22nd Congress of the European Hematology Association

Madrid, Spain
June 22-25, 2017

ABSTRACT BOOK
Become an EHA member

Support our mission to promote excellence in patient care, research and education in hematology.

Join your fellow EHA members worldwide and enjoy membership benefits for both professional and personal development within the field of hematology.

**BECOME A MEMBER!**
- Full Membership € 155/year
- Junior Membership € 20/year
- Health Care Affiliated Professional Membership € 90/year
- Emeritus Membership € 90/year

**ENJOY OUR MEMBERSHIP BENEFITS ALL-YEAR ROUND**

- Monthly subscription to Haematologica
- Access to EHA Membership Directory
- Unlimited access to the EHA Learning Center
- Discount on EHA Congress and other EHA events
- Nomination and voting rights
- Access to the CV Passport online
- Subscription to EHA newsletters

ALREADY A MEMBER? RENEW YOUR MEMBERSHIP NOW!

EHA Board and Organization 22nd Congress

Executive Board
AR Green, United Kingdom [President]
P Sonneveld, the Netherlands [President Elect]
C Chomienne, France [Past President]
M Muckenthaler, Germany [Secretary]
A Engert, Germany [Treasurer]

Councilors
S Fröhling, Germany
G Gaidano, Italy
J Gribben, United Kingdom
S Izraeli, Israel
E Macintyre, France
MV Mateos, Spain
HA Papadaki, Greece
K Porkka, Finland
F Rodeghiero, Italy
V Sexl, Austria

Scientific Program Committee 22nd Congress
S Izraeli, Israel [Chair]
S Eichinger, Austria
A Engert, Germany
A Fielding, United Kingdom
S Fröhling, Germany
K Grønbæk, Denmark
J Jansen, the Netherlands
JJ Kiladjian, France
N Kröger, Germany
H Ludwig, Austria
C Moreno, Spain
M Muckenthaler, Germany
G Ossenkoppele, the Netherlands
JA Pérez-Simón, Spain
D Rees, United Kingdom
A Reiter, Germany
F Rodeghiero, Italy
S Soverini, Italy
S Stanworth, United Kingdom
CH Toh, United Kingdom
MM van den Heuvel-Eibrink, the Netherlands

Local Representative 22nd Congress
A Alegre, Spain

Scientific Program Committee Advisory Board 22nd Congress
I Aurer, Croatia
H Avet-Loiseau, France
C Bonini, Italy
JP Bourquin, Switzerland
M Delforge, Belgium
B Eichhorst, Germany
N Gökbuget, Germany
JB Hansen, Norway
H Hasle, Denmark
H Hasselbalch, Denmark
T Holyoake, United Kingdom
M Hutchings, Denmark
A Iolascon, Italy
PA Kyrie, Austria
T Lapidot, Israel
JI Martin-Subero, Spain
A Nagler, Israel
M Olsson, Sweden
RA Padua, France
D Pospíšilová, Czech Republic
D Prati, Italy
S Saußele, Germany
H Tamary, Israel
A Undas, Poland

Journal of the European Hematology Association

Owned & published by the Ferrata Storti Foundation
Word of Welcome

On behalf of the EHA Board and the Scientific Program Committee we are pleased to introduce to you this year’s Abstract Program. The richness of the program is a testament to EHA’s spirit: unity through diversity.

The Scientific Program Committee has compiled an exciting program of Simultaneous Oral and Poster Sessions from close to 2500 submitted abstracts representing all fields of hematology. For the second year, a number of presenters will have the opportunity to pitch their abstract. These Poster pitches are an exciting opportunity to promote basic science and research, and to invite delegates to the poster walks.

The six Best Abstracts will be presented during the Presidential Symposium on Friday afternoon. This will be a session not to miss. During this plenary session EHA is also awarding, for the first time, the best abstracts by trainees in four categories in basic and clinical hematology research. These awardees and the travel grant winners can be found on the next page. YoungEHA are the future of hematology!

