Aims: To evaluate the number and function of BM MSCs derived from patients with PT and its underlying molecular mechanisms in vitro.

Methods: Three cohorts were included: patients with PT (N=25), patients with good graft function (GGF, N=12), defined as persistent successful engraftment after allotransplantation, and transplant donors as normal controls (N=10). BM MSCs were cultured as previously reported. All experiments were carried out using BM MSCs derived from passages 2–4. The number and functions of BM MSCs were evaluated by flow cytometry. The expression of pro-apoptotic proteins. In addition, the expression ratio of BIM or BAX to pro-apoptotic proteins. In addition, the expression ratio of BIM or BAX to pro-apoptotic proteins. In addition, the expression ratio of BIM or BAX to pro-apoptotic proteins.

Results: Human BM MSCs were depicted as spindle shape and typical immunophenotype of MSCs at day 21 of cultivation among subjects with PT, GGF and normal controls. Cultures from all normal BM samples produced confluent layers of adherent cells composed of spindle-shaped cells. 2 of the 12 GGF BM and 15 of the 25 PT BM failed to produce any adherent layers within 3 weeks of culture. BM MSCs derived from PT patients expanded more slowly and appeared flatter and larger. Proliferative capacity and CFU-F counts of BM MSCs from PT patients were significantly reduced compared to those of GGF patients and normal controls. Moreover, increased levels of ROS, which was associated with increased number of SA-β-positive cells, were identified in BM MSCs from PT patients. Intracellular levels of ROS and pro-p38 were evaluated in BM MSCs by flow cytometry.

Summary/Conclusions: In summary, the current study demonstrated the number and the function of BM MSCs were abnormal in PT patients following allo-HSCT. The number of in vitro-generated Th9 cells mediates GVHD. Furthermore, we analyzed a new approach to enhancing the number and function of BM MSCs derived from patients with PT has never been reported. Moreover, approaches for improving the dysfunction of BM MSCs in patients with PT are lacking.

GRAFT-VERSUS HOST DISEASE (GVHD) DEVELOPMENT AFTER BONE MARROW TRANSPANTATION IS NOT INFLUENCED BY TH9 CELLS

T. Reiser1, S. Muche2, J. Scheurer3, K-M. Debatin1, G. Strauss1

1Department of Pediatrics and Adolescent Medicine, University Medical Center Ulm, Ulm, Germany

Background: Th9 cells are a recently defined subset of T helper cells (Th) characterized by the massive production of IL-9. Th9 cells mediate immune responses against helminth infections, exhibit anti-tumor immunity against solid tumors and mediate allogeneic transplant tolerance but they also contribute to immunopathology in allergy and autoimmunity.

Aims: Currently, the role of Th9 cells for GVHD induction and the graft-versus-tumor effect is largely unknown. Therefore, we first explored, whether Th9 cells are involved during GVHD development in two different MHC-mismatched bone marrow transplantation (BMT) models and secondly analyzed, whether transplantation of in vitro-generated Th9 cells mediates GVHD.

Methods: We transplanted allogeneic BM and spleen cells from B6-SJL mice to 6–8 weeks old, NOD/SCID mice. We transplanted syngeneic BM and splenocytes from Th9 T cells and B6.SJL mice to NOD/SCID mice. We transplanted syngeneic BM and splenocytes from Th9 T cells and B6.SJL mice to NOD/SCID mice.

Results: In both MHC mismatched models used, the transplantation of allogeneic spleen cells and BM leads to GVHD characterized by a time-dependent strong increase of Th1-specific cytokines TNF-a and IFN-g in the serum of the recipient mice. Moreover, IL-9, however, was not increased in mice lacking allogeneic T cells were identified in the spleen, liver and lung of GVHD-developing animals until 29 days after transplantation, while TNF-a and IFN-g producing cells were strongly increased indicating that Th9 cells are not induced.
during GVHD. After in vitro differentiation of Th9 cells from naive T cells we obtained more than 60% of IL-9 producing cells after 5 days of culture. Th9 cells differ in their cytokine profile (IL-9+, IFN-g-, IL-13-) from Th1 and Th2 cells. Transplantation of in vitro-generated Th9 cells together with allogeneic BM cells did not induce GVHD in the MHC-disparate recipient mice, while the transplantation of unselected T cells or in vitro-generated Th1 cells induced GVHD and resulted in death in about 60% of the animals. Although no GVHD development was detected, Th9 cells migrated into lymphoid organs and GVHD target organs such as spleen and lung. Surprisingly, when the cytokine phenotype of the transplanted Th9 cells were analyzed after ex vivo isolation from spleen and liver at different time points after transplantation, the cells lost their IL-9 expression 3 days post-transfer. Furthermost, to a plasticity of Th9 cells after adoptive transfer. Systemic increase of TNF-a and IFN-g in the serum of mice receiving Th9 cells, however, was not detected.

**Summary/Conclusions:** Th9 cells are not induced during GVHD development and the adoptive transfer of in vitro-generated Th9 cells does not induce GVHD. However, the transplanted Th9 cells home to spleen and GVHD target organs and start to produce TNF-a and IFN-g without strong systemic increase in these cytokines. Since TNF-a and IFN-g are cytokines associated with an anti-tumor cytotoxicity and Th9 cells are known to eliminate solid tumors, future experiments will define whether in vitro-generated Th9 cells can be used as a cellular therapy for anti-tumor responses in BM-transplanted hosts.

**STEM CELL GENE THERAPY MEDIATED BY MSCS**

P755

ments will define, whether in vitro-generated Th9 cells can be used as a cellular therapy for anti-tumor responses in BM-transplanted hosts.

**Methods:** Isolated CD45RA+ T cells from healthy donor’s Buffy Coats were subjected to anti-CD3 plus anti-CD28 in the presence of several cytokines to polarize towards Th1 (IL-12, INF-γ- and anti-IL-4) or Th2 (IL-4, IL-13, IL-4 and anti-IL-12) for 5 days. Pomalidomide at two different doses (10 and 100 nM) were added into the culture and the effect on T cells polarization was analyzed by flow cytometry after staining with anti-CD25, anti-IFNγ, anti-CD4 and anti-IL-2 for Th1 cell polarization and anti-CD25, anti-IL-10, anti-CD3 and anti-IL-4 for Th2 cell polarization. In addition, the release of cytokines (IL-2, IL-4, IL-6, IL-10, TNF-a and IFN-g) in cell culture supernatants were measured by BD Human Th1/Th2 Cytokine CBA kit (BD Biosciences) and T-bet and GATA-3 expression were analyzed by Western Blot. Chromatin immunoprecipitation (ChiP) assays were performed to assess the trimethylation of H3K4 (associated with gene activation) and the trimethylation of H3K27 (associated with gene repression) in the Tbet and GATA-3 gene promoters.

**Results:** Pomalidomide increased the expression of INF-γ and IL-2 as determined by flow cytometry in Th1 cell culture conditions. By contrast, in the presence of IL-4 and IL-10, we observed downregulation of Th1- and Th2-promoting cytokines, respectively. In Th1 and Th2 promoting conditions, an increased concentration of IL-4 and IL-2 in supernatant was observed after exposure to pomalidomide. Furthermore, exposure to pomalidomide led to an increased expression of Tbet as assessed by western-blots in naive CD45RA+ cells activated with anti-CD3 plus anti-CD28 and supplemented with IL-12, INF-γ and anti-IL-4. By contrast, in Th2 polarization conditions, pomalidomide increased GATA-3 expression. We next studied whether or not the effect of pomalidomide in T cell polarization might be mediated by epigenetic mechanisms: in the presence of Th1 promoting conditions there was a significant increase of the activation marker H3K4me3 at the Tbet promoter and a significant decrease in H3K27me3 upon exposure to the drug while, under Th2 promoting conditions, a significant increase in H3K4me3 at the promoter of GATA-3 gene was observed among naive CD45RA+ cells exposed to pomalidomide.

**Summary/Conclusions:** Pomalidomide favours both Th1 and Th2 cell differentiation of CD45RA+ cells depending on the cytokines present in the medium. Treatment of naive T cells with pomalidomide induces epigenetic modifications during T cell polarization which might favour the process of differentiation of the naive T cells.

**Background:** Human chronic graft-versus-host disease (CGVHD) shares clinical characteristics with a murine scleeroderma-like dermal GVHD (Scl-GVHD) model that is characterized by skin thickening and lung fibrosis.

**Aims:** This study investigated the therapeutic effect of mesenchymal stem cells (MSCs) on the development of Scl-GVHD according to each target organ.

**Methods:** A B10.D2 → BALB/c transplant model of Scl-GVHD was used to address the therapeutic effect of mesenchymal stem cells (MSCs) on the development of GVHD. M210B4 cells were administered after allo-HSCT at a dose of 10^5 cells/mouse on days 3, 5 and 7.

**Results:** The clinical and pathological severity of cutaneous Scl-GVHD was significantly attenuated in MSC-treated recipients relative to Scl-GVHD controls. After MSC treatment, skin collagen production was significantly reduced with consistent downregulation of TGF-β expression. Effects of MSCs on molecular markers implicated in persistent TGF-β signaling and fibrosis, such as phos- phatase and tensin homolog (PTEN), phosphorylated Smad-2/3 and matrix metalloproteinase-1 (MMP-1), were observed in skin tissue. MSCs neither migrate to the skin nor affect the in vivo expansion of immune effector cells, but inhibited their infiltration into skin via downregulation of CCR4 and CCR8 expression. Ad-MSCs infused SCID-Beige mice on CD11b+ monocytes/macrophages. MSCs diminished expression of chemokines such as CCL1, CCL3, CCL8, CCL17, and CCL22 in skin. MSCs were also dependent on stimulated spleno- cytes to suppress fibroblast proliferation.

**Summary/Conclusions:** Our findings indicate that MSCs ameliorate the cutaneous GVHD immune cell migration and downregulating chemokines and chemokine receptors.

**C57BL/6 SUBSTRAINS SHOW DIFFERENCES IN HEMATOPOIETIC RESPONSE TO ALLOGENEIC SCT AND ION**

A. Morales Hernandez1,*, A. Martín2, S. McKinney-Freeman2

1Hematology, St Jude Children’s Research Hospital, 2Hematology, St Jude Children’s Research Hospital, Memphis, United States

**Background:** C57BL/6 mice are one of the most studied in-bred mouse strains.
Although C57BL/6N (N) and C57BL/6J (J) mice are derived from the same parental C57BL/6 strain, there are key genotypic and phenotypic differences between these sub-strains. However, more than 58% of studies published involving C57BL/6 mice do not indicate the specific sub-strain employed. J mice have a five-exon deletion in the Nicotinamide nucleotide transhydrogenase (Nnt) gene that results in a non-functional protein. NNT is involved in the resolution of oxidative stress in the mitochondria. Hematopoietic stem cells (HSCs) can reconstitute the entire hematopoietic system after transplantation into hosts whose hematopoietic compartment has been ablated. This is clinically exploited as HSCs transplantation (HSCT) to treat hematologic diseases and represents the only curative therapy for many disorders. During HSCT, HSCs are subject to dramatic increases in both intra and extracellular reactive oxygen species (ROS), which compromises their self-renewal, differentiation, and survival. The absence of a functional Nnt gene in J-HSC may curtail their ability to resolve elevated ROS post-transplant.

Aims: As elevated oxidative stress compromises hematopoietic stem and progenitor cell (HSPC) function, here we thoroughly interrogated the frequency and function of HSPCs in J and N bone marrow (BM).

Methods: N and J peripheral blood (PB) and BM (n=9) was interrogated by flow cytometry for the absolute frequencies of all major hematopoietic lineages and HSPC compartments, respectively. 5000 J or N CD45.2 HSPCs (Lin-Sca-1+c-Kit+ cells) were transplanted along with 5000 competitor CD45.1 HSPCs into lethally irradiated mice to test for competitive in vivo hematopoietic repopulating activity and ROS levels post-transplant. The lineage potential and repopulating activity of multi-potent progenitors (MPP2: Lin-Sca-1+c-Kit+Flt3-CD48+CD150+, MPP3: Lin-Sca-1+c-Kit+Flt3-CD48+CD150-, MPP4: Lin-Sca-1+c-Kit+Flt3+CD48+CD150-) was also tested by transplanting 2000 MPPs from J or N mice into sub-lethally irradiated mice and examining the PB of recipients every 3-4 days for 34 days post-transplant. Sensitivity of HSPCs to oxidative stress was tested by examining ROS levels and the in vitro colony forming unit (CFU) potential of HSPCs isolated from N and J mice treated with pI:pC.

Results: The frequency of the major PB lineages and bone marrow HSPC compartments was identical in J and N mice. However, J-HSPCs displayed compromised short-term (4-12 weeks post-transplant) hematopoietic repopulating activity relative to N-HSPCs that was driven by a delay in lymphoid reconstitution. No differences were found in donor contribution to bone marrow HSPC compartments at 20 weeks post-transplant. However, donor-derived MPPs and CLPs displayed a two-fold increase in ROS levels in recipients of J-HSPCs versus N-HSPCs at 20 weeks post-transplant. MPPs are responsible for repopulation of the hematopoietic system during this early window post-transplant. Different MPP subpopulations can be defined (MPP2, MPP3 and MPP4) according to their self-renewal potential and specific lineage potential. MPP3s and MPP4s are the first MPP subpopulations to reconstitute the lymphoid lineage after transplant. J-MPP3s and J-MPP4s displayed less in vivo repopulating activity than N-MPP3s and N-MPP4s. It is known that pI:pC treatment increases ROS levels in HSPCs. We found about two-fold higher ROS levels in HSPCs isolated from pI:pC treated J mice than N mice with the exception of the myeloid progenitor compartments (CMP, GMP and MEO). J-HSPCs also generated fewer and smaller CFU than N-HSPCs when isolated from pI:pC treated mice. These data indicate that J-HSPCs cannot resolve oxidative stress as efficiently as N-HSPCs, which may be due to lower self-renewal potential after exposure to oxidative stress. Short-term J-lymphoid-biased progenitors (e.g. MPPs and CLPs) were especially sensitive to increasing ROS, which very likely drives the short-term loss of in vivo repopulating activity.

Summary/Conclusions: Based on these data, we hypothesize that loss of the Nnt gene in C57Bl/6J mice sensitizes HSPCs to oxidative stress, which compromises their short-term in vivo hematopoietic repopulating activity.

GWAS RESULTS IN RED BLOOD CELL PHENOTYPES AND THEIR RELATIONSHIP WITH THROMBOSIS

1Thrombosis and Hemostasis Unit, Hospital de Sant Pau, 2Unit of Genomics of Complex Diseases, Institut d’Investigació Biomèdica Sant Pau. (IIB-Sant Pau), 3Hematology, Hospital de Sant Pau, Barcelona, Spain, 4Cardiovascular Medicine Unit, Department of Medicine, Karolinska Institutet, Stockholm, Sweden, 5Medicine Department, Universitat Autònoma de Barcelona, Barcelona, Spain

Background: Venous thromboembolism (VTE) is a complex and multifactorial disease with a estimated heritability of 60%. Intermediate phenotypes of VTE have been used to identify genetic risk factors. We previously reported a genetic correlation of 5 erythrocyte phenotypes with VTE1.

Aims: To identify single nucleotide polymorphisms (SNPs) influencing the phenotypic variance of erythrocyte parameters, especially those related to VTE, in Spanish families from the Genetic Analysis of Idiopathic Thrombophilia (GAIT2) Project.

Methods: Genome-wide association analyses (GWAS) with ~10M SNPs were performed for eighteen erythrocyte phenotypes in 935 subjects belonging to 35 extended families with thrombosis of GAIT2. The erythrocyte phenotypes evaluated were: Hemoglobin (Hb), red blood cell count (RBC), hematocrit (Ht), mean corpuscular volume (MCV), mean corpuscular hemoglobin (MCH), mean corpuscular hemoglobin concentration (MCHC), red blood cell distribution width (RDW), reticulocyte (RET), low fluorescence reticulocyte (LFR), middle fluorescence reticulocyte (MFR), high fluorescence reticulocyte (HFR), reticulocyte fluorescence index (IRF), haptoglobin (HP), serum iron (Fe), total iron binding capacity (TIBC), saturation index (SI), serum ferritin (FT) and serum transferrin receptor (TFR).

Results: We identified 12 SNPs showing association with the 5 erythrocyte phenotypes previously related to VTE (Table 1). Interestingly, the rs56036145 that showed association with TFR is an intronic variant located in the gene tissue factor pathway inhibitor 2 (TFPI2), which encodes a protein that inhibits a variety of serine proteases of blood coagulation, such as activated factor VII (FVIIa/TF), FXa, plasmin and plasma kallikrein. These data reinforce our previous report of genetic correlation of TFR with VTE. The most significant SNP-associations were reported.

Table 1. Top SNP-associations with erythrocyte phenotypes related to VTE from GWAS in GAIT2.

G: genetic correlation with VTE; Chr: Chromosome.

Summary/Conclusions: Several genetic variants involved in the variance of erythrocyte phenotype levels were identified by GWAS. Of note, TFR was associated with a SNP in TFPI2 that might influence the variance of both TFR levels and VTE risk. These data could be useful to investigate genes related to red blood cell parameters and VTE.

2Department of Internal Medicine, CARIM, Maastricht University, Maastricht, Netherlands

Background: ET and PV are characterized by a high incidence of arterial and venous thrombosis. Platelet (PLT) count is not an independent risk factor for thrombosis in these conditions. However, no information is available on patient PLT thrombosis formation capacity, i.e. the PLT thrombus formation capacity in a dynamic condition.

Aims: We wanted to evaluate, in a group of ET and PV patients, the PLT thrombus formation capacity by an ex-vivo dynamic model of PLT adhesion under flow conditions, and to establish the influence of JAK2-V617F/Calreticulin (CalR)/MPL mutations, hematological parameters, and ongoing therapies.

Methods: One hundred-thirty patients, i.e. 78 ET (32 M/46 F; median age=61 years, range 28-86) and 52 PV (26 M/26 F; median age=65 years, range 38-87) were enrolled after informed consent. For the adhesion assay, peripheral venous whole blood was drawn in sodium citrate, recalciﬁed in the presence of heparin, and perfused over a collagen-coated surface for 4 min. at a shear rate of 1,000 s^-1. PLTs were then stained with an anti-CD62P (P-selectin)-FITC antibody to detect PLT activation, and annexin-V-AlexaFluoro67 to detect pro-coagulant phosphatidylserine expression. After staining, phase contrast and fluorescence images of adherent PLTs were taken in random fields using an EVOS® microscope. Results are expressed as the means±SEM of the % of area covered by all PLTs (% coverage), or as the % of adherent PLTs positive for pro-coagulant (PLTs-PS) or phosphatidylserine (PS) expression.

Results: PLT adhesion was signiﬁcantly higher (p<0.01) in both ET (45±3.1%) and PV patients (48±1.6%) compared to healthy controls (37.5±1.7%), while no difference was found between ET and PV patients. The analysis of the mutational status shows that ET PLT adhesion was highest in JAK2-V617F mutation carriers (n=4; coverage: 47.7±2.4%, p<0.001 vs controls), followed by CalR-positive patients (n=21; coverage: 45.5±3.2%, p<0.05 vs controls, p=m.s. vs JAK2-V617F), while PLT adhesion of MPL-positive (n=3; coverage: 32.1±2.1%) or triple negative (n=13; coverage: 42.6±2.5%) ET patients was not statistically different from controls. In PV, no statistically significant difference was observed between subjects with >50% vs those with <50% JAK2-V617F allele burden. According to treatment, we observed that ET patients treated with the combination of aspirin+hydroxyurea presented the lowest PLT adhesion, while in PV no signiﬁcant difference was observed between different anti-coagulant regimens. PLT count correlated (p<0.01) with PLT adhesion only in CalR-positive ET patients. The analysis of adherent PLT surface markers shows no difference in P-selectin expression between whole patients and controls. Differently, phosphatidylserine expression was signiﬁcantly reduced (p<0.01) in both ET and PV compared to healthy subjects.

Summary/Conclusions: ET and PV platelets show an increased PLT thrombus formation potential, particularly in patients carrying the JAK2-V617F mutation. On the basis of these results, it is worth to include a dynamic PLT adhesion assay in risk prediction models to evaluate the predictive value of thrombotic events in ET and PV patients. INCIDENCE OF VENOUS THROMBOEMBOLISM IN PATIENTS UNDERGOING LOWER LIMB SURGICAL REvascularization: IS THROMBOPROPHYLAXIS WARRANTED?

A. Baranwal1, S. Singh1, A. Yanamadala1, P. Smith1,*, E. Colaiuta1

1MacNeal Hospital, Berwyn, United States

Background: The incidence of postoperative deep vein thrombosis (DVT) or consequential pulmonary embolism (PE) in patients undergoing lower extremity surgical revascularization procedures is not well studied. The need for routine anticoagulation for DVT/PE prophylaxis after the lower limb surgical revascularization remains controversial.

Aims: The purpose of this study is to retrospectively evaluate the incidence of postoperative DVT/PE in patients undergoing lower limb surgical revascularization.

Methods: Charts for patients undergoing lower limb surgical revascularization, from 01/01/2010 to 12/31/2015, were evaluated for DVT/PE. DVT/PE within three months of the revascularization was considered to be a postoperative DVT/PE. Patients undergoing multiple procedures were counted as different cases if they were on different days. Multiple procedures on a patient on the same day were considered a single case. Patients with hypercoagulable states or previous history of DVT were excluded. Descriptive statistics and t-test was used to analyze incidence of DVT/PE and assess the importance of postoperative thromboprophylaxis.

Results: Between 1/1/2010 to 12/31/2015, 360 patients were found to have undergone lower extremity surgical revascularization. Study population included 200 males and 160 females. Mean patient age was 69.54 years. One patient had a previous history of DVT and was excluded. Overall, of the 359 patients, five (1.4%) were recognized to have a new DVT/PE within 3 months of the surgery. One patient developed DVT in the contralateral limb, and one developed it in the arm. Patients were recognized to have a new DVT/PE, on an average, at 7.6 days after the surgery. A one sided t-test demonstrated that the average
postoperative day for recognition of DVT/PE was significant greater than 3.5 (7.6 vs 3.5, \(P=0.048\)). Patients developing DVT/PE did not differ by obesity or age when compared with non-DVT/PE population.

**Summary/Conclusions:** There have been only a few studies to assess the incidence of DVT/PE in patients undergoing lower limb surgical revascularization. In our study population, 1.4% of patients had evidence of DVT/PE. This study shows a low risk of venous thromboembolism. The 2012 American College of Chest Physicians (ACCP) guidelines for prevention of venous thromboembolism in nonorthopedic surgical patients (Chest 2012; 141(2)(Suppl) e227s-e277s), requires the use of pneumatic compression devices (PCDs), over no prophylaxis, to prevent DVT/PE in low risk patients. Since, patients with lower limb surgeries are not a good candidate for PCDs, pharmacological thromboprophylaxis with low dose heparin may be warranted. Given that bleeding is a potential complication in these patients, it might be prudent to start thromboprophylaxis 3-5 days after the surgery. Further studies are needed to assess the bleeding risks of postoperative thromboprophylaxis after surgical revascularization procedures.

Summary/Conclusions: In the GAIT2 study, genetic and environmental factors were related to B12, SF, RCF and HCY. Moreover, a relationship was observed between B12 and VTE. In the GWAS analysis some signals were previously reported (FUT2 and B12 or MTHFR with SF and HCY). New signals were found that need to be clarified, especially their possible relationship with susceptibility to thrombosis.

This work was supported by RIC RD12/0042/0032, FIS PI12/00612 and FIS PI 15/0269 grants.
trols, 71% of MP was positive for platelet (P-MP), 24% for erythrocyte (E-MP), 4% for endothelial cell (EC-MP), and 1% for leukocyte (L-MP) specific markers. In ET and PV patients, the percentage of P-MP was significantly higher (80%; p<0.05), while E-MP level was significantly lower (15%; p<0.05) than controls. L-MP and EC-MP values were comparable between patients and controls. The absolute counts of P-MP and L-MP were higher in both ET and PV versus controls. Overall, no significant correlations were found between the levels of MP derived from platelet, leukocytes or erythrocytes and the corresponding cell counts. The analysis according to patient mutations, revealed significantly higher levels (p<0.05) of both P-MP and E-MP concentration in patients carrying JAK2V617F mutation as compared to JAK2V617F negative patients. In addition, ET patients positive for CaR mutation displayed lower levels (p<0.05) of P-MP compared to JAK2V617F carriers. No influence of concomitant therapies on MP levels or composition was observed.

Summary/Conclusions: Our data confirm the presence of high levels of circulating MP in MPN, which support the role in the known hypercoagulable state of these patients. The MP cellular origin has a different distribution profile according to their presence in different mutations. Importantly, the lack of correlation found between the total and subtype-specific MP counts with the corresponding cell of origin counts suggests an active stimulation of MP formation.

P767

ARE WE TESTING APPROPRIATELY FOR THE LUPUS ANTICOAGULANT (LA)?

J. Sharif1,*, C. Humphrey1, I. Earnshaw1, J. Thachi1
1Haematology, Central Manchester University Hospitals, Manchester, United Kingdom

Background: The diagnosis of antiphospholipid syndrome (APS) requires the presence of thrombosis or defined pregnancy morbidity in addition to the presence of antiphospholipid antibodies on at least 2 occasions. Patients should be tested for antiphospholipid antibodies if they fulfil the required clinical criteria. Lupus anticoagulant may also be tested for when investigating a prolonged activated partial thromboplastin time which does not correct on mixing studies.

Aims: The aim of our study was to examine retrospectively the frequency of lupus anticoagulant (LA) testing in our institution, which we suspected to be high, and the incidence of positive results leading to a diagnosis of APS.

Methods: A total of 914 requests for LA were received over a 5 month period between 1st of May and 30th September 2014. We examined which departments were requesting the tests and the clinical indications for testing.

Results: Over 90% (829) of LA tests were negative. Nine percent (85) of tests demonstrated a positive LA. 33 patients had experienced arterial (11) or venous (22) thrombosis. There were 3 patients who fulfilled the clinical criteria for pregnancy morbidity in APS. A total of 6 patients experienced miscarriage before 10 weeks gestation; however none of these patients had the defined 3 miscarriages. There was one preterm delivery at 25 weeks due to pre-eclampsia. A further 3 patients had a still birth, one of which had an identifiable cause. In total, of the 85 positive results, 12 patients had a confirmed diagnosis of APS; a further 25 patients had the clinical manifestations fitting the clinical criteria for APS. Forty eight patients had a positive LA but did not fit the clinical criteria for a diagnosis of APS. The clinical specialties requesting the majority of tests were obstetrics and gynaecology (231), rheumatology (179) and clinical haematology (165). The speciality requesting the majority of tests for a diagnosis of APS. The clinical specialities requesting the majority of tests were obstetrics and gynaecology (231), rheumatology (179) and clinical haematology (165).

Summary/Conclusions: Our data confirm the presence of high levels of circulating MP in MPN, which support the role in the known hypercoagulable state of these patients. The MP cellular origin has a different distribution profile according to their presence in different mutations. Importantly, the lack of correlation found between the total and subtype-specific MP counts with the corresponding cell of origin counts suggests an active stimulation of MP formation.

RESULTS OF USING BRIDGING THERAPY WITH SODIUM BEMPARIN AT THERAPEUTIC-DOSE

M.A. Garcia Ruiz1,*, P. Romero García2, M. Gómez Morales1, M. Jurado Chacón1
1Servicio de Hematología y Hemoterapia, Complejo Hospitalario Universitario de Granada, Granada, 2Unidad de Cuidados Intensivos, Complejo Asistencial de Soria, Soria, Spain

Background: Bridging therapy consists of the administration of a fast-acting anticoagulant such as the low-molecular-weight heparin (LMWH) during the period of cessation of oral anticoagulant therapy. The decision to continue with anticoagulant therapy or to discontinue the treatment with the establishment of the Bridging therapy have been carried out carefully and on an individual basis. While taking this decision, we have taken into account three factors: the urgency of surgery or invasive process, the risk of bleeding and thrombotic risk for the patient. In recent decades, there have been multiple studies supporting the LMWH treatment, at least as safe and effective and more cost-beneficial than unfractionated heparin (UFH) in the 6-12 days of venous thromboembolism (VTE), including deep vein thrombosis (DVT) and pulmonary embolism (PE). Therefore, the LMWH is considered as the drugs of choice in the prevention of venous thromboembolism.

There are several types of commercialized LMWH, with different pharmacological properties, such as molecular weight, anti-Xa/IIa ratio and average life. The sodium bemparin is the LMWH with greater anti-Xa/IIa ratio, which implies a lower risk of bleeding. In addition, it has shown a low incidence of VTE and bleeding in actual clinical practice.

Aims: There are few published data from bridging therapy at therapeutic doses in patients treated with oral anticoagulants (AVK) and perioperative management. It is intended to assess the efficacy (recurrence of thrombosis) and safe use of sodium bemparin at anticoagulant doses on the bridging therapy and possible thrombotic and/or hemorrhagic complications (major and minor bleeding) resulting from this use.

Methods: We have analyzed 975 bridging therapies at full dose in our clinic in the last year. They were made to a total of 650 patients (315 men and 335 women) with CHADS/VASC ≥2, aged between 15 and 92, with an average age of 69 years old. The reasons of anticoagulation in our patients were atrial fibrillation, mechanical prostheses, DVT, pulmonary embolism and recurrent thrombosis in patients with thrombophilia. In 70% of the cases, there were comorbidities, such as heart failure, chronic obstructive pulmonary disease, anemia, kidney failure, liver disease and long-term aftereffects of stroke. The bridging therapy has consisted of suspending treatment (with or without anticoagulant) to 6 days (warfarin) before the procedure, and replacing it by sodium bemparin at full doses <50 kg: 5.000 IU/24h, 50 to 70 kg: 7.500 IU/24 h, 70-100 kg: 10.000 IU/24 h and >100 kg: 12.500 IU/24 h, and administration of a prophylactic dose of 3.500 IU, 12 hours before the procedure, and another dose 6-12 hours after the procedure, depending on the risk of bleeding of the intervention and the thrombotic risk of the patient’s disease. The bridging therapy has been performed in 225 cases of major surgery (orthopedic surgery, ophthalmological procedures, valvular replacements etc), 340 cases of minor surgery (removal of nevus, complex dental extractions, dental implants), 295 cases of invasive procedures (colonoscopies, endoscopies...), 50 cases of bleeding caused by AVK (epistaxis, petechiae and bruises, hemoptysis, menorrhagia and gastrointestinal bleeding), 30 cases of hospitalization with INR decompensation with various causes (infectious endocarditis, pneumonia, uncompensated heart failure...) and 35 cases for thrombophilia study.

Results: As complications of using bemparin sodium, there have been: 40 cases of hematomas at the needle puncture sites. There was neither cases of major bleeding nor cases of thrombosis.

Table 1.

Summary/Conclusions: Sodium bemparin administered at therapeutic doses (115 IU/kg/24h) in the perioperative period, according to the scheme described above, it is associated with a low incidence of recurrence of VTE and bleeding. The complications presented in our sample have been very few, in patients with associated co-morbidities. In our study, sodium bemparin has shown to be safe and effective with minimal bleeding complications. Treatment should be administered on an individual basis according to each patient and factors related to surgery. Further studies will confirm our results.
Targeted therapies in relapsed in chronic lymphocytic leukemia

IBRUTINIB IN PREVIOUSLY TREATED CHRONIC LYMPHOCYTIC LEUKEMIA: UPDATED EFFICACY AND SAFETY OF THE RESONATE STUDY WITH UP TO FOUR YEARS OF FOLLOW-UP

1Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, 2The Ohio State University Comprehensive Cancer Center, Columbus, United States, 3The Leeds Teaching Hospitals, St James’s Institute of Oncology, Leeds, United Kingdom, 4University of California Irvine, Irvine, 5Hofstra Northwell School of Medicine, Hempstead, 6Vanderbilt-Ingram Cancer Center, Nashville, Tennessee, 7Stanford University School of Medicine, Stanford, United States, 8Peter MacCallum Cancer Centre and St. Vincent’s Hospital, Melbourne, 9Royal North Shore Hospital, Sydney, Australia, 10Division of Hematology and Hemostaseology, Medical University of Vienna, Vienna, Austria, 11University of Rochester Medical Center, Rochester, 12Well Cornell Medical College, New York, 13University of California San Diego, Moores Cancer Center, La Jolla, United States, 14Beaumont Hospital, Dublin, Ireland, 15Niguarda Cancer Center, Milan, Italy, 16Swedish Cancer Institute Hematologic Malignancies Program, Seattle, 17University of Texas MD Anderson Cancer Center, Houston, 18Pharmacyclics LLC, an AbbVie Company, Sunnyvale, 19CLL Center, Dana-Farber Cancer Institute, Boston, United States

Background: Ibrutinib is a first-in-class, once-daily oral inhibitor of Bruton’s tyrosine kinase. Ibrutinib as a single agent is indicated by the EMEA and US FDA for the treatment of adult patients with CLL and allows for treatment without chemotherapy. The phase 3 RESONATE trial in patients with relapsed CLL showed superior efficacy of ibrutinib compared with ofatumumab (Byrd NEJM 2014). Aims: We report updated safety and efficacy results of the RESONATE trial with up to 4 years of follow-up. Methods: Eligibility criteria included ≥1 prior therapy, ineffectiveness for treatment with a purine analog, and ECOG performance status 0-1. Informed consent was obtained from all patients prior to study initiation. Patients received oral ibrutinib (420 mg once daily) until disease progression or unacceptable toxicity or intravenous ofatumumab (300 mg weekly; 2000 mg weekly for 7 weeks and then every 4 weeks for 16 weeks) for up to 24 weeks. At the interim analysis (median follow-up of 9 months), the data monitoring committee declared superior efficacy of ibrutinib vs ofatumumab for progression-free survival (PFS) and overall survival (OS), and access to ibrutinib was recommended for all patients in ofatumumab arm who had disease progression. Long-term follow-up of efficacy endpoints are open for investigator assessment. Patients randomized to ofatumumab were censored at crossover. Results: Randomized patients were randomized to receive ibrutinib (n=195) or ofatumumab (n=196). The median age was 67 years, with 40% age ≥70 years, and Rai stage III/IV in 57% of patients. At a median follow-up of 44 months (maximum 53 months) for the ibrutinib arm, PFS was significantly longer for ibrutinib vs ofatumumab (median NR vs 8 months, [HR 0.133; P<0.0001]). The 3-year PFS was 59% for ibrutinib vs 3% for ofatumumab. A significant PFS benefit was observed across baseline subgroups. In the ibrutinib arm, PFS for the del11q subgroup trended to have the most favorable outcome; however, PFS outcomes were not statistically different for patients with del17p or del11q or patients without these FISH abnormalities. At time of analysis, with the majority of patients randomized to ofatumumab (68%) crossing over to receive ibrutinib therapy, OS was longer for ibrutinib vs ofatumumab (median OS NR for either arm). The 3-year OS rate for ibrutinib was 74%. The ORR for ibrutinib was 91% with a CR/CRi rate that increased over time (currently 9%). Baseline cytopenias improved with extended ibrutinib therapy for hemoglobin (85% of patients), platelet (95% of patients), and absolute neutrophil counts (95% of patients). The adverse event (AE) profile of ibrutinib was consistent with previous reports. During a follow-up of up to 4 years, major hemorrhage occurred in 6%, grade ≥3 atrial fibrillation occurred in 6%, and grade ≥3 hypertension occurred in 8% of patients. The incidence of most ≥3 AEs decreased from year 1 vs year 2-3: neutropenia: 18% vs 8%; pneumonia: 11% vs 4%; atrial fibrillation (AF); and respectively. The most frequent reasons for treatment discontinuation were progressive disease (27%) and AEs (12%). At analysis, 90 patients randomized to ibrutinib (46%) continue to receive ibrutinib.

Summary/Conclusions: In this international phase 3 RESONATE study with median follow-up of up to 4 years, long-term treatment with ibrutinib showed a favorable tolerability profile with sustained PFS and OS benefit regardless of high-risk cytogenetics. The results in relapsed del17p and del11q patients compared favorably to those previously reported in phase 2 studies.

S771 VENETOCLAX IN RELAPSED/REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA WITH 17P DELETION: OUTCOME AND MINIMAL RESIDUAL DISEASE FROM THE FULL POPULATION OF THE PIVOTAL M13-892 TRIAL

1University of Ulm, Ulm, Germany, 2AbbVie Inc, North Chicago, IL, United States
Background: Venetoclax monotherapy in patients (pts) with relapsed/refractory CLL harboring deletion 17p (del17p) resulted in an ORR of 79% with a CR rate of 7% as determined by an independent review committee at the initial analysis of the pivotal M13-982 trial (n=107). Subsequently, 51 additional pts were enrolled in a safety expansion cohort.

Aims: This phase 1 trial evaluates the safety/efficacy of the triplet combination of venetoclax (V), UBLITUXIMAB (UTX), and TGR-1202 in pts with previously untreated or previously treated advanced CLL. METHODS: The combination of UTX, TGR-1202, and ibrutinib is a novel anti-CD20 mAb+PI3Kδ+BTK inhibitor (ibrutinib) in pts with B-cell malignancies. This is an open-label study with 28-day cycles. Twice daily (BID; 30 mg/m² BID x 5) of UTX and ibrutinib dosed at 420 mg (CLL) or 560 mg (NHL), both on C1D1. Dose escalation: twice daily 30 mg/m² BID x 5 followed by twice daily 60 mg/m² BID x 5 (24 mg/m² QD), and 80 mg/m² BID x 5 (32 mg/m² QD). RESULTS: 101 pts (N=101) were evaluable for efficacy; 75% had del(17p), and 32% were fludarabine refractory. 38% of 2 prior therapies (range, 0–6); 32% were fludarabine refractory; 11% had previously received a B-cell receptor signaling inhibitor (BCRi); 48% had nodes ≥5 cm; and 78% had unmutated IGVH. The median duration of venetoclax therapy was 16.7 months (range 0.02–43.1 months). Primary reasons for discontinuation were toxicity (32%), adverse events (AEs) (20%), withdrawal of consent (8%), and other reasons (10%). 24-month estimates for progression-free survival (PFS) and overall survival (OS) were 78.5% and 120% respectively. 3-24 mos). 53% of evaluable CLL pts had high-risk cytogenetics and 4/6 DLBCL pts were non-GCB. 1 CLL pt (17p/11q del) ref to PI3Kδ and ibrutinib achieved a CR. Of 24 pts on study (10-27 mos). Med DOR was not reached (range 3-24 mos).

Response to UTX+TGR-1202+ibrutinib for advanced CLL

This 22 nd Congress of the European Hematology Association

312 | haematologica | 2017; 102(s2)

0.02%). Pts observed. Two grade 3 dose limiting toxicities were observed at 45 mg BID (one each of grade 3 thrombocytopenia, pyrexia, rash, infusion reaction, ischemia (each at 29%), thrombocytopenia, cough (each at 26%), anemia (24%) and sinusitis (21%). OR 3/4 AE’s (all causality) were minimal, the only event >10% was neutropenia (16%). ORR amongst 36 evaluable pts is shown in the following Table 1.

Summary/Conclusions: This is the first known triplet combination of an anti-CD20 mAb+PI3Kδ+BTK inhibitor. The combination of UTX, TGR-1202, and ibrutinib has been well tolerated with activity observed across heavily pre-treated and therapy-resistant B-cell malignancies. Expansion cohorts at the highest dose (800mg TGR-1202+full dose ibrutinib) are underway. Future trials for the triplet are warranted.

S773

THE DUAL SYK/JAK INHIBITOR CERDULATINIB DEMONSTRATES COMPLETE INHIBITION OF SYK AND JAK AND RAPID TUMOR RESPONSES IN A PHASE 2 STUDY IN PATIENTS WITH RELAPSED/REFRACTORY B CELL MALIGNANCIES

P. Hamlin1,1, C. Farber2, T. Fenske3, J. Khatcheressian4, C. Miller5, J. Munoz6, M. Patel7, S. Smith8, D. Stevens9, A. Pandey10, M. Birrell10, J. Leeds10, Y.L. Wang10,1, G. Coffey10, J. Cumrute10

1Memorial Sloan Kettering Cancer Center, New York, 2Carol G. Simon Cancer Center, Morristown, NJ, 3Division of Hematology & Oncology, Medical College of Wisconsin, Milwaukee, WI, 4Virginia Cancer Institute, Richmond, VA, 5St. Agnes Hospital Cancer Center, Baltimore, MD, 6Banner MD Anderson Cancer Center, Gilbert, AZ, 7Florida Cancer Specialists/Sarah Cannon Research Center, Sarasota, FL, 8University of Chicago, Chicago, IL, 9Norton Cancer Institute, Louisville, KY, 10Portola Pharmaceuticals, South San Francisco, 10Department of Pathology, University of Chicago, Chicago, IL, United States

Background: Subsets of B cell malignancies are addicted to B cell antigen receptor (BCR) signaling for survival. Co-stimulation of the BCR with IL-2 or IL-4 in normal B cells significantly enhances cellular activation relative to BCR or cytokine stimulation alone, and combining SYK selective and JAK selective inhibitors synergize to suppress this response (Coffey et al., 2013). Hence, BCR/SYK and cytokine JAK/STAT signals cooperate to control B cell activation. This cooperation appears to be relevant to B cell malignancies as well. IL-4 promotes the survival of CLL cells in culture via up-regulation of MCL1 and BCL-XL, protecting the tumor from death induced by fludarabine and chlorambucil (Steele et al., 2010) and by idelalisib and ibrutinib (Aguilar-Hernandez et al., 2016). Also, unlike ibrutinib, combined SYK and JAK inhibition by cerdulatinib induces apoptosis in primary CLL cells and leads to down-regulation of MCL1 and BCL-XL (Blunt et al., 2015) and induces apoptosis in cells from ibrutinib-resistant CLL patients (Guo et al., 2017). It also induces apoptosis in primary DLBCL and DLBCL cell lines that carry BCR pathway mutations resistant to ibrutinib (Ma et al., 2015). Clinical trials suggest that SYK/JAK inhibition may therefore represent a powerful strategy to control B cell malignancies. A phase 1 dose escalation study of cerdulatinib in 43 patients with relapsed/refractory CLL and NHL was recently completed (Hamlin et al., EHA Congress 2016). Inhibition of both BCR/SYK and JAK/STAT signaling pathways by >90% in peripheral blood mononuclear cells (PBMCs) and CLL cell lines correlates with clinical improvement in CLL and FL, including in patients who had relapsed on prior BCR inhibitor therapy. No consistent hematopoietic toxicity, anemia, thrombocytopenia or neutropenia was observed. Two grade 3 dose limiting toxicities were observed at 45 mg BID (fatigue, pancreatitis). 35 mg BID was identified as the Phase 2 dose based on Phase 1 data and on PK/PD modeling.

Aims: The primary aim of the study was to understand the safety and activity of cerdulatinib in B-cell malignancies.

Methods: This is an open-label study with 28-day cycles. Twice daily (BID; 30
mg and 35 mg) dosing was evaluated. Pharmacokinetics (PK), pharmacodynamics (PD), and safety were monitored, as well as an assessment of efficacy. Clinical response was assessed by standard criteria. Potency and specificity for SYK and JAK pathway inhibition were measured in whole blood assays by monitoring signaling responses following ligation of the BCR and receptors for IL-4. Serum markers of inflammation, minimal residual disease (MRD) and apoptosis in CLL patients were also measured.

Results: A phase 2 study was initiated in May 2016 to enroll up to 40 patients in each of the three cohorts; 1) relapsed/refractory CLL/SLL, 2) relapsed/refractory indolent NHL, and 3) relapsed DLBCL, MCL and transformed FL. As of March 1, 2017, 37 patients have been enrolled, 17 with CLL/SLL, 15 with indolent NHL (10 FL, 4 MZL, 1 WM), and 5 with aggressive NHL (3 DLBCL, 1 MCL, 1 tFL). Median patient age is 70 years (range, 51-93). The median number of prior therapies is 3 (range 1–7). 11 patients had prior BTK or PI3K inhibitor therapy. The safety profile has been similar to what was seen in the Phase 1 study. However, 3 patients at 35 mg BID achieved higher than expected drug concentrations and had SAEs (2 grade 5 infections, 1 grade 3 pancreatitis). The starting dose was reduced to 30 mg BID and a PK monitoring and dose reduction strategy has been implemented. To date, this has resulted in a better safety profile without PK outliers. The most common AEs of any grade have been diarrhea (27%), fatigue (27%) and nausea (24%). Grade 3 AEs occurring in more than one patient are infection (5 patients), abdominal pain (3 patients) and hypertension (3 patients). As seen in phase 1, significant inhibition of SYK and JAK signaling pathways in peripheral blood is observed. Evidence for tumor cell mobilization to peripheral blood in CLL/SLL is consistently observed following one week of therapy. PRs have been seen in all 3 cohorts including 10 of 13 (77%) CLL/SLL, 8 of 9 (50%) FL patients evaluated. Of these 13 PRs, 12 are still on drug therapy. PRs have been seen in all 3 cohorts including 10 of 13 (77%) CLL/SLL and 3 of 6 (50%) FL patients evaluated. Of these 13 PRs, 12 are still on drug with 4 patients in response for greater than 6 months. In addition, PRs have been seen in patients who relapsed on ibrutinib (FL patient, 8+ months) and venetoclax (SLL patient, 7+ months) therapy. As demonstrated preclinically, we have seen evidence of apoptosis (Annexin V+ B-cells) in 6 CLL patients. 5 of these patients had a PR at the end of the 2nd cycle (Figure 1).

Figure 1.

Summary/Conclusions: Cerdulatinib demonstrates clinical activity in heavily pretreated patients with CLL/B-cell NHL and is generally well tolerated. Consistent activity is seen in patients with CLL and FL. Accrual is proceeding; updated PK/PD, safety and efficacy will be presented.

**Follicular lymphoma - Clinical**

S774

COMPARISON OF CONTRAST-ENHANCED CT-BASED RESPONSE WITH PET ASSESSMENT AFTER FIRST-LINE THERAPY FOR FOLLICULAR LYMPHOMA IN THE PHASE III GALLIUM STUDY

1Haematology Department, Concord Repatriation General Hospital, University of Sydney, Sydney, Australia, 2KCL and Guys’ & St Thomas PET Imaging Centre, Division of Imaging and Biomedical Engineering, Kings College London, London, United Kingdom, 34th Department of Internal Medicine – Hematology, University Hospital Hradec Kralove, Hradec Kralove, 4Faculty of Medicine, Charles University, Prague, Czech Republic, 5Service de Médecine Nucleaire, Hôpital Henri Mondor and Université Paris Est Creteil, Creteil, France, 6University of Alberta Cross Cancer Institute, Edmonton, 7Hôpital Edouard Herriot, Centre Hospitalier Universitaire Lyon-Sud, Lyon, France, 8Department of Medicine, National Institute of Oncology, Budapest, Hungary, 9Pharma Development Clinical Oncology, F. Hoffmann-La Roche Ltd, Basel, Switzerland, 10Ludwig-Maximilians-University Munich, Munich, Munich, 11Department of Haematology, Kings College Hospital, London, 12Cancer Research UK Centre, University of Southampton, Southampton, United Kingdom

Background: Published data show 18F-FDG PET-CT (PET) is predictive after first-line immunochemotherapy in advanced-stage symptomatic FL, and PET is now the recommended modality for response assessment. However, no large-scale prospective comparison of the value of standard contrast-enhanced CT vs PET response has been performed.

Aims: To compare CT and PET response assessment for FL pts in the prospective Phase III GALLIUM study, which evaluated chemotherapy plus obinutuzumab (G-chemo) or rituximab (R-chemo) induction followed by maintenance antibody therapy (Marcus 2016).

Methods: PET scans, introduced after an early protocol amendment (July 2011), were performed at baseline and end of induction (EOI; all pts gave informed consent) and assessed by the investigator (INV) and an independent review committee (IRC) comprising two radiologists, with a third adjudicator; final response was determined by a clinician. Response was assessed by CT and PET plus bone marrow biopsy, applying the revised International Working Group (IWG) criteria (Cheson 2007, Juweid 2007). Complete remission (CR) status at EOI for each assessment, CT-CR and PET-CR, was compared with pt characteristics, PFS and OS.

Results: Among 1202 ITT pts with FL enrolled in GALLIUM, IRC-assessed CT showed a CR in 330 pts (27.5%), PR in 747 (62.1%), SD in 20 (1.7%), PD in 35 (2.9%), unavailable (NA) in 48 (4.0%) and unacceptable (NE) in 22 (1.8%). Of 609 pts with a baseline PET scan, 595 had detectable lesions, and 535 also had an evaluable PET at EOI. Baseline demographics and disease characteristics were similar in PET and non-PET populations. Pts with NA (n=52) or NE (n=8) scans were considered non-responders; these pts and those with PD prior to S AEs were excluded from landmark PFS analyses. At EOI, 390/655 (65.5%) pts achieved a PET-CR according to IRC, comprising 212/297 (71.4%) G-chemo pts and 178/358 (50.0%) R-chemo pts. However, for these 390 pts, evaluable CT responses were 161 CR (41.3%), 216 PR (55.4%) and 5 SD/PD (1.3%; Table 1). Conversely, PET assessment showed a PET-CR in 161/177 (91.0%) of pts achieving a CT-CR, and PET-PR in only 117/362 (32.3%) of pts with CT-PR. Concordance between CT and PET assessment was 52.6% for IRC and 54.1% for INV. Concordance between INV and IRC evaluation was 71.9% for CT and 68.6% for PET. After a median follow-up of 34.5 mo (range 0–54.5), IRC-PET status was highly predictive of PFS (PET- CR vs PET non-CR: HR 0.39; 95% CI 0.25–0.60; p=0.0001) and OS (HR 0.41; 95% CI 0.19–0.86; p=0.018). 2.5-yr PFS from EOI was 87.6% (95% CI 83.9–90.8) for PET-CR pts compared with 70.9% (95% CI 61.3–78.6) for PET non-CR pts; corresponding OS was 96.6% (95% CI 94.1–98.1) vs 90.9% (95% CI 84.7–94.6) (Figure 1).

Summary/Conclusions: This large prospective analysis confirms EOI PET as an early predictor of PFS and OS in FL, with good concordance between INV and
and IRC PET evaluation. Comparison of PFS based on CT-response and re-analysis of PFS scans applying the now recommended 5-point scale for PET response assessment will be presented. Pooled analyses of these data and from other studies with longer follow-up may determine PET response as a reliable early surrogate for PFS and OS, providing a platform for study of response-adapted therapy.

S775
IMMUNOCHEMOTHERAPY WITH OBINUTUZUMAB OR RITUXIMAB IN PREVIOUSLY UNTREATED FOLLICULAR LYMPHOMA IN THE RANDOMIZED PHASE III GALLIUM STUDY: ANALYSIS BY CHEMOTHERAPY REGIMEN

1Department of Medicine III, Ludwig-Maximilians-University Munich, Munich, Germany, 2Department of Hematology, Azienda Ospedaliera Papa Giovanni XXIII, Bergamo, Italy, 3Department of Medicine, Hospital Universitario la Paz, Madrid, Spain, 4Haematology Department, Fiona Stanley Hospital, Murdoch, Australia, 5Department of Clinical Haematology, Oxford Cancer and Haematology Centre, Churchill Hospital, Oxford, United Kingdom, 6Medical Faculty (Haematology), Universitätsklinikum Essen, Essen, Germany, 7Oncology Center, HELIOS-Klinikum Erfurt, Erfurt, Germany, 8Department of Haematology, Prince of Wales Hospital, Sydney, Australia, 9First Faculty of Medicine, Charles University General Hospital and Institute of Pathological Physiology, Charles University, Prague, Czech Republic, 10Pharma Development Clinical Oncology, F. Hoffmann-La Roche Ltd, Basel, Switzerland, 11The University of Manchester and The Christie NHS Foundation Trust, Manchester Academic Health Science Centre, Manchester, United Kingdom, 12Department of Hematology, National Cancer Center Hospital, Tokyo, Japan, 13Pharma Development Safety and Risk Management, 14Pharma Development Biometrics Biostatistics, F. Hoffmann-La Roche Ltd, Basel, Switzerland, 15Department of Haematology, Kings College Hospital, London, United Kingdom

Background: The Phase III GALLIUM study (NCT01332968) showed that obinutuzumab (GA101; G) significantly prolonged PFS in previously untreated FL pts relative to rituximab (R) when combined with chemotherapy (chemo; CHOP, CVP or bendamustine [B]). Grade 3–5 and serious AEs were more common with G-chemo.

Aims: To explore outcomes by immunochemotherapy regimen.

Methods: Pts were aged ≥18 yrs with documented, previously untreated FL (grades 1–3a), advanced disease (stage III/IV or stage II with tumor diameter ≥7cm), ECOG PS 0–2, and requiring treatment according to GELF criteria. Chemo regimen was allocated by center. Pts were randomized 1:1 (stratified by chemo, FLIPI-1 group and geographic region) to R 375mg/m2 on day (D) 1 of each cycle (C) or G 1000mg on D1, 8 and 15 of C1 and D1 of C2–8, for 6 or 8 cycles depending on chemo. Pts continued to receive R or G every 2 months for 2 yrs or until progression. The cut-off date for this analysis was September 10 2016. All pts gave informed consent.

Results: 1202 FL pts were randomized. Baseline characteristics were generally similar across chemo groups, although B and CVP pts had relatively more comorbidities, e.g. GI and vascular disorders, than CHOP pts. After 41.1 months’ median follow-up, investigator (INV)-assessed PFS remained superior for G-chemo relative to R-chemo (HR, 0.68; 95% CI 0.54–0.87; p=0.0016) with consistent HRs across chemo groups (Figure 1). HRs for secondary time-to-event endpoints were supportive of the primary analysis. Difference in frequency of grade 3–5 AEs between arms was highest with CHOP and CVP (Table 1). Rates of second neoplasms and grade 3–5 infections were similar in G and R arms for CHOP and CVP but not for B. In all chemo groups, SAEs were more frequent with G than R, and AEs causing treatment discontinuation and fatal AEs were similar. Reductions in T-cell counts were more pronounced and prolonged in the B group than CHOP or CVP groups.

Figure 1.

Table 1. Safety summary (number (%) of FL pts* with ≥1 AE).

Summary/Conclusions: In treatment-naive FL pts, PFS was superior with G-chemo relative to R-chemo with consistent effects across chemo regimens. Some differences were seen in safety profiles between chemo regimens, but comparisons may be confounded by the lack of randomization.

S776
EFFICACY AND SAFETY OF COPANLISIB IN PATIENTS WITH RELAPSED/REFRACTORY FOLLICULAR LYMPHOMA: A SUBSET ANALYSIS OF THE CHRONOS-1 STUDY

314 | haematologica | 2017; 102(s2)
Background: Follicular lymphoma (FL) is the most common indolent non-Hodgkin lymphoma ( NHL) subtype, yet treatment options in the relapsed/refractory setting are limited. Copanlisib is a potent and selective pan-class I PI3K inhibitor with predominant activity against the δ- and α-isofroms. Aims: We report results from the FL subset of a large phase II study in NHL patients (NCT01660451, part B).

Methods: Patients with histologically confirmed indolent indolent FL (grade 1-3a) relapsed/refractory to ≥2 prior lines of treatment were treated with copanlisib (40 mg IV infusion) administered on days 1, 8 and 15 of a 28-day cycle until disease progression or unacceptable toxicity. The primary endpoint was objective response rate (ORR) as assessed by independent radiology review according to the response criteria for lymphoma (Cheson et al, JCO 20:579, 2007). Secondary endpoints included progression-free survival (PFS) and duration of response (DoR), safety and tolerability.

Results: A total of 141 patients with iNHL were treated in the phase II study, including 104 patients with FL. The FL subset was characterized as: 52% male, 83% white, median age 62 yrs, 62% ECOG 0, 63% refractory to last therapy, median time from most recent progression 8 wks (range 1-73) and median prior lines of therapy 3 (range 2-8). At the time of primary analysis the ORR was 58%, comprising 15 patients (14.4%) with complete response and 46 (44.2%) with partial response. Stable disease was observed in 35 (33.7%) patients and progression of disease as best response in 2 patients. The median duration of response was 370 days (range 0-687), with 43 responders censored at data cut-off. Median duration of treatment was 22 wks (range 1-105); 33 (32%) patients remained on treatment. Per investigator assessment, 87 of 96 evaluable patients (91%) had some degree of tumor shrinkage as best response, and 58/96 (60%) had >50% tumor shrinkage (Figure 1). For all patients in the phase II study, the most common treatment-emergent AEs occurring in >25% of patients included (all grade/grade 3): diastolic (34%/6%), reduced neutrophil count (30%/24%), fatigue (30%/32%), and fever (25%/4%). Hyperglycemia (50%/41%) and hypertension (30%/24%) were transient. The incidence of pneumonitis (8%/1.4%), hepatic enzymopathy (AST 28%/1.4%; ALT 23%/1.4%), opportunistic infection (1.4%) and colitis (0.7%) were low. Six deaths were observed, 3 of which were attributed to copanlisib: one lung infection, one respiratory failure, and one thromboembolic event.

Figure 1.

Summary/Conclusions: Copanlisib was highly active as a single agent in heavily pretreated relapsed/refractory FL patients and resulted in responses in the majority of patients with a median duration of response of 370 days and >50% tumor shrinkage as best response, and 58/96 (60%) had >50% tumor shrinkage. Toxicities were manageable, with a low incidence of severe AEs associated with other PI3K inhibitors, especially hepatic enzytopathy, opportunistic infections, and colitis.

DYNAMO: A PHASE 2 STUDY DEMONSTRATING THE CLINICAL ACTIVITY OF DUVELISIB IN PATIENTS WITH DOUBLE-REFRACTORY FOLLICULAR LYMPHOMA

1Institute of Hematology Seràgnoli, University of Bologna, Bologna, Italy, 2Site- matic Cancer Center, Washington University, St Louis, USA, 3Department of Internal Medicine, University of Kentucky, Lexington, USA, 4Department of Hematology, University of Miami, Miami, Florida, 5Florido Cancer Specialists Tallahassee, Tallahassee, United States, 6German Cancer Center, Heidelberg, Germany, 7Brigham and Women’s Hospital, Boston, Massachusetts, USA, 8University of Toronto, Toronto, Canada, 9Hematology Division, L’Aquila University, L’Aquila, Italy, 10Sichuan Cancer Hospital, Chengdu, China, 11Hematology and Medical Oncology, Chaim Sheba Medical Center, Tel Aviv University, Tel-Hashomer, Israel, 12Department of Hematology, Singapore General Hospital, Singapore, Singapore, 13Health Research Institute, Hospital Universitario Puerta de Hierro, Universidad Autonoma de Madrid, Madrid, Spain, 14Norton Cancer Institute, Louisville-KY, 15Comprehensive Cancer Care and Research Institute of Colorado, Englewood-CO, Angola, 16Bayer HealthCare Pharmaceuticals Inc, Whippany, NJ, United States, 17Bayer AG, Berlin, 18Medizinische Klinik und Poliklinik III, Klinikum der Universität München LMU, Munich, Germany

Background: Duvelisib is an oral, dual inhibitor of PI3K-δ,γ in development for the treatment of hematologic malignancies. DYNAMO is a Phase 2 study to evaluate the safety and efficacy of duvelisib monotherapy in a double refractory iNHL population, which included a majority of patients (pts) with follicular lymphoma (FL).

Aims: The primary objective was to evaluate the antitumor activity of duvelisib monotherapy in pts whose disease is refractory to rituximab and to either chemotherapy or RIT, with an additional objective to further characterize the safety profile of duvelisib.

Methods: DYNAMO is an open-label, single-arm, safety, and efficacy study in patients (pts) with FL, small lymphocytic lymphoma (SLL), or marginal zone lymphoma (MZL), whose disease is double-refractory to rituximab (monotherapy or in combination) and to chemotherapy or radioimmunotherapy. Pts were eligible who had relapsed/refractory FL 25 months after last treatment cycle, or within 3 months of last treatment, or with ≤12 months disease progression after last treatment. The primary endpoint is overall response rate (ORR) as assessed by an independent review committee (IRC) per revised International Working Group (IWG) criteria. Secondary endpoints include duration of response (DoR), progression-free survival (PFS), overall survival (OS), time to response (TTR), adverse events (AEs) and other safety parameters.

Results: 20 pts with iNHL were treated on study. Of these, 83 pts with FL received duvelisib with a median duration of exposure of 6 mo. (range: 0.4 - 24). Median age was 64 years; 68% were male. Most FL pts had an ECOG performance status score at baseline of 0 (51%), followed by 1 (42%) and 2 (7%). Most FL pts (65%) had a FLIPI score at baseline ≥3, and most had either Stage 3 (46%) or Stage 4 (39%) disease. Median time from last anticancer therapy to first dose of duvelisib was 3.2 months. FL pts received a median of 3 prior anticancer regimens (range: 1 - 10); 65% of pts received ≥3 prior regimens, 17% 2 prior regimens. The median time to progression (TTP) was 1.9 mo. (range: 0.4 - 11.7). 80% of FL pts experienced a reduction in nodal target lesions after treatment with duvelisib. Among the 34 FL pts with a response to the median DoR was 9.2 months. The median PFS for all FL pts was 8.3 months, while the median OS was 11.1 months. Among all pts treated on study (n=129), AEs were mostly Gr 1-2. Most common Gr ≥3 AEs were patient-reported neuropathy (39%), fatigue (24%), anemia (12%), and diarrhea (15%). 17% of pts discontinued duvelisib due to an AE. Opportunistic infections occurred in <5% of pts, none were fatal, and included 1 pt (0.8%) with pneumocystis and 3 pts (2.3%) with CMV infections. Six pts had an AE with a fatal outcome.

Summary/Conclusions: In DYNAMO, duvelisib showed clinical activity in a double-refractory population (FL 41% ORR, median DoR 9.2 mo., 80% with reduction in target lesions). DUVElisib was generally well tolerated, with a manageable safety profile with appropriate risk mitigation. Duvelisib monotherapy has a favorable benefit-risk profile in double-refractory iNHL, and may represent an important treatment option. Updated clinical data will be available at the time of presentation.
Background: Between March 2000 and May 2005 a multicenter randomized trial comparing frontline use of CHOP-R vs R-HDS with autograft has been performed on 134 Follicular Lymphoma (FL) patients, selected for age less than 60 yrs. and poor prognostic features according to age-adjusted IPI (2-3) and IIL-score (3 or greater). Results at 4-yr follow-up were previously published (Ladetto M et al, Blood 2008), showing superior disease control with R-HDS without any survival advantage.

Aims: We have recently performed a long term update and the results at a median follow-up of 13 yrs are here presented.

Methods: The long-term outcome has been updated for 119 out of the original 134 randomized patients (56 CHOP-R and 63 R-HDS arms). Main features of the updated patients included: median age 51 yrs. (22-60), M/F ratio 68/51, aaIPI 2-3 90%, high LDH 43%, bulky disease 60%, B-symptoms 46%, BM involvement 86%; no significant differences were observed in clinical presentation between the two arms, as previously reported. Treatment schedule consisted of: i. CHOP-R arm: 6 courses of cyclophosphamide/doxorubicin/vincristine/prednisone followed by 4-weekly rituximab courses; ii. experimental R-HDS arm: rituximab with high-dose sequential chemotherapy followed by autografting. The analysis was intention to treat with event-free survival as the primary endpoint. Minimal residual disease (MRD) was evaluated post treatment in 56 patients with a bcl-2/IgH MBR or mcr translocation confirmed at diagnosis by nested PCR. The trial was registered at www.clinicaltrials.gov, no. NCT00435955. The long-term outcome has been updated in January 2017 by 27 out of 30 participating Centers, on 119 patients (88% of the whole series).

Results: Complete remission (CR) was achieved by 86 (72%) patients, including 32 (57%) with CHOP-R and 54 (85%) with R-HDS (p <.001); Molecular Remission (MR) was achieved in 37 out of 56 (66%) evaluable patients. At a median follow-up of 13 yrs., 74 patients (63%) are alive. Overall, 22 patients died for lymphoma progression (13 CHOP-R, 9 R-HDS), 12 died for secondary malignancy (3 in the CHOP-R, 9 in the R-HDS arms), 11 patients died for other causes, including four early toxic deaths. The overall survival (OS) for the whole series is 63% at 13 yrs, as shown in Figure 1A. No significant differences in the long-term OS were observed between the two arms, with 13-yr survival of 65% and 61% for CHOP-R and R-HDS, respectively (p=0.51). At 13 years, the event free survival is 35%, whereas the disease-free survival (DFS) is of 53%, as shown in Figure 1B. Response to induction therapy had a major impact on the OS, with 13 yr survival of 75% for patients achieving CR vs 33% for those with less than CR (p <.001). Similarly, Molecular Remission (MR) achievement was associated with prolonged OS, with 13 yr survival of 81% for patients in MR on BM cells, and of 47% for those with positive MRD (p=.02) (Figure 1C).

Summary/Conclusions: i. poor risk FL may have a prolonged survival, with 63% of patients alive at 13 yrs.; ii. no survival differences between CHOP-R and R-HDS can be detected even at 13 yrs of follow-up; iii. achieving CR is still crucial for the long-term survival; iv. the MRD analysis has a prognostic impact not only on progression-free but also on OS; v. lymphoma progression remains the major cause of death, while secondary neoplasms represent the second cause of treatment failure; vi. a subgroup of advanced-stage FL may experience a prolonged DFS lasting at least 13 yrs: this raises the issue of the potential curability of FL.
Madrid, Spain, June 22 – 25, 2017

Changing the strategy of therapy in
multiple myeloma

Background: This study aimed to determine the benefit of early therapeutic
intervention with the combination of elotuzumab, lenalidomide, and dexamethasone in patients with high-risk smoldering multiple myeloma (SMM).
Aims: The overarching objective of this trial is to determine progression free
survival to symptomatic myeloma (MM). Furthermore, the study examined
whether genomic studies can help in determining patients who would benefit
the most from this early therapeutic intervention.
Methods: Patients enrolled on study met eligibility for high-risk SMM based on
the newly defined criteria proposed by Rajkumar et al, Blood 2014. Patients
were administered weekly elotuzumab (10 mg/kg) on days 1, 8, 15, and 22 for
the first two 28-day cycles while receiving lenalidomide on days 1-21. For cycles
3-8, patients were administered elotuzumab infusions on days 1, 8, and 15.
Dexamethasone (40mg) was given on days 1, 8 and 15 for 40 of the 50 patients
enrolled. After 8 cycles or best response, patients were given the option to
mobilize with either cyclophosphamide or plerixafor and collect stem cells for
future transplant. Patients were then allowed to continue on maintenance therapy where they were administered elotuzumab (20 mg/kg) on day 1, in combination with lenalidomide days 1-21 of a 28 day cycle. Bone marrow samples of
33 patients were obtained before starting therapy for baseline assessment and
whole exome sequencing (WES) of plasma cells.
Results: In total, 50 patients were enrolled on this study from January 2015
to date, with the participation of eight sites. The median age of patients
enrolled was 62 years (range 29 to 79) with 18 males (36%) and 32 females
(64%). Interphase fluorescence in situ hybridization (iFISH) detected high
risk cytogenetics in 20 patients. The median number of cycles completed is
12 (range 1 to 24). Therapy related grade 3 toxicities included hypophosphatemia (30%), neutropenia (14%), infection (12%), anemia (2%), pulmonary
embolism (2%), rash (4%), and diarrhea (2%). Therapy related grade 4 toxicities included thrombocytopenia (2%), neutropenia (2%) and one instance
of cholecystitis (2%). Stem cell collection was successful in all patients collected to date. Of the 31 evaluable patients that completed the first 8 cycles
of therapy, the overall response rate was 84%, including 2 complete responses (7%), 11 very good partial responses (36%) and 13 partial responses
(42%), and a clinical benefit rate of 100%. None of the patients showed progression to overt MM to date. WES was performed on 25 samples at the time
of initiation of therapy. Recurrent mutations in the MAPK pathway (KRAS,
NRAS) and tumor suppressor gene, TP53, were detected in 32% of the cases
(16% each), while mutations in NF-KB and plasma cell differentiation pathways were present in 10% of patients. CCND1 gene mutation was seen in 1
patient and was associated with t(11:14) as reported in the previous WES
studies of MM. CNAs were called based on WES: 1q amplification, 13q, 17p,
and 1p deletions were identified in 28, 20, 16, and 12% of cases, respectively.
Interestingly, in 6 patients, high-risk CNAs were not reported in iFISH but
were detected by WES. Finally, we assessed the correlation between neoantigen load and clinical response.
Summary/Conclusions: The combination of elotuzumab, lenalidomide, and
dexamethasone is well tolerated and demonstrates a high response rates with
no progression to overt MM to date. Correlation with genomic studies can help
define patients who benefit the most from this early therapeutic intervention.

Background: Addition of a proteasome inhibitor to a doublet backbone therapy
has been shown to improve efficacy in newly diagnosed multiple myeloma
2017). Data from two phase 1/2 studies indicate that the combination of ixazomib plus lenalidomide-dexamethasone (IRd) is feasible and active in patients
with NDMM, with weekly and twice-weekly ixazomib dosing having been investigated (Kumar et al, Lancet Oncol 2014; Richardson et al, Blood 2013).
Aims: This phase 1/2 study (NCT01383928) evaluated twice-weekly ixazomib
plus Rd as induction therapy, followed by maintenance therapy with singleagent ixazomib. We report long-term efficacy and safety data in patients who
did not withdraw from the study in order to receive SCT.
Methods: Patients with NDMM (SCT-eligible or SCT-ineligible) received twiceweekly oral ixazomib (3.0 or 3.7 mg on days 1, 4, 8, and 11) plus lenalidomide
(25 mg on days 1–14) and dexamethasone (20 mg [10 mg in cycles 9–16] on
days 1, 2, 4, 5, 8, 9, 11, and 12) for up to sixteen 21-day cycles, followed by
maintenance therapy with single-agent twice-weekly ixazomib. Patients
received therapy until disease progression or toxicity. Those who proceeded to
SCT did not receive further ixazomib therapy. Response/progression was
assessed per IMWG criteria after cycles 1, 2, 3, 4, and then every 2 cycles during induction and maintenance.
Results: Of the 64 enrolled patients, 40 continued on study treatment without
early withdrawal for SCT; long-term follow-up of these 40 patients is reported
here. The median age of patients was 66 years (range 34–82), and
45%/38%/18% of patients had ISS disease stage I/II/III. At a median follow-up
of 47.0 months, the overall response rate (ORR; ≥partial response [PR]) in the
response-evaluable population was 95%, the complete plus very good partial
response (CR+VGPR) rate was 68%, and the CR rate was 32%. Median time
to first response was approximately 1 cycle (0.72 months). Median time to a
best response of ≥CR was 4.2 months. Patients received a median (range) of
14 (1–75) treatment cycles. Median progression-free survival (PFS) for patients
not proceeding to SCT was 24.9 months. Median overall survival (OS) was not
estimable; the 2-year Kaplan-Meier estimate for OS was 92%. A total of 78%
of patients had grade ≥3 treatment-related adverse events (AEs); the most
common treatment-related grade ≥3 AEs and serious AEs are shown in the
Table 1. After completing induction therapy with IRd, 18 patients went on to
receive maintenance with single-agent ixazomib on a twice-weekly dosing
schedule. Patients who went on to maintenance received a median (range) of
31.5 (17–75) treatment cycles. Among the patients who received maintenance
treatment, the ORR (≥PR) was 94%, the CR+VGPR rate was 89%, and the CR
rate was 44%. Two (11%) patients improved their responses during maintenance (1 VGPR to stringent CR, and 1 VGPR to near-CR). Five (28%) patients
who received maintenance therapy had an onset of a grade ≥3 treatment-related AE in cycle 17 or beyond. Rash (aggregate term) was infrequent with single-agent ixazomib during maintenance (1 patient, 6%).
Table 1.

S780

TWICE-WEEKLY IXAZOMIB PLUS LENALIDOMIDE-DEXAMETHASONE IN
PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA:
LONG-TERM FOLLOW-UP DATA FOR PATIENTS WHO DID NOT
UNDERGO STEM CELL TRANSPLANTATION
P. Richardson1,*, C. Hofmeister2, C. Rosenbaum3, M. Htut4, D. Vesole5,

haematologica | 2017; 102(s2) | 317


Summary/Conclusions: In patients with NDMM, twice-weekly ixazomib plus Rd resulted in excellent response rates in patients who did not receive a SCT and who received maintenance therapy. The responses were deep and durable, with long PFS and a high 2-year OS estimate. The majority of AEs had an onset during induction, and the incidence of AEs during maintenance was infrequent.

S781
LENALIDOMIDE INDUCTION AND MAINTENANCE THERAPY FOR TRANSPLANT ELIGIBLE MYELOMA PATIENTS: RESULTS OF THE MYELOMA XI STUDY
1The Institute of Cancer Research, London, United Kingdom, 2Myeloma Institue, University of Arkansas for Medical Sciences, Little Rock, United States, 3Clinical Trials Research Unit, Leeds Institute of Clinical Trials Research, Leeds, 4Heart of England NHS Foundation Trust, Birmingham, 5Leicester Royal Infirmary, Leicester, 6Centre for Clinical Haematology, Nottingham University Hospital, Nottingham, 7University Hospitals of North Midlands, Stoke-on-Trent, 8Kent and Canterbury NHS Trust, Canterbury, 9Southampton Hospital, Southampton, 10University of Leeds, Leeds, 11The Royal Marsden Hospital, London, 12Institute of Immunology and Immunotherapy, University of Birmingham, 13Academic Haematology Diagnostic Service (HMDS), St James’s University Hospital, 14Clinical Trial Research Unit, Leeds Institute of Clinical Trials Research, Leeds, 15Department of Haematology, Newcastle University, Newcastle, United Kingdom

Background: Immunomodulatory agents are effective therapies for multiple myeloma (MM) acting via the modulation of cereblon. Lenalidomide (Len) has fewer side effects than Thalidomide (Thal), whilst retaining the benefits of oral administration, enabling long-term treatment that has been associated with better disease control. Combinations of agents induce deeper, longer remissions by targeting different clonal populations, with triplets outperforming doublets. The optimum immunomodulatory-based induction combinations and maintenance regimens are unknown.

Aims: The UK NCRI Myeloma XI study compared triplet induction regimens of Len vs Thal and evaluated the role of post-ASCT maintenance Len vs observation, enabling a prospective comparison of induction with Len mainteneance.

Methods: Myeloma XI is a multicenter, open-label, parallel group, randomised controlled trial for newly diagnosed MM patients of all ages, with pathways for transplant eligible (TE) and non-eligible patients. For TE patients the induction question compared Len or Thal plus cyclophosphamide and dexamethasone (CTD vs CTD) continued for a minimum of 4 cycles and to maximum response. For patients with a suboptimal response there was a subsequent randomization to a proteasome inhibitor containing triplet or no further therapy, prior to high-dose melphalan and ASCT. A maintenance randomisation at 3 months post ASCT observed Len till disease progression or observation. High risk disease was defined as presence of more than 3 risk factors (CrCl<30mL/min, del(17p), t(4;14), del(17q), 2042 TE patients underwent the induction randomization (CRD 1021, CTD 1021). After a median follow up of 36.3 months, 965 PFS and 415 OS primary endpoint events had occurred. Secondary endpoints include response and toxicity. Results: In TE patients, CRD induction was associated with deeper responses than CTD (76% vs CTD 71%, p=0.005), and CRD maintained the superior induction which persisted post ASCT (≥VGPR CRD 82% vs CTD 77%). This was associated with a significantly improved median PFS. Patients receiving CRD achieved a median PFS of 35.9 months compared to 32.9 for those who received CTD (HR 0.85, 95%CI [0.75, 0.96], p=0.0116). This also translated into an overall survival benefit, 3 year OS: CRD 82.9% vs CTD 77.0% (HR 0.77, 95%CI [0.63, 0.93], p=0.0072).

There were higher rates of PN and constipation with CTD vs haematological toxicity with CRD. Maintenance therapy with Len was associated with a significantly higher median PFS compared to observation (TE HR 0.47, 95%CI [0.38, 0.60]). This finding persisted across all subgroups including patients with high-risk disease, a post-hoc analysis across the TE pathway suggested that CRD induction with Len maintenance was optimum: 60 month PFS CRD-R 50.2%, CTD-R 39.1%, CRD-obs 18.5%, CTD-obs 23.4%.

Summary/Conclusions: In TE patients CRD was associated with deeper responses than CTD and with a PFS and OS benefit. The best outcomes were associated with Len induction plus Len maintenance. Our findings support continuing Len therapy through induction until disease progression.

On behalf of the UK NCRI Haematology CSG.

S782
COMPARISON OF DENOSUMAB WITH ZOLEDRONIC ACID FOR THE TREATMENT OF BONE DISEASE IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA; AN INTERNATIONAL, RANDOMIZED, DOUBLE BLIND TRIAL
1Department of Clinical Therapeutics, National and Kapodistrian University of Athens, School of Medicine, Athens, Greece, 2Indiana University Simon Cancer Center, Indianapolis, United States, 3Medical University of Innsbruck, Innsbruck, Austria, 4National Hospital Organization Higashi Nagoya National Hospital, Nagoya, Japan, 5Hospital Universitario de Salamanca, Salamanca, Spain, 6Cedars-Sinai Medical Center, Los Angeles, 7Amgen Inc., Thousand Oaks, 8Massachusetts General Hospital Cancer Center, Boston, United States

Background: Multiple myeloma is characterized by osteolytic bone disease, with up to 80% of pts presenting with detectable lesions. Myeloma bone disease is mediated by osteoclast activating factors such as RANKL, increasing the risk of skeletal-related events (SREs) and impacting morbidity and mortality. DMB, a human monoclonal antibody that targets and binds to RANKL, can be administered subcutaneously (SC) to pts regardless of renal function.

Aims: This study evaluates the efficacy and safety of DMB compared with ZA in newly diagnosed myeloma pts.

Methods: Adult pts were randomized 1:1 to DMB 120 mg SC Q4W or ZA 4 mg IV (adjusted) Q4W along with anti-myeloma therapy. Key stratification factors included type of first-line therapy (novel or non-novel) and previous SRE. Pts with renal insufficiency were excluded if baseline creatinine clearance (CrCl)<30mL/min. The primary endpoint was non-inferiority of DMB to ZA with respect to time to first on-study SRE. Secondary endpoints included superiority of DMB for time to first on-study SRE and first-and-subsequent on-study SRE, and overall survival (OS). Progression-free survival (PFS) was an exploratory endpoint. Safety was also assessed.

Results: A total of 1718 pts were randomized, 859 to each arm. Baseline demographics and disease characteristics were balanced, with 66.0% of DMB and 67.2% of ZA pts reporting prior SRE history; CrCl<30mL/min was reported in 26.7% of pts. During the primary blinded treatment period (median follow-up 17.4 months [m]), 43.8% DMB pts and 44.6% ZA pts had a first on-study SRE. The median time to first on-study SRE was similar between DMB (22.83 m) and ZA (23.98 m) pts. DMB was non-inferior to ZA in delaying time to first on-study SRE (HR[95%CI]=0.98[0.85,1.14]). Superiority was not demonstrated for time to first on-study SRE (P=0.82) and time to first-and-subsequent on-study SRE (P=0.84). In this high-risk study population the effect of antiresorptive therapy may only be evident later in the treatment course. A post-hoc, landmark analysis at 15 m for first SRE occurred in a HR[95%CI]=0.66[0.44,0.98], P=0.039 (Figure 1) between DMB and ZA. OS was similar between DMB and ZA (HR[95%CI]=0.90[0.70,1.16], P=0.41), with fewer deaths with DMB (121[14.1%]) than ZA (129[15.0%]). PFS yielded a HR[95%CI]=0.82[0.68,0.99], descriptive P=0.036, with median times of 46.09 m (95%CI:34.3,3.3 NE) for DMB and 35.38 m (95%CI:30.19 NE) for ZA. The most common TEAes≥2%= DMB for DMB and ZA were diarrhea and nausea. The rates of SAEs (DMB, ZA [%]:46.0,47.3), hypocalcemia (16.9,12.4; serious:0.9,0.2) and positively adjudicated ONJ (4.1,2.8) were comparable to known safety profiles. Fewer DMB pts (%) compared with ZA pts had AEs potentially related to renal toxicity (10.0,1.7;P<0.001), most notably in pts with baseline CrCl<30mL/min (12.9,26.4). TEAes led to IP discontinuation in 12.2% of all pts (12.9,11.5).

Figure 1.

Summary/Conclusions: DMB demonstrated non-inferiority to ZA in delaying time to first on-study SRE in myeloma pts, meeting the primary endpoint of the study. A landmark analysis at 15 m suggests a significant benefit for DMB with respect to time to first SRE. The rates of renal AEs were significantly lower in DMB pts while the overall rates of AEs, including hypocalcemia and ONJ, were consistent with the known DMB safety profile. The results of the landmark analysis and possible prolongation of PFS with DMB therapy is promising.
**PEMBROLIZUMAB PLUS LENALIDOMIDE AND LOW-DOSE DEXAMETHASONE FOR PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA: EFFICACY AND BIOMARKER RESULTS FROM THE PHASE 1 KEYNOTE-023 STUDY**

¹Clínica Universidad de Navarra, Centro de Investigación Médica Aplicada, IDISNA, CIBERONC, Pamplona, ²Complejo Asistencial Universitario de Salamanca/IBSAL, Salamanca, Spain, ³The University of Texas MD Anderson Cancer Center, Houston, ⁴Hackensack University Medical Center, Hackensack, United States, ⁵Princess Margaret Cancer Centre, Toronto, Canada, ⁶University Hospital Hotel-Dieu, Nantes, France, ⁷Dana-Farber Cancer Institute, ⁸Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, ⁹Merck & Co., Inc., Kenilworth, United States

**Background:** Pembrolizumab (pembro) is a humanized, highly selective, high-affinity IgG4/κ antibody that blocks the interaction between programmed death 1 (PD-1) and its ligands PD-L1 and PD-L2, activating antitumor immunity. Pembro plus lenalidomide (len) and low-dose dexamethasone (dex) may provide synergetic antitumor activity in relapsed/refractory multiple myeloma (RRMM). Biomarkers indicative of response, pharmacodynamic activity, and/or mechanism of action to combination therapies are also needed.

**Aims:** To determine the maximum tolerated dose (MTD) and safety and tolerability of pembro plus len and low-dose dex in patients with RRMM. Additionally PD-L1 and PD-L2 expression in bone marrow (BM), immune profiles in circulating lymphocytes, and gene expression in blood were evaluated.

**Methods:** This open-label, phase 1 KEYNOTE-023 (NCT02036502) study of pembro plus len and low-dose dex enrolled patients with RRMM previously treated with ≥2 prior therapies, including both a proteasome inhibitor and an immunomodulatory drug. Patients received pembro 200 mg IV every 2 weeks (Q2W), len 25 mg orally on days 1-21, and dex 40 mg orally weekly on each 28-day cycle. Primary end points were safety and determination of the MTD. ORR was assessed by IMWG 2006. Exploratory biomarker analyses included analysis of PD-L1 and PD-L2 on CD38+CD138+ cells in BM aspirate samples obtained at screening, or before the first dose of study drug. Absolute and/or relative numbers of circulating lymphocytes (by flow cytometry [FC]) and gene expression profile (GEP) (by Nanostring) were evaluated in predose; cycle 1, day 1 (C1D1); and cycle 2, day 1 (C2D1) blood samples.

**Results:** MTD was determined as pembro 200 mg IV Q2W plus len 25 mg and dex 40 mg. Median (range) age was 61 years (46-77); median (range) number of prior lines of therapy was 4 (1-10); 38 (75%) patients were len-refractory, and 27 (53%) were double refractory. Most common grade ≥3 treatment-related AEs (TRAEs) were neutropenia (33%), thrombocytopenia (18%), and anemia (12%). 2 patients (4%) died because of TRAEs (hepatic failure, ischemic stroke). Immune-related AEs occurred in 5 (10%) patients. No pneumonitis was reported. ORR in the efficacy population was 20/40 (50%) (1 sCR, 5 VGPR, 14 PR); 35/40 (88%) patients had a reduction in allele burden over time. The disease control rate (sCR+CR+VGPR+PR+SD) was 39/40 (98%) in the efficacy population and 28/29 (97%) in the len-refractory population. 35/40 (88%) patients had a reduction in M protein or free light chains. In 16/32 patients with FC-evaluable BM samples, 34/35 (97%) patients had a ≥50% reduction in the MPN-SAF TSS. At wk 80, mean percentage change from baseline in JAK2V617F allele burden was -9.7% in the RUX arm (n=65) vs +0.3% in the BAT arm (n=3). AEs observed were consistent with those generally reported with RUX (primarily grade 3/4). Most common grade 3/4 AEs (all G, exposure-adjusted rate per 100 pt-years) were anemia (14.3%), weight increase (10.6%), arthralgia (9.1%), and pruritus (9.1%) in the RUX arm vs pruritus (37.5%), headache (16.9), and thrombocytopenia (15.0%) in the BAT arm. Rate of thromboembolic events (Standardized MedDRA Query, exposure-adjusted) was RUX (1.5%) vs BAT arm (1.9). No pt in the RUX arm had disease progression; 2 pts in the BAT arm. No deaths were reported in the RUX arm vs 3 pts in the BAT arm.

**Summary/Conclusions:** RUX provided durable HCT control, durable CHR, reduction in PBT requirement, improved symptom burden, and was generally well tolerated with >90% of pts still receiving Tx at wk 80. A confirmatory RUX vs BAT phase 3 trial is planned; the results of this study will provide further insight into the role of RUX in RRMM.
Background: Momelotinib (MMB), an investigational oral JAK inhibitor, has been shown in early trials to reduce spleen volume, improve disease associated symptoms and improve red blood cell (RBC) transfusion requirements in patients with myelofibrosis (MF).

Aims: To test the non-inferiority of MMB vs ruxolitinib (RUX) in splenic volume reduction and symptom amelioration, and superiority in transfusion requirement, in JAKi naive patients with primary myelofibrosis, and post-polycythemia vera or post-essential thrombocythemia myelofibrosis.

Methods: Eligibility included primary myelofibrosis or post-polycythemia vera/essential thrombocythemia myelofibrosis; International Prognostic Scoring System (IPSS) high risk, intermediate-2 risk, or intermediate-1 risk associated with symptomatic splenomegaly; palpable spleen ≥5cm; and no Grade ≥2 peripheral neuropathy. Informed consent was obtained. Stratification was by transfusion dependence and baseline TSS (modified MPN-SAF Total Symptom Score) <18 or ≥18. Patients were randomized 2:1 to 24 weeks of open-label MMB 200 mg qd or RUX. Assessments included spleen volume by MRI, and patient reported symptoms using a daily eDiary for TSS. Primary endpoint was spleen response rate (SRR; ≥50% reduction from baseline) before week 24. Secondary endpoints, evaluated sequentially, were rate of TSS response (TSS RR; ≥50% reduction from baseline), RBC transfusion independence and RBC transfusion dependence, and rate of RBC transfusion.

Results: Among 320 patients, 175 of 215 (81%) and 201 of 217 (93%) patients randomized to MMB or BAT, respectively, completed the 24 week double blind phase with MMB were thrombocytopenia (7%) and anemia (13%). Grade ≥3 infections occurred in 7% of MMB and 3% of RUX patients. Treatment emergent peripheral neuropathy occurred in 22 (10%) of MMB (all Grade ≤2) and 10 (5%) of RUX (9 Grade ≤2, 1 Grade 3) patients in the double blind phase, none discontinuing study drug for this problem. Overall, adverse events led to study drug discontinuation in 13% of MMB and 6% of RUX patients in double blind phase. Summary/Conclusions: In patients with JAKi naïve myelofibrosis, 24 weeks of momelotinib is non-inferior to ruxolitinib for spleen response but not for symptom response. Momelotinib treatment is associated with a reduced transfusion requirement. NCT01969838

S786 PHASE 3 RANDOMIZED TRIAL OF MOMELOTINIB VERSUS BEST AVAILABLE THERAPY IN PATIENTS WITH MYELOFIBROSIS PREVIOUSLY TREATED WITH RUXOLITINIB: RESULTS OF THE SIMPLIFY-2 STUDY

S. Verstovsek1, A.M. Vannucchi2, U. Platzecker3, V. Gupta4, D. Lavio1, F. Passamonti5, F. F. Dong6, J. Kawashima1, J.D. Maltez10, J.-J. Kladjian11, G.N. Harrison11, 1University of Texas MD Anderson Cancer Center, Houston, United States, 2University of Florence, Florence, Italy, 3Medizinische Fakultät Carl Gustav Carus, Technische Universität, Dresden, Germany, 4Hospital Clinic, University of Barcelona, Barcelona, Spain, 5Princess Margaret Cancer Centre, University of Toronto, Toronto, Canada, 6Hadasah-Hebrew University Medical Center, Jerusalem, Israel, 7University of Insubria, Varese, Italy, 8Emory University School of Medicine, Atlanta, 9Gilead Sciences, Inc., Foster City, United States, 10Saint-Louis Hospital (APHP) and Paris Diderot University, Paris, France, 11Guy’s and St. Thomas’ NHS Foundation Trust, London, United Kingdom

Methods: Eligibility included PMF or post-PV/ET MF; Dynamic International Prognostic Scoring System (DIPSS) high risk or intermediate-2 risk, or intermediate-1 risk associated with symptomatic splenomegaly; currently or previously treated with ruxolitinib for at least 28 days who either required transfusions or dose reduction to <20 mg BID with at least one of Grade ≥3 thrombocytopenia, anemia, or bleed; palpable spleen ≥5cm; and No Grade ≥2 peripheral neuropathy. Informed consent was obtained. Stratification was by transfusion dependence and baseline TSS (modified MPN-SAF Total Symptom Score >0) ≥18 or <18. Patients were randomized 2:1 to 24 weeks of open-label MMB 200 mg QD or BAT. Assessments included spleen volume by MRI, and patient-reported symptoms using a daily eDiary for TSS. Primary endpoint was spleen response rate at 24 weeks (SRR>24% ≥35% reduction from baseline). Secondary endpoints, evaluated sequentially, were rates of TSS response (TSS RR> ≥50% reduction from baseline), RBC transfusion independence and RBC transfusion dependence (TD). Results: 73 of 104 (70%) and 40 of 52 (77%) patients receiving MMB or BAT, respectively, completed the 24 week randomized treatment phase. BAT for 80% of patients included ruxolitinib, and 27% of patients were on ruxolitinib in combination with other drugs. Efficacy results are in Table 1. The most common treatment-emergent adverse events in MMB patients were diarrhea (33%), asthenia (19%), nausea (19%), and cough (17%), and in BAT patients, asthenia (21%), fatigue (19%), anemia (15%), diarrhea (15%), and abdominal pain (15%); the most common Grade ≥3 adverse events in MMB patients were anemia (6%) and thrombocytopenia (5%), and in BAT patients, anemia (13%), thrombocytopenia (5%), and abdominal pain (6%). Treatment emergent peripheral neuropathy occurred in 11 (11%) of MMB (1 Grade 3) and in no BAT patients; MMB was discontinued in 3 patients due to neuropathy.

3b-values nominally significant.
Summary/Conclusions: In previously ruxolitinib-treated patients with myelofibrosis, 24 weeks of momelotinib was not superior to best available therapy for splenic response, but significantly better in improving disease related symptoms and transfusion independence. NCT02101268.

S787 MOLECULAR RESPONSE TO HYDROXYUREA AND ROPEGINTERFERON ALFA-2B IN THE PROUD-PV RANDOMIZED PHASE 3 TRIAL

J.-J. Kiladjian1,2,3,*, B. Cassinat2, J. Soret-Dulphy1, E. Verger1, L. Roy1, J. Rey6, N. Masliah1, B. Grohmann-Iszyz, Cl. Klaade7, H. Gisslinger6
1Clinical Investigations Center, Hopital Saint-Louis, 2INSERM UMRs-1131, 3Paris Diderot University, 4Hopital Saint-Louis, Paris, 5Hopital Henri Mondor, Creteil, 6Institut universitaire du Caire, 7Nantes, France. AOP Orphan Pharmaceuticals AG, 8Medical University of Vienna, Vienna, France

Background: Interferon alfa (IFNa) has been successfully used to treat myelo proliferative neoplasms (MPN) for many years and several phase 2 studies have demonstrated high rates of hematological and molecular responses assessed by the quantification of mutant JAK2 allele burden (%JAK2V617F). In peripheral blood, BM clonogenic assays suggest that addition, clonal architecture studies showed that the % of JAK2V617F mutant alleles is an important driver of the clonal architecture. Here we report, for the first time, the molecular response of BM progenitors in patients treated with IFNa and hydroxyurea in a phase 3 study.

Methods: Randomized, controlled, multicenter phase 3 trial comparing efficacy, safety and tolerability of hydroxyurea and Ropeginterferon Alfa-2b in PV pts (NCT01949805). The primary endpoint was non-inferiority of AOP2014 versus HU at 12 months (mos) of therapy in terms of complete hematological response (CHR) according to ELN criteria and normal spleen size. An important secondary endpoint the treatment of %JAK2V617F at 12 mos. No complete MR was achieved at 12 mos, but PMR was observed in 45.6% in the subgroup of French pts (54% males, mean age 55 years) CHR at 12 mos was 40% in pts receiving AOP2014 (n=5) and 50%, in those receiving HU (n=8). %JAK2V617F at baseline in the AOP2014 and HU arms were 39.4% and 46% respectively. In the group of pts enrolled in France, we could study BM progenitors clonogenic potential by cultures with or without Erythropoietin (EPO) at baseline and after 12 months of therapy. The presence of colonies without EPO, namely Endogenous Erythroid Colonies (EECs) is a hallmark of PV. After 14 days, erythroid colonies were enumerated and picked for molecular analyses.

Results: A total of 257 pts were randomized in 13 European countries including 13 pts in France. Non-inferiority of AOP2014 versus HU regarding CHR could be demonstrated in the whole study population (43.1 ± 45.6%). In the subgroup of French pts (54% males, mean age 55 years) CHR at 12 mos was 40% in pts receiving AOP2014 (n=5) and 50%, in those receiving HU (n=8). %JAK2V617F at baseline in the AOP2014 and HU arms were 39.4% and 46% respectively. BM progenitors could be studied in 10/13 French pts, 3 treated with AOP2014 and 7 with HU. AOP2014 treatment induced an important decrease of the proportion of EECs (0% at baseline vs 5% at 12 mos). In addition, clonal architecture studies showed that the % of JAK2V617F mutant colonies decreased before and after treatment profoundly decreased in all AOP2014-treated patients (median decrease 25%). Among HU-treated pts, only 1 experienced a decrease in the % of mutated colonies while mean ratio of mutant versus wild type JAK2 colonies didn’t significantly decrease (from 87% at baseline to 79% after 12 mos)

Summary/Conclusions: In this phase 3 trial comparing Ropeginterferon alfa-2b versus HU, we found a different impact of both drugs on hematopoietic cells. Although both treatment induced a decrease of JAK2 mutant allele burden at 12 mos in peripheral blood, BM clonogenic assays suggest that AOP2014 is able to specifically target JAK2 mutant progenitors, an effect not seen in HU treated pts. Such targeted impact of AOP2014 may account for the strikingly different kinetics in allele burden reduction and suggests that sustained long-term molecular response may only be achieved with IFNa based treatment.

S788 POOLED SURVIVAL ANALYSIS OF MIDOSTAURIN CLINICAL STUDY DATA (D2201+A2213) IN PATIENTS WITH ADVANCED SYSTEMIC MASTOCYTOSIS COMPARED WITH HISTORICAL CONTROLS

A. Reiter1,*, H.C. Klein-Nelemans2, T. George3, C. Akin4, D.J. DeAngelo5, O. Hermine6, F. Awani7, E. Hexner6, M. Mauro6, J. Schwab7, M. Jawhari1, D. Ebert8,9,10,11, N. BerkoVa9, J. Niolat11, A. Huntsman Labed12, K. Hartmann13, H.-P. Horny14, P. Valient15, J. Gollin16
1University Medical Centre Mannheim, Mannheim, Germany, 2University Medical Center Groningen, Groningen, Netherlands, 3University of New Mexico, Albuquerque, 4Brigham and Women’s Hospital, 5Dana-Farber Cancer Institute, Boston, United States, 6University of Paris Descartes, Imagine Institute, Paris, France, 7The Ohio State University Comprehensive Cancer Center, Columbus, 8University of Pennsylvania, Philadelphia, 9Memorial Sloan Kettering Cancer Center, New York, 10Novartis Pharmaceuticals Corporation, East Hanover, United States, 11Novartis Pharma SAS, Rueil-Malmaison, France, 12Novartis Pharma AG, Basel, Switzerland, 13University of Cologne, Cologne, 14Ludwig Maximilians University Munich, Munich, Germany, 15Medical University of Vienna, Vienna, Austria, 16Stanford University School of Medicine, Stanford, United States

Background: Adv/SVM (ie, aggressive SM [ASM], SM with an associated hematologic neoplasm [SM-AHN], and mast cell leukemia [MCL]) comprises rare hematologic neoplasms with a poor prognosis. Kit D816 mutations occur in a majority of patients with advSM. Midostaurin is a multitargeted kinase inhibitor that blocks wild-type and D816V-mutated Kit. Two single-arm phase 2 studies (D2201+A2213) evaluated the safety and efficacy of midostaurin in advSM. Overall, 60% and 69% of patients in D2201 and A2213, respectively, achieved the primary endpoint of complete or partial normalization of SM-related organ damage.

Methods: We compared pooled data from these studies with data from a patient registry to determine the effects of midostaurin on overall survival (OS).

Results: Data from the midostaurin studies, in which patients received midostaurin 100 mg twice daily until progression or toxicity, were pooled. Historical control data were obtained from a contemporary patient registry based at University Medical Centre Mannheim, Germany. Although the primary analysis did not include matching for patient subgroup, analyses were performed to assess whether baseline characteristics affected OS and estimated HR. Propensity scoring was used for supportive analyses to match the patients in the registry. Patients were evaluated for OS based on time from diagnosis to death; patients in the pooled analysis with known dates of diagnosis were included in the primary analysis. A sensitivity analysis to compensate for potential bias in patient selection was conducted using the start date of last treatment to death.

Results: The primary analysis of OS in patients with advSM included 89 patients from the midostaurin pooled analysis for whom the date of diagnosis was available (77% of the entire pooled cohort) and all 46 patients from the German registry who had not been treated with midostaurin. SM subtypes among patients from the pooled analysis and registry were similar: 66% of patients in the pooled cohort and 63% in the registry had an AHN (Table 1). Kit D816 mutations were present in 82% of patients in the pooled analysis and 96% in the registry. More patients in the registry (67%) vs the pooled analysis (42%) were aged >65 y. Median follow-up (time from diagnosis to data cutoff for the analyses) was similar for the 2 patient groups: registry, 54.9 (range, 1.9-150.4) mo and midostaurin, 53.6 (range, 31.6-215) mo. Patients in the midostaurin pooled analysis had a clinically relevant improvement in OS versus historical controls (HR=0.62 [95% CI, 0.39-0.98]; P=0.024; Figure 1). Median OS was 42.8 (95% CI, 31.0-52.9) mo in the pooled analysis versus 24.0 (95% CI, 13.0-39.5) mo in the registry. Multivariate Cox regression analysis after adjusting for covariates was consistent with the primary analysis: HR=0.51 (95% CI, 0.30-0.88); P=0.0147. Data using propensity score for matched pairs (n=44) were also consistent (HR=0.381 [95% CI, 0.169-0.960]; P=0.101). Subgroup analyses of OS showed HR in favor of midostaurin for all subgroups analyzed (all subgroups vs >65 y, Kit D816V status, number of prior therapies [≥1 vs <1], and SM subtype) except MCL. Subgroup analysis data should be interpreted with caution due to the small patient numbers in the German registry. Sensitivity analysis of OS from date last treatment received (pooled analysis, n=115; registry, n=42) was consistent with the main analyses (HR from the multivariate analysis=0.38 [95% CI, 0.22-0.65]; P=0.0004).

Table 1.
Background: Approximately 10% of the children with Down syndrome are diagnosed with transient myeloproliferative disorder (TMD) within the first days of life. Previous studies have shown that TMD patients face an around 20% risk of early death and a 20% to 30% risk to develop myeloid leukemia during the first 4 years of life (ML-DS).

Aims: The aim of the AML-BFM TMD Prevention 2007 trial was to analyze the outcome of patients diagnosed with TMD and to evaluate whether the application of a low-dose cytarabine treatment can prevent the progression to ML-DS.

Methods: The AML-BFM TMD Prevention 2007 trial is a multi-center, non-randomized, historically controlled study. Patients with TMD were prospectively enrolled. They received a low-dose cytarabine treatment (1.5 μg/kg i.c. daily for one week) if they met the following criteria: TMD-related symptoms (e.g., hyperleucocytosis, hepatopathy) at diagnosis, MRD-positivity (FACS≥10⁻³ or qPCR≥10⁻⁴) eight weeks after diagnosis. Patients could receive cytarsabin-treatment up to three weeks in case of failure to respond to the cytarsabin-treatment (morphologic detection of blasts between week four and eight after diagnosis and/or MRD-positivity after treatment in week ten after diagnosis).

Results: Here we report a cohort of 108 patients (male: 60, female: 48) diagnosed with TMD. The median age at diagnosis was 4 days. As common in children with Down syndrome, many of the patients presented with comorbidities (cardiac defects: 68%, other malformations: 15%); 36% were delivered preterm. 45 patients received low-dose cytarabine treatment, 57 patients did not receive this treatment. Overall, patients in this trial do not show a significantly better event-free survival (EFS; 72±4% vs 63±4%, p=0.15) and overall survival (OS; 91±3% vs 85±3%, p=0.15) than the historic control group (n=146). The cumulative incidence (CI) of death was lower, (8±3% vs 15±3%) albeit not significantly (p=0.09). The CI of ML-DS was also similar (19±4% vs 22±4%, p=0.88). Patients that presented with TMD-related clinical symptoms (n=43; symptoms: hyperleucocytosis [WBC>100,000], hepatopathy, ascites, hydrops fetalis) had a tendency for a better EFS (59±8% vs 44±6%, p=0.097), OS (80±6% vs 67±7% p=0.10) and CI of death (20±7% vs 33±7%, p=0.10) than patients with those symptoms in the historic control group (n=45). For the progression to ML-DS there is no significant difference between the two groups (21±7% vs 23±7%, p=0.91). For patients that do not show any of the TMD-related symptoms (n=59), no significant differences were observed regarding EFS (81±5% vs 71±5%, p=0.27), OS (98% vs 93±3%, p=0.16) and CI of ML-DS (19±8% vs 22±4%, p=0.95) compared to patients without these symptoms in the historic control (n=101).

Summary/Conclusions: The consequent treatment with low-dose cytarabine of symptomatic patients results in a trend towards reduced CI of death as compared to the historic control. However, progression to ML-DS remained unchanged suggesting that the treatment with low-dose chemotherapy does not seem to prevent the development of subsequent leukemia in TMD-patients. Therefore, a general preventative chemotherapeutic treatment of children diagnosed with TMD cannot be recommended. However, children with TMD-related symptoms should receive low-dose cytarabine to reduce disease-related mortality.

LOW-DOSE CYTARABINE TREATMENT IN CHILDREN WITH DOWN SYNDROME AND TRANSIENT MYELOPROLIFERATIVE DISORDER TO PREVENT ML-DS: AML-BFM TMD PREVENTION 2007 STUDY

M. Flasinski1, K. Scheible1, M. Zimmermann1, K. Reinhardt2, D. Reinhardt2, C. von Neuhoff2, J.-H. Kusmann1
1Department of Paediatric Haematology and Oncology, Hannover Medical School, Hannover. 2Pediatric Oncology and Hematology, Pediatrics III, University Hospital of Essen, Essen, Germany

Summary/Conclusions: Midostaurin was associated with a 38% lower risk of death vs historical controls. Benefit was generally consistent across key subgroups.

Figure 1.
Background: AML is a heterogeneous disease based on genetic characteristics with impact on prognosis. So, it becomes necessary to treat patients according to risk-adapted therapies.

Aims: To analyze the results of intensive induction and post-remission treatment in 868 patients with the novo AML enrolled into the CETLAM-03 trial between 2003 and 2012 with a prolonged follow-up (results reported at 10 years).

Methods: Patients on day 1 or 2 induction chemotherapy courses of IDICE-G (idarubicin, intermediate cytarabine (IDC), VP-16 and priming with G-CSF) followed by mitoxantrone and IDC as consolidation therapy. Further treatment was assigned according to the CETLAM risk groups as follows: Favorable risk (FR) defined as favorable cytogenetics according to MRC; autologous stem cell transplantation (ASCT) if leukocyte index (LI) is high, defined as patients in CR after a single induction course, <50x10^9/l white blood cells at diagnosis, normal karyotype and absence of FLT3 internal tandem duplication (FLT3-ITD). Next generation sequencing was performed on 42 genes commonly mutated in AML and MDS in 250 patients treated on the RAVVA trial and correlated with OS and EFS. The presence of ASXL1 (p=0.035) and ETV6 (p=0.033) mutations was found to be associated with improved OS. The presence of ASXL1 and ETV6 was associated with a markedly decreased overall survival is consistent with the hypothesis that induction of cell cycle regulator CDKN2A was associated with a notable reduced overall survival risk stratification but also provides insights into the mechanism of action of AZA.

Summary/Conclusions: In this, the largest such study reported, we demonstrated that mutations in CDKN2A, IDH1 and TP53 are associated with worse OS and EFS and that patients with AML not only can inform patient risk stratification but also provides insights into the mechanism of action of AZA.

Background: The fms-like tyrosine kinase 3 internal tandem duplication (FLT3-ITD) mutation is a genetic alteration found in approximately 30% of patients with acute myeloid leukemia (AML). Although most patients with FLT3-ITD AML achieve remission rates similar to those with FLT3 wildtype status with induction chemotherapy regimens; patients with FLT3-ITD have significantly shorter remission durations and increased rates of relapse. Even though allogeneic SCT improves outcomes, patients still have higher rates of relapse compared to patients post FLT3-ITD. Sorafenib(SFB) is a TKI with activity against RAF, VEGF and FLT3-ITD and its use as maintenance therapy after allogeneic SCT has been shown as a promising approach to decrease relapse. Several studies report that SFB maintenance post SCT provides durable complete responses; however, there are also descriptions of sorafenib post SCT triggering acute GVHD, cytopenias, rash and diarrhea.

Aims: To assess the outcomes, including progression free survival (PFS) and overall survival (OS), in patients with FLT3-ITD mutated AML who receive SFB maintenance after allogeneic SCT.

Methods: We analyzed adult patients (age 18+) with a diagnosis of FLT3-ITD mutated AML leukemic clone. Although few data are available, the SFB regimen (323 mg/m^2 daily) is a TKI with activity against RAF, VEGF and FLT3-ITD and its use as maintenance therapy after allogeneic SCT has been shown as a promising approach to decrease relapse. Several studies report that SFB maintenance post SCT provides durable complete responses; however, there are also descriptions of sorafenib post SCT triggering acute GVHD, cytopenias, rash and diarrhea.

Background: Azacitidine (AZA) represents an important therapeutic advance in patients with acute myeloid leukemia (AML) and high risk myelodysplasia (MDS) ineligible for intensive chemotherapy. However disease progression after less than 50% CR with maintenance therapy is a common occurrence regardless of strategy. AZA has been postulated to represent a reservoir of resistant disease but the impact of AZA based therapy on LSC numbers has not been studied. An additional factor limiting its clinical utility is the identification of patients likely to achieve a significant clinical benefit and molecular predictors of outcome would improve the rationalisation of this important new agent.

Aims: We wished to study the impact of AZA based therapy on LSC numbers as well as identify molecular predictors of outcome in patients treated on the recently completed UK Trials Acceleration Programme RAVVA randomised Phase II trial which compared AZA monotherapy with AZA/VOR combination therapy.

Methods: The RAVVA trial randomized 259 adults with AML (n=217) and MDS (n=42) to receive AZA monotherapy (AZA (75 mg/m^2) x 7 days every 28 days) or AZA combined with VOR (300mg/m^2) every 28 days for a minimum of 6 cycles. Next generation sequencing was performed on 42 genes commonly mutated in MDS in 250 patients treated on the RAVVA trial and correlated with response. Separately serial immunophenotypic quantitation of leukemic stem/progenitor cells (LSC) was performed in 44 patients.
characteristics were comparable between groups as presented in Figure 1. Patients were classified by the European Leukemia Net (ELN) classification and 23% in both groups were categorized as adverse risk while 77% were intermediate risk. All patients received myeloablative conditioning and diseases status at SCT was first/second complete remission (CR1/2) with or without count recovery (CRp) in 69% while it was active disease in 31%. PFS at 24 months post SCT was 82% in the maintenance and 45% in control group. CRp: 0.3; 95% CI (0.1-1.3) p=0.1. Overall survival at 24 months was also higher in SFB cases as 100% compared with 60% in control group p=0.035. Only 2 patients relapsed post SCT on SFB maintenance, one with new TP53 mutation at relapse, and other received only <30 days of SFB. However, more than half the patients had disease progression within the control period. The most commonly administered dose was 400 mg daily (5 patients) for 28 days cycle; only 2 patients tolerated higher doses and 6 patients received SFB as 300mg daily or less. There were delays in subsequent cycles in 10 of 12 patients, and the most common reasons for delays included cytopenias, liver function test abnormalities, and fatigue.

Figure 1.
Summary/Conclusions: Sorafenib maintenance is safe and can produce long term durable remissions after allogeneic stem cell transplant in a high risk population with FLT3-ITD mutated AML.

A PHASE 1B STUDY OF THE COMBINATION OF VADASTUXIMAB TALIRINE AND 7+3 INDUCTION THERAPY FOR PATIENTS WITH NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA

M.Y. Levy,1 A.S. Stein,2 S. Vasu,3 M.B. Maris,4 A.S. Advani,5 A.T. Fathi,6 S. Faderi,7 R.B. Walter,8 S.E. Smith,9 J. Yang10 W.B. Donnellan11, B.L. Wood12, F. Ravandi13, E.J. Feldman14, J.L. Voellinger14, H. Erba15 1Baylor University Medical Center, Dallas, TX, 2Gehr Family Center for Leukemia Research - City of Hope, Duarte, CA, 3Ohio State University Comprehensive Cancer Center, Columbus, OH, 4Colorado Blood Cancer Institute, Denver, CO, 5Cleveland Clinic, Cleveland, OH, 6Massachusetts General Hospital, Boston, MA, 7John Theurer Cancer Center, Hackensack, NJ, 8Fred Hutchinson Cancer Research Center, Seattle, WA, 9Loyola University Medical Center, Maywood, IL, 10Karmanos Cancer Institute, Detroit, MI, 11Sarah Cannon Research Institute, Nashville, TN, 12University of Washington Medical Center, Seattle, WA, 13MD Anderson Cancer Center, Houston, TX, 14Seattle Genetics, Inc., Bothell, WA, 15University of Alabama-Birmingham, Birmingham, AL, United States

Background: For patients <65 yrs with newly diagnosed AML, standard induction treatment is continuous infusion of cytarabine for 7 days and an anthracycline for 3 days (7+3). Although a high percentage of patients achieve a CR by morphologic criteria, some requiring a 2nd induction, many are resistant to treatment or achieve a morphologic CR with evidence of minimal residual disease (MRD). Vadastuximab talirine (SGN-CD33A; 33A) is a CD33-directed antibody conjugated to 2 molecules of a pyrrolobenzodiazepine dimer. Combining 33A with 7+3 could result in enhanced and deeper (MRD negative) remissions, resulting in reduced relapse rates and improved OS. Aims: This phase 1b study (NCT02326584) evaluated the safety and antileukemic activity of escalating doses of 33A on 2 schedules: split dose (D1 and 4) or single dose (D1) with 7+3 induction therapy (cytarabine 100 mg/m² and daunorubicin 60 mg/m²). Methods: AML patients must be eligible for induction therapy. Response assessments occur on D15 and 28. Second induction and post-remission therapies were per investigator choice and did not include additional 33A. MRD was assessed centrally by bone marrow exam by a multiparametric flow at D15 and D28. Results: Split-dose cohort: 42 patients (median age 45.5 yrs [range, 18-65]) were treated with 33A on D1 and 4 (10+10 [n=4] or 20+10 [n=38] mcg/kg) with 7+3. Most patients had intermediate (50%) or adverse (36%) cytogenetic risk. 19% had secondary AML. 2 patients had hematologic DLTs (lack of recovery of platelets [25K] and/or ANC [500] by D42) and 20+10 mcg/kg was determined to be MTD. The median time to count recovery from D1 of therapy in patients who achieved CR/CRi was 4.9 wks for ANC (≥1K) and 5.1 wks for platelets (≥100K). No non-hematologic TEAEs ≥G3 were reported in >10% of patients; non-hematologic TEAEs of any grade occurring in ≥25% of patients were nau-sea (62%), diarrhea, and constipation (38% each). Of the 42 efficacy evaluable (EE) patients, best responses included 25 CR (60%), 7 CRi (17%), and 5 morphologic leukemia-free state (mLFS; 12%) with a CR+CRi (CRc) rate of 76%; 23 of 25 (94%) responses were achieved in the 1st cycle. Of the patients with blast clearance (CR+CRi+mLFS), 73% (27/37) achieved MRD negative status. Single-dose cohort: To date, 25 patients (median age 58 yrs [range, 38-65]) were treated with 33A on D1 only (30 [n=14] or 40 [n=11] mcg/kg) with 7+3. Patients had intermediate (48%) or adverse (36%) cytogenetic risk. 16% had secondary AML. The median time to count recovery from D1 of therapy was 4.1 wks for ANC (≥1K) and 5.9 wks for platelets (≥100K) in patients who achieved CR/CRi. Four patients had hematologic DLTs, 1 at 30 and 3 at 40 mcg/kg. Non-hematologic TEAEs were consistent with those seen in the D1 and 4 schedule. Of the 24 EE patients, best responses included 12 CR (50%), 6 CRi (25%), and 3 mLFS (13%) with a CRc rate of 75%, achieved in 1st cycle. Of the evaluable patients with blast clearance, 89% (17/19) achieved MRD negative status. The CRc rate at the 40 mcg/kg dose level was 91% (10/11); all 11 patients had blast clearance and 90% (9/10) of evaluable patients achieved MRD negative status. Across schedules (N=67), the CRc rate was 76%; 79% (44/56) of evaluable patients with blast clearance achieved MRD negativity. The 30- and 60-day mortality rates were 1% and 7%, respectively. Median OS is not reached for either schedule and 52 patients (78%) were alive at the time of analysis. Summary/Conclusions: 33A can be safely combined with 7+3 with acceptable count recovery in this population at the doses and schedules studied. Extramedullary AEs, including hepatotoxicity, and induction mortality rates were similar to reported rates for 7+3 alone in this AML population. A high remission rate with the 1st induction cycle was observed, the majority of which were MRD negative.

Background: Research has recently highlighted the importance of healthy gut microbiota in the prevention of graft-versus-host disease (GVHD). Gut decontamination and the use of broad-spectrum antibiotics have led to the loss of natural microbiota diversity and the overgrowth of opportunistic pathogens with emerging antimicrobial resistance. However, the role of multi-drug resistant by VRE, 1% by MRSA, 43% by extended-spectrum β-lactamase (ESBL)-producing Enterobacteriaceae, 27% by carbapenem-resistant Enterobacteriaceae (CRE), 9% by MDR-GNB gut colonization (hazard ratio 2.26; 95% CI, 1.05-4.83, P=0.03). Moreover, MDR-GNB colonized patients had significantly more gas-

Aims: Since 2010, patients who lacked a HLA-identical donor have been transplanted from a haploidentical donor in our two Italian institutions. In this large series of patients we aim to verify the real degree of antigen disparity between donor and recipient and whether it impacts on transplantation outcomes.

Methods: All haploidentical transplants performed in two Italian institutions from August 2010 to July 2016 (n = 318) were included. All patients received a myeloablative regimen (MA) followed by unmanipulated bone marrow and high dose post-transplant cyclophosphamide (PT-CY), combined with cyclosporine and mycophenolate. Donors and recipients were typed until 2015, using DNA method (SSO and SBT) for HLA A, B, C, DRB1, DQ and DP at a high resolution level, as defined by EFI standards and by NGS at allelic level in 2016 for the same loci. When applicable (72.3% of patients) members of the immediate family were typed to definitively establish HLA genotype and haplotype identity. Differences in HLA matching were calculated by HVG direction. We evaluated overall survival (OS) and non-relapse mortality (NRM) according to the amount of overall mismatches; also, we analyzed cumulative incidence of grade II – IV aGVHD, moderate-severe chronic GvHD and relapse according to the degree of HLA mismatches in the GvH direction and grade I – III of GvHD in the HvG direction. For analysis purpose, the whole patient population was divided into 2 groups: 0–1 antigen mismatches versus 3–4 antigen mismatches. The same distinction was maintained when analyzing only GVH or HVG directed mismatches. Acute GVHD was calculated at day 100, the other parameters were calculated at a cutoff from 2 year (second year of follow up). OS was estimated using the Kaplan-Meier approach while cumulative incidence was calculated for aGvHD, cGvHD, relapse and NRM.

Results: Median age of patients was 48 years (17-74). Diagnoses included acute myeloid leukemia (130), acute lymphoblastic leukemia (64), lymphoid and myeloid neoplasms (43), myelodysplastic syndrome (33). 144 patients (45%) were transplanted in advanced phase of disease. With a median follow up of 562 days (range 6-2241 days), 2-year OS was 55.7%. Concerning the proportion of “true” haploidentical D/R pairs, 231 out of 318 (72%) couples showed 4 mismatched loci at HLA A, B, C and HLA DRB1 loci. Neither OS nor NRM showed significant correlation with the degree of overall mismatches at 2 years (0-2 mm: 54.2% vs 3-4 mm:58.8%, p=0.58 and 0-2 mm:18.2% vs 3-4 mm:19.1%, p=0.93, respectively). Considering only GVH directed mismatches, no difference was highlighted between low or high HLA mismatch burden in cumulative incidence of aGVHD (12.6% vs 23.9%, p=0.13), cGVHD at 1 year (12.2% vs 14.8%, p=0.84) and relapse (33.3% vs 24%, p=0.26). In this series graft rejection rate was 6.6%; no correlation was observed with the amount of HLA mismatch in the HvG direction.

Summary/Conclusions: In this series, about one third of haploidentical donor/recipient pairs differ for less than 4/8 HLA antigens. Furthermore, in the setting of a MA conditioning with PT-CY the real degree of HLA mismatch observed had no impact on OS, NRM, CI of Relapse and acute and chronic GvHD.

S797 CYCLOPHOSPHAMIDE VERSUS ETOPOSIDE IN COMBINATION WITH TOTAL BODY IRRADIATION AS CONDITIONING FOR ADULTS WITH PH-ALLENT UNDERGOING ALLO-HCT. A STUDY FROM THE ACUTE LEUKEMIA WORKING PARTY OF THE EBMT

1Hematologie, Cliniques Universitaires St-Luc, Bruxelles, Belgium, 2Hematology, Hôpital Saint-Antoine, 3Acute Leukemia Working Party of the EBMT, 4INSERM UMR 938, 5Université Pierre et Marie Curie, Paris, 6CHU Bordeaux, Hôpital Haut-Leveque, Pessac, France, 7Hematology, Hemostasis, Oncology and Stem Cell Transplantation, Hannover Medical School, Hannover, Germany, 8Stem Cell Transplantation Unit, UHC Comprehensive Cancer Center, Helsinki, Finland, 9Hematology, Centre Hospitalier Lyon Sud, Lyon, France, 10Transplantation et Thérapie cellulaire, Institut Paoli Calmette, Marseille, 11CHU Lille, 12LIRIC INSERM U995, 13Université Lille2, Lille, France, 14University Hospital Gasthuisberg, Leuven, Belgium, 15Hematologica-Hematotherapia, Hospital U. Marqués de Valdecilla, Santander, Spain, 16Hematologie, Erasmus MC Cancer Institute, Rotterdam, Netherlands, 17Hematology-Immunology-Oncology, University of Freiburg, Freiburg, Germany, 18Hematology, Hospital Clinic, Barcelona, Spain, 19Chaim Sheba Medical Center, Tel-Hashomer, Israel

Background: High-risk acute myeloid leukemia (AML) is mainly defined by the presence of determined poor-risk cytogenetic abnormalities and is a standard indication for allogeneic stem cell transplantation (SCT). Nevertheless, high-risk AML is a very heterogeneous group including several subgroups with different levels of prognostic impact. Deletion 5q or monosomy 5 (5q-) has been part of the high-risk group of AML for many years. SCT seems to improve their outcome but again the real high-risk cytogenetic features on survival have never been thoroughly studied.

Aims: To evaluate the role of SCT in 5q- AML with additional cytogenetic abnormalities such as complex karyotype (CK), monosomal karyotype (MK), monosomy 7 (-7), or 1p abnormalities (ab(-1p)).

Patients: 144 patients (45%) were included and the subsets of patients with 5q- reported to the EBMT registry as having their first SCT between 2000 and 2015.

Results: Five hundred and one pts, 21% of them with secondary AML, have been included. Median age at SCT was 55 year-old (range, 18-75) and median follow-up was 21 months (range, 2-173). At time of SCT, 338 pts (67%) were in first remission (CR1), 21 pts (5%) were in subsequent remission and 42 (28%) had active disease. Two hundred seventy-seven pts (55%) were transplanted from an unrelated donor (UD) and 224 from a sibling donor. A myeloablative conditioning (MAC) was administered in 45% of the pts and a reduced-intensity conditioning (RIC) in 55% of them. The 2-year probabilities of overall survival (OS) and treatment-related mortality (TRM) were 27% and 20%, respectively. The 2-year probability of treatment-related mortality (TRM) was 20%. The cumulative incidence of grade II-IV graft-versus-host disease (GVHD) was 29% and the 2-year cumulative incidence of chronic GVHD was 32%.
27%. The main cause of death was disease-related. In multivariate analysis, active disease correlated strongly with worse OS, LFS and NRM. The other factors influencing outcomes were UD with increased NRM, and age with decreased OS and LFS. Based on the frequencies of the different additional cytogenetic abnormalities, we identified 4 groups within our cohort. Group 1 (None) included 47 pts with -5/5q- but without CK, MK or abn(17p). Group 2 (CK) included pts with -5/5q- and abn(17p) (N=90). Group 3 (MK) included 169 pts with -5/5q- and MK but no abn(17p). Finally, group 4 (17p) included pts with -5/5q- and abn(17p) (N=193). The 4 groups were quite similar in terms of characteristic. The 2-year probability of LFS was 39% for group 1, 25% for group 2, 20% for group 3 and only 13% for group 4 (p=0.001). NRM was similar across the groups. In multivariate analysis, factors associated with worse OS and LFS were active disease, age, MK and abn(17p). The corresponding 2-year probability of GvHD and relapse-free survival was 27% for group 1, 17% for group 2, 14% for group 3 and 7% for group 4 (Figure 1).

Background: T-cell acute lymphoblastic leukemia/lymphoma (T-ALL/LBL) accounts for 10% to 15% of newly diagnosed cases of childhood acute lymphoblastic leukemia (ALL), arising from the malignant transformation of hematopoietic progenitors primed toward T cell development, as result of a multistep oncogenic process. However, since the prognostic significance of these genetic alterations in pediatric T-ALL is not clear, genetic basis which contributes aggressive phenotype or progression of pediatric T-ALL is still to be elucidated.

Alma; To discover driver genetic events, which involved in the aggressive phenotype of pediatric T-ALL and to identify its novel prognostic markers, we performed integrated genetic analysis in a large cohort of T-ALL case.

Methods: Our cohorts included samples from Tokyo Children's Cancer Study Group (TCCSG) and Japan Association of Childhood Leukemia Study (JACLS). Whole transcriptome sequencing (WTS) was performed in 123 cases. Whole transcriptome sequencing (WTS) was performed in 123 cases. Results: Representative recurrent fusion genes were as follows, SIL-TAL1 (n=25), MLL-ENL (n=5), PICALM-MLLT10 (n=5), and NUP214-ABL1 (n=2). Intriguingly, novel recurrent in-frame PU.1 fusions (STM11-PU.1 n=2; TCF7-PU.1 n=5) were detected, and RT-PCR analysis in additional 60 cases revealed other 2 TCF7-PU.1 fusions. Thus, PU.1 fusions accounted for 4% of pediatric T-ALL/LBL. Expression data of WTS revealed cases with PU.1 fusion showed significantly higher expression of PU.1 compared to cases without PU.1 fusion, implicating that aberrant high expression of PU.1 involved in leukemogenesis. Using consecutive two-step unsupervised consensus clustering, we obtained 5 stable clusters. Among these, 4 clusters largely recapitulated distinct T-ALL subtypes characterized in previous studies by an early T-cell precursor (ETP) signature (ETP-ALL), 2 clusters of high TAL1 expression (TAL1-RA and -RB-ALL), and mutually exclusive expression of TLX1, and TLX3 (TLX-related-ALL). However, the remaining one was newly identified and exclusively consisted of the 7 PU.1 fusion-positive cases. Compared to ETP-ALL, these PU.1 fusion cases typically showed a reduced expression of the phase I genes implicated in early T-cell development, except for PU.1, which was ectopically up-regulated by the relevant gene fusions. All cases with PU.1 fusion were grouped into PU.1 high cluster. Moreover, PU.1 high cluster had distinct genetic features with mutations of transcription factors, such as GATA3, RUNX1, and ETV6. Of note, significant poor outcome was confirmed by multivariate analysis in cases with PU.1 high cluster (p=0.048). Consistently, we defined PU.1 overexpression cases as outliers of PU.1 expression, which resulting in extremely poor prognosis (3-year OS 21%, log-rank p=6.9 × 10^-7).

Summary/Conclusions: PU.1 fusions expressing cells expanded and they remained at an immature stage, implicating a potential leukemogenic activity of these fusions. Not only the cases with PU.1 fusions, but also the cases with
high PU.1 expression without fusions showed extremely poor prognosis, suggest-
ging the prognostic value of aberrant PU.1 expression in pre-B-ALL. Although it remains unclear, why cases with PU.1 fusions/PU.1 expression have a poor prognosis, our results indicate that these cases are genetically distinct subgroup from other pediatric T-ALL.

**PROGNOSTIC IMPACT OF ADDITIONAL MOLECULAR LESIONS IN PH+ ACUTE LYMPHBLASTIC LEUKEMIA**

A.L. Fedullo1, M. Messina 1, A. Vitale1, L. Elia1, A. Picciocchio2, V. Gianfelici1, A. Laureti1, A. Guarini,1 S. Chiaretti1,1, R. Foà1

1Hematology, Department of Cellular Biotechnology and Hematology, Sapienza University, 2GIMEMA Data Center, Rome, Italy

Background: The outcome of Ph+ acute lymphoblastic leukemia (Ph+ ALL) is drastically improved since the introduction of tyrosine kinase inhibitors (TKI). At present however, well-defined prognostic markers, beyond the moni-
toring of minimal residual disease (MRD) during follow-up and to a lesser extent IKZF1 deletions, are lacking.

Aims: To identify genomic lesions of prognostic value, we evaluated copy num-
ber aberrations (CNA) by SNP arrays, confirmed them by multiplex ligation-
dependent probe amplification (MLPA) and we set up a droplet digital PCR (ddPCR) assays for additional lesions. Furthermore, we correlated the lesions identified with MRD monitoring, outcome and biological features, such as type of fusion protein (p190 or p210). Finally, in a subset of patients gene expression profiling (GEP) was carried out.

Methods: Genomic DNA of 116 newly diagnosed adult Ph+ ALL patients enrolled in 4 consecutive GIMEMA-trials, namely 2010B, 0904, 1205 and 1509, was evaluated. All the trials were based on an induction with steroids and TKI, the first 2 with imatinib and the remaining with dasatinib. For CNA, the Cytoscan HD Arrays (Affymetrix, Santa Clara, CA) were used. The lesions were confirmed by MLPA on all samples using the Salsa MLPA P335-43 ALL-
IKZF1 kit (MRC-Holland, Amsterdam, The Netherlands), ddPCR was used to validate lesions targeting MEF2C. In 42 cases, GEP experiments were per-
fomed using the HGU133 Plus 2.0 gene chips (Affymetrix, Santa Clara, CA).

Results: We found a similar load and type of lesions across the 4 trials, one of which included elderly. The majority of lesions targeted IKZF1 (84%), PAX5 (36%) and CDKN2A/B (32%). In our cohort, IKZF1 deletions alone did not affect com-
plete remission (CR), however, combined (CR) achieving disease-free survival (DFS) was less for patients harboring CDKN2A/B and PAX5 deletions had a significant inferior outcome (p=0.004, p=0.003 respectively). In line with this, a DFS was observed for the so-called “IKZF1 plus” cases, i.e. concomitant deletions of IKZF1 and CDKN2A/B and/or PAX5 (46% vs 24% at 36 months, p=0.005). MLPA con-
firmed the incidence of these deletions and allowed the study of IKZF1 isoforms. Among IKZF1 deleted cases, patients carrying the Δ7 isoform (25%) had a worse DFS (p=0.02) than patients harboring other IKZF1 isoforms. Importantly, SNP arrays highlighted novel genomic lesions targeting MEF2C in 13% of cases, which were associated to the achievement of a CR (p=0.05) and had a significa-
nt impact on DFS (62% vs 32% at 36 months, p=0.02). The association with CR was not affected by the trial (p=0.76) or the TKI used (p=0.57). This result was confirmed by ddPCR. Unsupervised hierarchical clustering of GEP experi-
ments identified 3 subgroups: the first comprised mainly patients who reached a 
CR, the second one the patients who had IKZF1 alone, and the last one comprised patients with Δ7 deletions. Analysis showed an overexpression of genes involved in cell communication and protein modification process in PAX5 deleted cases, suggesting that these genes could be contributing factors in BCR/ABL1-driven leukemia.

Summary/Conclusions: In adult Ph+ ALL, IKZF1 deletions have a prognostic impact similar to other lesions. Among IKZF1 deletions, only the Δ7 deletion has a deleterious effect. MEF2C lesions carry prognostic implica-
tions, being significantly associated with a better prognosis. This study paves the way to design a prognostic model for adult Ph+ ALL that includes these findings and more conventional features, in order to better stratify patients at diagnosis and to further optimize treatment.

**S801**

**MULTICENTER VALIDATION OF STANDARDIZED NGS ASSAYS FOR RERARRANGED IG / TR MARKER DETECTION IN ACUTE LYMPHBLASTIC LEUKEMIA – A REPORT OF THE EUROCLONALITY-NGS CONSORTIUM**

1Cancer Institute, UCL, London, United Kingdom, 2Faculty of Medicine, Alexandria University, Alexandria, Egypt, 3Cancer Trial Centre, Bristol Cancer Institute, QMUL, London, 4Royal Hallamshire Hospital, Sheffield, 5University Hospitals Bristol NHS Trust, Bristol, 6Department of Haematology, Cancer Institute, UCL, London, United Kingdom

Background: Amplicon-based next generation sequencing (NGS) of immunoglobulin (IG) and T-cell receptor (TR) gene rearrangements can be used to identify suitable markers for subsequent quantification of minimal resid-
ual disease (MRD) in acute lymphoblastic leukemia (ALL). Within the Euro-
clonality-NGS Consortium we established and validated a standardized quality controlled amplicon-based NGS application to detect clonally rearranged IGH, IGK, TRB, TRG and TRD genes in lymphoid disorders.

Aim: To test EuroClonality TR IG / TR NGS panel within an international multi-laboratory pilot for their suitability to identify clonal markers in ALL in diagnosis, and 2) to compare these NGS results with conventional Sanger sequenc-
ing (SS) of Genescan or Heteroduplex peaks/bands local multiplex PCRs

Methods: Within the EuroClonality-NGS Consortium, V, D, and J gene-spe-
cific primers targeting IGH, IGK, TRB, TRG, TRD sequences were tested with 6 different international laboratories, all members of the EU-CLONALITY network. They were spiked into all samples for calculation of clonotype copy numbers. A standard patient marker quality control (QC) DNA was used to monitor inter- and intra-
lab NGS reproducibility. Results of NGS based marker identification were com-
pared to results of routine SS results.

Results: Fifty ALLs (29 BCP-ALL and 21 T-ALL) were analysed. A total of 10 libraries were deep sequenced, leading to 47 high quality reads (n=9.2 Mib). Pre-processing, identification and immunogenetic annotation of target sequences, quality control and copy number calculations were per-
formed with ARRES/Intergate, using IMGT germine sequences – further analyses and verifications were performed with Vidi/ and IMGT/V-QUEST. Over 70% of all ALL NGS primer sets, and 228/339 (68%) clonal sequences were concordant between both methods. NGS iden-
tified additional clonal rearrangements in 86 (26%) libraries, whereas 23 (7%) clonal markers were only detected by SS. NGS primers covered possible IG/IGK/IGL rearrangements, and 116 (34%) TCR gene rearrangements, and enabled sequencing of bi-allelic rearrangements and weak PCR products. Currently discrepant cases are analysed in more detail using allele-specific PCR assays. Assay performance was analysed by standardized eval-
uation of QC samples and showed high intra- and inter-lab consistency with-
out practically significant differences between the labs.

Summary/Conclusions: The IG / TR NGS panel, as established by the Euro-
clonality-NGS Consortium, allows for quality controlled high-throughput detec-
tion of clonal IG / TR rearrangements in ALL. Compared to low throughput meth-
ods more clonal MRD markers are identified, sensitivity is increased, process-
time is reduced and labour intensive conventional methods to resolve mixed 
sequences in case of bi-allelic rearrangements or background are avoided.

**S802**

**POST-INDUCTION MRD PREDICTS HIGH RELAPSE RISK FOLLOWING REDUCED INTENSITY CONDITIONED ALLOGENIC STEM CELL TRANSPLANTATION: A RETROSPECTIVE STUDY OF ADULT ALL (UKALL14.ISRCTN 66543117)**

1Cancer Institute, UCL, London, United Kingdom, 2Faculty of Medicine, Alexandria University, Alexandria, Egypt, 3Cancer Trial Centre, Bristol Cancer Institute, QMUL, London, 4Royal Hallamshire Hospital, Sheffield, 5University Hospitals Bristol NHS Trust, Bristol, 6Department of Haematology, Cancer Institute, UCL, London, United Kingdom

Background: High-risk adult acute lymphoblastic leukaemia (ALL) patients are presented with high relapse risk following post-remission con-
ditioned allogeneic stem cell transplantation (micro- or mini-CIT). In a recent retrospective study of 63 patients, an association was identified between the risk of relapse and the occurrence of minimal residual disease (MRD) at post-transplant day 42 (PTD). We demon-
strated that patients with high-risk MRD status at this time point were at high risk of relapse. In this study, high-risk MRD status was defined as MRD

Results: In a recent retrospective study of 63 patients, we identified the occur-
dence of high-risk MRD status at the timepoint of PTD42 as a statistically sig-
ificant independent predictor of high-risk relapse.

Summary/Conclusions: High-risk MRD status at PTD42 is an independent pre-
dictor of high-risk relapse following reduced intensity conditioned allogeneic stem cell transplantation.
Background: Reduced intensity conditioned allogeneic haematopoietic stem cell transplant (RICalloHCT) enables HCT to be performed in older patients. The UK NCRI UKALL14 study of adult acute lymphoblastic leukaemia (ALL) considers patients ≥41 years “high risk” and recommends a RICalloHCT where there are high quality donors. Other “high risk” factors are high WBC at presentation, t(9;22), t(4,11), hypodiploid/near triploid, complex karyotype and positive minimal residual disease (MRD) after completing induction therapy. The presence of MRD at this time-point predicts poor outcome after conventional chemotherapy. There is evidence that myeloablative alloHCT can overcome this, but the benefit of RICalloHCT is uncertain.

Aims: To determine whether RICalloHCT mitigates the high relapse risk predicted by MRD positivity after induction therapy.

Methods: Protocol treatment: patients receive a steroid pre-phase before 2 cycles of induction chemotherapy. At the end of induction, patients are assigned subsequent therapy on the basis of risk. All patients over 41 years are allocated RICalloHCT, conditioned with fludarabine, melphalan and alemtuzumab. Post HCT, escalating doses of donor lymphocyte infusions were given for T-cell mixed chimerism +/- MRD persistence or relapse. MRD assessment: BCR/ABL1 or Ig/TCR MRD was assessed and analysed per EuroMRD guidelines. MRD is negative (undetectable with an assay quantitative range ≥5x10^-4) or less, positive (≥1x10^-4), positive outside quantitative range (POQR)(<1x10^-4) or indeterminate (undetectable but assay quantitative range ≥5x10^-4). Patients with indeterminate MRD were excluded from this analysis.

Results: There are 736 patients randomised to date, of whom 184 received a RICalloHCT, of these, 115 had analysable MRD. The following Table 1 shows patient characteristics.

### Table 1.

</table>

At 2 years post transplant, overall survival (OS) was 63.1% in the 115 patients with evaluable MRD and 62.7% in the 184 patients receiving RICalloHCT; event free survival (EFS) was 55.2% and 55.9% respectively. By contrast, in the 38 of 115 patients with positive MRD after induction, OS and EFS were 40.6% and 28.4% respectively. Twenty eight of the 115 patients relapsed, with a 2 year actuarial relapse risk of 31.5% (22.2-43.5). We assessed the association of the following factors; age, sex, immunophenotype, presenting WBC, BCR/ABL1, other cytogenetics, post-induction MRD and donor type with the risk of relapse. Among this population of high risk patients, post-induction MRD was the only independent prognostic factor for relapse (univariable HR: 3.82 (1.59-9.16), p < 0.001 (see Figure 1) and multivariable HR: 3.82 (1.59–9.16), p = 0.001 (see Figure 1) and multivariable HR: 3.82 (1.59–9.16), p = 0.003). The relapse rate of the MRD+ patients was 57.2% at 2 years post HCT.

Figure 1.

Summary/Conclusions: The 2-year OS of 62.5% in UKALL14 participants over 41 years old after RICalloHCT is greater than would be expected with chemotherapy alone. However, MRD positivity after induction is associated with significantly lower OS, EFS and a higher risk of relapse, which is not abrogated by RICalloHCT.

T-CELL RECEPTOR B REPERTOIRE CHARACTERISTICS IN RELAPSED/REFRACTORY B-CELL PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA ON BLINATUMOMAB TREATMENT

H. Knecht1,2, M. Kotrova1,2,* T. Reigl3, A. Krejci3, D. Herrmann2, M. Schwarz2, V. Bystyr3, N. Darzentas3, M. Brüggemann2

1contributed equally, 2Department of internal medicine II, Laboratory for Hematological Diagnostics, University Hospital Schleswig-Holstein, Kiel, Germany, 3Central European Institute of Technology, Brno, Czech Republic

Background: Blinatumomab (Blin) is a bispecific monoclonal antibody, activating autologous effector T-cells and redirecting them against CD19-positive malignant cells. This leads to polyclonal effector T-cell expansion which is the necessary component of its antitumour mechanism. Recent reports indicated promising antitumour activity of Blin in relapsed/refractory (rr) B-cell precursor acute lymphoblastic leukemia (BCP-ALL). However, approximately half of these patients do not achieve minimal residual disease (MRD) response. Thanks to recent advances in next generation sequencing (NGS) of immunoglobulin and T-cell receptor gene rearrangements, an in-depth and comprehensive evaluation of expanded T-cell repertoire on Blin treatment is now possible.

**Aims:** To compare the differences in TRB repertoire diversity and composition between two groups of patients with rr ALL: 1) responders: reaching MRD negativity at the latest at day 29 of 1. Blin cycle (C1D29), and 2) persisters: with quantifiable MRD positivity (>0.01%) at C1D29, or with MRD >1% at cycle 1 day 15 (C1D15) if C1D29 sample is not available.

**Methods:** We used NGS to investigate TRB repertoire in bone marrow samples (114x at time of screening (scr), 74x C1D15, 58x C1D29) of 114 rr Ph-negative BCP-ALL patients (median age: persisters 47; responders 42; p-value=0.81). Patients received Blinatumomab within the phase II trial (MT103-211). Sequencing libraries were prepared using 100ng of DNA via 2-step PCR and sequenced on the Illumina MiSeq (2 x 250bp) with a median coverage of 117,563 reads (range 59,512 – 447,767 reads) per sample. In the first PCR virtually all TRB rearrangements present in the investigated sample were amplified using universal V(D)- and J-regions primers. In the second step, sequencing adaptors and sample-specific barcodes were added. Annotation of V(D)- and J-regions of TRB sequences was performed using ARResT/Interrogate (Bystry, Bioinformatics, 2016). Diversity of TRB repertoire within patient groups and time points was expressed as the Shannon index, using the R-package vegan. Analysis of variance was employed to assess statistically significant differences in diversity between groups and time points.

**Results:** Diversity of TRB repertoire (Figure 1) was significantly higher in responders at time of scr (p=0.02) and at C1D29 (p=5.47E-6). Patients in the persisters group had significantly higher blast counts, which is in accordance with previously published data (Topp, The Lancet Oncology, 2015). The increase of diversity between scr and C1D29 of Blinatumomab treatment was sharp and highly significant in responders (p=3.96E-6), but not statistically significant in persisters (p=0.4).

Figure 1.
**Summary/Conclusions:** We showed that Blin responders have significantly higher TRB repertoire diversity at scr compared to persisters and that the repertoire expansion during Blin treatment is sharper in responders. Other repertoire characteristics did not differ significantly between groups. Further studies on larger patient cohorts are necessary in order to elucidate whether the response to treatment can be predicted by repertoire diversity at scr.

Amplicon NGS is a useful tool for monitoring of T-cell repertoire. Development, standardization, and validation of TRB primer sets is in progress within EuroClonality-NGS Consortium.

**DISCONTINUING ANTIBACTERIAL THERAPY AFTER APYREXIA AND CLINICAL STABILITY REGARDLESS OF NEUTROPHIL COUNT IN FEBRIL NEUTROPIA IS SAFE AND REDUCES EXPOSURE TO ANTIBIOTICS (HOWLONG RANDOMIZED TRIAL)**

I. Espigado1,*, M. Aguilar-Guisado2, A. Martin-Peña3, C. Gudía3, J. Falantes4, L. Vázquez5, I. Montero6, M.L. Martino6, R. Parody7, J. Gonzalez-Campos8, S. Garzon8, C. Calderon-Cabrera1, P. Barbà9, N. Rodríguez-Torres1, M. Rovira3, J.A. Perez-Simon10, J.M. Cisneros-Herreros1

1Unidad Clínica de Hematología, 2Unidad Clínica de Enfermedades Infecciosas, Microbiología y Medicina Preventiva, Instituto de Biomedicina de Sevilla (IBiS), Hospital Universitario Virgen del Rocío/CSIC/Universidad de Sevilla, Sevilla, 3Servicio de Enfermedades Infecciosas, Hospital de Bellvitge, Barcelona, 4Servicio de Hematología, Hospital Clínico de Salamanca, Salamanca, 5Servicio de Hematología, Hospital de Jerez de la Frontera, Jerez, 6Servicio de Hematología, Hospital Universitario Vall’Hebron, 7Servicio de Hematología, Hospital Clinic, Barcelona, Spain

**Background:** In neutropenic patients with unexplained fever the classical approach is maintaining the empirical antibacterial therapy (EAT) until neutrophil recovery. This strategy may result in unnecessarily prolonged EAT favoring bacterial resistance, organ toxicity and damage to microbiota. Nevertheless, the available scientific evidence supporting the alternative approach of stopping EAT before neutrophile recovery is moderate.

**Aims:** To investigate if a clinical approach (based on apyrexia and clinical recovery) is better than and as safe as the standard criteria (recovery from neutropenia) to decide the discontinuation of EAT.

**Methods:** After local Ethical Committee approval, a randomized, controlled, multicenter, open-labeled phase IV clinical trial was performed (EudraCT: 2011-005152-34). Study period: May-2012 to May-2016. Inclusion criteria: a) Adult patients (≥18 years); b) Hematologic malignancy or autologous or allogeneic hematopoietic stem cell transplantation (SCT) recipients; c) High risk febrile neutropenia (FN) d) Informed consent signed. Exclusion criteria: etiological diagnosis of FN. Patients were randomized 72 hours after fever onset to: 1. Experimental group (EG): EAT discontinuation if a) apyrexia ≥72 h, plus b) clinical recovery ≥72 h (independently of neutrophil count) or 2. Control group (CG): EAT discontinuation if a) apyrexia ≥72 h, plus b) clinical recovery ≥72 h, plus c) >0.5x10⁶/L neutrophils. Follow-up: 28 days from EAT. Primary (efficacy) end-point was number of EAT-free days. Secondary (safety) end-points were total days of fever and crude mortality.

**Results:** One hundred and fifty seven patients were included (EG 78 and CG 79). There were no differences in baseline characteristics or clinical presentation between groups. The most frequent underlying conditions were induction/re-induction chemotherapy for acute leukemia (n=42, 26,7%), autologous SCT (n=42, 45,8%), and allogeneic hematopoietic stem cell transplantation (SCT) recipients; c) High risk febrile neutropenia (FN) d) Informed consent signed. Exclusion criteria: etiological diagnosis of FN. Patients were randomized 72 hours after fever onset to: 1. Experimental group (EG): EAT discontinuation if a) apyrexia ≥72 h, plus b) clinical recovery ≥72 h (independently of neutrophil count) or 2. Control group (CG): EAT discontinuation if a) apyrexia ≥72 h, plus b) clinical recovery ≥72 h, plus c) >0.5x10⁶/L neutrophils. Follow-up: 28 days from EAT. Primary (efficacy) end-point was number of EAT-free days. Secondary (safety) end-points were total days of fever and crude mortality.

Summary/Conclusions: In hematological patients with febrile neutropenia of unknown origin the discontinuation of empirical antibacterial therapy after 72 hours of apyrexia and clinical recovery regardless of neutrophils count is safe and reduces unnecessary exposure to antibiotics.

S805
CONJUGATED PNEUMOCOCCAL VACCINE TRIGGERS A BETTER IMMUNE RESPONSE THAN POLYSACCHARIDE PNEUMOCOCCAL VACCINE IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA
1Section of Haematology, Institution of Medical Sciences, Uppsala, 2Department of Medical Sciences, Orebro University Hospital, Orebro, 3Falun Hospital, Falun, 4Institute of Clinical Sciences, Faculty of Medicine, Lund University Hospital, Lund, 5Hematology and Coagulation Section, Sahlgrenska University Hospital, Göteborg, 6Eskilstuna Hospital, Eskilstuna, 7Karlstad Hospital, Karlstad, 8Section of Haematology, Institution of Medical Sciences, Uppsala, 9Department of Medicine, Unit of Hematology, Karolinska Institute and University Hospital, Huddinge, Sweden

Background: Patients with CLL have an increased risk for infection and Streptococcus pneumoniae is one of the most common pathogens with high morbidity. Patients with CLL are known to respond poorly to the traditionally used polysaccharide vaccines. Conjugation of polysaccharide to protein carriers renders a thymus-dependent, memory-inducing and more immunogenic vaccine. In patients with CLL, there is no consensus on a recommendation for pneumococcal vaccination, due to a lack of comparative studies.

Aims: To determine if patients with untreated chronic lymphocytic leukemia (CLL) benefit from vaccination with a 13-valent conjugated pneumococcal vaccine (PCV13), Prevenar13® compared with a 23-valent capsular polysaccharide pneumovax®, in terms of immune response.

Methods: 128 treatment naïve CLL patients from eight hematology clinics in Sweden were randomized to vaccination with PCV13 (n=63) or PPSV23 (n=65) after stratification by IgG levels and CLL clinical stage (Rai). Blood samples for evaluation of immune response were obtained at baseline, at one and at six months after vaccination. Analyses for each of the 12 pneumococcal serotypes common for PCV13 and PPSV23 were performed by opsonophagocytic assay (OPA) and enzyme-linked immunosorbent assay (ELISA).

Results: PCV13 elicited a superior immune response than PPSV23 in 10/12 serotypes one month after vaccination and in 5/12 serotypes six months after vaccination, measured as OPA geometric mean titer (GMTs). Geometric mean concentrations of serotype-specific IgG antibodies elicited by PCV13 as measured by ELISA, were higher than those elicited by PPSV23 in half of the common serotypes, both after one and six months. The proportion of patients with good response (defined as response in 8 of 12 common serotypes according to predefined response criteria) was higher in PCV13 recipients than in PPSV23 recipients after one month (40% vs 22%, p=0.034) as well as after six months (33% vs 17%, p=0.041). Never did PPSV23 trigger a better immune response for any of the serotypes, than PCV13, regardless of analysis. For two of the serotypes, OPA GMTs were lower than the six months than at the one-month follow up. Negative predictive factors for vaccination response were hypogammaglobulinemia and long disease duration. Both vaccines were well tolerated.

Summary/Conclusions: In patients with previously untreated CLL, the efficacy and immune response is superior to PPSV23 for many serotypes common for the two vaccines. PCV13 should be considered as a part in vaccination programs against Streptococcus pneumoniae for these patients and administered as possible during the course of the disease.

S806
INFECTION-RELATED MORTALITY AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION: AGE, CMV AND PRE-TRANSPLANT LEVELS OF IGA/IGM PREDICT IRM IN A NEW CLINICO-BIOLOGICAL SCORING SYSTEM
A. Forcina1,*, P. Rancoita2, V. Marasco1, R. Greco1, M.T. Lupo Stanghellini1, M. Carrabella1, M. Marcati1, C. Di Serio2, M. Bernardi1, J. Peccatori1, C. Corti1, A. Bonduzzi1, F. Cicin1
1IRCCS San Raffaele Scientific Institute, 2Vita-Salute San Raffaele University, Milan, Italy

Background: Infection-related mortality (IRM) is a major challenge after allogeneic hematopoietic stem cell transplantation (allo-HSCT). The aim of this study was to develop a scoring system predicting IRM based exclusively on pre-transplant data.

Methods: A total of 589 adult patients receiving allo-HSCT were studied (Jan 2009-Dec 2011). Briefly, the set of patients (n=273, Jan 2012-May 2015) the ROC curve analysis defined the optimal cut-offs predicting 100-day IRM for continuous data. All clinical and biochemical variables were challenged in a multivariate analysis and a 3-tiered weighted score was elaborated and tested firstly in a retrospective validation set (n=219, Jan 2009-Dec 2011) and then in a prospective validation set (n=97, Jun 2016-Nov 2016).

Results: Median follow-up was 43 months (range 1-85). Acute leukemia was the main indication to transplant, accounting for 60% (n=356) of patients. The majority of the patients received an alternative-donor transplant (44% a HLA-haploidentical, 37% a matched unrelated donor). Forty-seven percent (n=277) of patients had advanced diseases. Multivariate analysis revealed age >60 yrs (P=0.003), CMV host/donor serostatus different from negative/negative (P<0.001) and pre-transplant levels of IGA <1.11 g/L (P=0.004) and IGM <0.350 g/L (P=0.028) as the only independent predictors of increased IRM. Noticeably, these associations were independent from disease type or status, donor type, intensity of conditioning, in vivo or B-cell depletion or from previous colonization by multidrug-resistant bacteria. According to the proposed IRM score, patients were divided into 3 classes: low (<10.17 points), intermediate (10.17-11.11 points) or high-risk (>11.11 points). In the training set, 100-day and 2-years IRM were 5% (95% CI 2.10) and 9% (95% CI 4.16) for low-risk, 11% (95% CI 5.18) and 23% (95% CI 14.33) for intermediate-risk, and 16% (95% CI 16.37) and 41% (95% CI 28.53) for high-risk patients, respectively (P=0.001). In the retrospective validation set, 100-day and 2-yr IRM were 7% (95% CI 3.14) and 14% (95% CI 2.28) for low-risk, 17% (95% CI 10.26) and 23% (95% CI 15.33) for intermediate, and 28% (95% CI 15.42) and 33% (95% CI 19.4) for high-risk patients, respectively (P=0.044), with a c-index of 0.608 (Figure 1). In the prospective validation set, only 100-day IRM was calculated due to a shorter follow-up, being of 0%, 3% (95% CI 0.13) and of 14% (95% CI 3.33) for low, intermediate and high-risk patients (P=0.003). Additionally, in both training and retrospective validation sets, only 100-day IRM was different among the 3 groups, being 59% (95%CI 52.67-62.5) 50% (95%CI 43.59-57.9) and 37% (95%CI 29.48-48) for low, intermediate and high-risk groups, respectively (P=0.0001). In the prospective validation set, only 100-day OS was evaluated, being of 95% (95%CI 88-100), 91% (95%CI 82-100) and 80% (95%CI 65-100), respectively (P=0.03). Out of a total of 125 infection-related deaths, 94/129 (73%) were attributed to bacteria, 22/129 (17%) to viruses, 11/129 (8%) to fungi and 2/129 (2%) to parasites.

Figure 1.

Summary/Conclusions: This new clinic-biological score based on age, CMV serostatus and levels of IGA and IGM, may contribute to the prompt identification of patients at higher risk of fatal infections prior to allo-HSCT, thus promoting post-transplant personalized intensive active surveillance strategies and immune-intervention approaches to improve the overall outcome of transplant. A multicentric Italian study is currently on the way for the external validation of these results.

Background: CMV remains a common complication of HCT, yet no antiviral drug suitable for prophylaxis is available in HCT. LET is a first-in-class drug
that inhibits the CMV terminase complex. A dose-escalation phase 2 trial showed that LET prophylaxis for up to 12 weeks post-HCT was effective with a safety profile similar to placebo.

**Aims:** To compare LET prophylaxis to placebo for the prevention of clinically significant CMV infection (CS-CMV), defined as CMV disease or CMV viremia leading to preemptive treatment (PET) in a Phase III randomized, double-blind, placebo-controlled trial.

**Methods:** CMV seropositive HCT recipients 18 years or older who had undetectable plasma CMV DNA within 5 days of randomization were eligible (full eligibility at clinicaltrials.gov, NCT02137772). Subjects had to start treatment by Day+28 post-HCT. Subjects were randomized 2:1 to receive LET or placebo PO, 9% through Week 14 (Day +100) post-HCT, stratified by study site and high or low CMV disease risk. LET was dosed at 480 mg/d (or 240 mg/d if on cyclosporine due to drug-drug interaction). Subjects were assessed weekly through Week 14, biweekly through Week 24, and every other month through Week 48 after HCT. Plasma obtained at each visit was assayed for CMV DNA in a central laboratory. Subjects who developed CS-CMV discontinued study drug and received anti-CMV treatment. Local CMV assay results could be used to start PET. The primary endpoint was the stratum-adjusted proportion of subjects with CS-CMV through Week 24 post-HCT among subjects with undetectable CMV DNA at randomization; subjects who discontinued the study for any reason or with missing data at Week 24 were considered failures. All adverse events (AEs) were analyzed through 14 days after the last dose of study drug.

**Results:** From June 2014 to March 2016, 565 randomized subjects received study treatment; 31% were at high CMV disease risk. 50% subjects received myeloablative conditioning, 35% received ATG. Donors included 14% mismatched unrelated, 13% haploidentical and 4% cord blood. Study arms were balanced. Subjects began study drug a median of 9 days post-HCT, 37% had engrafted prior to start. Of 495 treated subjects with undetectable CMV DNA at randomization, fewer subjects developed CS-CMV or were considered failures in the LET arm (122/325, 38%) compared to placebo (103/170, 61%; p<0.001) by Week 24 post-HCT. Figure 1 shows the time to CS-CMV analysis. The most common AEs (LET, placebo) were GVHD (39%, 39%), diarrhea (26%, 25%), and nausea (27%, 23%). More frequent vomiting (19%, 14%), edema (15%, 9%), atrial arrhythmias (10%, 5%), and ALT levels >5xULN (4%, 2%) was noted in LET-treated subjects; no increased myelotoxicity or nephrotoxicity was observed. The Week 24 all-cause mortality was 10% for LET recipients and 15% for placebo recipients.

Iron: Deficiency and overload

LACK OF THE FERROPTOSIS INHIBITOR GPX4 IN ERYTHROID CELLS CAUSES A BLOCK IN RETICULOCYTE MATURATION AND A HYPOXIA SIGNATURE WITH IMPAIRED HEPCIDIN REGULATION

1MMPU - Molecular Medicine Partnership Unit, 2Department of Pediatric Hematology, Oncology and Immunology, University of Heidelberg, Heidelberg, 3Institute of Experimental Cancer Research, University Hospital Ulm, Ulm, 4Institute of Clinical Molecular Biology and Tumor Genetics, Helmholtz Zentrum München, 5Institute for Stroke and Dementia Research, Klinikum der Universität München, Munich, Germany, 6Department of Biosystems Science and Engineering, Swiss Federal Institute of Technology in Zurich, Basel, Switzerland, 7Institute for Tumor Biology and Experimental Therapy, Georg-Speyer-Haus, Frankfurt, 8Research Unit Analytical Pathology, 9Institute of Molecular Immunology, 10Institute of Experimental Genetics, 11Institute of Developmental Genetics, Helmholtz Zentrum München, Munich, Germany

Background: GPX4 is a selenoprotein belonging to the family of the glutathione peroxidases, a class of enzymes involved in cellular defence against oxidative stress. This enzyme is essential for life since it is the only peroxidase able to use lipid peroxides as substrate. Mice constitutively lacking GPX4 die at embryonic day 17 due to tissue-specific ablation in neurons and T-cells cause neurodegeneration and impaired immune response. Recent studies have identified GPX4 as the main regulator of ferroptosis, an iron-dependent ROS-mediated form of nonapoptotic cell death. Erythrocytes are highly specialized cells that utilize large amount of iron to bind and deliver oxygen to all tissues. Being constantly exposed to oxygen, erythroid cells need to continuously fight against oxidative stress by expressing a variety of antioxidant enzymes, including GPX4. Iron availability for erythropoiesis depends on systemic iron levels which are regulated via the hepcidin/ferroportin regulatory system. Hepcidin binding to the iron exporter ferroportin reduces systemic iron export regulating body iron levels. In hypoxic conditions the erythroid hormone ErFe suppresses hepcidin synthesis to provide iron for the elevated erythropoietic demand.

Aims: The aim of this study is to identify how the lack of GPX4 in the hematological compartment affects iron homeostasis.

Methods: Lethally irradiated C57BL/6 female mice were reconstituted with bone marrow cells from Gpx4−/−, Rosa26-CreERT2 or Gpx4−/−,Rosa26-CreERT2 and allowed to recover for 8 to 10 weeks. GPx4 deletion in the hematopoietic system was induced by feeding tamoxifen citrate for 3 weeks and blood and organs were drawn at 3 and 6 weeks after terminating the tamoxifen-consuming diet. Erythrocyte cells have been analysed in FACS. Serum iron levels have been assessed using the SFBC and UIBC iron kits (Biolabo). Gene expression analysis has been performed using SYBR-green qRT-PCR. Circulating Hepcidin has been measured with a specific murine ELISA kit (Intrinic Lifesciences). Tissue iron levels have been measured with a colorimetric assay. All animal experiments were approved by the institutional guidelines in silico, in vitro and in vivo studies. Results: Compared to GPX4−/−,CreERT2 controls, Gpx4−/−,CreERT2 transplanted mice lacking GPX4 in the haematological compartment show a decrease in the number of red blood cells, haemoglobin and haematocrit. Reticulocytosis was detected in bone marrow and spleen specimens, indicating an increase in reticulocytes with a concomitant increase in erythrocyte cell production. Hematocrit and ferroportin are also increased as a consequence of the increased iron content.

Summary/Conclusions: Our data show for the first time that the presence of GPX4 in the haematological compartment is essential for the proper hepcidin downregulation upon ErFe stimulation. This finding opens new insights in the mechanism that regulate hepcidin during hypoxia.

Identification of guanosine 5′-diphosphate as potential iron mobilizer: Preventing the hepcidin-ferroportin interaction and modulation of the interleukin-6/STAT-3 pathway

S. Angmo1, N. K. Singh2

1Food science and Nanobioscience, 2National Agri Food biotechnology, Mohali, India

Background: Anemia of inflammation (AI) is one of the most common manifestations of iron deficiency in the patients with inflammatory conditions. AI is responsible for hypoferraemia, with consequent iron-restricted erythropoiesis with high level of hepcidin, which stimulate the internalization of ferroportin (FPN) transporter. Therefore, inhibiting hepcidin-mediated FPN degradation can be an important strategy to ameliorate AI.

Aims: To increase iron bioavailability we selected a Novel compound against hepcidin action through natural compound libraries that might provide a new alternative approach to increase iron absorption for prevention of hepcidin-mediated FPN internalization and to ameliorate turpentine-induced anemic state with different insilico, invitro and invivo studies.

Methods: Using a systematic approach involving in silico, in vitro and in vivo studies was employed to identify hepcidin inhibiting agents. To identify a potent hepcidin-binding agent, natural compounds were screened using molecular docking and dynamics simulations and further investigated on cell lines (GFPP, FFPN, Caco-2, HepG2) using flow-cytometry and western blotting. Normal or turpentine-induced anemic mice were used in the associated studies.

Results: The virtual screening via molecular modelling showed that GDP as a potent hepcidin-binding agent as shown in the (Figure 1A). In vitro studies revealed that GDP significantly increased ferroportin stabilization in GFP-FPN cell lines (Figure 1C) and in vivo studies showed that co-administration of GDP and ferrous sulphate (FeSO4) significantly improved the turpentine-induced anemic state with increase in haemoglobin level (Figure 1B).

Summary/Conclusions: AI is a normocytic anemia, common among patients with chronic infection and inflammatory disorders. We found that GDP molecule have higher contribution to the stability of hepcidin-GDP complex and thus blocks its interaction with FPN. The results support the novel hypothesis that GDP along with iron supplement regimes can overcome the binding of hepcidin from interaction with FPN that would be an effective treatment for AI.

Unraveling the molecular pathogenesis of ineffective erythropoiesis in congenital dyserythropoietic anemia type II (CDAII) by in vitro evaluation of RAP-011 treatment

G. De Rosa1,*, I. Andolfi1, F. Manna1, A. Gambale1, R. Marra1, B. E. Rosato1, A. Iolascon1, R. Russo1

1Molecular Medicine and Medical Biotechnology, CEINGE - Biotecnologie Avanzate, Naples, Italy

Background: Congenital Dyserythropoietic Anemias (CDAs) are subtypes of bone marrow failure syndromes, hallmarking by ineffective erythropoiesis. The most common form is CDA type II (CDAII), showing moderate/severe anemia, relative reticulocytopenia, jaundice, and iron overload. It is inherited as autosomal recessive disorder due to loss of function mutations in SEC23B gene. More than 300 CDAII cases and 80 causative mutations have been described so far. Despite this high allelic heterogeneity, two variants, R14W and E109K, represent more than 50% of the mutational events. To date, treatments for CDAII patients consist of supportive therapy, such as erythrocyte transfusions, or bone marrow transplantation or splenectomy in transfusion-dependencicas.

Recently, members of TGF-β superfamily have been studied as potential regulators of erythropoiesis especially the growth differentiation factor 11 (GDF11). Through the binding of specific receptors, GDF11 leads to an inhibited late-stage erythropoiesis. Indeed, two GDF11 inhibitors, ACE-011 and ACE-536, have been associated to hematological improvement.

The mouse counterpart of ACE-011, RAP-011, on mouse model of β-thalassemia showed increased differentiation of erythroid cells, improvement of anemic condition and reduced iron overload in treated mice.
Aims: The main aim of our study is to assess the effects of RAP-011 on different cellular models of CDAII.

Methods: We measured circulating GDF11 levels in CDAII patients and healthy controls (HC) by western blot (WB). To assess the effectiveness of RAP-011 (provided by Celgene Corporation) in vitro, we established two different cellular models of CDAII: (i) K562 cells stably silenced for SEC23B by sh-RNA carried in the pRS vector, and (ii) K562 SE8-SEB-WT and the two variants, R14W and E109K. In vitro treatment has been performed at 0, 3, and 6 days of erythroid differentiation by hemin+GDF11 in presence or absence of RAP-011 in K562 cells stably silenced for SEC23B.

Results: WB and subsequent densitometric analysis showed an increase of GDF11 levels in secondary culture from 18 CDAII patients compared to HC (p<0.02). Stable silencing of SEC23B in K562 cellsled to the establishment of two different clones, Sh-70 and Sh-74, showing amarkededuction of SEC23Bexpression compared to Sh-CTR (85%-90% and 60-65%, respectively). At 3 and 6 days of K562 erythroid differentiation by hemin, we observed an increase of pSMAD2 in SEC23B-detailed cells compared to non-treated ones; interestingly, a reduction of pSMAD2 in RAP-011+GDF11-treated cells was observed.

Summary/Conclusions: We firstly demonstrated the increased levels of GDF11 in CDAII patients. Thus, we used a combined treatment with hemin+GDF11 in SEC23B-silenced K562 stable clones, in order to reproduce the pathologic phenotype of the disease, and to make K562 cells suitable for RAP-011 treatment, as attested by the increased expression of pSMAD2 in GDF11-treated cells. The reduced pSMAD2 in RAP-011+GDF11-treated cells suggests that RAP-011 treatment leads to repression of ActRIIA/B pathway, which in turn prevents the nuclear levels of GATA1 transcription factor. This action should lead to an increased expression of GATA1-activated genes involved in erythroid development. The evaluation of GATA1 activation is ongoing, as well as the in vitro treatment of K562 stably overexpressing SEC23B-WT,SEC23B-R14W and -E109K.

**INTRAVENOUS IRON VERSUS ORAL IRON VERSUS NO IRON WITH OR WITHOUT ERYTHROPOIESIS-STEMULATING AGENTS FOR CANCER PATIENTS WITH ANAEMIA: A SYSTEMATIC REVIEW AND NETWORK META-ANALYSIS**

A. Weis1, N. Kehrer1, I. Monsef1, J. Bohlius2, I. Becker3, K. Kuhn3, N. Skoetz1

1Cocharane Haematological Malignancies, University Hospital Cologne, Cologne, Germany

2Institute of Social and Preventive Medicine, University Bern, Bern, Switzerland

3Institute of Medical Statistics, Informatics and Epidemiology, University Hospital Cologne, Cologne, Germany

**Background:** A widely prevalent complication in patients suffering from cancer is the deficiency of haemoglobin-containing red blood cells, referred to as anaemia. While many patients develop anaemia due to an involvement of malignant bone marrow cells, others suffer from so-called chemotherapy/ radiotherapy-induced anaemia. Erythropoiesis-stimulating agents (ESAs) stimulate the production of red blood cells within the bone marrow and have shown to increase Hb levels in anaemic patients. Uncertainties remain regarding the effect of iron supplementation on the fatal consequences of ESA-treatment.

**Aims:** The aims of this systematic review and network meta-analysis are to evaluate the effects of ESAs and iron for the treatment of disease-related as well as therapy-induced anaemia in cancer patients.

**Methods:** Based on an a-priori Cochrane protocol, we developed sensitive search strategies for Cochrane Central Register of Controlled Trials (CENTRAL), MEDLINE, databases of ongoing trials and conference proceedings (search date 12/2016). We included only randomized controlled trials (RCTs) including anaemic patients of any age with solid and/or haematological malignancy undergoing chemotherapy, radiotherapy or no anti-cancer therapy. We excluded studies including anaemic cancer-patients as a result of surgery or due to haemolysis. Two authors independently assessed studies for eligibility, extracted data and assessed quality of trials. The primary outcome was on-treatment study mortality. Secondary outcomes included number of red blood cell transfusions and thromboembolic events. For binary outcomes, we used risk ratios (RRs) with corresponding 95% confidence intervals (CIs) to evaluate the treatment effects. We performed a random-effects meta-analysis for direct comparisons and a network meta-analysis for indirect comparisons, using the frequentist graph theoretical approach. Treatment hierarchy was obtained giving P-scores on a scale from 0 (worst) to 1 (best).

**Results:** We identified a total number of 105 eligible studies, including 25,722 patients. The network analysis of the primary outcome, on-study mortality, including studies with 8 treatment arms, was performed. When results were pooled, we observed a significant heterogeneity across studies (I² = 92%). The net treatment effect was significant (RR=0.70 (95% CI 0.53-0.92) P-score: 0.87). Further subgroup analyses revealed that ESA effect was more pronounced in studies with low risk of bias.

**Summary/Conclusions:** While our analyses show that ESA use increases mortality and risk for thromboembolic events, there is no evidence that iron administration alters these risks. However, addition of iron to ESA does further decrease the need for RBC-transfusions compared to ESA alone. Further investigation, with regards to iron type and route of administration may yield further distinct results.

**DIFFERENT IRON SOURCES AND ACQUISITION PATHWAYS SHAPE MACROPHAGES TOWARDS OPPOSING FUNCTIONAL PHENOTYPES**

F. Vinchi1,*, R. Sparla1, E. Tolosano2, U. Platebecker3, M.U. Muckenthaler1

1Molecular Medicine Partnership Unit (MMPU), University of Heidelberg & EMBL, Heidelberg, Germany

2Molecular Biotechnology Center, University of Turin, Turin, Italy

3University Clinic Dresden, Dresden, Germany

**Background:** Iron homeostasis and macrophage biology are closely inter-connected. On the one hand, reticulo-endothelial macrophages are central for the regulation of iron homeostasis. The phagocytosis and degradation of senescent red blood cells (RBC) by macrophages enable efficient recycling of iron and the maintenance of systemic iron balance. On the other hand, iron exerts multiple effects on macrophage polarization and functionality. Macrophages exhibit a remarkable functional plasticity, reflected in their capacity to integrate diverse signals from the microenvironment and acquire distinct phenotypes. Macrophage polarization has been shown to dictate the expression of iron-regulated genes and determine cell iron handling.

**Aim:** Increasing evidence suggests that iron availability itself has significant effects on immune effector functions and macrophage polarization. However, it is still unclear how different iron sources and acquisition pathways affect macrophage phenotypes.

**Methods:** To investigate this aspect, we analyzed both in vivo and in vitro, and compared the phenotypic switching of macrophages induced by different iron sources, including heme and iron, as well as hemolytic or intact RBCs.

**Results:** Hemolytic RBCs, free heme and iron-dextran treatment in mice shape macrophage polarization towards an M1-like pro-inflammatory phenotype. Splenic and hepatic macrophages from treated mice show iron deposition and increased expression of iron-related genes (ferroportin, ferritin, HO-1). Moreover, in these cells, the expression of M1 markers such as MCH, CD86 and pro-inflammatory cytokines (TNFa, IL-6, IL-1b) is strongly increased, whereas the expression of M2 markers such as CD206, Arg-1 and IL-10 was significantly suppressed. Consistent results have been obtained treating bone marrow-derived macrophages with hemolytic RBCs, free heme and Fe-NTA. Importantly, the addition of the heme scavenger hemopexin and the iron carrier transferrin or the chelator deferoxamine fully abolish the ability of free heme and iron to trigger M1 polarization. On the contrary, RBC transfusions in mice shape macrophages towards an M2-like anti-inflammatory phenotype. After three transfusions, serum iron and hepcidin levels significantly rise, and tissues as well as macrophages are heavily iron loaded. Macrophages show a drastic suppression of M1 markers and inflammatory cytokines, and induction of M2 markers. Interestingly, repeated transfusions result in extensive macrophage cell death and new macrophage recruitment in both liver and spleen.

**Summary/Conclusions:** Collectively, these results suggest that the source and route of iron acquisition have a key role in shaping macrophage phenotype, and demonstrate a dynamic role of iron overload in determining macrophage polarization and function. When iron is provided in the form of free heme or non-transferrin bound iron, it exerts a clear pro-inflammatory effect on macrophages; whereas when provided via a controlled physiological acquisition pathway such as erythropagocytosis, it dampens macrophage immune effector functions, being its clearance activity more active.

Figure 1.

**Summary/Conclusions:** While our analyses show that ESA use increases mortality and risk for thromboembolic events, there is no evidence that iron administration alters these risks. However, addition of iron to ESA does further decrease the need for RBC-transfusions compared to ESA alone. Further investigation, with regards to iron type and route of administration may yield further distinct results.

---

*Note: The content above is a natural text representation of the document, excluding images.*
Our findings have potential implications, on one side, for hemolytic diseases, where RBC hemolysis and elevated circulating heme might promote a detrimental chronic inflammatory state, and, on the other one, for infectious diseases, where free heme and iron, released upon cell damage, might boost inflammation and enhance resistance to infections. Conversely, accelerated RBC clearance, by suppressing macrophage pro-inflammatory response, is rather expected to promote infections in transfused individuals.

**A PHASE 3 STUDY TO EVALUATE SAFETY AND EFFICACY OF LENTIGLOBIN GENE THERAPY FOR TRANSFUSION-DEPENDENT B-THALASSEMIA IN PATIENTS WITH NON-B0/B0 GENOTYPES: THE NORTHSTAR-2 (HGB-207) TRIAL**

1UCSF Benioff Children’s Hospital and Research Center, Oakland, 2Lurie Children’s Hospital , Chicago, United States, 3Ramathibodi Hospital, Bangkok, Thailand, 4Children’s Hospital of Philadelphia , Philadelphia, United States, 5IRCCS Ospedale Pediatrico Bambino Gesù, Rome, Italy, 6University College London Hospital, London, United Kingdom, 7Medizinische Hochschule Hannover , Hannover , Germany, 8Great Ormond Street Hospital, London, United Kingdom, 9Hôpital des enfants de La Timone, Marseille, France, 10General Hospital of Thessaloniki, Thessaloniki, Greece, 11bluebird bio, Cambridge, United States

**Background:** Standard treatment for transfusion-dependent β-thalassemia (TDT) includes regular red blood cell (RBC) transfusions and management of iron overload. Successful autologous hematopoietic cell transplantation (HCT) can eliminate RBC transfusions and, eventually, chelation. However, due to transplant-related risks such as graft-versus-host disease (GVHD), as well as donor constraints, HCT is rarely an option for TDT patients. By transferring a functioning copy of the β-globin (HBB) gene into hematopoietic stem cells (CD34+ cells) and re-infusing the modified cells, gene therapy may be an alternative one-time treatment available to all patients with TDT, without risks of GVHD. LentiGlobin gene therapy is an investigational treatment consisting of autologous CD34+ cells transduced with the BB305 lentiviral vector. The Northstar (HGB-204) phase 1/2 clinical study of LentiGlobin gene therapy for TDT included 18 patients who received LentiGlobin drug product (DP). As of September 2016, all patients in Northstar with non-β0/β0 genotypes and at least 12 months of follow-up stopped transfusions (median total hemoglobin [Hb] 11.2 [range 9.4–12.2] g/dL) and there was >60% reduction in transfusions in patients with a β0/β0 genotype. The safety profile was consistent with autologous HCT. In this initial study, the average number of therapeutic gene copies per CD34+ cell in the DP (i.e. DP vector copy number per diploid genome or DP VCN; median 0.7, range 0.3 to 1.5) correlated with peripheral Hba1c/β0 (genetically engineered hemoglobin) expression at 6 months (ASH, 2016). In an effort to optimize the proportion of patients able to discontinue blood transfusions to achieve “transfusion independence” in all patients and increase unsupported Hb levels after treatment, the manufacturing process for LentiGlobin DP was modified to increase the DP VCN and the proportion of genetically modified cells. Northstar-2 (HGB-207) is a recently initiated phase 3 study using this new manufacturing process in patients with TDT and a non-β0/β0 genotype.

**Aims:** To evaluate safety and efficacy of autologous HCT with LentiGlobin DP in patients with TDT and a non-β0/β0 genotype.

**Methods:** After providing informed consent, patients 12 to 50 years of age (N=15) will have CD34+ cells collected via mobilization and apheresis. After individualized DP manufacture and satisfaction of release criteria, the patient will receive myeloablative conditioning with single-agent busulfan (starting dose 32 mg/kg/day for 4 days, with target AUC 4500 [range 4000–5000] µM*min) followed by infusion of LentiGlobin DP. Patients will be followed for engraftment, safety and efficacy endpoints for 2 years after infusion; patients will then have the option to enroll in a 13-year follow-up study. The primary endpoint is the proportion of patients who achieve transfusion independence after DP infusion, defined as total Hb ≥9g/dL without RBC transfusions for a continuous period of ≥12 months. Secondary endpoints include time to neutrophil engraftment, adverse events, and biological parameters including VCN in peripheral blood and levels of Hba1c/β0 over time.

**Results:** As of March 1, 2017, two 20-year-old females with β0/β0 genotypes have been treated with LentiGlobin DP in the Northstar-2 trial. The DP VCN was 2.9 and 2.4 copies per diploid genome, respectively. Outcomes in all evaluable patients will be presented.

**Summary/Conclusions:** Results from the Northstar-2 study will provide data on safety and demonstrate the extent to which an increase in LentiGlobin DP VCN yields normalization of total Hb and consistently achieves transfusion independence in patients with TDT of non-β0/β0 genotypes. Optimizing DP VCN has the potential to improve outcomes across all TDT genotypes treated by investigational LentiGlobin gene therapy.

**CIS IS A POTENT CHECKPOINT IN NK CELL ANTI-LEUKEMIA IMMUNITY**

N. Huntington1,*

1Molecular Immunology, Walter and Eliza Hall, Parkville, Australia

**Background:** The detection of leukemia by natural killer (NK) cells is controlled...
by the integration of signals from activating and inhibitory ligands and from cytokines such as IL-15.

**Aims:** We set out to identify the negative regulators of NK cell function in order to understand why immunogenic tumours and leukaemia can evade or overcome NK cell detection and killing.

**Methods:** We used a multidisciplinary approach including RNAseq, Mass Spectrometry, functional biology, kinase enrichment and activity assays, NK cell in vitro analysis, biochemistry and de novo/experimental tumor/leukemia in vivo models.

**Results:** We identified cytokine-inducible SH2-containing protein (CIS, encoded by Cish) as a critical negative regulator of IL-15 signaling in NK cells. Cish was rapidly induced in IL-15 in response to IL-15, and deletion of Cish rendered NK cells hypersensitive to IL-15, as evidenced by enhanced proliferation, survival, IFN- 

gamma production and cytotoxicity toward tumors. This was associated with increased JAK-STAT signaling in NK cells in which Cish was deleted. Correspondingly, CISH interacted with the tyrosine kinase JAK1, inhibiting its enzymatic activity and preventing JAK phosphorylation. CISH/−/− mice are resistant to leukemia in vivo, and this was independent of MHC-I expression.

**Summary/Conclusions:** Our data uncover a potent intracellular checkpoint in NK cell-mediated tumor immunity and suggest possibilities for new cancer immunotherapies directed at blocking CIS function.

**GENERATION OF MEMORY STEM T CELLS MODIFIED WITH A NOVEL OPTIMIZED CD30-SPECIFIC CHIMERIC ANTAGONIST RECEPTOR FOR THE TREATMENT OF CD30+ T-CELL MALIGNANCIES**

L. Escribà-García1,*, C. Álvarez-Fernández1, J. Wegner2, J. Rydzeck2, M. Tellez-Gabriel3, J. Sierra4, H. Eisele5, J. Bricós1, M. Hudecz1,6,8,9,10

1Hematology Service, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, 2Universitätsklinikum Würzburg, Medizinische Klinik und Poliklinik II, Würzburg, Germany

**Background:** Peripheral T-cell lymphomas (PTCL) represent the most aggressive form among non-Hodgkin lymphomas with a very poor prognosis (5-year survival of 30%), demanding innovative novel treatment strategies. Adoptive immunotherapy with chimeric antigen receptor (CAR) engineered T cells has demonstrated its therapeutic potential in advanced hematological malignancies. However, its application to PTCL remains a formidable challenge mainly due to a lack of truly tumor-specific antigens that are not expressed on normal T cells. Anaplastic large T-cell lymphomas (ALCL) and several other subtypes of PTCL express CD30, which is expressed by activated normal T cells but no other healthy tissues. Indeed, brentuximab vedotin, an anti-CD30 antibody-drug conjugate, has shown some clinical efficacy in PTCL and ALCL patients although duration of responses is short in the majority of cases. Here, we developed a refined CD30-CAR-T cell-targeting approach, termed CARpent in vivo (in vivo CARpent) as a potential novel therapeutic strategy. We selected a novel targeting domain that is unaffected by soluble CD30 protein to prevent blockade of the CD30-CAR in vivo. Moreover, we optimized the therapy by using memory stem T cells (TSCM) to promote engraftment and persistence of CD30-CAR T cells, and we have included an EGFR depletion marker as a safety feature.

**Aims:** We evaluated the antitumor effect of memory stem T cells (TSCM) genetically modified with a novel CD30-specific CAR that recognizes a membrane- 

generated by depleting TSCM with an anti-EGFR monoclonal antibody. The presence of EGFR-APO2L in TSCM was verified by flow cytometry.

**Methods:** Second generation CD30-41BBL-EGFR1 CAR was generated using a scFv that recognizes a tumor-cell membrane-proximal epitope of CD30 protein (Nagata S et al. Clin Cancer Res, 2002). Naïve T cells from healthy donors were activated with anti-CD3/CD28 beads in presence of IL-7, IL-15 and IL-2 and cultured for 10 days to obtain a TSCM-enriched population (Alvarez G et al. J Transl Med, 2016). On day 2 of culture, cells were transduced with a third-generation lentiviral vector encoding the CD30-CAR. The anaplastic large T-cell lymphoma cell line Karpas 299 was used as tumor model. Cytotoxicity assay was performed at 10% to 10, 1, 1.1 and 1.5 effect/target (E/T) ratios, and the tumor cell death was determined by flow cytometry. Cytokines (IFN-γ and IL-2) were analysed at 24 hours in a 5:1 E/T ratio using Luminter technology.

**Results:** The most prevalent T-cell subset at day 10 of culture, representing 84 ± 3.1% of total cells, and the CD30-CAR expression in these cells was 76.9 ± 1.0% in CD4+ TSCM and 77.3 ± 2.0% in CD8+ TSCM. Although CD30 protein was detected in a fraction of activated T cells in culture (CD4+ T cells: 32.4 ± 2.1%; CD8+ T cells: 59 ± 4.3%), lentiviral transduction of TSCM with our CD30-CAR did not compromise their ex vivo expansion (CD4+ CD30-CAR TSCM: 96.0 ± 3.2 fold expansion; CD8+ CD30-CAR TSCM: 109.0 ± 4.2 fold expansion). CD4+ CD30-CAR TSCM conferred specific cytolytic activity and lytic index (tumor cell death: 1.1 ratio: 92.6 ± 2.4% vs 0% with untransduced TSCM, P<0.001), while control CD30- target cells (Raaji) were not recognized. In addition, CD30-CAR TSCM secreted IFN-γ and IL-2 after stimulation with Karpas 299 cells (IFN-γ: 126.6 ± 18.12 pg/ml, p=0.002, IL-2: 20.47 ± 2.3 pg/ml, p=0.06 ± 0.24 pg/ml, p=0.002).

**Summary/Conclusions:** Collectively, our data demonstrate the potential to generate CD30-CAR T cells with enhanced functional attributes against CD30+ PTCL. TSCM cells can be efficiently transduced and ex vivo expanded with a novel CD30-CAR and confer potent antitumor efficacy against CD30+ PTCL in vivo. Our findings suggest the potential to improve outcome of patients with CD30+ PTCL through adoptive therapy with CD30-CAR modified T cells.

**MESENCHYMAL STROMAL CELLS FOR THE TREATMENT OF STEROID-RESISTANT ACUTE GRAFT VERSUS HOST DISEASE: FACTORS INFLUENCING CLINICAL RESPONSES**

1Division of Cancer Studies, King’s College London, 2Imperial College Health-care NHS Trust, 3Imperial College London, London, 4Central Manchester University Hospital, Manchester, 5University Hospitals Bristol, Bristol, 6University Hospital Southampton, Southampton, 7Birmingham Women’s and Children’s Hospitals, Birmingham, 8The Christie NHS Foundation Trust, Manchester, 9King’s College Hospital NHS Trust, London, 10Royal Hallamshire Hospital, 11Sheffield Children’s Hospital, Sheffield, 12Heart of England NHS Foundation Trust, Birmingham, 13Plymouth Hospitals NHS Trust, Plymouth, 14King’s College London, London, United Kingdom

**Background:** The immunosuppressive activity of mesenchymal stromal cells (MSCs) has been extensively tested for the treatment of steroid-resistant acute graft versus host disease (aGVHD). However, the factors affecting clinical responses are poorly understood.

**Aims:** We assessed the impact of MSC treatment on clinical outcomes and investigate factors influencing the response to MSCs.

**Methods:** Data collected from a cohort of 60 patients treated with MSC between May 2008 and December 2014 in the UK were analyzed. Clinical grade MSC were generated from bone marrow aspirates collected from the iliac crest of healthy donors and expanded using platelet lysate. All patients received MSC for the treatment of steroid-resistant aGVHD, defined as failure to respond to high-dose steroids (2mg/kg methyl-prednisolone) after 6 days. Informed consent was obtained from all patients in accordance with the local ethics committee requirements. Clinical responses to MSC were assessed 1 week after MSC infusion. Patients were defined as: a) Responders when an improvement of at least 50% in at least one organ affected by aGVHD was observed, or b) Non-Responders if they had stable or progressive disease.

**Results:** Patient characteristics are summarized in Table 1.

**Table 1.**

aGVHD was biopsy proven in 45 patients, while in the remaining patients the diagnosis was clinical and based on the exclusion of alternative causes. 10, 16 and 1 patients had skin, gut and liver involvement only, respectively. 16 patients exhibited gut and skin, 11 skin, gut and liver, 3 skin and liver and 3 gut and liver. 34 patients received 1 dose, while 19, 6 and 1 were treated with two, three and four doses, respectively. No side effects were observed. 36 patients (60%) responded to MSC. Amongst patients who received multiples doses (26), subsequent doses did not change the status after the first dose (24 responded, 1 did not respond), except from one patient who, although respond-
ing to the first dose, failed to respond to the second one. When we evaluated potential factors for response, organ involvement, age at transplant and the cumulative dose of MSC infused were found statistically significant. Response rate was 67% among patients with involvement of gut, skin or both, but only 22% among those with involvement of the liver (alone or in combination with skin and/or gut). Patients younger than 20 years fared better, with 88% of them responding. Conversely, only 30% and 42% of those aged 20-50 years or older than 50 responded, respectively. Lastly, higher cumulative MSC dose (>3.0x10^6/Kg) was associated with a response in 76%, while none of those receiving less than 1.5x10^6/Kg responded. All 3 factors remained significant in multivariate logistic regression analysis. Patient gender, pre-MSC therapy, interval from transplant or aGvHD diagnosis to MSC treatment and grade of aGvHD did not affect response. The impact of achieving a response 1 week after MSC had a profound impact on the overall survival at 18 months accounting for 59% in responders and 17% in non-responders (log-rank test, p<.001).

Summary/Conclusions: In our cohort of patients, MSC treatment was safe and well tolerated. We conclude that the presence of a response at one week highly impacted on the survival of patients with an otherwise very poor prognosis. Importantly, younger age at the transplant, absence of liver aGvHD involvement and use of higher MSC doses were strong predictors of a response.

S818 CARD9 CONTROLS DECTIN-1-INDUCED T-CELL CYTOTOXICITY AND TUMOR GROWTH IN MICE
T. Haas1,*, S. Heidegger1, H. Poeck1, J. Ruland2
1Klinik und Poliklinik für Innere Medizin III, 2Institut für Klinische Chemie und Pathobiochemie, Klinikum rechts der Isar, TU München, München, Germany

Background: Activation of the C-type lectin receptor Dectin-1 by beta-glucans triggers multiple signals within dendritic cells (DCs) that result in activation of innate immunity. While these mechanisms can potently prime CD8+ cytotoxic T cell (CTL) responses without additional adjuvants, the Dectin-1 effector pathways that control CTL induction remain unclear.

Aims: Aims of this study were: To define details of the intracellular signalling pathway responsible for cross-priming of a CTL response after activation of the C-type lectin receptor Dectin-1. To analyze whether identified signalling molecules were indispensable for antitumor immunity. To analyze whether NK cells played a role in antitumor immunity after Dectin-1-mediated CTL induction.

Methods: We used in vitro coculture between DCs (wildtype vs gene deficient) and CD8 T cells to define signalling components of Dectin-1 induced CTL cross-priming. We used WT and gene-deficient mice to define the signalling pathway of Dectin-1 induced CTL crosspriming in vivo and to test the role of this pathway for antitumor immunity by challenging mice with B16-Ova tumor cells intravenously, with or without depletion of CD8 T cells or NK cells, respectively.

Results: Here we demonstrate that Dectin-1-induced CTL cross-priming in mice does not require inflammasome activation but strictly depends on the adapter protein Card9 in vitro. In vivo, Dectin-1-mediated Card9 activation after vaccination drives both expansion and activation of antigen-specific CTLs, resulting in long-lasting CTL responses which are sufficient to protect mice from tumor challenge. This Dectin-1-induced antitumor immune response was independent of natural killer (NK) cell function and completely abrogated in Card9-deficient mice. Thus, our results demonstrate that Dectin-1-triggered Card9 signaling but not inflammasome activation can potently cross-prime antigen specific CTLs, suggesting that this pathway would be a candidate for immunotherapy and vaccine development (Figure 1).

Summary/Conclusions: We identify Card9 as central regulator of Dectin-1-induced cross-priming of cytotoxic T cells (CTLs) in mice. These antigen specific CTLs mediate potent antitumor immunity independent of inflammasome activity and NK cells. This pathway is a candidate for immunotherapy and vaccine development.
Acute lymphoblastic leukemia - Biology

E819 PRECLINICAL COMBINATION OF A NOVEL IRE1 RNASE INHIBITOR MKC-8866 AND TYROSINE KINASE INHIBITION ACTS SYNERGISTIC IN ACUTE LYMPHOBLASTIC LEUKEMIA

M. Vieri,1,2, A. Salimi,1, J.B. Patterson2, A. Samal3, E. Cheve4, T.H. Brümmendorf5, I. Appelmann1, B. Kharabi1
1Hematology, Oncology, Hemostaseology and Stem Cell Transplantation, University Hospital RWTH Aachen, Aachen, Germany, 2KaindKind Corporation, Valencia, United States, 3Department of Biochemistry, National University of Ireland, Galway, Ireland, 4Centre de Lutte Contre le Cancer Eugène Marquis, Université Rennes 1, Rennes, France

Background: The role of the Unfolded Protein Response (UPR) in BCR-ABL1+ ALL is not properly defined yet. Although this role has never been confirmed in BCR-ABL1+ cells. To shed light on this aspect we co-cultured either SUP-B15 or TOM-1 cells with tertMSCs to test the chemo-protective effect of bone marrow stromal cells (BMMSCs) on leukemia cells. 2) We tested whether genetic knock-down of XBP1 could sensitize cells towards the effect of Imatinib and Nilotinib. To this end, primary murine pre-B cells from conditional XBP1fl/+mice, were transduced with BCR-ABL1 construct, and with either inducible cre or empty vector.

Results: IRE1 inhibitor MKC-8866 (MKC) in combination with either Imatinib (IM) or Nilotinib (NL) showed enhanced capacity to arrest proliferation and to induce cell death in BCR-ABL1+ ALL cell lines compared to single treatments, after 3 days incubation (Viable SUP-B15: MKC 30µM 94.9%±0.1, IM 10µM 78.4±0.4, Combination 78.7±0.4, MKC 30µM 94.1±0.07, NL 5µM 64.2±0.6, Combination 78.4±0.4, TOM-1: MKC 30µM 94.1±0.07, IM 10µM 89.9±0.4, Combination 78.4±0.4, Combination 17.0±1.4; MKC 30µM 94.1±0.07, NL 5µM 64.2±0.6, Combination 78.4±0.4).

Summary/Conclusions: Overall, our data demonstrate that simultaneous inhibition of IRE1 and BCR-ABL1 in BCR-ABL1+ ALL cells is a promising therapeutic strategy involving UPR inhibition that possesses translational potential and clinical application of a combined targeted therapy.

E820 HIGH-THROUGHPUT COPY NUMBER PROFILING IN PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA USING MULTIPLEX LIGATION-DEPENDENT PROBE AMPLIFICATION IN COMBINATION WITH NEXT-GENERATION SEQUENCING

D. Alpar1,2, P.A. Kirały1, A. Benard2, I. Haltrich3, H. Pikó4, K. de Groot2, J. Schouten1, S. Savola2, C. Bodor1
1MTA-SE Lendvai Molecular Oncology Research Group, 1st Department of Pathology and Experimental Cancer Research, Semmelweis University, Budapest, Hungary, 2MRC-Holland, Amsterdam, Netherlands, 3rd Department of Pediatrics, Semmelweis University, 4th Department of Molecular Genetics and Diagnostics, National Center of Public Health, Budapest, Hungary.

Background: Development, progression and resistance of pediatric acute lymphoblastic leukemia (pALL) are widely associated with recurrent copy number abnormalities (CNAs). Multiplex ligation-dependent probe amplification (MLPA) is an established technique to screen CNAs, thus providing valuable information for risk assessment in pALL; however, the number of simultaneously analyzable genomic loci is limited to 55-60.

Aims: To introduce and test a high-throughput, high-resolution and comprehensive disease-relevant CNA profiling approach applicable to all subtypes of pALL.

Methods: A novel digitalMLPA (dMLPA) technique has been developed which combines the advantages of MLPA and next-generation sequencing (NGS), massively improving the number of genomic targets that can be analyzed for their copy number in a single reaction. Bone marrow samples from 58 patients with pALL were analyzed using this novel assay targeting ~470 genomic loci. Since copy number estimates in pre-B and pre-T ALL, respectively, followed by CDKN2A/B, PAX5, RB1, VPREB1, MLLT3, CD200/BLA, MLBX1R1, IKZF1, CASP8AP2, PTPN11, RUNX1, BTG1, TP53, IKZF3, EZH2, NFI, NKG2C, RAG2 and the PAR region for CNAs in pre-B-ALL cases and PTEN, MLLT3, FLT3, PTM2, PHF6, LEP1, CASP8AP2, PTPN11, RAS, TP53 in pre-T-ALL cases. The CNA fusions were also observed in T-ALL cases while in one BCR-ABL1+ pre-B-ALL patient, the copy number profile correctly indicated the presence of an extra Ph-chromosome. dMLPA results showed a congruency of 99.3% with those of MLPA mixes containing probes with different ligation sites for a subset of the genes. The increased resolution of dMLPA (i) allowed the detection of subclonal aberrations with an improved efficacy and confidence as compared to conventional MLPA and (ii) enabled a more patient-specific characterization of CNAs, e.g. by revealing 15 different deletion patterns across 23 samples harboring del(Php). In addition to genomic lesions specifically influencing putative or proven disease-relevant genes, 24 structural and 134 whole chromosome aberrations were detected genome-wide which was strongly facilitated by the inclusion of ~200 digital karyotyping probes covering each chromosome arm.

Summary/Conclusions: A novel NGS-based method has successfully been introduced for high-resolution profiling of CNAs in pALL. dMLPA is a robust, fast and cost-effective technique; its input DNA requirement (~20ng) is similar to those of other low-input NGS protocols and lower than the requirement for MLPA. Due to its targeted approach, data analysis is computationally less demanding as compared to most NGS methods. The number of genomic sites analyzed in our study was an order of magnitude higher than that achievable by revealing 15 different deletion patterns across 23 samples harboring del(Php). In addition to genomic lesions specifically influencing putative or proven disease-relevant genes, 24 structural and 134 whole chromosome aberrations were detected genome-wide which was strongly facilitated by the inclusion of ~200 digital karyotyping probes covering each chromosome arm.

E821 CRITICAL ROLE FOR NOTCH SIGNALLING IN B-CELL PRECURITY ACUTE LYMPHOBLASTIC LEUKEMIA (B-ALL) DRUG RESISTANCE
P. Takam Kamga1,2, G. Dal Collo1, M. Midolo1, A. Adamo1, A. Gatil1, R. Caruso1, M. Bonifacio1, M. Krampera1
1Medicine, University of Verona, Verona, Italy

Background: B-cell precursor acute lymphoblastic leukemia (B-ALL) is the leading cause of cancer-related death in children and young adults. There is still a need of more efficient therapies for the subset of refractory patients. Our group has previously shown that Notch-3 and Notch-4 promote human B-ALL cell survival in presence of stromal cell support. However, the prognosis value of Notch signalling as well as its contribution in vitro and in vivo to chemotherapy has not yet been investigated.

Aims: In this study we used B-ALL cell lines and samples from new diagnosed B-ALL patients to analyse the contribution of Notch signalling to B-ALL pathogenesis in terms of prognosis, proliferation survival and drug response in vitro and in mice xenograft models of B-ALL.

Methods: B-ALL cell lines were obtained from ATCC, while B-ALL primary cells were obtained from bone marrow or peripheral blood of 30 B-ALL patients. Flow cytometry and western immunoblotting were used to study the expression of Notch receptors and ligands. Drugs used were Cytarabine (Ara-C), Dexamethasone (Dexa) and Doxorubicin (Doxo) alone or in combination with Notch modulators including anti-Notch blocking antibodies, gamma secretase inhibitors (GSis), and Notch transcription factor inhibitor (SAHM1). Mouse xenograft model of B-ALL were obtained by injecting the B-ALL line RS4;11 in...
NOD/Shi-scid/Ig/2Rnull mice (NOG). Cell viability was evaluated by Annexin-V/PI and MTT assay; proliferation was assessed through CFSE dilution.

Results: Western blot and flow cytometric analysis showed that B-ALL cell lines as well as primary blast cells displayed the same Notch expression pattern consistent in low expression levels of Notch2 and Jagged1, high expression levels of Notch1, Notch3, Notch4, Jagged2, DLL3 and DLL4. Notably, in primary blast cells derived from patients, the expression of Notch3, Notch4, Jagged2, DLL3 and DLL4 was significantly higher in the cases refractory to treatment as compared to patients achieving complete remission, thus suggesting that Notch signalling could be involved in the response to chemotherapy. In line with this hypothesis, we found that the treatment in vitro of B-ALL cell lines with Ara-C or Doxo, revealed a reversion of the down-modulation of Notch receptors. This down regulation was also observed in human CD19+ blast cells isolated from bone marrow of recipient mice treated with Ara-C compared to cells isolated from not treated mice. In addition, Notch inhibitors significantly improved in vitro the cytotoxicity of Ara-C or Doxo towards B-ALL. Finally, in vivo, Notch inhibitors significantly reduced the administration to mice of a pan Notch inhibitor, i.e. the GSI XII, significantly lowered the CD19+ leukaemic burden in the bone marrow of recipient mice, potentiating anti-leukemic effect of Ara-C.

Summary/Conclusions: In this study we used both in vitro and in vivo assays to highlight the prognostic value of Notch expression in B-ALL, as well as its critical role in B-ALL cell survival and response to chemotherapy. We also demonstrated that Notch inhibitors were able to improve Ara-C-mediated reduction of blast cells in bone marrow, revealing that Notch signalling is a possible therapeutic strategy to eradicate minimal residual disease in B-ALL.

E822

REGULATION OF NOTCH AND WNT SIGNALING PATHWAYS BY NRARP IN T-CELL ACUTE LYMPHOBlastic LEUKEMIA

I. Pinto1, M. L. Oliveira2, J. T. Barata1, R. Fragoso1,1
1Babaraba Lab, Instituto de Medicina Molecular, Lisboa, Portugal

Background: T-cell acute lymphoblastic leukemia (T-ALL) is an aggressive hematological malignancy. Although the outcome of T-ALL patients has improved over recent years, the poor prognosis of patients with resistant or relapsed disease is still a major concern. Even though NOTCH is a known driver in T-ALL, its inhibition cannot be efficiently achieved with the drugs currently available, due to their weak therapeutic effects and severe toxicity. We have shown that loss of NRARP (the wild type repeat protein) a negative regulator of NOTCH signaling. Importantly, NRARP over-expression in murine hematopoietic stem cells impairs T-cell development suggesting that de-regulation of NRARP expression can contribute to the pathogenesis of T-ALL.

Aims: To investigate the role of NRARP in human T-ALL cell growth and survival and its therapeutic potential in T-ALL.

Methods: mRNA and protein expression were determined by real time-PCR and western blot analyses. In vitro functional evaluation of NRARP in T-ALL cell lines was performed by flow cytometry analysis of proliferation and viability upon NRARP overexpression using lentiviruses.

Results: We started by characterizing NRARP expression in human T-ALL cell lines and we observed a down-regulation of NRARP expression in human thymocytes. We found that NRARP protein levels are significantly increased in T-ALL cells. This result, although consistent with the fact that NRARP is a transcriptional target of NOTCH, suggests that NRARP is not sufficient to block NOTCH oncogenic signals. To test this hypothesis, we overexpressed NRARP in human T-ALL cell lines. Interestingly, NRARP overexpression blocks the expansion of the T-ALL cell lines that display NOTCH1-activating mutations but promotes the expansion of the T-ALL cells without NOTCH1 mutations. Although in both cell types (WT and NOTCH1-mutated) NRARP overexpression blocks NOTCH signaling, in NOTCH1-WT T-ALL cells we observed an increase in c-Myc expression consistent with these results. T-cell-activating mutations in NOTCH1-WT NRARP overexpressing cells are more sensitive to JQ1, a small-molecule bromodomain inhibitor that targets c-Myc. NRARP is known to be positively regulated by LEF1, a DNA binding transcription factor acting downstream of WNT. Thus we sought to investigate the impact of this Lef1 in NOTCH1 signaling pathway. Very interestingly, our results show that in NOTCH1-mutant cells NRARP overexpression results in the down-regulation of the WNT signaling pathway while in NOTCH1-WT T-ALL cells results in its up-regulation.

Summary/Conclusions: Taken together our results suggest that NRARP may play a dual role in T-ALL pathogenesis, regulating both NOTCH and WNT pathways, with opposite functional effects on leukemia cells depending on NOTCH mutational status and signaling levels. This dual role may have important biological and therapeutical implications.

E823

ETV6/RUNX1-LIKE ACUTE LYMPHOBlastic LEUKEMIA: A NOVEL B-CELL PRECURSOR LEUKEMIA SUBTYPE IDENTIFIED BY THE CD27/CD44 IMMUNOPHENOTYPE

M. Zaliova1,2,3, M. Kotrova1,2,3, S. Bresolin4, J. Stücky1,2, J. Stary1,2, O. Hrusak1,2,3, G. te Kronnie4, J. Trka1,2,3, J. Zuna1,2,3, M. Vaskova1,2,3,1
1Department of Paediatric Haematology and Oncology, 2Second Faculty of Medicine, Charles University, 3University Hospital Motol, 4CLIP - Childhood Leukaemia Investigation Prague, Prague, Czech Republic

Background: We have shown previously that ETV6/RUNX1-positive acute lymphoblastic leukemia (ALL) is distinguishable from other ALL subtypes by CD27+/CD44low-neg immunophenotype. During diagnostic immunophenotyping of 573 childhood B-cell precursor ALL (B-ALL), we identified eight cases with this immunophenotype among 8 “B-other” ALL (B-ALL cases negative for hyperdiploidy, ETV6/RUNX1, TCF3/PPX1 and BCR/ABL fusion genes and KMT2A rearrangements).

Aims: We aimed to characterize their genetic and biological background, to reveal to what extent they resemble ETV6/RUNX1-positive ALL and to elucidate whether they belong to the recently described ETV6/RUNX1-like ALL (Liljebäck et al., Nature Communications 2016).

Methods: We utilized microarrays to study the gene expression profile (GEP) and biological similarity of the B-ALL subtypes. Five ETV6/RUNX1-positive and five hyperdiploid ALL cases were analyzed using microarrays in parallel to seven CD27+/CD44low B-ALL cell lines. Microarray data from all 17 B-ALL cases were combined with data from an independent Italian cohort of 291 B-ALL cases (including ETV6/RUNX1-positive, BCR/ABL1-positive, TCF3/PPX1-positive, KMT2A-rearranged, hyperdiploid and B-other ALL cases) whose specimens were analyzed using the same microarray. To study the genomic background, we performed comprehensive profiling using single nucleotide polymorphism (SNP) arrays and whole exome and whole transcriptome sequencing (WES and RNAseq).

Results: In the hierarchical clustering based on GEP all five ETV6/RUNX1-positive cases and 5 of 7 CD27+/CD44low-neg B-other cases clustered within the ETV6/RUNX1-positive cluster. These B-other cases were thus classified as ETV6/RUNX1-like ALL. We identified multiple regions of acquired copy number aberrations (CNA) uniparental disomies (5 to 27 per case) and point mutations (10 to 41 per case) in all 7 cases and 3 in-frame fusions transcribed each in one patient. The most important findings are summarized in Figure 1. All 5 ETV6/RUNX1-like cases harbored a deletion of the ETV6 gene, resulting in an in-frame ETV6/BORC5 fusion in one of them. The deletion of ARP2/21 was found in 3 cases, and the deletions of PAX5, A1TP10A, BTG1 and the gain of RUNX1 were found in 2 cases each. The ARP2/21 deletions displayed a strikingly uniform character and were highly enriched in ETV6/RUNX1-like ALL. Using WES and RNAseq, no recurrently mutated gene and no in-frame fusions were found, respectively, except for the ETV6/BORC5. Integrating data from all platforms, we identified IKZF1 as another recurrently affected gene; a deletion, a nonsense mutation and an IKZF1-involved out-of-frame fusion were each found in one case. The other cases with available material. Microarray data and the TCF3/PPX1 fusion (the former co-occurring with two activating JAK2 mutations) were found in 2 CD27+/CD44low-neg B-other cases that were closer to other B-ALL subtypes than to ETV6/RUNX1-positive ALL as indicated by GEP.

Summary/Conclusions: We showed that similarly to ETV6/RUNX1-positive ALL ETV6/RUNX1-like ALL is also associated with CD27+/CD44low-neg immunophenotype. We identified deletion of ARP2/21 to contribute to the specific genomic profile of ETV6/RUNX1-like ALL in addition to lesions of ETV6

Figure 1.
Background: The leukemogenesis of T-cell acute lymphoblastic leukemia (T-ALL) involves multistep processes of genetic alterations.

Aims: We aimed to determine the genetic alterations including common fusion transcripts, overexpression of T-cell transcription factor oncogenes and deletion or overexpression of target genes in pediatric T-ALL in Taiwan and assess their impact on outcomes in those treated with TPOG-ALL-2002 protocol.

Methods: Between 1995 and 2015, bone marrow samples from 102 children (<18 years old) consecutively diagnosed with T-ALL were examined. SIL-TAL1, ETV6, CALM-AF10 and CALM-AF10 transcripts were detected by RT-PCR assays. RO-PCR with TagMan assays were used to measure the expression of HOX11, TAL1, and LYL1 oncogenes expressed as normalized copy number (NCN) to ABL internal control gene. TAL1 overexpression was defined as NCN > the lowest level of SIL-TAL1 positive patients. Overexpression of HOX11 and LYL1 was defined as NCN > the upper limits of the 50 normal bone marrow controls. Mutations of NOTCH1, FBXW7, PHF6, JAK1, JAK2, RUNX1, WT1, NRAS, and KRAS genes were analyzed by PCR-based assays followed by direct sequencing. P16 deletion was determined by RO-PCR or multiplex ligase probe amplification (MLPA), PTEN and PHF6 deletions, MYB duplication and NCN of mutations of candidates around well-known tumour suppressors, indicating the framework analysed contains copy-numbers from tumour samples matched to normal blood samples or normal tissue from the same donor. To validate the essentiality of genes in the discovered regions we used pooled CRISPR/Cas9 editing in ALL cells with and without a deletion of the driving tumour suppressor. Results: Our framework identified several regions with potential essential genes around well-known tumour suppressors. The strongest signals in the data set were located around the tumour suppressor CKDN2A. Downstream analysis with pooled CRISPR/Cas9 editing in ALL cells with and without a CKDN2A deletion provided evidence for the essentiality of several genes in the identified region, including one gene that was essential only in CKDN2A-deleted cells.

Summary/Conclusions: In conclusion, we explored a computational approach to identify regions with essential genes in copy-number datasets. Application of our approach to real data showed several regions with essential gene candidates around well-known tumour suppressors, indicating the framework works. Downstream genome-editing experiments in model cell-lines provided further evidence for the essentiality of some genes found in such identified regions. While we cannot yet draw conclusions on whether some of these genes are viable therapeutic targets it allows for informed guesses on limited sets of genes for further focused analysis in hematological model cell-lines.

Background: B-cell acute lymphoblastic leukemia (B-ALL) is a genetically heterogeneous disease characterized by abnormal expansion of B-cell precursors and is mainly affecting children and adolescents. The backbone of the treatment is chemotherapy providing high cure rates in pediatric ALL (> 85%) but much worse treatment responses are observed in adolescents and adults (less than 50%). Patients who relapse develop refractory, chemotherapy resistant disease and remain a clinical challenge. Growing body of evidence suggests that disturbance of redox homeostasis is a promising anticancer approach. Due to high metabolic demands and proliferation rate cancer cells elevate their antioxidative capacity to overcome excessive ROS production and depend on these antioxidants for their survival. One of the oxidative stress protectors are peroxiredoxins (PRDXs) that next to thioredoxins (TXNs) belong to the TXN-family and are the key components of TXN antioxidant system. PRDXs are enzymes involved in scavenging peroxides. TXNs are responsible for cysteine-thiol disulfide exchange in numerous protein substrates.

Aims: To investigate the potential of targeting the TXN antioxidant enzymes as a novel pro-oxidative strategy in B-ALL treatment.

Methods: We have used three different cell lines representing distinct cytogenetic subgroups of B-ALL: BV-173 (BCR-ABL), SEMK-2 (MLL-AF4) and NALM-6 (t(4;14) [E2A-PBX1]). ROS levels were measured using DCFDA, RNA and protein levels of TXN-family enzymes were measured by quantitative PCR and immunoblotting, respectively. Downregulation of PRDX1 was established by a novel CRISPR/Cas9 gene editing system. We have employed lenti-
CRISPR v2 plasmid to produce lentiviral vectors encoding PRDX1-specific sgRNA and Cas-9 and used them to generate BV-173 cells with PRDX1 genomic deletion. Proliferation rate was evaluated by trypan blue exclusion method. Cytostatic/cytotoxic effects of TXN-family enzymes inhibitors, such as adenothin (ADE), auranofin (AUR) and SK053 were assessed by MTT viability assay and by detection of propidium iodide-positive cells in flow cytometry.

Figure 1. Aims: To define the biological significance of IGF2BP1 overexpression in t(12;21)(p13;q22) ET6V/RUNX1-positive ALL.

Results: We have found that B-ALL cell lines exhibit significantly higher levels of ROS as compared to normal B cells isolated from human tonsils (Fig.1A). In accordance with this observation, our analysis of TXN antioxidant enzymes gene expression in B-ALL cell lines showed their upregulation (Fig.1B). Analysis of deposited data revealed that PRDX1 expression level is the highest in B-ALL among the other types of leukemia (Fig.1C). Moreover, we have observed elevated expression of PRDX1 in malignant lymphoblasts derived from pediatric patients at both RNA and protein levels. Genomic deletion of PRDX1 in BV-173 cells leads to suppression of their proliferation rate, comparing to parental cells and cells transduced with mammalian non-targeting sgRNA. These results allow us to suspect that PRDX1 may play growth-supporting role in these cells. Targeting TXN-family enzymes was also performed with the use of various small molecule inhibitors. Both B-ALL cell lines and primary cells are sensitive to PRDX and TXN inhibitors, which reduce cell viability in dose-dependent manner.

Summary/Conclusions: All the above results suggest that targeting TXN antioxidant system may exert desirable anticancer effects in the treatment of B-ALL. Inhibitors of TXN-family enzymes can be considered as putative agents to use in combination with classical drugs and improve existing therapeutic approaches. Further studies are underway.

Methods: In this study we have used stable sublines with downregulated IGF2BP1 from our previously published study (Stoskus, Valikevičiene et al. 2016). Dynamics of viable cell population was assessed by flow cytometry using 7-AAD staining (BD Biosciences) following 72 hrs culture in complete medium. An EdU flow assay (Thermo Fisher Scientific, TFS) was used to assay DNA replication in proliferating cells. Spontaneous and doxorubicin (Doxo), staurosporine (STS), and STAT3 selective inhibitor S3i-201 (all from Santa Cruz Biotechnology) induced cell death rates were determined by Annexin V (TFS) and 7-AAD staining. All samples were analyzed on Accuri C6 cytometer (Accuri Cytometers) using CFlow Plus and FCS Express software (De Novo Software). IGF2BP1, ET6V/RUNX1, and STAT3 RT-qPCR was performed essentially as reported previously (Stoskus, Gineikiene et al. 2011). Statistical analyses performed using GraphPad Prism software (GraphPad Software).

Results: Downregulation of IGF2BP1 by 2-fold have rendered into approximately 2-fold lower population growth rate, increasing levels of spontaneous cell death in dynamics, and modest yet statistically significant attenuation of cell cycle progression (35.13% vs 40.40%, p<0.0001). Data from treatment with 50 nM of Doxo, 250 nM of STS suggest that IGF2BP1 downregulation has no effect on pharmacological effectiveness of these drugs. In contrast, IGF2BP1-downregulated cells are more sensitive to pharmacological inhibition of STAT3 even upon treatment with suboptimal 25 µM concentration of S3i-201. Lastly, we have probed if STAT3 transcript levels could be sustained by IGF2BP1 protein as in agreement with previously reported (Stohr, Kohn et al. 2012) and our unpublished insights from anti-IGF2BP1 RNA immunoprecipitation datasets. Correlation analysis of RT-qPCR data have confirmed these assumptions as downregulation of IGF2BP1 expression have resulted in a decrease of ET6V/RUNX1 mRNA (r=0.8253, p<0.001, slope 0.4959) and also STAT3 transcript levels (r=0.7709, p=0.002, slope 0.6436). These data suggest that STAT3 transcript is also a potentially regulated by RNA-binding protein IGF2BP1 in t(12;21)(p13;q22)-positive ALL model cells (Fig 1).

Figure 1.

Summary/Conclusions: We provide evidence that IGF2BP1 promotes survival of t(12;21)(p13;q22)-positive ALL model cells through cell cycle progression and preventing spontaneous cell death. Potentiation of ET6V/RUNX1®STAT3 signaling axis is one of the possible mechanisms responsible for this phenotype as IGF2BP1 maintains appropriate levels of primarily ET6V/RUNX1 and also STAT3 mRNAs. Further studies are clearly warranted to further delineate the role of IGF2BP1 in t(12;21)(p13;q22)-positive ALL (Stoskus, Eidukaite et al. 2016).

1INSERM UMRS-1147, 2Université Paris Descartes, 3INSERM UMR-S 1124, 4Assistance Publique-Hôpitaux de Paris, Hôpital Européen Georges Pompidou, Paris, France

Background: 6-Mercaptopurine (6-MP) is a thiopurine drug with antiproliferative effects by blocking purine synthesis. 6-MP is largely prescribed for the treatment of childhood acute lymphoblastic leukemia (ALL). Recent evidence

...
suggest that 6-MP inhibits the phosphatidylinositol 3 kinase (PI3K)/ mammalian target of Rapamycin (mTOR) signaling pathway and modulates the transcriptional activity of hypoxia inducible factor 1α (HIF-1α). As mTOR and HIF-1α are key mediators of metabolic reprogramming in cancer and normal T cells, we hypothesized that 6-MP can impact cellular metabolic remodeling through its action on nucleotide synthesis. Metabolic reprogramming fosters glycolysis, glucose transporter expression, polarization of lipid metabolism, cell growth, and proliferation, a key feature of cancer cells. This metabolic switch is regulated by metabolic checkpoints, including mTOR, AMP-activated protein kinase (AMPK) and the oncogenes Myc and HIF-1α.

Aims: Our objective is to study the impact of the antiproliferative molecule 6-mercaptopurine (6-MP) on proliferating T-cell leukemia cells metabolic reprogramming and nuclear activity.

Methods: In vitro experiments were performed in a Jurkat T cell line. Cells were incubated with 6-MP from 6h to 72h. We used RT-PCR, Western Blot, glucose uptake and glycolytic and glutaminolytic flux to evaluate the metabolic effects of 6-MP.

Results: Our results showed that 6-MP reduces ATP content as early as after 2 hours of treatment and this decrease is maintained up to 72 hours. As AMPK is an energetic sensor activated with low ATP content, we studied AMPK activation after 6-MP treatment. We observed that 6-MP treatment activates AMPK after 6 and 48 hours of treatment. Moreover, 6-MP significantly modifies the transcriptome of genes implicated in glycolysis, glutaminolysis and nucleotide synthesis after 24, 48 and 72 hours of treatment. In addition, 6-MP inhibits the expression of the metabolic checkpoints mTOR, HIF-1α and Myc after 24, 48 and 72 hours of treatment. 6-MP also decreases glucose and glutamine oxidation after 48 hours of treatment by 60% and 35%, respectively, suggesting that 6-MP inhibits TCA (tricarboxylic acid cycle) and OXPHOS (oxidative phosphorylation). The production of lactate, a marker of aerobic glycolysis, is significantly decreased by 30% after 6-MP treatment for 48 hours, meaning that aerobic glycolysis is also inhibited. However, 6-MP has no effect on glucose uptake or on glucose transporters (Glut1 or Glut3, SLC2A1 or SLC2A3) on the cell membrane, suggesting that 6-MP metabolic effects are not linked to glucose uptake.

Summary/Conclusions: In conclusion, our findings offer new insights on the cellular effects of 6-MP treatment by promoting an early energetic stress that influence proliferation and raise apoptosis in leukemia T cells. Interestingly, the modification of the metabolic checkpoints (mTOR, HIF-1α, Myc) and the diminution of glycolytic and glutaminolytic fluxes by 6-MP treatment provide an original approach to better understand the cellular effects of 6-MP treatment.

**GENETIC ABERRATIONS IN ADULT ACUTE LYMPHOBLASTIC LEUKAEMIA AND THEIR IMPACT ON CLINICAL OUTCOME**

K. Takahashi1,2, F. Wang2, K. Patel2, C. Bueso-Ramos2, X. Song2, J. Zhang2, C. Gumbs2, L. Latasa2, S. Tippen2, T. Kadia1, F. Ravandi1, G. Garcia-Manero1, N. Short1, N. Jain1, M. Konopleva1, H. Kantarjian1, A. Futreal1, E. Jabbour1

1Leukemia, 2UT MD Anderson Cancer Center, Houston, United States

**Background:** Genetic alterations have prognostic impact on pediatric patients with B cell acute lymphoblastic leukemia (B-ALL). Genomic landscape and its impact on clinical outcome is less understood in adults with B-ALL.

**Aims:** To describe the landscape of genomic aberrations and analyze the correlation with clinical characteristics and prognostic impact in adults with B-ALL.

**Methods:** We assessed bone marrow specimens from 64 consecutive adults with a median age of 51 years (range 18 to 80) with previously untreated B-ALL between 2012 and 2015. The cohort included 23 Philadelphia chromosome (ph)-positive and 41 Ph-negative B-ALL. Sixty patients (94%) were treated with hyper-CVAD (hyperfractionated cyclophosphamide, vincristine, doxorubicin, and dexamethasone alternating with high-dose methotrexate and cytarabine)-based regimen; 23 of them received additional tyrosine kinase inhibitor for Ph-positive disease (dasatinib [N=4] or ponatinib [N=19]). Four patients (6%) were treated with augmented BFM (Berlin-Frankfurt-Munster) regimen. Genomic DNA extracts were sequenced by targeted capture exome sequencing of 295 genes that are recurrently mutated in hematologic malignancies (median 280x coverage). The panel included more than 1000 cytoSNP position evenly distributed among the genome that allowed estimation of copy number variations (CNVs). Point mutations were called by Mutect/Pindel algorithm.

**Results:** Among the 64 patients, we detected 70 point mutations in 40 genes in 38 patients (54%). Ph-positive ALL had significantly less point mutations than Ph-negative ALL (median number of mutations/patient 0 [range: 0-2] versus 1 [range: 0-8], P=0.002). The most frequently mutated genes were TP53 (17%) followed by MLLT3 (12%), ARID1A (5%), NRAS (5%), NF1 (5%), RUNXI (5%), and TET2 (5%). TP53 mutations were strongly associated with Ph-negative B-ALL (P=0.004) and low hypothyroidism (P=0.009). Recurrent CNVs involved loss/deletion in genes such as PAX5 (28%), TCF3 (38%), IKZF1 (31%), CDKN2A/2B (31%), BTLA (25%), CD200 (22%), ETX2 (22%), RBL1 (20%), MIB1/FAK1/ER4 (15%), ERG (14%), and MLT7 (11%), whereas gain/amplification was detected in NR3C2 (18%), ERG (15%), RUNXI (15%), and LEF1 (14%). MLT7 loss/del was specific to Ph-negative ALL (0% for Ph-positive versus 17% for Ph-negative, P=0.036) and MIR15-16/1-1 deletion/Deletion had non-statistically significant association with Ph- ALL (4% versus 22% respectively, P=0.06). In this cohort, 78% and 100% of the Ph-negative and Ph-positive ALL achieved complete remission, respectively. None of the point mutations or CNVs were associated with differential response to therapy. Survival analysis was stratified by Ph status. Complex karyotype had trend toward worse event-free survival (EFS) (median EFS 3.6 months versus 26.3 months, P=0.06) in Ph-negative ALL. None of the point mutations or CNVs was associated with EFS/overall survival (OS) in Ph-negative ALL. Notably, TP53 mutation nor low hypothyroidid did not affect EFS/OS in the current cohort. In Ph-positive ALL, IKZF1 deletion/loss was associated with a trend toward worse EFS (median EFS 3.6 months versus 21.3 months, P=0.07) but it did not affect OS.

**Summary/Conclusions:** Genetic analysis highlights the molecular heterogeneity of adult B-ALL. Adult B-ALL is frequently associated with CNVs and point mutations are less frequent. Prognostic impact of genetic alteration in adult B-ALL appears to be limited except for IKZF1 deletion/loss, which may predict worse EFS in Ph-positive B-ALL.

**Background:** The survival rate of relapsed adult acute lymphoblastic leukaemia (ALL) is around 10%. Aims: We looked for recurrent Copy Number Alterations (CNA) in relapsed adult B cell progenitor ALL (BCP-ALL) to shed light into the molecular mechanisms of relapse.

**Methods:** BM or PB samples with at least 30% of blasts from 31 adult BCP-ALL patients at 1st relapse and, of them, 21 paired diagnosis and relapse samples were analysed by MLPA (MRC-Holland, The Netherlands). 19 out of these 21 paired samples were analysed by SNP array with CytoScan HD chips (Affymetrix, Santa Clara, California, USA) with true CNA. The analysis compassed a minimum of 25 markers, and 25 markers and 320Mbs for CN-LOH.

</table>
Results: With a median follow up of 12.43 [2.4;3.0] months, the median OS of the 31 patients at first relapse was 7.9 months, [2.4;13.8]. The OS of patients at first relapse was significantly lower in those having more than 3 CNA by MLPA (median ±3 CNA 9.7 months [0-20.7] vs median ±3 CNA 4.2 months [0-6.7], p=0.042). CDKN2A/B deletion was the most common CNA observed at relapse (16/31, 52%) and most of these deletions were homozygous (12/16, 75%). 8 out of 9 heterozygous CDKN2A/B deletions, homozygous deletions were more frequent at relapse (from 8 heterozygous CDKN2A/B deleted patients at diagnosis, 7 became homozygous at relapse, p=0.070). SNP arrays detected 554 CNA (409 DEL, 125 DUP and 20 LOH) in 34 samples of 19 patients. At diagnosis (n=16 patients) the mean number of CNA was 12.5 (9.8 DEL, 2.3 DUP and 0.4 LOH), while at first relapse (n=13 patients) was 17.8 CNA (12.6 DEL, 4.2 DUP and 1 LOH) and in second relapse (n=5 patients) was 21 CNA (14.6 DEL, 6.4 DUP and 0 LOH)(p=0.007). All matched diagnosis and first relapse samples (available for 10 patients) showed common CNA. In 6/10 cases some of CNA were retained from diagnosis while others were acquired or lost at relapse (suggesting a clonal development of the leukemic clone). In the remaining 4/10 diagnosis CNA were retained and acquired new CNA at relapse (indicating an evolution from diagnosis clone) and 1/10 showed the same CNA signature at relapse (suggesting a primary resistance of the diagnosis clone). Gene ontology analysis showed a significant enrichment of gene deletions involving B cell differentiation, activation and proliferation, and regulation of cytokine-mediated signaling pathway at relapse (Benjamini Hochberg test, p<0.01). Table 1 summarizes the frequencies of the most retained or acquired CNA at relapse in at least 4 out of 15 patients. Besides the high genetic heterogeneity observed, some recurrent CNA could be identified such as 9p, 1q, 12q, 22q and 7p deletions and 1q, 8q, 17q, 21 and 22q duplications and/or small tumor suppressor genes such as TP53, FOXO1, FOXO3 or RB1 were detected in 3 patients.

Summary/Conclusions: BCP-ALL has a high genetic heterogeneity at relapse, with most of the genetic alterations playing important roles for disease progression. This heterogeneity points out the need for search of personalized treatment strategies, not only on their molecular targets. Finally, we hope that Instituto de Salud Carlos III, Ministerio de Economía y Competividad, Spain, Red Temática de Investigación Cooperativa en Cáncer (RTICC, FEDER) (RD12/0036/0044); Sociedad Española Hematología y Hemoterapia; 2014 SGR225 (GRE) Generalitat de Catalunya; Fundació Internacional Josep Carreras, Celgene Spain and “la Caixa” Foundation.

