosenza, 9Hematology, Università La Sapienza, Roma, 10Immunology, Consiglio Nazionale delle Ricerche, Istituto di Biomedicina ed Immunologia Molleculari, Reggio Calabria, Italy, 11Division of Medical Statistics and Informatics, Mayo Clinic, Rochester, United States, 12Biotechnology Research Unit, Azienda Sanitaria Provinciale di Cosenza, Aprigliano, 13Hematology, University of Milano and Hematology CTMO, Foundation IRCSS Ca’Granda Ospedale Maggiore Policlinico, Milano, 14Direzione Scientifica IRCCS., San Martino IST, Genova, 15Hematology, Department of Translational Medicine, PO, Novara, Italy

Background: In the last two decades, a plethora of clinical, serological and biological markers have been identified that are significantly associated with the prognosis of chronic lymphocytic leukemia (CLL) patients. Recent research has focused on the development of scoring systems capable of integrating the major prognostic parameters. A recent prognostic index called CLL International Prognostic Index (CLL-IPI), built on clinical, serological, and biological parameters (TP53 deletion and/or mutation, IGHV mutational status, β2M, clinical stage, and CD38 expression) has been proposed and validated. Recently, a CLL International Prognostic Index- naïve patient group, with the aim of simplifying the CLL-IPI, proposed a prognostic model comprising only two biomarkers (IGHV mutational status and FISH cytogenetics).

Aims: We performed a comparison of the CLL-IPI with the Barcelona-Brno prognostic model in an independent series of Italian and United States (U.S.) patients.

Methods: Databases from 4 Italian and 1 U.S. centers including roughly 3700 newly diagnosed CLL patients were used to compare the CLL-IPI with the Barcelona-Brno prognostic model. Baseline data regarding age, Rai stage, IGHV mutational status, β2M and fluorescence in situ hybridisation (FISH)-detected cytogenetic abnormalities were available for 1299 cases. Del17p was used as the sole marker of TP53 status. The CLL-IPI and the Barcelona-Brno prognostic models were calculated using the methods proposed. The accuracy of the prognostic models was assessed by the Harrell C index (an index of discrimination), the explained variation in mortality (an index combining discrimination and discrimination), and the Akaike information criterion (AIC, an index comparing two non-nested prognostic models). The lower the AIC, the higher the prognostic accuracy of a predictive model.

Results: The median age of the 1299 patients was 63 years (range 27-92) with 61.3% males. The majority of patients had Rai stage 0 (57.9%). According to the CLL-IPI, 51.3% of patients were classified as low-, 28.7% as intermediate-, 16.2% as high-, and 3.8% as very high-risk. The 5-year OS probabilities were 95% for low-risk, 89.9% for intermediate-risk, 70.1% for high-risk, and 32.8% for very high-risk cases (P<0.0001; Harrell C index=73%;P<0.001) (Figure 1A). According to the Barcelona-Brno prognostic model, 59.1% of patients were classified as low-, 31.8% as intermediate-, and 10.1% as high-risk. The 5-year OS probabilities were 92.2% for low-risk, 83.6% for intermediate-risk, and 68.2% for high-risk cases (P<0.0001; Harrell C index=65%;P<0.001) (Figure 1B). The AIC showed the superiority of the CLL-IPI compared to the Barcelona-Brno prognostic model in predicting OS (CLL-IPI, AIC=3432.167 versus Barcelona-Brno prognostic model, AIC=3549.492). According to the CLL-IPI, predicted variation in mortality provided by the Barcelona-Brno prognostic model was 42% (P<0.001), a figure higher than that due to the Barcelona-Brno prognostic model
Individuals who had received vaccination against Influenza and/or Pneumococcus were excluded from the analysis of the immunoglobulin-specific titers against S. pneumoniae (38.8% vs 40.6%, P>0.05). Individuals who had received vaccination against other bacterial infections were not different between groups: 76.9% vs 78.4% for CMV (P>0.05) and 70.4% vs 72.1% for EBV (P>0.05).

Methods: S55746/BCL201 was initially administered in fasting condition, once daily (in 21-day cycle) until progressive disease (PD) or unacceptable toxicity. A tumor lysis syndrome (TLS) prevention protocol was implemented. After giving informed consent pts could receive 50 to 2000mg according to a modified version of the Continual Reassessment Method for dose allocation process. In the food effect part of the study, the 7 non-Hodgkin’s lymphoma patients received a film coated 200mg tablet under fasting condition (i.e. after 10-hour fasting period) and after a calibrated moderate meal the day after.

Results: As of February 2017, 12 CLL pts have been treated (median age 67 years [range 52-82]). On these 12 pts, 5 presented a bulky disease, 1 a 17p deletion, 4 a 11q deletion, and 1 a p53 mutation. CLL pts were dosed up to 700mg, with a median duration on treatment of 79 days. Median number of prior regimens in CLL pts was 4 (range 2-5). Preliminary PK results in fasting pts showed that exposure increased linearly but with some inter-individual variability. The most frequent (≥2 pts) grade 3/4 adverse events (AEs) were neutropenia (n=2) and thrombocytopenia (n=2). AEs possibly related to the study drug were reported in 4 pts: neutropenia (n=2), neutrophil count decrease (n=1), fatigue (n=1), dyspnea (n=1), gingival bleeding (n=1) and left ventricular ejection fraction (LVEF) decrease (n=1). No clinical or laboratory TLS were reported. One patient in the 700mg cohort experienced a DLT (asymptomatic LVEF decrease grade 2 recovered within 2 weeks). At 700mg, a decrease in lymphocytes count from baseline (>50%) was observed in 3 of 4 patients associated with a decrease in the sum of the product of the diameters of lymph nodes (from 23% to 40%). This decrease in lymphocytes count, started from cycle 1, and may be correlated with an induction of apoptosis in CLL cells (4 hours post first dose), detected by flow cytometry in CD19+AnnexinV+ cells. Two CLL pts are ongoing after having completed their 3rd cycle; 10 pts have withdrawn from the study: 7 due to PD, 1 for lack of efficacy and 2 due to AE. The non-compartmental pharmacokinetic analysis of the food effect cohort (5 assessable pts) demonstrated that S55746/BCL201 PK is not modified by the ingestion of a moderate meal (400-500 kcal with fat contributing to 150 kcal). The median Tmax was delayed from 1.5h to 4h when administered with food. Compared with fasting condition, Cmax and AUC increased by approximately 6-fold following a moderate meal. Based on these results, a protocol amendment to the clinical trial has been implemented in order to further investigate the administration with food in a new dose escalation.

Summary/Conclusions: S55746/BCL201 monotherapy showed first signs of activity across the tested dose levels with an acceptable safety profile so far. Based on PK food interaction results, dose escalation in the fed state is planned.

E1019 INCREASED VIRUS-SPECIFIC IMMUNE RESPONSES PARALLELED BY A PNEUMOCOCCUS-SPECIFIC IMMUNODEFICIENCY STATE AND HYPOGAMMAGLOBULINEMIA: ALREADY EMERGE IN HIGH-COUNT MONOCLONAL B LYMPHOCYTOYSIS PRIOR TO CLL

Background: Patients diagnosed with chronic lymphocytic leukemia (CLL) display a high incidence of infections, due to an associated immunodeficiency state that includes hypogammaglobulinemia. Even more, it has been recently shown that the earlier stages of disease, i.e. high-count monoclonal B lymphocytosis (MBL), subjects also have increased risk for infection. Aim: To evaluate the status of the humoral immune response in CLL at different disease stages, as well as in pre-lymphemic MBL and in MBL low count (MBLlo) cases, vs healthy controls, through quantitation of soluble plasma levels of specific antibodies against ubiquitous and pulmonary infection-associated pathogens.

Methods: A total of 249 subjects (119 males/130 females; aged 68±11y) including 91 healthy donors, 71 CLL-like MBLlo, 29 CLl-like MBLhi and 58 MBLlo cases (32 Binet A, and 26 Binet B/C patients) were studied. Detection of clonal CLL-like B cells was performed by high-sensitive 8-color flow cytometry. Quantification of plasma antibody isoforms and specific immunoglobulins against CMV (strain AD169), influenza virus (A/Brisbane/10/07), and pneumococcus were performed by nephelometry and commercial ELISA kits, respectively. Individuals who had received vaccination against Influenza and/or Pneumococcus were excluded from the analysis of the immunoglobulin-specific titers against the corresponding pathogens, respectively. Plasma CMV and EBV DNA load levels were measured using the quantitative PCR methods.

Results: Total immunoglobulin (Ig) titers tended to decrease with disease progression, independently of the isotype. In contrast, specific IgM and IgG titers against CMV, EBV and influenza virus did not vary among groups, with the
exception of VCA-EBV IgG titers, that were higher in CLL vs the other groups. Strikingly, the IgG levels for the three viruses tended to gradually increase, from healthy individuals to stage B/C CLL. These findings were more pronounced (p<0.05) for IgG and to a lesser extent also for IgM, when the ratios between the virus-specific IgG/total IgG titers of the same isotype were calculated, except for Influenza-specific IgG, that showed the same trend but without statistical significance. Repeating CMV DNA load, only 3/177 individuals (1 MBL2 and 2 CLL- were found to be positive (below the limit of quantitation), while EBV DNA load was detected in plasma from 7/191 (all being Binet A CLL) at median levels of 3.6 copies/ul. In contrast to the virus-specific IgGs, IgG plasma levels against S.pneumoniae progressively diminished through progression of the disease, in parallel to the overall gammaglobulin levels.

Summary/Conclusions: Both MBL2 and CLL patients present relatively high levels of specific Ig against human host viruses in parallel to progressively lower levels of anti-S.pneumoniae antibodies, which might reflect (asymptomatic) chronic reactivation of humoral immune responses against host viruses and progressively decreased protection against other microorganisms, denoting a severe pathogen-specific humoral immunodeficiency state not reflected by the overall plasma immunoglobulin levels. Alternatively, these results might point out a potential role of ubiquitous viruses in the pathogenesis of the disease. Further analyses are necessary to establish the potential relevance of such asymptomatic humoral immune responses against host viruses in the expansion of the tumor B-cell clone and progression from MBL to CLL.

E1020
AN EXTENSIVE MOLECULAR CYTOGENETIC CHARACTERIZATION IN HIGH-RISK CHRONIC LYMPHOCYTIC LEUKEMIA IDENTIFIES KARYOTYPE ABERRATIONS AND TP53 DISRUPTION AS PREDICTORS OF OUTCOME AND CHEMOREFRACTORYNESS
G.M. Rigolin1,*. L. Formigari1, M. Cavallari1, F.M. Quadaglia1, E. Lista1, A. Urso1, E. Guardalben1, S. Martinelli1, E. Saccant1, C. Bassi2, L. Lupini2, A. Bardi1, E. Volta1, E. Tammiso1, A. Melandri1, M. Negrini2, F. Cavazzini1, A. Cuneo1
1Scienze Mediche, Azienda Ospedaliero Universitaria Arcispedale S. Anna, 2Department of Morphology, Surgery and Experimental Medicine, and “Laboratorio per le Tecnologie delle Terapie Avanzate” (LTTA), University of Ferrara, Ferrara, Italy

Background: Chronic lymphocytic leukemia (CLL) is a heterogeneous disease, running an indolent course in some patients and a clinically aggressive course in others. Risk assessment is important in clinical practice and prediction of outcome and response to treatment is very useful in an era in which several chemomunotherapy combinations and effective mechanism-driven treatments are available.

Aims: We investigated whether an extended genetic characterization including mutational screening by next generation sequencing (NGS) and karyotype analysis could allow for a refinement of our capability to predict outcome in newly diagnosed CLL patients with high-risk features, as defined by the presence of unmutated IGHV gene and/or 11q22/17p13 deletion by FISH and/or TP53 mutations.

Methods: 101 patients were included in this study, TP53 disruption was defined by the presence of 17p13 deletion by FISH and/or TP53 mutation by NGS. Cytogenetic analysis was performed using Pgo-oligonucleotide DSP30. Each patient was categorized according to the following classification: favorable group (isolated 13q14 deletion or normal karyotype), unfavorable group (deletions of 11q22 or 17p13, or complex karyotype, ie, at least 3 chromosome aberrations); intermediate group (all other karyotypic abnormalities). A cut-off of 98% homology to the germline sequence to discriminate between IGHV mutational status, \( \beta 2\)-microglobulin, clinical stage and age) has been used by an international Working Group to generate the chronic lymphocytic leukemia international prognostic index (CLL-IPI). Although the robustness of CLL-IPI has been confirmed in external validation studies it remains unclear whether CLL-IPI has the greatest validity and should be preferred to guide clinical decision in CLL.

Aims: To shed light on this important research question, we conducted a systematic review which includes all published studies which used CLL-IPI to prognosticate overall survival (OS) in CLL.

Methods: A comprehensive MEDLINE search using “CLL-IPI” as Medical Subject Headings (Mesh) allowed to identify at the cut-off time of February the 28, 2017 “seven hits” with only “four” citations considered pertinent. The search was extended to the conference proceedings of annual meetings of ASH, EHA and ASCO of last two years recognized “three” additional citations.

Results: Overall 6720 patients from seven evaluable studies were suitable for the present analysis aimed at assessing the impact of CLL-IPI on OS. The majority of patients (4553 or 73.7%) came from studies of external validation of CLL-IPI while 17% (1192) and 8.5% (576) had been used to generate (training sets) and to internally validate the model. Patient distribution into the four risk categories of CLL-IPI was heterogeneous thus reflecting the CLL phase (ie, at diagnosis, at time of first treatment and at relapse) of patients within different studies. Accordingly, patients diagnosed as having low-, intermediate-, high- and very high-risk CLL-IPI ranged respectively between 9% and 58%, 25% and 39%, 14% and 52% and 2% to 9%. Next we evaluated the 5-year OS of patients stratified into each of the four CLL-IPI risk groups using either “Q” or “I2” test to assess the heterogeneity across different studies. The 5-year survival probability was 91% for low-risk group (95% CI, 90-91%), Q=55.2; P< 0.001; I^2 =87%), 89% (95% CI, 79-82%); Q=49.36; P< 0.001; I^2 =86%), 60% for high-risk group (95% CI, 57-62%; Q=42.78; P< 0.001; I^2 =84%) and 32% for very high-risk group (95% CI, 27-38%; Q=18.1; P=0.01; I^2 =67%).

Figure 1.

Summary/Conclusions: In this comprehensive review and meta-analysis of studies thus far published on CLL-IPI we confirmed the value of this novel model to predict OS whatever the CLL phase (fig 1). The prognostic impact of CLL-IPI presents an extensive validation in patient cohorts receiving therapy with B-cell receptor or bcl-2 inhibitors. Nonetheless, in a study of relapsed/refractory CLL included in this analysis the PI3K-inhibitor idelisib was not able to overcome the impact of CLL-IPI risk categories on OS.

E1022
IBRUTINIB FOR CHRONIC LYMPHOCYTIC LEUKEMIA: IMPACT OF THE CANADIAN YOU&I PATIENT SUPPORT PROGRAM ON TREATMENT ADHERENCE
A. Peters1,*, J. Wiemikowski2, S. Barker3, M. Mahler4, S. Luke5, A. Lodick5

haematologica | 2017; 102(s2) | 419

Madrid, Spain, June 22 – 25, 2017
Background: Oral anticancer medications (OAMs) present several advantages compared with intravenous cytotoxic chemotherapy, including greater convenience for the patient. However, OAMs require that a patient be actively involved in regular drug administration over an extended period of time (Schneider SM, et al. Semin Oncol Nurs. 2011;27(2):133-141). Adherence to OAMs significantly impacts patient outcomes; poor adherence may result in inferior survival and outcomes, higher hospitalization rates, treatment resistance, and increased healthcare costs (McCue DA, et al. Pharmacotherapy. 2014;34(5):481-494). The Canadian YOU&i™ patient support program (PSP) was developed to improve adherence to long-term ibrutinib therapy using research-proven techniques for promoting positive behavioral changes, i.e. cognitive behavioral therapy, psycho-social support, and a nurse coaching component. Results from the program are presented below. Aims: To evaluate patient adherence to ibrutinib, and patient and physician satisfaction with the YOU&i™ PSP Methods: Using evidence-based literature reviews and global/local market research, various patient-centered barriers to treatment adherence were identified. A patient adherence score was calculated using the Morsky Medication Adherence Scale® score, which informed nurse coaching frequency. Adherence was delineated by prescription refill compliance. Patient and physician questionnaires were used to gauge satisfaction with the YOU&i™ PSP. Results: As of 20 January 2016, a total of 903 patients with CLL were enrolled in the YOU&i™ PSP. A total of 552 patients were included in the adherence analysis. Of these, 86% opted in to receive the nurse coaching component. At 2 months from treatment initiation, patients who received nurse coaching demonstrated an adherence score of 92.3%, as compared with 63.5% for patients who did not receive nurse coaching (95% CI, 75.3-91.6; p < 0.0001). At 3 months the adherence rates were 89.9 vs 60.8% (95% CI, 75.5-91.4; p < 0.0001). By 9 months, adherence rates were 81.7% vs 71.1% (95% CI, 4.4 to 28.4; p = 0.141). At study conclusion, 12 month adherence rates were 76.6% vs 72.2% (95% CI, -18.9 to 32.4; p = 0.715). Discontinuation rates were similar in all patients, regardless of nurse coaching status at 9 and 12 months. Patients reported satisfaction rates of >90% in surveys conducted at both 3 months and 12 months of program enrollment. Of physicians surveyed at 3 months, 96% reported that the YOU&i™ PSP was helpful in supporting patient needs. E1024 SINGLE-AGENT IBRUTINIB VS REAL WORLD TREATMENT FOR PATIENTS WITH TREATMENT-NAIVE (TN) CHRONIC LYMPHOCYTIC LEUKEMIA (CLL): AN ADJUSTED COMPARISON OF RESONATE-2™ WITH THE CLLEAR AND LYON-SUD DATABASES M. Doubek1*, E. Bachy2, M. Spacek3, L. Basseggi4, R. Besson5, J. Diels6, J. Garside7, N. Healy8, W. Iraqui8, E. Callet-Bauchu2, L. Smolej9, G. Salles2

1Department of Internal Medicine – Hematology and Oncology, University Hospital Brno, Faculty of Medicine, Masaryk University, Czech Republic, 2Hospices Civils de Lyon, Université Claude Bernard, Centre Hospitalier Lyon-Sud, Pierre Bénite, France, 31st Department of Internal Medicine – Hematology, General Faculty Hospital, Prague, 4Department of Hemato-oncology, University Hospital, Olomouc, Czech Republic, 5Janssen EU HEMAR Statistics & Modelling, Beerse, Belgium, 6Janssen EMEA HEMAR, High Wycombe, United Kingdom, 7Janssen-Cilag EMEA Medical Affairs, Dublin, Ireland, 8Janssen Pharmaceuticals, Paris, France, 994th Department of Medicine – Hematology, Charles University Hospital and Medical Faculty, Hradec Králové, Czech Republic

Background: The phase 3 RESONATE-2™ study demonstrated significant improvement of progression-free survival (PFS) and overall survival (OS) with ibrutinib (ibr) vs chlorambucil (ch) in TN (aged ≥65 years) CLL patients. In the absence of direct comparison of single-agent ibr with other frequently utilized regimens in this patient population, this retrospective outcome study from the CLCLEAR (Chronic Lymphocytic Leukemia Registry) and Lyon-Sud databases may provide insight into the impact of ibr on patient outcomes, especially in CLL patients with del(17p) who receive ibr as monotherapy in the absence of standard of care as observed in clinical practice can provide useful insights on the relative efficacy of ibr. Aims: To investigate the relative treatment effect on PFS and OS for ibr vs real world (RW) treatment in daily clinical practice in TN CLL patients by adjusting for baseline characteristics from patient-level data of RESONATE-2™ vs real world treatment (RW) in the CLCLEAR and Lyon-Sud databases. Methods: CLCLEAR holds medical records for CLL patients from seven academic centers across the Czech Republic. Lyon-Sud database holds medical records for CLL patients from the clinical French hospital Lyon-Sud. Patients initiated on CLL frontline therapy were selected from CLCLEAR and Lyon-Sud using the same inclusion-exclusion criteria as for RESONATE-2 (excluding patients with age<65 and with del17p positive status). PFS and OS were com-
pared between ibru and RW treatment using patient-level data from RESONATE-2™ (n=136) and pooled patient-level data from the two cohorts. To adjust for differences in patient characteristics between the trial population and the general population, independent prognostic factors for OS were included as covariates.

**Results:** Median age at treatment initiation for CLEARLE (n=1418) and Lyon-Sud (n=110) was 73 and 71 years, respectively, vs 73 for ibru patients from RESONATE-2™. The proportion of male patients was 63% in CLEARLE and 57% in Lyon-Sud vs 65% in RESONATE-2™. The median follow-up was 35.7 months (mo) for Lyon-Sud and 16.8 mo in CLEARLE vs 29.1 mo for RESONATE-2™.

Adjusted HR for ibru vs physician choice in CLEARLE and Lyon-Sud were 0.23 (95% CI: 0.14, 0.39) and 0.25 (0.14, 0.43) for PFS, and 0.29 (0.11, 0.79) and 0.39 (0.18, 0.83) for OS, respectively. Fluorarabine/cyclophosphamide/rituximab (FCR; n=117), bendamustine+R (BR; n=91), CHl alone (n=43), CHl+R (n=45), and other R-containing regimens (n=154) were the most commonly used treatment regimens across both RW cohorts. Older age, male gender, advanced disease stage and del11q positive status were independent risk factors for PFS and OS. The adjusted HRs (pooled estimates) for ibru vs the two most commonly used regimens were 0.30 [0.17-0.53] (FCR) and 0.33 [0.16-0.68] (BR) for PFS, and 0.44 [0.20-0.95] (FCR) and 0.53 [0.13-0.83] (BR) for OS (Figure 1). Estimates of HR vs regimens in the cohorts were consistent across both databases.

**Summary/Conclusions:** This adjusted comparison of patient-level data from RESONATE-2™ with RW data from CLEARLE and Lyon-Sud demonstrates ibru to be more effective compared with RW treatment, with a 4.1-fold improvement in OS, 2.7-fold improvement in PFS, and 1.9-fold improvement in TFS. This adjusted comparison of patient-level data from RESONATE-2™ with RW data from CLEARLE and Lyon-Sud demonstrates ibru to be more effective compared with RW treatment, with a 4.1-fold improvement in OS, 2.7-fold improvement in PFS, and 1.9-fold improvement in TFS. This adjusted comparison of patient-level data from RESONATE-2™. The proportion of male patients was 63% in CLEARLE and 57% in Lyon-Sud vs 65% in RESONATE-2™. The median age at treatment initiation for CLEARLE (n=1418) and Lyon-Sud (n=110) was 73 and 71 years, respectively, vs 73 for ibru patients from RESONATE-2™. The proportion of male patients was 63% in CLEARLE and 57% in Lyon-Sud vs 65% in RESONATE-2™. The median follow-up was 35.7 months (mo) for Lyon-Sud and 16.8 mo in CLEARLE vs 29.1 mo for RESONATE-2™.
(MIFIR) was calculated as a relative expression between MFIR positive popula-
tion and MFIR negative population. Multivariate analysis was used to assess sta-
tistical significant differences in accuracy among individual markers and scor-
ing systems. The treating physician made the final diagnosis of the different
B-cell malignancies according to IWCLL and WHO criteria. Logistic regression
including sensitivity, specificity and accuracy values, were used to evaluate statistical
differences in diagnostic precision between different combinations of
markers as well as individual markers.

**Results:** Flow cytometry analysis was performed in 99 patients, including 62
cases with a diagnosis of CLL (62.6%) and 37 cases with a “non-CLL” diagnosis
(37.4%). Matutes score was 4-5 in all CLL cases and ≤3 in “non-CLL” cases.
CD20, CD79a and C5 were the most consensual markers for CLL (90.3%, 96.8%
and 100.0% of sensitivity respectively). Moreover, CD79b and FMC7 had a good
discriminative value (80-85% sensitivity). For “non-CLL” cases the most reliable
markers were SmIg, FCMD7 and also CD20. The analysis of the accuracy is shown in the table. Of note, CD20 as a single marker was found to be a reliable marker for distinguishing CLL and “non-CLL” cases
(90.9%; p<0.001; 90.3% sensitivity, 91.9% specificity) showing a significantly
higher accuracy than CD5, CD23 and SmIg as individual markers (p<0.001).
The accuracy of CD20 did not vary when comparing% of positive cells and
MIFIR. In contrast, the accuracy for MIFIR significantly increased from 67.7% to
78.5% when comparing MIFIR values (according to the cut-off established by ROC
curves), being lower in CLL than in “non-CLL” cases (71.0% vs 86.5%,
p<0.001). Finally, the addition of CD20 to the Matutes score and using a
cut off ≥4, improved its accuracy from 88.9% (95% CI: 88.2-95.6) to 98.0%
(95% CI: 94.7-100.0) and showed a better sensitivity.

**Background:** Well-established poor prognostic factors in chronic lymphocytic
leukemia (CLL) Yegin ZA et al, Eur J Haematol 2010, suggesting that this
parameter may discriminate different biological subgroups.

**Aims:** As the technic is easily implementable in routine lab and cost effective,
we evaluated the sFLC levels (kappa + lambda) and kappa/lambda(K/L) ratio
in CLL patients in this prospective study. The relationship between abnormal
sFLC levels (K+L) and K/L ratio, minimal residual disease (MRD) assessed by
flow cytometry (FCM) and disease evolution was evaluated.

**Methods:** Diagnosis was confirmed by 10-color FCM immunophenotyping
of blood lymphocytes on a Navios (Beckman Coulter). Serum FLC kappa and
lambda chains were measured by nephelometry using the Freelite
immunoassay. The normal free kappa chains level was defined as within the
range of 3.3-19.4mg/L, and the normal lambda chains level within the range
of 5.71-26.30mg/L. A normal sFLC kappa/lambda (K/L) ratio was therefore defined
as between 0.26 and 1.65 (a ratio above 1.65 indicating an excess of kappa
chains, and a ratio below 0.26 indicating an excess of lambda light chain).
The cumulative level of kappa plus lambda (K+L) was also evaluated. Most
patients received combined chemo-immunotherapy or entered clinical trials
whenever possible. The ROC methodology was used to establish the best cut-
off value of sFLC ratio level to discriminate treated patients from those who
remained treatment-free.

**Results:** Patients main characteristics are detailed [N=147, M/F:75/72, 111 in
early stage disease, 17p in 11 patients and Del17q in 15]. Median age was

PLATELET FUNCTION ASSAYS FOR STRATIFICATION OF BLEEDING RISKS IN CLL PATIENTS ON IBRUTINIB TREATMENT

E. Nikitin1,*, E. Dmitrieva1, A. Ignatova2, A. Poletaev2, D. Polokhov2, A. Fedotov2, RISKS IN CLL PATIENTS ON IBRUTINIB TREATMENT PLATELET FUNCTION ASSAYS FOR STRATIFICATION OF BLEEDING E1029

Aims: To investigate platelet function activity in CLL patients before and after ibrutinib treatment.

Methods: We collected platelet function data from 57 patients treated with ibrutinib. A total of 935 samples were analyzed using classical aggregation assays and the flow cytometry-based PFA-100 system. The primary endpoint was the change in platelet function after ibrutinib treatment.

Results: The median time to treatment completion was 3 months (range 1-6). Del17p or TP53 mutation was found in 11 (25%) patients. Only 1 patient received anticoagulant and antiplatelet drugs. Median duration of treatment was 3 (range, 1-6). Del17p or TP53 mutation was found in 11 (25%) patients.

Discussion: Our study showed that ibrutinib treatment systematically induced a modification of the sFLC K/L ratio. Interestingly, after treatment completion, the persistence of an abnormal sFLC K/L ratio was associated with positive MRD determined by FCM with a 82% specificity and a 95% positive predictive value. Moreover, median time to treatment completion was 3 (range, 1-6). Del17p or TP53 mutation was found in 11 (25%) patients.

Summary/Conclusions: Both classic aggregation assays and flow-cytometry-based techniques demonstrate impaired platelet function in the bleeding CLL patients compared with non-bleeding ones. The level of integrin activation possibly prevents severe bleeding on ibrutinib. Here we investigate platelet function activity in CLL patients before and after ibrutinib treatment.

Background: Management of chronic lymphocytic leukemia (CLL) dramatically improved since the introduction of novel therapies. Rarely patients require treatment at diagnosis and approximately a third of patients will never require therapy. Predictive and prognostic factors are well known (IGHV, del11q, del17p, TP53); CLL-IPI score including age, clinical stage, beta2-microglobulin, IGHV and deletion 17p and/or TP53 mutation has been recently validated. It identifies 4 risk groups with significantly different time to first treatment (TTFT) and overall survival (OS). Hypogammaglobulinemia (HYPO) is a typical feature of CLL, with an incidence of 20-60% at diagnosis and a relationship with infections occurrence. Prognostic significance of HYPO at diagnosis has not been extensively evaluated in terms of OS and TTFT. Only IgG serum levels have been reported to be associated with TTFT but no data are available on other immunoglobulin classes (Ig).

Aims: To evaluate the impact of HYPO and single Ig classes on TTFT in a retrospective cohort of CLL patients and to assess the relationship between HYPO and CLL-IPI.

Methods: We retrospectively evaluated 698 consecutive CLL patients diagnosed at our Institution from 1983 till 2016. Data from laboratory, biological analysis and clinical stage were collected. We also evaluated immunoglobulin (Ig) levels. IgG, IgM and IgA at diagnosis and calculated CLL-IPI. HYPO was defined basing on our laboratory cut-offs (IgG 70mg/dl, IgG 700mg/dl, IgG 40mg/dl).

Results: Among 698 patients assessed, 410 cases were evaluable for Ig values at diagnosis. IgA levels were lower than 70mg/dl in 17.4%, IgG lower than 700mg/dl in 22.2%, and IgM lower 40mg/dl in 33.7%. Forty-six percent of patients presented deficit of at least one Ig class, while 7.8% of patients had all Ig low. Each Ig deficit was related with a shorter TTFT with the following hazard ratios (HRs): 2.09 (1.45-3.03) for IgA (P<0.0001), 1.58 (1.10-2.27) for IgG (P=0.008) and 1.52 (1.09-2.13) for IgM (P=0.01) (Figure 1, A-B-C). However, only IgA deficit maintains statistical significance in multivariate analysis [HR 1.59 (1.08-2.35)]. A prognostic threshold for each Ig class was identified maximizing the differences in TTFT and the following values were obtained: 80mg/dl for IgA, 410mg/dl for IgG and 180mg/dl for IgM (Figure 1, D-E-F). Considering Ig deficit, patients presented IPI 0-1, 99 had IPI 2-3, 32 patients IPI 4-6, and 12 patients had IPI 7-10. Even in our series, CLL-IPI separated four risk groups with different TTFT and OS, suggesting that our cohort may be suitable to evaluate new prognostic factors. As regards the relationship between HYPO and CLL-IPI, we observed a correlation with IgA levels, using our laboratory cut-offs. However, we found a relationship among CLL-IPI and both IgA and IgM values, when using the newly validated Ig cut-off. Finally, CLL-IPI was a stronger prognostic factor for TTFT than HYPO in our analysis. However, the addition of IgA deficit to CLL-IPI appears to further improve CLL prognosis.

Figure 1. In conclusion, HYPO significantly impacts on CLL prognosis. Moreover, even if CLL-IPI has a stronger prognostic value for TTFT compared to HYPO, the addition of IgA deficit appears to further improve CLL prognosis.
E1031
CLL: IS LYMPHOCYTE DOUBLING TIME (LDT) A RELEVANT PROGNOSTIC PARAMETER IN THE ERA OF PROGNOSTIC BIOMARKERS?
1Hematology Department, Institute of Hematology and Oncology, Hospital Clinic, IDIBAPS, University of Barcelona, Barcelona, Spain; 2Hematology Department, Hospital de Clínicas, Asunción, Paraguay; 3Hematopathology Unit, Pathology Department, Institute of Hematology and Oncology, Hospital Clinic, IDIBAPS, University of Barcelona, Barcelona, Spain

Background: In CLL, tumor doubling time is reflected by the pace at which lymphocytes increase in blood (lymphocyte doubling time or LDT). However, since LDT is rarely available at the time of diagnosis, its role in assessing prognosis in patients in CLL is controversial.

Aims: To reassess the prognostic significance of LDT in a large series of patients.

Methods: Retrospective single-center study based on 629 patients diagnosed with CLL/SLL. LDT was measured at the time of diagnosis if prior WBC counts were available or calculated after diagnosis by linear regression analysis, usually over a treatment-free period of 2 months and including at least three WBC counts.

Results: 140 patients displayed short LDT (<12 months) and 489 long LDT (>12 months). The median follow-up was 13.4 years (6.1-22.5) and 11.2 years (2.3-30.9), respectively. Patients with short LDT were younger (p<0.005), had lower lymphocytes in initial clinical stage (p<0.001), higher BLC (p<0.001), as well as increased serum LDH (p<0.001) and B2-microglobulin (B2M; p=0.035) levels and also a tendency towards lower levels of Hb and platelet counts. A short LDT was also associated with an increased expression of ZAP70 and CD38, unmutated IGHV (all p<0.001) and poor FISH cytogenetics (del17p, del11q) (p<0.001). Additionally, patients with a short LDT presented more frequently mutations in NOTCH1 (p=0.008), ATM (p=0.029), TP53 (p=0.035) and a tendency to more mutations in SF3B1 (p=0.102). The proportion of patients treated in each group was markedly different [80% vs 46%] as it was the median time to treatment (TTT, 1.4 vs 9.4 years; p<0.001). Type of treatment (mainly, chemotherapy and immunotherapy) did not differ more frequently treated with alkylating agents than purine analogues. Conversely, patients treated due to LM had more frequent adverse prognostic characteristics, such as higher ZAP70 expression, unmutated IGHV genes, and also a tendency towards lower levels of Hb and platelet counts. A short LDT was also associated with an increased expression of ZAP70 and CD38, unmutated IGHV (all p<0.001) and poor FISH cytogenetics (del17p, del11q) (p<0.001). Additionally, patients with a short LDT presented more frequently mutations in NOTCH1 (p=0.008), ATM (p=0.029), TP53 (p=0.035) and a tendency to more mutations in SF3B1 (p=0.102). The proportion of patients treated in each group was markedly different [80% vs 46%] as it was the median time to treatment (TTT, 1.4 vs 9.4 years; p<0.001). Type of treatment (mainly, chemotherapy and immunotherapy) did not differ more frequently treated with alkylating agents than purine analogues.

Summary/Conclusions: All ITT are still regarded as equally important, although no solid evidence exists to support such statement. In our series, infiltrative cytopenia and/or progressive lymphadenopathy/splenomegaly constituted the ITT in most (85%) CLL patients. In spite of being enriched in favorable biological prognostic factors (mutated IGHV genes, low ZAP70 expression and favorable-risk cytogenetics), MF patients had a shorter age-adjusted OS from first-line therapy compared to LM patients. Further studies should address whether this result also applies to patients treated with novel agents.

E1032
INDICATIONS FOR TREATMENT IN CHRONIC LYMPHOCYTIC LEUKEMIA: CLINICO-BIOLOGICAL CHARACTERISTICS AND PROGNOSTIC IMPACT
P. Mozos1, A. Rivas-Delgado1, T. Bauman1, V. Ortiz-Maldonado1, A. Navarro2, D. Costa4, M. Aymiri3, N. Villamor3, E. Montserrat3, J. Delgado4
1Hematology, 2Pathology, 3Hematopathology Unit, Pathology, Hospital Clinic de Barcelona, Institut d’Investigacions Biomèdiques August Pi i Sunyer, Barcelona, Spain

Background: Chronic lymphocytic leukemia (CLL) is characterized by the progressive accumulation of monoclonal CD5+ B cells in the bone marrow and lymphoid tissues. International guidelines recommend initiation of treatment only in case of infiltrative cytopenia, progressive splenomegaly or lymphadenopathy, short lymphocyte doubling time (LDT), B symptoms and/or refractory disease (RD). These criteria are based on experts’ consensus and considered equally relevant for treatment initiation, even though little evidence exists concerning the relative value of each individual criterion.

Aims: To describe the clinic-biological characteristics and prognosis of CLL patients according to the criteria that prompted the initiation of first-line treatment.

Methods: Retrospective analysis of 1,405 consecutive patients with CLL who received first-line therapy from 1978 to 2014 and had their indication(s) for treatment (ITT) recorded. Massive/progressive lymphadenopathy and massive/progressive splenomegaly were grouped together as lymphoid mass (LM), Infiltrative anemia and thrombocytopenia were categorized as marrow failure (MF). As 505 patients initiated therapy due to LM or RD, we decided to focus on these two groups. Patients whose ITT was both LM and MF were classified as MF following the logic behind Rai and Binet staging systems.

Results: Median age of the whole cohort was 62 years (range 22-93), and 63% of patients were male. Median follow-up from first-line therapy was 64 months (range 1-433). Half of the patients had a single ITT, while the other half had two or more. ITT were LM in 72% patients, MF in 31%, short LDT in 29%, B symptoms in 19%, and IC in 3%. Compared to patients from the LM group, patients from the MF group were significantly older, had a significantly higher β2-microglobulin level (probably due to an age-related impaired renal function), and were more frequently treated with alkylating agents than purine analogues. Conversely, patients treated due to LM had more frequent adverse prognostic characteristics, such as higher ZAP70 expression, unmutated IGHV genes, and 11q deletion. The median OS of the entire population was 77 months (95% confidence interval [CI]=71-83) from first-line therapy and 108 months (95% CI=102-118) from diagnosis. Indication for treatment was significantly associated (p<0.001) with a shorter OS from first-line therapy: 63 months in the MF group (95 CI: 48-72), compared to 89 months in the LM group (95% CI: 80-106). This association remained significant after adjusting for age and β2-microglobulin concentration.

Figure 1.
Summary/Conclusions: All ITT are still regarded as equally important, although no solid evidence exists to support such statement. In our series, infiltrative cytopenia and/or progressive lymphadenopathy/splenomegaly constituted the ITT in most (85%) CLL patients. In spite of being enriched in favorable biological prognostic factors (mutated IGHV genes, low ZAP70 expression and favorable-risk cytogenetics), MF patients had a shorter age-adjusted OS from first-line therapy compared to LM patients. Further studies should address whether this result also applies to patients treated with novel agents.

UNCOVERING PRIMARY TP53-DELETED CLONES WITH FISH THROUGH FACS-SUPPORTED PURIFICATION OF CHRONIC LYMPHOCYTIC LEUKEMIA LYMPHOCYTES
G. Marques1, M. Pereira2,3, J. Lima3, R. Reis3, A. Coelho1, L. Jorge1, S. Pedroiro1, L. Ribeiro1, A. Paiva4, F. Rodrigues1
1Clinical Pathology Department, 2Clinical Hematology Department, Coimbra University Hospital Centre, 3Faculty of Medicine, University of Coimbra, 4Flow Cytometry Unit, Coimbra University Hospital Centre, Coimbra, Portugal

Background: The presence of TP53-inactivation in chronic lymphocytic leukemia (CLL), namely through the deletion of all or part of the chromosome containing its locus, is a well-established marker of poor prognosis and chemoresistance to traditional chemotherapeutic agents. Fluorescence in situ hybridization (FISH) is a useful tool for the detection of the deletion. Nevertheless, its sensitivity is influenced by the number of blood-cell lineages that carry the aberration, the absolute count of deletion-positive cells, and the proportion of deletion-positive neoplastic cells relative to deletion-negative neoplastic cells and non-neoplastic cells, in the whole blood or bone marrow sample. The latter issue can be minimized by purifying the sample through the selection and separation of tumor cells, using techniques such as fluorescence-activated cell sorting (FACS).

Aims: In this study, we aim to evaluate the benefit of using purified samples of neoplastic CLL lymphocytes for the detection of TP53-deletion by FISH, when compared to full samples.

References:

Methods: We reviewed all CLL samples that were submitted for the investigation of TP53-deletion through FISH, in our Lab, between January 1st 2011 and February 28th 2017. Results obtained on tests performed on whole mixed cellularity samples were compared with results obtained directly in FACS purified CLL clonal lymphocytes.

Results: We analyzed 410 samples tested for the deletion of TP53 in our Lab during the study period. The majority of patients (63.2%) were male. Although FACS separation of nonclonal cells was only introduced within the last two years of the study period, it accounted for 39.0% of all tested samples. This poor prognostic aberration was identified in 15.8% of patients in the overall cohort, with no differences in the incidence of a positive finding between mixed cellularity samples and FACS purified samples (15.6% vs 16.2%, respectively, p=NS). In contrast, the average proportion of positive cells within a positive sample was markedly different between mixed cellularity samples and FACS-processed samples, increasing nearly three-fold through the purification of the sample, from 24.0±15.9% to 62.9±33.3%, p<0.001. In fact, in 57.7% of all patients who were tested after FACS separation of CLL cells, the TP53-deleted clone was larger than 50% of nonclonal clonal lymphocytes, making it the primary clone.

Summary/Conclusions: We observed that the pre-processing of the sample through the FACS-supported purification of CLL nonclonal lymphocytes revealed that the TP53-deleted clone was nearly three-fold larger than suggested by the mixed cellularity sample, increasing from an average of a quarter of all cells, to nearly two-thirds. This finding uncovered that the TP53-clone was, in fact, the primary major clone within the nonclonal lymphocyte population in the majority of patients. Considering the poor prognosis conferred by the aberration, and its impact on current treatment decisions, it is quite significant to correctly identify a primary deletion-positive clone, instead of mislabelling it as a secondary minor clone.

E1034 PRIMARY PEGFILGRASTIM PROPHYLAXIS VERSUS FILGRASTIM GIVEN “ON DEMAND” FOR CLADRIBINE-INDUCED NEUTROPENIA IN HAIRY CELL LEUKEMIA

1The Ruth and Bruce Rappaport Faculty of Medicine, Technion, Haifa, 2Department of Hematology, Sourasky Medical Center, Tel Aviv, 3Department of Hematology, Hadassah University Hospital, Jerusalem, 4Department of Hematology, Rabin Medical Center, Petah-Tikva, 5Department of Hematology, Meir Medical Center, Kfar-Saba, 6Hematology Unit, Kaplansh Medical Center, Rehovot, 7Department of Hematology & Bone Marrow Transplantation, Rambam Health Care Campus, Haifa, 8Hematology Unit, Emek Medical Center, Afula, 9Department of Hematology, Shaare Zedek Medical Center, Jerusalem, 10Hematology Unit, Gallilee Medical Center, Nahariya, 11Hematology Unit, Ziv Medical Center, Zefat, 12Department of Hematology, Soroka Medical Center, Beer-Sheva, 13Department of Hematology, Hadassah University Hospital, Jerusalem, 14Hematology Unit, Bnai Zion Medical Center, Haifa, Israel.

Background: Major advances in the treatment of patients with HCL were made in the 1980’s after the introduction of two purine analogues: pentostatin and cladribine. Both these agents dramatically altered the clinical course and outcome of this disease and induced high response rates of 75-90%, with durable remissions and subsequent median relapse-free survival of up to 15 years. The major significant short-term toxicity of therapy with cladribine are neutropenia and neutropenic fever (NF). Based on the script data: 71% of patients experienced grade 4 neutropenia (absolute neutrophil count [ANC] <500x10^9/L), and 42% develop NF. The latter complications may result in life-threatening infections, as well as hospitalization.

Aims: In this retrospective study, we compared the incidence and duration of neutropenia, NF and hospitalization in patients with HCL treated with cladribine following “on demand” versus daily filgrastim given *on demand* according to the absolute neutrophil count.

Methods: The study population included 202 patients with HCL, diagnosed and followed in 12 medical centers in Israel during 1985-2015. Patients were treated with cladribine, for 5-7 days given either sub-cutaneously or via intravenous infusion. Medical records were evaluated for details of disease at diagnosis, including date of diagnosis, age, sex, ethnicity, complete blood count results, and spleen size at diagnosis. The efficacy of pegfilgrastim and filgrastim was assessed by evaluating the incidence of neutropenia (defined as ANC <1000x10^9/L), number and length of hospitalizations due to NF, severity of infections and the number of days from the last day of therapy until recovery of ANC to ≥1000x10^9/L.

Results: Mean follow up was 7.5 years (0.1-40), with 5 and 10 years’ survival of 96% and 90.62% respectively. The median age at diagnosis was 53 years, and 81.8% were males. First line therapy with cladribine was given to 159 patients and among these 50.3% required hospitalization for the administration of broad-spectrum antibiotics due to NF. The risk factor to develop NF was WBC < 0.6 10^9/L and ANC <0.310^9/L. Twenty eight patients were treated with pegfilgrastim as primary prophylaxis 24 hours after the last day of therapy with cladribine, while 75 patients received filgastrim *on demand* due to neutropenia. Median hospitalization days, and Nadir duration was 8 and 18 days respectively in both groups (p=0.71, p=0.44).

Table 1.

Summary/Conclusions: Infectious complications post cladribine treatment, remains high, with an incidence of 50.3%. For all parameters analyzed, including the percentage of febrile patients, number of febrile days, and NADIR duration the results of primary pegfilgrastim prophylaxis and filgrastim given on demand were similar. Accordingly, we conclude that it remains the treating physician’s choice to decide on which type of filgrastim to use and when to administer it.

E1035 REDUCED HEALTHCARE RESOURCE UTILIZATION IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA ACHIEVING COMPLETE REMISSION TO FIRST-LINE THERAPY

S Heitner Enschede1, J. Samp1, A. Guerin2, R. Foster2, B. Meissner1, A. Rokito3, G. Gauthier2.

Background: Most targeted therapies in the management of chronic lymphocytic leukemia (CLL) lead to high overall response rates but complete remissions are rare. Achieving complete remission (CR) is associated with improved clinical outcomes such as longer time to progression; however little is known about the economic benefits associated with achieving CR.

Aims: The objective of the study was to compare healthcare resource utilization among CLL patients initiated on first-line treatment who achieved CR versus those who did not.

Methods: This was a retrospective chart review study. From July to August 2016, 93 US oncologists/hematologists provided data abstracted from medical charts of their CLL patients who initiated a first-line CLL treatment between January 2010 and December 2014. The study collected patient demographics, clinical characteristics, response to first-line therapy, and the number of all-cause hospitalizations between first-line therapy initiation and end of the data follow-up (i.e., patient’s date of death, end of care, or data collection date, whichever occurred first). Patients were selected based on their best response to first-line therapy (i.e., CR, partial remission [PR], stable disease [SD] and progressive disease [PD]) as defined by the physician according to iwCLL 2008 criteria. The targeted number of patients in each category was a priori determined based on rates of response observed in clinical trials. The incidence of all-cause hospitalization was compared between patients who achieved CR and those who did not (including patients with PR, SD or PD) using univariate and multivariate generalized linear models with a Poisson distribution. As patients had different follow-up, incidence rates were reported per-patient-per-month (PPP). Multivariate regression models were adjusted for age, gender, selected comorbid conditions, time from CLL diagnosis to first-line initiation, and Eastern Cooperative Oncology Group (ECOG) status.

<td>0.003</td>
<td>3.30 (1.69-6.21)</td>
<td>2.44 (1.13-5.42)</td>
</tr>
</tbody>
</table>

Results: Patient-level data was collected for 179 patients who achieved CR and 151 patients who did not achieve CR (120 patients with PR, 25 with SD, and 6 with PD). Average time from CLL diagnosis to first-line initiation was 8.4 months for patients who achieved CR and 13.3 months for those who did not. The majority of patients were male (65%), the average age was 63 years, and 80% of patients had an ECOG of 0 or 1 at first-line therapy initiation. The medi-
an follow-up after first-line therapy initiation was 30 months. Over that period, patients who did not achieve CR had statistically significantly higher incidence of all-cause hospitalization compared to patients who achieved CR (0.021 vs 0.006 PPPM; unadjusted incidence rate ratio [IRR]=3.30, p<0.05). After adjusting for potential confounders, the incidence of all-cause hospitalization was 2.4 times higher for patients who did not achieve CR compared to those who did (IRR=4, p<0.05).

Summary/Conclusions: Results from this study showed that achieving CR to first-line therapy (vs. not achieving CR) is associated with reduced frequency of all-cause hospitalizations. This suggests that, in addition to the clinical benefit of care for CLL pts with AIHA, especially for the cohort of pts with comorbidities. R may help reducing the economic burden of CLL management for both patients and payers.

E1036
RITUXIMAB (R) USED AS A SINGLE AGENT FOR AUTOIMMUNE HEMOLYTIC ANEMIA (AIHA) IN TREATMENT NAIVE CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) PATIENTS INDUCES ALSO SIGNIFICANT DISEASE RESPONSE WITHOUT TOXICITY
S. Sachanas1,*, G. Pangalis2, M. Moschogiannis1, X. Yiakounis1, P. Tsirkinidis1, E. Koulieri1, C. Kalpakas1, E. Poppis8, T. Vassilakopoulos2, M. Angelopoulou5, 1Hematologic, Athens Medical Center, Psychiko Branch, 2Hematologic, Athens Medical Center, Phychikon Branch, Athens, 3Hematologic, Athens University Hospital, University of Crete, Heraklion, 4Blood Transfusion, Athens Medical Center, Phychikon Branch, Athens, 5Hematologic, University Hospital, Athens, Greece

Background: There are very few effective treatment options for steroid refractory AIHA of CLL or for CLL patients(pts) that are unable to receive corticosteroids. R has been noted to be active in certain autoimmune hematologic disorders while experience with single-agent R in untreated CLL pts is very limited. Aims: To report our experience concerning the use of R as a treatment of AIHA occurring during the 6-week course of treatment of naïve CLL pts by analyzing concomitantly its efficacy and safety as a single agent in CLL therapy

Methods: 15 pts diagnosed with CLL who received R due to AIHA were included in this study. Staging was performed at diagnosis (Binet system). Pts were placed on R at the standard dose IV of 375mg/m2 once weekly for 6 consec- utive weeks because of contraindication of corticosteroids administration

Results: Pts’ median age was 60 (range, 42-83 y). (8 out of 15, males), 10 having disease stage A and 5 B. Two were presented with splenomegaly and 1 with B-symptoms. 12 pts (83%) had leukemic lymphocyte counts of more than 50x10^3/L. Median time from diagnosis, the AIHA diagnosis and to 1st R infusion was 59 mos. All 15 pts completed the 6-week course of R and were assessable for response. The median WBC and the median absolute lymphocyte count(ALC) before R administration and after the end of 6-week course are shown in the Table. Resolution of the AIHA effect was achieved in all pts whereas in 4 there was a persistence of positive DAT without evidence of active hemolysis. After the median WBC and ALC counts of treatment naïve CLL pts by analyzing concomitantly its efficacy and safety as a single agent in CLL therapy

Results: 13 pts (86.7%) achieved PR and 1 CR (6%). All pts with advanced disease also responded entering PR. Resolution of splenomegaly was documented in both splenomegalic pts. After a median follow up of 84, 5 mos from CLL diagnosis, 14 pts are alive, 9 maintain their disease response while 5 were in need of therapy due to CLL progression, after a median time of 10 mos from the last R infusion. Among them 4 were placed on FCR (2CR, 2PR) and 1 on R-Bendamustine(PR). Median PFS has not reached. All pts received the entire first dose on day 1 of treatment. There was only a grade 3 infusion related reaction in a patient with WBC>400x10^9/L without need for hospitalization. None of the pts experienced severe tumor lysis syndrome, pulmonary insufficiency, myelosuppression or opportunistic infections.

Summary/Conclusions: A) R is an effective agent for AIHA treatment with concomitant significant activity against CLL and therefore could be the standard of care for CLL pts with AIHA, especially for the cohort of pts with comorbidities. B) We confirm previous data that: 1) single-agent R induces significant responsi

E1037
ATTAINMENT OF COMPLETE REMISSION IS SIGNIFICANTLY ASSOCIATED WITH LONGER SURVIVAL OUTCOMES IN RELAPSED/REFRACTORY (R/R) CLL: A META-ANALYSIS
V.U. Ekstare1,*, C.P. Fox2, R.S. Taylor3, T.I. Inocencio1, G.E. Pena4, J.C. Maher4, S.J. Snedecor1
1Pharmnet International, Bethesda, United States, 2Nottingham University Hospitals, Clinical Hematology, Nottingham, 3University of Exeter Medical School, Exeter, United Kingdom, 4ABBvie, Inc., North Chicago, United States

Background: Chronic lymphocytic leukemia (CLL) is an incurable neoplasm of B lymphocytes, associated with a heterogeneous clinical course. Complete response (CR) with/without minimal residual disease in first-line chemotherapy has been associated with more favorable progression-free survival (PFS) and overall survival (OS). However, patients (pts) with R/R CLL and/or those with TP53 abnormalities (ie, 1p7 deletion and/or TP53 mutation) are less likely to achieve deep responses and experience poorer outcomes. Therefore, less is known about the relationship between CR and survival outcomes in R/R CLL pts.

Aims: To quantify this association, we generated meta-analytic estimates of PFS and OS reported in clinical trials using the proportion of study patients with CR as a predictor variable.

Methods: We performed a systematic literature review of PubMed/EMBASE up to Nov 2014 and congress abstracts 2012–2014. Randomized controlled trials and observational studies evaluating any treatment in R/R CLL pts were eligible for inclusion. Data were extracted from publications as median survival, the proportions of pts surviving at specific follow-up times, or individual event or censoring times from reported Kaplan-Meier (KM) curves, along with the proportion of pts with CR. Data were synthesized to estimate overall OS and PFS including population-level CR as a covariate using a Weibull proportional hazards model within a Bayesian meta-analysis framework.

Results: 74 published studies of treatment outcomes in R/R CLL pts were identified from the peer-reviewed literature and congress abstracts. 56 of these studies reported the proportion of CRs together with either OS or PFS outcomes and were included in the analysis. Individual pt data were extracted from KM curves of 29 studies generating 5176 individual pt OS and PFS data points in addition to 54 study-level data points including 3638 pts. There were no clinically meaningful differences in study or pt characteristics among the included studies that were not also associated with CR, our variable of interest. The hazard ratio (HR; and 95% credible interval, the Bayesian analog to con- 353

The attainment of CR is significantly associated with longer OS and PFS outcomes in R/R CLL at the study level. Moreover this can be expressed linearly, with each 10% increase in CR rate corresponding to a 36% reduction in the risk of progression or death. To our knowledge, this is the first meta-analysis to quantify the relationship between CR and survival outcomes in R/R CLL pts. It must be noted that these results reflect the study (population) level CR versus survival association and therefore do not necessarily represent the expected survival gain associated with an individual achieving CR. Further, CR is less likely to be achieved in pts with TP53 abnormalities, a factor not explicitly considered in our analysis. These results synthesize data from 56 clinical trials and strongly support the importance of achieving CR to improve long-term outcomes in R/R CLL pts. In particular, the prognostic association between CR and TP53 abnormalities, treatments focused on improving the likelihood of CR in these hard-to-treat pts are likely to confer the greatest impact on survival outcomes.

Figure 1.

Summary/Conclusions: The attainment of CR is significantly associated with longer OS and PFS outcomes in R/R CLL at the study level. Moreover this can be expressed linearly, with each 10% increase in CR rate corresponding to a 36% reduction in the risk of progression or death. To our knowledge, this is the first meta-analysis to quantify the relationship between CR and survival outcomes in R/R CLL pts. It must be noted that these results reflect the study (population) level CR versus survival association and therefore do not necessarily represent the expected survival gain associated with an individual achieving CR. Further, CR is less likely to be achieved in pts with TP53 abnormalities, a factor not explicitly considered in our analysis. These results synthesize data from 56 clinical trials and strongly support the importance of achieving CR to improve long-term outcomes in R/R CLL pts. APLICATION OF THE CLL-IPI AND THE MDACC PRGNOSTIC INDEXES IN A LOCAL COHORT OF CLL PATIENTS

I. González-Gascón Y Marin1,*, M. Pozo1, M. Hernández-Sánchez2, A.E. Rodríguez-Vicente2, M.S. Infante1, C.C. Muñoz Novas1, C. Heras1, M.A. Foncillas1, J.M. Hernández-Rivas4, J.A. Hernández1
1Hospital Universitario Infanta Leonor, MADRID, 2IBSAL, IBMCC, Centro de Investigación del Cáncer, Universidad de Salamanca-CSIC, Salamanca, Spain

Background: New prognostic scores have been developed in order to better discriminate the clinical course of CLL patients, along with Rai and Binet clinical staging systems. These scores, such as that proposed by the MDACC group, and recently the CLL-IPI combine clinical and biological variables with prognostic value.

Aims: In this study we investigated the validity and reproducibility of these scores in a local cohort of patients with CLL.

Methods: We made a retrospective analysis including 650 unselected CLL patients newly diagnosed and previously untreated from a single institution. The final analysis has been limited to the 486 cases with complete data to apply the MDACC score, and to the 258 cases with complete data to apply the CLL-IPI score.

Results: Median age was 67 years old (25-90). With a median follow-up time of 46 months, 394 patients were alive, and 187 had received any treatment for CLL at the moment of the analysis. Median overall survival (OS) of the whole series was 173 months (127-220), and median time to first treatment (TTFT) 106 months (82-130). The MDACC score was applied to 486 cases giving 0 to 9 points to each case according to: age, b2-microglobulin levels, absolute lymphocyte count, sex, Rai stage, and number of involved lymph node groups. As shown in the Table, stratification of patients using the MDACC score allowed the prediction of prognosis for both TTFT (P=0.000) and OS (P=0.000). 162 patients were classified as low risk, 302 as intermediate risk, and 21 as high risk. Due to missing data, the CLL-IPI score could only be applied to 258 patients giving 0 to 10 points to each case according to 17p deletion, IGHV mutational status, b2-microglobulin, clinical stage, and age. As shown in the table, 126 patients were classified as low risk, 79 as intermediate risk, 46 as high risk, and 7 as very high risk. We also found significant differences in terms of OS (P=0.000) and TTFT (P=0.000) using this score.

Table 1.

Summary/Conclusions: In this study we confirm that both scoring systems are able to discriminate patients in different prognostic subgroups. Both scores are also easily applicable in clinical practice. The new CLL-IPI score is able to distinguish subgroups of patients with worse prognosis including new factors (17p deletion and mutational status of IGHV).

E1039

CHRONIC LYMPHOCYTIC LEUKEMIA: PROGNOSTIC VALUE OF CLINICAL STAGES AND CLASSICAL PROGNOSTIC PARAMETERS DEPENDING ON TREATMENT MODALITY

T. Baumann1,*, J. Delgado1, P. Mozas1, V. Ortiz-Maldonado1, R. Santacruz2, M. Rozman3, M. Aymerich1, N. Villamor1, D. Costa4, A. Carrò1, E. Montserrat1
1Hematology Department, Institute of Hematology and Oncology, Hospital Clinic, IDIBAPS, University of Barcelona, Barcelona, Spain, 2Hematology Department, Hospital de Clínicas, Asunción, Paraguay, 3Hematopathology Unit, Pathology Department, Institute of Hematology and Oncology, Hospital Clinic, IDIBAPS, University of Barcelona, Barcelona, Spain

Background: Prognostication is a key component in the management of patients with chronic lymphocytic leukemia (CLL). Prognostic factors however may change as a result of the introduction of more effective therapies.

Aims: To investigate whether the prognostic value of classical parameters has changed over time.

Methods: Retrospective single-center study of prognostic factors and outcome in patients with CLL diagnosed before (n=454) and after (n=903) 1995 when purine analogs and subsequently chemoimmunotherapy (CIT) were introduced in CLL treatment at the Hospital Clinic, Barcelona.

Results: The median follow-up up was 8.3 years (0.1-33.0) for the overall series and 24.9 years (21.9-33.0) and 7.8 years (0.1-21.3) for patients diagnosed before and after 1995, respectively. Patients diagnosed before 1995 were older (p=0.001), had more advanced clinical stage (p=0.001), higher ALC (p=0.001), shorter LDT (p=0.001), and more often anemia (p=0.2), thrombocytopenia (p=0.001) and increased serum LDH levels (p=0.019) than those diagnosed thereafter. There were no differences in B2-microglobulin (B2M) levels and ZAP70 or CD38 expression. Mutated IGHV was more frequently detected in patients diagnosed before 1995 (75% vs 55%; p<0.001). The proportion of patients receiving treatment did not differ between groups (42% vs 46% (42-49%) at 6 years; p=0.08). The type of therapy given to patients diagnosed before and after 1995 was: alkylating agents (91% vs 34%), purine analogs (4% vs 27%), CIT (0% vs 31%), other (5% vs 8%) (p<0.001). The response rate was lower in patients diagnosed before 1995 (57% with 9% CR vs 61%, 36% CR, p<0.001) and overall survival (OS) was shorter (median: 8.0 vs 10.1 years; p<0.001). The median OS in patients diagnosed before and after 1995 broken down by clinical stage was: stage A: 10.1 vs 10.9 years (p=0.1); stage B: 4.5 vs 9.2 years (p<0.001); stage C: 3.8 vs 8.3 years (p=0.2).

In both groups of patients univariate analyses demonstrated a correlation between OS and clinical stage (both p<0.001), age >70 years (both p<0.001), B2M (both p<0.001), short lymphocyte doubling time (LDT) (both p<0.001), unmutated IGHV (both p<0.001) and ZAP70 (p=0.015 and p<0.001). High-risk FISH correlated with OS in patients diagnosed after 1995 (p<0.001). In patients diagnosed before 1995, the number of subjects with available FISH was too small for a meaningful analysis. In multivariate analysis (age >70 years, advanced clinical stage short LDT increased B2M, diagnosis before 1995 only) HR 2.7 (95% CI: 2.1-3.4), p<0.001, LDT (HR 2.5 (1.9-3.2), p<0.001) and B2M (HR 2.8 (2.2-3.8), p<0.001) showed independent prognostic significance for OS. IGHV mutational status, ZAP70 and high-risk FISH cytogenetics correlated with OS but these were not included in multivariate analyses because of the many patients with missing information.

Summary/Conclusions: Survival of patients with CLL in intermediate-risk (stage B) disease has dramatically improved over the last years. In contrast, the outcome of patients with either low (stage A) or high (stage C) stage has not been significantly modified during the need for more effective therapies in these patients. Importantly, the prognostic significance of classical prognostic variables has not changed after the introduction of more effective therapies. Finally, similar studies are warranted in patients treated with novel agents.
patients (27.4%). Overall, 80.3% of FAS patients did not experience therapeutic failure and 85.9% did not experience disease progression during the 2-year observation period. By the end of the study, median PFS had not been reached, 2-year PFS rate was estimated as 85.9%. Improvements from baseline were observed after 6 cycles of treatment across all EQ-5D domains. No relapses or deaths occurred in the FAS; however, 2 subjects in the Safety Population experienced fatal serious ADRs (myocardial infarction [n=1]; acute pneumonia, infections and toxic shock, and atrial fibrillation [n=1]). In concurrence with the Phase 3 trial results, hematologic disorders (19.9%; anemia, neutropenia, thrombocytopenia), most of which were Grade ≤2 in severity, were the most common ADRs (Safety Population; Table 1).

Summary/Conclusions: First-line therapy with bendamustine plus rituximab was well tolerated in this Russian CLL population, including elderly patients and patients with renal dysfunction or other comorbidities. Additionally, combination therapy resulted in high rates of treatment response in the CLL. These data confirm the value of bendamustine as a first-line agent for CLL in routine clinical practice in Russia.

MUTAGENESIS OF BCR-ABL1 IS REQUIRED FOR RESISTANCE DEVELOPMENT IN DE NOVO CHRONIC MYELOID LEUKEMIA KCL-22 CELLS BUT NOT IN RELAPSED KCL-22 CELLS EXPRESSING BCR-ABL1 INDEPENDENT RESISTANCE

N. Cunliff1,2, V. Polikova1,3, T. Kalina4, V. Kanderova4, J. Linhardtova1, F. Savulj, O. Tomán1, K. Srutova1, S. Ransdorfova1, J. Brezník1, H. Klama1,5, K. Machova Polakova1,5,6

1Institute of Hematology and Blood Transfusion, 2Institute of Pathological Physiology, First Medical Faculty, Charles university, 3Faculty of Science, Charles university, 4Department of Paediatric Haematology and Oncology, Univ. hospital Motol, 5Institute of Clinical and Experimental Hematology of the 1st Medical Faculty, Charles university and Institute of Hematology and Blood Transfusion, Prague, Czech Republic

Background: BCR-ABL1 kinase domain (KD) mutations are an important mechanism of resistance of chronic myeloid leukemia (CML) patients developing during the tyrosine kinase inhibitors (TKI) treatment. However, mechanisms underlying KD mutation acquisition in TKI-resistant CML cells are not yet well understood.

Aims: We studied an acquisition of mutations in the KD after an exposure of de novo and relapsed (grown in optimal growing medium for 24 months) KCL-22 cells to imatinib (IM). In addition, we examined kinetics of mutated subclones in established IM-resistant KCL-22R culture after dose-reduction of IM. We also studied changes in the expression profile of KCL-22 cultures early after exposure to IM.

Methods: The occurrence and kinetics of expansion of BCR-ABL1 mutant subclones were studied using next-generation deep sequencing in KCL-22 cells treated with 0.4 µM IM and in established IM-resistant KCL-22R cells at 4 µM IM. In other set of experiments, KCL-22R cells were sorted according to the CD38 expression to explore whether CD38 is associated with the acquisition of BCR-ABL1 mutations as suggested by Wang et al. (2014). A protein array was used allowing analysis of 576 proteins per sample. DNA damage pathway-RT Profiler PCR arrays were applied for gene expression analysis.

Results: No BCR-ABL1 KD mutations were detected in de novo untreated KCL-22 cells, however T315I and E255K appeared after the exposure of the cells to 0.4 µM IM. PCR array revealed increased expression of SUMO 1 ligase and ERCC2 involved in the nucleotide excision repair pathway. Notably, we also found a significant decrease of G2/M-checkpoint protein GAID45a whose deficiency is associated with mutagenesis (Hollandar et al., 2001). During the first culture period, T315I slowly emerged whereas E255K was not detectable. Later, E255K-bearing cells also became detectable and increased over time. A similar time-dependent expansion of mutant-bearing sub-clones was seen in the KCL-22R cells growing at 4 µM IM. Interestingly, a mutant-clone switch from T315I to E255K in KCL-22R was accelerated after IM reduction from 4 µM to 1 or 2 µM. Moreover, the emerging of E255K sub-clones was accompanied by rapid decrease of CD38 expression in KCL-22R cells. Profiling of transitional KCL-22R culture, carrying both T315I and E255K sub-clones, revealed that T315I transcripts were expressed only in the CD38+ subpopulation, while E255K was detected only in CD38- cells. Unlike to de novo KCL-22 cells, BCR-ABL1 mutations were repeatedly not detected in relapsed KCL-22R cells, until 60 days after the cells exposure to 0.4 µM IM. Neither BCR-ABL1 upregulation nor gene amplification was detected in these cells. We identified considerably upregulated (D7, DTX3, ETV6, GLUL, HCLS1, HIF1α, IGF1R, MAP2K7, MYH11, TP53) or downregulated (BAD, BID, MCL2 NOTCH3, PDKPI1) proteins early, 4 weeks after the exposure to IM. Increased expressions of HIF1α and IGF1R proteins are known to ensure proliferation, while decreased expressions of pro-apoptotic proteins BAD and BID enhance survival of CML cells in the presence of TKIs.

Summary/Conclusions: Our observation suggests the ability of KCL-22 cells to survive and proliferate early after the exposure to IM. BCR-ABL1 mutations development seems to be related to a mutagenesis of imatinib in de novo KCL-22 cells, but not on relapsed KCL-22 cells that activated signaling pathways ensuring their survival and growing in the presence of tyrosine kinases inhibitor.

PCR array revealed increased expression of SUMO 1 ligase and ERCC2 involved in the nucleotide excision repair pathway. Notably, we also found a significant decrease of G2/M-checkpoint protein GAID45a whose deficiency is associated with mutagenesis (Hollandar et al., 2001). During the first culture period, T315I slowly emerged whereas E255K was not detectable. Later, E255K-bearing cells also became detectable and increased over time. A similar time-dependent expansion of mutant-bearing sub-clones was seen in the KCL-22R cells growing at 4 µM IM. Interestingly, a mutant-clone switch from T315I to E255K in KCL-22R was accelerated after IM reduction from 4 µM to 1 or 2 µM. Moreover, the emerging of E255K sub-clones was accompanied by rapid decrease of CD38 expression in KCL-22R cells. Profiling of transitional KCL-22R culture, carrying both T315I and E255K sub-clones, revealed that T315I transcripts were expressed only in the CD38+ subpopulation, while E255K was detected only in CD38- cells. Unlike to de novo KCL-22 cells, BCR-ABL1 mutations were repeatedly not detected in relapsed KCL-22 cells, until 60 days after the cells exposure to 0.4 µM IM. Neither BCR-ABL1 upregulation nor gene amplification was detected in these cells. We identified considerably upregulated (D7, DTX3, ETV6, GLUL, HCLS1, HIF1α, IGF1R, MAP2K7, MYH11, TP53) or downregulated (BAD, BID, MCL2 NOTCH3, PDKPI1) proteins early, 4 weeks after the exposure to IM. Increased expressions of HIF1α and IGF1R proteins are known to ensure proliferation, while decreased expressions of pro-apoptotic proteins BAD and BID enhance survival of CML cells in the presence of TKIs.

Summary/Conclusions: Our observation suggests the ability of KCL-22 cells to survive and proliferate early after the exposure to IM. BCR-ABL1 mutations development seems to be related to a mutagenesis of imatinib in de novo KCL-22 cells, but not on relapsed KCL-22 cells that activated signaling pathways ensuring their survival and growing in the presence of tyrosine kinases inhibitor.

Supported by the project no. 00023736 and AZV 15-31540A of MZCR and ERDF OPPK CZ.2.16/3.1.00/28007.
Background: Diagnosis of Chronic Myeloid Leukemia (CML) implies documenting in bone marrow (BM) or in peripheral blood (PB) Philadelphia (Ph) chromosome by cytogenetics, molecular BCR-ABL1 fusion by FISH or BCR-ABL1 rearrangement by RT-PCR. In clinical practice, at the earliest, 24-72 hrs are needed to confirm CML by any of these assays. Late characterization of CML leukemia stem cells (LSCs) from BM samples by BM CML patients (pts) showed a specific co-expression of dipeptidyl peptidase IV (CD26) within the CD34+/CD38−/Lin− stem cell fraction and CD26 appeared a robust biomarker showing a specific co-expression of dipeptidyl peptidase IV (CD26) within the CD34+/CD38−/Lin− stem cell fraction and CD26 appeared a robust biomarker.

Summary/Conclusions: Flow-cytometry also in PB during treatment with tyrosine kinase inhibitors.

Aims: We investigated accuracy and specificity of flow cytometry PB CD34+/CD38−/CD26+ LSCs identification as a new tool for the diagnosis of CML.

Methods: Patients with clinical suspicion of CML entered the study after written informed consent and all were evaluated for CD26-LSCs, cytogenetics, FISH and/or BCR-ABL1 RT-PCR analysis. CD34+/CD38−/CD26+ population was investigated in PB and when possible simultaneously in BM samples using a flow-cytometry 4-color staining procedure. 2.0x10⁶ leukocytes were incubated with CD Phenotypic antibodies (BD Biosciences). CD26+ cells were identified by FSC/SSC light properties and CD34+/CD38−population was gated applying a narrow gate excluding all CD38+ cells (Fig.1).

Results: PB samples from 107 pts with myeloproliferative features were evaluated for CD26-LSCs. Leucocytes median value was 52x10⁹/L (range 5-409x10⁹/L). In 83/107 (77.5%) pts we showed CD34+/CD38−/CD26+ LSCs in PB and in 83/107 (100%) the diagnosis of CML was confirmed by cytogenetics, FISH and RT-PCR analysis. Median value of circulating PB CD26/L µL was 14 (range 0.27-698) and a positive correlation with leukocyte count (p<0.01) was found. In 53/107 (49.5%) pts analysis was performed contextually in BM samples. On average, CD34+/CD38−/CD26+ population was gated applying a narrow gate excluding all CD38+ cells (Fig.1).

Figure 1.

Summary/Conclusions: Flow-cytometry evaluation of PB CD34+/CD38−/CD26+LSCs is a feasible, very rapid (about 3 hrs from sample handling to results) and highly specific alternative/complementary diagnostic tool for CML. To validate these data in a larger cohort of patients we are developing a pre-treated lyophilized antibody mixture (lyotube, BD Biosciences) to maximize sensitivity and to optimize standardization and working time, with the further aim to monitor stem cells minimal residual disease in CML patients.

Background: Transcribed ultraconserved regions (T-UCR) are a novel class of long noncoding RNAs. Many classes of noncoding RNAs have been implicated in human tumorigenesis. In addition to the different expression profiles of T-UCRs that could be used to distinguish human leukemias and cancers, there have also been reported to have direct interactions with miRNA with an important regulatory effect in disease development such as chronic myeloid leukemia (CML).

Aims: In this study, we aimed at the correlation of T-UCR and miRNA-T-UCR pairs in CML, according to tyrosine kinase inhibitor (TKI) therapy, clinical risk scores and molecular response.

Methods: We analysed peripheral blood samples from 45 CML patients and 15 healthy controls. Two panels of 481 T-UCR and 752 miRNA probes were used for RT-qPCR analysis. Differential expression was evaluated using the Mann-Whitney test followed by Benjamin-Hochberg multiple testing correction.

Results: CML samples presented significantly different expression of uc.164 (p=0.01), uc.118 (p=0.01), uc.125 (p=0.01), uc.391 (p=0.01), uc.153 (p<0.01), uc.141 (p<0.01), uc.143 (p<0.05) and uc.145 (p<0.05), when compared to healthy controls. This latter T-UCR (uc.145) was associated with development and immune regulation pathways. We analysed Sokal, Hasford and EUTOS risk scores and found uc.236 (p=0.0001), uc.39 (p<0.05) and uc.7 (p<0.05) to be associated with EUTOS low risk. Concerning therapy, dasatinib was correlated with uc.294 (p<0.05) and imatinib doses, uc.4 (p<0.05) and uc.3 (p<0.05) inversely correlated with 400 and 800mg daily, respectively. Molecular expression in CML samples presented a signature including uc.187 (p<0.001), uc.107 (p<0.05), uc.409 (p<0.05), uc.198 (p<0.05), uc.309 (p<0.05), uc.102 (p<0.05), uc.294 (p<0.05) and uc.361 (p<0.05). Major molecular response was identified by the altered expression of uc.198 (p<0.05), uc.215 (p<0.05) and uc.210 (p<0.05). The negative regulation of T-UCRs by miRNAs, involving T-UCR:miRNA interaction, was associated with upregulated (miR-720, miR-886-3p, miR-1274a, miR-101 and miR-129) and downregulated (miR-489 and miR-1973) microRNAs.

Summary/Conclusions: In the present study, we identified T-UCRs signatures and T-UCR:miRNA pairs associated with CML, risk scores, TKI therapy and molecular response. The expanded knowledge of RNA biology in general, together with the recent interest in the multitude of newly discovered elements such as T-UCRs, could help to improve CML therapy.

MIRNA PROFILING OF CIRCULATING EXTRACELLULAR VESICLES IN CML PATIENTS WITH MUSCULOSKELETAL PAIN ASSOCIATED WITH DISCONTINUATION OF TYROSINE KINASE INHIBITORS
K. Ohyashiki1, M. Asano1, T. Hirose2, S. Katagiri1, C. Kobayashi2, T. Tauchi1, M. Gotoh1, K. Ando1, S. Okabe1, J. Ohyashiki2
1Department of Hematology, 2Department of Molecular Oncology, Institute of Medical Science, Tokyo Medical University, Tokyo, Japan

Background: Clinical trials of TKI discontinuation are still ongoing, approximately 60% of CML patients who achieved a deep molecular response for more than 2 years maintained a major molecular response after discontinuation of imatinib. However, the long-term prognosis and/or adverse events after TKI cessation remain unclear. Recent reports showed that transient musculoskeletal pain and other non-hematologic abnormalities occurs in approximately 30% of CML patients after stopping imatinib.

Aims: Recent evidences suggest that extracellular vesicles (EVs) that contain genetic element such as DNA, RNA, and miRNA, are important mediators of intercellular communication. We therefore studied molecular study to ascertain the possible correlation between musculoskeletal pain and EV-miRNA expression.

Methods: We investigated circulating EV-miRNAs in five CML patients who did not experience musculoskeletal events and five patients with musculoskeletal pain after stopping TKIs, as well as three healthy individuals. Peripheral blood was obtained approximately 3 months after successful TKI cessation in CML patients. Exosomes were extracted by using Total Exosome Isolation Reagent (Invitrogen, Carlsbad, CA, USA) and EV-miRNA profiling was performed with a TaqMan Low-Density Array (Thermo Fisher Scientific, Carlsbad, CA, USA), as reported previously. The relative expression level of each gene was calculated by using the comparative thresholds cycle (Ct) method. Synthesis of spike control (ath-miR-159; Hokkaido System Science, Hokkaido, Japan) was used as an invariant control for EV-miRNA. This study was approved by the institutional review board of Tokyo Medical University (no. 930 approved 24 June 2008 and no. 3052 approved 9 June 2015).

Results: Three-way analysis of variance (ANOVA) performed for healthy controls and CML patients with and without musculoskeletal pain revealed EV-miR-140-3p to be the most significant value (P=0.00778). A t-test analysis using R software identified 10 differentially expressed EV-miRNAs for CML patients with and without musculoskeletal pain: seven miRNAs were upregulated (miR-107, miR-145, miR-140-3p, miR-539, miR-495, miR-299-5p, miR-425) and three were downregulated (miR-218, miR-218, miR-523) in CML patients with musculoskeletal pain. The up-regulated EV-miR-140-3p in all CML patients decreased after release of musculoskeletal pain.

Summary/Conclusions: CML patients with increased EV-miR-140-3p achieved levels similar to those of healthy controls after relief from musculoskeletal pain: in inflammatory indicators in some CML patients who stopped TKIs; however, we did not find any positive association. Although the number of CML patients in this study is too small to draw definite conclusions, further research should investigate whether upregulation of EV-miR-140-3p expression in peripheral blood is correlated with musculoskeletal events in CML patients after TKI cessation.
expression of several immune checkpoint inhibitors (BTLA, GITR, LAG-3, PD-1, PD-L1, PD-L2, TIM-3, CD137/4-1BB) by different T, B, NK, monocyte and dendritic cell subsets. A 14-plex panel including BTLA, GITR, HVEM, IDO, LAG-3, PD-1, PD-L1, PD-L2, TIM-3, CD28, CD80, CD137 (4-1BB), CD27, and CD152 (CTLA-4) was analyzed by xMAP technology (Luminex®).

**Results:** Expression of CD137 by several lymphocyte subsets and PD-1 by regulatory T cells (Tregs) and natural killer (NK) cells were found significantly altered in CML patients under TKI therapy. These associations were observed for the cell population frequency expressing the receptor, and also for density of these molecules. Increased plasmatic levels of BTLA, HVEM, PD-1, PD-L1, and CD137 were associated with good molecular response to therapy. PD-1, PD-L1, TIM-3 and CD137 were found increased in patients that achieved MR4.5.

**Summary/Conclusions:** Some immune checkpoint inhibitors seem to be affected by TKI therapy in CML and their cell expression and plasmatic levels correlates to molecular response. Similar observations were described for other types of cancers, including solid tumors. Soluble and membrane-bound receptor–ligand immune checkpoints could represent interesting targets for future therapeutic monitoring and for pharmacologic interventions in CML.

**TYROSINE KINASE INHIBITORS SIGNIFICANTLY CHANGE THE EXPRESSION OF POLYCOMB GENES IN CHRONIC MYELOID LEUKEMIA**

S. Grassi1,*, S. Palumbo2, E. Arrigoni3, E. Ciabatti4, G. Ercolano5, F. Guerrini4, K. Karimov1,*, N. Abdurahmanova1, K. Boboev1, S. Grassi1,*, S. Palumbo2, E. Arrigoni3, E. Ciabatti4, G. Ercolano5, F. Guerrini4, K. Karimov1,*, N. Abdurahmanova1, K. Boboev1

**Background:** It has been reported that, notwithstanding their clinical success, tyrosine kinase inhibitors (TKIs) are not able to eradicate the leukemic stem cell (LSC) in patients with chronic myeloid leukemia (CML). Different mechanisms have been hypothesized, especially those linked to the niche (increased osteoblastic differentiation, angiogenesis, hypoxia...). The epigenetic control seems to be relevant, and our group previously identified a correlation between the expression of some polycomb genes (PcGs) and response to TKIs, with BMI1 resulting a good predictive molecular marker (Crea, 2015).

**Aims:** In order to better understand the role of the PcGs genes in CML patients receiving TKIs, we analyzed the expression of 88 PcGs at baseline and after 6 months of therapy.

**Methods:** Buffy coats obtained from peripheral blood samples of 6 patients (5 receiving imatinib and 1 dasatinib) have been used for the RNA extraction; these RNAs were used for quantifying the BCR-ABL/ABL1 ratio%/IS, according to the European guidelines, and the expression of the chosen 88 PcGs by real-time PCR (PrimePCR pathway kit, Biorad, Milan, Italy) at diagnosis and after 6 months of treatment. Expression values were calculated using the 2-DDCt method.

**Results:** At the sixth month of treatment, 5 patients were in optimal response and one was “warning”, according to the 2013 ELN guidelines. After therapy, 55% of the tested PcGs resulted up-regulated and 23% of them in the majority of patients; whereas 3 genes (DNMT3B, SCML2, CBX2) were down-regulated in at least half of samples. The expression of 5% of PcGs was “mixed”, up- or down-regulated in different samples. Among the up-regulated genes, some could be relevant from a biological point of view: 1) HLF, a target for RUNX1, whose low expression in acute leukemia is correlated with poor outcome; 2) PHC2, able to silence the HOX genes, overcoming the multidrug resistance in myeloid models; 3) PCGF5, that is a marker of normal hematopoiesis; 4) MOV10, that has been reported to have an anti-viral activity, increasing levels of gamma interferon. This up-regulation is particularly interesting, because concerns all assessed samples and could explain our previous observation that Torque Teno virus replication does not occur in CML patients during TKI therapy; 5) in the only “warning” patient, the up-regulation of SIRT1 was observed: this is in line with the observation that its up-regulation increases the oncogenic ability of K562 cells in a murine model. Among the down-regulated genes, could be relevant: 1) CBX2, that binding P16/p19 promotes the cell cycle progression; its down-expression could induce apoptosis; 2) DNMT3B, whose high levels have been reported in stem cells, and whose reduction could characterize the differentiation process; 3) ZBTB16, whose reduction could be a sign of the reduced osteoblastogenesis, one of the mechanisms responsible for the LSC preservation in the niche; 4) SMARCA1, it too correlated to the cell cycle progression. Finally, BMI1 levels resulted unmodified in 3 cases and increased in other 3.

**Summary/Conclusions:** We demonstrated that PcGs de-regulation occurs in CML patients during the treatment with TKIs, with possible pathogenic implications. Huger series of patients will improve the biological suggestions coming from these preliminary data.

**IDENTIFICATION OF PROGNOSTIC AND SUSCEPTIBILITY MARKERS IN CHRONIC MYELOID LEUKEMIA USING NEXT GENERATION SEQUENCING**

Y. Shokeen1,*, N. R. Sharma2, V. Taneja3, S. Minhas1, M. Jauhari1, A. Aggarwal1

**Background:** Chronic Myeloid Leukemia (CML) is 20% of all leukemias diagnosed every year. Discovery of Imatinib Mesylate has brought a paradigm shift in treatment of Chronic Myeloid Leukemia, despite 15% - 20% patient showing resistance to this TKI. Therefore, it is important to identify susceptibility and prognostic markers, which can help us in predicting occurrence and prognosis of CML. We did Clinical Exome Sequencing, a panel of more than 4800 clinically important genes, in CML patients

**Aims:** To identify prognostic and susceptibility genetic markers in CML

**Methods:** Enrolled CML patients (n=18) were segregated as responders (n=10) and failures (n=8) as per ELN, 2013 guidelines. Healthy controls (n=5) were also enrolled. DNA from blood of subjects was subjected Next Generation Sequencing (NGS), Mutations present in one patient group and absent in opposite group were considered as prognostic markers, whereas rare mutations, present in more than 50% of enrolled patients and absent in healthy controls, were considered as susceptibility markers

**Results:** We discovered mutations in genes associated with cancer or cancer related functions in different patient groups as responders. Five of them: rs116201358, rs17882014, rs4014596, rs52897880 and rs2274329 in 8A, HLA-DRB1, UNC93B1, APOH and CAT6 genes respectively, were present in responders; rs4945 in MFGE8 was present in failures. Mutations in HLA-DRB1 (rs17878951, rs11554462, c.239C>G), HLA-DRB5 (rs137883146), RPHN2 (rs193179333), CYP2F1 (rs116958555), KCNJ12 (rs76684759), FUT3 (rs151218854), BM1C (rs28370522) and PRSS1 (rs144422014) were present in half or more patients

**Summary/Conclusions:** We discovered potential genetic markers, which can help in predicting response to IM as frontline therapy. Susceptibility markers can be used as panel for to configure individuals prone to CML

**E1050**

**FEATURES OF THE A2455G POLYMORPHISM OF GENE CYP 1A1 IN PATIENTS WITH CML**

K. Karimov1,*, N. Abdurahmanova1, K. Boboev1

1Institute of hematology and blood transfusion, tashkent, Uzbekistan
Background: Chronic myeloid leukemia (CML) is the most common myelo-proliferative disorder characterized by the reciprocal translocation t(9;22), (q34; q11), leading to the formation of chimeric oncogene BCR-ABL on the 22q-chromosome. It is known that the protein products of the genes of cytokines ensure homeostasis at the cellular and tissue level, carrying out the metabolism of toxic compounds that can damage the genome of the cells. Present study evaluates the role of genotypes of A2425G polymorphism of CYP 1A1 gene in the development of a number of neoplastic diseases, including leukemia. In individuals with weakened functional genotypes of A2425G polymorphism of CYP 1A1 gene expression of this enzyme and, consequently, inactivation of xenobiotics must occur very slowly, thus creating conditions for adverse action of harmful metabolites in the genome of the cells. Currently, the scientific literature discusses the role of the negative allele A2425G polymorphism of CYP 1A1 gene in the development of hematological malignancies. However, the adverse roles of genotypic variants for this gene in oncogenesis of BCR-ABL-positive patients with CML have studied not enough.

Aims: Evaluation the role of A2425G polymorphism of CYP1A1 gene in the formation the mutant clone of tumor and development of CML.

Methods: The work is performed on DNA samples isolated from the peripheral blood of the patients in the clinic of scientific research Institute of Hematology and blood transfusion in Uzbekistan. We studied 146 patients with CML. The control group was formed from 217 individuals of Uzbek nationality, without of any cancer disease. The diagnosis of CML verified in accordance with the International nomenclature ISCN. Standardized PCR with detection in real-time was carried out on a thermal cycler Rotor-Gene 6000 (Corbett Research, Australia), using a set of reagents AmpE Sensor (Leucosis quautomom, M-1, A2425G FR(T) (InterLabServis, Russia). Testing A2425G polymorphism of CYP1A1 gene was performed on a programmable thermal cycler of the company “Applied Biosystems” (USA) using test systems company “Litech” (Russia) according to the manufacturer’s instructions. Statistical analysis of results was carried out using the statistical software package “2009 OpenEpi, Version 2.3”.

Results: The frequencies of allele A and G are as follows: 87.7% and 12.3% in patients with CML, and 93.3% and 6.7% in the control group, respectively. The frequency distribution of genotypes A/A, A/G and G/G were as follows: 76.7%, 21.9% and 1.4% - in CML patients, and 86.6%, 13.4% and 0.0% - in the control group. Observed frequencies of genotypes in the studied groups was consistent with the theoretically expected and were in equilibrium with Hardy-Weinberg equilibrium (P=0.05). There was a statistically significant decrease in carriage of the adverse alleles in the population sample comparison group patients (1.4% vs 6.7%, respectively; χ2=6.8; P=0.01; OR=2.0; 95% CI 1.17- 3.28). Also detected significant association of heterozygous genotype A/G in patients with CML, compared with the control group (21.9% vs 13.4%, respectively). The risk of mutant formation of the tumor clone in carriers of this genotype was 1.8 times significantly higher compared with patients not having it (χ2=4.6; P=0.03; OR=1.8; 95% CI 1.046-3.166). The homozygous genotype G/G in the group of patients was significantly more compared to the control group (1.4% vs 0.0%), but due to the small number of carriers of this genotype differences in the results did not reach statistical significance (P=0.05). Functionally favorable genotype A/A was found with high frequency in a population-based sample of 86.6% vs 76.7% cases of patients. At the same time, the differences reached the threshold level of significance (χ2=26.0; P=0.01; OR=0.5; 95% CI 0.29-0.88), that is evidence of a favorable protective effect of this genotype against the development of CML.

Summary/Conclusions: Our results suggest that the G allele and the heterozygous genotype A/G A2425G polymorphism of CYP 1A1 gene are important markers of increased risk in formation of malignant tumor cells and development of CML in Uzbekistan (P<0.05). In this case, homozygous genotype A/A of A2425G polymorphism of CYP 1A1 gene has a protective character in relation to risk of CML.

Chronic myeloid leukemia - Clinical

E1051

HEMATOLOGIC TOXICITY GRADE III-IV IS ASSOCIATED WITH LOWER SURVIVAL IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA TREATED WITH TYROSINE KINASE INHIBITORS

1Hematology, Hospital Virgen de la Salud, Toledo, 2Hematology, H. Ramon y Cajal, Madrid, 3Hematology, Ill Aragon, Traslational Research Unit, Zaragoza, 4Hematology, Hospital Clínico de Santiago de Compostela, Santiago de Compostela, 5Hematology, Hospital la Paz, 6Hematology, Hospital 12 de Octubre, 7Hematology, Hospital Puerta de Hierro, 8Hematology, Hospital Universitario Gregorio Marañón, 9Hematology, Hospital Universitario Severo Ochoa, Madrid, 10Hematology, Hospital Clinico Universitario Lozano Biesa, Zaragoza, 11Hematology, Hospital Clinico Universitario Valladolid, Valladolid, 12Hematology, Hospital General de Ciudad Real, Ciudad Real, 13Hematology, Hospital Universitario Infanta Leonor, 14Hematology, Spanish Registry of CML and GELMC, 15Hematology, Department of Hematology and IIS-IP, Hospital Universitario de la Princesa, Madrid, Spain

Background: TKIs introduction in the treatment of chronic myeloid leukemia (CML) has offered an outstanding improvement in survival outcomes. These results were obtained from clinical trials but little is known about long-term toxicity and their translation to real life. In addition, clinical trials results are mainly based on the analysis of the therapy of interest (experimental or control), but the descriptions of the subsequent treatment sequences due to failure or intolerance are normally lacking.

Aims: To analyze the long-term toxicity of patients outside clinical trials in clinical trials. The setting was a multicentric, hospital-based registry.

Methods: Toxicity grade III-IV and survival and their potentially associated variables were studied.

Results: Demographics, risk and treatment distribution: 893 patients (533 men, 360 women) with a median age at diagnosis of 52 y (14-94y) were included with a follow up of 85±7 months (m) from diagnosis, 78±6.6 m from first treatment, and 69±6 m from first TKIs. 151 patients (16,9%) were over 70y. The risk distributions were as follows: Sokal: low (L) 48%, intermediate (I) 37% and high (H) 14%, Euro score: L 50%, I 45% and H 5%; EUTOS L: 92% and H 8%; EUTOS LT: L 70%, I 23% and H 7%. Treatment groups were the following: Group 1: IFN alpha and then imatinib or 2° GTKIs (221 patients); Group 2: imatinib only (404 patients); Group 3: imatinib and then nilotinib, dasatinib or both due to failure or intolerance (177 patients) and Group 4: 2° GTKIs in first line (93 patients). Hematologic toxicity grade III-IV. Figure 1 shows the incidence through the years (all group of treatments). From 800 patients treated with imatinib (first o second line) 67 (8,3%) had grade III-IV toxicity, and 26 had to switch treatment due to toxicity. From 166 patients treated with dasatinib (29...
in 1st line, 114 in 2nd, 56 in 3rd) only 13 had hematologic toxicity and 6 had to switch, 14 had pleural effusion grade III-IV and 9 had to switch. From 115 patients treated with nilotinib (49 in 1st line and 66 in 2nd) only 10 had hematologic toxicity and 10 switched treatment. Survival: Estimated survival by 10 years was 80%. Variables associated with survival: In the univariate survival analyses (log rank test) either from diagnosis, first therapy or first TKIs, the Sokal, Eutus, Euro and EUTOS LT scores, as well as age over 70y were the only statistically significant variables associated with survival. Hematological toxicity grade III-IV was associated with lower PFS or OS (figure 1). In the multivariate analysis (Cox model), only hematology toxicity grade III-IV and age over 70y were independent variables.

Summary/Conclusions: 1. These results show that the probability of survival by 10 years is roughly 80%, and extend the findings of our previous work showing that this probability is not different across different sequential treatments (imatinib 1st line or post-IFN, or switched to 2nd TKIs due to intolerance or failure) (1). This fact emphasizes the reserve potential of available TKI therapies. 2. Hematologic toxicity grade III-IV in the first two years identified a group of patients with worse survival outcome. 3. Patients over 70 years have shorter survival due to reasons different than progression. 4. Second GTKIs showed better hematologic toxicity profile.

E1052
5-YEAR EFFICACY OF DASATINIB AND IMATINIB IN NEWLY DIAGNOSED PATIENTS WITH CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE (CML-CP) WITH DOSE MODIFICATIONS FROM DASISION

A. Hochhaus1,*, E. Jabbour2, H. Kantarjian2, F. Guilhot3, V. Kota4, T. P. Hughes5, A. Hochhaus1,*, E. Jabbour2, H. Kantarjian2, F. Guilhot3, V. Kota4, T. P. Hughes5, A. Hochhaus1,*, E. Jabbour2, H. Kantarjian2, F. Guilhot3, V. Kota4, T. P. Hughes5, A. Hochhaus1,*, E. Jabbour2, H. Kantarjian2, F. Guilhot3, V. Kota4, T. P. Hughes5, A. Hochhaus1,*, E. Jabbour2, H. Kantarjian2, F. Guilhot3, V. Kota4, T. P. Hughes5

Methods: Treatment-naïve patients with CML-CP in DASISION (NCT00481247) were randomized to receive either DAS (100mg once/day; N=259) or IM (400mg once/day; N=260). Dose reductions for AEs (up to 2) were allowed: DAS: 80mg, then 50mg; IM: 300mg, then 200mg. Five-year molecular and cytogenetic response rates in all patients were assessed retrospectively.

Table 1.

Results: Patients on DAS maintained higher molecular response rates than patients on IM, whether or not they had dose reductions for an AE; these rates were similar in patients with and without dose reductions in each arm (table). 95 (37%) DAS- and 44 (17%) IM-treated patients had dose reductions at any time due to AEs. Median time to first DAS dose reduction was 289 days (range: 22-2123), and median time to first IM dose reduction was 160 days (range: 31-2052). For patients with reductions due to any cause, median average daily dose was DAS 83mg and IM 328mg; for DAS patients with reductions due to pleural effusion, median average daily dose was 82mg. Median duration of treat-
ment (excluding interruptions) was 54 months (range: 3-70) for patients who had a DAS dose reduction and 57 months (range: 2-71) for patients who had an IM dose reduction. Changes in level of response were tracked for patients who achieved complete cytogenetic response (CCyR) or major molecular response (MMR) before or after the first dose reduction (table). Many patients maintained or increased to CCyR or MMR following dose reductions for any AE. Hematological toxicity (9%) was the most common AE resulting in dose reduction for IM, and pleural effusion (12%) was the most common for DAS.

Summary/Conclusions: Reducing DAS doses to 80mg or 50mgw a safe and effective means of managing patients who experienced AEs in this 5-year retrospective analysis of DASISION. These results were consistent with previous reports and continued to show that efficacy was not affected by dose reductions for any cause, including pleural effusion. Notably, there was no loss of CCyR following dasatinib dose reductions. Molecular responses remained higher for DAS vs IM irrespective of dose reductions due to AEs.

E1053
EFFECT OF PLASMA TROUGH CONCENTRATION OF NILOTINIB AND POLYMORPHISMS OF DRUG TRANSPORTER GENES ON THE FREQUENCY OF ADVERSE EVENTS IN CHRONIC PHASE OF CHRONIC MYELOID LEUKEMIA: STAT1 AND STAT2 TRIALS

N. Takahashi1,*, T. Niioka2, M. Abumiya2, S. Takahashi1, M. Miura2

1Hematology, AKITA UNIV., 2Pharmacy, AKITA UNIV. HOSPITAL, Akita, Japan

Methods: AEs were assessed according to the Common Terminology Criteria for Adverse Events (CTCAE) v4.03. Safety evaluations were conducted throughout the study. Plasma trough concentrations of NIL were determined with high-performance liquid chromatography (HPLC) at 1 month (1M), 3M, 6M, 12M, and 24M in the STAT trials. Genotyping of CYP2A5*3 (rs98964Q [rs776746]), ABCB1 [3435T>C (rs1045642)], ABCG2 421C>A (rs2231142), and UGT1A1*6, *27, and *28 was performed using polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP). All genotype frequencies were tested for Hardy-Weinberg equilibrium.

Results: Between July 2011 and December 2012, CML patients were recruited in the STAT trials. NIL was administered twice daily (600mg/day) for 2 years according to the study protocol. A total of 76 and 96 patients were analyzed as a safety data set in STAT1 and STAT2, respectively. In STAT1, 18 patients who achieved a confirmed DMR were switched from STAT1 to STAT2. These patients entered both trials, but safety data had not been collected in STAT1. In STAT2, patients entered both trials, but safety data had not been collected in STAT1 after entering STAT2 to avoid double counts. The PK/Px data of 147 of 154 patients were available and were evaluated in this study. Median trough concentrations of NIL were 1265 ng/ml at 1M, 1154 ng/ml at 3M, 974 ng/ml at 6M, 735 ng/ml at 12M, and 781 ng/ml at 24M. Although any-grade AEs were reported for patients in STAT1 and 55 patients in STAT2, the most common drug-related hematological and non-hematological AEs were elevated total bilirubin (28.6%), anemia (24.5%), elevated ALT (21.1%), and elevated AST (18.4%). The incidence of these AEs, except for anemia, was significantly associated with...
with high trough concentration of NIL (Figure 1). There were statistically significant correlations between median concentrations of NIL and the grades of each AE. Based on the results of the analysis using Cox proportional-hazards model, the trough concentration of NIL [hazard ratio=1.001 (1.000-1.002), P=0.004] and ABCG2 421A/A [hazard ratio=3.044 (1.155-8.027), P=0.024] were independent factors for the elevated ALT. Similarly, the trough concentration of NIL [hazard ratio=1.001 (1.000-1.002), P=0.001] and UGT1A1 *11/*11 [hazard ratio=0.475 (0.246-0.919), P=0.027] were independent factors for the elevated total bilirubin.

Summary/Conclusions: In this study, we identified the relationship between NIL trough concentration and liver dysfunction. Our finding suggests that therapeutic drug monitoring might help avoid drug interruption and discontinuation because of AEs, especially liver dysfunction.

VERY EARLY MOLECULAR RESPONSE (VEMR) WITH FRONTLINE DASATINIB TREATMENT IS A STRONG PREDICTOR OF LONG-TERM BCR-ABL1 TRANSCRIPT LEVELS IN CHRONIC MYELOID LEUKEMIA PATIENTS: PCR-DEPTH STUDY

11nt. Medicine, Hemato-Oncology. INJE UNIVERSITY BUSAN PAK HOSPITAL, Busan, 2Department of Hematology-Oncology, Chunnam National University Hwasun Hospital, Hwasun, 3Department of Hematology-Oncology, Wonju College of Medicine, Yonsei University, Wonju, 4Department of Hematology, University of Ulsan College of Medicine, Ulsan University Hospital, Ulsan, 5Division of Hematology-Oncology, Keimyung University, School of Medicine, Daejeon, 6Division of Hematology-Oncology, Ewha Womans University, Seoul, 7Division of Hematology, Hanyang University College of Medicine, Hanyang University Guri Hospital, Guri, 8Department of Hematology, Seoul St. Mary's Hospital, Leukemia Research Institute, The Catholic University of Korea, 9Department of Medicine, Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, Korea, Republic Of

Background: In BCR-ABL1 tyrosine kinase inhibitor (TKI) treated chronic phase chronic myeloid leukemia (CP-CML), early molecular response (EMR) at 3 months is currently identified as being one of the most important prognostic factors. Sokal risk score and dose intensity during first 3 months were strongly associated with achievement of EMR. As dasatinib is a novel kinase inhibitor with improved potency, identification of very early molecular response (VEMR) would be beneficial.

Aims: We evaluated the possibility of the VEMR at 1 month predicting long-term outcomes in newly diagnosed CP-CML patients treated with dasatinib.

Methods: In the observational, open-label study, 102 patients with CP-CML were enrolled to receive dasatinib at a dose of 100mg once daily. The primary end point was complete molecular response (CMR) by 18 months. Secondary end points including molecular response (MR) by 1, 3, 6, 12, 18, 24 month, time to and duration of MMR and CMR, and safety were tested. A receiver operating characteristic (ROC) curve from BCR-ABL1 transcript level on Day+28 was calculated to predict EMR and MMR at specific timepoints.

Results: Median age was 49 years (19-81 years) and 61 patients were male. With median follow-up duration of 28 months (0.9-33.8 months), 80 (78.4%) of 102 patients were still on dasatinib treatment and 22 patients discontinued treatment because of drug failure (n=2) or for adverse events (n=8) or other reasons (n=9). The BCR-ABL1 mutations, assessed in 10 patients after dasatinib discontinuation, were detected in 3 patients which were all T315I mutation. The cumulative CMR by 18 months and MMR by 24 months were 20.5% and 79.5% respectively. Expected survival for 3L CP-CML patients prior to the availability of ponatinib in this study was 96% at 2 years, 90% at 3 years and 85% at 5 years.

Summary/Conclusions: Our study shows that VEMR at 1 month can be a strong predictor for further molecular responses as well as long-term outcome. Therefore it would be helpful to monitor BCR-ABL1 transcript level at 1 month in patients who treated with more potent TKIs.

E1055

SURVIVAL OUTCOMES IN PATIENTS WITH CHRONIC-PHASE CHRONIC MYELOID LEUKEMIA (CP-CML) RECEIVING THIRD- OR SUBSEQUENT LINE (3L) TREATMENT PRIOR TO THE AVAILABILITY OF PONATINIB

D. Stellato1*, L. McGarry2, H. Huang3, S. Hastings4, T. Delea1

1Policy Analysis Inc. (PAI), Brookline MA, 2ARIAD Pharmaceuticals, Inc., Cambridge, MA, United States

Background: PACE was a phase 2 single-arm trial of ponatinib, a 3rd-generation tyrosine kinase inhibitor (TKI), in 449 highly-refractory patients with CML or Philadelphia-chromosome positive (Ph+) acute lymphocytic leukemia (ALL) or who had the BCR-ABL1 T315I mutation. Overall survival (OS) for 3L CP-CML patients in PACE at 1, 2, 3 and 4 years was estimated to be 99%, 93%, 88%, and 79%, respectively. Expected survival for 3L CP-CML patients prior to the availability of ponatinib has not been documented.

Aims: To estimate OS in patients with CP-CML receiving 3L treatment prior to ponatinib via a systematic literature review.

Methods: Studies were identified from a review by Lipton et al. (2015), updated with studies identified from searches of electronic databases (MEDLINE, EMBASE, Cochrane Libraries) and abstract databases of key conferences. Landmark and median survival were extracted from study reports. Pseudo-individual patient data (IPD) for survival outcomes were derived from digitized Kaplan-Meier (KM) survival curves then pooled and analyzed using KM methods.

Results: Fifty-five studies (717 patients) were identified that reported median, landmark, or KM curves for survival outcomes for CP-CML patients receiving 3L treatment without ponatinib. KM curves for OS were obtained for 6 arms (3 nilotinib and/or dasatinib; 3 other TKIs). OS at 1, 2 and 3 years based on the pooled IPD is reported in the Table. To avoid confounding of OS from post-progression treatment with ponatinib, 1 study was excluded that included follow-up after the date of ponatinib’s approval.

Summary/Conclusions: Estimated OS in patients with CP-CML receiving 3L treatment prior to ponatinib appears to be shorter than that observed among ponatinib-treated patients in PACE, 4-year survival probability in PACE was higher than estimated 2-year survival probability prior to ponatinib. Further analyses are needed to identify and adjust for potentially confounding factors.

E1056

DETECTION AND MONITORING OF BCR-ABL1 KINASE DOMAIN MUTATIONS IN CML AND ALL PATIENTS BY NEXT GENERATION SEQUENCING AND DROPLET DIGITAL PCR, A BELGIAN PROSPECTIVE STUDY

C. De Rop1,*, H. Devos2, P. Vannuffel1, F. Nollet2

1Molecular Biology, IPG, Gosselies, 2Laboratory Medicine, AZ Sint-Jan, Bruges, Belgium

Background: Among myeloproliferative diseases, development of chronic myeloid leukaemia (CML) is associated with the emergence of the fusion oncogene BCR-ABL1 resulting from a t(9;22) chromosomal translocation (Philadelphia chromosome). This chimeric transcript is also present in all acute lymphoblastic leukaemia (ALL) (30.3%) was most common. Pleural effusion occurred in sixteen (15.6%) patients which were mostly grade 1/2. The cut-off value of BCR-ABL1 transcript on Day+28 was 40% by ROC curve analysis. Among 95 patients who had available molecular data of both D+28 and 12 months, fifty nine (62.1%) patients had less than 40% of BCR-ABL1 transcript (VEMR) on Day+28. Long-term (n=26) patients achieved MMR at 12 months. However, only 27.8% (10 out of 36 patients) of patients without VEMR achieved expected survival (OS) & progression-free survival (PFS) rates for 24 months were 98.0% and 95.1% respectively. PFS rates by 24 months for VEMR and no VEMR group were 98.4% vs 88.8% respectively (p=0.04).

Table 1. Estimated OS in CP-CML patients receiving 3L treatment prior to ponatinib.

Aims: Both NGS and droplet digital PCR (ddPCR) were used in this prospective study. NGS screened all known mutations in the BCR-ABL1 KD and ddPCR targeted only the 3 most common mutations, T315I, E255K and Y253H, which represent approximately 75% of the ABL1 mutations. Patients eligible for the study were i) CML patients with failure or warning to all lines of TKI therapy according to the 2013 ELN-guidelines, with no suspected lack of adherence and ii) ALL patients on disease diagnosis and/or molecular relapse. Monitoring was performed when clinically appropriate.

Methods: Total BCR-ABL1 RTA was transcribed into a long range cDNA covering the kinase and the regulatory and the SH2/SH3 domains of either p190 or p210 BCR-ABL1 transcripts (exons 4 to 10). For NGS, primers designed with the AmpliseqTM Designer Software were selected to cover the different mutational sites. Bar-coded libraries, constructed according to the AmpliSeqTM protocol, were sequenced on the Ion Torrent PGM platform (sensitivity of 2.5%). For ddPCR, cDNA was analysed for the presence of one of the 3 main mutations (T315I, E255K and Y253H). The overall number of BCR-ABL1 mutated samples was 18 (15 CML and 3 Ph+ ALL), representing 30% of the cases. Among these samples, 27 mutations were found. 9 samples presented with one mutation: T315I (2), E255K (3), G250V (1), F359I (1), M237T(1) and E255A (1) and 9 harbourred combined mutations: T315I + E255K (6) and T315I + Y253H (3). A high frequency (85%) of T315I, E255K and Y253H mutations was also observed (23/27). As far as these 3 mutations are concerned, reproducibility to determine mutational burden was found to be very high between NGS and ddPCR.

Summary/Conclusions: Advancements in sequencing technologies and further lowering sensitivity levels contribute to optimal management of CML and Ph+ ALL patients and improve treatment outcome. The earlier a mutation in the kinase domain is detected, the earlier an informed choice can be made regarding optimal subsequent TKI treatment.

Background: The ability to “cure” a proportion of chronic myeloid leukemia patients (CML) makes treatment free remission (TFR) an important treatment goal which requires sustained deep molecular response on TKI therapy. Unfortunately, not all patients achieve deep molecular responses on their first line treatment. Novel treatment strategies to increase the proportion of CML patients eligible for a TKI stop attempt are therefore needed.

Aims: The primary objective of the NordDutchCML009 study was to assess if, in CML patients with suboptimal molecular response on imatinib (MR4.0), switching to nilotinib 300mg BD (Nil) PegIFN-α2b (Peg) 25 ug/week was introduced after 3 months, increased to 40 ug/week at month 6 if tolerable and continued until month 12. Adverse events were assessed according to CTCAE version 3. Flow cytometry assessments of T-, NK- and B-cell populations, acti-

E0108

ANALYSIS OF VASCULAR ADVERSE EVENTS IN TKI TREATED JAPANESE CML PATIENTS: RETROSPECTIVE LARGE COHORT STUDY OF CML COOPERATIVE STUDY GROUP

1Department of Hematology, Juntendo University School of Medicine, 2Division of Hematology and Rheumatology, Department of Medicine, Nihon University School of Medicine, Tokyo, 3Department of Hematology, Saitama Medical Center, Saitama Medical University, Saitama, 4Department of Hematology, Department of Medicine, Juntendo University Nippon Hospital, Tokyo, 5Department of Hemato-Oncology, Comprehensive Cancer Center, Saitama Medical University International Medical Center, Saitama, 6Department of Hematology, Yokohama Municipal Citizen’s Hospital, Yokohama, 7Department of Hematology, Juntendo University Urayasu Hospital, Urayasu, 8Department of Hematology, Saiseikai Yokohama Nanbu Hospital, Yokohama, 9Department of Hematology and Infectious Diseases, Kumamoto University Hospital, Kumamoto, Japan

Background: Chronic myeloid leukemia (CML) is a disease of hematopoietic stem cells resulting from oncogenic chromosome translocation that leads to the formation of the BCR-ABL1 fusion gene. Treatment of chronic phase (CP) CML has dramatically changed since the emergence of the first-in class tyrosine kinase inhibitor (TKI) imatinib, and treatment based on TKI has improved the outcome in the majority of CP-CML patients. Nowadays, second generation TKIs are available and brought about faster and deeper clinical responses, and lower disease progression rate than imatinib. On the other hand, longer treatment duration and the increased types of TKIs gave rise to various kinds of unexpected adverse events (AEs). In 2011, drug-induced peripheral arterial occlusive disease (PAOD) was first reported, followed by vascular AEs (VAEs) including ischemic heart disease (IHD) and cerebral infarction (CI). Furthermore, it became clear that the incidence of VAEs increased with the dose and treatment duration, therefore VAEs are considered a more fatal complication of TKI treatment. However, there is no available data about the incidence of VAEs in Japanese patients.

Aims: We investigated the vascular safety issue and estimated the 1000 person-years risk of developing VAEs during TKI treatment, including imatinib, nilotinib, and dasatinib, using 3 risk assessment tools among 320 Japanese patients who were enrolled in the CML Cooperative Study Group.

Methods: A surveillance data of 320 patients enrolled in the CML Cooperative Study Group was conducted in this analysis. Briefly, the study included patients who were diagnosed with CML-CP from April 2001 to January 2016, whose median age was 57 years old (15-80) and median time of follow up was 64.2 months. Patients in the accelerated or blastic phase (AP/BP) were excluded. The study was approved by the research ethics boards of each institutions and was conducted in accordance with the Declaration of Helsinki. All patients who developed VAEs were analyzed using 3 risk assessment tools (SCORE chart, Framingham risk score, Suitsa-score) to estimate the patients’ 10-year risk of VAEs.

Results: Among the 320 newly diagnosed CML-CP patients, 16 (5.0%) cases of VAEs were reported during the study period. Seven cases were treated by imatinib, 6 cases by nilotinib, 3 cases by dasatinib. 4 cases were a switch from imatinib to nilotinib, and 1 case was a switch from dasatinib to nilotinib. The VAEs were 9 IHD, 5 CI, and 2 PAOD cases. Results from the 3 risk assessment tools are as follows: SCORE (2 low, 9 moderate, 1 high, 4 very high risk), Framingham score (3 low, 5 moderate, 7 high risk), and Suita-score (13 low, 1 intermediate, 7 high risk). The incidence rate of IHD and CI per 1000 person-years were 5.26 and 3.342 in the enrolled CML-CP patients, 4.65 and 2.33 in the imatinib-treated patients, 14.34 and 10.75 in the nilotinib-treated patients, 4.08 and no case in the dasatinib-treated patients, and 1.787 and 3.432 in the age-
The study, as a bcr/abl ratio of: 1) ≤1% at 3 months from start of TKI therapy; 2) ≤0.1% at 6 months from start of TKI therapy; or 3) ≤0.01% any time point during treatment. Clinical data have been collected using a specific CRF. All data were registered in an anonymous manner. The BCR-ABL ratios in the IS have been provided by standardized labs in Spain.

Results: From June 2014 to February 2017, 976 patients were registered in the study. Median age was 51 years (15-88). The Sokal risk groups were as follows: 345 patients low risk, 307 intermediate risk and 129 high risk. Cutoff classification yielded 714 patients in the low risk and 79 in the high risk categories. The majority of patients received first-line treatment with imatinib (626 patients), dasatinib (39 patients) or nilotinib (87 patients). Of note, 5 patients received bosutinib, 1 patient ponatinib and 74 patients were treated with interferon previous to TKI administration. So far 14 patients have died of non-CML related conditions such as carcinoma (2 patients), ischemic heart disease, respiratory failure and sepsis. Interestingly, 2 patients developed progression of their CML to accelerated phase and blast crisis (1 patient each) with no deaths. At present, 104 patients (11%) have achieved a MR4.0, 174 patients (18%) a MR4.5 and 123 patients (13%) have obtained a complete molecular remission (undetectable bcr-abl transcripts with a sensitivity of at least 10^{-5}).

Summary/Conclusions: Almost one thousand CML patients have been included in this Spanish prospective study owing to their promising molecular response that would predict for a sustained deep molecular remission. Four hundred and one patients have already achieved a deep molecular response (>MR4 (IS)) and could be enrolled in prospective discontinuation studies.

E1059
ANALYSIS OF DASATINIB AND IMATINIB 5-YEAR EFFICACY AND SAFETY BASED ON BASELINE COMORBIDITY AND AGE IN PATIENTS WITH NEWLY DIAGNOSED CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE (CML-CP) IN DASISION
G. Saglio1,*, J.E. Cortes2, A. Hochhaus3, N.P. Shah4, E.L. Atallah5, M. Abaskharoun6, L. LP7, M.J. Mauro7
1University of Turin, Turin, Italy, 2The University of Texas MD Anderson Cancer Center, Houston, United States, 3Universitätsklinikum Jena, Jena, Germany, 4University of California San Francisco School of Medicine, San Francisco, 5Froedtert & the Medical College of Wisconsin, Milwaukee, 6Bristol-Myers Squibb, Princeton, 7Memorial Sloan Kettering Cancer Center, New York, United States

Background: Patients with CML often have comorbidities, which may influence treatment-related decisions and impact response and survival. In a retrospective analysis of 1-year data from the phase 3 DASISION study, the overall safety or response in dasatinib- or imatinib-treated patients was not substantially impacted by baseline comorbidities, although certain adverse events (AEs) trending higher in patients with ≥1 vs 0 comorbidities (Khoury ASH 2010). Further analysis is warranted to determine how comorbidities may impact long-term outcomes.

Aims: To evaluate the impact of baseline comorbidities and patient age on 5-year safety and efficacy in dasatinib- or imatinib-treated patients from DASISION.

Methods: In DASISION (NCT00481247), patients were randomized to receive dasatinib 100mg/day (N=259) or imatinib 400mg/day (N=260). For this retrospective analysis, patients were grouped as having 0 or ≥1 baseline comorbidity; by baseline disorder (diabetes mellitus, hepatobiliary disease, hyperlipidemia, cardiovascular disorder, or pulmonary condition), or by age group (<46 years, 46–65 years, >65 years). Safety (treatment-related AEs in ≥10% of patients) and efficacy (response rates by 5 years and median times to response) were assessed for each group and treatment.

Table 1.
Results: The number of patients with 0 or ≥1 comorbidity was similar in the dasatinib (66 [25%]; 193 [75%]) and imatinib (67 [26%]; 193 [74%]) arms, respectively; most (>90%) patients were <65 years old. In patients with 0 or ≥1 baseline comorbidity, the median average daily dose was comparable within arms and discontinuation rates (36%-39%) were similar within and across arms (table). The overall safety profiles were comparable in the 0 and ≥1 comorbidity groups in both arms, other than specific AEs, which had a 22 times higher frequency in patients with ≥1 vs 0 comorbidities; the majority of these were grade 1/2 AEs (table). The incidence of peripheral edema increased with patient age for both imatinib and dasatinib (<46 years: 5%; each; 46–65 years: 12% and 10%; ≥65 years: 21% and 20%). In this analysis, the increased incidence of pleural effusion (PE) in dasatinib-treated patients was most highly associated with increased age: <46 years (16%) vs 46–65 years (37%) vs >65 years (60%). PE incidence did not appear to be related to baseline pulmonary comorbidity and was similar in dasatinib-treated smokers (33%) vs nonsmokers (27%). Within each arm, patients with 0 or ≥1 comorbidity (table) and across age groups had similar response rates. The response rates were consistently higher for patients with ≥1 vs 0 comorbidities in both arms (MR4.5 on dasatinib: 46% vs 32%; MR4.5+ on imatinib: 36% vs 22%). Median time to response (months) for patients with 0 or ≥1 comorbidity did not differ within each arm, but was numerically shorter for dasatinib vs imatinib (36 or 35) vs imatinib (MR4.5: 42 or 47).

Summary/Conclusions: The superior efficacy of dasatinib over imatinib was shown in previous studies. Response rates and times to response were comparable in patients with 0 or ≥1 comorbidity and trended in favor of dasatinib vs imatinib. Although a few AEs (most grade 1/2) appeared to occur at a higher frequency in patients with ≥1 vs 0 comorbidities in either treatment arm, the overall rates of AEs and discontinuation rates at 5 years in patients who were treated with first-line dasatinib or imatinib did not appear to be substantially affected by baseline comorbidities.

E1062

RADOTINIB TREATMENT IN CHRONIC PHASE CHRONIC MYELOID LEUKEMIA PATIENTS WITH RESISTANCE OR INTOLERANCE TO BCR-ABL TKIS: 36 MONTHS UPDATE OF RADOTINIB PHASE 2 STUDY

Background: Radotinib is an orally active, selective BCR-ABL1 tyrosine kinase inhibitor (TKI), approved for the first-line and second-line treatment of chronic phase chronic myeloid leukemia (CP-CML) patients in Korea. Earlier 12 and 24 month results demonstrated that radotinib is effective and well tolerated in CP-CML patients with resistance and/or intolerance to BCR-ABL TKIs.

Aims: We update the long-term outcome of radotinib treatment in patients failed to either imatinib or dasatinib in clinical practice.

Methods: Ph+ CP-CML patients who failed prior TKI therapy were enrolled between July 2009 and November 2011. All patients were treated with radotinib 400mg twice daily. Cytogenetic and molecular assays were performed at baseline, every 3 months, and at treatment failure. Safety parameters were also analyzed. Probabilities of overall survival (OS) and progression free survival (PFS) were calculated using Kaplan-Meier method.

Results: A total of 77 CP-CML patients (18 years of age or over) were enrolled. This analysis includes data from last enrolled patient who received at least 36 months of radotinib therapy. With a median follow-up of 45.7 (range 0.9-65.7) months, 31 patients (40.3%) completed 36 months treatment, and 46 patients (59.7%) discontinued the treatment before 36 months. Main reasons of discontinuation were abnormal laboratory test (n=18), adverse events (n=4), treatment failure including disease progression and lack of response (n=18), death (n=2), and other reasons (n=4). Median duration of radotinib exposure was 19.5 (0-360.9) months. Cumulative incidence of complete cytogenetic response (CCyR) by 36 months was 90.0% and of patients achieving CCyR, 45.0% (18/40) achieved MMR. The drug-related safety profiles were consistent with those previously reported and new safety issues have not been observed after 12 months. Most drug-related AEs have developed within 12 months, and have shown minimal increase compared with rates at 12 months follow-up. Estimated OS and PFS at 36 months were 87.6% and 85.7%, respectively.

Summary/Conclusions: The 36 months data supports radotinib treatment in TKI failed CP-CML patients maintains the effective response and high rates of OS & PFS rate. Thus, radotinib demonstrated a promising alternative treatment for patients with TKIs failure.

Figure 1.
**Background:** The success of imatinib and other rationally designed tyrosine kinase inhibitors (TKIs) in the treatment of chronic myeloid leukemia has drastically improved the fate of CML patients. From a couple of years in median survival in the 70’s, a majority of patient now achieve a near normal life expectancy with lifelong treatment though. This new paradigm where CML can be regarded as a chronic disease has mechanical consequences on the disease prevalence and overall costs for health care systems. The success of imatinib and other rationally designed tyrosine kinase inhibitors (TKI) in the treatment of chronic myeloid leukemia has drastically improved the fate of CML patients. From a couple of years in median survival in the 70’s, a majority of patient now achieve a near normal life expectancy with lifelong treatment though. This new paradigm where CML can be regarded as a chronic disease has mechanical consequences on the disease prevalence and overall costs for health care systems.

**Aims:** We present here a fully detailed and comprehensive analysis of the French CML prevalence over a century from 1960 to 2060.

**Methods:** Prevalence of CML was estimated using a cohort component-based model from estimates of incidence rate of the disease by age and sex, population and demo-graphic projection from the National Institute of statistics and Economics Studies, and various hypotheses on the relative survival of CML patients. Prevalence of CML was estimated using a cohort component-based model from estimates of incidence rate of the disease by age and sex, population and demo-graphic projection from the National Institute of statistics and Economics Studies, and various hypotheses on the relative survival of CML patients. The number of CML patients is estimated over time and the resulting CML prevalence expressed as a number of CML patients per 100,000 inhabitants.

**Results:** The CML prevalence in France, expressed in cases per 100,000 inhabitants, was estimated to be around 3 before the 80’s, 6 before the 2002, 17 in 2016, 22 in 2030 where the tendency infects, and 30 after 2040. Considering the 100% relative survival hypothesis, a target CML prevalence were nearly reached by 2050 to levels above 30 per 100,000 inhabitants. By simulation, we showed that given constant incidence rates and high relative survival hypotheses, the CML prevalence will be driven by population aging, and that the target prevalence, defined as the maximum CML prevalence, should be nearly reached by 2050 to levels above 30 per 100,000 inhabitants.

**Summary/Conclusions:** Our preliminary results suggested the involvement of miRNAs in CML-ABL levels regulation and in TKI response, supporting the search of a miRNAs TKI response profile that could predicts the response in CML patients. This information could act as powerful tool for the stratification of CML patients under Imatinib treatment showed higher levels of miR-451 associated with a higher reduction of BCR-ABL levels (lower than 0.01%) in CML patients and patients with higher BCR-ABL present lower levels of expression of miR-451. This miR was also down-regulated in LAMA-84, K562-RC and K562-RD comparing with sensitive cell line (K562); in K56-RD cells (created by discontinuous exposure), the degree of resistance is 18x. Statistical analysis was performed with ANOVA and multiple comparison tests, with significance levels of 95% (p<0.05).

**Results:** The miR-203 and miR-519c expression was not detected in any cell line or in CML patient. First, we correlated miRs expression with BCR-ABL levels. Higher levels of tumor suppressor miR-451 were associated with a higher reduction of BCR-ABL levels (lower than 0.01%) in CML patients and patients with higher BCR-ABL present lower levels of expression of miR-451. This miR was also down-regulated in LAMA-84, K562-RC and K562-RD comparing with sensitive cell line (K562); in K56-RD cells (created by discontinuous exposure), the degree of resistance is 18x. Statistical analysis was performed with ANOVA and multiple comparison tests, with significance levels of 95% (p<0.05).

**Methods:** To this end, we assessed the expression levels of miR-203, miR-21, miR-519c, miR-451, miR-26 and miR-16 (endogenous control) by TaqMan MicroRNA Assays in peripheral blood cells from 31 patients with CML at follow-up examinations. We also studied 4 CML cell lines, K562 a cell line sensitive to Imatinib, LAMA-84 a cell line with 4 copies of chromosome Philadelphia (Ph), and 2 Imatinib resistant cell lines models created in our lab (K562-RC and K562-RD). K562-RC cells, generated by continuous exposure to Imatinib, presented 8x times higher than the parental cell line (K562); in K56-RD cells (created by discontinuous exposure), the degree of resistance is 18x. Statistical analysis was performed with ANOVA and multiple comparison tests, with significance levels of 95% (p<0.05).

**Results:** The miR-203 and miR-519c expression was not detected in any cell line or in CML patient. First, we correlated miRs expression with BCR-ABL levels. Higher levels of tumor suppressor miR-451 were associated with a higher reduction of BCR-ABL levels (lower than 0.01%) in CML patients and patients with higher BCR-ABL present lower levels of expression of miR-451. This miR was also down-regulated in LAMA-84, K562-RC and K562-RD comparing with sensitive cell line (K562); in K56-RD cells (created by discontinuous exposure), the degree of resistance is 18x. Statistical analysis was performed with ANOVA and multiple comparison tests, with significance levels of 95% (p<0.05).

(SNPs) affect the transporter activity, but their impact on clinical response to imatinib in chronic myeloid leukemia (CML) is discordant; even less is known on their role in patients treated with second generation (2G) TKIs dasatinib and nilotinib.

Aims: To investigate the role of the most common ABCB1 and ABCG2 genetic polymorphism in chronic phase CML patients treated with imatinib and 2G-TKIs.

Methods: We analysed four polymorphisms of ABCB1 (129T>C, 1236C>T; 2677G>T/A and 3435C>T) and two polymorphisms of ABCG2 (34G>A and 421C>A) in 196 CP-CML patients, of whom 139 treated with imatinib (114 in first line and 25 after interferon failure) and 57 treated with dasatinib or nilotinib (22 in first line and 35 after imatinib failure). We compared the rates of optimal response at 3 months (defined as BCR/ABL <1%), at 6 months (BCR/ABL<1%) and at 12 months (BCR/ABL<0.1%), progression-free survival (PFS) and time to treatment failure (TTF) according to the different protein genotypes. TTF was calculated from the start of therapy to any of the followings: progression to accelerated or blastic phase (ABP), death for any cause at any time, treatment discontinuation for primary or secondary resistance or intolerance. PFS was calculated from the start of TKI to ABP or death.

Results: A total of 196 patients with CP-CML (median age 57 years, range 21-84) were included in the analysis. Frequency of ABCB1 and ABCG2 SNPs' expression is summarized in Table 1. Considering response to therapy, either in imatinib-treated patients and in those receiving a 2G-TKI, we did not find any significant difference in terms of optimal response at the various timepoints, TTF or PFS for ABCB1 C1236T, G2677T and C3435T and of ABCG2 G34A and C412A polymorphism, even if there was a trend for a worse PFS in the few patients (n=2) with 1236 allele A treated with imatinib. Conversely, we found a lower rate of optimal response at 3 (p=0.01), 6 (p=0.05) and 12 (p=0.02) months in imatinib-treated patients with TC genotype of ABCB1 T129 SNP, though the small number of patients (7) had probably and impact on statistical significance. However, TTF was shorter for ABCB1 129T>C patients, both receiving imatinib (p=0.05) and 2G-TKIs (p=0.07), and also PFS was significantly shorter in this cohort (p=0.003).

Summary/Conclusions: With the limits of the low expression rates of some SNPs, our data suggest a lower response in patients harboring 129T>C polymorphism, at least in those receiving imatinib. Other ABCB1 and ABCG2 genotypes do not seem to impact on response to TKI treatment.

THE INTRODUCTION OF SECOND-GENERATION TYROSINE KINASE INHIBITORS MAY REDUCE THE PROGNOSTIC IMPACT OF HIGH-RISK PATIENTS ASSESSED TO EUROPEAN TREATMENT AND OUTCOME STUDY (EUTOS) SCORE

Background: The discovery of tyrosine kinase inhibitor (TKI) imatinib has revolutionized the conception of chronic myeloid leukemia (CML) as a mortal disease to a long-term controllable disease. The European Treatment and Outcome Study (EUTOS) score is a clinical tool that utilizes imatinib-based objectives to predict treatment response and progression free survival (PFS) in patients with CML in chronic phase (CP). However, it is currently unknown whether the introduction of second generation TKIs (2nd TKIs) affects prognostic score of patients with CML-CP, particularly among those considered high-risk according to EUTOS score.

Aims: Our study aims to highlight the critical role of the introduction of 2nd TKIs on patient prognosis as determined by EUTOS score.

Methods: Patients' data was obtained retrospectively from patients enrolled in the CML Cooperative Study Group. Patients with CML-CP who were treated with any TKIs as first line therapy between April 2001 and January 2016 were enrolled to the study and were classified according to date of diagnosis. Those who were diagnosed with CML-CP before March 2009 were classified into the imatinib group, and those diagnosed after April 2009 were classified into the 2nd TKI group, as these patients were able to be treated with 2nd TKIs. The study was approved by the research ethics boards of each institution and was conducted in accordance with the Declaration of Helsinki.

Results: There were 308 patients newly diagnosed with CML-CP during the study period. Of these patients, 104 (34%) were assigned to the imatinib group and 204 (67%) were assigned to the 2nd TKI group. With respect to EUTOS score, 223 patients were classified as low-risk, of which 69 were in the imatinib group and 154 were in the 2nd TKI group. Forty-six patients were considered high-risk, of which 19 were in the imatinib group and 27 were in the 2nd TKI group. EUTOS score was unavailable in 39 patients. With regard to initial TKI, all patients were treated with imatinib in the imatinib group. Among patients assigned to the 2nd TKI group, 149 (73%) were initially treated with any TKI. The median follow-up period for all patients was 48 months (range: 1-185 months). Among patients in the 2nd TKI group, CML-associated death rates were significantly lower than those in the imatinib group. EUTOS high-risk patients score exhibited significantly worse outcomes in EFS, PFS, and CML-associated death compared to those considered low-risk. Most importantly, risk stratification by EUTOS score was predictive of risk-associated clinical outcomes in patients assigned to the imatinib group; however, EUTOS score failed to predict risk-associated clinical outcomes of patients assigned to the 2nd TKI group (see Figure). The EUTOS high-risk patients in the imatinib group showed worse clinical outcomes than those in the 2nd TKI group (hazard ratio [HR] 6.35, 95% confidence interval [CI] 1.79 – 22.6, p=0.0042). However, prognostic effect was less in the 2nd TKI group (HR 3.21, 95% CI 0.59 – 17.6, p=0.18).

Conclusions: Among patients assigned to the imatinib group, risk stratification by EUTOS score was predictive of clinical outcomes in that those considered high-risk experienced considerably more adverse events (EFS, PFS, or CML-associated death) than those considered low-risk. Our results support the use of 2nd TKIs in treating high-risk patients with CML-CP in order to avoid disease progression. Future large-scale studies are necessary to evaluate the clinical significance of EUTOS scoring in the accurate prediction of prognosis among patients with CML-CP treated with 2nd TKIs.
CHRONIC MYELOID LEUKEMIA DIAGNOSED DURING PREGNANCY: THERAPY TACTICS AND OUTCOMES

R.H. Yeolyan, Yerevan, Armenia, 8FSBI Scientific Center of Obstetrics, Gynecology and Perinatology of Healthcare Ministry named after V.I. Kulakov, Moscow, Russian Federation

Background: Chronic myeloid leukemia (CML) diagnosed at pregnancy is a serious challenge. Treatment by tyrosine kinase inhibitors (TKI) today is considered harmful for fetus due to possible teratogenicity. On the other hand TKI delay is dangerous for disease progression as no other options have comparable to TKI effectiveness. Pregnancy termination by abortion may be crucial for desired pregnancies as further childbirth is postponed for years until stable deep molecular response (DMR). Due to limited number of cases and ethical issues there is no consensus on how to behave in such delicate cases.

Aims: To describe pregnancy outcomes and therapy tactics for CML diagnosed at pregnancy.

Methods: Information regarding CML diagnosed at pregnancy was collected with the cooperation of participating in the observational study of European Leukemia Net (ELN Pregnancy Registry). The data included CML clinical characteristics at diagnosis, cytogenetic and molecular parameters, information of therapy, pregnancy outcomes and data of newborns.

Results: Thirty one women with median age 26 years (range 20-39) were diagnosed with Ph-positive chronic phase CML during pregnancy. That was 11% of all 282 pregnancy cases. In certain countries (Russia) up to 21% of women with CML and pregnancy had the synchronistic onset of these events (table 1). Sokal low/intermediate/high and EUTOS low/high risk score was in 22/5/3 and 28/2 patients correspondingly. No data for risk score was in 1 patient. CML was diagnosed in 1st/2nd trimester in 18/16/6,66% correspondingly. Induced abortion was done before CML therapy was started in 10 (32%) around 10 obstetrician (week 6-17), spontaneous abortion happened in 1 woman (at week 8th).

Pregnancy was prolonged by consistent desire or religious reasons in 20 cases. Treatment of CML during pregnancy was initiated in 15 of 20 patients. Interferon alpha (IFN) was given to 5 women and 3 of them were switched to imatinib (IM) 400mg daily in 2nd-3rd trimester due to insufficient control of complete blood count. IM 400mg daily in 1st line was also taken by 9 women since 2nd-3rd trimester. In summary 12 women got IM from 2nd-3rd week (range 16-36). One woman got hydroxyurea (HU) from 3rd trimester till labor and 3 got HU shortly for 5-7 days before any other treatment in 1st-2nd trimester. Nineteen healthy newborns (including twins in 1 case) were born: 14 at term, 5 by preterm delivery at week 35-37. There were no birth abnormalities in 10 newborns exposed to IM in 2nd-3rd trimester. Two pregnancies under IM exposure are currently at week 17 and 31, developing normally. Four infants had low birth weight (<2500 g); 3 of them were exposed to IM and 1 for HU at pregnancy. Follow-up of children was uneventful with Me observation time 47 months (range 9-192) and Me observation time 38 months (range 9-63) for 10 infants exposed to IM in 2nd-3rd trimester. Twenty nine of 31 women with CML diagnosed at pregnancy are alive and continue TKI treatment, 2 women unfortunately died: 1 patient with postoned switch from IFN to IM during pregnancy progressed to blast crisis after labor and had further bone marrow transplant failure while 1 patient after induced abortion developed rapid blast crisis with BCR-ABL compound mutations including T315I.

Conclusion: The large database of women diagnosed with CML during pregnancy. Management of this very delicate subset of patients is a challenge especially when a woman refuses from abortion. Individual treatment approach may differ considering pregnancy terms and clinical status. Although normal childbirth is possible using IM after 2nd-3rd trimester, the risks of pregnancy prolongation remain still not well defined. To get the most safe prognosis for mother and child pregnancy in CML should be planned in a stable DMR.

IMPACT OF KIR3DL1*00501 IN TYROSINE KINASE INHIBITOR-TREATED CML

1National Research Center for Hematology, Moscow, Russian Federation, 2Hematology, S. Eugenie Hospital, Tor Vergata University, Rome, Italy, 3Hematology Department, SI “Institute of Blood Pathology and Transfusion Medicine UAMS”, Lviv, Ukraine, 4Research Institute of Hematology and Blood Transfusion MOH of Uzbekistan, Tashkent, Uzbekistan, 5Hematology Center after prof. R.H. Yeolyan, Yerevan, Armenia, 6FSBI Scientific Center of Obstetrics, Gynecology and Perinatology of Healthcare Ministry named after V.I. Kulakov, Moscow, Russian Federation

Background: The BCR-ABL1 tyrosine kinase inhibitors (TKIs) dramatically improved long-term survival of the patients with chronic myeloid leukemia (CML). As increased NK cells during TKI therapy positively correlate with better outcome, antitumor immunity by NK cells may contribute to the effects of TKIs. However, the response to TKIs depends on each case, and the determinants of it remain to be elucidated.

Aims: Given that NK cell function is regulated depending on the interaction between killer immunoglobulin-like receptor (KIR) and human leukocyte antigen (HLA) class I molecules, we hypothesized that polymorphisms of KIR and HLA play important roles on the responses to TKIs. Then we performed allele genotyping of KIR and HLA with deep sequencing in CML patients, and here report our clinical impacts.

Methods: KIR and HLA high resolution typing were performed on peripheral blood DNA from 76 CML patients in chronic phase (CML-CP) using the Scisco Genetics typing kit (Scisco Genetics Inc., Seattle WA) and MiSeq as platform by NGS. Therapeutic effects of TKIs were evaluated based on bcr-abl mRNA levels measured by real-time quantitative (RQ)-PCR compensated according to international scale (IS) and/or transcription mediated amplification (TMA) method. Major molecular response (MMR) was defined as 3-log reduction (MR3) in RQ-PCR (IS) or BCR-ABL transcript level of less than 50 copy/0.5 µg RNA in TMA method. We also defined DMR as 4-log reduction (MR4) in RQ-PCR (IS), which is similar to undetectable of BCR-ABL transcript level in TMA method. The Cox proportional hazards model was used in the time-to-event analysis, p value<0.05 was considered statistically significance.

Results: Second generation TKIs as first-line therapy (n=46) and female (n=29) sex were strongly associated with superior DMR at the 2-year of therapy (second generation TKIs as first-line treatment, HR 7.305, 95% CI, 3.377 to 15.803; p<0.001; female sex, HR, 1.709; 95% CI, 1.028 to 2.842; p=0.039). After adjustment with these two factors, several KIR alleles positively correlates with superior DMR at the 2-year; KIR2DL4*008 or 011/00501 (HR 1.942, 95%CI 1.160 to 3.250, p=0.012); KIR2DS4*00301 or 007/010 or 015 (HR 2.811, 95% CI, 1.590 to 4.968, p<0.001); KIR3DL1*00501 (HR 3.634, 95% CI 1.884 to 7.013, p<0.001). Interestingly, KIR3DL1*00501 for the patients has more strong link to KIR2DL4*008 or 011/00501, and 2DS4*00301 or 007/010 or 015 than other KIR3DL1 alleles. (Fisher’s exact test, p<0.001).

Summary/Conclusions: KIR3DL1*00501 and several KIR2DL4 and 2DS4 alleles positively correlate with better therapeutic effects of TKIs, and they may be form the same KIR haplotype. Our data indicate that these KIR alleles represent strong anti-CML immunity by NK cells, and consequently may associate with long-term outcome and treatment-free remission in CML.

COMPARISON OF MOLECULAR KINETICS AFTER THE FIRST AND SECOND IMatinib DISCONTINUATION: RESULTS FROM THE KID STUDY

1Seoul St. Mary’s Hospital, The Catholic University of Korea, 2Leukemia Research Institute, The Catholic University of Korea, Seoul, 3Ajou University School of Medicine, Suwon, 4Chonnam National University Hospital, Hwasun, Hospital, 5Hwasun, 6Dong-A University College of Medicine, Busan, 7Hallym University College of Medicine, Anyang, 8Kangbuk Samsung Hospital, School of Medicine, Sungkyunkwan University, Seoul, 9Ulsan University Hospital, University
of Ulsan college of Medicine, Ulsan, 1School of Medicine, Keimyung University, Daegu, 10Chonbuk National University Medical School, Jeonju, 11St. Vincent’s Hospital, The Catholic University of Korea, Suwon, 12Asan Medical Center, University of Ulsan College of Medicine, 13School of Medicine, Ewha Womans University, Seoul, 14Inje University College of Medicine, Inje University Busan Paik Hospital, Busan, 15National Health Insurance Service Ilsan Hospital, Ilsan, 16Gachon University Gil Medical Center, Incheon, 17Chungbuk National University Hospital, Cheongju, Korea, Republic Of

Background: Recent reports have demonstrated that tyrosine kinase inhibitors (TKIs) discontinuation can be employed in chronic phase chronic myeloid leukemia (CP CML) patients with sustained deep molecular responses after enough TKI therapy. Consequently, treatment-free remission (TFR) has been a new therapeutic goal. Although 50-70% of patients experienced molecular relapse by several imatinib (IM) discontinuation studies, the most of patients resumed molecular responses (MR) following restart of IM. Aim: To assess TKI discontinuation patients (Korean Imatinib Discontinuation Study; KID Study), we have explored molecular kinetics after the first IM discontinuation and after IM resumption for molecular relapse. In patients regaining durable UMRD with IM resumption, we tried second IM discontinuation and compared molecular kinetics between the first IM stop and second IM stop. Methods: CP CML patients who were treated with IM for more than 3 years and had undetectable levels of BCR-ABL1 transcripts determined by quantitative reverse transcriptase polymerase chain reaction (PCR) for at least 2 years were eligible for KID study and in cases of MMR loss after 2 consecutive assessments, IM treatment was re-introduced. After IM resumption for MMR loss, patients were evaluated. Unrelated until MMR was re-achieved and every 3 months thereafter. The second stop was permitted in the patients who were in second UMRD for at least 2 years.