The late breaking abstract submission is an integral part of the scientific program. The late breaking submission is intended for abstracts with “hot” data that were not available by the time of the regular submission deadline. Only few abstracts, with the most exciting results are selected for a presentation in the Late Breaking Oral Session on Sunday morning.

A selection of abstracts will be presented during the regular Poster Walks. The Poster Session consists of two parts: the Poster Walk and dedicated Poster Browsing Time. This setup guarantees sufficient time for discussion of the important research presented, so look out for the Poster Walk Moderators in their red baseball caps! There will also be E-posters available on the E-poster screens, for which a specific time is allocated during the Poster Browsing Time at the end of each Walk. The Simultaneous Oral Sessions are spread over three days (Friday to Sunday) providing you with ample opportunity to attend a number of these important sessions.

All posters can be viewed on the E-poster screens from Friday morning to Saturday evening. All the abstracts are also available on the EHA Learning Center, for which you have complimentary access after the congress: learningcenter.ehaweb.org.

On behalf of the EHA Board, the committees and all the people involved in this year’s EHA Congress, we thank you for coming to Madrid and wish you a great meeting.

Shai Izraeli
Chair Scientific Program Committee 22nd Congress
Travel Grant Winners

For this Congress 140 travel grants have been awarded to junior members of EHA, based on the mean score of their abstracts.

EHA congratulates the following persons with their travel grants:

Agrawal M, Germany
Anagnostou T, USA
Arriazu E, Spain
Barcia Duran JG, USA
Beekman R, Spain
Bhoi S, Sweden
Binder M, USA
Birgisdóttir AM, Iceland
Blunt M, United Kingdom

YoungEHA Best Abstract Awards

One of the primary missions of the European Hematology Association is to support young hematology clinicians and researchers. This year we are proud to announce the launching of the YoungEHA Best Abstract Awards. These will be awarded to the highest ranking abstracts in the following four categories: Clinicians or medical students training for a PhD degree, PhD research students, postdoctoral fellows and clinical hematology trainees. We are honored that these outstanding YoungEHA trainees will be presenting during the EHA congress – they are the future of Hematology!

**CLINICAL TRAINEE AWARD**
K C Pawlyn, United Kingdom

**MD-PHD AWARD**
K O Schwartzman, Israel

**PHD RESEARCH STUDENT AWARD**
K JB Barcia Duran, USA

**POSTDOCTORAL RESEARCH TRAINEE AWARD**
K F Vinchi, Italy
Information for readers, authors and subscribers

Haematologica (print edition, pISSN 0890-6078, eISSN 1592-8721) publishes peer-reviewed papers on all areas of experimental and clinical hematology. The journal is owned by a non-profit organization, the Ferrata Storti Foundation, and serves the scientific community following the recommendations of the World Association of Medical Editors (www.wame.org) and the International Committee of Medical Journal Editors (www.icmje.org).

Haematologica publishes editorials, research articles, review articles, guideline articles and letters. Manuscripts should be prepared according to our guidelines (www.haematologica.org/information-for-authors), and the Uniform Requirements for Manuscripts Submitted to Biomedical Journals, prepared by the International Committee of Medical Journal Editors (www.icmje.org).

Manuscripts should be submitted online at http://www.haematologica.org/.

Conflict of interests. According to the International Committee of Medical Journal Editors (http://www.icmje.org/#conflicts), “Public trust in the peer review process and the credibility of published articles depend in part on how well conflict of interest is handled during writing, peer review, and editorial decision making”. The ad hoc journal’s policy is reported in detail online (www.haematologica.org/content/policies).

Transfer of Copyright and Permission to Reproduce Parts of Published Papers. Authors will grant copyright of their articles to the Ferrata Storti Foundation. No formal permission will be required to reproduce parts (tables or illustrations) of published papers, provided the source is quoted appropriately and reproduction has no commercial intent. Reproductions with commercial intent will require written permission and payment of royalties.