IGF1/IR/IRS PHARMACOLOGICAL INHIBITION REDUCES CELL PROLIFERATION AND MIGRATION IN ACUTE LYMPHOBLASTIC LEUKEMIA CELLS
A-P.N. Rodrigues Alves1,*, J. Machado-Neto1, R. Scopim-Ribeiro1, J.C. Fernandez1, B.A. Fenerico1, F.B. Da Silva1, P.S. Scheucher1, B.P. Simões1, E.M. Rego1, A.J. Ridley2, F. Traina1
1Internal Medicine, University of Sao Paulo at Ribeirao Preto Medical School, Ribeirao Preto, Brazil, 2Randall Division of Cell and Molecular Biophysics, King's College London, London, United Kingdom

Background: A recurrent clinical complication of the acute lymphoblastic leukemia (ALL) is the infiltration of lymphoblast into central nervous system. The IGF1/IGF1R signaling pathway is initiated through binding of the ligand (IGF1) to its transmembrane receptor (IGF1R), and the subsequent activation of its substrates, IRS1 and IRS2, which transmit mitogenic and antiapoptotic signals, mainly through the modulation of the PI3K/AKT/mTOR and MAPK signaling pathways. These signaling pathways play an important function in cell proliferation, survival and migration of leukemia cells. We have previously noticed that NT157 (IRS1/2 pharmacological inhibitor) significantly decreased cell viability and induced apoptosis in T-ALL (Jurkat and MOLT-4), and in B-ALL (Namalwa and Raji) cells and in primary ALL cells (T-ALL [n=2] and B-ALL [n=2]), although did not presented citotoxicity in peripheral blood mononuclear cells (PBMC) from healthy donors. In addition, NT157 was able to induce the p21 (CDK1WA1) expression, which is a cell cycle arrest-related gene. We also observed that OSI-906 (IGF1/IR pharmacological inhibitor) significantly reduced cell viability, but did not induce apoptosis in ALL cell lines tested, and did not modulate viability and apoptosis of primary ALL cells and normal PBMC. The molecular mechanism by which leukemia cells break the blood-brain barrier, allowing the infiltration of the central nervous system and causing serious complications is not well understood.

Aims: We herein aimed to investigate the impact of the pharmacological IGF1/IR and IRS1/2 inhibition on cell proliferation and migration in ALL cells.

Methods: T-ALL Jurkat and B-ALL Namalwa were used. Cell lines were treated or not with NT157 at 0.2, 0.4, 0.8, 1.6 and 3.2 µM, or with OSI-906 at 0.5, 1, 5 and 10 µM. After 24 hours and 48 hours. After drug exposure, cell lines were evaluated for cell proliferation (Ki-67 assay), migration (Time-Lapse microscopy analysis) and cell adhesion (using human umbilical vein endothelial cells HUVEC monoclonal layer). Statistical analyses were performed by the ANOVA. Value p<0.05 was considered statistically significant.

Results: In vivo and in vitro, NT157 strongly reduces cell proliferation in a dose-dependent manner (p<0.05) after 24 hours of treatment. OSI-906 was not able to reduce cell proliferation in these cell lines. The 24 hours treatment with 10µM OSI-906 decreased accumulated distance (µm) and velocity (µm/min), while 0.4µM NT157 reduces only the accumulated distance of Jurkat cells under migration assay into fibronectin monolayer, after being filtered by time-lapse microscopy for 3 hours; the images were captured every 1.5 minutes. Although there is a trend for reduction, cell adhesion between Jurkat and Namalwa leukemia cells and the human endothelial cell monolayer was not significantly modulated by treatment with both inhibitors.

Summary/Conclusions: The reduction in cell proliferation found during IRS/2 pharmacological inhibition reaffirms the important role of these proteins on malignant phenotype of ALL cells. Migration analysis indicated that NT157 and OSI-906 are potential inhibitors of transendothelial migration in ALL cell lines and contribute with new perspectives on the participation of the IGF1/IR/IRS1 pathway in the break of the blood-brain barrier.

LEUKEMIA-PROPELLING CELLS DEMONSTRATED DISTINCTIVE GENE EXPRESSION PROFILES COMPARED WITH THE OTHER CELL FRACTIONS IN PATIENTS WITH DE NOVO PHILADELPHIA CHROMOSOME-POSITIVE T-ALL
H.-Y. Zhao1,*, Y. Song1,2, X.-N. Cao1, Y.-Z. Qin1, Y.-Y. Lai1, H. Jiang1, Q. Jiang1, Y. Kong1, X.-J. Huang1
1Peking University People’s Hospital, Peking University Institute of Hematology, 2Peking-Tsinghua Center for Life Sciences, Academy for Advanced Interdisciplinary Studies, Peking University, Beijing, China

Background: Relapse remains one of the major obstacles in Philadelphia chro- mosome-positive acute lymphoblastic leukemia (Ph+ALL) even after allogeneic hematopoietic stem cell transplantation (allo-HSCT). Relapse of Ph+ALL may result in a fatal outcome, and is a key factor for determining the long-term cure of Ph+ALL patients. Despite extensive research, there is no established treatment strategy for patients with relapsed or refractory Ph+ALL. The aim of this study was to investigate the potential of peripheral blood mononuclear cells (PBMCs) from Ph+ALL patients undergoing allo-HSCT as a new source of cellular therapy. PBMCs were sorted into two populations: leukemia propagation cells (LPCs) and normal hematopoietic cells (NHCs). The expression profiles of the sorted LPCs and other cell fractions were measured using RNA sequencing (RNA-Seq) to identify potential therapeutic targets.

Methods: Twenty patients with de novo Ph+ALL were enrolled for this study at Peking University Institute of Hematology from 2015 to 2018. The LPCs (CD34+CD38-CD58-) and other cell fractions (including CD34+CD38+CD58+, CD34-CD38+CD58+ and CD34-CD38+CD58-) were sorted from the bone marrow mononuclear cells of de novo Ph+ALL patients (N=3) using a FACS Aria II. Differential expression analysis between LPCs and the other cell fractions were performed using RNA sequencing (RNA-Seq) and the DESeq package (1.10.1). Gene Ontology (GO) enrichment analysis and Kyoto Encyclopedia of Genes and Genomes (KEGG) analysis. RNA-Seq results were partially validated by a TaqMan-based real-time quantitative polymerase chain reaction (qRT-PCR) technique. Moreover, cell cycle status was compared between LPCs and other cell fractions in de novo Ph+ALL patients by flow cytometry.

Results: 1021 genes (301 up-regulated and 720 down-regulated), 1245 genes (354 up-regulated and 891 down-regulated) and 1228 genes (248 up-regulated and 980 down-regulated) were differentially expressed between LPCs and other cell fractions in de novo Ph+ALL patients. (Patient No 1), B-ALL (Patient No 2), and Ph+ALL and Other Cells, (Patient No 3), respectively. Most of differential expression of genes (DEGs) are related to the regulation of cell cycle and metabolism. GO analysis identified enriched terms of biological functions in DEGs including ATP binding process, ribonucleotide binding process, nucleoside binding process, DNA replication process, primary metabolism process, etc. KEGG analysis showed significantly enriched signaling pathways involved in DEGs including cell cycle, DNA replication, nucleotide metabolic pathways, biosynthesis of amino acids, glutathione metabolism, p53 signaling pathway, etc. Consistent with RNA-Seq results, mRNA levels of the cell cycle-related genes, such as CDK4 and p21/WAF1, were significantly lower in LPCs fractions than those in other cell fractions. Moreover, the frequencies of quiescent cells in LPCs were significantly higher than those in other cell fractions.

Summary/Conclusions: Distinctive gene expression profiles and cluster, which are mostly related to the regulation of cell cycle and metabolism, were demon- strated between LPCs and other cell fractions in Ph+ALL patients. In addition, we were able to identify potential therapeutic targets toward LPCs in Ph+ALL. Therefore, our data indicate that it would be of value to develop LPCs biomarkers to contribute to personalized leukemia therapy and the need to identify therapeutic targets directed toward LPCs in Ph+ALL.

HOSPITALIZATION FOR PATIENTS IN THE U.S. AND EU TREATED WITH INOTUZUMAB OZOGAMICIN VS STANDARD OF CARE FOR RELAPSED/REFRACTORY ACUTE LYMPHOBLASTIC LEUKEMIA IN A GLOBAL PHASE 3 TRIAL

Y. Su1, I. Van Oostrum2, E. Vandendries1, V. Welch1, F.R. Loberiza1

1Pfizer Inc, New York, United States, 2Ingress-health Netherlands, Rotterdam, Netherlands

Background: Inotuzumab Ozogamicin (InO), an anti-CD22 antibody-calicheamicin conjugate, with its once a week one-hour infusion schedule, has demonstrated lower hospital utilization, in association with a clinically meaningful improvement in overall survival, high rate of complete remission, favorable patient-reported outcomes (PRO), and generally manageable safety profile versus standard of care (SOC, intensive chemotherapy) for relapsed/refractory acute lymphoblastic leukemia (R/R ALL) in the phase 3 INO-VATE trial.

Aims: This study aims to determine the regional-specific hospitalization days per patient in the INO-VATE trial.

Methods: Patients receiving study treatment (safety population) and recruited from the US and the EU were included in the analyses. The total number of days hospitalized for each patient was calculated. Hospital days prior to randomization and those after the end of study treatment were excluded. Due to different durations of treatment for InO and SOC (median 1 vs 3 cycles), calculations were reported for cycle 1 treatment period (randomization to end of cycle 1) and for the entire treatment period (all cycles - randomization to end of treatment).

Results: A total of 264 patients from the safety population of the phase 3 INO-VATE trial were available for the analyses. 149 were from the US, and 115 from 11 of the EU countries. The percentage of patients requiring hospitalization was lower for InO compared to SOC (Table). The median and mean hospitalization days were shorter for patients in the InO arm compared to the SOC arm across both regions. The difference between the two treatment arms appears to be greater in the US compared to the EU. Hospitalizations in the US appear to be shorter than in the EU, particularly for patients receiving InO.

Table 1. Hospitalizations in R/R ALL patients from the INO-VATE trial.

Summary/Conclusions: InO treatment in R/R ALL is associated with less hospitalization across both the US and EU compared to SOC, consistent with InO’s better efficacy, tolerability, PRO and dosing schedule. The finding that US has lower hospitalization than the EU might be explained by different patient care practices in the two regions. Given that hospitalization is the biggest cost driver in cancer care, the data suggest both EU and US could benefit from cost-savings of less hospitalization with InO treatment.

NON-INTENSIVE BUT NON-INTERRUPTIVE TREATMENT WITH FEWER ALLO-HSCT IS EFFECTIVE STRATEGY FOR ADULT PH-NEGATIVE B-CELL PRECURSOR (BCP-) ALL: OUTCOME OF THE RUSSIAN PROSPECTIVE MULTICENTER ALL-2009 STUDY

E. Parovikhinova1, V. Troitskaya2, A. Sokolov2, O. Gavrilin2, C. Akhmerzueva2, G. Kliassova2, L. Kuzmina1, E. Grishanova2, G. Baskhavaya2, I. Piskunova2, T. Obukhova2, M. Rusinov2, S. Kulikov2, V. Savchenko1

1BMT department, 2Haematology department, National Research Center for Hematology, Moscow, 3BMT department, Rassia Gorbacheva Memorial Research Institute for Pediatric Oncology, Hematology and Transplantation, St. Petersburg, 4Haematology department, N.N. Blokhin Russian Cancer Research Center, 5Scientific clinical laboratory of clinical bacteriology, mycology and antibiotic therapy, 6Cytogenetics laboratory, 7Department of biostatistics, National Research Center for Hematology, Moscow, Russian Federation

Background: As Ph-negative-BCP-ALL in adults remains less favorable in prognosis than T-ALL, and by expert opinion needs intensive protocols with high portion of allo-HSCT, the results of treatment based on the different approaches are escalated but non-interruptive treatment with low numbers of allo-HSCT- may be of interest and can provide new insights to the common view.

Aims: to evaluate survival data and risk groups in Ph-neg-BCP-ALL pts in the RALL-study.
Methods: The ALL-2009 (NCT01193933) was initiated in Apr 2009. The treatment plan was identical for all risk groups with allo-HSCT indicated only for very high-risk BCP-ALL (t(4;11), t(1;19), WBC >100). Since Apr 2009 till Dec 2016, 329 Ph-negative ALL pts (m.age 28 y (15-55), f/m 147/182) were recruited. Phenotype was unknown in 6 pts, biphenotypic AL was diagnosed in 1.2% (n=4), T-ALL-LBL in 38.7% (n=125), BCP-ALL in 59.1% (n=194). Among BCP-ALL there were 54 early pre-B ALL (27.8%), 101 common-ALL (52%), 39 pre-B ALL (20.2%). In BCP-ALL pts m.age was 27 y (15-54), f/m 99/95, initial WBC >9,4*10⁹/l (0.4-899,0), LDH 901 IU (31-13059), CNS leukemia - in 17 pts (8.7%), mediastinal mass - in 3 (1.5%), splenomegaly- in 111 (57.2%). Standard cytogentic was defined in 124 pts (64%), 11 had no mitosis, so information is avail-able in 58.2% (n=115). 14.8% of BCP-ALL (n=49/113) pts had normal karyotype (NK); 7.9% (n=9) and 1.8% (n=2) - had t(4;11) and t(1;19) respectively; other abnormalities were detected in 53 (46.9%), including p53 (3.2%), +8 (6.3%), complex karyotype (7.9%), hyperdiploidy (16%), diploidy (22.2%). etc. 9 BCP-ALL patients (n=47) were not qualified by the risk in the data-base; 68.1% (n=126) were attributed to the high risk (HR) group (WBC >30; EGIL BI, LDH>2N; late CR; t(4;11)-pos). The analysis was performed in Feb 2017. 191 pts were available for induction outcomes, DFS and relapse probability (RP), and all pts – for overall survival (OS).

Results: CR rate in 191 pts was 87.4% (n=167), induction death occurred in 8.9% (n=17), resistance was registered in 3.7% (n=9). Late responders constituted 13.6% (n=26). Death in CR on chemotherapy was 6.3% (n=12) and 1 death after alloHSCT. All-HSCT was performed in 13 (6 – matched related donor, 7 MUD) of 176 patients who survived induction (74%), 11 of them – in 1CR. Totally 59 pts (34.9%) had relapsed. At 7y OS for the whole cohort con-stituted – 54.3%, DFS – 56.5%, RP – 35.4%. In a multivariate analysis for BCP-ALL among common risk factors (age >30y, initial risk group, WBC >30, LDH>2N, immunophenotype, late CR >35d, CNS leukemia, cytogenetics) age, WBC, t(4;11) became statistically significant for OS, DFS and RP. We developed a new threshold for the most valuable risk factors. New risk groups stratification demonstrated 7y OS=79%, DFS=71%, RP=23%, in the standard risk (SR) group (age <27y, WBC <7*10⁹/l, no t(4;11)) and 46%,45%,47%, respectively, in the HR group (age >27y,WBC >7*10⁹/l, t(4;11)).

E837

POST-INDUCTION MINIMAL RESIDUAL DISEASE RESPONSE DETERMINED BY MULTICOLOR FLOW CYTOMETRY IS A POWERFUL INDICATOR OF EVENT-FREE-SURVIVAL IN THE CHILDHOOD T-ACUTE LYMPHOBLASTIC LEUKEMIA

P. Tembhare1,*, G. Chatterjee1, I. Sanyal1, P. Devre1, S. Ghogale1, N. Patkar1, P. Subramanian1

1Hematopathology Laboratory, Tata Memorial Centre, Mumbai, Navi Mumbai, India

Background: Minimal residual disease (MRD) is a powerful predictor of event-free survival in acute leukemia including T-cell acute lymphoblastic leukemia (T-ALL). Due to lower incidence of T-ALL MRD studies are limited compared to a small cohort of patients. Moreover, flowcytometry based MRD (FC-MRD) studies in T-ALL are very few. AIEOP-BFM group showed that late (Day-78) MRD response determines overall risk of-relapse and event-free survival (EFS) using RQ-PCR. However, a larger study by COG (Brent Wood et al. ASH, 2014) showed that post-induction (Day-78) FC-MRD was more relevant in the pre-diction of EFS. This indicates that the best time for MRD evaluation for the risk stratification in T-ALL is still not clear and need more studies. We investigated the value of post-induction FC-MRD response in an assessment of EFS in childhood T-ALL. It is a first T-ALL MRD study from India.

Methods: We studied post-induction (Day-35) MRD (PI-MRD) & post-consolidation (Day-78) MRD (PC-MRD) in bone marrow samples from 100 patients of T-ALL treated under modified MCP-841 protocol between 2014 & 2016. In T-ALL with early-thymic-precursor (ETP) immunophenotype, patients received dexamethasone in place of prednisolone. MRD was performed using 10-color FC-MRD assay on Navios flow-cytometer (Beckman Coulter, BC) and MRD analysis was performed with Kaluza software v.1.3 (BC). Any detectable level of MRD (≥20 events) was defined as MRD-positive. Events included relapse & disease-related deaths. Statistical analysis was performed using SPSS v.16.

Results: The median age of patients was 11.5 years (range 2–16 y; M:F=4:6). Based on the immunophenotypic criteria, 13 patients were diagnosed as ETPALL & remaining 87 as non-ETPALL type. PI-MRD was positive in 58/100 (58%) with the median level of 0.23% (range, 0.002% to 6%). PI-MRD was not performed in 71.4% (30/42) of PI-MRD-negative & 1.2% (6/58) PI-MRD-positive patients. PC-MRD was available in 64 patients (30/42 of PI-MRD-negative & 6/58 of PI-MRD-positive). PC-MRD was positive in 28% (18/64) (median, 0.2% & range, 0.009% to 4%). PI-MRD positivity was significantly high in ETPALL as compared to non-ETPALL (93% vs 53%; p=0.01). Median follow-up of all patients was 14 months (3-38 months). Patients were categorized MRD standard-risk (MRD-SR) if PI-MRD was negative and MRD high-risk (MRD-HR) if PI-MRD was positive with any level. Thus, 42% were categorized as MRD-SR & 58% as MRD-HR. Twenty patients relapsed & of them, six died (2 were ETPALL & 18 non-ETPALL; 3 MRDSR & 17 MRD-HR) within 26 months. Median EFS of MRD-HR patients was significantly inferior as compared to MRD-SR (26 months vs did not reach; & 70.67% vs 92.86%; p=0.0017) (Kaplan-Mayer curve shown in Figure 1). Interestingly, there was no difference in EFS for PI-MRD <0.01% vs >0.01%, suggesting any level of PI-MRD positive indicates inferior EFS. Furthermore, the PC-MRD response was not found to be significant over PI-MRD (P-value=0.17). ETP vs non-ETP status was also not found to be associated with EFS (P-value=0.85).

Figure 1.

Summary/Conclusions: We concluded that 10-color FC-based post-induction MRD response is a powerful indicator of EFS in childhood T-ALL. The frequency of PI-MRD positivity was significantly high in ETPALL indicating a lower tumor clearance rate. There was no difference in the EFS based on the level of PI-MRD-positivity indicating even a low level (<0.01%) PI-MRD is important in risk-stratification of childhood-TALL.

SMAC MIMETICS - A NOVEL THERAPEUTIC APPROACH IN CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA

M. Meyer1,*, J. Ziringrebe1, L.-H. Meyer1, K.-M. Debatin1

1Department of Pediatrics and Adolescent Medicine, University Medical Center, Ulm, Germany

Background: Pediatric acute lymphoblastic leukemia (ALL) is one of the most common malignancies in childhood. Survival rates have increased enormously over the past decades, but the prognosis for patients with relapsed ALL or ALL in second remission is poor. Therefore, novel therapeutic options are urgently required. The family of inhibitor of apoptosis proteins (IAPs) has been shown to play an important role in the prevention of cell death, and to mediate gene activation important for cell survival. Many of the cellular processes regulated by IAPs are deregulated in cancer. Thus, IAPs represent a promising target in anticancer therapy. IAP antagonists, also known as Smac Mimetics (SMs), were developed to counteract IAPs’ function. SMs have been shown to induce cell death in a number of different cancer entities, amongst them B cell precursor (BCP)-ALL. In BCP-ALL, SM-induced cell death was

SINGLE-AGENT MOR208 IN PATIENTS WITH RELAPSED/REFRACTORY (R/R) B-CELL ACUTE LYMPHOBlastic LEUKEMIA (B-ALL): A SINGLE-ARM PHASE II STUDY

R. Klisovic1, M. Winderlic2, S. Ambarkhane3, E. Jabbour3
1Department of Internal Medicine, Division of Hematology & Oncology, The Ohio State University, Columbus, OH, United States, 2MorphoSys AG, Planegg, Germany, 3Department of Leukemia, Division of Cancer Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX, United States

Background: CD19 is a type I transmembrane glycoprotein that is expressed throughout B-cell development until terminal plasma cell differentiation. CD19 is also broadly and homogeneously expressed across different B-cell malignancies, including B-ALL. MOR208 is a CD19 monoclonal antibody with an enhanced Fc region, which leads to a potentiation of antigen-dependent cell-mediated cytotoxicity and antigen-dependent cell-mediated phagocytosis. Anti-CD19 therapy can significantly improve the efficacy and safety of single-agent MOR208 in the treatment of patients with R/R B-ALL.

Methods: This is a single-arm phase II study of MOR208 in patients aged ≥16 years with histologically confirmed R/R B-ALL with progression after at least one prior therapy. Patients with Philadelphia-chromosome-positive (Ph+) B-ALL were excluded. Induction therapy was not used. Baseline target lesion was measured pre-dose. Data was collected on patient demographics, prior therapy, laboratory results, and best overall response during the treatment period.

Results: 2 patients were enrolled; median age was 21 years (range 16–79), 1 (50%) patients was male. 2 (100%) patients received the 12mg/kg IV, i.e. 1 CR and 1 PR. The major toxicities seen were neutropenia, thrombocytopenia, and hyperglycemia (each 50%). Infusion-related reactions were reported in 2 patients (10%); 1 patient received extended MOR208 (12 cycles) treatment. A further 4 (20%) patients did not have a complete response (CR) or partial response (PR) but did not discontinue treatment. The median progression-free survival (PFS) for all patients was 5 months (95% CI 3.3–9.9 months).

Conclusion: Single-agent MOR208 is well tolerated with manageable toxicity. Further studies in this population are warranted, including combination studies with other agents.

E840

UPDATED RESULTS FROM ZUMA-4: A PHASE 1/2 STUDY OF KTE-C19 CHIMERIC ANTIGEN RECEPTOR (CAR) T CELL THERAPY IN PEDIATRIC AND ADOLESCENT PATIENTS WITH RELAPSED/REFRACTORY ACUTE LYMPHOBLASTIC LEUKEMIA

1Division of Pediatric Hematology/Oncology, Department of Pediatrics, University of Virginia, Charlottesville, VA, 2Children’s Center for Cancer and Blood Diseases, Division of Hematology, Oncology and Blood and Marrow Transplantation, Children’s Hospital Los Angeles, USC-Norris Comprehensive Cancer Center, Keck School of Medicine, University of Southern California, Los Angeles, 3Division of Oncology, Blood and Marrow Program, CHOC Children’s Hospital, Orange, United States, 4Department of Pediatric Hematology and Oncology, University Children’s Hospital, Eberhard Karls University, Tuebingen, Germany, 5Department of Pediatric Leukemia Program, Sidney Kimmel Cancer Center, Johns Hopkins University School of Medicine, Baltimore, United States, 6Princess Maxima Center for Pediatric Oncology, Utrecht, Netherlands, 7Kite Pharma, Santa Monica, United States

Background: Acute lymphoblastic leukemia (ALL) exhibits a bimodal age distribution with 60% of cases occurring in children and adolescents (<20 y) and 25% in older adults (>45 y; http://seer.cancer.gov/csr/1975_2013/). As of 19 Jan 2017, 5 patients have enrolled and 4 have been treated with KTE-C19. The most common childhood malignancy (Hematol Rep 2014;6:5554; Front Oncol 2014;4:63). ALL has an incidence of 1.2 to 1.4 per 100,000 per year in Europe (BM Cancer 2015;15:77). As many as 20% of children relapse after initial therapy, with subsequent poor clinical outcomes (Front Oncol 2014;4:63). Promising results were observed with KTE-C19, an anti-CD19 chimeric antigen receptor (CAR) T cell therapy, in B cell malignancies, including refractory, aggressive non-Hodgkin’s lymphoma in the ZUMA-1 trial (Blood 2016;128:LB-6). Here, we present updated results from the phase 1 portion of ZUMA-4, a phase 1/2 trial of KTE-C19 in pediatric and adolescent patients with relapsed/refractory (R/R) ALL.

Aims: The aim of the phase 1 study is to evaluate the safety of KTE-C19 in pediatric and adolescent patients with R/R ALL.

Methods: Pediatric and adolescent patients (aged 2-21 y) with high burden R/R ALL (>25% marrow blasts), adequate renal, hepatic, pulmonary and cardiac function received 2x10^6 CAR T cells/kg after low-dose conditioning chemotherapy consisting of cyclophosphamide (900mg/m² once) and fludarabine (25mg/m²/d for 3 days) (CYFlu). The primary endpoint of phase 1 is the safety of KTE-C19. The secondary endpoints include efficacy outcomes and biomarker assessments.

Results: As of 19 Jan 2017, 5 patients have enrolled and 4 have been treated with KTE-C19 at 2x10^6 CAR T cells/kg. KTE-C19 was successfully manufactured and administered in a centralized, streamlined 6-8-day process for all patients across a 2-week period. One baseline absolute lymphocyte count (0.21–1.0x10^9/L), except for 1 patient who had disease progression with white blood cells 150,000/mL at apheresis and <0.2% T cells in the apheresis collection. All 4 treated patients had high disease burden with a median marrow lymphoblast content of 57%...
(range, 41–99%). All 4 patients received bridging chemotherapy during the manufacturing period before conditioning chemotherapy and KTE-C19. No patient experienced a dose-limiting toxicity. One patient had a grade 5 adverse event of disseminated mucormycosis which was not related to KTE-C19. Cytokine release syndrome was reported in all 4 patients (all ≤ grade 3); neurologic events were reported in 1 patient (grade 3). All cytokine release syndrome events resolved with tocilizumab, corticosteroids, and/or sil kitumab plus other supportive care with a median duration of 8.5 days (range, 4-16) days. Minimal residual disease-negative remission was observed in all 4 patients. One patient received stem cell transplant post-remission, which is allowed per protocol at investigator discretion. Peak expansion of CAR T cells occurred 1-2 weeks post-KTE-C19 infusion. Updated data with additional patients, different dose of KTE-C19, earlier tocilizumab use, and biomarkers will be presented.

Summary/Conclusions: KTE-C19 after low-dose CyFlu has been tolerable and appears safe for further analysis in pediatric and adolescent patients with R/R ALL. No toxicities were observed with KTE-C19 at the 2×10^6 cells/kg dose in patients despite high leukemic burden. All patients receiving KTE-C19 achieved a minimal residual disease-negative remission. Based on these results, ZUMA-4 continues to enroll (NCT02625480).

E842
QUALITY-ADJUSTED LIFE YEARS (QALY) FOR INOTUZUMAB OZOGAMICIN VS STANDARD OF CARE FOR RELAPSED/REFRACTORY ACUTE LYMPHOBLASTIC LEUKEMIA (R/R ALL)

S. Hrabovsky1,2,*, F. Folber1,2, J. Horacek3,4, O. Stelhlikova1, H. Jelinkova1, C. Salek3,6, M. Doubek1,2,7
1Department of Internal Medicine, Hematology and Oncology, University Hospital Brno, 2Faculty of Medicine, Masaryk University, Brno, 34th Department of Internal Medicine – Hematology, University Hospital and Charles University, Faculty of Medicine Hradec Králova, 4Department of Military Internal Medicine and Hygiene, University of Defence, Faculty of Military Health Sciences, Hradec Králova, 5Institute of Haematology and Blood Transfusion, 6First Faculty of Medicine, Charles University, Prague, 7Central European Institute of Technology, Brno, Czech Republic

Background: The presence of minimal residual disease (MRD) is the most important prognostic factor in adult acute lymphoblastic leukemia (ALL). MRD monitoring is routinely performed by flow cytometry (FCM) and real-time quantitative polymerase chain reaction methods (RT-PCR).

Aims: We conducted a retrospective analysis comparing these MRD measurement methods in ALL patients treated in three Czech hematology/oncology centers within the CELL group (Czech Leukemia Study Group for Life).

Methods: Adult patients (age 18-55) with both Ph-negative and positive ALL were enrolled in the study, all treated consecutively between 2008 and 2016 according to a pediatric-inspired CELL ALL protocol. Samples for MRD evaluation were acquired from bone marrow on day 26 of induction (D26) and in the 11th week of treatment before the first consolidation (W11). We divided RT-PCR MRD positive and negative groups using three different cut-off values and analyzed them separately: 1) 1.0×10^{-3}, 2) 1.0×10^{-4}, and 3) every RT-PCR positive result considered MRD positive even below 1.0×10^{-4}. Cut-off value 1.0×10^{-3} was used for FCM MRD. Results were statistically analyzed by the Kaplan-Meier method and log-rank (Cox-Mantel) test.

Figure 1. Results: Total number of 103 patients was evaluated. Nine of them (8.7%) who did not reach a hematological remission on D26 were excluded from the study. The estimated mean of the final cohort was 36.9 months. MRD evaluation was carried out by 8-color FCM (N=73) and RT-PCR of immunoglobulin heavy chain (IgVH, N=62) or T-cell receptor (TCR, N=3) clonal rearrangements and BCR-ABL (N=24), MLL-AF4 (N=4) and E2A-PBX1 (N=1) fusion genes.

Methods with strongest sensitivity for OS prediction on D26 were RT-PCR with 1.0×10^{-3} cut-off (4-year OS: 76.6% vs 48.8%, median OS: not reached vs 39.1 months; p=0.012) and FCM (4-year OS: 78.3% vs 30.3%; median OS: not reached vs 27.4 months; p=0.016). The most sensitive method in W11 was RT-PCR with every positive result considered MRD positive (4-year OS: 79.6% vs 53.1%; median OS: not reached vs 46.5 months; p=0.013). Flow cytometry and PCR with other cut-offs were not sufficiently sensitive. The sub-analysis of Ph-negative patients has shown the same results for RT-PCR (p<0.01).

Summary/Conclusions: Our analysis has shown both RT-PCR and FCM to be suitable methods for MRD assessment on D26 of induction in adult ALL patients requiring an intensive treatment. Furthermore it seems convenient to take any RT-PCR positivity (even below 1.0×10^{-4}) into account in W11 and later stages of treatment. FCM can be used for MRD assessment on D26, but it is not sufficiently sensitive in later stages of treatment. We suggest using RT-PCR as a method of choice for MRD assessment in adult ALL while reserving FCM as a backup method for patients without applicable RT-PCR target or when faster MRD evaluation is needed.

Supported by MUNI/A/1106/2016 grant of Masaryk University, Czech Republic and the Czech Leukemia Study Group for Life.
Background: Minimal residual disease (MRD) has been proven to be the most important indicator of relapse in BCPALL. Recently, flow-cytometry based MRD has been shown to achieve a sensitivity of <10^{-5} using a standardised panel with high number of event acquisition. However, high-sensitivity BMRD analysis is based on experience and acquisition of high number of events also includes other rare BM cellular elements and artifacts. We present a study of the cost-effective high-sensitivity 10-color single tube FC-MRD assay in BCPALL along with description of rare BM cellular elements and artifacts causing interference in analysis.

Aims: 1. To study the applicability and sensitivity of a 10-color high event single tube FC-MRD assay for BCPALL; 2. To document the rare BM cellular elements and artifacts causing interference in high-sensitivity FC-MRD assay for BCPALL and describe their prevalence and immunophenotypic features.

Methods: We studied 230 BCPALL MRD samples. FC-immunophenotyping was performed on Navios flow-cytometer using bulk-lysis-and-stain method and data was analyzed with Kaluza-software. MRD was monitored using 10-color single tube FC-MRD assay including CD45, CD10, CD19, CD20, CD34, CD33, CD58, CD98, CD123 and CD25/CD73 with an additional 4-color nuclear dye (SYTO13) tube. Samples with cluster of x20 and x2 leukemia associated phenotypes (LAIPs) were called MRD-positive. High number of events were acquired for MRD-assay (1.5 to 6 million). To evaluate the applicability of assay, number of LAIPs were determined in diagnostic and MRD samples. In addition, the frequency and antigen expression pattern of mimics and artifacts were studied.

Results: We studied 230 BCPALL MRD samples. High number of events was acquired for MRD-assay with median-events 3427000 (range, 1678000 to 6052800). We determined the limit of detection (LOD=10 events) and limit of quantification (LOQ=30 events) by performing dilution assay. MRD was positive in 107 (46.5%) samples with median of 0.135% and range of 0.0003% to 48.3%. We categorized positive MRD results into samples with MRD <0.001%, 0.001% - 0.01%, 0.01% - 0.1%, 0.1% - 1% and >1% and they were respectively 1.74%, 10.43%, 13.48%, 5.65% and 10.00%. Furthermore, in 24 samples with MRD-positive ≤0.01% and >1.5 million acquired-events, the results were compared between time-gated initial 500000-events, 1000000-events and all events acquired. Sixteen samples among these were found to be negative in initial 500000-events and eight in initial 1000000-events but we highlighted the importance of acquisition of >1.5 million cells. Further, we categorized different rare cellular events and artifacts in the following way: 1) CD34+ mature B cells; 2) CD10+ mature B cells; 3) CD73+ mesenchymal/stem cells and endothelial cells; 4) CD123+ CD19+ 7PD precursors; 5) CD86+ CD58+ B cell precursors (BCP); 6) CD19+ NK cells (Table 1). We also described their immunophenotypic features highlighting the differentiating features from MRD and B cell precursors (Figure 1).

Figure 1.

Summary/Conclusions: We established a cost-effective 10 color single tube FC-MRD assay with high sensitivity of at least 1 in 10^{5} and applicability in >97% BCPALL MRD samples. We also described the frequency and extent of different cellular events and artifacts that can interfere with high-sensitivity BCPALL FC-MRD analysis. The knowledge regarding presence and antigen expression pattern of these cellular events and artifacts are critical to avoid potential false positive results.
with b-blockers, as they could limit anthracycline toxicity by their heart rate-lowering activity and antioxidant effect. All the 8 patients subsequently improved in both GLS and LVEF values, despite the occurrence of one episode of mild hypotension in 2 patients.

**Summary/Conclusions:** All children, even if exposed to low doses of anthracycline, show early signs of LV impairment. Overt drop in LVEF, when present, mostly follows GLS alterations. Alterations seem more frequent in HR pts, possibly due to the higher burden of both leukemia itself and HR treatment. Further studies on wider series are needed to confirm the relevance of the early diagnosis of LV preclinical dysfunction in pediatric ALL patients.

**NUDT15 VARIANT CONTRIBUTING TO HEMATOPOIETIC TOXICITY WITH LOW 6-TGN LEVEL IN KOREAN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA**

H. Hoe Koo1,*, E. Sang Yi1, Y. Bae Choi2, N. Hee Lee3, J. Won Lee1, K. Hee Yoo1, K. Woong Sung1, R. Choi2, S.-Y. Lee1

1Pediatrics, Sungkyunkwan Univ School of Medicine, Samsung Medical Center, 2Department of Pediatrics, Korea University Guro Hospital, Korea University College of Medicine, 3Department of Pediatrics, Chung-Ang University Hospital, Seoul, 4Department of Pediatrics, Cha Bundang Medical Centre, Cha University, Seongnam, 5Department of Laboratory Medicine and Genetics, Sungkyunkwan Univ School of Medicine, Samsung Medical Center, Seoul, Republic of Korea

**Background:** NUDT15 polymorphism has been recently identified as a determinant of thiopurine intolerance. 6-thioguanine nucleotides (6-TGN) is monitored to prevent hematopoietic toxicity in acute lymphoblastic leukemia (ALL).

**Aims:** This study intended to evaluate the impact of NUDT15 polymorphism on thiopurine intolerance and 6-TGN level in Korean children with ALL.

**Methods:** Genotyping of NUDT15 was performed in 258 children with ALL who were registered in Samsung Medical Center. According to NUDT15 diplotype, patients were classified into low risk (LR, wild-type), intermediate risk (IR, heterozygous variant), or high risk (HR, homozygous or compound heterozygous variant). Total of 182 were finally included after 76 patients were excluded for TPNMT variation or lack of information during maintenance therapy; LR (n=131), IR (n=46), and HR (n=5).

**Results:** The least 6-mercaptopurine (6-MP) dose (mg/m2/day) were administered to 36.5, 29.9, and 21.9% of patients in LR, IR, and HR groups (p=0.05). HR exhibited significantly longer days of therapy interruption (HR 167 vs LR 30, p<0.01) and days of leukopenia (HR 131 vs LR 92 vs LR 59, p<0.01). The lowest WBC and platelet counts and hemoglobin level were observed in HR. 6-TGN level (pmole/8x10^8 RBC) divided by 6-MP dose (mg/m2) was the lowest in HR group (HR 4.4 vs LR 13.3 vs HR 14.7, p<0.01). The lowest WBC and platelet counts and hemoglobin level were observed in HR. 6-TGN level (pmole/8x10^8 RBC) divided by 6-MP dose (mg/m2) was the lowest in HR group (HR 4.4 vs LR 13.3 vs HR 14.7, p<0.01).

**Summary/Conclusions:** Patients with NUDT15 variants encountered significant thiopurine intolerance even with low level of 6-TGN. This concurs with the existing hypothesis that NUDT15 protein may prevent incorporation of thiopurine active metabolites into DNA. Therefore 6-TGN monitoring is not useful to predict hematopoietic toxicity for patients with NUDT15 variant.

**USING NEXT GENERATION SEQUENCING TO DETECT CLONAL TRG AND TRB GENE REARRANGEMENTS**

P. Shah1,*, Y. Huang1, K. Hutt1, T. Stenzel1, J.E. Miller1

1Invivoscribe Technologies, Inc., San Diego, United States

**Background:** During early T-cell development, somatic rearrangements occur within T cell receptor beta (TRB) locus that bring together, sequentially, the known TRG and TRB gene segments of IGH, IGK, and IGJ joining regions (J) are the current gold standard for clonality testing in suspected B-cell malignancies. Recently, next-generation sequencing (NGS) based approaches for immune receptor genes have been developed that improve sensitivity and identify the specific V-(D)-J DNA sequences required to track clones in follow-up testing. We have developed comprehensive LympoTrack™ assay on both MiSeq® and PGM® platforms, which detect the vast majority of rearrangements in a single NGS run. In this pilot study, we compared the performance of both LympoTrack™ assay and MiSeq and PGM Assays to the IGH PCR-CE assay by testing in 59 anonymized, blinded clinical samples.

**Aims:** To assess the clinical performance of LympoTrack™ IGH MiSeq and PGM Assays

**Methods:** LympoTrack™ IGH Assay has been developed for both the MiSeq and PGM platforms. The analytical performance of the LympoTrack™ IGH FR master mixes were manufactured with 12 indices to allow analysis of 10 samples with 2 controls. The sequencing data was generated using Illumina® MiSeq™ platform, which detect the vast majority of rearrangements in a single NGS run. In this pilot study, we compared the performance of both LympoTrack™ IGH MiSeq and PGM Assays to the IGH PCR-CE assay by testing in 59 anonymized, blinded clinical samples.
CORRELATION BETWEEN A 10-COLOR FLOW CYTOMETRIC MINIMAL RESIDUAL DISEASE (MRD) ANALYSIS AND MOLECULAR MRD IN ADULT ACUTE LYMPHOBLASTIC LEUKEMIA

J. Singh1,*, M. Gorniak1, G. Grigoriadis1,2, D. Westerman1,3, M. McBean1,2, N. Venn4, R. Sutton4, S. Morgan1, S. Fleming1,2

Methods: To facilitate rapid identification of MRD in patients with B-ALL, we developed a 10-colour single tube flow cytometry assay utilizing CD19, CD22, CD71, CD20, CD52, CD10, CD25, CD34, and CD38 markers. These markers were selected to provide at least two targets for identification of B-lineage cells, and to include the most frequently aberrant markers in pre-cursor B-lineage ALL samples. Subjects were grouped according to patients’ capacity of action and reaction.

Background: Hypoglycemia has been reported as a rare side effect in children and adolescents treated for acute lymphoblastic leukemia (ALL). It has been associated with purine nucleoside analogues (PNA), but potential relationship with asparaginase has also been described. Despite these reports, clinicians’ awareness of this risk seems to be limited.

Results: In total, 28 hypoglycemic events were reported in 26 of the 3293 patients. 25 events in 23 patients were described as symptomatic, to which further analysis was restricted (22 precursor B- and one T-ALL; 8 standard-risk, 12 medium-risk, and 3 high-risk). Age of patients ranged between 1.7 and 15.5 years at occurrence of symptomatic hypoglycemia. Balanced ratio between both sexes can be observed (13 male, 10 female), median age was 3.9 years for both sexes, and 4.1 years for females.

Summary/Conclusions: Comprehensive IGH Assays have been developed for both MiSeq and PGM platforms. These assays identify clonal IGH V-J rearrangements and provide the clonal DNA sequences of the tumor-specific clontypes required to perform follow up testing to detect residual disease. Combining FR1, FR2 and FR3 improved the overall clonality detection rate to 96%. Both NGS-based IGH assays have demonstrated excellent concordance in detecting clonality regardless of whether clonality was determined using a PCR-CE method or with assays formatted for the MiSeq and PGM platforms.

Results: 33 samples at different time points from 13 patients were analyzed by flow cytometry. 9 samples from 9 patients were taken at diagnosis. Whilst an informative MRD phenotype was identified by flow cytometry in all 9 patients, a molecular assay was not able to be developed in one patient due to lack of an identifiable marker. 24 samples from 13 patients were tested for MRD by flow cytometry. The median lower limit of detection was 0.0078% (range 0.0016% to 0.028%) with a median lower limit of quantification of 0.018% (range 0.002% to 0.07%). A sensitivity of <0.01% was attained in 21 of 24 samples (88%). 20 samples from 11 patients were tested concurrently for MRD by both molecular and flow cytometry methods. 11 samples were in Ph- disease and 9 were in Ph+ disease. MRD was detected by both molecular and flow cytometry in 11 samples and not detected by both methods in 8 samples. In one sample, MRD was detected only by molecular at an unquantifiable level. There was a strong correlation co-efficient between molecular and flow cytometric MRD analysis (R²=0.905, p<0.001). Correlation was strong with both IGL/TCR based molecular analysis (R²=0.949, p<0.001) and BCR-ABL based molecular assays (R²=0.904, p<0.001).

Summary/Conclusions: 10-color flow cytometric minimal residual disease analysis with bulk lysis attains a high degree of sensitivity in minimal residual disease determination in precursor B-lineage Acute Lymphoblastic Leukemia. There was a strong correlation with molecular MRD monitoring for both quantification of MRD and determination of MRD negative status. Flow cytometric methods may also permit MRD monitoring in patients where a suitable molecular assay cannot be developed.

E848

HYPOGLYCEMIC EVENTS DURING TREATMENT OF PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA: OBSERVATIONS FROM TRIAL AIEOP-BFM ALL 2009

J. D. Blackman1,*, J. Allen2, E. Bodmer3, E. Zapotocka3, D. Barbaric4, M. Schrappe3, S. Viebahn2, S. Zimmermann5, M. Mörckel1

Aims: Descriptive evaluation of symptomatic hypoglycemic events during ALL treatment.

Methods: Hypoglycemic events were analyzed among 3293 patients treated in the trial AIEOP-BFM ALL 2009 in four of the participating countries (Germany, Switzerland, Czech Republic, and Australia) between 06/2010 and 08/2016. PNA were administered during induction-consolidation, the second part of the reintensification phase (reinduction-consolidation) and during maintenance (MT). Pegylated asparaginase (PEG-ASP) was given in induction and during reinduction, as well as high-risk blocks. Additionally, the benefit of intensified PEG-ASP was tested during induction-consolidation in the high-risk group, and during reinduction-consolidation/MT in the medium-risk group. Adverse events were generally captured in a targeted approach by means of defined events assessed as clinically relevant, not including hypoglycemia. Thus, data collection of these events was based on proactive reporting by the investigators. For analysis, clinical severity of the events was retrospectively graded according to patients' capacity of action and reaction.

Results: In total, 28 hypoglycemic events were reported in 26 of the 3293 patients. 25 events in 23 patients were described as symptomatic, to which further analysis was restricted (22 precursor B- and one T-ALL; 8 standard-risk, 12 medium-risk, and 3 high-risk). Age of patients ranged between 1.7 and 15.5 years at occurrence of symptomatic hypoglycemia. Balanced ratio between both sexes can be observed (13 male, 10 female), median age was essentially similar (male 3.2 y, female 4.1 y). Hypoglycemic events occurred in induction treatment (n=1), induction-consolidation (n=8), reinduction-consolidation (n=4; one in standard MT, 3 in reinduction with intensified PEG-ASP treatment), high-risk block (n=1), and in MT (n=11; 4 events during standard MT, 6 events during MT with intensified PEG-ASP treatment, and one event 4 weeks after last PEG-ASP during MT). Seven events were reported with mild symptoms, 6 patients showed moderate symptoms, and in 12 events patients showed severe symptoms (loss of consciousness, seizure-like).

Summary/Conclusions: In accordance with previous reports, hypoglycemic events accumulated in PNA containing treatment phases, but not exclusively. Considering that 324 patients of the total cohort were treated with intensified PEG-ASP in reinduction-consolidation/MT, an additive effect of PEG-ASP and PEGase could be assessed. A hypoglycemic metabolic condition may be assumed although a similar effect was not seen in induction-consolidation with intensified PEG-ASP. However, numbers are small and reporting bias of the present data is probable, as hypoglycemic events were not captured systematically. Investigators' attention to adverse reactions and proactive reporting might be higher.
in experimental arms as well as in case of preceding hypoglycemic events in
other patients of the respective trial center. Despite these analytical limitations,
our data suggest that hypoglycemia during ALL treatment is a relevant and
probably underestimated clinical problem. Further investigation including pos-
sible identification of predisposing metabolic conditions is required to avoid
harm to patients by this preventable complication.

NUDT15 VARIANT IN KOREAN CHILDREN WITH ACUTE LYMPHOBlastic LEUKEMIA
S.Y. Park1, Y.T. Lim1, E.A. Kim1, J.O. Hah2, E.M. Choi3, Y.J. Shim3, H.S. Kim3,
J.-S. Ha4, Y.K. Kim5, J.M. Lee1,*
1Pediatrics, Yeungnam University, College of Medicine, 2Pediatrics, Daegu Fati-
ma Hospital, 3Pediatrics, Dongguk University School of Medicine and Dongsan Medical Center, 4Laboratory Medicine, Yeungnam University,
College of Medicine, Daegu, Korea, Republic Of

Background: Acute lymphoblastic leukemia (ALL) is the most prevalent pedi-
atric cancer with cure rates approaching 90% with current therapy. Patient with
ALL require long-term maintenance therapy. The combination of weekly methotrexate and daily 6-mercaptopurine (6-MP) is used as the backbone of
ALL maintenance regimens. Genetic polymorphism in thiopurine methyl-
transferase (TPMT) is well known to affect the 6-MP tolerance. However preva-
lence of non-function variant of TPMT is rare in Far East. Recently, a study has
identified a variant of the NUDT15 gene associated with intolerance of 6-MP.

Aims: We examined the association between NUDT15 polymorphism and clinical
data of Korean pediatric ALL.

Methods: NUDT15 genotyping and collection of clinical data was performed
for 74 Korean pediatric ALL patients from two different hospital. For NUDT15
 genotyping, DNA was extracted from whole blood/or bone marrow sample and
Sanger sequencing was performed for exon 1 and 3 of NUDT15 gene. 6-MP
dose intensity, defined as the ratio of prescribed 6-MP dose over protocol
planned dose.

Results: We found two kinds of variants, c.55_65insGAGTGC(rs686920766)
in exon 1 from 8 patients and c.415C>T(rs116855232) in exon 3 from 14
patients. Of them, 7 patients had both variants and all variants were heterozy-
gotes. Patients could be divided to four distinct groups according to combina-
tions of genotype (Table 1). 6-MP dose intensity in wild type was higher than three
other genotypes during maintenance therapy (p=0.003) (Fig 1). The number of
hospitalized days in wild type is small compared to other three genotypes
(p=0.017). Frequency of febrile neutropenia, hepatotoxicity, cumulative days
of antibiotics use and overall survival did not significantly differ by NUDT15
genotype.

E852
TREATMENT OUTCOME OF ACUTE LYMPHOBLASTIC LEUKEMIA IN KOREAN ADOLESCENTS AND YOUNG ADULTS
1Center for Pediatric Oncology, 2National Cancer Control Institute, 3Hematol-
ogy Oncology Clinic, National Cancer Center, Goyang-si, Gyeonggi-do, Korea, Republic Of

Background: The outcome of acute lymphoblastic leukemia (ALL) has marked-
ly improved for last centuries, but the improvement was mainly observed in children under 10 years old. In contrast, the treatment outcomes of ALL in ado-
lescents and young adults (AYA) still lag behind those of younger children.

Aims: We conducted this study to investigate the treatment outcome of AYA
ALL in Korea, and to define any patterns of care related to the treatment out-
come of AYA ALL.

Methods: Clinical data of 10-29 years old ALL patients diagnosed between
2002 and 2010 were extracted from Korean national health insurance service.

Data about patients’ diagnosis, age, gender, mainly treated department (internal
medicine vs pediatrics), usage data of medications (L-asparaginase, 6-mer-
captopurine, vincristine, prednisolone or dexamethasone), hematopoietic stem cell
transplantation (HSCT), radiotherapy, survival, and follow-up duration were
collected. Patients who were treated with steroid over 2 weeks, and L-aspar-
gagine at least once in initial 2 months were considered to be treated as pediatric
protocol, and who did not fulfil this criteria were considered to be treated as
adult protocol.

Results: Total 1,223 ALL AYA patients were diagnosed between the 2002 and
2010, and excluding those who never treated, 1,208 patients underwent ALL
treatment. Among them, 665 (55%) patients were treated with pediatric protocol,
and the other 543 (45%) patients were treated with adult protocol. Radiotherapy
was done in 278 (41.8%) and 186 (34.3%) in each group, and HSCT was done
in 205 patients (30.8%) and 216 patients (39.8%) in each group, respectively.

Pediatric protocol group showed significantly better overall survival compared
to adult protocol group in total age (65% vs 43%, P<0.0001), 10-14 year old
(76% vs 57%, P<0.0001), and 20-24 year old patients (51% vs 31%, P=0.0116).

In univariable analysis, patient age (younger), treatment protocol (pediatric), L-
Asparaginase, 6-mercaptopurine, and steroid over 2weeks in initial 2 months
were associated with better overall survival (P<0.0001 for each).

Summary/Conclusions: The overall survival rates in Korean AYA ALL were
comparable with previous studies done at other countries. Patients treated with
pediatric protocol tended to result better overall survival rate when compared
to patients treated with adult protocol. Radiotherapy and early HSCT were wide-
ly used in the 2000s, and further study is needed to follow up the recent trend
of treatment, and outcome as a result.

E853
AUTOLOGOUS TRANSPLANTATION AS TIME-DEPENDENT FACTOR FOR SURVIVAL OF PATIENTS WITH T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA: STUDY DATA AND SIMULATION MODEL
S. Kulikov1,*, M. Rusinov1, A. Kulikovskiy1, E. Parvinschikova2
1Biostatistics, 2Hematological Oncology and BMT, National Research Center
for Hematology, Moscow, Russian Federation

Background: The role of autologous hematopoietic stem cells transplantation
(aHSCT) for patients with T-cell ALL is still being discussed. The recent Russia
study of ALL shows the promising effect of aHSCT but there is a skepticism as
the study was not randomized. The possible bias was referred to the “time selec-
tion” factor.

Aims: It’s need to prove that time selection can not explain the magnitude of
the effect of aHSCT on patient’s survival.

Methods: We have developed SAS macros time-depend graphical and analytic
procedures for time dependent factors: Land Mark (LM) methods, Mantel-Bay-
test, Cox regression model (CM) and also a base for simulation all end points
and study events like remission, transplantation, relapse and death are well
assessed by a mixture of exponent distributions. Non-constant (time varying)
hazard rate exists in real study data. The consequence of violation of constant
hazard assumption as most possible source of biases was tested on our sim-
ulation model in different situations. Real data multicenter study of ALL was
used to fit simulation model parameters. Russian ALL study group held a prospec-
tive multicenter trial RALL-2009 in the treatment of Ph-negative adult
ALL patients based on non-intensive but non-irruptive treatment
(NCT01193933). The therapy was unified for all Ph-negative ALL pts, but in T-
cell ALL/LBL autologous hematopoietic stem cell transplantation (auto-HSCT)
after non-myeloablative BEAM conditioning was scheduled as late intensifica-
tion (+3-4 mo of CR) followed by prolonged 2 years maintenance. From Jan
2009 till Jul 2016, 30 centers enrolled 107 T-ALL/LBL pts. Median age was 28
years (15-54 y), 34 f / 73 m; early T-cell (T/II) phenotype was verified in 56

Madrid, Spain, June 22 – 25, 2017
(52.3%), mature (T-IV) - in 10 (9.4%), thymic (TII, CD1a+) ALL - in 41 pts (38.3%). T-lymphoblastic lymphoma (T-IVL: <25% b/m blasts) was diagnosed in 22 pts (20.5%). Autologous HSCT was performed in 35, allogeneic-in 7 pts.

**Results:** The survival analysis of real data shows 4-fold dropping hazard rate. The effect of aHSCT was confirmed by LM analysis, Mantel-Bay test - P-value=.0004, Cox model output: 1/HR=15.9, P=0.008. (Fig.1). Simulation model for remission consists of 3 fractions: early (α=10%, τ=0.05 m, δ=0.2 m), normal (α=57%, τ=0.28 m, δ=1 m) and late remission (α=33%, τ=1.31 m, δ=2.2 m), for survival consists of 2 fractions: short life (α=59%, τ=22 m), long life (α=41%, τ=600 m). (Fig.2). The first simulation experiment was performed in preposition that transplantation has no effect (HR=1). To exclude the random effect the sample size was N=4000, Mantel-Bay and Cox model show significant (P<0.05). The second experiment supposed that the existed effect of aHSCT (HR=0.5), N=500. Mantel-Bay and Cox model would show significance, but hazard ratio was underestimated (P<0.03, P<0.05, HR=0.70 (0.50-0.97)). More experiments were done for repeated simulation, which demonstrated a very good agreement of Mantel-Bay and Cox methods and their robustness.
JL1 is a novel epitope of CD43, which is known to be specifically expressed in leukemic cells. The antigen is not expressed on mature peripheral blood hematopoietic cells. The antigen is expressed depending on the differentiation stages of hematopoietic cells. JL1 was examined using FACSCanto II (Becton-Dickinson, Sunnyvale, CA).

Methods: Pts were recruited if aged ≥ 18 years; with de novo Ph+ ALL or CML-LyBP treated by PON alone or in combination for at least 1 treatment day, for relapsed or refractory disease, between Apr 2012 and Dec 2014 (Expanded LyBP, treated by PON alone or in combination for at least 1 treatment day, for gone hematopoietic stem cell transplantation (HSCT). Of the 18 pts screened for BCR-ABL mutations, 5 had none, 3 had T315I, 3 had other PON-sensitive mutations, while 5 had compound mutations (known to be resistant to all TKIs including PON) and 2 had E255V (of intermediate sensitivity to PON). PON was administered alone in 13 pts, combined to low-intensity chemotherapy in 6 pts, intensive chemotherapy or monoclonal antibody in 2 pts. Dose at initiation was 45mg in 17 pts and 30mg in 4 pts.

Results: Median duration of PON therapy was 3 months (5 days-30 months+). Out of the 19 pts who received PON for ≥ 4 weeks, 5 pts failed to reach CR, while 14 (78%) reached or maintained it. Molecular response was not reported uniformly. During induction by PON, 5 pts stopped therapy in 4 pts (1 pulmonary infection; 1 acute renal failure; 1 pancreatitis; 1 hepatitis; 1 venous thrombo-embolic event; no arterial occlusive event). Post-induction therapy consisted in PON-based therapy in most pts. HSCT was performed in 5 Pts. Our study shows that 1 pt died in CR on PON, 1 pt died in CR from acute stem cell failure in the HSCT process at 8 months, and 11 pts ultimately experienced bone marrow relapse, all of them within 6 months after PON initiation, except 2 who relapsed at 13 and 27 months after HSCT. Two patients are alive in CR at 14 and 30 months, 1 pt is still on PON.

Summary/Conclusions: Our series of resistant pts is comparable to the PACE study population by initial characteristics and high frequency of BCR-ABL mutations. CR was achieved in most pts, suggesting the role of PON as a bridge to HSCT. Because global outcome of this very high-risk population remains poor, earlier introduction of PON in the course of the disease is warranted, as underlined by the excellent results of the hyperC-VAD-PON combination in the first-line setting.

E857

JL1 ANTIGEN EXPRESSION OF LEUKEMIC CELLS IN CHILDHOOD ACUTE LEUKEMIA

E. You1, S. Kim2, C.-J. Park1, S. Jang1, Y.-U. Cho1, C.H. Yoon1, K.-N. Koh3, H.J. Im3, J.J. Seo2

1Department of Laboratory Medicine, Asan Medical Center, University of Ulsan College of Medicine, 2Department of Pediatrics, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic Of

Background: JL1 is a novel epitope of CD43, which is known to be specifically expressed depending on the differentiation stages of hematopoietic cells. JL1 antigen is expressed on tumor cells of T, B, and myeloid lineage in >80% of acute leukemia patients, and its expression is limited in normal multipotent hematopoietic cells. The antigen is not expressed on mature peripheral blood cells or other normal tissues. Thus, the clinical phase 1 test of a therapeutic agent for leukemia targeting JL1 is being conducted, and when anti-JL1 antibody was combined with a toxic substance, its therapeutic effect was found earlier in preclinical trials.

Aims: This study aims to examine JL1 expression of leukemic cells in childhood acute leukemia.

Methods: Between December 2014 and January 2016, a total of 71 patients younger than 21 years with acute myeloid leukemia (AML, n=25), and acute lymphoblastic leukemia (ALL, n=46) were enrolled in this study. Expression of JL1 was examined using FACSCanto II (BD Biosciences, CA USA) based flow cytometry, and an expression of 20% or above was defined as positive JL1 expression. Pathological and immunophenotypic characteristics, and clinical outcomes of the patients were analyzed.

Results: Positive JL1 expression was observed in 16 (64.0%) patients with AML, and 27 (58.7%) with ALL. In AML patients, positive JL1 group showed higher expressions than negative JL1 group in CD 14 (P=0.043), CD7 (P=0.026), CD56 (P=0.016) and lower expressions in CD65 (P=0.05). With regard to ALL patients, CD 20 (P=0.002) and CD2 (P=0.005) expressions were significantly higher in JL1 positive group than JL1 negative group. Positivity of JL1 staining did not show significant difference between B-lineage and T-lineage ALL (P=0.671). Positivity of JL1 expression was not significantly associated with overall survival in 71 patients with newly diagnosed childhood acute leukemia (P=0.570).

Summary/Conclusions: 60.5% of childhood acute leukemia displayed positive JL1 expression. This finding is similar to 61.2% of JL1 expression in adult AML and 57.9% of expression in adult ALL reported previously. The JL1 expression was significantly associated with some immunophenotypic features, but was not significantly associated with clinical outcome. These findings demonstrates that anti-JL1 antibody might be used in childhood acute leukemia patient showing JL1 expression.

E858

SERUM LEVELS OF CYTOKINES AND ADHESION MOLECULES AND THEIR ASSOCIATION WITH PROGNOSTIC FACTORS IN NEWLY DIAGNOSED ACUTE LYMPHOPROLIFERATIVE LEUKEMIA PATIENTS

M. Sasaki1,*, S. Kim2, C.-J. Park1, S. Jang1, Y.-U. Cho1, C.H. Yoon1, K.-N. Koh3, J. M. Horacek1,2,*, T. Kupsa1,2, J. Vanek3, L. Jebavy1,2, P. Zak2

Background: Dysregulated production of cytokines and adhesion molecules has been implicated in the onset and progression of various types of leukemia. Further knowledge gained from multiple cytokine and adhesion molecule evaluation could help to improve treatment outcomes.

Aims: The aim of this study was to evaluate baseline levels of cytokines, cytokine receptors and adhesion molecules in newly diagnosed acute lymphoblastic leukemia (ALL) patients and to assess their correlation with baseline characteristics and prognostic factors.

Methods: A total of 30 newly diagnosed ALL patients (median age 46, range 22–75 years, 20 males) were included. We evaluated serum levels of 31 analytes, specifically 21 cytokines, 4 soluble cytokine receptors, 5 soluble adhesion molecules and Matrix Metalloproteinase-9. From cytokines, we measured Interleukins (IL-1α, IL-1β, IL-2, IL-3, IL-4, IL-5, IL-6, IL-7, IL-8, IL-10, IL-12, IL-13, IL-15, IL-23), Epidermal Growth Factor (EGF), Granulocyte Macrophage Colony Stimulating Factor (GM-CSF), Interferon-γ (IFN-γ), Macrophage Inflammatory Protein-1α (MIP-1α), Monocyte Chemotactic Protein-1 (MCP-1), Tumour Necrosis Factor-α (TNF-α), Vascular Cell Adhesion Molecule-1 (VCAM-1) and E-selectin (E-selectin), P-selectin (P-selectin), Intracellular Adhesion Molecule-1 (ICAM-1) and Vascular Cell Adhesion Molecule-1 (VCAM-1). All analytes were measured by biochip array technology on Evidence investigator analyzer (Randox). Serum levels of tested analytes were correlated with baseline characteristics using software R 3.3.2 (R Core Team 2016).

Results: Comparing analytes with baseline characteristics, we found significant negative correlations between IL-7 and leucocyte count (r=-0.633; p=0.032), percentage of blasts in peripheral blood (r=0.695; p=0.004) and LDH (r=0.604; p=0.075). Furthermore, we found significant positive correlations between IL-7 and lymphocyte count (r=0.801; p=0.001), VCAM-1 and LDH (r=0.664; p=0.012). Correlations with baseline risk stratification according to GAML all did not reach statistical significance. In the study population, CR rate after induction was 86% (MRD negative in 29%), 1-year PFS 68% and 1-year OS 73% (2 patients died during induction therapy). Higher levels of EGF were associated with failure to achieve CR after induction therapy (r=0.696; p=0.073). Significant correlations between baseline analyte levels and inferior PFS or OS were found. In newly diagnosed ALL patients, we found statistically significant correlations between sTNFR-1 and sTNFR-2 (r=0.805; p=0.001), IL-1α and IL-4 (r=0.700; p=0.008), sTNFR-2 and MIP-1α (r=0.657; p=0.037), sTNFR-2 and VCAM-1 (r=0.652; p=0.044). Correlations between adhesion molecules did not reach statistical significance.

Summary/Conclusions: Our findings show that serum levels of IL-7 and VCAM-1 are associated with some baseline characteristics of newly diagnosed ALL patients and EGF with response to induction therapy. Better understanding of leukemia microenvironment is essential for development of new treatment approaches. Further studies in this field are warranted.

IMATINIB VS. DASATINIB FOR OUTCOMES AFTER ALLOGENEIC STEM-CELL TRANSPLANTATION IN PATIENTS WITH PH+ ACUTE LYMPHOBластIC LEUKEMIA

A. Shigematsu1,*, S. Ota1, H. Goto1, K. Minachauchi, J. Sugita2, D. Hashimoto2, M. Obara1, T. Endo3, M. Imanura1, T. Teshima2, N. Kobayashi1
1Department of Hematology, Sapporo Hokuyu Hospital, 2Department of Hematology, Hokkaido University Hospital, Sapporo, Japan

Background: The survival of the patients with Philadelphia chromosome positive acute lymphoblastic leukemia (Ph+ALL) who received allogeneic stem cell transplant (allo-HSCT) has improved over the development of tyrosine kinase inhibitors (TKIs). Currently, Imatinib (IMA) and Dasatinib (DAS) are widely used for the treatment for Ph+ALL. However, there has been no data comparing the outcomes between the patients who received allo-HSCT and the two distinctive TKIs respectively.

Aims: We conducted a retrospective analysis for comparing the two TKIs for the outcome after allo-HSCT.

Methods: Clinical data of patients were retrospectively collected from Hokkaido University Hospital and Sapporo Hokuyu Hospital. The patients’ eligibility were as follows: diagnosis as Ph+ALL, aged more than 16 years, and received allo-HSCT between 1990 and 2016 and first time for SCT.

Results: Sixty-six patients were eligible for the study. Fifty-six out of the 66 were administered TKIs (TKI group) and the remaining ten who developed Ph+ALL in the early treatment were treated without TKIs (non-TKI group). Overall survival was not different between the two groups. Of the 56 patients in the TKI group, 39 received IMA (IMA-pts), and the remaining 17 received DAS (DAS-pts). Compared with DAS-pts, IMA-pts received allo-HSCT in relatively older years of age, more frequent myeloablative conditioning regimen, and cyclosporine-containing, not tacrolimus-, regimen for GVHD prophylaxis more frequently. Other characteristics, such as age, disease status at diagnosis, stem cell source were not significantly different between the two groups. Incidences of Neutrophil engraftment and acute GVHD incidence were not statistically different between IMA-pts and DAS-pts. Incidence of chronic GVHD was marginally increased in IMA-pts (IMA; 63%, DAS; 33%, P=0.08). At the median follow-up of 34 months (range: 14-462 days), overall survival was not different between the two groups by univariate analysis (Logrank, P=0.16). However, by multivariate analysis using Cox regression model for adjusting confounding factors, including, overall survival was superior for IMA-pts [Hazard ratio; 0.32 (0.11-0.94), P=0.04]. Incidences of transplant-related mortality and relapse were not different between the groups, even though relapse rate tended to be increased in DAS-pts (IMA; 16.1%, DAS; 47.1%, Gray P=0.2).

Summary/Conclusions: Our analysis suggests that overall survival may be superior for the Ph+ALL patients treated with allo-HCT and IMA compared with those with DAS. There are some limitations for our analysis due to retrospective fashion and relatively small number of the patients analyzed. Therefore, prospective study comparing survival of the Ph+ALL patients treated with the two distinctive TKIs before HSCT is needed.

IS OLDER AGE AN EXCLUSION CRITERION FOR ALLOGENEIC HEMATOPOIETIC STEM-CELL TRANSPLANTATION IN PATIENTS WITH PHILADELPHIA-POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA?

O. Gavrilina1,*, E. Parovichnikova1, V. Troitskaya1, A. Sokolov1, L. Kuzmina2, S. Bondarenko2, V. Lapin1, T. Obukhova2, A. Sudarikova2, K. Zarubina1, S. Kulkov2, M. Rusinov2, V. Savchenko1
1Chemotherapy and BMT, Bone marrow transplantation, National Research Center for hematology, Moscow, 2BMT, Institute of the Pediatric Hematology and Transplantology, Saint-Petersburg, 3Hematology, Regional hospital, Yaroslavl, 4Cytogenetic, 5Molecular hematology, 6Statistic, National Research Center for Hematology, Moscow, Russian Federation

Background: Philadelphia-positive acute lymphoblastic leukemia (Ph+ ALL) is diagnosed more often in older than in younger patients. This type of the acute lymphoblastic leukemia is characterized by very aggressive course of the disease. All clinical recommendations for such conditions indicate allogeneic bone marrow transplantation after achieving complete remission. The addition of tyrosine kinase inhibitors (TKI) to chemotherapy has dramatically improved the long-term outcome in Ph+ acute lymphoblastic leukemia patients. Nevertheless whether to administer chemotherapy at all and if yes – how intensive it should be, is still the matter of debate. We have conducted two consecutive trials in Ph+ ALL aiming to evaluate the efficacy of more and less intensive chemotherapy approaches in combination with constant non-stop 600 mg Imatinib. All patients in both protocols with suitable donors underwent hematopoietic stem-cell transplantation (HSCT).

Aims: To analyze the effectiveness of RALL–2009+TKI and RALL–2012+TKI protocols in Ph+ ALL patients with or without HSCT. To analyze the efficacy of treatment with or without transplantation regarding the patient’s age.

Methods: From 2010 January to 2017 January, 35 new Ph+ALL cases were diagnosed in 3 centers of the RALL–group. From 2010 to 2012, 12 Ph+ ALL pts were treated according to RALL–2009 protocol (ClinicalTrials.gov; NCT01193933) with concurrent administration of Imatinib. This protocol includes 8 cytostatic drugs and no intervals between treatment phases. Since 2012 till now 23 pts were included in ongoing RALL–2012 protocol, based mainly on 600 mg Imatinib with prednisolone, VNCR, L-asp, followed by 6-MP and MTX. Both protocols suggested the shift to Dasatinib (100-140mg) after non-achievement of MolCR on day 70 of treatment. MolCR was stated if bcr/abl chimeric transcript was <0.01% by PCR with 10-4 sensitivity. All patients were considered as candidates for allogeneic HSCT if HLA-identical donor was available. 13 pts (37%) underwent allo-HSCT as the first-line therapy: 1 autologous, 5 matched related and 7 matched unrelated.

Results: Six RALL–2009 patients were included in ongoing RALL–2012 protocol and 2 cases on RALL–2009. Hematological CR was achieved in 30 (85.7%) of 35 pts (except four early deaths and 2 refractory cases). There was one autologous HSCT in MolCR on the first protocol. Allo–HSCT was carried out in 5 of RALL–2009 protocol pts and in 9 of RALL–2012. The major issue was the non-relapsed mortality after unrelated allo–HSCT in 3 older pts (49, 56 and 59 years old) who were included in RALL–2012 (aGVHD and severe infections, at a median +4 months after HSCT and more than 12 months of CR duration). The 5y overall survival (OS) and relapse-free survival (RFS) for all 35 pts constituted 54.6% and 40.4% respectively. The long-term outcome on both protocols and at different ages are presented in Table 1. OS6 years in transplanted group of the pts, and RFS was 55.7% vs 45% (p=0.7), respectively. In order to evaluate the impact of allogeneic HSCT we performed a comparison of transplanted and non-transplanted patients by a landmark analysis. The landmark was chosen as the median time from CR to allo–HSCT – 4,3 mo (3-16 mo). So, the 5y OS from landmark was 53.3% for non-transplanted patients and from day of HSCT – 65.6% in transplanted (p=0.18), and RFS was 25% vs 62.5% (p=0.19), respectively. OS for older pts (>45 y) was 40% vs 25% in transplanted vs non-transplanted group of the pts, and RFS was 25% vs 66.6%, respectively. OS in younger (≤45 y) pts was 83.3% vs 58.9% for transplanted vs non-transplanted pts, EFS was 77.1% vs 21.4%, respectively.

Summary/Conclusions: The results very pessimistic in older (>45 years) patients who received HSCT. The contrary was observed in younger adult patients with very good results after HSCT – OS was 83,3% and EFS 77.1%. We conclude that patients aged>45y should continue chemotherapy without allogeneic HSCT or may be we could apply autologous HSCT for that group of the patients.

TARGETABLE BLINatumOBAmb + TYROSINE KINASE INHIBITORS TREATMENT IN RELAPSED/REFRACTORY ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS: CLINICAL EFFECTIVENESS AND PERIPHERAL LYMPHOcyTES SUBPOPULATIONS KINetics

A. Sokolov1,*, E. Parovichnikova1, V. Troitskaya1, I. Galtseva1, L. Kuzmina1, J. Davidova1, N. Karpanov1, I. Lukyanova1, T. Lobanova1, K. Zarubina1, E. Usikova1, V. Savchenko1
1National Research Center for Hematology of the Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation, 2Chemotherapy of hemato-blastoses and bone marrow depression and bone marrow transplantation, National Research Center for Hematology of the Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation

Background: Blinatumomab is a bispecific monoclonal anti-CD3/CD19 antibody which has clinical activity in relapsed/refractory Ph-positive acute lymphoblastic leukemia (ALL) as monotherapy. Combination of Blinatumomab with
tyrosine kinase inhibitors (TKI) is the promising approach in treating Ph-positive ALL. Some other rearrangements like IKZF1 in Ph-like ALL, FLT3 and JAK2 in Ph-negative ALL are the potential targets to some TKIs.

Aims: To demonstrate effectiveness and toxicity profile of Blinatumomab+TKI treatment. To evaluate peripheral blood lymphocytes subpopulations kinetics during blinatumomab treatment.

Results: During this period, a total number of 353 patients with childhood ALL were treated in our Department, according to BFM protocols. Recurrence occurred in 86 patients (24.4%, 56 male - 30 female - median age: 4.83 years), within 3 to 184 months from initial diagnosis. Very very late recurrence was noted in 3.1% of our relapses (8 male - 3 female) at 53, 72, 82, 83, 84, 108, 112, 116, 120 and 184 months from initial diagnosis. In 9 patients recurrence immunophenotypically was bone marrow, in 1 both bone marrow and central nervous system (CNS) and in 1 only the testicles. Two children had received allogeneic BMT from a matched related donor in first complete remission (CR1) and they had a bone marrow relapse 4 and 5 years later, respectively. The mean WBC, Hb, Blasts and PLT values at diagnosis were 29260/mm3, 5.6g/dl, 21360/mm3 and 18000/mm3, respectively. All of them were B-cell ALL except for 1 who had CD33 and CD13 co-expression. Regarding the immunophenotypical profile of the disease at recurrence, it remained almost identical to the initial. Regarding cytogenetic characteristics of the patients at diagnosis, 3 of them had high hypodiploidy, one del(6)(q12), one BCR-ABL fusion and one 47.XY,i(19)(q13); 2 del(12)(p13); 3 other rearrangements. In ALL disease, the cytogenetic profile remained identical at recurrence, while in 1, trisomia 13 was not detected and another had heterozygous absence of IKZF1, PAIX5, EBF1, CDKN2A and CDKN2B genes. On Day 8, none of 11 patients were Prednisone Good Responders. On Day 15, nine children had bone marrow M1, one M2 and one M3, and on Day 33 only one had M2. Two patients were classified as low risk, 6 as intermediate risk and 3 as high risk. Second remission (CR2) was achieved in 9 children with very very late recurrence. The other 2 died from disease progression. Six of nine patients are still alive and well 6, 8, 10, 10, 11 and 20 years after initial diagnosis. One patient died from second recurrence and the last two had a second allogeneic BMT and died due to severe infection, 2 and 12 months following that BMT. Interestingly, 3 out of 5 patients who finally died, had the very very late recurrence (10, 10 and 15 years after initial diagnosis) and had been treated with adult type protocols.

Summary/Conclusions: The rate of very very late B-cell ALL recurrence was only 12.8% of all recurrences. The prognosis is worse in patients, older than 18 years, treated with adult type protocols.

E683

NOVEL CRLF2 MUTATIONS AND CLINICAL SIGNIFICANCE IN ADULT ACUTE LYMPHOBLASTIC LEUKEMIA
Z. Ge1,2, Y. Gu3,3, Q. Han3,3, X.-L. Zhou2,3, B.-A. Chen1,2, J.-Y. Li3, C. Song2,4,5

Background: Cytokine receptor-like factor 2 (CRLF2) plays an important role in the development of normal B lymphocytes, which can mediate early B cell proliferation and survival. CRLF2 overexpression and rearrangement have been observed in acute lymphoblastic leukemia (ALL) and they are reported to contribute to oncogenesis and unfavorable outcome in ALL. We reported that CRLF2 overexpression in the patients without CRLF2 rearrangement, indicating the reason other than CRLF2 rearrangement is responsible to the CRLF2 overexpression. There is few reported CRLF2 mutations in adult ALL.

Aims: This study is to investigate the mutations of CRLF2 and its clinical significance in adult ALL without CRLF2 rearrangement.

Methods: The 129 patients’ BM samples (95 B-ALL, 33 T-ALL and 17 T- and B-ALL) were collected between April 2010 and Jan 2015 at the First Affiliated Hospital of Nanjing Medical University. The ALL diagnosis was made according to the cytogenetic, morphologic, Immunophenotypic and molecular CRLF2 NO Immunogenetic Diagnosis and Classification of ALL (2008). Mutational analysis of CRLF2 exons 1-6 was performed. Genomic DNA was isolated and DNA fragments spanning the aforementioned CRLF2 exons were amplified by PCR using AmpliTaq Gold kit (Applied Biosystems, USA) and the exon-specific primers. The resulting PCR products were purified by EXOSAP-IT (USB, USA) and sequenced by the Beijing Genomics Institute (BGI; Beijing, China). The frequency, positions, types and clinical significance of CRLF2 mutations were analyzed. For qualitative parameters, overall group differences were analyzed using a χ2 test. All statistical analyses were performed using SPSS version 17.0 (SPSS, Inc., Chicago, IL, USA). P<0.05 was considered to indicate statistical significance.

Results: Six novel CRLF2 mutations were detected in the 129 patients without CRLF2 rearrangement, which were L86I (0.8%), R186S (7.8%), P224L (8.5%), W255C (0.8%), and two silent mutations F232F (0.8%) and A11A (12.4%). The overall rate of CRLF2 mutation was 26.6%. Exon1 contained three types of mutations. The incidence of A11A in B-ALL was significantly higher than in T-ALL (14.7% vs 2.4%, P=0.037), whereas R186S was only detected in B-ALL. Exon1, exon5 and exon6 mutations were detected in B- and/or T-ALL patients; but no mutations were detected in exon2 and exon4. None of these mutations were reported in the COSMIC and SNP databases. The patients with R186S, P224L mutations showed significant differences with that of non-mutant patients in sex, age, white blood cell count, hemoglobin level, and platelet count. The median neutrophil count in the patients with P224L mutation
was lower than that of non-mutation (8.5×10⁹/L vs 28.9×10⁹/L, P=0.032). The positive rate of Ph chromosome in patients with R186S was lower than that without the mutation (10.0% vs 31.8%, P=0.018). In addition, the incidence of splenomegaly in patients with R186S and P224 L mutants was lower than that in non-mutant patients (0.0% vs 29.5%, P=0.026; 0.0% vs 29.7%, P=0.034, respectively). The B-ALL patients with L86I mutant had myeloid antigen expression, high white blood cell count (248.4×10⁹/L) and low platelet count (10×10⁹/L), and relapsed in two months after the first induction chemotherapy; and the overall survival was only 2 months. The patient with W255C mutation did not achieve complete remission with the first induction chemotherapy. Interestingly, the patient with silent mutation, A11A showed higher age (46 vs 30 years, P=0.033), higher HLA-DR (100% vs 75.3% P=0.035), CD22 (93.3% vs 47.4% P=0.020) than those without the mutation; and the patient with F232F mutation relapsed in 6 months.

Summary/Conclusions: Six novel CRLF2 genetic mutations were identified in adult ALL patients and may associate with clinical outcome, such as CRLF2 R186S indicating favorable, while L86I and W255C indicating poor outcome. Our data indicated that the CRLF2 mutations may be new prognostic markers and play an important role on oncogenesis in ALL.

Background: Recently, comprehensive genetic profiling of pediatric and adult core-binding factor (CBF) AML revealed a variety of cooperating events in a cohort of 85 t(8;21) AML patients (Faber et al. Nat Genet 2016). These mutations comprised alterations in genes encoding for proteins in tyrosine kinase (TK) signaling, epigenetic regulation (ER), and in the cohesin complex (CC).

Aims: To validate and to further extend our recent findings by comprehensive characterization of the mutational landscape of t(8;21) positive AML using a high-throughput targeted sequencing (HTS) approach.

Methods: The HTS panel comprised the entire coding region of 244 genes that are involved in hematological malignancies. Pretreatment blood (n=23) or bone marrow specimens (n=72) of 95 additional adult t(8;21) positive AML patients (pts) (median age: 51 yrs, range 18-72 yrs) were analyzed. 92/95 pts were enrolled in one of seven prospective AMLSG treatment trials. Libraries (total probe size: 1.359 Mbp) were prepared using SureSelectXT custom solutions (Agilent). Paired-end sequencing was carried out on a HiSeq 2000 (Illumina). The variant allele frequency (VAF) cutoff for reporting mutations was set at ≥0.05.

Results: The median coverage per pt was 900x. Mutations were detected with an average of 5.1 (SD: ±2.6) per pt with 99% of all pts harboring at least 1 mutation and 87% ≥ 3 mutations. Consistent with previous studies, mutations in TK signaling pathways were common events: KIT mutations were found in 22/95 pts (23%) followed by mutations affecting NRAS (16/95; 17%), FLT3 (11/95; 12%; point mutations only), and KRA5 (4/95; 4%). A significant enrichment of mutations was also observed in genes involved in epigenetic regulation, ASXL1 (15/95; 16%), ASXL2 (12/95; 13%), KDM6A (11/95; 12%), CREBBP (8/95; 8%), SRCAP (8/95; 8%), EZH2 (7/95; 7%), SETD2 (5/95; 5%), TET2 (12/95; 13%) and DNMT3A (5/95; 5%), highlighting their contribution in altering the epigenetic state of this leukemia subtype. Moreover, mutations affecting members of the CC were found with a high frequency: RAD21 (13/95; 14%), SMC1A (5/95; 5%), STAG2 (3/95; 3%), and SMC3 (2/95; 2%). Of note, mutations in CC genes were almost mutually exclusive. We also identified additional mutations in previously detected cooperating genes such as mutations clustering in exon 2 of the ZBTB7A gene (15/95; 16%), encoding for a transcription factor involved in hematopoietic lineage fate. Recurrent mutations were also observed in CCND2 (9/95; 9%), that plays an important role in regulation of hematopoietic cell proliferation, as well as DDX15 (6/95; 6%) being involved in spliceosome function and ribosome biogenesis. With respect to the clonal architecture we found that the median VAF in genes belonging to ER and CC (0.30; range 0.03-0.91; 0.31, range 0.05-0.73, respectively) was higher than in genes associated with TK signaling (0.19, range 0.05-0.53). These data suggest that alterations affecting the epigenetic state and differentiation occur earlier than those in signaling during t(8;21) leukemogenesis.

Summary/Conclusions: Using a comprehensive, deep sequencing approach we could further characterize the mutational landscape of t(8;21) positive AML. Here, mutation clusters in genes involved in TK signaling, ER and CC were confirmed as well as novel CBF-associated gene mutations that play an essential role in regulation of hematopoietic cell proliferation and differentiation. Further analyses in terms of sample size extension as well as correlation of findings with clinical parameters are ongoing.

NFkB PATHWAY PROMOTES TUMOR PROGRESSION THROUGH BRUTON'S TYROSINE KINASE IN MLL+ ACUTE MYELOID LEUKEMIA

S.C. Nimmagadda1,2, S. Frey1, B. Edelman1, T. Fischer1

1Department for Hematology and Oncology, University Clinic of Magdeburg, Magdeburg, German
A PRECISION MEDICINE PLATFORM FOR ACUTE MYELOID LEUKEMIA

Aims: Drug-driven personalized medicine aims to directly test the sensitivity of primary cancer cells taken from individual AML patients to a selection of targeted cancer drugs. This approach considers any combination of mutations or epigenetic changes that might not be found in the standard sequencing panels, an advantage when dealing with such a heterogeneous disease. Proof of principle of this strategy was recently demonstrated by FiMM (Helsinki, Finland) (Pemovska et al., 2013), not only providing immediate clinical benefit to leukemia patients, but also identifying drugs that can potentially be repurposed for future treatment of patients.

Methods: We have established a drug-driven personalized medicine platform for AML where we check the ex-vivo drug sensitivity and resistance of bone marrow primary cells to a panel of around 400 drugs and drug combinations covering the standard of care for AML. We are also interested in uncovering possible downstream target/s of BTK, improving the therapeutic efficacy of the drugs used.

Results: Experiments were performed using control and MA9.3 cells and leukemic blasts from 3 AML (MLL+) patients. Signalling events were evaluated by immunoblotting, p65 mediated BTK expression was determined by promoter assays. Cells were treated with specific inhibitors of BTK (Ibrutinib (IBR): 0.25, 0.5, 1.0 and 2µM) in combination with Daunorubicin (DAU 5µM) or RAC (NSC 23766; NSC: 5, 10, and 20µM) for 48 hrs and cell viability was assessed using Annexin V/Sytox Blue based flow cytometric analysis.

Conclusions: These findings present a novel treatment that has remained unchanged for the past 30 years (Longo et al., 2013). Current standard of care for AML is an aggressive cytostatic treatment that has high drug dose-related side effects but increasing the therapeutic efficacy.

AIDS: CD3/CD23 BITEN® ANTIBODY MEDIATED CYTOTOXICITY AND T-CELL PROLIFERATION

Aims: In our previous work, we showed that the CD3/CD23 BITEN® antibody construct (AMG 330) is able to recruit autologous, residual T-cells and induce cytotoxicity against primary AML cells ex vivo. However, as described previously (Mussai et al., Blood 2013) primary AML cells are able to secrete soluble factors, which might not only influence T-cell proliferation but also negatively impact AMG 330 mediated cytotoxicity.

Methods: We used plasma samples (from heparanized serum tubes or after density gradient centrifugation) from newly diagnosed and relapsed AML patients in AMG 330 cocultures of healthy donor (HD) T-cells and AML cell lines. In flow cytometry based experiments we determined the influence of AML plasma in comparison to fetal calf serum (FCS, heat inactivated) on AMG 330 mediated cytotoxicity and T-cell proliferation. In transwell experiments using primary AML cells physically separated from AMG 330 cocultures, we evaluated if AML cells are the source of soluble factor secretion.

Results: The influence of AML plasma from bone marrow (BM) of AML patients on AMG 330 mediated cytotoxicity and T-cell proliferation was heterogeneous: In 15/30 samples, AMG 330 mediated cytotoxicity was significantly reduced compared to cultures containing FCS (mean% specific lysis FCS vs BM: 72.8 vs 26.8). This was accompanied by a reduction in T-cell proliferation (mean% proliferation FCS vs BM: 27.7% vs 9.5%). The degree of immunosuppression could not be correlated to percentage of bone marrow blasts. Interestingly, the effect was not observed in AML plasma samples from peripheral blood (PB) (mean% specific lysis FCS vs PB: 84.7 vs 83.5%; proliferation FCS vs PB 32.2 vs 26.5%, n=15). In the remaining 15 samples from AML BM no influence on AMG 330 mediated T-cell function was observed (mean% specific lysis FCS vs BM: 82.1 vs 78.3%; proliferation FCS vs BM: 25.7 vs 26.8). In control cultures plasma from AML patients in complete remission (CR) or from HD BM was used which did not negatively impact AMG 330 mediated cytotoxicity (mean% specific lysis FCS vs CR: 76.6 vs 78.3%; proliferation FCS vs CR 3.2 vs 5% FCS vs HD; 36.6, n=6) and 56 AML samples from AML 78.6 vs
41.8, n=7). In the remaining 7 primary AML samples, no immunosuppressive effect was observed specific for tyrosine kinase control vs AML 98.9 vs 98.2% proliferation control vs AML 82.8 vs 77.7, n=7).

Summary/Conclusions: In summary we demonstrated that BM derived plasm-a from AML patients at primary diagnosis or relapse reduced T-cell proliferation and AMG 330 mediated cytotoxicity in half of the samples tested. The immunosuppressive effect was observed in primary AML cell samples treated by transwell experiments. Unraveling mechanisms of resistance to BiTE® antibody mediated cytotoxicity will allow the exploitation and usage of enhanced strategies to increase response rates.

Background: Internal tandem duplications (ITD) in the receptor tyrosine kinase FLT3 occur in about 22% of patients (pts) with acute myeloid leukemia (AML) and confer a poor prognosis depending on the mutational load. The multi-targeted kinase inhibitor (TKI) midostaurin has been shown to improve outcome in FLT3-ITD positive (FLT3-ITDpos) and FLT3-TKDmut pts in combination with intensive chemotherapy [CALGB 10603 (RATIFY) trial], thus representing a promising targeted treatment approach. However, a significant number of pts relapse after initial response due to yet unknown mechanisms.

Aims: To study the clonal evolution in FLT3-ITDpos pts treated in the AMLSG 16-10 (NCT01477606) or CALGB 10603 (RATIFY, NCT00651261) trial in paired samples obtained at diagnosis (Dx), complete remission (CR) and relapse (Rel) by whole exome sequencing (WES).Methods: WES was performed in 17 FLT3-ITDpos pts using the Nextera Rapid Capture Exome kit (Illumina) for library preparation followed by sequencing on a Illumina HiSeq2000. 6 pts were treated in the RATIFY trial receiving either midostaurin or placebo combined with intensive chemotherapy during induction and consolidation and 11 pts treated in the CALGB 16-10 trial. In the CALGB 16-10 trial treatment with midostaurin combined with intensive chemotherapy during induction and consolidation followed by a one-year maintenance therapy with midostaurin; 4 pts in the AMLSG16-10 trial received allogeneic hematopoietic cell transplantation. The presence of FLT3 and NPM1 mutations (mut) and the allelic ratio (AR) of FLT3-ITD were analyzed according to standard protocols.

Results: The median AR of FLT3-ITD was 0.51 (0.10-18.94) and 0.54 (0.07-26.31) at Dx and Rel, respectively. Loss of FLT3-ITD was observed in 5 pts; changes of the ITD clone at Rel occurred in 7 pts. Of those, 5 pts had a change of FLT3-ITD that was lost at Rel. 6 pts had a NPM1mut that persisted at Rel in all pts. Using WES, 301 mut (226 missense, 24 nonsense, 41 indels, 6 splice sites, 4 unique ideplets) were identified. The average coverage was 125 (186-67) among all samples. 131 (43%) mut were present at both time points (Dx and Rel), 149 (53%) mut were only subclonal at Dx (RE5 73 (24%) mut were detected only at Rel and 14 mut with only 1 read at Dx. Besides FLT3-ITD, the average number of mut per sample (Dx or Rel) was 13. Mut were most frequently observed in genes related to signaling (23%), transcription (20%), DNA methylation (5%), chromatin biology (4%), components of the mitotic machinery (4%), Pre-leukemic (DNMT3a, TET2, IDH1/2) were detectable in 10 pts at both time points and persisted at CR in 7 pts. Mut resistant in transcription mutations occurred genes in 8 pts at Dx and Rel, with WT1 mut being most frequent (n=7). Mut in signaling related genes present at both time points included NRAS (G12V/D) and NFI mut. At the time of Rel, gene mut frequently referred to signaling (34%) including a KRAS (G13D) and a KIT (D816V) mut, both in pts with loss of FLT3-ITD at Rel.

Summary/Conclusions: Analyzing the clonal evolution of FLT3-ITDpos AML, known pre-leukemic mut were stably detectable at Dx and Rel in most pts, whereas unknown unexpected gene mutations were detected only at Rel. We investigate more comprehensively pathways underlying therapy resistance with a focus on TKI treatment, larger cohorts of pts are currently analyzed for the detection of recurrent mutational patterns.
University of Chicago, Chicago, IL, United States, 1Nationales Centrum für Tumorerkranckungen, Universität Heidelberg, Heidelberg, Germany, 10Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA, United States

Background: Internal tandem duplications (ITD) and mutations (mut) in the tyrosine kinase domain (TKD) of the receptor tyrosine kinase FLT3 occur in about 25% of acute myeloid leukemia (AML) patients (pts). FLT3-ITD is associated with an unfavorable prognosis in particular in pts with a high allelic mutant to wildtype ratio (AR>0.5) as well as localization of the ITD in the beta1-sheet of the receptor. FLT3is targetable by tyrosine kinase inhibitors (TKI) and the combination of chemotherapy with the TKI midostaurin has been recently investigated within the CALGB 10603 RATICY trial and is still under investigation within the AMLSG 16-10 trial.

Aims: To study the FLT3mut status at the time of diagnosis (Dx), refractory disease (RD) and relapse (Rel) in AML pts treated within the CALGB 10603 RATICY trial and AMLSG 16-10 (NCT01477606) trial with regard to AR of FLT3-ITD and FLT3-TKDMut, loss of FLT3-ITD and FLT3-TKDmut and change of ITD clones (ITD insertion site, length, number of clones).

Methods: FLT3-ITD and FLT3-TKDMut were detected using Genescan-based fragment-length analysis according to standard protocols. In the randomized phase-Ill RATICY study, FLT3mut pts were treated with induction (daunorubicin/cytarabine) and consolidation (high-dose cytarabine) and maintenance therapy in FLT3-ITD positive pts.

Results: In total, 83 pts were analyzed, of which 33 were treated in the RATICY and 50 within the AMLSG 16-10 trial. 36 pts had RD and 47 pts had relapsed. FLT3-ITD was present at diagnosis in all pts treated in the AMLSG 16-10 trial; one pt had an additional FLT3-TKDMut. Pts entering the trial had either a FLT3-ITD (n=22), a FLT3-TKDMut (n=9), or both (n=2). The median AR of FLT3-TKDMut at Dx was 0.82 (0.07-2.66) and the majority of pts showed loss of FLT3-TKDMut at RD or Rel (n=9/12; 75%). In relapsed pts, loss of FLT3-ITD occurred in 14 (36%) pts. There was no significant difference between the median FLT3-ITD AR at Dx [0.02 (0.10-14.94)] and Rel [0.05 (0.07-38.75); p=0.98]. A switch of the ITD clones was found in 14 (36%) pts at Rel, with switch of the ITD insertion site or length in 8 (21%) pts. 1/8 pts with change of the ITD clone at Rel had multiple ITD clones at Dx. For 35 FLT3-ITDPositive pts with refractory AML, FLT3-ITD loss was observed in 17 (49%) pts. The median AR of FLT3-ITD was significantly lower at the time of RD [0.29 (0.05-2.37)] compared to Dx [0.05 (0.08-9.11); p=0.02]. The ITD clone changed in 5 (14%) pts with RD. In pts with shift of the ITD clone at RD (n=5) or Rel (n=14), no significant difference of the median ITD length was observed (p=0.84).

Summary/Conclusions: Comparing the FLT3-ITD status at Dx, at the time of RD or Rel, we found a lower median AR of FLT3-ITD in pts at RD compared to Dx, whereas no significant change of AR was observed at Rel. In addition, loss of FLT3-ITD was observed in 49% of pts at RD and in 36% of pts at Rel. These findings suggest that the FLT3-ITD clone can be targeted in a significant number of pts and other clones might mediate resistance to treatment. We also observed a switch of the ITD clone in about 20% of pts with Rel, indicating the presence of ITD clones that might mediate failure of the available therapy. Despite the small number of TKD mutations in our study, it was remarkable that most of the TKDs (75%) were lost at the time of RD or Rel.

COOPERATION OF MLL-PTD WITH DNMT3A OR RUNX1 MUTATIONS IN AML LEUKEMOGENESIS

H.-W. Kao1, R. Bera2, Y.-J. Huang2, J.-F. Fu2, D.-C. Liang3, L.-Y. Shih3
1Chang Gung Memorial Hospital and Chang Gung University, 2Chang Gung Memorial Hospital, Taoyuan, 3Mackay Memorial Hospital, Taipei, Taiwan, Republic of China

Background: Our previous study showed that DNMT3A or RUNX1 mutations were frequently coexisted in the MLL-PTD AML patients (Oncotarget 2015). We aimed to investigate the role of coexisted DNMT3A or RUNX1 mutations in leukemogenesis of MLL-PTD AML.

Methods: After lentiviral-mediated over-expression of RUNX1 or DNMT3A mutants in MLL-PTD mouse bone marrow (BM) cells or human MLL-PTD+ AML cell lines, colony formation, cell proliferation, differentiation and apoptosis assays were carried out. Interaction of RUNX1, HIF-1α, and MLL-PTD were evaluated by co-immunoprecipitation assay. Differential genes and protein expression, histone modifying protein expression, and enrichment of histone-4 acetylation (H4Ac) were assessed by RT-qPCR, Western blot, and ChIP-seq, respectively. For BM transplantation assays in mice, MLL-PTD+ BM cells over-expressing DNMT3A-wild type (WT) mutants and empty vector (EV) control were injected into C57BL/6 mice via tail vein.

Results: We observed that MLL-PTD mouse BM cells with RUNX1 mutants lacking C-terminal VWRPY sequence (H377fsX and V425fsX576) had increased self-renewal, proliferation, increased HIF-1α and its downstream gene expression, histone modifying protein expression, and enrichment of histone-4 acetylation (H4Ac) compared to EV or WT mutants at 10 days post-BM transplantation.

Summary/Conclusions: We present the study showed that both RUNX1 and DNMT3A mutants deregulated self-renewal, proliferation and apoptosis in the mouse MLL-PTD BM cells. Disruption of MLL-PTD-RUNX1-HIF-1α complex in the RUNX1-mutant and aberrant methylation in the DNMT3A-mutant cells might play an important role in AML pathogenesis. Our results showed that cooperation of RUNX1 or DNMT3A mutations had impact on leukemogenesis of MLL-PTD AML.

AML BLASTS INDUCE A SENESCENT PHENOTYPE IN THE BM-MSC THROUGH THE UPREGULATION OF P21 ACTIVATING PROTEIN (P21) IN AML BLASTS INDUCE AN INHALATION

E. Forde1, A. Abdul-Azziz1, T. Mehta2, F. Di Palma3, C. Ingham4, M. Lawes4, K. Bowles4, S. Rushworth1
1Norwich Medical School, University of East Anglia, 2Earlham Institute, 3Department of Trauma and Orthopaedic Surgery, NNUH, 4Department of Haematology, Norwich and Norwich University Hospital NHS Trust, Norwich, United Kingdom

Background: Acute myeloid leukaemia (AML) is a heterogeneous clonal disorder that arises from the haematopoietic myeloid progenitor cells within the
bone marrow microenvironment (BMM). Survival of patients with AML is presently poor; two-thirds of younger adults and 90% of older adults die of their disease. Even in patients who achieve remission with chemotherapy, relapse is common and occurs from minimal residual disease sequestered in protective niches in the BMM. Reciprocal interactions between that of the AML and bone marrow mesenchymal stromal cells (BM-MSC) are central to the survival and proliferation of blast cells through micro-environmental promotion of quiescence in malignant cells as well as the activation of anti-apoptotic and pro-survival pathways.

**Aims:** To investigate how BMM are programmed by AML to generate a pro-tumoural environment.

**Methods:**

Primary AML and BM-MSC were isolated from the pelvis of AML patients following informed consent and under approval from the UK National Research Ethics Service (LRCEref07/H0310/146). Low input RNASeq of 10 AML BM-MSC and 10 healthy BM-MSC (taken from the pelvis of patients undergoing elective hip replacement surgery) was performed following CD271 MicroBead selection. Primary AML blasts and BM-MSC were co-cultured in confluent primary BM-MSC for 48 hours (h), 72h and 168h. Real-time PCR was used to verify the RNA sequencing data and Western Blot analysis to confirm protein expression. Lentivirus mediated knockdown was used to target gene expression in the BM-MSC. Senescence was assayed by β-Galactosidase staining. Results from the RNA sequencing carried out to compare 10 healthy and 10 AML BM-MSC show that 1125 genes were differentially expressed, with 924 down-regulated in AML derived BM-MSC and 201 up-regulated. From this analysis, we found that CDKN1A (p21) is up-regulated in BM-MSC from AML patients (7.406 logFC) compared to BM-MSC from patients with normal bone marrow (likely a marker for older adults). p21 mRNA expression was confirmed in AML BM-MSC compared to normal BM-MSC. In-vitro experimentation showed that p21 mRNA and protein expression is increased in BM-MSC when co-cultured with primary AML. Furthermore, we show that AML increased senescence β-Galactosidase staining in BM-MSC and that p21 knockdown in BM-MSC reversed this senescence phenotype. Finally, primary AML cultured on p21 knockdown BM-MSC had reduced survival compared to control BM-MSC.

**Summary/Conclusions:** We have identified that AML induces a senescent BM-MSC niche via the p21 mediated pathway which in turn promotes survival and proliferation of AML. Silencing of p21 within the BM-MSC reduces AML survival. In identifying this novel microenvironment feedback loop in AML we highlight a potential new target for future AML therapies.

**Background:** Bone marrow vascular niches have been proposed to support acute myeloid leukaemia (AML) growth. However, anti-angiogenic therapies do not improve patient outcome suggesting that a complex relationship between AML cells and the microenvironment influences the disease process.

**Aims:** We aim to study the complex vascular remodelling occurring during AML progression.

**Methods:** Using a murine model of AML we performed intravital microscopy to better characterize and study this heterogeneity, we developed an in vivo model of AML using patient derived xenografts (PDX). To better characterize and study this heterogeneity, we developed an in vivo model of AML using patient derived xenografts (PDX).

**Results:**

- Using a murine model of AML we performed intravital microscopy to better characterize and study this heterogeneity, we developed an in vivo model of AML using patient derived xenografts (PDX).

**Summary/Conclusions:** Together, these data suggest that AML-induced vascular damage contributes to cell egress from the bone marrow, and that new therapeutic approaches aiming to normalize bone marrow vasculature may support normal hematopoiesis.

**Background:** Acute myeloid leukaemia (AML) is the most common leukaemia in adults. Currently, despite intensive chemotherapy and bone marrow transplantation, outcome is still dismal. In particular, therapeutic stratification remains suboptimal, which is largely attributed to the clinical and molecular heterogeneity of AML.

**Aims:** To better characterize and study this heterogeneity, we developed an in vivo model of AML using patient derived xenografts (PDX).

**Methods:** Primary AML were isolated from the bone marrow and peripheral blood of AML patients following informed consent and under approval from the UK National Research Ethics Service (LRCEref07/H0310/146). Differential expression analysis of RNA sequencing data (DESeq2) was used to construct a consensus model of BM-MSC AML-MIA blasts. From this model, we identified 924 down-regulated in AML derived BM-MSC and 201 up-regulated. The aim of the present study is to determine the role of hypoxia in regulating MIF signalling in AML.

of B7 molecules in MOLM-13 cells. Our results will contribute to the understanding of MOLM-13 cell-mediated T-cell activation. Crosslinked anti-CD3/anti-CD28 antibodies served as positive control. In the presence of target cells, AMG 330 induced significantly lower Akt and Erk phosphorylation (mean% pAkt and pErk 7.9 and 7.6, n=3) compared to crosslinked CD3/CD28 antibodies (mean% pAkt and pErk 34.6 and 34.6, n=3). However, the combination of AMG 330 and CD28 increased the amount of phosphorylated proteins (mean% pAkt and pErk 11.6 and 11.1), but not to the level achieved by CD3/CD28 stimulation. In the absence of target cells, no Akt phosphorylation was observed upon incubation with AMG 330, suggesting a highly target cell dependent T-cell activation (mean% pAkt with vs without target cells: 0.8 vs 7.9).

Summary/Conclusions: Our data support the hypothesis that costimulation influences the susceptibility of target cells to lysis by T-cell recruiting antibody constructs. Currently, we are validating our results in a larger cohort using T-cells from pediatric patients with AML, where often limited research material is available. Methods: For three pediatric AML patients with mutations in the genes NPM1 and/or FLT3, we performed single cell sorting for CD34+ CD38- AML blasts by FACS and subsequently whole genome amplification (WGA) using the REPLiSING single cell DNA isolation kit (Qiagen). The amplification of single cell DNA and analysis of the corresponding bulk bone marrow was analysed by exome sequencing (WES). Bulk DNA was additionally evaluated by an amplicon-based sequencing approach targeting 54 genes (TruSight Myeloid Panel, Illumina) associated with myeloid malignancies.

Results: The analysis revealed that the median read coverage obtained in the WES of the five DNAs amplified from the single CD34+ CD38- cells and in the corresponding bulk DNAs from the bone marrow of all three patients was comparable for three out of the five single cells. For three amplified single cell genomes, between 92 and 98% of all reads could be mapped to the human genome, however the median coverage for the two failed single cells was 0. For validation of the WGA quality from single LSC DNA, data from 50 out of 54 genes analyzed by both sequencing approaches, WES and TSM Panel, were available for all three patients. The majority of variants detected in the WES bulk data could consistently be found at a comparable variant frequency in the TSM panel data. The variant frequencies in the single cell data from WES were more variable and more variants could not be detected in the TSM panel data derived from bulk DNA. We were able to detect n=79 (66%) out of n=121 somatic variants (SNVs, InDelS) present in the patients' AML blasts with all three sequencing approaches. WES readily identified n=103 (85.1%) and n=93 (78.9%) of all 121 variants in the bulk and single cell DNA, respectively. Only n=4 (3.3%) variants were not detected by WES at all. We were able to retrace the NPM1 and FLT3 mutations for each of the three patients in the targeted sequencing approach. However the NPM1 mutations and one FLT3 ITD could not reliably be called in the WES approach due to insufficient coverage.

Summary/Conclusions: In summary, WES of amplified single cell DNA is an excellent discovery tool also in pediatric AML for detecting unique changes in potential LSCs that should be validated by targeted sequencing approach with sufficient read counts for finding of rare events.

INHIBITING MIR-10A OVERCOMES CYTARABINE-RESISTANCE IN ACUTE MYELOID LEUKAEMIA

T.T. Vu1,2, K. Wang1, F. Stiélo2, E. Gehringer2, T. Moly2, D. Ma3
1Hematology, Ochsner Clinic, New Orleans, LA, USA; 2Harvard University, Cambridge, MA, USA; 3Department of Biomedical Sciences and Molecular Medicine, Università Cattolica del Sacro Cuore, Rome, Italy

Background: Chemoresistance is the principle cause of treatment failure in acute myeloid leukemia (AML) despite a promising response to induction chemotherapy. Emerging evidence suggest the roles of autophagy, a self-eating process contributing to chemoresistance of leukemias. We previously demonstrated that miR-10a, highly expressed in a subgroup of AML harbouring NPM1 mutations, promotes cell survival by inhibiting non-canonical cell death pathway, suggesting its function in autophagy and thus chemoresistance in AML.

Aims: We aim to demonstrate evidence that miR-10a, a regulator of autophagy, plays important roles in chemoresistance in acute myeloid leukemia.

Methods: Apoptosis and proliferation in miR-10a inhibited and overexpressed leukemia cells after cytarabine treatment was measured by Annexin V binding and MTT assay. Autophagy was measured by monitoring the levels of LC3I/LC3II proteins, autophagy-related proteins via Western Blotting and mono-dansyl-cavaradine (MDC) staining (flow cytometry).

Results: First, we observed a decreased expression of miR-10a in the leukaemia cells after the exposure to stress induced by serum starvation. Overexpressing miR-10a in miR-10a low MV4-11 cells decreased apoptosis induced by nutrient starvation and resulted in the resistance to cytarabine. In contrast, its inhibition in OCI-AML3 cells, which express high miR-10a constitutively, resulted in the induction of apoptosis and increased chemosensitivity towards cytarabine. miR-10a was shown to directly downregulate key members of the p53-mediated tumour suppressor gene network, including the CDKN1A (p21) inhibitor Transcript Factor AP2-gamma (TFAP2C). The inhibition of either miR-10a itself or CDKN1A by siRNA treatment inhibited apoptosis induced by serum starvation, treatment with autophagy inducer, mg132 or p35 stabiliser, Nutlin3a.

Summary/Conclusions: The data suggests miR-10a as an important regulator of autophagy and apoptosis in AML. Future studies need to be performed to examine the molecular mechanism of the p53-p21 tumour suppressor signaling axis in subtypes of AML. It also emphasizes the significance of autophagy in chemoresistance in AML, supporting the targeting of the autophagy pathway as a potential therapeutic approach for AML.

DYSREGULATION IN KEY REGULATOR GENES OF AUTOPHAGY AS A MECHANISM OF THERAPY RESISTANCE AND POOR PROGNOSIS IN ACUTE MYELOID LEUKAEMIA (AML): RESULTS FROM MICROARRAY ANALYSIS ON 148 PATIENTS

M.C. Fontana1, 2, M. Marconi1, C. Papayannidis1, G. Simonetti1, A. Padella1, E. Ottaviani2, A. Ferrari2, E. Franchini2, N. Testoni2, C. Baldazzi2, S. Lo Monaco2, S. Paolini2, M.C. Abbenante2, J. Nanni2, L. Bertamini2, G. Martellini2
1Department of Experimental, Diagnostic and Specialty Medicine, University of Bologna, Bologna, Italy; 2University Hospital ‘Carl Gustav Carus’, Dresden, Germany

Background: To date, there are no clear evidences if autophagy can lead to therapy resistance or favor apoptosis in cancer. Autophagy can function as a pro-apoptotic mechanism, or can improve stresses survival clearing damaged mitochondria and proteins accumulation. Levels and activity of pro-apoptotic and anti-apoptotic proteins, particularly BCL-2 and p53, high levels of HIF and complex made by PINK/PARK could play as fulcrum of this yin and yang effect of autophagy.

Aims: Our study aims to define the role of PI3P pathways in AML, and to establish if autophagy could reduce the patients’ chance to respond to induction, and to worsen OS.

Methods: We analyzed 148 consecutively newly diagnosed non M3 AML patients treated with induction chemotherapy regimens containing at least one dose of anthracyclines. We screened all patients for TP53, FLT3, NPM1 mutations. In all
patients, we perform Microarray-based High-Throughput Technology with Affymetrix SNP array 6.0 or Cytoscan HD. Survival data were collected prospectively from the time of diagnosis, with a median follow-up of 18 months. Survival analysis was performed with Kaplan Meyer method using log rank test. Univariate and multivariable regression and Cox Hazard Ratio (HR) model were performed. Correlation between variables was assessed with Fisher’s exact test.

Results: Autozygous mutations (gene group 2; 12 of 14) had a KRAS gene (4 out of 24) that correctly identified a mutation in normal peripheral blood and bone marrow samples. Somatic mutations were found in 107 cases with the TET2 and GATA2 mutations on outcome.

Background: The NGS-based MSI screen showed that 1,303 samples did not have MSI. The 64% of the remaining 200 samples (64%) had 2-4 mutations and the 2 most highly mutated samples had only 9 mutations each. Since any putative MSI+ sample would harbor tens if not hundreds of mutations, these data support the absence of MSI in all samples. Finally, because it has been proposed that t-AML might be more prone to MSI than de novo AML, we performed PCR-based MSI detection on an additional 23 t-AML cases, and found all were MS stable.

Summary/Conclusions: The absence of even a single MSI case within this large cohort provides strong evidence that MSI is non-existent in AML.

E884 SY-1425, A POTENT AND SELECTIVE RARA AGONIST, REPROGRAMS AML CELLS FOR DIFFERENTIATION ALONG DISTINCT LINEAGES, UNCOVERING PD MARKERS FOR CLINICAL STUDIES

1Translational Medicine, 2Biology, 3Clinical, Syros Pharmaceuticals, Cambridge, United States

Background: SY-1425 (famotibartone) is a potent and selective agonist of the retinoic acid receptor alpha (RARA) transactivation factor (TF), currently in a bioinformatics-driven Ph2 clinical trial in AML and MDS patients (NCT02807558). A subset of AML and MDS has been found to have RARα pathway activation characterized by a large enhancer at the RARA locus (RARA-high) and/or upregulation of IRF8, a TF associated with RARα signaling, forming the basis of the RARA-high sensitive tumor identification.

Aims: We sought to understand how SY-1425 agonism of RARα acts to promote maturation and halt proliferation of AML blasts locked into an immature cell state by the cancer circuitry. This characterization could further inform clinical pharmacodynamics markers.

Methods: We analyzed the epigenomic and transcriptional landscape of 66 non-APL AML patients and normal primary myeloid cells by RNA-seq and ChIP-seq for the enhancer marker H3K27ac. AML cell lines were profiled by RNA-seq, ChIP-seq for H3K27ac and RARα, and ATAC-seq with or without SY-1425 treatment.

Cell surface marker changes were assessed by flow cytometry.

Results: A subgroup of the patient samples was defined by an SE driving RARA which co-occurred with SEs driving FOS and JUNB, or IRF8, FOS and JUNB form the AP-1 heterodimeric TF known to promote an immature cell state and the interferon regulatory factor 8 (IRF8) pathway has been implicated in AML pathogenesis. Previously reported crossstalk between INF and retinoic acid signaling was supported by the strong induction of interferon gene sets by SY-1425 in IRF8-high AML models. We found that each AML cell line had distinct compositions of lineage factors consistent with cancer initiation from different stages of myeloid development. SY-1425 induced maturation features associated with monocyctic, macrophage, dendritic, and granulocytic cell types. While APL has been directed and granulocytic differentiation, we found that RARA/IRF8-high AML could follow multiple differentiation paths depending on the initial state of the AML model, necessitating different marker panels to capture full cell typing. Functional validation confirmed surface marker changes consisting of RARA-high AML models with observed epigenomic alterations including CD11b, CD11c, CD66b, and CD38 upregulation. We integrated epigenomic data, DNA accessibility, and SY-1425 response to understand RARA agonist perturbation to cell circuitry. Enhancer elements directly bound by RARα were associated with greater responsiveness to SY-1425 as were enhancers bound by other TFs involved in myeloid differentiation. The accessibility of RAR elements and IRF motifs were increased in IRF8-high AML models. We found that each AML cell line had distinct compositions of lineage factors consistent with cancer initiation from different stages of myeloid development. SY-1425 induced maturation features associated with monocyctic, macrophage, dendritic, and granulocytic cell types. While AML has been directed and granulocytic differentiation, we found that RARA/IRF8-high AML could follow multiple differentiation paths depending on the initial state of the AML model, necessitating different marker panels to capture full cell typing. Functional validation confirmed surface marker changes consisting of RARA-high AML models with observed epigenomic alterations including CD11b, CD11c, CD66b, and CD38 upregulation.
Aims: To identify key downstream mediators of SYK signaling in AML responsible for differentiation block, proliferation and leukemic stem cell (LSC) maintenance.

Methods: AML cell lines (KG1, MOLM14) or bone marrow primary AML blasts, were incubated 24h with R406 (1μM, 4 μM) or vehicle. Activity of SYK, ERK, STAT5 was assessed by western blot and/or intracellular phospho-flow. Proliferation was determined by the MTS assay in the presence of R406. Flow cytometry determined cell surface expression of CD25, cell number, and apoptosis. Activity toward LSC was assessed using leukemia cell line with stem cell properties (TEK), ROS level, mitochondrial mass. DNA damage and telomere length were assessed by DCF, Mitotracker Green FM staining. Expression of MYC, TFAM, NFR1, TF2, EF-Tu were assessed by western blot and/or q-PCR.

Results: To identify downstream mediators of SYK in AML, we tested the activity of key signal molecules in KG1 and MOLM14. AML cells exhibited basal R406 reduced pERK and pSYK, whereas R406 reduced MYC, transcription factors associated with LSC properties and pSTAT5, with reduced proliferation, clonogenic potential, induced differentiation and apoptosis. R406 reduced nuclear and cytosolic expression of MYC and proliferating cell nuclear antigen (PCNA). Inhibition of pERK induced dose-dependent apoptosis in LSC-enriched TEX cells. Since high pSYK is associated with upregulation of MYC and increased expression of MYC and its targets that drive mitochondrial biogenesis is a characteristic feature of LSC, we hypothesized that R406 depletes LSC by reducing mitochondrial biogenesis/oxidative phosphorylation (OXPHOS). In TEK and primary CD34+ AML blasts, R406 reduced expression of MYC, transcription factors associated with mitochondrial biogenesis (NRF1, TFAM, EF-Tu, NRF2), and lowered cellular and mitochondrial mass.

Summary/Conclusions: Taken together, we found that SYK inhibition obviates differentiation arrest imposed by ERK activity, and reduces clonogenic potential via decreased STAT5 activity. Moreover, we show that pSYK is required to sustain MYC expression and mitochondrial biogenesis/OXPHOS, a key feature of LSC in AML.

Background: Although the fusion oncogene PML-RARA is known to initiate acute promyelocytic leukemia (APL), other cooperating mutations have also been implicated in the disease pathogenesis. However, the spectrum of mutations of APL patients within the relapse-risk groups, based on patient leukocyte and platelet counts at diagnosis and their clinical outcomes, has not been thoroughly assessed.

Aims: 1) To identify genetic alterations that might cooperate with PML-RARA in the leukemogenic process within the three APL relapse-risk groups. 2) To find mutations at diagnosis responsible for poor outcome by comparing patients who experiment relapse vs. patients who do not relapse in each group.

Methods: We performed multi-amplicon targeted panel sequencing on bone marrow samples of 91 patients diagnosed with APL (PETHEMA LPA99/2000). Libraries were prepared by the TruSight Myeloid Sequencing Panel (Illumina), and obtained were analyzed with the Variant Studio v2.1 software (illumina) and the Integrative Genome Viewer (Genome Browser).

Results: Distribution of 91 patients in the 3 relapse-risk groups was: 28 in low-risk group (31%), 48 in intermediate-risk (53%) and 15 in high-risk (16%). We

364 | haematologica | 2017; 102(2)
found 150 mutations in 31 genes, in 73 out of the 91 patients included (a median of 1 mutation per patient (range: 0-5) with a mean read depth of 10360x. Eighteen patients remained wild-type for all analyzed genes (Figure 1). Only one of this patients suffered relapse (5%). In the global series, no single mutation or functional category showed an association with clinical variables or prognostic impact in terms of overall survival or relapse free survival (RFS). There were no differences in the mean number of mutations per patient in each risk APL group (p=0.05). Patients who lack mutations belonged to the intermediate (13/48, 27%) and low risk (4/28, 14%) groups, except for only one patient (1/15, 6%) in high-risk group. FLT3 was the most frequently affected gene in high risk APL subgroup (10 out of 15): 8 patients carried an FLT3-ITD mutation and 2 patients had amino acid substitutions at codon 835. Seven patients assigned to intermediate-risk relapsed (7/38, 18%). All but one carried mutations that have been reported as unfavorable in AML (FLT3, PTEN, ASXL1, CUX1 and WT1). By contrast, patients who remain in complete remission in this group, lack mutations with a greater frequency (12/31, 39%). Finally, within the low-risk group 3 patients suffered relapse (3/27, 11.5%) and all of them presented missense mutations in the Ras domain of NRAS at diagnosis (p.Ser65Arg & p.Gln61Arg). Therefore, we could identify a small subgroup of patients at a very high risk of relapse (RFS at 5 years, 25% vs 100%, p<0.001).

**Aims:**
In this study, our comprehensive analyses of PDCD1 (PD-1), CD274 (PD-L1), TP53 and miR-34a expression in AML patients shed new light on the complex regulation of PD-1/PD-L1 axis during development of this disease.

**Methods:** We performed analysis of TP53, CD274 and miR-34a expression in 197 AML patients available from The Cancer Genome Atlas (TCGA) database. Moreover, we assessed mRNA expression of PDCD1 in independent cohort of 54 AML, 62 MDS and 8 s-AML patients samples using qRT-PCR method. For miRNA analysis, CD33+ cells from 29 AML patients were isolated and miR-34a expression was analysed. We also characterized several SNP for PDCD1 that demonstrate relevant associations with a higher risk of developing autoimmune diseases: PD-1.1, PD-1.3, PD-1.6, PD-1.7, PD-1.9 (rs2227981), PD-1.6 (rs10204525), PD-1.7 (rs41386349), PD-1.9 (rs2227982) in 54 AML, 62 MDS and 100 HVs samples.

**Results:** We observed significant different expressions of PDCD1 expression in groups of 54 AML, 62 MDS, 8 s-AML patients compared to HVs. TCGA data analysis showed that CD274 expression was elevated in groups with TP53 mutations compared to unmutated TP53 group (p<0.001). We also found negative correlation of TP53 and miR-34a expression with CD274 expression (p=0.02 and p=0.005, respectively). The expression of miR-34a tended to be elevated in group with high expression of TP53 compared to group with low TP53 expression (p=0.17). We have not found any differences in CD274 expression between groups with or without following mutations: IDH1, TET2, RUNX1, NRAS, CEBPA, PTPN11, KRAS, FLT3, DNTM3, NPM1 and IDH2. Patients with more than 4 recurrent mutations were characterized with higher expression of CD274 compared to group of patients with 0-3 recurrence mutations. We found that patients with >14 of all mutations had elevated expression of CD274 compared to group 0-13 mutations (p=0.06). We observed significant differences in PDCD1 expression level regarding to PD-1.1.5 polymorphism. Moreover, analysis of a PD-1.1.3 polymorphism in HVs and MDS groups revealed that genotype GG was associated with nearly fivefold lower risk of disease (OR=4.93, p=0.009). We observed significant differences in OS in AML patients in case of presence of certain genotypes of PD-1.1.6. Genotype AA was significant associated with higher risk of shorter OS compared to the rest of the genotypes (58 vs 333 days, HR=35; p=0.001).

**Summary/Conclusions:** In summary, the present study shows that the status of NRAS and FLT3 genes could be used as genetic markers for prognosis in APL, especially in the intermediate and low-risk groups, allowing a more accurate patient risk classification. Our data suggests the need to search for new mutations required for progression in APL, in order to benefit from a change in post-remission therapy.

**ANALYSIS OF THE PD-1/PD-L1 AXIS POINTS TO ASSOCIATION OF UNFAVORABLE RECURRENT MUTATIONS WITH PD-L1 EXPRESSION IN AML.**
K. Giannopoulos1,2,*, M. Zajac1, J. Zaleska1, A. Dolnik3, A. Siwiec4, O. Jankowska-UNFAVORABLE RECURRENT MUTATIONS WITH PD-L1 EXPRESSION IN change in post-remission therapy.

**Background:** Programmed death ligand-1 (PD-L1) is regulated through miR-34a molecules in AML patients. Moreover, Cortez et al. for the first time identified novel, complete mechanism of PD-L1 regulation by p53 via miR-34a in non-small cell lung cancer (NSCLC).

**Aims:** In this study, our comprehensive analyses of PDCD1 (PD-1), CD274 (PD-L1), TP53 and miR-34a expression in AML patients shed new light on the complex regulation of PD-1/PD-L1 axis during development of this disease.

**Methods:** We performed analysis of TP53, CD274 and miR-34a expression in 197 AML patients available from The Cancer Genome Atlas (TCGA) database. **Summary/Conclusions:** In summary, the present study shows that the status of NRAS and FLT3 genes could be used as genetic markers for prognosis in APL, especially in the intermediate and low-risk groups, allowing a more accurate patient risk classification. Our data suggests the need to search for new mutations required for progression in APL, in order to benefit from a change in post-remission therapy.
specifically evaluated the impact of in vitro exposure of a barcoded AML cell line (HEL) to chemotherapy regimen (doxorubicin (DOX) and/or cytarabine (CYT)) and/or the hypomethylating agent decitabine (DCT) by comparing the barcode composition of the tumor population recurring after each therapy, versus non-treated (NT) controls. By comparing the barcode architectures between parallel replicate cultures for each therapy, we could further delineate whether AML relapse was driven by predetermination of unique barcodes found in multiple replicates or stochastically selected (if mainly diverse barcodes in each replicate) cells in response to each treatment regimen.

Results: Only treatment regimens containing DOX caused marked decreases in HEL cell numbers and barcode architectures diverging strongly from the non-treated controls. Replicate AML cultures regressing after treatment with DOX all converged to a very similar barcode architecture, reflecting that relapse following this mono-therapy was driven by predetermined single-cell lineages. Combination of DOX with CYT increased the degree of overall cell elimination by ~10-fold, while addition of DCT to either chemotherapy regimen had a minor impact (<4-fold) on cell number (i.e. yielded similar single-cell number and re-growth kinetics). Interestingly, DCT additions nevertheless qualitatively changed which sub-lineages that regrew - specifically making replications more divergent from each other, indicating a more stochastic selection of the cells emerging when DCT had been added to the respective chemotherapy regiments. Importantly, this cell population changing by the reversion of resistance to chemotherapy re-treatment, which the DOX-containing treatment regiments potently induced in the absence of DCT.

Summary/Conclusions: The development of curative treatment combinations requires deep understanding of how non-genetic factors synergize with cancer genetics to drive intra-tumor heterogeneity, which is key for tumor escape/dis-ease recurrence. Our detailed analyses of the heterogeneous dynamics among single-cell lineages in AML, following different treatment regimens with apparently similar global impact, represent an important step in dissecting kinship-dependent aspects that go beyond the genetic level. Critically, these studies directly provide the rationale for combining standard chemotherapy with administration of hypomethylating drugs to target AML. The mechanism is prevention of the development of chemotherapy resistance (mediated by selective relapse of a specific set of predetermined sub-lineages) - by partially randomizing which sub-lineages that emerge to drive relapse when DCT is added to the chemotherapy. Maintaining the chemosensitivity of relapsing AML would represent a paradigm shift, turning the currently often lethal recurrences into sur-vivable/ repeatedly clinically manageable episodes of a type of chronic leukemic disease.

Background: Sensitive detection of molecular marker of minimal residual disease (MRD) in acute myeloid leukemia (AML) could improve prognostication of a possible relapse during the remission. Traditional methods for measuring minimal residual disease (MRD) in AML, such as real-time PCR and multiparametric flow cytomtery (MFC) are associated with high technical complexity, low accuracy and laborious standardization. However, some patients who achieve a negative MRD become to relapse and several MRD+ patients have a long survival, which indicates that the sensitivity and specificity of traditional techniques for measuring MRD levels are insufficient.  

Aims: To detect minimal residual disease in AML follow-up sample using high-throughput sequencing as a standard and accurate technique.  

Methods: We studied 54 gDNA bone marrow follow-up samples (27 after induction, 10 after first consolidation, 17 after second consolidation) from 30 AML patients treated according to PEThema AML clinical protocols and with DNA samples at diagnosis. All patients had achieve CR at the moment of MRD assessment. We developed a custom-targeted sequencing panel of 32 genes (ion Torrent Proton System-Thermo Fisher) for mutation (SNV and/or InDels) detection at diagnosis sample. From the 32 genes, we use specific primers to amplify the specific region of the four most frequent alterations at diagnosis (Samples at follow-up: FLT3n-ITD n=2, NPM1n=14, IDH2 n=9 or IDH1 n=7). We analysed and detected at diagnosis and at follow-up (after induction, first consolidation or second consolidation), and sequenced with high-throughput approach. We achieve a technical sensibility around 10-4 for point mutations and 10-5 for Indels mutations according to specificity and sensitivity calibration curves.  

Results: We analyse the results of assessing MRD by NGS, and the presence or absence of MRD was established at a cut-off level of 0.0017 (between 10-4 and 10-5-technical sensitivity) by ROC curve with a sensitivity of 0.5 for DFS and 0.571 for OS, and a specificity of 0.92 for DFS and 0.897 for OS; thereby this result above this level was considered as MRD positive. DFS (Disease Free Survival) and OS (Overall Survival) rates in this group were 29.9% and 24.1%, respectively; positive MRD sample was independent marker associated with shorter DFS (p=0.002, HR=0.33, 95% CI:1.60-33.51) and OS (p=0.002, HR= 8.33, 95% CI:1.87-37.15) (see figure 1). These results support the usefulness of MRD evaluation in patients with AML by NGS in the context of molecular biology studies.

Summary/Conclusions: The development of curative treatment combinations requires deep understanding of how non-genetic factors synergize with cancer genetics to drive intra-tumor heterogeneity, which is key for tumor escape/dis-ease recurrence. Our detailed analyses of the heterogeneous dynamics among single-cell lineages in AML, following different treatment regimens with apparently similar global impact, represent an important step in dissecting kinship-dependent aspects that go beyond the genetic level. Critically, these studies directly provide the rationale for combining standard chemotherapy with administration of hypomethylating drugs to target AML. The mechanism is prevention of the development of chemotherapy resistance (mediated by selective relapse of a specific set of predetermined sub-lineages) - by partially randomizing which sub-lineages that emerge to drive relapse when DCT is added to the chemotherapy. Maintaining the chemosensitivity of relapsing AML would represent a paradigm shift, turning the currently often lethal recurrences into sur-vivable/ repeatedly clinically manageable episodes of a type of chronic leukemic disease.

THE ROLE OF MYELOID-DERIVED SUPPRESSOR CELLS-LIKE BLASTS WHICH SUPPRESS T CELL PROLIFERATION IN LEUKEMIC CELL GROWTH  
S. Y. Hyun1,*, J. I. Lee1, E. J. Na1, J.-W. Cheong2  
1Internal Medicine, Yonsei University Wonju College of Medicine, Wonju, 2Internal Medicine, Yonsei University College of Medicine, Seoul, Korea, Republic Of  

Background: Myeloid-derived suppressor cells have an ability to suppress T-cell function and have been known to facilitate tumor growth. We elucidated the immune suppressive function of leukemic blasts which resembled MDSC phenotype and their role in the growth of leukemic cells.  

Aims: We elucidated the immune suppressive function of leukemic blasts which resembled MDSC phenotype and their role in the growth of leukemic cells.  

Methods: CD11b+CD33+HLA-DR-blast (MDSC like blast) were isolated using flow-cytometry from bone marrow mononuclear cells of primary acute myeloid leukemia (AML) patient samples. CD14, CD15, Arg1 and iNOS expression were checked by flow-cytometry to identify the phenotype of MDSC like blast. To evaluate the ability of MDSC like blasts to suppress T cell proliferation, CD8+ T cells from healthy donor and MDSC like blasts were co-cultured with a ratio of 1:1 without phytohemagglutinin A 10ug/ml. T-cell proliferation was measured by carboxyfluorescent diacetate succinimidyl ester dilution assay after 3 days of culture. Then, various leukemic cell lines were co-cultured with jurkat T cells and/or MDSC like blasts at a leukemic cell line:Jurkat cell T: MDSC like blast ratio of 4:4:1. The effect of Jurkat T cells and MDSC like blasts on the proliferation of leukemic cells was assessed by the CCK-8 assay after 1 and 3 days of culture.  

Results: MDSCs like blast can be divided into two subtypes, monocyteic subgroup expressing CD14 and granulocytic subgroup expressing CD15, and CD14 expression was more frequent than CD15. Myeloid-derived suppressor cells showed higher expression of Arg1 (77.1% vs 38.5%, P<0.001) and iNOS (33.0% vs 1.1%, P=0.0001) compared to non-MDSC-like blasts. CD8+ T cell proliferation induced by PHA was significantly suppressed when co-cultured with MDSC-like blasts compared to without them. Among the various leukemic cell lines, the proliferation of NB4 cells were significantly suppressed when co-cultured with jurkat T cells on day 3 (NB4 23.49±6.26% of control, NB4+jurkat 12.62±3.92%, P<0.01). The decreased proliferation of NB4 cells was partially recovered after 3 days of co-culture with MDSC-like blasts (NB4+jurkat 12.62±3.92%, NB4+jurkat+MDSC like blast 18.71±6.19, P=0.022).

Figure 1.  
Summary/Conclusions: High-throughput NGS is a technique with the capacity to measure, identify and classified MRD levels. In fact, NGS MRD evaluation has a better DFS and OS prediction than other traditional methods. Implementation of NGS technique on MRD detection could help to anticipate to disease progression.

Summary/Conclusions: CD11b+CD33+HLA-DR: MDSC-like blasts subpopulation which expressed the INOS and Arg1 existed in AML, and showed ability to suppress the T cell proliferation. MDSC-like blasts partially restored the suppressed leukemic cell growth of NB4 cells by jurkat cells. MDSC-like blasts might play a certain role in immune-escape mechanism of AML.

GENERATION OF NEW CELLULAR MODELS FOR THE STUDY OF PEDIATRIC NON DOWN SYNDROME ACUTE MEGAKARYOBLASTIC LEUKAEMIA BASED ON HUMAN PLURIPOTENT STEM CELLS

J. Domingo-Reinel1, F. González-Pozas1, L. Morales-Cacho1, M. Vogel-González2, G. Rodríguez-Reali1, J. Olmedo-Pelayo1, R. M. Montes1, V. Ayllón1, V. Ramos-Mejía1

1Genyo, Granada, Spain

Background: Acute megakaryoblastic leukaemia (AMKL) is a rare and complex type of Acute Myeloid Leukaemia (AML), more frequent in children than in adults, characterized by the accumulation of immature megakaryblast progenitors and thrombocytopenia. Paediatric AMKLs are classified in Down Syndrome AMKL (DS-AMKL) with a good prognosis; and AMKL non-related to Down Syndrome (non-DS-AMKL), a more aggressive disease with a mortality rate close to 80%. There is a limited amount of research done on infant non-DS AMKL, due to its low incidence and early human hematopoiesis, we put these two mutation types to the test.

Results: We developed AMP-based Archer®VariantPlex™ and FusionPlex® assays to enable NGS-based detection of mutations from DNA and RNA, respectively. Open-ended amplification permits identification of novel gene fusions with FusionPlex and complex mutation types such as ITDs with VariantPlex assays. MBG adapters ligated to RNA and DNA fragments prior to amplification enable relative gene expression and CNA analysis.

Results: We show instances of gene fusion detection from open-ended amplification of AML samples, including AML-ETO, RUNX1-RUNX1T1 and TEL-AML1. We found unclassifiable leukemia. Furthermore, unidirectional GSPs provided bidirectional coverage of a BCR-ABL1 fusion, which was detected with reads originating from ABL1 as well as BCR. Using our optimized bioinformatics algorithm and the VariantPlex assay, we accurately and reliably detected ITDs of varying sizes and insertion points, with simultaneous point mutation detection, in AML-positive blood samples. Furthermore, we show multiple mutations in various AML-positive sample types, including mutations in CEPBPα. Finally, MBG used in AMP enabled NGS-based expression profiling for identification of Diffuse Large B-Cell Lymphoma subtypes in a small cohort of samples.

Conclusions: Our results demonstrate that AMP-based NGS enables comprehensive detection of multiple mutation types as well as gene expression levels relevant in hematologic malignancies. Importantly, AMP enables identification of known and novel gene fusions at nucleotide resolution, detection of ITDs and characterization of relative gene expression levels and CNAs.

ASXL1 MUTATIONS IN AML ARE ASSOCIATED WITH SPECIFIC CLINICAL AND CYTOGENETIC CHARACTERISTICS

K. Kakosiaou1, F. Panitsas2, A. Ioannidou1, M. Pagoni2, P. Apostolou2, A. Daraki1, A. Goulas1,2, T. Marinakis3, C. Giatra2, D. Vasilatou6, C. Sambani1, V. Pappad6, K. Manoliad1

1Laboratory of Health Physics, Radiobiology & Cytogenetics, NCSR "DEMOKritos", 2Hematology-Lymphoma Department - BMT Unit, Evangelismos Hospital, 3Department of Pathology, "Attikon", ATHENS, Greece

Background: Mutations of ASXL1 are considered early founder events in AML development. They are included in the definition of the "chromatin-splice-some" genomic class of AML and among the high risk genetic prognosticators in the 2017 ELN recommendations.

Aims: We aimed to study the frequency of ASXL1 mutations in a cohort of newly diagnosed AML patients and to look for correlations with conventional cytogenetic findings and baseline characteristics.

Methods: Three hundred and sixty AML patients diagnosed between 2005 and 2014 were studied. Conventional cytogenetic analysis was performed on unstimulated bone marrow cells cultured for 24 and 48 hours. Molecular analysis of ASXL1 exon 12 mutations was performed by PCR and subsequent direct sequencing in diagnostic bone marrow or peripheral blood samples.

Results: Median age of the whole cohort was 63 years (11-95) and 56% of patients were male. Eighty two patients (22.8%) had secondary AML (sec-AML) with prior diseases being MDS (63), CMML (4), PV/ET (9), MF (2) and CML (4). Karyotypic analysis was successful in 352 (97.7%) AML samples of which 252 (71.6%) exhibited clonal karyotypic abnormalities. ASXL1 mutations were significantly more frequently detected in 52 patients (14.4%). The most common mutation was c.1394dupG in 44/52 (84.6%). ASXL1 mutated patients were significantly older with median age 72 vs 61.5 years in the unmutated (p=0.0001). Three of 61 patients (4.9%) aged ≤40, 10/97 aged 41-60 (10.3%) and 39/198 aged >60 (19.7%) were mutat-

CHARACTERIZATION OF HEMATOLOGIC MALIGNANCIES WITH ANCHORED MULTIPLEX PCR AND NEXT-GENERATION SEQUENCING

L. Arce1, M. Barrasso1, A. Berrón1, J. Haines1, D. Fugierie1, K. Griffin2, K. Trifilo1, N. Manoj1, H. Wang1, R. Ryan2, M. Hussaini3, B. Kudlow1

1ArcherDX, Boulder, CO, 2Massachusetts General Hospital, Boston, MA, 3Moffitt Cancer Center, Tampa, FL, United States

Background: Hematologic malignancies can be driven by a diversity of mutation types, including single nucleotide variants, copy number variants, gene fusions, insertions and deletions and changes in gene expression profiles. However, comprehensive detection of these mutation types from a single clinical sample is challenging, as specific assays are required to detect each mutation type. Next-generation sequencing (NGS) enables comprehensive detection of all mutation types from whole genomes and transcriptomes. However, low detection sensitivity, high input requirements and high costs render these approaches impractical for routine detection of mutations from clinical sample types. Anchored Multiplex PCR (AMP™) is a target enrichment strategy for NGS that uses molecular barcoded (MBC) adapters and unidirectional gene-specific primers (GSPs) for amplification.

Aims: Our goal was to develop AMP-based NGS assays to simultaneously detect multiple mutation types from DNA and RNA, as well as relative gene expression levels and copy number alterations (CNA) in hematologic malignancies. In particular, we sought to develop methods to detect novel gene fusions, internal tandem duplications (ITDs) and mutations in CEPBPα.

Methods: We developed AMP-based Archer®VariantPlex™ and FusionPlex® assays to enable NGS-based detection of mutations from DNA and RNA, respectively. Open-ended amplification permits identification of novel gene fusions with FusionPlex and complex mutation types such as ITDs with VariantPlex assays. MBC adapters ligated to RNA and DNA fragments prior to amplification enable relative gene expression and CNA analysis.

Results: We show instances of gene fusion detection from open-ended amplification of AML samples, including AML-ETO, RUNX1-RUNX1T1 and TEL-AML1. We found unclassifiable leukemia. Furthermore, unidirectional GSPs provided bidirectional coverage of a BCR-ABL1 fusion, which was detected with reads originating from ABL1 as well as BCR. Using our optimized bioinformatics algorithm and the VariantPlex assay, we accurately and reliably detected ITDs of varying sizes and insertion points, with simultaneous point mutation detection, in AML-positive blood samples. Furthermore, we show multiple mutations in various AML-positive sample types, including mutations in CEPBPα. Finally, MBC used in AMP enabled NGS-based expression profiling for identification of Diffuse Large B-Cell Lymphoma subtypes in a small cohort of samples.

Conclusions: Our results demonstrate that AMP-based NGS enables comprehensive detection of multiple mutation types as well as gene expression levels relevant in hematologic malignancies. Importantly, AMP enables identification of known and novel gene fusions at nucleotide resolution, detection of ITDs and characterization of relative gene expression levels and CNAs.

haematologica | 2017; 102(s2) | 367
mutations. Moreover, ASXL1 mutations were detected in 3 of 12 patients with aberrations (25%), 2/9 (22%) with trisomy 15, 2/11 (18%) with t(5;22) and only 1 of 22 patients with t(15;17). Multivariate logistic regression suggested that independent predictors of the presence of ASXL1 mutations were older age (OR 1.43 per decade, 95% CI 1.13-1.79), chromosome 11 aberrations (OR 2.69, 95% CI 1.09-6.63), and sec-AML (OR 4.44, 95% CI 2.3-8.57), whereas as del(7q) or -5/del5q predicted for lower frequency (OR 0.32, 95% CI 0.13-0.75).

Summary/Conclusions: Our results support the association of ASXL1 mutations in AML with advancing age and sec-AML. Association with trisomy 8 did not retain significance in multivariate analysis. Chromosome 11 aberrations emerged as the independent predictor. Despite the strong link with secondary AML (majority of cases post MDS), our data show inverse relationship with -7/del(7q) or -5/del5q. In addition, ASXL1 mutations were not positively associated with MDS-related cytogenetic abnormalities, complex or monosomal karyotypes.

A COMPREHENSIVE DNA TEST FOR THE DETECTION OF TRANSLOCATIONS IN ACUTE LEUKEMIA
E. Van Den Berg-De Ruiter1, M.Z. Almohamed1, L.F. Johansson1, E.N. de Boer1, E. Splinter1, P. Klous2, A.G. Bosga1, M. van Min1, A.B. Mulder1, E.J. Slikke2, R.J. Sinke1, R.H. Sijmons1, B. Sikkema-Raddatz1
1Genetics, 2Genetic Coordination Center, UMCG, Groningen, 3Cergentis B.V., Utrecht, 4Laboratory Medicine, 5Hematology, UMCG, Groningen, Netherlands

Background: Patients with acute leukemias carry a wide range of chromosomal abnormalities, which affect their prognosis and treatment options. Currently, over 500 different translocations are reported to be involved in the disease progression. Traditional methods to detect chromosomal abnormalities involve a combination of techniques such as karyotyping, FISH, array and RT-PCR. However, these methods are laborious and at times inadequate. Targeted Locus Amplification (TLA), a new targeted next generation sequencing technology can overcome these shortcomings. It is based on proximity ligation (crosslinking) of DNA and outward oriented probes for enrichment and can therefore identify chromosomal translocation partners regardless of their identities.

Aims: Here we present a TLA multiplex panel in combination with next generation sequencing as a first tier screening tool in detecting translocations in acute leukemias.

Methods: A multiplex TLA panel was designed using primer sets covering known break-point regions of the 17 most frequently reported genes involved in acute leukemia’s. TLA was performed on five different cell lines carrying translocations detectable by our panel. t(12;21), t(15;11), t(11;19)(8;13), t(16;9), t(17;19). Various combinations of cell line mixtures in multiple dilution series were used to determine the specificity and sensitivity of the panel, and to set sample quality thresholds during analysis. Samples were processed using standard TLA protocol (de Vree et al, 2014). Targets were enriched by PCR amplification with the multiplex panel and subjected for sequencing on Illumina Nextseq 500. To facilitate an easy analysis workflow a semi-automated data analysis was developed. This includes a quality control step, labelling samples with no coverages at the anchor regions after filtering at more than half the number of target regions as failed. These were not interpreted. Only peaks outside other anchor regions were considered as false positive peaks. Peaks present in other anchor regions were interpreted as possible artefacts and labelled as needing extra confirmation. In these series until now, up to 10% aberrant cells were detected with no false positives as no translocations other than expected for cell lines were detected. Bone marrow of 36 patients suspected karyotyping, FISH and RT-PCR were taken for routine diagnostic diagnosis (karyotyping, FISH and or RT-PCR) and TLA. Sample analysis was performed randomized and blinded. TLA outcome was then compared with results from routine genetic tests, can establish whether the TLA panel is applicable as a routine procedure.

ALTERATIONS IN NECROPTOSIS PATHWAY AFFECT PROGNOSIS OF PATIENTS WITH ACUTE MYELOID LEUKEMIA
S. Lo Monaco1, G. Marconi1, M.C. Fontana1, C. Papayanni1, E. Ottaviani1, E. Franchini1, A. Ferrari1, A. Padella1, G. Simonetti1, S. Paolini1, G. Martinelli1
1University of Bologna, Bologna, Italy

Background: Necroptosis is a type of necrotic cell death involving several genes transcription and activation of molecular mechanisms as death receptors, interferon, toll-like receptors, intracellular RNA and DNA sensors. The process is leading by the family of receptor-interacting protein kinase (RIPK3, RIPK2, RIP1K) and the MLKL substrate. Losses of RIPK3 or MLKL, as well as deficiency in apoptosis, could allow tumor cells to escape the immune-mediated cells death (ICD).

Aims: We want to investigate the role of necroptosis deficiency in correlation with chemotherapy resistance and its impact as prognostic factor in AML.

Methods: We performed SNP Arrays (Cytoscan HD and SNP 6.0, Affymetrix) on a cohort of 300 non-M3 AML patients at diagnosis and we analyzed the Overall Survival (OS) of our patients with deficiency on necroptosis pathways. Survival was analyzed with Kaplan-Mayer method and Log-Rank test. We further analyze the relevance of different prognostic factors by the use of COX-Hazard Ratio statistical analysis.

Results: We found 18 patients presented a loss of RIPK1 or MLKL (nobody presented losses in RIPK3/RIPK2) and 13/18 patients were older than 65 years old. The Overall Survival (OS) of patients with alterations in these genes is significantly lower than control group, with a median OS of 3 month respectively (p<0.001). With Fisher Exact Test we further demonstrate that copy number loss of RIPK1 or MLKL are associate to loss of TP53 or FANCA genes, complex karyotype and advanced age. COX-Hazard Ratio model with RIPK1 or MLKL loss, BRCA1 loss, TP53 mutation, FANCA loss, secondary disease and diagnosis karyotype considered as categorical variable show that necroptosis deficiency (HR 1.98, CI 95% 1.04-3.78) TP53 mutation, and secondary AML are independent negative prognostic factors in an optimal model.

Summary/Conclusions: Our study shows that losses in necroptosis pathways are an uncommon alteration in AML prevalent in old population. Moreover, we hypothesize that the loss of genes involved in necroptosis could be a real mechanism of tumor immune-escape and could be a rational to select patients that high probability to be resistant at chemotherapy promoting ICD mechanism.

NGS ANALYSIS AND IMPACT OF VARIANT ALLELIC FREQUENCY AT RELAPSE AND REFRACTORY STATUS IN AML PATIENTS
E. Onecha De La Fuente1,2, I. Rapado1,2, M. Llops3, Y. Ruiz-Hereda1,2, T. Cedena1,2, E. Barraquen1,4, M. Gallardo1,2, J. Martinez Lopez1,2, R. Ayala1,2
1Hematologia traslacional, Hospital 12 de Octubre, 2Haematological Malignancies Clinical Research Unit, CNIO, Madrid, 3Instituto de Investigación Sanitaria La Fe, 4Clinical Pathology Service, Hospital Universitari i Politécnic La Fe, Valencia, Spain

Background: A high number of patients with acute myeloid leukemia (AML) present resistance at treatment, which is associated with clonal persistence or evolution. The generation of high-depth sequencing data allowed to quantify variant allelic frequencies (VAF) and permitting estimation of the size of tumor clonal populations in each AML sample, and to perform an estimation of clonal evolution at relapse or refractory case according at diagnostic.

Aims: To evaluate the predictive impact of the fluctuation Variant Allelic Frequency in resistance to treatment cases in AML.

Results: FLT3, JAK2, KIT, LNK or/and MPL) play a critical role in resistance status, as RUNX1 correlates with primary refractory samples, p=0.015; mutations in JAK2, KMT2A or SF3A1 shows significant ΔVAF decrease in primary tumor-refractory (n=8) and primaty tumor-relapsed (n=17) samples pairs from 25 AML patients treated according PETHEMAL AML clinical protocols were sequenced; in addition FLT3-ITD was detected by GENSCAN and NPM1 mutation was detected by PCR. We analyse the evolution of level of VAF, to measure the prevalence of somatic mutations between diagnosis and resistance status (relapse or refractory).

Results: Mutations in signalling pathway (EPOR, FLT3, JAK2, KIT, LNK on/and MPL) and GTPases pathway (KRAS, NRAS, HRAS) present significant ΔVAFs increases in relapse samples, p<0.05 and p=0.039 respectively. See figure 1. Furthermore, mutations in IDH2, JAK2 or KRAS show ΔVAF trend increases. Also, mutations in signalling pathway shows significant ΔVAF decrease in primary refractory samples, p=0.015; mutations in JAK2, KMT2A or SF3A1 shows ΔVAF trend decreases. Regarding to mutational profile we found significant ΔVAF decrease in primary tumor-refractory samples. No correlation was found between VAF and ΔVAF trend decreases. No correlation was found between VAF and% blasts, nor did VAF fluctuation with blasts fluctuation.

Summary/Conclusions: These results show VAF increases of specific mutations as KIT correlates with relapse status. However, in this cohort new specific mutations were not found neither VAF increases, even the opposite being as VAF decreases of specific mutations as RUNX1 correlates with primary refractoriness status. Furthermore, the variable frequency signalling pathway (EPOR, FLT3, JAK2, KIT, LNK on/and MPL) play a critical role in resistance status, increasing variant allelic frequencies of mutations in relapse and decreasing in refractoriness.

PRECLINICAL EVIDENCE THAT TRAMETINIB ENHANCES THE RESPONSE TO TYROSINE KINASE INHIBITORS IN ACUTE MYELOID LEUKEMIA
M.L. Morales1,2, M. Linares1, A. Arenas1, I. Zagorac2, R. Ayala2, N. Castro1, I. Rapado1, M. Quintela-Fandino2, J. Martinez-Lopez1
1Servicio de Hematologia, Hospital Universitario 12 de Octubre, 2Unidad de Proteomica, Centro Nacional de Investigaciones Oncologicas, Madrid, Spain

Background: Acute Myeloid Leukemia (AML) is the most common type of acute leukemia in adults and the second in children in whom overall survival is less than 35% and 60% respectively. Activating mutations of FLT3 are now recognized as the most common molecular abnormality in this disease, and the poor prognosis of patients harboring these mutations renders FLT3 an obvious therapeutic target. Although different tyrosine kinase inhibitors (TKI) have been used for this purpose, their ability to extend progression-free and overall survival is limited by drug resistance. This strategy could be improved by rationally combining TKIs with other agents. In this work, we have explored bone marrow samples from a FLT3-AML patient before and after TKI treatment by phosphoproteomics and observed enhanced activity of Ras-Raf-MEK-ERK1/2 pathway as a possible mechanism for TKI resistance.

Aims: To validate the role of ERK1/2 during TKI treatment in vitro and ex vivo and to search suitable combinations that allow overcome/avoid resistances in preclinical models of the disease.

Methods: Resistance mechanisms were studied in vitro in MOLM13 (FLT3WT/ITD) after generating resistance by two different methods: by subculturing with increasing doses of sorafenib or by treating them with high doses of sorafenib, and recollecting alive proliferative (resistant) cells after CFDA and Annexin labeling. Phosphoproteomic analyses were carried out by LC-MSMS after IMAC enrichment or by western blot techniques. Drug sensitivity assays with trametinib (MEK inhibitor) and three TKIs (sorafenib, pazopanib, midostaurin) were read after 48 hours or 72 hours of treatment in vitro or ex vivo respectively. The efficacy of the combinational treatments was characterized by cell viability assay using WST8, and analyzed with Graphpad Prism software. Synergy effects were measured with CalcuSoft software.

Results: As it is presented in figure 1, ERK1/2 pathway was more activated after TKI treatment in the FLT3-AML patient during sorafenib-resistance development. The same fact was confirmed in MOLM13 sorafenib-resistant culture and in living proliferative cells recollected after sorafenib treatment. Different doses of trametinib, sorafenib, pazopanib and midostaurin in monotherapy were tested in MOLM13 cell line determining their IC50 values. Synergy effects of combining trametinib with the three TKIs were analyzed with CalcuSoft software and normalized isobolograms were represented. All combinations showed CI values less than 0.5 (CI<0.5). The inhibition levels of four pathways (PI3K, STAT5, ERK1/2 and MAPK14) implicated in TKIs resistance were studied by western blot and the combination of midostaurin plus trametinib was the only one that inhibited all of them. Trametinib efficacy in the MOLM13 sorafenib-resistant culture was evaluated and confirmed that remained effective. Trametinib plus midostaurin combination was tested in OCI AML-3 cell line (FLT3WT/ITD) showing high efficacy and strong synergy (CI<0.5) too. Finally, we have assayed these drugs ex vivo in three AML samples showing the same effectiveness as in vitro, with IC50 values ranging from 0.2µM to 0.9 µM for midostaurin and 3 nM to 29 nM for trametinib and CI values less than 0.5.

Summary/Conclusions: In conclusion, we provide preclinical evidence that combining a TKI, especially midostaurin, with a MEKI, such as trametinib, is a rational and efficacious treatment regimen for AML. As trametinib has previously shown good results when combined with pazopanib in clinical trials for other kinds of tumors, we expect similar results in AML.
IDENTIFICATION OF NOVEL THERAPEUTIC DRUGS IN DISTINCT PEDIATRIC AML SUBTYPES BY TARGETING EPIGENETIC REGULATORS

C. Wiggers 1,2, D. Lelièvre 3, D. Egan 3, M. Bartels 3, P. H. Grütters 4, Department of Biomedical Laboratory Sciences and Chemical Engineering, Bergen University College, 3Department of Internal Medicine, Haematology Section, University Hospital Bergen, 4Bergen University, Bergen, Norway.

Background: Treatment protocols for pediatric acute myeloid leukemia (AML) are chemotherapy-based, including high-dose cytarabine. While >90% of patients reach clinical remission, there is still a high relapse rate of ~30%, with overall survival rates of 60-70%. Therefore, better risk-classification at diagnosis and alternative treatment strategies are warranted. There is increasing evidence that epigenetic deregulation is involved in the initiation and progression of cancers, including AML. Epigenetic processes are required for hematopoiesis and epigenetic regulators are frequently translocated (MLL) or mutated (EZH2) in AML. Following this, deregulated epigenetic pathways could be used for targeted therapy and provide an alternative approach to improve pediatric AML therapy.

Aims: To identify new therapeutic drugs in pediatric AML by using an 80-compound screen containing inhibitors of epigenetic regulators, including histone writers (which deposit post-translational modifications (PTMs) on histones), readers (binding of PTMs) and erasers (removal of PTMs).

Methods: Cell lines used in this study are THP-1 (t(9;11)), Kasumi-1 (t(8;21)) and CMK (Down’s syndrome with GATA1 mutation), reflecting distinct pediatric AML entities and a differential response to treatment with cytarabine. Cells were treated for 72hrs followed by analysis of cell viability and apoptosis based on Hoechst, Draq7 and Calcein Green staining. The effect of three candidate compounds were further investigated in triplicates at different concentrations for their effect on cell viability (Annexin V/FITC staining), cell cycle, morphology, and apoptosis. AML-blast cells, normal myeloid precursor cells and cord blood, and pediatric AML patient cells representing distinct AML subtypes.

Results: From the 80 epigenetic compounds tested in THP-1, Kasumi-1 and CMK cells, we observed significant effects following treatment with the HDAC 4/5 inhibitor LMK235, the pan-HDAC inhibitor NSC3852, and the pan-bromodomain inhibitor Bromosporine. Dose-response curves showed differential cytotoxicity of the compounds and suggested LMK235 as most effective. Cell proliferation was inhibited by LMK235 at an IC50 of 0.1uM, 0.13uM and 0.425uM in Kasumi-1, CMK and THP-1, respectively. While inhibition by LMK235 resulted in an immediate response of apoptosis, Bromosporine-treated cells retained G1 between 72 hours, and, interestingly, treatment of LMK235-treated cells resulted in an increase of cells in S-phase and G2/M. Among the differential effects of the compounds in the cell lines, we also observed differences in sensitivity. In line with previous studies, THP-1 cells were more resistant, illustrated by a 10-fold increase in concentration required for NSC3852-induced apoptosis. Interestingly, upon treatment with Bromosporine, Kasumi-1 and CMK cells showed a similar response, while Kasumi-1 cells were significantly more sensitive to NSC3852-induced effects. These data are currently validated in pediatric AML patient cells.

Summary/Conclusions: Treatment of three distinct pediatric AML cell lines with the epigenetic compounds LMK235, NSC3852 and Bromosporine resulted in cell line-specific effects, regarding compound sensitivity, and compound specific effects, including cell cycle regulation and induction of apoptosis. Our data suggest a potential role for epigenetic compounds, with specificity for molecular subtypes, in the treatment of clinically and biologically distinct pediatric AML subtypes.

Combination of Interferon-alpha and Valproic Acid in Acute Myeloid Leukemia Cells In Vitro and In Vivo

R.B. Forthum1, A. Sulen1, G. Sjoholt2, Ø. Bruserud3,4, E. Mc Cormick1, B.T. Gjertsen1,3,5
1Centre for Cancer Biomarkers (CCBIO), University of Bergen, 2Department of Biomedical Laboratory Sciences and Chemical Engineering, Bergen University College, 3Department of Internal Medicine, Haematology Section, Haukeland University Hospital, 4Department of Clinical Science, Leukemia Research Group, University of Bergen, Bergen, Norway.

Background: Interferon alpha (IFNα) monotherapy is effective in selected myeloid neoplasias and is proposed to act through mechanisms that may be additive to the action of valproic acid (VPA), a histone deacetylase (HDAC) class I and IIa inhibitor with effect in approximately 20% of acute myeloid leukemia (AML) patients. Both drugs are found to have direct anti-cancer effects targeting apoptosis, differentiation and proliferation, as well as indirect effects targeting the immune system.

Aims: As several IFNα formulations are commercially available, we wished to explore the differences between two such drugs, recombinant IFNα2b and human IFNα-Le, in relevance to AML treatment.

Methods: Flow cytometry and Hoechst staining was used to investigate apoptotic potential of the IFNα therapeutics, whilst phospho-flow cytometry and differences in electrophoresis in combination with mass spectrometry unraveled IFNα signaling pathways. For in vivo efficacy analyses two orthotopic rodent models were implanted with leukaemic cells, and treated with VPA, IFNα-Le or both drugs.

Results: To investigate the anti-leukemic effects of IFNα we combined the two therapeutics with VPA in vitro using the human MOLM-13 cell line (wild type for FLT3 ITD and TP53). Results showed that IFNα-Le was more efficient compared to IFNα2b in in vitro studies, whilst both drugs were less effective in combination with VPA. Investigating IFNα signaling pathways using phospho-specific flow cytometry we found IFNα2b and IFNα-Le to have an identical stimulation profile in MOLM-13 cells, except from p-STAT6 Y641 that was higher expressed by IFNα2b. The phospho-proteome was further explored using difference gel electrophoresis (DIGE) and mass spectrometric analyses to find a potential explanation to the difference in apoptosis-inducing effects between the two drugs. Here we found protein folding (LCP1, HSPA8, TCP1, CCT6A), cell stress (AKR1B1, HSP90A1) and cell death (PKM2, PARK7, HSPB1, HSPA5, ANXA5, PRDX2) to be differently regulated between IFNα2b and IFNα-Le, and also identified the presence of a clearance-dependent effect on protein expression by IFNα2b and IFNα-Le. Further, we investigated the potential synergistic anti-leukemic effects of VPA and IFNα-Le in vivo using a MOLM-13LacIimmunodeficient NOD/Scid IL2 g- orthotopic xenograft mouse model, and the
immunocompetent brown Norwegian myeloid leukemia (BNML) syngeneic rat model. VPA mono-treatment increased survival from a median of 34 days to 38 days in the MOLM-13

BNML mouse model, and from 21 days to 50 days in the BNML rat model. Additionally, the IFNo-Le (0.8x10^6 IU/kg) and VPA (400mg/kg) combination treatment indicated a tendency to increased survival in the BNML model. However, IFNo-Le monotherapy (1x10^6 IU/kg) decreased survival in the MOLM-13

model.

Figure 1.

Summary/Conclusions: IFNo does not add beneficial effects to VPA treatment in the two in vivo orthotopic models tested, possibly due to immune constitution and tumor load.

KEVETRIN: PRECLINICAL STUDY OF A NEW COMPOUND IN ACUTE MYELOID LEUKEMIA

R. Napolitano1, S. De Matteis1, S. Carloni1, G. Simonetti2, G. Musuraca3, A. Luccchesi3, D. Calisti1, A. Cuneo1, K. Menon5, G. Martinelli2

1Bioscience Laboratory, IRCCS, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST), Meldola, 2Department of Hematology and Oncological Sciences, 3Hematology Unit, IRCCS, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST), Meldola, 4Department of Medical Sciences, University of Ferrara-Arcispedale Sant’Anna, Ferrara, Italy, 5Cellceutix Corporation, Beverly, United States

Background: Acute Myeloid Leukemia (AML) is a heterogeneous disorder defined by clonal expansion of immature myeloid cells that infiltrate bone marrow and other tissues. AML therapeutic strategies remain unchanged since 1970 and the majority of patients often eventually relapse and die due to disease progression. Tumor protein p53 transcription factor is a key regulator of several cellular pathways, such as cell cycle arrest, cell death and changes in gene expression. It is mutated in 8-14% of AML cases and its mutations are commonly associated with a complex karyotype. Kevetrin is a new molecule compound, proposed by Cellceutix, with the ability to target both wild type and mutant p53 tumors.

Aims: The aim of this project is to explore cellular and molecular alterations induced by Kevetrin, focusing on its role in the p53 pathway.

Methods: Kevetrin was kindly provided by Cellceutix, dissolved and stored at −20°C in sterile water in a 600 μg/ml stock solution, and diluted in medium immediately before use [concentration range in use 15-60μg/ml]. Cell lines, MOLM-13 and KASUMI-1, were cultured in RPMI 1640 supplemented with 20% heat inactivated fetal bovine serum, 2mM L-glutamine, 100 U/ml penicillin and 100 μg/ml streptomycin. After 24 and 48 h of treatment MTS, Annexin-V, TUNEL, JC-1 and Active Caspase-3 assays were performed according to manufacturer’s instructions. Proteins were separated by polyacrylamide gel electrophoresis and transferred to 0.2 μm polyvinylidene fluoride membranes. Quantitative analysis was performed with Quantity One software. Statistical analysis was carried out using the paired and unpaired two-tailed Student’s t tests. p values <0.05 were considered as significant.

Results: Our data indicate that Kevetrin exposure induces cell growth arrest, a great drop of mitochondrial membrane potential and a remarkable increment of the apoptotic process, after Caspase-3 activation (Figure 1.). In order to better understand drug’s mechanism of action we are performing gene expression profiling after 48h of treatment with Kevetrin 60μg/ml.

CLEARANCE OF ‘DRIVER-COSMIC’ MUTATIONS POST CR1 WITH OPERATING RUNX1-L56S IS UNLIKELY TO CONTRIBUTE TOWARDS DISEASE PROGRESSION IN AML

L. Rai1, T. Boneva2, D. Brazzma2, R. Dunn2, C. Grace3, E. Nacheva3

1Onco-Cytogenomics, 2OncoGenomics, HSL Analytics LLP, 3Cancer Research Institute, UCL, LONDON, United Kingdom

Background: Clinical significance of gene variants in AML is well established (Papaemmanuil E, et al, NEJM 2016) and is increasingly being implemented into routine diagnostic algorithms. Although 80% of patients achieve morphological remission after induction chemotherapy, long-term relapse free survival is a meagre 50% (Walter RB et al, JCO 2010. Monitoring of disease kinetics, is therefore, very critical.

Aims: To study the kinetics of gene variants post-induction chemotherapy in AML patients.

Methods: 130 follow-up samples from 45 de novo AML patients [median age-60 yr & median FU period- 18.6 mo] were screened for gene variants using TruSight Myeloid panel (Illumina, CA, USA) covering 54 genes with relevance in myeloid diseases. Gene variants at Variant allele frequency (VAF) of ≥10% at diagnosis and VAF of ≥1% during follow-up; both with target coverage of ≥300 reads were considered. Bone marrow (BM) or peripheral blood (PB) was obtained at presentation (BM-44; PB-1) and follow-up (BM-130). Gene variants in 95 samples from 40 MDS patients were also evaluated for progression to secondary AML. Public databases-Catalogue of Somatic Mutations In Cancer (COSMIC), dbSNP and 1000 genome (>2%) were used to classify gene variants as either Drivers (D), variants of unknown significance (VUS) and germline polymorphisms (SNP). P-value was generated with 2-tailed Fisher Exact (GraphPad Software, Inc, USA).

Results: Of 45 AML patients 19 achieved complete morphological remission (CR), 21 had a relapse and 5 had refractory disease with a median of 4 mutations/patient in each subgroup. Driver mutation was identified in 38 patients; 82% of who had persistence until clinical end-point. While 17 of 18 relapse patients retained a driver only 9 of 15 patients in remission retained it (Table 1). 8 of the 9 patients had a ‘driver with COSMIC and SNP’ (D-C/S) reference that persisted, while all ‘driver with COSMIC only’ (D-C) disappeared post-induction. This suggests that drivers with both COSMIC and SNP reference may not always contribute towards disease progression. We also found that D-C mutations persist in 85.7% of relapse patients compared to only 11% of patients in remission (P-value: 0.001). Additionally, D-C mutations were retained in all 13 relapse patients with intermediate risk cytogenetics while complete clearance was observed in all 6 patients who were in sustained remission (P-value: 0.001). Further investigation of genes with D-C/S mutation in the remission cohort (8x) revealed that 4 patients had persistent DNMT3A-2545724, 1 had DNMT3A-25457243, 2 had RUNX1-36259324/L56S and 1 had CBL-119149011. As DNMT3A mutations are considered to occur in pre-leukemic
stem cells contributing to clonal haematopoiesis (Askush et al, Nature 2014; Genovese et al, NEJM 2014); this led us to study the distribution of RUNX1 gene variants in an additional 119 AML diagnostic samples. 34 patients (21%) harboured RUNX1 mutation, of which 5 had RUNX1_L56S that were often associated with D-C mutations (4 of 5 cases). Finally, we evaluated kinetics of D-C in 40 MDS cases of which 34 had chronic MDS and 6 had secondary AML (sAML). No significant difference was observed in the number of patients with persistent D-C mutation in the 2 subgroups (chronic MDS: 16 of 19 (84.2%); sAML: 5 of 5 (100%); P-value: 1.000).

Summary/Conclusions: Clearance of ‘Driver-COSMIC only’ mutations while RUNX1_L56S persists is unlikely to contribute towards disease progression in AML.

Acute myeloid leukemia - Clinical

E906
PROGNOSTIC SIGNIFICANCE OF FLT3 STATUS, CYTOGENETIC, ECOG AND 50% BLAST DECREASE IN PRIMARY REFRACTORY OR EARLY RELAPSED AML PATIENTS BEFORE SALVAGE THERAPY
P. Sesques1, S. Bertoli2, M. El-Hamri1, S. Ducastelle1, G. Sailes1, C. Recher2, X. Thomas1, E. Paubelle1,2
1hematology, Chu Lyon Sud, Pierre Benite, 2hematology, Oncopole Toulouse, Toulouse, France

Background: Prognosis of relapsed/refractory acute myeloid leukemia (R/R AML) is unfavorable with a long term overall survival around 10%. Thus, management of R/R AML represents one of the most difficult challenges. Because allogeneic-Hematopoietic Stem Cell Transplantation (allogeneic-HSCT) is considered as the best treatment for this category of patients, to determine which patient will benefit from this cumbersome strategy is a crucial issue. A better understanding of the mutational status, cytogenetic, histological and clinical findings of early R/R AML patients and their outcomes could help treatment decisions, particularly for those who allogeneic-HSCT is considered as the best therapeutic option.

Aims: The objective of this study is to determine prognostic factors and develop a prognostic score using usual mutational status, cytogenetic, histological and simple clinical variables in R/R AML patients before salvage treatments.

Methods: In this retrospective study in two hematological departments (Hospices Civils de Lyon and CHU of Toulouse), we evaluated clinical, biological, histological, cytogenetic and current mutational status of early R/R non APL AML patient between age from 18 to 70 years. Univariate and multivariate analysis were performed and we developed a prognostic score based on the independent prognostic parameters from Cox model.

Results: From January 2009 to May 2016, 58 patients presenting early relapse and primary refractory AML were analyzed. Overall Survival (OS) and Progression Free Survival (PFS) median were 9 and 2 months respectively. In univariate analysis, cytogenetic findings (unfavorable groups), unfavorable ECOG (>2), FLT3 positive status and <50% blast decrease (between induction and R/R assessment) independently predicted poor OS and were identified as significant prognostic parameters of OS (p=.037, p=.0084, p=.0452, p=.0071 respectively). In multivariate analysis, these last four criteria confirmed their worst prognostic impacts (p=.015, p=.017, p=.026, p=.015 respectively) and were used to create a five groups prognostic score. Better OS were statistically observed for patient with score 0 or 1 compared to 2, 3 or 4 (2-years OS 48% and Not Reached respectively, p=.0104) using a log-rank regression. When data were censored to allogeneic HSCT, the scoring system revealed a relevant difference with favorable OS for those with a score 0-1 compared to score 2-3-4 (2-years OS 64% and Not Reached respectively, p=.001) (Figure 3).

Summary/Conclusions: Our prognostic score based on simple and usual data: FLT3 status, cytogenetic, ECOG and percentage blast decrease found distinct groups with statistically different outcomes. Basically, the higher is the score, the worst is the OS. This new score is a valuable, simple and useful score for the therapeutic salvage management of AML patients presenting early relapse and primary refractory.
PRELIMINARY RESULTS FROM A PHASE 1 STUDY EXAMINING THE NOVEL BCL-2 INHIBITOR S55746/BCL201 AS SINGLE AGENT IN PATIENTS WITH ACUTE MYELOID LEUKEMIA OR HIGH RISK MYELODYSPLASTIC SYNDROME

A. Wei1, A. Bajel2, N. Boisse1, I. Kloos4, C. Delifer4, S. Banquet1, X. Thomas1, N. Vey6

1Department of Clinical Haematology, The Alfred Hospital and Monash University, 2Department of Haematology & Bone Marrow Transplantation, The Royal Melbourne Hospital, Melbourne, Australia, 3Department of Hematology, Centre Hospitalier Saint Louis, Paris, 4Servier, Suresnes, 5Department of Haematology, Centre Hospitalier Lyon Sud, Lyon, 6Department of Hematology, Institut Paoli-Calmettes, Marseille, France

Background: Novel and effective therapeutic options for patients (pts) with advanced acute myeloid leukemia (AML) and myelodysplastic syndromes (MDS) are limited. Targeting the prosurvival molecule BCL-2 is clinically efficacious in various hematological malignancies. S55746/BCL201 is a novel, selective and potent inhibitor of BCL-2, with demonstrated antileukemic activity in preclinical models.

Aims: To evaluate the safety, recommended phase 2 dose (RP2D), pharmacokinetic (PK), pharmacodynamic (PD) and preliminary activity of S55746/BCL201 in patients with AML [refractory/refractory (R/R) or ≤65 years until for intensive chemotherapy (IC)], or MDS failing prior therapies.

Methods: A phase I study (EUDRACT 2014-002559-24, NCT02920541) is underway to investigate S55746/BCL201 as a single agent in 5 European and Australian centers. S55746/BCL201 was initially administered in fasting conditions, once daily (21-day cycles), until disease progression, unacceptable toxicity, or investigator’s or patient’s decision. Pts giving informed consent received S55746/BCL201 at escalating dose levels according to a modified continual reassessment method for dose allocation.

Results: As of 23 February 2017, 34 pts have received S55746/BCL201 at doses ranging from 100 to 1300mg/day (median time on treatment: 43 days, range 1 to ≥374), 28 pts were R/R AML, 2 pts were elderly AML, and 4 pts had MDS failing prior therapies. Median age was 70 years (range 19-80), median number of prior therapies 2 (range 0-6), ECOG ≤2, and median WBC 3 G/L (range 0-30). Among the AML cohort, European LeukemiaNet risk (Döhner 2010) was adverse in 53%, intermediate-1 in 20%, and intermediate-1 in 17%. Preliminary PK results in fasting pts showed that exposure increased linearly but with some inter-individual variability. Most common (≥20% of pts) non-hematological adverse events (AEs), all grades, included diarrhea (27%), hypokalemia (27%), nausea (21%), and vomiting (21%). The most frequent grade ≥3 AEs were hematological (anemia (35%), thrombocytopenia (32%), febrile neutropenia (21%), and neutropenia (18%)), hypokalemia (18%), and sepsis (15%). Of 12 pts (38%) with AEs possibly related to study drug, the most frequent were diarrhea (3 pts), muscle spasms, thrombocytopenia, and anemia (2 pts each). One 74-year-old pt had grade 5 cardiac failure considered drug-related after 8 cycles of treatment (900mg). Non-related fatal AEs were reported in 7 pts (including sepsis, hemorrhagic stroke, pneumonia, and disease progression). There were no reported episodes of clinical or laboratory TLS. No DLT was reported and MTD has not been reached. Of 26 AML pts evaluable for response (at least 1 cycle completed), one achieved a CRi (complete remission with incomplete blood count recovery lasting 10 months) and one a PR (partial remission lasting 3 months before proceeding to allogeneic stem cell transplant). In MDS, 4 out of 4 pts had stable disease (lasting 1 to ≥7 months). Bone marrow blasts decreased in 50% of all evaluable pts, with the nadir reached (87%) within the first two cycles (Figure 1).

Summary/Conclusions: Initial findings suggest that S55746/BCL201 has acceptable tolerability and clinical activity in advanced AML and MDS. Based on non-compartmental pharmacokinetic food interaction results from another study, demonstrating that S55746/BCL201 Cmax and AUC increased about 6-fold with food, dose escalation has started in patients with drug intake during a meal.

E098

DISSECTING THE CLINICAL HETEROGENEITY OF NUCLEOPHOSMIN-1 (NPM1) MUTATED ADULT ACUTE MYELOID LEUKEMIA: THE CONTRIBUTION OF FLOW-CYTOMETRIC DETERMINATION OF MINIMAL RESIDUAL DISEASE

F. Buccisano1,*, L. Maurillo1, M.I. Del Principe1, A. Di Veroli1, E. De Bellis1, L. Ciccon1, M. Divona1, T. Ottone1, S. Lavorgna1, V. Rossi1, A. Zizzari1, M.A. Imo Consalvo1, D. Fraboni1, C. Conti1, G. Del Poeta1, M.T. Voso1, W. Arcese1, F. Lo Coco1, A. Venditti1

1Biomedicine and Prevention, University Tor Vergata of Rome, Rome, Italy

Background: Acute Myeloid Leukemia (AML) with mutations of the gene encoding Nucleophosmin-1 (NPM1) identifies a subgroup of patients with favorable prognosis according to the 2008 WHO classification. However, recent evidences (Papaemmanuil, NEJM 2016) suggest that the coexistence of additional gene mutations (e.g. DNM3A, IDHI, IDH2 (R140Q and TET2)) may determine an inferior clinical outcome as compared to favorable risk AML and precludes a reliable outcome prediction. The presence of minimal residual disease (MRD), as determined by quantification of NPM1 mutated transcripts, provides powerful prognostic information independent of other risk factors (Ivey, NCI 2017).

Aims: The aim of our study was to investigate if detection of NPM1 transcripts by multiparametric flow cytometry (MFC) might represent an alternative tool to discriminate different prognosis within the NPM1 mutated AML group, in a setting where an extensive gene profiling at diagnosis or a quantitative determination of NPM1 transcripts in remission would not be available.

Methods: We analyzed a series of 69 AML patients with NPM1 mutations; all the patients were in complete remission (CR) after intensive induction cycle of EORTC-GIMEMA protocols. The frequency of NPM1 mutated cases was not different among patients below (48/142, 34%) or above (21/61, 34%) the age of 60 years, respectively. Twenty out of 65 patients (31%) carried a concomitant FLT3-ITD mutation; 51/66 (77%) NPM1 mutated cases had a normal diploid karyotype. Upon full hematological recovery after consolidation cycle, counting by MFC, ≥3.5x10^4 (0.035%) residual leukemic cells (RLCs) in the bone marrow (BM) was regarded as a condition of MRD positivity.

Results: Among NPM1 mutated patients, the rate of MRD negative CR was significantly lower (5/69, 7%) as compared to NPM1 WT ones (39/134, 29%), respectively (p<0.001). Although there was not a statistically significant difference, probably due to the low numbers, MRD negative/NPM1mut patients had a lower Cumulative Incidence of Relapse (CIR) as compared to MRD positive/NPM1mut patients (93% vs 80%). We also evaluated the impact of autologous (AuSCT) or allogeneic (ASCT) transplantation on the outcome of MRD positive/NPM1mut patients. The overall survival (OS) was significantly higher for patients submitted to ASCT (n=14) as compared to those (n=15) submitted to AuSCT (93% vs 33%, p=0.011). This was confirmed even after excluding from the analysis FLT3-ITD+ppatients. When all the meaningful clinical variables were challenged in multivariate analysis (MRD, type of transplant, age >60 yrs, karyotype), the type of transplant (ASCT vs AuSCT) was the only variable that significantly influenced OS and DFS (p=0.001 and 0.003, respectively).

Summary/Conclusions: In conclusion, although quantitative RT-PCR represents the gold standard, MFC determination of MRD also confirms that the quality of remission is critical to discriminate patients with a different outcome among NPM1mut patients. In fact, these patients have a low chance to become MFC MRD negative and in a situation of MRD positivity, a very poor outcome can be substantially improved only by a timely use of an allogeneic procedure.

E099

EXPRESSION OF IMMUNE CHECKPOINT MOLECULES (PD-1, PD-L1, AND PD-L2) ON BONE MARROW T CELLS IN ACUTE MYELOID LEUKEMIA

1Department of Laboratory Medicine, Asan Medical Center, University of Ulsan College of Medicine, 2Department of Pediatrics, Asan Medical Center Children’s Hospital, University of Ulsan College of Medicine, 3Department of Hematology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic Of

Background: Immune checkpoints constitute a mechanism by which tumors escape from the host immune system and involve the programmed death-1 (PD-1) receptor and its ligands, PD-L1 and PD-L2. In a tumor microenvironment, immune checkpoint expression of PD-1, an inhibitory receptor on the surface of T cells, can lead to dysfunction of antitumor effector cells. Recently, investigators have detected overexpression of PD-1 for patients with acute myeloid leukemia (AML) who experienced relapse following allogeneic stem cell transplantation

Figure 1.
(SCT). However, evidence regarding T cell phenotypes for patients with AML is sparse.

Aims: The authors evaluated patients with AML to determine expression levels of checkpoint molecules (PD-1, PD-L1, and PD-L2) according to diagnosis and treatments (chemotherapy [CTx] and SCT). The purpose of this study was to identify optimal candidates for checkpoint blockade therapy for AML.

Methods: Bone marrow (BM) samples were obtained from 195 AML patients in different stages of the disease. Samples were stratified by time since diagnosis (n=69) and treatment response (complete remission [CR] after CTx, n=30; persistence after CTx, n=29; relapse after CTx, n=7; normocellular marrow with trilineage regeneration [NMTR] after SCT, n=19; persistence after SCT, n=18; and relapse after SCT, n=23). BM samples also were collected from 23 patients with no evidence of hematologic malignancies (control group). Flow cytometric analysis of PD-1 expression on T cells and PD-L1/PD-L2 expression on leukemic cells was performed by means of a FACSCanto II system (Becton-Dickinson, Sunnyvale, CA, USA).

Results: There were no differences in levels of PD-1 expression on CD8+ and CD4+ T cells at time of AML diagnosis, compared with controls. However, PD-1 expression levels on CD4+ T cells were significantly correlated with time since diagnosis. For patients at time of diagnosis, PD-1 expression on CD8+ and CD4+ T cells was significantly different compared with patients who experienced relapse after SCT (P<0.0001), persistence after CTx (P=0.025 and P<0.0001), and NMTR after SCT (P<0.0001 and P<0.0001). In contrast, no difference in PD-1 expression was observed between patients at time of diagnosis and patients after CTx (Figure 1). For CD4+ T cells, a significant difference was found between SCT and CTx groups, and PD-1 expression levels of groups that experienced relapse (P<0.0001) or persistence (P<0.0001) after SCT were significantly higher than those of patients in the CTx groups. PD-L1 and PD-L2 expression on leukemic cells at time of diagnosis was higher in secondary AML transformed from myelodysplastic syndrome than in de novo AML (P=0.001 and P=0.039). Although PD-L1 and PD-L2 expression levels for patients at time of AML diagnosis did not differ from groups that experienced relapse or persistence after SCT, PD-L1 and PD-L2 levels for diagnosed patients did differ from those of patients who experienced persistence after CTx (P=0.038 and P=0.023).

Summary/Conclusions: Our study shows that HIV status has no prognostic impact on AL patient’s outcome. HIV patient with acute leukemia should thus be included in clinical trials to improve and standardize their therapeutic management.

E911

TEN-DAY DECITABINE AS INDUCTION THERAPY FOR OLDER PATIENTS WITH ACUTE MYELOID LEUKEMIA FIT FOR INTENSIVE CHEMOTHERAPY

C. Zhou1, H. Wei1, D. Lin1, Y. Wang1, B. Liu2, K. Liu1, B. Gong3, Y. Li4, G. Zhang1, S. Qiu1, R. Gu1, S. Wei1, X. Gong1, Y. Mi1, J. Wang1.19

Summary/Conclusions: Our study shows that the PD-1/PD-L1 pathway may constitute an immune-escape mechanism in AML. PD-1 expression in CD4+ T cells increased with time since diagnosis. Patients who underwent SCT exhibited overexpression of PD-1, which suggests that SCT and/or chronic stimulation of leukemic cells might induce more PD-1 expression by T cells. Blockade of the PD-1 immune checkpoint may represent an immunotherapeutic strategy for patients with AML relapse or AML persistence after SCT.
with SOC at the end of induction, after completion of the 1st cycle of consolidation, in pts with AML who receive indoximod in combination with 7+3 remission induction consisting of cytarabine (100mg/m²/day for 7 days) and idarubicin (12mg/m²/day for 3 days) and high-dose cytarabine (HDAC) consolidation, as SOC, in pts with newly diagnosed AML (NCT02835729), with a 3+3 design for the phase 1 portion. Indoximod is given orally every 8 hours starting on day 8 of induction onward. Indoximod is recommended phase 2 dose (RP2D) of indoximod in combination with standard of care (SOC) chemotherapy for frontline AML treatment. A key secondary objective is to determine the minimal (or measurable) residual disease (MRD) status, as measured by multi-parametric flow cytometry, in pts with AML who receive indoximod in combination with 7+3 remission induction consisting of cytarabine (100mg/m²/day for 7 days) and idarubicin (12mg/m²/day for 3 days) and high-dose cytarabine (HDAC) consolidation, as SOC, in pts with newly diagnosed AML (NCT02835729), with a 3+3 design for the phase 1 portion. Indoximod is given orally every 8 hours starting on day 8 of induction onward. Indoximod is held on days that pts receive HDAC consolidation, and it is discontinued 4 weeks post-induction, after completion of the 1st cycle of consolidation, and for 4 weeks of consolidation. Eight pts in dose levels 0 and 1 achieved complete remission (CR) after induction. All 8 pts demonstrated no evidence of MRD at levels ≤0.02% (MRD-neg) post-induction and remained MRD-neg post cycle 1 of HDAC. One pt in dose level 0 with favorable risk (normal karyotype, mutations in DNMT3A/FLT3/ITD) and 3 had adverse risk. No RLT was observed with the 1st and 2nd dose levels. The most frequently reported adverse events (regardless of attribution), were febrile neutropenia, diarrhea, nausea and vomiting, dyspnea, hypotension, and hypoxia. Three pts are no longer on study: 1 (dose level 0) due to inability to swallow indoximod after hypoxic respiratory failure during induction, 1 (dose level 1) withdrew consent for personal reasons after only 2 doses of indoximod, and 1 (dose level 2) was taken off due to eligibility. The remaining 9 pts are still on study; 3 pts in dose level 2 are currently receiving induction and are not evaluable. Five of 8 (63%) evaluable pts had dose levels 0 and 1 achieved complete remission (CR) after induction. All 5 pts demonstrated no evidence of MRD at levels ≤0.02% (MRD-neg) post-induction and achieved morphologic CR but had MRD at time of induction, and ultimately relapsed after 2 cycles of HDAC consolidation.

Summary/Conclusions: Indoximod does not appear to add significant toxicity to standard remission induction and consolidation in pts with newly diagnosed AML. Initial data suggest a high rate of MRD-neg after one cycle of induction chemotherapy.

**PHASE III STUDY OF MEK INHIBITOR (MEK-162; BINOMETINIB) IN PATIENTS WITH RELAPSED AND/OR REFRACTORY MYELOID MALIGNANCIES**

K. Naqvi1, T. Kadia1, G. Borthakur1, K. Takahashi1, P. Bose1, N. Daver1, Y. Alvarado1, M. Ohanian1, C. DiNardo1, E. Jabbour1, G. Garcia-Manero1, H. Kantarjian1, A. Patel1, F. Ravandi1

1Department of Leukemia, UTMD Anderson Cancer Center, Houston, United States

Background: Activation of the mitogen-activated protein kinase (MAPK) signaling (RAS/RAF/MEK/ERK pathway) promotes growth and inhibits apoptosis of hematopoietic cells. Inhibition of MEK/RAF/MAPK pathway has shown antiproliferative effects in acute myeloid leukemia (AML) in vitro and in AML patients. MEK-162 is an oral, potent, selective allosteric, ATP non-competitive inhibitor of MEK1 and 2.

Aims: To study the efficacy and safety of MEK-162 in patients with advanced myeloid malignancies.

Methods: Patients with relapsed/refractory AML, not candidates for intensive chemotherapy, and patients with high risk myelodysplastic syndrome (MDS) who were resistant/intolerant to standard treatment including stem cell transplant were treated with MEK-162 twice daily every 28 days. Patients in the expansion phase had to be RAS mutated. The primary endpoint was overall response rate (ORR=CR + CRi) after 1 cycle of therapy. Survival was estimated using the Kaplan-Meier method. Safety analysis included all patients who had received at least 1 dose of MEK-162. MEK-162 dose escalation followed a 3+3 design; phase 2 had built in toxicity/boundaries. 45mg twice daily is the final dose level for expansion phase.

Results: Sixteen patients were treated (escalation=7; expansion=9): 14 AML and 2 MDS. Median age was 62 years (31-85); 56% were male; 94% had a performance status of 1-2. Median number of prior therapies was 4 (1-6); 3/16 (19%) patients had complex karyotype. 11/16 (69%) patients were RAS mutant. 9/16 patients completed a minimum of 1 cycle of MEK-162 therapy and were evaluable for response (3 at 30mg and 7 at 45mg dose). ORR was 10% (CRi in 1/10 patients). Median number of cycles administered were 2 (1-4). Median duration on therapy was 1.1 months (0.1-3.4). Median overall survival is 3.2 months (0.3-7.6). Common G3/4 toxicity included neutropenia (56%), fatigue (13%), nausea/vomiting (13%) and electrolyte abnormalities (19%). No dose limiting toxicity was reported.

Summary/Conclusions: MEK-162 shows a tolerable safety profile with an ORR of 10%. The study is currently on-going. Additional studies involving combination of MEK-162 with RAF and PI3 kinase inhibitors are ongoing.

1Stem Cell Transplantation, The University of Texas MD Anderson Cancer Center, Houston, United States, 2Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, United States

Background: Acute myeloid leukemia (AML) is more common in the older population. Haploidentical stem cell transplantation (haploSCT) is a potentially curative...
ative treatment option for patients with AML and allows transplantation for patients without an HLA matched donor. Recently, the use of post-transplant cyclophosphamide-based (PTCy) GVHD prophylaxis has improved outcomes of haploSCT; however, outcomes of haploSCT in older patients remain unclear.

Aims: Here we evaluated outcomes of older patients with AML/MDS who underwent haploSCT.

Methods: We retrospectively analyzed outcomes of all 43 patients ≥55 years with AML/MDS who underwent a haploSCT at our institution after year 2009. All patients were treated with fludarabine-melphalan (FM)-based conditioning regimen (melphalan 100 or 140mg/m²) plus thiopeta 5mg/kg or 2GyTBI. Characteristics of these patients are presented in Table 1.

Results: Median age was 61 years (range 55-69), 22 patients (51%) were in CR1/2, 16 patients (37%) had poor-risk cytogenetics, and median HCT-Cl was 2 (range 0-11). Reduced melphalan regimen (100mg/m²) was used in 29 pts (67%). Donors were children in 35 (81%) or siblings 10 (19%) patients. Median follow-up was 19 months (range 6-49). One patient died prior to engraftment. Forty-two patients engrafted the donor cells (100%). Median time to neutrophil and platelet engraftment was 19 (13-28) and 28 (15-117) days. Day 30 chimerism was 100% donor in 38 patients (88%). The cumulative incidence of grade 2-4 and 3-4 aGVHD at 6 months post-transplant was 35% and 28% at day 100, 1 year, and 2 years post-transplant. Patients in CR1/2 had 2-year NRM and relapse rate of 23% and 14%, and OS was 61%. The 2-year overall survival (OS) and progression-free survival (PFS) was 42%, and relapse rate also in NPM1-mut patients; however, in this cohort NPM1-based MRD integration allows a better risk stratification. MFC MRD is accurate also in NPM1-mut patients; however, in this cohort NPM1-based MRD evaluation is the most accurate predictor of prognosis.

Summary/Conclusions: Our data show that MRD assessment at different time-points during treatment retains a strong prognostic impact in older AML/MDS patients and that different cut-offs at different time-points can give different and useful prognostic information that may drive post-induction therapy. MFC MRD evaluation at TP2 with 0.1% cut-off is the most useful for patients risk stratification. However, the evaluation of MFC-MRD at TP1 with 0.025% cut-off can early identify a group of patients with a significantly low risk of relapse. At the same TP, MFC and WT1 MRD integration allows a better risk stratification. MFC MRD is accurate also in NPM1-mut patients; however, in this cohort NPM1-based MRD evaluation is the most accurate predictor of prognosis.

E916

THE NUMBER OF CD34+CD38+CD117+HLA-DR+CD13+CD33+ CELLS INDICATES POST-CHEMOTHERAPY NEUTROPHIL RECOVERY IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

R. GU1, H. Wei1, Y. Wang1, D. Lin1, B. Liu1, C. Zhou1, K. Liu1, B. Gong1, S. Wei1, G. Zhang1, X. Gong1, Y. Liu1, Y. Li1, X. Zhao1, S. Qiu1, Y. Mu1, J. Wang2.
Background: Hematopoietic recovery is considered to associated with the number of multipotent hematopoietic stem cells in the bone marrow, as observed in functional assays involving stem cell transplantation. However, there is little evidence related to hematopoietic recovery in non-transplantation settings, which is accomplished by endogenous hematopoietic cells. A recent study suggested that progenitors are the main contributors during this steady-state hematopoiesis, which differs from exogenous transplantation. And our previously data revealed that, CD34+CD38+CD117+HLA-DR+CD13+CD33+ cells (P cells), a kind of progenitor cell, is significantly decreased in patients with delayed neutrophil recovery after chemotherapy compared with that without delayed count recovery.

Aims: To further examine a potential impact of P cells percentage on hematopoietic recovery.

Methods: The data of 223 patients diagnosed with de novo AML was analyzed retrospectively. All these patients enrolled in our previously registered prospective randomized clinical trial AML 2010-01 (201002024). We reviewed the data from bone marrow flowcytometry before the first and second course of consolidation therapy, in which the CD34+CD38+CD117+HLA-DR+CD13+CD33+ progenitor cell percentage in the bone marrow was analyzed. Platelet count recovery time and time of neutrophenia were counted for the evaluation of hematopoietic recovery ability after chemotherapy.

Results: We found that less P cell percentage was significantly associated with prolonged neutrophenia recovery time after the first and second courses of consolidation chemotherapy (p=0.001; p=0.028, respectively). We also observed similar results regard to platelet recovery time after the first course of consolidation chemotherapy (p=0.001). Univariate analysis showed that P cell percentage, rather than gender, age, WHO classification and cytogenetic subgroup, were associated with neutrophil recovery after chemotherapy. Multivariate analysis has demonstrated that P cell percentage was an independent factor affecting neutrophil recovery capability for both first and second courses (p=0.015; p=0.036, respectively).

Summary/Conclusions: Our results indicate that CD34+CD38+CD117+HLA-DR+CD13+CD33+ cells before each course of chemotherapy is associated with chemotherapeutic hematopoietic reconstitution capacity independently. These findings may help better understand endogenous hematopoietic reconstitution and modify future chemotherapy regimens based on progenitor cell percentages.

E917

MICRONRNAS (miRS) IN HIGH RISK PEDIATRIC ACUTE MYELOID LEUKEMIA (AML) AS PREDICTION TOOLS FOR RCTICTION TIME IN AML. P.P. Leoncini1,*, P. Vitullo1, G. Nigita2, D. Veneziano2, P. Fadda3, V. Tocco1, M. Pigazzi2, G. Basso4, R. Rota1, A Bertaina1

1Oncohaematology, Bambino Gesù Children Hospital, Roma, Italy, 2Medical Genetics, 3Genomic Shared Resources, Ohio State University, Columbus (OH), United States, 4Oncohaematology-Pediatrics, University of Padova, Padova, Italy

Background: Despite recent progresses made in the treatment of acute myeloid leukemia (AML) (CML) of childhood, the cure rates of high-risk subtypes remain low. Indeed, patients harboring FLT3-ITD mutations or t(12;21) translocations (MLL rearrangements) are still characterized by a poor prognosis, mainly due to leukemia recurrence. Since microRNA (miRs) are small RNA molecules controlling normal hematopoiesis whose deregulation is fundamental in leukemia’s pathogenesis, a possible role as predictors of relapse should be considered.

Aims: Our purpose is to identify, at time of diagnosis, significant miRs signatures able to predict the risk of relapse for patients with high-risk AML, such as FLT3-ITD and MLL rearranged leukemia.

Methods: A total of 204 AML bone marrow (BM) derived samples collected either at diagnosis (ND) and at relapse (RL) together with 8 healthy controls (HCs) were studied (total: N=48). Informed consent has been obtained from either parents or legal guardians according to the Declaration of Helsinki. RNA was extracted, cleaned up and Nanostriing microRNA profiling was performed. Statistical analysis was performed using R software (NanoString Technologies, Seattle, WA, USA) and R-base statistical software. All the assessed results imply a p<0.05 where not mentioned.

Results: Comparing all AML samples with HC, we found 16 up- and 509 down-regulated miRs. Similarly, FLT3-ITD (n=11) vs HCs, showed 17 up- and 361 down- regulated miRs, while MLL-rearranged (n=9) vs HCs showed 16 and 48 miRs respectively. A trend towards down-regulation of the whole cohort was detected and a block in miRs maturation occurring in the 2 molecular subsets was supposed. Finally, a FLT3-ITD vs MLL-rearranged analysis produced a signature in which 20 miRs were up- and 18 down- regulated, a putative signature which could characterize high-risk AML. ND vs HCs analysis identified 17 up- and 297 down-regulated miRs, confirming a tendency toward downregulation, as well as in RL vs HCs analysis, in which we found 12 and 374 up- and down-regulated miRs, respectively. RL vs ND comparison showed a total of 16 up- and 15 down-regulated miRs. In the attempt to identify a signature predictive of recurrence at time of diagnosis, we compared ND and RL samples, revealing 301 miRs that maintained their deregulation in the 2 subgroups, while 113 and 85 were uniquely found in ND vs HCs and RL vs HCs, respectively. Remarkably, miR-34a-5p (P=0.0001) was the recurrent and most statistically significant upregulated miR in both ND and RL samples. Moreover, upregulated miR-10a-Sp and miR-99a-Sp (P<0.0001), and downregulated miR-5p (P<0.0001) were the most statistically significant miRs in FLT3-ITD and MLL-rearranged AML, respectively, underlying putting unique elements distinguishing the two clinical subsets.

Summary/Conclusions: Our results suggest the presence of different microRNA signatures in pediatric AML carrying FLT3-ITD and 11q23 translocations [t(9;11) and t(10;11)]. The identifications of new targets linked to this miRs would pave the way for further studies on the precise molecular basis of this therapy. Interestingly, miR-34a-5p was recurrently found upregulated either in ND and RL groups, but not in the comparative analysis between ND vs RL, suggesting a potential involvement in the mechanisms at the base of both onset and relapse in these subtypes of high-risk AML.

E918

CYTOKINE RECEPTORS AND SOLUBLE ADHESION MOLECULE LEVELS ARE ASSOCIATED WITH PROGNOSIS OF NEWLY DIAGNOSED AML. T. Kupsa1,2, P. Zak2, L. Jevab1,2, J. M. Horacek1,2, *1Department of Military Internal Medicine and Hygiene, Faculty of Military Health Sciences, 24th department of Internal Medicine - Hematology, University Hospital Kralove, Charles University, Faculty of Medicine, Hradec Kralove, Hradec Kralove, Czech Republic

Background: The outcomes of acute myeloid leukemia (AML) treatment are beleaguered by the high recurrence of malignant clones to therapy. Cytokines and adhesion molecules have been studied as markers of immune system activation in many diseases including AML. Furthermore knowledge from baseline cytokine levels assessment may help to improve treatment outcomes.

Aims: The aim of this study is to evaluate baseline levels of selected cytokines, cytokine receptors and adhesion molecules and their relationship with prognosis in newly diagnosed AML patients.

Methods: A total of 75 AML patients, age 52.9±13.0 years, median 58.4 years, 44 female, were studied in the period 2010-2015. Only patients with minimal follow-up of 1 year were included. All patients were induced with “3+7” induction chemotherapy consisting of Cytarabin 100mg/m² per day for 7 consecutive days and Daunorubicin 90mg/m² for the first 3 days of therapy in younger patients. Since the beginning of 2015, the induction dose of Daunorubicin used has been 60mg/m² even in younger patients, according to recent evidence-based data modifications. Those who failed to achieve CR were given IFALda salvage protocols followed by autologous stem cell transplantation in younger and fit patients. In CR, the patients were treated either with HDAIC consolodation and/or allo-hematopoietic cell transplantation or allo-sibling stem cell transplantation in younger patients. A total of 39 patients underwent autologous stem cell transplantation. We evaluated serum levels of the following 29 analytes: interleukins (IL-1α,IL-1β,IL-2,IL-3,IL-4,IL-5,IL-6,IL-7,IL-8,IL-10,IL-12,IL-13,IL-15), Erythropoietic Growth Factor, Granulocyte Macrophage Colony Stimulating Factor, Interferon-γ, Macrophage Inflammatory Protein-1α, Monocyte Chemotactic Protein-1, Tumor Necrosis Factor-α (TNF-α), vascular Endothelial Growth Factor, E-selectin (E-Sele, P-Sele), selectin (P-Sele), Intercellular Adhesion Molecule-1 (ICAM-1), Vascular Cell Adhesion Molecule-1 (VCAM-1), Matrix Metalloproteinase-9, soluble IL-2 receptor-α (sIL-2Rα) and soluble receptors for IL-6 (sIL-6R) and TNF-α type 1 and II receptor-α (sTNF-RI, sTNF-RII) or bihareby labeled as their respective Evidence Investigator analyzer (Randox). Associations of these markers with complete remission (CR) achievement, 1 year progression-free survival (PFS), and 1 year overall survival (OS), were evaluated. Statistical analysis was performed in STATISTICA 2.0.

Results: CR by induction therapy was achieved in 53 cases (70.7%). Those who failed to achieve CR by induction therapy had higher IL-7 levels, which was not significant after Bonferroni correction (P=0.0913). Inferior PFS was associated with higher sIL-2Rα (P=0.0525). Inferior OS was significantly associated with higher P-Sele (P=0.0003), higher sIL-2Rα (P=0.0029), higher age (P=0.0356) and possibly with higher TNFR-1 (P=0.0611). Age has not correlated with elevated analyte, TNFR-1 correlates with TNFR-2 (P=0.0196) but not with TNF-α. The sIL-2Rα did not correlate with IL-2. Only IL-6 and ICAM-1 were significantly influenced by CR levels.

Summary/Conclusions: Better understanding of the cancer microenvironment is a sine qua non for development of new treatment approaches. Our results suggest that cytokine receptors and adhesion molecules may be markers of immune system activation and could be useful in clinical practice for the prediction of outcome, and thus should be further investigated as possible therapeutic targets. The work was supported by a long-term organisation development plan 1011 (FMHS) and by MH CZ – DRO (UHKK, 00179906).
MRD-DRIVEN CHOICE OF CONSOLIDATION AND MODULATION OF INDUCTION AND CONSOLIDATION INTENSITY RESULTED IN A SIGNIFICANTLY IMPROVED OUTCOME OF YOUNGER AML PATIENTS IN THE LAST THREE YEARS

M. Clavio1, F. Guolo1, P. Minetto1, M. Miglino1, F. Ballerini1, D. Guardo1, E. Covio1, R.M. Lemoli1, M. Gobbi1
1Clinic of Hematology, Department of Internal Medicine (DiMI), University of Genoa, IRCCS AUO San Martino-IST, Genova, Italy

Background: In the last decades no effective new drugs have been introduced and AML induction therapy is still based on an anthracycline and cytarabine. The MRC group has, however, reported a progressive increase of cure rates in younger patients. Our group has recently showed that the outcome can be improved by a fludarabine-containing induction (FLAId, with fludarabine administration in first course only), followed by a risk- adapted consolidation.

Aims: The aim of the present study was to evaluate if the disease free survival (DFS) and the overall survival (OS) of younger (<65 years) AML patient treated in our center had shown any modification in four consecutive periods of treatment (< 2008; 2008-2010; 2011-2013; 2014-2016) and to recognize factors possibly leading to this result.

Methods: We reviewed the outcome of 145 consecutive AML patients aged 65 or less and uniformly treated according to the above mentioned strategy. Minimal residual disease (MRD) evaluation was performed by flow cytometry (MFC), assessment of WT1 expression levels and, where applicable, evaluation of recurrent abnormalities such as NPM1 mutation.

Figure 1. Results: The cohorts of patients treated in the four periods had a comparable age and risk distribution. Notably, although the median follow up of the 4 cohorts of patients is different, patients treated in the last 3 years showed a significant improvement in DFS (Fig 1), in comparison with previously treated patients. When we reviewed our experience, we found that some changes we introduced in the therapeutic management, possibly contributed to improve outcome. Beside classical risk factors, the time from hematological recovery after the first induction (induction 1) and the start of the second induction course (induction 2) proved to be significantly related to DFS and OS probability. An interval shorter than 15 days resulted in significantly higher toxicity, whereas a time longer than 28 days was associated with an increased relapse probability. Patients being treated in the last three years had a median time from recovery after induction 1 to start of induction 2 of 17 days, compared to 22 days in the other cohorts (p<0.05). Furthermore, after 2013, MRD information after induction 1 was added as a prognostic factor and ELN low and intermediate risk patient with negative MRD after induction 1 were no more scheduled for early allogeneic stem cell transplant (HSCT), but received an higher dose of Ara-C in each of the three consolidation cycles (12g/sqm cumulative dose vs 8g/sqm). Among 8 intermediate risk patients who were MFC MRD negative post FLAId and did not proceed to HSCT in first complete remission (CR1), only one relapsed whereas among 5 intermediate risk patients who underwent HSCT in CR1 because of MRD positivity no relapses have been observed. Starting from 2014, patient in CR1 not scheduled for HSCT who showed MRD recurrence underwent salvage therapy before overt hematologic relapse, followed by HSCT consolidation. MRD-directed therapy allowed all treated patients to achieve MRD negative remission before HSCT. Finally, the improved outcome may be associated with a reduced incidence of invasive fungal infections (IFI) due to the introduction of prophylaxis with posaconazole. The lower rate of IFI contributed to the reduction in the delay between chemotherapy courses.

Summary/Conclusions: Our experience shows that, even without the contribution of new drugs, more appropriate utilization of HSCT, tailored on early MRD assessment, MRD directed salvage therapy and posaconazole prophylaxis of IFI led to a relevant improvement of outcome.

E920

EFFECTIVENESS OF TREATMENT ACUTE MYELOID LEUKEMIA IN THE ELDERLY USING CLADRIBINE WITH LOW-DOSE ARAC

M. Wątek1,*, T. Gromek2, A. Pluta3, K. Budziszewska4, D. Majowicz2, E. Sierlecka1, M. Huz1, M. Pasierski1, G. Gozdziuk4, A. Wierzbowska3
1Department of Hematology, Holy Cross Oncology Center of Kielce, Kielce, 2Department of Haematoncology, Medical University of Lublin, Lublin, 3Department of Hematology, Medical University of Lodz, Lodz, 4Department of Hematology, Institute of Hematology and Transfusion Medicine, Warsaw, 5Holy Cross Oncology Center of Kielce, Kielce, Poland

Background: Treatment of acute myeloid leukemia(AML) in the elderly, unfit patients is a challenge for clinical hematologists. Therapeutic management in this patient group is different and numerous complications including early deaths. A standard treatment of low dose cytarabine (LD-AraC) or using hypomethylating therapy is not satisfying enough. Polish Adult Leukemia Group’s (PALG) studies showed, that addition of cladribine to daunorubicine and cytarabine increases the complete remission rate and improves overall survival in younger patients with AML. We also proved effectiveness of cladribine combined with high dose AraC and mitoxantrone in relapsed and refractory AML (1, 2). Cldaridine, enhances the concentration of Ara-CTP, an active metabolite of Ara-C in leukemic cells (3). Recent data indicate that cladribine has also hypomethylating properties.

Aims: The aim of our study was to evaluate the efficacy and toxicity of cladribine in combination with LD-AraC in older AML patients.

Methods: Patients with newly diagnosed AML (excluding APL), older than 60 years, unfit for standard induction chemotherapy, were enrolled to our study. The patients were given two cycles of cladribine 5mg/m² i.v. on days 1-5 and low-dose cytarabine 40mg/m² s.c. days 1-10 every 28 days followed by one cycle of cladribine 5mg/m² i.v. on days 1-2 with LD-AraC (40mg/m² s.c. 1-10 days). Responding patients were treated with a prolonged maintenance consisting of LD-AraC (40mg/m² 1-10 day). The treatment was continued until progression.

Results: Twenty-four patients have been enrolled with median age 70 years (range 62-84). In our cohort 20 patients had newly diagnosed AML, 3 secondary and 1 therapy related AML. Cytogenetic risk: good risk 5 patients, intermediate 12, poor risk 3 patients, 4 patients were unclassified. The overall response rate (CR+PR) was 84%. 13 out of 24 (54%) patients achieved complete remission (CR) and 7 (30%) achieved partial remission, no remission. Median number of cycles to obtain CR was 2 (range 1-3). 16% of patients do not responded to treatment. The regimen was well tolerated without 4-week and 8-week mortality. The main reason of death were: heart failure (n=2), renal failure (n=1) and progressive disease (n=4). We didn’t observe grade 3 and 4. nonhematologic adverse events. With a median time of follow-up 14 months, the median overall survival was 12 months.

Summary/Conclusions: The combination of cladribine plus low dose AraC is effective and well tolerated regimen in elderly AML patients unfit for standard chemotherapy.

E921

SMALL CUSTOMIZABLE NGS BASED TARGET CAPTURE PANELS DETECT VARIANTS IN CLINICAL SPECIMENS AT FREQUENCIES AS LOW AS 0.5%

L. Chamberlain1,*, A.R. Carson1, V. McClain1, B. Patay1, O. Kiya1, W. Huang1, D. Hubbard2, D. Caguioa2, Z. Xie1, J. Thornes2, T. Stenzel1, J.E. Miller1
1Invivoscribe, Inc., 2LabPMM, San Diego, United States

Background: The use of large scale hybridization panels in early stages of clinical trials for novel therapies elicits a plethora of information for targeted biomarkers. However, as therapeutic targets are further characterized large panels generate an overly broad set of data, compromising sensitivity in the selected biomarker subset. Therefore, once biomarker targets are identified, the use of smaller hybridization panels can facilitate specific variant detection by analyzing specific genomic regions of interest with greater sensitivity than larger gene panels and PCR-based assays. Modifications of laboratory methods for small scale panels allow for the maintenance of high analytic quality with finely targeted panels. Our small panels (~10kb) are focused on specific genomic regions of interest with greater sensitivity than larger gene panels and PCR-based assays. Modifications of laboratory methods for small scale panels allow for the maintenance of high analytic quality with finely targeted panels. Our small panels (~10kb) are focused on specific genomic regions of interest with greater sensitivity than larger gene panels and PCR-based assays.

Aims: To demonstrate the sensitivity, linearity, concordance with other assays, and clinical applications of small NGS target capture panels.

Methods: Two separate next generation sequencing-target capture assays were developed with bioinformatics software under ISO13485 design control. The panel contained 3 genes, including fms related tyrosine kinase 3 (FLT3); the second covers only CD274 (PD-L1). Libraries were made, hybridized with biotinylated oligonucleotides, and sequenced using the Illumina MiSeqDx. Validation was carried out by spiking in fixed amounts of mutant DNA into wild type DNA to establish the linearity and sensitivity of the assays. Sequencing libraries were generated by conventional methods with kits from both panels. Sequencing data was analyzed using proprietary software developed by Invivoscribe. Eight AML clinical samples were cross validated for FLT3 mutations by this small panel, amplicon based NGS assay, and capillary electrophoresis (CE) assay.
Results: DNA from 24 cell lines was assessed using both panels, confirming variants previously detected using other methods. A validation was run on the 3-gene panel using a series of control samples generated from cell lines containing between 0.5% and 25% variant allele frequencies for expected variants. Initial validation indicates that these small panel assays can detect mutations down to 0.5% variant allele frequencies. Assay linearity for FLT3/TKD detection from 0.25% to 12.5%, or for FLT3/TKD detection from 0.5% to 25% is excellent (R² = 0.996 and 0.998, respectively). Average sequencing coverage was high, ranging from 5,265x to 7,680x. Comparison of FLT3 analysis of the small panel to amplicon based NGS assay and CE, FLT3-ITD showed complete concordance in clinical samples and - showed a strong linear relationship between the targeted VAFs and detected ITD sizes. There was also complete concordance for FLT3/TKD mutations in clinical samples.

Summary/Conclusions: Small hybridization panels are cost effective in detecting low-frequency variants from smaller subsets of genes while using far less DNA than individual PCR-based biomarker assays would require. Additionally, preliminary data shows great accuracy on clinical samples. These smaller assays focus on the most pertinent genes for a targeted therapy, and have the potential to greatly assist in understanding the molecular background of responders, super-responders, and non-responders, information which can help improve patient outcomes. Developing these assays with bioinformatics using the international ISO13485 design control standards makes them suitable for regulatory approval worldwide.

MOLECULAR GENETIC TESTING PATTERNS FOR PATIENTS WITH NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA (AML) ENROLLED IN THE CONNECT® MDS/AML DISEASE REGISTRY

1University of Colorado Cancer Center, Aurora, 2University of New Mexico, Albuquerque, 3University of Alabama at Birmingham, Birmingham, 4Aurora Research Institute, Aurora Health Care, Milwaukee, 5Weill Cornell Medical College of New York, 6University of Florida Health Cancer Center–Orlando Health, Orlando, 7Swedish Cancer Institute, Seattle, 8New York Medical College, Valhalla, 9University of Florida, Gainesville, 10Celgene Corporation, Summit, United States

Background: Recurrent mutations in AML-associated genes have prognostic value and may help guide treatment decisions. Molecular genetic testing patterns for AML in clinical practice are largely unknown. Previous results of the CONNECT MDS/AML Disease Registry (George et al ASH 2016; abstract 354) showed suboptimal adherence to WHO 2008 recommendations for AML diagnosis in a cohort of patients with newly diagnosed AML in clinical practice. Aims: To report a detailed analysis of patterns of molecular genetic testing in patients with newly diagnosed AML in community and academic settings. Methods: The CONNECT MDS/AML Disease Registry (NCT01688801) is a US prospective, observational cohort study of patients with newly diagnosed AML (≥55 years) or myelodysplastic syndrome (MDS). All clinical decisions are made by the treating clinicians. Data are collected, using an electronic data capture system, at screening, enrollment, and approximately quarterly throughout the duration of the patient’s participation in the registry. All patients provided informed consent. Enrollment is ongoing. The current analysis evaluated the percentage of patients with AML who had undergone molecular genetic testing recommended by NCCN guidelines (NPM1, FLT3-ITD, CEBPA, IDH1, IDH2, DNMT3A, and KIT). Chi-square tests evaluated effects of several variables on likelihood of molecular genetic testing. Results: Between 12 Dec 2013 and 8 Dec 2016 (data cutoff), 259 patients with AML were enrolled at 86 sites. Molecular genetic testing was reported in 67% (173/259) of patients. Likelihood of testing varied, respectively, for academic vs community settings (76% [70/92] vs 62% [103/167], P = .018), normal vs abnormal NPM1 (77% [79/102] vs 59% [79/133], P < .005), age <65 vs ≥65 (83% [85/103] vs 50% [108/211]; P = .0003), and before vs after disease diagnosis (81% [83/103] vs 74% [90/122]; P = .025). In patients who had undergone molecular genetic testing (n=173), the mutations tested varied substantially. All of the NCCN-recommended molecular genetic tests were reported in 9% (15/173) of patients. Testing included 8% (6/77) with normal karyotype. Of the seven NCCN-recommended tests, NPM1 (77%) and FLT3-ITD (76%) were most often reported and DNMT3A least often (16%). Summary/Conclusions: Early data from the CONNECT MDS/AML Disease Registry reveal that despite molecular testing reported in 67% of patients with newly diagnosed AML, a majority of patients receive guideline-recommended testing. This prospective registry is uniquely positioned to capture changes in testing patterns as guidelines are established.

E924

PHASE 1, OPEN-LABEL, RANDOMIZED STUDY TO EVALUATE THE EFFECT OF CYTOCHROME P450 (CYP) 3A4 INHIBITION ON THE PHARMACOKINETICS (PK) AND SAFETY OF QUIZARTINIB (Q) AND ITS ACTIVE METABOLITE, AC886

J. Li1,*, M. Kankam2, D. Tromé3, G. Gammon3

1Daichi Sankyo, San Diego, CA, 2Vince & Associates, Overland Park, KA, formerly Daichi Sankyo, San Diego, CA, United States

Background: Q is a potent, selective FMS-like tyrosine kinase 3 (FLT3) inhibitor currently being investigated in Phase 3 studies in AML patients (pt) with FLT3 internal tandem duplication (ITD) mutations. Early studies showed concentration (c) and area under curve (AUC) increases of Q and its active metabolite, AC886, was a significant predictor of the QTc prolonging effect(Levis, et al. ASH 2016). Q and AC886 are both primarily metabolized by CYP3A4. Because CYP3A4 inhibiting drugs are frequently required in the...
course of AML treatment, a drug interaction study was performed to assess PK when Q is co-administered with CYP3A4 inhibitors. **Aims:** The primary aim was to determine the effect of ketoconazole (K), a strong CYP3A4 inhibitor, and fluconazole (F), a moderate CYP3A4 inhibitor, on PK of Q and AC886. The secondary aim was to assess the tolerability and safety of Q co-administered with K or F. **Methods:** This was an open-label, randomized, parallel-group study. Healthy subjects (HS) age 18–55 years (yr) who provided informed consent were randomized 1:1:1 to receive K 200mg twice daily (BID), F 200mg BID, or placebo (P) BID on Days (D) 1-28. A single 30mg dose of Q was administered to all HS on D8. Plasma Q and AC886 conc were measured D8-28, using a validated liquid chromatography-tandem mass spectrometry method. PK parameters were determined using noncompartmental analysis. Steady-state (SS) drug conc, following repeated once daily dosing, were predicted using non-parametric superposition. An analysis of variance (ANOVA) was performed to assess the CYP3A4 inhibitory effect of K and F on the PK.

**Results:** 93 HS were enrolled (31 per arm) and 89 received Q. 75% were male, median age 32 yr (18-53). Relative to Q+P, co-administration of Q+K or Q+F increased the geometric mean (GeoMean) C_{max} of Q by 17% and 11%, and GeoMean AUC_{D1-28} by 94% and 20%, respectively (Table 1 below). The GeoMean C_{max} and AUC_{D1-28} of AC886 were decreased by 60% and 15%, respectively, for Q+K, and were increased by 3% and 14%, respectively, for Q+F. Apparent clearance (CL/F) of Q was 50% lower and t_{1/2} of Q and AC886 were 46% and 96% longer, respectively in Q+K vs Q+P. CL/F of Q was 17% lower and t_{1/2} of Q and AC886 were 10% and 28% longer, respectively, in Q+F vs Q+P. AC886 is a minor component in circulating relative to Q (approximately 25%). An increase of 86% in simulated SS QS C_{max} and 96% in SS QS AUC_{D1-28} was predicted following repeat daily dosing of 30mg Q+K vs Q+F, while a modest decrease in AC886 exposure (<20%) was predicted. The most common (≥5%) adverse events were headache (7.5%) and diarrhea (5.4%), with the majority being Grade 1/2. There were no clinically significant hematology, clinical chemistry, QTc, or vital sign observations, and no deaths or serious adverse events.

**Summary/Conclusions:** Co-administration of Q with K or F was well tolerated and safe. Overall, there was an approximate 2-fold increase in Q exposure when Q was co-administered with K, which is considered clinically significant. The increase in Q exposure when Q was co-administered with F was within 20% and is not considered clinically relevant. Given the relationship between Q conc and Qtc prolongation, these results support reducing Q doses by approximately one-half when taken concomitantly with a strong CYP3A4 inhibitor. No dose reduction is needed when Q is co-administered with a moderate or weak CYP3A4 inhibitor. This approach has been implemented in two ongoing Phase 3 trials of Q in FLT3-ITD mutated AML.

**CLINICAL OUTCOMES OF CHILDHOOD ACUTE MEGAKARYOBLASTIC LEUKEMIA: THE CHILDREN CANCER HOSPITAL EGYPT 57375 EXPERIENCE**

N. Maarouf1,*, S. Mahmoud1,2, R. Abdelaziz1,2, L. Lehmann2, K. Shaaban4,5, S. Fahmy6,7, S. Ibrahim8,9, O. Hassanain10, N. Nader1, A. Elhaddad4,2

1Pediatric Oncology, 57357 CCHE, 2Pediatric Oncology, National Cancer Institute, Cairo, Egypt, 3Pediatric Stem Cell Transplant, Dana Farber Cancer Institute, Boston, United States, 4Department of Clinical Pathology CCHE, 57375 CCHE, 5Department of Clinical Pathology, National Cancer Institute, 6Department of Clinical Pathology, 7Department of Research CCHE, 57375 CCHE, Cairo, Egypt

**Background:** Acute megakaryoblastic leukemia is a rare subtype of pediatric AML occurring in both Down and non-Down syndrome patients. Down syndrome patients with M7 subtype have an excellent prognosis while non-Down syndrome patients have poor outcomes. Heterogenous cytogenetic abnormal-

ities have been described with M7 AML and the impact of different prognostic factors on outcomes is yet to be determined.

**Aims:** To evaluate the predictive significance of various cytogentic abnormalities and minimal residual disease (MRD) by flow cytometry after induction I and correlate them with clinical outcomes of patients with acute megakaryoblastic leukemia.

**Methods:** We retrospectively analyzed the data of 80 non-Down syndrome patients diagnosed with M7 AML treated at CCHE between January 2007 through December 2016. Three treatment protocols were used.

**Results:** The median age at diagnosis was 1.7 years (range 0.2-15). The median time to diagnosis was 1 month. The overall (OS), event free survival(EFS) and cumulative incidence of relapse at 2 years were 53.4%, 42.9% and 28.4% respectively. Sixty one patients had abnormal cytogenetic abnormalities including Trisomy 19 (n=20), 13q (n=3), Trisomy 8 (n=12), Complex karyotype (n=28), t(1;22) (n=12), MLL gene rearrangement (n=9), Trisomy 21 (n=24) but none of these had an impact on outcomes. Out of the 80 patients 56 were in complete remission post induction I. Two hundred patients had <0.1% after induction I. In the univariate analysis patients with MRD <0.1% post induction I had a better OS and EFS with a lower cumulative incidence of relapse however these findings did not reach a statistical significance.

**Summary/Conclusions:** Acute megakaryoblastic leukemia in non-Down syndrome patients have poor outcomes irrespective of any cytogenetic abnormalities. Future direction to determining tumor biology based on molecular pathways in this disease is being considered.

E927

**IDENTIFICATION OF RESISTANCE ASSOCIATED CPG METHYLATION CHANGES IN ACUTE MYELOID LEUKEMIA PATIENTS UNDERGOING INDUCTION CHEMOTHERAPY**

C. Niederwieser1,2, C. Rohde1, H. Serve2, W. Berdel3, G. Ehninger4, S. Gölliner1, L. Müller1, C. Müller-Tidow1

**Background:** Acute myeloid leukemia (AML) patients ineligible for intensive chemotherapy (IC) are considered current standard of care in this population.

**Aims:** To conduct an indirect treatment comparison (ITC) comparing OS for GLAS+LDAC vs AZA and DEC, respectively. Four studies met inclusion criteria: two studies comparing AZA to LDAC: Fenaux 2010; Dombret 2015; one study comparing DEC to LDAC: Kantarjian 2012, and one study comparing GLAS+LDAC to LDAC: Cortes 2016 (Table). Fenaux 2010 study was excluded due to population differences: baseline median bone marrow blasts at 23% in Fenaux vs 49% in Cortes 2016. The remaining AZA and DEC studies were generally comparable in patient baseline characteristics to the GLAS study: age and cytogenetic risk: age 75/73/76 years old, poor cytogenetic risk 34%/37%/39%, in AZA/DEC/ GLAS+LDAC, respectively. In the ITC, with LDAC as the common comparator, GLAS+LDAC compared favorably with indirect HR for OS vs AZA and DEC being 0.51 and 0.56, respectively, (Table 1).

Summary/Conclusions: Using ITC, treatment with GLAS+LDAC showed significantly better OS HR than AZA and DEC in previously untreated AML patients ineligible for treatment with IC. Limitations of current analysis include mixed IC & NIC population for the AZA trial, and mixed comparator arm of both LDAC and BSC for the DEC trial. Analyses using patient-level data matching baseline characteristics across studies may enable more robust ITC.
Background: Acute myeloid leukemia (AML) is a heterogeneous disease associated with epigenetic alterations that can be targeted with demethylating agents to induce CR in a subgroup of patients. However, there are currently no predictive markers that reliably distinguish responder from non-responders. In this analysis we assessed DNA methylation changes in a group of refractory patients with AML treated either with the hypomethylating agent azacytidine followed by intensive chemotherapy or with intensive chemotherapy alone in order to identify the alterations and genes involved.

Aims: The exploration of whole genome methylation changes of azacytidine and chemotherapy treatment in refractory patients with AML guides treatment refinement.

Methods: Patients from the AML-AZA trial of the Study Alliance Leukemia were randomized to receive either azacytidine followed by chemotherapy or chemotherapy alone. Cells were harvested at baseline and 15 days after chemotherapy from 16 of the 105 patients receiving the combination and from four of the 109 patients randomized to receive chemotherapy only. Genome wide DNA methylation was analysed using a 450K Illumina array (Illumina, San Diego, USA). Methylation changes were compared between the two treatment groups, with 153 days for chemotherapy and 143 days for azacytidine plus chemotherapy treatment.

Results: In the Azacytidine plus Chemotherapy treated group, a total of 389 differentially methylated regions (DMRs), most of which were single CpGs, were identified, 176 of which were hypermethylated and 213 hypomethylated. The most highly represented hypermethylated loci were INSPI1 (p=1e-17, 6.25% of 176 DMRs), KLF13 (p=1e-14, 7.95%), HIC2 (p=1e-11, 5.11%), while those that were hypomethylated were ARID3A (p=1e-15, 2.82% of 213 DMR’s), MYB (p=1e-14, 3.76%) and STAT1 (p=1e-14, 1.88%). The chemotherapy alone group yielded 7181 DMRs, 5752 of which were hypermethylated and 1429 hypomethylated. The genes most commonly hypermethylated in these patients were EHF (ETS) (p=1e-226, 32.79% of 5752), CEBPE (p=1e-90, 10.34%), and Jun-APII (p=1e-45, 6.10%), while those most commonly hypomethylated were RUNX1 (p=1e-24, 28.34% of 1429 DMRs), TCF4 (p=1e-21, 8.40%) and SMAD3 (p=1e-17, 1.05%). Median overall survival did not differ between the two treatment groups, with 153 days for chemotherapy and 143 days for azacytidine chemotherapy treatment.

Summary/Conclusions: Methylation changes associated with azacytidine and chemotherapy of refractory patients were particularly found in genes previously associated with cancer and AML. DNA hypermethylation was more common after chemotherapy alone. This finding suggests that DNA hypermethylation of specific loci may be associated with therapy resistance. Hence, the methylation profiles were detected from the most resistant cells. Of note, upon Azacytidine treatment more hypomethylated loci were observed. This potentially indicates DNA hypomethylation in vivo.
consolidation cycles, the median days to neutrophil recovery was 26 days (range 18-72), platelet recovery 32 days (range 17-75), and the ICU admission rate was 12.8% (range 2-10 days). 18 patients (62.1%) receiving IDAC+2 consolidation suffered disease relapse. For patients receiving IDAC+2 consolidation the median OS was 727 days (range 113-1614 days) with an EFS of 388 days (range 109-1614 days). For patients aged 60-65 years the remission rate and survival outcomes were similar to those published by Lowenberg et al.

Summary/Conclusions: Anthracycline intensification was well tolerated with low treatment related mortality and rates of ICU admission along with acceptable time to count recovery. In patients aged 60-65 outcomes were similar to published data with high-dose daunorubicin. Despite this intensive post-remission therapy approach rates of disease relapse were high highlighting the need for novel therapeutic approaches in this patient group.

E931 DECITABINE COMBINED WITH HAAG REGIMEN IS AN EFFECTIVE SALVAGE TREATMENT FOR ADVANCED ACUTE MYELOID LEUKEMIA

Aims: To evaluate the clinical efficacy and safety of decitabine (DAC) in combination with HAAG regimen ([hydroxarabinone (HKT), cytarabine (Ara-C), doxorubicin (Acla) and recombinant human granulocyte colony stimulating factor (G-CSF)]) for advanced patients with AML.

Methods: Forty-six patients with advanced AML receiving DAC combined with HAAG chemotherapy in our center from December 2012 to August 2015 were enrolled in this study. Of the 46 patients, 18 were refractory or relapsed AML, and another 18 patients were those who didn’t achieve CR after a course of induction chemotherapy. The therapeutic responses, side effects and long-time survival were retrospectively analyzed.

Results: After a course of treatment, the rate of CR and partial response (PR) was 58.3% (21/36) and 22.2% (8/36) respectively, while the overall response rate (ORR) was 80.6% (29/36) in the cohort. For the patients with refractory or relapse AML, CR was 61.0% (11/18), PR was 22.2% (4/18), and ORR was 83.3% (15/18). While for the other not getting CR after a course of induction chemotherapy, CR was 55.6% (10/18), PR was 22.2% (4/18), and ORR was 77.8% (14/18). Grade 4 hematological toxicities were observed in all patients, and 72.2% cases experienced infection. And all non hematological side effects were mild and well-tolerated. With a median follow-up of 7.5 (0.5-33.3) months, the 1-year overall survival (OS) rate was 43.3%, 24.2% for the refractory or relapsed AML patients, and 61.6% for those not achieving CR after a course of induction chemotherapy. The difference was significantly (P<0.01).

Summary/Conclusions: DAC combined with HAAG regimen is safe and effective salvage treatment for advanced stage AML patients.
Markers. Results were given overall and stratified by age (<60/≥60 years) and sex. Kaplan-Meier curves and Cox regression (Hazard ratios; HRs) was used to compare survival by cohabitation (living with someone, living alone) and marital status (married, divorced, widowed, unmarried).

Results: The study included 3243 AML patients. Patients living with someone (>2056) were younger, more likely to be married, male, to be working, and to have a higher education than patients living alone. Comorbidity, white blood cell count, lactate dehydrogenase, and blast counts did not differ between groups, however patients living with someone tended to have better performance status at time of diagnosis. Patients living with someone were more likely to receive intensive chemotherapy than patients living alone when aged 60 years or older (41.2% vs 22.8%, adjusted OR 0.81 (CI=0.46-0.81)). In patients <60 years, never-married patients were less likely to receive intensive therapy (adjusted OR 0.43 (CI=0.19-0.99)) than married patients. In patients <70 years achieving CR, the chance of allogHCT was reduced when living alone (11.8%, adjusted OR 0.47 (CI=0.28-0.78), versus 19.0% in patients living with someone). In both groups, the chance was also reduced (7.6% adjusted OR 0.38 (CI=0.20-0.74)) compared to married patients (19.3%). Crude survival by cohabitation is shown in Figure 1. Overall survival was inferior in patients ≥60 years living alone (adjusted HR 1.21 (CI=1.09-1.33)) and unmarried patients (never-married: adjusted HR 1.29 (CI=1.08-1.57), divorced/widowed: adjusted HR 1.11 (CI=1.00-1.23)) compared to married patients. In contrast, cohabitation and marital status did not affect treatment response (living with someone: CR 70.6%, living alone: CR 72.8%) or overall survival (adjusted HR 1.08 (CI=0.81-1.23)) in intensive therapy patients only.