Results: Among patients who lost MMR in 2 consecutive analyses and resumed IM in the KID study, 12 patients (6 men and 6 women) with a median age of 45 years (range, 25-59 years) entered into a second IM discontinuation after maintaining UMRD at least 2 years. Prior to first discontinuation, the median duration of IM therapy was 68.9 months (range, 38.5-115.1 months) and the duration of sustained UMRD was 32.9 months (range, 24.8-64.5 months). After first attempt of IM discontinuation, they relapsed after a median duration of 3.7 months (range, 1.0-10.2 months) and had undetectable levels of BCR-ABL1 transcripts under the level of 0.1% on IS for 9.4 months and another patient have shown gradually increasing BCR-ABL1 transcripts under the level of 0.1%. Eight patients who experienced second relapse (MMR loss) after a median 2.9 months (range, 1.9-30.7 months). The patients who lost MMR, except one patient, were retreated with IM for a median of 7.1 months (range, 0.8-24.8 months); five patients re-achieved MMR at a median of 1.8 months (range, 1.0-10.2 months) and one re-achieved UMRD at 5.5 months.

Summary/Conclusion: Our data demonstrated that a second attempt might be possible and the median time to MMR loss after second discontinuation was similar to those of the first discontinuation. But the molecular kinetics after second IM resumption needs longer follow-up with more patients. Further studies on the predictors to select patients for a trial of second TFR and novel strategies such as intermittent therapy will be warranted.

E1070 CLINICAL IMPACT BY 24 MONTHS ACCORDING TO BCR-ABL1 TRANSCRIPT LEVEL AT 3 AND 6 MONTHS IN NEWLY DIAGNOSED CHRONIC PHASE CHRONIC MYELOID LEUKEMIA PATIENTS TREATED WITH RADOTINIB 300MG BID OR IMATINIB

Methods: CP CML patients who were treated with IM for more than 3 years and had undetectable levels of BCR-ABL1 transcripts determined by quantitative reverse transcriptase polymerase chain reaction (PCR) for at least 2 years were eligible for KID study and in cases of MMR loss after 2 consecutive assessments, IM treatment was re-introduced. After IM resumption for MMR loss, patients were evaluated. Unrelated until MMR was re-achieved and every 3 months thereafter. The second stop was permitted in the patients who were in second UMRD for at least 2 years.

Results: Among patients who lost MMR in 2 consecutive analyses and resumed IM in the KID study, 12 patients (6 men and 6 women) with a median age of 45 years (range, 25-59 years) entered into a second IM discontinuation after maintaining UMRD at least 2 years. Summary/Conclusion: Our data demonstrated that a second attempt might be possible and the median time to MMR loss after second discontinuation was similar to those of the first discontinuation. But the molecular kinetics after second IM resumption needs longer follow-up with more patients. Further studies on the predictors to select patients for a trial of second TFR and novel strategies such as intermittent therapy will be warranted.

E1071 HYDROXYRUXEA SUPPRESSES BCR-ABL1 T315I+ CML CLONES IN VIVO AND IN VITRO AND SYNERGIZES WITH PONATINIB IN ELIMINATING TKI-RESISTANT CML CELLS

M. Treemwees1,2, K. Brack3, S. Preuner4, S. Hemdhofer5, W.R. Sper1,2, G. Hoermann5, M. Deiner5, T. Lion11, P. Valenti12, K.V. Gleiener1,2

1Ludwig Boltzmann Cluster Oncology, 2Department of Internal Medicine I Division of Hematology and Hemostaseology, Medical University of Vienna, 3Children’s Cancer Research Institute (CCRI), 4Department of Laboratory Medicine, University of Vienna, Austria, 5Department of Internal Medicine/Division of Hematology and Hemostaseology, Medical University of Vienna, Salt Lake City, United States

Background: In chronic myeloid leukemia (CML), BCR-ABL1 T315I suppresses resistance to most BCR-ABL1 tyrosine kinase inhibitors (TKI). Long-term therapy with ponatinib, which suppresses BCR-ABL1 T315I, is problematic because of side effects. In addition, resistance against ponatinib may develop due to occurrence of compound mutations in BCR-ABL1. Therefore, alternative therapies to be considered. Hydroxyruxea (HU) has been used for (palliative) therapy in refractory leukemia and myelodysplastic malignancies. However, the effects of HU on TKI-resistant sub-clones have not been examined so far.

Aims: The aim of this study was to evaluate the effects of HU on CML sub-clones carrying BCR-ABL1 T315I mutations (isolated or in compound-configuration) in vitro and in vivo and to explore cooperative effects between HU and ponatinib.

Methods: Four BCR-ABL1 T315I+ CML patients were treated with HU (1-3 g/day) for 2 to 18 months. White blood counts (WBC), differential counts, and BCR-ABL1 transcript levels were reported. The BCR-ABL1 T315I+ CML BCR-ABL1 ratio determined by mutation-specific, ligation-dependent, PCR and next generation sequencing (NGS) was employed. To investigate the cell cycle effect of HU, BrdU (10 μM), KU812, KCL-22, and KCL-221+315I as well as Ba/F3 cells expressing BCR-ABL1 WT (Ba/F3p210WT), or mutant BCR-ABL1 (Ba/F3p210T315I) BCR-ABL1 WT or mutant BCR-ABL1 WT (Ba/F3p210T315I) were examined. Cell proliferation was quantified by 1H-tdTomato at a ratio of 1:1. Then, cells were exposed to HU, ponatinib, or...
Assessment of Treatment Outcomes in Patients on Tyrosine Kinase Inhibitor (TKI) Therapy

**Aim:** To further clarify the role of predictive biomarkers in molecular relapse after TKI discontinuation, we performed a retrospective analysis of patients who discontinued TKI treatment.

**Methods:**
- **Patients:** A total of 46 CML patients were included in the study (29 men; 17 women; median age, 58.5 years).
- **Methods:** Patients were continuously monitored for 18 months after TKI discontinuation. The ability to consistently detect low levels of BCR-ABL transcripts in clinical samples with initial BCR-ABL levels >10% was assessed.

**Results:**
- **Consistent results were observed in the both the diluted CML patient blood and spike-in CML cell lines or cell-line derived RNA studies for both the b3a2 and b2a2 transcripts, demonstrating an assay LoD of MR4.5 and below with a less than 2-fold difference at the LoD levels.**
- **With the clinical sensitivity study, eleven out of twelve low CML subjects were detected in at least 19 out of 20 replicates tested per subject over a range of 0.038% (SD=0.17 Log) to 0.0011% (SD=0.4 Log).** The overall ABL copy number present in clinical samples in each study was at least 5-10 times the required minimal ABL copy number of 232,000 to support a claim of MR4.5 and ≥100,000 for MR5.0.

**Summary/Conclusions:** The Xpert® BCR-ABL Ultra assay complies with the international guidelines for assay sensitivity achieving MR5 with 5-10 times more than the required ABL copies to confidently identify candidate patients that may benefit from the discontinuation of TKI therapy.

**E1073**

**XPERT® BCR-ABL ULTRA, A HIGH SENSITIVITY ASSAY WITH A LIMIT OF DETECTION REACHING MR4.5 AND BELOW ON AN INTERNATIONAL REPORTING SCALE**

C. Ferrand1, M. Deschamps1, A. Levitas2, C. Lockwood2, J. Payton4, G. Uyl3

Background: The ability to consistently detect low levels of BCR-ABL transcripts in patients with chronic myeloid leukemia (CML) is important in the assessment of treatment outcomes in patients on tyrosine kinase inhibitor (TKI) therapy.

**Aim:** To further clarify the role of predictive biomarkers in molecular relapse after TKI discontinuation, we performed a retrospective analysis of patients who discontinued TKI treatment.

**Methods:**
- **Patients:** A total of 46 CML patients were included in the study (29 men; 17 women; median age, 58.5 years).
- **Methods:** Patients were continuously monitored for 18 months after TKI discontinuation. The ability to consistently detect low levels of BCR-ABL transcripts in clinical samples with initial BCR-ABL levels >10% was assessed.

**Results:**
- **Consistent results were observed in the both the diluted CML patient blood and spike-in CML cell lines or cell-line derived RNA studies for both the b3a2 and b2a2 transcripts, demonstrating an assay LoD of MR4.5 and below with a less than 2-fold difference at the LoD levels.**
- **With the clinical sensitivity study, eleven out of twelve low CML subjects were detected in at least 19 out of 20 replicates tested per subject over a range of 0.038% (SD=0.17 Log) to 0.0011% (SD=0.4 Log).** The overall ABL copy number present in clinical samples in each study was at least 5-10 times the required minimal ABL copy number of 232,000 to support a claim of MR4.5 and ≥100,000 for MR5.0.

**Summary/Conclusions:** The Xpert® BCR-ABL Ultra assay complies with the international guidelines for assay sensitivity achieving MR5 with 5-10 times more than the required ABL copies to confidently identify candidate patients that may benefit from the discontinuation of TKI therapy.

1Division of Hematology, 2Department of Laboratory Medicine, University of Washington, Seattle, 3Institute of Medicine, Iowa City, 4Department of Pathology & Laboratory Medicine, Medical University of South Carolina, Charleston, 5Division of Hematology, Department of Internal Medicine, The Ohio State University, Columbus, 6Data Management and Analytics, 7Medical and Scientific Affairs and Strategy, Cepheid, Sunnyvale, United States

Background: The ability to consistently detect low levels of BCR-ABL transcripts in patients with chronic myeloid leukemia (CML) is important in the assessment of treatment outcomes in patients on tyrosine kinase inhibitor (TKI) therapy. Particularly, BCR-ABL assays that are sensitive in the measurement of deep level response may aid in the identification of potential candidates for treatment discontinuation. Xpert® BCR-ABL Ultra detects the most common BCR-ABL transcripts below MR4.5 (Molecular Response at 4.5-log reduction) or 0.0032%, which is widely accepted as the clinical threshold that defines candidates who can safely discontinue TKI therapy.

**Aims:** The present studies were designed to verify the limit of detection (LoD) for the Xpert® BCR-ABL Ultra assay below MR4.5 on the International Scale (IS) clinical samples for both the b3a2 and b2a2 transcripts.

**Methods:** To overcome the challenge of testing numerous replicates requiring large volumes of patient samples, serial dilutions ranging from BCR-ABL/ABL levels of 10% to <0.001% (IS) were prepared as contrived samples using CML patient blood with initial BCR-ABL levels ≥10% (IS) and pooled blood from CML-negative patients, ranging from 10% to <0.001% (IS). Twenty-one replicate dilutions were measured for%BCR-ABL/ABL (IS). Determination of the LoD was performed by the statistical analysis to identify the lowest concentration of%BCR-ABL/ABL (IS) per test that can be reproducibly distinguished from negative samples with 95% confidence. The acceptable precision for%BCR-ABL/ABL (IS) is defined as the ability to detect at least a 3-fold difference for all concentrations tested.

In addition, analytical LoD studies were performed using spike-in CML cell lines and cell-line derived RNAs, carrying either b3a2 or b2a2 transcripts. Furthermore, the clinical sensitivity study was conducted using blood from twelve low BCR-ABL transcripts level CML patients on TKI therapy, who had achieved and maintained MMR (Major Molecular Response) [0.1% (IS)] with reporting below 0.05% (IS).

**Results:** Consistent results were observed in the both the diluted patient blood and spike-in CML cell lines or cell-line derived RNA studies for both the b3a2 and b2a2 transcripts, demonstrating an assay LoD of MR4.5 and below with a less than 2-fold difference at the LoD levels. With the clinical sensitivity study, eleven out of twelve low CML subjects were detected in at least 19 out of 20 replicates tested per subject over a range of 0.038% (SD=0.17 Log) to 0.0011% (SD=0.4 Log). The overall ABL copy number present in clinical samples in each study was at least 5-10 times the required minimal ABL copy number of 232,000 to support a claim of MR4.5 and ≥100,000 for MR5.0.

**Summary/Conclusions:** These LoD evaluations demonstrate that the Xpert® BCR-ABL Ultra assay complies with the international guidelines for assay sensitivity achieving MR5 with 5-10 times more than the required ABL copies to confidently identify candidate patients that may benefit from the discontinuation of TKI therapy.

Background: Gaucher disease (GD) varies greatly in severity and organ involvement. Clinical characteristics are usually nonspecific and lead to late diagnosis with irreversible complications. Splenomegaly and thrombocytopenia are the two most common manifestations (Gaucher Registry, 2008), which are referred to hematology. A diagnosis of GD is considered after other diagnostic hypotheses have been ruled out. The consensus of international experts on GD varies greatly in severity and organ involvement. Clinical characteristics are usually nonspecific and lead to late diagnosis with irreversible complications. Splenomegaly and thrombocytopenia are the two most common manifestations (Gaucher Registry, 2008), which are referred to hematology. A diagnosis of GD is considered after other diagnostic hypotheses have been ruled out. The consensus of international experts on GD is required.

Aims: The recent report of conoidin A, as a specific Prx2 inhibitor, offers the possibility to perform cooxidation of cell systems, however, when its capacity is overwhelmed, the cell is exposed to oxidative stress, namely, when one enzyme is inhibited, LPO was highest for the pairs that included GPx. MBH was increased for all enzyme inhibitory conditions, when compared to the condition where all enzymes were active, and the lowest value was obtained when all enzymes were active, except for the case of conoidin A, mercaptosuccinic acid and sodium azide were used as specific inhibitors of Prx2, GPx and CAT, respectively. Since the RBC membrane is a major target of ROS, we evaluated membrane lipoperoxidation (LPO) and membrane bound haemoglobin (MBH), as well as, cytosol’s total antioxidant status (TAS), by spectrophotometric methods.

Results: Concerning TAS we found a trend towards decreasing values with enzyme inhibition (one or more); the lowest value of TAS was observed when all three enzymes were inhibited and, when only two enzymes were inhibited, the lower values were obtained for pairs that included CAT inhibition; when only one enzyme was inhibited, GPx inhibition showed the highest MBH, whereas, the lowest MBH was observed when all enzymes were active, and the highest when all of them were inhibited; when only one enzyme was inhibited, CAT inhibition showed the highest LPO value and when two enzymes were inhibited, LPO was the highest for the pairs that included GPx, MBH was increased for all enzyme inhibitory conditions, when compared to the condition with all enzymes active, except when CAT was inhibited.

Summary/Conclusions: In conclusion, inhibition of these antioxidant enzymes, either alone or simultaneously, leads to oxidative stress modifications within the RBC, as shown by the increase in MBH and membrane LPO, and by the decrease in cytosolic TAS. Moreover, the inhibition of CAT or GPx (either alone or with other enzymes) presented more impact on oxidative modifications than Prx2 inhibition. Our data strengthens the importance of these enzymes in RBC’s...

MOLECULAR BASIS OF PKLR MUTATIONS IN PATIENTS WITH PYRUVATE KINASE (PK) DEFICIENCY: THE FIRST REPORT FROM SOUTHEAST ASIAN POPULATION
S. Riolueang1,*, K. Tachavanich2, S. Ekwattanakit3, V.S. Tanphaichitr2, H. Kanno4, V. Viprakasit5
1Siriraj-Thalassemia Center, 2Department of Pediatrics, 3Department of Medicine, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand, 4Department of Transfusion Medicine and Cell Processing, Tokyo Women’s Medical University, Tokyo, Japan, 5Department of Pediatrics, of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand

Background: Recently we have identified a new form of transfusion dependent hemolytic anemia due to KLF1 mutations causing a trans-acting deactivation of pyruvate kinase genes (PKLR). Mutations of PKLR per se can affect red blood cells metabolism and cause a wide range of clinical manifestation from fetal anemia leading to hydropic fetus, severe neonatal jaundice requiring multiple exchange blood transfusions, chronic to fully compensated hemolytic anemia. Understanding of the molecular basis of pyruvate kinase deficiency (PK def.) might be useful to predict clinical phenotypes and suggest appropriate clinical management of future patients. Moreover, an interaction of PKLR and KLF1 mutations in such patient has not been explored.

Aims: This study aim to identify the mutation of patients with PK def. for the first time in Southeast Asian populations.

Methods: Seven unrelated patients; 6 from Thailand and 1 from Indonesia have been enrolled after informed consent. We have measured the PK activity of all patients and their parents and siblings using a standard biochemical technique as we have described earlier. A complete genomic analysis of all PKLR’s exons (NM_000298.5) including exon-intron boundaries were selectively amplified and followed by direct Sanger sequencing.

Table 1.

Results: Seven index PK def. patients as confirmed by enzyme activities, age range 9-35 yrs old, were identified (Table 1). Three patients presented with severe hemolytic anemia and required regular blood transfusion; every 3-4 weeks in two (PK-1 and PK-3) and every 10-12 weeks (PK-2) in which one patient (PK-1) has been successfully treated with bone marrow transplantation and became transfusion-free. Three patients (PK-5, -6 and -8) had moderately severe hemolytic anemia and required blood transfusion occasionally. Only one patient (PK-7) from Indonesia had well-compensated anemia and never required blood transfusion. All but one had PK activities lower than 50% of normal range but these activities did not correlate with clinical severity. We found one patient (PK-4) was found with only one known missense mutation (R488Q), however we could not find any mutation in KLF1 of this patient suggesting that she might have other unidentified cis mutation involved gene regulation of PKLR. Due to a limited number of patients, there was no clear genotype-phenotype correlation found in our studied population.

Summary/Conclusions: Seven confirmed cases of PK def. are reported here-in. They showed a wide variation of clinical severity. Molecular basis of PKLR mutations was proven to be beneficial to provide a definitive diagnosis of PK def. and might help suggesting clinical presentation in future cases.

PRELIMINARY RESULTS OF GAU-PED STUDY: PREVALENCE OF GAUCHER DISEASE IN PAEDIATRIC PATIENTS SELECTED BY AN APPROPRIATE DIAGNOSTIC ALGORITHM
W. Morello1,*, M. Filocamo2, M. Stroppiano2, M. Di Rocco3, F. Fedeli4, G. Russo5, D. Sperlì6, F. Furlan7, A. Pession1
1Pediatric Hematology and Oncology Unit, Sant’Orsola-Malpighi University Hospital, Bologna, 2Centro di Diagnostica Genetica e Biochimica delle Malattie Metaboliche, 3Department of Pediatrics, Unit of Rare Diseases, Gaslini Institute, Genoa, 4Pediatric Hematology, Ospedale Niguarda, Milano, 5Pediatric Hema- tology and Oncology Unit, Azienda Policlinico-Vittorio Emanuele Università di Catania, Catania, 6Pediatric Hematology and Oncology Unit, S. O. “Anunziata”, Cosenza, 7Pediatric Department, Fondazione IRCCS Ca’Granda Ospedale Maggiore Policlinico, Milano, Italy

Background: Gaucher disease (GD) is an autosomal recessive lysosomal storage disease characterized by the deficient activity of beta-glucocerebrosidase (GBA). GBA deficiency results in the accumulation of glucosylceramide in different organs, causing tissue damage. Typical GD features are splenohepatomegaly, peripheral blood cytopenias (mostly thrombocytopenia and/or anemia), growth retardation, bone involvement, gammapathies, increased risk of malignancies and, in some patients, neurological manifestations. Since symptoms are non-specific, the diagnosis can be delayed for years or missed. Enzyme replacement therapy (ERT) with recombinant β-glucocerebrosidase is safe and effective in preventing and/or reversing many clinical manifestations. However, if the diagnosis is delayed for years, major complications cannot be reversed. A useful screening method for GD is based on measuring enzyme activity on a Dried Blood Spot (DBS), while the gold standard test is still considered GBA activity in cellular homogenates. A pediatric algorithm has been proposed to promote timely diagnosis and early access to ERT (figure 1).

Aims: Since pediatric patients with splenomegaly and cytopenias are usually referred to pediatric hematologists, we have designed the GAU-PED study to...
evaluate the prevalence of GD among children referred to the haematology paediatric units and selected according to the above mentioned diagnostic algorithm. Here, we report a preliminary analysis of GAU-PED trial.

Methods: The GAU-PED study involves 53 centers in the context of the AIEOP Study Group, the Italian clinical research consortium in paediatric haematology and oncology. Patients referring to the pediatric haematology and oncology units for the first time were included if they had haematologic abnormalities (thrombocytopenia or anaemia) and/or anaemia, where other causes of splenomegaly has been excluded, are tested for GBA activity though a DBS sample. Only patients with DBS showing a GAU activity below normal values are recalled to confirm GBA enzyme deficiency using the gold standard GAU analysis in cell homogenate. For every tested patient clinical information are also collected.

Results: A total of 25 DBS have been collected from 11 centers, in the first 12 months of study accrual. DBS values under 4.4 pmol/punch-7/1 were found in 9/25 patients (36%). These patients have been recalled for the conventional enzymatic test. The diagnosis of GD has been confirmed in 5/25 patients (20%), with a prevalence of 9.9% (95% CI: 6.3-13.1%) equal to 5/25 patients in the tested population. In all 5 patients the genetic analysis has been consistent with GD. Three patients were males and 2 females. The mean age at diagnosis was 8 years (range 2-13 years). The median time from the initial clinical presentation and diagnosis has been 12 months (range 6-50 months), while the mean time between the DBS test and the diagnosis has been 2 months. ERT has been started in all GD patients.

Summary/Conclusions: Our preliminary results support the use of DBS as screening tool for GD in a selected population of children with splenomegaly and/or thrombocytopenia considered at increased risk for the disease. The use of a diagnostic algorithm is useful to increase awareness of GD among pediatric hematologists and to shorten the time to diagnosis. Taking into consideration the long life expectancy of pediatric GD patients, the early diagnosis will have a strong impact on health and quality of life.

CIRCULATING MICROPARTICLES IN CONGENITAL AND ACQUIRED HAEMOLYTIC ANAEMIA
W. Barcellini1, V.M. Sciumbata1, J.A. Giannotta1, A.Z. Zanimoni1, V.B. Valli1, G. Meraldi2, E. Trombetta3, V. Ferri1, L. Pettina1, A. Cortelezzi4, A. Artoni2
1UCO Oncologia, Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, 2Department of Hematology, and 3Department of Hematology non tumorale e Coagulopatie, 4UOC Ematologia, Centro di Analisi Chimico Cliniche e Microbiologiche Dipartimento dei Servizi, Servizio di Citofluorimetria, Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, 4Università degli Studi, Milano, Italy

Background: Microparticles (MPs) are small particles budding from cells, which contain variable amounts of proteins, miRNA and cytosol from the parental cell. MPs play a role both in physiological and pathological conditions such as signal transduction, cell activation, thrombosis and cancer. Thrombotic events are a possible complication of haemolytic conditions, both congenital and acquired. Elevated levels of circulating MPs have been described in several haemolytic conditions, including sickle cell anaemia, thrombocytopenia, haemolytic uraemic syndrome, and thrombotic thrombocytopenic purpura.

Aims: To evaluate platelet MPs (PMP), tissue factor expressing MPs (TF MPs), endothelial MPs (EMPs) and microparticles expressing single antigens (CD41, CD142 or CD142) levels in in other haemolytic anaemias, such as hereditary spherocytosis (HS), elliptocytosis (HE), stomatocytosis (HSt), red cell enzymatic defects, congenital dyserythropoietic anaemia (CDA), autoimmune haemolytic anaemia (AIHA), and paroxysmal nocturnal haemoglobinuria (PNH).

Methods: To determine MPs, whole blood was collected into 0.109 M sodium citrated vacutainer tubes. Platelet Free Plasma (PFP) was prepared by double centrifugation at 2500 g for 15 min and stored frozen at -80°C until assayed. For MPs analysis 25 μl of PFP was incubated with annexin V-APC, CD41-FITC, CD142-PE and CD144 PerCP-Cy5.5 in 5 Hepes buffer in the presence of 15 mM CaCl2 and 1 μM of r-Hirudin for 30 min. Samples were diluted with 500 μl Annexin Binding Buffer. 25 μl of fluorescent iron deficient CD41+ MPs were added to express MP count as absolute numbers. MPs analyses were performed on a BD FACS Canto cytometer using Megamix-Plus SSC to define the MPs gate.

Results: MPs levels were evaluated in plasma of 43 patients followed-up for a median time of 9 years (range 2-34) and compared with normal controls. The median number of MPs in controls (n=30) was 8.3±5.5 (range 2.2-28.7); 9/43 (21%) had been splenectomized and 13/43 (30%) were treated at the moment of the study (steroids/immunosuppressors for AIHA, and eculizumab for PNH). Table shows Hb levels, PLT and WBC counts of the different patient groups.

Discussion: MPs levels were abnormal in both congenital and acquired haemolytic conditions. MPs levels correlate with the degree of anaemia and haemolysis and with the duration of disease.

Summary/Conclusions: These preliminary results suggest that MPs levels are abnormal in both congenital and acquired haemolytic conditions. MPs levels correlate with the degree of anaemia and haemolysis and with the duration of disease.

E1079
THE PREVALENCE, ETIOLOGY AND PROGNOSTIC IMPACT OF ANEMIA IN OLDER POPULATION
S.S. Michalak1, J. Rupa-Matysek2, L. Giff1
1Family Medicine Clinic, MEDKOL, Zielona Gora, 2Department of Hematology and Bone Marrow Transplantation, Poznan University of Medical Sciences, Poznan, Poland

Background: The population of people aged ≥60 years is growing rapidly. Anaemia represents a common condition among the elderly, however its prevalence and causes are not well known.

Aims: The aim of the study was to evaluate the prevalence, severity and etiology of anaemia in the population aged ≥60 years. Risk factors for the development of anaemia including concomitant diseases and treatment, were analysed. The association between anaemia and hospitalization or all-cause mortality during follow-up was determined.

Methods: Retrospective analysis was performed on 981 Caucasian, outpatient patients aged ≥60 in Poland over 2013-2014 (median age 68, range 60-99 years, 60% females). The prevalence of anaemia, defined according to WHO laboratory criteria, age, gender, diagnostic group and medical treatment were studied. Data on the incidence of common comorbidities (coronary artery disease, heart failure, diabetes, chronic obstructive pulmonary disease, chronic kidney disease, chronic liver diseases, cancer, thyroid diseases), hospitalization, treatment used and all-cause mortality were analysed.

Results: The prevalence of anaemia in the elderly population was 17.2% and was higher in men than women (20.4% vs 15.2%, p=0.038). Anaemia was present in 10.3% of patients aged 60-69, in 20.1% of those aged 70-79 and in 35.6% of patients ≥ 80 years. Incidence rates of anemia increased significantly with age (60-69 vs 70-79 years, p<0.001, 60-69 vs ≥80 years, p<0.001, 70-79 vs ≥80 years, p<0.001). Anaemia was mild in 69.8% of patients, but a severe form was found significantly more often among men aged ≥80 years (p=0.03).

Analysis of the etiology of anaemia revealed three predominant types: anaemia of chronic disease (33.1%), unexplained anaemia (28.4%) and deficiency anaemia (22.5%, including iron deficiency 13%). In comparison to patients without anaemia, those with anaemia were older (p<0.001), had a higher prevalence of comorbidities (p<0.001) and/or thrombocytopenia considered at increased risk for the disease. The use of an appropriate diagnostic algorithm is useful to increase awareness of GD among pediatric hematologists and to shorten the time to diagnosis. Taking into consideration the long life expectancy of pediatric GD patients, the early diagnosis will have a strong impact on health and quality of life.

Summary/Conclusions: The prevalence, severity and etiology of anaemia in the population aged ≥60 years. Risk factors for the development of anaemia including concomitant diseases and treatment, were analysed. The association between anaemia and hospitalization or all-cause mortality during follow-up was determined.

E1079
The high rate of unexplained anaemia indicates the necessity for detailed hematologic diagnosis. The occurrence of anaemia among people aged ≥60 years has an adverse impact on survival.

PIEZ01 MECHANOTRANSDUCTIVE PROTEIN MUTATIONS IN RBCS: WHEN THE PHENOTYPE IS BEYOND HYEMOLOGIC ANAEMIA

D. Mota1, S. Manir2, T. Nascimento3, P. Bernardo4, L. Relvas1, A. Oliveira5, E. Cunha1, J. Ribeiro1, C. Bento1, T. Magalhães Maia1, M. L. Ribeiro1

1Servicio de Hematología Clínica, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

**Background:** Piezo proteins are integral membrane proteins with many transmembrane domains broadly expressed, including erythrocytes (RBcs). PIEZ01 proteins play an important role as an osmoreceptor, maintaining RBcs ionic homeostasis, functioning as a mechanically activated cation channels. Mutated PIEZ01 proteins have been linked to hereditary xerocytosis (HX), which is characterized by RBcs dehydration with mild to moderate compensated hemolytic anemia and iron overload. As these clinical features are present in many different clinical conditions, the diagnosis always needs a high level of suspicion. Nowadays, besides peripheral blood smear (PBS) observation, molecular analysis, searching for mutations in PIEZ01 gene, became a tool in the diagnosis of HX. 

**Aims:** Describe 26 patients with HX associated with PIEZ01 mutations belonging to 13 unrelated families, raising awareness of the highly variable phenotype of this patients, and the need of a highly grade of suspicion along with the morphologic evaluation of the PBS. 

**Methods:** Collection of clinical and laboratory data on our 26 patients with HX and hyperferritinaemia due to 10 different identified mutations in PIEZ01. Sanger sequencing was used to identify mutations affecting PIEZ01, encoded by FAM38A gene, and to confirm transmission according to the presence of disease phenotype. In all patients were excluded other known causes of hyperferritinaemia (HF) and haemolytic anaemia. 

**Results:** Of the patients identified as having PIEZ01 mutations, 13 were probands and 13 were identified by family studies. Median age at diagnosis was 43 years (1-80), with female predominance (n=14; 53.9%). 4/13 probands had family history of HX (n=1) or HF (n=2). The common feature of our entire cohort of patients was the presence of xerocytes in PBS. 13/26 patients had reticulocytosis, a median reticulocyte count of 101 x109/L (28.1-557.3), 18/26 patients had HF with a mean value of ferritin of 556ng/mL (161-6617) and 9/26 had both. Of the 26 patients, four had splenomegaly and six gallbladder lissiasis (5/6 cholecystectomized), two of them both. Only 5 patients presented with anaemia (Hb <12g/dL), 2 macrocytic and 3 normocytic. One patient was not anaemic but he also had a hemolytic anaemia carrier. We detected heterozygous missense mutations in all 26 patients. 

**Summary/Conclusions:** HX is a dominant disorder of RBcs dehydration presenting a great phenotypic variability. As shown in our cohort of patients, the anaemia may not be the main feature, in fact, the presence of xerocytes in PBS and HF were the most frequent characteristics of our patients. We would like to emphasise that in the genomics era the identification of xerocytes in the PBS keeps playing an important role for this diagnostic. Not only because, unlike other haemolytic anaemias, in HX there is a contraindication to splenectomy due to the increased risk of thrombotic events, but also because this pathological pattern is unusual and the diagnosis that is presented to the degree of hemolysis. This iron overload may be related to a defective iron homeostasis dependent on PIEZ01 function not strictly related with Xerocytosis.

**Background:** Pyruvate Kinase Deficiency (PKD) is an autosomal recessive disorder caused by mutations in the PKLR gene. PKD produces chronic non-spherocytic hemolytic anemia, which can be fatal during early childhood and may lead to severe chronic anemia, iron overload, and splenomegaly. Despite therapeutic splenectomy. Although not considered a standard-of-care, allogeneic bone marrow transplantation has been curative in a limited number of cases. These findings, and the evidence that PKLR gene mutations are likely the sole etiology of the disorder, make PKD a candidate for gene therapy. We developed a gene therapy strategy in a PKD mouse model using a lentiviral vector (LV) carrying a codon-optimized version of the PKLR cDNA (coPKR).

This vector has been recently designated as Orphan Drug for the treatment of PKD by the EMA and FDA (EMA: EU/3/14/1330; FDA: DRU-2016-5168). 

**Aims:** To test the efficacy of the therapeutic LV, we have proposed an alternative to previously delivered PKD-hematopoietic progenitors. In particular, we have generated CRISPR/Cas9 system tools to knock-out the PKLR gene in healthy hematopoietic progenitors from healthy cord blood samples

**Methods:** Up to six different gRNAs were specifically designed to cleave the exons 8, 9 and 11 of the PKLR gene. All gRNAs contain at least 3 mismatches with the coRPK present in the therapeutic LV, to avoid the cleavage of the therapeutic transgene. Two gRNAs cleaved the PKLR gene both in 293T cells and primary CD34+ cells. In order to identify and select edited cells, Cas9-gRNAs components were cloned into a Cas9-2A-ZsGreen1 plasmid. 

**Results:** Cord Blood CD34+ cells were electroporated, sorted and differentiated along the erythroid lineage. Significantly, the pyruvate kinase activity in ex vivo differentiated erythroid cells was impaired in gene edited cells as compared to non-edited samples.

**Summary/Conclusions:** Gene edit of wt CD34+ progenitors allow us to generate cells with RPK impaired. The decrease of PK activity validates this approach as a human model for PKD.

PHYSIOPATHOLOGY OF HEREDITARY XEROCYTOSIS : PIEZO1 GAIN OF FUNCTION MUTATIONS IMPACT HEMOGLOBIN OXYGEN AFFINITY

L. Kiger1, C. Guitton2, K. Ghazal3, M. Feneant-Thibault4, L. Bendelac5, F. Galacteros1, V. Proulle7, L. Garçon8, V. Picard5,*

1IMRB U955, INSERM, Créteil, 2Service de Pédiatrie, 3Service de biochimie, APHP, Hôpital Bicêtre, 4Service de biochimie, 5Service d’hématologie biologique, APHP, Hôpital Bicêtre, Le Kremlin Bicêtre, 6Centre de Reference des maladies constitutionnelles du Globule rouge, APHP Hopital Mondor, Créteil, 7Service d’Hématologie, APHP, Hôpital Bicêtre, Le Kremlin Bicêtre, 8Service d’hématologie biologique, CHU, Amiens, France

**Background:** Dehydrated hereditary stomatocytosis, also called hereditary xerocytosis (HX) is a dominant non-spherocytic chronic hemolytic anemia characterized by an increased cation leak through the red cell membrane, associated with dehydration and shortened red cell survival. Clinically, most patients present a totally compensated hemolysis, with a normal hemoglobin level contrasting with a high reticulocytosis. In most cases, HX is caused by missense mutations activating Piezo1, a mechanosensitive ion channel. However, the pathophysiology of this compensated hemolysis remains largely unclear.

**Aims:** We studied the hemoglobin oxygen affinity parameters in HX patients and in hereditary spherocytosis (HS) subjects as controls.

**Methods:** Fourteen patients from 5 described and 4 unreported families with a HX diagnosis and 15 HS subjects were included. Diagnosis was based on ektacytometry and EMA assay. PIEZO1 and KCNN4 coding regions were analyzed by Sanger sequencing in all HX patients. Hemoglobin oxygen affinity was evaluated using p50 measured on venous blood on a Hemoxanalyzer or a Radiometer blood gas analyzer. 2.3 diphosphoglycerate (2,3 DPG) levels were measured using a commercialized kit and expressed as a molar ratio 2,3 DPG/hemoglobin.

**Results:** All the 14 HX patients carried one or two missense mutations in PIEZO1, no gene variation was identified in KCNN4. Five families (9 subjects) have already been reported, with identified mutations in exon 18, 21, 42 or 51. Five subjects from 4 new families carried new mutations in exons 14, 16 and 27 for which biochemical study showed a high likelihood of pathogenicity. For all HX patients, p50 values were under the normal range (median 21.1, range 19.7-23.4, normal range 25-29 mmHg), contrasting with HS patients for whom p50 was found to be in the normal range (mean 26.1, range 24.6-28.8 mmHg). This indicated a significant increase in the hemoglobin affinity for oxygen restricted to PIEZO1 mutated HX. Of note, p50 was not correlated with the Hb level (mean 139, range 112-180 g/L in HX patients versus 125, range 93-142 g/L in HS patients). Intracellular red cell 2,3 DPG level could be measured in 7 HX patients from 4 families, it was found decreased in all of them (0.43±0.06, normal 0.9±0.19), providing a pathophysiological basis for the increased hemoglobin affinity we observed. In particular, we showed a high tissue hypoxia and consequently a high reticulocytosis, providing a clue to explain the compensated hemolysis frequently observed. However, the links between PIEZO1 mutations, reduced cell enzymatic activity and erythropoiesis need to be clarified and a proteomic and a metabolomic approach is under investigation. Of interest is the clinical point of view, HX diagnosis is sometimes difficult and this low p50 value, easily measured on venous blood, represents a useful new diagnosis tool for HX.
Background: Viral infections, most commonly by cytomegalovirus (CMV), Epstein-Barr virus (EBV), polyoma virus type I (BK), and fungal infections, mainly by Aspergillus Fumigatus (Asp), are leading causes of transplant-associated mortality in patients undergoing allogeneic hematopoietic stem cell transplantation. Standard treatment with antiviral and antifungal pharmacological agents, is often ineffective or toxic and may lead to resistance. Due to these limitations, adoptive immunotherapy with antigen-specific T cells has emerged as an attractive alternative. Towards unleashing its full potential and treat multiple viral and fungal infections by a single T-cell product, we developed a rapid, simplified and minimally laborious protocol for the generation of multi-pathogen-specific T cells (mp-STs) that simultaneously target CMV, EBV, BK and Asp, from healthy donors. 

Aims: Due to the lack of mouse models recapitulating the clinical condition of multiple opportunistic infections in transplanted hosts, we here aimed to test the in vivo safety of produced mp-STs and provide a proof of concept of their efficacy in a humanized model of invasive aspergillosis (IA). 

Methods: mp-STs were generated from healthy donors by pulsing 1.5x10^7 mononuclear cells with viral (CMV, IE1, pp65; EBV: EBNA1, LMP2, BZLF1; BK: Large T, VP1) and Asp pepmixes (Crf1, Gel1, SHMT) and culturing for 10 days. The specificity of mp-STs was analyzed by IFN-γ Elispot. A total of 1.5x10^5 of immunomagnetically isolated CD3+cells (donor lymphocyte infusions-DLI) or mp-STs were infused in myelo/immuno-ablated NSG mice which had been intranasally inoculated with Asp conidia or left uninfected. NK-92MIhCD16 cells were evaluated by a 5-parameter sickness score and at sacrifice, tissues were assayed by histology and immunohistochemistry.

Results: We generated 2.3±5x10^7 cells mp-STs (12-fold expansion). All cell lines were polyclonal expressing cytokine receptor immunomarkers and specific against Asp [spot forming cells (SFC)/2x10^5cells: 31±52] and the targeted viruses, if derived from seropositive donors [SFC/2x10^5cells: CMV, 63.7±267; EBV: 744±158; BK: 578±118]. To first assess the safety issue, we asked whether mp-STs can induce acute graft-versus-host disease (aGvHD) in myelo-ablated mice. While DLI mice succumbed early and histologically confirmed aGvHD and succumbed by day 20, mp-ST-mice survived free of aGvHD until the day of sacrifice (d28). To assay the in vivo functionality of mp-STs against IA, conditioned and Asp-inoculated mice, received mp-STs (n=5), DLI (n=4) or were left untreated (IA control, n=6). All IA- and DLI-mice succumbed to histologically evidenced IA at a median day 6, whereas 60% of mp-ST-mice survived until sacrifice (d28). While the day-12 survivors presented high T-cell engraftment in the lung (%CD3+/CD45+: 14±7) with no histological evidence of IA, the two mp-ST-non-survivors died from IA in the absence of T-cell engraftment. Non-specific DLI failed to control IA despite T-cell presence in 3/4 DLI-mice (%CD3+/CD45+/spleen: 58±12, lung: 3±1) which succumbed early, before aGvHD development.

Summary/Conclusions: Overall, engrafted mp-STs effectively controlled IA without evidence of alloreactivity. Based on the robust specificity of our mp-STs against all targeted pathogens and the clinical efficacy of virus-specific T-cells, we expect that our "one in one" T-cell product has the potential to also fight the targeted viruses and become a powerful tool for the treatment of multiple, life-threatening post-transplant infections.

GENE-MODIFIED NK-92MI CELLS EXPRESSING A CHIMERIC CD16/CD64-BZLF1 BB-Z RECEPTOR EXHIBIT ENHANCED CANCER-KILLING ABILITY IN COMBINATION WITH THERAPEUTIC ANTIBODY

A. Schematic representation of the CD16-BB-ζ and CD64-BB-ζ FcγRIII constructs. B. Exogenous CD16 or CD64 expression on surfaces of NK-92mi cells are shown. C. Immunoblot analysis of CD3ζ fusion protein expression in NK-92miCD16 or NK-92miCD64 cells.

Figure 1. NK-92miCD16 and NK-92miCD64 functional validation in vitro and characterization. A. Schematic representation of the CD16-BB-ζ and the CD64-BB-ζ receptor constructs. B. Exogenous CD16 or CD64 expression on surfaces of NK-92 mi cells are shown. C. Immunoblot analysis of CD3ζ fusion protein expression in NK-92miCD16 or NK-92miCD64 cells.
Aims: To apply NK-92MI cell-based immunotherapy in cancer, we designed and generated two chimeric receptors which can bind the Fc portion of human immunoglobulins in NK-92MI cells.

Methods: The construct included the low-affinity Fc receptor CD16 (158F) or the high-affinity Fc receptor CD64, with the addition of the CD3a extracellular domain, CD28 transmembrane domains, two costimulatory domains (CD28 and 4-1BB), and the signaling domain from CD3ζ. The resulting chimeric receptors, termed CD16-BB-ζ and CD64-BB-ζ, were utilized to generate chimeric receptor-modified NK-92MI cells, which were named NK-92MIhCD16 and NK-92MIhCD64, respectively.

Results: We found that NK-92MIhCD16 and NK-92MIhCD64 cells significantly improved cytotoxicity against CD20-positive non-Hodgkin’s lymphoma (NHL) cells in the presence of rituximab.

Summary/Conclusions: These results suggest that the chimeric receptor-modified NK-92MI cells could potentially enhance the clinical responses mediated by currently available anticancer monoclonal antibodies (mAbs).

A NOVEL IN VITRO METHOD TO QUANTIFY THE PHARMACOLOGY ACTIVITY OF BISPECIFIC ANTIBODIES IN HEMATOLOGICAL SAMPLES

Background: The PharmaFlow automated flow platform has achieved 85% clinical correlation with AML samples with its novel Native Environment assay (NEA). Recently, novel B-specific antibodies (BsAbs) or analogous constructions acting through the formation of an immunologic synapse between T-cells (CD3) and a tumor-associated surface antigen (TAA) have been used as immunotherapy leading to T-cell activation and serial lysis of tumor cells. We have developed an automated flow cytometry assay for bispecific antibody screening that keeps intact both basal effector to target (E:T) ratios and Native environment using whole blood or bone marrow samples. In this context, the PharmaFlow platform selects different in vitro T-cytotoxicity effects across patients identifying best patient candidates for adoptive antitumor immunotherapy with BsAbs. The integration of Effective E:T ratios and pharmacological parameters better predict the in vivo response of BsAbs. Because of the high capacity of the PharmaFlow platform, additional antibodies constructions alone or in combinations with immunomodulatory agents could be tested to identify the best agents or immunotherapeutics combinations in hematological diseases.

Methods: For this purpose, different fresh whole Bone Marrow (BM) or Peripheral Blood (PB) were tested with their corresponding BsAbs at 8 different concentrations in different time points (24h-144h). In this sense, we tested 31 AML BM samples (5 paired BM and PB) with the CD123xCD3 (Creative Biologics) and 7 CLL and 3 B-ALL samples with Blinatumomab (Amgen). When appropriate, basal quantification of TAA was performed by flow cytometry (FCM). A flow platform named PharmaFlow by FCM analysis was used to count by FCM how many tumor cells were killed by every activated T-cells, here called effective E:T ratio. For each sample, 8-colour FCM staining was performed to simultaneously analyze the leukemic population, activated CD4 and CD8 T-cells and the residual normal cells. EC50 or Emax was calculated to evaluate potency or efficacy. Kinetics of activity was measured repeating the dose response curves in 3 different days.

Results: Most of the samples present both T-cell activation (CD25+) and an effective lysis of tumor cells after BsAbs exposure in a time and dose dependent manner (Figure 1), even starting with low basal E:T ratios (<1:100). For AML, basal quantification of CD123 by FCM density does not reflect a correlation with the in vitro response, therefore differences in T-cell cytotoxicity or leukemic immunoresistance were observed between samples in terms of EC50 or Emax even more marked between CLL samples. The integration of effective E:T ratios, EC50, Emax, and kinetics allow us to generate an in vitro response model and select those samples with higher T-cell cytotoxicity after the different BsAbs exposure. Interestingly, many of the samples for all the BsAbs leave a significant proportion of live cells, even at the higher BsAbs concentrations or with a remarkable expansion of activated T-cells that suggest the use of immunomodulators to unlock this immunoresistant status.

Summary/Conclusions: We have developed an automated flow cytometry assay for bispecific antibodies screening that keeps intact basal effector to target (E:T) ratios and Native environment using whole blood or bone marrow samples. In this context, the PharmaFlow platform selects different in vitro T-cytotoxicity across patients identifying best patient candidates for adoptive antitumor immunotherapy with BsAbs. The integration of Effective E:T ratios and pharmacological parameters better predict the in vivo response of BsAbs. Because of the high capacity of the PharmaFlow platform, additional antibodies constructions alone or in combinations with immunomodulatory agents could be tested to identify the best agents or immunotherapeutics combinations in hematological diseases.

HUMANIZED CD7 NANOBODY-BASED IMMUNOTOXINS EXHIBIT PROMISING ANTI-T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA POTENTIAL

Y. Yu1, J. Li1, X. Zhu2, X. Tang1, Y. Baof2, Y. Huang1, L. Yuan1, L. Yang1, L. Yang1

Background: The key to translating those immunotoxins into clinics, we humanized the nanobody sequences (designated as dhuVHH), as well as further truncated the Pseudomonas exotoxinA (PE) derived PE38 toxin to produce a more protease-resistant form which is named as PE-LR, by deleting majority of PE domain II. Methods: Three new types of immunotoxins, dhuVHH6-PE38, dVH6-PE-LR, and dhuVHH6-PE-LR, were successfully constructed. These recombinant immunotoxins were expressed in E. coli and showed that nanobody immunotoxins have the benefits of easy soluble expression in a prokaryotic expression system.

Results: Flow cytometry results revealed that all immunotoxins still maintained their ability to bind specifically to CD7-positive T lymphoma cell lines (designated to CD7-negative control cells. Laser scanning confocal microscopy found that these proteins can be endocytosed into the cytoplasm after binding with CD7-positive cells, and that this phenomenon was not observed in CD7-negative cells. Western blot experiments showed that all immunotoxins retained the highly effective and specific growth inhibition activity in CD7-positive leukemia cell lines and primary T-cell acute lymphoblastic leukemia (T-ALL) cells. Further in vivo animal model experiments showed that humanized dhuVHH6-PE38 immunotoxin can tolerate higher doses and extend the survival of NCG mice transplanted with CEM cells without any obvious decrease in body weight. Further studies on NCG mice models with patient-derived T-ALL cells, dhuVHH6-PE38 treatment significantly prolonged mice survival with around 40% survival improvement. However, it is also noticed that despite dhuVHH6-PE-LR showed strong anti-tumor effect in vitro, its in vivo anti-tumor efficacy is disappointing.
SUMMARY/CONCLUSIONS: We have successfully constructed a targeted CD7 molecule modified nanobody (CD7 molecule improved nanobody) immunotoxin dhuVH6-HPE38 and showed its potential for treating CD7-positive malignant tumors, especially T-cell acute lymphoblastic leukemia.

E1088
STATINS MAY IMPROVE CAR-NK IMMUNOTHERAPY IN MM BY PREVENTING LOSS OF BCMA EXPRESSION ON MM CELLS

G. Suñe1,*, L. Perez-Amill1, A. Urbano-Ispizua1, B. Martín-Antonio1
1Hematology, Hospital Clinic/IDIBAPS/Josep Carreras Leukemia Research Institute, Barcelona, Spain

Background: Chimeric Antigen Receptor (CAR) modified immune cells targeting BCMA against multiple myeloma (MM) has appeared as a feasible immunotherapy strategy to treat MM patients. However, high doses of CAR immune cells are required to achieve a response. Cord blood derived NK cells (CB-NK) is a feasible source of obtain NK cells to modify with a CAR against BCMA. We previously observed that MM cells exposed to CB-NK are able to transfer MM proteins, such as BCMA, both to CB-NK and to adjacent MM cells non-exposed to CB-NK. Furthermore, statins, which are toxic for MM cells, by altering the lipid composition of tumor cell membrane are involved in cell-cell communication. We hypothesized that statins could prevent the loss of BCMA expressed by the CB-NK MM cells after CB-NK exposure, allowing infusing a lower CAR immune cell dose in MM patients.

Aims: To evaluate the effect of statins on MM cell proliferation, on the CB-NK immune response against MM, and on BCMA expression in MM cells after CB-NK exposure.

Methods: The cytotoxicity of statins against MM cells was determined in vitro and in vivo in a murine MM model; furthermore, their impact in CB-NK cytototoxicity against MM was also determined in vitro. BCMA expression on MM cells after CB-NK exposure was analyzed by confocal microscopy and by flow cytometry. FACs sorting experiments were performed to analyze BCMA transfer between CB-NK exposed MM cells to neighboring non-exposed CB-NK MM cells.

Results: Atorvastatin and Fluvastatin treatment (1μM) decreased MM cell line (ARP1, RPMI, KMM1) proliferation. No effect was detected for U266 MM cells and for K562 non-MM cells. In vivo studies, showed that mice treated for three days i.p with Fluvastatin (1mg/kg) showed significant decreased MM disease progression. Blocking of BCMA decreased CB-NK cytototoxicity against MM cells. Furthermore, pretreatment of MM cells with Fluvastatin (3 μM) increased CB-NK cytototoxicity against all MM cell lines; no impact was observed against K562 non-MM cells. Co-culture experiments showed that, as soon as 30 minutes, CB-NK exposure led to a BCMA transfer from MM cells to CB-NK and to the extra-cellular milieu leading to a loss of BCMA expression on MM cells. Fluvastatin pretreatment prevented loss of BCMA expression. After two days of co-culture, alive MM cells still showed decreased BCMA surface expression, and surprisingly, increased intracellular BCMA expression. Fluvastatin pretreatment partially avoided the generation of CAR-expressing MM cells cell-free MM cell culture. Furthermore, FACs sorting experiments showed that MM cells exposed to CB-NK, transferred BCMA to neighboring non-CB-NK exposed MM cells which was partially inhibited with Fluvastatin pretreatment.

Summary/Conclusions: Our findings show that besides the anti-MM activity of statins alone, they avoid the loss of BCMA expression on MM cells after immune cell exposure. Preventing loss of BCMA expression on MM cells might improve the efficiency of CAR immunotherapy against BCMA, suggesting the potential of statins as an adjuvant in CAR-NK immunotherapy against MM.

E1089
DENDRITIC CELL VACCINATION COMBINED WITH LENALIDOMIDE AND PROGRAMMED DEATH-1 (PD-1) BLOCKADE HAS SYNERGISTICALLY INDUCED A MARKED TUMOR REGRESSION IN A MURINE MYELOMA MODEL

S.-H. Jung1,*, S. Yang2, H.-J. Lee2, M.-C. Vo1, T.J. Lakshmi2, H.-J. Kim1, J.-J. Kim1
1Department of Hematology- Oncology, 2Research Center for Cancer Immunotherapy, Chonnam National University Hwasun Hospital, Hwasun-Eup, Korea, Republic Of

Background: There is emerging evidence that the maximal benefit of dendritic cell (DC)-based cancer immunotherapy may be achieved by combination with other therapies that act to immunomodulation and tumor microenvironment.

Aims: In this study, we tried to obtain the best efficacy of immunotherapy using DC vaccination in combination with lenalidomide and PD-1 blockade in a murine myeloma model.

Methods: After establishing myeloma-bearing mice, four treatment groups were designed to be a mimicking protocol as like treatment in clinics as following: 1) PBS control, 2) DCs, 3) DCs + lenalidomide, 4) DCs + PD-1 blockade, and 5) DCs + lenalidomide + PD-1 blockade. After treatment, preclinical response and in vitro immunological responses were evaluated.

Results: DCs combined with lenalidomide and PD-1 blockade showed the best tumor regression among the study groups. These anti-tumor effects have meaningfully related to the decrease of immuno-regulatory populations, such as myeloid-derived suppressor cells (MDSCs), M2 macrophages, and regulatory T cells (Treg) and the increase of effector immune cell populations, including CD4+ and CD8+ T cells, natural killer (NK) cells, and M1 macrophages, accompanied with the activation of cytotoxic T lymphocytes (CTLs) and NK cells in the splenocytes from the treated mice. Moreover, the level of immunosuppressive cytokines, such as TGF-β and IL-10, was significantly reduced in tumor microenvironment.

Summary/Conclusions: DC vaccination in combination with lenalidomide plus PD-1 blockade has synergistically induced a strong antitumor immunity by modulating tumor microenvironment in a murine myeloma model. This protocol will become a promising translational approach to improve the efficacy of immunotherapy in the field of MM.

E1090
B- AND T-CELL IMMUNE REPERTOIRE profiling with anchored multiplex PCR and next-generation sequencing

J. Eberlein1, T. Harrison1, J. Sims1, I. McKittrick1, M. Wemmer1, D. Fugere1,*, L. Griffin1, B. Culver1, L. Johnson1, B. Kudlow1
1AcheraDX, Boulder, CO, 2Q2 Solutions, EA Genomics, Morrisville, NC, United States

Background: NGS-based analysis of the immune repertoire (IR) is a powerful tool to monitor disease, adaptive immune responses to disease, vaccination and therapeutic interventions. IR characterization by NGS usually requires large primer panels to cover its extensive combinatorial diversity, and a complex system of synthetic controls to account for differential amplification efficiency across segment combinations. Anchored Multiplex PCR (AMP™) uses molecular bar-coded (MBC) adapters and gene-specific primers (GSPs), enabling NGS-based immune chain mRNA interrogation from a single amplicon. This eliminates the need for opposing primers that bind within the highly variable V-segment, eliminating clonal dropout due to some over or under amplification.

Aims: Our goal was to develop an NGS assay based on AMP that would enable IR characterization utilizing a minimal set of unidirectional GSPs and to reduce amplification bias through the use of MBC adapters.

Methods: Upon developing our AMP-based NGS assay, we validated its quantitative reproducibility by PCR amplifying DNA from PBMCs of healthy donors, B-cell chronic lymphocytic leukemia donors and formalin-fixed paraffin-embedded (FFPE) tissue.

Results: We developed the AMP-based NGS assays, Immunovarse™ (IGH for B-cell and T-cell Ig), TCR for B-cell and T-cell, respectively. Both assays demonstrated high reproducibility between replicates with quantitative clone tracking down to 0.01%. The ability to determine isotype, clonotype and IGHV mutational status in a single assay was demonstrated. Preliminary TCR assay data indicates that CDR3 sequence capture is possible from FFPE tissue with clonotype calling being driven by input quantity, T-cell content, and, to a lesser degree, mRNA quality.

Summary/Conclusions: AMP-based NGS with MBC quantification and error-correction is a powerful method to characterize the immune repertoire.

SYNERGISTIC ANTITUMOR IMMUNITY BY DENDRITIC CELLS IN COMBINATION WITH POMALIDOMIDE AND DEXAMETHASONE IN A MURINE MYELOMA MODEL

S.-H. Jung1,*, S. Yang2, H.-J. Lee2, M.-C. Vo1, T.J. Lakshmi2, H.-J. Kim1, J.-J. Kim1
1Department of Hematology-Oncology, 2Research Center for Cancer Immunotherapy, Chonnam National University Hwasun Hospital, Hwasun-Eup, Korea, Republic Of

Background: Pomalidomide (Pom) plus dexamethasone (Dex) could be considered one of the new treatment options in patients with relapsed and/or refractory multiple myeloma (MM). Recently, several diverse agents would be combined to improve the therapeutic efficacy of immunotherapy.

Aims: In this study, we investigated the preclinical efficacy of combined therapy with dendritic cells (DCs) and Pom-Dex in a murine myeloma model.

Methods: After establishing myeloma-bearing mice, four treatment groups were designed to be a mimicking protocol as like treatment in clinics as following: 1) PBS control, 2) DCs, 3) Pom + Dex, and 4) DCs + Pom + Dex. After vaccination, preclinical and in vitro immunological responses were evaluated.

Results: Among four treatment groups, DC combined with POM and DECA strongly inhibited tumor growth, compared with other groups. in vitro immunological analyses revealed that these enhanced anti-tumor effects were closely associated with the decrease of regulatory cell populations, such as regulatory T cells (Tregs) and type 2 macrophages (M2), and the increase of effector cell populations, including activated CD4 T cells, and type 1 macrophages (M1), accompanied with the activation of cytotoxic T lymphocytes (CTLs) and natural killer (NK) cells in the splenocytes from vaccinated mice.

Summary/Conclusions: This protocol combined with POM and DECA synergistically enhance the anti-tumor immunity in a murine myeloma model, by skewing immuno-suppressive status toward immuno-suppressive status in tumor microenvironment.
ALTERATIONS IN T-CELL SUBPOPULATIONS AFTER CO-CULTURING WITH MSCS DERIVED FROM DIFFERENT DONORS

N. Kapranov1,*, Y. Davydova1, I. Galtseva1, N. Petinati1, N. Drize1, L. Kuzmina1, E. Parovichnikova1, V. Sydorenko1
1Research Center for Hematology of the Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation

Background: Study of interactions between lymphocytes and mesenchymal stromal cells (MSCs) in vitro revealed increase of HLA-DR expression on T-cells after co-cultivation with some MSCs samples. On lymphocytes derived from one donor the elevation of HLA-DR was observed after co-cultivation with half of MSCs samples (group A). On the others the HLA-DR expression level did not change (group B). MSCs were divided into two groups based on HLA-DR rise on lymphocytes. Study of T-cell subpopulations after interactions with MSCs could explain ineffectiveness of some MSCs as an immunomodulating agent in clinical applications.

Aims: The aim of the study was to discriminate variations in T-cell subpopulations, co-cultured with MSCs from two groups.

Methods: MSCs were isolated from bone marrow of 13 donors for allogeneic hematopoietic cells transplantation and cultured by a standard method. MSCs were seeded 10^5 cells per flask, and then 10^6 allogeneic lymphocytes from one donor were added to all MSCs cultures. For lymphocytes activation 5ng/ml phytomagnesium (PHA) was added to half of these cultures. Lymphocytes were removed from MSCs. Than MSCs were removed from the bottom of the flask by trypsin and expression of HLA-DR on their surface was measured by flow cytometry. Activation markers CD25, CD38, CD69, HLA-DR expression of CM and PD-1+ CD4+ cells was measured by flow cytometry. Activation markers CD25, CD38, CD69, HLA-DR expression of CM and PD-1+ CD4+ cells was lower, compared to group A and control samples. At the same time the number of effector T-cells were analyzed on 4th day of cultivation. p<0.05 was considered statistically significant; all data are presented as medium ± SEM.

Results: Expression of HLA-DR on lymphocytes after 4 days of cultivation without MSCs did not change compared to 1st day. When lymphocytes were co-cultured with some MSCs samples expression of HLA-DR was higher. Elevated percentage of HLA-DR positive cells correlates between CD4+ and CD8+ cells (R^2=0.932). Thus samples of MSCs were divided into two groups: in group A proportion of HLA-DR lymphocytes was 3 times greater than in group B. Subpopulations of lymphocytes co-cultured with MSCs from group A and B were compared. Subpopulations which significantly differed between groups A and B are presented in the table. In lymphocytes co-cultured with MSCs there were higher number of naive cells compared to control (47.4±3.5% and 54.9±2.0% for group A and B vs 36.9±1.4% for lymphocytes cultured without MSCs, p<0.001). Group B showed lower number of EM and TM cells. Differences between groups were more pronounced when lymphocytes were activated. In group B proportion of HLA-DR CD4+ and CD8+ cells was significantly lower, compared to group A and control samples. At the same time the number of CM and PD-1+ CD4+ cells was lower in group B, but number of TE was increased. Investigation of HLA-DR expression on MSC after co-culturing with lymphocytes showed higher level of fluorescence signal (MFI) in group A then in group B (635±130 vs 289±18, p=0.03). These data indicated that MSCs from group A had become more immunogenic after interaction with lymphocytes and could not show immunomodulating properties in same way as MSCs from group B.

Summary/Conclusions: The immunomodulatory properties of MSCs depend on the donor. This could explain why administration of MSCs is not always successful. Preliminary study of MSCs prior to their administration may be used to predict their efficiency in the future.

The materials are supported by grant from the Russian Science Foundation, Project № 16-15-00102.

GRANULOCYTE COLONY STIMULATING FACTOR AND ERYTHROPOIETIN ENTIRELY GIVEN FOR NEONATES RECOVERING FROM GUT SURGERIES: RANDOMIZED CONTROLLED TRIAL

E.1093

Feeding intolerance is a common problem among neonates recovering from surgery for congenital abnormalities of the gastrointestinal tract (GIT) such as small bowel atresia, omphalocoele or gastrochisis. Feeding intolerance is a multifactorial process, but one of the important reasons is congenital maldevelopment of the small bowel villi. Disuse atrophy of the small bowel mucosa following several days of post-operative enteral fasting is one factor that can contribute to feeding intolerance. The human fetus swallows over 200 ml/kg/day of amniotic fluid and such swallowing is essential for normal small bowel development. Growth factors found in the amniotic fluid have been shown to promote proliferation of fetal intestinal cells. These growth factors include epidermal growth factor, granulocyte colony stimulating factor (G-CSF) and erythropoietin (EPO). We postulated that infants recovering from surgeries for congenital obstructive bowel abnormalities could be provided with physiologic quantities of recombinant human G-CSF and EPO by the intermittent oro-gastric or nasogastric administration of 20 mL/kg/day of sterile isotonic solution that contained cytokine concentrations comparable to what they would have ingested from amniotic fluid in utero.

Aims: To test a hypothesis suggesting that feeding tolerance could be improved in neonates recovering from surgeries for congenital obstructive bowel abnormalities by enterally administering recombinant human G-CSF and EPO in an amount included within similar uptake with suckling

Methods: This double-blinded randomized controlled clinical trial was conducted on 40 neonates recovering from GIT surgeries for congenital bowel abnormalities. Hemodynamically unstable babies, and those with any contraindication to enteral feeding were excluded. Neonates were randomly divided postoperatively into 2 groups; 20 neonates received the test solution (called Simulated Amniotic Fluid-like solution given Enterally; SAFE); 20 neonates enterally received distilled water (control). Treatment was started postoperative and the test solution (or distilled water) was discontinued when enteral intake reached 100cc/kg/day. Feeding tolerance and adverse effects of treatment (if any) were assessed.

Results: All the studied neonates tolerated the received solution well without side effects that could be attributed to its intake. The study group showed better feeding tolerance as reflected by earlier achievement of 50, 100, 120 and full enteral feeding with higher enteral caloric intake 7 days after SAFE administration and higher rate of weight gain (p<0.05). No significant increase was found in the level of WBCs count, hemoglobin and hematocrit values either pre-initiation or 7 days after administration of SAFE (p>0.05).

Summary/Conclusions: This study provides further insights on the importance of neonatal outcomes and help to decrease morbidities from post-operative malnutrition and feeding intolerance. Enteral administration of rhG-CSF and rhEPO may play a critical role in preventing viillos atrophy, thereby, reducing feeding intolerance in neonates recovering from surgeries for congenital bowel abnormalities.
Results: Although a high toxicity and low efficiency were observed with the elecrotransfection technique used, up to 96% colony forming units showed the specific integration. Experiments directed to improve efficacy and reduce toxicity were then conducted. A high percentage of gene edited HPCs were detected by shortening the cell expansion and puromycin selection periods. Importantly, gene edited HPCs were detected after infusion in immunodeficient (NSG) mice. More recently, site-specific correction has been developed aiming at the correction of PKD patient’s specific mutations.

Summary/Conclusions: Overall, we showed that gene editing in engraftable HPCs is feasible, although the efficiency of the procedure should be further improved prior to consideration of these strategies in the clinic.

E1095 BLAST KINETICS AFTER NON-ENGRAFTING HAPLOIDENTICAL MICROTRANSPLANTATION IN PATIENTS WITH REFRACTORY ACUTE MYELOID LEUKEMIA Z. Ernarah1,2, S. Shaama1,2, M. El-Zaafarany1,2, N. Essa3,4, M. Khalaf1, 1Medical Oncology Unit, Oncology Center, Mansoura University, 2Medical Oncology Unit, Internal Medicine Department, Faculty of Medicine, Mansoura University, 3Clinical Hematology Unit, Oncology Center, Mansoura University, 4Clinical Hematology Unit, Internal Medicine Department, Faculty of Medicine, Mansoura University, Mansoura, 2Clinical Hematology Department, Hematology and Oncology Hospital, Maadi Armed Forces Medical Compound, Cairo, Egypt

Background: Multiple trials have showed that granulocyte colony-stimulating factor (G-CSF)– mobilized donor peripheral-blood stem cells (GPBSCs) based on allo-graft can be effective in mediating graft-versus-leukemia (GVL) effects and promote hematologic recovery without triggering of acute GVHD.

Aims: To analyze the safety and efficacy of non-engraftment haploidentical cellular therapy for patients with refractory acute myeloid leukemia by assessment of bone marrow blast and hematopoietic cells percent kinetics.

Methods: Seven patients (4 males 57.1%, 3 females 42.9%) with refractory acute myeloid leukemia were enrolled into this Phase I/II study. They were treated with chemotherapy including fludarabine 30mg/m2, cytarabine 1gm/m2, etoposide 100mg/m2, endoxan 750mg/m2 followed by infusion of haploidentical unmanipulated GPBSCs 24 hour after last chemotherapy infusion. Morphologic assessment of bone marrow blast kinetic by bone marrow aspiration conducted before therapy, D14 and D30 after therapy. Hematopoietic cells percent kinetics (Hematologic recovery) was assessed by Complete blood count every day till Day 40.

Results: At day +30, 6 patients were evaluable for response and one patient had died. One patients out of 7 showed PR, then developed CR after a second microtransplantation and the patient who died showed PR at D14 marrow evaluation (8% blast). So collectively objective response rate was 28.6%. The patient who developed CR was consolidated with an HLA-matched sibling transplant at day +75 from the 1st microtransplantation (day +50 from 2nd microtransplantation). Three patients attain neutrophil recovery with median time 25 days (range, 13-40) days, while the other five patient did not. Two patients attain platelet recovery with median time 34.5 (range, 29-40) days, while the other five did not. The cellular therapy did not elicit statistically significant changes in bone marrow blast% over time, F(2, 10)=1.558, p=.258, partial η2=.256, etoposide 100mg/m2, endoxan 750mg/m2 followed by infusion of haploidentical unmanipulated GPBSCs 24 hour after last chemotherapy infusion. Morphologic assessment of bone marrow blast kinetic by bone marrow aspiration conducted before therapy, D14 and D30 after therapy. Hematopoietic cells percent kinetics (Hematologic recovery) was assessed by Complete blood count every day till Day 40.

E1096 ALTERATIONS IN T-CELLS SUBPOPULATIONS AFTER CO-CULTIVATION WITH MULTIPOTENT MESENCHYMAL STEM CELLS

E. Bevarela1, N. Kapranov2, C. Cuadra3, N. Petinati4, N. Dinze1, L. Kuzmina1, E. Parovichnikova1, V. Savchenko1, 1Federal State-Funded Institution National Research Center for Hematology of the Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation

Background: Lymphocyte population depends on immunological state of organism and varies in different diseases and during treatment. Multipotent mesenchymal stromal cells (MSCs) are widely used for cell therapy due to their immunomodulatory properties. Administration of MSCs is not always effective. Immunomodulatory properties of MSCs could be induced by different cytokines, e.g. IFN-γ. After injection MSCs interact with activated and non-activated lymphocytes. Changes in lymphocytes subpopulations characterize the influence of MSCs on immunological state.

Aims: The aim of the study was to determine the distribution of naïve and effector cells in lymphocytes co-cultured with MSCs.

Methods: MSCs were derived from bone marrow of 13 donors (7 male and 6 female aged 22 to 62 years, median 27 years). MSCs were co-cultured with allogeneic lymphocytes in a ratio of about 1:10 for 4 days and their basic properties were analyzed over time. Lymphocytes were activated by adding to the culture medium 5mg/ml of PHA (PHA-lymphocytes). Some MSCs were treated for 4 hours with 500 U/ml IFNγ (gMSCs). Activation markers CD25, CD38, CD69, HLA-DR and CD2 were measured using flow cytometry as well as distribution of naïve (CD45RA+CD62L+) and effector memory T-cells (CD45RA+CD62L-) in 1st, 2nd, 3rd and 4th day of co-culture.

Results: By the fourth day of incubation the proportion of naïve CD4+ cells reduced by 30% (from 47.5±3.0% to 32.8±3.3%) in cultured lymphocytes. It did not happen in lymphocytes co-cultured with MSCs and gMSCs (p=0.001). At the same time in cultured lymphocytes to the fourth day the number of CD4+ effector memory cells increased in 1.8 times from 19.5±1.9% to 34.6±2.4%, which did not occur when co-cultured with both MSCs and gMSCs (p=0.001). Thus, co-culturing with MSCs or gMSCs prevented naïve T-lymphocytes transit into effector cells. The proportion of CD4+PD-1+ T-cells increased from 8.2±1.1% to 10.9±0.7% by the 4th day of cultivation. When co-cultured with MSCs and gMSCs the proportion of gMSCs did not change (p=0.0125).

The proportion of HLA-DR+ both on CD4+ and CD8+ cells in lymphocytes remained unchanged for 4 days. When co-cultured with MSCs and gMSCs for 4 days there was a consistent increase in the proportion of CD4+/HLA-DR+ (6.2±0.3% to 15.6±1.1%, p=0.005) and CD8+/HLA-DR+ (9.7±0.8% to 26.0±3.7%, p=0.024). So allogeneic MSCs induced peptide presentation on lymphocytes. The proportion of CD4+ central memory cells increased in PHA-lymphocytes from 37.4±4.4 at 1ST day to 68.2±6.5 at 4th day. MSCs inhibited this increase - the proportion of CD4+ central memory cells increased from 24.4±2.7% to 46.2±5.4% (p=0.047). Thus the interaction of T lymphocytes with PHA-lymphocytes with MSCs inhibited their activation and preserved naïve state.

Summary/Conclusions: The composition of lymphocyte population changes during cultivation. The proportion of naïve cells reduced, while the number of effector and the proportion of PO-1+ increased, indicating the lymphocyte activation probably due to the presence of xenogeneic serum in the culture medium. Co-cultivation with MSCs maintained lymphocytes in not activated state. The interaction of activated lymphocytes with MSCs inhibits their activation and preserves naïve state. IFN-γ priming did not enhance MSCs inhibitory effect on lymphocytes activation. It was shown that MSCs both on naïve and effector lymphocyte condition have an inhibitory effect on their activation. The materials are supported by grant from the Russian Science Foundation, Project № 16-15-00102

E1097 OPTIMIZATION OF TRANSDUCTION CONDITIONS WITH GMP LIKE LENTIVIRAL VECTORS FOR THE GENE THERAPY OF PYRUVATE KINASE DEFICIENCY

S. Navarro1,2, O. Quintana-Bustamante1,2, C. Trigueros1,3, M. Villarueva1,2, A. López-Manzaneda1,2, A. J. Bueren1,2, J. C. Ramírez1,2, J. Segovia1,2, 1Unidad Mixta de Terapias Avanzadas, Instituto de Investigación Sanitaria Fundación Jiménez Díaz, 2Hematopoietic Innovative Therapies, CIEMAT/CIBER-ER, Madrid, 3VIVEBioTECH, San Sebastian, Spain

Background: Pyruvate kinase deficiency (PKD) is an autosomal recessive disorder caused by mutations in the PKLR gene. PKD is the most common erythroid inherited enzymatic defect causing chronic nonspherocytic hemolytic anemia. PKD is associated with reticulocytosis, splenomegaly and hepatic iron overload, and may be life-threatening in severely affected patients. To-date, allogeneic bone marrow transplant remains the only curative treatment for severely affected patients but has been employed infrequently. Splenectomy confers reduced transfusion-dependence in many patients, but 10-15% of PKD patients remain transfusion-dependence despite splenectomy, which confers increased likelihood of transfusion reactions. Precipitation of the PKD genes that are conducted in pyruvate kinase deficient mice have shown the safety and the efficacy of a new PCoRPKW-17 therapeutic lentiviral vector that has been granted orphan drug designation (EMA: EU/3/14/1330; FDA: DRU-2016-5168).

The aim of the study was to determine the distribution of naïve and effector cells in lymphocytes co-cultured with MSCs.
Aims: In order to develop a gene therapy clinical trial for PKD we are optimizing transduction procedures compatible with a clinical application.

Methods: Using a GMP-grade lentiviral vector production according to manufacturing processes of the CMO VIVEBioTECH (www.vivebiotech.com) using a solid phase bioreactor iCLELLis. These viral batches have been tested for transduction efficiency in healthy cryopreserved cord blood CD34+ cells compared with different viral concentration and transduction conditions.

Results: Increased doses of virus concentration revealed, as expected, increasing levels of transduction that ranged 40-90% both by scoring transduced colony forming units and by flow cytometry analysis in hematopoietic progenitors maintained for 15 days in liquid culture. Analysis of vector copy number (VCM) by qPCR ranged from 0.5 to 3 VCM/cell, demonstrating good transduction efficiency, compatible with a clinical application. Two cycles of transduction showed an increased level of transduction at limiting concentrations of the viral vector, improving the VCM up to 2-fold.

Summary/Conclusions: Transduction optimizations are being carried out in order to reduce the amount of viral vector needed to achieve optimal transduction efficiencies.

Lomonosov, 4Bone Marrow Transplantation Department, 5National Research Center for Hematology, Moscow, Russian Federation

Background: Multipotent mesenchymal stromal cells (MSCs) are widely used for cell therapy of autoimmune diseases and graft-versus-host disease. MSCs have long been reported to be hypoimmunogenic or ‘immune privileged’. The treatment of MSCs with interferon-g (IFNg) increases their immunomodulating properties, but induce HLA-DR expression on their surface. When administered intravenously MSCs interact with activated and non-activated lymphocytes. It is impossible to follow the fate of MSCs in the recipient’s organism. The only way to study the changes in the properties of MSCs after intravenous administration is in vitro model.

Aims: The aim of the study was to investigate the properties of MSCs after interaction with lymphocytes.

Methods: MSCs were isolated from 13 bone marrow samples used for allo-genic hematopoietic cells transplantation and cultured by a standard method. MSCs were seeded 10^5 cells per flask and a day later 500 units/mL of IFN-g were added for 4 hours to half of the cultures (gMSCs). Some cultures were seeded with 10^6 allogeneic lymphocytes, to half of these cultures 5mg/ml phytohemagglutinin (PHA) was added for lymphocytes activation (PHA-Lymphocytes). For each of the MSCs cultures the mean fluorescent signal intensity (MFI) of CD90 PE, CD54 APC, HLA-DR APC was measured. Relative expression level (REL) of CD90, CFH, PTGES, IL6, CSF1, ICAM-1 was analyzed in gMSCs by RT-PCR. MFI and REL were investigated on the 1st, 2nd, 3rd and 4th days of cultivation.

Results: IFN-g transduction showed an increased level of transduction at limiting concentrations of the viral vector, improving the VCM up to 2-fold. Increased doses of virus concentration revealed, as expected, increasing levels of transduction that ranged 40-90% both by scoring transduced colony forming units and by flow cytometry analysis in hematopoietic progenitors maintained for 15 days in liquid culture. Analysis of vector copy number (VCM) by qPCR ranged from 0.5 to 3 VCM/cell, demonstrating good transduction efficiency, compatible with a clinical application. Two cycles of transduction showed an increased level of transduction at limiting concentrations of the viral vector, improving the VCM up to 2-fold.

Summary/Conclusions: Transduction optimizations are being carried out in order to reduce the amount of viral vector needed to achieve optimal transduction efficiencies.

FUNCTIONALy HETEROGENEOus POPULATION OF MEGAKaryocyte Progenitors cEASES Abruptly bY E10.25 and constITUTES a FUNCTIONALLY DISTINCT POPULATION

T. Kumorode1, H. Tanaka1, R. Fujiiwara1, K. Sano1, K. Sertizawa1, Y. Taniguchi1, M. Kashiwagi1, M. Masumura1

1Hematology and Rheumatology, Kindai University Faculty of Medicine, Osaka, Japan

Background: Recent studies have supported the model in which hematopoietic stem cell (HSC) compartment consists of functionally distinct subsets with discrete self-renewal and differentiation potentials. However, their immunophenotypes and the functional diversities remain poorly understood. We previously reported that the authentically identified HSC population includes a subset of cells expressing the C-type lectin-like receptor 2 (CLEC2), which efficiently give rise to megakaryocyte progenitors (MKPs) and megakaryocytes bypassing the pathway from common myeloid progenitor (CMP) to megakaryocyte/erythrocyte progenitor (MEP) (21th Congress of EHA, # P356, 2016).

Background: Recent studies have supported the model in which hematopoietic stem cell (HSC) compartment consists of functionally distinct subsets with discrete self-renewal and differentiation potentials. However, their immunophenotypes and the functional diversities remain poorly understood. We previously reported that the authentically identified HSC population includes a subset of cells expressing the C-type lectin-like receptor 2 (CLEC2), which efficiently give rise to megakaryocyte progenitors (MKPs) and megakaryocytes bypassing the pathway from common myeloid progenitor (CMP) to megakaryocyte/erythrocyte progenitor (MEP) (21th Congress of EHA, # P356, 2016).

The materials, supported by grant from the Russian Science Foundation, Project № 16-15-00102.
Aims: In this study, we analyzed in vivo dynamics of CLEC2high HSCs to clarify their functional roles in adult hematopoiesis.

Methods: In this experiment, we defined Lin–Sca1+Kit+CD150+CD34+ cells as HSCs and Lin–Sca1+Kit+CD150+CD41+ as MPPs. We performed transplantation assays using HSCs isolated from EGFP transgenic (CAG-EGFP) mice to trace donor-derived HSCs and their progeny. Excepting enucleated transplantation in non-leukemic and GFP– mice, CLEC2high and CLEC2low HSCs were transplanted into lethally irradiated mice, respectively. Chimerism and lineage distribution of donor-derived cells were evaluated periodically by tracing EGFP. Secondary transplantation was performed by transferring 1x10^7 BM cells from the recipient mice 16 weeks after the first transplantation.

Results: Bone marrow arrest revealed that both EGFP+CLEC2high and CLEC2low donor-derived HSC populations were detected for up to 12 weeks after transplantation. Also, these subsets were capable of generating all lineages of cells transplanted mice. Interestingly, CLEC2high HSCs generated CLEC2high megakaryocytes (MKs), whereas CLEC2low MKs showed only steady output of MKPs and MKPs, in contrast with CLEC2high MKs. Consistent with these reciprocal transplants, both types of HSCs could have reconstituted hematopoiesis in the secondary recipients. However, CLEC2high HSCs showed significantly reduced repopulating activity than CLEC2low cells, especially at 12 weeks after transplantation (mean of EGFP+HSC proportion in the primary recipients with CLEC2high HSCs vs CLEC2low HSCs, each = 5%): 21.1% ± 6.6% at 4 weeks (p = 0.054); 2.14% ± 48.3% at 12 weeks (p = 0.05). In addition, the recipient mice transplanted with CLEC2low HSCs kept high chimeric levels of EGFP+CMP and MEP, while these levels decreased in the recipients with CLEC2high HSCs. On the other hand, CLEC2high HSCs yielded 2.8-fold more MKPs than CLEC2low HSCs in short-term grafts (1 to 2 weeks after transplantation) (p < 0.05). Consistent with this finding, CLEC2high HSCs yielded more CD4+ platelets than CLEC2low HSCs by 6.0-fold at 1 week after transplantation (p < 0.05), which peaked 10 weeks earlier than in CLEC2low recipient mice. These platelets yielded through the transplantation of CLEC2high MKs were rare at several levels during reconstitution. Furthermore, treatment with fostamatinib (R788), a Syk kinase inhibitor that is an indispensable component for CLEC2 signaling, blocked more potent and rapid megakaryopoesis in the CLEC2high recipients, indicating that CLEC2 signaling is essential for rapid and enhanced megakaryopoiesis from CLEC2high HSCs.

Summary/Conclusions: Here, we showed that CLEC2 expression on HSCs demonstrates its oscillation for serving as a potent source of megakaryopoesis, and found that CLEC2/Syk signaling would be involved in differential regulation between CLEC2high and CLEC2low HSC subtypes.

PRE-TRANSPLANT DEFECTS OF BONE MARROW ENDOTHELIAL CELLS MAY CAUSE THE OCCURRENCE OF POOR GRAFT FUNCTION AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

Y. Kong1, M.-M. Shi1,2,*, Y. Song1,2, Y.-H. Chen1, T.-T. Han1, Y.-Q. Sun1, Y. Wang1, X.-H. Zhang1, R.-P. Xu1, X.-J. Huang1
1Peking University People’s Hospital, Peking University Institute of Hematology, Peking-Tsinghua Center for Life Sciences, Academy for Advanced Interdisciplinary Studies, Peking University, Beijing, China

Background: Poor graft function (PGF) is a serious complication after allogeneic hematopoietic stem cell transplantation (allo-HSCT). PGF is defined as complete donor hematological chimerism with no residual or recurrent leukemia, but a hypo- or aplastic bone marrow (BM) with 2 or 3 of the following: (1) neutrophils ≤70 g/L for at least 3 consecutive days after day +28 post-HSCT. The exact pathogenesis of PGF remains unclear. Mouse studies suggest that endothelial factors for PGF, pre-HSCT risk factors with a poor graft function (PGF) post-HSCT. All in training group and validation group pre-HSCT, significantly reduced percentage of BM EPCs were observed in PGF patients than those in GGF patients, whereas no significant differences were found in the percentage of BM HSCs and their progeny. Persistently low percentage and high levels of ROS in post-transplant patients with PGF, and GGF groups, significantly lower percentages of BM EPCs and HSCs, whereas remarkably higher ROS levels were observed in BM EPCs and HSCs in PGF patients.

Methods: To compare the reconstitution kinetics of BM EPCs, HSCs and their functional roles in adult hematopoiesis. In this regard, we previously reported that CLEC2/Syk signaling would be involved in differential regulation between CLEC2high and CLEC2low HSC subtypes.

Summary/Conclusions: Here, we showed that CLEC2 expression on HSCs demonstrates its oscillation for serving as a potent source of megakaryopoesis, and found that CLEC2/Syk signaling would be involved in differential regulation between CLEC2high and CLEC2low HSC subtypes.

E1102

EFFICIENT LYMPHOID DIFFERENTIATION OF HEMATOPOIETIC STEM CELLS REQUIRES CXCR4 DESENSITIZATION

C. Freitas1, M. Wittner2, J. Nguyen1, V. Rondeau1, J. Donadieu3, F. Bachelerie1, A. Cañete Sánchez1,*, R. Carmona1, L. Ariza1, M.J. Sánchez2, A. Rojas3, M. Lozoya4
1INSERM U996, Clamart, 2INSERM UMR_S1170, Villejuif, 3Service d’Hématologie Pédiatrique, Hôpital Trousseau, Paris, France

Background: The Warburg Hypogammaglobulinemia Infections and Myelokathexis Syndrome (WS) is a rare immunohaematological disorder characterised by chronic lymphopenia. It is mostly caused by inherited heterozygous autosomal gain-of-function mutations in CXCR4, which engender a distinct truncation in the C-terminal domain and lead to a desensitization-resistant receptor. Given that CXCR4 is widely expressed on non-hematopoietic cells and virtually on all leukocytes at multiple stages of development, one possibility could be that the WS-associated peripheral blood lymphopenia is a consequence of skewed production, differentiation or distribution of lymphocytes related to altered CXCR4-mediated signaling. Recently, we have been able to replicate the hematologic phenotype of WS using a knock-in mouse strain that harbors the WS-linked heterozygous CXCR4S338X mutation causing a distal truncation of the last 15 residues of the C-terminal domain (Balabanian et al., Blood, 2012). Mutant mice displayed lymphopenia with enhanced migration to Cxcr4+ tissues and failed to maintain antibody titers after immunization (Biajoux et al., Cell Reports, 2016). First-line analyses of +/-103 mice suggested developmental defects at the pre/pre-B cell stage in the bone marrow (BM) and during the early double-negative stages of thymocyte maturation. However, whether impaired lymphopoiesis stems from an upstream cell-intrinsic or cell-extrinsic hematopoietic defect remains to be established.

Aims: We took advantage of our relevant knock-in model and the access to blood samples from WS patients to investigate the impact of CXCR4 desensitization on BM and extra-medullary splenic hematopoiesis and recirculation of hematopoietic cells (HPCs).

Methods: The global hematopoietic development, including quiescence, cycling and survival properties of HSCs, was examined in non-manipulated and BM chimeric mice using flow-cytometric and clonogenic-based assays. Cxcr4 expression and function were assessed using internalization, in vivo homing and AMD3100-promoted mobilization experiments. Both multipotency and self-renewal abilities of HSCs have been assessed using serial BM transplantation experiments. Immune-phenotypic and clonogenic analyses of HSPCs were performed from blood samples of five WS patients and age-, sex-matched healthy control donors.

Results: We showed that Cxcr4 desensitization is required for quiescence/cycling balance of murine short-term HSCs and their differentiation into multipotent (MPPs) and downstream lymphoid-biased progenitors (i.e. LMPPs and CLPs). Alteration in this negative feedback mechanism resulted in dramatic decrease of circulating HSPCs in five patients with WS. This was also evident in WS mice and mirrored by accumulation of HSPCs in the spleen, where enhanced extramedullary hematopoiesis occurred.

Summary/Conclusions: Efficient Cxcr4 desensitization is critical for the lymphopoietic differentiation of HPCs and its impairment is a key mechanism underpinning the lymphopenia observed in mice and likely in WS patients.
Background: GATA4 is a transcription factor expressed in mesoderm and endoderm during development. Members of the family such as GATA-1-3, but not GATA4, are critically involved in hematopoiesis. An enhancer (G2) of the mouse Gata4 gene directs its expression throughout the lateral mesoderm and the allantois, beginning at E7.5, becoming restricted to the septum transversum by E10.5, and disappearing by midgestation (Rojas et al., Development, 2005, 132:3405). Our previous work has shown that inactivation of Gata4 using this G2 cre driver is lethal by midgestation (Delgado et al., Hepatology, 2014, 59:2358). The anemia observed in the G2Cre;Gata4floxed/floxed embryos was attributed to a failure in the expansion of the hematopoietic progenitors in the fetal liver. Interestingly, a small population of hepatic YFP+ cells was positive for leukocyte and megakaryocyte markers, suggesting that a lineage of hematopoietic cells could derive from GATA4 expressing progenitors.

Aims: To study in our murine models the origin and properties of the hematopoietic lineage derived from progenitors expressing GATA4 under control of the G2 enhancer.

Methods: We analyzed hematopoietic organs of G2-Gata4cre;R26R Yap mice, adults and embryos, by flow cytometry, RT-PCR and confocal microscopy. Cells obtained from different tissues were cultured and transplanted to analyze in vitro and in vivo potential.

Results: YFP+ cells represented around 20% of the hematopoietic system of adult mice and contributed in the same proportion to the lymphoid, myeloid and erythroid lineages. Adult YFP+ hematopoietic stem cells (Figure 1) constituted a long-term repopulating, transplantable population. Fetal YFP+ hematopoietic progenitors were much more abundant in the placenta than in the fetal liver. These placental YFP+ progenitors were clonogenic in the MethoCult assay and fully reconstituted hematopoiesis in adult mice and contributed in the same proportion to the lymphoid, myeloid and erythroid lineages. Gata4 expression decreased with age in the G2Cre driver is lethal by midgestation (Delgado et al., Hepatology, 2014, 59:2358). The anemia observed in the G2Cre;Gata4floxed/floxed embryos was positive for leukocyte and megakaryocyte markers, suggesting that a lineage of hematopoietic cells could derive from GATA4 expressing progenitors.

Figure 1.

Summary/Conclusions: A lineage of adult hematopoietic stem cells in mice is characterized by the expression of GATA4 in their embryonic progenitors and probably by its extraembryonic (placental) origin. Both lineages basically express lymphoid, myeloid and erythroid genes (HBB, HBG1, and SLC4A1), whereas repressed that of HBA, HBG2, and SLC4A1. We demonstrated that activating marks (H3K4ac, H3K9ac, and H3K4me3) were significantly increased at the GATA1-activated gene loci, whereas repressed that of GATA1-activated genes. Therefore, we conclude that in hematopoietic stem cells, GATA4 expression is required to maintain HSCs in a progenitor state.

THE FUNCTIONAL RELEVANCE OF DNMT3A SPlice VARIANTS IN HEMATOPOIETIC DIFFERENTIATION
T. Bozic1, J. Frobel 1, A. Raić 1, S. Heilmann-Heimbach 2, T.W. Goecke 3, T. Bozic1, J. Frobel 1, A. Raić 1, S. Heilmann-Heimbach 2, T.W. Goecke 3,
1Department of Genomics, Institute of Human Genetics, Life & Brain Center, University of Bonn, Bonn, 2Department of Obstetrics and Gynecology, RWTH Aachen University Hospital, 3Clinic for Oncology, Hematology, and Stem Cell Transplantation, RWTH Aachen University Medical School, Aachen, Germany
Background: DNA methyltransferase 3A (DNMT3A) plays a pivotal role for de novo DNA methylation (DNAm) during development. It seems to be of particular relevance in hematopoietic differentiation because it is frequently mutated in acute myeloid leukemia or clonal hematopoiesis. So far, it is unclear how DNMT3A governs the multitude of lineage-specific DNAm patterns. It is conceivable that this can at least partly be attributed to alternative splicing of DNMT3A.
Aims: In this study, we followed the hypothesis that specific splice variants of DNMT3A impact on hematopoietic differentiation or DNAp patterns. Therefore, we addressed the role of specific splice variants of DNMT3A in hematopoietic stem and progenitor cells (HSPCs).
Methods: Expression of DNMT3A splice variants was modulated in HSPCs: transcript 1+3 (Tr.1+3), transcript 2 (Tr.2), or transcript 4 (Tr.4) of DNMT3A were either knocked down by short hairpin RNA or constitutively overexpressed by lentiviral infection. Expression changes were validated by qRT-PCR. Subsequently, we evaluated the impact on colony formation potential (CFU assay), proliferation (CFSE assay), and the immunophenotype (CFD43+ and CD133+). Global DNAp profiles were generated with the Infinium HumanMethylation450 BeadChip platform and gene expression profiles with the Human Affymetrix GeneChip® U133 version 2.0 platform.
Results: Downregulation of either Tr.2 or Tr.4 reduced the proliferation rate of HSPCs significantly (n=3, p<0.05). HSPCs maintained CD34 expression for a higher number of cell divisions upon knockdown of Tr.2 (n=3, p>0.05). In colony forming unit (CFU) assays downregulation of Tr.4 resulted in a clear bias towards erythroid colonies (n=3, p<0.05). Overall, CFU frequency was reduced by knockdown of DNMT3A transcripts, whereas it was increased by overexpression. Subsequently, we analyzed the impact of specific DNMT3A variants on the DNAp patterns: several CpG sites revealed significant differences in DNAp amounts upon knockdown of Tr.2 and Tr.1+3 (8,905 and 352 CpGs, respectively; n=3, adjusted p-value <0.05). Notably, these patterns were regulated in the opposite direction upon overexpression of the same transcripts. Knockdown of Tr.4, which does not have the DNA-methyltransferase domain, did not evoke significant changes in DNAp. Furthermore, modulation of DNMT3A splice variants resulted in transcript-specific gene expression changes, which may at least partly be attributed to the DNAp changes.
Summary/Conclusions: Our results demonstrate that the various splice variants of DNMT3A have different functional sequel on HSPCs. Knockdown and overexpression resulted in opposite and transcript-specific DNAp changes. Thus, alternative splicing of DNMT3A is relevant for site-specific epigenetic modifications in hematopoietic development.

Background: Notch signaling is a highly conserved pathway important in multiple developmental processes. Canonical signaling through all Notch receptors converges on the CSL transcription factor recombination signal binding protein for immunoglobulin kappa J region (Rbpfj). In haematopoiesis, Notch is critical for the development of the hematopoietic stem cells (HSCs) in the embryo and in thymic T cell development. Contrastingly, canonical Notch signaling has been shown to be dispensable for HSC homeostasis in the adult bone marrow (aBM). Recent studies have however suggested a role of Notch in promoting megakaryocyte (Mk), erythroid (E) and granulocyte-macrophage (GM) development as well as in suppressing granulocyte-macrophage (GM) progenitor expansion and acting as a tumor-suppressor in myeloid malignancies. However, these findings were largely made through genetic approaches potentially also affecting regulatory pathways distinct from canonical Notch signaling.

Methods: We examined expression levels of 342 cell surface markers in the HSCs (Lin-CD34+CD38-CD45RA-CD90+) by FACS using commercially-available antibodies. Single-cell gene expression profiling of isolated subfractions was performed using Fluidigm C1 system in combination with BioMark. Differentiation potential of each HSC fraction was assessed by single-cell colony assays in methylcellulose, in vitro lineage tracing in liquid culture of CFU, and transplantation experiments for the demonstration of functional clonogenicities.

Summary/Conclusions: Our data suggest that HSCs can be further subdivided into subfractions based on their CD35 expression. CD35+ cells may have a functional advantage in that they may be able to prospectively isolate the most primitive human HSC fraction. In vivo functional assays using xenotransplantation models are currently underway, and the results will be discussed at the meeting.

IDENTIFICATION OF NOVEL HUMAN HEMATOPOIETIC STEM CELL SUBPOPULATIONS VIA COMPREHENSIVE SURFACE MARKER ANALYSIS

T. Jirouma1,*, K. Miyawaki1, Y. Moni1, H. Iwasaki1, T. Maeda1, K. Akashi1

1Medicine and Biosystemic Science, Kyushu University, Fukuoka, Japan

Background: All hematopoietic cells are derived from hematopoietic stem cells (HSCs), which exhibit capacities for multilineage differentiation and long-term self-renewal. Human HSCs can be isolated by Fluorescence-activated cell sorting (FACS) with the combination of several surface markers, such as CD34+, CD45RA−, CD90+, and Lin−. This approach is based on the assumption that HSCs reside in functionally heterogeneous subpopulations, including multi-potent and/or lineage-agersensitive progenitors (Notta:2016hi) and HSC-like populations with reduced self-renewal capacity (Notta:2011bg); however, prospective isolation of bona fide human HSCs is still challenging due, at least in part, to the lack of specific surface marker(s) that enables prospective isolation of functionally-distinct HSC subpopulations.

Methods: We produced a PMMA-based 3D scaffold and compared the growth of CML and AML cell lines grown in this scaffold in the presence and absence of imatinib and doxorubicin respectively.

Results: We produced a PMMA-based 3D scaffold and compared the growth of CML and AML cell lines grown in this scaffold in the presence and absence of imatinib and doxorubicin respectively.

Summary/Conclusions: Our data suggest that HSCs can be further subdivided into subfractions based on their CD35 expression. CD35+ cells may have a functional advantage in that they may be able to prospectively isolate the most primitive human HSC fraction. In vivo functional assays using xenotransplantation models are currently underway, and the results will be discussed at the meeting.

Methods: Scaffold production: PMMA solution was prepared by dissolving PMMA in chloroform and adding appropriate amount of hydroxyapatite to poly-MMA in chloroform. We examined expression levels of 342 cell surface markers in the HSCs (Lin-CD34+CD38-CD45RA-CD90+) by FACS using commercially-available antibodies. Single-cell gene expression profiling of isolated subfractions was performed using Fluidigm C1 system in combination with BioMark. fibre. Treatment of K562 or HL60 cells with imatinib or doxorubicin respectively resulted in a lower level of apoptosis in cells grown on the 3D scaffold compared to those grown in 2D culture. Further development of this 3D culture by adding stromal cells HS-5 to the scaffold reduced even further the sensitivity of K562 or HL60 to imatinib or doxorubicin, respectively.

Figure 1.

Summary/Conclusions: The relative resistance to either imatinib or doxorubicin that we observed in cells grown in 3D culture supports a role for the bone marrow matrix in the protection of leukemic cells against chemotherapeutic agents. A combination of the PMMA-HA with HS-5 cells made this system more similar to the bone marrow microenvironment as this is a model in which all the basic components of the bone marrow microenvironment such as scaffold, stromal cells and cytokines (secreted by HS-5) are present. The results of this study show adding extra complexity to the microenvironment changes the sensitivity of the cells to therapeutic agents, better recapitulating the situation observed in-vitro. Three dimensional cultures using the PMMA-HA/HS-5 model may prove useful in the investigation of therapy resistance in leukemia and for the discovery of new agents capable of eradicating quiescent leukemic stem cells.

WHOLE EXOME SEQUENCING REVEALED SEQUENTIAL GAIN OF MUTATIONS IN TWO CASES OF DONOR CELL HAEMATOLOGICAL MALIGNANCY AFTER HEMATOPOIETIC TRANSPLANTATION

J. Suárez González1,2, A. Martínez-Laperche2,3, M. Kwon2,3, G. Rodríguez-Macías3, A. Figuera4, A. Balas5, N. Martínez6, P. Balsalobre2,3, D. Serrano2,3, M. A. Piris7,8, J. L. Vicario9, J. Gayoso2,3, J. L. Díez2,3, I. Buño1,2,3

Background: The leukemic transformation of otherwise healthy donor stem cells provides a useful model for the study of leukemogenesis. The leukemic transformation of otherwise healthy donor stem cells (SCs) infused as well as on BM samples from recipient after allo-HSCT show adding extra complexity to the microenvironment changes the sensitivity of the cells to therapeutic agents, better recapitulating the situation observed in-vitro. Three dimensional cultures using the PMMA-HA/HS-5 model may prove useful in the investigation of therapy resistance in leukemia and for the discovery of new agents capable of eradicating quiescent leukemic stem cells.

Methods: Case 1: A 43-year-old female diagnosed with lymphoblastic leukemia (B-ALL) at diagnosis and in whom whole-exome sequencing (WES) was performed in bone marrow (BM) samples from recipient at different times after allogeneic hematopoietic stem cell transplantation (allo-HSCT) in order to study the dynamics of emergence of mutations that precede the development of donor cell leukemia (DCL) and donor cell myelodysplastic syndrome (DC-MDS). Case 2: A 65-year-old male diagnosed with mantle cell lymphoma, who developed MDS 45,XX,-7,del(12)(p12) of donor origin, 16 months after unrelated cord blood transplantation (UCBT). Case 2: A 65-year-old male diagnosed with mantle cell lymphoma, who developed MDS 45,XX,-7,del(12)(p12) of donor origin, 16 months after unrelated cord blood transplantation (UCBT). Case 2: A 65-year-old male diagnosed with mantle cell lymphoma, who developed MDS 45,XX,-7,del(12)(p12) of donor origin, 16 months after unrelated cord blood transplantation (UCBT). Case 2: A 65-year-old male diagnosed with mantle cell lymphoma, who developed MDS 45,XX,-7,del(12)(p12) of donor origin, 16 months after unrelated cord blood transplantation (UCBT).

Results: Donor cell leukemia (DCL) and myelodysplastic syndrome (DC-MDS) developed in 45,XX,-7,del(12)(p12) of donor origin, 16 months after unrelated cord blood transplantation (UCBT). Treatment of K562 or HL60 cells with imatinib or doxorubicin respectively resulted in a lower level of apoptosis in cells grown on the 3D scaffold compared to those grown in 2D culture. Further development of this 3D culture by adding stromal cells HS-5 to the scaffold reduced even further the sensitivity of K562 or HL60 to imatinib or doxorubicin, respectively.

**POTENTIAL PREDISPENSING GERMLINE MUTATIONS IN PATIENTS WITH CONCOMITANT MYELOID AND LYMPHOID MALIGNANCIES**

F. Asmar1,*, M. Munk-Johansen1, T.C. El-Galaly2, H.E. Johnszen2, C. Westmose Yde3, D. El Fassi4, K. Grenbaek1

1Department of Hematology, Rigshospitalet, Copenhagen, 2Department of Hematology, University hospital of Aalborg, Aalborg, 3Center of Genomic Medicine, Rigshospitalet, Copenhagen, 4Department of Hematology, University Hospital Herlev and Gentofte, Herlev, Denmark

**Background:** Recent findings have suggested that mutations predisposing the development of either acute myeloid leukemia (AML) or chronic lymphocytic leukemia (CLL) may arise in pre-leukemic hematological stem cells. In addition, genes involved in epigenetic regulation, such as TET2, and RNA processing, such as SFB31, are mutated in both myeloid and lymphoid malignancies. This could indicate a possible genetic link between myeloid and lymphoid malignacies. Therapy related AML (t-AML) is a known complication to treatment with cytotoxic drugs such as alkylating agents and topoisomerase inhibitors. The susceptibility of developing t-AML has been associated with variation in DNA-repair pathways, drug metabolism and transport.

**Aims:** In this study, we aimed to investigate a possible common genetic origin of hematological cancers in patients with concomitant CLL and de novo AML or myeloproliferative syndrome (MDS) and in patients with concomitant therapy-related AML (t-AML) and CLL.

**Methods:** The presence of concomitant lymphoid and myeloid malignancies in patients is rare, however we managed to include 3 patients with de novo AML and CLL, one patient with MDS and CLL, one patient with chronic myelomonocytic leukemia(CMML) and CLL, and two patients with t-AML and CLL. The patients’ diagnoses were based on the evaluation of the morphology, immunohistochesmistry, cytogenetics, and flowcytometry analysis in accordance to the WHO classification. For each patient mononuclear cells (MNCs) from blood or bone marrow were isolated using Ficoc gradient centrifugation and used for fluorescence activated cell sorting (FACS) of the malignant clones and the T-cells. Paired end exome sequencing (2x150) aiming for an average coverage of 50-100x was performed using either the HiSeq2500 or NextSeq500 platforms from Illumina. Raw sequencing data was processed using CASAVA-1.8.2. Mapping to the human genome (hg19/GRCh37 UCSC) was performed using CLC Biomedical Genomics Workbench (Qiagen) m_clc software. Variants with a frequency of 5% or above were called.

**Results:** We identified possible pre-disposing germline mutations in all 7 patients by comparing variants between the myeloid malignant clone, CLL cells, and T cells, as well as using saliva to aid in characterizing the mutations as either germline or only present in the hematological compartment. In all the patients except one with de novo AML and CLL, we identified a potential damaging germline variant in a DNA-repair related gene, such as ATM (387dupA, D1309*4), SMARCA1 (2114C>T, T705I), HEGQ (393_397delAGGTG, 1323+16), SWI5 (652C>T, R218*), LIG1(2168A>G, Q761R) and PRKD2(502G>A, C301Y). In the remaining patient with concomitant de novo AML and CLL, we identified a potential damaging germline variant in an epigenetic regulator believed to play a role in normal and malignant hematopoiesis, KDM2B(44delIC, P159fs*2). Furthermore, we identified the somatic mutational landscapes of the malignant clones using T-cells as germline tissue for the patients’ diagnoses, indicating development of two independent malignancies.

**Summary/Conclusions:** Our results suggest a possible role of germline variations in the susceptibility to development of concomitant de novo hematological cancers as well as t-AML. However, further studies including more patients are needed to confirm this hypothesis.

**THE MUTATIONAL LANDSCAPE OF DNMT3A MUTATIONS IN CLONAL HAEMATOPOIESIS OF INDETERMINATE POTENTIAL. CHIPPING AWAY AT THE PROBLEM**

S. Chaudry1,*, T. Chevassut1

1Brighton and Sussex Medical School, Brighton, United Kingdom

**Background:** Dysfunction of epigenetic modifiers contributes significantly to the pathogenesis of acute myeloid leukaemia (AML). One frequently mutated gene involved in epigenetic modification is DNMT3A (DNA methyltransferase-3-alpha). Approximately 22% of de-novo AML and 36% of cytogenetically normal AML, are found to have DNMT3A mutations and around 60% of these mutations affect the R882 codon. In particular, the R882H mutation has been associated with a poor prognosis and survival outcomes for patients. A large number of DNMT3A mutations are present in clonal cells in healthy individuals with no characteristics of haematological malignancy and is termed as clonal haematopoiesis of indeterminate potential (CHIP).

**Figure 1.**

**Aims:** We aimed to compare here the locations and types of mutations identified in AML and in CHIP in the DNMT3A gene by several different studies.

**Methods:** To review the mutations found in CHIP and AML, we carried out an extensive literature search of CHIP studies and AML studies that had mapped a large number of mutations in this gene. Mutations were collated to form several diagrams illustrating and comparing these findings.

**Results:** When DNMT3A mutations in CHIP were compared to mutations in AML the R882 residue was still found to be the most frequently mutated residue in both CHIP and AML. Figure 1 clearly illustrates the mutations in comparison to AML. However, only 13% of all reported mutations were found at the R882 residue in CHIP, while in AML 60% DNMT3A mutations are found at the R882H mutations.

**Summary/Conclusions:** Analysis of the mutational landscape of CHIP has clearly highlighted the role of DNMT3A mutations in clonal haematopoiesis in older healthy individuals, the significance of such preleukaemic clones is yet to be determined.

**NEXT-GENERATION REFERENCE INTERVALS FOR PEDIATRIC HEMATOLOGY**

J. Zierk1,*, J. Hirschmann2, D. Toddenroth2, F. Arzideh3, T. Streichert4, R. Haeckel5, H.-U. Prokosch2, M. Rauh1, M. Metzler1

1Department of Pediatrics and Adolescent Medicine, University Hospital Erlangen, 2Chair of Medical Informatics, Friedrich-Alexander-University Erlangen-Nuremberg, Erlangen, 3Department of Statistics, University of Bremen, Bre- men, 4Department of Clinical Chemistry, University Hospital of Cologne, Cologne, 5Bremer Zentrum für Laboratoriumsmedizin, Klinikum Bremen Mitte, Bremen, Germany

**Background:** Interpretation of hematology analytes in children is challenging due to extensive changes in hematopoiesis with age leading to pronounced sex- and age-specific dynamics. To facilitate clinical decision making based on quantitative hematology test results, reference intervals are used to classify samples according to upper and lower limits, and age-related change is represented using reference intervals partitioned into separate age groups. However, this approach can only approximate the continuous physiological dynamics of hematological analytes in childhood and does not enable appropriate quantification of test results in relation to the reference distribution. Conversely, percentile charts as used in anthropometric quantities (e.g. pediatric weight-for-age charts) would allow adequate appreciation of pediatric hematology test results. However, the ethical and practical challenges unique to pediatric reference intervals have restricted the creation of such percentile charts, and limitations in current approaches to laboratory test result display prevent their integration into clinical decision making.

**Aims:** To create percentile charts for hematology analytes from birth to adulthood using a data-mining approach and to demonstrate their integration into clinical care with benefits in clinical decision making.
Methods: We applied a data-mining algorithm to generate percentile charts for hematology analytes using laboratory data collected during the clinical care of patients. A total of 9,517,245 samples from 343,463 patients (72,614–337,011 samples per analyte) from 8 German tertiary care centers and 2 German laboratory service providers were examined. Percentile charts were calculated using an established statistical approach which extracts the proportion of samples from healthy individuals from the unfiltered input dataset containing both non-pathologic and pathologic samples. To evaluate the clinical benefit of hematology test result interpretation using percentile charts, accuracy and speed of pediatricians assessing eight different predefined clinical situations were measured in comparison to conventional test result representations.

Results: We created percentile charts for hematology analytes in girls and boys from birth to 18 years which can be used as common reference intervals. Results are provided for hemoglobin, hematocrit, red cell indices, red cell count, red cell distribution width, white cell count, and platelet count, example charts for hemoglobin, mean corpuscular volume, and platelet count are shown in the accompanying figure. A web application at www.pedref.org/hematology demonstrates hematology test result interpretation using percentile charts and z-scores with special consideration of pediatric dynamics. Comparison of pediatricians’ decision times when assessing different clinical scenarios using percentile charts and conventional representations shows more correct decisions (75.9% vs 68.4%, p<0.01) which are made in shorter time (2.7 s vs 3.8 s, p<0.01) when using percentile charts.

Summary/Conclusions: The created percentile charts enable the appropriate differential diagnosis of changes in hematology analytes due to disease and changes due to physiological development. Integration of suitable forms of result reporting using the provided percentile charts into clinical decision making improves assessment of the unique dynamics in pediatric hematology.

GROWTH FACTOR INDEPENDENCE 1 (GFI1) REGULATES THE AML SUPPORTING FUNCTION OF MESENCHYMAL STROMAL CELLS
Y. Al-Matary1,*, L. Botezatu 1, A. Thivakaran 1, R. Köster 1, J. Schütte 1, J. Göthert 1, U. Dührsen1, B. Opalka1, C. Khandanpour1
1University Hospital of Essen/ West centre of tumor, Essen, Germany

Background: Mesenchymal stromal cells (MSCs) harbor and support the function of normal hematopoietic stem cells. Less is known about their interaction with leukemic cells, e.g. in acute myeloid leukemia (AML). The prognosis of AML, a clonal malignant disease of the bone marrow (BM), is still poor with only 25% of patients living longer than 5 years.

Aims: In the current study, we investigated the interaction between MSCs and AML cells, and we also investigated the underlying molecular mechanism.

Methods: We used cell cultures using primary cells from human and mice and cell lines of MSCs and AML cells. Different Mouse models of human AML were used in our study to confirm the results obtained from human sample. MSCs were characterized by differentiation assay, flow cytometry and RT-PCR. Matrigel test was also applied in this study.

Results: MSCs from AML patients called AML-associated MSCs (AMSCs) or from murine models of human leukemia enhance significantly in vitro the growth of leukemic cells compared to AML cells growing without MSCs or in presence of MSCs from non-leukemic patients or mice. Among other, AMSCs increased entry of leukemic cells into the cell cycle, and at the same time protected the leukemia cells against exogenous toxic events such as chemotherapy or irradiation. The interaction between AMSCs and leukemia cells is dependent on cell-to-cell contact. In vivo, absolute and relative numbers of AMSCs and other stromal cells, i.e. endothelial cells and osteoblast lineage cells were highly expanded in the BM of mice modeling of human AML. AMSCs showed a higher efficiency of capillary tube formation in the matrigel assay than normal MSCs which gives an additional indication that AMSCs were polarized by leukemia cells towards a tumor-supporting state. On a molecular level, the polarization of MSCs towards an AML-supporting state depends on upregulated expression of the transcription factor Growth factor independence 1 (Gfi1). Loss of Gfi1 diminished the tumor-supporting state of AML-associated MSCs.

Summary/Conclusions: We conclude that leukemia cells polarize AMSCs towards a leukemia-supporting state in a Gfi1-dependent manner, which could open the way to new therapeutic approaches.
Hodgkin lymphoma - Clinical

BASLINE LEUKOCYTE AND EOSINOPHIL COUNTS PREDICT OUTCOME IN RELAPSED OR REFRACTORY CLASSICAL HODGKIN LYMPHOMA PATIENTS TREATED WITH PD1 INHIBITION

I. Hude1,2,*, S. Sasse2, P.J. Broeckelmann3, B. von Tresckow2, J. Momotow2, A. Engert1, S. Borchmann2
1Department of Internal Medicine, Division of Hematology, University Hospital Center Zagreb, Zagreb, Croatia, 2German Hodgkin Study Group (GHSG), First Department of Internal Medicine, University Hospital Cologne, Cologne, Germany

Background: Despite encouraging efficacy of anti-PD1 antibodies in relapsed or refractory (rr) classical Hodgkin lymphoma (cHL), not all patients achieve a lasting response, with few complete remissions (CR) observed. Thus, identification of predictive biomarkers is important. Recently, two models using readily available differential blood count parameters have been suggested to predict outcome in melanoma patients treated with immune checkpoint inhibition.

Aims: In this study, we aimed to identify baseline differential blood count parameters associated with response and progression free survival (PFS) in rr cHL patients treated with anti-PD1 antibody nivolumab.

Methods: We retrospectively investigated baseline differential blood count parameters and their association with response and progression free survival (PFS) in 30 rr cHL patients treated with the anti-PD1 antibody nivolumab. All 30 patients had previously received multiple lines of treatment, including treatment with high dose chemotherapy followed by autologous stem cell transplant (ASCT) for rr disease; the median number of prior treatment lines was 5 (2-11) and 21 patients received prior brentuximab vedotin. To investigate the association of baseline blood count parameters (white blood cell count (WBC), relative monocyte count (RMC), relative neutrophil count (RNC), relative lymphocyte count (RLC) and relative eosinophil count (REC)) with outcome after PD1 inhibition, we used the last differential blood count performed immediately prior to the first received dose of nivolumab.

Results: RMC, RNC and RLC did not have a prognostic impact on PFS, whereas, higher WBC (≥ 7.78x10³/µl) and lower REC (<1.7%) were associated with worse PFS in both univariate and multivariate analysis. We constructed a simple score to prognosticate PFS. By adding 1 point each for WBC ≥ 7.78x10³/µl and REC<1.7% to the score, we could clearly differentiate a low (score=0), intermediate (score=1) and high risk (score=2) group for disease progression (p<0.001). Only one PFS event occurred in the best prognostic group (n=10, median PFS (days): NA) whereas 5 out of 11 patients in intermediate (median PFS (days): 365 [129-NA]) and 7 out of 9 patients in high risk group progressed (median PFS (days): 197 [50-NA]). Evaluation of best response achieved according to the initial risk score showed a trend towards higher CR-rates in low risk group, but was not significant.

Summary/Conclusions: Our simple prognostic model, mainly characterized by a normal to high REC, robustly discriminates three risk groups for PFS. Almost all patients in the low risk group achieved a durable remission without disease progression throughout the study period, despite often achieving just a partial response. In contrast, high-risk patients often progressed quickly despite initially achieving a partial or complete response. Further validation of this score which is easily available from routine clinical parameters in a larger cohort of patients and further investigation of its potential predictive impact is needed. Moreover, efforts to clearly understand a possible mechanistic role of eosinophils in cHL patients treated with PD1-inhibition are warranted.

THE PROGNOSTIC SIGNIFICANCE OF BETA-2 MICROGLOBULIN (B2M) LEVELS IN PATIENTS WITH HODGKIN LYMPHOMA (HL) TREATED WITH ABVD OR EQUIVALENT (ABVD/EQ) CHEMOTHERAPY OR COMBINED MODALITY THERAPY (CT/CMT)

11) and 21 patients received prior brentuximab vedotin. To investigate the association of baseline blood count parameters (white blood cell count (WBC), relative monocyte count (RMC), relative neutrophil count (RNC), relative lymphocyte count (RLC) and relative eosinophil count (REC)) with outcome after PD1 inhibition, we used the last differential blood count performed immediately prior to the first received dose of nivolumab.

THE PROGNOSTIC VALUE OF INTERIM PET-CT IN ELDERLY PATIENTS WITH HODGKIN LYMPHOMA

O.S. Bentur1,*, D.J. Eldad2, E. Paran3, D. Lavie4, B. Nachmias4, N. Dally5, O. Gutwink6, Y. Heishanu1, N. Sardi1, C. Perry7, I. Avivi7

Background: The prognosis of HL primarily depends on clinical stage (CS) as well as limited-stage risk classification schemes and the International Prognostic Score (IPS), both of which are typically used for early and late stages. B2m is a well-established prognostic factor for several hematologic malignancies, but its role in HL is yet controversial. Between 1993 and 2016, several reports from other groups have yielded heterogenous results in small-sized unselected patient series of no more than 220 patients, frequently under variable treatment.

Aims: Our aim was to investigate the prognostic significance of serum b2m levels in HL.

Methods: We analyzed 864 patients with HL treated with ABVD/Deq CT/CMT (1990-2016) and selected solely based on the availability of pretreatment b2m levels. B2m [P1] levels (upper normal limit 2.4mg/L) were analyzed according to other baseline features and prognostic factors as well as according to the outcome. Freedom From Progression (FFP) was defined as time between treatment initiation and treatment failure (primary refractoriness, PR switch to alternative CT or relapse); deaths of unrelated causes were censored. Overall survival (OS) was measured from treatment initiation to death of any cause. ROC curves and sequential cut-offs (1.8-3.5 by 0.1 increments) were used to explore the potential impact of b2m on FFP and OS.

Results: The median follow-up for currently living patients was 88 months. Univariate Analysis: FFP was significantly inferior in patients with higher b2m at all tested cut-off points. At 2.4mg/L (normal versus elevated) the 10-year FFP was 81% vs 71% (p=0.003). However, the best cut-off was the observed median value of this series, calculated at 2.1mg/L, with 10-year FFP of 84% vs 71% (p=0.0001). In early stages (IA/IIA) significant results were obtained at cut-offs between 1.8 and 2.1mg/L. The best cut-off was 1.9mg/L, a close approximation of the median b2m level of early stage patients, with 10-year FFP of 89% vs 78% (p=0.003). In advanced stages, none of the cut-offs yielded statistically significant results (borderline at 2.0mg/L, 10-year FFP 77% vs 67%, p=0.057). Multivariate Analysis: B2m levels remained significant for FFP after adjustment for IPS factors, ESR and B-symptoms at both 2.1mg/L and 2.4mg/L cut-offs (hazard ratio (HR) 1.78, p=0.001 and 1.41, p=0.04 respectively) in the whole series of 864 patients. In early stages, 2.2mg/L was a significant predictor of FFP at the cut-offs of 1.9mg/L and 2.1mg/L (HR 2.00, p=0.01 and 1.83, p=0.02 respectively), but only borderline at the cut-off of 2.4mg/L (HR 1.65, p=0.07). In advanced stages, b2m emerged as an independent prognostic factor for FFP at the cut-off of 2.2mg/L (HR 1.59, p=0.046 despite the lack of significance in univariate analysis), but was marginal at the cut-off of 2.4mg/L (HR 1.24, p=0.09). The optimal cut-off for the evaluation of serum b2m in HL may be stage-dependent and appear to lie between 1.9 and 2.2mg/L, thus performing better than a “normal versus high” evaluation (cut-off 2.4mg/L).

Summary/Conclusions: Higher serum b2m emerged as a significant independent predictor of FFP at the cutoff of 2.0mg/L for the whole series and the 1.9mg/L for early-stage patients. The prognostic significance in advanced stages was weaker (best cut-off 2.2mg/L). Serum b2m was also highly predictive of OS. This is by far the largest report on the prognostic significance of b2m in HL, highlighting the significance of the cut-off used to define “high” levels. Its significance is more pronounced in early stage disease. The optimal cut-off for the evaluation of serum b2m in HL may be stage-dependent and appear to lie between 1.9 and 2.2mg/L, thus performing better than a “normal versus high” evaluation (cut-off 2.4mg/L).
Background: Hodgkin lymphoma (HL), a disease of mostly young patients, also peaks in the elderly. Despite the profound improvement in the clinical outcome of young patients, in the elderly, 5-year overall survival (OS) is estimated at only 40-55%. Interim PET-CT (iPET), known to be highly predictive for progression-free survival (PFS) in young patients with HL, has not been sufficiently validated in elderly patients, nor have many other outcome predictors in HL of the elderly.

Aims: The objective of the present study was to evaluate the significance of iPET in elderly patients with HL.

Methods: All consecutive patients (age ≥60) diagnosed with HL between 1998-2016 were retrospectively reviewed in this multi-center study. Baseline characteristics as well as PET-CT results at diagnosis, interim analysis and end of treatment (EOT) were recorded and analyzed. PET-CT results were classified as no evidence of disease (NED), partial response (PR), stable disease (SD) and progressive disease (PD).

Results: Ninety five patients from 5 centers were identified. Median age was 71 (range 60-89) years. Subtype was nodular sclerosis in 48% and mixed cellularity in 23%. Sixty three (69%) patients had advanced disease and mean international prognostic score (IPS) was 3.5±1.4. Fifty nine (63%) patients received first line treatment with ABVD, in 13 (14%) chemotherapy was followed by involved field radiotherapy. At EOT, sixty seven (82%) patients achieved OR, 6 (7%) achieved PR, 10 (11%) were primary refractory and 2 (2%) died during treatment. Fifteen (16%) patients experienced relapse. Five years FOS and OS were 56% and 78%, respectively. ABVD treated patients had 5 year FOS and OS of 99% and 82% as opposed to 48% and 68% for all other regimens, but these differences were not statistically significant. Seventy two (76%) patients had undergone both iPET and EOT-PET. 50 patients had NED on iPET; 20 had PR, 1 SD and 1 PD. NED EOT-PET was achieved in 47/50 (94%) patients who had NED iPET, 12/20 (60%) patients who had PR iPET and none of the patients with SD/PD iPET (p<0.01). In patients with either NED or PR on iPET, relapse occurred in 11 (15%) patients and 5 year FOS and OS were 82% and 95%, respectively. The 5 year FOS of these patients differed according to the depth of response on iPET - 69% vs 45%, (p=0.02, fig 1) in patients achieving NED vs PR, while 5 year OS did not reach statistical significance, 90% vs 71% (p=0.08). Restricted analysis, evaluating only 59 patients who were treated with ABVD, showed similar results with 94% of NED iPET vs 45% of PR iPET achieving NED on EOT-PET (p<0.01). Outcome differed according to the depth of response in iPET with 5 year FRS rates of 74% vs 34%, in patients achieving NED vs PR, respectively (p=0.01). 5 year OS rates were 92% vs 76%, in patients achieving NED vs PR (p=0.1).

Summary/Conclusions: We present a cohort of elderly patients with HL, most were treated with ABVD. Outcome was comparable or even superior to previously published cohorts. Traditional outcome measures for HL have not been extensively validated in the elderly. iPET and EOT-PET, known to be highly predictive for PFS in young HL patients, appeared to be highly predictive in elderly individuals. The improved prognosis, suggested by our results, may be related to the high rate of iPET which was used in this cohort. The importance of this tool in HL in the elderly is emphasized by the diminished prediction power of the traditional outcome measures in elderly HL patients.
Background: In the last decades, Hodgkin and Non-Hodgkin Lymphoma (HL-NHL) therapies have resulted in high cure rates and increased survival. However, they differ in late toxicities, such as, gonadal toxicity that can result in permanent sterility.

Aims: to evaluate different aspects of fertility (menstrual status, pregnancy, and menopause) in women with HL and NHL in reproductive age before and after chemotherapy.

Methods: By a phone interview we administered a questionnaire to the patients. The interview was composed of questions concerning reproduction (prognancies, menses and abortion) and also menopausal status. The analyses were made using data collected in a cohort 109 women patients from two Italian hematologic centers. Statistical analysis was carried out in Graphpad® system, data were compared by the chi-square (P value<0.05) to consider results as statistically significant.

Results: the median age (in years) at the time of the treatment was 31 (range 16-49), 69/109 (63%) had HL and 40/109 (37%) NHL, 74/109 [81%] (64%) of the patients had a stage I-II. All HL patients were treated with ABVD, whereas the NHL patients were treated with R-CHOP (20%) or similar regimens (16%), respectively. Radiotherapy was delivered to the 62/109 (57%) of the sample. Complete Remission (CR) was obtained by the 101/109 (93%) and only 16/101 (16%) relapsed. Considering the gynecologic history of the patients there were no statistically significance difference between the regularity of menses and the event of an abortion pre and post treatment. As for pregnancies, 35% of patients had children before therapy and 17% after. Among these 109 patients, 68/109 (62%) received gonadotropin-releasing hormone (GnRH) analogues and/or oral contraception, while 41 (38%) were not treated with hormonal therapy. Among the 68 patients who received hormonal therapy regular menses recovered in 61/68 (90%) while in those of the control group a recover of menses was observed in 20/41 (48%). This difference was statistically significant (P<0.05). The same was observed as for early menopause. In this case excluding patients who had a natural menopause, a lower cases of early menopause was observed in those who received hormone therapy (8/65, 12%) vs. the 30% of the control group (P=0.05). Considering only the 81/109 (74%) patients who had regular menses after chemotherapy, 61/81 (75%) received hormonal therapy and 20/81 (25%) were not treated with hormonal therapy. Before treatment for lymphoma, 16% of patients belonging to the hormonal group had pregnancies versus 45% of the control group (P=0.05). Following therapy, pregnancies were still maintained in 23% of these receiving hormonal therapy vs 5% of the control group (P=0.05).

Summary/Conclusions: the use of hormonal therapy is fundamental not only to favor of pregnancies and motherhood but in particular to avoid the consequences of an irregular cycle or an early menopause with its symptoms and clinical implications.

25(OH)VITAMIN D SERUM LEVELS IN HODGKIN LYMPHOMA

A. Cuccaro1,*, E. Galli1, F. Visconti1, I. Zangrilli1, F. Corrente1, S. Bellesi1, U. Basile2, U. Annunziata3, V. Rufini4, M. Balducci5, F. D’Alò1, S. Hohaus1

1Hematology, Federico II University, Naples, Italy

Background: Vitamin D has pleiotropic effects on cellular differentiation, proliferation, apoptosis and angiogenesis in addition to maintaining serum calcium and skeletal homeostasis. Several studies suggest that low serum 25(OH)D levels may be associated with inferior outcome in solid tumors as colorectal and breast cancer, and in Non-Hodgkin lymphomas [Drake et al, J Clin Oncol 2010; 28:4191] as diffuse large B cell lymphoma [Bittenbring et al, J Clin Oncol 2014; 32:3243], and follicular lymphoma [Kelly et al, J Clin Oncol 2010; 33:1482-93]. 25(OH)Vitamin D levels have not been reported for Hodgkin Lymphoma (HL).

Aims: to evaluate vitamin 25(OH)D levels in patients with HL and analyze for associations with clinical characteristics and clinical outcome.

Methods: We studied 76 patients with cHL (40 females, 36 males, median age 56 years, <15% of patients had unfavorable stage) and 33 patients with NHL (20 females, 13 males, median age 48 years). All patients were treated between 2004 and 2016. Treatment consisted in ABVD (66 patients), BEACOPP d.e. (7 patients), and COPP (2 patients). One patient received only radiotherapy. Serum samples for vitamin D quantification were collected before the first day of chemotherapy. 25(OH)D was measured in patients sera using a standardized clinical assay, the DiaSorin Liaison 25-OH Vitamin D TOTAL. 25(OH)D levels were defined according to three conditions: deficient (<10 ng/ml), insufficient (10-30 ng/ml), and sufficient (>30 ng/ml).

Results: The median 25(OH)D level at diagnosis was 20.6 ng/ml (range: 5.5 to 42.3 ng/ml). 25(OH)D levels were considered normal in 8 (10.5%) patients, insufficient in 59 (77.5%) patients, and deficient in 9 (12%) patients. Looking at patient characteristics, 25(OH)D levels were lower in patients with age over 60 years (p=0.002), reduced performance status (ECOG>1) (p=0.01), stage IV disease (p=0.01), and IPS (Hasenclever score) >2 (p=0.002). Furthermore levels were lower in patients with hemoglobin below 10.5 g/dl (p=0.08). No association was found with gender, albumin level, B symptoms. In addition, there was a significant seasonal variation, with 25(OH)D levels to be lowest in the first quarter and highest in the third quarter (p=0.03). FDG-PET evaluation after 2 cycles of chemotherapy according to the 5-point Deauville scale was available in 66 patients. Vitamin D levels were not associated with interim PET response. With a median of 12 months follow-up of patients, still alive. Patients with deficient levels (n=9) had a significantly worse PFS than patients with higher levels (n=67) (p=0.002). The probability of progression-free survival at 12 months was 87% (95% C.I., 75-94%) in patients with 25(OH)D levels>10 ng/ml, while patients with levels<10 ng/ml had a 12 months PFS of 47% (95% C.I., 12-76%). We included 25(OH)D levels, (that includes age, stage and hemoglobin level), ECOG and season in a multivariate Cox analysis. Deficient 25(OH)D level had a borderline significance (HR 5.65, 95% C.I., 0.98-32.55; p=0.05).

Summary/Conclusions: 25(OH)D serum levels are frequently low in patients with Hodgkin Lymphoma and are associated with patient-related and disease-related characteristics. Our preliminary analysis suggests that low 25(OH)D levels might be associated with worse prognosis.

Quantitative PET parameters predicts outcome in patients with classical Hodgkin lymphoma (HL). Several prognostic factors have been associated with a higher rate of relapse after autologous stem cell transplant (ASCT) for patients with Hodgkin lymphoma (HL). These factors include advanced disease stage, lymphocytic predominance, and younger age. The aim of this study was to evaluate the role of quantitative PET parameters in predicting response to ASCT and long-term survival in patients with HL. The study included 31 patients who underwent ASCT and completed PET scans at baseline, post-induction, and post-ASCT. The quantitative PET parameters evaluated included metabolic tumor volume (MTV), total lesion glycolysis (TLG), and mean standardized uptake value (SUVmean).

Results: The study found that quantitative PET parameters were significantly associated with outcomes following ASCT. Specifically, MTV and TLG were found to be independent predictors of event-free survival (EFS) and overall survival (OS). A higher TLG at post-induction was associated with an increased risk of disease progression. Conversely, a lower MTV at post-ASCT was associated with improved EFS and OS.

Conclusion: Quantitative PET parameters may play a predictive role in identifying patients who are at high risk of treatment failure. These results should be evaluated prospectively in larger cohorts with longer follow-up.

BIOMARKER ANALYSIS OF PATIENTS WITH FOLLICULAR LYMPHOMA TREATED WITH IBRUTINIB IN THE PHASE 2 DAWN STUDY

1Hospices Civils de Lyon-Univérsité de Lyon, Pierre-Bénite cedex, Lyon, France, 2The University of Washington/Fred Hutchison Cancer Research Center, Seattle, 3Seattle Cancer Care Alliance, Seattle, WA, 4Lymphoma Program, Abramson Cancer Center of the University of Pennsylvania, Philadelphia, PA, United States, 5Haematology Department, Concord Hospital, University of Sydney, Sydney, NSW, Australia, 6Department of Hematology/Oncology, Johannes Gutenberg University, Langenbeckstr, Mainz, Germany, 7Division of Hematology/Oncology, University of Pittsburgh Medical Center and University of Pittsburgh Cancer Institute, Pittsburgh, PA, 8University of Kansas Medical Center, Kansas City, KS, 9Cedars-Sinai Medical Center, Los Angeles, CA, 10Weill Cornell Medical College, New York, NY, United States, 11Hematology, Azienda Ospedaliero Universitaria Città della Salute e della Scienza di Torino, Turin, Italy, 12Alfred Hospital-Monash University, Melbourne, Australia, 13University of Manchester and the Christie NHS Foundation Trust, Manchester Academic Health Science Centre, Manchester, United Kingdom, 14Department of Hematology, Jagiellonian University, Kraków, Poland, 15Haematology and Oncology Clinics of Australia, Milton, QLD, Australia, 16Blokoan Cancer Research Center, Russian Academy of Medical Sciences, Moscow, Russian Federation, 17Istituto Biosanitario di Salamanca (IBSAL), Hospital Clínico Universitario, Salamanca, Spain, 18Janssen Research & Development, Raritan, NJ, United States, 19Janssen Research & Development, Leiden, Netherlands, 20Lombardi Comprehensive Cancer Center, Georgetown University Hospital, Washington, DC, 21Department of Lymphoma/Myeloma, University of Texas MD Anderson Cancer Center, Houston, TX, United States

Background: Ibrutinib, a first-in-class, oral, covalent inhibitor of Bruton’s tyrosine kinase, has demonstrated robust clinical activity and is approved in various B-cell non-Hodgkin’s lymphomas. To assess the efficacy and safety of ibrutinib in patients (pts) with follicular lymphoma (FL), the DAWN study (FLR2002, NCT01779791) investigated single-agent ibrutinib in chemotherapy (CIT)-refractory FL pts. Ibrutinib may exert immune-modulatory effects on T-cell activity via inhibition of ITK, a key regulator of T-cell activity, possibly through modulation of T regulatory cells (Tregs) at C3D1 in 14 responders (CR + PR, mean decrease 17 to 12.9% CD4, p=0.02) but not in 43 nonresponders (SD + PD, 11.5 to 10.4% CD4, p=0.0025). Flow cytometry analysis revealed significant downregulation of CD4+CD25+CD127− Tregs at C3D1 in 14 responders (CR + PR, mean decrease 17 to 12.9% CD4, p=0.022 and 0.016, respectively). Here we describe the effect of ibrutinib treatment on T-cell dynamics and cytokines in pts in the DAWN study.

Aims: To determine the effect of ibrutinib on circulating T-cells, chemokines, and cytokines in ibrutinib-treated CIT-refractory FL pts.

Methods: The DAWN study was an open-label, multicenter, single-arm, phase 2 study of ibrutinib in pts with CIT-refractory (i.e., ≥3 prior lines of therapy) and progressive disease [PD] ≤12 months after last dose of a CIT regimen. All pts received ibrutinib (560 mg QD) on a 21-day cycle until PD or unacceptable toxicity. The primary end point was Independent Review Committee (IRC)-assessed overall response rate (ORR) (complete response [CR] + partial response [PR]). Flow cytometry assessed T-cell subsets in pts at baseline (C1D1) and at cycle 3 (C3D1) for 57 pts (14 responders and 43 nonresponders); cytokine and chemokine analyses were performed at C1D1 and at cycle 2 (C2D1) for 50 pts (21 responders and 29 nonresponders).

Results: Results from the DAWN study have been presented previously (Gopal et al., ASH 2016). Briefly, 110 pts with a median age of 61.5 years and a median of 3 prior therapies were enrolled. Ibrutinib achieved an ORR of 20.9% (CR rate, 10.9%) and a median duration of response of 19.4 months. Flow cytometry analysis revealed significant downregulation of CD4+CD25+CD127− Tregs at C3D1 in 14 responders (CR + PR, mean decrease 17 to 12.9% CD4, p=0.022 and 0.016, respectively). These data suggest that immunomodulatory effects of ibrutinib could play a role in its antitumor activity in FL, so combinations with other immune-oncology therapies may prove beneficial.

Summary/Conclusions: Here we show immunomodulatory effects of ibrutinib in pts with CIT-refractory FL, which may be related to response to therapy. In responders pts at early time points, downregulation of Tregs was observed, along with increases in Th1-associated cytokines IFN-γ and IL-12. This shift in T-cell population may be linked to the antitumor response; in nonresponders, these cytokines were decreased but Tregs were not. Chemokine changes observed also indicate variation in chemotactic migration of T-cells and monocytes/macrophages. These data suggest that immunomodulatory effects of ibrutinib could play a role in its antitumor activity in FL, so combinations with other immune-oncology therapies may prove beneficial.

E1130

DYNANO: THE CLINICAL ACTIVITY OF DUVELISIB IN PATIENTS WITH CIT-REFRACTORY SMALL LYMPHOCYTIC LYMPHOMA IN A PHASE 2 STUDY

1Institute of Hematology Serágnoli, University of Bologna, Bologna, Italy, 2Site- man Cancer Center, Washington University, St Louis, 3Saint Agnes Hospital, Baltimore, 4Florida Cancer Specialists - Tallahassee, Tallahassee, United States, 5University Hospital Ospedale di Circolo, Varese, Italy, 6Florida Cancer Specialist, Fort Myers, 7Veraestam Inc, Needham, 8Tennessee Oncology, Nashville, United States

Background: Duvelisib is an oral, dual inhibitor of PI3K-δ,γ in development for the treatment of hematologic malignancies. DYNANO is a Phase 2 study to evaluate the safety and efficacy of duvelisib in a double refractory iNHL population, which included 28 patients (pts) with small lymphocytic lymphoma (SLL).

Aims: The primary objective was to evaluate the antitumor activity of duvelisib monotherapy in pts whose disease is refractory to rituximab and to either chemotherapy or RIT, with an additional objective to further characterize the safety duvelisib.

Methods: DYNANO is an open-label, single-arm, safety, and efficacy study in patients (pts) with FL, small lymphocytic lymphoma (SLL), or marginal zone lymphoma (MZL), whose disease is double refractory to rituximab (monotherapy or in combination) and to chemotherapy or radioimmunotherapy. Pts received duvelisib 25mg BID in 28-day treatment cycles until disease progression or unacceptable toxicity. The primary endpoint is overall response rate (ORR) as assessed by an independent review committee (IRC) per revised IWG criteria. Secondary endpoints include duration of response (DoR), progression-free survival (PFS), overall survival (OS), time to response (TTR), adverse events (AEs), and changes in safety laboratory values. Pneumocystis jiroveci pneumonia (PJP) prophylaxis was mandated for all SLL pts.

Results: 129 pts with iNHL were treated on study. Of these, 28 pts with SLL received duvelisib with a median duration of exposure of 9 mo. (range 6.5-12). Median age was 65 years; 68% were male. Most SLL pts had either host SLL (61%) or disease-host SLL (39%). Median time from last anticancer therapy to first dose of duvelisib was 3 months. SLL pts received a median of 3 prior anticancer regimens (range: 1-8); 43% of pts received ≥4 prior anticancer regimens, 29% ≥6 regimens. The ORR for SLL pts was 68% (95% CI: 48, 84) per IRC assessment. All responses (19) were PRs. Four (14%) pts had a best response of SD and 3 (11%) pts had a best response of PD. 2 pts were unevaluable for response. Per Investigator assessment, the ORR was 79% (including 1 CR). Median time to IRC response was 1.9 months (range 1.4-5.5). 93% of pts had a reduction in nodal target

Figure 1.
lesions. Among the 19 SLL pts with a response per IRC, the median DOR was 9.8 months. The median PFS among all SLL pts was 11.3 months, while the median OS was not reached. The estimated probability of survival at 12 months was 83.9%. Among all pts treated (n=129), AES were mostly Gr 1-2. Most common ≥ Gr 3 AES were transient cytopenias (neutropenia [23%], anemia [12%], and thrombocytopenia [10%]), and diarrhoea (15%). 4 SLL pts had SAEs that led to discontinuation of duvelisib: NSCLC, neuroendocrine carcinoma of the skin, pseudomembranous colitis, and pneumonia. Two SLL pts has a fatal AE, 1 pneumonia and 1 viral infection.

**Summary/Conclusions:** In DYNAMO, duvelisib showed clinical activity in a double-refractory SLL population (68% ORR, median DOR 9.8 mo., 93% with a reduction in target lesions). Duvelisib was generally well tolerated, with a manageable safety profile with appropriate risk mitigation. Duvelisib monotherapy appears to have a favorable benefit-risk profile in double refractory SLL. Updated clinical data will be available at the time of presentation.

**E1133**

**CLINICAL CHARACTERISTICS AND LONG-TERM RESULTS OF TREATMENT OF IDIOTENT NON-HODGKIN’S LYMPHOMA ASSOCIATED WITH HEPATITIS C (IL + C)**

S. Lepkov1,1, I. Subortseva1, G. Tumyan3, P. Zheinvalova1, O. Kolomeljcev3, Y. Ryabukhina3, A. Semenova1, N. Kosokadze1, N. Kupryshina1, K. Komarova3, O. Malikova1, E. Etinger1, S. Borisovskaya1, I. Lazarev2, V. Ivanova4, R. Ishvanchenko4, A. Kovrigina1, I. Nikitin1, Y. Kemin2

**Background:** According to the WHO classification (2008) hepatitis C virus is one of the causes of non-Hodgkin lymphoma. The incidence of chronic hepatitis C (HCV) in patients with indolent B-cell non-Hodgkin’s lymphoma (IL + C) is 15%. Diagnosis of hepatitis C-related lymphoma (IL + C) is established in cases where tumor or tumor tissue contains IgG antibodies to express proteins of hepatitis C virus. These proteins could be defined by immunohistochemistry (IHC).

**Aims:** The aim of this work was evaluation of the results of treatment of IL associated with hepatitis C in comparison with a control group of patients with IL without viral hepatitis markers.

**Methods:** The study included 107 patients with indolent lymphoma who were identified in the blood markers of hepatitis C.

**Results:** Histological types were follicular lymphoma - 74%, marginal zone lymphoma - 32%. The age of patients ranged from 28 to 82 years (median 50). Men / women ratio was 1: 1. Stage I + II were in 3%, II stage was in 24% of patients, IV stage was at 73% of patients. Primary extranodal lymphoma was diagnosed in 33% of patients. Extranodal lesions: splenic lesion - in 53% of patients, liver injury - 21% of the patients, the bone marrow - 62% of patients. LDH > 450 IU / l was at 76% cases, ALT >40 IU / l was at 82% cases, albumin <35 g / l was at 31% of patients. 57 patients were treated with interferon and Ribavirin as a first-line treatment. Treatment lasted for 2 years after reaching the antitumor effect. 50 patients were treated with immunotherapy (R-CHOP, R-CVP) as a first-line treatment. Antiviral therapy was effective in 88% patients, immunotherapy was effective in 64% of patients. Median progression-free survival in patients with IL + C treated with antiviral treatment was 42 months in patients with IL + C treated with immunotherapy - 19 months (p=0.00001). Five-year overall survival was 67% and 32%, respectively (p=0.0003). It was diagnosed disease relapses after immunotherapy in 39 patients. All the patients in the second-line was received antiviral treatment. 40% of patients was in the ongoing antiviral therapy was associated with 72% of cases. Medi-an progression-free survival in relapsed lymphoma was 31 months.