Detailed information about subscriptions is available online at www.haematologica.org. Haematologica is an open access journal. Access to the online journal is free. Use of the Haematologica App (available on the App Store and on Google Play) is free.

For subscriptions to the printed issue of the journal, please contact: Haematologica Office, via Giuseppe Belli 4, 27100 Pavia, Italy (phone +39.0382.27129, fax +39.0382.394705, E-mail: info@haematologica.org).

Rates of the International edition for the year 2017 are as following:

S100
NEXT GENERATION SEQUENCING METHODOLOGY FOR DETERMINING CYTOGENETIC RISK STATUS IN THE DARATUMUMAB PHASE 3 CASTOR AND POLLUX STUDIES IN RELAPSED OR REFRACTORY MULTIPLE MYELOMA
C. Chiu1, D. Soong1, L. Spicka2, M. Beksaç3, M. Schaefer4, N. J. Bahlis5, M. A. Dimopoulos6
1Janssen Research & Development, LLC, Spring House, PA, United States, 2First Faculty of Medicine, Charles University, Prague, Czech Republic, 3ANKARA University, Ankara, Turkey, 4Janssen Research & Development, LLC, Ranir, NJ, United States, 5Tom Baker Cancer Center, University of Calgary, Calgary, Alberta, Canada, 6National and Kapodistrian University of Athens, Athens, Greece

Background: Cytogenetic risk status in multiple myeloma (MM) studies is traditionally determined by using fluorescence in situ hybridization (FISH) or karyotyping to assess chromosomal abnormalities. However, these technologies have limited resolution and a narrow target range, and reproducible interpretation may be confounded by inter-laboratory variation.

Aims: To describe the NGS methodology used to determine cytogenetic risk status in the daratumumab phase 3 CASTOR and POLLUX studies in RRMM.

Methods: Bone marrow aspirates were collected at screening and assessed centrally via NGS. Whole exome sequencing (exome-sequ) and RNA sequencing (RNA-sequ) was performed using the illumina HiSeq platform to identify the presence or absence of defined risk markers: t(4;14), t(14;16), or del17p. The use of RNA-sequ allowed for investigation of chromosomal translocations in expressed genomic locations at a higher resolution than FISH, and exome-sequ data was used to derive the copy number status in coding regions across the genome. RNA-sequ was performed using total RNA and rRNA removal to capture translocations involving coding and intronic regions. Translocation calls were made using two fusion callers, and gene expression was quantified to allow for evaluation of genes associated with translocation events. For t(14;14) translocations, the detected events involved RNA-sequ reads fuses between IgH and WHSC1 or FGFR3. For t(14;16), the detected translocations involved IgH and WWOX, Manual inspection of patients with t(4;14) showed higher WHSC1 or FGFR3 expression, whereas t(14;16) patients showed higher MAF and CCND2 expression. For del17p detection, exome data of each tumor was compared against 100 peripheral blood mononuclear cell (PBMC) control samples from CASTOR and POLLUX studies. Copy number variation data from two callers were combined to utilize information on relative read depth, systematic biases (observed in pooled normal controls), as well as SNP allele frequency (indicative of loss of heterozygosity events). A del17p event was detected when >50% of the 17p region was deleted.

Results: Based on the RNA-Seq and exome results, cytogenetic risk status in the CASTOR and POLLUX studies was defined as high risk with either t(4;14), t(14;16), or del17p, and standard risk with the confirmed absence of these molecular abnormalities. Comparisons of NGS with FISH showed high concordance for t(4;14), t(14;16), and del17p in both studies (Table 1).

PFS analyses investigating differences between treatment groups and between risk groups using FISH-derived risk and NGS-derived risk showed consistent results between FISH and NGS, with improvements in PFS being associated with the addition of daratumumab to standard-of-care regimens in both high- and standard-risk subgroups (Figure 1).