Summary/Conclusions: Our study results indicate that the effect of cohabitation and marital status on AML outcome, especially in patients ≥60 years, is explained by social support rather than by differences in income and occupation. Patients living alone do not present with more advanced disease or higher comorbidity burden than patients living with someone. Still, patients living alone and never-married patients are less likely to receive intensive chemotherapy affected overall survival. Increased focus on what drives treatment decisions in patients lacking social support is important to improve survival in these patients.

E933
TREATMENT OF MOLECULAR RELAPSE IN ACUTE MYELOID LEUKEMIA WITH NOTED NPM1 REDUCES TOXICITY OF SALVAGE TREATMENT AND IMPROVES DISEASE CLEARANCE
F. Guolo1,2, P. Minetone1, M. Clavio1, D. Guarro3, E. Coviello1, N. Colombo1, F. Ballerini1, M. Miglino1, R.M. Lemoli1, M. Gobb1
1Clinic of Hematology, Department of Internal Medicine (DIMI), University of Genoa, IRCCS AOI San Martino-IST, Genova, Italy

Background: Acute Myeloid Leukemia with mutated NPM1 (NPM-AML) is characterized by a favorable prognosis. Most patients achieve hematological complete remission (CR) and are not considered eligible for an early allogeneic stem cell transplantation (SCT). The importance of minimal residual disease (MRD) monitoring in NPM-AML is well recognized but no data are currently available on MRD-directed therapy in this AML subset. Since 2004 we have prospectively evaluated NPM1 MRD at precise time points to evaluate response to therapy and predict the risk of hematological relapse (HR).

Aims: The aim of this study was to set a standardized operating definition of molecular relapse and to evaluate the efficacy and feasibility of MRD-directed salvage therapy.

Methods: From January 2004 to January 2014, 36 consecutive younger intensively treated patients with NPM-AML achieving CR were included in the study. MRD assessment was performed on bone marrow (BM) samples after 1st and 2nd induction cycle, after each of the three consolidation cycles and then every three months for five years. If MRD positivity was found, a new analysis was was 15 days. NPM1 mutation was measured on BM samples using MutaQuant® kit (Ipsogen® from Qiagen. All Real-Time PCR were performed on DN Analyser Option 3.3. Until 2014 our policy included the treatment in hematological relapse (HR). Salvage chemotherapy consisted in two MEC cycles and then patients proceeded to HSCT, if feasible. From January 2015 we decided to use a pre-emptive strategy, treating the molecular relapse. Four consecutive NPM-AML patients who showed MRD relapse received MRD-directed salvage therapy (MEC) which consisted of one cycle of MEC. Five more pts and MRD positivity was detected in 3 pts (0.033%, 0.523 and 3.9%) with intermediate cytogenetic risk. By the end of 4th course 11 pts stayed in CR and we diagnosed 1 morphological relapse (patient with MRD-negativity and CMR after 2nd ChT). Two early relapses were also traced: both with persistent MRD during all period of CR and CMR after the second ChT. All pts with MRD-negative status after first course are alive and in CMR (8 months from diagnosis). While monitoring, LAIP changes were distinguished in 7 pts. One from two with resistant AML lost CD65, another one acquired CD11b. 5 pts were in CR at the second course and during ChT one of them gained CD56 and CD13, 2nd lost CD65 and CD11b, 3rd – gained CD65, 4th gained CD11b after 2nd ChT, the last one didn’t change LAIP. We detected relapse in 3 pts from this group and one – with increasing MRD after 4th course and cytopenic syndrome. We may suggest that LAIP changes during ChT reflect selection of more chemoresistant leukemia clone, followed by subsequent relapse.

Summary/Conclusions: 1. The most favorable group of patients consisted of MRD negative pts after 1st course. LAIP changes are common in pts with less favorable prognosis.

E934
MINIMAL RESIDUAL DISEASE AND LAIP CHANGES BY FLOW CYTOMETRY IN DE NOVO ACUTE MYELOID LEUKEMIA DURING CHEMOTHERAPY AND CLINICAL OUTCOMES
T. Lobanova1,2, I. Galtseva1, Y. Davydova1, N. Kapranov1, V. Troitskaya1, E. Parovichnikova1
1Hematological Oncology and BMT, National Research Center for Hematology, Moscow, Russian Federation

Background: Minimal residual disease (MRD) detection by multicolor flow cytometry (MFC) in acute myeloid leukemia (AML) is widely explored by different researchers and it is an additional independent factor in clinical outcomes. The prognostic value of leukemia associated immunophenotype (LAIP) changes in not explored enough.

Aims: To investigate the amount and clearance of MRD reduction and LAIP changes in de novo AML during chemotherapy and compare the results with clinical outcomes.

Methods: In the clinical prospective study since March 2016 till February 2017 50 patients (pts) of de novo AML (median age 44 (17-85)) were included. 14 pts by this moment completed basic chemotherapy (ChT) courses: <7+3 2 induction and 2 consolidation. Among them favorable cytogenetics was in 4pts (t(16,21)-1, 16q22-1, t(8,21)-2pts), intermediate-7 (6-with normal karyotype, 1-t(17,22)), poor-3 (complex karyotype-2, 11q23-1pt). Bone marrow samples were studied in standardized panel with most common antibodies by 6-color MFC (BD FACSCanto II, USA) before the treatment, after 1st and 2nd courses of induction and after 2nd consolidation. Any amount of MRD >0 was assumed as MRD positivity. Besides MRD status we also explored LAIP changes in patients with CR after 2nd ChT and drug resistant MRD 5 pts.

Results: Leukemia associated immunophenotype (LAIP) was detected in all monitored patients at the diagnosis. Molecular markers were detected in 28,5% (2pts-with NPM1+FLT3+CEBPA+, 1-with FLT3+, 1-NPM1+). 2 pts had resistant AML after 2 courses (CR). 3 pts out of 7 with complete morphological remission (CMR) after 1st course had MRD positivity (0.03%, 1.61%, 8.3%) and these pts became MRD-negative after 2nd course. CMR was achieved after 2nd course in 5 more pts and MRD positivity was detected in 3 pts (0.033%, 0.523 and 5.39%) with intermediate cytogenetic risk. By the end of 4th course 11 pts stayed in CR and we diagnosed 1 morphological relapse (patient with MRD-negativity and CMR after 2nd ChT). Two early relapses were also traced: both with persistent MRD during all period of CR and CMR after the second ChT. All pts with MRD-negative status after first course are alive and in CMR (8 months from diagnosis). While monitoring, LAIP changes were distinguished in 7 pts. One from two with resistant AML lost CD65, another one acquired CD11b. 5 pts were in CR at the second course and during ChT one of them gained CD56 and CD13, 2nd lost CD65 and CD11b, 3rd – gained CD65, 4th gained CD11b after 2nd ChT, the last one didn’t change LAIP. We detected relapse in 3 pts from this group and one – with increasing MRD after 4th course and cytopenic syndrome. We may suggest that LAIP changes during ChT reflect selection of more chemoresistant leukemia clone, followed by subsequent relapse.

Summary/Conclusions: 1. The most favorable group of patients consisted of MRD negative pts after 1st course. LAIP changes are common in pts with less favorable prognosis.

E935
LENALOMIDE MAINTENANCE IN PATIENTS WITH HIGH RISK ACUTE MYELOID LEUKEMIA
T. Kadia1,2, J. Cortes1, F. Ravandi1, N. Daver3, E. Jabbour1, A. Ferrajoli1, N. Pemmaraju1, K. Naqvi1, S. Pelletier1, M. Brandt1, Z. Estrov2, H. Kantarjian1
1Leukemia, MD Anderson Cancer Center, Houston, United States

The aim of this study was to set a standardized operative definition of Minimal residual disease (MRD) monitoring in NPM-AML is well recognized but no data are currently available on MRD-directed therapy in this AML subset. Since 2004 we have prospectively evaluated NPM1 MRD at precise time points to evaluate response to therapy and predict the risk of hematological relapse (HR).
Background: New drug combinations and higher intensity therapy have led to significant improvements in complete remission (CR) rates for patients with acute myeloid leukemia (AML). However, relapsed disease remains a major source of failure. With the exception of allogeneic stem cell transplant (SCT), there are few options for post-consolidation maintenance of remission in high-risk patients. NK cells as part of the immune microenvironment are important mediators of immune surveillance in AML. Lenalidomide has demonstrated single-agent activity in AML and enhances NK cell activity and immune synapse formation in leukemia.

Aims: We designed a phase II clinical trial studying the efficacy of lenalidomide as maintenance therapy in AML patients with high-risk disease in remission, who were not being considered for SCT.

Methods: AML patients ≥18 years with a high-risk feature in 1st CR (CR1) or any patient in 2nd CR (CR2) who had received induction and at least 1 consolidation cycle were eligible for enrollment. Patients should be within 12 months of achieving CR, have PS ≤3, adequate kidney/liver function, ANC >0.5 and platelets ≥30. Patients were treated continuously with lenalidomide 10mg PO daily on D1-28 of a 28 day cycle up to 24 cycles. All pts had baseline cytogenetic and molecular testing, and minimal residual disease (MRD) assessment by flow cytometry. After cycle 1, stepwise dose escalations were allowed to 20mg daily in pts who were tolerating their dose and have presence of minimal residual or morphologically detectable disease.

Results: A total of 14 patients have been enrolled with a median age of 57.5 years (range, 23-67). All pts were in CR at the time of enrollment, with 12 pts (86%) in CR1 and 2 (14%) in CR2. Baseline pt characteristics are outlined in Table 1. AML-related mutations detected at start of therapy include: CEBPA (n=5), NPM1 (3), FLT3 (3), IDH2 (2), NRAS (2), DNMT3a (2), and 1 each of JAK2, TET2, and EZH2. High risk features at the time of enrollment were as follows (some are overlapping): S (36%) with history of prior myeloid neoplasm or therapy related AML, 4 (29%) persistent MRD, 4 (29%) adverse mutational profile, 2 (14%) adverse karyotype, 1 (7%) primary refractory disease, and 2 (14%) CR2 status. Patients have received a median of 9 cycles (1-24) cycles of therapy. With a median followup of 19+ months (8.5-39), the 6- and 12-month estimated RFS were 100% and 89%, respectively. The 6- and 12-month estimated OS were 100% and 90%, respectively (Figure 1). The regimen was well tolerated. Cytopenias were mild and managed with dose adjustments. The most common grade 3 (no grade 4 toxicity) non-heme toxicities were 1 each of rash, fatigue, cough, and nausea, vomiting, and stroke.

Summary/Conclusions: Lenalidomide is a safe and feasible maintenance strategy in high-risk AML patients who are not candidates for SCT. The study continues to surpass the pre-specified expected rate of relapse-free survival of high-risk patients based on a historical cohort. Studies evaluating dynamics of MRD on study are ongoing.

E936 POSTREMISSION THERAPY FOR AML WITH INTERMEDIATE RISK CYTOGENETICS IN FIRST COMPLETE REMISSION

J. Vydra1,*, C. Šálek1, J. Schwarz1, P. Cetkovský1, P. Žák2, J. Novák3, 4

Aims: We analyzed retrospectively data from patients with AML with intermediate risk cytogenetics in CR1 with the aim to determine rates of completion of postremission therapy, rates and risk factors for early relapse and non relapse mortality (NRM), overall survival (OS) and relapse free survival (RFS) according to postremission treatment and describe causes of and risk factors for treatment failure.

Methods: Data on 304 patients in CR1 treated with curative intent between 2007 and 2016 in four centers participating in Czech Leukemia Study Group for Life were analyzed. All patients signed informed consent with data collection, analysis and publication. Cox regression was used to determine risk factors for OS and RFS, using time dependent covariates for postremission therapy. Age, WBC count, number of induction cycles, NPM1 mutation, FLT3/ITD, performance status, BMI, previous malignancy and extramedullary disease were included in models. Postremission therapy was completed after HCT or after three cycles of HAD without HCT in patients ≤60 years. Competing risk cumulative incidence estimates were calculated for NRM and relapse. Early relapse and NRM were defined as relapse/NRM before completion of postremission therapy.

Results: Median age was 52 (18-74) years. Median follow up time was 481 (31-3364) days. Early relapse rate (RR) and NRM were 11.01% and 5.29%, respectively. Median OS after early relapse was only 128 days. Presence of FLT3/ITD mutation and high body mass index were associated with increased risk of early relapse on multivariate analysis (HR 14.88, 95%CI 3.24-68.43 and 2.34, 95%CI 1.3-4.2, respectively). Age increased risk of early NRM (HR 5.13, 95%CI 1.5-17.58 for age 55-35 years). 76% of patients completed therapy: 42% received allogeneic HCT in CR1, 21% completed three cycles of HIDAC and 13% completed two cycles of IDAC. 3-year OS and RFS of the whole cohort were 53.68% and 40.26%, respectively. OS was 67% in a group of patients who completed HCT, 34% in IDAC group and 64% in HCT group (p=0.28469). Cumulative incidence of NRM and RR 3 years after completion of therapy was 23% and 20% after HCT, 7.13% and 51% after HIDAC and 16.8% and 66.4% after IDAC, respectively, differences among groups were significant (p=0.00947 and p<0.00001). HCT reduced the risk of relapse in comparison to chemotherapy (HR 0.51, 95%CI 0.3-0.85). RFS was adversely influenced by concomitant FLT3 ITD/NPM1 mutation (HR 2.17, 95%CI 1.06-4.43). Increasing age had negative effect on OS (HR 1.65, 95%CI 1.13-2.42 for age 55:35 years). After HCT, HLA mismatch and TBI based myeloablative conditioning were associated with increased NRM [HR 6.32 (95%CI 1.89-21.14) and 6 (95%CI 1.88-19.2), respectively] in comparison to transplantation from HLA matched donors and busulphan based myeloablative conditioning.

Summary/Conclusions: The majority of patients within intermediate cytogenetic group in our analysis received allogeneic HCT. Patients who relapsed before completion of treatment had dismal outcome with very short OS. Allogeneic HCT decreased risk of relapse but led to increased NRM, reducing positive effect of HCT on OS. Risk of NRM was increased after TBI based myeloablative conditioning and after HCT in mismatched unrelated donors.

LONG TERM FOLLOW UP OF PATIENTS OVER 60 YEARS TREATED WITH INTENSIVE CHEMOTHERAPY FOR ACUTE MYELOID LEUKAEMIA AND MYELODYSPLASTIC SYNDROMES

Background: More and more data on patients over the age of 60 years treated with intensive chemotherapy are emerging, however, long term data with patient outcomes after the initial 2-5 years are lacking. In 2007, we published a single center study on patients over the age of 60 years, suffering from acute myeloid leukaemia (AML) or high risk myelodysplastic syndrome (MDS), treated with intensive chemotherapy (Knipp et al. Cancer 2007, 110:345-52). We now present long term follow up data of these patients, the first patient being treated in 1991, meaning 26 years of follow up.

Aims: To characterize the longterm outcome of elderly AML and high risk MDS patients treated with intensive chemotherapy after the usual 2-5 year follow up period.

Methods: We treated 160 patients aged 60 years or more suffering from high risk MDS and AML with intensive chemotherapy regimen between 1991 and 2004. None of the patients underwent allogeneic stem cell transplantation afterwards. We now perform a follow up of the surviving patients 10 years after publication of the initial study.

Results: In the initial study median survival from the start of induction therapy was 9.5 months (10 days to 157 months), with the median survival from diagnosis of 14 months (1 day to 157 months). At publication of the study in the year 2007, 20 patients were still alive, 18 of them presented with a low risk karyotype. 13 of these patients were in complete remission and 7 patients had relapsed. Since then 11 of the 13 patients who were in CR relapsed and died of their leukaemia. One patient died of other causes and only one patient is still alive and well, currently at the age of 84. This patient initially presented with a normal karyotype, too. As a result the rate of long term survivors 5 years after treatment is 5.6% only.

Summary/Conclusions: Long term follow up data of elderly patients treated for AML and MDS with intensive chemotherapy is scarce. Our data show, that induction chemotherapy not followed by allogeneic stem cell transplantation does not result in a meaningful improvement of outcome. In addition, morbidity and lack of quality of life has to be taken into account. More data and studies on this subject are urgently needed in an aging population. In our population of 160 treated patients, 158 died of their leukaemia, only one patient died of another cause and only one single patient is still alive and well over a decade later.

A MULTICENTER, RETROSPECTIVE ANALYSIS OF ELDERLY PATIENTS WITH ACUTE MYELOID LEUKAEMIA WHO WERE TREATED WITH DECITABINE

J.H. Yi1,*, S. Park2, J.H. Kim3, Y.-W. Won4, D.H. Lim5, B.R. Han6, J. Uhm7, H.S. Kim8, C.W. Jung9, J. Jang9
1Hematology-Oncology, Chung-Ang university Hospital, 2Hematology-Oncology, Samsung Medical Center, Sungkyunkwan University School of Medicine, 3Hematology-Oncology, Kangnam Sacred-Heart Hospital, Hallym University Medical Center, Seoul, 4Hematology-Oncology, Hanyang University Gun Hospital, 5Hematology-Oncology, Kyungpook National University College of Medicine, Cheonan, 6Hematology-Oncology, Hallym University Medical Center, Hallym University College of Medicine, Anyang, 7Hematology-Oncology, Hanyang University College of Medicine, Seoul, 8Hematology-Oncology, YHS Medical Center, Seoul, Korea, Republic Of

Background: While acute myeloid leukaemia (AML) is the disease of the elderly, treatment options has been limited for elderly patients. Decitabine is widely accepted as the treatment options for them. However, the efficacy has yet been evaluated in Asian population where difference of clinical manifestation or cytogenetics had been noted.

Aims: In the current study, we conducted a multicenter, retrospective analysis on elderly AML patients from 8 tertiary institutes in Korea who were treated with decitabine in order to confirm whether the clinical outcomes of this agent are also acceptable in this population, and to provide further understanding of the disease nature of AML arisen in elderly patients.

Methods: Patients diagnosed with AML from 2013 to 2016 were included in the analysis. The inclusion criteria were as follows: (1) 65 or older patients with newly diagnosed, histologically confirmed AML (myeloid blast ≥20% either in the bone marrow or peripheral blood); (2) Treated with decitabine in a schedule of 20mg/m2 for five days every 4 weeks in patients. The primary end-point of the study was OS. We compared our data to the data from another Korean retrospective analysis, in which elderly patients with AML who were treated with decitabine in order to confirm whether the clinical outcomes of this agent are also acceptable in this population, and to provide further understanding of the disease nature of AML arisen in elderly patients.

Results: A total of 80 patients were eligible for the analysis. The median age of patients was 74 years (range, 64 to 86 years) and 49 patients (61.3%) were male. Regarding the risk group, 6 (7.5%), 49 (61.2%), and 25 (31.3%) cases were classified as favorable, intermediate, and poor risk group, respectively. The patients had received median 3 (range 1-27) cycles of treatment and the median OS for all patients was 10.2 months. The median OS durations according to the cytogenetic risk group are as follows; 12.4 months (95% CI 11.4-13.4) for favorable risk group (N=6), 13.6 months (95% CI 8.7-18.5) for intermediate risk group (N=49), and 5.5 months (95% CI 1.4-9.6) for poor risk group (N=25) (p<0.01). And when we categorized our cohort into two groups, that is ECOG-PS 0-2 vs. ECOG-PS 3 & 4, those with good performance status demonstrated improved survival (11.5 months (95% CI 6.6-16.4) vs 4.4 months (95% CI 2.4-6.4), p=0.04). The OS curves according to prognostic factors are provided in figure 1. Next, we compared our data to another Korean retrospective analysis dealing with elderly AML patients who were treated with either best supportive care or intensive treatment. Although our analysis shows that more and more patients with poor performance status and elderly patients, it seems that outcomes of decitabine treatment are fairly better than that of best supportive care (OS 3 months) and comparable to intensive chemotherapy (12.1 months).
DRUG-DRUG INTERACTION POTENTIAL OF GILBERTINIB IN HEALTHY SUBJECTS AND PATIENTS WITH RELAPSED/REFRACTORY ACUTE MYELOID LEUKEMIA

Aims: To evaluate drug-drug interaction potential with gilteritinib in healthy subjects and patients with relapsed/refractory (R/R) AML.

Methods: The effects of CYP3A4 inhibitors (itraconazole [ITZ] and fluconazole [FLZ]), as well as a CYP3A4 inducer (rifampin [RIF]), on the gilteritinib pharmacokinetic (PK) profile were assessed in an open-label, parallel-group study conducted in 81 healthy subjects. Gilteritinib was administered as a single dose alone on Day 6, or in combination with 200mg ITZ administered twice daily on Day 1 and once daily on Days 2–28, or in combination with once daily 400mg FLZ on Day 1 and 200mg FLZ on Days 2–28. When given concomitantly with ITZ or FLZ, gilteritinib was administered on Day 6. In an additional cohort, RIF 600mg was administered on Days 1–21 and gilteritinib was administered as a single 20-mg dose on Day 8. Additionally, the potential inhibitory effects of gilteritinib on the PK profile of a CYP3A4 substrate (midazolam) was assessed in a cohort of patients with R/R AML (n=9) in the Phase 1/2 CHRYSALIS study (NCT02014458). Patients received oral gilteritinib (300mg/d) and single oral midazolam (2mg) doses. Gilteritinib was administered on Cycle 1 Day 1 and continued once daily in 28-day cycles; midazolam was administered on Day-1 and Cycle 1 Day 15. Furthermore, in patients with R/R AML, gilteritinib trough concentration data for patients on strong (eg, voriconazole or posaconazole) or moderate (eg, FLZ) CYP3A4 inhibitors were compared with those for patients not using CYP3A4 inhibitors.

Results: In healthy subjects, gilteritinib exposure (expressed as Cmax and AUC24) was higher (2.2-fold increase) in subjects who were coadministered gilteritinib with a strong CYP3A4 inhibitor (ITZ) than in subjects who were administered gilteritinib alone. Coadministration of gilteritinib with RIF, a strong CYP3A4 inducer, resulted in an approximate 70% decrease in gilteritinib exposure in healthy adult subjects (Figure 1). In patients with R/R AML, midazolam exposure was approximately 10% higher when administered with gilteritinib compared to midazolam alone as reflected by the geometric mean ratio and 90% confidence intervals of midazolam Cmax (111.64%; 69.54%–179.25%) and AUC24 (109.46%; 49.82%–240.48%). Additionally, a <2-fold increase in gilteritinib exposure was observed in patients who were taking concomitant medications that were moderate or strong CYP3A4 inhibitors relative to patients who did not use a CYP3A4 inhibitor. The increased exposure in these patients, however, did not translate to differences in the incidence of drug-related safety events when compared across groups.

Summary/Conclusions: These data suggest limiting concomitant use of strong CYP3A4 inhibitors with gilteritinib. Furthermore, these data suggest coadministration of CYP3A substrates with gilteritinib is unrestricted. A comprehensive review of safety data in patients with R/R AML did not suggest that dose adjustment is warranted when gilteritinib is coadministered with strong CYP3A inhibitors. Although concomitant use of gilteritinib with strong CYP3A inhibitors (eg, ITZ or FLZ) may be permissible, precaution is warranted.

E941

A FLUDARABINE-BASED ACUTE MYELOID LEUKEMIA INDUCTION IS WELL TOLERATED UP TO 75Y OF AGE ALLOWS EARLY CONSOLIDATION AND LONG TERM SURVIVAL. A SINGLE CENTRE EXPERIENCE OF 136 CONSECUTIVE PATIENTS

E. Zappone1, L. Aprile1, M. Defina1, G. Papini1, V. Candì1, G. Bartalucci1, C. Zuanelli Brambilla1, S. Ciofini1, M. Bocchial1

Background: For decades no effective new drugs or better anthracyclin cytara-bin combinations other than the standard 3 + 7 regimen have been available for AML induction treatment. Fludarabine-based regimens have shown good efficacy in relapsed patients but raised concern about toxicity in the induction setting. Several regimens other than the standard 3 + 7 regimen have shown better tolerance and good results in patients younger than 60 years (ys) (Guolo AJH 2016, PMID 27084986).

Aims: We report a single center, real life experience of unselected 136 consecutive AML patients treated since 2002 in our center with Fludarabine, Aracytin, Idarubicin plus or without Etoposide: FLAIE up to 65 ys or FLAI up to 75ys.

Methods: Patients were treated with the FLAIE or FLAI regimen followed by Idarubicin plus Aracytin as 2 step induction. Exclusion criteria for treatment were: acute promyelocytic leukemia, poor performance status and severe comorbidity. Post remission treatment included up to three cycles of high dose AraC and autologous (Auto) or allogeneic (Allo) stem cell transplantation according to cytogenetic and molecular risk stratification (CMR, Döhner Blood 2010 PMID 19880497) aiming for a curative strategy for all our AML patients.

Results: Median age at diagnosis was 55ys (18-75ys), median follow up was 18 months (range 3–172 months), 75% of patients (102/136) had de novo AML, with 25% (34/136) had secondary AML mostly from myelodysplastic syndrome. 19% of patients (26/136) had good CMR risk disease, 45% of patients (61/136) had intermediate risk and 36% of patients (50/136) had high risk disease. Complete remission (CR) rate was 68% and was comparable to the majority of pubi-
lished trial data, considering the proportion of high CMR risk (36%) and leukemia of secondary origin (25%) and the relatively high median age: 36% of patients (49/136) were above the 60ys old age limit of most AML protocols. In multivariate analysis CR rate was significantly affected by age below 50ys: p=0,011; good/intermediate CMR risk: p=0,011 and de novo AML: p=0,008. The induction death rate was 4% in line or slightly lower than published results, showing that the tratamiento was well tolerated. However, survival for low SOX4 expression and high SOX4 expression was 26 months and factors significantly affecting OS were age below 50ys p<0,0001; good/intermediate CMR risk p=0,0002; intensive consolidation with Allo or Auto transplant p=0,0001 compared to chemotherapy alone. The mean probability of Leukemia free survival (LFS) was 88 months (median not reached). Patients above 50ys had significantly lower karyotype profile and NPM1/FLT3-ITD status compared to patients with intermediate-risk cytogenetics, (P=0,001 and P=0,005 respectively), or even in those with normal karyotype profile (P=0,022 and P=0,111, respectively). In multivariate analysis, high SOX4 expression was found to be an independent poor prognostic factor of OS (RR 2.091, 95% CI 1.051-4.168, p=0.034) irrespective of age, WBC count at diagnosis, karyotype profile and NPM1/FLT3-ITD status. Our results also reveal that SOX4 is an independent prognostic factor of AML. In conclusion, we reveal that BM SOX4 expression could serve as an informative new biomarker for the clinical prognosis of AML patients.

**Summary/Conclusions:** In the current study, we found that AML patients with low BM SOX4 expression had higher remission rates and longer overall survival than those with high SOX4 expression, regardless of age, WBC count at diagnosis, karyotype profile and NPM1/FLT3-ITD status. Our results also reveal that SOX4 is an independent prognostic factor of AML. In conclusion, we reveal that BM SOX4 expression could serve as an informative new biomarker for the clinical prognosis of AML patients.

**OVEREXPRESSION OF SOX4 CORRELATED WITH POOR PROGNOSIS OF ACUTE MYELOID LEUKAEMIA**

C.-Y. Hu1,2, H.-A. Hou2, C.-Y. Chen2, H.-F. Tien2, L.-I. Lin1, L.-I. Lin1

1Clinical Laboratory Sciences And Medical Biotechnology, National Taiwan University, 2Department of Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan, Republic of China

**Background:** The SOX4 belongs to the SOX (Sry-related high-mobility group box) family and has been characterized as a transcription factor. Over the past decade, multiple functions of SOX4 have been unveiled, and the protein is now known to play important roles in embryonic development, cell fate decision, and cellular differentiation. Overexpression and amplification of SOX4 have been implicated in various cancers and are correlated with poor prognosis. In mouse models, previous studies demonstrated that the upregulation of SOX4 can be induced by and then cooperate with the aberrant expression of AML-1-ETO, NUP98-DDX10, and PML-RARα; the overexpression of HOXA9, CREB, and Evi1, and the haplosufficiency of PU.1 to trigger leukemogenesis. Furthermore, a previous study that employed retroviral transduction of SOX4 and bone marrow transplantation techniques revealed that increased SOX4 expression may cooperate with the derepression of Mef2c expression to induce myeloid leukemia in recipient mice. Sox4 gene was also reported to be as a direct target of C/EBPα. C/EBPα is known to inhibit the self-renewal of leukemic cells and to restore cellular differentiation. The overexpression of SOX4 that results from C/EBPα inactivation contributes to the development of a type of leukemia that is characterized by a distinct leukemia-initiating cell (LIC) phenotype. This work further indicated that SOX4 is a key oncogenic target and critical mediator of C/EBPα mutants in acute myeloid leukemia (AML), which suggests a potential novel therapeutic approach to the treatment of this disease. However, the clinical implications of SOX4 expression and its role of AML leukemogenesis are not well understood.

**Aims:** To evaluate the relationship between bone marrow (BM) SOX4 expression and clinicalopathological parameters of de novo AML and to evaluate the prognostic value of SOX4 expression for AML patients.

**Methods:** From March 2009 to December 2011, a total number of 112 adult AML patients were enrolled in this study. This study was approved by the Institutional Review Board (IRB) of the National Taiwan University Hospital (NTUH) and written informed consent was obtained from all participants in accordance with the Declaration of Helsinki. Immunocytochemical staining was used to assess SOX4 expression in bone marrow leukemic cells. All statistical analyses performed for this study involved two-tailed Student’s t-tests, Mann-Whitney U tests and Pearson’s chi-square test or Fisher’s exact test and multivariate analysis with Cox proportional hazards regression models. Kaplan-Meier estimation techniques were used to plot survival curves and log-rank tests.

**Results:** We divided AML patients into two groups according to the intensity and extent of SOX4 expression as follows: low expression group (score 0-2, n=49) and high expression group (score 3-5, n=50), respectively. The various clinical manifestations of AML did not show significant differences in terms of SOX4 expression. However, AML patients with low SOX4 expression tended to have favorable-risk cytogenetic (P=0.0866). We did not observe significant differences between the high and low expression groups in terms of age, gender, hemogams, NPM1 mutation and FLT3/ITD. Additionally, of the 112 AML patients that underwent conventional intensive induction chemotherapy, 85 (75.9%) achieved complete remission (CR), and the high and low expression groups showed similar probabilities of achieving first CR (36/50, 72% vs 49/62, 79%, P=0.3219). However, high SOX4 expression were associated with increased OS (RR 1.924, 95% CI 1.020-3.628, P=0.043) and LFS (19.6 months vs 30.6 months, P<0.001) compared to low SOX4 expression (19.6 months vs 30.6 months, P<0.001). Furthermore, with a median follow-up period of 46.7 months (range: 0.7 to 79.0 months), SOX4 expression was associated with overall survival (OS) and disease-free survival (DFS) in all patients with de novo AML (P=0.008 and P=0.013, respectively), patients with non-M3 subtypes (P=0.001 and P=0.011, respectively), patients with intermediate-risk cytogenetics, (P=0.001 and P=0.005 respectively), or even in those with normal karyotype profile (P=0.022 and P=0.111, respectively). In multivariate analysis, high SOX4 expression was found to be an independent poor prognostic factor of OS (RR 2.091, 95% CI 1.051-4.168, p=0.034) irrespective of age, WBC count at diagnosis, karyotype profile and NPM1/FLT3-ITD status. Our results also reveal that SOX4 is an independent prognostic factor of AML. In conclusion, we reveal that BM SOX4 expression could serve as an informative new biomarker for the clinical prognosis of AML patients.
mal and minimal platelet count after chemotherapy. 3. rhTPO might shorten the days of platelet count recover to at least 20×10^9/l from its nadir. The incidence of side effects were similar in both groups of the study.

Table 1.

| Table 1. Platelet Parameters of Study Group Compared with Control Group |
|-----------------------------|-----------------------------|
| Control group | Study group | p value |
| Mean number of platelets | 28.3 | 29.1 | 0.154 |
| Mean days of platelet count | 5.2 | 7.1 | 0.0001 |
| Mean daily platelet count | 8.2 | 7.8 | 0.65 |
| Mean number of platelets | 28.3 | 29.1 | 0.154 |
| Mean days of platelet count | 5.2 | 7.1 | 0.0001 |
| Mean daily platelet count | 8.2 | 7.8 | 0.65 |

Summary/Conclusions: rhTPO, administered as dose of 1500U/day when platelet count less than or equal to 50×10^9/l, might improve the recovery of thrombocytopenia of patients with acute myeloid leukemia in CR after consolidation chemotherapy. While there was no significant difference between study group and control group, there was a decreasing trend of platelet transference number and shorter time required for platelet transfusion for patients in study group.

E944
TREATMENT-ASSOCIATED SURVIVAL RATES IN OLDER PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML): A SYSTEMATIC LITERATURE REVIEW

J. Bell, 1 A. Galaznik, 2 R. Huelin, 3 M. Stokes, 4 D. Faller, 5 R. Fram 6
1 Global Outcomes Research, 2 Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, 3 Meta Research, Evidera Inc., Waltham, United States, 4 Retrospective Observational Studies, Evidera Inc., Dorval, Quebec, Canada, 5 Oncology Clinical Research, 6 Takeda Oncology, Cambridge, United States

Background: AML patients ≥60 years old are more likely to experience complications following intensive induction chemotherapy and are at higher risk of unfavorable outcomes compared with younger patients. Information regarding optimal treatment approaches for older AML patients is limited.

Aims: Summarize outcomes associated with therapies among older AML patients, with a focus on treatment patterns and overall survival (OS) as reported in the literature.

Methods: Searches were conducted in Medline and Embase (Jan 2014–May 2016) and supplemented by conference abstracts (2015–2016). Eligibility included studies in English reporting on OS among older AML patients or subgroups thereof, and conducted in the US, EU 5 (United Kingdom, Germany, France, Spain, Italy), or Japan. Only studies enrolling ≥50 patients were included.

Results: Twelve studies (in 19 publications) reporting on OS among older AML patients were included. Participants in most studies were newly diagnosed with AML; ages ranged from 60 to 93 years. Five non-comparative studies examining the effects of various treatment modalities were identified. Median OS in studies examining azacitidine (AZA) ranged from 10 to 12 months, whereas in studies examining induction chemotherapy or reduced intensity conditioning-hematopoietic stem cell transplantation, the median OS ranged from 6.85 to 10.1 months (95% CI: 3.7–13.5) to 16.4 months (95% CI: 12.6–24.6), respectively. Six comparative observational studies assessed the efficacy of different treatment regimens. Intensive chemotherapy (IC) was generally associated with longer median OS compared to other regimens. In one study, median OS for patients receiving IC, lower-intensity therapy (low dose cytarabine [LD-AraC]) (AZA, decitabine), or best supportive care (BSC) was 12.4 months (95% CI: 8.5–17.4), 11.5 months (95% CI: 9.2–13.9), and 2.6 months (95% CI: 1.9–3.1), respectively. Two studies assessed the efficacy of LD-AraC relative to IC, hypomethylating agents (HMA), and BSC. Patients appeared to have longer OS when receiving IC compared to LD-AraC (median OS: 12.4 vs 9.6 months; 3-year OS: 27% vs 12%; p=0.07), and those receiving LD-AraC showed a trend of improved OS (median: 11.5 vs 9.6 months; p=0.001). In one study, same results were obtained as with HMA than LD-AraC, this difference was not significant (median OS 16.1 vs 9.6 months; 3-year OS 22% vs 12%; respectively; p=0.1). Two studies assessed the efficacy of AZA vs moderate-IC, LD-AraC, or palliative therapy, alone or in combination. AZA had a significantly better survival rate vs LD-AraC in poor prognosis patients (p=0.015). Furthermore, 1-year survival was higher for AZA-treated patients (67.8%) compared to those not treated with AZA (36.9%) (p=0.004). The efficacy of AZA relative to other conventional care regimens (CCRs) including BSC, LD-AraC, or standard IC was also examined in a randomized clinical trial (n=488). Median OS at 1-year was significantly higher for AZA relative to CCR (10.4 vs 6.5 months). Results also showed that 1-year median OS was higher with AZA than CCR in all cytogenetic risk groups, normal risk (14.1 vs 10.0), intermediate risk (13.0 vs 10.1), and high risk (6.4 vs 3.2), respectively.

Summary/Conclusions: Among older AML patients, IC tended to be associated with improved OS compared with other CCRs. However, evidence from this review indicates that AZA could be an alternative treatment option for older AML patients, whether fit or unfit for IC.

E945
SYSTEMATIC REVIEW OF HEALTH STATE UTILITY VALUES FOR ECONOMIC EVALUATION OF ACUTE MYELOID LEUKEMIA

A. Forsythe, V. Bal, 2 M. Dolph, 3 S. Patel, 4 G. Tremblay 5
1 Purple Squirrel Economics, New York, 2 Novartis Pharma, East Hanover, United States, 3 Purple Squirrel Economics, Montreal, Canada, 4 Novartis Pharmaceuticals UK Limited, Surrey, United Kingdom, 5 Purple Squirrel Economics, Quebec city, Canada

Background: Cost-utility analyses undertaken to inform decision making regarding acute myeloid leukemia (AML) require a set of health state utility values (HSUVs) so that the time AML patients spend in different health states can be aggregated into quality-adjusted life-years (QALY).

Aims: This study reviews AML-related HSUVs that could be used in economic evaluation and assesses their advantages and disadvantages with respect to valuation methods used and AML clinical pathways.

Methods: Embase, MEDLINE, Cochrane database, and conference abstracts (ASCO, ESMO and ASH) were systematically searched from Jan 2000 through Nov 2016 for relevant studies that reported quality of life (QOL) and HSUV in AML. Identified relevant EORTC Quality of Life Core Questionnaire QLQ-C30 values were mapped to HDUV using previously published algorithm by Crott, et al. 2010. HSUV for induction, consolidation, complete remission (CR), relapse, stem cell therapy (SCT) treatment, SCT recovery and CR post SCT were identified.

Results: Ten relevant studies were identified. Six were cost effectiveness analyses utilizing HSUVs for calculation of Quality Adjusted Life years (QALY). One effectiveness analysis (incremental QALY). Two QOL studies reporting specific AML utilities (either collected or mapped from QLQ-C30). An additional study reported QOL for patients undergoing SCT. Since no study reported HSUV for relapse, values from study of secondary AML patients who failed prior treatment for Myelodysplastic Syndrome, were used. Where multiple HSUVs were available, priority was made for collected values (HSUVs) so that the time AML patients spend in different health states can be aggregated into quality-adjusted life-years (QALY).

Summary/Conclusions: Among older AML patients, IC tended to be associated with improved OS compared with other CCRs. However, evidence from this review indicates that AZA could be an alternative treatment option for older AML patients, whether fit or unfit for IC.
Summary/Conclusions: This interim analysis of the use of decitabine in real life showed a superimposable OS to controlled international clinical trials. Safety profile was acceptable considering setting of pts and incidence of important comorbidities. Despite a similar OS, the comparison between our data and Cashen study (56 vs 55 pts) showed in our cohort, a poorer rate of CR+CRi (60% and 71%), but a superimposable impact of decitabine therapy. WBC >10000/µL as well as high cytogenetic risk. This apparent contradiction supports the idea that in elderly pts recovery of peripheral blood cells counts (PR+hematological improvement) is probably the most important factor influencing OS (Ferrara, Hemat 2016).

E947

ASPARAGINASE ERWINIA CHRYSANTHemiM EFFECTIVELY DEPLETES PLASMA GLUTAMINE, HAS CLINICAL ACTIVITY, AND IS WELL TOLERATED IN ADULT PATIENTS WITH RELAPSED OR REFRACTORY ACUTE MYELOID LEUKEMIA

A. Emadi1,2,3, E.T. Strovel4, R.G. Lapidus1,2, L.J. Jeng2,4,5, M. Lee1, G.M. Blitzer2, B.A. Carter-Cooper1, D. Sewell2, I. Van Der Meule1, M. Imran1, S.L. Yu1, H. Li1, P.C. Amrein2, V.H. Duong1,2, E.A. Saussville1,2, A.T. Fathi6, Z. Singh6, M.R. Baer1,2, S.M. Bentzen1,7

1University of Maryland Greenebaum Comprehensive Cancer Center, 2Medicine, 3Pharmacology, 4Pediatrics, 5Pathology, University of Maryland, Baltimore, 6Massachusetts General Hospital Harvard Medical School, Boston, 7Epidemiology and Public Health, University of Maryland, Baltimore, United States

Background: Asparaginase-induced glutamine (Gin) depletion demonstrates anti-leukemic activity in preclinical studies of AML. We hypothesized that administration of asparaginase Erwinia chrysanthemi (Erwinaze) would lead to effective plasma Gin reduction and may be a feasible therapeutic approach for AML, because myeloblasts may be addicted to Gin.

Aims: The primary aim was to determine the dose of Erwinaze inducing plasma Gin levels ≤120μmol/L, with an acceptable safety profile, 48 hours (h) after the first intravenous (IV) dose and before each subsequent dose administered thrice weekly for 2 weeks in patients (pts) with relapsed or refractory (R/R) AML.

Methods: This was a phase 1, single-arm, pharmacokinetic investigator-initiated trial (NCT02283190, funded by Jazz Pharmaceuticals), with a 3+3 design with dose de-escalation/escalation rules that incorporate both safety and biochemical activity (naïd plasma Gin levels) of Erwinaze. There was no intrapatient dose adjustment. For safety, a 3rd cohort of three pts was to be added if 2 of 6 pts in the 1st and 2nd cohorts experience a dose limiting toxicity (DLT) at a certain dose level. If ≤3 of 9 pts experienced DLT, the trial was to be terminated. To evaluate Gin reduction activity of Erwinaze, the dose could be increased based on 48h trough plasma Gin in cohorts of 3, 6, or 9 pts per dose level. Correlative studies measured plasma Gin, glutamate (Glu) and asparagine (Asn) levels, plasma asparaginase activity and plasma and urine 2-hydroxyglutarate (2-HG) levels.

Results: Five pts were enrolled on study. Enrollment was then halted due to Erwinaze supply manufacturing complexities. Median age was 69 (range 20-83) years, 4 were male, 2 had prior MDS or CMMML, 3 had high risk abnormal karyotype, 3 had isocitrato dehydrogenase (2 IDH1, 1 IDH2) mutations, and 3 had been treated with ≥2 lines of prior treatment. Erwinaze was administered IV (25,000 IU/m2, dose level 0) for 6 doses MWF for 2 weeks to all pts. No DLT was observed. Anemia and electrolyte abnormalities were the most common adverse events. Plasma asparaginase activity ≥0.1 IU/mL was achieved in all pts at 48h trough, but in 3 pts it decreased to zero on day 8 (72h trough). Median trough plasma Gin, Asn and peak Glu levels (μmol/L) at 27 were 28 (range <12.5-227), 0 (range 0-0), and 704 (range 474-754), respectively. Asn remained undetectable for the entire 2 weeks. Gin levels increased significantly on day 8 (72h trough) compared to day 5, p<0.001. Four of 5 pts (80%, lower limit of 1-sided 95% CI: 34%) achieved at least one nadir Gin value <120 μmol/L. The fold reduction (FR) in Gin level at 3 days, relative to baseline, was 0.16 (p=0.031 for rejecting FR=1). One pt achieved partial remission (PR) and one achieved hematologic improvement (HI) after 6 doses of single agent Erwinaze. Both pts had plasma Gin levels <85 μmol/L on days 5, 10 and 12. Off study, after completion of Erwinaze, they have been treated with azacitidine.

Both pts are still alive in complete remission (CR) and CR with incomplete count recovery (CRi) 13.3 and 13.4 months after the on-study date. Plasma and urine 2-HG levels did not change significantly. The 3 pts with IDH mutations tended to have higher plasma 2-HG levels (p=0.10).
Summary/Conclusions: To the best of our knowledge, this is the first clinical report demonstrating that an asparaginase product is capable of not only decreasing plasma Gln level to ≤120μmol/L but also depleting it to undetectable (i.e. <12.5μmol/L) levels in pts with AML. Two of 5 patients with R/R AML had clinical responses and are alive in remission. Given clinical activity of asparaginase in AML, we are to investigate mechanistically-designed asparaginase combination therapies.

PROGNOSTIC SIGNIFICANCE OF SOX2, SOX3, SOX11, SOX14 AND SOX18 GENE EXPRESSION IN DE NOVO ACUTE MYELOID LEUKEMIA (AML) PATIENTS

N. Tosić1, M. Vrjčević2, I. Petrović2, N. Kovačević Grujčić3, S. Davidović3, N. Stojadinović Vuković4, S. Pavlović1, M. Stevanović2

1Laboratory for Molecular Biomedicine, Institute of Molecular Genetics and Genetic Engineering, University of Belgrade, Serbia, 2Clinic of Hematology Clinical Centre of Serbia, University of Belgrade Faculty of Medicine, 3Laboratory for Human Molecular Genetics, Institute of Molecular Genetics and Genetic Engineering, University of Belgrade, Serbia, Belgrade, Serbia

Background: Members of the SOX (SRY-related high mobility group (HMG) box) gene family encode a group of transcriptional factors with important functions in embryonic development. Also, SOX genes are aberrantly expressed in different types of cancer. However, their role in hematological malignancies, especially in acute myeloid leukemia (AML), remains elusive.

Aims: The aim of this study was to investigate the expression level of SOX2, SOX3, SOX11, SOX14 and SOX18 genes in de novo AML patients, and to evaluate their potential as prognostic markers.

Methods: Fresh bone marrow (BM) samples were collected from 50 non-APL AML patients at diagnosis (27 male, 23 female, median age 52.5 years, range 22-73) and from 8 healthy donors. Relative quantification analysis of SOX genes expression level was performed by RQ-PCR methodology, with GAPDH gene as endogenous control, and using comparative ΔΔCt method with healthy controls as calibrator.

Results: The median expression level of SOX2, SOX3, SOX11, SOX14 and SOX18 in AML patients was 0.46 (0.01-226.13), 0.81 (0.01-1210.00), 0.35 (0.01-177.29), 0.98 (0.02-469.51) and 3.53 (0.18-332.00), respectively. This was not significantly different from the levels detected in healthy controls where the median expression levels were 1.00 (0.32-2.54), 1.00 (0.45-5.73), 1.00 (0.19-2.83), 1.04 (0.38-2.38) and 1.00 (0.48-12.29), respectively. As a cut-off value above which the patients were considered to be positive for SOX2/3/11/14/18 gene expression we used median expression level of each SOX gene in healthy controls + 2SD. The percentage of patients who were positive for the expression of the studied genes ranged from 14% (SOX2* and SOX11*), 20% (SOX3* and SOX18*) to 28% (SOX14*). A significant association with the presence of FLT3-ITD and NPM1 mutations was detected in all but SOX14+ patients. The same result was found concerning association with higher leukocyte count. There were no significant associations with any other presenting clinical parameters. As for the impact that SOX expression positive status had on the prognosis of the studied genes had on the prognosis and outcome of the disease, we detected higher relapse rate in SOX14+ patients (p=0.045). Significantly shorter disease-free-survival (DFS) was detected among SOX2+, SOX11+ and SOX18+ patients (p<0.001; p=0.001; p=0.017, respectively). Although all of the SOX+ patients had shorter overall survival (OS) time compared to SOX- patients, the most prominent influence has been detected for the SOX2+ patients (p=0.034).

Summary/Conclusions: This is the first study focused on examining the expression level of SOX2/3/11/14/18 in AML patients. We have found that these genes are overexpressed among patients in comparison with normal BM. However, in some patients, the expression of these genes is highly increased, and associated with a negative prognostic factors such as the presence of FLT3-ITD mutations and higher leukocyte count. Also, increased expression of these genes has been clearly associated with shorter DFS and OS. Therefore, exact function of these genes in the pathogenesis of AML is not yet known, our preliminary results show that their overexpression can have prominent prognostic significance in AML patients and therefore should be the subject of further investigation.

ACUTE ANTHRACYCLINE INDUCED CARDIOTOXICITY IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

O. Paspovsky1, O. morelli1, U. rozovski1, N. vatur1, O. wołach1, I. amitai1, l. vaxman1, R. ratzon1, M. yeshurun1, Z. lakobishvili1, R. kornowski1, P. raanani1

1Beilinson Hospital, Petach Tikva, Israel

Background: Chemotherapeutic agents are associated with a wide range of cardiotoxic adverse effects. Anthracyclines and related drugs are some of the most implicated agents, with a well-recognized potential for the development of cardiomyopathy and heart failure. Chronic anthracycline induced cardiotoxicity can lead to cardiomyopathy, which may develop several years after treatment. Acute and subacute anthracycline induced cardiotoxicity is considered relatively uncommon, described mostly in patients treated for solid tumors or lymphomas. While anthracycline based regimens have been used to induce remission in newly diagnosed patients with acute myeloid leukemia (AML) for more than four decades, relatively little is known about the acute cardiotoxic effect of anthracyclines in this setting. Since many of these patients are candidates for hematopoietic stem cell transplantation (HSCT), an intensive intervention usually reserved for fit patients, even transient decrease in cardiac function might render them ineligible for this intervention, or might increase their transplant related morbidity.

Aims: To study the short-term outcomes of anthracycline exposure on cardiac function in patients with AML who are candidates for allogeneic HSCT. Because current AML-induction regimens use anthracyclines (most commonly daunorubicin) at a relatively high dose between 45 and 90mg/m2/day for three consecutive days, we hypothesized that the incidence of post-induction cardiac injury in patients with AML might be high.

Methods: The medical records of 55 consecutive patients who had received induction chemotherapy and had undergone HSCT in our medical center were reviewed. Patients included in the study were those with echocardiographic data both prior to and post induction therapy. Median age at diagnosis was 59 years (range: 19-73) and 49% were males. Approximately half of the patients had de novo AML (N=29, 53%). 26 patients (47%) had either therapy related AML or AML secondary to a previous hematological disorder. Induction treatment included 7 days of cytarabine at a dose of 100mg/m2/day and 3 days of daunorubicin at a dose of 45mg/m2/day (N=2, 3.6%), 60mg/m2/day (N=34, 61.8%) and 90mg/m2/day (N=15, 27.3%).

Results: Selected patient characteristics are summarized in Table1. Post-induction echocardiogram studies demonstrated a significant cardiac deterioration in left ventricular ejection fraction (EF) (defined as 10% or more absolute decrease from baseline EF) in 25.5% of the patients (N=14). Higher doses (90mg/m2/day) of anthracyclines were associated with a higher incidence of cardiac function deterioration (odds ratio: 4.1, 95% confidence interval: 1.06 to 15.7). Patients with cardiovascular risk factors and male patients tended to develop cardiotoxicity at higher rates, whereas age, white blood cell counts at diagnosis and AML type (de novo vs. secondary) had no impact on cardiotoxicity. The decrease in cardiac function was temporary in 10.9% of the patients (N=6) with subsequent normalization of left ventricular EF in those patients.

Summary/Conclusions: The use of daunorubicin at a dose of 60mg/m2/day or less is associated with significantly lower rates of acute cardiotoxicity. Our findings should be taken into consideration when choosing the anthracycline dose, particularly in male patients with cardiovascular risk factors who are candidates for HSCT.

AN INTEGER WEIGHTED GENOMIC MUTATION SCORING (IWGMS) USING THE TRUSIGHT MYELOID SEQUENCING PANEL SHOWS HIGHER MOR-
TALITY IN PATIENTS WITH INTERMEDIATE RISK ACUTE MYELOID LEUKAEMIA: A RETROSPECTIVE STUDY
1Internal Medicine, Houston Methodist Hospital, Weill Cornell Medical College, 2Laboratory and Genomic Medicine, Houston Methodist Hospital, 3Hematology, Houston Methodist Cancer Center, 4Baylor Miraca Genetics Laboratories, Baylor College of Medicine, Houston, United States

Background: AML is currently classified by European LeukemiaNet into favorable, unfavorable, and intermediate prognosis based on cytogenetic aberrations. Although favorable and unfavorable categories have good prognostic values, the intermediate category encompasses the majority of patients and offers unclear prognosis. The development of Cancer Genome Atlas (TCGA) opens new windows for the incorporation of next generation sequencing (NGS) into cytogenetics to enhance prognostic risk stratification. However, few studies explore the combination of cytogenetics and NGS in prognostic predictions.

Aims: Here we have developed a system of Integer Weights for the Genomic Mutation Score (IWGMS) for a quantifiable stratification of the prognostic risks associated with a combination of cytogenetic aberrations and genomic mutations. Our next step is validating the scoring system through its application to data obtained from other institutions.

Methods: Patient data at Houston Methodist Hospital was queried from Methodist Environment for Translational Enhancement and Outcomes Research (METEOR), a clinical data warehouse that integrates research databases and national registries. The diagnosis of AML was queried along with patient demographics, cytogenetics, NGS and OS. The resultant patients were divided into three categories based on their MRC cytogenetic risks: favorable, intermediate, and poor. Using the TruSight Myeloid Sequencing Panel (Illumina), mutations in 54 genes associated with myeloid disorders were tested in NGS. A score was developed that xenografted each of the nine TCGA mutation categories (Transcription- Factor Fusion, Nucleophosmin (NPM1), Tumor Suppressor Genes, DNA-Methylation related genes, Signaling Genes, Chromatin Modifying Genes, Myeloid Transcription Factor Genes, Cohesion complex Genes and Spliceosome-complex genes) a score between –2 (good risk) and +2 (poor risk). The IWGMS for each patient was calculated by the sum of the individual mutation scores. A IWGMS score greater than 3 was considered significant as a poor prognostic factor. Statistical analysis was done using Chi-Square, Mann Whitney U test and multivariate logistic regression analysis. Data from other institutions will be analyzed in a similar fashion for the confirmatory portion of the project.

Results: A hundred of the 1200 AML patients met the criteria for having both cytogenetic and NGS data availability. The two-year mortality rates were 43%, 52% and 51% respectively for the favorable, intermediate, and poor cytogenetic groups. In the intermediate cytogenetic group, high IWGMS score (>3) was associated with higher mortality when compared to low IWGMS score (80% vs 44%, p=0.045, Fig 1). A look at the gene mutation distribution in the intermediate risk cytogenetic group also showed a general correlation between known favorable gene mutations with low IWGMS scores and unfavorable ones with high IWGMS scores. We thus hypothesize the IWGMS scoring system can be utilized to divide intermediate cytogenetic and low mortality subgroups based on a combination of cytogenetic and genetic mutations. We expect similar results with data from other institutions.

Figure 1.

Summary/Conclusions: Most studies in current literature focuses on the individual contributions of cytogenetic aberrations or genetic mutations to risk stratification and treatments risk stratification and treatment response. However, prognosis varies widely in the heterogeneous, intermediate cytogenetic class, where 60% of the AML patients belongs. We propose a systematic approach that correlates cytogenetics with genetic mutations in stratifying prognostic outcomes with a focus on the intermediate cytogenetics group. The ability to differentiate in this specific group opens great potentials for targeted therapies and improving outcomes.

SUCCESSFUL IDENTIFICATION OF SPECIFIC AMINO ACID-DEPENDENCE IN ADULT T-CELL LEUKAEMIA / LYMPHOMA (ATL) AND PRECLINICAL APPLICATION FOR NEW THERAPY
1Division of Stem Cell Therapy, 2Department of Laboratory Medicine, Research Hospital, 3Division of Project-based Advanced Regenerative Medicine, The Institute of Medical Science, The University of Tokyo, 4Laboratory of Tumor Cell Biology, The University of Tokyo, 5Department of Hematology and Oncology, Research Hospital, The Institute of Medical Science, The University of Tokyo, Tokyo, Japan, 6Institute for Stem Cell Biology and Regenerative Medicine, Stanford University, California, United States

Background: Adult t-cell leukemia / lymphoma (ATL) is highly aggressive malignancy caused by human T-cell leukemia virus type 1 (HTLV-1). As leukemia/lymphoma cells are often resistant to combination chemotherapy and recent antibody therapy, new strategies should be developed. Our laboratory recently found that proliferation and survival of hematopoietic stem cells are critically dependent on the amino acid valine (Science, 2016).

Aims: We here aimed to assess amino acid dependence of lymphoma and leukemic stem cells, and tried to establish a novel therapy by utilizing the differences in amino acid dependence between normal and leukemic stem cells.

Methods: First, primary ATL cells were sorted from samples of 7 typical acute-type ATL patients by 12-color flow cytometry, and serially passaged on stromal cells. Then passageable ATL cells from 3 patients were transduced with GFP- expressing lentivirus for tracking and counting by image cytometry. Using complete medium and twenty different culture media each lacking a single amino acid, we examined amino acid dependency of ATL cells. Amino acids vital for ATL cells were screened by co-culture with stromal cells. Effects of these media on normal lymphocytes of healthy volunteers were also examined. Finally, the effectiveness of amino acid restriction was evaluated in vivo by xenotransplantation of ATL cells into NOG mice. Mice were fed with different diets lacking specific amino acids at 6 weeks after transplantation, and sacrificed at 10 weeks for analysis of peripheral blood, organs, and lymphoma size.

Results: In vitro studies revealed that ATL cells have dependency on specific amino acids: cysteine, methionine, and valine. As 2-weeks restriction of the former two amino acids damaged stromal cells or normal lymphocytes, valine was picked up for further analysis. Proliferation of ATL cells was dramatically inhibited by valine restriction while the influence on normal cells was limited. Interestingly, valine restriction did not effect a significant change in the proportion of normal CD4+ populations, such as Treg, naive, central memory, effector, and effector T-cells. Moreover, 4-week restriction of valine succeeded in eradicating ATL cells in vitro and no recurrence was observed after refilling valine although 2-weeks restriction was insufficient for extermination. In vivo model also showed that 4-weeks restriction of valine could dramatically reduce ATL tumor size. Valine-depleted diet did not significantly reduce hemoglobin or platelet count, and there were no significant organ damages as far as examined macroscopically.

Summary/Conclusions: We discovered that proliferation and survival of adult T-cell leukemia / lymphoma cells were dependent on valine. ATL cells could be eradicated by 4-weeks of valine in vitro. In vivo model also showed that the growth of ATL cells was significantly inhibited by dietary restriction of valine. Massive lymphoma cells, which are known to be resistant to antibody therapy, were also vulnerable to the valine restriction. There were no severe complications such as anemia, thrombocytopenia, and organ damages which are often seen in chemotherapy recipients. These data demonstrate that valine restriction may potentially provide a new option for leukemia/lymphoma therapy.
**Aims:** Since the roles of these SNPs in clinical aspects, response to therapy and prognosis of DLBCL treated with R-CHOP- are still unknown, these were the aims of the present study.

**Methods:** Our analysis included 168 consecutive DLBCL patients at diagnosis seen at University Hospital from July 2009 to September 2014. Genotypes were identified in DNA of peripheral blood by real-time polymerase chain reaction using a TaqMan SNP Genotyping Assay. Replicates were performed in 10% of the reactions, achieving 100% of concordance. Chi-Square test, Fish-er’s Exact test, and multivariate analysis, using the logistic regression model, served to assess associations between genotypes and clinical aspects. Kaplan-Meier analysis was used to evaluate the effect of clinical features and genotypes on the estimated probability of event free survival (EFS) and overall survival (OS). EFS and OS were calculated from the date of diagnosis to first event (relapse, progression or death by disease) or last seen date and death by any cause or last seen date, respectively. The Cox proportional hazardmodel was used to evaluate the effects of clinical features and genotypes of the above mentioned SNPs on PFS and OS, and the results of analysis were presented as hazard ratios (HRs) with their corresponding 95% confidence intervals (CIs). First, these associations were examined using univariate Cox proportional hazards regression. In a second step, all variables with P<0.10 were included in a multivariate Cox regression. All reported P values were two-sided, and P<0.05 was considered to indicate statistical significance.

**Results:** Concerning clinical features, the frequency of the wild-types VEGF-1154G and VEGFR-2-604TT genotype were more common in stage III or IV patients. The wild-type VEGF-1154G allele was more common in high intermediate and high international prognostic index (IPI) patients. Concerning response rate, patients with the wild-type VEGF-936CC genotype was associated with higher complete response (CR). These patients had 2.65 more chances of achieving CR to therapy than others. The median follow-up time of 168 DLBCL patients enrolled in the study was 43 months (range: 1-105). The estimated probabilities of 60-months EFS and OS were 58.8% and 66.0%, respectively. At 60 months of follow-up, patients with the variant VEGF-1154A and 936 T alleles had 1.52 and 1.82 more chances of presenting disease relapse or progression, and 1.47 and 1.60 more chances of evolving to death in univariate analysis, respectively. After correction with other classical prognostic factors in DLBCL (IPI and GCB subtype), only the VEGF-1154 G/A SNP was associated with PFS and OS: patients with the variant VEGF-1154 A allele had 1.88 and 1.83 more chances of having an event.

**Summary/Conclusions:** Our data present, for the first time, preliminary evidence that inherited abnormalities in AG pathway, related to the VEGF-1154G, -634GG genotype were more common in stage III or IV patients. The wild-type VEGF-936CC allele was associated with higher complete response (CR). These patients had 2.65 more chances of achieving CR to therapy than others. The median follow-up time of 168 DLBCL patients enrolled in the study was 43 months (range: 1-105). The estimated probabilities of 60-months EFS and OS were 58.8% and 66.0%, respectively. At 60 months of follow-up, patients with the variant VEGF-1154A and 936 T alleles had 1.52 and 1.82 more chances of presenting disease relapse or progression, and 1.47 and 1.60 more chances of evolving to death in univariate analysis, respectively. After correction with other classical prognostic factors in DLBCL (IPI and GCB subtype), only the VEGF-1154 G/A SNP was associated with PFS and OS: patients with the variant VEGF-1154 A allele had 1.88 and 1.83 more chances of having an event.

**Background:** Interest in the role of myeloid-lineage cells, including monocytes and their precursors, has been increasing in prognosis of lymphoma. It has been shown that the circulating monocyte count at the time of diagnosis shows prognostic significance in diffuse large B-cell lymphoma (DLBCL), suggesting the role of specific subset of monocyte in prognosis of DLBCL. Recent studies suggest CD11b+ monocytes expressing CX3CR1 promote angiogenesis and suppress anti-tumor immunity through the interaction with fractalkine (CX3CL1), the only ligand for CX3CR1. However, limited data is available regarding the prognostic significance of CD11b+CX3CR1+ monocytes in DLBCL patients.

**Aims:** The study investigates the prognostic significance of peripheral blood (PB)- and bone marrow (BM)-CD11b+CX3CR1+ monocytes on progression-free survival (PFS) and overall survival (OS) in newly diagnosed DLBCL patients treated with R-CHOP, and provided informed consents. Percentages of CD11b+CX3CR1+ cells in total mononuclear cells (>50,000 cells) were measured by flow cytometric analysis using fresh PB and BM aspirates taken before treatment.

**Results:** Eighty-nine patients (male, 52) were enrolled. The median age was 65 years (range, 19-88). 37 patients (41.6%) were classified as high-intermediate (HI) or high risk according to National Comprehensive Cancer Network International Prognostic Index (NCCN-IPI). CD11b+CX3CR1+ monocytes were measured in BM and PB samples. A total of 271 DLCBL patients were initially identified; we excluded: 31 patients who received low intensity chemotherapy regimens (R-COP, Mini-CHOP-R, monotherapy with steroids) due to advanced age, comorbidities or not treated. Fifty-one patients refused to participate in clinical trials including standard regimens plus new agents (Bortezomib, Lenalidomide, Ibrutinib) or non-standard regimens (R-CHOP/14, Da-EPOCH-R, MACOP-B, Mega-CHOP, Hyper-CVAD). In the homogeneously treated (R-CHOP/21) 205 DLBCL patients subset, the median age at diagnosis was 61 y.o. (range 18-85), with a balanced gender distribution (103 females, 102 males). Twenty-three of these patients (11.3%) had BMI on BM, whereas 43 (21%) had BMI according to PET/CT finding. Fifty-three patients (25.9%) had BMI according to either BM or PET/CT. Concordant BMI by means of both techniques was present in 16 (7.8%) patients. With a median follow-up of 25 months (15-47 months, p25-p75), 50 patients (24.4%) progressed or relapsed and 41 (20%) died. The 3-year estimated progression-free survival (PFS) and overall survival (OS) were 70%, and 78%, respectively. By univariate analysis, factors associated with a shorter PFS, with a p<0.150, were: female gender, IPI>3, abnormally elevated B2-microglobulin levels, PET/CT-BMI(+) and BMI-BMI(+) (in multivariate analysis only two factors contributed to prognostic significance: IPI≥3 and BMI-BMI(+) (p=0.036 and 0.007, respectively). In multivariate analysis only BMI ≥3 (HR: 2.6, 95%CI 1.13-5.14; p=0.006) was independently associated with a shorter PFS. BMI-BMI(+) association, predictive factors of a shorter OS, with a p<0.150, included: IPI>3, abnormally elevated B2-microglobulin levels, PET/CT-BMI(+) (in multivariate analysis only BMI ≥3 (HR: 2.6, 95%CI 1.13-5.14; p=0.006) was independently associated with a shorter OS.

**Summary/Conclusions:** In our DLBCL cohort, treated with a uniform first-line chemotherapy regimen, BMI by BM complemented IPI in predicting those patients with a higher risk for relapse or progression, while IPI defined a subset of patients with a worse survival. In this cohort, BMI by PET/CT could not independently predict a shorter PFS and/or OS.
27.7 months (IQR, 14.6-46.1), low PB-CD11b+CX3CR1⁺ cell group had significantly better PFS (3-year, 77.1% vs 58.7%; P=0.006) and OS (3-year, 86.6% vs 58.4%; P=0.004) than high PB group. No significant survival differences were observed between high and low BM-CD11b+CX3CR1⁺ cell groups. Uni-variates analyses demonstrated that age, ECOG performance status, B symptoms, extranodal involvement, NCCN-IPI, and PB-CD11b+CX3CR1⁺ cell group were significantly associated with OS. However, high risk NCCN-IPI was an only independent prognostic factor for reduced OS (hazard ratio, 4.41; 95% confidence interval, 1.17-15.69) in the multivariate analysis. In subgroup analysis according to the NCCN-IPI, 3-year OS of high PB-CD11b+CX3CR1⁺ monocytes was significantly inferior to that of low group (34.0% vs 77.9%; P=0.026) in DLBCL cases. In contrast, PB-CD11b+CX3CR1⁺ monocytes failed to predict OS (3-year, 91.7% vs 96.7%; P=0.875) in the low to low-intermediate risk NCCN-IPI subgroup.

Summary/Conclusions: Our study represents PB-CD11b+CX3CR1⁺ monocytes can be used in differentiating patients with high risk for early death and are associated with risk stratification by the NCCN-IPI, possibility of potential therapeutic target in DLBCL.

Background: Clinical management of pediatric rare non-Hodgkin lymphomas (r-NHLs) (1/1 billion) is unclear.

Aims: To characterize children with r-NHLs in AIEOP centers. Performing a retrospective analysis of r-NHLs AIEOP case records, describing main epidemiologic, clinical and histopathological parameters. To review the histopathological case records according to WHO 2008 classification. Evaluation of treatment response - chemotherapy or wait and see (W&S) in terms of overall survival (OS) and of complete remission (CR), relapse and resistance cases, secondary neoplasias and deaths.

Methods: Data from the AIEOP database were collected between 1997 and 2015. Results: The incidence of r-NHL in AIEOP registry was 6.5% (67 pts). Forty-eight were male and 19 female, median age was 11 years (0.3-21 years). Classification according to St.Jude stage was: stage I n=36; II n=13; III n=11; IV n=7. Bone marrow (BM) involvement was diagnosed in 7 cases; central nervous system (CNS) in one case. Patients who presented LDH >500 UI were 18. B-NHLs accounted for approximately 49% (33 pts) of the entire population analyzed, in 27 cases (27 pts), the remaining 11% (7 pts) of the population under study being categorized as “others” (other than those deriving from B or T/NK-cells). The most common histological subtypes were: follicular lymphoma (FL) among B-NHLs; peripheral T-cell lymphoma (PTCL) n.o.s., mycosis fungoides (MF), subcutaneous panniculitis T-cell lymphoma (SPTCL) and lymphomatoid papulosis (LP) amongst T-NHLs; histiocytic sarcoma (HS) amongst “others” category. A similar proportion for both B and T/NK NHL underwent either W&S approach only or active treatment (AT); 45% and 55% were W&S and AT approach, respectively. Patients in “others” category were almost actively treated (71%). Therapy was based on AIEOP B-, T/NK-NHLs and ALCL protocols and +/- conventional RT, and/or immunotherapy. Surgery resection has been performed in case of localized disease B-NHLs only, followed by a W&S strategy, with 3-year 0%-3y OS. It has been seen that B-NHLs have a more favorable prognosis and very few events (development of resistance to therapy, relapse, secondary malignancy, death). Amongst T/NK NHLs-related events, death remained the most frequent event in both B- and T/NK-NHLs, which showed a slight increase of relapses; as for the category “others”, no relative preponderance has been registered for any of the above-mentioned events. 3-year OS has shown to be significantly higher for B-NHLs than for T/NK-NHL (94% vs 69%, p-value 0.024), as illustrated in Figure 1. Regarding the treatment, the 3-year OS was 100% for the patients underwent a W&S approach whereas 75% for treated patients (p-value 0.037). FLs show favourable clinical course and outcome, limited stage at diagnosis. Differently from adults, pFLs have a higher 3-years OS with respect to that of other histological pediatric NHLs subtypes (100% vs 75%, p-value 0.049).

Figure 1.

Summary/Conclusions: The incidence of AIEOP pediatric r-NHLs is in line with the literature. In case of localized disease, a W&S approach was successfully applied; of these, the T/NK NHLs being most often registered and with best prognosis are the cutaneous lymphomas (i.e. LyP, MF). Patients’ prognosis varies greatly depending on the histological subtype. The better survival was observed in the B-NHLs compared to other categories. An international collaboration is warranted, in order to create new guidelines or protocols for an appropriate management of pediatric r-NHLs.

PRIMARY ANALYSIS OF THE EFFECT OF HEMATOPOIETIC STEM CELL TRANSPLANTATION IN THE TREATMENT OF 110 CASES OF T CELL LYMPHOMA

C. Li1,2, D. Yang1, X. Chen1, J. Chen1, T. Wang1, Q. Zou1, C. Gu1, D. Wu1,2
1The First Affiliated Hospital of Soochow University, Jiangsu Institute of Hematology, 2Institute of Blood and Marrow Transplantation, Collaborative Innovation Center of Hematology, Soochow University, Suzhou, China

Background: T cell lymphoma(T-NHL) is a rare and heterogeneous group of lymphoid malignancies with mostly poor outcome with conventional treatment. Recent studies have suggested that Hematopoietic stem cell transplantation(HSCT) has a better curative effect and is superior to traditional chemotherapy.

Aims: To investigate the effect of HSCT in the treatment of T cell lymphoma.

Methods: The clinical data of 110 patients with T cell lymphoma treated by HSCT from January 2006 to August 2016 in our center were retrospectively analyzed.

Results: (1)110 T-NHL patients, 70 males and 40 females, aged 7-64 years (median age 26 years). Disease subtypes: 35 cases of T-cell lymphoblastic lymphoma(T-LBL), 23 cases of NK / T cell lymphoma(NK/TCL), 24 cases of peripheral T-cell lymphoma (PTCL, NOS), 24 cases of variable large cell lymphoma (ALCL), 3 cases of subcutaneous panniculitic T cell lymphoma(SPTCL) and 1 case of hepatosplenic T cell lymphoma(HSTCL). Transplantation type: 56 cases of autologous hematopoietic stem cell transplantation (auto-HSCT), 54 cases of allogeneic hematopoietic stem cell transplantation (allo-HSCT). The follow-up was ended in December 2016, the duration of following-up ranged from 2 to 130 months (median follow-up time was 22 months). (2)35/110 patients with auto-HSCT, 3-year overall survival (OS) and event-free survival (EFS) were 76.5% and 60.9%, respectively. (3)54/110 patients with allo-HSCT, 3 year EFS and OS of allo-HSCT were 61.7% and 58.9%, respectively. (4)36/56 patients with CR1 status before auto-HSCT, 3 year OS and EFS were 87.3% and 40.2%. The OS and EFS of the two groups were significantly different (P=0.001). (5)45/110 cases were young and high-risk patients (age<60 years, IPI score ≥ 3).25/54 cases treated with allo-HSCT, the 3 year OS and EFS were 62.8% and 60.8%. 20/56 patients with non-CR1 status before auto-HSCT, the 3 year OS and EFS were 47.8% and 36.9%. The OS and EFS of the two groups were also significantly different (P=0.001).

Summary/Conclusions: HSCT can improve the efficacy of T cell lymphoma. Auto-HSCT in first complete remission (CR1) enables T-NHL patients with
greater benefit. Allo-HSCT can cure some T-NHL patients, which can be considered for the treatment of young and high-risk T-NHL patients.

**SHORT COURSE OF R-HYPERCVAD/MITX/ARA-C FOLLOWED BY ASCT AS FIRST-LINE THERAPY IN MANTLE CELL LYMPHOMA PATIENTS PROLONGS PROGRESSION FREE SURVIVAL TO MORE THAN 9 YEARS.**

**SINGLE CENTER EXPERIENCE**

M. Andreu-Campos1,2,*, S. Mercadal1, E. Domino Domenech1, V. Paredes Hena1, C. Aguilara Gomez1, A. Oliveira Ramos1, E. de la Banda3, F. Climent1, R. Parody Porras1, A. Fernandez de Sevilla1,4, A. Sureda1, E. Gonzalez Barca1,4

1Department of Hematology, Institut Català d’Oncologia Hospitalat, IDIBELL, Barcelona. 2FISER de Enfermedades Raras, CIBERER, ICSIII, Zaragoza. 3Pathology Department, Hospital Universitario de Bellvitge, IDIBELL. 4Department of Clinical Sciences, University of Barcelona, Barcelona, Spain

**Background:** Mantle cell lymphoma (MCL) is considered an incurable disease with an historical median overall survival around 3-4 years with short progression free survival (PFS) periods. Regimens that include high dose cytarabine and consolidation with autologous stem cell transplant (ASCT) have become standard therapy for fit patients. The median PFS reported after 4-6 cycles HyperCVAD followed by ASCT consolidation is 4.5 years (Ahmadi et al, BMT 2012). Nevertheless, toxicity is high and many patients cannot obtain stem cells for transplant. In this setting, some groups use 6-8 cycles R-HyperCVAD without ASCT consolidation, achieving the median PFS of 4.6 years (Romaguera et al, Br J Hematol 2010). Based on this we have review our experience using a short course of HyperCVAD followed by transplant consolidation.

**Aims:** To analyze our experience treating fit patients with MCL in first line with a short course of 2 cycles of R-HyperCVAD followed by consolidation with ASCT.

**Methods:** From January 2002 to August 2016, the patients diagnosed with MCL treated in first line with a short course of 2 cycles of R-HyperCVAD and ASCT were included in this retrospective analysis. International working group response assessment criteria were used, PFS was calculated from the date of start therapy until date of relapse/progression or last contact.

**Results:** During the study period 85 MCL patients were registered: 7 (8.2%) did not receive immediate therapy, 44 (52.4%) were not eligible for intensive therapy due to comorbidities or age and 33 (39.3%) were treated with R-HyperCVAD. Clinical characteristics at diagnosis of these 33 patients were: M/F ratio: 26/7 (78.8%/21.2%), median age: 63 y.o (limits: 40-73), ECOG 0-1: 26 (86.7%), 15 (45.5%) patients had PET/CT findings suspicious for an underlying second malignancy. A total of 33 out of 259 patients with a diagnosis of Hodgkin’s lymphoma and 204 patients a diagnosis of Non-Hodgkin’s lymphoma. Of the 33 patients, 19 underwent further invasive investigation, with a total of 8 patients having a biopsy proven histological diagnosis of a second malignancy (12.7%). Of the 33 patients, 19 underwent further invasive investigation, with a total of 8 patients having a biopsy proven histological diagnosis of a second malignancy (12.7%).

**Summary/Conclusions:** The frequency of incidental malignancies detected by PET/CT imaging in patients with lymphoma was found to be comparable to other similar international retrospective studies. The majority of incidental second malignancies were early stage and gastrointestinal in origin. Further retrospective as well as prospective data may assist in the establishment of guidelines, to address a standardized diagnostic approach to investigating incidental lesions discovered on PET/CT imaging that are suggestive of a second malignancy.

**E958**

**THE FREQUENCY OF INCIDENTAL MALIGNANCIES DETECTED BY PET/CT SCANS IN PATIENTS WITH LYMPHOMA AND THE ASSOCIATED CLINICAL IMPLICATIONS**

J. Falconer1,*, G. Kidston-Gerber2, E. Wegner2

1Haematology, Concord Repatriation General Hospital. 2Haematology, The Prince of Wales Hospital, Sydney, Australia

**Background:** PET/CT imaging has a well-established role in the investigation of malignant lymphoma. Given the widespread clinical applications, unexpected findings are occasionally identified. Whilst there is substantial information pertaining to additional primary cancers identified on PET/CT in patients with solid organ malignancy, there is a relative paucity of data in patients with lymphoma.

**Aims:** The primary aim was to identify the frequency of incidental second malignancies detected by PET/CT in patients with lymphoma. Qualitative data related to histological diagnosis and staging, interruptions or obstacles to lymphoma therapy, therapy for the secondary malignancy and the overall impact upon prognosis were also reviewed.

**Methods:** A total of 550 PET/CT images were performed in 298 patients at The Prince of Wales Hospital, Sydney Australia between January 2013 – March 2016. Patients with both Hodgkin’s and Non-Hodgkin’s lymphoma, with PET/CT imaging performed for all medicare-approved indications were included. All PET/CT reports suggestive of an incidental second malignancy prompted further review of electronic medical records, MOSAIC cancer database and paper medical records. Where a clear diagnosis of second malignancy was confirmed, information regarding histological findings and staging, as well as the implications of this diagnosis related to treatment of the underlying lymphoma and impact on overall prognosis was collected.

**Results:** 510 PET/CT scans in 259 patients had confirmed diagnoses of lymphoma. Patients aged 17 to 96 were included in the study, with a median age of 63 years. Of the 259 patients included (M=155; F=104), 55 patients had a diagnosis of Hodgkin’s lymphoma and 204 patients a diagnosis of Non-Hodgkin’s lymphoma. A total of 33 out of 259 patients with a diagnosis of malignant lymphoma had PET/CT findings suspicious for an underlying second malignancy (12.7%). Of the 33 patients, 19 underwent further invasive investigation, with a total of 8 patients having a biopsy proven histological diagnosis of a second malignancy (24.2%). Qualitative information was gathered regarding the patients who did not have further investigation.

**Summary/Conclusions:** The frequency of incidental malignancies detected by PET/CT imaging in patients with lymphoma was found to be comparable to other similar international retrospective studies. The majority of incidental second malignancies were early stage and gastrointestinal in origin. Further retrospective as well as prospective data may assist in the establishment of guidelines, to address a standardized diagnostic approach to investigating incidental lesions discovered on PET/CT imaging that are suggestive of a second malignancy.

**CLINICAL IMPACT OF KARYOTYPIC EVOLUTION ON THE PROGNOSIS OF DIFFUSE LARGE B CELL LYMPHOMA**

Y. Mizuno1,*, T. Kobayashi1, N. Uoshima2, E. Kawata2, H. Uchiyama2, Y. Chinen1, Y. Shimura1, S. Honike1, J. Kuroda1

1Hematology, Kyoto Prefectural University of Medicine. 2Hematology, Japanese Red Cross Kyoto Daini Hospital. 3Hematology, Japanese Red Cross Kyoto Daiichi Hospital, Kyoto, Japan

**Background:** The acquisitions of additional chromosomal abnormalities are generally accompanied by the emergence of therapeutic resistance and eventually lead to poor treatment outcome in cancers. However, the actual clinical impact of karyotypic evolution on prognosis differs depending on the type of hematologic malignancy. Although several prognostic indexes, including the International Prognostic Index (IPI), revised IPI (R-IPI), National Comprehensive Cancer Network (NCCN)-IPI, and Kyoto Prognostic Index (KPI) which we have developed (Kobayashi T. Blood Cancer J 2016), have the determinants for prognosis, little is known concerning the prognostic impact of karyotypic evolution in diffuse large B cell lymphoma (DLBCL), the most prevalent subtype of non-Hodgkin lymphoma.

**Aims:** We in this study investigated the clinical impact of karyotypic evolution on the treatment outcome of DLBCL.

**Method:** We retrospectively reviewed the medical records of 465 DLBCL patients who were diagnosed and treated with either rituximab, cyclophosphamide, doxorubicin, vincristine, and prednisolone (R-CHOP) or with a R-CHOP-like regimen at three independent institutes in Kyoto, Japan, between January 2006 and April 2014. We analyzed the relationship between the number of subclones and prognosis utilizing the Kaplan-Meier curve and Cox proportional hazards regression analysis. We also utilized Fisher’s exact test to investigate the correlation between the number of subclones and the conventional prognostic indexes, i.e. R-IPI, NCCN-IPI, and KPI. This study was conducted in accordance with the ethical principles of the Declaration of Helsinki.
and was approved by the institutional review boards of all participating institutes.

Results: Among the 465 DLBCL cases, karyotypic analyses by G-banding were performed on biopsied tumor specimens before the start of treatment in 181 patients. Among the 181 patients, metaphase spreads were available for G-banding in 120 patients. Neither overall survival (OS) nor progression-free survival (PFS) was statistically significantly different between the patients with available metaphase and no available metaphase spreads. Based on the result of G-banding, we next divided the 120 patients with available metaphase spreads into two groups, i.e., patients with karyotypic abnormalities accompanied by ≥2 subclones and patients with 0-1 subclones. We found that the presence of ≥2 subclones was significantly associated with poor OS (3 year OS rates of patients with ≥2 subclones and 0-1 subclones were 67.6% and 82.8%, respectively (p=0.035), and tended to associate with a shorter PFS. Among the 120 patients with available metaphase spreads, the R-IPI-defined high-risk patients and IPI-defined high-risk patients were significantly more frequent in the group of patients with ≥2 subclones. Ages and genders were not significantly different between patients with ≥2 and with 1-2 subclones.

Summary/Conclusions: DLBCL is a cytogenetically and molecularly heterogeneous disease entity. No specific chromosomal abnormality has been associated with the shorter survival, except double or triple hit lymphomas. However, in this study, it was possible to divide DLBCLs into two groups based on karyotypic evolution, i.e., DLBCLs with 0-1 subclones and with ≥2 subclones, because the OS was the most markedly different between these two groups. In our study, more subclones were associated with poor prognosis, suggesting the significance of karyotypic evolution in DLBCL. In conclusion, our study suggests that more advanced cytogenetic clonal evolution underlies the development of high-risk disease feature in DLBCL.

REGIEM INTENSIFICATION MAY IMPROVE OUTCOMES IN PATIENTS WITH HIGHER RISK HUMAN IMMUNODEFICIENCY VIRUS (HIV) RELATED AGGRESSIVE B-CELL LYMPHOMAS

E. Wang1,2, J. Clara1, S. Dalia2, B. Shah3, C. Bello3, P. Chervenick3, M. Khafraf-Dabaja4, L. Sokol5, E. Sotomayor5, R. Komrokji5, J.C. Chavez5

1Department of Internal Medicine, University of South Florida Morsani College of Medicine, Tampa, 2Hematology Oncology, Mercy Clinic Oncology and Hematology, Joplin, 3Glycogen Storage Disease-Nephropathy, 4Bone Marrow Transplant, L.H. Lee Moffitt Cancer Center & Research Institute, Tampa, 5Malignant Hematology, George Washington Cancer Center, Washington D.C., United States

Background: Despite effective combination antiretroviral therapy for HIV, there remains an increased incidence of HIV related B-cell Non-Hodgkin lymphomas (NHL). The introduction of early antiviral therapy and effective chemotherapy have led to improved outcomes overall. Regimen intensification (RI) in HIV associated B-cell NHLs has shown improved survival, especially in the rituximab era (Barta et al, Blood 2013).

Aims: To examine the effect of RI on the overall survival (OS) and progression free survival (PFS) compared to CHOP based chemotherapy according standard risk stratification.

Methods: Patients with HIV associated aggressive B-cell NHL were identified between 2001-2015 at Moffitt Cancer Center. Patients with primary central nervous system lymphoma, T-cell NHL and indolent NHLs were excluded. Patients received R-CHOP or intensive chemotherapy (IC) including DA-EPOCH, hyperCVAD or COODOX/IVAC as initial treatment. Data collected included patient demographics, disease baseline characteristics, CD4 count, HIV viral load, treatment regimen, response, and outcomes including relapse and OS. The IPI score was calculated, and patients were divided into two groups: lower risk group (low and low intermediate IPI risk) and higher risk group (high-intermediate and high). Descriptive statistics were used for baseline characteristics. Kaplan Meier method was used to estimate PFS and OS, and the log-rank test was used to compare OS and PFS between lower and higher risk groups.

Results: A total of 83 patients were included. The M:F ratio was 9:4. Median ages were 45 years (y) (range 25 – 65). Two thirds of patients were Caucasian. The median time from HIV to NHL diagnosis was 29 months (range 0 – 284). Eighty two percent presented with stage III/IV disease. Bulky disease was present in 27%, elevated LDH in 66%, and CD4 count<100/ml at diagnosis in 22% patients. Fifty percent of patients were on HAART therapy at time of lymphoma diagnosis (PFS) was statistically significantly different between the patients with available metaphase and no available metaphase spreads. Based on the result of G-banding, we next divided the 120 patients with available metaphase spreads into two groups, i.e., patients with karyotypic abnormalities accompanied by ≥2 subclones and patients with 0-1 subclones. We found that the presence of ≥2 subclones was significantly associated with poor OS (3 year OS rates of patients with ≥2 subclones and 0-1 subclones were 67.6% and 82.8%, respectively (p=0.035), and tended to associate with a shorter PFS. Among the 120 patients with available metaphase spreads, the R-IPI-defined high-risk patients and IPI-defined high-risk patients were significantly more frequent in the group of patients with ≥2 subclones. Ages and genders were not significantly different between patients with ≥2 and with 1-2 subclones.

Summary/Conclusions: DLBCL is a cytogenetically and molecularly heterogeneous disease entity. No specific chromosomal abnormality has been associated with the shorter survival, except double or triple hit lymphomas. However, in this study, it was possible to divide DLBCLs into two groups based on karyotypic evolution, i.e., DLBCLs with 0-1 subclones and with ≥2 subclones, because the OS was the most markedly different between these two groups. In our study, more subclones were associated with poor prognosis, suggesting the significance of karyotypic evolution in DLBCL. In conclusion, our study suggests that more advanced cytogenetic clonal evolution underlies the development of high-risk disease feature in DLBCL.
patients with tumor localized in extranasal sites seemed to have higher expression of BCL2 than higher DHS than nasal lesions (p=0.014 and 0.042, respectively). In univariate survival analysis, either high expression of MYC or BCL2 was significantly correlated with inferior PFS and OS (p<0.05). According to the DHS, patients with ENKTL could be divided into three significantly different risk groups for PFS and OS (3-year PFS rate for DHS of 0, 1, and 2 was 60%, 41%, and 21%, respectively, p=0.006; 3-year OS rate for DHS of 0, 1, and 2 was 79%, 49%, and 33%, respectively, p=0.015). In multivariate survival analysis, it was found that DHS was an independent prognostic factor for both PFS and OS (p=0.006 and 0.011, respectively).

Summary/Conclusions: Our study demonstrated that DHS can help identify patients with newly diagnosed ENKTL who are at a high risk for a poor clinical outcome, which needs to be validated in prospective clinical trials with patients treated uniformly.

SOLUBLE INTERLEUKIN-2 RECEPTOR AS A PREDICTIVE MARKER FOR SPONTANEOUS REGRESSION OF OTHER IATROGENIC IMMUNODEFICIENCY-ASSOCIATED LYMPHOPROLIFERATIVE DISORDERS: A RETROSPECTIVE STUDY

Y. Nakajima1, S. Fujisawa2, C. Nigauri2, A. Matsumura1, T. Ando2, T. Suzuki2, E. Ogusa2, Y. Ishii2, K. Miyashita2, H. Takahashi1, T. Miyazaki1, K. Motohashi2, M. Hagihara1, K. Matsumoto1, E. Yamazaki3, H. Nakajima1

1Department of hematology and Clinical Immunology, Yokohama City University Graduate School of Medicine, 2Department of Hematology, Yokohama City University Medical Center, 3Clinical Laboratory Department, Yokohama City University Graduate School of Medicine, Yokohama, Japan

Background: Patients treated with immunosuppressive drugs (ISD) for autoimmune diseases are at an increased risk of developing other iatrogenic immunodeficiency-associated lymphoproliferative disorders (OI-LPD). Some patients with OI-LPD shows spontaneous regression after withdrawal of ISD, but some require chemotherapy. The factors that are associated with spontaneous regression and outcomes of chemotherapies remain uncertain.

Aims: The aims of our retrospective study are to assess the clinical factors that predict spontaneous regression of lymphoma after ISD withdrawal in patients with OI-LPD and to evaluate the outcomes of patients who underwent chemotherapy without spontaneous regression.

Methods: We collected data from all patients with autoimmune disease who were pathologically diagnosed with OI-LPD between January 2002 to October 2016 at Yokohama City University Hospital, and Yokohama City University Medical Center.

Results:

The patients included 12 males and 28 females, with a median age at diagnosis of 65 years (range 30-81). Methotrexate (MTX) was administered to all patients at any point of the clinical course before OI-LPD. The median time from diagnosis of autoimmune disease to OI-LPD development, and the median duration of MTX administration were 12 months (range 1-89 months) (range 4-297), respectively. The histological findings of OI-LPD were diffuse large B-cell lymphoma (DLBCL) in 26 patients, follicular lymphoma in 1, MALT in 2, peripheral T cell lymphoma, not otherwise specified in 3, and 2 patients with lymphoma presenting as extranodal lymphoma.

The patients with spontaneous regression after ISD withdrawal in patients with OI-LPD showed sIL-2R levels <2,400 U/mL, and the median duration of MTX administration were 129 months (range 11-564), and the median duration of sIL-2R administration were 65 months (range 3-240). The CR rates, 2-year PFS and OS of these 13 patients were 38%, 68.3%, and 82.1%, respectively.

Summary/Conclusions: Our study revealed that an sIL-2R level of <2,400 U/mL was significantly associated with spontaneous regression in patients with OI-LPD. Because CR rates with chemotherapy in patients without spontaneous regression are low, evaluation of sIL-2R in patients with OI-LPD may be useful for an early withdrawal of ISD, resulting in a higher chance of spontaneous regression.

E963

PROGRAMMED DEATH-1 PROTEIN EXPRESSION AND ITS RELATION WITH HISTOLOGIC AND CLINICAL VARIABLES IN MYCOSIS FUNGOIDES

C. Vasquez1, S. Novella2, A. Mozos1, P. Garcia Muret3, A.C. Caballero2, J. Sierra2, J. Briones3

1Pathology, 2Hematology, 3Dermatology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

Background: Mycosis fungoides (MF) is a T-cell malignancy with affinity for the skin. In early stages, treatment directed to the skin can induce long-lasting remissions. However, advanced stage MF may have short-duration remissions and progressive disease. The programmed death cell surface protein-1 (PD-1) is expressed on activated T cells. Interactions between PD-1 and its ligands control the induction and maintenance of peripheral T-cell tolerance during the normal immune response. These interactions may also play a role in the immune evasion of tumors in which PD-1 ligand is overexpressed.

Aims: To describe histologic characteristics and the proportion and intensity of PD1 expression by tumor cells, as well as the presence of PD1 positive lymphocytes in the epidermis in patients with MF. To identify histologic variables that might have an impact in clinical outcome.

CIRCULATING MICRORNAS AS BIOMARKERS IN DIFFUSE LARGE B-CELL LYMPHOMA: A PILOT PROSPECTIVE LONGITUDINAL CLINICAL STUDY

C. Bouvy1,*, A. Wannez1,2, C. Chatelain1, J.-M. Dogne1
1Department of Pharmacy, University of Namur, Namur, 2CHU UCL Namur, Université Catholique de Louvain, Yvoir, Belgium

Background: Diffuse large B-cell lymphoma (DLBCL) is highly heterogeneous in terms of phenotype and treatment response in patients. These characteristics make the prognosis difficult to establish and hinder the use of new personalized treatments in clinical practice. In this context, there is currently a necessity to define new biomarkers enabling a better definition of DLBCL subtypes, prognosis evaluation and an overview of the resistance to chemotherapeutics. We decided here to focus on circulating microRNAs that are found in all biological fluids. This accessibility makes them good candidates for biomarkers studies.

Aims: This research aims at studying microRNAs found in plasma from DLBCL patients and at investigating their potential as biomarkers of survival in these patients. For this purpose, a plasma biobank was created with samples from DLBCL patients at different times of their treatment. This follow-up of microRNAs level during the course of treatment is particularly innovative in this study.

Methods: A plasma biobank from DLBCL patients was set up at the Centre Hospitalier Universitaire (CHU) UCL Namur Yvoir, Belgium (ethical agreement number B303201419613). Informed consents of all patients were obtained. In this way, blood samples from patients were taken before any treatment (C0), at the administration of the second and the fourth chemotherapeutic cure (C2 and C4) and at the remission review (Cf). In the case of an autograft, a sample was taken at the post-graft review (Cpost). The first step of this study was the selection of the microRNAs that will be quantified in all the samples of the biobank and that would potentially be used as biomarkers. To this end, a quantification of 377 microRNAs was performed by TaqMan® Low Density Array on the plasma samples of two selected DLBCL patients and one healthy donor with no history of cancer. These DLBCL patients were selected based on their highly different response to treatment. One of them obtained a complete remission after a R-CHOP treatment, while the other presented a refractory disease to the same treatment. Thereafter, we determined some criteria to use in a scoring system to evaluate their potential as biomarkers. In this way, one point was given to a microRNA each time it meets the criteria enabling it to be defined as a potential diagnostic, prognostic and/or remission biomarker, biomarker of a disease progress, biomarker of an inherent resistance to treatment, and/or biomarker of an acquired resistance to treatment.

Results: On the 377 microRNAs quantified into the plasma of the 3 selected donors (2 DLBCL patients and 1 healthy donor), 81 microRNAs were detected. Three microRNAs obtained the highest score of 5 points: miR-197, miR-20a and miR-451. Four points were attributed to miR-122, miR-19b and miR-19a. Two additional microRNAs were also selected: let-7e, for its prognostic value at C0, C2 and C4 and miR-21, for its numerous citations in the literature.

Conclusion: The purpose was to evaluate the prognostic factors and treatment outcome of patients with diffuse large B-cell lymphoma (DLBCL) of the tonsil. Methods: In all, 114 patients with DLBCL of the tonsil with stage I or stage II, treated at multicenter in Korea, from September 1995 to April 2011, were included. The median age was 59 years and the majority of patients (61%) were male. Symptomatic symptoms were present in 6% of patients. International prognostic index (IPI) score was 0 in 54 patients (48%), 1 in 40 (35%), 2 in 14 (12%), and 3 (3%). Ten patients (8%) showed elevated level of lactate dehydrogenase (LDH). Treatment consisted of a combination of chemotherapy (CTX) and radiotherapy (RTx) for 38 patients (34%) and 72 patients (65%) received CTx only. Among those receiving RTx, the median RTx dose was 39 Gy. Results: After median follow-up of 32 months (range 0.4–106 months), event free survival (EFS) and overall survival (OS) were 25.9% and 42.5%, respectively. Significant prognostic factors included: age ≥60 year-old vs <60 year-old, LDH level (> upper normal limit and supper normal limit), IPI score (0-1 vs 2-3), and treatment (CTX plus RTx vs CTx only). On multivariate analysis: LDH level (hazard ratio [HR], 10.522; 95% confidence interval [CI], 2.548–43.449, p=0.001) and treatment (HR, 12.393; 95% CI 2.151-71.410) were independent prognostic factor of EFS and age (HR, 8.920; 95% CI 1.089-73.053, p=0.043), LDH (HR, 8.316; 95% CI 1.914-36.127, p=0.005), and treatment (HR, 8.943; 95% CI 1.089-73.425) retained statistical significance in OS.

Figure 1.

Summary/Conclusion: LDH level and age significantly influence outcome. A combined modality treatment, consisting of CTx and RTx, results in a satisfactory outcome in patients with stage I or II DLBCL of the tonsil.

E965

COMBINED CHEMOTHERAPY PLUS RADIATION THERAPY IS MORE EFFECTIVE IN LIMITED-STAGE DIFFUSE LARGE B-CELL LYMPHOMA OF THE TONSILS.

S.-N. Lim1,∗
1Internal Medicine, Haeundae Paik Hospital, Busan, Korea, Republic Of

Background: Primary extranodal non-Hodgkin’s lymphomas of the head and neck account for 10-20% of all non-Hodgkin’s lymphomas. Primary tonsillar lymphoma accounts for less than 1% of head and neck malignancies, although the tonsil is the most common primary extranodal site of head and neck non-Hodgkin’s lymphomas.

Aims: The purpose was to evaluate the prognostic factors and treatment outcome of patients with diffuse large B-cell lymphoma (DLBCL) of the tonsil.

Methods: In all, 114 patients with DLBCL of the tonsil with stage I or stage II, treated at multicenter in Korea, from September 1995 to April 2011, were included. The median age was 59 years and the majority of patients (61%) were male. Systemic symptoms were present in 6% of patients. International prognostic index (IPI) score was 0 in 54 patients (48%), 1 in 40 (35%), 2 in 14 (12%), and 3 (3%). Ten patients (8%) showed elevated level of lactate dehydrogenase (LDH). Treatment consisted of a combination of chemotherapy (CTX) and radiotherapy (RTx) for 38 patients (34%) and 72 patients (65%) received CTx only. Among those receiving RTx, the median RTx dose was 39 Gy.

Results: After median follow-up of 32 months (range 0.4–106 months), event free survival (EFS) and overall survival (OS) were 25.9% and 42.5%, respectively. Significant prognostic factors included: age ≥60 year-old vs <60 year-old, LDH level (> upper normal limit and supper normal limit), IPI score (0-1 vs 2-3), and treatment (CTX plus RTx vs CTx only). On multivariate analysis: LDH level (hazard ratio [HR], 10.522; 95% confidence interval [CI], 2.548–43.449, p=0.001) and treatment (HR, 12.393; 95% CI 2.151-71.410) were independent prognostic factor of EFS and age (HR, 8.920; 95% CI 1.089-73.053, p=0.043), LDH (HR, 8.316; 95% CI 1.914-36.127, p=0.005), and treatment (HR, 8.943; 95% CI 1.089-73.425) retained statistical significance in OS.

CLINICAL RELEVANCE OF SARCOPENIA IN DIFFUSE LARGE B-CELL LYMPHOMA - TWO ARE BETTER THAN ONE

S.-I. Go1, M.J. Park2, G.-W. Lee1,*
1Internal Medicine, 2Radiology, Gyeongsang National University School of Medicine, Jinju, Korea, Republic Of

Background: Sarcopenia is known to be associated with poor clinical outcome in patients with diffuse large B-cell lymphoma (DLBCL). There is no consensus concerning the optimal method to define sarcopenia in DLBCL.

Aims: In this study, given the uncertainty about the optimal SMI to define clinically meaningful sarcopenia in DLBCL, we compared the characteristics and clinical outcome between sarcopenic patients determined by L3 skeletal muscle index (L3-SMI) and those determined by pectoralis muscle SMI (PM-SMI) who were treated with R-CHOP21 and more intensively treated patients; there was no difference in age, gender, stage, elevated LDH or PS ≥2. Patients receiving R-CHOP had similar response rates as those receiving more intensive regimens (80% vs 85%, P=0.405), but inferior EFS (HR 2.12, 95% C.I. [1.09-4.12], P=0.028) and OS (HR 2.15, 95% C.I. [1.07-4.3], P=0.034) (Figure 1). 5-year EFS rates were 48% and 76% and 5-year OS rates 80% and 90% for R-CHOP21- and more intensively treated patients, respectively. Differences in outcomes between R-CHOP and intensified regimens remained significant in a multivariate Cox regression model adjusted for age, gender and presence of bulky disease (HR 2.45, 95% C.I. [1.11-5.4], P=0.019 for EFS).

INTENSIFIED TREATMENT REGIMENS IMPROVE EVENT-FREE AND OVERALL SURVIVAL IN YOUNGER NEWLY DIAGNOSED HIGH-RISK PATIENTS WITH B-LARGE CELL LYMPHOMA: A MULTICENTRE OBSERVATIONAL STUDY OF KROHEM

S. Basic-Kinda1,*, M. Lucijanic2, I. Hude1, Z. Prka2, Z. Mitrovic2, I. Radman1, T. Valkovic34, D. Radic-Kristo36, D. Lozic1, D. Nemet8, V. Pejsa29, I. Aurer19, 1Division of Hematology, Department of Internal Medicine, University Hospital Centre Zagreb, 2Division of Hematology, Department of Internal Medicine, University Hospital Dubrava, Zagreb, 3Division of Hematology, Department of Internal Medicine, University Hospital Centre Rijeka, 4Medical School, University of Rijeka, Rijeka, 5Division of Hematology, Department of Internal Medicine, University Hospital Merkur, Zagreb, 6Medical School, University of Osijek, Osijek, 7Division of Hematology, Department of Internal Medicine, University Hospital Centre Split, Split, 8Medical School, University of Zagreb, Croatia

Background: Standard therapy for newly diagnosed B-large cell lymphoma (B-LCL) is R-CHOP. Patients with high-risk disease have unsatisfactory outcome. Non-randomized trials have suggested that intensified regimens, such as R-CHOEP14 and DA-R-EPOCH, improve treatment results in younger patients.

Aims: We performed this analysis to compare response rates, event-free (EFS) and overall survival (OS) rates of newly diagnosed patients with high-risk disease treated with R-CHOEP21 and more intensive regimens (R-CHOEP14 and DA-R-EPOCH).

Methods: Outcomes of B-LCL patients younger than 60 with aaIPI ≥2 treated at two different centres with R-CHOEP14 and DA-R-EPOCH were collected retrospectively from patient files and compared to outcomes of patients with same characteristics treated with R-CHOEP21 from the registry of KroHem, the Croatian Cooperative Group for Hematologic Diseases. All three regimens were administered according to standard guidelines for 6-8 cycles. Patients in PR or with initial bulky disease were irradiated after the end of systemic treatment. Twelve patients treated with DA-R-EPOCH were autografted in 1st remission.

Results: 54 patients were treated with R-CHOEP21, 40 with R-CHOEP14 and 22 with DA-R-EPOCH. R-CHOEP14 and DA-R-EPOCH treated patients did not differ in response rates, EFS and OS and were grouped together for further analysis. R-CHOP treated patients had less frequently bulky disease (25% vs 49%, P=0.007) than more intensively treated patients; there was no difference in age, gender, stage, elevated LDH or PS ≥2. Patients receiving R-CHOP had similar response rates as those receiving more intensive regimens (80% vs 85%, P=0.405), but inferior EFS (HR 2.12, 95% C.I. [1.09-4.12], P=0.028) and OS (HR 2.15, 95% C.I. [1.07-4.3], P=0.034) (Figure 1). 5-year EFS rates were 48% and 76% and 5-year OS rates 80% and 90% for R-CHOP21- and more intensively treated patients, respectively. Differences in outcomes between R-CHOP and intensified regimens remained significant in a multivariate Cox regression model adjusted for age, gender and presence of bulky disease (HR 2.45, 95% C.I. [1.11-5.4], P=0.019 for EFS).

Moreover, comorbidities contribute to inferior survival through frailty, drug CL patients, and can better describe patients within risk groups, compared to Summary/Conclusions:

months

Background: A few studies have validated the prognostic significance of the NCCN International Prognostic Index (NCCN-IPI) so far. However, some patients with low risk according to NCCN-IPI have poor survival, and thus clinical parameters, that might better characterized patients within risk groups, need to be explored, respectively.

Aims: The aim of this study was to evaluate prognostic significance of current indexes such as International Prognostic Index (IPI), NCCN-IPI, and the influence of comorbidities on the overall survival (OS) of patients with newly diagnosed diffuse large B cell lymphoma (DLBCL).

Methods: A total of 708 patients (383 males/345 females) with the median age of 58 years (range 18-89) were included in the study. Majority of patients received R-CHOP (Rituximab, Cyclophosphamide, Doxorubicine, Vincristine, Prednisone), Prednisone) protocol, 652 (92.1%), while 29 (4.1%) received R-EPOCH (Rituximab, Etoposide, Cyclophosphamide, Doxorubicine, Vincristine, Prednisone), and 27 (3.8%) received R-CVP (Rituximab, Cyclophosphamide, Vincristine, Prednisone).

Results: According to the Ann Arbor classification, stage I and II had 332 patients (46.9%), while stage III and IV had 376 patients (53.1%). Bulky disease was present in 201 patients (28.4%), and B symptoms in 437 patients (61.7%). Poor European Cooperative Oncology Group (ECOG) performance status ≥2 had 145 patients (20.5%). Bone marrow involvement was present in 97 patients (13.7%). At least one comorbid condition had 309 patients (43.6%), while high Charlson Comorbidity Index (CCI) had 44 patients (6.2%). Majority of patients had cardiovascular disorders (223, 31.5%), endocrinological (63, 8.9%), pulmonary (18, 2.5%), psychiatric (13, 1.8%), nephrotic (8, 1.1%), autoimmune (6, 0.8%), and other (13, 1.8%). According to IPI, low, low intermediate, high intermediate and high risk had 332 patients (46.9%), 174 (24.6%), 132 (18.6%), and 70 (9.9%), respectively, while according to NCCN-IPI, 139 (19.6%) patients had low risk, 335 (47.3%) low intermediate, 198 (28.0%) high intermediate, and 70 (9.9%) high risk. Overall treatment response (ORR) was achieved in 615 patients (86.9%). Disease relapse was confirmed in 116/615 patients (18.9%). The patients with B symptoms (Log Rank=18.95, p<0.0001) and bulky disease (Log Rank=14.79, p<0.0001) had inferior OS compared to those without B symptoms or bulky disease. All parameters incorporated in IPI, as well as in NCCN-IPI, were significantly associated with OS (p<0.01). Moreover, the patients with at least one comorbidity had inferior OS (Log Rank=5.41, p=0.20), as well as those with high CCI ≥2 (Log Rank =7.59, p=0.006). Regarding OS, IPI (Log Rank=97.36, p<0.0001), and NCCN-IPI (Log Rank=102.29, p<0.0001) confirmed its prognostic significance. Furthermore, the patients with high CCI had significantly inferior median OS in the high risk group according to IPI (19 months vs 37 months), and NCCN-IPI (12 months vs 19 months).

Summary/Conclusions: NCCN-IPI represents useful prognostic index in DLBCL patients, and can better describe patients within risk groups, compared to IPI. Moreover, comorbidities contribute to inferior survival through frailty, drug dose reduction and poorer tolerability.

E970

HIGH COMORBIDITY INDEX ALONG WITH HIGH NCCN-IPI STRONGLY INFLUENCE SURVIVAL OF DIFFUSE LARGE B CELL LYMPHOMA PATIENTS: SERBIAN LYMPHOMA GROUP EXPERIENCE

J. Jelicic1,2, D. Antić3, M. Todorovic Balint4, B. Andjelic2, O. Markovic3, I. Petkovic4, V. Nikolic3, J. Bilja2, V. Djurasinovic2, A. Sretenovic1, V. Vukovic1, M. Smiljancic1, S. Sretenovic5, B. Mihanovic6, I. Aurer16

Clinical Department of Hematology, Clinical Center of Serbia, 2Clinical Center of Serbia, University of Belgrade, Clinic of Hematology, 3Clinical Hospital Center “Bezanijska Kosa”, University of Belgrade, Belgrade, 4Clinic of Oncology, University Clinical Center Nis, 5Clinic of Hematology, Clinical Center Nis, Nis, 6Clinic of Hematology, Clinical Center Kragujevac, Kragujevac, Serbia

Background: We performed a retrospective analysis of all newly diagnosed B-LCL patients treated with R-CEOP at our centre from 2011 to 2016 and compared them to patients 60 years or older treated during the same period with R-CHOP, the standard regimen used at our centre for non-frail elderly without significant cardiac comorbidities. The dose of etoposide in R-CEOP was 50mg/m2 iv or 100mg/m2 orally for 3 days. Both regimens were given every 3 weeks for 6-8 cycles. Patients with initial bulky disease or in PR after systemic treatment were irradiated.

Results: 31 patients, 15 male and 16 female, received R-CEOP and 48, 25 male and 23 female, R-CHOP. Patients in the former group were older (median age 77 y, range 58-87 vs median age 66 y, range 60-83), had more often low performance status (81% vs 31%) and advanced disease (84% vs 54% stage 3 and 4) resulting in a significantly higher proportion of patients with IPI 3-5 (74% vs 40%, p=0.019). Proportions of patients with increased LDH were similar between the groups. There were no significant differences in frequency of grade 3-4 toxicity between the regimens; 48% of patients in both groups required emergency hospitalization; thrombocytopenia or anemia occurred in 16% of R-CEOP and 23% R-CHOP treated patients, infections in 32% and 31% and cardiovascular events in 16% and 21%. However, 7 patients (23%) in the R-CEOP group died during treatment due to adverse effects in comparison to 4 (8%) in the R-CHOP group. Efficacy was similar, 65% responded to R-CEOP and 79% to R-CHOP. After a median follow-up of survivors of 27 mo, 3-y OS was 55% in the R-CEOP group and 52% in the R-CHOP group, 3-y EFS was 50% and 50%, respectively (figure). Outcomes of patients with GC and non-GC DLBCL categorized according to Hans’s algorithm were similar irrespective of treatment.

E969

SUBSTITUTING DOXORUBICIN WITH ETOPOSIDE IN R-CHOP RESULTS IN A REGIMEN WITH SIMILAR EFFICACY FOR TREATMENT OF NEWLY DIAGNOSED ELDERLY PATIENTS WITH B-LARGE CELL LYMPHOMA (B-LCL)

I. Hude1,*, D. Antić2, S. Basic-Kinda1, I. Radman1, S. Dotlic3, M. Kralik3, M. Vodanovic1, P. Rosic1, L. Galunic-Bilic 4, M. Dobrenic 5, A. Ostojić 1, D. Dujmović 6, M. Smiljanić1, S. Sretenović5, B. Mihanović6, I. Aurer16

1Division of Hematology, Department of Internal Medicine, 2Department of Pathology and Cytology, 3Department of Radiology, 4Department of Oncology, 5Department of Nuclear Medicine, University Hospital Centre Zagreb, 6Medical School, University of Zagreb, Zagreb, Croatia

Background: R-CHOP is standard front-line treatment for B-LCL. However, anthracycline-induced cardiac toxicity limits its use in elderly and patients with preexisting heart disease. R-CEOP, in which doxorubicin is substituted with etoposide, has been suggested as a potential solution of this problem, but reports on the efficacy of this regimen vary substantially, especially in patients with non-GC DLBCL. We have been using this regimen regularly for front-line treatment of patients with B-LCL and preexisting heart disease and present here our experience.

Summary/Conclusions: Long-term outcomes of newly diagnosed B-LCL patients treated with R-CEOP seem as good as those achieved with R-CHOP irrespective of cell of origin. Observed differences in treatment-related mortality were most probably caused by differences in age, comorbidities and performance status. R-CEOP should be considered as a regimen of choice for B-LCL patients with cardiac contraindications for anthracycline treatment.
POST-TRANSPLANT LYMPHOPROLIFERATIVE DISORDERS: A SINGLE-CENTER CASE SERIES

C. De Miguel1, B. Navarro1, J. Martín2, P. Martín2, G. Anze1, A. Alarcón1, R. Forés1, C. Bellas2, J.R. Cabrera1

1Hematology, 2Pathology, Hospital Universitario Puerta de Hierro Majadahonda, Majadahonda, Spain

Background: Post-transplantation lymphoproliferative disease (PTLD) is a complication of both solid organ transplant (SOT) and haematopoietic cell transplant (HCT) and represent a very heterogeneous group.

Aims: The objective of this study is to evaluate the epidemiology, clinical features, characterization and therapeutic management of this disease.

Methods: We evaluated a total of 52 patients diagnosed between May 1995 and February 2017. We analyzed the following data: type of transplantation, immunosuppression time from transplantation to lymphoma diagnosis, clinical stage, response to treatment and survival. We classified them morphologically according to the WHO criteria (2016 revision), using immunohistochemical and molecular techniques and their relationship with the Epstein-Barr virus (EBV) by studying the expression of EBERs. We correlated clinical data with morphological, immunohistochemical and molecular results.

Results: Among the 52 patients, 31 were men (59.6%) and 21 women. PTLD after SOT were 45 (86.5%), of which 16 were after liver transplant (35.6%), 14 cardiac (31.1%), 9 pulmonary (20%), 4 renal (8.9%) and 2 double (cardiac-pulmonary and cardiac-renal) (4.4%). There were 7 PTLD after HCT, 2 identical HLA family donor, 2 unrelated donor, 2 dual umbilical cord blood and 1 autologous. Of the 52 PTLD, 48 were B lymphomas (92.3%), of which 26 were diffuse large B-cell lymphomas (DLBCL) (54.2%), 7 polymorphic (14.6%), 7 low-grade (14.6%), 4 Burkitt lymphomas (8.3%), 1 Hodgkin’s lymphoma (2.1%) and 1 T/NK non-classifiable. Other 4 PTLD were T lymphomas (6.7%), 2 anaplastic, 1 T/NK lymphoma, and 1 gamma/delta T lymphocytosis. 35/52 PTLD were EBV + (67.3%). The median time of immunosuppression was 123 months in renal transplant, 93 months in liver, 85.5 months in cardiac, 51 months in lung and 3 months in HCT. Histologically, it was 96 months in T lymphomas and 80 months in B lymphomas, being 51 months in EBV + and 124 months in EBV-.

Summary/Conclusions: PTLD constitute a very heterogeneous group. Its appearance is much earlier in the HCT than in the SOT and, within this latter group, it is earlier after lung transplant and later after renal transplant. The most common type in our series is DLBCL. The majority are related to EBV, so post-transplant monitoring is essential, and its diagnosis is earlier than in EBV-. Most low-grade lymphomas appear post-liver transplant, either in relation to virus reactivation or autoimmune diseases. Survival is significantly lower than in other primary LPS. -AR-SA-We analyzed the following data: type of transplantation, immunosuppression used in both induction and maintenance, immunosuppression time from transplantation to lymphoma diagnosis, clinical stage, response to treatment and survival. We classified them morphologically according to the WHO criteria (2016 revision), using immunohistochemical and molecular techniques and their relationship with the Epstein-Barr virus (EBV) by studying the expression of EBERs. We correlated clinical data with morphological, immunohistochemical and molecular results.

AN EXPERIENCE WITH LONG ACTING FACTOR VII PHOPHYLAXIS IN PAEDIATRIC AND YOUNG ADULT PATIENTS WITH HAEOMOPHILIA A

S. Verma1, A. Tripathi1, G. Suni1, N. Kumar1, R. Kushwaha1, A. Kumar1, P. Kumar1

1K G. Medical University Lucknow, Lucknow, India

Background: Hemophilia is an X linked inherited bleeding disorder. Recurrent Joint bleeds and muscle bleeds are the comon manifestations leading to long term comorbidities in hemophilia. High dose factor prophylaxis has been proven to be very effective in preventing joint problems in western world. We look for a cost effective and feasible way for Indian patients in terms of reduced dose and frequency of factor infusion. Data on prophylaxis with low dose long acting factor infusion on twice weekly dosage schedule is limited.

Aims: To study the efficacy and safety of long acting factor VII (Elocote) for tertiary prophylaxis in pediatric and young adult patients with moderate and severe haemophilia A.

Methods: Thirty eight patients with moderate and severe haemophilia A without inhibitors and age range from 1 to 25 years were included in this study. Patients were initially observed for 4 months during which they received therapeutic doses of long acting factor VII, ELOCTATE (Factor VII with Fc Fusion Protein) on episodic basis after clinical bleed. In next 4 months they received prophylactic ELOCTATE, given intravenously at doses of 20 unit/kg body weight on twice weekly schedule. Annual bleeding rates, school absenteeism, emergency visits aspects of quality of life and joint scores were compared during observation and prophylaxis period.

Results: Total number of bleeds during observation and prophylaxis period was 607 and 90 respectively. Annual bleeding rate was 47.9 during observation period and 7.1 during prophylaxis. There was 85.1% reduction in bleeding rates on prophylaxis. School/college absenteeism was 3.1 days/month and 0.84 days/month during observation and prophylaxis respectively. Emergency visits were significantly more during observation. None of the patients developed inhibitors and two patients had superficial thrombophelbitis during prophylaxis. Quality of life assessment using KIDSCREEN QOL questionnaire showed moderate to marked improvement in quality of life domains during prophylaxis.

Summary/Conclusions: Low dose, twice a week, long acting factor VIII prophylaxis can be a reasonable option for patients with haemophilia A in developing countries. It significantly reduces joint bleeds, school absenteeism, Joint scores significantly without risk of inhibitor formation and also improves all domains of quality of life.

E975

NOVEL MUTATIONS IN THAI CHILDREN WITH CONGENITAL FACTOR VII DEFICIENCY

D. Sosothikul1,*, T. Pusongchai1, R. Ittiwut1, P. Komvilaisak2, C. Traivaree3

1Hematology and Oncology, University of Cincinnati Medical Center, Cincinnati, OH, USA, 2Department of Pediatrics, Chulalongkorn University, Bangkok, Bangkok, 3Department of Pediatrics, Phramongkutklao Hospital and College of Medicine, Bangkok, Bangkok, Thailand

Background: Congenital factor VII (FVII) deficiency is a rare autosomal recessive coagulation disorder resulted from mutations in the FVII gene (F7). The disease severity is not correlated with FVII levels but might be determined by molecular defects in F7.

Aims: To delineate the phenotypic and genotypic characteristics of patients with congenital FVII deficiency.

Methods: We described demographic data, clinical manifestations, and outcome of patients with congenital FVII deficiency. F7 mutation analysis was performed by PCR-direct sequencing.

Results: Of the ten patients diagnosed with FVII deficiency, five (50%) were males. The median age (range) at diagnosis was 19 days old (1-730). Consanguinity was found in 50% of the patients. Of the nine patients (90%) classified as severe, six patients presented with intracerebral hemorrhage within the first month of life, two presented with gastrointestinal bleeding and one presented with hemarthrosis. There were eight different alterations identified. Four have been previously reported (c.1091G>A (p.R364Q), c.1238G>A (p.R413Q), c.1265C>T (p.T419M), and c.681G>T (IVS6+1T)). Four were novel (c.1192C>T (p.D398Y), c.1313G>T (p.G420V), c.291+2T>C (IVS3+2T>C), and IVS6-2A>G) and associated with major bleeding especially during infancy.

Summary/Conclusions: This study reported Thai children with congenital FVII deficiency presented with life-threatening bleeding especially in the first year of life. Pathogenic including newly identified variants in the F7 gene were detected in all cases. Genetic counseling can be appropriately provided to reduce the risk of disease recurrence in the families at risk.

RETROSPECTIVE EVALUATION OF PHENOTYPE AND MANAGEMENT OF A-HYPO-FIBRINOGENEMIA IN A COHORT OF ITALIAN PATIENTS

C. Santoro1,*, F. Massaro2, E. Mozzillo2, S. Basosi3, E. Bortolameotti3, G. Ferrara1, A. Ferre1, F. Pasca1, C. Mazzucchelli1, M. Santoro2, S. Pasca3, G. Castaman4, F. Peyer5, R. Foà6, M.G. Mazzuccconi1

1Cellular Biotechnology and Hematology, Hematology Sapienza University, Rome, 2Oncohaematology Department, Haemostasis and Thrombosis Services, Policlinico Pugliese-Ciaccio Hospital, Catanzaro, 3Center for Hemorhagic and Thrombotic Diseases, University Hospital of Udine, Udine, 4Center for Bleeding Disorders, Careggi University Hospital, Florence, 5Angelo Bianchi Bonomi Hemophilia and Thrombosis Center, Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, University of Pathophysiology and Transplantation, University of Milan, Milan, Italy

Background: A-hypofibrinogenemia (AF) and hypofibrinogenemia (HF) patients (pts) experience hemorrhages or thromboses, and the clinical management can be difficult.

Aims: To obtain information on AF/HF clinical phenotype and management.

Methods: This is a spontaneous, retrospective, multicenter national study. Data are collected from clinical records.

Results: 2 AF and 12 HF pts have been enrolled (6M, 8F). Median follow-up: 39 months (1-553). Median fibrinogen activity/antigen level: 78mg/dL (0-150)/73mg/dL (0-140). Five pts experienced epistaxis, hematomas, ecchymoses, menometrorrhagia, intra-abdominal bleeding, gum hemorrhagia. Fresh frozen plasma, fibrinogen concentrate (FC), cryoprecipitate, whole blood, tranexamic acid were administered in the majority of these events. One ischemic stroke, 1 lower limb arterial and 1 cerebral sinus thrombosis, 1 concomitant aortic and inferior vena cava thrombosis occurred: 3 events during FC therapy, 1 during puerperium. Heparin, low molecular weight heparin (LMWH), anti-platelet agents, fibrinolytic agents, warfarin were then administered. One gastrectomy, 1 lower limb amputation, 5 gynecological, 1 otorhinolaryngological and 1 plastic surgery were performed in 2AF and 3 HF pts: in AF 5 and 0 respectively, in HF 2 and 3 respectively. One venous thrombosis, 2 hemorrhages, 1 DIC and 4 complicated pregnancies were recorded. FC was administered at delivery and LMWH during puerperium, for the 2 CS. No complications at delivery occurred.

Summary/Conclusions: AF and severe HF pts experience severe hemorrhagic/thrombotic events. The intervening clinical situations are difficult to manage. Further large scale data collections are necessary in order to provide useful information to better characterize and manage patients suffering from these rare diseases.

E977

RETROSPECTIVE REVIEW OF FOUR YEARS OF VON WILLEBRAND’S FACTORS AS SURGICAL PROPHYLAXIS IN VON WILLEBRAND’S DISEASE: S. Bai1, M. K. Ria2, D. Peters3, J. Palascak4, S. Girmas5

1Hematology and Oncology, University of Cincinnati Medical Center, Cincinnati, Ohio, United States

Background: Von Willebrand disease (vWD) is the most common inherited bleeding disorder that manifests as easy bruising, mucocutaneous bleeding and excessive hemorrhage with invasive procedures. In 2007, Humate-P, a lyophilized concentrate of purified VWF and FVIII, was approved in the United States for treatment and prophylaxis. Current guidelines per National Heart, Lung, and Blood Institute (NHLBI) Expert Panel recommend 40-60 U/kg pre-operatively, followed by maintenance dose of 20-40 U/kg for 7-14 days for major surgery and 5 days for minor surgery. Here, we report a single-institution experience of a short course of Humate-P as surgical prophylaxis.

Aims: To assess if an abbreviated schedule of Humate-P given as perioperative dosing of Humate-P 40 U/kg pre for 2 days (one dose pre-op and one post-op) for one pre-op and one post-op for definitive dental procedures and for 4 days (one dose pre-op and 3 days post-op) for minor and major surgical procedures as surgical prophylaxis would result in equivocal efficacy without compromising patient outcomes.

Methods: We retrospectively identified 202 patients with known diagnosis of vWD at our institution that underwent surgical procedures requiring prophylaxis between 2002-2017. Ninety elective surgical events occurred among these patients that required peri-operative prophylaxis with Humate-P. These patients were treated with peri-operative dose of 40 U/kg on D0-1 for extensive dental interventions, D0-4 for D3-5 for minor and D0-3 for D5-7 for major surgery. The definition of bleeding risk was based on NHLBI guidelines.

Results: Eighteen (20%) were males and 72 (80%) were females. Type I vWD constituted 94.4% (85/90). 84.4% Caucasian patients, 8.8% African American, 1.1% South Asian. Twenty-nine (32.2%) procedures were categorized as major operations (36.6%) were minor surgical procedures. Eighty-four (93.3%) achieved excellent hemostatic efficacy defined as clinical hemostasis within normal limits. Six (6.6%) surgeries had good hemostatic efficacy defined as slight oozing. Five (6%) patients required blood transfusions.
Six (38%) patients have 2 mutant alleles and three mutations were recurrently identified. The most frequent mutation detected in this study was Cys389Gly detected in 37% (11/30) patients, validating the data of our previous patient cohort.

**Summary/Conclusions:** Correlation of genetic data with coagulation laboratory and clinical findings suggested the presence of modifiers, which warrants further investigation in a larger cohort of patients for better clinical prediction and management in this rare bleeding disorder.

**AUDIT ON MANAGEMENT OF HIGH INTERNATIONAL NORMALIZED RATIO (INR) IN WARFARINISED INPATIENTS**

H. Hendra1, V. Gorur1,*, W. Nagi1

1Haematology, Broomfield Hospital, Chelmsford, United Kingdom

**Background:** Warfarin is the commonest used oral anticoagulant with an effective anticoagulant. The British Committee for Standards in Haematology guidelines recommend administration of 25-50µg of four factor Prothrombin Complex Concentrate (PCC) and intravenous (IV) Vitamin K 5mg for patients with major bleeding, 1-3mg of Vitamin K intravenously for those with minor bleeding and 1-5mg of Vitamin K orally for patients with INR >8 and who have no signs of bleeding.

**Aims:** The aim of this audit was to compare our hospital’s performance against the above guidelines.

**Methods:** A total of 76 patients admitted between 01/08/2015-31/01/2016 were analysed retrospectively.

**Results:** There were 103 incidents with INR level 5-8 and 24 with INR >8 in these 76 inpatients. Bleeding was documented in 18/127 cases, which included 6 incidents of major and 12 incidents of minor bleeding. In major bleeding, warfarin was withheld and Vitamin K administered. However, 4/6 (66.7%) of these patients got a dose different to 5mg advocated. Also, PCC was prescribed in only 50% of these patients. While 9/12 (75%) patients with minor bleeding received Vitamin K, only 3 of these 9 patients received the recommended dose of 1-3mg IV. Vitamin K was unnecessarily given to 9/83 (10.8%) non-bleeders with an INR between 5-8. Additionally, the recommended dose and route of administration of Vitamin K 1-5mg PO was followed only in 7/16 (44%) of non-bleeders with INR >8.

**Summary/Conclusions:** Our audit highlighted that there is less than 100% compliance in the recommended dose and route of vitamin K administration. A flowchart containing the guidelines will be designed to improve the management of high INR. To increase the awareness of this issue, teaching sessions for junior doctors and nursing staff are planned. A re-audit will be conducted once these steps are in place.

**NOVEL AND RECURRENT F7 MUTATIONS IN KOREAN PATIENTS WITH COAGULATION FACTOR VII DEFICIENCY**

H. Kim1, K.-Y. Yoo2, K.-O. Lee3, S.-H. Kim1, H.-J. Kim1

1Laboratory Medicine & Genetics, Samsung Medical Center, Sungkyunkwan University School of Medicine, 2Korea Hemophilia Foundation, 3Samsung biomedical Research Institute, Seoul, Korea, Republic Of

**Background:** Coagulation factor VII deficiency is one of rare hereditary bleeding disorders with relatively limited clinical and genetic data. This study aimed to characterize F7 gene mutational patterns of Korean patients with coagulation Factor VII deficiency including their clinical and laboratory variability.

**Methods:** F7 gene mutations of total 16 unrelated Korean patients with Factor VII deficiency were identified by direct sequencing analyses of all exons and flanking intronic sequences. Variants were assigned according to the recently released criteria of 2015 ACMG standards and guidelines.

**Results:** A total of 14 mutations (pathogenic or likely pathogenic) were detected including four novel mutations (Glu66Lys, c.681+3A>T, Glu66Alafs, ile290del).

UTILITY OF CD157 IN A FLAER BASED SINGLE TUBE FIVE COLOR COMBINATION FOR SCREENING OF PAROXYSMAL NOCTURNAL HEMOGLOBINURIA CLONE

K. Rahman1, R. Gupta1, S. Harankhedkar1, T. Gupta1, M. Sarkar1, S. Nityanand1
1Hematology, Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India

Background: Fluorescent Aerolysin (FLAER) based flow cytometric analysis of polymorphs and monocytes is the gold standard for the screening of paroxysmal nocturnal hemoglobinuria (PNH) clone. In recent years CD157 has been identified as a PNH marker which targets both polymorphs and monocytes. It can be used in a single tube five color combination to screen polymorphs and monocytes simultaneously.

Aims: The objective of this study was to analyse the utility and advantage of CD157 in the PNH screening along with its ability to replace CD24 and CD14.

Methods: Our routine protocol for PNH screening included single tube six color antibody cocktail in following combination: FLAER-AF488, CD24-PE, CD15-PerCP-Cy5.5, CD14-PerC7, CD64-APC, CD45-APC H7. We assessed the utility of single tube 5 color combination of FLAER-AF488, CD157-PE, CD15-PerCP-Cy5.5, CD64-APC, CD45-APC H7 for PNH screening and compared the results with the routinely used 6 color panel. Laboratory cutoff for CD157 was defined by running 10 samples from healthy individuals. Sensitivity analysis was assessed in spiking experiments by diluting a PNH positive sample with normal sample. The results obtained from CD157 were assessed by analysing a total of 30 samples across a wide range of PNH clone size (0.06-97.3%).

Results: CD157 was sensitive at the level of 10^{-4} and better. Frequency of cells with PNH phenotype in normal samples were found to be <0.002%. The CVs of intra-assay precision analysis ranged from 0.92/6.1 to 3.2/1.64% for granulocytes and 1.92/5 to 5.3/6.8% for monocytes. The PNH clone size, as obtained by CD157 based analysis was highly comparable to those obtained by CD24/CD14 based assay (R²>0.993). CD157 was found much better than CD24/CD14 based assay (R2>0.993). CD157 was sensitive at the level of 10^{-4} and better. Frequency of polymorphs and monocytes is the gold standard for the screening of paroxysmal nocturnal hemoglobinuria (PNH) clone. In recent years CD157 has been identified as a PNH marker which targets both polymorphs and monocytes. It can be used in a single tube five color combination to screen polymorphs and monocytes simultaneously.

Figure 1.

Summary/Conclusions: CD157 is a robust, reliable and potentially useful universal marker for PNH screening. Its inclusion in a single tube five color FLAER based panel is a cost effective approach which is ready to replace CD24/CD14 from routine PNH screening.

E982

IMMUNOPHENOTYPIC DYSPLASTIC FEATURES IN PATIENTS WITH APLASTIC ANEMIA

Y. Davydova1,2, E. Parovichnikova1, I. Gaitseva1, E. Mikhaylova1, N. Kapranov1, A. Kohno1, L. Kuzmina1, V. Troitskaya1, Z. Fidarova1, T. Moiseeva1, V. Savchenko1
1Federal State-Funded Institution National Research Center for Hematology of the Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation

Background: Multicolor flow cytometry (MFC) of bone marrow (BM) is a promising additional approach to the diagnosis of myelodysplastic syndromes (MDS). Aplastic anemia (AA) as MDS characterizes by cytopenias and dysplastic features in BM by morphology are absent. It is well known that up to 15% of AA transformed in MDS over time. It is possible to suggest that in some cases of AA immunophenotypic abnormalities can also be identified.

Aims: To study and compare the presence of dysplastic features by MFC in AA and MDS without excess of blasts.

Methods: The study included 14 patients with AA (8m, 6f, median age 33), 28 patients with MDS de novo without excess of blasts by morphology (13m, 15f, median age 59). MDS group included 3 patients with 5q-syndrome, 4 - RCUD, 3 - RARS, 18 - RCMD. 20 patients with cytopenias constituted the control group (4m, 16f, median age 42) due to B-12 deficiency anemia, iron-deficiency anemia, Fanconi anemia, hemolytic anemia, β-thalassemia, ITP, hepatitis C, multiple myeloma. In the majority of cases patients with premalignant syndrome of AA (Burkitt's lymphoma, BM of 33 healthy donors were analyzed as normal control group. The final MFC conclusion was done by scale Ogata/Wells (van de Loosdrecht, 2013): A - does not correspond to MDS; B - reveals some features which commonly appears in MDS; C - results are consistent with MDS.

Results: Among MDS patients without excess of blasts assessment “B” and “C” scores were obtained in 78.6% (sensitivity). Increased proportion of CD34+ myeloblasts was in 35.7% of cases, increased CD56 and CD7 - in 42.9%. The most common abnormalities were: increased CD56 (53.6%), abnormal patterns (39.3%), low granularity (35.7%) in granulocytes; increased proportion (21.4%) and abnormal patterns (28.6%) in monocytes. 64.3% (n=9) patients with AA (AA) were assessed as “A”, 21.4% (n=3) - “B” and 14.3% (n=2) - “C”. Increased proportion of CD117 and expression of CD56 on CD34+ polymorphs was assessed by analysing a total of 30 samples across a wide range of PNH clone size (0.06-97.3%).

Summary/Conclusions: Flow cytometry MDS study with Ogata/Wells scale has a high sensitivity and specificity. Immunophenotypic abnormalities characterizing dysplastic features can also be found in AA patients up to 35% of cases. Increased expression of CD36 on CD34+ myeloblasts, granulocytes and monocytes is commonly found in AA patients. Perhaps the appearance of MFC dysplastic features foreshadows the MDS-transformation of AA, but requires further prospective studies.

SURGICAL MANAGEMENT OF PATIENTS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA (PNH) – DATA FROM THE SPANISH PNH REGISTRY

S. De La Iglesia1,2,*, C. Notario McDonell 2, A. Gaya Valls 3, M.T. Cedena
1Centre for Haematology, Fundación Jiménez Díaz, Madrid, Spain
2Department of Haematology, Hospital Universitario de Guadalajara, Guadalajara, Spain
3Department of Haematology, Hospital Universitario de Salamanca, Salamanca, Spain

Background: Bone marrow failure syndromes include paroxysmal nocturnal hemoglobinuria (PNH), aplastic anemia, Fanconi anemia, and dysmyelopoiesis. The aim of our study was to analyze the surgical management of patients with paroxysmal nocturnal hemoglobinuria (PNH), aplastic anemia, Fanconi anemia, and dysmyelopoiesis in Spain.

Methods: A total of 14 patients with PNH were included in the study, 13 male and 1 female, median age of 59 years. The surgical procedures performed included bone marrow transplantation (BMT), autologous stem cell transplantation (ASCT), and allogeneic stem cell transplantation (AlloSCT). The outcomes of these procedures were evaluated based on the rate of engraftment, the incidence of complications, and the overall survival rate.

Results: All patients received a successful engraftment, with a median time of 21 days. The incidence of complications was low, with only one patient developing graft-versus-host disease (GVHD) and one patient experiencing a bacterial infection. The overall survival rate at 1 year was 78.6%.

Summary/Conclusions: The surgical management of patients with paroxysmal nocturnal hemoglobinuria (PNH) is a complex process that requires a multidisciplinary approach. Our study demonstrates the feasibility and safety of bone marrow transplantation (BMT), autologous stem cell transplantation (ASCT), and allogeneic stem cell transplantation (AlloSCT) in patients with PNH. Further research is needed to improve the outcomes of these procedures and to evaluate the role of new therapeutic strategies in this patient population.

Aims: Here we report data on the clinical management and treatment results of patients with PNH undergoing surgery.

Methods: We collected data on 14 surgical interventions of 11 patients (8 males; age, 25-76 years). All patients had a high prevalence of PNH clone cells (55-99% in PMN) and were receiving eculizumab (ECU). Types of surgery were: 6 laparoscopic cholecystectomies, a transjugular intrahepatic portosystemic shunt, a distal splenorenal shunt, a laparoscopic Achilles allograft ligation, a gastrectomy, an emergency appendectomy, and 3 urologic interventions. Ten patients received ECU 900mg, while one (patient E, surgery 6) received 1200mg since he had developed hemolysis at a previous surgical intervention (surgery 5). In two cases (patient G, surgery 8; patient H surgery 11), an additional dose of ECU was administered before surgery. Patient H (surgery 11) had developed hemolysis at previous surgical interventions (surgeries 9 and 10). In most cases, either the date of the ECU dose was taken into account when scheduling surgery or the ECU dose was moved forward to coincide with the date of surgery. The time between the last ECU dose and surgery was normally one day (range, 1-8).

Results: In nine cases, transfusions were required due to hemorrhagic complications. Patient I (surgery 12) had a thrombotic event leading to acute myocardial infarction one week after surgery. Increased hemolysis was observed (increased LDH and/or presence of hemoglobinuria) in five cases (patients E, H, I and K; surgeries 5, 9, 10, 12 and 14) during the week following surgery. Two of these patients (patients E and H) later underwent additional surgery (surgery 6, and surgeries 10 and 11, respectively). The pre-surgical ECU dose was increased in surgery 6 (patient E) and an extra dose was administered in surgery 11 (patient H) and no hemolysis was observed. (See Table 1).

Summary/Conclusions: Our findings lead us to recommend to perform the intervention within 24 hours of the administration of Ecu in programmed surgery for which it is necessary to program the dose. While in urgent surgical interventions put a new dose on the day of the intervention independently of the previous dose. Also the normal ECU dose could be increased or an extra dose be administered in order to minimize the risk of hemolysis in high-risk patients or in those with a previous history of surgery-related hemolysis.
Summary/Conclusions: Clinical outcomes with eculizumab were significantly improved compared with the baseline in patients with both PNH/AA and classic PNH. This study demonstrated that eculizumab has a beneficial role in the management of patients with PNH/AA, similar to that of classic PNH, by inhibiting hemolysis and reducing transfusion requirements, thus resulting in the improvement of clinical signs and symptoms.

E985
DIAGNOSIS AND FOLLOW-UP OF THE CLONES OF PAROXYSMAL NOCTURNAL HEMOGLOBINURIA BY FLOW CYTOMETRY
S. Ouki1, S. Taoussil1, N. Rebak1, M. T. Abad1
1Hematology, EHS ELCC CAC, Bilda, Algeria

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a very rare chronic disease associated with a clonal expansion of one or several hematopoietic stem cells carrying acquired somatic mutations of PIG-A gene resulting in GPI-AP deficient blood cells and great susceptibility to complement mediated cell lysis. Diagnosis of PNH is of importance and flow cytometry (FC) is a required tool for this. We report 33 cases of PNH diagnosed and monitored by FC.

Aims: To show the interest of flow cytometry for the diagnosis and follow-up of PNH clones in some risky haemopathies.

Methods: A PNH clone has been researched in 234 patients since August 2009 to January 2017. The PNH clone was investigated for bone marrow aplasia with or without haemolysis, regenerative hematologic anemia with negative direct coombs test (DCT), myelodysplasia (MDS), unexplained cytopenia and thrombosis. The search for the PNH clone by FC is based on the analysis of the following mononclonal antibodies: Fear and CD59 with gaging on CD45 for neutrophils, CD59 with gating on CD54 for monocytus and CD59 with gaging on Glycophrin A for red blood cells. We judged that the patient has a PNH clone when the deficiency is >50% on at least two markers highlighted on two different lines. FC surveillance is provided in the absence of a deficit or in the case of a very low or single-line deficit.

Results: Out of 234 cases analyzed, 201 cases (85%) showed absence of PNH clone and 33 cases (14%) had a PNH clone. There are 14 women and 19 men; Sex ratio (M/F) = 1.35, mean age = 42.27 years (17-73). Among patients that should be screened for positive PNH clone we have bone marrow failure: 25 positive (21.9%) of 114 cases screened, hematologic anemia with negative direct coombs test: 4 positive/63 cases (6.34%), thrombosis: 2 positive/28 (7.14%), one negative case of AML2, myelodysplasia with 02 (11.2%) positive/18 cases and cytopenias: 0 positive/13 cases. The types of PNH were type II in 3 cases (9%), type III in 24 cases (72.8%) and mixed deficits in 6 cases (19.2%). The mean degree of CD59 deficiency was 29.4% (5-82) on red blood cells 48.21% (5-95) on neutrophil (N); the mean degree of Fear was 55.33% (6-99) on N in 22 cases ; the mean degree of CD14 deficiency on monocytes was 44% (7-97) in 17 cases, the mean degree of Fear (8 cases) was 51.8% (12.9-92). During surveillance, PNH clone appeared in 02 cases and clone size increased in 1 case. Patients with at least two GPI-liked antigens decreased 2,8- and 1,9-fold, respectively, and further in CR this tendency persisted. Duration of IST-free period less than 1 year and ≥1 year was accompanied by a significant and stable decrease of NK-T cells in PB and BM. It is known that PNH-clone presence is a favourable factor for treatment response of AA. Therefore, this study is important to study the behaviour of NK-T cell clone in AA remission with the size of PNH-clone. In subgroup with small PNH-clone (0-1 %) NK-T cell clone was decreased as compared to primary AA patients, and it significantly decreased further along with growth of PNH-clone size.

Table 1. NK-T cell level (%) in patients with AA in remission according to subgroups.

Summary/Conclusions: Thus, in patients with AA the decrease of NK-T cell level was observed along with recovery of hemopoiesis in all the subgroup variants. Previously we have shown that the decrease of NK-T cells accompanies the recovery of any cytopenias and in case of AA, this pattern, taking into consideration our earlier obtained data, may be the evidence of the role of NK-T cells in regulation of balance Th1:Th2 and produced by them cytokines.

E987
A NOVEL DUAL-REAGENT SINGLE TUBE FLOW CYTOMETRIC ASSAY TO SCREEN PAROXYSMAL NOCTURNAL HEMOGLOBINURIA
Brommann1,1, M U S. Sachan2, Ahluwalia3, P Bose3, N Varma3
1Hematology, Post Graduate Institute of Medical Education and Research, Chandigarh, India

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is an acquired hematopoietic stem cell disorder resulting from loss of membrane-bound glycosyl phosphatidylinositol (GPI) anchor protein. The disease is characterized by heterogeneous clinical phenotypes including intravascular hemolysis, cytopenia(s), bone marrow hypoplasia and atypical site thrombosis. Screening guidelines recommend documentation of the lack of at least two GPI-APs on at least two cell lineages. Alexa fluo 488 conjugated fluorescent Aerolysin (FLAER-AF488) has become a mandatory component in FCM based PNH assays.

Aims: We have analyzed the feasibility of a novel dual-reagent assay for screening a single tube, single line approach for PNH screening.

Methods: EDTA anti-coagulated peripheral blood of patients referred to department of Hematology with clinical suspicion of classical-PNH/ aplastic anaemia, was tested with a single tube panel of FLAER-AF488/CD33/CDAPC. Simultaneously, the routine two tube flow cytometry assay (established sensitivity of 0.1%) was performed for PNH screening. FLAER-AF488 (€80000000CF granulocytes and FLAER/CD33/CD14 for monocytes) was performed in the same sample. Each tube was run till a minimum of 50,000 granulocytes were acquired or till the tube ran dry. A cluster of at least 20 FLAER negative events was considered for reporting PNH-clone positivity in both granulocytes and monocytes. The granulocytes and monocytes were considered positive and the respective clone sizes detected by both the strategies were compared.

Results: A total of 33 patients and 7 healthy controls were analyzed by both dual-reagent and conventional strategies. Among the thirty-three patients, twelve patients concurrently showed the presence of PNH clones by both methods. The positive clones were further confirmed by FLAER-AF488 in granulocytes and monocytes by both strategies, indicating complete concordance at a sensitivity of 0.2% (Chi Square p=0.000). Of the PNH positive cases, the mean PNH clone sizes among the granulocytes by dual-reagent and conven-
E888 TREATMENT OF REFRACTORY APLASTIC ANEMIA WITH ELTROMBOPAG: EXPERIENCE OF A CENTER
M. Gomes1,*, M.J. Teles2, F. Ferreira1, J.E. Guimarães1
1Clinical Hematology, 2Clinical Pathology, São João Hospital Centre, Porto, Portugal

Background: Eltrombopag, a thrombopoietin receptor agonist, was approved in 2008 for the treatment of immune thrombocytopenic purpura. More recently, benefits demonstrated in the proliferation and maintenance of hematopoietic stem and progenitor cells (HSTC) led to its use and approval in the treatment of severe aplastic anemia (AA) refractory to immunosuppressive therapy.

Aims: In this report, we evaluated response to eltrombopag in patients with severe aplastic anemia (AA) refractory to immunosuppression with a simple, cost-effective and widely applicable dual-reagent, single tube PNH-screening assay at a sensitivity of 0.2%. The study needs to recruit patients of various hematological disorders besides healthy controls, and although seems effective for analyzing classic and subclinical PNH, the strategy has to be further standardized to achieve a sensitivity of 0.01%.

Methods: Retrospective analysis of six patients with a diagnosis of aplastic anemia and thrombocytopenia (platelet count ≤30,000/μL), refractory to immunosuppressive therapy and ineligible for allotransplant, treated with eltrombopag. Patients' characteristics, response, clinical evolution and adverse effects were evaluated.

Results: Four patients were female and median age at diagnosis was 66 years (36-76). Previous treatments included horse antithymocyte globulin (1), cyclosporine (4), intravenous immunoglobulin (1), corticosteroids (4) and danazol (1). Treatment with eltrombopag was associated with significant decreased (1502±1327 vs 2515±1826; p<0.0063) granulocyte PNH clone sizes (Pearson’s r=0.993, p=0.000) and the monocyte PNH clone sizes (Pearson’s r=0.991, p=0.000) detected by both the analysis strategies.

Summary/Conclusions: This pilot study demonstrates the practical feasibility of a simple, cost-effective and widely applicable dual-reagent, single tube PNH-screening assay at a sensitivity of 0.2%. The study needs to recruit patients of various hematological disorders besides healthy controls, and although seems effective for analyzing classic and subclinical PNH, the strategy has to be further standardized to achieve a sensitivity of 0.01%.

E899 DECREASED EXPRESSION OF ADHESION MOLECULES IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) CELLS OF PATIENTS TREATED WITH IBRUTINIB
A. Guarni1,2,*, M.S. De Propris1, N.L. Milani1, S. Intoppa1, S. Faraone1, N. Peragine1, F. Mariou1, M.C. Puzzolo1, F.R. Mauro1, J. Del Giudice1, R. Fossi1
1Department of Cellular Biotechnologies and Hematology, 2Department of Molecular Medicine, Hematology, Sapienza University, Rome, Italy

Background: The B-cell receptor (BCR) pathway in CLL plays a well recognized role in the onset and progression of the disease and the resulting development of mechanism-driven drugs is revolutionizing the therapeutic manage-
ment. Ibrutinib is a BTK inhibitor that plays an important role in the BCR pathway and induces several alterations in CLL cells.

Aims: The modulation of the expression of adhesion molecules on the surface of CLL cells from patients treated with ibrutinib has been evaluated to analyze the effect of treatment on the relationship between the microenvironment, that promotes cell survival and proliferation, and the leukemia cells with the conse-
quent cell mobilization and increased drug exposure.

Methods: In a cohort of 101 CLL patients treated with ibrutinib (420mg/die) and rituximab (375mg/m²/week) in the GIMEMA CLL1114 trial, we evaluated, before and after 15 days of therapy, the surface expression on leukemic cells of several adhesion molecules. In detail, using 8 color antibody combinations (all from Becton Dickinson, BD, San José, CA) we evaluated the MIF expression (using the FACSDianto II, BD) of CD11a, CD18, CD38, CD40, CD43, CD44, CD49d, CD62L, CD69, CD80, CD86, CD154, CD184 on CD5/CD19+ leukemic cells.

Results: The number of CD5/CD19+ did not increase after 15 days of treatment (52.8±58.5 vs 53.4±51.5 x 10^6/L; p=0.36) probably because of the concomitant rituximab administration, which 'masks' the mobilization effect induced by ibrutinib. We observed a significant down-modulation of CD46 (261±435 vs 171±148; p<0.0001), a molecule (L-selectin) that has been reported as the key factor controlling the binding of CLL cells to the endothelial walls in vivo. CD69 expression resulted also significantly decreased (744±784 vs 438±716; p<0.0041), is expressed on CLL cells in the tissue microenvironment, both in the bone marrow and in lymph nodes. We observed the significant down-modulation of the expression of CD43 (3265±2282 vs 2515±1826; p=0.0063) of several adhesion molecules, and therefore do not seem a reliable marker in patients treated with ibrutinib. On the contrary, CD81 expression, another antigen utilized for MRD detection, resulted unchanged after 15 days of treatment. CD185 expression was significantly decreased (1502±1327 vs 804±687; p<0.001), while we unexpectedly observed the up-modulation of CD164 (2244±2022 vs 3162±1877; p=0.003), both antigens participate in the BTK signaling pathway. CD40, that interacts with activated CD4+ T cells, resulted down-modulated (722±467 vs 395±262; p<0.0001). CD38 and CD49d, when expressed in >20% of the leukemic cells, resulted significantly down-modulated (p<0.028 and p<0.021) both molecules have a role in the crosstalk between the leukemia cells and the microenvironment. Despite these changes, the expression of the CD11a, CD18, CD43, CD44, CD80, CD86 and CD154 did not change.
Background: The gene expression profile of chronic lymphocytic leukemia (CLL) cells revealed a homogeneous phenotype related to memory B cells accompanied by an aberrant expression of several proteins. For example, lipoprotein lipase (LPL), typically expressed in adipocytes, is readily detected in CLL cells. However, unlike their normal counterparts which are resting cells, CLL cells do proliferate. What energy source CLL cells use and which metabolic pathways they recruit is currently unknown. Because the gene expression profile of CLL cells is skewed towards that of adipocytes, and because they proliferate at similar rates, we hypothesized that lipodabetic CLL cells utilize free fatty acids (FFA).

Aims: (A) Determine whether CLL cells are capable of utilizing FFA for energy production. (B) Determine whether lipid metabolism in CLL is LPL dependent.

Methods: Peripheral blood (PB) and bone-marrow derived lymphocytes were obtained from previously untreated patients with CLL. Imaging of CLL cells was done by electron microscopy, and PB lymphocytes were stained for Oil red O. Confocal microscopy studies helped in determining the cellular localization of LPL. To study the capacity of CLL cells to utilize FFA we developed an assay that measured the oxygen concentration in the sera of cultured CLL cells prior to and after adding FFA. In addition we measured the oxygen consumption of CLL cells derived from ibritinib-treated patients. We used an immuno precipitation (CHIP) and luciferase assays to study the binding of STAT3 to the LPL promoter.

Results: To study whether CLL cells are capable of utilizing FFA we cultured fresh and immortlized CLL cells with FFA. The concentration of cultured media-dissolved O2 (dO2) prior to and after adding FFA, assuming that if the cells oxidize the acid, dO2 levels will drop. Indeed, after 48 hours incubation with FFA dO2 levels were markedly reduced as compared with the dO2 media levels of CLL cell incubated without FFA. Remarkably, unlike cultured normal cells, small levels of cultured CLL B cells did not change dO2. Intriguingly, the levels of dO2 remained unchanged if CLL cells were incubated in the presence of FFA and ibritinib. Similarly, the dO2 levels of CLL cells obtained from ibritinib-treated patients remained constant, suggesting that ibritinib disrupts the capacity of CLL cells to utilize FFA. Oil Red O staining of CLL bone marrow smears detected lipid deposits and electron microscopy confirmed the presence of lipid vacuoles in the cytoplasm of peripheral blood CLL cells but not in normal B cells, suggesting that like adipocytes, CLL cells store lipids in intracytoplasmic lipid vacuoles. Similar to adipocytes CLL cells express LPL which mediates the uptake of lipid particles into the cells and catalyzes the hydrolysis of triglycerides to FFAs. Indeed, we detected LPL in the cytoplasm of CLL cells and in the cytoplasm of CLL cells. Furthermore, using small interfering RNA (siRNA) we knocked-down LPL mRNA levels and found that LPL-siRNA reduced the capacity of CLL cells to utilize FFA, suggesting that the lipid metabolism in CLL is LPL dependent. Because STAT3 is constitutively active in CLL cells, and because the LPL gene harbors STAT3 binding sites, we sought to determine whether STAT3 activates the LPL gene. Indeed, transcription of luciferase reporter gene constructs driven by LPL promoter fragments into MM1 cells revealed that STAT3 activates the LPL promoter. In addition, CHIP confirmed the binding of STAT3 to the LPL promoter. Furthermore, transfection of CLL cells with STAT3-shRNA downregulated LPL transcripts and protein levels, confirming that STAT3 activates the LPL gene.

Summary/Conclusions: Our data suggest that CLL cells undergo metabolic reprogramming and use strategies normally utilized by adipocytes. This process is driven by constitutively activated STAT3 and is inhibited by ibritinib.

E992

INHIBITION OF ARGININE UPTAKE VIA HUMAN CATIONIC AMINO ACID TRANSPORTER-1 (CAT-1): A NOVEL APPROACH FOR CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) THERAPY

A. Werner1,2, N. Leuchtner1,3, A. Habermeier2, H. Echchannaoui1,3, J. Rupp2, K. Rajalingam3,4, M. Theobald3,1,4, E. Closs3, M. Munder1,3,4,5

1Third Department of Medicine (Hematology, Oncology, and Pneumology), 2Department of Pharmacology, University Medicine Mainz, Mainz, 3German Cancer Consortium (DKTK), partner site Frankfurt / Mainz, Germany, 4German Cancer Research Center (DKFZ), Heidelberg, 5Research Center for Immunotherapy, University Medicine Mainz, Mainz, Germany

Background: Interference with cancer metabolism by specifically restricting the availability of extracellular arginine. Arginine uptake into cells is currently explored clinically in phase I-II studies. An alternative, largely unexplored strategy to restrict nutrient availability for cancer cells would be to target the specialized cell membrane transporter proteins.

Aim: (i) If CLL cells depend on exogenous arginine, (ii) which transporter is responsible for arginine transport in human CLL cells and (iii) if the reduction of arginine availability via knockdown of this transporter inhibits CLL cell growth and viability.

Methods: Experiments were performed with both, primary human CLL cells, isolated from highly leukemic peripheral blood, and immortalized CLL cell lines. Primary CLL cells were left unstimulated or were stimulated via Toll-like receptor 9. The expression levels of arginine transporters were determined by quantitative RT-PCR and Western Blot. Arginine uptake was measured by [3H]-arginine import, cell proliferation by [3H]-thymidine DNA incorporation and cell viability by the MTS assay in flow cytometry. The expression of hCAT-1 was downregulated in HG3 CLL cells using lentiviral siRNA technology. HG3_hCAT-1 knockdown cells were injected s.c. in NOD/SCID/gcnull mice and tumor growth was monitored.

Results: We show that primary and immortalized CLL cell proliferation depends on the availability of extracellular arginine. Screening a large panel of individual CLL patient samples and different immortalized CLL cell lines demonstrated that hCAT-1, y+LAT1 and y+LAT2 are the predominantly expressed arginine transporters. Upon activation the expression level of hCAT-1 further increased significantly. Arginine uptake in both, primary and immortalized HG3 CLL cell lines, was inhibited by the CAT inhibitor N-ethylmaleimide. Lentiviral downregulation of the hCAT-1 transporter in HG3 CLL cells resulted in a significant reduction of arginine uptake, associated with an inhibition of cell proliferation and viability in vitro. The corresponding in vivo data of tumor growth upon hCAT-1 knockdown in a murine xenograft model will be presented at the conference.

Summary/Conclusions: Our results demonstrate that the hCAT-1 transporter is a potential pharmacological target structure in CLL cells. Development of small molecule- or antibody-based inhibitors of hCAT-1 might lead to a novel therapeutic approach for CLL.

E993

FCMR IS A NEGATIVE REGULATOR OF B-CELL RECEPTOR SIGNALING IN CHRONIC LYMPHOCYTIC LEUKEMIA CELLS

S. Gobessi1,2, B. Sas1, G. Pozzato1, I. Innocenti1, L. Lauro1, D. Efremov1

1FCMR International Centre for Gene Engineering & Biotechnology, 2Department of Medical and Surgical Sciences, University of Trieste, Trieste, 3Institute of Hematology, Catholic University Hospital “A. Gemelli”, Rome, Italy

Background: Chronic lymphocytic leukemia (CLL) cells frequently display features of anergic B cells, including reduced B-cell receptor (BCR) signaling capacity and downregulation of membrane IgM (mIgM). These features are particularly evident in freshly isolated peripheral blood (PB) CLL cells belonging to the indolent, M-CLL subset (Lanham S et al, Blood. 2003). The mechanism responsible for this phenomenon is still unclear, but chronic stimulation with autoantigens has been considered as a possible explanation because of the observation that BCR signaling capacity and mIgM expression can spontaneously recover in CLL cells following prolonged in vitro culture (Mockridge CI et al, Blood. 2007). An alternative explanation for this phenomenon is that these anergic features are induced by soluble IgM molecules, which are absent from standard culture media, and could interact in vivo with the leukemic BCRs through recently described intermembrane immunoglobulin interactions or by binding to the Fc receptor (FcR). The latter is highly overexpressed in CLL cells, particularly those belonging to the M-CLL subset (Li FJ et al, Blood, 2011). An implication is the role of Fc receptor interactions in regulating the BCR signaling capacity.

Methods: CLL cells were isolated from PB or lymph nodes (LNs) using standard procedures. FcR stimulation was done using pentameric human Fc fragment, whereas BCR stimulation was done using goat anti-human IgM or anti-human Ig light chain F(ab')2 fragments. FcμR knockdown was done by RNA interference using the Nucleofector system and solution VICTOR-909 program. Surface FcPr and IgM levels were measured by flow cytometry on gated CD19+/CD5+ cells.

Results: We recently reported that FcμR stimulation results in activation of certain downstream BCR signaling pathways and increased CLL cell survival in vitro (Gobessi S et al, ASH 2016, abstract 2015). To investigate whether FcμR regulates BCR signaling capacity, we analyzed activation of downstream signaling molecules in CLL cells that had been pretreated for one hour with Fcμ and then stimulated with an anti-lg light chain antibody. Decreased phosphorylation of SYK, AKT and ERK in FcμR knockdown mice, suggesting that FcμR negatively regulates BCR signaling in CLL cells. Consistent with this finding, we also observed that FcμR knockdown by RNA interference resulted in greater activation of SYK, AKT and ERK in anti-IgM stimulated primary CLL cells. Because IL-4 was recently shown to increase BCR signaling capacity and surface IgM expression on CLL cells (Aguilar-Hernandez MM et al, Blood. 2016; Guo B et al, Blood 2016), we next investigated whether it will have an opposite effect on FcμR expression. Stimulation of CLL cells (n=7) for 48 hours with IL-4 resulted in a mean 2.4 fold reduction in surface FcμR expression whereas a 3.9 fold increase in surface IgM expression compared to unstimulated cells (P<0.001 and P=0.016, respectively). Since IL-4 is produced by T cells, which typically interact with CLL cells in LNs, we next compared surface FcμR and IgM expression in two paired LN and PB CLL samples. Interestingly, the expression levels of both FcμR and IgM were downregulated in LNs, whereas no difference was detected in the expression of surface IgM. To further understand the mechanisms through which IL-4 regulates BCR signaling, we compared BCR signaling capacity of CLL cells cultured for 48 hours in the presence of IL-4.
Summary/Conclusions: These data show that FcgR is a negative regulator of BCR signaling in CLL cells. Overexpression of FcgR could be at least in part responsible for the reduced BCR signaling capacity of PB CLL cells. FcgR is downregulated by IL-4 and shows reduced expression in LN CLL cells, which could represent a mechanism to allow CLL cells to respond more effectively to stimulation with antigen encountered in the appropriate context.

E994 TRANSCRIPTION FACTORS AND CHECKPOINT INHIBITORS EFFECT ON WITH AGE: MARKERS OF IMMUNOSENESCENCE?

1Clinical and Experimental Hematology, 2Molecular Immunology, 3Anatomopathology, INSTITUT JULES BORDET, ULB, Brussels, Belgium

Background: Aging is characterized by a progressive decline in immune surveillance that favors tumor development in older patients. One mechanism used by malignant cells to escape immune surveillance is the upregulation of immune checkpoint inhibitors. Another process associated with aging is genetic or epigenetic modifications of tumor suppressor genes (TSGs).

Aims: Investigate the role of a correlation on BCR signaling and progression into a T cell lymphoproliferative disease, identifying the BACH2 gene as a candidate TSG. We thus examined the expression of specific transcription factors (BACH2 and PRDM1) and checkpoint inhibitors (PD-1 and PD-L1) in the different lymphocytes subsets for their potential impact on immunosenescence.

Methods: Peripheral blood mononuclear cells were isolated from whole blood using Lymphoprep (Stemcell Technologies) density gradient centrifugation. Lymphocyte subsets (CD19+, CD3+CD4+, CD3+CD8+) were isolated for subsequent molecular analyses using the MACS Technology (Miltenyi), with the purchase of each lymphocyte subpopulation between 95%-99%. PD-1 (PDCD1), PD-L1 (CD274), IL-4, IFNG, BACH2 and PRDM1 mRNA transcripts were quantified using qRT-PCR. BACH2 and BLIMP1 (PRDM1) protein expression were examined by Western blotting.

Results: Blood samples were obtained from 60 healthy volunteers and 41 untreated B-CLL patients (median age: 67yo). Healthy donors (HD) between the ages of 20 to 90 years subdivided into <50 yrs (median: 36yo) and >50 yrs (median: 65yo). BACH2 mRNA expression in the HD groups is significantly down-regulated in CD4+, CD8+ T cells and CD19+B cells from the older HD group (p=0.0012; 0.0045 and 0.0367, respectively). BACH2 expression was further reduced in CD4+, CD8+ T cells and CD19+B cells from CLL patients compared to HD well balanced for age (p=0.001; <0.0001 and 0.0043). PRDM1 mRNA expression was inversely correlated with BACH2 in CD4+, CD8+ T cells and CD19+B cells (r=0.61; 0.71 and 0.85, respectively). Curiously, PRDM1 was – as expected - significantly up-regulated in CD4+ and CD8+ T cells (p=0.0034; p=0.0017) from B-CLL patients but not in their leukemic B cells. Western blotting analysis demonstrated that BACH2 and BLIMP1 (PRDM1) protein expressions in the T and B cell subpopulations were significantly correlated with transcript expression. BACH2/PRDM1 gene expression was up-regulated in CD4+ producing CD4+ T cells. We also observed that BACH2 down-regulation is correlated with increased IL-4 mRNA expression (r=0.67) but not IFNγ in CD4+ T cells. These observations suggest that BACH2 down-regulation in CD4+ T cells could enhance the expression of effector memory-related genes, particularly Th2, such as IL-4 and PRDM1. PD-1 mRNA expression was up-regulated in CD4+, CD8+ T cells (p=0.0153 and 0.0214) in the older HD group and also up-regulated in the T cells from B-CLL patients (p=0.0014 and 0.0023) when compared to age-matched HD population. High PD-1 mRNA expression was correlated with increased age in HD B cells (p=0.04) with a further increase detected in CD8+ cells (p=0.001). We also observed an inverse correlation between BACH2 and PD-1 in CD4+, CD8+ T cells (r=0.62 and 0.68), and between BACH2 and PD-L1 in CD19+B cells (r=0.66).

Summary/Conclusions: These data suggest that down-regulation of BACH2/PRDM1 and up-regulation of PD1/PD-L1 mRNA expression in major lymphocytes subsets from CLL patients and older healthy controls are significantly correlated with the aging immune cells and could be part of the immunosenescence process.

E995 T-CELL EXHAUSTED PHENOTYPE IS ENHANCED DURING DISEASE PROGRESSION IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL)

I. Jiménez1,*, S. Bobillo2, P. Abrisqueta2, C. Palacio2, J. Carabia1, M.J. Terol3, M. Crespo1, F. Bosch1
1Experimental Hematology, 2Hematology, Vall d’Hebron Institute of Oncology, Barcelona, 3Hematology, INCLIVA Biomedical Research Institute, Valencia, Spain

Background: The different biological mechanisms leading the clinical progression of CLL from early stages are currently not fully elucidated. Different prognostic factors that show a higher probability of progression, such as increased number of circulating mature B cells (BC), have been associated with the clinical course of CLL. Nevertheless, the bulk of CLL patients are still not able to identify an important proportion of patients that eventually progress. Clinical progression from early stages to an advanced CLL is associated with a certainly reduced acquisition of molecular changes that are not able to explain the fifty percent of the CLL cases progressing. CLL cells are dependent on survival and proliferative signals from the microenvironment and are able to evade immune anti-tumoral responses using different mechanisms, which is a crucial feature for cancer development. T-cell dysfunction is one of the main sources of impaired anti-tumor immunity. In CLL, T cells show functional defects and have increased expression of the exhaustion markers PD1, CD244 and CD137 compared to T cells from healthy individuals. Taking this into account, we hypothesize that changes in the microenvironment, and particularly in T-cell exhaustion component, are contributing to the clinical progression of CLL.

Aims: In order to explore the role of the immune system in the progression of CLL we studied the immunophenotype of T cells from CLL patients using paired samples at diagnosis and progression.

Methods: A total of 14 CLL patients (median age, 69 years; median time of progression of 29.5 months) and 6 patients diagnosed with CLL that did not experience clinical progression during a median follow up of 34 months were included in the study. Multicolor flow cytometry was performed in matched samples at two time-points: diagnosis and progression before treatment or diagnosis and follow-up. We studied T-cell differentiation status based on CD45RA and CCR7 expression and the inhibitory receptors PD1, CD244, CD160, LA93, TIM3 and CTLA4. We also analyzed the expression of the transcription factors BACH2/PRDM1 and Eomes.

Results: We observed a significant increase in CD8+ absolute numbers (P=0.0107) and a significant decrease of the CD4:CD8 ratio (P=0.0012) with progression. T cells increased their effector memory (EM) (CD45RA-CCR7-) phenotype during progression (EM CD4+ P=0.0353; EM CD8+ P=0.0023), PD1 expression was significantly increased during progression in absolute numbers and percentages (PD1+CD8+ cell subset (P=0.0169) as well as in the PD1+ EM subset (EM PD1+CD4*; EM PD1+CD8* P=0.0024). Interestingly, we did not observe these changes in CLL patients that did not progress where the absolute numbers of cells expressing PD1 were either diminished or maintained during the follow-up, pointing out an important role of PD1 in regard to CLL progression. We observed that the percentage of CD3+CD8+ T cells and CD4+CD160 were higher at the time of progression, especially for CD244 (P=0.0078). Moreover, the co-expression of these markers with PD1 was found on CD8+ T cells and its percentage was increased during progression (P=0.0078). Among the differentiation subsets, the EM and EM CD45RA* (TEMRA) CD8+ T cells expressed the highest percentages of CD244 and CD160. We did not observe changes in LA93, TIM3 and CTLA4. T-bet and Eomes are essential to regulate T-cell differentiation and their expression has also been associated with a progenitor (T-bethi PD1hi) or a terminal (Eomeshi PD1hi) exhausted phenotype in chronic viral infections. The percentage of CD8+ T cells expressing the exhausted signature (Eomeshi PD1hi) was significantly increased during progression (P=0.0186 and P=0.0286, respectively) whereas T-bet expression was more stable.

Summary/Conclusions: T cells from patients with progressed CLL show a more severe exhausted phenotype compared to diagnosis, which is characterized by an effector memory subset with higher expression and co-expression of PD1, CD244 and CD160, as well as higher levels of the transcription factor Eomes, indicating that the terminal exhausted phenotype (Eomeshi PD1hi) is predominant. These changes may contribute to the immune evasion that facilitates the progression and to the immunosuppressive scenario that dominates advanced CLL stages. Functional assays to explain why this T cell subset is enhanced during progression are currently ongoing.

E996 EARLY SPECIFIC INCREASED EXPRESSION OF SURFACE IGDM BUT NOT OF OTHER ASSOCIATED MOLECULES APPEARS TO REFLECT ANTIGEN DROPOUT AND ENHANCE IN CLL PATIENTS ON IBUTINIB THERAPY

1Haematology Oncology Group, Cancer Sciences Unit, University of Southampton, Southampton, United Kingdom, 2Padua University School of Medicine, Department of Hematology and Clinical Immunology, University of Padua, Padua, Italy, 3Cancer Sciences Unit, University of Southampton, 4Haematology Department, University Hospital Southampton NHS Trust, Southampton, United Kingdom

Background: B cell receptor (BCR) signaling through surface IgM (sIgM) is key to the survival and proliferation of normal and chronic lymphocytic leukemia (CLL) cells, and can be targeted effectively by the BTK inhibitor ibrutinib. Chronic exposure of the BCR to (super)antigen leads to downmodulation of sIgM,
but not of sIgD, levels and signaling capacity. This is evident in the circulating CLL B-cells which are characterized by variably reduced sIgM levels/signaling. The variability influences outcome and cases with relatively higher sIgM levels/signaling capacity, but not sIgD, have more rapid progression, likely due to a proliferative component.

Aims: The aim of this study was to investigate the effect of ibrutinib in vivo on the T-cell compartment and function of sIgM and of other surface molecules associated with the BCR complex on the circulating CLL cells of patients during the early phases of therapy (first 3 months).

Methods: Peripheral blood mononuclear cells were collected from 12 CLL patients prior to (pre-) and at 1 week, 1 month and 3 months following commencement of single agent ibrutinib therapy. Expression of BCR-complex associated sIgM, sIgD, CD19 and other surface markers was assessed by flow cytometry. Signaling capacity following sIgM stimulation was measured by immunoblotting. Following biotinylation of cell surface proteins, the N-glycosylation pattern of the μ chain was assessed by immunoblotting as a readout of sIgM expression. ImmunoSEQ® analysis was obtained from all patients (REC: H22/020). Results: At week 1 of ibrutinib therapy, there was a dramatic increase in the expression of sIgM on the circulating CLL cells (mean fold increase 1.6, P=0.001), while expression of sIgD and CD19 remained constant. At this time point, increased sIgM expression associated with full N-glycan maturation of sIgM heavy-chain, indicative of recovery from antigen engagement at tissue sites. Also, the sIgM levels correlated with increased anti-igM mediated SYK phosphorylation (r=0.64, P=0.03), to indicate functionality upstream of BTK. Sequential assessment at month 1 and 3 revealed that sIgM levels were similar to that observed prior to therapy, with preserved upstream signaling ability. In marked contrast, the other BCR complex associated molecules sIgD, CD19 and CD20 all reduced expression (P<0.001). Reduction of these markers was also accompanied by reduction of cell size and of other surface markers while overexpression of autophagy marker LC3B2 was documented.

Summary/Conclusions: Our data point to two major events dissociating sIgM expression and function from other BCR-complex associated molecules. In the initial phase, the increased sIgM expression and maturation, with no changes of other BCR-associated molecules, appears consequent to lack of antigen encounter, likely due to inhibition of chemokine-mediated entry to tissue sites. In the later phases the circulating CLL cells will suffer lack of tissue derived protective stimuli. In their absence, CLL cells will reduce expression of several markers and cell size, possibly explained by autophagic mechanisms aiming to protect the circulating CLL cells from death unless ibrutinib therapy is withheld.

TRB REPertoire PROFILING OF T-Cell-1 TRANSGENIC MICE USING NOVEL NGS TECHNOLOGIES REVEALS OLIGOClonAL EXPANSIONS: SIMILARITIES WITH CHRONIC LYMPHOcytic LEUKEMIA

A. Agathangelides1, 2, A. Rovida2, S. Bonfigli2,2, E. Vlachonikola1, L. Scarpò2,2, A. Hadzidimitriou1, K. Stamatopoulos1, P. Ghia2

1Institute of Applied Biosciences (INAB), Centre for Research and Technology Hellas (CERTH), Thessaloniki, Greece, 2Strategic Research Program on CLL and B-cell neoplasia Unit, Division of Experimental Oncology, Università Vita-Salute San Raffaele and IRCCS Istituto Scientifico San Raffaele, Milan, Italy

Background: Findings from independent studies reported that the BcR pathway and antigen stimulation occupy a central spot in the development of leukemia in the Eμ-TCL-1 transgenic (tg) mouse, as in the case of chronic lymphocytic leukemia (CLL). Recently, the detailed characterization of the T-cell receptor beta chain (TRB) gene repertoire in patients with CLL revealed gene expression biases and oligoclonality. These characteristics strongly suggested that not only leukemic B cells, but also T cells are selected by antigenic elements that may shape the T-cell compartment in TCL-1 mice, similar to human CLL. This result further support the notion that this mouse model closely resembles CLL, at least from an immunogenetic perspective.

ROLE OF THE COMBINATION MEK1/2 INHIBITOR BINimetinib AND AKT INHIBITOR MK2206 IN CLL

S. Sandhu1,2,3, S. Mulligan2,3, G. Best2

1Acute Medical Unit, Royal Melbourne Hospital, Parkville, 2Northern Blood Research Centre, Kolling Institute of Medical Research, 3Haematology, Royal North Shore Hospital, St Leonards, Australia

Background: Clinical trials of ibrutinib and idelisib demonstrated the efficacy of B-cell receptor-targeted therapies for CLL. We sought to investigate the efficacy of targeting both the BcR and the MAPK-ERK1/2 signaling pathways. Aims: To evaluate the role of targeting the Ras-Raf-MEK1/2-ERK1/2 together with the PI3K-AKT pathways as a potential novel approach in treating chronic lymphocytic leukemia. In particular, assessing the efficacy of MEK1/2 inhibitor, binimetinib (MEK162), in combination with either a PI3K inhibitor, idelisib or an AKT inhibitor, M2206.

Methods: All experiments conducted on primary CLL cells were co-cultured with CD40L-expressing stroma which mimics the support conferred by the tumour environment. Firstly, the effects of binimetinib in combination with MK2206 in primary CLL cells were investigated by western blotting with changes in the expression of phosphorylated and total forms of AKT, MCL-1, and ERK1/2 assessed. Expression of B-actin was used as a loading control.

Figure 1. Results: MK2206 is effective against CLL cells co-cultured with stromal cells in a dose dependent manner. It was also observed that the primary CLL cells co-cultured with the CD40L-expressing stroma were significantly more sensitive to MK2206 than to idelisib (Figure 1A). No cytotoxic effects of binimetinib...
were observed while the combination with MK2206 was significantly more effective than either alone, suggestive of synergistic action between the two drugs (Figure 1B). The analysis of binimetinib at 20µM with idelalisib failed to demonstrate any additive effects or suggestion of synergy between the two drugs (Figure 1C). Binimetinib treatment led to an increase in the activity of AKT and a decrease in ERK1/2 phosphorylation. MK2206 completely abrogated the activation of AKT and MCL-1 phosphorylation when combined with binimetinib (Figure 2A). Although we observed a reduction in AKT phosphorylation following idelalisib alone, it had no effect on the levels of AKT activity induced by binimetinib or the levels of phosphorylated MCL-1 protein. This result was irrespective of the dose of idelalisib used (Figure 2B). We explored the possibility that protein kinase C (PKC) may be involved in binimetinib-induced AKT phosphorylation. Using the pan-PKC inhibitor GF109203X (GFX), we demonstrated that inhibition of PKC significantly reduces binimetinib-induced phosphorylation of AKT with no effect on the activity of ERK1/2-MAPK (Figure 2C). These data suggest a role for PKC in the regulation of AKT activity in CLL cells.

Summary/Conclusions: The combination of binimetinib and MK2206 in vitro has been shown to be effective strategy to treat primary CLL cells. The western blot data reinforce that the increased activity observed in AKT activity in CLL cells following binimetinib treatment is independent of the idelalisib and totally abrogated by MK2206. This PI3-kinase independent regulation may be regulated by other factors as well, most probably by PKC.

E999
TARGETING HIF-1A AND ITS REGULATORY PATHWAYS AS A STRATEGY TO HAMPER LEUKEMIA-MICROENVIRONMENT INTERACTIONS IN CHRONIC LYMPHOCYTIC LEUKEMIA

C. Vitale 1,2,*, V. Griggio 1,2, M. Todaro 1,2, C. Riganti 3, I. C. Salaroglio 3, A. Neri 5, M. Vignetti 1, F.R. Mauro 1, A. Guarini 1, R. Pila 5
1Cellular Biotechnologies and Hematology, Sanpaolo University of Turin, Turin, 2Department of Molecular Biotechnology and Health Sciences, 3Department of Oncology, University of Torino, Torino, 4Hematology, A.O. Santa Croce e Carle, Cuneo, Italy

Background: The CXCL12/CXCR4 axis has a fundamental role in the microenvironment-mediated protection of chronic lymphocytic leukemia (CLL) cells from spontaneous and drug-induced cell death. The binding of CXCL12 with CXCR4 activates multiple intracellular pathways, including RhoA- and Ras-dependent signaling. We have previously shown that co-culture with stromal cells (SC) induces in CLL cells the activation of RhoA/RhoA kinase and Ras/ERK1-2 signaling, the upregulation of Akt, and an increased activity of the transcription factor HIF-1α (Rigoni et al., Oncotarget 2015).

Aims: The purpose of this study was to identify new potential pharmacological targets involved in the CXCL12/CXCR4 axis in order to impair the protection exerted by SC towards spontaneous and fludarabine-induced apoptosis in CLL cells.

Methods: Peripheral blood was collected from 62 patients with CLL. In selected experiments, the M2-10B4 murine SC line and the HS-5 human SC line were used. Patient-derived bone marrow SC were generated from 12 patients with CLL. Where indicated, cell cultures were treated with recombinant CXCL12 (100 ng/ml), CXCR4 inhibitor AMD3100 (5 µg/ml), fludarabine (F-ar-A, 10 µM), simvastatin (1 µM), ERK1-2 kinase inhibitor PD98059 (10 µM), HIF-1α inhibitor BAY87-2243 (1 µM), and PI3K inhibitor idelalisib (10 µM). RhoA and Ras activities were evaluated by an ELISA based assay and by pull-down assay, respectively. ERK1-2, HIF-1α amount in whole cell extracts and in nuclear fraction, and HIF-1α phosphorylation were evaluated by Western Blot. RhoA kinase, Akt and HIF-1α activities were measured with specific immunoassay kits. CXCL12 was quantified by ELISA. Cell viability was determined by Annexin-V-propidium iodide immunostaining and flow cytometry analysis.

Results: The exposure of CLL cells to recombinant CXCL12 led to the activation of RhoA- and Ras-dependent signaling, and to the downstream upregulation of HIF-1α. The CXCR4 antagonist AMD3100 completely abrogated the positive regulation exerted by both CXCL12 and SC, thus unveiling the key role of the CXCL12/CXCR4 axis in the SC-induced modulation of these signaling pathways. The inhibition of Ras and RhoA activity by simvastatin, and the inhibition of ERK1-2 and HIF-1α by PD98059 and BAY87-2243 effectively blocked the SC-induced expression and activity of HIF-1α, significantly impairing the SC-mediated protection of CLL cells, both in absence and presence of fludarabine. Similiar effects were observed by targeting the PI3K/Akt pathway with Idelalisib. We then investigated whether targeting RhoA- and Ras-dependent signaling could modulate HIF-1α also at the SC level. Simvastatin and BAY87-2243 effectively inhibited HIF-1α expression both in SC lines and in patient-derived SC. Moreover, simvastatin significantly reduced the secretion of CXCL12, which is a known transcriptional target of HIF-1α.

Summary: Our data demonstrate that the targeting of HIF-1α and its regulatory pathways, both at the tumor cell and at the SC level is an appealing strategy to overcome the microenvironment-mediated protection to spontaneous and fludarabine-induced apoptosis in CLL cells.

THE ROLE OF GENETIC-BASED PROGNOSTIC FACTORS IN PREDICTING MINIMAL RESIDUAL DISEASE NEGATIVITY IN CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS TREATED WITH FLUDARABINE, CYCLOPHOSHAMIDE AND OFATUMUMAB

S. Raponi1,*, I. Del Giudice1, C. Iani1, C. Luciana1, I. Della Starza1, M.S. De Propriis1, M. Nanni1, M. Cavalli1, L.A. De Novi1, P. Mariglia1, F. Mancini1, M.G. Nardacci1, A. Picciocchi1, F. Albano3, G. Specchia3, A. Cuneo4, S. Fabris5, A. Neri6, M. Vignetti6, F.R. Mauro1, A. Guarini1, R. Pila5
1Cellular Biotechnologies and Hematology, Sanpaolo University of Turin, Turin, 22nd Congress of the European Haematology Association
et al., 2013), the high and intermediate risk groups (del17p/TP53/del11q+ or del11q/NOTH1/SF3B1) showed a significantly lower probability of achieving a MRD negativity (36%, 10/28) than the low and very low risk groups (<10% negative FISH/del13q/WT for 4 genes: 81%, 29/36) (p=0.0003). The 40 flow cytometry MRD- cases were also evaluated by ROC-PCR: 22 (55%) were reclassified as MRD-. By combining the two methods, 47/65 cases (72%) were MRD- and 18/65 (28%) MDR- at the end of FCO. Mutated (M-)IGHV status was significantly associated to a molecular MRD- (12 MRD-15 MRD+ 44%) compared to unmutated (UM)-IGHV cases (5 MRD-32 MRD+, 13%) (p=0.0092). Moreover, when M-IGHV status is reinforced by the absence of del17p/TP53mut/del11q, the association with a deep MRD negativity got stronger (12 MRD-22 MRD+ 36%, 47/135 cases), with a median time of 77.5 months [22-291] from the diagnosis. Karyotype was completed in 195 CLL patients harboring a 17p deletion, i.e. 17p- CLl. Gains and losses of chromosome 17 were identified by FISH (40) and/or flow cytometry. A multivariate model including FISH lesions, gene and IGHV mutations supports the independent role of FISH and IGHV profile in predicting MRD negativity by flow and ROC-PCR, respectively.

Summary/Conclusions: In CLL patients treated with the FCO combination (LLC0911 Gimema trial), a greater MRD negativity by flow cytometry (82%) can be predicted by the FISH profile: 74% in patients without del17p/del11q vs 14% in del17p+/del11q+ cases. A deeper MRD negativity by ROC-PCR (28%) can be anticipated by the IGHV status (44% M vs 13% UM) or by combining IGHV and FISH. A longer follow-up will determine whether these parameters can identify patients who maintain over time a good quality of response.

### E1002

**THE MICROENVIRONMENT REGULATES THE EXPRESSION OF MIr-21 AND TUMOR SUPPRESSOR GENES PTEN, PIA3 and PDCD4 THROUGH THE MICROENVIRONMENT REGULATES THE EXPRESSION**

**Aims:** First, we observed that miR-21 expression was significantly higher in miR-21 positive cases (74%) compared to miR-21 negative cases (26%) (p=0.0375), the presence of unbalanced translocations in 17p- CLl (17q) confers a shorter OS than the other 17p abnormalities. In addition, the gain8q remained significant for OS.

**Summary/Conclusions:** Among the high risk group of 17p- CLl, (17q) confers a shorter OS than the other 17p abnormalities. In addition, the gain8q aggravates the outcome as well as the presence of additional unbalanced translocations. These results confirm that patients with 17p- CLl have a variable clinical course and highlight the relevance of conventional karyotyping to identify the alterations that modulate the prognosis within these patients.

**Background:** Microenvironment found in bone marrow and lymph nodes supports survival, proliferation and drug resistance in chronic lymphocytic leukemia (CLL). Indeed, CLL cells are highly dependent on interactions with the microenvironment. The BCR is one of the key players involved in the crosstalk between CLL cells and the microenvironment. Furthermore, it has a critical role in pathogenesis and prognosis of CLL. Accordingly, different factors related to increased BCR signaling are adverse prognostic factors in CLL, such as IGHV genes, high expression of ZAP-70 and increased serum levels of CCL3. Expression of ZAP-70 in CLL cells has been related to enhanced response to BCR stimulation, as well as to increased response to diverse migrative and survival stimuli from the microenvironment. MiR-21 is an oncogenic microRNA that has been found to be overexpressed in a wide variety of neoplasms where it participates in oncogenic events such as proliferation, resistance to treatment, and metastasis; its overexpression in CLL has been associated to refractoriness to flu-}

**ISOCHROMOSOME 17Q, UNBALANCED TRANSLocations AND 8q GAIN REPRESENT ADVERSE PROGNOSTIC FACTORS IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) WITH 17p DELETION. A GFCH STUDY**

**Aims:** To identify the clinical parameters associated with the time to first treatment (TTFT) of patients with 17p deletion. Despite the high frequency of 17p deletion (12-17% of all CLL patients), it is still unclear whether del17p is an adverse prognostic factor. We collected data from a multicentric and retrospective cohort of 195 CLL patients harboring a 17p deletion. Gains and losses of chromosome 17 were identified by FISH, with an informative conventional karyotype and the additional aberrations could influence the prognosis. Patients with 17p- typically progress quickly and are refractory to most conventional therapies.

**Summary/Conclusions:** The presence of additional unbalanced translocations in 17p- CLl (17q) confers a shorter OS than the other 17p abnormalities. In addition, the gain8q aggravates the outcome as well as the presence of additional unbalanced translocations. These results confirm that patients with 17p- CLl have a variable clinical course and highlight the relevance of conventional karyotyping to identify the alterations that modulate the prognosis within these patients.

**Background:** Chromosomal abnormalities are present in about 80% of CLL. Among them, the loss of the short arm of the chromosome 17 (17p-), unassociated with del17p, is frequently accompanied by genomic complexity. Patients with 17p- typically progress quickly and are refractory to most conventional therapies.

**Summary/Conclusions:** The presence of additional unbalanced translocations in 17p- CLl (17q) confers a shorter OS than the other 17p abnormalities. In addition, the gain8q aggravates the outcome as well as the presence of additional unbalanced translocations. These results confirm that patients with 17p- CLl have a variable clinical course and highlight the relevance of conventional karyotyping to identify the alterations that modulate the prognosis within these patients.

**Methods:** Peripheral blood mononuclear cells (PBMC) from 48 patients diagnosed with CLL were isolated by Ficoll-Paque Plus density gradient centrifugation. Ramos B-cells stably transfected with a vector encoding for ZAP-70 protein fused with Green fluorescent protein (GFP) or GFP only as a control were treated with anti-IgM (LY294002), MAPK (PD98059) and STAT3 (USI-124) inhibitors for 1 hour. BCR was stimulated with F(ab)2 anti-IgM. PBMC were co-cultured with bone marrow stromal cells with CD40L and CpG to mimic the microenvironment found in proliferation centers. After 48 hours CLL cells were harvested to analyze cell viability, cell proliferation and mRNA expression. Expression levels of primary miR-21, miR-21, PTEN, PDCD4 and PIA3 were measured by QRT-PCR.

**Results:** First, we observed that miR-21 expression was significantly higher in patients with high expression of ZAP-70. Subsequently, using stably transfected Ramos B-cells with ZAP-70 protein we found that pri-miR-21 and mature miR-21 expression were significantly increased upon BCR stimulation, which was enhanced by ectopic expression of ZAP-70. We also observed that inhibition of both MAPK and STAT3 pathways impairs the regulation of miR-21 expression after ZAP-70 activation. Moreover, the induction of miR-21 expression after ZAP-70 activation also induced downregulation of the tumor suppressor genes PTEN, PDCD4 and PIA3. In conclusion, miR-21 may play a role in the crosstalk between CLl cells and the microenvironment.

**Summary/Conclusions:** Inclusion, stimuli from the microenvironment are capable of regulating expression of miR-21 and tumor suppressor genes
IMPACT OF RECURRENT MUTATIONS ON PROGRESSION-FREE SURVIVAL IN CLL PATIENTS TREATED WITH FRONT LINE RITUXIMAB-BASED REGIMENS

M. Hlochová1,*, J. Malíková1, N. Tom1, M. Bonský1, V. Břychová1, M. Doubek1, A. Panovská1, E. Divisková1, M. Mráz2, S. Pospisilová1, J. Mayer1, M. Trbuská1, V. Svobodová1,2, K. Musilová1,2, K. Čerňa1,2, G. Pavlásova1,2,*, M. Borsky2, A. Panovska1, E. Diviskova1, M. Mraz1, S. Pospisilova1, J. Mayer1, M. Trbusek1, E1004

Background: Regimens consisting of rituximab and DNA-damaging drugs represent an important therapeutic option for patients with chronic lymphocytic leukemia (CLL). Up-to-date studies including clinical trials agreed upon the adverse outcome of TP53-defective patients that should be provided alternative treatment approaches. Additionally, mutations in NOTCH1 gene were connected with a lack of benefit from rituximab added to chemotherapy. A potential impact of other mutations commonly occurring in CLL patients remains less clear, namely regarding a role in relapse development.

Aims: (a) to assess impact of mutations in ATM, SF3B1, NOTCH1 and BIRC3 genes on progression-free survival (PFS) in CLL patients treated with front line rituximab-based regimens, and (b) to analyze clonal evolution of mutations in relapse.

Methods: We analyzed 53 CLL patients administered first line regimens (R, FCR (fludarabine, cyclophosphamide, rituximab) or Q-FCR (FCR with reduced doses) or BR (bendamustine, rituximab); all harbored intact TP53 gene as assessed by FISH and the yeast functional assay; 46/53 (87%) had unmutated IGHV. The next generation sequencing using MiSeq (Illumina) was done in 48 patients (100%) and 41 relapsed samples using three and five gene panels: ATM (exons 2-6; median coverage (MC) 8100), SF3B1/NOTCH1/BIRC3 (exons 14-16, part of 34, and 7-10, respectively, MC 11200), and TP53 (exons 2-11; MC 31500). Functional impact of ATM mutations was verified by SIFT and PolyPhen online tools. Only mutations present in >10% of reads were considered for the PFS analyses (log-rank (Mantel-Cox) test); the interval was calculated from therapy completion to clinical progression (as defined by the iwCLL recommendations).

Results: In the pre-therapy analysis, we identified 23 patients with one disrupted gene and 7 patients with two disrupted genes; the rest of the cohort (n=6) did not have any mutations (wt). ATM was the most frequently affected gene (n=15; only mutations with predicted functional impact considered), followed by SF3B1 (10 cases; hot-spot mutations), NOTCH1 (7 cases; all deletion c.7541T>7542) and BIRC3 (5 cases; frame-shift mutations). We did not observe significant differences in PFS among the employed regimens; the median PFS of FCR (used in 30 patients; median: 4 cycles), 15 m for Q-FCR (15 patients; 4 cycles); and 14 m for BR (8 patients; 3.5 cycles); P=non-significant (ns). In univariate analyses of individual affected genes, we did not observe an adverse impact of mutations on PFS: ATM-mut median 19 m vs 14 m in wt patients; SF3B1-mut 19.5 m vs 16 m; NOTCH1-mut 32 m vs 15.5 m; BIRC3-mut 16 m vs 16 m (all analyses P=ns). In a more detailed analysis, we observed a higher percentage of patients with double ATM mutations (in seven patients) and one case of ATM mutation from two (from 2.3% to 7.7%, and 5.4% to 6.54%) and ATM mutations in two cases (8% to 15% and wt to 18%), as well as more complex changes involving both increase and decrease of mutations in BIRC3 gene in three patients.

Summary/Conclusions: Our pilot analysis with limited number of samples does not indicate an adverse impact of studied mutations in rituximab-based regimens. Some relapsed samples showed quite distinct mutation profile. Supported by projects AZV 16-32743A, MUNI/A/1106/2016 and FNBr, 65269705.

Cancer Immunology, Genomics and Oncology, University Hospital Brno and Faculty of Medicine, Masaryk University, Brno, Brno, Czech Republic

Methods: Peripheral blood samples from CLL patients (N=17) were obtained and analysed before (day 0) and 24 hours (day 1) after RTX administration (375mg/m², single agent).

Results: It was described that CLL cells that interacted with stromal cells in vivo can be characterised by relatively weak cell-surface expression of chemokine receptor CXCR4 and high expression of activation marker CD5. Here, we present a study that correlates the interaction of CXCR4 with CD5 expression in CLL cells from patients treated with rituximab, as well as their meeting with the leukemic cells in vivo. We observed that CXCR4-defective cells tend to have a higher CD20 expression than CLL cells circulating in the peripheral blood without contact with immune niches (CXCR4high/CD5dim; Pavlova et al., 2016). We hypothesised that the higher levels of CD20 on CXCR4dim/CD5dim cells make them the primary target for RTX in vivo, since the cell line is rendered CD20 expresser by the RTX (Kroeger et al., 2001). We analysed blood samples obtained from CLL patients treated with RTX as a single agent and indeed, we observed that RTX preferentially and nearly completely eliminates the CXCR4dim/CD5dim subpopulation after the first RTX dose (8.3% pre-RTX vs 2.1% post-RTX, P<0.0001). We further showed that RTX down-regulates signaling efficiency of the CXCR4 receptors in CD20+ subpopulation, since CD20 was proposed to play a role in BCR signalling. We observed that CXCR4dim/CD5dim CLL cells have higher immunoglobulin (IgM) expression (~2-fold, P<0.005) which was coupled with higher responsiveness to BCR crosslinking with anti-IgM (P<0.005). Moreover, CXCR4dim/CD5dim cells also have higher levels of CD19 (1.8-fold, P<0.0001), which is an important component of BCR complex that augments signal transduction. Furthermore, we demonstrated that CXCR4dim/CD5dim cells have higher phosphorylation of several proteins involved in PI3K/BCR/NFkB signalling pathway (P<0.05) compared to CXCR4high/CD5dim cells obtained from the same patient. This led us to hypothesize that the down-regulation of CXCR4 expression is likely of physiological importance for PI3K/BCR signalling. Indeed, we observed significant reduction in phosphorylation of tyrosine-protein kinases associated with PI3K/BCR signalling after silencing of CD20 by siRNA in B cells.

Summary/Conclusions: We showed that CXCR4dim/CD5dim CLL subpopulation in peripheral blood of CLL patients has the highest surface levels of CD20 and is therefore preferentially and effectively eliminated by RTX. These CLL cells likely represent the most “aggressive” subclone of CLL cells since they have relatively high proliferative and BCR signalling capacity.

REGULATION OF BCR SIGNALLING IN CHRONIC LYMPHOCYTOCYC LEUKAEMIA: ROLE OF E3 UBIQUITIN LIGASE C-CBL

V. Martiní1,2, R. Molfetta3, F. Severini1,2, V. Trimarco1,2, F. Frizzo1,2, F. Raggi1,2, L. Martirello1, A. Visentin1, E. Scomazzon1, M. Facco1,2, G. Semenza1,2, R. Padon2, L. Trentin1,3,4

Background: In normal B cells, the E3 ubiquitin ligase Cbl (c-CBL) is involved in the ubiquitin-dependent Lyn degradation and in the down-regulation of BCR signalling. Cbl is activated by phosphorylation that releases C-cbl from its autoinhibited structure by triggering a conformational change that leads to an enhanced transfer of ubiquitin from the E2 enzyme to the substrate proteins. Mutations in this RING/Linker region result in the loss of ubiquitin ligase activity thus prohibiting lysosomal or ubiquitin/proteasome-mediated degradation of tyrosine kinases and thereby unleashing tyrosine kinase signaling. We reported that in Chronic Lymphocytic Leukemia (CLL) Lyn is over-expressed and is in an active conformation as integral component of an aberrant cytosolic multiprotein complex, associated with several proteins, (CXCR4, BIRC3, HS1 and SHP-1L). In particular, Hsp90 appears tightly bound to Lyn c-Cbl complex structure, facilitating Lyn translocation to the cytosol, thus stabilizing the aberrant complex and converting individual transient interactions into stable ones.

Aims: The accumulation of clonal B lymphocytes in CLL is mostly due to apoptosis resistance but also to proliferative activity. Abnormalities of molecules involved in signal transduction are associated with BCR-mediated cell survival and a critical role has already been ascribed to B-cell receptor (BCR)-Lyn axis. Here, we investigated the expression and the role of c-Cbl in CLL B cells since in normal B cells is involved in the ubiquitin-dependent Lyn degradation and in the down-regulation of BCR signalling. Moreover, the studied samples were collected from 30 CLL patients and 15 controls. Untouched peripheral blood B cells were purified using the RosetteSep isolation kit for human B cells. We characterized c-Cbl total protein level and c-Cbl(Y700) by Western blotting. To evaluate the interaction between c-Cbl and Lyn in CLL
B cells we performed a co-immunoprecipitation assay, followed by Western blotting analysis, at steady state and after IgM (10µg/ml) stimulus. We also evaluated the interaction between c-Cbl and Lyn after treatment with 17-DMAG (500nM), a potent HSP90 inhibitor.

Results: We demonstrated that c-Cbl is overexpressed (p<0.001). Student’s t test in CLL B lymphocytes with respect to normal B cells. We found that in neoplastic B cells c-Cbl did not co-immunoprecipitate with Lyn neither after BCR trigger. We obtained similar results when we treated neoplastic B lymphocytes with 17-DMAG to dissociate the Lyn-Hsp90 complex: after 1h, 2h and 4h of treatment we immunoprecipitated Lyn demonstrating that neither before nor after IgM stimulation c-Cbl interacts with this kinase. These results support the hypothesis that c-Cbl is not involved in Lyn turnover. Data obtained from 10 independent experiments showed that in CLL neoplastic cells the phosphorylation on Y700 increased after 5' and 10' of IgM stimulus, highlighting the involvement of c-Cbl in BCR signaling.

Summary/Conclusions: These preliminary results prompt us to investigate the role of c-Cbl in the dysregulation of neoplastic clone. In CLL cells c-Cbl is overexpressed with respect to normal B cells, and upon BCR engagement it undergoes Y700 phosphorylation. However, c-Cbl is unable to stably interact with Lyn suggesting an altered c-Cbl function that contribute to affect cell homeostasis.

ACTIVATION OF SHP-1/PP2A PATHWAYS TRIGGERS APOPTOSIS IN CHRONIC LYMPHOCYTIC LEUKEMIA CELLS

F. Severin1,2, E. Tibaldi2, M.A. Pagano3, F. Frezzato2, V. Trimmero1,2, V. Martinii1,2, F. Raggi2, L. Martinello1, F. Facco2, G. Zagotto2, G. Ribaudo3, V. Maserati1, L. Bordin1, L. Visceniti2, F. Zonta2, G. Semenzato1, A.M. Brunati3, L. Trentin1,2

1Department of Medicine, University of Padua, 2Venetian Institute of Molecular Medicine (VIMM), 3Department of Molecular Medicine, 4Department of Pharmaceutical and Pharmacological Sciences, 5Department of Biomedical Sciences, University of Padua, Padova, Italy

Background: CLL B cells inability to reach programmed cell death is due to intrinsic defect and extrinsic factors. Among the intrinsic fault there is the misregulation of the phosphorylation pattern. Reversible protein phosphorylation is a fundamental post-translational modification by which virtually all cellular events are regulated. The crucial players involved in this dynamic process are protein kinases and protein phosphatases, which are placed at the different levels of cellular signaling. The Src Family Kinase (SFK) Lyn is a key factor in the dysregulation of survival and apoptotic pathways of malignant B cells in CLL. One of the effects of Lyn’s action is the spatial and functional segregation of the tyrosine phosphatase SHP-1 into two pools, one beneath the plasma membrane in an active state promoting pro-survival signals, the other in the cytosol in an inhibited conformation and unable to counter the elevated level of cytosolic tyrosine phosphorylation.

Aim: Because CLL is characterized by a high level of Lyn-dependent tyrosine phosphorylation in the cytosol, we focused our attention on compounds capable of directly or indirectly driving the activation of SHP-1 which in turn could counter the action of Lyn and induce cell demise. The goal is to discover new therapeutic strategies to defeat a still incurable disease as CLL.

Methods: B cells were isolated from 37 CLL patients. Freshly isolated CLL cells incubated with increasing concentrations of nintedanib (0-24 μM) and MP07-66 (2,2-diethoxyethyl[di-(hexyloxy)phenyl(methyl)]amine) for 24 and 48 hours with/without a ligand of Mesenchymal Stromal Cells (MSCs). Caspase-dependence was demonstrated using the pan-caspase inhibitor z-VADfmk. CLL B cells viability was tested by Flow Cytometer with Annexin V/PI test and PPP2Ac expression and phosphorylation were evaluated by Western Blotting.

Results: We performed in vitro phosphatase activity assays on the cytosolic pool of SHP-1 in the presence of increasing concentrations of nintedanib, a receptor tyrosine kinase inhibitor recently shown to trigger SHP-1 activity. Nintedanib treatment could activate the phosphorylated (at Ser591), and inhibited, form of SHP-1 and to induce apoptosis, depending on the caspase activation, after 24h and 48h at marked level. Interestingly, we recently demonstrated that Ser591 phosphorylation of SHP-1 could be dephosphorylated by PP2A. In this scenario, the restoration of PP2A activity by a finkglobin, a drug devoid of immunosuppressive action, called MP07-66, and the subsequent dephosphorylation of PP2A substrates, was shown to trigger apoptosis, like nintedanib, in a caspase-dependent manner. Since our data suggest that the activation of either PP2A or SHP-1 triggered by specific small molecules caused stimulation of each of events activity, we treated CLL cells with nintedanib and MP07-66 together demonstrating an improved effect when used in combination. Similar results, in all the conditions, were obtained in presence of a MASC layer, showing the capability of these treatments to counteract the protective action of tumor microenvironment.

Summary/Conclusions: In conclusion, our findings indicate that phosphatase activators may represent a new weapon against this form of leukemia. Overall, these data corroborate the hypothesis that the inhibition of PP2A is central to CLL cell viability and that its activation is facilitated by the supportive action of SHP-1, as demonstrated by the effect produced by the simultaneous use of the respective activators.

TARGETING NANOPARTICLES TO CHRONIC LYMPHOCYTIC LEUKAEMIA: EXPLOITING THE PROPERTIES OF CXCR4

C. Micalion1, A. Booth1, J. Adams3, K. Rees-Unwin3, A. Peters1, A. Pluemen4, S. Webb1, J. Burthem3

1School of Chemistry, University of Manchester, Manchester, 2School of Chemistry, University of Leeds, Leeds, 3Institute of Cancer Sciences, 4School of Pharmacy, University of Manchester, Manchester, United Kingdom

Background: Nanoparticle carriers of therapeutic agents (‘drug delivery vehicles’) can be used to deliver drugs to specific cells through the incorporation of a ‘targeting ligand’. Targeting provides the therapeutic benefit of achieving high local drug concentrations while reducing off-target effects against other cells; the combined ligand/delivery vehicle system can also be manipulated to determine the uptake pathway or modulate biological effects. The CXCR4 chemokine-receptor is an attractive target for drug delivery vehicles. It is overexpressed in cancers including chronic lymphocytic leukaemia (CLL) (Doman ska et al., 2013) and binding to its ligand (CXCL12) may induce proliferation, survival or entry into protective cellular niches (Ganju et al., 1998). Targeted nanoparticles that can bind and antagonise CXCR4 could therefore allow specific drug delivery to cancer cells while simultaneously blocking CXCL12-induced chemoprotection.

Aims: A drug-design strategy was developed to synthesise and evaluate a novel CXCR4 targeting motif (BAT1) with structural similarity to Plerixafor, a CXCR4-antagonist in clinical use. A key design principle was to incorporate a polyethylene glycol (PEG) tether with a functional end-group to provide an attachment point for cargoes, particularly liposomes. The evaluation aim was to assess the effectiveness of BAT1 to deliver a chemotherapy cargo to CLL cells within an ex vivo culture system.

Methods: A three-step synthesis was used to generate BAT1 (Figure 1A); its structure and purity was confirmed using NMR, MS and HPLC. Bioactivity testing employed primary CLL lymphocytes. Assays performed: CXCR4 binding-affinity (flow cytometric competition assays), cell-binding characteristics (immunocytotlourescence) and blockade of CXCL12-induced signalling (immunoblot). Initial targeting assay used a fluorescent label (Cy5) conjugated to the functional PEG tether. Cholesteryl chloroformate was then selected to conjugate BAT1 to PEGylated liposomes.

Results: The binding affinity of BAT1 (Figure 1B) was demonstrated using competition assays (CXCL12, anti-CXCR4 ab, and the bis(cyclam) drug Plerixafor). The studies confirmed BAT1 had high affinity for CXCR4 receptors expressed on primary CLL cells. Immunocytolourescence comparison with its native ligand confirmed binding of BAT1 to the CLL cell surface, while immunoblotting demonstrated blocking of CXCL12-induced signalling (Figure 1C and 1D). The fluorescent moiety Cy5 was covalently linked to the PEG moiety as a test-cargo, demonstrating that binding affinity was retained in the presence of a cargo and that the drug competed for CXCR4 binding with related bis(cyclam) drugs. This work has been extended to attach BAT1 to liposomes, with present work optimising liposome characteristics for binding and uptake by CLL and the delivery of cytotoxic payload.

Summary/Conclusions: A novel bis(cyclam) CXCR4 antagonist and targeting motif (BAT1) has been synthesised. BAT1 demonstrates high affinity for the CXCR4 receptor, supporting targeted delivery to CLL cells. Receptor binding is associated with simultaneous blockade of CXCL12-mediated signal initiation and effect, and therefore biological modulation of target cell behaviour. BAT1

Figure 1.

Summary/Conclusions: A novel bis(cyclam) CXCR4 antagonist and targeting motif (BAT1) has been synthesised. BAT1 demonstrates high affinity for the CXCR4 receptor, supporting targeted delivery to CLL cells. Receptor binding is associated with simultaneous blockade of CXCL12-mediated signal initiation and effect, and therefore biological modulation of target cell behaviour. BAT1

THE ROLE OF THROMBOPOIETIN AS A TOOL OF IMMUNE MODULATION IN CHRONIC LYMPHOCYTIC LEUKEMIA

S. Ringelstein-Harlev1,*, M. Fanadka2, N. A. Horowitz1, T. Katz1
1Department of Hematology and Bone Marrow Transplantation, Rambam Health Care Campus, 2Bruce Rappaport Faculty of Medicine, Technion, Israel Institute of Technology, Haifa, Israel

Background: Thrombopoietin (TPO) is the major regulator of platelet production, synthesized mainly by liver cells. The TPO receptor (TPO-R) is known to be expressed on platelets, megakaryocytes and CD34+ cells. It has been reported that patients with immune thrombocytopenic purpura, treated with TPO-R agonists, developed alterations in the T-cell repertoire and pattern of cytokine secretion from B- and T-cells. Thus, clinical activity of these agents could be attributed in part to immune modulation. In chronic lymphocytic leukemia (CLL), characterized by aberrant T-cell responses, high TPO serum levels coexist with low levels of TPO gene transcripts in the malignant cells. These observations could imply that TPO acts as an immune modulator in CLL.

Aims: The aim of the current study was to explore the role of TPO in T-cell modulation in CLL.

Methods: B-cells and CD4+ T-cells were isolated from peripheral blood mononuclear cells (PBMCs) of untreated CLL patients (Rai stages 0-IV) and healthy donors. Using qRT-PCR we detected ROR1 mRNA expression in five patients tested consecutively in several time-points. We distinguished malignant population from healthy B-cells. Using qRT-PCR we detectable on residual CLL cells during disease remission with the ability to distinguish malignant population from healthy B-cells. Using qRT-PCR we detected significantly higher levels of ROR1 mRNA in samples of treated patients (p<0.01). This observation was supported by analysis of ROR1 mRNA expression in five patients tested consecutively in several time-points. We detected ROR1 mRNA expression increase in disease progression before therapy and further increase during therapy administration. In case of remission induction we observed decrease of ROR1 mRNA level. In patients treated with ibritinib or ibrutinib and idelalisib we observed steep increase of ROR1 expression compared to patients treated with a single agent regimen.

Summary/Conclusions: R101 protein remains detectable on CLL cells during disease course even in complete remission. R101 mRNA levels are highly influenced by therapy administration especially in the case of treatment with BcR inhibitors.

E1010

NORMAL SERUM PROTEIN ELECTROPHORESIS IDENTIFIES AN ANGELI STAGE II-RECLUSION PROGNOSIS GROUP AMONG IGHV MUTATED PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA, WITH A MEDIAN TFS OVER 18 YEARS

J. Chauzeix1,*, N. Bargues1, M.-P. Laforte1, M. Deveza1, V. Combeau1, V. Renat1, E. Guerin1, F. Trimoreau1, N. Dymtryuk3, J. Feuillard1, N. Gachard1, D. Rizzo1
1Service d'hématologie biologique, CHU Limoges, 2UMR7276, Université de Limoges, 3Service d'hématologie clinique, CHU Limoges, Limoges, France

Background: Approximately 36% of patients with chronic lymphocytic leukemia (CLL) have normal serum protein electrophoresis (SPE) either with hypermagnolubinenia or with monoclonal immunoglobulin (Ig) peak. In this study, we compared locally recruited patients with normal and abnormal SPE.

Aims: The aim was to identify prognosis parameters.

Methods: A total of 189 patients (132 abnormal SPE and 57 normal SPE) were included. The patients' diagnoses were performed between 1980 and 2015. Prognosis parameters investigated were IGHV mutation status, presence of SF3B1, NOTCH1 or BIRC3 mutations (determined by high throughput and Sanger sequencing), and cytogenetic abnormalities such as del17p, del11q, del13q and trisomy 12 (assessed by standard cytotype, FISH analysis and QMPSF).

Results: In this series, 73%, 19% and 8% of patients were at Binet stage A, B and C respectively, and 30% had a normal SPE at diagnosis. Ninety six percent of patients with normal SPE were at Binet stage A, versus 63% of patients with abnormal SPE (Chi2 test : p<10^-4). Median lymphocytosis at diagnosis was lower in patients with normal SPE (12.82 G/L versus 19.54 G/L in abnormal SPE, respectively; p=0.010). In patients with normal SPE, we found that 58% of cases with normal SPE had a good prognosis profile (mutated IGHV and/or isolated del13q, with no other genetic abnormality detected), meanwhile 65.2% of patients with abnormal SPE exhibited at least one poor prognosis marker (unmutated IGHV, mutation of SF3B1, NOTCH1, del17p, del11q or trisomy 12, Chi2 test : p<10^-4). In patients with normal SPE, only 3.5% cases were SF3B1 mutated against 15.2% in case of abnormal SPE (Chi2 test : p=0.002). Among other strong differences, 10.5% patients with normal SPE had a trisomy 12 against 18.2% for abnormal SPE. Isolated del13q was found in 38.6% and 21.2% of cases with normal and abnormal SPE respectively. Mutated IGHV status was found in 65% in normal SPE and 56.5% with abnormal SPE. Compared to the whole series, IGHV repertoire analysis shows bias in IGHV1-2, and IGHV4-3 rearrangements, with decreases usage of IGHV3-21 and IGHV3-48. Treatment free survival was markedly increased in patients with normal SPE (median of 10.0 years versus 3.0 years for normal and normal SPE respectively, Kaplan-Meier, log rank test: p<0.01). In patients with normal SPE, death or progression (D or P) occurred in 14.5% of patients vs 53.8% of patients with abnormal SPE (log rank test: p<0.001).

Results: In this study, we aimed to differentiate ROR1 expression in CLL cells during different stages of the disease using flow cytometry and qRT-PCR with focus on patients undergoing therapy; ii) analyze changes in ROR1 expression within individual patients during the disease course.

Methods: CLL cohort consisted of 96 CLL patients (152 samples): 23 patients with stable disease, 16 patients with active disease prior first therapy intervention, 6 patients during first therapy, 13 patients in progression before second line treatment, 3 patients in complete remission, 10 refractory patients, 9 patients treated with ibritinib and idelalisib and 4 patients treated with ibrutinib or idelalisib. ROR1 changes in ROR1 expression we tested serial samples from 5 CLL patients (median follow up 76 months (66-131), median number of sampling points 12 (5-18)). For surface ROR1 protein analysis we used 8-flow colour flow cytometry (modified MRD protocol: CD45/CD3/CD19/CD5/CD81/CD79b/CD22/ROR1) in all samples. To quantify ROR1 mRNA expression changes within individual patients we performed qRT-PCR in separated CLL cells (>95% CD19+CD5+). CLL cells from patients in remission were separated immunomagnetically (Whole Blood Anti-ROR1 MicroBead Kit, Miltenyi Biotec).

Results: Using multicolour flow cytometry we confirmed ROR1 antigen/protein expression on CLL cells. We focused on RNA samples. The ROR1 antigen was detectable on residual CLL cells during disease remission with the ability to distinguish malignant population from healthy B-cells. Using qRT-PCR we detected significantly higher levels of ROR1 mRNA in samples of treated patients (p<0.01). This observation was supported by analysis of ROR1 mRNA expression in five patients tested consecutively in several time-points. We detected ROR1 mRNA expression increase in disease progression before therapy and further increase during therapy administration. In case of remission induction we observed decrease of ROR1 mRNA level. In patients treated with ibrutinib or ibrutinib and idelalisib we observed steep increase of ROR1 expression compared to patients treated with a single agent regimen. The aim of the current study was to explore the role of TPO in T-cell modulation in CLL.

Methods: B-cells and CD4+ T-cells were isolated from peripheral blood mononuclear clear cells (PBMCs) of untreated CLL patients (Rai stages 0-IV) and healthy donors. Using qRT-PCR we detected ROR1 mRNA expression in five patients tested consecutively in several time-points. We distinguished malignant population from healthy B-cells. Using qRT-PCR we detected ROR1 antigen/protein expression on residual CLL cells during disease remission with the ability to distinguish malignant population from healthy B-cells. Using qRT-PCR we detected significantly higher levels of ROR1 antigen in samples of treated patients (p<0.01). This observation was supported by analysis of ROR1 mRNA expression in five patients tested consecutively in several time-points. We detected ROR1 mRNA expression increase in disease progression before therapy and further increase during therapy administration. In case of remission induction we observed decrease of ROR1 mRNA level. In patients treated with ibrutinib or ibrutinib and idelalisib we observed steep increase of ROR1 expression compared to patients treated with a single agent regimen.

Summary/Conclusions: R101 protein remains detectable on CLL cells during disease course even in complete remission. R101 mRNA levels are highly influenced by therapy administration especially in the case of treatment with BcR inhibitors.
median TFS of 4 years (log rank test: \( p = 0.0003 \)). Thus, patients with normal SPE and IGHV mutated status constitute a group with excellent prognosis.

**Summary/Conclusions:** In conclusion, normal SPE was associated with good outcome with decreased accumulation of side genetic events (in particular, SF3B1 mutations). This analysis shows a bias in IGHV repertoire according to SPE status. These results also clearly suggest that patients with a normal SPE and mutated IGHV have an extremely quiet CLL natural history. This could be either due to the weaker activity of the disease and/or to the absence of adverse consequences of a concomitant paraprotein.

**Background:** The search for molecules involved in apoptosis resistance/ increased survival of B cells from Chronic Lymphocytic Leukemia (CLL) is still ongoing since this disease remains not definitively understood. We recently found that the Heat Shock Protein of 70kDa (HSP70), expressed in response to a wide variety of stress signals and allowing cells to survive to lethal conditions, was particularly overexpressed in neoplastic B cells from CLL. Moreover, the Heat Shock Factor 1 (HSF1), the major responsible for the transcription of HSP70, is itself overexpressed in CLL and strictly correlated to HSP70. In response to stress, HSF1 becomes phosphorylated, forms homotrimers, binds DNA and activates heat shock gene transcription. HSF1 is regulated by a fine balance of activatory/inhibitory phosphorylations mediated by kinases belonging to pathways triggered by RAS (i.e. PI3K/AKT/mTOR and RAF/MEK/ERK). Aims: Since HSP70 is overexpressed in CLL neoplastic B cells and most of “HSF1-1phosphorylating agents” belong to signalling pathways taking part from RAS, being the PI3K/AKT/mTOR and the RAF/MEK/ERK pathways, we are herein aimed at gaining information and dissecting this network in CLL B cells.

**Methods:** In a Reverse Phase Protein Array (RPPA) study, previously performed from 57 CLL patients and 11 healthy subjects, we evaluated the activation/expression of key signalling proteins. Herein, we focused on HSP70, AKT-Ser473, mTOR-Ser244, GSK3α/b-Ser21/9, CDK2, CREB-Ser133, and p38MAPK-Thr180/Thr182, SAPK-JNK-Thr183/Tyr185 and PDK1-Ser241. Cluster and separation analyses have been performed.

**Results:** We divided our patients in HSP70-high and HSP70-low considering as cut-off the value of the median of HSP70 expression levels calculated by RPPA and demonstrated that the examined proteins behave in a different way between patients expressing high or low levels of HSP70. HSP70-high patients present high AKT-Ser473, an inhibitor of GSK3α/b, that in the inhibited form, prevents HSF1 inhibition. By contrast, HSP70-low patients have high MEK1/2-Ser217/221 and ERK-Thr202/Tyr204, known to negatively regulate HSF1. Intriguingly, p38MAPK-Thr180/Tyr182 which has been described to both activate and inhibit HSF1 at different sites, is overexpressed in those patients presenting low levels of HSP70.

**Summary/Conclusions:** These data would suggest that, in CLL, HSP70 expression is regulated by the modulation of HSF1 activity through the activation of one or the other way triggered by RAS. In particular, an activation of the PI3K/AKT/mTOR pathway leads, as result, to a higher expression of HSP70 while an activation of the RAF/MEK/ERK signalling rather results in HSP70 down regulation. The dissection of signalling pathways connected to HSP70-HSF1 axis in CLL will contribute to define the biology and understand the pathogenesis of this disease.

\(^1\)Department of Medicine, University of Padua, Padova, Italy, \(^2\)Venetian Institute of Molecular Medicine (VIMM), \(^3\)Department of Women’s and Children’s Health, University of Padua, Padova, Italy

**Background:** Chronic lymphocytic leukemia (CLL) is the most frequent leukemia in the Western world and it is characterized by the clonal expansion of CD5 positive B cells. In CLL, different T cells dysfunctions have been described, probably related to the interaction with malignant B cells. TH17 and regulatory T cells (Tregs) are subpopulations of T lymphocytes which play a fundamental part in inflammatory response and immune tolerance. However, their role in the immunopathogenesis of CLL has not yet been fully clarified.

**Aims:** The aim of this study is to clarify the interplay between TH17 and Tregs in the pathogenesis of CLL.

**Methods:** After obtaining the patient’s informed consent, peripheral blood was collected from 30 untreated CLL patients and 30 age-matched healthy volunteers (HV). Cytokine production was evaluated before and after a 48 h culture of CD4+ T cells in complete medium with IL-6 (10ng), followed by a 5 h stimulation with PMA, Ionomyc and Monensin (PIM), or with anti-CD3/CD28 PE or anti-CD4/CD28 PE. Statistical analysis were carried out using the paired and unpaired two-tailed Student’s t tests and confirmed with the non-parametric Wilcoxon signed-rank test.

**Results:** We observed a reduced production of IFN-γ and IL-4, respectively from TH1 and TH2 and an increase of IL-17A from TH17, compared to HV. All the observed differences were statistically significant. We also evaluated the ability of CD4+ T cells to secrete IL-17A, IL-10 or both. We reported a statistically significant increase in the frequency of CD4+ IL-17A-producing cells in CLL patients compared to HV, whereas the percentage of IL-17A+IL-10+ cells remained unchanged. In order to evaluate the functional effects of the observed alterations, we analyzed IFN-γ+CD4+ T cells-mediated response after stimulation with C. Albicans for 48 h, with or without deprivation of IL-17A-secreting cells. The frequency of IFN-γ-producing T cells resulted statistically significant increased in patients with IL-17A-secreting T cells depletion. Conversely, after IL-17A+ CD4+ T cells depletion, we didn’t observe significant differences in term of IFN-γ production. We also observed increased IL-23 plasma levels in patients compared to HV. In addition our data highlighted a significantly higher frequency of CD4+CD25\(^\text{hi}\)FoxP3\(^+\) cells (Tregs) in CLL samples, with a statistically significant increase in Tbet+ Tregs, RORct+ Tregs and GATA3+ Tregs subpopulations (Figure 1).

**Figure 1.**

**Summary/Conclusions:** Our results reported a down-regulation of IFN-γ and IL-4 producing T cells, associated to an increased frequency of Tregs and their subsets in CLL patients, probably trying to overcome the deficit of effector T cells. On the other hand, we observed a rise in IL-17A secreting T cells related to the increased IL-23 production by dendritic cells in order to restore TH17 pool, without changing the percentage of IL-17A+IL-10+ cells. These data support the idea of the protective function of TH17 that show an effector and not a regulatory T phenotype. Starting from these observations, this study could pave the way to further researches and applications in the comprehension of the biological and regulatory mechanisms of TH17 and Tregs, supporting the study of a pioneering anticancer therapy in CLL.

**Background:** Recently, it has been shown that CDK6-mediated repression of CD25 is required for induction and maintenance of NOTCH1-induced T-cell acute lymphoblastic leukemia.

**Aims:** The aim of this study was to identify the NOTCH1 mutational status detected by deep sequencing in a cohort of 138 untreated patients and to correlate it with the immunophenotypic profile and CDK4 and CDK6 expression.

**Methods:** We performed targeted NGS sequencing of blood samples, collected at diagnosis, from 138 CLL patients. We designed a TrueSeq Custom Amplicon

---

*haematologica | 2017; 102(s2) | 415*

Madrid, Spain, June 22 – 25, 2017
containing 13 genes and covering 28,099 bases. Pair-end sequencing was performed with MISEQ v2.2 chemistry, and a mean depth of 96× across the base was obtained. Every patient underwent, at baseline, a flow cytometry characterization with a panel including (si)gκ, (si)gλ, CD19, CD5, CD11b, CD81, CD10, CD79b, CD29, CD38, FMC7, CD22, CD45, CD103, CD11c, CD25, ZAP70, CD11a, and CD24. CD4K and CD6K expression levels were quantified by RT-qPCR.

Results: With a median age of 66 y.o. (range, 31-89) and a slight male preponderance, the median follow up time of our cohort was 43 months (24-104). We found that 38/138 (28%) patients harbored at least one mutation, with NOTCH1 (n=16, 12%), ATM (n=12, 9%), TP53 (n=9, 7%), and SF3B1 (n=8, 6%) being the most commonly mutated genes. Those patients with NOTCH1 mutation showed a lower CD25 expression (24 mean fluorescence intensity units (MFU)) than those without a mutation (43 MFU), p=0.03. We could not validate the recently reported association between the presence of NOTCH1 mutations and a low expression of CD25. In our cohort, the MFI expression in NOTCH1 mutated and non-mutated patients was 163 and 146 units, respectively (p>0.05). We measured CDK4 and CDK6 expression in the CD19+ sorted fraction RNA of 7 NOTCH1 mutated cases and 11 non mutated cases, without finding significant differences (0.26 vs 0.27 for CDK6, 0.025 vs 0.022 for CDK4; p>0.5 in both cases).

Summary/Conclusions: We found a significant inferior expression of CD25 when activating NOTCH1 mutations are present in CLL patients. The relationship found between these two variables, with an inverted direction to that found in physiological conditions, has also been shown in the setting of NOTCH1-mutated T acute lymphoblastic leukemia. In CLL cases, it seems to be independent of CDK4/6 expression, prompting further studies checking CDK4 and CDK6 regulators.

E1014 GENE MUTATIONS ANALYZED BY NEXT-GENERATION SEQUENCING ALLOW US TO DEFINE THE PROGNOSIS OF CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS WITH EARLY-STAGE DISEASE AND 13Q-DELETION M. Martín1, A. M. Casado2, C. Agüera3, M. Olalla4, M. Barbero5, J. Hernández-Rivas1, A. J. Martín6, R. Benito1, M. J. Vidal-Manceñido2, J. Galende3, J. M. Alonso4, J. M. Hernández-Rivas1

Background: Next-Generation sequencing (NGS) studies have revealed a number of recurrently mutated genes in chronic lymphocytic leukemia (CLL). It is reasonable to argue that evaluation of the newly gene mutations as prognostic markers would help to improve prognostication of CLL patients. Interestingly, gene mutations could help us to refine the prognosis in the group of CLL patients with other prognostic markers associated with good prognosis.

Aims: To analyze the presence of mutations of a panel of genes by NGS and its prognostic impact in patients with CLL, focusing in the patients with good prognosis characteristics.

Methods: Amplicon-based NGS was performed using 454 platform in 147 CLL patients to evaluate the mutational status of genes (TP53, NOTCH1, SF3B1, XPO1, FBXW7 and MYD88). Samples were obtained at diagnosis or before treatment in all cases. 70.1% were Binet A and 53% had 13q deletion (13q-). A cut-off 2% was applied to define variants. All the mutations were validated.

Results: 1. NGS analysis showed that 37.4% of CLL patients (55/147) showed mutations in any of the analyzed genes. The frequency of mutations was 16.3% for NOTCH1, 10.2% for SF3B1, 6.8% for TP53, 4.8% for XPO1, 3.4% for FBXW7, and 1.4% for MYD88. The presence of mutations in any of these genes except MYD88 (mutated CLL) was significantly associated with clinical progression (60.0% for mutated CLL vs. 38.2% for unmuted CLL; P=0.05). Interestingly, mutated CLL patients showed a shorter time to first treatment (TFT) than mutated unmutated CLL patients (30 months vs. 88 months; P=0.006). By contrast, MYD88 mutations were detected in CLL with mutated IGHV and 13q- 2. Of note, 23.6% of the mutations had a mutational load of >15% and thus would not have been detected by capillary Sanger sequencing. CLls with mutations in >40% of cells had a shorter TFT than those without mutations (18 vs. 88 months; P=0.018), and similar to CLL patients with mutations >15% of cells (P=0.370). In addition, 14.5% of mutated CLL patients showed 2mutations. Patients with more than one mutation had a shorter TFT than CLL patients with one mutation (7 months vs 31 months). In the group of CLL patients with 13q-, 32.8% of them showed mutations in any of the analyzed genes. Interestingly, CLL patients Binet A with mutations (except to MYD88) showed a shorter TFT than CLL patients without mutations (31 vs 131 months, P=0.001). Besides this, CLL with 13q- as the sole cytogenetic alteration and gene mutations had also a shorter TFT that unmutated 13q- CLL patients (p<0.001).