**Summary/Conclusions:** Antiviral therapy in first-line and relapse of disease surpasses all the indicators of efficiency of treatment IL + HCV. In this category of patients preferred option is to conduct anti-viral treatment.
WALDENSTRÖM MACROGLOBULINEMIA (WM). A STUDY ON 114
patients in CR after first-line therapy.
Methods: A retrospective analysis was performed including all the patients who have received RIT with 90Y-IT. Inclusion criteria were: patients 18 years or older with a grade 1-2a follicular lymphoma, RIT was received as a consolidation therapy in complete response (CR) after a first-line therapy. Demographic and follow-up data were included. International working group (IWG) criteria of response was used. Progression free survival (PFS) was calculated from the date of RIT to the date of a confirmed relapse according IWG criteria, overall survival (OS) was calculated from the FL diagnosis to the last contact. Results: A total of 31 FL patients have received 90Y-IT been in CR after a first-line of therapy and were included for the study. Mean age at diagnosis was 61.2 (29-86) years with a female predominance (19, 61.3% vs 12, 38.7%), 80.6% (26) with ECOG 0-1 and 19.4 ECOG 2. A third of them (10, 32.3%) were diagnosed with low tumor burden (stage I-II), 2 (8.7) of them presented extra nodal infiltration (subcutaneous and gut) and 12 (38.7%) showed bone marrow infiltration demonstrated by flow cytometry or biopsy. There were no patients with bulky disease. Stages: I: 7 (22.6%), II: 3 (9.7%), III: 9 (29.1%), IV: 12 (38.7%). As first-line therapy the patients received: Rx4: 11 (35.5%) cases, R-Chlorophosphamide vincristine prednisone (COPx4): 3 (9.7%) cases and 17 (54.8) R-Chlorophosphamide doxorubicin, vincristine and prednisone (R-CHOPx4-6). The median follow-up was 58.0 (10-107) months. During this time only 5 (16.1%) of patients have relapsed and need another therapy. None of the patients that have received R-CHOP+90Y-IT have relapsed; the relapsed patients received Rx4 (4) and R-COP (1). The median PFS after 90Y-IT has not been reached, the mean was 83.3 (71.9-94.9) months, see Fig 1. Four (12.9%) patients have died, none of them were relapsed and the mortality was due to other causes. The median OS was not reached, the mean was 95.8 (85.6-106.1) months. As long-term events one 82 years old patient developed a colon cancer after 67 months of RIT; one 72 years old female a breast cancer after 17 months of RIT and one 71 years patient angUS after 24 months of RIT, none of them related with mortality events.

Figure 1.

Summary/Conclusions: The use of immunotherapy with rituximab or combined schedules with immunochemotherapy (R-COP and R-CHOP) followed by consolidation with 90Y-IT remains as a valid option for follicular lymphoma patients. After ~6 years of follow-up: 63.6% (Rx4+RIT), 66.7% (R-COP+RIT) and 100% (R-CHOP+RIT) of patients continue with complete response and off of therapy.

E1135
ASSESSING RISK OVER TIME IN PATIENTS WITH SYMPTOMATIC WALDENSTRÖM MACROGLOBULINEMIA (WM). A STUDY ON 114 PATIENTS
Background: By contrast, with follicular lymphoma (J Clin Oncol 2015:33:2516) or other chronic hematological malignancies (Blood 2009;114:1299; Blood 2016;128:902), few reports attempted to decipher the evolution of pts with WM, a disorder associated with delayed response to therapy in some pts.
Aims: To assess the prognostic role during the clinical course of initial international prognostic index (IPSSWM), response and progression (according to 6th International Workshop for reviewing a series of 114 symptomatic WM pts treated in our 2 institutions between 1993 and 2016 (median age 70, male/female ratio=1.91, high, low/intermediate and unavailable IPSSWM in 57, 36 and 21 pts respectively).
Methods: We took advantage of our continuously updated clinical database for reviewing a series of 114 symptomatic WM pts treated in our 2 institutions between 1993 and 2016 (median age 70, male/female ratio=1.91, high, low/intermediate and unavailable IPSSWM in 57, 36 and 21 pts respectively). Kaplan-Meier curves for each efficacy endpoint were calculated according to Kaplan-Meier.

E1136
TIME TO NEXT TREATMENT ANALYSIS FOR EARLY AND ADVANCED STAGES OF MYCOSIS FUNGOIDES /SEZARY SYNDROME TREATED WITH BEXAROTENE AND PUVA IN COMBINATION
Background: With failure of PUVA in combination, no other effective induction therapy is available. We therefore tested the hypothesis that bexarotene could induce a response in the time to next therapy (TTNT) when used in combination with PUVA.
Methods: We recruited patients with stages I-IV MF who had failed PUVA (early disease) or several systemic regimens (early and advanced disease). We designed a “mini” and “standard” protocols in which Bexarotene and PUVA administration were individually titrated, and tailored during induction and maintenance according to previous therapy, disease stage and toxicity. Survival curves for each efficacy endpoint were calculated according to Kaplan-Meier.
Results: We enrolled 21 patients, 12 males and 9 females, with median age of 67 years (range, 30-77), of which 15 affected by early MF (13 with stage IIB, 2 with stage IIA, 1 with stage III B and 1 with stage IVA). Six patients had previously received PUVA therapy only, while fifteen patients had received other therapies. The protocol proved to be effective, well tolerated and able to induce an overall response of 55.6% at the end of induction phase (93.4% of early stage patients and 66.6% of advanced stage patients) and of 76.2% at the end of maintenance phase (86.7% of early stage patients and 14.2% of advanced stage patients). Median follow up for all patients was 85 months (6-118) with respectively 98 months (21-118) for early stages and 46 months (6-102) for advanced stages. For the entire cohort, median OS, PFS and TTNT were respectively, 105, 103 and 79 months, and median EFS was 58 months. For advanced stage patients, median OS, PFS, EFS and TTNT were 32, 29, 18 and 39 months respectively. 

Summary/Conclusions: Our combination treatment seems to have superior TTNT compared to data published in the literature for PUVA and bexarotene used in monotherapy. When considering early and advanced MF, 66% of our patients are estimated to be free from further treatment at 2 years, a higher percentage compared to the results of Hughes et al. (Blood, 2015) for patients treated with PUVA (54.2%) or bexarotene (36.8%) as single agents. Moreover, TTNT seems to be longer in our study than in the study by Hanel et al. (AJH 2016) on patients treated by retinoids in monotherapy, respectively 79 vs 60 months (mean TTNT values) in the early stages and 39 vs 9 months (median TTNT values) in the advanced stages. We believe that our results strongly suggest a synergistic or additive effect between PUVA and bexarotene compared to either agent alone in the treatment of both limited-stage and advanced stage MF.

E1137
PERIPHERAL BLOOD INVOLVEMENT IN PATIENTS WITH ADVANCED STAGE FOLLICULAR LYMPHOMA: CLINICAL-BIOLOGICAL CHARACTERISTICS AND PROGNOSTIC IMPACT
A. Rivas-Delgado1−, L. Magnano1, P. Mozas1, I. Dlouhy1, J. Rovira1, A. Martinez-Trillos1, O. Balague2, A. Martinez2, E. Gine3, T. Baumann1, J. Delgado1, N. Villamar2, E. Campo3, E. Mateus2, A. Lopez-Guillermo3
1Hematology department, 2Hematopathology Unit, 3Pathology department, Hospital Clinic, Barcelona, Spain

Background: Follicular lymphoma (FL) is a clinically heterogeneous indolent lymphoma. The majority of patients have a non-aggressive clinical course, but a small percentage shows a rapidly progressive disease, including histological transformation in some cases. Although disseminated disease and bone marrow infiltration are common, only a small percentage of FL patients have peripheral blood (PB) involvement. The clinical significance of the PB involvement is unclear. TTNT seems to be longer in our study than in the study by Hanel et al. (AJH 2016) on patients treated by retinoids in monotherapy, respectively 79 vs 60 months (mean TTNT values) in the early stages and 39 vs 9 months (median TTNT values) in the advanced stages. We believe that our results strongly suggest a synergistic or additive effect between PUVA and bexarotene compared to either agent alone in the treatment of both limited-stage and advanced stage MF.

Methods: We selected 304 patients in stage IV out of 654 patients diagnosed with FL between 1991 and 2014 in a single institution. Patients with a diffuse large B-cell lymphoma component, histological grade 3b and primary cutaneous FL were not included. Fifty-six (18%) had PB expression (PB+) defined by the presence of circulating FL cells by morphology, further confirmed by immunophenotyping. The main clinical and biological characteristics, response to treatment and outcome were analyzed.

Results: Patients with PB+ more frequently had splenic involvement, anemia, elevated β2-microglobulin and LDH and high FLIPI score than those without PB involvement (PB−) and differences were statistically significant. There were no differences concerning the proportion of patients undergoing a watchful waiting approach (7% vs 9%), type of treatment, or overall response rate (93% vs 88%) and complete response rate. Overall, 149 patients had refractory disease or relapsed, including 34/52 (65%) PB+ and 115/225 (51%) PB−. The median follow-up was 7 years (range 0.7 - 22.2 years). The 5-year progression-free survival (PFS) of treated patients was 28% (95% CI: 14-42%) compared with 48% in the PB− (95% CI: 41-55%) (p=0.013). However, when the analysis was restricted to patients receiving rituximab combination regimen, 5-year PFS was 45% (95% CI: 24-66%) vs 64% (95% CI: 54-74%) (p=NS). Ninety-six patients died during the follow-up (19 PB+ and 77 PB−), with a 5-year overall survival (OS) of 68% (95% OR: 54-82%) in the PB+ group and of 81% (95% CI: 76-86%) in the PB− group (p=NS) (Figure). Finally, there was no difference in the risk of histological transformation or secondary malignancies.

Summary/Conclusions: Peripheral blood involvement in FL is associated with particular clinical features, higher tumor burden load and shorter PFS, although in the short-term it appears that has not impact on overall survival.

E1138
TREATMENT PATTERNS OF PATIENTS WITH FOLLICULAR LYMPHOMA IN A LARGE US-INSURED DATABASE FROM 2010 TO 2014
M. Mehra1,*, N. Monga1, B. Schenkel2, R. Potluri3, L. Parisi1
1Janssen Research & Development, LLC, Raritan, NJ, United States, 2Janssen Scientific Affairs, Horsham, PA, United States, 3SmartAnalyst Inc., New York, NY, United States, United States

Background: Follicular lymphoma (FL) is the second most common type of non-Hodgkin’s lymphoma. While there are therapeutic options for patients with FL, it remains an incurable disease with conventional therapies. Furthermore, real-world treatment patterns for patients with FL are not well characterized in the literature.

Aims: To characterize the real-world treatment patterns by line of therapy (LOT) for patients with FL in a large US-insured database.

Methods: Using the Optum integrated database, patients with FL who were identified and included if 1) they were diagnosed with the International Classification of Diseases, Ninth Revision (ICD-9) codes 202.0 or 202.00 to 202.08 between January 2010 and December 2014; 2) their age was ≥ 18 years at the index date (defined as date of FL diagnosis); 3) they did not have any other primary cancers during the period from 3 years prior to index date up to 1 month post-index date; and 4) they had continuous insurance coverage for 365 days prior to index date. All reporting was done using descriptive statistics.

Results: A total of 2569 patients with FL met the inclusion criteria and were included in the analysis. In this cohort, the mean age was 60 years; 51% were male; 72% were Caucasian, 5% African American, 2% Asian, and 20% other. The median duration of follow-up was 610 days. Across all LOTs, 1180 patients (46%) had at least one National Comprehensive Cancer Network (NCCN) guideline-recommended treatment for FL, and 153 patients (6%) had FL only in their follow-up. Across all LOTs, rituximoblate monotherapy (RTX) was the most frequently used regimen (26%; average duration of therapy [DOT]: 96 days), followed by rituximoblate-cyclophosphamide-doxorubicin-vincristine-prednisolone (R-CHOP) or R-CHOP-containing regimens (19%; average DOT: 75 days) and bendistatin-rituximoblate (BR) (12%; average DOT: 129 days). These regimens represented 21%, 16%, and 14% of the first LOT, and 27%, 16%, and 11% of the second LOT, respectively. Across all LOTs, the use of other FL treatments was very low, including rituximoblate-cyclophosphamide-vincristine-
E1139

A PHASE 1 STUDY EVALUATING THE SAFETY AND PHARMACOKINETICS (PK) OF VENETOCLAX (VEN) IN JAPANESE PATIENTS (PTS) WITH NON-HODGKIN LYMPHOMA (NHL) AND MULTIPLE MYELOMA (MM)

1Department of Clinical Research and Department of Hematology and Cell Therapy, Aichi Cancer Center Hospital, Nagoya, Japan, 2Department of Hematology and Oncology, The Cancer Institute Hospital, Japanese Foundation for Cancer Research, Tokyo, Japan, 3Department of Hematology and Rheumatology, Tohoku University Hospital, Sendai, Japan, 4Department of Hematology and Oncology, Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan, 5Department of Hematology, National Hospital Organization Nagoya Medical Center, Aichi, Japan, 6Department of Hematology, National Cancer Center Hospital, Tokyo, Japan, 7AbbVie GK, Tokyo, Japan, 8AbbVie Inc., North Chicago, IL, United States

Background: The antiapoptotic protein BCL-2 is commonly overexpressed in hematologic malignancies. VEN is a potent, orally bioavailable BCL-2 inhibitor that has demonstrated acceptable safety and antitumor activity in NHL and MM pts.

Aims: To evaluate the PK profile, and preliminary antitumor activity of single-agent VEN in Japanese pts with NHL or MM.

Methods: Phase 1 open-label, dose-escalation study of VEN in Japanese pts with relapsed or refractory (R/R) NHL or MM (NCT02265731). Dose escalation followed a 3+3 design. After a 2-week ramp-up period with weekly dose escalation, VEN was administered at final doses of 300, 600, 900, or 1200mg on 21-day cycles until progression. All pts received prophylaxis (allopurinol, hydration, hospitalization and monitoring) starting at least 72 hours before the first VEN dose and before each dose escalation. Adverse events (AEs) were assessed by NCI CTCAE v4.0. Dose-limiting toxicities (DLTs) were determined during the ramp-up period and during cycle 1. Response were assessed by 2007 IWG (NHL) or 2006 IMWG (MM) criteria.

Results: As of January 19, 2017, 20 pts (50% male; median age 65 years [39–81]) have been enrolled: 3 pts in the 300-mg, 7 pts in the 600-mg, 7 pts in the 900-mg, and 3 pts in the 1200-mg VEN dose cohorts. Eighteen (90%) pts had NHL (stage III/IV, n=14), including 11 with follicular lymphoma (FL), 6 with diffuse large B-cell lymphoma (DLBCL), and 1 with concurrent FL+DLBCL; 2 (10%) pts had MM at diagnosis. Treatment-emergent AEs (all grades) >20% pts were lymphopenia (80%), neutropenia (60%), leukopenia (50%), and anemia (25%), and non-hematologic toxicities including nausea (55%), vomiting, diarrhea, and nasopharyngitis (30% each). Grade ≥3 treatment-related AEs were lymphopenia (45%), neutropenia (40%), and leukopenia (30%). One pt in the 900-mg dose cohort experienced febrile neutropenia with neutrophils <500/mm3 post VEN. RTX-containing regimens were used in 69.5% of regimens across all LOTs. 2 pts died while on study due to disease progression. No TLS events were reported.

Summary/Conclusions: A SIMPLIFIED APPROACH IN THE ASSESSMENT OF T-CELL CLONALITY BY TARGETING T-CELL RECEPTOR β CONSTANT REGION

1Radiumhospitalet, 2Oslo University Hospital, 3Nordic Nanovector, Oslo, Norway, 4Northland University Hospital, Umea, Sweden, 5University of Manchester, Manchester, United Kingdom

Background:aining T cell clonality by targeting T-cell receptor β constant region (TRBC1). The α/β TCR is a pan T-cell antigen, expressed on >90% of T-cell population, will exclusively express TRBC1 or 2. TCR-V(β)-R repertoire analysis (TCR-V(β)-R) is a sensitive method for detection of T-cell clonality; however, the assay is cumbersome owing to the required eight-part analyses that limit its clinical utility.

Aims: Here we describe a simplified flow cytometric method utilising a monoclonal antibody that targets the T-cell receptor β constant domain 1 (TRBC1). The εβ TCR is a pan T-cell antigen, expressed on >90% of T-cell lymphomas and all normal T-cells. A feature of the TCR is that the β-constant region comprises 2 functionally identical genes: TRBC1 and TRBC2. Each T-cell expresses only one of these. Consequently, normal T-cells will be a mixture of individual cells expressing either TRBC1 or 2, while a clonal T-cell disorders will exclusively express TRBC1 or 2.

Methods: Using multiparameter flow cytometry we assessed the expression of VDJ1 in normal donors (n=19), T-cell leukaemia cell line (n=1), T-LGL (n=9), T-NHL (n=3), Sézary syndrome (n=3) and patients with reactive lymphocytosis (n=9). A comparison of VDJ1- and TRBC1-V-β-R was also performed to compare the two approaches.

Results: VDJ1 expression within the CD4 and CD8 compartments of T-cells in normal donors was a median of 42.6% (range 33.7%> 49%) and 36.4% (range 22.3%> 48.5%) respectively. The T-cell line, Jurkat was exclusively positive for VDJ1. Of the 9 patients with T-LGL, 7 patients shared a common T-cell phenotype CD3+CD8+, CD4-, CD3+CD4+CD8+, CD3+CD4+CD8+CD7- respectively were either positive or negative for VDJ1. Patients with persistent lymphocytosis were also assessed for VDJ1 expression. In this group all patients had Jurkat-positive and negative compartments within CD4 and CD8 T-cells.

Summary/Conclusions: In summary we have demonstrated a novel approach in the assessment of T cell clonality by targeting T-cell receptor β constant domain 1 (TRBC1). The addition of VDJ1- in routine practice could improve the clinical evaluation of abnormal T-cell populations by flow cytometry.

A SIMPLIFIED APPROACH IN THE ASSESSMENT OF T-CELL CLONALITY BY FLOW CYTOMETRY

M. Sarto1, E. Lau1, V. Lou1, Z. Timbol1, S. Wong3, S. Deo1, L. Pasalic1, D. Brown2, E. Tegg1, D. Gottlob2

1Haematology, 2Immunopathology, Weatmead Hospital, 3Faculty of medicine, Sydney University, Sydney, Australia

Background: T-cell lymphoproliferative disorders are amongst the most challenging diagnoses in haematology. Flow cytometric T-cell receptor (TCR-V(β)-R) repertoire analysis (TCR-V(β)-R) is a sensitive method for detection of T-cell clonality; however, the assay is cumbersome owing to the required eight-part analyses that limit its clinical utility.

Aims: Here we describe a simplified flow cytometric method utilising a monoclonal antibody that targets the T-cell receptor β constant domain 1 (TRBC1). The εβ TCR is a pan T-cell antigen, expressed on >90% of T-cell lymphomas and all normal T-cells. A feature of the TCR is that the β-constant region comprises 2 functionally identical genes: TRBC1 and TRBC2. Each T-cell expresses only one of these. Consequently, normal T-cells will be a mixture of individual cells expressing either TRBC1 or 2, while a clonal T-cell disorders will exclusively express TRBC1 or 2.

Methods: Using multiparameter flow cytometry we assessed the expression of VDJ1 in normal donors (n=19), T-cell leukaemia cell line (n=1), T-LGL (n=9), T-NHL (n=3), Sézary syndrome (n=3) and patients with reactive lymphocytosis (n=9). A comparison of VDJ1- and TRBC1-V-β-R was also performed to compare the two approaches.

Results: VDJ1 expression within the CD4 and CD8 compartments of T-cells in normal donors was a median of 42.6% (range 33.7%> 49%) and 36.4% (range 22.3%> 48.5%) respectively. The T-cell line, Jurkat was exclusively positive for VDJ1. Of the 9 patients with T-LGL, 7 patients shared a common T-cell phenotype CD3+CD8+, CD4-, CD3+CD4+CD8+, CD3+CD4+CD8+CD7- respectively were either positive or negative for VDJ1. Patients with persistent lymphocytosis were also assessed for VDJ1 expresion. In this group all patients had Jurkat-positive and negative compartments within CD4 and CD8 T-cells.

Summary/Conclusions: In summary we have demonstrated a novel approach in the assessment of T cell clonality by targeting T-cell receptor β constant domain 1 (TRBC1). The addition of VDJ1- in routine practice could improve the clinical evaluation of abnormal T-cell populations by flow cytometry.
of prior therapies ranged from 1 to 7. Median body weight was 79 kg (range: 58-118 kg). The administered activity across all treatment groups ranged from 746 to 1982 MBq. The table below shows the median of the PK and haematology safety results for $^{177}$Lu-lilotomab by treatment group. The activity-adjusted $\text{AUC}_{\infty 0-\infty}$ of $^{177}$Lu-lilotomab increased with 100mg/m$^2$ of ililotomab compared to the other pre-dosing regimens ($p<0.001$ compared to 40mg ililotomab). The median volume of distribution and clearance were both reduced with 100mg/m$^2$ of ililotomab compared with the other pre-dosing regimens. However, activity adjusted $\text{C}_{\text{max}}$ was similar. Smaller percentage post-treatment reductions in platelet and neutrophil counts were observed in patients receiving 100mg/m$^2$ ililotomab. Most common grade 3/4 AEs were hematological and were transient and reversible.

### Summary/Conclusions
A higher pre-dose of ililotomab increases the activity-adjusted AUC and decreases the volume of distribution and clearance rate of $^{177}$Lu-lilotomab in iNHL pts. Despite the increase in AUC the percentage reductions in neutrophil and platelet counts were smaller, indicating that a higher dose of ililotomab may have a protective effect against the myelosuppression associated with $^{177}$Lu-lilotomab. Further characterisation of 20 MBq/kg dose of $^{177}$Lu-lilotomab with 100mg/m$^2$ of ililotomab pre-dosing is ongoing and will be presented.

---

**E1142**

**PHARMACOKINETICS AND TOLERABILITY OF OFATUMUMAB AND BENDAMUSTINE IN PATIENTS WITH INDOLENT B-CELL NON-HODGKIN’S LYMPHOMA**

$^1$Division of Hematology / Clinical Oncology, University of Alabama at Birmingham, Alabama, USA, $^2$West Cancer Center, Tennessee, $^3$Houston Methodist Cancer Center, Houston, $^4$West Virginia University, Morgantown, $^5$Novartis Oncology, East Hanover, NJ, United States, $^6$Novartis Pharma AG, Basel, Switzerland, $^7$Cancer Therapy & Research Center, San Antonio, United States

**Background:** Anti-CD20 antibody rituximab (R)-based immunochemotherapy is the standard treatment for untreated or relapsed indolent B-cell non-Hodgkin lymphoma (iNHL). Due to the inevitable relapse of patients with iNHL, an unmet need remains for active and well-tolerated novel therapies. Bendamustine (BEN) is approved for the treatment of refractory iNHL, and the combination therapy BEN-R showed efficacy in the treatment of relapsed iNHL. Ofatumumab (OFA) is an anti-CD20 human monoclonal antibody (mAb) with high binding affinity and slower dissociation from a distinct membrane-proximal epitope on both small and large loops of CD20. OFA is indicated for the treatment of chronic lymphocytic leukemia (CLL) and is being investigated for the treatment of iNHL. The combination of OFA and BEN may provide additional clinical benefit in lymphocytic leukemia (CLL) and is being investigated for the treatment of iNHL. The combination of OFA and BEN may provide additional clinical benefit in patients with iNHL and therefore the potential for drug-drug interaction was investigated.

**Aims:** The study aimed to evaluate the pharmacokinetics (PK) of OFA and BEN alone and in combination, along with the safety and tolerability assessments in patients with previously untreated or relapsed iNHL.

**Methods:** In this Phase I open-label, multicentre study, patients (aged ≥18 years) with previously untreated or relapsed iNHL were randomized 1:1 to Arm A (OFA + BEN) or Arm B (OFA alone) to receive at least four cycles and up to eight cycles of treatment (cycle length 28 days). All patients provided informed consent. Arm A patients received single-sequence treatment of BEN, then OFA (1000mg) on day 1 of weeks 2, 3, and 4 of cycle 1 and on day 1 of cycles 2-8. Patients in Arm B received OFA alone at the same dosing schedule. Blood samples including all end-of-infusion (EOI) PK samples were collected for plasma concentration over time. The primary PK parameters $\text{C}_{\text{max}}$, $\text{AUC}_{\infty 0-\infty}$, $\text{AUC}_{0-\infty}$ were derived using non-compartmental analysis. All adverse events (AEs) and severe AEs (SAEs) were recorded for safety assessments.

**Results:** Thirty two patients were randomized (15 in Arm A and 17 in Arm B), 3 patients in Arm A discontinued study treatment due to consent withdrawal (2 patients) and infusion related AE (1 patient). All 32 patients were included for safety and PK concentration analysis while 30 patients (15 in each arm) were included for PK parameters. Patient and disease characteristics were similar between treatment arms; the majority of patients from both arms did not receive prior NHL therapy. PK concentration profiles and PK parameters of OFA were comparable when administered alone or co-administered with BEN (Table 1). As compared to OFA alone, there was a decrease of 14% in $\text{C}_{\text{max}}$ and 15% in $\text{AUC}_{\infty 0-\infty}$ when OFA was co-administered with BEN, which was not considered relevant (Table 1). BEN PK concentration profiles and PK parameters were comparable with or without OFA co-administration (Table 1). All patients reported AEs. The most frequent treatment-related AEs were infusion related reaction in 53% and 47%, nausea in 33% and 35%, fatigue in 33% and 18% patients in Arm A and Arm B, respectively. The percentages of patients with grade 3/4 AEs were higher in Arm A (53%) compared to Arm B (24%). Cytopenias were present in 40% of patients in Arm A and 6% in Arm B. Four SAEs were related to study treatment in Arm A while none in Arm B.

**Summary/Conclusions:** No relevant drug-drug interaction between OFA and BEN was observed in this study. OFA alone or in combination with BEN exhibited manageable safety profile in patients with iNHL.

ASSESSMENT OF INTERNATIONAL CONSENSUS GROUP FOR HEMATOLOGY (ICGH) SMEAR REVIEW RULES FOR AUTOMATED PLATFORMS IN THE DETECTION OF MALARIA

J. Vaughan1,2,*, E. Benade1,2, S. Havyarimana1,2, N. Alli1,2

1Haematology, National Health Laboratory Services, 2Molecular Medicine and Haematology, University of the Witwatersrand, Johannesburg, South Africa

Background: Peripheral blood smear review (SR) is a useful adjunct to the full blood count (FBC) and differential white cell count (DWCC), but is labor intensive and time consuming. For this reason, the international consensus group for hematology (ICGH) published guidelines to reduce SR rates in clinical laboratories using rules based on a combination of blood parameters and instrument suspect flags. These rules have reduced SR rates in many laboratories, but adjustment is often required to accommodate for local pathology/clinician preferences. As malaria is common in Johannesburg (JHB) (although not endemic), this study was undertaken to retrospectively evaluate the performance of modified ICGH SR rules for detection of malaria at the Chris Hani Baragwanath Academic Hospital Laboratory (CHBAH) (part of the National Health Laboratory Service (NHLS) network) in JHB, South Africa.

Aims: To assess the performance of the CHBAH NHLS SR rules in the detection of malaria.

Methods: Malaria test results (P. falciparum antigen & thick/thin SR) were extracted from the laboratory information system and corresponding FBCs assessed in those with parasitemia. All ICGH rules were applied to patients with both FBC and DWCC requested, while only the parameter related rules were applied to patients with only a FBC performed. Samples were processed using a Sysmex XE-5000 analyser (Sysmex, Kobe, Japan), and the rules violated for each FBC recorded. As a retrospective laboratory based study, informed consent was not obtained. However, the study was approved by the Human Research Ethics Committee of the University of the Witwatersrand.

Results: Of the 153 samples included, all had P. falciparum parasitemia and 37 were collected from patients with severe malaria. A FBC with a DWCC was performed in 72/153 (47.1%) patients, and a FBC alone in 81/153 (52.9%). SR rules were triggered in 132 (86.3%) patients (68/94.0% in those with only a FBC performed, and 64/88.9% in those with a FBC and DWCC). The thrombocytopenia (platelets (Plt) <100x109/l) andemia (Hb <7g/dl) rules were the most common, triggering in 105 (79.5%) and 24 (15.7%) patients respectively. Common analyzer morphology flags included those querying the presence of atypical lymphocytes, immature granulocytes and blasts, but 1/4 of these triggering the parameter related flags in only 5/7% of patients with a DWCC requested. There were 21 (13.7%) unflagged (false negative (FN)) samples, of which 20 (95.2%) had a Hb level ≥10g/dl, 14 (70.0%) had both a Hb ≥10g/dl and a pit count >120x109/l and 8 (38.1%) had a Hb ≥10g/dl and a pit count >150x109/l. On SR, malaria parasites were missed in a further 13.0% of cases, predominantly when the parasitemia was low (median 0.35% in those missed vs 3.1% in those with parasites identified). Reassuringly, SR rules were triggered in all the patients with severe malaria, and the parasites identified in 90.5% of these.

Summary/Conclusions: ICGH SR rules are FN in 13.7% of patients with malaria, largely in those with near-normal blood counts. Furthermore, SR failed to identify the parasites in a further 13.0% of cases (particularly those with very low parasitemia). Elimination of a proportion of FN samples is thus not likely to be possible, and clinical vigilance for this condition is required. Reassuringly, SR rules were flagged in all patients with severe malaria, thus increasing the likelihood of this entity being diagnosed if not tested for specifically.

BRONCHOALVEOLAR LAVAGE AS SYSTEMATIC APPROACH FOR EARLY DIAGNOSIS OF LUNG INFLTRATES AND INVASIVE PULMONARY MALIGNANCY IN HEMATOLOGIC PATIENTS: A PROSPECTIVE SINGLE INSTITUTION STUDY

F. Marchesi1,*, A. Spada1, F. Pimpinelli2, G. Pirgiano3, M. Gaglia3, D. Forcella4, S. Gumenyuk1, D. Renzi1, F. Palombi1, A. Vulcano1, F. Pisani1, A. Romano1, E. Papa1, F. Faccoli1, F. Ensoli1, C. Gim renta3, M. Mancardi3, A. Mengarelli1, G. Fossi1, Unit of Medical Oncology and Stem Cell Transplantation, Regina Elena National Cancer Institute, 2Molecular Virology, Pathology and Microbiology Laboratory, San Gal liano Dermatological Institute, 3Microbiology and Infectious Diseases Biorepository Laboratory, National Institute of Infectious Diseases “L. Spallanzani”, 4Thoracic Surgery Unit, Regina Elena National Cancer Institute, 5Hematology Unit, Sapienza University, Rome, Italy

Background: The best diagnostic approach of lung infiltrates (LI) remains to be established. Despite bronchoscopy with bronchoalveolar lavage (BAL) appears to be useful for LI diagnosis, hematologists and thoracic surgeons commonly have doubts in performing bronchoscopy due to the high-risk of procedure-related complications. A proper diagnostic approach at LI seems to be particularly relevant in neutropenic patients and/or in patients with an unfavorable clinical response to broad-spectrum antibiotics, in which the cause of LI are often filamentous fungi, as Aspergillus spp. To date, there were stratified risk factors and diagnostic panel to apply in hematologic patients undergoing bronchoscopy for LI.

Aims: To evaluate the feasibility of bronchoscopy with BAL as systematic diagnostic approach at LI in hematologic patients, focusing on its role to diagnose invasive pulmonary aspergillosis (IPA).

Methods: Bronchoscopy was performed in all hospitalized patient with diagnosis of acute leukemia and LI at onset of disease before therapy start, and in any other hematologic patient in any phase of disease with LI requiring hospitalization because of concomitant febrile neutropenia and/or respiratory distress not responding to broad-spectrum antibiotics. Criteria for not response to broad-spectrum antibiotics were defined as (1) fever >48 h (in neutropenic patients), (2) persistent respiratory distress. In all cases we performed the same diagnostic work-up including blood-swabs cultures, serum galactomannan (GM) assessment (in three consecutive checks), serum beta-D-glucon, serum PCR for CMV, BAL.
E1146
ESCAPE DRUG-RESISTANT INFECTIONS IN HEMATOLOGICAL MALIGNANCIES. DARE TO REVIEW!
C. Gentile Sanchez1,*, K. Sun1, P. Teegavarapu1, Q. Qian1, P. Mamta2, S. Wong2, I. Ibrahim1, L. Rice1, S.R. Pingali1, S. Iyer1
1Houston Methodist Cancer Center, 2Houston Methodist Research Institute, 3Houston Methodist Department of Hematology, Houston Methodist Hospital, Houston, United States

Background: Patients with hematological cancers are at a high risk for increasingly resistant and severe infections. The Infectious Diseases Society of America has defined commonly resistant bacteria as ESKAPE (Enterococcus, Staphylococcus aureus, Klebsiella pneumoniae, Acinetobacter, Pseudomonas aeruginosa, Enterobacter). As suggested in recent literature, other common and difficult-to-treat infections such as Clostridium difficile and Enterobacteriaceae organisms (E. coli, Proteus) can be added to this group and change the acronym from ESKAPE to ESCAPE.

Aims: We performed a retrospective review of the rate of ESCAPE infections, resistance profile, and outcomes in patients with various hematological malignancies at the Houston Methodist Hospital from 2006 to 2015.

Methods: The patient data was obtained from METEOR (Methodist Environment for Translational Enhancement and Outcomes Research), a clinical data warehouse that contains records dating back to January 1, 2006, with over 3 million patients and over 10 million unique patient encounters. We queried for leukemia (AML, CML, ALL, CLL), amyloidosis and myelodysplastic syndrome (MDS) along with hospitalizations due to bacterial infections. Baseline demographics and overall outcomes were also obtained.

Table 1.

Results: Out of 6017 patients with Hematological Malignancies, 660 patients with 684 malignant diagnoses were found; 235 had MDS, 174 had AML, 105 had CML, 44 had CML, 39 had AML, and 10 had an unspecified hematological cancer. Of 1132 infectious events, 62% were ESCAPE infections. The bacteria most frequently isolated were Enterococcus (23.4%), Staphylococcus aureus (18.5%) and Pseudomonas (16.9%). Bacteremia was the most predominant type of infection (41.9%) followed by urinary tract infections (38.2%). Patients with MDS (39.6%) and AML (29.3%) were mainly affected. A prevalent resistance to levofloxacin was detected in gram positives (38.2%). Patients with MDS (39.6%) and AML (25.3%) were mainly affected. A prevalent resistance to levofloxacin was detected in gram positives (38.2%). Patients with MDS (39.6%) and AML (25.3%) were mainly affected.

Summary/Conclusions: Hematological cancers with risk for neutropenia such as MDS and AML were the most affected by ESCAPE. Bacteremia was frequently seen. Gram-negative pathogens had an increased resistance to broad-spectrum antibiotics, and gram-positive organisms (E. coli, Proteus) can be added to this group and change the acronym from ESKAPE to ESCAPE. The Infectious Diseases Society of America has defined commonly resistant bacteria as ESKAPE (Enterococcus, Staphylococcus aureus, Klebsiella pneumoniae, Acinetobacter, Pseudomonas aeruginosa, Enterobacter). As suggested in recent literature, other common and difficult-to-treat infections such as Clostridium difficile and Enterobacteriaceae organisms (E. coli, Proteus) can be added to this group and change the acronym from ESKAPE to ESCAPE.

E1147
PROPOSED PEGIFLGRASTIM BIOSIMILAR CHS-1701 DEMONSTRATES PHARMACOKINETIC AND PHARMACODYNOMIC SIMILARITY TO MARKETED PEGIFLGRASTIM IN A RAT NEUTROPIA MODEL AND IN HEALTHY SUBJECTS
P. O’Connor1,*, H. Tang1, F. Civoli1, B. Finck1, V. Vexler1
1Coherus BioSciences, Inc., Redwood City, United States

Background: CHS-1701, a proposed biosimilar of pegfilgrastim, is being developed to decrease infection in patients receiving myelo-suppressive anticancer drugs associated with febrile neutropenia.

Aims: The aim of the preclinical study was to compare pharmacokinetic (PK) and pharmacodynamic (PD) effects of CHS 1701 and marketed pegfilgrastim (MP) in a rat model of cyclophosphamide (CAPA)-induced neutropenia. Since pegfilgrastim has the same mechanism of action in humans and rats, preclinical models of CPA-induced neutropenia are considered to be pharmacologically and clinically relevant models of chemotherapy-induced neutropenia in cancer patients. The aim of the clinical program was to demonstrate the PK and bioequivalence of CHS-1701 to MP in a multi-center, randomized, single-blind, 3-sequence, 3-period crossover study.

Methods: In the rat model, a single SC dose of CHS-1701 or MP was administered at 24 hours after CPA administration, when the peripheral neutrophil counts had been reduced by ~60-70% from baseline. Doses from 30 to 1000 μg/kg were evaluated in order to provide a broad range of exposures to pegfilgrastim and allow for the comparison of CHS-1701 and MP dose response in a steep part of the PD dose response curve. The PD response was evaluated in the blood by analyzing time-dependent changes in absolute neutrophil counts (ANC) and calculating ANC AUC0-last in the bone marrow by analyzing time-dependent changes in the number of peripheral neutrophils and in the bone marrow. The two treatments displayed similar safety profiles. Investigator-designated treatment-related AEs occurred in 71.9%, 71.2%, and 62.8% of subjects during the CHS-1701 and MP in PD (Fig. 1) or PK were observed across the tested dose range.

Results: In the clinical study, CHS-1701 and MP demonstrated similar time- and dose-dependent changes in the number of peripheral neutrophils and in the proliferative response in the bone marrow. No differences between CHS-1701 and MP in PD (Fig. 1) or PK were observed across the tested dose range. In the clinical study, PK bioequivalence criteria were met for Cmax (GMR=105.0; 90% CI 95.5, 115.4) and AUC0-∞ (GMR=97.5; 90% CI 88.6, 107.2). Pre-specified PD bioequivalence criteria (90% CI) and more stringent criteria (95% CI) were met for ANCmax (GMR=99.6; 90% CI: 98.2, 102.3; 95% CI: 95.5, 103.9) and ANC AUC0-∞ (GMR=96.7; 90% CI: 92.2, 101.4; 95% CI: 91.4, 102.4).

The two treatments displayed similar safety profiles. Investigator-designated treatment-related AEs occurred in 71.9%, 71.2%, and 62.8% of subjects during the CHS-1701, first MP, and second MP dosing periods, respectively, and most commonly included back pain (46.9%, 42.3%, 30.8%), headache (29.2%, 36.9%, 29.5%), and arthralgia (8.3%, 13.5%, 7.7%). There were no treatment-related serious AEs.

Figure 1.

Summary/Conclusions: The dose-dependent changes in the neutropenia model were consistent with the PK effects of pegfilgrastim in humans and demonstrate that CHS-1701 results in comparable neutrophil recovery and time course compared to marketed pegfilgrastim. The clinical study demonstrates highly similar PK, PD, and safety profiles in humans for CHS-1701 and marketed pegfilgrastim. Overall, preclinical and clinical results suggest that CHS-1701 would provide similar PK, PD, safety, and efficacy to marketed pegfilgrastim in patients with chemotherapy-induced neutropenia.

E1148
A RETROSPECTIVE REVIEW IDENTIFIES RESISTANT MICROBIAL STRAINS, ANTIMICROBIAL SENSITIVITIES AND RISK STRATIFICATION OF FIRST LINE ANTIBIOTIC USE IN ADULT CANCER PATIENTS WITH NEUTROPENIC SEPSIS
A. Danga1,*, Y.M.T. Hu1, K. Lazarus3, T. Sugah1
1Coherus BioSciences, Inc., Redwood City, United States

Background: CHS-1701 was a proposed biosimilar of pegfilgrastim, is being developed to decrease infection in patients receiving myelo-suppressive anticancer drugs associated with febrile neutropenia.
Background: Neutropenic sepsis remains a leading cause of morbidity and mortality in both haematopoietic and oncology patients on chemotherapy. The emergence of multi drug resistant strains of micro-organisms, high-risk individuals not to be identified early and first line antimicrobial treatment regimens tailored according to patient factors alongside local antibiogram. Aims: To retrospectively review appropriate antibiotic use, microbial identification and antibiotic sensitivities amongst adult cancer patients with neutropenic sepsis. To identify if any patient or disease characteristics are associated with the outcome of patients that would suggest the upfront usage of aminoglycosides containing antibiotic treatment regimens. Methods: A retrospective review of patients treated for neutropenic sepsis was conducted for the period between 1/4/2015 to 11/10/2016. Analysis of potential risk factors including primary disease, age, sex, treatment regimen, albumin, neutrophil and lymphocyte count to assess potential association with adverse outcomes. Results: There were 116 episodes of neutropenic sepsis in 92 patients in this period. Of these, 61 were haematology-oncology patients and 31 general oncology. 42 of 76 positive cultures identified gram-negative organisms. 40 patients received single agent Tazocin and 71 patients (61.2%) received Tazocin and an aminoglycoside as first line antimicrobial treatment. Fourteen isolates demonstrated resistance, including 2 cases of stenotrophomonas maltophilia and 12 cases of enterobacteriaceae. 13 of the 14 resistant isolates were found in haematology-oncology patients. Nine of these cases were resistant to single agent Tazocin but sensitive to an aminoglycoside. The mean age of cases with resistant bacteria was 54.2 years (range 25-84 years). There was no difference in sex or degree of neutropenia/lymphopenia in the cases that contracted resistance bacterial strains compared to those that were culture negative. Of the 4 fatal cases with resistant bacteria, 3 had low albumin (mean 25.5g/L cf. mean of 34g/L in resistant bacteria cases surviving). Summary/Conclusions: This retrospective analysis supports the use of combination antimicrobials upfront as first line treatment in high-risk patients with neutropenic sepsis. The study has demonstrated that the patient cohort most at risk of developing drug resistant bacteriae are patients with high-risk or relapsed haematological disorders like AML or high-grade lymphoma, requiring multiple cycles of intensive chemotherapy. Of the patients who isolate resistant bacteria, identifying low albumin early may be a potential marker for adverse outcome in terms of morbidity and mortality. Of interest only one oncology patient isolated a resistant strain of bacteria, furthermore only 25% of general oncology patients treated with neutropenic sepsis had positive cultures compared to 75.8% of haematology-oncology patients. When comparing these findings to UK NICE recommendations it is clear that first line use of Tazocin in general oncology patients may well suffice in initial treatment of neutropenic sepsis. However with haematology-oncology patients early or up front consideration for the additional usage of an aminoglycoside is essential to optimize favorable outcomes. In this analysis, the proposed risk factors of isolating resistant strains of bacteria leading to adverse outcomes would be aggressive haematological malignancies, receiving more intensive cytoxic therapy, multiple lines of treatment and low albumin. Further analysis in a multi center trial could also help determine patient population. Side close collaboration between clinicians and microbiologists is essential in providing optimal antimicrobial therapy algorithms in neutropenic patients.

E1149 PRELIMINARY RESULTS FROM A LONG-TERM REPEAT DOSE TOXICITY AND TOXICOGENIC STUDY OF ANF-RHO, A NOVEL ANTI-NEUTROPENIC FACTOR

J. Valentino1, J. Misra1, J. A. Neuward2
1Prolong Pharmaceuticals, Prolong Pharmaceuticals, South Plainfield, NJ, 2Toxicology, Toxikon, Bedford, United States

Background: ANF-Rho is a novel polyethylene glycol-modified granulocyte colony stimulating factor that has biophysical and biological properties that produce a prolonged pharmacokinetic and pharmacodynamic profile as compared to pegfilgrastim (Neulasta®). As such, it has potential applications in chemotherapy induced neutropenia and chronic idiopathic neutropenia. These disorders require continuous and prolonged administration due to the on-going need for neutrophil treatment, fore, long term toxicity, genotoxicity and juvenile studies were conducted with ANF-Rho.

Aims: A 13-week study was conducted in Sprague Dawley rats and cynomol- gus primates to assess various safety and pharmacokinetics of ANF-Rho as compared to Neulasta® (pegfilgrastim).

Methods: The study design used 288 rats, divided into 5 dosage groups: control, 100, 300, 1000 (high) and 1000 (positive) µg/kg. A total of 58 monkeys were also divided into 5 dosage groups: control, 75, 250, 750 (high dose) and 750 (positive) µg/kg of ANF-Rho. Doses were administered by weekly subcutaneous injections on Day 1, 8, 15, 22, 29, 36, 43, 50, 57, 64, 71, 78, 85 and 92 at a dose volume of 5 mL/kg. Genotoxicity assessments were evaluated using Salmonella typhimurium and Escherichia coli reverse mutation assay, rodent blood micronucleus assay and chromosomal aberration assay. Toxicology assessment included clinical observations, body weight change, food consumption, ophtalmic examination, function observational battery (motor activity, behavioral changes, coordination and sensory/motor reflex response), organ weight, bioanalytical and toxicokinetic analysis, immunogencity, gross necropsy and histopathology.

Results: No observed clinical signs seemed to be related to ANF-Rho administration. There were no related effects in body weight changes or food consumption. Observed ophthalmic effects were considered procedural related due to low incidence. No biologically meaningful findings were noted during the function observational battery assessment. Preliminary study showed a non-related increase in kidney weight in rats and a dose dependent decrease in kidney weight in primates. Genotoxicity studies found no signs of mutagenicity, clastogenicity or cytotoxicity.

Summary/Conclusions: The results from this preliminary toxicity studies are unremarkable and consistent with those of an earlier 28-day study. Results from the 28-day rat neutropenia dosage model found that the blood pharmacodynamics parameters of ANF-Rh® were significantly superior to PEG-filgrastim. Both PK and PD data demonstrate relatively predictable systemic exposures and activity following SC or IV dose levels in both rat and primate. It is anticipated that this long term 13-week study will provide evidence of safety and pharmacokinetics support advancement of ANF-Rho into clinical studies in chemotherapy-induced neutropenia and chronic idiopathic neutropenia in Europe, USA and India.

E1150 USE OF MICAFUNGIN IN PROPHYLAXIS ON IN-HOSPITAL: RESULTS OF AN OBSERVATIONAL, MULTICENTER, PROSPECTIVE FRENCH STUDY (OLYMPÉ)

J.-E. El-cheikh1,*, H.-J. Daillé2, S. Ducastelle-Leprêtre3, J.-B. Quiniou4, P. Ceballos5, R. Herbrec6
1American Hospital, Beirut, Lebanon, 2Hôpital Robert Debré, Paris, 3Hospital Saint-Eloi, University Medical Center, Montpellier, 4Centre Hospitalier Universitaire, Montpellier, 5Centre Hospitalo-Universitaire, Strasbourg, France, 6Centre Hospitalo-Universitaire, Montpellier, France

Background: Invasive fungal infections are becoming increasingly common in haematology/onco-hematology patients. The low rate of serious adverse events confirms micafungin use in onco-hematology where most-at risk patients of invasive fungal infections (IFI) are managed.

Aims: The therapeutic arsenal is extensive and requires a better understanding of micafungin use in onco-hematology where most-at risk patients of invasive fungal infections (IFI) are managed.

Methods: Observational study was conducted in 18 onco-hematology units in adult patients and children treated with micafungin in prophylaxis with a 3-months follow-up period.

Results: 150 patients (95 adults, 55 children) were included and represent the analysis population. In total, 15 patients (10%) presented an IHI during micafungin treatment. Among them, 11 presented a probable or proven IHI. The rate of IHI was higher in children (15%, n=8) than in adults (7%, n=7) and seem to be related to the type of hemopathy and if the patient was allo-grafted or not: 13% (n=8) in allo-grafted patients, 9% (n=4) in patients with AML or SMD and 7% (n=3) in other patients. Median time to infection was 24 days (1 to 68 days) and was longer in adults (25 days, 4 to 68 days) than in children (16.5 days, 1 to 68 days). Twelve patients (8 children and 4 adults) presented at least one clinical or radiological sign of suspected IHI. Fungus was identified in 8 patients (62%), mostly in blood cultures (50%, n=4): candidiasis in 4 patients, aspergillosis in 3 patients and infection related to Rhisopus in 1 patient. Incidence rate of IHI (10%, 5 patients) was inferior to prophylaxis failure rate (23%, 34 patients). Prophylaxis failure rate takes in account patients who switched to empirical treatment besides patients who switched to preemptive or curative treatment. After the end of prophylaxis, 4 patients (3%, 3 adults and 1 child) presented a proven IHI. Median time to infection after the end of treatment was 10.5 days in adults (7 to 24 days) and 52 days in children. Micafungin was overall well tolerated: only 10 patients (7%, mostly children) presented grade 1 or 4 adverse events related to micafungin, including 5 patients (3%) with grade 3 or 4 adverse events.

Summary/Conclusions: Effectiveness and safety profile of micafungin in prophylaxis are similar to what was observed in previous studies. Incidence IHI of micafungin confirms the clinical effectiveness of micafungin in prophylaxis in high risk patients. The low rate of serious adverse events confirms micafungin safety profile, in children included.

E1151 OUTBREAK OF MULTI-DRUG RESISTANT PSEUDOMONAS AERUGINOSA (MPA) IN A HAEMATOLOGY WARD (HW): MANAGEMENT AND INFECTION CONTROL MEASURES

D. Armiento1,2, E. Cerchiara1, A. Annibali3, M. Becilli4, E. Cricchetta1, S. Ferraro1, A. Pagano1, A. Scardocci1, M. Tafuri1, M. C. Tirindelli2, G. Avvisati1
1A. F. Cari, Bari, Italy, 22nd Congress of the European Hematology Association, 3Sanità, Rome, Italy, 4Ospedali Riuniti di Crotone, Italy

Aims: To present an outbreak involving MPA in a HW. Description of the outbreak and the measures taken to control and prevent it. Summary/Conclusions: Pseudomonas aeruginosa is a ubiquitous Gram-negative Gram-negative bacillus that can cause a wide spectrum of infections, from localized infections, such as skin and soft tissue infections, to severe infections such as pneumonia, septicemia, and meningitis. The organism is found in a multitude of environments, including soil, water, and the human gastrointestinal, respiratory, and urinary tracts. Infections caused by this organism are often difficult to treat due to the presence of multiple resistance mechanisms. Management and prevention strategies need to be developed to control and prevent such outbreaks. Summary/Conclusions: The described outbreak was managed and prevented using a combination of infection control measures, such as strict hand hygiene, environmental cleaning, and isolation precautions. The measures were effective in controlling the outbreak, and the infection control measures were reinforced to prevent future outbreaks.
Background: Voriconazole is a highly lipophilic triazole derivative and a fungus-specific broad-spectrum antifungal agent that is effective against most Candida species, as well as Aspergillus, Fusarium, and other molds. However, it is mostly used for the treatment of invasive fungal diseases (IFD), such as invasive aspergillosis and Candida bloodstream infections. Voriconazole is highly metabolized by the hepatic cytochrome P450 isoenzyme 2C19 (CYP2C19). In recent years, a growing concern has been raised regarding CYP2C19 polymorphism and its potential impact on voriconazole plasma concentrations. CYP2C19 polymorphism and its association with voriconazole plasma concentrations have been extensively studied. However, the clinical relevance of CYP2C19 polymorphism and its impact on voriconazole plasma concentrations in the treatment of IFD remains unclear.

Aims: To assess the impact of CYP2C19 polymorphism on voriconazole plasma concentrations during the treatment of IFD.

Methods: A retrospective study was conducted to evaluate the impact of CYP2C19 polymorphism on voriconazole plasma concentrations during the treatment of IFD. Patients were divided into two groups based on their CYP2C19 genotype: CYP2C19*1/*1 (wild-type) and CYP2C19*1/*2, *1/*3, *2/*2, *2/*3, *3/*3 (polymorphic). Voriconazole plasma concentrations were measured at baseline and during treatment. The impact of CYP2C19 polymorphism on voriconazole plasma concentrations was assessed using a linear mixed-effects model.

Results: A total of 45 patients were included in the study. The CYP2C19*1/*1 group consisted of 30 patients (66.7%) and the CYP2C19*1/*2, *1/*3, *2/*2, *2/*3, *3/*3 group consisted of 15 patients (33.3%). The baseline voriconazole plasma concentrations were similar between the two groups. During treatment, a significant difference was observed in voriconazole plasma concentrations between the two groups. Patients with CYP2C19*1/*2, *1/*3, *2/*2, *2/*3, *3/*3 genotypes had significantly higher voriconazole plasma concentrations compared to patients with CYP2C19*1/*1 genotypes (p < 0.05).

Conclusion: CYP2C19 polymorphism significantly affects voriconazole plasma concentrations during the treatment of IFD. Patients with CYP2C19*1/*2, *1/*3, *2/*2, *2/*3, *3/*3 genotypes require close monitoring of voriconazole plasma concentrations to prevent toxicity.

**GLYCOSYLATED FERRITIN MEASURING SIGNIFICANCE FOR SECONDARY HEMOPHAGOCYTIC SYNDROME DIAGNOSTICS**

V. Potapenko1,2, M. Pervaková2, S. Lapin2, A. Klimovich1, O. Mironova1, N. Petrov1, N. Ovram2, S. Zaitseva1, N. Skorobogatov1, E. Karyagina1, E. Kornyakov1, E. Pavlichenko2, N. Potlikhonova1, T. Kulkaba1, N. Medvedev1, A. Afanasyev1

1Municipal clinical hospital №31, 2Academican I.P. Pavlov First St. Petersburg State Medical University, 3Municipal hospital №15, 4I.I. Mechnikov North-Western State Medical University, 5Russian Scientific Research Institute of Hematology and Transfusiology, 6Saint-Petersburg State University, Saint-Petersburg, Russian Federation

**Background:** Hemophagocytic syndrome (HPS) is a clinicopathological condition characterized by systemic inflammatory reaction with cytopenia and tissue damage. The HPS may be primary (genetic associated) or secondary (SHPS), caused by different systemic disorders (immune, infectious, neoplastic). The overall clinical symptoms are similar to sepsis, so it could be difficult to differentiate among these entities. Ferritin levels are high in both cases, but the glycosylated/nonglycosylated ferritin fractions ratio is seems to be indicative.

**Aims:** The estimation of the ferritin fractions ratio and biochemical profile in patients with sepsis and SHPS.

**Methods:** The data from 64 patients were analyzed: 40 pts with diagnosed SHPS (median age 57, range 8-74 years) and 24 with lethal septic shock (median age 57.5, range 18-82 years). SHPS in patients with persistent fever refractory to antibacterial therapy and/or prolonged cytopenia and/or organ (lungs, CNS) involvement was established after the other conditions had been excluded. Sepsis diagnostics was based on the confirmed infection site and systemic inflammation with multorgan failure. The following serum values were analyzed: alkaline phosphatase (ALP), alanineaminotransferase (ALT), aspartateaminotransferase (AST), lactate dehydrogenase (LDH), bilirubin, creatinine, INR, CRP, PCT, lactate dehydrogenase (LDH), bilirubin, creatinine, INR, CRP, PCT, high-sensitivity C-reactive protein (hsCRP), procalcitonin (PCT), total ferritin, and glycosylated ferritin percentage. Mann-Whitney U test and ROC-analysis were used for statistical analyses.

**Results:** No differences were found in sepsis and SHPS for ALAT, ASAT, ALP, LDH, and bilirubin levels. The difference of INR, CRP, PCT, creatinine (CRI), levels were significant (p<0.01). The most substantial difference in SHPS and sepsis groups had serum concentrations of ferritin, triglycerides, level of ferritin glycosylation (p<0.01) (Table 1). According to ROC-analysis, the area under the curve for ferritin, triglycerides and percentage of ferritin glycosylation were 0.78, 0.82, and 0.92, respectively.

**Table 1.**

<table>
<thead>
<tr>
<th>Ferritin</th>
<th>Triglycerides</th>
<th>Glycosylated Ferritin</th>
</tr>
</thead>
<tbody>

<td>1.5 mmol/L</td>
</tr>
<tr>
<td>Sepsis</td>
<td>150 µg/L</td>
<td>1.2 mmol/L</td>
</tr>
</tbody>
</table>

**Summary/Conclusions:** The most difference between sepsis and SHPS was observed for triglycerides, ferritin and percentage of glycosylated ferritin. Percentage of glycosylated ferritin fraction seems to be the most indicative, which may make it useful for SHPS diagnostics and its differentiation from sepsis.

**SERUM HEPcidin QUANTIFICATION IN INFLAMMATORY BOWEL DISEASES**

V. Manolov1,2, V. Vasiliev3, K. Tzatchev1, O. Georgiev3, D. Stefanova-Petrova2, R. Tzrantcheva2, V. Mitev3

1Municipal clinical hospital №31, 2Academican I.P. Pavlov First St. Petersburg State Medical University, 3Department of Medical chemistry and biochemistry, Medical University, Sofia, Sofia, Bulgaria

**Background:** Inflammatory bowel diseases (IBD) includes different intestinal pathologies, most common among them are Crohn’s Disease (CD) and Ulcerous Colitis (UC). The IBDs may be transfusion dependent. The ineffective erythropoiesis and the transfusional iron load puts these patients at risk for iron overloading and there is very scarce data on the iron loading and chelation types in these patients.

**Aims:** We aimed to summarize the chelation results of our patients with CDA from a single center.

**Methods:** Of the 33 patients with CDA, 11 were initiated iron chelation treatment either for receiving more than 20 packed RBC transfusions previously or for having serum ferritin levels above 1000ng/ml.
E1159

ORAL IRON CHELATION FOR TREATMENT OF HEREDITARY HEMOCROMATOSIS IN CHILDREN

M. Moraki,1,2 C. Repoussi1, D. Kyriakopoulou1, P. Delaporta1, A. Kattamis1, F. Thalassasemia Unit, First Department of Pediatrics, National and Kapodistrian University of Athens, ‘Aghia Sophia’ Children’s Hospital, Athens, Greece

Background: Hereditary hemochromatosis (HH) very rarely presents during childhood. The most common form of HH in children is Juvenile Hemochromatosis (JH), a rare genetic disorder inherited with an autosomal recessive manner, resulting from mutations in either the hemochromatosis (HJV) (type 2A) or the hepcidin (HAMP) gene (type 2B). Early diagnosis and closely monitoring of iron overload indexes, namely, serum ferritin levels, transferrin saturation and tissue iron measurement by magnetic resonance imaging (MRI) are essential in order to prevent permanent organ damage and potentially life threatening complications (cirrhosis, diabetes mellitus, cardiac dysfunction, and hypogonadism). Therapeutic intervention in children with HH may be problematic, as erythropoiesis is invasive and may not be well tolerated in young children. Iron chelation therapy can be implemented as an alternative treatment to erythrocytapheresis.

Aims: The scope of this study was to evaluate the use of an oral iron chelation therapy in young children with HH.

Methods: 3 children (2 females and 1 male) were diagnosed with HH at the ages of 4, 6 and 8 years old, respectively, based on increased ferritin and transferrin saturation levels and tissue iron measured by magnetic resonance imaging (MRI). Genetic analysis were performed in all 3 patients and showed positive results in 2 of them, while on the 3rd no genetic changes could be identified. All patients were at pre-symptomatic stage of the disease and they were referred for evaluation after hyperferrihemina. Genetic analysis were performed in all 3 patients and showed positive results in 2 of them, while on the 3rd no genetic changes could be identified. All patients were at pre-symptomatic stage of the disease and they were referred for evaluation after hyperferrihemina. Genetic analysis were performed in all 3 patients and showed positive results in 2 of them, while on the 3rd no genetic changes could be identified.

Results: All 3 patients responded promptly to therapy and showed decreased levels of ferritin, LIC and cardiac iron concentration. Gastrointestinal disturbances were noted in 1 patient, which resolved with H2-blockers and with changing the treatment to 5d/wk (patient 2). Mild increase in serum creatinine (>33% from baseline but within normal range for her age) was observed in patient 3, which resolved with temporary cessation of the chelation therapy.

Summary/Conclusions: None of the patients were found to have cardiac iron loading at chelation initiation, whereas 2 had severe and 1 had moderate LIC values. Serum ferritin levels prior to and by the end of 1 year of chelation and by the end of 1 year were compared and the difference was found statistically insignificant.

M-TOR INHIBITORS-ASSOCIATED MICROCYTIC ANEMIA AFTER AUTOLOGOUS STEM CELL TRANSPLANTATION

R. Angel F.1,2, A. Monter1, A. Esquirol1, R. Martino1, I. Garcia-Cadenas1, J. Remacha1, S. Payan1, S. Brunel1, J. Sierra1

1Hematology, Hospital de Sant Pau, Barcelona, Spain

Background: Neutrophil hypersegmentation (NH) has been accepted as a hallmark of the macrocytic anemias associated with the deficiency of cobalamin or folate. However, there are a small number of reports stating that NH might accompany iron deficiency anemia. The aim of the present study was to determine the association of NH with iron deficiency (with or without anemia).

Aims: The aim of the present study was to determine the association between the presence of NH with iron deficiency (with or without anemia) in adults and also to determine the association of NH with iron deficiency anemia (with or without anemia).

Methods: Fifty-six patients with iron deficiency and 20 age and sex matched controls were included in this prospective, single blind, case-control study between February-November 2016. Subjects were included if they were ≥ 18 years of age, and had normal serum vitamin B12 and folate levels, liver, thyroid and renal function tests. Pregnant women and patients with a history of blood transfusion within last 3 months and/or those with acute renal failure, anemia of chronic disease, hypothyroidism, additional cytopenias and infection were excluded. Patients with iron deficiency were divided into 2 groups being with iron deficiency anemia (IDA) and iron deficiency without anemia (ID). Those without anemia were further evaluated prior and after iron replacement.

Results: The results of the study groups were compared to age and sex matched healthy controls. Blinded peripheral blood smear slides were evaluated by a haematologist by counting 200 neutrophils. Hypersegmentation was defined as reported by Bain et al. Iron deficiency was diagnosed based on the findings of iron parameters including serum iron, total iron binding capacity, and ferritin. Anemia was defined according to the WHO recommendation. Cohort characteristics were given in Table 1.

E1115

NEUTROPHIL HYPERSEGMENTATION IN ADULTS WITH IRON DEFICIENCY: A CASE-CONTROL STUDY

I. Erdogan Ozunami1, D. Keskin1, E. Durcan2, Y. Gunay2, S. Bilgin2, S. Berk1

1Department of Internal Medicine, Division of Hematology, 2Department of Internal Medicine, Istanbul University Cerrahpasa Faculty of Medicine, Istanbul, Turkey

Background: Neutrophil hypersegmentation (NH) has been accepted as a hallmark of the macrocytic anemias associated with the deficiency of cobalamin or folate. However, there are a small number of reports stating that NH might accompany iron deficiency anemia. The aim of the present study was to determine the association of NH with iron deficiency (with or without anemia).

Aims: The aim of the present study was to determine the association between the presence of NH with iron deficiency (with or without anemia) in adults and also to determine the association of NH with iron deficiency anemia (with or without anemia).

Methods: Fifty-six patients with iron deficiency and 20 age and sex matched controls were included in this prospective, single blind, case-control study between February-November 2016. Subjects were included if they were ≥ 18 years of age, and had normal serum vitamin B12 and folate levels, liver, thyroid and renal function tests. Pregnant women and patients with a history of blood transfusion within last 3 months and/or those with acute renal failure, anemia of chronic disease, hypothyroidism, additional cytopenias and infection were excluded. Patients with iron deficiency were divided into 2 groups being with iron deficiency anemia (IDA) and iron deficiency without anemia (ID). Those without anemia were further evaluated prior and after iron replacement.

Results: The results of the study groups were compared to age and sex matched healthy controls. Blinded peripheral blood smear slides were evaluated by a haematologist by counting 200 neutrophils. Hypersegmentation was defined as reported by Bain et al. Iron deficiency was diagnosed based on the findings of iron parameters including serum iron, total iron binding capacity, and ferritin. Anemia was defined according to the WHO recommendation. Cohort characteristics were given in Table 1.

Results: Of these 11 patients, 7 were CDA type II. The median age of diagnosis was 12 months (3-144) months and male to female ratio was 7/4. Median transfusion requirement per year at previous year prior to initiation of chelation was 12 times (0-17). All of the patients were on chronic transfusion programme at initiation of iron chelation except for 2 (one receives occasional transfusion, and the other patient was on chronic transfusion programme but became transfusion independent after splenectomy). The median age at last visit was 70 months (32-40 years). The median value of serum ferritin at initiation of iron chelators was 822 ng/ml. All of the patients were initiated deferasirox for iron chelation at a median dose of 24mg/kg/day (10-40) and the median chelation follow-up duration was 27 months (2-54 months). Three of the patients were evaluated with cardiac and hepatic T2* assessment prior to and by the end of 1 year of chelation and none of the patients were found to have cardiac iron loading at chelation initiation, whereas 2 had severe and 1 had moderate LIC values. In the subsequent assessment under chelation of these 3 patients all still had cardiac T2* values above 20 ms, whereas 1 had mild and 2 had moderate LIC values. Serum ferritin levels prior to and by the end of 1 year of chelation and by the end of 1 year were compared and the difference was found statistically insignificant.

Summary/Conclusions: Patients with CDA are at risk for iron loading and they need to be screened for the iron loading periodically. The prompt chelation therapy in these patients prevent organ failure risks at long term including cardiac failure, cirrhosis and endocrinopathies.
Background: Immunosuppression with mTOR inhibitors (sirolimus or everolimus) has been associated with development of microcytic anemia after solid organ transplantation. The prevalence reaches 27 to 57% in the case of kidney transplantation. This anemia has been attributed to hepcidin increase induced by the inhibition of mTOR protein.

Aims: To evaluate the prevalence of microcytic anemia after allogeneic hematopoietic stem cell transplantation in patients receiving mTOR inhibitors.

Methods: 61 consecutive allogeneic stem cell reduced intensity conditioning (alloRIC) recipients were analyzed. In all cases, a non-related donor was used. Baseline disease was: 23 acute leukemia (37.7%), 12 non-Hodgkin lymphomas (19.7%), 10 myelodysplastic syndromes (16.4%), 7 Hodgkin lymphomas 7 (11.4%), 4 multiple myelomas (6.5%), 3 chronic lymphocytic leukemia (4.9%), and 2 myelofibrosis (3.2%). All of them received Fludarabine-based conditioning treatment and the combination sirolimus (mTOR inhibitor)-tacrolimus (calcineurin inhibitor) as GVHD prophylaxis. Drug doses were adjusted according to blood levels and renal function. Levels of Hb, MCV and iron parameters were evaluated and compared when MCV was below 80 fl.

Results: At 6 months 56 out of 61 (92%) were alive. Anemia was observed in 30 (49%) of them, with only 8 cases (13.1%) showing Hb level below 10 g/dl. Microcytic anemia was diagnosed in 2 of them (3.3%). One patient showed an iron deficiency anemia due to gastrointestinal bleeding (Hb 94 g/dl, MCV 69 fl, serum ferritin 21 μg/l). However, the second one, a 61-year old male with an acute leukemia, had a microcytic anemia with iron parameter changes similar to those observed in kidney transplantation and associated with increased hepcidin (see table). Anemia progressively improved with sirolimus tappering.

</tr>
</thead>
</table>

**Summary/Conclusions:** In contrast to kidney transplantation, microcytic anemia related to immunosuppression with mTOR inhibitors was seldom observed in alloRIC recipients. However, this association should be taken in account in this setting, as a rare cause of anemia. In case of microcytic anemia, the evaluation of iron parameters and hepcidin provides the diagnosis of this rare type of anemia.

E1161

**IRON METABOLISM IN PATIENTS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA**

E. Lukina1, K. Tandilova1, N. Tsvetaeva1, O. Nikulina1, E. Sysoyeva1, I. Karpova2, E. Meshrina1, V. Sinitsy3

1Department of Orphan Diseases, 2Central Clinical Diagnostic Laboratory, National Research Center for Hematology, 3Radiology Department, Federal Center of Treatment and Rehabilitation, Moscow, Russian Federation

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a rare acquired clonal non-malignant hematological disorder that is associated with hemolytic anemia, intravascular coagulation, thrombosis. At the onset of the condition is often interpreted as iron deficiency anemia that leads to the prescription of ferrotherapy.

Aims: Study iron metabolism in patients with PNH.

Methods: The study group included 19 patients (11 men and 8 women aged from 20 to 70 years, median age 43 years) with a diagnosis of PNH, followed up in the Center between 2014 and 2017. The median hemoglobin level was 8.1 g/dl. The erythrocyte PNH clone size ranged from 17 to 99%, median - 47%. Granulocyte and monocyte PNH clone sizes were 85% and 89%, respectively. The following parameters were studied to characterize iron metabolism: ferritin, transferrin, iron concentration, total iron binding capacity (TIBC), transferrin saturation, serum hepcidin and iron absorption under oral iron supplementation.

Results: Serum hepcidin levels in IV and Oral iron groups were significantly higher compared with control group. However, serum iron levels were elevated only in oral iron group. In immunohistochemical analyses, expression levels of duodenal DMT1 were not detected in all groups and expression levels of duodenal FPN in IV and Oral iron groups were significantly lower than control group. As for iron distribution in liver, iron was accumulated in reticuloendothelial system of liver and hemosiderosis were absent in only 1 out of 10 examined patients. Patient’s iron parameter changes were similar to those observed in kidney transplantation and associated with increased hepcidin. Anemia progressively improved with sirolimus tappering.

**Summary/Conclusions:** In this study, we investigated the activity of iron absorption under oral iron supplementation in mice as well as under intravenous iron supplementation. In addition, we also analyzed iron distribution under intravenous and oral iron supplementation.

Methods: To load iron orally, a diet including 200 ppm of iron was used as control and a diet including approximately 5000 ppm of ferric citrate was used as iron-rich diet. 6-week-old male C57BL/6NCrj mice were divided into 3 groups: control group, intravenous iron (IV iron) group, and oral iron (Oral iron) group (n=5). Mice in IV iron group were fed a control diet from days 0 and intravenously administered 0.4mg/mouse of iron-dextran on days 9. Mice in Oral iron group were fed an iron-rich diet from days 0 and intravenously administered 0.4mg/mouse of dextran as vehicle on days 9. Mice in control group were fed a control diet from days 0 and intravenously administered 0.4mg/mouse of dextran on days 9. All mice were euthanized by exsanguination under anesthesia with isoflurane on days 14. For analyses of iron absorption, serum hepcidin and iron were measured and expression of duodenal DMT1 and FPN were evaluated immunohistochemically. For analyses of iron distribution, blue staining for liver and hematological indices were evaluated.

Results: Serum hepcidin levels in IV and Oral iron groups were significantly higher compared with control group. However, serum iron levels were elevated only in oral iron group. In immunohistochemical analyses, expression levels of duodenal DMT1 were not detected in all groups and expression levels of duodenal FPN in IV and Oral iron groups were significantly lower than control group. As for iron distribution in liver, iron was accumulated in reticuloendothelial cells in IV iron group, on the other hand, in Oral iron group iron was accumulated in parenchyma. In hematological analyses, although red blood cell and reticulocyte count were not significantly different among all groups, Ret-He and MCH in Oral iron group were higher than IV iron groups.

**Summary/Conclusions:** It was demonstrated in this study that serum iron levels were elevated in spite of high hepcidin levels and down-regulation of duodenal iron transporters under oral iron supplementation. Furthermore, iron was distributed in liver parenchyma and hemosiderin contents in each reticuloocyte and erythrocyte were up-regulated only under oral iron supplementation. We speculated that high serum iron lead to excess iron uptake into tissues and erythrocyte fraction. These data might provide an opportunity to rethink the importance of proper use of iron supplements.
Background: Children with haemoglobinopathy and rare anaemias often require regular red cell transfusions at some stage of their lives. Iron overload is therefore inevitable and iron chelation is a key component of therapy for children in this group. However, its use has not been validated especially in children under two years of age. Deferasirox (Exjade®; Novartis Pharma AG, Basel, Switzerland) is an iron chelator that is conclusively proven to be effective and safe in transfusional anaemia such as haemoglobinopathies.

Aims: We aim to look at the efficacy and safety of Deferasirox in children with severe anaemias.

Methods: We present a case report of 6 children with severe anaemias treated with Deferasirox in a tertiary pediatric hematology centre in London, UK.

Results: Here we report 6 cases where Deferasirox has been used in young children with rare anaemias and sickle cell disease. Patients 1 and 2 presented within the first year of life with pancytopenia requiring regular transfusion and were diagnosed with Pearson syndrome. Deferasirox was started at the age of 30 months and 4 months respectively. Patient 5 presented with pure red cell aplasia at the age of 3 months and was diagnosed with Diamond Blackfan anaemia. He was initially treated with steroid but became resistant at around 40 months of age. He was then started on regular transfusion and was started at deferrioxamine at 4 years of age. Patient 6 was diagnosed at birth with sickle cell anaemia. He suffered from stroke at the age of 8 months and was started on chronic transfusion program. Deferasirox was started at around at the age of 1. He had a successful maternal haplo-identical blood transplant.

Deferasirox were subsequently stopped. Deferasirox was started at around the age of 1. He had a successful maternal haplo-identical bone marrow transplant at the age of 3 years old. Transfusion and deferasirox were subsequently stopped.

Summary/Conclusions: Here we report 6 cases where deferasirox has been used in young children with rare anaemias and sickle cell disease where evidence is sparse.
were examined once in the control group and twice in the patient group, before and after treatment.

**Results:** When the patient and control groups were compared, there was no significant difference in terms of age, sex, height, weight, BMI, waist and hip circumference. The pretreatment plasma hepaticin and ghrelin levels of the patient group were significantly lower than those of the control group (80±21 ng/ml vs 179 ng/ml p <0.001 for hepaticin, 152±119 pg/ml vs 213±167 for ghrelin, p=0.028). There was a significant increase in terms of weight (mean 1.15 kg, p <0.001), BMI (25.86 kg/m² vs 26.33 kg/m², p <0.001), waist and hip circumference measurements (mean 0.81cm in both, p <0.001) after treatment in the patient group. After treatment, the levels of hepaticin was significantly increased compared to the pre-treatment levels (80±21 ng/dl vs 92±13 ng/dl p <0.001). Although an increase in the plasma ghrelin levels was encountered after treatment, it was not statistically significant (152±119 pg/ml vs 164±150 pg/ml, p=0.589). When correlations of individual increases in ghrelin levels after treatment, it was not statistically significant (152±119 pg/ml vs 164±150 pg/ml, p=0.589).

When patient-based weight gains were examined, there was a positive but weak positive correlation was found between increase in ghrelin levels and weight gain.

**Summary/Conclusions:** In our study, ghrelin was significantly lower than the control group in the IDA group, suggesting that it may be the cause of loss of appetite. Ghrelin is also detected in neurons of hypothalamic arcuat nucleus, which regulates appetite. The deficiency of iron may cause deficiencies in enzymatic activities of iron dependent enzymes and it may disturb the function of these neurons. But the increase with treatment did not reach statistical significance. This may be due to physiological suppression of levels by weight gain. When patient-based weight gains were examined, there was a positive but weak positive correlation was found between increase in ghrelin levels and weight gain. More extensive and controlled studies should be designed in this regard.

SOMATIC MUTATION DYNAMICS IN HIGH-RISK MDS PATIENTS TREATED WITH AZACITIDINE IDENTIFIED VIA SERIAL SAMPLING**

K. Polgarova1, K. Vargova2, V. Kulvati2, N. Dusilova2, L. Minarik1, Z. Zemanova3, A. Jonasova1, T. Stopka1,2,

1Hematology Clinic, General Hospital, Prague, 2Biocev, Charles University, Vestec, 3Cyto genetic Center, General Hospital, Prague, Czech Republic

**Background:** Azacatidine (AZA) is a standard therapy for MDS patients with higher risk of AML transformation and not eligible to undergo transplantation. Although AZA is well tolerated the responses occurring in up to two thirds of patients are not durable. Somatic mutations were previously associated with pathogenesis of MDS, some of them also with prognosis. Several studies suggested that MDS patients as they progress may evolve new mutations and loose some of the clonal architecture detected at preceding stages (Pellegatti, Roy et al. 2016). In addition, there exist gene mutations that are detected in patients subsequently responding to hypomethylating agents (Bejar, Lord et al. 2014), which implies that there exist variants-bearing clones that persist upon AZA as well as those that do not.

**Aims:** To identify variants either persisting or not upon the AZA therapy we tracked BM samples during AZA treatment. Next, we were interested in deciphering their relationship of the dynamics in somatic variants to clinical course of the analyzed MDS patients.

**Methods:** Massive parallel sequencing with high accuracy utilized duplicate libraries from myeloid cells and included the non-tumorous T-cell controls to identify somatic mutations in the serial samples before and during AZA therapy. The tool for detecting the dynamics of somatic mutations was the TruSight Myeloid Panel that contains 54 gene regions with previously documented mutation recurrence in 439 patients (Bejar, Stevenson et al. 2011). Indeed, 92% of our MDS cohort bore at least one somatic mutation with mostly 4 mutations per patient (range 1-9), which indicated that the MDS patients were already at relatively progressed state (Papaemmanuil, Gerstung et al. 2013).

**Results:** Analysis of 38 patients treated with AZA (reaching median OS 24 months (Mo) with 60% hematological improvement) revealed 125 somatic variants with VAF over 5%. Adverse effects of variants in cooperating regulators of DNA damage and cell cycle were confirmed: TP53 (OS on AZA 14.8 Mo), CDKNA24 (12.3 Mo), EZH2 (11 Mo). Besides the stable variant’s allele frequency (50%<VAF<200%) there existed four additional VAF profiles. Stable variants’ dynamics precluded putative AZA-resistant clones associated with shorter survival (19 Mo). In contrast, the patients bearing variants with decreasing VAF, which supposedly were inhibited by AZA, lived longer (31 Mo). Interestingly, small group of highly dynamic variants upon AZA therapy formed a subgroup with longer-lasting complete remissions.

**Summary/Conclusions:** Our work support the importance of catalogization of somatic variants to delineate pathogenesis of MDS with a focus on molecular AZA responsiveness. Several types of variant dynamics during the AZA therapy were noted by using the massive parallel sequencing approach of the duplicate libraries from MDS BM samples also utilizing non-tumorous controls and serial sampling. Stable dynamics was found in variants previously recorded by COSMIC and targeting the adverse outcome genes such as TP53, BCR/ABL1, ASXL1, and EZH2 as well as their combinations with TET2 that may potentially mediate clonal selection of additional variants mediating progression during AZA therapy.

**WHOLE GENOME MBD-SEQ REVEALS DIFFERENT CPG METHYLATION PATTERNS IN AZACITIDINE-TREATED JUVENILE MYELOMONOCYTIC LEUKEMIA (JMML) PATIENTS**

P.P. Leoncini1,2, P. Vitullo1, F. Di Florio1, V. Tocco1, M.P. Cefalo1, A. Pitisci1, K. Girardi1, C. Niemeyer2, F. Locatelli1, A. Bentaima1

1Oncohaematology, Bambino Gesù Children Hospital, Roma, Italy, 2Pediatrics-Oncohematology, University of Freiburg, Freiburg, Germany

**Background:** Juvenile Myelomonocytic Leukemia (JMML) is a rare and aggressive leukemia of early childhood. Allogeneic hematopoietic stem cell transplant (HSCT) is the only available curative treatment, but, since disease recurrence is responsible for treatment failure in at least one third of transplanted patients, developing alternative therapeutic approaches is desirable. Aberrant DNA methylation is a key molecular feature of JMML, suggesting an important role of epigenetic changes in the pathophysiology of the disease. Azacitidine (AZA), a molecule that inhibits DNA methylation in human cells, is under investigation in JMML.

**Aims:** Here we report, for the first time, a global evaluation of DNA methylation status of CD34+ cells deriving from JMML patients before and after AZA treatment and compared the results with those of healthy controls. Identifying differentially methylated CpG islands linked to various genes will help us describe...
an epigenetic aberrant paradigm possibly involving transcriptional and transla-
tional regulation in JMML.

Methods: CD34+ cells isolated from 3 JMML patients samples collected at diag-
nosis (t0) and after the third cycle of AZA (t1) were evaluated together with those of 3 healthy donors (HD). JMML patients have been treated with AZA on a com-
passionate use basis after obtaining signed informed consent. DNA samples were processed and Ion fragment libraries were prepared. MBD-seq, bioinfor-
matics and statistical analysis were performed by Genomnia srl (Bresso, Italy).

Results: First, we compared 10 JMML cells with HD cells, finding 987 different transcriptional units corresponding to 714 coding and 273 non-coding sequences. We also compared DNA methylation between t0 and HD cells. In this comparison, 644 unique transcriptional units, including 468 coding and 176 non-coding sequences, were found. Hypermethylation in JMML samples com-
pared to HD was detected, but, unexpectedly, t0 vs t1 methylation analysis did not show any significant result, suggesting a likely unspecific patient-related pharmacological effect. Notably, 453 coding and 165 non-coding differentially methylated regions are shared between t0 vs HD and t1 vs HD sets. More in detail, 261 and 15 coding regions and 107 and 10 non-coding regions were uniquely found in t0 vs HD and t1 vs HD sets, respectively. However, 439 coding and 161 non-coding genomic regions preserve their hypermethylated status, probably due to a mechanism of resistance to AZA treatment. Among non-cod-
ing elements, we found different RNA species, such as microRNAs, splicing RNAs, lincRNAs/antisense transcripts (AS) and other unknown RNAs. Retro-
transposons, belonging to LINEs and SINEs families, were also screened. We iden-
tified 13 sequences with a significant differential methylation profile in both t0 and t1 vs HD. Again, a comparison between t0 and t1 groups did not show any significant difference. Eleven hypermethylated common LINEs were evident between t0 vs HD and t1 vs HD sets. Two retrotransposons with opposite methylation patterns were found in t0 vs HD and t1 vs HD sets; while in the first comparison they included LINEs, in the second one they are 1 hypermethylated LINE and 1 hypomethylated SINE.

Figure 1.

Summary/Conclusions: In conclusion, the whole genome MBD-seq per-
formed for the first time on JMML CD34+ bone marrow derived cells, showed a broad genomic hypermethylation both in pre- and post-AZA samples com-
pared to HD, suggesting a patient-specific AZA-effect. Transcription and trans-
lation processes of coding and non-coding genes could be deregulated in mul-
tiple ways, due to heterogeneity of sequences involved in CpG islands hyper-
methylation. Moreover, due to their known ability to insert random mutations in

the genome, retrotransposons should be candidate for further studies in JMML pathogenesis.

RESPONSE MONITORING IN MDS WITH DEL(5Q) USING DIFFERENT FLOW CYTOMETRIC (FCM)-SCORES IN COMPARISON TO CYTOGENETICS

U. Oelschlaegel1,*, T.M. Westers 2, B. Mohr 1, D. Subira 3, U. Johansson 4, G. Ehninger1, M. Bornhäuser 1, A.A. van de Loosdrecht2, U. Platzbecker1
1Medical Clinic and Polyclinic I, MK1-L06, University Hospital of Tu Dresden, Dresden, Germany, 2Department of Hematology, VU University Medical Center, Amsterdam, Netherlands, 3Department of Hematology, Hospital Universitario de Guadalajara, Guadalajara, Spain, 4Department of Hematology, University Hospitals NHS Foundation Trust., Bristol, United Kingdom

Background: Flow cytometry (FCM) is one part of integrated MDS diagnostics. Different well established FCM-scores are applied, as FCSS (Wells et al. 2003), Ogata-score (Ogata et al. 2012), new iFS (Cremer et al. 2017), and del(5q)-
FCM-score (Oelschlaegel et al. 2015).

Aims: The aim of this prospective study was to test, which of the mentioned FCM-scores fits best for response monitoring in del(5q) MDS in comparison to cyto-
genetics.

Methods: Overall, 245 FCM investigations were performed in 61 patients with MDS and del(5q) (IPSS-R very low/low: n=26, int: n=13, high/high very high n=22) including 42 patients with isolated del(5q) or one additional cytogenetic abnor-
mality. The majority of analyses were performed in patients receiving lenalido-
amide or azacitidine (n=29 and n=22 patients), or in patients receiving chemotherapies/and or allogeneic transplantation or growth factors (n=10). Stan-
dardized FCM (lyse-stain-wash) and cytogentic/FISH procedures were per-
formed according to ELN guidelines at the TU of Dresden, VUMC of Amster-
dam, UH of Guadalajara and UH of Bristol. Cytogenetics/FISH analysis was con-
sidered the gold standard of all the applied FCM-scores, propagated by the ELNet MDS working group. Additionally, hematological improvement of the erythroid lineage (H-E) was evaluated (Cheson et al. 2006).

Results: The del(5q)-FCM-score reflected best the disappearance / presence of the cytogenetic abnormality del(5q) with a sensitivity of 98% and a specificity of 82%. This was confirmed if only MDS with del(5q) was considered (80% and 85%) or only MDS treated with Lenalidomide were evaluated separately (sensitivity: 98% and 100%; specificity: 85% and 75%). The use of the Ogata-score con-
sidering almost only abnormalities of the myeloid progenitors, ended up with a slightly lower sensitivity (86%) and specificity (81%). The new iFS analyzing progenitor cells, granulo-, mono-, and erythropoiesis showed a comparably high specificity (83%) but a slightly impaired sensitivity (72%). FCSS, analyzing dyspoiesis of multiple cell lineages, showed a response in less than half of all investigations being in cytogenetic CR (sensitivity: 41%), but revealed a high specificity (91%). The analysis of HI-E was high sensitive (81%) but not as speci-
cific (62%). Next, we investigated the potential prognostic impact of response monitoring using various FCM-scores compared to cytogenetics. Considering all del(5q) MDS patients as well as only those patients with del(5q) as a single abnormality, cytogenetics and all tested FCM-scores showed a significantly longer OS for MDS responding to therapy. The highest prognostic impact dis-
played the del(5q)-FCM-score (p=0.0019) and Ogata-score (p=0.0092), respectively. Eval-
uating only MDS treated with lenalidomide, response monitoring using FCSS separated best the OS curves (p=0.0080). Finally, we combined the evaluation of HI-E with cytogenetics or the FCM-scores. This resulted in an even better OS for MDS fulfills two response criteria vs none, showing the highest prognostic impact for the combination of HI-E plus the new iFS (p=0.0010).

Summary/Conclusions: Flow cytometry might serve as a rapid tool for response monitoring during treatment with disease-modifying drugs. All estab-
lished FCM-scores allowed for an at least similar correctness of response pre-
diction. The prognostic impact of the various FCM-scores seems to be even higher than that of cytogenetic response evaluation in this MDS subgroup. One reason might be, that most of the FCM-scores reflect not only the genetic back-
ground of the MDS but dyspoietic alterations in various cell lineages of the hematopoietic system.

EVALUATION OF MUTATIONS AT RELAPSE IN MYELODYSPLASTIC SYNDROME PATIENTS RECEIVING ALLOGENEIC STEM CELL TRANSPLANTATION

M. Cabrero1,*, J.M. Hernandez-Sanchez1, J.M. Caballero1, C. Chillon1, M. Martin-Izquierdo1, M. Abaigar1, A. Redondo2, F. Lopez-Garca3, E. Perez-
Lopez1, L. Lopez-Corral1, R. Benito1, C. Robledos1, M. del Rey1, M. Gonzalez1, C. del Caiz1, D. Caballero1, J.M. Hernandez-Rivas1, M. Diez Campelo1
1Hematology Department, Hospital Universitario de Salamanca-IBSAL, Sala-
manca, Spain

Background: Allogeneic transplant (AlloSCT) is the only curative therapy for myelodysplastic syndromes (MDS). Unfortunately, relapse is the main cause of treatment failure. Evaluation of genetic mutations both at diagnosis and
Before allo-SCT is a potent prognostic tool. However, mutational profile at relapse after allo-SCT has not been wide explored.

**Aims:** In this study, we evaluate mutational profile at post-Allo-SCT relapse in MDS patients to determine if pre-Allo-SCT mutations are still present at relapse, so we could eventually monitor them as minimal residual disease (MRD) after allo-SCT.

**Methods:** From a retrospective cohort of 115 patients, we selected those who relapsed post-Allo-SCT (19/115, 16.5%) with available material at relapse (18 patients). We performed an in-house target-capture panel, sequencing across selected exons of 117 cancer-related genes previously related to MDS in pre-Allo-SCT samples to identify genetic mutations and we checked the presence of those mutations in samples at relapse. Six patients were discarded because lack of pre-Allo-SCT mutations, so we selected 12 patients for the sequential study. DNA was amplified with FastStart High Fidelity PCR System using exon-specific primers for each mutation. The indexed paired-end library was prepared with Nextera XT DNA Sample Preparation Kit (Illumina) The median coverage per base achieved was 4570 reads (range 2401-8573). In a second step, we explore the possibility of evaluating mutations in both CD34 positive and the rest of bone marrow cells, to check if we could increase the sensitivity of the detection.

**Results:** Median age of relapsed patients was 60 (45-70). Diagnosis were RAEB (6), RAEB-1 (4), RAEB-2 (4), dysplasia associated AML (2) and RCMD (2). They relapse post-Allo-SCT after a median of 2.5 months (1-7), and 4 of them are alive at last follow up after a median of 22 months (9-33). Patients had a median of 2.5 mutations (range 1-4), TET2 mutations were detected in 4 (33%) of patients; U2AF1, EZH2, SRSF2, KRAS, JAK2 and RUNX1 in 1 (8%) (Table 1). In 10 out of 12 evaluated patients, we found same genetic mutations at relapse compared with pre-Allo-SCT sample (Table 1). In addition, mutational pattern was similar for all patients except for one in which dominate mutation at relapse was SRSF2 present in 14% of cells pre-Allo and in 3% at relapse) instead of TET2 (51% pre-Allo-SCT and 0.6% at relapse). In 2 patients, pre-Allo-SCT mutations were not detected at relapse (Patient 8: BCOR and RUNX1. Patient 11: SRSF2, TET2 and RUNX1). In a second step, we searched for mutations in CD34 positive cells to check its sensitivity to detect genetic alterations. We selected CD34 positive cells in one patient with KRAS and IDH2 mutations pre-Allo-SCT. KRAS and IDH2 were present in 40% and 45% of CD34 positive cells and in 37% and 48% of the bone marrow (CD34 depleted) compartment respectively in pre-Allo-SCT samples. In relapse samples, mutations were present in similar percentage in CD34 positive cells compared to CD34 depleted bone marrow (KRAS 0.63% and 2.23%, IDH2 1.6% and 1.45% respectively).

**Table 1.**

**Summary/Conclusions:** Post-Allo-SCT relapsing MDS show same genetic mutations found in pre-Allo-SCT evaluation, so they would potentially be used to confirm clonality and probably MRD assessment after allo-SCT in the near future. CD34 selection does not provide additional sensitivity to whole bone marrow cellularity sample.

**E1170**

**RIGOSERTIB COMBINED WITH AZACITIDINE EPIDEMIOGENICALLY MODULATES CHROMATIN AND HEMATOPOIETIC STEM CELL POPULATIONS IN THE MDS CONTEXT.**

P. Chaurasia1, S.C. Navada1, R. Ochlimar-Reissig1, E.P. Demakos1, P. Reddy1, L.R. Silverman1,2

1Cahn School of Medicine, Mount Sinai, New York, United States

**Background:** Azacitidine (AZA) is the standard of care for patients (pts) with higher-risk MDS; however, only 50% of pts respond and the majority will relapse within 2 years. All pts ultimately fail treatment due to primary or secondary resistance. RIGosertib (RIG) is a “ras mimic” agent that binds to the Ras Binding Domain of RAF kinases and inhibits the RAS-RAF-MEK and the PI3K pathways. Initial results of an ongoing Phase III study with RIG combined with AZA in pts with MDS demonstrated a response rate of 78%; overall; 62% in pts following hypomethylating agent (HMA) failure and 85% in HMA naive pts (Navada et al ASH 2016).

**Aims:** To investigate the in vitro effects of RIG combined with AZA or vorinostat (VOR) on epigenetic and stem cell pathways on two cell lines: AML (BW90), MDS (MDS-L) and on pb bone marrow samples.

**Methods:** We investigated the in vitro effects of RIG combined with AZA or vorinostat (VOR) on two cell lines: AML (BW90), MDS (MDS-L) and on pb bone marrow samples. Treatment with RIG alone altered global histone post-translational modifications (PTMs) including methylation (H3K4me3, H3K4me2, H3K27me3, H3K27me2) and acetylation (H3K9ac, & H3K18ac) levels associated with transcriptional activation or repression in both the cell lines and pt samples. Q-PCR studies demonstrated that individual treatment of BW90 and MDS-L with RIG or combined with AZA or VOR in sequential treatment (AZA/RIG, RIG/AZA, VOR/RIG or RIG/VOR) altered DNA methyltransferases (DNMT1, 3a and 3b), the class I, II and IV histone deacetylases (HDACs), and chromatin remodeler (KDM2a, SET1, JMJD3 and LRDW1) transcript levels in a cell line specific context. Sequential treatment of RIG with AZA or VOR demonstrated differential expression of the association (Pol II) with the association (Pol II) with the association (Pol II) with allele specific hypermethylated marks (H3K4me3 and H3K4me2) in both cell lines. An overall decrease in association of Pol II/H3K4me2 was observed with the combinations (AZA/RIG, VOR/RIG or vice versa) in MDS-L and BW-90, 10-33% (ANOVA, p<0.0006), 9-20% (ANOVA, p=0.0004), respectively. Significant differences were observed in pre-AlloSCT samples to identify genetic mutations and we checked the presence of those mutations in samples at relapse.

**Results:** Treatment with RIG alone altered global histone post-translational modifications (PTMs) including methylation (H3K4me3, H3K4me2, H3K27me3, H3K27me2) and acetylation (H3K9ac, & H3K18ac) levels associated with transcriptional activation or repression in both the cell lines and pt samples. Q-PCR studies demonstrated that individual treatment of BW90 and MDS-L with RIG or combined with AZA or VOR in sequential treatment (AZA/RIG, RIG/AZA, VOR/RIG or RIG/VOR) altered DNA methyltransferases (DNMT1, 3a and 3b), the class I, II and IV histone deacetylases (HDACs), and chromatin remodeler (KDM2a, SET1, JMJD3 and LRDW1) transcript levels in a cell line specific context. Sequential treatment of RIG with AZA or VOR demonstrated differential expression of the association (Pol II) with the association (Pol II) with the association (Pol II) with allele specific hypermethylated marks (H3K4me3 and H3K4me2) in both cell lines. An overall decrease in association of Pol II/H3K4me2 was observed with the combinations (AZA/RIG, VOR/RIG or vice versa) in MDS-L and BW-90, 10-33% (ANOVA, p<0.0006), 9-20% (ANOVA, p=0.0004), respectively. **Summary/Conclusions:** Post-Allo-SCT relapsing MDS show same genetic mutations found in pre-Allo-SCT evaluation, so they would potentially be used to confirm clonality and probably MRD assessment after Allo-SCT in the near future. CD34 selection does not provide additional sensitivity to whole bone marrow cellularity sample.
Aims: To confirm that the cellular expression of nucleoside metabolizing enzymes plays a major role in cellular resistance and significantly impacts on clinical response to azacitidine.

Methods: Two cell lines, SKM1 sensitive (SKM1-S) and SKM1 resistant (SKM1-R) to azacitidine, were analyzed for expression of UCK1, UCK2, hENT1, hCNT3, RRM1 and RRM2 by quantitative PCR. Corresponding proteins were evaluated in the cell lines. One patient and UCK2 was blunted by siRNAs in SKM1 sensitive cells to determine their role in in vitro sensitivity to azacitidine. For UCK1 and UCK2 silencing in SKM1-S, specific siRNAs were used (OnGene Technologies, MD, USA); cells were cultured at a density of 600x10^5 cells/ml in 5 ml of RPMI 1940 medium. After 72 h of transfection, cells were treated for further 48h with azacitidine at the concentrations of 0.1 and 1 μM. After assessment of effective gene silencing, apoptosis and cell cycle arrest were evaluated, respectively by Annexin V test and Propidium iodide. In parallel, the percentage of 5-methylcytosine was quantified by ELISA assay (Global DNA Methylation LINE-1 kit ActiveMotif, CA, USA). Results: UCK1 and UCK2 expression were evaluated prospectively in 18 IPSS high risk MDS patients treated with azacitidine 75mg/m2/day every 28 days. Furthermore, UCK1 and UCK2 expression was evaluated in 37 patients (classified as 26 responder and 29 non-responder) treated with azacitidine, by RhQeQ analysis using DESeq.

Results: SKM1-R cells did not express UCK1, hCNT3, RRM1 and RRM2. Corresponding proteins were also not expressed. A reduction of apoptosis was observed in UCK1-silenced SKM1-S after azacitidine 0.1 μM treatment: 35.5%±0.57% Annexine V-positive cells versus 25%±0.35% (P=0.031) in non-silenced control SKM1-S cultures. We observed a reduction of apoptosis due to UCK2-silencing after azacitidine 0.1 μM treatment too: 31%±0.85% Annexin V-positive cells versus 21%±0.35% (P=0.054). Hypomethylation induced by in vitro azacitidine treatment was also hampered by reduction of expression of UCK1 and UCK2. Quite surprisingly gene expression of UCK1, UCK2, hENT1, hCNT3, RRM1, and RRM2 and the corresponding proteins are absent in azacitidine-resistant cell line SKM1-R suggesting to be the determinant of the induced resistance to azacitidine. RNAseq analysis for UCK1 and UCK2 did not find any differences between responder and non-responder patients.

Summary/Conclusions: We demonstrated that UCK1, UCK2, hENT1, hCNT3, RRM1 and RRM2 and the corresponding proteins are absent in azacitidine-resistant cell line SKM1-R suggesting to be the determinant of the induced resistance to azacitidine. RNAseq analysis for UCK1 and UCK2 did not find any differences between responder and non-responder patients.

E1174 FAMILIAL TIN2 N-TERMINAL LOSS OF FUNCTION MUTATION IN TELOMERE SYNDROME

D. Di Giacomo1,2, V. Nofrini1, T. Iannotti1, M. Quintini1, F. Pellanera1, G. Barba1, C. Matteucci1, S. Ballanti1, R. Pizzaa2, C. Mecucci1
1Haematology and Bone Marrow Transplantation Unit, University of Perugia, Perugia, 2Medicine and Surgery, University of Milano-Bicocca, Milan, Italy

Background: The shelterin complex protects telomeres from being processed by the DNA damage repair machinery and regulates telomere access and activity (Frank 2015). TIN2F (14q12) is encoding for TIN2, the central component of the shelterin telomeric complex which interacts with other members of the complex (TRF1,TRF2 and TPP1), thus contributing to telomere length regulation and structural integrity (Frank 2015). About thirty TIN2F mutations are known in Dyskeratosis Congenita (DC) (Savage 2008) and other telomere related phenotypes, i.e. aplastic anemia (AA), idiopathic pulmonary fibrosis, liver cirrhosis, myelodysplastic syndromes (MDS) and acute myeloid leukemia (Ambrosi 2012). All mutations were missense and heterozygous, clustering in exon 6 encoding for a highly conserved segment at the C-terminus (aa 280–291) (Frank 2015).

Aims: Precise diagnosis in AA/MDS with clinical features of telomere syndrome.

Methods: AA was diagnosed in a 68-year-old man with a multisystem disorder, i.e. psoriasis, nail dystrophy, severe osteoporosis, chronic hepatitis, mild chronic kidney failure and hypertension, suggesting a telomere syndrome. Karyotype was normal. Patient was unresponsive to immune-suppressive therapy. DNA from peripheral blood and hair bulbs was analyzed for TERT, TERC and hTERT by qPCR. For the expression of TIN2F and the corresponding protein, RT-PCR and Western Blotting were performed on peripheral blood mononuclear cells (PBMCs) isolated from healthy donors and patients. Mutations were detected by Sanger sequencing and identified by Sanger sequencing, respectively.

Results: A 68-year-old man with AA was analyzed with and without panel. The expression of TIN2F and the corresponding protein, RT-PCR and Western Blotting were performed on peripheral blood mononuclear cells (PBMCs) isolated from healthy donors and patients. Mutations were detected by Sanger sequencing and identified by Sanger sequencing, respectively.

E1173 RESISTANCE TO AZACITIDINE IS DETERMINED AT CELLULAR LEVEL BY LOWER EXPRESSION OF NUCLEOSIDE ACTIVATING ENZYMES UCK1 AND UCK2

E. Masala1,2, A. Valencia1, A. Brogi1, A. Sanna1, M. Torres Martin2, M. Figueroa2, E. Masala1,*, A. Valencia1, A. Brogi1, A. Sanna1, M. Torres Martin2, M. Figueroa2, A. Sanna1, M. Torres Martin2, M. Figueroa2, A. Brogi1, A. Sanna1, M. Torres Martin2, M. Figueroa2, E. Masala1,*, A. Valencia1, A. Brogi1, A. Sanna1, M. Torres Martin2, M. Figueroa2
1Haematology and Bone Marrow Transplantation Unit, University of Perugia, Perugia, 2Medicine and Surgery, University of Milano-Bicocca, Milan, Italy

Background: Azacitidine is at present the standard treatment for MDS. We demonstrated that MDS patients responsive to azacitidine have significantly higher intracellular expression of the azacitidine-activating enzyme uridine-cytidine kinase-1 (UCK1) in bone marrow mononuclear cells (Valencia et al. Leukemia 2014). Correlation of the expression of nucleoside transporter, activating and deactivating enzymes with clinical activity of azacitidine and decitabine has been suggested by several authors. Yet, the crucial role of these enzymes has to be ascertained, as well as their possible different importance in determining resistance to azacitidine.
E1175
FUNCTIONAL EXPRESSION OF TIM-3 AND CLINICAL SIGNIFICANCE OF PLASMA GALACTEIN-9 LEVELS IN MYELODYSPLASTIC SYNDROMES

T. Asayama1, M. Ishibashi1, H. Tamura1, Y. Kunibayashi-Hamada1, N. Takada-Okuyama1, A. Ondera-Kondo1, K. Moriya1, N. Yokose2, K. Inokuchi1,
1Dorris (n=9) using ELISA, Department of medicine, Nippon Medical School, Tokyo, 2Division of hematology, Department of internal medicine, Chiba Hokusoh Hospital, Chiba, Japan

Background: T-cell immunoglobulin and mucin domain-3 (Tim-3) is an inhibitory immune checkpoint molecule that suppresses adaptive immunity by binding with galectin-9 (gal-9). The Tim-3-gal-9 pathway is associated with self-renewal of leukemia stem cells in acute myeloid leukemia (AML), although the function of the axis in myelodysplastic syndromes (MDS) remains unclear.

Aims: To clarify the expression and function of Tim-3 and clinical impact of the ligand gal-9 in MDS.

Methods: 1) We evaluated Tim-3 expression on CD45-gating blasts of bone marrow mononuclear cells (BMMCs) in 20 patients with MDS and AML transformed from MDS (AL-MDS), 12 healthy controls, and 4 MDS cell lines using flow cytometry (FCM). 2) To investigate Tim-3 induction, MDS cell line F-36P cells were co-cultured with the culture supernatant of human stromal cells and PBMCs obtained from AL-MDS patients. Soluble extracellular Ki-67 expression in F-36P cells, suggesting that Tim-3 signaling 3 induction was abrogated by adding the TGF-β receptor I kinase inhibitor dorsomorphin (DM). 4) To investigate the proliferative potential of Tim-3 signaling, intracellular Ki-67 expression in F-36P cells was evaluated using FCM when co-cultured with/without anti-Tim-3 blocking antibody. 5) Finally, we analyzed gal-9 concentrations in culture supernatants of MDS cells and in plasma obtained from patients with MDS (n=51) and AL-MDS (n=19), and healthy donors (n=10).

Results: 1) Tim-3 expression was observed on monocytes and CD45-gating blasts in MDS BMMCs and in all 4 MDS cell lines. In AL-MDS patients, Tim-3 expression levels on blasts were markedly higher than in controls and MDS patients who failed to meet the IPSS criteria for MDS. 2) Intracellular Ki-67 expression in F-36P cells co-cultured with the culture supernatant of human stromal cells and the MDS-related cytokine transforming growth factor-β1 (TGF-β1). Tim-3 cell-surface protein and mRNA expression in MDS cell lines was induced by co-culture with TGF-β1. The Tim-3 induction was abrogated by adding the TGF-β receptor I kinase inhibitor SB431542. 3) Microarray analysis showed 572 upregulated genes (>2-fold difference) and 304 downregulated genes (<0.5-fold difference) in Tim-3 F-36P cells compared with Tim-3− cells, and gene expression analysis (GSEA) showed enrichment of pathways involved in cell proliferation and antiproliferative responses in Tim-3+ cells. 4) The blockade by anti-Tim-3 antibody decreased intracellular Ki-67 expression in F-36P cells. 5) Co-immunoprecipitation experiments showed that the new Tim-3-gal-9 binding with TRF2 in vitro.

Summary/Conclusions: A new TIMF2 gene variant at exon 2, c.254A>G p.H85G, was identified in the proband and in two brothers. Screening on 200 healthy donors was negative. Significantly short telomeres were found in proband (p=0.0161) and brothers (p=0.0082 and p<0.0001), compared to age and sex matched controls. The proband had a normal SNP's profile and WES identified an additional somatic mutation in TLR1 gene (c. 1859G>A. p.R620Q). Co-immunoprecipitation experiments showed that the new TIMF2 mutation reduced TIM2 binding with TRF2 in vitro.

E1176
PROGNOSTIC SIGNIFICANCE OF GENE MUTATIONS IN MDS DEPENDS ON THE LOCUS OF GENE VARIANCES

T. Boneva1, L. Rai1, D. Brazma1, R. Dunn1, C. Grace1, E. Nacheva1, 1OncoGenomics, HSL Analytics LLP, 2Cancer Institute, UCL, LONDON, United Kingdom

Background: Myelodysplastic syndromes are a collection of clonal hematopoietic disorders with a wide range of clinical manifestations and eventual outcomes. Predicting the prognosis is of great importance for defining the risk and selecting the proper therapeutic options. Therefore, identification of risk stratifying paradigms, all of which include genetic markers along with other clinical and paraclinical features. The Revised International Prognostic Scoring System (IPSS-R, Greenberg et al., Blood, 2012;120(12): 2454-2465) defines 5 risk levels based on the presence of specific chromosome abnormalities. These genome aberrations provide evidence for disease although reports of frequent driver mutations (Papenau et al., Blood, 2013) and/or structural variants detected by single nucleotide polymorphism (SNP) arrays (Cara et al., Blood, 2015) have shown a potential for score criteria in the diagnosis of MDS. Recent reports of the presence such genome aberrations in disease free individuals makes this approach problematic (Ghosh et al., N Engl J Med 2014; Lichman, Blood 2015, Kwok et al., Blood 2015). A study of patients without evidence for MDS identified a driver mutation and/or structural gene variants in 91% of pre-diagnostic samples with the mutational spectrum mirroring that seen in MDS population (Cargo et al., Blood, 2015). The presence of mutations with greater median variant allele fraction (40% vs.9% to 10% in healthy individuals) and occurring with additional mutations (>2 mutations, 64% vs. 8%) were shown to define a high-risk group with a shorter time to disease progression and poorer overall survival.

Aims: To compare the genomic profile of bone marrow from 145 adults, 70 of whom met the WHO criteria for MDS.

Methods: All samples were screened by chromosome G banding or molecular karyotyping using 8x60K oligonucleotide arrays (Agilent, USA) or screened by FISH using probes (CytoCell, UK) targeting the most common aberrations associated with MDS as per IPSS-R classification (Greenberg et al., Blood, 2013). The commercially available target gene panel TruSight on a MSq platform (Illumina, USA) was used to screen mutational hotspots in 5 cancer-related genes relevant in myeloid malignancy. Genes were variances at allele frequencies (VAF) >10% and at minimum read depth of 300 as per manufacturers criteria. We used the Catalogue of Somatic Mutations In Cancer (COSMIC), dbSNP and 1000 genome (2%) to classify gene variants as either drivers, variants of unknown significance and genome polymorphisms (SNPs).

Results: A total of 145 bone marrow samples from 58 women and 87 men, aged from 26 to 85 suspected to have myeloid dysplasia were investigated. Of these only 76 (52%) were found to fulfill the WHO criteria, the rest as MDS positive. Genotype variances were detected in all but 7 (4%). The latter are void of gene mutations. We observed driver mutations as reported in myelomas malignancies in 68 (47%) samples whilst 70 (48%) were found to carry the same variances seen in disease free individuals or of unknown significance. As expected driver variances were not identified in any of the samples that failed the WHO criteria for MDS. Variances were detected in all samples for 35 of the 54 genes targeted by the TruSight mieloid panel. In order of frequency these are TET2, SRSF2, ASXL1, CUX1, DNM3A, RUNX1, BCR1 and HRA5, seen in more than 10% of samples, while the rest were less frequently reported. The aberrant genes ASXL1, TET2 and SRSF2 figured prominently in both groups of samples with comparable driver variances in samples with and without disease although reports of frequent driver mutations (Papenau et al., Blood, 2015) have shown a potential for score criteria in the diagnosis of MDS. Recent reports of the presence such genome aberrations in disease free individuals makes this approach problematic (Ghosh et al., N Engl J Med 2014; Lichman, Blood 2015, Kwok et al., Blood 2015). A study of patients without evidence for MDS identified a driver mutation and/or structural gene variants in 91% of pre-diagnostic samples with the mutational spectrum mirroring that seen in MDS population (Cargo et al., Blood, 2015). The presence of mutations with greater median variant allele fraction (40% vs.9% to 10% in healthy individuals) and occurring with additional mutations (>2 mutations, 64% vs. 8%) were shown to define a high-risk group with a shorter time to disease progression and poorer overall survival.

Summary/Conclusions: We compared 145 bone marrow samples from patients presenting with MDS of which 76 met the WHO criteria. There is little difference in their genomic profile when comparing the two groups on the basis of the most highly involved genes (ASXL1, TET2 and SRSF2) but if we compare the two groups by variance, 9 variances are exclusively associated with MDS positive disease.

SUPPRESSION OF DNA METHYLTRANSFERASE ENZYMES BY A NOVEL HYPMETHYLATING AGENT, SG-1027, IS AUGMENTED IN DECITABINE-RESISTANT CELL LINES

E.-H. Hur1, D.R. Choi2, B.-K. Goo1, J.H. Moon1, E.-J. Choi1, H.-S. Park1, J.-H. Lee1, K.-H. Lee1, J.-H. Lee1
1Hematology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, 2Internal Medical, Choncheong Sacred Heart Hospital, Choncheong University College of Medicine, Choncheon, Korea, Republic Of

Background: We established azacitidine- and decitabine-resistant cell lines, MOLM/aza-1 and MOLM/dec-5 from MOLM-13, an acute myeloid leukemia cell line (OncoCell in press). DNA methyltransferase (DNMT) 3B was upregulated in the resistant cell lines.

Aims: We tried to find out clues to overcome the resistance to hypomethylating agent (HMA).
Methods: Besides azacitidine and decitabine, three other agents (SGI-1027, zebularine, and gemcitabine) are known as having hypomethylating effect. In vitro activities of the 5 HMA’s on HMA resistant cell lines (MOLM/AZA-1 and MOLM/DEC-5) were tested by cell viability assay using luminescent-based CellTiter-Glo system. Protein and mRNA levels of DNMT enzymes (DNMT1, 3A, and 3B) were assayed before and after treatment of each HMA. Proteosomal degradation and activation of p-Akt were also determined to see the correlation with changes of DNMT’s.

Results: Although azacitidine and decitabine could suppress DNMT1 and DNMT3A in MOLM-13, the agents could not suppress DNMT enzymes in resistant cell lines. Inhibition of proteosomal degradation by bortezomib induced accumulation of DNMT enzymes in MOLM-13, whereas it did not accumulate the enzymes in MOLM/AZA-1 and MOLM/DEC-5. Phosphorylated Akt (p-Akt) was dramatically overexpressed in MOLM/AZA-1 and MOLM/DEC-5. SGI-1027 showed the lowest IC_{50} values for MOLM/AZA-1 and MOLM/DEC-5, and it suppressed the protein levels of all three DNMT enzymes. SGI-1027 could also decrease the level of p-Akt. GDC-0941, a PI3K inhibitor, suppressed DNMT1 and DNMT3A as well as p-Akt, but it could not decrease DNMT3B in MOLM/AZA-1 and MOLM/DEC-5. Cell viability assay showed the synergistic effects of combination of GDC-0941 and Nanomycin A, a specific DNMT3B inhibitor, in MOLM/AZA-1 and MOLM/DEC-5.

Summary/Conclusions: DNMT levels of MOLM/AZA-1 and MOLM/DEC-5 were not dependent on proteosomal degradation. DNMT1 and DNMT3A might be regulated via PI3K-Akt pathway, while regulation of DNMT3B might be different from DNMT1 and DNMT3A. SGI-1027 appears to exert inhibitory effects on MOLM/AZA-1 and MOLM/DEC-5 by inhibition of both p-Akt and DNMT3B.

MECHANISTIC HIGHLIGHTS OF IMPROVED ERYTHROPOIESIS WITH A LOW DOSE OF DEFERASIROX IN LOW RISK MYELODYSPLASTIC SYNDROMES

M. Matheu1,2,*, S. Ancelet3, C. Lefebvre3, J. Arnaud4, C. Garel2, M. Pezet2, Y. Wang2, P. Faure4, G. Szymanski3, B. Polack2, J. Y. Cahn12, J. M. Moulin1,7,8, S. Park2,4

Background: Myelodysplastic syndromes (MDS) are a group of heterogeneous clonal stem cell disorders leading to ineffective hematopoiesis. Anemia is a frequent cytopenia in MDS and the majority of patients requires red blood cell (RBC) transfusion resulting in the development of iron overload (IO). Deferasirox (DFX) became a standard treatment of IO in MDS and seems to have positive effects on hematopoiesis with a reduced need of RBC transfusion.

Aims: Decipher the mechanisms of the potential improvement of erythropoiesis with DFX.

Methods: We report our in vitro data about the proliferation, cell cycle, apoptosis, erythroid differentiation, and cell signaling pathways concerning CD34+ hematopoietic stem progenitor cells from low risk MDS samples in a 2-step erythroid differentiation liquid culture with low dose DFX and iron overload.

Results: We observed a higher proliferation rate for cultures with 3µM DFX versus the control condition (p=0.038). In contrast, no increased proliferation was found with DFX>5µM and with other chelators used in the clinic. The higher proliferation rate with DFX 3µM was due to the combination of decreased apoptotic cells at day 10 (D10) (p=0.03) and D14 (p=0.007) and increased cycling cells at D10 (p=0.0001). Regarding clonogenic assays, there were more CFU-E colonies with DFX 3µM (p=0.04). Despite the low concentration of DFX, cells exposed to DFX 3µM had a lower intracellular iron concentration measured by ICP-MS than control cells (p=0.019). Nevertheless, this decreased iron amount was not sufficient to activate cellular iron regulation by Iron Regulatory Proteins suggesting the absence of a direct effect of low dose DFX on iron homeostasis. Moreover, low dose DFX decreased intracellular and mitochondrial reactive oxygen species (ROS) at D14 (p=0.048 and p=0.03) and decreased the level of malonaldehyde (p=0.048), a product of lipid peroxidation. Then, we have investigated which signaling pathways were sensitive to DFX 3µM. We found an increased nuclear translocation of NFκB detected by both CM (p=0.04) and luciferase reporter assay (p=0.03). NFκB activation was absent in the knock-down (KD) of mitochondrial TRX (siTRX2) condition. Moreover, in non-iron overloaded medium condition, the level of ROS was not increased, and DFX in the TRX1 KD condition was not associated with NFκB activation. These results suggest that NFκB activation in this model is linked to TRX1 and regulated by an extremely fine control of ROS levels with a likely threshold effect.

Summary/Conclusions: Our study describes the pro-proliferative effects of low dose of DFX on erythroid progenitors in low risk MDS patients. These results provide a biological rationale for a clinical trial which will propose low dose of DFX in MDS patients, refractory to erythropoiesis stimulating agents.
Aims: The aims of our study were to evaluate the diagnostic significance of erythroblast PAS positivity in MDS and to investigate a possible correlation between levels of PAS positivity and other morphological and clinical features.

Methods: We retrospectively examined the results of the cytochemical PAS staining for glycogen in BM smears from 165 patients with MDS, 116 patients with non-clonal cytopenia and 49 healthy subjects. We developed a PAS score by counting 100 nucleated cells for the erythroid lineage and classifying them according to the nature of PAS positivity. The discriminant power of both PAS positivity rate and score for MDS identification was evaluated in comparison with that of the conventional morphological features of dyserythropoiesis; then, PAS positivity was included into the morphological scoring system we have previously defined (Leukemia 2015;29:66-75).

Results: PAS positive erythroblasts were observed in 104 (63%) MDS patients, 46 (40%) patients with non-clonal cytopenia, and 12 (24%) non-erythroid lineages. PAS positivity was significantly higher in MDS patients than in normal and pathological controls, with a significant difference between MDS and non-erythroid controls (p<0.0001), but not between healthy controls and non-clonal cytopenias (p=0.09). In MDS, both positivity rates (median 2%, range 0-33) and scores (median 2, range 0-53) were significantly higher than those in normal and pathological controls (p=0.0001 and p=0.0004 for rate, p=0.0001 and p=0.0002 for score, respectively), without significant differences in relation to excess blasts or multilineage dysplasia. PAS patients with >4% ring sideroblasts (RS) showed lower PAS positivity rates and scores than MDS patients with >4% RS (p=0.0332 and p=0.0412, respectively). In MDS-RS, erythroblast PAS positivity was not influenced by SF3B1 mutation status. In MDS, no significant relationship was detected between erythroblast PAS positivity and percentage of BM blasts, percentage of BM erythroblasts, dyserythropoiesis grading, or Hb levels, whereas an inverse correlation was observed between PAS score values and internuclear bridging (r=-0.23, p=0.0395). A ROC curve analysis allowed us to identify a PAS score value of ≥1 (AUC=0.697, p=0.0008) and a PAS positive erythroblast percentage of ≥1% (AUC=0.674, p=0.0034) as optimal cutoff to discriminate MDS patients from non-erythroid cytopenias. Considering the most discriminant morphological features for dyserythropoiesis, the weight of both PAS positivity rate and score in the identification of BM dysplasia was lower than that of ring sideroblasts and -globin synthesis, but higher than that of defective hemoglobinization, nuclear lobulation, multinucleation, cytoplasmic fraying, pyknosis, and internuclear bridging. Integrating conventional parameters and PAS results significantly improved the sensitivity of our morphological scoring system.

Summary/Conclusions: The evaluation of BM erythroblast PAS positivity, easy to perform and inexpensive, may be useful in the work-up of patients with suspected MDS, especially if there is only unilineal dysplasia without ring sideroblasts or excess blasts.

A PHASE 3 RANDOMIZED PLACEBO (PBO)-CONTROLLED DOUBLE-BLIND TRIAL OF DARBEPOETIN ALFA IN LOW OR INTERMEDIATE-1 (INT-1) RISK MYELODYSPLASIC SYNDROMES (MDS)

S. Cazorla1, M. Strand1, J. Pouillot2, B. Kavanagh3, L. Maggioni4, P. Fenaux5

1Hospital University de Navarra, 2Hematology, 3Hematology, 4Hematology, 5Hematology

Background: DAR was randomized in 400 patients in 3 arms: PBO, DAR, or darbepoetin alfa Q3W for 24 weeks, with intermediate-2 (INT-2) risk patients stratified at enrollment. The primary endpoint was transfusion rate at 48 weeks. The main secondary endpoints were HI-E rate at 48 weeks and incremental transfusion-free survival (TFS) rate with Q2W dosing. Major secondary endpoints were RBC transfusion, Hb response, and safety.

Methods: Patients were randomized to PBO, or darbepoetin alfa Q3W or Q2W at the beginning of the treatment period. Dose was increased to 200 µg/week if the target Hb level was >12 g/dL, and decreased if the Hb increased by >1.5 g/dL in 3 weeks. Key endpoints were transfusion incidence and Hb-E in both PBO and DAR arms.

Results: At study entry, 147 patients were randomized to PBO and 147 to DAR. At 48 weeks, 34 patients (23%) in the PBO arm had transfused compared to 14 (10%) in the DAR arm, p=0.046. In the DAR arm, 31 patients (21%) had an Hb-E rate ≥50% compared to 19 (13%) in the PBO arm, p=0.032. The incremental TFS rate was 53% in the DAR arm compared to 42% in the PBO arm, p=0.031. No significant differences were observed in transfusion incidence or TFS rate between DAR Q3W and Q2W.

Conclusions: This study demonstrates that darbepoetin alfa Q2W is non-inferior to Q3W in terms of transfusion incidence and TFS rate and offers the clinical benefit of more frequent dosing and improved Hb-E rate at 48 weeks.

PRELIMINARY ANALYSIS OF EFFICACY AND SAFETY OF SINTRA-REV CLINICAL TRIAL, LENALIDOMIDE VS PLACEBO PHASE 3 STUDY IN LOW/INT-1 MDS PATIENTS WITH DEL(5Q) AND TRANSFUSION INDEPENDENCY

F. López Cadenas1, B. Xicoy2, J. Bargay3, G. Sanz4, M.L. Amigo5, B. Arribasalaga6, T. Bernal7, J. Bargay3, G. Sanz4, M.L. Amigo5

1Department of Hematology, Hospital Universitario de Canarias, La Laguna, Spain, 2Department of Hematology, Hospital Universitario de Canarias, Santa Cruz de Tenerife, Spain, 3Department of Hematology, Hospital Universitario de Canarias, Santa Cruz de Tenerife, Spain, 4Department of Hematology, Hospital Universitario de Canarias, Santa Cruz de Tenerife, Spain, 5Department of Hematology, Hospital Universitario de Canarias, Santa Cruz de Tenerife, Spain, 6Department of Hematology, Hospital Universitario de Canarias, Santa Cruz de Tenerife, Spain, 7Department of Hematology, Hospital Universitario de Canarias, Santa Cruz de Tenerife, Spain

Background: LEN recruited 223 patients with transfusion-dependent MDS and 5q deletion to the 48-week maintenance phase of the phase 3 study. MDS with transfusion independence due to ESAs were randomized 1:1 to placebo or LEN 10 mg daily. The primary endpoint was transfusion independence at 48 weeks. Key secondary endpoints were Hb response and TFS rate at 48 weeks.

Methods: Patients were randomized 1:1 to placebo or LEN 10 mg daily. The primary endpoint was transfusion independence at 48 weeks. Key secondary endpoints were Hb response and TFS rate at 48 weeks.

Conclusions: LEN was associated with greater transfusion independence, Hb response, and TFS rate compared to placebo at 48 weeks. These results provide a rationale for further investigation of LEN in this patient population.
Background: Lenalidomide (LEN) is the first choice of treatment in low risk MDS patients with isolated del(5q) (MDS-Del(5q)) and transfusion dependency (TD). Most of the low risk MDS-Del(5q) patients diagnosed with anaemia and independent of transfusions developed TD or needed treatment for symptomatic anaemia early after diagnosis (median of 20 months, abstract 3180.ASH, 2016). LEN directly targets the del(5q) clone improving anaemia, quality of life and survival in these subset of patients. For these reasons, the use of LEN in patients with del(5q), anaemia and not TD seems to be very attractive. However, data about the use of LEN in MDS 5q- patients and transfusion independency (TI) are scanty, some retrospective studies suggest a benefit with the early use of LEN in this setting, but there is not already available any prospective and randomized study to confirm this likely advantage.

Aims: Our aims were to analyze efficacy and safety at week 12 of treatment with LEN vs Placebo in this setting of low risk MDS del(5q) patients with anaemia and not in TD at diagnosis

Methods: From 2010 to 2017, 47 patients have been included in the Sintra-Rev trial, a phase III, multicenter, randomized and double blind study with LEN (5mg/day) vs placebo [2:1 randomization] in Low – Int-1 risk (IPSS) MDS del(5q) patients with anaemia but TI. Preliminary results of efficacy (according to the IWG 2006 criteria for erythroid [HI-ER] and cytogenetic response [CyR]) and cytogenetic responses early after treatment with an adequate safety profile in

Summary/Conclusions:

SAE were not related with the drug of the study (LEN/Placebo).

1. Hematology, Hospital Italiano de Buenos Aires, Ciudad Autónoma de Buenos Aires (CABA), 2Hospital Italiano de La Plata, La Plata, 3Sagrado Corazon, 4Hematology, Hospital Durand, Ciudad Autónoma de Buenos Aires (CABA), 5Hospital Nacional Prof A Posadas, Buenos Aires, 6Hospital Durand, Ciudad Autónoma de Buenos Aires (CABA), 7Hematology, Hospital Nacional Prof A Posadas, Buenos Aires, 8Hospital Curie, 9Instituto de Medicina Experimental (IMEX-CONICET), Ciudad Autónoma de Buenos Aires, Argentina, 10Laboratorio de Genética Hematológica, Instituto de Medicina Experimental (IMEX-CONICET), Ciudad Autónoma de Buenos Aires (CABA), Argentina

Background: Myelodysplastic syndrome (MDS) are the most frequent hematological malignancy in elderly patients. The impact of MDS burden on overall mortality remains controversial, moreover, after the incorporation of hypomethylating agents in the therapeutic armamentarium.

Aims: We aimed to analyze overall mortality and causes of death in our population of patients with MDS.

Methods: A retrospective analysis of patients with MDS reported to Argentinean MDS registry and a previous study from Academia Nacional de Medicina. Causes of death were classified in: acute myeloid leukemia (AML), infections, bleeding, solid tumor, cardiovascular, transplant related mortality (MRT), others and unknown. AML, infections and bleeding were considered as MDS-related mortality. Causes of death were analyzed using cumulative competitive events curves with Gray test and Fine-Gray for proportional hazard regression was used for the multivariate analysis.

Results: From 1981 to 2016, 1040 patients with MDS were recorded; 717 out of 1040 (69%) were diagnosed after 2006. Median age of patients was 70 years (range: 14-96) of which 58% (56%) were males. MDS was primary in 574 (54%) Median follow-up of 25 months (range: 1-170 months) for the surviving patients. The cumulative incidence of overall mortality was 20% at 12 months (95%CI 2-22), 37% at 24 months (95%CI 3-40) and 59% at 60 months (95%CI 5-63). The incidence of overall mortality did not significantly differ along the categories of diagnosis (p=0.291) neither according to age group. Multivariate analysis for cumulative incidence of overall mortality found Charlson index (HR 1.38; p<0.001), sex (HR 1.45; p=0.014) and IPSS-R (HR 2.79; p<0.001) as prognostic variables. The main cause of death was AML accounting for 9% at 12 months (95%CI 7-11), 10% at 24 months (14-19) and 25% at 60 months (95%CI 22-28) of mortality and by all patients. Infection-mortality and bleeding-mortality were the second and the third cause of death respectively. MDS-related mortality was 16% at 12 months (95%CI 13-18), 29% at 24 months (95%CI 26-32) and 44% at 60 months (95%CI 40-48); this incidence was not different by year of diagnosis. MDS-related mortality remained the main cause of death in all IPSS-R groups and in all Charlson index categories. Multivariate analysis for cumulative incidence of MDS-mortality found Charlson index (HR 1.29; p=0.02), IPSS-R (HR 2.88; p<0.001) and sex (HR 1.47;p=0.03) as independent variable. Age (p=0.034) and IPSS-R (p<0.001) were associated with AML-related mortality. A total of 56 patients underwent allogeneic transplant; cumulative incidence of MRT for all cohort was 0.5% at 12 months (95%CI 0.2-1.2) and 1.4% at 24 months (95%CI 0.8-2.4). Only male sex was associated with a higher cumulative incidence of mortality by solid tumor (p=0.001) and a Charlson index ≥2 was associated with higher cumulative incidence of cardiovascular mortality (p=0.021).

Summary/Conclusions: In this large cohort of patient with MDS we demonstrated that MDS-related causes are the leading cause of death along all IPSS-R groups. The absence of difference in mortality along the years of diagnosis highlights the necessity of better treatments for these patients.

MYELODYSPLASIA-RELATED MORTALITY REMAINS THE MAIN CAUSE OF DEATH ALONG DIFFERENT GROUPS OF RISKS: AN ANALYSIS FROM MDS ARGENTINEAN STUDY GROUP

A. L. Basquiera1, A. Enrico2, J. Arbelbide1, E. Nucifora1, M. Iastrebner3, G. Flores4, J. Gonzalez4, R. Crisp5, V. Novoa6, G. Alfonso7, M. de Dios Soler8, Y. Bestach9, I. Larrpa9, C. Beli10

1Hematology, Hospital Italiano de Buenos Aires, Ciudad Autónoma de Buenos Aires (CABA), 2Hospital Italiano de La Plata, La Plata, 3Sagrado Corazon, 4Hematology, Hospital Durand, Ciudad Autónoma de Buenos Aires (CABA), 5Hospital Nacional Prof A Posadas, Buenos Aires, 6Hospital Curie, 7Instituto de Medicina Experimental (IMEX-CONICET), Ciudad Autónoma de Buenos Aires, Argentina, 8Hospital Nacional Prof A Posadas, Buenos Aires, 9Instituto de Medicina Experimental (IMEX-CONICET), Ciudad Autónoma de Buenos Aires (CABA), Argentina

Results: Main clinical characteristics are summarized in table 1, 85% were females, median age was 72 years (37-89) and most of patients (95%) had del(5q) as the only cytogenetic abnormality. Among 47 patients, only 38 were evaluable at week 12 (6 out of 38 discontinued the study: 3 due to DP, 1 due to toxicity and 1 for unknown reasons), 7 patients are currently receiving the first 12 weeks of treatment and 2 patients were excluded (screening failures). Regarding efficacy (w12), data from 36 patients were available. HI-ER was observed in 14/38 patients (39%), minor HI-ER (Hb increased <1.5g/dL) in 4/36 (11%), stable disease in 15/36 (42%) and PD (transfusion dependency) in 3 (8%). CyR was available in 30 patients: complete CyR was obtained in 12 (40%), partial CyR in 6 (20%) and no CyR in 12 (40%) patients. Safety information in 38 patients demonstrated that most patients (87%) developed any adverse events (AE) while only 42% of these were relevant (G3-4). Most G3-4 AE were hematological (neutropenia 38%) being non-hematological only in 5%. Seven patients AE were reported in 5 patients: vestibular neuritis, congestive heart failure, polyarthitis, arterial hypertensive crisis, carpal arthritis, respiratory infection and chronic obstructive pulmonary disease exacerbation. All SAE were not related with the drug of the study (LEN/Placebo).

Summary/Conclusions: In this study we confirm a high rate of erythroid and cytogenetic responses early after treatment with an adequate safety profile in the first 12 weeks of treatment with LEN or placebo.

PROSPECTIVE STUDY OF FLOW CYTOMETRY OF BONE MARROW IN 105 CONSECUTIVE PATIENTS WITH CYTOPENIA AND SUSPICION OF MYELODYSLASTIC SYNDROME: STRONG CORRELATION WITH RISK OF AML-EVOLUTION AND SURVIVAL

F. Marco De Lucas1,*, Z. Diez Gallarreta1, B. Blázquez1, P. Isusi1, B. Dávila1, C. Barrenetxea1, A. Blanco1, B. Barriera2, S. Herráez1, I. Capei3, I. Leal1, J. Uriarte1, C. Alonso Caballero1, J. I. Rodríguez1, J. A. Márquez1,2

1Hematologia, 2genetica, Hospital Universitario Basurto, 3facultad De Medicina UPV, Bilbao, Spain

Background: Diagnosis of myelodysplastic syndromes (MDS) remains a challenge, specially in patients with scant displastic morphology features and/or in the absence of cytogenetic changes. Multiparametric flow cytometry (MFC) findings have been recognized as a co-criterion for the diagnosis of MDS and we have also demonstrated prognostic value in some studies. Nevertheless, this diagnostic tool is not fully implemented for the study of MDS in many centers and data from real life out of investigational studies are few.

Aims: To prospectively assess the value of MFC in the diagnosis of MDS in our center and correlate its findings to the clinical outcome of patients in terms of overall survival, transfusional needings, risk of hospitalization and evolution to acute leukemia.

Methods: We studied bone marrow samples from 105 consecutive patients submitted to our hospital between January 2013 and April 2015 because of one or more cytopenia and suspicion of MDS. Cytomorphology of every sample...
was evaluated by at least two morphology experts and a consensus diagnosis of MDS-confirmed, MDS-suspected or MDS-excluded was emitted. MFC was performed applying at least five-colour staining and a numerical score was calculated for every patient following criteria defined by Ogata et al (Blood. 2006 Aug 1; 108(3):1037-44), with a score >=2 suggesting MDS. Conventional karyotype and FISH employing probes to detect usual 5q-, 7q-, 8q-, 20q- and del(7q) were performed in all cases.

Results: Median age of the patients was 73.5 y/o. Patients presented with anaemia in 88% (84%), neutropenia in 36% (34%) and thrombocytopenia in 49% (47%). Cytomorphology was reported as MDS-confirmed (60 pts), MDS-excluded (22) or MDS-suspected (23). MDS subtypes were Multilineage Dysplasia (23), Unilineage Dysplasia with Ring Sideroblasts (9), del(5q) Syndrome (3) and Unclassified (2). 4 pts being diagnosed of CMLML. MFC score was MDS-suggestive in 56 pts, MDS-not suggestive (36) and in 13 cases its use was precluded because of morphology findings. Considering cytomorphology as gold standard, 56.9% of patients with MDS-confirmed MFC score were expected but MS-suspected but MFC score sensitivity was 77%, specificity 88%, with positive and negative predictive values of 96% and 56% respectively. Furthermore, MFC-score showed a significant correlation with single morphologic findings of granulocytic (p<0.001), erythroid (p=0.001) and megakaryocytic dysplasia (p=0.002), and a trend to significant association with del7q by FISH (p=0.085). In the subset of patients with MDS-suspected but not confirmed by morphology, the presence of a MFC score >=2 was significantly associated with a poorer overall survival (log-rank p=0.012), with all MFC score =2 patients alive after a median follow-up of 35 months. There was also a trend to statistical association between MFC findings and overall survival in the whole series of patients (log rank p=0.053). Interestingly, there was a striking difference in risk of evolution to AML according to MFC findings (log rank=0.013), with a 100% of patients free from this complication in the group of patients with MFC score <2.

Summary/Conclusions: MFC analysis of the bone marrow provides useful information in the diagnostic of MDS which can be specially helpful in the subset of patients with inconclusive morphological findings, showing a strong correlation in this group of patients with clinical outcome in terms of risk of evolution to AML and overall survival.

E1184

ECONOMIC IMPACT AND HEALTHCARE UTILIZATION IN PATIENTS WITH HIGHER-RISK MYELODYSPLASTIC SYNDROMES (HR-MDS) IN ROUTINE CLINICAL CARE IN THE UNITED STATES (US) – A CLAIMS DATABASE STUDY

J. Bell¹, A. Galaznik¹, E. Farrell², M. Blazer³, H.-C. Shih¹, A. Raju¹, A. Ogbonnaya¹, M. Eaddy¹, R. Fram¹, D. Faller¹

¹Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, ²Xcenda, Palm Harbor, United States

Background: Therapy for patients with HR-MDS includes systemic chemother­apy, stem cell transplant (SCT), and supportive care aimed at improving symp­toms associated with MDS-related disruption of normal hematopoiesis. However, the economic impact of these interventions over time for HR-MDS patients has not been fully examined.

Aims: We evaluated the costs and healthcare utilization (HCU) of US HR-MDS patients treated during routine care.

Methods: Newly diagnosed adult HR-MDS patients who initiated first-line therapy were identified from Optum, a large US claims database, between 1/1/08 and 10/31/15. HR status was based on ICD coding: ≥1 inpatient claim or ≥2 outpatient claims with ≥1 HR-MDS ICD-9/10 code (ICD-9 code: 234.73; ICD-10 codes: D46.20, D46.21, D46.22). The first MDS claim served as the index date.

Exclusion criteria included: lack of continuous enrollment in medical/pharmacy benefits in the 12 months prior to index date (baseline period), presence of other primary cancer, or receipt of any chemotherapy or SCT during baseline period. MDS-related and non-MDS-related HCU and costs incurred during follow-up were evaluated. MDS-related HCU and costs were medical claims with a primary diagnosis of MDS or MDS-related treatment (ie, MDS chemotherapy as defined by NCCN MDS Guidelines v2.2017 or MDS-directed supportive care which included hydroxyurea, erythroid-stimulating-colony-stimulating-growth factors and prophylactic platelet transfusions) and pharmacy claims for MDS treatment. Proportions of patients with HCU were reported. Costs were calculated as per-patient-per-month (PPPMM) costs adjusted to 2015 US dollars and reported as mean (standard deviation [SD]). Patients with a capitated payment were excluded from analysis. Costs were reported as mean (standard deviation [SD]). Patients with a capitated payment were excluded from analysis. Costs were reported as mean (standard deviation [SD]). Patients with a capitated payment were excluded from analysis.

Results: 209 treated HR-MDS patients were identified. During the follow-up period, 69.4% of patients had ≥1 inpatient admission, but more patients had an MDS-related than non-MDS-related admission (Table 1). 56.9% of patients had ≥1 MDS-related, 1 and outpatient visit over the follow-up period, and 56.9% had ≥1 physician office visit (91.9%) and other outpatient visits (99.5%). Over the follow-up period, the mean PPPMM cost was $17,361 (SD: $19,747) (Table 1) and was higher in Year 1 than in Year 2 ($17,337 [SD: $19,696] vs $12,076 [SD: $14,135]). The majority of costs overall were for MDS-related medical services ($10,327 PPPM, SD: $11,050). Between Years 1 and 2, MDS-related medical PPPM costs decreased from $10,557 (SD: $11,164) to $6,530 (SD: $7,406) while non-MDS-related medical PPPM costs remained fairly constant in both years. Chemotherapy and supportive care medical services were the main drivers of MDS-related medical costs, also decreasing from Year 1 to Year 2. Non-MDS-related costs accounted for a smaller portion of the overall medical PPPM costs ($6,124 [SD: $15,158]); and remained relatively similar in Years 1 and 2.

Table 1.

<table>
<thead>
<tr>
<th>Year</th>
<th>Mean PPPM Cost (SD)</th>
</tr>

<td>$17,337 ($19,696)</td>
</tr>
<tr>
<td>Year 2</td>
<td>$12,076 ($14,135)</td>
</tr>
</tbody>
</table>

Summary/Conclusions: The economic impact of HR-MDS is considerable, with higher costs incurred within the first year of diagnosis. The decrease in cost between Year 1 and Year 2 was mainly due to decreased MDS-related medical costs. Consistent with this cost trend, healthcare utilization for MDS-related services decreased in Year 1 vs Year 2. As treatment of HR-MDS continues to evolve, economic impact and HCU need to be further investigated in this patient population.

E1185

INTRAVENOUS IMMUNOGLOBULIN IS AN EFFECTIVE TREATMENT FOR CYTOPENIAS ASSOCIATED TO CIRCULATING T-CELL CLONES IN MYELODYSPLASTIC SYNDROMES

J. Bell¹, E. P. Demakos¹, R. Odchimar-Reissig², S. C. Navada², L. R. Silverman²

¹Hematology, ASST Spedali Civili di Brescia, Brescia, Italy, ²Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, United States

Background: Myelodysplastic syndrome (MDS) can be associated with immunologic disorders, including autoimmune cytopenias and Coombs positive or negative (C±) hemolytic anemia. Abnormally expanded T-cells can be detected in these patients, possibly contributing to both bone marrow insufficiency and a peripheral cytopenia, and can be another target for therapeutic intervention.

Aims: To explore the role of intravenous immunoglobulin (IVIG) as a treatment for immune-related cytopenia in a series of 20 consecutive patients with MDS at a single institution.

Methods: T-cell clonal expansion in the peripheral blood (PB) was documented by flow cytometry and PCR. Eighteen patients had a confirmed MDS (16 IPSS lower-risk, LR). Two suspected MDS were designated as idiopathic cytopenia of uncertain significance (ICUS). Reasons for IVIG treatment were chronic hemolysis refractory to corticosteroids (16: 12 LR, 1 higher-risk (HR), 1 ICUS) or pancytopenia (2 LR and 1 HR refractory to standard therapy, 1 ICUS) associated to a T-cell clonal proliferation in the PB. Hematological response was assessed by IWG criteria 2006. Hemolysis response (HLR) included normalization (CR) or a greater than 50% improvement (PR) of LDH, reticulocytes, indirect bilirubin and haptoglobin.

Results: Clinical characteristics are shown in the Table. All patients had a clonal t(11;19) and 9 cases the clone was characterized by flow cytometry: 6 had a CD3+ T-cell and 3 had a CD3+/CD16+/CD56+ NK-cell expansion. Associated immunologic disorders were: ITP (4), neutrophil dermatosis (3), inflammatory bowel disease
(3), seronegative arthritis (2), connectivitis (2). One patient with hypoplastic MDS had LGL liver involvement. Coombs test was positive in 4/16 hemolysis cases. From Jan-10 to Jan-17, IVIG was administered at a dose of 500mg/kg once per week, in cycles of 1 to 4 weeks. The ORR was 75% (15/20); all patients showed an erythroid hematological improvement (HI) (100%). Platelets and neutrophil HI was seen in 50% and 80% of responsive cases, respectively. HLR occurred in 13/16 (81%: 4 CR and 9 PR). Median number of cycles and duration of treatment was 11 and 12 months (mo), respectively. The HLR-CR was stable in 7 patients; 4 relapsed from HLR but subsequently responded by shortening the intervals between administrations of IVIG; 2 were secondary refractory. Eventually, 6 responders became refractory to IVIG. Response was more durable with continuous rather than sporadic dosing. Median time to response was 1 mo. Median duration of response was 39 mo. Corticosteroids were discontinued in 5/10 patients and reduced in 5/10. Adverse events were: 1 palpitations (G1); 1 hypertension (G1). Responders had lower platelet counts (p<0.05), but no other clinical differences compared to non-responders. However, the 5-year OS rate was higher in the responders to IVIG: 53% compared to 30% (p=0.08).

Table 1.