Summary/Conclusions: These studies represent the first, comprehensive use of NGS in global phase 3 clinical trials in RRMM. The NGS methodology accurately identified the presence of defined risk populations t(4;14), t(14;16), and del17p and showed good concordance with FISH. As FISH was performed locally with different probes and pathologists, the high degree of concordance between FISH and NGS is notable and supports the use of NGS for determining cytogenetic risk in patients with RRMM. The utility of NGS in these clinical studies extends far beyond the detection of cytogenetic abnormalities and additional analysis are planned to interrogate these datasets in the identification of novel biomarkers.

S101
EFFICACY BY CYTOGENETIC RISK STATUS FOR DARATUMUMAB IN COMBINATION WITH LENALIDOMIDE AND DEXAMETHASONE OR BORTezOMIB AND DEXAMETHASONE IN RELAPSED OR REFRACTORY MULTIPLE MYELOMA
1Clinica Universidad de Navarra-CIMA, IDISNA, Pamplona, Spain, 2Universitätsklinikum Tübingen der Eberhard-Karls-Universität, Abteilung fuer Innere Medizin II, Tuebingen, Germany, 3St James’s Institute of Oncology, Leeds Teaching Hospitals NHS Trust and University of Leeds, Leeds, United Kingdom, 4Sheba Medical Center, Tel Hashomer, Ramat Gan, Israel, 5Japanese Red Cross Medical Center, Department of Hematology, Tokyo, Japan, 6Division of Hematology, Mayo Clinic, Rochester, MN, United States, 7Department of Experimental, Diagnostic and Specialty Medicine, University of Bologna, Bologna, Italy, 8Unite de Genomique du Myelome, CHU Rangueil, Toulouse, France, 9University of Melbourne, St. Vincent’s Hospital, Victoria, Australia, 10mandade Da Santa Casa De Misericordia De Sao Paulo, Sao Paulo, Brazil, 11Division of Hematology/Oncology, Columbia University, New York, NY, United States, 12Department of HaematologyOncology, University Hospital Ostrava and Faculty of Medicine and Faculty of Science, University of Ostrava, Ostrava Czech Republic, 13Department of Hematology, Erasmus MC, Rotterdam, Netherlands, 14Janssen Research & Development, LLC, Spring House, PA, 15Janssen Research & Development, Ranir, NJ, United States, 16National and Kapodistrian University of Athens, Athens, Greece

Background: Daratumumab (D) is a human CD38-targeting monoclonal antibody that exerts its antimyeloma activity through both direct (on-tumor) and indirect (immunomodulatory) mechanisms of action. Two randomized phase 3 trials in patients with relapsed or refractory multiple myeloma (RRMM) demonstrated that combining D with the standard-of-care regimens lenalidomide + dexamethasone (Rd, POLLUX) or bortezomib + dexamethasone (Vd, CASTOR)
significantly improved progression-free survival (PFS) and achieved higher overall response rates (ORRs) compared with the respective standard-of-care regimen alone (Dimopoulos MA et al., N Engl J Med 2016;375(14):1319-1331; Palumbo A et al., N Engl J Med 2016;375(8):754-766.). Due to its novel mechanisms of action, addition of D to standard-of-care regimens may benefit RRMM patients who have poor prognoses resulting from high-risk cytogenetic abnormalities.

**Aims:** To examine the efficacy of DRd and DvD in RRMM patients with standard or high cytogenetic risk status.

**Methods:** Bone marrow aspirates were collected at screening visits from 311/569 patients from POLLUX and from 353/498 patients from CASTOR, and cytogenetic abnormalities were detected via next-generation sequencing (NGS). Patients were considered to be of high cytogenetic risk if they had ≥1 of the following abnormalities: t(4;14), t(14;16), or del17p; patients were considered to be of standard cytogenetic risk if they lacked these abnormalities. Minimal residual disease (MRD) was assessed at suspected complete response (CR) at 3 sensitivity thresholds (10−4, 10−5, and 10−6) using the ClonoSEQ™ NGS-based assay (Adaptive Biotechnologies, Seattle, WA). Efficacy analyses included PFS, ORR, and MRD-negative rates.