Summary/Conclusions: 1) CLL patients with mutations in TP53, NOTCH1, SF3B1, XPO1 and FBXW7 show a worse prognosis than CLL patients without mutations. 2) Gene mutations in TP53, NOTCH1, SF3B1, XPO1 and FBXW7 in a low percentage of the cells are associated with a shorter TFT. 3) Among CLL patients with good prognostic characteristics (Binet A and 13q-), gene mutations help us to define the prognosis of the patients.

E1015 ALTERED COMPLEX C5 IS ASSOCIATED WITH COMPROMISED COMPLEMENT ACTIVITY IN CHRONIC LYMPHOCYTIC LEUKEMIA A. Braester1,2, M. Barhoum3, R. Michiels1

1Haematology, Galilee Medical Center, Nahariya, 2Faculty of Medicine, Bar-Ilan University, Safed, Israel

Background: The therapeutic monoclonal antibodies used for the treatment of Chronic lymphocytic leukemia (CLL) mediate anti-tumor effects through several independent cell-mediated cytotoxicity (ADCC), and phagocytosis. CDC efficacy thus depends on the expression level of the target B-cell antigen, the integrity of apoptotic cascades within tumor cells, the functional capacity of effector cells, and the availability and activity of the complement (C) system. Published data indicate deficiency of one C protein or more in most CLL patients, as well as additional factors that may affect C activity. The role of structural abnormalities of C complexes in affecting C function has not been investigated.

Aims: To study the structural integrity of circulating C complexes, focusing mainly on C5, and to establish its importance for C activity in CLL.

Methods: Blood samples were obtained from 35 (Binet A and 13q-) CLL patients and 10 healthy controls (HC). Biochemical and haematological parameters, and CLL staging were recorded. The isoforms of two key C components, C3 and C5 were studied by Western blot analysis. The activity of the C system before and after in-vitro activation via the classical or alternative pathways was followed by the levels of C3-b and CD59, anti-apoptotic protein dependent cell-mediated cytotoxicity (ADCC), and phagocytosis.

Results: The data indicate a possible link between the activation potential of the C system in CLL patients and alterations in the complex structure of C5. The differences in C activation via the classical and alternative pathways may indicate disturbance in the classical pathway in patients with abnormal C5. The exact mechanisms by which abnormal C5 disturbs the C activity need further clarification. Yet, the appearance of abnormal C5 pattern compared to sera from the other subjects' groups. The data indicate a possible link between the activation potential of the C system in CLL patients and alterations in the complex structure of C5. The differences in C activation via the classical and alternative pathways may indicate disturbance in the classical pathway in patients with abnormal C5. The exact mechanisms by which abnormal C5 disturbs the C activity need further clarification. Yet, the appearance of abnormal C5 pattern compared to sera from the other subjects' groups.

Summary/Conclusions: The data indicate a possible link between the activation potential of the C system in CLL patients and alterations in the complex structure of C5. The differences in C activation via the classical and alternative pathways may indicate disturbance in the classical pathway in patients with abnormal C5. E1016
ASSOCIATION OF CGP-STIMULATED KARYOTYPE WITH TIME-TO-FIRST TREATMENT FOR CLL

Background: Prognostic factors correlate with clinical outcomes, independent of treatment. B cell receptor (BCR) signaling pathway inhibitors can nullify the prognostic impact of some markers, such as IGHV mutation status. CpG-stimulated metaphase karyotype can identify clonal cytogenetic abnormalities in CLL that may not be seen with standard non-stimulated karyotype or by FISH. Complex cytogenetics, defined as 3 or more chromosome abnormalities in 2 or more metaphases was the highest-risk feature for shorter progression-free and overall survival in patients receiving ibrutinib for relapsed/refractory CLL. Complex karyotype is not uncommon among relapsed/refractory CLL cases, particularly those who previously received genotoxic chemotherapy.

Aims: The aim of this study is to report the incidence and the impact of CpG-stimulated karyotype in the treatment of naïve CLL.

Methods: We evaluated 501 treatment-naive patients with CLL at MDACC between July 2013 and June 2016. CpG-stimulated metaphase karyotype of CLL cells from blood or bone marrow was performed by culture of mononuclear cells for 72 hrs in media containing CpG-868 (20μg/mL), phorbol 12-myristate 13-acetate (PMA; 0.04μg/ml) and Pokeweed mitogen (PWM; 0.1μg/mL). Banding and analyses were by standard laboratory procedures. Twenty metaphases were analyzed per culture and patients were categorized as having diploid karyotype, a single, 2 or 3 or more(complex) clonal chromosome abnormalities present in more than 1 metaphase by CpG-stimulated karyotype. The frequency and distribution of chromosome abnormalities with other prognostic factors and time-to-first treatment from diagnosis (TTFT) were analyzed (Table + Figure).

Results: The majority (69%) of patients had diploid cytogenetics. Higher-risk prognostic features such as del17p, del11q, unmutatedIGHV and ZAP70 expression were associated with presence of complex karyotype abnormalities. Shorter TTFT from diagnosis was associated with 1, 2, and complex clonal chromosome abnormalities compared to diploid karyotype (<0.005). A model was developed, which identified patient characteristics independently associated with shorter TTFT including: 1 or more clonal chromosome abnormality by CpG stimulated karyotype; unmutatedIGHV; 3 involved lymph node sites; and CD38 expression (>30%).

Figure 1. Aims: The aim of this study is to report the incidence and the impact of CpG-stimulated karyotype in the treatment of naïve CLL.

Figure 1. Aims: The aim of this study is to report the incidence and the impact of CpG-stimulated karyotype in the treatment of naïve CLL.

Methods: We evaluated 501 treatment-naive patients with CLL at MDACC between July 2013 and June 2016. CpG-stimulated metaphase karyotype of CLL cells from blood or bone marrow was performed by culture of mononuclear cells for 72 hrs in media containing CpG-868 (20μg/mL), phorbol 12-myristate 13-acetate (PMA; 0.04μg/ml) and Pokeweed mitogen (PWM; 0.1μg/mL). Banding and analyses were by standard laboratory procedures. Twenty metaphases were analyzed per culture and patients were categorized as having diploid karyotype, a single, 2 or 3 or more(complex) clonal chromosome abnormalities present in more than 1 metaphase by CpG-stimulated karyotype. The frequency and distribution of chromosome abnormalities with other prognostic factors and time-to-first treatment from diagnosis (TTFT) were analyzed (Table + Figure).

Results: The majority (69%) of patients had diploid cytogenetics. Higher-risk prognostic features such as del17p, del11q, unmutatedIGHV and ZAP70 expression were associated with presence of complex karyotype abnormalities. Shorter TTFT from diagnosis was associated with 1, 2, and complex clonal chromosome abnormalities compared to diploid karyotype (<0.005). A model was developed, which identified patient characteristics independently associated with shorter TTFT including: 1 or more clonal chromosome abnormality by CpG stimulated karyotype; unmutatedIGHV; 3 involved lymph node sites; and CD38 expression (>30%).

Figure 1. Aims: The aim of this study is to report the incidence and the impact of CpG-stimulated karyotype in the treatment of naïve CLL.

Methods: We evaluated 501 treatment-naive patients with CLL at MDACC between July 2013 and June 2016. CpG-stimulated metaphase karyotype of CLL cells from blood or bone marrow was performed by culture of mononuclear cells for 72 hrs in media containing CpG-868 (20μg/mL), phorbol 12-myristate 13-acetate (PMA; 0.04μg/ml) and Pokeweed mitogen (PWM; 0.1μg/mL). Banding and analyses were by standard laboratory procedures. Twenty metaphases were analyzed per culture and patients were categorized as having diploid karyotype, a single, 2 or 3 or more(complex) clonal chromosome abnormalities present in more than 1 metaphase by CpG-stimulated karyotype. The frequency and distribution of chromosome abnormalities with other prognostic factors and time-to-first treatment from diagnosis (TTFT) were analyzed (Table + Figure).

Results: The majority (69%) of patients had diploid cytogenetics. Higher-risk prognostic features such as del17p, del11q, unmutatedIGHV and ZAP70 expression were associated with presence of complex karyotype abnormalities. Shorter TTFT from diagnosis was associated with 1, 2, and complex clonal chromosome abnormalities compared to diploid karyotype (<0.005). A model was developed, which identified patient characteristics independently associated with shorter TTFT including: 1 or more clonal chromosome abnormality by CpG stimulated karyotype; unmutatedIGHV; 3 involved lymph node sites; and CD38 expression (>30%).
(21%, P<0.001), indicating that the CLL-IPI had a higher prognostic accuracy for mortality compared to that of the biomarkers-only prognostic model. Then, we also compared the ability of the two scores to predict TTFT in newly diagnosed patients. The Harrell C-index of the Barcelona-Brno prognostic model was 0.70 (P=0.001), lower than that of the CLL-IPI score (0.73, P<0.001). The AIC showed the superiority of the CLL-IPI compared to the Barcelona-Brno prognostic model in predicting TTFT (CLL-IPI, AIC=6060.503 versus biomarkers-only prognostic model, AIC=6010.929). Accordingly, the explained variation provided by the CLL-IPI was 33% (P<0.001), a figure higher than that achieved by the Barcelona-Brno prognostic model (28%, P<0.001), indicating that the CLL-IPI had a higher prognostic accuracy for predicting TTFT as compared to that of the Barcelona-Brno prognostic model.

Figure 1.

Summary/Conclusions: Our results confirm the validity of both scores (CLL-IPI and biomarkers-only prognostic model) to predict survival and TTFT among patients with previously untreated CLL. Moreover, we have demonstrated that the CLL-IPI which combines clinical and serological data with biological parameters has a higher accuracy for predicting prognosis and TTFT of CLL patients than the Barcelona-Brno biomarkers-only prognostic model.

E1018

PRELIMINARY RESULTS OF S55746/BCL201 (A NEW BCL2 INHIBITOR) IN RELAPSED OR REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS AND EFFECT OF CALIBRATED MODERATE MEAL ON THE PHARMACOKINETICS

V. Ribrag1, M. Wermke2, F. Morschhauser3, S.T. Lim4, G. Salles5, I. Kloos6, A. Becquart7, A. Derreal6, L. Kraus-Berthier6, S. Pennaforte6, J.-M. Michot1, M. González5, A. Orfao1, J. Almeida1

1Institut Gustave Roussy, Villejuif, France, 2Universitätsklinikum Carl Gustav Carus, Dresden, Germany, 3CHRU - Hôpital Claude Huriez, Lille, France, 4National Cancer Centre, Singapore, Singapore, 5Hematology, Hopital Lyon Sud, Lyon, 6Servier, SURESNES, France, 7University of Ulm, Ulm, Germany, 8Lymphoid Malignancies, Maria Sklodowska-Curie Memorial Institute and Oncology Centre, Warsaw, Poland, 9Hematology, CHRU Nantes, Nantes, France

Background: BCL-2 is an anti-apoptotic protein overexpressed in chronic lymphocytic leukemia (CLL). BCL-2 is responsible for apoptosis machinery dysregulation and contributes to chemotherapy resistance. S55746/BCL201 is a novel, oral, selective BCL-2 inhibitor.

Aims: The current first-in-human study evaluates the safety and aims to establish the recommended phase 2 dose; main secondary objectives include evaluation of pharmacokinetics (PK), food effect, pharmacodynamics and preliminary activity in patients (pts) with relapsed or refractory CLL.

Methods: S55746/BCL201 as single agent is being investigated in a phase I (EUDRACT, NCT02920697), open-label, multinational, international dose escalation trial. S55746/BCL201 was initially administered in fasting condition, once daily (in 21-day cycle) until progressive disease (PD) or unacceptable toxicity. A tumor lysis syndrome (TLS) prevention protocol was implemented. After giving informed consent pts could receive 50 to 2000mg according to a modified version of the Continual Reassessment Method for dose allocation process. In the food effect part of the study, 7 non-Hodgkin’s lymphoma patients received a film coated 200mg tablet under fasting condition (i.e. after 10-hour fasting period) and after a calibrated moderate meal the day after. Results: As of February 2017, 12 CLL pts have been treated (median age 67 years [range 52-82]). On these 12 pts, 5 presented a bulky disease, 1 a 17p13 deletion, 4 a 11q deletion, and 1 a p53 mutation. CLL pts were dosed up to 700mg, with a median duration on treatment of 79 days. Median number of prior regimens in CLL pts was 4 (range 2-5). Preliminary PK results in fasting pts showed that exposure increased linearly but with some inter-individual variability. A maximum frequent (2x pts) grade 3/4 adverse events (AEs) were neutropenia (n=2) and thrombocytopenia (n=2). AEs possibly related to the study drug were reported in 4 pts: neutropenia (n=2), neutrophil count decrease (n=1), fatigue (n=1), dyspnea (n=1), gingival bleeding (n=1) and left ventricular ejection fraction (LVEF) decrease (n=1). No clinical or laboratory TLS were reported. One patient in the 700mg cohort experienced a DLT (asymptomatic LVEF decrease grade 2 recovered within 2 weeks). At 700mg, a decrease in lymphocytes count from baseline (>50%) was observed in 3 out of 4 patients associated with a decrease in the sum of the product of the diameters of lymph nodes (from 23% to 40%). This decrease in lymphocytes count, started from cycle 1, and may be correlated with an induction of apoptosis in CLL cells (4 hours post first dose), detected by flow cytometry in CD19+AnnexinV+ cells. Two CLL pts are ongoing after having completed their 3rd cycle; 10 pts have withdrawn from the study: 7 due to PD, 1 for lack of efficacy and 2 due to AE. The non-comparitional pharmacokinetic analysis of the food effect cohort (5 assessed pts) demonstrated that S55746/BCL201 PK is not affected by the ingestion of a moderate meal (400-500 kcal with fat contributing to 150 kcal). The median Tmax was delayed from 1.5h to 4h when administered with food. Compared with fasting condition, Cmax and AUC increased by approximately 6-fold following a moderate meal. Based on these results, a protocol amendment to the clinical trial has been implemented in order to further investigate the administration with food in a new dose escalation.

Summary/Conclusions: S55746/BCL201 monotherapy showed first signs of activity across the tested dose levels with an acceptable safety profile so far. Based on PK food interaction results, dose escalation in the fed state has started.

E1019

INCREASED VIRUS-SPECIFIC IMMUNE RESPONSES PARALLELED BY A PNEUMOCOCCUS-SPECIFIC-IMMUNODEFICIENCY STATE AND HYPOGAMMAGLOBULINEMIA: ALREADY EMERGE IN HIGH-COUNT MONOCLONAL B LYMPHOCYTOSIS PRIOR TO CLL

1Department of Medicine, Cancer Research Center (IBMCC, CSIC-USAL), Centro de Investigación Biomédica en Red de Salud Pública, Centro de Atención Primaria de Salud Miguel Armijo, 2Centro de Atención Primaria de Salud de Ledesma, 3Service of Hematology, 4Service of Biochemistry, University Hospital of Salamanca, Salamanca, Spain

Background: Patients diagnosed with chronic lymphocytic leukemia (CLL) display a high incidence of infections, due to an associated immunodeficiency state that includes hypogammaglobulinemia. Even more, it has been recently shown that the earlier stages of disease, i.e. high-count monoclonal B lymphocytosis (MBL2), subjects also have increased risk for infection. Aim: To evaluate the status of the humoral immune response in CLL at different disease stages, as well as in pre-leukemic MBL1 and MBL low count (MBLb) cases, vs healthy controls, through quantitation of soluble plasma levels of specific antibodies against ubiquitous and pulmonary infection-associated pathogens.

Methods: A total of 249 subjects (119 males/130 females; aged 68±11y) including 91 healthy donors, 71 CLL-like MBL1b, 29 CLL-like MBL1b and 58 CLL cases (32 Binet A, and 26 Binet B/C patients) were studied. Detection of clonal CLL-like B cells was performed by high-sensitive 8-color flow cytometry. Quantification of plasma antibody isotypes and specific immunoglobulins against CMV (cytomegalovirus), EBV (Epstein Barr Virus), influenza virus and S.pneumoniae were performed by nephelometry and commercial ELISA kits, respectively. Individuals who had received vaccination against Influenza and/or Pneumococcus were excluded from the analysis of the immunoglobulin-specific titers against the corresponding pathogen, respectively. Plasma CMV and EBV DNA load were measured using real-time PCR.

Results: Total immunoglobulin (Ig) titers tended to decrease with disease progression, independently of the isotype. In contrast, specific IgM and IgG titers against CMV, EBV and influenza virus did not vary among groups, with the
exception of VCA-EBV IgG titers, that were higher in CLL vs the other groups. Strikingly, the IgG levels for the three viruses tended to gradually increase, from healthy individuals to stage B/C LL. These findings were more pronounced (p<0.05) for IgG and to a lesser extend also for IgM, when the ratios between the virus-specific IgG/total IgG titers of the same isotype were calculated, except for Influenza-specific IgG, that showed the same trend but without statistical significance. Repeat CMV DNA load, only on 3177 individuals (1 MBL and 2 CLL- were found to be positive (below the limit of quantitation), while EBV DNA load was detected in plasma from 7/191 (all been Binet A CLL) at medium levels of 3.6 copies/ul. In contrast to the virus-specific Igs, IgG plasma levels against S.pneumoniae progressively diminished through progression of the disease, leading to the overall lower gammaglobulin levels.

**Summary/Conclusions:** Both MBL and CLL patients present relatively high levels of specific Ig against human host viruses in parallel to progressively lower levels of anti-S.pneumoniae antibodies, which might reflect (asymptomatic) chronic reactivation of humoral immune responses against host viruses and virus-specific decreased protection against other microorganisms, denoting a severe pathogen-specific humoral immunodeficiency state not reflected by the overall plasma immunoglobulin levels. Alternatively, these results might point out a potential role of ubiquitous viruses in the pathogenesis of the disease.

Further analyses are necessary to establish the potential relevance of such asymptomatic humoral immune responses against host viruses in the expansion of the tumor B-cell clone and progression from MBL to CLL.

**AN EXTENSIVE MOLECULAR CYTOGENETIC CHARACTERIZATION IN HIGH-RISK CHRONIC LYMPHOCYTIC LEUKEMIA IDENTIFIES KARYOTYPIC ALTERATIONS AND TP53 DISRUPTION AS PREDICTORS OF OUTCOME AND CHEMOREFRACTORINESS**

G.M. Rigolin1,*, L. Formigaro1, M. Cavallari1, F.M. Quaglia1, E. Lista1, A. Urso1, A. Guardalben1, S. Martinelli1, E. Saccenti1, C. Bassi2, L. Lupini2, A. Bardi1, E. Volta1, E. Tassi2, A. Melandri1, M. Negrini1, F. Cavazzini1, A. Cuneo1, S. Baracchi1, E. Saccenti1, C. Bassi2, L. Lupini2, A. Bardi1, E. Volta1, E. Tassi2, A. Melandri1, M. Negrini1, F. Cavazzini1, A. Cuneo1, S. Baracchi1, E. Saccenti1, C. Bassi2, L. Lupini2, A. Bardi1, E. Volta1, E. Tassi2, A. Melandri1, M. Negrini1, F. Cavazzini1, A. Cuneo1, S. Baracchi1.

**Background:** Chronic lymphocytic leukemia (CLL) is a heterogeneous disease, running an indolent course in some patients and a clinically aggressive course in others. Risk assessment is important in clinical practice and prediction of outcome and response to treatment is very useful in an era in which several chemomunotherapy combinations and effective mechanism-driven treatments are available.

**Aims:** We investigated whether an extended genetic characterization including mutational screening by next generation sequencing (NGS) and karyotype analysis could allow for a refinement of our capability to predict outcome in newly diagnosed CLL patients with high-risk features, as defined by the presence of unmutated IGHV gene and/or 11q22/17p13 deletion by FISH and/or TP53 mutations.

**Methods:** 101 patients were included in this study, TP53 disruption was defined by the presence of 17p13 deletion by FISH and/or TP53 mutation by NGS. Cytogenetic analysis was performed using CpG-oligonucleotide DSP30. Each patient was categorized according to the following classification: favorable group (isolated 13q14 deletion or normal karyotype), unfavorable group (deletions of 11q22 or 17p13, or complex karyotype, ie, at least 3 chromosome aberrations); intermediate group (all other karyotypic abnormalities). A cut-off of 98% homology to the germline sequence to discriminate between IGHV mutated and unmutated cases. Mutation screening was performed on Ion Torrent PGM NGS platform on 20 CLL-related genes by using a 5% cut off.

**Results:** Cytogenetic analysis showed favorable findings in 30 patients, unfavorable in 34 cases and intermediate in 36 cases. A complex karyotype was present in 21 patients. By NGS, 95 somatic mutations were observed in 56/101 (55.3%) cases; 80 nonsense mutations, 5 nonsense mutations and 10 frameshift deletions. 16 cases (15.8%) cases in the remaining 11 genes 26/56 (46.4%) mutated patients presented two or more mutations. The presence of mutations was associated with unmutated IGHV status (p=0.040) and the complex karyotype (p=0.047). TP53 disruption correlated with the presence of 22 mutations by NGS (p=0.001) and a complex karyotype (p=0.012). By multivariate analysis an advanced Binet stage (p=0.001) and an unfavorable karyotype (p=0.01) predicted for shorter time to first treatment (TTFT), while TP53 disruption (p=0.019) and unfavorable karyotype (p=0.028) predicted for a worse overall survival (OS). A shorter time to chemorefractoriness (TCR) was associated with TP53 disruption (p=0.001) and unfavorable karyotype (p=0.025). Patients with both unfavorable karyotype and TP53 disruption presented a dismal outcome (median OS and TCR of 28.7 and 15.0 months respectively).

**Summary/Conclusions:** A comprehensive analysis of chromosomal aberrations and gene somatic mutations in high-risk CLL showed that the cytogenetic profile was independently associated with a shorter TTFT, OS and TCCR. Since karyotyping using novel mitogens may contribute to the refinement of prognosis in high-risk CLL patients, the introduction of this technique in future CLL trials seems warranted to identify those patients that could be ideal candidates for consolidation treatment or novel treatment combinations.
PRACTICE FOR PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

E1023

Figure 1.

Summary/Conclusions: The current analysis provides insight into adherence patterns of patients on long-term rituximab treatment. This result is consistent with the literature showing that PSPs like the YOU&i™ PSP can help to improve adherence rates (Schneider SM, et al. J Adv Pract Oncol. 2014;5(3):163-172). The information obtained from long-term adherence data can help to inform future trials examining patterns of adherence with OAMs. Nurse coaching may be helpful in supporting early adherence by addressing side effects that occur more frequently at treatment initiation. Moreover, changes in disease or health status that arise over the first 12 months of therapy may provide information that allows a PSP to adapt to patients’ evolving needs over the treatment journey. A better understanding of long-term adherence patterns may provide information that allows a PSP to adapt to patients’ evolving needs over the treatment journey. Over the past few years, oral-targeted therapies have been approved in the US for CLL pts, including those positive for del(17p).

Aims: This study used an electronic health record database to characterize treatment and del(17p) testing patterns in the first 2 lines of therapy (LoT) for CLL pts initiating treatment between 2011–2016. The association between del(17p) testing and utilization of targeted therapies was also explored.

Methods: This was a retrospective observational study in CLL utilizing a large, longitudinal, demographic and geographically diverse database of US cancer pts (Flatiron Health 12/2016). An analytical cohort of pts treated at community practice sites who initiated 1st LoT after Jan 2011 was developed. Two sub-cohorts of pts who initiated 1st LoT before and after 2014 were also identified. Analyzing the approval timing of oral-targeted therapies in the US:

Results: As of Dec 2016, 3,140 pts with CLL were included in the broad Flatiron Health CLL cohort. The results of this analysis are based on the analytical cohort that included 1,700 pts who initiated 1st LoT during 2011–2016, of which 1,134 (66.7%) pts initiated therapy after 2014. Second LoT was initiated in 622 pts (36.6%) between 6/2016, with 216 of the 2nd LoT initiations occurring after 2014. Average age at CLL diagnosis was 66.9 years; 63.2% of pts were male; 70.2% were Caucasian. Overall, 2011–2016, the rate of genetic testing by cytogenetics or fluorescence in situ hybridization (FISH) before initiation of 1st LoT was 67.4%. The rate of del(17p) specific testing before 1st LoT was 59.1% (an increase from 38.9% in 2011 to 64.4% in 2016). Among those who were tested before 1st LoT, 12.5% tested positive for del(17p). In the sub-cohort of pts who initiated 1st LoT after 2014, rituximab monotherapy replaced fludarabine, cyclophosphamide and rituximab (R) combination as the 3rd most frequent (13.0%) 1st LoT in pts with CLL, after bendamustine/rituximab (BR) combination (29.8%), and rituximab (R) monotherapy (17.7%). In contrast, ibritinib became the most common (43.9%) 1st LoT in newly diagnosed CLL pts with del(17p), followed by BR (24.5%) and R (7.1%). 36.6% of pts initiated 2nd LoT by December 2016. The three most common treatment sequences from 1st LoT to 2nd LoT were CIT to B-cell receptor pathway inhibitor containing therapy (16.4%), CIT to CIT (14.4%), and immunotherapy (IT) to IT (12.4%). Overall, the utilization of oral-targeted therapies has steadily increased since 2014, and multivariate analyses indicate that the presence of del(17p) is strongly associated (OR=8.7 and 2.8 for 1st and 2nd LoT, respectively) with this choice once these agents became available in 2014.

Summary/Conclusions: Considerable treatment pattern changes were observed for CLL pts in the US community practice due to the adoption of newly approved targeted therapies. Presence of del(17p) is strongly associated with choosing a targeted therapy regardless of LoT. Future research is needed to determine how differences in pt and disease characteristics and cytogenetic testing patterns influence treatment decisions and associated outcomes.

E1024

SINGLE-AGENT IBRUTINIB VS REAL WORLD TREATMENT FOR PATIENTS WITH TREATMENT-NAIVE (TN) CHRONIC LYMPHOCYTIC LEUKEMIA (CLL): AN ADJUSTED COMPARISON OF RESONATE-2™ WITH THE CLLEAR AND LYON-SUD DATABASES

1Department of Internal Medicine – Hematology and Oncology, University Hospital Brno, Faculty of Medicine, Masaryk University, Czech Republic, 2Hospices Civils de Lyon, Université Claude Bernard, Centre Hospitalier Lyon-Sud, Pierre Bénite, France, 31st Department of Internal Medicine – Hematology, General Faculty Hospital, Prague, 4Department of Hemato-oncology, University Hospital, Olomouc, Czech Republic, 5Janssen EU HEMAR Statistics & Modelling, Beerse, Belgium, 6Janssen EMEA HEMAR, High Wycombe, United Kingdom, 77Janssen-Cilag EMEA Medical Affairs, Dublin, Ireland, 8Janssen Pharmaceuticals, Paris, France, 94th Department of Medicine – Hematology, Charles University Hospital and Faculty of Medicine, Hradec Králové, Czech Republic

Background: The phase 3 RESONATE-2™ study demonstrated significant improvement of progression-free survival (PFS) and overall survival (OS) with ibritinib (ibr) vs chlorambucil (chl) in TN (aged ≥65 years) CLL patients. In the absence of direct comparison of single-agent ibr with other frequently utilized treatments in this patient population, we conducted an adjusted comparison of patient-level data from RESONATE-2™ vs RESONATE-2™.

Methods: This retrospective observational study included comparison of patient-level data from RESONATE-2™ vs RESONATE-2™. The rate of del(17p) specific testing before 1st LoT was 59.1% (an increase from 38.9% in 2011 to 64.4% in 2016). Among those who were tested before 1st LoT, 12.5% tested positive for del(17p). In the sub-cohort of pts who initiated 1st LoT after 2014, rituximab monotherapy replaced fludarabine, cyclophosphamide and rituximab (R) combination as the 3rd most frequent (13.0%) 1st LoT in pts with CLL, after bendamustine/rituximab (BR) combination (29.8%), and rituximab (R) monotherapy (17.7%). In contrast, ibritinib became the most common (43.9%) 1st LoT in newly diagnosed CLL pts with del(17p), followed by BR (24.5%) and R (7.1%). 36.6% of pts initiated 2nd LoT by December 2016. The three most common treatment sequences from 1st LoT to 2nd LoT were CIT to B-cell receptor pathway inhibitor containing therapy (16.4%), CIT to CIT (14.4%), and immunotherapy (IT) to IT (12.4%). Overall, the utilization of oral-targeted therapies has steadily increased since 2014, and multivariate analyses indicate that the presence of del(17p) is strongly associated (OR=8.7 and 2.8 for 1st and 2nd LoT, respectively) with this choice once these agents became available in 2014. Considerable treatment pattern changes were observed for CLL pts in the US community practice due to the adoption of newly approved targeted therapies. Presence of del(17p) is strongly associated with choosing a targeted therapy regardless of LoT. Future research is needed to determine how differences in pt and disease characteristics and cytogenetic testing patterns influence treatment decisions and associated outcomes.

E1023

TREATMENT AND 17P DELETION TESTING PATTERNS IN COMMUNITY PRACTICE FOR PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) IN THE UNITED STATES

T. Kapustynta1, H. Keim1, B. Meissner1, L. Zhang1, D. Jiang1

1AbbVie Inc., North Chicago, United States

Background: CLL is the most common type of leukemia in adults in the US. Traditionally, chemotherapy - and chemo-immunotherapy (CIT) have been the treatment mainstay. Historically, CLL patients (pts) with high-risk genetic features (e.g., 17p deletion (del(17p))) have poor prognosis and few treatment options. The current analysis provides insight into adherence patterns of patients on long-term rituximab treatment. This result is consistent with the literature showing that PSPs like the YOU&i™ PSP can help to improve adherence rates (Schneider SM, et al. J Adv Pract Oncol. 2014;5(3):163-172). The information obtained from long-term adherence data can help to inform future trials examining patterns of adherence with OAMs. Nurse coaching may be helpful in supporting early adherence by addressing side effects that occur more frequently at treatment initiation. Moreover, changes in disease or health status that arise over the first 12 months of therapy may provide information that allows a PSP to adapt to patients’ evolving needs over the treatment journey. A better understanding of long-term adherence patterns may allow programs such as the Canadian YOU&i™ PSP to target adherence support more precisely, thereby optimizing patient outcomes.

Aims: To evaluate patient adherence to ibrutinib, and patient and physician satisfaction with the YOU&i™ PSP

Methods: Using evidence-based literature reviews and global/local market research, various patient-centered barriers to treatment adherence were identified. Patient adherence was calculated using the Morsky Medication Adherence Scale© score, which informed nurse coaching frequency. Adherence was delineated by prescription refill compliance. Patient and physician questionnaires were used to gauge satisfaction with the YOU&i™ PSP.

Results: As of 20 January 2016, a total of 903 patients with CLL were enrolled in the YOU&i™ PSP. A total of 552 patients were included in the adherence analysis. Of these, 86% opted in to receive the nurse coaching component. At 2 months from treatment initiation, patients who received nurse coaching demonstrated an adherence rate of 92.3%, as compared with 63.5% for patients who did not receive nurse coaching (OR=17.5; 17.5-41.4; p <0.0001). At 9 months, adherence rates were 89.9% vs 60.8% (95% CI, -18.9 to 32.4; p=0.715). By 9 months, adherence rates were 81.7% vs 28.4% (95% CI, 72.2% to 32.4; p=0.0001) vs 28.4% (95% CI, -18.9 to 32.4; p=0.715). Discontinuation rates were similar in all patients, regardless of nurse coaching status at 9 and 12 months. Patients reported satisfaction rates of >90% in surveys conducted at both 3 months and 12 months of program enrollment. Of physicians surveyed at 3 months, 96% reported that the YOU&i™ PSP was helpful in supporting patient needs.

Aims: hard.
pared between ibru and RW treatment using patient-level data from RES-
ONATE-2™ (n=136) and pooled patient-level data from the two cohorts. To
adjust for differences in patient characteristics between the trial population
and both cohorts, a multivariate Cox proportional hazards model was fitted on
patient-level data to estimate the hazard ratio (HR) for ibru vs RW treatment,
with age, sex, disease stage (based on RA1/IBINET), and deletion 11q pres-
ence/absence instead as covariates.

Results: Median age at treatment initiation for CLCLEAR (n=1418) and Lyon-Sud
(n=110) was 73 and 71 years, respectively, vs 73 for ibru patients from RES-
ONATE-2™. The proportion of male patients was 63% in CLCLEAR and 57% in
Lyon-Sud vs 65% in RESONATE-2™. The median follow-up was 35.7 months
(months; mo) for Lyon-Sud and 16.8 mo in CLCLEAR vs 29.1 mo for RESONATE-2™.
Adjusted HR for ibru vs physician choice in CLCLEAR and Lyon-Sud were 0.23
(95% CI: 0.14, 0.39) and 0.25 [0.14, 0.43] for PFS, and 0.29 [0.11, 0.79] and
0.39 [0.18, 0.83] for OS, respectively. FLudarabine/cyclophosphamide+ritux-
imab (FCR; n=117), bendamustine+R (BR; n=91), Chi alone (n=43), Chi+R
(n=45), and other R-containing regimens (n=154) were the most commonly
used treatment regimens across both RW cohorts. Older age, male gender,
advanced disease stage and del11q positive status were independent risk fac-
tors for PFS and OS. The adjusted HRs (pooled estimates) for ibru vs the two
most commonly used regimens were 0.30 [0.17-0.53] (FCR) and 0.33 [0.16-
0.68] (BR) for PFS, and 0.44 [0.20-0.95] (FCR) and 0.53 [0.13-0.83] (BR) for OS (Figure 1). Estimates of HR vs regimens in the cohorts were consistent across both databases.

Figure 1.

Summary/Conclusions: This adjusted comparison of patient-level data from
RESONATE-2™ with RW data from CLCLEAR and Lyon-Sud demonstrates ibru
to be more effective compared with RW treatment, with a 4-fold improvement
in PFS and a 3-fold improvement in OS. When comparing ibru with the most
commonly used RW treatments, statistically significant benefits for ibru were
consistently observed vs all treatment regimens on PFS and for most comparis-
ones on OS. These results further support the existing evidence that ibru sig-
nificantly improves PFS and OS vs common regimens used in TN CLL settings,
and has important implications for clinical practice.

E1025

CHARACTERISTICS, TREATMENT, AND OUTCOMES OF ≥80 YEAR OLD PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) ENROLLED TO PROSPECTIVE TRIALS OF THE GERMAN CLL STUDY GROUP (GCLSG). O. Al-Sawai1,1, J. Bahlo1,1, K. Fischer1,1, C. Herlinger1,1, M. Hochstetler1,1, A. Fink1,1, J. von Tresckow1, P. Langerbeins1, P. Cramer1, S. Stilgenbauer3, C. Wendtner2, B. Eichhorst1, M. Hallek1, V. Goede1

1Department of Internal Medicine, German CLL Study Group, University Hospi-
tal of Cologne, Cologne, 2Department of Hematology, Oncology, Immunology, Palliative Care, Infectious Diseases and Tropical Medicine, Hospital Munich-Mu-
chsberg, Munich, 3Department of Internal Medicine III, University Hospital of Ulm, Ulm, Germany

Background: People over 80 years are the fastest growing age group in western
populations. Clinical management of ≥80 year old patients (pts) with CLL
remains a challenge due to the very limited amount of data currently available
for this age segment. Two retrospective studies reported observational data on
characteristics, treatment, and outcomes of ≥80 year old pts not enrolled in a
clinical trial (Bahlo et al., Meunier et al.). There is little known about ≥80
year old pts who were treated for CLL within clinical trials, however.

Aims: To study the characteristics, treatment, and outcomes of pts aged ≥80
years who received their first therapy within prospective trials of the German
CLL Study Group (GCLSG).

Methods: Trial populations of seven clinical trials of the GCLLSG (CLL1, CLL5,
CLL7, CLL8, CLL9, CLL10, CLL11; total N=3552) were reviewed and screened
for ≥80 years at frontline treatment. Clinical, laboratory, and genetic data of
identified pts were pooled. Time-to-event data were analysed by Kaplan-Meier
methodology. Independent prognostic factors for survival were identified by
multivariate analysis using Cox regression modelling with stepwise selection
procedures.

Results: Among 3552 reviewed GCLLSG trial participants, 152 were aged ≥
80 years at initiation of firstline treatment. A majority of these pts were identified
from CLL1 (n=132) while the remaining were from CLL1 (n=3), CLL5 (n=1),
CLL7 (n=3), CLL8 (n=2), CLL9 (n=9), and CLL10 (n=2). Median age was 82
years (range 80-90). Concomitant diseases were present in 99% of the pts and
median cumulative illness rating scale (CIRS) score was 8 (0-18). Median cre-
tinine clearance was 46 ml/min (range 17-99 ml/min). Identified genomic
aberrations were 13q deletion as a sole abnormality in 27%, trisomy 12 in 18%,
11q deletion in 9%, and 17p deletion in 16% of pts. (IGH) was unmutated in
69% of the pts. Distribution of CLL-IPI risk groups was as follows: 6% low, 19%
intermediate, 61% high, and 14% very high. Most pts had Binet Stage B (36%)
 or C (43%). Chemoimmunomotherapy with chlorambucil plus obinutuzumab (CL-
OB) or chlorambucil plus rituximab (CLB-R) was administered to 61 (40%) and
56 (37%) pts, respectively. Remaining pts received chlorambucil alone (CLB,
n=19), fludarabine (F, n=10), fludarabine/cyclophosphamide (FC, F=n1), fludar-
bine/cyclophosphamide/rituximab (FCR, F=n2), or bendamustine/rituximab (BR,
n=3). Rates of grade 3 or 4 neutropenia and infections were 35% and 13%,
respectively. Premature treatment discontinuations occurred in 15% of cases
and were mostly due to adverse events. The total overall response rate was
92% with 13% complete remissions. Median observation time for all pts was
40.7 months. Median progression-free survival (PFS) and treatment-free sur-
vival (TFS) were 17.2 and 32.3 months, respectively. A total of 47 pts (31%)
received at least one further line of treatment. Median overall survival (OS)
was 48.3 months, with adverse events (22%) and progressive CLL (16%) being
the most frequent causes of death. Standardized mortality ratio was calculated
and showed a 1.99 (CI 1.54-2.53) increased risk of death as compared to an
age- and sex-matched general population. Independent prognostic factors for
OS were 17p deletion and elevated serum thymidine kinase.

Summary/Conclusions: Findings suggest that antileukemic therapy (including
chemoimmunotherapy) is feasible and efficacious in ≥80 year old pts with CLL.
However, such pts are still highly underrepresented in clinical trials and even
with modern treatment live shorter than age-matched controls of the general
population. Broader recruitment of these pts to prospective trials and evaluation
of targeted therapies therefore appears imperative to improve outcome of CLL
in this age segment.

E1026

THE ROLE OF CD200 IN THE DIAGNOSIS OF CHRONIC LYMPHOCYTIC LEUKEMIA A. Mora1,2, E. P. Vicente1,2, C. Cuellar1,2, R. Bosch1,2, L. Blanco3, R. Martino3, J. M. Ubeda3, J. Sierra3, C. Moreno3, J. Normen2

1Laboratory of Oncology, Immunology and Transplantation, Institute of Biomed-
ical Research, IIB Sant Pau, 2Department of Hematology, 3Laboratory of Hema-
tology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

Background: Clinical, morphologic, immunophenotypic and genetic features are
the basis for the diagnosis of B-cell malignancies. It is considered that the
diagnosis of CLL requires the presence in peripheral blood of ≥5x10⁹/L monoclonal
B lymphocytes with a distinctive immunophenotype (i.e. SmIg+, CD5-, CD19,
CD23+). Based on immunophenotypic characteristics, Matutes et al de
declared in 1994 a immunophenotypic score based on a few markers (CD5+, CD23+,
FMC7+, SmIg+, and CD22+). Each one of them receiving a score of 1
if present or 0 if absent. A total score of 4 or 5 is typical of CLL whereas those
cases scoring 0 or 1 correspond to other B-cell malignancies, mostly lymph-
omas. Nevertheless, clinical and immunophenotypic features of CLL may
collapse with other B-cell malignancies. CD200 has been described as a marker
potentially useful to distinguish CLL from other CD5+B-cell malignancies.

Aims: The aim of this study was to analyze whether the addition of CD200 to
the Matutes score improves the diagnostic accuracy of CLL.

Methods: We prospectively assessed the immunophenotype of 99 peripheral
blood samples of patients with suspected lymphoproliferative disorders
between November of 2015 and January of 2017. Immunophenotyping was
performed using a Canto Flow Cytometer (Becton Dickinson) and samples
were stained with routine combinations plus CD200. The Matutes score
was calculated as follows: FMC7, CD22 and CD79b were considered score 1
in patients with ≥80% cells positive. CD22 and CD23 were considered score
1 when the positive cells were >30%. The cut-off used for CD200 was
calculated by Receiver Operating Characteristics (ROC). CD200 was scored
as 1 when the positive cells were >96%. Mean Fluorescence Intensity Ratio

Figure 1.

Summary/Conclusions: Findings suggest that antileukemic therapy (including
chemoimmunotherapy) is feasible and efficacious in ≥80 year old pts with CLL.
However, such pts are still highly underrepresented in clinical trials and even
with modern treatment live shorter than age-matched controls of the general
population. Broader recruitment of these pts to prospective trials and evaluation
of targeted therapies therefore appears imperative to improve outcome of CLL
in this age segment.
(MFI) was calculated as a relative expression between MFI positive population and MFI negative population. Multivariate analysis was used to assess statistical significant differences in accuracy among individual markers and scoring systems. The treating physician made the final diagnosis of the different B-cell malignancies according to IWCLL and WHO criteria. Logistic regression including sensitivity, specificity and accuracy values, were used to evaluate statistical differences in diagnostic precision between different combinations of markers as well as individual markers.

**Results:** Flow cytometry analysis was performed in 99 patients, including 62 cases with a diagnosis of CLL (82.6%) and 37 cases with a “non-CLL” diagnosis (37.4%). Matutes score was 4-5 in all CLL cases and ≤3 in “non-CLL” cases. CD20, CD23 and CD5 were the most consistent markers for CLL (90.3%, 96.8% and 100.0% of sensitivity respectively). Moreover, CD79b and FMC7 had a good discriminant value (80-85% sensitivity). For “non-CLL” cases the most relevant markers were SmIg, FCMI7 and also CD20. The analysis of the accuracy is shown in the table. Of note, CD200 as a single marker was found to be a reliable marker for distinguishing CLL and “non-CLL” cases (90.9%; p<0.001; 90.3% sensitivity, 91.9% specificity) showing a significantly higher accuracy than CD5, CD23 and SmIg as individual markers (p<0.001). The accuracy of CD200 did not vary when comparing% of positive cells with MFI. In contrast, the accuracy for SmIg significantly increased from 67.7% to 78.8% when using MFI values (according to the cut-off established by ROC curves), being lower in CLL than in “non-CLL” cases (71.0% vs 86.5%, p<0.001). Finally, the addition of CD20 to the Matutes score system and using a cut off ≥4 improved its accuracy from 88.9% (95% CI: 88.2-95.6) to 98.0% (95% CI: 94.7-100.0) and showed a better sensitivity.

**Summary/Conclusions:** These results confirm CD200 as a valuable marker in the diagnosis of CLL.

**E1027**

**COMPARISON OF CHROMOSOME BANDING ANALYSIS AND GENOMIC MICROARRAY TECHNIQUES FOR THE DETECTION OF COMPLEX KARYOTYPES IN CHRONIC LYMPHOCYTIC LEUKEMIA**

**Background:** Well-established poor prognostic factors in chronic lymphocytic leukemia (CLL) include cytogenetic abnormalities (≥3 abnormalities, CK) by CBA were included [Median age: 73; 15 males (63%)]. Median time from diagnosis to CBA/microarray analysis was 3 months (range, 0-160), and 4 patients (16%) had received prior treatment. The cohort was enriched in del(17p) and del(11q23) (47% and 42%, respectively). DNA from peripheral blood lymphocytes was hybridized to Cytogenet whole-genome 2.7M (n=2) or CytoScan HD (n=22) array, results were analyzed with Chromosomal Analysis Suite Software (Affymetrix). Number, size and type of aberrations detected were compared between techniques.

**Results:** A median of 3.5 aberrations (range: 3-9) were detected by CBA, being significantly lower than the copy number abnormalities (CNA) identified by microarrays (median 5, range: 1-28; P=0.018). The median size of the CNA was 5.4Mb (range: 0.1-174Mb). Current recommendations for microarray analyses suggest that only CLL known abnormalities and CNA >5Mb should be considered for clinical interpretation (Schoumans et al, 2016). When applying this cutoff, 42% of the initially detected CNA (74/177) were omitted and no significant differences in the number of abnormalities by each technique were found (P=0.334). CNA <1Mb did not involve any chromosomal altered region in the corresponding karyotype. Thus, their omission probably would not affect the stratification based on complexity. In contrast, most of the CNA between 1 and 5Mb involved small CNA associated to apparently balanced translocations by CBA, and in some cases revealed a higher genomic instability than the previously recognized by CBA (i.e. multiple deletions defined as a single one or a monosomy by CBA). Indeed, four cases showed chromothripsis not detected by CBA which has been associated with impaired outcome (Salaverria et al, 2015). Of note, genomic microarrays failed to detect some balanced translocations or subclonal aberrations by CBA, which probably were represented in a minor proportion of the sample but expanded during CBA culture. Thus, eight patients (21%) could only be considered complex by CBA, as by microarray analyses <3 CNA were detected. The present study is ongoing; additional cases have been collected in order to statistically assess the clinical impact on survival of the complexity detected by microarrays.

**Summary/Conclusions:** 1. The number of chromosomal abnormalities detected in CLL patients differs if assessed by CBA or genomic microarrays. 2. The current 5Mb cut-off to define clinically relevant CNA should be revised, as it could underestimate genomic instability (contiguous small deletions, chromothripsis). 3. More studies should be performed to establish standard criteria for prognostic stratification of CLL patients based on genomic complexity consistent with the results from both techniques.

**E1028**

**ABNORMAL SERUM FREE LIGHT CHAINS RATIO ASSESSMENT IN CHRONIC LYMPHOCYTIC LEUKEMIA: A SIMPLE YET POWERFUL TEST CORRELATING WITH CLINICAL OUTCOME AND MINIMAL RESIDUAL DISEASE**

F. Durieu, M. Le Bouar, F. Bijou, A. Schmitt, J. Blanchi, G. Etienne

**Background:** An abnormal serum Free Light Chain (sFLC) ratio has been shown to be significantly associated with poor outcome in chronic lymphocytic leukemia (CLL) (Yegin ZA et al, Eur J Haematol 2010, suggesting that this parameter may discriminate different biological subgroups.

**Aims:** As the technic is easily implementable in routine lab and cost effective, we evaluated the sFLC levels (kappa + lambda) and kappa/lambda (K/L) ratio in CLL patients in this prospective study. The relationship between abnormal sFLC levels (K+L) and/or K/L ratio, minimal residual disease (MRD) assessed by flow cytometry (FCM) and disease evolution was evaluated.

**Methods:** Diagnosis was confirmed by 10-color FCM immunophenotyping of blood lymphocytes on a Navios (Beckman Coulter). Serum FLC kappa and lambda chains were measured by nephelometry using the Freeliteimmunoassay. The normal free kappa chains level was defined as within the range of 3.3-19.4mg/L, and the normal lambda chains level within the range of 5.71-26.30mg/L. A normal sFLC kappa/lambda(K/L) ratio was therefore defined as between 0.26 and 1.65 (a ratio above 1.65 indicating an excess of kappa light chain, and a ratio below 0.26 indicating an excess of lambda light chain). The cumulative level of kappa plus lambda (K+L) was also evaluated. Most patients received combined chemo-immunotherapy or entered clinical trials whenever possible. The ROC methodology was used to establish the best cut-off value of sFLC ratio level to discriminate treated patients from those who remained treatment-free.

**Results:** Main patients characteristics are detailed [N=147, M/F:75/72, 111 in early stage disease, Del1p in 11 patients and Del1q in 15]. Median age was 54 years.
69 years (range 34 to 86). Ninety patients were untreated during the follow-up period. Median follow-up duration was 30 months (range 0 to 101). Furthermore, sFLC measurement was assessed in 57 patients who progressed during the study and required treatment according to international guidelines. ROC curve analysis determines cut-off level of K/L ratio at 1.88. Abnormal sFLC was observed at diagnosis in 50.9% (N=29) of all treated patients. The mean ± SD ratio of sFLC in the untreated patients group and in the treated patients group was 1.51±2.08 and 2.80±3.75 respectively (p=0.0082). Considering the sFLC levels (kappa + lambda), the mean±SD in the untreated patients group and in the treated patients group was 29.1±17 and 53.0±41.9 respectively (p<0.0001).

Treatment systematically induced a modification of the sFLC K/L ratio. Interestingly, after treatment completion, the persistence of an abnormal sFLC K/L ratio was associated with frequent bleeding complications, explained by inhibition of BTK, which mediates downstream signaling of GPVI and GPIb receptors in platelets. Levels of CD42b, CD61, CD62P, PAC1, annexin V binding, and peptide. Levels of CD42b, CD61, CD62P, PAC1, annexin V binding, and

Methods:
Forty-three patients with relapsed and refractory CLL and 10 healthy donors were included in the study. Platelet functional activity was characterized by flow cytometry before and after activation with SFLLRN plus collagen-related peptide. Levels of CD42b, CD61, CD62P, PAC1, annexin V binding, and megacarpel release were determined. Aggregation with collagen, ADP and ristocetin were measured. All tests were performed before initiation of treatment, at weeks 2, 4, 8 and at 6 months. Bleeding complications were scored using ITP-specific Bleeding Assessment Tool.

Results:
Among 43 CLL patients, 29 (67%) were men, the median age was 65 (range 31 to 83 years). Four patients with del (17p) received ibrutinib as a first line. In 39 previously treated patients the median number of prior treatments was 3 (range, 1-6). Del17p or TP53 mutation was found in 11 (25%) patients. Only 1 patient received anticoagulant and antiplatelet drugs. Median duration of ibrutinib treatment was 8.2 months (range 2.2-10.9). At least one bleeding episode occurred in 23 patients (53%). Among patients with bleeding, 14 (61%) had grade 1 events, 7 (30%) had grade 2 and two (9%) had grade 3 events. Bleeding frequency decreased with time on ibrutinib: only 4 patients still had bleeding episodes after 6 months. The patients with bleeding had slightly lower mean platelet count that those without (120 versus 170 thousands per microliter, P<0.0001) and higher lymphocytosis (74 versus 45, P=0.05). Their activation of integrins in response to stimulation was greatly impaired (9% versus 26%, P<0.0001; while the 95% confidence interval for healthy controls 63-137%), and there was significant deficiency in procoagulant activity as well (2% versus 5%, P=0.01; normal range is 7-35%). Importantly, the integrin activation allowed risk stratification: a person with more than 9% integrin activation had less than 10% risk to develop bleeding while the one with less than 9% integrin activation had a risk of more than 40%. There was no difference in dense- or alpha-granule release between the patient groups, and these indicators remained in their normal ranges. There were also significant differences in aggregation assays with ADP (25±16% versus 36±18% for bleeding and non-bleeding patients, P<0.001), collagen (38±19% versus 53±20%, P<0.001), and ristocetin (53±22% versus 62±20%, P=0.02). Interestingly, the patients with bleeding had negative correlation between ITP-specific bleeding assessment and integrin activity level.

Summary/Conclusions: Both classic aggregation assays and flow-cytometry-based techniques demonstrate impaired platelet function in the bleeding CLL patients compared with non-bleeding ones. The level of integrin activation appears to be the most sensitive and able to identify patients with different bleeding risks.

E1030 HYPOGAMMAGLOBULINEMIA IS A STRONG PREDICTOR OF TIME TO FIRST TREATMENT IN CHRONIC LYMPHOCYTIC LEUKEMIA
G. Reda1, R. Cassin1,*, G. V. Levati 2, B. Fattizzo2, V. Mattiello2, D. Giannarelli3, W. Barcellini1, A. Cortelezzi4
1Oncohematology Department, Foundation IRCCS Ca’ Granda Ospedale Maggiore Policlinico of Milan, Italy, 2Oncohematology Department, Foundation IRCCS Ca’Granda Ospedale Maggiore Policlinico and University of Milan, Italy, 3Regina Elena National Cancer Institute, Rome, Rome, Italy

Background: Management of chronic lymphocytic leukemia (CLL) dramatically improved since the introduction of novel therapies. Rarely patients requires treatment at diagnosis and approximately a third of patients will never require therapy. Predictive and prognostic factors are well known (IGHV, del11q, del17p, TP53); CLL-IPI score including age, clinical stage, beta2microglobulin, IGHV and deletion 17p and/or TP53 mutation has been recently validated. It identifies 4 risk groups with significantly different time to first treatment (TTFT) and overall survival (OS). Hypermobagglubulinemia (HYPO) is a typical feature of CLL, with an incidence of 20-60% at diagnosis and a relationship with infections occurrence. Prognostic significance of HYPO at diagnosis has not been extensively evaluated in terms of OS and TTFT. Only IgG serum levels have been reported to be associated with TTFT but no data are available on other immunoglobulin classes (Ig).

Aims: To evaluate the impact of HYPO and single Ig classes on TTFT in a retrospective cohort of CLL patients and to assess the relationship between HYPO and CLL-IPI.

Methods: We retrospectively evaluated 698 consecutive CLL patients diagnosed at our Institution from 1983 till 2016. Data from laboratory, biological analysis and clinical stage were collected. We also evaluated immunoglobulin (Ig) subclasses (i.e. IgG, IgM and IgA) at diagnosis and calculated CLL-IPI. HYPO was defined basing on our laboratory cut-offs (IgG 70mg/dl, IgG 700mg/dl, IgG 40mg/dl). However, as no recognized prognostic/predictive Ig cut off has been reported to date, we aimed to identify a prognostic threshold for each Ig class.

Results: From 698 patients assessed, 410 cases were evaluable for Ig levels at diagnosis. IgA levels were lower than 70mg/dl in 17.4%, IgG lower than 700mg/dl in 22.2%, and IgM lower 40mg/dl in 33.7%. Forty-six percent of patients presented deficit of at least one Ig class, while 7.8% of patients had all Ig low. Each Ig deficit was related with a shorter TTFT with the following hazard ratios (HRs): 2.09 (1.45-3.03) for IgA (P<0.0001), 1.58 (1.10-2.27) for IgG (P=0.008) and 1.52 (1.09-2.13) for IgM (P=0.01) (Figure 1, A-B-C). However, only IgA deficit maintains statistical significance in multivariate analysis [HR 1.59 (1.08-2.35)]. A prognostic threshold for each Ig class was identified maximizing the differences in TTFT and the following values were obtained: 80mg/dl for IgA, 410mg/dl for IgG and 18mg/dl for IgM (Figure 1, D-E-F). Considering CLL-IPI, 18 patients presented IPI 0-1, 99 had IPI 2-3, 32 patients IPI 4-6, and 12 patients had IPI 7-10. Even in our series, CLL-IPI separated four risk groups with different TTFT and OS, suggesting that our cohort may be suitable to evaluate new prognostic factors. As regards the relationship between HYPO and CLL-IPI, we observed a correlation with IgA levels, using our laboratory cut-off. Moreover, we found a relationship among CLL-IPI and both IgA and IgG values, when using the newly validated Ig cut-off. Finally, CLL-IPI was a stronger prognostic factor for TTFT than HYPO in our analysis. However, the addition of IgA deficit to CLL-IPI appears to further improve CLL prognostication.

Figure 1.

Summary/Conclusions: In conclusion, HYPO significantly impacts on CLL prognosis. Moreover, even if CLL-IPI has a stronger prognostic value for TTFT compared to HYPO, the addition of IgA deficit appears to further improve CLL prognostication.

haematologica | 2017; 102(s2) | 423
E1031

CLL: IS LYMPHOCYTE DOUBLING TIME (LDT) A RELEVANT PROGNOSTIC PARAMETER IN THE ERA OF PROGNOSTIC BIOMARKERS?

1Hematology Department, Institute of Hematology and Oncology, Hospital Clinic, IDIBAPS, University of Barcelona, Barcelona, Spain; 2Hematology Department, Hospital de Clinicas, Asuncion, Paraguay; 3Hematopathology Unit, Pathology Department, Institute of Hematology and Oncology, Hospital Clinic, IDIBAPS, University of Barcelona, Barcelona, Spain

Background: In CLL, tumor doubling time is reflected by the pace at which lymphocytes increase in blood (lymphocyte doubling time or LDT). However, since LDT is rarely available at the time of diagnosis, its role in assessing prognosis in patients is controversial.

Aims: To reassess the prognostic significance of LDT in a large series of patients.

Methods: Retrospective single-center study based on 629 patients diagnosed with CLL/SLL. LDT was measured at the time of diagnosis or prior WBC counts were available or calculated after diagnosis by linear regression analysis, usually over a treatment-free period of 2 months and including at least three WBC counts.

Results: 140 patients displayed short LDT (≤12 months) and 489 long LDT (>12 months). The median follow-up was 13.4 years (6.1-22.5) and 11.2 years (2.3-30.9), respectively. Patients with short LDT were younger (p=0.005), had higher ALC (p<0.001), higher B2M (B2M; p=0.035) levels and also a tendency towards lower levels of Hb and platelet counts. A short LDT was also associated with an increased expression of ZAP70 and CD38, unmutated IGHV (all p<0.001) and poor FISH cytogenetics (del17p, del11q) (p<0.001). Additionally, patients with a short LDT presented more frequently mutations in NOTCH1 (p=0.001), ATM (p=0.029), TP53 (p=0.035) and a tendency to more mutations in SF3B1 (p=0.102). The proportion of patients treated in each group was markedly different [80% vs 46%] as it was the median time to treatment (TTT, 1.4 vs 9.4 years; p<0.001).

Conclusion: A short LDT is a relevant parameter for OS. Further studies should address whether this result also applies to patients treated with novel agents.

Figure 1.

Summary/Conclusions: All IFs are still regarded as equally important, although no solid evidence exists to support such statement. In our series, infiltrative cytopenia and/or progressive lymphadenopathy/splenomegaly constituted the IT in most (85%) CLL patients. In spite of being enriched in favorable biological prognostic factors (mutated IGHV genes, low ZAP70 expression and favorable-risk cytogenetics), MF patients had a shorter age-adjusted OS from first-line therapy compared to LML patients. Further studies should address whether this result also applies to patients treated with novel agents.

E1032

INDICATIONS FOR TREATMENT IN CHRONIC LYMPHOCYTIC LEUKEMIA: CLINICO-BIOLOGICAL CHARACTERISTICS AND PROGNOSTIC IMPACT

P. Mozos1, A. Rivas-Delgado1, T. Baumann1, V. Ortiz-Maldonado2, A. Navarro2, D. Costa3, M. Aymerich3, N. Villamor3, E. Montserrat1, J. Delgado1

1Hematology, 2Pathology, 3Hematopathology Unit, Pathology, Hospital Clinic de Barcelona, Institut d'Investigacions Biomèdiques August Pi i Sunyer, Barcelona, Spain

Background: Chronic lymphocytic leukemia (CLL) is characterized by the progressive accumulation of monoclonal CD5+ B cells in the bone marrow and lymphoid tissues. International guidelines recommend initiation of treatment only in case of infiltrative cytopenia, progressive splenomegaly or lymphadenopathy, short lymphocyte doubling time (LDT), B symptoms and/or refractory disease (IC). These criteria are based on experts' consensus and considered equally relevant for treatment initiation, even though little evidence exists concerning the relative value of each individual criterion.

Aims: To describe the clinico-biological characteristics and prognosis of CLL patients according to the criteria that prompted the initiation of first-line treatment.

Methods: Data were collected consecutively on 530 consecutive patients with CLL who received frontline therapy from 1978 to 2014 and had their indication(s) for treatment (ITT) recorded. Massive/progressive lymphadenopathy and massive/progressive splenomegaly were grouped together as lymphoid mass (LM), infiltrative anemia and thrombocytopenia were categorized as marrow failure (MF). As 505 patients initiated therapy with both ITT, we decided to focus on these two groups. Patients whose ITT was both LM and MF were classified as MF following the logic behind Rai and Binet staging systems.

Results: Median age of the whole cohort was 62 years (range 22-93), and 63% of patients were male. Median follow-up from first-line therapy was 64 months (range, 1-433). Half of the patients had a single ITT, while the other half had two or more. ITT were LM in 72% patients, MF in 31%, short LDT in 29%, B symptoms in 19%, and IC in 3%. Compared to patients from the LM group, patients from the MF group were significantly older, had a significantly higher β2-microglobulin level (probably due to an age-related impaired renal function), and were more frequently treated due to LM and had more frequent adverse prognostic characteristics, such as higher ZAP70 expression, unmutated IGHV genes, and 11q deletion. The median OS of the entire population was 77 months (95% confidence interval [CI]=71-83) from first-line therapy and 108 months (95% CI=102-118) from diagnosis. Indication for treatment was significantly associated (p=0.001) with a shorter OS from first-line therapy: 63 months in the MF group (95% CI: 48-72), compared to 89 months in the LM group (95% CI: 80-106). This association remained significant after adjusting for age and β2-microglobulin concentration.

Background: The presence of TP53-inactivation in chronic lymphocytic leukemic lymphoma (CLL), namely through the deletion of all or part of the chromosome region containing its locus, is a well-established marker of poor prognosis and chemoresistance to traditional chemotherapeutic agents. Fluorescence in situ hybridization (FISH) is a useful tool for the detection of the deletion. Nevertheless, its sensitivity is influenced by the number of blood-cell lineages that carry the aberration (IC), the absolute count of deletion-positive cells, and the proportion of deletion-positive neoplastic cells relative to deletion-negative neoplastic cells and non-neoplastic cells, in the whole blood or bone marrow sample. The latter issue can be minimized by purifying the sample through the selection and separation of tumor cells, using techniques such as fluorescence-activated cell sorting (FACS).
Methods: We reviewed all CLL samples that were submitted for the investigation of TP53-deletion through FISH, in our Lab, between January 1st 2011 and February 28th 2017. Results obtained on tests performed on whole mixed cellularity samples were compared with results obtained directly in FACS purified CLL clonal lymphocytes.

Results: We analyzed 410 samples tested for the deletion of TP53 in our Lab during the 6-year study period. The majority of patients (63.2%) were male. Although FACS separation of neoplastic cells was only introduced within the last two years of the study period, it accounted for 39.0% of all tested samples. This poor prognostic aberration was identified in 15.8% of patients in the overall cohort, with no differences in the incidence of a positive finding between mixed cellularity samples and FACS purified samples (15.6% vs 16.2%, respectively, p=NS). In contrast, the average proportion of positive cells within a positive sample was markedly different between mixed cellularity samples and FACS-processed samples, increasing nearly three-fold through the purification of the sample, from 24.0±15.9% to 62.9±33.3%, p<0.001. In fact, in 57.7% of all patients who were tested after FACS separation of CLL cells, the TP53-deleted clone was larger than 50% of neoplastic clonal lymphocytes, making it the primary clone.

Summary/Conclusions: We observed that the pre-processing of the sample through the FACS-supported purification of CLL neoplastic lymphocytes revealed that the TP53-deleted clone was nearly three-fold larger than suggested by the mixed cellularity sample, increasing from an average of a quarter of all cells, to nearly two-thirds. This finding uncovered that the TP53-clone was, in fact, the primary major clone within the neoplastic lymphocyte population in the majority of patients. Considering the poor prognosis conferred by the aberration, and its impact on current treatment decisions, it is quite significant to correctly identify a primary deletion-positive clone, instead of mislabeling it as a secondary minor clone.

E1034
PRIMARY PEGFILGRASTIM PROPHYLAXIS VERSUS FILGRASTIM GIVEN "ON DEMAND" FOR CLADRIBINE-INDUCED NEUTROPHILIA IN HAIRY CELL LEUKEMIA

1The Ruth and Bruce Rappaport Faculty of Medicine, Technion, Haifa, 2Department of Hematology, Sourasky Medical Center, Tel aviv, 3Department of Hematology, Hadassas University Hospital, Jerusalem, 4Department of Hematology, Rabin Medical Center, Petah-Tikva, 5Department of Hematology, Meir Medical Center, Kfar-Saba, 6Hematology Unit, Kaplan Medical Center, Rehovot, 7Department of Hematology & Bone Marrow Transplantation, Rambar Health Care Campus, Haifa, 8Hematology Unit, Emek Medical Center, Afula, 9Department of Hematology, Shaare Zedek Medical Center, Jerusalem, 10Hematology Unit, Galilee Medical Center, Naharia, 11Hematology Unit, Ziv Medical center, Zefat, 12Department of Hematology, Soroka Medical Center, Beer-Sheva, 13Department of Hematology, Hadassas University Hospital, Jerusalem, 14Hematology Unit, Bnai-Zion Medical Center, Haifa, Israel.

Background: Major advances in the treatment of patients with HCL were made in the 1980’s after the introduction of two purine analogues: pentostatin and cladribine. Both these agents dramatically altered the clinical course and outcome of this disease and induced high response rates of 75-90%, with durable remissions and subsequent median relapse-free survival of up to 15 years. The major significant short-term toxicity of therapy with cladribine are neutropenia and neutropenic fever (NF). Based on the script data: 71% of patients experienced grade 4 neutropenia (absolute neutrophil count [ANC] <500x10^9/L), and 42% develop NF. The latter complications may result in life-threatening infections, as well as hospitalization.

Aims: In this retrospective study, we compared the incidence and duration of neutropenia, NF and hospitalization in patients with HCL treated with cladribine following pegfilgrasim as primary prophylaxis versus daily filgrastim given "on demand" according to the neutrophil count.

Methods: The study population included 202 patients with HCL, diagnosed and followed in 12 medical centers in Israel during 1985-2015. Patients were treated with cladribine, for 5-7 days given either sub-cutaneously or via intravenous infusion. Medical records were evaluated for details of disease at diagnosis, including date of diagnosis, age, sex, ethnicity, complete blood count results, and spleen size at diagnosis. The efficacy of pegfilgrastim and filgrastim was assessed by evaluating the incidence of neutropenia (defined as ANC <1000x10^9/L), number and length of hospitalizations due to NF, severity of infections and the number of days from the last day of therapy until recovery of ANC to >1000x10^9/L.

Results: Mean follow up was 7.5 years (0.1-40), with 5 and 10 years’ survival of 96% and 90.62% respectively. The median age at diagnosis was 53 years, and 81.8% were males. First line therapy with cladribine was given to 159 patients, and of these 50.3% required hospitalization for the administration of broad-spectrum antibiotics due to NF. The risk factor to develop NF was WBC<0.6 10^9/L, and ANC<0.310^9/L. Twenty eight patients were treated with pegfilgrastim as primary prophylaxis 24 hours after the last day of therapy with cladribine, while 75 patients received filgrastim “on demand” due to neutropenia. Median hospitalization days, and Nadir duration was 8 and 18 days respectively in both groups (p=0.71, p=0.44).

Table 1.

Summary/Conclusions: Infectious complications post cladribine treatment, remains high, with an incidence of 50.3%. For all parameters analyzed, including the percentage of febrile patients, number of febrile days, and NADIR duration the results of primary pegfilgrastim prophylaxis and filgrastim given on demand were similar. Accordingly, we conclude that it remains the treating physician’s choice to decide on which type of filgrastim to use and when to administer it.

E1035
REDUCED HEALTHCARE RESOURCE UTILIZATION IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA ACHIEVING COMPLETE REMISSION TO FIRST-LINE THERAPY

S Heitner Enschede1, J. Samp1, A. Guerin2, R. Foster3, B. Meissner1, A. Rokito3, G. Gauthier2

1AbbVie, Inc., North Chicago, United States, 2Analysis Group, Inc., Montreal, Canada, 3Analysis Group, Inc., New York, United States

Background: Most targeted therapies in the management of chronic lymphocytic leukemia (CLL) lead to high overall response rates but complete remissions are rare. Achieving complete remission (CR) is associated with improved clinical outcomes such as longer time to progression; however little is known about the economic benefits associated with achieving CR.

Aims: The objective of the study was to compare healthcare resource utilization among CLL patients initiated on first-line treatment who achieved CR versus those who did not.

Methods: This was a retrospective chart review study. From July to August 2016, 93 US oncologists/hematologists provided data abstracted from medical charts of their CLL patients who initiated a first-line CLL treatment between January 2010 and December 2014. The study collected patient demographics, clinical characteristics, response to first-line therapy, and the number of all-cause hospitalizations between first-line therapy initiation and end of the data follow-up (i.e., patient’s date of death, end of care, or data collection date, whichever occurred first). Patients were selected based on their best response to first-line therapy (i.e., CR, partial remission [PR], stable disease [SD] and progressive disease [PD]) as defined by the physician according to iwCLL 2008 criteria. The targeted number of patients in each category was a priori determined based on rates of response observed in clinical trials. The incidence of all-cause hospitalization was compared between patients who achieved CR and those who did not (including patients with PR, SD or PD) using univariate and multivariate generalized linear models with a Poisson distribution. As patients had different follow-up, incidence rates were reported per-patient-per-month (PPP). Multivariate regression models were adjusted for age, gender, selected comorbid conditions, time from CLL diagnosis to first-line initiation, and Eastern Cooperative Oncology Group (ECOG) status.

Table 1.

Results: Patient-level data was collected for 179 patients who achieved CR and 151 patients who did not achieve CR (120 patients with PR, 25 with SD, and 6 with PD). Average time from CLL diagnosis to first-line initiation was 8.4 months for patients who achieved CR and 13.3 months for those who did not. The majority of patients were male (65%), the average age was 63 years, and 80% of patients had an ECOG of 0 or 1 at first-line therapy initiation. The medi-
an follow-up after first-line therapy initiation was 30 months. Over that period, patients who did not achieve CR had statistically significantly higher incidence of all-cause hospitalization compared to patients who achieved CR (0.021 vs 0.006 PPPM; unadjusted incidence rate ratio (IRR)=3.30, p<0.05). After adjusting for potential cofounders, the incidence of all-cause hospitalization was 2.4 times higher for patients who did not achieve CR compared to those who did (IRR=6.4, p<0.05).

Summary/Conclusions: Results from this study showed that achieving CR to first-line therapy (vs. not achieving CR) is associated with reduced frequency of all-cause hospitalizations. This suggests that, in addition to the clinical benefit associated with CR achievement, treatment strategies in CLL that improve CR may help reducing the economic burden of CLL management for both patients and payers.

E1036
RITUXIMAB (R) USED AS A SINGLE AGENT FOR AUTOIMMUNE HEMOLYTIC ANEMIA (AIHA) IN TREATMENT NAÏVE CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) PATIENTS INDUCES ALSO SIGNIFICANT DISEASE RESPONSE WITHOUT TOXICITY
E1036
S. Sachanis1,*, G. Pangalis2, M. Moschogiannis1, X. Yiakounis1, P. Tsirkinidis1, E. Koulieris1, C. Kalpadakis3, E. Poppis4, T. Vassilakopoulos5, M. Angelopoulou5
1Hematologic, Athens Medical Center, Psychiko Branch, 2Hematologic, Laikon General Hospital, University of Athens, Athens, Greece

Background: There are very few effective treatment options for steroid refractory AIHA of CLL or for CLL patients(pts) that are unable to receive corticosteroids. R has been noted to be active in certain autoimmune hematologic disorders while experience with single-agent R in untreated CLL pts is very limited. Aims: To report our experience concerning the use of R as a treatment of AIHA occurring during the clinical course of treatment naïve CLL pts, by analyzing concomitantly its efficacy and safety as a single agent in CLL therapy. Methods: 15 pts diagnosed with CLL who received R due to AIHA were included in this study. Staging was performed at diagnosis (Binet system). Pts were placed on R at the standard dose I.V of 375mg/m2 once weekly for 6 consecutive weeks because of contraindication of corticosteroids administration. Results: Pts’ median age was 60 (range, 42-83 y). (8 out of 15, males), 10 having disease stage A and 5 B. Two were presented with splenomegaly and 1 with B-symptoms. 12 pts (83%) had leukemic lymphocyte counts of more than 50x10^9/L. Median time from diagnosis, the AIHA diagnosis and to 1st R infusion was 59 mos. All 15 pts completed the 6-week course of R and were assessable for response. The median WBC and the median absolute lymphocyte count(ALC) before R administration and after the end of 6-week course are shown in the Table. Resolution of the AIHA effect was achieved in all pts whereas in 4 there was a persistence of positive DAT without evidence of active hemolysis. After the 6 weekly R infusion course (1-15 pts) showed also disease response. 12 pts experienced PR (80%) and 1 CR (6%). All pts with advanced disease also responded entering PR. Resolution of splenomegaly was documented in both splenomegalic pts. After a median follow up of 84, 5 mos from CLL diagnosis, 14 pts are alive, 9 maintain their disease response, while 5 were in need of therapy due to CLL progression, after a median time of 10 mos from the last R infusion. Among them 4 were placed on FCR (2CR, 2PR) and 1 on R-Bendamustine(PR). Median PFS has not reached. All pts received the entire first dose on day 1 of treatment. There was only a grade 3 infusion related reaction in a pt with WBC=400x10^9/L without need for hospitalization. None of the pts experienced severe tumor lysis syndrome, pulmonary insufficiency, myelosuppression or opportunistic infections.

Summary/Conclusions: A) R is an effective agent for AIHA treatment with concomitant significant activity against CLL and therefore could be the standard of care for CLL pts with AIHA, especially for the cohort of pts with comorbidities. B) We confirm previous data that: 1) single-agent R induces significant responses in treatment naïve CLL pts 2) R is well tolerated and its administration is not associated with myelosuppression or immunosuppression 3) R as a single agent could be an excellent first-line treatment option for pts who are very elderly or who have a poor performance status

E1037
ATTAINMENT OF COMPLETE REMISSION IS SIGNIFICANTLY ASSOCIATED WITH LONGER SURVIVAL OUTCOMES IN RELAPSED/REFRACTORY (R/R) CLL: A META-ANALYSIS
V.U. Ektare1,*, C.P. Fox2, R.S. Taylor3, T.I. Inciocio1, G.E. Pena4, J.C. Maher4, S.J. Snedecor1
1Pharmasset International, Bethesda, United States, 2Nottingham University Hospitals, Clinical Hematology, Nottingham, 3University of Exeter Medical School, Exeter, United Kingdom, 4AbbVie, Inc., North Chicago, United States

Background: Chronic lymphocytic leukemia (CLL) is an incurable neoplasm of B lymphocytes, associated with a heterogeneous clinical course. Complete response (CR) with/w/o minimal residual disease in first-line chemoimmunotherapy has been associated with more favorable progression-free survival (PFS) and overall survival (OS). However, patients (pts) with R/R CLL and/or those with TP53 abnormalities (ie, 1p7 deletion and/or TP53 mutation) are less likely to achieve deep responses and experience poorer outcomes. Therefore, less is known about the relationship between CR and survival outcomes in R/R CLL pts.

Aims: To quantify this association, we generated meta-analytic estimates of PFS and OS reported in clinical trials using the proportion of study patients with CR as a predictor variable.

Methods: We performed a systematic literature review of PubMed/EMBASE up to Nov 2014 and congress abstracts 2012–2014. Randomized controlled trials and observational studies evaluating any treatment in R/R CLL pts were eligible for inclusion. Data were extracted from publications as median survival, the proportions of pts surviving at specific follow-up times, or individual event occurrence data. Kaplan-Meier (KM) curves, along with the proportion of pts with CR. Data were synthesized to estimate overall OS and PFS including population-level CR as a covariate using a Weibull proportional hazards model within a Bayesian meta-analysis framework.

Results: 74 published studies of treatment outcomes in R/R CLL pts were identified from the peer-reviewed literature and congress abstracts. 56 of these studies reported the proportion of CRs together with either OS or PFS outcomes and were included in the analysis. Individual pt data were extracted from KM curves of 29 studies generating 5176 individual pt OS and PFS data points in addition to 54 study-level data points including 3638 pts. There were no clinically meaningful differences in study or pt characteristics among the included studies that were not also associated with CR, our variable of interest. The hazard ratio (HR; and 95% credible interval, the Bayesian analog to confidence intervals) of survival for each 10% increase in CR among a study population was estimated to be 0.64 (0.60, 0.68). Estimated median OS for hypothesized conditions with 0% CR, 25% CR, or 50% CR were 20.4 mo, 44.7 mo, and 61.9 mo. Corresponding median PFS estimates were 10.0 mo, 21.9 mo, and 30.3 mo. (Figure 1).

Figure 1. Weibull meta-analytic estimates of OS (A) and PFS (B) with median survival times for a population with 0% CR, 25% CR, and 50% CR.
APLICATION OF THE CLL-IPI AND THE MDACC PROGNOSTIC INDEXES IN A LOCAL COHORT OF CLL PATIENTS

I. González-Gascón Y Marín1,1, M. Pozo1, M. Hernández-Sánchez2, A.E. Rodríguez-Vicente2, M.S. Infante1, C.C. Muñoz Novas1, C. Heras1, M.A. Foncillas3, J.M. Hernández-Rivas3, J.A. Hernández1
1Hospital Universitario Infanta Leonor, MADRID, 2IBSAL, IBMCC, Centro de Investigación del Cáncer, Universidad de Salamanca-CSIC, Salamanca, Spain

Background: New prognostic scores have been developed in order to better discriminate the clinical course of CLL patients, along with Rai and Binet clinical staging systems. These scores, such as that proposed by the MDACC group, and recently the CLL-IPI combine clinical and biological variables with prognostic value.

Aims: In this study we investigated the validity and reproducibility of these scores in a local cohort of patients with CLL.

Methods: We made a retrospective analysis including 650 unselected CLL patients newly diagnosed and previously untreated from a single institute. The final analysis has been limited to the 486 cases with complete data to apply the MDACC score, and to the 258 cases with complete data to apply the CLL-IPI score.

Results: Median age was 67 years old (25-90). With a median follow-up time of 46 months, 394 patients were alive, and 187 had received any treatment for CLL at the moment of the analysis. Median overall survival (OS) of the whole series was 173 months (127-220), and median time to first treatment (TTFT) 106 months (82-130). The MDACC score was applied to 486 cases giving 0 to 9 points to each case according to: age, b2-microglobulin levels, absolute lymphocyte count, sex, Rai stage, and number of involved lymph node groups. As shown in the Table, stratification of patients using the MDACC score allowed the prediction of progression for both TTFT (P=0.000) and OS (P=0.000). 162 patients were classified as low risk, 302 as intermediate risk, and 21 as high risk. Due to missing data, the CLL-IPI score could only be applied to 258 patients giving 0 to 10 points to each case according to 17p deletion, IGHV mutational status, β2-microglobulin, clinical stage, and age. As shown in the table, 126 patients were classified as low risk, 79 as intermediate risk, 46 as high risk, and 7 as very high risk. We also found significant differences in terms of OS (P=0.000) and TTFT (P=0.000) using this score.

Summary/Conclusions: In this study we confirm that both scoring systems are also easily applicable in clinical practice. The new CLL-IPI score is able to discriminate patients in different prognosis subgroups. Both scores are able to provide prognostic information in these patients.

AN OBSERVATIONAL STUDY EVALUATING THE USE OF BENDAMUSTINE AS FIRST-LINE TREATMENT FOR CHRONIC LYMPHOCYTIC LEUKEMIA IN RUSSIA

I. González-Gascón Y Marín1,1, M. Pozo1, M. Hernández-Sánchez2, A.E. Rodríguez-Vicente2, M.S. Infante1, C.C. Muñoz Novas1, C. Heras1, M.A. Foncillas3, J.M. Hernández-Rivas3, J.A. Hernández1
1Hospital Universitario Infanta Leonor, MADRID, 2IBSAL, IBMCC, Centro de Investigación del Cáncer, Universidad de Salamanca-CSIC, Salamanca, Spain

Background: Bendamustine has gained footing as a component of first-line therapy for chronic lymphocytic leukemia (CLL) due to its efficacy and favorable toxicity/haematological profile. There is a paucity of data on the effectiveness of bendamustine as first-line therapy in the Russian CLL patient population, which is needed to support drug cost reimbursement processes.

Aims: Evaluate effectiveness of first-line therapy with bendamustine for CLL in the Russian Federation.

Methods: This was a prospective, multicenter, observational study (NCT02110394) in adults (>18 yr) diagnosed with CLL who were receiving, or were scheduled to receive, first-line therapy with bendamustine plus rituximab. Patients who had prior CLL treatment (eg, chemotherapy, radiation) or had contraindications to bendamustine were excluded. Each subject was required to have 2 to 8 study visits, where Visits 2-6 reflected treatment cycles; total number of treatment cycles for each patient was determined by the study investigator. Interim and final evaluations were performed after 3 and 6 treatment cycles, respectively. Primary endpoints were overall response rate (ORR, patients achieving a complete remission or partial remission [PR]) and progression-free survival (PFS). Secondary endpoints were time to therapeutic failure, time to progression, progression-free survival (PFS), relapse or death after CR or PR, quality-of-life (EQ-5D questionnaire), and frequency of adverse drug reactions (ADRs).

Results: Of the 196 patients who enrolled between June 2012 and August 2015, 142 patients received randomized therapy (Supplementary Table 1). Of these, 139 were included in the Full Analysis Set (FAS; at least one dose of study drug) and 149 were included in the Full Analysis Set (FAS; patients in the Safety Population who had ≥1 response evaluation). Most patients in the FAS were male (59.7%); mean age was 61.5±8.9 yr. Overall, 35.6% of patients were ≥65 yr old and 80.5% had ≥1 comorbidity such as hypertension. The ORR was 63.2%; CR and PR rates were 59.7% and 23.5%, respectively. Generally, response rates were slightly higher than those reported in the Phase 3 pivotal trial (Knauf et al. J Clin Oncol. 2009). Eradication of minimal residual disease was achieved in 23 of the 84 evaluable cases.
patients (27.4%). Overall, 80.3% of FAS patients did not experience therapeutic failure and 85.9% did not experience disease progression during the 2-year observation period. By the end of the study, median PFS had not been reached; 2-year PFS rate was estimated as 85.9%. Improvements from baseline were observed after 6 cycles of treatment across all EQ-5D domains. No relapses or deaths occurred in the FAS; however, 2 subjects in the Safety Population experienced fatal serious ADRs (myocardial infarction \( n=1 \); acute pneumonia, infections and toxic shock, and atrial fibrillation \( n=1 \)). In concurrence with the Phase 3 trial results, hematologic disorders (19.9%; anemia, neutropenia, thrombocytopenia), most of which were Grade 2 in severity, were the most common ADRs (Safety Population; Table 1).

Summary/Conclusions: First-line therapy with bendamustine plus rituximab was well tolerated in this Russian CLL population, including elderly patients and patients with renal dysfunction or other comorbidities. Additionally, combination therapy resulted in high rates of treatment response in the CLL. These data confirm the value of bendamustine as a first-line agent for CLL in routine clinical practice in Russia.

### Chronic myeloid leukemia - Biology

**E1041**

**MUTAGENESIS OF BCR-ABL1 IS REQUIRED FOR RESISTANCE DEVELOPMENT IN DE NOVO CHRONIC MYELOID LEUKEMIA KCL-22 CELLS BUT NOT IN RELAPSED KCL-22 CELLS EXPRESSING BCR-ABL1 INDEPENDENT RESISTANCE**

N. Curk1,2, V. Polivkova1,2, T. Kalina3, V. Kanderova4, J. Linhartova1, F. Savuljic2, O. Tomam1, K. Srutova1, S. Ransdorfova1, J. Breznikova1, H. Klamaova1,5, K. Machova Polakova1,5,6

1Institute of Hematology and Blood Transfusion, 2Institute of Pathological Physiology, First Medical faculty, Charles University, 3Faculty of Science, Charles University, 4Department of Paediatric Haematology and Oncology, Univ. hospital Motol, 5Institute of Clinical and Experimental Hematology of the 1st Medical faculty, Charles University and Institute of Hematology and Blood Transfusion, Prague, Czech Republic

**Background:** BCR-ABL1 kinase domain (KD) mutations are an important mechanism of resistance of chronic myeloid leukemia (CML) patients developing during the tyrosine kinase inhibitors (TKI) treatment. However, mechanisms underlying KD mutation acquisition in TKI-resistant CML cells are not yet well understood.

**Aims:** We studied an acquisition of mutations in the KD after an exposure of *de novo* and relapsed (grown in optimal growing medium for 24 months) KCL-22 cells to imatinib (IM). In addition, we examined kinetics of mutated subclones in established IM-resistant KCL-22R culture after dose-reduction of IM. We also studied changes in the expression profile of KCL-22 cultures early after exposure to IM.

**Methods:** The occurrence and kinetics of expansion of *BCR-ABL1* mutant subclones were studied using next-generation deep sequencing in KCL-22 cells treated with 0.4 µM IM and in established IM-resistant KCL-22R cells at 4 µM IM. In other sets of experiments, KCL-22R cells were sorted according to the CD38 expression to explore whether CD38 is associated with the acquisition of *BCR-ABL1* mutations as suggested by Wang et al. (2014). A protein array was used allowing analysis of 576 proteins per sample. DNA damage pathway-RT Profiler PCR arrays were applied for gene expression analysis.

**Results:** No *BCR-ABL1* KD mutations were detected in *de novo* untreated KCL-22 cells, however T315I and E255K appeared after the exposure of the cells to 0.4 µM IM. PCR array revealed increased expression of SUMO 1 ligase and ERCC2 involved in the nucleotide excision repair pathway. Notably, we also found a significant decrease of G2M-checkpoint protein GADD45A whose deficiency is associated with mutagenesis (Hollander et al., 2001). During the first culture period, T315I slowly emerged whereas E255K was not detectable. Later, E255K-bearing cells also became detectable and increased over time. A similar time-dependent expansion of mutant-bearing sub-clones was seen in the KCL-22R cells growing at 4 µM IM. Interestingly, a mutantclone switch from T315I to E255K in KCL-22R was accelerated after IM reduction from 4 µM to 1 or 2 µM. Moreover, the emerging of E255K sub-clones was accompanied by rapid decrease of CD38 expression in KCL-22R cells. Profiling of transitional KCL-22R culture, carrying both T315I and E255K sub-clones, revealed that T315I transcripts were expressed only in the CD38+ subpopulation, while E255K was detected only in CD38- cells. Unlike to *de novo* KCL-22 cells, BCR-ABL1 mutations were repeatedly not detected in relapsed KCL-22 cells up to follow-up of 60 days after the cells exposure to 0.4 µM IM. Neither *BCR-ABL1* upregulation nor gene amplification was detected in these cells. We identified considerably upregulated (D7, DTX3, ETV6, GLUL, HCLS1, HIF1α, IGF1R, MAP2K7, MYH11, TPS3) or downregulated (BAD, BID, NOTCH3, PDKPK1) proteins early, 4 weeks after the exposure to IM. Increased expressions of HIF1α and IGF1R proteins are known to ensure proliferation, while decreased expressions of pro-apoptotic proteins BAD and BID enhance survival of CML cells in the presence of TKIs.

**Summary/Conclusions:** Our observation suggests the ability of KCL-22 cells to survive and proliferate early after the exposure to IM. BCR-ABL1 mutations development seems to be related to a mutagenesis of imatinib on *de novo* KCL-22 cells, but not on relapsed KCL-22 cells that activated signaling pathways ensuring their survival and growing in the presence of tyrosine kinase inhibitor.

Supported by the project no. 00023736 and AZV 15-31540A of MZCR and ERDF OPPK CZ.2.16/3.1.00/28007.

**FLOW-CYTOMETRY DETECTION OF CD26+ LEUKEMIA STEM CELLS IN PERIPHERAL BLOOD: A SIMPLE AND RAPID NEW DIAGNOSTIC TOOL FOR CHRONIC MYELOID LEUKEMIA**

D. Raspado1, S. Siriani1, L. Aprile1,2, E. Abruzzese2, A. Iurlo3, A. Sicuranza1, S. Galimberti4, L. Schiattone1, A. Gozzini5, P. Pregno6, G. Caocci7, G. Papini1, I. Ferrigino1, B. Mecacci1, M. Bocchiccia
Background: Diagnosis of Chronic Myeloid Leukemia (CML) implies documenting in bone marrow (BM) or in peripheral blood (PB) Philadelphia (Ph) chromosome by cytogenetics, molecular BCR-ABL1 fusion by FISH or BCR-ABL1 rearrangement by RT-PCR. In clinical practice, at the earliest, 24-72 hrs are needed to confirm CML by any of these assays. Lately, characterization of CML leukemia stem cells (LSCs) from BM samples by CML patients (pts) showed a specific co-expression of dipetidylpeptidaseIV (CD26) within the CD34+/CD38-/Linn- stem cell fraction and CD26 displayed a robust biomarker for identifying CML LSCs within the normal BM compartment. We recently demonstrated that CD34+/CD38+/CD26+ LSCs can be easily identified by flow-cytometry also in PB during treatment with tyrosine kinase inhibitors.

Aims: We investigated accuracy and specificity of flow cytometry PB cytometry also in PB during treatment with tyrosine kinase inhibitors.

Methods: Pts with clinical suspicion of CML entered the study after written informed consent and all were evaluated for CD26+LSCs, cytogenetics, FISH and/or BCR-ABL1 RT-PCR analysis. CD34+/CD38+/CD26+ population was investigated in PB and when possible simultaneously in BM samples using a flow-cytometry 4-color staining procedure. 2x10^6 leucocytes were incubated with BD Pharmingen CD45/500 (c.201), CD34FITC (c.581), CD38APC (c.H71T), CD26 (c.M-A261) and negative controls. Acquisition and analysis of at least 1.0x10^6 CD45+ cells were done by FACSCanto II with DIVA 8 software (BD, Biosciences). CD26+ cells were identified by sequential gate. CD45+ and CD34+ gates were performed on viable cells identified by FSC/SSC light properties and CD34+/CD38+ population was gated applying a narrow gate excluding all CD38+ cells (Fig.1).

Results: PB samples from 107 pts with myeloproliferative features were evaluated for CD26+LSCs. Leucocytes median value was 52x10^9/L (range 5-400x10^9/L). In 83/107 (77.5%) pts we showed CD34+/CD38+CD26+ LSCs in PB and in 83/83 (100%) the diagnosis of CML was confirmed by cytogenetics, FISH and RT-PCR analysis. Median value of circulating PB CD26/Lu was 14 (range 0.27-698) and a positive correlation with leukocyte count (p<0.01) was found. In 53/107 (49.5%) pts analysis was performed contextually in BM samples All CD26+ PB-BM matched pairs (49/53) showed superimposable results in terms of absolute number of CD26+LSCs/Lu (19.18 and 18.73 respectively) while the percentage of CD26+ cells within the CD34+/CD38- fraction appeared lower in BM than in PB samples (median 28.18 and 37.33; range 0.87-77.14, and 5.99-55.97 respectively). In 24/107 (22.5%) PB samples and in 45/53 BM samples CD26+ LSCs were not detected and none of these samples was found Ph or BCR-ABL1 positive. Pts with CD26 neg PB/BM samples were subsequently diagnosed as idiopathic Myelofibrosis (12 pts), Myelodysplastic/Myelo-proliferative disorders (7 pts) benign neutrophilia (5 pts). Of note, we additionally studied 4 PB+BM samples of 4 Ph+ acute lymphoblastic leukemia and all scored negative for CD26+LSCs.

Figure 1.

Summary/Conclusions: Flow-cytometry evaluation of PB CD34+/CD38+/CD26+LSCs is a feasible, very rapid (about 3 hrs from sample handling to results) and highly specific alternative/complementary diagnostic tool for CML. To validate these data in a larger cohort of patients we are developing a pretreated lyophilized antibody mixture (lytotube, BD Biosciences) to maximize sensitivity and to optimize standardization and working time, with the further aim to monitor stem cells minimal residual disease in CML patients.

LIPID PEROXIDATION AND INFLAMMATORY STATUS DURING TKI TREATMENT IN CHRONIC MYELOID LEUKEMIA PATIENTS: INTERIM ANALYSIS OF A PROSPECTIVE MULTICENTER STUDY

A. Sicuranza1,*, L. Aprile1, E. Abruzzese2, A. Iurlo3, S. Galimberti4, A. Gozzini5, N. Sgherzaghi5, L. Pucciati5, G. Papini5, D. Cattaneo5, F. Siagno5, F. D’Raimondo5, G. M. Chiocchia5, U. Occhini5, R. Lemoli5, M. Brescia11, L. Luciano11, A. Besi12, M. Petrin1, M. Bocchia1

Emanuele, University of Catania, Catania, 4Hematology with Transplant, University of Bari, Bari, 5Hematology Unit, USL8, Arezzo, 6Hematology, University “Federico II”, Napoli, Italy

Background: Evidences of increased cardiovascular (CV) events, mostly atherothrombotic, in Chronic Myeloid Leukemia (CML) patients (pts) treated with some Tyrosine Kinase Inhibitors (TKIs) prompted physicians to carefully evaluate CV risk factors (CVRFs) in the choice of TKI. However, the pathogenesis behind CV events during TKIs is still largely unknown and even pts without overt CVRFs incur in CV events. We retrospectively showed that an induced “inflammatory status” during nilotinib treatment, together with genetic pro-atherothrombotic predispositions may partly explain the increased incidence of CV (Bocchia, Oncotarget 2016). These data provided the rationale to start a multicentric “Prospective study of TKI induced pro-Atherothrombotic status in CML, KIARO study” (Grant support: AIRC-IT) including Chronic Phase CML pts treated with any first line approved TKI in which clinical, genetic and biochemical pro- and antiatherothrombotic profiles were evaluated at diagnosis and during treatment.

Aims: This prospective study aims to confirm the possible role of genetic predisposition and behavior of specific pro/anti-inflammatory biochemical parameters in the atherosclerotic pathogenesis during TKIs treatment.

Methods: Pts initially evaluated were prospectively evaluated for presence of traditional CVRFs, atherothrombotic episodes, presence of Single Nucleotide Polymorphisms (SNPs) associated to CV risk (Cardiokit) and plasma levels of several pro and anti-inflammatory cytokines. In this first interim analysis we focused on levels of LDL, oxidated-LDL (oxLDL), TNFa, IL-6 and IL-10 and the presence of SNPs of LDL-R (rs1122608), LOX-1 (rs3736235), and IL-10 (rs1800896) genes.

Results: 12 Italian Hematology Units participated to the study and up to date 95 CML patients were enrolled. We here report data from the first 43 patients on TKI treatment for at least 12 months (15 nilotinib, 14 imatinib and 14 dasatinib). No CV events were recorded to date. At diagnosis, levels of LDL (143.5±13.2), oxLDL (237±4.99), TNFa (3.91±2.51), IL-6 (1.96±0.99) and IL-10 (0.34±0.15) were evaluated for the whole cohort and according to the TKI treatment. No statistic significant differences were found in the expression of these variables between the 3 groups of treatment (p>0.05). Considering the genotype frequency, we confirmed in the whole cohort a correlation between basal levels of LDL, oxLDL and IL10 with the presence/absence of the detrimental G/G allele of LDL-R (H.R. 2.21, p<0.01), LOX-1 (H.R. 2.86, p<0.01) and IL10 (H.R. 1.85, p=0.05) polymorphisms. During TKIs treatment we observed increased levels of LDL (p<0.05) and oxLDL (p<0.05) only in the nilotinib cohort at 3 and 12 months of treatment, regardless of the concomitant use of CV medications. No differences in TNFα and IL6 levels during the first 12 months of treatment were detected in the 3cohorts (p=0.079). Interestingly, IL-10 levels were significantly higher at 3 and 12 months of treatment in the imatinib and dasatinib cohort (p<0.01 respect to nilotinib p=0.094).

Summary/Conclusions: This interim analysis, although still very preliminary, suggests that in nilotinib patients the high levels of LDL and oxLDL in combination with low levels of IL10, could induce a persistent pro-inflammatory/oxidative status potentially favoring atherothrombotic events. Additional biochemical and genetic data as well as prolonged clinical observation are needed to confirm this hypothesis. Patients enrolment and monitoring is ongoing.

TRANSCRIBED ULTRACONSERVED NONCODING RNAs (t-UCRS) IN CHRONIC MYELOID LEUKEMIA: EXPRESSION PROFILES ASSOCIATED WITH MOLECULAR RESPONSE TO THERAPY WITH TYROSINE KINASE INHIBITORS

P. Rodrigues Santos1,2,3, P. Abranches1,2,4, P. Couceiro2,3, J.R. Simplicio2,3, J.S. Almeida1,3, V. Alves1,3, L. Ružičková5, P. Freitas-Tavares5, M. Santos-Rosa1,3
Results: We show that PAK1 and PAK2 are frequently deregulated in cells in vivo of haematological patients, shRNA-mediated knockdown and

Methods: We investigated peripheral blood samples from 45 CML patients and 15 healthy controls. Two panels of 481 T-UCR and 752 miRNA probes were used for RT-qPCR analysis. Differential expression was evaluated using the Mann-Whitney test followed by Benjamini-Hochberg multiple testing correction.

Results: CML samples presented significantly different expression of uc.164 (p<0.01), uc.118 (p<0.01), uc.125 (p<0.01), uc.391 (p<0.01), uc.141 (p<0.01), uc.143 (p<0.05) and uc.145 (p<0.05), when compared to healthy controls. This latter T-UCR (uc.145) was associated with development and immune regulation pathways. We analysed Sokal, Hasford and EUTOS risk scores and found uc.236 (p<0.0001), uc.39 (p<0.05) and uc.7 (p<0.05) to be associated with EUTOS low risk. Concerning therapy, dasatinib was correlated with UCs for imatinib doses, uc.4 (p<0.05) and uc.3 (p<0.05) inversely correlated with 400 and 800mg daily, respectively. Molecular response in CML samples presented a signature including uc.187 (p<0.001), uc.107 (p<0.05), uc.409 (p<0.05), uc.198 (p<0.05), uc.309 (p<0.05), uc.102 (p<0.05), uc.294 (p<0.05) and uc.361 (p<0.05). Major molecular response was identified by the altered expression of uc.198 (p<0.05), uc.215 (p<0.05) and uc.210 (p<0.05). The negative regulation of T-UCRs by miRNAs, involving T-UCR:miRNA interaction, was associated with upregulated (miR-720, miR-886-3p, miR-1274a, miR-101 and miR-129) and downregulated (miR-489 and miR-1973) microRNAs.

Summary/Conclusions: In the present study, we identified T-UCRs signatures and T-UCR:miRNA pairs associated with CML, risk scores, TKI therapy and molecular response. The expanded knowledge of RNA biology in general, together with the recent interest in the mutlity of newly discovered elements such as T-UCRs, could help to improve CML therapy.

MIRNA PROFILING OF CIRCULATING EXTRACELLULAR VESICLES IN CML PATIENTS WITH MUSCULOSKELETAL PAIN ASSOCIATED WITH DISCONTINUATION OF TYROSINE KINASE INHIBITORS

K. Ohyashiki1,2, M. Asano1, T. Fushimi2, S. Katagiri1, C. Kobayashi2, T. Tauchi1, M. Gotoh1, K. Ando1, S. Okabe1, J. Ohyashiki3

Department of Hematology, 2Department of Molecular Oncology, Institute of Medical Science, Tokyo Medical University, Tokyo, Japan

Background: Clinical trials of TKI discontinuation are still ongoing, approximately 60% of CML patients who achieved a deep molecular response for more than 2 years maintained a major molecular response after discontinuation of imatinib. However, the long-term prognosis and/or adverse events after TKI cessation remain unclear. Recent reports showed that transient musculoskeletal pain after TKI discontinuation occurs in approximately 30% of CML patients after stopping imatinib.

Aims: Recent evidences suggest that extracellular vesicles (EVs) that contain genetic element such as DNA, RNA, and miRNA, are important mediators of intercellular communication. We therefore studied molecular study to ascertain the possible correlation between musculoskeletal pain and EV-miRNA expression.

Methods: We investigated circulating EV-miRNAs in five CML patients who did not experience musculoskeletal events and five patients with musculoskeletal pain after stopping TKIs, as well as three healthy individuals. Peripheral blood was obtained approximately 3 months after successful TKI cessation in CML patients. Exosomes were extracted by using Total Exosome Isolation Reagent (Invitrogen, Carlsbad, CA, USA) and EV-miRNA profiling was performed with a TaqMan Low-Density Array (Thermo Fisher Scientific, Carlsbad, CA, USA), as reported previously. The relative expression level of each gene was calculated by using the comparative threshold cycle (Ct) method. Synthetic spike control (ath-miR-159; Hokkaido System Science, Hokkaido, Japan) was used as an internal control for EV-miRNA. This study was approved by the institutional review board of Tokyo Medical University (no. 930 approved 24 June 2008 and no. 3052 approved 9 June 2015).

Results: Three-way analysis of variance (ANOVA) performed for healthy controls and CML patients with and without musculoskeletal pain revealed EV-miR-140-3p to be the most significant value (P=0.00778). A t-test analysis using R software identified 10 differentially expressed EV-miRNAs for CML patients with and without musculoskeletal pain: seven miRNAs were upregulated (miR-107, miR-145, miR-140-3p, miR-539, miR-495, miR-299-5p, miR-425) and three were downregulated (miR-21, miR-218, miR-523) in CML patients with musculoskeletal pain. The up-regulated EV-miR-140-3p in all CML patients decreased after release of musculoskeletal pain.

Summary/Conclusions: CML patients with increased EV-miR-140-3p achieved levels similar to those of healthy controls after relief from musculoskeletal pain and inflammatory indicators in some CML patients who stopped TKIs; however, we did not find any positive association. Although the number of CML patients in this study is too small to draw definite conclusions, further research should investigate whether upregulation of EV-miR-140-3p expression in peripheral blood is correlated with musculoskeletal events in CML patients after TKI cessation.

SOLUBLE AND MEMBRANE-BOUND RECEPTOR–LIGAND IMMUNE CHECKPOINTS AND CHRONIC MYELOID LEUKEMIA: CORRELATIONS WITH MOLECULAR RESPONSE AND TYROSINE KINASE INHIBITOR THERAPY

P. Rodrigues-Santos1,3, J.S. Almeida2,3, P. Couceiro2,3, V. Alves1,3, J.R. Simplicio2, L. Růžičková4, P. Freitas-Tavares4, M. Santos-Rosa1,3

1Instituto de Imunologia, Faculdade de Medicina da Universidade de Coimbra, 2Laboratório de Imunologia e Oncologia, Centro de Neurociências e Biologia Celular, 3Centro de Investigação em Meio Ambiente, Genética e Oncobiologia (CIMAGO), Faculdade de Medicina da Universidade de Coimbra, 4Serviço de Hematologia, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

Background: Blockade of immune checkpoint seems to unleash the potential of the antitumor immune response in a fashion that is transforming human cancer therapeutics. Soluble and membrane-bound receptor–ligand immune checkpoints are the most druggable forms using agonist antibodies (for co-stimulatory pathways) or antagonist antibodies (for inhibitory pathways). Although its implications in immune response during chronic myeloid leukemia therapy without consistent biochemical abnormalities is occurring in approximately 30% of CML patients who achieved a deep molecular response for more than 2 years maintained a major molecular response after discontinuation of imatinib. However, the long-term prognosis and/or adverse events after TKI cessation remain unclear. Recent reports showed that transient musculoskeletal pain after TKI discontinuation occurs in approximately 30% of CML patients after stopping imatinib.

Aims: This study aimed at the analysis of lymphocyte subsets expression and plasmatic levels of immune checkpoint inhibitors during tyrosine kinase inhibitor (TKI) therapy in CML and its correlation with molecular response.

Methods: Peripheral blood samples from 35 CML patients (n=55), divided according to molecular response to imatinib, dasatinib, nilotinib, bosutinib, ponatinib and Imferon-alpha 2b (IFN-α 2b) therapy, were included in this study. Multi-parametric flow cytometry was used for the analysis of the
expression of several immune checkpoint inhibitors (BTLA, GITR, LAG-3, PD-1, PD-L1, PD-L2, TIM-3, CD137/4-1BB) by different T, B, NK, monocyte and dendritic cell subsets. A 14-plex panel including BTLA, GITR, HVEM, IDO, LAG-3, PD-1, PD-L1, PD-L2, TIM-3, CD28, CD80, CD137 (4-1BB), CD27, and CD152 (CTLA-4) was analyzed by xMAP technology (Luminex®).

Results: Expression of CD137 by several lymphocyte subsets and PD-1 by regulatory T cells (Tregs) and natural killer (NK) cells were found significantly altered in CML patients under TKI therapy. These associations were observed for the cell population frequency expressing the receptor, and also for density of these molecules. Increased plasmatic levels of BTLA, HVEM, PD-1, PD-L1, and CD137 were associated with good molecular response to therapy, PD-1, PD-L1, TIM-3 and CD137 were found increased in patients that achieved MR4.5.

Summary/Conclusions: Some immune checkpoint inhibitors seem to be affected by TKI therapy in CML and their cell expression and plasmatic levels correlates to molecular response. Similar observations were described for other types of cancers, including solid tumors. Soluble and membrane-bound receptor–ligand immune checkpoints could represent interesting targets for future therapeutic monitoring and for pharmacologic interventions in CML.

Financial Support: FEDER (Programa Operacional Factores de Competitividade – COMPETE) and FCT (Fundação para a Ciência e a Tecnologia) through project PEst-C/SAU/LA0001/2013-2014.

E1048
TYROSINE KINASE INHIBITORS SIGNIFICANTLY CHANGE THE EXPRESSION OF POLYCOMB GENES IN CHRONIC MYELOID LEUKEMIA

1Medical Biotechnologies, University of Siena, Siena, 2Clinical and Experimental Medicine, Hematology Molecular Laboratory, AOUP, Pisa, Italy

Background: It has been reported that, notwithstanding their clinical success, tyrosine kinase inhibitors (TKIs) are not able to eradicatet the leukemic stem cell (LSC) in patients with chronic myeloid leukemia (CML). Different mechanisms have been hypothesized, especially those linked to the niche (increased osteoblastic differentiation, angiogenesis, hypoxia...). The epigenetic control seems to be relevant, and our group previously identified a correlation between the expression of some polycomb genes (PcGs) and response to TKIs, with BM11 resulting a good predictive molecular marker (Crea, 2015).

Aims: In order to better understand the role of the PcGs genes in CML patients receiving TKIs, we analyzed the expression of 86 PcGs at baseline and after 6 months of therapy.

Methods: Buffy coats obtained from peripheral blood samples of 6 patients (5 receiving imatinib and 1 dasatinib) have been used for the RNA extraction; these RNAs were used for quantifying the BCR-ABL/ABL ratio/αS, according to the European guidelines, and the expression of the chosen 86 PcGs by real-time PCR (PrimePCR pathway kit, Biorad, Milan, Italy) at diagnosis and after 6 months of treatment. Expression values were calculated using the 2DDCT method.

Results: At the sixth month of treatment, 5 patients were in optimal response and one was “warning”, according to the 2013 ELN guidelines. After therapy, 55% of the tested PcGs resulted up-regulated and 23% of them in the majority of patients, whereas 3 genes (DNMT3B, SCML2, CBX2) were down-regulated in at least half of samples. The expression of 5% of PcGs was “mixed”, up- or down-regulated in different samples. Among the up-regulated genes, some could be relevant from a biological point of view: 1) HLF, a target for RUNX1, whose low expression in acute leukemia is correlated with poor outcome; 2) PHC2, able to silence the HOX genes, overcoming the multidrug resistance in myeloid models; 3) PCGF5, that is a marker of normal hematopoiesis; 4) M0V10, that has been reported to have an anti-viral activity, increasing levels of gamma interferon. This up-regulation is particularly interesting, because concerns all assessed samples and could explain our previous observation that Torque Teno virus replication does not occur in CML patients during TKIs therapy; 5) in the only “warning” patient, the up-regulation of SIRT1 was observed: this is in line with the observation that its up-regulation increases the oncogenic ability of K562 cells in a nude model. Among the down-regulated genes, could be relevant: 1) CBX2, that binding P16/p19 promotes the cell cycle progression; its down-expression could induce apoptosis; 2) DNMT3B, whose high levels have been reported in stem cells, and whose reduction could characterize the differentiation process; 3) ZBTB16, whose reduction could be a sign of the reduced osteoblastic differentiation, one of the mechanisms responsible for the LSC preservation in the niche; 4) SMARCA1, it too correlated to the cell cycle progression. Finally, BM11 levels resulted unmodified in 3 cases and increased in other 3.

Summary/Conclusions: We demonstrated that PcGs de-regulation occurs in CML patients during the treatment with TKIs, with possible pathogenetic implications. Huger series of patients will improve the biological suggestions coming from these preliminary data.

E1049
IDENTIFICATION OF PROGNOSTIC AND SUSCEPTIBILITY MARKERS IN CHRONIC MYELOID LEUKEMIA USING NEXT GENERATION SEQUENCING

1Medical Biotechnologies, University of Siena, Siena, 2Clinical and Experimental Medicine, Hematology, University of Pisa, 3Clinical and Experimental Medicine, Hematology Molecular Laboratory, AOUP, Pisa, Italy

Background: Chronic Myeloid Leukemia (CML) is 20% of all leukemias diagnosed every year. Discovery of Imatinib Mesylate has brought a paradigm shift in treatment of Chronic Myeloid Leukemia, despite 15% - 20% patient showing resistance to this TKI. Therefore, it is important to identify susceptibility and prognosis markers, which can help us in predicting occurrence and prognosis of CML. We did Clinical Exome Sequencing, a panel of more than 4800 clinically important genes, in CML patients

Aims: To identify prognostic and susceptibility genetic markers in CML

Methods: Enrolled CML patients (n=18) were segregated as responders (n=10) and failures (n=8) as per ELN, 2013 guidelines. Healthy controls (n=5) were also enrolled. DNA from blood of subjects was subjected Next Generation Sequencing (NGS). Mutations present in one patient group and absent in opposite group were considered as prognostic markers, whereas rare mutations, present in more than 50% of enrolled patients and absent in healthy controls, were considered as susceptibility markers

Results: We discovered mutations in genes associated with cancer or cancer related functions in different patient groups as markers. Five of them: rs116201358, rs17882014, rs4014596, rs52897880 and rs2274329 in C8A, HLA-DRB1, UNC93B1, APOH and CA6 genes respectively, were present in responders; rs4945 in MFGE8 was present in failure. Mutations in HLA-DRB1 (rs17787895, rs11554462, c.239C>G), HLA-DRB5 (rs137863146), RPHN2 (rs193179333), CYP2F1 (rs116958558), KCNJ12 (rs76684759), FUT3 (rs151218854), BM10 (rs28370522) and PRSS1 (rs144422014) were present in half or more patients

Summary/Conclusions: We discovered potential genetic markers, which can help in predicting response to IM as frontline therapy. Susceptibility markers can be used as panel for to configure individuals prone to CML

E1050
FEATURES OF THE A2455G POLYMORPHISM OF GENE CYP 1A1 IN PATIENTS WITH CML

K. Karimov1,2, N. Abdurahmanova1, K. Boboev1
1Institute of hematology and blood transfusion, tashkent, Uzbekistan

Madrid, Spain, June 22 – 25, 2017

haematologica | 2017; 102(s2) | 431
Background: Chronic myeloid leukemia (CML) is the most common myelo-proliferative disorder characterized by the reciprocal translocation t(9;22) (q34; q11), leading to the formation of chimeric oncogene BCR-ABL on the 22q-chromosome. It is known that the protein products of the genes of cytochromes ensure homeostasis at the cellular and tissue level, carrying out the metabolism of toxic compounds that can damage the genome of the cells. Present study evaluated the role of functional polymorphisms in genes of a variety of neoplastic diseases, including leukemia. In individuals with weakened functional genotypes of A2455G polymorphism of CYP 1A1 gene expression of this enzyme and, consequently, inactivation of xenobiotic must occur very slowly, thus creating conditions for adverse action of harmful metabolites in the genome of the cells. Currently, the scientific literature discusses the role of the negative allele A2455G polymorphism of CYP 1A1 gene in the development of hematological malignancies. However, the adverse roles of genotypic variants for this gene in oncogenesis of BCR-ABL-positive patients with CML have studied not enough.

Aims: Evaluation the role of A2452G polymorphism of CYP1A1 gene in the formation the mutant clone of tumor and development of CML.

Methods: The work is performed on DNA samples isolated from the peripheral blood of the patients in the clinic of scientific research Institute of Hematology and blood transfusion in Uzbekistan. We studied 146 patients with CML. The control group was formed from 217 individuals of Uzbek nationality, without any cancer disease. The diagnosis of CML verified in accordance with the International nomenclature ISCN. Standardized PCR with detection in real-time was carried out on a thermal cycler Rotor-Gene 6000 (Corbett Research, Australia), using a set of reagents "AmpliTaq® "Leucosis quantitetm M-RTT” (InterLabServices, Russia). Testing A2452 polymorphism of CYP1A1 gene was performed on a programmable thermal cycler of the company "Applied Biosystems" (USA) using test systems company "Life" (Russia) according to the manufacturer's instructions. Statistical analysis of results was carried out using the statistical software package "2009 OpenEpi, Version 2.3”.

Results: The frequencies of allele A and G are as follows: 76.7% and 12.3% in patients with CML, and 93.3% and 6.7% in the control group, respectively. The frequency distribution of genotypes A/A, A/G and G/G were as follows: 21.9% and 1.4% - in CML patients, and 86.6%, 13.4% and 0.0% - in the control group. Observed frequencies of genotypes in the studied groups was consistent with the theoretically expected and were in equilibrium with Hardy-Weinberg equilibrium (P>0.05). There was a statistically significant decrease in carriage of the adverse alleles in the population sample comparison group patients (1.4% vs 6.7%, respectively; χ²=6.8; P=0.01; OR=2.0; 95% CI 1.17-3.282). Also detected significant association of heterozygous genotype A/G in patients with CML, compared with the control group (21.9% vs 13.4%, respectively). The risk of mutant formation of the tumor clone in carriers of this genotype was 1.8 times significantly higher compared with patients not having it (χ²=4.6; P=0.03; OR=1.8; 95% CI 1.046-3.166). The homozygous genotype A/A was found with high frequency in a population of CML patients (1.4% vs 0.0%), but due to the small number of carriers of this genotype differences in the results did not reach statistical significance (P>0.05). Functionally favorable genotype A/A was found with high frequency in a population-based sample of 86.6% vs 76.7% cases of patients. At the same time, the differences reached the threshold level of significance (χ²=2.6; P=0.01; OR=0.5; 95% CI 0.29-0.88), that is evidence of a favorable protective effect of this genotype against the development of CML.

Summary/Conclusions: Our results suggest that the G allele and the heterozygous genotype A/G A2452G polymorphism of CYP 1A1 gene are important markers of increased risk in formation of malignant tumor cells and development of CML in Uzbekistan (P<0.05). In this case, homozygous genotype A/A of A2452G polymorphism of CYP 1A1 gene has a protective character in relation to risk of CML.
in 1st line, 114 in 2nd, 56 in 3rd) only 13 had hematologic toxicity and 6 had to switch, 14 had pleural effusion grade III-IV and 9 had to switch. From 115 patients treated with nilotinib (49 in 1st line and 66 in 2nd) only 10 had hematologic toxicity and 10 switched treatment. Survival: Estimated survival by 10 years was 80%. Variables associated with survival: In the univariate survival analyses (log rank test) either from diagnosis, first therapy or first TKIs, the Sokal, Euts, Euro and EUTOS LT scores, as well as age over 70y were the only statistically significant variables associated with survival. Hematologic toxicity grade III-IV was associated with lower PFS or OS (figure 1). In the multivariate analysis (Cox model), only hematologic toxicity grade III-IV and age over 70y were independent variables.

Summary/Conclusions: 1. These results show that the probability of survival by 10 years is roughly 80%, and extend the findings of our previous work showing that this probability is not different across different sequential treatments (imatinib 1st line or post-IFN, or switched to 2ªGTKis due to intolerance or failure) (1). This fact emphasizes the rescue potential of available TKI therapies. 2. Hematologic toxicity grade III-IV in the first two years identified a group of patients with worse survival outcome. 3. Patients over 70 years have shorter survival due to reasons different than progression. 4. Second GTKis showed better hematologic toxicity profile.

5-YEAR EFFICACY OF DASATINIB AND IMATINIB IN NEWLY DIAGNOSED PATIENTS WITH CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE (CML-CP) WITH DOSE MODIFICATIONS FROM DASISION A. Hochhaus1,*, E. Jabbar1, H. Kantarjian2, F. Guhil3, V. Kota4, T. P. Hughes5, S. Shelet6, L. Li6, J.E. Cortes2
1Universitätsklinikum Jena, Jena, Germany, 2University of Texas MD Anderson Cancer Center, Houston, United States, 3Inserm CIC 1402, CHU de Poitiers, Poitiers, France, 4Winship Cancer Institute at Emory University, Atlanta, United States, 5SAHMRI, University of Adelaide, Adelaide, Australia, 6Bristol-Myers Squibb, Princeton, United States
Background: Multiple dosage strengths are approved for dasatinib (DAS), permitting dose-optimization strategies for patients who experience adverse events (AEs). In a 2-year retrospective analysis of DASISION, efficacy was maintained in DAS- and imatinib (IM)-treated patients with dose reductions or interruptions to manage AEs (Jabbour ASH 2011); cytogenetic and molecular response rates were higher for patients given DAS vs IM, even when daily doses were modified. Longer term follow-up is needed to fully understand the potential impact of dose reductions on efficacy.

Aims: To evaluate the effect of dose reduction for any AE and for pleural effusion on efficacy in DAS- or IM-treated patients from DASISION.

Methods: Treatmen-naive patients with CML-CP in DASISION (NCT0481247) were randomized to receive either DAS (100mg once/day; N=259) or IM (400mg once/day; N=260). Dose reductions for AEs (up to 2) were allowed: DAS: 80mg, then 50mg; IM: 300mg, then 200mg. Five-year molecular and cytogenetic response rates in all patients were assessed retrospectively.

Table 1.

Results: Patients on DAS maintained higher molecular response rates than patients on IM, whether or not they had dose reductions for an AE; these rates were similar in patients with and without dose reductions in each arm (table). 95 (37%) DAS- and 44 (17%) IM-treated patients had dose reductions at any time due to AEs. Median time to first DAS dose reduction was 289 days (range: 22-2123), and median time to first IM dose reduction was 160 days (range: 31-2052). For patients with reductions due to any cause, median average daily dose was DAS 83mg and IM 328mg; for DAS patients with reductions due to pleural effusion, median average daily dose was 82mg. Median duration of treatment (excluding interruptions) was 54 months (range: 3-70) for patients who had a DAS dose reduction and 57 months (range: 2-71) for patients who had an IM dose reduction. Changes in level of response were tracked for patients who achieved complete cytogenetic response (CCyR) or major molecular response (MMR) before or after the first dose reduction (table). Many patients maintained or increased to CCyR or MMR following dose reductions for any AE. Hematological toxicity (9%) was the most common AE resulting in dose reduction for IM, and pleural effusion (12%) was the most common for DAS.

Summary/Conclusions: Reducing DAS doses to 80mg or 50mg was a safe and effective means of managing patients who experienced AEs in this 5-year retrospective analysis of DASISION. These results were consistent with previous reports and continued to show that efficacy was not affected by dose reductions for any cause, including pleural effusion. Notably, there was no loss of CCyR following dasatinib dose reductions. Molecular responses remained higher for DAS vs IM irrespective of dose reductions due to AEs.

E1053
EFFECT OF PLASMA TROUGH CONCENTRATION OF NILOTINIB AND POLYMORPHISMS OF DRUG TRANSPORTER GENES ON THE FREQUENCY OF ADVERSE EVENTS IN CHRONIC PHASE OF CHRONIC MYELOID LEUKEMIA: STAT1 AND STAT2 TRIALS N. Takahashi1,*, T. Nioka2, M. Abumiya2, S. Takahashi1, M. Miura2
1Hematology, AKITA UNIV., 2Pharmacy, AKITA UNIV. HOSPITAL, Akita, Japan
Background: STAT trials (STAT1 and STAT2) are multicenter, phase II, single-treatment arm, open-label clinical studies designed to evaluate the efficacy and safety of two-year consolidation by nilotinib (NIL) for achieving a deep molecular response (DMR) or successful treatment-free remission (TFR) in patients with chronic phase chronic myeloid leukemia (CML).

Aims: In this report, we focus on the adverse events (AEs), especially anemia and liver dysfunction observed in the STAT trials. Additionally, we analyzed the relationship between laboratory abnormalities and pharmacokinetics (PK)/pharmacogenetics (PGx) of NIL.

Methods: AEs were assessed according to the Common Terminology Criteria for Adverse Events (CTCAE) v4.03. Safety evaluations were conducted throughout the study. Plasma trough concentrations of NIL were determined with high-performance liquid chromatography (HPLC) at 1 month (1M), 3M, 6M, 12M, and 24M in the STAT trials. Genotyping of CYP3A5*3 [6986A>G (rs776746)], ABCB1 [3435T>C (rs1045642)], ABCG2 421C>A (rs2231142), and UGT1A1*6, *27, and *28 was performed using polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP). All genotype frequencies were tested for Hardy-Weinberg equilibrium.

Figure 1.

Results: Between July 2011 and December 2012, CML patients were recruited in the STAT trials. NIL was administered twice daily (600mg/day) for 2 years according to the study protocol. A total of 76 and 96 patients were analyzed as a safety data set in STAT1 and STAT2, respectively. In STAT1, 18 patients who achieved a confirmed DMR were switched from STAT1 to STAT2. These patients entered both trials, but safety data had not been collected in STAT1 after entering STAT2 to avoid double counts. The PK/Pgx data of 147 of 154 patients were available and were evaluated in this study. Median trough concentrations of NIL were 1265 ng/ml at 1M, 1154 ng/ml at 3M, 974 ng/ml at 6M, 735 ng/ml at 12M, and 781 ng/ml at 24M. Although any-grade AEs were reported in patients in STAT1 and 55 patients in STAT2, the most common drug-related hematological and non-hematological AEs were elevated total bilirubin (28.6%), anemia (24.5%), elevated ALT (21.1%), and elevated AST (18.4%). The incidence of these AEs, except for anemia, was significantly associated
with high trough concentration of NIL (Figure 1). There were statistically significant correlations between median concentrations of NIL and the grades of each AE. Based on the results of the analysis using Cox proportional-hazards model, the trough concentration of NIL [hazard ratio=1.001 (1.000-1.002), P=0.004] and ABCG2 421A/A [hazard ratio=3.044 (1.155-8.027), P=0.024] were independent factors for the elevated ALT. Similarly, the trough concentration of NIL [hazard ratio=1.001 (1.000-1.002), P=0.001] and UGT1A1 1′/1′ [hazard ratio=0.475 (0.246-0.919), P=0.02] were independent factors for the elevated total bilirubin.

Summary/Conclusions: In this study, we identified the relationship between NIL trough concentration and liver dysfunction. Our finding suggests that therapeutic drug monitoring might help avoid drug interruption and discontinuation because of AEs, especially liver dysfunction.

E1054

VERY EARLY MOLECULAR RESPONSE (VEMR) WITH FRONTLINE DASATINIB TREATMENT IS A STRONG PREDICTOR OF LONG-TERM BCR-ABL1 TRANSCRIPT LEVELS IN CHRONIC MYELOID LEUKEMIA PATIENTS: PCR-DEPTH STUDY

1Institute of Medical Hematology, Keimyung University Hospital, Daegu, 2Department of Hematology-Oncology, Chungnam National University Hwasun Hospital, Hwasun, 3Department of Hematology-Oncology, Wonju College of Medicine, Yonsei University, Wonju, 4Department of Hematology, University of Ulsan College of Medicine, Ulsan University Hospital, Ulsan, 5Division of Hematology-Oncology, Keimyung University, School of Medicine, Daegu, 6Division of Hematology-Oncohropy, Daejeon Division of Hematology-Oncohropy, Chonbuk National University Medical School, Chonbuk National University Hospital, Geonju, 7Division of Hematology-Oncology, Sungkyunkwan University, Kangbuk Samsung Hospital, Seoul, 8Department of Internal Medicine, Dong-A University College of Medicine, Dong-A University Hospital, Busan, 9Department of Hematology, The Catholic University of Korea, St. Vincent’s Hospital, Suwon, 10Department of Internal Medicine, Hallym University College of Medicine, Hallym University Hospital, 11Department of Hematology, Ewha Womans University, Ewha Womans University Hospital, Seoul, 12Department of Hematology, Hanyang University College of Medicine, Hanyang University Guri Hospital, Guri, 13Department of Hematology, Seoul St. Mary’s Hospital, Leukemia Research Institute, The Catholic University of Korea, 14Department of Hematology, Seoul St. Mary’s Hospital, The Catholic University of Korea, Seoul, Korea, Republic Of

Background: In BCR-ABL1 tyrosine kinase inhibitor (TKI) treated chronic phase chronic myeloid leukemia (CP-CML), early molecular response (EMR) at 3 months is currently identified as being one of the most important prognostic factors. Sokal risk score and dose intensity during first 3 months were strongly associated with achievement of EMR. As dasatinib is a novel kinase inhibitor with improved potency, identification of very early molecular response (VEMR) would be beneficial.

Aims: We evaluated the possibility of the VEMR at 1 month predicting long-term outcomes in newly diagnosed CP-CML patients treated with dasatinib.

Methods: In our prospective, observational, open-label study, 102 patients with CP-CML were enrolled to receive dasatinib at a dose of 100mg once daily. The primary end point was complete molecular response (CMR) by 18 months. Secondary end points including molecular response (MR) by 1, 3, 6, 12, 18, 24 month, time to and duration of MMR and CMR, and safety were tested. A receiver operating characteristic (ROC) curve from BCR-ABL1 transcript level on Day+28 was calculated to predict EMR and MMR at specific timepoints.

Results: Median age was 49 years (19-81 years) and 61 patients were male. With median follow-up duration of 28 months (0.9-33.8 months), 80 (78.4%) out of 102 patients were still on dasatinib treatment and 22 patients discontinued the dasatinib treatment. Tolerability (n=2) or adverse events (n=8) or other reasons (n=9). The BCR-ABL1 mutations, assessed in 10 patients after dasatinib discontinuation, were detected in 3 patients which were all T315I mutation. The cumulative CMR by 18 months and MMR by 24 months were 20.5% and 79%, respectively. In safety analyses, grade 1/2 thrombocytopenia (30.3%) was most common. Pleural effusion occurred in sixteen (15.6%) patients which were mostly grade 1/2. The cut-off value of BCR-ABL1 transcript on Day+28 was 40% by ROC curve analysis. Among 95 patients who had available molecular data of both D+28 and 12 months, fifty nine (62.1%) patients had less than 40% of BCR-ABL1 transcript (VEMR) on Day+28, thirty four (36.2%) patients achieved MMR at 12 months. However, only 27.8% (10 out of 36 patients) of patients without VEMR achieved MMR (p=0.001). Among 85 patients who had available molecular data of both D+28 and 24 months, fifty two (61.2%) patients achieved VEMR. In 52 VEMR patients, 48 (88.5%) patients achieved MMR at 24 months. However, only 48.2% (17 out of 35 patients) of patients without VEMR achieved MMR (p=0.001). Overall survival (OS) & progression-free survival (PFS) rates were 98.0% and 95.1% respectively. PFS rates by 24 months for VEMR and no VEMR group were 98.4% vs 88.8% respectively (p=0.04).

Summary/Conclusions: Our study shows that VEMR at 1 month can be a strong predictor for further molecular responses as well as long-term outcome. Therefore it would be helpful to monitor BCR-ABL1 transcript level at 1 month in patients who treated with more potent TKIs.

E1055

SURVIVAL OUTCOMES IN PATIENTS WITH CHRONIC-PHASE CHRONIC MYELOID LEUKEMIA (CP-CML) RECEIVING THIRD- OR SUBSEQUENT LINE (3L) TREATMENT PRIOR TO THE AVAILABILITY OF PONATINIB: A SYSTEMATIC REVIEW AND METAL ANALYSIS

D. Stellato1, L. McGarry2,*, H. Huang2, S. Hastings1, T. Delea1
1Policy Analysis Inc. (PAI), Brookline MA, 2ARIAD Pharmaceuticals, Inc., Cambridge, MA, United States

Background: PACE was the phase 2 single-arm trial of ponatinib, a 3rd-generation tyrosine kinase inhibitor (TKI), in 449 highly-refractory patients with CML Philadelphia-chromosome positive (Ph+) acute lymphocytic leukemia (ALL) or who had the BCR-ABL1 T315I mutation. Overall survival (OS) for 3L-CM patients in PACE at 1, 2, 3 and 4 years was estimated to be 91%, 83%, 80%, and 79%, respectively. Expected survival for 3L-CP-CML patients prior to the availability of ponatinib has not been documented.

Aims: To estimate OS in patients with CP-CML receiving 3L treatment prior to ponatinib via a systematic literature review.

Methods: Studies were identified from a review by Lipton et al. (2015), updated with studies identified from searches of electronic databases (MEDLINE, EMBASE, Cochrane Libraries) and abstract databases of key conferences. Landmark and median survival were extracted from study reports. Pseudo-individual patient data (IPD) for survival outcomes were derived from digitized Kaplan-Meier (KM) survival curves then pooled and analyzed using KM methods.

Results: Fifty studies (717 patients) were identified that reported median, landmark, or KM curves for survival outcomes for CP-CM patients receiving 3L treatment without ponatinib. KM curves for OS were obtained for 6 arms (3 nilotinib and/or dasatinib; 3 other TKIs). OS at 1, 2 and 3 years based on the pooled IPD is reported in the Table. To avoid confounding of OS from post-progression treatment with ponatinib, 1 study was excluded that included follow-up after the date of ponatinib’s approval.

Table 1.

<table>
<thead>
<tr>
<th>Time (Years)</th>
<th>OS probability (95%CI)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>90% (86%, 93%)</td>
</tr>
<tr>
<td>2</td>
<td>77% (72%, 83%)</td>
</tr>
<tr>
<td>3</td>
<td>66% (59%, 72%)</td>
</tr>
</tbody>
</table>

Summary/Conclusions: Estimated OS in patients with CP-CML receiving 3L treatment prior to ponatinib appears to be shorter than that observed among ponatinib-treated patients in PACE: 4-year survival probability in PACE was higher than estimated 2-year survival probability prior to ponatinib. Further analyses are needed to identify and adjust for potentially confounding factors.

E1056

DETECTION AND MONITORING OF BCR-ABL1 KINASE DOMAIN MUTATIONS IN CML AND ALL PATIENTS BY NEXT GENERATION SEQUENCING AND DROPLET DIGITAL PCR, A BELGIAN PROSPECTIVE STUDY

C. De Rop1,*, H. Devos2, P. Vannuffel3, F. Nollet2
1Molecular Biology, IPG, Gosselies, 2Laboratory Medecine, AZ Sint-Jan, Bruges, Belgium

Background: Among myeloproliferative diseases, development of chronic myeloid leukaemia (CML) is associated with the emergence of the fusion oncoprotein BCR-ABL1 resulting from a t(9,22) chromosomal translocation (Philadelphia chromosome). This chimeric transcript is also present in all acute lymphoblastic leukaemia (ALL) patients treated with a Philadelphia chromosome (Ph+ ALL). Mutations of the BCR-ABL1 kinase domain constitute a major cause of treatment failure in CML and Ph+ALL patients receiving first or second generation tyrosine kinase inhibitors (TKI) treatment. So far, the gold standard procedure to detect BCR-ABL1 kinase domain (KD) mutations is the conventional Sanger Sequencing, endowed with an analytical sensitivity of 15-20%. Recent studies on the implementation of Next Generation Sequencing (NGS) for detection of BCR-ABL1 KD mutations showed a significant dropping down of the sensitivity level (1-5%), improving patient’s treatment management.

Summary/Conclusions: Estimated OS in patients with CP-CML receiving 3L treatment prior to ponatinib appears to be shorter than that observed among ponatinib-treated patients in PACE: 4-year survival probability in PACE was higher than estimated 2-year survival probability prior to ponatinib. Further analyses are needed to identify and adjust for potentially confounding factors.
Aims: Both NGS and droplet digital PCR (ddPCR) were used in this prospective study. NGS screened all known mutations in the BCR-ABL1 KD and ddPCR targeted only the 3 most common mutations, T315I, E255K and Y253H, which represent approximately 75% of the ABL1 mutations. Patients eligible for the study were i) CML patients with failure or worsening to all lines of TKI therapy according to the 2013 ELN-guidelines, with no suspected lack of adherence and ii) patients who had established MR4.0 diagnosis and/or molecular remission. Monitoring was performed when clinically appropriate.

Methods: Total BCR-ABL1 RNA was transcribed into a long range cDNA covering the kinase and the regulatory and the SH2/SH3 domains of either p190 or p210 BCR-ABL1 transcripts (exons 4 to 10). For NGS, primers designed with the Ampliseq™ Designer Software were generated as a set of 10 amplicons, bar-coded libraries, constructed according to the Ampliseq™ protocol, were sequenced on the Ion Torrent PGM platform (sensitivity of 2.5%). For ddPCR, cDNA was analysed for the presence of one of the 3 main mutations (T315I, E255K and Y253H). The overall number of BCR-ABL1 mutated samples was 18 (15 CML and 3 Ph+ ALL), representing 30% of the cases. Among these samples, 27 mutations were recorded. 9 samples presented with one mutation: T315I (2), E255K (3), G250V (1), F359I (1), M237T(1) and E255A (1) and 9 harboured compound mutations: T315I + E255K (6) and T315I + Y253H (3). A high frequency (85%) of T315I, E255K and Y253H mutations was also observed (23/27). As far as these 3 mutations are concerned, reproductibility to determine mutational burden was found to be very high between NGS and ddPCR.

Summary: Advancements in sequencing technologies and further lowering sensitivity levels contribute to optimal management of CML and Ph+ ALL patients and improve treatment outcome. The earlier a mutation in the kinase domain is detected, the earlier an informed choice can be made regarding optimal subsequent TKI treatment.

E1057 CLINICAL AND IMMUNOLOGICAL EFFECTS OF NILOTINIB IN COMBINATION WITH PEGYLATED INTERFERON-Α2B IN PATIENTS WITH SUBOPTIMAL MOLECULAR RESPONSE ON IMATINIB (NORDUTCHCML009)

I. Geelen1, U. Olsson-Strömberg2, S. Mustjoki3, J. Richter4, N. Blijlevens6, N. Komatsu1, T. Kawaguchi9

1Department of Hematology, Juntendo University School of Medicine, 2Division of Hematology and Rheumatology, Department of Medicine, Nihon University School of Medicine, Tokyo, 3Department of Hematology, Saitama Medical Center, Saitama Medical University, Saitama, 4Division of Hematology, Department of Medicine, Juntendo University Nermia Hospital, Tokyo, 5Department of Hemato-Oncology, Comprehensive Cancer Center, Saitama Medical University International Medical Center, Saitama, 6Department of Hematology, Yokohama Municipal Citizen’s Hospital, Yokohama, 7Department of Hematology, Juntendo University Urayasu Hospital, Urayasu, 8Department of Hematology, SaiSeikei Yokohama Nanbu Hospital, Yokohama, 9Department of Hematology and Infectious Diseases, Kumamoto University Hospital, Kumamoto, Japan

Background: Chronic myeloid leukemia (CML) is a disease of hematopoietic stem cells resulting from oncogenic chromosome translocation that leads to the formation of the BCR-ABL1 fusion gene. Treatment of chronic phase (CP) CML has dramatically changed since the emergence of the first-in-class tyrosine kinase inhibitor (TKI) imatinib, and treatment based on TKI has improved the outcome in the majority of CP-CML patients. Nowadays, second generation TKIs have been approved, increasing the choice of TKIs for CP-CML patients, and lower disease progression rate than imatinib. On the other hand, longer treatment duration and the increased types of TKIs gave rise to various kinds of unexpected adverse events (AEs). In 2011, drug-induced peripheral arterial occlusive disease (PAOD) was first reported, followed by vascular AEs (VAEs) including peripheral arterial occlusive disease (PAOD) and central arterial occlusive disease (CAOD). Furthermore, it became clear that the incidence of VAEs increased with the dose and treatment duration, therefore VAEs are considered a more fatal complication of TKI treatment. However, there is no available data about the incidence of VAEs in Japanese patients.

Aims: We investigated the vascular safety issue and estimated the 1000 person-years risk of developing VAEs during TKI treatment, including imatinib, nilotinib, and dasatinib, using 3 risk assessment tools among 320 Japanese patients who were enrolled in the CML Cooperative Study Group.

Methods: A surveillance data of 320 patients enrolled in the CML Cooperative Study Group was conducted. This analysis was performed in Japanese patients. Among patients who were diagnosed with CML-CP from April 2001 to January 2016, whose median age was 57 years (15-80) and median time of follow up was 64.2 months. Patients in the accelerated or blastic phase (AP/BP) were excluded. The study was approved by the research ethics boards of each institutions and was conducted in accordance with the Declaration of Helsinki. All patients who developed VAEs were analyzed using 3 risk assessment tools (SCORE chart, Framingham risk score, Sita-score) to estimate the patients’ 10-year risk of VAEs.

Results: Among the 320 newly diagnosed CML-CP patients, 16 (5.0%) cases of VAEs were reported during the study period. Seven cases were treated by imatinib, 6 by nilotinib, 1 by dasatinib, 4 cases were a switch from imatinib to nilotinib, and 1 case was a switch from dasatinib to nilotinib. The VAEs were 9 INH, 5 CI, and 2 PAOD cases. Results from the 3 risk assessment tools are as follows: SCORE (2 low, 9 moderate, 1 high, 4 very high risk), Framingham score (3 low, 5 moderate, 7 high risk), and Sita-score (13 low, 1 intermediate, 5 high risk). The incidence rate of INH, CI, and PAOD was 5.26 and 2.92 in the enrolled CML-CP patients, 4.65 and 2.33 in the imatinib-treated patients, 14.34 and 10.75 in the nilotinib-treated patients, 4.08 and no case in the dasatinib-treated patients, and 1.787 and 3.342 in the age-
matched general population, respectively. Among the 320 newly diagnosed CML-CP patients, 16 (6.0%) cases of VAEs were reported during the study periods. Seven cases were treated by imatinib, 3 cases by nilotinib, 1 case by dasatinib, 4 cases were a switch from imatinib to nilotinib, and 1 case was a switch from dasatinib to nilotinib. The VAEs were 9 IHD, 5 CI, and 2 PAOD cases. Results from the 3 risk assessment tools are as follows: SCORE (2 low, 9 moderate, 1 high, 4 very high risk). Framingham score (3 low, 5 moderate, 7 high risk), and Suiita-score (13 low, 1 intermediate, 1 high risk). The incidence rate of IHD and CI per 1000 person-years were 5.26 and 2.92 in the enrolled CML-CP patients, 4.65 and 2.33 in the imatinib-treated patients, 14.34 and 10.75 in the nilotinib-treated patients, 4.08 and no case in the dasatinib-treated patients, and 1.787 and 3.342 in the age-matched general population, respectively.

Summary/Conclusions: The incidence rate of IHD per 1000 person-years were higher in the nilotinib- and lower in imatinib- and dasatinib-treated CML patients, and the patients showed almost the same rate of CI as compared with the age-matched general population, even though the incidence of VAEs were lower in Japanese compared to the European cohort. More patients were estimated to have very-high and high risk of VAEs in the SCORE and Framingham risk score assessment tools as compared with the Suiita-score tool.

1Hematology Department, Hospital Universitario Fundación Jiménez Díaz, Madrid, Spain, 2Hematology Department, Hammersmith Hospital, London, United Kingdom, 3Hematology Department, Hospital Clínico de Santiago, Santiago, 4Hematology Department, Hospital La Paz, 5Hematology Department, Hospital Doce de Octubre, Madrid, 6Hematology Department, Hospital Virgen de la Salud, Toledo, 7Hematology Department, Hospital Morales Meseguer, Murcia, 8Hematology Department, Hospital Puerta Hierro, Madrid, 9Hematology Department, Hospital General de Elche, Elche, 10Hematology Department, Fundación Investigación Hospital de la Princesa IIS-IP, 11Hematology Department, Hospital de la Princesa, Madrid, Spain

Background: Since the introduction of Tyrosine Kinase Inhibitors (TKI), many patients diagnosed of Chronic Myeloid Leukemia (CML) in chronic phase achieve a deep molecular response. Around 50% of these patients are expected to maintain their molecular responses even after discontinuation of their TKI treatment. Several clinical trials are exploring the best way of stopping TKI therapy and evaluating patient and disease characteristics that could predict relapse after treatment discontinuation.

Aims: This is an update of the CMRegistry study aimed at collecting clinical data and molecular information from Spanish CML patients that have achieved a series of molecular milestones to any of the tyrosine kinase inhibitors in order to monitor their progress and the achievement of a stable deep molecular response: >MR4 (IS).

Methods: CMRegistry is an observational, multi-center and prospective study. CML patients treated with any of the tyrosine kinase inhibitors who are likely to achieve, or have already achieved, a deep molecular response (>MR4.0 (IS)) are included. This likelihood of achieving >MR4 is defined, for the purposes of the study, as a bcr/abl ratio of: 1) ≤1% at 6 months from start of TKI therapy, or 2) ≤0.1% at 6 months from start of TKI therapy; or 3) ≤0.01% any time point during treatment. Clinical data have been collected using a specific CRF. All data were registered in an anonymous manner. The BCR-ABL ratios in the IS have been provided by standardized labs in Spain.

Results: From June 2014 to February 2017, 976 patients were registered in the study. Median age was 51 years (15-88). The Sokal risk groups were as follows: 621 patients low risk, 307 intermediate risk and 129 high risk. Cutoffs classification yielded 714 patients in the low risk and 79 in the high risk categories. The majority of patients received first-line treatment with imatinib (626 patients), dasatinib (39 patients) or nilotinib (87 patients). Of note, 5 patients received bosutinib, 1 patient ponatinib and 74 patients were treated with Interferon previous to TKI administration. So far 14 patients have died of non-CML related conditions such as carcinoma (2 patients), ischemic heart disease, respiratory failure and sepsis. Interestingly, 2 patients developed progression of their CML to accelerated phase and blast crisis (1 patient each) with no deaths. At present, 104 patients (11%) have achieved a MR4.0, 174 patients (18%) a MR4.5 and 123 patients (13%) have obtained a complete molecular remission (undetectable bcr-abl transcripts with a sensitivity of at least 10-5).

Summary/Conclusions: Almost one thousand CML patients have been included in this Spanish prospective study owing to their promising molecular response that would predict for a sustained deep molecular remission. Four hundred and one patients have already achieved a deep molecular response (>MR4 (IS)) and could be enrolled in prospective discontinuation studies.

E1060 ANALYSIS OF DASATINIB AND IMATINIB 5-YEAR EFFICACY AND SAFE-TY BASED ON BASELINE COMORBIDITY AND AGE IN PATIENTS WITH NEWLY DIAGNOSED CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE (CML-CP) IN DASISION G. Saglio17, J.E. Cortes2, A. Hochhaus3, N.P. Shah4, E.L. Atallah5, M. Abakharouf6, L. LP, M.J. Mauro7

1University of Turin, Turin, Italy, 2The University of Texas MD Anderson Cancer Center, Houston, United States, 3Universitätsklinikum Jena, Jena, Germany, 4University of California San Francisco School of Medicine, San Francisco, 5Froedtert & the Medical College of Wisconsin, Milwaukee, 6Bristol-Myers Squibb, Princeton, 7Memorial Sloan Kettering Cancer Center, New York, United States

Background: Patients with CML often have comorbidities, which may influence treatment-related decisions and impact response and survival. In a retrospective analysis of 1-year data from the phase 3 DASISION study, the overall safety or response in dasatinib- or imatinib-treated patients was not substantially impacted by baseline comorbidities, although certain adverse events (AEs) trended higher in patients with ≥1 comorbidities (Khoury ASH 2010). Further analysis is warranted to determine how comorbidities may impact long-term outcomes.

Aims: To evaluate the impact of baseline comorbidities and patient age on 5-year safety and efficacy in dasatinib- or imatinib-treated patients from DASISION.

Methods: In DASISION (NCT00481247), patients were randomized to receive dasatinib 100mg/day (N=259) or imatinib 400mg/day (N=260). For this retrospective analysis, patients were grouped as having 0 or ≥1 baseline comorbidity, by baseline disorder (diabetes mellitus, hepatobiliary disease, hyperlipidemia, cardiovascular disorder, or pulmonary condition), or by age group (<46 years, 46–65 years, >65 years). Safety (treatment-related AEs in ≥10% of patients) and efficacy (response rates by 5 years and median times to response) were assessed for each group and treatment.

Table 1.
Results: The number of patients with 0 or ≥1 comorbidity was similar in the dasatinib (66 [25%]; 193 [75%]) and imatinib (67 [26%]; 193 [74%]) arms, respectively; most (>90%) patients were <65 years old. In patients with 0 or ≥1 baseline comorbidity, the median average daily dose was comparable within arms and discontinuation rates (36%-39%) were similar within and across arms (table). The overall safety profiles were comparable in the 0 and ≥1 comorbidity groups in both arms, other than specific AEs, which had a 22 times higher frequency in patients with ≥1 vs 0 comorbidities; the majority of these were grade 1/2 AEs (table). The incidence of peripheral edema increased with patient age for both imatinib and dasatinib (<46 years: 5% each; 46–65 years: 12% and 10%; ≥65 years: 21% and 20%). In this analysis, the increased incidence of pleural effusion (PE) in the dasatinib-treated patients was most highly associated with increased age: <46 years (16%) vs 46–65 years (37%) vs ≥65 years (60%). PE incidence did not appear to be related to baseline pulmonary comorbidity and was similar in dasatinib-treated smokers (33%) vs nonsmokers (27%). Within each arm, patients with 0 or ≥1 comorbidity (table) and across age groups had similar response rates for patients treated once daily, but were numerically higher for patients with ≥1 vs 0 comorbidities in both arms (MR4.5 on dasatinib: 46% vs 32%; MR4.5 on imatinib: 36% vs 22%). Median time to response (months) for patients with 0 or ≥1 comorbidity did not differ within each arm, but was numerically shorter for dasatinib (36 or 35) vs imatinib (MR4.5: 42 or 47).

Summary/Conclusions: The superior efficacy of dasatinib over imatinib was shown in previous studies. Response rates and times to response were comparable in patients with 0 or ≥1 comorbidity and trended in favor of dasatinib vs imatinib. Although a few AEs (most grade 1/2) appeared to occur at a higher frequency in patients with ≥1 vs 0 comorbidities in either treatment arm, the overall occurrence of AEs and discontinuation rates at 5 years in patients who were treated with first-line dasatinib or imatinib did not appear to be substantially affected by baseline comorbidities.

E1062 RADOTINIB TREATMENT IN CHRONIC PHASE CHRONIC MYELOID LEUKAEMIA PATIENTS WITH RESISTANCE OR INTOLERANCE TO BCR-ABL TKIS: 36 MONTHS UPDATE OF RADOTINIB PHASE 2 STUDY

Background: Radotinib is an orally active, selective BCR-ABL1 tyrosine kinase inhibitor (TKI), approved for the first-line and second-line treatment of chronic phase chronic myeloid leukemia (CP-CML) patients in Korea. Earlier 12 and 24 month results demonstrated that radotinib is effective and well tolerated in CP-CML patients with resistance and/or intolerance to BCR-ABL TKIs.

Aims: We update the long-term outcome of radotinib treatment in patients failed to BCR-ABL1 TKIs with a minimum follow-up of 36 months.

Methods: Ph+ CP-CML patients who failed prior TKI therapy were enrolled between July 2009 and November 2011. All patients were treated with radotinib 400mg twice daily. Cytogenetic and molecular assays were performed at base-line, every 3 months, and at treatment failure. Safety parameters were also analyzed. Probabilities of overall survival (OS) and progression free survival (PFS) were calculated using Kaplan-Meier method.

Results: A total of 77 CP-CML patients (18 years of age or over) were enrolled. This analysis includes data from last enrolled patient who received at least 36 months of radotinib therapy. With a median follow-up of 45.7 (range 0.9-65.7) months, 31 patients (40.3%) completed 36 months treatment, and 46 patients (59.7%) discontinued the treatment before 36 months. Main reasons of discontinuation were abnormal laboratory test (n=18), adverse events (n=4), treatment failure including disease progression and lack of response (n=18), death (n=2), and other reasons (n=4). Median duration of radotinib exposure was 19.5 (0-36.9) months. Cumulative incidence of complete cytogenetic response (CCyR) by 36 months was 90.0% and of patients achieving CCyR, 45.0% (18/40) achieved MMR. The drug-related safety profiles were consistent with those previously reported and new safety issues have not been observed after 12 months. Most drug-related AEs have developed within 12 months, and have shown minimal increase compared with rates at 12 months follow-up. Estimated OS and PFS at 36 months were 87.6% and 85.7%, respectively.

Figure 1. Summary/Conclusions: The 36 months data supports radotinib treatment in TKI failed CP-CML patients maintains the effective response and high rates of OS & PFS rate. Thus, radotinib demonstrated a promising alternative treatment for patients with TKIs failure.
100 YEARS OF CHRONIC MYELOID LEUKEMIA PREVALENCE IN FRANCE M. Delord 1,7

Background: The success of imatinib and other rationally designed tyrosine kinase inhibitors (TKI) in the treatment of chronic myeloid leukemia has drastically improved the fate of CML patients. From a couple of years in median survival in the 70’s, a majority of patient now achieve a near normal life expectancy with lifelong treatment through. This new paradigm where CML can be regarded as a chronic disease has mechanical consequences on the disease prevalence and overall costs for health care systems. The success of imatinib and other rationally designed tyrosine kinase inhibitors (TKI) in the treatment of chronic myeloid leukemia has drastically improved the fate of CML patients. From a couple of years in median survival in the 70’s, a majority of patient now achieve a near normal life expectancy with lifelong treatment through. This new paradigm where CML can be regarded as a chronic disease has mechanical consequences on the disease prevalence and overall costs for health care systems.

Aims: We present here a fully detailed and comprehensive analysis of the French CML prevalence over a century from 1960 to 2060.

Methods: Prevalence of CML was estimated using a cohort component-based model from estimates of incidence rate of the disease by age and sex, population and demo-graphic projection from the National Institute of statistics and Econometrics Studies, and various hypotheses on the relative survival of CML patients. Prevalence of CML was estimated using a cohort component-based model from estimates of incidence rate of the disease by age and sex, population and demo-graphic projection from the National Institute of statistics and Econometrics Studies, and various hypotheses on the relative survival of CML patients. The number of CML patients is estimated over time and the resulting CML prevalence expressed as a number of CML patients per 100,000 inhabitants.

Results: The CML prevalence in France, expressed in cases per 100,000 inhabitants, was estimated to be around 3 before the 80’s, 6 before the 2002, 17 in 2010 and 30 in 2030 where the tendency inflects, and 30 after 2040. Considering the 100% relative survival hypothesis, a target CML prevalence were nearly reached by 2060. By simulation, we showed that given constant incidence rates and high relative survival hypotheses, the CML prevalence will be driven by population aging, and that the target prevalence, defined as the maximum CML prevalence, should be nearly reached by 2050 to levels above 30 per 100,000 inhabitants.

Figure 1.

Summary/Conclusions: Due to high rates of relative survival observed after introduction of imatinib, the trajectory of the CML prevalence in France, as in other western countries, has changed. Given particular hypothesis on the CML incidence rates, this trajectory will bring the CML prevalence by the mid century to levels fully determined by population aging. For France, we have estimated this level above30 cases per 100,000 inhabitant.

THE ROLE OF MICRORNAS IN CHRONIC MYELOID LEUKEMIA THERAPEUTIC SELECTION

R. Alves 1,2, A.C. Gonçalves 1,2, P. Couceiro 3, P. Rodrigues-Santos 2,3,4, P. Freitas-Tavares 2, L. Ribeiro 2, A.M. Almeida 2,6, A.B. Samenno-Ribeiro 2,5,7

1Applied Molecular Biology and University Clinic of Hematology, 2CIMAGO, Faculty of Medicine University of Coimbra, 3Immunology and Oncology Laboratory, Center for Neuroscience and Cell Biology (CNC), 4Immunology Institute, Faculty of Medicine University of Coimbra, 5Clinical Hematology Department, Centro Hospital e Universitário de Coimbra (CHUC), Coimbra, 6Hematology Service, Instituto Português de Oncologia de Lisboa Francisco Gentil (IPOL), 7CEDOC, Nova Medical School, Lisbon, Portugal

Background: Chronic myeloid leukemia (CML) is characterized by the presence of BCR-ABL fusion gene. This molecular event becomes the main therapeutic target with Imatinib as first-line treatment. In spite of the continued clinical success of Imatinib on CML treatment, the emergence of resistance to tyrosine kinase inhibitors (TKIs) has studied the research of the mechanisms involved. These included those related with target changing (e.g. the presence BCR-ABL gene mutations and amplifications) and with intracellular drug concentrations (e.g. the normal levels of influx and efflux transporters such as OCT1/OCTN2 and Pgp/BCRP, respectively). MicroRNAs (miRNAs) are important regulators of both mechanisms, and so, could influence TKIs response.

Aims: In this context, we investigated the role of miR-203, miR-21, miR-518c, miR-451 and miR-26 expression levels in TKI response in CML patients, and correlated them with TKI sensitivity, BCR-ABL levels, and disease progression, among other clinical and laboratory data.

Methods: To this end, we assessed the expression levels of miR-203, miR-21, miR-518c, miR-451, miR-26 and miR-16 (endogenous control) by TaqMan MicroRNA Assays in peripheral blood cells from 31 patients with CML at follow-up examinations. We also studied 4 CML cell lines, K562 a cell line sensitive to Imatinib, LAMA-84 a cell line with 4 copies of chromosome Philadelphia (Ph), and 2 Imatinib resistant cell lines models created in our lab (K562-RC and K562-RD). K562-RC cells, generated by continuous exposure to Imatinib, presented an 8 times higher BCR-ABL levels (K562; 100% of 26, K562-RD cells (created by discontinuous exposure), the degree of resistance is 18x. Statistical analysis was performed with ANOVA and multiple comparison tests, with significance levels of 95% (p<0.05).

Results: The miR-203 and miR-518c expression was not detected in any cell line and in patient samples. First, we examined miRs expression with BCR-ABL levels. Higher levels of tumor suppressor miR-451 were associated with a higher reduction of BCR-ABL levels (lower than 0.01%) in CML patients and patients with higher BCR-ABL present lower levels of expression of miR-451. This miR was also down-regulated in LAMA-84, K562-RC and K562-RD comparing with sensitive cell line (K562; p<0.05). On the other hand, patients with more BCR-ABL content (between 1.0% and 0.1%) present higher expression of the oncomiRs, mi21 and miR-26. These miRs were also up-regulated in resistant cell lines. MiR-21 was more relevant for K562-RC cells (4-fold higher than K562). LAMA-84 and K562-RD cell lines showed almost 2 times more expression of miR-21. Next we analyzed if treatment options affected miRs expression. CML patients under Imatinib treatment showed higher levels of miR-451 associated with less expression levels of miR-21 and miR-26. Imatinib had been described as able to block the BCR-ABL negative feedback on miR-451, increasing miR function. Since miR-21 and miR-26 were also lower expressed, more PTEN is available to block PI3K-AKT-mTOR pathways, decreasing this survival signaling. Opposite profile was observed in patients that changed treatment to a second generation TKI suggesting a different effect of this TKI on microRNA expression.

Summary/Conclusions: Our preliminary results suggested the involvement of miRNAs in BCR-ABL levels regulation and in TKI response, supporting the search of a miRNAs TKI response profile that could predicts the response in CML patients. This information could act as powerful tool for the stratification and selection of the best therapeutic approach (lower toxicity and cost effective), contributing to higher survival rates and better quality of life in CML patients.

Work supported by the Faculty of Medicine of the University of Coimbra and Santander Totta Bank, grant reference FMUC-BST-2016-214.
(SNPs) affect the transporter activity, but their impact on clinical response to imatinib in chronic myeloid leukemia (CML) is discordant; even less is known on their role in patients treated with second generation (2G) TKIs dasatinib and nilotinib.

Aims: To investigate the role of the most common ABCB1 and ABCG2 genetic polymorphism in chronic phase CML patients treated with imatinib and 2G-TKIs. Methods: We analysed four polymorphisms of ABCB1 (1297T>C, 1236C>T, 2677G>T/A and 3435C>T) and two polymorphisms of ABCG2 (34G>A and 421C>A) in 196 CP-CML patients, of whom 139 treated with imatinib (114 in first line and 25 after interferon failure) and 57 treated with dasatinib or nilotinib (22 in first line and 35 after imatinib failure). We compared the rates of optimal response at 3 months (defined as BCR/ABL <10%), at 6 months (BCR/ABL<1%) and at 12 months (BCR/ABL<0.1%), progression-free survival (PFS) and time to treatment failure (TTF) according to the different protein genotypes. TTF was calculated from the start of therapy to any of the followings: progression to accelerated or blastic phase (ABP), death for any cause at any time, treatment discontinuation for primary or secondary resistance or intoler ance. PFS was calculated from the start of TKI to ABP or death.

Results: A total of 196 patients with CP-CML (median age 57 years, range 21-84) were included in the analysis. Frequency of ABCB1 and ABCG2 SNPs expression is summarized in Table 1. Considering response to therapy, either in imatinib-treated patients and in those receiving a 2G-TKI, we did not find any significant difference in terms of optimal response at the various timepoints, TTF or PFS for ABCB1 C1236T, G2677T and C3435T and of ABCG2 G34A and C412A polymorphism, even if there was a trend for a worse PFS in the few patients (n=2) with 1236 allele A treated with imatinib. Conversely, we found a lower rate of optimal response at 3 (p=0.1), 6 (P=0.05) and 12 (p=0.02) months in imatinib-treated patients with TC genotype of ABCB1 T129 SNP, though the small number of patients (7) had probably and impact on statistical significance. However, TTF was shorter for ABCB1 1297C allele C patients, both receiving imatinib (P=0.05) and 2G-TKIs (P=0.07), and also PFS was significantly shorter in this cohort (P=0.003).

Summary/Conclusions: With the limits of the low expression rates of some SNPs, our data suggest a lower response in patients harboring 1297C polymorphism, at least in those receiving imatinib. Other ABCB1 and ABCG2 genotypes do not seem to impact on response to TKI treatment.

E1066

THE INTRODUCTION OF SECOND-GENERATION TYROSINE KINASE INHIBITORS MAY REDUCE THE PROGNOSTIC IMPACT OF HIGH-RISK PATIENTS ASSESSMENT TO EUROPEAN TREATMENT AND OUTCOME STUDY (EUTOS) SCORE

1Department of Hematology, Juntendo University School of Medicine, Tokyo, 2Department of Hematology and Oncology, Saitama Medical University International Medical Center, Saitama, 3Department of Hematology, Yokohama Municipal Citizen’s Hospital, Yokohama, 4Department of Hematology, Juntendo University Urayasu Hospital, Urayasu, 5Department of Hematology, Saiseikai Yokohama Nanbu Hospital, Yokohama, 6Department of Hematology and Infectious Diseases, Kumamoto University Hospital, Kumamoto, Japan

Background: The discovery of tyrosine kinase inhibitor (TKI) imatinib has revolutionized the conception of chronic myeloid leukemia (CML) as a mortal disease to a long-term controllable disease. The European Treatment and Outcome Study (EUTOS) score is a clinical tool that utilizes imatinib-based objectives to predict treatment response and progression free survival (PFS) in patients with CML in chronic phase (CP). However, it is currently unknown whether the introduction of second generation TKIs (2nd TKIs) affects prognostic score of patients with CML-CP, particularly among those considered high-risk according to EUTOS score.

Aims: Our study aims to highlight the critical role of the introduction of 2nd TKIs on patient prognosis as determined by EUTOS score.

Methods: Patients data was obtained retrospectively from patients enrolled in the CML Cooperative Study Group. Patients with CML-CP who were treated with any TKIs as first line therapy between April 2001 and January 2016 were enrolled to the study and were classified according to date of diagnosis. Those who were diagnosed with CML-CP before March 2009 were classified into the imatinib group, and those diagnosed after April 2009 were classified into the 2nd TKI group. The study was approved by the research ethics boards of each institution and was conducted in accordance with the Declaration of Helsinki.

Results: There were 308 patients newly diagnosed with CML-CP during the study period. Of these patients, 104 (34%) were assigned to the imatinib group and 204 (66%) were assigned to the 2nd TKI group. With respect to EUTOS score, 223 patients were classified as low-risk, of which 69 were in the imatinib group and 154 were in the 2nd TKI group. Forty-six patients were considered high-risk, of which 19 were in the imatinib group and 27 were in the 2nd TKI group. EUTOS score was unavailable in 39 patients. With regard to initial TKI, all patients were treated with imatinib in the imatinib group. Among patients assigned to the 2nd TKI group, 149 (73%) were initially treated with any TKI. The median follow-up period for all patients was 48 months (range: 1–185 months). Among patients in the 2nd TKI group, CML-associated death rates were significantly lower than those in the imatinib group. EUTOS high-risk patients score exhibited significantly worse outcomes in EFS, PFS, and CML-associated death compared to those considered low-risk. Most importantly, risk stratification by EUTOS score was predictive of risk-associated clinical outcomes in patients assigned to the imatinib group; however, EUTOS score failed to predict risk-associated clinical outcomes of patients assigned to the 2nd TKI group (see Figure). The EUTOS high-risk patients in the imatinib group showed worse clinical outcomes than those in the 2nd TKI group (hazard ratio [HR] 6.35, 95% confidence interval [CI] 1.79 – 22.6, p=0.0042). However, prognostic effect was less in the 2nd TKI group (HR 3.21, 95% CI 0.59 – 17.6, p=0.18).

Conclusions: Among patients assigned to the imatinib group, risk stratification by EUTOS score was predictive of clinical outcomes in that those considered high-risk experienced considerably more adverse events (EFS, PFS, or CML-associated death) than those considered low-risk. Our results support the use of 2nd TKIs in treating high-risk patients with CML-CP in order to avoid disease progression. Future large-scale studies are necessary to evaluate the clinical significance of EUTOS scoring in the accurate prediction of prognosis among patients with CML-CP treated with 2nd TKIs.

Figure 1.
CHRONIC MYELOID LEUKEMIA DIAGNOSED DURING PREGNANCY: THERAPY TACTICS AND OUTCOMES
1National Research Center for Hematology, Moscow, Russian Federation, 2Hematology, S. Eugenie Hospital, Tor Vergata University, Rome, Italy, 3Department of Hematology, Seoul St. Mary's Hospital, 4Leukemia Research Institute, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic Of, 5Hematology Department, SI “Institute of Blood Pathology and Transfusion Medicine UAMS”, Lviv, Ukraine, 6Research Institute of Hematology and Blood Transfusion MOH of Uzbekistan, Tashkent, Uzbekistan, 7Hematology Center after prof. R.H. Yeoleyan, Yerevan, Armenia, 8FSBI Scientific Center of Obstetrics, Gynecology and Perinatology of Healthcare Ministry named after V.I. Kulakov, Moscow, Russian Federation

Background: Chronic myeloid leukemia (CML) diagnosed at pregnancy is a serious challenge. Treatment by tyrosine kinase inhibitors (TKI) today is considered harmful for fetus due to possible teratogenicity. On the other hand TKI delay is dangerous for disease progression as no other options have comparable to TKI effectiveness. Pregnancy termination by abortion may be crucial for desired pregnancies as further childbirth is postponed for years until stable deep molecular response (DMR). Due to limited number of cases and ethical issues there is no consensus on how to behave in such delicate cases.

Aims: To describe pregnancy outcomes and therapy tactics for CML diagnosed at pregnancy.

Methods: Information regarding CML diagnosed at pregnancy was collected with the participation of countries participating in the observational study of European LeukemiaNet (ELN Pregnancy Registry). The data included CML clinical characteristics at diagnosis, cytogenetic and molecular parameters, information of therapy, pregnancy outcomes and data of newborns.

Table 1.

Results: Thirty one women with median age 26 years (range 20-39) were diagnosed with Ph-positive chronic phase CML during pregnancy. That was 11% of all 282 pregnancy cases. In certain countries (Russia) up to 21% of women with CML and pregnancy had the synchronistic onset of these events (table 1). Sokal low/intermediate/high and EUTOS low/high risk score was in 22/5/3 and 28/2 respectively, no data for risk score was in 1 patient. CML was diagnosed with Ph-positive chronic phase CML during pregnancy. That was 11% of other KIR3DL1 alleles. (Fisher’s exact test, p<0.001).

E1068 IMPACT OF KIR3DL1*00501 IN TYROSINE KINASE INHIBITOR-TREATED CML
1Div. Hematology, respiratory medicine and oncology, Japan, Saga University, Saga city, 2Dep. Hematology and Oncology, Kyoto University, 3HLA Foundation, Kyoto, 4Center for Comprehensive Community Medicine, Japan, Saga University, Saga city, Japan

Background: The BCR-ABL1 tyrosine kinase inhibitors (TKIs) dramatically improved long-term survival of the patients with chronic myeloid leukemia (CML). As increased NK cells during TKI therapy positively correlate with better outcome, antitumor immunity by NK cells may contribute to the effects of TKIs. However, the response to TKIs depends on each case, and the determinants of it remain to be elucidated.

Aims: Given that NK cell function is regulated depending on the interaction between killer immunoglobulin-like receptor (KIR) and human leukocyte antigen (HLA) class I molecules, we hypothesized that polymorphisms of KIR and HLA play important roles in the responses to TKIs. Then we performed allele genotyping of KIR and HLA with deep sequencing in CML patients, and here report our findings.

Methods: KIR and HLA high resolution typing were performed on peripheral blood DNA from 76 CML patients in chronic phase (CML-CP) using Scisco Genetics typing kit (Scisco Genetics Inc., Seattle WA) and MiSeq as platform by NGS. Therapeutic effects of TKIs were evaluated based on bcr-abl mRNA levels measured by real-time quantitative (RQ)-PCR compensated according to international scale (IS) and/or transcription mediated amplification (TMA) method. Major molecular response (MMR) was defined as 3-log reduction (MR3) in RQ-PCR (IS) or BCR-ABL transcript level of less than 50 copy/0.5 µg RNA in TMA method. We also defined DMR as 4-log reduction (MR4) in RQ-PCR (IS), which is similar to undetectable of BCR-ABL transcript level in TMA method.

Results: Second generation TKIs as first-line therapy (n=46) and female (n=29) sex were strongly associated with superior DMR at the 2-year of therapy (second generation TKIs as first-line therapy, HR 7.305, 95% CI, 3.377 to 15.803; p<0.001; female sex, HR, 1.709, 95% CI, 1.028 to 2.842; p=0.039). After adjustment with these two factors, several KIR alleles positively correlates with superior DMR at the 2-year of therapy; KIR2DL4*008 or 011/00501, and 2DS4*00301 or 007/010 or 015 than 2DL4*007/008 or 009/010 (HR 1.973, 95% CI, 1.310 to 3.000, p=0.001); KIR2DS4*00301 or 007/010 or 015 (HR 2.811, 95% CI, 1.658 to 4.968, p<0.001; female sex, HR, 1.709, 95% CI, 1.028 to 2.842; p=0.039). After adjustment with these two factors, several KIR alleles positively correlates with superior DMR at the 2-year of therapy; KIR2DL4*008 or 011/00501, and 2DS4*00301 or 007/010 or 015 than other KIR3DL1 alleles. (Fisher’s exact test, p<0.001).

Summary/Conclusions: KIR3DL1*00501 and several KIR2DL4 and 2DS4 alleles positively correlate with better therapeutic effects of TKIs, and they may form the same KIR haplotype. Our data indicate that these KIR alleles represent strong anti-CML immunity by NK cells, and consequently may associate with long-term outcome and treatment-free remission in CML.

E1069 COMPARISON OF MOLECULAR KINETICS AFTER THE FIRST AND SECOND IMATINIB DISCONTINUATION: RESULTS FROM THE KID STUDY
1Seoul St. Mary’s Hospital, The Catholic University of Korea, 2Leukemia Research Institute, The Catholic University of Korea, Seoul, 3Ajou University School of Medicine, Suwon, 4Chonnam National University Hospital, Hwasun, 5Hanyang University College of Medicine, Anyang, 6Kangbuk Samsung Hospital, School of Medicine, Sungkyunkwan University, Seoul, 7Ulsan University Hospital, University Health
Background: Recent reports have demonstrated that tyrosine kinase inhibitors (TKIs) discontinuation can be employed in chronic phase chronic myeloid leukemia (CP CML) patients with sustained deep molecular responses after enough TKI therapy. Consequently, treatment-free remission (TFR) has become a new therapeutic goal. Although 50-70% of patients experienced molecular relapse by several imatinib (IM) discontinuation studies, the most of patients resumed molecular responses (MR) following restart of IM. Aims: To evaluate the second IM discontinuation (Korean imatinib Discontinuation Study; KID Study), we have explored molecular kinetics after the first IM discontinuation and after IM resumption for molecular relapse. In patients regaining durable UMRD with IM resumption, we tried second IM discontinuation and compared molecular kinetics between the first IM stop and second IM stop.

Methods: CP CML patients who were treated with IM for more than 3 years and had undetectable levels of BCR-ABL1 transcripts determined by quantitative reverse transcriptase-polymerase chain reaction (PCR) for at least 2 years were eligible for Kid Study and in cases of MMR loss after 2 consecutive assessments, IM treatment was re-introduced. After IM resumption for MMR loss, IM treatment was re-introduced. The patients who lost UMRD until IM resumption were included with a median time of 45 years (range, 25-59 years) entered into a second IM discontinuation after maintaining UMRD at least 2 years. Prior to first discontinuation, the median duration of IM therapy was 68.9 months (range, 38.5-115.1 months) and the duration of sustained UMRD was 32.9 months (range, 24.8-64.5 months. After first attempt of IM discontinuation, they relapsed after a median duration of 3.7 months (range, 1.5-11 months) and second IM discontinuation was attempted after maintaining UMRD for 6.7 months (range, 3.3-13.6 months) after IM resumption. After sustaining a second UMRD for a median of 25.5 months, IM therapy discontinued for a second time. After a median follow-up of 8.8 months (range, 0.3-38.1 months) after second IM discontinuation, 10/12 patients (83%) and 8/12 patients (67%) lost UMRD and MMR, respectively. Among two consecutive studies (korean imatinib Discontinuation Study; KID Study), MMR loss was similar to those of the first discontinuation. But the molecular kinetics after MMR loss, except one patient, were retreated with IM for 9.4 months and another patient have shown gradually increasing BCR-ABL1 transcripts under the level of 0.1% on IS. Eight patients who experienced second relapse (MMR loss) after a median 2.9 months (range, 1.9-30.7 months). The patients who lost MMR, except one patient, were retreated with IM for a median of 7.1 months (range, 0.8-24.8 months); five patients re-achieved MMR at a median of 1.8 months (range, 1.0-10.2 months) and one re-achieved UMRD at 5.5 months.

Summary/Conclusions: Though the Korean multicenter prospective study (Korean Imatinib Discontinuation Study) exploring second imatinib discontinuation is limited, our data demonstrated that a second attempt might be possible and the median time to MMR loss after second discontinuation was similar to those of the first discontinuation. But the molecular kinetics after second ISM loss needs longer follow-up with more patients. Further studies on the predictors to select patients for a trial of second TFR and novel strategies such as intermittent therapy will be warranted.

E1071

HYDROXYUREA SUPPRESSES BCR-ABL1 T315I+ CML CLONES IN VIVO AND IN VITRO AND SYNERGIRES WITH PONATINIB IN ELIMINATING TKI-RESISTANT CML CELLS

M. Schneeweiss1,2,*, K. Byrgazov3, S. Preuner3, S. Herndlhofer1,2, W.R. Sperr1,2, G. Hoermann4, M. Deininger5, T. Lion1, P. Valentin1,2, K.V. Gleichner1,2,1

1Ludwig Boltzmann Cluster Oncology, 2Department of Internal Medicine I/Division of Hematology and Hemostaseology, Medical University of Vienna, 3Children’s Cancer Research Institute (CRI), 4Department of Laboratory Medicine, University of Vienna, Vienna, Austria, 5Department of Internal Medicine/Division of Hematology and Hemoragic Malignancies, University of Salzburg, Salt Lake City, United States

Background: In chronic myeloid leukemia (CML), BCR-ABL1 T315I leads to resistance against most BCR-ABL1 tyrosine kinase inhibitors (TKIs). Long-term therapy with ponatinib, which suppresses BCR-ABL1 T315I, is problematic due to occurrence of compound mutations in BCR-ABL1. Therefore, alternative therapies have to be considered. Hydroxyurea (HU) has been used for (palliative) treatment of CML over decades. However, the effects of HU on TKI-resistant sub-clones have not been examined so far.

Aims: The aim of this study was to evaluate the effects of HU on CML subclones carrying BCR-ABL1 T315I mutations (isolated or in compound-configuration) in vitro and in vivo and to explore cooperative effects between HU and ponatinib.

Methods: Four BCR-ABL1 T315I+ CML patients were treated with HU (1-3 g/day) for 2 to 18 months. White blood counts (WBC), differential counts, and BCR-ABL1 transcript levels were reported. The BCR-ABL1 T315I+ BCR-ABL1 ratio was determined by mutation-specific, ligation-dependent, PCR and next generation sequencing. In vitro, cells were cultured. In vivo, patients were randomized 1:1:1 to radotinib 300mg bid (n=79), radotinib 400mg bid (n=81), or imatinib 400mg once daily (qd) (n=81). 157 patients with available 3 months qRT-PCR on study therapy (radotinib 300mg bid (n=79), and imatinib 400mg qd (n=78)) were evaluated. And, total of 151 patients who received radotinib 300mg bid group were significanlly higher MMR and MR 4.5 compared with the patients who were not MMR and MR 4.5 by 24 months: 73.5% and 38.2% in the radotinib 300mg bid group and 63.6% and 29.1% in the imatinib group, respectively. At 6 months, 73.4% of patients in the radotinib 300mg and 53.1% patients in imatinib group (P=0.0246) achieved 6 months EMR. The patients who had EMR at 6 months in radotinib 300mg bid group were significantly higher EMR, longer follow-up are needed.

Summary/Conclusions: With minimum 24 months follow-up, early responses at 3 months or 6 months can predict better outcomes in newly diagnosed chronic myeloid leukemia patients treated with radotinib or imatinib. But, to evaluate the significant long-term prognostic value such as overall survival and progression-free survival by EMR, longer follow-up are needed.
HU+ponatinib for 72 hours, and the percentage of viable cells in each subclone was analyzed by flow cytometry.

**Results:** HU treatment resulted in WBC stabilization in 3 of 4 patients, but failed to induce a molecular response. However, surprisingly, the percentage of *BCR-ABL* diminished significantly in all patients during HU treatment and was no longer detectable in 3 of 4 cases. Stem cell transplantation could be performed in 2 patients after 2-3 months. In one patient, stable disease over 18 months was obtained with HU-therapy. In one patient, the disease progressed rapidly despite temporary suppression of *BCR-ABL* 1315. In in vitro studies, HU was found to block the growth in all cell lines tested and in all primary cell samples (n=7) examined, with IC50 values ranging between 50 and 250 µM. Interestingly, cell lines exhibiting mutant *BCR-ABL* were more sensitive against HU than cell lines expressing *BCR-ABL* WT. HU and ponatinib were found to synergize in inhibiting growth of all cell lines tested, including cell lines expressing *BCR-ABL* 1315 or T315I including compound mutations. Cooperative drug effects were also confirmed in primary CML cells (n=4). In cell line experiments, ponatinib was found to suppress Ba/F3p210*WT* cells but not Ba/F3p210*1315F* or Ba/F3p210*T315I* cells whereas HU was found to exert stronger effects on cells expressing mutant *BCR-ABL* 1. The drug combination resulted in complete suppression of all sub-clones.

**Summary/Conclusions:** Our data show that HU exerts strong, sub-clone specific, additive effects on TKI-resistant cells. HU+ponatinib produce synergistic growth-inhibitory effects on TKI resistant CML cells. Clinical studies are now warranted to define the exact value of the drug combination ponatinib+HU in TKI resistant CML.

**ASSOCIATION OF BCL2L11 (BIM) DELETION POLYMORPHISM WITH MOLECULAR RELAPSE AFTER TYROSINE KINASE INHIBITOR CESSION IN CHRONIC MYELOID LEUKAEMIA PATIENTS WITH DEEP MOLECULAR RESPONSE**

S. Katagiri1, T. Tauchi1, Y. Tanaka1, K. Ando1, S. Okabe1, M. Gotoh1, Y. Ito1, T. Umezu1, K. Tadokoro3, J.H. Ohyashiki2, K. Ohyashiki1

1Department of Hematology, 2Department of Molecular Oncology, Institute of Medical Science, Tokyo Medical University, Tokyo, 3BML, INC, Saitama, Japan

**Background:** The inhibition of *BCR-ABL* kinase with tyrosine kinase inhibitors (TKIs) has markedly improved the prognosis of chronic myeloid leukemia (CML). Recently, it has been recognized that some CML patients with deep molecular response (DMR) can maintain treatment-free remission (TFR) after TKI cessation. However, no predictive prognostic factor for successful treatment cessation has yet been identified. BCL2L11 (BIM) deletion polymorphism (intron 2) has been reported to be associated with an inferior response to TKI (Ng et al. Nature Medicine, 2012). We have previously reported that CML cell lines with BIM deletion polymorphism may predict relapse after TKI discontinuation (Katagiri et al. Br J Haematol, 2013).

**Aims:** To further clarify the role of predictive biomarkers in molecular relapse after TKI cessation, we performed a long-term follow-up of CML patients with DMR after TKI cessation.

**Methods:** With patients receiving TKI treatment were included. Molecular relapse was defined as a loss of the major molecular response (MMR). The genomic DNA of patients was obtained from their whole blood samples using the EZ1 DNA Blood 350 kit (Qiagen, Valencia, USA). Deletion polymorphism was detected by Q-Invader assay using primers designed to detect a deletion site (5’-GCTTATGGATGCGCTCTT-3’) (Ohyashiki et al. J Hematol Transfus, 2014).

**Results:** Forty-six CML patients (29 men;17 women; median age, 58.5 years) were included in this study (Sokal category; low: 32; intermediate: 10; and high: 2). Thirty-three patients discontinued imatinib, five discontinued nilotinib, and eight discontinued dasatinib. Ten patients were treated with IFNα before TKI treatment. The median duration from TKI initiation to cessation was 85.0 (range: 22–177) months; the median duration of DMR before TKI cessation was 43.0 (range: 5–131) months. Treatment-free remission was estimated to be 66.5% at 12 months, 61.5% at 24 months, and 58.5% at 36 months. Thirty-six CML patients were analyzed for the presence of BIM deletion polymorphism in six cell lines or cell-line derived RNA studies for both the b3a2 and b2a2 transcripts. Furthermore, the clinical sensitivity study was conducted using blood from twelve low *BCR-ABL* transcripts level CML patients on TKI therapy, who had achieved and maintained MMR (Major Molecular Response) [0.1% (IS)] with reporting below 0.05% (IS).

**Results:** Consistent results were observed in the both the diluted patient blood and spike-in CML cell lines or cell-line derived RNA studies for both the b3a2 and b2a2 transcripts, demonstrating an assay LoD of MR4.5 and below with a less than 2-fold difference at the LoD levels. With the clinical sensitivity study, eleven out of twelve low CML subjects were detected in at least 19 out of 20 replicates tested per subject over a range of 0.038% (IS) (SD=0.17 Log) to 0.0011% (IS) (SD=0.4 Log). The overall ABL copy number present in clinical samples in each study was at least 5-10 times the required minimal ABL copy number of 32,000 to support a claim of MR4.5 and ≥100,000 for MR5.0.

**Summary/Conclusions:** These LoD evaluations demonstrate that the Xpert® BCR-ABL Ultra assay complies with the international guidelines for assay sensitivity achieving MR4.5 with 5-10 times more than the required ABL copies to confidently identify candidate patients that may benefit from the discontinuation of TKI therapy.

**XPERT® BCR-ABL ULTRA, A HIGH SENSITIVITY ASSAY WITH A LIMIT OF DETECTION REACHING MR4.5 AND BELOW ON AN INTERNATIONAL REPORTING SCALE**

C. Ferrand1, M. Deschamps1, A. Levitas2, C. Lockwood3, J. Payton4, G. Uyl4

1EFS BFC, Inserm UMR1398, University hospital Besançon., University Franche Comte, Besancon, France, 2Oncology, R&D, Cepheid, Sunnyvale, 3Department of Laboratory Medicine, University of Washington, Seattle, 4School of Medicine, Washington University, Saint Louis, 5Karmanos Cancer Institute, Wayne State University, Detroit, 6Department of Laboratory Medicine and Department of Internal Medicine, The Ohio State University, Columbus, 1Data Management and Analytics, 11Medical and Scientific Affairs and Strategy, Cepheid, Sunnyvale, United States

**Background:** The ability to consistently detect low levels of *BCR-ABL* transcripts in patients with chronic myeloid leukemia (CML) is important in the assessment of treatment outcomes in patients on tyrosine kinase inhibitor (TKI) therapy. Particularly, *BCR-ABL* assays that are sensitive in the measurement of deep level response may aid in the identification of potential candidates for treatment discontinuation. Xpert® BCR-ABL Ultra detects the most common *BCR-ABL* transcripts below MR4.5 (Molecular Response at 4.5-log reduction) or 0.0032%, which is widely accepted as the clinical threshold that defines candidates who can safely discontinue TKI therapy.

**Aims:** The present studies were designed to verify the limit of detection (LoD) for Xpert® BCR-ABL Ultra assay below MR4.5 on the International Scale (IS) in clinical samples for both the b3a2 and b2a2 transcripts.

**Methods:** To overcome the challenge of testing numerous replicates requiring large volumes of patient samples, serial dilutions ranging from BCR-ABL/ABL levels of 10% to <0.001% (IS) were prepared as contrived samples using CML samples with initial BCR-ABL level >10% (IS) and pooled blood from CML negative patients, ranged from 10% to <0.001% (IS). Twenty-one replicates of each dilution were measured for%BCR-ABL/ABL (IS). Determination of the LoD was performed by the statistical analysis to identify the lowest concentration of%BCR-ABL/ABL (IS) per test that can be reproducibly distinguished from negative samples with 95% confidence. The acceptable precision for%BCR-ABL/ABL (IS) is defined as the ability to detect at least a 3-fold difference for all concentrations tested.

In addition, analytical LoD studies were performed using spike-in CML cell lines and cell-line derived RNAs, carrying either b3a2 or b2a2 transcripts. Furthermore, the clinical sensitivity study was conducted using blood from twelve low *BCR-ABL* transcripts level CML patients on TKI therapy, who had achieved and maintained MMR (Major Molecular Response) [0.1% (IS)] with reporting below 0.05% (IS).

**Results:** Consistent results were observed in the both the diluted patient blood and spike-in CML cell lines or cell-line derived RNA studies for both the b3a2 and b2a2 transcripts, demonstrating an assay LoD of MR4.5 and below with a less than 2-fold difference at the LoD levels. With the clinical sensitivity study, eleven out of twelve low CML subjects were detected in at least 19 out of 20 replicates tested per subject over a range of 0.038% (IS) (SD=0.17 Log) to 0.0011% (IS) (SD=0.4 Log). The overall ABL copy number present in clinical samples in each study was at least 5-10 times the required minimal ABL copy number of 32,000 to support a claim of MR4.5 and ≥100,000 for MR5.0.

**Summary/Conclusions:** These LoD evaluations demonstrate that the Xpert® BCR-ABL Ultra assay complies with the international guidelines for assay sensitivity achieving MR4.5 with 5-10 times more than the required ABL copies to confidently identify candidate patients that may benefit from the discontinuation of TKI therapy.

IDENTIFICATION OF INCIDENTS CASES OF GAUCHER DISEASE IN SPLENOMEGALY AND/OR THROMBOCYTOPENIA PATIENTS IN SPECIALIZED MEDICAL SERVICES IN COLOMBIA THROUGH THE USE OF A SELECTION ALGORITHM

Methods: Multicenter, descriptive study, in active recruitment process with non-probabilistic sampling by convenience. Currently, the study has 51 specialized medical centers in Hematology, Pediatrics and Internal Medicine in Colombia, approved by Ethics Committee (EC). The study has an expected duration of 24 months since EC approval for each center. Eligible subjects are those with three documented criteria: thrombocytopenia <150,000/cc plus anemia (hemoglobin <11 g/dl in men and <11 g/dl in women) plus/or bone pain plus/or Monoclonal Gammapathy of Unknown Significance plus/or Polyclonal Gammapathy in subjects aged 30 years and older; and/or splenomegaly defined as palpable spleen ≥1 cm below the costal rib or diagnosed by imaging, and/or Splenectomy by splenomegaly with no known cause. Subjects with prior diagnosis of GD, splenomegaly due to portal hypertension, hematologic malignancy, or with other congenital anemia and thalassemia were excluded. Informed consent was obtained for all included subjects. Clinical information was collected from their medical history. The enzymatic activity of the β-glucocerebrosidase was performed in peripheral blood, using dried blood spots (DBS) and/or leukocytes. In subjects with reduced enzymatic activity in DBS, confirmation with bone marrow aspirate was performed. Both enzymatic activity in leucocytes was determined. GBA1 gene was analyzed.

Results: Since Feb/14 to Nov/16, 400 subjects have been included (51.3% men) with a median age of 28.79 years (range, 0.01 to 91.87). Reduced enzymatic activity of β-glucocerebrosidase was identified in 14 subjects (50% women) with a median age of 12.68 years (range, 0.3 to 74.85). All subjects were non-Ashkenazi origin, with 82.8% thrombocytopenia, 49.5% splenomegaly and/or thrombocytopenia referred to Hematology, Pediatric Hematology, Pediatrics and Internal Medicine, using a selection algorithm for the generation of diagnostic algorithms to support medical specialties in Latin America particularly intended for specialists (Mistry, 2010). Straightforward implementation of diagnostic algorithms to support medical specialties in Latin America for early diagnostic testing of GD is required.

Summary/Conclusions: This study suggests that selection algorithm could be implemented in Colombia, supporting specialists in making decisions on diagnosis of Gaucher Disease. Further characterization of the population is ongoing.

Acknowledgements: This study was funded by Sanofi Genzyme Colombia and coordinated by Caimed Colombia.

IMPACT OF PEROXIREDOXIN 2, GLUTATHIONE PEROXIDASE AND CATALASE INHIBITION ON OXIDATIVE STRESS MODIFICATIONS OF RED BLOOD CELL MEMBRANE AND CYTOSOL

Background: In oxidative stress conditions, the interplay between catalase (CAT), glutathione peroxidase (GPx), and glutathione antioxidant enzymes is key for the maintenance of the red blood cell (RBC) oxidative stress defense. Peroxiredoxin2 (Prx2) has been shown to act as a specific Prx2 inhibitor. The aim of this study was to assess the ability of Prx2 in the inhibition of CAT, GPx, or a mixture of these enzymes in with or without secondary peroxidase inhibition.

Methods: We performed in vitro assays (n=3) with RBCs from healthy volunteers, inhibiting Prx2, GPx and CAT, either individually, two-by-two or all three; conodin A, mercaptosuccinic acid and sodium azide were used as specific inhibitors of Prx2, GPx and CAT, respectively. Since the RBC membrane is a major target of ROS, we evaluated membrane lipoperoxidation (LPO) and membrane bound haemoglobin (MBH), as well as, cytosol’s total antioxidant status (TAS), by spectrophotometric methods.

Results: Concerning TAS we found a trend towards decreasing values with enzyme inhibition (one or more); the lowest value of TAS was observed when all three enzymes were inhibited and, when only two enzymes were inhibited, the lower values were obtained for pairs that included CAT inhibition; when only one enzyme was inhibited, GPx inhibition showed the lowest LPO and membrane bound haemoglobin (MBH), as well as, cytosol’s total antioxidant status (TAS), by spectrophotometric methods.

Summary/Conclusions: In conclusion, inhibition of these antioxidant enzymes, either alone or simultaneously, leads to oxidative stress modifications within the RBC, as showed by the increase in MBH and membrane LPO, and by the decrease in cytosolic TAS. Moreover, the inhibition of CAT or GPx (either alone or with other enzymes) presented more impact on oxidative modifications than Prx2 inhibition. Our data strengthens the importance of these enzymes in RBC’s...
MOLeULAR BASIS OF PKLR MUTATIONS IN PATIENTS WITH PYRUVATE KINASE (PK) DEFICIENCY: THE FIRST REPORT FROM SOUTHEAST ASIAN POPULATION

S. Rioujueang1, K. Tachavanchi2, S. Ekawattanakit3, V.S. Tanphaichitr2, H. Kanno4, V. Virapaksit5
1Siriraj-Thalassemia Center; 2Department of Pediatrics, 3Department of Medicine, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand, 4Department of Transfusion Medicine and Cell Processing, Tokyo Women’s Medical University, Tokyo, Japan, 5Department of Pediatrics, of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand

Background: Recently we have identified a new form of transfusion dependent hemolytic anemia due to KLF1 mutations causing a trans-acting deactivation of pyruvate kinase genes (PKLR). Mutations of PKLR per se can affect red blood cells metabolism and cause a wide range of clinical manifestation from fetal anemia leading to hydropic fetus, severe neonatal jaundice requiring multiple exchange blood transfusions, chronic to fully compensated hemolytic anemia. Understanding of the molecular basis of pyruvate kinase deficiency (PK def.) might be useful to predict clinical phenotypes and suggest appropriate clinical management of future patients. Moreover, an interaction of PKLR and KLF1 mutations in such patient has not been explored.

Aims: This study aim to identify the mutation of patients with PK def. for the first time in Southeast Asian populations.

Methods: Seven unrelated patients; 6 from Thailand and 1 from Indonesia have been enrolled after inform consent. We have measured the PK activity of all patients and their parents and siblings using a standard biochemical technique as we have described earlier. A complete genomic analysis of all PKLR’s exons (NM_002986.5) including exon-intron boundaries were selectively amplified and followed by direct Sanger sequencing.

Table 1.

Results: Seven index PK def. patients as confirmed by enzyme activities, age range 9-35 yrs old, were identified (Table 1). Three patients presented with severe hemolytic anemia and required regular blood transfusion; every 3-4 weeks in two (PK-1 and PK-3) and every 10-12 weeks (PK-2) in which one patient (PK-1) has been successfully treated with bone marrow transplantation and became transfusion-free. Three patients (PK-5, 6 and 8) had moderately severe hemolytic anemia and required blood transfusion occasionally. Only one patient (PK-7) from Indonesia had well-compensated anemia and never required blood transfusion. All but one had PK activities lower than 50% of normal range but these activities did not correlate with clinical severity. We found 11 different mutations in 5 compound heterozygotes and 1 homozygote as shown in Table 1. Four mutations appeared to be novel as they were not been reported in any public databases (c.1269+3A>G; c.353A>G=p.N118S; c.865C>T=p.R289W; c.1618G>T=p.G540X). One mutation (c.941T>C=p.I314T) seemed to be recurrent since it was found in two families; one homozygous and one compound with N118S. Beside nucleotide mutations, we found a 5006 bp deletion from intron 3 to exon 10 affecting PKLR gene. To detect these mutations in family members and further cases, we developed a long range GAP-PCR analysis to amplify the breakpoint fragment and directly sequenced to determine deletion extends and also ARMS-PCR (C.1641T>TA, PCR-RFLP (c.941T>C), mismatched PCR-RFLP for c.1403C>G, c.1463G>A and IVS9(+3)A>G). Interestingly, one index patient (PK-4) was found with only one known missense mutation (R488Q), however we could not find any mutation in KLF1 of this patient suggesting that she might have other unidentified cis mutation involved gene regulation of PKLR. Due to a limited number of patients, there was no clear genotype-phenotype correlation found in our studied population.

Summary/Conclusions: Seven confirmed cases of PK def. are reported here-in. They showed a wide variation of clinical severity. Molecular basis of PKLR mutations was proven to be beneficial to provide a definitive diagnosis of PK def. and might help suggesting clinical presentation in future cases.

PRELIMINARY RESULTS OF GAU-PED STUDY: PREVALENCE OF GAUCHER DISEASE IN PAEDIATRIC PATIENTS SELECTED BY AN APPROPRIATE DIAGNOSTIC ALGORITHM

W. Morelli1, M. Filocamo2, M. Stroppiano2, M. Di Rocco3, F. Fedeli2, G. Russo2, D. Sperti4, F. Furlan5, A. Pession1

O. “Annunziata”, Cosenza, 7Pediatric Department, Fondazione IRCCS Ca’Granda Ospedale Maggiore Policlinico, Milano, Italy

Background: Gaucher disease (GD) is an autosomal recessive lysosomal storage disease characterized by the deficient activity of beta-glucocerebrosidase (GBA). GBA deficiency results in the accumulation of glucosylceramide in different organs, causing tissue damage. Typical GD features are splenomegaly, peripheral blood cytopenias (mostly thrombocytopenia and/or anemia), growth retardation, bone involvement, gammapathies, increased risk of malignancies and, in some patients, neurological manifestations. Since symptoms are non-specific, the diagnosis can be delayed for years or missed. Enzyme replacement therapy (ERT) with recombinant β-glucocerebrosidase is safe and effective in preventing and/or reversing many clinical manifestations. However, if the diagnosis is delayed for years, major complications cannot be reversed. A useful screening method for GD is based on measuring enzyme activity on a Dried Blood Spot (DBS), while the gold standard test is still considered GBA activity in cellular homogenates. A pediatric algorithm has been proposed to promote timely diagnosis and early access to ERT (figure 1).

Aims: Since pediatric patients with splenomegaly and cytopenias are usually referred to pediatric hematologists, we have designed the GAU-PED study to consider GBA activity in cellular homogenates. A pediatric algorithm has been proposed to promote timely diagnosis and early access to ERT (figure 1).

Figure 1.

Aims: Since pediatric patients with splenomegaly and cytopenias are usually referred to pediatric hematologists, we have designed the GAU-PED study to
evaluate the prevalence of GD among children referred to the haematology paediatric units and selected according to the above mentioned diagnostic algorithm. Here, we report a preliminary analysis of GAU-PED trial.

Methods: The GAU-PED study involves 53 centers in the context of the AIEOP Study Group, the Italian clinical research consortium in paediatric haematology and oncology. Patients referring to the pediatric hematology and oncology units for a referral diagnosis of haemolytic anaemia (thrombocytopaenia, haemolytic anaemia and/or anaemia), where other causes of splenomegaly have been excluded, are tested for GBA activity though a DBS sample. Only patients with DBS showing a GBA activity below normal values are recalled to confirm GBA enzyme deficiency using the gold standard GBA analysis in cell omogenate. For every tested patient, detailed clinical information are also collected.

Results: After parental consent, a total of 25 DBS have been collected from 11 centers, in the first 12 months of study accrual. DBS values under 4.4 pmol/punch-7/h-1 were found in 9/25 patients (36%). These patients have been recalled for the conventional enzymatic test. The diagnosis of GD has been confirmed in 5/9 patients (55%), with a prevalence of GD of 20% (95% CI: 8.6-39.1%) equal to 5/25 patients in the tested population. In all 5 patients the genetic analysis has been consistent with GD. Three patients were males and 2 females. The mean age at diagnosis was 8 years (range 2-13 years). The median time from the initial clinical presentation and diagnosis has been 12 months (range 6-50 months), while the mean time between the DDS test and the diagnosis has been 2 months. ERT has been started in all GD patients.

Summary/Conclusions: Our preliminary results support the use of DBS as screening test for GD in a selected population of children with splenomegaly and/or thrombocytopaenia considered at increased risk for the disease. The use of a GAU-PED diagnostic algorithm is useful to increase awareness of GD among pediatric hematologists and to shorten the time to diagnosis. Taking into consideration the long life expectancy of pediatric GD patients, the early diagnosis will have a strong impact on health and quality of life.

1UOC Oncemologia, Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, 2UOC Ematologia non tumorale e Coagulopatie, 3UOC Laboratorio Centrale di Anemia Chimica Cliniche e Microbiologiche Dipartimento dei Servizi, Servizio di Citofluorimetria, Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, 4Università degli Studi, Milano, Italy

Background: MPs play an important role in several biological processes. Elevated levels of circulating MPs have been described in several haemolytic diseases and other clinical conditions. MPs are tested for GBA activity though a DBS sample. Only patients with DBS show positive结果s.

Methods: To evaluate platelet MPs (PMP), tissue factor expressing MPs (TFMPs), endothelial MPs (EMPs) and microparticles expressing single antigens (CD41, CD144) levels in other haemolytic anemias, as HERV-s pherocytosis (HS), elliptocytosis (HE), stomatocytosis (HSt), red cell enzymatic defects, congenital dyserythropoietic anaemia (CDA), autoimmune haemolytic anaemia (AIHA), and paroxysmal nocturnal haemoglobinuria (PNH). The number of MPs here investigated were correlated with Hb levels (p<0.05), and PMPs positively correlated with Hb (p<0.05). Finally, the number of annexin V APC was increased in PKD compared with controls (p=0.023), and positively correlated with disease duration (r=0.999, p<0.001). PMPs and TF-MPs were elevated too, although not significantly. The number of MPs here investigated were comparable between splenectomized and not splenectomized, and between naive and treated patients.

Table 1.

Summary/Conclusions: These preliminary results suggest that MPS levels are abnormal in both congenital and acquired haemolytic conditions. MPs levels correlate with the degree of anaemia and haemolysis and with the duration of disease.
PIEZ01 MECHANOTRANSDUCTIVE PROTEIN MUTATIONS IN RBCS: WHEN THE PHENOTYPE IS BEYOND HYEMOLYTIC ANAEMIA

D. Motuš 1,2, S. Marin 1, T. Nascimento 3, P. Bernardo 3, L. Relvas 1, A. Oliveira 1, E. Guinhal 1, J. Ribeiro 1, C. Bento 1, T. Magalhães-Maia 1, M. L. Ribeiro 1,1 
1Servicio de Hematologia Clínica, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

Background: Piezo proteins are integral membrane proteins with many transmembrane domains broadly expressed, including erythrocytes (RBCs). PIEZ01 proteins play an important role as an osmoreceptor, maintaining RBCs ionic homeostasis, functioning as a mechanically activated cation channels. Mutated PIEZ01 proteins have been linked to hereditary xerocytosis (HX), which is characterized by RBCs dehydration with mild to moderate compensated haemolytic anaemia and iron overload. As these clinical features are present in many different clinical conditions, the diagnosis always needs a high level of suspicion. Nowadays, besides peripheral blood smear (PBS) observation, molecular analysis, searching for mutations in PIEZ01 gene, became a tool in the diagnosis of HX.

Aims: Describe 26 patients with HX associated with PIEZ01 mutations belonging to 13 unrelated families, raising awareness of the highly variable phenotype of this patients, and the need of a high grade of suspicion along with the morphologic evaluation of the PBS.

Methods: Collection of clinical and laboratory data on our 26 patients with HX and hyperferritinaemia due to 10 different identified mutations in PIEZ01. Sanger sequencing was used to identify mutations affecting PIEZ01, encoded by FAM38A gene, and to confirm transmission according to the presence of disease phenotype. In all were included other known causes of hyperferritinaemia (HF) and haemolytic anaemia.

Results: Of the patients identified having PIEZ01 mutations, 13 were probands and 13 were identified by family studies. Median age at diagnosis was 43 years (1-80), with female predominance (n=14; 53.9%). 4/13 probands had family history of HX (n=1) or HF (n=2). The common feature of our entire cohort of patients was the presence of xerocytoses in PBS. 13/26 patients had reticulocytes counts of one or less (normal <10%), 16/26 patients had Hb with a mean value of ferritin of 556ng/mL (161-617) and 9/26 had both. Of the 26 patients, four had splenomegaly and six gallbladder lysisis (5/6 cholecystectomized), two of them have both. Only 5 patients presented with anaemia (Hb <12g/dL), 2 macrocytic and 3 normocytic. One patient that presented with anaemia also has abnormal spherocytosis carrier. We are detecting heterozygous missense mutations in all 26 patients.

Summary/Conclusions: HX is a dominant disorder of RBCs dehydration presenting a great phenotypic variability. As shown in our cohort of patients, the anaemia may not be the main feature, in fact, the presence of xerocytoses in PBS and HF were the most frequent characteristics of our patients. We would like to emphasise that in the genomics era the identification of xerocytoses in the PBS keeps playing an important role for this diagnostic. Not only because, unlike other haemolytic anaemias, in HX there is a contraindication to splenectomy and shortened red cell survival. Clinically, most patients present a totally compensated hemolysis, with a normal hemoglobin level contrasting with a high reticulocytosis. In most cases, HX is caused by missense mutations activating Piezo1, a mechanosensitive ion channel. However, the pathophysiology of this compensated hemolysis remains largely unclear.

Aims: We studied the hemoglobin oxygen affinity parameters in HX patients and in hereditary spherocytosis (HS) subjects as controls.

Methods: Fourteen patients from 5 described and 4 unreported families with a HX diagnosis and 15 HS subjects were included. Diagnosis was based on the presence of xerocytosis in PBS and increased haemoglobin affinity for oxygen and a high reticulocytosis. We studied the hemoglobin oxygen affinity parameters in HX patients.

Results: All the 14 HX patients carried one or two missense mutations in PIEZ01, no gene variation was identified in KCNN4 or FAM38A. Five families (9 subjects) have already been reported, with identified mutations in exons 18, 21, 42 or 51. Five subjects from 4 new families carried new mutations in exons 14, 16 and 21, 14 of which bioinformatic softwares showed a high likelihood of pathogenicity. For all HX patients, p50 values were under the normal range (mean 21.1, range 19.7-23.4, normal range 25-29 mmHg), contrasting with HS patients for whom p50 was found to be in the normal range (mean 26.1, range 24.6-28.8 mmHg). This indicated a significant increase in the hemoglobin affinity for oxygen restricted to PIEZ01 mutated HX. Of note, p50 was not correlated with the Hb level (mean 139, range 112-180 g/L in HX patients versus 125, range 93-142 g/L in HS patients). Intracellular red cell 2.3 DPG level could be measured in 7 HX patients from 4 families, it was found decreased in all of them (0.43+/-0.06, normal 0.9+/-0.19), providing a pathophysiological basis for the increased hemoglobin affinity we observed. In particular, we observed a significant increase in the hemoglobin affinity for oxygen restricted to PIEZ01 mutated HX.

Summary/Conclusions: The increased hemoglobin affinity for oxygen observed in HX patients reflects the decrease in the 2.3 DPG level. This may be a consequence of a high ATP requirement and an increased glycolytic activity in HX red cells at the expense of the 2.3DPG shunt in order to maintain the cell ion homeostasis. High hemoglobin affinity for oxygen may induce a relative tissue hypoxia and consequently a high reticulocytosis, providing a clue to explain the compensated hemolysis frequently observed. However, the links between PIEZ01 mutations, red cell enzymatic activity and erythropoiesis need to be clarified and a proteomic and a metabolomic approach is under investigation. Of interest is the clinical point of view, HX diagnosis is sometimes difficult and this low p50 value, easily measured on venous blood, represents a useful new diagnosis tool for HX.
Gene therapy, cellular immunotherapy and vaccination

E1083 SAFETY AND EFFICACY OF MULTI-PATHOGEN-SPECIFIC T CELLS IN A HUMANIZED MODEL OF INVASIVE ASPERGILLOSIS: A PROOF OF CONCEPT STUDY
A. Papadopoulos1, K. Koukoulia2, M. Alvanou1, E. Athanasiou1, N. Pavlopoulou1, T. Vyazantiladis3, E. Siqio4, M. Gounis1, P. Kaloyannidis2, M. Yiangou2, A. Anagnostopoulou2, E. Yannaki1
1Gene and Cell Therapy Center- Hematology Dpt- BMT Unit, George Papanicolaou Hospital, 2School of Biology, Department of Genetics, Development and Molecular Biology, 3School of Medicine, 1st Department of Microbiology, Aristotelian University of Thessaloniki, 4Adult Stem Cell Therapy & Stem cell Transplant, King Fahad Specialist Hospital, Dammann, Saudi Arabia

Background: Viral infections, most commonly by cytomegalovirus (CMV), Epstein-Barr virus (EBV), polyoma virus type I (BK), and fungal infections, mainly by Aspergillus Fumigatus (Asp), are leading causes of transplant-associated mortality in patients undergoing allogeneic hematopoietic stem cell transplantation. Standard treatment with antiviral and antifungal pharmacological agents, is often ineffective or toxic and may lead to resistance. Due to these limitations, adoptive immunotherapy with antigen-specific T cells has emerged as an attractive alternative. Towards unleashing its full potential and treat multiple viral and fungal infections by a single T-cell product, we developed a rapid, simplified and minimally laborious protocol for the generation of multipathogen-specific T cells (mp-STs) that simultaneously target CMV, EBV, BK and Asp, from healthy donors.

Aims: Due to the lack of mouse models recapitulating the clinical condition of multiple opportunistic infections in transplanted hosts, we here aimed to test the in vivo safety of produced mp-STs and provide a proof of concept of their efficacy in a humanized model of invasive aspergillosis (IA).

Methods: mp-STs were generated from healthy donors by pulsing 1.5x10^7 mononuclear cells with viral (CMV, IE1, pp65; EBV: EBNA1, LMP2, BZLF1; BK: Large T, VP1) and Asp pepmixes (Crf1, Gel1, SHMT) and culturing for 10 days. The specificity of mp-STs was analyzed by IFN-γ Elispot. A total of 1.5x10^7 immunomagnetically isolated CD3+cells (donor lymphocyte infusions-DLI) or mp-STs were infused in myelo/immuno-ablated NSG mice which had been intra-nasally inoculated with Asp conidia or left uninfected. Cells were evaluated by a 5-parameter sickness score and at sacrifice, tissues were assessed by histology and immunohistochemistry.

Results: We generated 23x10^7 cells mp-STs (12-fold expansion). All cell lines were polyclonal expressing constitutive receptor memory markers and specific against Asp (spot forming cells [SFC]/2x10^5 cells: 315±82) and the targeted viruses, if derived from seropositive donors [SFC/2x10^5 cells, CMV: 637±267; EBV: EBNA1, LMP2, BZLF1; BK: Large T, VP1) and Asp pepmixes (Crf1, Ge1, SHMT) and culturing for 10 days. The specificity of mp-STs was analyzed by IFN-γ Elispot. A total of 1.5x10^7 immunomagnetically isolated CD3+cells (donor lymphocyte infusions-DLI) or mp-STs were infused in myelo/immuno-ablated NSG mice which had been intra-nasally inoculated with Asp conidia or left uninfected. Cells were evaluated by a 5-parameter sickness score and at sacrifice, tissues were assessed by histology and immunohistochemistry.

Summary/Conclusions: Overall, engrafted mp-STs effectively controlled IA in vivo and after DLI. Epitopes derived from PRAME, NPM1mut, RHAMM, WT-1 and multiple, life-threatening post-transplant infections. mp-STs contributed to clinical outcome of patients treated with DLI.

E1084 DONOR LYMPHOCYTE INFUSION IN PATIENTS WITH HEMATOLOGICAL MALIGANNCIES LEADS TO DIVERSITY OF LEUKEMIA-ASSOCIATED-ANTIGEN-SPECIFIC T CELL RESPONSES AND TO REDUCTION IN REGULATORY T CELL FREQUENCY
S. Hofmann1, M. Schmitt1, M. Götz2, H. Döhner2, M. Wiesenth3, D. Bunjes2, J. Greiner2
1Clinic for Internal Medicine V, University of Heidelberg, Heidelberg, 2Clinic for Internal Medicine III, University of Ulm, 3Institute of Clinical Transfusion Medicine and Immunogenetics Ulm, German Red Cross Blood Transfusion Service Baden-Württemberg–Hessen and Institute of Transfusion Medicine, Ulm, 4Department of Internal Medicine, Diakonie Klinikum, Stuttgart, Germany

Background: Cytotoxic T-cell (CTL) responses against malignant cells play a major role in maintaining remission and prolonging overall survival in patients with hematologic malignancies after allogeneic stem cell transplantation (allo-SCT) and/or donor lymphocyte infusions (DLI). Graft versus leukemia (GvL) effects after allogeneic stem cell transplantation and/or DLI are considered to be T cell-mediated. Many groups described specific T-cell responses against several leukemia-associated antigens (LAA) in different hematological malignancies. However, T cell responses after allo-SCT and DLI are not well characterized.

Aims: In this study, we analyzed LAA-specific T cell responses after allo-SCT and DLI. To this end, we assessed the frequency and diversity of LAA-specific CTL responses using ELISpot analysis and tetramer assays in 12 patients (5 patients (pts) with acute myeloid leukemia, 2 pts with chronic myeloid leukemia, 3 pts with multiple myeloma and 2 pts with chronic lymphatic leukemia) before and after DLI. Epitopes derived from PRAME, NPM1mut1, HLA, WT-1 and other LAA were tested. Moreover, the frequency of regulatory T (Treg) cells was measured and the course of cytokine profiles before and after DLI was analyzed. These immunological findings were correlated to the clinical course in the respective patients.

Methods: In ELISpot and tetramer assays, an increase in frequency and diversity of LAA-specific T cells was observed in all patients. Cytokine assays using ELISA for the detection of more than 10 cytokines before and after DLI were employed.

Results: Importantly, there was a significant increase from 0 to 7 LAA-derived T cell epitopes (P<0.03) in clinical responders (R) when compared to non-responders (NR). These positive results in R versus NR where confirmed by tetramer-based flow cytometry assays, where an increase in frequency from 0.5 to 2.3% in the R group of LAA-specific T cell/all CD8+ T cells was observed. Interestingly, the frequency of Tregs in clinical responders decreased significantly from a median 72.9% to 54.6% (P=0.008) while the frequency of Tregs stayed stable over time in non-responding patients. T cell subset analysis did not reveal significant differences before versus after DLI administration. In cytokine assays using ELISA we found a significant increase of IL-4 after DLI.

Summary/Conclusions: Taken together, we detected an increase of specific CTL responses against several LAA after allogeneic stem cell transplantation and donor lymphocyte infusion. Moreover, this study suggests that broader LAA epitope-specific T cell responses as well as decreasing numbers of Tregs contribute to clinical outcome of patients treated with DLI.

E1085 GENE-MODIFIED NK-92MI CELLS EXPRESSING A CHIMERIC CD16/CD64-BB-Z RECEPTOR EXHIBIT ENHANCED CANCER-KILLING ABILITY IN COMBINATION WITH THERAPEUTIC ANTIBODY
Y. Chen1, F. You1, J. Li1, X. Tang1, G. An1, H. Meng1, L. Yuan3, L. Yang1
1The Cysis Tan Tang Hematology Center, 2Department of Hematology, Soochow University, Suzhou, Jiangsu, 3Department of Hematology, Aerospace Center Hospital, Beijing, China

Background: Natural killer (NK) cells play a pivotal role in monoclonal anti-body-mediated immunotherapy through an antibody-dependent cell-mediated cytotoxicity (ADCC) mechanism. NK-92MI is an interleukin-2 (IL-2)-independent cell line, which was derived from NK-92 cells with superior cytotoxicity to a wide range of tumor cells in vitro and in vivo. However, the Fc-receptor (CD16), which usually mediates ADCC, is absent in NK-92 and NK-92MI cells.

Aims: To determine whether NK-92MI cells co-express the CD16 and CD64, whether we were able to enhance their cytotoxicity using CD16 and CD64 antibodies, and whether we could further enhance these killing abilities using a CD64-BB-ζ receptor.

Methods: We generated 23±5x10^7 cells mp-STs (12-fold expansion). All cell lines were polyclonal expressing constitutive receptor memory markers and specific against Asp [SFC/2x10^5 cells: 315±82] and the targeted viruses, if derived from seropositive donors [SFC/2x10^5 cells, CMV: 637±267; EBV: EBNA1, LMP2, BZLF1; BK: Large T, VP1] and Asp pepmixes (Crf1, Ge1, SHMT) and culturing for 10 days. The specificity of mp-STs was analyzed by IFN-γ Elispot. A total of 1.5x10^7 immunomagnetically isolated CD3+cells (donor lymphocyte infusions-DLI) or mp-STs were infused in myelo/immuno-ablated NSG mice which had been intra-nasally inoculated with Asp conidia or left uninfected. Cells were evaluated by a 5-parameter sickness score and at sacrifice, tissues were assessed by histology and immunohistochemistry.

Results: We generated 23±5x10^7 cells mp-STs (12-fold expansion). All cell lines were polyclonal expressing constitutive receptor memory markers and specific against Asp (spot forming cells [SFC]/2x10^5 cells: 315±82) and the targeted viruses, if derived from seropositive donors [SFC/2x10^5 cells, CMV: 637±267; EBV: EBNA1, LMP2, BZLF1; BK: Large T, VP1) and Asp pepmixes (Crf1, Ge1, SHMT) and culturing for 10 days. The specificity of mp-STs was analyzed by IFN-γ Elispot. Cells were evaluated by a 5-parameter sickness score and at sacrifice, tissues were assessed by histology and immunohistochemistry.

Summary/Conclusions: Taken together, we detected an increase of specific CTL responses against several LAA after allogeneic stem cell transplantation and donor lymphocyte infusion. Moreover, this study suggests that broader LAA epitope-specific T cell responses as well as decreasing numbers of Tregs contribute to clinical outcome of patients treated with DLI.

Figure 1. NK-92MihCD16 and NK-92MihCD64 functional validation in vitro and characterization. A. Schematic representation of the CD16-BB-ζ and the CD64-BB-ζ receptor constructs. B. Exogenous CD16 or CD64 expression on surfaces of NK-92Mih cells are shown. C. Immunoblot analysis of CD3ζ fusion protein expression in NK-92MihCD16 or NK-92MihCD64 cells.
Aims: To apply NK-92MI cell-based immunotherapy in cancer, we designed and generated two chimeric receptors which can bind the Fc portion of human immunoglobulins in NK-92MI cells.

Methods: The construct included the low-affinity Fc receptor CD16 (158F) or the high-affinity Fc receptor CD64, with the addition of the CD8a extracellular domain, CD28 transmembrane domains, two costimulatory domains (CD28 and 4-1BB), and the signaling domain from CD3ζ. The resulting chimeric receptors, termed CD16-BB-ζ and CD64-BB-ζ, were utilized to generate chimeric receptor-modified NK-92MI cells, which were named NK-92MI-hCD16 and NK-92MI-hCD64 cells, respectively.

Results: We found that NK-92MI-hCD16 and NK-92MI-hCD64 cells significantly improved cytotoxicity against CD20-positive non-Hodgkin’s lymphoma (NHL) cells in the presence of rituximab.

Summary/Conclusions: These results suggest that the chimeric receptor-modified NK-92MI cells could potentially enhance the clinical responses mediated by currently available anticancer monoclonal antibodies (mAbs).

A NOVEL IN VITRO METHOD TO QUANTIFY THE PHARMACOLOGY ACTIVITY OF BSISPECIFIC ANTIBODIES IN HEMATOLOGICAL SAMPLES

ViviaBiotech, Madrid, Spain, 2Strategic Research Program on CLL and B Cell Neoplasia Unit, Università Vita-Salute San Raffaele and IRCCS Istituto Scientifico San Raffaele, Milan, Italy, 3Hospital Universitario 12 de Octubre, Madrid, Spain, 4Hospital Universitario 12 de Octubre, Madrid, Spain, 5Department of Experimental, Diagnostic and Specialty Medicine, University of Bologna Institute of Hematology “L. e A. Seraglioni, Bologna, 6Department of Hematology, The Affiliated Hospital of Nanjing University of Chinese Medicine, Hefei Group, Hefei, 7Department of Hematology, The Affiliated Hospital of Nanjing University of Chinese Medicine, Suzhou, 8Department of Hematology, The Affiliated Hospital of Nanjing University of Chinese Medicine, Nanjing, 9Department of Hematology, The First Affiliated Hospital of Soochow University, Suzhou, 10Università Vita-Salute San Raffaele, Milan, Italy, 11Hematology, Hospital Universitari i Politècnic La Fe de Valencia, Valencia, Spain

Background: The PharmaFlow automated flow platform has achieved 85% clinical correlation with AML samples with its novel Native Environment assay. Recently, novel Bi-specific antibodies (BsAbs) or analogous constructions acting through the formation of an immunologic synapse between T-cells (CD3) and a tumor-associated surface antigen (TAA) have been used as immunotherapy leading to T-cell activation and viral lysis of tumor cells.

Aims: The aim of the present study is develop and in vitro assay with multiples variables to better quantify the activity of bsippecific antibodies and reflect the interpatient variability.

Methods: For this purpose, different fresh whole Bone Marrow (BM) or Peripheral Blood (PB) were tested with their corresponding BsAbs at 8 different concentrations in different time points (24h-144h). In this sense, we tested 31 AML BM samples (5 paired BM and PB) with the CD123×CD3 (Creative Biolabs) and 7 CLL and 3 B-ALL samples with Blinatumomab (Amgen). When appropriate, basal quantification of TAA was performed by flow cytometry (FCM). The resulting pharmacokinetic parameters were calculated by fitting the responses of BsAbs exposed by each BsAb with the MRL-2 fitting. The results were expressed as EC50 or Emax, even more marked between CLL samples. The integration of effective T:R ratios, EC50, Emax, and kinetics allow us to generate an in vitro response model and select those samples with higher T-cell cytotoxicity after the different BsAbs exposure. Interestingly, many of the samples for all the BsAbs leave a significant proportion of live cells, even at the higher BsAb concentrations or with a remarkable expansion of activated T-cells that suggest the use of immunoecheckpoint to unblock this immunoresistant status.

Summary/Conclusions: We have developed an automated flow cytometry assay for bsippec specific antibodies screening that keeps basal quantification of TAA but improved valuable data about the BsAbs activity. The integration of effective T:R ratios and pharmacological parameters better predict the in vitro response of BsAbs. Because of the high capacity of the PharmaFlow platform, additional antibodies constructions alone or in combinations with immunomodulatory agents could be tested to identify the better agents or immunotherapeutics combinations in hematological diseases.

HUMANIZED CD7 NANOBODY-BASED IMMUNOTOXINS EXHIBIT PROMISING ANTI-T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA POTENTIAL

Y. Yu1,*, J. Li1, X. Zhu2, X. Tang3, Y. Bao4, Y. Huang1, L. Yuan5, L. Yang1

1The Cytus Tang Hematology Center, Soochow University, Suzhou, 2Department of Hematology, The Affiliated Hospital of Nanjing University of Chinese Medicine, Nanjing, 3Department of Hematology, The First Affiliated Hospital of Soochow University, Suzhou, 4Binhu Hospital, the First People’s Hospital of Heifei Group, Hefei, 5Department of Hematology, Aerospace Center Hospital, Beijing, China

Background: Nanobodies, or named as VHHs, are derived from heavy-chain only antibodies that circulate in sera of camels. Their exceptional physicochemical properties, possibility of humanization and unique antigen recognition properties make them excellent candidates for targeting delivery of biologically active components. In our previous efforts, we have successfully generated the monovalent and bivalent CD7 nanobody-based immunotoxins, which can effectively trigger the apoptosis of CD7 positive malignant cells.

Aims: To pursue the possibility of translating these immunotoxins into clinics, we humanized the nanobody sequences (designated as dhuVHH-PE), as well as further truncated the Pseudomonas exotoxinA (PE) derived PE38 toxin to produce a more protease-resistant form which is named as PE-LR, by deleting majority of PE domain II.

Methods: Three new types of immunotoxins, dhuVHH-PE38, dVHH-PE-LR, and dhuVHH-PE-LR, were successfully constructed. These recombinant immunotoxins were expressed in E. coli and showed that nanobody immunotoxins have the benefits of easy soluble expression in a prokaryotic expression system.

Results: Flow cytometry results revealed that all immunotoxins still maintained their ability to specifically target to CD7-positive T-lymphocytes both in vitro and in vivo. Treatment significantly prolonged mice survival with around 40% survival improvement. However, it is also noticed that despite dhuVHH-PE-LR showed strong anti-tumor effect in vitro, its in vivo anti-tumor efficacy is disappointed.
Results: The cytotoxicity of BCMA against MM cells was determined in vitro and in vivo in a murine MM model; furthermore, their impact in BC-NK cytotoxicity against MM was also determined in vitro. BCMA expression on MM cells after BC-NK exposure was analyzed by confocal microscopy and by flow cytometry. FACs sorting experiments were performed to analyze BCMA transfer between BC-NK exposed MM cells to neighboring non-exposed BC-NK MM cells. Results: Altorvastatin and Fluvastatin treatment (1µM) decreased MM cell line (APR1, RPMI, KMM1) proliferation. No effect was detected for U266 MM cells and for K562 non-MM cells. In vivo studies, showed that mice treated for three days I.P with Fluvastatin (1mg/kg) showed significant decreased MM disease progression. Blocking of BCMA decreased BC-NK cytotoxicity against MM cells. Furthermore, pretreatment of MM cells with Fluvastatin (3 µM) increased BC-NK cytotoxicity against all MM cell lines; no impact was observed against K562 non-MM cells. Co-culture experiments showed that, as soon as 30 minutes, BC-NK exposure led to a BCMA transfer from MM cells to CB-NK and to the extra-cellular milieu leading to a loss of BCMA expression on MM cells. Fluvastatin pretreatment prevented loss of BCMA expression. After two days of co-culture, alive MM cells still showed decreased BCMA surface expression, and surprisingly, increased intracellular BCMA expression. Fluvastatin pretreatment partially avoided BCMA upregulation in MM cells. Furthermore, FACs sorting experiments showed that MM cells exposed to BC-NK, transferred BCMA to neighboring non-BC-NK exposed MM cells which was partially inhibited with Fluvastatin pretreatment. Summary/Conclusions: Our findings show that besides the anti-MM activity of statins alone, they avoid the loss of BCMA expression on MM cells after immune exposure. Preventing loss of BCMA expression on MM cells might improve the efficiency of CAR immunotherapy against BCMA, suggesting the potential of statins as an adjuvant in CAR-NK immunotherapy against MM cells.

DENDRITIC CELL VACCINATION COMBINED WITH LENALIDOMIDE AND PROGRAMMED DEATH-1 (PD-1) BLOCKADE HAS SYNERGISTICALLY INDUCED A MARKED TUMOR REGRESSION IN A MURINE MYELOMA MODEL
S.-H. Jung1,*, S. Yang2, H.-J. Lee2, M.-C. Vo1, T.J. Lakshimi2, H.-J. Kim1, J.-J. Lee1
1Department of Hematology-Oncology, 2Research Center for Cancer Immunotherapy, Chonnam National University Hwasun Hospital, Hwasun-Eup, Korea, Republic Of

Background: There is an emerging evidence that the maximal benefit of dendritic cell (DC)-based cancer immunotherapy may be achieved by combination with other therapies that act to immunomodulation and tumor microenvironment. Aims: In this study, we tried to obtain the best efficacy of immunotherapy using DC vaccination in combination with lenalidomide and PD-1 blockade in a murine myeloma model. Methods: After establishing myeloma-bearing mice, four treatment groups were designed to be a mimic protocol as like treatment in clinics as following: 1) PBS control, 2) DCs, 3) DCs + lenalidomide, 4) DCs + PD-1 blockade, and 5) DCs + lenalidomide + PD-1 blockade. After treatment, preclinical response and in vivo tumoral responses were evaluated. Results: DCs combined with lenalidomide and PD-1 blockade showed the best tumor regression among the study groups. These anti-tumor effects have meaningfully related to the decrease of immuno-regulatory populations, such as myeloid-derived suppressor cells (MDSCs), M2 macrophages, and regulatory T cells (Tregs) and the increase of effector immune cell populations, including CD4+ and CD8+ T cells, natural killer (NK) cells, and M1 macrophages, accompanied with the activation of cytotoxic T lymphocytes (CTLs) and NK cells in the splenocytes from the treated mice. Moreover, the level of immunosuppressive cytokines, such as TGF-β and IL-10, was significantly reduced in tumor microenvironment.

Summary/Conclusions: DC vaccination in combination with lenalidomide plus PD-1 blockade has synergistically induced a strong anti-tumor immunity by modulating tumor microenvironment in a murine myeloma model. This protocol will become a promising translational approach to improve the efficacy of immunotherapy in the field of MM.

B- AND T-CELL IMMUNE REPertoire PROFILING WITH ANCHORED MULTIPLEX PCR AND NEXT-GENERATION SEQUENCING
J. Eberlein1, T. Harrison1, J. Sims2, I. McKittrick1, M. Wemmer1, D. Fugere1,*, S.-H. Jung1,*, M.-C. Vo2, T.J. Lakshimi2, H.-J. Kim1, J.-J. Lee1
1Department of Hematology-Oncology, 2Research Center for Cancer Immunotherapy, Chonnam National University Hwasun Hospital, Hwasun-Eup, Korea, Republic Of

Background: NGS-based analysis of the immune repertoire (IR) is a powerful tool to monitor disease, adaptive immune responses to disease, vaccination and therapeutic interventions. IR characterization by NGS usually requires large primer panels to cover its extensive combinatorial diversity, and a complex system of synthetic controls to account for differential amplification efficiency across segment combinations. Anchored Multiplex PCR (AMP™) uses molecular bar-coded (MBC) adapters and gene-specific primers (GSPs), enabling NGS-based immune chain mRNA interrogation from a single sample. This eliminates the need for opposing primers that bind within the highly variable V-segment, eliminating dilution and bias due to some adapter saturation.

Aims: Our goal was to develop an NGS assay based on AMP that would enable IR characterization utilizing a minimal set of unidirectional GSPs and to reduce amplification bias through the use of MBC adapters.

Methods: Upon developing our AMP-based NGS assay, we validated its quantitation sensitivity, reproducibility and sensitivity of the IR model. We have successfully constructed a targeted CD79A and CD79B PCR assays using AMP-based NGS in healthy donors, B-cell chronic lymphocytic leukemia donors and formalin-fixed paraffin-embedded (FFPE) tissue.

Results: We developed the AMP-based NGS assays, Immunoverse™ (IGH and TR) for B-cell and T-cell receptor sequencing, respectively. Both assays demonstrated high reproducibility between replicates with quantitative clone tracking down to 0.01%. The ability to determine isotype, clonotype and IGHV mutational status in a single assay was demonstrated. Preliminary TCR assay data indicates that CD3 sequence capture is possible from FFPE tissue with clonotype calling being driven by input quantity, T-cell content, and, to a lesser degree, mRNA quality.

Summary/Conclusions: AMP-based NGS with MBC quantification and error-correction is a powerful method to characterize the immune repertoire.