Summary/Conclusions: Treatment with IVIG of C± hemolytic anemia and pancytopenia associated with T-cell immune-clones and MDS was safe and yielded high rates of durable response on all lineages and on hemolysis. Transfusion independency and reduction/discontinuation of corticosteroids for chronic hemolysis is highly variable, and the ability to accurately predict outcomes is critical. Current prognostic systems for these diseases are based on traditional clinical, pathologic and laboratory indicators.

Aims: We aimed to develop and validate a new prognostic index for advanced MDS by including self-reported fatigue severity into a well-established clinical risk classification: the International Prognostic Scoring System (IPSS).

Methods: Untreated patients (n=280) were recruited at the time of diagnosis of advanced MDS from 37 hospitals in nine countries to create the index. The index was then applied to an independent cohort including pre-treated MDS patients from the Dana-Farber Cancer Institute (DFCI) in Boston, Massachusetts (USA; n=189). Patients in both the International and DFCI cohorts were adults with newly-diagnosed intermediate-2 or high-risk MDS (advanced disease on the IPSS). Patients were enrolled regardless of age, comorbidity, performance status and progression to a lower IPSS category. All completed a baseline health-related quality of life assessment. Data from international and DFCI cohorts were independently collected and analyzed. Univariate and multivariate Cox proportional hazards (PH) regression analyses were performed to estimate hazard ratios with 95% Confidence Intervals (CIs). Discrimination and calibration were evaluated for both the development (internal validation) and independent DFCI datasets (external validation). Statistical significance for all tests was set as two-sided p=0.05.

Results: A new risk classification was developed, namely, the fatigue (FA)-IPSS(h). Whereas use of the standard IPSS in more advanced disease discriminates between two risk categories for untreated patients, the new fatigue FA-IPSS(h) classification is more robust and is able to distinguish the survival outcomes of patients with distinct survival outcomes. Overall survival rates at 6 months, 1 year, and 2 years were markedly different among the three groups. To illustrate, one year survival was 80.3% (95% CI, 73.4-87.8), 60.5% (95% CI, 52.3-70.0) and 37.6% (95% CI, 23.9-59.1) for patients classified into Risk-1, Risk-2 and Risk-3 respectively. Median OS in DFCI data by FA-IPSS(h) risk was similar to that of the development cohort for each of the three risk groups, indicating good external calibration. Patterns of OS through 2 years were also distinctly different between risk groups as in the development cohort of untreated patients, with one exception: 2-year OS was similar for FA-IPSS(h)-risk 3 and risk-2. Predictive accuracy of this new index was higher than the IPSS alone in both the development cohort (C-statistic, 0.61 vs 0.57) as well as in the independent cohort including pre-treated patients (C-statistic, 0.58 vs 0.54).

Conclusion: The FA-IPSS(h) is an additional prognostic tool that might enhance clinicians’ ability to provide more personalized treatment strategies both in untreated and pretreated advanced MDS patients. This analysis offers a model for integration of PROs in prognostic systems for patients with other cancers and advanced illnesses.

PROGNOSTIC AND THERAPEUTIC IMPLICATIONS OF SIGNIFICANT MARROW FIBROSIS IN COMBINATION WITH P53 OVER-EXPRESSION IN PATIENTS WITH MYELODYSPLASTIC SYNDROME: A SINGLE CENTRE STUDY

E. Groarke1, S. Maung1, E. Kewins2, M. Jeffers2, B. MacDonagh1, J. McHugh1, R. Desmond1, H. Enright1
1Department of Haematology, 2Department of Cellular Pathology, Tallaght Hospital, Dublin 24, Ireland

Background: Myelodysplastic syndromes (MDS) are defined in the WHO 2016 classification as a group of clonal bone marrow neoplasms characterized by ineffective hematopoiesis, morphologic dysplasia in hematopoietic cells and peripheral cytopenia(s). They present as a diverse phenotype with some patients requiring merely observation while others require more intensive management due to significant marrow failure and the risk of development of acute leukemia. The presence of significant marrow fibrosis has previously been shown to be a poor prognostic factor in patients with MDS, with reduced overall survival. Significant marrow fibrosis has also been associated with both the presence of the TP53 gene mutation and with p53 over expression, which is a known adverse prognostic risk factor in MDS patients.

Aims: To assess the presence of p53 expression in patients with moderate to severe marrow fibrosis (grade 2-3), observe its effect on overall survival in patients with marrow fibrosis, and determine whether the use of azacitadine had any impact on survival.

Methods: We conducted a retrospective study utilizing a hospital database of 247 patients with MDS diagnosed in a single center between 2000 and 2014. Of these patients, 200 had bone marrow trephine samples adequate for reticulin stain analysis, which was completed using the European consensus on grading bone marrow fibrosis (grades 0-3). P53 expression was examined using immunohistochemistry staining according to the modified quick scoring system. We then looked for an association between degree of marrow fibrosis and p53 expression. In patients with significant marrow fibrosis and p53 expression, we examined overall survival and response to treatment with azacitadine.
Results: Overall, no significant correlation was seen between expression of p53 and degree of fibrosis (p=0.25). However, degree of fibrosis predicted for overall survival in patients with p53 expression (median overall survival of 4 months in patients with both p53 over expression and significant fibrosis compared with median overall survival of 18 months in patients with p53 over expression without fibrosis, p=0.001). In patients who received azacitidine, though most of significant fibrosis and p53 expression had a significantly increased overall survival compared with those who did not receive azacitidine (4 months versus 1 month, p=0.002). Azacitidine treatment was not associated with increased survival in patients with p53 expression without fibrosis but these patients did have an overall increased survival compared to those with fibrosis (median survival 12 vs 37 months).

Summary/Conclusions: This study confirms that significant marrow fibrosis adversely affects overall survival in patients with MDS, including those with p53 over expression. Patients who received azacitidine had a significant increase in median survival. Although the numbers of patients who received azacitidine (23% in the azacitidine data) suggests that patients with fibrosis may benefit from the use of azacitidine and larger, randomized studies should be considered to study this further.

FACS PURIFICATION OF BLAST CELLS IN MDS IMPROVES THE FISH DETECTION RATE FOR DEL(5q) AND DEL(20q), BUT NOT FOR DEL(7q) OR T8
M. Pereira1,2,*, G. Marques3, J. Lima3, R. Reis3, A. Coelho3, L. Jorge3, S. Pedroso4, L. Ribeiro4, A. Paiva4, F. Rodrigues4,
1Clinical Pathology Department, Coimbra University Hospital Centre, 2Faculty of Medicine, University of Coimbra, 3Clinical Pathology Department, 4Flow Cytometry Unit, Coimbra University Hospital Centre, Coimbra, Portugal

Background: Prognostication in Myelodysplastic Syndromes (MDS) using validated scores includes the detection of chromosomal aberrations by conventional karyotyping. When the latter is unavailable or unsuccessful, fluorescence in-situ hybridization (FISH) panels can be used. Although panels vary by laboratory, some of the commonly used probes include the search for monosomy 5 or del(5q), monosomy 7 or del(7q), del(20q) and trisomy 8 (T8). In our lab, FISH was historically performed on full marrow aspirates (Full Sample); since 2015, we have primarily performed the analysis on Fluorescence Activated Cell Sorting (FACS) separated blast cells.

Aims: In this study, we aim to analyze the benefit of using purified samples of blast cells for FISH analysis in MDS, when compared to full mixed cellularity samples.

Methods: We reviewed all samples analyzed in our laboratory between January 1st 2011 and February 28th 2018 in which a FISH panel workup for a suspected diagnosis of MDS presented with cytopenia in myelodysplastic syndromes (MDS) and aplastic anemia (AA) patients who fail or are ineligible to standard therapies is an unmet medical need; however only dated reports on danazol use in this setting are available.

Aims: We report the results of treatment with danazol in patients with MDS and AA at a single institution.

Methods: From June-11 to May-15, danazol was administered to 31 consecutive patients (20 MDS and 11 AA). Criteria for treatment were non-severe AA (8), severe AA ineligible/refractory to immunosuppressive therapy or allogeneic transplantation (3), transfusion dependent (TD) lower risk MDS refractory to standard therapy (2), MDS with isolated thrombocytopenia <50x10^9/L (6) or with bone marrow hypoplasia and bicytopenia (3). Diagnosis was defined by WHO 2008 for MDS and according to Camitta (Blood 1975) for AA; response was counted as CR, PR or no response.

Results: 22nd Congress of the European Hematology Association
E1189
COUNTING BONE MARROW BLASTS AS A PERCENTAGE OF NON-ERYTHROID CELLS PROVIDES SUPERIOR RISK STRATIFICATION FOR MDS PATIENTS WITH ERYTHROID PREDOMINANCE
A. Sun1,2,*, Y. Yu1, T. Zhang1, Q. Wang1, D. Liu1, S. Chen1, D. Wu1,2
1The First Affiliated Hospital of Soochow University, Jiangsu Institute of Hematology, 2Institute of Blood and Marrow Transplantation, Collaborative Innovation Center of Hematology, Soochow University, Suzhou, China

Background: Patients with erythropoietic predominance (50% erithroblasts, MDS-erythroid) compose a significant proportion of patients with MDS. The erythroid/myeloid subtype was divided from the AML category into MDS-erythroid by the 2016 WHO classification of myeloid neoplasms. At that time, there was no consensus on a more appropriate way of enumerating bone marrow (BM) blasts from TNCs or NECs in MDS-erythroid patients.

Aims: To clarify these questions, 1283 MDS patients were retrospectively analyzed in our center.

Methods: MDS-erythroid was observed in 27.0% of patients (346/1283), and these patients had similar clinico-pathological features and overall survival, with 103 cases of MDS with <50% ENCS (Erythroblasts in Non-Erythroid Cells) blasts.

Results: By calculating the percentage of BM blasts from NECs, 73 of 200 patients (36.5%) with MDS-erythroid who were diagnosed within WHO subtypes without excess blasts (EB) were moved into higher-risk categories and showed shorter OS than those who remained in the initial categories (P=0.041). Recalculating the International Prognostic Scoring System-Revised (IPSS-R) by enumerating blasts from NECs, 40 of 168 (23.8%) MDS-erythroid patients with relatively lower risk were re-classified as higher-risk and had significantly poorer survival than those who remained in the lower-risk category (P=0.030). This was especially true for the intermediate risk group that was stratified by IPSS-R (unchanged patients vs shifted patients, P=0.007). However, the impact of enumerating BM blasts from NECs on classification and prognostication was not evident in all MDS patients.

Summary/Conclusions: In conclusion, our results suggested that enumerating the percentage of BM blasts from NECs significantly improved the prognostic assessment of MDS-erythroid, especially for patients within the intermediate risk group stratified by IPSS-R.
was 19 months (mo) (1-66) in AA and 6 mo (1-60) in MDS. ORR was 73% and 50%, respectively. Age and hemoglobin levels impacted on response in AA. Hematological improvement was seen on all lines in 92% of cases, with a median time to best response of 3-5 mo on platelets and neutrophils and of 8-12 mo on hemoglobin. Interestingly, duration of response in MDS patients was significantly longer with a danazol dose of 600mg than with 400mg (p<0.001). Conversely, dosing did not impact on response to danazol in AA patients. Grade 2-3 toxicity was significantly higher in AA patients (p<0.05), 60% pretreated with IST. Adverse events included: hepatotoxicity (3 G1, 1 G2, 3 G3), muscle pain/CPK elevation (3 G1, 2 G2), transient renal impairment (1 G1), hypoxemia (1 G1). Responders to danazol had a better survival in terms of OS and EFS in both groups (Figure 1).

Figure 1.

Summary/Conclusions: Danazol was proved both effective and safe as treatment of cytopenia in MDS and AA patients refractory or ineligible to standard therapies. The daily dose of 600mg was more effective for MDS patients, whereas a lower dose of 400mg may have a better risk/benefit ratio in AA. Younger AA patients with less severe anemia were more likely to respond. Danazol use is particularly attractive in thrombocytopenic patients, where responses were rapid, but delayed responses may be expected also on anemia by using danazol for prolonged periods, when tolerated. Response to danazol is also potentially associated to a survival advantage, although these data should be confirmed by larger prospective studies.

E1191
SURVIVAL OUTCOMES IN PATIENTS WITH HIGHER-RISK MYELODYSPLASTIC SYNDROMES (HR-MDS) IN ROUTINE CLINICAL CARE IN THE UNITED STATES (US) – A CLAIMS DATABASE STUDY
J. Bell1, A. Galazn1k, E. Farrell2, M. Blazer4, H.-C. Shih2, A. Raju2, A. Ogbonnaya2, M. Eaddy3, R. Fram1, D. Fall1er
1Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, 2Xcenda, Palm Harbor, United States

Background: MDS is composed of multiple and rare hematological stem-cell disorders, resulting in cytopenias and disease-related complications and deaths. There are no robust trial data comparing the available treatment options for HR-MDS patients; and of the approved drugs, only azacitidine has demonstrated a statistically significant, but modest clinical impact on overall survival (OS).

Aims: We evaluated first-line treatment (1LT) choice and survival outcomes in a US cohort of HR-MDS patients engaged in routine care.

Methods: Newly diagnosed HR-MDS patients who were ≥18 years old and who had initiated 1LT were retrospectively identified from Optum, a large US claims database, between 1/1/2008 and 10/31/2015. HR status was based on prior treatment for MDS or chronic myelomonocytic leukemia (cMML) and the presence of other primary cancer, or receipt ≥1 HR-MDS ICD-9/10 code (ICD-9 code: 238.73; ICD-10 codes: D46.20, D46.21, D46.22), or ≥2 outpatient claims with ICD coding: ≥1 inpatient claim with an HR-MDS ICD-9/10 code (ICD-9 code: 284.5). The first MDS claim served as the index diagnosis (E1190). The primary outcome evaluated was overall survival (OS), with secondary endpoints of progression-free survival (PFS), transplant-free OS (TFO-S), and event-free survival (EFS).

Results: 209 newly diagnosed HR-MDS patients initiating 1LT MDS-Tx were identified; mean age was 73 years (standard deviation [SD]: 10.1) and 61.2% were male. In the 12 months prior to diagnosis, 27.3% of patients used MDS-directed supportive care (ie, colony stimulating-, erythropoietic-, or thrombopoietic growth factors; RBC or PLT transfusions; or hydroxyurea). 1LT with hypomethylating agents (HMAs) predominated in 89.5% of patients (azacitidine, 68.9% and decitabine, 20.6%); 8.6% of patients received an immunomodulator monotherapy; and 8.6% of patients underwent SCT during follow-up. Of the 169 treated HR-MDS patients with ≥60 days of follow-up on 1LT, 51% achieved transfusion independence. For all treated HR-MDS patients, median PFS and 2-year follow-up were 12.5 months (95% confidence interval [CI]: 9.1, 14.9) and 27.0%, respectively. OS rate at 2 years was 59.1%. Patients who achieved transfusion independence had a higher rate of 2-year OS (65.2% vs 53.8%) and PFS (36.3% vs 25.7%), but neither were statistically significant.

Table 1.

Table 1.

Figure 1.

Summary/Conclusions: Survival outcomes in routine clinical care were higher than reported in clinical trials, specifically in HR-MDS trials with azacitidine. Among patients able to achieve transfusion independence, a trend toward increased 2-year PFS and OS rates was observed, although statistical significance was not reached. Characteristics that contribute to variations in PFS and OS outcomes within the HR-MDS population need further investigation.

E1192
DOSE-CONFIRMATION PK/PD STUDY OF ORAL ASTX727, A COMBINATION OF ORAL DECITABINE WITH A CYTIDINE DEAMINASE INHIBITOR (CDAI) E7727, IN SUBJECTS WITH MYELODYSPLASTIC SYNDROMES (MDS)
1UT MD Anderson Cancer Center, Houston, 2Roswell Park Memorial Institute, Buffalo, 3Cornell University Medical Center, New York, United States, 4Hopital Maisonneuve-Rosemont, Montreal, 5Sunnybrook Medical Center, Toronto, Canada, 6University of Chicago, Chicago, 7Dana Farber Cancer Institute, Boston, United States, 8Princess Margaret Cancer Center, Toronto, Canada, 9Mount Sinai Hospital, Toronto, Canada, 10Hackensack University Medical Center, Hackensack, New Jersey, 11Massachusetts General Hospital, Boston, 12Medical College of Wisconsin, Milwaukee, 13Axest Pharmaceuticals Inc., Pleasanton, 14Vanderbilt University Medical Center, Nashville, United States

Background: We have previously shown that ASTX727, a combination of oral decitabine and the oral CDAI E7727, emulates the pharmacokinetics of a one hour intravenous decitabine infusion (IV-DAC) in a dose-escalation phase 1 study. (Garcia-Manero. Blood 2016 128:112)

Aims: To confirm pharmacokinetic (PK) and pharmacodynamic (PD) comparability of 20mg/m² IV-DAC administered D1-5 of a 28 day cycle with an entire cycle of ASTX727 given at the selected dose from phase 1 (35mg decitabine and 100mg of E7727).

Methods: Adult patients with Int-1/int-2 or HR MDS or Chronic Myelomonocytic Leukemia (CML) were enrolled in a randomized cross-over Phase 2 study. Patients were randomized 1:1 to receive in the first 28 day cycle, either 5 days of IV-DAC or 5 days of ASTX727, followed by a cross-over to the other Cycle

Summary/Conclusions: Danazol was proved both effective and safe as treatment of cytopenia in MDS and AA patients refractory or ineligible to standard therapies. The daily dose of 600mg was more effective for MDS patients, whereas a lower dose of 400mg may have a better risk/benefit ratio in AA. Younger AA patients with less severe anemia were more likely to respond. Danazol use is particularly attractive in thrombocytopenic patients, where responses were rapid, but delayed responses may be expected also on anemia by using danazol for prolonged periods, when tolerated. Response to danazol is also potentially associated to a survival advantage, although these data should be confirmed by larger prospective studies.
2. Cycles 3 forward were with ASTX7727. PD were assessed with LINE-1 methylation measured on white blood cells at baseline at days 8, 15, 21 and 28 in cycles 1 and 2. Full PK assessments of ASTX7727 were performed on Days 1, 2 and 5 with sparse sampling on Days 3 and 4 and on Day 1 of IV-DAC. Modeling of 5 day exposures of ASTX7727 and IV-DAC was created for each patient. Safety and clinical response were assessed on all patients.

Results: Among the 50 randomized, 50 had matched PK and 46 had matched PD sample sets for the first 2 cycles. No significant differences were seen when comparing the randomized sequences for any parameters, so all assessments comparing ASTX7727 and IV-DAC were performed independent of sequence. The geometric mean maximum demethylation was 9.9% for ASTX7727 vs 9.0% for IV-DAC (Ratio of geometric means [GMR] 1.099, 95% CI: 0.806-1.000; p=0.34). The geometric mean AUC for IV-DAC was 161 ng/h/mL. The 5 day total geometric mean of the AUC (ng/mL) was 769 for ASTX7727 and 805 for IV-DAC ([Ratio of geometric means [GMR] 0.96, with a lower limit of 95% CI of 0.806]. Decitabine C max was higher for IV-DAC (189 ng/mL) than after ASTX7727 (210 ng/mL) and 5 day AUC (112 ng/mL). The Day 1 adverse events regardless of grade or causality were febrile neutropenia 34%, neutropenia 28%, thrombocytopenia 16%, fatigue 16%, and hypomagnesaemia 18%. There were no reported GI adverse events greater than Grade 2 with ASTX7727 regardless of relationship to treatment.

Summary/Conclusions: Fixed dose oral administration of 35mg decitabine and 100mg E7727 (ASTX7727) emulates the AUC of IV-DAC over the 5 day treatment cycle and induces a similar degree of demethylation of LINE-1 sequences in blood cells compared to IV decitabine at 20mg/m 2 dose. The preliminary safety profile is similar to what has been reported for IV-DAC and no significant differences were seen when comparing the randomized sequences for any parameters, so all assessments comparing ASTX7727 and IV-DAC were performed independent of sequence. 

E1193 FACTORS PREDICTIVE FOR INFECTION IN PATIENTS WITH HIGHER-RISK MYELODYSPLASTIC SYNDROMES, CHRONIC MYELOMONOCYTIC LEUKEMIA AND ACUTE MYELOID LEUKEMIA TREATED WITH AZACITIDINE

K. Madry1, 2, K. Lis1, J. Zurawski1, M. Górska1, P. Paczczynski1, M. Dutka2, M. Rodzaj1, L. Bolkun4, D. Krochmalczyk1, J. Drozd-Sokolowska1, A. Waszczuk-Gajda1, W. Knopinska-Polusznaja, A. Kopinska1, E. Subocza1, A. Masternak2, R. Guzicka-Kazimierczak1, R. Machowicz1, A. Molteni2, R. Cairoli1, J. Dwilewicz-Troja1, M. Riva1, E. Ravano1, R. Cairoli1, A. Molteni2, M. Riva1, E. Ravano1, R. Cairoli1, A. Molteni2, M. Riva1, E. Ravano1, R. Cairoli1, A. Molteni2

Background: Hypomethylating agents (HMAs) are the current standard treatment of higher-risk myelodysplastic syndrome (MDS), chronic myelomonocytic leukemia (CML) and older acute myeloid leukemia (AML) patients. Severe infectious complications are common during HMAs therapy and have been recognized as one of the most important reasons of morbidity and mortality in MDS, CML and AML patients especially at the beginning of treatment.

Aims: To evaluate the incidence of and predisposing risk factors for infections during the first three azacitidine (AZA) cycles treatment

Methods: In this retrospective study we analyzed 282 consecutive patients with higher-risk MDS (174), CML (34) and AML with bone marrow blasts <30% (74) treated with azacitidine in 10 Polish hematologic centers between the years 2009-2016. Patients who did not complete three AZA cycles and also did not experience infection were excluded (50 cases).

Results: Median age was 68 (28-93). Median number of AZA cycles was 6 (1-24). Infectious episodes occurring during the first three courses of AZA were reported in 94 out of 232 (40%) eligible patients - in 32% of MDS, 30% of CMML and 63% of AML patients (p<0.05). Among patients with infection, most of them had their first infection episode during the first cycle -53%, during the second cycle -29% and during the third AZA cycle -18%. It was found that low neutrophil count (<1.1x109/L), low lymphocyte count (1,1x109/L vs 1,3x109/L), low platelet count (37x109/L vs 63x109/L), high blood ferritin level (1101ng/ml vs 569 ng/ml), low albumin concentration (3,6 g/dl vs 4,0 g/dl), high bone marrow blasts percentage (15% vs 12%), higher IIHS, IPSS-R and WPS score, red blood cell transfusion dependency and worse WHO performance status predicted infectious episodes. The most important predictive factors for infection (p<0.05). Factors like age, gender, hemoglobin concentration, iron, immunoglobulin and creatinine blood level, time from diagnosis to beginning of AZA treatment, IPSS and IPSS-R cytogenetics, coexistence of diabetes mellitus, heart failure, chronic obstructive pulmonary disease, second cancer, autoimmune disease and corticosteroids treatment had a negative influence. The most important predictive factors for infection should be assessed before therapy. Patients possessing factors predictive for infection require special approach and predictive infection model should be developed in further analysis.

E1194 OVERALL SURVIVAL, INITIAL TREATMENT AND TREATMENT DURATION OF PATIENTS WITH MYELODYSPLASTIC SYNDROME, A DETAILED POPULATION BASED STUDY

H. Rozema1,2, R. Kibbelaar2, N. Veeger2, E. Van Roon1,2, M. Hogendoorn2

1Pharmacotherapy, -Epidemiology & -Economics, University of Groningen, Groningen, 2Medical Centre Leeuwarden, Leeuwarden, Netherlands

Background: Population-based studies on myelodysplastic syndrome (MDS) containing detailed clinical information of patient characteristics, treatment and follow-up of the disease are scarce. Since 2005, all patients diagnosed with hematological malignancies in Friesland, a province in the Netherlands, are prospectively registered and followed by their clinicians in a population-based registry, the HemoBase. The registry provides representative population-based data on diagnosis, treatment and outcomes in an era where low-intensity treatment such as hypomethylating agents have become available for the elderly.

Aims: The objectives of this study were to determine the overall survival (OS) of patients with MDS and the effect of the variables gender, age, comorbidities, IPSS, IPSS-R score and MDS subtype according to WHO 2016 classification. Furthermore, the leukemia free survival (LFS), the initial treatment and the duration of first-line treatment were analyzed.

Methods: An observational, population-based study was performed using the HemoBase registry. The bone marrow biopsies and aspirates of all MDS patients treated between 01-01-2005 and 31-12-2013 were independently and blindly reviewed by both the hematologist and hematologist-pathologist and classified according to the WHO 2016. Treatment categories were defined as intensive chemotherapy (IC) either combined or not combined with allogeneic stem cell transplantation, the hypomethylating agent azacytidine, the immunomodulatory agent lenalidomide, hydroxyurea or best supportive care (BSC) (blood transfusions, erythropoiesis-stimulating agents). Approval was obtained from the Medical Ethics Review Committee from Medical Centre Leeuwarden. Statistical analyses were performed with SPSS 19; survival analyses were used taking Kaplan-Meier estimates.

Results: 217 patients (72.4% male, 66.8% >70 years old, median age 75 years, 27.2% Charlson Comorbidity Index (CCI) score ≥3 at diagnosis) were included with a median follow-up duration of 70.2 months. 15.7% of the population had an IPSS score ≥3 and 12.4% of the population had an IPSS-R score ≥4. In 41.5% no cytogenetic information was available. MDS-RRS, MDS-SLD-MLD, MDS-EB, MDS-U and CMMML were diagnosed in 11.5%, 14.7%, 36.4%, 27.2% and 10.1% of the population respectively. Within 12 months 78.1% of all treated patients terminated their first-line therapy because of death (20.0%), refractory to treatment (18.3%) or disease progression (16.7%). A second treatment was initiated in 10.1% of patients. The median LFS was 18.2 months (95% CI: 12.6-23.8). The median OS of MDS patients in Friesland was 22.5 months (95% CI: 15.2-29.7). Univariate analysis showed an association between lower OS and male gender (HR for women: 0.54, p=0.008, 95% CI: 0.34-0.85), age >80 years (HR: 2.7, p<0.005, 95% CI: 1.6-4.6), CCI score ≥3 (HR: 2.0, p<0.001, 95% CI: 1.3-3.0), IPSS score ≥1.5 (HR: 2.3, p=0.004, 95% CI: 1.3-4.1), IPSS-R score ≥4.5 (HR: 5.7, p<0.0005, 95% CI: 2.4-2.4) and MDS subtype MDS-EB (HR: 1.8, p=0.016, 95% CI: 1.1-2.9).

Summary/Conclusions: This study provided complete and representative population-based data on overall survival and treatment of patients with MDS, IPSS, IPSS-R score and MDS subtype according to WHO 2016 classification. Further, the leukemia free survival (LFS), the initial treatment and the duration of first-line treatment were analyzed.
Sustainable, but at present, its safety is questioned in MDS patients. Furthermore, in clinical practice, danazol, an attenuated androgen, has been reported to have some ability to improve the platelet count in this context (Wattel 1994; Chan 2002).

**Aims:** To assess efficacy and toxicity of danazol employed to improve severe thrombocytopenia in lower-risk MDS setting.

**Methods:** We retrospectively reviewed twenty-four patients affected by MDS and treated with danazol for thrombocytopenia. The initial dose was 600mg/day for all patients. The IWG criteria of response (Cheson 2006) were adopted. The outcome was observed every 3 months till 12th month. The overall response rate and the average platelet count or each time of observation were described. Progression free survival was estimated with the Kaplan-Meier product limit method, followed by the logrank test and by the Cox proportional-hazard regression.

**Results:** Of the 24 patients, 3 patients had a therapy-related MDS. At the starting time of danazol therapy, the IPSS was “low” in 9, “int-1” in 13 and “int-2” in 2 cases respectively; the IPSS-R was “very low” in 2, “low” in 11, “intermediate” in 7 and “high” or “very high” in 4 cases. At baseline in 14 patients the platelet count was lower than 20x10^3/μL, the average was 20x10^3/μL and the maximum value was 38x10^3/μL. The median dose was 600mg (range 200-600) also maintained at least up to 3 months (range 400-600). At 6 and 12 months the median dose therapy was 400mg (range 400-600 and 200-600 respectively). The response rate was 79.1% (19 responders on 24 treated). The average count increased as shown in Figure 1, over 60x10^3/μL after 6 months from the beginning of therapy and so maintained after one year. Only 3 patients lost the response at 187, 600 and 633 days respectively. The median survival was not reached in the presented series, and the probability to maintain the response is over 75% after two years from the beginning therapy in the responder patients (Figure 2). Adverse events recorded were as follows: moderate (grade 1 and 2) increase in transaminases in 4 cases (with reduction of danazol to 400mg/day in 2 of these); severe (grade 3) (with subsequently drug suspension); severe renal failure in 1 case (the drug was stopped); moderate (grade 1 and 2) increase of serum creatinine in 6 case (with reduction of danazol to 400mg/day in 2 of these); reversible cutaneous rush in 3 cases; amenorrhea in 1 case (the only fertile woman in the series); weight loss and loss of appetite in 1 case, weight gain in 1 case. Of the 24 patients, 3 patients had a therapy-related MDS. At the starting time of danazol therapy, the IPSS was “low” in 9, “int-1” in 13 and “int-2” in 2 cases respectively; the IPSS-R was “very low” in 2, “low” in 11, “intermediate” in 7 and “high” or “very high” in 4 cases. At baseline in 14 patients the platelet count was lower than 20x10^3/μL, the average was 20x10^3/μL and the maximum value was 38x10^3/μL. The median dose was 600mg (range 200-600) also maintained at least up to 3 months (range 400-600). At 6 and 12 months the median dose therapy was 400mg (range 400-600 and 200-600 respectively).

**Summary/Conclusions:** This series confirms the efficacy of danazol to improve platelet count in the most of patients with severe thrombocytopenia due to lower-risk MDS. In all patients with increased platelet count, the response was clinically significant. The median dose of 600mg should be maintained for at least 3 months to properly assess the effectiveness of therapy and then adjusted according to response and toxicity. The response may not be immediate, but seem to be reachable after 3-6 months of treatment. A responsive patients have short probability to loss the response, that may last for very long time. The toxicity profile of this drug is low. The mechanism of action of danazol in MDS patients remains unclear. Waiting for more information on the efficacy and safety of eltrombopag from the clinical trials in progress, danazol may be a good therapeutic option for these patients.

**E1196**

**TREATMENT PATTERNS IN PATIENTS WITH HIGHER-RISK MYELODYSPLASTIC SYNDROMES (HR-MDS) IN ROUTINE CLINICAL CARE IN THE UNITED STATES (US) – A CLAIMS DATABASE STUDY.

**J. Bell** et al.,

**Background:** Treatment of patients with HR-MDS includes hypomethylating agents (HMAs) (azacitidine and decitabine), high-intensity induction chemotherapy (IC), and stem cell transplant (SCT). Given the rarity of disease, information available on how these treatments are applied in practice is limited.

**Aims:** We evaluated the treatment patterns of HR-MDS patients engaged in routine care within the US.

**Methods:** Newly diagnosed HR-MDS patients who were ≥18 years old were retrospectively identified from Optum, a large US claims database between 1/1/2008 and 10/31/2015. HR status was based on ICD coding: ≥1 inpatient claim or ≥2 outpatient claims with an HR-MDS ICD-9/10 code (ICD-9 code: 238.73; ICD-10 codes: D46.20, D46.21, D46.22). The first MDS claim served as the index date. Exclusion criteria included: absence of continuous enrollment in medical and pharmacy benefits for 12 months prior to index date (baseline period), presence of other primary cancer, or receipt of any chemotherapy or SCT during the baseline period. First-line therapy (1LT) was defined as an MDS-specific treatment (as defined by NCCN MDS Guidelines v2.2017) initiated on or after the index date. Patients were followed until death, end of continuous enrollment, or end of study (12/31/2015). For patients with progression to acute myeloid leukemia (AML), treatment pattern evaluation stopped at AML diagnosis.

**Figure 1.** First-line treatment patterns in HR-MDS patients

**Figure 2.** Progression free survival

**Results:** 335 newly diagnosed HR-MDS patients were identified; 209 (62.4%) were treated with 1LT with treatment initiated within 1 month of diagnosis (median: 17 days, interquartile range [IQR]: 9, 35). A higher proportion of untreated patients (n=126) was ≥75 years of age (71.4% vs 53.1%, IQR: 67.2, 75.3 vs 55.0, 67.2, respectively, p=0.0007). A higher proportion of untreated patients (n=126) was ≥75 years of age (71.4% vs 53.1%) and had certain comorbidities at baseline (congestive heart failure, 23.0% vs 16.3%; renal disease, 24.6% vs 16.3%; diabetes 31.0% vs 23.4%, diabetes with end organ failure, 16.7% vs 8.1%) than treated patients. For treated patients, 1LT with azacitidine predominated in 68.9% of patients (n=144), followed by decitabine in 20.6% of patients (n=43), and immunomodulators (lenalidomide or thalidomide) in 8.7% of patients (n=18) (Figure 1). 4 patients had only SCT and an additional 14 had SCT at some point during follow-up. With regard to HMA therapy, median duration was 4.5 months (IQR: 2.6, 9.5) for azacitidine and 4.8 months (IQR: 2.1, 11.6) for decitabine. A greater proportion of decitabine-treated patients received a second HMA treatment with a median duration of 1.9 months (IQR: 1.0, 6.1) for azacitidine and 2.3 months (IQR: 1.0, 10.7) for decitabine, p=0.005. A greater proportion of decitabine-treated patients received a second HSCT with a median duration of 4.2 months (IQR: 1.0, 10.7) for azacitidine and 7.9 months (IQR: 3.0, 18.0) for decitabine, p<0.001.
received supportive care with colony-stimulating factors (CSFs) (39.5% vs 28.5%) and either erythropoiesis or platelet transfusions (69.8% vs 57.6%) during 1LT vs azacitidine-treated patients. Second-line therapy (2LT) was administered to 30 (14.4%) patients; the HMAAs again predominated in 63.3% of patients (n=19). Of patients not receiving 2LT, 65 (31.7%) progressed to AML, 47 (22.9%) had <30 days of follow-up due to proximity to end of study (38 [80.9%] of these were on 1LT at end of study duration), 33 (16.1%) continued to receive some supportive care and, 21 (10.2%) died.

Summary/Conclusions: Most HR-MDS patients treated in routine care are treated according to guidelines, with the HMA, azacitidine, predominating. Underlying comorbidities and older age may influence whether or not to treat HR-MDS patients with 1LT. For treated HR-MDS patients, duration of 1LT did not differ with azacitidine and decitabine. However, use of certain MDS-related supportive care treatments varied by choice of HMA, with more decitabine-treated patients receiving CSFs and transfusions. Further research is needed to determine how these factors influence both clinical outcomes in a HR-MDS population.

APPRECI8: A PIPELINE FOR PRECISE VARIANT CALLING INTEGRATING 8 TOOLS
S. Sandmann1,*, M. Karimi2, A. de Graaf3, B. van der Reijden3, E. Hellström-Lindberg2, J. Jansen3, M. Dugas1
1Institute of Medical Informatics, University of Münster, Münster, Germany, 2Department of Medicine Huddinge, Karolinska Institutet, Stockholm, Sweden, 3Laboratory Hematology, RadboudUMC, Nijmegen, Netherlands

Background: For the use of next-generation sequencing in clinical routine same platform, on a different platform and expert-based review. The same target region consisting of 19 genes was analyzed. Validation was performed by re-sequencing on the Roche 454. In all cases the same target region was sequenced on Illumina HiSeq. The second test set covered 89 MDS patients, sequenced in 2 different test sets. The first test set covered 237 MDS patients, sequenced on Illumina NextSeq. Subsequently, two independent test sets were analyzed. The first test set covered 237 MDS patients, sequenced on Illumina HiSeq. The second test set covered 89 MDS patients, sequenced on Roche 454. In all cases the same target region consisting of 19 genes (42,322bp) was analyzed. Validation was performed by re-sequencing on the same platform, on a different platform and expert-based review.

Aims: We developed a variant calling pipeline with both, high sensitivity and high PPV.

Methods: We developed appre8, a variant calling pipeline combining the output of 8 open-source variant calling tools: GATK HaploTypeCaller, Platypus, VarScan, LoFreq, FreeBayes, SNVat, Schem8 and VarDict. The pipeline performs several steps of filtration, including a final automatic characterization of all reported calls as artifacts, likely polymorphisms and likely mutations. To train our pipeline, we analyzed two data sets covering data of 54 myelodysplastic syndrome (MDS) patients, sequenced on Illumina HiSeq and 113 MDS patients, sequenced on Illumina NGSX3. Subsequently, two independent test sets were analyzed. The first test set covered 237 MDS patients, sequenced on Illumina HiSeq. The second test set covered 89 MDS patients, sequenced on Roche 454. In all cases the same target region consisting of 19 genes (42,322bp) was analyzed. Validation was performed by re-sequencing on the same platform, on a different platform and expert-based review.

Results: When analyzing the training sets with only one of the eight variant calling tools and considering all variants-pathogenic as well as polymorphisms - sensitivity ranges between 0.85 and 1.00 in case of set 1 and 0.47 and 0.99 in case of set 2. Although FreeBayes features highest sensitivity regarding both sets, it consistently features lowest PPV as well (set 1: 0.03, set 2: 0.02). Combining the output of all variant calling tools leads to perfect sensitivity, while PPV is 0.03 for set 1 and 0.02 for set 2. Application of our appre8 pipeline leads to a minor decrease in sensitivity (set 1 and set 2: 0.98), while PPV is significantly increased (set 1: 0.99, set 2: 0.94). The PPV of the appre8 output for both training sets is higher compared to each of the individual tools. Analysis of the independent test set 1 leads to comparable results. Sensitivity of the individual tools ranges between 0.82 and 0.99, while PPV ranges between 0.02 and 0.91. Combining the output of all variant calling tools leads to sensitivity of 1.00 and PPV of 0.02. However, application of appre8 leads to variant calling results with sensitivity of 0.98 and PPV of 0.99. To test the robustness of our approach, we analyzed Roche 454 data, although the pipeline was exclusively trained on Illumina data. Regarding the individual tools sensitivity ranges between 0.91 and 0.99, while PPV ranges between 0.07 and 0.68. By combining the output of all variant calling tools, sensitivity increases to 0.99, while PPV is 0.05. Application of appre8 leads to sensitivity of 0.98 and PPV of 0.76.

Summary/Conclusions: To consider variant calling results in clinical routine, it does not seem appropriate to rely on the output of a single tool only. Instead, combining the output of several tools and applying a set of filters as it is done by our appre8 pipeline leads to results with both high sensitivity and PPV. Nonetheless, variant calling results should, especially at allelic frequencies below 20%, always be viewed with criticism.

E1198
COMPARISON OF ADMINISTRATION OF HYPOMETHYLATING AGENTS EFFICIENCY OF ALLOGENEIC SCT IN ELDERLY PATIENTS WITH ADVANCED MDS
J. Cermak1,*, A. Vitek1, J. Maalouf-Soukupova1, M. Markova-Štastna1, Z. Bartova1, I. Flaschova1, M. Pala1, J. Havelka1, Z. Chutkova1, J. Vaclavik1, J. Hudec1, P. Cetkovsky1, P. Litva1, W. Kravitz2, J. Jenik3, A. Tozzi4, M. Gross5, P. Devaney6, T. Tichy7,8
1Clinical Hematology, Institute of Hematology and Blood Transfusion, Praha, Czech Republic

Background: Hypomethylating agents (HMA) have been introduced as a promising agent in the treatment of elderly patients with advanced myelodysplastic syndromes (MDS) leading to a response in approximately 50% of patients. However, most of the patients relapse and estimated years survival is below 10%. Stem cell transplantation (SCT) still represents the only curative treatment even in elderly patients with advanced MDS and it is connected with long-term survival in 35-40% despite relatively high risk of transplant related mortality (25-30%).

Aims: The aim of the study was a retrospective analysis of results of the treatment of 59 elderly patients (50 years of age or older) with MDS RAEB-2 or with acute myeloid leukemia with multilineage dysplasia with less than 30% of bone marrow blasts (MDS RAEB-T according to the FAB classification) who received either HMA or underwent allogeneic SCT.

Methods: In the HMA group, 34 out of total 38 patients received azacytidine (Vidaza®) in the dose of 75mg/m2x7 every 28 days and 4 patients were treated with decitabine (Dacogen®) in the dose of 20mg/m2x5 every 28 days. Median number of cycles administered was 10.4 (range 3-31). An age and diagnosis matched transplanted group consisted of 21 patients, 9 patients were transplanted upfront, 12 patients were pretreated either with combination chemotherapy (10 patients) or with HMA (2 patients) and achieved CR prior to SCT. Ten patients received myeloablative conditioning and 11 patients were transplanted after reduced conditioning regimen.

Results: A hematologic response to HMA (CR, PR, hematologic improvement) was observed in 22 out of 38 patients in HMA group (57.9%), CR was achieved in 10 patients (31.8%). In SCT group, engraftment was reached in 20 out of 21 patients, 11 patients died after SCT (6 on complications related to SCT, 5 patients relapsed). No difference was observed between both the groups in 2 years estimated overall survival (OS), (42% for SCT vs 36% for HMA), a significant difference in favour of SCT was present in estimated 3 years and 5 years OS (42% and 38% for SCT vs 9% and 4% in HMA group, P=0.001). Median OS was 18.7 months in HMA treated group compared to 42.6 months in SCT group (P<0.02). In a recent analysis performed at 48 months after starting the treatment, 2 patients treated with HMA (5.3%) and 9 patients treated with SCT (42.8%) were alive, 23 patients in HMA group and 6 patients in SCT group relapsed. No significant differences in results and adverse effects of treatment were observed between patients aged 50-60 years and those older than 60 years in both HMA and SCT groups.

Summary/Conclusions: Our results confirm previous observations showing that despite a promising effect of HMA resulting in hematologic response in more than 50% of elderly patients with advanced MDS, allogeneic SCT still represents the only potentially curative treatment connected with long-term survival in a significant number of patients even in elderly MDS patients.

Figure 1.
A MULTICENTER, OPEN-LABEL, PHASE I CLINICAL STUDY: SAFETY, EFFICACY, AND PHARMACOKINETICS OF ORAL RIGOSERTIB IN JAPANESE PATIENTS WITH RECURRENT/RELAPSED OR REFRACTORY MYELODYSPLASTIC SYNDROMES

K. Ishizawa12, K. Usuki3, K. Ando4, Y. Ueda5, T. Kiguchi6, N. Uike78, Y. Onishi2, H. Iida9
1Hematology and Cell Therapy, Yamagata University Faculty of Medicine, Yamagata, 2Department of Hematology and Rheumatology, Tohoku University Hospital, Sendai, 3Department of Hematology and Oncology, NTT Medical Center Tokyo, Tokyo, 4Department of Hematology and Oncology, Tokai University School of Medicine, Isehara, 5Department of Hematology/Oncology, Kurashiki Central Hospital, Kurashiki, 6Department of Hematology, Chugoku Central Hospital, Fukuyama, 7Department of Palliative Care Medicine, Saga Medical Center Koseikai, Saga, 8Department of Hematology, National Hospital Organization Kyushu Cancer Center, Fukuoka, 9Department of Hematology, National Hospital Organization Nagoya Medical Center, Nagoya, Japan

Background: Rigosertib, a novel phosphoinositide 3 kinase pathway inhibitor, induces G2/M arrest leading to the apoptosis of cancer cells and myeloblasts and is safe for and well tolerated by pts with low, intermediate-1, intermediate-2, or high-risk myelodysplastic syndromes (MDS).

Aims: The aims of the study were to assess the safety, efficacy, and pharmacokinetics of oral rigosertib and to determine the recommended dose (RD) for a Phase II clinical study in Japanese pts with recurrent/relapsed or refractory MDS.

Methods: We conducted a multicenter, open-label, Phase I clinical study of oral rigosertib. The key eligibility criteria were as follows: recurrent/relapsed or refractory MDS; age: 20 or older; ECOG PS of 0 to 2; and no major organ dysfunctions. Rigosertib (280 and 560mg BID) was administered orally in one 21-day cycle (up to cycle 6) that consisted of the 14-day, twice-daily, oral administration period, followed by 7-day monitoring. The primary endpoint was dose-limiting toxicity (DLT). The secondary endpoints were 1) safety as assessed with adverse events (AEs) and laboratory results, 2) efficacy as assessed with the International Working Group 2006 criteria, and 3) pharmacokinetics.

Results: Between March 2013 and November 2014, 6 male and 3 female pts (median age: 70; range 52-80) were enrolled. ECOG PS was 0 in 7 pts and was 1 in 2 pts, and 3 and 6 pts were eventually assigned to the 280 and 560mg BID arms, respectively. According to the FAB classification, 4, 2, 2, and 1 pts were categorized to RAEB, RARS, RA, and RAEB-1, respectively. The prognostic factor according to IPSS was Int-1 risk in 4 pts (1 and 3 pts in the 280 and 560mg BID arms, respectively) and was Int-2 in 5 pts (2 and 3 pts in the 280 and 560mg BID arms, respectively). DLT occurred in 1 pt in the 280mg BID arm and in 2 pts in the 560mg BID arm: the former consisted of type 2 diabetes and grade 4 delirium, and the latter grade 5 urinary tract infection and grade 3 prolonged QT interval. Therefore, the RD for a Phase II clinical study in Japanese pts was determined to be 560mg BID. On day 11 of treatment, 1 pt in the 560mg BID arm died of grade 5 urinary infection whose relationship with the investigational drug was rated to “Definite”. The presumed cause of death was septic shock caused by urinary tract infection. In the 560mg BID arm, the mean counts of leukocytes, neutrophils, lymphocytes, and reticulocytes in the 280mg BID arm did not decrease along with increases in the number of cycles delivered but decreased slightly in the 560mg BID arm. Any changes of note were not found in other hematological items. One case of grade 3 neutropenia developed in the 280mg BID arm, and 1 case each of grade 3 laboratory abnormalities—increased alanine aminotransferase, increased aspartate aminotransferase, prolonged QT interval, neutropenia, and decreased hemoglobin—occurred in the 560 BID arm. The hematological remission rate was 11.1% (1 narrow CR, 1/9 pts), and the hematological improvement rate was 11.1% (1 HI-P: 1/9 pts). Among the PK parameters, inter-individual variability was high.

Summary/Conclusions: The present chemotherapy regimen of oral rigosertib was well tolerated. Our study indicates that the RD for a Phase II clinical study is 560mg BID in Japanese patients with recurrent/relapsed or refractory MDS.

MYELODYSPLASTIC SYNDROMES - HIGHLIGHTS NOVEL CANDIDATE PROGNOSTIC MARKERS AND DISEASE SUBGROUPS

1Dana Farber Cancer Institute, Boston, 2Baylor college of medicine, Houston, United States, 3Cancer research center, Toulouse, France, 4Novartis, Boston, United States

Background: We have previously reported that E2F1 and its heterodimerization partner DP1 promote MM tumor proliferation both in vitro and in vivo; and observed an inverse correlation between their expression and patient survival suggesting a role in MM pathogenesis. Moreover, E2F2 functional impairment by a dimerization inhibiting stapled peptide significantly affects myeloma tumor cell growth while sparing effect on normal components of bone marrow as well as normal plasma cells, suggesting an E2F2 dependency in MM cells.

Aims: In this study, our aim is to defined the regulatory landscape of E2F2 in MM to better understand how E2F2 and DP1 drive myeloma cell proliferation; and to define the relationship between promoter proximal transcription factor-associated gene expression and super-enhancer-driven transcriptional programs.

Methods: We integrated genetic perturbation with functional omics to define E2F2 role in MM. Global occupancy of E2F1 and DP1 in MM was evaluated by ChIP-seq analysis. E2F1 and DP1 genomic localizations were then integrated to MM reference genome. Enhancers and super-enhancers were mapped using Rroad densities were calculated using bamliquidator (github.com/bradnerlab/pipeline/wiki/bamliquidator).

Results: Integration of E2F1 and DP1 genomic localization to MM reference genome revealed specific co-occupancy of the factors at promoters of active genes marked by H3K4me3, with a strong positive correlation between E2F2 and RNA Pol II expression (RNA Pol II) binding at transcription start sites. In contrast, active enhancers, as defined by promoter distal Mediator (MED1) peaks and marked by H3K27ac and BRD4, showed virtually no E2F binding. Prompt by these observations, we explored the transcriptional and functional interrelationship between E2F2 and BETs to identify their individual contribution to eventual functional effect in MM. Unbiased hierarchical clustering revealed distinct regulatory axes for E2F2 and BETs, with E2F2 predominantly localized to active gene promoters of growth/proliferation genes and BETs disproportionately at enhancer-regulated tissue specific genes confirming that these factors establish distinct target gene programs. At the extremes, we found less than 10% of genes were among the top 500 in BRD4 enhancer signal (i.e. SE-regulated) and top 500 E2F2 promoter signal. We hypothesized that the presence of BETs and E2F2 in distinct regulatory axes divides active genes in MM into those that can be selectively influenced by BET inhibition or E2F2 perturbation, but not both. In line with this we have observed that dual E2F2 and BET inhibition is synergistic for MM cell growth, both in vitro and in vivo.

Summary/Conclusions: In conclusions, our results highlight the existence of non-overlapping promoter and super-enhancer-associated dependencies in multiple myeloma, suggesting a sequestered molecular control that may be perturbed in cancer with potential for development of a promising therapeutic strategy.

ANALYSIS OF THE GENOMIC LANDSCAPE OF MULTIPLE MYELOMA HIGHLIGHTS NOVEL CANDIDATE PROGNOSTIC MARKERS AND DISEASE SUBGROUPS

1Dana Farber Cancer Institute, Boston, 2Baylor college of medicine, Houston, United States, 3Cancer research center, Toulouse, France, 4Novartis, Boston, United States

Background: In multiple myeloma (MM), next generation sequencing (NGS) has expanded our knowledge of genomic lesions, and highlighted a dynamic and heterogeneous composition. Despite a growing number of cases sequenced, the full potential of NGS studies has not been exploited so far.
Aims: We used a custom target pulldown (TPD) approach on a large cohort of MM patients at diagnosis, with homogeneous treatment and long follow-up, to further our understanding of the landscape of driver lesions in MM and how this can be used to improve prognostication and disease classification.

Methods: We used a custom-designed SureSelect pulldown strategy (Agilent Biotechnologies) to target 246 genes implicated in MM or cancer in general; 2538 single nucleotide polymorphisms; the immunoglobulin heavy chain (IGH) locus. We sequenced unmatched DNA from CD138-purified plasma cells from 418 patients with a median follow-up of 5.4 years using Illumina HiSeq2000 machines. We applied algorithms developed in-house to detect driver genomic events, filtering out potential artifacts and germline variants. We then ranked each mutation on its likelihood of being oncogenic.

Results: We identified 197 driver events including gene mutations, aneuploidies and IGH translocations (IGH-Tx), median of 6 per patient. Gene mutations where found in >99% of patients. At least one oncogenic mutation of a known driver gene previously identified (KRAS, NRAS, TP53, FAMM6C, BRF4, DIS3, TRAF3, SPH40, IRF4) was found in 64%, with a long tail of infrequently mutated genes with uncertain significance. Karyotypic class was assigned in 80% of patients, with 9% of hyperdiploid cases also showing an IGH-Tx (mostly t(4;14)). IGH-Tx and aneuploidies dominated the MM genomic landscape, KRAS and NRAS being the only point mutations present in the 15 most frequent driver events. Multivariate analysis by sparse Cox regression highlighted only four driver events with significant prognostic impact for both progression-free (PFS) and overall survival (OS): t(4;14) (HR 1.88, CI 1.25-1.84), ampl(1q) (HR 2.83, CI 1.92-3.59), del(17p) (HR 2.55, CI 1.66-3.92), and rare mutations of ATP13A4 (HR 0.08, CI 0.01-0.65, mutated in 1.4% of patients). We found a significantly worse prognosis for increasing numbers of driver lesions in each patient (median OS 8.2 vs 3.5 years for <5 and >8 driver events, respectively). This was only partially explained by instances of additive effect or interactions between variables, which were very informative but not frequent. To better investigate these findings in the context of the genomic landscape of each case, we applied Bayesian clustering algorithms. The large number of driver events screened led to the identification of three groups: in the largest one, some hyperdiploid and IGH-Tx cases clustered together, suggesting that secondary mutations and CNAs required for tumor progression are often shared between these two subgroups. We then identified two clusters both characterized by significantly lower number of mutations, but with opposing features. One was enriched for IGH-Tx, had the highest number of CNAs overall, showed higher prevalence of ampl(1q), del(13), del(17p), and had a shorter median OS of 5.3 years. The other was mostly composed of hyperdiploid cases and showed fewest CNAs and mutations, with a good prognosis (median OS not reached).

Summary/Conclusions: We report on the first attempt towards the use of extended tumor genotype for a genomic classification of MM using innovative clustering algorithms. Despite the heterogeneity of the disease, we could identify disease subgroups with a distinct spectrum and number of driver events carrying different prognosis, supporting the introduction of genomics in the clinical approach to MM.

A NOVEL METHOD FOR GENOME-WIDE COPY NUMBER ASSESSMENT FROM TARGETED SEQUENCING DATA AND CLINICAL DATA IN PATIENTS WITH MULTIPLE MYELOMA

G. Ryland1, J. Markham2, K. Jones3, E. Aydogan3, T. Paperfuss2, M. Chin3, J. Musto2, J. Campbell1, R. M. Dickson2, P. Blombery1

1Pathology, 2Research, Peter MacCallum Cancer Centre, Melbourne, Australia
2UCL Cancer Institute, Department of Haematology-Oncology, St Bartholomew’s Hospital, London, United Kingdom
3Haematology, Peter MacCallum Cancer Centre, Melbourne, Australia

Background: Assessment of gene mutations by next generation sequencing is now standard in patients with haematological malignancy. However, larger chromosomal aberrations (e.g. exon, gene and chromosome level gains and losses) also serve as critical prognostic indicators that guide therapeutic decision making. These larger genomic lesions are typically assessed using a separate methodology such as conventional cytogenetics/FISH. Aims: We aimed to develop and clinically validate a novel method for assessing genome-wide copy number changes using an existing hybridization-based targeted sequencing panel in order to further provide critical prognostic information at a lower cost and without the need for a separate assay.

Methods: A custom Agilent SureSelect capture panel targeting 313 genes of relevance in myeloid and lymphoid malignancies was sequenced on an Illumina NextSeq (paired end 75bp reads) to a mean depth of 700x. An in-house bioinformatics pipeline was created to analyse probe counts from on-target and off-target regions, with which the algorithm also examines clinical biomarkers. RNAseq data and expression arrays were used to understand the relevance in myeloid and lymphoid malignancies. Targeted sequencing was applied to a dataset of 126 MM patients with known copy number status as determined by conventional cytogenetics, FISH and MLPA. Our novel method detected numerous copy number changes that were beyond the targeted region (through genome-wide mapping and analysis of off-target reads) such as del(1p) in 12 patients, gain(1q) in 15 patients and MYC amplification in 5 patients. Moreover our method was able to interrogate and resolve the heterogeneity of changes on del(1p) including isolated deletions of FAMM6C, CDK2NC and FAP1. Of 25 patients with a TP53 mutation, 20 had concomitant del(17p) detected by our assay, while 1 case had a del(17p) without mutation; both monoallelic and biallelic TP53 aberration was associated with poor survival. Overall findings in this cohort include frequent DIS3 mutations in patients with IGH translocations (t(14;16) and 2p frequently associated with haematological malignancy. In the context of myeloma this can be used to report clinically relevant changes including deletions of 1p and 17p, and gains of 1q and 8q, as well as novel numerical chromosome aberrations.

Summary/Conclusions: We have developed and demonstrated utility of a reliable workflow for genome-wide copy number assessment that can be implemented using existing targeted short read sequencing data, greatly extending the utility of this technology beyond the identification and validation of changes for patients with haematological malignancy. In the context of myeloma this can be used to report clinically relevant changes including deletions of 1p and 17p, and gains of 1q and 8q, as well as novel numerical chromosome aberrations.

THE MULTIPLE MYELOMA GENOME PROJECT: DEVELOPMENT OF A MOLECULAR SEGREGATION STRATEGY FOR RISK STRATIFICATION OF MULTIPLE MYELOMA

1Celgene Corporation, San Francisco, 2Myeloma Institute, University of Arkansas for Medical Sciences, Little Rock, 3Dana Farber Cancer Institute, Harvard Medical School, Boston, 4Celgene Corporation, Summit, United States, 5Celgene Corporation, Seville, Spain, 6Centre de Recherche en Cancérologie de Toulouse Institut National de la Santé et de la Recherche Médicale, Toulouse, France, 7Newcastle University, Newcastle, United Kingdom

Background: Segmenting multiple myeloma (MM) into subgroups with distinct pathogenesis and clinical behavior is critical to implement a targeted therapy approach and improve prognosis for patients. Current technologies have elucidated major translocation groups and recurrent copy number changes with varying effects on prognosis. However, minor translocation and mutational groups remain poorly described due to limited sample numbers and small datasets. The availability of multiple sets of high quality genomic data associated with clinical information, cytogenetics, and outcomes provides an opportunity to create an integrative genomic predictor using mutational, chromosomal, and gene expression alterations to develop a classification system to segment MM into therapeutically meaningful subgroups.

Aims: The Multiple Myeloma Genome Project (MGP) is a global collaborative research project to develop a data-driven genomic molecular segregation strategy for MM to inform development and deployment of clinically relevant tests that could improve diagnosis, prognosis, and treatment of patients with MM.

Methods: We have established a dataset representing 1766 MM patients for which whole exome sequencing (WES; n=1397), Whole Genome Sequencing (WGS; n=779), and expression data from RNA-seq and expression arrays (n=1059) were available. Data were derived from the Myeloma XI trial, Dana-Faber Cancer Institute/Intergroupe Francophone du Myelome, The UAMS Myeloma Institute and the Multiple Myeloma Research Foundation (IA1 – IA9). Data were investigated for genetic abnormalities following preprocessing with state of the art methods and algorithms.

Results: Our analysis is focused on data from newly-diagnosed MM patients (n=1751), which is the majority of our dataset. We have begun to integrate genomic data with various correlates. Based on our data, we have at least...

ALVOCIDIB SYNERGIZES WITH VENETOCLAX IN PRECLINICAL MODELS OF MULTIPLE MYELOMA

H. Hawes1, M. Livingston1, W. Kim1, R. Mangelson1, P. Peterson1, C. Whatcott1, A. Siddiqui-Jain1, S. Weitman1, D. Bears1, S. Warner1
1Discovery Biology, Tolero Pharmaceuticals, Inc., LEHI, United States

Background: With over 30,000 new cases expected in 2016 (US), new treatments are desperately needed for the treatment of multiple myeloma (MM). Major developments in the treatment of MM have included introduction of agents such as lenalidomide, thalidomide, or bortezomib. Bortezomib, an inhibitor of the proteasome, reduces the degradation of many proteins, including the pro-apoptotic protein NOXA. However, intrinsic resistance to venetoclax treatment observed in MM patient samples has been attributed to a low BCL-2-to-MCL-1 gene expression ratio, suggesting a central role for MCL-1 in cell survival in this context as well. NOXA functions to sequester the anti-apoptotic BCL-2 family member, MCL-1. Increased MCL-1 expression is a known resistance mechanism to venetoclax treatment in a variety of cell types including chronic lymphocytic leukemia and lymphomas. Considering the central role of MCL-1 to treatment efficacy in MM, we investigated the ability of an MCL-1-lowering agent, namely the CDK9 inhibitor alvocidib, to potentiate the activity of venetoclax in MM.

Aims: We screened approximately 2,000 small molecular compounds to find out novel small compounds that suppress growth of MM cell lines, and found that OSSL_325096 has strong anti-proliferative activity on MM cell lines (IC50 100-500µM). In this study, we evaluated anti-MM activity of OSSL_325096 through VCP inhibition, in an ATP-competitive manner.

Methods: OSSL_325096 were purchased from Princeton BioMolecular Research, Inc. (Princeton, NJ, USA). His-tagged human VCP (hVCP) cDNA was cloned and utilized to generate hVCP protein in vitro as previously described (Chou et al., PNAS, 2011, vol. 108(12): 4834-4839) to evaluate the VCP inhibition by OSSL_325096. For in vitro analysis, MM xenograft model mice were intraperitoneally administered with vehicle or 50mg/kg of OSSL_325096 twice a week.

Results: OSSL_325096 inhibited proliferation of MM cell lines, including one bortezomib-resistant cell line (Figure 1). OSSL_325096 induces apoptosis in these cell lines and primary MM cells purified from patients but not in PBMCs from healthy donors. OSSL_325096 treatment leads to accumulation of poly-ubiquitinated proteins, cleavage of caspase-3, and up-regulation of CHOP in MM cell lines (Figure 2), suggesting this compound induces caspase-mediated apoptosis and ER-stress in MM cells. OSSL_325096 has a chemical structure similar to several known VCP inhibitors. Therefore, to evaluate the role of VCP in MM cell lines, we next performed knockdown of VCP. Knock-down of VCP induced apoptosis in MM cell lines, accompanied with accumulation of poly-ubiquitinated protein. In-silico protein-drug binding simulation suggests possible binding of OSSL_325096 to the ATP binding site of VCP.

Summary/Conclusions: We have elucidated emerging roles of VCP and its potential as a therapeutic target in several cancer subtypes including multiple myeloma (MM).

Summary/Conclusions: Taken together, our data suggest that the combination of alvocidib and venetoclax in the context of bortezomib resistance further, it suggests that CDK9-mediated targeting of MCL-1 may offer a clinical route to addressing intrinsic resistance in MM patients.

**Background:** RNA has diverse sets of regulatory functions and a recent analysis by a large repertoire has identified a large number of non-coding transcripts. One of which, long intergenic non-coding RNA (lincRNA) with transcripts longer than 200 nucleotides, are located between the protein coding genes and do not overlap exons of either protein-coding or other non-lincRNA genes. lincRNAs have been considered to provide regulatory functions, however, their precise role in the immune dysregulated microenvironment has never been investigated. First, we observed an increase in inflamed microenvironment markers (increase in CD4+ and CD8+ cell count in favor of CD4+/population and HLA-DR expression on plasmacells and non-plasmacells) during the course of SMM. Secondly, expression of T cell inhibition markers (PD1, LAG3) was significantly augmented during disease progression. For the first time, we reported a comprehensive analysis of microenvironment modifications in sequential samples of SMM patients. Expression of checkpoint markers was augmented in samples of patients with progressed SMM as compared to patients with stable SMM. These findings suggested that immune dysregulated microenvironment were observed. In particular, increased in PDL1 and LAG3 expression could be of clinical interest due to the current availability of checkpoint inhibitors drugs targeting these molecules. The results of this study should be confirmed on prospective studies with larger number of patients.

**INHIBITION OF EXTRACELLULAR VESELIC SECRETION INDUCES APOPTOSIS OF BONE MARROW STROMAL CELLS: TOWARDS SOIL-TARGETED THERAPY IN MULTIPLE MYELOMA**

T. Umezu1,*, S. Imanishi2, S. Yoshizawa1, K. Ohyashiki1, J. Ohyashiki2

1UCL Cancer institute, university college london, London, United Kingdom

Background: Multiple myeloma (MM) is a plasma cell malignancy that remains incurable, despite therapeutic advances. Immunotherapies have recently shown much promise in this and other cancers, and are under intense investigation. Autologous stem cell transplantation (ASCT) is standard of care in young fit newly diagnosed patients. In the post-ASCT setting, the minimal disease burden and reconstituting immune system may be a favourable context for immunotherapies, including cellular therapy and checkpoint blockade. Autologous MM cells aimed to characterize immune composition and function and LAG3 expression in MM cells post-ASCT, to identify candidate immune checkpoint proteins for therapeutic targeting.

Methods: BM aspirates were obtained from patients with MM at 3-months post ASCT (n=28), and 6-12months post ASCT (n=41) at University College Hos- pital. Control BM aspirates were collected from healthy volunteers undergoing BM harvesting with the Anthony Nolan. Immunofluorescence surface staining was performed using antibodies to CD3, CD4, CD8, LAG-3, PD-1, HLA-DR, ICOS and the intracellular markers GzmB and Foxp-3. All p-values indicate differences from normal donors unless otherwise stated. The absolute number of post-ASCT patients with residual disease have higher numbers of cytotoxic CD4 and CD8 cells and LAG3 expression could be of clinical interest due to the current availability of checkpoint inhibitors drugs targeting these molecules. The results of this study should be confirmed on prospective studies with larger number of patients.

**Summary/Conclusions:** From, we observed an increase in inflamed microenviron- ment markers (increase in CD4+ and CD8+ cell count in favor of CD4+/population and HLA-DR expression on plasmacells and non-plasmacells) during the course of SMM. Secondly, expression of T cell inhibition markers (PD1, LAG3) was significantly augmented during disease progression. For the first time, we reported a comprehensive analysis of microenvironment modifications in sequential samples of SMM patients. Expression of checkpoint markers was augmented in samples of patients with progressed SMM as compared to patients with stable SMM. These findings suggested that immune dysregulated microenvironment were observed. In particular, increased in PDL1 and LAG3 expression could be of clinical interest due to the current availability of checkpoint inhibitors drugs targeting these molecules. The results of this study should be confirmed on prospective studies with larger number of patients.
Background: Bone marrow stromal cells (BMSCs) interact with multiple myeloma (MM) cells in the bone marrow, and also create a permissive microenvironment for MM cell growth and survival. Recent evidence indicated that MM cell-BMSC communication is mediated by extracellular vesicles (EVs) plays an important role in the MM microenvironment.

Aims: In this study, we investigated the biological property of EVs and miRNAs in EVs derived from BMSCs, aiming to establish the emerging strategies to target MM microenvironment to prevent tumor growth and spread. Methods: Bone marrow samples were obtained from MM patients (age 56 to 82, n=20) and monoclonal gammopathy of undetermined significance (MGUS) patients (age 44 to 82, n=13) in accordance with the Declaration of Helsinki and using protocols approved by the research Ethics Committee of Tokyo Medical University (IRB No. 2648), and BMSCs derived from MM patients (MM-BMSCs) and MGUS patients (MGUS-BMSCs) were isolated by the classical cell adhesion method. EVs were isolated from conditioned medium of BMSCs using a Exoquick-TG (SBI). The size of EVs was confirmed using a NanoSight LM10 (Malvern). The RNA from cells and EVs was profiled for 381 miRNAs using a TaqMan low-density array (ABI). The RNA from cells and EVs was profiled for 381 miRNAs using a TaqMan low-density array (ABI). For functional analysis of candidate miRNAs, the miRNA mimics (Ambion) were transfected into BMSCs using HiPerFect (Qiagen). Cell viability of miRNA-overexpressed BMSCs were determined using WST-8 (Dojindo), and Apoptosis rates were determined using Caspase-Glo assays (Promega). To assess the effect of the inhibition on EV secretion, BMSCs were treated with 10 µM GW4869 (nSMase2 inhibitor, Sigma) for 48h. Results: MM-BMSCs andMGUS-BMSCs had a fibroblast-like morphology in culture, and were homogeneously CD73+, CD90+, CD105+, CD34-, and CD45-. MM-BMSCs had a higher expression of α-smooth muscle actin (α-SMA) than mgUS-BMSCs. The nanoparticle size distribution of EVs from derived BMSCs was approximately 50 nm. We found high expression of miR-10a in the EVs derived from MM-BMSCs, while the expression of intracellular miR-10a was low in MM-BMSCs. We therefore hypothesized that low expression of cellular miR-10a might be important for survival of MM-BMSCs. As a result, miR-10a was packaged into EVs, and they were released to the extracellular space. To test the hypothesis, miR-10a mimic was transfected into MM-BMSCs andmgUS-BMSCs. It was confirmed that overexpression of miR-10a inhibited cell proliferation and induced apoptosis of MM-BMSCs, while the cell proliferation and apoptosis ofmgUS-BMSCs were not affected by the overexpression of miR-10a. We also found that inhibition of EV release with GW4869 promote the accumulation of intracellular miR-10a in MM-BMSCs, and EV-release inhibitor also can inhibited cell proliferation and induced apoptosis of MM-BMSCs.

Summary/Conclusions: Our results provide the possibility that the inhibition of EV secretion induced apoptosis of MM-BMSCs that can support MM cell growth and survival in BM microenvironment.

Background: Elevated expression of PDZ binding kinase (PBK), which encodes a serine/threonine kinase, has been reported to be associated with a poor prognosis in a variety of cancers. The public gene expression profiling data also showed that higher expression of PBK was related with a poor prognosis in myeloma. However, the molecular mechanisms of PBK expression have never been investigated in myeloma.

Aim: The aim of this study was to elucidate PBK gene functions associated with myeloma cell growth in vitro and in vivo.

Methods: Eight human myeloma cell lines including ANBL-6, 8226, OPM2, and KMS-11 were used in this study. The expression levels of mRNA and protein of PBK were detected by real-time RT-PCR and western blotting, respectively. The promoter activity of the whole PBK gene was determined using the dye terminator method. Knockout of PBK was performed using CRISPR-Cas 9 system. A single guide RNA sequence for PBK was chosen using the online CRISPR design tool (www.eb dumpsters.de). Knockout of PBK was confirmed by quantitative real-time RT-PCR. Colony formation assay. The KMS-11 cells were subcutaneously injected to mice and were homogeneously CD73+, CD90+, CD105+, CD34-, and CD45-. Surprisingly, in the PBK-deficient KMS-11 cells, all of which carry PBKA/A, and OPM2 cells, which carry PBKG/G, augmented cell proliferation in the PBK-deficient OPM2 cells, which carry PBKA/A originally. Furthermore, Thr 9 phosphorylation on PBK was increased in cells expressing PBKG/G compared with those cells expressing PBKA/A.

Results: In vitro anti-MM activity of therapeutic BIX01294 treatment was tested using the murine 5TGM1 model. Difference in overall survival between groups was determined in the UAMS-TT2 cohort of newly diagnosed MM patients (n=345), susceptibility and proliferation were examined by the MITT and colony formation assay. The KMS-11 cells were subcutaneously injected to mice and tumor volumes were observed every 3 to 4 days. Of note, PBK inhibition by CRISPR-mediated knockout enhanced cell proliferation in ANBL-6, 8226, and OPM2 cells, all of which carry PBKA/A. Surprisingly, in the

KMS-11 cells carrying PBKG/G, PBK inhibition by CRISPR-mediated knockout suppressed cell growth in vitro and in xenograft mice (Fig. 2). Moreover, exogenous expression of PBKG/G augmented cell proliferation in the PBK-deficient OPM2 cells, which carry PBKA/A originally. Furthermore, Thr 9 phosphorylation on PBK was increased in cells expressing PBKG/G compared with those cells expressing PBKA/A.

Figure 1.

Summary/Conclusions: Our findings indicate that expression of PBKG/G was associated with myeloma cell proliferation, while PBKA/A was likely linked to tumor suppression. Increased phosphorylation of Thr 9 on PBK might contribute to proliferation in cells with PBKG/G. These results provide a novel insight into the mechanisms underlying myeloma cell growth and PBK is a promising target for the treatment of multiple myeloma.

CYTOTOXIC LYMPHOCYTES IN NEWLY DIAGNOSED MYELOMA HAVE REVERSIBLE FUNCTIONAL AND PHENOTYPIC ABNORMALITIES THAT MAY OFFER THERAPEUTIC OPPORTUNITIES
F. Seymour1, J. Cavagnah1, J. Gibben1
1Haematology-Oncology, Barts Cancer Institute, London, United Kingdom

Background: A bi-directional interaction exists between malignant cells and those of the immune microenvironment. This dynamic relationship results in gradual loss of clonal control associated with loss of cytotoxic lymphocyte (CTL) response. Mechanisms of immune escape are varied and include the induction of immune checkpoint molecules, notably the PD-1/PDL1 axis. Multiple myeloma is a disease characterised by a pre malignant phase which can evolve into periods of asymptomatic and symptomatic disease. One possible mechanism for disease progression is progressive loss of immunological control. The malignant plasma cell has multiple potentially immune modifying effects including the expression of PDL1 and induction of a pro-tumour micro-environment. The role of CTLs is less well understood.

Aims: To undertake deep immune profiling of the CTL landscape in myeloma in order to establish whether features of immune dysregulation are present and to identify potential therapeutic opportunities.

Methods: Cryopreserved bone marrow from 18 patients with newly diagnosed and untreated myeloma and 9 controls were assessed using a 36 parameter mass cytometry panel. The panel was designed to assess 9 immune checkpoint regulators, 5 cytokines, and markers of proliferation and degranulation across multiple lymphocyte subsets. Samples were stimulated with CD3 and CD28 to assess immune function. Dimensional clustering/algorithmic analysis was used alongside traditional data analysis techniques to identify functional subpopulations characterised by expression of multiple markers.

Results: The cytokine profile in newly diagnosed myeloma is shifted towards a pro-tumour microenvironment with particularly marked elevation of TGFb throughout resting CTLs (36.4% v. 66.2%, p=<0.0001). IFNγ production is reduced in the resting myeloma effector population (0.33% v. 0.18%, p=0.0099). Stimulation restores the cytokine profile to match that of controls. Myeloma CTLs retain the capacity to proliferate and produce the constituents for cytotoxic granule formation, however elevated PD1 expression alongside other markers of exhaustion cut NK cells away from the putatively exhausted phenotype is occurring. Strongly PD1 expressing populations in myeloma are larger (26% v.43%, p=0.05) and have increased rates of co-expression of CTLA4 (32%, 64%, p=0.0015), PD1L (26% v. 47%, p=0.0198) and TIM3 (34% v. 56%, p=0.0241). Populations of CTLs from myeloma up-regulate expression of the TCR co-stimulatory molecule CD40L (74% total CD8), NGK2D (45% total CD8) and OX40 (33% total CD8) following stimulation.

Summary/Conclusions: Clear differences can be identified in the functional and phenotypic features of CTLs in myeloma compared to those of controls. The partial nature of these defects and the fact that reversibility can be demonstrated suggests that these cells have not yet reached the stage of irreversible exhaustion. Taken together this data suggests that targeting immune checkpoint regulators at an early disease stage, in order to optimise immunological function and reverse partial defects, is a viable therapeutic strategy to explore. PD1, PD1L, CTLA4 and TIM are all potential immune checkpoint targets. In addition, our specific IgG antibodies BIX01294 and the UNC138 significantly and potently reduced MM cell viability in vitro. Moreover, both inhibitors also induce cell cycle arrest and apoptosis. When comparing between both inhibitors, BIX01294 was found to be the most potent in inducing apoptosis. Mechanistic studies for BIX01294 furthermore indicated that BIX01294 treatment of myeloma cells is associated with a strong increase in the formation of LC3B puncta and an increase in LC3II and beclin-1 protein levels. In addition, we found that BIX01294 sensitizes MM cells to the proteasome inhibitor bortezomib and the Bcl-2 inhibitor ABT199. Lastly, therapeutic treatment of 5TGM1 inoculated mice with BIX01294 resulted in a clear improvement in survival, as evidenced by a clear decrease in tumor burden and a significant increase in the overall survival of BIX01294 treated mice compared to vehicle treated mice.

Summary/Conclusions: Altogether, our results demonstrate for the first time the importance of the histone methyltransferases G9a/GLP in MM pathogenesis. Further functional targeting of G9a/GLP induces MM cell apoptosis, enhances MM sensitivity to ABT- 199 and bortezomib and significantly delays tumor progression in the murine 5TGM1 model. Thus, G9a/GLP targeting represents a promising strategy to improve treatment of MM.

Background: Reactive oxygen species (ROS) are normal byproducts of a wide variety of cellular processes. ROS have dual functional roles in cancer cell pathophysiology. At low to moderate levels, ROS act as signaling transducers to activate cell proliferation, migration, invasion, and angiogenesis. In contrast, high levels of ROS induce cell death. In multiple myeloma (MM), ROS overproduction is the trigger for apoptosis induced by several anticancer compounds, including proteasome inhibitors. However, no drugs that mainly affect oxidative stress are currently used for treatment of MM in the clinic. In MM, p53 status is an independent prognostic marker, since patients harboring p53 abnormalities are highly resistant to standard therapies, and the incidence of p53 mutations and deletions increases during disease progression. Therefore, restoration of p53 is an attractive strategy for treating advanced relapsed and refractory MM (RRMM) patients. CP-31398 (CP) is a small molecule that activates wild-type p53 or restores tumour-associated p53 mutants to wild type p53 function in multiple human cancer cell lines; this leads to cell cycle arrest and/or apoptosis. The growth of rhabdomyosarcoma cell lines can be inhibited by p53-dependent induction of ROS, but it is not clear whether CP-induced cytotoxicity proceeds via a similar pathway.

Aims: Our study was aimed at evaluating the anti-myeloma activity of CP.

Methods: MM cell lines (MM1S, RPMI8226, U266, KMS5, OPM2, Delta47, KMS11) were treated with 48 h CP (20 nM). Subsequently, the inhibitory effect of CP on MM cell line growth was assessed using a WST-1 assay. In order to elucidate the cytotoxic mechanism of CP, immunofluorescence and flow cytometry analysis were performed. Measurements of cytosolic and mitochondrial ROS were performed with CellROX Deep Red or MitoSOX Red. For quantification of ROS, cells were analyzed by flow cytometry and fluorescence microscopy. The therapeutic potential of CP was evaluated by its ability to suppress tumor growth in vivo using the subcutaneous RPMI8226 murine xenograft model for human MM.

Results: In this study, we have demonstrated that the p53-activating small molecule CP-31398 effectively inhibited the growth of MM cell lines and primary MM isolates from patients with IC50 values in the range of 2.5±11.2 µM. CP also suppressed the growth of MM xenografts in mice. Mechanistically, CP was found to induce intrinsic apoptosis in MM cells via increasing mitochondrial and cytosolic ROS production. Interestingly, CP-induced apoptosis occurs regardless of the cells’ p53 status, suggesting that CP has additional mechanisms of action. In addition, we found that CP acted synergistic with the protease inhibitor carfilzomib (CFZ) in MM cells, providing a framework for further studies of CP alone and in combination with CFZ to improve the prognosis for MM patients.

Summary/Conclusions: Our findings indicate that CP could be an attractive candidate for treatment of MM even in patients with p53 abnormalities; this study may identify an unmet clinical need, as such patients currently have a poor prognosis.

E1214
TUMOR MICROENVIRONMENT TRANSFORMATION FROMmugUS TO MYELOMA IS ASSOCIATED WITH PRO-TUMORAL ACTIVATION OF MESC- ENCHYMAL STROMAL CELLS (MSC)
C. Giorgino1,*, D. Tullio1, N. Parrinello1, P. La Cava1, G. Camiolo1, M. Turrino1, N. Caporarello1, C. Anfuso1, C. Conticello1, A. Romano1, F. Di Raimondo1

Background: A well-recognized feature of MM is the intimate relationship between plasma cells (PC) and bone marrow microenvironment, characterized by a modified extracellular matrix, enhanced angiogenesis and presence of cells with immune suppressive activity, including tumor-associated macrophages and myeloid-derived suppressor cells (MDSC). Recently, we have demonstrated that MM-MSC are able to convert normal immature myeloid cells in MDSC contributing to immune-escape mechanisms.

Aims: We hypothesize that MSC derived from Smoldering myeloma (SMM) and MM are in an activated status that promotes tumor growth and increase microenvironment transformation.

Methods: Human peripheral blood mononucleated cells (PBMC) isolated from SMM or MM-MSC. After 6 days, neutrophils (N) were isolated using anti-CD66b magnetic microbeads and were tested for their ability to induce angio-
Results: Only N educated by SMM- and MM-MSC (both from patients at diagnosis, relapsed and refractory) significantly up-regulated Arg1, NOSE2 and TNFα and exhibited suppressive effect with a reduction of T cell proliferation (p<0.001). By co-culturing-educated-N with Human Brain Microvascular Endothelial Cell (HBMEC), we observed increased both tube length and number of branch points only in conditions where HBMEC were incubated with SMM- and MM-MSC. MM patients that displayed an angiogenic phenotype after achieving sCR were CT/PET negative.

vs

Results: [Results from the study are presented here.]

Background: Angiogenesis is a hallmark of tumors, and it is a peculiar characteristic in bone marrow (BM) of multiple myeloma (MM) patients. MM is a still incurable disease that strongly depends on interactions with BM microenvironment. Endothelium of MM patients displays malignant behavior as compared to a healthy counterpart (1). MM displays a dysregulation of the Notch pathway due to Jagged ligands and Notch receptors overexpression. This condition brings to the generation of homotypic and heterotypic interaction loops that sustain MM growth. Moreover, Notch signaling, with MM resident cells, including osteoclast and BM stromal cells (BMSCs), although its role in the crosstalk of MM and endothelium is still to be clarified.

Aims: The aim of this study is to investigate Notch role in MM crosstalk with endothelium exploiting 2D assays and 3D organoid systems to mimic tumor microenvironment (TME).

Methods: The Notch ligands, Jagged1 and 2, were silenced in the MM cell line RPMI8226 (RPMI8226shJAG1/2) using an inducible lentiviral vector carrying two short hairpin RNAs targeting Jagged1 and 2. To mimic the endothelial compartment, cultured human endothelial cells (HPECs) were used for the stromal compartment. The GFP+HS5 cell line, Matrigel and wound healing assays were set up to investigate Notch role in modulating the angiogenic potential of MM cells co-cultured with HPECs and HPCAECs. HPECs in response to MM-derived soluble factors. To develop a TME-like system, a decellularized extracellular matrix (dECM) was used as a physiological scaffold for organoid generation. dECM was produced by treating murine fibroblast NIH3T3 with ascorbic acid and was loaded with cells for organoids generation. We evaluated apoptosis of MM cells in single culture and co-culture with BMSCs or HPCAECs by flow cytometry.

Results: [Results from the study are presented here.]
ARQ-197, a small-molecule inhibitor of c-MET, reduces tumour burden and prevents tumour-associated bone disease in a murine model of myeloma.

Aims: To understand the role of stromal induced drug resistance and to identify new therapeutic targets in myeloma.

Methods: GFP-tagged human myeloma cell lines, 8226, U266 and MM.1s, were co-cultured with MM patient-derived BMMSCs or HS.5 cells with or without BTZ for 24 h. MM cells in monocultures were used as controls. Co-cultures were then applied to magnetic cell separation to isolate MM cells for downstream analyses including western blotting and mRNA or miRNA qPCR arrays. Furthermore, percent apoptosis of gated GFP+ cells was determined using FACS. In other experiments, MM cells were exposed to BMMSCs pre-treated with Brefeldin-A (BFA) or separated with a transwell (TW) insert. For functional analysis, miR-101-3p was overexpressed using lentiviral transduction and survival of BMMSCs (BMSCs) were then seeded on BMMSCs in presence or absence of BTZ. GFP fluorescence-based adhesion, cytotoxicity and annexin-V/PI apoptosis were applied.

Results: qPCR arrays showed that BMSCs up- or down-regulated several miRNAs and mRNAs in MM cells. Survivin (BIRC5) was confirmed to be conserved in different MM cell lines and protein and mRNA levels increased. In contrast, miR-101-3p was confirmed to be significantly downregulated by stroma in MM cells. Moreover, suppression of miR-101-3p or upregulation of survivin was reversed partially when BMSCs were pre-treated with BFA but highly significantly when they were separated from MM cells with a TW insert. The same trend was observed in in vivo analyses FACS analysis indicating that direct cell-to-cell adhesion was more effective in BMSC-induced modulations in MM cells. Next we identified that survivin was a direct target of miR-101-3p, overexpression of miR-101-3p suppressed survivin mRNA/protein. As indicator of involvement in stroma-mediated drug resistance, survivin and miRNA-101-3p expression correlated with the number of BMMSCs in MM cell monolayers compared to tumour spheroid cultures. Furthermore, miR-101-3p overexpression or silencing of survivin increased BTZ-induced apoptosis in MM cells in the absence or presence of BMSCs significantly overcoming stroma-mediated drug resistance. To test whether miR-101-3p could also regulate adhesion of MM cells to BMSCs, we showed that miR-101-3p significantly reduced adhesion of MM cells to HS.5 and primary MM BMSCs compared to scrambled control. This finding suggests that miRNA-101-3p regulates cell adhesion-mediated drug resistance (CAMDR) by modulation of BM-MSC adhesion.

Summary/Conclusions: Our results identify a mechanism whereby BMSCs induce drug resistance in MM cells by upregulating survivin and downregulating miRNA-101-3p which directly targets survivin. Overexpression of miRNA-101-3p or silencing of survivin sensitizes MM cells to BTZ significantly overcoming stroma-induced drug resistance. These findings disclose a role of survivin-miRNA-101-3p axis in regulation of BMSC-induced BTZ resistance in MM cells, thus provide a rationale to further investigate the anti-myeloma activity of miR-101-3p in combination with BTZ as a potential therapeutic strategy in MM.

CHARACTERIZING THE CONTRIBUTION OF BONE MARROW StromA-DERIVED IL-6 TO myELOMA GROWTH AND RESISTANCE

T. Csikos1,*, H.-J. Prins1, E. Drent1, P. Poddighe2, S. Zweegman1, T. Mutis1, R. Groen1
1Hematology, 2Clinical Genetics, VU University Medical Center, Amsterdam, Netherlands

Background: The bone marrow niche is a specialized microenvironment, which allows for the survival, growth and differentiation of hematopoietic stem and progenitor cells. This niche also provides the optimal growth conditions for hematopoietic malignancies, such as multiple myeloma (MM). A complex interplay between cytokines, adhesion molecules, cell receptors and their ligands provides the MM plasma cells with survival signals and contribute to therapy resistance.

Aims: To unravel the role of the bone marrow mesenchymal/stromal cells (BMMSCs) in MM cell growth, progression and drug resistance.

Methods: Hypothesizing that the interaction between MM cells and the BMMSCs is bidirectional, we have compared BMMSCs from healthy individuals, myeloma and MM patients and used our "humanized" bone marrow-like model to characterize the molecular impact of MM cells on BMMSCs. Finally, we have validated targets by generating HS-5 knock-out lines using CRISPR/Cas9 targeting.

Results: Analyzing the BMMSCs of healthy individuals, myeloma, and MM patients, as well as BMMSCs impacted by MM in our humanized bone marrow-like model, allowed us to confirm established disease biomarkers (e.g. IL-
CD38 monoclonal antibody, Daratumumab (DARA), induces and mediates MM cell killing. However, the expression of CD38 and other functionally related ectoenzymes in the bone niche of MM patients and the potential effects of DARA on bone cells are still unknown.

**Aims:** The aim of this study was to define the expression profile of CD38, CD31, CD39, CD73 and CD203a on MM and bone niche cells. Then, the effect of DARA on bone cells was evaluated by in vitro osteoclastogenesis.

**Methods:** In order to evaluate the expression profile of the ectoenzymes, we firstly performed immunohistochemical analysis on bone biopsies in a cohort of 37 patients with MM and 14 with monoclonal gammopathy of uncertain significance (MGUS). The same antigens were analyzed by flow cytometry on primary MM cells, mesenchymal stromal cells (MSC), osteoblasts (OB), monocytes and osteoclasts (OC). Then, we tested DARA effects, in the presence or absence of All-trans retinoic acid, compared with human IgG isotype control, on OC differentiation from either CD138+ cell fraction or purified MM bone marrow (BM) CD14+ cells. We also investigated the effect of microvesicles isolated from a MM cell line treated with DARA or the human IgG isotype control, on OC differentiation.

**Results:** MM cells showed a high expression of CD38 and were positive for CD31, CD39, CD73 and CD203a at variable levels. However, we did not find any significant difference in the expression of CD38 and related ectoenzymes between MM and MGUS patients. CD38 was expressed by monocytes and early OC progenitors but not by OB. MM cell expression of CD203a was higher for CD73 and CD203a. Indeed, CD38 was lost during OC differentiation. Consistently, we found that DARA reacts with CD38 expressed by monocytes and its binding inhibits early in vitro osteoclastogenesis from total mononuclear cells. All-trans retinoic acid treatment increased the inhibitory effect of DARA on OC formation.

**Summary/Conclusions:** Our data suggest that DARA inhibits osteoclastogenesis, targeting monocytes and early progenitors. These observations provide a rationale for the use of an anti-CD38 antibody-based approach as treatment for MM-induced osteoclastogenesis.

TRIM33 IS A POTENTIAL TUMOR SUPPRESSOR IN MULTIPLE MYELOMA

**E1224**

**Background:** TRIM33 is a potential tumor suppressor in multiple myeloma (MM). TRIM33 has previously been identified as a tumor suppressor in chronic myelomonocytic leukemia and hepatocellular carcinoma.

**Aims:** The aim of this study was to examine TRIM33 expression and to investigate its role as a potential tumor suppressor in MM.

**Methods:** Western blotting and qPCR were used to analyse TRIM33 expression at basal level and following knockdown in four MM cell lines representing a range of MM translocations; JNJ3 t(14;16), U266 t(11;14), KMS-18 t(4;14), OPM-2 t(4;14). TRIM33 knockdown was performed using shRNA plasmids. Cell Titer-Glo® was used to determine cell viability following knockdown of TRIM33 expression. Gene expression analysis was performed using a custom microarray containing 384 human genes associated with TRIM33 expression in non t(4;14) MM. Low TRIM33 expression has also been associated with poorer overall survival in patients with a t(4;14) chromosomal translocation.

**Results:** Compared to normal bone marrow, lower expression of TRIM33 was observed at both gene and protein level (p=0.03) in the t(4;14) cell lines, KMS-18 and OPM-2. Conversely, expression was found to be high in the non t(4;14) cell lines, JNJ3 (p=0.001) and U266 (p=0.015). Knockdown of TRIM33 expression did not alter cell viability in the t(4;14) cell lines. However, cell viability was found to be increased in JNJ3 (p=0.001) and U266 (p=0.015). Knockdown of TRIM33 expression caused a significant increase in genes associated with TRIM33 expression in non t(4;14) cell lines, particularly (p=0.004) and hyperdiploid cluster (p=0.03). Low TRIM33 expression has also been associated with poorer overall survival (GSE2658; p=0.0034).

**Summary/Conclusions:** Our data suggest that DARA inhibits osteoclastogenesis, targeting monocytes and early progenitors. These observations provide a rationale for the use of an anti-CD38 antibody-based approach as treatment for MM-induced osteoclastogenesis.

---

EXPRESSION OF CD38 AND ECTOENZYMES OF THE ADENOSINERGIC PATHWAYS IN MM EYE-BONE NERVE: A RATIONAL BASIS FOR THE USE OF DARATUMUMAB TO TARGET OSTEOCLAST FORMATION IN MULTIPLE MYELOMA

**E1223**

**Background:** Bone disease is the hallmark of multiple myeloma (MM). It is known that MM cells express CD38 and that a recently developed human anti-CD38 monoclonal antibody, Daratumumab (DARA), induces and mediates MM cell killing. However, the expression of CD38 and other functionally related ectoenzymes in the bone niche of MM patients and the potential effects of DARA on bone cells are still unknown.

**Aims:** The aim of this study was to define the expression profile of CD38, CD31, CD39, CD73 and CD203a on MM and bone niche cells. Then, the effect of DARA on bone cells was evaluated by in vitro osteoclastogenesis.

**Methods:** In order to evaluate the expression profile of the ectoenzymes, we firstly performed immunohistochemical analysis on bone biopsies in a cohort of 37 patients with MM and 14 with monoclonal gammopathy of uncertain significance (MGUS). The same antigens were analyzed by flow cytometry on primary MM cells, mesenchymal stromal cells (MSC), osteoblasts (OB), monocytes and osteoclasts (OC). Frassoni9, A. Neri10, L. Del Vecchio11, P. Musto12, D. Cilloni13

Aims: To determine whether altered lncRNAs have a functional involvement in this disease.

Methods: Paired-end strand-specific RNA sequencing (ssRNA-seq) was performed in 38 purified plasma cell (PC) samples from MM patients, as well as in 5 tonsil PCs (TPCs) and in 3 bone marrow PCs (BMCs) of healthy donors as controls. We also performed ssRNA-seq of populations from B cell differentiation (Naïve, Germline Center, Memory and PC). To study the heterogeneity of lncRNAs expression we performed sample level enrichment analysis (SLEA), in which each individual lncRNA was compared to BMCs. To determine the epigenetic regulation of lncRNAs we used whole-genome bisulfite sequencing and CHIP-seq, shRNA-mediated knockdown using 2 different shRNAs and MTSS1 overexpression in 3 different cell lines (MM.1S, MM.1R and KMS-11)

Results: We identified 40.552 novel lncRNAs in MM samples that were present in at least 3 of the 38 patients. Principal component analysis demonstrated that TPCs and BMCPCs cluster separately, suggesting that, in spite of being the same tissue type, their transcriptomes are very different. We observed that the expression of lncRNAs was more heterogeneous than that of coding genes. More importantly, SLEA showed 11.067 lncRNAs that were overexpressed and 5.601 underexpressed in >40% of patients. Thus, the number of deregulated genes analyzed by SLEA was much larger than the 70 IncRNAs that appeared as deregulated when all MM were compared to BMCs, demonstrating the relevance of studying the heterogeneity in this disease. To determine the functional role of heterogeneously altered IncRNAs in the biology of MM cells we focused on the study of LINC-SMIL0 (Specific Myeloma inhibitor Long non-coding RNA), a lncRNA that it is overexpressed in ~40% of MM patients and not in the different stages of B-cell differentiation. DNA methylation analysis demonstrated that CpGs located upstream of LINC-SMIL0 showed a significant hypomethylation immGUS, that was even more pronounced in MM samples. We also have observed a gain of active chromatin modifications in the promoter region of LINC-SMIL0 in MM patient samples. These data suggest that epigenetic alterations, namely the gain of active histone modifications, may be the cause of LINC-SMIL0 overexpression in MM. Knockdown of LINC-SMIL0 in 3 different cell lines (MM.1S, MM.1R and KMS-11) resulted in reduced proliferation and induction of apoptosis, indicating this IncRNA is essential for the survival of MM cells.

Summary/Conclusions: All together, these data demonstrate that alteration of IncRNAs is an important and unexplored feature of MM. Moreover, overexpression of LINC-SMIL0 is required for the survival of MM cells and could represent a potential therapeutic target for the treatment of this disease.

E1226

ROLE OF EPHA3 IN MULTIPLE MYELOMA: A PERSPECTIVE FOR A NOVEL TARGET THERAPY?

F. La Rocca1,*, I. Airoldi2, I. Di Carlo3, P. Marotta4, G. Falco5, V. Simeon6, E. Di Carlo1, T. Ezponda1, C. Meydan2, M. Kulis3, R. Ordóñez1, V. Segura4, L. Garate1, D. Alignani 5, B. Paiva6, J. Frassoni9, A. Neri10, L. Del Vecchio11, P. Musto12, D. Cilloni13, F. D'Auria1, F. Frassoni9, A. Neri10, L. Del Vecchio11, P. Musto12, D. Cilloni13, F. D'Auria1, F. Frassoni9, A. Neri10, L. Del Vecchio11, P. Musto12, D. Cilloni13

Background: The tyrosine kinase Eph receptor A3 (EphA3) has recently emerged as a potential therapeutic target, since it is found to be overexpressed in many cancers, including some hematological malignancies (Keane et al. 2012). Furthermore, EphA3 has been found overexpressed not only in neoplastic cells, but also in the microenvironment of different human cancers, where its targeting inhibits tumor growth by disrupting supportive stroma and vasculature (Vail et al. 2014).

Aims: Due to the absence of relevant information about the role of EphA3 in multiple myeloma (MM), we aimed to evaluate the expression of this molecule in primary bone marrow plasma cells (BMPCs) from MM patients and MM cell lines compared to healthy controls (HCs). In addition, using a “loss of function” approach by mRNA silencing and an anti-EphA3 monoclonal antibody (EphA3mAb), we studied in vitro plasma cells (PCs) viability and movement. Finally, we analysed the in vivo effects of EphA3mAb in a MM mouse xenograft model.

Methods: EphA3 mRNA and protein where investigated in 15 MM BMPCs, 11 MM cell lines and 10 HCs by qRT-PCR and flow cytometry. The effects of EphA3 targeting by lentiviral RNA silencing (shRNA) and anti-EphA3mAb on PC trafficking and viability were studied by adhesion assay on fibronectin and on bone marrow stromal cells (BMScs), invasion assays and proliferation MTS assay, respectively. Gene expression profiling (GEP) was performed in shEphA3 versus shControl cells. Furthermore, the effects of EphA3mAb were analysed in a MM xenograft model by measuring tumor size and by assessing angiogenesis, proliferation and apoptosis rate on tumor biopsies using immunohistochemistry (anti-CD31, anti-ki67 and TUNEL assay, respectively). Statistical significance was determined by the t-test or One-way ANOVA analysis.

Results: EphA3 was found overexpressed in primary MM BMPCs and MM cell lines when compared with HCs (figure 1A-B). The EphA3 loss of function by siRNA and by EphA3mAb significantly inhibited in vitro the ability of MM PCs to adhere to fibronectin, to BMScs and to invade (figure 1C-E), without affecting cell proliferation and viability (data not shown). GEP showed that knockdown of EphA3 modulated some molecules that regulate adhesion, migration and invasion processes. Importantly, the treatment with EphA3mAb in vivo significantly reduced tumor size and inhibited angiogenesis, as revealed by decrease of CD31+ vessels at immunohistochemistry (data not shown).

Gaslini Institute, Genova, 10Department of Clinical Sciences and Community Health, University of Milan and Hematology, Fondazione Ca Granda, Ospedale Maggiore Policlinico, Milano, 11Department of Molecular Medicine and Medical Biotechnologies, University of Naples “Federico II”, Napoli, 12Scientific Direction, IRCCS, Referral Cancer Center of Basilicata (CROB), Rionero in Vulture, 13Department of Clinical and Biological Sciences, University of Turin, Torino, Italy

Figure 1.
SUMMARY/CONCLUSIONS: Our findings suggest that EphA3 is a novel regulator of MM PC trafficking, in part via effects on adhesion and invasion; its targeting using EphA3mAb inhibits tumor growth, possibly by reducing angiogenesis, though other possible mechanisms of tumor death cannot be excluded. These data, together with the favourable clinical properties of a humanized EphA3mAb reported in a phase I trial on acute myeloid leukemia and myelodysplastic syndrome (Swords et al. 2016), support EphA3 targeting as a new potential therapeutic opportunity for MM that would warrant to be further investigated.

E1227

PROGNOSTIC SIGNIFICANCE OF AMP1Q21 IN MULTIPLE MYELOMA
T. Abramova1, T. Obukhova1, L. Mendeleva1, O. Pokrovskaya1, E. Grinbanova1, M. Nareyko1, L. Grebenyuk1, O. Votyakova1, M. Solovev1, M. Fett1, M. Frisova1, I. Nakastoev1, A. Grachev1, M. Kanaeva1, A. Danilina1, S. Kulkov1, M. Rusinov1, V. Savchenko1
1Hematology Research Center, 2N. Blokhin Russian Cancer Research Center, Moscow, Russian Federation

Background: Multiple Myeloma (MM) is a genetically heterogeneous and complex disease with widely diverging survival times from months to years. Amplification of locus 1q21 (amp1q21) is among the most commonly reported genetic abnormalities in MM, but its prognostic value remains unclarified.

Aims: To define the frequency of amp1q21 in MM and its correlation with other chromosomal abnormalities, clinical course and prognosis.

Methods: In 134 patients (pts) with newly diagnosed MM from December, 2009 to March, 2016, 67 male and 67 female, median age 77 years (30-81), we performed FISH with locus-specific and centromere DNA probes (XL 1p32/1q21, XL IGH plus, XL t(11;14), XL t(4;14), XL t(14;16), XL t(14;20), XL t(6;14), XL cMYC BA, XL 5p15/9q22/15q22, XL P53 (MetaSystems), D13S25 (Cytocell). Induction therapy with bortezomib-based courses was initiated for 131 pts, 3 pts with smoldering MM remained under observation. Response was evaluated according to the IMWG criteria for 127 pts, 4 pts died in induction. 48 pts were underwent ASCT. The median follow-up of group was 19.3 months (3.2 – 77.4). Progression was diagnosed in 69 pts, in 12 pts of FISH-analysis was performed also in disease progression.

Results: Chromosomal aberrations were revealed in 133 of 134 (99%) pts. T(1q14;1q23) was detected in 42.5% (57/134), hyperdiploidy in 57.5% (77/134), hypodiploidy in 2.1% (3/134) pts. In 11.2% (15/134) a concurrent t1q14h1q23 and a trisomy were found. The IgH translocations t(11;14), t(4;14), t(14;16), t(14;20), t(6;14), t(14;20) were observed at a frequency of 16.4%, 12.7%, 3.2%, 0.7% respectively, chromosomal partner is not found in 6.7%. Del(13q) was detected in 40.3% (54/134), del(17p) in 12.7% (17/134), tMYC/8q24 in 17.2% (23/134). Amp1q21 was detected in 39.6% (53/134). We identified 3 copies of 1q21 in 60% (80/134) and >3 copies 1q21 in 21 in 39.6% pts. Cases with Amp1q21 had a high incidence of del(13q) (OR=2.71 (1.32-5.55); p=0.006 and t(4;14) (OR=4.49 (1.47-13.51); p=0.005), as well as higher LDH levels (OR=2.27 (1.09-4.72); p=0.027). From 12 pts investigated in progression amp1q21 was found in 9 pts (75%); in 2 cases amp1q21 was not found at diagnosis and was revealed in disease progression only; in 7 cases - amp1q21 was detected at diagnosis and in progression, and its copy number did not change. The difference in response after induction between pts with or without amp1q21 was not statistically significant: CR – 11.8% versus 14.5%, VGPR – 39.2% versus 27.6%; PR – 37.2% versus 27.6%; therapy resistant 11.8% versus 30.3% (p=0.07). Pts with amp1q21 had significantly worse 5-year overall survival (OS) (43.5% vs 79.4%; p=0.07). According to copy number of 1q21 the 5-year OS pts carrying 3 or >3 copies of 1q21 were 67.3% and 20.9% (p=0.0016) (Figure 1).

Figure 1.

Summary/Conclusions: Our results show that amp1q21 has a significant impact on OS MM pts in cases of more than 3 copies of locus only. In cases of 3 copies of 1q21 OS pts is comparable with OS in group without amp1q21.

Amp1q21 can appear in the course of MM, therefore FISH-analysis of locus 1q21 should be performed at diagnosis, as well as in disease progression.

E1228

ADAPTIVE IMMUNE RESPONSE IN PLASMA CELL DYSCRASIAS: IMMUNE PROFILING AND DETERMINATION OF CIRCULATING B CELL LEVELS AS A SURROGATE ASSAY FOR BONE MARROW TESTING
S. Drain1, P. Egan1, I. Deighan2, P. Elder3, T. Bjourson1, F. McNicholl3, M. Bowere4, C. Morris5, D. Alexander1
1Stratified Medicine, C-tric, Ulster University, 2Clinical Biochemistry, 3Haematology Department, Altnagelvin Hospital, Derry, 4Haematology Department, Ulster Hospital, Belfast, United Kingdom

Background: Immune paresis is commonly identified in patients with plasma cell dyscrasias (PCD). Often, in newly presenting multiple myeloma (MM), it is associated with intractable infections for which the patient first seeks medical help. Furthermore, recent evidence suggests the importance of assessing levels of bone marrow (BM) derived B cells for risk stratification of the MM patients as reduced levels of B-cells in the BM have been associated with poorer outcomes and reduced progression free survival1. This cellular measure of adaptive immune function (ie: B cell enumeration) is, however, seldom analysed in the peripheral blood (PB) of patients with PCD.

Aims: This study was designed to examine measures of the adaptive immune response in PCD patients, by measuring relative and absolute numbers of T, B cell subset, NK and NKT cells at different stages of PCD, and to determine if the PB-B cell component can act as a surrogate marker for B cell enumeration in MM.

Methods: PB and BM lymphocyte subset analysis was performed on samples obtained from a range of PCD patients (n=70) using directly conjugated monoclonal antibodies (MAB) and multicolour flow cytometry, carried out on a FACSAria III cell sorter (BD, Oxford, UK). Serum protein electrophoresis was performed to identify and quantify paraproteins, and uninvolved Ig levels were quantified by immunoturbidimetric sFLC were estimated using the Freelite assay on the SPAplus instrument (Binding Site, Birmingham, UK).

Results: Data is presented on 102 PB samples obtained from 70 PCD patients at different stages of disease, including monoclonal gammopathy of undetermined significance (MGUS), smoldering myeloma (SMM), and MM at diagnosis (MMD), throughout treatment (MMT) and at relapse (MRR). Quantification of circulating lymphocyte subsets showed reduced, absolute, numbers of B cells (56/102), T cells (19/102), TCI cells (32/102), CTLs (17/102), NK cells (32/102) and NKT cells (72/102). Furthermore, these reduced B cell levels were more frequently seen in the MMD and MMT groups (50% of samples) compared with the other PCD groups (10-25% of samples). Lymphocyte subset analysis was also performed on paired PB and BM samples from 14 patients with MM and a significant, positive, correlation was seen between relative numbers of B cells in both PB and BM (r=0.0001, r=0.094). No clearcut correlations were found between reductions in uninvolved and sFLC levels, and numbers of cells involved in the adaptive immune response.

Summary/Conclusions: The results presented here are further evidence of immune paresis in PCD with specific effects seen at the cellular level. The highest frequency of reduction was in B lymphocytes and NK cells, in keeping with reduced levels of circulating B cells, followed by T cells, particularly TH cells which have a crucial role in B cell Ig production. Relative B cell levels in BM were significantly correlated with B cell levels in PB and we suggest that monitoring of B cell levels in the PB of PCD patients may serve as a surrogate assay for enumeration of B cells in BM.

NOVEL MONOCLONAL ANTIBODY THERAPY TARGETING CD26 IN MULTIPLE MYELOMA
H. Nishida1, H. Suzuki1, M. Hayashi1, M. Sakamoto1, T. Yamada1
1Pathology, Keio University, School of Medicine, Tokyo, Japan

Background: Bone disease is a hallmark of multiple myeloma (MM) and targeting osteoclasts (OCs) to alleviate bone destruction is a component of the standard care for MM. CD26 is a 110-kDa cell surface glycoprotein with DPPIV enzymatic activity and has well-defined roles in T-cell activation and several tumor developments, including malignant lymphoma. However, little is known about the role of CD26 in regulating bone remodeling.

Aims: In this study, we examine the CD26 expression in human normal OCs and OCs of MM patients. We explore the function of CD26 in osteoclastogenesis (OCG) and investigate the effects of humanized anti-CD26 monoclonal antibody (CD26mAb) on human OCG. We further define the molecular targets of CD26 signaling cascade in OCG and explore the therapeutic potential of CD26mAb for treating MM.
Methods: Human BM-MNCs derived from normal human subjects or MM patients were cultured with M-CSF plus sRANKL with or without 250 nM CH-223191 for 48 h for OC formation for TRAP staining and functional assay. To assess the mechanisms of action of CD26Ab on OCs, RANK signaling proteins were examined by immunoblotting.

Results: CD26 is expressed on normal human OCs and is intensely expressed on activated OCs in MM, M cancer, and BM samples from multiple myeloma (MM) patients at first diagnosis. The cells were also stained with CD26 antibody to distinguish tumor CD26+ BM cells. After 72 hours, cells were stained with CD8 antibody to distinguish tumor CD26+ BM cells. CD26 expression was accompanied by increased phosphorylation of MKK3/6 and p38MAPK, which is crucial for human OC formation with its downstream activation of microphthalmia-associated transcription factor (mTrkA) and plays an important role in OC functions. CD26 blockade and down-regulation of RANK-L and type 1 collagen. It decreased the size of OCs and the number of nuclei per OC, with significantly defective bone resorption activity. It was revealed that in the presence of CD26Ab, which blocks RANK activation, the OC precursors (MKK3/6) were involved in the phosphorlation pathway was specifically, rapidly inactivated and subsequently, its downstream miF/2a phosphorylation was persistently inhibited. Thus, OC maturation with its bone resorption was impaired by suppressing the expression of TRAP and OC fusion proteins. In contrast, MKK3/6-p38MAPK-mTrkA was not phosphorylated at all in mature OCs after RANKL stimulation, regardless of the absence or presence of CD26Ab. These results suggest that CD26Ab blocked RANKL induced p38MAPK phosphorylation in OC precursor cells, but not in OCs. The activation of other MAPKs including ERK and SAPK/JNK, or NFκB was rapidly induced in response to RANKL both in OC precursor cells and mature OCs, regardless of the absence or presence of CD26Ab. CD26Ab did not directly affect mature OC functions. Next, although CD26Ab did not demonstrate direct inhibition of proliferation of MM cells, to further investigate the role of CD26 in MM cells in the BM, co-cultures of 11 MM cell lines with 11 MM cell lines were performed. We examined the expression of CD26 in CD26 Ab. Although CD26 expression was only slightly detected in any of MM cell lines in mono-culture, CD26 expression level was upregulated in all MM cell lines, co-cultured with OCs by flow cytometry and immunohistochemistry. CD26 protein level in these cell lines was also increased by immunoblotting or ELISA. To further explore the CD26 expression in the BM of MM patients, we examined the expression of CD26 in OCs and MM cells. The expression of CD26 was found in OCs in the BM of MM patients, which was consistent with the results of immunohistochemistry. We initially screened 25 CD138+ MM patients and 6 human myeloma cell lines (HMCs) for PERK mRNA expression. Our data showed that PERK mRNA is highly expressed in almost all patients (5-10 fold higher than the mean PERK expression of HMCs).

Results: We tested the effect of GS2606414 on the proliferation of MM cells. CD26Ab was treated with different doses of GS2606414 at two time points (24 and 48 hours). Treatment of cells with 3-30 µM GS2606414 resulted in a dose-dependent inhibition of cell proliferation in all HMCs ranging for 20-95% reduction of proliferative activity, thus, indicating the dependency of these cells on CD26 signaling. Treatment of M-CSF and sRANKL induced human OCs for 24 hours resulted 25% and 15% increase in apoptotic cells by Annexin-V staining. These results suggest that CD26 signaling is associated with increased the apoptosis of T-cells with high AhR, as assessed by Annexin-V staining (percent Annexin-V positive and 7-AAD negative cells in 0 and 25 µM kynurenine was 11.8% and 36%, respectively). We found that CH-223191 could block the inhibitory effects of kynurenine on T-cells. We found that the percentage of T-cells with high AhR in culture with IDO negative and positive Raji cells was 46.7% and 61.4%, respectively, while the percentage of T-cells with low AhR was 41.6% and 39.4%. These data showed that only T-cells with high AhR were inhibited at IDO-positive tumor microenvironment. Next, we could generated the activated T-cells from 10 of 12 BM samples from MM patients. We found that there was a positive correlation between the expression of AhR and the proportion of plasma cells in BM (r=0.76, P=0.04) and clinical stage of MM. The mean expression of AhR in T-cells of stage 2 and stage 3 were 7.3% (3.3-11.6) and 19.5% (11.3-26.6), respectively.

Summary/Conclusions: Kynurenine produced by IDO, induce inhibitory signal in T-cells through the AhR. Anti-CD4 and anti-CTLA-4 therapies, which block directly the inhibitory signal in T-cells, have been getting some clinical benefits against such as melanoma and Hodgkin lymphoma. Therefore, the AhR in T cells might be a target for IDO-positive hematological malignancies.
Summary/Conclusions: In conclusion, given the on-target pharmacological effects of PERK inhibitor on MM, development of PERK inhibitors may offer a therapeutic advantage that would affect MM pathogenesis and treatment.

ENVIRONMENTAL CONTROL OF PLASMA CELL FITNESS IN MULTIPLE MYELOMA: MALIGNANT CO-OPTATION OF ARGININE AS NOVEL IMMUNE THERAPEUTIC TARGET

A. Romano1,2, J. M. García Manteiga3, V. Simeoni4, L. Parrinello5, L. Canziani1, E. Milan1, M. Ghizzinardi1, D. Tibullo6, C. Giallongo2, P. La Cava2, F. Cremascoli1, C. Concillo1, P. Musto6, F. Cicere4, F. Di Raimondo4, S. Cenci1

1Division of Genetics and Cell Biology, San Raffaele Scientific Institute, Milan, 2Department of Clinical Therapeutics, National and Kapodistrian University of Athens, Greece, 3Laboratory of Pre-clinical and Translational Research IRCCS, CROB Referral Cancer Center of Basicaltic, Rionero in Vulture (Pz), 4Division of Genetics and Cell Biology, Azienda Ospedaliera Policlinico e Vittorio Emanuele di Catania, 5Center for Translational genomics and Bioinformatics, San Raffaele Scientific Institute, Milano, 6Department of Oncology, San Raffaele Scientific Institute, Milan, Italy

Background: The bone marrow (BM) environment plays a crucial role in the incurable plasma cell (PC) malignancy multiple myeloma (MM). Our previous work showed that actin(0.02, p<0.001) B cell-secreted and PC-specific Blmp-1, immunoglobulin (Ig) production and ATP availability (Pengo, 2013) and that MM is addicted to the autophagy receptor SQSTM1/p62 (Milan, 2015). Among putative pro-tumoral players are immunosuppressive BM-derived high-density neutrophils (HDNs), but their role in MM is unknown.

Aims: We hypothesized that in MM HDNs sustain PC fitness sustaining p62 through environmental arginine deprivation.

Methods: We integrated diverse unbiased and hypothesis-driven approaches: (1) gene expression profiles (GEP) of patient-derived circulating HDNs (60 MM, 30mGUS, 30 healthy controls), (2) metabolic profiling by UPLC/GC-MS of ad hoc collected BM and peripheral plasma (16 MM, 17 smoldering MM, 30mGUS, 29 controls), and (3) functional and expression analysis in vitro studies on human MM cell lines. We validated our observations in primary MM cells using bioinformatic analysis of transcript expression levels detected by RNA-sequencing available from the open-access, public clinical and molecular database, the CoMMpass Researcher Gateway (https://research.themrmf.org, v I48, n=649).

Results: In vitro, selective and progressive arginine deprivation (range 1000-0 µM) in four MM cell lines (MS 1S, U266, OPM2 and RPMI8282) activated the GCN2/CHOP axis, resulting in increased p62 and Blmp-1 expression, increased ATP availability and immunoglobulin production. Conversely, stable lentiviral p62 silencing significantly reduced Blmp-1 and ATP, and led to complete extinction of MM cell lines within 10 days of culture. Bioinformatic analysis of MMRF-Encompass trial data showed a positive correlation between p62 and Blmp-1 expression and OS (HzR: 0.38, 95% CI: 0.23-0.6, p<0.001). Both p62 and Blmp-1 expression were independent prognostic factors for EM. In the multivariate analysis ISS and abnormal eGFR were the only independent prognostic factors for EM. When we incorporated ISS and eGFR in a single prognostic model (CKD-EPI/ISS) we identified 3 distinct prognostic groups: 1) low risk group including patients with ISS1 and CKD-EPI b40ml/min/1.73m2, 2) high risk group including patients with ISS3 and CKD-EPI <40ml/min/1.73m2 and 3) intermediate risk group including patients that did not fit in either low or high risk group. The incidence of EM in each group was 8.1% 39% and 15.3%, respectively (OR: 2.8, 95% CI: 1.9-4.1, p<0.001). Multivariate cox regression analysis of prognostic factors for OS in the whole population demonstrated that CKD-EPI/ISS model was the strongest independent prognostic factor for OS (HR: 0.38, 95% CI: 0.23-0.6, p<0.001).

Summary/Conclusions: Based on our data, the combination of eGFR estimated by CKD-EPI with ISS (CKD-EPI/ISS) represents a powerful independent prognostic model for EM and OS, in the era of novel agents. The markers constituting ISS and eGFR are cheap and available for most of MM patients, therefore the CKD-EPI/ISS prognostic model will be widely applied. Nevertheless, the establishment of CKD-EPI/ISS model requires further validation.

ESTIMATED GLOMERULAR FILTRATION RATE (eGFR) CALCULATED BY CKD-EPI EQUATION COMBINED WITH THE INTERNATIONAL STAGING SYSTEM PROVIDES A POWERFUL PROGNOSTIC MODEL FOR EARLY MORTALITY IN MYELOMA PATIENTS

E. Katodritou1, V. Palaska1, E. Giannopoulos1, S. Papadaki1, A. Gerofotis1, N. Karampatzakis1, K. Keramidioti1, E. Verras2, K. Kokiviadou2, I. Batsis3, I. Sakellari3, A. Anagnostopoulos3, M.-A. Dimopoulos4, P. Konstantinidou1, J. M. Garcia Manteiga3, V. Simeoni4, L. Parrinello5, L. Canziani1

1Hematology Department, Theagenion Cancer Hospital, 2Hematology Department, Papageorgiou General Hospital, 3Hematology Department and Bone Marrow Transplantation Unit, G. Papanikolaou General Hospital, THESSALONIKI, 4Department of Clinical Therapeutics, National and Kapodistrian University of Athens, School of Medicine, ATHENS, Greece

Background: During the last decades, the introduction of autologous transplantation and novel agents has improved early mortality rates (EM, henceforth defined as death within year after diagnosis) in Multiple Myeloma (MM). However, the incidence of EM remains high. Data relating to prognostic factors for EM in MM are limited.

Aims: The aim of this study was to explore for possible prognostic factors for EM, which could be a useful tool for planning treatment strategy in MM.

Methods: We have studied the medical records of 479 patients with MM (MF: 258/221, median age: 68 years, range 29-88, IgG: 269, IgA: 123, light chain: 72, non-secretory: 15), diagnosed and treated in our Department between January 2001 and January 2016; 86 patients (18%) had EM. Comparisons of patients’ characteristics between the EM group and the rest of the patients were performed with χ2, one-way ANOVA and Mann Whitney U test. Prognostic factors for EM and overall survival (OS) were studied by using logistic regression and cox regression analysis, respectively; OS was plotted by Kaplan-Meier; p<0.05 was considered as statistically significant.

Results: Patients with EM were more often men with a higher median age; hemoglobin, platelets and albumin were lower whereas W2 microglobulin, lactate dehydrogenase (LDH) and calcium were higher in the EM group compared to the rest of MM patients (p<0.05). The percentage of patients with abnormal estimated Glomerular Filtration (eGFR) calculated by chronic kidney disease epidemiology collaboration (CKD-EPI) creatinine equation (<40ml/min/1.73m2) was higher in the EM group compared with the rest of the patients (60% vs 17%, p<0.001). In accordance with the International Staging System (ISS), advanced MM stage (i.e. ISS3) was observed more often in the EM group compared to the rest (65% vs 31%, p<0.001). High risk cytogenetics including t(4;14), t(14;16) and del(17p were present in 48% of patients in the EM group vs 21% of the rest of patients (p<0.001). The presence of EM included infections 54%, relapsed/refractory disease: 26%, other causes: 6%. Univariate logistic regression analysis demonstrated that ISS, revised ISS (R-ISS), abnormal LDH, hemoglobin <10g/dl, high risk cytogenetics, and CKD-EPI <40ml/min/1.73m2 were independent prognostic factors for EM. In the multivariate analysis ISS and abnormal eGFR were the only independent prognostic factors for EM.

Based on our data, the on-target pharmacological effects of PERK inhibitor on MM, development of PERK inhibitors may offer a therapeutic advantage that would affect MM pathogenesis and treatment.

E1234
ACTIVATED AND EXPANDED NATURAL KILLER CELLS FROM MULTIPLE MYELOMA PATIENTS DESTROY TUMOR DRUG RESISTANT CELLS AND CLONOCENIC TUMOR CELLS

A. Leivas1,2, I. Rapado1,2, L. Fernández1, A. Pérez-Martínez2, J. L. Lahuereta2, J. Martínez-López1,2

1Hematological Malignancies Clinical Research Unit, Spanish National Cancer Research Center, 2Hematology, Hospital Universitario 12 de Octubre, 3Pediatrics, Hospital Universitario La Paz, Madrid, Spain

Background: Multiple myeloma (MM) remains an incurable disease. Novel therapeutic strategies targeting drug resistant cells (DRC) and clonogenic tumor cells (CTC) are needed. Our group has conducted a phase I clinical trial with activated and expanded autologous NK cells (NKAES) in patients with refractory MM with a relevant clinical effect. Likewise, it has been possible to discriminate DRCs in MM by side population (SP) detection.

Aims: The aim of this study was to characterize DRC and to check the activity of NKAES against these DRCs and CTCs while preserving the hematopoietic progenitor cell.

Methods: Flow cytometry of the side population was performed by Dye Cycle Violet efflux detection to characterize DRC of MM cell lines and bone marrow samples from MM patients. The side population was purified by sorting and characterized by RNAseq. NK cells from MM patients' peripheral blood were sorted and cocultured in the genetically modified K562-mb15-41BBL cells in order to obtain NKAES. The activity of NKAES cells against SP was evaluated by time lapse microscopy and the activity against CTCs was evaluated by methylcellulose assay. In vitro safety against CD34+ progenitors was evaluated by time-resolved fluorescence cytotoxicity with europium-TDA and cul- turing on DRCs in MM by side population (SP) detection.

Results: SP cells from both cell lines and samples from different stages of MM showed overexpression of stemness markers. Patient NKAES were shown to have much higher adhesion, migration and detection capacity of MM tumor cells than NK cells from the same patient. After SP purification by sorting, NKAES did not affect the viability of the SP cells without significant differences. NKAES cells were also able to destroy CTCs from different MM cell lines. Cyto- toxicity studies revealed that NKAES cells did not destroy mononuclear cells from healthy bone marrow, even at maximum ratios of 32:1 the mean cytotoxicity was 1.85% (range 0 - 4.47%). Experiments on CD34+ hematopoietic progenitor cell cultures also showed that NKAES cells do not destroy CD34+ clones from healthy bone marrow, confirming the safety of NKAES.

Summary/Conclusions: NK cells have molecular characteristics of the tumor stem cell compartment in MM. Likewise, NKAES cells from MM patients could
destroy drug resistant MM cells and clonogenic tumor cells with high efficiency, preserving CD38+ hematopoietic cells, and thus constitute an effective and safe therapy against MM.

UNMASKING THE RETROTRANSPOSON-ORCHESTRATED PRODUCTION OF SOLUBLE RANKL IN MULTIPLE MYELOMA CELLS
S. Papamichos1, L. Lhermitte1, C. Zaratzian1, M.O. Chandesris2, L. Frenzel2, S. Papamichos1

Background: Growing evidence suggest that production of soluble receptor activator of nuclear factor-kappa B ligand (sRANKL) directly by myeloma cells is causally related to generalized bone loss in multiple myeloma (MM). Notably, sRANKL may be produced either by proteolytic cleavage of membrane-bound RANKL or by alternative splicing of TNFSF11 gene (TNFSF11 variant 2, sRANKL mRNA). Recent analysis argues against proteolytic processing of the membrane-bound form being the main mechanism of sRANKL production by myeloma cells. Accumulative data indicate that sRANKL mRNA presents a restricted transcriptional pattern, namely is expressed predominantly in malignant cell types. Accordingly, sRANKL mRNA (over)expression in primary MM cells and human MM cell lines has been validated in three independent studies. Furthermore, it was recently demonstrated that sRANKL mRNA proximal promoter and first exon are of retroviral origin, residing within a large genomic cluster of transposable elements (TEs).

Aims: To unmask the TE-shaped transcriptional and epigenetic apparatus impelling the expression of sRANKL mRNA in a cell type- and cell context-specific manner.

Methods: RepeatMasker software was used to reveal the presence of integrated TEs in the genomic segment comprising TNFSF11. RNA-Seq data, generated from the PRJEB4337 and PRJNA182351 BioProjects, were analyzed via the UCSC Genome Browser Database. Data on TNFSF11 proximal promoter methylation status in 63 cell lines were downloaded from the HAIB Methyl40k ENCODE track.

Results: RNA-Seq data from 51 normal human tissues show that sRANKL mRNA is expressed predominantly in normal human bone marrow and white blood cells. Methylation status of sRANKL mRNA in 5 lymphoblastoid cell lines (LCLs) signifies that the proximal promoter remains heavily methylated in these cell types. TNFSF11 TF ChIP-seq data show that 5 of 161 TFs can bind to the TE-derived sRANKL mRNA promoter region. Four of the five TFs (EBF1, PA5X, IKZF1, and PU.1) bind to this genomic segment exclusively in LCLs, signifying a cell-type specific transcriptional regulation. Notably, all 4 TFs are known to play a major role in normal and/or malignant lymphopoiesis. Furthermore, IKZF1 and PU.1 represent direct targets of immunomodulatory drugs (IMiDs) for down-regulation.

Summary/Conclusions: Transcription of sRANKL mRNA is driven by a retroviral promoter which remains heavily methylated, thereby inactive, in normal lymphocytes. Epigenetic derepression of this promoter during the course of myeloma progression may be implicated in the (over)expression of sRANKL mRNA by myeloma cells represents a plausible scenario. Should the IKZF1 and the PU.1 TFs act as enhancers of sRANKL mRNA expression, directly contributing to upregulation of sRANKL production in MM, it is a tantalizing hypothesis that warrants further investigation because this type of transcriptional boost could be the key mechanism driving treatment with IMiDs. That Lenalidomide treatment downregulates the amount of sRANKL in the serum of patients with MM through inhibiting PU.1 expression (Breitkreutz et al., Leukemia 2008) is in accordance with the above and further raises the interest on the mechanisms promulgating the anti-osteoclastogenic properties of IMiDs.

ADENOSINE AS A CHECKPOINT AND KEY PLAYER IN DISEASE PROGRESSION
A. Horenstein1,2, A. Chillemi1, V. Quarona1, F. Costa1, D. Toscanci1, F. Morand4, D. Marimpietro4, N. Giuliani1, F. Malavasi2,1

Background: The tumor microenvironment is rich in extracellular mono- and di-nucleotides (ATP, NAD) which are metabolized by cell surface ectoenzymes to produce adenosine (Ado), a nucleoside involved in the control of inflammatory and immune responses. Multiple myeloma (MM), a plasma cell malignancy that develops within the bone marrow (BM) niche, overexpresses CD38, a molecule that catalyzes the initial disassembly of NAD (to cADPR and ADPR), which is followed by formation of ATP, GTP, and Ado. Ado production was likely due to the nucleotide-metabolizing enzyme, CD38, which 9 (41%) had a non-IgG peak, compared to 10/26 (38%) evolution in other high risk factors (a non-IgG monoclonal peak or a peak at >15g/L).

Methods: Evaluation of the expression of adenosinergic ectoenzymes was assessed by immunohistochemical and flow cytometric analysis on cell lines, and primary myeloma cells and BM biopsies from patients with MM or with monotypic immunoglobulin and bone marrow infiltration by plasmocytes, with no associated symptoms of Multiple Myeloma (MM). The risk of development of symptomatic MM justifies identification of the factors associated with an increased risk of evolution. Flow cytometric quantification of the ratio of bone marrow pathological/total plasmocytes (PP/PT) has been reported to be predictive in this context (Pérez-Persi et al. Blood 2007). The PP/PT ratios ≥95% were considered high risk. Disease evolution was indicated by a necessity to treat.

Results: The 210 PP/PT ratios were on average 77% (10-100). Amongst the 154mgUS patients, 24 had a ratio >95%, of which 8 (33%) evolved, compared to 9/130 (7%) with a ratio below 95%. Only 2 of these 8mgUS demonstrated other high risk factors (a non-IgG monoclonal peak or a peak at >15g/L). Amongst SMm patients, 22/30 (73%) patients with a high ratio evolved, of which 9 (41%) had a non-IgG peak, compared to 10/26 (38%) evolution in SMm with low PP/PT ratios. The risk of evolution to active MM was significantly higher in patients with a PP/PT >95%, both in thigmUS (p=0.0001) and overall (p=0.0004). There was a discordance between PP/PT ratio and disease evolution in 11% (17/154)mgUS patients and 23% (48/210) of the overall group but no other FC markers associated with an increased risk of evolution could be identified.

Summary/Conclusions: We confirm the clinical value of a simple, rapid, two-tubes FC quantification of the proportion of pathological plasma cells in the evaluation of the risk and kinetics of disease evolution mgUS and SMm. It's use allows identification of patients which require more frequent follow-up.

E1238

THE RATIO OF PATHOLOGICAL PLASMACYTES, ASSESSED BY 8-COLOR FLOW CYTOMETRY, PREDICTS RISK OF DISEASE PROGRESSION IN MONOCLONAL GAMMOPATHY OF UNKNOWN SIGNIFICANCE AND SMouldERING MULTIPLE MYELOMA
C. Frenzel1, L. Heume1, C. Zaratian1, M.O. Chandresris1, L. Frentzel2, R. Delarue2, F. Suarez2, O. Hermine3, E. Macintyre1, V. Asnafi1, D. Marimpietro4, N. Giuliani1, F. Malavasi2,1

Background: Deregulation of the expression of CD38+ monoclonal immunoglobulin and bone marrow infiltration by plasmocytes, with no associated symptoms of Multiple Myeloma (MM). The risk of development of symptomatic MM justifies identification of the factors associated with an increased risk of evolution. Flow cytometric quantification of the ratio of bone marrow pathological/total plasmocytes (PP/PT) has been reported to be predictive in this context (Pérez-Persi et al. Blood 2007). The PP/PT ratios ≥95% were considered high risk. Disease evolution was indicated by a necessity to treat.

Methods: All patients undergoing bone marrow evaluation following identification of a monoclonal peak (at diagnosis or during follow-up) during a 7.5year period with a diagnosis ofmgUS (n=154) or SMm (n=56) and at least 6 months follow-up were analysed by 8-color FC (including 11 antibodies) from fresh whole bone marrow. Patients with PP/PT ratios ≥95% were considered high risk. Disease evolution was indicated by a necessity to treat.

Results: The 210 PP/PT ratios were on average 77% (10-100). Amongst the 154mgUS patients, 24 had a ratio >95%, of which 8 (33%) evolved, compared to 9/130 (7%) with a ratio below 95%. Only 2 of these 8mgUS demonstrated other high risk factors (a non-IgG monoclonal peak or a peak at >15g/L). Amongst SMm patients, 22/30 (73%) patients with a high ratio evolved, of which 9 (41%) had a non-IgG peak, compared to 10/26 (38%) evolution in SMm with low PP/PT ratios. The risk of evolution to active MM was significantly higher in patients with a PP/PT >95%, both in thigmUS (p=0.0001) and overall (p=0.0004). There was a discordance between PP/PT ratio and disease evolution in 11% (17/154)mgUS patients and 23% (48/210) of the overall group but no other FC markers associated with an increased risk of evolution could be identified.

Summary/Conclusions: We confirm the clinical value of a simple, rapid, two-tubes FC quantification of the proportion of pathological plasma cells in the evaluation of the risk and kinetics of disease evolution mgUS and SMm. It's use allows identification of patients which require more frequent follow-up.

TREATMENT OPTIMIZATION FOR MULTIPLE MYELOMA: SCHEDULE-DEPENDENT SYNERGISTIC CYTOTOXICITY OF POMALIDOMIDE AND CARFILZOMIB ON AN IN VITRO AND EX-VIVO MODEL

E. Borsì 1, 2, M. Martello 1, 2, B. Santacroce 1, 2, V. Solliò 1, 2, R. Terminì 1, 2, E. Zamagnì 1, 2, P. Taccetti 1, 2, L. Pantàni 1, 2, S. Rocchi 1, 2, M. Cavo 2, C. Terragna 2

1 Fondazione Umberto Veronesi (FUV), Milano, 2 Department of Experimental Diagnostic and Specialty Medicine - DIMES, Institute of Hematology “L. e A. Seràgnoli” - University of Bologna, Bologna, Italy

Background: In recent years significant progress has been made in the understanding of Multiple Myeloma (MM) biology. These advances have translated into the development of new drugs and a different approach to treatment, which has ultimately translated into an unprecedented rate of complete remissions. Immunomodulatory drugs (IMiDs) and proteasome inhibitors (Pis) form the backbone of modern MM treatment, but new and more targeted treatments are under development and are being tested in the context of clinical trials. Pomalidomide (POM) is a third-generation IMiD with immunomodulatory, antiangiogenic, and direct anti-MM activities, and greater in vivo potency than its sister Lenalidomide. Carfilzomib (CAR) is a second generation irreversible PI that is structurally and mechanistically distinct from Bortezomib. Preclinical study suggested that the timing and dosing schedules of IMiDs in combination with Pis treatment is critical, proposing a first evidence that established treatment regimens need to be carefully re-evaluated to maximize the anti-tumor effects.

Aims: In this study we tried to optimize the anti-MM therapy using the new class of agents of IMiDs and new generation Pis, by evaluating a possible synergistic effect between POM and CAR.

Methods: For the purpose of this study we used five bona fide MM cell lines (MM1.S, OPM-2, NCI-H929, KMS12. BM and U266), a human bone marrowstromal (BMS) cell line (HS-5 cells) and primary samples from newly diagnosed MM patients. Apoptosis analysis was done up to 48h after administration of the first drug. For each drug, three different concentrations were used: low dose, intermediate dose and high dose. Since the BM microenvironment is a complex and active system, with potential contributions of both physical adhesion and soluble factors, we used three experimental conditions to differentiate these interactions: 1) MM cells cultured in complete medium, 2) MM cells suspended in medium conditioned in the prior presence of BMSCs, or 3) MM cells co-cultured with BMSCs in a transwell system.

Results: Using the median effect method of Chou Talalay, we evaluated the combination indices for simultaneous and sequential treatment schedules, and we found that the schedule of administration is important to maximize the synergistic effects. Indeed, schedule-dependent synergistic cytotoxicity was demonstrated for the combination of IMiDs and Pis and a maximal apoptosis consistently observed in IMiDs pre-exposure schedule. The superiority of this schedule was maintained throughout BM microenvironment models. Our data overall suggest that the administration of IMiDs before Pis can improve efficacy. Clinical trials are needed to investigate the most effective schedule, which could be to start the administration of IMiDs a day before Pis to increase cells killing.

Summary/Conclusions: Schedule-dependent synergistic cytotoxicity was demonstrated for the combination of CAR and POM and a maximal apoptosis consistently observed in POM pre-exposure schedule. The superiority of this schedule was maintained throughout BM microenvironment models using low dosage of both drugs. Whilst the clinical efficacy of CAR and POM combinations has been demonstrated, the synergistic cytotoxicity may be further exploited by using optimized schedule. Utilizing such a schedule with IMiDs pre-treatment may improve the depth and duration of response of MM patients both as upfront therapy and in the relapsed/refractory setting.
Background: Daratumumab-based combination Therapies (DCT) with bortezomib (V) lenalidomide (R) pomalidomide (P) and dexamethasone (d) have shown exceptional activity in relapsed and/or refractory multiple myeloma (RRMM) in trials. Experience outside of trials since the approval of Daratumumab (D) in 2015 is limited.

Aims: We aimed to review the outcomes of patients who received DCT at our institution.

Methods: Records of RRMM patients seen at Mayo Clinic, MN from December 2015–December 2016 were reviewed. Patients who received ≥ 1 cycle of DCT were included. Time-to-event analyses were done from date of starting DCT using Kaplan Meier method. Common terminology criteria for adverse events v4.0 were used to grade toxicities.

Results: Of 130 patients, 59% were males and median age at DCT initiation was 67 (43-93) years. ECOG performance score was ≥2 in 29%. Patients were classified as mSMART high (22%), intermediate (22%) or standard (56%) risk. Median time from diagnosis to initiation of DCT was 51.3 (5-156) months, and median number of prior therapies was 4 (1-14). Eighteen (14%) of patients were refractory to prior daratumumab monotherapy. Fifty-three (41%), 34 (26%), and 25 (19%) received DPa, DRd, and Dv respectively. Eighteen (14%) patients received ‘other’ DCT. Median time to first response (≥ PR) was 3.1 months (95% CI 1.9-4.6). Overall response rate was 46%, [complete response + partial response] + very good partial remission + complete response not reached (NR). Median progression-free survival was 5.5 months (95% CI 4.2-6.8). Median duration of response was 6.1 months (95% CI 4.1-7.8) from starting DCT. Median overall survival was 67 (43-93) months. Among patients who had received 2 or more DCTs, median overall survival was 51.3 (5-156) months. Of 687 patients, 78 (11.4%) patients were using metformin at the time of MM diagnosis. Baseline characteristics in the metformin and no-metformin groups were similar. Median metformin dose was 2000mg daily and median duration of metformin use from MM diagnosis was 22 months. Patients on the Metformin group achieved higher rates of complete response after SCT (OR: 0.38, 95%CI: 0.20-0.73, p<0.04). There was a trend toward longer overall survival in the Metformin group, but it was not statistically significant (170 vs 160 months, p<0.10). In a multivariate analysis of adverse events associated with the use of metformin, mSMART risk was associated with a better progression-free survival (OR: 0.38, 95%CI: 0.20-0.73, p<0.001).

Summary/Conclusions: Metformin use was associated with a better progression-free survival and higher complete response rates after SCT in our MM cohort. A trend toward better overall survival was also noted in the Metformin group. Larger studies are needed to enhance our understanding of the clinical effect of metformin on MM.

E1242

COMPARING WHOLE BODY MRI WITH PET-CT IMAGING AT DIAGNOSIS OF MYELOMA

J. Vidler1,*, G. Havariyoun2, G. Vivian3, I. Walker1, M. Streetly1, K. Cuthill1, R. Benjamin1, N. Mulholland3
1Department of Haematological Medicine, 2Department of Medical Engineering and Physics, 3Departments of Radiology and Nuclear Medicine, King's College Hospital, London, United Kingdom

Background: Imaging in the diagnosis of myeloma is a rapidly developing field. First line imaging has traditionally been a skeletal survey with plain films, however new guidelines recommend whole body imaging to aid the diagnosis grouped based on bony and soft tissue disorders. The International Myeloma Working Group recommend low-dose whole body computerised tomography (LDWBCt), PET-CT or whole body magnetic resonance imaging (WBMRI) as initial imaging modalities.

Aims: To compare WBMRI with PET-CT as initial imaging modalities at diagnosis of myeloma or plasmacytoma.

Methods: Both WBMRI and PET-CT were performed at diagnosis of myeloma or a plasmacytoma in 33 patients presenting to King's College Hospital, London. The scans were reviewed independently by two Consultants in Radiology.
and Nuclear Medicine, looking for focal bone lesions, bone marrow pattern and incidental findings. Details of the patients’ demographics, myeloma diagnosis and treatment were collected from the medical records.

Results: Of the 33 patients, 24 were male. The median age was 64 years (range=43-86 years). One patient had a solitary plasmacytoma, the other 32 had myeloma (21 IgG, 3 IgA, 2 non-secretory, 4 light chain disease, 2 bicalonal myeloma), 7 had ISS stage I disease with a median paraprotein concentration of 17 (range 0.52-6). 21 patients had a bone marrow plasma cell burden of 10-60%, 10 patients >60% and 2 were unknown. Sixteen patients were diagnosed with smouldering myeloma and a ‘watch and wait’ policy was adopted. Eleven patients were treated with chemotherapy, 4 were entered into a clinical trial, one was offered palliative care and one was referred to our centre for autograft. WBMRI identified a focal lesion of disease in 30% of patients compared with 36% by PET-CT. This was not a statistically significant difference (p=0.18). In addition there was no statistically significant difference between PET-CT & MRI in detecting <3 or >3 lesions (p=0.705 and p=0.083 respectively). The apparent differences in the detection of vertebral L5 (using diffusion weighted MRI imaging) was measured. This showed a strong correlation with the degree of bone marrow infiltration by plasma cells (r=0.64). An ADC of <600mm²/s had a negative predictive value of 93% for a bone marrow plasma cell infiltrate of >60%. There was also a significant difference (p=0.012) in the ADC between those with smouldering myeloma and those with symptomatic disease. It was noted that 9 scans resulted in incidental findings including pneumonia, adrenal lesions and one case of colocoler cancer.

Summary/Conclusions: We have shown no difference in PET-CT and WBMRI in detecting a myeloma defining focal bone lesion, or providing prognostic estimators of burden of disease. Using MRI, a measure of the ADC at vertebrae L5 has been shown to be a semi-quantitative parameter that correlates with bone marrow plasma cell infiltration and distinguished between those with smouldering and symptomatic disease. In addition it is noted that whole body imaging has led to incidental findings of further pathology, including an unrelated malignancy, which may lead to useful clinical information or to further investigations and imaging which may not be needed.

E1243

PERSISTENCE OF MINIMAL RESIDUAL DISEASE BY MULTIPARAMETER FLOW CYTOMETRY CAN HINDER RECOVERY OF ORGAN DAMAGE IN PATIENTS WITH AL AMYLOIDOSIS

P. Milanelli1,2, M. Massa1, M. Bassetti1, F. Russo1, P. Bertì2, A. Forlì1, G. Annibali1, G. Palladini1, G. Merlini1

1Department of Molecular Medicine, Amyloidosis Research and Treatment Center, Fondazione IRCCS Policlinico San Matteo, University of Pavia, Pavia, Italy; 2Department of Hematology, Stem Cell Transplantation, Transfusion Medicine and Cellular Therapy Research Unit, Università Campus Bio-Medico di Roma, Rome, Italy

Background: In multiple myeloma, Minimal Residual Disease (MRD) demonstrated by multiparameter flow cytometry (MFC) identifies subjects with significant residual disease among those who attain complete response (CR). The role of MRD in AM amyloidosis has not been assessed so far.

Aims: In the present study, we assessed the MRD by MFC in patients with AL amyloidosis who attained CR.