**Results:** For POLLUX, the median follow-up was 17.3 months. Treating high-risk patients with DRd significantly prolonged median PFS vs Rd (top panel Figure 1) and numerically increased ORR (85% vs 67%; P=0.14). Responses to DRd vs Rd included CR or better in 33% vs 6% of these patients, and very good partial responses (VGPR) or better in 63% vs 31%. In standard-risk patients, DRd vs Rd also resulted in significant improvements in median PFS (Figure 1) as well as ORR (95% vs 82%; P=0.0020). Responses to DRd vs Rd included CR or better in 32% vs 24% of these patients, and VGPR or better in 84% vs 51%. At 10−5 sensitivity threshold, MRD-negative rates for DRd vs Rd were 18% vs 0% (P=0.0027) among high-risk patients and 30% vs 10% (P=0.0001) for standard-risk patients. For CASTOR, the median follow-up was 13.0 months. Treating both high- and standard-risk patients with DvD vs Vd significantly prolonged median PFS (bottom panel Figure 1) and increased ORR (high risk: 82% vs 62%; P=0.039; standard risk: 85% vs 64%; P=0.0003). Responses to DvD vs Vd among high-risk patients included CR or better in 30% vs 9% of patients and VGPR or better in 64% vs 34%; among standard-risk patients, responses included CR or better in 25% vs 8% of patients and VGPR or better in 64% vs 27%. At 10−5 sensitivity threshold, MRD-negative rates for DvD vs Vd were 14% vs 0% (P=0.0018) among high-risk patients and 12% vs 2% (P=0.0011) for standard-risk patients.

**Summary/Conclusions:** Adding D to Rd or Vd improved treatment outcomes irrespective of cytogenetic risk status in patients with RRMM. Both DRd and DvD appear to benefit RRMM patients who have poor prognoses due to high-risk cytogenetic abnormalities. Updated data, including analyses based on individual cytogenetic abnormalities, will be presented at the meeting based on longer follow-up.

**MINIMAL RESIDUAL DISEASE BY MULTIPARAMETER FLOW CYTOMETRY IN TRANSPLANT ELIGIBLE PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA: RESULTS FROM THE EMM02/H095 PHASE 3 TRIAL**

S. Oliva1, D. Hofste op Bruinink2, L. Rihova3, S. Spada1, B. van der Holt4, R. Troia1, M. Gambella1, L. Pantani5, S. Grammatico5, M. Gilestro2, R. Omedè1, V. van der Velden6, M. Boccadoro5, P. Sonneveld7, M. Cavo5, P. Zhang1, Y. Zhang1, F. Wang1, B. Lei1, L. Gu1, Y. Yang1, J. Bai1, R. Zhang1, Q. Zhuang2, F.X. Fan2

1Hematology, Second Affiliated Hospital of Xi’an Jiaotong University, Xi’an, 2Nanjing Legend Biotech, Nanjing, China

**Background:** Multiple myeloma (MM) is still an incurable disease and patients may relapse despite achievement of complete remission (CR). Available data show that MRD detection is a sensitive strategy to appropriately measure response in MM patients.

**Aims:** We evaluated MRD by MFC in patients with newly diagnosed MM enrolled in the EMM02/H095 phase 3 trial.

**Methods:** Patients were ≥65 years of age and treatment consisted of Bortezomib-Cyclophosphamide-Dexamethasone (VCD) induction, mobilization and stem cell collection, intensification with Bortezomib-Melphalan-Prednisone (VMP) or High-Dose-Melphalan (HDM) followed by stem cell transplant, consolidation with Bortezomib-Lenalidomide-Dexamethasone (VRD) vs no consolidation, and Lenalidomide maintenance. MRD was assessed in patients achieving at least a very good partial response (VGPR) before starting maintenance (after HDM, VMP or VRD) and during maintenance every 6–12 months; samples were centralized to 3 European labs. MFC was performed on bone marrow according to Euroflow-based methods (8 colors, 2 tubes) with a sensitivity of 10−5. Quality checks were done to compare sensitivity and to show correlation between protocols (Hofste op Bruinink D, ASH 2016 abstract 2072).