SYNERGISTIC ANTITUMOR IMMUNITY BY DENDRITIC CELLS IN COMBINATION WITH POMALIDOMIDE AND DEXAMETHASONE IN A MURINE MYELOMA MODEL
S.-H. Jung1,*, S. Yang2, H.-J. Lee2, M.-C. Vo1, T.J. Lakshimi2, H.-J. Kim1, J.-J. Lee1
1Department of Hematology-Oncology, 2Research Center for Cancer Immunotherapy, Chonnam National University Hwasun Hospital, Hwasun-Eup, Korea, Republic Of

Background: Pomalidomide (Pom) plus dexamethasone (Dex) could be considered one of the new treatment options in patients with relapsed and/or refractory multiple myeloma (MM). Recently, several diverse agents would be combined to improve the therapeutic efficacy of immunotherapy.

Aims: In this study, we investigated the preclinical efficacy of combined therapy with dendritic cells (DCs) and Pom-Dex in a murine myeloma model.

Methods: After establishing myeloma-bearing mice, four treatment groups were designed to be a mimic protocol as like treatment in clinics as following: 1) PBS control, 2) DCs, 3) Pom + Dex, and 4) DCs + Pom + Dex. After vaccination, preclinical and in vitro immunological responses were evaluated.

Results: Among four treatment groups, DC combined with Pom and DexA strongly inhibited tumor growth, compared with other groups. In vitro immunological analyses revealed that these enhanced anti-tumor effects were closely associated with the decrease of regulatory cell populations, such as regulatory T cells (Tregs) and type 2 macrophages (M2), and the increase of effector cell populations, including activated CD4 T cells, and type 1 macrophages (M1), accompanied with the activation of cytotoxic T lymphocytes (CTLs) and natural killer (NK) cells in the splenocytes from vaccinated mice.

Conclusion: Our findings show that combined therapy of the DC combined with Pom and DexA synergistically enhance the anti-tumor immunity in a murine myeloma model, by skewing immuno-suppressive status toward immuno-suppressive status in tumor microenvironment.

ALTERATIONS IN T-CELL SUBPOPULATIONS AFTER CO-CULTURING WITH MSCS DERIVED FROM DIFFERENT DONORS

N. Kapranov1, Y. Davydova1, I. Galtseva1, N. Petinati1, N. Drize1, L. Kuzmina1, E. Parpinchikova1, V. Savchenko1
1Research Center for Hematology of the Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation

Background: Study of interactions between lymphocytes and mesenchymal stromal cells (MSCs) in vitro revealed increase of HLA-DR expression on T-cells after co-cultivation with some MSCs samples. On lymphocytes derived from one donor the elevation of HLA-DR was observed after co-cultivation with half of MSCs samples (group A). On the other the HLA-DR expression level did not change (group B). MSCs were divided into two groups based on HLA-DR rise on lymphocytes. Study of T-cell subpopulations after interactions with MSCs could explain ineffectiveness of some MSCs as an immunomodulating agent in clinical applications.

Aims: The aim of the study was to discriminate variations in T-cell subpopulations, co-cultured with MSCs from two groups.

Methods: MSCs were isolated from bone marrow of 13 donors for allogeneic hematopoietic cells transplantation and cultured by a standard method. MSCs were seeded 10^5 cells per flask, and then 10^4 allogeneic lymphocytes from single donor were added to all MSCs cultures. For lymphocytes activation 5mg/ml phytohemagglutinin (PHA) was added to half of these cultures. Lymphocytes were removed from MSCs. Then MSCs were removed from the bottom of the flask by trypsin and expression of HLA-DR on their surface was measured by flow cytometry. Activation markers CD25, CD38, CD69, HLA-DR and PD-1 were studied by flow cytometry as well as distribution of naïve and effector T-cells were analyzed on 4th day of cultivation. p<0.05 was considered statistically significant; all data are presented as medium ± SEM.

Table 1.

Results: Expression of HLA-DR on lymphocytes after 4 days of cultivation without MSCs did not change compared to 1st day. When lymphocytes were co-cultured with some MSCs samples expression of HLA-DR was higher. Elevated percentage of HLA-DR positive cells correlates between CD4+ and CD8+ cells (R^2=0.932). Thus samples of MSCs were divided into two groups: in group A proportion of HLA-DR lymphocytes was 3 times greater than in group B. Subpopulations of lymphocytes co-cultured with MSCs from group A and B were compared. Subpopulations which significantly differed between groups A and B are presented in the table. In lymphocytes co-cultured with MSCs there were higher number of naïve cells compared to control (47.4±3.5% and 54.9±2.0% for group A and B vs 36.9±1.4% for lymphocytes cultures without MSCs, p<0.001). Group B showed lower number of EM and TM cells. Differences between groups were more pronounced when lymphocytes were activated. In group B proportion of HLA-DR CD4+ and CD8+ cells was significantly lower, compared to group A and control samples. At the same time the number of CM and PD-1+ CD4+ cells was lower in group B, but number of TE was increased. Investigation of HLA-DR expression on MSC after co-culturing with lymphocytes showed higher level of fluorescence signal (MFI) in group A then group B (635±130 vs 289±18, p=0.03). These data indicated that MSCs from group A had become more immunogenic after interaction with lymphocytes and could not show immunomodulating properties in same way as MSCs from group B.

Summary/Conclusions: The immunomodulatory properties of MSCs depend on the donor. This could explain why administration of MSCs is not always successful. Preliminary study of MSCs prior to their administration may be used to predict their efficiency in the future.

The materials are supported by grant from the Russian Science Foundation, Project № 16-15-00102.

Background: Feeding intolerance is a common problem among neonates recovering from surgery for congenital abnormalities of the gastrointestinal tract (GIT) such as small bowel atresia, omphalocele or gastroschisis. Feeding intolerance is a multifactorial process, but one of the important reasons is congenital maldevelopment of the small bowel villi. Disuse atrophy of the small bowel mucosa following several days of post-operative enteral fasting is one factor that can contribute to feeding intolerance. The human fetus swallows over 200 ml/kg/day of amniotic fluid and such swallowing is essential for normal small bowel development. Growth factors found in the amniotic fluid have been shown to promote proliferation of fetal intestinal cells. These growth factors include epidermal growth factor, granulocyte colony stimulating factor (G-CSF) and erythropoietin (EPO). We postulated that infants recovering from surgeries for congenital obstructive bowel abnormalities could be provided with physiologic quantities of recombinant human G-CSF and EPO by the intermittent orogastric or nasogastric administration of 20 ml/kg/day of sterile isotonic solution that contained cytokine concentrations comparable to what they would have ingested from amniotic fluid in utero.

Aims: To test a hypothesis suggesting that feeding tolerance could be improved in neonates recovering from surgeries for congenital obstructive bowel abnormalities by enterally administering recombinant human G-CSF and EPO included within simultaneously administered sterile saline solution.

Methods: This double-blinded randomized controlled clinical trial was conducted on 40 neonates recovering from GIT surgeries for congenital bowel abnormalities. Hemodynamically unstable babies, and those with any contraindication to enteral feeding were excluded. Neonates were randomly divided postoperatively into 2 groups; 20 neonates received the test solution (called Simulated Amniotic Fluid-like solution given Enterally; SAFE); 20 neonates enterally received distilled water (control). Treatment was started postoperative and the test solution (or distilled water) was discontinued when enteral intake reached 100cc/kg/day. Feeding tolerance and adverse effects of treatment (if any) were assessed.

Results: All the studied neonates tolerated the received solution well without side effects that could be attributed to its intake. The study group showed better feeding tolerance as reflected by earlier achievement of 50, 100, 120 and full enteral feeds with higher enteral caloric intake 7 days after SAFE administration and higher rate of weight gain (p<0.05). No significant increase was found in the level of WBCs count, hemoglobin and hematocrit values either pre-initiation or 7 days after administration of SAFE (p>0.05).

Summary/Conclusions: This study provides further insights on the improve ment of neonatal outcomes and help to decrease morbidities from post-operative malnutrition and feeding intolerance. Enteral administration of rhG-CSF and rhEPO may play a critical role in preventing villous atrophy, thereby, reducing feeding intolerance in neonates recovering from surgeries for congenital bowel abnormalities.

Background: Pyruvate Kinase Deficiency (PKD) is a rare erythroid metabolic disease caused by mutations in the PKLR gene which encodes the erythroid specific Pyruvate Kinase (RPK) enzyme. The defective enzyme fails to produce normal ATP levels and consequently, erythrocytes from PKD patients show an energetic imbalance and are susceptible to hemolysis. Site-specific hematopoietic stem cell gene therapy would be the safest approach to treat PKD patients. In this study, different gene editing approaches have been explored to correct PKD, either by the Knock-in of a PKLR cDNA sequence in the second intron of PKLRF1 or by the site-directed correction of specific mutations.

Aims: In the Knock-in system, that previously showed to correct the PKD phenotype of PKD-iPSC lines, a recombination matrix carrying codon optimized exons 3-11 of the PKLR cDNA sequence in the second intron of PKLR, either by the Knock-in of a PKLR cDNA sequence in the second intron of PKLRF1 or by the site-directed correction of specific mutations.

Methods: Thus, the therapeutic matrix together with specific TALENS as DNA plasmid or mRNA, for the second exon of PKLR were electroporated in purified CD34+ cells from healthy cord bloods. Cells were then expanded and puromycin selected to enrich the population for gene edited ones.
E1095 BLAST KINETICS AFTER NON-ENGRAFTING HAPLOIDENTICAL MICROTRANSPLANTATION IN PATIENTS WITH REFRACTORY ACUTE MYELOID LEUKAEMIA

Z. Emarah1,2, S. Shamaali-Mossalaei2, M. El-Zaafarany1,2, N. Essa2,4, M. Khalaifi1
1Medical Oncology Unit, Oncology Center, Mansoura University, 2Medical Oncology Unit, Internal Medicine Department, Faculty of Medicine, Mansoura University, 3Clinical Hematology Unit, Oncology Center, Mansoura University, 4Clinical Hematology Unit, Internal Medicine Department, Faculty of Medicine, Mansoura University, Mansoura, 3Clinical Hematology Department, Hematology and Oncology Hospital, Maadi Armed Forces Medical Compound, Cairo, Egypt

Background: Multiple trials have showed that granulocyte colony-stimulating factor (G-CSF)-mobilized donor peripheral-blood stem cells (GPBSCs) based on allo-graft can be effective in mediating graft-versus-leukemia (GVL) effects and promote hematologic recovery without triggering of acute GVHD.

Aims: To analyze the safety and efficacy of non-engraftment haploidentical cellular therapy for patients with refractory acute myeloid leukaemia by assessment of bone marrow blast and hematopoietic cells percent kinetics.

Methods: Seven patients (4 males 57.1%, 3 females 42.9%) with refractory acute myeloid leukaemia were enrolled into this Phase I/II study. They were treated with chemotherapy including fludarabine 30mg/m2, cytarabine 1gm/m2, and melphalan 140mg/m2 plus busulfan 16mg/m2. Three patients (2 males 80%, 1 female 20%) were transplanted at day +50 from the 1st microtransplantation and at day +100 (day +75 from the 2nd microtransplantation). Three patients (2 males 66.6%, 1 female 33.3%) were transplanted at day +60 from the 1st microtransplantation (day +30 from 2nd microtransplantation). The cellular therapy was performed using unmanipulated GPBSCs 24 hour after last chemotherapy infusion. Morphologic assessment of bone marrow blast kinetic by bone marrow aspiration conducted before therapy, D14 and D30 after therapy. Hematopoietic cells percent kinetics (Hematologic recovery) was assessed by complete blood count every day till Day 40.

Results: At day +30, 6 patients were evaluable for response and one patient had died. One patient out of 7 showed PR, then developed CR after a second microtransplantation. Seven patients (4 males 57.1%, 3 females 42.9%) with refractory acute myeloid leukaemia were transplanted into this Phase I/II study. They were treated with chemotherapy including fludarabine 30mg/m2, cytarabine 1gm/m2, and melphalan 140mg/m2 plus busulfan 16mg/m2. Three patients (2 males 80%, 1 female 20%) were transplanted at day +50 from the 1st microtransplantation and at day +100 (day +75 from the 2nd microtransplantation). Three patients (2 males 66.6%, 1 female 33.3%) were transplanted at day +60 from the 1st microtransplantation (day +30 from 2nd microtransplantation). The cellular therapy was performed using unmanipulated GPBSCs 24 hour after last chemotherapy infusion. Morphologic assessment of bone marrow blast kinetic by bone marrow aspiration conducted before therapy, D14 and D30 after therapy. Hematopoietic cells percent kinetics (Hematologic recovery) was assessed by complete blood count every day till Day 40.

Aim: The aim of the study was to determine the distribution of naive and effector cells in lymphocytes co-cultured with MSCs.

Methods: MSCs were derived from bone marrow of 13 donors (7 male and 6 female aged 22 to 62 years, median 27 years). MSCs were co-cultured with allogeneic lymphocytes in a ratio of about 1:10 for 4 days and their basic properties were analyzed over time. Lymphocytes were activated by adding to the culture medium 5mg/ml of PHA (PHA-lymphocytes). Some MSCs were treated for 4 hours with 500 U/ml IFN-γ (mMSCs). Activation markers CD25, CD38, CD69, HLA-DR and PD-1 were studied by flow cytometry and the distribution of naive and effector T-cells in T-cells were analyzed.

Results: By the fourth day of incubation the proportion of naive CD4+ cells reduced by 30% (from 47.5±3.0% to 32.8±3.3%) and cellularized lymphocytes. It did not happen in lymphocytes co-cultured with MSCs and mMSCs (p=0.001). At the same time in cultured lymphocytes to the fourth day the number of CD4+ central memory cells increased in 1.8 times from 19.5±1.9% to 34.6±2.4%, which did not occur when co-cultured with both MSCS and mMSCS (p=0.001). Thus, co-culturing with MSCS or mMSCS prevented naive T-lymphocytes transiting into effector cells. The proportion of CD4+PD-1+ cells increased from 8.2±1.1% to 10.9±0.7% by the 4th day of cultivation. When co-cultured with MSCS and mMSCS the proportion of CD4+ cells did not change (p=0.0125). The proportion of HLA-DR+ on both CD4+ and CD8+ cells in lymphocytes remained unchanged for 4 days. When co-cultured with MSCS and mMSCS for 4 days there was a consistent increase in the proportion of CD4+/HLA-DR+ (e.g. 10.1±1% to 15.6±1.1%, p=0.005) and CD8+/HLA-DR+ (from 9.7±0.8% to 26.0±3.7%, p=0.024). So allogeneic MSCS induced peptide presentation on lymphocytes. The proportion of CD4+ central memory cells increased in PHA-lymphocytes from 37.4±4.4 at 1st day to 68.2±6.5 at 4th day. MSCS inhibited this increase - the proportion CD4+ central memory cells increased from 24.4±2.7% to 46.6±4.5% (p=0.047). Thus the interaction of PHA-lymphocytes with MSCS inhibited their activation and preserved naive state.

Summary/Conclusions: The composition of lymphocyte population changes during cultivation. The proportion of naive cells reduced, while the number of effector cells and the proportion of PD-1+ increased, indicating lymphocyte activation probably due to the presence of xenogeneic serum in the culture medium. Co-cultivation with MSCS maintained lymphocytes in not activated state. The interaction of activated lymphocytes with MSCS inhibits their activation and preserves naive state. IFN-γ priming did not enhance MSCS inhibitory effect. Lymphocyte activation showed that MSCS both preserve naive lymphocyte condition and have an inhibitory effect on their activation.

Lomonosov, 4Bone Marrow Transplantation Department, 5National Research Center for Hematology, Moscow, Russian Federation

Aims: To determine the precise window of specification of HE hematopoietic precursors and interrogate at the single cell level their functional heterogeneity.

Methods: Dams pregnant with Cdh5ERT2-CreROSA26Confetti/+ embryos were treated with tamoxifen (TAM) at E7.5, E8.5, E9.5, E10.0 or E11.5. Here, TAM induces the permanent and random labeling of endothelial cells and their progeny with one of the Confetti allele fluorescence reporters (YFP, GFP, CFP or RFP). The blood of resulting adult Cdh5ERT2-CreROSA26Confetti/+ offspring was then examined for the presence of Confetti+ cells by flow cytometry. Clonal ex vivo assays: VE-Cadherin+CD45- cells, which contain HE, were isolated by FACs from E9.5, E10.5 or E11.5 embryos and co-cultured at limiting dilution either with or without PHA-activated lymphocytes. HE and HE-derived endothelial cells engineered to express Myr-AKT (AA-ECS), which both support hematopoietic output from HE ex vivo. Co-cultures were scored for hematopoietic colony formation, which were then analyzed for hematopoietic re-plating activity and flow cytometry for hematopoietic cell surface markers.

Results: To estimate the temporal window of TAM activity, CD45.2+ROSA26ERT2-Cre/Confetti+ bone marrow (BM) cells were transplanted into CD45.2+CD45.1+ recipients treated with TAM three, two, one or zero days before transplant. Only the PB of recipients treated on the same day of transplant showed 100% CoC and Confetti+cells. HE recruitment was observed in PB of recipients treated with TAM 2, 1 or 0 days before transplant. TAM-induced HE recruitment was not observed in recipients treated with TAM 3 days before transplant. The only observed TAM-induced recruitment was detected in recipients treated with TAM 2 days before transplant. The results show that the window of TAM activity is approximately 24 hours. Analysis of 10 weeks old Cdh5ERT2-CreROSA26Confetti+ mice revealed that only mice exposed to TAM in utero at E8.5 and E9.5 had Confetti+ blood. Thus, specification of HE begins at E8.5 and is complete by E10.5. Next, E11.5 AGMs isolated from CD45.2+ Cdh5ERT2-CreROSA26Confetti+ embryos exposed to TAM at E10.5 were cultured as explants for three days under conditions that preserve ongoing HSC specification from HE, dissociated, and then transplanted into CD45.2+CD45.1+ recipients. Remarkably, although the CD45.2+ chimera was (~80%) in the blood of recipients, all CD45.2+ blood was negative for the Confetti label, further indicating that HE recruitment is complete by E10.5 and cannot be reactivated during explant culture. Limiting dilution culture of E9.5, E10.5, and E11.5 VE-Cadherin+CD45- endothelium revealed the frequency of functional HE to be 0.1, 1.1 and 0.19% at these time-points, respectively. Phenotypic analysis of primary hematopoietic colonies revealed cells expressing the C-type lectin-like receptor 2 (CLEC2) and the only a small population of colonies producing phenotypic HSCs in AA-ECS co-cultures. These data suggest the presence of HE precursors with distinct functional output or the existence of a continuum of HE at different stages of maturation.

Summary/Conclusions: We have defined the window of mammalian HE specification. The abrupt loss of ongoing HE recruitment at E10.25 suggests an active mechanism that terminates this process. We also observed large phenotypic and functional variability amongst individual HE precursors examined throughout ontogeny.

Background: Hematopoietic stem cells (HSCs) arise from hematopoietic endothelial (HE) precursors between embryonic day 10.5 (E10.5) and 12.5 of murine development, primarily in the aorta-gonad-mesonephros (AGM) region and the umbilical (UA) and vitelline arteries (VA). The window of specification of HE has not been defined in any mammalian system.

Aims: To determine the precise window of specification of HE hematopoietic precursors and interrogate at the single cell level their functional heterogeneity.

Methods: Dams pregnant with Cdh5ERT2-CreROSA26Confetti/+ embryos were treated with tamoxifen (TAM) at E7.5, E8.5, E9.5, E10.0 or E11.5. SPECIFICATION OF MURINE HEMOGONIC ENDOTHELIAL HEMATOPOIETIC PRECURSORS CEASES ABRUPTLY BY E10.25 AND CONSTITUTES A FUNCTIONALLY HETEROGENEOUS POPULATION

T. Kumode1,*, H. Tanaka1, R. Fujiwara1, K. Sano1, K. Serizawa1, Y. Taniguchi1

1Hematology and Rheumatology, Kindai University Faculty of Medicine, Osaka, Japan

Background: Recent studies have supported the model in which hematopoietic stem cell (HSC) compartment consists of functionally distinct subsets with discrete self-renewal and differentiation potentials. However, their immunophenotypes and the functional diversities remain poorly understood. We previously reported that the authentically identified HSC population includes a subset of cells expressing the C-type lectin-like receptor 2 (CLEC2) that are able to give rise to megakaryocyte progenitors (MKPs) and megakaryocytes bypassing the pathway from common myeloid progenitor (CMP) to megakaryocyte/erythrocyte progenitor (MEP) (21th Congress of EHA, # P356, 2016).
Aims: In this study, we analyzed in vivo dynamics of CLEC2high HSCs to clarify their functional roles in adult hematopoiesis.

Methods: In this experiment, we defined Lin−Sca1+Kit+CD150+CD34− cells as HSCs and Lin−Sca1+Kit+CD150+CD41+ as MP. We performed transplantation assays using HSCs isolated from EGFP transgenic (CAG-EGFP+) mice to trace donor-derived HSCs and their progeny. Consequently, excepting enucleated donor-derived Mpk, CLE2high HSCs and CLEC2low HSCs were transplanted into lethally irradiated mice, respectively. Chimerism and lineage distribution of donor-derived cells were evaluated periodically by tracing EGFP. Secondary transplantation was performed by transferring 1x107 BM cells from the recipient mice 16 weeks after the 1st transplantation.

Results: Bone marrow analysis revealed that both EGFP+CLEC2high and CLEC2low donor-derived HSC populations were detected for up to 12 weeks after transplantation. Also, these subsets were capable of generating all lineages of cells in transplanted mice. Interestingly, CLEC2high HSCs generated CLEC2high donor-derived HSCs already observed in the steady-state BM, vice versa. Consistent with these reciprocal transition, both types of HSCs could effectively reconstitute hematopoiesis in the secondary recipients. However, CLEC2high HSCs showed significantly reduced repopulating activity than CLEC2low cells, especially at 12 weeks after transplantation (mean of EGFP+ HSC proportion in the primary recipients with CLEC2high HSCs vs CLEC2low HSCs: (each n=5): 21.1% vs 66.1% at 4 weeks (p=0.054); 2.14% vs 48.3% at 12 weeks (p<0.05)). In addition, the recipient mice transplanted with CLEC2low HSCs kept high chimeric levels of EGFP+ CMP and MEP, while these levels decreased in the recipients with CLEC2high HSCs. On the other hand, CLEC2high HSCs yielded 2.5-fold more Mpk than CLEC2low HSCs in short-term grafts (1 to 2 weeks after transplantation) (p<0.05). Consistent with this finding, CLEC2high HSCs yielded more CD41+ platelets than CLEC2low HSCs by 6.0-fold at 1 week after transplantation (p<0.05), which peaked 10 weeks earlier than in CLEC2low recipient mice. These platelets yielded through the transplantation of CLEC2high HSCs were rare during a certain level 12 weeks after transplantation. Furthermore, treatment with fostamatinib (R788), a Syk kinase inhibitor that is an indispensable component for CLEC2 signaling, blocked more potent and rapid megakaryopoiesis in the CLEC2high recipients, indicating that CLEC2 signaling is essential for rapid and enhanced megakaryopoiesis from CLEC2high HSCs.

Summary/Conclusions: Here, we showed that CLEC2 expression on HSCs demonstrates their oscillation for serving as a potent source of megakaryopoiesis, and found that CLEC2/Syk signaling would be involved in differential regulation between CLEC2high and CLEC2low HSC subtypes.

PRE-TRANSPLANT DEFECTS OF BONE MARROW ENDOTHELIAL CELLS MAY CAUSE THE OCCURRENCE OF POOR GRAFT FUNCTION AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

Y. Kong1, M.-M. Shi1,2, Y. Song1,2, Y.-H. Chen1, T.-T. Han1, Y.-Q. Sun1, Y. Wang1, X.-H. Zhang1, P. Xu1, X.-J. Huang1
1Peking University People’s Hospital, Peking University Institute of Hematology, Peking, China
2Peking-Tsinghua Center for Life Sciences, Academy for Advanced Interdisciplinary Studies, Peking University, Beijing, China

Background: Poor graft function (PGF) is a serious complication after allogeneic hematopoietic stem cell transplantation (allo-HSCT). PGF is defined as complete donor hematological chimerism with no residual or recurrent leukemia, but a hypo- or aplastic bone marrow (BM) with 2 or 3 of the following: (1) neutrophils <0.5 x 10^{9}/L; (2) platelets <20 x 10^{9}/L; and/or (3) hemoglobin concentration <0.10 on univariate logistic regression analysis between PGF and pre-HSCT, significantly reduced percent- age of BM EPCs were observed in PGF patients than those in GGF patients, whereas no significant differences were found in the percentage of BM HSCs and their progeny. Moreover, similar ROS levels were demonstrated in BM EPCs and HSCs between PGF and GGF patients. Although there was no difference in transplanted CD34+ cell dose between the PGF and GGF groups, significantly lower percentages of BM EPCs and HSCs, whereas remarkably higher ROS levels were observed in BM EPCs and HSCs in PGF recipients than those in GGF patients. Moreover, inverse correlations were observed between BM EPCs frequency and their ROS levels post-HSCT, as well as BM HSCs frequency and their ROS levels post-HSCT. Multivariate analyses revealed that the reduced BM EPCs and the disease status pre-HSCT were independent risk factors for the occurrence of PGF following allo-HSCT.

Summary/Conclusions: We identified that patients with impaired BM EPCs pre-transplant were at a high risk for the occurrence of PGF post-allo-transplant. Moreover, persistent low percentage and high levels of ROS in BM EPCs may hamper the hematopoietic reconstitution of engrafted donor HSCs in patients with PGF. Therefore, strategies to repair the impaired BM EPCs appear to be a promising therapeutic approach in patients with PGF after allo-HSCT.

E1102
EFFICIENT LYMPHOID DIFFERENTIATION OF HEMATOPOIETIC STEM CELLS REQUIRES CXCR4 DESENSITIZATION

C. Freitas1, M. Wittebrood, J. Nguyen1, V. Rondeau2, J. Donadi3, F. Bachelet1 and M. Espéli1,2
1INSERM U996, Clamart, 2INSERM UMR_S1170, Villejuif, 3Service d’Hématologie Pédiatrique, Hôpital Trousseau, Paris, France

Background: The Warts, Hypogammaglobulinemia Infections and Myelokathexis Syndrome (WS) is a rare immunohematological disorder characterized notably by a chronic lymphopenia. It is mostly caused by inherited heterozygous autosomal gain-of-function mutations in CXCR4, which enforces a distal truncation in the C-terminal domain and leads to a desensitization-resistant receptor. Given that CXCR4 is widely expressed on non-hematopoietic cells and virtually on all leukocytes at multiple stages of development, one possibility could be that the WS-associated peripheral blood lymphopenia is a consequence of skewed production, differentiation or distribution of lymphocytes related to altered CXCR4-mediated signaling. Recently, we have been able to replicate the hematologic phenotype of WS using a knock-in mouse strain that harbors the WS-linked heterozygous CXCR4S338X mutation causing a distal truncation of the last 15 residues of the C-terminal domain (Balabanian et al., Blood, 2012). Mutant mice displayed lymphocytes with enhanced migration to Ccxl2, phagocytosed severe lymphopenia and failed to maintain antibody titers after immunization (Biajoux et al., Cell Reports, 2016). First-line analyses of 1x10^13 mice suggested developmental defects at the pro/pre-B cell stage in the bone marrow (BM) and during the early double-negative stages of thymocyte maturation. However, whether impaired lymphopoiesis stems from an upstream cell-intrinsic or the hematopoietic defect remains to be established.

Aims: We took advantage of our relevant knock-in model and the access to blood samples from WS patients to investigate the impact of CXCR4 desensitization on BM and extra-medullary splenic hematopoiesis and recirculation of lymphoid precursors (HSPCs).

Methods: The global hematopoietic development, including quiescence, cycling and survival properties of HSPCs, was examined in non-manipulated and BM-chimeric mice using flow-cytometric and clonogenic-based assays. Cxcr4 expression and function were assessed using internalization, transgenic in vivo homing and AMD3100-promoted mobilization experiments. Both multipotency and survival properties of HSPCs have been assessed using serial BM transplantation experiments. Immunophenotypic and clonogenic analyses of HSPCs were performed from blood samples of five WS patients and age-, sex-, matched healthy controls. Furthermore, the hematopoietic defect remains to be established.

Aims: To investigate whether the BM HSCs in subjects with PGF are impaired pre-HSCT. To compare the reconstitution kinetics of BM HSPCs, their ROS levels in subjects with PGF and good graft function (GFF) post-HSCT.

Methods: A total of 115 patients who will receive allo-HSCT were prospectively recruited, and randomly selected as training group (n=32) and validation group (n=83). The percentage of BM CD45-CD34+VEGF+2+ EPCs, CD34+ HSCs, and reactive oxygen species (ROS) levels in EPCs and HSCs were evaluated in all of the enrolled patients pre-HSCT by flow cytometry. Furthermore, 59 patients were monitored for the frequency and ROS levels of BM EPCs and HSCs by flow cytometry. In order to identify risk factors for PGF, pre-HSCT risk factors with a P<0.10 on univariate logistic analysis were included in the multivariate logistic regression analysis, and factors with a P<0.05 were considered independently associated with PGF.

Results: A total of 18 patients including 5 patients in training group (15.63%) and 13 subjects in validation group (15.67%) developed PGF post-HSCT. Both in training group and validation group pre-HSCT, significantly reduced percentage of BM EPCs were observed in PGF patients than those in GGF patients, whereas no significant differences were found in the percentage of BM HSCs and their progeny. Moreover, similar ROS levels were demonstrated in BM EPCs and HSCs between PGF and GGF patients. Although there was no difference in transplanted CD34+ cell dose between the PGF and GGF groups, significantly lower percentages of BM EPCs and HSCs, whereas remarkably higher ROS levels were observed in BM EPCs and HSCs in PGF recipients than those in GGF patients. Moreover, inverse correlations were observed between BM EPCs frequency and their ROS levels post-HSCT, as well as BM HSCs frequency and their ROS levels post-HSCT. Multivariate analyses revealed that the reduced BM EPCs and the disease status pre-HSCT were independent risk factors for the occurrence of PGF following allo-HSCT.

Summary/Conclusions: We identified that patients with impaired BM EPCs pre-transplant were at a high risk for the occurrence of PGF post-allo-transplant. Moreover, persistent low percentage and high levels of ROS in BM EPCs may hamper the hematopoietic reconstitution of engrafted donor HSCs in patients with PGF. Therefore, strategies to repair the impaired BM EPCs appear to be a promising therapeutic approach in patients with PGF after allo-HSCT.

Background: GATA4 is a transcription factor expressed in mesoderm and endoderm during development. Members of the family such as GATA-1-3, but not GATA-4, are critically involved in hematopoiesis. An enhancer (G2) of the mouse Gata-4 gene directs its expression throughout the lateral mesoderm and the allantois, beginning at E7.5, becoming restricted to the septum transversum by E10.5, and disappearing by midgestation (Rojas et al., Development, 2005, 132:3405). Our previous work has shown that inactivation of Gata-4 using this G2Cre driver is lethal by midgestation (Delgado et al., Development, 2014, 59:2358). The anemia observed in the G2Cre-;Gata-diofluor+ embryos was attributed to a failure in the expansion of the hematopoietic progenitors in the fetal liver. Interestingly, a small population of hepatic YFP+ cells from G2Cre;R26REYFP embryos was positive for leukocyte and megakaryocyte markers, suggesting that a lineage of hematopoietic cells could derive from GATA4 expressing progenitors.

Aims: To study in our murine models the origin and properties of the hematopoietic lineage derived from progenitors expressing GATA4 under control of the G2 enhancer.

Methods: We analyzed hematopoietic organs of G2-Gata4Cre;R26REYFP mice, adults and embryos, by flow cytometry, RT-PCR and confocal microscopy. Cells obtained from different tissues were cultured and transplanted to analyze in vitro and in vivo potential.

Results: YFP+ cells represented about 20% of the hematopoietic system of adult mice and contributed in the same proportion to the lymphoid, myeloid and erythroid lineages. Adult YFP+ hematopoietic stem cells (Figure 1) constituted a long-term repopulating, transplantable population. Fetal YFP+ hematopoietic progenitors were much more abundant in the placenta than in the fetal liver. These placental YFP+ progenitors were clonogenic in the MethoCult assay and fully reconstituted hematopoiesis in adult mice and contributed in the same proportion to the lymphoid, myeloid and erythroid lineages.

Figure 1.

Summary/Conclusions: A lineage of adult hematopoietic stem cells in mice is characterized by the expression of GATA4 in their embryonic progenitors and probably by its embryonic (placental) origin. Both lineages basically showed similar physiological behavior in normal mice, but this finding raises a number of questions, for example: Does this hematopoietic stem cell subpopulation show a different response in physiopathological conditions? Does this subpopulation show a different profile of gene expression? Does a similar heterogeneity exist in human HSCs? We are currently investigating the transcriptome of the G2-GATA4 lineage HSC in order to answer these questions.

Background: The stem cell zinc finger 1 (SZF1) / ZNF589 protein, a member of the family of Krüppel associated box-zinc finger (KRAB-ZNF) transcription factors, has an isoform exclusively expressed in CD34+ hematopoietic stem cell progenitor cells (HSPC) suggesting its role as an epigenetic regulator of specific genes involved in hematopoiesis. The SZF1/ZNF589 gene exhibits a human-specific evolutionary nucleotide DNA-change leading to a complex molecular organization and to a protein structure peculiar for humans, as compared to all other primates, potentially conferring human-specific functional properties. SZF1/ZNF589 has recently been shown to control cell viability in the hematopoietic system. It is regulated by the HIF-1a hypoxia-induced transcription factor and is differentially expressed in a cytokine-dependent manner during hypoxia in CD34+ HSPCs (Venturini et al., Exp Hematol 2016; 44: 257-268). Thus, SZF1/ZNF589 may play a role in the maintenance of hematopoietic cell viability, homing and survival, known to be influenced by the hypoxic state in the bone marrow niche.

Aims: We studied the effects of SZF1/ZNF589 overexpression in vitro and evaluated its tumor suppressor potential in vivo.

Figure 1. The side population of the bone marrow from G2-Gata4Cre;R26REYFP mice identified by Hoechst 2224 staining, which contains adult HSCs, includes a fraction of YFP+ cells. (From Cafeite et al., 2017).

Summary/Conclusions: A lineage of adult hematopoietic stem cells in mice is characterized by the expression of GATA4 in their embryonic progenitors and probably by its embryonic (placental) origin. Both lineages basically showed similar physiological behavior in normal mice, but this finding raises a number of questions, for example: Does this hematopoietic stem cell subpopulation show a different response in physiopathological conditions? Does this subpopulation show a different profile of gene expression? Does a similar heterogeneity exist in human HSCs? We are currently investigating the transcriptome of the G2-GATA4 lineage HSC in order to answer these questions.

Aims: We studied the effects of SZF1/ZNF589 overexpression in vitro and evaluated its tumor suppressor potential in vivo.
Methods: K562 (BCR-ABL positive chronic myeloid leukemia in blast crisis)-Luciferase-control or K562-Luciferase-SZF1/ZNFS89 cells were directly injected into the femurs of NSG mice and tumor development was monitored by bioluminescence. Furthermore, K562 cells with or without SZF1/ZNFS89 overexpression were studied by proliferation assay, cytomorphology, flow cytometry, cell cycle analysis, cyclin B1 expression and beta-galactosidase assay. Results: K562-dependent tumor growth was efficiently inhibited in NSG mice transplanted with K562-Luc-control-cells, leading to significantly prolonged survival, demonstrating a strong tumor suppressive potential of SZF1/ZNFS89 in vivo. In vitro, overexpression of SZF1/ZNFS89 dramatically inhibited proliferation of K562 cells which, instead of dying, became giant and dysplastic, without other significant morphological changes and in absence of polyplody. Cell cycle analysis revealed a blockade in G2/M phase, with cyclin B1 accumulation characteristic for mitotic arrest. As suggested by morphology and beta-galactosidase assays, these cells were entering premature senescence.

Summary/Conclusions: SZF1/ZNFS89 controls survival of hematopoietic cells mediated by mitotic arrest and premature senescence, exhibiting tumor suppressive functions in vivo.

E1106 THE FUNCTIONAL RELEVANCE OF DNMT3A SPLICE VARIANTS IN HEMATOPOIETIC DIFFERENTIATION

1Stem Cell Biology and Cellular Engineering, Helmholtz-Institute for Biomedical Engineering, RWTH Aachen University Medical School, Aachen, 2Department of Human Genetics, Life & Brain Center, University of Bonn, Bonn, 3Department of Obstetrics and Gynecology, RWTH Aachen University Hospital, 4Clinic for Oncology, Hematology, and Stem Cell Transplantation, RWTH Aachen University Medical School, Aachen, Germany

Background: DNA methyltransferase 3A (DNMT3A) plays a pivotal role for de novo DNA methylation (DNAm) during development. It seems to be of particular relevance in hematopoietic differentiation because it is frequently mutated in acute myeloid leukemia or clonal hematopoiesis. So far, it is unclear how DNMT3A governs the use of lineage-specific DNAm patterns. It is conceivable that this can at least partly be attributed to alternative splicing of DNMT3A.

Aims: In this study, we followed the hypothesis that specific splice variants of DNMT3A impact on hematopoietic differentiation or DNAm patterns. Therefore we addressed the role of specific splice variants of DNMT3A in hematopoietic stem and progenitor cells (HSPCs).

Methods: Expression of DNMT3A splice variants was modulated in HSPCs: transcript 1+3 (Tr.1+3), transcript 2 (Tr.2), or transcript 4 (Tr.4) of DNMT3A were either knocked down by short hairpin RNA or constitutively overexpressed by lentiviral infection. Expression changes were validated by qRT-PCR. Subsequently, we evaluated the impact on colony formation potential (CFU assay), proliferation (CFSE assay), and the immunophenotype (CD34+ and CD133+). Global DNAm profiles were generated with the Infinium HumanMethylation450 BeadChip platform and gene expression profiles with the Human Affymetrix GeneChip GT1 1.0 platform.

Results: Downregulation of either Tr.2 or Tr.4 reduced the proliferation rate of HSPCs significantly (n=3, p<0.05). HSPCs maintained CD34 expression for a higher number of cell divisions upon knockdown of Tr.2 (n=3, p<0.05). In colony forming unit (CFU) assays downregulation of Tr.4 resulted in a clear bias towards erythroid colonies (n=3, p<0.05). Overall, CFU frequency was reduced by knockdown of DNMT3A transcripts, whereas it was increased by overexpression. Subsequently, we analyzed the impact of specific DNMT3A variants on the DNAm patterns: several CpG sites revealed significant differences in DNAm levels upon knockdown of Tr.2 and Tr.1+3 (8,905 and 352 CpGs, respectively; n=3, adjusted p-value <0.05). Notably, these patterns were regulated in the opposite direction upon overexpression of the same transcripts. Knockdown of Tr.4, which does not have the DNA-methyltransferase domain, did not evoke significant changes in DNAm. Furthermore, modulation of DNMT3A splice variants resulted in transcript-specific gene expression changes, which may at least partly be attributed to the DNAm changes.

Summary/Conclusions: Our results demonstrate that the various splice variants of DNMT3A have different functional sequel on HSPCs. Knockdown and overexpression resulted in opposite and transcript-specific DNAm changes. Thus, alternative splicing of DNMT3A is relevant for site-specific epigenetic modifications in hematopoietic development.

Background: Erythropoietin (EPO) is a crucial kidney-derived hormone responsible for erythropoiesis; however, its extra-erythroid effects are substantial and correlate with EPO receptor (EPO-R) expression in both hematopoietic and non-hematopoietic tissues. Bone turnover is regulated by the coupled actions of osteoblasts, the bone-forming cells, and monocyte-derived osteoclasts, which mediate bone resorption. In this regard, we have recently reported that EPO directly stimulates bone resorption via activation of EPO-R signaling in the monocytic lineage (Hiram-Bab et al., 2015). Monocyte differentiation into osteoclasts relies on macrophage-macrophage colony-stimulating factor (M-CSF) and the receptor activator of nuclear factor kappa B ligand (RANKL). B cells are also known to regulate bone metabolism, chiefly via paracrine signals. Osteoclasts and B cells arise from distinct myeloid and lymphoid progenitors, respectively, which are downstream of a common multipotent progenitor cell.

In the bone marrow (BM), Pro-B cells sequentially differentiate into Pre-B and immature B cells. Whether BM B cells can transdifferentiate into osteoclasts remains controversial, since osteoclast differentiation from residual mononuclear precursors in the cultures was not included in earlier studies.

Aims: We set to determine whether B cells can transdifferentiate to osteoclasts and to assess the effect of EPO on this process.

Methods: Experiments were conducted on C57BL/6j or CD19-Cre;R26R-EYFP, 5-12-week-old female mice in accordance with the approval of the Institutional Animal Care and Use Committee of Tel-Aviv University (M-14-043). BM cells were flushed from femurs, tibiae, and pelvic bone and red blood cells were lysed. Cells were stained with labelled anti-mouse antibodies: PE-B220, FITC-CD19, PerCP-igm, PeCy7-CD43, and APC-M-CSF receptor/CD115; and sorted by flow cytometry. Cells were then cultured in α-MEM containing 10% fetal bovine serum, M-CSF and RANKL. Multinucleated osteoclasts were stained for tartrate-resistant acid phosphatase (TRAP) and pit resorption was assessed.

Results: B cells isolated from BM of CD19-Cre;R26R-EYFP mice cultured with M-CSF and RANKL differentiated into TRAP+ multinucleated osteoclasts that were also positive for EYPF, thus tracing back their B cell origin (Figure 1A).

Next, we dissected which B cell progenitor subtype possesses this osteoclastogenic capacity and found that only Pro-B (B220+CD19+CD43HighIgM-), but not Pre-B (B220+CD19+CD43lowCD115+), nor immature B cells (B220+CD19+CD43IgMhi) could transdifferentiate into osteoclasts (16%±3.7 vs. 0.79%±0.28 and 0.48%±0.13 osteoclasts’ area, respectively). Moreover, among the Pro-B cells, only those expressing M-CSF receptor (CD115) could transdifferentiate into functional osteoclasts (18%±5.5 vs. 0.11±0.05 osteoclasts’ area, respectively, Figure 1B and C). Using an anti-EPO-R specific antibody we detected EPO-R on the surface of B cells and noted that EPO enhanced the differentiation of the Pro B cells into osteoclasts by as much as 70% (p=0.04) (Figure 1D).

Figure 1: Osteoclastogenesis in vitro from sorted B cells. (A) Trans-differentiation of 180,000 cells/well CD19-Cre;R26R-EYFP into osteoclasts. (B) TRAP staining of osteoclasts derived from indicated sorted cells from BM (10,000 cells/well) and cultured with M-CSF and RANKL. Left – Pro-B cells expressing CD115 (B220+CD19+CD43hiIgMhiCD115+). Right – Pre-B cells not expressing CD115 (B220+CD19+CD43IgMhiCD115+). Data are means±SEM of osteoclast area, n=5 mice in each group; *p<0.05. (C) Pit resorption area from the indicated sorted cells cultured on calcium phosphate-coated plates. (D) TRAP staining of osteoclasts derived from sorted Pro-B cells (B220+CD19+CD43hiIgMhiCD115+). Data are means±SEM of osteoclast area, n=5 mice in each group; *p<0.05.
BONE MARROW MYELOPOIESIS INDEPENDENTLY OF CANONICAL NOTCH SIGNALING

**Background:** Notch signaling is a highly conserved pathway important in multiple developmental processes. Canonical signaling through all Notch receptors converges on the CSL transcription factor recombination signal binding protein for immunoglobulin kappa J region (Rbpj). In haematopoiesis, Notch is critical for the development of the haematopoietic stem cells (HSCs) in the embryo and in thymic T cell development. Contrastingly, canonical Notch signaling has been shown to be dispensable for HSC homeostasis in the adult bone marrow (aBM). Recent studies have however suggested a role of Notch in promoting megakaryocyte (Mk) and erythroid (E) development, as well as in suppressing granulocyte-macrophage (GM) progenitor expansion and acting as a tumor-suppressor in myeloid malignancies. However, these findings were largely made through genetic approaches potentially also affecting regulatory pathways other than Notch signaling. Moreover, whether dual inhibition of Notch1 and 2 could ever affect the normal lifespan of mice has never been addressed.

**Aims:** To unambiguously investigate the role of canonical Notch signaling in aBM myeloipoiesis, in steady-state and following transplantation.

**Methods:** BS-SLJDC45.1, Rbpj deficient mice were used. Flow cytometry (FACS) was applied for phenotypic analyses. Gene expression levels were measured by real-time reverse transcription PCR. MK, E and GM in vitro colony-forming potentials were applied in mouse colony assays. For transplantation studies, lethally irradiated recipients were competitively transplanted (1:1) and reconstitution assessed 7-9 weeks after transplantation.

**Results:** FACS staging of GM, Mk and E progenitors in aBM of old flanked Rbpj mice crossed to both Mx1-Cre, Vav-Cre and Vwf-eGFP BAC mice were used. Flow cytometry (FACS) was applied for phenotypic analyses. Gene expression levels were measured by real-time reverse transcription PCR. MK, E and GM in vitro colony-forming potentials were applied in mouse colony assays. For transplantation studies, lethally irradiated recipients were competitively transplanted (1:1) and reconstitution assessed 7-9 weeks after transplantation.

**E1110 DEVELOPMENT OF A 3-DIMENSIONAL CULTURE TO MIMICK THE BONE MARROW MICROENVIRONMENT AND RECAPITULATE DRUG RESISTANCE FOR IN VITRO STUDY**

**Background:** Chronic myeloid leukemia (CML) is a haematological malignancy caused by the acquisition of the BCR-ABL1 oncogene. Demonstration of the central role of BCR-ABL1 kinase activity in CML pathogenesis led to the development of 1-specific tyrosine kinase inhibitors (TKI). Most patients on imatinib attain good clinical and molecular responses, despite the persistent presence of a low level of therapy-refractory leukaemia stem cells (LSCs), which reside in the bone marrow niche. However, in a significant majority of patients these cells eventually provide a reservoir for disease relapse and subsequent malignant progression. A greater understanding of the biology of imatinib-resistant LSCs could therefore be of significant clinical benefit. One of the proposed mechanisms of drug resistance in CML LSCs is close contact with the surrounding microenvironment, however an in-vitro model of the bone marrow matrix is currently lacking.

**Methods:** Development of a 3-dimensional culture using fibre scaffolds to mimic bone marrow microenvironment in order to study the mechanism of resistance to anti-leukaemia agents.

**Results:** PMMA-based 3D scaffold and compared the growth of CML and AML cell lines grown in this scaffold in the presence of cytotoxic or targeted therapy to that of cells grown in 2D culture. PMMA-HA scaffold was not toxic to the leukaemia cells as primary AML cells and also K562 cells grew in the presence of scaffold and also concentrated around the scaffold.
fibres. Treatment of K562 or HL60 cells with imatinib or doxorubicin respectively resulted in a lower level of apoptosis in cells grown on the 3D scaffold compared to those grown in 2D culture. Further development of this 3D culture by adding stromal HS-5 to the scaffold reduced even further the sensitivity of K562 or HL60 to imatinib or doxorubicin, respectively.

Figure 1.

Summary/Conclusions: The relative resistance to either imatinib or doxorubicin that we observed in cells grown in 3D culture supports a role for the bone marrow matrix in the protection of leukaemic cells against chemotherapy agents. A combination of the PMMA-HA with HS-5 cells made this system more similar to the bone marrow microenvironment as this is a model in which all the basic components of the bone marrow microenvironment such as scaffold, stromal cells and cytokines (secreted by HS-5) are present. The results of this study show adding extra complexity to the microenvironment changes the sensitivity of the cells to therapeutic agents, better recapitulating the situation observed in-vitro. Three dimensional cultures using the PMMA-HA-HS-5 model may prove useful in the investigation of therapy resistance in leukaemia and for the discovery of new agents capable of eradicating quiescent leukaemic stem cells.

E1113

WHOLE EXOME SEQUENCING REVEALED SEQUENTIAL GAIN OF MUTATIONS IN TWO CASES OF DONOR CELL HAEMATOPOETIC TRANSPLANTATION MALIGNANCY AFTER HEMATOPOETIC TRANSPLANTATION J. Suárez González1,2, C. Martínez-Laperche2,3, M. Kwon2,3, G. Rodríguez-Macias3, A. Figuera4, A. Balas5, N. Martínez6, P. Balsalobre2,3, D. Serrano2,3, M.Á. Piris6,7, J.L. Vicario5, J. Gayoso2,3, J.L. Díez2,3, I. Buño1,2,3

Background: Santander, Spain

Methods: Case 1: A 43-year-old female diagnosed with lymphoblastic leukaemia- B (11;19), who developed acute myeloid leukemia (AML) with normal karyotype, NPM1+ of donor origin 16 months after unrelated cord blood transplantation (UCBT). Case 2: A 65-year-old male diagnosed with mantle cell lymphoma, who developed acute myeloid leukemia from his HLA-identical brother. WES (SureSelect-XT Human-exon 50Mb) was performed by next generation sequencing (HiSeq) on donor stem cells (SCs) infused as well as on BM samples from recipient after allo-HSCT. The exome of donor SCs and BM samples, from case 1, were aligned to the human reference genome (GRCh 37/hg19) and donor SCs and 9 BM samples were aligned to GRCh 38/hg38 in the second case.

Results: WES analysis revealed progressive emergence of multiple somatic mutations probably related to the development of leukaemia in bone marrow samples post allo-HSCT (Figure 1). Both SCs showed alterations that may be involved in leukaemogenesis. (Case 1: SH2B3 and case 2: KMT2C, KMT2A, ARHGAP26 and monosomy 7). Somatic mutations, acquired over time, fall into genes that play well-established roles in signalling pathways. Mutations in leukemic subclones that disappear after chemotherapy were indentified, as well as the acquisition of new mutations in resistant subclones. We propose a possible model of leukaemogenesis in these cases (Figure 2).

Summary/Conclusions: The present study reveals a process of sequential clinical (transitions), promoted by the acquisition of additional distinct somatic mutations in donor hematopoietic cells. Detection of heritable or acquired gene mutations in donor associated with predisposition to haematological malignancies could have clinical implications for the patients undergoing to allo-HSCT. Although the cause of donor cell derived haematological malignancy onset seems to be multifactorial, the infussion of a SCU with pre-leukemic potential in a context of transplant environment characterized by a decreased immune surveillance may well have played role in these cases. The study of a greater number of DCL cases by next generation sequencing could help to understand this process and to detect new mutations involved in the emergence of AML.

E1114

LEUKEMIC STEM CELL-RELATED MRNA EXPRESSION ANALYSIS USING A NOVEL FLOW CYTOMETRY-BASED ASSAY B. Depreter1,2,*, K. Vandepoele3, B. De Moerloose4, B. Denys3, J. Philippé1,3, T. Lammens2

1Department of Clinical Chemistry, Microbiology and Immunology, 2Department of Paediatric Haematology-Oncology and Stem Cell Transplantation, Ghent University, 3Department of Laboratory Medicine, 4Department of Paediatric Haematology-Oncology and Stem Cell Transplantation, Ghent University Hospital, Ghent, Belgium

Background: Gene expression analysis of protein-coding (mRNA) and non-coding RNA in paediatric and adult acute myeloid leukaemia (AML) has become of paramount importance for therapeutic decision-making, revealing prognostic information and for the identification of novel therapeutic targets. AML is a clinically, phenotypically and molecularly heterogeneous haematological malignancy, with different leukaemic cell populations organized in a hierarchical fashion, and leukaemic stem cells (LSCs) residing at the apex herein. Unfortunately, gene expression profiling is commonly performed on unfractinated bulk samples, leading to expression averaging of these heterogeneous cell populations. Multicolor flow cytometry (FCM) is capable of distinguishing heterogeneous cell populations based on the phenotypic characterization at a single-cell level. However, fluorochrome-conjugated antibodies are not available for intracellular RNA targets.

Aims: To evaluate the applicability of a novel flow cytometry-based technique, PrimeFlow™ RNA assay, to measure cell-of-interest RNA expressions in heterogeneous AML samples.

Methods: Technical assessment was performed using six neuroblastoma cell lines with varying levels of MYCN gene amplification. Correlation to expression data obtained by the gold standard RT-qPCR, performance in rare (0.1%) cell populations, effects of cryopreservation and off-target effects were evaluated. Next, diagnostic material of de novo AML patients was used to measure target gene (Wilms' tumour 1 (WT1)) and reference gene (RPL13a, GAPD) expression. Expression analysis was performed in unfractinated bulk leukemic cells as well as blasts and rare subsets of leukemic cells, e.g. LSCs. FCM analyses were performed on a FACSCount II (BD Biosciences) with set-up according to EuroFlow guidelines. Infinicyt™ (Cyognos®) was used for data analysis and mean fluorescence intensities (MFI) values (with/without normalisation) were interpreted. P-values < 0.05 were considered significant.

Results: mRNA expression quantified by PrimeFlow™ significantly correlated with data obtained by RT-qPCR and remained detectable in rare (0.1%) cell populations. WT1 expression was shown to be statistically significantly higher in bulk leukemic cells of those patients characterized by WT1 overexpression, as defined by RT-qPCR, showing a mean 52% MFI upregulation by PrimeFlow™ if WT1 was overexpressed as present, as shown by the gold standard RT-qPCR. Moreover, WT1 overexpression could be detected within heterogeneous cell populations, e.g. the CD34+CD38+ cell population and the LSC (defined as CD34+CD38+), showing a 63% and 45% MFI upregulation, respectively, compared to patients with normal WT1 expression levels, although only statistically significant in 11/19 cases. The expression of WT1 was statistically significantly higher in CD34+CD38+ cells compared to LSCs.

Figure 1.

Methods: Case 1: Patient 1: 5 BM samples were aligned to GRCh 37/hg19 in the first case and 9 BM samples were aligned to GRCh 38/hg38 in the second case. Case 2: WES (SureSelect-XT Human-exon 50Mb) was performed by next generation sequencing (HiSeq) on donor stem cells (SCs) infused as well as on BM samples from recipient after allo-HSCT. The exome of donor SCs and 5 BM samples, from case 1, were aligned to the human reference genome (GRCh 37/hg19) and donor SCs and 9 BM samples were aligned to GRCh 38/hg38 in the second case.

Results: WES analysis revealed progressive emergence of multiple somatic mutations probably related to the development of leukaemia in bone marrow samples post allo-HSCT (Figure 1). Both SCs showed alterations that may be involved in leukaemogenesis. (Case 1: SH2B3 and case 2: KMT2C, KMT2A, ARHGAP26 and monosomy 7). Somatic mutations, acquired over time, fall into genes that play well-established roles in signalling pathways. Mutations in leukemic subclones that disappear after chemotherapy were indentified, as well as the acquisition of new mutations in resistant subclones. We propose a possible model of leukaemogenesis in these cases (Figure 2).

Summary/Conclusions: The present study reveals a process of sequential clinical (transitions), promoted by the acquisition of additional distinct somatic mutations in donor hematopoietic cells. Detection of heritable or acquired gene mutations in donor associated with predisposition to haematological malignancies could have clinical implications for the patients undergoing to allo-HSCT. Although the cause of donor cell derived haematological malignancy onset seems to be multifactorial, the infussion of a SCU with pre-leukemic potential in a context of transplant environment characterized by a decreased immune surveillance may well have played role in these cases. The study of a greater number of DCL cases by next generation sequencing could help to understand this process and to detect new mutations involved in the emergence of AML.
Summary/Conclusions: Key mRNA target expressions in AML, e.g. WT1 gene expression, could be evaluated using PrimeFlow™ RNA assay, including rare and heterogeneous cell populations herein, e.g. LSCs. This study demonstrates that PrimeFlow™ is a technique of interest for the discovery of novel LSC-specific targets.

POTENTIAL PREDISPOSING GERMLINE MUTATIONS IN PATIENTS WITH CONCOMITANT MYELOID AND LYMPHOID MALIGNANCIES
F. Asmar1,*, M. Munk-Johansen1, T.C. El-Galaly2, H.E. Johansen2, C. Westmose Yde3, D. El Fassi4, K. Grenbæk1
1Department of Hematology, Rigshospitalet, Copenhagen, 2Department of Hematology, University hospital of Aalborg, Aalborg, 3Center of Genomic Medicine, Rigshospitalet, Copenhagen, 4Department of Hematology, University Hospital Herlev and Gentofte, Herlev, Denmark

Background: Recent findings have suggested that mutations predisposing the development of either acute myeloid leukemia (AML) or chronic lymphocytic leukemia (CLL) may arise in pre-leukemic hematological stem cells. In addition, genes involved in epigenetic regulation, such as TET2, and DNA processing, such as SFB3, are mutated in both myeloid and lymphoid malignancies. This could indicate a possible genetic link between myeloid and lymphoid malignancies. Therapy related AML (t-AML) is a known complication to treatment with cytotoxic drugs such as alkylating agents and topoisomerase inhibitors.

Methods: We aimed to identify mutations in patients with concomitant AML and diagnosis of de novo AML or myelodysplastic syndrome (MDS) and in patients with concomitant therapy-related AML (t-AML) and CLL.

Results: Three patients with de novo AML and CLL, one patient with MDS and CLL, one patient with chronic myelomonocytic leukemia (CMML) and CLL, and two patients with t-AML and CLL. The patients’ diagnoses were based on the evaluation of the morphology, immunohistochemistry, cytogenetics, and flow cytometry analysis in accordance with the WHO classification.

Aims: In this study, we aimed to investigate a possible common genetic origin of hematological cancers in patients with concomitant CML and de novo AML or myelodysplastic syndrome (MDS) and in patients with concomitant therapy-related AML (t-AML) and CLL.

Background: Recent findings have suggested that mutations predisposing the development of either acute myeloid leukemia (AML) or chronic lymphocytic leukemia (CLL) may arise in pre-leukemic hematological stem cells. In addition, genes involved in epigenetic regulation, such as TET2, and DNA processing, such as SFB3, are mutated in both myeloid and lymphoid malignancies. This could indicate a possible genetic link between myeloid and lymphoid malignancies. Therapy related AML (t-AML) is a known complication to treatment with cytotoxic drugs such as alkylating agents and topoisomerase inhibitors. The susceptibility of developing t-AML has been associated with variation in DNA-repair pathways, drug metabolism and transport.

Aims: In this study, we aimed to investigate a possible common genetic origin of hematological cancers in patients with concomitant CML and de novo AML or myelodysplastic syndrome (MDS) and in patients with concomitant therapy-related AML (t-AML) and CLL.

Methods: The presence of concomitant lymphoid and myeloid malignancies in patients is rare, however we managed to include 3 patients with de novo AML and CLL, one patient with MDS and CLL, one patient with chronic myelomonocytic leukemia(CMML) and CLL, and two patients with t-AML and CLL. The patients’ diagnoses were based on the evaluation of the morphology, immunohistochemistry, cytogenetics, and flow cytometry analysis in accordance with the WHO classification. For each patient mononuclear cells (MNCs) from blood or bone marrow were isolated using Ficoll gradient centrifugation and used for fluorescence activated cell sorting (FACS) of the malignant clones and the T-cells. Paired exome sequencing (2x150) aiming for an average coverage of 50-100x was performed using either the HiSeq2500 or NextSeq500 platforms from Illumina. Raw sequencing data was processed using CASAVA 1.8.2. Mapping to the human genome (hg19/GRCh37 UCSC) was performed using CLC Biomedical Genomics Workbench (Qiagen) mapping cell software. Variants with a frequency of 5% or above were called.

Results: Identified possible pre-existing germline mutations in all 7 patients by comparing variants between the myeloid malignant clone, CLL cells, and T cells, as well as using saliva to aid in characterizing the mutations as present in the germline and/or in the hematological compartment. In all the patients except one with de novo AML and CLL, we identified a potential damaging germline variant in a DNA-repair related gene, such as ATM (387dupA, D130fs*4), SMARCA1 (2114C>T, T705I), HELQ (393_397delAGGTG, D132fs*16), SWI5 (652C>T, R218*), LIG1(2168A>G, Q761R) and PRKDC(802G>A, G301Y). In the remaining patient with concomitant de novo AML and CLL, we identified a potential damaging germline variant in an epi- genetic regulator believed to play a role in normal and malignant hematopoiesis, KDM2B. De novo AML and CLL, we identified a potential damaging germline variant in an epigenetic regulator believed to play a role in normal and malignant hematopoiesis.

Figure 1. Aims: We aimed to compare here the locations and types of mutations identified in AML and in CHIP in the DNMT3A gene by several different studies.

Results: When DNMT3A mutations in CHIP were compared to mutations in AML the R882 residue was found to be the most frequently mutated residue in both AML and CHIP. Figure 1 clearly illustrates the mutations in comparison to AML. However, only 13% of all reported mutations were found at the R882 residue in CHIP, while in AML 60% DNMT3A mutations are found at the R882H mutations.

Summary/Conclusions: Analysis of the mutational landscape of CHIP has clearly highlighted the role of DNMT3A mutations in clonal hematopoiesis in older healthy individuals, the significance of such preleukaemic clones is yet to be determined.

NEXT-GENERATION REFERENCE INTERVALS FOR PEDIATRIC HEMATOLOGY
J. Zierk1,*, J. Hirschmann2, D. Toddenroth2, F. Arzidech3, T. Streichert4, R. Haeckel5, H.-U. Prokosch2, M. Rauh1, M. Metzler1
1Department of Pediatrics and Adolescent Medicine, University Hospital Erlangen, 2Chair of Medical Informatics, Friedrich-Alexander-University Erlangen-Nuremberg, Erlangen, 3Department of Statistics, University of Bremen, Bremen, 4Department of Clinical Chemistry, University Hospital of Cologne, Cologne, 5Bremer Zentrum für Laboratoriumsmedizin, Klinikum Bremen Mitte, Bremen, Germany

Background: Interpretation of hematology analytes in children is challenging due to extensive changes in hematopoiesis with age leading to pronounced sex- and age-specific dynamics. To facilitate clinical decision making based on quantitative hematology test results, reference intervals are used to classify samples according to upper and lower limits, and age-related change is represented using reference intervals partitioned into separate age groups. However, this approach can only approximate the continuous physiological dynamics of hematological analytes in childhood and does not enable appropriate quantification of test results in relation to the reference distribution. Conversely, percentile charts as used in anthropometric quantities (e.g. pediatric weight-for-age charts) would allow adequate appreciation of pediatric hematology test results. However, the ethical and practical challenges unique to pediatric reference intervals have restricted the creation of such percentile charts, and limitations in current approaches to laboratory test result display prevent their integration into clinical decision making.

Aims: To create percentile charts for hematology analytes from birth to adulthood using a data-mining approach and to demonstrate their integration into clinical care with benefits in clinical decision making.
Methods: We applied a data-mining algorithm to generate percentile charts for hematology analytes using laboratory data collected during the clinical care of patients. A total of 9,517,245 samples from 343,463 patients (72,614–337,011 samples per analyte) from 8 German tertiary care centers and 2 German laboratory service providers were examined. Percentile charts were calculated using an established statistical approach which extracts the proportion of samples from healthy individuals from the unfiltered input dataset containing both non-pathologic and pathologic samples. To evaluate the clinical benefit of hematology test result interpretation using percentile charts, accuracy and speed of pediatricians assessing eight different predefined clinical situations were measured in comparison to conventional test result representations.

Results: We created percentile charts for hematology analytes in girls and boys from birth to 18 years which can be used as common reference intervals. Results are provided for hemoglobin, hematocrit, red cell indices, red cell count, red cell distribution width, white cell count, and platelet count, example charts for hemoglobin, mean corpuscular volume, and platelet count are shown in the accompanying figure. A web application at www.pedref.org/hematology demonstrates hematology test result interpretation using percentile charts and z-scores with special consideration of pediatric dynamics. Comparison of pediatricians’ decision times when assessing different clinical scenarios using percentile charts and conventional representations shows more correct decisions (75.9% vs 68.4%, p<0.01) which are made in shorter time (2.7 s vs 3.8 s, p<0.01) when using percentile charts.

Summary/Conclusions: The created percentile charts enable the appropriate differential diagnosis of changes in hematology analytes due to disease and changes due to physiological development. Integration of suitable forms of result reporting using the provided percentile charts into clinical decision making improves assessment of the unique dynamics in pediatric hematology.

GROWTH FACTOR INDEPENDENCE 1 (GFI1) REGULATES THE AML SUPPORTING FUNCTION OF MESENCHYMAL STROMAL CELLS

Y. Al-Matary1,*, L. Botezatu1, A. Thivakaran1, R. Köster1, J. Schütte1, J. Göthert1, U. Dührsen1, B. Opalka1, C. Khandanpour1

1University Hospital of Essen/ West centre of tumor, Essen, Germany

Background: Mesenchymal stromal cells (MSCs) harbor and support the function of normal hematopoietic stem cells. Less is known about their interaction with leukemic cells, e.g. in acute myeloid leukemia (AML). The prognosis of AML, a clonal malignant disease of the bone marrow (BM), is still poor with only 25% of patients living longer than 5 years.

Aims: In the current study, we investigated the interaction between MSCs and AML cells, and we also investigated the underlying molecular mechanism.

Methods: We used cell cultures using primary cells from human and mice and cell lines of MSCs and AML cells. Different Mouse models of human AML were used in our study to confirm the results obtained from human sample. MSCs were characterized by differentiation assay, flow cytometry and RT-PCR. Matrigel test was also applied in this study.

Results: MSCs from AML patients called AML-associated MSCs (AMSCs) or from murine models of human leukemia enhance significantly in vitro the growth of leukemic cells compared to AML cells growing without MSCs or in presence of MSCs from non-leukemic patients or mice. Among other, AMSCs increased entry of leukemic cells into the cell cycle, and at the same time protected the leukemia cells against exogenous toxic events such as chemotherapy or irradiation. The interaction between AMSCs and leukemia cells is dependent on cell-to-cell contact. In vivo, absolute and relative numbers of AMSCs and other stromal cells, i.e. endothelial cells and osteoblast lineage cells were highly expanded in the BM of mice modeling of human AML. AMSCs showed a higher efficiency of capillary tube formation in the matrigel assay than normal MSCs which gives an additional indication that AMSCs were polarized by leukemia cells towards a tumor-supporting state. On a molecular level, the polarization of MSCs towards an AML-supporting state depends on upregulated expression of the transcription factor Growth factor independence 1 (Gfi1). Loss of Gfi1 diminished the tumor-supporting state of AML-associated MSCs.

Summary/Conclusions: We conclude that leukemia cells polarize AMSCs towards a leukemia-supporting state in a Gfi1-dependent manner, which could open the way to new therapeutic approaches.
BASELINE LEUKOCYTE AND EOSINOPHIL COUNTS PREDICT OUTCOME IN RELAPSED OR REFRACTORY CLASSICAL HODGKIN LYMPHOMA PATIENTS TREATED WITH PD1 INHIBITION

I. Hude1,2,*, S. Sasse2, P.J. Broeckelman1, M. von Tresckow2, J. Momotow2, A. Engert1, S. Borchmann2
1Department of Internal Medicine, Division of Hematology, University Hospital Center Zagreb, Zagreb, Croatia, 2German Hodgkin Study Group (GHSG), First Department of Internal Medicine, University Hospital Cologne, Cologne, Germany

Background: Despite encouraging efficacy of anti-PD1 antibodies in relapsed or refractory (rrt) classical Hodgkin lymphoma (cHL), not all patients achieve a lasting response, with few complete remissions (CR) observed. Thus, identification of predictive biomarkers is important. Recently, two models using readily available differential blood count parameters have been suggested to predict outcome in melanoma patients treated with immune checkpoint inhibition.

Aims: In this study, we aimed to identify baseline differential blood count parameters associated with response and progression free survival (PFS) in rtt cHL patients treated with anti-PD1 antibody nivolumab.

Methods: We retrospectively investigated baseline differential blood count parameters and their association with response and progression free survival (PFS) in 30 rtt cHL patients treated with the anti-PD1 antibody nivolumab. All 30 patients had previously received multiple lines of treatment, including treatment with high dose chemotherapy followed by autologous stem cell transplant (ASCT) for rrt disease; the median number of prior treatment lines was 5 (2–11) and 21 patients received prior brentuximab vedotin. To investigate the association of baseline blood count parameters (white blood cell count (WBC), relative monocyte count (RMC), relative neutrophil count (RNC), relative lymphocyte count (RLC) and relative eosinophil count (REC)) with outcome after PD1 inhibition, we used the last differential blood count performed immediately prior to the first received dose of nivolumab.

Results: RMC, RNC and RLC did not have a prognostic impact on PFS, whereas higher WBC ≥ 7.78x10³/µl and lower REC<1.7% were associated with worse PFS in both univariate and multivariate analysis. We constructed a simple score to prognosticate PFS. By adding 1 point each for WBC ≥ 7.78x10³/µl and REC<1.7% to the score, we could clearly differentiate a low (score=0), intermediate (score=1) and high risk (score=2) group for disease progression (median PFS (days): 197 [50–NA]). Evaluation of best response achieved according to the initial risk score showed a trend towards higher CR-rates in low risk group, but was not significant.

Results: ROC curves and sequential cut-offs (1.8–3.5 by 0.1 increments) were used to explore the potential impact of b2m on PFS and OS.

Methods: We analyzed 864 patients with HL treated with ABVD/C T/C early stage patients, with 10-year FFP of 99% (p=0.001). In advanced stages, b2m emerged as an independent prognostic factor for FFP post-adjustment for IPS factors, ESR and B-symptoms at both 2.1mg/L (HR 2.00, p=0.01) and 2.4mg/L (HR 2.14, p=0.01). In a 2.4mg/L cut-off, the 10-year FFP was 81% vs 71% (p=0.003). However, the best cut-off was the observed median value of this series, calculated at 2.1mg/L, with 10-year FFP of 84% vs 71% (p=0.0001). In early stages (IA/IIA) significant results were obtained at cut-offs between 1.8 and 2.1mg/L. The best cut-off was 1.9mg/L, a close approximation of the median b2m level of early stage patients, with 10-year FFP of 99% vs 78% (p=0.003). In advanced stages, none of the cut-offs yielded statistically significant results (borderline at 2.0mg/L, 10-year FFP 77% vs 67%, p=0.057). Multivariate Analysis: B2m levels remained significant for FFP after adjustment for IPS factors, ESR and B-symptoms at both 2.1mg/L and 2.4mg/L cut-offs (hazard ratio (HR) 1.78, p=0.001 and 1.41, p=0.04 respectively). ROC curves and sequential cut-offs (1.8–3.5 by 0.1 increments) in the whole series of 864 patients were used to explore the potential impact of b2m on FFP and OS.

Results: We analyzed 864 patients with HL treated with ABVD+C T/C (1990–2016) and selected solely based on the availability of pretreatment b2m levels. B2m [P1] levels (upper normal limit 2.4mg/L) were analyzed according to other baseline features and prognostic factors as well as according to the outcome. Freedom From Progression (FFP) was defined as time between treatment initiation and treatment failure (primary refractoriness, PR with switch to alternative CT or relapse); deaths of unrelated causes were censored. Overall Survival (OS) was measured from treatment initiation to death of any cause. ROC curves and sequential cut-offs (1.8–3.5 by 0.1 increments) were used to explore the potential impact of b2m on FFP and OS.

Results: The median follow-up for currently living patients was 88 months. Univariate Analysis: FFP was significantly inferior in patients with higher b2m at all tested cut-off points. At 2.4mg/L (normal versus elevated) the 10-year FFP was 81% vs 71% (p=0.003). However, the best cut-off was the observed median value of this series, calculated at 2.1mg/L, with 10-year FFP of 84% vs 71% (p=0.0001). In early stages (IA/IIA) significant results were obtained at cut-offs between 1.8 and 2.1mg/L. The best cut-off was 1.9mg/L, a close approximation of the median b2m level of early stage patients, with 10-year FFP of 99% vs 78% (p=0.003). In advanced stages, none of the cut-offs yielded statistically significant results (borderline at 2.0mg/L, 10-year FFP 77% vs 67%, p=0.057). Multivariate Analysis: B2m levels remained significant for FFP after adjustment for IPS factors, ESR and B-symptoms at both 2.1mg/L and 2.4mg/L cut-offs (hazard ratio (HR) 1.78, p=0.001 and 1.41, p=0.04 respectively). ROC curves and sequential cut-offs (1.8–3.5 by 0.1 increments) in the whole series of 864 patients were used to explore the potential impact of b2m on FFP and OS.

Results: We analyzed 864 patients with HL treated with ABVD+C T/C (1990–2016) and selected solely based on the availability of pretreatment b2m levels. B2m [P1] levels (upper normal limit 2.4mg/L) were analyzed according to other baseline features and prognostic factors as well as according to the outcome. Freedom From Progression (FFP) was defined as time between treatment initiation and treatment failure (primary refractoriness, PR with switch to alternative CT or relapse); deaths of unrelated causes were censored. Overall Survival (OS) was measured from treatment initiation to death of any cause. ROC curves and sequential cut-offs (1.8–3.5 by 0.1 increments) were used to explore the potential impact of b2m on FFP and OS.
The objective of the present study was to evaluate the significance of PET in elderly patients with HL.

Methods: All consecutive patients (age ≥60) diagnosed with HL between 1998-2016 were retrospectively reviewed in this multi-center study. Baseline characteristics as well as PET-CT results at diagnosis, interim analysis and end of treatment (EOT) were recorded and analyzed. PET-CT results were classified as no evidence of disease (NED), partial response (PR), stable disease (SD) and progressive disease (PD).

Results: Ninety five patients from 5 centers were identified. Median age was 71 (range 60-89) years. Subtype was nodular sclerosis in 48% and mixed cellularity in 23%. Sixty three (65%) patients had advanced disease and mean international prognostic score (IPS) was 3.5±1.4. Fifty nine (63%) patients received 1st line treatment with ABVD, in 13 (14%) chemotherapy was followed by involved field radiotherapy. At EOT, sixty seven (82%) patients achieved OS, 6% (7%) achieved PR, 10 (11%) were primary refractory and 2 (2%) died during treatment. Fifteen (16%) patients experienced relapse. Five years PFS and OS were 56% and 78%, respectively. ABVD treated patients had 5 year PFS and OS of 59% and 82% as opposed to 48% and 68% for all other regimens, but these differences were not statistically significant. Seventy two (76%) patients had undergone both PET and EOT-PET. 50 patients had NED on PET, 20 had PR, 1 SD and 1 PD. NED EOT-PET was achieved in 47/50 (94%) patients who had NED PET, 12/20 (60%) patients who had PR PET and none of the patients with SD/PD PET (p<0.01). In patients with either NED or PR on PET, relapse occurred in 11 (15%) patients and 5 year PFS and OS were 62% and 85%, respectively. The 5 year PFS of these patients differed according to the depth of response on PET - 69% vs 45%, (p=0.02, fig. 1) in patients achieving NED vs PR, while 5 year OS did not reach statistical significance, 90% vs 71% (p=0.08). Restricted analysis, evaluating only 59 patients who were treated with ABVD, showed similar results with 84% of NED PET vs 45% of PR PET achieving NED on EOT-PET (p<0.01). Outcome differed according to the depth of response in PET with 5 year PFS rates of 74% vs 34%, in patients achieving NED vs PR, respectively (p=0.01). 5 year OS rates were 92% vs 76%, in patients achieving NED vs PR (p=0.1).

Summary/Conclusions: We present a cohort of elderly patients with HL, most were treated with ABVD. Outcome was comparable or even superior to previously published cohorts. Traditional outcome measures for HL have not been extensively validated in the elderly. PET and EOT-PET, known to be highly predictive for PFS in young HL patients, appeared to be highly predictive in elderly individuals. The improved prognosis, suggested by our results, may be related to the high rate of PET which was used in this cohort. The importance of this tool in HL in the elderly is emphasized by the diminished prediction power of the traditional outcome measures in elderly HL patients.

Figure 1.

Summary/Conclusions: High-dose bendamustine plus brentuximab has shown relevant efficacy and a relatively good safety profile in a setting of heavily pretreated patients with HL. Adequate monitoring of CMV reactivation is recommended. This combination could be considered as a bridge to second autologous or allogeneic SCT. However, these results should be validated by controlled and prospective studies involving larger number of patients.

Figure 1.

Summary/Conclusions: High-dose bendamustine plus brentuximab combination is effective and has a favourable toxicity profile in the treatment of refractory and relapsed Hodgkin lymphoma.

Background: The management of patients with refractory or relapsed Hodgkin lymphoma (HL), especially after autologous stem cell transplantation (ASCT), remains controversial. Bendamustine has demonstrated efficacy in several lymphoproliferative disorders but limited data are available regarding the schedule in patients with HL, in particular its dosage and the possible combinations for a synergistic effect. Brentuximab Vedotin is a CD30-directed antibody-drug conjugate, currently approved for the treatment of relapsed or refractory HL.

Aims: The objective of this retrospective observational trial was to evaluate efficacy and safety of salvage cytotoxic regimens in patients with refractory and/or relapsed HL. Three different regimens were evaluated.

Methods: From May 2011 to December 2016, 32 consecutive patients (19 M/13 F) with a median age of 31.7 years (range, 16-73) received a salvage regimen after failure of ASCT. Patients were by chance assigned to one of these three arms: standard dose bendamustine (90mg/sqm) days 1 and 2 plus standard DHAP schedule (every 4 weeks) x 3 cycles (Arm A, n= 10 cases), brentuximab single agent 1.8mg/kg (every 3 weeks) x 4-8 cycles (Arm B, n= 11 cases), high dose bendamustine (120mg/sqm) days 1 and 2 plus brentuximab 1.8mg/kg (day 3) x 4-6 cycles (Arm C, n= 11 cases). Each cycle in arm C was repeated every 28 days and growth factor support was systematically administered, in association with antimicrobial prophylaxis. The treatment efficacy in each arm was evaluated according to Revised Response Criteria for Malignant Lymphoma by Cheson et al. Adverse events occurred were recorded and classified for type and grade using NCI-CTCAE criteria (v.4.0).

Results: In arm A, the overall response rate (ORR) was 40% (4/10 patients), with 4 (40%) complete remission (CR) and 6 (60%) progressive disease (PD). Hematological toxicity was grade 3 thrombocytopenia in 4 patients (40%) and bone marrow aplasia in 1 patient (10%); extra-hematological toxicity was gastrointestinal toxicity of grade 2 in 6 patients (60%) and grade 1 in 3 patients (30%). In arm B, ORR was 60% (7/11 patients), with 5 (45%) CR, 2 (18%) partial response (PR) and 4 (36%) PD. Hematological toxicity was grade 2 neutropenia in 4 patients (36%), extra-hematological toxicity was grade 3 neuropathy in 2 patients (18%). In arm C, ORR was 100% (11/11 patients), with 11 CR followed by SCT (second autologous transplant, 6 cases; and haploidentical transplant, 5 cases) with persistence of complete remission in all patients at a median follow-up of 33.4 months (range, 12-60). Hematological toxicity was grade 3 thrombocytopenia in 4 patients (36.3%); extra-hematological toxicities were increase of transaminase (grade 2) in 2 patients (27%) and cytomegalovirus (CMV) reactivation in 2 patients (18%), treated successfully with valganciclovir. Three patients had fever during infusion at first cycle, together with a skin rash, managed with corticosteroid injections, and a successful antihistamine plus corticosteroid prophylaxis in the next cycles of treatment.

Figure 1.
Rome, 2Clinica di Ematologia, AUO Ospedali Riuniti Università Politecnica delle Marche, Ancona, 3assoiazione Onlus Gemme dormienti, 4Unità di ginecologia, Ospedale San Carlo di Nancy, Rome, Italy

Background: In the last decades, Hodgkin and Non-Hodgkin Lymphoma (HL-NHL) therapies have resulted in high cure rates and increased survival. However, patients treated with EBV or cytotoxic late toxicities, such as, gonadal toxicity that can result in permanent sterility.

Aims: to evaluate different aspects of fertility (menstrual status, pregnancy, and menopause) in women with HL and NHL in reproductive age before and after chemotherapy.

Methods: By phone interview we administered a questionnaire to the patients. The interview was composed of questions concerning reproduction (pregnancies, menses and abortion) and also menopausal status. The analyses were made using data collected in a cohort 109 women patients from two Italian hematologic centers. Statistical analysis was carried out in Graphpad® system, data were compared by the chi-square (P value <0.05) to be statistically significant.

Results: the median age (in years) at the time of the treatment was 31 (range 16-49), 69/109 (63%) had HL and 40/109 (37%) NHL, 74/109 [ES1] (64%) of the patients had a stage I-II. All HL patients were treated with ABVD, whereas the NHL patients were treated with R-CHOP (20%) or similar regimens (16%), respectively. Radiotherapy was delivered to the 62/109 (57%) of the sample. Complete Remission (CR) was obtained by the 101/109 (93%) and only 16/101 (16%) relapsed. Considering the gynecologic history of the patients there were no statistically significance difference between the regularity of menses and the event of an abortion pre and post treatment. As for pregnancies, 35% of patients had children before therapy and 17% after. Among these 109 patients, 68/109 (62%) received gonadotropin-releasing hormone (GnRH) analogues and/or oral contraception, while 41 (38%) were not treated with hormonal therapy. Among the 68 patients who received hormonal therapy regular menses recovered in 51/68 (76%) in 6 months and in those of the control group a recover of menses was observed in 20/41 (48%). This difference was statistically significant (P<0.05). The same was observed as for early menopause. In this case excluding patients who had a natural menopause, a lower cases of early menopause was observed in those who received hormone therapy (6/85, 7% vs 11/20, 55%); P<0.05. Considering only the 81/109 (74%) patients who had regular menses after chemotherapy, 61/81 (75%) received hormonal therapy and 20/81 (25%) were not treated with hormonal therapy. Before treatment for lymphoma, 16% of patients belonging to the hormonal group had pregnancies versus 45% of the control group (P<0.05). Following therapy, pregnancies were observed in 23% of those receiving hormonal therapy vs 5% of the control group (P<0.05).

Summary/Conclusions: The use of hormonal therapy is fundamental not only to favor of pregnancies and motherhood but in particular to avoid the consequences of an irregular cycle or an early menopause with its symptoms and clinical implications.

NODULAR LYMPHOCYTE PREDOMINANT HODGKIN LYMPHOMA: A NEW RISK ADAPTED TREATMENT STRATEGY BASED ON RITUXIMAB

R. Della Pepa 1,*, M. Picardi 1, C. Giordano 1, I. Zacheo 1, N. Pugliese 1, C. Cerchione1, F. Pane 1

1Hematology, Federico II University, Naples, Italy

Background: Nodular lymphocyte-predominant Hodgkin lymphoma (NLPHL) is a rare variant of Hodgkin’s lymphoma (HL), that only accounts for 5% of all HL. Due to its rarity, consolidated and widely accepted guidelines of treatment still lack for this type of HL. Due to NLPHL cells expression of CD20, targeted therapy with Rituximab (R), a chimeric anti-CD20 monoclonal antibody, has been explored as a treatment option.

Aims: This study analyzed two different risk-adapted therapeutic strategies to cure patients newly diagnosed with NLPHL. The aim was to compare the efficacy and safety of the conventional chemotherapy plus irradiation versus the R-including treatment of patients with NLPHL.

Methods: Within a retrospective study, we collected the medical records of 24 consecutive adult patients with NLPHL, taken from the total of 484 patients with HL, who referred to our institution from 1 October 2001 to 31 July 2014. According to our institutional guidelines, the 12 patients diagnosed from October 2001 to November 2007 received a treatment based on ABVD with/without involved-field radiotherapy (IFRT). Treatment was modulated according to the stage. The 9 patients with stages I and II received 4 courses of ABVD plus IFRT, while 3 patients in stages III or IV received 6 cycles of ABVD. The subsequent 12 patients (diagnosis from December 2007 to July 2014) received R (375mg/m²) alone or combined with ABVD. The stage-adapted strategy of therapy was applied for these patients, as well. The 5 patients with early favourable disease according to the stage and baseline EORTC risk factors, received R as single agent (once per week for four consecutive weeks) followed by R maintenance (MR) (once every three months for 2 years); the 2 patients with early unfavorable stage were treated with R (once per month on day 1) plus 4 cycles of ABVD, while the remaining 5 advanced stage patients received R (on day 1 and 15) plus ABVD for 6 weeks. The primary end-point was DFS rate, and secondary end-points were ORR and treatment-related toxicity evaluation.

Results: At final restaging, 4 weeks after the cycle of treatment or completion of IFRT, 23/24 patients (95.8%) were in CR while one patient showed refractory disease and was addressed to rescue therapy with autologous hematopoietic stem cell transplantation. There were no statistically significant differences in OS between the 2 groups. However, DFS was significantly higher in the R-adapted arm than in the conventional arm (P=0.021).

Summary/Conclusions: The R-adapted strategy resulted in a significantly better DFS rate compared to the conventional therapy. Further investigation is needed to confirm these results in a larger study population.
stem cell transplantation (ASCT). Patients treated with R alone or R+ABVD had better DFS (p=0.04) than those treated with ABVD with/without IFRT. Specifically, the year Kaplan-Meier estimates for DFS were 100% for the R treated group versus 50% for those treated with ABVD with/without IFRT. Four patients in the latter group, showed insufficient response to the therapy: 1 refractory disease in the early stage group and 3 recurrent diseases in the advanced stage group were recorded. The median follow-up time of the entire cohort of patients was 4.3 years (range, 0.5-8.2 years). Over the study period, one patient died for infectious pneumonitis due to severe neutropenia following the last cycle of R-ABVD. Of the 9 patients treated with addition of IFRT, adverse events regarded mainly thyroid (4), bone (2), lung (1) and salivary glands (1).

Nobody developed a secondary malignancy.

Summary/Conclusions: Our results confirm the value of R in NLPHL and show that R induction and maintenance combined with chemotherapy only in the presence of risk factors or in more advanced stages give excellent treatment results. Radio-conventional radio-chemotherapy either in term of ORR and of DFS while sparing long term toxicity usually seen in patients affected by classical HL who receive chemo and irradiation.

E1126

CASE-BASED LEARNING IN CONTINUING EDUCATION: IMPROVING HEMATOLOGIST/ONCOLOGIST EVIDENCE-BASED DECISIONS FOR PREVENTING HODGKIN LYMPHOMA POST-TRANSPLANT RELAPSE

P. Repetto1,*, C. Moskowitz2

1Oncology, Medscape, Groveville, 2Oncology, Memorial Sloan Kettering Cancer Center, New York, United States

Background: Several prognostic factors have been identified as associated with a higher rate of relapse after autologous stem cell transplantation (ASCT) for patients with Hodgkin lymphoma (HL). Due to the rarity of this disease, many hematologists/oncologists (hem/oncs), especially those in the community setting, lack experience in correctly identifying patients who may be at risk of post-transplant relapse. Proper risk assessment and understanding of treatment options in the pre- and post-transplant setting are critical to ensure optimal long-term progression-free survival for qualified patients.

Aims: Underlying clinical practice gaps and educational needs were identified, and a study was conducted to determine whether an online, case-based educational intervention could improve knowledge, competence, and confidence of hem/oncs in managing patients with HL.

Methods: The educational format presented patient case scenarios (2) followed by a series of 4-6 questions that “tested” learner knowledge and competence before delivering the education focused on the optimal approach to the case using evidence-based medicine. Case questions assessed degree of patient risk for disease relapse or progression prior to ASCT and consolidation strategies, taking into consideration patients’ prior received therapies. To assess educational effectiveness, participants served as their own controls by responding to a series of same questions again after (post-assessment) exposure to the content. For all questions combined, the McNemar’s chi-square test assessed differences from pre- to post-assessment. P values are shown as a measure of significance. P values <0.05 are statistically significant. Cramer’s V calculation determined the change in proportion of 184 participants who answered questions correctly from pre- to post-assessment and who qualified for the study.

Results: At post-assessment, there was a large effect to the education (V=0.442), indicating a sizable improvement in evidence-based choices and significant improvement in knowledge, competence, and confidence related to managing patients with HL, including: 138% relative improvement regarding the implications of type and number of prognostic factors on risk of HL relapse and benefit of consolidation brentuximab vedotin after ASCT (P<0.001); 101% relative improvement in knowledge that a higher rate of relapse after ASCT is associated with a CR duration of less than 1 year, extranodal disease at relapse, and the presence of symptoms at relapse (P<0.001); 5% relative improvement in knowledge regarding the efficacy of brentuximab vedotin in relapsed/refractory HL after ASCT (P<0.001); Responses to a self-efficacy question indicated that 42% of hematologists became more confident in managing patient on consolidation therapy for HL after participating in the education.

Summary/Conclusions: This study demonstrated the success of an online, case-based format using a predisposing pre/post-assessment was effective in improving the evidence-based practice patterns of hem/oncs in the management of patients with HL. Despite the marked improvement in knowledge, competence, and confidence, hematologist education needs specific to accurate risk assessment, treatment selection, and adverse effect monitoring remain. The education gaps uncovered during this intervention and the evolving treatment landscape outside of the United States lay a foundation for future global education initiatives to bridge education gaps in HL.

E1127

QUANTITATIVE PET PARAMETERS PREDICTS OUTCOME IN PATIENTS WITH HODGKIN’S LYMPHOMA

I. Kriačokį1,*, O. Novosad1, I. Pastushenko1, T. Skrypets1, T. Kadnikova1, I. Tytorenko1, E. Kushchevyvy1, K. Ulianchenko1, K. Filonenko1, Y. Stepanishyna1, Y. Kmetnyk2, O. Karpova2, L. Mykhalksa3, O. Kindrakevych3, G. Pylypenko4, E. Lukjanets4, V. Dumia4, V. Kozlova4, L. Batyuk1, O. Ryzhak1, N. Srembistska5, H. Chikalova6, M. Chuprynya1, I. Kozlov6

1Oncohematology, National Cancer Institute, 2Radiology, 3Hematology, Clinical Hospital “Feofaniya”, Kiev, 4Hematology, Regional Oncology Center, Cherkassy, 5Hematology, Regional Clinical Hospital, 6Hematology, National Medical University, Odessa, Ukraine

Background: Positron emission tomography [18F] fluoroodeoxyglucose (FDG-PET) has emerged as the standard response assessment after 1st line therapy for classical Hodgkin’s lymphoma (HL). Quantitative PET parameters are not well established as a predictive factor for disease progression in HL.

Aims: Thus, the aim of this study was to test the hypothesis that tumor burden characterized by mean standardized uptake value (SUVmean), maximum SUV (SUVmax), metabolic tumor volume (MTV) and total lesion glycosylation (TLG) could be independent prognostic factors.

Methods: We analyzed the relation of absolute value PET parameters, negative predictive value (negative PET scan and no treatment failure, NPV) and positive predictive value (positive PET scan and treatment failure, PPV) with event-free survival (EFS) or overall survival (OS). Quantitative PET parameters of the baseline (PET-1), interim (PET-2) and end of treatment (PET-3) PET-CT scans were investigated in the retrospective study. MTV was computed by using the 41% maximum SUV thresholding method, and the optimal cut-off for survival prediction was determined.

Results: Thirty one patients with HL and a stage I-II—51.6%, III-IV—48.4% consecutively admitted from April 2009 to December 2016, by 5 Ukrainian hematological centers were included in the analysis. Patients were staged at baseline, after 2-4 cycles of chemotherapy with PET/CT and at the end of chemotherapy. All patients were treated with ABVD, BEACOPP-14/sec. All 31 patients achieved CR or PR and 67.7% had a negative PET-2, while 16.3% had a positive PET-2. Patients with negative PET-2 and positive PET-2 had CR rates of 64.5% and 12.1%, respectively, which yielded a PPV of 26% and NPV of 74%. ROC analysis revealed that PETV and NPV are an important markers associated with EFS in patients with HL (Se=100%; Sp=100%; AUC=1.0). 3-year EFS was 100% for NPV patients and 12% for PPV patients, which was statistically significant (p<0.001). At the last cycle of chemotherapy, OS was 100% for NPV patients and 12% for PPV patients, respectively (p<0.01). Quantitative parameters at PET-1 and PET-2 were not statistically significant in predicting clinical outcome in this study. This may be due to the small sample size in our study. PET-3 was negative in 67.7% cases. ROC analysis showed that 3MTV at PET-3 is an important marker associated with reduced EFS in patients with HL (Se=75%; Sp=100%; AUC=0.97, p<0.001). 3-year EFS was 80% and 25% in patients with ∑MTV <4.75 and ∑MTV >4.75, respectively (p=0.005). Also, ROC analysis revealed that TLG at PET-3 was associated with decrease EFS in patients with HL (Se=75%; Sp=100%; AUC=0.97, p<0.001). Multivariate analysis confirmed ∑MTV and TLG at PET-3 were the only significant variables for EFS with HRs of 1.07 [95% confidence interval(CI) 1.0–1.15, p=0.003] and 2.9 [95% (CI) 9.13–0.05, p=0.05], respectively.

The PET-3 SUVmax and SUVmean were not statistically significant in predicting EFS.

Summary/Conclusions: Quantitative PET parameters may play a predictive role for identifying patients at high risk of treatment failure. These results should be evaluated prospectively in larger cohorts with longer follow-up.
Indolent Non-Hodgkin lymphoma - Clinical

BIOMARKER ANALYSIS OF PATIENTS WITH FOLLICULAR LYMPHOMA TREATED WITH IBRUTINIB IN THE PHASE 2 DAWN STUDY

1Hospices Civils de Lyon-Université de Lyon, Pierre-Bénite cedex, Lyon, France, 2The University of Washington/Fred Hutchinson Cancer Research Center, Seattle, Washington, USA, 3Lymphoma Program, Abramson Cancer Center of the University of Pennsylvania, Philadelphia, PA, 4University of Chicago, Chicago, IL, 5Georgia Cancer Center, St. Louis, MO, 6University of Washington, Seattle, WA, 7The Joint Research Institute of Cancer and Hematology, Azienda Ospedaliero Universitaria Città della Salute e della Scienza di Torino, Turin, Italy, 8Alfred Hospital-Monash University, Melbourne, Australia, 9University of Manchester and the Christie NHS Foundation Trust, Manchester Academic Health Science Centre, Manchester, United Kingdom, 10Department of Hematology, Jagiellonian University, Kraków, Poland, 11Haematology and Oncology Clinics of Australia, Milton, QLD, Australia, 12Blokhin Cancer Research Center, Russian Academy of Medical Sciences, Moscow, Russian Federation, 13Instituto Biosanitario de Salamanca (IBSAL), Hospital Clínico Universitario, Salamanca, Spain, 14Janssen Research & Development, Raritan, NJ, United States, 15Department of Hematology/Oncology, Johannen Gutenberg University, Langenbecksst, Mainz, Germany, 16Division of Hematology/Oncology, University of Pittsburgh Medical Center and University of Pittsburgh Cancer Institute, Pittsburgh, PA, 17University of Kansas Medical Center, Kansas City, KS, 18Cedars-Sinai Medical Center, Los Angeles, CA, 19Weill Cornell Medical College, New York, NY, United States, 20Hematology, Azienda Ospedaliero Universitaria Città della Salute e della Scienza di Torino, Torino, Italy, 21Hospices Civils de Lyon-Université de Lyon, Pierre-Bénite cedex, Lyon, France.

Background: Ibrutinib, a first-in-class, oral, covalent inhibitor of Bruton’s tyrosine kinase, has demonstrated robust clinical activity and is approved in various B-cell non-Hodgkin’s lymphomas. To assess the efficacy and safety of ibrutinib in patients (pts) with follicular lymphoma (FL), the DAWN study (FLR2002, NCT01779791) investigated single-agent ibrutinib in chemotherapy-naïve patients (pts) with follicular lymphoma (FL), small lymphocytic lymphoma (SLL), or marginal zone lymphoma (MZL), whose disease is double refractory to rituximab (monotherapy or in combination) and to chemotherapy or radioimmunotherapy. Pts received duvelisib 25mg BID in 28-day treatment cycles until disease progression or unacceptable toxicity. The primary endpoint is overall response rate (ORR) as assessed by an independent review committee (IRC) per revised International Working Group (IWG) criteria. Secondary endpoints include progression-free survival (PFS), overall survival (OS), time to response (TTR), adverse events (AEs), and changes in safety laboratory values. Pneumocystis jirovecii pneumonia (PJP) prophylaxis was mandated for all pts.

Methods: DAWN study was an open-label, multicenter, single-arm, phase 2 study of ibrutinib in pts with CIT-refractory (i.e., ≥3 prior lines of therapy and progressive disease [PD]) ≤12 months after last dose of a CIT regimen. All pts received ibrutinib (560mg QD) on a 21-day cycle until PD or unacceptable toxicity. The primary end point was Independent Review Committee (IRC)-assessed overall response rate (ORR) (complete response [CR] + partial response [PR]). Flow cytometry assessed T-cell subsets in peripheral blood mononuclear cells (PBMCs) at baseline (C1D1) and at cycle 3 (C3D1) for 57 pts (14 responders and 43 nonresponders); cytokine and chemokine analyses were performed at C1D1 and at cycle 2 (C2D1) for 50 pts (21 responders and 29 nonresponders).

Results: Results from the DAWN study have been presented previously (Gopal A, et al. ASH 2016). Briefly, 110 pts with a median age of 61.5 years and a median of 3 prior therapies were enrolled. Ibrutinib achieved an ORR of 20.9% (CR rate, 10.9%) and a median duration of response of 19.4 months. Flow cytometry analysis revealed significant downregulation of CD4+CD25+CD127− at C3D1 in 14 responders (CR + PR, median decrease ≥17.2% of CD4+CD25+CD127− in 43 non responders). Th1 cytokines interferon-gamma (IFN-γ) and IL-12 were increased in responders but decreased in nonresponders (p=0.0025 and p=0.035, respectively). Conversely, the chemokines IFN-γ-induced protein 10 (IP-10) and monocyte-chemotactic protein 3 (MCP-3) were decreased in responders but increased in nonresponders (p=0.022 and p=0.016, respectively).

Summary/Conclusions: Here we show immunomodulatory effects of ibrutinib in pts with CIT-refractory FL, which may be related to response to therapy. In responders pts at early time points, downregulation of T-regulatory cells was observed, along with increases in Th1-associated cytokines IFN-γ and IL-12. This shift in T-cell population may be linked to the antitumor response; in nonresponders, these cytokines were decreased but Treg were not decreased. Chemokine changes observed also indicate variation in chemotraction of T-cells and monocytes/macrophages. These data suggest that immunomodulatory effects of ibrutinib could play a role in its antitumor activity in FL, so combinations with other immun-ontcology therapies may prove beneficial.

E1130

DYNAMO: THE CLINICAL ACTIVITY OF DUVELISIB IN PATIENTS WITH DOUBLE-REFRACTORY SMALL LYMPHOCYTIC LYMPHOMA IN A PHASE 2 STUDY

1Institute of Hematology Serágnoli, University of Bologna, Bologna, Italy, 2Site Specialist, Fort Myers, 3Saint Agnes Hospital, Baltimore, 4Florida Cancer Specialists - Tallahassee, Tallahassee, United States, 5University Hospital Ospedale di Circolo, Varese, Italy, 6Florida Cancer Specialist, Fort Myers, 7Verastem Inc, Needham, 8Tenesse Oncology, Nashville, United States.

Background: Duvelisib is an oral, dual inhibitor of PI3K-δ,γ in development for the treatment of hematologic malignancies. DYNAMO is a Phase 2 study to evaluate the safety and efficacy of duvelisib in a double refractory iNHL population, which included 28 patients (pts) with small lymphocytic lymphoma (SLL). This study aimed to establish the safety and tolerability of duvelisib.

Aims: The primary objective was to evaluate the antitumor activity of duvelisib monotherapy in pts whose disease is refractory to rituximab and to either chemotherapy or RIT, with an additional objective to further characterize the safety duvelisib.

Methods: DYNAMO is an open-label, single-arm, safety, and efficacy study in patients (pts) with FL, small lymphocytic lymphoma (SLL), or marginal zone lymphoma (MZL), whose disease is double refractory to rituximab (monotherapy or in combination) and to chemotherapy or radioimmunotherapy. Pts received duvelisib 25mg BID in 28-day treatment cycles until disease progression or unacceptable toxicity. The primary endpoint is overall response rate (ORR) as assessed by an independent review committee (IRC) per revised IWG criteria. Secondary endpoints include duration of response (DoR), progression-free survival (PFS), overall survival (OS), time to response (TTR), adverse events (AEs), and changes in safety laboratory values. Pneumocystis jirovecii pneumonia (PJP) prophylaxis was mandated for all pts.

Results: 129 pts with iNHL were treated on study. Of these, 28 pts with SLL received duvelisib with a median duration of exposure of 9 mo. (range 6.5-12). Median age was 65 years; 68% were male. Most SLL pts had an ECOG performance status score at baseline of 0 (43%), followed by 1 (54%) and 2 (4%). Most SLL pts had either low (25%) or high (25%) performance status. Median time from last antitumor therapy to first dose of duvelisib was 3 months. SLL pts received a median of 3 prior anticancer regimens (range: 1-8); 43% of pts received ≥4 prior anticancer regimens, 29% ≥6 regimens. The ORR for SLL pts was 68% (95% CI: 48, 84) per IRC assessment. All responses (19) were PFRs. Four (14%) pts had a best response of SD and 3 (11%) pts had a best response of PD. 2 pts were unevaluable for response. Per Investigator assessment, the ORR was 79% (including 1 CR). Median time to IRC response was 1.9 months (range 1.4-5.5). 93% of pts had a reduction in nodal target
lesions. Among the 19 SLL pts with a response per IRC, the median DOR was 9.8 months. The median PFS among all SLL pts was 11.3 months, while the median OS was not reached. The estimated probability of survival at 12 months was 83.9%. Among all pts treated (n=129), AEs were mostly Gr 1-2. Most common ≥ Gr 3 AEs were transient cytopenias (neutropenia [23%], anemia [12%], and thrombocytopenia [10%]), and diarrhea (15%). 4 SLL pts had SAEs that led to discontinuation of duvelisib: NSCLC, neuroendocrine carcinoma of the skin, pseudomembranous colitis, and pneumonia. Two SLL pts has a fatal AE, 1 pneumonia and 1 viral infection.

Summary/Conclusions: In DYNAMO, duvelisib showed clinical activity in a double-refractory SLL population (68% ORR, median DOR 9.8 mo., 93% with a reduction in target lesions). Duvelisib was generally well tolerated, with a manageable safety profile with appropriate risk mitigation. Duvelisib monotherapy appears to have a favorable benefit-risk profile in double refractory SLL. Updated clinical data will be available at the time of presentation.

WALDENSTROM MACROGLOBULINEMIA: UK REAL WORLD EXPERIENCE
D. El-Sharkawi1,*, H. Renshaw1, M. Lunn2, D. Hughes3, A. Rismani1, S. D’Sa1
1Cancer Division, University College London Hospital (UCLH), 2Peripheral Nerve Service, National Hospital for Neurology and Neurosurgery, 3Haematology, UCL, London, United Kingdom

Background: There are few randomised controlled trials in Waldenström macroglobulinemia (WM) due to its rarity and indolent nature. As a result, there is no standard treatment approach and management is variable. Aims: The aim of this retrospective study was to review “real world” management of WM in the UK and correlate this with survival outcomes.

Methods: All patients with a diagnosis of WM seen at ULCH between 01/07/2002 and 31/12/2016 were included. Patient characteristics, presenting features, lines of treatment, responses and overall outcome were recorded. Response to the ongoing antiviral therapy was achieved in 77% of cases. Median progression-free survival in patients with IL + C treated with antiviral treatment was 42 months, in patients with IL without viral hepatitis markers.

Methods: The study included 107 patients with indolent lymphoma who were identified in the blood markers of hepatitis C. Results: Histological types were follicular lymphoma - 74%, marginal zone lymphoma - 32%. The age of patients ranged from 28 to 82 years (median 50). Men / women ratio was 1: 1. Stage I + II were in 3%, III stage was in 24% of patients. Primary extranodal lymphoma was diagnosed in 33% of patients. Extranodal lesions: splenic lesion - in 53% of patients, liver injury - 21% of the patients, the bone marrow - 62% of patients. LDH > 450 IU / l was at 76% of cases, ALT > 40 IU / l was at 82% of cases, albumin < 35 g / l was at 31% of patients. 57 patients were treated with interferon and Ribavirin as a first-line treatment. Treatment lasted for 2 years after reaching the antitumor effect. 50 patients were treated with immunochemo therapy (R-CHOP, R-CVP) as a first-line treatment. Antiviral therapy was effective in 88% patients, immunochemo therapy was effective in 64% of patients. Median progression-free survival in patients with IL + C treated with antiviral treatment was 42 months. In patients with IL + C treated with immunochemo therapy - 19 months (p=0.00001). Five-year overall survival was 67% and 32%, respectively (p=0.0003). It was diagnosed disease relapses after immunochemo therapy in 39 patients. All the patients in the second-line was received antiviral treatment. The size of the disease was ongoing in 73% of cases. Medi an progression-free survival in relapsed lymphoma was 31 months.

Summary/Conclusions: Antiviral therapy in first-line and relapse of disease surpasses all the indicators of efficiency of treatment IL + HCV. In this category of patients preferred option is to conduct anti-viral treatment.
(R every 8 weeks for 4 or 12 doses) still appears as an optional part of the therapy (NCCN V3:2016). Radiomunotherapy with 90Ytrium-ibritumomab tiuxetan (90Y-IT) is available in our institution since 2006 and more than 100 patients have been treated with RIT since then. Here an institutional analysis focus in their use as consolidation is presented

Aims: To analyze the experience with 90Y-IT as a consolidation therapy in patients in CR after first-line therapy.

Methods: A retrospective analysis was performed including all the patients that have received RIT with 90Y-IT. Inclusion criteria were: patients 18 years or older with a grade 1-2a follicular lymphoma, RIT was received as a consolidation therapy in complete response (CR) after a first-line therapy. Demographic and follow-up data were included. International working group (IWG) criteria of response was used. Progression free survival (PFS) was calculated from the date of RIT to the date of a confirmed relapse according IWG criteria, overall survival (OS) was calculated from the FL diagnosis to the last contact.

Results: A total of 31 FL patients have received 90Y-IT been in CR after a first-line therapy and were included for the study. Mean age at diagnosis was 61.2 (29-86) years with a female predominance (19, 61.3% vs 12, 38.7%). 80.6% (26) with ECOG 0-1 and 19.4 ECOG 2. A third of them (10, 32.3%) were treated for stage III-IV. As long-term events one 82 years old patient developed a colon infiltration demonstrated by flow cytometer or biopsy. There were no patients with bulky disease. Stages: I: 7 (22.6%), II: 2 (6.7%), III: 9 (29.1%), IV: 12 (38.7%). As first-line therapy the patients received: Rx4: 11 (35.5%) cases, R-Chlorophosphamide vinristine prednisone (COPx4): 3 (9.7%) cases and 17 (54.8) R-Chlorophosphamide doxorubicin, vinristine and prednisone (R-CHOPx4). The median follow-up was 58.0 (10-107) months. During this time only 5 (16.1%) of patients have relapsed and need another therapy. None of the patients that have received R-CHOP+90Y-IT have relapsed; the relapsed patients received Rx4 (4) and R-COP (1). The median PFS after 90Y-IT has not reached, the mean was 83.3 (71.7-94.9) months, see Fig 1. Four (12.9%) patients have died, none of them were relapsed and the mortality was due other causes. The median OS was not reached, the mean was 95.8 (85.6-106.1) months. As long-term events one 82 years old patient developed a colon cancer after 67 months of RIT; one 72 years old female a breast cancer after 17 months of RIT and one 71 years patient amgUS after 24 months of RIT, none of them related with mortality events.

Summary/Conclusions: The use of immunotherapy with rituximab or combined schedules with immunochemotherapy (R-COP and R-CHOP) followed by consolidation with 90Y-IT remains as a valid option for follicular lymphoma patients. After ~6 years of follow-up: 63.8% (Rx4+RIT), 66.7% (R-COP+RIT) and 100% (R-CHOP+RIT) of patients continue with complete response and off of therapy.

E1135

ASSESSING RISK OVER TIME IN PATIENTS WITH SYMPTOMATIC WALDENSTROM MACROGLOBULINEMIA (WM). A STUDY ON 114 PATIENTS

1Service d’Hematologie, CHU Poitiers, Poitiers, 2Department of Biostatistic, CHRU Lille, Lille, 3Service d’Hematologie, CH Lens, Lens, 4Service d’Hematologie, CHU d’Amiens, Amiens, 5Department of Biostatistics, CHRU Lille, Lille, France

Background: By contrast, with follicular lymphoma (J Clin Oncol 2015;33:2616) or other chronic hematological malignancies (Blood 2009;114:1299; Blood 2016;128:902), few studies attempted to decipher the evolution of pts with WM, a disorder associated with delayed response to therapy in some pts.

Aims: To assess the prognostic role during the clinical course of initial interna tional prognostic index (IPSSWM), response and progression (according to 6th International Workshop guidelines) on survival.

Methods: We took advantage of our continuously updated clinical database for reviewing a series of 114 symptomatic WM pts treated in our 2 institutions between 1993 and 2016 (median age 70, male/female ratio=1.91, high, low/intermediate and unavailable IPSSWM in 57, 36 and 21 pts respectively). The follow-up after 1st line therapy was 70%. Sixty-two, 37 and 19 pts received a 2nd a 3rd and 4 to 6 lines of therapy respectively according to the 2nd International Workshop guidelines. Monitoring of serum monoclonal immunoglobulin concentration (SMIC) throughout the evolution of the disease was available in 106 pts. Informed consent was obtained according to the protocol submitted to EJD 2016.

Results: Median survival after 1st line was estimated 79 months. It was esti mated 69 and 65 months after 2nd line and 3rd line respectively. High IPSSWM (hiPSSWM vs low/intermediate) retained prognostic value for survival after 1st treatment initiation (SAFTI, p=0.0005). However, plot of hazard function showed a decrease of hazard ratio over time with a departure from the proportional hazard hypothesis (Grimbsch and Theerneau test: p=0.053). Consequently, Dxy concordance index obtained in multiple landmark analyses decreased from 0.27 to 0.12, during the first 6 years of follow-up. In Cox model of SAFTI with time dependent covariate, onset of response (whatever cut-off in SMIC >25%) and progression had significant prognostic value. By contrast, onset of progression and initiation of 2nd line therapy, retained prognostic values for SAFTI (p=0.0038 and p=0.004 respectively). Only 2 thresholds in SMIC defined a response status (observed between onset of response and progression) of prognostic value for SAFTI: namely >25% reduction in SMIC (i.e. minor response or better: p=0.041) and >50% (i.e. partial response or better: p=0.026). In similar Cox models with hiPSSW M, onset of progression (p=0.0034) and 2nd treatment initiation (p=0.0031) retained independent prognostic value inside hiPSSWM (p<0.0026). Times elapsed from the initiation of 1st line therapy to 1st progression and to the ini tiation of 2nd line therapy had no prognostic value for subsequent survival. In similar Cox model of survival after 2nd line therapy with time dependent covar iate no threshold in SMIC were found to be associated with a significant value of onset of response or response status. Neither onset of progression nor next treatment initiation had significant prognostic value. Similar results were observed after the 3rd line of therapy.

Summary/Conclusions: The prognostic value of initial hiPSSWM decreased in part during the first 6 years of evolution. Onset of progression and 2nd treat ment initiation provided additional prognostic information for predicting SAFTI. Therefore progression-free survival or time to next treatment may be satisfac tory surrogate endpoint of SAFTI in WM. Further international collaborative studies are mandatory for this purpose. Assessing response in more advanced phase of the disease may require specific tools.

E1136

TIME TO NEXT TREATMENT ANALYSIS FOR EARLY AND ADVANCED STAGES OF MYCOSIS FUNGOIDES /SEZARY SYNDROME TREATED WITH BEXAROTENE AND PUVA IN COMBINATION

S. Rupoli1,*, G. Goteri2, G. Micucci1, I. Federici1, L. Canafoglia1, P. Leoni1, G. Brandozzi3, F. Giantomassi2, G. Mozzicafreddo4, R. Alterini5, M. Simonacci6, L. Bugatti1, S. Serresi1, R. Ospedale Careggi di Firenze, Firenze, Italy

Background: Bexarotene is a synthetic retinoid effective in early and advanced stages of Mycosis Fungioides (MF)/Sezary Syndrome (SS) both in monotherapy and combination schemes. Time to next treatment (TTNT) seems to be a clinically meaningful endpoint that incorporates both symptom control and disease progression. It has been investigated in few retrospective studies focusing on retinoids in monotherapy both in limited-stage and advanced stage MF, but up to now no data are available concerning the use of retinoids in combination.

Aims: We aimed to evaluate TTNT together with the usual time-to-event measures (OS and EFS) in our series of 21 refractory and/or relapsed patients with MF treated with Bexarotene and PUVA combination. We recently published (Rupoli et al, EJD 2016). The follow-up of these protocols was prolonged up to February 2017.

Methods: We recruited patients with stages I-IV MF who had failed PUVA (early disease) or several systemic regimens (early and advanced disease). We designed “mini” and “standard” protocols in which Bexarotene dose and PUVA administration were individually titrated, and tailored during induction and maintenance according to previous therapy, disease stage and toxicity. Survival curves for each efficacy endpoint were calculated according to Kaplan-Meier.
Results: We enrolled 21 patients, 12 males and 9 females, with median age of 67 years (range, 30-77), of which 15 affected by early MF (13 with stage IB, 2 with stage IIA) and 7 by advanced disease (2 with stage IIB, 2 with stage IIIA, 1 with stage IIIB and 1 with stage IVA). Six patients had previously received PUVA therapy only, while fifteen patients had received other therapies. The protocol proved to be effective, well tolerated and able to induce an overall response of 55.6% at the end of induction phase (93.4% of early stage patients and 66.6% of advanced stage patients) and of 76.2% at the end of maintenance phase (86.7% of early stage patients and 14.2% of advanced stage patients). Median follow up for all patients was 85 months (6-118) with respectively 98 months (21-118) for early stages and 46 months (6-102) for advanced stages. For the entire cohort, median OS, PFS and TTNT were not reached; mean values of OS, PFS and TTNT were respectively, 105, 103 and 79 months, and median EFS was 58 months. For advanced stage patients, median OS, PFS, EFS and TTNT were 32, 29, 18 and 39 months respectively.

Summary/Conclusions: Our combination treatment seems to have superior TTNT compared to data published in the literature for PUVA and bexarotene used in monotherapy. When considering early and advanced MF, 66% of our patients are estimated to be free from further treatment at 2 years, a higher percentage compared to the results of Hughes et al. (Blood, 2015) for patients treated with PUVA (54.2%) or bexarotene (36.8%) as single agents. Moreover, TTNT seems to be longer in our study than in the study by Hanel et al (AJH 2016) on patients treated by retinoids in monotherapy, respectively 79 vs 60 months (mean TTNT values) in the early stages and 39 vs 9 months (median TTNT values) in the advanced stages. We believe that our results strongly suggest a synergistic or additive effect between PUVA and bexarotene compared to either agent alone in the treatment of both limited-stage and advanced stage MF.

E1137
PERIPHERAL BLOOD INVOLVEMENT IN PATIENTS WITH ADVANCED STAGE FOLLICULAR LYMPHOMA: CLINICAL-BIOLOGICAL CHARACTERISTICS AND PROGNOSTIC IMPACT
A. Rivas-Delgado1,*, L. Magnano 2, P. Mozas 1, I. Dlouhy 1, J. Rovira 1

To describe the clinico-biological characteristics and to determine the clinical-biological characteristics and to determine the prognostic impact of blood involvement in patients with advanced FL.

Methods: We selected 304 patients in stage IV out of 654 patients diagnosed with FL between 1991 and 2014 in a single institution. Patients with a diffuse large B-cell lymphoma component, histological grade 3b and primary cutaneous FL were not included. Fifty-six (18%) had PB involvement (PB+) defined by the presence of circulating FL cells by morphology, further confirmed by immunophenotyping. The main clinical and biological characteristics, response to treatment and outcome were analyzed.

Results: Patients with PB+ more frequently had splenic involvement, anemia, elevated β2-microglobulin and LDH and high FLIPI score than those without PB involvement (PB-) and differences were statistically significant. There were no differences concerning the proportion of patients undergoing a watchful waiting approach (7% vs 9%), type of treatment, or overall response rate (93% vs 88%) and complete response rate. Overall, 149 patients had refractory disease or relapsed, including 34/52 (65%) PB+ and 115/225 (51%) PB-. Median follow-up was 7 years (range 0.7 - 22.2 years). The 5-year progression-free survival (PFS) of treated was 28% (95% CI: 14-42%) compared with 48% in the PB- (95% CI: 41-55%) (p=0.013). However, when the analysis was restricted to patients receiving rituximab combination regimen, 5-year PFS was 45% (95% CI: 24-66%) vs 64% (95% CI: 54-74%) (p=NS). Ninety-six patients died during the follow-up (19 PB+ and 77 PB-), with a 5-year overall survival (OS) of 68% (95% OR: 54-82%) in the PB+ group and of 81% (95% CI: 76-86%) in the PB group (p= NS) (Figure). Finally, there was no difference in the risk of histological transformation or second malignancies.

Summary/Conclusions: Peripheral blood involvement in FL is associated with particular clinical features, higher tumor burden load and shorter PFS, although in the short-term it appears that has not impact on overall survival.

E1138
TREATMENT PATTERNS OF PATIENTS WITH FOLLICULAR LYMPHOMA IN A LARGE US-INSURED DATABASE FROM 2010 TO 2014
M. Mehra1,*, N. Monga1, B. Schenkel2, R. Potluri3, L. Parisi1

1Janssen Research & Development, LLC, Raritan, NJ, United States, 2Janssen Scientific Affairs, Horsham, PA, United States, 3SmartAnalyst Inc., New York, NY, United States, United States

Background: Follicular lymphoma (FL) is the second most common type of non-Hodgkin’s lymphoma. While there are therapeutic options for patients with FL, it remains an incurable disease with conventional therapies. Furthermore, real-world treatment patterns for patients with FL are not well characterized in the literature.

Aims: To characterize the real-world treatment patterns by line of therapy (LOT) for patients with FL in a large US-insured database.

Methods: Using the Optum integrated database, patients with FL were identified and included if 1) they were diagnosed with the International Classification of Diseases, Ninth Revision (ICD-9) codes 202.0 or 202.00 to 202.08 between January 2010 and December 2014; 2) their age was ≥ 18 years at the index date (defined as date of FL diagnosis); 3) they received guideline-recommended treatment for FL, and 153 patients (6%) had steroids as first-line treatment, while 1180 patients (63%) received guideline-recommended therapy for FL. The median duration of follow-up was 610 days. Across all LOTs, 1180 patients (63%) were treated by rituximab in monotherapy, respectively 79% of early stage patients and 11% of the second LOT, respectively. Across all LOTs, the use of other FL treatments was very low, including rituximab-cyclophosphamide-vincristine-
E1139

A PHASE 1 STUDY EVALUATING THE SAFETY AND PHARMACOKINETICS (PK) OF VENETOCLAX (VEN) IN JAPANESE PATIENTS (PTS) WITH NON-HODGKIN LYMPHOMA (NHL) AND MULTIPLE MYELOMA (MM)

1Department of Clinical Research and Department of Hematology and Cell Therapy, Aichi Cancer Center Hospital, Nagoya, Japan, 2Department of Hematology and Oncology, The Cancer Institute Hospital, Japanese Foundation for Cancer Research, Tokyo, Japan, 3Department of Hematology and Rheumatology, Tohoku University Hospital, Sendai, Japan, 4Department of Hematology and Oncology, Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan, 5Department of Hematology, National Hospital Organization Nagoya Medical Center, Aichi, Japan, 6Department of Hematology, National Cancer Center Hospital, Tokyo, Japan, 7AbbVie GK, Tokyo, Japan, 8AbbVie Inc., North Chicago, IL, United States

Background: The antiapoptotic protein BCL-2 is commonly overexpressed in hematologic malignancies. VEN is a potent, selective, orally bioavailable BCL-2 inhibitor that has demonstrated acceptable safety and antitumor activity in NHL and MM pts.

Aims: To evaluate the PK profile, and preliminary antitumor activity of single-agent VEN in Japanese pts with NHL or MM.

Methods: Phase 1 open-label, dose-escalation study of VEN in Japanese pts with relapsed or refractory (R/R) NHL or MM (NCT02265731). Dose escalation followed a 3+3 design. After a 2-week ramp-up period with weekly dose escalation, VEN was administrated at daily final doses of 300, 600, 900, or 1200mg on 21-day cycles until progression. All pts received tumor lysis syndrome (TLS) prophylaxis (allopurinol, hydration, hospitalization and monitoring) starting at least 72 hours before the first VEN dose and before each dose escalation. Adverse events (AEs) were assessed by NCI CTCAE v4.0. Dose-limiting toxicities (DLTs) were determined during the ramp-up period and during cycle 1. Responses were assessed by 2007 IWG (NHL) or 2006 IMWG (MM) criteria.

Results: As of January 19, 2017, 20 pts (50% male; median age 65 years [39–81]) have been enrolled: 3 pts in the 300-mg, 7 pts in the 600-mg, 7 pts in the 900-mg, and 3 pts in the 1200-mg VEN dose cohorts. Eighteen (90%) pts had NHL (stage III/IV, n=14), including 11 with follicular lymphoma (FL), 6 with diffuse large B-cell lymphoma (DLBCL), and 1 with concurrent FL+DLBCL: 2 (10%) pts had MM at diagnosis. Treatment-emergent AEs (all grades) in >20% of pts included lymphopenia (80%), neutropenia (60%), leukopenia (50%), and anemia (25%), and non-hematologic toxicities including nausea (55%), vomiting, diarrhea, and nasopharyngitis (30% each). Grade ≥3 treatment-related AEs were lymphopenia (45%), neutropenia (40%), and leukopenia (35%). One pt in the 600-mg cohort experienced dose-limiting thrombocytopenia as DLT after receiving 2 doses of 100-mg VEN on day 2 of the dose ramp-up period. One DLBCL pt died while on study due to disease progression. No TLS events were reported. Stable-state VEN exposures were nearly dose proportionally across 300-mg to 900-mg doses. At the 1200-mg dose, exposures to VEN increased less than dose proportionally, which is consistent with non-Najapanese subjects. VEN exposures were comparable between Japanese and non-Japanese pts at the 300-mg dose. At higher doses, individual exposures were generally within the range observed in non-Japanese pts but mean exposures were 30–100% higher. Overall, the OR rate was high, with nearly half the pts with NHL achieving an OR. Further evaluation of VEN in Japanese pts with hematologic malignancies is ongoing.

E1140

A SIMPLIFIED APPROACH IN THE ASSESSMENT OF T-CELL CLONALITY BY FLOW CYTOMETRY

M. Sarto1, E. Lau1, V. Lou1, Z. Timbol1, S. Wong1, S. Deo1, L. Pasalic1, D. Brown2, E. Tegg1, D. Gottlob1

1Haematology, 2immunopathology, Weatmead Hospital, 3Faculty of medicine, Sydney University, Sydney, Australia

Background: T-cell lymphoproliferative disorders are among the most challenging diagnoses in haematology. Flow cytometric T-cell receptor (TCR)-β chain repertoire analysis (TCR-(V)β-R) is a sensitive method for detection of T-cell clonality; however, the assay is cumbersome owing to the required eight-part analyses that limit its clinical utility.

Aims: Here we describe a simplified flow cytometric method utilising a monoclonal antibody that targets the T-cell receptor β constant domain 1 (TRBC1). The cβ TCR is a pan T-cell antigen, expressed on >90% of T-cell lymphomas and all normal T-cells. A feature of the TCR is that the β-constant region comprises 2 functionally identical genes: TRBC1 and TRBC2. Each T-cell phenotype CD3+CD8+CD4-, CD3+CD4+CD8+, CD3+CD4+CD8- and CD3+CD4+CD8- respectively. The T-cell line, Jurkat was exclusively positive for JurA1. Of the 9 patients with T-LGL, 7 patients shared a common T-cell phenotype CD3+CD8+CD4-, one patient was predominantly CD4+ and the other patient was dual negative for CD4 and CD8. Jovi-1 expression within the normal T-cell population of this group of patients was >90% restricted to one compartment; these findings were confirmed by TCR-(V)β-R analysis. Similar results were also obtained in each case of T-NHL and Sezary syndrome, more than 90% of T-cells from the population with an abnormal phenotype (CD3dim/CD4+CD8-, CD3+CD4+CD8+, CD3+CD4+CD8- and CD3+CD4+CD8- respectively) were either positive or negative for Jovi-1. Patients with persistent lymphocytosis were also assessed for Jovi-1 expression in this group all patients had JurA1-positive and negative compartments within CD4 and CD8 T-cells.

Summary/Conclusions: In summary we have demonstrated a novel approach in the assessment of T cell clonality by targeting T-cell receptor β constant domain 1 (TRBC1). The addition of Jovi-1 in routine practice could improve the clinical evaluation of abnormal T-cell populations by flow cytometry.

E1141

A HIGHER AMOUNT OF LILOTOMAB PRE-DOSE INCREASES THE ACTIVITY-ADJUSTED AUC AND HAS A PROTECTIVE EFFECT AGAINST MYELOPRESERVATION OF LUTETIUM (177Lu)-LILOTOMAB SATETRAX-1 IN INDOLENT NHL PATIENTS

A. Kolstad1,*, U. Madsbu1, C. Stokke2, J. Blakkisrud2, A. Muftuler Løndalen1, E1141

1Radiumhospitalet, 2Oslo University Hospital, 3Nordic Nanovector, Oslo, Norway, 4Norrland University Hospital, Umeå, Sweden, 5University of Manchester, Manchester, United Kingdom

Background: Lutetium (177Lu)- Elliotomab satetrax-1 (Lil), V-80714, is a novel CD37-binding murine IgG1 antibody radionuclide conjugate (ARC), in a ready-to-use formulation currently in Phase 1/2 clinical development for the treatment of non-Hodgkin lymphoma (NHL). Previously, pharmacokinetic (PK) data have been reported from 2 treatment arms of the ongoing LYMRT-37-01 study. In this abstract PK data from 4 treatment arms are presented for the first time.

Aims: This PK sub-study in INHL patients (pts) was designed to determine the PK profile of 177Lu-lilotomab when administered after different four pre-dosing schedules.

Methods: Patients with relapsed incurable indolent NHL, with platelet counts ≥150 x10⁹/L and <25% bone marrow involvement were eligible for inclusion in the study. All pts received either one or two doses of rituximab to deplete normal B cells. In addition, prior to 177Lu-lilotomab administration pts also received: - 40mg lilotomab prior to 10, 15 or 20 MBq/kg 177Lu-lilotomab; - no pre-dosing prior to 10 or 15 MBq/kg 177Lu-lilotomab; - 250 or 375mg/m² rituximab prior to 15 MBq/kg 177Lu-lilotomab; - 100mg/m² lilotomab prior to 10 or 20 MBq/kg 177Lu-lilotomab.

PK samples were collected at 0 and 5 minutes, then after 1, 2, and 20 hours and at 2, 3, 4, 7, 11 and 21 days post-177Lu-lilotomab administration. The patients were followed with weekly blood counts for 12 weeks post-treatment.

Results: A total of 22 pts were enrolled into this PK sub-study, 19 with follicular lymphoma, 2 with mantle cell and 1 with marginal zone histologies. The number

468 | haematologica | 2017; 102(s2)
of prior therapies ranged from 1 to 7. median body weight was 79 kg (range: 58-118kg). The administered activity across all treatment groups ranged from 746 to 1982 MBq. Table 1 shows a summary of the median PK and haematology safety results for 177Lu-lilotomab by treatment group.

Aims: To investigate the potential for drug-drug interaction between OFA and BEN alone and in combination, along with the safety and tolerability assessments in patients with iNHL.

Methods: In this Phase I open-label, multicentre study, patients (aged ≥18 years) with previously untreated or relapsed indolent B-cell non-Hodgkin lymphoma (iNHL), due to the inevitable relapse of patients with iNHL, an unmet need remains for active and well-tolerated novel therapies. Bendamustine (BEN) is approved for the treatment of refractory iNHL, and the combination therapy BEN-R showed efficacy in the treatment of relapsed iNHL. Ofatumumab (OFA) is a human monoclonal antibody (mAb) with high binding affinity and slower dissociation from a distinct membrane-proximal epitope on both small and large loops of CD20. OFA is indicated for the treatment of chronic lymphocytic leukemia (CLL) and is being investigated for the treatment of iNHL. The combination of OFA and BEN may provide additional clinical benefit in lymphoma patients with iNHL and therefore the potential for drug-drug interaction was investigated. Ofatumumab (OFA) alone or in combination with BEN exhibited manageable safety profile in patients with iNHL.

Summary/Conclusions: A higher pre-dose of lililotomab increases the activity-adjusted AUC and decreases the volume of distribution and clearance rate of 177Lu-lilotomab in iNHL pts. Despite the increase in AUC the percentage reductions in neutrophil and platelet counts were smaller, indicating that a higher dose of lililotomab may have a protective effect against the myelosuppression associated with 177Lu-lilotomab. Further characterisation of 20 MBq/kg dose of 177Lu-lilotomab with 100mg/m2 of lililotomab pre-dosing is ongoing and will be presented.

E1142
PHARMACOKINETICS AND TOLERABILITY OF OFATUMUMAB AND BENDAMUSTINE IN PATIENTS WITH INDOLENT B-CELL NON-HODGKIN’S LYMPHOMA
A. Forero-Torres1,*, J.C. Chandler 2, S.P. Iyer3, A.S. Kanate4, M. Quinlan 5, P. Hoever6, M. Izquierdo6, V. Duval6, S. Madan7
1Division of Hematology / Clinical Oncology, University of Alabama at Birmingham, Alabama, 2West Cancer Center, Tennessee, 3Houston Methodist Cancer Center, Houston, 4West Virginia University, Morgantown, 5Novartis Oncology, East Hanover, NJ, United States, 6Novartis Pharma AG, Basel, Switzerland, 7Cancer Therapy & Research Center, San Antonio, United States

Background: Anti-CD20 antibody rituximab (R)-based immunochemotherapy is the standard treatment for untreated or relapsed indolent B-cell non-Hodgkin lymphoma (iNHL). Due to the inevitable relapse of patients with iNHL, an unmet need remains for active and well-tolerated novel therapies. Bendamustine (BEN) is approved for the treatment of refractory iNHL, and the combination therapy BEN-R showed efficacy in the treatment of relapsed iNHL. Ofatumumab (OFA) is an anti-CD20 human monoclonal antibody (mAb) with high binding affinity and slower dissociation from a distinct membrane-proximal epitope on both small and large loops of CD20. OFA is indicated for the treatment of chronic lymphocytic leukemia (CLL) and is being investigated for the treatment of iNHL. The combination of OFA and BEN may provide additional clinical benefit in patients with iNHL and therefore the potential for drug-drug interaction was investigated.

Aims: The study aimed to evaluate the pharmacokinetics (PK) of OFA and BEN alone and in combination, along with the safety and tolerability assessments in patients with previously untreated or relapsed iNHL.

Methods: In this Phase I open-label, multicentre study, patients (aged ≥18 years) with previously untreated or relapsed iNHL were randomized 1:1 to Arm A (OFA + BEN) or Arm B (OFA alone) to receive at least four cycles and up to eight cycles of treatment (cycle length 28 days). All patients provided informed consent. Arm A patients received single-sequence treatment of BEN, then OFA (1000mg) on day 1 of weeks 2, 3, and 4 of cycle 1 and on day 1 of cycles 2-8. Patients in Arm B received OFA alone at same dosing schedule. Blood samples including all end-of-infusion (EOI) PK samples were collected for plasma concentration over time. The primary PK parameters Cmax, AUClast, AUCinf were derived using non-compartmental analysis. All adverse events (AEs) and severe AEs (SAEs) were recorded for safety assessments.

Results: Thirty two patients were randomized (15 in Arm A and 17 in Arm B), 3 patients in Arm A discontinued study treatment due to consent withdrawal (2 patients) and infusion related AE (1 patient). All 32 patients were included for safety and PK concentration analysis while 30 patients (15 in each arm) were included for PK parameters. Patient and disease characteristics were similar between treatment arms; the majority of patients from both arms did not receive prior NHL therapy. PK concentration profiles and PK parameters of OFA were comparable when administered alone or co-administered with BEN (Table 1). As compared to OFA alone, there was a decrease of 14% in Cmax and 15% in AUClast when OFA was co-administered with BEN, which was not considered relevant (Table 1). BEN PK concentration profiles and PK parameters were comparable with or without OFA co-administration (Table 1). All patients reported AEs. The most frequent treatment-related AEs were infusion related reaction in 53% and 47%, nausea in 33% and 35%, fatigue in 33% and 18% patients in Arm A and Arm B, respectively. The percentages of patients with grade 3/4 AEs were higher in Arm A (53%) compared to Arm B (24%). Cytopenias were present in 40% of patients in Arm A and 6% in Arm B. Four SAEs were related to study treatment in Arm A while none in Arm B.

Summary/Conclusions: No relevant drug-drug interaction between OFA and BEN was observed in this study. OFA alone or in combination with BEN exhibited manageable safety profile in patients with iNHL.

Spallanzani", 9Thoracic Surgery Unit, Regina Elena National Cancer Institute, 10Molecular Virology, Pathology and Microbiology Laboratory, San Gallina Dermatological Institute

**Methods:**

Of the 153 samples included, all had *P. falciparum* parasitemia and 37 were collected from patients with severe malaria. A FBC with a DWCC was performed in 72/153(47.1%) patients, and a FBC alone in 81/153(52.9%). SR rules were triggered in 132(86.3%) patients (68(84.0%) in those with only a FBC and 64(88.9%) in those with a FBC and DWCC). The thrombocytopenia (platelets (Plt) <100x10^9/l) and anemia (Hb <7g/dl) rules were the most common, triggering in 105(79.5%) and 24(15.7%) patients respectively. Common analyzer morphology flags included those querying the presence of atypical lymphocytes, immature granulocytes and blasts, but 1/4 of these triggers were in the and DWCC requested, while only the parameter related rules were applied to patients with only a FBC performed. Samples were processed using a Sysmex XE-5000 analyser (Sysmex, Kobe, Japan), and the rules violated for each FBC recorded. As a retrospective laboratory based study, informed consent was not obtained. However, the study was approved by the Human Research Ethics Committee of the University of the Witwatersrand.

**Results:**

Of the 153 samples included, all had *P. falciparum* parasitemia and 37 were collected from patients with severe malaria. A FBC with a DWCC was performed in 72/153(47.1%) patients, and a FBC alone in 81/153(52.9%). SR rules were triggered in 132(86.3%) patients (68(84.0%) in those with only a FBC and 64(88.9%) in those with a FBC and DWCC). The thrombocytopenia (platelets (Plt) <100x10^9/l) and anemia (Hb <7g/dl) rules were the most common, triggering in 105(79.5%) and 24(15.7%) patients respectively. Common analyzer morphology flags included those querying the presence of atypical lymphocytes, immature granulocytes and blasts, but 1/4 of these triggers were in the and DWCC requested, while only the parameter related rules were applied to patients with only a FBC performed. Samples were processed using a Sysmex XE-5000 analyser (Sysmex, Kobe, Japan), and the rules violated for each FBC recorded. As a retrospective laboratory based study, informed consent was not obtained. However, the study was approved by the Human Research Ethics Committee of the University of the Witwatersrand.

**Summary/Conclusions:**

ICGH SR rules are FN in 13.7% of patients with malaria, with 3% being largely in those with near-normal blood counts. Furthermore, SR failed to identify the parasites in a further 13.0% of cases (predominantly when the parasitemia was low (median 0.35% in those missed vs 3.1% in those with parasites identified). Reassuringly, SR rules were triggered in all the patients with severe malaria, and the parasites identified in 90.5% of these.

**A PROSPECTIVE MULTICENTER STUDY OF CANDIDEMIA IN NEUTROPENIC PATIENTS WITH HEMATOLOGICAL DISEASES: INCIDENCE, RISK FACTOR AND OUTCOMES**

C. H. Yan1,*, D.-P. Wu2, J.-D. Hu3, H. Huang4, M. Jiang5, J. Li6, M. Hou7, H. Huang4, M. Jiang5, J. Li6, M. Hou7

1Haematology, National Health Laboratory Services, 2Molecular Medicine and Haematology, University of the Witwatersrand, Johannesburg, South Africa

**Methods:**

A total of 1139 consecutive cases were enrolled in this study. Out of 1139 neutropenic cases, 8 developed candidemia. The median time from neutropenia to diagnosis of candidemia was 18 days (range: 8-20 days). Among the 8 cases with candidemia, 5 were neutropenic and 3 were critically ill. The cumulative incidence of candidemia in neutropenic patients with hematological diseases was 0.00% [95% confidence interval (CI): 0.00, 0.00%] at 7 days, 0.26% (0.00, 0.65%) at 14 days, 2.24% (0.67, 3.81%) at 21 days and 2.24% (0.67, 3.81%) at 28 days after neutropenia, respectively. Among 8 cases with candidemia, 3 were from patients receiving HSCT, other 8 were from patients who had acute myeloid leukemia (AML) and receiving induction chemotherapy.

The cumulative incidence of candidemia in patients with AML and receiving induction chemotherapy was also significantly higher than that in patients receiving HSCT and other patients (5.45% vs. 3.1% vs 0.00%, P=0.023).

**Summary/Conclusions:**

This study provided a description for the epidemiological study of candidemia in neutropenic patients with hematological diseases. This study defined the risk factors associated with candidemia in these patients, and confirmed that based on the risk factors, risk-stratification could identify the patients with a high-risk of candidemia.
fluid was studied by bacterial and fungal cultures, GM and PCR for Streptococcus pneumoniae, Legionella pneumophila, Chlamydophila pneumoniae, Mycoplasma pneumoniae, Bordetella pertussis, Bordetella parapertussis, Haemophilus influenzae, respiratory virus including CMV, Pneumocystis jiroveci, Mycobacterium tuberculosis complex, Nocardia spp., Lysteria monocytogenes and Aspergillus spp. Available commercial kits were used according to manufacturer’s instructions.

Results: Out of 769 patients consecutively admitted in our ward, 85 had LI and 47 of them underwent BAL (total amount: 51 procedures). A causal agent of LI was detected in 33 cases (65%) allowing to modify the ongoing antimicrobial treatment in 25 of these ones (76%). Twelve cases of LI fulfilling the radiologic criteria for IPA, though presenting only a positive Aspergillus PCR on BAL, were detected and treated as probable IPA. One life-threatening post-procedure complication was observed.

Summary/Conclusions: BAL seems a safe approach for an early diagnosis of LI in hematologic patients. The assessment of a broad diagnostic panel allowed the detection of a putative agent in 65% of cases. Assessment of Aspergillus by PCR on BAL proved useful for probable IPA diagnosis.

E1146
ESCape drug-resistant infections in hematological malignancies. DARE to Review!

C. Gentille Sanchez 1,*, K. Sun 1, P. Teegavarapu 1, Q. Qian 1, P. Mamta 2, S. Wong 2, I. Ibrahim 1, L. Rice 3, S.R. Pingali 1, S. Iyer 1
1 Houston Methodist Cancer Center, 2 Houston Methodist Research Institute, 3 Houston Methodist Department of Hematology, Houston Methodist Hospital, Houston, United States

Background: Patients with hematological cancers are at a high risk for increasingly resistant and severe infections. The Infectious Diseases Society of America has defined commonly resistant bacteria as ESCAPE (Enterococcus, Staphylococcus aureus, Klebsiella pneumoniae, Acinetobacter, Pseudomonas aeruginosa, Enterobacter). As suggested in recent literature, other common and difficult-to-treat infections such as Clostridium difficile and Enterobacteriaceae organisms (E. coli, Proteus) can be added to this group and change the acronym from ESCAPE to ESCAPE-A.

Aims: We performed a retrospective review of the rate of ESCAPE infections, resistance profile, and outcomes in patients with various hematological malignancies at the Houston Methodist Hospital from 2006 to 2015.

Methods: The patient data was obtained from METEOR (Methodist Environment for Translational Enhancement and Outcomes Research), a clinical data warehouse that contains records dating back to January 1, 2006, with over 3 million patients and over 10 million unique patient encounters. We queried for hematologic patients with hematological cancers at a high risk for increasingly resistant and severe infections. The Infectious Diseases Society of America has defined commonly resistant bacteria as ESCAPE (Enterococcus, Staphylococcus aureus, Klebsiella pneumoniae, Acinetobacter, Pseudomonas aeruginosa, Enterobacter). As suggested in recent literature, other common and difficult-to-treat infections such as Clostridium difficile and Enterobacteriaceae organisms (E. coli, Proteus) can be added to this group and change the acronym from ESCAPE to ESCAPE-A.

Results: Out of 6017 patients with Hematological Malignancies, 660 patients with 684 malignant diagnoses were found; 235 had MDS, 174 had AML, 105 had ALL, 244 had CML, 39 had ALL, and 10 had an unspecified hematological cancer. Of 1132 infectious events, 62% were ESCAPE infections. The bacteria most frequently isolated were Enterococcus (23.4%), Staphylococcus aureus (18.5%) and Pseudomonas (16.9%). Bacteremia was the most predominant type of infection (41.9%) followed up by urinary tract infections (38.2%). Patients with MDS (39.6%) and AML (25.3%) were mainly affected. A prevalent resistance to levofloxacin was detected in gram positives and gram-negative organisms (29-54%). Pseudomonas, E. coli, Proteus and Klebsiella pneumoniae showed a significant resistance to broad-spectrum antibiotics including aztreonam (23-34%), cefepime (7-23%), and imipenem (22-39%). Pseudomonas had the highest mortality rate (45.2%), followed by Enterococcus (44.2%), and Pseudomonas (36.7%).

Summary/Conclusions: Hematological cancers with risk for neutropenia such as MDS and AML were the most affected by ESCAPE. Results: Out of 769 patients consecutively admitted in our ward, 85 had LI and 47 of them underwent BAL (total amount: 51 procedures). A causal agent of LI was detected in 33 cases (65%) allowing to modify the ongoing antimicrobial treatment in 25 of these ones (76%). Twelve cases of LI fulfilling the radiologic criteria for IPA, though presenting only a positive Aspergillus PCR on BAL, were detected and treated as probable IPA. One life-threatening post-procedure complication was observed.

Summary/Conclusions: BAL seems a safe approach for an early diagnosis of LI in hematologic patients. The assessment of a broad diagnostic panel allowed the detection of a putative agent in 65% of cases. Assessment of Aspergillus by PCR on BAL proved useful for probable IPA diagnosis.

E1147
Proposed Pegfilgrastim Biosimilar CHS-1701 Demonstrates Pharmacokinetic and Pharmacodynamic Similarity to Marketed Pegfilgrastim in a Rat Neutropenia Model and in Healthy Subjects

P. O'Connor 1,*, H. Tang 1, F. Civoli 1, B. Finck 1, V. Vexler 1
1 Coherus BioSciences, Inc., Redwood City, United States

Background: CHS-1701, a proposed biosimilar of pegfilgrastim, is being developed to decrease infection in patients receiving myelosuppressive anticancer drugs associated with febrile neutropenia.

Aims: The aim of the preclinical study was to compare pharmacokinetic (PK) and pharmacodynamic (PD) effects of CHS-1701 and marketed pegfilgrastim (MP) in a rat model of cyclophosphamide (CPA)-induced neutropenia. Since pegfilgrastim has the same mechanism of action in humans and rats, preclinical models of CPA-induced neutropenia are considered to be pharmacologically and clinically relevant models of chemotherapy-induced neutropenia in cancer patients. The aim of the clinical program was to demonstrate the PK and bioequivalence of CHS-1701 to MP in a multi-center, randomized, single-blind, 3-period crossover study.

Methods: In the rat model, a single SC dose of CHS-1701 or MP was administered at 24 hours after CPA administration, when the peripheral neutrophil counts had been reduced by ~60-70% from baseline. Doses from 30 to 1000 µg/kg were evaluated in order to provide a broad range of exposures to pegfilgrastim and allow for the comparison of CHS-1701 and MP dose response in a steep part of the PD dose response curve. The PD response was evaluated in the blood by analyzing time-dependent changes in absolute neutrophil counts (ANC) and calculating ANC AUC0-∞ if the 90% confidence interval (CI) for the geometric mean ratio (GMR) was within 80-125% and for PD (ANCmax and ANC AUC0-∞) if the 90% CI for the GMR was within 80-125%.

Results: In the rat model, CHS-1701 and MP demonstrated similar time- and dose-dependent changes in the number of peripheral neutrophils and in the proliferative response in the bone marrow. No differences between CHS-1701 and MP in PD (Fig. 1) or PK were observed across the tested dose range. In the clinical study, PK bioequivalence criteria were met for Cmax (GMR=105.0; 90% CI 95.5, 115.4) and AUC0-∞ (GMR=97.5; 90% CI 88.6, 107.2). Pre-specified PD bioequivalence criteria (90% CI) and more stringent criteria (95% CI) were met for ANCmax (GMR=99.6; 90% CI: 96.2, 103.2; 95% CI: 95.5, 103.9) and ANC AUC0-∞ (GMR=96.7; 90% CI: 92.2, 101.4; 95% CI: 91.4, 102.4). The two treatments displayed similar safety profiles. Investigator-designated treatment-related AEs occurred in 71.9%, 71.2%, and 62.8% of subjects during the CHS-1701, first MP, and second MP dosing periods, respectively, and most commonly included back pain (46.9%, 42.3%, 30.8%), headache (29.2%, 36.9%, 29.5%), and arthralgia (8.3%, 13.5%, 7.7%). There were no treatment-related serious AEs.

Figure 1.

Summary/Conclusions: The dose-dependent changes in the neutropenia model were consistent with the PD effects of pegfilgrastim in humans and demonstrate that CHS-1701 results in comparable neutrophil recovery and time course compared to marketed pegfilgrastim. The clinical study demonstrates highly similar PK, PD, and safety profiles in humans for CHS-1701 and marketed pegfilgrastim. Overall, preclinical and clinical results suggest that CHS-1701 would provide similar PK, PD, safety, and efficacy to marketed pegfilgrastim in patients with chemotherapy-induced neutropenia.

E1148
A Retrospective Review Identifies a Resistant Microbial Strain, Antimicrobial Sensitivities and Risk Stratification of First Line Antibiotic Use in Adult Cancer Patients with Neutropenic Sepsis

A. Danga 1,*, Y.M.T. Hui 2, K. Lazarus 3, T. Sugia 4
1 Coherus BioSciences, Inc., Redwood City, United States
Background: Neutropenic sepsis remains a leading cause of morbidity and mortality in both haematology-oncology and general oncology patients on cytotoxic chemotherapy. Micafungin is a novel echinocandin approved as prophylaxis in haematology patients. We aimed to assess the efficacy and toxicity of micafungin in prophylaxis in neutropenic patients.

Methods: A retrospective review of patients treated for neutropenic sepsis was conducted for the period between 1/4/2015 to 11/10/2016. Analysis of potential risk factors including primary disease, age, sex, treatment regimen, albumin, neutrophil and lymphocyte count to assess potential association with adverse outcomes.

Results: There were 116 episodes of neutropenic sepsis in 92 patients in this period. Of these, 61 were haematology-oncology patients and 31 general oncology. 42 of 76 positive cultures identified gram-negative organisms. 40 patients received single agent Tazocin and 71 patients (61.2%) received Tazocin and an aminoglycoside as first line antibiotic treatment. Fourteen isolates demonstrated resistance, including 2 cases of stenotrophomonas maltophilia and 12 cases of enterobacteriaceae. 13 of the 14 resistant isolates were found in haematology-oncology patients. Nine of these cases were resistant to single agent Tazocin but sensitive to an aminoglycoside. The mean age of cases with resistance to Tazocin was 54.2 years (median 62). There was no significant difference in sex or degree of neutropenia/lipopenia in the cases that contracted resistant bacterial strains compared to those that were culture negative. Of the 4 fatal cases with resistant bacteria, 3 had low albumin (mean 25.5g/L cf. mean of 34g/L in resistant bacteria cases surviving).

Summary/Conclusions: This retrospective analysis supports the use of combination antimicrobials up front as first line treatment in high-risk patients with neutropenic sepsis. The study has demonstrated that the patient cohort most at risk of developing drug resistant bacteria are patients with high-risk or relapsed haematology-oncological disorders like AML or high-grade lymphoma, requiring multiple cycles of intensive chemotherapy. Of the patients who isolate resistant bacteria, identifying low albumin early may be a potential marker for adverse outcome in terms of morbidity and mortality. Of interest only one oncology patient isolates a resistant strain of bacteria, furthermore only 25% of general oncology patients treated with neutropenic sepsis had positive cultures compared to 75.8% of haematology-oncology patients. When comparing these findings to UK NICE recommendations it is clear that first line use of Tazocin in general oncology patients may well suffice in initial treatment of neutropenic sepsis. However with haematology-oncology patients early or up front consideration for the additional usage of an aminoglycoside is essential to optimize favorable outcome in 2012, UK NICE guidelines. From this study, the proposed risk factors of isolating resistant strains of bacteria leading to adverse outcomes would be aggressive haematological malignancies, receiving more intensive cytotoxic therapy, multiple lines of treatment and low albumin. Further analysis in a multi center setting may support patient population and side close collaboration between clinicians and microbiologists is essential in providing optimal antimicrobial therapy algorithms in neutropenic patients.

E1150

USE OF MICAFUNGIN IN PROPHYLAXIS IN ONCO-HEMATOLOGY: RESULTS OF AN OBSERVATIONAL, MULTICENTER, PROSPECTIVE FRENCH STUDY (OLYMPRE)

1American Hospital, Beirut, Lebanon, 2Hôpital Robert Debré, Paris, 3Hospices Civils, Lyon, 4Medical Affairs, Astellas Pharma France, Levallois-Perret, 5Centre Hospitalo-Universitaire, Montpellier, 6Centre Hospitalo-Universitaire, Strasbourg, France

Background: Antifungal prophylaxis is being used increasingly.

Aims: The therapeutic arsenal is extensive and requires a better understanding of micafungin use in onco-hematology where most-at-risk patients of invasive fungal infections (IFI) are managed.

Methods: This observational study was conducted in 18 onco-hematology units in adult patients and children treated with micafungin in prophylaxis with a 3-months follow-up period.

Results: 150 patients (96 adults, 55 children) were included and represent the analysis population. In total, 15 patients (10%) presented an IFI during micafungin treatment. Among them, 11 presented a probable or proven IFI. The rate of IFI was higher in children (15%, n=8) than in adults (7%, n=7) and seem to have been influenced by the type of hematology and if the patient was allo-grafted or not: 13% (n=8) in allografted patients, 9% (n=4) in patients with AML or SMD and 7% (n=3) in other patients. Median time to infection was 24 days (1 to 68 days) and was longer in adults (25 days, 4 to 68 days) than in children (16.5 days, 1 to 68 days). Twelve patients (8 children and 4 adults) presented at least one clinical or radiological sign of suspected IFI. Fungus was identified in 8 patients (62%), mostly in blood cultures (50%, n=4); candidiasis in 4 patients, aspergillosis in 3 patients and infection related to Rhisopus in 1 patient. Incidence rate of IFI (10%, 5 patients) was inferior to prophylaxis failure rate (23%, 34 patients). Prophylaxis failure rate takes in account patients who switched to empirical treatment besides patients who switched to preemptive or curative treatment. After the end of prophylaxis, 4 patients (3 adults and 1 child) presented a proven IFI. Median time to infection after the end of treatment was 10,5 days in adults (7 to 24 days) and 52 days in children. Micafungin was overall well tolerated: only 10 patients (7%, mostly children) presented grade 1 to 4 adverse events related to micafungin, including 5 patients (3% with grade 3 or 4 adverse events).

Summary/Conclusions: Efficacy and safety profile of micafungin in prophylaxis are similar to what was observed in previous studies. Incidence IFI at 3 months confirms the clinical effectiveness of micafungin in prophylaxis in high risk patients. The low rate of serious adverse events confirms micafungin safety profile, in children included.

OUTBREAK OF MULTI-DRUG RESISTANT PSEUDOMONAS AERUGINOSA (MPA) IN A HAEMATOLOGY WARD (HW): MANAGEMENT AND INFECTION CONTROL MEASURES

D. Armentino1,2*, E. Cerchiara1, O. Annibali1, M. Becilli1, E. Circhetta1, S. Ferraro1, A. Pagona1, A. Scardocci1, M. Tufani1, C. M. Tinndelli2, G. Avvisati1

1Haematology, North West London NHS Trust, 2Haematology, West Middlesex University Hospital, Renal Medicine, Imperial College Healthcare NHS Trust, 4Haematology, Hillingdon Hospital NHS Trust, London, United Kingdom
Background: Voriconazole is a triazole antifungal agent that has broad spectrum antifungal activity. It is widely used in the treatment of invasive fungal infections. However, there is limited information about its safety and effectiveness in hematologic patients who received voriconazole for the treatment or prevention of invasive fungal disease.

Methods: Between January to August 2016, 76 hematological patients who received voriconazole for the treatment or prevention of invasive fungal disease were enrolled in this study. The population CYP2C19 polymorphism of voriconazole were performed using PCR-Pyrosequencing. The trough plasma concentrations of voriconazole (Ctrough) was determined using high-performance liquid chromatography (HPLC).

Results: Genotyping for CYP2C19 polymorphic isozyme variations showed that 32 subjects (43.42%) for the CYP2C19 wild-type, 43 (56.58%) for the CYP2C19 polymorphic isozyme, and 1 subject had a combination genotype. No significant difference was found between the two groups in the trough values (1.56±1.86μg/ml vs 3.30±2.35μg/ml; p=0.00). The Ctrough of the 45 patients were detected for 119 times totally. The medium of the Ctrough 45 hematological patients were 3.9±0.5μg/ml.

Summary/Conclusions: Voriconazole has been widely used in treatment and prevention invasive fungal disease for immunodeficiency hematological patients. And the voriconazole plasma drug levels were associated with its efficacy and toxicity. The hepatic cytochrome P450 isoenzyme 2C19 plays a important role in voriconazole metabolism and drug plasma level in setting of Asian population especially in hematologic patients is unknown. The hepatic cytochrome P450 isoenzyme 2C19 plays a important role in voriconazole metabolism and drug plasma level in setting of Asian population especially in hematologic patients is unknown. The hepatic cytochrome P450 isoenzyme 2C19 plays a important role in voriconazole metabolism and drug plasma level in setting of Asian population especially in hematologic patients is unknown.

GLYCOSYLATED FERRITIN MEASURING SIGNIFICANCE FOR SECONDARY HEMOPHAGOCYTIC SYNDROME DIAGNOSTICS

V. Potapenko1,2, M. Pervakova2, S. Lapin2, A. Klimovich1, O. Mironova1, N. Petrova1, N. Othimyanoya1, N. Skorobogatova1, E. Karyagina1, E. Karayev1, E. Pavlichenko2, N. Potikhonova1, T. Kultabaev1, N. Medvedeva1, B. Afanasyev2 1Municipal clinical hospital №31, 2Academician I.P. Pavlov First St. Petersburg State Medical University, 3Municipal hospital №15, 4I. I. Mechnikov North-Western State Medical University, 5Russian Scientific Research Institute of Hematology and Transfusiology, 6Saint-Petersburg State University, Saint-Petersburg, Russian Federation

Background: Hemophagocytic syndrome (HPS) is a clinicopathologic condition characterized by systemic inflammatory reaction with cytopenia and tissue damage. The HFS may be primary (genetic associated) or secondary (SHPS), caused by different systemic disorders (immune, infectious, neoplastic). The overall clinical symptoms are similar to sepsis, so it could be difficult to differentiate among these entities. Ferritin levels are high in both cases, but the glycosylated/nonglycosylated ferritin fractions ratio is seems to be indicative.

Aims: The estimation of the ferritin fractions ratio and biochemical profile in patients with sepsis and SHPS.

Methods: The data from 64 patients were analyzed: 40 pts with diagnosed SHPS (median age 57, range 8-74 years) and 24 with lethal septic shock (median age 57.5, range 18-52 years). SHPS in patients with persistent fever refrac- tory to antibacterial therapy and/or prolonged cytopenia and/or organ (lungs, CNS) involvement was established after the other conditions had been excluded. Sepsis diagnostics was based on the confirmed infection site and systemic inflammation with multiorgan failure. The following serum values were analyzed: alkaline phosphatase (ALP), alanine aminotransferase (ALT), aspartate transaminase (AST), lactate dehydrogenase (LDH), bilirubin, creatinine, INR, C-reactive protein (CRP), procalcitonin (PCT), total ferritin, and glycosylated ferritin percentage. Mann-Whitney U test and ROC-analysis were used for statistical analyses.

Results: No differences were found in sepsis and SHPS for ALAT, ASAT, AlPh, LDH, and bilirubin levels. The difference of INR, CRP, PCT, total ferritin, and glycosylated ferritin percentage. Mann-Whitney U test and ROC-analysis were used for statistical analyses.

Results: No differences were found in sepsis and SHPS for ALAT, ASAT, AIPH, LDH, and bilirubin levels. The difference of INR, CRP, PCT, creatinine levels was significant ($p<0.01$). The most substantial difference in SHPS and sepsis groups had serum concentrations of ferritin, triglycerides, level of ferritin glycosylation ($p<0.01$) (Table 1). According to ROC-analysis, the area under the curve for ferritin, triglycerides and percentage of ferritin glycosylation were 0.78, 0.82, and 0.92, respectively.

Table 1. Significant laboratory differences ($p$ values) between sepsis and SHPS.

Summary/Conclusions: The most difference between sepsis and SHPS was observed for triglycerides, ferritin and percentage of glycosylated ferritin. Percentage of glycosylated ferritin fraction seems to be the most indicative, which may make it useful for SHPS diagnostics and its differentiation from sepsis.

E1155

SERUM HEPCIDIN QUANTIFICATION IN INFLAMMATORY BOWEL DISEASES

V. Manolov1,2, V. Vasiliev3, K. Tzatchev1, O. Georgiev3, D. Stefanova-Petrova2, R. Tzantcheva2, V. Mitcheva2, R. Popcheva2 1Dept. of Clinical laboratory and clinical immunology, 2Department of Propaedeutics of Internal diseases, 3Department of Medical chemistry and biochemistry, Medical University, Sofia, Sofia, Bulgaria

Background: Inflammatory bowel diseases (IBD) includes different intestinal pathologies, most common among them are Colitis Ucerosa (CU) and Crohn’s Disease (CD). Pathogenesis of IBD is still unclear, however they are multifactor diseases, with genetic and autoimmune compounds, in combination of environmental factors. One of IBD symptoms is iron deficiency anemia.

Aims: We aimed to search for connection between serum hepcidin quantification and anemia in IBD.

Methods: We included 64 patients with IBD - 29 with Colitis Ucerosa (CU), and 35 with Crohn’s Disease (CD). They were diagnosed in University “Alek-sandrovska” hospital in Clinic of Gastroenterology. Their results were compared to age and gender matched healthy controls. Laboratory assessments were analyzed for included groups – iron, ferritin, CRP, IL-6 and hepcidin. AAS, nephelometric, ELISA and statistical methods were used during analyzes and obtained results interpretation.

Results: 53 from our patients had with iron deficiency anemia (IDA) and low hepcidin concentrations (5.9±1.1 µg/L) compared to control group (19.9±2.8 µg/L). P<0.001. 11 of included patients had combination of chronic disease (ACD). Their hepcidin levels were increased (59.9±4.6 µg/L) in comparison to healthy controls (19.9±2.8 µg/L); P<0.001. In patients with ACD/IDA, quantified serum hepcidin correlates positively to increased IL-6 (r=0.758, P<0.005) and CRP concentrations (r=0.899, P<0.001).

Summary/Conclusions: Quantity of serum hepcidin levels in IBD patients might be a key element in diagnosis and treatment of anemia in these patients. Serum hepcidin levels are useful marker for differential diagnosis between iron deficiency anemia and combination iron deficiency anemia/ anemia of chronic disease.

E1156

MUTATIONS IN YARS2 CAUSE CONGENITAL SIDEROBLASTIC ANEMIA WITHOUT SHOWING EVIDENCES OF MYOPATHY AND LACTIC ACIDOSIS

C. Bertholi1,2, V. Gostec1,2, M. Bode-Boger1,2, J. Gostec1,2, D. Kick1,2, R. Acosta1,2, S. Festa1,2, G. Biagi1,2, L. Maia1,2, R. Tripepi1,2, S. Gianni1,2, D. Gabetta1,2, R. Gavioli1,2, M. Tripepi1,2 1Iron Metabolism: Regulation and Diseases, Josep Carreras Leukaemia Research Institute (JIC), BADALONA, 2Hematology Service, Hospital del Mar, Barcelona, Spain

Background: Mutations in the gene YARS2 encoding mitochondrial tyrosyl-tRNA synthetase have previously been identified as a cause of MLASA2, a mitochondrial respiratory chain disorder presenting with myopathy, lactic acidosis and congenital sideroblastic anemia (OMIM #610957, OMIM #2598). Up to date in the literature it has been reported 9 families with 11 affected individuals with mutations in YARS2 gene and affected from MLASA2.

Aims: Here we report a new case with a different clinical presentation.

Methods: We have identified two novel variations in YARS2 gene using Next Generation Sequencing (NGS) panel containing 10 genes involved in congenital and acquired sideroblastic anemia.

Results: The proband is a young woman aged 24 where we have identified 2 novel variations in YARS2 gene. One pathogenic splicing mutation NM_001040436.2 c.[1104-1G>A], and a missense variation NM_001040436.2 c.608 G>T, which are on-going to confirm pathogenicity of the novel missense variation.

Summary/Conclusions: Here, we reported a patient with mutation in YARS2 gene showing congenital sideroblastic anemia but presenting neither lactic acidosis nor myopathy. Therefore, patients with defect in YARS2 gene may present with a less severe clinical manifestations only involving congenital sideroblastic anemia without other extra-hematopoietic defects. MLASA2 must be consider in patients presenting with only congenital sideroblastic anemia since early diagnosis and supportive therapy will be important to prevent complications.

E1157

IRON CHELATION DATA OF CONGENITAL DYSERYTHROPOIETIC ANEMIA PATIENTS: A SINGLE CENTER EXPERIENCE

M. Celini1,2, N. Kalkan1, T. Bayhan1, F. Gumruk1, S. Unal1 1Hacettepe University, Division Of Pediatric Hematology, Ankara, Turkey

Background: Congenital dyserythropoietic anemia (CDA) is a rare, genetically heterogeneous disorder characterized with ineffective erythropoiesis, and congenital malformations in certain types. Patients present with varying degrees of anemia, and some of the patients may have mild disorder whereas others may be transfusion dependent. The ineffective erythropoiesis and the transfusional iron load puts these patients at risk for iron overloading and there is very scarce data on the iron loading and chelation types in these patients.

Aims: We aimed to summarize the chelation results of our patients with CDA from a single center.

Methods: Of the 33 patients with CDA, 11 were initiated iron chelation treatment either for receiving more than 20 packed RBC transfusions previously or for having serum ferritin levels above 1000ng/ml.
Results: Of these 11 patients, 7 were CDA type II. The median age of diagnosis was 12 months (3-144 months) and male to female ratio was 7:4. Median transfusion requirement per year at previous year prior to initiation of chelation was 12 times (0-17). All of the patients were on chronic transfusion programme at initiation of iron chelation except for 2 (one receives occasional transfusion, and the other patient was on chronic transfusion programme but became transfusion independent after splenectomy). The median age at last visit was 70 months (32m-40 years). The median value of serum ferritin at initiation of iron chelators was 822 ng/ml. All of the patients were initiated deferasirox for iron chelation at a median dose of 24mg/kg/day (10-40) and the median chelation follow-up duration was 27 months (2-54 months). Three of the patients were evaluated with cardiac and hepatic T2* assessment prior to and by the end of 1 year of chelation and none of the patients were found to have cardiac iron loading at chelation initiation, whereas 2 had severe and 1 had moderate LIC values. In the subsequent assessment under chelation of these 3 patients all still had cardiac T2* values above 20 ms, whereas 1 had mild and 2 had moderate LIC values. Serum ferritin levels prior to initiation and by the end of 1 year were compared and the difference was found statistically insignificant.

Summary/Conclusions: Patients with CDA are at risk for iron loading and they need to be screened for the iron loading periodically. The prompt chelation in these patients prevent organ failure risks at long term including cardiac failure, cirrhosis and endocrinopathies.

E1158

ORAL IRON CHELATION FOR TREATMENT OF HEREDITARY HEMOCHROMATOSIS IN CHILDREN

M. Moraki1,2, E. Repousi1, D. Kyniakopoulou1, P. Delaporta1, A. Kattamis1,1 Thalassemia Unit, First Department of Pediatrics, National and Kapodistrian University of Athens, ‘Aghia Sophia’ Children’s Hospital, Athens, Greece

Background: Hereditary hemochromatosis (HH) very rarely presents during childhood. The most common form of HH in children is Juvenile Hemochromatosis (JJH), a rare genetic disorder inherited with an autosomal recessive manner, resulting from mutations in either the hemochromatosis HJV (type 2A) or the hepcidin (HAMP) gene (type 2 B). Early diagnosis and closely monitoring of iron overload indexes, namely, serum ferritin levels, transferrin saturation and tissue iron measurement by magnetic resonance imaging (MRI) are essential in order to prevent permanent organ damage and potentially life threatening complications (cirrhosis, diabetes mellitus, cardiac dysfunction, and hypogonadism). Therapeutic intervention in children with HH may be problematic, as erythropoiesis is invasive and may not be well tolerated in young children. Iron chelation therapy can be implemented as an alternative treatment to erythrocytapheresis.

Aims: The scope of this study was to evaluate the use of an oral iron chelation therapy in young children with HH.

Methods: 3 children (2 females and 1 male) were diagnosed with HH with the age of 4, 6 and 8 years old, respectively, based on increased ferritin and transferrin saturation indexes and exclusion of other causes of hyperferritinemia. Genetic analysis were performed in all 3 patients and showed positive results in 2 of them, while on the 3rd no genetic changes could be identified. All patients were at pre-symptomatic stage of the disease and they were referred for evaluation after hyperferritinemia was discovered on a routine screening examination. Liver iron concentration (LIC) and cardiac iron concentration were evaluated by MRI (table 1). Iron chelation therapy with deferasirox (DFX) at low dose (10 mg/kg/24h) was initiated, after evaluation was completed and permission from regulatory authorities obtained.

Results: All 3 patients responded promptly to therapy and showed decreased levels of ferritin, LIC and cardiac iron concentration. Gastrointestinal disturbances were noted in 1 patient, which resolved with H2-blockers and with changing the treatment to 5d/wk (patient 2). Mild increase in serum creatinine (>33% from baseline but within normal range for her age) was observed in patient 3, which resolved with temporary cessation of the chelation therapy.

Summary/Conclusions: Although the mechanism of neuropsychiatric hypersegmentation in iron deficiency anaemia is not clear, it is thought that iron acts as a cofactor in folate metabolism and / or DNA synthesis in granulocytes. There are a limited number of studies dealing with NH associated with ID in the literature. However most of these studies were observational and did not include controls or were not blinded. Our study is the first to demonstrate the association of NH with iron deficiency anaemia in adults in the absence of megaloblastic anemia.

E1159

NEUROPHIL HYPERSEGMENTATION IN ADULTS WITH IRON DEFICIENCY: A CASE-CONTROL STUDY

I. Erdogan Ozuna1, D. Keskin1, E. Durcan2, Y. Gunay2, S. Bilgin2, S. Berk1, D. Ozmens, N. Ozglu Yurttas1, S. Sadein1, A. Salihoglu1, A. E. Eskinazer1, M. C. Arf1, S. Ongoren1, Z. Baslar1, Y. Aydin1, A. L. Yildiran1, T. Soyasl1

1Department of Internal Medicine, Division of Hematology, 2Department of Internal Medicine, Istanbul University Cerrahpasa Faculty of Medicine, Istanbul, Turkey

Background: Neutrophil hypersegmentation (NH) has been accepted as a hallmark of the macrocytic anaemias associated with the deficiency of cobalamin or folate. However, there are a small number of reports stating that NH might accompany iron deficiency anaemia. The aim of the present study was to determine the association of NH with iron deficiency (with or without anaemia).

Aims: The aim of the present study was to determine the association of NH with iron deficiency (with or without anaemia) in adults and also to compare neutrophil segmentation status in anaemia group before and after oral or parenteral iron treatment.

Methods: Fifty-six patients with iron deficiency and 20 age and sex matched controls were included in this prospective, single blind, case-control study between February-November 2016. Subjects were included if they were ≥ 18 years of age, and had normal serum vitamin B12 and folate levels, liver, thyroid and renal function tests. Pregnant women and patients with a history of blood transfusion within last 3 months and/or those with acute renal failure, anaemia of chronic disease, hypothyroidism, additional cytopenias and infection were excluded. Patients with iron deficiency were divided into 2 groups being with iron deficiency anaemia (IDA) and iron deficiency without anaemia (ID). Those who were anaemia were further evaluated prior and after iron replacement. Results of the study groups were compared to age and sex matched healthy controls. Blinded peripheral blood smear slides were evaluated by a haematologist by counting 200 neutrophils. Hypersegmentation was defined as reported by Bain et al. Iron deficiency was diagnosed based on the findings of iron parameters including serum iron, total iron binding capacity, and ferritin. Anaemia was defined according to the WHO recommendation. Cohort characteristics were given in Table 1.

Results: Hypersegmentation was detected in 25 individuals with iron deficiency (45%) and 1 healthy control (5%). It was significantly more frequent in the IDA group (48.8%) than in the ID group (30.7%) [p<0.001]. After iron treatment 3 IDA patients’ peripheral blood smear were checked and with normalization of iron parameters and hemoglobin, hypersegmentation was undetectable. The study is still ongoing and rest of the IDA group are still on treatment, their peripheral blood smears are to be examined after iron treatment is over.

Figure 1.
Background: Immunosuppression with mTOR inhibitors (sirolimus or everolimus) has been associated with development of microcytic anemia after solid organ transplantation. The prevalence reaches 27 to 57% in the case of kidney transplantation. This anemia has been attributed to hepcidin increase induced by the inhibition of mTOR protein.

Aims: To evaluate the prevalence of microcytic anemia after allogeneic hematopoietic stem cell transplantation in patients receiving mTOR inhibitors.

Methods: 61 consecutive allogeneic stem cell reduced intensity conditioning (alloRIC) recipients were analyzed. In all cases, a non-related donor was used. Baseline disease was: 23 acute leukemia (37.7%), 12 non-Hodgkin lymphomas (19.7%), 10 myelodysplastic syndromes (16.4%), 7 Hodgkin lymphomas 7 (11.4%), 4 multiple myelomas (6.5%), 3 chronic lymphocytic leukemia (4.9%), and 2 myelofibrosis (3.2%). All of them received Fludarabine-based conditioning treatment and the combination sirolimus (mTOR inhibitor)-taclidomus (calcineurin inhibitor) as GVHD prophylaxis. Drug doses were adjusted according to blood levels and renal function. Levels of Hb, MCV and iron parameters were also systematically evaluated after alloRIC. Microcytosis was considered when MCV was below 80 fl.

Results: At 6 months 56 out of 61 (92%) were alive. Anemia was observed in 30 (49%) of them, with only 8 cases (13.1%) showing Hb level below 100 g/l.

Microcytic anemia was diagnosed in 2 of them (3.3%). One patient showed an iron deficiency anemia due to gastrointestinal bleeding (Hb 94 g/l, MCV 69 fl, serum ferritin 21 µg/l). However, the second one, a 61-year old male with an acute leukemia, had a microcytic anemia with iron parameter changes similar to those observed in kidney transplantation and associated with increased hepcidin, (see table). Anemia progressively improved with sirolimus tapering.

Table 1.

| Inh: inhibitors, Hb: hemoglobin, MCV: mean corpuscular volume, Fe: iron, TIBC: total iron binding capacity,%SAT: % transferrin saturation, Bm: bone marrow, Nv: normal values. |

Summary/Conclusions: In contrast to kidney transplantation, microcytic anemia related to immunosuppression with mTOR inhibitors was seldom observed in alloRIC recipients. However, this association should be taken in account in this setting, as a rare cause of anemia. In case of microcytic anemia, the evaluation of iron parameters and hepcidin provides the diagnosis of this rare type of anemia.

E1161

IRON METABOLISM IN PATIENTS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA

E. Lukina1,*, K. Tandilova1, N. Tsveateva1, O. Nikulina1, E. Sysoyeva1, I. Karpova2, E. Marshina3, V. Sinitsyn3
1Department of Orphan Diseases, 2Central Clinical Diagnostic Laboratory, National Research Center for Hematology, 3Radiology Department, Federal Center of Treatment and Rehabilitation, Moscow, Russian Federation

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a rare acquired clonal non-malignant hematological disorder that is associated with hemolytic anemia, immune-mediated failure, thrombosis. At the onset, the condition is often interpreted as iron deficiency anemia that leads to the prescription of ferotherapy.

Aims: Study iron metabolism in patients with PNH.

Methods: The study group included 19 patients (11 men and 8 women aged from 20 to 64 years, median age 43 years) with a diagnosis of PNH, followed up in our Center between 2014 and 2017. The median hemoglobin level was 8.1 g/dl. The erythrocyte PNH clone size ranged from 17 to 99%, median - 47%. Granulocyte and monocyte PNH clone sizes were 85% and 89%, respectively. The following parameters were studied to characterize iron metabolism: ferritin, transferrin, iron concentration, total iron binding capacity (TIBC), transferrin saturation. In addition, we also analyzed iron distribution under intravenous and oral iron supplementation. Furthermore, we investigated the activity of iron absorption under oral iron supplementation in mice as well as under intravenous iron supplementation. In addition, we also analyzed iron distribution under intravenous and oral iron supplementation.

Results: Serum iron levels in IV and Oral iron groups were significantly higher compared with control group. However, serum iron levels were elevated only in oral iron group. In immunohistochemical analyses, expression levels of duodenal DMT1 were not detected in all groups and expression levels of duodenal FPN in IV and Oral iron groups were significantly lower than control group. As for iron distribution in liver, iron was accumulated in reticuloendothelial cells in IV iron group, on the other hand, in Oral iron group iron was accumulated in parenchyma. In hematological analyses, although red blood cell and reticulocyte count were not significantly different among all groups, Ret-He and MCH in Oral iron group were higher than IV iron groups.

Summary/Conclusions: It was demonstrated in this study that serum iron levels were elevated in spite of high hepcidin levels and down-regulation of duodenal iron transporters under oral iron supplementation. Furthermore, iron was distributed in liver parenchyma and hemoglobin contents in each reticuloocyte and erythrocyte were up-regulated only under oral iron supplementation. We speculated that high serum iron lead to excess iron uptake into tissues and erythrocyte fraction. These data might provide an opportunity to rethink the importance of proper use of iron supplemements.

E1163

DEFERASIROX FOR SEVERE ANAEMIAS IN YOUNG CHILDREN

A. Gunawan1,2,*, S. Korenev3, H. Mundy4, M. Pelidis3, J. Alamelu3, B. Inusa3
1Haematology, Guy’s and St Thomas’ NHS Trust, 2Pediatric, Evelina Hospital, Guy’s and St Thomas’ NHS Trust, 3Pediatric, Evelina Hospital, Guy’s and St Thomas’ NHS Trust, London, United Kingdom
Background: Children with haemoglobinopathy and rare anaemias often require regular red cell transfusions at some stage of their lives. Iron overload is therefore inevitable and iron chelation is a key component of therapy for children in this group. However its use has not been validated especially in children under two years of age. Deferasirox (Exjade®; Novartis Pharma AG, Basel, Switzerland) is an iron chelator that is conclusively proven to be effective and safe in transfusional anaemia such as haemoglobinopathies.

Aims: We aim to look at the efficacy and safety of Deferasirox in children with severe anaemias.

Methods: We present a case report of 6 children with severe anaemias treated with Deferasirox in a tertiary pediatric haematology centre in London, UK.

Results: Here we report 6 cases where Deferasirox has been used in young children with rare anaemias and sickle cell disease where evidence is sparse. Our patients were aged 1-36 months of age. Deferasirox was started at the age of 2 months and 4 months respectively. Patients 3 and 4 presented with neonatal anaemia requiring regular transfusion and were diagnosed with Pyruvate Kinase deficiency. Deferasirox was started at 12 and 19 months consecutively. Patient 5 presented with pure red cell aplasia at the age of 3 months and was diagnosed with Diamond Blackfan anaemia. He was initially treated with steroid but became resistant at around 40 months of age. He was then started on regular transfusion and was started at deferasirox at 4 years of age. Patient 6 was diagnosed at birth with sickle cell anaemia. He suffered from stroke at the age of 8 months and was started on chronic transfusion program. Deferasirox was started at around at the age of 1. He had a successful maternal haplo-identical stem cell transplant at the age of 3 years old. Transfusion and deferasirox were subsequently stopped.

Figure 1.

Summary/Conclusions: All of these children had stabilization or improvement of ferritin values after initiation of deferasirox as shown in figure 1. Deferasirox is licensed in Europe to be used in children with thalassaemia older than 6 years of age or older than 2 year of age when desferoxamine therapy is inappropriate or inadequate. Deferasirox is preferable in severe anaemias due to better side effect profile on the bone marrow compared to deferoxprone; the use of which can cause agranulocytosis or neutropenia. Furthermore, its oral administration improved compliance compared to desferrioxamine that required prolonged subcutaneous administrations. Deferasirox has been associated with renal impairment. However, none of patients developed renal or liver impairment during the use of deferasirox. Furthermore, it is crucial to conduct eye and ear screening tests both before and after the commencement of deferasirox. None of our patients had neurological side effects. Three of these children had deferasirox started at younger than 2 years of age. Hence, we have shown that deferasirox is safe and efficacious in treating iron overload in very young children with rare anaemias and sickle cell disease where evidence is sparse.

E1164

MONITORING ORAL IRON THERAPY IN CHILDREN WITH IRON DEFICIENCY ANEMIA. AN OBSERVATIONAL, PROSPECTIVE, MULTICENTRIC STUDY
G. Russo1,2, V. Guardabasso3, P. Samperi2, L. Lo Valvo2, U. Ramenghi4

1Clinical and Experimental Medicine, University of Catania, 2Pediatric Hematology-Oncology Unit, 3Azienda Policlinico Vittorio Emanuele, Catania, 4Department of Pediatric and Public Health Sciences, University of Torino, Turin, 5Pediatric Hematology-Oncology Unit, University of Padova, Padova, 6Pediatric Hemato-Oncology Unit, IRCCS Candiolo dell’Ospedale San Giovanni Rotondo, 7Pediatric Hemato-Oncology Unit, Policlinico S.Osvaldo Malpighi, Bologna, 8Pediatric Unit, Carlo Poma Hospital, Mantova, 9Department of Cellular Biotechnologies and Hematology, “Sapienza” University, Roma, 10Maria Paternò Arrez Hospital, Ragusa, 11Hospital, Treviso, 12Central Teaching Hospital, Bolzano, 13Spedali Civili, Brescia, 14Ospedale Meyer, Firenze, Italy

Background: Iron deficiency anemia (IDA) is the most common hematological disease in infancy and childhood. Oral iron administration is a well-established, effective, and widely accepted treatment for anemia because of its efficacy, safety, and cost-effectiveness. Recently new preparations of oral iron compounds were launched, including droplet formulations, i.e. liposomal preparations and bis-glycinate iron; little is known on their effectiveness in real clinical practice.

Aims: To evaluate the efficiency of different oral iron preparations in children with IDA.

Methods: This observational study collected clinical and hematological data from 12 AIEOP (Associazione Italiana di Ematologia ed Oncologia Pediatrica) centers. Inclusion conditions for patient enrollment were age 3-months-12 years, diagnosis of IDA; exclusion criteria were all conditions interfering with iron absorption such as celiac disease, gastro-intestinal disorders and other chronic conditions. Local Physicians were free to prescribe any oral iron formulation, according to their standard practice. A calendar of laboratory test was suggested, including basal assessment of whole blood count, reticulocytes, iron status, with subsequent check points at 3 days (WBC and reticulocytes only), 2 weeks, 8 weeks, and at 6 months. Clinical data regarding compliance to therapy, unwanted effects, final outcome were recorded.

Results: 112 (M 58) patients were enrolled. Ethnic distribution was: Caucasian 74, African 23, Asian 10, Other 5. The median age at diagnosis of IDA was 1.5 years, with a bimodal distribution with frequency peaks at ages 0-3 and 12-14 years. Sixty-eight patients received bis-glycinate ferrous iron 0.45mg/kg, 19 elemental iron (ferrous gluconate/sulfate) 2mg/kg, 12 liposomal iron 0.7-1.4mg/kg, and 15 other preparations. Eating habits were reported as normal in 48 patients, inadequate weaning in 21, meatfish restriction in 32, other in 11. Gastro-intestinal side effects were reported in 9/68 (13%) in the bis-glycinate iron group, in 3/19 (16%) of the elemental iron group, and in 0/12 of the liposomal iron group. Suspension of therapy due to side effects was needed only in 5 patients, 4 in the bis-glycinate and 1 in the elemental iron group, respectively. Final outcome was available for 77 patients; it was recorded as solved IDA, persistent IDA, or lost at follow up. Solved cases were 40/53 (75%) in the bis-glycinate iron group, 3/19 (16%) in the elemental iron group, and 8/13 (62%) in the liposomal iron group. Persistent cases were 8/53 (15%) in the bis-glycinate iron group, 6/11 (55%) in the elemental iron group, and 1/13 (8%) in the liposomal iron group. Lost at follow up were 5/53 (9%) in the bis-glycinate iron group, 1/11 (9%) in the elemental iron group and 4/13 (31%) in the liposomal iron group.

Summary/Conclusions: The collected data show that both bis-glycinate and liposomal iron formulations have a good efficacy/safety profile and offer a sustainable alternative to classic elemental iron preparations.

E1165

AN INVESTIGATION ABOUT WEIGHT GAIN WITH TREATMENT OF IRON DEFICIENCY ANEMIA: CHANGES OF GHRELIN AND HEPcidin LEVELS WITH TREATMENT
H. C. Kılınç1, B. Onec2, K. Onec1, E. Caliskan3, H. Ankaralı4

1Internal Medicine, 2Hematology, 3Medical Microbiology, 4Biostatistics, Duzce University Faculty of Medicine, Duzce, Turkey

Background: Iron deficiency anemia (IDA) is a global health problem and problems in compliance with oral iron therapy are frequently seen. It has been shown that medications are not used regularly or discontinued due to weight problems during the treatment process.

Aims: We investigated ghrelin, known as appetite hormone and its relationship with hepcidin, the homeostatic regulator of intestinal iron absorption, in order to explain some symptoms of IDA and weight gain during iron treatment.

Methods: A hundred and twenty adult IDA patients, referred to our clinic between October 2015 and October 2016 were included in the study. The study was completed with 87 patients, who gave the informed content and a control group consisted of 50 healthy people. Information about age, gender, weight, height, body mass index (BMI), waist-hip circumference and blood samples were taken from the patient and control groups. The treatment of IDA was done according to the dose and method recommended by the responsible physician, including basal assessment of whole blood count, reticulocytes, iron status, with subsequent check points at 3 days (WBC and reticulocytes only), 2 weeks, 8 weeks, and at 6 months. Clinical data regarding compliance to therapy, unwanted effects, final outcome were recorded.

Results: 112 (M 58) patients were enrolled. Ethnic distribution was: Caucasian 74, African 23, Asian 10, Other 5. The median age at diagnosis of IDA was 1.5 years, with a bimodal distribution with frequency peaks at ages 0-3 and 12-14 years. Sixty-eight patients received bis-glycinate ferrous iron 0.45mg/kg, 19 elemental iron (ferrous gluconate/sulfate) 2mg/kg, 12 liposomal iron 0.7-1.4mg/kg, and 15 other preparations. Eating habits were reported as normal in 48 patients, inadequate weaning in 21, meatfish restriction in 32, other in 11. Gastro-intestinal side effects were reported in 9/68 (13%) in the bis-glycinate iron group, in 3/19 (16%) of the elemental iron group, and in 0/12 of the liposomal iron group. Persistent cases were 8/53 (15%) in the bis-glycinate iron group, 6/11 (55%) in the elemental iron group, and 1/13 (8%) in the liposomal iron group. Lost at follow up were 5/53 (9%) in the bis-glycinate iron group, 1/11 (9%) in the elemental iron group and 4/13 (31%) in the liposomal iron group.

Summary/Conclusions: The collected data show that both bis-glycinate and liposomal iron formulations have a good efficacy/safety profile and offer a sustainable alternative to classic elemental iron preparations.
were examined once in the control group and twice in the patient group, before and after treatment.

**Results:** When the patient and control groups were compared, there was no significant difference in terms of age, sex, height, weight, BMI, waist and hip circumference. The pretreatment plasma hepcidin and ghrelin levels of the patient group were significantly lower than in the control group, showing a significant increase with treatment, but it was not associated with weight gain. Interestingly, these neurons showed a positive but weak correlation with the increase in ghrelin levels of those people. Hepcidin plasma levels increased compared to the pretreatment levels (80 ± 21 ng/dl vs 164 ± 150 ng/ml, p < 0.001). Although an increase in the plasma ghrelin levels was encountered after treatment, it was not statistically significant (152 ± 119 pg/ml vs 164 ± 150 pg/ml, p = 0.589). When correlations of individual increases in ghrelin levels were examined, a weak positive correlation was found between increase in ghrelin levels and weight gain.

**Summary/Conclusions:** In our study, ghrelin was significantly lower than the control group in the IDA group, suggesting that it may be the cause of loss of appetite. Ghrelin is also detected in neurons of hypothalamic arcuate nucleus, which regulates appetite. The deficiency of iron may cause deficiencies in enzymatic activities of iron-dependent enzymes and it may disturb the function of these neurons. But the increase with treatment did not reach statistical significance. This may be due to physiological suppression of levels by weight gain. When patient-based weight gains were examined, there was a positive but weak correlation with the increase in ghrelin levels of those people. Hepcidin plasma levels increased compared to the pretreatment levels (80 ± 21 ng/dl vs 92 ± 13 ng/ml, p < 0.001). Although an increase in the plasma ghrelin levels was encountered after treatment, it was not statistically significant (152 ± 119 pg/ml vs 164 ± 150 pg/ml, p = 0.589). When correlations of individual increases in ghrelin levels were examined, a weak positive correlation was found between increase in ghrelin levels and weight gain.

**Summary/Conclusions:** In our study, ghrelin was significantly lower than the control group in the IDA group, suggesting that it may be the cause of loss of appetite. Ghrelin is also detected in neurons of hypothalamic arcuate nucleus, which regulates appetite. The deficiency of iron may cause deficiencies in enzymatic activities of iron-dependent enzymes and it may disturb the function of these neurons. an epigenetic aberrant paradigm possibly involving transcriptional and transla-
tional regulation in JMML.

Methods: CD34+ cells isolated from 3 JMML patients samples collected at diag-
nosis (t0) and after the third cycle of AZA (t1) were evaluated together with those
of 3 healthy donors (HD). JMML patients have been treated with AZA on a com-
passionate use basis after obtaining signed informed consent. DNA samples
were processed and ion fragment libraries were prepared. MBD-seq, bioinfor-
matics and statistical analysis were performed by Genomnia srl (Bresso, Italy).

Results: First, we compared t0 JMML cells with HD cells, finding 987 different
transcriptional units corresponding to 714 coding and 273 non-coding
sequences. We also compared DNA methylation between t1 and HD cells. In
this comparison, 644 unique transcriptional units, including 468 coding and 175
non-coding sequences, were found. Hypermethylation in JMML samples com-
pared to HD was detected, but, unexpectedly, vs t1 methylation analysis did
not show any significant result, suggesting a likely unspecific patient-related
pharmacological effect. Notably, 453 coding and 165 non-coding differentially
methylation regions are shared between t0 vs HD and t1 vs HD sets. More in
detail, 261 and 15 coding regions and 107 and 10 non-coding regions were
uniquely found in t0 vs HD and t1 vs HD sets, respectively. However, 439 coding
and 161 non-coding genomic regions preserve their hypermethylated status,
probably due to a mechanism of resistance to AZA treatment. Among non-cod-
ing elements, we found different RNA species, such as microRNAs, splicing
RNAs, lincRNAs/antisense transcripts (AS) and other unknown RNAs. Retro-
transposons, belonging to LINEs and SINEs families, were also screened. We
identified 13 sequences with a significant differential methylation profile in both
t0 and t1 groups. Again, a comparison between t0 and t1 groups did not show
any significant difference. Eleven hypermethylated common LINEs were evident
between t0 vs HD and t1 vs HD sets. Two retrotransposons with opposite
methylation patterns were found in t0 vs HD and t1 vs HD sets; while in the first
comparison they included LINEs, in the second one they are 1 hypermethylated
LINE and 1 hypomethylated SINE.

Summary/Conclusions: In conclusion, the whole genome MBD-seq per-
formed for the first time on JMML CD34+ bone marrow derived cells, showed
a broad genomic hypermethylation both in pre- and post-AZA samples com-
pared to HD, suggesting a patient-specific AZA-effect. Transcription and trans-
lation processes of coding and non-coding genes could be deregulated in mul-
tiple ways, due to heterogeneity of sequences involved in CpG islands hyper-
methylation. Moreover, due to their known ability to insert random mutations in
the genome, retrotransposons should be candidate for further studies in JMML
pathogenesis.

E1168
RESPONSE MONITORING IN MDS WITH DEL(5q) USING DIFFERENT
FLOW CYTOMETRIC (FCM)-SCORES IN COMPARISON TO CYTOGENETICS
AN EMLNET IMDS-FLOW EXPERIENCE

U. Oelschlägel1, T.M. Wesiers1, B. Mohr1, D. Subira3, U. Johansson4,
G. Ehnlinger1, M. Bornhäuser1, A.A. van de Loosdrecht2, U. Pflatzbecker1
1Medical Clinic and Polyclinic I, MKI-1.L06, University Hospital of Tu Dresden,
Dresden, Germany, 2Department of Hematology, VU University Medical Center,
Amsterdam, Netherlands, 3Department of Hematology, Hospital Universitario
de Guadalajara, Guadalajara, Spain, 4Department of Hematology, University
Hospitals NHS Foundation Trust., Bristol, United Kingdom

Background: Flow cytometry (FCM) is one part of integrated MDS diagnostics.
Different well established FCM-scores are applied, as FCSS (Wells et al. 2003),
Ogata-score (Ogata et al. 2012), new iFS (Cremers et al. 2017), and del(5q)-
FCM-score (Oelschlaegl et al. 2015).

Aims: The aim of this prospective study was to test, which of the mentioned
FCM-scores fits best for response monitoring in del(5q) MDS in comparison to
cytogenetics.

Methods: Overall, 245 FCM investigations were performed in 61 patients with
MDS and del(5q) (IPSS-R very low/low: n=26, int: n=13, high/very high n=22)
including 42 patients with isolated del(5q) or one additional cytogenetic abnor-
mality. The majority of analyses were performed in patients receiving lenalido-
amide or azacitidine (n=29 and n=22 patients), or in patients receiving
cytarabine chemotherapy and/or allogeneic transplantation or growth factors (n=10):
Standardized FCM (lyse-stain-wash) and cytogenetics/FISH procedures were per-
formed according to ELN guidelines at the TU of Dresden, VUMC of Amster-
dam, UH of Guadalajara and UH of Bristol. Cytogenetics/FISH analysis was
considered the gold standard. All of the applied FCM-scores were propagated
by the ELNet MDS working group. Additionally, hematological improvement of
the erythroid lineage (Hi-E) was evaluated (Cheson et al. 2006).

Results: The del(5q)-FCM-score reflected best the disappearance / presence
of the cytogenetic abnormality del(5q) with a sensitivity of 88% and a specificity
of 85%. This was confirmed if only MDS with del(5q) was as a single abnormality
or only MDS treated with Lenalidomide were evaluated separately (sensitivity:
98% and 100%; specificity: 85% and 75%). The use of the Ogata-score con-
sidering almost only abnormalities of the myeloid progenitors, ended up with a
slightly lower sensitivity (86%) and specificity (81%). The new iFS analyzing
progenitor cells, granulo-, mono- and erythropoiesis showed a comparably
high specificity (83%) but a slightly impaired sensitivity (72%). FCSS, analyzing
dyspoiesis of multiple cell lineages, showed a response in less than the half of
all investigations being in cytogenetic CR (sensitivity: 41%), but revealed a high
specificity (91%). The analysis of Hi-E was high sensitive (81%) but not as spe-
cific (62%). Next, we investigated the potential prognostic impact of response
monitoring using various FCM-scores compared to cytogenetics. Considering
all del(5q) MDS patients as well as only those patients with del(5q) as a single
abnormality, cytogenetics and all tested FCM-scores showed a significantly
longer OS for MDS responding to therapy. The highest prognostic impact dis-
played the new iFS (p=0.0019) and Ogata-score (p=0.0092), respectively. Eval-
uating only MDS treated with lenalidomide, response monitoring using FCSS
separated best the OS curves (p=0.0080). Finally, we combined the evaluation
of Hi-E with cytogenetics or the FCM-scores. This resulted in an even better
prognostic impact for the combination of Hi-E plus the new iFS (p=0.0010).

Summary/Conclusions: Flow cytometry might serve as a rapid tool for
response monitoring during treatment with disease-modifying drugs. All estab-
lished FCM-scores allowed for an at least similar correctness of response pre-
diction. The prognostic impact of the various FCM-scores seems to be even
higher than that of cytogenetic response evaluation in this MDS subgroup. One
reason might be, that most of the FCM-scores reflect not only the genetic back-
ground of the MDS but dyspoietic alterations in various cell lineages of the
hematopoietic system.

EVALUATION OF MUTATIONS AT RELAPSE IN MYELODYSPLASTIC
SYNDROME PATIENTS RECEIVING ALLOGENIC STEM CELL
TRANSPLANTATION

manca, Spain

Background: Allogeneic transplant (AlloSCT) is the only curative therapy for
myelodysplastic syndromes (MDS). Unfortunately, relapse is the main cause of
treatment failure. Evaluation of genetic mutations both at diagnosis and

haematologica | 2017; 102(s2) | 479

Madrid, Spain, June 22 – 25, 2017
before AlloSCT is a potent prognostic tool. However, mutational profile at relapse after AlloSCT has not been widely explored.

**Aims:** In this study, we evaluate mutational profile post-AlloSCT relapse in MDS patients to determine if pre-AlloSCT mutations are still present at relapse, so we could eventually monitor them as minimal residual disease (MRD) after AlloSCT.

**Methods:** From a retrospective cohort of 115 patients, we selected those who relapsed post-AlloSCT (19/115, 16.5%) with available material at relapse (18 patients). We performed an in-house target-capture panel, sequencing across selected exons of 117 cancer-related genes previously related to MDS in pre-AlloSCT samples to identify genetic mutations and we checked the presence of those mutations in samples at relapse. Six patients were discarded because lack of pre-AlloSCT mutations, so we selected 12 patients for the sequential study. DNA was amplified with FastStart High Fidelity PCR System using exon-specific primers for each mutation. The indexed paired-end library was prepared with Nextera XT DNA Sample Preparation Kit (Illumina) The median coverage per base achieved was 4570 reads (range 1450-6873). In a second step, we explore the possibility of evaluating mutations in both CD34 positive and the rest of bone marrow cells, to check if we could increase the sensitivity of the detection.

**Results:** Median age of relapsed patients was 60 (45-70). Diagnosis were MDS (MDS-L) and on pt bone marrow samples.

**Methods:** We investigated the in vitro effects of RIG combined with AZA or vorinostat (VOR) on epigenetic and stem cell pathways on two cell lines: AML (BW90), MDS (MDS-L) and on pt bone marrow samples.

**Background:** Azacitidine (AZA) is the standard of care for patients (pts) with higher-risk MDS, however, only 50% of pts respond and the majority will relapse within 2 years. All pts ultimately fail treatment due to primary or secondary resistance. RIGosertib (RIG) is a “ras mimetic” agent that binds to the Ras Binding Domain of RAF kinases and inhibits the RAS-RAF-MEK and PI3K pathways. Initial results of an ongoing Phase III study with RIG combined with AZA or vorinostat (VOR) in patients with MDS demonstrated a response rate of 76% (90% in pts following hypomethylating agent (HMA) failure) and 85% in HMA naïve pts (Navada et al ASH 2016).

**Aims:** To investigate the in vitro effects of RIG combined with AZA or vorinostat (VOR) on epigenetic and stem cell pathways on two cell lines: AML (BW90), MDS (MDS-L) and on pt bone marrow samples.

Madrid, Spain, June 22 – 25, 2017
Results: 156 patients were included between January 2014 and December
2015 with a mean age of 68 years [65.8-70.3] and 47.4% of men. 127 patients
(81.4%) had a bone marrow analysis. 53 patients (34.0%) were reported in the
group “positive NGS” and 103 patients (66.0%) in the group “negative NGS”.
In univariate analysis, significant variable associated with “positive NGS” were
age (p <10-7), no history of auto-immune disease (p=0.002), hemoglobin
<12g/dL (p=0.017), platelets >150000/mm3 (p=0.015), >10% dysplastic cells
in erythroid (p=0.012) and granulocytic lineage (p=0.034). Trend test on dysplastic lineage number was significant (p=0.006). Normal karyotype (78.1%)
was comparable in the two groups (p=0.352). Cirrhosis and/or portal hypertension were comparable in the two groups (14.1%, p=0.092) as well as mean
serum creatinine (p=0.24). In multivariate analysis, age >70 years (p=0.0011)
and platelets >150000/mm3 (p=0.0213) remained significantly associated to
positive NGS (Table 1). In “positive NGS” group, 1 (58.5%), 2 (32.1%), 3 (7.5%)
or 4 (1.9%) mutation(s) were found per patient. Most frequent mutations were
TET2 (25.9%), DNMT3A (17.3%), SF3B1 (12.3%), ASXL1 (12.3%), SRSF2
(8,6%), U2AF1 (4,9%), TP53 (3,7%) and ZRSR2 (3,7%). Other mutations were
reported in less than 3 patients. As expected in this elderly population, if a
unique mutation was found, TET2 and DNMT3A were predominant (35.5% and
25.8% respectively) but interestingly mutation R882 of DNMT3A was found in
only one patient. Sideroblasts were found>15% in 46.2% of patients with a
mutation of SF3B1, SRSF2, U2AF1 or ZRSR2.
Table 1.

Aims: To confirm that the cellular expression of nucleoside metabolizing
enzymes plays a major role in cellular resistance and significantly impacts on
clinical response to azacitidine.
Methods: Two cell lines, SKM1 sensitive (SKM1-S) and SKM1 resistant (SKM1R) to azacitidine, were analyzed for expression of UCK1, UCK2, hENT1,
hCNT3, RRM1 and RRM2 by quantitative PCR. Corresponding proteins were
quantitated by western blotting in both cell lines. The expression of UCK1 and
UCK2 was blunted by siRNAs in SKM1 sensitive cells to determine their role
in in vitro sensitivity to azacitidine. For UCK1 and UCK2 silencing in SKM1-S,
specific siRNAs were used (OriGene Technologies, MD, USA); cells were cultured at a density of 600x105cells/ml in 5 ml of RPMI 1940 medium. After 72 h
of transfection, cells were treated for further 48h with azacitidine at the concentrations of 0,1 and 1 μM. After assessment of effective gene silencing, apoptosis and cell cycle arrest were evaluated, respectively by Annexin V test and
Propidium Iodide. In parallel, the percentage of 5-methylcytosine was quantitated by ELISA assay (Global DNA Methylation LINE-1 kit ActiveMotif, CA,
USA). In addition, the expression of nucleoside metabolizing enzymes was
evaluated prospectively in 18 IPSS high risk MDS patients treated with azacitidine 75mg/m2/7 days every 28 days. Furthermore, UCK1 and UCK2 expression was evaluated in 37 patients (classified as 26 responder and 29 nonresponder) treated with azacitidine, by RNAseq analysis using DEXseq2.
Results: SKM1-R cells did not express UCK1, UCK2, hENT1, hCNT3, RRM1
and RRM2. Corresponding proteins were also not expressed. A reduction of
apoptosis was observed in UCK1-silenced SKM-1 S after azacitidine 0.1 μM
treatment: 35,7%±0,77% Annexine V-positive cells versus 25%±0,35% (P=0.031)
in non-silenced control SKM1-S cultures. We observed a reduction of apoptosis
during UCK2-silencing after azacitidine 0.1 μM treatment too: 31%±0,85% Annexin V-positive cells versus 21%±0,35% (P=0.054). Hypomethylation induced by in
vitro azacitidine treatment was also hampered by reduction of expression of
UCK1 and UCK2. Quite surprisingly gene expression of UCK1, UCK2, hENT1,
hCNT3, RRM1 and RRM2 in primary cells did not predict different clinical
response to azacitidine. RNAseq analysis for UCK1 and UCK2 did not find any
differences between responder and non-responder patients.
Summary/Conclusions: We demonstrated that UCK1, UCK2, hENT1, hCNT3,
RRM1 and RRM2 and the corresponding proteins are absent in azacitidineresistant cell line SKM1-R suggesting to be the determinant of the induced
resistance to azacitidine. UCK1 and UCK2 silencing induced by synthetic siRNAs significantly decreased azacitidine effects. Prospective evaluation of the
predictive role of cellular expression of genes involved in azacitidine metabolism
is ongoing in a larger cohort of MDS patients.
E1174

Summary/Conclusions: In the context of unexplained cytopenias, a third of
patients had at least one MDS-associated somatic mutation. Age above 70
years and no thrombopenia seems to be good arguments to realize NGS in
this context. Probably thrombopenia is frequently associated to other causes
than MDS. If NGS is positive, aging genes are the most frequently mutated
genes and they can reflect age-related clonal cytopenias. Even if their clinical
significance is uncertain, monitoring is recommended because of an increased
risk of hematologic cancer.

RESISTANCE TO AZACITIDINE IS DETERMINED AT CELLULAR LEVEL
BY LOWER EXPRESSION OF NUCLEOSIDE ACTIVATING ENZYMES UCK1
AND UCK2
E. Masala1,*, A. Valencia1, A. Brogi1, A. Sanna1, M. Torres Martin2, M. Figueroa2,
V. Santini1

2Department of Human Genetics, University of Miami Miller School of Medicine,
Miami, United States

Background: Azacitidine is at present the standard treatment for MDS. We
demonstrated that MDS patients responsive to azacitidine have significantly higher intracellular expression of the azacitidine-activating enzyme uridine-cytidine
kinase-1 (UCK1) in bone marrow mononuclear cells (Valencia et al. Leukemia
2014). Correlation of the expression of nucleoside transporter, activating and disactivating enzymes with clinical and in vitro response to hypomethylating drugs
azacitidine and decitabine has been suggested by several authors. Yet, the crucial
role of these enzymes has to be ascertained, as well as their possible different
importance in determining resistance to azacitidine.

FAMILIAL TIN2 N-TERMINAL LOSS OF FUNCTION MUTATION IN TELOMERE
SYNDROME
D. Di Giacomo1,*, V. Nofrini1, T. Iannotti1, M. Quintini1, F. Pellanera1, G. Barba1,

Background: The shelterin complex protects telomeres from being processed
by the DNA damage repair machinery and regulates telomerase access and
activity (Frank 2015). TINF2 (14q12) is encoding for TIN2, the central component of shelterin which interacts with other members of the complex
(TRF1,TRF2 and TPP1), thus contributing to telomere length regulation and
structural integrity (Frank 2015). About thirty TINF2 mutations are known in
Dyskeratosis Congenita (DC) (Savage 2008) and other telomere related phenotypes, i.e. aplastic anemia (AA), idiopathic pulmonary fibrosis, liver cirrhosis,
myelodysplastic syndromes (MDS) and acute myeloid leukemia (Armanios
2012). All mutations were missense and heterozygous, clustering in exon 6
encoding for a highly conserved segment at the C-terminus (aa 280–291)
(Frank 2015).
Aims: Precise diagnosis in AA/MDS with clinical features of telomere syndrome.
Methods: AA was diagnosed in a 69-year-old man, with a multisystem disorder,
i.e. psoriasis, nail dystrophy, severe osteoporosis, chronic hepatopathy, mild
chronic kidney failure and hypertension, suggesting a telomere syndrome. Karyotype was normal. Patient was unresponsive to immune-suppressive therapy.
DNA from peripheral blood and hair bulbs was analyzed for TERT, TERC and
TINF2 using DHPLC and Sanger sequencing. Q-FISH investigated telomere
length. SNPs were performed following manifacturer’s instructions (Affymetrix).
Paired-end libraries for Whole Exome Sequencing (WES) were generated with
NimbleGen Exome Capture v3 (Roche), according to manufacturer. DNA from
CD3+ population was used for germinal matching. Data were aligned to the
human reference genome (GRCh38/hg38) and analyzed with the in-house
CEQer2 software (Piazza 2013). Mutational analysis and telotype were performed in both proband and familial members. TERF2 and TINF2 coding
sequences were cloned in pGem-Teasy vector and site direct mutagenesis reproduced in vitro the mutation. Using expression vectors, respectively pEGFP-C1
and pDsRed-Express-C1, TRF2 and TIN2 wild type or TRF2 and TIN2 mutated
were co-expressed in HEK-293T cell line. Co-immunoprecipitation was performed with anti-GFP antibody and differences in TRF2 binding between TIN2wt
and TIN2mut were revealed by western blotting.

haematologica | 2017; 102(s2) | 481


Results: A new TINF2 germline variant at exon 2, c.254A>G p.H85A, was identified in the proband and in two brothers. Screening on 200 healthy donors was negative. Significantly short telomeres were found in proband (p=0.0161) and brothers (p=0.0082 and p<0.0001), compared to age and sex matched controls. The proband had a normal SNPs profile and WES identified an additional somatic variation in TLR1 gene (c.1859G>A, p.R620Q). Co-immunoprecipitation experiments showed that the new TINF2 mutation reduced TIN2 binding with TRF2 in vitro.

Summary/Conclusions: A new TINF2 germline variant at exon 2, c.254A>G p.H85A, was identified in the proband and in two brothers. Screening on 200 healthy donors was negative. Significantly short telomeres were found in proband (p=0.0161) and brothers (p=0.0082 and p<0.0001), compared to age and sex matched controls. The proband had a normal SNPs profile and WES identified an additional somatic variation in TLR1 gene (c.1859G>A, p.R620Q). FUNCTIONAL EXPRESSION OF TIM-3 AND CLINICAL SIGNIFICANCE OF PLASMA GALACTEIN-9 LEVELS IN MYELODYSPLASTIC SYNDROMES

T. Asayama1, M. Ishibashi1, H. Tamura1, Y. Kubayashi-Hamada1, N. Takada-Okuyama1, A. Onodera-Kondo1, K. Moriya1, N. Yokose2, K. Inokuchi1

1Division of hematology, Department of internal medicine, Chiba Hokusho Hospital, Chiba, Japan

Background: T-cell immunoglobulin and mucin domain-3 (Tim-3) is an inhibitory immune checkpoint molecule that suppresses adaptive immunity by binding with galectin-9 (gal-9). The Tim-3–gal-9 pathway is associated with self-renewal and cell proliferation. We compared 145 bone marrow samples from 58 women and 87 men, aged from 26 to 85 suspected to have myeloid dysplasia were investigated. Of these only 76 (52%) were found to fulfill the WHO criteria referred to as MDS positive, the rest as MDS negative. Gene variances were detected in all but 7 samples (42%). The latter as expected were devoid of gene mutations. We observed driver mutations as reported in myeloid malignancies in 68 (47%) samples whilst 70 (48%) were found to carry the same variations seen in disease free individuals or of unknown significance. As expected driver variances were not identified in any of the samples that failed the WHO criteria for MDS. Variance were detected in all samples for 35 of the 54 genes targeted by the TruSight panel. In order of frequency these were TET2, SRSF2, ASXL1, CUX1, DNMT3A, RUNX1, BCR and HRAS, seen in more than 10% of all samples, while the rest were less frequently reported. The aberrant genes ASXL1, TET2 and SRSF2 figured prominently in both groups of samples with comparable frequencies as may be expected from published data and there were in addition a number of aberrant genes unique to the MDS group albeit at low frequency. When we examined the distribution of individual variances (rather than genes) we found a number of unique loci of the genes ASXL1 at 131022441, U2AF at 131021822 and TET2 at 106192728 to be associated with the MDS positive group. A more detailed analysis on the significance of these findings will be presented.

Summary/Conclusions: We compared 145 bone marrow samples from patients presenting with MDS of which 76 met the WHO criteria. There is little difference in their genomic profile when comparing the two groups on the basis of the most highly involved genes (ASXL1, TET2 and SRSF2) but if we compare the two groups by variance, 9 variances are exclusively associated with MDS positive disease.

SUPPRESSION OF DNA METHYLTRANSFERASE ENZYMES BY A NOVEL HYPOMETHYLATING AGENT, SG-1027, AND AZACITIDINE IN DECITABINE-RESISTANT CELL LINES

E.-H. Hur1, D.R. Choi2, B.-K. Goo1, J.H. Moon1, E.-J. Choi1, H.-S. Park1, J.-H. Lee1, K.-H. Lee1, J.-H. Lee1

1OncoGenomics, HSL Analytics LLP, 2Cancer Institute, UCL, LONDON, United Kingdom

Background: Myelodysplastic syndromes are a collection of clonal hematopoietic disorders with a wide range of clinical manifestations and eventual outcomes. Predicting the prognosis is of great importance for defining the risk and choosing appropriate therapeutic options. Among risk factors of poor stratification are, all of which include genetic markers along with other clinical and paraclinical features. The Revised International Prognostic Scoring System (IPSS-R, Greenberg et al., Blood. 2012;120(12): 2454-2465) defines 5 risk levels based on the presence of specific chromosome abnormalities. These genome aberrations provide evidence for disease (p<0.008) and reports of frequent driver mutations (Papamorga et al., Blood, 2013) and/or structural variants detected by single nucleotide polymorphism (SNP) arrays (Tiu et al., Blood, 2011) have shown a potential for score criteria in the diagnosis of MDS. Recent reports of the presence such genetic aberrations in disease free individuals makes this approach problematic (Genovese et al., N Engl J Med 2014; Lichman, Blood 2015, Kwok et al., Blood 2015). A study of patients without evidence for MDS identified a driver mutation and/or structural gene variants in 91% of pre-diagnostic samples with the mutational spectrum mirroring that seen in MDS population (Cargo et al. Blood, 2015). The presence of mutations with greater median variant allele fraction (40% vs 9% to 10% in healthy individuals) and occurring with additional mutations (>2 mutations, 64% vs 8%) were shown to define a high-risk group with a shorter time to disease progression and poorer overall survival.

Aims: To compare the genomic profile of bone marrow from 145 adults, 76 of whom met the WHO criteria for MDS.

Methods: All samples were screened by chromosome G banding or molecular karyotyping using 8x60K oligonucleotide arrays (Agilent, USA) or screened by FISH using probes (Cytocell, UK) targeting the most common aberrations associated with MDS as per IPSS-R classification (Greenberg et al., Blood, 2013). The commercially available target gene panel TruSight on a MiSeq platform (Illumina, USA) was used to screen mutational hotspots in 54 cancer-related genes relevant in myeloid malignancy. Gene variances were reported at allele frequencies (VAF) >10% and at minimum read depth of 300 as per manufacturers criteria. We used the Catalogue of Somatic Mutations In Cancer (COSMIC), dbSNP and 1000 genome (≥2%) to classify gene variants as either drivers, variants of unknown significance and germline polymorphisms (SNPs).

Results: A total of 145 bone marrow samples from 58 women and 87 men, aged from 26 to 85 suspected to have myeloid dysplasia were investigated. Of these only 76 (52%) were found to fulfill the WHO criteria referred to as MDS positive, the rest as MDS negative. Gene variances were detected in all but 7 samples (42%). The latter as expected were devoid of gene mutations. We observed driver mutations as reported in myeloid malignancies in 68 (47%) samples whilst 70 (48%) were found to carry the same variations seen in disease free individuals or of unknown significance. As expected driver variances were not identified in any of the samples that failed the WHO criteria for MDS. Variance were detected in all samples for 35 of the 54 genes targeted by the TruSight panel. In order of frequency these were TET2, SRSF2, ASXL1, CUX1, DNMT3A, RUNX1, BCR and HRAS, seen in more than 10% of all samples, while the rest were less frequently reported. When we examined the distribution of individual variances (rather than genes) we found a number of unique loci of the genes ASXL1 at 131022441, U2AF at 131021822 and TET2 at 106192728 to be associated with the MDS positive group. A more detailed analysis on the significance of these findings will be presented.

Summary/Conclusions: We compared 145 bone marrow samples from patients presenting with MDS of which 76 met the WHO criteria. There is little difference in their genomic profile when comparing the two groups on the basis of the most highly involved genes (ASXL1, TET2 and SRSF2) but if we compare the two groups by variance, 9 variances are exclusively associated with MDS positive disease.
Methods: Besides azacitidine and decitabine, three other agents (SGI-1027, zebularine, and gemcitabine) are known as having hypomethylating effect. In vitro activities of the 5 HMA’s on HMA resistant cell lines (MOLM/AZA-1 and MOLM/DEC-5) were tested by cell viability assay using luminescent-based CellTiter-Glo system. Protein and mRNA levels of DNMT enzymes (1, 3A, and 3B) were assayed before and after treatment of each HMA. Proteosomal degradation and activation of Akt were also determined to see the correlation with changes of DNMT’s.

Results: Although azacitidine and decitabine could suppress DNMT1 and DNMT3A in MOLM-13, the agents could not suppress DNMT enzymes in resistant cell lines. Inhibition of proteosomal degradation by bortezomib induced accumulation of DNMT enzymes in MOLM-13, whereas it did not accumulate the enzymes in MOLM/AZA-1 and MOLM/DEC-5. Phosphorylated Akt (p-Akt) was dramatically overexpressed in MOLM/AZA-1 and MOLM/DEC-5. SGI-1027 showed the lowest IC50 values for MOLM/AZA-1 and MOLM/DEC-5, and it suppressed the protein levels of all three DNMT enzymes. SGI-1027 could also decrease the level of p-Akt. GDC-0941, a PI3K inhibitor, suppressed DNMT1 and DNMT3A as well as p-Akt, but it could not decrease DNMT3B in MOLM/AZA-1 and MOLM/DEC-5. Cell viability assay showed the synergistic effects of combination of GDC-0941 and Nanomycin A, a specific DNMT3B inhibitor, in MOLM/AZA-1 and MOLM/DEC-5.

Summary/Conclusions: DNMT levels of MOLM/AZA-1 and MOLM/DEC-5 were not dependent on proteosomal degradation. DNMT1 and DNMT3A might be regulated via PI3K-Akt pathway, while regulation of DNMT3B might be different from DNMT1 and DNMT3A. SGI-1027 appears to exert inhibitory effects on MOLM/AZA-1 and MOLM/DEC-5 by inhibition of both p-Akt and DNMT3B.

MECHANISTIC HIGHLIGHTS OF IMPROVED ERYTHROPOIESIS WITH A LOW DOSE OF DEFERASIROX IN LOW RISK MYELODYSPLASTIC SYNDROMES

M. Mathieu1,2*, S. Ancelet2, C. Lefebvre2, J. Arnaud4, M. Pezet5, S. Park1,2

1Clinique Universitaire d’hématologie, CHU Grenoble Alpes, 2Equipe TheREx-MODES, 3Laboratoire TIMC, Université Grenoble Alpes, 4Laboratory of hematology, 5Unité de Biochimie Hormonale et Nutritionnelle, D閞閛p閙ent de Biologie - Toxicologie, 6Laboratoire d'h閚閠ologie, CHU Grenoble Alpes, 7Plateforme de Microscopie Pharmakologie - Ctym閠閠rie en Fluix, Institut Albert Bonniot, Universit閑 Grenoble Alpes, 8LBFA, Inserm U1055, 9CEA-Grenoble, Bioscience and Biotechnology Institute, 10Laboratory of Fundamental and Applied Bioenergetics, and Environmental and Systems Biology, Universit閑 Grenoble Alpes, Grenoble, France

Background: Myelodysplastic syndromes (MDS) are a group of heterogeneous clonal stem cell disorders leading to ineffective hematopoiesis. Anemia is a frequent cytopenia in MDS and the majority of patients requires red blood cell (RBC) transfusion resulting in the development of iron overload (IO). Deferasirox (DFX) became a standard treatment of IO in MDS and seems to have positive effects on hematopoiesis with a reduced need of RBC transfusion.

Aims: Decipher the mechanisms of the potential improvement of erythropoiesis with DFX.

Methods: We report our in vitro data about the proliferation, cell cycle, apoptosis, erythroid differentiation, and cell signaling pathways concerning CD34+ hematopoietic stem progenitor cells from low risk MDS samples in a 2-step erythroid differentiation liquid culture with low dose DFX and iron overload.

Results: We observed a higher proliferation rate for cultures with 3µM DFX versus the control condition (p=0.038). In contrast, no increased proliferation was found with DFX>5µM and with other chelators used in the clinic. The higher proliferation rate with DFX 3µM was due to the combination of decreased apoptotic cells at day 10 (D10) (p=0.03) and D14 (p=0.007) and increased cycling cells at D10 (p=0.0001). Regarding clonogenic assays, there were more CFU-E colonies with DFX 3µM (p=0.04). Despite the low concentration of DFX, cells expressed in DFX 3µM had a lower intracellular iron concentration measured by ICP-MS than control cells (p=0.019). Nevertheless, this decreased iron amount was not sufficient to activate cellular iron regulation by Iron Regulatory Proteins suggesting the absence of a direct effect of low dose DFX on iron homeostasis. Moreover, low dose DFX decreased intracellular and mitochondrial reactive oxygen species (ROS) at D14 (p=0.048 and p=0.03) and decreased the level of malonaldehyde (p=0.048), a product of lipid peroxidation. Then, we have investigated which signaling pathways were sensitive to DFX 3µM. We found an increased nuclear translocation of NFκB detected by both CM (p=0.04) and luciferase reporter assay (p=0.03). NFκB activation was absent in the knock-down (KD) of mitochondrial TRX (siTRX2) condition. Moreover, in non-iron overloaded medium condition, the level of ROS was not increased, and DFX in the TRX1 KD condition was not associated with NFκB activation. These results suggest that NFκB activation in this model is linked to TRX1 and regulated by an extremely fine control of ROS levels with a likely threshold effect.

Summary/Conclusions: Our study describes the pro-proliferative effects of low dose of DFX on erythroid progenitors in low risk MDS patients. These results provide a biological rationale for a clinical trial which will propose low dose of DFX in MDS patients, refractory to erythropoiesis stimulating agents.
E1179
EVALUATING ERYTHROBLAST PAS POSITIVITY IN THE DIAGNOSTIC APPROACH OF MYELODYSPLASIC SYNDROME

Background: According to WHO minimal morphological criteria for myelodysplastic syndrome (MDS) diagnosis, at least 10% of bone marrow (BM) cells of at least one hematopoietic lineage must show unequivocal dysplasia to be considered as dysplastic. Morphological abnormalities of erythroid cells include cytoplasmic Periodic acid-Schiff (PAS) positivity, but the diagnostic power of this cytochemical reaction is not yet fully clear.

Aims: The aims of our study were to evaluate the diagnostic significance of erythroblast PAS positivity in MDS and to investigate a possible correlation between levels of PAS positivity and other morphological and clinical features.

Methods: We retrospectively examined the results of the cytochemical PAS staining for glycogen in BM smears from 165 patients with MDS, 116 patients with non-clonal cytopenia and 49 healthy subjects. We developed a PAS score by counting 100 nucleated cells for the erythroid lineage and classifying them according to their degree of PAS reactivity. The discriminant power of both PAS positivity rate and score for MDS identification was evaluated in comparison with that of the conventional morphological features of dyserythropoiesis; then, PAS positivity was included into the morphological scoring system we have previously defined (Leukemia 2015;29:66-75).

Results: PAS positive erythroblasts were observed in 104 (63%) MDS patients, 46 (40%) patients with non-clonal cytopenia, and 12 (24%) non-cytopenic controls, with a significant difference between MDS and non cytopenic controls (p<0.001) or non-clonal cytopenias (p=0.001), but not between healthy controls and non-clonal cytopenias (p=0.09). In MDS, both positivity rates (median 2%, range 0-33) and scores (median 2, range 0-53) were significantly higher than those in normal and pathological controls (p=0.0001 and p=0.0004 for rate, p=0.0001 and p=0.0002 for score, respectively), without significant difference in relation to excess blasts or multilineage dysplasia. MDS patients with >4% ring sideroblasts (RS) showed lower PAS positivity rates and scores than MDS patients with ≤4% RS (p=0.0332 and p=0.0412, respectively). In MDS-RS, erythroblast PAS positivity was not influenced by SF3B1 mutation status.

In MDS, no significant relationship was detected between erythroblast PAS positivity and percentage of BM blasts, percentage of BM erythroblasts, dyserythropoiesis grading, or Hb levels, whereas an inverse correlation was noticed between PAS score values and internuclear bridging (r=-0.23, p=0.0395). A ROC curve analysis allowed us to identify a PAS score value ≥1 (AUC=0.697, p=0.0008) and a PAS positive erythroblast percentage ≥1% (AUC=0.674, p=0.0034) as optimal cutoff to discriminate MDS patients from non-clonal cytopenias. Considering the most discriminant morphological features for dyserythropoiesis, the weight of both PAS positivity rate and score in the identification of BM dysplasia was lower than that of ring sideroblasts and megaloblastosis, but higher than that of defective hemoglobinisation, nuclear lobulation, multinuclearity, cytoplasmic fraying, pyknosis, and internuclear bridging. Integrating conventional parameters and PAS results significantly improved the sensitivity of our morphological scoring system.

Summary/Conclusions: The evaluation of BM erythroblast PAS positivity, easy to perform and inexpensive, may be useful in the work-up of patients with suspected MDS, especially if there is only unilateral dysplasia without ring sideroblasts or excess blasts.

E1180
A PHASE 3 RANDOMIZED PLACEBO (PBO)-CONTROLLED DOUBLE-BLIND TRIAL OF DARBEPOETIN ALFA IN LOW OR INTERMEDIATE-1 (INT-1) RISK MEYLODYSPLASTIC SYNDROMES (MDS)

Background: There is a lack of PBO-controlled data for erythropoiesis-stimulating agents (ESAs) in MDS.

Aims: To evaluate darbepoetin alfa (DAR) in IPSS low/int-1 risk MDS (EudraCT2009-016522-14, NCT01362140).

Methods: Patients with MDS per WHO 2008 criteria with IPSS low/int-1 risk, anaemia [hemoglobin (Hb)≤10 g/dL], low transfusion burden, no previous treatment with ESAs or biologic response modifiers, and serum EPO≤500mU/mL were randomized 2:1 to 24 weeks (wk) SC DAR 500 µg or PBO every 3 wk (Q3W), stratified by IPSS, then 48 wk open label (OL) DAR follow-up is ongoing. Doses were withheld for Hb>12g/dL and decreased if Hb increased by >1.5 g/dL in 3 wk. Key endpoints were transfusion incidence and Hi-E per IWG 2006.

Results: Randomized patients [N=147] had median Hb of 9.3 (min-max:5.5-10.6) g/dL and median baseline EPO of 69 (min-max:4.3-497) mU/mL. WHO classification was RA:15%, RARS:14%, RAEB-1:16%, RAEB-2:16%, and MDS-U/unknown:2%. Transfusion incidence wk 5-24 was significantly reduced with DAR [DAR:36.1% vs PBO:59.2%, p=0.008]. In the 48-wk OL DAR period, 50.8% of patients had transfusions. More DAR patients achieved Hi-E in the double blind period [DAR:14.7% (11/75 evaluable) vs PBO:0% (0/35 evaluable), p=0.016]. In the 48-wk OL DAR period, 34.7% (34/98) of patients achieved Hi-E. Improved Hi-E and transfusion responses were seen with more favorable status for IPSS-R but not IPSS. In the 48-wk OL DAR period, dose frequency increased from Q3W to Q2W in 81% of patients; doses were held/reduced frequently. Safety results from this trial were consistent with the previous DAR phase 2 MDS trial, with similar AML rates in PBO and DAR arms.

Figure 1. Summary/Conclusions: In this phase 3, randomized, double-blind, PBO-controlled trial in anemic IPSS low/int-1 risk MDS patients, 24 wk of darboepoetin alfa Q3W significantly reduced transfusions and increased Hi-E rates with no new safety signals. Most patients met criteria to change to Q2W dosing during the 48-wk OL period, suggesting that Q2W dosing may offer more benefit. The true clinical benefit of darbepoetin alfa may have been underestimated due to the nature of IWG 2006 Hi-E criteria and trial design (Hb measured Q3W, dosing rules).
Background: Lenalidomide (LEN) is the first choice of treatment in low risk MDS patients with isolated del(5q) (MDS-del(5q)) and transfusion dependency (TD). Most of the low risk MDS-del(5q) patients diagnosed with anaemia and independent of transfusions developed TD or needed treatment for symptomatic anaemia early after diagnosis (median of 20 months, abstract 3180.ASH, 2016). LEN directly targets the del(5q) clone improving anaemia, quality of life and survival in these subset of patients. For these reasons, the use of LEN in patients with del(5q), anaemia and not TD seems to be very attractive. However, data about the use of LEN in MDS 5q- patients and transfusion independency (TI) are scanty, some retrospective studies suggest a benefit with the early use of LEN in this setting, but there is not already available any prospective and randomized study to confirm this likely advantage.

Aims: Our aims were to analyze efficacy and safety at week 12 of treatment with LEN vs Placebo in this setting of low risk MDS del(5q) patients with anaemia and not in TD at diagnosis

Methods: From 2010 to 2017, 47 patients have been included in the Sintra-Revl trial, a phase III, multicenter, randomized and double blind study with LEN (5mg/day) vs placebo [2:1 randomization] in Low – Int-1 risk (IPSS) MDS del(5q) patients with anaemia but TI. Preliminary results of efficacy (according to the IWG 2006 criteria for erythroid [HI-ER] and cytogenetic response [CyR]) and safety has been analyzed at week 12. Progression disease (DP) in the trial was defined as the development of TD.