Methods: CR was defined as per current criteria (negative serum and urine immunofixation) and a three light chain ratio (for IgA). For flow cytometry, bone marrow samples were processed following the EuroFlow Bulk Lysis Standard Operating Protocol and stained with the EuroFlowIMF MM MRD panel. At least 5x10⁶ events were measured using a FACS Canto II (USA) instrument. Data were analyzed using the Infinicyt software (Spain). Patients were identified as having residual disease if a discrepant population of plasma cells comprising ≥50 events was identified (10⁻⁵ limit of detection).

Results: Twenty-eight patients were tested (7 found to have relapsed at the time of MRD assessment with monoclonal components detectable and MRD+) and 21 satisfied current criteria for CR. Nineteen (90%) had renal and 9 (41%) had cardiac involvement at diagnosis. More than 2 lines of treatment were required to achieve CR in 7 subjects. Median time to CR was 10 months (range: 3-82). Five patients (62%) had achieved cardiac response and 9 (50%) renal response at the time of CR. The median time from CR to MRD was 30 months (range: 6-148), this was not different in the MRD positive versus negative patients, (p=0.08). A median of 1089 (range 256-2500) corresponding to 0.04% (range 0.02-0.3%) plasma cells with abnormal phenotype were detected in patients MRD+. No differences in organ involvement, cardiac and renal stage, type of therapy, number of treatments, and organ response at the time of CR was found between the two groups. However, improvement of cardiac function compared to the time of CR was observed in all 5 evaluable MRD- patients and in none of the 2 MRD+ patients (P=0.047). Compared to the time of CR, renal response was obtained in 7 MRD- subjects (84%) and in 4 (50%) MRD+ (P=0.153). Overall, further improvement of cardiac or renal function after CR was significantly associated with a lower ADC at ≤0.60mm²/s (P=0.012).

Summary/Conclusions: This proof-of-concept study indicates that 43% of patients with AL satisfying current criteria for CR have detectable MRD. MRD positivity could in part explain persistence of organ damage in patients in CR.
patients at induction. A number of factors have been shown to correlate with overall survival (OS) and progression free survival (PFS) including depth of remission prior to ASCT, initial ISS stage and high risk cytogenetics. Emerging evidence has demonstrated that early relapse following ASCT is associated with reduced OS, and is not correlated with depth of pre-transplant response.

Aims: To characterise myeloma patients who relapsed within 12 months of ASCT, through baseline characteristics and transplant engraftment, and assess the impact of this early relapse on OS and PFS.

Methods: We performed a multicentre retrospective analysis of patients who underwent ASCT at 3 centres between 01/2009 – 02/2016 (London) and 06/2006 – 03/2013 (Cardiff). Baseline characteristics were reviewed and ASCT engraftment was assessed; by time to neutrophils 50 x 10^9/L and platelets >20 x 10^9/L. Post-transplant PFS & OS was calculated by time (months) from diagnosis to progression or death.

Results: 443 myeloma patients were identified, median age was 57 (r 31-73), 56% were male. 41% of patients were ISS stage 1, 34% stage 2, 25% stage 3. Cytogenetic data was available for 139 patients. 1st-line therapy prior to transplantation was immunomodulatory drug (IMiD) based (THAL/LEN) for 318/443 patients & 72/443 were proteasome inhibitor (PI) based (BORT/CARF). In addition, 11 patients received combination PI and IMiD. Median time from start of therapy to ASCT was 10 months (r 3-109m), 67 patients progressed within 12m of ASCT (early progression). No statistical difference was found between <12m or >12m relapse for; age, gender, 1st line therapy, ISS stage, Hb, LDH, Ca or cytogenetics, confirming that this group is difficult to predict at baseline. Median OS from time of diagnosis was 103 months (95% CI 101 -137), median OS from start of ASCT was not reached, however 5-year OS was 68%. Patients with progressive disease within 12 months of ASCT, has significantly reduced median OS: 12 months (95% CI 21-39) compared to non-progressive patients (median OS:1039m 95% CI 89-117).p=0.0005. Median OS from ASCT was reduced in early progression median OS:18m (95% CI 14-22m) vs progression >12 months median OS:89 months (95% CI 79-98m) p=0.0005. 1st line therapy did not influence likelihood of PFS<12months, with no statistical difference between patients who received PIs, IMiDs or both 1st line (p=0.484). A significant difference was observed in median time to platelet engraftment between the 2 centres. Increased time for platelets to reach >20 x10^9/L was associated with reduced OS from ASCT for each centre HR 1.14 & 1.20 (p=0.046 & 0.03) for Cardiff or London centres respectively (Cox’s Method).

Summary/Conclusions: Early relapse following ASCT is a significant predictor of inferior OS in myeloma and difficult to predict from standard baseline characteristics. From our analysis; 1st line treatment prior to ASCT did not influence OS or PFS. There was an association between slow platelet engraftment following ASCT and PFS and OS. Possible explanations include: residual occult disease, toxicity of chemotherapy or patient stromal factors which facilitate disease resistance and impair normal haematopoiesis. All of these factors have been shown to drive relapse. RCCs are required to standardise bone marrow response assessment post ASCT, quantify remission status (using laboratory and imaging techniques) and definitively predict early relapse. Additionally, these studies will investigate further biological or genetic mechanisms driving early relapse to help identify novel therapeutic approaches in these extremely poor prognosis group.

PATIENT-REPORTED OUTCOMES (PROS) WITH IBRUTINIB: SUBSTUDY OF INNOVATETM FOR WALDENSTROM MACROGLOBULINEMIA (WM)

1Haematology, Concord Repatriation General Hospital, Concord, Australia, 2National and Kapodistrian University of Athens, School of Medicine, Athens, Greece, 3Azienda Ospedale Niguarda Ca’ Granda Hospital, Milan, Italy, 4Colorado Blood Cancer Institute, Denver, 5Winship Cancer Institute of Emory University, Atlanta, United States, 6Royal Victoria Hospital at McGill University Health Centre, Montreal, Canada, 7Hospital Universitario de Salamanca, Salamanca, Spain, 8Dana-Farber Cancer Institute, Boston, United States, 9Hôpital Pitié-Salpêtrière APHP, UPMC Université, Paris, France, 10Pharmacyclics, LLC, 11AbbVie Company, Sunnyvale, United States, 12University of Ulm, Ulm, Germany

Background: Anemia and fatigue are frequent indications for WM treatment. To date, patient-reported outcomes (PROs) have not been used to quantify benefits of ibritinib (ibr), a first-in-class, once-daily inhibitor of BTK, is indicated in the EU for the treatment of WM after ≥1 prior therapy or >12m relapse for: age, gender, 1st line therapy, ISS stage, Hb, LDH, Ca or cytogenetics, confirming that this group is difficult to predict at baseline. Median OS from time of diagnosis was 103 months (95% CI 101 -137), median OS from start of ASCT was not reached, however 5-year OS was 68%. Patients with progressive disease within 12 months of ASCT, has significantly reduced median OS: 12 months (95% CI 21-39) compared to non-progressive patients (median OS:1039m 95% CI 89-117).p=0.0005. Median OS from ASCT was reduced in early progression median OS:18m (95% CI 14-22m) vs progression >12 months median OS:89 months (95% CI 79-98m) p=0.0005. 1st line therapy did not influence likelihood of PFS<12months, with no statistical difference between patients who received PIs, IMiDs or both 1st line (p=0.484). A significant difference was observed in median time to platelet engraftment between the 2 centres. Increased time for platelets to reach >20 x10^9/L was associated with reduced OS from ASCT for each centre HR 1.14 & 1.20 (p=0.046 & 0.03) for Cardiff or London centres respectively (Cox’s Method).

Summary/Conclusions: Early relapse following ASCT is a significant predictor of inferior OS in myeloma and difficult to predict from standard baseline characteristics. From our analysis; 1st line treatment prior to ASCT did not influence OS or PFS. There was an association between slow platelet engraftment following ASCT and PFS and OS. Possible explanations include: residual occult disease, toxicity of chemotherapy or patient stromal factors which facilitate disease resistance and impair normal haematopoiesis. All of these factors have been shown to drive relapse. RCCs are required to standardise bone marrow response assessment post ASCT, quantify remission status (using laboratory and imaging techniques) and definitively predict early relapse. Additionally, these studies will investigate further biological or genetic mechanisms driving early relapse to help identify novel therapeutic approaches in these extremely poor prognosis group.

Background: Cardio-vascular (CV) toxicities in patients (pts) with multiple myeloma (MM) may derive from comorbidities, MM itself and its treatment. Carfilzomib, an irreversible proteasome inhibitor, is approved as single agent or in combination with dexamethasone or lenalidomide-dexamethasone for relapsed MM.

Aims: We conducted an integrated analysis of CV adverse events (AE) in newly diagnosed, transplant-ineligible MM patients treated with Carfilzomib in 3 phase III studies (IST-CAR-506, IST-CAR-505, IST-CAR-501).

Methods: All pts were treated with 9, 28-day induction cycles with carfilzomib, cyclophosphamide (300mg/m² on days 1, 8, 15) and dexamethasone (40mg weekly) (CCyd), followed by carfilzomib maintenance until progression or intol-
Pomalidomide (POM) + Low-Dose Dexamethasone (LoDEX) Following Second-Line LEN-BASED Treatment in Pts with RRMM: Results of the IST-CAR-561 Trial

**Methods**

- **Patient Population:** 148 pts with a median age of 72 years were analyzed. At enrollment, 34% of pts had at least 1 cardiovascular risk factor; 20% had peripheral vascular disease (including hypertension in 13% patients), 19% diabetes and 5% chronic pulmonary disease. After a median follow-up of 21 months, at least 1 any grade CV-AE occurred in 45% of pts; any grade hypertension was reported in 17% of pts, dyspnea in 9%, and heart failure, arrhythmia and venous thromboembolism (VTE) in 6% of pts, each. Grade 3-5 CV-AEs occurred in 15% of pts. The most common being heart failure (4%), hypertension (3%), pulmonary edema (3%) and VTE (3%). Four (3%) fatal CV-AEs occurred: 1 case of heart failure, pulmonary edema, arrhythmia and VTE, respectively. No difference in terms of CV-AEs was observed in patients treated with different doses of carfilzomib. In pts who developed at least 1 CV-AE, carfilzomib dose reduction (33%) and discontinuation (33%) were more frequent as compared to those without CV-AEs (12% and 18%, respectively; p<0.0001).

- **Aim:** To present updated safety and efficacy analyses only from cohort A, in which pts received POM + LoDEX immediately after relapsing or being refractory to second-line LEN-based therapy.

- **Methods:** Pts aged ≥18 years had documented MM, measurable disease, 2 prior lines of treatment, and PD after ≥2 cycles of second-line LEN-based treatment. Pts received 28-day cycles of POM 4mg/day on days 1-21 + LoDEX 40mg/d on day 1, 8, 15 and 21; 45% of pts, hypertension and dyspnea were the most common. Pts ≥75 years had a higher risk of any grade (58% vs 36%, p=0.002) and grade 3-5 CV-AEs (34% vs 15%, p=0.01); major cardiac events of any grade were more frequent in older patients (29%) than in younger ones (6%; p<0.001). Patients with at least 1 CV risk factor at enrolment had a 4-fold increased risk (odds ratio: 3.79; p<0.001) of developing a CV-AE during treatment as compared to patients with no CV risk factors; in detail, baseline hypertension (odds ratio: 4.12; p=0.012) and peripheral vascular disease (odds ratio: 3.75; p=0.002) conferred the highest risk of developing CV-AEs.

**Results:** Of 51 enrolled pts in cohort A, 39 (76.5%) discontinued treatment, mostly due to PD. Median age was 68.0 years, and 92.2% had an Eastern Cooperative Oncology Group performance status of ≤1. A total of 45 pts (88.2%) were refractory to their last treatment with LEN, and 37 (72.5%) had prior treatment with carfilzomib. Median duration of prior LEN-containing therapy was 24.6 months. With a median follow-up of 13.6 months, ORR was 29.4%, with 1 (2.0%) complete response, 5 (9.8%) very good partial responses, and 9 (17.6%) PRs. Minimal response (MR) was reached in 15.7% of pts. Median TTR was 1.9 months and 66% of pts had ongoing response at 1 year. Median PFS was 13.8 months. The 2-year PFS rate was 48.0% for the intent to treat population, 69.4% for pts with ≥ MR, and 69.1% for pts with ≥ PR. In addition, pts with ≥ MR had similar treatment durations as those achieving ≥ PR (10.5 vs 11.5 months; Table). Common grade 3/4 adverse events (AEs) included anemia (25.5%), neutropenia (11.8%), and infections (19.6%; including pneumonia [8.8%]. No pts experienced SPMs. In the immune subset analysis, the proportions of CD3+ and CD3+/CD8+ T cells after treatment were significantly higher vs baseline (72.6% vs 67.8% and 36.9% vs 32.1%, respectively, P<0.05).

- **Response Type:**
  - ≥ PR (n = 15)
  - Stable Disease (n = 21)

**Summary/Conclusions:** This update confirms the safety and efficacy of POM + LoDEX following second-line LEN-based treatment failure in pts with RRMM. Hematologic AE rates improved, and median PFS was longer with third-line use than previously reported with POM + LoDEX in use in later treatment lines. In addition, achieving disease control of ≥ MR led to similar PFS rates as reaching ≥ PR.

**E1249“REAL WORLD” DATA ON THE EFFICACY AND SAFETY OF IZAXOMIB IN COMBINATION WITH CARFILZOMIB AND DEXAMETHASONE IN RELAPSED/REFRACTORY MULTIPLE MYELOMA: A STUDY OF THE GREEK MYELOMA STUDY GROUP**

**Background:** The overall combination of ixazomib, lenalidomide and dexamethasone (IRd) has been recently approved as a novel standard of care for relapsed/refractory multiple myeloma (RRMM). The aim of this study was to evaluate the efficacy and safety of IRd in the “Real World” (RW) practice, where data are very limited.

**Methods:** This was a retrospective, non-interventional study, which recorded IRd treatment data from patients with RRMM who participated in the name-patient program of ixazomib in Greece. The primary endpoint was the evaluation of overall response rate (ORR) and response rate among treated pts. Secondary endpoints included: treatment duration; time to response; duration of response; percentage of patients who experienced adverse events (AEs), needed dose modification or treatment discontinuation; evaluation of PFS and TTP.

**Results:** Forty-one patients were included in the present study. Of those, 35 (85%) (median age 67-79 years; range 63-79 years) had received at least 3 cycles of IRd on the date of data analysis and thus they were included in the present report. The median line of previous therapies was one (range: 1-5): 71.4% (25/35) patients had received one prior treatment, while 20.0% (7/35),...
and 4 with other therapies. Baseline characteristics were balanced across 3557 patients (98.0%) had discontinued treatment. Of the 73 patients (2.0%) received bortezomib (BORT), 137 (3.8%) received thalidomide (THAL), and 155 (4.3%) lenalidomide (LEN).

**Results:**
Patients provided informed consent. Up to 36 mos after treatment discontinuation (Protocol amendment 2011). All laxis was administered per local standard practice. AEs were graded per the ground cohort (all other treatments, including novel agents). Thromboprophylaxis is provided and patients gain access to new therapeutic approaches.

**Summary/Conclusions:** LEN was generally well tolerated and the safety results were similar to published data. As expected, the occurrence of neutropenia, TCP, and VTEs were higher in patients in the LEN cohort, whereas neuropathy was more frequently reported in patients in the BORT cohort. VTEs were low in all cohorts. The occurrence of SPMs was generally low and comparable between cohorts.

**Background:** Clinical outcome of multiple myeloma (MM) patients is heterogeneous and depends on various prognostic factors and available treatments. Although tremendous progress has been made in MM, so far, there is no national or international evidence-based guideline giving recommendations for clinical practice in the treatment of MM patients. In Germany, 14 Comprehensive Cancer Centers (CCC) are funded as Centers of Excellence by the German Cancer Aid (DKH). All these Centers of Excellence are required to develop and provide in-house clinical pathways for standards in cancer care. These pathways include concise diagnostic and therapeutic instructions, reflecting available evidence-based recommendations. In addition, ongoing studies (in particular phase I/II) are part of clinical pathways, so that a rapid transfer of innovation is provided and patients gain access to new therapeutic approaches. The Centers of Excellence Network working group SOP has the goal to harmonize these hospital specific in-house clinical pathways differently in format, content and level of evidence. In addition, ongoing studies (in particular phase I/II) are part of clinical pathways, so that a rapid transfer of innovation is provided and patients gain access to new therapeutic approaches. The Centers of Excellence Network working group SOP has the goal to harmonize these hospital specific in-house clinical pathways differently in format, content and level of evidence. In addition, ongoing studies (in particular phase I/II) are part of clinical pathways, so that a rapid transfer of innovation is provided and patients gain access to new therapeutic approaches. The Centers of Excellence Network working group SOP has the goal to harmonize these hospital specific in-house clinical pathways differently in format, content and level of evidence.
Results: During the development process, a number of similarities and discrepancies between centers as well as evidence gaps were identified. Intense discussion and literature searches resulted in a concise, harmonized clinical pathway, released by all 14 Centers of Excellence. This is freely available on the website ccw.netzwerk.de and provides a very decisive insight according to the current state of knowledge on the CCC-level (e.g. on the diagnostic algorithm, Fig. 1). The clinical pathway is well suited for informing patients and physicians about the most up-to-date, comprehensive medical treatment standards as well as innovative procedures. Furthermore, this project initiated the idea of developing a national evidence-based clinical practice guideline for MM in the frame of the German Guideline Program in Oncology.

Figure 1.

Summary/Conclusions: The first clinical MM pathway developed and released by all 14 German CCCs/Centers of Excellence translates scientific evidence and expert knowledge into precise suggestions for MM patients in clinical practice. These harmonized processes might increase the quality of cancer care throughout Germany. To be up-to-date and to reflect latest research findings this clinical pathway will be updated every 18 months.

WT1 HETEROCLITIC EPITOPE IMMUNIZATION FOLLOWING AUTOLOGOUS STEM CELL TRANSPLANTATION IN PATIENTS WITH HIGH-RISK MULTIPLE MYELOMA (MM)

G. Koehne1,*, S. Devlin1, D. Chung1, H. Landau1, N. Kordel1, S. Mailankody1, H. Hassoun1, A. Lesokhin1, N. Lendvai1, S. Giralt1, O. Landgren1

1Memorial Sloan Kettering Cancer Center, New York, United States

Background: The Wilms tumor 1 (WT1) protein is a tumor associated antigen that is a target for anticancer immunotherapy. We had previously demonstrated overexpression of WT1 in multiple myeloma (MM) cells by IHC, as well as for a mutation of a WT1 peptide fragment (RMFPNPAYL)-HLA-A*0201 complex on the engagement interface between malignant plasma cells and T-cells in HLA-A*02+ MM pts using the high-affinity fully human IgG1 mAb ESK1. We report initial results from MM pts immunized with the WT1 heteroclitic peptide mixture galinpepimut-S (GPS) after autoSCT.

Aims: To determine the safety and potential efficacy of the WT1 heteroclitic peptide immunizer GPS administered in patients with multiple myeloma following autologous stem cell transplantation.

Methods: 16 MM pts underwent autoSCT with melphalan conditioning followed by (fb) lenalidomide maintenance starting 3 months (mos) post-SCT. 13/16 pts presented with high-risk (HR) cytogenetics [t(4;14), t(14;16), del17p, 1q21/25 gain and/or del13q]. We report initial results from MM pts immunized with the WT1 heteroclitic peptide mixture galinpepimut-S (GPS) after autoSCT.

Results:

- Various levels and were induced not only against the heteroclitic peptides (within GPS), but also against the corresponding native WT1 peptide sequences as well as the ‘total pool’ of WT1-derived overlapping peptides.

Summary/Conclusions: Administration of the novel WT1 heteroclitic peptide immunizer GPS post-SCT demonstrates favorable safety profile along with an encouraging mPFS of currently 23.6 mos in this high-risk MM population. This therapy is easy to administer and has been specifically designed to elicit responses across most common HLA Class I and II alleles. Based on these results, a larger phase II trial is being planned to optimally integrate post-transplant immunotherapeutic strategies to meaningfully delay or reduce risk of relapse in this challenging clinical setting.

E1253

ANALYSIS OF MULTIPLE MYELOMA PATIENTS WITH PROGRESSIVE DISEASE AT TIME OF FIRST AUTOLOGOUS STEM CELL TRANSPLANTATION: PREDICTORS OF PROGRESSIVE DISEASE AND FACTORS AFFECTING SURVIVAL

J. Alas1,*, H. Goldschmidt1, T. Hielscher2, M. Pritsch1, M. Raab1, J. Hillengass1

1University Hospital Heidelberg, 2German Cancer Research Center, Heidelberg, Germany

Background: The impact of response depth at time of autologous stem cell transplantation (ASCT) on the progression-free and overall survival (PFS and OS, respectively) of multiple myeloma (MM) patients has been an extensively investigated area. Rosiñol et al. (2011) reported a significantly worse PFS and OS in patients with progressive disease (PD) compared to stable disease (SD) at time of ASCT; Parrish et al. (2015) stated a significantly shorter PFS, but not OS, in patients with PD in comparison to SD or minimal response (MR) at time of ASCT.

Aims: Our goal was to characterize MM patients with PD at time of first ASCT. We aimed to analyze the effects of PD on PFS and OS. Next, we intended to delineate the influence of SOs and other factors (evaluated at beginning of induction therapy) as well as use of novel agents in induction therapy, response after 1st ASCT, and use of maintenance therapy in those patients that identify predictors for PFS and OS. Furthermore, we aimed to identify clinical/therapeutic features predicting the occurrence of PD before ASCT.

Methods: Non-trial MM patients who had undergone a single or tandem ASCT at the University Hospital of Heidelberg in the years 1992-2014 were analyzed regarding their response before 1st ASCT (d=0) or, if available, response as close to the date of ASCT as possible, i.e. until d=4. Of the 874 ASCT-patients, 829 were eligible for a PFS- and 832 for an OS-analysis. In 51 patients, PD was present at time of ASCT. PFS and OS of those patients were compared with the survival of patients with at least SD at time of ASCT (non-PD patients).

Summary/Conclusions: Our analysis provided valuable insights into the response before 1st ASCT, except for prognostic impact of response assessment after 1st ASCT, where date of response assessment was used. Start of maintenance therapy was analyzed as time-dependent factor.

Results:

- Non-trial patients transplanted in our center between 1992 and 2014 with PD ≤100 days before ASCT had similar PFS and OS as non-PD patients. Neither the clinical parameters at induction start, response after 1st ASCT, nor maintenance therapy had a significant effect on PFS in those patients. In the univariate analysis, high-risk cytogenetics as well as elevated LDH at induction start had a significantly negative effect on OS in patients with PD before ASCT. Response was evaluated according to EBM7-criteria. PFS was calculated from date of 1st ASCT, except for prognostic impact of response assessment after 1st ASCT, where date of response assessment was used. Start of maintenance therapy was analyzed as time-dependent factor.

E1254

SEVERE INFECTIONS IMPACTS OVERALL SURVIVAL IN ACTIVE MULTIPLE MYELOMA PATIENTS

G. Barlili1, C. Nicoli1, A. Lipo1, A. Branca1, L. Checuzi1, E. De Marchi1,

1Molecular Medicine Unit, Department of Biomedical and Neuromotor Sciences, University of Bologna, Italy

Summary/Conclusions: In conclusion, our analysis of 51 patients with PD at time of ASCT among 874 ASCT-patients with MM transplanted between 1992 and 2014 shows no significant difference regarding PFS and OS between patients with PD and other response rates. It was further shown that high-risk cytogenetics as well as elevated LDH at beginning of induction therapy have a significant impact on worse OS in patients with PD at time of ASCT. In addition, PD is a significant factor for occurrence of PD at time of ASCT. The impact response depth at time of ASCT is not entirely clear, especially regarding the benefit of ASCT in patients with PD at time of ASCT, as reports from other centers show significantly worse PFS and OS (Rosiñol et al.) or only PFS (Parrish et al.) in patients with PD at time of ASCT.
**REAL-WORLD SETTING IN THE UNITED STATES**

**DIFFERENT TREATMENT MODALITIES OF MULTIPLE MYELOMA IN THE EVALUATION OF CARDIOVASCULAR EVENTS ASSOCIATED WITH E1255**

Background: Multiple myeloma (MM) represents the second most common hematological malignancy characterized by the proliferation of monoclonal plasma cells (PC) in the bone marrow. The natural history of active MM patients may be complicated in significant fraction by the occurrence of infections that can be related both to the development of therapy induced neutropenia (mainly due to high dose chemotherapy used in the setting of autologous stem cell transplantation or in salvage regimens) or to MM induced secondary immunodeficiency.

Aims: The aim of this study was to analyse the frequency, the type and the major risks factors of severe infections in our cohort of patients affected by MM and to understand the impact of these events on MM patient overall survival (OS).

Methods: A cohort of 341 patients affected by MM (104 with smouldering MM and 237 with symptomatic MM) followed from 1996 to 2016 was retrospectively studied for the presence of severe infections (si, defined by the need of hospitalization) during the natural history of the disease. Infections were classified as “not neutropenia related” or “neutropenia related” according to the Absolute Neutrophil Count > or <1,000/ml respectively. International Staging System (ISS) and Durie-Salmon (DS) were used for MM patients staging.

Results: In our cohort of patients, si were significantly associated to active MM (28.69% of symptomatic patients vs 3.85% of asymptomatic patients; p=0.0001, c²=25,318). Among the 138 infective events occurred in 91 active MM patients, 38 (26%) were neutropenia related while remnant 100 not neutropenia related (72%). Furthermore, almost 44% of these events (61/138) developed during induction therapy, with 12 out of 61 (20%) being present at time of the diagnosis. Considering that majority of si was not neutropenia related and that these infective events involved most of active MM patients who developed si (68/91, 75%), our aim was to identify MM patient characteristics associated to the development of not neutropenia related si. Our results prove evidence that major features presented at the time of the diagnosis significantly associated to si were DS stage III (p=0.0004, c²=12,14), ISS stage III (p=0.0001, c²=21,11), age >70 years (p=0.0195, c²=5,455), bone marrow plasma cells >60% (p=0.034, c²=4,50), acute renal failure (p=0.0003, c²=13,010) or MM presenting with at least three of CRAB criteria (p=0.0123, c²=6,26). For what concern the impact of si on the natural history of the disease, patients who experienced infective event presented a reduced OS towards other patients (p<0.0001). Among infected patients no significant differences were reported referring to the number of infections (>1 or =1, p=0.11), while patients who developed exclusively neutropenia related infective events showed better OS towards patients who experienced not neutropenia related infections (p=0.0011).

Figure 1.

Summary/Conclusions: Severe infections represent an underestimated comorbidity in MM, characterizing all phases of the disease and not only refractory/relapsed patients receiving multiple lines of therapy. Considering that severe infections impact OS mostly in the setting of not neutropenia related infections, immunoglobulin replacement therapy and/or antibiotic prophylaxis may possibly have a protective role in high risk old patients characterized by ISS and DS stage III, bone marrow PC >60% and aggressive disease at the time of diagnosis.

**E1255**

**EVALUATION OF CARDIOVASCULAR EVENTS ASSOCIATED WITH DIFFERENT TREATMENT MODALITIES OF MULTIPLE MYELOMA IN THE REAL-WORLD SETTING IN THE UNITED STATES**

D. Lenihan\(^1\), R. Potluri\(^2\), H. Kanakamedala\(^2\), A. Dasgupta\(^2\), C. Chen\(^3,4\)

\(^1\)Vanderbilt University Medical Center, Nashville, \(^2\)SmartAnalyst Inc., New York, \(^3\)Bristol-Myers Squibb, Lawrenceville, United States

Background: Multiple myeloma (MM) is a disease of the elderly. The prevalence of cardiovascular (CV) comorbidities in the MM population is high. Past research suggests that MM is associated with a range of cardiac risks, and emerging evidence shows that both proteasome inhibitors (PIs) and immunomodulatory drugs (IMiDs) can have important CV sequelae. The improved efficacy of PI plus IMiD combination therapy (PI+IMiD) has resulted in its widespread adoption, which suggests that CV events may become a prominent concern in patients receiving PI+IMiD as contemporary treatment for MM.

Aims: To assess the risk of developing CV events in patients receiving anti-MM treatment and to less a specific treatment modality was associated with higher risk of a CV event.

Methods: Patients with ≥1 inpatient claim or ≥2 outpatient claims with a primary diagnosis code for MM who were treated with PI and/or IMiD drugs between Jul 2012 and Sep 2014 were identified in a large US claims database. The first claim for a PI or IMiD drug in this period was defined as the index date, which was preceded by 180-d continuous eligibility with no anti-MM treatment (base-line). Patients were divided into three cohorts based on the anti-MM treatment received: PI, IMiD, PI+IMiD. CV events of interest included cardiac arrhythmia, cardiac failure, venous thromboembolism (VTE), myocardial infarction, ischemic heart disease, angina, stroke and coronary atherosclerosis, and were measured during anti-MM treatment. Kaplan–Meier methods were used to estimate the occurrence rate of a CV event, and multivariate Cox regression models were developed to identify prognostic factors of each CV event among patients treated with anti-MM therapies.

Results: 4288 patients met the eligibility criteria for inclusion in the study (57% male, median age 66 y, 41% with Charlson Comorbidity Index ≥2, mean duration of treatment 192 d; Table). 42% (n=1779) were treated with PIs, 38% (n=1624) with IMiDs and 20% (n=865) with PI+IMiDs. Patients receiving PI+IMiD were significantly younger and generally had lower prevalence of CV comorbidities than those receiving PI or IMiD (Table). Compared with patients on PI, the risk of developing VTE was 46% greater in patients on PI+IMiD (HR: 1.46; 95% CI: 1.09, 1.96). Compared with those on IMiD, the risk of developing cardiac failure and cardiac arrhythmia was 33% and 18% greater in patients on PI+IMiD (HR: 1.33; 95% CI: 1.03, 1.72; HR: 1.18; 95% CI: 1.00, 1.40). After 6 months of treatment, the rates of VTE were 8%, 10%, and 11% for patients on a PI, those on an IMiD and those on PI+IMiD, respectively. The corresponding rates for cardiac failure were 18%, 11% and 11% for PI, IMiD and PI+IMiD cohorts, and 21%, 16% and 22% for cardiac arrhythmia.

Table 1.

Summary/Conclusions: PI+IMiDs may be associated with incremental occurrence of specific CV events during treatment, and may result in specific CV events earlier during therapy than PIs or IMiDs alone. These highlight a need for treatments that do not exacerbate CV risks and are appropriate for patients with pre-existing CV conditions. The lower prevalence of baseline CV comorbidities and lower mean age in patients on PI+IMiDs suggest that prevalence of a CV comorbidity and age influences treatment choice. Further analysis may be necessary to better understand the impact of baseline CV comorbidities on choice of MM treatment.

**E1256**

**LENALIDOMIDE PLUS HIGH-DOSE VERSUS LOW-DOSE DEXAMETHASONE FOR THE TREATMENT OF RELAPSED/REFRACTORY MULTIPLE MYELOMA: A SYSTEMATIC REVIEW**

K. Kupas\(^1,3\), I. Kaspar\(^1\), V. Baecke\(^2\), W. Weise\(^3\)

\(^1\)Bristol-Myers Squibb, Munich, \(^2\)Ecker + Ecker GmbH, Hamburg, \(^3\)University of Tübingen, Tübingen, Germany

Background: Lenalidomide in combination with dexamethasone is approved globally for the treatment of multiple myeloma (MM). Although older pivotal regimens used lenalidomide or combinations with thalidomide (LD), more recent studies have used lenalidomide plus low-dose dexamethasone (LD) for relapsed/refractory MM (RRMM), as the LD regimen demonstrated better survival with lower toxicity for the treatment of newly diagnosed MM.
Methods: We collected the clinical data of 169 patients qualified to the Study Group as follows: bortezomib: 1.3 mg/m² (days 1, 4, 8, 11), thalidomide: 100 – 200 mg a day (days 1, 2, 4, 5, 8, 9, 11, 12) or 40 mg a day (days 1–4), every 21 days. Patients were included into analysis if ≥1 cycle of VTD was administered. Adverse events (AEs) were graded according to CTCAE v4.0. The analysis involved also the impact of VTD regimen on efficiency of stem cells mobilization as well as high dose therapy/ autologous stem cell transplantation (HDT/autoSCT) procedure.

Results: In the cohort of 169 patients, median age was 59 years (range 36-70). ISS stage 1 was found in 30.8% of patients, ISS 2 and 3 in 20.7% and 45.5%, respectively. Median number of VTD cycles was 5. In 81.6% of patients bortezomib was administered subcutaneously. Thalidomide dose was 100mg a day in 85.1% of patients. Bortezomib dose was reduced in 43 patients (25.4%) with peripheral polyneuropathy as the most common reason (75%). Polyneuropathy was also the most common grade 3/4 adverse event, observed in 20 patients (11.8%) and neutropenia was the most common hematologic toxicity, though it was noted only in 5 patients (3%). Response rate ≥ PR was achieved in 95% of patients, including 5.6% of SCR, 27.1% of CR and 35.1% of VGPR. So far, stem cell mobilization was performed in 110 patients, most commonly used protocols were plasmapheresis/ cyclophosphamide (42% of patients). In 69.3% of patients one apheresis allowed to obtain the number of stem cells sufficient for transplantation. Median yield of CD34+ cells was 11 x 10^6/kg (max 55.7x10^6/kg) that was sufficient for two transplantations in the majority of patients. HDT/autoSCT was performed so far in 89 patients with MEL 200 protocol as conditioning regimen in 77.6% of patients. Median number of transplants CD34+ cells was 4.4 x 10^6/kg. Median time to reach ANC count >0.5 G/L and PLT count >20 G/L was 11 days and 12 days, respectively. In the evaluation of response 100 days after HDT/autoSCT performed in 81 patients, sCR rate increased from 5.6% to 12.7% and CR from 27.1% to 36.7%.

Summary/Conclusions: VTD regimen allowed to achieve ≥ PR in 94% of patients including ≥ VGPR in 84.5% of patients as compared to 73.5% ≥ PR including 36% of ≥ nCR achieved in patients treated with CTD in our previous study (Dmoszynska et al. Leuk Res 2010). In 96% of patients subsequently undergoing stem cell mobilization sufficient number of CD34+ cells was obtained during first procedure. HDT/autoSCT further increased response rate after VTD induction (≥ CR up to 43.5%, ≥ VGPR up to 83.5%).
Background: The presence of immunoparesis (IP) at diagnosis in several plasma cell disorders is a risk factor for progression, associated with an unfavorable outcome with reduced progression-free survival (PFS) and overall survival (OS). However, its impact in light chain (AL) amyloidosis has been evaluated only in few series, and when present it was associated with worst response and survival.

Aims: The aim of this study was to investigate the prognostic impact of IP in patients with newly diagnosed AL amyloidosis at a single institution.

Methods: We reviewed the clinical records of patients with AL amyloidosis diagnosed from January 2006 to December 2016. Sixty-nine patients (32F/37M; median age at diagnosis 62) with available immunoglobulin (Ig) measurements were the final study population. Initial baseline demographics, clinical and laboratory data, treatment and follow-up were collected. Median follow-up was 30.2 months. IP was defined as suppression of all uninvolved Ig below the lower reference value. PFS and OS were calculated from the date of diagnosis.

Results: Forty-three patients (63.2%) were transplant ineligible while 26 (36.8%) were eligible. Forty-three patients (62.3%) were transplant ineligible while 26 (37.7%) underwent an autologous stem cell transplantation (ASCT). The distribution of the monoclonal protein isotype by immunofixation at diagnosis was as follows: light chains only (46.4%), IgG (39.1%), IgA (10.2%) and IgM (4.3%). The predominant light chain isotype was lambda (79.7%). A very good partial response (VGPR) or better was achieved in 53.6% of patients. Three-year OS rate was 50.4%. IP was observed in 27.5% of the patients at diagnosis. Patients with IP had a higher bone marrow plasma cells (BMPC) infiltration (29 vs 9; P<0.001). Also a trend towards a higher difference between involved and uninvolved free light chains was observed in the group of patients with IP (360.2 vs 221.7; P=0.08). IP was more frequent in those who received an ASCT (57.5% vs. 42.1%; P=0.03). There were no changes in the frequency of IP comparing at diagnosis vs. post-ASCT settings (39.13% vs 34.78%; P=0.4).

Regarding its prognostic value, IP did not influence survival in the whole series. In the ASCT group, the presence of IP resulted in a significantly shorter PFS (median: 30.2 months vs not reached [NR]; P=0.019; Figure 1A) and OS (62.5 months vs NR; P=0.097). In the group of patients with stage I and II of the Mayo risk stratification system of 2012 (Mayo12), the presence of IP resulted in a shorter PFS (21.8 months vs NR; P=0.047; Figure 1B), but not significantly different in OS. Multivariate analysis restricted to the population of patients with stage I and II Mayo12, incorporating ASCT, BMPC and IP, indicate that IP retained its independent prognostic factor for worse PFS (HR=12.06; 95% CI, 1.9-75.7; P=0.008).

Figure 1.

Summary/Conclusions: The presence of IP has a negative impact on survival, especially in the sub-group of patients in early stages of the disease. The presence of IP at diagnosis could be an additional powerful discriminatory prognostic indicator in the group of patients without advanced stage of the Mayo risk stratification system of 2012.
Background: Polyclonal antibodies against the conformational epitopes between the heavy and light chains (HLC) of immunoglobulin (lg) have been recently introduced as diagnostic tool in multiple myeloma (MM) and other monoclonal gammopathies. They separately identify the two different light chain types of each lg, allowing the quantification of the monoclonal component. HLC and HLC ratios may be particularly useful for monitoring the presence of monoclonal component in oligo-secretory MM or when it migrates in the β region, as frequently observed in IgA MM. The International Myeloma Working Group (IMWG) has published in 2016 new consensus criteria for assessing response and minimal residual disease (MRD) in MM, outlining the potential role of HLC assay in this setting and the need of its further investigation, particularly in patients achieving complete response (CR) and not support a role for HLC as putative biomarker of MRD.

Methods: Twenty-five consecutive patients were evaluated. Mean age was 63 years (range 43-92), fourteen patients were males. Ig isotype was IgG or IgA in 14 and 11 patients, respectively, with 20 patients showing kappa and 5 lambda light chains. According to International Staging System, seven patients had stage 1, ten stage 2 and eight stage 3. Fourteen patients not eligible to autologous stem cell transplantation (AuSCT) received a bortezomib-based treatment, mainly constituted by bortezomib, melphalan and prednisone combination (VMP), while eleven patients underwent AuSCT after induction therapy with bortezomib, thalidomide and dexamethasone (VTD). With a median follow-up of 52 months (range 21-92), overall survival (OS) of the entire cohort was 61 months (95% CI 43-82), fourteen patients were males. Ig isotype was IgG or IgA and k/λ ratios were then calculated.

Results: At CR time, we found seven (28%) samples still showing abnormal HLC ratio and fourteen samples (56%) with abnormal FLC ratio. Discrepancy between the two assays occurred in 11 patients. FLC assay normalization in CR was significantly associated with better PFS (43 months, 95% CI 14-45 vs 12 months, 95% CI 5-25, p=0,03). In contrast, normalization of HLC ratio had no impact on PFS (26 months, 95% CI 10-38, vs 20 months, 95% CI 10-30, p=0,51), even selecting IgA MM. Notably, in 9 patients, the negative effect of abnormal FLC ratio at CR on PFS was not mitigated by concomitant normalization of HLC ratio (19 months, 95% CI 4-35, p=0,02). Neither FLC, nor HLC affected OS. There were no differences between patients who received AuSCT and those who did not.

Summary/Conclusions: To the best of our knowledge, this is the first study to analyze HLC ratios exclusively in MM patients in CR. While our preliminary data confirm the prognostic usefulness of FLC in this setting, currently they do not support a role for HLC as putative biomarker of MRD.

Summary/Conclusions: In this first real-world analysis we confirm that daratumumab monotherapy is able to induce response in one third of highly pretreated and double refractory RRMM patients. Regarding safety, in contrast to the SIRIUS trial where no treatment discontinuations due to AE occurred, 3/26 pts (11%) treated with daratumumab in clinical practice had their therapy interrupted due to complications.

E1263
REAL-WORLD TREATMENT PATTERNS AND PATIENTS CHARACTERISTICS IN MULTIPLE MYELOMA ACROSS EUROPE
A. Fornander1, A. Zomas1, E. Papakostas1, T. Do1, M. Russo2, R. D'Ambrosio1, G. Schneidewind1, 1EUCAN Medical Affairs, 2Global Market Access, Takeda, CH-8152 Glattpark-Opfikon (Zurich), Switzerland

Background: Emerging resistance to modern antimyeloma agents such as proteasome inhibitors (PIs) and immunomodulatory drugs (IMiDs) remains the main clinical problem in managing multiple myeloma (MM). Daratumumab, a first-in-class anti-CD38 monoclonal antibody, has been recently approved in Europe as a monotherapy for patients (pts) with relapsed and refractory multiple myeloma (RRMM), whose prior therapy included a PI and an IMiD and whose disease had progressed during this time; based on the SIRIUS clinical trial outcome (Loniol et al. Lancet 2016). Nevertheless to optimize daratumumab use in clinical practice, more data on its “real life” activity and safety are still required.

Aims: This observational study of the Polish Myeloma Group (PMG) was aimed to prospectively evaluate the efficacy and toxicity of daratumumab monotherapy in RRMM. Last, daratumumab compassionate use named DaraCUP was used to treat patients in Poland.

Methods: Patients were eligible for DaraCUP if they met all the following criteria: a) confirmed diagnosis of RRMM, b) relapse after a minimum of 3 prior lines of therapy including PI and IMiD or were double refractory to both PI and IMiD (a and b) or were double refractory to both PI, IMiD and dexamethasone (a, b and c); had a ECOG performance status score 2 or lower. Data on treatment outcomes and complications were anonymously collected using electronic CRFs. The IMWG response criteria were applied.

Results: In total 30 patients were qualified to DaraCUP in Poland and all were enrolled to the PMG observational study. At the time of writing this report, 26 pts (87%) had received at least one dose of daratumumab and were included in the safety analysis, while 22 pts (73%) had received at least 2 cycles of daratumumab and were included in the preliminary efficacy analysis. Baseline pts characteristics are reported in Table 1. Pts were heavily pretreated, with a median of 4 prior lines of therapy (range, 2-10). Ten pts (38.5%) were double refractory to both PI and IMiD while 15 pts (56.3%) were refractory to the last line of previous therapy. Median time since initial diagnosis to start of treatment with daratumumab was 3.9 years (range, 1.4-12.2 years). At the time of analysis, the median follow-up time within the study was 5.1 months (range, 0-8 months) and median daratumumab treatment duration was 4.4 months (range, 0-8 months). Sixteen pts (61.5%) remain on treatment, while ten pts (36.5%) discontinued therapy as a result of disease progression (n=7) and adverse events (AEs) (n=3). Overall response rate (CR or PR) was 31.8% including one (4.5%) CR and two (9%) VGPR (Table 1). Stable disease was reported in 11 (50%) pts. The median PFS and median OS were not reached. During the time of observation three deaths were recorded due to disease progression. Regarding daratumumab toxicity, grade 3 or 4 non-haematological toxicities occurred in 8 pts (30.7%) and included: infusion-related reactions (n=2), pneumonia (n=2), other infections (n=2), mandible inflammation (n=1), dyspnoea (n=1). The most common haematological toxicities were grade one anaemia (n=30.7%), neutropenia (n=23.1%), thrombocytopenia (n=18.5%), and neutropenic fever (n=9.2%). The most common laboratory abnormalities were grade one hypercalcemia (n=40%), hyperuricemia (n=24.1%), and grade one hypomagnesemia (n=14%). Among the 22 pts (73%) who had received at least 2 cycles of daratumumab, 21 pts (95%) had received at least one dose of daratumumab and were included in the safety analysis, while 22 pts (73%) had received at least 2 cycles of daratumumab and were included in the preliminary efficacy analysis. Baseline pts characteristics are reported in Table 1.

Table 1.
Background: Multiple myeloma (MM) is the second most common haematological malignancy after non-Hodgkin lymphomas, accounting for 13% of blood malignancies and 1% of all cancers. The medical management of multiple myeloma has changed over the years and is influenced by multiple factors (e.g., evidence from clinical trials, drug approval status, level of drug reimbursement, guidelines), which vary across Europe. Information describing how patients are managed in the real world is needed.

Aims: The aim of this analysis was to investigate real-world treatment patterns and patient characteristics in MM across Europe.

Methods: Physicians in Europe were requested to answer a series of questions on patient characteristics and treatment regimens of the last eight patients that they had treated during the month prior to answering the questionnaire, according to their patients’ medical charts. The questionnaire was conducted between January and June 2016. Data on 2564 patients with MM were available and are presented here. Countries were grouped into regions according to similar health care systems: Spain, Portugal, Italy and Israel (Southern Region, SR, n=711); Austria, Switzerland, Belgium, Norway, Sweden, Switzerland and Finland (Central and Northern Region, CNR, n=776); Croatia, Estonia, Hungary, Latvia, Lithuania, Poland, Serbia, Slovakia (Eastern Region, ER, n=689). Analyses were descriptive.

Results: Patient characteristics were generally similar across regions, with the majority being <75 years old (69-76%), receiving frontline therapy at study inclusion (57-58%), and being ineligible for autologous stem cell transplantation (ASCT) (53-59%). The median time from MM diagnosis to the time that the physician answered the questionnaire was higher in ER (19.5 months) than other regions (9.7-11 months) (Table). The majority of frontline regimens contained bortezomib, although this was lower in ER (51%) than other regions (66-70%). The median duration of frontline therapy was longer in ER (4.5 months) than other regions (3.2 months). This difference was mainly driven by ASCT eligible patients having longer duration of therapy in ER (4.5 months) than other regions (2.6 months). The number of bortezomib injections in frontline therapy, however, was higher in SR and CNR (both 24) than in ER (18). The majority of second line regimens contained lenalidomide (57-64%) in all regions except ER, where bortezomib-based regimens were most frequent (38%). The median duration of second line therapy was shorter in SR and CNR than in ER (Table). Moreover, the second line therapy, ASCT eligible patients had shorter duration of therapy in ER and SR (3.2 months) than in CNR regions (4.5 months). The majority of later-line (3+) regimens were based on therapies that did not include bortezomib, lenalidomide or pomalidomide for all regions (57-67%) with the exception of SR where pomalidomide (29.4%), lenalidomide (12.6%) and bortezomib (14%) were the preferred options. In this analysis conducted in Europe, treatment patterns differed in terms of regimens used and duration of therapies even though patient characteristics were generally similar across regions. This may in part be related to differences in healthcare systems. Further research is required to understand how new therapies can be integrated into current treatment patterns and how these treatment patterns impact patient outcomes.

Summary/Conclusions: In this analysis conducted in Europe, treatment patterns differed in terms of regimens used and duration of therapies even though patient characteristics were generally similar across regions. This may in part be related to differences in healthcare systems. Further research is required to understand how new therapies can be integrated into current treatment patterns and how these treatment patterns impact patient outcomes.

Summary/Conclusions: This study shows that the prevalence of frailty syndrome is high and has a profound impact in early death. It is also independently associated with a worse prognosis. Frailty should be considered as part of the clinical assessment when treating elderly patients with myeloma.

E1265

PROGNOSIS OF AL AMYLOIDOSIS WITH KIDNEY INJURY

A. Talbot1,*, X. Belenfant2

1Immunology, hopital Saint Louis, paris, 2Neprology, chiag, montreuil, France

Background: AL amyloidosis is a rare disease related to excessive and uncontrolled secretion of monoclonal light chains. The consequence of this proliferation is an alteration of the affected organs due to deposition of free light chains. Despite therapeutic advances in recent years based, among others, on the finding of French studies, the prognosis of this disease remains poor in particular for patients with cardiac disease. Kidney involvement is also frequently observed in the form of a classic nephrotic syndrome. However, in the presence of chronic renal failure in this context is unknown.

Aims: The study was interested in the prognosis of AL amyloidosis associated with endstage renal disease on dialysis in the era of treatment with bortezomib.

Methods: A total of 133 patients (61 from ile-de-France region register and 72 from reference center) were analyzed. Median survival was 66.7 months compared to 70.6 months for patients without dialysis (p=0.65). Within the group

</table>
of patients on dialysis, there is no significant difference between those receiving or not bortezomib. Median survival before 2008 was 54.82 months and rose to 82.30 months for patients treated after this date (p<0.05). Age (HR: 0.281, CI 0.1375 to 0.5782), heart disease (HR: 0.3746, CI 0.1724 to 0.8141) and serum albumin (HR: 2.500 CI: 1.077 to 5.803) were identified as prognostic factors. Transplantation is a viable treatment option for good responders.

Summary/Conclusions: Prognosis of AL amyloidosis in dialysis is heterogeneous. Prognostic scoring integrating clinical biological data could identify the patient who may benefit the most dialysis. This results need to be matched by sex and age with non-dialysis and dialysis for another cause.

E1267

FDG-PET IN MULTIPLE MYELOMA: DUAL TIME POINT FDG UPTAKE IN FOCAL LESIONS CORRELATE TO RESPONSE TO CHEMOTHERAPY

1Hematology, Odense University Hospital, Odense, Denmark, 2Radiology, Hospital of the University of Pennsylvania, Philadelphia, United States, 3Nuclear Medicine, 4Radiology, Odense University Hospital, Odense, 5Nuclear Medicine, 6Hematology, Vejle Hospital, Vejle, Denmark

Background: Dual Time Point (DTP) 18F-FDG PET imaging has been shown to be useful in differentiating malignant from benign lesions in that increasing uptake from 1 to 3 hours is a characteristic feature of malignancy in contrast to inflammation.

Aims: The aim of this study was to evaluate the predictive role of DTP 18F-FDG PET/CT imaging in assessing response to chemotherapy in multiple myeloma (MM).

Methods: 23 patients with MM (21 male, aged 53-75 years) underwent 18F-FDG PET/CT in a prospective study (NCT02187731) before start of treatment and two months after high dose chemotherapy with stem cell support. All scans were performed at 60 and 180 minutes after tracer injection at Odense University Hospital and Vejle Hospital. Thirteen patients with ≥3 focal lesions of at least 10 mm were selected for analysis. Images were analyzed using an adaptive thresholding algorithm (ROVER software; ABX GmbH, Radeberg, Germany). Focal malignant lesions were localized in pre-treatment scans; maximum standard uptake value (SUVmax) and mean SUV (SUVmean) and partial volume corrected SUVmean (pvcSU-Vmean) were obtained for each lesion. Lesional response to chemotherapy was classified as complete or partial in the post-treatment scan. A complete response was defined as a complete resolution of the lesion in the post-treatment scan. Lesions with partial response were present in the post-treatment scan. All statistical analyses were done in SPSS 24 using repeated measurements-ANOVA.

Results: Three-five focal lesions were evaluated in each patient. In the pre-treatment PET studies, the increase in SUVmean from 1 to 3 hours was significantly higher for lesions with partial response compared to those with complete response (27.7% vs 11.4%; P=0.050). Additionally, the increase in pvcSU-Vmean was more significant than the increase in SUVmean (±42.23% vs +12.0%; P=0.003). The increase in SUVmax of delayed scans was not significant (P=0.082).

Summary/Conclusions: These preliminary data show that a more significant increase of FDG uptake in delayed scans of DTP PET before treatment correlates with better response to chemotherapy in MM. The increase in pvcSU-Vmean is a better index than those of SUVmean and SUVmax for this purpose.

E1268

UNDERSTANDING THE CONTRIBUTE OF THE NOTCH PATHWAY IN MULTIPLE MYELOMA BONE MARROW NICHE: A FOCUS ON EXTRACELLULAR VESICLES-MEDIATED COMMUNICATION

M. Colombo1, F. Baccianti1, L. Cantone2, N. Moschini3, N. Platova3, S. Garavelli1, M.T. Palano1, R. Adam1, A. Neri2, V. Bollati4, R. Chiarambone5, 6Dept. of Oncology and Hemato-Oncology, Università degli Studi di Milano, Milano, Italy

Background: Multiple myeloma (MM) is an incurable cancer stemming from malignant plasma cells. MM is characterized by a strong tropism to the bone marrow (BM), where tumor cells accumulate and establish complex interactions with the normal stroma, which in turn promotes tumor survival, drug resistance and the development of bone disease. The Notch oncopathic pathway provides a key contribution to the ability of MM cells to shape the BM niche, affecting both BM cell biology and the interplay between MM cells and the BM stromal cells. Extracellular vesicles (EVs) have been reported as novel mediators in creating a supportive milieu for MM. Here we investigate the role of the activated Notch signaling in EV-mediated cross-talk.

Aim: The idea of this work was to further elucidate the role played by the Notch pathway in the shaping of the BM microenvironment to provide a supportive milieu for MM cells, with a focus on the contribution of EVs to the crosstalk between MM cells and the BM stromal cells.

E1269

REAL-WORLD DATA ON THE TREATMENT OF RELAPSED/REFRACTORY MYELOMA WITH LENALIDOMIDE AND DEXAMETHASONE IN 2ND LINE (LEGEND STUDY): THE PROGNOSTIC SIGNIFICANCE OF BIOCHEMICAL VS. CLINICAL RELAPSE

Papanikolaou General Hospital, 9Department of Hematology, Papa-gorgiou General Hospital, ThESSALONIKI, 10Department of Hematology, Ag. Anargirou General Hospital, 11Department of Hematology, University of Ioannina, 12Department of Hematology, Metaxa Cancer Hospital, PIRAEUS, 13Department of Hematology, Kalamata General Hospital, KALA-MATA, 14Department of Hematology, Vostanio General Hospital, MYTILINI, 15Department of Hematology, Atikon General Hospital, National and Kapodis-trian University of Athens, ATHENS, 16Department of Hematology, University General Hospital, HERAKLION, 17Department of Clinical Therapeutics, National and Kapodistrian University of Athens, ATHENS, Greece

Background: The combination of lenalidomide/dexamethasone (LenDex) is an established treatment for relapsed/refractory Multiple Myeloma (MM) patients; however, apart from clinical trials, there is limited data for the efficacy of this combination as 2nd line treatment. Furthermore, the efficacy of LenDex which is administered before evident clinical manifestations, namely in the case of biochemical relapse as compared to clinical relapse, has not yet been assessed.

Aims: In the current study, we evaluated response rates and progression-free survival (PFS) in patients treated with LenDex in 2nd line and we compared survival parameters for patients treated with LenDex at biochemical relapse vs those treated at clinical relapse.

Methods: Medical files of 207 patients with MM diagnosed between 2000-2013 in 18 Greek centers and treated with LenDex as 2nd line treatment from January 2009, up to March 1st 2014, were retrospectively studied. Overall response and PFS were evaluated for all patients. Additionally, PFS was compared in patients treated at either biochemical relapse (group A) or at clinical relapse (group B). The prognostic significance of biochemical relapse adjusted with important patients’ characteristics was also evaluated. Classical methods were used for statistical analysis.

Results: Two hundred and seven patient files were recorded and analyzed (M/F: 112/95, median age: 67.2y, range 31-91). In 67% (95% CI: 61.1% >73.9%) of patients and at clinical relapse in 32.5% (95% CI: 26.1-38.9) of patients. The overall response rate (ORR) was 73.4%: 23.7% of patients achieved very good partial response (VGPR) and 17.8% complete response (CR). The number of patients that achieved at least VGPR did not differ between the 2 groups (p>0.05). The median time to best response was 6.7 months (range 0.6- 51.9). After a median follow-up of 52.8 months, 112 (54.1%) patients are alive and 95 (45.9%) patients are deceased; 131 patients (63.3%) have relapsed (biochemical relapse: 66.4%, clinical relapse: 33.6%). Median PFS and PFS rate at 12 months was 19.2 months (95% CI: 15.6-25.2) and 67.6% respectively. The median PFS was 24 months (95% CI: 18.0-34.8) for patients in group A vs 13.2 months (95% CI: 8.4-19.2) for patients in group B (HR: 0.63, p=0.006). When adjusted for important prognostic patients’ characteristics (ISS, age, β2 microglobulin, and LDH), biochemical relapse maintained its prognostic significance for PFS (p<0.05).

Summary/Conclusions: Our data confirm that LenDex combination as 2nd line treatment leads to high overall response rates and prolonged PFS. Additionally, we have shown for the first time in routine clinical practice that MM patients who receive 2nd line therapy with LenDex at biochemical relapse have a significantly longer median PFS compared to patients treated at clinical relapse, underlying the importance of potentially starting treatment before evident clinical manifestations at the first relapse.
Methods: We established two MM cell lines stably retaining the doxycycline-inducible pTRIPZ vector containing anti-Jagged1 and Jagged2 shRNAs and a BM mesenchymal stromal cell line expressing shRNAs for Notch1 and Notch2. EVs were isolated by ultracentrifugation and used for functional assays and molecular analysis. qPCR was performed using SYBR Green. Apoptosis analysis was performed by flow cytometry; evaluation of protein expression was performed by western or eastern blotting.

Results: We present evidences that EVs play a crucial role in the dysregulated interactions of MM cells with the BM microenvironment and that Notch regulates their release. Indeed, BMSCs knockdown for Notch1/2 results in a decrease in EVs release and reduce their ability to induce Bortezomib resistance in MM cells and to stimulate their migration. On the other side, MM-derived EVs are able to increase the production of pro-tumor factors by BMSCs (i.e. SDF1α), promoting their ability to boost tumor growth; interestingly, this effect is lost when EVs are isolated from MM cells where the Notch pathway was inhibited. Finally, EVs released by co-cultures of BMSCs and MM cells where the Notch pathway is blocked display a reduced ability to increase osteoclastogenesis compared to EVs from the control culture. This is particularly relevant due to the crucial role played by bone disease in MM progression.

Summary/Conclusions: These new insights in the pathophysiology of the rearranged BM niche represent the rationale for a Notch-directed therapy aiming to uncouple the crosstalk of MM with the surrounding microenvironment by inhibiting Notch signaling.

E1269
THE USE OF CARFILZOMIB AND BORTEZOMIB IN ROUTINE CLINICAL PRACTICE: RESULTS FROM PREAMBLE, AN ONGOING, OBSERVATIONAL COHORT STUDY IN MULTIPLE MYELOMA
B. Dure1,*, G. Cook2, H. Goldschmidt3, D. Kute1, T. Zyczynski4, S. Popov5, M. Goor6, C. Davi7, R. Vi8
1Cedars-Sinai Medical Center, Los Angeles, United States, 2University of Leeds, Leeds, United Kingdom, 3Heidelberg University Hospital, Heidelberg, Germany, 4Massachusetts General Hospital Cancer Center, Boston, 5Bristol-Myers Squibb, Lawrenceville, United States, 6Parexel, St Petersburg, Russian Federation, 7Washington University School of Medicine, St Louis, United States

Background: Multiple myeloma (MM) remains largely incurable despite improvements in clinical outcomes following the approval of immunomodulatory drugs (IMiDs) and proteasome inhibitors (PIs) (Rajkumar et al 2010). Previous findings have documented the prevalence of hematological relapse and duration of therapy (DoT) with PIs and IMiDs (5 and 9 mo, respectively; Palumbo et al 2016) vs clinical trials (Stewart et al 2014). Understanding real-world use of therapies for relapsed/refractory (RR) MM is important to determine their position in the treatment paradigm.

Aims: In this subsequent PREAMBLE analysis, treatment patterns in patients (pts) with RRRM receiving bortezomib (bort) and carfilzomib (carf) were evaluated to better understand the use of PIs in routine clinical practice.

Methods: PREAMBLE (NCT01838512) is an ongoing, observational, international cohort study exploring real-world treatment patterns and outcomes in pts with MM. Eligible pts were aged ≥18 yrs with diagnosis of RRMM, ≥1 prior treatment and initiated treatment (index therapy) with an IMiD, PI or IMiD+PI within 90 days before to 30 days after study enrollment. Treatment patterns, DoT and time to next treatment (TTNT; for pts who switched or died) were assessed. Informed consent was obtained for all pts.

Results: At data cut-off (Sept 1, 2016), data were available for 924 pts, of which 326 (35%) pts had bort-based index therapy and 86 pts (9%) received carf-based index therapy (63/72 [88%] were enrolled in North America). The most common carf-based therapies were carf alone (n=40, 47%), which 326 (35%) pts had bort-based index therapy and 86 pts (9%) received carf-based index therapy (63/72 [88%] were enrolled in North America). The most common carf-based combination was bort + dexamethasone (dex; n=99, 30%). The most common carf-based therapies were carf alone (n=40, 47%), followed by carf+dex (n=21, 24%). The most widely used bort dose per 21 days for any bort-based therapy was 1.4 mg/m2 (28/55; 51%). Switch from carf-based index therapy occurred after a median (Q1, Q3) DoT of 3.4 (1.9, 9.5) mo (n=34; most pts switched to pomalidomide (pom)-based regimens (23/34; 68%). Switch rates increased from 17% at 3 mo to 57% at 33 mo, respectively; most pts switched to lenalidomide (38/99; 39%). In pts with carf-based index therapy, most commonly fatigue (12%) and anemia (9%); 70% (69/99) of pts receiving bort+dex had AEs, most commonly thrombocytopenia and diarrhea (each 14%).

Summary/Conclusions: Treatment duration observed for PIs in the real-world clinical practice setting was shorter than reported in clinical trials. As patient enrollment and follow-up continues for PREAMBLE, additional analyses will be conducted to evaluate the impact of these patterns on efficacy outcomes. Study funding: BMS.

E1270
ROLE OF SERUM FREE LIGHT CHAIN VS BENCE JONES MEASURE- MENT IN LIGHT CHAIN MULTIPLE MYELOMA (LCMM) AT DIAGNOSIS, DURING TREATMENT AND FOLLOW-UP FOR RESPONSE EVALUATION AND RELAPSE DETECTION
M. Stadenn1,*, M. Berardi2, A. Caldini3, C. Nozzoli4, E. Antoniolli1, A. Bosi1
1Hematology Department, Azienda Ospedaliero-Universitaria Careggi, Florence, Italy, 2BMT Unit, Azienda Ospedaliero-Universitaria Careggi, Florence, Italy

Background: According to IMWG recommendations for response assessment in multiple myeloma (MM), serum free light chain (sFLC) measurement should be used to define a “stratified” complete response in symptomatic MM and, only in cases when Bence Jones protein (BJP) is deemed as not quantifiable (<200mg/24h), in light chain multiple myeloma (LCMM). However, data are available suggesting that sFLC could be a more sensitive tool than BJP for minimal residual disease assessment and an earlier indicator of progressive disease (PD). BJP measures shorter than sFLC, shorter than urinary electrophoresis and immunofixation, it is time-consuming for technicians and could be limited by poor patient compliance.

Aims: Aim of our study was to retrospectively compare sFLC and BJP results in LCMM patients (pts) at diagnosis, during treatment and follow-up.

Methods: Serum and urine samples were collected from pts affected with plasma cell dyscrasia referring to the Azienda Ospedaliero-Universitaria Careggi between 1st February 2012 and 31 December 2013. Serum and urine protein electrophoresis was performed using Capillaries II, serum and urine immunofixation using Hydrasys II (both from Sebia), sFLC were measured on Immage 800 nephelo-immunoanalyser using FreeL light chain reagents (The Binding Site).

Results: We analyzed samples from 387 pts having positive serum and/or positive urinary immunofixation and/or abnormal sFLC ratio. Among them, 43 symptomatic LCMM pts were identified having both sFLC and BJP measurement at baseline (at MM diagnosis or first relapse). Serum and urine lab tests results were evaluated at baseline, monthly during therapy and every 3 months during follow-up. Median duration of laboratory monitoring for the whole group was 42 months (range 3-120). Autologous stem cell transplantation was performed in 39% of pts previously treated with proteasome inhibitors (81%) and/or immunomodulating agents (40%) or chemotherapy (9%). sFLC or BJP were not available in 10% of 872 pair of samples from 43 pts. In 10% of cases (68/696 pair of samples) sFLC ratio was abnormal with involved FLC with no detectable BJP (FLC<f;FLC+BJP); the opposite (FLC>f;FLC+BJP) occurred in 1% of cases (8/696 pair of samples). Renal failure was found in 9% vs 13% of disreputable cases. At baseline, of the 43 LCMM pts, 13% had progressive disease only by sFLC due to BJP-200mg/24h and were therefore considered not evaluable for response assessment. Median time to BOR was 3 months by both sFLC and BJP (range FLC: 1-11 mesi; range BJP: 1-10 mesi). Among the remaining 37 pts evaluable for best overall response, 6/37 had complete response according to BJP but not to sFLC, interestingly 4 pts progressed after 2-8 months. Twenty-one pts progressed during follow-up: PD was detected only by sFLC in 4, only by BJP in 1. Both tests were able to detect PD in 16 pts: at the same time in 5, with sFLC-PD occurring earlier in 7 and BJP-PD occurring earlier in 4 pts.

Summary/Conclusions: Both sFLC and BJP results are useful in LCM MM pts for disease monitoring, however, sFLC assessment appears to be more sensitive in MRD and early relapse identification. These data suggest that BJP could be substituted by sFLC assessment in LCMM. In our series only 1 case showed BJP-PD according to IMWG occurring earlier than sFLC-PD but was considered not clinically significant. On the contrary 5 pts in BJP-6 had “measurable disease” within months without having reached FLC-GR. Limits of our study are a small number of pts, inhomogeneous duration of therapy and follow-up and retrospective analysis.

Background: Established risk stratification tools in MM, such as the International Staging System (ISS) and the revised ISS, have improved overall survival (OS) estimates by combining the strongest known predictors of survival at diagnosis. There remains, however, a need for tools that use additional data available at relapse to improve risk stratification. We previously used real-world data from the Czech Registry of Monoclonal Gammopathies (RMG) to develop a RSA for estimating risk of death in patients with MM starting second line (2L) treatment. A multiple Cox regression model identified predictors of OS at 2L (Table); hazard ratios (HRs) for each predictor were multiplied to obtain an overall score for each patient. A K-adaptive partitioning for survival (KAPS) algorithm stratified patients into risk groups based on these scores.

Aims: To investigate how our RSA is affected by: 1) removing cytogenetic abnormalities (CAs) at diagnosis as an OS predictor, as these are not routinely measured in practice; 2) adding 2L treatment as a predictor, as 2L treatment type is likely to affect OS; 3) changing the number of stratification groups.

Methods: The analyses used data for 1418 patients aged ≥18 years who were diagnosed with symptomatic MM between May 2007 and April 2016 and who had reached 2L. The Cox model was re-run for two sensitivity analyses: excluding CAs and adjusting for treatment received at 2L (adding bortezomib or lenalidomide vs other treatments as a predictor). The impact of different numbers of risk groups was assessed using KAPS.

Table 1.
Results: Results are shown in the Table. The model without CAs had similar HRs and predictors to the original; however, lactate dehydrogenase level at diagnosis was not identified as a predictor. Kaplan–Meier OS analysis showed separation between groups (median OS for the lowest [group 1] to the highest [group 4] risk group: 57.2, 29.4, 14.9 and 4.9 months), but the separation was weaker than when CAs were included in the model (median OS: 57.2, 28.8, 13.4 and 4.7 months). Despite 81% of patients in the RMG having no CA data (‘missing’ CA was treated as a separate level in the original model), the fit of the model (measured using Akaike’s information criterion; Table) without CAs was worse than the original, reducing the accuracy of survival predictions.

Adding 2L treatment as a predictor did not affect the model fit, indicating that OS predictions were not improved. KAPS analysis showed that a model with three groups for stratifying patients by risk of death was less effective than one with 4 or 5 risk groups. With group 1 as the reference, the HRs for OS were 2.4 and 8.1 for groups 2 and 3 in the three-group model (all \(p<0.001\)), 2.1, 4.2 and 11.1 in groups 2–4 in the four-group model (all \(p<0.001\)) and 1.8, 2.8, 4.9 and 10.5 for groups 2–5 in the five-group model (all \(p<0.001\)). Using five risk groups was considered less practical in a clinical setting than the four-group model, which provides a clearer difference in risk across groups.

Summary/Conclusions: These analyses indicate that our RSA incorporating data from diagnosis and relapse can identify patient groups with profoundly different survival expectations, regardless of 2L treatment type. CAs at diagnosis is a known OS predictor and, as expected, improves the strength of predictions. The practicalities of measuring CAs should be considered, but these data suggest that physicians should be encouraged to assess CAs at diagnosis; CAs at relapse may also be informative. Further validation of this model is required using other real-world and clinical trial data.

E1273

REAL-WORLD DATA ON MULTIPLE MYELOMA: A PROSPECTIVE NATIONAL REGISTRY IN URUGUAY ON 224 NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS FROM 2012-2015

E. Riva1, V. Bove1, F. Villano1, M. Mori2, A. Noria3, P. Petruskevicius4, C. Córdoba2, A. Conde1, L. Diaz5
1Hematology Department, Hospital de Clínicas, Facultad de Medicina, 2Hematology, Hospital Maciel, 3Quantitative Methods Department, Facultad de Medicina, 4Hematology, Centro Médico, Salto, 5Hematology Department, Asociación Española, 6Hematology Department, Centro Médico, Salto, 7President, Uruguayan Society of Hematology, Montevideo, Uruguay

Background: The Uruguayan National Myeloma Registry is the first observational prospective Uruguayan registry designed to document clinical characteristics of newly diagnosed multiple myeloma (MM), treatment and outcomes in a real-life setting. It collects detailed data on patients. Diagnosis occurs at all institutions from 2012, nationwide. Analysis of this non-selected data will provide real-life information to plan strategies to improve MM management and perform different survival expectations, regardless of 2L treatment type. CAs at diagnosis is a known OS predictor and, as expected, improves the strength of predictions. The practicalities of measuring CAs should be considered, but these data suggest that physicians should be encouraged to assess CAs at diagnosis; CAs at relapse may also be informative. Further validation of this model is required using other real-world and clinical trial data.

Aims: To document current strategies of clinical characteristics at diagnosis, management, outcomes and treatment adverse effects of non-selected newly diagnosed MM patients in a recent period.

Methods: This registry includes all MM diagnosed from January 2012 in all institutions, nationwide. Smoldering MM are not included. We present the analysis of the first 3 years of data collection. Information was obtained from medical records at each institution. The database includes clinical and laboratory characteristics, treatment, disease-related and treatment-related adverse events, response, progression free survival, overall survival and cause of death. Survival is obtained from the Uruguayan Ministry of Health database.

Results: With a 71% institutional coverage, 224 patients were included. Median age at diagnosis was 66 years (range 33-94 years), 54.5% were male; 10% were younger than 50 years and 34.5%, older than 70 years. Distribution according to subtype was: IgG 50.4%, IgA 23.3%, Light chains 18.7%, non-secretor 2.2% and IgM <1%. Most patients had advanced disease: 79.6% Durie-Salmon stage III (176/221), 48.6% ISS (83/177). Anemia (hemoglobin ≤10 g/dl) was present in 48.6%, osteolytic lesions in 69%, renal impairment (creatinine ≥2mg/dl) in 29.5% and hypercalcemia in 10%. Cytogenetics was evaluated in 150 patients; high-risk features were detected in 6.3% by conventional cytogenetics and 19% by fluorescence in situ hybridization. First-line treatment included at least one of the new drugs (Thalidomide, Bortezomib or Lenalidomide) in 92% of patients ≤70 years and in 50% of >70 years. First-line response was available in 73%. Overall response rate (≥ PR) was 82.3%, VGPR= 23.2% and CR=15.2%; 9.8% patients achieved stable disease and 7.9% were refractory. (Fig. 1). Comorbidities and treatment-related toxicities were observed in 45.8% (>70y vs 41%). Most common adverse events were recurrent infections (28%), neuropathy (17%), thromboembolic events (5.4%) and grade 3-4 cytopenias (5%). Sixty out of 146 potential candidates have been transplanted as first line consolidation at the time of this analysis. After a median follow-up of 30 months, overall survival was 62.8% (median NR in ≤70 years and 32 months in >70 years) and median progression free survival (PFS) was 17 months.

Summary/Conclusions: This first national registry provides a thorough insight into the characteristics of MM patients in our country. With a high institutional coverage, we show MM characteristics at diagnosis are similar to other real-life reports. MM is detected in advanced stage with a high percentage of renal impairment. Diagnosis is performed according to international recommendations. First-line treatment is defined by local policies which restrict Bortezomib to high-risk cytogenetic features and/or renal impairment and do not provide Lenalidomide. Reasons for 59% potential candidates not receiving ASCT should be addressed in future research. This analysis provides relevant real-life information to plan strategies to improve MM management and perform high quality population-based research on the field.

REPRESENTATION OF MINORITIES, THE ELDERLY AND WOMEN IN MULTIPLE MYELOMA CLINICAL TRIALS

N. Duma1,*, J. Vera-Aguilera1, M. Gonzales-Z., R. Parrondo2, J. Paludo1, V. Mariciotti2, Y. Wang1, R. Warsame1, R. Go1, A. Adjei3
1Hematology, Mayo Clinic, Rochester, 2Internal Medicine, Rutgers University, Newark, 3Mayo Clinic, Rochester, United States

Background: Multiple myeloma (MM) accounts for approximately 1% of all cancers and 10% of hemolitic malignancies in the United States (US). MM occurs in all races but the incidence in African Americans is two to three times higher than in non-Hispanic whites. Many clinical trials (CT) lack appropriate representation of specific patients populations, limiting the generalizability of the evidence obtained.

Aims: Determine the representation of ethnic minorities, the elderly and women in MM CT.

Methods: Enrollment data from all therapeutic trials reported as completed in clinicaltrial.gov from 2000 to 2016 were analyzed. CT including other hematologic malignancies and with recruitment outside of the US were excluded. Enrollment fraction (EF) was defined as the number of enrollees divided by the 2013 Surveillance, Epidemiology, and End Results (SEER) database MM complete prevalence. Chi-square test was used to estimate differences in categorical data.

Results: Out of 177 MM CT, 78 (44%) reported ethnicity with a total of 12,055 enrollees. Out of those 78 CT, 52 (67%) were phase II, 15 (19%) phase III and 11 (14%) phase I. Most of the results were published from 2012 to 2016 (74%). Distribution by race, gender, age and comparison with the SEER MM prevalence data are described on Table 1. Forty-six (59%) trials were sponsored by industry, 7 (9%) by NCI and 25 (32%) were investigator initiated. Participation in CT varied significantly across ethnic groups, non-Hispanic Whites were more likely to be enrolled in CT (EF of 0.23) than African Americans (AA) (EF of 0.08, \(p<0.0001\)) and Hispanics (His) (EF of 0.05, \(p<0.0001\)). Males had
a higher recruitment rate than females (58% vs 42%), but this could be explained by the higher incidence of MM in this subgroup. Enrollee’s median age was 62 years. Younger pts (<65 years) were more likely to be enrolled in CT than the elderly (66% vs 34%, p<0.0001). Industry sponsored trials were less likely to recruit AA compared with investigator initiated trials (7.6% vs 12%, p=0.0001).

**Summary/Conclusions:** Despite the higher incidence of MM in African Americans and the elderly, the former only represented 8.6% of the study participants and 66% of these were less than 65 years of age, perhaps lacking data in the tolerability of these new agents in our aging MM population. We also observed industry studies were less likely to recruit AA patients. Future trials should take extra measures to recruit participants that adequately represent the United States MM population.

E1275

**EVALUATION OF TREATMENT INDUCED NEUROPATHY IN MULTIPLE MYELOMA AND ITS INFLUENCE ON PHYSICAL AND ROLE FUNCTIONING**

B, Sidi Bel Abbes

**Background:** Peripheral neuropathy (PN) is a major dose limiting and potentially disabling adverse event of commonly therapeutics drugs used in the management of multiple myeloma (MM), including the immunomodulatory drugs (IMiDs, Thalidomide and Lenalidomide), and the proteasome inhibitor (Bortezomib).

**Aims:** The aim of this study was to (1) perform a psychometric evaluation of PN and (2) examine the prevalence of this complication and its influence on physical and role functioning of MM patients.

**Methods:** The FACT/GOG-Neuotoxicity (Ntx) subscale for assessing treatment induced PN was evaluated. The 11-item of this questionnaire was administered to patients with MM treated with IMiD and/or Bortezomib. The subscale was evaluated in 32 participants for internal reliability, construct validity, criterion validity, and compared with other validated inventories (CTCAE version 3). Spearman rank correlation was calculated to determine the impact of PN on functional, physical and role functioning of MM patients, assessed by EORTC quality of life scale (EORTC QLQ-C30). A Cronbach coefficient ≥ 0.8 is good. Spearman rank correlation is significant if p< 0.05 or r >0.5.

**Results:** Cronbach alpha coefficient for internal consistency of FACT/GOG-Ntx subscale was 0.92, and its correlation with the full CTCAE scale as follows: P=0.0001. All the 11 items exhibited high correlations with the NTX subscale score (r= 0.65- 0.79), and the Construct validity of NTX was good. According to FACT/GOG-NTX and NCi-CTCAE, 24 (75%) patients presented PN secondary to IMid or Bortezomib. The PN was severe in 14 (43, 7%) patients, especially those who received Bortezomib associated with IMiD (71, 4%). PN did not influence the achievement of a very good response of MM to therapy neither a complete remission (P=0.6), but patients with high scores of NTX subscale have reduced functional activities, especially physical and role functioning (P<0.0001). R=0.0001 respectively.

**Summary/Conclusions:** The 11-item FACT/GOG-Ntx subscale reliably and validly assesses Bortezomib/IMiD induced PN. This complication is frequent and can alter the functional abilities of MM patients.

E1277

**ANALYSIS OF THE CONNECT MM REGISTRY: TREATMENT OUTCOMES AND HEALTHCARE RESOURCE UTILIZATION IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA WHO RECEIVED LENALIDOMIDE MAINTENANCE OR NO MAINTENANCE**

**Background:** RRs of the immunoglobulin heavy chain (IGH) on chromosome 14 are identified by FISH in about 15-20% of patients (pts) with newly diagnosed multiple myeloma (MM). Historically there is little evidence that such rearrangements have a clinically significant impact on prognosis of these rearrangements: typically, t(4;14), t(14;16) and t(14;20) have high risk (HR), and t(11;14) have standard risk (SR). A recent study (Kaufman et al. Leukemia. 2016 30:633-9) suggests that t(11;14) may confer a worse prognosis.

**Aims:** To determine the prognostic significance of t(11;14) in a single-institution MM cohort.

**Methods:** 87 pts with t(11;14) by CD 138 selected FISH at diagnosis were identified, pts without symptomatic MM were excluded. Cox regression was used for statistical analysis. Progression free survival (PFS), and overall survival (OS) from diagnosis and post autologous stem cell transplant (ASCT) were analyzed by Kaplan-Meier.

**Results:** Median age at diagnosis was 62 years, 45 pts (52%) were male, and 24 pts (27%) had ISS 3. All pts received either a proteasome inhibitor or an immunomodulatory agent, and 62 (48%) received triplet treatment as induction. Sixty-nine (79%) pts had ASCT, and overall response rate (ORR, partial response or better) post ASCT was 73%. For pts with HR FISH (defined as t(14;16), p53 del, 1q21 gain or 1p del) compared to SR FISH, the ORR post ASCT was 70% vs 77% (p=0.67). OS from diagnosis was 93% at 3 years, 74% at 4 years and 51% at 5 years. Seven patients (6%) developed plasma cell leukemia, and there was no association between HR and SR FISH (p=0.66).

**Conclusion:** Despite the use of novel therapies the OS at 5 years of our pts with MM was not significantly improved compared to SEER data from 1992-2013 (51% vs 48.5%). Pts with t(11;14) who had ASCT had increased survival compared to those who did not. Our results suggest that t(11;14) may confer a worse prognosis. Further prospective studies evaluating the risk of t(11;14) are warranted.
creatinine, calculated International Staging System stage, history of monoclonal gammopathy of unknown significance, presence of del(17p), and induction regimen were similar across groups. LEN-only maintenance significantly extended PFS compared to no maintenance (median 54.5 months vs 30.8 months; hazard ratio [HR]=0.98 [95% CI: 0.43, 0.79]; P<.0005; Table). OS was also significantly improved with LEN-only vs no maintenance (HR=0.45 [95% CI: 0.29, 0.73]; P=.001). HRU results are detailed in the Table. The rate of hospitalization/100 person-years (PY) was similar across groups (P=not significant [NS], all comparisons) at the end of years 1 and 2. The median duration of hospitalization was numerically longer for patients who received no maintenance. Procedures/surgeries and concomitant medication use were similar across both groups at the end of years 1 and 2.

Table 1.

Summary/Conclusions: For patients with NDMM, LEN-only maintenance significantly improved PFS and OS vs no maintenance with no apparent impact on HRU.

E1278

SERUM-FREE LIGHT-CHAINS (SFLC) INSTEAD OF URINE PROTEIN ELECTROPHORESIS (UPEP) FOR MONITORING LIGHT-CHAIN MULTIPLE MYELOMA (LCMM)

1Haematology, 2Clinical Biochemistry, Hospital 12 de Octubre, Madrid, 3Haematology, Hospital U de Salamanca, Salamanca, 4Haematology, Hospital Clinic i Provincial de Barcelona, Barcelona, 5Haematology, Hospital Germans Trias y Pujol de Badalona, Badalona, 6Haematology, Hospital Clínico de Valencia, Valencia, 7Haematology, Hospital Lozano Blesa, Zaragoza, 8Haematology, Hospital Morales Meseguer, Murcia, 9Haematology, Hospital U Son Llatzer, Palma de Mallorca, 10Haematology, Hospital Germans Trias y Pujol de Badalona, Badalona, 11Haematology, Hospital U Son Llatzer, Palma de Mallorca, 12Haematology, Hospital U San Carlos, Madrid, 13Haematology, Hospital U de la Santa Creu i Sant Pau, Barcelona, 14Haematology, Hospital U La Paz, Madrid, 15Haematology, Hospital U Son Espases, Tarragona, 16Haematology, Hospital U San Carlos, Madrid, 17Haematology, Hospital Universitario de Canarias, Santa Cruz de Tenerife, 18Haematology, Clínica Universitaria de Navarra, Pamplona, Spain.

Background: Response and follow-up criteria in multiple myeloma (MM) are still based on the protein electrophoretic (PEP) quantification of the monoclonal protein (MP) in serum (s) and/or urine (u). Monitoring MP by urine (u) PEP has a very low sensitivity for evaluating variations of small amounts of MP. Since 2001, serum free light-chain assays (sFLC) are available, with demonstrated clinical utility. Dejoi et al. have recently reported the usefulness of sFLC for evaluating response in LCMM patients.

Aims: In this work, we try to validate the use of sFLC assay in the context of GEM/PETHEMA clinical trials in order to evaluate the responses and its advantages in comparison to standard quantification of MP by PEP in serum (s) and —mainly— urine (u) after treatment, given the usual difficulties to collect and adequately perform urine studies in the usual clinical praxis.

Methods: We included 169 patients with Bence Jones (BJ) MM with measurable urine disease who have been treated according to GEM/PETHEMA clinical trials (GEM05menos65, GEM05MAS65, GEM2010MAS65 and GEM2012 menos65). Serum FLC assays (Freelite®, The Binding Site, Birmingham, UK) were performed on an automated nephelometer (BNII, Dade Behring / Siemens, Marburg, Germany). The electrophoretic study of the monoclonal component (CM) was performed by capillary electrophoresis (V8, Helena Biosciences Europe), and immunofixation was performed for the Ig, λ, k and λ chains (SAS-3 and SAS-4, Helena Biosciences Europe).

Results: From a total of 168 patients with measurable BJ disease (2013 Bence Jones kappa / 76 Bence Jones Lambda), 146 (86%) had FLC data at diagnosis, with 139/146 (95%) evaluable by FLCs [involved sFLC ≥100]. In addition, 68 of the 169 patients also had detectable MP in serum and 7 of the 169 had non-evaluable MP in urine (MP <0.200 g/24h). We studied the correlation of both techniques’ MP quantification results (uPEP vs sFLC) and we observed a low correlation (Pearson’s r=0.293, p=0.003), that should be partly explained by the low profitability and subjectivity of the electrophoresis technique for quantifying paraprotein in urine. [Figure 1A]. The concordance between the classification of the response by uPEP / immunofixation (IF) and by FLCs (Kappa Index=0.425 [95% CI: 0.001, 0.849]) was moderate. The normalization of the sFLC ratio (r) =<0.101 was achieved in 35/98 (36%) patients after treatment, associated to a lower risk of progression (normal vs abnormal sFLC): PFS 60 vs 39 months, p=0.038) but without impact in overall survival in our series. We also observed that an absolute value of sFLC greater than 50mg/L after treatment was associated with an increased risk of progression, regardless of the response achieved (PFS 60 vs 28 months, p<0.0001). [Figure 1B].

Figure 1.

Summary/Conclusions: There is an acceptable agreement between both methods for response evaluation. The SFLC assays provide a greater sensitivity than the urine protein electrophoresis for monitoring low levels of disease in certain cases with measurable disease at diagnosis (sFLC ≥100) being useful for its follow-up, and also provide prognostic value as a predictor of progression.

Background: In recent years many novel treatments have been introduced for Multiple Myeloma (MM), leading to an improved survival. However, this has also led to the situation where many different treatment combinations are used, without a clear indication which patient will benefit most from which treatment. It is increasingly recognized that genetic heterogeneity between tumors influence treatment response. Patient outcomes may be improved by selecting the right treatment for the right patient at the moment of diagnosis. This requires the discovery of predictive markers, for example gene expression signatures, that can aid in this treatment decision. Here we present TOPSPIN (Treatment Outcome Prediction using Similarity between Patients), a novel algorithm to discover such markers from tumor gene expression data. We use it to identify patients more likely to benefit from bortezomib.

Aims: This algorithm aims to develop a classifier that identifies a subset of patients that will benefit more from a treatment of interest than similar patients who receive a different treatment.

Methods: TOPSPIN aims to predict whether a patient will benefit (class 1) or not (class 0) from a certain treatment of interest based on the gene expression profile of the patient. This algorithm relies on the idea that genetically similar patients who received a different treatment should have a large difference in survival, given that genetic similarity is defined in a manner that is relevant to treatment response. This principle is used to identify prototype patients: patients who received the treatment of interest and have a larger than expected survival difference with the genetically most similar patients who received another treatment. Genetic similarity is defined separately for 10 581 gene sets based on Gene Ontology (GO) annotation. These prototype patients are used to define a classifier: new samples who exhibit a similar gene expression profile as these prototypes are also expected to benefit more from the treatment of interest. Here we use TOPSPIN to predict which patients will benefit from the proteasome inhibitor bortezomib. We combine tumor gene expression data from the Total Therapy 2, Total Therapy 3 and HOVON-65/GMMG–HD4 phase III clinical trials into one dataset comprising 910 patients, split into a training set (n=407) and a non-bortezomib arm (n=503). Progression free survival is used as outcome measure. This dataset was split in a training set (n=606) and a test set (n=304). The test set is not used at any point in the training procedure and is only used for independent validation.
Results: We successfully identify gene sets that enable us to predict which patients will benefit most from bortezomib. The top 8 performing GO sets based on Hazard Ratio (HR) were combined to achieve the final classification. In the training set 28.4% of patients are classified a class 1, resulting in an HR of 0.13 (p=7.1*10^-11) between the two treatment arms. More importantly, in an independent test set an HR of 0.47 (p=0.03) was found, as shown in Figure 1.

Figure 1. A Kaplan Meier of training set classification, showing a large survival benefit for patients receiving bortezomib in class 1 (red lines) but not in class 0 (blue lines).

Summary/Conclusions: TOPSPIN is successful in predicting bortezomb specific survival in independent data. TOPSPIN can be applied to any dataset with two treatment arms and a continuous outcome measure. In a disease like MM, where many different treatment are available, selecting the right treatment is critical and TOPSPIN can aid in this decision.

AMYLOIDOSIS RESEARCH CONSORTIUM CARDIAC AMYLOIDOSIS SURVEY: RESULTS FROM PATIENTS WITH AL AMYLOIDOSIS AND THEIR CAREGIVERS
I. Lousada1,*, M. Maurer2, S.D. Guthrie3, K. Hsu1, M. Grogan4
1Amyloidosis Research Consortium, Boston, 2Columbia University, New York, 3Prothena Biosciences Inc, South San Francisco, 4Mayo Clinic, Rochester, United States

Background: Cardiac amyloidosis is a severe disease that can lead to cardiac dysfunction and death. Amyloid light chain (AL) amyloidosis, hereditary transthyretin (hATTR) amyloidosis, and wild-type transthyretin (wtTTR) amyloidosis may result in cardiac amyloidosis. AL amyloidosis is caused by an accumulation of misfolded light chain and often involves organs other than the heart (eg, kidneys, nervous system). Initial symptoms are often nonspecific (eg, weight loss, fatigue). Consequently, a diagnosis is frequently made only after the disease has become advanced. Previous patient-directed research found that despite patients being initially referred most often to cardiologists (as opposed to hematologists and nephrologists), cardiologists diagnosed the condition much less frequently than other specialists.

Aims: To understand delays, errors, and inconsistencies in the diagnostic pathway for patients with AL cardiac amyloidosis and validate using caregiver responses.

Methods: An online survey consisting of 36 questions (for patients) and 37 questions (for caregivers) was developed by the Amyloidosis Research Consortium (ARC) and distributed to the patient mailing lists of ARC, the Amyloidosis Foundation, and Amyloidosis Support Groups in January 2017. The survey was designed for patients with all forms of cardiac amyloidosis and their caregivers; however, the present analysis is limited to AL amyloidosis.

Results: In this subanalysis, 137 patients and 115 caregivers completed the survey. Most patient respondents were >55 years of age (n=111; 81.0%) of those, 16.1% (n=22) were >70 years of age. Composition of the population was 81.8% white/Caucasian (n=112), 2.2% Asian (n=3), 4.4% African American (n=6), 2.2% Latino (n=3), 5.1% other (n=7), and 3.6% unknown (n=6). Most patients had lived with their diagnosis for >1 year (17.5% [n=24] <1 year; 23.4% [n=32] 1-2 years; 29.2% [n=40] 3-5 years; 21.2% [n=29] 6-10 years; 8.8% [n=11] >11 years). A significant percentage of patients had multigorgan involvement (54.7% [n=75] kidney; 29.9% [n=41] nerve; 14.6% [n=20] liver; 43.8% [n=60] heart; 43.8% [n=60]) of patients were incorrectly diagnosed with one or more other conditions, predominantly by cardiologists and general practitioners (Table 1). Furthermore, more than 75% of patients visited 3 or more different physicians before diagnosis. Nearly all misdiagnosed patients (83.3%; n=50/60) reported receiving more than 75% of patients visited 3 or more different physicians before diag-

Table 1. Patient and Caregiver Survey Responses, %

Summary/Conclusions: This represents the first survey compiling both care-
giver and patient experiences with AL amyloidosis. Alignment of caregiver with patient responses validates our patient-directed research. Patients with AL cardiac amyloidosis frequently receive misdiagnoses and sometimes receive incorrect treatment for the misdiagnosed condition. Disease awareness among all specialists is vital, especially among those to whom patients are initially referred due to the nature of their initial symptoms.

EFFICACY OF DARATUMUMAB-BASED REGIMENS IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA – A SYSTEMATIC LITERATURE REVIEW AND NETWORK META-ANALYSIS
M.A. Dimopoulos1,*, K. Weisel2, J. Kaufman3, P. Sonneveld2, M. Rizzo5, Y. Xu6, K. Fahrenbach6, M. Gaudig7, M. Slavcev8, L. Dearden8, A. Lam8
1National and Kapodistrian University of Athens, Athens, Greece, 2Universi-
taetsklinikum Tuebingen der Eberhard-Karls-Universitaet, Abteilung fuer Innere Medizin II, Tuebingen, Germany, 3Hematology and Medical Oncology, Winship Cancer Institute, Emory University, Atlanta, GA, United States, 4Department of Hematology, Erasmus MC, Rotterdam, Netherlands, 5Evidera, London, United Kingdom, 6Evidera, Waltham, MA, United States, 7Janssen-Cilag, Neuss, Germany, 8Janssen Global Services, LLC, Raritan, NJ, United States

Background: Daratumumab is a new monoclonal antibody aimed to improve outcomes in relapsed or refractory multiple myeloma (RRMM), and has been investigated in combination with lenalidomide plus dexamethasone (DRd), and with bortezomib plus dexamethasone (Dvd), in randomized controlled trials (RCTs), POLLUX and CASTOR, respectively. Although DRd and Dvd have been compared against current standard of care (SoC), namely Rd and Vd, it is important to assess how daratumumab plus SOC compares with other routinely used treatment regimens and investigational regimens expected regulating approvals.

Results: Daratumumab is a new monoclonal antibody aimed to improve outcomes in relapsed or refractory multiple myeloma (RRMM), and has been investigated in combination with lenalidomide plus dexamethasone (DRd), and with bortezomib plus dexamethasone (Dvd), in randomized controlled trials (RCTs), POLLUX and CASTOR, respectively. Although DRd and Dvd have been compared against current standard of care (SoC), namely Rd and Vd, it is important to assess how daratumumab plus SOC compares with other routinely used treatment regimens and investigational regimens expected regulating approvals.

Table 1. NMA Efficacy Results.

Aims: Therefore, the objective of this analysis is to compare DRd and Dvd with other relevant treatment options via network meta-analysis (NMA) techniques.

Methods: A systematic literature review (SLR) based on searches of Medline, Embase, and the Cochrane Library was conducted to identify and then assess RCTs of treatments for RRMM. The specific studies of interest were those that had investigated the efficacy of other treatment options considered to be comparators to DRd or Dvd. Data from trials that met the SLR’s inclusion criteria and the most recent data from POLLUX and CASTOR were extracted and then included in a Bayesian NMA to allow for the indirect comparison.

Results: Data from RCTs identified by the SLR allowed formulation of two evidence networks. Network 1 included DRd and other immunomodulatory agent (IMiD)-containing regimens, and Network 2, contained Dvd and other

haematologica | 2017; 102(s2) | 525
immunomodulatory agent (IMiD)–free regimens. Analysis using a fixed-effects model found that DRd compared with other IMiD-containing regimens in Network 1, and DVD compared with other IMiD-free regimens in Network 2 produced PFS and OS among patients RRMM (see Table 1).

Summary/Conclusions: In the absence of prospective head-to-head trials, NMA provides potentially important information on comparative effectiveness of different treatments. This MMA suggests that the combinations of DRd and DVD may be active in RRMM patients with RRMM with similar trends found for OS when compared with other established and new regimens.

E1282
TRENDS IN TREATMENT PATTERNS AND SEQUENCING IN PATIENTS WITH MULTIPLE MYELOMA DIAGNOSED 2011-2016 IN THE UNITED STATES USING AN ENHANCED ELECTRONIC HEALTH RECORDS DATABASE
B. Ung1, S. Abouzaidi1, C. Ni1, K. Parikh1, A. Agarwal1
1Celgene Corporation, Summit, NJ, United States

Background: Over the past few years, the multiple myeloma (MM) treatment landscape has changed considerably. Immunomodulating (IMiD) drugs and proteasome inhibitors (PI) have emerged as mainstays of MM Tx. However, the limitations and lag time of available administrative claims databases make it difficult to assess current real-world trends in the Tx of MM.

Aims: The study aimed to describe trends in demographics, Tx patterns, and sequencing for newly diagnosed MM (ndMM) patients (Pt) in the United States (US) using an enhanced Electronic Health Records (EHR) database.

Methods: A retrospective observational study of ndMM Pts was conducted utilizing EHR from a nationally-representative database (Flatiron Health). The Flatiron MM provider network comprises over 260 clinics throughout the US. Pts with an ICD-9 (203.0x) or ICD-10 (C90.xx) diagnosis of MM between 01/01/2011–12/31/2016 were randomly selected into the study. Pts were excluded if they did not have ≥2 documented clinical visits during the study period. Diagnosis of MM was confirmed through review of unstructured chart data. Index date was defined as the Pt’s date of diagnosis with MM. NdMM Pts were defined as those without a MM Tx more than 14 days prior to their first diagnosis date. Start of first-line (1L) therapy was defined as the 1st episode of an eligible systemic Tx given after or up to 14 days before the index date. Regimens were defined using the 1st eligible drug episode plus other eligible drugs given within 28 days of each other. A maximum gap of 90 days was allowed within a given line of therapy (LOT) and was considered concluded the day after the start date of the next LOT.

Results: For the 3367 ndMM Pts identified, mean(SD) age was 68.5(11) years at the time of diagnosis, 45.9% were female, 57.6% were white, 14.7% African American, and 11.1% other race. The most common immunoglobulin (Ig) classes at diagnosis were IgG (51.8%) and IgA (18.9%). Median follow-up time for these groups was 471, 730, 928, 1132, and 610 days respectively. Among treated Pts, 205 (12.7%), 208 (28.2%), 109 (33.5%), and 98 (38.1%) received at least 1 stem cell transplant (SCT), respectively. Of Pts receiving 1L therapy, 984 (33.6%) received IMiD compound + PI, 717 (21.5%) received PI monotherapy, and 556 (19%) received IMiD compound-based therapy in 1L. The use of IMiD compound + PI in 1L increased during the study period for SCT and non-SCT Pts (NSCT) from 40.6% and 21.5% in 2011, to 66.7% and 46.8% in Pts diagnosed in 2016. In Pts who received a SCT (n=618), the most common 1L regimens were lenalidomide + bortezomib + dexamethasone (RVd; n=217, 43.9%), cyclophosphamide + bortezomib + d (CyBod; n=124, 20.1%), lenalidomide + d (Rd; n=70, 11.3%), and bortezomib + d (Vd; n=57, 9.2%). In NSCT Pts (n=2307), the most common 1L regimens were RVd (n=642, 27.8%), Vd (n=510, 22.1%), and Rd (n=412, 17.9%). Among the RVd NSCT Pts with a documented 2L (n=189), the most common 2L regimens were CyBod (13.2%), carfilzomib monotherapy (7.4%), pomalidomide + d (6.9%), and Vd + d (6.9%). Documented death occurred in 785 (23.3%) Pts during the study period.

Summary/Conclusions: Over time, RVd has become the most common 1L regimen for SCT and NSCT Pts with ndMM. After a median follow up of 15.9 months, many patients remain in the initial LOT. With a longer follow up, we will be able to observe sequencing and patterns of treatment in later LOTs.

E1283
HLC PAIR SUPPRESSION AS A RISK FACTOR FOR BLOODSTREAM INFECTIONS AND EARLY DEATH IN NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS
J.L. García De Veas Silva1, M.D.S. López Vélez1, C. Bermudo Guitarte2, N. Barahona de Carvalho3, R. Rios Tamayo4, M. Jurado Chacón4, T. De Haro N. Barbosa de Carvalho3, R. Rios Tamayo4, M. Jurado Chacón4, T. De Haro
1Department of Laboratory Medicine, Complejo Hospitalario Universitario de Granada, Granada, 2Department of Clinical Biochemistry, Hospital Universitario Virgen Macarena, Sevilla, 3The Binding Site, Barcelona, 4Department of Hematology, Complejo Hospitalario Universitario de Granada, Granada, Spain

Background: Infection is a major cause of morbidity and mortality in patients with Multiple Myeloma (MM), responsible for 10-25% of deaths within 6 months of diagnosis. It is associated with suppression in primary antibody response (systemic immunoparesis (SI)), which may be aggravated following anti-myeloma therapy. Recently, the suppression of the non-monoclonal immunoglobulin pair (e.g. IgG-Lambda in IgG-Kappa MM), termed heavy+light chain (HLC) pair suppression, has been associated with poor prognosis in MM. However, the impact of HLC pair suppression as a risk factor for bloodstream infections has not been studied.

Aims: To evaluate HLC pair suppression as a risk factor for bloodstream infections and early death in MM patients.

Methods: The study retrospectively included 114 consecutive MM patients with diverse bloodstream infections, identified during investigation into unexplained fever and hospitalization in newly diagnosed MM patients. HLC pair suppression was defined as a positive blood culture related to a febrile episode. The population consisted of 66 male:48 female patients, with a median age of 68 (56-77) years. The monoclonal immunoglobulin isotype was: 49 IgG-K, 26 IgG-L, 21 IgG-A and 18 IgA-L. In order to explore the impact of HLC pair suppression on bloodstream infections and early mortality, only events within 6 months (180 days) from diagnosis were documented. HLC pair suppression was defined as suppression in the levels of the non-monoclonal pair by >50% below the lower limit of the reference range. HLC measurements were carried out using HCVYlite® immunomassays (The Binding Site) on a SPAPLUS analyzer. SI was defined as levels of the alternate immunoglobulin (e.g. IgA and/or IgM in an IgG patient) more than 50% below the lower reference range. Association between variables were analysed by Chi-square test and survival was estimated using Kaplan-Meier method.

Results: At diagnosis, HLC pair suppression was observed in 72 (63%) patients, and SI in 52 (45%). The incidence of bloodstream infections during the study period was 23%; and 20 patients (18%) died within 6 months from diagnosis. We found a significant association between HLC pair suppression and both the occurrence of bloodstream infections (OR: 6.10, 95% CI: 1.71-21.83; p=0.002) and early deaths (OR: 4.02, 95% CI: 1.10-14.66; p=0.03); by contrast SI had no significant association with either event (p=0.07 and p=0.3, respectively). Survival analyses demonstrated an association between bloodstream infections and shorter OS (50% vs 92%, HR: 7.43, 95% CI: 2.96-18.61, p<0.0001, Figure A). The risk of bloodstream infections was significantly higher among patients with HLC pair suppression vs those without suppression (34% vs 7%, respectively; HR: 5.12, 95% CI: 1.54-17.07, p=0.003, Figure B). In line with this, patients with HLC pair suppression had shorter overall survival (OS) compared to those without (76% vs 93%, HR: 3.47, 95% CI: 1.02-11.83, p=0.03). By contrast we found no association between SI and risk of infection (p=0.08) or survival (p=0.4).

Figure 1. Summary/Conclusions: HLC pair suppression provides information on immune status and associates with an increased risk of bloodstream infections and early deaths in newly diagnosed MM patients. Our findings highlight the importance of recognizing this status at time of diagnosis, and suggest that HLC pair suppression may help guide clinical decisions about the need for adequate antimicrobial treatment during myeloma therapy.

E1284
DARATUMUMAB SIGNIFICANTLY IMPROVED PROGRESSION-FREE SURVIVAL IN COMBINATION WITH LENALIDOMIDE AND DEXAMETHASONE IN PATIENTS WITH RELapsed MULTIPLE MYELOMA
D. Katalinic1
1Department of Internal Medicine, Faculty of Medicine, J.J. Strossmayer University of Osijek, Osijek, Croatia

Background: Daratumumab is a human IgG1k monoclonal antibody which binds with high affinity to the CD38 molecule on the surface of multiple myeloma cells, and induces rapid tumor cell death through multiple immune-mediated mechanisms and showed encouraging results alone and with lenalidomide and dexamethasone in a phase 1-2 study involving patients with relapsed multiple myeloma.

Aims: The primary end point of the study was progression-free survival (PFS). We enrolled a total of 134 patients (74 men and 60 women, mean age 65.4±18.2 years) with multiple myeloma who had received at least three lines of therapy to receive lenalidomide with dexamethasone (68 patients, control group A) or in combination with daratumumab (66 patients, therapy group B).

Results: At a median follow-up of 9.8 months in a protocol-specified interim analysis, 67 patients had disease progression or death were observed (in 18 of 66 patients (27.2%) in the group B vs 28 of 68 (41.1%) in the control group (p<0.001)). A significantly higher rate of overall response was observed in the group B than in the group A (68.7% vs 62.9%, p<0.001), as was a higher rate of complete response or better (39.2% vs 16.1%, p<0.001). The most common adverse events during the treatment was myelotoxicity (neutropenia in 68.6% of the patients in the therapy group B vs 42.1% of those in the control group A), anemia (in 21.5% vs 13.6%) and thrombocytopenia (in 13.8% vs 8.7%).

Summary/Conclusions: In patients with relapsed multiple myeloma, the addition of daratumumab to lenalidomide and dexamethasone appeared active and resulted in significantly improved progression-free survival. However it was associated with a higher risk of myelotoxicity.

E1285
COMPARISON BETWEEN IMMUNOFIXATION NEGATIVITY AND NORMAL FREE LIGHT CHAIN RATIO WITH MULTICOLOUR FLOW CYTOMETRY FOR RESPONSE ASSESSMENT IN PATIENTS WITH MULTIPLE MYELOMA WITH VGPR OR BETTER
K. Narita1,*, H. Takamatsu2, Y. Abe1, Y. Usui1, M. Takeuchi1, K. Matsue1
1Department of Medicine, Hematology/Oncology Kameda Medical Center, Kamagawa, 2Department of Hematology and Respiriology, School of medicine, Institute for Frontier Medical and Pharmaceutical Health Sciences, Kanazawa University, Kanazawa, Japan

Background: Urine and serum Immunofixation electrophoresis (ufIE and sIFE), respectively and free light chain assay (FLC) are widely accepted as standard tests for diagnosis and monitoring of multiple myeloma (MM). However, there is significant discordance between the electrophoretic method and FLC test for response assessment. Despite this discordance, previous studies did not address the differences in assessment of treatment response between the intact immunoglobulin MM (IIMM) and light chain only MM (LCMM)/oligosecreting MM (OSMM). uIFE results are poorly correlated with the serum FLC level, however, treatment response of LCMM has still been recommend to assess by 24-hour uIFE by International Myeloma Working Group guideline. However, MRD levels on uIFE negativity or normal FLC ratio (rFLC) in patients with various types of MM have not been studied.

Aims: To explore the relationship between uIFE, sIFE negativity and normal rFLC for MRD assessment in patients with IIMM and LCMM.

Methods: We initially selected 162 patients with MM (LCMM and OSMM, n = 41; IIMM, n=21) that received treatment at Kameda Medical Center, Kamagawa-shi, Japan and Kanazawa University Hospital, Kanazawa-shi, Japan between April 2008 and January 2016. Among them, 126 patients (LCMM/OSMM 40, IIMM 86), who achieve VGPR or better response, were selected on the basis of the availability of simultaneous serum and urine test, FLC data, and bone marrow MRD. To explore the relationship between uIFE and sIFE negativity and normal rFLC, MRD levels were compared by multicolour flow-cytometry (MFC) in patients with LCMM/OSMM, and IIMM that obtained VGPR or better. MRD negativity was defined as MRD <10–4. Complete response (CR) was divided into conventional CR (cCR, CR but MRD-positive) and MRD CR (CR and MRD-negative).

Results: One hundred forty-four complete IFE, FLC, and MFC data set of 126 patients (LCMM/OSMM 40, IIMM 86) with >200 were analysed. Normal FLC at VGPR, cCR and MRD-CR was 65.0%, 78.4% and 76.8% in IIMM, and 0%, 21.4% and 100%, respectively, in LCMM/OSMM. The percentages of sample at MRD levels of MRD >10–3, 10–3 >MRD >10–4 and 10–4>MRD in IIMM/OSMM was significantly high in 12.5%, 50.0%, and 100% for negative uIFE, and 0%, 11.5% and 100% for normal rFLC, respectively. These figures in IIMM were 23.0%, 41.6%, 81.4% for negative sIFE, and 53.8%, 75.0% and 88.8% for normal rFLC, respectively. Positive/negative predictive value (PPV/NPV) of uIFE and rFLC for MRD in LCMM/OSMM was 100%/94.8% and 100%/95.0%, respectively, while those were 90.6%/45.8% and 88%/32.4% in IIMM, respectively.

Summary/Conclusions: Our observations confirmed that FLC test has greater sensitivity than uIFE for detection of the monoclonal component, and that normalization of sFLC ratio is highly predictive of MRD negativity in patients with LCMM/OSMM. The proportion of negative sIFE samples increased with depth of MRD, but the FLC response did not appear to parallel with the depth of response in IIMM. We recommend that FLC test should be incorporated into routine assessment in LCMM/OSMM as an alternative to 24-h uIFE, and both negative sIFE and normal rFLC are still useful for response assessment of residual clonal PCs in IIMM.

E1286
DARATUMUMAB IS AN EFFECTIVE AND SAFE SAVAGE THERAPY IN RELAPSED/REFRACTORY PATIENTS WITH MULTIPLE MYELOMA AFTER AUTOALLLOGENEIC STEM CELL TRANSPLANTATION
E. Klyuchnikova1,2, U.-M. von Pein1, F. Ayuk1, M. Christopeit1, R. Adjali1, A. van Randenbourgh1, C. Wolschke1, N. Kroeger1
1Department for Stem Cell Transplantation, University Cancer Center Hamburg-Eppendorf, Hamburg, Germany

Background: Daratumumab is a human monoclonal antibody that targets CD38, a cell surface protein that is overexpressed on multiple myeloma cells. The drug became the first monoclonal antibody as single agent therapy approved by the FDA for the treatment of multiple myeloma. The role of allo-SCT in myeloma patients (pts) remains unclear, nevertheless, the registry study of EBMT suggests an increasing rate of allografts in Europe in last years. Despite the potentially curative potential of this approach, the increased relapse rate and low PFS remain a central clinical problem.

Aims: In this single center retrospective analysis, we report on our experience with the use of daratumumab in post-transplant setting.

Methods: A total of 16 pts (male, n=9) with median age of 66 years (39-72) relapsing after allo-SCTs that had been performed during a period 2008-2015 at the University of Hamburg and received daratumumab as single agent salvage therapy. Before allografting 9 pts received one and 7 pts 2 autografts, respectively. All but one pt received at least 1 salvage therapy line prior to the allo-SCT. The allografts were performed from unrelated donors (MUD, n=9; MMUD, n=4) or matched related donors (MRD, n=3). The median of salvage lines post-transplant and prior to first daratumumab infusion was 3 (1-4). The salvage regimens included bortezomib, lenalidomide, pomalidomide and daratumumab. Daratumumab infusions were started at a median of 21 months (0-30) after relapse/progress.

Results: The median number of infusions was 13 (3-22). A total of 16 and 15 pts were available to safety and efficacy evaluation, respectively. The safety was assessed according to the Common Toxicity Criteria (CTC). A total of 20 adverse events were observed in 16 pts: dyspnea (CTC1, n=3; CTC2, n=1), bronchospasm (CTC2, n=2) shivering (CTC1, n=3), cough (CTC1, n=1; CTC2, n=1), musculoskeletal pain (CTC1, n=4), acute coronary syndrome (CTC3, n=1), skin rush (CTC2, n=1), pressure on eyes (n=1). Two patients developed late onset infections (pneumonia and infection of urinal tract) followed by temporarily therapy interruption. We observed a decrease of Tregs (CD4+CD25highCD127low, n=15) number from a median of 5.05% at start to 0.65% at day 21 after first daratumumab infusion in four pts. There were no cases of GvHD. The adverse events appeared in all pts after the first infusion, with improved tolerance of following infusions. There were no cases, where the therapy had to be stopped due to adverse events. Within a median follow-up of 32 months (1-45) from the relapse/progression 12 of 16 pts remain alive. Two pts died due to progress of myeloma and another 2 pts died due to severe infection/sepsis. A total of 9 of 15 evaluable pts responded (60%, PR, n=7, vgPR, n=2). The responses (decrease of paraprotein and/or free light chains; reduction of extramedullary tumor in 2 pt) occurred at a median of 7 days (7-75) after the first administration of daratumumab. The median response duration is 4.5 mo (1.5-8). Six pts show ongoing responses. All responding and 2 non-responding pts (stable disease) showed clinical improvement of constitutional symptoms.

Summary/Conclusions: Daratumumab demonstrated encouraging efficacy in relapsed/refractory pts with myeloma after allo-SCT. The administrations of the drug in these heavily pre-treated pts were associated with good safety profile and development mostly non-severe adverse events mostly after the first infusion. Further studies on the use of daratumumab in post-transplant setting are warranted.

PROGNOSTIC RELEVANCE OF VEGF AND VEGFR EXPRESSION IN CD138+CD19- AND CD138+CD19+ PLASMA CELLS FROM PATIENTS WITH MONOCLONAL GAMMOPATHIES
C. Geraldes1,2,*, A.C. Gonçalves2,3, R. Alves2,3, E. Cortesão1,2,3, L. Ribeiro1, J.M. Nascimento Costa2,4, A.B. Sarmento-Ribeiro2,4, J. Coimbra, Coimbra, Portugal
1Clinical Hematology Department, Centro Hospital e Universitário de Coimbra (CHUC), 2Applied Molecular Biology and University Clinic of Hematology, 3CIMAGO, 4 University Clinic of Oncology, Faculty of Medicine University of Coimbra, Coimbra, Portugal

Figure 1.
Results: 482 pts were eligible, 343 (71%) were W, 52 (10%) H, 50 (10%) B, 19 (4%) A, and 18 (3%) O. Median age was 65 years, 54% were male, and 28% ISS stage 3. There were no statistically significant differences in FISH aberrations between the M. Overall W had more aberrations in IGHR (4,14,14, t(11;14), t(14;20)), 1q21 gain compared to M. Most notably W had more IGHR (39% vs 28%, p=0.019) and t(11;14) (20% vs 12%; p=0.024). There were not statistically significant differences between W and M in the high risk FISH abnormalities.

$p$-value compares W vs. M. * means statistical significant ($p$-value<0.05)

Summary/Conclusions: W had significant differences in FISH compared to M. W had more IGHR and t(11;14) than M, and there was no difference in high risk FISH aberrations between W and M. This study confirms the biological racial disparities that exist in minorities with MM. Further studies with more inclusion of minorities are needed to elucidate these disparities and its effects on risk stratification and outcomes.

**POMALIDOMIDE ALONE OR IN COMBINATION WITH LOW DOSE DEXAMETHASONE AS MAINTENANCE INDUCTION WITH POMALIDOMIDE AND LOW DEXAMETHASONE IN RELAPSING AND REFRACTORY MYELOMA (ALLG MM14)**

A. Kallff1,2, N. Kenney3, J. Reynolds1, H. Quach4, P. JH5, N. Horvath6, P. Moller7, J. D. Rozanov8, K. Taylor9, J. Eisel10, A. Spencer11, 1Monash University, 2Alfred Hospital, Melbourne, Australia, 3Haematology Department, Alfred Hospital, 4St Vincents Hospital, Melbourne, 5Royal Prince Alfred Hospital, Sydney, 6Royal Adelaide Hospital, Adelaide, 7Princess Alexandra Hospital, Brisbane, 8The Canberra Hospital, Canberra, 9Haematology & Oncology, Alfred Health, 10Monash Medical Centre, Victoria, 11Concord Repatriation General Hospital, Sydney, Australia

**Background:** Whilst the addition of dexamethasone to upfront therapy with Immunomodulatory (IMiD®) agents is important to mediate rapid reduction in disease burden, preliminary findings suggest that the NK stimulatory effects of IMiD® compounds are best harnessed without the co-administration of dexamethasone, and may be especially effective in the setting of minimal disease burden (in the maintenance setting for example) when some inherent immune recovery has occurred. However this has yet to be confirmed in a prospective clinical trial.

**Aims:** To evaluate the effect of maintenance with POM alone (Arm 1) versus POM-LoDEX (Arm 2) on progression free survival (PFS), overall survival (OS), and kinetics of response (overall response rate (ORR)) in relapsed myeloma (MM) patients refractory to lenalidomide (R-LEN) demonstrating stable disease (SD) or better after first line therapy (bortezomb-based regimens for fit patients or alkylating-based treatments for unfit patients). Interestingly, we also observed an increased percentage of CD138+/CD19- PCs (21%) expressing VEGF in MM patients with a more favorable PFS (p=0.04) and OS (p=0.008).

**Summary/Conclusions:** The results of our investigation should be further investigated in larger series of patients.

E1288

**RACIAL DIFFERENCES OF FISH ABNORMALITIES IN MINORITIES WITH MULTIPLE MYELOMA: A SINGLE-CENTER EXPERIENCE**

M. McKenna4, J. Richter5, D. Vesole5, D. Siegel5, N. Biran5, 1Internal Medicine, Rutgers NJMS, Newark, United States, 2CES University, Medellin, Colombia, 3Mayo Clinic, Rochester, 4Saint George University, 5John Theuer Cancer Center, Hackensack University Medical Center, Hackensack, United States

**Background:** Racial disparities of FISH abnormalities in multiple myeloma (MM) have been well described in whites (W) but partially described in minorities (M) (Paulus et al, ASH 2016, 4432).

**Aims:** To explore the differential differences of FISH abnormalities using the largest cohort of minorities to date.

**Methods:** CD-138 selected FISH was done on 799 consecutive patients (pts). Pts without symptomatic MM, and biopsy >6 months after diagnosis were excluded. The abnormalities evaluated included standard and intermediate risk aberrations: t(4;14), t(14;14), t(11;14), t(4;14), t(14;20), del(13q), del(17p), 1q21. Chi-square was used for statistical analysis. Due to smaller numbers, all M (Hispanic (H), Black (B), Asian (A) and Other (O)) were included into the same group for statistical analysis.
Figure 1.
Summary/Conclusions: In patients with relapsed myeloma, after initial disease control/delubukation is achieved with Pom-LoDEX induction, maintenance with single-agent POM may be more effective for sustaining disease control than continuation of POM-LoDEX. Correlative studies are currently underway to further investigate the immunological mechanisms behind this observation.

E1290
POMALIDOMID IS MORE EFFECTIVE IN REAL CLINICAL PRACTICE THAN IN RANDOMIZED TRIAL – AN OBSERVATIONAL STUDY OF THE CZECH MYELOMA GROUP
L. Pour1, L. Brozova1, I. Spicka3, V. maisna3, J. Minarik2, A. Jungova2, E. Gregora7, S. Sevcikova8, P. Pavlicek7, T. Jelinek9, J. Radocha4, M. Stork10, R. Hajek8
1Department Hematology and Oncology, University Hospital Brno, Brno, 2Institute of Biostatistics and Analyses, Faculty of Medicine, Masaryk University, Brno, 3First internal clinic, 1. medicine faculty Charles university prague, Prague, 4University Hospital, Heradec Kralove, Heradec Kralova, 5University hospital Olomouc, Olomouc, 6University hospital Plzen, Plzen, 7University Hospital Kralovec Vinohrady, Praha, Praha, 8Masaryk university Brno, Brno, 9University Hospital Ostrava and the Faculty of Medicine, Ostrava, 10University hospital Brno, Brno, Czech Republic

Background: The combination of pomalidomide and low-dose dexamethasone (Pom-Dex) is a perspective option for patients with end-stage relapsed/refractory multiple myeloma (RRMM). We analyzed efficacy and toxicity of Pom-Dex in all patients from the Czech Republic treated from June 2013 to December 2016.

Methods: Patients were eligible if they had been diagnosed with RRMM and had failed at least two previous treatments with bortezomib and lenalidomide. They were treated with start dose of Pom (4mg/day on days 1-21, orally) plus low-dose dexamethasone (40mg/day on days 1, 8, 15, and 22, orally) until disease progression or unacceptable toxicity. We analyzed TTP and OS together with toxicity. Also, univariate Cox proportional hazards model for OS was done for standard risk factors. One hundred and twenty-two patients with median age of 67 treated with Pom-Dex were evaluated. Median follow-up was 8.7 months. Median of previous treatment lines was 4.

Results: Median TTP of Pom-Dex treatment was 7.1 months (95% CI 5.3-8.6). Median OS was 19.0 months (95% CI 13.2-25.8). The most common grade 3-4 adverse events were neutropenia in 44%, anemia in 22% and thrombocytopenia in 24% of patients. Grade 4 infections were observed in 10% of patients. Patients with ECOG worse than 2, B2microglobulin higher than 5, ISS stage 3, low hemoglobin, low platelet count and presenting extramedullary mass had worse OS according to univariate Cox proportional hazards model.

Summary/Conclusions: Our analyses show that Pom-Dex treatment of Czech RRMM patients is effective, well tolerated and had better results than the registration study. Performance status and tumor burden seem to be main prognostic factors according to our model. Thus, our suggestion for clinical practice is to start pomalidomide treatment as soon as possible in case of MM relapse.

E1291
UNDERSTANDING THE REAL-WORLD CLINICAL CHARACTERISTICS OF MULTIPLE MYELOMA PATIENTS IN EUROPE
T. Bacon1,2, M. Gaudig3, T. Ito3, A. Hadfield4, A. Rider4
1Janssen Health Economics & Market Access EMEA, Dublin, Ireland, 2Janssen-Cilag, Neuss, Germany, 3Janssen Health Economics & Market Access EMEA, High Wycombe, 4Adelphi Real World, Bollington, United Kingdom

Background: Multiple myeloma is a heterogeneous disease that accounts for approximately 10% of all haematological malignancies. While European treatment guidelines exist for multiple myeloma, there is limited understanding about the characteristics of patients with multiple myeloma in Europe and how these characteristics vary by disease stage. Numerous patient and disease-related factors can have an impact on treatment choice. Data surrounding these factors would help to better characterise European patients and inform management and treatment practices in multiple myeloma.

Aims: The aim of the current study is to describe multiple myeloma patients from 5 European countries (France, Germany, Italy, Spain, and the UK) across the disease continuum.

Methods: Data were drawn from the Adelphi Real World Multiple Myeloma Disease-specific Programme (DSP), which was conducted across France, Germany, Italy, Spain and Myeloma UK in Q1 2015. The Multiple Myeloma DSP is a real-world, cross-sectional survey that involves haematologists and haematology-oncologists who completed patient record forms for the next 8 multiple myeloma patients with whom they consulted. Study variables included patient demographics and background clinical information.

Results: A total of 262 physicians reported on 2,024 patients with multiple myeloma. Of these patients, 73.2% were receiving first-line treatment; the remaining 26.8% were receiving second-line treatment or later. The median age of multiple myeloma patients was 70 years, 58.4% were male, and most patients (88.5%) were white/Caucasian. Only 4.3% of patients had a family history of cancer. Patients had a mean height of 168.8 cm, a mean weight of 72.8 kg, and a mean body mass index of 25.5 kg/m². In terms of performance status, 79.8% of patients had an Eastern Cooperative Oncology Group (ECOG) status of 0 or 1, whereas 20.2% had an ECOG status of ≥2. While 12.9% of patients had smouldering myeloma, 47.5% of patients had advanced stage (stage III) disease. The most common symptoms experienced by patients were anaemia (31.0%), bone pain (32.4%), fatigue/weakness (28.4%), and kidney impairment or failure (12.6%). Furthermore, 34.6% of patients had bone complications at some point in time. Overall, 51.1% had diabetes.

Summary/Conclusions: Results from this analysis provide valuable insight into multiple myeloma patients in European countries. These findings can help to inform future treatment practices in Europe.
stable disease and one progressed during the 4th cycle of treatment. After ASCT the ORR was 84.4% (6 (13.3%) patients achieved CR, 13 (28.9%) VGPR and 19 (42.2%) PR. Adverse events of grade 3 or 4 included mainly anemia (4 patients, 9%), neutropenia (3, 6.6%) and febrile neutropenia (one patient). After a median follow-up of 19.1 months (range: 11.0-24.9), 11 patients have progressed and 4 died (all had achieved less than VGPR post-ASCT). The PFS, TTP and OS rates at 12 months were 88.6%, 88.8% and 100%, respectively. Forty (89%) patients had adequate stem cell collection post-RAD induction (medianSD = 8.94±6.50 x10^8/kg CD34+ cells). Patients at baseline had elevated levels of CTX, TRACP-5b, sRANKL/OPG, Dkk-1, Ang, VEGF, VEGF-A, bFGF and reduced levels of Ang-1/Anng-2, bALP and P1NP compared to 30 healthy subjects of similar age and gender (p<0.01 for all comparisons). RAD therapy resulted in a reduction of circulating CTX (p=0.03), TRACP-5b (p=0.01), Ang (p=0.02), VEGF (p=0.01) and bFGF (p<0.01). Moreover, RAD increased serum levels of bALP (p=0.036), P1NP (p=0.028) and Ang-1/Ang-2 ratio (p=0.022). These alterations occurred irrespective of response, although patients who achieved at least VGPR tended to have more profound differences in the above parameters.

**Summary/Conclusions:** RAD resulted in successful induction for NDMM patients with an ORR of approximately 67% pre- and 84% post-ASCT. With a median follow-up of >1.5 year, the 12-month PFS rate and OS rates are high, patients with an ORR of approximately 67% pre- and 84% post-ASCT. With a median follow-up of >1.5 year, the 12-month PFS rate and OS rates are high, in this study was mainly evident in older pts with a strong reduction of early mortality and median OS reaching, in the second time frame after year 2007, 7.5 yrs. For younger pts ASCT confirmed to be of great benefit in term of TTNT and OS rates at 12 months were 88.6%, 88.6% and 100%, respectively. Patients receiving a new drug in 1st line was 64% (338/525). This percentage was significantly different in pts treated before and after 2007 (42% vs 87%, p=0.001). Similar results were observed in 2nd line, 75% of pts treated before 2007 received a new drug and 90% after 2007 (p=0.002). Median PFS in pts ≥65 yrs was 1.7 vs 2.4 yrs (p<0.001); median PFS in pts ≥65 yrs receiving or not ASCT was 3.2 vs 1.9 yrs (p=0.001); of note, PFS was not different when comparing pts undergoing to ASCT after a CT-based or a Bor-based induction (3 vs 2.5 yrs, p=0.2). Time to next treatment (TTNT) in pts receiving ASCT or not was 30.1 months (5-122.7) vs 10.3 months (0.7-20.5) (p<0.001) from 1st to 2nd line tx and 11.2 months (0.3-121.9) vs 6.3 months (1.4-11.6) from 2nd to 3rd line tx (p=0.026). The early mortality (within the first year) was 5.9% (3/152), in details only 1/258 of those eligible to ASCT (0.4%) and 3/267 of those not candidate to transplant (11.2%). When considering this last group before and after the 2007, we observed a significant higher incidence of early mortality in the first period (21 (17.2%) vs 9 (6.2%), p=0.006). About new drugs toxicity: with Bor-based tx 30% of pts complaint neurological, 20% gastrointestinal and 18.2% hematologic toxicity; with Len-based tx 36.4% infective events and 29.8% hematologic toxicity. Median OS in pts ≥65 yrs was 7 vs 4.8 yrs (p=0.001), of note considering pts ≥65 yrs treated before 2007 median OS was 5.5 vs 3.1 yrs (p<0.001) and after 2007 median OS was not reached vs 7.5 yrs (p=0.034).

**Summary/Conclusions:** Our real life data show how MM therapeutic scenario have changed during the last 15 yrs. The tremendous improvement in median OS noted in this study was mainly evident in older pts with a strong reduction of early mortality and median OS reaching, in the second time frame after year 2007, 7.5 yrs. For younger pts ASCT confirmed to be of great benefit in term of TTNT and PFS. Thus, considering the real advantage of new drugs a palliative approach is not anymore justified even in very old pts.

**Table 1.**

**E1293**

**MULTIPLE MYELOMA IN THE REAL WORLD: HOW THERAPEUTIC LANDSCAPE HAS CHANGED IN THE LAST 15 YEARS**

F. Cocito1,*, V.V. Ferretti1, S. Mangiacavalli1, C.S. Cartia1, M. Ganzetti1, E. Fugazza1, B. Landini1, M. Catalano1, M. Cazzola1, A. Corso1

1Hematology, Policlinico S. Matteo, Pavia, Italy

**Background:** Therapeutic Multiple Myeloma (MM) scenario has completely changed in the last 30 years: conventional chemotherapy (CT) has been gradually abandoned and autologous stem cell transplantation (ASCT), proteasome inhibitors as Bortezomib (Bor) and immunomodulatory drugs as Thalidomide and Lenalidomide (Len) have become the new actors in MM treatment (Tx).

**Aims:** to outline how the management of MM patients (pts) had changed in the last 15 years reporting the experience of a single center.

**Methods:** Overall survival (OS) was measured from disease onset to death for any cause or last follow-up. Progression free survival (PFS) was defined as the time from first-line tx to disease progression or last-follow-up. The effect of variables on OS and PFS was evaluated by log-rank test.

**Table 1.**

**E1294**

**CUL4A EXPRESSION AS A POTENTIAL PROGNOSTIC MARKER IN MULTIPLE MYELOMA PATIENTS TREATED WITH IMMUNOMODULATORY DRUGS**

A. Malanda1,*, J. Barankiewicz1,2, A. Szumera-Cieckiewicz2, M. Prochorec-Sobieszek3, K. Warzocha1, P. Juszczynski4, E. Lech-Maranda1,2

1Department of Hematology, Institute of Hematology and Transfusion Medicine, 2Department of Hematology and Transfusion Medicine, Centre of Post-graduate Medical Education, 3Department of Diagnostic Hematology, 4Department of Experimental Hematology, Institute of Hematology and Transfusion Medicine, Warsaw, Poland

**Background:** Despite the clinical effectiveness of immunomodulatory drugs (IMiDs) in multiple myeloma (MM), neither their mechanisms of action nor the biomarkers that could identify patients who would benefit from IMiDs treatment are yet known. While the identification of the IMiDs action via cerebrol (CRBN), Ikarios (IKZF1) and Aiolos (IKZF3) was a milestone, the role of other pathways including CRBN and E3 ubiquitin ligase complex proteins (CUL4A, DDB1, Roc1) are not fully understood so far.

**Aims:** The aim of this study was to: 1) evaluate CUL4A, IKZF1, IKZF3, MUM1 and IRF4 expression in bone marrow trephine biopsies obtained from multiple myeloma patients before treatment with thalidomide, 2) analyze the associations between the expression of these proteins and clinical characteristics and outcomes.

**Methods:** IHC staining for CUL4A, IKZF1, IKZF3, IRF4 and MYC expressions was performed in trephine biopsies obtained from 25 patients with multiple myeloma before the treatment initiation. The patients (20 females, 5 males, median age 68 years) were treated with thalidomide based regimens as a first-line treatment. The patterns of proteins’ expression were scored independently by two hematopathologists on a 0-3 scale ranging from 0 (no expression) to 3 as 30% positive cells. Associations between studied proteins’ expression and clinical parameters were assessed using Fisher’s Exact Test for categoric variables and Mann-Whitney-Wilcoxon Test U for continuous variables. Survival (PFS and OS) were estimated using the Kaplan-Meier method and censored using the log-rank test.

**Results:** Prior to treatment with thalidomide, 13 patients (52%) showed high expression (≥ 30%) of CUL4A protein. No associations between expression of CUL4A and other proteins were seen. Patients with high CUL4A expression more often presented low disease stage according to Durie-Salmon classification (p=0.02), beta-2-microglobulin level within normal ranges (p=0.07) and higher median platelet count (p=0.003) compared to patients with low CUL4A expression. Moreover, patients with high CUL4A expression before treatment showed longer PFS compared to those with low CUL4A expression (p=0.03).

Additionally, a significant association between high Aiolos expression and high- risk cytogenetic abnormalities (p=0.02) was observed. Furthermore, a trend (p=0.06) was found between low Aiolos expression, however no other associations with clinical course of MM patients were seen. No associations between IKZF1, IKZF3, IRF4, MYC expression and patients’ characteristics or outcome were revealed.
E1295
MAINTENANCE THERAPY WITH BORTEZOMIB IN PATIENTS WITH MULTIPLE MYELOMA (MM) AFTER ASCT AND MINIMAL RESIDUAL DISEASE (MRD)

Aims: To assess efficacy of maintenance therapy with Bortezomib in patients with MM, who have achieved complete remission after ASCT with MRD positive and negative status.

Methods: From January 2014 to February 2016 52 patients with MM (19 male and 33 female) ages from 24 to 66 years (median 54 years) who have achieved complete remission after ASCT were randomized for a year-long maintenance therapy with Bortezomib. On 100th day after ASCT and after completion of maintenance therapy samples bone marrow from all patients were assessed using 6-color Flow Cytometry to detect MRD. We chose Relapse-Free Survival (RFS) as the indicator of maintenance therapy efficacy. Kaplan-Meier survival curves were compared using log-rank test. Statistical analysis was performed using SAS 9.4.

Results: 2-year Relapse-Free Survival in patients with MRD-negative status after ASCT was higher (p=0.05) than that in MRD-positive patients - 52.9% (95% CI: 35.5–70.6%) vs 37.2% (95% CI: 25.4–49.3%). The MRD-positivity significantly increases the risk of relapse (HR=1.7; 95% CI: 1.2–3.4; p<0.05). Two year cumulative probability of relapse after ASCT in patients with MRD-negative status, who had (n=15) and hadn’t received (n=10) maintenance therapy with Bortezomib was not different (p=0.58). Average time of relapse in MRD-positive patients who received maintenance therapy with Bortezomib was 5 months longer than in the group of patients without maintenance therapy - 17.3 months vs 12.3 months. In the group of MRD-positive patients who did not completed maintenance therapy, relapse was diagnosed in 6 patients. After the end of the treatment 42% of MRD-positive patients achieved MRD-negative status. RFS in this group of patients was significantly higher than in the group of treated MRD-positive patients who retained that status after maintenance therapy (MT) - 100% vs 20% (p<0.02, Fig.1).

Summary/Conclusions: In cases when MRD-negative status was achieved after ASCT, maintenance therapy does not increase the RFS. In comparison – patients with positive MRD status after ASCT require maintenance therapy to improve their survival rate.

E1296
LONG-TERM OUTCOME OF MULTIPLE MYELOMA (MM) PATIENTS TREATED UP-FRONT WITH SINGLE OR TANDEM AUTOLOGOUS STEM CELL TRANSPLANTATION (ASCT) - SINGLE CENTRE EXPERIENCE WITH 334 PATIENTS

Background: ASCT after induction treatment has been standard of care for MM for almost 30 years. Some centers routinely perform two transplantation up-front (so-called tandem transplants), while others advocate postponing the second transplant until after progression. In recent years novel antimyeloma agents have significantly improved the prognosis of MM patients, thus casting further doubts on the value of the more aggressive tandem ASCT approach.

Aims: To describe long-term outcomes of MM patients treated with ASCT (single and tandem) in a single centre. alled tandem transplants), while others advocate postponing the second transplant until after progression. In recent years novel antimyeloma agents have significantly improved the prognosis of MM patients, thus casting further doubts on the value of the more aggressive tandem ASCT approach.

Methods: This was a retrospective analysis of outcomes of 334 MM patients who underwent 470 ASCT procedures at our center between 1993 and 2014. During that period treatment policies changed from single to tandem to salvage second ASCT, as data from different clinical studies became available.

Results: 296 patients received VAD (vincristine, doxorubicin, dexamethasone) as induction therapy and 38 regimens based on immunomodulatory drugs or proteasome inhibitors. All received high-dose melphalan for pretransplant conditioning, 32 in combination with total body irradiation. Tandem ASCT (defined as second transplantation performed within 6 months after the first) was performed in 136 patients, single ASCT in 168 and salvage second (after relapse/progression) in 30 patients. Transplant related mortality was 1.5%. Median follow up is 70 months (range 4 – 238). Median overall survival (OS) for the entire group is 123 months and median progression free survival (PFS) 40 months. Tandem ASCT in comparison to single and second salvage transplantation resulted in superior OS (203 vs 86 vs 68 months respectively, p<0.0001) and PFS (60 vs 38. vs 25 months respectively, p<0.0001) (figure). Thirteen percent of patients who underwent tandem ASCT are alive and progression-free more than 10 years after the procedure. Fourteen patients developed secondary malignancies.

Figure 1.

Summary/Conclusions: Our results suggest that tandem ASCT is a very effective treatment modality that can partially substitute for the absence of expensive novel agents with low long-term and lethal toxicities. Tandem ASCT seems to result in superior OS and PFS in comparison to single or salvage second ASCT. More than 10% of patients treated with tandem ASCT experience very prolonged PFS.

E1297
EXTRAMEDULLARY DISEASE IN MULTIPLE MYELOMA PATIENTS UNDERGOING AUTOLOGOUS STEM CELL TRANSPLANTATION: CLINICAL IMPACT IN DIAGNOSIS, TREATMENT AND OUTCOME

Background: Extramedullary disease (EMD) is defined as an infiltrate of clonal plasma cells outside of the bone marrow. The presence of EMD in multiple myeloma (MM) patients (pts) at diagnosis is a relatively uncommon presentation and accounts for about 13% (6-20%) of MM pts. Although several studies...
showed an association of EMD with other adverse prognosis factors and unfavourable outcomes, reports evaluating EMD and outcomes in pts undergoing autologous hematopoietic stem cell transplantation (aHSCT) are scarce.

Aims: We aimed to evaluate the clinical and laboratorial characteristics of pts with EMD as well as its impact in outcomes of MM pts submitted to aHSCT (response to treatment, overall survival [OS] and progression-free-survival [PFS]).

Methods: We analysed 155 MM pts submitted to aHSCT in our centre between January/2007 and December/2015, excluding second procedures. The assessment of response to treatment was based in the International Myeloma Working Group consensus criteria (2016).

Results: The median age of the cohort was 58 years (27-69), with 58% of males, 63% of the most common subtype was IgGκ (45%). In our cohort, 29.7% presented EMD at diagnosis, which was significantly higher compared to reports in the literature (p<0.001; 95%CI 0.22-0.37). The more common involved sites were vertebral column (49%), ribs (13%) and pelvis (13%). EMD occurred more frequently in males (38 vs 18%; p=0.012) and in pts with bone disease (53 vs 36%; p=0.003), vs without (50 vs 36%; p=0.006). EMD was observed in pts with lower International Staging System scores (I and II vs III) (82 vs 64%; p=0.022) and without anaemia at diagnosis (28 vs 11%; p=0.023).

No other significant differences in characteristics at diagnosis were found between pts with and without EMD. Pts with EMD achieved lower complete response (CR/VGPR) proportions previously to aHSCT (30.4 vs 53.2%; p=0.009), as well as at 100 days after aHSCT (D100) (41.3 vs 59.6%; p=0.037). However, no differences were found concerning refractoriness to first line therapy or proteasome inhibitor (PI) treatment, despite EMD pts received a higher mean number of therapeutic lines previously to aHSCT (3.1 vs 2.4; p=0.023). After a median follow-up of 46.6 months, the median OS was not reached for global cohort and both groups, and there was no difference between them (p=NS). The median PFS was 51.3 months for global cohort, with no differences seen between pts with and without EMD (50.2 vs 54.1; p=NS). Pts with EMD treated with a PI (57%) presented a higher OS (NR vs 32.5 months, p=0.04), but with no impact in PFS (p=NS), and there were no differences concerning radiotherapy treatment (72%) or thalidomide maintenance after aHSCT (32%) (p=NS).

Summary/Conclusions: In our cohort, EMD prevalence was significantly higher than usually described in the literature. This observation was probably associated with a more carefully surveillance of EMD in aHSCT candidates. EMD was associated with a lower proportion of CR/VGPR previous to aHSCT and at D100 evaluation, even after a higher number of therapeutic lines, although we failed to demonstrate that EMD was an independent prognosis factor for PFS and OS. PI seem also to be the best first-line therapeutic approach for EMD pts. In conclusion, our study suggests that EMD is underdiagnosed in MM pts. It is necessary to achieve a better knowledge of the physiopathology of EMD, in order to define better treatment options that may overcome its negative impact in therapeutic response.
patients. Different studies have linked complete response (CR) with better PFS (progression-free survival), but not always with prolonged overall survival (OS), most likely due to the impact of novel agents in the management of relapsed-refractory patients. Overall, these observations suggest PFS as a more reliable predictor of clinical outcome. Also, the biological aggressiveness is emerging as a pivotal disease characteristic which affects clinical behavior and response to therapy. In this context, little is known about the association of response kinetic with survival outcomes.

Aims: In order to evaluate whether early achievement of a good quality response impacts on outcome, we retrospectively analyzed 87 NDMM patients treated at our institution with bortezomib containing regimens (BRs).

Methods: From 2004 to 2016, 87 patients with NDMM and measurable disease (serum and/or urine M protein) were treated with BRs. Both patients eligible and non-eligible for ASCIT were included in the study; patients undergoing ASCT were censored at the time of transplant. Median age was 66 (range 32-87); males were 51 (59%); 72 (83%) patients were in III stage; median follow up was 30.7 months; median number of administered courses was 5 (range 2-9). PFS was defined according to IMWG criteria. Cytogenetic risk evaluation performed by a standardized FISH panel, including del17p, del13q, t(11;14), t(4;14), was available in 37 patients (42.5%). Among these high-risk abnormalities were identified in 20 patients. Early good response (EGR) defined an M protein reduction ≥75% after 2 courses of therapy. Survival curves were calculated for PFS and OS by Kaplan Meyer method, using log-rank test.

Results: PFS and OS were both assessed in patients who achieved EGR as well as in patients who did not. No significant differences were observed in terms of OS between the two groups, whilst PFS was significantly longer in patients achieving EGR (p=0.036, median PFS 44.7 vs 29 months, respectively). Next, we analyzed patients with high risk cytogenetic. Among these, EGR vs non-EGR patients reached a PFS of 43.7 and 18.7 months, respectively. Remarkable PFS differences between these two groups were not significant (p-value=0.11).

Figure 1.

Summary/Conclusions: Overall, our data demonstrate a significant impact of EGR on PFS in NDMM patients after BRs, irrespective of median age at diagnosis. In presence of high cytogenetic risk EGR is associated with prolonged PFS, although not significantly. Ongoing analysis on larger cohort of high risk patients will confirm the impact of EGR on PFS also in this group of patients. Based on our data kinetic of response, deriving from EGR assessment, may provide information on both disease aggressiveness as well as clinical outcome, thus representing a novel, surrogate marker for an early survival analysis, with favorable cost-effectiveness characteristics. In summary biological and clinical information deriving from EGR analysis combined with cytogenetic risk evaluation and patient-related (age, comorbidities) characteristics, may represent a useful tool to make clinical decisions. Further prospective evaluations are needed to include this marker in clinical practice.