**Results:** A total of 316 patients could be evaluated before maintenance: median age was 57 years (IQR: 52-62), 18% (57/316) had ISS III and 22% (70/316) had high risk cytogenetic abnormalities defined as presence of either one among del17, t(4;14) or t(14;16); 63% (199/316) had received HDM and 37% (117/316) VMP thereafter 51% (160/316) had received VRD. After a median follow-up of 30 months from MRD enrolment, 76% (239/316) patients were MRD-negative: 64% (153/239) in the HDM vs 36% (86/239) in the VMP groups. The 3-year PFS was 50% in MRD-positive vs 77% in MRD-negative patients (HR 2.87, 95% CI: 1.75 - 4.72, p<0.001). Subgroup analyses were carried out to assess the risk factors for MRD-positivity according to baseline characteristics and therapies: high risk cytogenetic abnormalities were the most important risk factors (HR 9.87, 95% CI: 4.3 – 22.63; interaction-p=0.001). Finally, 48% of MRD positive patients at pre-maintenance who had a second MRD evaluation after at least 1 year of lenalidomide became MRD-negative.

**Summary/Conclusions:** MRD by MFC is a strong prognostic factor in MM patients receiving intensification with novel agents or transplant; lenalidomide maintenance further improved depth of response; high risk cytogenetic abnormalities are the most important prognostic factors in MRD-positive patients.

**PHASE I, OPEN-LABEL TRIAL OF ANTI-BCMA CHIMERIC ANTIGEN RECEPTOR T CELLS IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA**

W. Zhang1, W. Zhao2, J. Liu1, A. He1, Y. Chen1, X. Cao2, N. Yang2, B. Wang1, P. Zhang1, Y. Zhang1, F. Wang1, B. Lei1, L. Gu1, Y. Yang1, J. Bai1, R. Zhang1, X. Wang1, X. Ma1, J. Wang1, J. Wang1, L. Wei1, J. Zhang1, X. Zang1, C. Zhuang1, F.X. Fan2

1Hematology, Second Affiliated Hospital of Xi’an Jiaotong University, Xi’an, 2Nanjing Legend Biotech, Nanjing, China

**Background:** Immunotherapy has emerged as a potentially curative treatment in hematological malignancies. Uniformly expressed in plasma cells, B-cell maturation antigen (BCMA) is an appropriate target antigens for CAR T-cell therapies in multiple myeloma.

**Aims:** This phase I, open-label trial was conducted to assess the efficacy and
Neud001 is a novel investigational monoclonal antibody that targets misfolded LC and may neutralize circulating LC aggregates and clear insoluble deposits. Patients' survival depends upon rapid suppression of the misfolded protein.

Methods: All patients underwent leukapheresis to obtain peripheral blood mononuclear cells and their T cells were engineered to express anti-BCMA CAR. Three doses of 300 mg/m² cyclophosphamide were administered on day -5, -4, and -3 (before the recruitment, patients took the same chemotherapy to identify they were refractory to cyclophosphamide monotherapy) and engineered T cells were reinfused on day 0, 2, and 6. This trial was divided into the dose escalation stage and expansion cohort. Toxicity and responses were assessed according to the Common Terminology Criteria for Adverse Events (version 4.0) and International Myeloma Working Group (IMWG) Uniform Response Criteria for Multiple Myeloma, respectively.