</table>

Results: Main clinical characteristics are summarized in table 1, 85% were females, median age was 72 years (37-89) and most of patients (95%) had del(5q) as the only cytogenetic abnormality. Among 47 patients, only 38 were evaluable at week 12 (5 out of 38 discontinued the study. 3 due to DP, 1 due to toxicity and 1 for unknown reasons), 7 patients are currently receiving the first 12 weeks of treatment and 2 patients were excluded (screening failures). Regarding efficacy (w12), data from 36 patients were available. HI-ER was observed in 14/36 patients (39%), minor HI-ER (Hb increased<1.5g/dl) in 4/36 (11%), stable disease in 15/36 (42%) and PD (transfusion dependency) in 3 (8%). CyR was available in 30 patients: complete CyR was obtained in 12 (40%), partial CyR in 6 (20%) and no CyR in 12 (40%) patients. Safety information in 38 patients demonstrated that most patients (87%) developed any adverse events (AE) while only 42% of these were relevant (G3-4). Most G3-4 AE were hematological (neutropenia 38%) being non-hematological only in 42% of these were relevant (G3-4). Most G3-4 AE were hematological (neutropenia 38%) being non-hematological only in 42% of these were relevant (G3-4). Most G3-4 AE were hematological (neutropenia 38%) being non-hematological only in 42% of these were relevant (G3-4).

Summary/Conclusions: In this study we confirm a high rate of erythroid and cytogenetic responses early after treatment with an adequate safety profile in the first 12 weeks of treatment with LEN or placebo.
was evaluated by at least two morphology experts and a consensus diagnostic of MDS-confirmed, MDS-suspected or MDS-excluded was emitted. MFC was performed applying at least five-colour staining and a numerical score was calculated for every patient following criteria defined by Ogata et al (Blood. 2006 Aug 1; 108(3):1037-44), with a score >2 suggesting MDS. Conventional karyotype and FISH employing probes to detect usual 5q-, 7q-, 8+, 20q- and del(7q) was performed. **Summary/Conclusions:** The economic impact of HR-MDS is considerable, with higher costs incurred within the first year of diagnosis. The decrease in cost between Year 1 and Year 2 was mainly due to decreased MDS-related medical costs. Consistent with this cost trend, healthcare utilization for MDS-related services decreased in Year 1 vs Year 2. As treatment of HR-MDS continues to evolve, economic impact and HCU need to be further investigated in this patient population.

**E1185**

**INTRAVENOUS IMMUNOGLOBULIN IS AN EFFECTIVE TREATMENT FOR CYTOPENIAS ASSOCIATED TO CIRCULATING T-CELL CLONES IN MYELODYSPLASTIC SYNDROMES**

**Background:** Myelodysplastic syndrome (MDS) can be associated with immunologic disorders, including autoimmune cytopenias and Coombs positive or negative (C+) hemolytic anemia. Abnormally expanded T-cells can be identified in these patients, possibly contributing to both bone marrow insufficiency and immune-related cytopenia in a series of 20 consecutive patients with MDS at a single institution.

**Methods:** 17 patients with refractory anemia (RA) and 3 patients with RA plus excess blasts (RAEB) were included in this study. All patients were treated with intravenous immunoglobulin (IVIG) at a dose of 400 mg/kg/week for a minimum of 3 months. A complete hematologic response was defined by the absence of peripheral cytopenia and an increase in peripheral blood counts.

**Results:** A complete hematologic response was achieved in 12 patients (60%), with a median duration of 6 months (range 3-12 months). The remaining 5 patients showed a partial hematologic response. There were no serious adverse events associated with IVIG therapy.

**Summary/Conclusions:** IVIG appears to be an effective treatment for immune-related cytopenia in patients with MDS, with a high rate of complete hematologic responses. Further studies are needed to confirm these findings and evaluate the long-term benefits of IVIG in the management of MDS-related immune-related cytopenia.

**E1186**

**ECONOMIC IMPACT AND HEALTHCARE UTILIZATION IN PATIENTS WITH HIGHER-RISK MYELODYSPLASTIC SYNDROMES (HR-MDS) IN ROUTINE CLINICAL CARE IN THE UNITED STATES (US) – A CLAIMS DATABASE STUDY**

**Background:** The economic impact of HR-MDS is considerable, with higher costs incurred within the first year of diagnosis. The decrease in cost between Year 1 and Year 2 was mainly due to decreased MDS-related medical costs. Consistent with this cost trend, healthcare utilization for MDS-related services decreased in Year 1 vs Year 2. As treatment of HR-MDS continues to evolve, economic impact and HCU need to be further investigated in this patient population.

**Methods:** Newly diagnosed adult HR-MDS patients who initiated first-line therapy were identified from Optum, a large US claims database, between 1/1/08 and 10/31/15. HR status was based on ICD-10 coding: ≥1 inpatient or ≥2 outpatient claims with ≥1 HR-MDS ICD-9/10 code (ICD-9 code: 234.73; ICD-10 codes: D46.20, D46.21, D46.22). The first MDS claim served as the index date. Exclusion criteria included: lack of continuous enrollment in medical/pharmacy benefits in the 12 months prior to index date (baseline period), presence of other primary cancer, or receipt of any chemotherapy or SCT during baseline period. MDS-related HCU and costs were medical claims with ≥1 HR-MDS ICD-9/10 code (ICD-9 code: 234.73; ICD-10 codes: D46.20, D46.21, D46.22). The first MDS claim served as the index date.

**Summary/Conclusions:** The economic impact of HR-MDS is considerable, with higher costs incurred within the first year of diagnosis. The decrease in cost between Year 1 and Year 2 was mainly due to decreased MDS-related medical costs. Consistent with this cost trend, healthcare utilization for MDS-related services decreased in Year 1 vs Year 2. As treatment of HR-MDS continues to evolve, economic impact and HCU need to be further investigated in this patient population.
(3), seronegative arthritis (2), connectivitis (2). One patient with hypoplastic MDS had LGL liver involvement. Coombs test was positive in 4/16 hemolysis cases. From Jan-10 to Jan-17, IVIG was administered at a dose of 500mg/kg once per week, in cycles of 1 to 4 weeks. The ORR was 75% (15/20); all patients showed an erythroid hematological improvement (H1) (100%). Platelets and neutrophil H1 was seen in 50% and 80% of responsive cases, respectively. HLR occurred in 13/16 (81%: 4 CR and 9 PR). Median number of cycles and duration of treatment were 11 and 12 months (mo), respectively. The HLR-CR was stable in 7 patients; 4 relapsed from HLR but subsequently responded by shortening the intervals between administrations of IVIG; 2 were secondary refractory. Eventually, 6 responders became refractory to IVIG. Response was more durable with continuous rather than sporadic dosing. Median time to response was 1 mo. Median duration of response was 39 mo. Corticosteroids were discontinued in 5/10 patients and reduced in 5/10. Adverse events: 1 palpitations (G1); 1 hypertension (G1). Responders had lower platelet counts (p<0.05), but no other clinical differences compared to non-responders. However, the 5-year OS rate was higher in the responders to IVIG: 53% compared to 30% (p=0.08).

Table 1.

Summary/Conclusions: Treatment with IVIG of Ce hemolytic anemia and pancytopenia associated with T-cell immune-clones and MDS was safe and yielded high rates of durable response on all lineages and on hemolysis. Transfusion independency and reduction/discontinuation of corticosteroids for chronic pancytopenia associated with T-cell immune-clones and MDS was safe and may be considered a standard of care. The median OS and CR rates were 98% and 100%, respectively. Median time to response was 1 mo. Median duration of response was 39 mo. Corticosteroids were discontinued in 5/10 patients and reduced in 5/10. Adverse events included 1 palpitations (G1); 1 hypertension (G1). Responders had lower platelet counts (p<0.05), but no other clinical differences compared to non-responders. However, the 5-year OS rate was higher in the responders to IVIG: 53% compared to 30% (p=0.08).

E1186 DEVELOPMENT AND EXTERNAL VALIDATION OF A NEW PATIENT-CENTERED PROGNOSTIC INDEX FOR PATIENTS WITH ADVANCED MYELODYSPLASTIC SYNDROMES

F. Efaccia1,*, F. Cottone1, G. Abel2, P. Niccola3, G. Gaidano4, F. Bonnetain5, A. Antoni6, G. Caocchi7, A. Cronin2, L. Fianchi7, M. Breccia8, R. Stauder9, A. Anota5, G. Caocci 6, A. Cronin 2, L. Fianchi 7, M. Breccia 8, R. Stauder 9, 1Department of Haematology, 2Department of Cellular Pathology, Tallaght Hospital, Dublin 24, Ireland

Aims: We aimed to develop and validate a new prognostic index for advanced MDS by including self-reported fatigue severity into a well-established clinical risk classification: the International Prognostic Scoring System (IPSS).

Methods: Untreated patients (n=280) were recruited at the time of diagnosis of advanced MDS from 37 hospitals in nine countries to create the index. The index was then applied to an independent cohort including pre-treated MDS patients from the Dana-Farber Cancer Institute (DFCI) in Boston, Massachusetts (USA; n=189). Patients in both the International and DFCI cohorts were adults with newly-diagnosed intermediate-2 or high-risk MDS (advanced disease on the IPSS). Patients were enrolled regardless of age, comorbidity, performance status and progression rate. We used a lower IPSS category. All completed a baseline health-related quality of life assessment. Data from international and DFCI cohorts were independently collected and analyzed. Univariate and multivariate Cox proportional hazards (PH) regression analyses were performed to estimate hazard ratios with 95% Confidence Intervals (CIs). Discrimination and calibration were evaluated for both the development (internal validation) and independent DFCI datasets (external validation). Statistical significance for all tests was set as two-sided α=0.05.

Results: A new risk classification was developed, namely, the fatigue (FA)-IPSS(h). Whereas use of the standard IPSS in more advanced disease discriminates between two risk categories for untreated patients, the new fatigue FA-IPSS(h) classification is able to distinguish three survival subgroups in patients with distinct survival outcomes. Overall survival rates at 6 months, 1 year, and 2 years were markedly different among the three groups. To illustrate, one year survival was 80.3% (95% CI, 73.4;87.8), 60.5% (95% CI, 52.3;70.0) and 37.6% (95% CI, 23.9;59.1) for patients classified in Risk-1, Risk-2 and Risk-3 respectively. Median OS in DFCI data by FA-IPSS(h) risk was similar to that of the development cohort for each of the three risk groups, indicating good external calibration. Patterns of OS through 2 years were also distinct between risk groups as in the development cohort of untreated patients, with one exception: 2-year OS was similar for FA-IPSS(h) risk 3 and risk 2. Predictive accuracy of this new index was higher than the IPSS alone in both the development cohort (C-statistic, 0.56 vs 0.57) as well as in the independent cohort including pre-treated patients (C-statistic, 0.58 vs 0.54).

Summary/Conclusions: The FA-IPSS(h) is an additional prognostic tool that might enhance clinicians’ ability to provide more personalized treatment strategies both in untreated and pretreated advanced MDS patients. This analysis offers a model for integration of PROs in prognostic systems for patients with other cancers and advanced illnesses.

E1187 PROGNOSTIC AND THERAPEUTIC IMPLICATIONS OF SIGNIFICANT MARRROW FIBROSIS IN COMBINATION WITH P53 OVER-EXPRESSION IN PATIENTS WITH MYELODYSPLASTIC SYNDROME: A SINGLE CENTRE STUDY

E. Groarke1,*, S. Maung1, K. Ewins1, M. Jeffers2, B. MacDonagh1, J. McHugh1, R. Desmond1, H. Enright1

1Department of Haematology, 2Department of Cellular Pathology, Tallaght Hospital, Dublin 24, Ireland

Background: Myelodysplastic syndromes (MDS) are defined in the WHO 2016 classification as a group of clonal bone marrow neoplasms characterized by ineffective hematopoiesis, morphologic dysplasia in hematopoietic cells and peripheral cytopenia(s). They present as a diverse phenotype with some patients requiring merely observation while others require more intensive management due to significant marrow failure and the risk of development of acute leukemia. The presence of significant marrow fibrosis has previously been shown to be a poor prognostic factor in patients with MDS, with reduced overall survival. Significant marrow fibrosis has also been associated with both the presence of the TP53 gene mutation and with p53 over expression, which is a known adverse prognostic risk factor in MDS patients.

Aims: To assess the presence of p53 expression in patients with moderate to severe marrow fibrosis (grade 2-3), observe its effect on overall survival in patients with marrow fibrosis, and determine whether the use of azacitidine had any impact on survival.

Methods: We conducted a retrospective study utilizing a hospital database of 247 patients with MDS diagnosed in a single center between 2000 and 2014. Of these patients, 200 had bone marrow trephine samples adequate for reticulin stain analysis, which was completed using the European consensus on grading bone marrow fibrosis (grades 0-3). P53 expression was examined using immunohistochemistry staining techniques according to the modified quick scoring system. We then looked for an association between degree of marrow fibrosis and p53 expression. In patients with significant marrow fibrosis and p53 expression we examined overall survival and response to treatment with azacitidine.
Results: Overall, no significant correlation was seen between expression of p53 and degree of fibrosis (p<0.05). However, degree of fibrosis predicted for overall survival in patients with p53 expression (median overall survival of 4 months in patients with both p53 over expression and significant fibrosis compared with median overall survival of 18 months in patients with p53 over expression without fibrosis, p<0.001). In patients who received azacitadine, those with negative significant fibrosis and p53 expression had a significantly increased overall survival compared with those who did not receive azacitadine (4 month versus 1 month, p=0.002). Azacitadine treatment was not associated with increased survival in patients with p53 expression without fibrosis but these patients did have an overall increased survival compared to those with fibrosis. 

Summary/Conclusions: This study confirms that significant narrow fibrosis adversely affects overall survival in patients with MDS, including those with p53 over expression. Patients who received azacitadine had a significant increase in median survival. Although the numbers of patients who received azacitadine was lacking, our data suggests that patients with fibrosis may benefit from the use of azacitadine and larger and randomized studies should be considered to study this further.

FACS PURIFICATION OF BLAST CELLS IN MDS IMPROVES THE FISH DETECTION RATE FOR DEL(5Q) AND DEL(20Q), BUT NOT FOR DEL(7Q) OR T8

M. Pereira1,2,*, G. Marques 3, J. Lima 3, R. Reis 3, A. Coelho 3, L. Jorge 3, M. Pereira1,2,*, G. Marques 3, J. Lima 3, R. Reis 3, A. Coelho 3, L. Jorge 3, F. Schieppati1,*, A.M. Pelizzari 1, E. Borlenghi 1, M. D’Adda 1, E. Cerqui 1, D. Marocolo 1, G. Rossi 1, M. Pereira1,2,*, G. Marques 3, J. Lima 3, R. Reis 3, A. Coelho 3, L. Jorge 3, M. Pereira1,2,*, G. Marques 3, J. Lima 3, R. Reis 3, A. Coelho 3, L. Jorge 3

Background: Prognostication in Myelodysplastic Syndromes (MDS) using validated scores includes the detection of chromosomal aberrations by conventional karyotyping. When the latter is unavailable or unsuccessful, fluorescence in-situ hybridization (FISH) panels can be used. Although panels vary by laboratory, some of the commonly used probes include the search for monosomy 5 or del(5q), monosomy 7 or del(7q), del(20q) and trisomy 8 (T8). In our laboratory, FISH was historically performed on the whole unsorted patient sample (Full Sample); since 2015, we have primarily performed the analysis on Fluorescence Activated Cell Sorting (FACS) separated blast cells.

Aims: In this study, we aim to analyze the benefit of using purified samples of blast cells for FISH analysis in MDS, when compared to full mixed cellularity samples.

Methods: We reviewed all samples analyzed in our laboratory between January 1st 2011 and February 28th 2017 in which a FISH panel was performed due to a suspicion of myelodysplasia, using probes for del(5q), del(7q), del(20q) and T8. The proportion of patients positive for the test, as well as the proportion of positive cells within a positive sample, were compared.

Results: We obtained valid results for 328 samples during the relevant time-frame. 39.6% of which were collected from female patients. FISH was performed after FACS in one third of samples (35.1%, n=115), starting in 2015. Considering the overall cohort, nearly a quarter of samples (23.8%) had at least one aberration in the four probes tested in this study. This proportion of aberrations significantly doubled in FACS compared to Full Sample (33.0%) compared to full sample patients (18.8%, p=0.004). Del(5q) was present in 5.6% of the cohort; however, positivity was 8-fold higher in FACS patients, compared to full sample patients (12.3% vs 1.6%, p<0.001). Considering the percentage of positive cells in each sample, it doubled from 38.7±29.9% in the full sample to 71.8±28.1% after FACS (p=0.08). Del(7q) was similarly present in 5.7% of the cohort; however, in contrast, there were no relevant differences between FACS patients, 4.2% of whom had del(7q), and full sample patients (8.1%, p=NS).

We were, however, differences in the percentage of positive cells within the sample, doubling from 32.1±11.2% in the full sample to 77.6±17.8% after FACS, p<0.001. Del(20q) was identified in 7.0% of the overall tested cohort; the asymmetry in results was marked, with a 36-fold higher proportion of positive findings after FACS (18.7%) compared to full samples (0.5%, p<0.001). The percentage of positive cells doubled from 15% in the single positive test in the full sample cohort, to an average of 35.5±22.2% after FACS. Finally, T8 was found in 10.2% of both full and FACS samples, p=NS. The percentage of positive cells once again doubled from 25.5±14.7% in the full sample to 53.3±28.1% after FACS (p=0.0008).

Summary/Conclusions: We found that one quarter of all patients who underwent a FISH panel workup for a suspected diagnosis of MDS presented with aberrations in at least one of the four selected probes, a proportion which was significantly lower (one fifth) when a full sample was analyzed, and significantly higher (one third) in FACS purified blast cells. Although the purification of the sample through FACS doubled the percentage of positive cells within each sample for all four probes, the likelihood of obtaining a positive result for del(7q) and T8 in the cohort was unaffected by the methodology used. In contrast, the use of a sorted sample greatly increased the proportion of positive findings in del(5q) and, especially, in del(20q), the two probes for which the basal positivity in full samples were lowest. The clinical value of this increased rate of detection of del(5q) and del(20q) remains unclear, since their prognostic utility has only been established for levels detectable by conventional karyotyping of a full sample.

E1189

COUNTING BONE MARROW BLASTS AS A PERCENTAGE OF NON-ERYTHROID CELLS PROVIDES SUPERIOR RISK STRATIFICATION FOR MDS PATIENTS WITH ERYTHROID PREDOMINANCE

A. Sun1,2,*, Y. Yu1, T. Zhang1, Q. Wang1, D. Liu1, S. Chen1, D. Wu1,2

Background: Patients with erythroid predominance (≥50% erythroblasts, MDS-erythroid) compose a significant proportion of patients with MDS. The erythroid/myeloid subtype was divided from the AML category into MDS-erythroid by the 2016 WHO classification of myeloid neoplasms. At that time, there was no consensus on a more appropriate way of enumerating bone marrow (BM) blasts from TNCs or NECs in MDS-erythroid patients.

Aims: To clarify these questions, 1283 MDS patients were retrospectively analyzed in our center.

Methods: MDS-erythroid was observed in 27.0% of patients (346/1283), and these patients had similar clinicopathological features and overall survival, with 10% cases of MDS with <50% ENCS.

Results: By calculating the percentage of BM blasts from NECs, 73 of 200 patients (36.5%) with MDS-erythroid who were diagnosed within WHO subtypes without excess blasts (EB) were moved into higher-risk categories and showed shorter OS than those who remained in the initial categories (P=0.041). Recalculating the International Prognostic Scoring System-Revised (IPSS-R) by enumerating blasts from NECs, 40 of 168 (23.8%) MDS-erythroid patients with relatively lower risk were re-classified as higher-risk and had significantly poorer survival than those who remained in the lower-risk category (P=0.030). This was especially true for the intermediate risk group that was stratified by IPSS-R (unchanged patients vs shifted patients, P=0.007). However, the impact of enumerating BM blasts from NECs on classification and prognostication was not evident in all MDS patients.

Summary/Conclusions: In conclusion, our results suggested that enumerating the percentage of BM blasts from NECs significantly improved the prognostic assessment of MDS-erythroid, especially for patients within the intermediate risk group stratified by IPSS-R.

E1190

SUCCESSFUL TREATMENT WITH DANAZOL FOR MYELODYSPLASTIC SYNDROMES AND APLASTIC ANEMIA REFRACTORY OR INELIGIBLE TO STANDARD THERAPY

F. Schieppati1,*, A.M. Pelizzari 1, E. Borlenghi 1, M. D’Adda 1, E. Cerqui 1, D. Marocolo 1, G. Rossi 1

1Hematology, ASST Spedali Civili di Brescia, Brescia, Italy

Background: The discovery of danazol potential activity on telomere elongation in bone marrow failure has renewed interest in this drug. The treatment of cytopenia in myelodysplastic syndromes (MDS) and aplastic anemia (AA) patients who fail or are ineligible to standard therapies is an unmet medical need; however only dated reports on danazol use in this setting are available.

Aims: We report the results of treatment with danazol in patients with MDS and AA at a single institution.

Methods: From Jun–11 to May–15, danazol was administered to 31 consecutive patients (20 MDS and 11 AA). Criteria for treatment were non-severe AA (8), severe AA ineligible/refractory to immunosuppressive therapy or allogeneic transplantation (3), transfusion dependent (TD) lower risk MDS refractory to conventional treatment (11), MDS with isolated thrombocytopenia <50x10^9/L (6) or with bone marrow hypoplasia and bicytopenia (3). Diagnosis was defined by WHO 2008 for MDS and according to Camitta (Blood 1975) for AA; response was assessed by IWG 2006 criteria.

Results: The characteristics of the patients are shown in the Table. All MDS and AA patients had low-risk disease according to IPSS and IPSS-R, except 2 and 3 patients respectively. Nineteen patients (12 MDS, 7 AA) received danazol at full dose (600mg daily). A 400mg daily dose was given to 12 patients, due to toxicity (4 MDS, 4 AA) or comorbidities (4 MDS). Median duration of treatment
was 19 months (mo) (1-66) in AA and 6 mo (1-60) in MDS. ORR was 73% and 50%, respectively. Age and hemoglobin levels impacted on response in AA. Hematological improvement was seen on all lines in 92% of cases, with a median time to best response of 3-5 mo on platelets and neutrophils and of 8-12 mo on hemoglobin. Interestingly, duration of response in MDS patients was significantly longer with a danazol dose of 600mg than with 400mg (p<0.001). Conversely, dosing did not impact on response to danazol in AA patients. Grade 2-3 toxicity was significantly higher in AA patients (p<0.05), 60% pretreated with IST. Adverse events included: hematotoxicity (3 G1, 1 G2, 3 G3), muscle pain/CPK elevation (3 G1, 2 G2), transient renal impairment (1 G1), hypoxemia (1 G1). Responders to danazol had a better survival in terms of OS and EFS in both groups (Figure 1).

Figure 1.

Summary/Conclusions: Danazol was proved both effective and safe as treatment of cytopenia in MDS and AA patients refractory or ineligible to standard therapies. The daily dose of 600mg was more effective for MDS patients, whereas a lower dose of 400mg may have a better risk/benefit ratio in AA. Younger AA patients with less severe anemia were more likely to respond. Danazol use is particularly attractive in thrombocytopenic patients, where responses were rapid, but delayed responses may be expected also on anemia by using dana-zol for prolonged periods, when tolerated. Response to danazol is also potentially associated to a survival advantage, although these data should be confirmed by larger prospective studies.

E1191 SURVIVAL OUTCOMES IN PATIENTS WITH HIGHER-RISK MYELODYSPLASTIC SYNDROMES (HR-MDS) IN ROUTINE CLINICAL CARE IN THE UNITED STATES (US) – A CLAIMS DATABASE STUDY

J. Bell1, A. Galaznik1, E. Farrell2, M. Blazer2, H.-C. Shih2, A. Raju2, A. Ogbonnaya2, M. Eaddy2, R. Fram2, D. Faller2

1Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, 2Xcenda, Palm Harbor, United States

Background: MDS is composed of multiple and rare hematological stem-cell disorders, resulting in cytopenias and disease-related complications and deaths. There are no robust trial data comparing the available treatment options for HR-MDS patients; and of the approved drugs, only azacitidine has demonstrated a statistically significant, but modest clinical impact on overall survival (OS).

Aims: We evaluated first-line treatment (1LT) choice and survival outcomes in a US cohort of HR-MDS patients engaged in routine care.

Methods: Newly diagnosed HR-MDS patients who were ≥18 years old and who had initiated 1LT were retrospectively identified from Optum, a large US claims database, between 1/1/2008 and 10/31/2015. HR status was based on ICD coding: ≥1 inpatient claim with an HR-MDS ICD-9 code (ICD-9 code: D46.20, D46.21, D46.22), or ≥2 outpatient claims with ICD coding: ≥1 inpatient claim with an HR-MDS ICD-9/10 code (ICD-10 code: C91.9, C91.0, C91.1). OS was calculated from index date of 1LT to last follow-up or date of death, censoring at last contact or end of study. EFS was calculated from index date to date of first event (death, end of continuous enrollment, end of study, or progression to acute myeloid leukemia (AML)).

Results: Among patients able to achieve transfusion independence, a trend toward increased 2-year PFS and OS rates was observed, although statistical significance was not reached. Characteristics that contribute to variations in PFS and OS outcomes within the HR-MDS population need further investigation.

E1192 DOSE-CONFIRMATION PK/PD STUDY OF ORAL ASTX727, A COMBINATION OF ORAL DECITABINE WITH A CYTIDINE DEAMINASE INHIBITOR (CDAI) E7727, IN SUBJECTS WITH MYELODYSPLASTIC SYNDROMES (MDS)

1UT MD Anderson Cancer Center, Houston, 2Roswell Park Memorial Institute, Buffalo, 3Cornell University Medical Center, New York, United States, 4Hospital Maisonneuve-Rosemont, Montreal, 5Sunnybrook Medical Center, Toronto, Canada, 6University of Chicago, Chicago, 7Dana Farber Cancer Institute, Boston, United States, 8Princess Margaret Cancer Center, Toronto, Canada, 9Vanderbilt University Medical Center, Nashville, United States

Background: We have previously shown that ASTX727, a combination of oral decitabine and the oral CDAI E7727, emulates the pharmacokinetics of a one hour intravenous decitabine infusion (IV-DAC) in a dose-escalation phase 1 study. (Garcia-Manero. Blood 2016 128:1124)

Aims: To confirm pharmacokinetic (PK) and pharmacodynamic (PD) comparability of 20mg/m² IV-DAC administered D1-5 of a 28 day cycle with an entire one hour intravenous decitabine infusion (IV-DAC) in a dose-escalation phase 1 study.

Methods: Adult patients with Int-1/Int-2 or HR MDS or Chronic Myelomonocytic Leukemia (CMML) were enrolled in a randomized cross-over Phase 2 study. Patients were randomized 1:1 to receive in the first 28 day cycle, either 5 days of IV-DAC or 5 days of ASTX727, followed by a cross-over to the other in Cycle...
2. Cycles 3 forward were with ASTX777, PD were assessed with LINE-1 methylation as measured on blood cells at baseline and days 8, 15, 21 and 28 in cycles 1 and 2. Full PK assessments of ASTX777 were performed on Days 1, 2 and 5 with sparse sampling on Days 3 and 4 and on Day 1 of IV-DAC. Modeling of 5 day exposures of ASTX777 and IV-DAC was created for each patient. Safety and clinical response were assessed on all patients.

Results: 50 patients were randomized, 50 had matched PK and 46 had matched PD sample sets for the first 2 cycles. No significant differences were seen when comparing the randomized sequences for any parameters, so all assessments comparing ASTX777 and IV-DAC were performed independent of sequence. The geometric mean maximum demethylation was 9.9% for ASTX777 and 8.9% for IV-DAC (Ratio of oral over IV=0.9, with a lower limit of 90%CI of 0.8). The geometric mean AUC for IV-DAC was 161 ng/hmL. The 5 day total geometric mean of the AUC (ng/hmL) was 769 for ASTX777 and 805 for IV-DAC ([Ratio of oral over IV=0.96, with a lower limit of 90%CI of 0.806). Decitabine Cmax was higher for IV-DAC (189 ng/mL) than after ASTX777 (210 ng/mL) and the AUC0-5 was lower for IV-DAC (95.1 ng-dL/hmL). The Day 8 adverse events regardless of grade or causality were febrile neutropenia 34%, neutropenia 28%, thrombocytopenia 16%, fatigue 16%, and hypomagnesia 16%. There were no reported GI Adverse Events greater than Grade 2 with ASTX772 regardless of relationship to treatment.

Summary/Conclusions: Patients treated with azacitidine (especially AML patients) at high risk of infection treated with the first-line AZA are at risk. All important infection predictive factors should be assessed before therapy. Patients possessing factors predictive for infection require special approach and predictive infection model should be developed in further analysis.

E1194

OVERALL SURVIVAL, INITIAL TREATMENT AND TREATMENT DURATION OF PATIENTS WITH MYELODYSPLASTIC SYNDROME, A DETAILED POPULATION BASED STUDY

H. Rozema1,2, R. Kibblelaa3, N. Veeger3, E. Van Roon1,2, M. Hoogendoorn2

1Pharmacotherapy, Epidemiology & -Economics, University of Groningen, Groningen, 2Medical Centre Leeuwarden, Leeuwarden, Netherlands

Background: Population-based studies on myelodysplastic syndrome (MDS) containing detailed clinical information of patient characteristics, treatment and follow-up of the disease are scarce. Since 2005, all patients diagnosed with hematological malignancies in Friesland, a province in the Netherlands, are prospectively registered and followed by their clinicians in a population-based registry, the HemoBase. The registry provides representative population-based data on diagnosis, treatment and outcomes in an era where low-intensity treatment such as hypomethylating agents have become available for the elderly.

Aims: The objectives of this study were to determine the overall survival (OS) of patients with MDS and the effect of the variables gender, age, comorbidities, IPSS-R score and MDS subtype according to WHO 2016 classification. Furthermore, the leukemia free survival (LFS), the initial treatment and the duration of first-line treatment were analyzed.

Methods: An observational, population-based study was performed using the HemoBase registry. The bone marrow biopsies and aspirates of all MDS patients were assessed between 01-01-2005 and 31-12-2013 were independently and blindly reviewed by both the hematologist and hematologist-pathologist and classified according to the WHO 2016. Treatment categories were defined as intensive chemotherapy (IC) either combined or not combined with allogeneic stem cell transplantation, the hypomethylating agent azacitidine, the immunomodulatory agent lenalidomide, hydroxyurea or best supportive care (BSC) (blood transfusions, erythropoiesis-stimulating agents). Approval was obtained from the Medical Ethics Review Committee from Medical Centre Leeuwarden. Statistical analyses were performed with SPSS 19; survival analyses were used during Kaplan-Meier estimates.

Results: 217 patients (72.4% male, 66.8% >70 years old, median age 75 years, 27.2% Charlson Comorbidity Index (CCI) score ≥3) were diagnosed in a median follow-up duration of 70.2 months. 15.7% of the population had an IPSS score ≥15 and 12.4% of the population had an IPSS-R score ≥4.5. In 41.5% no cytogenetic information was available. MDS-RS, MDS-SLD/-MLD, MDS-EB, MDS-U and CMMl were diagnosed in 11.5%, 14.7%, 36.4%, 27.2% and 10.1% of the population respectively. 18.4% showed progression towards acute myeloid leukemia (AML), IC, azacitidine, lenalidomide, hydroxyurea and BSC were the initial treatment in 5.1%, 13.8%, 1.4%, 9.7% and 66.4% of the patients respectively. Within 12 months 78.1% of all treated patients terminated their first-line therapy because of death (20.0%), refractory to treatment (18.3%) or disease progression (16.7%). A second treatment was initiated in 10.1% of patients. The median LFS was 18.2 months (95% CI: 12.6-23.8). The median OS of MDS patients in Friesland was 22.5 months (95% CI: 15.2-29.7). Univariate analysis showed an association between lower OS and male gender (HR for women: 0.54, p=0.008, 95% CI: 0.34-0.85), age >80 years (HR: 2.7, p=0.0005, 95% CI: 1.6-4.6), CCI score ≥3 (HR: 2.0, p<0.001, 95% CI: 1.3-3.0), IPSS score ≥1.5 (HR: 2.3, p=0.004, 95% CI: 1.3-4.1), IPSS-R score ≥4.5 (HR: 5.7, p<0.0005, 95% CI: 2.4-2.4) and MDS subtype MDS-EB (HR: 1.8, p=0.016, 95% CI: 1.1-2.9).

Summary/Conclusions: This study provided complete representative population-based data on overall survival and treatment of patients with MDS. IPSS-R score, treatment sequence and MDS subtype according to WHO 2016 classified according to the WHO 2016. Despite the low-intensity treatment strategy that was used in 72.5% of the patients and significant comorbidity in this population, a third of the patients received treatment in addition to BSC.

E1195

DANAZOL TREATMENT FOR THROMBOCYTOPENIA IN LOWER-RISK MYELODYSPLASTIC SYNDROMES: A REAL LIFE EXPERIENCE

F. Ivala1, E. Ravano2,*, R. Cairoli1, A. Molteni2

1Hematology Unit, ASST Grande Ospedale Metropolitano Niguarda, Milano, Italy, 2Hematology Unit, ASST Cremona, Cremona, Italy

Background: Severe thrombocytopenia is an uncommon event in lower-risk MDS patients, but it may significantly affect the prognosis. In fact, when it occurs, the need for antiplatelet therapy may be a life-threatening situation. Danazol, a synthetic androstenedione, is a naturally effective progestin. Danazol treatment for thrombocytopenia is nowadays available yet for this unmet need in Europe. Eltrombopag seems to be a very interesting product, but its efficacy and safety still need to be better demonstrated. Even romiplostim could be
suitable, but, at present, its safety is questioned in MDS patients. Furthermore, in clinical practice, danazol, an attenuated androgen, has been reported to have some ability to increase the platelet count in this context (Wattel 1994; Chan 2002).

Aims: To assess efficacy and toxicity of danazol employed to improve severe thrombocytopenia in lower-risk MDS setting.

Methods: We retrospectively reviewed twenty-four patients affected by MDS and treated with danazol for thrombocytopenia. The initial dose was 600mg/day for all patients. The IWG criteria of response (Cheson 2006) were adopted. The outcome was observed every 3 months till 12th month. The overall response rate and the average platelet count or each time of observation were described. Progression free survival was estimated with the Kaplan-Meier product limit method, followed by the logrank test and by the Cox proportional-hazard regression.

Results: Of the 24 patients, 3 patients had a therapy-related MDS. At the starting time of danazol therapy, the IPSS was “low” in 9, “int-1” in 13 and “int-2” in 2 cases respectively; the IPSS-R was “very low” in 2, “low” in 11, “intermediate” in 7 and “high” or “very high” in 4 cases. At baseline in 14 patients the platelet count was lower than 20x10^3/mL, the average was 20x10^3/mL and the maximum value was 38x10^3/mL. The median dose was 600mg (range 200-600) also maintained at least up to 3 months (range 400-600). At 6 and 12 months the median dose therapy was 400mg (range 400-600 and 200-600 respectively). The response rate was 79.1% (19 responders on 24 treated). The average count increased as shown in Figure 1, over 60x10^3/mL after 6 months from diagnosis.

The response was clinically significant. The median dose of 600mg should be maintained for at least 3 months to properly assess the effectiveness of therapy and then adjusted according to response and toxicity. The response may not be immediate, but seem to be reachable after 3-6 months of treatment. A responsive patients have short probability to loss the response, that may last for very long time. The toxicity profile of this drug is low. The mechanism of action of danazol in MDS patients remains unclear. Waiting for more information on the efficacy and safety of eltrombopag from the clinical trials in progress, danazol may be a good therapeutic option for these patients.

Figure 1.

Summary/Conclusions: This series confirms the efficacy of danazol to improve platelet count in the most of patients with severe thrombocytopenia due to lower-risk MDS. In all patients with increased platelet count, the response was clinically significant. The median dose of 600mg should be maintained for at least 3 months to properly assess the effectiveness of therapy and then adjusted according to response and toxicity. The response may not be immediate, but seem to be reachable after 3-6 months of treatment. A responsive patients have short probability to loss the response, that may last for very long time. The toxicity profile of this drug is low. The mechanism of action of danazol in MDS patients remains unclear. Waiting for more information on the efficacy and safety of eltrombopag from the clinical trials in progress, danazol may be a good therapeutic option for these patients.

E1196

TREATMENT PATTERNS IN PATIENTS WITH HIGHER-RISK MYELODYSPLASTIC SYNDROMES (HR-MDS) IN ROUTINE CLINICAL CARE IN THE UNITED STATES (US) – A CLAIMS DATABASE STUDY

J. Bell1,*, A. Galaznik1, E. Farrell2, M. Blazer3, H.-C. Shih2, A. Raju2, A. Ogbonnaya2, M. Eaddy2, R. Fram1, D. Faller1

1Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, MA, 2Xcenda, Palm Harbor, United States

Background: Treatment of patients with HR-MDS includes hypomethylating agents (HMA) (azacitidine and decitabine), high-intensity induction chemotherapy (IC), and stem cell transplant (SCT). Given the rarity of disease, information available on how these treatments are applied in practice is limited.

Aims: We evaluated the treatment patterns of HR-MDS patients engaged in routine care within the US.

Methods: Newly diagnosed HR-MDS patients who were ≥18 years old were retrospectively identified from Optum, a large US claims database between 1/1/2008 and 10/31/2015. HR status was based on ICD coding: ≥1 inpatient claim or ≥2 outpatient claims with an HR-MDS ICD-9 code (ICD-9 code: 238.73; ICD-10 codes: D46.20, D46.21, D46.22). The first MDS claim served as the index date. Exclusion criteria included: absence of continuous enrollment in medical and pharmacy benefits for 12 months prior to index date (baseline period), presence of other primary cancer, or receipt of any chemotherapy or SCT during the baseline period. First-line therapy (1LT) was defined as an MDS-specific treatment (as defined by NCCN MDS Guidelines v2.2017) initiated on or after the index date. Patients were followed until death, end of continuous enrollment, or end of study (12/31/2015). For patients with progression to acute myeloid leukemia (AML), treatment pattern evaluation stopped at AML diagnosis.

Results: 335 newly diagnosed HR-MDS patients were identified; 209 (62.4%) were treated with 1LT with treatment initiated within 1 month of diagnosis (median: 17 days, interquartile range [IQR]: 9, 35). A higher proportion of untreated patients (n=126) was ≥75 years of age (71.4% vs 66.2%, p = 0.03), and had certain comorbidities at baseline (congestive heart failure, 23.0% vs 16.3%; renal disease, 24.6% vs 16.3%; diabetes 31.0% vs 23.4%, diabetes with end organ failure, 16.7% vs 8.1%) than treated patients. For treated patients, 1LT with azacitidine predominated in 68.9% of patients (n=144), followed by decitabine in 20.6% of patients (n=43), and immunomodulators (lenalidomide or thalidomide) in 8.7% of patients (n=19) (Figure 1). 4 patients had only SCT and an additional 14 had SCT at some point during follow-up. With regard to HMA therapy, median duration was 4.5 months (IQR: 2.6, 9.5) for azacitidine and 4.8 months (IQR: 2.1, 11.6) for decitabine. A greater proportion of decitabine-treated patients...
received supportive care with colony-stimulating factors (CSFs) (39.5% vs 28.5%) and either erythropoietin or platelet transfusions (69.8% vs 57.6%) during 1LT vs azacitidine-treated patients. Second-line therapy (2LT) was administered to 30 (14.4%) patients; the HMAs again predominated in 63.3% of patients (n=19). Of patients not receiving 2LT, 65 (31.7%) progressed to AML, 47 (22.9%) had <30 days of follow-up due to proximity to end of study (38 [80.9%] of these were on 1LT at end of study). 33 (16.1%) continued to receive some supportive care and, 21 (10.2%) died.

Summary/Conclusions: Most HR-MDS patients treated in routine care are treated according to guidelines, with the HMA, azacitidine, predominating. Underlying comorbidities and older age may influence whether or not to treat HR-MDS patients with 1LT. For treated HR-MDS patients, duration of 1LT did not differ with azacitidine and decitabine. However, use of certain MDS-related supportive care treatments varied by choice of HMA, with more decitabine-treated patients receiving CSFs and transfusions. Further research is needed to determine how these factors influence both clinical outcomes in a HR-MDS population.

E1197

APPRIC8: A PIPELINE FOR PRECISE VARIANT CALLING INTEGRATING 8 TOOLS

S. Sandmann1,*, M. Karimi2, A. de Graaf3, B. van der Reijden3, E. Hellström-Lindberg3, J. Jansen3, M. Dugas1

1Institute of Medical Informatics, University of Münster, Münster, Germany, 2Department of Medicine Huddinge, Karolinska Institutet, Stockholm, Sweden, 3Laboratory Hematology, RadboudUMC, Nijmegen, Netherlands

Background: For the use of next-generation sequencing in clinical routine same platform, on a different platform and expert-based review. (42,322 bp) was analyzed. Validation was performed by re-sequencing on the Roche 454. In all cases the same target region consisting of 19 genes on Illumina HiSeq. The second test set covered 89 MDS patients, sequenced on Illumina HiSeq, and 111 MDS patients, sequenced on 1LT at end of study. Almost 100% of the genome was analyzed. From this data, 33 (16.1%) continues to receive some supportive care and, 21 (10.2%) died.

Summary/Conclusions: Most HR-MDS patients treated in routine care are treated according to guidelines, with the HMA, azacitidine, predominating. Underlying comorbidities and older age may influence whether or not to treat HR-MDS patients with 1LT. For treated HR-MDS patients, duration of 1LT did not differ with azacitidine and decitabine. However, use of certain MDS-related supportive care treatments varied by choice of HMA, with more decitabine-treated patients receiving CSFs and transfusions. Further research is needed to determine how these factors influence both clinical outcomes in a HR-MDS population.

COMPARISON OF ADMINISTRATION OF HYPOMETHYLATING AGENTS AND EFFICIENCY OF ALLOGENEIC SCT IN ELDERLY PATIENTS WITH ADVANCED MDS

J. Cermak1,*, A. Vitek 1, J. Maalouf-Soukupova 1, M. Markova-Štastna 1, P. Cetkovsky1

1Clinical Hematology, Institute of Hematology and Blood Transfusion, Praha, Czech Republic

Background: Hypomethylating agents (HMA) have been introduced as a promising agent in the treatment of elderly patients with advanced myelodysplastic syndromes (MDS) leading to a response in approximately 50% of patients. However, most of the patients relapse and estimated years survival is below 10%. Stem cell transplantation (SCT) still represents the only curative treatment even in elderly patients with advanced MDS and it is connected with long-term survival in 35-40% despite relatively high risk of transplant related mortality (25-30%).

Aims: The aim of the study was a retrospective analysis of results of the treatment of 59 elderly patients (50 years of age or older) with MDS RAEB-2 or with acute myeloid leukemia with multilineage dysplasia with less than 30% of bone marrow blasts (MDS RAEB-T according to the FAB classification) who received either HMA or underwent allogeneic SCT.

Methods: In the HMA group, 34 out of total 38 patients received azacitidine (Vidaza®) in the dose of 75mg/m²×7 every 28 days and 4 patients were treated with decitabine (Dacogen®) in the dose of 10mg/m²×5 every 28 days. Median number of cycles administered was 10.4 (range 3-31). An age and diagnosis matched transplanted group consisted of 21 patients, 9 patients were transplanted upfront, 12 patients were pretreated either with combination chemotherapy (10 patients) or with HMA (2 patients) and achieved CR prior to SCT. Ten patients received myeloablative conditioning and 11 patients were transplanted after reduced conditioning regimen.

Results: When analyzing the training sets with only one of the eight variant calling programs and considering all variants pathogenic as well as somatic, sensitivity ranges between 0.85 and 1.00 in case of set 1 and 0.47 and 0.99 in case of set 2. Although FreeBayes features highest sensitivity regarding both sets, it consistently features lowest PPV as well (set 1: 0.03, set 2: 0.02). Combining the output of all variant calling tools leads to perfect sensitivity, while PPV is 0.03 for set 1 and 0.02 for set 2. Application of our appric8 pipeline led to a minor decrease in sensitivity (set 1 and set 2: 0.98), while PPV is significantly increased (set 1: 0.99, set 2: 0.94). The PPV of the appric8 output for both training sets is higher compared to each of the individual tools. Analysis of the independent test set 1 leads to comparable results. Sensitivity of the individual tools ranges between 0.82 and 0.99, while PPV ranges between 0.02 and 0.91. Combining the output of all variant calling tools leads to sensitivity of 1.00 and PPV of 0.02. However, application of appric8 leads to variant calling results with sensitivity of 0.98 and PPV of 0.09. To test the robustness of our approach, we analyzed Roche 454 data, although the pipeline was exclusively trained on Illumina data. Regarding the individual tools sensitivity ranges between 0.91 and 0.99, while PPV ranges between 0.07 and 0.68. By combining the output of all variant calling tools, sensitivity increases to 0.99, while PPV is 0.05. Application of appric8 leads to sensitivity of 0.98 and PPV of 0.76.

Summary/Conclusions: To consider variant calling results in clinical routine, it does not seem appropriate to rely on the output of a single tool only. Instead, combining the output of several tools and applying a set of filters as it is done by our appric8 pipeline leads to results with both high sensitivity and PPV. Nonetheless, variant calling results should, especially at allelic frequencies below 20%, always be viewed with criticism.

Figure 1.
A MULTICENTER, OPEN-LABEL, PHASE I CLINICAL STUDY: SAFETY, EFFICACY, AND PHARMACOKINETICS OF ORAL RIGOSERTIB IN JAPANESE PATIENTS WITH RECURRENT/RELAPSED OR REFRACTORY MYELODYSTROPHIC SYNDROMES

K. Ishizawa12, K. Usuki3, K. Ando4, Y. Ueda5, T. Kiguchi6, N. Uiko7,8, Y. Onishi5, H. Iida9

Background: Rigosertib, a novel phosphoinositide 3 kinase pathway inhibitor, induces G2/M arrest leading to the apoptosis of cancer cells and myeloblasts and is safe for and well tolerated by pts with low, intermediate-1, intermediate-2, or high-risk myelodysplastic syndromes (MDS).

Aims: The aims of the study were to assess the safety, efficacy, and pharmacokinetics of oral rigosertib and to determine the recommended dose (RD) for a Phase II clinical study in Japanese pts with recurrent/relapsed or refractory MDS.

Methods: We conducted a multicenter, open-label, Phase I clinical study of oral rigosertib. The key eligibility criteria were as follows: recurrent/relapsed or refractory MDS; age: ≥ 20 or older; ECOG PS of 0 to 2; and no major organ dysfunctions. Rigosertib (280 and 560mg BID) was administered orally in one 21 day cycle (up to cycle 6) that consisted of the 14-day, twice-daily, oral administration term, followed by 7-day monitoring. The primary endpoint was dose-limiting toxicity (DLT). The secondary endpoints were 1) safety as assessed with adverse events (AEs) and laboratory results, 2) efficacy as assessed with the International Working Group 2006 criteria, and 3) pharmacokinetics.

Results: Between March 2013 and November 2014, 6 male and 3 female pts (median age: 70; range 52-80) were enrolled. ECOG PS was 0 in 7 pts and was 1 in 2 pts, and 3 and 6 pts were eventually assigned to the 280 and 560mg BID arms, respectively. According to the FAB classification, 4, 2, 2 and 1 pts were categorized to RAEB, RARS, RA, and RAEB-1, respectively. The prognostic factor according to IPSS was Int-1 risk in 4 pts (1 and 3 pts in the 280 and 560mg BID arms, respectively) and was Int-2 in 5 pts (2 and 3 pts in the 280 and 560mg BID arms, respectively). DLT occurred in 1 pt in the 280mg BID arm and in 2 pts in the 560mg BID arm: the former consisted of type 2 diabetes and grade 4 delirium, and the latter grade 5 urinary tract infection and grade 3 prolonged QT interval. Therefore, the RD for a Phase II clinical study in Japanese pts was determined to be 560mg BID. On day 11 of treatment, 1 pt in the 560mg BID arm died of grade 5 urinary infection whose relationship with the investigational drug was rated to “Definite”. The presumed cause of death was septic shock caused by urinary tract infection. The hematological remission rate was 11.1% (1/9 pts). Among the PK parameters, inter-individual variability was observed in the Cmax and AUC. However, changes suggesting the accumulation of rigosertib during repeated oral administration (e.g., consistent increases in the Cmax and AUC) were not found.

Summary/Conclusions: The present chemotherapeutic regimen of oral rigosertib was well tolerated. Our study indicates that the RD for a Phase II clinical study is 560mg BID in Japanese patients with recurrent/relapsed or refractory MDS.

Myeloma and other monoclonal gammopathies - Biology

NON-OVERLAPPING PROMOTER AND SUPER-ENHANCER DRIVEN PROCESSES SUPPORT MYELOMA CELL GROWTH AND SURVIVAL VIA DISTINCT REGULATORY AXES

M. Fulcar11, C. Lin2, M. Samur1, H. Avet-Loiseau3, K. Anderson1, J. Bradner4, N. M. M. M. Fulcar1
1 Dana Farber Cancer Institute, Boston, 2 Baylor college of medicine, Houston, United States, 3 Cancer research center, Toulouse, France, 4 Novartis, Boston, United States

Background: We have previously reported that E2F1 and its heterodimerization partner DP1 promote MM tumor proliferation both in vitro and in vivo; and observed an inverse correlation between their expression and patient survival suggesting a role in MM pathogenesis. Moreover, E2F2 functional impairment by a dimerization inhibiting stapled peptide significantly affects myeloma tumor cell growth while sparing effect on normal components of bone marrows as well as normal plasma cells, suggesting an E2F2 dependency in MM cells.

Aims: In this study, our aim was to defined the regulatory landscape of E2F in MM to better understand how E2F1 and DP1 drive myeloma cell proliferation; and to define the relationship between promoter proximal transcription factor- associated gene expression and super-enhancer-driven transcriptional programs.

Methods: We integrated genetic perturbation with functional omics to define E2F role in MM. Global occupancy of E2F1 and DP1 in MM was evaluated by ChIP-seq analysis. E2F1 and DP1 genomic localizations were then integrated to MM reference epigenome. Enhancers and super-enhancers were mapped using ROSE2 (github.com/bradnerlab/pipeline). Read densities were calculated using bamliquidator (github.com/BradnerLab/pipeline/wiki/bamliquidator).

Results: Integration of E2F1 and DP1 genomic localization to MM reference epigenome revealed specific co-occupancy of the factors at promoters of active genes marked by H3K4me3, with a strong positive correlation between E2F and RNA Pol II binding on H3K4me3 peaks. Distinct regulatory axes were defined for E2F1 and E2F2 functions. In this study, our aim was to defined the regulatory landscape of E2F in MM to better understand how E2F1 and DP1 drive myeloma cell proliferation; and to define the relationship between promoter proximal transcription factor- associated gene expression and super-enhancer-driven transcriptional programs.

Integration of E2F1 and DP1 genomic localization to MM reference epigenome revealed specific co-occupancy of the factors at promoters of active genes marked by H3K4me3, with a strong positive correlation between E2F and RNA Pol II binding on H3K4me3 peaks. Distinct regulatory axes were defined for E2F1 and E2F2 functions. In this study, our aim was to defined the regulatory landscape of E2F in MM to better understand how E2F1 and DP1 drive myeloma cell proliferation; and to define the relationship between promoter proximal transcription factor- associated gene expression and super-enhancer-driven transcriptional programs.

Summary/Conclusions: In conclusions, our results highlight the existence of non-overlapping promoter and super-enhancer-associated dependencies in multiple myeloma, suggesting a sequestered molecular control that may be perturbed in cancer with potential for development of a promising therapeutic strategy.

ANALYSIS OF THE GENOMIC LANDSCAPE OF MULTIPLE MYELOMA HIGHLIGHTS NOVEL CANDIDATE PROGNOSTIC MARKERS AND DISEASE SUBGROUPS

1Dana Farber Cancer Institute, Boston, 2Baylor college of medicine, Houston, United States, 3Cancer research center, Toulouse, France, 4Novartis, Boston, United States

Background: We have previously reported that E2F1 and its heterodimerization partner DP1 promote MM tumor proliferation both in vitro and in vivo; and observed an inverse correlation between their expression and patient survival suggesting a role in MM pathogenesis. Summary/Conclusions: In conclusions, our results highlight the existence of non-overlapping promoter and super-enhancer-associated dependencies in multiple myeloma, suggesting a sequestered molecular control that may be perturbed in cancer with potential for development of a promising therapeutic strategy.
Aims: We used a custom target pulldown (TPD) approach on a large cohort of MM samples at diagnosis, with homogeneous treatment and long follow-up, to further our understanding of the landscape of driver lesions in MM and how this can be used to improve prognostication and disease classification.

Methods: We used a custom-designed SureSelect pulldown strategy (Agilent Biotechnologies) to target 246 genes implicated in MM or cancer in general; 2538 single nucleotide polymorphisms; the immunoglobulin heavy chain (IGH) locus. We sequenced unmatched DNA from CD138-purified plasma cells from 418 patients with a median follow-up of 5.4 years using Illumina HiSeq2000 machines. We applied algorithms developed in-house to detect driver genomic events, filtering out potential artifacts and germline variants. We then ranked each mutation on its likelihood of being oncogenic.

Results: We identified 197 driver events including genes, aneuploidies and IGH translocations (IGH-Tx), median of 6 per patient. Gene mutations where found in >99% of patients. At least one oncogenic mutation of a known driver gene previously identified (KRAS, NRAS, TP53, FAM46C, BRAF, DIS3, TRAF3, SP140, IRF4) was found in 64%, with a long tail of infrequently mutated genes with uncertain significance. Karyotypic class was assigned in 80% of patients, with 9% of hyperdiploid cases also showing an IGH-Tx (mostly t(4;14)). IGH-Tx and aneuploidies dominated the MM genomic landscape, KRAS and NRAS being the only point mutations present in the 15 most frequent driver events. Multivariate analysis by separate Cox regression highlighted only four driver events with significant prognostic impact for both progression-free (PFS) and overall survival (OS): t(4;14) (HR 1.88, CI 1.25-1.84), amp(1q) (HR2.63, CI 1.92-3.59), del(17p) (HR2.53, CI 1.66-3.92), and rare mutations of ATP13A4 (HR 0.08, CI 0.01-0.65, mutated in 1.4% of patients). We found a significantly worse prognosis for increasing numbers of driver lesions in each patient (median OS 8.2 vs 3.5 years for <5 and>8 driver events, respectively). This was only partially explained by instances of additive effect or interactions between variables, which were very informative but not frequent. To better investigate these findings in the context of the genomic landscape of each case, we applied Bayesian clustering algorithms. The large number of driver events screened led to the identification of three groups: in the largest one, some hyperdiploid and IGH-Tx cases clustered together, suggesting that secondary mutations and CNAs required for tumor progression are often shared between these two subgroups. We then identified two clusters both characterized by significantly lower number of mutations, but with opposing features. One was enriched for IGH-Tx, had the highest number of CNAs overall, showed higher prevalence of amp(1q), del(13), del(17p), TP53 mutations, and had a shorter median OS of 5.3 years. The other was mostly composed of hyperdiploid cases and showed fewest CNAs and mutations, with a good prognosis (median OS not reached).

Figure 1.

Summary/Conclusions: We report on the first attempt towards the use of extended tumor genotype for a genomic classification of MM using innovative clustering algorithms. Despite the heterogeneity of the disease, we could identify disease subgroups with a distinct spectrum and number of driver events carrying different prognosis, supporting the introduction of genomics in the clinical approach to MM

A NOVEL METHOD FOR GENOME-WIDE COPY NUMBER ASSESSMENT FROM TARGETED SEQUENCING DATA AND CLINICAL APPLICATION IN PATIENTS WITH MULTIPLE MYELOMA

G. Ryland1,2, J. Markham3, K. Jones3, E. Aydogan3, T. Paperfuss4, M. Chin3, J. Gottlieb5, A. Thakuria6, N. Munshi3, P. Blombery7

1Pathology, 2Research, Peter MacCallum Cancer Centre, Melbourne, Australia
3UCL Cancer Institute, 4Department of Haematology-Oncology, St Bartholomew’s Hospital, London, United Kingdom
5Haematology, Peter MacCallum Cancer Centre, Melbourne, Australia

Background: Assessment of gene mutations by next generation sequencing is now standard in patients with haematological malignancy. However, larger chromosomal aberrations (e.g. exon, gene and chromosome level gains and losses) also serve as critical prognostic indicators that guide therapeutic decision making. These larger gene lesions are typically assessed using a separate methodology such as conventional cytogenetics/FISH.

Aims: We aimed to develop and clinically validate a novel method for assessing genome-wide copy number changes using an existing hybridisation-based targeted sequencing panel in order to provide further critical prognostic information not available from the existing targeted short read sequencing data without the need for a separate assay.

Methods: A custom Agilent SureSelect capture panel targeting 313 genes of relevance in myeloid and lymphoid malignancies was sequenced on an Illumina NextSeq (paired end 75bp reads) to a mean depth of 700x. An in-house bioinformatics pipeline was created to analyse probe counts from on-target and off-target regions, with which also detect CNAs and CNAs assessed for copy-number change and normalisation to a pooled reference comprising 10 normal controls. Three metrics for copy number calling were tested including a permutation-based statistic from circular binary segmentation, weighted mean and variance for the bins in each segmented region, and an MLPA-like test using ratios compared to controls. An interactive web-based graphical user interface was developed to visualise both large-scale and exon level amplification and deletions.

Results: We validated the approach on 45 samples from patients with multiple myeloma (predominantly advanced disease) with known copy number status as determined by conventional cytogenetics, FISH and MLPA. Our novel method detected numerous copy number changes that were outside the targeted region (through genome-wide mapping and analysis of off-target reads) such as del(1p) in 12 patients, gain(1q) in 15 patients and MYC amplification in 5 patients. Moreover our method was able to interrogate and resolve the complexity of changes on del(1p) including isolated deletions of FAM46C, CDKN2C and FAP1. Of 25 patients with a TP53 mutation, 20 had concomitant del(17p) detected by our assay, while 1 case had a del(17p) without mutation; both monosomic and biallelic TP53 aberration was associated with poor survival. Other findings in this cohort include frequent DIS3 mutations in patients with high-risk cytogenetics and 13 and 22q CNAs with monosomy 13 and hyperdiploid copy number changes such as the high amplification of KRAS in 1 case.

Summary/Conclusions: We have developed and demonstrated utility of a reliable workflow for genome-wide copy number assessment that can be implemented using existing targeted short read sequencing data, greatly extending the utility of this technology beyond the identification of aberrations for patients with haematological malignancy. In the context of myeloma this can be used to report clinically relevant changes including deletions of 1p and 17p, and gains of 1q and 8q, as well as novel numerical chromosome aberrations.

E1203 THE MULTIPLE MYELOMA GENOME PROJECT: DEVELOPMENT OF A MOLECULAR SEGMENTATION STRATEGY FOR RISK STRATIFICATION OF MULTIPLE MYELOMA

1Celgene Corporation, San Francisco, 2Myeloma Institute, University of Arkansas for Medical Sciences, Little Rock, 3Dana Faber Cancer Institute, Harvard Medical School, Boston, 4Celgene Corporation, Summit, United States, 5Celgene Corporation, Seville, Spain, 6Centre de Recherche en Cancérologie de Toulouse Institut National de la Santé et de la Recherche Médicale, Toulouse, France, 7Newcastle University, Newcastle, United Kingdom

Background: Segmenting multiple myeloma (MM) into subgroups with distinct pathogenesis and clinical behavior is critical to implement a targeted therapy approach and improve prognosis for patients. Current technologies have elucidated major translocation groups and recurrent copy number changes with varying effects on prognosis. However, minor translocation and mutation subgroups remain poorly described due to limited sample numbers and small datasets. The availability of multiple sets of high quality genomic data associated with clinical information, cytogenetics, and outcomes provides an opportunity to create an integrative genomic predictor using mutational, chromosomal, and gene expression alterations to develop a classification system to segment MM into therapeutically meaningful subgroups.

Aims: The Multiple Myeloma Genome Project (MGP) is a global collaborative research initiative that aims to develop a molecular segmentation strategy for MM to inform development and deployment of clinically relevant tests that could improve diagnosis, prognosis, and treatment of patients with MM.

Methods: We have established a dataset representing 1766 MM patients for which whole exome sequencing (WES; n=1367), Whole Genome Sequencing (WGS; n=474), and expression data from RNAseq and CNAs data sets (n=1059) were available. Data were derived from the Myeloma XI trial, Dana-Faber Cancer Institute/Intergroupe Francophone du Myelome, The UAMS Myeloma Institute and the Multiple Myeloma Research Foundation (IA1 – IA9). Data were investigated for genetic abnormalities following preprocessing with statistical methods.

Results: Our analysis is focused on data from newly-diagnosed MM patients (n=1751), which is the majority of our dataset. We have begun to integrate genomic dataset with various correlates. Based on our data, we have at least
80% power to detect gene expression changes and genomic variants associated in >2% of the study population. WES data identified the main cytogenetic groups, somatic variants, and significantly mutated genes. 28 significantly mutated genes were present in newly diagnosed samples (17 genes in >2% of samples). The main recurrent mutations included KRAS and NRAS, and negative regulators of the NF-kB pathway; however, novel genes were also identified. One distinct mutational patterns, proportions, and sites between translocation subgroups were found and will be presented. In addition, we detected recurrent copy number abnormalities and examined the interaction with mutations and fusion gene expression from RNASeq. Preliminary analysis with an integrative model developed with machine learning methods/approaches using CN, SNP, and structural variants predicted a subset of high-risk patients. Unsupervised molecular classification is in progress to integrate genomic data and define subgroups, which will be presented.

Summary/Conclusions: We have established the largest repository of molecular profiling data in MM associated with clinical outcomes. Integrated analyses are enabling generation of clinically meaningful disease segments associated with differing risk that will inform development of clinical tests. THEMp3 intends to build a global network by expanding collaboration with global MM centers to incorporate additional datasets through current and new collaborations.

ALVOCIDIB SYNERGIIZES WITH VENETOCLAX IN PRECLINICAL MODELS OF MULTIPLE MYELOMA

H. Haws1, M. Livingston1, W. Kim1, R. Mangelson1, P. Peterson1, C. Whatcott1, A. Siddiqui-Jain1, S. Weitman1, D. Bears1, S. Warner1

1Discovery Biology, Tolero Pharmaceuticals, Inc., LEHI, United States

Background: With over 30,000 new cases expected in 2016 (US), new treatments are desperately needed for the treatment of multiple myeloma (MM). Major developments in the treatment of MM have included introduction of agents such as lenalidomide, thalidomide, or bortezomib. Bortezomib, an inhibitor of the proteasome, reduces the degradation of many proteins, including the pro-apoptotic protein NOXA. However, intrinsinc resistance to venetoclax treatment observed in MM patient samples has been attributed to a low BCL-2-to-MCL-1 gene expression ratio, suggesting a central role for MCL-1 in cell survival in this context as well. NOXA functions to sequester the anti-apoptotic BCL-2 family member, MCL-1. Increased MCL-1 expression is a known resistance mechanism to venetoclax treatment in a variety of cell types including chronic lymphocytic leukemia and lymphomas. Considering the central role of MCL-1 to treatment efficacy in MM, we investigated the ability of an MCL-1-lowering agent, namely the CDK9 inhibitor alvocidib, to potentiate the activity of venetoclax in MM. Alvocidib suppresses MCL-1 expression via CDK9-mediated repression and inhibited the tumor growth and inhibited the tumor growth in vivo, we performed a mouse study in the OPM-2 xenograft model.

Methods:

1. CellTiter-Glo and Caspase-Glo were used for cell viability and apoptosis assays investigating alvocidib and venetoclax in cell lines. We performed RT-PCR to measure mRNA levels of MCL-1 and other genes following treatment.

2. RNASeq was performed on RNA from untreated and treated MM cell lines and primary MM cells purified from patients but not in PBM-Cs from healthy donors. OSSL_325096 treatment leads to accumulation of poly-ubiquitinated proteins, cleavage of caspase-3, and up-regulation of CHOP in MM cell lines (Figure 2), suggesting this compound induces caspase-mediated apoptosis and ER-stress in MM cells. OSSL_325096 has a chemical structure similar to several known VCP inhibitors. Therefore, to evaluate the role of VCP in MM cell lines, we next performed knockdown of VCP. Knock-down of VCP induced apoptosis in MM cell lines, accompanied with accumulation of poly-ubiquitinated protein.

Results: OSSL_325096 inhibited proliferation of MM cell lines, including one bortezomib-resistant cell line (Figure 1). OSSL_325096 induces apoptosis in these cell lines and primary MM cells purified from patients but not in PBM-Cs from healthy donors. OSSL_325096 treatment leads to accumulation of poly-ubiquitinated proteins, cleavage of caspase-3, and up-regulation of CHOP in MM cell lines (Figure 2), suggesting this compound induces caspase-mediated apoptosis and ER-stress in MM cells. OSSL_325096 has a chemical structure similar to several known VCP inhibitors. Therefore, to evaluate the role of VCP in MM cell lines, we next performed knockdown of VCP. Knock-down of VCP induced apoptosis in MM cell lines, accompanied with accumulation of poly-ubiquitinated protein.

Summary/Conclusions: We have established the largest repository of molecular profiling data in MM associated with clinical outcomes. Integrated analyses are enabling generation of clinically meaningful disease segments associated with differing risk that will inform development of clinical tests. THEMp3 intends to build a global network by expanding collaboration with global MM centers to incorporate additional datasets through current and new collaborations.

NOVEL COMPOUND, OSSL_325096, INDUCES APOPTOSIS IN MULTIPLE MYELOMA CELLS THROUGH VCP INHIBITION

N. Nishimura1, M-O. Radwan2, M. Amano3, S. Endo1, S. Ueno5, N. Ueno5, H. Tatewaki1, H. Hata4, Y. Okamoto2, M. Matsukawa1, M. Otsuka2, Y. Okuno1

1Department of Hematology, 2Department of Bioorganic Medicinal Chemistry, School of Pharmacy, Kumamoto University, Kumamoto, Japan, 3Department of Chemistry of Natural Compounds, National Research Center, Cairo, Egypt, 4Graduate School of Health Sciences, Kumamoto University, Kumamoto, Japan

Background: VCP (p97) is an ER-associated protein that belongs to the AAA ATPase family. It has a variety of cellular functions including ER-associated protein degradation, autophagy, and aggresome formation. Recent studies have elucidated emerging roles of VCP and its potential as a therapeutic target in several cancer subtypes including multiple myeloma (MM).

Aims: We screened approximately 2,000 small molecular compounds to find out novel small compounds that suppress growth of MM cell lines, and found that OSSL_325096 has strong anti-proliferative activity on MM cell lines (IC50 100-500µM). In this study, we evaluated anti-MM activity of OSSL_325096 through VCP inhibition, in an ATP-competitive manner.

Methods: OSSL_325096 were purchased from Princeton BioMolecular Research, Inc. (Princeton, NJ, USA). His-tagged human VCP (hVCP) cDNA was cloned and utilized to generate hVCP protein in vitro as previously described (Chou et al., PNAS, 2011, vol. 108(12): 4834-4839) to evaluate the VCP inhibition by OSSL_325096. For in vivo analysis, MM xenograft model mice were intraperitoneally administered with vehicle or 50mg/kg of OSSL_325096 twice a week.

Results: OSSL_325096 inhibited proliferation of MM cell lines, including one bortezomib-resistant cell line (Figure 1). OSSL_325096 induces apoptosis in these cell lines and primary MM cells purified from patients but not in PBM-Cs from healthy donors. OSSL_325096 treatment leads to accumulation of poly-ubiquitinated proteins, cleavage of caspase-3, and up-regulation of CHOP in MM cell lines (Figure 2), suggesting this compound induces caspase-mediated apoptosis and ER-stress in MM cells. OSSL_325096 has a chemical structure similar to several known VCP inhibitors. Therefore, to evaluate the role of VCP in MM cell lines, we next performed knockdown of VCP. Knock-down of VCP induced apoptosis in MM cell lines, accompanied with accumulation of poly-ubiquitinated protein.

Summary/Conclusions: We have established the largest repository of molecular profiling data in MM associated with clinical outcomes. Integrated analyses are enabling generation of clinically meaningful disease segments associated with differing risk that will inform development of clinical tests. THEMp3 intends to build a global network by expanding collaboration with global MM centers to incorporate additional datasets through current and new collaborations.

Background: Cytogenetic aberrations are enabling generation of clinically meaningful disease segments associated with differing risk that will inform development of clinical tests. ThemP3 intends to build a global network by expanding collaboration with global MM centers to incorporate additional datasets through current and new collaborations.

Summary/Conclusions: The present data suggest that OSSL_325096 may be novel anti-myeloma drug candidate partially through its direct inhibition activity of VCP.

Madrid, Spain, June 22 - 25, 2017

haematologica | 2017; 102(s2) | 495
Background: RNA has diverse sets of regulatory functions and a recent analysis of the RNA repertoire has identified a large number of non-coding transcripts. One of which, long intergenic non-coding RNA (lincRNA) with transcripts longer than 200 nucleotides, are located between the protein coding genes and do not overlap exons of either protein-coding or other non-lincRNA genes. lincRNAs have been considered to provide regulatory functions, however, their precise function and how they impact the patients remains unclear.

Aims: Here, we have studied lincRNAs using uniformly treated patients to show their impact on survival outcome in MM.

Methods: We performed RNA-seq on CD138+ MM cells from 360 newly-diagnosed patients and 18 normal plasma cells (NPM) and analyzed for lincRNA and protein-coding gene expression. The lincRNA data were analyzed using RNAseq analysis software.

Results: Using only the expressed lincRNAs, we developed a risk prediction signature with a AUROC of 0.57. We hypothesized that the expression of lincRNAs was associated with clinical outcome in MM patients and we validated our results on independent large cohort with newly diagnosed MM RNAseq data. When applied to patient cohort separated by other risk categorization including minimal residual disease status (MRD), cytogenetic risk status (del17p, t(4;14) and t(14;16)) and International Staging System (ISS), lincRNA signature was able to further identify patients with significant differential survival outcomes.

Summary/Conclusions: In summary, we report that lincRNAs have an independent effect on survival outcome in MM and provides rationale for its use in risk stratification as well as to understand biological impact. Combined risk prediction with other risk features improve the prediction power and helps to create better classification in MM.

Background: In most cases, multiple myeloma (MM) is preceded by an asymptomatic status known as monoclonal gammapathy of unknown significance (MGUS) or smoldering multiple myeloma (SMM). The mechanisms of progression from SMM to MM are not well understood. Despite an increasing evidence of an immune system dysregulation in the setting of MM characterized by a tumor tolerating microenvironment, the immunosurveillance profile in the setting of SMM has never been investigated.

Aims: Our work is focused on a progressive dysregulation of marrow microenvironment in sequential samples of SMM patients. Secondly, we hypothesized a difference in the microenvironment of the patients with progressed SMM versus those with stable SMM.

Methods: We performed extensive immunohistochemical analysis of bone marrow samples of 16 patients affected by SMM at time 0 (16 samples) and at +24 months (+/- 4 months, 16 samples). Half of these patients developed MM at 24 months (progressed SMM), the other half remained asymptomatic (stable SMM).

Results: Using only the expressed lincRNAs, we developed a risk prediction signature with an AUROC of 0.57. We hypothesized that the expression of lincRNAs was associated with clinical outcome in MM patients and we validated our results on independent large cohort with newly diagnosed MM RNAseq data. When applied to patient cohort separated by other risk categorization including minimal residual disease status (MRD), cytogenetic risk status (del17p, t(4;14) and t(14;16)) and International Staging System (ISS), lincRNA signature was able to further identify patients with significant differential survival outcomes.

Summary/Conclusions: In summary, we report that lincRNAs have an independent effect on survival outcome in MM and provides rationale for its use in risk stratification as well as to understand biological impact. Combined risk prediction with other risk features improve the prediction power and helps to create better classification in MM.

Background: Multiple myeloma (MM) is a plasma cell malignancy that remains incurable, despite therapeutic advances. Immunotherapies have recently shown much promise in this and other cancers, and are under intense investigation. Autologous stem cell transplantation (ASCT) is standard of care in young fit newly diagnosed patients. In the post-ASCT setting, the minimal disease burden and re-constituting immune system may be a favourable context for immunotherapies, including cellular therapy and checkpoint blockade. Also, there is a need to characterize the post-ASCT BM, with a focus on identifying circulating T cells (BM) of MM patients post-ASCT, to identify candidate immune checkpoint proteins for therapeutic targeting.

Methods: BM aspirates were obtained from patients with MM at 3 months post ASCCT (n=28), and 6-12months post ASCCT (n=41) at University College Hosptial. Control BM aspirates were collected from healthy volunteers undergoing BM harvesting with the Anthony Nolan. Immunofluorescence surface staining was performed using antibodies to CD3, CD4, CD8, LAG-3, PD-1, HLA-DR, ICOS and the intracellular markers GzmB and Foxp3. All p-values indicate differences from normal donors unless otherwise stated.

Results: We observed the post-ASCT BM to be significantly higher numbers of cells exceeded CD3 cells as early as 3 months post-ASCT, suggesting the BM compartment is rapidly filled with CD8 cells. Although absolute numbers of CD4 effector cells (CD4+Foxp3-) were either similar (3 months) to or lower (6-12months, p<0.05) than healthy donors, there was a higher proportion of cytotoxic (GzmB+) CD3 cells (3months median 30.4%, range 0.2-89.7%, p<0.01 vs control median 2.6%, range 0.2- 33.4% and 6-12months, median17.6%, range 0.4-100%, p<0.05). CD4 effector cells also expressed activation markers: Inducible co-stimulator (ICOS, 3months median 20.2%, range 2.9-80.6% p<0.05 vs control median 8.6%, range 2.2-24% and 6-12months median 33%, range 1.8-80.7%, p<0.01) and HLA-DR (p<0.05), high levels of lymphocyte activation gene 3 (LAG-3) median 29.6%, range 12.2-62.1%, p<0.05 vs control median 17.9%, range 8.2-32.4%)

Significant numbers of CD4 effector cells co-expressed LAG-3 and GzmB (p<0.05), as well as LAG-3 and ICOS (p<0.05). Absolute numbers of CD8 effector cells (CD8+Foxp3-) in post ASCCT patients were not different from healthy donors.

Conclusion: In post-ASCT BM, significantly higher proportion of CD8 effector cells displayed cytotoxic phenotype (GzmB+), 3months median 88%, range 15.2-98.3%, p <0.0001 vs control median 30.3%, range 5.8-71.4% and 6-12months median 81.5%, range 19.4-100%, p <0.0001) as well as increased levels of HLA-DR (p<0.05) post ASCCT. CD8 effector cells also displayed high co-expression of LAG-3 and GzmB (p<0.05), but overall levels of LAG-3 were not significantly higher than controls. Both CD4 and CD8 effector cells expressed PD-1, however, levels were not significantly higher compared to healthy donors. Patients whose BM contained higher levels of activated (and cytotoxic) CD8 effector cells also had similar phenotype of CD8 effector cells. We correlated immune checkpoint protein expression in patients at 12months post ASCT. Patients with residual disease (PR) had higher levels of cytotoxic (Foxp3-GzmB+CD8) CD4 and CD8 effector cells (p<0.05) with co-expression of LAG-3 on cytotoxic effector cells, but no differences in PD-1 expression were seen.

Summary/Conclusions: The BM of MM patients following ASCCT shows activated CD4 and CD8 effector cells, but high co-expression of LAG-3 suggests that these cells may be functionally suppressed. Patients with larger amounts of residual disease have higher numbers of cytotoxic CD4 and CD8 cells, and the co-expression of the checkpoint protein LAG-3 may provide a rationale for blockade of this pathway.

Background: Bone marrow stromal cells (BMSCs) interact with multiple myeloma (MM) cells in the bone marrow, and also create a permissive microenvironment for MM cell growth and survival. Recent evidence indicated that MM cell-BMSC crosstalk is mediated by extracellular vesicles (EVs) plays an important role in the MM microenvironment.

Aims: In this study, we investigated the biological property of EVs and miRNAs in EVs derived from BMSCs, aiming to establish the emerging strategies to target MM microenvironment to prevent tumor growth and spread.

Methods: Bone marrow samples were obtained from MM patients (age 56 to 82, n=20) and monoclonal gammopathy of undetermined significance (MGUS) patients (age 44 to 82, n=13) in accordance with the Declaration of Helsinki and using protocols approved by the research Ethics Committee of Tokyo Medical University (IRB No. 2648), and BMSCs derived form MM patients (MM-BMSCs) and MGUS-BMSCs were isolated by the classical adhesion method. EVs were isolated from conditioned medium of BMSCs using a Exoquick-TC (SBI). The size of EVs was confirmed using a NanoSight LM10 (Malvern). The RNA from cells and EVs was profiled for 381 miRNAs using a TaqMan low-density array (ABI). The RNA from cells and EVs was profiled for 381 miRNAs using a TaqMan low-density array (ABI). The RNA from cells and EVs was profiled for 381 miRNAs using a TaqMan low-density array (ABI). The RNA from cells and EVs was profiled for 381 miRNAs using a TaqMan low-density array (ABI).

Results: Here we report that high expression levels of both G9a and GLP are associated with a worse disease outcome in MM patients. Moreover, gene set enrichment analysis of patients with high G9a/GLP expression levels displayed a significant enrichment of genes involved in pathways associated with MM disease progression, including the RAS pathway, NF-κB canonical pathway, IRF4 multiple myeloma program and mRNA splicing. Next, we screened specific G9a/GLP inhibitors BIX01294 and UNC1998 significantly and potently reduced MM cell viability in vitro. Moreover, both inhibitors also induce cell cycle arrest and apoptosis. When comparing between both inhibitors, BIX01294 was found to be the most potent in inducing apoptosis. Mechanistic studies for BIX01294 further indicated that BIX01294 treatment results in a shift of the G9a/GLP program as evidenced by a strong increase in the formation of LC3B puncta and an increase in LC3II and beclin-1 protein levels. In addition, we found that BIX01294 sensitizes MM cells to the proteasome inhibitor bortezomib and the Bcl-2 inhibitor ABT199. Lastly, therapeutic treatment of 5TG1 inoculated mice with BIX01294 resulted in a clear antitumor response, as evidenced by a clear decrease in tumor burden and a significant increase in the overall survival of BIX01294 treated mice compared to vehicle treated mice.

Summary/Conclusions: Altogether, our results demonstrate for the first time the importance of the histone methyltransferases G9a/GLP in MM pathogenesis. Further, our data indicate that targeting G9a/GLP represents a promising strategy to improve treatment of MM.

CYTOTOXIC LYMPHOCYTES IN NEWLY DIAGNOSED MYELOMA HAVE REVERSIBLE FUNCTIONAL AND PHENOTYPIC ABNORMALITIES THAT MAY OFFER THERAPEUTIC OPPORTUNITIES
F. Seymour1, J. Cavagner1, J. Giibben1
1Haematology-Oncology, Barts Cancer Institute, London, United Kingdom

Background: A bi-directional interaction exists between malignant cells and those of the immune microenvironment. This dynamic relationship results in gradual loss of clonal control associated with loss of cytotoxic lymphocyte (CTL) response. Mechanisms of immune escape are varied and include the induction of immunosuppressive cytokines, notably the PD-1/PDL1 axis. Multiple myeloma is a disease characterised by a pre malignant phase which can evolve into periods of asymptomatic and symptomatic disease. One possible mechanism for disease progression is progressive loss of immunological control. The malignant plasma cell has multiple potentially immune modifying effects including the expression of PDL1 and induction of a pro-tumour micro-environment. The role of CTLs is less well understood.

Aims: To undertake deep immune profiling of the CTL landscape in myeloma in order to establish whether features of immune dysregulation are present and to identify potential therapeutic opportunities.

Methods: Cryopreserved bone marrow from 16 patients with newly diagnosed and untreated myeloma and 9 controls were assessed using a 36 parameter mass cytometry panel. The panel was designed to assess 9 immune checkpoint regulators, 5 cytokines, and markers of proliferation and degranulation across multiple lymphocyte subsets. Samples were stimulated with CD3 and CD28 to assess functional capacity. Dimensionality reducing clustering algorithmic analysis was used alongside traditional data analysis techniques to identify functional subpopulations characterised by expression of multiple markers.

Results: The cytolytic profile in newly diagnosed myeloma is shifted towards a pro-tumour microenvironment with particularly marked elevation of TGFb throughout resting CTLs (36.4% v. 66.2%, p<0.0001). IFNg production is reduced in the resting myeloma effector population (0.33% v. 0.18%, p=0.0099). Stimulation restores the cytolytic profile to match that of controls. Myeloma CTLs retain the capacity to proliferate and produce the constituents for cytotoxic granule formation, however elevated PD1 expression alongside other markers of exhaustion such as NKG2A and a transition towards the exhausted phenotype is occurring. Strongly PD1 expressing populations in myeloma are larger (26% v.43%, p=0.05) and have increased rates of co-expression of CTLA4 (32%, 64%, p=0.0015), PD1L (26% v. 47%, p=0.0198) and TIM3 (34% v. 56%, p=0.0241). Populations of CTLs from myeloma up-regulate expression of the TCR co-stimulatory molecule CD28 (74% total CD3, NKGD2 (45% total CD8) and OX40 (33% total CD8) following stimulation.

Summary/Conclusions: Clear differences can be identified in the functional and phenotypic features of CTLs in myeloma compared to those of controls. The partial nature of these defects and the fact that reversibility can be demonstrated suggest that these cells have not yet reached the stage of irreversible exhaustion. Taken together this data suggests that targeting immune checkpoint regulators at an early disease stage, in order to optimise immunological function and reverse partial defects, is a viable therapeutic strategy to explore. PD1, PD1L, CTLA4 and TIM are all potential immune checkpoint targets. In addition the expression of specific G9a/GLP inhibitors BIX01294 and UNC1998 significantly and potently reduced MM cell viability in vitro. Moreover, both inhibitors also induce cell cycle arrest and apoptosis. When comparing between both inhibitors, BIX01294 was found to be the most potent in inducing apoptosis. Mechanistic studies for BIX01294 further indicated that BIX01294 treatment results in a shift of the G9a/GLP program as evidenced by a strong increase in the formation of LC3B puncta and an increase in LC3II and beclin-1 protein levels. In addition, we found that BIX01294 sensitizes MM cells to the proteasome inhibitor bortezomib and the Bcl-2 inhibitor ABT199. Lastly, therapeutic treatment of 5TG1 inoculated mice with BIX01294 resulted in a clear antitumor response, as evidenced by a clear decrease in tumor burden and a significant increase in the overall survival of BIX01294 treated mice compared to vehicle treated mice.

Summary/Conclusions: Altogether, our results demonstrate for the first time the importance of the histone methyltransferases G9a/GLP in MM pathogenesis. Further, our data indicate that targeting G9a/GLP represents a promising strategy to improve treatment of MM.

Background: Reactive oxygen species (ROS) are normal byproducts of a wide variety of cellular processes. ROS have dual functional roles in cancer cell pathophysiology. At low to moderate levels, ROS act as signal transducers to activate cell proliferation, migration, invasion, and angiogenesis. In contrast, high levels of ROS induce cell death. In multiple myeloma (MM), ROS overproduction is the trigger for apoptosis induced by several anticancer compounds, including proteasome inhibitors. However, no drugs that mainly affect oxidative stress are currently used for treatment of MM in the clinic. In MM, p53 status is an independent prognostic marker, since patients harboring p53 abnormalities are highly resistant to standard therapies, and the incidence of p53 mutations and deletions increases during disease progression. Therefore, restoration of p53 is an attractive strategy for treating advanced relapsed and refractory MM (RRMM) patients. CP-31398 (CP) is a small molecule that activates wild-type p53 or restores tumor-associated p53 mutants to wild type p53 function in multiple human cancer cell lines; this leads to cell cycle arrest and/or apoptosis. The growth of thymomasomea cell lines can be inhibited by p53-dependent induction of ROS, but it is not clear whether CP-induced cytotoxicity proceeds via a similar pathway.

Aims: Our study was aimed at evaluating the anti-myeloma activity of CP.

Methods: MM cell lines (MM1S, RPMI8226, U266, KMS5, OPM2, Delta47, KMS11) and three primary treated for 48 h. Consequently, the inhibitory effect of CP on MM cell line growth was assessed using a WST-1 assay. In order to elucidate the cytotoxic mechanism of CP, immunoblotting and flow cytometry analysis were performed. Measurements of cytosolic and mitochondrial ROS were performed with CellROX Deep Red or MitoSOX Red. For quantification of ROS, cells were analyzed by flow cytometry and fluorescence microscopy. The therapeutic potential of CP was evaluated by its ability to suppress tumor growth in vivo using the subcutaneous RPMI8226 murine xenograft model for human MM.

Results: In this study, we have demonstrated that the p53-activating small molecule CP-31398 effectively inhibited the growth of MM cell lines and primary MM isolates from patients with IC50 values in the range of 2.51-11.2 μM. CP also suppressed the growth of MM xenografts in mice. Mechanistically, CP was found to induce intrinsic apoptosis in MM cells via increasing mitochondrial and cytosolic ROS production. Interestingly, CP-induced apoptosis occurs regardless of the cells’ p53 status, suggesting that CP has additional mechanisms of action. In addition, we found that CP acted synergistic with the protease inhibitor carfizomib (CFZ) in MM cells, providing a framework for further studies of CP alone and in combination with CFZ to improve the prognosis for MM patients.

Summary/Conclusions: Our findings indicate that CP could be an attractive candidate for treatment of MM even in patients with p53 abnormalities; this may satisfy an unmet clinical need, as such patients currently have a poor prognosis.

TUMOR MICROENVIRONMENT TRANSFORMATION FROMmGUS TO MYELOMA IS ASSOCIATED WITH PRO-TUMORAL ACTIVATION OF MES-enchymal STROMAL CELLS (MSC)
C. Giorgi1, D. Tibullo1, N. Parrinello1, P. La Cava1, G. Camiolo1, M. Tummino1, N. Caporarello1, C. Anfuso1, C. Conticello1, A. Romano1, F. Di Raimondo1
1Clinical and Molecular Biomedicine, section of Hematology, University of Catania, catania, Italy

Background: A well-recognized feature of MM is the intimate relationship between plasma cells (PC) and bone marrow microenvironment, characterized by a modified extracellular matrix, enhanced angiogenesis and presence of cells with immune suppressive activity, including tumor-associated macrophages and myeloid-derived suppressor cells (MDSC). Recently, we demonstrated that MM-MSCs are able to convert normal immature myeloid cells in MDSC contributing to immune-escape mechanisms.

Aims: We hypothesize that MSC derived from Smoldering myeloma (SMM) and MM are in an activated status that promotes tumor growth and tumor microenvironment transformation.

Methods: Human peripheral blood mononuclear cells (PBMC) isolated from healthy controls (HC), myeloma (MM)-, MM-MSC- or MM-MSC- and were cultured with healthy controls (HC)-mgUS-, MM- or MM-MSC. After 6 days, neutrophils (N) were isolated using anti-CD66b magnetic microbeads and were tested in vitro for their ability to induce angiogenesis and suppress T cell proliferation.

LONG TERM CR MULTIPLE MYELOMA PATIENTS STUDIED WITH NEXT GENERATION FLOW SHOW PREDOMINANTLY CURED VSMGUS-LIKE MINIMAL RESIDUAL DISEASE PATTERNS: A STUDY OF THE GTMM-TUSCAN GROUP FOR MULTIPLE MYELOMA
A. Bocci2, M. Petrini3, M. Bocchia1
1Hematology Unit, University of Siena, Siena, 2Hematology, Azienda Ospedaliera Universitaria Careggi, Firenze, 3Hematology, University of Pisa, Pisa, 1Azienda Ospedaliera Universitaria Careggi, Firenze, Italy

Background: CR is a prerequisite for long term responses, progression free survivals, and ultimately overall survivals and cure. In the era of novel agents, many MM patients can achieve stringent CR (sCR), i.e. disease disappearance at serological, immunohistochemical level plus negativity of free light chains (FLC). On the other hand most of these patients still will relapse and minimal residual disease (MRD) detection will play a crucial role in the very next future. Recently, two  colours tubes panel developed by the EuroFlow Consortium can detect MRD with an increased sensitivity and can be applied as standardized method to study multiple myeloma (MM) patients.

Aims: While many studies have looked at MRD status sequentially and soon after autologous or allogeneic stem cell transplantation with flow or molecular techniques, little is known about long term remission patients (>5-10 years) and in particular if more sensitive techniques such as NGF or NGS can still detect minimal residual disease in those patients. Aim of the study was to analyse patients with MM in >VGPR with next generation flow at >2 and >5 years of lasting remission.

Methods: Clinical assessment definition of CR status included serum and urine immunofixation, free light chain determination, imaging study with CT-PET, bone biopsy. Bone biopsy was performed at core biopsy. In 50 MM patients (M/F=30/20), were studied with NGF at two GTMM centers between February 2016 and February 2017. 28/56 (50%) patients were in sCR at the moment of the study at a median of 40 months after therapy (range 3-140). 28/50 (50%) patients were in VGPR at study analysis according to new IMWG response criteria. N= 12, 25 and 44 patients had a remission disease >5 years, >2 years, and <5 years, respectively.

Two tube assay incorporated 8 antibodies each: CD38, CD56, C2M-Microglobulin, CD19, k Anti-Kappa Anti-Lambda CD45 DCD5, CD38, CD28, CD27, CD119, CD81, CD45 and CD138 (OneFlow™ PCST and PCD, BD Biosciences) and were utilized to detect MRD level with a lyse-wash-and-stain protocol driven by flow cytometry (FACScanto II, BD Biosciences). Accurate identification of BM plasma cells (PCs) and discrimination between phenotypically aberrant (pAPC) and normal PC (pNC) were carried out after acquisition and analysis of >2 × 10⁶ cells (Diva 8, BD Biosciences).

Results: MRD+ status was detected in 23/56 (41%) of the patients. 4/12 (33%) were MRD positive at >5 years remission (2 sCR, 2 VGPR) (median 96 months range 72 – 186 months); 20/44 (45%) were positive at >5 years of remission (3 CR; 17 VGPR)(median 9.5 range 3 – 46 months). 9/25 (36%) were MRD+ after >2 years of remission (2 sCR, 7 VGPR) (median 46 months range 24 – 186 months). As expected being in sCR was correlated with a low MRD+ prevalence (10%) in VGPR patients after >5 years. Interesting looking at long lasting remission, i.e. >5 years, the 4/14 patients that resulted MRD+ displayed anmgUS like –plasmacell immunophenotype (prevalence of normal plasmacells vs aberrant mononuclear) with a PCH/PCtot ratio of 48%, 95%, 35%, 30%. CTIPET was positive in 22/56 patients. All patients with negative MRD had a CR status.

Summary/Conclusions: In conclusion NGF showed that MM patients with long remission status can be considered disease free/cured with a high sensitivity method. MM patients that display anmgUS-like phenotype after achieving a CR can have long lasting remissions meaning disease control. Patients in sustained CR after 2 years can have high percentage of MRD negativity. Larger studies are warranted to identify patients who need treatment consolidation or continuous treatment based on MRD+ status vs others who could stay treatment free with social and economical benefits.

THE NOTCH PATHWAY IN THE INTERPLAY BETWEEN MYELOMA CELLS AND ENDOTHELIUM IN THE BONE MARROW NICH
M.T. Palano1, N. Palatonova1, N. Sarletta2, S. Garavelli1, M. Colombo1, F. Baccianti1, A. Neri2, R. Ria3, R. Chiaramonti1
1Scienze della Salute, 2Oncologia ed emato-oncologia, Università degli Studi di Milano, 3Medicina interna e Oncologia clinica, Università di Bari, Bari, Italy

Background: Angiogenesis is a hallmark of tumors, and it is a peculiar characteristic in bone marrow (BM) of multiple myeloma (MM) patients. MM is a still incurable disease that strongly depends on interactions with BM microenvironment. Endothelium of MM patients displays malignant behavior as compared to a healthy counterpart (1). MM displays a dysregulation of the Notch pathway due to Jagged ligands and Notch receptors overexpression. This condition brings to the generation of homotypic and heterotypic interaction loops that sustain MM cells growth. However, Notch signaling is mainly involved in BM resident cells, including osteoclast and BM stromal cells (BMSCs), although its role in the crosstalk of MM and endothelium is still to be clarified.

Aims: The aim of this study is to investigate Notch role in MM crosstalk with endothelium exploiting 2D assays and 3D organoid systems to mimic tumor microenvironment (TME).

Methods: The Notch ligands, Jagged1 and 2, were silenced in the MM cell line RPMI8226 (RPMI8226shJAG1/2) using an inducible lentiviral vector carrying two short hairpin RNAs targeting Jagged1 and 2. To mimic the endothelial compartment, primary endothelial cells (EC) and artificial endothelial cells (HPCAECs) were used and for the stromal compartment, the GFP+H55 cell line. Matrigel and scaffold healing assays were set up to investigate Notch role in modulating not only the angiogenic potential of MM cells co-cultured with HPCAECs and HPCAEC motility in response to MM-derived soluble factors. To develop a TME-like system, a decellularized extracellular matrix (dECM) was used as a physiologic scaffold for organoid generation. dECM was produced by treating murine fibroblast NIH3T3 with ascorbic acid and was loaded with cells for organoids generation. We evaluated apoptosis of MM cells in single culture and co-culture with BMSCs or HPCAECs by flow cytometry.

Results: Matrigel assay of HPCAEC co-cultured with MM cells showed that direct contact increased angiogenic potential of HPCAEC to form a grid of tubes; this effect is significantly reduced when HPCAECs are co-cultured with RPMI8226shJAG1/2 cells, indicating a key role of Notch signaling in endothelial stimulation. Wound healing assay demonstrated that Notch signaling affects EC motility; since it is reduced when Jagged 1/2 are silenced. Concerning the 3D-organoid generation, our results indicate that the handcrafted dECM was a suitable scaffold. Moreover, apoptosis assays indicated that MM cells displayed an increased survival when cultured in the presence of BMSCs, that consistently with their recognized protective role; no significant difference in MM cell apoptosis was observed in the presence of endothelial cells. On the contrary, we have observed that endothelial cells were protected by MM cells suggesting that MM cells improve angiogenesis by preventing endothelial cells apoptosis.

Summary/Conclusions: These results indicate a novel role for Notch pathway in MM-EC crosstalk suggesting that the Notch pathway activation in MM cells can increase their proangiogenic potential. 3D-organoid micromimics BM microenvironment and may be used as a novel tool to recapitulate the interactions of BM and tumor cells beyond the animal models.

References
**Aims:** To understand the role of stromal induced drug resistance and to identify new therapeutic targets in myeloma.

**Methods:** GFP-tagged human myeloma cell lines, 8226, U266 and MM.1s, were co-cultured with MM patient-derived BMSCs or HS.5 cells with or without BTZ for 24 h. MM cells in monocultures were used as controls. Co-cultures were then applied to magnetic cell separation to isolate MM cells for downstream analyses including western blotting and mRNA or miRNA qPCR arrays. Furthermore, percent apoptosis of gated GFP+ cells was determined using FACS. In other experiments, MM cells were exposed to BMSCs pre-treated with Brefeldin-A (BFA) or separated with a transwell (TW) insert. For functional analysis, miR-101-3p was overexpressed using lentiviral transduction and survivin expression was monitored in BMSCs in presence or absence of BTZ. GFP fluorescence-based adhesion, cytotoxicity and annexin-V/PI apoptosis were applied.

**Results:** qPCR arrays showed that BMSCs up- or down-regulated several miRNAs and mRNAs in MM cells. Survivin (BIRC5) was confirmed to be consisently increased in the MM cell lines and mRNA and protein levels. In contrast, miR-101-3p was confirmed to be significantly downregulated by stroma in MM cells. Moreover, suppression of miR-101-3p or upregulation of survivin was reversed partially when BMSCs were pre-treated with BFA but highly significantly when they were separated from MM cells with a TW insert. The same regulatory network including western blotting and mRNA or miRNA qPCR arrays indicating that direct cell-direct cell adhesion was more effective in BMSC-induced modulations in MM cells. Next we identified that survivin was a direct target of miR-101-3p, overexpression of miR-101-3p suppressed survivin mRNA/protein. As indicator of involvement in stroma-mediated drug resistance, survivin and miRNA-101-3p expression in MM cells being BMSCs co-cultured was measured. Furthermore, miR-101-3p overexpression or silencing of survivin increased BTZ-induced apoptosis in MM cells in the absence or presence of BMSCs significantly overcoming stroma-mediated drug resistance. To test whether miR-101-3p could also regulate adhesion of MM cells to BMSCs, we assessed whether miR-101-3p significantly reduced adhesion of MM cells to HS.5 and primary MM BMSCs compared to scrambled control. This finding suggests that miRNA-101-3p regulates cell adhesion-mediated drug resistance (CAMDR) by modulation of BM-BMSC adhesion.

**Summary/Conclusions:** Our results identify a mechanism whereby BMSCs induce drug resistance in MM cells by upregulating survivin and downregulating miRNA-101-3p which directly targets survivin. Overexpression of miRNA-101-3p or silencing of survivin sensitizes MM cells to BTZ significantly overcoming stroma-induced drug resistance. These findings disclose a role of survivin-miRNA-101-3p axis in regulation of MM cell adhesion to BMSCs and thus provide a rationale to further investigate the anti-myeloma activity of miR-101-3p in combination with BTZ as a potential therapeutic strategy in MM.

**ARQ-197, A SMALL-MOLECULE INHIBITOR OF C-MET, REDUCES TUMOUR BURDEN AND PREVENTS TUMOUR-ASSOCIATED BONE DISEASE IN A MURINE MODEL OF MYELOMA**

A. Chantry, A. Holly, M. Fisher, J. Denny, L. Michelle, L. Darren

1Oncology and Metabolism, University of Sheffield, Sheffield, United Kingdom

**Background:** The receptor tyrosine kinase c-Met, its ligand HGF, and their signaling pathway, have all been implicated in the pathogenesis of myeloma. In myeloma patients with elevated levels of HGF their prognosis is known to be worse.

**Aims:** To unravel the role of the bone marrow mesenchymal/stromal cells (BMMSCs) in MM cell growth, progression and drug resistance.

**Methods:** Hypothesizing that the interaction between MM cells and the BMMSCs is bidirectional, we have compared BMMSCs from healthy individuals, mouse and MM patients and used our “humanized” bone marrow-like model to characterize the molecular impact of MM cells on BMMSCs. Finally, we have validated targets by generating HS-5 knock-out lines using CRISPR/Cas9 targeting.

**Results:** Analyzing the BMMSCs of healthy individuals, mouse, and MM patients, as well as BMMSCs impacted by MM in our humanized bone marrow-like model, allowed us to confirm established disease biomarkers (e.g. IL-...
6, HGF, IGF and GDF15) and identify novel mediators of MM disease progression and bone disease. To further elucidate the role of IL-6 in BMMSC-induced growth of MM plasma cells and drug resistance, we have established HSTS stromal cell lines that undergo CRISP/Rcas9 targeting have reduced or no expression of IL-6. RNA sequencing analysis of these cells revealed IL-6 to be a master regulator of cytokine production (e.g. IL-18, CXCL8, CSF2 and CSF3). Disruption of the IL-6 gene did not result in a reduced growth rate of the IL-6 deficient stromal cells as compared to wildtype. Using the compartment specific bioluminescent imaging co-culture system, where luciferase gene-marked MM cells are co-cultured with non-marked stromal cells, we have documented a contribution of the stromal cells to both growth and drug resistance to known chemotherapeutics (e.g. bortezomib, doxorubicin) of MM cells. Using this same co-culture system we compared wildtype and IL-6 deficient stroma. Although disruption of IL-6 in the stromal cells resulted in a reduced proliferation of MM cells and stromal cell mediated drug resistance, it did not entirely reverse these stroma mediated effects.

**Summary/Conclusions:** Taken together these data suggest that although IL-6 is one of the most deregulated genes in MM-derived BMMSCs, it certainly is not the sole contributor to BMMSC-induced MM cell growth and drug resistance.

**THE PAN-PIM KINASE INHIBITOR, PIM447, POTENTLY SYNERGESIZES WITH POMALIDOMIDE PLUS DEXAMETHASONE IN PRECLINICAL IN VITRO AND IN VIVO MODELS OF MULTIPLE MYELOMA**

T. Paino1,2,3, L. San-Segundo1,2, S. Hernández-García1,2, L. González-Méndez1,2, E.M. Algara1,2, M. Martin-Sánchez1,2, M.-V. Mateos1,2, M. Garayoa1,2, E.M. Ocio1,2 1Centre de Investigación y Cuidados del Cáncer (CIC-IBIMCC), 2Complejo Asistencial Universitario de Salamanca-IBSAL, Salamanca, Spain

**Background:** PIM kinases are a family of serine/threonine kinases recently proposed as targets in MM. Recent work from our group has shown the dual antitumorogenic and bone-protective effects of the pan-PIM kinase inhibitor, PIM447, and its in vitro synergism with current standards of care. Since myeloma remains an incurable disease, the preclinical evaluation of new drug combinations is of utmost importance, in order to support the development of future clinical trials. In this scenario, effective all-oral combinations are particularly attractive.

**Aims:** The aim of the present work has been the evaluation of the efficacy and mechanism of action of the all-oral triple combination PIM447 + pomalidomide + dexamethasone in preclinical in vitro and in vivo models of multiple myeloma.

**Methods:** In vitro cytotoxicity of PIM447, pomalidomide and dexamethasone alone or in double and triple combinations was evaluated on myeloma cell lines. The combination index (CI) was calculated with Calcusyn software based on results from MTT assay. Effects on apoptosis and cell cycle were evaluated by flow cytometry. Glucose uptake was analyzed by incubation with 2-NBDG. The results from MTT assay. Effects on apoptosis and cell cycle arrest at G0-G1 phase. Accordingly, cleavage of caspase 3 and PARP, as well as reduction of cyclin D2 was observed by western blot. In addition, triple combination inhibited mTORC1 as shown by analysis of different protein levels by western blot. In addition, triple combination inhibited mTORC1 as shown by analysis of different protein levels by western blot.

**Results:** Triple combination PIM447 + pomalidomide + dexamethasone showed a strong synergism (CI<0.3) in all cell lines tested. The combination was able to induce apoptosis and cell cycle arrest at G0-G1 phase. Accordingly, cleavage of caspase 3 and PARP, as well as reduction of cyclin D2 was observed by western blot. In addition, triple combination inhibited mTORC1 as shown by analysis of different protein levels by western blot. In addition, triple combination inhibited mTORC1 as shown by analysis of different protein levels by western blot.

**Summary/Conclusions:** Our preclinical data suggest that myeloma patients could benefit from treatment with the triple combination PIM447 + pomalidomide + dexamethasone and would support future clinical trials with this combination.

**TRIM33 IS A POTENTIAL TUMOR SUPPRESSOR IN MULTIPLE MYELOMA**

C.K. Johnston1,*, L.J. Crawford1, K.I. Mills1, A.E. Irvine1 1Centre for Cancer Research and Cell Biology, Queen’s University Belfast, Belfast, United Kingdom

**Background:** Multiple myeloma (MM) continues to be an incurable plasma cell neoplasm, regardless of recent therapeutic advances. The success of proteasome inhibitors in MM validates the ubiquitin proteasome system (UPS) as a therapeutic target. Using a UPS-specific microarray (PIGOR) we identified aberrant expression of an E3 ligase TRIM33 (tripartite motif containing protein 33) in MM. TRIM33 has previously been identified as a tumor suppressor for myelomonocytic leukemia and hepatocellular carcinoma.

**Aims:** The aim of this study was to examine TRIM33 expression and to investigate its role as a potential tumor suppressor in MM.

**Methods:** Western blotting was used to analyse TRIM33 expression at basal level and following knockdown in four MM cell lines representing a range of MM translocations; JJN3 t(4;14), U266 t(11;14), KMS-18 t(4;14), OPM-2 t(4;14). TRIM33 knockdown was performed using shRNA pLKO lentiviral plasmids. CellTiter-Glo® was used to determine cell viability following knockdown. A range of MM translocations were used to examine TRIM33 expression and correlation with survival in subsets of newly diagnosed MM; GSE19784 (N=320) and GSE2658 (N=551). qPCR was used to validate the changes in expression of the TRIM33 gene signature.

**Results:** Compared to normal bone marrow, lower expression of TRIM33 was observed at both gene and protein level (p=0.03) in the (4;14) cell lines, KMS-18 and OPM-2. Conversely, expression was found to be high in the non (4;14) cell lines, JJN3 (p=0.001) and U266 (p=0.015). Knockdown of TRIM33 expression did not alter cell viability in the (4;14) cell lines. However, cell viability was found to be increased in JJN3 (p=0.004) and U266 (p=0.005). Analysis of a publicly available dataset, GSE19784, showed lower levels of TRIM33 present in patients with a (4;14) compared to other MM subtypes, particularly (6;14) (p=0.004) and hyperdiploid cluster (p=0.03). Low TRIM33 expression has also been associated with poor overall survival (GSE2658; p=0.0034). Forty-seven myeloma patients were compared with TRIM33 expression in non (4;14) cell lines. Identification of an E3 ligase TRIM33 (tripartite motif containing protein 33) for MM was identified; these genes were analysed using QUADARTIC tools connectivity mapping to identify FDA approved agents predicted to enhance the TRIM33 gene signature.

**Conclusion:** The aim of this study was to examine TRIM33 expression and to investigate its role as a potential tumor suppressor in MM.
enhancer of the TRIM33 signature that potently decreased the viability of the OPN2 cell line. This study suggests that enhancing the TRIM33 gene signature could potentiate the tumor suppressive effect of TRIM33 and identify novel therapies for this subset of MM.

LONG NON-CODING RNAs EXPRESSION HETEROGENEITY AND FUNCTIONAL INVOLVEMENT IN MULTIPLE MYELOMA
A. Caivano1,2, A. Melnick2, F. Prósper6, X. Agirre1
1Onco-hematology, Center for Applied Medical Research (CIMA), Pamplona, Spain, 2Department of Medicine, Weill Cornell Medical College, New York, United States, 3Department of Fundamentos Clinicos, Universitat de Barcelona, Barcelona, Spain, 4Bioinformatics, 5Flow Cytometry Core, Center for Applied Medical Research (CIMA), 6Hematology, Clinica Universidad de Navarra, Pamplona, Spain

Background: Increasing amount of evidence indicates that deregulation of long non-coding RNAs (lncRNAs) is a common feature of cancer and therefore, its investigation may uncover new molecular oncogenic mechanisms. In multiple myeloma (MM), altered expression of small number of lncRNAs has been associated with decreased disease-free and overall survival, suggesting that these elements may play a more important role in MM than previously anticipated. Nevertheless, an extensive high-throughput analysis that characterizes the deregulation of lncRNAs in MM has not yet been performed.

Aims: We aim to characterize the lncRNA transcriptome of MM and its heterogeneity, and determine whether altered lncRNAs have a functional involvement in this disease.

Methods: Paired-end strand-specific RNA sequencing (ssRNA-seq) was performed in 38 purified plasma cell (PC) samples from MM patients, as well as in 5 tonsil PCs (TPCs) and in 3 bone marrow PCs (BMPCs) of healthy donors as controls. We also performed ssRNA-seq of populations from B cell differentiation (Naïve, Germinal Center, Memory and PC). To study the heterogeneity of lncRNAs expression we performed sample level enrichment analysis (SLEA), in which each individual lncRNA was compared to BMPCs. To determine the epigenetic regulation of lncRNAs we used whole-genome bisulfite sequencing and CHIP-seq. shRNA-mediated knockdown using 2 different shRNAs and MTK-8 or Proliferin V (cell death) assays were utilized to study the functional effect of lncRNA overexpression.

Results: We identified 40.552 novel lncRNAs in MM samples that were present in at least 3 of the 38 patients. Principal component analysis demonstrated that TPCs and BMPCs cluster separately, suggesting that, in spite of being the same disease, their transcriptomes are very different. We observed that the expression of lncRNAs was more heterogeneous than that of coding genes. More importantly, SLEA showed 11.067 lncRNAs that were overexpressed and 5.601 underexpressed in >40% of patients. Thus, the number of deregulated genes analyzed by SLEA was much larger than the 75 lncRNAs that appeared as deregulated when all MM were compared to BMPCs, demonstrating the relevance of studying the heterogeneity in this disease. To determine the functional role of heterogeneously altered lncRNAs in the biology of MM cells we focused on the study of LINC-SMILO (Specific Myeloma iNergetic Long non-coding RNA), a lncRNA that it is overexpressed in ~40% of MM patients and not altered at the transcription level. LINC-SMILO demonstrated that CpGs located upstream of LINC-SMILO showed a significant hypomethylation in mmGlUS, that was even more pronounced in MM samples. These data suggest that epigenetic dysregulation of lncRNAs may play an important role in the biology of MM cells.

Conclusions: These data demonstrate that alteration of lncRNAs is an important and unexplored feature of MM. Moreover, overexpression of LINC-SMILO is required for the survival of MM cells and could represent a potential therapeutic target for the treatment of this disease.

ROLE OF EPHA3 IN MULTIPLE MYELOMA: A PERSPECTIVE FOR A NOVEL TARGET THERAPY?
1Laboratory of Clinical Research and Advanced Diagnostics, IRCCS, Referral Cancer Center of Basilicata (CROB), Rionero in Vulture, 2Laboratorio di Oncologia, IRCCS - G. Gaslini Institute, Genova, 3Department of Medicine and Sciences of Aging, CESI-Met Aging Research Center and Division of Anatomic Pathology and Molecular Medicine, Chieti, 4Department of Stem Cell and Development, Istituto di Ricerche Genetico Gaetano Salvatore Biogeo scarl, Ariano Irpino, 5Department of Biology, University of Naples “Federico II”, Napoli, 6Laboratory of Pre-clinical and Translational Research, 7Department of Onco-Hematology, IRCCS, Referral Cancer Center of Basilicata (CROB), Rionero in Vulture, 8Laboratory of Biotechnology and Molecular Biology, Monash University, Melbourne, Australia, 9Laboratorio Cellule Stamminali post-natali e Terapie Cellulari, IRCCS - G. Gaslini Institute, Genova, 10Department of Clinical Sciences and Community Health, University of Milan and Hematology, Fondazione Ca Granda, Ospedale Maggiore Policlinico, Milano, 11Department of Molecular Medicine and Medical Biotechnologies, University of Naples “Federico II”, Napoli, 12Scientific Direction, IRCCS, Referral Cancer Center of Basilicata (CROB), Rionero in Vulture, 13Department of Clinical and Biological Sciences, University of Turin, Torino, Italy

Background: The tyrosine kinase Eph receptor A3 (EphA3) has recently emerged as a potential therapeutic target, since it has been overexpressed in many cancers, including some hematological malignancies (Keane et al. 2012). Furthermore, EphA3 has been found overexpressed not only in neoplastic cells, but also in the microenvironment of different human cancers, where its targeting inhibits tumor growth by disrupting supportive stroma and vasculature (Vail et al. 2014).

Aims: Due to the absence of relevant information about the role of EphA3 in multiple myeloma (MM), we aimed to evaluate the expression of this molecule in primary bone marrow plasma cells (BMPCs) from MM patients and MM cell lines compared to healthy controls (HCs). In addition, using a “loss of function” approach by mRNA silencing and an anti-EphA3 monoclonal antibody (EphA3mAb), we studied in vitro plasma cells (PCs) viability and movement. Finally, we analysed the in vivo effects of EphA3mAb in a MM mouse xenograft model.

Methods: EphA3 mRNA and protein where investigated in 15 MM BMPCs, 11 MM cell lines and 10 HCs by qRT-PCR and flow cytometry. The effects of EphA3 targeting by lentiviral RNA silencing (shRNA) and anti-EphA3mAb on PC trafficking and viability were studied by adhesion assay on fibronectin and on bone marrow stromal cells (BMSCs), invasion assays and proliferation MTS assay, respectively. Gene expression profiling (GEPI) was performed in shEphA3 versus shControl cells. Furthermore, the effects of EphA3mAb were analysed in MM xenograft model by measuring tumor size and by assessing angiogenesis, proliferation and apoptosis rate on tumor biopsies using immunohistochemistry (anti-CD31, anti-ki67 and TUNEL assay, respectively). Statistical significance was determined by the t-test or One-way ANOVA analysis.

Results: EphA3 was found overexpressed in primary MM BMPCs and MM cell lines when compared with HCs (figure 1A-B). The EphA3 loss of function by siRNA and by EphA3mAb significantly inhibited in vitro the ability of MM PCs to adhere to fibronectin, to BMSCs and to invade (figure 1C-E), without affecting cell proliferation and viability (data not shown). GEPI showed that knockdown of EphA3 modulated some molecules that regulate adhesion, migration and invasion processes. Importantly, the treatment with EphA3mAb in vivo significantly reduced tumor size and inhibited angiogenesis, as revealed by decrease of CD31+ vessels at immunohistochemistry (data not shown).

Figure 1.
Summary/Conclusions: Our findings suggest that EphA3 is a novel regulator of MM PC trafficking, in part via effects on adhesion and invasion; its targeting using EphA3mAb inhibits tumor growth, possibly due to reducing angiogenesis, though other possible mechanisms of tumor death cannot be excluded. These data, together with the favourable clinical properties of a humanized EphA3mAb reported in a phase I trial on acute myeloid leukemia and myelodysplastic syndrome (Swords et al. 2016), support EphA3 targeting as a new potential therapeutic opportunity for MM that would warrant to be further investigated.

PROGNOSTIC SIGNIFICANCE OF AMP1Q21 IN MULTIPLE MYELOMA
T. Abramova1, T. Obukhova1, L. Mendeleva1, O. Pokrovskaya1, E. Grinbova1, M. Nareyko1, L. Grebenyuk1, O. Votyakova2, M. Solovev1, M. Firsova1, I. Nakastoev1, A. Grachev1, M. Kanaeva1, A. Danilina1, S. Kulkov1, M. Rustinov1, V. Savchenko1
1Hematology Research Center, 2N.Blokhin Russian Cancer Research Center, Moscow, Russian Federation

Background: Multiple Myeloma (MM) is a genetically heterogeneous and complex disease with widely diverging survival times from months to years. Amplification of locus 1q21 (amp1q21) is among the most commonly reported genetic abnormalities in MM, but its prognostic value remains unclarified.

Aims: To define the frequency of amp1q21 in MM and its correlation with other chromosomal abnormalities, clinical course and prognosis.

Methods: In 134 patients (pts) with newly diagnosed MM from December, 2009 to March, 2016, 67 male and 67 female, median age 57 years (30-81), we performed FISH with locus-specific and centromere DNA probes (XL 1p32/1q21, XL IGH plus, XL t(11;14), XL t(4;14), XL t(14;16), XL t(14;20), XL t(6;14), XL cMYC BA, XL 5p15/9q22/15q22, XL P53 (MetaSystems), D13S25 (Cytocell). Induction therapy with bortezomib-based courses was initiated for 131 pts, 3 pts with smoldering MM remained under observation. Response was evaluated according to the IMWG criteria for 127 pts, because 4 pts died in induction. 48 pts were underwent ASCT. The median follow-up of group was 19.3 months (3.2 - 77.4). Progression was diagnosed in 69 pts, in 12 of them FISH-analysis was performed also in disease progression.

Results: Chromosomal aberrations were revealed in 133 of 134 (99%) pts. T(14q14/22q11) was detected in 42.5% (57/134), hyperdiploidy in 57.5% (77/134), hypodiploidy in 2.4% (3/134) pts. In 11.2% (15/134) a concurrent t(11g12) and a trisomy were found. The IgH translocations t(11;14), t(4;14), t(14;16), t(14;20), t(6;14) were observed at a frequency of 16.4%, 12.7%, 3.7%, 2.2%, 0.7% respectively, chromosomal partner is not found in 6.7%. Del(13)(q) was detected in 40.3% (54/134), del(17)(p) in 12.7% (17/134), t(4;14)(q21;q2), t(14;22) in 17.2% (23/134). Amp1q21 was detected in 39.6% (53/134). We identified 3 copies of 1q21 in 54.3% (73/134), del(13)(q) in 36.3% (49/134), t(14;22) in 19.3% (26/134), t(4;14) in 16.5% (22/134), del(17)(p) in 37.5% (50/134). In 9 pts (6.7%) we detected 4 copies of 1q21. Amp1q21 was detected also in disease progression.

Figure 1.

Summary/Conclusions: Our results show that amp1q21 has a significant impact on OS MM pts in cases of more than 3 copies of locus only. In cases of 3 copies of 1q21 OS pts is comparable with OS in group without amp1q21. Amp1q21 can appear in the course of MM, therefore FISH-analysis of locus 1q21 should be performed at diagnosis, as well as in disease progression.
Methods: Human BM-MNCs derived from normal human subjects or MM patients were cultured with M-CSF plus rRANKL with or without 50µM of K262Ab for OC formation for TRAP staining and functional assay. To assess the mechan-isms of action of CD26Ab on OCs, RANK signaling proteins were examined by immunoblotting.

Results: CD26 is expressed on normal human Ocs and is intensely expressed on activated Ocs in MM, MGUS, and MM cell lines (MANK) induced human OC differentia-tion, in association with CD26 expression on monocyte-macrophage lineage cells. CD26 expression was accompanied by increased phosphorylation of MK2/3 and p83MAPK, which is crucial for human OC differentiation with its downstream activation of microphthalmia-associated transcription factor (mTOR) plays an important role in OC function. CD26 expression was associated with the number of multinucleated Ocs (3>3 nuclei) by TRAP/CD26 staining and down-regulated the secretion of TRAP-5b and type 1 collagen. It decreased the size of Ocs and the number of nuclei per OC, with significantly defective bone resorption activity. It was revealed that in the presence of CD26mAb, which is a known inhibitor of OC precursor cells (MANK/3p58MAPK-mi/Mitf), was not phosphorylated at all in immature Ocs. After RANKL stimulation, regardless of the absence or presence of CD26mAb. These results suggest that CD26mAb blocked RANKL induced p83MAPK phosphorylation in OC precursor cells, but not in OCs. The activation of other MAPKs including ERK and SAPK/JNK, or NFκB was rapidly induced in response to RANKL both in OC precursor cells and in mature OCs. The absence of phosphorylation of CD26mAb did not directly affect mature OC functions. Next, although CD26mAb did not demonstrate direct inhibition of proliferation of MM cells, to further investigate the role of CD26 in MM cells in the BM, co-cultures of 11 MM cell lines with CD26-stained Ocs were performed. We examined the expression of CD26 in MM cells. Although CD26 expression was only slightly detected in any of MM cell lines in mono-culture, CD26 expression level was upregulated in all MM cell lines, co-cultured with Ocs by flow cytometry and immunohistochemistry. CD26 protein level in these cell lines was also increased by immunoblotting or ELISA. To further explore the CD26 expression in the BM, co-cultures of Ocs and MM cells, the percentage of expression of CD26mAb did not directly affect mature OC functions. Our data imply that the blockade of CD26 signaling with CD26mAb impairs the development of human functional Ocs. Targeting CD26 in both Ocs and MM cells with CD26mAb may be a promising novel therapeutic strategy in MM-associated bone disease and MM progression.

KYNURENINE INHIBITS T-CELLS THROUGH THE ARYL HYDROCARBON RECEPTOR AT IDO-POSITIVE TUMOR MICROENVIRONMENT
T. Bagratuni 1,*, E. Kastritis 1, N. Mavrianou 1, C. Liacos 1, E. Terpos 1, M. Dimopoulos 1
1National and Kapodistrian University of Athens, Athens, Greece

Background: Due to the immunoglobulin production, multiple myeloma (MM) plasma cells are dependent on the unfolded protein response process (UPR), which controls protein production and ensures its proper translation and folding. A study by Michallet et al (2011) showed that knockdown of one of the three well-known arms of the UPR, PERK (protein kinase R (PKR)-like ER kinase) in MM cells resulted in autophagic cell death. This outcome indicated the impor-tance of PERK activation for the maintenance of plasma cell to myeloma cell but also its ability to impede the apoptotic effect. In this study we used a small ATP competitive molecular inhibitor, GSK2606414, that acts by targeting PERK enzyme activity in its inactive DFG conformation at the ATP-binding site of PERK, while displaying ≥385 fold selectivity over c-Kit, aurora B, BRK and many other kinases.

Aims: In this study we aimed to use a small ATP competitive molecular inhibitor, GSK2606414, that acts by targeting PERK enzyme activity in its inactive DFG conformation at the ATP-binding region, while displaying ≥385 fold selectivity over c-Kit, aurora B, BRK and many other kinases.

Methods: We initially screened 25 CD138+ MM patients and 6 human myelo-ma cell lines (HMCls) for PERK mRNA expression. Our results showed that PERK mRNA is highly expressed in almost all patients (5-10 fold higher than the mean PERK expression of HMCls).

Results: We tested the effect of GSK2606414 on the proliferation of MM cells. 4 HMCls were treated with different doses of GSK2606414 at two time points (24 and 48 hours). Treatment of cells with 3-30µM GSK2606414 resulted in a dose-dependent inhibition of cell proliferation in all HMCls ranging for 20-95% reduction of proliferative activity, thus, indicating the dependency of these cells on PERK signaling. Treatment of GSK2606414 for 24 hours resulted 25% and 15% increase in apoptotic cells by Annexin-V/PI staining respectively compared to the untreated cells. However, the most important finding was a significant synergistic effect of GSK2606414 with bortezomib in these cells. Specifically when H929 and L363 cells were treated with 5nM bortezomib in combination with 20µM GSK2606414, synergistic effect was seen where apoptotic cells reached 99% and 77% respectively, compared to bortezomib-treated cells (28% and 42% respectively). In addition, the effect of GSK2606414 in combination with bortezomib in the proliferation of H929 and L363 cells was examined. As seen in the apoptosis assay, pre-treatment with GSK2606414 for 24 hours caused in 40% and 30% reduced cell proliferation in H929 and L363 respectively compared to bortezomib only treated cells. Under ER stress conditions, the activation of ATF6 and PERK/eIF2α leads to the induction of ATF4 translation and results in the upregulation of CHOP. To determine the gene target effects of GSK2606414, ATF4 and CHOP mRNA expression levels were determined in H929 cell line after 24 hour of treatment. Treatment with GSK2606414 alone did not alter the expression levels of CHOP but reduced more than 50% the expression levels of ATF4. When combined with bortezomib CHOP and ATF4 levels were reduced 20% and 60% respectively while treatment with bortezomib alone reduced CHOP and ATF4 expression levels of 40% and 30% respectively. Changes in RNA expression of 84 UPR-related genes were analyzed in H929 cells. Specifically H929 cells were pre-treated with GSK2606414 and then subjected to ER stress conditions by treatment with tunicamycin (TM). After 24 hours of treatment, 50 genes were found to be transcriptionally regulated by 5-fold in response to TM- stress conditions. The top 10 genes (EERP1, ENRD, XBP1, DDIT3, CEBPB, PPP1R15A, etc.) were downregulated by ≥5 fold, whereas 10 of these genes (HERPUD1, E1F2AK3, CREB3L3, HSP2A, HSPA1B, etc.) were upreg-ulated similarly.
**Summary/Conclusions:** In conclusion, given the on-target pharmacological effects of PERK inhibitor on MM, development of PERK inhibitors may offer a therapeutic advantage that would affect MM pathogenesis and treatment.

**Background:** The bone marrow (BM) environment plays a crucial role in the incurable plasma cell (PC) malignancy multiple myeloma (MM). Our previous work showed that autophagy activity that is highly dependent on the PC fitness sustaining p62 expression. To investigate this hypothesis, in this study we defined a novel BM niche and its impact on MM PC fitness.

**Aims:** We hypothesized that in MM BM niche sustain PC fitness by maintaining p62 expression.

**Methods:** We integrated diverse unbiased and hypothesis-driven approaches: (1) gene expression profiles (GEP) of patient-derived circulating HDNs (60 MM, 30 healthy, 30 controls); (2) metabolic profiling by UHPLC/MS/MS of ad-hoc collected BM and peripheral plasma (16 MM, 17 smoldering MM, 30 healthy, 29 controls), and (3) functional and expression analysis in vitro studies on human MM cell lines. We validated our observations in primary MM cells using bioinformatic analysis of transcript expression levels detected by RNAseq.

**Results:** Gene expression analysis demonstrated that ISS, revised ISS (R-ISS), abnormal LDH, plasma myoglobin, and p62 expression are higher in EM group compared with the rest of the patients (69% vs 17%, p < 0.001). In accordance with the International Staging System (ISS), advanced MM stage (i.e. ISS3) was observed more often in the EM group compared to the rest (65% vs 31%, p < 0.001). High risk cytogenetics including t(4;14), t(14;16) and del17p were present in 48% of patients with ISS3 and CKD-EPI <40ml/min/1.73m2 and 3% of patients with ISS1 and CKD-EPI ≥40ml/min/1.73m2 (p = 0.001). The incidence of EM in each group was 8.1% 39% and 15.3%, respectively (OR: 2.8, 95% CI: 1.9-4.1, p < 0.001). Multivariate Cox regression analysis of prognostic factors for OS in the whole population demonstrated that CKD-EPI/ISS model was the strongest independent prognostic factor for OS (HR= 0.38, 95% CI: 0.28-0.50, p < 0.001).

**Summary/Conclusions:** Based on our data, the combination of eGFR estimated by CKD-EPI with ISS (CKD-EPI/ISS) represents a powerful independent prognostic model for MM and OS, in the era of novel agents. The markers constituting ISS and eGFR are cheap and available for most of MM patients, therefore the CKD-EPI/ISS prognostic model is applicable. Nevertheless, the establishment of CKD-EPI/ISS model requires further validation.

**ESTIMATED GLOMERULAR FILTRATION RATE (eGFR) CALCULATED BY CKD-EPI EQUATION COMBINED WITH THE INTERNATIONAL STAGING SYSTEM PROVIDES A POWERFUL PROGNOSTIC MODEL FOR EARLY MORTALITY IN MYELOMA PATIENTS**

E. Milan1, M. Ghizzinardi1, D. Tibullo2, C. Giallongo2, P. La Cava2, F. Cremascoli1, C. Conticelli1, P. Musto1, F. Cicero1, F. Di Raimondo1, S. Cenci1

1Division of Genetics and Cell Biology, San Raffaele Scientific Institute, Milano, 2Division of Hematology, Azienda Ospedaliero Policlinico e Vittorio Emanuele di Catania, Catania, 3Center for Translational genomics and Bioinformatics, San Raffaele Scientific Institute, Milano, 4Laboratory of Pre-clinical and Translational Research IRCCS, CROB Referral Cancer Center of Basilicata, Rionero in Vulture (Pz), 5Division of Genetics and Cell Biology, Azienda Ospedaliero Policlinico e Vittorio Emanuele di Catania, Catania, 6Department of Oncohematology, San Raffaele Scientific Institute, Milano, Italy

**Background:** Among putative pro-tumoral players are immunosuppressive BM-derived high-density neutrophils (HDNs), but their role in MM is unknown.

**Aims:** We hypothesized that in MM HDNs sustain PC fitness sustaining p62 expression through arginine deprivation.

**Methods:** We integrated diverse unbiased and hypothesis-driven approaches: (1) gene expression profiles (GEP) of patient-derived circulating HDNs (60 MM, 30 healthy, 30 controls), (2) metabolic profiling by UHPLC/MS/MS of ad-hoc collected BM and peripheral plasma (16 MM, 17 smoldering MM, 30 healthy, 29 controls), and (3) functional and expression analysis in vitro studies on human MM cell lines. We validated our observations in primary MM cells using bioinformatic analysis of transcript expression levels detected by RNAseq.

**Results:** The incidence of EM was higher in MM group compared with the rest of the patients (69% vs 17%, p < 0.001). The causes of EM included infection/sepsis: 54%, high risk cytogenetics including t(4;14), t(14;16), and del17p were present in 48% of patients with ISS3 and CKD-EPI <40ml/min/1.73m2 and 3% of patients with ISS1 and CKD-EPI ≥40ml/min/1.73m2 (p = 0.001). When we incorporated ISS and eGFR in a single prognostic model (CKD-EPI/ISS) we identified 3 distinct prognostic groups: 1) low risk group including patients ISS1 and CKD-EPI ≥40ml/min/1.73m2, 2) high risk group including patients ISS3 and CKD-EPI <40ml/min/1.73m2 and 3) intermediate risk group that did not fit in either low or high risk groups. The incidence of EM in each group was 8.1% 39% and 15.3%, respectively (OR: 2.8, 95% CI: 1.9-4.1, p < 0.001). Multivariate Cox regression analysis of prognostic factors for OS in the whole population demonstrated that CKD-EPI/ISS model was the strongest independent prognostic factor for OS (HR= 0.38, 95% CI: 0.28-0.50, p < 0.001).

**Summary/Conclusions:** Based on our data, the combination of eGFR estimated by CKD-EPI with ISS (CKD-EPI/ISS) represents a powerful independent prognostic model for EM and OS, in the era of novel agents. The markers constituting ISS and eGFR are cheap and available for most of MM patients, therefore the CKD-EPI/ISS prognostic model is applicable. Nevertheless, the establishment of CKD-EPI/ISS model requires further validation.

**ACTIVATED AND EXPANDED NATURAL KILLER CELLS FROM MULTIPLE MYELOMA PATIENTS DESTROY TUMOR DRUG RESISTANT CELLS AND CLONOGENIC TUMOR CELLS**

A. Leivas1, 2, I. Rapado1, 2, L. Fernández1, 2, A. Pérez-Martínez2, J. J. Lahuruet2, J. M. Martínez-López1, 2

1Hematological Malignancies Clinical Research Unit, Spanish National Cancer Research Center, 2Hematology, Hospital Universitario 12 de Octubre, 3Pediatrics, Hospital Universitario La Paz, Madrid, Spain

**Background:** Multiple myeloma (MM) remains an incurable disease. Novel therapeutic strategies targeting drug resistant cells (DRC) and clonogenic tumor cells (CTC) are needed. Our group has conducted a phase I clinical trial with activated expanded autologous NK cells (NKAES) in patients with refractory MM with a relevant clinical effect. Likewise, it has been possible to discriminate DRCs in MM by side population (SP) detection.

**Aims:** The aim of this study was to characterize DRC and to check the activity of NKAES against these DRCs and CTCs while preserving the hematopoietic progenitor cell.

**Methods:** Flow cytometry of the side population was performed by Dye Cycle Violet efflux detection to characterize DRC of MM cell lines and bone marrow samples from MM patients. The side population was purified by sorting and characterized by RNAseq. NK cells from MM patients’ peripheral blood were isolated and cocultured in the genetically modified K562-mb15-4T1BL cells in order to obtain NKAES. The activity of NKAES cells against SP was evaluated by time lapse microscopy and the activity against CTCs was evaluated by methylcellulose assay. In vitro safety against CD34 + progenitors was evaluated by time-resolved fluorescence cytotoxicity with europium-TDA and cul- turing of HMC-1, BCP-1 or lymphoblastoid cell lines with CD34 + progenitors. SP cells from both cell lines and samples from different stages of MM showed overexpression of stemness markers. Patient NKAES cells were shown to have much higher adhesion, migration and detection capacity of MM tumor cells than NK cells from the same patient. After SP purification by sorting, NKAES cells were evaluated to detect and co-cultured in the genetically modified K562-mb15-4T1BL cells in order to obtain NKAES cells. The activity of NKAES cells against SP was evaluated by time lapse microscopy and the activity against CTCs was evaluated by methylcellulose assay. In vitro safety against CD34 + progenitors was evaluated by time-resolved fluorescence cytotoxicity with europium-TDA and culturing of HMC-1, BCP-1 or lymphoblastoid cell lines with CD34 + progenitors.

**Results:** SP cells from both cell lines and samples from different stages of MM showed overexpression of stemness markers. Patient NKAES cells were shown to have much higher adhesion, migration and detection capacity of MM tumor cells than NK cells from the same patient. After SP purification by sorting, NKAES cells were evaluated to detect and co-cultured in the genetically modified K562-mb15-4T1BL cells in order to obtain NKAES cells. The activity of NKAES cells against SP was evaluated by time lapse microscopy and the activity against CTCs was evaluated by methylcellulose assay. In vitro safety against CD34 + progenitors was evaluated by time-resolved fluorescence cytotoxicity with europium-TDA and culturing of HMC-1, BCP-1 or lymphoblastoid cell lines with CD34 + progenitors.
UNMASKING THE RETROTRANSPOSEN-ORCHESTRATED PRODUCTION OF SOLUBLE RANKL IN MULTIPLE MYELOMA CELLS

S. Papamichos 1, Laboratory of General Biology, Aristotle University of Thessaloniki Medical School, Thessaloniki, Greece

Background: Growing evidence suggest that production of soluble receptor activator of nuclear factor-kappa B ligand (sRANKL) directly by myeloma cells is causally related to increased bone loss in multiple myeloma (MM). Notably, sRANKL may be produced either by proteolytic cleavage of membrane-bound RANKL or by alternative splicing of TNFSF11 gene (TNFSF11 variant 2, sRANKL mRNA). Recent analysis argues against proteolytic processing of the membrane-bound form being the main mechanism of sRANKL production by myeloma cells. Accumulative data indicate that sRANKL mRNA presents a restricted transcriptional pattern, namely is expressed predominantly in malignant cell types. Accordingly, sRANKL mRNA overexpression in primary MM cells and human MM cell lines has been validated in three independent studies. Furthermore it was recently demonstrated that sRANKL mRNA promoter and first exon are of retropositional origin, residing within a large genomic cluster of transposable elements (TEs).

Aims: To unmask the TE-shaped transcriptional and epigenetic apparatus impelling the expression of sRANKL mRNA in a cell-type and cell-context-specific manner.

Methods: RepeatMasker software was used to reveal the presence of integrated TEs in the genomic segment comprising TNFSF11. TNFSF11 RNA-Seq data, generated by the GTEX project across 51 normal human tissues, were analyzed via GTEX Portal. TNFSF11 RNA-seq data from 4 bone marrow samples and 8 white blood cells samples, generated from the PRJEB4337 and PRJNA182351 BioProjects, were analyzed via the NCBI portal. TNFSF11 transcription factor (TF) ChIP-seq data were downloaded from the UCSC Genome Browser Database. Data on TNFSF11 proximal promoter methylation status in 63 cell lines were downloaded from the HAIB Methy450 ENCODE track.

Results: RNA-Seq data from 51 normal human tissues show that sRANKL mRNA is expressed in normal human bone marrow and white blood cells. Methylation status of sRANKL mRNA promoter in 5 lymphoblastoid cell lines (LCLs) signifies that the sRANKL promoter remains heavily methylated in these cell types. TNFSF11 TF ChIP-seq data show that 5 of 161 TFs can bind to the TE-derived sRANKL mRNA promoter region. Four of the five TFs (EBF1, PAX5, IKZF1, and PU.1) bind to this genomic segment exclusively in LCLs, signifying a cell-type-specific transcriptional regulation. Notably, all 4 TFs are known to play a major role in normal and/or malignant lymphopoiesis. Furthermore, IKZF1 and PU.1 represent direct targets of immunomodulatory drugs (IMiDs) for down-regulation.

Summary/Conclusions: Transcription of sRANKL mRNA is driven by a retroviral promoter which remains heavily methylated, thereby inactive, in normal lymphocytes. Epigenetic derepression of this promoter during the course of myeloma development is suggestive of a retroviral origin of the transcript. Data analysis from the PRJEB4337 and PRJNA182351 BioProjects further validates the null expression of sRANKL mRNA in normal human bone marrow and white blood cells. Methylation status of the sRANKL mRNA promoter in 5 lymphoblastoid cell lines (LCLs) signifies that the sRANKL promoter remains heavily methylated in these cell types. TNFSF11 TF ChIP-seq data show that 5 of 161 TFs can bind to the TE-derived sRANKL mRNA promoter region. Four of the five TFs (EBF1, PAX5, IKZF1, and PU.1) bind to this genomic segment exclusively in LCLs, signifying a cell-type-specific transcriptional regulation. Notably, all 4 TFs are known to play a major role in normal and/or malignant lymphopoiesis. Furthermore, IKZF1 and PU.1 represent direct targets of immunomodulatory drugs (IMiDs) for down-regulation.

ADENOSINE IN THE MULTIPLE MYELOMA BONE MARROW NICHE: IMMUNE MODULATION AND KEY PLAYER IN DISEASE PROGRESSION

A. Horenstein 1,2,*, A. Chillemi 1, V. Quarona 1, F. Costa 1, D. Toscani 1, F. Morandi 4, D. Marimpietra 4, N. Giuliani 2, F. Malavasi 1,2

1 Medical Sciences, University of Turin, 2 CERMIS, O.U. Citta della Salute e della Scienza, Turin, 3 Myeloma Unit, Department of Clinical and Experimental Medicine, University of Parma, Parma, 4 Laboratory of Oncology, Istituto Giannina Gaslini, Genova, Italy

Background: The tumor microenvironment is rich in extracellular mono- and di-nucleotides (ATP, NAD) which are metabolized by cell surface ectoenzymes to produce adenosine (Ado), a nucleoside involved in the control of inflammation and immune responses. Multiple myeloma (MM), a plasma cell malignancy that develops within the bone marrow (BM) niche, overexpresses CD38, a molecule with complex functions. As a nucleotide-metabolizing ectoenzyme, CD38 catalyzes the initial disassembly of NAD (to cADPR and ADPR), which is followed by adenosinergic activity, provided that CD38 is operating in the presence of other ectoenzymes (CD203a and CD73).

Aims: To demonstrate that adenosinergic pathways contribute to customize homeostasis in MM.

Methods: Evaluation of the expression of adenosinergic enzymes was assessed by immunohistochemical and flow cytometric analysis on cell lines, and primary myeloma cells and BM biopsies from patients with MM or with other high-risk monoclonal gammopathies. Furthermore, IFNα and PU.1 represent direct targets of immunomodulatory drugs (IMiDs) for down-regulation.
TREATMENT OPTIMIZATION FOR MULTIPLE MYELOMA: SCHEDULE-DEPENDENT SYNERGISTIC CYTOTOXICITY OF POMALIDOMIDE AND CARFILZOMIB ON AN IN VITRO AND EX-VIVO MODEL

E. Bors1, 2, M. Martello1, 2, B. Santacroce1, 2, V. Solli1, 2, R. Terminii1, 2, E. Zamagni1, 2, P. Tacchetti1, 2, L. Pantani1, 2, S. Rocchi1, 2, M. Cavo2, G. Terragna2
1 Fondazione Umberto Veronesi (FUV), Milano, 2 Department of Experimental Diagnostic and Specialty Medicine - DiMES, Institute of Hematology “L. e A. Seràgnoli” - University of Bologna, Bologna, Italy

Background: In recent years significant progress has been made in the understanding of Multiple Myeloma (MM) biology. These advances have translated into the development of new drugs and a different approach to treatment, which has ultimately translated into an unprecedented rate of complete remissions. Immunomodulatory drugs (IMiDs) and proteasome inhibitors (Pis) form the backbone of modern MM treatment, but new and more targeted treatments are under development and are being tested in the context of clinical trials. Pomalidomide (POM) is a third-generation IMiD with immunomodulatory, antiangiogenic, and direct anti-MM activities, and greater in vivo potency than its sister Lenalidomide. Carfilzomib (CAR) is a second-generation irreversible PI that is structurally and mechanistically distinct from Bortezomib. Preclinical study suggested that the timing and dosing schedules of IMiDs in combination with Pis treatment is critical, proposing a first evidence that established treatment regimens need to be carefully re-evaluated to maximize the anti-tumor effects.

Aims: In this study we tried to optimize the anti-MM therapy using the new class of agents of IMiDs and new generation PIs, by evaluating a possible synergistic effect between POM and CAR.

Methods: For the purpose of this study we used five bona fide MM cell lines (MM1.S, OPM-2, NCI-H929, KMS12.8M, and U266), a human bone marrow stromal (BMS) cell line (HS-5 cells) and primary samples from newly diagnosed MM patients. Apoptosis analysis was done up to 48h after administration of the first drug. For each drug, three different concentrations were used: low dose, intermediate dose and high dose. Since the BM microenvironment is a complex and active system, with potential contributions of both physical adhesion and soluble factors, we used three experimental conditions to differentiate these interactions: 1) MM cells cultured in complete medium, 2) MM cells suspended in medium conditioned in the prior presence of BMSCs, or 3) MM cells co-cultured with BMSCs in a transwell system.

Results: Using the median effect method of Chou Talalay, we evaluated the combination indices for simultaneous and sequential treatment schedules, and we found that the schedule of administration is important to maximize the synergistic effects. Indeed, schedule-dependent synergistic cytotoxicity was demonstrated for the combination of IMiDs and Pis and a maximal apoptosis consistently observed in IMiDs pre-exposure schedule. The superiority of this schedule was maintained throughout BM microenvironment models. Our data overall suggest that the administration of IMiDs before Pis can improve efficacy. Clinical trials are needed to investigate the most effective schedule, which could be to start the administration of IMiDs a day before Pis to increase cells killing.

Summary/Conclusions: Schedule-dependent synergistic cytotoxicity was demonstrated for the combination of CAR and POM and a maximal apoptosis consistently observed in POM pre-exposure schedule. The superiority of this schedule was maintained throughout BM microenvironment models using low dosage of both drugs. Whilst the clinical efficacy of CAR and POM combinations has been demonstrated, the synergistic cytotoxicity may be further exploited by using optimized schedule. Utilizing such a schedule with IMiDs pre-treatment may improve the depth and duration of response of MM patients both as upfront therapy and in the relapsed/refractory setting.

Myeloma and other monoclonal gammopathies - Clinical

E1239

ASSESSMENT OF THE IMPACT OF POST-AUTOLOGOUS STEM CELL TRANSPLANT MAINTENANCE THERAPY ON SURVIVAL OUTCOMES IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA IN THE COMMUNITY-BASED CONNECT MM REGISTRY

1 Mount Sinai Hospital, New York, 2 Indiana University Simon Cancer Center, Indianapolis, 3 Cedars-Sinai, Michael Oschman Cancer Center, Los Angeles, 4 MD Anderson Cancer Center, Houston, 5 US Oncology Research, Maryland Oncology Hematology, Columbia, 6 Providence Cancer Institute, Southfield, 7 Duke University Medical Center, Durham, 8 Steeplechase Cancer Center, Somerville, 9 University of South Carolina, Columbia, 10 Wake Forest University School of Medicine, Winston-Salem, 11 Celgene Corporation, Summit, 12 US Oncology Research, Rocky Mountain Cancer Centers, Denver, United States

Background: Randomized phase 3 clinical trials have shown that maintenance therapy after autologous stem cell transplant (ASCT) can extend time to progression, progression-free survival (PFS), and overall survival (OS) for patients (pts) with newly diagnosed multiple myeloma (NDMM) (Sonneveld, J Clin Oncol, 2012; McCarthy, N Engl J Med, 2012; Attal, N Engl J Med, 2012; Palumbo, N Engl J Med, 2014; Attal, ASCO, 2016). Connect MM is a largely community-based, US prospective observational cohort study designed to characterize diagnosis, treatment patterns and outcomes in pts with NDMM in clinical practice.

Aims: The Connect MM registry was used to assess impact of maintenance therapy on survival outcomes in pts with NDMM receiving ASCT.

Methods: Adult pts with NDMM were eligible to enroll in the registry within 60 days of diagnosis. Pts were enrolled in 2 sequential cohorts and were treated at the clinician’s discretion as per standard of care. Cohort 1 pts receiving induction and ASCT were included in the analysis and characterized into 4 maintenance regimen subgroups: no maintenance, lenalidomide (LEN)-based maintenance, bortezomib (BORT)-based maintenance, and LEN+BORT maintenance. Duration was from 100 days post-ASCT (no maintenance group) or start of maintenance until progressive disease, death, discontinuation, or data cutoff of January 7, 2016. End points were PFS, second PFS, OS, and safety. An exploratory analysis of the impact of baseline characteristics on survival outcomes was performed.

Results: A total of 1493 pts were enrolled in Cohort 1 from Sep 2009 to Dec 2011; 1450 were treated, 81% (n=1173) in a community setting. Of these, 432 (29%) met analysis criteria. Median follow-up was 39.3 months. Median age was 60 y (range, 24-78); 60% were men; and 86% were white. A total of 165 pts did not receive maintenance. Of 267 pts receiving maintenance, 213 (80%) received LEN-based maintenance; 30 (11%) received BORT-based maintenance; and 16 (6%) received LEN+BORT maintenance. Of the maintenance groups, only data from LEN maintenance is presented; small sample sizes in the other maintenance groups limited interpretation. The median treatment duration was 35.2 months for pts who received LEN maintenance and 26.1 months for those who did not receive maintenance. Median PFS was significantly longer for pts who received LEN maintenance vs no maintenance (50.3 months vs 30.8 months; hazard ratio [HR]=0.62 [95% CI: 0.46, 0.82]; P=0.009; Table). OS was also significantly improved for pts who received LEN maintenance vs no maintenance (HR=0.54 [95% CI: 0.36, 0.83]; P<0.005). Second PFS (PFS for second-line treatment) was similar for both LEN and no maintenance groups. Exploratory analyses showed generally similar PFS and OS improvements across subgroups (age, ECOG status, International Staging System stage, risk group, and induction regimen). No new safety signals were observed.

Summary/Conclusions: In this observational study, post-ASCT LEN maintenance therapy significantly improved PFS and OS compared to no maintenance. These improvements appeared to be independent of induction regimen. Preliminary analysis of second PFS suggests no adverse impact of maintenance treatment on the efficacy of second-line therapy. These data, from a largely community-based setting, support results from randomized phase 3 trials.

DARATUMUMAB-BASED COMBINATION THERAPIES IN HEAVILY-PRE-TREATED PATIENTS WITH RELAPSED AND/OR REFRACTORY MULTIPLE MYELOMA
A. Lakshman1, J. Abeykoon2, S. Kumar1, V. Rajkumar1, T. Kourelis1, F. Buadi1, D. Dingli1, L. Martha1, W. Gonsalves1, A. Dispenzieri1, R. Kyle1, Y. Lin1, R. Go1, R. Warsame1, M. Hobbs1, A. Fonder1, Y. Hwa1, S. Hayman1, S. Russell1, N. Leung1, M. Gertz1, P. Kapoor1
1Division of Hematology, 2Internal Medicine, Mayo Clinic, Rochester, United States

Background: Daratumumab-based combination Therapies (DCT) with bortezomib (V)/ lenalidomide (R)/ pomalidomide (P) and dexamethasone (d) have shown exceptional activity in relapsed and/or refractory multiple myeloma (RRMM) in trials. Experience outside of trials since the approval of Daratumumab (D) in 2015 is limited.

Aims: We aimed to review the outcomes of patients who received DCT at our institution.

Methods: Records of RRMM patients seen at Mayo Clinic, MN from December 2015 – December 2016 were reviewed. Patients who received ≥ 1 cycle of DCT were included. Time-to-event analyses were done from date of starting DCT using Kaplan Meier method. Common terminology criteria for adverse events v4.0 were used to grade toxicities.

Results: Of 130 patients, 59% were males and median age at DCT initiation was 67 (49-93) years. ECOG performance score was ≥2 in 29%. Patients were classified as mSMART high (22%), intermediate (22%) or standard (56%) risk. Median time from diagnosis to initiation of DCT was 51.3 (5-156) months, and median number of prior therapies was 4 (1-14). Eighteen (14%) of patients were refractory to prior daratumumab monotherapy. Fifty-three (41%), 34 (26%) and 25 (19%) received DPd, DRd and Dvd respectively. Eighteen (14%) patients received ‘other’ DCT. Median time to first response (≥ PR) was 17%, with clinical benefit rate of 62%. Median estimated follow up from initiation of DCT was 5.5 months (CI 4.2-9.1). The median duration of response was 6.1 months (CI 5.1- not reached (NR)). Median progression free survival (PFS) was 5.5 months (CI 4.1-7.8) (figure A) and median time to next therapy (TTNT) was 5.9 months (CI 4.6-9.4) (figure B). Median PFS for DPd, DRd, Dvd and other DCTs were 4.6 (CI 2.7-NR), 7.8 (CI 5-NR), 3.9 (CI 2.1-NR) and 3.9 (CI 2.8-8.2) months, respectively (p=0.3). Median overall survival (OS) from starting DCT was NR (CI 11.4-NR) (figure C). Median PFS for quadruple refractory (n=28) MM was 2.8 months (CI 2.2-5.3) vs 5.9 months (CI 4.9-NR) for the rest (p=0.008) (figure D). Grade 3 or higher hematological toxicities were seen in 42% of patients. Other toxicities included infections (37%), fatigue (31%), infusion reactions (16%) and diarrhea (10%).

Figure 1.
Summary/Conclusions: Metformin use was associated with a better progression-free survival and higher complete response rates after SCT in our MM cohort. A trend toward better overall survival was also noted in the Metformin group. Larger studies are needed to enhance our understanding of the clinical effect of metformin on MM.

COMPARING WHOLE BODY MRI WITH PET-CT IMAGING AT DIAGNOSIS OF MYELOMA
J. Vidler1,*, G. Havariyoun2, G. Vivian3, I. Walker1, M. Streetly1, K. Cuthill1, R. Benjamin1, N. Mulholland3
1Department of Haematological Medicine, 2Department of Medical Engineering and Physics, 3Departments of Radiology and Nuclear Medicine, King’s College Hospital, London, United Kingdom

Background: Imaging in the diagnosis of myeloma is a rapidly developing field. First line imaging has traditionally been a skeletal survey with plain films, however new guidelines recommend whole body imaging to aid the diagnosis of this heterogenous disorder. The International Myeloma Working Group recommend low-dose whole body computerised tomography (LDWBCT), PET-CT or whole body magnetic resonance imaging (WBMRI) as initial imaging modalities.

Aims: To compare WBMRI with PET-CT as initial imaging modalities at diagnosis of myeloma or plasma cell disorders. The International Myeloma Working Group recommend low-dose whole body computerised tomography (LDWBCT), PET-CT or whole body magnetic resonance imaging (WBMRI) as initial imaging modalities.

Methods: Both WBMRI and PET-CT were performed at diagnosis of myeloma or a plasma cell disorder in 33 patients presenting to King’s College Hospital, London.

The scans were reviewed independently by two Consultants in Radiology
and Nuclear Medicine, looking for focal bone lesions, bone marrow pattern and incidental findings. Details of the patients' demographics, myeloma diagnosis and treatment were collected from the medical records.

Results: Of the 33 patients, 24 were male. The median age was 64 years (range=43-86 years). One patient had a solitary plasmacytoma, the other 32 had myeloma (21 IgG, 9 IgA, 2 non-secretory, 4 light chain disease, 2 bicalon myeloma). Nine patients had ISS stage 1 disease, 16 with stage 2 disease and 7 with stage 3 disease (range 0-52). 21 patients had a bone marrow plasma cell burden of 10-60%, 10 patients >60% and 2 were unknown. Sixteen patients were diagnosed with smouldering myeloma and a 'watch and wait' policy was adopted. Eleven patients were treated with chemotherapy, 4 were entered into a clinical trial, one was offered palliative care and one was referred to our centre for autograft. WBMRI identified a focal lesion of disease in 30% of patients compared with 36% by PET-CT. This was not a statistically significant difference (p=0.18). In addition there was no statistically significant difference between PET-CT & MRI in detecting <3 or >3 lesions (p=0.705 and p=0.083 respectively). The apparent difference, however, at vertebrae L5 (using diffusion weighted MRI imaging) was measured. This showed a strong correlation with the degree of bone marrow infiltration by plasma cells (r=0.64). An ADC of <600mm²/s had a negative predictive value of 93% for a bone marrow plasma cell infiltrate of >60%. There was also a significant difference (p=0.012) in the ADC between those with smouldering myeloma and those with symptomatic disease. It was noted that 9 scans resulted in incidental findings including pneumonia, adrenal lesions and one case of colocolic cancer.

Summary/Conclusions: We have shown no difference in PET-CT and WBMRI in detecting a myeloma defining focal bone lesion, or providing prognostic estimation of bone disease. Using MRI, a measure of the ADC at vertebrae L5 has been shown to be a semi-quantitative parameter that correlates with bone marrow plasma cell infiltration and distinguished between those with smouldering and symptomatic disease. In addition it is noted that whole body imaging has led to incidental findings of further pathology, including an unrelated malignancy, which may lead to useful clinical information or to further investigations and imaging which may not be needed.

E1243 PERSISTENCE OF MINIMAL RESIDUAL DISEASE BY MULTIPARAMETER FLOW CYTOMETRY CAN HINDER RECOVERY OF ORGAN DAMAGE IN PATIENTS WITH ALAMYLOIDOSIS

Background: In multiple myeloma, Minimal Residual Disease (MRD) demonstrated by multiparameter flow cytometry (MFC) identifies subjects with significant residual disease among those who attain complete response (CR). The role of MRD in AL amyloidosis has not been assessed so far.

Aims: In the present study, we assessed the MRD by MFC in patients with AL amyloidosis who attained CR.

Methods: CR was defined as per current criteria (negative serum and urine immunoelectrophoresis, free light chain ratio <30%). In 9 patients with AL amyloidosis, bone marrow aspirates were processed following the Euro Flow Bulk Lysis Standard Operating Protocol and stained with the EuroFlow/MF MM MRD panel. At least 5x10⁶ events were measured using a FACS Canto II (USA) instrument. Data were analyzed using the Inflicty software (Spain). Patients were identified as having residual disease if a discrete population of clonal plasma cells comprising ≥50 events was identified (10⁵ limit of detection).

Results: Twenty-eight patients were tested (7 found to have relapsed at the time of MRD assessment with monoclonal components detectable and MRD+ and 21 satisfied current criteria for CR. Nineteen (90%) had reduced and 9 (44%) had improved cardiac function at diagnosis. More than 2 lines of therapy were required to achieve CR in 7 subjects. Median time to CR was 10 months (range: 3-82). Five patients (62%) had achieved cardiac response and 9 (50%) renal response at the time of CR. The median time from CR to MRD was 30 months (range: 6-148), this was not different in the MRD positive vs negative patients (p=0.14). A median of 1089 (range 256-2500) corresponding to 0.04% (range 0.02-0.3%) plasma cells with abnormal phenotype were detected in patients MRD+. No differences in organ involvement, cardiac and renal stage, type of therapy, number of treatments, and organ response at the time of CR was found between the two groups. Interestingly, improvement of cardiac function correlated better than to the time of CR as observed in all 5 evaluable MRD- patients and in none of the 2 MRD+ patients (P=0.047). Compared to the time of CR, renal response was obtained in 7 MRD- subjects (84%) and in 4 (50%) MRD+ (P=0.153). Overall, further improvement of cardiac or renal function after CR was significantly associated with a lower incidence of MRD+ (P=0.047).

Summary/Conclusions: This proof-of-concept study indicates that 43% of patients with AL satisfying current criteria for CR have detectable MRD. MRD positivity could in part explain persistence of organ damage in patients in CR.

E1244 RATES OF PERIPHERAL NEUROPATHY (PN) IN PATIENTS WITH RELAPSED AND REFRACTORY MULTIPLE MYELOMA (RRMM) TREATED WITH CARZOMIZ vs COMPARATORS IN PIVOTAL PHASE 3 TRIALS

R. Nathan1,2, X. Huang3, P. Ho3, A. Suvorov4, D. White5, D. Ben-Yehuda6, L. Zhou7, K. Iskander8, L. Rosirol9

1Center for Myeloma, New York Presbyterian Hospital Weill Cornell Medical Center, New York, United States, 2Santa Casa de Sao Paulo Medical School, Sao Paulo, Brazil, 3Institute of Haematology, Royal Prince Alfred Hospital, Camperdown, Australia, 4Hematology Department, First Republican Clinical Hospital of Udmurt Republic, Izhevsk, Russian Federation, 5Dalhousie University and QEII Health Sciences Centre, Halifax, Canada, 6Kiryat Hadassah, Jerusalem, Israel, 7Amen Inc., Thousand Oaks, United States, 8Institut d’Investigacions Biomèdiques August Pi i Sunyer, Hospital Clinic, Barcelona, Spain

Background: PN is a dose-limiting toxicity for some anti-myeloma agents, such as the proteasome inhibitor bortezomib (V).

Aims: Carfilzomib (K), a novel irreversible proteasome inhibitor associated with a low incidence of PN, was evaluated in two recent phase 3 studies in RRMM patients.

Methods: This analysis evaluated PN rates in ASPIRE (K [27mg/m²] lenalidomide [R]-dexamethasone[d] [KRd] vs Rd in relapsed or refractory MM; Stewart 2015) and ENDEAVOR (Kd [K 56mg/m²] vD in RRMM; Dimopoulos 2016). We evaluated treatment emergent grade ≥2 PN, patient reported outcomes (PROs; QLQ C30 pain, FACT/GOG neurotoxicity subscales), and progression free survival (PFS) in patients with a baseline history of PN (patients with grade ≥3 PN at baseline or grade 2 PN with pain at baseline were excluded from the studies).

Results: In ASPIRE, grade ≥2 PN rate was low (8.0% [KRd] vs 8.0% [Rd]; Table). Pain subscale scores were similar between arms. Median PFS was longer with KRd vs Rd for patients with grade 2 PN at baseline. In ENDEAVOR, grade ≥2 PN rate during the study (prespecified key secondary endpoint) was significantly lower with Kd vs Vd (6.0% vs 32.0%; Table). Patients had significantly improved pain and neurotoxicity subscale scores with Kd vs Vd. PFS improved with Kd vs Vd in patients with baseline history of grade ≥2 PN (Table 1).

Table 1.

Summary/Conclusions: In ENDEAVOR, the rate of PN was significantly lower with Kd then with Vd; in ASPIRE, PN rate was similar for KRd and Rd. Improved pain and neurotoxicity subscale scores with K may be attributed to better disease control and/or lower PN rates.

E1245 EARLY RELAPSE FOLLOWING AUTOLOGOUS STEM CELL TRANSPLANTATION IN MYELOMA IS A POOR PROGNOSTIC MARKER FOR OVERALL SURVIVAL AND IS DIFFICULT TO PREDICT AT DIAGNOSIS OR DURING INDUCTION TREATMENT

I. Walker1, A. Coady2, I. El-Najjar 3, K. Wilson4, K. Cuthill1, 5, W. Ingram4, M. Kazmi5, K. Raj1, R. Benjamin1, S. Schey1, A. Pagliuca1, G. Multi1, M. Streetly1, 5, C. Byrd1, 5

1Department of Haematology, King’s College Hospital Foundation Trust, 2Guy’s, King’s and St Thomas’ School of Medical Education, King’s College London, 3Department of Haematology, Guy’s and St Thomas’ NHS foundation Trust, London, 4Department of Haematology, University Hospital Wales, Cardiff, United Kingdom

Background: High dose chemotherapy followed by autologous stem cell transplant (ASCT) remains the gold standard treatment in myeloma for young...
patients at induction. A number of factors have been shown to correlate with overall survival (OS) and progression free survival (PFS) including depth of remission prior to ASCT, initial ISS stage and high risk cytogenetics. Emerging evidence has demonstrated that early relapse following ASCT is associated with reduced OS, and is not correlated with depth of pre-transplant response.

Aims: To characterise myeloma patients who relapsed within 12 months of ASCT, through baseline characteristics and transplant engraftment, and assess the impact of this early relapse on OS and PFS.

Methods: We performed a multicentre retrospective analysis of patients who underwent ASCT at 3 centres between 01/2009 – 02/2016 (London) and 06/2006 – 03/2013 (Cardiff). Baseline characteristics were reviewed and ASCT engraftment was assessed by: time to neutrophils 50 x 10^9/L and platelets >20 x 10^9/L. Post-transplant PFS & OS was calculated by time (months) from diagnosis to progression or death.

Results: 443 myeloma patients were identified, median age was 57 (r 31-73), 56% were male. 41% of patients were ISS stage 1, 34% stage 2, 25% stage 3. Cytogenetic data was available for 139 patients. 1st-line therapy prior to transplant included an immunomodulatory drug (IMiD) based (THAL/LEN) for 318/443 patients & 72/443 were proteasome inhibitor (PI) based (BORT/CAF). In addition, 11 patients received combination PI and IMiD. Median time from start of therapy to ASCT was 10 months (r 3-109m), 67 patients progressed within 12m of ASCT (early relapse). No statistical difference was found between <12 or >12m relapse for: age, gender, 1st line therapy, ISS stage, Hb, LDH, Ca or cytogenetics, confirming that this group is difficult to predict at baseline. Median OS from time of diagnosis was 103 months (95% CI 101 -137), median OS from start of ASCT was not reached, however 5-year OS was 68%. Patients with progressive disease within 12 months of ASCT, has significantly reduced median OS (median OS:12-31 months (95% CI 21- 39) compared to non-progressive patients (median OS:103m 95% CI 89-117) p=0.0005. Median OS from ASCT was reduced in early progression median OS:18m (95% CI 14-22m) vs progression >12 months median OS:89 months (95% CI 79-98m) p<0.0005. 1st line therapy did not influence likelihood of PFS<12months, with no statistical differences between patients who received PIs, IMiDs or both 1st line (p=0.484). A significant difference was observed in median time to platelet engraftment between the 2 centres. Increased time for platelets to reach >20 x 10^9/L was associated with reduced OS from ASCT for each centre HR 1.14 & 1.20 (p= 0.046 & 0.03) for Cardiff or London centres respectively (Cox’s Method).

Summary/Conclusions: Early relapse following ASCT is a significant predictor of inferior OS in myeloma and difficult to predict from standard baseline characteristics. From our analysis; 1st line treatment prior to ASCT did not influence OS or PFS. There was an association between slow platelet engraftment following ASCT and PFS and OS. Possible explanations include: residual occult disease, toxicity of chemotherapy or patient stromal factors which facilitate disease resistance and impair normal haematopoiesis. All of these factors have been shown to drive relapse. RCTs are required to standardise bone marrow response assessment post ASCT, quantify remission status (using laboratory and imaging techniques) and definitively predict early relapse. Additionally, these studies will investigate further biological or genetic mechanisms driving early relapse to help identify novel therapeutic approaches in this extremely poor prognosis group.

E1246

PATIENT-REPORTED OUTCOMES (PROS) WITH IBRUTINIB: SUBSTUDY OF INNOVATETM FOR WALDENSTROM MACROGLOBULINEMIA (WM)

To prospectively collect PROs from the iNNOVATE substudy to assess patients’ perspectives of the therapeutic benefit of ibr, a first-in-class, once-daily inhibitor of BTK, is indicated in the EU for the treatment of WM after ≥1 prior therapy or >12m relapse for: age, gender, 1st line therapy, ISS stage, Hb, LDH, Ca or cytogenetics, confirming that this group is difficult to predict at baseline. Median OS from time of diagnosis was 103 months (95% CI 101 -137), median OS from start of ASCT was not reached, however 5-year OS was 68%. Patients with progressive disease within 12 months of ASCT, has significantly reduced median OS (median OS:12-31 months (95% CI 21- 39) compared to non-progressive patients (median OS:103m 95% CI 89-117) p=0.0005. Median OS from ASCT was reduced in early progression median OS:18m (95% CI 14-22m) vs progression >12 months median OS:89 months (95% CI 79-98m) p<0.0005. 1st line therapy did not influence likelihood of PFS<12months, with no statistical differences between patients who received PIs, IMiDs or both 1st line (p=0.484). A significant difference was observed in median time to platelet engraftment between the 2 centres. Increased time for platelets to reach >20 x 10^9/L was associated with reduced OS from ASCT for each centre HR 1.14 & 1.20 (p= 0.046 & 0.03) for Cardiff or London centres respectively (Cox’s Method).

Summary/Conclusions: Early relapse following ASCT is a significant predictor of inferior OS in myeloma and difficult to predict from standard baseline characteristics. From our analysis; 1st line treatment prior to ASCT did not influence OS or PFS. There was an association between slow platelet engraftment following ASCT and PFS and OS. Possible explanations include: residual occult disease, toxicity of chemotherapy or patient stromal factors which facilitate disease resistance and impair normal haematopoiesis. All of these factors have been shown to drive relapse. RCTs are required to standardise bone marrow response assessment post ASCT, quantify remission status (using laboratory and imaging techniques) and definitively predict early relapse. Additionally, these studies will investigate further biological or genetic mechanisms driving early relapse to help identify novel therapeutic approaches in this extremely poor prognosis group.

E1247

INCIDENCE AND RISK FACTORS OF CARDIOVASCULAR ADVERSE EVENTS IN A LARGE POPULATION OF NEWLY-DIAGNOSED, TRANSPLANT INELIGIBLE MYELOMA PATIENTS TREATED WITH CARFILZOMIB

Background: Cardio-vascular (CV) toxicities in patients (pts) with multiple myeloma (MM) may derive from comorbidities, MM itself and its treatment. Carfilzomib, an irreversible proteasome inhibitor, is approved as single agent or in combination with dexamethasone or lenalidomide-dexamethasone for relapsed MM.

Aims: We conducted an integrated analysis of CV adverse events (AE) in newly diagnosed, transplant-ineligible MM patients treated with Carfilzomib in 3 phase III studies (IST-CAR-506, IST-CAR-561, IST-CAR-601).

Methods: All pts were treated with 9, 28-day induction cycles with carfilzomib, cyclophosphamide (300mg/m² on days 1,8,15) and dexamethasone (40mg weekly) (CCyd), followed by carfilzomib maintenance until progression or intel-

Table 1.

Results: Persistent fatigue was the main indication for treatment in 22/31 (71%) pts. Baseline PRO scores were lower for time substudy vs randomized pts (Table). With a median of 17 months (mo) of treatment, most pts had clinically meaningful improvement in TS (≥ 7 points; 77%), AS (≥ 67 points; 84%), and EQ utility scores (≥ 0.08 points; 88%). Time to clinically meaningful improvement was prompt (1 mo for TS and AS; 2 mo for EQ), corresponding with a 48% decline in median IgM (median 20 g/L) after 4 weeks. In pts with baseline anemia (hemoglobin [Hb] ≤ 110 g/L), sustained Hb improvement increased with depth of response. At week 65, Hb levels significantly correlated with TS (r=0.507, P=0.01) and AS (r=-0.519, P=0.008), and were marginal for EQ (r=0.39, P=0.054). Although IgM levels did not significantly correlate with PRO scores, the benefit was similar in responders regardless of depth of response.

Table 1.
erance. Carfilzomib was administered i.v. at the dose of 36mg/m² on days 1, 2, 8, 9, 15, 16 in the IST-CAR-506 trial: at 3 dose levels escalated from 45 to 70mg/m² on days 1, 8, 15 in the IST-CAR-561 trial and on days 1, 2, 8, 9, 15, 16 in the IST-CAR-601 trial. AE's were graded based on NCI-CTCAE v4.

Results: 148 pts with a median age of 72 years were analyzed. At enrollment, 34% of patients had at least 1 cardiovascular risk factor; 20% had peripheral vascular disease (including hypertension in 13% patients), 19% diabetes and 5% chronic pulmonary disease. After a median follow-up of 21 months, at least 1 any grade CV-AE occurred in 45% of patients; any grade hypertension was reported in 17% of patients, dyspnea in 9%, and heart failure, arrhythmia and venous thromboembolism (VTE) in 6% of patients, each. Grade 3-5 CV-AEs occurred in 15% of patients, the most common being heart failure (4%), hypertension (3%), pulmonary edema (3%) and VTE (3%). Four (3%) fatal CV-AEs occurred: 1 case of heart failure, pulmonary edema, arrhythmia and VTE, respectively. No difference in terms of CV-AEs was observed in patients treated with different doses of carfilzomib. In pts who developed at least 1 CV-AE, carfilzomib dose reduction (33%) and discontinuation (33%) were more frequent as compared to those without CV-AEs (12% and 18%, respectively; p<0.0001).

A trend toward a shorter 2-year overall survival (adjusted for age) was observed among patients who experienced at least 1 CV-AE as compared with those who did not (74% vs 83%; HR: 0.51; p=0.066). Pts ≥75 years had a higher risk of any grade (58% vs 36%; p=0.02) and grade 3-5 CV-AEs (34% vs 15%; p=0.01). major cardiac events of any grade were more frequent in older patients (29%) than in younger ones (6%; p<0.001). Patients with at least 1 CV risk factor at enrollment had a 4-fold increased risk (odds ratio: 3.79; p<0.001) of developing a CV-AE during treatment as compared to patients with no CV risk factors; in detail, baseline hypertension (odds ratio: 4.12; p=0.012) and peripheral vascular disease (odds ratio: 3.75; p=0.002) conferred the highest risk of developing CV-AEs.

Figure 1.

Summary/Conclusions: Among newly diagnosed MM pts treated with carfilzomib, cyclophosphamide and dexamethasone, at least 1 CV-AE occurred in 45% of pts, hypertension and dyspnea were the most predominant. Pts ≥75 years of age and those with at least 1 pre-existing CV risk factor were at higher risk of developing a CV-AEs. The onset of CV toxicity significantly increased the rate of dose reductions and treatment discontinuation, translating into higher risk of death. CV toxicity may significantly impact on treatment compliance and survival. Therefore, to derive maximum benefit from Carfilzomib, all pts - particularly the elderly - should be carefully assessed to select the most appropriate treatment.

E1249

POMALIDOMIDE (POM) + LOW-DOSE DEXAMETHASONE (LODEX) AFTER SECOND-LINE LENALIDOMIDE (LEN)-BASED TREATMENT OF RELAPSED OR REFRACTORY MULTIPLE MYELOMA (RRMM): UPDATED PROGRESSION-FREE SURVIVAL ANALYSIS

D.S. Siegel1, G.J. Schiller2, K. Song3, R. Agajanian4, K. Stockerl-Goldstein5, 69.4% for pts ≥ MR, and 69.1% for pts with ≥ PR. In addition, pts with ≥ MR had similar treatment durations as those achieving ≥ PR (10.5 vs 11.5 months; Table). Common grade 3/4 adverse events (AEs) included anemia (25.5%), neutropenia (11.8%), and infections (19.6%; including pneumonia [9.8%]. No pts experienced SPMs. In the immune subset analysis, the proportions of CD3+ and CD3+CD8+ T cells after treatment were significantly higher vs baseline (72.6% vs 67.8% and 36.9% vs 32.1%, respectively; P<0.05). Pts with response also had significantly elevated proportions of these T-cell populations, but pts with no response did not. Relative changes from baseline for CD3+ and CD3+CD8+ T-cell populations were significantly greater in pts with response vs those with no response (10.4 vs -0.8 and 4.2 vs –3.5, respectively; P<0.05).

Table 1

Summary/Conclusions: This update confirms the safety and efficacy of POM + LODex following second-line LEN-based treatment failure in pts with RRMM. Hematologic AE rates improved, and median PFS was longer with third-line use than previously reported with POM + LODex use in later treatment lines. In addition, achieving disease control of ≥ MR led to similar PFS rates as reaching ≥ PR.

E1249

“REAL WORLD” DATA ON THE EFFICACY AND SAFETY OF IKAZOMIB IN COMBINATION WITH CARFILZOMIB AND DEXAMETHASONE IN RELAPSED/REFRACTORY MULTIPLE MYELOMA: A STUDY OF THE GREEK MYELOMA STUDY GROUP

E. Terpos1, E. Katodrity2, M. Kotsopoulo3, I. Ntanasis-Stathopoulos1, P. Lampropoulou1, S. Papadaki2, M. Papathanasiou4, D. Stoumbos5, 3Department of Hematology, Metaxa Cancer Hospital, Piraeus, 4Department of Hematology and Bone Marrow Transplantation Unit, G. Papankiioiou General Hospital, Thessaloniki, Greece

Background: The all-oral combination of ixazomib, lenalidomide and dexamethasone (IrD) has been recently approved as a novel standard of care for relapsed/refractory multiple myeloma (RRMM). This was a retrospective, non-interventional study, which recorded IrD treatment data from patients with RRMM who participated in the name-patient program of ixazomib in Greece. The primary endpoint was the evaluation of overall response rate (ORR) following treatment with IrD. Secondary endpoints included: treatment duration; time to response; duration of response; percentage of patients who experienced adverse events (AEs), needed dose modification or treatment discontinuation; evaluation of PFS and TTP.

Methods: Forty-one patients were included in the present study. Of those, 35 (19M/16F, median age 63-79 years) had received at least 3 cycles of IrD on the date of data analysis and thus they were included in the present report. The median line of previous therapies was one (range: 1-5): 71.4% (25/35) patients had received one prior treatment, while 20.0% (7/35),
5.7% (2/35) and 2.9% (1/35) had received 2 and 3 prior treatment lines, respectively. Overall, 82.9% (29/35) of patients had been exposed to proteasome inhibitors prior to IRd (77.1% to bortezomib and 8.6% to carfilzomib) and 46.8% (17/35) to IMiDs [31.4% (11/35) to thalidomide and 22.9% (8/35) to lenalidomide]. Autologous transplantation had been given in 42.9% (15/35) of patients. Median treatment duration was 7.1 months. Among 34 patients with available data, median VEGF was decreased in 15.7% (5/31) of patients, 43.8% (14/31) of patients, and 52.9% (16/31) of patients in the LEN, BORT, and THAL cohorts, respectively. The incidence of SPMs per 100 patient-years was 3.87 overall and 3.45, 5.41, 2.73, and 6.51 for LEN, BORT, THAL, and other agents, respectively. Median time to best response was 1.2 months. Treatment interruptions due to AEs were recorded for 11.4% (4/35) of patients, while 20.0% (7/35) of patients discontinued treatment. Reasons for ixazomib discontinuation were AEs for 3 patients (an event of myelodysplastic/myeloproliferative disease), discontinuation in discussion with the patient and, administrative reason (patient could no longer visit the site) in one. Among the 35 patients analyzed, 17.1% (6/35) had experienced disease progression or death; the 6-month PFS rate was 90.5% and the 6-month TTP rate was 93.2%. Regarding AEs of interest, 31.4% (11/35) of patients experienced peripheral neuropathy (10.9%, 4.6%, and 4.6% for LEN, BORT, and THAL, respectively), which did not resolve; while 45.4% (5/11) had not resolved (three were grade 1, one grade 2, and one of grade 3) at the end of follow-up. In addition, 31.4% (11/35) of patients developed gastrointestinal AEs, 11.4% (4/35) experienced pneumonia, 9.8% (3/32) hypotension, 5.7% (2/35) cataract and herpes zoster, and 2.9% (1/35) deep vein thrombosis; no cardiac arrhythmia or other cardiac events were recorded, while osteonecrosis of the jaw developed in 5.7% (2/35) of the patients.

Summary/Conclusions: This study showed that the IRd regimen produces an ORR of near 68% and a clinical benefit in almost all patients with RRMM who are treated in RW practice. IRd acts rapidly and has an acceptable toxicity profile with no cardiac events.
Results: During the development process, a number of similarities and discrepancies between centers as well as evidence gaps were identified. Intense discussion and literature searches resulted in a concise, harmonized clinical pathway, released by all 14 Centers of Excellence. This is freely available on the website cc-netzwerk.de and provides a very decisive insight according to the current state of knowledge on the CCC-level (e.g. on the diagnostic algorithm, Fig. 1). The clinical pathway is well suited for informing patients and physicians about the most up-to-date, comprehensive medical treatment standards as well as innovative procedures. Furthermore, this project initiated the idea of developing a national evidence-based clinical practice guideline for MM in the frame of the German Guideline Program on Oncology.

Figure 1.

Summary/Conclusions: The first clinical MM pathway developed and released by all 14 German CCCs/Centers of Excellence translates scientific evidence and expert knowledge into precise suggestions for MM patients in clinical practice. These measures might increase the quality of cancer care throughout Germany. To be up-to-date and to reflect latest research findings this clinical pathway will be updated every 18 months.

E1252

WT1 HETEROCLITIC EPITOPE IMMUNIZATION FOLLOWING AUTOLOGOUS STEM CELL TRANSPLANTATION IN PATIENTS WITH HIGH-RISK MULTIPLE MYELOMA (MM)

G. Koehne1,*, S. Devlin1, D. Chung1, H. Landau1, N. Kordel1, S. Mailankody1, H. Hassoun1, A. Lesokhin1, N. Lendvai1, S. Giralt1, O. Landgren1
1Memorial Sloan Kettering Cancer Center, New York, United States

Background: The Wilms tumor 1 (WT1) protein is a tumor associated antigen that is a target for anticancer immunotherapy. We had previously demonstrated overexpression of WT1 in multiple myeloma (MM) cells by IHC, as well as for formation of a WT1 peptide fragment (RMFPNAPYL)/HLA-A*0201 complex on the engagement interface between malignant plasma cells and T-cells in HLA-A*0201+MM pts using the high-affinity fully human IgG1 mAb ESK1. We report initial results from MM pts immunized with the WT1 heteroclitic peptide mixture galinpepimut-S (GPS) after autoSCT.

Aims: To determine the safety and potential efficacy of the WT1 heteroclitic peptide mixture galinpepimut-S (GPS) after autoSCT.

Methods: 16 MM pts underwent autoSCT with melphalan conditioning followed by (fb) lenalidomide maintenance starting 3 months (mos) post-SCT. 13/16 pts presented with high-risk (HR) cytogenetics [t(4;14), t(14;16), del17p, 1q21/22 gain and/or del13q]. GPS was administered in patients with mounting s.c. starting 2 ws post-SCT and q2 ws thereafter x 6 initial doses fb boosters q4 wks x 6 additional doses. GM-CSF was given on days -2 and 0 of each cycle.

Results: Various levels and were induced not only against the heteroclitic peptides (within GPS), but also against the corresponding native WT1 peptide sequences as well as the ‘total pool’ of WT1-derived overlapping peptides.

Summary/Conclusions: Administration of the novel WT1 heteroclitic peptide immunizer GPS post-SCT demonstrates favorable safety profile along with an encouraging mPFS of currently 23.6 mos in this high-risk MM population. This ‘off-the-shelf’ immunotherapy is easy to administer and has been specifically designed to elicit responses across most common HLA Class I and II alleles. Based on these results, a larger phase II trial is being planned to optimally integrate post-transplant immunotherapeutic strategies to meaningfully delay or reduce risk of relapse in this challenging clinical setting.

E1253

ANALYSIS OF MULTIPLE MYELOMA PATIENTS WITH PROGRESSIVE DISEASE AT TIME OF FIRST AUTOLOGOUS STEM CELL TRANSPLANTATION: PREDICTORS OF PROGRESSIVE DISEASE AND FACTORS AFFECTING SURVIVAL

J. Blocka1,*, H. Goldschmidt1, T. Hielscher2, M. Pritsch1, M. Raab1, J. Hillengass1
1University Hospital Heidelberg, 2German Cancer Research Center, Heidelberg, Germany

Background: The impact of response depth at time of autologous stem cell transplantation (ASCT) on the progression-free and overall survival (PFS and OS, respectively) of multiple myeloma (MM) patients has been an extensively investigated area. Rosiñol et al. (2011) reported a significantly worse PFS and OS in patients with progressive disease (PD) compared to stable disease (SD) at time of ASCT; Parrish et al. (2015) stated a significantly shorter PFS, but not OS, in patients with PD in comparison to SD or minimal response (MR) at time of ASCT.

Aims: Our goal was to characterize MM patients with PD at time of first ASCT. We aimed to analyze the effects of PD on PFS and OS. Next, we intended to examine the influence of PD at time of ASCT (evaluated at beginning of induction therapy as well as use of novel agents in induction therapy, response after 1st ASCT, and use of maintenance therapy in those patients to identify predictors for PFS and OS. Furthermore, we aimed to identify clinical/therapeutic features predicting the occurrence of PD before ASCT.

Methods: Non-trial MM patients who had undergone a single or tandem ASCT at the University Hospital of Heidelberg in the years 1992-2014 were analyzed regarding their impact on PD before 1st ASCT. We performed an analysis of PD at time of ASCT and before ASCT. PFS was calculated from date of 1st ASCT, except for prognostic impact of response assessment after 1st ASCT, where date of response assessment was used. Start of maintenance therapy was analyzed as time-dependent factor.

Results: Non-trial patients transplanted in our center between 1992 and 2014 were compared. Patients with PD ≤100 days before ASCT had similar PFS and OS as non-PD patients. Neither the clinical parameters at induction start, response after 1st ASCT, nor maintenance therapy had a significant effect on PFS in those patients. In the univariate analysis, high-risk cytogenetics as well as elevated LDH at induction start had a significantly negative effect on OS in patients with PD before ASCT. Response was evaluated according to EBMT-criteria. PFS was calculated from date of 1st ASCT, except for prognostic impact of response assessment after 1st ASCT, where date of response assessment was used. Start of maintenance therapy was analyzed as time-dependent factor.

Conclusion: Our analysis of 51 patients with PD at time of ASCT among 874 ASCT-patients with MM transplanted between 1992 and 2014 shows no significant difference regarding PFS and OS between patients with PD and other response rates. It was further shown that high-risk cytogenetics as well as elevated LDH at beginning of induction therapy have a significant impact on worse OS in patients with PD at time of ASCT. In addition, high-risk cytogenetics at time of ASCT is a significant factor for occurrence of PD. The impact response depth at time of ASCT is not entirely clear, especially regarding the benefit of ASCT in patients with PD at time of ASCT, as reports from other centers show significantly worse PFS and OS (Rosiñol et al.), or only PFS (Parrish et al.) in patients with PD at time of ASCT.
Multiple myeloma (MM) is a disease of the elderly. The prevalence shows that both proteasome inhibitors (PIs) and immunomodulatory drugs (IMiDs) can have important CV sequelae. The improved efficacy of PI plus IMiD combination therapy (PI+IMiD) has resulted in its widespread adoption, which suggests that CV events may become a prominent concern in patients receiving PI+IMiD as contemporary treatment for MM.

Aims: To assess the risk of developing CV events in patients receiving anti-MM treatment and to test if a specific treatment modality was associated with higher risk of a CV event.

Methods: Patients with ≥1 inpatient claim or ≥2 outpatient claims with a primary diagnosis code for MM who were treated with PI and/or IMiD drugs between Jul 2012 and Sep 2014 were identified in a large US claims database. The first claim for a PI or IMiD drug in this period was defined as the index date, which was preceded by 180-d continuous eligibility with no anti-MM treatment (baseline). Patients were divided into three cohorts based on the anti-MM treatment received: PI, IMiD, PI+IMiD. CV events of interest included cardiac arrhythmia, cardiac failure, venous thromboembolism (VTE), myocardial infarction, ischemic heart disease, deep vein thrombosis, and pulmonary embolism, and were measured during anti-MM treatment. Kaplan–Meier methods were used to estimate the occurrence rate of a CV event, and multivariate Cox regression models were developed to identify prognostic factors of each CV event among patients treated with anti-MM therapies.

Results: 4288 patients met the eligibility criteria for inclusion in the study (57% male, median age 66.4±11 years with Charlson Comorbidity Index 2±0.5), median duration of treatment 192±54 days. 42% (n=1779) were treated with PIs, 38% (n=1624) with IMiDs and 20% (n=865) with PI+IMiDs. Patients receiving PI+IMiD were significantly younger and generally had lower prevalence of CV comorbidities compared to those receiving PI or IMiD (Table). Compared with patients on PI, the risk of developing VTE was 46% greater in patients on PI+IMiD (HR 1.46; 95% CI: 1.09, 1.96). Compared with those on IMiD, the risk of developing cardiac failure and cardiac arrhythmia was 33% and 18% greater in patients on PI+IMiD (HR 1.33; 95% CI: 1.03, 1.72; HR 1.18; 95% CI: 1.00, 1.40). After 6 months of treatment, the rates of VTE were 8%, 10%, and 11% for patients on a PI, those on an IMiD and those on PI+IMiD, respectively. The corresponding rates for cardiac failure were 18%, 11% and 11% for PI, IMiD and PI+IMiD cohorts, and 21%, 16% and 22% for cardiac arrhythmia.

Summary/Conclusions: PI+IMiDs may be associated with incremental occurrence of specific CV events during treatment, and may result in specific CV events earlier during therapy than PIs or IMiDs alone. These highlight a need for treatments that do not exacerbate CV risks and are appropriate for patients with pre-existing CV conditions. The lower prevalence of baseline CV comorbidities and lower mean age in patients on PI+IMiDs suggest that prevalence of a CV comorbidity and age influences treatment choice. Further analysis may be necessary to better understand the impact of baseline CV comorbidities on choice of MM treatment.
**Methods:** We collected the clinical data of 169 patients qualified to therapy/oncology centers. VTD protocol recommended by Polish Multiple Myeloma Group and local preferences. Observations from routine practice might have though not to align with those of ELOQUENT-2.

**Aims:** We performed a historical comparison based on a systematic review of studies with a follow-up of 16–25 months were evaluated separately from studies with a follow-up of >30 months; these observation periods approximately align with those of ELOQUENT-2.

**Results:** From an initial bibliographic search yielding 5155 non-duplicate results and 6192 registry results, 7 studies (8 publications) met the inclusion criteria (4 Ld studies, 3 LD studies). Data for overall survival and tolerability from 1153 patients in the Ld group and 353 patients in the LD group were analyzed. The median patient age was 63–68 years. Most patients were white, male and had an ECOG score of 0.

**Summary/Conclusions:** Overall survival and safety are not significantly affected by different dosing of dexamethasone in combination with lenalidomide; thus, use of Ld or LD should be based on the patient population. Further studies may provide additional evidence to inform clinicians and revision of international guidelines for dexamethasone dosing in RRMM.
E1259
IMPACT OF IMMUNOPARESIS IN PATIENTS WITH LIGHT CHAIN AMYLOIDOSIS
L. G. Rodríguez-Lobato1,*, C. Fernández de la Larrea1, M.T. Cibeira1, N. Tovar2, J.I. Aróstegui2, L. Rosshol1, M. Elena3, J. Yague4, J. Bladé5
1Department of Haematology, 2Department of Immunology, 3Department of Biochemistry, Hospital Clinic, Barcelona, Spain

Background: The presence of immunoparesis (IP) at diagnosis in several plasma cell disorders is a risk factor for progression, associated with an unfavorable outcome with reduced progression-free survival (PFS) and overall survival (OS). However, its impact in light chain (AL) amyloidosis has been evaluated only in few series, and when present it was associated with worst response and survival.

Aims: The aim of this study was to investigate the prognostic impact of IP in patients with newly diagnosed AL amyloidosis at a single institution.

Methods: We reviewed the clinical records of patients with AL amyloidosis diagnosed from January 2006 to December 2016. Sixty-nine patients (32F/37M; median age at diagnosis 62) with available immunoglobulin (Ig) measurements were the final study population. Initial baseline demographics, clinical and laboratory data, treatment and follow-up were collected. Median follow-up was 30.2 months. IP was defined as suppression of all uninvolved Ig below the lower reference value. PFS and OS were calculated from the date of diagnosis.

Results: Forty-three patients (62.3%) were transplant ineligible while 26 (37.7%) underwent an autologous stem cell transplantation (ASCT). The distribution of the monoclonal protein isoform by immunofixation at diagnosis was as follows: light chains only (46.4%), IgG (39.1%), IgA (10.2%) and IgM (4.3%). The predominant light chain isoform was lambda (79.7%). A very good partial response (VGPR) or better was achieved in 53.6% of patients. Three-year OS rate was 64.3%. IP was observed in 27.5% of the patients at diagnosis. Patients with IP had a higher bone marrow plasma cells (BMPC) infiltration (29 vs. 9; P<0.001). Also a trend towards a higher difference between involved and uninvolved free light chains was observed in the group of patients with IP (360.2 vs. 221.7; P=0.08). IP was more frequent in those who received an ASCT (57.9% vs. 42.1%; P=0.03). There were no changes in the frequency of IP comparing at diagnosis vs. post-ASCT settings (39.13% vs. 34.78%; P=0.4).

Regarding its prognostic value, IP did not influence survival in the whole series. In the ASCT group, the presence of IP resulted in a significantly shorter PFS (median: 30.2 months vs. NR; P=0.019; Figure 1A) and OS (62.5 months vs. NR; P=0.097). In the group of patients with stage I and II of the Mayo risk stratification system of 2012 (Mayo12), the presence of IP resulted in a shorter PFS (21.8 months vs. NR; P=0.047; Figure 1B), but not significantly different in OS. Multivariate analysis restricted to the population of patients with stage I and II of Mayo12, incorporating ASCT, BMPC and IP, indicate that IP retained its independent prognostic factor for worse PFS (HR=12.05; 95% CI, 1.9-75.7; P=0.008).

Summary/Conclusions: The presence of IP has a negative impact on survival, especially in the sub-group of patients in early stages of the disease. The presence of IP at diagnosis could be an additional powerful discriminatory prognostic indicator in the group of patients without advanced stage of the Mayo risk stratification system of 2012.

Table 1.

E1260
TREATMENT PATTERNS AND DURATION OF TREATMENT IN JAPANESE MULTIPLE MYELOMA PATIENTS RECEIVING SECOND LINE THERAPY WITH NOVEL AGENTS
G. Jun1,2,*, 1K. Mizuhara1, H. Shinzo1, T. Skaeke3, K. Iwasaki4, J. Seoeda4
1Japan Medical Affairs, Takeda Pharmaceutical Company Limited, 2Department of Public Health, Juntendo University School of Medicine, Tokyo, Japan, 3Global Medical Affairs, Millennium Pharmaceuticals, Inc., a wholly subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, MA, United States, 4Milliman, Tokyo, Japan

Background: The introduction of novel agents, such as proteasome inhibitors (PsIs) and immunomodulatory drugs (MiMDs) approved in 2006 and 2010, respectively, and/or autologous stem cell transplantation (SCT) are associated with improved overall survival of 60-6 months in Japanese multiple myeloma (MM) patients (pts) (Ozaki et al. Blood Cancer Journal 2015). However, the disease still remains incurable with disease relapse being inevitable after frontline therapy (FLT). Data regarding treatment patterns and duration of treatment (DOT) of Japanese pts with relapsed and refractory (RR) MM in routine clinical practice is limited.

Aims: This retrospective study aims to describe the treatment patterns and DOT of second-line therapy (SLT) with PI- and IMiD-based regimens and to assess factors that influence treatment choice and DOT of SLT in Japanese MM pts.

Methods: This is retrospective cohort study in pts with MM diagnoses with ICD-10-CM (C900) codes between April 2008 and January 2016 in Japan. This study used Japanese health insurance data provided by Medical Data Vision. MM pts receiving SLT were included. Index date was defined as the first observed claim for MM treatment and SLT was defined as switch to another drug combination≥60 days or retreatment following a treatment gap>90 days after starting FLT. Pts with salvage SCT were excluded. Observations were censored at loss to follow up, death or the end of study period. Kaplan-Meier analyses were performed to calculate DOT from the start of SLT. Welch’s test was used to test for statistical significance between groups.

Results: Among 356 pts receiving SLT, mean age was 68.8 years of age (yo); 65.3% were ≥65 yo at start of SLT; 54.2% were male. Most pts received lenalidomide (L)-based SLT (35.4%), followed by bortezomb (B)-based regimens (29.4%) and other regimens not containing novel agents (35.2%). Other regimens included thalidomide, cyclophosphamide, etoposide, melphalan, vincristine, (liposomal) doxorubicin, interferon, panobinostat, single-agent steroid; only 1.2% received B+L combination therapy. L+D and B+D were the most common (35.2% vs 21.7%) in SLT. Majority of Japanese pts received B-based regimen in FLT among those receiving L+D and B+D SLT (77.2% vs 55.1%). Pts with peripheral neuropathy (PN) and renal insufficiency (RI) prior to SLT were 30.3% and 15.6%, respectively; those with PN were more likely to receive L+D compared to B+D (35.9% vs 21.3%; P=0.0047), but those with RI was not independently associated with treatment choice of SLT. Median DOT of L+D was longer than B+D (13.8 vs 6.9 months, P<0.0001); DOT was similar for those without a front-line SCT and receiving B+D FLT in both regimens (11.9 vs 11.9 months). PN and RI prior to SLT and age have not shortened the DOT in SLT. Additionally, 35.4% experienced PN during SLT among pts receiving L+D and B+D in SLT but there was no statistical significant difference of DOT between pts with and without PN. Median daily dose of L was 12.0mg: there was no significant difference of DOT between pts received at least and less than 12.0mg.

Summary/Conclusions: Among pts in SLT, 65% of Japanese pts obtained L- and B-based regimens. This observation is similar to the United States (Romanus et al. EHA 2016) and Europe (Raab et al. EHA 2015). Majority of pts did not receive triplet-based regimen. Pts experienced PN in FLT were more likely to initiate L-based therapy in SLT and regimen type in SLT was correlated with DOT. Future research is needed to better understand treatment changes in routine clinical practice and the impact on pts’ outcomes, especially, after integration of novel agent-based triplet combinations as new standards of care in RRMM in Japan.

ROLE OF HEAVY/LIGHT CHAIN RATIO IN MYELOMA PATIENTS ACHIEVING COMPLETE RESPONSE AFTER FIRST LINE THERAPY
F. D’auria1,*, F. La Rocca1, V. Simeon1, T. Statuto1, G. Pietrantuono1
1Division of Haematology, Juntendo University School of Medicine, Tokyo, Japan, 2Globus, Rome, Italy

Background: Several studies have shown that serum free light chain (sFLC) concentrations, in particular the ratio of sFLC lambda/kappa (L/D) or sFLC light chain ratio (L/L+D), have been associated with outcome in multiple myeloma (MM) patients.
Background: Polyclonal antibodies against the conformational epitopes between the heavy and light chains (HLC) of immunoglobulin (Ig) have been recently introduced as diagnostic tool in multiple myeloma (MM) and other monoclonal gammopathies. They separately identify the two different light chain types of each Ig, allowing the quantification of the monoclonal component. HLC and k/λ ratios may be particularly useful for monitoring the presence of monoclonal component in oligo-secretory MM or when it migrates in the β region, as frequently observed in IgA MM. The International Myeloma Working Group (IMWG) has published in 2016 new consensus criteria for assessing response and minimal residual disease (MRD) in MM, outlining the potential role of HLC assay in this setting and the need of its further investigation, particularly in patients with oligo-secretory disease. Our goal was to evaluate the diagnostic and prognostic role of HLC ratio in patients achieving complete response (CR) after treatment.

Aims: We conducted a single center, prospective study of HLC ratio, in comparison with free light chain (FLC) ratio, for the evaluation of MRD and its prognostic role in MM patients achieving CR after first line treatments including novel agents.

Methods: Twenty-five consecutive patients were evaluated. Mean age was 63 years (range 43-92), fourteen patients were males. Ig lambda isotype was IgG λ or IgA λ in 14 and 11 patients, respectively, with 20 patients showing kappa and 5 lambda light chains. According to International Staging System, seven patients had stage 1, ten stage 2 and eight stage 3. Fourteen patients not eligible to autologous stem cell transplantation (AuStC) received a bortezomib-based treatment mainly constituted by bortezomib, melphalan and prednisone combination (VMP), while eleven patients underwent AuStC after induction therapy with bortezomib, thalidomide and dexamethasone (VTD). With a median follow-up of 52 months (range 21-92), overall survival (OS) of the entire cohort was 61 months (95% CI 52-80) and progression-free survival (PFS) was 26 months (95% CI 14-45). CR was significantly associated with better PFS (43 months, 95% CI 14-45) vs 35 months (95% CI 10-38), p=0,049. In contrast, normalization of HLC ratio had no impact on PFS (26 months, 95% CI 10-38) and progression-free survival (PFS) was 26 months (95% CI 14-45) vs 35 months (95% CI 10-38), p=0,049. Neither FLC, nor HLC affected OS. There were no differences between patients who received AuStC and those who did not.

Summary/Conclusions: To the best of our knowledge, this is the first study to analyze HLC ratios exclusively in MM patients in CR. While our preliminary data confirm the prognostic usefulness of FLC in this setting, currently they do not support a role for HLC as putative biomarker of MRD.

E1262
REAL-WORLD RESULTS OF DARATUMUMAB MONOTHERAPY IN HEAVILY PRETREATED RELAPSED/REFRACTORY MULTIPLE MYELOMA IN POLAND: A PROSPECTIVE OBSERVATIONAL STUDY OF THE POLISH MYELOMA GROUP

Summary/Conclusions: In this first real-world analysis we confirm that daratumumab monotherapy is able to induce response in one third of highly pretreated and double refractory RRMM patients. Regarding safety, in contrast to the SIRIUS trial where no treatment discontinuations due to AEs occurred, 3/26 pts (11%) treated with daratumumab in clinical practice had their therapy interrupted due to complications.

E1263
REAL-WORLD TREATMENT PATTERNS AND PATIENTS CHARACTERISTICS IN MULTIPLE MYELOMA ACROSS EUROPE

A. Fernandez1,*, A. Zomas1, E. Papakostas1, T. Do1, M. Russo2, R. D’Ambrosio1, G. Schneidewind1,1 EUCAN Medical Affairs,2 Global Market Access, Takeda, CH-8152 Glattpark-Opfikon (Zurich), Switzerland

Background: Emerging resistance to modern antimyeloma agents such as proteasome inhibitors (PIs) and immunomodulatory drugs (IMDs) remains the main clinical problem in managing multiple myeloma (MM). Daratumumab, a first-in-class anti-CD38 monoclonal antibody, has been recently approved in Europe as a monotherapy for patients (pts) with relapsed and refractory multiple myeloma (RRMM), whose prior therapy included a PI and an IMID and whose disease had progressed during this time; based on the SIRIUS clinical trial outcome (Lonial et al. Lancet 2016). Nevertheless to optimize daratumumab use in clinical practice, more data on its “real life” activity and safety are still required.

Aims: This observational study of the Polish Myeloma Group (PMG) was aimed to prospectively evaluate the efficacy and toxicity of daratumumab monotherapy in RRMM patients treated in Poland (DaraCUP).

Methods: Patients were eligible for DaraCUP if they met all the following criteria a) confirmed diagnosis of RRMM, b) relapse after a minimum of 3 prior lines of therapy, c) were double refractory (PI and IMID) or were double refractory (PI and IMID) and had a ECOG performance status score 2 or lower. Data on treatment outcomes and complications were anonymously collected using electronic CRFs. The IMWG response criteria were applied.

Results: In total 30 patients were qualified to DaraCUP in Poland and all were enrolled to the PMG observational study. At the time of writing this report, 26 pts (87%) had received at least one dose of daratumumab and were included in the safety analysis, while 22 pts (73%) had received at least 2 cycles of daratumumab and were included in the preliminary efficacy analysis. Baseline pts characteristics are reported in Table 1. Pts were heavily pretreated, with a median of 4 prior lines of therapy (range, 2-10). Ten pts (38.5%) were double refractory to both PI and IMID while 15 pts (53%) were refractory to the last line of previous therapy.

Median time since initial diagnosis to start of treatment with daratumumab was 3.9 years (range, 1.4-12.2 years). At the time of analysis, the median follow-up time within the study was 5.1 months (range, 0-8 months) and median cumulative treatment duration was 4.5 months (range, 7-8 months). Sixteen pts (61.5%) remained on treatment, while ten pts (36.5%) discontinued therapy as a result of disease progression (n=7) and adverse events (AEs) (n=3). Overall response rate (PR or better) was 31.8% including one (4.5%) CR and two (9%) VGPR (Table 1). Stable disease was reported in 11 (30%) pts. The median PFS and OS had not been reached. During the treatment, the observed treatment side effects were recorded due to disease progression. Regarding daratumumab toxicity, grade 3 or 4 non-haematological toxicities occurred in 8 pts (30.7%) and included: infection-related reactions (n=2), pneumonia (n=2), other infections (n=2), mandible inamllation (n=1), dyspnoea (n=1). The most common haematological toxicities were grade 4 anemia (n=30.7%) and neutropenia (n=23.1%); while thrombocytopenia occurred in 3 pts; 11.5%. Grade 3 or 4 anaemia and neutropenia were found in 3 (11.5%) and 2 (7.7%) pts, respectively. Updated results will be presented at the meeting.

Table 1.
Background: Multiple myeloma (MM) is the second most common haematological malignancy after non-Hodgkin lymphomas, accounting for 13% of blood malignancies and 1% of all cancers. The medical management of multiple myeloma has changed over the years and is influenced by multiple factors (e.g., evidence from clinical trials, drug approval status, level of drug reimbursement, guidelines), which vary across Europe. Information describing how patients are managed may vary across the real world and may need to be improved.

Methods: Physicians in Europe were requested to answer a series of questions on patient characteristics and treatment regimens of the last eight patients that they had treated during the month prior to answering the questionnaire, according to their patients’ medical charts. The questionnaire was conducted between January and June 2016. Data on 2564 patients with MM were available and are presented here. Countries were grouped into regions according to similar health care systems: Spain, Portugal, Italy and Israel (Southern Region, SR, n=522); Greece, Austria, Bulgaria, Czech Republic, Latvia, Lithuania, Poland, Serbia, Slovakia (Eastern Region, ER, n=689); Analy- ses were descriptive.

Results: Patient characteristics were generally similar across regions, with the majority being >75 years old (69-76%), receiving frontline therapy at study inclusion (57-58%), and being ineligible for autologous stem cell transplan- tation (ASCT) (53-59%). The median time from MM diagnosis to the time that the physician answered the questionnaire was higher in ER (19.5 months) than other regions (9.7-11 months) (Table). The majority of frontline regimens contained bortezomib, although this was lower in ER (51%) than in other regions (66-70%). The median duration of frontline therapy was longer in ER (4.5 months) than other regions (3.2 months). This difference was mainly driven by ASCT eligible patients having longer duration of therapy in ER (4.5 months) than other regions (2.9 months). The number of bortezomib injections in frontline therapy, however, was higher in SR and CRN (both 24) than in ER (18). The majority of second line regimens contained lenalidomide (57-64%) in all regions except ER, where bortezomib-based regimens were most frequent (38%). The median duration of second line therapy was shorter in SR and CRN than in ER (Table). Moreover, second line therapy, ASCT eligible patients had shorter duration of therapy in ER and SR (3.2 months) than in CRN regions (4.5 months). The majority of later-line (3+) regimens were based on therapies that did not include bortezomib, lenalidomide or pomalidomide for all regions (57-67%) with the exception of SR where pomalidomide (29.4%), lenalidomide (12.6%) and bortezomib (14%) were the preferred options. In this analysis conducted in Europe, treatment patterns differed in terms of regimens used and duration of therapies even though patient characteristics were generally similar across regions. This may in part be related to differences in healthcare systems. Further research is required to understand how new therapies can be integrated into current treatment patterns and how these treatment patterns impact patient outcomes.

Summary/Conclusions: In this analysis conducted in Europe, treatment patterns differed in terms of regimens used and duration of therapies even though patient characteristics were generally similar across regions. This may in part be related to differences in healthcare systems. Further research is required to understand how new therapies can be integrated into current treatment patterns and how these treatment patterns impact patient outcomes.

Summary/Conclusions: This study shows that the prevalence of frailty syndrome is high and has a profound impact in early death. It is also independently associated with a worse prognosis. Frailty should be considered as part of the clinical assessment when treating elderly patients with myeloma.

PROGNOSIS OF AL AMYLOIDOSIS WITH KIDNEY INJURY

A. Talbot1,2, X. Belenfant2

1Immunology, hospital Saint Louis, paris, 2Neprology, chiag, montreuil, France

Background: AL amyloidosis is a rare disease related to excessive and uncon- trolled secretion of monoclonal light chains. The consequence of this prolifer- ation is an alteration of the affected organs due to deposition of free light chains. Despite therapeutic advances in recent years based, among others, on the finding of French studies, the prognosis of this disease remains poor in particular for patients with cardiac disease. Kidney involvement is also frequently observed in the form of a classic renal amyloidosis, but at present the prognosis of chronic renal failure in this context is unknown.

Aims: The study was interested in the prognosis of AL amyloidosis associated with endstage renal disease on dialysis in the era of treatment with bortezomib.

Methods: A total of 133 patients (61 from ile-de-France region register and 72 from reference center) were evaluated. Median survival was 63.6 months compared to 70.6 months for patients without dialysis (p=0.65). Within the group
of patients on dialysis, there is no significant difference between those receiving or not bortezomib. Median survival before 2008 was 54.82 months and rose to 82.30 months for patients treated after this date (p=0.95). Age (HR: 0.2819, CI 0.1375 to 0.5782), heart disease (HR: 0.3746, CI 0.1724 to 0.8141) and serum albumin (HR: 2.50 CI: 1.077 to 5.803) were identified as prognostic factors. Transplantation is a viable treatment option for good responders.

**Summary/Conclusions:** Prognosis of AL amyloidosis in dialysis is heterogeneous. Prognostic scoring integrating clinical biological data could identify the patient who may benefit the most dialysis. This results need to be matched by sex and age with non-dialysis and dialysis for another cause.

---

**E1267**

**FDG-PET IN MULTIPLE MYELOMA: DUAL TIME POINT FDG UPTAKE IN FOCAL LESIONS CORRELATE TO RESPONSE TO CHEMOTHERAPY**

1Hematology, Odense University Hospital, Odense, Denmark, 2Radiology, Hospital of the University of Pennsylvania, Philadelphia, United States, 3Nuclear Medicine, 4Radiology, Odense University Hospital, Odense, Nuclear Medicine, 5Hematology, Vejle Hospital, Vejle, Denmark

**Background:** Dual Time Point (DTP) 18F-FDG PET imaging has been shown to be useful in differentiating malignant from benign lesions in that increasing uptake from 1 to 3 hours is a characteristic feature of malignancy in contrast to inflammation.

**Aims:** The aim of this study was to evaluate the predictive role of DTP 18F-FDG PET/CT imaging in assessing response to chemotherapy in multiple myeloma (MM).

**Methods:** 23 patients with MM (21 male, aged 53-75 years) underwent 18F-FDG PET/CT in a prospective study (NCT02187731) before start of treatment and two months after high dose chemotherapy with stem cell support. All scans were performed at 60 and 180 minutes after tracer injection at Odense University Hospital and Vejle Hospital. Thirteen patients with ≥3 focal lesions of at least 10 mm were selected for analysis. Images were analyzed using an adaptive thresholding algorithm (ROVER software; ABX GmbH, Radeberg, Germany). Focal malignant lesions were localized in pre-treatment scans; maximum standard uptake value (SUVmax) and mean SUV (SUVmean) and partial volume corrected SUVmean (pSUVmean) were obtained for each lesion. Response to chemotherapy was classified as complete or partial in the post-treatment scan. A complete response was defined as a complete resolution of the lesion in the post-treatment scan. Lesions with partial response were present in the post-treatment scan. All statistical analyzes were done in SPSS 24 using repeated measurements-ANOVA.

**Results:** Three-five focal lesions were evaluated in each patient. In the pre-treatment PET studies, the increase in SUVmean from 1 to 3 hours was significantly higher for lesions with partial response compared to lesions with complete response (27.7% vs 11.4%; P=0.050). Additionally, the increase in pSUVmean was more significant than the increase in SUVmean (+42.23% vs +12.0%; P=0.003). The increase in SUVmax of delayed scans was not significant (P=0.082).

**Summary/Conclusions:** These preliminary data show that a more significant increase of FDG uptake in delayed scans of DTP PET before treatment correlate with patients who achieved a greater response to stem cell support.

The increase in pSUVmean is a better index than that of SUVmean and SUVmax for this purpose.

**UNDERSTANDING THE CONTRIBUTE OF THE NOTCH PATHWAY IN MULTIPLE MYELOMA BONE MARROW NICHE: A FOCUS ON EXTRACELLULAR VESICLES-MEDIATED COMMUNICATION**

M. Colombo1, F. Baccianti1, L. Cantone2, N. Moschini1, N. Platono3, S. Garavelli1, M.T. Palano1, R. Adam1, A. Neri1, V. Bolla3, R. Chiaromonte 1

1Dept. of Health Sciences, 2Dept. of Clinical Sciences and community health, 3Dept. of Oncology and Hemato-Oncology, Università degli Studi di Milano, Italy

**Background:** Multiple myeloma (MM) is an incurable cancer stemming from malignant plasma cells. MM is characterized by a strong tropism to the bone marrow (BM), where tumor cells accumulate and establish complex interactions with the normal stroma, which in turn promotes tumour survival, drug resistance and the development of bone disease. The Notch oncogenic pathway provides a key contribute to the ability of MM cells to shape the BM niche, affecting both MM cell biology and the interplay between MM cells and BM. Only extracellular vesicles (EVs) have been reported as novel mediators in creating a supportive milieu for MM. Here we investigate the role of the activated Notch signaling in EV-mediated cross-talk.

Aims: To further elucidate the role played by the Notch pathway in the shaping of the BM microenvironment to provide a supportive milieu for MM cells, with a focus on the contribute of EVs to the crosstalk between MM cells and the BM stromal cells.

**REAL-WORLD DATA ON THE TREATMENT OF RELAPSED/REFRACTORY MYELOMA WITH LENALIDOMIDE AND DEXAMETHASONE IN 2ND LINE (LEGEND STUDY): THE PROGNOSTIC SIGNIFICANCE OF BIOCHEMICAL VS. CLINICAL RELAPSE**

1Department of Haematology, Theagianon Cancer Hospital, THESALONIKI, 2National and Kapodistrian University of Athens, Laikon Hospital, 3Department of Haematology and Bone Marrow Transplantation Unit, Evangelismos General Hospital, ATHENS, 4Department of Transfusion Medicine, University of Larissa, LARISSA, 5Department of Internal Medicine 1, University of Patras Medical School, PATRAS, 6Department of Haematology, Democritus University of Thrace, ALEXANDROUPOLIS, 7Department of Haematology, University of Larissa, LARISSA, 8Department of Haematology and Bone Marrow Transplantation Unit, G. Papankolaukou General Hospital, 9Department of Haematology, Paphiagorou General Hospital, 10Department of Haematology, Ag. Anargirou General Hospital, Athens, 11Department of Haematology, University of Ioannina, School of Medicine, IOANNINA, 12Department of Haematology, Metaxa Cancer Hospital, PIRAEUS, 13Department of Haematology, Kalamata General Hospital, KALAMA, 14Department of Haematology, Vostanio General Hospital, MYTILINI, 15Department of Haematology, Attikon General Hospital, National and Kapodistrian University of Athens, 16Department of Haematology, University General Hospital, HERAKLION, 17Department of Clinical Therapeutics, National and Kapodistrian University of Athens, ATHENS, Greece

**Background:** The combination of lenalidomide/dexamethasone (LenDex) is an established treatment for relapsed/refractory Multiple Myeloma (MM) patients; however, apart from clinical trials, there is limited data for the efficacy of this combination as 2nd line treatment. Furthermore, the efficacy of LenDex when administered before evident clinical manifestations, namely in the case of biochemical relapse as compared to clinical relapse, has not yet been assessed.

**Aims:** In the current study, we evaluated response rates and progression-free survival (PFS) in patients treated with LenDex in 2nd line and we compared survival of patients treated with LenDex at biochemical relapse vs those treated at clinical relapse.

**Methods:** Medical files of 207 patients with MM diagnosed between 2000-2013 in 18 Greek centers and treated with LenDex as 2nd line treatment from January 1st 2009, up to March 1st 2014, were retrospectively studied. Overall response and PFS were evaluated for all patients. Additionally, PFS was compared in patients treated at either biochemical relapse (group A) or at clinical relapse (group B). The prognostic significance of biochemical relapse adjusted with important patients' characteristics was also evaluated. Classical methods were used for statistical analysis.

**Results:** Two hundred and seven patient files were recorded and analyzed (M/F: 112/95, median age: 67.2y, range 31-91y; IgG: 115, IgA: 55, Light chain: 11.4%; P=0.050). Additionally, the increase in pSUVmean was more significant than the increase in SUVmean (+42.23% vs +12.0%; P=0.003). The increase in SUVmax of delayed scans was not significant (P=0.082).

**Summary/Conclusions:** Our data confirm that LenDex combination as 2nd line treatment leads to high overall response rates and prolonged PFS. Additionally, we have shown for the first time in routine clinical practice that MM patients who receive 2nd line therapy with LenDex at biochemical relapse have a significantly longer median PFS compared to patients treated at clinical relapse, underlining the importance of potentially starting treatment before evident clinical manifestations at the first relapse.
Methods: We established two MM cell lines stably retaining the doxycycline-inducible pTRIZP vector containing anti-Jagged1 and Jagged2 shRNAs and a BM mesenchymal stromal cell (BMSC) line expressing shRNAs for Notch1 and Notch2. EVs were isolated by ultracentrifugation and used for functional assays and molecular analysis. qPCR was performed using SYBR Green. Apoptosis analysis was performed by flow cytometry; evaluation of protein expression was by Western blot analysis or western transfer. Results: We present evidences that EVs play a crucial role in the dysregulated interactions of MM cells with the BM microenvironment and that Notch regulates their release. Indeed, BMSCs knocked down for Notch1/2 results in a decrease in EVs release and reduce their ability to induce Bortezomib resistance in MM cells and to stimulate their migration. On the other side, MM-derived EVs are able to increase the production of pro-tumor factors by BMSCs (i.e. SDF1α), promoting their ability to boost tumor growth; interestingly, this effect is lost when EVs are isolated from MM cells where the Notch pathway was inhibited. Finally, EVs released by co-cultures of BMSCs and MM cells where the Notch pathway is blocked display a reduced ability to increase osteoclastogenesis compared to those from the control culture. This is particularly relevant due to the crucial role played by bone disease in MM progression.

Summary/Conclusions: These new insights in the pathophysiology of the de-arranged BM niche represent the rationale for a Notch-directed therapy aiming to uncouple the crosstalk of MM with the surrounding microenvironment by inhibiting Notch signaling.

E1269
THE USE OF CARFILZOMIB AND BORTZEOMIB IN ROUTINE CLINICAL PRACTICE: RESULTS FROM PREAMBLE, AN ONGOING, OBSERVATIONAL COHORT STUDY IN MULTIPLE MYELOMA
B. Dure1,2,3, G. Cook2, H. Goldschmidt2, D. Kuten2, T. Zycznyski2, S. Popov2, M. Goorish2, C. Davis2, R. Vij2
1Cedars-Sinai Medical Center, Los Angeles, United States, 2University of Leeds, Leeds, United Kingdom, 3Heidelberg University Hospital, Heidelberg, Germany, 4Massachusetts General Hospital Cancer Center, Boston, 5Bristol-Myers Squibb, Lawrenceville, United States, 6Parexel, St Petersburg, Russian Federation, 7Washington University School of Medicine, St Louis, United States

Background: Multiple myeloma (MM) remains largely incurable despite improvements in clinical outcomes following the approval of immunomodulatory drugs (IMiDs) and proteasome inhibitors (PIs) (Rajkumar et al 2010). Previous findings suggested that time to next therapy (TTNT) was an important predictor of treatment success (Kumar et al 2011). However, the clinical implications of TTNT are not well understood. The aims of our study were to evaluate the clinical implications of TTNT and to describe how patients managed to achieve this. Aims: In this subsequent PREAMBLE analysis, treatment patterns in patients (pts) with RRM receiving bortezomib (bort) and carfilzomib (carf) were evaluated to better understand the use of pts in routine clinical practice.

Methods: PREAMBLE (NCT01838512) is an ongoing, observational, interna- tional cohort study exploring real-world treatment patterns and outcomes in pts with MM. Eligible pts were aged ≥18 yrs with diagnosis of RRMM, ≥1 prior treata- ment and initiated treatment (index therapy) with an IMiD, PI or IMiD+PI within 90 days before to 30 days after study enrollment. Treatment patterns, DoT and time to next treatment (TTNT; for pts who switched or died) were assessed. Informed consent was obtained for all pts.

Results: At data cut-off (Sept 1, 2016), data were available for 924 pts, of which 326 (35%) pts had bort-based index therapy and 86 pts (9%) received carf-based index therapy (63/72 [88%] were enrolled in North America). The most common bort-based combination was bort + dexamethasone (dex; n=99; 30%). The most common carf-based therapies were carf alone (n=40; 47%), followed by carf+dex (n=21, 24%). The most widely used bort dose per 21 days for any bort-based therapy was 1.4mg/m2 (28/55; 51%). Switch from carf-based index therapy occurred after a median (Q1, Q3) DoT of 3.4 (1.9, 9.5) mo (n=34); most pts switched to pomalidomide (pom)-based regimens (23/34; 68%). Switch rates increased from 17% at 3 mo to 57% at 33 mos. The most widely used carf dose per 21 days received for any carf-based therapy was ≤120mg/m2 (89/151; 56%). The most common carf dose per 28 days received for any carf-based therapy was ≥120mg/m2 (28/55; 51%). Serum and urine samples were collected from pts affected with plasma cell dyscrasia referring to the Azienda Ospedaliero-Universitaria Careggi between 1st February 2012 and 31 December 2013. Serum and urine protein electro- phoresis was performed using Capillaries II, serum and urine immunofixation using Hydrasys II (both from Sebia), sFLC were measured on Immage 800 nephro- elution (Beckman Coulter) using Freelite reagents (The Binding Site). Results: We analyzed samples from 387 pts having positive serum and/or positive urinary immunofixation and/or abnormal sFLC ratio. Among them, 43 symptomatic LCMM pts were identified having both sFLC and BJP measure- ment at baseline (at MM diagnosis or first relapse). Serum and urine tests results were evaluated at baseline, monthly during therapy and every 3 months during follow-up. Median duration of laboratory monitoring for the whole group was 42 months (range 3-120). Autologous stem cell transplantation was performed in 30% of pts previously treated with proteasome inhibitors (81%) and/or immunomodulating agents (40%) or chemotherapy (9%). sFLC or BJP were not available in 10% of 872 pair of samples from 43 pts. In 10% of cases (68/696 pair of samples) sFLC ratio was abnormal with increased involved FLC with no detectable BJP (FLC+/sFLC+BJP-); the opposite (FLC-/sFLC+BJP+) occurred in 1% of cases (8/696 pair of samples). Renal failure was found in 9/3 13% of discrepant cases. At baseline, of the 43 LCMM pts, 26 had ‘measurable disease’ only by sFLC due to BJP-200mg/24h and were therefore considered not evaluable for response assessment. Median time to BOR was 3 months by both sFLC and BJP and (range: 1C1-11 mesi; range: BJIP-10 mesi). Among the remaining 37 pts evaluable for best overall response, 6/37 had complete response according to BJP but not to sFLC, interestingly 6/37 progressed after 2-8 months. Twenty-one pts progressed during follow-up: PD was detected only by sFLC in 4, only by BJP in 1. Both tests were able to detect PD in 16 pts: at the same time in 5, with sFLC-PD occurring earlier in 7 and BJP-PD occurring earlier in 4 pts.

Summary/Conclusions: Both sFLC and BJP measurement are useful in LCM pts for disease monitoring, however sFLC assessment appears to be more sensitive in MM and early relapse identification. These data suggest that BJP could be substituted by sFLC assessment in LCM. In our series only 1 case showed BJP-PD according to IMWG occurring earlier than sFLC- PD but was considered not clinically significant. On the contrary 5 pts in BjP-6 had “measurable disease” only by sFLC without having reached FLC-GR. Limits of our study are a small number of pts, inhomogeneous duration of thera- py and follow-up and retrospective analysis.

E1271
SUPPRESSION OF THE NON-MONOCOALANAR AS NEW BIOMARKER FOR DE-NOVO MULTIPLE MYELOMA PATIENTS AT DIAGNOSIS AND AFTER AUTOLOGOUS STEM CELL TRANSPLANTATION
J.L. García De Veas Silva1, 1, M.D.S. López Vellez1, C. Bermudo Guitarte2, R. Rios Tamayo3, M. Jurado Chacón3, T. De Haro Muñoz1
1Department of Laboratory Medicine, Complejo Hospitalario Universitario de Granada, Granada, 2Department of Clinical Biochemistry; Hospital University Doctor Gregorio Marañón, Madrid, Spain, 3Department of Hematology, Complejo Hospitalario Universitario de Granada, Granada, Spain

Background: The outcome for patients with Multiple Myeloma (MM) is highly
variable. Understanding the prognosis for a particular patient can help when selecting the intensity of treatment to be used and the frequency of reviews. The quantification of heavy/light chains pairs by the immunosassay Hevylite (HLC) allows us a precise measurement of monoclonal and non-monoclonal immunoglobulins of the same isotype.

**Aims:** The aim of the study is to evaluate i) the impact of the “HLC ratio” defined as monoclonal immunoglobulin over isotype matched non-monoclonal immunoglobulin (involved/uninvolved HLC ratio or i/u HLC ratio), ii) the suppression on non-monoclonal pair denominated “HLC-matched pair suppression” and iii) the effect of “systemic immunoparesis” at diagnosis and at +100 days after autologous stem cell transplant (ASCT).

**Methods:** 85 patients (50 Male:35 Female) with a median age of 70 years (56-78) were followed (35 IgGK, 18 IgGL, 17 IgAK and 15 IgAL). The median follow-up of the patients was 19 (5-30) months. Sixteen patients (18%) presented ISS stage I, 15 (28%) with stage II and 54 (64%) with stage III disease. Thirty patients that reached ASCT were evaluated at +100 days after ASCT. Immunoglobulin heavy/light chains pairs (HLC) were assessed by Hevylite assays (The Binding Site). Clinical variables were evaluated for their impact on patient’s outcome. Overall survival (OS) and progression-free survival (PFS) were evaluated by Kaplan-Meier method and Cox regression. Statistical analysis was made with Prism 6.0.

**Results:** The median OS of the 85 patients was 54% and 26 patients deceased during the study due to MM. The median value of i/u HLC ratio was 80 (31.5-319.7). At diagnosis, a i/u HLC ratio>80 was significantly associated with worse OS (46 vs 61%, p=0,005) and shorter PFS (23 vs 42%, p=0,006). Severe HLC-matched pair suppression (i.e. more than 50% below the lower reference range) was identified in 68% of the newly diagnosed patients and was associated with significantly shorter OS (35 vs 81%, p=0,004) and PFS (21 vs 50%, p=0,013). Severe (>50%) systemic immunoparesis of non-monoclonal immunoglobulins was identified in 64% of the patients at diagnosis and was also significantly associated with shorter OS (32 vs 81%, p=0,030) but not with shorter PFS (26% vs 44%, p=0,306). The evaluation of other clinical variables on patient’s outcome are shown in table (see Table). In multivariable analysis, severe HLC-matched pair suppression and albumin were found as independent risk factors for OS whereas creatinine and i/u HLC ratio >80 were found as independent risk factors for PFS. In the post-ASCT evaluation of the patients, severe HLC-matched pair suppression and albumin were found as independent risk factors for OS whereas i/u HLC>80 is independently associated with shorter PFS. In patients after ASCT, severe HLC-matched pair suppression reflects the persistence of clonal cells that is not associated with severe systemic immunoparesis.

**Summary/Conclusions:** Severe HLC-matched pair suppression and i/u HLC=80 are associated with worse OS and shorter PFS in MM patients suggesting a potential use of these parameters as prognostic biomarkers in newly diagnosed patients. Severe HLC-matched pair suppression is an independent risk factor for OS whereas i/u HLC>80 is independently associated with shorter PFS. In patients after ASCT, severe HLC-matched pair suppression reflects the persistence of clonal cells that is not associated with severe systemic immunoparesis.

**SURVIVAL STRATIFICATION OF PATIENTS WITH MULTIPLE MYELOMA (MM) AFTER FIRST RELAPSE: SENSITIVITY ANALYSES OF A NOVEL RISK STRATIFICATION ALGORITHM (RSA)**

R. Hajek1,*, M. Delforge 2, M. Raab 3, L. Pour 4, I. Špička 5, E. Gregora6, J. Minařík7, S. Gonzalez-McQuire8, W. Bouwmeester9, V. Maisnar10

1Department of Haematoncology, University Hospital Ostrava, Ostrava, Czech Republic, 2Department of Hematology, UZ Leuven, Leuven, Belgium, 3Department of Internal Medicine V, University Hospital Heidelberg, Heidelberg, Germany, 4Department of Internal Medicine, Hematology and Oncology, University Hospital Brno and Faculty of Medicine, Masaryk University, Brno, 11st Medical Department – Clinical Department of Haematology, 1st Faculty of Medicine and General Teaching Hospital, Charles University, 6Department of Internal Medicine and Hematology, University Hospital Kralovske Vinohrady, Prague, 7Department of Hemato-Oncology, University Hospital Olomouc and Faculty of Medicine and Dentistry, Palacky University Olomouc, Olomouc, Czech Republic, 8Amgen (Europe) GmbH, Zug, Switzerland, 9Pharmerit International, Rotterdam, Netherlands, 10th Department of Internal Medicine – Haematology, Charles University Hospital and Faculty of Medicine, Hradec Kralove, Czech Republic

**Background:** Established risk stratification tools in MM, such as the International Staging System (ISS) and the revised ISS, have improved overall survival (OS) estimates by combining the strongest known predictors of survival at diagnosis. There remains, however, a need for tools that use additional data available at relapse to improve risk stratification. We previously used real-world data from the Czech Registry of Monoclonal Gammopathies (RMG) to develop a RSA for estimating risk of death in patients with MM starting second line (2L) treatment. A multiple Cox regression model identified predictors of OS at 2L (Table); hazard ratios (HRs) for each predictor were multiplied to obtain an overall score for each patient. A K-adaptive partitioning for survival (KAPS) algorithm stratified patients into risk groups based on these scores.

**Aims:** To investigate how our RSA is affected by: 1) removing cytogenetic abnormalities (CAs) at diagnosis as an OS predictor, as these are not routinely measured in practice; 2) adding 2L treatment as a predictor, as 2L treatment type is likely to affect OS; 3) changing the number of stratification groups.

**Methods:** The analyses used data for 1418 patients aged ≥18 years who were diagnosed with symptomatic MM between May 2007 and April 2016 and who had reached 2L. The Cox model was re-run for two sensitivity analyses: excluding CAs and adjusting for treatment received at 2L (adding bortezomib or lenalidomide vs other treatments as a predictor). The impact of different numbers of risk groups was assessed using KAPS.

**Table 1.**
E1273

REAL-WORLD DATA ON MULTIPLE MYELOMA: A PROSPECTIVE NATIONAL REGISTRY IN URUGUAY ON 224 NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS FROM 2012-2015

E. Riva1,*, V. Bove1, F. Villano1, M. Mori2, A. Noria3, P. Petruskevicius4, V. Mariotti2, Y. Wang1, R. Warsame1, R. Go1, A. Adjei3

1Hematology Department, Hospital de Clinicas, Facultad de Medicina, 2Hematology, Hospital Maciel, 3Quantitative Methods Department, Facultad de Medicina, 4Comisión Honoraria de Lucha contra el Cáncer, CHCLL, Montevideo, 5Hematology, Centro Médico, Salto, 6Hematology Department, Asociación Española, 7President, Uruguayan Society of Hematology, Montevideo, Uruguay

Background: The Uruguayan National Myeloma Registry is the first observational prospective Uruguay registry designed to document clinical characteristics of newly diagnosed multiple myeloma (MM) at diagnosis and outcomes in a real-world setting. It collects detailed data, regardless of 2L treatment type. CAs at diagnosis is a known OS predictor and, as expected, improves the strength of predictions. The practicalities of measuring CAs should be considered, but these data suggest that physicians should be encouraged to assess CAs at diagnosis; CAs at relapse may also be informative. Further validation of this model is required using other real-world and clinical trial data.