RELATIVE PROGRESSION-FREE SURVIVAL OVER TIME OF NOVEL TRIPLET REGIMENS FOR THE TREATMENT OF RELAPSED/REFRACTORY MULTIPLE MYELOMA

K. Betts1, C. Chen2, M. Zichlin1, A. Brun2, J. Signorovitch1, D. Makenbaeva2,*

1Department of Hematology, Erasmus Medical Center Cancer Institute, Rotterdam, 2Department of Research, Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht, 3Department of Public Health, Erasmus University Medical Center, Rotterdam, 4Department of Hematology, Radboud umc, Nijmegen, Netherlands

Background: In combination with lenalidomide (REV/LIMID®) and dexamethasone (d), elotuzumab (EMPLICITI™, E), carfilzomib (KYPROLIS®, K), and ixazomib (NINLARO®, N) were recently approved for the treatment of relapsed/refractory multiple myeloma (RRMM). In randomized controlled trials, all three drugs showed a significant relative reduction in the risk of disease progression or death as compared to patients who received Rd. To date, there have been no head-to-head trials comparing ErD, Krd, and/or Nrd.

Aims: To describe the time-specific progression-free survival (PFS) based on published Kaplan-Meier PFS curves for ErD, Krd, and Nrd relative to Rd.

Methods: Individual patient-level data (IPD) were reconstructed from the published Kaplan-Meier PFS curves from the ELOQUENT-2 (ErD), ASPIRE (Krd), and TOURMALINE-MM1 (Nrd) randomized, controlled, Phase III trials using digitization software and the methods described by Guyot, et. al. Using the reconstructed IPD, Kaplan-Meier survival curves were estimated for each arm within each trial. PFS curves were digitized by two independent researchers and the reconstructed curves were overlaid with the published data to validate the IPD. In each trial, the relative PFS benefit over time was calculated as the difference in the Kaplan-Meier PFS estimate of each triplet regimen and the Kaplan-Meier PFS estimate of Rd divided by the Kaplan-Meier PFS estimate of Rd: rPFS(t)=[SXRd(t) - SRd(t)] / SRd(t). Where S(t) denotes the Kaplan-Meier PFS estimate at time t, and X denotes E, K, or N, respectively.

Results: IPD from the three randomized controlled trials was successfully reconstructed and validated. Numerically, ErD had the highest relative PFS over the initial 10 months of treatment and showed sustained benefit from month 24 onwards (Figure 1). At 12 months, the relative PFS benefit was 17.9% for ErD, 21.7% for Krd, and 9.7% for Nrd. At 24 months, the relative PFS benefit was 45.1% for ErD, 34.3% for Krd and 24.1% for Nrd. At 36 months, the relative PFS benefit was 39.9% for ErD and 19.1% for Krd. ErD had a higher relative PFS than Nrd for almost the entirety of RRMM treatment. At the end of data availability, Nrd and Krd showed no additional PFS benefit relative to Rd, while ErD showed a sustained benefit through 40 months. Data will be updated for the conference, where available.

Figure 1.

Summary/Conclusions: For the treatment for RRMM, ErD showed an early and sustained benefit in relative PFS which was maintained through 40 months. Krd and Nrd showed initial benefits which faded by the end of data availability.

E1301

POMALIDOMIDE WITH LOW-DOSE DEXAMETHASONE IN PATIENTS WITH RELAPSED OR RELAPSED AND REFRACTORY MULTIPLE MYELOMA: A PROSPECTIVE ANALYSIS IN A POPULATION-BASED REGISTRY

R. Wester1,*, A. Dinmohamed1,2,3, P. Sonneveld1, A. Brojoi1, N. Blijlevens4

1Department of Hematology, Erasmus Medical Center Cancer Institute, Rotterdam, 2Department of Research, Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht, 3Department of Public Health, Erasmus University Medical Center, Rotterdam, 4Department of Hematology, Radboud umc, Nijmegen, Netherlands

Background: Patients with relapsed and/or refractory multiple myeloma (R/RMM) have limited treatment options and a poor prognosis. Previous trials showed that pomalidomide combined with low-dose dexamethasone is effective in these patients with improvement in response and survival. These studies led to the approval of pomalidomide as third line treatment in patients with RRMM. A subsequent prospective analysis in a population-based registry was conducted to assess response and survival in patients with R/RMM treated with a pomalidomide-based regimen. Also, we defined subgroups who benefit most of this treatment regimen.

Methods: Patients were eligible for pomalidomide if they received ≥2 prior lines of therapy including bortezomib, lenalidomide and alkylator therapy and developed progressive disease on their last therapy. This is a prospective analysis of patients registered at the nationwide Netherlands Cancer Registry. Treatment consisted of 4mg pomalidomide, day 1-21, combined with corticosteroids. Treatment was discontinued in case of progressive disease or unacceptable toxicity. Primary endpoint was progression-free survival (PFS). Secondary endpoints included overall survival (OS), overall response rate (ORR), toxicity, response per risk group (based on cytogenetics and ISS at initial diagnosis) and response per age group (>65 vs ≥65 years).
Results: A total of 82 patients (median age 68 years [range: 43-88]) were included in this analysis. CRAB criteria included anemia in 23 patients (28%), renal insufficiency in 8 (9.8%), hypercalcemia in 13 (16%) and bone lesions in 54 (66%). Median time from diagnosis to start pomalidomide was 5.75 years [range: 0.8-18.4], median number of treatment cycles was 3 [range: 1-17]. At time of analysis 59 patients had stopped pomalidomide treatment: 24 patients had progressive disease, 10 had unacceptable toxicity, 6 patients were refractory, 4 patients died during treatment and 15 patients stopped due to various other reasons. Grade ≥3 hematological adverse events occurred in 11% of patients, 4% had neutropenic fever. Grade ≥3 non-hematological toxicities occurred in 57% of patients, including infection in 22%, gastrointestinal disorders in 5% and renal disorders in 5%. Of 69 patients evaluable for response ORR was 41%, with a partial response (PR) rate and a very good partial response (VGPR) rate of 36% and 4% respectively. Response based on age was not significantly different (p=0.426). Median PFS for all patients was 3.8 months (95% confidence interval [CI] 2.3-6.6). Patients >65 years had a longer PFS of 5.7 months (95% CI 2.9-8.0) versus 2.8 months (95% CI 1.9-6.6) in patients ≤65, however, this was not statistically significant (p=0.427) (figure 1). For patients achieving ≥PR, median PFS was 9.6 months (95% CI 5.7-Not reached [NR]). Median PFS in patients diagnosed more than ten years prior to initiation of pomalidomide treatment was 9.6 months (95% CI 5.7-NR), as compared to 2.2 months (95% CI 1.9-6.6) among patients treated within 5 years after diagnosis (p=0.05). Data about previous treatment, ISS stage, cytogenetics at diagnosis and an update of OS will be presented at EHA.

Summary/Conclusions: In this analysis the experience in clinical practice of patients with RRMM treated with a pomalidomide-based regimen is reported. These data support results shown in clinical trials. Preliminary data presented here suggest that older patients and patients with a long interval between initial diagnosis and pomalidomide treatment (indicating a less aggressive multiple myeloma) may benefit from this treatment.

E1302

INVOLVED/UNINVOLVED HEAVY/LIGHT CHAIN INDEX CAN PREDICT PROGRESSION IN MULTIPLE MYELOMA PATIENTS AFTER AUTOLOGOUS PERIPHERAL BLOOD STEM TRANSPLANT. PRELIMINARY EXPERIENCE

M. Espíno Martínez1,1, A. Arteche López2, A. Arriero3, C. Muñoz-Calleja3, A. Alegre Amor3, M.J. Blanchard Rodríguez2, F.J. López Jiménez2, L.M. Villar1

1Immunology, University Hospital Ramon y Cajal, 2Clinical Analysis, 3Haematology, University Hospital La Princesa, 4University Hospital Ramon y Cajal, Madrid, Spain

Background: High-dose therapy followed by autologous peripheral blood stem transplant (APBSCT) has demonstrated to improve overall survival and progression-free survival with a high complete remission rate in multiple myeloma (MM) patients. However, most patients eventually present progression or relapse (P/R). Detection of P/R is mainly based on a significant increase of monoclonal protein (MC) or free light chains (sFLC). The identification of new biomarkers to early predict P/R might be clinically useful for an anticipated therapy.

Aims: The aim of our study was to evaluate the potential role of the Involved/Uninvolved Heavy/Light Chain index (I/Ui) in this setting.

Methods: We prospectively followed 44 MM transplanted patients: 19 with IgG-kappa isotype, 11 with IgG lambda, 9 with IgA-kappa and 5 with IgA-lambda. They were followed for 29.0±3.8 months (mean±standard error (SE)). Serial serum samples from each MM patients were collected periodically after APBSC. Relapse or progression was defined according IMWG criteria. To identify factors that predict disease progression in MM transplanted patients, we studied heavy/light chains (HLC) pair quantification, sFLC and total immunoglobulins levels in serial serum samples collected during the follow-up. Involved/uninvolved index (I/Ui) was calculated using the monoclonal chain (Involved) as numerator and the polyclonal chain of the same class (Uninvolved) as denominator. The HLC ratio (HHL) was calculated as IgGk/IgGλ or IgAk/IgAl with normal reference ranges established in 1.3-3.7 for IgG and 0.7-2.2 for IgA.

Results: In IgG MM patients, values of I/Ui were significantly increased in pre-relapse compared to basal samples (8.49±4.01 vs 2.23±0.67 p=0.012). By contrast, this index remained stable along follow-up in patients in complete remission (CR) or with a partial response (PR). However, the later showed higher values of I/Ui ratio, suggesting that the presence of an M-component induces immunosuppression of the uninvolved chain of the monoclonal protein. Regarding IgA MM, we established a cut-off value of 2.0 for I/Ui that allowed the discrimination of patients at high risk of early progression (values above 2.0) from those in CR, whose levels of I/Ui are always below 2.0 (p=0.02).

Summary/Conclusions: Our results show that HLC-pair measurement could detect progression or relapse and the increase of MC in transplanted MM patients earlier than other methods. Future studies will need to demonstrate the real value of the I/Ui index as a biomarker to anticipate progression in MM patients subjected to APBSCT.

MULTIPLE MYELOMA IMMUNOPHENOTYPIC REMISSION IS A SIGNIFICANT PREDICTOR OF PROGRESSION FREE SURVIVAL AFTER FIRST AUTOLOGOUS STEM CELL TRANSPLANTATION - PILOT STUDY

K. Beranova1,1, J. Radocha1, O. Soucek2, K. Machalkova1, J. Hanousek1, P. Zak1, V. Maisnar1

1IV. interni hematologicka klinika, 2Institute of Clinical Immunology and Allergology, Fakultni nemocnice Hradec Kralove, Hradec Kralove, Czech Republic

Background: Minimal residual disease in multiple myeloma assessed by multiparameter flow cytometry has become an increasingly important predictor of progression-free survival (PFS).

Aims: Our primary endpoint was to evaluate PFS in myeloma patients after stem cell transplantation who reached immunophenotypic CR (iCR) versus those who have not.

Methods: We prospectively evaluated prognostic importance of minimal residual disease detection by multiparameter flow cytometry (MFC) in multiple
myeloma patients who underwent autologous stem cell transplantation from January 2014 until December 2016. All patients were uniformly treated with bortezomib based induction therapy followed by high dose chemotherapy (Melphalan 200mg/m²) and autologous stem cell transplantation. Minimal residual disease (MRD) status was determined by S-colour MFC 1 month after autologous transplantation from bone marrow aspirate in all patients who achieved at least conventional VGPR or CR.

Results: We identified 56 patients who fulfilled the above mentioned criteria, 30 were males and 26 females, median age was 61.62.5% of patients (35/56 patients) achieved CR, 37.5% of patients (21/56) did not. Median follow up of the cohort was 19 months (6-59), 32.1% of patients (18/56) relapsed during the follow-up period. 16.1% of patients (9/56) died. 22.9% (13/56 patients) in CR and 47.6% (10/21 patients) not in CR relapsed during the follow up. Patients in CR showed significantly longer PFS with median 42 months than those in less than CR with PFS median 29 months (p=0.0196, log-rank test). This was associated with an increased hazard ratio of relapse (0.3565) in CR group.

Summary/Conclusions: Achieving immunophenotypic CR is clearly associated with longer progression free survival compared to conventional CR. Reaching CR should be a goal of myeloma treatment.

E1304
REGULATION OF NORMAL AND MONOCLONAL IMMUNOGLOBLIN SECRETION BY CYTOKINES (S- SYNDECAN-1, BLYS & TGF-BETA-1) IN PATIENTS WITH IG-SECRETING B-CELL DISORDERS AT PRESENTATION.

PROGNOSTIC IMPLICATIONS
E. Koulieri1, P. Papaioannou1,1, E. Nikolou1, K. Sariss1, D. Malertz1, S. Harding2, N. Kafassi3, K. Tsalimalma3, K. Bitsani1, T. Tzenou1, V. Bartzi1

Background: The most common neoplastic lymphoproliferative diseases that secrete paraprotein are multiple myeloma (MM), Waldenstrom’s Macroglobulinemia (WM) and chronic lymphocytic leukemia (CLL). The two first entities secrete paraprotein by definition, while serum free light chains (sFLC) are quantified in 50% of CLL cases. Microenvironmental factors, such as soluble Syndecan-1 (synd-1) and BlyS normally promote lymphoplasmacytic differentiation as well as their secretory activity, whereas other cytokines, like TGF-beta1, inhibit it. Determination of Ig is necessary in MM and WM for diagnostic purposes and for monitoring patients, while in CLL, sFLC has prognostic value. The total amount of secreted Ig does not really reflect disease burden. The heavy chain Ig can be accurately determined with the Heavyvite method (that measures separately HLC-IgA, -G, -M kappa or lambda), thus allowing exact quantification of the amount of pure monoclonal fraction but also the degree of suppression of polyclonal Ig, both being reflected by the corresponding ratios (HLCR).

Aims: To determine any possible relationship between the amount of IgG secreted by the B-cells and TGFBeta1, as well as with disease outcome.

Methods: We studied 269 patients: 105 with MM (79 IgG and 26 IgA, of whom 33%, 31%, and 36% were staged ISS 1, 2 and 3 respectively), 64 suffering from WM (44%, 28%, 28% staged WM-IPSS 1, 2, 3 respectively), and 100 with CLL (67%, 23%, 10% staged Binet 1, 2, 3 respectively). Patients were regularly followed-up from diagnosis to last visit or death (median follow up to 5 months). sFLC/sFLC and HLC/HLCR were determined by nephelometry (Freelite™ and Heavylite™, the Binding Site Birmingham, UK) while sSynd1, BLYS and TGFBeta1 by ELISA, either in fresh or in frozen sera sample drawn at the time of diagnosis. Statistical analysis was performed by standard methods using the SPSS v22.0, software.

Results: The main correlations observed between the Ig levels secreted in the 3 diseases and cytokines studied, as well as their impact with regard to patients’ outcome, are shown in table.

Summary/Conclusions: sSynd1 in MM and BLYS in WM and CLL correlated with disease outcome. By inhibiting both monoclonal and polyclonal Ig, TGFbeta1 correlated in MM with both HLC and FLC ratios and differences. In addition, the aforementioned variables are prognostic with regard to patients’ outcome.

E1305
PATIENTS WITH MULTIPLE MYELOMA (MM) IN LONG TERM COMPLETE REMISSION (LTRC) AFTER AUTOLOGOUS TRANSPLANT (APBSCT) EXPRESS A DISTINCTIVE IMMUNE PROFILE WITH POTENTIAL PROGNOSTIC VALUE
A. Arteche-Lopez1, A. Alegre Amor2, A. Kreutzmann3, B. Aguado2, M. Espino Martinez4, L. M. Villan2, P. Sanz1, A. Arriero2, C. Muñoz-Calleja2
1Clinic Analysis, 2Haematology, 3Immunology, University Hospital La Princesa, 4Haematology, Immunology, University Hospital Ramon y Cajal, Madrid, Spain

Background: A small fraction of patients with MM could be considered potentially cured as long as they remain for more than six years in long term complete remission after autologous transplantation (APBSCT). The exhaustive study of the immune status of these patients could highlight interesting information.

Aims: Here we present an observational study that evaluates the numbers and phenotype of T- and B-cells subsets in the peripheral blood (PB) of MM-LTRC patients, in order to confirm their specific immune signature, and also in the duration of complete remission (MM-LTCR) after autologous transplant (APBSCT). The research was performed in the comprehensive 8-color flow cytometry panel. Populations of CD4+ and CD8+ T-cells from PB were quantified, including naive, central and effector memory T-cells, as well as subpopulations of B-cells: naive, transitional, marginal zone-like, class-switched memory and plasmablasts. In order to confirm their specific immune signature, the analysis was repeated in the same LTRC-MM patients one year after the first analysis was done. A Kruskal- Wallis test was used to evaluate differences among the studied groups. A posteriori test was done to compare the control group with the two patient's group (patients and patients +1 year), independently of each other. A Wilcoxon matched test was used to compare a patient under group “patients” with the status of the same patient in the second group “patients +1 year”. Statistical analysis was done using GraphPad Prism software.

Methods: After approval by the ethics committee, we selected 13 patients diagnosed with MM, in sCR according to IMWG criteria for at least six years after APBSCT, and 15 healthy adults (HA) of similar ages as a comparative group. Group MM: 7 males and 6 females; median age: 61 Mabeian follow-up. In sCR, no patients were found when compared to HA. However, naive B-cells (CD19+CD10−CD21+IgM−) proportion was higher in patients and a corresponding reduction of marginal zone-like B-cells (CD21+CD23−CD10−CD19+) and plasmablasts (CD20+CD38++) in the PB of the two groups. When the analysis was repeated in the same LTRC-MM patients one year after the first analysis, no changes were detected neither when analysed as a group nor when analysed individually.

Summary/Conclusions: The MM-LTRC patients seem to express a distinctive immune “footprint” characterized by a decreased proportion of naive T-cells and an increased percentage of effecter T cells, which probably exert a competent immune surveillance. Conversely, the increase in naïve B cells may guarantee the humoral response host immunity, inducing survival of the individual plasma cells that might compete with myelomatous cells for normal bone marrow niches. The precise role of these refined immunological studies in the monitoring and therapeutic decisions in MM patients, and also in the duration of sCR, should be defined in the future.

Study partially performed with research grants from the spanish Leukemia and Lymphoma Foundation and Grant PI12/00494P from the Fondo de Investigaciones Sanitarias and FEDER funds.

E1306
IMPACT OF THE AFFORDABILITY OF NOVEL AGENTS IN PATIENTS WITH MULTIPLE MYELOMA: REAL WORLD DATA ON CURRENT CLINICAL PRACTICE IN MEXICO
L. Tarin-Arzaga1, V. Martinez-Pacheco2, A. Gomez-De Leon1, P. Colunga
Pedraza1, P. Santana-Hernandez1, G. Sotomayor-Duque1, D. Ameondo-Campos1, C. De la Cruz-De la Cruz1, O.G. Cantu-Rodriguez1, D. Gomez-Almaguer1
1Hematology, Hospital Universitario Dr Jose Eleuterio Gonzalez Universidad Autonoma de Nuevo Leon, Monterrey, Mexico

Background: The success of bortezomib and lenalidomide in improving outcomes as first-line therapies in multiple myeloma (MM) patients has been achieved at a very high cost. Treatment has become difficult to access for patients living in low to middle-income countries, as most receive assistance by public healthcare systems wherein novel drugs are unaffordable.

Aims: To compare the outcomes of MM patients who can afford private insurance and treatment in a private center (PrivC), with those managed in a public center (PubC), who do not have access to healthcare coverage and are treated on an out-of-pocket basis.

Methods: We analyzed records of 148 patients diagnosed with MM in two health sectors in Monterrey, Mexico, from October 2007 to July 2016; 77 (52%) from PubC, where the most common induction therapy was cyclophosphamide, thalidomide-dexamethasone, followed by thalidomide maintenance, and 71 (48%) from PrivC wherein bortezomib or lenalidomide-based induction and lenalidomide maintenance were used. We compared demographics, disease stage, response rate and survival among both groups.

Results: Median age, gender and frequency of immunoglobulin isotype did not differ significantly between the two groups. Patients treated in PubC were more likely to be diagnosed with advanced stage disease (ISS III 42% vs 26% p<0.05). Median follow-up was 36 months (range 3-120 months). Autologous transplantation was performed in 80% of the transplantation-eligible patients in PrivC and only in 31% of PubC. At least a very good partial response to induction therapy was achieved more often in the PrivC among transplantation-eligible (65% vs. 42%, p<0.05) and ineligible patients (66% vs. 41%, p<0.05). Overall survival was significantly higher in PrivC for transplantation-eligible (median 84 months vs 42 months, p<0.05). After controlling for disease stage and transplantation factors, the risk of mortality was still higher in PubC (HR 1.49; 95% CI:1.0-2.2, p<0.05).

Summary/Conclusions: Stage at diagnosis, induction therapy and autologous stem cell transplantation were contributors to survival disparities between patients treated in public vs private health care facilities in Mexico. These findings underscore the need for more efforts to improve the affordability of novel agents and transplantation settings in public health services.

BASAL CALCIUM, AN IMPORTANT ELEMENT IN THE DEVELOPMENT OF CALR MUTANT MPNS
M. Morian Mairal1,*, P. Papadopoulos2, M. Krstic-Demonacos 1, A. Aziz2
1Salford University, Manchester, United Kingdom, 2Hospital Clinico San Carlos, Madrid, Spain

Background: Calreticulin (CALR) is a calcium (Ca²⁺) buffering chaperone mutation of which has recently being associated with essential thrombocythemia and primary myelofibrosis without JAK2 mutations. These mutations have been suggested to impair the Ca²⁺ buffering activity of Calreticulin due to a change of the negative charge in its C-terminal domain. Ca²⁺ is known to be important during megakaryocyte activity; however its role during megakaryopoiesis and the possible link of CALR mutations and abnormal megakaryocyte production due to impaired Ca²⁺ buffering activity in myeloproliferative neoplasms (MPNs) remains unclear.

Aims: Here we aim to understand how basal Ca²⁺ fluctuations during normal megakaryopoiesis and how CALR mutations could affect the basal Ca²⁺ levels in megakaryocytes in MPNs.

Methods: Ca²⁺ staining was performed using Flu-8 dye and Ca²⁺ basal levels were measured by flow cytometry. Changes in basal Ca²⁺ during megakaryopoiesis using two cellular systems, K-562 cells and mouse bone marrow cells, were measured each 24 hours. Further studies using CALR mutant cellular models were performed using the same methodology.

Results: Our results showed a characteristic behaviour of fluctuations of basal Ca²⁺ during this megakaryopoiesis, where Ca²⁺ levels decrease in the last stage of megakaryocyte formation. These results suggest that Ca²⁺ reduction could be essential for megakaryopoiesis. In order to understand how CALR mutations affect basal Ca²⁺, Marimo cells and Dami cells expressing CALR mutations were analysed. Here we show a decrease in basal Ca²⁺ in Marimo cells and Dami cells harboring CALR type1 mutation compared to the controls. Moreover, Dami-CALR type1 did not show any significant reduction, suggesting possible differences in Ca²⁺ behaviour depending in CALR type mutation. We are currently working in the analysis of basal Ca²⁺ fluctuations during megakaryopoiesis in the presence of CALR mutations and preliminary results show abnormal basal Ca²⁺ levels throughout all the process of megakaryocyte differentiation.

Summary/Conclusions: Altogether, our findings indicate that basal Ca²⁺ could be an important element during megakaryopoiesis and CALR mutations found in MPN could impair the normal production of megakaryocytes due to changes in cellular Ca²⁺. However, further analysis need to be done in order to understand the role of CALR mutations and their effect in the Ca²⁺ buffering activity of CALR in MPNs.

THE INHIBITION OF JAK/STAT SIGNALING IS COMPENSATED BY ACTIVATION OF MAPK PATHWAY IN MYELOPROLIFERATIVE NEOPLASMS
T. Subotićski1, B. Belesin Cokić1, D. Djikić1, S. Mojsilović3, D. Šefer4, S. Bjelica3, J. Santibanez3, V. Čokić3, T. Subotićki1, B. Belesin Cokić2,*, D. Djikić1
1Laboratory of neuroendocrinology, Institute for Medical Research, University of Belgrade, 2Clinical for endocrinology, Diabetes and Metabolic Diseases, Clinical Center of Serbia, 3Laboratory of experimental hematology, Institute for Medical Research, University of Belgrade, 4Clinic of Hematology, Clinical Center of Serbia, Belgrade, Serbia

Background: Myeloproliferative neoplasms (MPN) remain incurable regardless of the advancement in the use of JAK2 inhibitor Ruxolitinib, which competence is unrelated to the JAK2V617F mutation.

Aims: We want to explore JAK1/2 inhibition dependency in correlation with activated JAK/STAT3 signaling and cell cycle in MPNs.

Methods: The immunoblotting has been used to analyze activation of JAK/STAT3, PI3K/AKT and MAPK signaling in JAK2V617F mutated HEL cells and granulocytes of MPN. The cell cycle and apoptosis of granulocytes are studied by flow cytometry.

Results: Concerning myeloproliferation, JAK1/2 inhibitors reduced the percentage of cells in G2M phase and increased apoptosis in JAK2V617F mutated HEL cells. Comparing to polycythemia vera (PV), the percentage of granulocytes is decreased in S and G2M phases of essential thrombocythemia (ET) and primary myelofibrosis (PMF) that demonstrated increased apoptosis. Hexa-bromocyclhexane increased percentage of granulocytes in GoG1 phase of JAK2V617F positive, but reduced in JAK2V617F negative PMF, the later one similar to Ruxolitinib. JAK1/2 inhibitors reduced percentage of apoptotic granulocytes in JAK2V617F positive, but increased in JAK2V617F negative PMF. JAK1/2 inhibitors could not impair constitutive activation of JAK/STAT3 signaling in HEL cells as well as in granulocytes of JAK2V617F positive ET and PMF. Absence of JAK2V617 mutation supported dephosphorylation of JAK/STAT3 pathway by JAK1/2 inhibitors in ET, but not in PMF. JAK1/2 inhibitor
Ruxolitinib largely activates MAPK signaling in MPN, while slightly PI3K/AKT signaling in PV and JAK2V617F negative PMF. Specific JAK2 inhibitor Hexa-bromocyclohexane activates PI3K/AKT signaling in JAK2V617F positive ET, but reduced in JAK2V617F negative ET and PMF.

Summary/Conclusions: This observation support cross-talk between examined pathways, where inhibition of JAK/STAT3 signaling is compensated by activation of MAPK pathway irrespective of JAK2V617F mutation, while PI3K/AKT signaling demonstrates JAK2V617F dependence in MPN.

E1309 CIRCULATING PLATELET AND MEGAKARYOCYTE-DERIVED MICROPARTICLES OF JAK2V617F MUTATED PATIENTS WITH MYELOFIBROSIS ARE DISRUPTED: A NOVEL LIQUID BIOPSY TOOL OF RESPONSE TO RUXOLITINIB?
M. Barone 1, F. Ricci2, D. Forte 1, D. Sollazzo 1, M. Romano 1, M. Spinsanti 1, E. Ottaviani1, M. Cavo 1, N. Vianelli1, P. Tazzari2, F. Palandri 1, L. Catani1 1Department of Experimental, Diagnostic and Specialty Medicine, Institute of Hematology, University of Bologna, Italy 2Immunohematology and Blood Bank Service, Azienda Ospedaliero-Universitaria S. Orsola-Malpighi, Bologna, Italy

Background: Microparticles (MPs) are small vesicles (0.1-1 micron) deriving from plasma membrane budding during homeostasis and cell activation. MPs express antigens and contain constituents from cell of origin and are increased in conditions that are characterized by high cell turnover or death, particularly inflammatory, autoimmune and neoplastic diseases. Myelofibrosis (MF) is a clonal neoplasia of the hematopoietic stem/progenitor cells characterized by diffuse stromal fibrosis, dysplasia of megakaryocytes (MK) development and platelet (PLT) activation. Mutations in 3 genes (JAK2, CALR, MPL) and chronic inflammation are the main pathogenic drivers of MF. Ruxolitinib (RUX), a JAK1/2 inhibitor, suppresses both clonal myeloproliferation and release of proinflammatory cytokines, reducing splenomegaly and constitutional symptoms in around 50% of patients (pts). We hypothesized that MPs, as mediators of inflammation, could be overexpressed in MF and possibly predict responses to RUX.

Aims: This study aims to: 1) enumerate circulating MK and PLT-derived MPs of MF pts; 2) evaluate the effect of RUX on MPs production by PLT and MK; 3) investigate whether circulating MK and PLT- MPs may be a biomarker of response to RUX.

Methods: EDTA-anticoagulated peripheral blood from healthy donors (HD, n=10) and JAK2V617F positive MF pts (n=12) at intermediate-2 high IPSS risk was collected at baseline and 3 and 6 months after RUX therapy and immediately centrifuged. Microparticles in megakaryocytes (MK) development and platelet (PLT) activation. Mutations in 3 genes (JAK2, CALR, MPL) and chronic inflammation are the main pathogenic drivers of MF. Ruxolitinib (RUX), a JAK1/2 inhibitor, suppresses both clonal myeloproliferation and release of proinflammatory cytokines, reducing splenomegaly and constitutional symptoms in around 50% of patients (pts). We hypothesized that MPs, as mediators of inflammation, could be overexpressed in MF and possibly predict responses to RUX.

Results: Among the TN cases we identified four MPL S204F/P cases that were analyzed separately given that part of their hematological parameters (MPV, RBC counts) were not similar to the rest of the ET cases. Additionally, flow cytometry analysis also showed that MPL S204F/P platelets are larger and express different surface marker expression patterns as compared to the other ET groups and HD. On the other hand, JAK2 V617F and CALR type 1 ET platelets exhibited normal to increased expression density of these receptors as compared to HD. Variable patterns were observed amongst the other ET genetic subgroups, with reduced responses especially upon challenge with Aggretin A or collagen, while platelets from the JAK2 ET subpopulation displayed reduced reactivity to collagen and the other ET groups. This study aimed to establish a better diagnosis/prognosis of the disease.

Summary/Conclusions: These preliminary results suggest that MPL S204F/P platelets are intrinsically defective (hypo-reactive), in contrast to JAK2 V617F platelets (hyper-reactive), while in other genetic subgroups, potential defects are most probably synergistic and/or acquired by treatment. Data suggests that JAK2 V617F and CALR type 1 platelets could also undergo basal degranulation or vesiculation in the circulation. Analysis of the platelets has identified characteristics in different genetic groups of ET that should be further investigated to account the different treatment conditions and using larger cohorts of patients. When specific functional and phenotypic platelet patterns are established it could contribute significantly to a better diagnosis/prognosis of the disease.

E1311 ASSOCIATION ANALYSIS OF CYTOGENETIC AND GENETIC ALTERATIONS IN PRIMARY MYELOFIBROSIS
R. Norvillas1,2, V. Dirse 1,3, E. Gineikien1, O. Mickeviciute1, S. Pakstyte1, M. Stoskus1, L. Griskevicius1,3
1Hematology, Oncology and Transfusion Medicine Center, Vilnius University Hospital Santariskiu Klinikos, 2Department of Innovative Medical Technologies and Health Research Science, State Research Institute Centre for Innovative Medicine, 3Department of Internal, Family Medicine and Oncology, Faculty of Medicine, Vilnius University, Vilnius, Lithuania

Background: A number of genomic abnormalities have been associated with primary myelofibrosis (PMF). None of the currently available peripheral blood and bone marrow cytogenetic panels (Illumina) are designed to efficiently screen for PMF genomic studies and certain cytogenetic and genomic associations have been determined. To better characterise the genomic landscape of PMF we performed comprehensive analysis of gene mutations and chromosomal aberrations in a population-based cohort of PMF patients.

Aims: To characterize genomic aberrations in PMF using SNP-A and NGS methods.

Methods: PMF peripheral blood samples were screened by Infinium HD whole-genome genotyping assay with the HumanCytoSNP-12 BeadChips (Illumina Inc., CA). NGS analysis was performed using TruSight Myeloid 54 gene panel (Illumina) and single nucleotide polymorphism array (SNP-A) methods and single nucleotide polymorphism array (SNP-A) methods and single nucleotide polymorphism array (SNP-A) methods and single nucleotide polymorphism array (SNP-A) methods and single nucleotide polymorphism array (SNP-A) methods as performed using Illumina BaseSpace Informatics suite (Illumina). JAK2, CALR, MPL mutations were additionally confirmed with Sanger sequencing while small indels – with DNA fragment analysis.
Results: 110 patients diagnosed with PMF according to WHO criteria between years 2013 and 2014 were included into this study. SNP-A analysis identified 77 chromosomal abnormalities in 61 patients (55.4%). These comprised the loss of heterozygosity (LOH) (59.7%), hemizygous deletions (23.4%) and copy number gains (16.9%). The most common aberrations in affected patients were: 5p LOH (55.7%), 20q deletion (11.5%), 1q duplication (4.9%), 19p deletion (3.2%), 1q LOH (3.2%), 6q LOH (3.2%). NGS analysis detected 219 gene mutations (in a total of 27 genes) in 108 patients (98%). The most frequently mutated genes were: JAK2 (62.9%), CALR (27.8%), ASXL1 (20.3%), TET2 (16.6%), MPL (7.4%), <5% ZRSR2, EZH2, DNMT3A, U2AF1, ET16, SF3B1, IDH1, IDH2. Recurrent specific mutations were identified in 10 genes. Sixty-two patients (57.4%) had more than one somatic mutation. Six patients (5.5%) had no JAK2, CALR or MPL mutations and were defined as “triple-negative”. Interestingly, out of the 267 BCR-ABL1 mutated cases the ratio was equal. Most of the patients (18/19) had one mutation with the higher load, whereas in 4 cases were present in 19/1775 (1%) cases:

**Summary/Conclusions:** A number of associations between gene mutations and chromosomal aberrations was revealed in PMF. Co-presence of 9p LOH with JAK2V617F and CALR mutations with 19p deletion indicate that further deregulation of these key signaling pathways may take place disrupting the second allele of the affected genes by different biological mechanism – LOH or deletion.

**E1312**

**FREQUENCY OF CONCURRENT BCR-ABL1, JAK2, CALR AND MPL MUTATIONS IN A COHORT OF 5,545 CASES WITH SUSPECTED MPN BY A DEEP SEQUENCING APPROACH**

S. Jeromin1, M. Meggendorfer1, A. Fasan1, C. Hafner1, W. Kien1, T. Hafner1
1Mll Munich Leukemia Laboratory, Munich, Germany

Background: Chronic myeloid leukemia (CML) is a myeloproliferative neoplasm characterized by BCR-ABL1, whereas in about 90% of BCR-ABL1-negative MPN a mutation in CALR, JAK2 or MPL can be detected. These genetic alterations are thought to be nearly mutually exclusive, however, an accurate frequency is still missing.

**Aims:** To determine the incidence of genetic markers occurring in parallel in a large cohort of patients with suspected MPN and characterize double mutated cases.

**Methods:** From July 2016 till January 2017 5545 samples were sent to our laboratory with suspected MPN. The male:female ratio was 1:1, and the median age was 60 years (range: 18-98 years). Median white blood cell count was 9x10^9/L, hemoglobin level (Hb) was 15g/dl and platelet count was 329x10^9/L. All of these cases were analyzed by an amplicon deep sequencing approach for mutations in JAK2 (exon12, exon14), CALR (exon9) and MPL (exon10) with a sensitivity of 1%. 3070 patients were additionally screened for BCR-ABL1 fusion by a multiplex PCR approach. Samples that were double mutated for JAK2, CALR and MPL were analyzed by amplicon deep sequencing for additional mutations in 13 myeloid genes.

**Results:** In total 1775/5545 (32%) of suspected MPN patients showed JAK2, CALR and/or MPL mutations. 1438 (26%) were JAK2, 267 (5%) CALR, and 89 (1%) MPL mutated. Of note, the analysis of a subgroup (n=3070) for BCR-ABL1 fusion identified 123 (4%) as CML cases. The JAK2 mutated cases presented mainly with Va117Phe (99%) and rarely with JAK2 exon12 mutations (1%). CALR mutations were primarily type 1 (54%) and type 2 (30%). MPL mutations were located at amino acid Trp515 in 96% of cases. Double mutated cases were present in 19/1775 (1%) cases: JAK2/MPL (63%), JAK2/CALR (32%) and CALR/MPL (3%). In nearly all CALR mutated cases (67%) the CALR mutation was detected with the higher load, whereas in JAK2/MPL double mutated cases the ratio was equal. Most of the patients (18/19) had one mutation with a load below 10% and could have been missed by other approaches. BCR-ABL1 together with JAK2 or CALR mutation was found in one patient, each (0.1%). The distribution of the 267 cases was similar to the genetic distribution in the whole cohort. However, the Kaplan–Meier method followed by sequencing of probably mutated samples. Karyotype research was done for 48 (43.6%) pts.

**Figure 1.**

**Results:** DM were detected in 81.8% pts: JAK2(+) - 50%, CALR(+) - 25.5%, MPL(+) - 6.4% cases. No DM were found in 18.2% pts considered triple-negative (TN). Mutations in ER genes were detected in 20.8% pts. High risk (HR) chromosomal aberrations (CNH) unfavorable CA (85% of DIPSS adverse muta-

tions), 1q deletions, 20q deletions and CALR(+)ASXL1 wide type (wt) pts seem to have better OS than CALR(-)ASXL1 wt (median not reached (with follow up period of 10.1 years) and 13.5 years, respectively, p=0.124).

Median OS estimated in pts due to presence/absence of DM and ASXL1 status

**E1313**

**A COMPREHENSIVE ASSESSMENT OF MOLECULAR AND CYTOGENETIC MARKERS OF PROGNOSIS IN PATIENTS WITH PRIMARY MYELOFIBROSIS**

L. Polushkina1, I. Martynkevich1, V. Shuvaev1, E. Motyk1, M. Fonmykh1, I. Krvolapov1,2, Z. Asaulenko1, L. Martynenko1, M. Ivanova1, N. Cybacova1, D. Shikhababava1, A. Zhemyakova1, S. Voloshin1, S. Bessmelenev1, A. Chechelkin1
1Russian Research Institute of Hematology and Transfusiology, 2North-Western State Medical University named after I.I. Mechnikov, St-Petersburg, Russian Federation

**Background:** According to recent reports the data of molecular and cytogenetic analysis (type or absence of driver mutation (DM), mutations in ASXL1, EZH2, IDH1/2 genes, karyotype and their combinations for overall survival (OS) in PMF patients.

**Methods:** We have examined 110 patients (pts) with PMF (34.5% males). Median (Me) age was 59 years (16-82). For all pts the detection of JAK2V617F was done. JAK2(+) samples were tested for MPL 515 codon mutations and exon 9 mutations of CALR (direct sequencing). All pts except 4 underwent the analysis of mutations in ASXL1, EZH2, IDH1/2 genes with high resolution melt- ing method followed by sequencing of probably mutated samples. Karyotype research was done for 48 (43.6%) pts.

**Summary/Conclusions:** One-third of the cases can be diagnosed having more than one mutation according to the detection of BCR-ABL1, CALR and/or MPL mutation in an unselected cohort with suspected MPN. The frequency of double mutated JAK2, CALR and MPL cases is 1%. In CML cases BCR-ABL1 fusion and JAK2 or CALR mutation were detected in 2% of the patients. Impact of these parallel genetic events on the clinical course of the disease has to be evaluated in the future.
was 0.9 years in TN/ASXL1mut. 3.6 years in TNASXL1wt, 13.8 years in DM(+)ASXL1wt and was not reached in DM(+)ASXL1mut (with follow up period of 10.3 years) group (p<0.0001). Differences in OS depending on the ASXL1 status were statistically significant in the TN (p=0.007) but not for DM(+) group (p=0.788). The better OS was observed in ASXL1 wt pts with low risk (LR) karyotype (Me 6.4 years, p=0.0058). There were no differences in OS of ASXL1 wt- HR, ASXL1mut-LR and ASXL1mut-HR pts (1.4 vs 1.6 vs 1.2 years, p=0.493).

Summary/Conclusions: The differences in OS were more statistically relevant in groups divided by TN/ASXL1 and karyotype/ASXL1 status. The presence of ASXL1mut significantly worsens OS in the TN group. In pts with in any of the findings: HR karyotype or ASXL1mut – was significantly shorter than in cytogenetically favorable ASXL1wt counterparts.

JAK2 HAPLOTYPE 46/1 (GGCC) HAS NO EFFECT ON THE PRIMARY RISK OF JAK2 V617F MUTATION, BUT IT STRONGLY POTENTIATES THE PROGRESSION OF GROWN ALLELE BURDEN IN MYELOPROLIFERATIVE NEOPLASMS

M. Stolyar1,2,*, O. Klimova3,4, M. Ivanov3,4, A. Gorbenko1, S. Titov3,4, I. Olkhovskiy1,5 1Krasnoyarsk Branch of the Federal State-Funded Institution «National Research Center for Hematology» of the Ministry of Healthcare of the Russian Federation, 2Siberian Federal University, Krasnoyarsk, 3AO Vector-Best, 4Institute of Molecular and Cellular Biology, Siberian Branch of Russian Academy of Sciences, Novosibirsk, 5Federal Research Center "Krasnoyarsk Scientific Center of the Russian Academy of Sciences, Siberian Branch", Krasnoyarsk, Russian Federation

Background: Several research groups have determined that the JAK2 46/1 (GGCC) haplotype in multiple ethnic groups is strongly associated with a predisposition to acquiring JAK2 V617F-positive MPNs. The role of the JAK2 46/1 haplotype in the natural evolution of the mutant JAK2V617F allele burden in PV but not ET or PMF has been shown [Alvarez-Larran A et al. Leukemia Research 2012, 36(3):324-326]. However, the data on the impact of the haplotype on the JAK2 V617F allele burden do not always agree. Using a highly sensitive test allowed to reveal a high prevalence JAK2 V617F among persons without symptoms of hematological disorders [Krichievsky S et al. Blood Cells, Molecules and Diseases., doi: 10.1016/j.bcmd.2017.01.001]. Influence of haplotype 46/1 for such cases is not known. There are two competing hypotheses of "hypermutability" and "fertile ground" explaining the causes of the higher frequency of mutations of JAK2V617F in haplotype 46/1 carriers. The "hypermutability" hypothesis refers to an increased risk of a primary mutation in carriers of haplotype 46/1. In this case, the increasing frequency of the haplotype in patients with low allelic burden (<5%) must also be observed, including those individuals without evidence of hematological disorders.

Aims: Studying the relations of haplotype 46/1 and JAK2 V617F allele burden

Methods: The diagnosis of chronic myeloproliferative neoplasms was based on the WHO (2008) criteria. The cohort included patients with JAK2 V617F mutation: 100 patients with PV, 51 with ET, 14 with MF, 41 patients with unclassified MPN, 17 patients were treated with hydroxyurea and 20 were treated with the PMF. 46/1 haplotype was closely associated with MPN patients if the allele burden exceeds 5% (Fig. 1) regardless of the phenotype or the treatment. In this case with an increase in JAK2V617F allele burden the JAK2V617F allele burden was significantly higher in patients with PV than in patients with ET (p=0.001), but no differences were observed with from patients with the PMF. 46/1 haplotype was significantly shorter than in cytogenetically favorable ASXL1wt counterparts.

Summary/Conclusions: No significant differences of the carrier haplotype JAK2V617F allele burden between control group and patients with minimal allelic burden (less than 5%) JAK2 2V617F have been observed. This is evidence against primary "hypermutability" hypothesis. A further increase in allelic load is more pronounced in carriers of haplotype 46/1 that supports the "fertile ground" hypothesis. We hypothesize that DNA mutation JAK2V617F repair is down-regulated in 46/1 haplotype carriers.

E1315

MINIMAL RESIDUAL DISEASE MONITORING BY DIGITAL PCR FOR JAK2V617F DETECTION IN PATIENTS WITH MYELOFIBROSIS (MF) OR ACUTE MYELOID LEUKEMIA SECONDARY TO MF AFTER ALLOGENEIC STEM CELL TRANSPLANTATION

S. Salmoiraghi1,*, C. Belotti, M.C. Finazzi, M.C. Millo1, A. Algarotti1, G. Finazzi1, M. Mascheroni 1, A. Salvi1, A. rambaldi12, O. Spinelli1,1 Hematology and Bone Marrow Transplant, ASST Papa Giovanni XXIII, Bergamo, 2Oncology and Hematoniology, University of Milan, Milan, Italy

Background: Myelofibrosis (MF) is one of the BCR-ABL1-negative Chronic Myeloproliferative Neoplasms (MPNs), characterized by clonal expansion of abnormal hematopoietic progenitors and gradual replacement of normal bone marrow with fibrous tissue. MF patients' prognosis is widely variable and the impact of radiation can vary between patients to many extent. At present, Allogeneic Stem Cell Transplantation (ASCT) is the only curative treatment option for these patients. The most frequent phenotype-driving mutation in MF is the V617F mutation in the JAK2 gene. A high sensitive quantification of JAK2V617F mutation load can be useful to assess Minimal Residual Disease (MRD) in treatment directed to eradicate the malignant clone, such as ASCT. Droplet Digital PCR (ddPCR) is a quantitative approach for the detection of rare allele characterized by a high level of sensitivity and specificity.

Aims: To evaluate the efficacy of ddPCR JAK2V617F mutation detection assay in monitoring the MRD level at consecutive time-points in a small cohort patients who underwent an ASCT for MF or MF-derived Acute Myeloid Leukemia (s-AML).

Methods: DNA from 9 patients affected by primary, secondary MF or s-AML were serially collected during the follow-up after ASCT (50-2500 days). These samples were investigated for hematologic chimerism by PowerPlex System (Promega, USA) and were evaluated for JAK2V617F mutation both by conventional allele specific PCR (ASO-PCR) and by a validated ddPCR mutation detection assay (Bio-rad, USA). Results were expressed as percentage of JAK2V617F mutated alleles on total evaluated alleles.

Results: The JAK2V617F ddPCR mutation assay was able to detect low mutation load (up to 0.006%), confirming to be much more sensitive than ASO-PCR (0.5%). In 4 patients, early after transplantation, we observed by ddPCR a low level of MRD that progressively increased during the follow-up and anticipated a decrease in donor chimerism level and a worsening of clinical situation. In 2 patients, who showed a full donor chimerism and complete hematologic remission of the disease, very low levels of MRD (ranging from 1% to 0.006%) could be detected by ddPCR in the 2 years after ASCT. With a longer follow-up, a full molecular remission was achieved as demonstrated by ddPCR. In 2 other patients, we observed a very early achievement of full donor chimerism and JAK2V617F molecular negativity (within 90 days post HSCT), also when evaluated by ddPCR. These patients entered a complete hematologic remission both by a high level of sensitivity and specificity.

Summary/Conclusions: The ddPCR proved to be a sensitive and accurate method in detecting JAK2V617F mutation. Therefore, this assay can be a valid tool for MRD monitoring in s-AML and s-AML. However, the use of this highly sensitive PCR should be considered with caution in the clinical management of transplanted patients to avoid inappropriate use of donor leukocyte infusion (DLI) and tampering of immunosuppression. S100A8/9 ACTIVATION OF MAPK PATHWAY IS SUPPORTED BY ITS RECEPTORS RAGE AND TLRI4 IN POLYCYTHEMIA VERA
M. Kovačić1,*, O. Mitrović-Ajtić1, B. Beleslin-Čokić2, M. Diklić3, D. Dijk Lil1, S. Momčilović1, D. Leković4,5, M. Gotić5, V. Čokić5
1Laboratory of neuroendocrinology, Institute for Medical Research, 2Clinic for Endocrinology, Diabetes and Metabolic Diseases, Genetic laboratory, Clinical Center of Serbia, 3Laboratory of experimental hematology, Institute for Medical Research, 4Clinic of Hematology, Clinical Center of Serbia, 5Medical Faculty, University of Belgrade, Belgrade, Serbia

Background: S100 proteins have been shown to regulate cell proliferation, excessively augmented in myeloproliferative neoplasms (MPN). S100A8/9 is produced by cells of myeloid origin as mediator of inflammation, while AKT and MAPK pathways mediate cell proliferation.

Aims: This study analyzed activation of AKT and MAPK pathways by S100A8/9 proteins in healthy controls and MPNs: polycythemia vera (PV), essential thrombocytopenia (ET), primary myelofibrosis (PMF), according to JAK2V617F and calreticulin (CALR) mutation status.

Methods: S100A8/9 factor is examined in granulocytes of MPN using immunoassay to evaluate the concentration of granulocytes is determined by flow cytometry. Mutations of JAK2V617F and CALR exon 9 are analyzed by DNA sequencing. Besides JAK2V617F+ PV patients, we formed per three groups of patients: JAK2V617F+, JAK2V617F-/CALR+, and JAK2V617F-/CALR- for ET and PMF.

Results: S100A8/A9 proteins demonstrated a common significant increase in plasma of MPN patients, whereas the presence of CALR mutation augmented S100A8/9 levels in granulocytes of ET and PMF patients. Activation of AKT pathway is generally reduced by S100A8/9 factor, further on ameliorated by inhibition of the receptor for advanced glycation end products (RAGE) in granulocytes of JAK2V617F+ and JAK2V617F-/CALR+ groups of ET and PMF patients, while it has been prevented by Toll-like receptor 4 (TLR4) inhibition in PV patients. MAPK pathway is significantly inhibited by S100A8/9 only in JAK2V617F+/ET patients and JAK2V617F-/CALR- PMFs, partially prevented by TLR4 inhibition in PMF. Inhibition of TLR4 reduced S100A8/9 mediated MAPK activation has been significantly augmented by S100A8/9 in the absence of CALR inhibition in PV patients. S100A8/9 stimulated granulocyte cycle arrest in G2M phase has been stopped by JAK1/2 inhibition.

Summary/Conclusions: S100A8/9 protein levels demonstrated stable elevation in MPN patients. Inhibition of AKT controlled by S100A8/9 has been prevented by TLR4 and RAGE inhibitor in PV patients. S100A8/9 stimulated granulocyte cycle arrest in G2M phase has been stopped by JAK1/2 inhibition.

Background: Hypereosinophilia-associated syndromes are a heterogeneous group of diseases characterized by sustained and elevated blood eosinophilia with evidence of eosinophil-induced organ damage. Classically, Eosinophilic Granulomatosis with Polyangiitis (EGPA) and Hypereosinophilic Syndrome (HES) are related to several overlapping clinical and laboratory features, making their differentiation challenging in both diagnosis and treatment. The common feature shared by EGPA is a significant T cell receptor gamma repertoire in EGPA patients, whereas the presence of CALR mutation augmented S100A8/9 factor, further on ameliorated by TLR4 inhibition in PMF. Inhibition of TLR4 reduced S100A8/9 mediated MAPK activation in JAK2V617F-/CALR+ ET. In contrast, S100A8/9 mediated MAPK activation in JAK2V617F+ and JAK2V617F-/CALR+ groups of ET and PMF patients, while it has been prevented by Toll-like receptor 4 (TLR4) inhibition in PV patients. MAPK pathway is significantly inhibited by S100A8/9 only in JAK2V617F+/ET patients and JAK2V617F-/CALR- PMFs, partially prevented by TLR4 inhibition in PMF. Inhibition of TLR4 reduced S100A8/9 mediated MAPK activation has been significantly augmented by S100A8/9 in the absence of CALR inhibition in PV patients. S100A8/9 stimulated granulocyte cycle arrest in G2M phase has been stopped by JAK1/2 inhibition.

Summary/Conclusions: S100A8/9 protein levels demonstrated stable elevation in MPN patients. Inhibition of AKT controlled by S100A8/9 has been prevented by TLR4 and RAGE inhibitor in PV patients. S100A8/9 stimulated granulocyte cycle arrest in G2M phase has been stopped by JAK1/2 inhibition.

MUTATIONAL PROFILE STUDY OF DOUBLE-NEGATIVE ESSENTIAL THROMBOCYTHEMIA BY HIGH-DEPTH NEXT GENERATION SEQUENCING (NGS)
E. Ajtić1,*, O. Mitrović-Ajtić1, M. Kovačić1, M. Diklić1, V. Čokić5
1Haematology, Hospital Universitario 12 de Octubre, Madrid, Spain

Background: Essential thrombocythemia is one of the three classical Philadelphia-negative myeloproliferative neoplasms. It is frequently difficult to diagnose and some molecular markers are used as diagnostic criteria according to WHO classification. Despite this, a significant proportion of patients do not present a clonality marker.

Aims: To identify the mutational profile of ET negative for V617F and CALR mutations and to correlate it with clinical data.

Methods: A cohort of 22 ET negative for mutations in JAK2 (qPCR) and CALR (GENESCAN) was selected. Median age at diagnosis was 46 years (range: 14-88), male:female ratio 9:13; 2 patients had a record of thrombotic event prior to diagnosis, 4 patients had symptoms at the time of diagnosis, 3 patients suffered a thrombotic event after diagnosis, 1 patient had suffered transformation to AML. Median Hb, WBC and platelets at diagnosis were respectively 14.75g/dl, 8.85 x10 9/L and 720x10 9/L. We performed targeted gene sequencing by NGS (Ion Torrent Proton System–Life Technologies) using a panel of 33 genes implicated in leukemia prognosis. X2 and t-student tests were used to find association between mutations and clinical data.

Results: On average, 97.94% of the target sequence showed a mean depth coverage around 2500. We discovered 17 non-synchronous mutations which 16 were somatic single nucleotide variants (SNVs) and 1 a nucleotide deletion in coding regions. No mutations were detected in 9 samples (40.9%), 10 samples (45.5%) had 1 mutation, the other 3 samples presented no or more mutations (13.6%). TET2 was the most frequently mutated gene (18.2% of patients, mean allele frequency of 24.45%), followed by JAK2 (13.6% V617F at a low mean allele frequency (5.8%), MPL (9.1%, one W515L, one with two mutations W515R and S505C, mean allele frequency of 21.95%), SF3B1 (4.5%, one DNM3A (4.5%), KIT (4.5%), BCL (4.5%) and KMT2A (4.5%). The samples with more than one mutation: one presented a CBL and two TET2 mutations, one two mutations in MPL and the other one mutation in TET2 and other in JAK2. No correlation was found between mutational profile and clinical data.

Summary/Conclusions: In ET, around 60% of patients present the JAK2V617F mutation, 15-30% show CALR mutations and around 5% present MPL mutations. In spite of this, there is still a significant percentage of ET patients without a molecular marker. Our study shows that the use of a NGS panel allows identifying markers of clonality as for example TET2. NGS also makes affordable to interrogate whole genes classically associated to ET, to detect mutations that were not found by traditional approaches. Finally, we can conclude, as previously described, that ET is an entity with a low mutational burden in comparison with other MPN as primary myelofibrosis.
PERCEPTION OF SYMPTOM BURDEN AND TREATMENT GOALS BETWEEN PHYSICIANS AND PATIENTS WITH MPNS: AN ANALYSIS FROM THE INTERNATIONAL MPN LANDMARK SURVEY

Background: The global MPN LANDMARK survey evaluated the patient (pt) and physician-reported impact of myeloproliferative neoplasms (MPNs), including myelofibrosis (MF), polycythemia vera (PV), and essential thrombocythemia (ET), among pts from 6 countries. We present an analysis comparing physician and pt perceptions of the impact of these MPNs.

Aims: To investigate differences between pt and physician perceptions of symptom burden, treatment goals, and disease management

Methods: This was a cross-sectional survey of pts with MPNs and physicians treating pts with MPNs. Respondents completed an online survey measuring their perception of the impact of MPNs on symptom burden, disease management, and treatment goals. Pts and physicians were recruited independently.

Results: Pts (n=699) from Australia (n=10), Canada (n=64), Germany (n=149), Italy (n=106), Japan (n=84), and the UK (n=286) completed the survey (MF, n=223; PV, n=174; ET, n=302). Most pts had been diagnosed within ≤2 years of experiencing symptoms (73%); 56% were women. Physicians (n=219) were from the same countries; most were hematologists (54%) or hemato-oncologists (27%). Overall, 54% of pts reported having a prognostic score; however, 71% of physicians reported using a prognostic risk classification. Physicians assessed symptoms by proactively asking pts how they were feeling (43%) or asking about specific symptoms (37%); 11% waited for pts to mention symptoms. Importantly, only 26% of physicians used a validated symptom assessment form; 44% used their own rating method. Pts and physicians both agreed that pts with MPNs have a high symptom burden and that MF had a higher degree of burden on daily living. Interestingly, a higher proportion of physicians

Figure 1. 

Results: Pts (n=699) from Australia (n=10), Canada (n=64), Germany (n=149), Italy (n=106), Japan (n=84), and the UK (n=286) completed the survey (MF, n=223; PV, n=174; ET, n=302). Most pts had been diagnosed within ≤2 years of experiencing symptoms (73%); 56% were women. Physicians (n=219) were from the same countries; most were hematologists (54%) or hemato-oncologists (27%). Overall, 54% of pts reported having a prognostic score; however, 71% of physicians reported using a prognostic risk classification. Physicians assessed symptoms by proactively asking pts how they were feeling (43%) or asking about specific symptoms (37%); 11% waited for pts to mention symptoms. Importantly, only 26% of physicians used a validated symptom assessment form; 44% used their own rating method. Pts and physicians both agreed that pts with MPNs have a high symptom burden and that MF had a higher degree of burden on daily living. Interestingly, a higher proportion of physicians
than pts felt that MPN symptoms have an impact on pt quality of life (92% vs 76%) and that pts had a substantial emotional burden associated with their disease. For instance, 34%, 29%, and 26% of pts with MF, PV, or ET reported feeling anxious or worried compared with 70%, 46%, and 36% of physicians reporting that their pts experience substantial anxiety or worry. Some pts did not recognize that their symptoms could be MPN related; for example, = one-fifth of pts did not think that their night sweats could result from their MPN (16% MF, 21% PV, 25% ET). Consistent with this, 60% of physicians indicated that pts could identify only few or some of their symptoms as MPN related. Pts and physicians were both concerned about reducing symptoms (pts: 70% MF, 61% PV, 53% ET; physicians: 80% MF, 55% PV, 60% ET); however, pts were also concerned about delaying MPN progression (58% MF, 57% PV, 66% ET; physicians: 43% MF, 28% PV, 37% ET; Figure 1). Compared with pts, physicians indicated a greater focus on prevention of vascular/thrombotic events in PV (66% vs 48%) and ET (80% vs 60%). Overall, only 27% of physicians felt they completely agreed with their pts on treatment goals; 66% felt they “somewhat” agreed. However, most pts (87%) were satisfied with their physician’s disease management/communication.

Summary/Conclusions: This study revealed a potential disconnect between physician and pt perceptions relating to communication and disease management, and an apparent lack of standardization in symptom assessment. Of note, some pts did not recognize that their symptoms could be MPN related and had different treatment goals than their physicians, indicating a need for improved pt education and pt-physician communication and a treatment plan that includes standardized monitoring of symptoms and agreement on treatment goals.

E1321
BASELINE QUALITY OF LIFE INDEPENDENTLY PREDICTS OVERALL SURVIVAL IN THE MYELOFIBROSIS: KEY INSIGHTS FROM THE COMFORT-I STUDY

R. Scherber1,2, H. Kosiorek3, H. Geyer4, S. Verstovsek5, J. Sloan6, B. Langhais3, L. Padmos1, J. Palmer7, A. Fleischman7, A. Dueck3, R. Mesa1, J. He1,*, M. Mehra1, J. Bussolari2, A. Rizo2, S. Mundle1

Background: Quality of life (QOL) is a critical aspect of cancer treatment and survival. A strong association exists between QOL and overall survival (OS) for numerous malignancies including breast, gastro-esophageal, colorectal, lung, prostate, ovarian, and head and neck cancer (Sloan 2012, Montazeri 2009, Nilsen 2017). Healthcare organizations have used symptom burden as a primary therapeutic endpoint when assessing the benefit of JAK inhibitors in myelofibrosis (MF) in clinical trials, although QOL was also considered. To date, little is known about the association of these items in regards to overall survival in MF.

Aims: To evaluate the prognostic relevance of QOL and symptom burden among patients with MF from the COMFORT-I study.

Methods: Data from the COMFORT-I trial of ruxolitinib (Verstovsek 2012) versus placebo was obtained from Incyte® for independent analysis. Association of total symptom burden (TSS; divided by the sample quartiles) and QOL (divided by the sample median) at baseline with OS among MF patients was estimated using the Kaplan-Meier method and tested using log rank tests and Cox regression. Symptom burden and QOL were assessed using the 5-symptom SF-36 and EORTC QLQ-C30 Global Health/QOL scale (Aaronson 1993), respectively. The PROMIS instrument was used to assess fatigue (Cella 2007).

Results: A total of 309 patients were available for analysis including 155 ruxolitinib-treated and 154 placebo-treated MF patients. Baseline demographics, disease-related variables, and calculated OS were similar to previous published results (Verstovsek 2015). Symptom Burden: When comparing OS by TSS quartiles at baseline, no significant differences in OS were observed (Figure 1A). Individual symptoms of bone or muscle pain, feeling full, pain under ribs on left side, abdominal discomfort, itchiness, or night sweats did not demonstrate significant associations when comparing OS by quartile symptom score. Baseline fatigue score demonstrated no difference in OS when stratified by median or quartiles. Global Health Status/QOL: Intention to treat analysis demonstrated significant survival advantage for patients with higher QOL at baseline (HR 1.47, p=0.02, Figure 1B). When censoring placebo patients at crossover, this hazard ratio improved to a HR 1.79 (p=0.008). Cox Proportional Hazards Modeling: Cox regression for survival analysis reached significance for items of age (p<0.001), sex (p<0.009), and QOL (p=0.009) when taking into consideration TSS, IPSS prognostic risk score, age, sex, COMFORT treatment arm, and QOL. When censoring for placebo patients at crossover, this analysis demonstrated that the same items remained significant (age [p<0.001], sex [p<0.001], and QOL [p=0.002]).

Summary/Conclusions: For the patients prospectively evaluated in the COMFORT-I trial, pre-treatment QOL is strongly prognostic for overall survival and MF-SAFv2.0 high risk pts demonstrated a significant survival benefit from symptom burden (scored worst) on OS. Notably, no other variable was found to impact survival (Verstovsek 2015). Consistent with previous published results, OS by TSS quartiles at baseline, we observed (Figure 1A). Individual symptoms of bone or muscle pain, feeling full, pain under ribs on left side, abdominal discomfort, itchiness, or night sweats did not demonstrate significant associations when comparing OS by quartile symptom score. Baseline fatigue score demonstrated no difference in OS when stratified by median or quartiles. Global Health Status/QOL: Intention to treat analysis demonstrated significant survival advantage for patients with higher QOL at baseline (HR 1.47, p=0.02, Figure 1B). When censoring placebo patients at crossover, this hazard ratio improved to a HR 1.79 (p=0.008). Cox Proportional Hazards Modeling: Cox regression for survival analysis reached significance for items of age (p<0.001), sex (p<0.009), and QOL (p=0.009) when taking into consideration TSS, IPSS prognostic risk score, age, sex, COMFORT treatment arm, and QOL. When censoring for placebo patients at crossover, this analysis demonstrated that the same items remained significant (age [p<0.001], sex [p<0.001], and QOL [p=0.002]).

E1322
CHARACTERIZATION OF DISEASE AND OUTCOMES OF PATIENTS WITH MYELOFIBROSIS: A POPULATION BASED STUDY

J. He1,*, M. Mehra1, J. Bussolari2, A. Rizo2, S. Mundie1

1Janssen Global Services LLC, 2Janssen Research & Development, LLC, Raritan, United States

Background: Myelofibrosis (MF) is a myeloproliferative neoplasm with profound negative effects on health related quality of life and survival. It is characterized by clonal myeloproliferation, ineffective erythropoiesis, bone marrow stromal changes, hepatosplenic extramedullary hematopoiesis, and aberrant cytokine expression. Although progress has been made in the understanding of the pathogenesis and management of MF, there are still unresolved issues regarding prognosis and causes of death.

Aims: This population-based study characterizes disease and outcomes in patients (pts) with MF by using the U.S. Surveillance, Epidemiology, and End Results (SEER) database.

Methods: We identified a total of 3,367 pts with primary myeloid fibrosis (PMF, ICD-O-3 morphology code as 9961/3 and primary site code as C420, C421 or C424) diagnosed between January 2000 to December 2013. Pts with missing survival status (n=753), pts lost to follow up (n=4), and pts with missing age record (n=1) were excluded. Kaplan-Meier analysis was performed to determine overall survival (OS) and cancer specific mortality. The effects of specific covariates on OS were analyzed using a Cox proportional hazards model.

Figure 1.
Results: The final study cohort comprised of 2,619 PMF pts. Median follow up period was 28 months (interquartile range 9-57 years) with 60.6% (n=1,586) ≥ 65 years old. More than half of the pts were male (58.5%; n=1,531); 82.2% (n=2,153) were white, and 16.4% (n=430) were diagnosed between 2012 and 2013. The geographic distribution was as follows: East 14.8%, South 18.4%, West 54.2% and Midwest 12.6%. Median OS was 42 months (Figure 1). The hazard ratio of all-cause mortality for age was 1.05 (95% Confidence interval (CI) 1.04-1.05), for female vs male was 0.72 (CI 0.64-0.80), for nonwhite vs white 1.01 (CI 0.87-1.16), for unmarried vs married was 1.04 (CI 0.94-1.16), for patients diagnosed 2012-2013 vs 2000-2011 was 0.95 (CI 0.75-1.20). Compared to West, the hazard ratio of OS for East, South and Midwest was 1.05 (CI 0.90-1.22), 1.28 (CI 1.12-1.47), 1.03 (CI 0.88-1.19) respectively.

Summary/Conclusions: This population based study showed that the overall survival of pts with PMF was short. Older and male pts were associated with higher mortality risk. There were significant differences across geographic regions of the United States. Although there is a trend of improvement in the period of 2012 to 2013, the result is not statistically significant, partially due to short follow up. These findings underscore the continuing need for effective therapies for pts with MF.

E1323

SERUM ALBUMIN IS A STRONG PREDICTOR OF SURVIVAL IN MYELOFIBROSIS, INDEPENDENT OF IPSS, DIPSS, AND DIPSS+ SCORES

A.T. Kuykendall 1,*, C. Talati 1, D.A. Sallman 2, K.L. Sweet 2, E. Padron 2, J.E. Lance2, A.F. Lis2, K.S. Zuckerman3, R.S. Komrokij2
1University of South Florida/Moffitt Cancer Center, 2Moffitt Cancer Center, Tampa, Florida, United States

Background: Albumin is the main protein in human plasma. Serum albumin (SA) is used as a surrogate marker of nutritional status and inflammation. The prognostic role of SA has been studied in many diseases, including hematologic malignancies. In myelofibrosis (MF), rouxotubin has been shown to improve SA levels in addition to other metabolic parameters. SA holds particular significance in MF given its ability to capture both nutritional status and inflammation level in a disease hallmarked by hyperactive inflammatory pathways and constitutional symptoms.

Aims: We aim to closely evaluate the significance of SA in MF patients as it pertains to clinical presentation, laboratory correlations, disease genomics, comorbidities and outcomes.

Methods: We retrospectively reviewed an institutional database of 376 MF patients who presented to Moffitt Cancer Center between 1/1/1998 and 12/31/2012 and had available SA levels within 30 days of presentation. Laboratory values and prognostic scores were determined at time of first presentation. Overall survival (OS) was measured from time of first presentation until date of death or censored at time of last follow-up. Progression free survival (PFS) was defined as time from first presentation to development of acute myeloid leukemia (AML).

Figure 1.

Results: Our cohort of MF patients had median age of 67 and 69 at diagnosis and presentation, respectively. Most patients had primary MF (73%) with 11% and 16% having post-PV MF and post-ET MF, respectively. First, we looked at the correlation between SA and other clinical factors. SA was positively correlated with hemoglobin (<0.01) and platelet count (<0.01), and negatively correlated with age (<0.01), peripheral blast percentage (<0.03), ferritin (<0.01), prognostic scoring models (<0.01 for IPSS, DIPPS and DIPSS+) and pack-year smoking history (<0.01). SA did not correlate with spleen size or any specific somatic mutation, but negatively correlated with somatic mutation burden (<0.03). On univariate regression, SA was associated with inferior PFS (HR: 0.31 [0.13-0.72]; p<0.01) and OS (HR: 0.25 [0.17-0.36]; p<0.01). Four cohorts were created based on SA: cohort I=SA 2.5-3.5 g/dl (n=31); cohort II=SA 3.6-4.0 g/dl (n=98); cohort III=SA 4.1-4.5 g/dl (n=182); and cohort IV=SA>4.5 g/dl (n=84). OS increased with increasing SA with median OS in (in months) of 9.34, 25.3, 48.4, and undefined in cohorts I-IV, respectively. On focused comparison, each cohort was significantly different than all others. On multivariate analysis, the influence of SA on OS remained significant after controlling for prognostic scoring (IPSS, DIPSS, DIPSS+) and comorbidities. For PNA/N, SA remained significant when controlling for IPSS and DIPSS (p<0.05). On univariate analysis, the influence of SA on OS remained significant after controlling for prognostic scoring (IPSS, DIPSS, DIPSS+) and comorbidities. SA was positively correlated with inferior PFS (<0.01) and OS (<0.01). Multivariate analysis was performed on a cohort of patients with available molecular data (n=138). SA significantly influenced OS after controlling for prognostic systems, comorbidities and mutations of SRSF2 and ASXL1. Lastly, its independent prognostic value incorporated into pre-existing prognostic models increased the accuracy of prediction. Its incorporation into known prognostic scoring systems provides an improved ability to accurately capture low and high-risk subgroups.

Summary/Conclusions: SA level is independently prognostic in MF and correlates with variables known to hold prognostic value. Its representation of nutritional indices, inflammation, and comorbidities imbues it with special status in predicting outcome. Its incorporation into known prognostic scoring systems provides an improved ability to accurately capture low and high-risk subgroups.

E1324

CLINICAL UTILITY OF NEXT-GENERATION SEQUENCING IN THE MANAGEMENT OF MYELOPROLIFERATIVE NEOPLASMS

1MPN program, Princess Margaret Cancer Centre, 2Hematology- Princess Margaret Cancer Centre, 3Advanced Molecular Diagnostics Laboratory, Princess Margaret Cancer Centre, 4Applied Molecular Oncology, Ontario Cancer Institute, University Health Network, Toronto, Canada, 5Division of Hematology, Department of Medicine, Brigham and Women’s Hospital, Boston, MA, United States, 6Department of Hematopathology, Toronto General Hospital, 7Molecular Diagnostics, Department of Pathobiology and Laboratory Medicine, University Health Network, University of Toronto, Toronto, Canada

Background: Although Next Generation Sequencing (NGS) has helped characterize the complex genomic landscape of myeloid malignancies, its clinical utility remains not well defined. Funding for NGS testing by healthcare systems or third party payers is variable due to the lack of data on its utility in a routine care setting. At our centre, targeted sequencing (TAR-seq) is offered to all new patients referred for myeloid malignancies as part of the Advanced Genomics in Leukemia (AGILE) program.

Aims: In this study, we evaluate the impact of TAR-seq on the management of patients with a diagnosis of MPN or post-MPN acute myeloid leukaemia (MPN/AML).

Methods: All consenting patients referred to the MPN program at the Princess Margaret Cancer Centre between February 2015 and December 2016 with a suspected or confirmed diagnosis of MPN were evaluated (n=188). TAR-seq was performed on DNA extracted from peripheral blood (n=159, 85%) or bone marrow (n=29, 15%) using the TruSight Myeloid Sequencing Panel (Illumina), a targeted NGS panel of 54 genes (39 hotspot region; 15 complete coding region coverage) implicated in myeloid malignancies. Repertoire was limited to high quality exon nonsynonymous, intrinsic splice site, frameshift, nonsense and known pathogenic synonymous variants. Variants with global mean allele frequency >1% were identified using multiple population databases (1000 genomes, ESP, ExAC) and excluded. Each patient’s TAR-seq results were reviewed alongside their clinical information systematically by at least two hematologists with expertise in MPN, and disagreements were resolved by consensus.

Results: 179 patients fulfilled the WHO diagnostic criteria for MPN: 107 were diagnosed with myelofibrosis (MF), 26 with polycythemia vera (PV), 21 with essential thrombocytosis (ET), 11 with other MPN, 15 with unclassifiable and 12 with MPN/AML. In 6 patients with ‘triple negative’ MPN, who lacked mutations in the driver genes JAK2, CALR or MPL, TAR-seq confirmed clonal hematopoiesis through identifying other mutations. In 61 transplant-eligible patients with MF, 32 (52%) were considered to carry a high molecular risk by IPSS (R1) profile based risk scoring at initial presentation in a cohort of 350, EZH2, IDH1/2, SRSF2 or TP53: or a total of three or more mutations. Of these, 11 patients (34%) were considered for early transplant, three with Intermediate-1 and eight with Intermediate-2 risk, who were responding well to JAK 12/2017.
inhibitor (JAKi) therapy. All high-risk, transplant-eligible MF patients were considered for transplantation irrespective of their HMR status. Nine patients with low/intermediate-1 risk MF bearing HMR mutations were considered for a clinical trial of early JAKi therapy, and one patient was successfully enrolled. Seven patients were identified with IDH1/2 mutations (five with MF and two with MPN/AML), and therefore can be potential candidates for enrolment into clinical trials with IDH inhibitors. In PV and ET, TAR-seq identified HMR profiles in 6/26 (23%) and 5/21 (24%) patients, respectively. These patients are monitored closely, but no therapeutic decisions were taken based on their HMR profile. In MPN/AML, TP53 mutations were detected in 4/12 (33%) patients. However, these patients progressed rapidly before their TAR-seq results became available to inform clinical management.

Summary/Conclusions: We have determined that TAR-seq improves the characterization of triple negative MPN patients, refines risk stratification and decisions related to the timing of transplant in MF, and can potentially identify candidates for future targeted therapies. Therefore, we suggest that NGS should be a part of the standard of care in MF, and in the investigation of triple negative MPN. Based on these findings and in conjunction with ongoing studies in the MPN program, an algorithm integrating NGS in the management of MF has been developed, and will be evaluated prospectively.

E1325
IMPACT OF COMORBIDITIES AND BODY MASS INDEX ON SURVIVAL IN PATIENTS WITH MYELOFIBROSIS TREATED WITH RUXOLITINIB
1Department of Hematology, University of Bologna, Bologna, 2Division of Hematology and BMT, Azienda Santaria Universitaria Integrata di Udine, Udine, 3Department of Hematology, University of Verona, Verona, 4Division of Hematology and Oncology, Ospedale Ferrarotto, University of Catania, Catania, 5Division of Hematology, Azienda Ospedaliero-IRCCS Arcispedale Santa Maria Nuova, Reggio Emilia, 6Unit of Blood Diseases and Stem Cell Transplantation, ASST Spedali Civili di Brescia, Brescia, 7Division of Hematology, IRCCS AOU San Martino IST, Genova, 8Division of Hematology, University of Ferrara, Ferrara, 9Hematology and Stem Cell Transplant Center, AORN Hospital, Pesaro, 10Hematology and Clinical Immunology Unit, University of Padova, Padova, 11Department of Cellular Biotechnologies and Hematology, University Sapienza, Roma, 12Division of Hematology, ASST Spedali Civili di Brescia, Brescia, 13Division of Hematology, Azienda Ospedaliero-Universitaria di Parma, Parma, 14Division of Hematology, Placenza, 15Division of Hematology, Casa Sollievo Sofferenza, San Giovanni Rotondo, 16U.O.S. Ematologia, Ospedale Nuovo Regina Margherita, Roma, Italy

Background: Charlson Comorbidity Index (CCI) and body mass index (BMI) are significantly associated with outcome in patients (pts) who receive continue treatment with tyrosine kinase inhibitors. Ruxolitinib (RUX) is the first JAK1/2 inhibitor that may induce spleen/symptom responses and improve quality of life in pts with myelofibrosis (MF). No data are yet available on the impact of comorbidities and BMI on pts treated with RUX.

Aims: To evaluate the impact of CCI and BMI on overall survival (OS) in a cohort of RUX-treated MF pts.

Methods: A multicenter observational study on WHO-defined MF treated with RUX according to standard clinical practice was conducted in 20 Italian Hematology Centers. Response to RUX was evaluated according to 2013 IWG-MRT criteria. OS was calculated from the date of RUX start to the time of death or last follow-up. Baseline parameters evaluated for correlation with OS were: blood cell count, spleen ≥10cm, marrow fibrosis grading, time from MF diagnosis to RUX start, transfusion dependency, mutation status, Total Symptom Score (TSS), CCI and BMI.

Results: Between June 2011 and Apr 2016, 343 pts with PMF (51.9%), or post-ET (20.1%) / post-PV (28.0%) were treated with RUX in participating Centers. At RUX start, median age was 67.5 years (range 35.6-89.0) with a male prevalence (57.1%); International Prognostic Score System (IPSS) was intermed evaluable-1 (16.0%), intm-2 (47.5%), high (36.4%). Transfusion dependency and spleen enlargement were present in 23.9% and 97.4% of pts, respectively (62.4% with spleen ≥10 cm). TSS was <20 in 131 pts (38.2%); 62 (18.1%) pts had a BMI<21 (corresponding to lower quartile). CCI was 0 in 105 pts (30.6%), one in 74 pts (21.6%), two in 58 pts (16.9%) and ≥ 3 in 106 pts (30.9%). Median RUX exposure was 21.2 months (3-56.2). In multivariable Cox regression analysis, factors negatively correlating with OS from RUX start were: transfusion dependency (HR: 2.65; p<0.001), CCI ≥3 (HR: 1.67; p<0.001), BMI<21 (HR: 1.74; p=0.039), and IPSS (intm-2: HR: 3.19; p=0.057, high risk: HR: 6.8; p<0.001). CCI ≥3 was an independent predictor of OS (p=0.001). Scoring values were assigned to OS at 3 years was 91.8%, 65.6% and 34.8% in group 1, 2 and 3, respectively (log rank p<0.001) for a median OS of undefined, 66.7 and 22.8 months. Notably, while 88.7% of high IPSS risk pts clustered in group3, only 60.5% of pts in group1 were at intm-2 IPSS risk, and 48.6% of pts in group2 were at high IPSS risk. The achievement of a spleen response at 6 months (39.2% vs 36.4%, p=0.71) was not influenced by lower BMI. However, pts achieving a spleen response at 6 months had significantly increased OS (Fig. 1A). Also, a higher CCI did not correlate with lower spleen response at 6 months (44% vs 34% of pts with CCI<3, p=0.11). The impact of higher CCI on survival was only mildly affected by the achievement of a spleen response at 6 months (Fig. 1B).

Figure 1.

Summary/Conclusions: Together with transfusion requirement, CCI and BMI may influence survival in RUX-treated MF pts. Taking into account these additional parameters may allow to better define survival probability beyond IPSS risk assessment. Unfavorable CCI and BMI did not hamper responses to RUX; also, the achievement of a spleen response counterbalanced the negative prognostic effects of a lower BMI.

E1326
ANALYSES OF 845 PATIENTS WITH PMF, PET-MF AND PPV-MF TREATED IN 35 GERMAN HEMATOLOGY CENTERS – A RETROSPECTIVE FIELD STUDY
B. Kragl1,*, C. Wassenberg2, H. T. Steinitz2, G. Springer1, K. Jentsch-Ullrich3, A. Gaumann4, J. Dengler1, C. Junghanss1
1Department of internal medicine 3, Hematology, Oncology, Palliative Care, University Hospital Rostock, Rostock, 2Gefos Dortmund mbH, Dortmund, 3Gemeinschaftspraxis für Onkologie und Hämatologie, Köln, 4Hämato-Onkologische Schwunpraxis, Stuttgart, 5Schwerpunktpraxis für Hämatologie und Onkologie, Magdeburg, 6Institut für Pathologie, Kaubeuren, 7Schwerpunktpraxis Onkologie, Heilbronn, Germany

Background: Primary myelofibrosis (PMF) as well as secondary post essential thrombocytethemia (pET)-MF and post polycythemia vera (pPV)-MF are considered rare diseases associated with significant morbidity. Diagnostics and therapeutic options have significantly improved during the last decade by development of novel drugs, improvement of allogeneic stem cell transplantation (SCT) procedures and supportive care. Whereas the characteristics of PMF, pET-MF and pPV-MF patients (pts) participating in clinical trials are well analyzed, data are rare for the general MF population including patients not included in or eligible for clinical trials.

Aims: In order to gain a broader, more comprehensive data set on the general MF population we performed a questionnaire poll in 35 German hematology centers gathering characteristics on 845 pts who were currently under care.

Methods: A questionnaire asking for general patient and disease specific data as symptoms, past/current treatment and blood count, degree of MF in bone marrow and transfusion frequency was designed. It was distributed to participating centers (n=35, mostly private offices) throughout Germany and analyzed centrally. Time period of collection

544 | haematologica | 2017; 102(s2)
was 03/2013-12/2015. 845 pts were included i.e. a median of 20 pts (range 6–90 pts) per center

Results: Gender was equally distributed (50%/50%). Pts ages at initial diagnosis as were as follows:<50 years (y) (11%), 50–69y (19%), 70+1y (31%), and >70y (40%). Current age was >65y in 70% of all pts. PMF represented the largest MF cohort (77%), followed by MP-MF (10%), PV-MF (9%) and unspecified (6%). Most pts (92%) had disease <5 years (29% 1–5 years; 1% <1y (15%); unknown (1%). Key current blood values at time of diagnosis included abnormal thrombocyte counts (<500GPT/L; 60%); <100GPT/L (10%); ≥450GPT/L (28%) and elevated WBC >25.000/μl (11%). Presence of circulating blasts in the peripheral blood was documented in 11% of pts. Hemoglobin (g/dL) was ≥10 (68%), 8–10 (21%), <8 (8%), unknown for 3% of the pts. Constitutional symptoms were present in 20% of the pts. Common symptoms included splenomegaly (60%), decreased fitness (41%) and weight loss (16%). Pruritus was present in 5% and night sweats in 9% of all pts. An individual Dynamic Prognostic Scoring System (DIPSS) score was calculable in 495 pts: 19% low risk, 52% intermediate-1, 20% intermediate-2 and 5% high risk disease. Concomitant ischaemic diseases were common, most often cardiac (56%). Most common medical treatments included cytostatic (37%), anticoagulation (25%), JAK-inhibitors (23%) and none (24%). Non-medical treatments were rare: stem cell transplantation (3%), splenectomy (2%) and spleen irradiation (3%). Only 31% of all pts received red blood cell transfusions, however 7% had received >90 units.

Summary/Conclusions: Daily practice MF pts share several characteristics with MF trial cohorts (e.g. COMFORT). As expected the diseases were not as progressed as in the trials. Interestingly gender was equally distributed in our study. SCT was a rarely used treatment within this cohort whereas JAK2 inhibitors were frequently used.

**Figure 1.**

Summary/Conclusions: We have found elevated of blood and endothelial cell activation markers at baseline in Ph-MPN. Cytoreductive and antiaggregatory therapy reduced the mean level of Le-Plt aggregates and concentration of soluble selectins. In subset of pts with thrombosis, therapy led to normalization of Le-Plt aggregate levels, with incompletely normalized soluble selectin levels. Even with normal Le-Plt aggregates, observed elevated selectin levels can explain persistent thrombotic risk due to intrinsic changes in relationship between blood and endothelial cells as a part of biology of Ph-MPN itself.

HEAT SHOCK PROTEIN 27 EXPRESSION IS INCREASED IN PATIENTS WITH PRIMARY AND SECONDARY MYELOFIBROSIS AND MAY BE AFFECTING THEIR SURVIVAL

1Hematology department, 2Clinical Institute of Laboratory Diagnosis, Division of Molecular Diagnosis and Genetics, 3Department of Clinical Cytology and Cytometry, 4Pathology department, University Hospital Dubrava, Zagreb, Croatia

Background: Increased heat shock protein 27 (HSP27/HSPB1) expression and phosphorylation were observed in a large number of neoplastic diseases and they have mostly been associated with aggressive disease features and poor prognosis. There are only few reports investigating HSP27 in primary myelofibrosis (PMF), a myeloproliferative neoplasm characterized by high inflammatory state reflecting in debilitating clinical symptoms.

Aims: To analyze HSPB1 mRNA expression in patients with PMF and secondary myelofibrosis (SMF) and to correlate it with clinical and hematological features.

Methods: We analyzed HSPB1 relative expression in bone marrow aspirates of 26 patients with PMF, four patients with SMF and 13 controls using quantitative real time polymerase chain reaction (RT-PCR). Spleen size was assessed by palpation. Association with overall survival was analyzed in 27 PMF and SMF patients evaluated at the time of diagnosis. The Kusak-Walls one way analysis of variance, The Mann Whitney U test, the Chi squared test, and Spearman rank correlation, the log-rank test and the Cox regression analysis were used, cut-off point for survival analyses was determined using the ROC curve analysis.

Results: Relative expression of HSPB1 differed significantly between diagnoses (P=0.001); it was significantly higher in patients with PMF and SMF than in control group (P=0.05 for both comparisons), but did not differ between PMF and SMF patients (non significant). Increased expression was associated with increase in the spleen size (P=0.009) and JAK2 V617F mutation (P=0.073). We did not detect significant associations with other disease specific features. Lower HSPB1 expression was associated with inferior overall survival in both univariate (HR 3.2; P=0.04) and multivariate analysis (HR 6.12; P=0.034) where effect was independent of age (non significant), gender (non significant) and the International Prognostic Scoring System (IPSS) score (HR 3.31; P=0.033).

E1330

NON-DRIVER MUTATIONS IDENTIFIED BY A 190-GENE NEXT GENERATION SEQUENCING PANEL IN PATIENTS WITH PRIMARY MYELOFIBROSIS AND POST-POLYCYTHAEMIC/ESSENTIAL THROMOCYTHAEMIA

B. Li1, Z. Xu1, T. Qian1, Y. Zhang1, J. Liu1, Z. Xiao1

1MDS and MPN Centre, Institute of Hematology and Blood Diseases Hospital Chinese Academy of Medical Sciences, Tianjin, China

Background: It is a consensus that the driver mutation is an independent prognostic factor in PMFs. Moreover, some non-driver mutations are found associated with initiation, progression and prognosis in PMFs. However, a recent study from the AGIMM (AIRC- Gruppo Italiano Malattie Mieloproliferative) group showed that the type of driver mutation did not influence prognosis in post-PV/ET MF. These observations proved that there were indeed some differences in these two types of MF.

Aims: The aim of current study was to describe the non-driver mutation landscape and the molecular differences between the patients with PMF and those with post-PV/ET MF.

Methods: Targeted gene sequencing was carried out at diagnosis. We sequenced 190 genes across 62 patients, resulting in 229 high-confidence mutation. The average gene coverage was 99%. The average read depth was 540×. Also, 92% of targeted regions were covered with >20×. Every mutation identified in this study was then compared against these expected patterns and categorized into “oncogenic,” “possible oncogenic variants,” or “unknown significance”. Using copy number-adjusted VAF, we reconstructed the clonal architecture to establish whether a mutant gene was an ancestral or subclonal mutation. According to the statistically differences in VAF among gene mutations, subjects were classified as two different clonal architecture, namely clone+subclone(s) (P<0.05) or clonal.

Results: In PMFs, 42 (93.3%) patients had at least one non-driver mutation. Within the 17 patients lacking the driver mutations in JAK2/V617F/Exon 12, MPLW515 and CALR, 2 had mutant genes (SH2B3 and PIAS3) involving in JAK-STAT pathway, 13 had mutations in other genes and 2 had no mutations. In Post-MFs, non-driver mutations were detected in 16 (94.1%) patients. There are no differences in the median number of non-driver mutations in PMFs vs. post-PV/ET MFs (3 vs. 3.18; P=0.085) and PMF patients with vs. without driver mutations (3 vs. 3.18; P=0.688). In PMFs, 12 non-driver genes were mutated in >5% of patients, namely ASXL1 33.3%, U2AF1 22.2%, TET2 15.6%, FAT1 15.6%, SETBP1 13.3%, SRSF2 8.9%, CUX1 8.9%, EP300 8.9%, FAT2 6.7%, NOTCH3 6.7%, EZH2 6.7%, and GATA3 6.7%. In post-PV/ET MFs, ASXL1 (41.2%) was the most frequent mutation, followed by TET2 (29.4%), U2AF1 and SRSF2 mutations were significantly more frequent in PMF than in post-PV/ET MF. Moreover, SETBP1 and FAT1 were mutated in PMF more often and not mutated in post-PV/ET MF. Figure 1 A-C show 3 illustrative patients. Clonal architecture was significantly different between PMFs and post-PV/ET MFs (Figure 1D). About 50% PMF patients were classified as clonal, however, most (87.5%) post-PV/ET MF patients were clone+subclone(s). In PMFs, driver mutation was an ancestral mutation with other non-driver mutations in 14 (31.1%) subjects as 2015-R02413 in Figure 1A. Moreover, driver mutation even was a subclonal mutation in 9 (16.7%) subjects as 2015-R02406 in Figure 1B.
ERITHROPOIESIS STIMULATING AGENTS CAN IMPROVE ANEMIA IN PATIENTS WITH MYELOFIBROSIS TREATED WITH RUXOLITINIB

E. Crisà,1,2 C. Danielia,3 E.M. Ellia,2 E. Beggia,1 C. Frairia,4 M. Carronia1,5 G. Lanzaronia,5 M. Marchettia,5 M. Mezzabottab,5 M. Boccadoroa,1 D. Ferreria,1

Background: Anemia is common in patients with myelofibrosis (MF) and it is one of the main causes of symptoms in this setting. Erythropoiesis stimulating agents (ESA) have been used in MF but mostly small series and no randomized trials have been published so far. Anemia response rate ranged between 23 and 60% in different reports (Cervantes et al. BJH 2004; Cervantes et al. BJH 2006; Tsiara et al., Acta Haematologica 2007) and a larger study recently published by Cervantes et al. in 2016 (Cervantes F et al. Blood 2016) showed a response rate of 50%. Ruxolitinib is currently approved for the treatment of intermediate 2 or high DIPSS/IPS risk MF and it is highly effective in reducing spleen size and controlling the symptoms of MF, thus resulting in a marked improvement in the patients' quality of life (Verstovsek et al. S. NEJM 2012; Harrison C. et al. NEJM 2012) and possibly a prolonged survival (Cervantes F et al. Blood 2016). However, one of ruxolitinib main side effects is anemia, which occurs in 40% of the patients and can be a limiting factor for treatment tolerability and thus compliance and optimal dosage, mostly in the first weeks of treatment.

Aims: To evaluate the efficacy and safety of combination therapy with ruxolitinib and ESA.

Methods: We retrospectively evaluated 32 patients who received concomitant therapy with ruxolitinib and ESA. ESA (epoetin alpha or zeta or darbepoetin) were given off-label after obtaining patient written consent and local pharmacy approval. Erythroid response was defined as transfusion independence with normal haemoglobin (HB), transfusion decrease of >50% or sustained HB increase of >2g/dl, partial response as a sustained HB increase of 1-2g/dl.

Results: We included 32 patients diagnosed with MF, 23,1% primary,34,6% secondary to PV and 42,3% to TE. 20 patients (62,5%) were male and median age at ESA start was 70 years (range 41-80). 87% of patients were at intermediate 2 and 13% at high risk according to DIPSS. Fifty-nine% of patients received epoetin alpha, 28% darbepoetin and 13% epoetin zeta. Median dose for epoetin alpha/zeta was 40000 U/week and for darbepoetin 150 mcg/week. Seven patients had started ESA treatment before ruxolitinib therapy, whereas 25 patients received epoetin after ruxolitinib start for persisting or worsening of anemia. In particular, 5 were already RCA transfusion dependent before commencing ruxolitinib while 13 patients required red blood cell (RBC) transfusions only after treatment start. Overall ruxolitinib treatment worsened anemia leading to RBC transfusion requirement in 52% of patients. Median time to response and median ESA start was 8.5 months (range 2.5-10). ESA dose was reduced in 31 patients (96.9%) and ESA was stopped in 1 patient (3,1%) due to RCA transfusion dependent. Median basal endogenous erythropoietin level was 58 U/I (range 8-146 U/I). Overall response rate was 87,6%, with 68,8% of erythroid response and 18,8% of partial response. Median time to response and median baseline TSS, a 3-level grouping factor for GH/QOL change (deterioration vs stable vs improvement), and an interaction term between baseline TSS and the GH/QOL grouping factor.

Results: 301 patients randomized to ruxolitinib [N=149] or placebo [N=152] completed TSS at baseline (45% female, median age 68 [range 40-91]). Median baseline TSS was 16.6 (range 0 to 52.7). Pooled SD at baseline and week 24 in TSS was 11.4 and 11.6, respectively, resulting in estimated meaningful changes of 3.8-5.8 points. For change and percentage change from baseline at week 24 in TSS, the pooled SDs were 9.8 and 75%, respectively, resulting in estimated meaningful changes of 3.3-4.9 points or 25%-38%. Among patients with TSS and QLG-C30 data at baseline and week 24, 51 (23%) patients had deterioration, 81 (47%) were stable and 110 (50%) had improvement based on QLG-C30 GH/QOL changes. Mean (95% CI) changes in TSS for the three groups were 0.8 (-2.5 to 4.2), -1.4 (-3.6 to 0.8), and -6.8 (-9.0 to 4.6), and for percent changes 20% (-6% to 46%), 17% (-11% to 44%) and -34% (-45% to -22%). ANCOVA revealed that baseline TSS statistically significantly impacted the predicted change in TSS, estimated mean (95% CI) changes in TSS for the improved group of -20.8 (-26.4 to -15.1), -11.7 (-14.3 to -9.0), and -2.6 (-5.1 to -0.1) for baseline TSS of 50, 30, and 10.

Summary/Conclusions: Distribution- and anchor-based approaches suggest that changes as small as 3-6 points on a 0-60 scale of the MFSAF v2.0 TSS may be meaningful to patients. However, estimates of meaningful change appear to increase in magnitude for higher baseline scores, though in a way that a static percentage change criterion would either require too much change for lower baseline TSS or not enough change for higher baseline TSS. All analyses suggest that some changes in symptoms which do not meet a 50% improvement may still be meaningful to patients.
response duration were 4 and 31 months respectively. 23% of patients lost response after a median time of 16 months. Seventy-five-fold patients responded to ruxolitinib in terms of spleen size, of whom 86.4% also achieved an erythropoietin response to ESA. A spleen increase during ESA treatment in patients responding to ruxolitinib was observed in 2 patients only.

No thrombotic events and no toxicity were reported over treatment with ESA. Success was effective in improving anemia in MF patients treated with ruxolitinib. We observed a high response rate in this patients series without significant toxicities. In particular no thrombotic event e no negative impact on response to ruxolitinib was reported. This results may be partially explained by the selection of patients with endogenous erythropoietin level below 250 U/I, but they could also suggest synergistic activity of ESA and ruxolitinib.

**E1334**

**COMPARING THE SAFETY AND EFFICACY OF RUXOLITINIB (RUX) IN PATIENTS (PTS) WITH DIPSS LOW/INTERMEDIATE-1–, INTERMEDIATE-2–, AND HIGH-RISK MYELOFIBROSIS (MF) IN JUMP, A PHASE 3B, EXPANDED-ACCESS STUDY**

1University of Insubria, Varese, Italy, 2Princess Margaret Cancer Centre, Toronto, Ontario, Canada, 3Azienda Ospedaliera Bianchi-Melacrinic-Morelli, Reggio Calabria, Italy, 4St. Paul's Hospital, University of British Columbia, Vancouver, British Columbia, Canada, 5Federal Almazov Medical Research Center of the Russian Ministry of Health, St. Petersburg, Russian Federation, 6University Hospital of Halle, Halle (Saale), Germany, 7Universidade Federal de Goiania, Goiania, Brazil, 8Ospedale di Circolo e Fondazione Macchi, Varese, Italy, 9Rabin Medical Center, Petah Tikva, Israel, 10Muqel Servert University Hospital and Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Zaragoza, Spain, 11Johannes Wesling Clinic, Minden, Germany, 12Novartis Pharma AG, Basel, Switzerland, 13Novartis Healthcare Pvt. Ltd, Hyderabad, India, 14CRIMM, Center for Research and Innovation of Myelo-proliferative Neoplasms, AOU Careggi, Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy

**Background:** RUX is a potent JAK1/JAK2 inhibitor that led to improvements in splenomegaly and symptoms and increased overall survival in pts with intermediate (Int)-2– and high-risk MF by the International Prognostic Scoring System (IPSS) in the phase 3 COMFORT studies. JUMP is a large, phase 3b, expanded-access trial in countries with no access to RUX outside a clinical trial and includes pts with IPSS Int-1–, Int-2–, and high-risk MF. To further evaluate RUX, we conducted an analysis assessing safety and efficacy of RUX by Dynamic IPSS (DIPSS) prognostic risk.

**Aims:** To compare the safety and efficacy of RUX in pts with DIPSS low/Int-1– vs Int-2– vs high-risk MF

**Methods:** Eligible pts had IPSS high- or Int-2–risk MF, or Int-1–risk MF and a palpable spleen (>9 cm). Starting dose was based on baseline platelet (PLT) count (5mg bid [≥50 to <100×109/L], 15mg bid [100-200×109/L], or 20mg bid [≥200×109/L]) and could be titrated during treatment. The primary endpoint was safety and tolerability of RUX. Changes in palpable spleen length and symptom scores were also assessed. DIPSS scores were determined using pt characteristics at baseline.

**Results:** Based on available pt data, DIPSS status was determined for 1840 of 2233 enrolled pts. JUMP included 893 low/Int-1–, 754 Int-2–, and 193 high-risk pts (primary MF, 57%, 63%, 62%) who started treatment ≥1 y before data cutoff (01 Jan 2016). Pts with higher-risk MF were older (62, 68, and 72 y), had lower Hb (<10 g/dL, 3%, 64%, 100%), and had higher blast counts (≤1%, 18%, 44%, 84.5%). Disease duration (50, 51, and 55 mo) and spleen size (12, 13, and 14.5 cm) were similar in all 3 groups. Most pts started at 20mg bid (68%, 57%, 59%) or 15mg bid (26%, 32%, 33%). Median exposure was 16, 11, and 9 mo; mean average daily dose was 30, 28, and 29mg. At data cutoff, most pts remained on treatment or had completed per protocol (70%, 56%, 45%). Reasons for treatment discontinuation included adverse events (AEs; 15%, 27%, 31%), disease progression (6%, 11%, 11%), and death (2%, 5%, 11%). The most common hematologic grade 3/4 AEs were anemia (22%, 44%, 55%) and thrombocytopenia (11%, 18%, 25%), but these rarely led to discontinuation.

Overall rates of nonhematologic grade 3/4 AEs were ≤2%, except for pneumonia (4.5%), pyrexia (2.3%), asthenia (2.2%), and dyspnea (2.2%). Infections in ≥25% of pts were pneumonia (7.3%), urinary infection (6.1%), and nasopharyngitis (5.3%). Herpes zoster was reported in 4.8% of pts. At wk 48, 64% (226/355), 52% (121/232), and 50% (26/52) of pts had a ≥50% reduction from baseline in spleen length; 19% (68/355), 19% (43/232), and 23% (12/52) had 25%-50% reductions. Best response in spleen length by wk 72 is shown in the **Figure.** 69%, 57%, and 51% of pts achieved ≥50% reductions. Median time to response was 4.7 wk (2.7-75 wk), 5.3 wk (2.6-80 wk), and 8.1 wk (3.1-72.3 wk). From wk 4 to 48, 39%, 43%, 41%, and 44%, and ≥50% of pts achieved a clinically meaningful response on the FACT-Lym TS; proportions of responders on the FACT-Fatigue were 42%-49%, 46%-49%, and 55%-61%.

**Summary/Conclusions:** RUX was safe and generally well tolerated. Interestingly, lower-risk pts received higher starting doses yet had lower rates of hematologic AEs. Additionally, lower-risk pts remained on treatment longer than higher-risk pts, with fewer discontinuations due to AEs. Lower-risk pts also achieved slightly better spleen size reductions and symptom improvement than higher-risk pts, suggesting that earlier RUX treatment may lead to greater benefits in pts with MF.
Methods: In pts with MF.

Aims: Of a subset of JUMP pts provides information on this approach. Up titrating may reduce the risk of cytopenia development. An ad hoc from clinical practice suggests that starting RUX at 10 mg bid and subsequently 200×10^9/L, >200×10^9/L, respectively). Although not per protocol, some pts started RUX at 10mg bid. The primary endpoint was safety. Secondary end points included changes in spleen length and symptoms.

Results: A total of 48 pts (primary MF, 60%) started RUX at 10 mg bid ± 1 y before data cutoff (01 Jan 2016). Mean baseline characteristics were: median age, 65.5 y (range, 20-83 y); male, 44%; spleen length, 12.3 cm; time since diagnosis, 56.6 mo; hemoglobin (Hb), 11.2 g/L (<100 g/L, 33.3%); PLT count, 351×10^9/L (<100×10^9/L, 10.4%). Pt characteristics were similar to those of the overall population and did not indicate an increased risk of developing cytopenias. At data cutoff, most pts remained on treatment or had completed treatment per protocol (58.3%). Primary reasons for treatment discontinuation included adverse events (AEs), disease progression, and death (8.3% each). Overall, 41.7% of pts had dose modifications (AEs, 33.3%); 20.8% had interruptions (all due to AEs). Median exposure was 14.4 mo. The mean average daily dose was 25.8 mg/day (SD, 10.1) and was comparable to those (33.2 and 23.3 mg/day) of patients starting at higher doses (20 and 15 mg bid; all due to AEs). A total of 151 MPN pts under cytoreductive therapy were included (ET, n=55; PV, n=55; MF, n=41). Primary MPN diagnosis was made between 1979 and 2012 at a median age of 55 years (range, 22-82). Mean duration of the disease until baseline of the study was 6.3 years (0-32.6). Median prospective observation time for the total cohort within the study period was 5.3 years (0.4-6.2). Most frequently used cytoreductive drugs were HU in 120 pts, followed by ruxolitinib in 59, anagrelide in 39, and pegylated Interferon-alpha (IFN-a) in 28 pts. Median cumulative HU exposure was 46 months (1-252), while the median cumulative treatment time for the corresponding cytoreductive drug was 24 months (1-267) [ruxolitinib: 22 months (2-64); anagrelide: 19 months (1-216); IFN-a: 64 months (1-267)]. Of 120 pts exposed to HU, 52 pts (43%) presented with skin abnormalities during the observational period occurring after a total HU treatment time of median 46 months (1-252). Sixteen of 120 pts (13%) discontinued HU due to skin toxicity, and 60 pts (50%) experienced significant improvements in symptoms. From wk 4 to 48, 43%-59% and 45%-68% of pts achieved a clinically meaningful response on the FACT-Lym TS and FACIT Fatigue, respectively.

Summary/Conclusions: A small cohort of pts in JUMP started at 10 mg bid, and had the dose uptitrated during the first 8 wks to a mean average daily dose comparable to those of pts starting at higher doses, leading to safety and efficacy outcomes consistent with those in the overall JUMP population. This alternative approach will be prospectively evaluated in anemic MF pts in the REALISE study (NCT02966353).

E1335 HYDROXYUREA IS ASSOCIATED WITH SKIN TOXICITY IN MYELOPROLIFERATIVE NEOPLASMS: RESULTS FROM A PROSPECTIVE NON-INTERVENTIONAL STUDY

F. Stiegemann1,2, K. Wille2, S. Schauer1, H. Döhner1, K. Döhner3, M. Griesshammer2
1University Hospital of Ulm, Ulm, 2University of Bochum, Minden, Germany

Background: Until today, hydroxyurea (HU) remains the most commonly used cytoreductive drug in patients (pts) with classic myeloproliferative neoplasms (MPN), i.e. essential thrombocythemia (ET), polycythemia vera (PV), and myelofibrosis (MF). However, mucosal lesions, cutaneous ulcers, and pre-carcinomatous skin alterations such as actinic keratoses are being considered as potential side effects of HU.

Aims: We sought to investigate the occurrence of skin toxicity in MPN pts under HU compared to other (non-HU) cytoreductive drugs in routine clinical practice.

Methods: Classic MPN pts regularly presenting at the outpatient centers of the University Hospital of Ulm and Johannes Wesling Clinic Minden were included in our non-interventional study after having given informed consent. Skin alterations were evaluated prospectively between December 2010 and November 2016.

Results: In total, 151 MPN pts under cytoreductive therapy were included (ET, n=55; PV, n=55; MF, n=41). Primary MPN diagnosis was made between 1979 and 2012 at a median age of 55 years (range, 22-82). Median duration of the disease until baseline of the study was 6.3 years (0-32.6). Median prospective observation time for the total cohort within the study period was 5.3 years (0.4-6.2). Most frequently used cytoreductive drugs were HU in 120 pts, followed by ruxolitinib in 59, anagrelide in 39, and pegylated Interferon-alpha (IFN-a) in 28 pts. Median cumulative HU exposure was 46 months (1-252), while the median cumulative treatment time for the corresponding cytoreductive drug was 24 months (1-267) [ruxolitinib: 22 months (2-64); anagrelide: 19 months (1-216); IFN-a: 64 months (1-267)]. Of 120 pts exposed to HU, 52 pts (43%) presented with skin abnormalities during the observational period occurring after a total HU treatment time of median 46 months (1-252). Sixteen of 120 pts (13%) discontinued HU due to skin toxicity, and 60 pts (50%) experienced significant improvements in symptoms. From wk 4 to 48, 43%-59% and 45%-68% of pts achieved a clinically meaningful response on the FACT-Lym TS and FACIT Fatigue, respectively.

Summary/Conclusions: A small cohort of pts in JUMP started at 10 mg bid, and had the dose uptitrated during the first 8 wks to a mean average daily dose comparable to those of pts starting at higher doses, leading to safety and efficacy outcomes consistent with those in the overall JUMP population. This alternative approach will be prospectively evaluated in anemic MF pts in the REALISE study (NCT02966353).

E1336 THE NEGATIVE PROGNOSTIC IMPACT OF BASOPHILIA, EOSINOPHILIA AND MONOCYTOSIS AT DIAGNOSIS IN PRIMARY MYELOFIBROSIS

M. Peres-Neto1,2, K. Hunderova2, J. Carda1,2, E. Cortesão1,2, R. Guilherme1,2, L. Ribeiro1,2, A.-B. Sarmento-Ribeiro1,2
1Clinical Hematology Department, Coimbra University Hospital Centre, 2Faculty of Medicine, University of Coimbra, Coimbra, Portugal

Background: Primary myelofibrosis (PMF) is a myeloproliferative neoplasm (MPN) with a variable clinical presentation, from asymptomatic disease to rapidly progressive bone marrow failure and/or leukemic transformation; prognostic stratification using the DIPSS-plus score isolates patient cohorts with median survival ranging from 16 months to 185 months. The development of monocytosis during the course of PMF has been associated with a worse outcome, and absolute monocyte counts have been shown to be of prognostic value in other MPNs. Basophilia and eosinophilia are frequent findings in BCR-ABL-

Figure 1.
positive MPNs, where they associate with an accelerated phase of disease, and seem to correlate with worse survival in myeloid dysplastic syndromes. However, the impact of these three findings at diagnosis in PMF remains unclear.

**Aims:** The aim of this work is to evaluate, at diagnosis, the prognostic impact of basophilia, eosinophilia and monocytosis in patients with PMF.

**Methods:** We identified all PMF patients diagnosed and followed-up in our Center between January 1st 2005 and August 31st 2016 who still fulfilled WHO criteria under the WHO 2016 diagnostic revision, have synchronous bone marrow (BM) and peripheral blood (PB) analyses dating from the time of diagnosis, and have complete charts with no missing data. After the exclusion of reactive causes, monocytosis was defined as an absolute count (AC) >1.5 G/L, eosinophilia as an AC >0.6 G/L and basophilia as an AC >0.2 G/L.

**Results:** We studied 55 evaluable patients (73% male) with a median age at diagnosis of 70.1±11.7 years old. At diagnosis, 20% of patients had monocytosis, with no significant differences according to gender or age. The median overall survival (OS) in PMF patients with monocytosis was 27.3 months, and twice as long (46.4 months) in patients without. In this cohort, a new cut-off of 0.75 G/L was better able to stratify patients according to survival with a specificity of 74.1% (95% CI: 53.7-88.9%); 32.7% of patients had an AC above the cut-off, with a median OS of 27.3 months, compared to 64.4 months for patients under the cut-off. We identified 12.7% of patients with eosinophilia at diagnosis, with no differences according to gender or age. PMF patients with eosinophilia had a five-fold lower median OS compared with patients without (6.1 vs 32.5 months, respectively). We obtained a new cut-off of 0.25 G/L of eosinophils, which separated patients with a specificity of 77.8% (95% CI: 57.7-91.4%); 29.1% of patients had an eosinophil AC above the cut-off, with a median OS of 7.3 months, compared to 43.8 months for patients under the cut-off. A total of 30.9% of patients had basophilia at diagnosis, with no differences according to gender or age. The median OS in patients with basophilia was 25.6 months, and 32.5 months in patients without. With a new cut-off of 0.25 G/L of basophils, with a specificity of 88.9% (95% CI: 70.8-97.64%); 20.0% of patients had a basophil AC above the cut-off and a median OS of 19.7 months, compared to 46.4 months for patients under the cut-off. Considering the whole cohort, 61.8% of patients had normal monocye, eosinophil and basophil ACs; the median OS in these patients was 56.1 months, compared to 28.5 months in patients with an increase in at least one AC. Applying the new cut-off, this difference in OS increased to 79.9 vs 64.4 months. Progression-free survivals were not calculated, since only 2 patients had BM- or PB-documented progression during follow-up.

**Summary/Conclusions:** We observed that the presence of monocytosis at diagnosis in PMF was associated with a halving of the median OS, while eosinophilia decreased the median survival to one-fifth; basophilia also associated with a reduction in survival, of approximately 20%. The application of specific cut-offs calculated for the cohort improved the differentiation and stratification of patients, with moderate to high specificity, further clarifying the negative prognostic impact of these three variables, at diagnosis, in PMF. Our results show that even simple, inexpensive and readily available parameters can be used to predict survival in PMF patients, and suggest that their integration into established scores could further increase the prognostic accuracy of the latter.
TL was determined in peripheral blood mononuclear cells using a monochrome multiplex quantitative PCR based on the original methods described by Cawthon. All results were corrected for age and gender.

Results: Regardless of driver mutation status ET patients had significantly shortened TL compared with age and gender matched controls, p<0.0001. Considering individual mutation status these differences remained significant e.g. JAK2 V617F positive (n=101; p<0.0005), JAK2 V617F negative (n=34/100) and p=0.012 in TN patients. TL appeared more markedly short in the CALR cohort; for the 18 patients, whose TL was below the first centile, 55% (10/18) were CALR positive vs 28% (5/18) JAK2V617F positive vs 17% (3/18) who were TN. Concerning the potential impact of therapies 31/100 patients were treated with hydroxyurea, busulphan or IFN (8 of these had prior exposure to HC). 34/100 were not on cytoreductive therapy. Remaining treatments were ruxolitinib (5), busulphan (4), anagrelide (1) and vorinostat (1). Independent of mutation status there was significant TL shortening in untreated patients, p=0.05; however, upon evaluating the impact of cytoreductive therapy on TL we found that those patients with either current or prior exposure had significantly shortened TL, p=0.0015 and p=0.0001 respectively. Strikingly, there was no significant difference in TL in IFN patients who had no previous exposure to HC, p=0.2 but those ET patients currently on IFN but with prior HC exposure still had shorter TL.

Summary/Conclusions: We document for the first time that ET patients, when compared to age and gender matched healthy controls, have shortened TL. This shortening is more pronounced in CALR and JAK2 V617F positive patients. Concerning therapy whilst present in untreated patients TL shortening was more pronounced in HC treated patients indicating that there may be a therapy effect as has been observed after HC treatment in sickle cell disease. Of note IFN treated patients had more normal TL suggesting that the disease related effects may be reversed by this agent.

NUTRITION IN MYELOFIBROSIS: CORRELATES FROM THE COMFORT-1 STUDY

R. Scherber 1,2,*, H. Kosiorek 3, H. Geyer 4, S. Verstovsek 5, B. Langlais 3, L. Padnos 1, J. Palmer 3, A. Dueck 3, A. Fleischman 6, R. Masa 1 2Hematology and Oncology, Mayo Clinic, Scottsdale; 3Hematology and Oncology, Oregon Health and Science University, Portland; 4Biostatistics, Internal Medicine, Mayo Clinic, Scottsdale; 5Hematology and Oncology, MD Anderson, Houston; 6Hematology and Oncology, University of California Irvine, Irvine, United States

Background: Nutritional status declines in most patients with myelofibrosis (MF). Sixty-seven percent of patients with MF lose weight over time and 27% of patients have a BMI decrease of at least one body mass index (BMI) category (Mesa et al. Blood. 2008;112(11):5224). MF also leads to deficient LDL and cholesterol levels compared to age matched controls (Mesa R A et al. Blood. 2011;70(10):2548). Both hypcholesterolemia (p<0.001) and weight loss>10% (p<0.001) have been associated with decreased survival in PMF patients (Mesa et al. Blood 2009 114:3918). JAK inhibitor therapy has been found to improve nutritional markers including weight, cholesterol, albumin, and leptin compared to placebo in the COMFORT-1 study (Mesa et al. Clin Lymphoma Myeloma Leuk. 2015 Apr; 15(4): 214–221; Verstovsek et al. N Engl J Med 2012; 366:799-807). However, the correlation of these factors with other disease related variables and overall survival has not been established.

Aims: To evaluate the correlation, if any, between nutritional markers other variables collected in the COMFORT-1 study.

Methods: Data from the COMFORT-1 trial of ruxolitinib versus placebo was obtained from the Incyte for independent analysis. Data was analyzed for correlation with symptom burden and survival along with other variables. Symptom burden was assessed by the MF-SAF v2.0 (Mesa et al. Leuk Res 2009) for individual items and total symptom score (TSS).

Results: A total of 309 patients were available for analysis including 155 ruxolitinib and 154 placebo treated patients. At baseline, the average BMI was 24.9 (SD=4.5). Baseline demographic and other disease-related variables can be found in previous publications (Verstovsek et al. N Engl J Med 2012; 366:799-807). Correlatives: Baseline: For all patients at baseline, numerous correlations between baseline nutritional markers and markers of nutrition (Figure 1a) were identified. Total Symptom Scores (TSS) inversely correlated with albumin, cholesterol, alpha-feto protein, HDL, and serum erythropoietin levels. Baseline leptin levels correlated with many items including BMI, albumin, cholesterol, LDL, erythropoietin, insulin and CRP. Placebo: For patients treated with placebo, changes in BMI inversely correlated with changes in CRP (r=-0.22, p=0.001) and most correlations were observed between baseline and final BMI with cholesterol (r=0.87, p<0.001) and HDL (0.41, p=0.001). In addition to LDL, HDL change inversely correlated with TSS score (-0.24, p=0.02), and positively correlated with changes in bone pain (0.23, p=0.02), abdominal fullness (r=0.22, p=0.02), erythropoietin levels (0.27, p=0.01) and cholesterol levels (r=0.39, p=0.01). Ruxolitinib: Most correlations with nutritional and metabolic markers mirrored with baseline scores (Figure 1b). For ruxolitinib-treated patients, changes in JAK2V617F mutation status inversely correlated with changes in serum cholesterol (-0.26, p=0.008), leptin (-0.38, p<0.0001), and LDL (-0.23, p=0.02). CRP changes were inversely correlated with change in cholesterol levels (-0.18, p=0.03).

Figure 1.

Summary/Conclusions: Nutrition decline remains an unmet need for many MF patients. JAK2 inhibition represents a potential source to improve symptom burden in those who qualify for therapy. Leptin closely correlated with many other nutritional values suggesting this may be a good marker of nutritional status in PMF patients. CRP was inversely correlated with BMI, suggesting the importance of inflammation as a contributor to weight loss. Further study into the unique nutritional needs of myelofibrosis patients is warranted.

Background: To evaluate the prognosis of patients with Essential Thrombocytemia (ET) in the first decade of the century we assessed retrospectively the thrombosis free survival (TFS) and the overall survival (OS) of the patients diagnosed from 01/01/2000 to 31/12/2009 and collected on the database of our group.

Aims: Diagnosis of ET was performed with PVSG, WHO 2001 or 2008 criteria, according to the date of the first observation. The whole population of 757 patients was then divided in two groups: the first (group I) with the diagnosis performed between 01/01/2000 to 31/12/2005 (334 patients), presented a median follow-up of 111,9 months, the second (group II) diagnosed between
01/01/2006 to 31/12/2009 (385 patients), with a median follow-up of 58.2 months.

Methods: The characteristics of two groups of patients are reported in the Table 1. No differences could be found between the two groups according age, gender, platelet and WBC count and Hb level. Cardio-Vascular Risk Factors (CVRF), spleen enlargement and the occurrence of previous thrombotic events. The frequency of the JAK-2 V617F mutation resulted significantly different (49.1% vs 68.4%) but in the group I the search of the mutation was never performed at the diagnosis. TFS and OS were calculated from the date of diagnosis of ET to the date of event with Kaplan-Meier product limit method; the comparison of proportions and median values was computed with the Chi-squared and the Mann-Withney tests, as indicated.

Results: No significant differences emerged neither for TFS (p= 0.09, HR 1.42, 95% C.I. 0.89-2.30) nor for OS (p= 0.15, HR 1.34, 95% C.I. 0.87-2.06). We also evaluated the type of treatment used in the two groups to assess the potential link between the therapy and TFS or OS (Table 2). No difference emerged between the two groups as for anti-aggregating (mainly ASA), equally utilized in both groups, 287/369, 77.8%, and 330/383, 78.3%, respectively (p=0.95). As for the cytoreductive therapy, Hydroxyurea was used in 74.8% vs 67.9% (p= 0.60) and alkylating agents in 1.9% vs 2.1% (p= 0.85), whereas the Anagrelide resulted utilized in 10.6% vs 3.9% (p= 0.001) and Interferon in 9.5% vs 5.2% (p= 0.037), respectively. The more frequent use of Anagrelide and Interferon in the first group (2000-2005) didn’t modify the prognosis (as for TFS and OS) of the patients.

Summary/Conclusions: Unfortunately, no improvement, neither as the TFS nor the OS was observed (Fig. 1 and 2): more efforts to better identify the groups at risk and, hopefully, the introduction of new drugs as JAK-2 inhibitors could change the prognosis of ET patients.

CUTANEOUS INVOLVEMENT IN PHILADELPHIA-NEGATIVE MYELOPROLIFERATIVE NEOPLASMS—SINGLE-CENTER EXPERIENCE
J. M. Sanchez-Raga1,2, N. Knöpfle1, M.D.M. Escudero-Góngora3, F. Sartori3, B. Lopez1, I. Herrera2, M.D.C. Ballestre2, M. Torres2, A. Martin-Santiago3, A. Sampol2, M.A. Durán2
1Hematology and Hemothery, Fundación de Investigación Sanitaria de las Islas Baleares Ramon Llull, 2Hematology and Hemothery, 3Dermatology, Hospital Universitari Son Espases, Palma de Mallorca, Spain

Background: Philadelphia-negative chronic myeloproliferative neoplasms (MPNs) may present clinical dermatological manifestations at the time of diagnosis, as well as during the course of the disease. On the other hand, also its treatments can present skin side effects.

Aims: We have performed a dermatological review of a cohort of patients we follow-up at our center with the aim of assessing the cutaneous manifestations.

Methods: A randomized selection of patients with a diagnosis of essential thrombocythemia and polycythemia vera was performed. We create a specific consultation in which a detailed history of each patient (sex, age, diagnosis, signs and symptoms, treatments and its duration) as well as a deep dermatological examination was done. All data was collected in an Excel database and analyzed using the SPSS system.

Results: 63 patients (54 ET and 9 VP) were reviewed. The most frequent skin lesions were xerosis and/or keratosis pilaris (76.2% patients), nail changes (41.3%), acniform keratosis (39.7%), hyperpigmentation of the skin (23.8%), pruritus (23.8%) and non-melanoma skin cancer (22.2%). In figure 1 we detail all the skin alterations that we have found.

Summary/Conclusions: Cutaneous involvement in MPNs is more frequent than expected and it is usually underdiagnosed. Some of these lesions could be prevented with the correct treatment of their pathology and adequate photoprotection measures. The results obtained support the recommendation of an annual review by a dermatologist in a systematic way, especially in patients with higher risk factors: low phototype, high sun exposure, past dermatological history and prolonged cytoreductive therapy.
presentation with thrombocytosis. No central pathology review was planned for this stage of the study.

Results: A total of 122 patients (58 males and 64 females; 54% >60 years of age; 65% with LDH ≥200 mU/mL) with a clinical history indicative of ET were initially assessed. A majority of patients (76%) presented with suspected ET within the last 5 years, likely because it was more difficult for clinicians to identify patients with BM biopsy collected within a year of presentation with thrombocytosis if they presented more than 5 years ago. Out of 122 patients, 48 met the hemoglobin and/or leukocytosis criteria outlined in the Carabbi algorithm. The figure. The BM examination was performed on 33 patients who met pre-defined criteria for the timing of bone marrow biopsy. About one third of the 33 patients did not present in the WHO classification for ET and one third for PMF. While 2 of the remaining patients met criteria for PV, the rest were uncertain whether to represent true ET or early PMF, i.e., represented MPN-U (Figure 1).

Summary/Conclusions: Despite its methodological limitations, this initiative confirms that in real world clinical practice the Carabbi algorithm can be used to further discriminate early PMF and early idiopathic myelofibrosis from other clinically suspected to have ET. It suggests a need for educational initiatives on using diagnostic algorithms to separate ET from PMF. It confirms the importance of hematologist-pathologist collaboration in reaching a final integrated diagnosis based on the WHO classification. These findings warrant investigation in larger prospective studies.

PK/PD MODELING COMPARING DIVIDED DOSING (200mg TWICE-DAILY [BID]) VS SINGLE DOSING (400mg ONCE-DAILY [QD]) OF PACRITINIB (PAC) IN PATIENTS WITH MYELOFIBROSIS (MF) ON THE PERSIST-2 PHASE 3 TRIAL

1CTI BioPharma Corp., Seattle, WA, 2Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY, 3University of Michigan, Comprehensive Cancer Center, Ann Arbor, MI, 4Cleveland Clinic, Cleveland, OH, 5Northwestern University, Feinberg School of Medicine, Chicago, IL, United States, 6Princess Margaret Cancer Center, University of Toronto, Ontario, Canada, 7Alpert Medical School of Brown University, Providence, RI, United States, 8Beatosent of West Scotland Cancer Centre, Glasgow, United Kingdom, 9Razyan's Clinical Hospital, Razyan, Russian Federation, 10Stanford Cancer Institute, Stanford, CA, 11University of California-San Diego, La Jolla, CA, United States, 12Guy’s and St Thomas’ NHS Foundation Trust, London, United Kingdom, 13Mayo Clinic, Scottsdale, AZ, 14MD Anderson Cancer Center, Houston, TX, United States

Background: MF is a life-threatening hematologic malignancy characterized by splenomegaly and debilitating constitutional symptoms. At the present, the JAK inhibitor ruxolitinib is the only therapy for patients (pts) with MF who have failed corticosteroids and/or splenectomy. PAC, a new oral inhibitor of JAK1/2/3, appears to translate into an improved benefit/risk profile of PAC BID regimens in pts with MF from the PERSIST-2 trial. These differences appear to translate into an improved benefit/risk profile of PAC vs QD regimens.

E1344
ZMYM2-F3LT3 IS A RARE, RECURRENT, CYTOGENICALLY CRITICAL FUSION IN MYELOID/LYMPHID NEOPLASMS WITH EOSINOPHILIA THAT IS RESPONSIVE TO FLT3 INHIBITION

1CTI BioPharma Corp., Seattle, WA, 2Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY, 3University of Michigan, Comprehensive Cancer Center, Ann Arbor, MI, 4Cleveland Clinic, Cleveland, OH, 5Northwestern University, Feinberg School of Medicine, Chicago, IL, United States, 6Princess Margaret Cancer Center, University of Toronto, Ontario, Canada, 7Alpert Medical School of Brown University, Providence, RI, United States, 8Beatosent of West Scotland Cancer Centre, Glasgow, United Kingdom, 9Razyan's Clinical Hospital, Razyan, Russian Federation, 10Stanford Cancer Institute, Stanford, CA, 11University of California-San Diego, La Jolla, CA, United States, 12Guy’s and St Thomas’ NHS Foundation Trust, London, United Kingdom, 13Mayo Clinic, Scottsdale, AZ, 14MD Anderson Cancer Center, Houston, TX, United States

Background: Myeloid/lymphoid neoplasms with eosinophilia are characterised by diverse tyrosine kinase (TK) fusion genes, many of which can be effectively targeted by small molecule inhibitors. More than 70 TK fusions have been described, most of which are associated with visible cytogenetic abnormalities. However these fusions are rare, and the pathogenesis of the great majority of patients presenting as myeloproliferative neoplasm with eosinophilia (MPN-eo) remains unexplained. We hypothesized that some MPN-eo cases may be driven by hitherto undetected cryptic TK fusion genes.

Aims: To screen cases with MPN-eo for TK fusion genes and evaluate the significance of any novel fusions

Methods: PolYA RNA extraction from MPN-eo cases, RNA-Seq library prepa-

Summary/Conclusions: As predicted by PK modeling and simulations analy-

Results: Of 20 cases tested by RNAseq analysis, just one cryptic TK fusion was identified: ZMYM2-F3LT3, predicted to arise as a consequence of an 8Mb inversion at 13q12. Unusually, both breakpoints fell within exons (ZMYM2 exon 20 and FLT3 exon 14, respectively) resulting in an in frame fusion. To test whether this might be recurrent, we analysed 105 additional cases by RT-PCR. One additional positive case was detected, with similar but not identical breakpoints to the initial case. Case 1, a 48 year old female, presented with leucocytosis (30x10⁹/L), eosinophilia (2x10⁹/L), elevated serum tryptase (37µg/l), splenomegaly and a hypercellular bone marrow (BM). Cyto- genetics was normal and FIP1L1-PDGFRα, KIT D816V and JAK2 V617F were all negative and no pathogenetically relevant mutations were identified by a myeloid NGS panel (28 genes). After 10 months, she progressed to myeloid blast phase. Because the disease was resistant to AML-induction chemotherapy (FLAG-Ida), an alloge- nic PBSCT from an unrelated donor was performed 13 months after diag- nosis. As a consequence of chronic GvHD and septic shock, the patient died 6 months after allogeneic PBSCT. The ZMYM2-F3LT3 fusion gene was identified post mortem. Case 2, a 47 year old male, presented with eosinophilia (4.7x10⁹/L, 47%) elevated serum tryptase (42µg/l) and a hypercellular BM Cyto- genetics was normal and FIP1L1-PDGFRα, KIT D816V and JAK2 V617F were all negative. There was no response on steroids or hydroxyurea. Following the finding of ZMYM2-F3LT3 positivity, treatment with sunitinib was commenced. Blood counts started to improve from day 4 and normalized after 3 weeks. Dur- ing a pause of 3 weeks due to pulmonary infection, leucocytes/eosinophils rap- idly increased, but no PCR recurrence was detected within weeks after restart of sunitinib. The patient has been maintained on sunitinib for 10 months (since re-start) and remains in complete hematologic remission.

Summary/Conclusions: ZMYM2 is the fourth gene reported to fuse to FLT3 in myeloid neoplasms but the first FLT3 fusion that is cytogenetically cryptic. Mechanistic studies of ZMYM2-F3LT3 may be amenable to treatment with FLT3 inhibitors and thus, although very rare, this fusion should be considered in the work up of MPN-eo cases. Due to their extensive diversity, we anticipate that RNAseq will become the method of choice to detect rare TK fusions.
E1345 COMPLETE HEMATOLOGIC AND CYTOTOGENETIC RESPONSE IN A PATIENT WITH FIBROBLAST GROWTH FACTOR RECEPTOR 1 ACTIVATED MYELOPROLIFERATIVE NEOPASMS RECEIVING INCBO54828 N. J. How, 1 J. E. Spruit, 1 E. 1Department of Haematology, Zealand University Hospital, University of Copenhagen, Copenhagen, 2Department of Clinical Epidemiology, Bispebjerg and Frederiksborg Hospital, University of Copenhagen, 3Department of Occupational and Environmental Medicine, Bispebjerg Hospital, University of Copenhagen, Copenhagen, 4Danish Knowledge Centre for Rehabilitation and Palliative care, University of Southern Denmark and Odense University Hospital, Odense, 5National Institute of Public Health, University of Southern Denmark, Copenhagen, 6Department of Clinical Epidemiology, Aarhus University Hospital, Aarhus, Denmark

Background: Study reveals that patients with inflammatory bowel disease (IBD) may have increased risk of haematological cancers. Moreover, Philadelphia negative chronic myeloproliferative neoplasms (MPNs) have previously been associated with autoimmune diseases, including IBD. Nevertheless, to our knowledge, the risk of IBD has not been investigated in patients with MPN.

Aims: We undertook a nationwide population-based matched cohort study, and estimated the risk of IBD in patients with MPN.

Methods: We used valid Danish national registries, covering more than 5 million inhabitants, and included all patients diagnosed with either essential thrombocythemia (ET), polycythemia vera (PV), myelofibrosis (MF), or unclassifiable myeloproliferative neoplasm (MPN-U) between 1994 and 2013. For each patient, 10 individually age- and sex-matched comparisons were included. Patients and comparisons were followed until first occurrence of any IBD diagnosis (ulcerative colitis or Crohn’s disease), death, emigration or end of 2013. The risk was only calculated if five or more individuals were diagnosed with IBD during the study period; including 37 ET patients, 28 PV patients, 1 MF patient and 14 MPN-U patients. During a total risk time of 45,241 years, the rate of IBD per 1000 person years at risk was 1.8 (95% confidence interval [95% CI]: 1.4-2.2) for the MPN patients. The corresponding rate for the 81,326 comparisons was 1.8 (95% CI: 1.7-2.0). The 10-year risks of IBD for MPN patients and comparisons were 0.8% (95% CI: 0.6-1.0) and 0.4% (95% CI: 0.4-0.5), respectively. The overall HR of IBD was 2.4 (95% CI: 2.1-2.9) for MPN patients, with HRs of 2.6 (95% CI: 2.1-3.2) for ulcerative colitis and 2.4 (95% CI: 1.7-3.4) for Crohn’s disease. The risk of IBD was increased 2 to 3 fold among ET, PV and MPN-U patients, with HRs of 2.8 (95% CI: 2.1-3.7) for ET patients, 2.1 (95% CI: 1.6-2.7) for PV patients and 2.2 (95% CI: 1.3-3.7) for MPN-U patients.

Summary/Conclusions: Patients with MPN are at increased risk of IBD compared to the general population. The absolute risks of IBD are low, but abdominal discomfort may in few patients be caused by underlying IBD.

E1346 THE GRADE OF STROMAL CHANGES IMPACTS ON PROGNOSIS IN PATIENTS WITH PRIMARY MYELOFIBROSIS U. Gianelli, 1 S. Fiori, 1 D. Cattaneo, 2 A. Bossi, 3 I. Cortinovis, 3 C. Bucelli, 3 N. Orofino, 2 A. Iurlo 2
1Division of Pathology, IRCCS Ca’ Granda - Maggiore Policlinico Hospital Foundation and University of Milan, 2Oncohematology Division, IRCCS Ca’ Granda Maggiore Policlinico Hospital Foundation, 3Department of Clinical Sciences and Community Health, University of Milan, Milano, Italy

Background: Recently, a detailed grading system for the assessment of bone marrow stromal changes has been proposed in primary myelofibrosis, proved to be reproducible and adopted by the updated WHO 2016 classification.

Aims: In this study, we aim to evaluate any possible prognostic implications of this grading system in a series of patients with primary myelofibrosis.

Methods: The study involved 122 consecutive patients with primary myelofibrosis diagnosed between 1998 and 2015 at the Oncohematology Division of the Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico of Milan, for whom a bone marrow trephine biopsy was available. The stromal grades were graded as follows: bone marrow fibrosis: MF-0 in 9 cases, MF-1 in 60, MF-2 in 31 and MF-3 in 22; collagen deposition: Co-0 in 64 cases, Co-1 in 23, Co-2 in 21 and Co-3 in 14; osteosclerosis: Oste-0 in 72 cases, Oste-1 in 24, Oste-2 in 19 and Oste-3 in 7. Patients’ population was composed of 56 males and 66 females (MF=1/1,2) with a median age at diagnosis of 68 years (range 30-85). Clinically, at presentation, anaemia with haemoglobin values less than 10 g/dL was present in 20 (16%) patients, leukocytosis more than 25 x10⁹/L was identifiable in 4 (3%) patients, and platelets count less than 100 x10⁹/L in 7 (6%) cases. JAK2V617F mutation was detected in 81 cases (66%). Among the remaining 41 JAK2-negative patients, 4 and 27 carried MPL and CALR mutations, respectively; 10 out of 122 resulted “triple-negative”. According to the International Prognostic Scoring System, 38 cases were stratified as low risk, 51 as intermediate-1 risk, 21 as intermediate-2 risk, and the remaining 12 as high risk. By the time of the analysis, 21 (17%) patients had died: leukemic evolution occurred in 14 (11.5%) patients, whereas thrombotic or hemorrhagic events occurred in 25 (20.5%). Subsequently, a comprehensive grade of bone marrow stromal changes ranging from 0 to 9 allows us to distinguish 68 (72%) cases with low-grade stromal changes (total score: 0-4) and 34 (38%) with high-grade stromal changes (total score: 5-9). Clinically, patients with high-grade stromal changes presented more frequently with anaemia, thrombocytopenia, leukocytosis, peripheral blood blasts and increased lactate dehydrogenase levels. The grade of bone marrow stromal changes resulted strictly associated with primary myelofibrosis, proved to be reproducible and adopted by the updated WHO 2016 classification.

Of the 8,210 MPN patients, 80 individuals were diagnosed with IBD during the study period; including 37 ET patients, 28 PV patients, 1 MF patient and 14 MPN-U patients. During a total risk time of 45,241 years, the rate of IBD per 1000 person years at risk was 1.8 (95% confidence interval [95% CI]: 1.4-2.2) for the MPN patients. The 10-year risks of IBD for MPN patients and comparisons were 0.8% (95% CI: 0.6-1.0) and 0.4% (95% CI: 0.4-0.5), respectively. The overall HR of IBD was 2.4 (95% CI: 2.1-2.9) for MPN patients, with HRs of 2.6 (95% CI: 2.1-3.2) for ulcerative colitis and 2.4 (95% CI: 1.7-3.4) for Crohn’s disease. The risk of IBD was increased 2 to 3 fold among ET, PV and MPN-U patients, with HRs of 2.8 (95% CI: 2.1-3.7) for ET patients, 2.1 (95% CI: 1.6-2.7) for PV patients and 2.2 (95% CI: 1.3-3.7) for MPN-U patients.

Summary/Conclusions: Patients with MPN are at increased risk of IBD compared to the general population. The absolute risks of IBD are low, but abdominal discomfort may in few patients be caused by underlying IBD.
ESSENTIAL THROMBOCYTHEMIA WITH AQUAGENIC PRURITUS: AN ENTITY WITH MORE AGGRESSIVE CLINICAL AND BIOLOGICAL PROFILE AT THE DIAGNOSIS AND A HIGH MORBIDITY DURING THE FOLLOW-UP. C. Le Gall-Ianotto1,2,*, R. Le Calloch3, L.-M. Mollard4, L. Miseri1, J.-C. Ianotto4
1Service dermatologie, CHU Brest - Hôpital Augustin Morvan, 2Laboratory of interactions epitheliums-neuromes, university of Brest, Brest, 3Service Hémato-
cologie, CHIC, Quimper, 4Service Hématologie, CHU Brest - Hôpital Augustin
Morvan, Brest, France

Background: Polycythemia vera (PV) and essential thrombocytosis (ET) are Ph-negative myeloproliferative neoplasms in which arterial or venous thromboses and phenotypic evolutions (leukemia, myelofibrosis) are the most frequent complications. Aquagenic pruritus (AP), induced by water contact, is a typical symptom of PV. However, we showed recently that ET patients also suffered from AP with clinical characteristics quite different from those observed in PV patients. In 2008, the presence of AP was associated with a lower risk of arterial thrombosis in PV patients.

Aim: It seemed particularly interesting to analyse the clinical relevance and the prevalence of the presence of AP in ET patients for such a risk.

Methods: In this study, we used the OBENE observatory (Observatoire Brestois des NEOplasies myeloprolifératives), a register of MPN patients followed in our University Hospital in which biological and clinical data of 396 ET patients have been collected. This register was approved by a local ethical committee and registered in clinicaltrials.gov (NCT02897297). To avoid masked polycythemia Vera diagnostics, all JAK2 positive cases were included and tested for isotopic red mass cells if appropriate.

Results: Among 396 ET patients, 42 (10.6%) suffered from AP. Interestingly, the median age at diagnosis of these patients was lower (51.6 vs 63.8%, p<0.0001). Furthermore, they presented more symptoms as erythrocytosis, hyperviscosity, constitutional symptoms and splenomegaly (p<0.01). ET patients with AP were more proliferative (more polycythemic but less thrombo-
cytemia, 0.04 vs 0.09, p=0.004) and were more difficult to treat (2.2 vs 1.1 treatment lines, p=0.005). Concerning the occurrence of thrombotic events (arterial or venous) at diagnosis, no significant difference between patients with or without AP was found. In contrast, the presence of AP induced an increase of thromb-
etic events during the follow-up (30.9 vs 17.2%, p=0.03). But surprisingly, these events appeared in the delayed timing. The arterial/venous rate of thrombo-
etic events was also different with 50/50 vs 25/131. Furthermore, we observed that about one-third of the patients with AP had phenotypic evolutions against 13.3% in the other group (p=0.0007); the most frequent evolutions were PV and secondary myelofibrosis (16.7 vs 5.4%, p=0.005 and 19 vs 4.8%, p=0.0003, respectively). Concerning the overall survival of the patients, we have noted that there was less death in the group with AP than without AP (11.9 vs 32.5%, p=0.006) in spite of a longer follow-up (12.1 vs 7.7 years, p=0.002).

Summary/Conclusions: AP is classically associated to PV. But we confirmed here that AP is also present in ET. Furthermore, ET patients suffering from AP were more proliferative, more symptomatic at diagnosis but had also higher risk of thromboses and phenotypic evolutions than ET without AP. Despite these patients have a higher overall survival. So, the presence of AP in ET with characteristics patients with high risk of morbidity (thromboses, pheno-
typic evolutions).So as in PV, the presence of AP in ET patients at the time of diagnosis should be systematically identified.

ANAGRELIDE RESPONSE ACCORDING TO THE MOLECULAR PROFILE: SOMETHING TO CONCLUDE ON THE MECHANISM OF ACTION OF THE DRUG IN MYELOPROLIFERATIVE NEOPLASMS (MPN)?
M. Montero1,*, T. Knight1, M. Domínguez1, E. Carrillo1, F. Márquez1, V. Escamilla1, M. C. Forsyth1,*, C. Tiley2, B. Wylie2, M. Dean2, T. Armytage2, K. Melville2
1Medicine, Wyong Hospital, Kanwal, 2Haematology, Gosford Hospital, Gosford, Australia

Background: Ph-negative MPNs are a heterogeneous group of stem cell derived, clonal bone marrow disorders characterised by increased production of mature blood cells. Patients with MPNs are at significantly increased risk of thrombotic and haemorrhagic complications which are a major cause of morbidity and mortal-
tality. The early diagnosis and treatment of MPN may reduce the incidence of thrombotic complications and the associated morbidity and mortality.

Aims: We performed a study to determine if the delayed-diagnosis of MPN was common and the implications of any such delay.

Methods: The medical records of patients treated at our centre with a new diagnosis of MPN between January 2010 and June 2016 were audited. We determined the duration from first appearance of a full blood count (FBC) abnor-
mality consistent with the diagnosis of MPN until the time of formal diagnosis. The occurrence of any thrombotic or haemorrhagic complications during this time was recorded.

Results: 143 patients were diagnosed with MPN: 35 with polycythemia vera, 79 with essential thrombocythemia, 25 with primary myelofibrosis and 13 with MPN-unclassifiable. Patient diagnosis median delay was 156 days (range 0-2650 days) and 26% had potentially preventable events. Patients with ET had median diagnosis delay of 823 days (range 0-8731 days) and 23% had potentially preventable thrombotic events including 2 patients with multiple events. Patients with PMF had a median diagnosis delay of 196 days (range 0-3684 days) and 12% had potentially preventable thrombotic events. In MPN-U the median diagnosis delay was 1371 days (range 42-3255) and 31% of patients had potentially preventable adverse events.

Summary/Conclusions: Over 5.5 years we identified 143 patients with a new diagnosis of Ph-negative MPN within our centre. The overall median diagnosis delay was 723 days (0-8731) with delays of more than 12 months in ET, PV and MPN-U, and more than 6 months in PMF. 21% of patients had potentially preventable thrombotic events and 2.8% had potentially preventable haemor-
ragic events. Earlier recognition of FBC abnormalities consistent with MPN may have prevented these clinical events. In the absence of an earlier diagnosis with earlier intervention, would be expected to prevent many thrombo-haemor-
ragic complications and reduce MPN-associated morbidity and mortality.