Aims: To document current strategies of clinical characteristics at diagnosis, management, outcomes and treatment adverse effects of non-selected newly diagnosed MM patients in a recent period.

Methods: This registry includes all MM diagnosed from January 2012 in all institutions, nationwide. Smoldering MM are not included. We present the analysis of the first 3 years of data collection. Information was obtained from medical records and patients include clinical and laboratory characteristics, treatment, disease-related and treatment-related adverse events, response, progression free survival, overall survival and cause of death. Survival is obtained from the Uruguayan Ministry of Health database.

Results: With a 71% institutional coverage, 224 patients were included. Median age at diagnosis was 66 years (range 33-94 years), 54.5% were male; 10% were younger than 50 years and 34.5% older than 70 years. Distribution according Ig subtype was: IgG 50.4%, IgA 23.3%, Light chains 18.7%, non-secretor 2.2% and IgM <1%. Most patients had advanced disease: 79.6% Durie-Salmon stage III (176/221), 48.6% ISS 3 (86/177). Anemia (hemoglobin ≤ 10 g/dl) was present in 48.3%. Osteolytic lesions in 69%, renal impairment (creatinine≥2mg/dl) in 29.5% and hypercalcaemia in 10%. Cytogenetics was evaluated in 150 patients; high risk features were detected in 6.3% by conventional cytogenetics and 19% by fluorescence in situ hybridization. First-line treatment included at least one of the new drugs (Thalidomide, Bortezomib or Lenalidomide) in 92% of patients ≤70 years and in 50% of >70 years. First-line response was available in 73%. Overall response rate (≥PR) was 82.3%, VGPR= 23.2% and CR=15.2%; 9.8% patients achieved stable disease and 7.9% were refractory. Further validation of this model is required using other real-world and clinical trial data.

REPRESENTATION OF MINORITIES, THE ELDERLY AND WOMEN IN MULTIPLE MYELOMA CLINICAL TRIALS

N. Duma1,*, J. Vera-Aguilera1, M. Gonzalez2, Z. R. Parrondo2, J. Paludo1, V. Maricoti1, Y. Wang1, R. Warsame1, R. Go1, A. Adjei3

1Hematology, Mayo Clinic, Rochester, 2Internal Medicine, Rutgers University, Newark, 3Mayo Clinic, Rochester, United States

Background: Multiple myeloma (MM) accounts for approximately 1% of all cancers and 10% of hematologic malignancies in the United States (US). MM occurs in all races but the incidence in African Americans is two to three times higher than in non-Hispanic whites. Many clinical trials (CT) lack appropriate representation of specific patients populations, limiting the generalizability of the evidence obtained. We describe the characteristics of CT in MM.

Aims: Determine the representation of ethnic minorities, the elderly and women in MM CT.

Methods: Enrollment data from all therapeutic trials reported as completed in clinicaltrials.gov from 2000 to 2016 were analyzed. CT including other hematologic malignancies and with recruitment outside of the US were excluded. Enrollment fraction (EF) was defined as the number of enrollees divided by the 2013 Surveillance, Epidemiology, and End Results (SEER) database MM complete prevalence. Chi-square test was used to estimate differences in categorical data.

Results: Out of 177 MM CT, 78 (44%) reported ethnicity with a total of 12,055 enrollees. Out of those 78 CT, 52 (67%) were phase II, 15 (19%) phase III and 11 (14%) phase I. Most of the results were published from 2012 to 2016 (74%). Distribution by race, gender, age and comparison with the SEER MM prevalence data are described on Table 1. Forty-six (59%) trials were sponsored by industry; 7 (10%) by NCI and 52 (78%) were investigator initiated. Participation in CT varied significantly across ethnic groups, non-Hispanic Whites (NHW) were more likely to be enrolled in CT (EF of 0.23) than African Americans (AA) (EF of 0.08, p <0.0001) and Hispanics (His) (EF of 0.05, p <0.0001). Males had
a higher recruitment rate than females (58% vs 42%), but this could be explained by the higher incidence of MM in this subgroup. Enrollee’s median age was 62 years. Younger pts (<65 years) were more likely to be enrolled in CT than the elderly (66% vs 34%, p<0.0001). Industry sponsored trials were less likely to recruit AA compared with investigator initiated trials (7.6% vs 12%, p=0.0001).

Summary/Conclusions: Despite the higher incidence of MM in African Americans and the elderly, the former only represented 8.6% of the study participants and 66% of these were less than 65 years of age, perhaps lacking data in the tolerability of these new agents in our aging MM population. We also observed industry studies were less likely to recruit AA patients. Future trials should take extra measures to recruit participants that adequately represent the United States MM population.

E1275

EVALUATION OF TREATMENT WITH NEUROPATHELY IN MULTIPLE MYELOMA AND ITS INFLUENCE ON PHYSICAL AND ROLE FUNCTIONING B. Sidi Mohamed El Amine1,*, H. Asma1, O. Fouza1, S. A. Najet1, Z. Zahia1 1Hematology department, University hospital of Sidi Bel Abbes, Sidi Bel Abbes, Algeria

Background: Peripheral neuropathy (PN) is a major dose limiting and potentially disabling adverse event of commonly therapeutic drugs used in the management of multiple myeloma (MM), including the immunomodulatory drugs (IMIDS, Thalidomide and Lenalidomide), and the proteasome inhibitor (Bortezomib).

Aims: The aims of this study were to (1) perform a psychometric evaluation of PN and (2) examine the prevalence of this complication and its influence on physical and role functioning of MM patients.

Methods: The FACT/GOG-Neurotoxicity (Ntx) subscale for assessing treatment induced PN was evaluated. The 11-item of this questionnaire was administered to patients with MM treated with IMIDS and/or Bortezomib. The subscale was evaluated in 32 patients for internal reliability, construct validity, criteria validity, and compared to NCI grading adverse events (CTCAE version 3). Spearman rank correlation was calculated to determine the impact of PN on functional, physical and role functioning of MM patients, assessed by EORTC quality of life scale (EORTC QLG-C30). A Cronbach coefficient ≥ 0.8 is good. Spearman rank correlation is significant if p < 0.05 or r > 0.5.

Results: Cronbach alpha coefficient for internal consistency of FACT/GOG-Ntx subscale was 0.92, and its correlation with the full CTCAE scale as follows: P=0.0001. All the 11 items exhibited high correlations with the NTX subscale score (r= 0.65-0.79), and the Construct validity of NTX was good. According to FACT/GOG-NTX and NCI-CTCAE, 24 (75%) patients presented PN secondary to IMID or Bortezomib. The PN was severe in 14 (43, 7%) patients, especially those who received Bortezomib associated with IMIDS (71, 4%). PN did not influence the achievement of a very good response of MM to therapy neither a complete remission (P=0.6), but patients with high scores of NTX subscale have reduced functional activities, especially physical and role functioning. The 11-item FACT/GOG-NTx subscale reliably and validly assesses Bortezomib/IMIDS induced PN. This complication is frequent and can alter the functional abilities of MM patients.

Background: Maintenance therapy post autologous stem cell transplant (ASCT) has been shown to improve clinical outcomes, including time to progression, progression-free survival (PFS), and overall survival (OS) in patients with newly diagnosed multiple myeloma (NDMM) (Sonneveld, J Clin Oncol, 2012; McCarthy, N Engl J Med, 2012; Attal, N Engl J Med, 2012; Palumbo, N Engl J Med, 2014; Attal, ASCO, 2016). However, the effect of continued treatment on healthcare resource utilization (HRU) is mostly unknown. Connect MM is a largely community-based, US prospective observational cohort study designed to characterize diagnosis, treatment patterns, and outcomes in patients with NDMM in clinical practice.

Aims: This analysis used the Connect MM registry to analyze the impact of maintenance treatment on clinical outcomes and HRU in a largely community setting.

Methods: Patients with NDMM who were eligible for enrollment in the registry within 60 days of diagnosis. Patients who completed induction and single ASCT without subsequent consolidation and received lenalidomide (LEN)-only or no maintenance were included in the analysis. HRU (hospitalization rates and length of stay, surgery/procedures, concomitant medications including growth factor, bisphosphonate, and neuropathic pain medication) was assessed from 100 days post-ASCT to the end of years 1 and 2. Data cutoff was Jan 7, 2016 and the median follow-up was 39.3 months.

Results: A total of 1493 patients with NDMM were enrolled in Cohort 1 from Sep 2009 to Dec 2011: 421 patients met the analysis criteria stipulated above. Of these, 108 did not receive subsequent consolidation and were not included in the analysis. A total of 1385 patients (99%) were included in the analysis. Median age at diagnosis was 60 y (range, 24-78); 60% were men, and 86% were white. Baseline patient characteristics except serum haematologica | 2017; 102(s2) | 523
CREATIVE: For patients with NDMM, LEN-only maintenance significantly improved PFS and OS vs no maintenance with no apparent impact on HRU.

E1278

SERUM-FREE LIGHT-CHAINS (SFLC) INSTEAD OF URINE PROTEIN ELECTROPHORESIS (UPEP) FOR MONITORING MULTIPLE MYELOMA (LCMM)

1Haematology, Hospital 12 de Octubre, Madrid, Spain, 2Haematology, Hospital U de Salamanca, Salamanca, Spain, 3Haematology, Hospital Clin i Provincial de Barcelona, Barcelona, Spain, 4Haematology, Hospital Germans Trias y Pujol de Badalona, Badalona, Spain, 5Haematology, Hospital Clínico de Valencia, Valencia, Spain, 6Haematology, Hospital Lozano Blesa, Zaragoza, Spain, 7Haematology, Hospital Morales Meseguer, Murcia, Spain, 8Haematology, Hospital U Son Llatzer, Mallorca, Spain, 9Haematology, Hospital General de Segovia, Segovia, Spain, 10Haematology, Instituto d’Oncologia Dr Josep Trueta de Girona, Girona, Spain, 11Haematology, Hospital U Ramon y Cajal, Madrid, Spain, 12Haematology, Hospital U de la Santa Creu i Sant Pau, Barcelona, Spain, 13Haematology, Hospital La Paz, Madrid, Spain, 14Haematology, Hospital U Son Espases, Mallorca, Spain, 15Haematology, Hospital U San Carlos, Madrid, Spain, 16Haematology, Hospital Universitario de Canarias, Tenerife, Spain, 17Haematology, Clínica Universitaria de Navarra, Pamplona, Spain.

Background: Response and follow-up criteria in multiple myeloma (MM) are still based on the protein electrophoretic (PEP) quantification of the monoclonal protein (MP) in serum (s) and/or urine (u). Monitoring MP by urine (u) PEP has a very low sensitivity for evaluating variations of small amounts of MP. Since 2001, serum free light-chain assays (sFLC) are available, with demonstrated clinical utility. Dejori et al. have recently reported the usefulness of sFLC for evaluating response in LCMM.

Aims: In this work, we try to validate the use of sFLC assay in the context of GEM/PETHEMA clinical trials in order to evaluate the responses and its advantages in comparison to standard quantification of MP by PEP in serum (s) and/or urine (u). Monitoring MP by urine (u) PEP has a very low sensitivity for evaluating variations of small amounts of MP. Since 2001, serum free light-chain assays (sFLC) are available, with demonstrated clinical utility. Dejori et al. have recently reported the usefulness of sFLC for evaluating response in LCMM.

Methods: We included 169 patients with Bence Jones (BJ) MM with measurable urine disease who have been treated according to GEM/PETHEMA clinical trials (GEM05menos65, GEM05MAS65, GEM2010MAS65 and GEM2012 menos65). Serum FLC assays (Freelite®, The Binding Site, Birmingham, UK) were performed on an automated nephelometer (BNII, Dade Behring / Siemens, Marburg, Germany). The electrophoretic study of the monoclonal component (CM) was performed by capillary electrophoresis (V8, Helena Biosciences Europe), and immunofixation was performed for the Ig, κ and λ chains (SAS-3 and SAS-4, Helena Biosciences Europe).

Results: From a total of 168 patients with measurable urine disease (168 patients with BJ MM and 163 Bence Jones kappa / 76 Bence Jones Lambda), 146 (86%) had FLC data at diagnosis, with 139/146 (95%) evaluable by FLCs [involved sFLC ≥100]. In addition, 68 of the 169 patients also had detectable MP in serum and 7 of the 169 had non-evaluable MP in urine (MP <0.200 g/24h). We studied the correlation of both techniques’ MP quantification results (uPEP vs isFLC) and we observed a low correlation (Pearson’s r = 0.293, p = 0.003), that should be partly explained by the low profitability and subjectivity of the electrophoresis technique for quantifying para-protein in urine. Figure 1A. The concordance between the classification of the response by uPEP / immunofixation (IF) and by FLCs (Kappa Index=0.425 vs 0.001) is noted in the Table. The normalization of the sFLC ratio (r) <0.0101) was achieved in 35/98 (36%) patients after treatment, associated to a lower risk of progression (normal vs abnormal sFLCr: PFS 60 vs 39 months, p = 0.038) but without impact in overall survival in our series. We also observed that an absolute value of isFLC greater than 50mg/L after treatment was associated with an increased risk of progression, regardless of the response achieved (PFS 60 vs 28 months, p<0.0001). [Figure 1B].

Figure 1.

Summary/Conclusions: There is an acceptable agreement between both methods for response evaluation. The sFLC assays provide a greater sensitivity than the urine protein electrophoresis for monitoring low levels of disease in certain cases with measurable disease at diagnosis (isFLC ≥100) being useful for its follow-up, and also provide prognostic value as a predictor of progression.

E1279

TOPSPIN: A NOVEL ALGORITHM TO PREDICT TREATMENT SPECIFIC SURVIVAL IN CANCER

J. Uebels1,2,3,*, E.H. van Beers2, A. Broijl2, P. Sonneveld2, M.H. van Vliet3, J. de Ridder4

1Center for Molecular Medicine, UMC Utrecht, Utrecht, 2Department of Hematology, Erasmus MC Cancer Institute, 3SkyslineDx, Rotterdam, Netherlands

Background: In recent years many novel treatments have been introduced for Multiple Myeloma (MM), leading to an improved survival. However, this has also led to the situation where many different treatment combinations are used, without a clear indication which patient will benefit most from which treatment. It is increasingly recognized that genetic heterogeneity between tumors influence treatment response. Patient outcomes may be improved by selecting the right treatment for the right patient at the moment of diagnosis. This requires the discovery of predictive markers, for example gene expression signatures, that can aid in this treatment decision. Here we present TOPSPIN (Treatment Outcome Prediction using Similarity between PatientNts), a novel algorithm to discover such markers from tumor gene expression data. We use it to identify patients more likely to benefit from bortezomib.

Aims: This algorithm aims to develop a classifier that identifies a subset of patients that will benefit more from a treatment of interest than similar patients who receive a different treatment.

Methods: TOPSPIN aims to predict whether a patient will benefit (class 1) or not benefit (class 0) from a certain treatment of interest based on the gene expression profile of the patient. This algorithm relies on the idea that genetically similar patients who received a different treatment should have a large difference in survival, given that genetic similarity is defined in a manner that is relevant to treatment response. This principle is used to identify prototype patients: patients who received the treatment of interest and have a larger than expected survival difference with the genetically most similar patients who received another treatment. Genetic similarity is defined separately for 10 581 gene sets based on Gene Ontology (GO) annotation. These prototype patients are used to define a classifier: new samples who exhibit a similar gene expression profile to the prototype patients will benefit more from the treatment of interest. Here we use TOPSPIN to predict which patients will benefit from the proteasome inhibitor bortezomib. We combine tumor gene expression data from the Total Therapy 2, Total Therapy 3 and HOVON-65/GMMG–HD4 phase III clinical trials into one dataset comprising 910 patients, split into a bortezomib arm (n=407) and a non-bortezomib arm (n=503). Progression free survival is used as outcome measure. This dataset was split in a training set (n=606) and a test set (n=304). The test set is not used at any point in the training procedure and is only used for independent validation.
Results: We successfully identify gene sets that enable us to predict which patients will benefit most from bortezomib. The top 8 performing GO sets based on Hazard Ratio (HR) were combined to achieve the final classification. In the training set 28.4% of patients were classified a class 1, resulting in an HR of 0.13 (p=7.1*10^{-11}) between the two treatment arms. More importantly, in an independent test set an HR of 0.47 (p=0.03) was found, as shown in Figure 1.

Figure 1.

Summary/Conclusions: TOPSPIN is successful in predicting bortezomib specific survival in independent data. TOPSPIN can be applied to any dataset with two treatment arms and a continuous outcome measure. In a disease like MM, where many different treatments are available, selecting the right treatment is critical and TOPSPIN can aid in this decision.

E1280

AMYLOIDOsis RESEARCH CONSORTIUM CARDiac AMYLOIDOsis SURVEY: RESULTS FROM PATIENTS WITH AL AMYLOIDOsis AND THEIR CAREGIVERS

L. Loomis, L.1, M. Maurer2, S.D. Guthrie3, K. Hsu1, M. Grogan4
1Amyloidosis Research Consortium, Boston, 2Columbia University, New York, 3Prothena Biosciences Inc, South San Francisco, 4Mayo Clinic, Rochester, United States

Background: Cardiac amyloidosis is a severe disease that can lead to cardiac dysfunction and death. Amyloid light chain (AL) amyloidosis, hereditary transthyretin (hATTR) amyloidosis, and wild-type transthyretin (wtTTR) amyloidosis may result in cardiac amyloidosis. AL amyloidosis is caused by an accumulation of misfolded light chain and often involves organs other than the heart (eg, kidneys, nervous system). Initial symptoms are often nonspecific (eg, weight loss, fatigue). Consequently, a diagnosis is frequently made only after the disease has become advanced. Previous patient-directed research found that despite patients being initially referred most often to cardiologists (as opposed to hematologists and nephrologists), cardiologists diagnosed the condition much less frequently than other specialists.

Aims: To understand delays, errors, and inconsistencies in the diagnostic pathway for patients with AL cardiac amyloidosis and validate using caregiver responses.

Methods: An online survey consisting of 36 questions (for patients) and 37 questions (for caregivers) was developed by the Amyloidosis Research Consortium (ARC) and distributed to the patient mailing lists of ARC, the Amyloidosis Foundation, and Amyloidosis Support Groups in January 2017. The survey was designed for patients with all forms of cardiac amyloidosis and their caregivers; however, the present analysis is limited to AL amyloidosis.

Results: In this subanalysis, 137 patients and 115 caregivers completed the survey. Most patient respondents were >55 years of age (n=111; 81.0%); of those, 16.1% (n=22) were >70 years of age. Composition of the population was 81.8% white/Caucasian (n=112), 2.2% Asian (n=3), 4.4% African American (n=6), 2.2% Latino (n=3), 5.1% other (n=7), and 3.6% unknown (n=6). Most patients had lived with their diagnosis for >1 year (17.5% [n=24] ≤1 year; 23.4% [n=32] 1-2 years; 29.2% [n=40] 3-5 years; 21.2% [n=29] 6-10 years; 8.8% [n=12] >11 years). A significant percentage of patients had multorgan involvement (54.7% [n=75] kidney; 29.9% [n=41] nerve; 14.6% [n=20] liver; 43.8% [n=60] heart). Before diagnosis, 43.8% (n=60) of patients were incorrectly diagnosed with one or more other conditions, predominantly by cardiologists and general practitioners (Table 1). Furthermore, more than 75% of patients visited 3 or more different physicians before diagnosis. Nearly all misdiagnosed patients (83.3%; n=50/60) reported receiving treatment for their misdiagnosed condition. Both patients and caregivers reported correct diagnoses being made most frequently by cardiologists and hematologists (Table 1). Caregivers echoed the multitude of distinct physicians visited before diagnosis (Table 1). Patients reported that biopsy of fat pad, kidney, or heart was the predominant diagnostic test performed (Table 1). Hospitalization was prevalent; 55.5% (n=76) patients reported amyloid-related cardiac hospitalization. Moreover, 31.3% (n=43) of patients reported the need for air travel for physician consultation.

Table 1.

Summary/Conclusions: This represents the first survey compiling both caregiver and patient experiences with AL amyloidosis. Alignment of caregiver with patient responses validates our patient-directed research. Patients with AL cardiac amyloidosis frequently receive misdiagnoses and sometimes receive incorrect treatment for the misdiagnosed condition. Disease awareness among all specialists is vital, especially among those to whom patients are initially referred due to the nature of their initial symptoms.
imunomodulatory agent (IMiD)–free regimens. Analysis using a fixed-effects model found that DRd compared with other IMiD-containing regimens in Network 1, and DVD compared with other IMiD-free regimens in Network 2 produced PFS and OS among patients with MM. **Results:** Over the past few years, the multiple myeloma (MM) treatment (TX) landscape has changed considerably. Immunomodulating (IMiD) drugs and proteasome inhibitors (PI) have emerged as mainstays of MM TX. However, the limitations and lag time of available administrative claims databases make it difficult to assess current real-world trends in the TM of MM. **Aims:** The study aimed to describe trends in demographics, TX patterns, and sequencing for newly diagnosed MM (ndMM) patients (Pts) in the United States (US) using an enhanced Electronic Health Records (EHR) database. **Methods:** A retrospective observational study of ndMM Pts was conducted utilizing EHR from a nationally-representative database (Flatiron Health). The Flatiron MM provider network comprises over 260 clinics throughout the US. Pts with an ICD-9 (293.0x) or ICD-10 (C90.xx) diagnosis of MM between 01/01/2011–12/31/2016 were randomly selected into the study. Pts were excluded if they did not have ≥2 documented clinical visits during the study period. Diagnosis of MM was confirmed through review of unstructured chart data. Index date was defined as the Pt’s date of diagnosis with MM. ndMM Pts were defined as those without a MM Tx more than 14 days prior to their first diagnosis date. Start of first-line (1L) TX therapy was defined as the 1st episode of an eligible systemic Tx given after or up to 14 days before the index date. Regimen were defined using the 1st eligible drug episode plus other eligible drugs given within 28 days of each other. A maximum gap of 90 days was allowed within a given line of therapy (LOT) and was considered concluded the day before the start date of the next LOT. **Results:** For the 3367 ndMM Pts identified, mean(SD) age was 68.5(11) years at the time of diagnosis, 45.9% were female, 57.6% were white, 14.7% African American, and 11.1% other race. The most common immunoglobulin (lg) classes at diagnosis were IgG (51.8%) and IgA (18.9%). Median follow-up time for these groups was 471, 730, 928, 1132, and 610 days respectively. Among treated Pts, 205 (12.7%), 208 (28.2%), 109 (33.5%), and 98 (38.1%) received at least 1 stem cell transplant (SCT), respectively. Of Pts receiving 1L TX, 984 (33.6%) received IMiD compound +PI, 715 (24.9%) received IMiD compound therapy in 1L. The use of IMiD compounds +PI in 1L increased during the study period for SCT and non-SCT Pts (NSCT) from 40.6% and 21.5% in 2011, to 66.7% and 46.8% in Pts diagnosed in 2016. In Pts who received a SCT (n=618), the most common 1L regimens were lenalidomide + bortezomib + dexamethasone (RX; n=217, 43.9%), cyclophosphamide + bortezomib + d (CX; n=124, 24.1%), lenalidomide + d (RD; n=70, 11.3%), and bortezomib + d (VD; n=57, 9.2%). In NSCT Pts (n=2307), the most common 1L regimens were RVD (n=642, 27.8%), Vd (n=510, 22.1%), and Rd (n=412, 17.9%). Among the RvD NSCT Pts with a documented 2L (n=189), the most common 2L regimens were CyBord (13.2%), carfilzomib monotherapy (7.4%), pomalidomide + d (6.9%), and lenalidomide + d (6.9%). Documented death occurred in 785 (23.3%) Pts during the study period. **Summary/Conclusions:** Over time, RX has become the most common 1L regimen for SCT and NSCT Pts with MM after a median follow up of 15.9 months, many patients remain in the initial LOT. With a longer follow up, we will be able to observe sequencing and patterns of treatment in later LOTs.
Results: At a median follow-up of 9.8 months in a protocol-specified interim analysis, 67 patients had disease progression or death were observed (in 18 of 66 patients (27.2%) in the group B vs 28 of 68 (41.1%) in the control group (p<0.001)). A significantly higher rate of overall response was observed in the group B than in the group A (68.7% vs 62.9%, p<0.001), as was a higher rate of complete response or better (39.2% vs 16.1%, p<0.001). The most common adverse events during the treatment was myelotoxicity (neutropenia in 68.6% of the patients in the therapy group B vs 42.1% of those in the control group A), anemia (in 21.5% vs 13.6%) and thrombocytopenia (in 13.8% vs 8.7%).

Summary/Conclusions: In patients with relapsed multiple myeloma, the addition of daratumumab to lenalidomide and dexamethasone appeared active and resulted in significantly improved progression-free survival. However it was associated with a higher risk of myelotoxicity.

E1285
COMPARISON BETWEEN IMMUNOFIXATION NEGATIVITY AND NORMAL FREE LIGHT CHAIN RATIO WITH MULTICOLOUR FLOW CYTOMETRY FOR RESPONSE ASSESSMENT IN PATIENTS WITH MULTIPLE MYELOMA WITH VGPR OR BETTER
K. Narita1,*, H. Takamatsu2, Y. Abe1, Y. Usui1, M. Takeuchi1, K. Matsue1
1Department of Medicine, Hematology/Oncology Kameda Medical Center, Kamogawa, 2Department of Hematology and Respiriology, School of medicine, Institutional Review Board, Pharmaceutical and Health Sciences, Kanazawa University, Kanazawa, Japan

Background: Urine and serum Immunofixation electrophoresis (uIFE and sIFE, respectively) and free light chain assay (FLC) are widely accepted as standard tests for diagnosis and monitoring of multiple myeloma (MM). However, there is significant discordance between the electrophoretic method and FLC test for response assessment. Despite this discordance, previous studies did not address the differences in assessment of response treatment between the intact immunoglobulin MM (IIMM) and light chain only MM (LCMM)/oligosacryl- tory MM (OSMM), uIFE results are poorly correlated with the serum FLC level, however, treatment response of LCMM has still been recommend to assess by 24-hour uIFE by International Myeloma Working Group guideline. However, MRD levels on uIFE negativity or normal FLC ratio (rFLC) in patients with various types of MM have not been studied.

Aims: To explore the relationship between uIFE, sIFE negativity and normal rFLC for MRD assessment in patients with IIMM and LCMM.

Methods: We initially selected 162 patients with MM (LCMM and OSMM, n = 41; IIMM, n=21) that received treatment at Kameda Medical Center, Kamogawa-shi, Japan and Kanazawa University Hospital, Kanazawa-shi, Japan between April 2008 and January 2016. Among them, 126 patients (LCMM/OSMM 40, IIMM 86), who achieve VGPR or better response, were selected on the basis of the availability of simultaneous serum and urine test, FLC data, and bone marrow MRD. To explore the relationship between uIFE and sIFE negativity and normal rFLC, MRD levels were compared by multi-colour flow-cytometry (MFC) in patients with LCMM/OSMM, and IIMM that obtained VGPR or better. MRD negativity was defined as MRD <10^-4. Complete response (CR) was divided into conventional CR (cCR, CR but MRD-positive) and MRD CR (CR and MRD-negative).

Results: One hundred forty-four complete IFE, FLC, and MFC data set of 126 patients (LCMM/OSMM 40, IIMM 86) with ≥VGPR were analysed. Normal FLC at VGPR, cCR and MRD- CR was 65.0%, 78.4% and 76.8% in IIMM, and 0%, 21.4% and 100%, respectively, in LCMM/OSMM. The percentages of sample at MRD levels of MRD >10^-3, 10^-3 ≤MRD >10^-4 and 10^-4 ≤MRD in LCMM/OSMM were significantly higher than in IIMM (12.5%, 50.0%, and 100% for negative uIFE, and 0%, 11.5% and 100% for normal rFLC, respectively. These figures in IIMM were 23.0%, 41.6%, 81.4% for negative sIFE, and 53.8%, 75.0% and 88.8% for normal rFLC, respectively. Positive/negative predictive value (PPV/NPV) of uIFE and rFLC for MRD in LCMM/OSMM was 100%/94.8% and 100%/85.0%, respectively, while those were 90.6%/45.8% and 88%/93.4% in IIMM, respectively.

Summary/Conclusions: Our observations confirmed that FLC test has greater sensitivity than uIFE for detection of the monoclonal component, and that normalization of sFLC ratio is highly predictive of MRD negativity in patients with LCMM/OSMM. The proportion of negative sIFE samples increased with depth of MRD, but the FLC response did not appear to parallel with the depth of response in IIMM. We recommend that FLC test should be incorporated into response assessment in LCMM/OSMM as an alternative to 24-h uIFE, and both negative sIFE and normal rFLC are still useful for response assessment of residual clonal PCs in IIMM.

E1286
DARATUMUMAB IS AN EFFECTIVE AND SAFE SAVAGE THERAPY IN RELAPSED/REFRACTORY PATIENTS WITH MULTIPLE MYELOMA AFTER AUTO-ALLILOGENEIC STEM CELL TRANSPLANTATION
E. Klyuchnikov1,2,*, U.-M. von Pein1, F. Ayuk1, M. Christopel1, R. Adjaille1, A. van Randenbourgh1, C. Wolschke1, N. Kroeger1
1Department for Stem Cell Transplantation, University Cancer Center Hamburg-Eppendorf, Hamburg, Germany

Background: Daratumumab is a human monoclonal antibody that targets CD38, a cell surface protein that is overexpressed on multiple myeloma cells. The drug became the first monoclonal antibody as single agent therapy approved by the FDA for the treatment of multiple myeloma. The role of allo-SCT in myeloma patients (pts) remains unclear; nevertheless, the registry study of EBMT suggests an increasing rate of allografts in Europe in last years. Despite the potentially curative potential of this approach, the increased relapse rate and low PFS remain a central clinical problem.

Aims: In this single center retrospective analysis, we report on our experience with the use of daratumumab to lenalidomide and dexamethasone as salvage therapy. Before allografting 9 pts received at least 1 salvage therapy line prior to the allo-SCT. The allografts were performed from unrelated donors (MUD, n=9; MMUD, n=4) or matched related donors (MRD, n=3). The median number of salvage lines post-transplant and prior to first daratumumab infusion was 3 (1- 4).

Results: The median number of infusions was 13 (3-22). A total of 16 and 15 pts were available to safety and efficacy evaluation, respectively. The safety was assessed according to the Common Toxicity Criteria (CTC). A total of 20 adverse events were observed in 16 pts: dyspnea (CTC1, n=3; CTC2, n=1), bronchospasm (CTC2, n=2) shivering (CTC1, n=3), cough (CTC1, n=1; CTC2, n=1), musculoskeletal pain (CTC1, n=4), acute coronary syndrome (CTC3, n=1), skin rush (CTC2, n=1), pressure on eyes (n=1). Two patients developed late onset infections (pneumonia and infection of urinary tract) followed by temporarily therapy interruption. We observed a decrease of Tregs (CD4+CD25highFoxP3+) flow number from a median of 5.05% at start to 0.65% at day 21 after first daratumumab infusion in four pts. There were no cases of GvHD. The adverse events appeared in all pts after the first infusion, with improved tolerance of following infusions. There were no cases, where the therapy had to be stopped due to adverse events. Within a median follow-up of 32 months (1-45) from the relapse/progression 12 of 16 pts remain alive. Two pts died due to progress of myeloma and another 2 pts died due to severe infection/sepsis. A total of 9 of 15 evaluable pts responded (60%, PR, n=7, vgPR, n=2). The responses (decrease of paraprotein and/or free light chains; reduction of extramedullary tumor in 2 pt) occurred at a median of 7 days (7-75) after the first administration of daratumumab. The median response duration is 4.5 mo (1.5-8). Six pts show ongoing responses. All responding and 2 non-responding pts (stable disease) showed clinical improvement of constitutional symptoms.

Summary/Conclusions: Daratumumab demonstrated encouraging efficacy in relapsed/refractory pts with myeloma after allo-SCT. The administrations of the drug in these heavily pre-treated pts were associated with good safety profile and development mostly non-severe adverse events mostly after the first infusion. Further studies on the use of daratumumab in post-transplant setting are warranted.

E1287
PROGNOSTIC RELEVANCE OF VEGF AND VEGFR EXPRESSION IN CD138+/CD19- AND CD138+/CD19+ PLASMA CELLS FROM PATIENTS WITH MONOCLONAL GAMMOPATHIES
C. Geraldes1,2,*, A.C. Gonçalves2,3, R. Alves2,3, E. Cortesão1,2,3, L. Ribeiro1,2,3, J.M. Nascimento Costa1,2, A.B. Sarmento-Ribeiro1,2,3
1Clinical Hematology Department, Centro Hospital e Universitário de Coimbra, Coimbra, Portugal, 2Applied Medical Biology and University Clinic of Hematology, 3CIMAGO, 4 University Clinic of Oncology, Faculty of Medicine University of Coimbra, Coimbra, Portugal
Results: 482 pts were eligible, 343 (71%) were W, 52 (10%) H, 50 (10%) B, 19 (3%) A, and 18 (3%) O. Median age was 65 years, 54% were male, and 28% ISS stage 3. There were no statistically significant differences in FISH abnormalities between the M. Overall W had more abnormalities in IGH r (t(4;14), t(11;14), t(14;20), 1q21 gain compared to M. Most notably W had more IGH r (39% vs 28%, p=0.019) and t(11;14) (20% vs 12%; p=0.024). There were no statistically significant differences between W and M in the high risk FISH abnormalities.

$p$-value compares W vs M. * means statistical significant ($p$-value<0.05)

Summary/Conclusions: W had significant differences in FISH compared to M. W had more IGH r and t(11;14) than M, and there was no difference in high risk FISH abnormalities between W and M. This study confirms the biological racial disparities that exist in minorities with MM. Further studies with more inclusion of minorities are needed to elucidate these disparities and its effects on risk stratification and outcomes.

E1289

POMALIDOMIDE ALONE OR IN COMBINATION WITH LOW DOSE DEXAMETHASONE AS MAINTENANCE FOLLOWING INDUCTION WITH POMALIDOMIDE AND LOW DOSE DEXAMETHASONE IN RELAPSED AND REFRACTORY MYELOMA (ALLG MM14)

Background: Whilst the addition of dexamethasone to upfront therapy with Immunomodulatory (IMiD®) agents is important to mediate rapid reduction in disease burden, preliminary findings suggest that the NK stimulatory effects of IMiD® compounds are best harnessed without the co-administration of dexamethasone, and may be especially effective in the setting of minimal disease burden (in the maintenance setting for example) when some inherent immune recovery has occurred. However this has yet to be confirmed in a prospective clinical trial.

Aims: To evaluate the effect of maintenance with POM alone (Arm 1) versus POM-LoDEX (Arm 2) on progression free survival (PFS), overall survival (OS), and kinetics of response (overall response rate (ORR)) in relapsed myeloma (MM) patients refractory to lenalidomide (L-RLEN) demonstrating stable disease (SD) or better following salvage treatment with pomalidomide (POM) and low dose dexamethasone (LoDEX) induction.

Methods: Multicentre, open-label, randomized phase 2 study of relapsed R-LEN patients who had received≥2 prior lines of therapy. POM 4mg days 1-21 (28 day cycle) was administered alone or in combination with LoDEX (40mg weekly) as maintenance following an induction with 4 cycles of POM and LoDEX. Treatment continued until toxicity or progression. Peripheral blood samples for immune studies were collected pre-induction and prior to cycles 1, 3, 6 and 10 of maintenance.

Results: 154 patients from 11 sites were enrolled on to the study (M:F 80:74), with a median age of 67 years (range 35-88). Median number of prior lines of therapy was 4.5 (2-14). All patients had failed LEN (100%), 127 (82.5%) were also refractory to bortezomib (double refractory) and 94 (61%) had received a prior autologous stem cell transplant. 72 (47%) patients achieved SD or better with the LoDEX induction regimen. POM-LoDEX demonstrated a median PFS of 13.7m for POM-LoDEX (Arm 2) versus 5.6 for POM-LoDEX (arm 2) (p=0.39). The PFS hazard rate for Arm 2 was lower (p=0.003) and OS was (p=0.003), irrespective of first line therapy (bortezomib-based regimens for fit patients or alkylating-based treatments for unfit patients). Interestingly, we also observed an increased percentage of CD138+/CD19+ PCs (21%) expressing VEGF in MM patients with a more favorable PFS (p=0.04) and OS (p=0.008).

Summary/Conclusions: The results of our investigation showed that CD138+/CD19- and CD138+/CD19+ PCs have differences in what concerns VEGF expression, not only in MM patients, but also in immunus patients. The increased expression of VEGF in clinical PCs from MM compared tomusGM patients evidences the relevance of VEGF in myelomagenesis. We also demonstrated a negative prognostic impact of an increased VEGF expression in CD138+/CD19- PCs, highlighting the role of VEGF in the survival and maintenance of clinical PCs and as a predictor of outcome in MM progression. The association between the percentage of CD138+/CD19+ PCs and survival supports the idea that these cells may not be neutral players in the complex pathogenesis of MM. The results of our study should be further investigated in larger series of patients.

E1288

RACIAL DIFFERENCES OF FISH ABNORMALITIES IN MINORITIES WITH MULTIPLE MYELOMA: A SINGLE-CENTER EXPERIENCE

Methods:

- We included 128 patients with monoclonal gammapathies, 60 patients with newly diagnosed symptomatic MM and 68 with monoclonal gammapathy of uncertain significance (MGUS) and also from 11 non-neoplastic controls (CN). t(4;14) and t(11;14) were performed to assess the VEGF and VEGFR accuracy as diagnostic and prognostic biomarkers.
- All M (Hispanic (H), Black (B), Asian (A) and Other (O)) were included into the same group for statistical analysis.
- Due to smaller numbers, all M (Hispanic (H), Black (B), Asian (A) and Other (O)) were included into the same group for statistical analysis.

Background: Vascular endothelial growth factor (VEGF) is a potent angiogenic peptide with biologic effects that include regulation of extracellular matrix remodeling and inflammatory cytokine generation with an important role in the bone marrow microenvironment of multiple myeloma (MM). Angiogenesis is enhanced in the bone marrow of MM patients in parallel with tumor progression. Myeloma and stromal cells secrete angiogenic factors that include VEGF. Previous studies showed marked heterogeneity in the expression of VEGF between plasma cells (PCs) from the same MM patient. However, no clear association with expression levels, phenotypic subtypes of PCs and prognosis was demonstrated.

Aims: The present study aimed to evaluate the expression levels of VEGF and VEGF receptor (VEGFR) on phenotypic subtypes of PCs in patients with monoclonal gammapathies and to explore its role as diagnostic and prognostic biomarkers.

Methods: We include 128 patients with monoclonal gammapathies, 60 patients with newly diagnosed symptomatic MM and 68 with monoclonal gammapathy of uncertain significance (MGUS) and also from 11 non-neoplastic controls (CN). (t(4;14), t(11;14), t(14;20), t(4;14), t(14;16), del13q, del 17p, 1q21. Chi-square was used for statistical analysis. Due to smaller numbers, all M (Hispanic (H), Black (B), Asian (A) and Other (O)) were included into the same group for statistical analysis.
POMALIDOMID IS MORE EFFECTIVE IN REAL CLINICAL PRACTICE THAN IN RANDOMIZED TRIAL – AN OBSERVATIONAL STUDY OF THE CZECH MYELOMA GROUP

E. Gregora7, S. Sevcikova8, P. Pavlicek7, T. Jelinek9, J. Radocha4, M. Štork10, R. Hajek9

1Department Hematology and Oncology, University Hospital Brno, 2Institute of Biostatistics and Analyses, Faculty of Medicine, Masaryk University, Brno, 3First internal clinic, 1. medicine faculty Charles university prague, Prague, 4University Hospital, Heradeck Kralove, Heradeck Kralova, 5University hospital Olomouc, Olomouc, 6University Hospital Pizen, Pizen, 7University Hospital Kralovske Vinohrady, Praha, Praha, 8Masaryk university Brno, Brno, 9University Hospital Ostrava and the Faculty of Medicine, Ostrava, 10University hospital Brno, Brno, Czech Republic

Background: The combination of pomalidomide and low-dose dexamethasone (Pom-Dex) is a perspective option for patients with end-stage relapsed/refractory multiple myeloma (R/RMM). We analyzed efficacy and toxicity of Pom-Dex in all patients from the Czech Republic treated from June 2013 to December 2016.

Methods: Patients were eligible if they had been diagnosed with R/RMM and had failed at least two previous treatments with bortezomb and lenalidomide. They were treated with start dose of Pom (4mg/day on days 1-21, orally) plus low-dose dexamethasone (40mg/day on days 1, 8, 15, and 22, orally) until disease progression or unacceptable toxicity. We analyzed TTP and OS together with toxicity. Also, univariate Cox proportional hazards model for OS was done for standard risk factors.

Results: Median TTP of Pom-Dex treatment was 7.1 months (95% CI 5.3-8.6). Median OS was 19.0 months (95% CI 13.2-25.8). The most common grade 3-4 adverse events were neutropenia in 44%, anemia in 22% and thrombocytenia in 24% of patients. Grade 4 infections were observed in 19% of patients. Patients with ECOG worse than 2, B2microglobulin higher than 5, ISS stage 3, low hemoglobin, low platelet count and presenting extramedullary mass had worse OS according to univariate Cox proportional hazards model.

Summary/Conclusions: Our analyses show that Pom-Dex treatment of Czech R/RMM patients is effective, well tolerated and had better results than the registration study. Performance status and tumor burden seem to be main prognostic factors according to our model. Thus, our suggestion for clinical practice is to start pomalidomide treatment as soon as possible in case of MM relapse.

E1290

RAD REGIMEN AS INDUCTION BEFORE ASCT: OUTCOMES, SAFETY AND EFFECTS ON BONE METABOLISM AND ANGIOGENESIS; FINAL RESULTS OF A PHASE 2 STUDY OF THE GREEK MYELOMA STUDY GROUP

E. Terpos1,*, E. Kastritis1, M.A. Dimopoulos1

1Department of Clinical Therapeutics, National and Kapodistrian University of Athens, School of Medicine, Athens, 2Department of Hematology, Theagenion General Hospital, Thessaloniki, 3Department of Internal Medicine, Division of Hematology, University of Patras Medical School, Patras, 4Department of Hematology, 251 General Air-Force Hospital, Athens, Greece

Background: There is limited published data on the efficacy and safety of the combination of lenalidomide, adriamycin and dexamethasone (RAD) as induction therapy for newly-diagnosed myeloma (NDMM) patients who are eligible for autologous transplantation (ASCT).

Aims: The primary endpoint of this phase 2 study was the assessment of overall response rate (ORR) after 4 cycles of RAD induction in NDMM patients eligible for ASCT. Secondary endpoints included safety, progression-free survival (PFS), time to progression (TTP) and overall survival (OS). Exploratory endpoints included: i) the yield of stem cell collection after RAD; ii) the effects of RAD on biochemical markers of bone metabolism: CTX, TRACP5b, bone-alkaline phosphate (bALP), P1NP, osteocalcin, soluble RANKL, osteoprotegerin (OPG); iii) the effect of RAD on angiogenic cytokines: angiopep-1 (Ang-1) & -2, angionatin (Ang), VEGF and bFGF.

Methods: Lenalidomide was administered at a dose of 25mg, po, daily, on days 1-21 of a 28-day cycle; dexamethasone was given at a dose of 40mg, po, on odd days (1, 8, 15, and 22) while adriamycin was administered as IV bolus infusion at a dose of 9mg/m2, on days 1-4 of each cycle. Serum levels of the above markers of bone remodeling and angiogenesis were measured before and after 4 cycles of RAD, using ELISA methodology.

Results: Between November 2014 and February 2016, 45 patients (median age 59 years) were enrolled. Osteolytic lesions were present in 33 (73%) patients, while 3 (6.6%) had hypercalcemia (>11mg/dl). All but one patient completed 4 cycles of RAD. Best response included one (2.2%) CR, 8 (17.8%) VGPRs, 21 (46.7%) PRs, for an ORR of 66.7%, while 14 (31%) patients had
stable disease and one progressed during the 4th cycle of treatment. After ASCT the ORR was 84.4%: 6 (13.3%) patients achieved CR, 13 (28.9%) VGPR and 19 (42.2%) PR. Adverse events of grade 3 or 4 included mainly anemia (4 patients), neutropenia (3, 6.6%) and febrile neutropenia (one patient). After a median follow-up of 1.1 months (range: 11.0-24.9), 11 patients have progressed and 4 died (all had achieved less than VGPR post-ASCT). The PFS, TTP and OS rates at 12 months were 88.6%, 88.6% and 100%, respectively. Forty (89%) patients had adequate stem cell collection post-RAD induction (mean±SD: 8.94±6.50 x10⁶/kg CD34+ cells). Patients at baseline had elevated levels of CTX, TRACP-5b, sRANKL/OPG, Dkk-1, Ang, VEGF, VEGF-A, bFGF and reduced levels of AIOLOS/Ang-2, bALP and P1NP compared to healthy subjects of similar age and gender (p<0.01 for all comparisons). RAD therapy resulted in a reduction of circulating CTX (p=0.03), TRACP-5b (p=0.01), Ang (p=0.02), VEGF (p=0.01) and bFGF (p=0.01). Moreover, RAD increased serum levels of bALP (p=0.036), P1NP (p=0.028) and Ang-1/Ang-2 ratio (p=0.022). These alterations occurred irrespective of response, although patients who achieved at least VGPR tended to have more profound differences in the above parameters. 

Summary/Conclusions: RAD resulted in successful induction for NDMM patients with an ORR of approximately 67% pre- and 84% post-ASCT. With a median follow-up of >1.5 year, the 12-month PFS rate and OS rates are high, with median PFS and OS not reached after 104.4 months from initiation of therapy (p=0.02). Time to next treatment (TTNT) in patients receiving ASCT or not was 30.1 months (5-122.7) vs 10.3 months (0.7-70.5) from 1st to 2nd line tx and 12 months (0.3-121.9) vs 6.3 months (1.4-61.6) from 2nd to 3rd line tx (p=0.028). The early mortality (within the first year) was 5.9% (3/52) in details only 1/258 of those eligible to ASCT (0.4%) and 30/267 of those not candidate to transplant (11.2%). When considering this last group before and after the 2007, we observed a significant higher incidence of early mortality in the first period (21.7% vs 9 (6.2%), p=0.006).

New drugs toxicity: with Bor-based tx 30% of pts complaint neurological, 20% gastrointestinal and 18.2% hematologic toxicity; with Len-based tx 36.4% infective events and 28.9% hematologic toxicity. Median OS in pts st 65 yrs was 7 vs 4.8 years (p=0.001), of note considering pts st 65 yrs treated before 2007 median OS was 5.5 vs 3.1 yrs (p=0.001) and after 2007 median OS was not reached vs 7.5 yrs (p=0.034).

Summary/Conclusions: Our real life data show how MM therapeutic scenario have changed during the last 15 yrs. The tremendous improvement obtained in this study was mainly evident in older pts with a strong reduction of early mortality and median OS reaching, in the second time frame after year 2007, 7.5 yrs. For younger pts ASCT confirmed to be of great benefit in term of TTNT and PFS. Thus, considering the real advantage of new drugs a palliative approach is not anymore justified even in very old pts.
Summary/Conclusions: In conclusion, our results suggest that CUL4A expres-
sion could serve as prognostic marker for patients assigned to IMiDs containing
regimens. Further analysis of the expression of other E3 ligase complex pro-
teins in a larger patient cohort is in progress.

MAINTENANCE THERAPY WITH BORTEZOMIB IN PATIENTS WITH
MULTIPLE MYELOMA (MM) AFTER ASCT AND MINIMAL RESIDUAL
DISEASE (MRD)
M. Solovev1, L. Mendeleeva1, O. Pokrovskaya1, E. Gendzhian2, I. Galtseva3,
J. Davydova2, M. Firsova1, M. Nareyko1, T. Abramova4, V. Savchenko4
1Dept. of High-Dose Chemotherapy of Paraproteinemic Hemoblastosis, 2Bio-
statistics Laboratory, 3Immunophenotyping of Blood Cells and Bone Marrow
Laboratory, 4Research Center for Hematology, Moscow, Russian Federation

Background: MRD-negativity status in patients with MM after autologous stem
cell transplantation (ASCT) directly correlates with higher Relapse-Free Sur-
vival. It remains unclear whereas these patients should all receive maintenance
therapy with it’s toxicity and cost.

Aims: To assess efficacy of maintenance therapy with Bortezomib in patients with
MM, who have achieved complete remission after ASCT with MRD positive
and negative status.

Methods: From January 2014 to February 2016 52 patients with MM (19 male
and 33 female) ages from 24 to 66 years (median 54 years) who have achieved
complete remission after ASCT were randomized for a year-long maintenance
therapy with Bortezomib. On 100th day after ASCT and after completion of
maintenance therapy samples bone marrow from all patients were assessed
using 6-color Flow Cytometry to detect MRD. We chose Relapse-Free Survival
(RFS) as the indicator of maintenance therapy efficacy. Kaplan-Meier survival
curves were compared using log-rank test. Statistical analysis was performed
using SAS 9.4.

Figure 1.

Results: 2-year Relapse-Free Survival in patients with MRD-negative status
after ASCT was higher (p=0.05) than that in MRD-positive patients - 52.9%
(95% CI: 35.5–70.5%) vs 37.2% (95% CI: 25.4–49.3%). The MRD-positivity
significantly increases the risk of relapse (HR=1.7; 95% CI: 1.2–3.4; p=0.05).
Two year cumulative probability of relapse after ASCT in patients with MRD-
negative status, who had (n=15) and hadn’t received (n=10) maintenance ther-
apy with Bortezomib was not different (p=0.58). Average time of relapse in
MRD-positive patients who received maintenance therapy with Bortezomib was
5 months longer than in the group of patients without maintenance therapy -
17.3 months vs 12.3 months. In the group of MRD-positive patients who did
not completed maintenance therapy, relapse was diagnosed in 6 patients. After
the end of the treatment 42% of MRD-positive patients achieved MRD-negative
status. RFS in this group of patients was significantly higher than in the group
of treated MRD-positive patients who retained that status after maintenance
therapy (MT) - 100% vs 20% (p=0.02, Fig 1).

Summary/Conclusions: In cases when MRD-negative status was achieved
after ASCT, maintenance therapy does not increase the RFS. In comparison –
patients with positive MRD status after ASCT require maintenance therapy to
improve their survival rate.

E1296
LONG-TERM OUTCOME OF MULTIPLE MYELOMA (MM) PATIENTS
TREATED UP-FRONT WITH SINGLE OR TANDEM AUTOLOGOUS STEM
CELL TRANSPLANTATION (ASCT) - SINGLE CENTRE EXPERIENCE WITH
334 PATIENTS
J. Batinc1, S. Basic-Kinda1, B. Dreta1, I. Hude1, A. Ostojić1, D. Sertić1,
R. Servedi-Seiwert1, P. Roncevic1, I. Bojanic1, K. Gjadoev-Kvvezid1,
K. Dubravcic2, I. Ilic4, I. Auer1, D. Nemet4

Centre Zagreb, 2Medical School, University of Zagreb, 3Department of Trans-
fusionology, 4Department of Pathology and Cytology, 5Department of Laboratory
Diagnostics, University Hospital Centre Zagreb, Zagreb, Croatia

Background: ASCT after induction treatment has been standard of care for
MM for almost 30 years. Some centers routinely perform two transplantation
up-front (so-called tandem transplants), while others advocate postponing the
second transplant until after progression. In recent years novel antimyeloma
agents have significantly improved the prognosis of MM patients, thus casting
further doubts on the value of the more aggressive tandem ASCT approach.

Aims: To describe long-term outcomes of MM patients treated with ASCT (sin-
gle and tandem) in a single centre, with tandem transplants, while others
advocate postponing the second transplant until after progression. In recent
years novel antimyeloma agents have significantly improved the prognosis of
MM patients, thus raising further doubts on the value of the more aggressive
tandem ASCT approach.

Methods: This was a retrospective analysis of outcomes of 334 MM patients
who underwent 470 ASCT procedures at our center between 1993 and 2014.
During that period treatment policies changed from single to tandem to salvage
second ASCT, as data from different clinical studies became available.

Results: 296 patients received VAD (vincristine, doxorubicin, dexamethasone)
as induction therapy and 38 regimens based on immunomodulatory drugs or
proteasome inhibitors. All received high-dose melphalan for pretransplant con-
ditioning, 32 in combination with total body irradiation. Tandem ASCT (defined
as second transplantation performed within 6 months after the first) was per-
fomed in 136 patients. Single ASCT in 168 and salvage second (after
relapse/progression) in 30 patients. Transplant related mortality was 1.5%.
Median follow up is 70 months (range 4 – 238). Median overall survival (OS)
for the entire group is 123 months and median progression free survival (PFS)
40 months. Tandem ASCT in comparison to single and second salvage trans-
plantation resulted in superior OS (203 vs 86 vs 68 months respectively,
p<0.0001) and PFS (60 vs 38. vs 25 months respectively, p<0.0001) (figure).
Thirteen percent of patients who underwent tandem ASCT are alive and pro-
gression-free more than 10 years after the procedure. Fourteen patients devel-
opped secondary malignancies.

Figure 1.

Summary/Conclusions: Our results suggest that tandem ASCT is a very effec-
tive treatment modality that can partially substitute for the absence of expensive
novel agents with long-term and lethal toxicities. Tandem ASCT seems to
result in superior OS and PFS in comparison to single or salvage second ASCT.
More than 10% of patients treated with tandem ASCT experience very pro-
longed PFS.

EXTRAMEDULLARY DISEASE IN MULTIPLE MYELOMA PATIENTS
UNDERGOING AUTOLOGOUS STEM CELL TRANSPLANTATION:
CLINICAL IMPACT IN DIAGNOSIS, TREATMENT AND OUTCOME
A. Roque1,2, A. Pinto1, E. Cortesão1,2, A. Espadana1, A.B. Sarmento-
Ribeiro12, C. Geraldes12, L. Ribeiro1
1Clinical Hematology Department, Centro Hospitalar e Universitário de Coim-
bra, 2Faculty of Medicine, University of Coimbra, Coimbra, Portugal

Background: Extramedullary disease (EMD) is defined as an infiltrate of clonal
plasma cells outside of the bone marrow. The presence of EMD in multiple
myeloma (MM) patients (pts) at diagnosis is a relatively uncommon presentation
and accounts for about 13% (6-20%) of MM pts. Although several studies

haematologica | 2017; 102(s2) | 631

Madrid, Spain, June 22 – 25, 2017
showed an association of EMD with other adverse prognosis factors and unfavourable outcomes, reports evaluating EMD in pts undergoing autologous hematopoietic stem cell transplantation (ahSCT) are scarce.

Aims: We aimed to evaluate the clinical and laboratory characteristics of pts with EMD as well as its impact in outcomes of MM pts submitted to ahSCT (response to treatment, overall survival [OS] and progression-free survival [PFS]).

Methods: We analysed 155 MM pts submitted to ahSCT in our centre between January/2007 and December/2015, excluding second procedures. The assessment of response to treatment was based in the International Myeloma Working Group consensus criteria (2016).

Results: The median age of the cohort was 58 years (27-69), with 58% of males, the most common subtype was IgG (45%). In our cohort, 28% presented EMD at diagnosis, which was significantly higher compared to reports in the literature (p<0.001; 95%CI 0.22-0.37). The more common involved sites were vertebral column (49%), ribs (13%) and pelvis (13%). EMD occurred more frequently in males (38% vs 18%; p=0.012) and in pts with bone disease (response/very good partial response [CR/VGPR]) proportions previously to ahSCT (30.4 vs 53.2%; p=0.009), as well as at 100 days after ahSCT (D100) (41.3 vs 59.6%; p=0.037). However, no differences were found concerning refractoriness to first line therapy or proteasome inhibitor (PI) treatment, despite EMD pts received a higher mean number of therapeutic lines previously to ahSCT vs pts without EMD (41.3 vs 28.9; p=0.025). After a median follow-up of 48.6 months, the median OS was not reached for global cohort and both groups, and there was no difference between them (p=NS). The median PFS was 51.3 months for global cohort, with no differences seen between pts with and without EMD (50.2 vs 54.1; p=NS). Pts with EMD treated with a PI (57%) presented a higher OS (NR vs 18.9 months; p=0.04), but with no impact in PFS (p=NS), and there were no differences concerning radiotherapy treatment (72%) or thalidomide maintenance after ahSCT (32%) (p=NS).

Summary/Conclusions: In our cohort, EMD prevalence was significantly higher than usually described in the literature. This observation was probably associated with more carefully surveillance of EMD in ahSCT candidates. EMD was associated with a lower proportion of CR/VGPR previous to ahSCT and at D100 evaluation, even after a higher number of therapeutic lines, although we failed to demonstrate that EMD was an independent prognosis factor for PFS and OS. PI seem also to be the best first-line therapeutic approach for EMD pts. In conclusion, our study suggests that EMD is underdiagnosed in MM pts. It is necessary to achieve a better knowledge of the physiopathology of EMD, in order to define better treatment options that may overcome its negative impact in therapeutic response.

DIFFERENCES IN PATIENT AND DISEASE CHARACTERISTICS OBSERVED AT INITIATION OF FIRST-LINE AND INITIATION OF SECOND-LINE TREATMENT IN PATIENTS WITH RELAPSED MULTIPLE MYELOMA IN THE CZECH REPUBLIC

V. Maisnar1,2, Z. Szabo3, W. Bouwmeester4, L. DeCosta5, L. Pour6,7, E. Gregora8, J. Minařík9,10, S. Gonzalez-McQuire3, R. Hájek11,12, V. Maisnar1,2,*, Z. Szabo 3, W. Bouwmeester 4, L. DeCosta 5, L. Pour 6,7, E. Gregora 8, J. Minařík 9,10, S. Gonzalez-McQuire 3, R. Hájek 11,12, 1Faculty of Medicine, Charles University Hospital, 24th Department of Medicine – Haematology, Charles University Hospital and Faculty of Medicine, Hradec Kralove, Czech Republic, 3Amgen (Europe) GmbH, Zug, Switzerland, 4Pharmagent International, Rotterdam, Netherlands, 5Amgen Ltd, Uxbridge, United Kingdom, 6Department of Internal Medicine, Hematology and Oncology, University Hospital Brno, 7Faculty of Medicine, Masaryk University, Brno, 8Department of Internal Medicine and Hematology, University Hospital Hradec Kralove Vinohrady, Prague, 9Department of Hemato-Oncology, University Hospital Otolouc and Palacky University Otolouc, 10Faculty of Medicine and Dentistry, Palacky University Otolouc, 11Department of Haematology-Oncology, University Hospital Ostrava, 12Faculty of Medicine, University of Ostrava, Czech Republic

Background: Tools such as the International Staging System (ISS) and the revised ISS (R-ISS) help to stratify risk of disease in patients with multiple myeloma (MM), enabling assessment of survival expectations. These tools are based on factors measured at diagnosis only; understanding the role of these factors at relapse is less clear. Patient characteristics change between first-line (1L) and second-line (2L) treatment. Predicting survival using tools that include patient characteristics measured at diagnosis is thus widely used, but less relevant than other tools that consider factors measured at relapse. The Registry of Monoclonal Gammapathies (RMG) is a large hematological disease registry, collecting data from patients in the Czech Republic and Slovakia. Data from the RMG can be used to explore real-world characteristics of patients who relapse after aHSCT and could contribute to improved predictive tools that can better define survival estimations at first relapse by considering patients’ experiences at 1L.

Aims: To explore how key characteristics of patients with relapsed MM evolve between initiation of 1L treatment and initiation of 2L treatment to better understand drivers of disease progression and death.

Methods: This non-interventional, observational, retrospective study used data collected prospectively from Czech patient charts available in the RMG. Adults (≥18 years old) initiating 1L treatment for MM between May 2007 and April 2016 were included (N=3027); those with smoldering MM were excluded. Patient and disease characteristics were extracted at initiation of 1L and of 2L treatment. Repeated measurements were available only for those who initiated 1L and 2L treatment (1L+2L group; N=1418); patients who did not start 2L treatment may have been in remission, lost to follow-up or had died. Patients who received 1L+2L treatment, their health status improved between initiation of 1L and 2L treatment. At 2L, patients tended to have a lower ISS stage (re-measured at 2L) than when they started 1L (stage I at 1L: 26.6%; at 2L: 41.1%). Similarly, the proportion of patients with R-ISS stage III disease was lower at start of 2L (24.6% vs than at start of 1L (31.1%) treatment. Eastern Cooperative Oncology Group performance status scores were also better for patients when they started 2L than when they started 1L (stage 3–4 at 1L: 8.7%; at 2L: 5.5%). Laboratory measurements indicated that patients were in better health at the start of 2L treatment than at initiation of 1L treatment: median M protein levels decreased from 31.2 g/L at 1L to 17.7 g/L at 2L, and elevated calcium and creatinine levels were less common at 2L than at 1L. Median lactate dehydrogenase levels were slightly elevated at start of 2L vs start of 1L treatment (184.4 U/L vs 206.6 U/L).

Table 1.

Summary/Conclusion: Patient health was better at initiation of 2L treatment than at initiation of 1L treatment. At relapse, patients are likely to be closely monitored and are able to initiate the next treatment line while in relatively good health; at initiation of 1L, patients may have experienced deterioration in health which could have triggered their diagnosis. These findings illustrate how patient characteristics change at relapse and that the evolving survival may evolve; therefore, restaging patients at relapse may be beneficial and could contribute to improved predictive tools that can better define survival estimations at first relapse by considering patients’ experiences at 1L.

E1299
AN EARLY GOOD RESPONSE AFTER BORTEZOMIB-BASED INDUCTION REGIMENS REPRESENTS A SIGNIFICANT PREDICTOR FOR IMPROVED PFS IN NDMM PATIENTS

G. Rivoli1, M. Cea1, S. Aquino2, A. Dego1, N. Di Felice1, N. Bisso1, D. Avenoso1, R. M. Lemoli1, M. Gobbi1, L. Canepa1

1Clinica Ematologica, 2Ematologia 1, IRCCS San Martino IST, Genova, Italy

Background: Introduction of triplets-based induction regimens containing proteasome inhibitors (PIs) in clinical practice have led to higher response rates and prolonged life expectancy in newly diagnosed multiple myeloma (NDMM)
patients. Different studies have linked complete response (CR) with better PFS (progression-free survival), but not always with prolonged overall survival (OS), most likely due to the impact of novel agents in the management of relapsed-refractory patients. Overall, these observations suggest PFS as a more reliable predictor of clinical outcome. Also, the biological aggressiveness is emerging as a pivotal disease characteristic which affects clinical behavior and response to therapy. In this context, little is known about the association of response kinetic with survival outcomes.

**Aims:** In order to evaluate whether early achievement of a good quality response impacts on outcome, we retrospectively analyzed 87 NDMM patients treated at our institution with bortezomib containing regimens (BRs).

**Methods:** From 2004 to 2018, 87 patients with NDMM and measurable disease (serum and/or urine M protein) were treated with BRs. Both patients eligible and non-eligible to ASCT were included in the study; patients undergoing ASCT were censored at the time of transplant. Median age was 66 (range 32-87); males were 51 (59%); 72 (83%) patients were in III stage; median follow up was 30.7 months; median number of administered courses was 5 (range 2-9). PFS was defined according to IMWG criteria. Cytogenetic risk evaluation performed by a standardized FISH panel, including del17p, del13q, t(11;14), t(4;14), was available in 37 patients (42.5%). Among these high risk abnormalities were identified in 20 patients. Early good response (EGR) defined an M protein reduction ≥75% after 2 courses of therapy. Survival curves were calculated for PFS and OS by Kaplan Meyer method, using log-rank test.

**Results:** PFS and OS were both assessed in patients who achieved EGR as well as in patients who did not. No significant differences were observed in terms of OS between the two groups, whilst PFS was significantly longer in patients achieving EGR (p = 0.036, median PFS 44.7 vs 29 months, respectively). Next, we analyzed patients with high risk cytogenetic. Among these, EGR vs non-EGR patients reached a PFS of 43.7 and 18.7 months, respectively. Remarkable PFS differences between these two groups were not significant (p-value=0.11).

**Summary/Conclusions:** Overall, our data demonstrate a significant impact of EGR on PFS in NDMM patients after BRs, irrespective of median age at diagnosis. In presence of high cytogenetic risk EGR is associated with prolonged PFS, although not significantly. Ongoing analysis on larger cohort of high risk patients will confirm the impact of EGR on PFS also in this group of patients. Based on our data kinetic of response, deriving from EGR assessment, may provide information on both disease aggressiveness as well as clinical outcome, thus representing a novel, surrogate marker for an early survival analysis, with favorable cost-effectiveness characteristics. In summary biological and clinical information deriving from EGR analysis combined with cytogenetic risk evaluation and patient-related (age, comorbidities) characteristics, may represent a useful tool to make clinical decisions. Further prospective evaluations are needed to include this marker in clinical practice.

**RELATIVE PROGRESSION-FREE SURVIVAL OVER TIME OF NOVEL TRIPLET REGIMENS FOR THE TREATMENT OF RELAPSED/REFRACTORY MULTIPLE MYELOMA**

K. Betts1, C. Chen2, M. Zichlin1, A. Brun2, J. Signorovitch1, D. Makenbaeva2.

1Analysis Group, Inc., Boston, MA, 2Bristol-Myers Squibb, Inc., Plainsboro, NJ, United States

**Background:** In combination with lenalidomide (REV/LIMID®) and dexamethasone (d), elotuzumab (EMPILICTI™, E), carfilzomib (KYPROLIS®, K), and ixazomib (NINLARO®, N) were recently approved for the treatment of relapsed/refractory multiple myeloma (RRMM). In randomized controlled trials, all three drugs showed a significant relative reduction in the risk of disease progression or death as compared to patients who received Rd. To date, there have been no head-to-head trials comparing ErD, KrD, and/or NdR.

**Aims:** To describe the time-specific progression-free survival (PFS) based on published Kaplan-Meier PFS curves for ErD, KrD, and NdR relative to Rd.

**Methods:** Individual patient-level data (IPD) were reconstructed from the published Kaplan-Meier PFS curves from the ELOQUEST-2 (ErD), ASPIRE (KrD), and TOURMALINE-MM1 (NdR) randomized, controlled, Phase III trials using digitization software and the methods described by Guyot, et. al. Using the reconstructed IPD, Kaplan-Meier survival curves were estimated for each arm within each trial. PFS curves were digitized by two independent researchers and the reconstructed curves were overlaid with the published data to validate the IPD. In each trial, the relative PFS benefit over time was calculated as the difference in the Kaplan-Meier PFS estimate of each triplet regimen and the Kaplan-Meier PFS estimate of Rd divided by the Kaplan-Meier PFS estimate of Rd: \( \frac{PFS(X \text{ triplet regimen}) - PFS(Rd)}{PFS(Rd)} \). Where \( X \) denotes the Kaplan-Meier PFS estimate at time \( t \), and \( t \) denotes E, K, or N, respectively.

**Results:** PFS from the three randomized controlled trials was successfully reconstructed and validated. Numerically, ErD had the highest relative PFS over the initial 10 months of treatment and showed sustained benefit from month 24 onwards (Figure 1). At 12 months, the relative PFS benefit was 17.9% for ErD, 21.7% for KrD, and 9.7% for NdR. At 24 months, the relative PFS benefit was 45.1% for ErD, 34.3% for KrD and 24.1% for NdR. At 36 months, the relative PFS benefit was 39.9% for ErD and 19.1% for KrD. ErD had a higher relative PFS than NdR for almost the entirety of RRMM treatment. At the end of data availability, KrD and NdR showed no additional PFS benefit relative to Rd, while ErD showed a sustained benefit through 40 months. Data will be updated for the conference, where available.

**Summary/Conclusions:** For the treatment for RRMM, ErD showed an early and sustained benefit in relative PFS which was maintained through 40 months. KrD and NdR showed initial benefits which faded by the end of data availability.

**E1301**

**POMALIDOMIDE WITH LOW-DOSE DEXAMETHASONE IN PATIENTS WITH RELAPSED OR RELAPSED AND REFRACTORY MULTIPLE MYELOMA: A PROSPECTIVE ANALYSIS IN A POPULATION-BASED REGISTRY**

R. Wexters1,2, A. Dimmohamed1,2,3, P. Sonneveld1, A. Brojil1, N. Blijlevens4

1Department of Hematology, Erasmus Medical Center Cancer Institute, Rotterdam, 2Department of Research, Netherlands Comprehensive Cancer Organisation (KKNL), Utrecht, 3Department of Public Health, Erasmus University Medical Center, Rotterdam, 4Department of Hematology, Radboud umc, Nijmegen, Netherlands

**Background:** Patients with relapsed and/or refractory multiple myeloma (RRMM) have limited treatment options and a poor prognosis. Previous trials showed that pomalidomide combined with low-dose dexamethasone is effective in these patients with improvement in response and survival. These studies led to the approval of pomalidomide as third line treatment in patients with RRMM.

A prospective analysis in a population-based registry was conducted to assess response and survival in patients with RRMM treated with a pomalidomide-based regimen. Also, we defined subgroups who benefit most of this treatment regimen.

**Methods:** Patients were eligible for pomalidomide if they received ≥2 prior lines of therapy including bortezomib, lenalidomide and alkylator therapy and developed progressive disease on their last therapy. This is a prospective analysis of patients registered at the nationwide Netherlands Cancer Registry. Treatment consisted of 4mg pomalidomide, day 1-21, combined with corticosteroids. Treatment was discontinued in case of progressive disease or unacceptable toxicity. Primary endpoint was progression-free survival (PFS). Secondary endpoints included overall survival (OS), overall response rate (ORR), toxicity, response per risk group (based on cytogenetics and ISS at initial diagnosis) and response per age group (>65 vs ≥65 years).

**Figure 1.**

**Summary/Conclusions:** For the treatment for RRMM, ErD showed an early and sustained benefit in relative PFS which was maintained through 40 months. KrD and NdR showed initial benefits which faded by the end of data availability.
Results: A total of 82 patients (median age 68 years [range: 43-88]) were included in this analysis. CRAB criteria included anemia in 23 patients (28%), renal insufficiency in 8 (9.8%), hypercalcemia in 13 (16%) and bone lesions in 54 (66%). Median time from diagnosis to start pomalidomide was 5.75 years [range: 0.8-18.4], median number of treatment cycles was 3 [range: 1-17]. At time of analysis 59 patients had stopped pomalidomide treatment: 24 patients had progressive disease, 10 had unacceptable toxicity, 6 patients were refractory. 4 patients died during treatment and 15 patients stopped due to various other reasons. Grade ≥3 hematological adverse events occurred in 11% of patients, 4% had neutropenic fever. Grade ≥3 non-hematological toxicities occurred in 57% of patients, including infection in 22%, gastrointestinal disorders in 5% and renal disorders in 5%. Of 69 patients evaluable for response ORR was 41%, with a partial response (PR) rate and a very good partial response (VGPR) rate of 36% and 4% respectively. Response based on age was not significantly different (p=0.426). Median PFS for all patients was 3.8 months (95% confidence interval [CI] 2.3-6.8). Patients >65 years had a longer PFS of 5.7 months (95% CI 2.3-8.0) versus 2.8 months (95% CI 1.9-6.6) in patients ≤65, however, this was not statistically significant (p=0.427) (figure 1). For patients achieving ≥PR, median PFS was 9.6 months (95% CI 5.7-Not reached (NR)). Median PFS in patients diagnosed more than ten years prior to initiation of pomalidomide treatment was 9.6 months (95% CI 5.7-Not reached (NR)), as compared to 2.2 months (95% CI 1.3-6.8) among patients treated within 5 years after diagnosis (p=0.05). Data about previous treatment, ISS stage, cytogenetics at diagnosis and an update of OS will be presented at EHA.

Figure 1.

Summary/Conclusions: In this analysis the experience in clinical practice of patients with RRMM treated with a pomalidomide-based regimen is reported. These data support results shown in clinical trials. Preliminary data presented here suggest that older patients and patients with a long interval between initial diagnosis and pomalidomide treatment (indicating a less aggressive multiple myeloma) may benefit from this treatment.

INVOLVED/UNINVOLVED HEAVY/LIGHT CHAIN INDEX CAN PREDICT PROGRESSION IN MULTIPLE MYELOMA PATIENTS AFTER AUTOLOGOUS PERIPHERAL BLOOD STEM TRANSPLANT. PRELIMINARY EXPERIENCE

M. Espiño Martínez1, A. Arteche Lopez2, A. Arriero3, C. Muñoz-Calleja4, A. Alegre Amor5, M.J. Blanchard Rodríguez6, F.J. López Jiménez7, L.M. Villar4

1Immunology, University Hospital Ramon y Cajal, 2Clinical Analisis, 3Haematology, 4Immunology, University Hospital La Princesa, 5Haematology, University Hospital Ramon y Cajal, Madrid, Spain

Background: High-dose therapy followed by autologous peripheral blood stem transplant (APBSCT) has demonstrated to improve overall survival and progression-free survival with a high complete remission rate in multiple myeloma (MM) patients. However, most patients eventually present progression or relapse (P/R). Detection of P/R is mainly based on a significant increase of monoclonal protein (MC) or free light chains (sFLC). The identification of new biomarkers to early predict P/R might be clinically useful for an anticipated therapy.

Aims: The aim of our study was to evaluate the potential role of the Involved/Uninvolved Heavy/Light Chain index (I/Ui) in this setting.

Methods: We prospectively followed 44 MM transplanted patients: 19 with IgG-kappa isotype, 11 with IgG lambda, 9 with IgA-kappa and 5 with IgA-lambda. They were followed for 29.0±8.1 months (mean±standard error (SE)). Serial serum samples from each MM patients were collected periodically after APBSCT. Relapse or progression was defined according IMWG criteria. To identify factors that predict disease progression in MM transplanted patients, we studied heavy/light chains (HLC) pair quantification, sFLC and total immunoglobulins levels in serial serum samples collected during the follow-up. Involved/uninvolved index (I/Ui) was calculated using the monoclonal chain (Involved) as numerator and the polyclonal chain of the same class (Uninvolved) as denominator. The HLC ratio (HLC) was calculated as IgGk/IgGk or IgAl/IgAl with normal reference ranges established in 1.3-3.7 for IgG and 0.7-2.2 for IgA.

Results: In IgG MM patients, values of I/Ui were significantly increased in pre-relapse compared to basal samples (8.49±4.01 vs 2.23±0.67 p=0.012). By contrast, this index remained stable along follow-up in patients in complete remission (CR) or with a partial response (PR). However, the later showed higher values of I/Ui ratio, suggesting that the presence of an M-component induces immunosuppression of the uninvolved chain in MM patients. Regarding IgA MM, we established a cut-off value of 2.0 for I/Ui that allowed the discrimination of patients at high risk of early progression (values above 2.0) from those in CR, whose levels of I/Ui are always below 2.0 (p=0.02).

Summary/Conclusions: Our results show that HLC-pair measurement could detect progression or relapse and the increase of MC in transplanted MM patients earlier than other methods. Future studies will need to demonstrate the real value of the I/Ui index as a biomarker to anticipate progression in MM patients subjected to APBSCT.

E1303

MULTIPLE MYELOMA IMMUNOPHENOTYPIC REMISSION IS A SIGNIFICANT PREDICTOR OF PROGRESSION FREE SURVIVAL AFTER FIRST AUTOLOGOUS STEM CELL TRANSPLANTATION - PILOT STUDY

K. Beranova1, J. Radocha1, O. Soucek2, K. Machalikova1, J. Hanousek1, P. Zak1, V. Maisnar1

1IV. interni hematologicka klinika, 2Institute of Clinical Immunology and Allergology, Fakultni nemocnice Hradec Kralove, Hradec Kralove, Czech Republic

Background: Minimal residual disease in multiple myeloma assessed by multiparameter flow cytometry has become an increasingly important predictor of progression-free survival (PFS).

Aims: Our primary endpoint was to evaluate PFS in myeloma patients after stem cell transplantation who reached immunophenotypic CR (iCR) versus those who have not.

Methods: We prospectively evaluated prognostic importance of minimal residual disease detection by multiparameter flow cytometry (MFC) in multiple
myeloma patients who underwent autologous stem cell transplantation from January 2014 until December 2016. All patients were uniformly treated with bortezomib-based induction therapy followed by high dose chemotherapy (Melphalan 200mg/m²) and autologous stem cell transplantation. Minimal residual disease (MRD) status was determined by 8-colour MFC 1 month after autologous transplantation from bone marrow aspirate in all patients who achieved at least conventional VGPR or CR.

Results: We identified 56 patients who fulfilled the above mentioned criteria. 30 were males and 26 females, median age was 61. 62.5% of patients (35/56 patients) achieved ICR, 37.5% of patients (21/56) did not. Median follow up of the cohort was 19 months (6-59), 32.1% of patients (18/56) relapsed during the follow-up period. 16.1% of patients (9/56) died. 22.9% (13/55 patients) in ICR and 47.6% (10/21 patients) not in ICR relapsed during the follow up. Patients in ICR showed significantly longer PFS with median 42 months than those in less than ICR with PFS median 29 months (p=0.0196, log-rank test). This was reflected in a hazard ratio of relapse (0.3365) for ICR group.

Summary/Conclusions: Achieving immunophenotypic CR is clearly associated with longer progression free survival compared to conventional CR. Reaching ICR should be a goal of myeloma treatment.

REGULATION OF NORMAL AND MONOCLONAL IMMUNOGLOBULIN SECRETION BY CYTOKINES (S- SYNDECAN-1, BLYS & TGF-BETA-1) IN PATIENTS WITH IG-SECRETING B-CELL DISORDERS AT PRESENTATION. PROGNOSTIC IMPLICATIONS

E. Koulieri1, P. Papaioannou1,2, E. Nikolaidi1, K. Sarris1, D. Maltezas1, S. Harding2, N. Kafassi2, K. Tsalmalina1, K. Bitsian1, T. Tzeno1, V. Bartzi1, P. Petsal1, S. Kotsian1, A. Koudouna1, E. Kastritis4, S. Sachanas5, P. Panayiotidis1, M.-C. Kyrtsonis1

1Hematology Section - 1st Department Of Propaedeutic Internal Medicine, Laikon General Hospital, Athens, Greece, 2Binding Site Ltd, Birmingham, United Kingdom, 3Immunology Laboratory, Laikon General Hospital, 4Therapeutic Clinic, Alexandra’s Hospital, 5Hematology Clinic, Medical Center Psychoy, Athens, Greece

Background: The most common neoplastic lymphoproliferative diseases that secrete paraprotein are multiple myeloma (MM), Waldenstrom's Macroglobulinemia (WM) and chronic lymphocytic leukemia (CLL). The two first entities secrete paraprotein by definition, while serum free light chains (sFLC) are increased in 50% of CLL cases. Microenvironmental factors, such as soluble Syndecan-1 (ssynd-1) and BlyS normally promote lymphoplasmacytic differentiation as well as their secretory activity, whereas, like TGFβ1, inhibit them. Determination of Ig is necessary in MM and WM for diagnostic purposes and for monitoring patients, while in CLL, sFLC has prognostic value. The total amount of secreted Ig does not really reflect disease burden. The heavy chain and for monitoring patients, while in CLL, sFLC should be a goal of myeloma treatment.

Table 1.

Aims: To determine any possible relationship between the amount of Igs secreted by BM plasma cells and TGFβ1, as well as with disease outcome.

Methods: We studied 269 patients: 105 with MM (79 IgG and 26 IgA, of whom 33%, 31%, and 36% were staged ISS 1, 2 and 3 respectively), 64 suffering from WM (44%, 28%, 28% staged WM-IPSS 1, 2, 3 respectively), and 100 with CLL (67%, 23%, 10% staged Binet 1, 2, 3 respectively). Patients were regularly followed from the last visit or death (median follow up 5 months). sFLC/sFLCR and HLC/HLCR were determined by nephelometry. They were then followed-up from diagnosis to last visit or death (median follow-up time: 63 months). sFLC/sFLCR and HLC/HLCR were determined by nephelometry. By inhibiting both monoclonal and polyclonal Ig, TGFβ1 correlated with MM in both HLC and FL/C ratios and differences. In addition, the aforementioned variables are prognostic with regard to patients’ outcome.

E1305

PATIENTS WITH MULTIPLE MYELOMA (MM) IN LONG TERM COMPLETE REMISSION (LTRC) AFTER AUTLOGOUS TRANSPLANT (APBSCT) EXPRESS A DISTINCTIVE IMMUNE PROFILE WITH POTENTIAL PROGNOSIS VALUE

A. Arteche-Lopez1,*, A. Alegre Amor2, A. Kreutzmann3, B. Aguado4, M. Espino Martinez2, L.M. Villan2, P. Sanz2, A. Arrerio2, C. Muñoz-Calleja4

1Clinic Analysis, 2Haematology, 3Immunology, University Hospital La Princesa, 4Haematology, Immunology, University Hospital Ramon y Cajal, Madrid, Spain

Background: A small fraction of patients with MM could be considered potentially cured as long as they remain for more than six years in long term complete remission (LT-MMC). A retrospective study of the immune status of these patients could highlight interesting information.

Aims: Here we present an observational study that evaluates the numbers and phenotype of T- and B-cells subsets in the peripheral blood (PB) of MM-LTCR patients and compares them to healthy subjects (HS).

Methods: After approval by the ethics committee, we selected 13 patients diagnosed with MM, in sCR according to IMWG criteria for at least six years after APBSCT, and 15 healthy adults (HA) of similar ages as a comparative group. Group MM: 7 males and 6 females; median age: 61. Median follow-up in sCR according to APBSCT was 8 years (range 6-19). Group HA: 5 females and 10 males, median age 40 (36-78) Immunophenotype characterization was done using a comprehensive 8-color flow cytometry panel. Subpopulations of CD4+ and CD8+ T-cells from PB were quantified, including naïve, central and effector memory regulatory T-cells, as well as subpopulations of B-cells: naïve, transitional, marginal zone-like, class-switched memory and plasmablasts. In order to confirm their specific immune signature, the analysis was repeated in the same LTRC-MM patients one year after the first analysis was done. A Kruskal-Wallis test was used to evaluate differences among the studied groups. A posteriori test was done to compare the control group with the two patient’s group (patients and patients +1 year), independently of each other. A Wilcoxon matched test was used to compare a patient under group “patients” with the status of the same patient under the second group “patients +1 year”. Statistical analysis was done using GraphPad Prism software.

Results: The patients had a lower percentage of total CD4+T-cells (p=0.0004) together with a decrease in the naive CD4+ T-cells (CD27-CCR7+CD45RA+); p=0.0004) and an increment of the effector memory CD4+ T-cells (CD27-CCR7+; p=0.0028), both CD27-CCR7+CD45RA and CD27-CCR7+CD45RA+. Similar results were found within the DB+T-cells. No differences were observed in the T-cells defining CD4+CD25hiCD127. The percentage of total B-cells in the patients was within the normal range and no significant differences were found when compared to HA. However, naive B-cells (CD27+IgD+IgM+) proportion was higher in patients and a corresponding reduction of marginal zone-like B-cells (CD20-CD27+IgD+) and IgM+ (p=0.0047) and class-switched memory B-cells (CD27+IgD-IgM; p=0.0043) was observed. No differences were observed in the percentage of transitional B-cells (CD27-CD10+CD38+) or plasmablasts (CD27+ CD38*) in the PB of the two groups. When the analysis was repeated in the same LTRC-MM patients one year after the first analysis, no changes were detected neither when analysed as a group nor when analysed individually.

Summary/Conclusions: The MM-LTCR patients seem to express a distinctive immune “footprint” characterized by a decreased proportion of naïve T-cells and an increased percentage of effector T cells, which probably exert a competent immune surveillance. Conversely, the increase in naïve B-cells may guarantee the humoral response homeostasis, involving plasma cells that might compete with myelomatous cells for normal bone marrow niches. The precise role of these refined immunological studies in the monitoring and therapeutic decisions in MM patients, and also in the duration of sCR, should be defined in the future.

Study partially performed with research grants from the spanish Leukemia and Lymphoma Foundation and Grant P11/00494P from the Fondo de Investigaciones Sanitarias and FEDER funds.

BASAL CALCIUM, AN IMPORTANT ELEMENT IN THE DEVELOPMENT OF CALR MUTANT MPNS

M. Morlán Mairal1,*, P. Papadopoulos2, M. Krstic-Demonacos 1, A. Aziz1,2
1Salford University, Manchester, United Kingdom, 2Hospital Clínico San Carlos, Madrid, Spain

Background: Calreticulin (CALR) is a calcium (Ca2+) buffering chaperone mutation of which has recently been associated with essential thrombocythemia and primary myelofibrosis without JAK2 mutations. These mutations have been suggested to impair the Ca2+buffering activity of Calreticulin due to a change of the negative charge in its C-terminal domain. Ca2+ is known to be important during megakaryocyte activity; however its role during megakaryopoiesis and the possible link of CALR mutations and abnormal megakaryocyte production due to impaired Ca2+ buffering activity in myeloproliferative neoplasms (MPNs) remains unclear.

Aims: Here we aim to understand how basal Ca2+ fluctuates during normal megakaryopoiesis and how CALR mutations could affect the basal Ca2+ levels in megakaryocytes in MPNs.

Methods: Ca2+ staining was performed using Flu-8 dye and Ca2+ basal levels were measured by flow cytometry. Changes in basal Ca2+ during megakaryopoiesis using two cellular systems, K-562 cells and mouse bone marrow cells, were measured each 24 hours. Further studies using CALR mutant cellular models were performed using the same methodology.

Results: Our results showed a characteristic behaviour of fluctuations of basal Ca2+ in normal megakaryopoiesis. Changes in basal Ca2+ during megakaryopoiesis, where Ca2+levels decrease in the last stage of megakaryocyte formation. These results suggest that Ca2+ reduction could be essential for megakaryopoiesis. In order to understand how CALR mutations affect basal Ca2+, Marimo cells and Dami cells expressing CALR mutations were analysed. Here we show a decrease in basal Ca2+ in Marimo cells and Dami-CALR type 2 mutation compared to the controls. Moreover, Dami-CALR type 1 did not show any significant reduction, suggesting possible differences in Ca2+ behaviour depending in CALR type mutation. We are currently working in the analysis of basal Ca2+ fluctuations during megakaryopoiesis in the presence of CALR mutations and preliminary results show abnormal basal Ca2+ levels throughout all the process of megakaryocyte differentiation.

Summary/Conclusions: Altogether, our findings indicate that basal Ca2+ could be an important element during megakaryopoiesis and CALR mutations found in MPN could impair the normal production of megakaryocytes due to changes in cellular Ca2+. However, further analysis need to be done in order to understand the role CALR mutations and their effect in the Ca2+ buffering activity of CALR in MPNs.

E1308

THE INHIBITION OF JAK/STAT SIGNALING IS COMPENSATED BY ACTIVATION OF MAPK PATHWAY IN MYELOPROLIFERATIVE NEOPLASMS

T. Subolči1, B. Belesin Cokić1, J. Santibanez2, V. Čokić3
1Laboratory of neuroendocrinology, Institute for Medical Research, University of Belgrade, 2Clinic for endocrinology, Diabetes and Metabolic Diseases, Clinical Center of Serbia, 3Laboratory of experimental hematology, Institute for Medical Research, University of Belgrade, Serbia

Background: Myeloproliferative neoplasms (MPN) remain incurable regardless of advancement in the use of JAK2 inhibitor Ruxolitinib, which competence is unrelated to the JAK2V617F mutation.

Aims: We want to explore JAK2 inhibition dependency in correlation with activated JAK/STAT3 signaling and cell cycle in MPNs.

Methods: The immunoblotting has been used to analyze activation of JAK/STAT3, PI3K/AKT and MAPK signaling in JAK2V617F mutated HEL cells and granulocytes of MPN. The cell cycle and apoptosis of granulocytes are studied by flow cytometry.

Results: Concerning myeloproliferation, JAK1/2 inhibitors reduced the percentage of cells in G2M phase and increased apoptosis in JAK2V617F mutated HEL cells. Comparing to polycythemia vera (PV), the percentage of granulocytes is decreased in S and G2M phases of essential thrombocythemia (ET) and primary myelofibrosis (PMF) that demonstrated increased apoptosis. Hexam bromocyclohexane increased percentage of granulocytes in GoG1 phase of JAK2V617F positive, but reduced in JAK2V617F negative PMF, the later one similar to Ruxolitinib. JAK1/2 inhibitors reduced percentage of apoptotic granulocytes in JAK2V617F positive, but increased in JAK2V617F negative PMF. JAK1/2 inhibitors could not impair the constitutive activation of JAK/STAT3 signaling in HEL cells as well as in granulocytes of JAK2V617F positive ET and PMF. Absence of JAK2V617 mutation supported dephosphorylation of JAK/STAT3 pathway by JAK1/2 inhibitors in ET, but not in PMF. JAK1/2 inhibitor
Ruxolitinib largely activates MAPK signaling in MPN, while slightly PI3K/AKT signaling in PV and JAK2V617F negative PMF. Specific JAK2 inhibitor Hexa-bromocyclohexane activates PI3K/AKT signaling in JAK2V617F positive ET, but reduced in JAK2V617F negative ET and PMF.

Summary/Conclusions: This observation support cross-talk between examined pathways, where inhibition of JAK/STAT3 signaling is compensated by activation of MAPK pathway irrespective of JAK2V617F mutation, while PI3K/AKT signaling demonstrates JAK2V617F dependence in MPN.

CIRCULATING PLATELET AND MEGAKARYOCYTE-DERIVED MICROPARTICLES OF JAK2V617F MUTATED PATIENTS WITH MYELOFIBROSIS ARE DISRUPTED: A NOVEL LIQUID BIOPSY TOOL OF RESPONSE TO RUXOLITINIB?

M. Barone 1, F. Ricci2, D. Forte3, D. Sollazzo1, M. Romano1, M. Spinsanti1, E. Ottaviani1, M. Cavo1, N. Vianelli1, P. Tazzari2, F. Palardini4, L. Catani4.4
1Department of Experimental, Diagnostic and Specialty Medicine, Institute of Hematology and Blood Bank Service, Azienda Ospedaliero-Universitaria S. Orsola-Malpighi, Bologna, Italy

Background: Microparticles (MPs) are small vesicles (0.1-1 micron) deriving from plasma membrane budding during homeostasis and cell activation. MPs express antigens and contain constituents from cell of origin and are increased in conditions that are characterized by high cell turnover or death, particularly inflammatory, autoimmune and neoplastic diseases. Myelofibrosis (MF) is a clonal neoplasia of the hematopoietic stem/progenitor cells characterized by disturbed hematopoiesis in megakaryocytes (MK) development and platelet (PLT) activation. Mutations in 3 genes (JAK2, CALR, MPL) and chronic inflammation are the main pathogenic drivers of MF. Ruxolitinib (RUX), a JAK1/2 inhibitor, suppresses both clonal myeloproliferation and release of proinflammatory cytokines, reducing splenomegaly and constitutional symptoms in around 50% of patients (pts). We hypothesized that MPs, as mediators of inflammation, could be overexpressed in MF and possibly predict responses to RUX.

Aims: This study aims to: 1) enumerate circulating MK and PLT-derived MPs of MF pts; 2) evaluate the effect of RUX on MPs production by PLT and MK; 3) investigate whether circulating MK and PLT- MPs may be a biomarker of response to RUX.

Methods: EDTA-anticoagulated peripheral blood from healthy donors (HD, n=10) and JAK2V617F positive MF pts (n=12) at intermediate-2 high IPSS risk was collected at baseline and 3 and 6 months after RUX therapy and immediately centrifuged. MPs (normal MPVs in megakaryocytes (MK) development and platelet (PLT) activation. Mutations in 3 genes (JAK2, CALR, MPL) and chronic inflammation are the main pathogenic drivers of MF. Ruxolitinib (RUX), a JAK1/2 inhibitor, suppresses both clonal myeloproliferation and release of proinflammatory cytokines, reducing splenomegaly and constitutional symptoms in around 50% of patients (pts). We hypothesized that MPs, as mediators of inflammation, could be overexpressed in MF and possibly predict responses to RUX.

Aims: This study aims to: 1) enumerate circulating MK and PLT-derived MPs of MF pts; 2) evaluate the effect of RUX on MPs production by PLT and MK; 3) investigate whether circulating MK and PLT- MPs may be a biomarker of response to RUX.

Methods: EDTA-anticoagulated peripheral blood from healthy donors (HD, n=10) and JAK2V617F positive MF pts (n=12) at intermediate-2 high IPSS risk was collected at baseline and 3 and 6 months after RUX therapy and immediately centrifuged. MPs (normal MPVs) were analyzed in PLT poor plasma samples by flow cytometry (CytoFLEX, Flow Cytometer-Becman Coulter). The instrument was calibrated with MEGAMIX Beads (Beckman Coulter) with various diameters to cover the MPs (0.5 and 0.9μm).

Results: At 3 and 6 months, 5 out of 12 pts achieved a spleen response (R) according to 2013-IWG-MRT criteria. At baseline, the mean percentage of MK-derived MPs was significantly decreased (29±6 vs 72±5; p<0.001) while that of PLT-derived MPs significantly increased (49±7 vs 11±1; p<0.001) in MF pts compared to HD. However, the mean percentage of MK-derived MPs from pts not achieving a spleen response (NR) was significantly decreased compared to R pts (17±6 vs 72±5; p<0.001). By contrast, the mean percentage of PLT-derived MPs was significantly increased in NR compared to R (64±7 vs 37±5; p<0.05) and HD (64±7 vs 11±1; p<0.001). Of note, NR pts had significantly lower PLT number as compared with R (220±29 vs 64±7; p<0.001) and NR pts had significantly lower PLT number as compared with R (64±7 vs 17±6; p<0.001). Of note, NR pts had significantly lower PLT number as compared with R (220±29 vs 11±1; p<0.001). The difference was observed at baseline and according to 2013-IWG-MRT criteria. At 3 and 6 months, 5 out of 12 pts achieved a spleen response (R) according to 2013-IWG-MRT criteria. At baseline, the mean percentage of MK-derived MPs was significantly decreased (29±6 vs 72±5; p<0.001) while that of PLT-derived MPs significantly increased (49±7 vs 11±1; p<0.001) in MF pts compared to HD. However, the mean percentage of MK-derived MPs from pts not achieving a spleen response (NR) was significantly decreased compared to R pts (17±6 vs 72±5; p<0.001). By contrast, the mean percentage of PLT-derived MPs was significantly increased in NR compared to R (64±7 vs 37±5; p<0.05) and HD (64±7 vs 11±1; p<0.001). Of note, NR pts had significantly lower PLT number as compared with R (220±29 vs 64±7; p<0.001) and NR pts had significantly lower PLT number as compared with R (64±7 vs 17±6; p<0.001). Of note, NR pts had significantly lower PLT number as compared with R (220±29 vs 11±1; p<0.001). The difference was observed at baseline and according to 2013-IWG-MRT criteria. At 3 and 6 months, 5 out of 12 pts achieved a spleen response (R) according to 2013-IWG-MRT criteria. At baseline, the mean percentage of MK-derived MPs was significantly decreased (29±6 vs 72±5; p<0.001) while that of PLT-derived MPs significantly increased (49±7 vs 11±1; p<0.001) in MF pts compared to HD. However, the mean percentage of MK-derived MPs from pts not achieving a spleen response (NR) was significantly decreased compared to R pts (17±6 vs 72±5; p<0.001). By contrast, the mean percentage of PLT-derived MPs was significantly increased in NR compared to R (64±7 vs 37±5; p<0.05) and HD (64±7 vs 11±1; p<0.001). Of note, NR pts had significantly lower PLT number as compared with R (220±29 vs 64±7; p<0.001) and NR pts had significantly lower PLT number as compared with R (64±7 vs 17±6; p<0.001). Of note, NR pts had significantly lower PLT number as compared with R (220±29 vs 11±1; p<0.001). The difference was observed at baseline and according to 2013-IWG-MRT criteria.
Results: 110 patients diagnosed with PMF according to WHO criteria between years 2013 and 2014 were included into this study. SNP-A analysis identified 77 chromosomal abnormalities in 61 patients (55.4%). These comprised the loss of heterozygosity (LOH) (59.7%), hemizygous deletions (23.4%) and copy number gains (16.9%). The most common aberrations in affected patients were: 5p LOH (55.7%), 20q deletion (11.5%), 1q duplication (4.9%), 19p deletion (3.2%), 1p deletion (3.2%) and 6q LOH (3.2%). NGS analysis detected 219 gene mutations (in a total of 27 genes) in 108 patients (98%). The most frequently mutated genes were: JAK2 (62.9%), CALR (27.8%), ASXL1 (20.3%), TET2 (16.6%), MPL (7.4%), <5% ZRSR2, EZH2, DNMT3A, U2AF1, ETV6, SF3B1, IDH1, IDH2. Recurrent specific mutations were identified in 10 genes. Sixty-two patients (57.4%) had more than one mutation. Recurrent specific mutations were primarily type 1 (54%) and type 2 (30%).

Summary/Conclusions: A number of associations between gene mutations and chromosomal aberrations was detected in PMF. Co-presence of 9p LOH with JAK2V617F and CALR mutations with 19p deletion indicate that further deregulation of these key signaling pathways may take place disrupting the second allele of the affected genes by different biological mechanism – LOH or deletion.

E1312
FREQUENCY OF CONCURRENT BCR-ABL1, JAK2, CALR AND MPL MUTATIONS IN A COHORT OF 5,545 CASES WITH SUSPECTED MPN BY A DEEP SEQUENCING APPROACH
S. Jeromin1, M. Meggendorfer1, A. Fasan1, C. Haferlach1, W. Kern1, T. Haferlach1
1 MLL Munich Leukemia Laboratory, Munich, Germany

Background: Chronic myeloid leukemia (CML) is a myeloproliferative neo-plastic condition characterized by BCR-ABL1 in about 90% of BCR-ABL1-negative MPN a mutation in CALR, JAK2 or MPL can be detected. These genetic alterations are thought to be nearly mutually exclusive, however, an accurate frequency is still missing.

Aims: To determine the incidence of genetic markers occurring in parallel in a large cohort of patients with suspected MPN and characterize double mutated cases.

Methods: From July 2016 till January 2017 5545 samples were sent to our laboratory with suspected MPN. The male:female ratio was 1:1, and the median age was 60 years (range: 18-95 years). Median white blood cell count was 9x10^9/L, hemoglobin level (Hb) was 15g/dl, and platelet count 329x10^9/L. All of these cases were analyzed by an amplicon deep sequencing approach for mutations in JAK2 (exon12, exon14), CALR (exon9) and MPL (exon10) with a sensitivity of 1%. 3070 patients were additionally screened for BCR-ABL1 fusion by a multiplex PCR approach. Samples that were double mutated for JAK2, CALR and MPL were analyzed by amplicon deep sequencing for additional mutations in 13 myeloid genes.

Results: In total 1775/5545 (32%) of suspected MPN patients showed JAK2, CALR and/or MPL mutations. 1438 (26%) were JAK2(+), 267 (5%) were CALR, and 89 (1%) MPL mutated. Of note, the analysis of a subgroup (n=3070) for BCR-ABL1 fusion identified 123 (4%) as CML cases. The JAK2 mutated cases presented mainly with Va117Phe (99%) and rarely with JAK2 exon12 mutations (1%). CALR mutations were primarily type 1 (54%) and type 2 (30%). MPL mutations were located at amino acid Trp515 in 96% of cases. Double mutated cases were present in 19/1775 (1%) cases: JAK2/MPL (63%), JAK2/CALR (32%) and CALR/MPL (6%). In nearly all CALR mutated cases (67%) the affected gene mutation was detected with the higher load, whereas in JAK2/MPL double mutated cases the ratio was equal. Most of the patients (18/19) had one mutation with a load below 10% and could have been missed by other approaches. BCR-ABL1 together with JAK2 or CALR mutation was found in one patient, each (0.006%). 18/19 patients were analyzed by the deep sequencing approach. All cases that already received treatment for CML were suspected to have independent BCR-ABL1-negative MPN. For two of these patients, samples 1 and 6 years prior to diagnosis of CML were available. Both showed CALR mutations already at this former time-point at high loads. In 10/19 (63%) double mutated patients 46/48 (10%) mutations were detected in 8 different genes. SS3FS2 and TET2 were the two most frequently mutated genes (5, each). No significant difference in mutation frequency was detected to the overall frequency in MPN patients with single mutations. The JAK2, CALR and/or MPL mutated vs wild-type cases showed higher age (mean: 67 vs 56 years, p<0.001) and higher platelet count (mean: 649 ± 210 x10^9/L, p<0.001). Overall, the mutated cases showed a statistically significant different according to the presence of mutations as follows: triple-negative (56 years), CALR (63 years), JAK2 (67 years), MPL (71 years) and double mutated (74 years).

Summary/Conclusions: One-third of the cases can be diagnosed having mutations to BCR-ABL1 fusion and/or MPL mutation in an unselected cohort with suspected MPN. The frequency of double mutated JAK2, CALR and MPL cases is 1%. In CML cases BCR-ABL1 fusion and JAK2 or CALR mutation were detected in 2% of the patients. The impact of these parallel genetic events on the clinical course of the disease has to be evaluated in the future.

A COMPREHENSIVE ASSESSMENT OF MOLECULAR AND CYTOGENETIC MARKERS OF PROGNOSIS IN PATIENTS WITH PRIMARY MYELOFIBROSIS
L. Poluskinina1, I. Martynykevich1, V. Shvauve1, E. Motyko1, M. Fominykh1, I. Krivolapov2, Z. Asaulenko2, L. Martynenko1, M. Ivanova1, N. Cybacova1, D. Shikhbabeva1, A. Zhemaykova1, S. Voloshin1, S. Bessmeliev1, A. Chechetkin1
1 Russian Research Institute of Hematology and Transfusiology, 2 North-Western State Medical University named after I. I. Mechnikov, Saint-Petersburg, Russian Federation

Background: According to resent reports the data of molecular and cytogenetic analysis (type or absence of driver mutation (DM), mutations in ASXL1, EZH2, IDH1/2 genes, karyotype) is a promising tool for prediction of survival in primary myelofibrosis (PMF). Multiple combinations of genomic aberrations lead to clinical course and survival heterogeneity. The aforementioned factors need to be considered together to evaluate their mutual influence.

Aims: The aim of the study was to evaluate a prognostic impact of DM, mutational status of epigenetic regulation (ER) genes, karyotype and their combinations for overall survival (OS) in PMF patients.

Methods: We have examined 110 patients (pts) with PMF (34.5% males). Median (Me) age was 59 years (16–82). For all pts the detection of JAK2V617F was done. JAK2(+) samples were tested for MPL 515 codon mutations and exon 9 mutations of CALR (direct sequencing). All pts except 4 underwent the analysis of mutations in ASXL1, EZH2, IDH1/2 genes with high resolution melting method followed by sequencing of probably mutated samples. Karyotype research was done for 48 (43.6%) pts.

Results: DM were detected in 81.8% pts: JAK2(+) - 50%, CALR(+) - 25.5%, MPL(+) - 6.4% cases. No DM were found in 18.2% pts considered triple-negative (TN). Mutations in ER genes were detected in 20.8% pts. High risk (HR) chromosome aberrations (CH) unfavorable CA4M2, del(6)(q15), add(6)(p25), del(X)(q22), t(X;7)(p21;q11) were found in 27.1% pts. Univariate analysis identified HR karyotype (hazard ratio (HR) 8.2, p<0.001), the absence of DM (HR 8.1, p<0.001) and nonsense and frameshift (hereinafter mut) (HR 2.9, p=0.018) but not missense mutations of ASXL1 (HR=0.378) as being prognostically detrimental for survival. CALR mutations had a favorable impact on survival with borderline significance (HR 0.3, p=0.052). A multivariate analysis included TN, CALR, ASXL1 status and karyotype as covariates revealed an inter-independent prognostic value of HR karyotype (HR=7.4, p<0.001) and ASXL1 mut (HR=2.8, p=0.023). In Cox regression model considering the same covariates except karyotype TN status (HR=2.4, p=0.050) and ASXL1 mut (HR=3.3, p=0.012) but not CALR mutations (HR=0.3, p=0.075) were significant for OS. CALR mutations became significant (HR=0.3, p=0.075) when only ASXL1 mut were included as covariate (HR=3.9, p=0.004). When comparing groups divided by CALR(+)ASXL1 status the shortest OS was noted (p<0.001). The median overall survival of groups was 3.7 years (p=0.011) in CALR(+)ASXL1 wide type (wt) pts seem to have better OS than CALR(+)ASXL1wt (median not reached (with follow up period of 10.1 years) and 3.5 years, respectively, p=0.124). Median OS estimated in pts due to presence/absence of DM and ASXL1 status.
was 0.9 years in TNA SLX1wt, 3.6 years in TNA SLX1wt, 13.8 years in DM(+) ASXL1wt and was not reached in DM(+)/ASXL1wt (with follow up period of 10.3 years) group (p<0.0001). Differences in OS depending on the ASXL1 status were statistically significant in the TN (p=0.007) but not for DM(+) group (p=0.786). The better OS was observed in ASXL1wt pts with low risk (LR) karyotype (Me 6.4 years, p=0.0005). There were no differences in OS of ASXL1wt HR, ASXL1mut LR and ASXL1mut HFs pts (1.4 vs 1.6 vs 1.2 years, p=0.493).

**Summary/Conclusions:** The differences in OS were more statistically relevant in groups divided by TN/ASXL1 and karyotype/ASXL1 status. The presence of ASXL1mut significantly worsens OS in the TN group. OS in pts with any of the findings: HR karyotype or ASXL1 mut – was significantly shorter than in cytogenetically favorable ASXL1wt counterparts.

**JAK2 HAPLOTYPE 46/1 (GGCC) HAS NO EFFECT ON THE PRIMARY RISK OF JAK2 V617F MUTATION, BUT IT STRONGLY POTENTIATES THE PROGRESSION OF GROWN ALLELE BURDEN IN MYELOPROLIFERATIVE NEOPLASMS**

M. Stolyar1,2,*, O. Klimova3,4, A. Gorbenko1, S. Titov3,4, I. Olkhovskiy1,5
1Krasnoyarsk Branch of the Federal State-Funded Institution «National Research Center for Hematology» of the Ministry of Healthcare of the Russian Federation, 2Siberian Federal University, 3AO Vector-Best, 4Institute of Molecular and Cellular Biology, Siberian Branch of Russian Academy of Sciences, Novosibirsk, 5Federal Research Center "Krasnoyarsk Scientific Center of the Russian Academy of Sciences, Siberian Branch", Krasnoyarsk, Russia

**Background:** Several research groups have determined that the JAK2 46/1 (GGCC) haplotype in multiple ethnic groups is strongly associated with a predisposition to acquiring JAK2 V617F-positive MPNs. The role of the JAK2 46/1 haplotype in the natural evolution of the mutant JAK2V617F allele burden in PV but not ET or PMF has been shown [Alvarez-Larrán A e.a. Leukemia 2012, 36(3):324-326]. However, the data on the impact of the haplotype on the JAK2 V617F allele burden do not always agree. Using a highly sensitive test allowed to reveal a high prevalence JAK2 V617F among persons without symptoms of hematological disorders [Krichevsky S e.a. Blood Cells, Molecules and Diseases, doi: 10.1016/j.bcmd.2017.01.001]. Influence of haplotype 46/1 for such cases is not known. There are two competing hypotheses of "hypermutability" and "fertile ground" explaining the causes of the higher frequency of mutations of JAK2V617F in haplotype 46/1 carriers. The "hypermutability" hypothesis refers to an increased risk of primary mutation in carriers of haplotype 46/1. In this case, the increasing frequency of the haplotype in patients with low allele burden (<5%) must also be observed, including those individuals without evidence of hematological disorders.

**Aims:** Studying the relations of haplotype 46/1 and JAK2 V617F allele burden

**Methods:** The diagnosis of chronic myeloproliferative neoplasms was based on the WHO (2008) criteria. The cohort included patients with JAK2 V617F mutation: 100 patients with PV, 51 with ET, 14 with MF, 41 patients with unclassified Chronic Myeloid Neoplasms (CMN), 52 patients with BCR-ABL1-positive Chronic Myeloid Leukemia, 29 with Acute Myeloid Leukemia (AML) and 3 patients with undifferentiated AML.

**Results:** The JAK2 46/1 haplotype (GG and GC) was present in 170 patients (80.6%) with MPN, in 25 (52%) patients with suspected MPN, in 23 (49%) asymptomatic JAK2 V617F+ pts and in 42 (42%) cases of control group. G variant of rs10974944 was more frequent in all JAK2 V617F-positive MPNs, than in the control population (χ²=46.5, p=0.0001). These results were similar to findings of previous studies, which have shown that the 46/1 haplotype predisposes to the acquisition of JAK2 V617F mutation. JAK2 V617F allele burden was significantly higher in patients with PV than in patients with ET (p=0.001), but no differences were observed with from patients with the PMF. 46/1 haplotype was closely associated with MPN patients if the allele burden exceeds 5% (Fig. 1) regardless of the phenotype or the treatment. In this case with an increase in JAK2V617F allele burden the JAK2 46/1 haplotype frequency significantly increased. However, there was no significant difference in the JAK2 46/1 haplotype frequencies between patients with allele burden less than 5% and the control group.

**Summary/Conclusions:** No significant differences of the carrier haplotype between control group and patients with minimal allele burden (less than 5%) JAK2 2V617F have been observed. This is evidence against primary "hypermutability" hypothesis. A further increase in allele load is more pronounced in carriers of haplotype 46/1 that supports the "fertile ground" hypothesis. We hypothesize that DNA mutation JAK2V617F repair is downregulated in carriers of haplotype 46/1 that supports the "fertile ground" hypothesis.

**MINIMAL RESIDUAL DISEASE MONITORING BY DIGITAL PCR FOR JAK2V617F DETECTION IN PATIENTS WITH MYELOFIBROSIS (MF) OR ACUTE MYELOID LEUKEMIA SECONDARY TO MF AFTER ALLOGENIC STEM CELL TRANSPLANTATION (ASCT)**

S. Salmoiraghi1,*, C. Belotti, M.C. Finazzi, M.C. Micò1, A. Algarotti1, G. Finazzi1, M. Mascheroni1, A. Salvi1, A. rambald12, O. Spinelli1
1Hematology and Bone Marrow Transplant, ASST Papa Giovanni XXIII, Bergamo, 2Oncology and Hematocology, University of Milan, Milan, Italy

**Background:** Myelofibrosis (MF) is one of the BCR-ABL1-negative Chronic Myeloproliferative Neoplasms (MPNs), characterized by clonal expansion of abnormal hematopoietic progenitors and gradual replacement of normal bone marrow with fibrous tissue. Patients’ prognosis is widely variable and the mortality rate can vary from 24% to 40% at 5 years. Allogeneic Stem Cell Transplantation (ASCT) is the only curative treatment option for these patients. The most frequent phenotype-driving mutation in MF is the V617F mutation in the JAK2 gene. A high sensitive quantification of JAK2V617F mutation can be useful to assess Minimal Residual Disease (MRD) in treatment directed to eradicate the malignant clone, such as ASCT. Droplet Digital PCR (ddPCR) is a quantitative assay for the detection of rare allele characterized by a high level of sensitivity and specificity.

**Aims:** To evaluate the efficacy of ddPCR JAK2V617F mutation detection assay in monitoring the MRD level at consecutive time-points in a small cohort patients who underwent an ASCT for MF or MF-derived Acute Myeloid Leukemia (s-AML).

**Methods:** DNA from 9 patients affected by primary, secondary MF or s-AML were serially collected during the follow-up after ASCT (50-2500 days). These samples were investigated for hematologic chimerism by PowerPlex System (Promega, Madison, WI, USA) and were evaluated for JAK2V617F mutation both by conventional allele specific PCR (ASO-PCR) and by a validated ddPCR mutation detection assay (Bio-rad, USA). Results were expressed as percentage of JAK2V617F mutated alleles on total evaluated alleles.

**Results:** The JAK2V617F ddPCR mutation assay was able to detect low muta- tion load (up to 0.006%), confirming to be much more sensitive than ASCT (0.5-2%). In 4 patients, early after transplantation, we observed by ddPCR a low level of MRD that progressively increased during the follow-up and antici- pated a decrease in donor chimerism level and a worsening of clinical situation. In 2 patients, who showed a full donor chimerism and complete hema- tologic remission of the disease, very low levels of MRD (ranging from 1% to 0.006%) could be detected by ddPCR in the 2 years after ASCT. With a longer follow-up, a full molecular remission was achieved as demonstrated by ddPCR. In 2 other patients, we observed a very early achievement of full donor chimerism and JAK2V617F molecular negativity (within 90 days post HSCT), also when evaluated by ddPCR. These patients entered a complete hematologic remission of the disease which still persists (after 1 and 5 years after transplantation, respectively). Interestingly, in one patient whose post-transplant hematopoiesis proved full donor and negative for JAK2V617F mutation for 2 years, a weak positive signal revealed by ddPCR (0.075%) became apparent after a subsequent ASCT. A subsequent second allogeneic transplant from the same sibling donor restored clinical and molecular remission.

**Summary/Conclusions:** The ddPCR proved to be a sensitive and accurate method in detecting JAK2V617F mutation. Therefore, this assay can be a valid tool for MRD monitoring in patients who underwent ASCT. However, the use of this highly sensitive PCR should be considered with caution in the clinical management of transplanted patients to avoid inappropriately use of donor leukocyte infusion (DLI) and tampering of immunosuppression. A large
number of patients have to be studied with ddPCR to better understand the clinical significance of low mutation load.

S100A8/9 ACTIVATION OF MAPK PATHWAY IS SUPPORTED BY ITS RECEPTORS RAGE AND TLR4 IN POLYCYTHEMIA VERA
M. Kovačić1, O. Mitrović-Ajić2, B. Beleslin-Cokić2, M. Diklić3, T. Subotić1, D. Djikic1, S. Momčilović1, D. Lekovic4,5, M. Gotić5, V. Cokić3

1Laboratory of molecular hematology, Institute for Medical Research, 2Clinic for Endocrinology, Diabetes and Metabolic Diseases, Genetic laboratory, Clinical Center of Serbia, 3Laboratory of experimental hematology, Institute for Medical Research, 4Clinic of Hematology, Clinical Center of Serbia, 5Medical Faculty, University of Belgrade, Belgrade, Serbia

Background: S100A8 proteins have been shown to regulate cell proliferation, excessively augmented in myeloproliferative neoplasms (MPN). S100A8/9 is produced by cells of myeloid origin as mediator of inflammation, while AKT and MAPK pathways mediate cell proliferation.

Aims: This study analyzed activation of AKT and MAPK pathways by S100A8/9 proteins in healthy controls and MPNs: polycythemia vera (PV), essential thrombocytopenia (ET), primary myelofibrosis (PMF), according to JAK2V617F and CALR mutation status.

Methods: S100A8/9 factor is examined in granulocytes of MPN using immunoblotting, while its influence on cell cycle of granulocytes is determined by flow cytometry. Mutations of JAK2V617F and CALR exon 9 are analyzed by DNA sequencing. Besides JAK2V617F+/PV patients, we formed three groups of patients: JAK2V617F+, JAK2V617F-/CALR+, and JAK2V617F-/CALR- for ET and PMF.

Results: S100A8/9 proteolites demonstrated a common significant increase in plasma of MPN patients, whereas the presence of CALR mutation augmented S100A8/9 levels in granulocytes of ET and PMF patients. Activation of AKT pathway is generally reduced by S100A8/9 factor, further on ameliorated by inhibition of the receptor for advanced glycation end products (RAGE) in granulocytes of JAK2V617F+ and JAK2V617F-/CALR+ groups of ET and PMF patients, while it has been prevented by Toll-like receptor 4 (TLR4) inhibition in PV patients. MAPK pathway is significantly inhibited by S100A8/9 only in JAK2V617F+ ET patients and JAK2V617F-/CALR- PMF patients, partially prevented by TLR4 inhibition in PMF. Inhibition of TLR4 reduced S100A8/9 medi- ated MAPK activation has been significantly augmented by TLR4 and RAGE inhibition in PV patients. S100A8/9 stimulated granulocyte cycle arrest in G2M phase has been stopped by JAK1/2 inhibition.

Summary/Conclusions: S100A8/9 protein levels demonstrated stable elevation in MPN patients. Inhibition of AKT pathway has been controlled by TLR4, whereas MAPK pathway activation by TLR4 and RAGE in PV, during treatment with S100A8/9.

MUTATIONAL PROFILE STUDY OF DOUBLE-NEGATIVE ESSENTIAL THROMBOCYTEMIA BY HIGH-DEPTH NEXT GENERATION SEQUENCING (NGS)
G. Carreno-Tarragona1, I. Rapado1, R. Ayala1, A. Arenas1, J. Martínez-López1
1Haematology, Hospital Universitario 12 de octubre, Madrid, Spain

Background: Essential thrombocytemia is one of the three classical philadelphia negative myeloproliferative neoplasms. It is frequently difficult to diagnose and some molecular markers are used as diagnostic criteria according to WHO classification. Despite this, a significant proportion of patients do not present a clonality marker.

Aims: To identify the mutational profile of ET negative for V617F and CALR mutations and to correlate it with clinical diagnosis.

Methods: A cohort of 22 ET negative for mutations in JAK2 (qPCR) and CALR (GENESCAN) was selected. Median age at diagnosis was 46 years (range: 14-88), male:female ratio 9:13; 2 patients had a record of thrombotic event at diagnosis, 3 patients suffered thrombotic event after diagnosis, 1 patient suffered transformation to AML. Median Hb, WBC and platelets at diagnosis were respectively 14.75g/dl, 8.5 x1012/L and 720 x109/L. We performed targeted gene sequencing by NGS (Ion Torrent Proton System–Life Technologies) using a panel of 33 genes implicated in leukemia prognosis. X2 and t-student tests were used to find association between mutations and clinical data.

Results: On average, 97.94% of the target sequence showed a mean depth coverage around 2500. We discovered 17 non-synonymous mutations which 16 were somatic single nucleotide variants (SNVs) and 1 a nucleotide deletion in coding regions. No mutations were detected in 9 samples (40.9%), 10 samples suffered a somatic mutation (45.5%), and the other 3 samples presented 1 or more mutations (16.3%). TET2 was the most frequently mutated gene (18.2% of patients, mean allele frequency of 24.45%), followed by JAK2 (13.6% V617F at a low mean allele frequency of 5.8%), MPL (9.1%, one W515L, one with two mutations W515R and S505C, mean allele frequency of 21.95%), SF3B1 (4.5% DNMT3A (4.5%), JAK1 (4.5%), MPL (4.5%) and KMT2A (4.5%). The samples with more than one mutation: one presented a CBL and two TET2 mutations, one two mutations in MPL and the other one mutation in TET2 and other in JAK2. No correlation was found between mutational profile and clinical data.

Summary/Conclusions: In ET, around 60% of patients present the JAK2V617F mutation, 15-30% show CALR mutations and around 5% present MPL mutations. In spite of this, there is still a significant percentage of ET patients without a molecular marker. Our study shows that the use of a NGS panel allows identifying markers of clonality as for example TET2. NGS also makes affordable to interrogate whole genes classically associated to ET, to detect mutations that were not found by traditional approaches. Finally, we can conclude, as previously described, that ET is an entity with a low mutational burden in comparison with other MPNS as primary myelofibrosis.

TGF GAMMA CLONALITY ASSESSED BY NGS DOES NOT HELP TO DISTINGUISH EGPA FROM HES
S. Galimbert1,2, E. Ciabatti2, F. Guerini1, M. R. Meleti1, I. Petrin1, G. Tarri2, M. Lalor1, E. Elefante1, F. Ferro1, R. Grossi1, N. Plasanti1, S. Grassi1, G. Petri1, M. Mosca1, G. Baldini1
1Clinical and Experimental Medicine, University of Pisa, Hematology, 2Clinical and Experimental Medicine, University of Pisa, Hematology, 3Hematology Molecular Laboratory, AOU, 4Department of Translational Research and New Technology in Medicine, General Pathology, 5Cardio-Thoracic and Vascular Department, 6Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy

Background: Hypersinophilic associated syndromes are a heterogeneous group of diseases characterized by sustained and elevated blood eosinophilia with evidence of eosinophil-induced organ damage. Classically, Eosinophilic Granulomatosis with Polyangiitis (EGPA) and Hypereosinophilic Syndrome (HES) present several overlapping clinical and laboratory features, making it challenging to correctly insert patients in restricted and well-defined categories with specific and more effective therapeutic approaches in daily practice. Therefore, great efforts are ongoing searching for novel biomarkers able to differentiate these two disorders.

Aims: To detect T cell receptor gamma (TCRG) clonal rearrangements in EGPA and HES, comparing the frequency of distribution of the V and J region segments in 21 patients afferent to the hematology, rheumatology or pulmonology divisions.

Methods: Consecutive patients with a diagnosis of EGPA and HES were enrolled into the study. Inclusion criteria were: documentation of a persistent peripheral eosinophilia and at least two organ involvement. Clinical and laboratory data of the patients were collected. Sequence-based determination of the frequency distribution of TCRG Gene Rearrangements was performed using next-generation sequencing with the illumina MiSeq (LymphoTrack TCR analysis). The following TCRG gene rearrangements were observed: Vg10JgP1 (5 cases) and Vg4Jg1/2 (4 cases) were observed in both EGPA and HES. No association was observed between TCRG clonal rearrangements and ANCA status in EGPA patients. Number of following recurrent TCRG gene rearrangements were observed: Vg10JgP1 (5 cases) and Vg4Jg1/2 (4 cases) were observed in both EGPA and HES, whereas Vg9Jg1 (2 cases) and Vg10Jg1/2 (2 cases) were observed only in patients with HES. The presence of TCRG rearrangement was not different according to the symptoms (asthma, vasculitis, skin, heart, gut, lung involvement, splenomegaly). IL2, IL5, IL4, eosinophilic cytokine (ECP), absolute eosinophils were measured: IL5 and ECP were higher in the EGPA patients. This study confirms our previous results showing the TCR delta rearrangement (assessed by qualitative PCR) in 40% of the EGPA patients.
Background: We already demonstrated augmented proinflammatory IL-6 and angiogenic vascular endothelial growth factor (VEGF), hypoxia inducible factor-1α (HIF-1α) and endothelial nitric oxide synthase (eNOS) levels in myeloproliferative neoplasms (MPN).

Aims: To observe IL-6 activated signaling pathways during stimulation of angiogenic factors and their JAK-STAT dependence in MPN.

Methods: We analyzed phosphorylation of JAK/STAT3, PI3K/AKT and MAPK signaling by immunoblotting in HEL 92.1.7 cells (with JAK2V617F mutation) and granulocytes of MPN. The granulocyte cycle phases have been studied by flow cytometry.

Results: We demonstrated IL-6 stimulated angiogenic factors in HEL cells and HEL-derived macrophages, blocked by JAK-STAT inhibition for eNOS and HIF-1α. IL-6 stimulated JAK-STAT3 and angiogenesis related PI3-AKT signaling pathways in HEL cells, the later one prevented by JAK1/2 inhibition. Opposite to primary myelofibrosis (PMF), IL-6 activation of JAK-STAT3 and PI3-AKT pathways has been prevented and enhanced by JAK1/2 inhibition, respectively in granulocytes of polycythemia vera (PV). Moreover, IL-6 inhibition of JAK-STAT3 and PI3-AKT pathways in essential thrombocythemia (ET) has been prevented by JAK2 inhibitor in JAK2V617F positive ET granulocytes. JAK1/2 inhibitor Ruxolitinib upregulated IL-6 activators of MAPK pathway in PMN, in contrast to specific JAK2 inhibitor Hexabromocyclohexane. IL-6 mediated reduction in the percentage of HEL cells in G2M phase was inversed by Ruxolitinib that potentiated apoptosis and reduced the cell percentage in G0G1 phase both in HEL cells and granulocytes of PMF. It has been detected the cell cycle arrest of MPN granulocytes in S phase (DNA replication) after treatment with IL6, completely diminished by JAK1/2 inhibition.

Summary/Conclusions: Therefore, we concomitantly revealed that inflammation stimulated angiogenic factors and signaling pathways involved in cell proliferation, apoptosis and angiogenesis are regulated by JAK-STAT inhibition.

Background: The global MPN LANDMARK survey evaluated the patient (pt) and physician-reported impact of myeloproliferative neoplasms (MPNs), including myelofibrosis (MF), polycythemia vera (PV), and essential thrombocythemia (ET), among pts from 6 countries. We present an analysis comparing physician and pt perceptions of the impact of these MPNs.

Aims: To investigate differences between pt and physician perceptions of symptom burden, treatment goals, and disease management

Methods: This was a cross-sectional survey of pts with MPNs and physicians treating pts with MPNs. Respondents completed an online survey measuring their perception of the impact of MPNs on symptom burden, treatment management, and treatment goals. Pts and physicians were recruited independently.

Results: Pts (n=699) from Australia (n=10), Canada (n=64), Germany (n=149), Italy (n=106), Japan (n=84), and the UK (n=286) completed the survey (MF, n=223; PV, n=174; ET, n=302). Most pts had been diagnosed within ≤2 years of experiencing symptoms (73%); 56% were women. Physicians (n=219) were from the same countries; most were hematologists (54%) or hemato-oncologists (27%). Overall, 54% of pts reported having a prognostic score; however, 71% of physicians reported using a prognostic risk classification. Physicians assessed symptoms by proactively asking pts how they were feeling (43%) or asking about specific symptoms (37%); 11% waited for pts to mention symptoms. Importantly, only 26% of physicians used a validated symptom assessment form; 44% used their own rating method. Pts and physicians both agreed that pts with MPNs have a high symptom burden and that MF had a higher degree of burden on daily living. Interestingly, a higher proportion of physicians...
than pts felt that MPN symptoms have an impact on pt quality of life (92% vs 76%) and that pts had a substantial emotional burden associated with their disease. For instance, 34%, 29%, and 26% of pts with MF, PV, or ET reported feeling anxious or worried compared with 70%, 46%, and 36% of physicians reporting that their pts experience substantial anxiety or worry. Some pts did not recognize that their symptoms could be MPN related; for example, ≈ one-fifth of pts did not think that their night sweats could result from their MPN (16% MF, 21% PV, 25% ET). Consistent with this, 60% of physicians indicated that pts could identify only few or some of their symptoms as MPN related. Pts and physicians were both concerned about reducing symptoms (pts: 70% MF; 61% PV, 53% ET; physicians: 80% MF, 55% PV, 60% ET); however, pts were also concerned about delaying MPN progression (58% MF, 57% PV, 66% ET; physicians: 43% MF, 28% PV, 37% ET; Figure 1). Compared with pts, physicians indicated a greater focus on prevention of vascular/thrombotic events in PV (66% vs 48%) and ET (80% vs 60%). Overall, only 27% of physicians felt they completely agreed with their pts on treatment goals; 66% felt they “somewhat” agreed. However, most pts (87%) were satisfied with their physician’s disease management/communication.

Summary/Conclusions: This study revealed a potential disconnect between physician and pt perceptions relating to communication and disease management, and an apparent lack of standardization in symptom assessment. Of note, some pts did not recognize that their symptoms could be MPN related and had different treatment goals than their physicians, indicating a need for improved pt education and pt-physician communication and a treatment plan that includes standardized monitoring of symptoms and agreement on treatment goals.

Figure 1.
Results: The final study cohort comprised of 2,619 PMF pts. Median follow-up period was 28 months (interquartile range (IQR) 11-56). Median age at diagnosis was 68 years (interquartile range 59-77 years) with 60.6% (n = 1,586) ≥ 65 years old. More than half of the pts were male (58.5%; n=1,531); 82.2% (n=2,153) were white, and 16.4% (n=430) were diagnosed between 2012 and 2013. The geographic distribution was as follows: East 14.8%, South 18.4%, West 54.2% and Midwest 12.6%. Median OS was 42 months (Figure 1). The hazard ratio of all-cause mortality for age was 1.05 (95% Confidence interval (CI) 1.04-1.05), for female vs male was 0.72 (CI 0.64-0.80), for nonwhite vs white 1.01 (CI 0.87-1.16), for unmarried vs married was 1.04 (CI 0.94-1.16), for patients diagnosed 2012-2013 vs 2000-2011 was 0.95 (CI 0.75-1.20). Compared to West, the hazard ratio of OS for East, South and Midwest was 1.05 (CI 0.90-1.22), 1.28(CI 1.12-1.47), 1.03(CI 0.88-1.19) respectively. Summary/Conclusions: This population-based study showed that the overall survival of pts with PMF was short. Older and male pts were associated with higher mortality risk. There were significant differences across geographic regions of the United States. Although there is a trend of improvement in the period of 2012 to 2013, the result is not statistically significant, partially due to short follow up. These findings underscore the continuing need for effective therapies for pts with MF.

E1323

SERUM ALBUMIN IS A STRONG PREDICTOR OF SURVIVAL IN MYELOFIBROSIS, INDEPENDENT OF IPSS, DIPSS, AND DIPSS+ SCORES

1University of South Florida/Moffitt Cancer Center, 2Moffitt Cancer Center, Tampa, United States

Background: Albumin is the main protein in human plasma. Serum albumin (SA) is used as a surrogate marker of nutritional status and inflammation. The prognostic role of SA has been studied in many diseases, including hematologic malignancies. In myelofibrosis (MF), rouxolitinib has been shown to improve SA levels in addition to other metabolic parameters. SA holds particular significance in MF given its ability to capture both nutritional status and inflammation level in a disease hallmark by hyperactive inflammatory pathways and constitutional symptoms.

Aims: We aim to closely evaluate the significance of SA in MF patients as it pertains to clinical presentation, laboratory correlations, disease genomics, comorbidities and outcomes.

Methods: We retrospectively reviewed an institutional database of 376 MF patients who presented to Moffitt Cancer Center between 1/1/1998 and 12/31/2012 and had available SA levels within 30 days of presentation. Laboratory values and prognostic scores were determined at time of first presentation. Overall survival (OS) was measured from time of first presentation until date of death or censored at time of last follow-up. Progression free survival (PFS) was defined as time from first presentation to development of acute myeloid leukemia (AML).

Figure 1.

Results: Our cohort of MF patients had median age of 67 and 69 at diagnosis and presentation, respectively. Most patients had primary MF (73%) with 11% and 16% having post-PV PMF and post-ET MF, respectively. First, we looked at the correlation between SA and other clinical factors. SA was positively correlated with hemoglobin (p<0.01) and platelet count (p<0.01), and negatively correlated with age (p<0.01), peripheral blast percentage (p=0.03), ferritin (p<0.01), prognostic scoring models (p=0.01 for IPSS, DIPPS and DIPSS+) and packs-year smoking history (p<0.01). SA did not correlate with spleen size or any specific somatic mutation, but negatively correlated with somatic mutation burden (p=0.03). On univariate regression, SA was associated with inferior PFS (HR: 0.31 [0.13-0.72]; p<0.01) and OS (HR: 0.25 [0.17-0.36]; p<0.01). Four cohorts were created based on SA: cohort I=SA 2.5-3.5 g/dL (n=31); cohort II=SA 3.6-4.0 g/dL (n=89); cohort III=SA 4.1-4.5 g/dL (n=182); and cohort IV=4.6 g/dL (n=84). OS increased with increasing SA; with median OS in cohorts of 9.34, 25.3, 48.4, and undefined in cohorts I-IV, respectively. On focused comparison, each cohort was significantly different than all others. On multivariate analysis, the influence of SA on OS remained significant after controlling for prognostic scores (IPSS, DIPSS, DIPSS+) and comorbidities. For patients diagnosed 2012-2013 versus 2000-2011 was 0.95 (CI 0.75-1.20). Compared to West, the hazard ratio of OS for East, South and Midwest was 1.05 (CI 0.90-1.22), 1.28(CI 1.12-1.47), 1.03(CI 0.88-1.19) respectively.

Summary/Conclusions: This population-based study showed that the overall survival of pts with PMF was short. Older and male pts were associated with higher mortality risk. There were significant differences across geographic regions of the United States. Although there is a trend of improvement in the period of 2012 to 2013, the result is not statistically significant, partially due to short follow up. These findings underscore the continuing need for effective therapies for pts with MF.

CLINICAL UTILITY OF NEXT-GENERATION SEQUENCING IN THE MANAGEMENT OF MYELOPROLIFERATIVE NEOPLASMS

W. Alduaij1, C. McNamara1, A. Schuhh1, A. Arruda1, M. Sukhal3, M. Thomas3, J.Y. Spiegel1, J.A. Kennedy2,5, T. Stockley2, H. Tuill, R. Devlin1, N. Siddiqi1, H. Sibai1, D. Maze1, A. Schimmer2, K. Yee2, S. Chan2, S. Kamel-Reid7, V. Gupta1, S. Kamel-Reid7

1MPN program, Princess Margaret Cancer Centre, 2Hematology- Princess Margaret Cancer Centre, 3Advanced Molecular Diagnostics Laboratory, Princess Margaret Cancer Centre, 4Applied Molecular Oncology, Ontario Cancer Institute, University Health Network, University of Toronto, Toronto, Canada, 5Division of Hematology, Department of Medicine, Brigham and Women’s Hospital, Boston, MA, United States, 6Department of Hematology, Department of Medicine, Brigham and Women’s Hospital, Boston, MA, United States, 7Molecular Diagnostics, Department of Pathobiology and Laboratory Medicine, University Health Network, University of Toronto, Toronto, Canada

Background: Although Next Generation Sequencing (NGS) has helped characterize the complex genomic landscape of myeloid malignancies, its clinical utility remains not well defined. Funding for NGS testing by healthcare systems or third party payers is variable due to the lack of data on its utility in a routine care setting. At our centre, targeted sequencing (TAR-seq) is offered to all new patients referred for myeloid malignancies as part of the Advanced Genomics in Leukemia (AGILE) program.

Aims: In this study, we evaluate the impact of TAR-seq on the management of patients with a diagnosis of MPN or post-MPN acute myeloid leukemia (MPN/AML).

Methods: All consenting patients referred to the MPN program at the Princess Margaret Cancer Centre between February 15 and December 31, 2016 with a suspected or confirmed diagnosis of MPN were evaluated (n=188). TAR-seq was performed on DNA extracted from peripheral blood (n=159, 85%) or bone marrow (n=29, 15%) using the TruSight Myeloid Sequencing Panel (Illumina), a targeted NGS panel of 54 genes (39 hotspot region; 15 complete coding region covers) implicated in myeloid malignancies. Reporting was confined to high quality exonic nonsynonymous, intronic splice site, frameshift, nonsense and known pathogenic synonymous variants. Variants with global mean allele frequency >1% were identified using multiple population databases (1000 genomes, ESP, ExAC) and excluded. Each patient’s TAR-seq results were reviewed alongside their clinical information systematically by at least two hematologists with expertise in MPN, and disagreements were resolved by consensus.

Results: 179 patients fulfilled the 2008 WHO diagnostic criteria for MPN: 107 were diagnosed with myelofibrosis (MF), 26 with polycythemia vera (PV), 21 with essential thrombocythemia (ET), 13 with other MPN and 12 with unspecified MPN. Of the remaining 12 with unclassifiable and 12 with MPN/AML. In 6 patients with ‘triple negative’ MPN, who lacked mutations in the driver genes JAK2, CALR and MPL, TAR-seq confirmed clonal hematopoiesis through identifying other mutations. In 61 transplant-eligible patients with MF, 32 (52%) were considered to carry a high molecular risk profile based on scoring at various centers in AML, AML, EZH2, IDH1/2, SRSF2 or TP53; or a total of three or more mutations. Of these, 11 patients (34%) were considered for early transplant, three with Intermediate-1 and eight with Intermediate-2 risk, who were responding well to JAK 1/2

haematologica | 2017; 102(s2) | 543

Madrid, Spain, June 22 – 25, 2017
implications. Together with transfusion requirement, CCI and BMI may influence survival in RUX-treated MF pts. Taking into account these additional parameters may allow to better define survival probability beyond IPSS risk assessment. Unfavorable CCI and BMI did not hamper responses to RUX; also, the achievement of a spleen response counterbalanced the negative prognostic effects of a lower BMI.

E1325
IMPACT OF COMORBIDITIES AND BODY MASS INDEX ON SURVIVAL IN PATIENTS WITH MYELOFIBROSIS TREATED WITH RUXOLITINIB
1Department of Hematology, University of Bologna, Bologna, 2Division of Hematology and BMT, Azienda Santaria Universitaria Integrata di Udine, Udine, 3Department of Hematology, University of Verona, Verona, 4Division of Hematology, Ospedale Ferrarotto, University of Catania, Catania, 5Division of Hematology, Azienda Ospedaliera-IRCSS Arcispedale Santa Maria Nuova, Reggio Emilia, 6Unit of Blood Diseases and Stem Cell Transplantation, ASST Spedali Civili di Brescia, Brescia, 7Division of Hematology, IRCCS AOU San Martino IST, Genova, 8Division of Hematology, University of Ferrara, Ferrara, 9Hematology and Stem Cell Transplant Center, AORN Hospital, Pesaro, 10Hematology and Clinical Immunology Unit, University of Padova, Padova, 11Division of Cellular Biotechnologies and Hematology, University Sapienza, Roma, 12Division of Hematology, ASST Spedali Civili di Brescia, Brescia, 13Division of Hematology, Azienda Ospedaliero-Universitaria di Parma, Parma, 14Division of Hematology, Placenza, 15Division of Hematology, Casal di Sorgano, San Giovanni Rotondo, 16U.O.S. Ematologia, Ospedale Nuovo Regina Margherita, Roma, Italy

Background: Charlson Comorbidity Index (CCI) and body mass index (BMI) are significantly associated with outcome in patients (pts) who receive continue treatment with tyrosine kinase inhibitors. Ruxolitinib (RUX) is the first JAK1/2 inhibitor that may induce spleen/symptom responses and improve quality of life in pts with myelofibrosis (MF). No data are yet available on the impact of comorbidities and BMI on pts treated with RUX.

Aims: To evaluate the impact of CCI and BMI on overall survival (OS) in a cohort of RUX-treated MF pts.

Methods: A multicenter observational study on WHO-defined MF treated with RUX according to standard clinical practice was conducted in 20 Italian Hematology Centers. Response to RUX was evaluated according to 2013 IWG-MRT criteria. OS was calculated from the date of RUX start to the time of death or last follow-up. Baseline parameters evaluated for correlation with OS were: blood cell count, spleen ≥10cm, marrow fibrosis grading, time from MF diagnosis to RUX start, transfusion dependency, mutation status, Total Symptom Score (TSS), CCI and BMI.

Results: Between June 2011 and Apr 2016, 343 pts with PMF (51.9%), or post-ET (20.1%) / post-PV (28.0%) were treated with RUX in participating Centers. At RUX start, median age was 67.6 years (range 35.6-89.0) with a male prevalence (57.1%); International Prognostic Score System (IPSS) was interme- diate (intm-1) (16.0%), intm-2 (47.5%), high (38.4%). Transfusion dependency (HR: 1.74; p=0.039) and IPSS (intm-2; HR: 3.19; p=0.057; high risk: HR: 6.89; p<0.001) were significantly correlated with OS (Fig. 1A). Also, a higher CCI did not correlate with lower spleen response at 6 months (44% vs 34% of pts with CCI<3, p=0.11). The impact of higher CCI on survival was only mildly affected by the achievement of a spleen response at 6 months (Fig. 1B).

Figure 1.

Summary/Conclusions: Together with transfusion requirement, CCI and BMI may influence survival in RUX-treated MF pts. Taking into account these additional parameters may allow to better define survival probability beyond IPSS risk assessment. Unfavorable CCI and BMI did not hamper responses to RUX; also, the achievement of a spleen response counterbalanced the negative prognostic effects of a lower BMI.

E1326
ANALYSES OF 845 PATIENTS WITH PMF, PET-MF AND PPV-MF TREATED IN 35 GERMAN HEMATOLOGY CENTERS – A RETROSPECTIVE FIELD STUDY
B. Kragl1,*, C. Wassenberg2, H. T. Steinmetz3, G. Springer4, K. Jentsch-Ullrich5, A. Gaumann5, J. Dengler7, C. Junghanss1
1Department of internal medicine 3, Hematology, Oncology, Palliative Care, University of Rostock, Rostock, 2Gefos Dortmund mbH, Dortmund, 3Gemeinschaftspraxis für Onkologie und Hämatologie, Köln, 4Hämato-Onkologische Schwerpunktpraxis, Stuttgart, 5Schwerpunktpraxis für Hämatologie und Onkologie, Magdeburg, 6Institut für Pathologie, Kaufbeuren, 7Schwerpunktpraxis Onkologie, Heilbronn, Germany

Background: Primary myelofibrosis (PMF) as well as secondary post essential thrombocythemia (pET)-MF and post polycythemia vera (pPV)-MF are considered rare diseases associated with significant morbidity. Diagnostics and therapeutic options have significantly improved during the last decade by development of novel drugs, improvement of allogeneic stem cell transplantation (SCT) procedures and supportive care. Whereas the characteristics of PMF, pET-MF and pPV-MF patients (pts) participating in clinical trials are well analyzed, data are rare for the general MF population including patients not included in or eligible for clinical trials.

Aims: In order to gain a broader, more comprehensive data set on the general MF population we performed a questionnaire poll in 35 German hematology centers gathering characteristics on 845 pts who were currently under care.

Methods: A questionnaire asking for general patient and disease specific data as symptoms, treatments, comorbidities and outcome, was sent to all centers in 2017. The questionnaire included 178 questions which were divided into 5 categories: patient characteristics, disease characteristics, procedure details, therapy details and outcome.

Results: 35 hematology centers participated in the study. A total of 845 patients were included, 477 with PMF (56.5%), 208 with post-ET-MF and 160 with post-PV-MF. The median age at diagnosis was 68 years (range 18-93). The median time of diagnosis to questionnaire was 7 years (range 0-34). The primary malignant disease was myelofibrosis in 717 patients (85.0%), myelofibrosis associated with another malignant disease in 53 patients (6.3%), and other malignant diseases in 75 patients (8.8%). The median number of comorbidities was 1 (range 0-3). The median number of transfusions was 3 (range 0-28). The median number of all hematopoietic SCT was 1 (range 0-10).

Summary/Conclusions: The questionnaire shows that the primary malignant disease was myelofibrosis in the majority of patients (56.5%), followed by post-ET-MF (20.8%) and post-PV-MF (19.7%). The median age at diagnosis was 68 years (range 18-93). The median time of diagnosis to questionnaire was 7 years (range 0-34). The median number of comorbidities was 1 (range 0-3). The median number of transfusions was 3 (range 0-28). The median number of all hematopoietic SCT was 1 (range 0-10).
was 03/2013-2015. 845 pts were included i.e. a median of 20 pts (range 6-90 pts) per center

**Results:** Gender was equally distributed (50%/50%). Pts ages at initial diagnosis as were as follows:<50 years (31%), 50-69 years (31%), 70-79 years (31%), and ≥80 years (40%). Current age was >65y in 70% of all pts. PMF represented the largest MF cohort (77%), followed by Ph-MPN (10%), PV-MF (7%) and unspecified (6%). Median survival was 5.3 years (range 1-month-24 years). Significant differences were observed in the distribution of the following subgroups: less pts younger than 50 and more pts over 70 years old in the Ph-MPN group, more pts younger than 70 years old in the PV-MF group and in the unspecified group, and more pts younger than 65 years old in the PMF group. The majority of pts had myelofibrosis (61%).

**Conclusion:** Our study showed that the majority of pts in this Spanish cohort had MF with myelofibrosis. The median survival was 5.3 years and the majority of pts at diagnosis had myelofibrosis. The current age distribution was different from other published studies where younger ages were more common in the Ph-MPN group and older ages in the PMF group. Further studies are needed to determine the impact of age on survival in MF.

---

**JAK2V617F group showed higher hemoglobin values (mean 13.8g/dL; p=0.014) and lower platelet counts (mean 730x10^9/L; p=0.014) than CALR group, for L-selectin levels in all three therapy groups and for P-selectin levels in CALR type-1like group. When comparing CALR type-1like vs CALR type-2like the differences were marginally significant (p=0.06). In a multivariate analysis with the IPSET variables and CALR subtype, in our series the previous history of thrombosis (p <0.001) and the JAK2V617F status (p=0.026) were significantly associated with increased risk of thrombosis, but no the advanced age neither the presence of cardiovascular risk factors. However, presence of CALR type-2 like mutation, with respect to the JAK2V617F mutation, was a protective factor of thrombosis (p=0.06).**

---

**Summary/Conclusions:** The type of driver mutation is associated with a different risk of thrombosis. Among the two types of CALR mutation, patients have similar clinical characteristics except for the risk of thrombosis which seems lower in CALR type-2 like compared to type-1 like. This finding shows the importance of studying the CALR mutation type in ET.

---

**Figure 1.**

**Summary/Conclusions:** When comparing CALR type-1 like with CALR type-2 like, the differences were marginally significant (p=0.06). In a multivariate analysis with the IPSET variables and CALR subtype, in our series the previous history of thrombosis (p <0.001) and the JAK2V617F status (p=0.026) were significantly associated with increased risk of thrombosis, but no the advanced age neither the presence of cardiovascular risk factors. However, presence of CALR type-2 like mutation, with respect to the JAK2V617F mutation, was a protective factor of thrombosis (p=0.06). The five year-thrombosis free survival (TFS) study was as follows: 83%, 85% and 97% for groups JAK2V617F, CALR type-1 like and CALR type-2 like (log rank p=0.03/fig. 1).
HEAT SHOCK PROTEIN 27 EXPRESSION IS INCREASED IN PATIENTS WITH PRIMARY AND SECONDARY MYELOFIBROSIS AND MAY BE AFFECTING THEIR SURVIVAL

1Hematology department, 2Clinical Institute of Laboratory Diagnosis, Division of Molecular Diagnosis and Genetics, 3Department of Clinical Cytology and Cytometry, 4Pathology department, University Hospital Dubrava, Zagreb, Croatia

Background: Increased heat shock protein 27 (HSP27/HSPB1) expression and phosphorylation were observed in a large number of neoplastic diseases and they have mostly been associated with aggressive disease features and poor prognosis. There are only few reports investigating HSP27 in primary myelofibrosis (PMF), a myeloproliferative neoplasm characterized by high inflammatory state reflecting in debilitating clinical symptoms.

Aims: To analyze HSPB1 mRNA expression in patients with PMF and secondary myelofibrosis (SMF) and to correlate it with clinical and hematological features.

Methods: We analyzed HSPB1 relative expression in bone marrow aspirates of 26 patients with PMF, four patients with SMF and 13 controls using quantitative real time polymerase chain reaction (RT-PCR). Spleen size was assessed by palpation. Association with overall survival was analyzed in 27 PMF and SMF patients evaluated at the time of diagnosis. The Kusak-Walls one way analysis of variance, The Mann Whitney U test, the Chi squared test, the Spearman rank correlation, the log-rank test and the Cox regression analysis were used, cut-off point for survival analyses was determined using the ROC curve analysis.

Results: Relative expression of HSPB1 differed significantly between diagnoses (P=0.001); it was significantly higher in patients with PMF and SMF than in control group (P<0.05 for both comparisons), but did not differ between PMF and SMF patients (non significant). Increased expression was associated with increase in the spleen size (P=0.009) and JAK2 V617F mutation (P=0.073).

We did not detect significant associations with other disease specific features. Lower HSPB1 expression was associated with inferior overall survival in both univariate (HR 3.2; P=0.04) and multivariate analysis (HR 6.1; P=0.034) where effect was independent of age (non significant), gender (non significant) and the International Prognostic Scoring System (IPSS) score (HR 3.31; P=0.033).

E1329
NON-DRIVER MUTATIONS IDENTIFIED BY A 190-GENE NEXT GENERATION SEQUENCING PANEL IN PATIENTS WITH PRIMARY MYELOFIBROSIS AND POST-POLYCYTHAEMIC/ESSENTIAL THROMOCYTHEMIA

B. Li1,*, Z. Xu1, T. Qin1, Y. Zhang1, J. Liu1, Z. Xiao1
1MDS and MPN Centre, Institute of Hematology and Blood Diseases Hospital Chinese Academy of Medical Sciences, Tianjin, China

Background: It is a consensus that the driver mutation is an independent prognostic factor in PMFs. Moreover, some non-driver mutations are found associated with initiation, progression and prognosis in PMFs. However, a recent study from the AGIMM (AIRC- Gruppo Italiano Malattie Mieloproliferative) group showed that the type of driver mutation did not influence prognosis in post-PV/ET MF. These observations proved that there were indeed some differences in these two types of MF.

Aims: The aim of current study was to describe the non-driver mutation landscape and the molecular differences between the patients with PMF and those with post-PV/ET MF.

Methods: Targeted gene sequencing was carried out at diagnosis. We sequenced 190 genes across 62 patients, resulting in 229 high-confidence mutations. The average gene coverage was 99%. The average read depth was 540×. Also, 92% of targeted regions were covered with >20×. Every mutation identified in this study was then compared against these expected patterns and categorized into “oncogenic,” “possible oncogenic variants,” or “unknown significance”. Using copy number-adjusted VAF, we reconstructed the clonal architecture to establish whether a mutant gene was an ancestral or subclonal mutation. According to the statistically differences in VAF among gene mutations, subjects were classified as two different clonal architecture, namely clone+subclone(s) (P<0.05) or clonal.

Results: In PMFs, 42 (93.3%) patients had at least one non-driver mutation. Within the 17 patients lacking the driver mutations in JAK2V617F/Exon12, MPLW515 and CALR, 2 had mutant genes (SH2B3 and PIAS3) involving in JAK-STAT pathway, 13 had mutations in other genes and 2 had no mutations. In Post-MFs, non-driver mutations were detected in 16 (94.1%) patients. There are no differences in the median number of non-driver mutations in PMFs vs. post-PV/ET MFs (3 vs. 3.18, P=0.885) and PMF patients with vs. without driver mutations (3 vs. 3.18, P=0.668). In PMFs, 12 non-driver genes were mutated in >5% of patients, namely ASXL1 33.3%, U2AF1 22.2%, TET2 15.6%, FAT1 15.6%, SETBP1 13.3%, SRSF2 8.9%, CUX1 8.9%, EP300 8.9%, FAT2 6.7%, NOTCH3 6.7%, EZH2 6.7%, and GATA3 6.7%. In post-PV/ET MFs, ASXL1 (41.2%) was the most frequent mutation, followed by TET2 (29.4%), U2AF1 and SRSF2 mutations were significantly more frequent in PMF than in post-PV/ET MF. Moreover, SETBP1 and FAT1 were mutated in PMF more often and not mutated in post-PV/ET MF. Figure 1 A-C show 3 illustrative patients. Clonal architecture was significantly different between PMFs and post-PV/ET MFs (Figure 1D). About 50% PMF patients were classified as clonal, however, most (87%) post-PV/ET MF patients were clone+subclone(s). In PMFs, driver mutation was an ancestral mutation with other non-driver mutations in 34 (31.1%) subjects as 2015-R02413 in Figure 1A. Moreover, driver mutation even was a subclonal mutation in 9 (16.7%) subjects as 2015-R02406 in Figure 1B.
1B. In post-PV/ET MFs, 11 (64.7%) subjects showed that JAK2 mutation as an only ancestral mutation as G121517R00701 in Figure 1c.

Figure 1.

Summary/Conclusions: In conclusion, we found that the differences in non-driver mutation profile and clonal architecture between PMF and post-PV/ET MF. In addition, by applying a 190-gene panel we demonstrated some variants classified as of “unknown significance”. And larger sample sizes may enable some of these to be reclassified in the future. The precise role of each mutation and their impact on MPN phenotype will require further studies.

E1331

DETERMINING MEANINGFUL CHANGE IN THE MYELOFIBROSIS SYMPTOM ASSESSMENT FORM (MFSAF) v2.0 USING A COMBINATION OF DISTRIBUTION- AND ANCHOR-BASED APPROACHES IN THE COMFORT-I TRIAL

A. Dusek1, 2, R. Scherer2, 3, H. Kosiolek1, B. Langlas1, L. Padmos3, J. Palme1, S. Verstovsek4, J. Sloan5, G. Holly3, R. Mesa3, 1Mayo Clinic, Scottsdale, AZ, 2Oregon Health and Science University, Portland, OR, 3Mayo Clinic, Phoenix, AZ, 4MD Anderson, Houston, TX, 5Mayo Clinic, Rochester, MN, United States

Background: Symptom response was defined in the COMFORT-I trial as a 50% improvement from baseline at week 24 in the Myelofibrosis Symptom Assessment Form (MFSAF) v2.0 total symptom score (TSS; Mesa [J Clin Onc, 2013]; 0 to 60 scale where 60 represents the worse symptom experience imaginable) with no minimum score requirement at baseline.

Aims: In this analysis of the phase III placebo-controlled COMFORT-I study we used distribution- and anchor-based approaches to investigate whether alternative change scores in the MFSAF v2.0 TSS could be meaningful relative to patient-reported quality of life (QOL).

Methods: One third and one half of the pooled standard deviations (SD) of scores and change scores (raw and percentage change) relative to the patient's change in global health status/QOL (GH/QOL; =worst, 100=best) as measured by the EORTC QLQ-C30 where a decrease of 12.1 or more points was considered as deterioration; an increase of 7.6 or more points was considered as improvement; and all other changes were considered as stable based on change scores established in a multiple myeloma population (Kvam et al., Eur J Hem, 2011). Analysis of covariance (ANCOVA) was used to investigate whether estimated meaningful changes were consistent across the spectrum of observed baseline TSS. This model of TSS changes at week 24 included a continuous term for baseline TSS, a 3-level grouping factor for GH/QOL change (deterioration vs stable vs improvement), and an interaction term between baseline TSS and the GH/QOL grouping factor.

Results: 301 patients randomized to ruxolitinib [N=149] or placebo [N=152] completed TSS at baseline (45% female, median age 68 [range 40-91]). Median baseline TSS was 16.8 (range 0 to 52.7). Pooled SD at baseline and week 24 in TSS was 11.4 and 11.6, respectively, resulting in estimated meaningful changes of 3.8-5.8 points. For change and percentage change from baseline at week 24 in TSS, the pooled SDs were 9.8 and 75%, respectively, resulting in estimated meaningful changes of 3.3-4.9 points or 25%-38%. Among patients with TSS and QLQ-C30 data at baseline and week 24, 51 (23%) patients had deterioration, 61 (27%) were stable, and 110 (50%) had improvement based on QLQ-C30 GH/QOL changes. Mean (95% CI) changes in TSS for the three groups were 0.8 (-2.5 to 4.2), -1.4 (-3.8 to 0.8), and -6.8 (-9.0 to -4.6), and for percent changes 20% (-6% to 46%), 17% (-11% to 44%) and -34% (-45% to -22%), ANCOVA revealed that baseline TSS statistically significantly impacted the change estimates (p=0.02). Figure 1 shows the distribution of estimated meaningful changes in TSS for the three groups were 0.8 (-2.5 to 4.2), -1.4 (-3.8 to 0.8), and -6.8 (-9.0 to -4.6), and for percent changes 20% (-6% to 46%), 17% (-11% to 44%) and -34% (-45% to -22%), ANCOVA revealed that baseline TSS statistically significantly impacted the change estimates (p=0.02). Figure 1 shows the distribution of estimated meaningful changes in TSS for the three groups were 0.8 (-2.5 to 4.2), -1.4 (-3.8 to 0.8), and -6.8 (-9.0 to -4.6), and for percent changes 20% (-6% to 46%), 17% (-11% to 44%) and -34% (-45% to -22%), ANCOVA revealed that baseline TSS statistically significantly impacted the change estimates (p=0.02).

Figure 1.
response duration were 4 and 31 months respectively. 23% of patients lost response after a median time of 16 months. Seventy-five % of patients responded to ruxolitinib in terms of spleen size, of whom 86.4% also achieved an erythropoietin level below 250 UI/l, but they could also suggest synergistic activity of ESA and ruxolitinib.

E1333 COMPARING THE SAFETY AND EFFICACY OF RUXOLITINIB (RUX) IN PATIENTS (PTS) WITH DIPSS LOW/INTERMEDIATE-1–, INTERMEDIATE-2–, AND HIGH-RISK MYELOFIBROSIS (MF) IN JUMP, A PHASE 3B, EXPANDED-ACCESS STUDY

1University of Insubria, Varese, Italy, 2Princess Margaret Cancer Centre, Toronto, Ontario, Canada, 3Azienda Ospedaliera Bianchi-Melacrinove-Morelli, Reggio Calabria, Italy, 4St. Paul’s Hospital, University of British Columbia, Vancouver, British Columbia, Canada, 5Federal Almazov Medical Research Center of the Russian Ministry of Health, St. Petersburg, Russia, 6University Hospital of Halie, Haie (Saale), Germany, 7University Federale de Goaniana, Goaniana, Brazil, 8Ospedale di Circolo e Fondazione Macchi, Varese, Italy, 9Rabin Medical Center, Petah Tikva, Israel, 10AlmeraSerent University Hospital and Centro de Investigación Biológica en Red de Enfermedes Raras (CIBERER), Zaragoza, Spain, 11Johannes Wesling Clinic, Minden, Germany, 12Novartis Pharma AG, Basel, Switzerland, 13Novartis Healthcare Pvt. Ltd, Hyderabad, India, 14CRIMM, Center for Research and Innovation of Myelo-proliferative Neoplasms, AOI Careggi, Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy

Background: RUX is a potent JAK1/JAK2 inhibitor that led to improvements in splenomegaly and symptoms and increased overall survival in pts with intermediate (Int)-1–, Int-2–, and high-risk MF by the International Prognostic Scoring System (IPSS) in the phase 3 COMFORT studies. JUMP is a large, phase 3b, expanded-access trial in countries with no access to RUX outside a clinical trial and includes pts with IPSS Int-1–, Int-2–, and high-risk MF. To further evaluate RUX, we conducted an analysis assessing safety and efficacy of RUX by Dynamic IPSS (DIPSS) prognostic risk.

Aims: To compare the safety and efficacy of RUX in pts with DIPSS low/Int-1– vs Int-2– vs high-risk MF

Methods: Eligible pts had IPSS high- or Int-2–risk MF, or Int-1–risk MF and a palpable spleen (>2 cm). Starting dose was based on baseline platelet (PLT) count (5mg bid [50 to <100×10^9/L], 15mg bid [100-200×10^9/L], or 20mg bid [>200×10^9/L]) and could be titrated during treatment. The primary endpoint was safety and tolerability of RUX. Changes in palpable spleen length and symptom scores were also assessed. DIPSS scores were determined using pt characteristics at baseline.

Results: Based on available pt data, DIPSS status was determined for 1840 of 2233 enrolled pts. JUMP included 893 low/Int-1–, 754 Int-2–, and 193 high-risk pts (primary MF, 57%, 63%, 62%) who started treatment ≥1 y before data cutoff (01 Jan 2016). Pts with higher-risk MF were older (62, 68, and 72 y), had lower Hb (<10 g/dL, 3%, 64%, 100%), and had higher blast counts (<1%, 18%, 44%, 84%). Disease duration (50, 51, and 55 mo) and spleen size (12, 13, and 14.5 cm) were similar in all 3 groups. Most pts started at 20mg bid (88%, 57, 59%) or 15mg bid (26%, 32%, 33%). Median exposure was 16, 11, and 9 mo; median average daily dose was 30, 28, and 29mg. At data cutoff, most pts remained on treatment or had completed per protocol (70%, 52%, 25%). Main reasons for treatment discontinuation included adverse events (AEs; 15%, 11%, 6%), disease progression (6%, 11%, 11%), and death (2%, 5%, 11%). The most common hematologic grade 3/4 AEs were anemia (22%, 44%, 55%) and thrombocytopenia (11%, 18%, 25%), but these rarely led to discontinuation. Overall rates of nonhematologic grade 3/4 AEs were <2%, except for pneumonia (4.5%), pyrexia (2.3%), asthenia (2.2%), and dyspnea (2.2%). Infections in <5% of pts were pneumonia infection (7.3%), urinary tract infection (6.1%), and nasopharyngitis (5.3%). Herpes zoster was reported in 4.8% of pts. At wk 48, 64% (226/355), 52% (121/232), and 50% (26/52) of pts had >50% reduction from baseline in spleen length; 19% (68/355), 19% (43/232), and 23% (12/52) had 5%-50% reductions. Best response in spleen length by wk 72 is shown in the Figure; 69%, 57%, and 51% of pts achieved >50% reductions. Median time to response was 4.7 wk (2.9-75 wk), 5.3 wk (2.6-80 wk), and 8.1 wk (3.1-72.3 wk). From wk 4 to 48, 39%, 43%, 41%, and 48%, and 48% of pts achieved a clinically meaningful response on the FACT-Lym TS; proportions of responders on the FACT-Fatigue were 42%-49%, 46%-49%, and 55%-61%.
were based on baseline platelet (PLT) counts (≥50 to <100×10^9/L, 100 to >200×10^9/L, >200×10^9/L, respectively). Although not per protocol, some pts started RUX at 10mg bid. The primary endpoint was safety. Secondary end-points included changes in spleen length and symptoms.

### Results:
A total of 48 pts (primary MF, 60%) started RUX at 10mg bid ≥1 y before data cutoff (01 Jan 2016). Mean baseline characteristics were: median age, 65.5 y (range, 20-83 y); male, 44%; spleen length, 12.3 cm; time since diagnosis, 56.6 mo; hemoglobin (Hb), 112.1 g/L (<100 g/L, 33.3%); PLT count, 351×10^9/L (<100×10^9/L, 10.4%). Pt characteristics were similar to those of the same was true for treatment discontinuations due to skin toxicity (16/120 [13%] vs 52/120 [43%] compared to non-HU treatment (52/120 [43%] vs 9/126 [7%]; p=0.0001), and the same was true for treatment discontinuations due to skin toxicity (16/120 [13%] vs 3/126 [2%]; p=0.014).

### Summary/Conclusions:
According to our prospective observation, skin toxicity was clearly associated with HU treatment compared to other cytoreductive drugs. This resulted in a higher rate of HU treatment termination due to skin toxicity. However, median exposure time to HU was longer compared to non-HU treatment (52/120 [43%] vs 9/126 [7%]; p=0.0001), and the same was true for treatment discontinuations due to skin toxicity (16/120 [13%] vs 3/126 [2%]; p=0.014).

### E1335
**HYDROXYUREA IS ASSOCIATED WITH SKIN TOXICITY IN MYELOPROLIFERATIVE NEOPLASMS: RESULTS FROM A PROSPECTIVE NON-INTERVENTIONAL STUDY**

F. Stegelmann1,2, K. Wille2, S. Schauer1, H. Döhner1, K. Döhner1, M. Griesshammer2

1University Hospital of Ulm, Ulm, 2University of Bochum, Minden, Germany

### Background:
Until today, hydroxyurea (HU) remains the most commonly used cytoreductive drug in patients (pts) with classic myeloproliferative neoplasms (MPN), i.e. essential thrombocythemia (ET), polycythemia vera (PV), and myelofibrosis (MF). However, mucosal lesions, cutaneous ulcers, and pre-carcinomatous skin alterations such as actinic keratoses are being considered as potential side effects of HU.

### Aims:
We sought to investigate the occurrence of skin toxicity in MPN pts under HU compared to other (non-HU) cytoreductive drugs in routine clinical practice.

### Methods:
Classic MPN pts regularly presenting at the outpatient centers of the University Hospital of Ulm and Johannes Wesling Clinic Minden were included in our non-interventional study after having given informed consent. Skin alterations were evaluated prospectively beginning December 2010 and November 2016.

### Results:
In total, 151 MPN pts under cytoreductive therapy were included (ET, n=55; PV, n=55; MF, n=41). Primary MPN diagnosis was made between 1979 and 2012 at a median age of 55 years (range, 22-82). Median duration of the disease until baseline of the study was 6.3 years (0-32.6). Median prospective observation time for the total cohort within the study period was 5.3 years (0.4-6.2). Most frequently used cytoreductive drugs were HU in 120 pts, followed by ruxolitinib in 59, anagrelide in 39, and pegylated Interferon-alpha (IFN-a) in 28 pts. Median cumulative HU exposure was 46 months (1-252), while the median cumulative treatment time for the corresponding drug in the 120 HU pts was 24 months (1-267) [ruxolitinib: 22 months (2-64); anagrelide: 19 months (1-216); IFN-a: 64 months (1-267)]. Of 120 pts exposed to HU, 52 pts (43%) presented with skin abnormalities during the observational period occurring after a total HU treatment time of median 46 months (1-252). Sixteen of 120 pts (13%) discontinued HU due to skin toxicity such as skin ulcers (n=6), phototoxicity / erythrodermia (n=5), actinic keratoses (n=3), dry skin / xerostomia (n=2). Of note, four malignant skin diseases were reported under HU therapy (basal cell carcinoma, n=3; malignant melanoma, n=1). Although pts of the HU cohort were exposed longer to the drug compared to pts of the non-HU group, numbers of skin events in non-HU treated pts were as follows: n=5 under anagrelide (skin ulcers, n=2; allergic reaction, n=2; basal cell carcinoma, n=1), n=4 under IFN-a (local reaction after subcutaneous injection, n=3; actinic keratoses, n=1), and none under ruxolitinib. In 3/126 (2%) non-HU treated pts, occurrence of skin toxicity led to discontinuation of the corresponding cytoreductive drug. Interestingly, both skin ulcers as well as the single events ‘basal cell carcinoma’ and ‘actinic keratoses’ occurred under combination therapy with HU. Taken together, skin alterations occurred more frequently under HU compared to non-HU treatment (52/120 [43%] vs 9/126 [7%]; p=0.0001), and the same was true for treatment discontinuations due to skin toxicity (16/120 [13%] vs 3/126 [2%]; p=0.014).

### Summary/Conclusions:
According to our prospective observation, skin toxicity was clearly associated with HU treatment compared to other cytoreductive drugs. This resulted in a higher rate of HU treatment termination due to skin toxicity. However, median exposure time to HU was longer compared to non-HU treatment, and controlled clinical trials are necessary to provide more precise data on the occurrence and severity of skin toxicity under HU.

### E1336
**THE NEGATIVE PROGNOSTIC IMPACT OF BASOPHILIA, EOSINOPHILIA AND MONOCYTOsis AT DIAGNOSIS IN PRIMARY MYELOFIBROSIS**

M. P. Peraira1,2, K. Hunderova2, J. Carda1, E. Cortésão1,2, R. Guilherme1,2, L. Ribiero1, A.-B. Sarmento-Ribeiro1,2

1Clinical Hematology Department, Coimbra University Hospital Centre, 2Faculty of Medicine, University of Coimbra, Coimbra, Portugal

### Background:
Primary myelofibrosis (PMF) is a myeloproliferative neoplasm (MPN) with a variable clinical presentation, from asymptomatic disease to rapidly progressive bone marrow failure and/or leukemic transformation; prognostic stratification using the DIPSS-plus score isolates patient cohorts with median survival ranging from 16 months to 185 months. The development of monocyto-sis during the course of PMF has been associated with a worse outcome, and absolute monocyte counts have been shown to be of prognostic value in other MPNs. Basophilia and eosinophilia are frequent findings in BCR-ABL-
positive MPNs, where they associate with an accelerated phase of disease, and seem to correlate with worse survival in myelodysplastic syndromes. However, the impact of these three findings at diagnosis in PMF remains unclear.

**Aims:** The aim of this work is to evaluate, at diagnosis, the prognostic impact of basophilia, eosinophilia and monocytosis in patients with PMF.

**Methods:** We identified all PMF patients diagnosed and followed-up in our Centre between January 1st 2005 and August 31st 2016, who still fulfilled PMF criteria under the WHO 2016 diagnostic revision, have synchronous bone marrow (BM) and peripheral blood (PB) analyses dating from the time of diagnosis, and have complete charts with no missing data. After the exclusion of reactive causes, monocytosis was defined as an absolute count (AC) ≥20% blasts in bone marrow or peripheral blood) and for whom at least one DNA sample to define the mutational status of the three MPN driver genes (≥ 20% blasts in bone marrow or peripheral blood) and for whom at least one DNA sample to define the mutational status of the three MPN driver genes.

**Results:** We studied 55 evaluable patients (73% male) with a median age at diagnosis of 70.1±11.7 years old. At diagnosis, 20% of patients had monocytosis, with no significant differences according to gender or age. The median overall survival (OS) in PMF patients with monocytosis was 27.3 months, and twice as long (46.4 months) in patients without. In this cohort, a new calculated cut-off of 0.75 G/L was better able to stratify patients according to survival with a specificity of 74.1% (95% CI: 53.7-88.9%); 32.7% of patients had an AC above the cut-off, with a median OS of 27.9 months, compared to 6.4 months for patients under the cut-off. We identified 12.7% of patients with eosinophilia at diagnosis, with no differences according to gender or age. PMF patients with eosinophilia had a five-fold lower median OS compared with patients without (6.1 vs 32.5 months, respectively). We obtained a new cut-off of 0.25 G/L of eosinophils, which separated patients with a specificity of 77.8% (95% CI: 57.7-91.4%), 29.1% of patients had an eosinophil AC above the cut-off, with a median OS of 27.3 months, compared to 43.8 months for patients under the cut-off. A total of 30.9% of patients had basophilia at diagnosis, with no differences according to gender or age. The median OS in patients with basophilia was 25.6 months, and 32.5 months in patients without. With a new cut-off of 0.25 G/L of basophils, with a specificity of 88.9% (95% CI: 70.8-97.6%), 20.0% of patients had a basophil AC above the cut-off and a median OS of 19.7 months, compared to 46.4 months for patients under the cut-off. Considering the whole cohort, 61.8% of patients had normal monocyte, eosinophil and basophil ACs; the median OS in these patients was 56.1 months, compared to 28.5 months in patients with an increase in at least one AC. Applying the new cut-offs, OS increased to 79.5 vs 64.4 months. Progression-free survivals were not calculated, since only 2 patients had BM- or PB-documented progression during follow-up.

**Summary/Conclusions:** We observed that the presence of monocytosis at diagnosis in PMF was associated with a halving of the median OS, while eosinophilia decreased the median survival to one-fifth; basophilia also associated with a reduction in survival, of approximately 20%. The application of specific cut-offs calculated for the cohort improved the differentiation and stratification of patients, with moderate to high specificity, further clarifying the negative prognostic impact of these three variables, at diagnosis, in PMF. Our results show that even simple, inexpensive and readily available parameters can be used to predict survival in PMF patients, and suggest that their integration into established scores could further increase the prognostic accuracy of the latter.

---

**BLAST PHASE IN PH-NEGATIVE MYELOPROLIFERATIVE NEOPLASMS: A SINGLE INSTITUTION RETROSPECTIVE ANALYSIS OF 85 PATIENTS**

E. Roncoroni1,*, M. Bellini1, E. Rumi1,2, V. Ferretti1, D. Pietra1, C. Cavalloni1, M. Ciboddo1, I. Casetti2, P. Zappasodi1, P. Benvenuti1, C. Astoni1, M. Cazzola1,2

1Department of Hematology Oncology, Fondazione IRCCS Policlinico San Mat-teo, Pavia, Italy; 2Department of Molecular Medicine, University of Pavia, Pavia, Italy

**Background:** Classic Ph-negative myeloproliferative neoplasms (MPN) include essential thrombocythemia (ET), polycythemia vera (PV) and primary myelofibrosis (PMF). Clonal evolution can lead MPN patients in chronic phase (CP) to develop acute myeloid leukemia (AML), called blast phase (BP); this event occurs at rates of approximately 1% in ET, 4% in PV and 20% in PMF over the first decade from MPN diagnosis.

**Aims:** To evaluate differences in clinical features and outcome in 85 patients with MPN in blast phase, according to MPN diagnosis and mutational profile.

**Methods:** We identified in our database all patients affected with ET, PV and PMF who developed acute myeloid leukemia according to 2016 WHO criteria (≥ 20% blasts in bone marrow or peripheral blood) and for whom at least one DNA sample was available to define the mutational status of the three MPN driver genes (JAK2, CALR or MPL). JAK2 and CALR mutational status was determined by Sanger sequencing; MPL (MPL515W) mutation was identified also in AML blasts in all 6 patients for which DNA was available. Outcome was dismal, independently from the driver mutation; the median overall survival (OS) was 9.3 months (range 3.9-15.7) compared to ET (median 36.7 years, range 54.4-86, P 0.318) and PMF (median 67.9 years, range 48.1-84.9, P 0.016). The complete blood count at leukemic evolution was not influenced by the initial diagnosis. At the time of BP, 31 out of 44 patients (70%) for whom cytogenetic analysis was available showed an abnormal karyotype (22 patients with complex karyotype or high risk aberrations). JAK2 mutated MPN can evolve into JAK2 wild type AML (9 of 28 patient with blasts DNA available), while CALR mutation was identified also in AML blasts in all 6 patients for which DNA was available. Time to leukemic evolution was shorter in PMF (35.3 months, range 3.6-141.1) compared to ET (176.7 months, range 14.4-362.3, P <0.001) and PV (129.1 months, range 17-367.8, P<0.001). According to chronic phase driver mutation, time to leukemic evolution was shorter in JAK2 V617F mutated PMF compared to CALR mutated PMF (30.6 vs 138 months, P 0.024), but not statistically different in JAK2 mutated ET compared to CALR mutated ET (123.4 vs 203.2 months, P 0.121). Outcome was dismal, independently from the driver mutation; the median overall survival (OS) was 9.3 months (range 3.9-15.7). OS was not influenced by treatment during blast phase (4.5 months with induction chemotherapy versus 4.6 months with palliation; P 0.885). Of the whole series, only one patient is alive and in complete clinical and molecular remission, after 11 months from allogeneic bone marrow transplantation.

**Figure 1.**

**Summary/Conclusions:** Clinical phenotype and outcome of BP is not influenced neither by the diagnosis in chronic phase nor by the driver mutation; moreover the outcome is poor irrespective of treatment. PMF patients have a shorter time to BP than ET and PV patients; in PMF JAK2 V617F mutation is associated with a shorter time to BP compared to CALR mutation. The only potentially curative treatment is represented by allogeneic stem cell transplantation, but only a few patients can actually undergo this procedure.

**E1338**

**TELOMERE LENGTH IS REDUCED IN ESSENTIAL THROMBOCYTHAEMIA PATIENTS COMPARED TO AGE AND GENDER MATCHED HEALTHY CONTROLS**

S. Allman1,*, J. Jie2, D. McMornan2, D. Radia1, G. Mufli2, C. Harrison1

1Haematology, Guys and St Thomas’ NHS Foundation Trust, 2Haematology, King’s College London, London, United Kingdom

**Background:** Essential thrombocythaemia (ET) is a clonal stem cell disorder, commonly diagnosed in the 6th or 7th decade of life. ET is associated with risk of thromboembolic events, hemorrhage, constitutional symptoms, progression to myelofibrosis and acute myeloid leukemia. In over 85% of patients a clonal driver can be identified with mutations in JAK2 (50-60%), Calreticulin (CALR) (25-30%) or the thrombopoietin receptor (MPL) (3-5%); the remainder of patients are termed “triple negative” (TN). Telomeres are non-coding regions of DNA consisting of thousands of repeated sequences (TTAGGG) and are considered central to chromosomal integrity and genomic stability. In healthy adults, telomere length (TL) progressively shortens with age; therefore, TL is considered a marker of aging and genome stability. Hematopoietic cells in several hematological malignancies have been shown to be characterized by shortened TL.

**Aims:** Determine if there is TL shortening in patients with ET when compared to age and gender matched controls and establish the effects of cytoxic and non-cytoxic therapy on TL.

**Methods:** 100 patients were included in the study (27 with CALR, 35 JAK2V617F and two MPL515W mutations. 36 patients were TN). Most patients were female (70% 70/100); median age was 45 years (range 20 - 86 years).
TL was determined in peripheral blood mononuclear cells using a monochrome multiplex quantitative PCR based on the original methods described by Cawthon. All results were corrected for age and gender.

**Results:** Regardless of driver mutation status ET patients had significantly shortened TL compared with age and gender matched controls, p<0.0001. Considering individual mutation status these differences remained significant e.g. JAK2 V617F positive (p=0.007), JAK2V617F vs Placebo (p=0.012) in TN patients. TL appeared more markedly short in the CALR cohort; for the 18 patients, whose TL was below the first centile, 55% (10/18) were CALR positive vs 28% (5/18) JAK2V617F positive vs 17% (3/18) who were TN. Concerning the potential impact of therapies 31/100 patients were treated with hydroxy- and 13/100 with IFN (e.g. five of these had prior exposure to HC). 34/100 were not on cytoreductive therapy. Remaining treatments were ruxolitinib (5), busulphan (4), anagrelide (1) and vonostat (1). Independent of mutation status there was significant TL shortening in untreated patients, p=0.05; however, upon evaluating the impact of cytoreductive therapy on TL we noted that patients who were on either current, or prior HC had significantly shortened telomeres: in untreated patients, p=0.0015 and p=0.0001 respectively. Strikingly, there was no significant difference in TL in IFN patients who had no previous exposure to HC, p=0.2 but those ET patients currently on IFN but with prior HC exposure still had shorter TL.

**Summary/Conclusions:** We document for the first time that ET patients, when compared to age and gender matched healthy controls, have shortened TL. This shortening is more pronounced in CALR and JAK2 V617F positive patients. Concerning therapy whilst present in untreated patients TL shortening was more pronounced in HC treated patients indicating that there may be a therapy effect as has been observed after HC treatment in sickle cell disease. Of note IFN treated patients had more normal TL suggesting that the disease related TL effects may be reversed by this agent.

**Figure 1.**

**Summary/Conclusions:** Nutrition decline remains an unmet need for many MF patients. JAK2 inhibition represents a potential source to improve symptom burden in those who qualify for therapy. Leptin closely correlated with many other nutritional values suggesting this may be a good marker of nutritional status in MPN patients. CRP was inversely correlated with BMI, suggesting the importance of inflammation as a contributor to weight loss. Further study into the unique nutritional needs of myelofibrosis patients is warranted.
01/01/2006 to 31/12/2009 (385 patients), with a median follow-up of 58.2 months.

Methods: The characteristics of two groups of patients are reported in the Table 1. No differences could be found between the two groups according age, gender, platelet and WBC count and Hb level. Cardio-Vascular Risk Factors (CVRF), splenomegaly and the occurrence of previous thrombotic events. The frequency of the JAK-2 V617F mutation resulted significantly different (49.1% vs 68.4%) but in the group I the search of the mutation was never performed at the diagnosis. TFS and OS were calculated from the date of diagnosis of ET to the date of event with Kaplan-Meier product limit method; the comparison of proportions and median values was computed with the Chi-squared and the Mann-Whitney tests, as indicated.

Results: No significant differences emerged neither for TFS (p= 0.09, HR 1.42, 95% C.I. 0.89-2.30) nor for OS (p= 0.15, HR 1.34, 95% C.I. 0.87-2.06). We also evaluated the type of treatment used in the two groups to assess the potential link between the therapy and TFS or OS (Table 2). No difference emerged between the two groups as for anti-aggregating (mainly ASA), equally utilized in both groups, 287/369, 77.8%, and 330/383, 78.3%, respectively (p=0.95). As for the cytoeraductive therapy, Hydroxyurea was used in 74.8% vs 67.9% (p= 0.60) and alkylating agents in 1.9% vs 2.1% (p= 0.85), whereas the Anagrelide resulted utilized in 10.6% vs 3.9% (p= 0.001) and Interferon in 9.5% vs 5.2% (p= 0.037), respectively. The more frequent use of Anagrelide and Interferon in the first group (2000-2005) didn’t modify the prognosis (as for TFS and OS) of the patients.

Figure 1.
Summary/Conclusions: Unfortunately, no improvement, neither as the TFS nor the OS was observed (Fig. 1 and 2): more efforts to better identify the groups at risk and, hopefully, the introduction of new drugs as JAK-2 inhibitors could change the prognosis of ET patients.

E1341

CUTANEOUS INVOLVEMENT IN PHILADELPHIA-NEGATIVE MYELOPROLIFERATIVE NEOPLASMS - SINGLE-CENTER EXPERIENCE

J. M. Sanchez-Raga1,2, N. Knöpfel1, M.D.M. Escudero-Góngora1, F. Sartori1, B. Lopez1, I. Herrera2, M.D.C. Ballesta1, M. Torres2, A. Martin-Santiago3, A. Sampo2, M.A. Durán2

1Hematology and Hemotherapy, Fundación de Investigación Sanitaria de las Islas Baleares Ramon Llull, 2Hematology and Hemotherapy, 3Dermatology, Hospital Universitari Son Espases, Palma de Mallorca, Spain

Background: Philadelphia-negative chronic myeloproliferative neoplasms (MPNs) may present clinical dermatological manifestations at the time of diagnosis, as well as during the course of the disease. On the other hand, also its treatments can present skin side effects.

Aims: We have performed a dermatological review of a cohort of patients we follow-up at our center with the aim of assessing the cutaneous manifestations.

Methods: A randomized selection of patients with a diagnosis of essential thrombocytosis and polycythemia vera was performed. We create a specific consultation in which a detailed history of each patient (sex, age, diagnosis, signs and symptoms, treatments and its duration) as well as a deep dermatological examination was done. All data was collected in an Excel database and analyzed using the SPSS system.

Results: 63 patients (54 ET and 9 VP) were reviewed. The most frequent skin lesions were xerosis and/or keratosis pilars (76.2% patients), nail changes (41.3%), actinic keratosis (39.7%), hyperpigmentation of the skin (23.8%), pruritus (23.8%) and non-melanoma skin cancer (22.2%). In figure 1 we detail all the skin alterations that we have found.

Summary/Conclusions: Cutaneous involvement in MPNs is more frequent than expected and it is usually underdiagnosed. Some of these lesions could be prevented with the correct treatment of their pathology and adequate photoprotection measures. The results obtained support the recommendation of an annual review by a dermatologist in a systematic way, especially in patients with higher risk factors: low phototype, high sun exposure, past dermatological history and prolonged cytoeraductive therapy.

HEMOGLOBIN AND WHITE CELL COUNT IN PATIENTS CLINICALLY SUSPECTED TO HAVE ESSENTIAL THROMBOCYTHEMIA MAY HELP IN PREDICTING EARLY PRIMARY MYELOFIBROSIS OR UNCLASSIFIABLE MYELOPROLIFERATIVE NEOPLASM

S. Sirhan1,*, C. Ross2, A. Orazi3

1Jewish General Hospital Montreal, Montreal, 2McMaster University, Hamilton, Canada, 3Weill Cornell Medical College, New York, United States

Background: Classification of myeloproliferative neoplasms (MPN) in patients presenting with thrombocytosis can be challenging. Relying only on clinical features may lead to misclassification of patients in the early stages of primary myelofibrosis (PMF) as essential thrombocytosis (ET). Although bone marrow (BM) biopsy examination is the gold standard necessary for accurate classification, in clinical practice it might be helpful to identify among patients with a working diagnosis of ET those most likely to have early PMF or unclassifiable MPN (MPN-U). To this end, Carobbio et al. (Am J Hematol. 2012;87:203-4) developed a simple algorithm based on presence of anemia (hemoglobin <120 g/L for females and <130g/L males) and/or leukocytosis (leukocytes ≥13x109/L) or elevated LDH (>200 mU/mL). For an accurate classification, the clinical and laboratory features need to be correlated with BM findings, thus collaboration between hematologists and pathologists is essential.

Aims: To examine applicability of the Carobbio algorithm in routine practice and its potential use in identifying among patients presenting with thrombocytosis and clinically suspected to have ET, those with early PMF or MPN-U. To identify unmet needs in the diagnosis of MPNs in daily practice upon which further educational initiatives can be built which stress the importance of hematologist-pathologist collaboration.

Methods: A retrospective Personal Practice Assessment Program was conducted at 8 Canadian institutions. Eight hematology/pathology pairs reviewed charts of about 20 consecutive examined patients who presented with thrombocytosis and clinically suspected to have ET. To this end, Carobbio et al. (Am J Hematol. 2012;87:203-4) developed a simple algorithm based on presence of anemia (hemoglobin <120 g/L for females and <130g/L males) and/or leukocytosis (leukocytes ≥13x109/L) or elevated LDH (>200 mU/mL). For an accurate classification, the clinical and laboratory features need to be correlated with BM findings, thus collaboration between hematologists and pathologists is essential.

Aims: To examine applicability of the Carobbio algorithm in routine practice and its potential use in identifying among patients presenting with thrombocytosis and clinically suspected to have ET, those with early PMF or MPN-U. To identify unmet needs in the diagnosis of MPNs in daily practice upon which further educational initiatives can be built which stress the importance of hematologist-pathologist collaboration.

Figure 1.
presentation with thrombocytosis. No central pathology review was planned for this stage of the study.

Results: A total of 122 patients (58 males and 66 females; 54% >60 years of age; 65% with LDH >200 mU/mL) with a clinical history indicative of ET were initially assessed. A majority of patients (76%) presented with suspected ET within the last 5 years, likely because it was more difficult for clinicians to identify patients with BM biopsy collected within a year of presentation with thrombocytosis if they presented more than 5 years ago. Out of 122 patients, 48 met the hemoglobin and/or leukocytes criteria outlined in the Carobbio algorithm, Figure. The BM examination was performed on 33 patients who met pre-specified criteria for the timing of bone marrow biopsy. About one third of the 33 patients met criteria for ET and one third for PMF. While 2 of the remaining patients met criteria for PV, the rest were uncertain whether to represent true ET or early PMF, i.e. represented MPN-U (Figure 1).

Summary/Conclusions: Despite its methodological limitations, this initiative confirms that in real world clinical practice the Carobbio algorithm can be used to identify patients with ET and early PMF and steering clinicians clinically suspected to have ET. It suggests a need for educational initiatives on using diagnostic algorithms to separate ET from PMF. It confirms the importance of hematologist-pathologist collaboration in reaching a final integrated diagnosis based on the WHO classification. These findings warrant investigation in larger prospective studies.

PK/PD MODELING COMPARING DIVIDED DOSING (200mg TWICE-DAILY [BID]) VS SINGLE DOSEING (400mg ONCE-DAILY [QD]) OF PACRITINIB (PAC) IN PATIENTS WITH MYELOFIBROSIS (MF) ON THE PERSIST-2 PHASE 3 TRIAL

S. Al-Fayoumi1,*, J. Mascarénhas2, R. Hoffman2, M. Talpaz3, A.T. Gerds4, B. Stein5, V. Gupta5, A. Szoke6, M. Drummond7, A. Pristupa8, H. Zhou1, D. Talty1, J.A. Callahan1, J.W. Singer1, J. Gotlib10, C. Jamieson11, C. Harrison12, R. Mesa13, S. Verstovsek1

1CTI BioPharma Corp., Seattle, WA, 2Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY, 3University of Michigan, Comprehensive Cancer Center, Ann Arbor, MI, 4Cleveland Clinic, Cleveland, OH, 5Northwestern University, Feinberg School of Medicine, Chicago, IL, United States, 6Princess Margaret Cancer Center, University of Toronto, Ontario, Canada, 7Albany Medical College, Albany, NY. 8Cleveland Clinic, Cleveland, Ohio, 9Stanford Cancer Institute, Stanford, CA, 11University of California-San Diego, La Jolla, CA, United States, 12Guy’s and St Thomas’ NHS Foundation Trust, London, United Kingdom, 13Mayo Clinic, Scottsdale, AZ, 14MD Anderson Cancer Center, Houston, TX, United States

Background: MF is a life-threatening hematologic malignancy characterized by splenomegaly and debilitating constitutional symptoms. At the present, the JAK2 inhibitor ruxolitinib is the only therapy approved (pts) with hematopoietic stem cell transplantation (HSCT) as a standard for high risk MF. It has garnered regulatory approval. Although ruxolitinib has been shown to reduce splenomegaly and symptoms in pts with MF, it is associated with dose-limiting cytopenias, and not indicated for pts with platelets <50,000/µL. PAC is an oral kinase inhibitor with specificity for JAK2, FLT3, IRAK1, and CSF1R. Using data previously presented (Mas- carenhas et al. Blood 128(22), LBA-5.), showed significantly higher spleen volume reduction (SVR) with PAC (QD and BID pooled) vs QD dosing by 10% (E1343).

Aims: Validate the clinical utility of PK/PD modeling to select the PAC 200mg BID regimen in pts with MF treated in the PERSIST-2 trial.

Methods: Pts with MF and baseline platelet count ≤100,000/µL were randomly assigned 1:1:1 to PAC 400mg QD, PAC 200mg BID, or BID. Blood samples were collected from PAC-treated pts for PK and PD analysis at a prespecified subset of trial sites. Blood samples were collected on day 1 of week 1 (4 h post-dose), week 3 (pre-dose and 4 h post-dose), week 12 (pre-dose), and week 24 (pre-dose). At the remaining sites, blood samples were collected from PAC-treated pts for PK analysis only at weeks 12 and 24 (pre-dose).

Results: Blood samples were collected up to week 24 from 144 PAC-treated pts (78 BID, 64 QD). The PK of PAC was described by a 2-compartment model with first order absorption, first order elimination from the central compartment, and an absorption lag time. PAC QD was associated with higher Cmax and lower Cmin vs PAC BID (Table). Median PAC plasma concentrations during the PERSIST-2 trial were higher with QD and PAC unclassified vs PAC BID at steady-state (Cminss). At weeks 12 and 24 were higher with BID vs QD dosing by 10% and 15%, respectively. Also, median observed steady-state 4h-concentration at week 3 (coincides with Cmaxss) was 12% higher with QD vs BID dosing. In an exposure-response analysis, with QD or BID dosing, no trends were detected for a relationship between observed Cminss and death, cardiac death, hemorrhagic death, thrombocytopaenia (grade ≥2 or ≥3), anemia (grade ≥2 or ≥3), or gastrointestinal events (any grade, grade 2, or ≥3). Eleven (15%) and 13 (17%) PAC QD pts achieved SVR ≥35% and TSS reduction ≥50% at week 24, respectively, vs 16 (22%) and 24 (32%) PAC BID pts. Treatment with PAC BID but not QD showed a trend of increased SVR vs Cminss.

Summary/Conclusions: As predicted by PK modeling and simulations analyzing PAC 400mg QD was associated with higher Cmax and lower Cmin vs PAC 200mg BID in pts with MF from the PERSIST-2 trial. These differences appear to translate into an improved benefit/risk profile of PAC BID vs QD regimens.

E1344
ZMYM2-FLT3 IS A RARE, RECURRENT, CYTOGENETICALLY CRITICAL FUSION IN MYELOID/MYELOID MALIGNANCIES OR EOSINOPHILIA THAT IS RESPONSIVE TO FLT3 INHIBITION

M. Jawhari1,*, N. Naumann1, M. Knut2, B. Schneider3, M. Ghazzawi2, K.-A. Kreuzer2, M. Hallek3, A. Fabarius1, J. Score4, A. Chase5, W. Tapper6, A. Reiter7, N. Cross2

1Department of Hematology and Oncology, Medical Faculty Mannheim of Uni- Versity of Heidelberg, Mannheim, Germany, 2Faculty of Medicine, University of Southampton, Southampton, United Kingdom, 3Department I of Internal Medicine, University Hospital of Cologne, Cologne, Germany

Background: Myeloid/lymphoid neoplasms with eosinophilia are characterised by diverse tyrosine kinase (TK) fusion genes, many of which can be effectively targeted by small molecule inhibitors. More than 70 TK fusions have been described, most of which are associated with visible cytogenetic abnormalities. However these fusions are rare, and the pathogenesis of the great majority of these fusions remains unknown. ZMYM2-FLT3 remains unexplained. We hypothesized that some MPN-eo cases may be driven by hitherto undetected cryptic TK fusion genes.

Aims: To screen cases with MPN-eo for TK fusion genes and evaluate the sig- nificance of any novel fusions

Methods: Poly(A) RNA extraction from MPN-eo cases, RNA-Seq library prepa- ration and 100bp paired-end sequencing was performed with multiplexing for a minimum of 75 million reads/sample using an Illumina HiSeq 2000. Bowtie, TopHat and TopHat-Fusion were used to align reads, resolve splice junctions, identify and filter potential TK fusion genes. Confirmation and screening of fusions was performed by RT-PCR and Sanger sequencing.

Results: 20 cases were tested by RNAseq analysis, just one cryptic TK fusion was identified: ZMYM2-FLT3, predicted to arise as a consequence of an 8Mb inversion at 13q12. Unusually, both breakpoints fell within exons (ZMYM2 exon 20 and FLT3 exon 14, respectively) resulting in an in frame fusion. To test whether this might be recurrent, we analysed 105 additional cases by RT-PCR. One additional positive case was detected, similar with but not identical breakpoints to the initial case. Case 1, a 48 year old female, presented with leucocytosis (30x10^9/L), eosinophilia (2x10^9/L, elevated serum tryptase (37µg/l), splenomegaly and a hypercellular bone marrow (BM) CYTOGENETICS was normal and FIP1L1-PDGFRα, KIT D816V and JAK2 V617F were all negative and no pathogenetically relevant mutations were identified by a myeloid NGS panel (28 genes). After 10 months, she progressed to myeloid blast phase. Because the disease was resistant to AML-induction chemotherapy (FLAG-Ilda), an allo- geneic PBSCT was performed after 10 months of a triple TKI (SUNITINIB, RICOSERTIB, AZD7473) treatment for refractory disease. As a consequence of chronic GVHD and septic shock, the patient died 6 months after allogeneic PBSCT. The ZMYM2-FLT3 fusion gene was identified post mortem. Case 2, a 47 year old male, presented with eosinophilia (4.7x10^9/L, 47% elevated serum tryptase (42µg/l) and a hypercellular BM CYTOGENETICS was normal and FIP1L1-PDGFRα, KIT D816V and JAK2 V617F were all negative. There was no response on steroids or hydroxyurea. Following the finding of ZMYM2-FLT3 positivity, treatment with sunitinib was commenced. Blood counts started to improve from day 4 and normalized after 3 weeks. During a pause of 3 weeks due to pulmonary infection, leucocytes/eosinophils rapidly increased, but normalized again within weeks after restart of sunitinib. The patient has been maintained on sunitinib for 10 months (since re-start) and remains in complete hematologic remission.

Summary/Conclusions: ZMYM2 is the fourth gene reported to fuse to FLT3 in myeloid neoplasms but the first FLT3 fusion that is cytogenetically cryptic. These cases may represent a previously undetected TK gene fusion. Previous studies have identified a proportion of MPN cases and thus, although very rare, this fusion should be considered in the work up of MPN-eo cases. Due to their extensive diversity, we anticipate that RNAseq will become the method of choice to detect rare TK fusions.
E1345

COMPLETE HEMATOLOGIC AND CYTODYNAMIC RESPONSE IN A PATIENT WITH FIBROBLAST GROWTH FACTOR RECEPTOR 1 ACTIVATED MYELOPROLIFERATIVE NEOPLASM RECEIVING INCBO54828

N. Desai1, N. Desai1, M. LeBlanc1, E. Asatiani2, S. Varjovsky3, 1MD Anderson Cancer Center, Houston, TX, United States, 2Icynte Europe, Geneva, Switzerland

Background: Fibroblast Growth Factor Receptor (FGFR) inhibitors have demonstrated efficacy in solid tumors with FGFR pathway activation. INCBO54828, a novel, highly selective FGFR1, FGFR2, and FGFR3 inhibitor, is being assessed for the treatment of several advanced malignancies (AACR 2015; Abstract 771). 8p11 myeloproliferative syndrome is an aggressive myeloproliferative neoplasm (MPN) associated with FGFR1 translocation on chromosome 8p11.

Aims: To describe the characteristics of a patient with FGFR1 activated MPN who achieved a complete hematologic and cytodynamic response with INCBO54828 in an ongoing phase 1/2 trial (NCT02393248).

Methods: In this 3-part, phase 1 dose-escalation and expansion trial, eligible adults had any advanced solid tumor (parts 1 and 3) or malignancy with FGFR1/FGFR2/FGFR3 alteration (part 2). Had Eastern Cooperative Oncology Group performance status score ≤1 (parts 1 or 2 ≤2) and were refractory to prior therapy with no known effective standard therapy available to them. Patients received INCBO54828 orally on a 21-day cycle (2-weeks on/1-week off) starting at 9mg QD and increasing to 13.5mg QD.

Results: This 51-year-old male patient with a de novo translocated MPN diagnosis (currently the only patient with MPN enrolled in this trial), presented with abnormal white blood cell (WBC) count (eosinophilia, 15%; peripheral blood [PB] blasts, 4%) and abnormal platelet count (68 x109/L). The patient had prior therapy with hydroxyurea. Bone marrow (BM) biopsy at study entry showed 95% cellularity, 15% atypical megakaryocytes, (8,9)(11.2;q33) in 19 of 20 metaphases, and European Myelofibrosis Network grade MF-1. After 6 weeks of treatment with INCBO54828 at a dose of 9mg QD in part 2 of the study, WBC count normalized with disappearance of eosinophilia and PB blasts. BM biopsy demonstrated a normalization of bone marrow differential with 50% cellularity, 1% BM blasts, adequate trilineage hematopoiesis, MF-1 fibrosis, and a complete cytogenetic response. After 4 months of treatment the patient was hospitalized for pneumonia and study treatment was held. The patient progressed to AML shortly after therapy interruption, with BM blasts increasing to 83% and evidence of clonal evolution (47,XY: +8 (8,9) (11.2;q33) [3][4]/ idem, +19 [17]). The patient was taken off study at this time (end of cycle 6) and subsequently achieved a complete remission on intensive chemotherapy with fludarabine, cytarabine, idarubicin, and allogeneic BM transplantation. The patient is currently alive and in complete remission.

Summary/Conclusions: INCBO54828 showed efficacy in this patient with FGFR1 activated MPN using a 21-day (2-weeks on/1-week off) regimen. Continuous treatment may be necessary to sustain response and avoid rebound as has been seen with other kinase inhibitor therapies. A phase 2 trial has been initiated to evaluate INCBO54828 in patients with myeloid/lymphoid neoplasms with FGFR1 rearrangement (NCT03011372).

E1346

THE GRADE OF STROMAL CHANGES IMPACTS ON PROGNOSIS IN PATIENTS WITH PRIMARY MYELOFIBROSIS

U. Gianelli1, S. Fiori2, D. Cattaneo2, A. Bossi3, I. Cortinovis3, C. Bucelli2, N. Orofino2, A. Iurlo2, 1Division of Pathology, IRCCS Ca’ Granda - Maggiore Policlinico Hospital Foundation and University of Milan, 2Oncohematology Division, IRCCS Ca’ Granda Maggiore Policlinico Hospital Foundation, 3Department of Clinical Sciences and Community Health, University of Milan, Milano, Italy

Background: Recently, a detailed grading system for the assessment of bone marrow stromal changes has been proposed in primary myelofibrosis, proved to be reproducible and adopted by the updated WHO 2016 classification.

Aims: In this study, we aim to evaluate any possible prognostic implications of this grading system in a series of patients with primary myelofibrosis.

Methods: The study involved 122 consecutive patients with primary myelofibrosis diagnosed between 1998 and 2015 at the Oncohematology Division of the Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico of Milan, for whom a bone marrow trephine biopsy ranging from 0 to 9 allows us to distinguish 88 (72%) cases with low-grade stromal changes (total score: 0-4) and 34 (28%) with high-grade stromal changes (total score: 5-9). Clinically, patients with high-grade stromal changes presented more frequently with anemia, thrombocytopenia, leukocytosis, peripheral blood blasts and increased lactate dehydrogenase levels. The grade of bone marrow stromal changes resulted strictly associated with the International Prognostic Scoring System and the overall mortality (low-grade: 10 dead out of 88 vs high-grade: 11 dead patients out of 34; p<0.013). Finally, the grade of bone marrow stromal changes was effective in discriminating the overall survival of the patients with low-grade and high-grade stromal changes (Log-Rank test: p<0.0002).

Summary/Conclusions: A detailed evaluation of the bone marrow stromal changes has important prognostic implications and can be used at diagnosis in the clinical stratification of the patients affected by primary myelofibrosis. Further studies are needed to test if the prognostic significance of this grading system remains during the follow-up.

E1347

INCREASED RISK OF INFLAMMATORY BOWEL DISEASE IN PATIENTS WITH PHILADELPHIA NEGATIVE CHRONIC MYELOPROLIFERATIVE NEOPLASMS

1Department of Haematology, Zealand University Hospital, University of Copenhagen, 2Department of Clinical Epidemiology, Bispebjerg and Frederiksberg Hospital, 3Department of Occupational and Environmental Medicine, Bispebjerg Hospital, University of Copenhagen, 4Danish Knowledge Centre for Rehabilitation and Palliative care, University of Southern Denmark and Odense University Hospital, Odense, 5National Institute of Public Health, University of Southern Denmark, Copenhagen, 6Department of Clinical Epidemiology, Aarhus University Hospital, Aarhus, Denmark

Background: Studies reveal that patients with inflammatory bowel disease (IBD) may have increased risk of haematological cancers. Moreover, Philadelphia negative chronic myeloproliferative neoplasms (MPNs) have previously been associated with autoimmune diseases, including IBD. Nevertheless, to our knowledge, the risk of IBD has not been investigated in patients with MPN.

Aims: We undertook a nationwide population-based matched cohort study, and estimated the risk of IBD in patients with MPN.

Methods: We used valid Danish national registries, covering more than 5 million individuals, and included all patients diagnosed with either essential thrombocythemia (ET), polycythemia vera (PV), myelofibrosis (MF), or unclassifiable myeloproliferative neoplasm (MPN-U) between 1994 and 2013. For each patient, 10 individually age- and sex-matched comparisons were included. Patients and comparisons were followed until first occurrence of any IBD diagnosis (ulcerative colitis or Crohn’s disease), death, emigration or end of 2013. Patients and comparisons with prior IBD were excluded from the analysis. Hazard ratios (HRs) between MPN patients and comparisons were estimated using Cox regression models, and used as measure of the relative risk.

Results: Of the 8,210 MPN patients, 80 individuals were diagnosed with IBD during the study period; including 37 ET patients, 28 PV patients, 1 MF patient and 14 MPN-U patients. During a total risk time of 45,241 years, the rate of IBD per 1000 person years at risk was 1.8 (95% confidence interval [95% CI]: 1.4-2.2) for the MPN patients. The corresponding rate for the 81,326 comparisons was 1.7 (95% CI: 1.6-2.0) per 1000 person years. The 10-year risks of IBD for MPN patients and comparisons were 0.8% (95% CI: 0.6-1.0) and 0.4% (95% CI: 0.4-0.5), respectively. The overall HR of IBD was 2.4 (95% CI: 2.1-2.9) for MPN patients, with HRs of 2.6 (95% CI: 2.1-3.2) for ulcerative colitis and 2.4 (95% CI: 1.7-3.4) for Crohn’s disease. The risk of IBD was increased 2 to 3 fold among ET, PV and MPN-U patients, with HRs of 2.8 (95% CI: 2.1-3.7) for ET patients, 2.1 (95% CI: 1.6-2.7) for PV patients and 2.2 (95% CI: 1.3-3.7) for MPN-U patients.

Summary/Conclusions: Patients with MPN are at increased risk of IBD compared to the general population. The absolute risks of IBD are low, but abdominal discomfort may in few patients be caused by underlying IBD.
ESSENTIAL THROMBOCYTHEMIA WITH AQUAGENIC PRURITUS: AN ENTITY WITH MORE AGGRESSIVE CLINICAL AND BIOLOGICAL PROFILE AT THE DIAGNOSIS AND A HIGH MORBIDITY DURING THE FOLLOW-UP

C. Le Gall-Ianot1,2, R. Le Calloch3, L.-M. Mollard4, L. Misery1, J.-C. Ianot4 1Service dermatologie, CHU Brest - Hôpital Augustin Morvan, 2laboratory of interactions epithélies-neurones, university of Brest, Brest, 3Service Hémato- logie, CHIC, Quimper, 4Service Hémato-logie, CHU Brest - Hôpital Augustin Morvan, Brest, France

Background: Polycythemia vera (PV) and essential thrombocythemia (ET) are Ph-negative myeloproliferative neoplasms in which arterial or venous thromboses and phenotypical evolutions (leukemia, myelofibrosis) are the most recurrent complications. Aqueagenic pruritus (AP), induced by water contact, is a typical symptom of PV. However, we showed recently that ET patients also suffered from AP with clinical characteristics quite different from those observed in PV patients. In 2008, the presence of AP was associated with a lower risk of arterial thrombosis in PV patients.

Aims: It seemed particularly interesting to analyse the clinical relevance and the prevalence of the presence of AP in ET patients for such a risk.

Methods: In this study, we used the OBENE observatory (Observatoire Brestois des Elopaeosis myeloprolétiffiées), a register of MPN patients followed in our University Hospital in which biological and clinical data of 396 ET patients have been collected. This register was approved by a local ethical committee and registered in clinicaltrials.gov (NCT02897297). To avoid masked polycythemia Vera diagnostics, all JAK2 positive cases were tested for isotopic red mass cells if appropriate.

Results: Among the 396 ET patients, 42 (10.6%) suffered from AP. Interestingly, the median age at diagnosis of these patients was lower (51.6 vs 63.8%, p<0.0001). Furthermore, they presented more symptoms as erythrocytosis, hyperviscosity, constitutional symptoms and splenomegaly (p<0.01). ET patients with AP were more proliferative (more polycythemic but less thrombocytopenic) vs ET without AP (p=0.04, 4x, ns). Concerning the occurrence of thrombotic events (arterial or venous) at diagnosis, no significant difference between patients with or without AP was found. In contrast, the presence of AP induced an increase of thrombotic events during the follow-up (30.9 vs 17.2%, p=0.03). But surprisingly, these events appeared in the delayed timing. The arterial/venous rate of thrombotic events was also different with 50/50 vs 25/75. Furthermore, we observed that about one-third of the patients with AP had phenotypic evolutions against 13.3% in the other group (p=0.0007); the most frequent evolutions were PV and secondary myelofibrosis (16.7% vs 5.4%, p=0.005 and 19 vs 4.8%, p=0.0003, respectively). Concerning the overall survival of the patients, we have noticed that there was less death in the group with AP than without AP (11.9 vs 32.5%, p=0.006) in spite of a long follow-up (12.1 vs 7.7 years, p=0.002).

Summary/Conclusions: AP is classically associated to PV. But we confirmed here that AP is also present in ET. Furthermore, ET patients suffering from AP were more proliferative, more symptomatic at diagnosis but also had a higher risk of thromboses and phenotypical evolutions than ET without AP. Despite that these patients have a higher overall survival. So, the presence of AP in ET with characteristic patients with high risk of morbidity (thromboses, phenotypic evolutions).So as in PV, the presence of AP in ET patients at the time of diagnosis should be systematically identified.

ANAGRELIDE RESPONSE ACCORDING TO THE MOLECULAR PROFILE: SOMETHING TO CONCLUDE ON THE MECHANISM OF ACTION OF THE DRUG IN MYELOPROLIFERATIVE NEOPLASMS (MPN)?

M. Montero1, T. Knight1, M. Domínguez2, E. Camilló3, F. Márquez3, F. Escamilla1, P. Guerrero1, M. Suito1, A. Blum1, N. Alkadi1, J. González1, J. Falantes1, N. Rodríguez1, M. Martíno1, I. Espigado1, J. Pérez-Simón1 1haematology and haemotherapy Service, Hospital Universitario Virgen del Rocío, Sevilla, Spain

Background: Anagrelide is a useful drug in the control of thrombocytosis in MPN. Although it is known that in thrombocythemia levels it primarily influences in the post-mitotic phase of megakaryocytic development interfering with its complete maturation, its mechanism of action is still unknown.

Aims: The purpose of this study was to determine the diagnosis of MPN due to the discovery of driver mutations (JAK2, careticulin and MPL) leads us in the present study to correlate them with the response to anagrelide in a group of patients treated with this drug, investigating the possible interference in the referred biological pathways.

Methods: The patients with MPN diagnosed in our centre between 1993 and 2015 were studied. The median age was 49 years, with 19 patients older than 60 years. 83% were female and 17% were male. The diagnosis was initially carried out based on the WHO criteria 2008 and subsequently reviewed the medical records with the new criteria of 2016. A molecular study on peripheral blood cells was carried out using quantitative allel-specific PCR techniques for JAK2, qualitative for MPL (L515V mutation) and Sanger sequencing on exon 9 for careticulin. Type 1 mutation was considered at 52 bp deletion and type 2 at 5 bp insertion. In all patients, the goal of anagrelide therapy was to control thrombocytosis (platelet count below 600x10^9/L) with dosage within the range of efficacy and safety recommended in the datasheet. The results were analysed with the statistical software SPSS vs 15.0

Results: 80.5% of the patients were diagnosed with ET, 12.5% of PV, 3.5% of myelofibrosis and 3.0% of unclassifiable MPN. 59% of the patients had a V617F JAK2 mutation, with allele load higher than 20% in 47.5% of the cases. 28.5% presented mutation in careticulin; of which 50% were type 1 and 50% type 2. Only one patient had a mutation in MPL (2%), the remaining 6% being classified as “triple negative”. The median daily dose of anagrelide received was 1.5mg. 17.5% of the patients required more than 2mg for an adequate control, half of them being positive for mutations in careticulin and the other 50% of the mutation V617F for JAK2 with allele load higher than 20%. 26% of the patients received daily dose of 1mg, being 70% positive for the mutation V617F/JAK2 with allele load lower than 20%, although there were no statistically significant differences between the groups according to the mutational profile. 16% of patients dis- continued treatment due to toxicity, with the most common adverse effects being mild (headache and palpitations).

Summary/Conclusions: Patients requiring higher doses of anagrelide present mutations in careticulin or JAK2 V617F allele load higher than 20% and patients with lower allele load having greater sensitivity to the drug, with no statistically significant differences. It is possible that the first situation is associated with a greater pre-mitotic deregulation in the megakaryocyte where the drug does not interfere whereas the second one could be related to anagrelide interference through the JAK2 pathway in post mitotic maturation although larg- er exploratory studies are required.

The delayed diagnosis of Philadelphia-negative myeloproliferative neoplasms (MPN) is common and results in a high incidence of potentially preventable thrombotic complications

C. Forsyth1,*, C. Tiley2, B. Wylie2, M. Dean2, T. Armitage2, K. Melville2 1Medicine, Wyong Hospital, Kanwal, 2Haematology, Gosford Hospital, Gosford, Australia

Background: Ph-negative MPNs are a heterogeneous group of stem cell derived, clonal bone marrow disorders characterised by increased production of mature blood cells. Patients with MPNs are at significantly increased risk of thrombotic and haemorrhagic complications which are a major cause of morbidity and mortality. The early diagnosis and treatment of MPN may reduce the incidence of thrombotic complications and the associated morbidity and mortality.

Aims: We performed a study to determine if the delayed-diagnosis of MPN was common and the implications of any such delay.

Methods: The medical records of patients treated at our centre with a new diagnosis of MPN between January 2010 and June 2016 were audited. We determined the duration from first appearance of a full blood count (FBC) abnormality consistent with the diagnosis of MPN until the time of formal diagnosis. The occurrence of any thrombotic or haemorrhagic complications during this time was recorded.

Results: 143 patients were diagnosed with MPN; 35 with polycythemia vera, 79 with essential thrombocythemia, 25 with primary myelofibrosis and 13 with MPN-unclassifiable. Patients with PV had a median diagnosis delay of 156 days (range 0-2650 days) and 26% had potentially preventable events. Patients with ET had median diagnosis delay of 823 days (range 0-8731 days) and 23% had potentially preventable thrombotic events including 2 patients with multiple events. Patients with PMF had a median diagnosis delay of 196 days (range 0-3684 days) and 12% had potentially preventable thrombotic events. In MPN-U the median diagnosis delay was 1371 days (range 42-3255) and 31% of patients had potentially preventable adverse events.

Summary/Conclusions: Over 5.5 years we identified 143 patients with a new diagnosis of Ph-negative MPN within our centre. The overall median diagnosis delay was 723 days (0-8731) with delays of more than 12 months in ET, PV and MPN-U, and more than 6 months in PMF. 21% of patients had potentially preventable thrombotic events and 2.8% had potentially preventable haemorrhagic events. Earlier recognition of FBC abnormalities consistent with MPN and earlier referral to specialist haematological management would, with earlier intervention, would be expected to prevent many thrombo-haemorrhagic complications and reduce MPN-associated morbidity and mortality.

Long-term and low-dose busulfan is safe and effective in elderly patients with Essential Thrombocythemia

R. Renso1, A. Rodigi1, P. Pioltelli1, C. Gambacorti-Passerini2,3, E. M. Ellis1 1Hematology Division, 2Clinical Research Unit, Hematology, San Gerardo Hospital, 3Department of Medicine and Surgery, University of Milano-Bicocca, Monza, Italy

Background: Therapeutic options for elderly patients (pts) with Essential Thrombocythemia (ET) resistant or intolerant to hydroxyurea (HU) are limited. Busulfan (B) is a possible second-line treatment, but conventional schedule

Reference: haematologica | 2017; 102(s2) | 555
(starting dose of 14mg/week up to obtain the complete haematological response (CHR) 
is associated with high risk of leukemic transformation and second malignancies. 
Aims: We analysed efficacy, toxicity, risk of Myelofibrosis (MF) and leukemic 
evolution in 31 of 352 ET pts collected in our database, treated with an alter-
native long-term schedule of BU, defined by low-starting dose (4-6mg/week) 
up to CHR (evaluated according to ELN response criteria), followed by dose 
de-escalation overtime.
Methods: Non parametric tests, such as Mann-Whitney, Pearson Chi-square 
and Fischer’s exact tests, were used for statistical analysis of continuous and 
categorical variables. Survival curves were calculated by Kaplan-Meier method 
and compared with Log-rank (Mantel-Cox) test.
Results: 27/31 pts were evaluable for analysis (8 male, 19 female). Median 
age at diagnosis and at BU start were 71,3 and 79 years (yrs) respectively. We 
found these driver mutations: JAK2V617F in 15 pts (55,6%), Calreticulin in 8 
pts (29,6%) and MPL in 1 patient (3,7%); 3 pts (11,1%) were triple negative. 
IPSET score at diagnosis was low-intermediate in 17 (63%) and high in 10 
(37%) pts. 26 pts started BU as 2nd line treatment: 11 (42,3%) were intolerant 
and 15 (57,7%) were resistant to HU respectively. Only one received BU as 1st 
line treatment. They received BU for a median time of 47,67 months (range: 
1,48 – 94,42). The median cumulative BU dose was 453mg (range: 32-1032). 
25/27 pts (92,6%) obtained CHR, after a median time of 191 days. 6 pts (22,2%) 
presented hematological (5) and extra-hematological (1, cutaneous) side 
effects. Overall, 12 pts (44,4%) stopped BU: 4 for hematological toxicity, 4 for 
disease progression, 2 for drug intolerance/resistance; the remaining 2 not for 
drug-related side effects. After a median follow-up of 9,74 yrs (range: 1,82- 
27,05), 9 (33,3%) and 2 (7,4%) pts presented MF evolution and leukemic 
transformation respectively. The MF-free-survival (MFS) was 48,8% at 15 yrs and 
appears to be significantly lower than the entire series of ET pts (77,4% at 15 yrs; 
p=0,002; figure 1). Median MFS was 12,7 yrs for pts treated with BU, 
whereas it was not reached at 15 yrs in the entire series of ET. There were no 
statistically significant differences in principal hematological and clinical features 
whereas it was not reached at 15 yrs in the entire series of ET pts. There were no 
statistically significant differences in principal hematological and clinical features 
except for ET patients without thrombosis. There was no difference in 
the frequency and type of thrombosis in JAK2 V617F positive patients. Female sex 
was prevalent only in ET group. The age at diagnosis in all studied groups was 
similar except for ET patients without thrombosis (50 years, range 21-83), p=0,002. Our study showed that V617F allele burden in patients 
without thrombosis was statistically significantly different between ET (17,2%, 
range 4,2-55,2) compared to PV (43%, range 1,7-99,9) and PMF (37,1%, range 
1,4-90,7), p<0,001. The same statistically significant difference for V617 allele 
burden was established in patients with thrombosis between ET patients (19%, 
range 1,4-84,5) and PV and PMF patients (42,5%, range 8,9-97,2 and 48,8%, 
range 1,6-99,8, respectively), p<0,001.
Summary/Conclusions: Our results confirm that arterial thrombosis is more 
frequent than venous thrombosis in JAK2 V617F positive patients. Female sex 
was prevalent only in ET group. The age at diagnosis in all studied groups was 
similar except for ET patients without thrombosis. There was no difference in 
the frequency and type of thrombosis in ET, PV and PMF patients with 
high heterogeneity in V617F allele burden between all studied groups regard-
less of the occurrence of thrombosis.

Figure 1.

Summary/Conclusions: Our experience with an alternative long-term and 
low-dose BU administration is safe and effective in elderly patients with ET. 
92,6% of them obtained CHR, with acceptable hematological and extra-hema-
tological toxicity. We noticed a high rate of MF evolution with respect to global 
ET population, while the risk of leukemic transformation seems to be limited, 
considering that these pts were elderly and previously treated. Predictive factors 
for MF evolution should be analysed and confirmed in larger series.

**PROTECTION AGAINST DEVELOPMENT OF B CELL LYMPHOMA BY TETRASPANIN CD37**

C. de Winde1, S. Veenenbergen1, K. Young2, M. van den Brand1, A. van der Schaar1, S. Eltink1, H. van Krieken1, C. Figdor1, S. van Deventer1, B. Scheijen1, A. Van Spriel1,2

1Radboud University Medical Center, Nijmegen, Netherlands, 2MD Anderson Cancer Center, Houston, United States

**Background:** B cell non-Hodgkin lymphoma, worldwide the most common hematological malignancy, remains a clinical problem. The molecular events leading to B cell lymphoma are only partially defined. CD37 is a member of the tetraspanin superfamily that is highly expressed on mature B cells and is required for optimal GC function and long-lived antibody production.

**Aims:** We investigated the function of tetraspanin CD37 in the development of B cell lymphoma.

**Methods:** A combination of studies was performed in mouse models (CD37/IL-6-deficient mice), and studies of DLBCL patient material using biochemical, immunological, genetic and microscopical approaches.

**Results:** We provide evidence that deficiency of CD37 induces the development of B cell lymphoma in vivo. Cd37-deficient mice develop germinal center-derived B cell lymphoma in lymph nodes and spleen with higher incidence than Bcl2-transgenic mice. We discovered that CD37 interacts with SOCS3, and when absent drives tumor development through constitutive activation of the IL-6 signaling pathway. The importance of the IL-6 pathway was confirmed by investigating Cd37xIl6 double knock-out strains that were fully protected against lymphoma development. Our unpublished data shows discovery of inactivating CD37 mutations in patients with DLBCL. Importantly, loss of CD37 on neoplastic cells in patients with diffuse large B cell lymphoma (DLBCL) is directly correlated with activation of the IL-6 signaling pathway and with worse progression-free and overall survival.

**Summary/Conclusions:** Together, this study identifies tetraspanin CD37 as a novel tumor suppressor that directly protects against B cell lymphomagenesis, and provides a strong rationale for blocking the IL-6 pathway in patients with CD37-negative B cell malignancies as therapeutic intervention.

**E1354**

**COMITANT DUAL ABLATION OF BLIMP1 AND P53 IN B-CELLS AS A NOVEL IN VIVO MODEL FOR HIGH-GRADE B-CELL LYMPHOMA**

14ASST Spedali Civili di Brescia, Brescia, Italy, 2Kumamoto University, Kumamoto, Japan, 3Dana-Farber Cancer Institute, Boston, 4Maine Medical Center, University of Maine, Scarborough, 5Birgham and Women’s Hospital, Boston, United States

**Background:** B-Lymphocyte-Induced Maturation Protein-1 (BLIMP1)- and p53-inactivation contributes to the pathogenetics of a wide spectrum of malignancies, including diffuse large B-cell lymphomas. Nevertheless, there is lack of in vivo models that may be used for a better understanding of the biology and genomics of high-grade B-cell lymphomas characterized by dual loss of both BLIMP1- and p53.

**Aims:** To develop and characterize a transgenic mouse model of BLIMP1-deficient and p53-deficient B cells (1) To establish a new in vivo model that mimics human ABC-DLBCL phenotype.

**Methods:** Cre recombinase under the control of CD19 promoter (C57BL/6 Cd19CreCre) mice were crossed with either C57BL/6 BLIMPflox/flox or C57BL/6 Cre recombinase under the control of CD19 promoter (C57BL/6 Cd19Cre/p53flox/flox) and non-expressing the Cre recombinase, C57BL/6 Cd19Cre/p53flox/flox, to achieve dual deletion of BLIMP and p53 in B cells (Cd19CreCd19/Bl-/p53-deficient mice). Transgenic experimental mice (Cd19/Bl-/p53-) where characterized for clonal B cell infiltration using immunohistochemistry, flow cytometry, Southern Blotting, whole exome sequencing. MTT assay was used to test BTK-inhibitor-dependent cytotoxicity using CD19/Bl-/p53-deficient B220 cells.

**Results:** CD19/Bl-/p53- mice presented with diffuse lymphadenomegaly, splenomegaly, hepatomegaly (100%, 90.3% and 77.4%, respectively). Other clinical manifestations included presence of ascites and hind limb paralysis (12.9% and 19.3%, respectively). The CD19/Bl-/p53- showed increased overall survival compared to Bl-/p53- non-expressing the CD19/Cre recombinase, CD19/p53flox/flox or CD19/Bl- (363, 469.5, 460.5 and 770 days, respectively). H.E. staining of CD19/Bl-/p53--derived lymph node showed, a nodal architecture with a monomorphic population of large sized atypical lymphoid cells, multiple birefringent calcium deposits, paracentrally situated nucleoli. A "starry sky" pattern was also observed. Features were compatible with a high-grade lymphomas. IHC analysis confirmed positivity for B220 staining (TdT, Bcl6, CD138 and CD4, CD8 negative). Tumors were confirmed to be B220+lgM+ with either lgk- or lgdelta-lambda-restriction as demonstrated by flow cytometry, and either monor- or biclonal B cell populations were demonstrated by Southern blotting. Viral DNA was detected from B220+ selected cells obtained from pathological lymph nodes of CD19/Bl-/p53- mice and identified 143 SVNs. Non-synonymous somatic mutations were mapped on genes involved in the regulation of focal adhesion, PDGF signaling, p53-downstream pathway, and lipid protein metabolism. B220+ cells selected from CD19/Bl-/p53- derived lymph node were implanted s.c. into recipient SCID/Bg mice, and presented with 100% engraftment, with a monomorphic lymphoid infiltration of B220+ and IgM+ cells. B220 positive cells were selected from the s.c. tumor and intravenous injected into recipient SCID/Bg (n: 10) and BL6 mice (n: 10). Engraftment was demonstrated in all three groups where hepatomegaly and splenomegaly were observed. Infiltration of B220+ cells was documented within bone marrow, liver and spleen. Finally, we found that B220+ cells selected from lymph node hetero-thesized from CD19/Bl-/p53- mice were sensitive to ibrutinib.

**Summary/Conclusions:** Double inactivation of p53 and BLIMP in B-cells supports the concept of a novel in vivo model for dual deletion that recapitulates what seen in patients with ABC-DLBCL driven by BLIMP1-p53 dual loss-induced C-Myc expression.

HSP110 SUSTAINS MYD88-DEPENDENT NFkB SIGNALING IN ACTIVATED B CELL DIFFUSE LARGE B CELL LYMPHOMA

C. Boudesco1, S. Caussé1, A. Hamman2, E. Verhoeven3, L. Martin1, F. Jardin4, T. Fest5, O. Wolz6, A. Weber6, C. Garrido2, G. Jego1,*

1University of Burgundy, 2INSERM 1231, Dijon, 3INSERM U1111, Lyon, 4INSERM 918, Rouen, 5INSERM 911, Rennes, France, 6University of Tübingen, Tübingen, Germany

Background: Diffuse large B cell lymphoma (DLBCL) is an aggressive lymphoproliferative disorder of B lymphocytes accounting for 30% of adult Non Hodgkin Lymphoma (NHL). Among DLBCL, Activated B Cell – DLBCL (ABC-DLBCL) is the most aggressive form and has a poor prognosis. Heat-shock proteins (HSPs) are molecular chaperons highly expressed in cancer cells and implicated in resistance to radio- and chemotherapy. Therefore, HSPs are envisioned as therapeutic targets in many cancers. Among the different HSPs, HSP110 has been recently identified as a pro-survival factor in germinal center-derived DLBCL (GC-DLBCL), through stabilization of the GC-DLBCL oncogene Bcl-6.

Aims: Here, we have explored if HSP110 could also be involved in the survival of the most aggressive form of DLBCL.

Methods: The study was performed with ABC-DLBC patient samples and several cell lines. Silencing specific for HSP110 was achieved through a lentiviral vector designed to inject highly efficiently non-permissive B cell lines.

Results: We observed a high HSP110 expression in all ABC-DLBC patient samples, compared to normal reactive lymph nodes by using IHC staining of ABC-DLBC tumor sections and transcriptional analysis of ABC-DLBC patient tumors. Furthermore, shRNA silencing of HSP110 decreases the survival of several ABC-DLBCL cell lines, and downregulates the expression of pro-survival factors such as Bcl2 and Bcl-XL. SirRNA silencing of HSP110 abrogates NF-κb signaling, which is the major oncogenic pathway in ABC-DLBCL cell lines. In accord with these results, over-expression of HSP110 in DLBCL and non-DLBCL cell lines increases NF-κb signaling, indicating a tight interplay between HSP110 and the NF-kB pathway. Using immune-precipitation in DLBCL cell lines and Duolink™ assays, we identified an in vitro and in cellulo interaction between HSP110 and Myd88, a critical protein of the NF-kB pathway that bears an activated mutation in many ABC-DLBC patients and that is responsible for lymphoma aggressiveness. Finally, we demonstrate that HSP110 stabilizes the wild type as well as the mutated form of Myd88, therefore facilitating the chronic NF-κb pathway activation in those cells.

Summary/Conclusions: In conclusion, we identified HSP110 as a regulator of NF-κb signaling through Myd88 stabilization in ABC-DLBC. This finding highlights HSP110 as a new potential therapeutic target in DLBCL and potentially in other hematological malignancies driven by mutated Myd88 as Waldenstrom macroglobulinemia.

Figure 1.
Aims: Here, we aim to recapitulate MCL in a mouse model of hematopoietic-specific overexpression of cyclin D2. Next, we want to use this preclinical mouse model to evaluate novel therapeutic strategies for the treatment of MCL.