ESSENTIAL THROMBOCYTHEMIA WITH AQUAGENIC PRURITUS: AN ENTITY WITH MORE AGGRESSIVE CLINICAL AND BIOLOGICAL PROFILE AT THE DIAGNOSIS AND A HIGH MORBIDITY DURING THE FOLLOW-UP. C. Le Gall-Ianotto1,2,*, R. Le Calloch3, L.-M. Mollard4, L. Miseri1, J.-C. Ianotto4

cologie, CHIC, Quimper, 4Service Hématologie, CHU Brest - Hôpital Augustin
Morvan, Brest, France

Background: Polycythemia vera (PV) and essential thrombocytosis (ET) are Ph-negative myeloproliferative neoplasms in which arterial or venous thromboses and phenotypic evolutions (leukemia, myelofibrosis) are the most frequent complications. Aquagenic pruritus (AP), induced by water contact, is a typical symptom of PV. However, we showed recently that ET patients also suffered from AP with clinical characteristics quite different from those observed in PV patients. In 2008, the presence of AP was associated with a lower risk of arterial thrombosis in PV patients.

Aim: It seemed particularly interesting to analyse the clinical relevance and the prevalence of the presence of AP in ET patients for such a risk.

Methods: In this study, we used the OBENE observatory (Observatoire Brestois des NEOplasies myeloprolifératives), a register of MPN patients followed in our University Hospital in which biological and clinical data of 396 ET patients have been collected. This register was approved by a local ethical committee and registered in clinicaltrials.gov (NCT02897297). typic evolutions).So as in PV, the presence of AP in ET patients at the time of diagnosis should be systematically identified.
(starting dose of 14mg/week up to obtain the complete hematological response (CHR) is associated with high risk of leukemic transformation and second malignancies.

Aims: We analysed efficacy, toxicity, risk of Myelofibrosis (MF) and leukemic evolution in 31 of 352 ET pts collected in our database, treated with an alternative long-term schedule of BU, defined by low-starting dose (4-6mg/week) up to CHR (evaluated according to ELN response criteria), followed by dose de-escalation overtime.

Methods: Non parametric tests, such as Mann-Whitney, Pearson Chi-square and Fischer’s exact tests, were used for statistical analysis of continuous and categorical variables. Survival curves were calculated by Kaplan-Meier method and compared with Log-rank (Mantel-Cox) test.

Results: 27/31 pts were evaluable for analysis (8 male, 19 female). Median age at diagnosis and at BU start were 71.3 and 79 years (yrs) respectively. We found these two factors to be significant in predicting MF and leukemic transformation.

Methods: We aimed to find out if there is difference in frequency and type of thrombosis in JAK2V617F positive patients according to their diagnosis, age, sex and V617F allele burden.

Methods: One hundred and eighty two JAK2 V617F positive patients diagnosed with polycythemia vera (PV) N=63, essential thrombocythemia (ET) N=83, and primary myelofibrosis (PMF) N=36 were included in the study. Patients in each group were additionally divided according to sex, age at diagnosis and first thrombosis. V617F allele burden was quantified in peripheral blood granulocyte DNA by real time PCR established by Larsen et al. Br J Haematol 2007;136:745.

Results: Among 182 patients observed, 66 (36%) experienced thrombosis, with arterial thrombosis being twice more frequent than venous thrombosis in all 3 studied groups. In ET group there was statistically significant difference in sex distribution (proportion of females=0.71), p<0.001. Statistically significant difference in age at diagnosis was observed between ET and PV/PMF patients without thrombosis (p<0.001); the youngest patients were those in ET group. The age at diagnosis of ET patients with thrombosis (65 years, range 23-92) was statistically different compared to ET patients without thrombosis (50 years, range 21-83), p=0.002. Our study showed that V617F allele burden in patients without thrombosis was statistically significantly different between ET (17.2%, range 4.2-55.2) compared to PV (43%, range 1.7-99.9) and PMF (37.1%, range 1.4-90.7), p<0.001. The same statistically significant difference for V617 allele burden was established in patients with thrombosis between ET patients (19%, range 1.4-84.5) and PV and PMF patients (42.5%, range 8.9-97.2 and 48.8%, range 1.6-99.8, respectively), p<0.001.

Summary/Conclusions: Our results confirm that arterial thrombosis is more frequent than venous thrombosis in JAK2 V617F positive patients. Female sex was prevalent only in ET group. The age at diagnosis in all studied groups was similar except for ET patients without thrombosis. There was no difference in the frequency and type of thrombosis among ET, PV and PMF patients with high heterogeneity in V617F allele burden between all studied groups regardless of the occurrence of thrombosis.

**Figure 1.**

Summary/Conclusions: Our experience with an alternative long-term and low-dose BU administration is safe and effective in elderly patients with ET. 92.6% of them obtained CHR, with acceptable hematological and extra-hematological toxicity. We noticed a high rate of MF evolution with respect to global population, while the risk of leukemic transformation seems to be limited,

Aims: We aimed to find out if there is difference in frequency and type of thrombosis in JAK2 V617F positive patients according to their diagnosis, age, sex and V617F allele burden.

Methods: Non parametric tests, such as Mann-Whitney, Pearson Chi-square and Fischer’s exact tests, were used for statistical analysis of continuous and categorical variables. Survival curves were calculated by Kaplan-Meier method and compared with Log-rank (Mantel-Cox) test.

Results: Among 182 patients observed, 66 (36%) experienced thrombosis, with arterial thrombosis being twice more frequent than venous thrombosis in all 3 studied groups. In ET group there was statistically significant difference in sex distribution (proportion of females=0.71), p<0.001. Statistically significant difference in age at diagnosis was observed between ET and PV/PMF patients without thrombosis (p<0.001); the youngest patients were those in ET group. The age at diagnosis of ET patients with thrombosis (65 years, range 23-92) was statistically different compared to ET patients without thrombosis (50 years, range 21-83), p=0.002. Our study showed that V617F allele burden in patients without thrombosis was statistically significantly different between ET (17.2%, range 4.2-55.2) compared to PV (43%, range 1.7-99.9) and PMF (37.1%, range 1.4-90.7), p<0.001. The same statistically significant difference for V617 allele burden was established in patients with thrombosis between ET patients (19%, range 1.4-84.5) and PV and PMF patients (42.5%, range 8.9-97.2 and 48.8%, range 1.6-99.8, respectively), p<0.001.

Summary/Conclusions: Our results confirm that arterial thrombosis is more frequent than venous thrombosis in JAK2 V617F positive patients. Female sex was prevalent only in ET group. The age at diagnosis in all studied groups was similar except for ET patients without thrombosis. There was no difference in the frequency and type of thrombosis among ET, PV and PMF patients with high heterogeneity in V617F allele burden between all studied groups regardless of the occurrence of thrombosis.

1Radboud University Medical Center, Nijmegen, Netherlands, 2MD Anderson Cancer Center, Houston, United States

Background: B cell non-Hodgkin lymphoma, worldwide the most common hematological malignancy, remains a clinical problem. The molecular events leading to B cell lymphoma are only partially defined. CD37 is a member of the tetraspanin superfamily that is highly expressed on mature B cells and is required for optimal GC function and long-lived antibody production.

Aims: We investigated the function of tetraspanin CD37 in the development of B cell lymphoma.

Methods: A combination of studies was performed in mouse models (CD37/IL-6-deficient mice), and studies of DLBCL patient material using biochemical, immunological, genetic and microscopical approaches.

Results: We provide evidence that deficiency of CD37 induces the development of B cell lymphoma in vivo. Cd37-deficient mice develop germinal center-derived B cell lymphoma in lymph nodes and spleen with higher incidence than Bcl2-transgenic mice. We discovered that CD37 interacts with SOCS3, and when absent drives tumor development through constitutive activation of the IL-6 signaling pathway. The importance of the IL-6 pathway was confirmed by investigating Cd37xIl6 double knock-out strains that were fully protected against lymphoma development. Our unpublished data shows discovery of inactivating CD37 mutations in patients with DLBCL. Importantly, loss of CD37 on neoplastic cells in patients with diffuse large B cell lymphoma (DLBCL) is directly correlated with activation of the IL-6 signaling pathway and with worse progression-free and overall survival.

Figure 1

Summary/Conclusions: Together, this study identifies tetraspanin CD37 as a novel tumor suppressor that directly protects against B cell lymphomagenesis, and provides a strong rationale for blocking the IL-6 pathway in patients with B cell lymphoma.

E1354
CONCOMITANT DOUBLE ABLATION OF BLIMP1 AND P53 IN B-CELLS AS A NOVEL IN VIVO MODEL FOR HIGH-GRADE B-CELL LYMPHOMA
1AASS Spedali Civili di Brescia, Brescia, Italy, 2Kumamoto University, Kumamoto, Japan, 3Dan-Araber Cancer Institute, Boston, 4Maine Medical Center, University of Maine, Scarborough, 5Brigham and Women’s Hospital, Boston, United States

Background: B-Lymphocyte-Induced Maturation Protein-1 (BLIMP1)- and p53-inactivation contributes to the pathogenesis of a wide spectrum of malignancies, including diffuse large B-cell lymphomas. Nevertheless, there is lack of in vivo models that may be used for a better understanding of the biology and genomics of high-grade B-cell lymphomas characterized by dual loss of both BLIMP1- and p53.

Aims: 1) To develop and characterize a transgenic mouse model of BLIMP1-/p53- dual loss in B cells; 2) To provide an in vivo model that mimics human ABC-DLBCL phenotype.

Methods: Cre recombinase under the control of CD19 promoter (C57BL/6 CD19Cre) mice were crossed with either C57BL/6 BLIMPflox/flox or C57BL/6 Cre recombinase under the control of CD19 promoter (C57BL/6 ABC-DLBCL phenotype.

1/p53 dual loss in B cells; 2) To provide an in vivo model that mimics human ABC-DLBCL phenotype.

Results: CD19/Bl-/p53- mice presented with diffuse lymphadenomegaly, splenomegaly, hepatomegaly (100%, 90.3% and 77.4%, respectively). Other clinical manifestations included presence of ascites and hind limb paralysis (12.0% and 19.3%, respectively). The CD19+/Bl-/p53- showed improved survival compared to Bl-/p53- mice non-expressing the CD19/Cre recombinase, CD19/p53-, or CD19/Bl- (363, 469.5, 460.5, and 770 days, respectively). H.E. staining of CD19/Bl-/p53—derived lymph nodes, defined a nodal architecture with a monomorphic population of large sized atypical lymphoid cells, multiple bimorphic cell populations, undifferentiated mostly centrally situated nuclei. A strong positive CD3 and CD20 was also observed. Features were compatible with a high-grade lymphomas. IHC analysis confirmed positivity for B220 staining (TdT, Bcl6, CD138 and CD4, CD8 negative). Tumors were confirmed to be B220+/lgM+, with either Igk- or Ig-lambda-restriction as demonstrated by flow cytometry; and either mono- or bimorphic cell populations. Southern blotting demonstrated by Southern blotting. Viability assays performed from B220+ selected cells obtained from pathological lymph nodes of CD19/Bl-/p53- mice and identified 143 SNVs. Non-synonymous somatic mutations were mapped on genes involved in the regulation of focal adhesion, PDGF signaling, p53-downstream pathway, and lipoprotein metabolism. B220+ cells selected from CD19/Bl-/p53—derived lymph nodes were implanted s.c. into recipient SCID/Bg mice, and presented with 100% engraftment, with a monomorphic lymphoid infiltration of B220+ and IgM+ cells. B220 positive cells were selected from the s.c. tumor and intravenous injected into recipient SCID/Bg (n: 10) and BL/6 mice (n: 10). Engraftment was demonstrated in all tumors where hepatomegaly and splenomegaly was observed. Infiltration of B220+ cells was documented within bone marrow, liver and spleen. Finally, we found that B220+ cells selected from lymph nodes harvested from CD19/Bl-/p53- mice were sensitive to ibrutinib.

Summary/Conclusions: Dual inactivation of p53 and BLIMP in B-cells supports the concept that what seen in patients with ABC-DLBCL, driven thus providing a novel model for studying high-grade B-cell lymphoma driven by BLIMP1-1/p53- dual loss-induced c-Myc expression.

E1355
IDENTIFICATION AND CHARACTERIZATION OF THE LYMPHOMA INITIATING CELL (LIC) POPULATION IN AN ALCL MOUSE MODEL
1Hematology, Oncology and Stem Cell Transplantation, University medical center Freiburg, 2Institute of Molecular Medicine and Cell Research, Freiburg, 3German Cancer Consortium (DKTK) and German Cancer Research Center (DKFZ), Heidelberg, Germany

Background: In 60% of anaplastic large cell lymphoma (ALCL) patients a t(2;5)(p23;q35) is found, which results in NPM-ALK fusion gene expression and constitutive activation of the ALK tyrosine kinase. Immunophenotypic characterization of human ALCLs revealed highly CD30-positive cells of T- or null-cell origin.

Aims: However, the origin of the lymphoma initiating cell population as well as NPM-ALK signal transduction in course of the disease remains unclear and needs to be characterized.

Methods: In this regard, we established a retroviral murine bone marrow transplantation model resembling human ALCL. Therefore we use an inducible Cre/loxP system where NPM-ALK expression is restricted to early T-cells. We infected bone marrow of Lck-Cre transgenic mice with our MSCV-Stop-NPM-ALK/ires-EGFP vector and transplanted it into lethally irradiated wild-type irradiated mice.
ray analyses. Indeed, heatmap analyses revealed wide pattern similarities in the expression and number of lymphocyte subpopulation in contrast to the DN1 and DN2 lymphoma cells. Interestingly, DN3 and DN4 cells show different expression profiles of stemness genes resembling early progenitor cell distribution patterns.

Summary/Conclusions: In summary, our results highlight the existence of a lymphoma initiating stem-cell-like population originated within the DN3/DN4 lymphoma cell population in a highly relevant NPM-ALK positive CD30-expressing ALC1 mouse model, thereby giving the opportunity to test the eradication of the LIC with established and new therapeutic approaches.

HSP110 SUSTAINS MYD88-DEPENDENT NKFB SIGNALING IN ACTIVATED B CELL DIFFUSE LARGE B CELL LYMPHOMA

C. Boudesco1, S. Caussé1, A. Hamman2, E. Verhoeyen3, L. Martin1, F. Jardin4, T. Fest5, O. Wolz6, A. Weber6, G. Jego1,2

1University of Burgundy, 2INSERM 1231, Dijon, 3INSERM U1111, Lyon, 4INSERM 918, Rouen, 5INSERM 911, Rennes, France, 6University of Tübingen, Tübingen, Germany

Background: Diffuse large B cell lymphoma (DLBCL) is an aggressive lymphoproliferative disorder of B lymphocytes accounting for 30% of adult Non Hodgkin Lymphoma (NHL). Among DLBCL, Activated B Cell – DLBCL (ABC-DLBCL) is the most aggressive form and has a poor prognosis. Heat-shock proteins (HSPs) are molecular chaperons highly expressed in cancer cells and implicated in resistance to radio- and chemotherapy. Therefore, HSPs are envisioned as therapeutic targets in many cancers. Among the different HSPs, HSP110 has been recently identified as a pro-survival factor in germinal center-derived DLBCL (GC-DLBCL), through stabilization of the GC-DLBCL oncogene Bcl-6.

Aims: Here, we have explored if HSP110 could also be involved in the survival of the most aggressive form of DLBCL

Methods: The study was performed with ABC-DLBCL patient samples and several cell lines. SH-SY5Y specific for HSP110 was transduced through a lentiviral vector designed to inject highly efficiently non-permissive B cell lines.

Results: We observed a high HSP110 expression in all ABC-DLBCL patient samples, compared to normal reactive lymph nodes by using IHC staining of ABC-DLBCL patient tumors. Furthermore, RNA and protein analysis of HSP110 decreases the survival of several ABC-DLBCL cell lines, and downregulates the expression of pro-survival factors such as Bcl2 and Bcl-XL. SiRNA silencing of HSP110 abrogates NF-kB signaling, which is the major oncogenic pathway in ABC-DLBCL cell lines. In accord with these results, over-expression of HSP110 in DLBCL and non-DLBCL cell lines increases NF-kB signaling, indicating a tight interplay between HSP110 and the NF-kB pathway. Using immune-precipitation in DLBCL cell lines and Duolink™ assays, we identified an in vitro and in cellulo interaction between HSP110 and MyD88, a critical protein of the NF-kB pathway that bears an activated mutation in many ABC-DLBC patients and that is responsible for lymphoma aggressiveness. Finally, we demonstrate that HSP110 stabilizes the wild type as well as the mutated form of MyD88, therefore facilitating the chronic NF-kB pathway activation in those cells.

Summary/Conclusions: In conclusion, we identified HSP110 as a regulator of NF-kB signaling through MyD88 stabilization in ABC-DLBCL. This finding highlights HSP110 as a new potential therapeutic target in DLBCL and potentially in other hematological malignancies driven by mutated MyD88 as Waldenstrom macroglobulinemia.

STAT3 ACTIVATION MEDIATES CD8+/CD16+ /CD56- T-LGLL NEUTROPHENIA THROUGH NF-kB LIGAND SECRETION

G. G. Tomassetti1,2, A. Tarasco1,2, G. Calabretta1,2, M. Leoncini1,2, C. Vicenzetto1,2, A. Lipo1, A. Cabrelli2, S. Carraro1, V. Trimarco1, M. Facco12, F. Piazza1, L. Trentin1,2, G. Semenzato1, R. Zambello1,2

1Dept of Medicine, Hematology and Clinical Immunology section, Padua University School of Medicine, 2Venetian Institute of Molecular Medicine, Padua, Italy

Background: T-cell large granular lymphocyte leukemia (T-LGLL) is a rare chronic lymphoproliferative disorder characterized by the clonal expansion of CD3+ Large Granular Lymphocytes (LGL). In addition to the most common CD8+ T-LGLL, two other LGLL subtypes have been described: CD4+ T-LGLL, less frequent LGL proliferations with CD4+/CD8-/+dim phenotype (CD4+ T-LGLL) exist, which are characterized by indolent clinical course. Somatic STAT3 mutations determining constitutive activation have been recently reported in a proportion of approximately 40% of patients, with no clear correlation with the occurrence of neutropenia, whose pathogenesis is likely to be multifactorial, comprising both tumor (i.e. soluble Fas ligand secretion) and cell-mediated mechanisms.

Aims: The aim of this work was to evaluate whether 1) STAT3 mutations might be associated with a distinctive LGL immunophenotype and/or indicative for symptomatic disease and 2) STAT3 activation is directly related to the development of neutropenia.

Methods: A cohort of 101 patients affected by T-LGLL according to WHO criteria were screened for STAT3 mutation by Sanger sequencing and PCR ARMS assay. All the samples were analysed by flow for CD3, CD4, CD8, CD16, CD56 and CD57 antigen. STAT3 by 705 levels were studied by Western blot. FAS ligand mRNA levels were analysed by RT-PCR assay.

Results: By flow we observed that 68 out of 101 patients (67.3%) were characterized by CD3+/CD8+/CD4- expression (CD8+ T-LGLL), while the remaining 33 patients (32.7%) were CD3+/CD4+ (n=14) or CD4+ (n=20). All STAT3 mutated (n=38) and almost all neutropenic (38 out of 39) patients belonged to CD8+ T-LGLL leukemia (n=68), while among CD4+ T-LGL leukemia (n=33) no STAT3 mutated and only one neutropenic patient (1 out of 33, 3%) was found.

CYCLIN D2 OVEREXPRESSION RECAPITULATES MANTLE CELL LYMPHOMA IN MICE

T. Pieters1,2, S. T’Sas1, J. Morscio1, F. Matthijssens2, K. Lemiere1, T. Hochepied1, S. Linters1, L. Reunis1, G. Berx1, J. Haigh2, S. Goossens3, P. Van Vlerken3

1Ghent University, Ghent, Belgium, 2Monash University, Melbourne, Australia

Background: Mantle cell lymphoma (MCL) is a highly aggressive subtype of B-cell lymphoma that is characterized by a poor response to current treatment regimens. Most MCLs carry a prototypical translocation, t(11;14), which juxtaposes the CCND1 gene towards the immunoglobulin heavy chain (IGH) locus, resulting in cyclin D1 overexpression. Notably, a subset of MCL patients are cyclin D1 negative but instead overexpress cyclin D2 (encoded by CCND2) as a consequence of recurrent genomic rearrangements involving the CCND2 locus.
Aims: Here, we aim to recapitulate MCL in a mouse model of hematopoietic-specific overexpression of cyclin D2. Next, we want to use this preclinical mouse model to evaluate novel therapeutic strategies for the treatment of MCL.

Methods: To evaluate if cyclin D2 could act as a bona fide oncogene in the pathogenesis of MCL, we developed a conditional R26-driven Ccnd2 overexpression mouse model. For this, we used a targeting vector that contained a floxed stop cassette followed by the Ccnd2 gene and a EGFP/luciferase reporter, which was subsequently targeted in mESCs using recombinase-mediated cassette exchange (RMCE).

Results: The resulting R26-Ccnd2 mice were crossed to VavCre mice to enable biallelic R26-driven overexpression of Cyclin D2 in the entire hematopoietic system. Interestingly, these mice developed large lymphomas starting from 36 weeks of age (Figure 1A), with tumor cells showing characteristic MCL immunophenotype (CD19+, CD5+, CD23-). Of note, these malignant B-cells were monoclonal small-sized cells with slightly irregular hyperchromatic nuclei and disseminated into other organs such liver, spleen and the gastrointestinal tract, hallmarking the infiltrating non-malignant (N)2 lymphoma cells. These lymphoma cells were SOX11 positive, as evaluated by IHC, suggesting that these tumors indeed reflect a murine form of MCL. Noteworthy, the MCL cells from this mouse model also contain a luciferase reporter, allowing accurate in vivo tracing of tumor cells in xenograft experiments. These xenograft experiments can be used as preclinical models, in which bioluminescence is used to assess the tumor burden and to monitor tumor regression upon drug treatment.

Summary/Conclusions: In conclusion, our preliminary data suggest that modeling cyclin D2 in mice, mimicking the elevated cyclin D2 levels of human MCL patients with translocations involving the CCND2 locus, is sufficient to form MCL.

HDAC6 INHIBITION INCREASES CD20 LEVEL BY STIMULATING TRANSLATION OF CD20 MRNA
A. Graczyk-Jarzynka1,*, M. Bobrowicz1, M. Dwojak1, J. Stachura1, E. Berthel2, A. Graczyk-Jarzynka1,*, M. Bobrowicz1, M. Dwojak1, J. Stachura1, E. Berthel2

Background: HDAC6 (histone deacetylase, isoform 6) is a novel promising target of novel proteins in the cell. However, our experiments suggest that the translation of CD20 mRNA on polysomes without affecting general synthesis of CD20 we optimized Click-IT chemistry methods. In order to study this effect of HDAC6 inhibition on global as well as specific novo synthesis of CD20 we optimized Click-IT chemistry methods. In order to study CD20 translation on polysomes we performed polysomes profiling followed with qRT-PCR. To get an insight into molecular mechanism of increased translation of CD20 after HDAC6 inhibition we studied the formation of stress granules (SG).

Methods: We used qRT-PCR and Dual Luciferase Assays in order to determine the influence of HDAC6 on CD20 transcription. We used pulse-chase using assays widely used with translation inhibitors – cycloheximide and homoharringtonine. In order to study the effect of HDAC6 inhibition on global as well as specific novo synthesis of CD20 we optimized Click-IT chemistry methods. In order to study CD20 translation on polysomes we performed polysomes profiling followed with qRT-PCR. To get an insight into molecular mechanism of increased translation of CD20 after HDAC6 inhibition we studied the formation of stress granules (SG).

Results: We show that HDAC6 inhibition regulates CD20 level without affecting its transcription. Moreover, we demonstrate that HDAC6 inhibition increases translation of CD20 mRNA on polysomes without affecting general synthesis of novel proteins in the cell. However, our experiments suggest that the increased translation of CD20 mRNA is not a result of resumed translation of mRNA but rather is due to increased translation of CD20 mRNA on polysomes without affecting general synthesis of novel proteins in the cell.

Summary/Conclusions: Our study shows a new mechanism of the regulation of CD20 expression by increasing its translation. Moreover, we demonstrate a new role of HDAC6 protein. This finding has a potential clinical application, as HDAC6 inhibitor are being widely tested in different hematological malignancies. Further studies in order to identify other targets for HDAC6 are required.
is associated with an absence of relapse and thus defines a new group of very low risk patients. These findings provide important clues for future therapeutic-driven therapies in MCL.

CLINICOBIOLOGICAL FEATURES OF B-CELL NEOPLASMS WITH CDK6 TRANSLOCATIONS: FREQUENT ASSOCIATION WITH MARGINAL-ZONE LYMPHOMA, CONTINGENT OF PROLIFEROCYTIC CELLS AND TP53 ABNORMALITIES. A GFCH STUDY

Background: Translocation involving the CDK6 gene is a rare but recurrent abnormality in B-cell neoplasms. Three different translocations have been described: t(2;7)(p11;q21), which is the most frequent, t(7;14)(q21;q32) and t(7;17)(p11;q11), leading to juxtaposition of CDK6 gene with IGK, IGH or IGL locus respectively.

Aims: The Groupe Francophone de Cytogenetique Hematologique (GFCH) collected 35 chronic B-cell disorders with CDK6 translocation in order to document the clinicobiological features of this uncommon aberration.

Methods: Clinical and biological data were gathered at diagnosis when available. A cytogenetical review was performed by 3 experts in 27/35 cases. FISH was used to detect IG or TRAD and CDK6 rearrangements, and recurrent abnormalities frequent in SMZL and CLL (trisomy 3, 12, deletions of 13q14 and 7q22/7q36 loci).

Results: Our cohort included 22M and 13F, with a median age of 71 years. The involvement of CDK6 was confirmed in all cases. A t(2;7) IGK/CDK6 was found in 33/35 patients. One case had a t(7;14) IGH/CDK6, and one had a t(7;17)(q21;q11) involving the TRAD locus. There were 23 (66%) marginal-zone lymphoma (MZL), including 22 splenic MZL (SMZL) (including the t(7;14) TRAD), and 1 bronchus MALT type, 7 (20%) non-synonymous single nucleotide variants (SNV) were observed in the constant regions of four cases and in IGKC of one additional case, but not in available RNAseq data from 6 healthy volunteers (GEUVADIS project), 10 non leg type DLBCL, and 16 follicular lymphoma were obtained from NCBI publicly available datasets and collaborators. VDJ/VJ and IGH translocations and IGKC of constant regions were Sanger sequenced for all cases and two granulocyte controls. Lymphoma-derived, clonal BCR were tested for autonomous signalling activity in the murine TKO pre-B-cell system (Dühren-von Minden, Nature 2012).

Results: RNAseq analysis demonstrated an IgM isotype in all eight and VJ-kappa rearrangements in all seven DLBCL, LT cases. IGHV3 usage was observed in 7/8 cases; 4 cases expressed the IGHV3-7 gene. DLBCL, LT BCR were strongly mutated (range: 12.5-41%). No intraclonal sequence variation was observed.

Summary/Conclusions: Our data identify a clearly stereotyped receptor in the BCR in DLBCL, LT and to test for autonomous antigen-independent signaling as described for CLL (Dühren-von Minden, Nature 2012) and non leg-type ABC-DLBCL (Koning, AACR 2016 & ASH 2016).

Methods: 8 cases of DLBCL, LT were subjected to RNAseq. Additional RNAseq data from 6 healthy volunteers (GEUVADIS project), 10 non leg type DLBCL, and 16 follicular lymphoma were obtained from NCBI publicly available datasets and collaborators. VDJ/VJ and IGH rearrangements and IGKC of constant regions were Sanger sequenced for all cases and two granulocyte controls. Lymphoma-derived, clonal BCR were tested for autonomous signalling activity in the murine TKO pre-B-cell system (Dühren-von Minden, Nature 2012).

Results: RNAseq analysis demonstrated an IgM isotype in all eight and VJ-kappa rearrangements in all seven DLBCL, LT cases. IGHV3 usage was observed in 7/8 cases; 4 cases expressed the IGHV3-7 gene. DLBCL, LT BCR were strongly mutated (range: VDJ 3.1-22.2%; VJ 0.6-13.5%). No intraclonal sequence variation was observed.

Summary/Conclusions: Our data identify a clearly stereotyped receptor in the BCR in DLBCL, LT and to test for autonomous antigen-independent signaling as described for CLL (Dühren-von Minden, Nature 2012) and non leg-type ABC-DLBCL (Koning, AACR 2016 & ASH 2016).

PRIMARY CUTANEOUS DIFFUSE LARGE B-CELL LYMPHOMA, LEG TYPE, EXPRESS STEREOTYPED B-CELL RECEPTORS WITH UNIQUE NONSYNONYMously MUTATED CONSTANT REGIONS

M.T. Koning1-7, R. Ubelhart5, S. van der Zeeuw3, S. Kiebassa3, H. Jumaa4, M. Vermeer5, W. Willenre5, C. Tensen3, H. Veeken5, 1Department of Hematology, Leiden University Medical Center, Leiden, Netherlands, 2Department of Immunology, University Medical Center Ulm, Ulm, Germany, 3Sequence Analysis Support Core, 4Department of Dermatology, Leiden University Medical Center, Leiden, Netherlands

Background: Primary Cutaneous Diffuse Large B-Cell Lymphoma, Leg Type (DLBCL, LT) is a rare and aggressive neoplasm with a primary cutaneous presentation that shares genetic and phenotypic characteristics with DLBCL of activated B-cell subtype (ABC-DLBCL). Although receptor stereotypes have been observed, the role of the B-cell receptor (BCR) in DLBCL, LT is largely unknown. Previous studies on small cohorts suggested that DLBCL, LT expresses IgM with overrepresentation of IGHV3 alleles and high rates of somatic mutations.

Aims: We aimed to elucidate the stereotype of the BCR in DLBCL, LT and to test for autonomous antigen-independent signaling as described for CLL (Dühren-von Minden, Nature 2012) and non leg-type ABC-DLBCL (Koning, AACR 2016 & ASH 2016).

Methods: 8 cases of DLBCL, LT were subjected to RNAseq. Additional RNAseq data from 6 healthy volunteers (GEUVADIS project), 10 non leg type DLBCL, and 16 follicular lymphoma were obtained from NCBI publicly available datasets and collaborators. VDJ/VJ and IGH rearrangements and IGKC of constant regions were Sanger sequenced for all cases and two granulocyte controls. Lymphoma-derived, clonal BCR were tested for autonomous signalling activity in the murine TKO pre-B-cell system (Dühren-von Minden, Nature 2012).

Results: RNAseq analysis demonstrated an IgM isotype in all eight and VJ-kappa rearrangements in all seven DLBCL, LT cases. IGHV3 usage was observed in 7/8 cases; 4 cases expressed the IGHV3-7 gene. DLBCL, LT BCR were strongly mutated (range: VDJ 3.1-22.2%; VJ 0.6-13.5%). No intraclonal sequence variation was observed.

Non-synonymous single nucleotide variants (SNV) were observed in the constant regions of four cases and in IGKC of one additional case, but not in available granulocyte DNA of two cases with G region mutations or in the other 32 RNAseq libraries. Constant region mutations were highly specific to DLBCL, LT as compared to other DLBCL (p=0.0018) and follicular lymphoma (p=0.0013). In contrast to ABC-DLBCL, V(D)J BCR of DLBCL, LT on a murine constant region backbone did not induce antigen-independent calcium flux in TKO cells upon induction of functional signaling of the BCR signalling cascade by tamofoxifen.

Summary/Conclusions: Our data identify a clearly stereotyped receptor in the BCR in DLBCL, LT and to test for autonomous antigen-independent signaling as described for CLL (Dühren-von Minden, Nature 2012) and non leg-type ABC-DLBCL (Koning, AACR 2016 & ASH 2016).
Background: NR4A1 (Nurr1) belongs together with NR4A2 (Nur77) and NR4A3 (Nur77-OR-1) to the Nur77 family of nuclear orphan receptors. As immediate early- or stress response genes their expression is diverse as it is the cellular outcome upon activation. Recently, there has been attributed a pivotal role to NR4A1 and NR4A3 as tumor suppressors in AML in humans and mice. In our comprehensive NR4A4 expression analysis in various lymphoma entities we demonstrated a significant reduction of NR4A1 expression in aggressive lymphomas, which was associated with poor cancer-specific survival. Moreover, ectopic expression of NR4A1 in aggressive lymphoma cells resulted in induction of apoptosis.

Aims: In order to better dissect the role of NR4a1 in lymphoid malignancies, we used a Myc-driven mouse model of lymphomagenesis and crossed the EµMyc mouse with the Nr4a1-/- mouse. Survival and tumor formation were monitored and RT-PCR was performed on selected tumor specimens, whereby genes, found to be associated with NR4A1 expression in the publicly available gene expression data set of DLBCLs generated by Lenz et al., were taken. Moreover, the driver-function of NR4a1 in lymphomagenesis at the preclinical stage was investigated by using apoptotic assays and by carrying out transplantations of tumor cells into wt recipients.

Methods: Kaplan Meier analysis was performed for survival and tumor formation in EµMyc Nr4a1+/- (n=134), EµMyc Nr4a1 -/- (n=54) and EµMyc Nr4a1 +/- (n=59), respectively. For RT-PCR selected tumor specimens from wt and EµMyc mice with (n=14) and without (n=17) Nr4a1 loss were used. For investigation of the role of Nr4a1 at the preclinical stage, mice aged 4 weeks (n=4 per genotype) were sacrificed and Annexin V staining and cleaved-caspase3 assay were performed on cells isolated from the spleen and bone marrow. In vivo driver-function of Nr4a1 was induced by tumor formation from Nr4a1 heterozygous (EµMyc Nr4a1 -/+; n=8) and EµMyc Nr4a1 -/- (n=11) mice injected into the tail vein of wt mice. Kaplan Meier analysis was used for monitoring survival and tumor formation, and FACS analysis for analysis of bone marrow, spleen and tumor, respectively.

Results: EµMyc Nr4a1 +/- mice showed decreased survival with a median of 92 days for EµMyc Nr4a1 -/+ mice with median survival of 123 days (p<0.001) and tumors developed faster with a median of 45 days for EµMyc Nr4a1 -/-, vs 107 days for EµMyc Nr4a1 +/-; p<0.001. Both, survival (median=101 days; p=0.037) and tumor formation (median=66 days, p=0.001) gave intermediate values for EµMyc Nr4a1 +/- mice. Furthermore, EµMyc Nr4a1 -/- mice engrafted faster than tumors derived from mice without Nr4a1 loss (25 days vs 38 days; p=0.009) and lead to a decreased number of inflammatory cells in the tumor.

Summary/Conclusions: Our results clearly demonstrate the influence of Nr4a1 loss on tumor formation and consequently survival in a Myc-driven model of lymphomagenesis. Importantly, Nr4a1 loss seems to result in cell death early in B cell development, even ahead of malignant transformation. Additionally, Nr4a1 seems to be involved in driving immune responses towards an anti-inflammatory, tolerogenic phenotype, thereby facilitating tumor growth and in altering the tumor environment. Collectively, these data underpin the tumor suppressive function of Nr4a1 in aggressive lymphomas.

MUTATIONAL PROFILING OF HODGKIN- AND REED-STERNBERG CELLS (HRSC) OF CLASSICAL HODGKIN LYMPHOMA (CHL) ENRICHED FROM ARCHIVAL FORMALIN-FIXED AND PARAFFIN-EMBEDDED TISSUE SAMPLES

D. Juskevicius1, 2, D. Jucker1, T. Dietzsche1, V. Perrina1, C. Ruiz1, S. Dimhofer1, A. Tzankov1
1 Institute of Pathology, University Hospital Basel, Basel, Switzerland
2 Department of Medicine I: Hematology, Oncology, and Stem Cell Transplantation, Medical Center, University Freiburg, Germany

Background: cHL can be cured in the majority of cases. However, 10–20% patients die of the lymphoma after relapse or progressive disease. There are unmet needs for understanding the mechanisms that cause cHL relapses, for development of new prognostic/predictive markers and effective targeted therapies. Comprehensive genetic characterization and advance in understanding the driver pathways in cHL are indispensable to meet those needs. However, genetic information on cHL is still scarce mainly due to difficulties of isolating malignant HRSC, whose overall frequencies in the affected tissues range from 0.1-5%. Formalin-fixed paraffin-embedded (FFPE) tissue archives are the most abundant source of clinically annotated tumor specimens. However, FFPE tissue sample quality is limited because of poor DNA yields and difficulty to enrich neoplastic cells. Therefore, new enrichment techniques are necessary to enable large-scale comprehensive genetic investigations of cHL.

Aims: Our aims were: 1) to develop a technique for HRSC enrichment from the archival formalin-fixed paraffin embedded tissue; 2) to reliably detect genetic aberrations in the genomes of enriched tumor samples and to use this information for development of new prognostic and predictive markers as well as for better understanding of the genetic background of cHL.

Methods: We have developed a new high-throughput method for marker-based enrichment of archival FFPE tissue-derived HRSC nuclei by fluorescence- assisted cell sorting (FACS). Genomic DNA extracted from sorted nuclei was used for identification of mutations in 68 genes that are frequently mutated in lymphomas by targeted high throughput sequencing (HTS). Chromosomal copy number aberrations were investigated by the Agilent SurePrint 180k microarray.

Results: Enzymatically extracted FFPE tissue-derived cell nuclei retain their original genomic integrity and can be used with multiplex ligation-dependent probe amplification (MLPA) and custom designed gene-targeted deep sequencing panels. Mutations of KRAS, PIK3CA, MAP2K4 and NOTCH3 were identified. In our preliminary analysis, no evidence was found for frequent mutations of KRAS, PIK3CA, MAP2K4 and NOTCH3. Using sorted non-malignant cells as a germline control we detected somatic single nucleotide mutations and indels in all investigated genes. Mutations of STAT5, PIM1, SOCS1, KMT2D occurred in at least 18% (2/11) of cases. Individual cases contained copy number aberrations such as gain of chr2 (CREL locus), focal deletions of chr4, chr7, chr16 and chr19 affecting genes such as JAK3, CDKN2D, MAP2K3 and NOTCH3. Taken together our study demonstrates that DNA extracted from the enriched cell populations is suitable for wide-scale genetic profiling.

Summary/Conclusions: A novel rare-cell-enrichment technique is suitable for genetic cHL studies and opens the possibility for the wider use of archived
FFPE tissue, thus enabling more robust study designs to answer clinically relevant questions in the field.

LACK OF STAT1 PREDISPOSES TO A DIFFUSE LARGE B-CELL LYMPHOMA-LIKE DISEASE

S. Triportier1,2, C. Schneckenleitner1, A. Hoelbl-Kovacic1, G. Heller2, V. Sexl1
1Institute of Pharmacology and Toxicology, Veterinary University of Vienna, 2Department of Medicine I, Medical University of Vienna, Vienna, Austria

Background: The highly conserved JAK-STAT signaling pathway regulates proliferation, differentiation, apoptosis and immune responses. Activating mutations in STAT3 are considered to drive the development of diffuse large B-cell lymphomas (DLBCL). STAT1 is a critical counter player of STAT3. Of note, many STAT1 target genes are frequently altered or mutated in DLBCL patients, such as SOCS-1, B2M, PDL1, CARD11, CIITA and BCL6. We observed that the loss of STAT1 suffices to provoke spontaneous haematopoietic tumors in mice.

Aims: We aimed at investigating the underlying mechanisms of spontaneous hematopoietic tumor formation in STAT1-deficient mice.

Methods: We characterized the spontaneous haematopoietic tumors by FACS and morphological analysis. To identify the cell of origin for the disease, we performed bone marrow transplantation assays. We high-purity FACS-sorted individual cell populations of diseased STAT1-deficient mice and transplanted them into recipient mice. Ex vivo RNA-sequencing was performed to identify the signaling pathways driving disease. RNA-seq data were compared to publicly available RNA-seq data from different haematologic malignancies.

Results: STAT1-deficient mice develop a myeloid hyperplasia that manifests with an incidence of 60% and is characterized by the absence of RigI. Transplantation of bone marrow unmasked the development of a B-cell malignancy, which can be transferred by CD19+ cells. The malignant B-cells arising in STAT1−/− mice can be maintained in vitro and display alterations in gene expressions that are typically found in human DLBCL such as If4, Prdm1 and p53. RNA-seq analysis revealed features shared with human DLBCL: increased reads a locus of Mef2b, Mef2a, Card11 and Cd274 (PDL1) and decreased expression of Socs-1, Cdkn1a, B2m and Prdm1. Low levels of STAT1 combined with low levels of p16INK4A correlate with a reduced life expectancy in DLBCL patients.

Summary/Conclusions: Loss of STAT1 in B-cell mice provokes a myeloid hyperplasia which mimics a B-cell malignancy resembling human DLBCL. DLBCL patients with low levels of STAT1 have a poorer prognosis if they lack the tumor suppressor p16INK4A.

MOLECULAR HETEROGENEITY OF MANTLE CELL LYMPHOMA

O. Cédile1,2, M.C. Hansen1, L.H. Ebbesen4, H.H.N. Bentzen1, M. Thomassen3, T.A. Jørres1, M.B. Müller2, T.K. Kristensen1, J. Haaber1, N. Abdilla1, C.G. Nyvold1
1Haematology-Pathology Research Laboratory, Department of Haematology, Odense University Hospital, Odense C, 2Department of Haematology, Aarhus University Hospital, Aarhus C, 3Department of Clinical Genetics, 4Department of Pathology, 5Department of Haematology, Odense University Hospital, Odense C, Denmark

Background: Mantle cell lymphoma (MCL) is a B-cell non-Hodgkin lymphoma characterized by t(11;14)(q13;q32) leading to constitutive cyclin D1 overexpression and cell cycle deregulation. The survival is still poor, especially for patients resistant to frontline drugs. Although patients are brought in remission, relapses often occur with disseminated lymphoma, which is more difficult to treat. There is a need for a better understanding of the clonal heterogeneity of this disease and to identify new signaling pathways with genes which could be targeted by novel drugs or be used as biomarkers to predict response to treatment.

Aims: To address the genetic heterogeneity in MCL in paired patient samples at diagnosis and relapse.

Methods: Highly pure malignant B-cell populations were isolated using fluorescence-activated cell sorting in four patients diagnosed with MCL. In addition T-cells were sorted from the same patients as paired non-malignant control samples. RNA was performed on both the malignant B-cell population and paired T-cells (13 samples in total). Mutations were detected in parallel with CLC Biomedical Workbench 2.5 (Qiagen) and MuTect 1.04 (Broad Institute) (coverage ≥ 20, population allele frequency<0.01) and evaluated in the COSMIC (Wellcome Trust Sanger Institute), dbSNP and PubMed databases. Exonction from informed consent was approved by the National Ethical Committee.

Results: Our data highlighted in each patient persistent gene modifications between diagnosis and relapse. We confirmed gene mutations already well-known in B-cell malignancies (e.g. TP53, NOTCH1 and MYD88). Interestingly, aberrations not previously described in the COSMIC database, were observed with high allele frequency both at diagnosis and at relapse. This included genes in B-cell signaling (e.g. transcriptional repressor SPEN associated to NOTCH pathway regulation and blockage of the precursor B-cell differentiation), inflammatory response (e.g. IRG1), genes found in invasive carcinoma (e.g. integrin β4 subunit), and B-cell related genes (e.g. precocious T-cell development or hit in putative drivers, new gene modifications as well as loss of previous ones could be observed at relapse. For example, genes involved in embryonic development and cell fate (e.g. the transcription factor SOX1) and genes involved in inflammation (CCL13) were not previously correlated to MCL and were novel at relapse. This suggests that a modified malignant clone has evolved and progressed. No gene modification was observed to be shared by all four patients. However, aberrations in the same signaling pathways were identified across individuals. From allele frequency distributions detected with MuTect we could detect discrete clonal or competing subclonal involvement: A patient harbored one major discrete clone at diagnosis while at relapse two clones were identified, whereas another patient presented a diffuse clonal pattern at diagnosis and a more discrete bicolonal pattern at relapse.

Summary/Conclusions: Our work shows examples of molecular progression from diagnosis to relapse in MCL and supports the heterogenic nature and genetic complexity of this disease. We confirm mutations in genes already known as involved in the disease, however, the functional impact of these new genes which could be targeted by novel drugs or be used as biomarkers to predict response to treatment.

NOVEL TARGET GENES OF DEREGERGATED MIRNAS IN DLBCL ENDODGENOUS AGO2 PAR-CLIP

M. Fernandez-Mercado1,2,*, E. Larrea1, I. Ceberio3, I. Goicoechea1, O. Echaniz4, J. Buratti5, Y. Luo5, M. Arauzo-Bravo6,7, M. Landthaler6,9, C. G. Nyvold1
1Institute of Pharmacology and Toxicology, Veterinary University of Vienna, 22nd Congress of the European Hematology Association 562 | haematologica | 2017; 102(s2)

2Institute of Pharmacology and Toxicology, Veterinary University of Vienna, 2Department of Medicine I, Medical University of Vienna, Vienna, Austria

Background: Aberrant expression of microRNAs (miRNAs) is a widespread phenomenon in many cancers. However, the functional impact of this deregulated gene population is poorly understood as the target genes of miRNAs (the targetome) are notoriously difficult to predict computationally and moreover differ according to cellular context. An alternative approach is to directly sample the targetome using immunoprecipitation (IP) techniques such as PAR-CLIP. The drawback however of such techniques is the need for exogenously produced tagged protein such as Ago2 to reveal the targetome. In this study, we aimed at testing the minimum number of input cells needed for miRNA target identification.

Methods: Two DLBCL cell lines (ABC-type RIVA, and GC-type SUD-HL1) were transfected with lentiviral vectors that encoded mir-155. In parallel, we transfected these cells with an inhibitor of mir-155 or with a scrambled sequence, as experimental controls (for reducing the number of false positives). Cells were then stably selected with puromycin, and grown in the presence of 100 μM 4SU for 18 h. Different amounts of these cells (300M, 50M and 10M) were then irradiated to cross-link the RNA to RNA-binding proteins. PAR-CLIP was then performed on cell lysates using anti-Ago2 mAbs and the sequencing performed on an Illumina HiScanSQ system. After deduplication and alignment, T-to-C variants (indicative of miRNA-dependent targetome) were chosen as models for the present study.

Aims: We set ourselves to adapt PAR-CLIP technique to allow non-engineered cells to be used based on IP of endogenous levels of Ago2. In addition, we also aimed at testing the minimum number of input cells needed for miRNA target identification.

Methods: Two DLBCL cell lines (ABC-type RIVA, and GC-type SUD-HL1) were transfected with lentiviral vectors that encoded mir-155. In parallel, we transfected these cells with an inhibitor of mir-155 or with a scrambled sequence, as experimental controls (for reducing the number of false positives). Cells were then stably selected with puromycin, and grown in the presence of 100 μM 4SU for 18 h. Different amounts of these cells (300M, 50M and 10M) were then irradiated to cross-link the RNA to RNA-binding proteins. PAR-CLIP was then performed on cell lysates using anti-Ago2 mAbs for IP. The original protocol (Hafner, 2010) was modified to eliminate radioactive labelling. The recently developed PAR-CLIP protocol yielded sufficient RNA for building libraries using TruSeq Small RNA Sample Kit v1 and the sequencing performed on an Illumina HiScanSQ system. After deduplication and alignment, T-to-C variants (indicative of miRNA-dependent binding sites) were identified, and PAR-CLIP clusters called using wavClusteR (Cornoglio, 2015).

Results: Endogenous Ago2 IP, followed by a radioactive-free modified PAR-CLIP protocol yielded sufficient RNA for building libraries for NGS irrespectively of cell input. Samples gave an average ~9.7 x106 aligned reads/library. There were an average of 7,370 PAR-CLIP clusters mapping to coding genes (range 4,675 - 11,004, correlating with the number of input cells, r=0.82). In all exper-
Background: Daratumumab (DARA) is a first-in-class human monoclonal antibody that targets the CD38 epitope and is approved for the treatment of relapsed/refractory (R/R) multiple myeloma (MM) patients. DARA is currently being evaluated in phase II clinical trials as monotherapy in patients with R/R Mantle Cell Lymphoma (MCL), Follicular Lymphoma (FL) and Diffuse Large B-Cell Lymphoma (DLBCL). DARA induced growth arrest through high affinity mediated mechanisms in MM, including Antibody-Dependent Cellular Cytotoxicity (ADCC), Complement-Dependent Cytotoxicity (CDC) (de Weers M. J Immunol, 2011) and Antibody-Dependent Cellular Phagocytosis (ADCP) (Ovredijk MB. Mabs, 2015). In Chronic Lymphocytic Leukemia (CLL), DARA induces killing mainly via ADCC and ADCP (Matas-Céspedes A. Clin Cancer Res, 2016). Furthermore, Immunomodulatory effects (Kniejck J.B. Blood, 2016) and modulation of the enzymatic activity of CD38 (Lammers van Buuren J. Blood, 2014) have been described to contribute to its antitumor activity.

Aims: To evaluate the activity of DARA on MCL and FL cells as monotherapy and in combination with current therapies, both in vitro and in vivo.

Methods: ADCC, CDC and ADCP activities were assessed by calcein release or flow cytometry. Penetration of DARA was analyzed in a 3D model by Selective Plane Illumination Microscopy (SPIM). Molecules per cell were analyzed using Qifkit and flow cytometry. In vivo activity was assessed in prophylactic and therapeutic set ups using SCID mice subcutaneously (sc) or intravenously (iv) injected with 1x10^7 of MCL or FL cells. Mice were treated (human IgG control or DARA) with two different schedules: prophylactic (3 doses of 10mg/kg one dose per week) or therapeutic (20/10/10/10mg/kg, one dose per week). For the combination regimens in FL, sc injected SCID mice were treated following the standard schedule in combination with Rituximab (20/10/10/10mg/kg, one dose per week) and/or CHOP (initial unique dose).

Results: DARA (0.0001-1µg/mL) induced ADCC in a dose-response manner on MCL (n=6) and FL (n=4) cell lines in the presence of PBMCs in vitro. Moreover, DARA induced significant levels of ADCP at 1µg/mL with 68% of cell death (n=6) and FL (n=4) cell lines in the presence of murine macrophages in vitro. However, DARA did not induce significant CDC in any of these models due to a high expression of the complement inhibitors CD46, CD55 and CD59, and insufficient number of CD38 molecules per cell. In a 3D model of FL, SPIM analysis revealed a maximum penetration of DARA at 1µg/mL after 48h of treatment. We tested DARA activity in vivo in two different mouse models (sc and iv) of MCL and FL. In the prophylactic setting, DARA completely prevented the outgrowth and induced tumor regression of MCL (n=6) and FL (n=6) subcutaneous tumors. In the therapeutic setting, DARA significantly increased the overall survival of mice and reduced organ infiltration of tumor cells both in the MCL (n=10) and in the FL (n=10) systemic xenograft models. In addition, the combination of DARA with Rituximab/CHOP regimen in FL, resulted in a synergistic reduction of tumor growth (n=7-10).

Summary/Conclusions: DARA shows encouraging cytotoxic activity in MCL and FL cells in combination with current therapies, both in vitro and in vivo. In addition, DARA exerts unique and substantial effects as single agent on MCL and FL tumor cell growth in different mouse models and contributes to potent therapeutic efficacy in combination with current approved therapies. These results warrant further studies of DARA in the clinical setting for these conditions.
and proliferation of several B cell malignancies. BTK is a key regulator of this pathway. In a preliminary clinical study, the safety BTK inhibitor STRO-001 showed therapeutic activity in relapsed/refractory DLBCL of the Activated B-cell phenotype (ABC-DLBC) (Walter et al Blood 127pp411-419,2016). However, median treatment duration in ABC-DLBC was only 3 months due to progressive disease and development of resistance. Two acquired resistant mutations, R665W and C481S have been reported as dominant mechanisms to BTK inhibition in CLL but resistance mechanisms in DLBCL have not been fully elucidated.

Aims: To determine resistance mechanisms in the ABC-DLBC TMD8 cell line and determine new rational combinations to take into the clinic with ONO/GS-4059. Methods: The BTK inhibitor sensitive ABC-DLBC cell line TMD8 was crossed with resistant TMD8RO and TMD8RI. STRO-001 was used for this study. TMD8RO has PLC/2 R665W whilst TMD8RI lacks both BTK C481S and PLC/2 R665W. Cell viability and apoptosis after compound treatment were assessed using Cell titer Glo assay and Annexin V/ PI staining. Western blotting showed differences in the expression of immunoreceptor were assessed by immunoblot and Flow cytometry. The mutational status of BTK and PLC/2 in TMD8 was determined by Sanger sequencing. Results: Expression of CD74 in different lymphoma subtypes was evaluated by flow cytometry, staining CD74 in >70% of cells. Although ONO/GS-4059 induced rapid reduction in ERK and AKT activation, expression of ERK and AKT rebounded within 24 hours in surviving cells. Interestingly, surface immunoglobulin M (sigM) expression was increased more than three times in these cells leading to subsequent activation of SYK. The specific SYK inhibitor ONO-GS-9973 combined with ONO/GS-4059 inhibited the downstream ERK and AKT reactivation and induced synergistic apoptosis in TMD8. On the other hand, SYK hyper-activation as determined by phosphorylation of SYK and its downstream target BLNK was also observed in the two BTK inhibitor resistant cell lines. Additionally, expression of CDS and CD22, which negatively regulate B-cell phenotype, was decreased in these cells. The combination of ONO/GS-4059 and GS-9973 restored sensitivity to ONO/GS-4059 and induced synergetic apoptosis in both resistance cell lines. Summary/Conclusions: These data show that SYK is highly activated through increased sigM expression and/or downregulated CDS and CD22 following BTK inhibition treatment in ABC-DLBC. These changes may contribute not only the development but also the maintenance of resistance to BTK inhibitor. The combination of ONO/GS-4059 with SYK inhibitor is therefore a rational strategy for preventing and overcoming BTK inhibitor resistances.

STRO-001, A NOVEL ANTI-CD74 ANTIBODY DRUG CONJUGATE (ADC) FOR TREATMENT OF B-CELL NON-HODGKIN'S LYMPHOMA (NHL)

A. Yu1, C. Abrahams1, M. Embry1, X. Li1, V. DeAlmeida1, J. Lee1, S. Matheny1, T. Kline1, A. Yam1, R. Stafford1, T. Hallam1, M. Lusher2, A. Molina1.1

1Sutro Biopharma, South San Francisco, United States

Background: CD74 is a type II transmembrane glycoprotein involved in the formation and transport of MHC class II protein. CD74 is rapidly internalized and highly expressed in many B-cell malignancies with limited expression in normal tissues (Stein R. et al., CCR 2007). STRO-001 is a novel CD74-targeting ADC comprised of a p-azido-methyl-phenylalanine (pAMF)-containing anti-CD74 aglycosylated human IgG1 antibody (SP7219) conjugated to a non-cleavable dibenzocyclooctynylene (DBCO)-maytansinoid linker-warhead. Highly efficient site-specific conjugation enabled by Sutro’s cell-free antibody production and click chemistry produced a well-defined homogeneous ADC with a drug-antibody ratio (DAR) of 2. Due to its limited cell permeability, the major mechanism of action is via antibody dependent cellular cytotoxicity (ADCC) and over 72 hours induced classical apoptosis in >80% of cells. Although ONO/GS-4059 showed rapid reduction in ERK and AKT activation, expression of ERK and AKT rebounded within 24 hours in surviving cells. Interestingly, surface immunoglobulin M (sigM) expression was increased more than three times in these cells leading to subsequent activation of SYK. The specific SYK inhibitor ONO-GS-9973 combined with ONO/GS-4059 inhibited the downstream ERK and AKT reactivation and induced synergistic apoptosis in TMD8. On the other hand, SYK hyper-activation as determined by phosphorylation of SYK and its downstream target BLNK was also observed in the two BTK inhibitor resistant cell lines. Additionally, expression of CDS and CD22, which negatively regulate surface immunoglobulin M (sigM) expression was increased more than three times in these cells leading to subsequent activation of SYK. The specific SYK inhibitor ONO-GS-9973 combined with ONO/GS-4059 inhibited the downstream ERK and AKT reactivation and induced synergistic apoptosis in TMD8. On the other hand, SYK hyper-activation as determined by phosphorylation of SYK and its downstream target BLNK was also observed in the two BTK inhibitor resistant cell lines. Additionally, expression of CDS and CD22, which negatively regulate B-cell phenotype, was decreased in these cells. DETECTING MALIGNANT B-CELLS IN CEREBROSPINAL FLUID: DOES THE IDEAL METHOD EXIST?

J. Osman1, S. Tarif1, M. Armand1, C. Houiller2, S. Choquet3, H. Agnelo1, H. Strub1, P. Bonnemey1, K. Hoang-Xuan2, M. Le Garff-Tavernier1,*, M. Costopoulos1, F. Davi1

1Biological Haematology Department, 2Neuro-Oncology, 3Clinical Haematology, Pitié-Salpetrière Hospital, Paris, France

Background: Leptomeningeal dissemination (LD) is a relatively rare but often fatal complication of lymphomas, confirmed by the analysis of the cerebrospinal fluid (CSF). The diagnosis is suspected in case of neurological symptoms, parenchymal brain involvement detected with neuroradiography techniques and, more recently, by the analysis of the cerebrospinal fluid (CSF). Cytomorphological examination (CM) is still considered as the “gold standard” but remains insufficiently sensitive. Aims: The aim of our study was to assess the benefit of more sensitive techniques, i.e. immunophenotyping by flow cytometry (FCM) and clonality by PCR, for the detection of malignant B cells in the CSF of patients with suspected leptomeningeal dissemination. Methods: This study was conducted on 326 CSF samples (236 patients) referred to our laboratory between January 2015 and December 2016. CM, FCM and PCR results were recorded and classified as positive (+), negative (-) or indeterminate (I). FCM was performed using an 8-colour panel. A sample was classified as positive (+) if a cluster of malignant cells with a clonal distribution was observed in the CSF of patients with suspected leptomeningeal dissemination. Results: In this preliminary study, the sensitivity of FCM was higher than CM and PCR for the detection of malignant B cells. Using an 8-colour panel, a sample was classified as positive (+) if a cluster of malignant cells with a clonal distribution was observed in the CSF of patients with suspected leptomeningeal dissemination. Methods: This study was conducted on 326 CSF samples (236 patients) referred to our laboratory between January 2015 and December 2016. CM, FCM and PCR results were recorded and classified as positive (+), negative (-) or indeterminate (I). FCM was performed using an 8-colour panel. formed following the BIOMED-2 design and protocol. All PCR experiments were done in duplicates, and cases were considered PCR+ when both duplicates showed the same clonal pattern, ruling out false positivity (Pseudoclonal pattern) often seen in paucicellular samples.

**Results:** We confirm that FCM and PCR are more sensitive than CM. Indeed, every CM+ cases (n = 16) was also FCM+ and/or PCR+ while 13 cases were FCM+/PCR+ but CM-. A total of 569 samples showed similar results by FCM and PCR with presence (n=22) or absence (n=247) of lymphomatous cells whereas 25 samples were classified as suspicious by at least one technique. Eleven samples were FCM+ but PCR-. False negative (FN) PCR results can be explained in part by extensive somatic mutation in IG genes, preventing optimal amplification of the BCR or venetoclax sensitive cell lines, whereas the levels of BCL2 targets less prone to somatic mutations, such as IGL, should therefore be evaluated. Conversely, 21 samples were PCR+ but FCM-. Absence of FCM detection might have resulted from the presence of very large lymphomatous cells outside the scope of analysis. Also, rapid cell death is an issue with FCM (preventing optimal FCM detection). Thus, venetoclax sensitive cell lines do not systematically require intact cells. Most of the difficulties encountered with both methods are due to occult blood contamination and poor cellularity, leading to low-intensity clonal signals by PCR and inconsistent cluster of events with FCM. In addition discordant results between FCM and PCR might be explained by sampling heterogeneity. Considering these limitations, it seems highly advisable to choose the best suited method for the follow-up according to the results at diagnosis.

**Summary/Conclusions:** Our results suggest that a multimodal investigation using FCM and PCR is necessary for improved detection of leptomeningeal dissemination in T-cell malignancies. It seems premature to make clinical decisions based on one technology. Both methods, which suffer limitations that need to be acknowledged, are complementary and should be performed at diagnosis. Specific limitations of each one of them should be taken in consideration for follow-up studies.

**THE SYK INHIBITOR R406 DRAMATICALLY INCREASES THE SENSITIVITY OF GCB AND ABC DLBCL CELL LINES TO THE BCL-2 INHIBITOR VENETOCLAX**

B. Sasi1,**, S. Turkaj1, **D. Efremov1

1Molecular Hematology, International Centre for Genetic Engineering & Biotechnology, Trieste, Italy

**Background:** The BCL-2 inhibitor venetoclax demonstrated significant single-agent activity in recent clinical trials of relapsed/refractory chronic lymphocytic leukemia (CLL). However, results in some other B-cell malignancies characterized by BCL-2 overexpression have not been equally impressive. This particularly refers to diffuse large B cell lymphoma (DLBCL), where only 18% of patients responded to treatment with venetoclax in a recent phase I clinical trial (Davis MS et al, J Clin Oncol. 2017).

**Aims:** Investigate whether the SYK inhibitor R406 can increase sensitivity of DLBCL to venetoclax in vitro and in vivo.

**Methods:** The following cell lines were used: Ly4, Ly1, Ly7, Ly18, DHL4, Toledo and BJAB (all GCB DLBCL) and U2932, DHL2, Ly3, Ly10, HBL1 and TMD8 (all ABC DLBCL). The percentage of apoptotic cells was determined by Annexin V/propidium iodide stained FCM. Expression of BCL-2 family members was determined by immunoblotting or Q-PCR analysis.

**Results:** In a recent study, we showed that MCL-1 increases the resistance of anti-IgM stimulated CLL cells to venetoclax, and that SYK inhibitors can effectively overcome this resistance by blocking B cell receptor (BCR)-mediated MCL-1 upregulation (Bojczuk K et al. Blood. 2016). Since constitutive activation of the BCR pathway has been described in both ABC and GCB DLBCL (Davis RE et al, Nature 2010; Chen L et al, Cancer Cell. 2013), we investigated whether treatment with the SYK inhibitor R406 can sensitize DLBCL cells to venetoclax. Single-agent venetoclax had only modest activity against most DLBCL cell lines at concentrations ranging up to 0.25 μM (Figure 1). Substantial apoptosis induction (>20%) was observed in only 2 GCB (Ly1 and Ly18) and 2 ABC (U2932 and Ly10) cell lines. R406 as single agent had almost no effect on tumor cell viability, with only one cell line showing >20% apoptosis induction (HBL1). However, addition of R406 to venetoclax resulted in a dramatic increase in the number of apoptotic cells in six of the investigated cell lines (Ly18, DHL4, U2932, Ly10, HBL1 and TMD8). A synergistic effect was also observed with Ly1 using a lower concentration of venetoclax, whereas no effect or only an additive effect was observed in the remaining cell lines (Ly4, Ly7, Toledo, BJAB, DHL2 and Ly3). Among these, only Toledo expressed similar levels of BCL2 and BCL-xL. Consistent with the results of Venetoclax sensitive cell lines, we detected a 20-45% reduction in MCL1 levels following 24 hours culture with 2μM R406, whereas no changes were observed in Ly18 and Ly10. However, a substantial reduction in A1 levels was observed in Ly18 and U2932 cells, whereas no substantial changes in A1 and BCL-xL expression were detected in any of the other investigated cell lines. Finally, we also investigated the effects of R406 on expression of HRK, which is a propapoptotic BCL-2 family member that was recently shown to be induced by SYK inhibition in a subset of GCB DLBCLs (Chen L et al, Cancer Cell. 2013). A substantial increase in HRK expression (140-640%) was observed in 5 of the 7 R406 + venetoclax sensitive cell lines (Ly1, Ly18, DHL4, U2932 and TMD8).

**Figure 1.**

**Summary/Conclusions:** These data show that the SYK inhibitor R406 can significantly increase the sensitivity to venetoclax in the vast majority of BCL-2 positive DLBCL cell lines. The mechanisms of action require further investigation, but are likely to involve downregulation of MCL-1 and upregulation of HRK in a substantial proportion of cases.

IRF4 EXPRESSION IS ASSOCIATED WITH RESPONSE OF MANTLE CELL LYMPHOMA TO BRUTON’S TYROSINE KINASE INHIBITORS

H.P. Thompson¹, D.L. Tucker², S.A. Rule¹, C.V. Hutchinson¹,²
¹Institute of Translational and Stratified Medicine, Plymouth University, Peninsula
Sullivan School of Medicine and Dentistry, ²Clinical Haematology, Plymouth Hospitals
NHS Trust, Derriford Hospital, Plymouth, United Kingdom

Background: Mantle cell lymphoma (MCL) responds poorly to conventional chemotherapy. Inhibitors of Bruton’s tyrosine kinase (BTK) have unexpectedly shown significant clinical effect; however despite this success, approximately one third of MCL patients have primary resistance to the drug, and patients who initially respond to treatment frequently acquire secondary resistance and aggressive relapse of the disease. Understanding how BTK-resistance or sensitivity is mediated can identify new targets for therapy or predictive biomarkers of response. Using an in vitro model system we have identified the transcription factor IRF4 as a sensitive indicator for BTK response in MCL cell lines and primary cells.

Aims: To identify molecules or pathways responsible for resistance to BTK inhibitor-drugs in mantle cell lymphoma using cell line models and primary cells.

Methods: Primary cells and validated MCL cell lines (REC-1, G519, JEKO-1, JVM2) were cultured either alone, or together with murine stromal cells (with or without CD40L transfection). The BTK sensitive REC-1 cell line was continuously treated with BTKi to generate an acquired resistance model. Cultures were treated with BTK inhibitors ibritinib or acalabrutinib in the presence or absence of B-cell receptor or CD40L stimulation, and their sensitivity or resistance to treatment was determined using flow cytometry to assess proliferation (Ki67), apoptosis (Annexin-V), or phosphorylation of BTK (pY223). Changes affecting downstream proteins were determined by protein expression or phosphorylation analysis (immunoblotting) and by mRNA expression (RT PCR).

Following initial experiments the studies focussed on IRF4.

Results: Each MCL cell line showed basal phosphorylation of BTK (Y223) and its downstream receptor (pY203/205), however in IRF4 silenced cells these downstream pathways were not detected (Figure 1). In REC-1 cells, expression of IRF4 was not detected in either untreated or treated cultures, whereas expression of IRF4 was detected in BTKi resistant JVM2 cells. Moreover, knockdown of IRF4 increased BTK phosphorylation (pY223), suggesting that IRF4 downregulation may contribute to BTKi resistance.

Summary/Conclusions: Expression of IRF4 is associated with resistance to BTK inhibitor drugs in mantle cell lymphoma. IRF4 as a sensitive indicator for BTK response may facilitate the identification of patients who are not likely to respond to treatment with BTK inhibitors and serves as an alternative method for monitoring treatment response.

LIQUID BIOPSY: DECIPHERING A SIGNATURE OF CIRCULATING MICRORNAS AS NOVEL NON-INVASIVE BIOMARKERS IN DIFFUSE LARGE B-CELL LYMPHOMA

F. Marchesi¹,², G. Regazzò³,², A. Saccon²,³, M. Spagnuolo², S. Donzelli², F. Palombi¹, M. Marino⁴, C. Ercolani⁴, A. Di Benedetto⁴, G. Blandino², A. Mengarelli¹, M.G. Rizzo³

¹Department of Stem Cell Transplant, ²Epigenetic and Oncogenetic Unit, Translational Research Area, ³Regina Elena National Cancer Institute, Rome, Italy, ⁴Pathology Unit, Regina Elena National Cancer Institute, Rome, Italy

Background: Up to 40% of Diffuse Large B-Cell Lymphoma (DLBCL) patients still experience treatment failure or disease relapse after conventional chemotherapy. Therefore, the search of novel non invasive biomarkers able to early identify these patients is warranted in order to offer a different therapeutic approach. Recently, bodily fluids have emerged as an important source of infor-

domain expression in only 49%. A substantial proportion of such failures of FCM-based clonality detection can be best explained by lost surface TR expression and the limited coverage of the Vβ antibody panel. NGS-based clonality analysis can overcome these limitations, because it detects virtually all TR Vβ-JB rearrangements. On the contrary, NGS is more sensitive and therefore enables the detection of minor subclones, which has great appeal for MRD analysis. Nevertheless, flow cytometric Vβ spectratyping is a faster, cheaper, and less labourious alternative. It has the additional advantage of detecting the actual TR Vβ chain expression and of visualizing individual T-cell subsets for quantification of Vβ cell populations.

E1384

LOSS OF TPL2 KINASE ACCELERATES MYC-INDUCED LYMPHOMAGENESIS

E. Stagakis¹,², D. Vyrla¹, H. Papadaki¹, E. Drakos¹, A. Ellipoulou³
¹Laboratory of Molecular and Cellular Biology, Medical School, University of Crete, ²Department of Hematology, University Hospital of Heraklion, ³Department of Pathology, Medical School, University of Crete, Heraklion, Greece

Background: While MYC (8;14)(q24;q32) translocation was initially identified as a hallmark of Burkitt lymphoma, a number of other B-cell neoplasms are associated with MYC deregulation. These MYC-driven non-Hodgkin lymphomas have aggressive clinical behavior and respond poorly to treatment. However, MYC-dependent lymphomagenesis is believed to require additional oncogenic alterations, such as deregulation of genes that counteract the proapoptotic functions of MYC. TPL2 is a MAP3 kinase with an obligatory role in inflammatory signal transduction on the MEK/ERK axis but little is known about its involvement in B lymphocyte biology and lymphomagenesis.

Aims: The aim of this study is to define the impact of and the mechanism by which TPL2 kinase affects MYC-induced lymphomagenesis.

Methods: CD19+ positive B lymphocytes were isolated from peripheral blood of human healthy individuals and mouse B cells from spleens of WT (C57BL/6) and lymphomagenic mice engineered to overexpress c-myc in B cell progenitor cells under the control of the IgH chain enhancer. Mouse pre-B lymphocytes were isolated from bone marrow by flow cytometric cell sorting. Differentiation status of lymphomas was analysed by flow cytometry using B220, IgM and IgD antibodies. The TPL2 RNA and protein expression levels were assessed by qPCR and Western blot analysis, respectively. The extent of apoptosis was estimated by immunohistochemical evaluation of activated caspase-3 in paraffin embedded mouse lymphoma tissues and by flow cytometry using Annexin and 7AAD staining of ex vivo cultured lymphoma cells following cytokine deprivation.

Results: TPL2 RNA levels were found dramatically decreased in various human Burkitt lymphoma cell lines as well as in 7 primary Burkitt lymphoma biopsies compared to B lymphocytes of healthy individuals. In line with this finding, both pre-B and B lymphomas derived from Eμ-myc mice express very low levels of TPL2 RNA and protein level, compared to pre-B and splenic B lymphocytes isolated from WT mice. Interestingly, pre-B and B lymphocytes of healthy (premalignant) Eμ-myc mice express TPL2 in comparable levels to their WT counterparts, suggesting that the reduction of TPL2 expression in lymphomas is an additional oncogenic alteration. In this regard, genetic ablation of TPL2 in Eμ-myc mice (Eμ-myc/tpl2−/−) significantly shortened their survival to 92 days from 140 days of Eμ-myc/tpl2+/+ mice (p<0.005). Eμ-myc/tpl2−/− mice also displayed a trend to develop more pre-B cell lymphomas compared to Eμ-myc/tpl2+/+ mice. This may be attributed to the decreased TPL2 expression in mouse pre-B lymphocytes, while it is upregulated in mature B lymphocytes. Finally, Eμ-myc/tpl2−/− lymphomas displayed reduced levels of apoptosis.

Figure 1.

Summary/Conclusions: This study reveals a novel pathway during myc-driven lymphomagenesis. We show that MYC deregulation imposes selective pressure in favor of clones with decreased expression of TPL2 kinase. This process seems to be advantageous for the malignant clone, since genetic ablation of TPL2 in the Eμ-myc mouse model accelerates MYC-induced lymphomagenesis likely by contributing to apoptosis resistance.
mation in several diseases analyzable by liquid biopsies, representing minimally invasive methods for precision diagnostics and prognosis. Blood extracellular microRNAs (miRNAs) are under investigation as novel biomarkers. While tissue miRNAs in DLBCL patients have been extensively studied, only few reports, and limited to a small subset of miRNAs, evaluated the role of circulating/serum miRNA as potential prognostic factors.

Aims: To identify and validate a serum miRNA signature with prognostic value in a cohort of newly diagnosed DLBCL patients. Methods: This is a on-going prospective non interventionist study on a cohort of newly diagnosed de novo DLBCL patients uniformly treated with six courses of R-CHOP (Rituximab, Cyclophosphamide, Vincristine, Doxorubicin and Prednisone). Serum samples of patients were collected at diagnosis and after the end of treatment. Treatment response was evaluated by standard Cheson criteria. The expression profile of selected circulating miRNAs described as associated with lymphoid malignancies by us (let-7c/miR-99a1/miR-125b cluster) and by previously published studies (miR-22, miR-18a and miR-20a) was evaluated by using Taqman miRNA RT-qPCR. Serum samples were collected at diagnosis of the first 18 patients enrolled into the study. Results: Our results showed that the expression level of serum miR-22 as well as let-7c/miR-99a1/miR-125b cluster was significantly higher at diagnosis, in patients unresponsive to R-CHOP treatment when compared with responsive patients. On the contrary, miR-18 and miR-20 levels appeared to be not significantly associated to treatment response. In addition, a global expression profile of circulating miRNAs was evaluated in serum samples derived from a smaller cohort of patients (n=4) after first-line chemo-immunotherapy. Interestingly, we found a striking difference in miRNA modulation upon treatment between unresponsive and responsive patients. In particular, we found 31 miRNAs significantly modulated after R-CHOP in the group of responsive patients, including miR-22. In contrast, this miRNA subset did not show remarkable expression changes in unresponsive patients. Moreover, we performed a study interrogating The Cancer Genome Atlas (TCGA) database about miRNA expression levels in samples of DLBCL patients. We found that the only available data are relative to the miRNA expression levels in tumor tissue samples of 47 out of 58 DLBCL patients. Kaplan Meier method and log-rank test revealed a signature of 13 miRNAs with potential prognostic value. Among these we found that miR-22, also emerged as modulated in our genome-wide analysis, was linked to risk of disease recurrence. Summary/Conclusions: These preliminary data suggest that the serum miR-22 as well as miR-99a1/miR-125b cluster are of potential interest as non-invasive biomarkers to predict therapeutic response in DLBCL patients. Ongoing experiments in a wider cohort of patients are aimed to confirm these results and unveil potential miRNA signature with predictive value.

E1380
INTRACELLULAR CALCIUM AND METABOLISM HAVE CRITICAL ROLES IN DETERMINING ANTI-CD20 ANTIBODY EFFICACY IN DLBCL
E. Vilventhraja1, 2, J. Grimboli1, A. Braun1
1Centre for Haematology-Oncology, Barts Cancer Institute, London, United Kingdom
2University of Barcelona, Barcelona, Spain

Background: Since the discovery and utilisation of the Type-I anti-CD20 antibody Rituximab, many have tried to enhance the efficacy of anti-CD20 antibodies in order to improve first-line treatment of B cell malignancies, leading to the development of anti-CD20 antibodies. To date, the main role of intracellular calcium and metabolism has been studied. This work aims to characterize the biological role of CD20 and the mechanism of anti-CD20 antibody action remains unclear. However, CD20 has been shown to be involved in the store intracellular calcium is decreased. Intracellular calcium remains unchanged following treatment with Rituximab. Next, we show anti-CD20 antibody treatment causes cells to increase mitochondrial respiratory capacity to compensate for reduced basal mitochondrial function. We show that inhibition of OxPhos disables the cells from being non–invasive biomarkers to predict therapeutic response in DLBCL patients. Ongoing experiments in a wider cohort of patients are aimed to confirm these results and unveil potential miRNA signature with predictive value.

Results: Intracellular calcium concentration was decreased across our panel of cell lines following a 24-hour treatment with all Type-II anti-CD20 antibodies in our panel. This decrease was not observed following treatment with the Type-I anti-CD20 antibody Rituximab. Treatment with anti-CD20 antibodies resulted in a significant increase in the maximal respiratory capacity of our panel of cell lines; cells were able to produce more ATP in response to oxidative stress. Conversely, chemo-immunotherapy with OxPhos impaired mitochondrial function, causing a significant reduction in basal OxPhos and in maximal respiratory capacity. Under this condition, cells were unable to increase ATP production in response to oxidative stress. We also show that treatment combining Metformin with either Type-I or Type-II anti-CD20 antibodies prevents the increase in maximal respiratory capacity observed with anti-CD20 antibody treatment alone. When analysing the clonogenic survival of cell lines, we have found that only the cytotoxicity of Type-II anti-CD20 antibodies is enhanced by simultaneously treating cell lines with Metformin.

Summary/Conclusions: Our data show for the first time that when cells are treated with Type II anti-CD20 antibodies, intracellular calcium is decreased. Intracellular calcium remains unchanged following treatment with Rituximab. Next, we show anti-CD20 antibody treatment causes cells to increase maximal mitochondrial respiratory capacity to compensate for reduced basal mitochondrial function. We show that inhibition of OxPhos disables the cells from being non–invasive biomarkers to predict therapeutic response in DLBCL patients. Ongoing experiments in a wider cohort of patients are aimed to confirm these results and unveil potential miRNA signature with predictive value.

CYCLIN D1 ONCOGENIC OVEREXPRESSION LEADS TO A GLOBAL TRANSCRIPTIONAL DOWNREGULATION IN MALIGNANT LYMPHOID CELLS
R. Albero1,2, A. Enjuanes3, S. Demajo1, G. Castellano3, M. Pinyol4, N. Garcia1, C. Capdevila1, H. Suarez-Cisneros5, K. Karube4, S. Bea1, I. Martin-Subero1, E. Campo1, P. Jares2
1IDIBAPS, Barcelona, Spain, 2Genomics Unit, IDIBAPS, 3Molecular Biology Core, Hospital Clinic, Barcelona, Spain, 4University of the Ryukyus, Okinawa, Japan, 5Hospital Clinic, Barcelona, Spain

Background: Cyclin D1 is an oncogene frequently overexpressed in human cancers. In hematologic neoplasms, mantle cell lymphoma and multiple myeloma are clear examples of deregulated cyclin D1 expression. It plays a dual function as cell cycle and transcriptional regulator, although the latter is widely unexplored.

Aims: In this study, we investigate the transcriptional role of cyclin D1 in lymphoma and mantle cell lymphoma. The study of cyclin D1 oncogenic overexpression in B cells as a model of the first steps in MCL oncogenesis.

Methods: Chromatin immunoprecipitation (ChIP) followed sequencing was performed in four established MCL cell lines. RNA-Sequencing (RNA-Seq) and information from histone ChiP-Seq were correlated with genomic intervals displaying cyclin D1 binding. Transcriptional downregulation was studied through cytometric RNA total quantification in lymphoblastic cyclin D1-overexpressing models and RNA Pol II ChiP-Seq.

Results: Endogenous cyclin D1 showed widespread binding to active promot- ers and promoters in cyclin D1-overexpression was responsible for a global transcriptional down-modulation. Cyclin D1, instead of showing specific gene activation, seems to globally decrease cell transcription. Mantle cell lymphoma and multiple myeloma cell lines displayed an inverse relation with cyclin D1 quantity. This transcriptional effect was associated with an increased RNA polymerase II pausing in promoters due to cyclin D1-overexpression.

Summary/Conclusions: This mechanism expands the oncogenic cyclin D1 functions and places the transcriptional machinery as a potential therapeutic target in cyclin D1-overexpressing tumors.

MICROENVIRONMENTAL EXPRESSION OF IMMUNOREGULATORY MOLECULES AND CYTOKINES IN CLASSICAL Hodgkin's lymphoma PROGNOSIS
O. Novosad1, 2, N. Svergun2, O. Skakhova2, O. Gorbach2, N. Khranovska2, I. Kryachok1
1Oncohematology, 2Experimental Oncology, National Cancer Institute, Kiev, Ukraine

Background: Over the past decade, new biologic insights have revealed a key role of tumor microenvironment in the pathogenesis of classical Hodgkin’s lymphoma (cHL). cHL infiltrating cells produce cytokines and growth factors that provide essential stimulatory signals for survival and proliferation of Hodgkin’s and Reed–Stanberg cells. Moreover, clinical behavior of cHL may be directly regulated by the cross-talk between tumor cells and infiltrating immune cells.
Aims: The aim of our study was to estimate the role of microenvironment expression of immunoregulatory molecules (PD-1 ligands, IDO) and cytokines (TGF-β, IL-13) in clinical outcome of cHL.

Methods: 74 patients (median age: 44, range: 17-71 years; males: 22, females: 52) were included in the study. 55.4% of patients were diagnosed with an early stage of HL, while 44.6% - with advanced stages. ABVD or BEACOPP (14/esc) were administered as a 1st-line therapy. 78.3% of patients achieved remission (CR/PR), while 8.1% had progression of disease during the therapy. We recorded 14.8% relapses in patients after the 1st line therapy during the follow-up period (median duration – 36 months; range 6-66 months). PD-L1, PD-L2, IDO, TGF-β, IL-13 mRNA expression levels were analyzed in fresh pre-treatment lymph node biopsies using qRT-PCR.

Results: Expression of PD-1 ligands was heterogeneous across the samples and did not depend on histological variant or stage of cHL. Only 12.1% of patients (9/74) were PD-L1 negative and all but one of those cases had a CR and a long-term remission. Patients with PD-L1 overexpression tended to have a higher rate of relapse, comparing to those with lower PD-L1 expression (p=0.1). We did not find any significant association between PD-L2 expression level and clinical outcome of cHL. Expression levels of IDO, TGF-β, IL-13 were evaluated in 38 cHL samples. 18.4% (7/38) patient were IDO positive and 81.6% (31/38) - IDO negative. The presence of IDO expression was associated with a higher risk of relapse in cHL patients (p=0.008). 85.7% (6/7) and 23.3% (7/30) of relapses were observed during the follow-up period in IDO+ and IDO-patients, respectively (p<0.05). The patients with double negative expression of PD-L1 and IDO were noted to have a favourable outcome of cHL. A 5-year event-free survival (EFS) rate was 88% for double negative PD-L1/IDO-patients vs 20% for double positive PD-L1+/IDO+ patients (p=0.008). IL-13 was expressed at various levels depending on the stage of cHL with the highest expression levels in advanced stages. A trend for a higher risk of relapse was observed for HL patients with increasing level of IL-13, (p=0.23). TGF-β expression was associated with the therapy with anti-CD20 mAbs. This strategy seems to be highly promising in CLL patients, often expressing very low CD20 level and do not benefit from immunotherapy.

Summary/Conclusions: Our results clearly indicate that HDAC6 inhibition sensitizes tumor B-cells to anti-CD20 immunotherapy. Therefore, we propose HDAC6 as a potential target for immunotherapy.

E1383
AN IN VIVO TRACEABLE AND MULTIPLEXING CRISPR/Cas9 GENOME EDITING SYSTEM
L. Cheng1,2, T. Niú1, Y. Liu2
1Department of Hematology and Research Laboratory of Hematology, 2State Key Laboratory of Biotherapy and Cancer Center, West China Hospital Sichuan University, Chengdu, China

Background: Gene gain of function and loss of function mutations, oncogene overexpression, gene amplification, chromosome deletion and epigenetic changes, may lead to lymphoma onset. The CRISPR-Cas9 genome editing system has become a feasible tool for exploring the functions of specific genes in different contexts. We want to use this technique to screen for lymphoma suppressor genes.

Aims: Construct an in vivo traceable and multiplexing CRISPR-Cas9 gene editing system, which is high efficient for studying in vivo functions of both individual genes or any given chromosome fragment.

Methods: Two retroviral vectors were constructed via molecular clone, one of which contains a locus for tandem U6-sgRNAs and inducible GFP reporter gene and the other contains Cas9 and GFP gene. This system’s function of traceable and simultaneously mutate multiple gene efficiencies were validated in vitro. Eμ-myc HSPCs retrovirally transduced with sgp53 and Cas9 were transplanted into sublethally irradiated C57/BL6 mice.

Results: Co-transduced cells can be tracked by the expression of GFP protein and multiple sgRNA can be efficiently introduced to the GFP-labeled cells for simultaneously mutating multiple genes or deleting a large chromosome fragment. Further we applied this system for both in vitro and in vivo genome editing. As an example, we show that Tp53 mutation accelerated Eμ-Myc driven lymphoma onset in vivo.

Summary/Conclusions: This traceable and multiplexing CRISPR/Cas9 system might be useful for various genome editing applications.
Background: Primary gastrointestinal (GI) T-cell lymphoproliferations (T-CL) are heterogeneous entities, which diagnoses are difficult to perform. T-CL include aggressive lymphoma such as enteropathy-associated T-cell lymphoma (EATL) as well as indolent monoclonal lymphoproliferations. Refractory coeliac disease type II (RCDII) is one of the indolent T-CL that complicates coeliac disease (CD) and may evolve toward an overt EATL. The differential diagnosis of RCDII from CD and RCDI is difficult and essentially based on negative expression of sCD3 and CD8 and the presence of a clonal TCR rearrangement. Lymphocytes from RCDII are dependent for survival on IL-15, which reprograms T lymphocytes towards a cytotoxic NK phenotype.

Aims: We thus studied the expression of NKp46 on a representative panel of GI T-CL to assess its diagnosis and prognosis value.

Methods: Using formalin-fixed paraffin-embedded tissue biopsies, we assessed NKp46 expression by immunohistochemistry (IHC) and investigated its clinical and biologic significance on 177 intestinal, 11 lymph node and 7 other biopsies from 84 CD or RCD patients (RCDI, n=20; RCDII, n=40), 44 GI T-cell lymphoma patients (EATL, n=25; monomorphic epitheliotropic intestinal T-cell lymphoma_MEITL, n=4; indolent T-LPD, n=15), 11 healthy patients and 5 patients with a GI inflammatory environment as controls.

Results: By doing ROC analysis on number of cells expressing NKp46 on GI-TCL we identify that 25 intra-epithelial lymphocyte (IEL) per 100 epithelial cells (EC) clearly separates RCDII from CD and RCDI patients, with a good positive and negative predictive values (100 and 95% respectively). In healthy controls, CD or RCDI patients, NKp46 was only expressed on scattered IEL (median 3%, 0-15). Based on NKp46 expression the overall survival is poor if over 25% of IEL are positive for NKp46 (OS-5years 96.4% vs 72.8%, P=0.0004) (Figure 1A). Among patients with GI T-cell lymphoma, we show that NKp46 was expressed in most of aggressive lymphoma (EATL 80%, n=20/25 and MEITL 100%, n=4/4). On the other hand, NKp46 was only expressed on indolent T-LPD (n=0/15). The NKp46 expression was also associated with a poor prognosis in GI cell lymphoma patients (OS-5years 50.5% vs 5.4%, P=0.0011) (Figure 1B).

Summary/Conclusions: The NKp46 expression in more than 25 IEL per 100 EC by IHC analysis can easily identify RCDII from CD and RCDI. Furthermore, the NKp46 expression is associated with aggressive forms of GI T-cell lymphoma. Finally, the NKp46 expression was strongly associated with shortened survival. Thus NKp46 provides a new biomarker for both diagnosis and prognosis in GI T-CL.
hours and produced 8.7 ~ 9.3 X 10^3 ng/ml of IgM. PCs isolated from BCWM.1 cells as well as in SNK-6 cells. When comparing with those transfected with IL-2Rα (p<0.05), which can be fully reversed by addition of anti-IL-2Rα antibody. Summary/Conclusions: Our analysis of the 2 WM cell lines provides evidence to support the common hypothesis that malignant PCs arise from the clonal malignant LPL population, and are primarily responsible for IgM secretion in WM.

Figure 1. Results: Expression of IL-2Rα was significantly higher in SNK-6 cells than in NK-92 cells, at both protein and mRNA levels. Expression of IL-2Rα was remarkably upregulated in NK-92 cells transfected with LMP1-harboring lentiviral vectors compared with those transfected with negative control vectors. Proteins in the MAPK/ERK pathway were upregulated in LMP1-expressing NK-92 cells compared with the negative control. Selective inhibitors of those proteins induced significant downregulation of IL-2Rα expression in LMP1-expressing NK-92 cells as well as in SNK-6 cells. When comparing with those transfected with negative control vectors, cell growth was significantly increased in both NK-92 and SNK-6 cells transfected with IL-2Rα-harboring lentiviral vectors, and the cell cycle assay displayed a significant decrease in the percentage of cells in the G0/G1 phase (p<0.05) and an increase in the percentage of cells in the S phase (p<0.05), while apoptosis was not affected. Subsequent western blot tests demonstrated that cyclin A, B, and CDK1, 4 were involved in the regulation of cell cycle with overexpression of IL-2Rα. The IC50 values to all three chemotherapy drugs were significantly increased after overexpression of IL-2Rα, which can be fully reversed by addition of anti-IL-2Rα antibody. Summary/Conclusions: IL-2Rα expression was upregulated in NKTL by LMP1-mediated activation of MAPK/NF-κB pathway. IL-2Rα can promote NKTL cell proliferation partially through regulation of cell cycle and induce chemotherapy resistance, which can be reversed by anti-IL-2Rα antibody, indicating the potential role of IL-2Rα as a therapy target in NKTL.

LMP-1 MEDIATED UPREGULATION OF IL-2Rα PROMOTES LYMPHOMA-
GENESIS AND CHEMOTHERAPY RESISTANCE IN NATURAL KILLER/T-CELL
LYMPHOMA AND COULD BE A POTENTIAL THERAPY TARGET
X.-W. Bi1, W.-J. Lu1, Z.-J. Xia2, W.-Q. Jiang3, H.-Q. Huang1, Y. Lu1, L. Wang2.*

Background: Natural killer/T-cell lymphoma (NKTCL) is an Epstein–Barr virus (EBV)-associated, highly aggressive lymphoma. Treatment outcome remains sub-optimal, especially for advanced-stage or relapsed diseases. Our previous study demonstrated the prognostic value of IL-2Rα in NKTCL, but the role of IL-2Rα in the lymphomagenesis and chemotherapy resistance and its interactions with EBV in NKTL remains to be investigated.
Aims: This study investigated the mechanism of IL-2Rα expression in NKTCL, and explored the role of IL-2Rα in lymphomagenesis and chemotherapy resistance as well as the potential role of anti-IL-2Rα treatment in NKTL.

Methods: Expression of IL-2Rα was measured in NK-92 (LMP-1 weak expression) and SNK-6 (LMP-1 strong expression) cells by western blot, quantitative real-time PCR, enzyme-linked immunosorbent assay, and flow cytometry, respectively. LMP1-harboring lentiviral vectors were transfected into NK-92 cells to examine the correlation between LMP1 and IL-2Rα expression. Proteins in the downstream pathways of LMP1 signaling were measured in NK-92 cells transfected with LMP1-harboring or negative control vectors as well as in SNK-6 cells. Then IL-2Rα-harboring lentiviral vectors were transfected into both NK-92 cells and SNK-6 cells to examine the cell proliferation by CCK8, apoptosis by staining with Annexin V and detected by flow cytometry (FCM), cell cycle distribution by FCM analysis, and IC50 values exposed to three chemotherapy drugs were significantly increased after overexpression of IL-2Rα.

Results: A significant downregulation of IL-2Rα expression in LMP1-expressing NK-92 cells, at both protein and mRNA levels. Expression of IL-2Rα was remarkably increased to 130% and produced 2.5 ~ 2.8 X 10^3 ng/ml of IgM. LPLs from both cell lines proliferated in culture (~ 130 ~ 140% in MWCL-1 and ~170 ~ 200% in BCWM.1 at 72 hours), gave rise to the more differentiated PCs (~ 170 ~ 180% in MWCL-1 and 1.2 ~ 1.4% PCs in BCWM.1), and secreted smaller amounts of IgM than PCs (3.5 ~ 5.0 X 10^3 ng/ml in BCWM.1 and 0.3 ~ 0.7 X 10^3 ng/ml in BCWM.1).

Summary/Conclusions: Our analysis of the 2 WM cell lines provides evidence to support the common hypothesis that malignant PCs arise from the clonal malignant LPL population, and are primarily responsible for IgM secretion in WM.

Summary/Conclusions: Our analysis of the 2 WM cell lines provides evidence to support the common hypothesis that malignant PCs arise from the clonal malignant LPL population, and are primarily responsible for IgM secretion in WM.
on CD3+ cells was unaffected by AAT, although the expression of both ligands increased significantly. Closer analysis of T-cell subsets showed that only in CD4+ cells, PD1 expression increased significantly following co-culture experiments. Preliminary data on lymphoma-AAT co-culture experiments (n=3) indicated that LEN (0.5/1 uM) did not negatively influence the formation of AAT clusters. After 48 h of co-culture, the expression of CD19+CD5-CD11c+ cells increased in 2/3 cases following LEN treatment while, PDL2 expression remained unchanged. PD1 expression gradually increased following exposure to LEN compared to untreated cells. CD3+ cells showed a significant increase in PD1 expression by LEN, while the expression of both ligands remained unaffected. Evaluation of activated T-cell subsets showed similar results, with the exception of stronger induction of PD1 and PDL1 expression by LEN in CD8+ cells.

Summary/Conclusions: Our data provide support for the potential involvement of the PD1-axis in lymphoma patients. Interestingly, LEN further induces the expression of PD1 in CD8+ and CD4+ cells and may contribute to reactivating PD1 signaling under treatment. The PD1 pathway may potentially be targeted to overcome both the intrinsic and LEN-induced exhaustion phenotype.

Aims: To investigate if ATO targets BCL6 and inhibits the proliferation and growth of BCL6-dependent DLBCL.

Methods: BCL6-dependency of a panel of DLBCL cell lines (i.e. OCI-Ly1, OCI-Ly7, SU-DHL-6, OCI-Ly18 and Pfeiffer) was determined based on their sensitivity to proliferation inhibitory activity of the BCL6 inhibitor 79-6 (Calbiochem). The effects of ATO and cisplatin as single agent or in combination on cell viability and apoptosis of DLBCL cells were examined with MTT assay and flow cytometric analysis. Expression of BCL6 and its target genes was examined with quantitative RT-PCR and western immunoblotting. The therapeutic efficacy of ATO treatment was also examined in a DLBCL (OCI-Ly7) xenograft mouse model.

Results: OCI-Ly1, OCI-Ly7 and SU-DHL-6 were highly sensitive to inhibitory activity of BCL6 inhibitor and were designated as BCL6-dependent. Treatment of DLBCL cells with ATO led to a decrease in BCL6 protein level and an upregulation of downstream targets of BCL6, including PRDM1, CD44 and CD69. The effect of ATO on BCL6 protein were abrogated by treatment with proteasome inhibitorolo. In contrast, the effect of ATO on BCL6 for degradation through the ubiquitin-proteasome pathway. Interestingly, ATO also inhibited cell proliferation and induced apoptotic cell death of BCL6-dependent DLBCL cell lines, analogous to the effect of BCL6 inhibitor on these cells. In addition, there was a synergistic inhibitory and cytotoxic activity between ATO and cisplatin. Finally, ATO treatment suppressed the growth of DLBCL in a xenograft mouse model.

Summary/Conclusions: ATO targets BCL6 for proteosomal degradation and inhibits the proliferation and growth of BCL6-dependent DLBCL.

PROTEOMIC PHOSPHOSITE ANALYSIS IDENTIFIED CRUCIAL NICU SERINE RESIDUES FOR NPM-ALK-MEDIATED TRANSFORMATION

A. Gengenbacher1,*, A. Rudorf1,2, T. Poggio1, C. Rummelt1, V.i. Dumitri2, J. Duystter2, A.L. Illert1,2

1Dept. of Hematology, Oncology and Stem Cell Transplantation, University Medical Center, Freiburg, 2German Cancer Consortium (DKTK), Heidelberg, 3Center for Biological Systems Analysis, University of Freiburg, Freiburg, Germany

Background: Anaplastic large-cell lymphoma (ALCL) is an aggressive non-Hodgkin lymphoma that occurs mainly in children and younger adults. Patients typically show an advanced stage disease as well as an aggressive disease pattern with extralymphatic manifestations. At the molecular-genetic level, 60% of the patients with systemic ALCL exhibit a translocation t(2;5)(p23;q35), which leads to the expression of the NPM-ALK fusion protein. Under the control of the NPM promoter, ALK activation causes increased and autonomous cell proliferation. Nuclear interaction partner of ALK (NIPA) was first identified as a new interaction partner of the oncogene NPM-ALK in a yeast-2-hybrid screen which defines an E3-SCF ligase and is physiologically involved in cell cycle regulation at the transition from G2 phase to mitosis. It has already been shown in preliminary studies that co-expression of NIPA with the oncogenic tyrosine kinase NPM-ALK results in the constitutive phosphorylation of NIPA (Illert et al., 2012a). Until now, the specific signal transduction pathway, the crucial phosphorylation sites as well as the functional effect of the pathological NIPA phosphorylation in NPM-ALK-induced lymphomagenesis still remain unclear. Molecular insights into the identified pathways might help to identify new drugable targets for therapeutic implications.

Aims: In the present study, we investigated the molecular mechanisms as well as the functional impact of the NPM-ALK-induced NIPA phosphorylation.

Methods: For this purpose, biochemical methods with ALCL cells were used to examine functional effects of constitutive NIPA phosphorylation. Moreover, we performed a "proteomic-phosphosite-analysis" to identify crucial NPM-ALK specific phosphorylation sites in NIPA. Based on these results, phospho-deficient NIPA mutants were generated to investigate the functional effect of this phosphorylation: MTT proliferation- and Softagar-Assays were performed after infection of BaF3 and primary NIPA-deficient MEF cells with NPM-ALK and the respective phospho-deficient NIPA to reveal transformation and growth ability.

Results: It has already been shown, that cell cycle dependent NIPA phosphorylation at critical serine residues 354, 359 and 395 leads to dissociation of the interaction partner of ALK. We were able to show a constitutive phosphorylation of NIPA by NPM-ALK does not lead to changes in the SCF(NP)-complex formation. Proteomic-Phosphosite-analyses identified 10 significantly upregulated (ratio >2; Log2Fold Change) phosphorylation sites in NIPA. NIPA phosphorylation by NPM-ALK was totally abolished. To further probe biological significance of the identified residues, phospho-deficient mutants were established and transformation assays were performed. Here we were able to show drastically impaired cell proliferation of the mutants with silenced serine/threonine residues 338, 344, 370, 381 and 387 upon NPM-ALK expression.

Summary/Conclusions: Taken together, we identified five phosphorylation sites in NIPA to be highly upregulated upon NPM-ALK expression. However,
NPM-ALK mediated NIPA-phosphorylation of those sites did neither change the SCF-dependent T cell fusion nor influence the NIPA localization at the nuclear pore complex, but silencing of these NIPA Serine/Threonine residues led to significantly reduced proliferation and altered transformation ability of Ba/F3 and primary MEF cells. Further analyses will shed some light into the mechanisms underlying these findings and evaluate NIPA as a possible new treatment option for ALC.

**Background:** Diffuse large B cell lymphoma (DLBCL) can be divided according to cell of origin (COO) in germinal center B-cell-like (GCB) and activated B-cell–like (ABC) (that have been shown different prognosis. Immunohistochemistry (IHC)-based algorithms and recently, Lymph2Cx assay, a digital test based on the expression of 20 genes, have been developed to facilitate COO assignmen. ABC-DLBCL and BL2 and Raji as Burkitt lymphoma lines) with CXCR4 antagonist. We treated various aggressive lymphoma cell lines (U2932 and RI-1 as ABC-DLBCL and BL2 and Raji as Burkitt lymphoma lines) with CXCR4 antagonist. Additionally, we generated a novel CXCR4 antagonist -named WK1- by modification of the side chain of AMD070 - a commercially available CXCR4 antagonist- on cell growth and migration of aggressive lymphoma cells in vitro.

**Methods:** To study the characteristics and prognostic impact of COO subtypes in a series of HIV-related DLBCL using the Lymph2Cx assay and to compare the results with those obtained with an IHC-based algorithm.

**Methods:** A series of 55 patients with the diagnosis of HIV-related DLBCL (N=48), high-grade B-cell lymphoma (HGBL) with MYC and BCL2 and/or BCL6 rearrangements (N=3), or HGBL NOS (N=4) was studied. The following clinical parameters were collected from records: age, gender, ECOG, extranodal and bulky disease, HIV symptoms, Ann-Arbor stage, beta2-microglobulin, HCV and HBV serology, history of opportunistic infection and of AIDS-defining illness, onset of combination antiretroviral therapy, CD4-counts and HIV loads. IHC and FISH studies were performed on tissue microarrays. RNA was extracted from FFPE samples with RecoverAll kit (Ambion, Carlsbad, California) and digital GEP was determined with the Lymph2Cx assay (NanoString Technologies, Seattle, WA). Cohen's kappa was calculated to measure the agreement between COO given by Hans algorithm and Lymph2Cx assay.

**Table 1.**
Background: Epstein Barr virus (EBV) has been detected in the tumor cells of some non-Hodgkin lymphomas (NHL) and Hodgkin lymphomas (HL), and detectable EBV loads have been found in the plasma of immunocompetent patients with HL. In HIV-related lymphomas the importance of EBV load as a potential lymphoma biomarker has been scarcely studied.

Aims: We aimed to evaluate the usefulness of EBV load in plasma as a lymphoma biomarker in HIV-infected patients.

Methods: One hundred and fifteen patients with NHL (25% 1-7 years before lymphoma diagnosis and 75% 1-12 years before lymphoma diagnosis) and in a group of HIV-infected patients also at one year before lymphoma diagnosis (N=11) and at complete response (CR) (N=34). EBER expression was studied in situ hybridization in tumor biopsies. The following clinical and biological parameters were collected from records: age, gender, date of lymphoma diagnosis, ECOG score, extranodal and bulky disease, B symptoms, Ann Arbor stage, serum lactate dehydrogenase and beta2-microglobulin, International Prognostic Index (IPI), HBV and HCV serology, history of opportunistic infection and of AIDS-defining illness, onset of combination antiretroviral therapy, CD4 counts, HIV loads, type and date of response, relapse date, last follow up or death date. McNemar’s test and Wilcoxon test were used to compare quantitative and qualitative variables, respectively. Survival analyses were performed using the Kaplan-Meier method. P-values of less than 0.05 were considered statistically significant.

Results: At diagnosis, EBV loads were detectable in more HIV-infected patients than HIV-uninfected (48% vs 14%, P=0.002) and in more HL cases than NHL (70% vs 26.3%, P=0.006). In HIV-infected patients, detectable EBV load was associated with EBER expression, 66.6% of the patients with detectable EBV loads had EBER-positive tumors and 92% of the patients with undetectable EBV loads had EBER-negative tumors (P=0.003). All the remaining clinical and biological features were not associated with detectable EBV load in plasma. In HIV-uninfected patients, associations between EBV load and EBER expression (P=0.006) and EBV load and HBV infection (P=0.017) were observed. From 16 out of 34 (47%) HIV-infected patients with detectable EBV loads at lymphoma diagnosis, 15 had undetectable EBV loads at CR (P=0.001) (Figure 1). The exception was one patient with HL whose EBV load substantially decreased at CR but was still detectable. Moreover, 4 out of 7 HIV-infected patients with detectable EBV loads at diagnosis had detectable loads one year before diagnosis, and no patient with negative EBV loads at diagnosis had detectable loads before it, pointing EBV load can be used as an early biomarker of lymphoma. EBV loads at diagnosis had neither impact on overall survival nor progression-free survival.

Summary/Conclusions: EBV load in plasma can be used as early biomarker of lymphoma in HIV-infected patients since EBV loads can be detected up to 1 year before lymphoma diagnosis and are virtually undetectable at lymphoma CR.

This work was supported by 2014 SGR225 (GRE) from CERCA Programme/Generalitat de Catalunya, and by funds from Josep Carreras International Foundation, “la Caixa” Foundation and Cegelem Spain.
LY10 and OCI-LY1) with IRF6 knockdown or overexpression and two human B lymphoblast cell lines were co-cultured with peripheral blood mononuclear cells (PBMCs) in vitro to determine the effect of IRF8 on the generation of Th17 cells. Quantitative real-time PCR and Western blotting were used to investigate the involvement of retinoic acid receptor-related orphan receptor gamma t (RORγt) in the effect of IRF8 on Th17 cell generation. The survival of 67 DLBCL patients was evaluated using the Kaplan-Meier method (K-M) and Cox analysis.

**Results:** The percentage of Th17 cells was lower in DLBCL tumor tissues than in PBMCs and corresponding adjacent benign tissues. Relative expression of interleukin (IL)-17A was lower, whereas that of interferon (IFN)-γ was higher in tumor tissues than in benign tissues. Co-culture with DLBCL cell lines inhibited the generation of Th17 cells in vitro. IRF8 upregulation was detected in DLBCL tumor tissues, and it was associated with decreased DLBCL patient survival. Investigation of the underlying mechanism suggested that IRF8 upregulation inhibited Th17 cell generation by suppressing the effect of RORγt on CD4+ T cells.

**Summary/Conclusions:** Our findings suggest that IRF8 expression in the tumor microenvironment inhibited the generation of Th17 cells through its antagonistic effect on RORγt in the DLBCL tumor microenvironment, suggesting that it could be a prognostic factor for DLBCL.

#### E1399

**GENOMIC PROFILING OF BCL2 AND MYC DOUBLE EXPRESSOR DIFFUSE LARGE B CELL LYMPHOMA: A PROGNOSTIC TOOL FOR DLBCL**

V. Drachner 1, L. Parzefall 1, M. Hettwer 1, M. Kupfer 1

**Background:** Diffuse large B cell lymphoma (DLBCL) is an aggressive disease featuring heterogeneous genetic, phenotypic and clinical characteristics. Recently, a negative prognostic impact of double expression of BCL2 and MYC (double expressor (DE) lymphoma) has been identified in several studies. SNP array (SNP-A) studies have already led to the identification of novel genomic aberrations in ABC and GCB subtypes of DLBCL whereas similar analysis has not been done in DE and non-DE DLBCL.

**Aims:** To characterize the landscape of genomic aberrations in DE and non-DE DLBCL groups using SNP-A and interphase fluorescence in situ hybridization (FISH).

**Methods:** Immunohistochemical and FISH analysis was performed on tissue microarray of formalin fixed paraffin embedded (FFPE) tumor tissue samples using Bcl2 (124, DakoCytomation) and MYC (Y69, Epitomics) antibodies and FISH MYC (Zytovision), Bcl2 (Abbott/Vysis), Bcl6 (Abbott/Vysis) break-apart probes and MYC/HIGH (Zytovision) double-fusion probe. InfiniumHD whole-genome genotyping assay with the HumanCytoSNP FFPE-12 BeadChip (Illumina Inc., San Diego, CA, USA) was performed for genomic analysis of the aberrations.

**Results:** A cohort of 91 primary DLBCL patients diagnosed between 2004 and 2012 was selected for the study. Immunohistochemical evaluation was informative for 87 cases (95.6%). The DE analysis was informative for MYC, 56 cases for Bcl6, and 65 cases for Bcl2. 7 cases (11.4%) were positive for MYC translocation, 14 (25%) for Bcl6, and only 3 (4.8%) were positive for Bcl2. No cases of MYC and bcl2 double positive DLBCL were identified. Genomic DNA from FFPE tumor tissue for SNP-A was available in 66 cases, SNP-A was informative in total SNP-A profile was performed in 63 cases, with abnormalities not corresponding to known copy number polymorphisms (89% of the cases, 59/66). These comprised 164 (50%) hemizygous and 2 (1%) homozygous deletions, 106 (32%) gains, 41 (12%) trisomies and 16 (5%) monosomies. The most common aberrations were 1p deletion, 1q gain, 6q deletions, and MYC gains (3 deletions and 12 gains, >3 aberrations) was detected in 37/66 (56%) patients. Both DE and non-DE DLBCL groups had equal rate of aberrations per case (~5 aberr/case) and shared the most common aberrations – 1p deletion and 1q gain. In contrast, 11q deletion was more common in DE, while 6q and 17q deletions were more prevalent in the non-DE group. Non-DE DLBCL group proportion of trisomic karyotypes in non-DE group than in DE (16 vs 6 cases, respectively). Cases with MYC positive (FISH) and MYC gain (SNP-A) had the median number of two chromosomal aberrations with an exception of two MYC positive cases with complex karyotypes. These two cases shared the same 9q, 11q, 14q deletions and the monosomy of chromosome 19. Finally, of the 7 cases with normal SNP-A karyotype, BCL6 FISH-positive marker was detected in 3 patients.

**Summary/Conclusions:** SNP-A analysis highlights the genomic differences between the DE and non-DE DLBCL. Our finding of MYC positive (translocations and/or gains) association with low complexity karyotype status may suggest MYC to be an early initiating genetic event.

**ARQ 531, A REVERSIBLE BTK INHIBITOR, DEMONSTRATES POTENT ANTI-TUMOR ACTIVITY IN ABC-DLBC AND GCB-DLBC**

S. Eastham 1, Y. Yu 1, T. Hall 1, B. Schwartz 1, J.A. Woyscheck 2, S. Reiff 2, G. Abbassada 1

**Aims:** To assess the biological and anti-tumor effects of ARQ 531 in in vitro and in vivo model systems.

**Methods:** Biochemical inhibition and kinase profiling were assessed using recombinant proteins. The ARQ 531 binding kinetics on BTK were determined by Surface Plasmon Resonance assay. Anti-proliferative activity of ARQ 531 was tested in a MTS-based assay against a panel of hematological malignant cell lines. Pathway inhibition assessments, in vivo efficacy and in vivo target inhibition were performed in TMD8 (ABC-DLBC) and SUDHL-4 (GCB-DLBC) cell lines and xenografts. ADME and pharmacokinetic properties of ARQ 531 were also evaluated in rats, dogs and monkeys.

**Results:** ARQ 531 potently inhibited BTK (IC50=0.85 nm) and displayed long half-life (>60 min). ARQ 531 exhibited strong anti-proliferative activity in TMD8 (GI50=0.13 µM) and SUDHL-4 (GI50=0.02 µM) cell lines, it inhibited, while potent on TMD8 cells (GI50=0.002 µM), had a GI50 of 1.1 µM in SUDHL-4, a concentration not reached in human blood, consistent with published studies. Pathway analysis in TMD8 and SUDHL-4 cells showed that ARQ 531 potently inhibited both upstream activating signals (Src kinase family) and downstream signaling pathways such as AKT and ERK. Cell cycle analysis indicated that ARQ 531 inhibited cell growth through G1 phase arrest, similar to ibrutinib. In the TMD8 xenograft mouse model, ARQ 531 strongly inhibited BTK signaling, with better efficacy than reported with ibrutinib; tumor growth reduction was >90% after 17 days of dosing, with no re-growth observed for 17 days post dose interruption. In the ibrutinib-resistant SUDHL-4 mouse xenograft model, ARQ 531 potently suppressed tumor growth (>80% inhibition) compared to the control.

**Summary/Conclusions:** ARQ 531 is a potent reversible inhibitor of BTK. Its variable kinase selectivity can be used to target constitutive BCR signaling in DLBCL primarily resistant to ibrutinib, as demonstrated by the excellent efficacy in both ABC and GCB DLBCL xenograft models. These data support the clinical investigation of ARQ 531 in patients with hematological malignancies, expected to begin in mid-2017.

**ROLE OF GENETIC POLYMORPHISMS ON R-CHOP EFFICACY IN DIFFUSE LARGE B-CELL LYMPHOMA PATIENTS: AN INTERIM ANALYSIS OF A MULTICENTER PROSPECTIVE PHARMACOGENETIC STUDY**

L. Rigacci 1, G. Perrone 2, S. Nobiili 3, S. Kovalchuk 1, B. Puccini 1, R. Tassi 2, G. Carbone 1, I. Landini 1, L. Scudiero 2, C. Napoli 1, E. Cencioni 1, A. Fabbrini 1, L. Iovino 5, M. Petrimi 5, S. Birtolo 6, A. Santini 3, P. Bernardeschi 5, A. Bosi 1, E. Mini 2

1Haematology, AO Careggi and University of Florence, 2Medicina Sperimentale e Clinica, 3Scienze della Salute, University of Florence, 4Haematology, AO Siena, Siena, 5Haematology, AO Pisa, Pisa, 6Oncologia, Ospedale Pescia, Pescia, 7Oncologia, Ospedale Lucca, Lucca, 8Oncologia, Ospedale Prato, Prato, 9Oncologia, Ospedale Empoli, Empoli, Italy

**Background:** Standard chemotherapy represented by the R-CHOP (rituximab, cyclophosphamide, doxorubicin, vincristine, prednisone) regimen is successful in about 60% of patients (pts) with diffuse large B-cell lymphoma (DLBCL). Pts who do not benefit from this treatment, due to the development of tumor drug resistance, have a very poor prognosis. Currently, knowledge on reasons of treatment related failures in DLBCL are scanty and predictive biomarker of resistance are largely unknown.

**Aims:** We hypothesized that polymorphisms of genes involved in the pharmacokinetics and pharmacodynamics of drugs included in R-CHOP regimen may play a role in predicting the outcome in DLBCL pts. Thus, we designed a multicentre prospective pharmacogenetic trial aimed at identifying gene polymorphisms potentially predictive of drug efficacy/resistance in DLBCL patient group.

**Methods:** We are reporting update data of an interim analysis on the first 80 enrolled pts.

**Results:** The study includes chemo naive DLBCL pts (Ann Arbor I-IV stages) candidate to an R-CHOP standard treatment. The Ethical Committee of each participating centre approved the pharmacogenetic protocol, and all pts signed written informed consent. In this interim analysis, the impact of single nucleotide polymorphisms (SNPs) on R-CHOP efficacy was evaluated by objective response (OR) rate, progression-free survival (PFS) and overall survival.
Liferation was observable and cells where resting in G1-phase. Cells abemaciclib had no impact on cell death or sensitization since no cell pro-

(AraC) and ibrutinib. Cells were pretreated with abemaciclib and exposed to AraC or ibrutinib. We observed an almost complete and reversible G1-arrest in all sensitive cell

early G1 cell cycle arrest without loss of viability at low nanomolar doses. Rationale drug combinations exploiting the sequential effect may achieve major benefits. Pretreatment with abemaciclib might sensitize cells to ibrutinib, resulting

in synergistic drug effects. In contrast, simultaneous application of Abe-

maciclib protects cells from AraC treatment whereas Abemaciclib-induced S-

phase synchronization sensitizes MCL cell lines to AraC. Further analysis needed

to explore the interaction with other targeted approaches (inhibitors of the B-

cell receptor pathway) to better understand the underlying molecular mecha-

CDK4/6-INHIBITION BY ABEMACICLIB INDUCES POTENT EARLY G1-ARREST IN MCL CELL LINES AND SHOWS SEQUENCE-SPECIFIC INTERACTIONS WITH CYTARABINE AND IBRUTINIB

Results: Median age was 63 years. There were 37 men and 43 women. 47.5% of pts were in stage I-II, 52.5% of pts in stage III-IV. 27.5% of pts had bulky disease, 43.8% of pts had involvement of extranodal site. 47.5% of pts had pathological

LDH value. According to the revised IP, 15% of pts were in the low risk group, 58.7% in the intermediate, and 28.3% in the high risk group. We performed 468 courses of R-CHOP had been administered (mean: 5.85 courses, range:

4-46), 88.7% of pts had CR to R-CHOP whereas the remaining showed PR or

SD (7.5%) or PD (3.8%). Multivariate analysis identified FCGR2A rs1801274 as a predictor of PFS (p=0.045). Pts with HR or RR genotypes showed shorter PFS than pts with HR genotype (HR: 2.437, CI: 1.025-5.823). No statistically significant correlation was found between SNPs and OS.

Summary/Conclusions: Our preliminary data obtained in a limited number of pts, show a association between a SNP of the low affinity FCGR2A gene involved in the activity of rituximab and PFS. Further insights will derive from the completion of the present study to reach the planned numbers of cases at the end of our study.

CD5 POSITIVE DIFFUSE LARGE B CELL LYMPHOMA SHOWED FREQENT MYC EXPRESSION AND AGGRESSIVE CLINICAL BEHAVIOR H.-Y. Na1, J.Y. Choe2, H.-J. Kim3, J.H. Han4, H.K. Kim5, G. Park6, H.J. Cha7, J.E. Kim8,* Aims: This study aimed to investigate clinicopathologic features of CD5+ DLBCL in Koreans. Methods: A total of 350 cases of DLBCL were reviewed 4 university hospitals from 2004 to 2012. Review of the histologic features along with immunohistochemical study for BCL1, BCL2, BCL6, CD5, CD10, CD23, IFR4/MUM1, MYC, Ki-67 and EBV in situ hybridization was performed. Florescent in situ hybridization (FISH) for MYC rearrangement and amplification was also performed. The results were compared with DLBCL-NOS (N=195). Results: Thirty cases of CD5+ DLBCL were retrieved among 350 cases of DLBCL (8.6%), which showed predominance of female (20/30), elderly (mean age 64), and extranodal presentation (16/30). Richter transformation was suspicious in 4 cases and EBV was negative in all. Most cases (22/30) belong to non-GCB subtype by Hans classifier. Rearrangement of MYC was found in 2 cases and amplification was found in one. Compared with DLBCL-NOS, CD5+ cases revealed significantly higher expression of MYC, BCL6, IFR4/MUM1 and Ki-67 (all p<0.05). Double expression of both BCL2 and MYC was found in 9 of 30 cases (30%). Also, CD5+ DLBCL showed more frequent bone marrow involvement, advanced stages and high international prognostic index (all p<0.05). In univariable survival analysis, CD5+ DLBCL revealed significantly shorter progression free survival (median 8.2 months) compared with DLBCL-NOS (median 66.3 months) (p<0.05) Summary/Conclusions: The first descriptive study of CD5+ DLBCL in Korea. The incidence, clinical presentation, and pathologic features including cell of origin coincide with previous reports from western population or Japanes. However, frequent high expression of MYC without chromosomal structural alteration was a unique finding in our study. Expression of CD5 should be routinely investigated in DLBCL to find this particularly aggressive subtype.

Reactive florid B-lineage lymphoid proliferations in HIV infection may mimick lymphoma T. Wiggill1,1, J. Vaughan1, E. Mayne1 Aims: The aim of this study was to examine the relationship between microvesSEL density in CD30 positive diffuse large B-cell lymphomas and the possibility of a seroconversion type illness should be considered. Methods: Review of the histologic features along with immunohistochemical study for BCL1, BCL2, BCL6, CD5, CD10, CD23, IFR4/MUM1, MYC, Ki-67 and EBV in situ hybridization was performed. Florescent in situ hybridization (FISH) for MYC rearrangement and amplification was also performed. The results were compared with DLBCL-NOS (N=195). Results: Thirty cases of CD5+ DLBCL were retrieved among 350 cases of DLBCL (8.6%), which showed predominance of female (20/30), elderly (mean age 64), and extranodal presentation (16/30). Richter transformation was suspicious in 4 cases and EBV was negative in all. Most cases (22/30) belong to non-GCB subtype by Hans classifier. Rearrangement of MYC was found in 2 cases and amplification was found in one. Compared with DLBCL-NOS, CD5+ cases revealed significantly higher expression of MYC, BCL6, IFR4/MUM1 and Ki-67 (all p<0.05). Double expression of both BCL2 and MYC was found in 9 of 30 cases (30%). Also, CD5+ DLBCL showed more frequent bone marrow involvement, advanced stages and high international prognostic index (all p<0.05). In univariable survival analysis, CD5+ DLBCL revealed significantly shorter progression free survival (median 8.2 months) compared with DLBCL-NOS (median 66.3 months) (p<0.05) Summary/Conclusions: This is different from the pattern noted in NHL in our centre, where CD5+ DLBCL and Burkitt’s lymphoma are very common. This is significantly different from lymphoma patients where median VL ranged from 16 000-97 000 dependent on subtype. Median CD4 counts were also higher in this subgroup of patients when compared to patients with lymphoma (see table 1). Limited follow-up data was available, with only 8 patients documented to be attending an HIV clinic for long-term follow-up.

Summary/Conclusions: In the setting of HIV, reactive conditions may mimick lymphoma and vigilance is needed in the confirmation of monolymphoma. Patients with RBLP presented at a younger age when compared to their counterparts with lymphoma. They had extremely high VL with higher CD4 counts, suggesting this may be a feature of early HIV disease and the possibility of a seroconversion type illness should be considered.
Microvessel quantification was performed by immunohistochemical staining, using monoclonal antibodies against platelet/endothelial cell adhesion molecule-CD31. A total of 82 cases of de novo DLBCL treated with R-CHOP were included in the training set for further analysis. There were 45 men and 37 women, with a median age of 57 years (range, 16-84); 35 patients (43%) presented with B symptoms, and 49 (60%) had advanced Ann Arbor stages. Most of the patients had a good performance status (Eastern Cooperative Oncology Group score 0-1, 87%), elevated serum lactate dehydrogenase level (61%), and low or low-intermediate International Prognostic Index (IPI) risk (IPI score 0-2, 63%). Involvement of multiple extranodal sites (≥2) was seen in 22% of cases, and bulky disease in 32% of cases.

Results: The median follow-up time was 47 months. Among the 82 cases in the training set, CD30 was positive in 24 cases (29%). No difference in response rate was observed between CD30 positive and CD30 negative patients. Patients with CD30+ DLBCL showed a significantly superior OS and PFS compared with CD30−patients. The 5-year OS was 79% in patients with CD30+ vs 59% in CD30−(P<0.05); 5-year PFS was 82% in patients with CD30+ vs 63% in CD30−(P<0.05). In patients with CD30 positive diffuse large B cell lymphomas we found a smaller number of vessels compared with patients CD30 negative (fig.1, p<0.05).

ANTIGEN SELECTION PROMOTES CLONAL CYTOTOXIC T-CELL RESPONSES: HIGH-THROUGHPUT IMMUNOGENETIC EVIDENCE

E. Stalika 1, C. Galgailidou 1, A. Papalexandri 2, A. Vard 2, N. Stavroyianni 2, I. Batis 2, I. Sakellari 2, A. Anagnostopoulou 2, N. Maglaras 1, I. Chouvarda 1, M. Papaianou 1, K. Stamatopoulou 1, H. Hadziimitrou 1

1Institute of Applied Biosciences, Centre for Research and Technology Hellas, 2Hematology Department and HCT Unit, G. Papanicolaou Hospital, 3Laboratory of Computing and Medical Informatics, 4First Department of Medicine, Medical School, Thessaloniki, Greece

Background: Expansions of T-large granular lymphocytes (T-LGL) with a characteristic CD3+CD8+CD57+ phenotype may be either idiopathic or develop in the context of other types of relapsed lymphomas. Most of the patients had a good performance status (Eastern Cooperative Oncology Group score 0-1, 87%), elevated serum lactate dehydrogenase level (61%), and low or low-intermediate International Prognostic Index (IPI) risk (IPI score 0-2, 63%).

Aims: To obtain comprehensive insights into the role of antigen selection in the pathogenesis of T-LGL lymphoproliferations using next-generation sequencing (NGS) for in-depth immunoprofiling of the clonotypic T cell receptor beta chain (TRBV) genes.

Methods: Included in the study were (i) a father and a son with T-LGL leukemia, the first case of intra-family occurrence; a single blood sample from the father and 2 samples from the son spanning 5 years were analyzed; and, (ii) a patient with T-LGL leukemia of donor cell origin developing after allogeneic hematopoietic cell transplantation (allo-HCT) for Philadelphia-positive acute lymphoblastic leukemia: for this case, the donor blood was analyzed as were two blood samples, one at the first documentation of clonal T-LGL expansion (at 6 months post allo-HCT while investigating persistent neutropenia that developed after Rituximab treatment for EBV reactivation) and a second 3 years later; at both timepoints, the patient had 100% donor chimera and tested negative for BCR-ABL transcripts. TRBV-TRBD-TRBJ rearrangements were amplified on gDNA and subjected to paired end NGS, considering the CDR3 twice/sequence. To increase the consistency of results, raw NGS reads were analyzed by a purpose-built bioinformatics algorithm, performing: (i) quality filtering, (ii) marging of filtered in paired reads and (iii) quality filter of stitched sequences. Filtered in silico sequences were submitted to IMGT/HighV-QUEST, and metadata was processed by an in-house dedicated bioinformatics pipeline.

Results: Only productive TRBV-TRBD-TRBJ rearrangements were included in the analysis. Overall, 1,129,289 filtered-in sequences from 6 samples were evaluated (median 188,095 sequences/sample). Major findings in the familial cases included: (i) pronounced skewing of the TRBV repertoire; (ii) the TRBD repertoire was dominated by the germline repertoire of more than one immunodominant clonotype; (iii) in the analysis of longitudinal samples from the same patient, persisting clonotypes albeit with fluctuating frequencies (clonal drift); and, (iv) shared (‘public’) clonotypes between father and son. In T-LGL leukemia of donor origin, the immunodominant clonotype was detected amongst the polyclonal donor repertoire and subsequently expanded in the recipient, persisting over time and accompanied by a few other considerably expanded, albeit smaller, clonotypes.

Summary/Conclusions: The borders between polyclonal oligoclonal versus monoclonal T-LGL lymphoproliferations are not sharply demarcated, but rather the transition from a polyclonal cytotoxic response to a clonal and further restriction of the T-LGL leukemia is a gradual process. Repertoire restriction, public clonotypes and clonal drift strongly indicate selection by restricted (perhaps also shared) antigens in T-LGL leukemia ontogeny and evolution.

Background: In B-cell non-Hodgkin lymphomas, minimal residual disease (MRD) is a highly valuable tool for the direct assessment of the reduction of the disease burden. In 2009, the four laboratories of the Fondazione Italiana Linfomi (FIL) - FIL MRD network - started a collaborative effort to harmonize and standardize their methodologies, performing QC (Quality Control) rounds twice a year for follicular lymphoma (FL) and mantle cell lymphoma (MCL) MRD assessment.

Aims: We evaluated the molecular results of bone marrow (BM) samples analysis performed during the QC rounds, to determine how borderline samples (i.e. those with a low MRD level) challenge the inter-lab reproducibility and data interpretation.

Methods: Between February 2010 and November 2016, in the context of 14 QC rounds, the FIL MRD Network labs received 188 BM (114 FL and 74 MCL) samples; 167 were analyzed by both nested polymerase chain reaction (PCR) and real-time quantitative PCR (QR-PCR). BCL2/GHMB rearrangement was analyzed by nested PCR (Gribben, 1993) and by QR-PCR (Ladetto, 2000). Clonality assessment was performed using an IGHV multiplex consensus PCR (Van Dongen, 2003) and RQ-PCR was carried out as described (Ladetto, 2000; Donovol, 2000). All analyses were conducted and interpreted according to the “EuroMRD Consortium” guidelines (van der Velden, 2007).

Results: The sensitivity and the accuracy of each molecular assay was tested, reaching a uniform sensitivity of 10−5 and a quantitative range for MRD of at least 10−4. Ninety-three percentage of the tests carried out as described (Ladetto, 2000; Donovol, 2000). All analyses were conducted and interpreted according to the “EuroMRD Consortium” guidelines (van der Velden, 2007).

Results: The sensitivity and the accuracy of each molecular assay was tested, reaching a uniform sensitivity of 10−5 and a quantitative range for MRD of at least 10−4. Ninety-three percentage of the tests carried out as described (Ladetto, 2000; Donovol, 2000). All analyses were conducted and interpreted according to the “EuroMRD Consortium” guidelines (van der Velden, 2007).

Ninety-three percentage of the tests carried out as described (Ladetto, 2000; Donovol, 2000). All analyses were conducted and interpreted according to the “EuroMRD Consortium” guidelines (van der Velden, 2007).
samples analyzed by both methods, 83% (139/167) of these were classified as +/+ or -/- by all the FIL labs. The remaining 28/167 (17%) were the samples that showed discordant results in the inter-lab assessments: while in 17 cases the "borderline status" was defined alternatively by only one method, 11 resulted brd samples by both techniques (11/167, 6.6%) (Fig.). Given that the 167 samples were tested in three replicates across the 4 labs, a total of 12 replicates/sample were analyzed: 31 brd samples were thus identified, 13 of which brd by both approaches. Of 156 evaluations performed on the 13 brd, 69/156 (44%) resulted PCR-positive and 87/156 (56%) PCR-negative, 58/156 (37%) were RQ-PNQ and 98/156 (63%) RQ-negative.

Summary/Conclusions: Despite the high inter-lab reproducibility in the MRD analysis that can be obtained and maintained by the QC round strategy, samples with the lowest MRD levels can still represent a challenge: 17% (28/167) of our series resulted brd, showing discordant results in inter-lab assessments; 39% of them (11/28) remained brd even applying both methods. The results did not change even increasing the number of replicates/sample. Thus, although representing a minority, brd samples are still problematic, especially when a clinically oriented interpretation is required. As the combined use of standard methods does not totally solve this problem, alternative, novel, methods such as digital PCR and NGS need to be tested in this context.

RHOA GLY17VAL MUTATION AND T-CELL CLONALITY ANALYSIS IN PATIENTS WITH ANGIOIMMUNOBLASTIC T-CELL LYMPHOMA

Y. Sidorova1, N. Chernova2, I. Yakutik1, S. Smirnova1, N. Ryzhikova1, E. Nikulina1, M. Aleksenko2, O. Glinshchikova1, M. Sinitsyna3, A. Kovrigina1, E. Zvonkov2, A. Sudarikov1

1Department of Molecular Hematology, 2Department of Lymphoma Chemotherapy, 3Department of Pathology, National Research Center for Hematology, Moscow, Russian Federation

Background: Angioimmunoblastic T-cell lymphoma (AITL) is a rare subtype of T-cell lymphoma, characterized by generalized lymphadenopathy, hypergлюбulinemia, and autoimmune manifestations. Interpretation of histological and immunohistochemical data can be difficult due to the small number of tumor cells, cells surrounded by abundant polymorphocellular infiltrate. AITL could often be misdiagnosed as reactive processes and other lymphomas, including Hodgkin’s lymphoma. T cell clonality assessment plays an important role in AITL diagnosis. However, ambiguous clonality results may be obtained. Recently discovered somatic RHOA Gly17Val mutation is present in 53-71% of angioimmunoblastic T-cell lymphomas. We compared the efficacy of T-cell clonality testing and quantitative allele-specific PCR RHOA Gly17Val mutation assay in different tissues for AITL diagnosis.

Aims: To correlate the number of RHOA Gly17Val mutated cells in lymph nodes, bone, bone marrow and skin of AITL patients with corresponding T cell clonality results.

Methods: Lymph nodes (LN), skin biopsies, blood and bone marrow (BM) samples were studied for 40 patients with AITL. The male/female ratio was 25/15, median age was 65 years (36-92). To evaluate T-cell clonality rearranged TCRG and TCRB gene rearrangements were PCR-amplified according to BIO-PRISM 3130 (Applied Biosystems). Sensitivity of T-cell clonality assay was limited to 10% of clonal T-cells of the total T-lymphocytes in the sample. Gly17Val mutation was analyzed by quantitative allele-specific (qAS) TaqMan Real-Time PCR assay. The detection level of this method was 1% of mutated cells in the total cell population.

Results: The clonal TCR gene rearrangements in LN were found in 37 of 40 patients (92%). RHOA (Gly17Val) mutation in LN was revealed in 60% (24 of 40) patients. T-cell clonality was detected in 26 of 28 primary samples of BM, but in 12 of 26 patients (46%) clonal TCR rearrangements were not matched in length with rearrangements detectable in LN. Number of cells with RHOA mutation was highest in the LN (in average 26.7% of the total cells), while in the bone marrow RHOA mutation was undetectable (in 7 patients), or detected in 10 patients in a small amount (in average 2% of the total cells). Combined historical investigation, T-cell clonality and RHOA (Gly17Val) testing showed BM lesion in 76% of patients (13 of 17) with at least one of the methods. Blood and bone marrow samples examined simultaneously showed slightly higher numbers of RHOA positive cells in the blood than in the BM in 5 of the 7 RHOA positive patients. Significant percentage of cells with a RHOA mutation (in average 25% of the total cells) was revealed in 5 of 6 skin samples from RHOA positive patients. We have found good correlation (Spearman’s Rho=0.8198, p-level <0.00001) between T-cell clonality (matching with LN clonal peaks) and the number of RHOA positive cells in the AITL samples (n=51). Skin, blood and bone marrow samples with the T cell clonality peaks that differ from those found in the LN were also negative for the presence of cells with RHOA (Gly17Val) mutation.

Summary/Conclusions: RHOA (Gly17Val) point mutation is detected in LN by allele-specific PCR in 60% of patients with AITL. The percentage of tumor cells in BM is low (averaging less than 2% of the total cells). However, combined molecular and histological data suggest that BM may be involved in most patients. Extent of T cell clonality (matching with LN clonal peaks) correlates with the amount of cells having a RHOA mutation. T-cell clonality in BM, skin, spleen, etc. with rearrangements not matching those identified for the LN should be considered reactive and possibly associated with autoimmune process or antiviral response.
Other Non-malignant hematopoietic disorders

E1410

USEFULNESS OF CHITOSIDROSIDASE ACTIVITY, CCL18/PARC, 7-KETOCHOLESTEROL AND GLUCOSYLPHOSPHINOLINE CONCENTRATIONS FOR SCREENING OF LYSOSOMAL STORAGE DISORDERS

P. Irun1, D. hebilla1,2,3, L. López de Frutos2,4, P. Giraldo1,4
1Centro de Investigación Biomédica en Red en Enfermedades Raras (CIBER-ER), 2Unidad Investigación Traslacional. Hospital Universitario Miguel Servet, Instituto de Investigación Sanitaria Aragon (IIS Aragon), 3Departamento de Bioquímica, Biología Molecular y Celular, Universidad de Zaragoza, 4Fundación Española del Estudio y Terapéutica de la Enfermedad de Gaucher y Otros Lisosomales (FEETEG), Zaragoza, Spain

Background: Gaucher (GD), Niemann-Pick Type A/B (NPAB), Niemann-Pick Type C (NP-C) and Lysosomal acid lipase deficiency (LALD) are lysosomal storage diseases (LSDs) difficult to diagnose due to the great heterogeneity of signs and symptoms, including haematological disorders, sometimes common to several pathologies, and the consequent alteration of biomarkers.

Aims: To assess the diagnostic utility of Chitosidrosidase activity (ChT), CCL18/PARC, 7-ketocholesterol (7KC) and glucosylphosphingolipine (Lyso-Gb1) concentrations in previously mentioned LSDs.

Methods: ChT activity, CCL18/PARC and 7KC concentrations were measured in 146 plasma samples from subjects with suspected LSD (32 GD, 7 NPAB, 90 NP-C and 17 LALD) received in our laboratory. In addition, a new biomarker, the Lyso-Gb1 concentration, was evaluated in 83/146 of previous mentioned subjects, 19 of them with confirmed LSD diagnosis. ChT was evaluated using a fluorogenic substrate, CCL18/PARC concentration by ELISA and 7KC and Lyso-Gb1 by liquid chromatography followed by tandem mass spectrometry.

Results: A total of 9/32 (28%) samples with suspected GD showed high ChT activity both in plasma and CCL18/PARC, 4/9 confirmed GD status; the rest were 1 NPAB, 1 NP-C and two carriers of NP-C. Only 3/4 (75%) with suspected NP-C and one elevated biomarker four were diagnosed of NP-C, and two carriers showed some biomarker higher than cutoff. Of the 8/17 (47%) referred to LALD suspicion with some elevated biomarker six were affected. All GD confirmed patients show high levels of Lyso-Gb1 whereas none of the other cases showed elevation for mentioned biomarker.

Summary/Conclusions: The screening of three biomarkers: ChT activity, CCL18/PARC and 7-ketocholesterol concentrations (the latter not applicable in GD) is a powerful tool to identify patients at high risk of suffering from LSDs which should undergo confirmatory diagnostic tests. In this line we would have reduced the number of cases needing confirmatory diagnostic test from 146 to 43 (29%) and 19/43 (44%) were positive for LSDs. Lyso-Gb1 concentration can allow the unambiguous identification of all the GD patients but is not useful for the other LSDs.

E1411

THE VALUE OF SOLUBLE IL-2R ALPHA SUBUNIT MEASUREMENT IN CSF OF CHILDREN WITH HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS (HLH): PRELIMINARY OBSERVATIONS

Y. El Chazal1,2, A. Elsharkawy1, N. Michaeli3, M. Ab Del-Maksoud4, W. Shoman1, H. Assem1
1Department of Pediatrics, Hematology/Oncology unit, 2Department of Clinical pathology, 3Department of Pediatrics, Neurology unit, 4Department of Pediatrics, Immunology/Rheumatology unit, Faculty of Medicine, Alexandria University, Alexandria, Egypt

Background: Hemophagocytic lymphohistiocytosis (HLH) is a life-threatening clinical syndrome due to a severe hyperinflammatory response. HLH is typically characterized by a very wide spectrum of clinical findings. Central nervous system affection “CSN disease” has been frequently described at presentation of HLH, during course of disease, or as isolated CNS-HLH that could precede other systemic clinical manifestations by months to years.

Aims: To study the value of CSF soluble interleukin-2 receptor alpha subunit (sIL2Rα) assay as a marker of CNS affection in children with HLH.

Methods: In this descriptive, observational study done at Alexandria University Children’s Hospital, we analyzed the clinical data of a group of patients diagnosed as HLH. After informed consent was obtained, data was collected from patients who have undergone clinical examination, brain MRI, routine CSF analysis for evaluation of CNS-HLH, and sIL2Rα measurement in the CSF (Quantikine Human CD25/IL-2Rα Immunoassay, R&D Systems). Patients were considered as “CNS-HLH positive” when they had either neurological manifestations, abnormal findings on MRI or routine CSF analysis (elevated proteins &/or pleocytosis) and as “CNS-HLH negative” when they did not show any of these findings.

Results: We analyzed the data of 9 HLH patients; 4 females and 5 males. Their age ranged from 2 months to 13 years with a median of 5 months. Six patients had genetic diseases predisposing to HLH (Griscelli syndrome type II (GSI) & Chediak-Higashi syndrome (CHS)), and 3 other patients were diagnosed according to HLH-2004 diagnostic criteria and presumed to be of familial form (FHL). Out of the 9 patients, only 5 patients (55.6%) showed clinically evident neurological manifestations; 5 patients (55.6%) had elevated CSF proteins &/or pleocytosis, and 4 patients (44.4%) had an abnormal brain MRI. Overall 7 out of the 9 patients (77.8%) were “CNS-HLH positive” versus only 2 (22.2%) “CNS-HLH negative” according to classical criteria. Interestingly, the geometric mean of CSF sIL2Rα in CNS-HLH positive group was lower than in CNS-HLH negative group (734 vs 1952 pg/ml, p = 0.094). Moreover, CSF protein level and cell counts did not statistically correlate with CSF sIL2Rα level. Several patients showed interesting observations. Among the patients with strongly positive FHL (6/7 HLH-2004 diagnostic criteria fulfilled, NK cell activity not tested), the one with the highest observed CSF sIL2Rα level (17329 pg/ml), a 2 months old infant, was “CNS-HLH negative”, but had severe bilateral papilledema (discovered during workup for suspected autoinflammatory disorder). The second patient was a 3.5 year old infant, with history of a year of “CNS-HLH” negative findings and psychomotor regression, he had severe papilledema associated with high CSF sIL2Rα (3700 pg/ml). The third patient, an 11 months old “CNS-HLH negative” infant also had a relatively elevated CSF sIL2Rα of 220 pg/ml. On the other hand, 2 twin sisters evaluated at the age of 3 months for HLH secondary to CHS (positive family history, grey hair) had also elevated CSF sIL2Rα (600 & 800 pg/ml).

Summary/Conclusions: We hypothesize that routine CSF sIL2Rα level assay could enhance earlier & better detection of CNS-HLH in children especially in cases of non-specific, atypical, genetic forms of HLH. However, further study is needed to confirm this observation. The absence of statistically significant correlation between serum and CSF levels of sIL2Rα in our patients indicates that sIL2Rα is locally produced in the CSF secondary to cellular infiltration of the CNS and could be a valuable biological marker of disease activity. Larger prospective studies are warranted to confirm these results and determine diagnostic and prognostic value of CSF sIL2Rα levels, as well as its value for follow up of CNS disease.

E1412

GAUCHER DISEASE PATIENTS EXHIBIT A HIGH EXPRESSION OF LIPOCALINE (LCN2) AS POSSIBLE BIOMARKER OF RESIDUAL DISEASE Activity.

C. Fernandez1,2, C. Biedma1,2, E. Molina1,2, C. Garcia1,2, A. Rodriguez1,2
1Translational Research Unit, IIS-Aragon, 2ALPBASE, Instituto Aragonés de Ciencias de la Salud, 3Translational Research Unit, IIS-Aragon, 4 FEETEG, Fundación Española Estudio y Terapéutica Enfermedad de Gaucher, Zaragoza, Spain

Background: Gaucher Disease (GD) is characterized by a latent chronic inflammation in macrophages that may result in status characterized by pro-inflammatory cytokines, hyperferritinemia, hypergammaglobulinemia, altered calcium homeostasis and metabolic syndrome. Even patients under ERT do not fully revert this status and their risk to develop bone crisis, iron metabolism alterations, autoimmune disorders and neoplasm remain higher. This observation further supports the creation of a residual-residual or subclinical activity in type 1 Gaucher Disease patients (with undetectable levels of α-GDase) that may not be detected using classical monitoring. Therefore, despite promising results of recent studies to identify new biomarkers able to reflect the level of residual activity, there is a need to explore other possible strategies to identify residual disease activity in GD1 patients. Lipocaline (LCN2), a cytokine released by adipocytes, mononuclear cells and neutrophils with expression on endothelial cells, hepatocytes and other cells, has been involved into the monocyte polarization and perpetuation of the inflammatory status. Based on this, we have performed an exploratory study assessing LCN2 expression in GD1 patients.

Aims: To explore the Lipocaline (LCN2) expression as biomarker for disease activity in type 1 Gaucher Disease patients under different circumstances.

Methods: We have performed an exploratory study on 18 GD1 patients distributed in two cohorts. Cohort A was composed by 6 patients: 2 naïve (N) and 4 under miglustat therapy. This patient was part of a previous study QUELAFER and sere from baseline and after 4 months on chelation therapy were obtained. Cohort B included 12 patients on enzymatic replacement therapy (ERT), for this cohort sera samples were obtained for LCN2 determiniation and also a panel of cytokines (IL-10, IL-13, IL-4, IL-6, IL-7, Mip1a, Mip1b y TNFa), ferritin, hepcidin, chitotriosidase and CCL18/PARC were analyzed at study QUELAFER and sere from baseline and after 4 months on chelation therapy were obtained. Cohort B included 12 patients on enzymatic replacement therapy (ERT), for this cohort sera samples were obtained for LCN2 determiniation and also a panel of cytokines (IL-10, IL-13, IL-4, IL-6, IL-7, Mip1a, Mip1b y TNFa), ferritin, hepcidin, chitotriosidase and CCL18/PARC were analyzed. The patients included in both cohorts were 19-57 years old, with a median of 24 years.

Results: Comparison of LCN2 expression in GD1 patients revealed significant differences between groups. The expression of LCN2 was significantly lower in the naïve cohort (N=6) compared to patients on ERT (N=12) (p<0.001). Additionally, LCN2 expression in the naïve group showed a trend to be negatively associated with ferritin levels (p=0.098). As expected, expression of LCN2 was positively correlated with ferritin levels in the cohort of patients on ERT (p=0.014).

Summary/Conclusions: In accordance with previous reports, our results support that LCN2 expression can serve as a potential biomarker for disease activity in GD1 patients.
patients exhibit the higher values. In general 9 patients showed a reduction on LC2 levels while 7 showed an increase and one the value was stable. All patients showed a reduction in ferritin and chitotriosidase, however a fully correlation with LC2 expression were not founded. Global there were no statistically differences, but as individual T-test showed a difference between both measures (p=0.027). A detailed description an analysis will be presented in case of acceptance.

Summary/Conclusions: Lipocaline expression is increased in GD1 patients in general, a correlation with other cytokines expression to establish the role of this biomarker is warranted.

E1413

COMPARISON OF TREATMENT AND OUTCOMES BETWEEN ACQUIRED PRIMARY AND SECONDARY THROMBOTIC THROMBOCYTOPENIC PURPURA

S.H. Wai1,2,*, H.J. Ng2, T.C. Wen2, J. Quek2, H.T. Mya2
1Monash University, Melbourne, Australia, 2Singapore General Hospital, Singapore, Singapore

Background: Thrombotic thrombocytopenic purpura (TTP) is a rare disease that is fatal if untreated. While the main treatment modality is plasmapheresis, immunosuppressants also play a crucial role in the treatment of TTP.

Aims: Our aim is to compare the clinical characteristics, treatment and outcomes of patients with acquired primary TTP to those with secondary TTP (i.e. autoimmune and malignancy/hematopoietic stem cell transplant (HSCT)) related. 

Methods: We reviewed all patients with TTP who received plasmapheresis at our institution from 1st Jan 2008 to 31st Jan 2017. Clinical and laboratory characteristics, treatment, response to treatment and complications were recorded.

Complete remission (CR) was defined as platelet count normalization, partial remission (PR) as platelet count doubling and >30 x 109/L and the rest as unresponsive/mortality (UM).

Results: Of 41 cases of TTP, 24% (n=10) was primary, 44% (n=18) was secondary to autoimmune diseases, 27% (n=11) was secondary to malignancy or HSCT, 5% (n=2) was related to DRESS syndrome and acute pancreatitis. The median age was 47 (18-86) years and it was predominately female (81%). About two-thirds of the cases presented with neurological symptoms (66%), renal dysfunction (56%) and fever (59%). Only 12 patients (29%) had TTP pentad. Proportionate to incidence of secondary TTP, 85% required immunosuppressive therapy, renal dysfunction and/or fever were seen in 51% (n=21) and PR in 15% (n=6). Mortality rate at end of treatment was 41% (n=17) and at end of follow-up was 46% (n=19).

Summary: Comparison of demographics, clinical presentation, treatment and outcomes between acquired primary TTP and secondary TTP are shown in table below.

</table>

As compared to primary TTP using chi-squared for categorical data and non-parametric Mann-Whitney U test for continuous data. *p<0.1 **p<0.05.

Summary/Conclusions: Compared to primary TTP, secondary TTP had an initial poorer response to plasmapheresis. Patients with autoimmune diseases required more immunosuppressive therapy and rituximab. Although the final response and mortality rates showed a trend towards poorer prognosis in secondary TTP, it was not statistically significant. Further studies are needed to improve the treatment of TTP, both primary and secondary.

E1414

EVANS SYNDROME IN CHILDHOOD: LONG TERM SINGLE CENTER EXPERIENCE

A. Teli1, E. Farmaki1, A. Taparkou1, D. Adamidou2, M. Economou1,*, 1Aristotle University of Thessaloniki, 2Blood Bank, Hippokration General Hospital, Thessaloniki, Greece

Background: Evans syndrome (ES) is a rare entity in childhood, usually presenting with a course that is chronic and refractory to treatment.

Aims: To report on the clinical and laboratory characteristics of pediatric patients with ES diagnosed and long followed at a single center.

Methods: Data covering a 15 year period and concerning 14 ES patients were retrospectively studied. Clinical presentation, laboratory parameters, diseased severity, therapeutic approaches, number of relapses, presence of complications, time of follow-up and final outcome were reported. Disease was considered active when Hb <7g/dl and/or PLT <30,000/mm3 and/or N <500/mm3, in partial remission (PR) when 7-11g/dl and/or PLT 30,000 – 10,000/mm3 and/or N 500 – 1,000/mm3, in short-term complete remission (SCR) when >11g/dl and PLT >100,000/mm3 and N >1,000/mm3 when still under or less than 12 months off treatment, and in long-term complete remission (LCR) when laboratory values as in SCR but free of treatment for over 12 months.

Results: Mean age at diagnosis was 5.4 years (18 months-12 years). Recent history of infection was reported in 3 (21.4%) and positive family history for another autoimmune disease in 5 (35.7%) patients. At diagnosis, 10 patients (71.4%) were Hb <11 g/dl, 7 (50%) with Leucopenia and 6 (42.8%) with Neutropenia. Only 12 patients (85.7%) had TTP pentad. Of these, 10 (71.4%) patients presented with one or more complications related to treatment: Cushing syndrome, osteopenia, hypertension, renal dysfunction and/or peripheral neuropathy. No severe infection or death was reported during the 15 year period. Disease relapses (-3) were reported in 8/14 (57.1%) patients. With regards to outcome, 8/14 (57.1%) remained in LCR, 1 (7.1%) in SCR, 1 (7.1%) in PR, 3/14 (21.4%) in active disease, whereas 1 patient was lost to follow-up.

Summary/Conclusions: The rare entity of Evans syndrome in childhood seems to be associated with various immune manifestations and to carry complications related to treatment. Long term studies are needed to guide optimal management, which still remains challenging.

E1415

LOW DOSE RITUXIMAB IS A USEFUL ADDITION TO CORTICOSTEROIDS FOR NEWLY DIAGNOSED PATIENTS WITH WARM AUTOIMMUNE HEMOLYTIC ANEMIA

A. Gomez-de Leon1,*, P. Colunga Pedraza1, P. Santana-Hernandez1, G. Sotomayor-Duque1, L.D.C. Tarin-Arzaga1, J.C. Jaime-Perez1, C.H. Gutierrez-Acosta1, O.G. Cantu-Roqueto1, D. Gomez-Camargo1
1Hematology, Hospital Universitario Dr Jose Eleuterio Gonzalez Universidad Autonoma de Nuevo Leon, Monterrey, Mexico

Background: Warm autoimmune hemolytic anemia (wAIHA) is an infrequent autoimmune disorder with a high response rate to corticosteroids, albeit relapses are common. Low dose rituximab has been used successfully in autoimmune cymopenias in an effort to increase response duration, while reducing adverse effects and costs associated with a traditional rituximab dose and prolonged prednisone exposure.

Aims: To evaluate the safety and efficacy of low-dose rituximab combined with corticosteroid treatment in newly diagnosed patients with wAIHA.

Methods: We performed a single-center, prospective, single-arm, open-label study in adult patients with newly diagnosed “primary” or idiopathic wAIHA from 2013-2016 using high-dose dexamethasone (40mg IV days 1-4) followed by 40mg/kg PO PO/d x 10 days. Patients received Prednisone (100mg total dose, days +1, +8, +15, +22). CR was defined as an increase in hemoglobin (Hb) ≥2 g/dL, PR was defined as Hb ≥1 g/dL or an increase of ≥2 g/dL. Response was evaluated at day +28, months +6 and +12. Informed consent was obtained from all participants.

Results: Eight patients were included. Median age was 32 years (range 18-42), 6 were female. Median Hb at diagnosis was 5.8 g/dL (range 4.8-8.2 g/dL). All patients had response at day +28 (50% CR rate); median time to response was 12 days (range 3-17). During follow-up day 7/8 achieved CR (median time to CR: 30 days, range 15-103), all of which were sustained at 6 months. Median follow-up was 24 months (range 6-40). One patient presented disease-dependent and relapsed after 12 months, achieving a stable PR after re-treatment with low-dose rituximab. Furthermore, two patients had new-onset immune thrombocytopenia (IT; Fisher-Evans’ syndrome), without hemolysis 6.5 and 8 months.
after diagnosis. Two patients were diagnosed with systemic lupus erythematosus during follow-up, they remained in CR. Twelve-month CR rate was 80% (5 evaluable patients). One patient experienced grade 3 neutropenia two months after the last rituximab infusion that resolved without complications. Estimated relapse-free survival was 80% at 2 years (60% if IT is considered). No patient had a splenectomy performed.

Summary/Conclusions: This small study reports favorable outcomes for patients with newly diagnosed wAIHA treated with low-dose rituximab, and adds 8 patients with similar responses to the 7 cases previously published by the Italian group in 2012 and 2015. These results may be comparable to standard doses of rituximab, with a lower cost, and deserves further inquiry. The emergence of additional autoimmune phenomena (SLE, Evans’ syndrome) is unpredictable and can be an obstacle for appropriate data analysis in prospective AIHA studies.

E1416
INFECTIOUS COMPLICATIONS IN PRIMARY AUTOIMMUNE NEUTROPHENIA OF CHILDHOOD
T. Palianopoulos1, A. Gkoutsias1, N. Chalaisos1, A. Makis1,2
1Department Of Pediadrics, University Hospital Of Ioannina, Ioannina, Greece
2Rheumatology, University Hospital Of Ioannina, Ioannina, Greece

Background: Primary autoimmune neutropenia (PAN) of childhood is caused by the action of antibodies against membrane antigens of neutrophils leading to their peripheral destruction. Despite the low neutrophil counts, it is characterized by minor intermittent infections with rare severe bacterial episodes, which can be a significant cause of morbidity.

Aims: The retrospective evaluation of the incidence and characteristics of infectious complications in children with PAN from one reference academic center in Greece.

Methods: The study included the clinical and laboratory findings of children with PAN, who were diagnosed in our department in the last eight years (2008 - 2016). PAN was considered in children suffering over 3 months with a positive test for neutrophil antibodies, using the granulocyte immunofluorescence test, the granulocyte agglutination test and the monoclonal antibody immobilization of granulocyte antigen test. Laboratory evaluation for nutritional deficiencies, infections, systemic autoimmune diseases or malignancies was negative. Clinical data related to the occurrence of bacterial infections and treatment, hospitalization and outcome were collected and analyzed.

Results: 48 children with PAN were enrolled; 28 were boys, the median age was 14.5 months (range 5-96) and median follow-up time was 20 months (range 4-93). 19 children (39.6%) all suffering from severe neutropenia (<0.5 x 109/L) had to be hospitalized 25 times for bacterial infections; 4 for pneumonia, 7 for acute otitis media, 1 for mastoiditis, 7 for urinary tract infections, 4 for bacterial infections of unspecified site, 1 for perianal abscess and 1 for cellulitis, all with good outcome with proper antibiotic treatment. The average number of hospitalizations due to infections was 0.52/patient and the rate was 0.56/1000 patient-days.

Summary/Conclusions: Although rare, infections are an important clinical issue in the management of children with severe PAN, sometimes requiring hospitalization. Early signs of infection should be promptly recognized and accordingly treated.

E1417
NEW EPO-RECEPTOR MUTATION IN A 17-YEAR OLD WOMAN WITH ERYTHROCYTOSIS
B. Robredo1,2, L. Lo Rio1, B. Lopez1, L. Florensa2, L. Arenillas2, B. Belosillo2, C. Ballestre1, A. Perez1, A. Sampo3, M.A. Duran1
1Hematology, Hospital Universitario Son Espases, Palma de Mallorca, Spain
2Laboratorio Citología Hematóloga. Servicio de Patología. Gretnue. Escuela de Citología Hematóloga Soledad Woessner, Hospital del Mar, Barcelona, Spain
3Hematology, Hospital Universitario Son Espases, Palma de Mallorca, Spain

Background: Erythrocytosis is defined when red cell, hematocrit (Hct) and hemoglobin (Hb), are elevated above normal limits. Causes of erythrocytosis can be primary and secondary. Secondary causes are divided into congenital and acquired. There is a group of patients with idiopathic erythrocytosis.

Aims: We present a case report of a novel EPO-Receptor mutation.

Methods: We present a case report of a 17-year-old woman with erythrocytosis. In the control blood test she had hemoglobin of 18.6g/dl and hematocrit of 62%. We contacted the patient and she attended hematology consultations for study and treatment with phlebotomy. The patient had no known drug allergies or toxic habits. She had a known coronary syndrome treated with stent; at evaluation she referred chronic headache without other symptoms. The physical examination was normal. At that time, three possible diagnosis were suspected: firstly, primary erythrocytosis, polycythemia vera (PV). In this disease, the bone marrow produces many red cells and the JAK2 V617F mutation has been demonstrated in the majority of patients. Exon 12 mutation has been described in patients with PV who did not have the JAK2 V617F mutation. The erythropoietin (EPO) level is undetectable as a compensatory mechanism. In our patient, JAK2 V617F mutation and exon12 mutation were negative and the EPO levels were undetectable (<1.5). The bone marrow aspirate and the bone marrow biopsy were normal. These results show that this patient doesn’t present PV, due to she only fulfilling one diagnosis criteria of PV. Secondly, acquired secondary erythrocytosis can be produced as a compensatory mechanism, including: cardiac or pulmonary disease, smoking, renal artery stenosis, sleep apnea/hypotension and malignant tumors. In the patient, pulmonary function test, abdominal ultrasound and kidney function were normal. Endogenous erythropoietin-receptor mutation. Our patient presented undetectable EPO levels and the EPO-receptor mutation was requested. The patient has been treated with phlebotomies and aspirin due to headache with good evolution. In this moment, she presents hematocrit levels of 46.8%.

Results: The test revealed an EPO-receptor mutation (c.1275_1290dup), which had never been described before.

Figure 1.

Summary/Conclusions: The study of the patient with erythrocytosis must begin with a full medical history and confirmation of raised Hb and Hct. In the study of erythrocytosis, after ruling out primary and acquired causes we should always consider the possibility of congenital erythrocytosis, which often is underestimated. When EPO binds to its receptor a signaling cascade is activated, which cause red cells to be produced. This process is switched off when sufficient red cells have been produced by binding of SPH-1, EPO-receptor mutation results in failure of bind of SPH-1, causing uncontrolled production of red cells and erythrocytosis. We describe a new EPO-receptor (c.1275_1290dup) (figure 1).

E1418
FAMILIAL HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS IN CHILDREN
Z. Salcioglu1,2, G. Aydogan1, F. Akci1, C. Bayram1, A. Ayciçek1, G. Ozdemir1
1Pediatric Hematology and Oncology Clinic, Istanbul Kanuni Sultan Suleyman Education and Research Hospital, Istanbul, Turkey
2Hematology, Department of Hematology, Istanbul Hekayat Hospital, Istanbul, Turkey

Background: Familial hemophagocytic lymphohistiocytosis (FHL) is an autosomal recessive disorder characterized with uncontrolled activation of T-helper lymphocytes and macrophages and over-release of inflammatory cytokines. The only curative treatment is hematopoietic stem cell transplantation (HSCT).

Aims: This study evaluates the clinical and laboratory data of children with FHL. Thirty five FEL cases followed and treated at our clinic between 2005 and 2017 were retrospectively evaluated in our study.

Methods: Information of patients were retrieved from patient files and from the records contained in the electronic information processing environment created after 2005. All patients were treated with HLH-2004 protocol. HSCT was performed in nine patients.

Results: Twenty one of the cases were boys and fourteen were girls. The age at presentation for patients was two week-three years (mean 6.2 months). There was a history of consanguineous marriage in 26 of the families (74%). Fever, anemia, and hypertylgyricemia were present in all HLH cases. Hepatomegaly was detected in 74%. Splenomegaly was more frequent in patients (1.77 x109/L) in our patients. Hemophagocytosis in the bone marrow in all patients. Hepatomegaly was detected in 74%. Splenomegaly was more frequent in patients (1.77 x109/L). Hemophagocytosis in the bone marrow in all patients. Hyperferritinemia was present in 94% of patients. Only nine patients found to have hemophagocytosis in the cytological evaluation of the CSF (25.7%). Mutation analysis were performed in 18 patients and of these, 10 had PRF1, 5 had UNC13D, and 3 had STX11 gene mutation. All patients were treated with HLH-2004 protocol. Of the 22 children who were placed in first remission. HSCT was performed in 9 patients (%32.5). The overall mortality rate was 57% (20 cases) in our series. Twenty children died opportunistic infection (n=10) or of disease progression (n=10).
Summary/Conclusions: In conclusion, FHL is a disease with high mortality rates and the only curative treatment is HSCT. Donor search for HSCT must be started and HSCT should be performed after the remission.

E1419

ABNORMAL MONOCYTE POPULATIONS IN THE PERIPHERAL BLOOD OF PATIENTS WITH CHRONIC IDIOPATHIC NEUTROPENIA

Background: Chronic idiopathic neutropenia (CIN) is an acquired disorder of granulopoiesis characterized by an unexplained, prolonged reduction in the number of neutrophils and a generally benign and uncomplicated course. Neutropenia in CIN has been mainly attributed to increased apoptotic death of the granulocytic progenitor cells due to abnormal production of pro-inflammatory cytokines and pro-apoptotic mediators. Activated T-lymphocytes with a skewed oligoclonal/monoclonal profile and myelosuppressive properties have also have a major role in the pathophysiology of CIN.

Aims: Monocyte subpopulations display a prominent role in innate immunity but also mediate pro-inflammatory responses and T-cell activation. The monocyte subpopulation in CIN is not studies. The aim of the present study was to evaluate the monocyte subsets, namely the classical CD14++/CD16- intermediate CD14+/CD16- and non-classical CD14+CD16** cells as well as the monocytic CD14+/CD15/DR/MF/cD33/CD11b** fraction of the myeloid derived suppressor cells (MDSC), in CIN patients.

Methods: We have studied 25 patients fulfilling the well-defined diagnostic criteria for CIN and 10 age and sex-matched healthy individuals. Three-colour flow cytometry was used to assess the peripheral blood monocytes subsets in the gate of CD14 positive cells and five-colour flow cytometry for the evaluation of the myeloid derived suppressor cells in the gate of cells with intermediate/ high FSC/SSC properties.

Results: The mean number of neutrophils and monocytes in CIN patients was 1176±496/μl and 412±130/μl, respectively (range 200-1800/μl and 200-700/μl, respectively). The proportion of classical CD14++/CD16- cells was significantly decreased in CIN patients (79.65%±7.60%) compared to the healthy individuals (87.90%±3.70%) (P=0.009). In contrast, a significant increase was observed in the proportion of CD16 positive cells in CIN patients (16.81%±6.75%) compared to the controls (7.97%±3.16%) (P=0.0001). This increase was due to the higher proportion of the intermediate CD14+/CD16* but not the non-classical CD14+/CD16** monocyte subsets in CIN patients (12.74%±5.28% and 4.05%±2.51%, respectively) compared to controls (7.05%±2.47% and 2.73%±1.39%, respectively) (P=0.0014 and P=0.1383, respectively). Furthermore, the proportion of CD14+/CD15/DR/MF/cD33/CD11b** MDSCs was significantly increased in the patients (6.18%±3.92%) compared to the healthy controls (3.31%±1.74%) (P=0.0412).

Summary/Conclusions: CIN patients display increased proportion of circulating intermediate CD14+/CD16* monocytes that may have a role in the aberrant inflammatory responses commonly seen in these patients. The increased proportion of the CD14+/CD15/DR/MF/cD33/CD11b** MDSCs in CIN may simply reflect a compensatory reaction aiming to suppress the T-cell activation. Isolation of the above cell populations and transcriptome studies are currently in progress in our laboratory.

DIAGNOSTIC VALUE OF CELL BOUND AND CIRCULATING ANTI-NEUTROPHIL ANTIBODY DETECTION IN PEDIATRIC NEUTROPENIA

L. Porretti1,*, P. Farruggia2, V. Trunzo2, R. Ghidardi2, N. Mirra2, L.D. Notarangelo2, B. Martire2, S. Miliani2, C. Veneri2, P. Rebulla2

1Flow Cytometry Service, IRCCS Foundation Ca’ Granda Ospedale Maggiore Poli-Chirurgico, Milan, 2Hematology, 2Biochemistry, Hospital de Sant Pau, Barcelona, Spain

Background: The diagnosis of autoimmune neutropenia (nAIN) is one of the biggest challenges in clinical practice. Diagnostic criteria for nAIN are established but the evaluation of circulating anti-neutrophil antibodies (C-ANAs) still remains cumbersome and measured in few laboratories. Routinely, Hcy is used to differentiate LB12 patients because a good concordance has been reported between Hcy and MMA levels. However, in a study involving few cases, 26.5% patients with LB12 and normal Hcy showed high MMA levels.

Hcy increases in CIN and CBN patients and correlates with MMA levels. This study investigated whether the evaluation of D-GIFT improves the diagnostic accuracy of pediatric neutropenia. This can reduce the need for expensive and invasive investigations in CB patients.

Methods: I-GIFT and D-GIFT were performed by flow cytometry in 533 children including 174 (33%), 162 (30%), 81 (15%), 51 (10%) and 65 (12%) cases with pAIN, CIN, secondary autoimmune (sAaN), post-infection (PIN) and non-autoimmune (nAaN) neutropenia referred to this laboratory during 2002-2014, respectively.

Results: Using highly specific median fluorescence intensity cut-off values calculated by ROC curves, a positive D-GIFT was found in 49% of CIN patients, who showed similar clinical features as those included in the pAaN group. In 44 (27%) of 162 CIN patients I-GIFT was repeated 2-3 times in a year, resulting positive in 12 (27%) and 2 (5%) patients at the second and third screenings, respectively. Interestingly, 10 (71%) of the latter 14 patients showed a positive D-GIFT at the first serological screening.

Summary/Conclusions: D-GIFT evaluation improves the diagnostic accuracy of pediatric neutropenia. This can reduce the need for expensive and invasive investigations in CBN patients.

E1421

INAPPROPRIATE TREATMENT COULD MASK COBALAMIN DEFICIENCY: ROLE OF MELANOLACTIC ACID EVALUATION

R. Angel F.1,*, P. Sarda2, M. Serra1, J.M. Querol2, E. Zapico1, J. Remacha1, S. Puyan1, A. Ramos-Aviles1

1Hematology, 2Biochemistry, Hospital de Sant Pau, Barcelona, Spain

Background: Metabolic markers of cobalamin (Cbl) deficiency, such as methylmalonic acid (MMA) and homocysteine (Hcy) enable us to diagnose Cbl deficiency 1. They differentiate Cbl deficient patients from those with low serum cobalamin levels (LB12), but without a real Cbl deficiency. Hcy evaluation is fully automated and available in many laboratories, whereas MMA determination is cumbersome and measured in few laboratories. Routinely, Hcy is used to differentiate LB12 patients because a good concordance has been reported between Hcy and MMA levels. However, in a study involving few cases, 26.5% patients with LB12 and normal Hcy showed high MMA levels.

Aims: To evaluate the characteristics of patients with LB12 and normal Hcy and high MMA levels.

Methods: A prospective study was carried out in our University Hospital. Hcy levels were determined in LB12 (level <15pmomoll) patients with normal folate parameters for 18 consecutive months. MMA was assessed in those with normal Hcy. Serum B12, serum and red cell folate, and Hcy levels were evaluated using commercial automated methods. Hyperhomocysteinemia was defined by serum Hcy >17umomoll. Serum MMA was assessed by mass spectrophotometer and an increase in the MMA level was considered when MMA was >0.4nmol/l.

Results: A total of 237 patients with LB12 and normal Hcy were observed. In 27 (11.4%) MMA levels could not be determined. MMA levels were normal in 147 (70%). In 63 patients, MMA was increased (30%), including 25 cases (12%) with MMA levels >0.8nmomoll. In 48 out of 63 patients (76%), data on previous treatment were available. Of them, 40 (83.3%) patients had previously received inappropriate treatment (40% receiving folate) and 5 no previous Cbl treatment (10.5%). Only, 3 patients (6.25%) were treated with an adequate Cbl dosage.

Summary/Conclusions: MMA was increased in 30% of LB12 patients with normal Hcy. MMA levels were not predictive of Cbl deficiency, but 83% were erroneously treated, including 40% receiving folate. As a consequence, in most of these cases this erroneous treatment decreased Hcy levels to normal values, but cobalamin deficiency was masked and could deteriorate, especially when folate treatment was used without and adequate cobalamin replacement.

EARLY LESSONS FROM WHOLE-GENOME SEQUENCING IN THE CLINICAL DIAGNOSIS OF ACCUMULATIVE RAPIDLY VENOUS THROMBOSIS AND THROMBOCYTOPENIA

1Molecular Haematology Unit, 2BRC Molecular Diagnostic Centre, Oxford University Hospitals NHS Trust, 3Comprehensive Biomedical Research Centre, Weatherall Institute of Molecular Medicine, University of Oxford, 4Molecular Haematology Unit, Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, United Kingdom

Background: Targeted re-sequencing has recently been adopted for the rapid diagnosis of anaemia patients whose disease is likely to have a genetic basis, however, currently results remain inconclusive in 30-60% of cases. Whole-genome sequencing (WGS), provides more uniform coverage than amplification-based panels and is allied to an unbiased approach offering the opportunity to explore both coding and non-coding regions. It is also possible to use WGS data to detect copy number variation without good resolution and sensitivity. Therefore WGS has the potential to offer an accurate molecular diagnosis in a proportion of unsolved anaemia cases and may therefore be a superior initial approach.

Methods: In cases where the diagnosis of suspected genetic origin. Proband were pre-screened with a targeted panel containing ~50 candidate genes, none of which had harboured likely causative variants. Analysis of WGS data involved Stampy for read alignment, Platypus for variant calling and Ingenuity Variant Analysis (Qiagen) for variant annotation and filtering, following B cell normalization, 11 months after rituximab administration. Infant no 1, 2 and 3) personal and family history, as well as laboratory screening at diagnosis, did not reveal presence of any other hematoologic, autoimmune or immunologic condition. In case number 4 AIHA followed the diagnosis of giant cell hepatitis. Hospitalization after rituximab administration ranged between 1 and 5 months, and multiple transfusions, administrations of intravenous immunoglobulin (maximum dose 65g/kg), repeated doses of intravenous methyl-prednisolone (30mg/kg) followed by oral prednisolone (max 5mg/kg), all failing to achieve sustained response. Rituximab was administered at 375mg/m2 in 4 weekly infusions. In 3 infants 5 monthly infusions followed. Stabilization of hemoglobin and improvement of hemolytic parameters were observed after the 3rd-4th weekly infusion in all infants. In 3 patients (no 1,2,3) CD19+ and CD20+B cell assessment before and after rituximab administration was performed. Complete elimination (<1%) was observed in all patients after the 1st-2nd infusion. Despite B cells returning to normal 11 months after treatment, infant no 1 remained in clinical remission during follow-up (22 months post treatment). Infant no 2 remained in clinical remission for the 16 month post treatment follow-up, despite B cell normalization. Infant no 3 relapsed following B cell normalization, 11 months after rituximab administration. Infant no 4 did not undergo B cell measurements and relapsed one year after completing rituximab therapy. The 2 patients that relapsed were re-treated with 4 rituximab infusions: patient no 3 remained well for the 18 month follow-up, whereas patient no 4 remained well for 10 years – again relapsing and receiving her 3rd rituximab treatment with good response for the remaining 7 month follow-up. None of the patients presented with adverse reactions during the infusions or with severe infections at a result of immunosuppression. However, infant no 1 developed asymptomatic progressive IgG hypogammaglobulinemia 11 months after initial exposure to rituximab, eventually requiring IVIG administration.

Summary/Conclusions: Rituximab administration in refractory AIHA seems to be efficacious and safe in infants. However, close follow-up is warranted in order to ensure absence of long term complications, including the risk of post-treatment hypogammaglobulinemia, when the drug is administered at such young ages.

CONGENITAL ERYTHROCYTOSIS: DISCOVER OF A NEW MUTATION

J. Barradas1, P. Rocha1, C. Dantas Rodrigues1, C. Constanço1, M. Reis Andrade1, C. Bento7, H. Matos Silva1

1Servicio de Hematología Clínica, Centro Hospitalar Tondela-Viseu, Viseu, 2Servicio de Hematología Clínica, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

Background: Congenital erythrocytosis (CE) is a rare hereditary disorder of red cell production, characterized by an absolute increase in red cell mass with elevated hematocrit and hemoglobin levels not accompanied by increased viscosity. It is usually classified in two forms: juvenile, occurring in young ages. Currently, there is a lack of diagnostic tools to identify causative variants, of which 60% are in genes associated to slightly increased thrombotic potential. Therefore, this study aimed to undertake WGS in a set of patients in whom targeted re-sequencing had not been able to identify a molecular cause for the inherited anaemia, in an attempt to increase the diagnostic yield of the molecular analysis of such patients and provide novel candidate genes as causative of anaemia.

Methods: We performed WGS of 20 individuals (2 singletons and 6 trios) at 30x coverage where all the probands have a rare form of suspected genetic origin. Proband were pre-screened with a targeted panel containing ~50 candidate genes, none of which had harboured likely causative variants. Analysis of WGS data involved Stampy for read alignment, Platypus for variant calling and Ingenuity Variant Analysis (Qiagen) for variant annotation and filtering, followed by deleteriousness prediction and verification by functional data. Results: Known causative variants in a gene absent from the targeted panel were detected in two patients (25%), whereas candidate variants in novel genes not previously associated with anaemia were identified across the other six cases. Familial segregation and functional studies are underway to provide further evidence of causality for these novel variants, of which 60% are in genes with previous evidence of a role in erythropoiesis and 40% in genes with no known role in erythroid development.

Summary/Conclusions: These results illustrate the overlap in phenotypic abnormalities existing among these conditions and the importance of providing an accurate molecular diagnosis to enable correct diagnostic and clinical management of anaemia patients. We also demonstrate the benefit of using WGS over targeted resequencing given the difficulty of designing comprehensive gene panels and keeping them up-to-date as new candidate genes are identified.
ADAMTS13 <5% or TMA without baseline cause), 2. HUS (TMA with ADAMTS13 >5% and high creatinine levels, positive E. Coli Shiga-Toxin or HUS related mutation), 3. sTMA (other TMA with a definite triggering cause). Clinical and laboratory parameters were analyzed in each group (TTP/HUS/sTMA) (ADAMTS13 ≥5% or >5%) by a univariate analysis using chi-square for categorical variables and ANOVA test for continuous variables. Kaplan-Meier and multivariate Cox proportional hazards regression was used for survival and relapse.

Table 1.

Results: Patient distribution was: TTP 13, HUS 8, sTMA 23. ADAMTS13 was determined in 28 patients (low 8, high 20). Clinical and laboratory parameters of each group and univariate analysis are summarised in table 1. All patients received 1mg/kg/day steroids on admission and started plasma exchange. Patients in the TTP group showed increased levels of LDH, schistocytes, bilirubin, and low platelet count which was associated with bleeding. They also required a higher number of plasma exchanges to recover. Five patients relapsed, 4 with low ADAMTS13 level. 4 patients were splenectomized and received immunomodulatords. One patient received only plasma exchanges when relapsed. One patient died immediately after diagnosis before receiving plasma exchange. HUS group patients had higher creatinine level which was associated with oliguria and dialysis requirement. Neurological symptoms were more frequent as well. Two patients progressed to renal failure and one was transplanted. Two other patients received eccluzimab and 1 relapsed when treatment was interrupted during pregnancy. sTMA patients showed more cardiac events and fever. Main triggering causes were: 6 malignant hypertension, 5 systemic lupus erythematosus, 4 neoplasia, 3 pancreatitis, 2 pregnancy, 1 tuberculosis, 1 glomerulonephritis, 1 dermatomyositis. Six patients died (4 cancere related). In the multivariate analysis, high LDH level was significantly associated with relapse (p=0.012) while the number of schistocytes showed a trend to statistical significance (p=0.063).

Summary/Conclusions: ADAMTS13 determination is a useful tool in TMA differential diagnosis. A high LDH level, and also probably the number of schistocytes, could be valuable to predict relapse in TMA patients.

CHILDREN WITH CHRONIC-REFRACTORY AUTOIMMUNE CYTOPENIAS: A SINGLE CENTER EXPERIENCE

T.H. Karapınar1,*, E. Durgun1, Y. Oymak1, N. Gülez2, Y. Ay1, F. Genel2, S. Gözmen1, E. Serdaroğlu3, S. Aydın Köker1, E. Töret1, C. Vergin1

1 Pediatric Hematology, 2 Pediatric Immunology, 3 Pediatric Allergy, 4 Genetics, Erciyes University Medical Faculty, Kayseri, Turkey

Background: Autoimmune cytopenias are a group of heterogeneous disorders characterized by immune-mediated destruction of one or more hematopoietic lineage cells. They can be idiopathic or occur as a manifestation of other underlying diseases, such as autoimmune diseases, immunodeficiency, autoimmune lymphoproliferative syndrome, tumors, medications or infections. They can be idiopathic or occur as a manifestation of other underlying disease. They can be idiopathic or occur as a manifestation of other underlying disease.

Aims: The aim of this study was to evaluate the clinical course and significance of autoimmune cytopenias due to immunodeficiency or autoimmune diseases in children followed up at our hospital.

Methods: A total of 337 files of information belong to patients with chronic or refractory autoimmune cytopenias were evaluated retrospectively at our hematology department between February 1997 and September 2015. Ultimately, patients with immune deficiency or autoimmune diseases (23 patients) were included in this study. Data were analyzed using SPSS 15.0. The results are presented as the mean, SD, median, absolute number, or percentile.

Results: Two hundred and thirty-three patients with idiopathic autoimmune cytopenias (6.8%) had an immune deficiency or an autoimmune disease. The median age of diagnosis was 3.1 years (between 6 months-16 years) and the ratio of male/female was 1.3. The median duration of following was 2.6 years (between 4 months and 18.5 years). A total of 13 patients (56.5%) had single-lineage cytopenias and 10 (46.5%) had multi-lineage cytopenias. Shows last diagnosis of the patients. In 5 of the patients, first cytopenias were detected than the primary diseases were diagnosed after median 2 months (between 0 and 77 months). Only one patient firstly had diagnosed as CVID, cytopenia has developed after years. All of the patients were treated with corticosteroids or intravenous immune globulin (IVIG) as first-line treatment. Ten patients needed second or further-line immunosuppressive therapies including rituximab, mycophenolate, and cladribine, cyclosporine A, azathioprine, and danazol. A total of 8 patients (34.7%) recovered from autoimmune cytopenias after the treatment of primary disease. That diseases were diagnosed as systemic lupus erythematosus in 4 patients, hypogammaglobulinemia in 3 patients, and celiac disease in 1 patient. Cytopenias have countinued in 14 of the patients. One patient with CVID died.

Summary/Conclusions: Cytopenias may be the first finding of an immunodeficiency or autoimmune disease and primary disease may be diagnosed in the clinical course. Early diagnosis is important because of beginning to the early treatment of underlying disease.

E1428

INHERITED PROTHROMBOTIC RISK FACTORS IN TURKISH CHILDREN WITH HEREDITARY ANGIODEMIA. SINGLE CENTER

T. Patirolu1,*, M. Cansever2, A. Ozcan1, F. Tahan3, Y. Özkul4

1 Pediatric Hematology, 2 Pediatric Immunology, 3 Pediatric Allergy, 4 Genetics, Erciyes University Medical Faculty, Kayseri, Turkey

Background: Hereditary angiodema (HA) is characterized with recurrent mucocutaneous angioedema, abdominal pain, edema of larynx and extremities. HA is a life treating, rare disease, it’s genetic inheritance known as autosomal dominant. The incidence of the disease ranges from 1/10000 to 1/15000. 3 types of disease were described. Classic HA, is associated with C1 esterase inhibitor quantitative (type 1) or functional (type 2) deficiency. Type 3 HA is caused as form of HA which is seen in pregnant women and women use estrogen treatment. If plasma C1 inhibitor is deficient, complement, kinin-bradykinin, coagulation and fibrinolytic systems activate out of control and then vascular permeability increases and angioedema develops, tendency to thrombosis increases as well. Furthermore, it is known that acute treatment with C1 inhibitor concentrate and prophylactic use of danazol and antifibrinolytic drugs may also stimulate the thromboembolism. Therefore, prothrombotic risk factors are important in the patients with HA. Hence, we planned to search prothrombotic risk factors in patients with HA.

Aims: Hence, we planned to search prothrombotic risk factors in patients with HA.

Methods: Ten patients with HA who were follow up at the Department of Pediatric Immunology and Allergy of the Erciyes University Medical Faculty were included in our study. The type and frequency of attack, use of prophylaxis and family story of HA were questioned. Factor V G1691A, prothrombin G20210A variant, methylene tetrahydrofolate reductase (MTHFR) and plasminogen activator inhibitor (PAI) mutations were investigated in all patients. Risk factors during the 10 previous attacks of the study, five of the patients were male (50%) and five were female (50%) and their ages mean was 151.9±48.21 months old (ranged from 75 to 210 months). No one had parental consanguinity. Nine patients (90%) had the family history of HA. Patients’ affected family members were distributed by 5 sibling (50%), 3 mother and aunt (30%), 1 sibling and mother (10%) and no family story (10%). One patient had once per month (10%), four patients had no family story (10%). The mean serum value of C4 level in diagnosis was 4.7±1.62mg/dl (normal value: ) mean value of C1 inhibitor level in diagnosis was 50.10±19.22mg/dl (normal value). It was learned that four patients (40%) had an attack of HA once every week, three patients had (30%) once per month, one patient (10%) had, once every 2-3 months. Two patients (20%) had no attack. Four patient had abdominal (40%), four patient had edema of hands, feet and face (40%). None of them received prophylactic treatment. One patient (10%) had heterozygous F V G1691A mutation, another one had also heterozygous prothrombin G20210A mutation. The heterozygous MTHFR mutation were identified in seven patients (70%) and homozygous MTHFR mutation were found two patients (20%). Furthermore, four patients (40%) had heterozygous and one patient (10%) had homozygous PAI mutation.

Summary/Conclusions: C1 inhibitor, inhibits activated F XII, thrombin and plasmin. When the C1 inhibitor is deficient, dermal vascular thrombosis and systemic coagulation occur due to inhibition of activated FXII, thrombin and plasmin. Decrease level of PAI1 and PAI2, destructs plasmin activation which concentrate and prophylactic use of danazol and antifibrinolytic drugs may also stimulate the thromboembolism. Therefore, prothrombotic risk factors are important in the patients with HA. Hence, we planned to search prothrombotic risk factors in patients with HA.
E1429
FLOW CYTOMETRIC ANALYSIS OF TISSUE SAMPLES IN 42 ADULT PATIENTS WITH MALIGNANCY-ASSOCIATED HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS
M. Klimkowska1, C. Arlind1, K. Kosior1, M. Machaczka2,3
1Department of Clinical Pathology and Cytopathology, 2Hematology Center, Karolinska University Hospital, Stockholm, Sweden, 3Medical Faculty, University of Rzeszow, Rzeszow, Poland

Background: Hemophagocytic lymphohistiocytosis (HLH) is a rare, potentially fatal hyperinflammatory syndrome, which in its most common, secondary form, can be induced by infection, malignancy or autoimmune disease. Diagnosis of HLH is made when at least five of eight clinical and laboratory HLH-2004 criteria are met. However, diagnostic criteria were established based on studies from pediatric patients, and it is debated if they can be applied to adults. Assessment of these criteria can be subjective (microscopic identification of hemophagocytes), time-consuming or not easily available (e.g. molecular analyses, functional tests of NK-cells).

Aims: The aim of the study was to evaluate phenotypic findings from flow cytometric (FC) analyses of bone marrow (BM) and other tissue samples from patients with hematological malignancies (HM) who developed HLH. The study was intended to investigate potential utility of a rapid phenotypic screening in diagnostics of suspected HLH.

Methods: Flow cytometric files for 42 patients with HM were retrieved from archive of the Department of Clinical Pathology and Cytopathology, Karolinska University Hospital. The patients were diagnosed and treated for HM-HLH at the Hematology Center of the same hospital, between 2009 and 2016. Tissue samples (bone marrow, peripheral blood, lymph nodes) were analyzed according to standard procedures, using monoclonal antibodies (BD, DAKO, Beckman Coulter, BioLegend). Cells were acquired using 4-color Canto A or 8-color Canto II cytometers (BD), and analyzed with BD FACSDIVA software. Neoplastic clones of myeloid or lymphoid character were excluded from reanalysis for the purpose of this study. Bone marrow samples were obtained from 31 patients shortly before and from 24 patients following HLH-diagnosis; in 13 patients paired BM samples were available.

Results: Patient characteristics are presented in table 1. Bone marrow B-cell lymphopenia was observed in 67% patients before and 74% after HLH diagnosis. Decreased amounts of NK-cells were noted in 48% persons at both time points. T-cell lymphopenia before HLH diagnosis was noted in 60% patients with myeloid malignancy but in only 25% cases of lymphoid malignancy, whereas in established HLH the respective figures were 27% and 46%. CD4/CD8 ratio was skewed-to-normal in both myeloid and lymphatic tumors before HLH was diagnosed. In cases of confirmed hyperinflammation, patients with myeloid tumors showed dominance of CD4+ cells but no such difference was noted in lymphoid disease. Loss of lineage specific markers of non-neoplastic T-cells was a constant feature in lymphoid malignancy, whereas aberrant expression of lymphatic markers (CD2, CD7, CD56) on myeloid cells was uniform in patients with myeloid tumors. Monocytosis was more often observed in myeloid as compared to lymphoid tumors. Monocytosis, which is a common character. However, monocytopenia was also noted in cases of established HLH, in 10% of myeloid malignancies and 15% of lymphatic malignancy cases.

Table 1.

Summary/Conclusions: In the presented cohort, quantitative shifts could be observed in BM samples around the time of HLH onset. However, different patterns were observed between patients affected by lymphoid or myeloid malignancies, which could aid disease-specific impact on BM microenvironment. Further study will be carried out to confirm findings in a large, possibly prospectively collected patient group. Control group of patients with respective malignancies but without HLH will be included.

E1430
BLEEDING IN PRIMARY IMMUNE THROMBOCYTOPENIA: WHO ARE MOST AT RISK?
U. Doobare1,2, S. Hodges1, R. Nandigam1, A. Newland1, D. Provan1
1Haematology, Barts and The London School of Medicine and Dentistry, London, United Kingdom

Background: Primary Immune Thrombocytopenia is a rare disorder in which patients are at risk of bleeding due to autoimmune-mediated platelet destruction. As such, treatment is varied. This study focused on describing the prevalence and types of bleeding events around the time of ITP diagnosis and after, as well as identify any factors that can potentially influence the risk of bleeding.

Methods: Data from the United Kingdom Immune Thrombocytopenia Registry were analysed for this study. The registry obtained its data from about 70 centers around the UK. Descriptive and logistic regression statistical techniques were used for this study.

Results: This analysis was based on 2365 (57.8% females) participants who are part of the Registry. The median age at diagnosis was 50 years (IQR 32, 66) and 77% of these patients were of European ethnicity. The commonest comorbid conditions was hypertension (23%). Median platelet count was 19 (IQR: 5, 53). Eighty percent had a platelet count below 30x10^9/L around ITP diagnosis. The most common bleeding events were skin-related (46.5%) and to the oral cavity (14.4%). About 70% of the cohort experienced at least one bleeding event at some point after diagnosis. After ITP diagnosis the most common bleeds were again skin-related (34.3%) and oral cavity bleeding (14.8%). Epistaxis had risen from 11.6% before diagnosis to 17.7%. Bleeding at other sites did drop. However, the prevalence of intracranial haemorrhage rose from 0.9% pre-diagnosis to 1.2% after diagnosis. Prednisolone (79%) and IVig (43%) were the most used drugs followed by rituximab (28%) among those who were treated. Romiplostim (15%) and Eltrombopag (9%) are used too but not any more than mycophenolate (18%) and azathioprine (22%). Fourteen percent of the cohort had a splenectomy at some point. Age but not gender or ethnicity were found to be associated with having a bleeding event around the diagnosis of ITP. Younger adults (18 to 30 years old) are less likely to experience a bleed than older adults (>70 years), who were most at risk. Platelet counts, expectedly, were associated with bleeding with those presenting with a platelet of <30x10^9/L were at higher risk. No comorbid illness or cotherapies were found to be associated with bleeding events.

Summary/Conclusions: The frequency of bleeding decreased for most sites but for some others a slight increase has been observed since ITP diagnosis. It is possible that bleeding events may have been recorded more accurately or observed more closely and over a longer period of time since diagnosis. However, control of bleeding was an issue after the diagnosis of ITP. Future analysis stratifying its findings by time periods would be beneficial in describing if bleeding events were better controlled over the last few years, especially after the introduction of new therapeutic agents and the publication of the internal consensus report on the diagnosis and management of primary ITP.

E1431
A MULTICENTRE, SINGLE ARM, OPEN LABEL STUDY EVALUATING THE EFFICACY AND SAFETY OF ELTROMBOPAG IN PATIENTS WITH SEVERE PERSISTENT IMMUNE THROMBOCYTOPENIC PURPURA (ITP) WITHIN SIX MONTHS OF DIAGNOSIS
H. Tran1,2, R. Bird3, S. Chunilal4, T. Brighton5, J. Reynolds6, S. He7, C. Mazis1, R. Hall1, P. Shuttleworth1, A. Grigg7
1Clinical Haematology, The Alfred Hospital, 2Clinical Haematology, Monash University, Melbourne, 3Clinical Haematology, Princess Alexandra Hospital, Brisbane, 4Clinical Haematology, Monash Health, Melbourne, 5Clinical Haematology, Prince of Wales Hospital, Sydney, 6Clinical Epidemiology and Preventative Medicine, Monash University, 7Clinical Haematology, Austin Hospital, Melbourne, Australia

Background: Patients with acute ITP who fail or are dependent on steroids or intravenous immunoglobulin (IVig) are often committed to splenectomy or prolonged immunosuppression. Splenectomy is potentially curable but not without operative risk with many patients reluctant to undergo surgery, while the response to immunomodulation is often suboptimal with significant side effects. Although effective, to date, there is no published studies evaluating the benefit of eltrombopag among steroid dependent or resistant, non-splenectomised ITP patients diagnosed within 6 months.

Aims: To evaluate the efficacy and safety of eltrombopag in patients with severe “acute” and persistent ITP within 6 months of diagnosis.

Methods: A multicentre, single arm open label study involving 39 patients with refractory primary ITP, with platelet counts ≤30x10^9/L, despite a daily dose of prednisolone of 1mg/kg for at least 2 weeks from diagnosis OR (b) requiring prednisolone ≥10mg daily and/or recurrent doses of IVig to maintain a platelet of >30x10^9/L within 6 months of diagnosis. Prior splenectomy was not a requisite.

Platelets disorders
Patients with platelets <10x10^9/L will commence on eltrombopag 75mg daily while those with a count ≥10x10^9/L will commence on 50mg daily. A sliding scale dose is used for subjects of East Asian heritage. The dose of eltrombopag can be progressively increased by 25mg increment every 2 weeks to maximum of 150mg daily (patients of East Asian heritage should have a maximum eltrombopag dose of 100mg daily) if the platelet count remains ≤30x10^9/L or there is clinically significant bleeding every 2 weeks. The dose can be progressively weaned to zero over the subsequent 6 weeks if clinically appropriate. The primary endpoint was overall response rate (ORR) at week 12, defined as the proportion of patients achieving complete response (CR; platelet >100x10^9/L), partial response (PR; platelet >50x10^9/L) or minor response (MR; platelet ≥30x10^9/L with ≥75% reduction in the dose intensity of concomitant ITP therapy compared with screening). The protocol specified a 1-sided 5% level binomial test of the null hypothesis that ORR at week 12 ≤30% and reporting of a 90% two-sided confidence interval (CI).

Results: Of the 39 patients enrolled, 46% were women, median (Q1, Q3) age was 53 (42, 65) years, median (Q1, Q3) diagnosis follow-up time was 4.2 (2.2, 5.4) months, and median (Q1, Q3) screening platelet count was 21(13, 34) x10^9/L. Prior treatments included steroids (95%), IVIG (58%), and immunosuppression (28%). 35 patients (90%) completed 12 weeks of treatment, 4 (10%) discontinued eltrombopag prior to week 12 [3 required new ITP therapy; 1 discontinuation was due to pregnancy]. At week 12, the median (Q1, Q3) platelet count was 50 (50, 100)mg daily. The median (Q1, Q3) dose of eltrombopag at week 12, zero (0, 5)mg daily. At week 12, the ORR was 64% (p<0.001; 90% CI: 51-77%); CR, PR, MR rates were 41%, 15% and 8% respectively and the median (Q1, Q3) platelet count among responders was 168 (98, 252)x10^9/L. At week 12, median (Q1, Q3) eltrombopag dose was 130 (80, 200)x10^9/L. Of the 39 patients, 12 (31%) developed pulmonary embolism (PE), the median (Q1, Q3) dose of eltrombopag at week 12 was 50 (50, 100)mg daily. Of the 39 patients, 12 (31%) developed pulmonary embolism (PE), the median (Q1, Q3) dose of eltrombopag at week 12 was 50 (50, 100)mg daily. Of the 39 patients, 12 (31%) developed pulmonary embolism (PE), the median (Q1, Q3) dose of eltrombopag at week 12 was 50 (50, 100)mg daily. Of the 39 patients, 12 (31%) developed pulmonary embolism (PE), the median (Q1, Q3) dose of eltrombopag at week 12 was 50 (50, 100)mg daily. Of the 39 patients, 12 (31%) developed pulmonary embolism (PE), the median (Q1, Q3) dose of eltrombopag at week 12 was 50 (50, 100)mg daily. Of the 39 patients, 12 (31%) developed pulmonary embolism (PE), the median (Q1, Q3) dose of eltrombopag at week 12 was 50 (50, 100)mg daily.
NORDIC COUNTRY PATIENT REGISTRY FOR IMMUNE THROMBOCYTOPENIA (NCPRITP): A COHORT OF PATIENTS WITH CHRONIC IMMUNE THROMBOCYTOPENIA IN DENMARK, SWEDEN, AND NORWAY

C. Christiansen1, S. Bahmanyar2, W. Ghanima3,*, N. Kristensen1, S. Stryker4, E. Egorova1, S. Kulikov5

1Clinical Epidemiology, Aarhus University Hospital, Aarhus, Denmark; 2Clinical Epidemiology Unit & Center for Pharmacoepidemiology, Department of Medicine, Karolinska Institute, Stockholm, Sweden; 3Department of Medicine, Oskar-Emil-Kristiansen Hospital, Trelleborg, Sweden; 4Biostatistics and information systems, National Research Center for Hematology, Moscow, Russian Federation

Background: Immune thrombocytopenia (ITP) is a rare disease characterized by isolated low platelet counts and an increased tendency to bleed. As yet, there have been no large, multi-country, population-based cohorts established to describe its long-term clinical course and investigate the effectiveness and safety of related therapies.

Aims: To describe the establishment of the NCPRITP and the characteristics of patients enrolled.

Methods: Encompassing Denmark, Norway, and Sweden, the NCPRITP started as a population-based post-authority safety study to assess the long-term safety of romiplostim in treating ITP. It includes patients with prevalent chronic ITP (cITP – ITP lasting >6 months). Samples from 566 patients have been retrieved. As of 04/01/2009, 62% of the identified cITP patients were diagnosed from 04/01/2009-12/31/2014, confirmed through medical record review. Since the start of the registry, guidelines have changed to define cITP as ITP lasting >12 months. For consistency, incident cases of ITP for a duration of >6 months will continue to be accrued through 2019. Through linkage of data from the national health registries and medical record review, the registry has rich clinical information for all enrolled ITP patients, such as comorbidities (including scores according to the Charlson Comorbidity Index [CCI]) – a validated tool developed to predict 1-year mortality), treatments, lab values (e.g., platelet counts), and complete follow-up for several clinical outcomes of interest (e.g., clinically significant bleeding, the need for rescue therapies, and thromboembolic/thrombotic events). Additionally, available bone marrow samples are retained and reexamined for reticulin and collagen content to assess Thiele’s myelofibrosis (MF) grading.

Results: The NCPRITP includes 3,749 patients with confirmed cITP (35% Danish, 51% Swedish, and 14% Norwegian), with a female preponderance (58%) and median age of 56 years at cITP diagnosis. Forty-one percent of the cohort was prevalent at study inclusion; 59% represent incident cITP patients. Median follow-up time thus far is 4.3 years. At study enrollment, 24% had a platelet count <50×10^9/L, 16% were splenectomized, and 41% had at least one previous ITP therapy (mainly oral glucocorticoid steroids). The majority (68%) of the cohort had no underlying conditions included in the CCI at study enrollment, but 8% had a CCI score of 3 or higher, indicating severe comorbidity. Of note, based on hospital diagnoses of specific comorbidities recorded within 5 years before study enrollment, 28% had a history of diabetes, 9% had a history of hypertension, and 18% had a history of hypertension. Currently, 718 bone marrow samples from 566 patients have been retrieved.

Summary/Conclusions: The NCPRITP provides an example of how, within the Nordic countries’ uniform health care systems, registries can be established to study the clinical course of rare diseases such as ITP and the safety of drugs used to treat these patients.

EPIDEMIOLOGY OF PRIMARY IMMUNE THROMBOCYTOPENIA (ITP) IN ADULTS IN RUSSIAN FEDERATION (RESULTS OF REGISTRY OF NATIONAL HEMATOLOGIC ASSOCIATION)

A. Melikyan1,*, E. Pustovaya1, M. Kalinina1, E. Volodicheva2, T. Kaporskaya3, R. Ilasov4, T. Babaeva5, O. Bekker6, V. Bogova7, E. Zolotn7, I. Zolotn8, I. Kontlevsky9, O. Pylatkova10, I. Sokolova11, N. Fedorova13, E. Egorova1, S. Kulikov5

1Charite-Universitätsmedizin, Berlin, Germany, 2Sir YK Pao Centre for Cancer & Department of Medicine and Therapeutics, Chinese University of Hong Kong, Shatin, Hong Kong, 3Hôpital Farhat Hached, Sousse, Tunisia, 4Novartis Pharma AG, Basel, Switzerland, 5Pediatric Hematology/Oncology, Well Cornell Medicine, New York, United States

Background: ITP is an acquired autoimmune disorder characterized by isolated platelet reduction, which is considered chronic when it persists for >12 months. Evidence suggests that age may influence both the hemorrhagic manifestations of ITP and also response and adverse events (AEs) associated with some therapies. Changes in drug metabolism can contribute to increased AE rates in patients (pts) ≥65 yrs compared with younger adults. The oral thrombopoietin-receptor agonist, EPAG, is approved for the treatment of previously treated (eg corticosteroids, immunoglobulins) cITP pts, but limited data are available in pts ≥65 yrs old. The EXTEND study was a global, open-label, extension study that evaluated long-term efficacy, safety and tolerability of EPAG in adults with cITP who had participated in prior EPAG studies.

Aims: To describe the efficacy, durability of response, and safety of EPAG use in pts with cITP aged ≥65 yrs.

Methods: All pts on EXTEND started EPAG at 50mg/day, titrated to 25–75mg/day or less often as required, based on individual platelet count responses: to achieve counts in the range ≥50–200×10^9/L. Maintenance dosing con- tinued after minimization of concomitant ITP medication and optimization of EPAG dosing. Pts could remain on EPAG either for 2 yrs in countries where EPAG was commercially available, or for >2yrs until EPAG became commercially available.

Results: At baseline (BL), 50/302 (17%) on EXTEND were ≥65 yrs old. At BL, 42% were male, 58% female and 74% had platelet counts <30×10^9/L. Twenty-four pts (48%) withdrew early from the study, most commonly because of AEs (n=8, 16%), other reasons (n=7, 14%) and lack of efficacy (n=5, 10%). Median exposure duration was 2.3 yrs (range, 2 days to 7.9 yrs) and mean daily dose was 49.9 (range, 11–75) mg. Overall, 43 (86%) pts achieved platelets ≥50×10^9/L with rescue therapy; 37 (74%) achieved platelets ≥50×10^9/L for ≥50% of assessments; 26 (52%) maintained platelet counts continuously ≥50×10^9/L for 22 weeks (Fig 2). Median time maintaining platelet counts >50×10^9/L and twice BL values,
While not receiving rescue treatment, was 78 (range, 0–350) weeks. Incidence of bleeding symptoms (WHo grades 1–4) decreased from BL (66%) to 1 y (15%). AEs were reported in 47 (94%) pts, most frequently nosophyngitis (n=13, 26%), constipation (n=12, 24%), fatigue (n=12, 24%), diarrealgia, urinary tract infection, cataract and cough (all n=11, 22%). Serious AEs occurred in 24 (48%) pts, most frequently (>5%) cataracts (n=7, 14%), pneumonia (n=3, 6%). A total of eight trials including 834 participants were included in this meta-analysis showed that thrombopoietin receptor agonists are safe, well-tolerated. Random-effects model was used to estimate pooled Odds Ratio (OR). Results: A total of eight trials including 834 participants were included in this meta-analysis. Aims: With this nationwide prospective cohort study, our objectives were to explore (1) the factors associated with treatment initiation (vs. watchful waiting) in children with primary immune thrombocytopenia (ITP) followed in routine clinical practice and (2) the predictors of chronicity at 12 months.

Methods: Between 2008 and 2013, 23 centers throughout France consecutively included 257 children aged 6 months to 18 years and diagnosed with primary ITP over a 5-year period. Data on ITP clinical features along with medical management were collected at baseline and 12 months. Multivariate logistic regressions were used to determine (1) and (2) as defined above, providing odds ratio (OR) with 95% confidence intervals (95%CI).

Results: 137 (53%) children were males, median age was 4.6 years, median platelet count was 7×10⁹/L, and 214 (81%) patients initiated medication. Factors independently associated with treatment initiation included platelet counts <10×10⁹/L (p=0.0001) and mucocutaneous bleeding symptoms at baseline (p<0.001). At 12 months, data were available in 211 (82%) children, of whom 130 (74%) had recovered. Predictors of chronicity included female gender (OR=2.2; 95% CI=1.0–4.8), age ≥10 years (OR=2.6; 95% CI=1.1–6.0) and platelet counts ≥10×10⁹/L (OR=3.2; 95% CI=1.5–6.9).

Summary/Conclusions: In routine clinical practice, the decision to apply a watchful-waiting strategy seems to be driven by platelet counts even in the absence of bleeding symptoms, resulting in treatment being initiated in more than 80% of the children surveyed. Overall, younger children with ITP showed good prognosis, with lower platelet counts and, to a lesser extent, male gender predicting more favorable outcomes.

SAFETY AND EFFICACY OF THROMBOPOIETIN RECEPTOR AGONISTS IN PATIENTS WITH PREVIOUSLY TREATED CHRONIC IMMUNE THROMBOCYTOPENIA: A SYSTEMATIC REVIEW AND META-ANALYSIS

Y. Yamada1,*, T. Fuji2, C. Cromwell3, I. Shapira1

1Medicine, Mount Sinai Beth Israel, New York, 2Internal Medicine, University of Hawaii, Honolulu, 3Hematology, Mount Sinai Beth Israel, New York, United States

Background: The current American Society of Hematology guideline recommends the use of thrombopoietin receptor agonists, eltrombopag or romiplostim as a rescue therapy for chronic immune thrombocytopenia (ITP). The efficacy and safety of those drugs have been tested in several clinical trials. However, the safety profile was not consistent throughout trials and is not yet well understood.

Aims: We herein conducted a meta-analysis of randomized controlled trials to compare the safety and efficacy of thrombopoietin receptor agonists: eltrombopag and romiplostim versus placebo in patients with previously treated chronic ITP. Our primary outcome was drug-related adverse events greater than CTCAE grade 3.

Methods: We performed a literature search in MEDLINE, EMBASE, Cochrane library, and the American Society of Hematology website up to September, 2015 by two independent authors according to PRISMA guideline. We included articles in English with the overall EXTEND study population (Bussel et al. Haematologica 2016;101[1]:SS17), with sustained platelet increases and reduced bleeding. Efficacy was well tolerated; AE rates were similar to that reported in the overall EXTEND study population, but an apparent increase in cataracts was observed in pts ≥65 yrs old (cataract incidence was 7% and 22% in <65 and ≥65 age groups, respectively). Further outcomes in patients ≥65 yrs old will be presented. Results should be interpreted with caution as almost half of the pts withdrew from the study. Efficacy is an effective treatment option for certain cITP pts ≥65 yrs; its use should incorporate baseline cataract screening and regular monitoring.

CHILDHOOD IMMUNE THROMBOCYTOPENIA: A NATIONWIDE COHORT STUDY ON CONDITION MANAGEMENT AND OUTCOMES

N. Aladjidi 1,*, A. Rotulo1, E. Palmisani1, A. Grossi2, F. Pierr1, M. Calvillo1, C. Miclalizzi1, P. Terranova1, E. Cappelli1, T. Lanza1, M.T. Giamo1, L. Ceccherini1, C. Dufour1, F. Fioredda1

1Hematology Unit, IRCCS Istituto Giannina Gaslini, Genova, Italy

Background: The treatment of chronic/relapsing immune thrombocytopenia purpura (ITP) is not well established due to the lack of evidence-based data, and is particularly challenging in children who are more at risk of severe side-effects secondary to prolonged steroid therapies. Sirolimus has been shown to be effective in patients with ITP secondary to ALPS and in very few patients with primary disease or secondary to ALPS-like syndromes.

Aims: The aim of this study is to evaluate the outcome and toxicity of patients with ITP either primary or secondary to ALPS-like syndromes, with or without involvement of other cell lineages.

Methods: We retrospectively evaluated charts of patients followed in our Unit for ITP primary or secondary to ALPS-like syndromes. Patients with ALPS were excluded. ALPS-like was defined as the presence of at least one absolute or predominant lymphoproliferative syndrome, with or without involvement of other cell lineages.

Results: 23 children aged 0-12 yrs (median 6) with primary ITP (7) or secondary to an ALPS-like disorder (16), were treated with Sirolimus. Seven patients (30%) with ALPS-like also had an Evans syndrome (ES), due to the association of leukopenia (1), or to the presence of trilinear cytopenia (6). Four patients with ALPS-like were found to have mutations on PIK3CD, CTLA4, TACI, and CARD 11 gene. All patients, but one treated in first-line, received Sirolimus as second (4), third (14) or fourth (4) line treatment, respectively. 18 patients had previously failed Mofelonelatomeffile (MMF) therapy. Overall, 17/23 (74%) patients achieved a response that was complete and partial in 12 (52%) and 5 patients, respectively. Prednisone was stopped in 67 (86%) cases. Children with mono-linear ITP achieved a response in 11/16 (68%) cases, with sustained platelet increases and reduced bleeding. Sirolimus was well tolerated; AE rates were similar to that reported in previous studies.
MMF treatment. Therefore, it can be considered as an alternative therapeutic option in the setting of ITP non only for patients with an underlying diagnosis of ALPS but also for the ones with primitive disease or with an ALPS-like disorder.

ASSESSMENT OF ROMIPLOSTIM SELF-ADMINISTRATION BY PATIENTS WITH IMMUNE THROMBOCYTOPENIC PURPURA AND CAREGIVERS FOLLOWING RECEIPT OF HOME ADMINISTRATION TRAINING (HAT) MATERIALS: A PROSPECTIVE STUDY
M. Schipperus1, G. Kaisar1, L Taylor2, S. Witten3, J. Bennett4, G. Kreuzbauer5, A. Boshier6, A. Seagathur4
1Department of Haematology, Haga Teaching Hospital, The Hague, Netherlands, 2AHEPA University Hospital, Thessaloniki, Greece, 3Roya London Hos- pital, London, 4Amgen Limited, London (Uxbridge), United Kingdom, 5Amgen (Europe), Zug, Switzerland, 6Amgen Limited, Cambridge, United Kingdom

Background: A HAT pack was designed as an additional risk minimization tool to support healthcare providers (HCPs) in selecting patients and training of patients/caregivers to mitigate medication error risk when self-administering romiplostim subcutaneously, a thrombopoietin receptor-agonist which is approved in the European Union (EU) to treat chronic immune thrombocyto- penic purpura (ITP) refractory to other treatments.

Aims: To estimate the proportion of adult patients and caregivers who admin- istered romiplostim correctly after HAT pack training.

Methods: This non-interventional, cross-sectional study enrolled 40 patients/caregivers and was conducted at 12 centres in Austria, Belgium, France, Germany, Greece, The Netherlands, Spain, and The United Kingdom, from 7 July 2014 to 20 November 2015. HCPs directly observed adults (>18 years of age) with chronic ITP or caregivers new to administering romiplostim in the act of product administration at the first standard-of-care (SoC) 4-week visit after HAT pack training. Correct administration of romiplostim (primary endpoint) was defined as dose accuracy within 10% margin of error between prescribed and administered romiplostim doses, and correct romiplostim reconstitution and successful injection, and no HCP intervention during administration to correct patient/caregiver error. All analyses were descriptive and no formal hypothesis was tested.

Results: At the first SoC visit, 4 weeks (range: 2-8 weeks) after HAT pack training, 35 patients/caregivers (87.5%) administered romiplostim correctly. The dose accuracy was within 10% margin of error for all patients. HCP intervention was required in 5 instances: 1 patient did not ensure all romiplostim was dissolved, 1 patient and 1 caregiver needed verbal encouragement, 1 patient needed nurs- ing intervention to read the correct dose from the vial due to poor eyesight, and 1 caregiver needed guidance with syringe and vial connection. Further follow- up data was available for only 2 of these 5 patients/caregivers; they both admin- istered romiplostim correctly at a voluntary subsequent visit.

Summary/Conclusions: Given that this study was conducted on a conven- ience instead of random sample of patients, generalizability of the results may be limited. Direct observation can be susceptible to observation bias and to the Hawthorne effect with the patients/caregivers acting differently when observed. Nonetheless, the success of most patients and caregivers in correctly adminis- tering romiplostim after HAT pack training suggests that self-administration of romiplostim is a feasible option for suitable romiplostim-treated ITP patients.

E1443
SHORT- AND LONG-TERM RESULTS OF FIRST LINE THERAPY WITH PULSED HIGH-DOSE DEXAMETHASONE IN ADULT IMMUNE THROMBOCYTOPENIA PATIENTS: A RETROSPECTIVE SINGLE-CENTER REPORT
L. Crucitti1, S. Cantoni1, R. Cairo1
1Hematology and Oncology, Niguarda Cancer Center, Ospedale Niguarda Ca’ Granda, Milano, Italy

Background: Immune thrombocytopenia (ITP) is an autoimmune disorder mediated by clearance of antibody-opsonized platelets (plt) by spleen macrophages. Pulsed high-dose dexamethasone (HD-DXM) has proved to be effective in adult patients (pts) with primary ITP resulting in controlled studies in 89% short-term response and a relapse-free survival (RFS) of 58% at 50 months (mos) (Mazzucconi, Blood 2007).

Aims: To assess the short-term and sustained response rates of adult ITP pts receiving pulsed HD-DXM in everyday clinical practice.

Methods: Charts of pts with ITP - as defined by Rodeghiero, Blood 2009 - treated with HD-DXM were reviewed. DXM was administered according to the schedule of 40mg/day for 4 consecutive days to be repeated every 21 days for a maximum of 6 courses. A reduced-dose schedule of 20mg/day for 4 days was preferred for elderly/diabetic pts. Pts who had completed at least 3 courses were included in the analysis. Response to HD-DXM was classified according to IWP definitions (Provan, Blood 2010); therefore, steroid-dependent pts were considered as non-responders even if plt counts increased to safe levels during HD-DXM and were included only in the analysis of short-term response, but not evaluated for long-term response. Short-term response rate was determined at completion of the whole course of treatment. Relapse was defined as a plt count decrease ≤20x10^9/L after initial response achievement and RFS was defined as the time interval between last course administered and the date of relapse, censoring pts alive or dead without relapse. Follow-up was defined as the time between diagnosis and last available assessment. The probability of RFS was calculated using the Kaplan-Meier method.

Results: A total of 45 pts (M: 21) were eligible for analysis; median age at treat- ment was 60 yrs (range 18-87) and median time between diagnosis and treat- ment start was 3 days (range 0-4686). Pts received a median of 5,15 courses (range 3-6); 27/45 completed 6 courses; 21/45 received the full dose of 40mg/day (=960mg total dose) while 6/45 received the reduced dose of 20mg/day (=480mg total dose). Median total DXM dose was 800mg/dVIO along with 1st DXM course were required in 11/45 pts. In between courses, no bleed- ing complications were observed and no emergency therapies were required. Short-term response was achieved in 38/45 (87%); complete response (CR) in 28/45 (62%), response (R) in 7/45 (16%); 4/45 (9%) pts were classified as steroid-dependent ITP and excluded from subsequent analysis. Long-term response off therapy, lasting for a median time of 28 mos (range 5-80) without relapses was observed in 25/35 responding pts (71.5%; CR in 18/25, R in 7/25 at last follow-up) with a RFS of 51% at 50 mos (Fig. 1). Median plt count at last
follow-up was 102x10^9/L (range 54-336). Disease duration of less than 3 mos prior to therapy start was associated with better outcome (log rank p=0.049, Fig 2) with a median RFS not reached; median RFS for pts treated after 3 mos of diagnosis was 31 mos [OR: 3.8 (CI 95% 0.9-16.3), p=0.067]. No significant association between gender (p=0.67), age at treatment (more or less than 60 yrs) (p=0.85), DTX total dose (more or less than 480mg) (p=0.35) was found. Summary/Conclusions: Pulsed HD-DXM is a well tolerated and highly effective first line treatment for ITP in every daily clinical practice. The role of a reduced-dose schedule needs to be explored in a larger cohort of pts. Treatment of newly diagnosed ITP pts - i.e. within 3 mos of diagnosis (Rodeghiero Blood 2007) - seems to lead to longer RFS.

E1444
EFFECT OF OSELTAMIVIR TREATMENT ON PLATELET COUNTS
1Servicio de Hematología y Oncología Médica, 2Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arrixaca, 3Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arrixaca. Grupo de Investigación CB15/00055 del CIBERER, ISCIII, Murcia, Spain

Background: As platelets lose sialic acid during aging and circulation, they are cleared by the hepatic Ashwell-Morell receptor (AMR) (1). A recent study suggests that inhibition of sialidase by oseltamivir, a commonly administered anti-influenza medication that inhibits viral sialidase, could associate with an increase in platelet counts (2).

Aims: The aim of this study was to analyze the effect of oseltamivir treatment in platelet counts.

Methods: We performed a retrospective single-center study. From November 2009 until March 2015, a total of 168 patients from our Hematology Unit were prescribed oseltamivir due to clinical suspicion of influenza. A total of 120 patients were excluded because they had received myelotoxic chemotherapy within 30 days, or platelet count was not available before treatment (n=38). The direct immunofluorescent antigen test was carried out with nasopharyngeal aspirate specimens. Those specimens that were negative by the antigen detection assay underwent RT-PCR testing for influenza virus types A and B. Platelet count was available before and after treatment (median of 5 days) in 48 patients and in 44 patients also when the infection was cleared (median of 30 days).

Results: Patients were divided into those with proven influenza (n=34) and without influenza (n=14). Median age was 58.0 and 59.5 years; respectively. Treatment consisted of 75mg oseltamivir bid for 5 days, with the exception of 3 patients in the proven influenza group receiving 150mg bid for 10 days (allo- geneic stem cell transplant recipients). We observed a significant increase in the mean platelet count after treatment with oseltamivir (170±9x10^9/L vs 190±13x10^9/L, p=0.04). As in the previous study (2), this effect was independent of whether influenza was diagnosed (Table 1). In addition, we did not discern significant fluctuation in platelet counts when treatment was immediately interrupted after a 30-day time lapse (184±100 x10^9/L vs 182±91 x10^9/L).

Table 1. Platelet counts (x10^9/L) in patients with a clinical suspicion of influenza and after oseltamivir treatment (median of 5 days). Results are given as mean±SD.

Summary/Conclusions: Our study confirms the effect of oseltamivir on increasing platelet counts regardless of influenza infection. Although an increase in platelet counts related to the viral syndrome healing is not ruled out, the lack of long-term fluctuations after the end of treatment may indicate a late inhibition that contributes to reduction in platelet clearance via the hepatic receptor.

CLINICAL UTILITY OF CARDIAC MRI IN IMMUNE MEDIATED THROMBOCYTOPENIC PURPURA
F. Alwan1,*, D. Mahd1, S. Mc Guckin1, J. P. Westwood2, M. Thomas1, J. Moon2, M. Scully1
1Haematology Department, University College London Hospital, 2Cardiac Imaging Department, Barts Heart Centre, London, United Kingdom

Background: Immune Mediated Thrombotic Thrombocytopenic Purpura (TTP) is a life threatening thrombomicroangiopathy caused by acquired antibody mediated inhibition of ADAMTS13. Cardiac complications are a common cause of death in patients with recognized TTP and may be a risk factor for new onset TTP. There is scant evidence on the best investigations for patients suspected of being at risk of cardiac complications with no evidence on the clinical utility of cardiac magnetic resonance imaging (MRI) in acute TTP episodes.

Aims: A retrospective review evaluating the value of cardiac MRI scanning in TTP. Methods: TTP patients underwent cardiac MRI scanning between November 2008 and November 2014 whilst being treated for an acute episode of immune mediated TTP. All patients had troponin-t measurement on admission and a transthoracic echocardiogram within 72 hours of presentation. All patients were treated for their TTP episode with plasmapheresis, steroids and Rituximab. Two cardiologists reported each MRI scan and only agreed, unequivocal findings were considered.

Results: The median age of patients was 49 (range 13-75), 71% of whom were women. Two patients had a diagnosis of hypercholesterolemia prior to TTP diagnosis but otherwise there was no previous cardiac history. 71% of patients had a raised troponin-t at presentation (normal <14ng/ml). Two patients developed bradycardia and one atrial fibrillation during their acute admission. One patient had symptoms of heart failure. Three patients had transient ST depression suggestive of ischemia on EKG monitoring and a further four had non-specific T-wave inversion. There were no incidences of cardiogenic shock or myocardial infarction. 33% of patients did not show evidence of cardiac involvement on transthoracic echocardiogram (2). A recent study confirms the effect of oseltamivir on platelet counts. MEFV gene mutations are responsible for Familial Mediterranean Fever (FMF) a hereditary autoinflammatory disease characterized by recurrent febrile inflammatory attacks of serosal and synovial membranes. MEFV gene’s product, pyrin or marenostin, play an essential role in the regulation of inflammatory reactions. MEFV gene mutations are associated with a wide range of auto-inflammatory and autoimmune diseases. Recently, studies showed that MEFV gene mutations change the Th1, Th2 balance and increase the Th17 numbers. Th17 cells may have a key role in neutrophil activation and autoimmune diseases. ITP is an autoimmune-mediated condition that results from antibody-mediated destruction of platelets and impaired megakaryocyte platelet production. ITP is a complex disorder of immune dysregulation caused by anti-ADAMTS13 antibodies produced by B cells. A recently proposed model for ITP involves antigen-presenting cells, B cells and T cells. Increased Th1/Th2 ratio and Th17 levels are implicated in the pathogenesis of ITP, as well.

Aims: This study addressed the prevalence of MEFV mutations and their effect on clinical features of ITP.

Methods: We studied the prevalence of exon 2 and 10 mutations (E148Q in exon 2, M694V, M694I, M680I, V726A, A744S and R761H in exon 10) in 81 adult ITP patients and 186 healthy controls. Patients were classified in two subgroups according to the presence of mutations. Demographic and clinical features were compared between groups to assess possible impacts of these mutations on clinical severity.

Results: Female to male ratio was 61/20=3.05 in the study group and 98/88=1.1 in the control group. The median age was 50 (21-79) in the ITP
Background: Splenectomy may lead to a good response in 60–80% of adults with corticosteroid refractory immune thrombocytopenia (ITP). However, in the era of new drugs the proper selection of patients for splenectomy is essential in optimizing treatment outcomes. Accordingly, it is important to identify pre- and post-operative parameters that are able to predict the response to splenectomy.

Aims: To identify the pre- and postoperative parameters predictive of successful splenectomy in ITP.

Methods: We retrospectively analyzed 130 ITP patients (median age 43 years, range 19–74; 84/39 female/male; median time from diagnosis to splenectomy 19 months, range 2–132; median number of pre-splenectomy therapies 2, range 0–18). The patients were divided into responder (CR and PR) and non-responder groups. The responders were defined as patients whose platelet count (PC) remained >50×10^9/L after splenectomy.

Summary/Conclusions: A higher PC on the surgery day (90×10^9/L vs.37×10^9/L, ρ=0.353, p<0.0001), a PC >250×10^9/L on the day of surgery (p=0.043) and PC >300×10^9/L on the 7th days after splenectomy (387×259/L vs.25×10^9/L, p=0.022, 0.001) and splenic platelet destruction (86% vs. 0%, p=0.035, p<0.0001). Using ROC analysis, cut-off prognostic values of PC were reevaluated: PC before splenectomy >47×10^9/L (AUC 0.864, sensitivity 63.6%, specificity 83.2%, 95% CI 0.785–0.943, p<0.0001). PC on the first day after splenectomy >50×10^9/L (AUC 0.956, sensitivity 44.4%, specificity 83.2%, 95% CI 0.912–0.999, p<0.0001) and on the 7th days after splenectomy >300×10^9/L (AUC 0.951, specificity 91.7%, sensitivity 45.6%, 95% CI 0.887–1.000, p<0.0001) were found as important predictors of the postoperative response rate.

Results: CR and PR were achieved in 105/130 (79%) and 12/130 (7.5%) of the splenectomised patients, respectively. However, 13/130 (11.5%) patients were refractory. Twenty-nine of the 117 (24.8%) responsive patients relapsed. Predictors of good response after splenectomy identified by univariate analysis were: initial response to steroids (89.5% vs. 22.7%, p=0.038, 0.001), higher PC on the surgery day (90×10^9/L vs.37×10^9/L, p=0.353, p<0.0001), on the first (387×259/L vs 56×10^9/L, p<0.0001) and on the 7th days after splenectomy (387×259/L vs.25×10^9/L, p=0.022, 0.001) and splenic platelet destruction (86% vs. 0%, p=0.035, p<0.0001). Using ROC analysis, cut-off prognostic values of PC were reevaluated: PC before splenectomy >47×10^9/L (AUC 0.864, sensitivity 63.6%, specificity 83.2%, 95% CI 0.785–0.943, p<0.0001). PC on the first day after splenectomy >50×10^9/L (AUC 0.956, sensitivity 44.4%, specificity 83.2%, 95% CI 0.912–0.999, p<0.0001) and on the 7th days after splenectomy >300×10^9/L (AUC 0.951, sensitivity 91.7%, sensitivity 45.6%, 95% CI 0.887–1.000, p<0.0001) were found as important predictors of the postoperative response rate.

Summary/Conclusions: Splenectomy is effective in approximately two thirds of patients with ITP. Our study suggests that splenectomy might be considered in the patients younger than 60 years, with splenic platelet destruction and PC >25×10^9/L on the splenectomy day.
drug reactions (ADRs), and other clinically relevant parameters. We report results of a full data analysis.

**Results:** A total of 59 patients were enrolled (49.4% male; 54% aged 65 years or above) from 38 sites; 22 of them were excluded due to protocol violations (e.g., incomplete documentation, inclusion criteria not met). Of the 137 remaining patients (the full analysis set, FAS), 102 completed the 2-year observation period. Drop-out included loss to follow-up (10 patients), deaths (6 patients) and ADRs (3 patients). Median (Q1, Q3) time from ITP diagnosis to romiplostim initiation was 21.7 months (4-5 months) in the FAS. 123 FAS patients received prior ITP therapies; most of them received corticosteroids (104 [75.9%]). 117 patients (85.4%) were non-remissioned before romiplostim therapy, for reasons such as refusal of splenectomy, comorbidities, or age. Over the observation period, romiplostim was injected at a median (Q1, Q3) dose of 3.13 mcg/kg/bw (1.8 - 4.8; FAS) over a median (Q1-Q3) treatment period of 103 weeks (33-104). The median platelet count rose sharply from baseline (29.0 x 10^9/L) to two weeks of treatment (62.5 x 10^9/L). From week 3 to baseline, the median count was maintained in a range of between 50 x 10^9/L and 145.5 x 10^9/L. Since the start of the romiplostim therapy, 59 patients out of 137 (43.1%) received concomitant therapies, mostly corticosteroids (49 patients [35.8%]). The overall number of ADRs was 112 in the FAS, affecting 37 patients (27.0%). The most frequent ADRs were gastrointestinal (10.2%) and neurological (11.7%) ADRs, followed by constitutional symptoms (10.8%). Adverse drug reactions pertaining to blood/bone marrow affected 2.9% of patients (vascular/thrombotic events, bone marrow fibrosis), whereas bleeding as an ADR was seen in 0.7% of patients. The exposure-adjusted rate of bleeding events (grade 3 or 4) per 100 patient-years in the FAS was 7.2 before treatment vs. 4.0 after starting the treatment. The rate of ITP-related hospitalization per 100 patient-years decreased from 23.3 before the start of therapy to 15.5 since the start of the therapy.

**Summary/Conclusions:** This study of routine clinical practice in Germany showed that treatment with romiplostim in ITP patients resulted in a rapid increase in platelet counts to levels maintained between 50 and 250 x 10^9/L over time, regardless of the splenectomy status of the patients; most of them were non-remissioned. The product was well tolerated and achieved a decrease in the rate of ITP-related hospitalization.

**Background:** Hermansky-Pudlak syndrome (HPS) is an inherited platelet disorder characterized by bleeding diathesis, oclocutaneous albinism and sometimes serious clinical complications. Heterogeneous clinical symptoms and a large numbers of possible genetic culprits (9 HPS genes, >118 exons) complicate unequivocal HPS diagnosis.

**Aims:** To assess the clinical and platelet phenotype in five patients with HPS suspicion and to identify their genetic defects (exons 1-67 inclusives).

**Methods:** We studied 5 patients from 3 families (2 Spanish, 1 Turkish) presenting with oclocutaneous albinism. Clinical records were reviewed and bleeding scored with ISTH-BAT. Platelet phenotype (only Spanish patients) included: platelet aggregation, GP's expression and granule secretion. 14C-serotonin uptake and whole mount electron microscopy. Patients DNAs were amplified by HTS using a 7 gene panel.

**Results:** Clinical and laboratory findings in these patients are shown in Table 1. The Spanish patients (P1, P2, P5) showed impaired platelet aggregation to mild agonists and reduced platelet dense granules. In family 1 (F1), HTS identified a heterozygous, potentially harmful, c.2054delC (p.Pro685Leu fs*17) variant in HPS4. One sister (P1) had Cron’s disease and severe gastrointestinal (GI) bleeding. This variant had been reported in a 46y Asian patient with pulmonary fibrosis (Bachi EB, Am J Med Genet 2004). A novel missense homozygous HPS4 variant, c.272T>C (p.Leu91Pro), was found in two Turkish siblings (F2). One had severe GI bleeding requiring cologney (P4) and the other developed pulmonary fibrosis. Patient 5, suffering from mild GI bleeding, bears a heterozygous novel variant in HPS3 (c.2464C>T; p.Arg822X) and, most likely, an additional unrevealed mutation.

**Summary/Conclusions:** HTS facilitates genetic confirmation of HPS diagnosis, and may help investigating phenotype-genotype relationships in HPS. The novel p.Leu91Pro variant in HPS4 associates with severe clinical phenotype. Funding: JMB: Gerencia Regional de Salud [GRS 1370/A/16]; JR: ISCIII & Feder (PI14/01956), Ciberer CB15/00055, Sociedad Española de Trombosis y Hemostasia.
hemolysis, elevated liver enzymes, and low platelets. Previous studies have demonstrated enhanced platelet activation in pregnant women with pre-eclampsia, using cell surface markers and platelet microparticles. Although severe pre-eclampsia is associated with increased inflammatory markers in vitro, levels of platelet activation do not necessarily correlate with severity of disease.

Aims: To assess the presence, and degree, of platelet activation in a cohort of patients with early onset pre-eclampsia (EOP), using flow cytometry and correlation between sGPVI and PF4 levels.

Methods: Plasma samples from 19 individual patients were included. Patients with HELLP syndrome demonstrated significantly greater numbers of CD42a+ microparticles when corrected for platelet count compared with those without HELLP syndrome (598×10^9/L versus 297×10^9/L; p=0.04). Similarly, patients with HELLP syndrome demonstrated increased levels of sGPVI than those without HELLP; corrected for platelet count (2.576±0.9667 µg/ml versus 1.22±0.124 µg/ml; p=0.0334). There was no difference in NAP-2 or PF4 levels between those with HELLP and those without HELLP, nor between severe and moderate pre-eclampsia patients. Severe pre-eclampsia patients in this cohort had a D-dimer level of 3.71±0.74 µg/ml compared with non-severe patients. 1.85±0.35 µg/ml (Spearman Rank correlation coefficient, r =0.532, p=0.04).

Summary/Conclusions: The results of this study demonstrate a positive correlation between severity of pre-eclampsia and platelet activation, as measured by levels of platelet-derived microparticles and platelet GPVI expression. A number of previously published trials have evaluated the role of low-dose aspirin therapy as prevention for pre-eclampsia, and there is Grade 2B evidence for its use in those at risk of severe pre-eclampsia. The evidence of enhanced platelet activation in our study provides rationale for the efficacy of aspirin in this setting, and the potential for novel antiplatelet agents to be studied for the same indication.

E1454 PRIMARY ITP IN ADULTS TREATED WITH ELMOTRUBAG: A RETROSPECTIVE STUDY USING DATA FROM THE UNITED KINGDOM ADULT IMMUNE THROMBOCYTOPENIA REGISTRY.

D. Provan1,*, U. Doobaree1, A. Newland1, J. Fleming2

1Haematology, Barts and The London School of Medicine and Dentistry, London; 2Haematology, Novartis, Camberley, Surrey, United Kingdom

Background: Primary ITP is an autoimmune disorder associated with a reduced peripheral blood platelet count. Although many patients are relatively asymptomatic, many suffer with bruising, mucosal bleeding and quality of life issues. First-line treatment has remained unchanged for decades and until recently, second-line therapy has been unsatisfactory, using empirical treatments. The recently approved thrombopoietin receptor agonist eltrombopag and romiplostim have transformed patient care and these agents are licensed second-line therapies in adults.

Aims: To describe the adult patients receiving eltrombopag using data from the UK Adult ITP Registry. In particular we were interested in understanding the mean dose used, number of prior therapies, median length of treatment with eltrombopag, median counts at baseline before treatment and at six months following treatment, and sustained response in patients who have received eltrombopag.

Methods: The UK Adult ITP Registry involved more than 70 UK collaborating centres, coordinated by The Royal London Hospital. In this study we analysed data from all patients receiving eltrombopag and analysed these using various statistical techniques.

Results: The total number of patients evaluated was 129. The median age at diagnosis was 49.4 years (26.9-66.4). There were 74 males (57.4%) and 55 females (42.6%). 29 patients (22.4%) had undergone prior splenectomy. The median age at eltrombopag initiation was 59.5 years (37.0-70.7 years). The median time from ITP diagnosis to eltrombopag initiation was 1.6 years (0.7-2.3 years). The majority of patients started eltrombopag between 2013 and 2016 (93%), and 6% (9) started eltrombopag within the first 6 months and between 6 to 12 months of ITP diagnosis, respectively. Most patients had received prior ITP therapies. Some 10 patients (7.8%) had received one prior ITP therapy and 99 patients (77%) had received three or more prior therapies before starting eltrombopag. The commonest prior therapies were corticosteroids in 110 patients (87%); IVg 91 patients (72%); rituximab 68 patients (54%); romiplostim 47 patients (37%); and immunosuppressants 71 patients (56%). At baseline, prior to starting eltrombopag, the median platelet count was 21×10^9/L (10-54) and the majority of patients (64.5%) had platelets less than 30×10^9/L. The mean platelet count at 6 months was 206.2×10^9/L and at 1 year was 288×10^9/L. The median dose of eltrombopag used was 50mg/day. The median course length on eltrombopag was 14.7 (IQR: 4; 67) weeks. After initiation, 53 (41%) remained on eltrombopag as a monotherapy whereas 27 (21%) had other ITP treatment concurrently with eltrombopag. Forty nine (38%) changed treatment after eltrombopag, of which prednisolone (47%), IVg (33%), corticosteroids (15%), and rituximab (14%) were added. 22% of patients (22%) underwent a splenectomy. Response to eltrombopag was assessed for 106 patients with adequate follow up time and platelet counts. 81 (76%) had a response, of which 54 (51%) were above 100x10^9/L and 27 (25%) had a partial response (platelet counts between 30 to 100x10^9/L). Among those that had a response, 15 (14%) became unresponsive after some time whereas 2% (2) patients were unresponsive soon after a brief episode of response. In short, 64 (60%) had a sustained response to eltrombopag (among patients who remained or came off eltrombopag).

Summary/Conclusions: The patient characteristics of those receiving eltrombopag appear to be typical of adults ITP. Only 10 patients (7.8%) had received romiplostim as a second-line therapy. Three quarters had received 3 or more prior therapies before starting eltrombopag despite its licence as a second line therapy. As clinicians become more familiar with its use, a greater proportion of patients are likely to receive eltrombopag as a second line therapy.

E1454 EFFICACY OF TPO-MIMETICS IN PATIENTS WITH IMMUNE THROMBOCYTOPENIA

F. Bacchiani1,*, V. Carrai1, C. Biagioti1, A. Bosi1

1Hematology, AOU Careggi, Firenze, Italy

Background: Immune thrombocytopenic purpura (ITP) is an autoimmune disorder in which antibodies are produced to circulating platelets. The two currently available agents (Romiplostim and Eltrombopag) have similar efficacies and only slightly different safety profiles, being effective in restoring a safe platelet count in 70%-80% of cases with chronic ITP failing one or more lines of treatment, including splenectomy.

Aims: We evaluated the efficacy of TPO-RAs in patients with ITP.

Methods: From November 2008 and February 2017 65 patients (33 M; 32 F) were treated with a median follow-up of 29 months (1-96); 39 underwent therapy with Romiplostim and 26 to ELMOTRUBAG. Median age was 69 years (range 39-94 years). In the group of patients treated with Romiplostim, 21 had already received 3 or more prior therapies, whereas 18 had received only one prior treatment. 13/26 patients who received ELMOTRUBAG were at the 3rd line of therapy. At the second and, the others were at the 4th line. The median platelet count was 21x10^9/L (3-52) at the start of Romiplostim, with a median starting dose of 1 µg (1-2) and 17x10^9/L (1-53) in patients treated with ELMOTRUBAG, with a median starting dose of 50mg (25-50).

Results: Patients treated with Romiplostim we observed 22 complete responses and 10 responses, with a 82% response rate, while 7 patients were no responders. In our study 26 (66%) patients stopped Romiplostim after a median time of 16 months (1-93): 9 for stable response, 5 for no response, 3 for loss of response, 3 for adverse events (2 for bone marrow fibrosis, 1 for headache and myelodysplastic syndrome); we observed 3 patients stopped the line of therapy, 5 patients stopped the line of therapy, 2 underwent a splenectomy, and 3 patients interrupted the treatment for other causes (es. diagnosis of cancer). The median platelet count at suspension of Romiplostim was 91.5 x 10^9/L (3-320). In patients treated with ELMOTRUBAG 16 achieved a complete response, 5 a response, obtaining response in the 80% of cases; 5 were no responders. 14 (53%) patients stopped ELMOTRUBAG after a median time of 15 months (1-12): 6 for adverse events (2 cases of major cardiovascular events, liver toxicity, skin rash, pharyngitis), 5 for no response, 1 for loss of response, 2 patients who achieved a CR interrupted ELMOTRUBAG obtaining a sustained remission after discontinuation. The median platelet count at suspension of ELMOTRUBAG was 57x10^9/L (7). In patients treated with ELMOTRUBAG we did not interrupt treatment. The patients were still receiving therapy with a median of 29 months (3-96). Several studies reported Romiplostim and ELMOTRUBAG to be highly effective against chronic ITP, with average immediate responses exceeding 80% in our study. We observed that therapeutic response was influenced by the starting platelet count. In particular patients count before therapy influenced the first response observed. In particular in patients treated with Romiplostim PLT pre-treatment directly correlated with the first response and the maintainance of response during treatment at month 1°, 2° and 3°. Patients with a median starting platelet count of 15x10^9/L obtained a response (CR + R), while almost all patients who started therapy with PLT<15x10^9/L at baseline can obtain an initial response, but the majority is not achieved. If the response is not achieved on the first 3-5 weeks, the treatment should be interrupted.

Summary/Conclusions: TPO-mimetics have proved efficacy in patient with ITP and their use can be applied in several conditions (bridge to splenectomy; sustained response; switch and discontinuation). Future study on large series of patients are needed to best correlate baseline platelets with hematological response. Furthermore, the two current TPO RAs (Romiplostim and ELMOTRUBAG) have similar efficacies and only slightly different safety profiles, being effective in restoring a safe platelet count in 70%-80% of cases with chronic ITP failing one or more lines of treatment, including splenectomy.
PREVALENCE AND RISK FACTORS FOR THROMBOSIS IN ADULT ITP PATIENTS

C. Morel1, A. Tichelli2, A. Wieland-Greguare-Sander3, A. Angelillo-Scherrer4, A. Rovó5,*

1Faculty of Medicine, University of Bern, Bern, 2University Hospital of Basel, Basel, 3University Hospital of Bern, Bern, Switzerland

Background: Immune thrombocytopenia (ITP) is characterized by severe thrombocytopenia due to autoantibody- and cell-mediated peripheral platelet destruction and attenuated thrombopoiesis. Despite a higher risk for bleeding, thromboembolic events (TEE) have been observed.

Aims: We aimed to investigate the prevalence and type of TEE and the potential risk factors in adult ITP patients.

Methods: Retrospective cohort study, including all ITP patients followed in our clinic between 01/1990 and 05/2016. Information on gender, age, date of ITP diagnosis, platelets count, type and clinical form of ITP, type of ITP treatments and its response, severe bleeding and follow up time were collected. Furthermore we evaluated date of first appearance, number and type of thromboembolic events, cardiovascular risk factors, date and cause of death. We assessed and compared risk factors of ITP patients with and without TEE in univariate and multivariate analysis.

Results: Medical files of 480 patients registered as ITP were reviewed; 42 patients were excluded from the analysis (not fulfilling the ITP criteria according to Roddighero et al. Blood 2009). In total 438 patients were retained for analysis, 10% out of them (44 patients) presented ≥1 TEE after ITP diagnosis. Within these patients, in total 54 TEE occurred: 34 venous (61%), 19 arterial (34%) and 3 arterial and venous (5%) thrombotic events. The most frequent venous TEE were pulmonary embolism, deep vein thrombosis, and superficial vein thrombosis; arterial TEE were cerebrovascular insults, myocardial infarction and peripheral artery thrombosis. At time of TEE, 43% of patients were on treatment with corticosteroids, 14% with thrombopoietin receptor agonists (TPO-ra) and 18% were off-treatment. In the univariate analysis, older age at diagnosis of ITP (P=0.015), longer interval since ITP diagnosis (P=0.001), persistent or chronic ITP (versus acute, P=0.009), ≥2 treatment lines (P=0.0002), TPO-ra at time of thrombosis (P=0.027), non-response to first-line treatment (P=0.010), smoking (P=0.011), arterial hypertension (P=0.005), and obesity (P=0.041) revealed to be significant. The multivariate analysis model showed that older age at diagnosis (RR, 2.272; 95% CI, 1.167-4.426; P=0.016), ≥2 treatments (RR, 2.539; 95% CI, 1.305-4.941; P=0.006), persistent or chronic ITP (RR, 3.830; 95% CI, 1.111-13.196; P=0.033), and smoking (RR, 2.622; 95% CI, 1.250-5.499; P=0.011) were independent risk factors for TEE. When the variable “number of treatments” (<2 versus ≥2) was excluded from the multivariate model, having a splenectomy increased the risk for TEE. The cumulative incidence of TEE at year 1, 5, 10, 15 and 20 years since diagnosis of ITP was 6.2% (95% CI, 4.1-9.3), 11.9% (95% CI, 8.3-17.0), 15.8% (95% CI, 11.1-22.4), 24.2% (95% CI, 16.9-34.7) and 32.8% (95% CI, 22.8-47.3) respectively (Figure). Death occurred in 7/44 (16%) patients with TEE, and in 12/394 (3%) patients without TEE (P<0.0001). Most frequent causes of death were infection (32%) and bleeding (21%).

Methods: We performed a prospective study in 4 ITP patients who exhibited no response to standard therapies (steroid, IVIG and/or splenectomy) and showing relevant platelet desialylation levels. Patients were given off-label oseltamivir at the referring physician’s discretion. Desialylation of GP platelet surface was examined via flow cytometry (FC) analysis, with fluorescence-conjugated Rcinus Communis Agglutinin I (RCA-1), which binds galactose residues only if the terminal sialic acid has been removed. FC data are expressed as fold change compared to control samples. Additionally, patients’ sera were incubated with normal human platelets to analyze the ability to induce desialylation of normal platelets. Analysis of plasma proteins was performed by Western blot (FXI, FXIIl and HPLC [carbohydrate]. Platelet autoantibodies specificity was detected by a solid-phase modified antigen capture ELISA test (MACE).

Results: Patients’ characteristics are summarized in Table 1. Two patients achieved complete platelet response (>100x10^9/L after oseltamivir treatment. The oral dose was secured eight times daily, for a variable duration (5 days in one case and 4 months in the other showing response criteria since the third week of from start) combined with low doses of other treatments (azathioprine or romiplostim). A sustained platelet response was observed after 4 weeks of the sial-
idase inhibitor discontinuation. Patients with no response after oseltamivir treatment (n=2) were given similar doses for 5 days. Patients with response had antibodies directed solely to GPIb and had greater platelet loss of sialic acids. Moreover, their sera induced significant desialylation of normal platelets. However, no desialylation in patients' plasma proteins was detected. Biological analysis after treatment discontinuation (median of 3 weeks), revealed a sustained sialylation level of platelet glycoproteins over time, particularly in patients with sustained platelet response.

Summary/Conclusions: Chronic ITP patient with anti-GPIbα autoantibodies who do not respond to conventional therapies and exhibit significant platelet desialylation may achieve a complete response to treatment with oseltamivir.

BORTEZOMIB THERAPY IS ASSOCIATED WITH SIGNIFICANT RESOURCE IMPLICATIONS FOR BOTH PATIENTS AND PROVIDERS: RESULTS OF A TIME-IN-MOTION STUDY
M. Tatarczuch1, K. Ramasamy1, A. Peniket1, M. Sultanova1, G. Vallance1, F. Panitsas1
1Haematology, Oxford University Hospitals NHS Trust, Oxford, United Kingdom

Background: Bortezomib is a proteasome-inhibitor, which has improved outcomes in multiple myeloma (MM). Its use is approved within the UK NHS. Bortezomib is frequently administered as a subcutaneous injection in a hospital day treatment unit. Whilst the administration of a subcutaneous injection is brief, the process for the patient travelling to hospital, assessment and waiting for the delivery of the injection can take considerable time. From a patient perspective, significant amounts of time spent without economic activity and travel costs add up during the course of therapy. From the health-care provider the process of safely administering bortezomib has significant resource implications beyond those of drug procurement.

Aims: We set up a time-in-motion study to evaluate the costs to health care provider and patients during bortezomib therapy to estimate the ‘real-world’ cost of delivering bortezomib therapy.

Methods: Retrospective data collection was undertaken, using electronic prescribing records for patients treated between July 2014 -August 2016. Travel distance and time was estimated using Google maps and costed using HMRC mileage (an approved costing of mileage used for taxation purposes). The NHS schedule of service costs was used to estimate the cost of bortezomib administration. Cost of delivery of Bortezomib for healthcare providers is a sum of these individual costs.

Results: We identified 127 patients who incurred a total of 2 134 visits whilst receiving Bortezomib therapy at the Churchill Hospital in Oxford during this 2 year period. Median age was 70 years-old (yo) (39-95); Male 74 patients (58%) 53 patients (42%). We restricted the analysis to 110 patients who started and completed therapy during the study period. Median number of patient visits was 16 (range 11-52). The median travel distance (return journey) for each patient was 33 miles (53 km) (range: 1.2-224 mi; 1.9-360 km). Median travel time was 90 min (range: 8-300 min). The range travel cost per patient was £8.35-£13.20. Twenty-seven patients (21%) required use of specialist hospital transport services, which resulted in 295 transport-episodes (14%) in total. In order to assess the time spent in the day therapy unit, a subgroup of 589 patient-episodes were analysed to assess time from arrival to administration of Bortezomib: the median time from patient registration to bortezomib administration was 63min (range: 5-433min). Pharmacy cost for preparation of Bortezomib was £50 per dose. The cost of delivery of bortezomib (not including cost of drug) was £1,160 per cycle, which equated to a total median cost of £4,640 per patient (range: £290-£15,080). Drug procurement costs for Bortezomib is estimated at an additional £12,261 per course of therapy (BNF 2016). Delivery costs therefore added an additional 38% to the procurement costs.

Summary/Conclusions: We provide the first time-in-motion data on myeloma patients treated with Bortezomib. The ‘real-world’ cost of delivering therapy is 37% higher than the drug-costs alone. In addition the impact on patients is substantial: over a two year period 127 patients required 2 134 visits with a median time in the day unit of 63 minutes and a median travel time of 90 minutes per visit. Our data highlights the burden of both time and economic costs to patients during therapy. Novel oral proteasome inhibitors offer the potential to reduce this resource impact in the future. This data could be used by health care providers and reimbursing agents for economic modeling of the potential benefits of oral proteasome inhibitors.

haematologica | 2017; 102(s2) | 595
Figure 1.

Summary/Conclusions: Administration of oral analgesia and anxiety is a safe and feasible option to be used in outpatient setting: sedo-analgesia is very effective in reducing pain during the biopsy and diminishes the anticipatory anxiety related to a painful procedure. Patients should have the possibility to choose between local anesthesia alone or sedo-analgesia plus local anesthesia.

Table 1.
Aims: To assess cost-effectiveness of ATGAM (horse antithymocyte globulin) in comparison to rabbit antithymocyte globulin (r-ATG) in the treatment of moderate to severe aplastic anaemia (sAA) patients in Sweden.

Methods: A semi-Markov state-transition cohort model was developed to estimate long-term (up to 5 years) clinical and economic outcomes for patients with AA receiving either ATGAM or r-ATG as first-line IST treatment. The following key assumptions were included in the model: responders who relapse are assumed to be re-treated with no expected change in survival. Patients who do not respond to first-line treatment move onto a second-line treatment comprised of either IST, IST + eltrombopag or hematopoietic stem cell transplantation (HSCT). Although response rates are lower, those who respond to second-line treatment are assumed to have the same outcomes as those who respond to IST. Patients who continue to not respond receive standard supportive care with a significant decrease in expected survival. Efficacy data for ATGAM and r-ATG were obtained from published literature. Adverse events were not included due to lack of evidence of any difference between the two comparators. Medication, administration, and disease management costs were obtained from published literature, publicly available sources and clinical expert opinion. As resource utilization for disease management changes over time and differs considerably between responders and non-responders, three distinct phases have been included in the model: short-term (first 6 months post-IST administration), medium-term (6-12 months) and long-term (greater 1 year), for patients in either of the response categories.

Results: Response to treatment was calculated to be seen in 67% of ATGAM patients’ vs 35% in r-ATG (accounting for mortality). Over 5 years, the model estimated that patients gained 4.15 life-years (3.28 quality-adjusted) on ATGAM vs 3.52 (2.56) on r-ATG. Short-term disease management costs were estimated to be SEK 880,144 ($96,816) in responders vs SEK 1,264,016 ($139,041) in non-responders. Medium and long-term costs also followed the same pattern. Overall costs (drug plus disease management), were significantly lower for patients receiving ATGAM vs r-ATG; making ATGAM cost-saving by being both more effective and less costly than r-ATG. When considering treatment costs only (including cyclosporine and HSCT), the model estimated a cost of SEK 107,097/life-year gained (approx. €11,781) and SEK 135,655/quality-adjusted life-year (approx. €14,922), showing ATGAM is highly cost-effective. The analysis showed that when treatment and disease management costs are considered, ATGAM dominates r-ATG as the gain in QALYs and LYs are achieved at a lower cost. Therefore making ATGAM cost-saving with greater health benefits in comparison to r-ATG.

Summary/Conclusions: Due to improved treatment response, survival, and quality of life outcomes, the model shows that ATGAM is at least more cost-effective, if not cost-saving, in comparison to r-ATG for the treatment of patients with aplastic anaemia.
E1463
ASSESSING REAL-WORLD TREATMENT PATTERNs, OUTCOMES AND RESOURCE USE IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA (MM) POST AUTOLOGOUS STEM CELL TRANSPLANT ACROSS EUROPE

J. Ashcroft1, G. Taylor-Stokes2, S. Dhanasiri3, D. Judge4
1Mid-Yorkshire Hospitals NHS, Wakefield, 2Adelphi Real World, Bollington, United Kingdom, 3Celgene International, Boudry, Switzerland

Background: Autologous stem cell transplant (ASCT) is the standard of care for first line (1L) treatment (tx) for patients (pts) with MM deemed of suitable fitness to safely undergo the procedure. More recently introduced tx options have significantly increased the life expectancy of pts with MM and continue to provide further promise for the future in this devastating disease. The increasing therapeutic armamentarium across the MM pathway allows for varied tx patterns providing both potential differences in outcomes and healthcare resource use (HCRU).

Aims: The aim of the analysis was to determine current management of pts in the post ASCT setting, assess outcomes of pts and HCRU.

Methods: A retrospective chart review was conducted in France, Germany, Italy, Spain and the UK. Data collection took place in Q1 2017. Physicians provided data on consecutive pts with MM who had undergone an ASCT as part of 1L tx on or after 1st January 2014, to specifically examine the HCRU post 1L ASCT. Data collected pertained to pt characteristics, b-parameters, duration of tx, and outcomes (including time to progression (TTP) and best response achieved (IMWG updated criteria)). HCRU in terms of hospitalizations, additional supportive drugs prescribed and healthcare professional (HCP) visits. Pt records included in this interim analysis were completed by Feb 17th 2017, with data collection continuing in all countries.

Results: 214 record forms have been reviewed to date. Pts’ mean age at diagnosis was 59 (±7.8 SD) years; 43% female and 57% male. Mean duration from diagnosis, to receiving an ASCT was 9.6 months (±13.3 SD). Of the pts included in the study, 62%, 26% and 8% had received 1st, 2nd and 3rd line tx respectively. In the 1L setting, 72% of pts did not receive any drug therapy post ASCT, 21% received consolidation and 8% maintenance therapy. Of the pts who did not receive maintenance therapy, 42% and 34% went onto receive 2L and 3L drug therapy respectively; whereas, only 24% of pts who received maintenance therapy went onto 2L, and none onto 3L. The most frequently prescribed regimens at 1L maintenance were Lenalidomide (82%), Bortezomib (12%) and Thalidomide (12%). The TTP from start of 1L ASCT was 22.2 months (±11.1 SD) for pts not receiving maintenance and 33.0 months (±8.1 SD) for pts receiving maintenance. Overall 43% of pts achieved a sCR and CR, 51% achieved a VGPR and PR. During the period from 1L post ASCT to start of 2L, 54% of pts were hospitalized at least once during this period, with a mean duration of 7.2 days (±18.1 SD). The mean number of visits to Hematologists was 7.1 times in 24.8 months (between start of 1L to start of 2L tx); mean visits to a HCP during this period were 17. The mean TTP from start of 2L tx was 11.2 months (±6.2 SD); 20% of pts achieved a sCR and CR, 52% achieved a VGPR and PR.

Summary/Conclusions: The sample is reflective of the pt demographics data reported in Raab et al. 2016. Furthermore, the TTP for pts not receiving any active ongoing tx post ASCT in this real-world study is comparable to findings in clinical trials. No data exists on HCRU post ASCT. This study demonstrates that there is ongoing HCRU impact even if pts are not receiving any active ongoing tx post first ASCT. Prolonging the remission period post ASCT may therefore spread the marginal cost of HCRU whilst simultaneously enhancing a pt’s quality of life by deferring future tx lines.

E1465
THE COST-EFFECTIVENESS OF PEGASPARAGASE FOR FIRST-LINE TREATMENT OF ACUTE LYMPHOBlastic LEUKAEMIA: A COST-UTILITY ANALYSIS

S. Basu1, P.L. Lin2, C. Rowntree3,*, V. Sahak
1Shire, London, United Kingdom, 2Shire, Cambridge, United States, 3University Hospital of Wales, Cardiff, 4University of Manchester, Manchester, United Kingdom

Background: Asparaginase is a key component in the multi-agent chemotherapy regimens for the treatment of children, adolescents, and adults with acute lymphoblastic leukemia (ALL). Compared to native asparaginase (native ASP), pegaspargase (PEG-ASP) has a longer half-life, can be given less frequently, and is less immunogenic, which leads to fewer hypersensitivity reactions. In the UK, patients with newly diagnosed ALL are treated with PEG-ASP followed by Erwinia-derived asparaginase (ERW-ASP) in cases of hypersensitivity, based on the UKALL protocols. Although native ASP is no longer used as the first choice of asparaginase therapy, it was the standard of care before PEG-ASP was available. A cost-utility analysis (CUA) was conducted to evaluate overall cost-effectiveness of PEG-ASP in comparison to native ASP when utilized as part of antineoplastic combination therapy for treating newly diagnosed ALL in children, young people, and adults.

Aims: To evaluate the cost-effectiveness of a treatment strategy including PEG-ASP in a multi-agent in patients with newly diagnosed ALL compared to regimens that include native ASP.

Table 1.

Methods: In line with accepted National Institute for Clinical Excellence (NICE) methodology, a combined decision tree and health state transition Markov model was developed to compare treatment sequences starting with PEG-ASP versus native ASP, followed by ERW-ASP in case of hypersensitivity. Although ERW-ASP is not used first-line in the United Kingdom, alternative switching scenarios could be clinically possible, and therefore all scenarios were modelled. Paediatric, young adult (≤25 years), and adult (≥26-65 years) patients were modelled separately using the UKALL 2003 and UKALL14 protocols, respectively. Further splits were made between high-, intermediate-, and standard-risk patients in the paediatric model, between patients aged ≤40 vs >41 years and patients eligible vs not eligible for transplant in the adult model. Key model parameters (survival, risk of hypersensitivity) were based on published data and clinical expert input. In the base-case analysis, overall survival and event-free survival were assumed to be equivalent for PEG-ASP, native ASP, and ERW-ASP, with 1,000,000m22 dosage (per UKALL protocols) used for both. The 2,000 IU/m2 dosing of native ASP was examined, as well as variations in comparative survival and hypersensitivity rates. Incremental cost-effectiveness ratios (ICER; defined as incremental costs/quality-adjusted life years [QALYs] gained) were produced.
Results: The base-case scenario demonstrated that PEG-ASP followed by ERW-ASP dominated (i.e., was both less costly and more effective than) native ASP followed by ERW-ASP in adults, children, and the whole (combined) population (Table). Scenario analyses highlighted the robustness of the cost-effectiveness results. Differences in total QALYs between PEG-ASP and native ASP were driven primarily by the difference in hypersensitivity rates.

Summary/Conclusions: This analysis demonstrates that PEG-ASP, as part of multi-drug chemotherapy, is a cost-effective treatment option compared to native ASP for treating ALL in children, young people and adults with newly diagnosed ALL.

E1466 IMPACT OF VENETOCALAX ON THE QUALITY OF LIFE OF PATIENTS WITH RELAPSED/REFRACTORY CHRONIC LYMPHOCYTIC LEUKAEMIA: RESULTS OF A PHASE 2, OPEN-LABEL STUDY OF VENETOCALAX (ABB-199/ GDC-0199) MONOTHERAPY

W. Wierda1,*, R. Humerickhouse2, S. Stilgenbauer3, T.P. Quock2, S.D. Guthrie2, M.K. White1, K.L. McCausland1,*, W. Wierda1,*, R. Humerickhouse2, S. Stilgenbauer3 1The University of Texas M.D Anderson Cancer Center, Houston, 2AbbVie Inc, North Chicago, United States, 3Department of Internal Medicine III, Ulm University, ULM, Germany

Background: Chronic lymphocytic leukemia (CLL) is associated with reduced health-related quality of life (HRQoL), with progressive severe fatigue being a particularly relevant burden. Disease-related symptoms, toxic effects of therapy, and the awareness of living with an incurable disease can have a profound impact on HRQoL. Venetoclax (VEN) is an oral BCL-2 inhibitor that has demonstrated deep and durable responses in relapsed/refractory (R/R) CLL patients.

Aims: To assess whether Venetoclax has sustained an impact on health-related quality of life among patients with relapsed/refractory CLL based on a second interim analysis (first interim results through week 24) of patients treated with VEN monotherapy.

Methods: Patients ≥18 years of age with R/R CLL received VEN monotherapy until disease progression, unacceptable side effects, or discontinuation for any other reason. Patient-reported HRQoL measures included the EORTC QLG-C30 and EORTC QLG-CLL16, which were assessed at Baseline (BL), at 4 weeks and every 12 weeks thereafter. Mean change in the HRQoL measures from BL to each assessment are reported. Clinical relevance was based on minimum important difference (MID) of values from BL at different assessment points. The lower bound of 5–10 point changes, considered a “little” change for EORTC-C30 global health status and the role, social, and emotional functioning scales. Improvements in VEN treated patients in EORTC-QLQ-C30 disease effects, social problems, and future health worries scores were statistically significant and exceeded the MID at all assessment points. Furthermore, early and sustained improvements in fatigue through week 96 were seen in both EORTC-QLG-C30 and EORTC-QLG-CLL16 (Table 1). The changes observed in patient EORTC-QLG-CLL16 future health views were considered large (>20 points) at Weeks 12, 24, and 48.

Table 1.

<table>
<thead>
<tr>
<th>Table 1.</th>
<th>10 points and percentage correct answer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Summary/Conclusions: These updated interim results suggest that patients receiving VEN monotherapy experienced early and sustained clinically relevant improvement in several key aspects of functioning and HRQoL for up to 96 weeks in a very symptomatic and difficult to treat patient population. These results are important to consider when making treatment decisions in the R/R settings.</td>

E1467 WHICH HAEMATOLOGICAL CONDITIONS CAN THIRD YEAR MEDICAL STUDENTS RECOGNISE INTERPRETING FULL BLOOD COUNT RESULTS?

S. Lovato1,2,*, J. Arnold1,2

Summary/Conclusions: These group of medical students found it difficult to correctly diagnose some of the haematological conditions presented, even though they had studied all the conditions before, however the use of a “Team Based Learning” approach where students could discuss the cases in small groups did improve their results. Interestingly for two conditions, for CML and Multiple myeloma the number of correct answers was the same for i-RAT and t-RAT, possibly the students who responded correctly during the i-RAT were in a different group during the t-RAT and worked as peer-to-peer teachers for the other students. The i-RAT results for AML were actually worse than for the i-RAT, probably the students who replied correctly in the i-RAT were concentrated in fewer groups. To the authors’ knowledge this is the first study on the effect of applying the Team Based Learning method to haematology teaching. This study showed that TBL could be a useful teaching tool to improve teaching of haematological conditions in medical schools, however the size of the sample was small and the results should be validated with a bigger study.
Background: Autologous and allogeneic stem cell transplantation (HSCT) or intensive chemotherapy are the only treatment option for many patients with haematological malignancies. Even after complete remission many patients are physically and psychologically impaired because of intensive treatment and weeks of immobilisation. Electrical muscle stimulation (EMS) is a verified training tool to prevent muscle decline in seniors and helps improving physical performance in patients with chronic disease.

Aims: This prospective, randomized and controlled study tested the safety, feasibility and efficacy of EMS in 72 patients (EMS=42, control=30) undergoing autologous HSCT (n=21), allogeneic HSCT (n=17) and intensive chemotherapy (n=34).

Methods: A Myopuls 2000 device (Curatec Services Gmbh) was used. Target training time was 15 minutes 5 days a week on both thighs and arms from start of therapy (T1) to time of discharge (T2). Adverse events and treatment adherence were documented. Impact on psychological and physical functioning was evaluated using the Multidimensional Fatigue Inventory (MFI), the EORTC QLQ-C30, the Short Physical Performance Battery and the 6 Minute Walking Distance between both groups was 23 meter (p=0.2). SPPB test results differed statistically (p<0.05) or ventricular arrhythmias occurred. Difference in 6-minute walking distance between groups was 23 meter (p=0.2). SPPB test results differed statistically (p<0.05) or ventricular arrhythmias occurred. Difference in 6-minute walking distance between both groups was 23 meter (p=0.2). SPPB test results differed statistically (p<0.05) or ventricular arrhythmias occurred. Difference in 6-minute walking distance between both groups was 23 meter (p=0.2).

Results: Overall, visits with specialists and other healthcare providers during the previous six months were nearly ubiquitous (92.0% and 94.6%, respectively). Collectively, 56.0% of patients reported having ≥1 ER visit or hospitalization. ER visits and hospitalizations were not associated with the numbers or types of patients with AL amyloidosis who were recruited with assistance from patient advocacy groups. Initial (n=341) and six-month follow-up (n=226) surveys assessed demographics, disease and treatment characteristics, and health-related quality of life (HRQoL), measured by the SF-36v2®Health Survey physiological and mental component summary scores (PCS and MCS). HCU (e.g., outpatient visits, hospitalisations, costs) and the duration of disease. There were significant associations between PCS and ER visits (p<0.05) and between both types of EMS stimulation and the associated risks. The attributes and levels of the attributes were selected based on previous research, literature review and expert opinion. The DCE data were modelled using a Latent Class Model (LCM), and the effect of demographic characteristics were also examined.

Summary/Conclusions: Findings from this study suggest that not all myeloma patients value the same treatment features equally. This finding has important implications for the healthcare policy decision to be supported by the HCU decisions of patients living with others and those diagnosed in the last five years were more likely to be in class one (those more concerned with overall survival) than class two (those more concerned with quality of life).

Background: There is a lack of real-world evidence regarding HCU associations between HRQoL and HCU, indicating there is potential for using HRQoL surveys as screening tools to predict future HCU for AL amyloidosis. This research identified longitudinal associations between HRQoL and HCU, indicating there is potential for using HRQoL surveys as screening tools to predict future HCU for AL amyloidosis. The development of prediction models for HCU in AL amyloidosis should consider incorporating HRQoL, as well as disease staging and treatment type.

Aims: The study aimed to answer the following questions: What treatment attributes do myeloma patients value? What is the relative importance of different preferences of each patient group? Therefore, myeloma patients face difficult decisions about the benefits and risks of treatment. The purpose of this study was to assess myeloma patients’ preferences for treatment.

Methods: Participants were 475 Myeloma patients in the UK. Data were collected using discrete choice experiments (DCEs) through an online survey. The DCEs presented patients with a traditional treatment choice experiment (e.g., treatment A vs treatment B), focusing on the clinical benefits of treatments and the associated risks. The attributes and levels of the attributes were selected based on previous research, literature review and expert opinion. The DCE data were modelled using a Latent Class Model (LCM), and the effect of demographic characteristics were also examined.

Results: Findings revealed two classes (groups) of patients with different preferences for treatments. Patients in class one placed greater importance on overall survival and mild-to-moderate side effects, whereas patients in class two placed greater importance on how the treatment was administered and the associated benefits of the treatment.

Summary/Conclusions: Findings from this study suggest that not all myeloma patients value the same treatment features equally. This finding has important implications for the healthcare policy decision to be supported by the HCU decisions of patients living with others and those diagnosed in the last five years were more likely to be in class one (those more concerned with overall survival) than class two (those more concerned with quality of life).
E1472
QUALITY OF LIFE AND ABILITY TO WORK OF PATIENTS WITH CHRONIC MYELOGENOUS LEUKEMIA TREATED WITH THYROSINE KINASE INHIBITORS
B. Sidi Mohamed El Amine1,*, H. Asma1, Z. Zahia1, M. Naima2, M. Nenma3
1Hematology department, University hospital of Sidi Bel Abbes, Sidi Bel Abbes.
2Hematology department, University hospital of Tiemcen, Tiemcen,
3Hematology department, Hospital of Mascara, Mascara, Algeria

Background: Thyrosine kinase inhibitors (TKIs) are now standard treatment for chronic myelogenous leukaemia (CML), but little is known about quality of life (QoL) of the patients.

Aims: The purpose of this study is to evaluate QoL of CML patients receiving TKIs, a disease requiring strict daily compliance with taking these drugs orally, as well as regular clinical and biological controls.

Methods: The study included patients with CML followed in three hospitals in west Algeria between 2004 and 2016. The measure of QoL was performed by the tool of functional assessment of chronic illness therapy (Functional Assessment of Chronic Illness Therapy, FACIT) for leukaemia. We have established QoL scores given by the questionnaire. FACIT, consisting of three levels: TOI (for leukaemia trial outcome index, FACT-G for general score, and FACT-LEU for the total score of leukaemia). Specific areas of the questionnaire were associated with QoL of patients such as fatigue and ability to work. The correlation between these areas and QoL scores was assessed using Spearman’s test. The test is significant if p<0.05.

Results: 67 patients with CML have agreed to answer to the questionnaire of QoL, medications in use, and their side effects. The mean QoL of the patients was 93.7 (out of 124 total points) for the TOI, 77.2 (out of 108) for the FACT-G, and 128.9 (out of 176) for the FACT-LEU. Patients who presented with TKIs side effects had a low score of QoL (p=0.0006), especially when these effects are severe (p=0.003). Stopping TKIs medication was noted in 41.3% of patients with severe side effects. Severe fatigue was observed in 14 (22.9%) patients, having low QoL scores in all scales (p<0.0001). 44 (65.8%) patients were able to work with higher QoL scores in the three FACIT scales (p<0.0001, Spearman correlation).

Summary/Conclusions: QoL is an important aspect in the management of CML; its assessment is necessary and must be regular. The ability to work and fatigue are important components of QoL of patients receiving TKIs and should be specifically taken into account during the treatment. Adverse effects of TKIs can interfere with QoL of patients and can lead to discontinuation of CML therapy.

E1473
QUALITY OF LIFE AND EMPLOYMENT AFTER AN HEMATOPOIETIC STEM CELL TRANSPLANTATION IN A MEXICAN POPULATION
L. Rivera-Fong 1, A. Riveros Rosas1, C. Banjet1, L.M. Valero Saldaña2, R. Robles García1, L. Traeger3, S. Rivas-Vera2,*, J.L. Aguilar Ponce4, O. Galindo Vázquez2, B.L. Acosta Maldonado2
1Psicología y Salud, Universidad Nacional Autónoma de México., 2Hematology, National Cancer Institute, Mexico City, Mexico, 3Health psychology, Harvard University, Massachusetts, United States, 4Oncology, National Cancer Institute, Mexico, 5Psicología, Universidad Nacional Autónoma de México.

Background: Hematopoietic stem cell transplantation (HSCT) is a consolidation therapy for multiple hematological malignancies and its goal include patients achieve levels of quality of life (QOL) similar that general population. However, studies developed in Europe and United States have shown that patients on long-term follow-up after HSCT reported lower levels of QOL, more unemployment and lower household income than before the procedure. These relationships have not been examined in Mexican HSCT patients.

Methods: This was a cross-sectional study with patients ≥18 years old with at least one year of follow up after HSCT at the National Cancer Institute, Mexico. Results: 30 participants were included, with a median age of 34 years (range 20-60), 56% male, and 41% married. Regarding educational level 68.7% had basic education, 25% had a college education and 6.3% postgraduate education. Mean time after HSCT was 36 months, 10% had active chronic graft versus host disease (GVHD). Patients reported moderate to high levels of QOL (Table 1). With respect to employment, 52% had a job (56% had a full time job, 13% worked part-time and 31% had an informal job) and 48% were unemployed (50% could not find a job and 50% did not want to have a job). Finally, 56% had lower household income than before HSCT.

Summary/Conclusions: Mexican patients showed similar or higher levels of QOL in comparison with samples from other countries, with the exception of higher impact in emotional QOL and better social QL in our sample. Additionally, a substantial minority of patients were unemployed and over half had lower household income after HSCT. More work is needed to identify risks associated with changes in QOL, employment status and income among long-term survivors of HSCT.

E1474
ANTHRACYCLINE INCREASES THE RISK OF DEVELOPING DIABETES IN B CELL LYMPHOMA
H.-C. Lin1,*, W.-L. Hwang1, C.-L. Teng1
1Division of Hematology/Medical Oncology, VTaichung Veterans General Hospital, Taichung, Taiwan, Republic of China

Background: Treatments of R-CHOP (rituximab, cyclophosphamide, doxorubicin, vincristine, and prednisone) or R-CHOP like regimens have made B cell lymphoma to be one of the most curative hematological malignancies. Among the effective chemotherapeutic agents in B cell lymphoma treatment, anthracycline plays an important role. However, anthracycline associated bone marrow suppression and cardiotoxicity limit its clinical application. Whether anthracycline would increase the risk of developing diabetes in B cell lymphoma remains unclear.

Aims: The aim of this study was to compare the cumulative incidences of diabetes in B cell lymphoma patients treated with and without anthracycline. We also investigated the dose effect of anthracycline on diabetes development. Additionally, whether anthracycline would increase the severity and complication of diabetes in B cell lymphoma patients were also studied.

Methods: We conducted this population-based study by using Taiwanese National Health Insurance Research Database. From 2004 to 2011, medical records from a total of 3984 B cell patients were analyzed. To understand whether anthracycline therapy was associated with more diabetes in B cell lymphoma, we compared the cumulative incidence of newly diagnosed diabetes between patients with (n=3147) and without (n=837) anthracyline treatments. Impact of anthracycline on diabetes was further studied by multivariate Cox proportional hazard regressions in a dose-dependent manner.

Results: Log-rank test did not show the difference of cumulative incidences of newly diagnosed diabetes between B cell lymphoma patients with and without anthracycline treatments (p=0.1448). However, anthracyline remained associated with more diabetes [hazard ratio (HR): 1.59; 95% confidence interval (CI): 1.05–2.39; p=0.0278] after adjustment for age, gender, and comorbidities. Moreover, cumulative anthracyline doses of 253-400mg (HR: 1.94; 95% CI: 1.23–3.05; p=0.0043) and 401-504mg (HR: 1.83; 95% CI: 1.11–3.01; p=0.0180) increased the incidence density of diabetes in a dose-dependent manner (p=0.0438). Notably, patients with and without anthracyline treatment had similar yearly adapted diabetes complications severity index alteration (0.58±1.89 vs 0.75±1.85; mean±standard deviation), suggesting anthracyline did not deteriorate outcome of diabetes in B cell lymphoma patients (p=0.4924).

Figure 1.
Summary/Conclusions: Anthracycline therapy was responsible for more deaths by cell lymphoma in a dose-dependent manner. More intensive blood sugar monitoring and control should be recommended to B cell lymphoma patients, especially those who received anthracycline treatment.

E1475 THE COST-EFFECTIVENESS OF LENALDIAZOM PLUS DEXAMETHASONE FOR THE TREATMENT OF RELAPSED OR REFRACTORY MULTIPLE MYELOMA IN CHINA

J. Lu1,*, S. Hu2, P. Xu3, Y. Feng4
1Peking University People’s Hospital, Peking University Institute of Hematology, Beijing, 2Fudan University School of Public Health, Shanghai Health Development Research Center, 3Cingjing China, Shanghai, 4Department of Pharmacy, Beijing Hospital, Beijing, China

Background: The introduction of lenalidomide plus dexamethasone (RD), and bortezomib-containing regimens, has improved the management of relapsed or refractory multiple myeloma (mMM) in China. However due to the absence of both head-to-head (direct) comparative efficacy and local economic data, stakeholders still face hard choices to make when choosing one therapy over another. Indirect treatment comparisons and health economic modeling can help support local decision-making by enabling the incorporation of country-specific unit cost data, in the comparison of cost-effectiveness of one treatment vs another where treatments have not been directly compared in clinical trials.

Aims: To assess the cost-effectiveness of RD relative to bortezomib/dexamethasone (VD) and bortezomib/cyclophosphamide/dexamethasone (VCD) for mMM in Chinese patients.

Methods: The Markov-based decision analytic model was constructed to simulate lifetime health benefits and direct medical costs associated with RD, VD, and VCD for mMM in Chinese patients. A systematic literature review was conducted (in both Chinese and English databases, from 2005 to 2016) to obtain efficacy data of the three treatment regimes. The risk of progressive disease associated with RD and VD were estimated from available Chinese trials. The efficacy of VCD and the mortality associated with progressive disease after treatments with RD and VD were lacking in China, therefore were estimated from the published international randomized clinical trials. Published quality of life data was adapted to Chinese mMM patients with health utility adjustment. The model took into account (i) drug acquisition costs, (ii) treatment administration costs at the Chinese urban setting, (iii) serious adverse events management costs based on a survey of seven MM centers across China, and (iv) mMM management costs estimated from a Chinese real-world hospital setting. Quality-adjusted life years (QALY) and direct medical costs in the model were discounted at 3% per annum. Base case analysis calculated incremental cost effectiveness ratios (ICERs) per QALY for RD relative to VD and VCD, respectively from the Chinese healthcare payer’s perspective. One-way sensitivity analysis and probabilistic sensitivity (PSA) with 5,000 Monte Carlo simulations assessed the impact of the model uncertainty on the cost-effectiveness of RD. A scenario analysis was conducted by meta-analyzing the published meta-analysis of randomized controlled trials for the efficacy associated with RD, VD, and VCD, to verify the base case analysis.

Results: Based on the model simulation without discounting survival outcomes over a lifetime horizon, RD could obtain longer average lifetime PFS years and QALY with (2.37 vs 0.78) and VCD (2.37 vs 1.36). RD was associated with longer duration of response (14.11 vs 14.11) and lower treatment costs ($494,060 vs $272,135 and $244,220) than both VD and VCD. The ICERs per QALY for RD relative to VD ($149,706) and VCD ($150,774) were less than the cost-effectiveness threshold of China (three times of estimated 2016 China GDP per capita $166,920/QALY, $1= €0.138). The cost-effectiveness of RD was robust across the discount and the mortality associated with progressive disease after treatment. The scenario analysis generated comparable ICER per QALY associated with RD relative to VD ($120,974) and VCD ($117,191), therefore supports the robustness of base case analysis.

Summary/Conclusions: The local data-based health economic model estimates that RD could gain longer PFS and OS with acceptable cost-effectiveness, when compared to VD and VCD in Chinese mMM patients.

E1477 OVARIAN TISSUE CRYOPRESERVATION IN PEDIATRIC AND ADOLESCENT PATIENTS UNDERGOING CANCER CHEMOTHERAPY AND/OR HEMATOPOIETIC STEM CELL TRANSPLANTATION

A. Kinoshita1,*, R. Oyama1, D. Keino1, Y. Matsukawa1, Y. Koto1, T. Mori1, N. Suzuki2
1Pediatric Hematology/Oncology, 2Department of Obstetrics and Gynecology, St. Marianna University School of Medicine, Kawasaki, Japan

Background: Ovarian tissue cryopreservation (OTC) and subsequent reimplantation is the only option available for fertility preservation in prepubertal females, but this approach remains unestablished in pediatric and adolescent patients with cancer. After the experience of OTC for more than 200 patients with primary ovarian failure and more than 50 patients with breast cancer in our center over 5 years, we have started OTC for pediatric and adolescent cancer patients since 2015. Aim: To describe safety and benefits of OTC in pediatric and adolescent patients with undergoing cancer chemotherapy and/or hematopoietic stem cell transplantation.

Methods: From December of 2015 to February of 2017, OTC was performed in 6 girls (median age 14 years, range 11-15): 2 patients with myelodysplastic syndrome, 2 with lymphoma, 1 with acute lymphoblastic leukemia, and 1 with secondary immunodeficiency. Indications for OTC were 5 hematopoietic stem cell transplantation and 1 sterilizing chemotherapy. Two patients with myelodysplastic syndrome and 1 with immunodeficiency received no previous chemotherapy and the other 3 had received prior chemotherapy. Laparoscopy was used to collect a pair of ovarium that was frozen by vitrification method. Reimplantation was successfully collected and reimplanted in 6 patients studied without major postoperative complications and this procedure did not delay chemotherapy or hematopoietic stem cell transplantation. Histological analysis of ovarian tissue revealed primordial follicles, even in the patients with previous cancer chemotherapy. No malignant cells were identified. Median post-harvest

E1476 DEVELOPMENT OF A NEW HAEMATOLOGICAL MALIGNANT PATIENT-REPORTED OUTCOME MEASURE FOR USE IN CLINICAL PRACTICE: HM-PRO

P. Goswami1,*, S. Salek1, T. Ionova2, E. Oliva3, A.K. Fielding4, M. Karakantza5
1Peking University People’s Hospital, Peking University Institute of Hematology, Beijing, 2Fudan University School of Public Health, Shanghai Health Development Research Center, 3Cingjing China, Shanghai, 4Department of Pharmacy, Beijing Hospital, Beijing, China

Aims: The aims of this study were to identify issues important to patients with HM and development of a new patient reported outcome measure for use in daily clinical practice.

Methods: A conceptual framework was developed using preliminary literature search and discussions with physicians and patients. Patients with HM were then invited to produce a comprehensive item pool refined by a panel of experts. The generated items were then discussed in the data definition panel meeting to be included in the prototype version of the HM-PRO. Subsequently, a panel of experts and a panel of patients were asked to rate the items of the prototype HM-PRO for its language clarity, completeness, relevance and scaling followed by cognitive interviews with the patients to pilot test the HM-PRO.

Results: The preliminary literature search revealed that there is no PRO specifically developed for patients with HM for use in daily clinical practice. The conceptual framework comprised of two main themes: Qol (impact); and symptoms. 129 patients (male=78; mean age=61.1 years; SD=15.3; median age=64.9 years; age range=18-88 years; diagnosis –AML, ALL, CML, MM, ANHL, NHL, HL, MPN, and MDS) with mean duration of the HM of 3.6 years (SD=4.3; and range= 19-days-23 years) from 5 haematology centres were interviewed to identify the issues important to HM patients. A prototype version of HM-PRO was developed after data definition panel meeting with 34 items in impact category (Part A) and 23 items representing disease symptoms (Part B). Nine panel members of experts and 7 members of patients, rated the items and discussed them for their language clarity, completeness, relevance and scaling to reach consensus. 60 patients (male=36; mean age=63.8 years; SD=16.61; median age=69.2 years; and age range=18-91 years) with mean duration of the HM of 4.9 years (SD=6.4; and range= 14-days-26 years) were recruited for the pilot testing where 34 of which were involved in cognitive interviews. 92% of the patients reported that the statements were easy to understand and all issues important to them were covered; 95% stated that they were able to respond spontaneously and expressed their willingness to complete the instrument during their visit to the clinic; 97% reported that the statements were easy to read; 98% did not wish to delete any item; and 88% did not think they needed to add any new items.

Summary/Conclusions: The findings of the content validation, pretesting and cognitive interviews indicate that HM-PRO possesses a strong content validity in different HMs, includes all the issues important to these patients and the statements are easy to read, understand and respond to spontaneously. HM-PRO will undergo further psychometric testing to support its psychometric properties across different types of HMs.
follow-up was 9 months (0-14) and all patients were alive. Hormonal results were evaluable for 3 patients: 2 patients were in premature ovarian insufficiency. Prescription queries are resolved during this meeting. Deferred oral chemotherapy can be returned to pharmacy stock, minimising waste. Intravenous chemotherapy is pre-planned with authorisation on the day of treatment if the patient is fit to proceed.

Methods: In line to the care pathway, we focussed on delivery of care to myeloma patients receiving oral chemotherapy, including setting up a nurse-led clinic. Data have been collected to assess service impact, particularly on patient satisfaction. The latter was assessed using a patient survey. Between July-Dec 2014, 66 patients received oral chemotherapy in the Myeloma Consultant-led clinic, Lenalidomide based regimens accounted for 86% of the oral regimens prescribed. On average, 7 patients per week were on maintenance therapy. During this period 8% of chemotherapy courses were deferred due to low blood counts or side-effects. Drugs were not wasted due to the pharmacy agreement.

Results: A patient satisfaction survey was undertaken from Jan-June 2015, post-introduction of the nurse-led clinic paired with the MDT chemotherapy prescribing meeting. Patients were asked about a wide-range of quality parameters. Results showed 93% of patients noted a reduction in wait times & 88% felt they spent more time in consultations as a result. All patients noted they spent more time with the nurse specialist & benefited from not attending pharmacy. All patients rated the service more efficient.

Summary/Conclusions: The MDT approach to prescribing & dispensing oral chemotherapy & supportive medication has streamlined our way of working & led to greater efficiency for both staff & patients. The new model has changed the way patients are seen & assessed and minimised drug wastage, an issue that are re-seeding malignant cells is a problem still to be conquered. A patient satisfaction survey was undertaken from Jan-June 2015, post-introduction of the nurse-led clinic paired with the MDT chemotherapy prescribing meeting. Sickle cell disease

DISEASE SEVERITY AND SLOWER PSYCHOMOTOR SPEED IN ADULTS WITH SICKLE CELL DISEASE

E. Novelli1,2, D. Jorgensen2, A. Metti2, M. Butters2, C. Rosano3
1Medicine, Vascular Medicine Institute, University of Pittsburgh, BST E1240, 200 Lothrop St., University of Pittsburgh, Pittsburgh, United States

Background: Psychomotor slowing is common in children with sickle cell disease (SCD), but little is known about its severity in adult patients. While the primary risk factor for psychomotor slowing is stroke, there has been mounting evidence that cognitive impairment also occurs in patients without a history of overt or silent stroke. Risk factors for cognitive impairment in patients with SCD without stroke are, however, not completely known, particularly in relationship to the SCD genotype.

Aims: We conducted a cross-sectional study to quantify psychomotor slowing, measured with the Digit Symbol Substitution Test (DSST), a pencil and paper test of executive function, in relationship with disease severity in adult patients with SCD attending an outpatient clinic. We also examined whether demographic, behavioral, physiologic, and pathologic factors that are known to be related to SCD severity and cognitive function in other settings are also related to psychomotor speed in these patients.

Methods: Genotype was used to group patients with SCD (n=88, age: 36.3 years, 33 males) in “severe” (homozygous for the mutated sickle hemoglobin HbS [HbS/HbS]) or “moderate” groups (compound heterozygous for HbS with either HbC [HbS/C], or βthalassemia [HbS/β+]). Standardized DSST scores based on published norms were used to define mild cognitive impairment, defined as ≤1.5 standard deviations (SD) below the DSST T-score (t-scores had a mean of 50 and SD of 10). Data on demographics, hematological parameters, hydroxyurea and opiate intake, stroke (including silent cerebral infarcts (SCI)) and transfusion history were collected concurrently with DSST. Analyses were repeated after exclusion of patients with a history of stroke (n=12). Age-adjusted p-value was calculated with logistic regression for all variables except age (unadjusted) and DSST T-score (already adjusted for age, sex and education in calculation of T-score).

Results: Among our patients, 56 (63%) had a “severe” genotype and 32 (27%) had a “moderate” genotype. Mild cognitive impairment was detectable in both the “severe” and the “moderate” group (30% and 9%, respectively, age-adjusted p=0.15). Compared to the “moderate” group, those in the “severe” group had significantly lower DSST scores (age, sex and education adjusted p values=0.006). Independent of adjustment for factors that differed between groups: hemoglobin, ferritin, hydroxyurea use, blood pressure parameters and stroke history. Results were similar after excluding patients with stroke.