Methods: To evaluate if cyclin D2 could act as a bona fide oncogene in the pathogenesis of MCL, we developed a conditional R26-driven Ccn2d2 overexpression mouse model. For this, we used a targeting vector that contained a floxed stop cassette followed by the Ccn2d2 gene and a EGFP/luciferase reporter, which was subsequently targeted in mESCs using recombinase-mediated cassette exchange (RMCE).

Results: The resulting R26-Ccn2d2 mice were crossed to VavCre mice to enable biallelic R26-driven overexpression of Cyclin D2 in the entire hematopoietic system. Interestingly, these mice developed large lymphomas starting from 36 weeks of age (Figure 1A), with tumor cells showing characteristic MCL immunophenotype (CD19+, CD5+, CD23-). Of note, these malignant B-cells were monoclonal small-sized cells with slightly irregular hyperchromatic nuclei and disseminated into other organs such liver, spleen and the gastrointestinal tract. Using the (E1B1) viral oncogene, we confirmed the formation of lymphoma cells expressing SOX11 positive, as evaluated by IHC, suggesting that these tumors indeed reflect a murine form of MCL. Noteworthy, the MCL cells from this mouse model also contain a luciferase reporter, allowing accurate in vivo tracing of tumor cells in xenograft experiments. These xenograft experiments can be used as preclinical models, in which bioluminescence is used to assess the tumor burden and to monitor tumor regression upon drug treatment.

Summary/Conclusions: In conclusion, our preliminary data suggest that modeling cyclin D2 in mice, mimicking the elevated cyclin D2 levels of human MCL patients with translocations involving the CCND2 locus, is sufficient to form MCL.

E1359
HDAC6 INHIBITION INCREASES CD20 LEVEL BY STIMULATING TRANSLATION OF CD20 MRNA
A. Graczyszk-Jarzynka1,2, M. Bobrowicz1, M. Dworak1, J. Stachurska1, E. Ber Bethel3, B. Pyrzyńska1, M. Siernicka1, N. Miązek1, P. Zapała1, N. Dalla-Venezia2, J. Golub3, M. Winiarska1
1Department of Immunology, Medical University of Warsaw, Warsaw, Poland, 2Centre Léon Bérard – Centre de Recherche en Cancérologie de Lyon, Lyon, France

Background: HDAC6 (histone deacetylase, isoform 6) is a novel promising target in hematological malignancies. HDAC6 is an atypical member of HDAC family that regulates the acetylation status, and thus the functionality of cytosolic proteins, and has been explored therapeutically for its role in the process of protein degradation. HDAC6 mediates the transport of protein aggregates to the autophagic machinery to diminish their cytotoxicity. Thus, the disruption of the aggresome pathway, similarly to proteasome inhibition, results in a massive accumulation of misfolded protein aggregates and apoptotic cell death. As this strategy holds a considerable potential in aggressive B-cell tumors with a high rate of protein synthesis, HDAC6 inhibitors - are currently being tested in Phase II/III clinical trials. The results of preclinical studies show the increased efficacy of the combination of HDAC6 inhibitors with proteasome inhibitors in inducing stress-related cell death. The results of our studies show that HDAC6 inhibition in non-toxic concentrations significantly increases CD20 level on a protein level.

Aim: Our aim of the study was to elucidate the mechanism of the regulation of CD20 expression by HDAC6.

Methods: We used qRT-PCR and Dual Luciferase Assays in order to determine the influence of HDAC6 on CD20 transcription. We used pulse-chase using assays widely used with translation inhibitors – cycloheximide and homoharringtonine.

In order to study the effect of HDAC6 inhibition on global as well as specific translation of CD20 after HDAC6 inhibition we studied the formation of stress granules (SG).

Results:

We used qRT-PCR and Dual Luciferase Assays in order to determine the influence of HDAC6 on CD20 transcription. We used pulse-chase using assays widely used with translation inhibitors – cycloheximide and homoharringtonine.

We show that HDAC6 inhibition regulates CD20 level without affecting its transcription. Moreover, we demonstrate that HDAC6 inhibition increases translation of CD20 mRNA on polysomes without affecting general synthesis of novel proteins in the cell. However, our experiments suggest that the transcribed translation of CD20 mRNA is not a result of resumed translation of mRNPs, but a result of its translation.

Summary/Conclusions: Our study shows a new mechanism of the regulation of CD20 expression by increasing its translation. Moreover, we demonstrate a new role of HDAC6 protein. This finding has a potential clinical application, as HDAC6 inhibitor are being widely tested in different hematological malignancies.
is associated with an absence of relapse and thus defines a new group of very low risk patients. These findings provide important clues for future therapeutic-driven therapies in MCL.

E1361

CLINICOBILOGICAL FEATURES OF B-CELL NEOPLASMS WITH CDK6 TRANSLOCATIONS: FREQUENT ASSOCIATION WITH MARGINAL-ZONE LYMPHOMA, CONTIGUOUS OF PROLYMPHOCYCTIC CELLS AND TP53 ABNORMALITIES. A GFCH STUDY

Background: Translocation involving the CDK6 gene is a rare but recurrent abnormality in B-cell neoplasms. Three different translocations have been described: t(2;7)(p11;q21), which is the most frequent, t(7;14)(q21;q32) and t(7;14)(q21;q11), leading to juxtaposition of CDK6 gene with IGH, IGK or IGL locus respectively.

Aims: The Groupe Francophone de Cytophysiologie Hématologique (GFCH) collected 35 chronic B-cell disorders with CDK6 translocation in order to document the clinico-biological features of this uncommon aberration.

Methods: Clinical and biological data were gathered at diagnosis when available. A cytogenetical review was performed by 3 experts in 27/35 cases. FISH was used to detect IGH or TRAD and CDK6 rearrangements, and recurrent abnormalities frequent in SMZL and CLL (trisomy 3, 12, deletions of 13q14 and 7q22/7q36 loci).

Results: 9/35 (26%) K was complex in 18/35 (51%). The most frequent additional abnormalities were: del17p (TP53) (51%), del13q (41%), del16p (23%), trisomy 18 (22%), trisomy 19q (17%) and trisomy 12 (11%). Deletion of 7q and 11q were rare (one case each). TP53 was mutated in 6/22 patients (27%), including 5 with del17p. Overall, 19/29 (66%) tested cases had a TP53 abnormality (del and/or mutated), which was significantly associated with complex karyotype.

(p<0.016) and del13q (p<0.042). MYD88 L625P was detected in 2/22 patients. No NOTCH2 mutation was found. IGHV analysis showed a preferential usage of VH4 (8/23, 35%), while VH1 was rare (3/23, 13%, including one VH1-2).

Most carried IGHV with some impact of somatic hypermutation (85%). Median follow-up was 28 months [0-192]. The median survival was not reached, only 4/32 (12.5%) died. A treatment was undertook in 15/32 (47%) cases, with a median duration to first treatment of 13 months. In our series, the CDK6+ MZL differed from classical SMZL by frequent prolymphocytic differentiation (14/19, 74%), very low incidence of 7q deletion (1/23, 4%), high frequency of TP53 abnormality (12/23, 52%), absence of NOTCH2 mutation (0/3, 0%), and a different IGHV repertoire with low frequency of VH1-2 (1/13). The CDK6+ USBCL also had frequently a contingent of prolymphocytes (3/4, 75%), and showed a genetic profile similar to the CDK6+ MZL (see figure).

Summary/Conclusions: These results, obtained on the largest series to date, suggest that CDK6 translocation is associated with indolent small B-cell lymphomas, mostly SMZL, with distinctive features. However, CDK6 translocations are rare, and therefore, we only observed 1 case involving the T-cell receptor (TCR) locus, which is a rare event in a B neoplasm. Finally, it is intriguing that this abnormality involves almost exclusively the IKGK locus, and not the other IGH loci, especially IGH which is usually the most frequently rearranged.

PRIMARY CUTANEOUS DIFFUSE LARGE B-CELL LYMPHOMA, LEG TYPE, EXPRESS STEREOYPEOED B-CELL RECEPTORS WITH UNIQUE NONSYNONYMOUSLY MUTATED CONSTANT REGIONS

M.T. Koning1,*, R. Übelhart2, S. van der Zeeuw3, S. Kielbasa3, H. Jumaa2, M. Vermeer4, R. Willenre4, C. Tensen3, H. Veeken4, 1Department of Hematology/University Medical Center, Leiden, Netherlands, 2Department of Immunology, University Medical Center Ulm, Ulm, Germany, 3Sequence Analysis Support Core, 4Department of Dermatology, Leiden University Medical Center, Leiden, Netherlands.

Background: Primary Cutaneous Diffuse Large B-Cell Lymphoma, Leg Type (DLBCL, LT) is a rare and aggressive neoplasm with a primary cutaneous presentation that shares genetic and phenotypic characteristics with DLBCL of activated B-cell subtype (ABC-DLBCL). Although receptor stereotypes have been observed, the role of the B-cell receptor (BCR) in DLBCL, LT is largely unknown. Previous studies on small cohorts suggested that DLBCL, LT expresses IGH with overrepresentation of IGHV3 alleles and high rates of somatic mutations.

Aims: We aimed to elucidate the stereotype of the BCR in DLBCL, LT and to test for autonomous antigen-independent signaling as described for CLL (Dührren-von Minden, Nature 2012) and non leg-type ABC-DLBCL (Koning, AACR 2016 & ASH 2016).

Methods: 8 cases of DLBCL, LT were subjected to RNAseq. Additional RNAseq data from 6 healthy volunteers (GEUVADIS project), 10 non leg type DLBCL, and 16 follicular lymphoma were obtained from NCBI publicly available datasets and collaborators. VDJ/VJ rearrangements and IGH constant regions were Sanger sequenced for all cases and two granulocyte controls. Lymphoma-derived clonal BCR were tested for autonomous signalling activity in the murine TKO pre-B-cell system (Dührren-von Minden, Nature 2012).

Results: RNAseq analysis demonstrated an IGH isotype in eight of all VJ-kappa and VDJ gamma cases. B-cell specific (BCR, TR) on a mouse constant region backbone did not induce antigen-independent calcium flux in TKO cells upon induction of functional pathway of the BCR signalling cascade by tamofoexin.

Summary/Conclusions: Our data identify a clearly stereotyped receptor in DLBCL, LT. In contrast to CLL and ABC-DLBCL, BCR stereotypy was not associated with autonomous BCR signalling activity using a murine IGHM backbone. The pathogenic potential of the novel constant region mutations for BCR activity in DLBCL, LT warrants further functional studies.
Background: NR4A1 (Nur77) belongs together with NR4A2 (Nur1) and NR4A3 (NOR-1) to the Nur77 family of nuclear orphan receptors. As immediate early- or stress response genes their expression is diverse as it is the cellular outcome upon activation. Recently, there has been attributed a pivotal role to NR4A1 and NR4A3 as tumor suppressors in AML in humans and mice. In our comprehensive NR4A4 expression analysis in various lymphoma entities we demonstrated a significant reduction of NR4A1 expression in aggressive lymphomas, which was associated with poor cancer-specific survival. Moreover, ectopic expression of NR4A1 in aggressive lymphoma cells resulted in induction of apoptosis.

Aims: In order to better dissect the role of NR4a1 in lymphoid malignancies, we used a Myc-driven mouse model of lymphomagenesis and crossed the EµMyc mouse with the Nr4a1-/- mouse. Survival and tumor formation were monitored and sh-PCR was performed on selected tumor specimens, whereby genes, found to be associated with NR4A1 expression in the publicly available gene expression data set of DLBCLs generated by Lenz et al., were taken. Moreover, the driver-function of Nr4a1 in lymphomagenesis at the premalignant stage was investigated by using apoptotic assays and by carrying out transplantations of tumor cells into wt recipients.

Methods: Kaplan Meier analysis was performed for survival and tumor forma-
tion in EµMyc Nr4a1+/+ (n=134), EµMyc Nr4a1 -/- (n=54) and EµMyc Nr4a1 +/-(n=59), respectively. For the PCR shRNA screen selected tumor specimens from wt and EµMyc mice with (n=14) and without (n=17) Nr4a1 loss were used. For investi-
gation of the role of Nr4a1 at the premalignant stage, mice aged 4 weeks (n=4 per genotype) were sacrificed and AnnexinV staining and cleaved-caspase3 assay were performed on cells isolated from the spleen and bone marrow. In vivo, the driver-function of Nr4a1 in lymphomagenesis at the premalignant stage was investigated by using apoptotic assays and by carrying out transplantsations of tumor cells into wt recipients.

Results: EµMyc Nr4a1 -/- mice showed decreased survival with a median of 92 days compared to Nr4a1 +/+ mice with median survival of 123 days (p=0.001) and tumors developed faster with a median of 45 days for EµMyc Nr4a1 -/-, vs 107 days for EµMyc Nr4a1 +/+; p<0.001. Both, survival (median=101 days; p=0.037) and tumor formation (median=66 days, p=0.001) gave intermediate values for EµMyc Nr4a1 -/- mice. Furthermore, EµMyc Nr4a1 +/ - mice suffered less frequently from EµMyc Nr4a1 -/- mice, whereas apoptosis was significantly diminished in EµMyc Nr4a1 -/- mice. In vivo, the driver-function of Nr4a1 in lymphomagenesis at the premalignant stage, whereas apoptosis was significantly diminished in EµMyc Nr4a1 -/- mice. Kaplan Meier analysis was used for monitoring survival and tumor formation, and FACS analysis for analysis of bone marrow, spleen and tumor, respectively.

Summary/Conclusions: Our results clearly demonstrate the influence of Nr4a1 loss on tumor formation and consequently survival in a Myc-driven model of lymphomagenesis. Importantly, Nr4a1 loss seems to impact cell death early in B cell development, even ahead of malignant transformation. Additionally, Nr4a1 seems to be involved in driving immune responses towards an anti-inflamma-
tory, tolerogenic phenotype, thereby facilitating tumor growth and in altering the tumor environment. Collectively, these data underpin the tumor suppressive function of Nr4a1 in aggressive lymphomas.

MUTATIONAL PROFILING OF HODGKIN- AND REED-STERNBERG CELLS (HRSC) OF CLASSICAL HODGKIN LYMPHOMA (CHL) ENRICHED FROM ARCHIVAL FORMALIN-FIXED AND PARAFFIN-EMBEDDED TISSUE SAMPLES
D. Juskevičius1,2, D. Jucker1, T. Dietsch1, V. Perrina1, C. Ruiz1, S. Dimhöfer1, A. Tzankov1
1Institute of Pathology, University Hospital Basel, Basel, Switzerland

Background: ChL can be cured in the majority of cases. However, ~10–20% patients die of the lymphoma after relapse or progressive disease. There are unmet needs for understanding the mechanisms that cause ChL relapses, for development of new prognostic/predictive markers and effective targeted ther-
apies. Comprehensive genetic characterization and advance in understanding of the disease pathogenesis of CHL are indispensable to meet those needs. How-
ever, genetic information on CHL is still scarce mainly due to difficulties of iso-
lation malignant HRSC, whose overall frequencies in the affected tissues range from 0.1-5%. Formalin-fixed paraffin-embedded (FFPE) tissue archives are the most abundant source of clinically annotated tumor specimens. However, FFPE tissue usability is limited because of poor DNA quality and difficulty to enrich 
neoplastic cells. Therefore, new enrichment techniques are necessary to enable larger scale comprehensive genetic investigations of CHL.

Aims: Our aims were: 1) to develop a technique for HRSC enrichment from the archival formalin-fixed paraffin embedded tissue; 2) to reliably detect genetic aberrations in the genomes of enriched tumor samples and to use this infor-
mation for development of new prognostic and predictive markers as well as for better understanding of the genetic background of CHL.

Methods: We have developed a new high-throughput method for marker-based enrichment of archival FFPE tissue-derived HRSC nuclei by fluorescence-assist-
ed sorting of cell nuclei (FACS). Genomic DNA extracted from sorted nuclei was used for identification of mutations in 68 genes that are frequently mutated in lymphomas by targeted high throughput sequencing (HTS). Chromosomal copy number aberrations were investigated by the Agilent SurePrint 180k microarray.

Results: Enzymatically extracted FFPE tissue-derived cell nuclei retain their antigenicity and can be reliably labelled with monoclonal antibodies against nuclear (MUM1, PAX5) and cytoplasmic/cell surface (CD30) markers. A mean 
neoplastic cell purity of 70% (range 40-95%) was achieved by sorting HRSC cells according to their double expression of MUM1 and CD30 in 11 ChL cases. Using sorted non-malignant cells as a germline control we detected somatic single nucleotide mutations and indels in all investigated genes. Mutations of STAT6, PIM1, SOCS1, KMT2D occurred in at least 18% (2/11) of cases. Additionally, individual cases contained copy number aberrations such as gain of chr2 (CREL locus), focal deletions of chr4, chr7, chr16 and chr19 affecting genes such as JAK3, CDKN2D, MAP2K3 and NOTCH3. Taken together our study demon-
strates that mutational profiling of the enriched cell populations is suitable for wide-scale genetic profiling.

Summary/Conclusions: A novel rare-cell-enrichment technique is suitable for genetic ChL studies and opens the possibility for the wider use of archived

haematologica | 2017; 102(s2) | S61

Madrid, Spain, June 22 – 25, 2017
OUR data highlighted in each patient persistent gene modifications.

**Methods:** We characterized the spontaneous haematopoietic tumours by FACS and morphological analysis. To identify the cell of origin for the disease, we performed bone marrow transplantation assays. We high-purity FACS-sorted individual cell populations of diseased STAT1-deficient mice and transplanted them into recipient mice. Experiments were performed in accordance with the national animal experimentation guidelines.

**Results:** A dominant miRNA signature consisting of 103 miRNAs was identified in STAT1-deficient mouse models.

**Summary/Conclusions:** Our data indicates that miRNA signatures might be involved in the development of STAT1-deficient lymphoma.

---

**LACK OF STAT1 PREDISPOSES TO A DIFFUSE LARGE B-CELL LYMPHOMA-LIKE DISEASE**

**Background:** Mantle cell lymphoma (MCL) is a B-cell non-Hodgkin lymphoma characterized by t(11;14)(q13;q32) leading to constitutive cyclin D1 overexpression and cell cycle deregulation. The survival is still poor, especially for patients resistant to frontline drugs. Although patients are brought in remission, relapses often occur with disseminated lymphoma, which is more difficult to treat.

**Aims:** To address the genetic heterogeneity in MCL in paired patient samples at diagnosis and relapse.

**Methods:** Highly pure malignant B-cell populations were isolated using fluorescence-activated cell sorting in four patients diagnosed with MCL. In addition, T-cells were sorted from the same patients as paired non-malignant control samples. Moreover, we performed on both the malignant B-cell population and paired T-cells (13 samples in total). Mutations were detected in parallel with CLC Biomedical Workbench 2.5 (Qiagen) and MuTect 1.04 (Broad Institute) (coverage ≥ 20, population allele frequency < 0.01) and evaluated against the COSMIC (Wellcome Trust Sanger Institute), dbSNP and PubMed databases. Exonction from informed consent was approved by the National Ethical Committee.

**Results:** Our data highlighted in each patient persistent gene modifications between diagnosis and relapse. We confirmed gene mutations already well-known in B-cell malignancies (e.g. TP53, NOTCH1 and MYD88). Interestingly, aberrations not previously described in the COSMIC database were observed with high allele frequency both at diagnosis and at relapse. This included genes in B-cell signaling (e.g. transcriptional repressor SPEN associated to NOTCH pathway regulation and blockade of the precursor B-cell differentiation), inflammatory response (e.g. JRG1), genes found in invasive carcinoma (e.g. integrin β4 subunit) and B PLAT monoclonal expression which were driven by somatic mutations or hit in putative drivers, new gene modifications as well as loss of previous ones could be observed at relapse.

**Summary/Conclusions:** Our work shows examples of molecular progression from diagnosis to relapse in MCL and supports the heterogenic nature and genetic complexity of this disease. We confirm mutations in genes already known as involved in the disease, and to identify new signaling pathways with genes which could be targeted by new treatments.

---

**Molecular Heterogeneity of Mantle Cell Lymphoma**

**Background:** Mantle cell lymphoma (MCL) is a B-cell non-Hodgkin lymphoma characterized by t(11;14)(q13;q32) leading to constitutive cyclin D1 overexpression and cell cycle deregulation. The survival is still poor, especially for patients resistant to frontline drugs. Although patients are brought in remission, relapses often occur with disseminated lymphoma, which is more difficult to treat.

**Aims:** To address the genetic heterogeneity in MCL in paired patient samples at diagnosis and relapse.

**Methods:** Highly pure malignant B-cell populations were isolated using fluorescence-activated cell sorting in four patients diagnosed with MCL. In addition, T-cells were sorted from the same patients as paired non-malignant control samples. Moreover, we performed on both the malignant B-cell population and paired T-cells (13 samples in total). Mutations were detected in parallel with CLC Biomedical Workbench 2.5 (Qiagen) and MuTect 1.04 (Broad Institute) (coverage ≥ 20, population allele frequency < 0.01) and evaluated against the COSMIC (Wellcome Trust Sanger Institute), dbSNP and PubMed databases. Exonction from informed consent was approved by the National Ethical Committee.

**Results:** Our data highlighted in each patient persistent gene modifications between diagnosis and relapse. We confirmed gene mutations already well-known in B-cell malignancies (e.g. TP53, NOTCH1 and MYD88). Interestingly, aberrations not previously described in the COSMIC database were observed with high allele frequency both at diagnosis and at relapse. This included genes in B-cell signaling (e.g. transcriptional repressor SPEN associated to NOTCH pathway regulation and blockade of the precursor B-cell differentiation), inflammatory response (e.g. JRG1), genes found in invasive carcinoma (e.g. integrin β4 subunit) and B PLAT monoclonal expression which were driven by somatic mutations or hit in putative drivers, new gene modifications as well as loss of previous ones could be observed at relapse. For example, genes involved in embryonic development and cell fate (e.g. the transcription factor SOX1) and genes involved in inflammation (COFL) were not previously correlated to MCL and were novel at relapse. This suggests that a modified malignant clone has evolved and progressed. No novel modification was observed to be shared by all four patients. However, aberrations in the same signaling pathways were identified across individuals. From allele frequency distribution detected with MuTect we could detect discrete clonal or competing subclonal involvement: A patient harbored one major discrete clone at diagnosis while at relapse two clones were identified, whereas in another patient present at diagnosis were identified a diffuse clonal pattern at diagnosis and a more discrete biclonal pattern at relapse.

**Summary/Conclusions:** Our work shows examples of molecular progression from diagnosis to relapse in MCL and supports the heterogenic nature and genetic complexity of this disease. We confirm mutations in genes already known as involved in the disease, and to identify new signaling pathways with genes which could be targeted by new treatments.
imential conditions we found that a number of the captured genes corresponded to experimentally validated targets of mirR-155. Crucially, oncotherapy analysis of the PAR-CLIP-captured genes demonstrated an enrichment of genes involved in haematopoietic and/or lymphomagenesis pathways.

**Summary/Conclusions:** To fully understand the role of a particular miRNA in a specific malignancy, it is essential to identify its target genes in a relevant cellular context. Using a haematopoietic malignancy model of high clinical interest we have developed an optimised method for interrogating the miRNA:mRNA interface (targetome) within a cellular system without the need of ectopically expressed tool genes. Moreover, our optimized protocol allowed us to reduce the number of input cells, therefore opening the exciting possibility of interrogating the targetome of patient primary samples.

**DARATUMUMAB, A NOVEL HUMAN CD38 MONOCLONAL ANTIBODY FOR THE TREATMENT OF B-CELL NON-HODGKIN LYMPHOMA**

A. Matas-Céspedes,1 A. Vidal-Crespo,1 V. Rodriguez1, C. Rossí,2 G. Roué1, A. López-Guillermo3, E. Giné3, A. Wiestner4, C. Bezosembés,5 E. Campob,6 D. Colomerc,6 S. Balasubramaniamc,6 C. Chiu6, P. Doshid,6 P. Pérez-Galán1

1Hematology-Oncology, IDIBAPS, Barcelona, Spain, 2Hematology-Oncology, Centre de Recherche en Cancérologie de Toulouse (CRC), Toulouse, France, 3Hematology-Oncology, National Institutes of Health, Bethesda, MD, United States, 4Pathology, Hospital Clinic, Barcelona, Spain, 5R&D, Janssen, Spring House, PA, United States

**Background:** Daratumumab (DARA) is a first-in-class human monoclonal antibody that targets the CD38 epitope and is approved for the treatment of relapsed/refractory (R/R) multiple myeloma (MM) patients. DARA is currently being evaluated in phase II clinical trials as monotherapy in patients with R/R Mantle Cell Lymphoma (MCL), Follicular Lymphoma (FL) and Diffuse Large B-Cell Lymphoma (DLBCL). DARA inhibits cell growth through high-affinity, neo-antibody-mediated mechanisms in MM, including Antibody-Dependent Cellular Cytotoxicity (ADCC), Complement-Dependent Cytotoxicity (CDC) (de Weers M. J Immunol, 2011) and Antibody-Dependent Cellular Phagocytosis (ADCP) (Ovredijk MB. Mabs, 2015). In Chronic Lymphocytic Leukemia (CLL), DARA induces killing mainly via ADCC and ADCP (Matas-Céspedes A. Clin Cancer Res, 2016). Furthermore, Immunomodulatory effects (Krijnck J. Blood, 2016) and modulation of the enzymatic activity of CD38 (Lamerts van Bueren J. Immunol, 2011) have been described to contribute to its antitumor activity.

**Aims:** To evaluate the activity of DARA on MCL and FL cells as monotherapy and in combination with current therapies, both in vitro and in vivo.

**Methods:** ADCC, CDC and ADCP activities were assessed by calcein release or flow cytometry. Penetration of DARA was analyzed in a 3D model by Selective Plane Illumination Microscopy (SPIM). Molecules per cell were analyzed using Qifikit and flow cytometry.

In vivo activity was assessed in prophylactic and therapeutic set ups using SCID mice subcutaneously (sc) or intravenously (iv) injected with 1x10^7 of MCL or FL cells. Mice were treated (human IgG control or DARA) with two different schedules: prophylactic (3 doses of 10mg/kg one dose per week) or therapeutic (20/10/10/10mg/kg, one dose per week). For the combination regimens in FL, sc injected SCID mice were treated following the therapeutic schedule in combination with Rituximab (20/10/10/10mg/kg, one dose per week) and/or CHOP (initial unique dose).

**Results:** DARA (0.0001-1µg/mL) induced ADCC in a dose-response manner on MCL (n=6) and FL (n=4) cell lines in the presence of PBMCs in vitro. Moreover, DARA induced significant levels of ADCP at 1µg/mL on MCL (n=6) and FL (n=4) cell lines in the presence of murine macrophages in vitro. However, DARA did not induce significant CDC in any of these models due to a high expression of the complement inhibitors CD46, CD55 and CD59, and insufficient number of CD38 molecules per cell. In a 3D model of FL, SPIM analysis revealed a maximum penetration of DARAA at 1µg/mL after 48h of treatment. We tested DARA activity in vivo in two different mouse models (sc and iv) of MCL and FL. In the prophylactic setting, DARA completely prevented the outgrowth and induced tumor regression of MCL (n=6) and FL (n=6) subcutaneous tumors. In the therapeutic setting, DARA significantly increased the survival of mice and reduced organ infiltration of tumor cells both in the MCL (n=10) and in the FL (n=10) systemic xenograft models. In addition, the combination of DARA with Rituximab/CHOP regimen in FL resulted in a synergistic reduction of tumor growth (n=7-10).

**Summary/Conclusions:** DARA shows encouraging cytotoxic activity in MCL and FL cells in culture as well as in vivo and in combination with current approved therapies. These results warrant further studies of DARA in the clinical setting for these conditions.

**E1370**

**ECTONUCLEOTIDASES CD39/CD73 ARE HIGHLY EXPRESSED ON ATLL CELLS AND RESPONSIBLE FOR GENERATING AMP/ADENOSINE**

Y. Nagate1, S. Ezoe1, J. Fujita1, M. Ichi1, J. Toda1, K. Oritani1, Y. Kanakura1

1Hematology and Oncology, Osaka University Graduate School of Medicine, Suita, Japan

**Background:** Adult T-cell leukemia/lymphoma (ATLL) is a mature T-cell neoplasm, linked to the human T-cell lymphotropic virus, HTLV-1. Patients with ATLL are often at the risk of opportunistic infections. It might be possible that this immunocompromised state could be induced by the function of ATLL cells having similar phenotypes with regulatory T cells (Tregs). However, difficulties of in vitro studies using primary tumor cells have hampered the progress of ATLL research, and it is still controversial whether ATLL tumor cells have the immunosuppressive characteristics.

**Aims:** In this study, we analyzed the roles of molecules expressed in ATLL cells associated with immunosuppressive functions of Tregs.

**Methods:** The protocol of this study was approved by the Investigational Review Board of Osaka University Hospital. Peripheral blood mononuclear cells (PBMCs) were collected from 8 asymptomatic HTLV-1 carriers and 20 ATLL patients (3 with smoldering type, 5 with chronic type, and 12 with acute type) after getting informed consent. PBMCs from 3 ATLL patients were separated into CD4+CD7-CADM1+ ATLL cells and adjacent CD4+CD7+CADM1- normal T cells using Fluorescence-activated Cell Sorter (FACS), and total RNA sequencing experiments were conducted. And we also examined the expression patterns of CD39 and CD73 in ATLL patients or carriers or each type of ATLL patients.

**Results:** We compared whole transcriptome of ATLL cells and normal CD4+ cells. Bioinformative analyses showed that many genes associated with immunosuppressive functions of Tregs were elevated or downregulated in ATLL cells. Among these genes we focused on CD39, CD73 and CD26, because recently it has been reported that extracellular adenosine, which is catalyzed by CD39, expressed in human Tregs, and CD73, expressed in murine but not in human Tregs, has strong anti-inflammatory function and plays major role in Treg-mediated immunosuppression. Therefore, we investigated the expression of CD39 and CD73 in ATLL cell lines and primary tumor cells. We found that all of 4 ATLL cell lines expressed CD39, but not CD73 as just human effector Tregs. In contrast, the expression patterns of CD39 in 20 ATLL patients were various (Table) and interestingly, some ATLL tumor cells express CD73. Also in asymptomatic carriers, we could detect CD39 and/or CD73 positive on CD7+CADM1- abnormal fraction of CD4+ cells. CD26, expressed in human naive but not in effector Tregs, was negative in all cell lines and primary cells except for abnormal cells in one smoldering patient. Next, the role of CD39 and/or CD73 in ATLL cells was assessed. Extracellular ATP is converted into AMP by CD39. As expected, CD39+ ATLL cells converted significantly more ATP than CD39- ATLL cells, which was comparable with normal effector Tregs. Conversely, mass spectrometry analysis of AMP/adenosine concentration indicated the activity of CD73 mediated AMP hydrolysis was very slow; less than 10% of 1mM AMP was converted to adenosine by CD73+ ATL cells, indicating that the aberrant expression of CD73 could not efficiently increase adenosine synthesis.

**Table 1.**

**Summary/Conclusions:** In this study, we showed that about two thirds of ATLL samples were CD39+/CD26+ just as effector Tregs and have comparable level of ATPase activity as Tregs, which are expected to play some immunosuppressive function in ATL patients. Recently it is also reported that in exhausted CD8+ T cells in cancer patients, CD39 is co-expressed with PD-1. CD39 expression in ATLL cells may also have some roles in immunosuppression and thus in the escape from anti-tumor immunity.

**ACTIVATION OF SYK TYROSINE KINASE INHIBITORS PLAYS A ROLE IN RESISTANCE AGAINST THE SELECTIVE BTK INHIBITOR ONO/GS-4059 IN DIFFUSE LARGE B CELL LYMPHOMA (DLBCL)**

K. Tsukamoto1,2, S. Miyake1, S.1,2, J. Sandrine1,2, M. J. Dyer1,2

1Cancer studies, 2Molecular and Cell Biology, 3The Ernest Waudby and Helen Scott Haematological Research Institute, University of Leicester, Leicester, United Kingdom

**Background:** Activation of syk tyrosine kinase is a potential therapeutic target in diffuse large B cell lymphoma (DLBCL). Syk is a tyrosine kinase that is activated downstream of B-cell receptor (BCR) through BTK. Syk activation contributes to malignant transformation and resistance to BTK inhibitors. Syk activation is also associated with chemoresistance and monoclonal antibody refractoriness.

**Objectives:** The aim of this study was to investigate the role of Syk in the resistance to BTK inhibitors in DLBCL cell lines and patient samples.

**Methods:** We performed dose-response analysis of BTK inhibitors (ONO/GS-4059 and ibrutinib) on DLBCL cell lines and patient samples. We also performed Western blotting and immunohistochemistry to detect Syk expression.

**Results:** Our results showed that Syk activation is associated with resistance to BTK inhibitors. Syk expression was significantly higher in resistant cell lines compared to sensitive cell lines. Syk inhibition potentiated the effects of BTK inhibitors, indicating that Syk is a potential therapeutic target in DLBCL.

**Conclusion:** Syk is a potential target for the treatment of DLBCL. Syk inhibition potentiates the effects of BTK inhibitors, suggesting that Syk inhibition could be used for the treatment of DLBCL.

**Acknowledgment:** This work was supported by the Japan Society for the Promotion of Science (JSPS) KAKENHI Grant Number 17H02348.
and proliferation of several B cell malignancies. BTK is a key regulator of this pathway. In a preliminary clinical study using the selective BTK inhibitor ONO-GS-4059 showed therapeutic activity in relapsed/refractory DLBCL of the Activated B-cell phenotype (ABC-DLBC) (Walter et al Blood 127 pp141-2016). However, median treatment duration in ABC-DLBC was only 3 months due to progressive disease and development of resistance. Two acquired resistant mutations to R665W have been described with resultant mechanisms to BTK inhibition in CL but resistance mechanisms in DLBCL have not been fully elucidated.

Aims: To determine resistance mechanisms in the ABC-DLBC TMD8 cell line and determine new rational combinations to take into the clinic with ONO-GS-4059. Methods: TMD8, an isogenic sensitive ABC-DLBC cell line TMD1 was cloned ONO-GS-4059 and bortezomib resistant TMD8 cell lines (TMD8RO and TMD8RI) were used for this study. TMD8RO has PCLy2 R665W while TMD8RI lacks both BTK C481S and PCLy2 R665W. Cell viability and apoptosis after compound treatment were assessed using Cell titer Glo assay and Annexin V / PI staining. Western Blot analysis was performed on both cell lines to determine expression of immunoreceptor were assessed by immunoblot and Flow cytometry. The mutational status of BTK and PCLy2 in TMD8 was determined by Sanger sequencing.

Results: ONO-GS-4059 induced apoptosis in TMD8 with nanomolar concentrations with apoptosis observed in >80% of cells. Although ONO-GS-4059 induced rapid reduction in ERK and AKT activation, induction of ERK and AKT rebounded within 24 hours in surviving cells. Interestingly, surface immunoglobulin M (sIgM) expression was increased more than three times in these cells leading to subsequent activation of SYK. The specific SYK inhibitor GS-9973 combined with ONO-GS-4059 inhibited the downstream ERK and AKT reactivation and induced synergistic apoptosis in TMD8. On the other hand, SYK hyper-activation as determined by phosphorylation of SYK and its downstream target BLNK was also observed in the two BTK inhibitor resistant cell lines. Additionally, expression of CDS and C22, which negatively regulate BCR signaling, was decreased in these cells. The combination of ONO-GS-4059 and GS-9973 restored sensitivity to ONO-GS-4059 and induced synergistic apoptosis in both resistance cell lines.

Summary/Conclusions: These data show that SYK is highly activated through increased sIgM expression and/or downregulated CDS and C22 following BTO treatment. The combination treatment of ONO-GS-4059 and SYK inhibitor may combine not only the development but also the maintenance of resistance to BTK inhibitor. The combination of ONO-GS-4059 with SYK inhibitor is therefore a rational strategy for preventing and overcoming BTK inhibitor resistances.

STRO-001, A NOVEL ANTI-CD74 ANTIBODY DRUG CONJUGATE (ADC) FOR TREATMENT OF B-CELL NON-HODGKIN’S LYMPHOMA (NHL)

A. Yu1, C. Abrahams1, M. Embry1, X. Li1, V. DeAlmeida1, J. Lee1, S. Matheny1, T. Kline1, A. Yam1, R. Stafford1, T. Hallam1, M. Lusher1, A. Molina1,*

1Sutro Biopharma, South San Francisco, United States

Background: CD74 is a type II transmembrane glycoprotein involved in the formation and transport of MHC class II protein. CD74 is rapidly internalized and highly expressed in many B-cell malignancies with limited expression in normal tissues (Stein R. et al., CCR 2007). STRO-001 is a novel CD74-targeting ADC (Biotinylated SP7219) conjugated to a non-cleavable dibenzocyclooctyne (DBCO)-maytansinoid linker-warhead. Highly efficient site-specific conjugation enabled by Sutro’s cell-free antibody production and click chemistry produced a well-defined homogeneous ADC with a potency

Aims: The aim of this study was to investigate the therapeutic potential of STRO-001 in non-Hodgkin’s lymphoma (NHL) cell lines and xenografts. A dose-escalating exploratory toxicity study was also conducted in cynomolgus monkeys.

Methods: Biotinylated SP7219 was used for immunochemistry (IHC). DBCO-Alexa647-conjugated SP7219 and flow cytometry were used for detection and quantification of CD74 expression on NHL cell lines and B-cells from normal human donors. STRO-001 was used to determine the EC50 and percent span of killing in NHL cell lines. The anti-tumor activity of STRO-001 in SCID mice xenografted with NHL xenografts was evaluated in a xenograft model and in mice bearing NHL tumor cell xenografts was examined. STRO-001 was administered to cynomolgus monkeys in an exploratory dose-escalating study of clinical pharmacology, Pitie-Salpetriere Hospital, Paris, France

Background: Leptomeningeal dissemination (LD) is a relatively rare but often fatal complication of lymphomas, confirmed by the analysis of the cerebrospinal fluid (CSF). The diagnosis is suspected in case of neurological symptoms, parenchymal brain involvement detected with neuroimaging techniques and increased sIgM concentration in the CSF. Cytological examination (CM) is still considered as the “gold standard” but remains insufficently sensitive.

Aims: The aim of our study was to assess the benefit of more sensitive techniques, i.e. immunophenotyping by flow cytometry (FCM) and clonality by PCR. The detection of malignant cells in CSF was performed by FCM and PCR in a slow growing disseminated NHL xenograft model. Vehicle-treated animals developed advanced disease with palpable tumors and distended abdomens, with median survival of 81.3 days. In contrast, Mino xenografts treated with STRO-001 at 3mg/kg or 10mg/kg exhibited improved survival, with most animals healthy and disease free at the time of sacrifice 135 days post inoculation. STRO-001 demonstrated B-cell depletion in cynomolgus monkeys, confirming the intended pharmacodynamic effect. Myelosuppression was observed at the highest dose but there was no evidence of off-target toxicity.

Table 1.
formed following the BIOMED-2 design and protocol. All PCR experiments were done in duplicates, and cases were considered PCR+ when both duplicates showed the same clonal pattern, ruling out false positivity (pseudoclonal pattern) often seen in paucicellular samples.

**Results:** We confirm that FCM and PCR are more sensitive than CM. Indeed, every CM+ cases (n=16) was also FCM+ and/or PCR+ while 13 cases were FCM+ and/or PCR+ but CM-. A total of 699 samples showed similar results by FCM and PCR with presence (n=22) or absence (n=247) of lymphomatous cells whereas 25 samples were classified as suspicious by at least one technique. Eleven samples were FCM+ but PCR-. False negative (FN) PCR results can be explained in part by extensive somatic mutation in IG genes, preventing optimal detection of the VDJ+ venetoclax sensitive cell lines, whereas the levels of BCL-2 targets less prone to somatic mutations, such as IGL, should therefore be evaluated. Conversely, 21 samples were PCR+ but FCM-. Absence of FCM detection might have resulted from the presence of very large lymphomatous cells outside the scope of analysis. Also, rapid cell death is an issue with FCM (preventing optimal detection of the venetoclax sensitive cell lines). This may not systematically require intact cells. Most of the difficulties encountered with both methods are due to occult blood contamination and poor cellularity, leading to low-intensity clonal signals by PCR and inconsistent cluster of events with FCM. In addition discordant results between FCM and PCR might be explained by sampling heterogeneity. Considering these limitations, it seems highly advisable to choose the best suited method for the follow-up according to the results at diagnosis.

**Summary/Conclusions:** Our results suggest that a multimodal investigation using FCM and PCR is necessary for improved detection of leptomeningeal dissemination in B-cell malignancies. It seems premature to make clinical decisions based on a single technology. Both methods, which suffer limitations that need to be acknowledged, are complementary and should be performed at diagnosis. Specific limitations of each of them should be taken in consideration for follow-up studies.

E1375

THE SYK INHIBITOR R406 DRAMATICALLY INCREASES THE SENSITIVITY OF GCB AND ABC DLBL CELL LINES TO THE B-2 INHIBITOR VENETOCLAX

B. Sasi1,2,*, S. Turkaj1, D. Efremov1

1Molecular Hematology, International Centre for Genetic Engineering & Biotechnology, Trieste, Italy

Background: The BCL-2 inhibitor venetoclax demonstrated significant single-agent activity in recent clinical trials of relapsed/refractory chronic lymphocytic leukemia (CLL). However, results in some other B-cell malignancies characterized by BCL-2 overexpression have not been equally impressive. This particularly refers to diffuse large B cell lymphoma (DLBCL), where only 18% of patients responded to treatment with venetoclax in a recent phase I clinical trial (Davids MS et al, J Clin Oncol. 2017).

Aims: Investigate whether the SYK inhibitor R406 can increase sensitivity of DLBCL to venetoclax in vitro and to venetoclax.

**Methods:** The following cell lines were used: Ly1, Ly7, Ly18, DHL4, Toledo and BJAB (all GCB DLBCL) and U2932, DHL2, Ly3, Ly10, HBL1 and TMD8 (all ABC DLBCL). The percentage of apoptotic cells was determined by Annexin V/FITC staining and propidium iodide (PI) staining and flow cytometry analysis. Expression of BCL-2 family members was determined by immunoblotting or Q-RPQ-PCR analysis.

**Results:** In a recent study, we showed that MCL-1 increases the resistance of anti-IGM stimulated CLL cells to venetoclax, and that SYK inhibitors can effectively overcome this resistance by blocking B cell receptor (BCR)-mediated MCL-1 upregulation (Bojarczuk K et al. Blood. 2016). Since constitutive activation of the BCR pathway has been described in both ABC and GCB DLBCL (Davies RE et al, Nature 2010; Chen L et al, Cancer Cell. 2013), we investigated whether treatment with the SYK inhibitor R406 can sensitize DLBCL cells to venetoclax. Single-agent venetoclax had only modest activity against most DLBCL cell lines at concentrations ranging up to 0.25 μM (Figure 1). Substantial apoptosis induction (≥20%) was observed in only 2 GCB (Ly1 and Ly18) and 2 ABC (U2932 and Ly10) cell lines. R406 as single agent had almost no effect on tumor cell viability, with only one cell line showing >20% apoptosis induction (HBL1). However, addition of R406 to venetoclax resulted in a dramatic increase in the percentage of apoptotic cells in six of the investigated cell lines (Ly18, DHL4, U2932, Ly10, HBL1 and TMD8). A synergistic effect was also observed with Ly1 using a lower concentration of venetoclax, whereas no effect or only an additive effect was observed in the remaining cell lines (Ly4, Ly7, Toledo, BJAB, DHL2 and Ly3). Among these, only Toledo expressed similar levels of BCL-2 to that observed in the venetoclax sensitive cell lines whereas the levels of BCL-2 in the other cell lines were extremely low or undetectable. To understand the mechanisms how R406 increases the sensitivity of DLBCL cells to venetoclax, we evaluated changes in the expression of MCL-1 and other antiapoptotic BCL-2 family proteins that have been associated with venetoclax resistance. Five of the seven R406 + venetoclax sensitive cell lines (Ly1, DHL4, U2932, HBL1 and TMD8) showed a 20-45% reduction in MCL-1 levels following 24 hours culture with 2μM R406, whereas no changes were observed in Ly18 and Ly10. However, a substantial reduction in A1 levels was observed in Ly18 and U2932 cells, whereas no substantial changes in A1 and BCL-2/L cl expression were detected in any of the other investigated cell lines. Finally, we also investigated the effects of R406 on expression of HRK, which is a proapoptotic BCL-2 family member that was recently shown to be induced by SYK inhibition in a subset of GCB DLBCLs (Chen L et al, Cancer Cell. 2013). A substantial increase in HRK expression (140-640%) was observed in 5 of the 7 R406 + venetoclax sensitive cell lines (Ly1, Ly18, DHL4, U2932 and TMD8).

Figure 1.

**Summary/Conclusions:** These data show that the SYK inhibitor R406 can significantly increase the sensitivity to venetoclax in the vast majority of BCL-2 positive DLBCL cell lines. The mechanisms of action require further investigation, but are likely to involve downregulation of MCL-1 and upregulation of HRK in a substantial proportion of cases.

E1376

VB EXPRESSION ASSESSMENT AND CLONALITY DETECTION IN T-CELL PROLYMPHOCYTIC LEUKEMIA (T-PLL) BY FLOW CYTOMETRY (FCM) AND NEXT GENERATION SEQUENCING (NGS): A COMPARISON OF BOTH METHODS

M. Kotrová1,2,*, M. Nováková 1,2, S. Oberbeck 3, P. Mayer3, A. Schrader3, H. Knechtle2, M. Herling3, Brüggemann2

1contributed equally, 2Medical Department ii, Unit for Hematological Diagnostics, University Hospital Schleswig-Holstein, Kiel, 3Dept. of Medicine I, Cologne University, Cologne, Germany

Background: VB repertoire analysis can distinguish monoclonal from polyclonal (reactive) T-cell proliferations. The molecular quantification of clonal T-cell receptor (TR) gene rearrangements can also be used to record minimal residual disease (MRD) in T-cell malignancies. TR clonality can either be assessed by FCM employing VB antibody panels covering ~70% of the normal human TR VB repertoire or by molecular techniques like NGS with primers that amplify virtually all possible VB-JB rearrangements. T-PLL is the most common (post-thymic) T-cell leukemia. Clonal TR gene rearrangements are detected in virtually all T-PLL by FCM or PCR from peripheral blood (PB) or bone marrow samples.

Aims: To compare the results of parallel TRB-based clonality analyses by FCM and NGS in T-PLL.

**Methods:** We investigated diagnostic PB leukocytes of 73 T-PLL patients with median lymphocytes at 66% (range 13-93; harboring T-cells at 97% (55-100)). FCM of surface (not intracellular) VB expression was assessed by the IOTest Beta Mark kit (Beckman Coulter). Libraries for NGS were prepared using 100ng of DNA via a 2-step PCR and sequenced on the Illumina MiSeq (2x300bp + v2) with a median coverage of 17,908 reads (range 1,125–41,193)/sample. In the first PCR TRB rearrangements were amplified using TRB BIOMED-2V- and J-region primers (van Dongen et al, Leukemia 2003). In the second PCR step, sequencing adaptors and sample-specific barcodes were added. Annotation of V, (D)- and J-regions of TRB sequences was done using ARResT/Interrogate (Bystry et al, Bioinformatics 2016).

**Results:** In all samples one or two dominant clonal TRB rearrangements were detected by NGS and represented in median by 83% of reads (range 15-95%). FCM of surface (not intracellular) VB expression was assessed by the IOTest Beta Mark kit (Beckman Coulter). Libraries for NGS were prepared using 100ng of DNA via a 2-step PCR and sequenced on the Illumina MiSeq (2x300bp + v2) with a median coverage of 17,908 reads (range 1,125–41,193)/sample. In the first PCR TRB rearrangements were amplified using TRB BIOMED-2 V- and J-region primers (van Dongen et al, Leukemia 2003). In the second PCR step, sequencing adaptors and sample-specific barcodes were added. Annotation of V, (D)- and J-regions of TRB sequences was done using ARResT/Interrogate (Bystry et al, Bioinformatics 2016).

**Results:** In all samples one or two dominant clonal TRB rearrangements were detected by NGS and represented in median by 83% of reads (range 15-95%). In 36/73 (49%) of these cases, also FCM demonstrated clonality. Interestingly, in 8/36 (22%) of cases the dominant VB by FCM differed from the molecular clonotype. In 5 of these cases the discrepancy was most likely accountable to a non-functional TRB clonotype detected by NGS corresponding to a bi-allelic TRB rearrangement with the second non-functional allele being preferentially identified by NGS. In 37/73 (51%) of cases no reaction with one of the VB antibodies was seen. In 16 (43%) of these cases this could be attributed to expression of a TRB rearrangement for which the appropriate VB antibody was not present in the FCM panel. In another 12 (33%) of these cases a non-productive TRB rearrangement represented the dominant NGS clonotype. However, in further 9 cases (24%), the functional TRB clonotype (TRBV 5-6, 6-5, 25-1, 18, 20-1, 27) was not detected by FCM despite theoretical coverage. Of note, overall 10/73 T-PLL (14%) lacked surface TRαβ chain expression.

**Summary/Conclusions:** T-cell clonality is detected by TRB NGS in all T-PLL, whereas FCM-based VB repertoire analysis identifies a dominant single VB
domain expression in only 49%. A substantial proportion of such failures of FC- or IFN-β-based clonality detection can best be explained by lost surface TR expression and the limited coverage of the VB antibody panel. NGS-based clonality analysis can overcome these limitations, because it detects virtually all TRV VB-JB rearrangements. On the contrary, NGS is more sensitive and therefore enables the detection of minor subclones, which has great appeal for MRD assessment. Nevertheless, flow cytometric VBJ spectratyping is a faster, cheaper, and less laborious alternative. It has the additional advantage of detecting the actual TR VB chain expression and of visualizing individual T-cell subsets for quantification of VB-cell populations.

E1377
IRF4 EXPRESSION IS ASSOCIATED WITH RESPONSE OF MANTLE CELL LYMPHOMA TO BRUTON’S TYROSINE KINASE INHIBITORS
H. P. Thompson1, D. L. Tucker2, S. A. Rule1, C. V. Hutchinson1,2
1Institute of Translational and Stratified Medicine, Plymouth University, Peninsula Schools of Medicine and Dentistry, 2Clinical Haematology, Plymouth Hospitals NHS Trust, Derriford Hospital, Plymouth, United Kingdom

Background: Mantle cell lymphoma (MCL) responds poorly to conventional chemotherapy. Inhibitors of Bruton’s tyrosine kinase (BTKi) have unexpectedly shown significant clinical effect; however despite this success, approximately one third of MCL patients have primary resistance to the drug, and patients who initially respond to treatment frequently acquire secondary resistance and aggressive relapse of the disease. Understanding how BTKi-resistance or sensitivity is mediated can identify new targets for therapy or predictive biomarkers of response. Using an in vitro model system we have identified the transcription factor IRF4 as a sensitive indicator for BTKi response in MCL cell lines and primary cells.

Aims: To identify molecules or pathways responsible for resistance to BTKi-inhibitor drugs in mantle cell lymphoma using cell line models and primary cells.

Methods: Primary cells and validated MCL cell lines (REC-1, G519, JEKO-1, JVM2) were cultured either alone, or together with murine stromal cells (with or without CD40L transfection). The BTKi sensitive REC-1 cell line was continuously treated with BTKi to generate an acquired resistance model. Cultures were treated with BTKi drugs: ibrutinib or acalabrutinib in the presence or absence of B-cell receptor or CD40L stimulation, and their sensitivity or resistance to treatment was determined using flow cytometry to assess proliferation (Ki67), apoptosis (Annexin-V), or phosphorylation of BTK (pY223). Changes affecting downstream proteins were determined by protein expression or phosphorylation analysis (immunoblotting) and by mRNA expression (RT PCR). Following initial experiments the studies focussed on IRF4.

Results: Each MCL cell line showed basal phosphorylation of BTK (Y223) and its downstream effector molecule ERK1/2 (Y204/187); in each case phosphorylation was prevented by BTKi. Of the cell lines tested however, only REC-1 cells showed growth inhibition by BTKi (ibrutinib and acalabrutinib), demonstrating both dose-dependent apoptosis (p<0.01) and inhibition of proliferation. Further investigation showed that only the BTKi-sensitive REC-1 cell line downregulated IRF4 in response to BTKi; this downregulation was an early and specific response (mRNA downregulated after 4 hours, and protein expression after 8 hours). Furthermore in REC-1 cells with acquired partial resistance to BTKi, the downregulation of IRF4 was significantly less than in the parental cell line. Finally in vitro co-culture of REC-1 cells with CD40L prevented IRF4 downregulation thereby counteracting the effect of BTKi induced apoptosis. Experiments with primary MCL cells reinforced these findings: in vitro CD40L induced proliferation, survival, prevented BTKi-induced IRF4 downregulation and protected the cells from BTKi-induced death. These findings were confirmed using ex vivo samples from treated patients (n=7) analysed before and during BTKi treatment. IRF4 was downregulated in 6 samples from patients shown to be clinically responding to BTKi and was not downregulated in 1 refractory case.

Summary/Conclusions: IRF4 was downregulated in 6 samples from patients shown to be clinically responding to BTKi and was not downregulated in 1 refractory case. Treatment with BTKi might be a biomarker for BTKi-sensitivity in MCL, and that downregulation and protected the cells from BTKi-induced apoptosis. Experiments with primary MCL cells reinforced these findings: in vitro CD40L induced proliferation, survival, prevented BTKi-induced IRF4 downregulation and protected the cells from BTKi-induced death. These findings were confirmed using ex vivo samples from treated patients (n=7) analysed before and during BTKi treatment. IRF4 was downregulated in 6 samples from patients shown to be clinically responding to BTKi and was not downregulated in 1 refractory case.

Figure 1.

Summary/Conclusions: This study reveals a novel pathway during myc-driven lymphomagenesis. We show that MYC deregulation imposes selective pressure in favor of clones with decreased expression of TPL2 kinase. This process seems to be advantageous for the malignant clone, since genetic ablation of TPL2 in the Eμ-myc mouse model accelerates MYC-induced lymphomagenesis likely by contributing to apoptosis resistance.

LIQUID BIOPSY: DECIPHERING A SIGNATURE OF CIRCULATING MICRONAS AS NOVEL NON-INVASIVE BIOMARKERS IN DIFFUSE LARGE B-CELL LYMPHOMA
F. Marchesi1,2, G. Regazzò1,2, A. Sacco1,2, M. Spagnuolo2, S. Donzelli2, F. Palombi1, M. Marino4, C. Ercolani4, A. Di Benedetto4, G. Bilandino4, A. Mengarelli1, M. G. Rizzo4
1Department of Hematology and Stem Cell Transplant, 2Epigenetic and Oncogenomic Unit, Translational Research Area, 3Regina Elena National Cancer Institute, Rome, Italy, 4Pathology Unit, Regina Elena National Cancer Institute, Rome, Italy

Background: Up to 40% of Diffuse Large B-Cell Lymphoma (DLBCL) patients still experience treatment failure or disease relapse after conventional chemotherapy. Therefore, the search of novel non invasive biomarkers able to early identify these patients is warrant in order to offer a different therapeutic approach. Recently, bodily fluids have emerged as an important source of infor-

566 | haematologica | 2017; 102(s2)
mation in several diseases analyzable by liquid biopsies, representing minimally invasive methods for precision diagnostics and prognosis. Blood extracellular microRNAs (miRNAs) are under investigation as novel biomarkers. While tissue miRNAs in DLBCL patients have been extensively studied, only few reports, and limited to a small subset of miRNAs, evaluated the role of circulating/serum miRNA as potential prognostic factors.

Aims: To identify and validate a serum miRNA signature with prognostic value in a cohort of newly diagnosed DLBCL patients.

Methods: This is a on-going prospective non interventionist study on a cohort of newly diagnosed de novo DLBCL patients uniformly treated with six courses of R-CHOP (Rituximab, Cyclophosphamide, Vincristine, Doxorubicin and Prednisone). Serum samples of patients were collected at diagnosis and after the end of treatment. Treatment response was evaluated by standard Cheson criteria. The expression profile of selected circulating miRNAs described as associated with lymphoid malignancies by us (let-7c/miR-99a/miR-125b cluster) and by previously published studies (miR-22, miR-18a and miR-20a) was evaluated by means of a quantitative competitive RT-PCR. Pt enrolled in our study were treated with R-CHOP and sampled at diagnosis of the first 18 patients enrolled into the study.

Results: Our results showed that the expression level of serum miR-22 as well as let-7c/miR-99a/miR-125b cluster was significantly higher at diagnosis, in patients unresponsive to R-CHOP treatment when compared with responsive patients. On the contrary, miR-18 and miR-20 levels appeared to be not significantly associated to treatment response. In addition, a global expression profile of circulating miRNAs was evaluated in serum samples derived from a smaller cohort of patients (n=4) after first-line chemo-immunotherapy. Interestingly, we found a striking difference in miRNA modulation upon treatment between unresponsive and responsive patients. In particular, we found 31 miRNAs significantly modulated after R-CHOP in the group of responsive patients, including miR-22. In contrast, this miRNA subset did not show remarkable expression changes in unresponsive patients. Moreover, we performed a study interrogating The Cancer Genome Atlas (TCGA) database about miRNA expression levels in samples of DLBCL patients. We found that the only available data are relative to the miRNA expression levels in tumor tissue samples of 47 out of 58 DLBCL patients. Kaplan Meier method and log-rank test revealed a signature of 13 miRNAs with potential prognostic value. Among these we found that miR-22, also emerged as modulated in our genome-wide analysis, was linked to risk of disease recurrence.

Summary/Conclusions: These preliminary data suggest that the serum miR-22 as well as miR-99a/miR-125b cluster are of potential interest as non–invasive biomarkers to predict therapeutic response in DLBCL patients. Ongoing experiments in a wider cohort of patients are aimed to confirm these results and unveil potential miRNA signature with predictive value.

E1380

INTRACELLULAR CALCIUM AND METABOLISM HAVE CRITICAL ROLES IN DETERMINING ANTI-CD20 ANTIBODY EFFICACY IN DLBCL

E. Vilventhraraja1,*, J. Gribben1, A. Braun1

1Centre for Haematolo-Oncology, Barts Cancer Institute, London, United Kingdom

Background: Since the discovery and utilisation of the Type-I anti-CD20 antibody Rituximab, many have tried to enhance the efficacy of anti-CD20 antibodies in order to improve first-line treatment of B cell malignancies, leading to the discovery of anti-CD20 antibodies with different intrinsic properties. Understanding the biological role of CD20 and the mechanism of anti-CD20 antibody action remains unclear. However, CD20 has been shown to be involved in the store operated calcium (Ca2+) system. This complex has the ability to facilitate mitochondrial function in several diseases analyzable by liquid biopsies, representing minimally invasive methods for precision diagnostics and prognosis. Blood extracellular microRNAs (miRNAs) are under investigation as novel biomarkers. While tissue miRNAs in DLBCL patients have been extensively studied, only few reports, and limited to a small subset of miRNAs, evaluated the role of circulating/serum miRNA as potential prognostic factors.

Aims: i) Assess and compare intracellular calcium concentration following treatment with anti-CD20 antibodies ii) Evaluate mitochondrial function of cells following treatment with anti-CD20 antibodies iii) Assess whether cytotoxicity of Type-I and Type-II anti-CD20 mAbs can be enhanced by exploiting cellular metabolism

Methods: We established a panel of four DLBCL cell lines (Karposi222, Pfeffer, OCI-LY7 and HUDHL4). Following a 24-hour treatment with one of four anti-CD20 antibodies (Rituximab) and three Type-II anti-CD20 antibodies (BHH2, Obinutuzumab and Tositumomab), intracellular calcium concentration was quantified and visualised using imaging flow cytometry. Next, we used the XF Seahorse Mito Stress Test to reveal bioenergetic profiles of the cell lines following a 24-hour treatment with the same antibodies. We used Metformin (a mitochondrial inhibitor) and oxypHos (an activator of mitochondrial function). Metformin was also used to reduce the mitochondrial membrane potential (MOMP) across our panel of cell lines. We confirmed MOMP reduction by staining cells with JC-1, a chameleon dye used as an indicator of MOMP and analysed samples using flow cytometry. Under the same conditions, we conducted clonogenic survival assays to see whether cytotoxicity of anti-CD20 antibodies could be enhanced by manipulating metabolism.

Results: Intracellular calcium concentration was decreased across our panel of cell lines following a 24-hour treatment with all Type-II anti-CD20 antibodies in our panel. This decrease was not observed following treatment with the Type-I anti-CD20 antibody Rituximab. Treatment with anti-CD20 antibodies resulted in a significant increase in the maximal respiratory capacity of our panel of cell lines; cells were able to produce more ATP in response to oxidative stress. Conversely, we observed a reduction in the respiratory capacity of cells following treatment with the Type-II anti-CD20 antibodies. Next, we show anti-CD20 antibody treatment causes cells to increase maximal mitochondrial respiratory capacity to compensate for reduced basal mitochondrial function. We show that inhibition of OxPhos disables the cells from being able to increase mitochondrial respiratory capacity observed with anti-CD20 antibody treatment alone. When analysing the clonogenic survival of cell lines, we have found that only the cytotoxicity of Type-II anti-CD20 antibodies is enhanced by simultaneously treating cell lines with Metformin.

Summary/Conclusions: Our data show for the first time that when cells are treated with Type-II anti-CD20 antibodies, intracellular calcium is decreased. Intracellular calcium remains unchanged following treatment with Rituximab. Next, we show anti-CD20 antibody treatment causes cells to increase maximal mitochondrial respiratory capacity to compensate for reduced basal mitochondrial function. We show that inhibition of OxPhos disables the cells from being able to increase mitochondrial respiratory capacity observed with anti-CD20 antibody treatment alone. When analysing the clonogenic survival of cell lines, we have found that only the cytotoxicity of Type-II anti-CD20 antibodies is enhanced by simultaneously treating cell lines with Metformin.

CYCLIN D1 ONCOGENIC OVEREXPRESSION LEADS TO A GLOBAL TRANSCRIPTIONAL DOWNREGULATION IN MALIGNANT LYMPHOID CELLS

R. Albero1,*, A. Enjuanes2, S. Demajo1, M. Pinyol2, N. Garcia1, C. Capdevila1, H. Suarez-Cisneros2, K. Karube4, S. Bea1, I. Martin-Subero1, E. Campo1, P. Jares3

1IDIBAPS, Barcelona, Spain, 2Genomics Unit, IDIBAPS, 3Molecular Biology Core, Hospital Clinic, Barcelona, Spain, 4University of the Ryukyus, Okinawa, Japan, 5Hospital Clinic, Barcelona, Spain

Background: Cyclin D1 is an oncogene frequently overexpressed in human cancers. In hematologic neoplasms, mantle cell lymphoma and multiple myeloma are clear examples of deregulated cyclin D1 expression. It plays a dual function as cell cycle and transcriptional regulator, although the latter is widely unexplored.

Aims: In this study, we investigate the transcriptional role of cyclin D1 in lymphoma and mantle cell lymphoma (MCL). In particular, we compared cyclin D1 oncogenic overexpression in B cells as a model of the first steps in MCL oncogenesis.

Methods: Chromatin immunoprecipitation (ChiP) followed sequencing was performed in four established MCL cell lines. RNA-Sequencing (RNA-Seq) and information from histone ChiP-Seq were correlated with genomic intervals displaying cyclin D1 binding. Transcriptional downregulation was studied through cytomtric RNA total quantification in lymphoblastic cyclin D1-overexpressing models and RNA Pol II ChiP-Seq.

Results: Endogenous cyclin D1 showed widespread binding to active promoters. Cyclin D1 overexpression was responsible for a global transcriptional down-regulation. Cyclin D1, instead of showing specific gene activation, seems to globally decrease cell transcription. Mantle cell lymphoma and multiple myeloma cell lines displayed an inverse relation with cyclin D1 quantity. This transcriptional effect was associated with an increased RNA polymerase II pausing in promoters due to cyclin D1 overexpression.

Summary/Conclusions: This mechanism expands the oncogenic cyclin D1 functions and places the transcriptional machinery as a potential therapeutic target in cyclin D1 overexpressing tumors.

MICROENVIRONMENTAL EXPRESSION OF IMMUNOREGULATORY MOLECULES AND CYTOKINES CLASSICAL IMMUNE-MEDIANATED MCL PROGNOSIS

O. Novosad1,*, N. Svergun2, O. Skachkova2, O. Gorbach2, N. Khranovska2, I. Kryachok1

1Oncohematology, 2Experimental Oncology, National Cancer Institute, Kiev, Ukraine

Background: Over the past decade, new biologic insights have revealed a key role of tumor microenvironment in the pathogenesis of classical Hodgkin’s lymphoma (cHL). cHL infiltrating cells produce cytokines and growth factors that provide essential stimulatory signals for survival and proliferation of Hodgkin’s and Reed–Stemberg cells. Moreover, clinical behavior of cHL may be directly regulated by the cross-talk between tumor cells and infiltrating immune cells.
Aims: The aim of our study was to estimate the role of microenvironment expression of immunoregulatory molecules (PD-1 ligands, IDO) and cytokines (TGF-β, IL-13) in clinical outcome of cHL.

Methods: 74 patients (median age: 44, range: 17-71 years; males: 22, females: 52) were included in the study. 55.4% of patients were diagnosed with an early stages of HL, while 44.6% - with advanced stages. ABVD or BEACOPP (14/15) were administered as a 1st-line therapy. 78.3% of patients achieved remission (CR/PR), while 8.1% had progression of disease during the therapy. We recorded 14.8% relapses in patients after the 1st line therapy during the follow-up period (median duration – 36 months; range 6-66 months). PD-L1, PD-L2, IDO, TGF-β, IL-13 mRNA expression levels were analyzed in fresh pre-treatment lymph nodes biopsies using qRT-PCR.

Results: Expression of PD-L1 ligands was heterogeneous across the samples and did not depend on histological variant or stage of cHL. Only 12.1% of patients (9/74) were PD-L1 negative and all but one of those cases had a CR and a long-term remission. Patients with PD-L1 overexpression tended to have a higher risk of relapse, comparing to low positive PD-L1 expression (p=0.1). We did not find any significant association between PD-L2 expression level and clinical outcome of cHL. Expression levels of IDO, TGF-β, IL-13 were evaluated in 38 cHL samples. 18.4% (7/38) patient were IDO positive and 81.6% (31/38) - IDO negative. The presence of IDO expression was associated with a higher risk of relapse in cHL patients (p=0.006). 85.7% (6/7) and 23.3% (7/30) of relapses were observed during the follow-up period in IDO+ and IDO-patients, respectively (p<0.05). The patients with double negative expression of PD-L1 and IDO were noted to have a favourable outcome of cHL. A 5-year event-free survival (EFS) rate was 80% for double negative PD-L1+/IDO-patients vs 20% for double positive PD-L1+/IDO+ patients (p=0.008). IL-13 was expressed at various levels depending on the stage of cHL with the highest expression levels in advanced stages. A trend for a higher risk of relapse was observed for HL patients with increasing level of IL-13; (p=0.23). TGF-β expression was analyzed with histological variants of relapsing HL, however multivariate analysis showed that TGFβ expression is a significant increase EFS in cHL patients with HRs of 6.7 [95% (CI) 1.3-2.1, p=0.04].

Summary/Conclusions: Our results suggest that tumor microenvironment plays an important role in clinical behavior of cHL. Hence, better understanding of molecular mechanisms of interaction between tumor and immune cells probably can provide us with a novel promising strategy for relapsed/refractory cHL treatment.

AN IN VIVO TRACEABLE AND MULTIPLYING CRISPR/CAS9 GENOME EDITING SYSTEM
L. Cheng1,*, T. Niu1, Y. Liu2
1Department of Hematology and Research Laboratory of Hematology, 2State Key Laboratory of Biotherapy and Cancer Center, West China Hospital Sichuan University, Chengdu, China

Background: Gene gain of function and loss of function mutations, oncogene overexpression, gene amplification, chromosome deletion and epigenetic changes, may lead to lymphoma onset. The CRISPR-Cas9 genome editing system has become a feasible tool for exploring the functions of specific genes in different contexts. We want to use this technique to screen for lymphoma suppressor genes.

Aims: Construct an in vivo traceable and multiplying CRISPR-Cas9 gene editing system, which is high efficient for studying in vivo functions of both individual genes or any given chromosome fragment.

Methods: Two retroviral vectors were constructed via molecular clone, one of which contains a locus for tandem U6-sgRNAs and inducible GFP reporter gene and the other contains Cas9 and MS4A1 coding gene. This system’s function of traceable and simultaneously mutate multiple gene efficiencies were validated in vitro. Eμ-myc HSPCs retrovirally transduced with sgp53 and Cas9 were transplanted into sublethally irradiated C57/BL6 mouse.

Results: Co-transduced cells can be tracked by the expression of GFP protein and multiple sgRNA can be efficiently introduced to the GFP-labeled cells for simultaneously mutating multiple genes or deleting a large chromosome fragment. Further we applied this system for both in vitro and in vivo genome editing. As an example, we show that Tp53 mutation accelerated Eμ-Myc driven lymphoma onset in vivo.

Summary/Conclusions: This traceable and multiplying CRISPR/Cas9 system might be useful for various genome editing applications.

HDAC6 INHIBITION SENSITIZES TUMOR CELLS TO ANTI-CD20 IMMUNOTHERAPY IN VIVO
M. Bobrovicz1,*, M. Dwojak1, J. Stachura1, M. Angelika1, P. Beata1, S. Marta1, N. Miazek1, P. Zapala1, J. Golab1, M. Winiarska1
1Department of Immunology, Medical University of Warsaw, Warsaw, Poland

Background: Down-regulation of CD20, a molecular target for monoclonal antibodies, constitutes a clinically significant issue leading to decreased efficacy of anti-CD20-based therapeutic regimens. The epigenetic modulation of CD20 coding gene (MS4A1) has been proposed as a mechanism for the reduced therapeutic efficacy of anti-CD20 antibodies and confirmed previously with clinically available non-specific histone deacetylase pan-inhibitors (HDACis). However, the identification of particular HDAC isoforms involved in CD20 regulation seems to be of paramount importance. Since the use of pan-HDACi is associated with substantial side effects, especially difficult to manage in elderly and frail patients, the new specific HDAC6 inhibitors are currently being tested in multiple myeloma and non-Hodgkin lymphoma. They have already been shown to sensitize tumor cells to proteasome inhibitors and novel kinase inhibitors e.g. Ibrutinib and demonstrated promising results in in vitro studies in chronic lymphocytic leukemia (CLL).

Aims: HDAC6 has been known for its regulatory role in protein degradation. We have previously reported that inhibition of proteasome activity can effectively increase CD20 levels in tumor cells. In our study we tested the hypothesis that selective HDAC6 inhibition sensitizes tumor cells to immunotherapy with anti-CD20 mAbs. The aim of the study was to test the hypothesis that selective HDAC6 inhibition sensitizes tumor cells to immunotherapy with anti-CD20 mAbs.

Methods: We assessed the influence of HDAC6 inhibition in a panel of different subtypes of human lymphoma cell lines (Burkitt, DLBCL: both EBV+ and EBV- cells) on CD20 expression using flow cytometry and Western blotting. We confirmed our observations in primary samples from the patients with CLL, known to express low CD20 levels. Moreover, we performed cytotoxic assays using flow cytometry in order to assess complement-dependent cytotoxicity (CDC) as well as apoptosis. We used HDAC6-specific chemical inhibitors (tubacin, trichostatin A and clinically tested nicotinostat) as well as HDAC6 shRNA assay. We also performed animal studies using SCID mice injected with Burkitt CD20+ lymphoma cell line s.c. and treated with rituximab i.p. We used both the pharmacological (i.p. administration of nicotinostat) and genetic (cells stably transduced with HDAC6 shRNA) approach.

Results: The results of our studies demonstrate that HDAC6 inhibition significantly increases CD20 level and sensitizes tumor cells to rituximab- and ofatumumab-induced CDC, as well as direct cytotoxicity of obinutuzumab. In vivo settings HDAC6 inhibition potentiated the efficacy of rituximab by significantly reducing tumor size and prolonging the survival of the mice.

Summary/Conclusions: Our results clearly indicate that HDAC6 inhibition sensitizes tumor B-cells to anti-CD20 immunotherapy. Therefore, we propose HDAC6 inhibition with specific inhibitors as an effective strategy to be associated with the therapy with anti-CD20 mAbs. This strategy seems to be highly promising in CLL patients, often expressing very low CD20 level and do not fully benefiting from immunotherapy.

Background: NKG2D ligands, such as NKL3 and Nkp46, have been identified as markers of normal cytotoxic T lymphocytes with NKG2D receptors. While NKL3 expression is generally low, Nkp46 expression is elevated in a variety of malignancies. There are only a few studies investigating NKp46 expression in gastrointestinal T-cell lymphoproliferations (GTCLs), including lymphomatoid papulosis (LP) and enteropathy-associated T-cell lymphoma (EATL).

Aims: To investigate the expression of Nkp46 in different subtypes of gastrointestinal T-cell lymphoproliferations (GTCLs), including lymphomatoid papulosis (LP) and enteropathy-associated T-cell lymphoma (EATL).

Methods: We performed immunohistochemical analysis of Nkp46 expression in a cohort of 102 patients with gastrointestinal T-cell lymphoproliferations (GTCLs), including lymphomatoid papulosis (LP) and enteropathy-associated T-cell lymphoma (EATL).

Results: Nkp46 expression was detected in 20% of patients with LP and 30% of patients with EATL. The expression of Nkp46 was significantly higher in patients with EATL compared to patients with LP. The expression of Nkp46 was also significantly higher in patients with EATL than in patients with other subtypes of gastrointestinal T-cell lymphoproliferations (GTCLs).

Summary/Conclusions: Our results suggest that Nkp46 expression is a diagnostic and prognostic biomarker in primary gastrointestinal T-cell lymphoproliferations. The expression of Nkp46 is significantly higher in patients with EATL compared to patients with LP and other subtypes of gastrointestinal T-cell lymphoproliferations (GTCLs).
INDUCTION OF APOPTOSIS

Background: Primary gastrointestinal (GI) T-cell lymphoproliferations (T-CL) are heterogeneous entities, which diagnoses are difficult to perform. T-CL include aggressive lymphoma such as enteropathy-associated T-cell lymphoma (EATL) as well as indolent monoclonal lymphoproliferations. Refractory coeliac disease type II (RCDII) is one of the indolent clonal T-GL that complicates coeliac disease (CD) and may evolve toward an overt EATL. The differential diagnosis of RCDII from CD and RCDI is difficult and essentially based on negative expression of sCD3 and CD8 and the presence of a clonal TCR rearrangement. Lymphocytes from RCDII are dependent for survival on IL-15, which reprograms T lymphocytes towards a cytotoxic NK phenotype.

Aims: We thus studied the expression of NKp46 on a representative panel of GI T-CL to assess its diagnosis and prognosis value.

Methods: Using formalin-fixed paraffin-embedded tissue biopsies, we assessed NKp46 expression by immunohistochemistry (IHC) and investigated its clinical and biologic significance on 177 intestinal, 11 lymph node and 5 other biopsies from 84 CD or RCD patients (RCDI, n=20; RCDII, n=40), 44 GI T-cell lymphoma patients (EATL, n=25; monomorphic epitheliotropic intestinal T-cell lymphoma_MUTL, n=4; indolent T-LPD, n=15), 11 healthy patients and 5 patients with a GI inflammatory environment as controls.

Results: By doing ROC analysis on number of cells expressing NKp46 on GI-TCL we identify that 25 intra-epithelial lymphocyte (IEL) per 100 epithelial cells (EC) clearly separates RCDII from CD and RCDI patients, with a good positive and negative predictive values (100 and 95% respectively). In healthy controls, CD, or RCDI patients, NKp46 was only expressed on scattered IEL (median 3%, 0-15). Based on NKp46 expression the overall survival is poor if over 25% of IEL are positive for NKp46 (OS-5years 96.4% vs 72.8%, P=0.0004) (Figure 1A). Among patients with GI T-cell lymphoma, we show that NKp46 was expressed in most of aggressive lymphoma (EATL 80%, n=20/25 and MEITL 100%, n=4/4). On the other hand, NKp46 was not expressed on indolent T-LPD (n=0/15). The NKp46 expression was also associated with a poor prognosis in GI T-cell lymphoma patients (OS-5years 50.5% vs 5.4%, P=0.0011) (Figure 1B).

Summary/Conclusions: The NKp46 expression in more than 25 IEL per 100 EC by IHC analysis can easily identify RCDII from CD and RCDI. Furthermore, the NKp46 expression is associated with aggressive forms of GI T-cell lymphoma. Finally, the NKp46 expression was strongly associated with shortened survival. Thus NKp46 provides a new biomarker for both diagnosis and prognosis in GI T-CL.
hours and produced 8.7 ~ 9.3 X 10^3 ng/ml of IgM). PCs isolated from BCWM.1 increased to 130% and produced 2.5 ~ 2.8 X 10^4 ng/ml of IgM. LPLs from both cells as well as in SNK-6 cells. When comparing with those transfected with IL-2Rα-harboring lentiviral vectors, and the smaller amounts of IgM than PCs (3.5 ~ 5.0 X 10^3 ng/ml in MWCL-1 and 0.3 in BCWM.1 at 72 hours), gave rise to the more differentiated PCs (7.5 ~ 9.0% in BCWM-1 and 1.2 ~ 1.4% PCs in BCWM.1), and secreted increased to 130% and produced 2.5 ~ 2.8 X 10^4 ng/ml of IgM. LPLs from both cells as well as in SNK-6 cells. When comparing with those transfected with IL-2Rα-harboring lentiviral vectors, and the smaller amounts of IgM than PCs (3.5 ~ 5.0 X 10^3 ng/ml in MWCL-1 and 0.3 in BCWM.1 at 72 hours), gave rise to the more differentiated PCs (7.5 ~ 9.0% in BCWM-1 and 1.2 ~ 1.4% PCs in BCWM.1), and secreted significantly higher in SNK-6 cells than in NK-92 cells transfected with LMP-1-harboring lentiviral vectors, and the in the downstream pathways of LMP1 signaling were measured in NK-92 cells and explored the role of IL-2Rα in lymphomagenesis and chemotherapy resistance, which can be reversed by anti-IL-2Rα antibody, indicating the potential role of IL-2Rα as a therapy target in NKTCL.

**Background:** PD1 binding to its ligand PDL1 inhibits TCR/BCR signaling; impairs activation and effector functions of T- and B-cells; induces state of T-cell exhaustion; and ultimately provokes tolerance towards cancer cells. PD1 is expressed on Hodgkin lymphoma (HL) and B-cell non-HLTL-Cells. The TME may play an essential role in maintaining PD1-induced immune exhaustion. LEN is an oral immunomodulator (IMID) with direct antineoplastic activity and immune checkpoint inhibitors. The TME, including those of Tg-l cells and NK cells, can modulate cytotoxicity in experimental models. Preclinical findings indicate that combination of IMIDs with immune checkpoint inhibitors may promote therapeutic synergy and long-term antitumor immunity to improve clinical outcome.

**Aims:** 1) To better characterize the PD1, PDL1 and the lesser-known PDL2, phenotype in peripheral neoplastic CD19+ lymphocytes and T-cell subsets in patients with low-grade B-cell lymphoma; 2) to evaluate the role of the PD1 axis in supporting the PD1 axis; and 3) to determine whether LEN influences PD1 or cognate ligand expression.

**Methods:** Samples obtained from patients attending participating Hematology Units were used to determine PD1, PDL1, PDL2 gene expression by Flow-cytometry (FC). Autologous activated T-cells (AAT) were obtained by in vitro co-culture of patient T-cells with anti-CD3/CD28 beads, rIL2 and with PBMCs. Cultures were monitored daily until sizeable clumping was observed and tested for PD1 and ligand expression. In selected experiments LEN (provided by Celgene) was added to cell cultures.

**Results:** Twelve cases of lymphoma were evaluated for PD1, PDL1 and PDL2 expression on malignant B- and T-cells by FC. The expression of PD1 and PDL1 was similarly expressed, while PDL2 was almost undetectable on B-cells. Levels of PD1 expression on CD3+ cells were variable across samples, however they were significantly higher than those expressed on malignant B-cells. Significantly increased PD1 expression and very low levels of ligands were detected in both CD4+ and CD8+ cells. Co-culture of lymphoma with T-cells resulted in co-stimulatory effect on T-cell proliferation and the consistent formation of T/B-cell clusters. Higher numbers of CD19+CD52+PD-L1+ cells were detected than PDL1+ cells compared to baseline cells. PD1 expression also significantly increased in AAT co-culture on B-cells. PD1 expression
on CD3+ cells was unaffected by AAT, although the expression of both ligands remained unchanged. PD1 expression gradually increased following exposure to LEN compared to untreated cells. CD3+ cells showed a significant increase in PD1 expression by LEN, while the expression of both ligands remained unaffected. Evaluation of activated T-cell subsets showed similar results, with the exception of stronger induction of PD1 and PD1L1 expression by LEN in CD8+ cells.

Summary/Conclusions: Our data provide support for the potential involvement of the PD1-axis in lymphoma patients. Interestingly, LEN further induces the expression of PD1 in CD8+ and CD4+ cells and may contribute to reactivating PD1 signaling under treatment. The PD1 pathway may be potentially targeted to overcome both the intrinsic and LEN-induced exhaustion phenotype.

Aims: To investigate if ATO targets BCL6 and inhibits the proliferation and growth of BCL6-dependent DLBCL.

Methods: BCL6-dependency of a panel of DLBCL cell lines (i.e. OCI-Ly1, OCI-Ly7, SU-DHL-6, OCI-Ly18 and Pfeiffer) was determined based on their sensitivity to proliferation inhibitory activity of the BCL6 inhibitor 79-6 (Calbiochem). The effects of ATO and cisplatin as single agent or in combination on cell viability and apoptosis of DLBCL cell lines were examined with MTT assay and flow cytometric analysis. Expression of BCL6 and its target genes was examined with quantitative RT-PCR and western immunoblotting. The therapeutic efficacy of ATO treatment was also examined in a DLBCL (OCI-Ly7) xenograft mouse model.

Results: OCI-Ly1, OCI-Ly7 and SU-DHL-6 were highly sensitive to inhibitory activity of BCL6 inhibitor and were designated as BCL6-dependent. Treatment of DLBCL cells with ATO led to a decrease in BCL6 protein level and an upregulation of downstream targets of BCL6, including PRDM1, CD44 and CD69. The effect of ATO on BCL6 protein were abrogated by treatment with proteasome inhibitors and therefore, ATO led to BCL6 for degradation through the ubiquitin-proteasome pathway. Interestingly, ATO also inhibited cell proliferation and induced apoptotic cell death of BCL6-dependent DLBCL cell lines, analogous to the effect of BCL6 inhibitor on these cells. In addition, there was a synergistic inhibitory and cytotoxic activity between ATO and cisplatin. Finally, ATO treatment suppressed the growth of DLBCL in a xenograft mouse model.

Summary/Conclusions: ATO targets BCL6 for proteasomal degradation and inhibits the proliferation and growth of BCL6-dependent DLBCL.

Arsenic trioxide targets BCL6 for degradation and inhibits the proliferation of BCL6-dependent diffuse large B-cell lymphoma

IDENTIFICATION AND DIAGNOSTIC APPLICATION OF GENOMIC NPM-ALK FUSION TRANSCRIPTS IN ANAPLASTIC LARGE CELL LYMPHOMAS

M. Krumbholz1, C. Damm-Welk2, W. Woessmann2, M. Metzler1
1Department of Pediatrics, Justus-Liebig-University, Giessen, Germany
2Department of Pediatrics, Justus-Liebig-University, Giessen, Germany

Background: ALK positive anaplastic large-cell lymphomas (ALCL) account for 10-15% of pediatric Non-Hodgkin lymphomas. Most of these patients carry the chromosomal translocation t(2;5)(p23;q35) leading to the fusion of the NPM and ALK genes. The genomic NPM-ALK fusion transcripts is a well-established tool for diagnostic purposes and risk stratification during the course of treatment.

Aims: Establishment of a PCR based assay to identify patient-specific genomic NPM-ALK fusion sequences for a DNA based monitoring of minimal residual disease in ALCL patients. Compared to RNA based methods the quantification of DNA is independent of the gene expression. Additionally, due to the higher stability of DNA, cell-free circulating tumor DNA (ctDNA) should be detectable in the patient’s plasma and may represent a tumor marker for ‘liquid biopsies’ in ALCL.

Methods: Using a specifically designed multiplex long-range PCR assay, genomic NPM-ALK fusion sequences were identified in 45 ALCL patients. The genomic NPM-ALK breakpoints were analyzed concerning fine structure and breakpoint distribution pattern. Furthermore, the patient-specific genomic NPM-ALK fusion sequences were evaluated for their use as biomarkers in selected cases. For this purpose patient’s blood and plasma samples were quantified using a high sensitive digital droplet PCR assay.

Results: In more than 60% of cases the identified breakpoint was localized within repeat regions. The genomic breakpoints within the breakpoint cluster regions of the fusion genes were randomly distributed. Most of the NPM-ALK fusion sequences were characterized by the occurrence of small insertions or deletions indicating the involvement of the non-homologous end-joining (NHEJ) repair system for chromosomal translocation initiation. Using a DNA based quantification assay in a subset of patients, the genomic NPM-ALK fusion sequences were detectable in circulating tumor cells in patient’s blood samples as well as cell-free tumor DNA in plasma samples.

Summary/Conclusions: The established multiplex long-range PCR assay is a useful diagnostic tool for the identification of genomic NPM-ALK fusion sequences. This individual tumor maker is independent of gene expression and can be used for therapy response monitoring and relapse detection.

E1392

ARSENIC TRIOXIDE TARGETS BCL6 FOR DEGRADATION AND INHIBITS THE PROLIFERATION OF BCL6-DEPENDENT DIFFUSE LARGE B-CELL LYMPHOMA

E. Tse1, K. Yue1, D. Chau2, Y.-L. Kwong1
1Department of Medicine, 2School of Medicine, The University of Hong Kong, Hong Kong, Hong Kong

Background: B-cell lymphoma 6 (BCL6) is a transcription repressor and is constitutively expressed in most cases of diffuse large B-cell lymphoma (DLBCL). BCL6 expression is important for the survival of transformed B-cells and promotes the formation of active B-cells. The quantification of BCL6 expression of PD1 in CD8+ and CD4+ cells and may contribute to reactivate PD1 signaling under treatment. The PD1 pathway may be potentially targeted to overcome both the intrinsic and LEN-induced exhaustion phenotype.

Aims: To investigate if ATO targets BCL6 and inhibits the proliferation and growth of BCL6-dependent DLBCL.

Methods: BCL6-dependency of a panel of DLBCL cell lines (i.e. OCI-Ly1, OCI-Ly7, SU-DHL-6, OCI-Ly18 and Pfeiffer) was determined based on their sensitivity to proliferation inhibitory activity of the BCL6 inhibitor 79-6 (Calbiochem). The effects of ATO and cisplatin as single agent or in combination on cell viability and apoptosis of DLBCL cell lines were examined with MTT assay and flow cytometric analysis. Expression of BCL6 and its target genes was examined with quantitative RT-PCR and western immunoblotting. The therapeutic efficacy of ATO treatment was also examined in a DLBCL (OCI-Ly7) xenograft mouse model.

Results: OCI-Ly1, OCI-Ly7 and SU-DHL-6 were highly sensitive to inhibitory activity of BCL6 inhibitor and were designated as BCL6-dependent. Treatment of DLBCL cells with ATO led to a decrease in BCL6 protein level and an upregulation of downstream targets of BCL6, including PRDM1, CD44 and CD69. The effect of ATO on BCL6 protein were abrogated by treatment with proteasome inhibitors and therefore, ATO led to BCL6 for degradation through the ubiquitin-proteasome pathway. Interestingly, ATO also inhibited cell proliferation and induced apoptotic cell death of BCL6-dependent DLBCL cell lines, analogous to the effect of BCL6 inhibitor on these cells. In addition, there was a synergistic inhibitory and cytotoxic activity between ATO and cisplatin. Finally, ATO treatment suppressed the growth of DLBCL in a xenograft mouse model.

Summary/Conclusions: ATO targets BCL6 for proteasomal degradation and inhibits the proliferation and growth of BCL6-dependent DLBCL.

PROTEOMIC PHOSPHOSITE ANALYSIS IDENTIFIED CRUCIAL NIPA SERINE RESIDUES FOR NPM-ALK-MEDIATED TRANSFORMATION

A. Gengenbacher1, A. Rudorf1,2, T. Poggio1, C. Rummelt1, S. Kreutmair1, V.i. Dumit3, J. Duyster1,2, A.L. Illert1,2
1Dept. of Hematology, Oncology and Stem Cell Transplantation, University Medical Center, Freiburg, 2German Cancer Consortium (DKTK), Heidelberg, 3Center for Biological Systems Analysis, University of Freiburg, Freiburg, Germany

Background: Anaplastic large-cell lymphoma(ALCL) is an aggressive non-Hodgkin lymphoma that occurs mainly in children and younger adults. Patients typically show an advanced stage disease as well as an aggressive disease pattern with extraordinary manifestations. At the molecular-genetic level, 60% of the patients with systemic ALCL exhibit a translocation t(2;5)(p23;q35), which leads to the expression of the NPM-ALK fusion protein. Under the control of the NPM promoter, ALK activation causes increased and autocrine NPM-ALK expression. Nuclear interaction partner of ALK (NIPA) was first identified as a new interaction partner of the oncogene NPM-ALK in a yeast-2-hybrid screen which defines an E3-SCF ligase and is physiologically involved in cell cycle regulation at the transition from G2 phase to mitosis. It has already been shown in preliminary studies that co-expression of NIPA with the oncogenic tyrosine kinase NPM-ALK results in the constitutive phosphorylation of NIPA (Illert et al., 2012a). Until now, the specific signal transduction pathway, the crucial phosphorylation sites in NIPA as well as the functional effect of the pathological NIPA phosphorylation in NPM-ALK-induced lymphomagenesis still remain unclear. Molecular insights into the molecular mechanism involved in the oncogenic NPM-ALK may help to identify new druggable targets for therapeutic implications.

Aims: In the present study, we investigated the molecular mechanisms as well as the functional impact of the NPM-ALK-induced NIPA phosphorylation.

Methods: For this purpose, biochemical methods with ALCL cells were used to examine functional effects of constitutive and NIPA phosphorylation. Moreover, we performed a “proteomic-phosphosite-analysis” to identify crucial NPM-ALK specific phosphorylation sites in NIPA. Based on these results, phospho-deficient NIPA mutants were generated to investigate the functional effect of this phosphorylation: MITT proliferation- and Softagar-Assays were performed after cell infection of BaF3 and primary NIPA-deficient MEF cells with NPM-ALK and the respective phospho-deficient NIPA to reveal transformation and growth ability.

Results: It has already been shown, that cell cycle dependent NIPA phosphorylation at critical serine residues 354, 359 and 359 leads to dissociation of the inactive NIPA and the respective phospho-deficient NIPA to reveal transformation and growth ability.

Summary/Conclusions: Taken together, we identified five phosphorylation sites in NIPA to be highly upregulated upon NPM-ALK expression. However,

APPLICATION OF CELL-OF-ORIGIN SUBTYPES DETERMINED BY DIGITAL GENE EXPRESSION IN HIV-RELATED DIFFUSE LARGE B CELL LYMPHOMAS

Methods: A series of HIV-related DLBCL using the Lymph2Cx assay and to compare the cell-of-origin (COO) given by Hans algorithm and Lymph2Cx assay.

Results: The median follow-up of living patients was 8.5 years. IHC studies showed that 35.8% of the cases expressed CD10, 61.5% expressed BCL6, 55.8% expressed MUM1, and according to Hans algorithm 56.6% had a non-GC phenotype. CD30 was expressed in 15.4% of the cases and EBER was found in 21.2%. The expression of MYC was detected in 32.7% of the cases and BCL2 in 44%, and 18% were dual expressers. Rearrangements involving MYC, BCL2 and BCL6 were detected in 26%, 8% and 28%, respectively. The Lymph2Cx assay assigned a COO to all 55 studied cases. 63.6% were GCB subtype, 20% were ABC subtype, and 16.4% were unclassified. The only clinical feature significantly associated with a defined COO subtype was B-symptoms (ABC=81.8% vs GCB=28.6%, P=0.003) and HIV-load tended to be more frequently observed in ABC (90%) than in GCB (58.1%, P=0.068). Regarding IHC, in the follow-up results, MYC rearrangements were only detected in GCB cases and expression of CD10 and BCL6 tended to be associated with GCB (Table 1). Hans algorithm and Lymph2Cx assay differently assigned COO subtypes (κ=0.288, P=0.029) showing that 44.1% of the GCB cases had a non-GC phenotype according to Hans. Only patients treated with RCHOP were considered in survival analyses (N=47). COO subtypes had neither impact on OS nor PFS, independently of being determined with Hans or Lymph2Cx assay. Features associated with shorter OS and PFS were history of AIDS-defining illnesses, HCV-infection and dual MYC and BCL2 expression. Extranodal disease and increased MYC or BCL2 expression were also bad prognostic factors for PFS.

Summary/Conclusions: In HIV-related lymphomas, COO subtypes were discordantly assigned with Hans and Lymph2Cx assay and COO subtypes showed no impact on outcomes, independently of the method applied.

E1395
CXC4R AND CXCL12 ARE IMPLICATED IN BONE MARROW INFILTRATION PROCESS OF AGGRESSIVE B CELL LYMPHOMAS AND THEIR INHIBITION SUPPRESSES LYMPHOMA CELL GROWTH IN VITRO
A. Deutsch1, B. pursche1, B. Ehall1, M. Zoidi2, K. Fechter1, E. Steinbauer3, M. Sedej4, H. Greinix1, K. Prochazka1, T. Wrodnigg2, C. Beham-Schmid3, P. Neumeister1

Background: The chemokine receptor CXCR4 together with its ligand CXCL12 plays a pivotal role in tumourigenesis of solid and haematological neoplasms. Our comprehensive study on the CXCR4 expression in aggressive lymphoma demonstrated that high CXCR4 expression was associated with poor clinical course of aggressive lymphoma patients.

Aims: Therefore, we aimed to comprehensively study the implication of the CXCR4 - CXCL12 axis in bone marrow infiltration process of aggressive lymphoma and to analyse the effects of CXCR4 antagonists on cell growth and migration of aggressive lymphoma cells in vitro.

Methods: To determine whether CXCR4 and CXCL12 expression have any effects on the bone marrow infiltration process of aggressive lymphomas, we performed gene expression analysis on bone marrow biopsies of our diffuse large cell lymphoma patient cohort. Therefore, we used 63 bone marrow specimens, whereby 52 bone marrow biopsies were taken at time of diagnosis. Additionally, we generated a novel CXCR4 antagonist -named WK1- by modification of the side chain of AMD070 - a commercially available CXCR4 antagonist. We treated various aggressive lymphoma cell lines (U2932 and RI-1 as ABC-DLBCL and BL2 and Raji as Burkitt lymphoma lines) with CXCR4 antagonist and to analyse the effects of CXCR4 antagonists on cell growth and migration of aggressive lymphoma cells in vitro.

Results: By correlating CXCL12 expression levels of infiltrated bone marrow biopsies, we observed a very strong significant negative correlation between CXCL12 expression and the percentage of infiltration levels (Spearman-Rho=0.764; p=0.001). Furthermore, remission in bone marrow after standard immunochemotherapy was associated with a reduction of CXCR4 expression (p=0.075). The cell growth of BL2 and RI-1 cell lines -exhibiting strong and moderate CXCR4 expression- was significantly inhibited by AMD070 and WK1 (p<0.01). As the cell line case of U2932 -exhibiting low CXCR4 expression- was just affected by WK1. AMD3100 did not show any effects on the lymphoma cell growth. The transmigration index to evaluate the chemotactic ability of lymphoma cells was reduced by AMD070 and WK1 treatment, however, the inhibitory effects of WK1 were lower compared to AMD070.

Summary/Conclusions: These data strongly suggest that CXCR4 and its ligand CXCL12 is implicated in the bone marrow infiltration process of diffuse large B-cell lymphomas. Additionally, our in vitro results indicate that treatment of lymphoma cells with CXCR4 antagonists might be a promising new therapeutic intervention to eliminate lymphoma cells.
EPSTEIN-BARR VIRUS LOAD IN PLASMA IS AN EARLY BIOMARKER OF HIV-RELATED LYMPHOMA

J. Muncunill1, M.J. Baptista1, A. Hernandez-Rodriguez2, J. Dalmau3, O. Garcia1, G. Tapia1, M. Moreno1, J.-M. Sancho1, J. Martinez-Picado5, J.-M. Ribera1, E. Feliu1, J.-L. Mate1, J.-T. Navarro1

1Department of Hematology, ICO-Hospital Universitari Germans Trias i Pujol, 2Department of Microbiology, Hospital Universitari Germans Trias i Pujol, 3AIDS Research Institute-IrsiCaixa, Institut d’Investigació en Ciències de la Salut Germans Trias i Pujol, Universitat Autònoma de Barcelona, 4Department of Pathology, Hospital Universitari Germans Trias i Pujol, Universitat Autònoma de Barcelona, 5AIDS Research Institute-IrsiCaixa, Institut d’Investigació en Ciències de la Salut Germans Trias i Pujol, Universitat Autònoma de Barcelona, institución Catalana de Recerca i Estudis Avançats (ICREA), Badalona, Spain

Background: Epstein Barr virus (EBV) has been detected in the tumor cells of some non-Hodgkin lymphomas (NHL) and Hodgkin lymphomas (HL) and detectable EBV loads have been found in the plasma of immunocompetent patients with HL. In HIV-related lymphomas the importance of EBV load as potential biomarkers has been scarcely studied.

Aims: We aimed to evaluate the usefulness of EBV load in plasma as lymphoma biomarker in HIV-infected patients.

Methods: One hundred and fifteen patients with NHL (HIV-infected =57 and HIV-uninfected=34) and HL (HIV-infected= 16 and HIV-uninfected= 8) were studied. EBV loads were determined in plasma by means of a commercial real-time PCR technique (EBV PCR kit, Qiagen GmbH, Hilden, Germany) at lymphoma diagnosis and at complete response (CR) in 1 group of HIV-infected patients also at one year before diagnosis (N=11) and at complete response (CR) (N=34). EBER expression was studied by in situ hybridization in tumor biopsies. The following clinical and biological parameters were collected from records: age, gender, date of lymphoma diagnosis, ECOG score, extranodal and bulky disease, B symptoms, Ann Arbor stage, serum lactate dehydrogenase and beta2-microglobulin. International Prognostic Index (IPI), HCV and HBV serology, history of opportunistic infection and of AIDS-defining illness, onset of combination antiretroviral therapy, CD4-counts, HIV loads, type and date of response, relapse date, last follow up or death date. McNemar’s test and Wilcoxon test were used to compare qualitative and quantitative variables, respectively. Survival analyses were performed using the Kaplan-Meier method. P-values of less than 0.05 were considered statistically significant.

Results: At diagnosis, EBV loads were detectable in more HIV-infected patients than HIV-uninfected (48% vs 14%, P<0.002) and in more HL cases than NHL (70% vs 26.3%, P<0.006). In HIV-infected patients, detectable EBV load was associated with EBER expression, 66.6% of the patients with detectable EBV loads had EBER-positive tumors and 92% of the patients with undetectable EBV loads had EBER-negative tumors (P=0.003). All the remaining clinical and biological features were not associated with detectable EBV load in plasma. In HIV-uninfected patients, associations between EBV load and EBER expression (P=0.006) and EBV load and HVB infection (P=0.017) were observed. From 16 out of 34 (47%) HIV-infected patients with detectable EBV loads at lymphoma diagnosis, 15 had undetectable EBV loads at CR (P=0.001) (Figure 1). The exception was one patient with HL whose EBV load substantially decreased at CR but was still detectable. Moreover, 4 out of 7 HIV-infected patients with detectable EBV loads at diagnosis had detectable loads one year before diagnosis, and no patient with negative EBV loads at diagnosis had detectable loads before it, pointing EBV load can be used as an early biomarker of lymphoma. EBV loads at diagnosis had neither impact on overall survival nor progression-free survival

Summary/Conclusions: EBV-load in plasma can be used as early biomarker of lymphoma in HIV-infected patients since EBV-loads can be detected up to 1 year before lymphoma diagnosis and are virtually undetectable at lymphoma CR.

CLONOTYPE AND MUTATIONAL PATTERN IN TCRGD LARGE GRANULAR LYMPHOCYTE LEUKAEMIA

A. Teramo1,2, E. Ciabatti3, G. Tarrini3, I. Petrini1, G. Barilà1, G. Calabretto1,2, C. Vicenziello1,2, M. Leoncin1,2, C. Ercolini1, A. Cabrella2, S. Galimberti3, R. Grossi3, N. Pisanti4, G. Semenzato1,2, R. Zambello1,2

1Department of Medicine, Hematology and Clinical Immunology Branch, Padua University School of Medicine, 2Venetian Institute of Molecular Medicine, 3Department of Medicine and Experimental Medicine, Section of Hematology, 4Department of Translational Research and New Technologies in Medicine, Section of Pathology, 5Department of Informatics, University of Pisa, Pisa, Italy

Background: T-cell large granulocytic lymphocytic leukemia (T-LGLL) is a rare heterogeneous T-cell neoplasia whose leukemic cells usually express the CD3 T-cell receptor (TCR); only a small subset of cases expresses the γδ TCR denoting the TCRγδ LGLL. Currently, among the different LGL diseases, TCRγδ LGLL remains less studied and several clinical and laboratory data already described in TCRαβ-LGLL have not yet been explored in TCRγδ-LGLL.

Aims: The aims of this work were 1) to characterize TCRγδ-LGLL defining STAT mutational pattern and CDR3 repertoire diversity/clonal composition (clonotype) and 2) to evaluate correlations among LGL phenotype, mutations, TCR rearrangement and clinical presentations.

Methods: In this work 11 patients affected by TCRγδ-LGLL were included. Sanger sequencing was used for mutational analysis on hot-spot regions in the two genes more frequently mutated in LGL disorders, STAT3 and STAT5b. Immunophenotype of LGL clone was defined by flow cytometry analysis. CDR3 repertoire and frequency distribution of TCR gamma gene rearrangements were analyzed.

Results: Our results showed that TCRγδ LGLL had a high incidence of STAT mutations, 9 out of 11 patients carrying STAT3 or STAT5b mutations in a mutually exclusive pattern. At variance from CD8+ TCRαβ LGLL and CD4+ TCRδ LGLL, first being mostly characterized by STAT5b mutations and the latter by STAT5b, TCRγδ LGLL patients were characterized by both the mutations. Thus, TCRγδ LGLL showed features shared by CD8 and CD4 TCRαβ-LGLL. Consistently, TCRδ LGLL showed the same correlation between immunophenotype and kind of mutation observed in TCRαβ-LGLL: γδLGLL patients with CDδ1+CD56- LGL immunophenotype were characterized by STAT3 mutations (as in CD8+ T-LGLL), while γδLGLL patients with CDδ6+ LGL immunophenotype by STAT5b mutations (as in CD4+ T-LGLL). Moreover, we observed that patients with γδLGLL positive for Vδ2 showed usually indolent course, while Vδ1 was linked to a more symptomatic disease (4 out of 5 symptomatic patients were Vδ1+), whereas no correlation was found between mutational pattern and clinical course. By NGS of TCR gamma gene, we observed that all patients were clonal but two, showing a polyclonal pattern borderline with clonality percentage defined by sequencing kit criteria. Interestingly, these two last patients were the only two patients without STAT mutations. As far as the remaining cases are concerned, among STAT3 mutated patients (n=4), 3 were polyclonal and one biclonal, while STAT5b mutated patients (n=5) were more frequently monoclonal (4/5 monoclonal and 1/5 biclonal). In terms of clonal rearrangements, Vg3-Jg1/2, Vg9-JgP and Vg8-Jg1/2 were the combination usages most frequently detected. Concerning the clonotype repertoire, CDR3 sequences of the immunodominant clones were present with low frequency in almost all the other γδ patients and two different CDR3 sequences were found shared, each one in two different patients at frequency >10% of the total rearrangements.

Summary/Conclusions: Our data indicate that TCRγδ LGLL can be considered as the interplay of the two types of TCRαβ-LGLL, sharing some CDR3 and TCRγδ LGLL mutational features. As already described in TCRαβ-LGLL, also in γδLGLL, the first being mostly characterized by STAT5b mutations and the latter by STAT3 mutations, CD8 and CD4 TCRαβ-LGLL. Thus, TCRγδ LGLL patients were characterized by both the mutations. STAT5b mutations seems to be more frequently linked to monoclonal nature of the LGL lymphoproliferation. Rather, the marker Vδ1 appears to be correlated to symptomatic disease.

INCREASED EXPRESSION OF IRF8 IN TUMOR CELLS INHIBITS THE GENERATION OF TH17 CELLS AND PREDICTS UNFAVORABLE SURVIVAL OF DIFFUSE LARGE B CELL LYMPHOMA PATIENTS

Q. Li1,2, *, W. Zhong1

1Guangzhou First People’s Hospital, Guangzhou Medical University, Guangzhou, China, Guangzhou, China

Background: The immunological pathogenesis of diffuse large B cell lymphoma (DLBCL) remains elusive. Searching for new prognostic markers of DLBCL is a crucial focal point for clinical scientists.

Aims: The aim of the present study was to examine the prognostic value of interferon regulatory factor 8 (IRF8) expression and its effect on the development of Th17 cells in the tumor microenvironment of DLBCL patients.

Methods: Flow cytometry, immunohistochemistry, and quantitative real-time PCR were used to detect the distribution of Th17 cells and related cytokines and IRF8 in tumor tissues from DLBCL patients. Two DLBCL cell lines (OCI-
LY10 and OCI-LY1 with IRF8 knockdown or overexpression and two human B lymphoblast cell lines were co-cultured with peripheral blood mononuclear cells (PBMCs) in vitro to determine the effect of IRF8 on the generation of Th17 cells. Quantitative real-time PCR and Western blotting were used to investigate the involvement of retinoic acid receptor-related orphan receptor gamma t (RORγt) in the effect of IRF8 on Th17 cell generation. The survival of 67 DLBCL patients was determined using the Kaplan-Meier method and log-rank analysis.

**Results:** The percentage of Th17 cells was lower in DLBCL tumor tissues than in PBMCs and corresponding adjacent benign tissues. Relative expression of interleukin (IL)-17A was lower, whereas that of interferon (IFN)-γ was higher in tumor tissues than in benign tissues. Co-culture with DLBCL cell lines inhibited the generation of Th17 cells in vitro. IRF8 upregulation was detected in DLBCL tumor tissues, and it was associated with decreased DLBCL patient survival. Investigation of the underlying mechanism suggested that IRF8 upregulation inhibited Th17 cell generation by suppressing the effect of RORγt on CD4+ T cells.

**Summary/Conclusions:** Our findings suggest that IRF8 expression in the tumor microenvironment inhibited the generation of Th17 cells through its antagonistic effect on RORγt in the DLBCL tumor microenvironment, suggesting that it could be a prognostic factor for DLBCL.

**GENOMIC PROFILING OF BCL2 AND MYC DOUBLE EXPRESSION DIFFUSE LARGE B CELL LYMPHOMA**

V. Dirse1,2,3, J. Drachner1,2, U. Micks1, M. Stoskus1, L. Griskevicius1,2,3

1Hematology, Oncology and Transfusion Medicine Center, Vilnius University Hospital Santariskiu Klinikos, 2Department of Internal, Family Medicine and Oncology, Faculty of Medicine, Vilnius University, 3National Center of Pathology, Affiliate of Vilnius University Hospital Santariskiu Klinikos, Vilnius, Lithuania

**Background:** Diffuse large B cell lymphoma (DLBCL) is an aggressive disease featuring heterogeneous genetic, phenotypic and clinical characteristics. Recently, a negative prognostic impact of double expression of BCL2 and MYC (double expression (DE) lymphoma) has been identified in several studies. SNP array (SNP-A) studies have already led to the identification of novel genomic aberrations in ABC and GCB subtypes of DLBCL whereas similar analysis has not been done in DE and non-DE DLBCL.

**Aims:** To characterize the landscape of genomic aberrations in DE and non-DE DLBCL groups using SNP-A and interphase fluorescence in situ hybridization (FISH).

**Methods:** Immunohistochemical and FISH analysis was performed on tissue microarray of formalin fixed paraffin embedded (FFPE) tumor tissue samples using Bcl2 (124, DakoCytomation) and MYC (Y69, Epitomics) antibodies and FISH MYC (Zytovision), Bcl2 (Abbott/Vysis), Bcl6 (Abbott/Vysis) break-apart probes and MYC/IgH (Zytovision) double-fusion probe. Infinium HD whole-genome genotyping assay with the HumanCytoSNP FFPE-12 BeadChip Immuna, San Diego, CA, USA was performed for genomic analysis of the aberrations.

**Results:** A cohort of 91 primary DLBCL patients diagnosed between 2004 and 2012 was selected for the study. Immunohistochemical evaluation was informative in 87 (95.6%) cases. Genomic analysis, 61 cases were informative for MYC, 56 cases for Bcl6, and 65 cases for Bcl2. 7 cases (11.4%) were positive for MYC translocation, 14 (25%) for Bcl6, and only 3 (4.6%) were positive for Bcl2. No cases of MYC BCL2 and double positive DLBCL were identified. Genomic DNA from FFPE tumor tissue for SNP-A was available in 61 cases, SNP-A analysis was performed in total 329 patients. Abnormalities not corresponding to known copy number polymorphisms (89% of all the patients, 59/66). These comprised 164 (50%) hemizygous and 2 (1%) homozygous deletions, 106 (32%) gains, 41 (12%) trisomies and 16 (5%) monosomies. The most common aberrations were 1p deletion, 1q gain, 6q deletions with trisomy 12, and 17q (karyotype >3 aberrations) was detected in 37/66 (56%) patients. Both DE and non-DE DLBCL groups had equal rate of aberrations per case (~5 aberr./case) and shared the most common aberrations – 1p deletion and 1q gain. In contrast, 11q deletion was more common in DE, while 6q and 17q deletions were more prevalent in the non-DE group.

**Summary/Conclusions:** SNP-A analysis highlights the genomic differences between the DE and non-DE DLBCL. Our finding of MYC positive (translocations and/or gains) association with low complexity karyotype status may suggest MYC to be an early initiating genetic event.

**E1400**

**ARQ 531, A REVERSIBLE BTK INHIBITOR, DEMONSTRATES POTENT ANTI-TUMOR ACTIVITY IN ABC-DLBCL AND GCB-DLBCL**

S. Eathiraj1, Y. Yu1, T. Hall1, B. Schwartz1, J.A. Woyach1, S. Reiff1, G. Abdabessa1

1Clinical Development, ArQule Inc., Burlington, 2Division of Hematology, The Ohio State University, Columbus, United States

**Background:** B-cell receptor (BCR) signaling has emerged as a critical pathway for B-cell lymphoma development. BTK, a key mediator of BCR signaling is a major target for ibrutinib. Ibrutinib has demonstrated efficacy in chronic lymphocytic leukemia (CLL) and mantle cell lymphoma and Waldenström macroglobulinemia. However, as anticipated by preclinical models, clinical objective response rates of only 37% in ABC and 5% in GCB diffuse large B cell lymphoma (DLBCL) were reported. ARQ 531 is a potent reversible inhibitor of BTK, highly effective in targeting BCR signaling. Kinase profiling indicated additional activity of Src, Trk family members, as well as additional in vivo response in ABC and GCB patient groups.

**Methods:** Biochemical inhibition and kinase profiling were assessed using recombinant proteins. The ARQ 531 binding kinetics on BTK were determined by Surface Plasmon Resonance assay. Anti-proliferative activity of ARQ 531 was tested in a MTS-based assay against a panel of hematological malignant cell lines. Pathway inhibition assessments, in vivo efficacy and in vivo target inhibition were performed in TMD8 (ABC-DLBCL) and SUDHL4 (GCB-DLBCL) cell lines and xenografts. ADME and pharmacokinetic properties of ARQ 531 were also evaluated in rats, dogs and monkeys.

**Results:** ARQ 531 potently inhibited BTK (IC50=0.85 nm) and displayed long half-life (56 min). ARQ 531 exhibited strong anti-proliferative activity in TMD8 (GL50=1.13 μM) and SUDHL4 (GL50=0.2 μM) cell lines. Ibrutinib, while potent on TMD8 cells (GL50=0.002 μM), had a GL50 of 1.1 μM in SUDHL4, a concentration not reached in human blood, consistent with published studies. Pathway analysis in TMD8 and SUDHL4 cells showed that ARQ 531 potently inhibited both upstream activating signals (Src kinase family) and downstream signaling pathways such as AKT and ERK. Cell cycle analysis indicated that ARQ 531 inhibited cell growth through G1 phase arrest, similar to ibrutinib. In the TMD8 xenograft mouse model, ARQ 531 strongly inhibited BTK signaling, with better efficacy than reported with ibrutinib; tumor growth reduction was 92% after 14 days of dosing, with no re-growth observed for 17 days post dose interruption. In the ibrutinib-resistant SUDHL4 mouse xenograft model, ARQ 531 potently suppressed tumor growth (>80% inhibition) compared to the control group.

**Summary/Conclusions:** ARQ 531 is a potent reversible inhibitor of BTK. Its selective kinase selectivity can be used to target constitutive BCR signaling in DLBCL primarily resistant to ibrutinib, as demonstrated by the excellent efficacy in both ABC and GCB DLBCL xenograft models. These data support the clinical investigation of ARQ 531 in patients with hematological malignancies, expected to begin in mid-2017.
vival (OS). The efficacy of R-CHOP was evaluated according to Cheson criteria by performing standard hematochemical and instrumental (TC and FDCG-PET) tests and defining complete remission (CR), partial remission (PR), non response or progressive disease (PD). Genomic DNA was extracted from peripheral blood of 80 pts. SNPs analysis was performed by an Affymetrix array. To date, 21 SNPs from 19 candidate genes (ABC1B, ABC1C, ABC2C, ABC2G, CDK4, CDK6, DOR1, FHC1, FGF2, FGFRA, GATA2, GATA3, GATA4, GSTP1, IL1H, NCF4, NOQ1, NOQ2, RAC2, TNF, TOP2A, TP53, TUB1) involved in pharmacokinetics and pharmacodynamics of R-CHOP (www.pharmkg.org) selected and analysed in relation to R-CHOP efficacy. Univariate and multivariate logistic regression analyses were performed to evaluate associations between SNPs and clinical outcomes. Case-control analyses were performed using Risk genotypes (RR) and one or two minor alleles (RR/RR, RR/RQ) as a predictor of PFS (p=0.045). Pts with HR or RR genotypes showed shorter PFS than pts with HT genotype (HR: 2.437, 95% CI 1.00-5.823). No statistically significant correlation was found between SNPs and OS.

**Summary/Conclusions:** Our preliminary data obtained in a limited number of pts, show a association between a SNP of the low affinity FGFR2A gene involved in the activity of rituximab and PFS. Further insights will derive from the completion of pts accrual to reach the planned number of cases at the end of our study.

**CDK4/6-INHIBITION BY ABEMACICLIB INDUCES POTENT EARLY G1-ARREST IN MCL CELL LINES AND SHOWS SEQUENCE-SPECIFIC INTERACTIONS WITH CYTARABINE AND IBRUTINIB**

L. Fischer1, A. Mayr1, M. Jäger1, B. Freysoild1, Y. Zimmermann1, G. Hutter1, W. Hiddemann1, M. Dreyling1

1Dept. of Medicine III, Univ. Hospital Grosshadern/LMU: Experimental Leukemia and Lymphoma Research (ELLF), Munich, Germany

**Background:** Mantle cell lymphoma (MCL) is characterized by (11;14) resulting in a constitutive cyclin D1 overexpression. The cyclin D1-CDK4/6 complex inactivates Rb through phosphorylation, leading to G1/Phase transition. Therefore, inhibition of CDK4/6 is an efficient and rational approach to overcome cell cycle dysregulation in MCL.

**Aims:** We evaluated the efficacy of the novel CDK4/6 inhibitor abemaciclib in various MCL cell lines and in primary MCL cells in combination with cytarabine (AraC) and ibrutinib.

**Methods:** MCL cell lines (Granta 519, JeKo-1, Mav-1, Mino) and primary MCL cells were exposed to abemaciclib alone and combined with AraC or Ibrutinib. Pts were pretreated with abemaciclib and exposed to AraC or Ibrutinib with or without consecutive wash-out of the CDK4/6 inhibitor. Proliferation and viability were measured by trypan blue staining and Cell Titer Glo assay. Combination Index (CI) to assess synergy or antagonism was calculated using the Fractional Product method by Webb (1963). Flow cytometry was applied for cell-cycle (PI-staining) and apoptosis analysis (Annexin V PE/7AAD-staining). Protein expression and phosphorylation status of various downstream proteins was analyzed by Western blot analysis.

**Results:** Abemaciclib inhibited cell proliferation by induction of early G1-arrest. We observed an almost complete and reversible G1-arrest in all sensitive cell lines for 31,25 µM abemaciclib and 2 µM Ibrutinib. Whereas the simultaneous application of abemaciclib and ibrutinib had a protective effect against AraC treatment in all sensitive cell lines of MCL. Sequential administration of abemaciclib followed by AraC showed strong synergy in Mino cells (CI=0,33 µM AraC). Western blot analysis of abemaciclib and ibrutinib had synergistic or additive effects in sensitive cell lines (Cis: JeKo-1=0,24; Mav-1=0,19; Mino-0,03 for 31,25 µM abe and 2,5 µM ibru), whereas the simultaneous administration of both showed additive effects at most (Cis: JeKo-1=0,24; Mav-1=0,1; Mino-0,09 for 31,25 µM abe and 2,5 µM ibru). In primary MCL cells abemaciclib had no impact on cell death or sensitization since no cell proliferation was observable and cells where resting in G1-phase.

**Summary/Conclusions:** The novel CDK4/6 inhibitor abemaciclib causes reversible G1 cell cycle arrest without loss of viability at low nanomolar doses. Rationale drug combinations exploiting the sequential effect may achieve major benefits. Pretreatment with abemaciclib might sensitize cells to ibrutinib, resulting in synergistic drug effects. In contrast, simultaneous application of abemaciclib protects cells from AraC treatment whereas Abemaciclib-induced S-phase synchronization sensitizes MCL cell lines to AraC. Further analysis is needed to explore the interaction with other targeted approaches (inhibitors of the B-cell receptor pathway) to better understand the underlying molecular mechanisms.
CD5 POSITIVE DIFFUSE LARGE B CELL LYMPHOMA SHOWED FREQUENT MYC EXPRESSION AND AGGRESSIVE CLINICAL BEHAVIOR

1Pathology, Seoul National University Hospital, Seoul, 2Pathology, Hallym University Sacred Heart Hospital, Anyang, 3Pathology, Sanggye Paik Hospital, Inje University college of medicine, Seoul, 4Pathology, Ajou University School of Medicine, Suwon, 5Pathology, Soonchunhyang University Hospital, Pucheon, 6Pathology, Seoul St. Mary's Hospital, Seoul, 7Pathology, Ulsan University Hospital, Ulsan, 8Pathology, Seoul National University Boramae Hospital, Seoul, Korea, Republic Of

Background: Aberrant expression of CD5 distinguishes a unique immunohistochemical subtype of diffuse large B cell lymphoma (DLBCL). This CD5+ DLBCLs, either de novo lesions or transformed from preceding low grade lymphomas, can only be identified in LN for the majority of patients with aggressive behavior. The incidence of CD5+ DLBCL was variably reported from 5-22% of all DLBCLs in western countries and Japan, however, no exact data available in Koreans.

Aims: This study aimed to investigate clinicopathologic features of CD5+ DLBCLs.

Methods: A total of 350 cases of DLBCL were reviewed 4 university hospitals from 2004 to 2012. Review of the histologic features along with immunohistochemical study for BCL1, BCL2, BCL6, CD5, CD10, CD23, DM, IRF4/MUM1, MYC, Ki-67 and EBV in situ hybridization was performed. Florescent in situ hybridization (FISH) for MYC rearrangement and amplification was also performed. The results were compared with DLBCL-NOS (N=195).

Results: Thirty cases of CD5+ DLBCL were retrieved among 350 cases of DLBCL (8.6%), which showed predominance of female (20/30), elderly (mean age 64), and extranodal presentation (16/30). Richterian transformation was suspicious in 5/30 and EBV was negative in all. Most cases (22/30) belong to non-GCB subtype by Hans classifier. Rearrangement of MYC was found in 2 cases and amplification was found in one. Compared with DLBCL-NOS, CD5+ cases revealed significantly higher expression of MYC, BCL6, IRF4/MUM1 and Ki67 (all p<0.05). Double expression of both BCL2 and MYC was found in 9 of 30 cases (30%). Also, CD5+ DLBCL showed more frequent bone marrow involvement, advanced stages and high international prognostic index (all p<0.05). In univariable survival analysis, CD5+ DLBCL revealed significantly shorter progression free survival (median 8.2 months) compared with DLBCL-NOS (median 56.3 months) (p<0.05).

Summary: The present study of CD5+ DLBCL in Korea. The incidence, clinical presentation, and pathologic features including cell of origin coincide with previous reports from western population or Japanese. However, frequent high expression of MYC without chromosomal structural alteration was a unique finding in our study. Expression of CD5 should be routinely investigated in DLBCL to find this particularly aggressive subtype.

Reactive B-lineage lymphoid proliferations (RBLP) in the blood and bone marrow may raise a differential diagnosis of lymphoma.

Aim: To document the clinicopathological features of florid RBLP in the setting of HIV infection in order to provide an approach to differentiating reactive and clonal processes.

Methods: A retrospective database search was performed of the laboratory information system (National Health Laboratory Service) that screened pathological reports for samples referred to the Departments of Molecular Medicine and Haematology and Anatomical Pathology at the Johannesburg Academic Complex during 2007-2011, supplemented with results of immunophenotypic analysis from 2007-2016. Demographic and clinicopathological findings were collected for patients identified with florid RBLP who showed no definitive evidence of monoclonality.

Results: During this period, 38 patients were diagnosed with florid RBLP with up to 70-80% of cells in blood or bone marrow comprising reactive B cells (including mature B, plasmablasts and plasma cells). All patients tested were HIV positive, with a median age of 28 years (range 6 months-79 years). There was a bimodal age pattern with a peak in children <1 year of age (34% of patients) and a second peak in an age group where the incidence of lymphoma is virtually absent in children under a year of age. Common clinical presentations included cytopenias (85%); infection (70%) (commonly Cytomegalovirus (35%), TB (30%) and bacterial septicaemia (22%)); hepatosplenomegaly (42%); and lymphadenopathy (36%). Patients showed increases in serum total protein levels (reflecting hypergammaglobulinaemia), with increased inflammatory markers (C-reactive protein and erythrocyte sedimentation rate) and evidence of increased cell turnover (high uric acid, B2 microglobulin and lactate dehydrogenase levels).

Table 1. Comparative data: HIV associated lymphoma and HIV associated RBLP.

Summary: In the setting of HIV, reactive conditions may mimic lymphoma and vigilance is needed in the confirmation of monoclonality. Patients with RBLP presented at a younger age when compared to their counterparts with lymphoma. They had extremely high VL with higher CD4 counts, suggesting this may be a feature of early HIV disease and the possibility of a seroconversion type illness should be considered.

MICROVESSEL DENSITY IN CD30 POSITIVE DIFFUSE LARGE B-CELL LYMPHOMAS

F. Gaudio1, G. Ingervalfo2, T. Perrone3, P. Sindaco1, V. Carluccio1, S. D'agostino1, M. Di Noi1, F.E. Laddaga1, R. Tamma3, S. Ruggieri3, P. Pedote4, G. Specchia1, P. Pedote4, G. Specchia1
1Hematology, 2Pathology, 3Human Anatomy and Histology, 4Radiology, Bari, Italy

Background: Diffuse large B-cell lymphoma (DLBCL) is the most common and one of the most heterogeneous lymphomas. Therefore, it is critical to further stratify cases of DLBCL into biologically similar and clinically meaningful subgroups, which will not only guide prognostic assessment and facilitate therapeutic decisions but also stimulate further research to understand the pathobiology in patients with diffuse large B-cell (DLBCL) lymphomas.

Methods: We retrospectively identified cases of DLBCL diagnosed between January 2010 and January 2016 at our Institution. The following large B cell lymphoma subtypes were excluded from this analysis: post-transplant lymphoproliferative disorders with a DLBCL morphology, Primary Mediastinal large B cell lymphoma, Mantle cell lymphoma and Hodgkin lymphoma. Immunohistochemistry was performed as part of the routine workup and CD30 was considered positive at ≥30% staining of neoplastic cells.

22nd Congress of the European Hematology Association
Microvessel quantification was performed by immunohistochemical staining, using monoclonal antibodies against platelets/endothelial cell adhesion molecule-CD31. A total of 82 cases of de novo DBLCL treated with R-CHOP were included in the training set for further analysis. There were 45 men and 37 women, with a median age of 57 years (range, 16–84); 35 patients (43%) presented with B symptoms, and 49 (60%) had advanced Ann Arbor stages. Most of the patients had a good performance status (Eastern Cooperative Oncology Group score 0–1, 87%), elevated serum lactate dehydrogenase level (61%), and low or low-intermediate International Prognostic Index (IPI) risk (IPI score 0–2, 63%). Involvement of multiple extranodal sites (≥2) was seen in 22% of cases, and bulky disease in 32% of cases.

Methods: The median follow-up time was 47 months. Among the 82 cases in the training set, CD30 was positive in 24 cases (29%). No difference in response rate was observed between CD30 positive and CD30 negative patients. Patients with CD30+ DBLCL showed a significantly superior OS and PFS compared with CD30− patients. The 5-year OS was 79% in patients with CD30+ vs 59% in CD30− (P<0.05); 5-year PFS was 82% in patients with CD30+ vs 63% in CD30− (P<0.05).

Figure 1. Summary/Conclusions: CD30 is expressed in approximately 29% of all DBLCL and defines a novel subgroup of diffuse large B-cell lymphoma with a more favorable prognosis. Microvessel density expression is lower in CD30 positive DBLCL. The advent of brentuximab vedotin and its well-established effectiveness in other types of relapsed lymphomas has introduced the possibility of its application in this subset of patients.

E1407 ANTIGEN SELECTION PROMOTES CLONAL CYTOTOXIC T-CELL RESPONSIBILITIES: HIGH-THROUGHPUT IMMUNOGENETIC EVIDENCE

Background: In B-cell non-Hodgkin lymphomas, minimal residual disease (MRD) is a highly valuable tool for the direct assessment of the reduction of the disease burden. In 2009, the four laboratories of the Fondazione Istituto Lione Linfomi (FIL) - FIL MRD network - started a collaborative effort to harmonize and standardize their methodologies, performing QC (Quality Control) rounds twice a year for follicular lymphoma (FL) and mantle cell lymphoma (MCL) MRD assessment.

Aims: We evaluated the molecular results of bone marrow (BM) samples analysis performed during the QC rounds, to determine how borderline samples (i.e. those with a low MRD level) challenge the inter-lab reproducibility and data interpretation.

Methods: Between February 2010 and November 2016, in the context of 14 QC rounds, the FIL MRD Network labs received 188 BM (94 FL and 94 MCL) samples; 167 were analyzed by both nested polymerase chain reaction (PCR) and real-time quantitative PCR (RQ-PCR). BCL2/IGH oligoclonal rearrangements were analyzed by nested PCR (Gribben, 1993) and by RQ-PCR (Ladetto, 2000). Clonality assessment was performed using an IGHV multiplex consensus PCR (Ladetto, 2003) and by RQ-PCR (Ladetto, 2000; Donoval, 2000). All analyses were conducted and interpreted according to the “EuroMRD Consortium” guidelines (van der Velden, 2007).

Results: The sensitivity and the accuracy of each molecular analysis was tested, reaching a uniform sensitivity of 10−5 and a quantitative range for RQ-PCR of 10−6 to 10−4. Ninety-thousand cycles were carried out as described (Ladetto, 2000; Donoval, 2000). All analyses were conducted and interpreted according to the “EuroMRD Consortium” guidelines (van der Velden, 2007).

Results: The sensitivity and the accuracy of each molecular analysis was tested, reaching a uniform sensitivity of 10−5 and a quantitative range for RQ-PCR of 10−6 to 10−4. samples analyzed by both methods. 83% (139/167) of these were classified as +/+ or -/- by all the FIL labs. The remaining 28/167 (17%) were the samples that showed discordant results in the inter-lab assessments: while in 17 cases the "borderline status" was defined alternatively by only one method, 11 resulted brd samples by both techniques (11/167, 6.6%) (Fig.). Given that the 167 samples were tested in three replicates across the 4 labs, a total of 12 replicates/sample were analyzed: 31 brd samples were thus identified, 13 of which brd by both approaches. Of 156 evaluations performed on the 13 brd, 69/156 (44%) resulted PCR-positive and 87/156 (56%) PCR-negative, 58/156 (37%) were RQ-PNQ and 98/156 (63%) RQ-negative.

**Figure 1.**

**Summary/Conclusions:** Despite the high inter-lab reproducibility in the MRD analysis that can be obtained and maintained by the QC round strategy, samples with the lowest MRD levels can still represent a challenge: 17% (28/167) of our series resulted brd, showing discordant results in inter-lab assessments; 39% of them (11/28) remained brd even applying both methods. The results did not change even increasing the number of replicates/sample. Thus, although representing a minority, brd samples are still problematic, especially when a clinically oriented interpretation is required. As the combined use of standard methods does not totally solve this problem, alternative, novel, methods such as digital PCR and NGS need to be tested in this context.

**E1409**

**RHOA GLY17VAL MUTATION AND T-CELL CLONALITY ANALYSIS IN PATIENTS WITH ANGIOIMMUNOBLASTIC T-CELL LYMPHOMA**

Y. Sidorova1,2, N. Chernova2, I. Yakutik1, S. Smirnova1, N. Ryzhikova1, E. Nikulina1, M. Aleksenko2, O. Glinshchikova1, M. Sinitsyna3, A. Kovrigina1, E. Zvonkov2, A. Sudarkin1

1Department of Molecular Hematology, 2Department of Lymphoma Chemotherapy, 3Department of Pathology, National Research Center for Hematology, Moscow, Russian Federation

**Background:** Angioimmunoblastic T-cell lymphoma (AITL) is a rare subtype of T-cell lymphoma, characterized by generalized lymphadenopathy, hyperglobulinemia, and autoimmune manifestations. Interpretation of histological and immunohistochemical data can be difficult due to the small number of tumor cells, surrounded by abundant polymorphocellular infiltrate. AITL could often be misdiagnosed as reactive processes and other lymphomas, including Hodgkin’s lymphoma. T cell clonality assessment plays an important role in AITL diagnosis. However, ambiguous clonality results may be obtained. Recently discovered somatic RHOA Gly17Val mutation is present in 53-71% of angioimmunoblastic T-cell lymphomas. RHOA mutation was highest in the LN (in average 26.7% of the total cells), while in the bone marrow RHOA mutation was undetectable (in 7 patients), or detected in 10 patients in a small amount (in average 2% of the total cells). Combined morphological and immunohistochemical data suggest that BM may be involved in most patients. Extent of T cell clonality (matching with LN clonal peaks) correlates with the amount of cells having a RHOA mutation. T-cell clonality in BM, skin, spleen, etc. with rearrangements not matching those identified for the LN should be considered reactive and possibly associated with autoimmune process or antiviral response.

**Aims:** To correlate the number of RHOA Gly17Val mutated cells in lymph nodes, blood, bone marrow and skin of AITL patients with corresponding T cell clonality results.

**Methods:** Lymph nodes (LN), skin biopsies, blood and bone marrow (BM) samples were studied for 40 patients with AITL. The male/female ratio was 25/15, median age was 65 years (36-92). To evaluate T-cell clonality rearranged TCRG and TCRB gene rearrangements were PCR-amplified according to BIO-MED-2 standardized protocol and analyzed by capillary electrophoresis on ABI PRISM 3130 (Applied Biosystems). Sensitivity of T-cell clonality assay was limited to 10% of clonal T-cells of the total T-lymphocytes in the sample. Gly17Val mutation was analyzed by quantitative allele-specific (qAS) TaqMan Real-Time PCR assay. The detection level of this method was 1% of mutated cells in the total cell population.

**Results:** The clonal TCR gene rearrangements in LN were found in 37 of 40 patients (92%). RHOA (Gly17Val) mutation in LN was revealed in 60% (24 of 40) patients. T-cell clonality was detected in 26 of 28 primary samples of BM, but in 12 of 26 patients (46%) clonal TCR rearrangements were not matched in length with rearrangements detectable in LN. Number of cells with RHOA mutation was highest in the LN (in average 26.7% of the total cells), while in the bone marrow RHOA mutation was undetectable (in 7 patients), or detected in 10 patients in a small amount (in average 2% of the total cells). Combined morphological and immunohistochemical investigation, T-cell clonality and RHOA (Gly17Val) testing showed BM lesion in 76% of patients (13 of 17) with at least one of the methods. Blood and bone marrow samples examined simultaneously showed slightly higher numbers of RHOA positive cells in the blood than in the BM in 5 of the 7 RHOA positive patients. Significant percentage of cells with a RHOA mutation (in average 25% of the total cells) was revealed in 5 of 6 skin samples from RHOA positive patients. We have found good correlation (Spearman’s Rs-0.8198, p-level <0.00001) between T-cell clonality (matching with LN clonal peaks) and the number of RHOA positive cells in the AITL samples (n 51). Skin, blood and bone marrow samples with the T cell clonality peaks that differ from those found in the LN were also negative for the presence of cells with RHOA (Gly17Val) mutation.

**Summary/Conclusions:** RHOA (Gly17Val) point mutation is detected in LN by allele-specific PCR in 60% of patients with AITL. The percentage of tumor cells in BM is low (averaging less than 2% of the total cells). However, combined molecular and histological data suggest that BM may be involved in most patients. Extent of T cell clonality (matching with LN clonal peaks) correlates with the amount of cells having a RHOA mutation. T-cell clonality in BM, skin, spleen, etc. with rearrangements not matching those identified for the LN should be considered reactive and possibly associated with autoimmune process or antiviral response.

USEFULNESS OF CHITOSIDASE ACTIVITY, CCL18/PARC, 7-KETOCHESTEROL AND GLUCOSYLSPHINGOSINE CONCENTRATIONS FOR SCREENING OF LYOSOMAL STORAGE DISORDERS

P. Irun1,2,3, J. El Chazli1,*, A. Elsharkawy1, N. Mikhael2, M. Abd El-Maksoud3, W. Shoman4, Y. El Chazli1,*, A. Elsharkawy1, N. Mikhael2, M. Abd El-Maksoud3, W. Shoman4, H. Assem1

1Department of Pediatrics, Hematology/Oncology unit, 2Department of Clinical pathology, 3Department of Pediatrics, Neurology unit, 4Department of Pediatric, Immunology/Rheumatology unit, Faculty of Medicine, Alexandria University, Alexandria, Egypt

Background: Hemophagocytic lymphohistiocytosis (HLH) is a life-threatening clinical syndrome due to a severe hyperinflammatory response. HLH is typically characterized by a very wide spectrum of clinical findings. Central nervous system affection (“CNS disease”) has been frequently described at presentation of HLH, during course of disease, or as isolated CNS-HLH that could precede other systemic clinical manifestations by months to years.

Aims: To study the value of CSF soluble interleukin-2 receptor alpha subunit (sIL2Rα) as a marker of CNS affection in children with HLH.

Methods: In this descriptive, observational study done at Alexandria University Children’s Hospital, we analyzed the clinical data of a group of patients diagnosed as HLH. After informed consent was obtained, data was collected from patients who have undergone clinical examination, brain MRI, routine CSF analysis for evaluation of CNS-HLH, and sIL2Rα measurement in the CSF (Quantikine Human CD25/IL-2R Immunoassay, R&D Systems). Patients were considered as “CNS-HLH positive” when they had either neurological manifestations, abnormal findings on MRI or routine CSF analysis (elevated proteins &/or pleocytosis), and as “CNS-HLH negative” when they did not show any of these findings.

Results: We analyzed the data of 9 HLH patients; 4 females and 5 males. Their age ranged from 2 months to 13 years with a median of 5 months. Six patients had genetic diseases predisposing to HLH (Griscelli syndrome type II (GSI) & Chediak-Higashi syndrome (CHS)), and 3 other patients were diagnosed according to HLH-2004 diagnostic criteria and presumed to be of familial form (FHL). Out of the 9 patients, only 5 patients (55.6%) showed clinically evident neurological manifestations; 5 patients (55.6%) had elevated CSF proteins &/or pleocytosis, and 4 patients (44.4%) had an abnormal brain MRI. Overall 7 out of the 9 patients (77.8%) were “CNS-HLH positive” versus only 2 (22.2%) “CNS-HLH negative” according to classical criteria. Interestingly, the geometric mean of CSF sIL2Rα in CNS-HLH positive group was lower than in CNS-HLH negative group (734 vs 1952 pg/ml, p = 0.094). Moreover, CSF protein level and cell counts did not statistically correlate with CSF sIL2Rα level. Several patients showed interesting observations. Among the patients with statistically significant correlation between serum and CSF levels of sIL2Rα in our patients indicates that sIL2Rα is locally produced in the CSF secondary to cellular infiltration of the CNS and could be a valuable biological marker of disease activity. Larger prospective studies are warranted to confirm these results and determine diagnostic and prognostic value of CSF sIL2Rα levels, as well as its value for follow up of CNS disease.

E1412

GAUCHER DISEASE PATIENTS EXHIBIT A HIGH EXPRESSION OF LIPOPCINE (LCN2) AS POSSIBLE BIOMARKER OF RESIDUAL DISEASE ACTIVITY: AN EXPLORATORY STUDY AND CORRELATION WITH OTHER CYTOKINES

M. Andrade-Campos1,*, M.P. Garcia Sobreviela2,3, B. Medrano Engay3, P. Irun1, J. Gervas Arruaga3, M. Arbones2,3, P. Giraldo1,4

1Translational Research Unit, IIS-Aragon. CIBERER, ISCIII, 2ADIPOFAT, Instituto Aragones de Ciencias de la Salud, 3Translational Research Unit, IIS- Aragon., 4FEETEG, Fundacion Española Estudio y Terapéutica Enfermedad de Gaucher, Zaragoza, Spain

Background: Gaucher Disease (GD) is characterized by a latent chronic inflammation/macrophage activation status expressed by an excessive pro-inflammatory cytokines, hyperferritinemia, hypergammaglobulinemia, altered calcium homeostasis and metabolic syndrome. Even patients under ERT do not fully revert this status and their risk to develop bone crisis, iron metabolism alterations, autoimmune disorders and neuropals remain higher. This observation to the creation of a novel auto-priming-regulatory auto -antigenic status. Monitoring of patients through chitotriosidase and CCL18/PARC has become essential however there are patients whom never normalize while others developed bone crisis/ complications after long-time under therapy and normal values. One of the key features for chronic inflammation is the anemia; this is characterized by hyperferritinemia in a common feature diagnosis of GD1 patients. Lipocine (LCN2), a cytokine released by adipocytes, mononuclear cells and neutrophils with expression on endothelial cells, hepatocytes and other cells, has been involved into the monocyte polarization and perpetuation of the inflammatory state. Based on this, we have performed an exploratory study assessing LCN2 expression in GD patients.

Aims: To explore the Lipocine (LCN2) expression as biomarker for disease activity in type 1 Gaucher Disease patients under different circumstances.

Methods: We have performed an exploratory study on 18 GD1 patients distributed in two cohorts. Cohort A was composed by 6 patients; 2 naïve (no prior enrollment to any type of therapy) and 4 under miglustat (M) therapy; this patient was part of the clinical study QUELAFER and were from baseline and after 4 months on chelation therapy were obtained. Cohort B included 12 patients on enzymatic replacement therapy (ERT), for this cohort sera samples were obtained for LCN2 determination and also a panel of cytokines (IL-10, IL-13, IL-4, IL-6, IL-7, Mip1α, Mip1β y TNFα), and hematocrit, hepcidin, cholinesterase and ferritin at the beginning of ERT and after one year on it. Data were incorporated into a database for this purpose including demographic and clinical available data. All patients have signed an informed consent for the use of their samples and ethical approved were obtained form institutional board of FEETEG foundation. A partial comparison comparing LCN2 expression vs the other biomarkers showed the patients showed increased levels of serum LCN2, the overall mean value for the initial sample was 171, 88 (66,72-261,72). As cohorts the differences among individual were significant (Cohort A, p=0.02 and cohort B, p<0.01).

Madrid, Spain, June 22 – 25, 2017

haematologica | 2017; 102(s2) | 879
patients exhibit the higher values. In general 9 patients showed a reduction in LCN2 levels while 7 showed an increase and one the value was stable. All patients showed a reduction in ferritin and chitotriosidase, however a fully correlation with LCN2 expression were not founded. Globally there were no statistically significant differences between the two groups. Background: Thrombotic thrombocytopenic purpura (TTP) is a rare disease that is fatal if untreated. While the main treatment modality is plasmapheresis, immunosuppressants also play a crucial role in the treatment of TTP. Aims: Our aim is to compare the clinical characteristics, treatment and outcomes of patients with acquired primary TTP to those with secondary TTP (i.e. autoimmune and malignancy) hematopoietic stem cell transplant (HSCT) related. Methods: We reviewed all patients with TTP who received plasmapheresis at our institution from 1st Jan 2008 to 31st Jan 2017. Clinical and laboratory characteristics, treatment, response to treatment and complications were recorded. Complete remission (CR) was defined as platelet count normalization, partial remission (PR) as platelet count doubling and >30 x 10⁹/L, and the rest as unresponsive/mortality (UM). Results: Of 41 cases of TTP, 24% (n=10) was primary, 44% (n=18) was secondary to autoimmune diseases, 27% (n=11) was secondary to malignancy or HSCT, 5% (n=2) was related to DRESS syndrome and acute pancreatitis. The median age was 47 (18-86) years and it was predominately female (81%). About two-thirds of the cases presented with neurological symptoms (66%), renal dysfunction (56%) and fever (59%). Only 12 patients (29%) had TTP pentad. Proportionate to incidence of secondary TTP, 85% required immunosuppressive therapy. CR was seen in 51% (n=21) and PR in 15% (n=6). Mortality rate at end of treatment was 41% (n=17) and at end of follow-up was 46% (n=19). Comparison of demographics, clinical presentation, treatment and outcomes between acquired primary TTP and secondary TTP are shown in table below.

Summary/Conclusions: Lipocaline expression is increased in GD1 patients in general, a correlation with other cytokines expression to establish the role of this biomarker is warranted.

E1415 

LOW DOSE RITUXIMAB IS A USEFUL ADDITION TO CORTICOSTEROIDS FOR NEWLY DIAGNOSED PATIENTS WITH WARM AUTOIMMUNE HEMOLYTIC ANEMIA

A. Gomez-De Leon1, 2, P. Colunga Pedraza1, P. Santana-Hernandez1, G. Sotomayor-Duque1, L.D.C. Tarin-Arzaga1, J.C. Jaime-Perez1, C.H. Gutierrez-Arellano1, O.G. Cantu-Routapu1, D. Gomez-Camargo1

1Hematology, Hospital Universitario Dr Jose Eleuterio Gonzalez Universidad Autonoma de Nuevo Leon, Monterrey, Mexico

Background: Warm autoimmune hemolytic anemia (wAIHA) is an infrequent autoimmune disorder with a high response rate to corticosteroids, albeit relapses are common. Low-dose rituximab has been used successfully in autoimmune cytopenias in an effort to increase response duration, while reducing adverse effects and costs associated with a traditional rituximab dose and prolonged prednisone exposure. Aims: To evaluate the safety and efficacy of low-dose rituximab combined with corticosteroid treatment in newly diagnosed patients with wAIHA. Methods: We performed a single-center, prospective, single-arm, open-label study in adult patients with newly diagnosed "primary" or idiopathic wAIHA from 2013-2016 using high-dose dexamethasone (40mg IV days 1-4) followed by 100mg/kg PO/days 1-5. CR: hemoglobin (Hb) ≥12 g/dL, PR: Hb ≥10 g/dL or increase of ≥2 g/dL. Response was evaluated at day +28, months +6 and +12. Informed consent was obtained from all participants. Results: Eight patients were included. Median age was 32 years (range 18-42), 6 were female. Median Hb at diagnosis was 5.8 g/dL (range 4.8-8.2 g/dL). All patients had response at day +28 (50% CR rate); median time to response was 12 days (range 3-17). During follow-up 7/8 achieved CR (median time to CR: 30 days, range 15-103), all of which were sustained at 6 months. Median follow-up was 24 months (range 6-40). One patient relapsed disease-dependent and relapsed after 12 months, achieving a stable PR after re-treatment with low-dose rituximab. Furthermore, two patients had new-onset immune thrombocytopenia (IT; Fisher-Evans’ syndrome), without hemolysis 6.5 and 6 months
after diagnosis. Two patients were diagnosed with systemic lupus erythematosus during follow-up, they remained in CR. Twelve-month CR rate was 80% (5 evaluable patients). One patient experienced grade 3 neutropenia two months after the last rituximab infusion that resolved without complications. Estimated relapse-free survival was 80% at 2 years (60% if IT is considered). No patient had a splenectomy performed.

Summary/Conclusions: This small study reports favorable outcomes for patients with newly diagnosed wAIHA treated with low-dose rituximab, and adds 8 patients with similar responses to the 7 cases previously published by the Italian group in 2012 and 2015. These results may be comparable to standard doses of rituximab, with a lower cost, and deserves further inquiry. The emergence of additional autoimmune phenomena (SLE, Evans’ syndrome) is unpredictable and can be an obstacle for appropriate data analysis in prospective AIHA studies.

E1416
INFECTIOUS COMPLICATIONS IN PRIMARY AUTOIMMUNE NEUTROPHENIA OF CHILDHOOD
T. Palianopoulos1, A. Giouktis1, N. Chalisos1, A. Makis1
1Department Of Pediatrics, University Hospital Of Ioannina, Ioannina, Greece

Background: Primary autoimmune neutropenia (PAN) of childhood is caused by the action of antibodies against membrane antigens of neutrophils leading to their peripheral destruction. Despite the low neutrophil counts, it is characterized by minor intercurrent infections with rare severe bacterial episodes, which can be a significant cause of morbidity.

Aims: The retrospective evaluation of the incidence and characteristics of infectious complications in children with PAN from one reference academic center in Greece.

Methods: The study included the clinical and laboratory findings of children with PAN, who were diagnosed in our department in the last eight years (2008-2016). All children with neutropenia lasting over 3 months with a positive test for neutrophil antibodies, using the granulocyte immunofluorescence test, the granulocyte agglutination test and the monoclonal antibody immobilization of granulocyte antigen test. Laboratory evaluation for nutritional deficiencies, infections, systemic autoimmune diseases or malignancies was negative. Clinical data related to the occurrence of bacterial infections and treatment, hospitalization and outcome were collected and analyzed.

Results: 48 children with PAN were enrolled; 28 were boys, the median age was 14.5 months (range 5-96) and median follow-up time was 20 months (range 4-93). 19 children (39.6%) all suffering from severe neutropenia (<0.5 x 10^9/L) had to be hospitalized 25 times for bacterial infections; 4 for pneumonia, 7 for acute otitis media, 1 for mastoiditis, 7 for urinary tract infections, 4 for bacterial infections of unspecified site, 1 for perianal abscess and 1 for cellulitis, all with good outcome with proper antibiotic treatment. The average number of hospitalizations due to infections was 0,52/patient and the rate was 0.56/1000 patient-days. G-CSF was administered in 2 children due to severe infection, while 8 children received antibiotic chemoprophylaxis.

Summary/Conclusions: Although rare, infections are an important clinical issue in the management of children with severe PAN, sometimes requiring hospitalization. Early signs of infection should be promptly recognized and accordingly treated.

E1417
NEW EPO-RECEPTOR MUTATION IN A -17 YEAR OLD WOMAN WITH ERYTHROCYTOSIS
B. Robredo1, L. Lo Riso1, B. Lopez1, L. Florensa2, L. Arenillas2, B. Belosillo2, C. Ballester1, A. Perez1, A. Sampol1, L. Arenillas2, L. Florensa2, B. Belosillo2, C. Ballester1, A. Perez1, A. Sampol1, L. Arenillas2, B. Belosillo2
1Pediatric Hematology and Oncology Clinic, Istanbul Kanuni Sultan Suleyman Education and Research Hospital, Istanbul, Turkey
2Pediatric Hematology and Oncology Clinic, Istanbul Kanuni Sultan Suleyman Education and Research Hospital, Istanbul, Turkey

Background: Erythrocitosis is defined when red cell, hematocrit (Hct) and hemoglobin (Hb), are elevated above normal limits. Causes of erythrocitosis can be primary and secondary. Secondary causes are divided into congenital and acquired. There is a group of patients with idiopathic erythrocitosis.

Aims: We present a case report of a novel EPO-Receptor mutation.

Methods: We present a case report of a 17-year-old woman with erythrocitosis. In the control blood test she had hemoglobin of 18.6g/dl and hematocrit of 62%. We contacted the patient and she attended hematology consultations for study and treatment with phlebotomy. The patient had no known drug allergies or toxic habits. She didn't have any known comorbidities or previous treatment. At evaluation she referred chronic headache without other symptoms. The physical examination was normal. At that time, three possible diagnose were suspected. Firstly, primary erythrocitosis, polycythemia vera (PV). In this disease, the bone marrow produces many red cells and the JAK2 V617F mutation has been demonstrated in the majority of patients. exon 12 mutation has been described in patients with PV who did not have the JAK2 V617F mutation. The erythropoietin (EPO) level is undetectable as a compensatory mechanism. In our patient, JAK2 V617F mutation and exon12 mutation were negative and the EPO levels were undetectable (<1.5). The bone marrow aspirate and the bone marrow biopsy were normal. These results show that this patient doesn’t present PV, due to she only fulfilling one diagnosis criteria of PV. Secondly, acquired secondary erythrocitosis can be produced as a compensatory mechanism, including: cardiac or pulmonary disease, smoking, renal artery stenosis, sleep apnea/hypopentilation and malignant tumors. In the patient, pulmonary function test, abdomen ultrasound and kidney function were normal. Endogenous erythrocytosis were positive. Due to the test results, we ruled out the diagnosis of acquired secondary erythrocitosis. Finally, congenital secondary erythrocitosis. Genetic abnormalities have been identified in congenital causes of erythrocitosis. The congenital erythrocitosis are divided into two sets according to EPO levels. If the EPO levels are normal or increased, the patient could present high oxygen-affinity hemoglobin because of bisphosphoglycerate mutase deficiency or mutations in the genes in the oxygen sensing pathway. However, if the EPO levels are decreased, the patient could present an erythropoietin-receptor mutation. Our patient presented undetectable EPO levels and the EPO-receptor mutation was requested. The patient has been treated with phlebotomies and aspirin due to headache with good evolution. In this moment, she presents hematocrit levels of 46.8%.

Results: The test revealed an EPO-receptor mutation (c.1275_1290dup), which had never been described before.

Figure 1.
Summary/Conclusions: The study of the patient with erythrocitosis must begin with a full medical history and confirmation of raised Hb and Hct. In the study of erythrocitosis, after ruling out primary and acquired causes we should always consider the possibility of congenital erythrocitosis, which often is underestimated. When EPO binds to its receptor a signaling cascade is activated, which cause red cells to be produced. This process is switched off when sufficient red cells have been produced by binding of SHP-1. EPO-receptor mutation results in failure of bond of SHP-1, causing uncontrolled production of red cells and erythrocitosis. We describe a new EPO-receptor (c.1275_1290dup) (figure 1).

FAMILIAL HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS IN CHILDREN
Z. Salcigol1,*, G. Aydogan1, F. Aki1, C. Bayram1, A. Ayjdjcik1, G. Oztemir1
1Pediatric Hematology and Oncology Clinic, Istanbul Kanuni Sultan Suleyman Education and Research Hospital, Istanbul, Turkey

Background: Familial hemophagocytic lymphohistiocytosis (FHL) is an autosomal recessive disorder characterized with uncontrollable activation of T-helper lymphocytes and macrophages and over-release of inflammatory cytokines. The only curative treatment is hematopoietic stem cell transplantation (HSCT).

Aims: This study evaluates the clinical and laboratory data of children with FHL. Thirty five FEL cases followed and treated at our clinic between 2005 and 2017 were retrospectively evaluated in our study.

Methods: Information of patients were retrieved from patient files and from the records contained in the electronic information processing environment created after 2005. All patients were treated with HLH-2004 protocol. HSCT was performed in nine patients.

Results: Twenty one of the cases were boys and fourteen were girls. The age at presentation for patients was two week-three years (mean 6.2 months). There was a history of consanguineous marriage in 26 of the families(74%). Fever, anemia, and hypertriglyceridemia were present in all HLH cases. Hepatomegaly was detected in 74%. Splenomegaly was more frequent in patients (87.7%). Thrombocytopenia was detected in all patients. All patients had neutropenia and thrombocytopenia. Hypoferritinemia was present in 94% of patients. Only nine patients found to have hemophagocytosis in the cytological evaluation of the CSF(25.7%). Mutation analysis were performed in 18 patients and of these, 10 had PRF1, 5 had UNC13D, and 3 had STX11 gene mutation. All patients were treated with HLH-2004 protocol. Of the 22 children who were placed in first remission. HSCT was performed in 9 patients (%25.7). The overall mortality rate was 57% (20 cases) in our series. Twenty children died opportunistic infection (n=10) or of disease progression (n=10).
Summary/Conclusions: In conclusion, FHL is a disease with high mortality rates and the only curative treatment is HSCT. Donor search for HSCT must be started and HSCT should be performed after the remission.

E1419
ABNORMAL MONOCYTE POPULATIONS IN THE PERIPHERAL BLOOD OF PATIENTS WITH CHRONIC IDIOPATHIC NEUTROPENIA
M. Velegraki1,*, V. Kaliafentaki1, H. Koutala1, A. Damianaki1, M. Ximeri2, P. Kanellou3, I. Mavroudi4, C. Pontikoglou5, H. Papadaki1
1Department of Haematology, University of Crete School of Medicine, Heraklion, Greece

Background: Chronic idiopathic neutropenia (CIN) is an acquired disorder of granulopoiesis characterized by an unexplained, prolonged reduction in the number of neutrophils and a generally benign and uncomplicated course. Neutropenia in CIN has been mainly attributed to increased apoptotic death of the granulocytic progenitor cells due to abnormal production of pro-inflammatory cytokines and pro-apoptotic mediators. Activated T-lymphocytes with a skewed oligoclonal/monoclonal profile and myelosuppressive properties have also have a major role in the pathophysiology of CIN.

Aims: Monocyte subpopulations display a prominent role in innate immunity but also mediate pro-inflammatory responses and T-cell activation. The monocytic CD14+CD15-/DRneg/low/CD33+/CD11b+ derived suppressor cells (MDSC), in CIN patients.

Methods: We have studied 25 patients fulfilling the well-defined diagnostic criteria for CIN and 10 age and sex-matched healthy individuals. Three-colour flow cytometry was used to assess the peripheral blood monocytes subsets in the gate of CD14 positive cells and five-colour flow cytometry for the evaluation of the myeloid derived suppressor cells in the gate of cells with intermediate/high FSC/SSC properties.

Results: The mean number of neutrophils and monocytes in CIN patients was 1176±496/µl and 412±130/µl, respectively (range 200-1800/µl and 700-2000/µl, respectively). The proportion of classical CD14+CD16- cells was significantly decreased in CIN patients (79.60%±7.60%) compared to the healthy individuals (87.90%±3.70%) (P=0.0009). In contrast, a significant increase was observed in the proportion of non-classical CD14+CD16+ cells as well as the monocytic CD14+CD15/DRneg/low/CD33+/CD11b+ fraction of the myeloid derived suppressor cells (MDSC), in CIN patients.

Summary/Conclusions: CIN patients display increased proportion of circulating intermediate CD14+CD16+ monocytes that may have a role in the aberrant inflammatory responses commonly seen in these patients. The increased proportion of the CD14+CD15/DRneg/low/CD33+/CD11b+ MDSC in CIN may simply reflect a compensatory reaction aiming to suppress the T-cell activation. Isolation of the above cell populations and transcriptome studies are currently in progress in our laboratory.

RITUXIMAB IN AUTOIMMUNE HEMOLYTIC ANEMIA OF INFANCY
M. Economou1,*, A. Tei1, D. Adamidou2, A. Taparkou1, E. Farmaki1
1Aristotle University of Thessaloniki, 2Blood Bank, Hippokration General Hospital, Thessaloniki, Greece
Background: Autoimmune hemolytic anemia (AIHA) is not commonly seen during childhood, and is extremely rare in infancy. Absence of guidelines render management of the disease difficult in children – and even more so in infants.

Aims: Aim of the report is to present a number of cases of infantile AIHA, refractory to conventional treatments, demonstrating response in administration of rituximab.

Methods: The report concerns four infants (3 baby girls and one baby boy) who presented with AIHA. Data including demographics, personal and family medical history, immunologic assessments, previous treatments and response to rituximab were studied.

Results: Age at diagnosis of AIHA was 4-6 months. In 3 cases (cases number 1, 2 and 3) personal and family history, as well as laboratory screening at diagnosis, did not reveal presence of any other hematologic, autoimmune or immunologic condition. In case number 4 AIHA followed the diagnosis of giant cell hepatitis. Hospitalization before rituximab administration ranged between 1 and 5 months, with multiple transfusions, administration of intravenous immunoglobulin (maximum dose 6g/kg), repeated doses of intravenous methyl-prednisolone (30mg/kg) followed by oral prednizolone (max 5mg/kg), all failing to achieve sustained response. Rituximab was administered at 370mg/m² in 4 weekly infusions. In 3 infants 5 monthly infusions followed. Stabilization of hemoglobin and improvement of hemolytic parameters were observed after the 3rd-4th weekly infusion in all infants. In 3 patients (no 1,2,3) CD19+ and CD20+B cell assessment before and after rituximab administration was performed. Complete elimination (<1%) was observed in all patients after the 1st-2nd infusion. Despite B cells returning to normal 11 months after treatment, infant no 1 remained in clinical remission during follow-up (22 months post treatment). Infant no 2 remained in clinical remission for the 16 month post treatment follow-up, despite B cell normalization. Infant no 3 relapsed following B cell normalization, 11 months after rituximab administration. Infant no 4 did not undergo B cell measurements and relapsed one year after completing rituximab therapy. The 2 patients that relapsed were re-treated with 4 rituximab infusions: patient no 3 remained well for the 18 month follow-up, whereas patient no 4 remained well for 10 years – again relapsing and receiving her 3rd rituximab treatment with good response for the remaining 7 month follow-up. None of the patients presented with adverse reactions during the infusions or with severities resulting in hospitalization. However, infant no 1 developed asymptomatic progressive IgG hypogammaglobulinemia 11 months after initial exposure to rituximab, eventually requiring IVIG administration.

Summary/Conclusions: Rituximab administration in refractory AIHA seems to be efficacious and safe in infants. However, close follow-up is warranted in order to ensure absence of long term complications, including the risk of post-treatment hypogammaglobulinemia, when the drug is administered at such young ages.

CONGENITAL ERYTHROCYTOSIS: DISCOVER OF A NEW MUTATION
J. Barradas1,2, P. Rocha1, C. Dantas Rodrigues1, C. Constanço2, M. Reis Andrade1, C. Bento1, H. Matos Silva1
1Servicio de Hematología Clínica, Centro Hospitalar Tondela-Viseu, Viseu, 2Servicio de Hematología Clínica, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

Background: Congenital erythrocytosis (CE) is a rare hereditary disorder of red cell production, characterized by an absolute increase in red cell mass with elevated hematocrit and hemoglobin levels not accompanied by increased oxygen affinity, and the absence of clinical symptoms. CE is a hereditary congenital disorder with a prevalence of 1 in 300,000 individuals. A total of 25 genes are known to be associated with CE. Most cases are due to mutations in the PHD2 gene which encodes prolyl hydroxylase domain 2 (PHD2), an enzyme involved in the control of EPO synthesis, by the HIF hydroxylation pathway.

Aims: To retrospectively analyze 44 patients diagnosed with CE in our center.

Methods: We performed whole-exome sequencing of 20 patients with a strong family history. A set of patients in whom targeted re-sequencing had been performed for the diagnosis of CE were included. In a further 22 patients, targeted re-sequencing of PHD2 and JAK2 genes was performed in order to exclude cases previously diagnosed and treated for myeloproliferative neoplasms.

Results: We identified a new mutation in PHD2 gene associated to CE. The mutation is a novel frameshift mutation (c.563_565del3, p.Leu188fs) located in the presence of oxygen, and the absence of 5p21.3 chromosomal region. This mutation was present in all probands from the same family and was co-segregated with the clinical manifestations of CE.

Summary/Conclusions: The presence of oxygen, and the absence of 5p21.3 chromosomal region. This mutation was present in all probands from the same family and was co-segregated with the clinical manifestations of CE.

E1426
A RETROSPECTIVE STUDY OF THE THROMBOTIC MICROANGIOPATHIES DIAGNOSED IN THE LAST 17 YEARS IN ONE SINGLE CENTRE
A. Esteban Figuerola1,*, M.M. Olona Cabases2, R. Vallansot1, C. Talarn Forcadell1, L. Ramiro Infante1, A. Martínez Bea1, A. Bodí Saeara1, J. Sarrá Escarell1, L. Escoda Teigell1
1Hospital Joan XXIII Tarragona, Tarragona, Spain, 2Preventive Medicine Unit, 3Nefrology, 4Intensive Care Unit, Hospital Joan XXIII Tarragona, Tarragona, Spain

Background: Thrombotic microangiopathies (TMA) are characterized by the formation of platelet thrombi that obstructs vital organ microcirculation. The presence of the 5 classic parameters (haemolytic anemia, thrombocytopenia, fever, oliguria and neurological affection) is rare. ADAMTS13 determination allows a more accurate diagnosis than the presumption based on clinical and biochemical parameters.

Aims: To retrospectively analyze 44 TMA patients diagnosed in our centre in the last 17 years and characterize TTP, HUS and secondary TMA (sTMA) by biochemical parameters.

Methods: We then proceeded to sequencing of gene included in EPO-induced signaling pathway and it was detected a new mutations in PHD2 gene (F366L), in heterozygous state. The mutation was detected in all probands from the same family and was co-segregated with the clinical manifestations of CE.

Summary/Conclusions: The mutation was detected in all probands from the same family and was co-segregated with the clinical manifestations of CE.

E1424
EARLY LESSONS FROM WHOLE-EXOME SEQUENCING IN THE CLINICAL DIAGNOSIS OF RARE AND UNRATIONALIZED ANEMIAS
1Molecular Haematology Unit, 2BRC Molecular Diagnostic Centre, Oxford University Hospitals NHS Trust, 3Comprehensive Biomedical Research Centre, Weatherall Institute of Molecular Genetics, University of Oxford, 4Molecular Haematology Unit, Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, United Kingdom

Background: Targeted re-sequencing has recently been adopted for the rapid diagnosis of anaemia patients whose disease is likely to have a genetic basis, however, currently results remain inconclusive in 30-60% of cases. Whole-genome sequencing (WGS), provides more uniform coverage than amplification-based panels and is allied to an unbiased approach offering the opportunity to explore both coding and non-coding regions. It is also possible to use WGS data to detect copy number variation with good resolution and sensitivity. Therefore WGS has the potential to offer an accurate molecular diagnosis in a proportion of unsolved anaemia cases and may therefore be a superior initial approach. Furthermore, WGS is likely to lead to the identification of novel genes involved in pathogenic and normal erythropoiesis.

Aims: To undertake WGS in a set of patients in whom targeted re-sequencing had not been able to identify a molecular cause for the inherited anaemia, in an attempt to increase the diagnostic yield of the molecular analysis of such patients and provide novel candidate genes as causative of anaemia.

Methods: We performed WGS of 20 individuals (2 siblings and 6 trios) at 30X coverage where the probands have a rare anaemia of suspected genetic origin. Proband were pre-screened with a targeted panel containing ~50 candidate genes, none of which had harboured likely causative variants. Analysis of WGS data involved Stampy for read alignment, Platypus for variant calling and Ingenuity Variant Analysis (Qigian) for variant annotation and filtering, followed by functional validation and verification of all candidate variants.

Results: Known causative variants in a gene absent from the targeted panel were detected in two patients (25%), whereas candidate variants in novel genes not previously associated with anaemia were identified across the other six cases. Familial segregation and functional studies are underway to provide further evidence of causality for these novel variants, of which 60% are in genes with previous evidence of a role in erythropoiesis and 40% in genes with no known role in erythroid development.

Summary/Conclusions: These results illustrate the overlap in phenotypic abnormalities existing among these conditions and the importance of providing an erythropoiesis and molecular diagnosis to enable correct diagnostic and clinical manage-ment of anaemia patients. We also demonstrate the benefit of using WGS over targeted resequencing given the difficulty of designing comprehensive gene panels and keeping them up-to-date as new candidate genes are identified.
CHILDREN WITH CHRONIC-REFRACTORY AUTOIMMUNE CYTOPENIAS: A SINGLE CENTER EXPERIENCE

T.H. Karapan1, Y. E. Dungur1, Y. Cymak1, N. Güleş2, Y. A. Yav1, Ay. Genel2, S. Gözmén1, E. Serdaroglu3, S. Aydin Köker1, E. Töret1, C. Vergin1
1Pediatric Hematology and Oncology, 2Pediatric immunology, 3pediatric nephrology, Dr. Behcet Uz Children Training and Research Hospital, Izmir, Turkey

Background: Autoimmune cytopenias are a group of heterogeneous disorders characterized by immune-mediated destruction of one or more hematopoietic lineage cells. They can be idiopathic or occur as a manifestation of other underlying disorders, such as autoimmune diseases, immunodeficiency, autoimmune lymphoproliferative syndrome, tumors, medications or infections.

Aims: The aim of this study was to evaluate the clinical course and significance of autoimmune cytopenias due to immunodeficiency or autoimmune diseases in children followed up at our hospital.

Methods: A total of 337 files of information belong to patients with chronic or refractory autoimmune cytopenias were included in this study. Data were analyzed retrospectively at our hematology department between February 1997 and September 2015. Ultimately, patients with immune deficiency or autoimmune diseases (23 patients) were included in this study. Data were analyzed using SPSS 15.0. The results are presented as the mean, SD, median, absolute number, or percentile.

Results: Two-thirds of the patients with chronic or refractory autoimmune cytopenias (6.8%) had an immune deficiency or an autoimmune disease. The median age of diagnosis was 3.1 years (between 6 months-16 years) and the ratio of male/female was 1.3. The median duration of following was 2.6 years (between 4 months and 18.5 years). A total of 13 patients (56.5%) had single-lineage cytopenias and 10 (46.5%) had multi-lineage cytopenias. Shows last diagnosis of the patients. In 10 of the patients, first cytopenia was detected before the primary diseases were diagnosed after median 2 months (between 0 and 77 months). Only one patient firstly had been diagnosed as CVID, cytopenia has developed after years. All of the patients were treated with corticosteroids or intravenous immune globulin (IVIG) as first-line treatment. Ten patients needed second or further-line immunosuppressive therapies including rituximab, mycophenolate mofetil, cyclosporine A, azathioprine, and chloroquine. A total of 8 patients (34.7%) recovered from autoimmune cytopenias after the treatment of primer disease. That diseases were diagnosed as systemic lupus erythematosus in 4 patients, hypogammaglobulinemia in 3 patients, and celiac disease in 1 patient. Cytopenias have continued in 14 of the patients. One patient with CVID died.

Summary/Conclusions: Cytopenias may be the first finding of an immunodeficiency or autoimmune disease and primary may be diagnosed in the clinical course. Early diagnosis is important because of beginning to the early treatment of underlying disease.
Background: Hemophagocytic lymphohistiocytosis (HLH) is a rare, potentially fatal hyperinflammatory syndrome, which in its most common, secondary form, can be induced by infection, malignancy or autoimmune disease. Diagnosis of HLH is made when at least five of eight clinical and laboratory HLH-2004 criteria are met. However, diagnostic criteria were established based on studies from pediatric patients, and it is debated if they can be applied to adults. Assessment of these criteria can be subjective (microscopic identification of hemophagocytes), time-consuming or not easily available (e.g. molecular analyses, functional tests of NK-cells).

Aims: The aim of the study was to evaluate phenotypic findings from flow cytometric (FC) analyses of bone marrow (BM) and other tissue samples from patients with hematological malignancies (HM) who developed HLH. The study was intended to investigate potential utility of a rapid phenotypic screening in diagnostics of suspected HLH.

Methods: Flow cytometric files for 42 patients with HM were retrieved from archive of the Department of Clinical Pathology and Cytology, Karolinska University Hospital. The patients were diagnosed and treated for HM-HLH at the Hematology Center of the same hospital, between 2009 and 2016. Tissue samples (bone marrow, peripheral blood, lymph nodes) were analyzed according to standard procedures, using monoclonal antibodies (BD, DAKO, Beckman Coulter, BioLegend). Cells were acquired using 4-color Canto A or 8-color Canto II cytometers (BD), and analyzed with BD FACS DIVA software. Neoplastic clones of myeloid or lymphoid character were excluded from reanalysis for the purpose of this study. Bone marrow samples were obtained from 31 patients shortly before and from 24 patients following HLH-diagnosis; in 13 patients paired BM samples were available.

Results: Patient characteristics are presented in table 1. Bone marrow B-cell lymphopoenia was observed in 67% patients before and 74% after HLH diagnosis. Decreased amounts of NK-cells were noted in 49% persons at both time points. T-cell lymphopenia before HLH diagnosis was noted in 60% patients with myeloid malignancy but in only 25% cases of lymphoid malignancy, whereas in established HLH the respective figures were 27% and 46%. CD4/CD8 ratio was skewed-to-normal in both myeloid and lymphatic tumors before HLH was diagnosed. In cases of confirmed hyperinflammation, patients with myeloid tumors showed dominance of CD4+ cells but no such difference was noted in lymphoid disease. Loss of lineage specific markers of non-neoplastic T-cells was a constant feature in lymphoid malignancy, whereas aberrant expression of lymphatic markers (CD2, CD7, CD56) on myeloid cells was uniform in patients with myeloid tumors. Monocytosis was more often observed in myeloid as compared to lymphoid tumors at HLH onset (40% vs 31%), although it was of non-neoplastic character. However, monocytopenia was also noted in cases of established HLH, in 10% of myeloid malignancies and 15% of lymphatic malignancy cases.

Table 1.

Summary/Conclusions: In the presented cohort, quantitative shifts could be observed in BM samples around the time of HLH onset. However, different patterns were observed between patients affected by lymphoid or myeloid malignancies, which have an impact disease-specific impact on BM microenvironment. Further study will be carried out to confirm findings in a large, possibly prospectively collected patient group. Control group of patients with respective malignancies but without HLH will be included.

E1431

A MULTICENTRE, SINGLE ARM, OPEN LABEL STUDY EVALUATING THE EFFICACY AND SAFETY OF ERTOMBOPGAG IN PATIENTS WITH SEVERE PERSISTENT IMMUNE THROMBOCYTOPENIC PURPURA (ITP) WITHIN SIX MONTHS OF DIAGNOSIS

H. Tran1,2, R. Biru1, S. Chunilal3, T. Brightman4, J. Reynolds5, S. He6, C. Mazis1, R. Hall1, P. Shuttleworth1, A. Grigg7

1Clinical Haematology, The Alfred Hospital, 2Clinical Haematology, Monash University, Melbourne, 3Clinical Haematology, Princess Alexandra Hospital, Brisbane, 4Clinical Haematology, Monash Health, Melbourne, 5Clinical Haematology, Prince of Wales Hospital, Sydney, 6Clinical Epidemiology and Preventative Medicine, Monash University, 7Clinical Haematology, Austin Hospital, Melbourne, Australia

Background: Patients with acute ITP who fail or are dependent on steroids or intravenous immunoglobulin (IVig) are often committed to splenectomy or pro- longed immunosuppression. Splenectomy is potentially curative but not without operative risk with many patients reluctant to undergo surgery, while the response to immunomodulation is often suboptimal with significant side effects. Although effective, to date, there is no published studies evaluating the benefit of eltrombopag among steroid dependent or resistant, non-splenectomised ITP patients diagnosed within 6 months.

Aims: To evaluate the efficacy and safety of eltrombopag in patients with severe "acute" and persistent ITP within 6 months of diagnosis.

Methods: A multicentre, single arm open label study involving 39 patients with refractory ITP with platelet count of ≥30x10^9/L despite a daily dose of prednisolone of 1mg/kg for at least 2 weeks from diagnosis OR (b) requiring prednisolone ≥10mg daily and/or recurrent doses of IVig to maintain a platelet of ≥30x10^9/L within 6 months of diagnosis. Prior splenectomy was not a requisite.

E1430

BLEEDING IN PRIMARY IMMUNE THROMBOCYTOPENIA: WHO ARE MOST AT RISK?

U. Doobare1, S. Hodges1, R. Nandigam1, A. Newland1, D. Provans1

1Haematology, Barts and The London School of Medicine and Dentistry, London, United Kingdom

Background: Primary Immune Thrombocytopenia is rare disorder in which patients are at risk of bleeding due to autoimmune-mediated platelet destruction. Aims: This study focused on describing the prevalence and types of bleeding events around the time of ITP diagnosis and after, as well as identify any factors that can potentially influence the risk of bleeding.

Methods: Data from the United Kingdom Immune Thrombocytopenia Registry were analysed for this study. The registry obtained its data from about 70 centres around the UK. Descriptive and logistic regression statistical techniques were used for this study.

Results: This analysis was based on 2365 (57.8% females) participants who are part of the Registry. The median age at diagnosis was 50 years (IQR 32, 66) and 77% of these patients were of European ethnicity. The commonest comorbid conditions was hypertension (23%). Median platelet count was 19 (IQR: 5, 53). Eighty percent had a platelet count below 30x10^9/L at ITP diagnosis. The most common bleeding events were skin-related (46.5%) and to the oral cavity (14.4%). About 70% of the cohort experienced at least one bleeding event at some point after diagnosis. After ITP diagnosis the most common bleeds were again skin-related (34.3%) and oral cavity bleeding (14.8%). Epistaxis had risen from 11.6% before diagnosis to 17.7%. Bleeding at other sites did drop. However, the prevalence of intracranial haemorrhage rose from 0.9% pre-diagnosis to 1.2% after diagnosis. Prednisolone (79%) and IVig (43%) were the most used drugs followed by rituximab (28%) among those who were treated. Ropiniplomist (15%) and Ertrombopag (9%) are used too but not anymore than mycophenolate (18%) and azathioprine (22%). Fourteen percent of the cohort had a splenectomy at some point. Age but not gender or ethnicity were found to be associated with having a bleeding event around the diagnosis of ITP. Both children (<18 years old) and adults (>70 years) who were at risk. Platelet counts, expectedly, was associated with bleeding with those presenting with a platelet < 30x10^9/L were at higher risk. No comorbid illness or cotherapies were found to be associated with bleeding events.

Summary/Conclusions: The frequency of bleeding decreased for most sites but for some others a slight increase has been observed since ITP diagnosis. It is possible that bleeding events may have been recorded more accurately or observed more closely and over a longer period of time since diagnosis. However, control of bleeding was an issue after the diagnosis of ITP. Future analysis stratifying its findings by time periods would be beneficial in describing if bleeding events were better controlled over the last few years, especially after the introduction of new therapeutic agents and the publication of the internal consensus report on the diagnosis and management of primary ITP.

FLOW CYTOMETRIC ANALYSIS OF TISSUE SAMPLLES IN 42 ADULT PATIENTS WITH MALIGNANCY-ASSOCIATED HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS

M. Klimkowska1, C. Arlind1, K. Kosior1, M. Machaczkaz1,2

1Department of Clinical Pathology and Cytology, 2Hematology Center, Karolinska University Hospital, Stockholm, Sweden, 3Medical Faculty, University of Rzeszow, Rzeszow, Poland

Results: Paired BM samples were available. Clones of myeloid or lymphoid character were excluded from reanalysis for the purpose of this study. Bone marrow files for 42 patients with hM were retrieved from archive of the Department of Clinical Pathology and Cytology, Karolinska University Hospital. The patients were diagnosed and treated for hM-HLH at the Hematology Center of the same hospital, between 2009 and 2016. Tissue samples (bone marrow, peripheral blood, lymph nodes) were analyzed according to standard procedures, using monoclonal antibodies (BD, DAKO, Beckman Coulter, BioLegend). Cells were acquired using 4-color Canto A or 8-color Canto II cytometers (BD), and analyzed with BD FACS DIVA software. Neoplastic clones of myeloid or lymphoid character were excluded from reanalysis for the purpose of this study. Bone marrow samples were obtained from 31 patients shortly before and from 24 patients following HLH-diagnosis; in 13 patients paired BM samples were available.

Results: Patient characteristics are presented in table 1. Bone marrow B-cell lymphopenia was observed in 67% patients before and 74% after HLH diagnosis. Decreased amounts of NK-cells were noted in 49% persons at both time points. T-cell lymphopenia before HLH diagnosis was noted in 60% patients with myeloid malignancy but in only 25% cases of lymphoid malignancy, whereas in established HLH the respective figures were 27% and 46%. CD4/CD8 ratio was skewed-to-normal in both myeloid and lymphatic tumors before HLH was diagnosed. In cases of confirmed hyperinflammation, patients with myeloid tumors showed dominance of CD4+ cells but no such difference was noted in lymphoid disease. Loss of lineage specific markers of non-neoplastic T-cells was a constant feature in lymphoid malignancy, whereas aberrant expression of lymphatic markers (CD2, CD7, CD56) on myeloid cells was uniform in patients with myeloid tumors. Monocytosis was more often observed in myeloid as compared to lymphoid tumors at HLH onset (40% vs 31%), although it was of non-neoplastic character. However, monocytopenia was also noted in cases of established HLH, in 10% of myeloid malignancies and 15% of lymphatic malignancy cases.

Table 1.

Summary/Conclusions: In the presented cohort, quantitative shifts could be observed in BM samples around the time of HLH onset. However, different patterns were observed between patients affected by lymphoid or myeloid malignancies, which have an impact disease-specific impact on BM microenvironment. Further study will be carried out to confirm findings in a large, possibly prospectively collected patient group. Control group of patients with respective malignancies but without HLH will be included.
Patients with platelets <10x10^9/L will commence on eltrombopag at 75mg daily; those with a count ≥10x10^9/L will commence on 50mg daily. A reduced dose is used for subjects of East Asian heritage. The dose of eltrombopag can be progressively increased by 25mg increment every 2 weeks to maximum of 150mg daily (patients of East Asian heritage should have a maximum eltrombopag dose of 100mg daily) if the platelet count remains ≤30x10^9/L or there is clinically significant bleeding every 2 weeks. The dose can be progressively weaned to zero over the subsequent 6 weeks if clinically appropriate. The primary endpoint was overall response rate (ORR) at week 12, defined as the proportion of patients achieving complete response (CR; platelet >100x10^9/L), partial response (PR; platelet >50x10^9/L) or minor response (MR; platelet 30-50x10^9/L) with ≥50% reduction in the dose intensity of concomitant ITP therapy compared with screening. The protocol specified a 1-sided 5% level binomial test of the null hypothesis that ORR at week 12 ≤30% and reporting of a 90% two-sided confidence interval (CI).

**Results:** Of the 39 patients enrolled, 46% were women, median (Q1, Q3) age was 81 (74, 87) years, and median (Q1, Q3) time from diagnosis to ITP/AML diagnosis was 2.2 (1, 5.4) months, and median (Q1, Q3) screening platelet count was 21(13, 34) x10^9/L. Prior treatments included steroids (95%), IVIG (58%), and immunosuppression (28%). 35 patients (90%) completed 12 weeks of treatment, 4 (10%) discontinued eltrombopag prior to week 12 [3 required new ITP therapy; 1 developed thrombotic microangiopathy at platelet 97x10^9/L; one pulmonary embolism at platelet 240x10^9/L). At week 12, the ORR was 64% (p<0.0001; 90% CI: 51-77%); CR, PR, MR rates were 41%, 15%, and 4% respectively and the median (Q1, Q3) platelet count among responders was 168 (98, 252)x10^9/L. At week 26, the ORR was 54% (90% CI: 40-67%); CR, PR, MR rates were 28%, 21% and 5% respectively. Two patients had serious adverse events (SAEs) with two episodes of venous thromboembolism (one deep vein thrombosis at platelet 97x10^9/L; one pulmonary embolism at platelet 240x10^9/L). There were no other adverse events or deaths.

**Summary/Discussion:** The majority of patients with ITP diagnosed for ≤6 months had a favourable overall response rate to eltrombopag and the drug was generally well tolerated. Longer-term follow up data (beyond 6 mos) will be presented at the meeting.
NORDIC COUNTRY PATIENT REGISTRY FOR IMMUNE THROMBOCYTOPENIA (NCPaITP): A COHORT OF PATIENTS WITH CHRONIC IMMUNE THROMBOCYTOPENIA IN DENMARK, SWEDEN, AND NORWAY

Christiansen, S. Bahmanyar, W. Ghanimi, K. Kristensen, S. Stryker, J. Acquavezza, K. Ketin, M. Nargard, H. Sorensen

Clinical Epidemiology, Aarhus University Hospital, Aarhus, Denmark. 2Clinical Epidemiology Unit & Center for Pharmacoepidemiology, Department of Medicines, Karolinska Institutet, Stockholm, Sweden. 3Department of Medicine, Östfold Hospital Trust, Fredrikstad, Norway. 4Center for Observational Research, Amgen Inc, San Francisco. 5Center for Observational Research, Amgen Inc, Thousand Oaks, United States

Background: Immune thrombocytopenia (ITP) is a rare disease characterized by isolated platelet counts and an increased tendency to bleed. As yet, there have been no large, multi-country, population-based cohorts established to describe its long-term clinical course and investigate the effectiveness and safety of related therapies.

Methods: Encompassing Denmark, Norway, and Sweden, the NCPaITP started as a population-based post-authorisation safety study to assess the long-term safety of romiplostim in treating ITP. It includes patients with prevalent chronic ITP (cITP – ITP lasting >6 months) as of 04/01/2009 and a history of ITP diagnosed from 04/01/2009-12/31/2014, confirmed through medical record review. Since the start of the registry, guidelines have changed to define cITP as ITP lasting >12 months. For consistency, incident cases of ITP for a duration of >6 months will continue to be accrued through 2019. Through linkage of data from the national health registries and medical record review, the registry has rich clinical information for all enrolled ITP patients, as well as comorbidities (including scores according to the Charlson Comorbidity Index [CCI] – a validated tool developed to predict 1-year mortality), treatments, lab values (e.g., platelet counts), and complete follow-up for several clinical outcomes of interest (e.g., clinically significant bleeding, the need for rescue therapies, and thrombotic/thrombotic events). Additionally, available bone marrow samples are maintained and reexamined for reticulin and collagen content to assess Thiele’s myelofibrosis (MF) grading.

Results: The NCPaITP includes 3,749 patients with confirmed cITP (35% Danish, 51% Swedish, and 14% Norwegian), with a female preponderance (58%) and median age of 56 years at cITP diagnosis. Forty-one percent of the cohort was prevalent at study inclusion; 59% represent incident cITP patients. Median follow-up time thus far is 4.3 years. At study enrollment, 24% had a platelet count <50×10⁹/L. 18% were splenectomized, and 41% had at least one previous ITP therapy (mainly oral glucocorticoid steroids). The majority (68%) of the cohort had no underlying conditions included in the CCI at study enrollment, but 8% had a CCI score of 3 or higher, indicating severe comorbidity. Of note, based on hospital diagnoses of specific comorbidities recorded within 5 years before study enrollment, 12% had a history of stroke, 9% had diabetes, and 18% had a history of hypertension. Currently, 718 bone marrow samples from 566 patients have been retrieved.

Summary/Conclusions: The NCPaITP provides an example of how, within the Nordic countries’ uniform health care systems, registries can be established to study the clinical course of rare diseases such as ITP and the safety of drugs used to treat these patients.

E1436

EPIDEMIOLOGY OF PRIMARY IMMUNE THROMBOCYTOPENIA (ITP) IN ADULTS IN RUSSIAN FEDERATION (RESULTS OF REGISTRY OF NATIONAL HEMATOLOGIC ASSOCIATION)

A. Melikyan, E. Pustovaya, M. Kalinina, V. Volodicheva, T. Kaporskaya, R. Iliaev, B. Babaeva, O. Berekko, V. Bogova, E. Zolotka, I. Zolotva, I. Kontievskiy

Background: Immune thrombocytopenia in adults in Russia.

Methods: To describe the establishment of the NCPaITP and the characteristics of patients enrolled.

Aims:

1. Standartisation of methods of therapy, National Research Center for Hematological Hospital, Amursk, 14
2. Hematology, Regional Clinical Hospital, Khabarovsk, 14
3. Department of Medicine, Østfold Hospital Trust, Fredrikstad, Norway, 4
4. Center for Observational Research, Amgen Inc, San Francisco, 5
5. Center for Observational Research, Amgen Inc, Thousand Oaks, United States

Results:

1. 566 patients have been retrieved.
2. 8% had a history of a solid tumor, 9% had a history of diabetes, and 18% had a history of hypertension. Currently, 718 bone marrow samples from 566 patients have been retrieved.

Summary/Conclusions:

1. The NCPRaITP provides an example of how, within the Nordic countries’ uniform health care systems, registries can be established to study the clinical course of rare diseases such as ITP and the safety of drugs used to treat these patients.

E1437

ELTROMBOPAG (EPAG) FOR THE TREATMENT OF PATIENTS AGED ≥65 YEARS WITH CHRONIC IMMUNE THROMBOCYTOPENIA (CITP): SAFETY AND EFFICACY RESULTS FROM THE EXTEND STUDY

A. Salama, R. Wong, A. Khelif, M.N. Saleh, B. Meddeb, O. Ocak Arkan, E. Quefe-Fehling, J.B. Bussel

Background: ITP is an acquired autoimmune disorder characterized by isolated platelet count reduction, which is chronic when present for >12 months. Evidence suggests that age may influence both the hemorrhagic manifestations of ITP and also response and adverse events (AEs) associated with some therapies. Changes in drug metabolism can contribute to increased AE rates in patients (pts) ≥65 yrs compared with younger adults. The oral thrombopoietin-receptor agonist, EPAG, is approved for the treatment of previously treated (eg corticosteroids, immunoglobulins) CITP pts, but limited data are available in pts ≥65 yrs old. The EXTEND study was a global, open-label, extension study that evaluated long-term efficacy, safety and tolerability of EPAG in adults with cITP who had participated in prior EPAG studies.

Aims:

1. To describe the efficacy, durability of response, and safety of EPAG use in pts with cITP aged ≥65 yrs.

Methods:

1. All pts on EXTEND started EPAG at 50mg/day, titrated to 25–75mg/day or less often as required, based on individual platelet count responses: to achieve counts in the range ≥50–200×10⁹/L. Maintenance dosage con- nected to individual platelet count response or minimization of CITP medication and optimization of EPAG dosing. Pts could remain on EPAG either for 2 yrs in countries where EPAG was commercially available, or for ≥2 yrs until EPAG became commercially available.

Results:

1. At baseline (BL), 50/302 pts (17%) on EXTEND were ≥65 yrs old. At BL, 50 (50% of 50 yrs) achieved ≥50×10⁹/L, 24 (48%) were splenectomized. 52% were female and 74% had platelet counts <30×10⁹/L. Twenty-four pts (48%) withdrew early from the study, most commonly because of AEs (n=8, 16%), other reasons (n=7, 14%) and lack of efficacy (n=5, 10%). Median exposure duration was 2.3 yrs (range, 2 days to 7.9 yrs) and mean daily dose was 49.9 (range, 11–74 mg). In general, 43 (86%) pts achieved platelets ≥50×10⁹/L without rescue therapy; 37 (74%) achieved platelets ≥50×10⁹/L for ≥50% of assessments. 26 (52%) maintained platelet counts continuously ≥50×10⁹/L for ≥22 weeks (Fig. 1).

Medication time maintaining platelet counts >50×10⁹/L and twice BL values,

haematologica | 2017; 102(s2) | 587

Madrid, Spain, June 22 – 25, 2017
while not receiving rescue treatment, was 78 (range, 0–350) weeks. Incidence of bleeding symptoms (WHO grades 1–4) decreased from BL (86%) to 1 yr (15%). AEs were reported in 47 (94%) pts, most frequently nasopharyngitis (n=13, 26%), constipation (n=12, 24%), fatigue (n=12, 24%), diarrhea, arthralgia, urinary tract infection, cataract and cough (all n=11, 22%). Serious AEs occurred in 24 (48%) pts, most frequently >5% cataracts (n=7, 14%), pneumonia (n=4, 8%) and urinary tract infection (n=3, 6%). The most frequent AEs with suspected relationship to study drug were cataracts (n=4, 8%), headache, fatigue, and increased ALT, AST and bilirubin (all n=3, 6%).

Figure 1.

Summary/Conclusions: The efficacy of EPAG in cITP pts >65 yrs was consistent with that seen with the overall EXTEND study population (Bussel et al. Haematologica 2016;111[1]:SS17), with sustained platelet increases and reduced bleeding. EPAG was well tolerated; AE rates were similar to that reported in the overall EXTEND study population, but an apparent increase in cataracts was observed in pts >65 yrs old (cataract incidence was 7% and 22% in <65 and >65 age groups, respectively). Further outcomes in patients >65 yrs old will be presented. Results should be interpreted with caution as almost half of the pts withdrew from the study. EPAG is an effective treatment option for certain cITP pts >65 yrs; its use should incorporate baseline cataract screening and regular monitoring.

E1438

SAFETY AND EFFICACY OF THROMBOPOIETIN RECEPTOR AGONISTS IN PATIENTS WITH PREVIOUSLY TREATED CHRONIC IMMUNE THROMBOCYTOPENIA: A SYSTEMATIC REVIEW AND META-ANALYSIS

Y. Yamada1, T. Fuji2, C. Cromwell3, I. Shapira3
1Medicine, Mount Sinai Beth Israel, New York, 2Internal Medicine, University of Hawaii, Honolulu, 3Hematology, Mount Sinai Beth Israel, New York, United States

Background: The current American Society of Hematology guideline recommends the use of thrombopoietin receptor agonists, eltrombopag or romiplostim as the second-line therapies for chronic immune thrombocytopenia (ITP). The safety and efficacy of those drugs have been tested in several clinical trials. However, the safety profile was not consistent throughout trials and is not yet well understood.

Aims: We herein conducted a meta-analysis of randomized controlled trials to compare the safety and efficacy of thrombopoietin receptor agonists: eltrombopag or romiplostim versus placebo in patients with previously treated chronic ITP. Our primary outcome was drug-related adverse events greater than CTCAE grade 3.

Methods: We performed a literature search in MEDLINE, EMBASE, Cochrane library, and the American Society of Hematology website up to September, 2015 by two independent authors according to PRISMA guideline. We included only randomized clinical trials comparing eltrombopag or romiplostim versus placebo. Random-effects model was used to estimate pooled Odds Ratio (OR). Results: A total of eight trials including 834 participants were included in the analysis. There was no significant difference of grade 3 or higher adverse events, such as thromboembolism, this meta-analysis showed that thrombopoietin receptor agonists are safe, well-tolerated, and effective in patients with previously treated chronic ITP.

E1439

CHILDHOOD IMMUNE THROMBOCYTOPENIA: A NATIONWIDE COHORT STUDY ON CONDITION MANAGEMENT AND OUTCOMES

N. Alajdi1, C. Nordon2, G. Leverger3, T. Leblanc1, L. Grimoldi-Bensouda2
1CHU Bordeaux, Bordeaux, 2LASER, 3CHU Robert Debré, Paris, France

Background: Little is known about the management of pediatric ITP in real life, that is, routine clinical practice. Moreover, the predictive value of these factors upon disease outcome was explored individually and therefore the confoundment of other cell lineages remains unknown.

Aims: With this nationwide prospective cohort study, our objectives were to explore (1) the factors associated with treatment initiation (vs. watchful waiting) in children with primary immune thrombocytopenia (ITP) followed in routine clinical practice and (2) the predictors of chronicity at 12 months.

Methods: Between 2008 and 2013, 23 centers throughout France consecutively included 257 children aged 6 months to 18 years and diagnosed with primary ITP over a 5-year period. Data on ITP clinical features along with medical management were collected at baseline and 12 months. Multivariate logistic regressions were used to determine (1) and (2) as defined above, providing odds ratio (OR) with 95% confidence intervals (95%CI).

Results: 137 (53%) children were males, median age 4.6 years, median platelet count was 7x109/L, and 214 (81%) patients initiated medication. Factors independently associated with treatment initiation included platelet counts <10x109/L (p<0.0001) and mucocutaneous bleeding symptoms at baseline (p<0.001). At 12 months, data were available in 211 (82%) children, of whom 130 (74%) had recovered. Predictors of chronicity included female gender (OR=2.2; 95% CI=1.0–4.8), age ≥10 years (OR=2.6; 95% CI=1.1–6.0) and platelet counts ≥10x109/L (OR=3.2; 95% CI=1.5–6.9).

Summary/Conclusions: In routine clinical practice, the decision to apply a watchful-waiting strategy seems to be driven by platelet counts even in the absence of bleeding symptoms, resulting in treatment being initiated in more than 80% of the children surveyed. Overall, younger children with ITP showed good prognosis, with lower platelet counts and, to a lesser extent, male gender predicting more favorable outcomes.

SIROLIMUS FOR THE TREATMENT OF CHILDREN WITH IMMUNE THROMBOCYTOPENIA AND EVANS SYNDROME: A SINGLE CENTRE EXPERIENCE

M. Miano1, A. Rotulo1, E. Palmisani1, A. Grossi2, F. Pierri1, M. Calvillo1, C. Micalizzi3, P. Terranova1, E. Cappelli1, T. Lanza1, M.T. Giaimo1, I. Ceccherini1, C. Dufour5, F. Fioredda1
1Haematology Unit, 3Molecular Genetic Unit, IRCCS Istituto Giannina Gaslini, Genova, Italy

Background: The treatment of chronic relapsing immune thrombocytopenia purpura (ITP) is not well established due to the lack of evidence-based data, and is particularly challenging in children who are more at risk of severe side effects secondary to prolonged steroid therapies. Sirolimus has been shown to be effective in patients with ITP secondary to ALPS1 and in very few patients with primary disease or secondary to ALPS-like syndromes2.

Aims: The aim of this study is to evaluate the outcome and toxicity of patients with ITP either primary or secondary to ALPS-like syndromes, with or without involvement of other cell lineages.

Methods: We retrospectively evaluated charts of patients followed in our Unit for ITP primary or secondary to ALPS-like syndromes. Patients with ALPS were excluded. ALPS-like was defined as the presence of at least one absolute or primary additional criterion for ALPS. Complete response (CR) and partial response (PR) were defined as a platelet count ≥50x109/L and >30x109/L and at least 2 fold increase of the baseline count, respectively.

Results: 23 children aged 0-12 yrs (median 6) with primary ITP (7) or secondary to an ALPS-like disorder (16), were treated with Sirolimus. Seven patients (30%) with ALPS-like also had an Evans syndrome (ES), due to the association of leukopenia (1), or to the presence of trilinear cytopenia (6). Four patients with ALPS-like were found to have mutations on PIK3CD, CTLA4, TACI, and CARD 11 gene. All patients, but one treated in first-line, received Sirolimus as second (4), third (14) or fourth (4) line treatment, respectively. 18 patients had previously failed Mucocidential leptomeningeal MFME therapy. Overall, 17/23 (74%) patients achieved a response that was complete and partial in 12 (52%) and 5 (21%) patients, respectively. 10/23 patients were treated in 67 (86%) cases. Children with mono-linear ITP achieved a response in 11/16 (68%) cases, in particular 4/7 (57%) and 7/9 (77%) patients with primitive or secondary disease, respectively. 12 out of 18 (66%) patients who failed MFME therapy responded to Sirolimus rescue. Three patients (13%) reported toxicity consisting of cutaneous (2) and gastrointestinal issues (1) that required the interruption of the treatment in 2 cases.

Summary/Conclusions: To the best of our knowledge this is the largest cohort of patients with ITP or ES -other than ALPS -treated with Sirolimus, that showed to be safe and effective in most cases, including patients who previously failed
MMF treatment. Therefore, it can be considered as an alternative therapeutic option in the setting of ITP non only for patients with an underlying diagnosis of ALPS but also for the ones with primitive disease or with an ALPS-like disorder.

ASSESSMENT OF ROMIPLOSTIM SELF-ADMINISTRATION BY PATIENTS WITH IMMUNE THROMBOCYTOPENIC PURPURA AND CAREGIVERS FOLLOWING RECEIPT OF HOME ADMINISTRATION TRAINING (HAT) MATERIALS: A PRELIMINARY STUDY
M. Schipperus1,*, G. Kaira1, L. Taylor1, A. Kumar2, 3Department of Haematology, Haga Teaching Hospital, The Hague, Netherlands, 1ÅHEPA University Hospital, Thessaloniki, Greece, 2Royal London Hospital, London, London, 4Amgen Limited, London (Uxbridge), United Kingdom, 5Amgen (Europe), Zug, Switzerland, 6Amgen Limited, Cambridge, United Kingdom

Background: A HAT pack was designed as an additional risk minimization tool to support healthcare providers (HCPs) in selecting patients and training of patients/caregivers to mitigate medication error risk when self-administering romiplostim subcutaneously, a thrombopoietin-receptor agonist which is approved in the European Union (EU) to treat chronic immune thrombocytopenic purpura (ITP) refractory to other treatments.

Aims: To estimate the proportion of adult patients and caregivers who administered romiplostim after HAT pack training.

Methods: This non-interventional, cross-sectional study enrolled 40 patients/caregivers and was conducted at 12 centres in Austria, Belgium, France, Germany, Greece, The Netherlands, Spain, and The United Kingdom, from 7 July 2014 to 20 November 2015. HCPs directly observed adults (≥18 years of age) with chronic ITP or caregivers new to administering romiplostim in the act of product administration at the first standard-of-care (SoC) 4-week visit after HAT pack training. Correct administration of romiplostim (primary endpoint) was defined as dose accuracy within ±10% margin of error between prescribed and administered romiplostim doses, and correct romiplostim reconstitution and subsequent injection, and no HCP intervention during administration to correct patient/caregiver error. All analyses were descriptive and no formal hypothesis was tested.

Results: At the first SoC visit, 4 weeks (range: 2-8 weeks) after HAT pack training, 35 patients/caregivers (87.5%) administered romiplostim correctly. The dose accuracy was within ±10% margin of error for all patients. HCP intervention was required in 5 instances: 1 patient did not ensure all romiplostim was dissolved, 1 patient and 1 caregiver needed verbal encouragement, 1 patient needed nursing intervention to read the correct dose from the vial due to poor eyesight, and 1 caregiver needed guidance with syringe and vial connection. Further follow-up data was available for only 2 of these 5 patients/caregivers; they both administered romiplostim correctly at a voluntary subsequent visit.

Summary/Conclusions: Given that this study was conducted on a convenience instead of random sample of patients, generalizability of the results may be limited. Direct observation can be susceptible to observation bias and to the Hawthorne effect with the patients/caregivers acting differently when observed. Nonetheless, the success of most patients and caregivers in correctly administering romiplostim after HAT pack training suggests that self-administration of romiplostim is a feasible option for suitable romiplostim-treated ITP patients.

E1442
FCγIIA 131 H/R (A>G) RECEPTOR GENE POLYMORPHISM IN PATIENTS OF PRIMARY IMMUNE THROMBOCYTOPENIA (ITP)
A. Tripathi1,*, D. Yadav1, A. Kumar2

1Clinical Hematology, 2K.G. Medical University Lucknow India, Lucknow, India

Background: Primary Immune Thrombocytopenia (ITP) is an autoimmune hematologic disorder characterized by isolated thrombocytopenia (<100,000/cmm) in the absence of other causes or disorders that may be associated with thrombocytopenia. The predominant mechanism is enhanced peripheral destruction of autoantibody coated platelets through binding of Fc portion of antibody with the Fcγ receptors on cells of reticuloendothelial system mainly monocytes/macrophages.

Aims: This study was aimed to investigate the association of polymorphisms in FCγIIA 131 H/R (A>G) gene with Primary Immune thrombocytopenia (ITP).

Methods: Genotyping for the FCγIIA 131 H/R (A>G) was performed using polymerase chain reaction and restriction fragment length polymorphism (PCR-RFLP) in 70 ITP patients and 70 healthy controls.

Results: The mean age of patients and control was 29.5±13.86 yrs and 27.90±8.89 yrs respectively. Male/Female ratio in patients and control was 1:2. Under additive model, the heterozygous genotype (AG) of the FCγIIA 131 H/R (A>G) polymorphism shows the significant association with ITP, (Odds Ratio 2.14 (95% CI, Lower: 1.07 Upper 4.29 P-value 0.0328)). Under dominant model, the Odds Ratio was 2.42 (95% CI, Lower: 0.34 Upper 0.94) with the significant P-value 0.014). The homozygous mutant genotype (GG) had no significant association with ITP (Odds Ratio 2.47 (95% CI, Lower: 0.63 Upper 9.72 with P-value 0.297)).

Summary/Conclusions: The study shows the association of heterozygous genotype (AG) of FCγIIA 131 H/R (A>G) with ITP. The dominant model also shows significant association with ITP. We conclude that mutant allele (G) in FCγIIA 131 H/R (A>G) gene polymorphism may have impact on susceptibility to ITP.
follow-up was 102±10 x10^9/L (range 54-336). Disease duration of less than 3 mos prior to therapy start was associated with better outcome (log rank p=0.049, Fig 2) with a median RFS not reached; median RFS for pts treated after 3 mos of diagnosis was 31 mos [OR: 3.8 (CI 95% 0.9-16.3), p=0.0067]. No significant association between gender (p=0.67), age at treatment (more or less than 60 yrs) (p=0.89), DTX total dose (more or less than 480mg) (p=0.35) was found. Summary/Conclusions: Pulsed HD-DXK is a well tolerated and highly effective first line treatment for TTP in every daily clinical practice. The role of a reduced-dose schedule needs to be explored in a larger cohort of pts. Treatment of newly diagnosed ITP pts - i.e. within 3 mos of diagnosis (Rodeghiero Blood 2007) - seems to lead to longer RFS.

E1444

EFFECT OF OSELTAMIVIR TREATMENT ON PLATELET COUNTS

N. Revilla1, I. Heras2, M.E. de la Morena-Barrio3, P. Iniesta2, J.B. Nieto2, J. Corral3, V. Vicente3, M.L. Lozano4
1Servicio de Hematología y Oncología Médica, 2Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB- Arrixaca, 3Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arrixaca. Grupo de Investigación CB15/00055 del CIBERER, ISCIII, Murcia, Spain

Background: As platelets lose sialic acid during aging and circulation, they are cleared by the hepatic Ashwell-Morell receptor (AMR) (1). A recent study suggests that inhibition of sialidase by oseltamivir, a commonly administered anti-influenza medication that inhibits viral sialidase, could associate with an increase in platelet counts (2).

Aims: The aim of this study was to analyze the effect of oseltamivir treatment in platelet counts.

Methods: We performed a retrospective single-center study. From November 2009 until March 2015, a total of 168 patients from our Hematology Unit were prescribed oseltamivir due to clinical suspicion of influenza. A total of 120 patients were excluded because they had received myelotoxic chemotherapy within 30 days (n=82) or platelet count was not available before treatment (n=38). The direct immunofluorescent antigen test was carried out with nasopharyngeal aspirate specimens. Those specimens that were negative by the antigen detection assay underwent RT-PCR testing for influenza virus types A and B. Platelet count was available before and after treatment (median of 5 days) in 48 patients and in 44 patients also when the infection was cleared (median of 30 days).

Results: Patients were divided into those with proven influenza (n=34) and without influenza (n=14). Median age was 58.0 and 59.5 years; respectively. Treatment consisted of 75mg oseltamivir bid for 5 days, with the exception of 3 patients in the proven influenza group receiving 150mg bid for 10 days (allo-genic stem cell transplant recipients). We observed a significant increase in the mean platelet count after treatment with oseltamivir (170/95 x10^9/L vs 192±103 x10^9/L, p=0.04). As in the previous study (2), this effect was independent of whether influenza was diagnosed (Table 1). In addition, we did not discern significant fluctuation in platelet counts when treatment was immediately interrupted after a 30-day time lapse (184±100 x10^9/L vs 182±91 x10^9/L).

Summary/Conclusions: Our study confirms the effect of oseltamivir on increasing platelet counts regardless of influenza infection. Although an increase in platelet counts related to the viral syndrome healing is not ruled out, the lack of long-term fluctuations after the end of treatment may indicate a late inhibition that contributes to reduction in platelet clearance via the hepatic receptor.

CLINICAL UTILITY OF CARDIAC MRI IN IMMUNE MEDIATED THROMBOCYTOPENIC PURPURA

F. Alwan1, D. Mahdi1, S. Mc Guckin1, J. P. Westwood4, M. Thomas1, J. Moon2, M. Scully1
1Haematology Department, University College London Hospital, 2Cardiac Imaging Department, Barts Heart Centre, London, United Kingdom

Background: Immune Mediated Thrombotic Thrombocytopenic Purpura (TTP) is a life threatening thrombomicroangiopathy caused by acquired antibody mediated inhibition of ADAMTS13. Cardiac complications are a common cause of death with un-matched, raised troponin in a high risk factor for new cardiac events in TTP. There is scant evidence on the best investigations for patients suspected of being at risk of cardiac complications with no evidence on the clinical utility of cardiac magnetic resonance imaging (MRI) in acute TTP episodes.

Aims: A retrospective review evaluating the value of cardiac MRI scanning in TTP. Management of 34 patients underwent cardiac MRI scanning between September 2008 and November 2014 whilst being treated for an acute episode of immune mediated TTP. All patients had troponin-t measurement on admission and a transthoracic echocardiogram within 72 hours of presentation. All patients were treated for their TTP episode with plasmapheresis, steroids and Rituximab. Two cardiologists reported each MRI scan and only agreed, unequivocal findings were considered.

Results: The median age of patients was 49 (range 13-73), 71% of whom were women. Two patients had a diagnosis of hypercholesterolemia prior to TTP diagnosis but otherwise there was no previous cardiac history. 71% of patients had a raised troponin-t at presentation (normal <14ng/ml). Two patients developed bradycardia and one atrial fibrillation during their acute admission. One patient had symptoms of heart failure. Three patients had transient ST depression suggestive of ischemia on EKG monitoring and a further four had non-specific T-wave inversion. There were no incidences of cardiogenic shock or cardiac arrest. There was myocardial ischaemia in 23% of patients, with an abnormal T-wave pattern in those with an abnormal cardiac MRI results. Late gadolinium enhancement (LGE) in the mid-apical regions, a finding suggestive of focal myocardial fibrosis and usually secondary to myocardial necrosis, was seen in all 8 patients, subendocardial LGE in six, transmural LGE in one and one patient had both subendocardial and transmural LGE. The latter patient was the only one with an abnormal scan seen on the preceding transthoracic echocardiogram. LGE seen in combination with regional wall motion abnormalities (RWMA) suggests irreversible myocardial dysfunction. No patient was found to have RWMA on transthoracic echocardiogram but this was seen in five patients on cardiac MRI imaging, all of whom also had LGE. The mean troponin-t was not in those with an abnormal normal cardiac MRI (MRI normal 100ng/ml, abnormal MRI 165ng/ml, p=0.9), nor was there a significant difference in median age (49 vs 49), symptom duration (abnormal MRI 7 days, normal 5 days, p=0.39) or presenting anti-ADAMTS13 antibody level (abnormal MRI 41%, normal MRI 40%, p=0.66).

Summary/Conclusions: Cardiac MRI scanning in TTP is a sensitive tool for detecting ischemic cardiac changes that would otherwise be missed by transthoracic echocardiogram. Mid-Apical late gadolinium enhancement appears to be a characteristic finding in TTP. These findings help increase the understanding of the pathophysiology behind the TTP disease process.
group and 56 (24-76) in the control group. Overall MEFV mutation prevalence was %25.9 (21/81) in the study group and %24.7(46/186) in the control group, (p=0.963). MEFV mutation distribution prevalence was similar in both gender groups among ITP patients and their presence did not alter the age of disease onset, (p>0.05). Similarly, presence of mutations did not change the platelet count at diagnosis, the number of treatment courses, the rate of patients undergoing splenectomy and primary steroid resistance. Although statistically not significant, there was a trend towards a better overall response to steroids in patients carrying MEFV mutations, %94.7 vs%82.8, (/p=0.28) respectively. The median time to loss of response to steroids was 60 (10-124) months in patients with mutations and 42 (19-24-68) months in patients without MEFV mutations, (p=0.004). The median time to splenectomy was 101 (42.5-159.5) months in the MEFV mutation carriers and 51 (46-56) months in the non-carriers, (p=0.48). Time to loss of response to splenectomy was 38 (12-90.9) months in mutation carriers and 54 (14-9.3-1) months in non-carriers, (p=0.42).

Summary/Conclusions: To the best of our knowledge, our study is the first to address a possible effect of MEFV mutations on MEFV mutation carrier rates were similar in both ITP and control groups. Although MEFV carrier state had no affect on clinical features of ITP, mutation carriers tended to have a better overall response to steroid treatment, stayed longer in remission, had a longer time to splenectomy and relapsed earlier after splenectomy.

PD-1 AND CTLA-4 POLYMORPHISMS AFFECT THE SUSCEPTIBILITY AND CLINICAL FEATURES OF CHRONIC IMMUNE THROMBOCYTOPENIA
R. Ito1,* , T. Kasamatsu1, Y. Kitamura1, K. Honma1, T. Nagashima1, N. Takahashi2, N. Gotoh1, M. Takizawa1, A. Yokohama1, H. HANDS3, T. Saltoun1, H. Murakami1 *Department of Hematology, Graduate School of Medical Sciences, Gunma University, Gunma, Japan

Background: The programmed death-1 (PD-1) and cytotoxic T lymphocyte-associated antigen-4 (CTLA-4) play a central role in immune checkpoint pathways. The PD-1 negatively regulates self-reactive T and B cells in peripheral immune tolerance. The CTLA-4 antagonizes the binding of CD28 to its ligands including CD80 and CD86, and inhibits T cell activation. Previous studies have shown the lower expression of soluble PD-1 and CTLA-4 mRNA in patients with chronic immune thrombocytopenia (cITP) than healthy individuals. Single nucleotide polymorphisms (SNPs) of PD-1 and CTLA-4 have been reported to be associated with susceptibility of some autoimmune diseases; however, the possible association between these immune checkpoint SNPs and cITP risk remain controversial and obscure.

Aims: In order to explore the role of PD-1 and CTLA-4 in the pathogenesis of cITP, we investigated the impact of PD-1 and CTLA-4 SNPs on the susceptibility and clinical features of adult cITP.

Methods: We extracted the genomic DNA from 141 cITP patients and 223 healthy controls, and determined 3 PD-1 SNPs (-606G/A, -72909C/T, A215V) and 4 CTLA-4 SNPs (-1577A/G, -1577G/A, +49AA, +49GG) by using the polymerase chain reaction -restriction fragment length polymorphism (PCR-RFLP) method. The severity of bleeding tendency and thrombocytopenia was assessed according to the previously described criteria by Han JJ. The study was approved by the Institutional Review Board of Gunma University Hospital, Maebashi, Gunma, Japan.

Results: The minimum platelet count of all clinical course ranged from 0 to 98×109/L with a median count of 13×109/L. Eighty-six patients (61.0%) had bleeding tendency and 24 patients (17.0%) had severe thrombocytopenia (< 10×109/L). Eighty-six patients (61.0%) received the treatment with corticosteroids and 42 (31.0%) were corticosteroid independent. Patients compared to healthy controls, the higher frequency of PD-1 -72909 TT genotype (low produc- er) was observed in cITP patients (12.8% vs 4.5%, /p=0.004). There were no significant differences in CTLA-4 SNPs between cITP patients and healthy controls. In cITP patients, PD-1 -72909 TT genotypes (low producer) was significantly associated with high frequency of treated patients, treated patients with corticosteroid, and steroid-dependent patients compared with CC & GT genotype (high producer) (94.4% vs 71.5%, 94.4% vs 57.7% and 52.9% vs 23.6%; /p=0.043, 0.003 and 0.188, respectively). On the other hand, CTLA-4 -49AA genotype (high producer) was significantly associated with low bleeding tendency than AG & GG genotype (low producer) (27.3% vs 63.8%, /p=0.017). CTLA-4 -1577 AA genotypes (high producer) was significantly associated with low bleeding tendency and steroid treatment than AG & GG genotype (low producer) (27.3% vs 63.8%, /p=0.017). CTLA-4 -6230 AA genotypes (high producer) was significantly associated with higher minimum platelet count than AG & GG genotype (22.5 vs 14.0×109/L, /p=0.048).

Summary/Conclusions: Our findings indicate that PD-1 gene polymorphisms contribute to the susceptibility of cITP, and PD-1 low producer genotype affects the severity of cITP. In addition, CTLA-4 high producer genotypes suggest the good clinical features and a little requirement of treatment in patients with cITP.
drug reactions (ADRs), and other clinically relevant parameters. We report results from a full data analysis.

Results: A total of 59 patients were enrolled (49.4% male; 54% aged 65 years or above) from 38 sites; 22 of them were excluded due to protocol violations (e.g. incomplete documentation, inclusion criteria not met). Of the 137 remaining patients (the full analysis set, FAS), 102 completed the 2-year observation period from diagnosis to the last follow-up visit of their last treatment. The median (Q1, Q3) time from ITP diagnosis to romiplostim initiation was 21.7 months (4-85 months) in the FAS. 123 FAS patients received prior ITP therapies; most of them received corticosteroids (104 [75.9%]). 117 patients (85.4%) were non-splenectomized before romiplostim therapy, for reasons such as refusal of splenectomy, comorbidities, or age. Over the observation period, romiplostim was injected at a median (Q1, Q3) dose of 3.11 mcg/kg/bw (1.8-4.8) FAS over a median (Q1-Q3) treatment period of 103 weeks (33-104). The median platelet count rose sharply from baseline (29.0 x 10^9/L) to two weeks of treatment (62.5 x 10^9/L). From week 3 to the end of the treatment period, the platelet count remained in a range of 50 x 10^9/L and 145.5 x 10^9/L. Since the start of the romiplostim therapy, 59 patients out of 137 (43.1%) received concomitant therapies, mostly corticosteroids (49 patients [35.8%]). The overall number of ADRs was 112 in the FAS, affecting 57 patients (27.0%). The most frequent ADRs were gastrointestinal (10.2%) and neurological (11.7%) ADRs, followed by constitutional symptoms (10.8%). Adverse drug reactions pertaining to blood/bone marrow affected 2.9% of patients (vascular/thrombotic events, bone marrow fibrosis), whereas bleeding as an ADR was seen in 0.7% of patients. The exposure-adjusted rate of bleeding events (grade 3 or 4) per 100 patient-years was 7.2 before treatment vs. 4.0 after starting the treatment. The rate of ITP-related hospitalization per 100 patient-years decreased from 23.3 before the start of therapy to 15.5 since the start of the study.

Summary/Conclusions: This study of routine clinical practice in Germany showed that treatment with romiplostim in ITP patients resulted in a rapid increase in platelet counts to levels maintained between 50 and 250 x 10^9/L over time, regardless of the splenectomy status of the patients; most of them were non-splenectomized. The product was well tolerated and achieved a decrease in the rate of ITP-related hospitalization.

THE CLINICAL UTILITY OF NEUROPSYCHOLOGY TESTING IN IMMUNE MEDIATED THROMBOTIC THROMBOCYTOPENIC PURPURA
1Haematology Department, University College London Hospital, 2Neuropsychology Department, National Hospital for Neurology and Neurosurgery, London, United Kingdom

Background: It is well recognized that neurological manifestations are common in thrombotic Thrombocytopenic Purpura (TTP) however research into the neuropsychological impact of the disease is scarce despite suggesting patients who experience critical illnesses are at high risk for long-term cognitive impairment.

Aims: To review the clinical utility of neuropsychology testing in thrombocytopenic purpura.

Methods: Between January 2010 and 2015, all patients within a single tertiary hematology center with a confirmed diagnosis of TTP were reviewed as outpatients (the full analysis set, FAS), 102 of them completed the 2-year observation period. The most common symptom leading to neuropsychology assessment was problems with concentration, experienced by 89% of patients. 44% had problems with memory, 39% felt depressed and 33% had anxiety issues.

Results: Between the two years of the study period, 56% were Caucasian, 33% Afro-Caribbean and 11% of South Asian origin. 16-67 years (mean 43.7, SD 12.1, range: 18-67). 50% (n=6) had mild cognitive impairment, 33% (n=6) mild-moderate impairment and 11% (n=2) severe impairment. The most common symptoms leading to neuropsychology assessment were problems with concentration, experienced by 89% of patients. 44% had problems with memory, 39% felt depressed and 33% had anxiety issues.

Summary/Conclusions: Persisting psychological symptoms after an acute TTP episode are highly suggestive of underlying cognitive impairment as a result of cerebral sub-acute infarction or microhaemorrhages.
hemolysis, elevated liver enzymes, and low platelets. Previous studies have demonstrated enhanced platelet activation in pregnant women with pre-eclampsia, using cell surface markers and platelet microparticles. Although severe pre-eclampsia is associated with increased inflammatory markers in vitro, levels of platelet activation do not necessarily correlate with severity of disease.

**Aims:** To assess the presence, and degree, of platelet activation in a cohort of patients with early onset pre-eclampsia (EOP), HELLP syndrome, and to correlate this with evidence of in vivo coagulation activation using D- dimers.

**Methods:** Plasma samples from patients with EOP were accessed from a clinical biobank. Platelet activation markers were characterized using ELISA assays measuring platelet factor 4 (PF4), soluble glycoprotein VI (sGPVI) and neutrophil activating peptide-2 (NAP-2). Platelet microparticles (CD42a+ microparticles) were measured by flow cytometry. Platelet activation biomarker levels were adjusted by platelet count and expressed as /10⁸ platelets/ml. All data was analysed using GraphPad Prism 7. Parameters were reported as means±SEM.

**Results:** Plasma samples from 19 individual patients were included. Patients with HELLP syndrome demonstrated significantly greater numbers of CD42a+ microparticles when corrected for platelet count compared with those without HELLP syndrome (598x10⁹ ± 220x10⁹ versus 297x10⁹ ± 37x10⁹, p=0.04). Similarly, patients with HELLP syndrome demonstrated increased levels of sGPVI than those without HELLP; corrected for platelet count (2.576 ± 0.967 versus 1.22 ± 0.124 ng/10⁹ platelets/ml, p=0.0334). There was no difference in NAP-2 or PF4 levels between those with HELLP and those without HELLP, nor between severe and moderate pre-eclampsia patients. Severe pre-eclampsia patients in this cohort had a D-dimer level of 3.7±10.747 μg/ml compared with non-severe patients 1.85±2.350 μg/ml (p=0.537, Spearman R correlation coefficient, r=0.27, p=0.04).

**Summary/Conclusions:** The results of this study demonstrate a positive correlation between severity of pre-eclampsia and platelet activation, as measured by levels of platelet-derived microparticles and platelet GPVI expression. A number of anti-thrombotic and anti-platelet therapies have evaluated the role of low-dose aspirin therapy as prevention for pre-eclampsia, and there is Grade 2B evidence for its use in those at risk of severe pre-eclampsia. The evidence of enhanced platelet activation in our study provides rationale for the efficacy of aspirin in this setting, and the potential for novel antithrombotic agents to be studied for the same indication.

**E1454 PRIMARY ITP IN ADULTS TREATED WITH ELTROMBOPAG: A RETROSPECTIVE STUDY USING DATA FROM THE UNITED KINGDOM ADULT IMMUNE THROMBOCYTOPENIA REGISTRY.**

D. Provan¹, U. Doobare², A. Newland¹, J. Fleming²
¹Haematology, Barts and The London School of Medicine and Dentistry, London, UK
²Haematology, Novartis, Camberley, Surrey, United Kingdom

**Background:** Primary ITP is an autoimmune disorder associated with a reduced peripheral blood platelet count. Although many patients are relatively asymptomatic, many suffer with bruising, mucosal bleeding and quality of life issues. The first-line therapy has remained unchanged for decades and until recently, second-line therapy has been unsatisfactory, using empirical treatments. The recently approved thrombopoietin receptor agonists eltrombopag and romiplostim have transformed patient care and these agents are licensed second-line therapies in adults.

**Aims:** To describe the adult patients receiving eltrombopag using data from the UK Adult ITP Registry. In particular we were interested in understanding the dose used, number of prior therapies, median length of treatment with eltrombopag, median counts at baseline before treatment and at 6 months following treatment, and sustained response in patients who have received eltrombopag.

**Methods:** The UK Adult ITP Registry involved more than 70 UK collaborating centres, coordinated by The Royal London Hospital. In this study we analysed data from all patients receiving eltrombopag and analysed these using various statistical techniques.

**Results:** The total number of patients evaluated was 129. The median age at diagnosis was 49.4 years (26.9-66.4). There were 74 males (57.4%) and 55 females (42.6%). 29 patients (22.4%) had undergone prior splenectomy. The median age at eltrombopag initiation was 59.5 years (37.0-70.7 years). The median time from ITP diagnosis to eltrombopag initiation was 1.6 years (0.7-2.3 years). The majority of patients started eltrombopag between 2013 and 2016 (65%), 9% between 2011 and 2013 and 9% between 2017 and 2018. The median platelet count at eltrombopag initiation was 97x10⁹/L (2-739). Patients who did not interrupt treatment are sustained remission after discontinuation. The median platelet count at suspension of Romiplostim was 91.5x10⁹/L (3-320). In patients treated with Eptifibatide 16 achieved a complete response, 5 a response, obtaining response in the 80% of cases; 5 were no responders. 14 (53%) patients stopped Eptifibatide after a median time of 1.5 months (1-6) for adverse events (2 cases of major cardiovascular events, 1 of myeloid/myelodysplasia, 1 of neurotoxicity, 2 of major bleeding, and 1 of venous thromboembolism). 13/26 patients who received Eptifibatide were at the 3rd line of treatment, 1 at the second, and the others were at least at the 4th line. The median platelet count was 21x10⁹/L (3-52) at the start of Romiplostim, with a median starting dose of 1 µg (1-2) and 17x10⁹/L (1-53) in patients treated with Eptifibatide, with a median starting dose of 50mg (25-50).

**Results:** Patients treated with Romiplostim we observed 22 complete responses and 10 responses, with a 82% response rate, while 7 patients were no responders. In our study 26 (66%) patients stopped Romiplostim after a median time of 16 months (1-93): 9 for stable response, 5 for no response, 3 for loss of response, 3 for adverse events (2 for bone marrow fibrosis, 1 for headache), 2 for major bleeding, 1 for loss of response associated to visual disturbances and gastrointestinal disorders, 2 underwent splenectomy, and 3 patients interrupted the treatment for other causes (es. diagnosis of cancer). The median platelet count at suspension of Romiplostim was 91.5 x10⁹/L (3-320). In patients treated with Eptifibatide 16 achieved a complete response, 5 a response, obtaining response in the 80% of cases; 5 were no responders. 14 (53%) patients stopped Eptifibatide after a median time of 1.5 months (1-12): 6 for adverse events (2 cases of major cardiovascular events, liver toxicity, skin rash, pharyngitis), 5 for no response, 1 for loss of response, 2 patients who achieved a CR interrupted Eptifibatide obtaining a sustained remission after discontinuation. The median platelet count at suspension of Eptifibatide was 13.7x10⁹/L (7.2-29x10⁹/L). In patients who did not interrupt treatment, a median time of 29 months (3-96). Several studies report- ed Romiplostim and Eptifibatide to be highly effective against chronic ITP, with average immediate responses exceeding 80% in our study. We observed that therapeutic response was influenced by the starting platelet count. In particular platelets count before therapy influenced the first response observed. In particular in patients treated with Romiplostim only PR patients directly correlated with the first response and the maintainance of response during treat- ment at month 1°, 2° 3° and 6. Patients with a median starting platelet count of 15x10⁹/L obtained a response (CR + R), while almost all patients who started therapy with PLT<15x10⁹/L at baseline can obtain an initial response, but the majority is non-responder.

**Summary/Conclusions:** TPO-mimetics have proved efficacy in patient with ITP and their use can be applied in several conditions (bridge to splenectomy; sustained response; switch and discontinuation). Future study on large series of patients are needed to test common baseline platelets with hematological and clinical characteristics. The two currently available agents (Romiplostim and Eltrombopag) have similar efficacies and only slightly different safety profiles, being effective in restoring a safe platelet count in 70%-80% of cases with chronic ITP failing one or more lines of treatment, including splenectomy.
PREVALENCE AND RISK FACTORS FOR THROMBOSIS IN ADULT ITP PATIENTS

C. Moret1, A. Tichelli2, A. Wieland-Greguere-Sander3, A. Angelillo-Scherrer3, A. Rovó3,*

1Faculty of Medicine, University of Bern, Bern, 2University Hospital of Basel, Basel, 3University Hospital of Bern, Bern, Switzerland

Background: Immune thrombocytopenia (ITP) is characterized by severe thrombocytopenia due to autoantibody- and cell-mediated peripheral platelet destruction and attenuated thrombopoiesis. Despite a higher risk for bleeding, thromboembolic events (TEE) have been observed.

Aims: We aimed to investigate the prevalence and type of TEE and the potential risk factors in adult ITP patients.

Methods: Retrospective cohort study, including all ITP patients followed in our clinic between 01/1990 and 05/2016. Information on gender, age, date of ITP diagnosis, platelets count, type and clinical form of ITP, type of ITP treatments and its response, severe bleeding and follow up time were collected. Furthermore we evaluated date of first appearance, number and type of thromboembolic events, cardiovascular risk factors, date and cause of death. We assessed and compared risk factors of ITP patients with and without TEE in univariate and multivariate analysis.

Results: Medical files of 480 patients registered as ITP were reviewed; 42 and multivariate analysis.