Results: As of the February 20th, 2017 data cut-off, 22 patients had been enrolled, two of whom were diagnosed as plasma cell leukemia. The male:female ratio was 11:11 and median age was 53.5 years. Chromosomal abnormalities were detectable by FISH in eight patients, two of whom involved in the deficiency of p53. Eleven patients were triple refractory (chemotherapy, proteasome inhibitors, and immunomodulatory drugs), 11 resisted to double prior treatments (chemotherapy and proteasome inhibitors/ immunomodulatory drugs), and four relapsed after autologous hematopoietic stem cell transplant. The median number of infused CAR T cells was 4.0×10^6 (range, 1.5×10^6-7.0×10^6) per kg. The median follow-up was 131.5 (range, 29-327) days. 100% of patients achieved an objective response. The first six patients achieved complete responses with flow MRD-negative; 14 patients achieved very good partial responses; one patient, with renal failure, achieved partial response; all these 22 patients had kept their best response at the end of follow-up. The pictures we enclosed were the subcutaneous nodules in one patient with extramedullary plasmacytoma. We found that the nodules were obviously decreased after the infusion and disappeared finally. Another one achieved transient partial response, which last for 12 days.

Discussion: We explored the potential impact on organ response of the number and type of organs affected and the number of, type of, and time since previous therapies at baseline. Depth of patients' best HR also was not related to the attainment of NEOD001 organ response (responder/stable: 35.6/36.6 months [cardiac] and 30.6/32.5 months [renal]; P>0.05). Depth of patients' best HR also was not related to the attainment of NEOD001 organ response (percentage of patients with organ response in CR/VGPR/PR after PCD: 47.1/66.7/42.9% [cardiac] and 68.8/63.6/62.5% [renal]; P>0.05). Similarly, time or depth of patients' last HR did not impact the NEOD001 organ response rate (P>0.05). Patients with NEOD001 organ responses were no more likely to have had their last PCD therapy <6 than 36 months from their first NEOD001 dose. Patients' previous PCD treatment type was not related to the corticosteroid for spinal meningioma. He terminally died with renal failure, achieved partial response; all these 22 patients had kept their best response at the end of follow-up. The pictures we enclosed were the subcutaneous nodules in one patient with extramedullary plasmacytoma. We found that the nodules were obviously decreased after the infusion and disappeared finally. Another one achieved transient partial response, which last for 12 days. He then took the secondary infusion but failed since the post-operation large-volume infusion.

Figure 1. Case #6

Summary/Conclusions: Our findings demonstrated the safety and amelioration activity of LCAR-B38M anti-BCMA CAR T cells.

S104

Patients with Light Chain Amyloidosis Treated with Neud001 Achieve Rapid Organ Responses That Are Independent of Previous Plasma Cell–Directed Therapies

1Mayo Clinic, Rochester; 2Tufts Medical Center, Boston; 3Memorial Sloan Kettering Cancer Center, New York; 4Boston University School of Medicine and Boston Medical Center, Boston; 5University of Pennsylvania, Philadelphia; 6Karmanos Cancer Institute, Detroit; 7JW Consulting, Hillsborough; 8Prothena Biosciences Inc, South San Francisco; 9Stanford University School of Medicine, Stanford, United States

Background: Light chain (AL) amyloidosis is a rare and often fatal disease caused by the accumulation of misfolded light chain (LC) aggregates that can lead to progressive failure of critical organs, causing significant morbidity and mortality. Patients' survival depends upon rapid suppression of the misfolded LC and stabilization or recovery of organ function. Current therapies limit LC production; however, ~75% of patients have persistent organ dysfunction. Neud001 is a novel investigational monoclonal antibody that targets misfolded LC and may neutralize circulating LC aggregates and clear insoluble deposits.

Aims: To assess the association between responses and time, depth, number or type of previous plasma cell–directed (PCD) treatments and organ response.

Methods: Inclusion criteria for this trial were: completed ≥1 PCD treatment before enrollment, attained partial hematologic response (HR) or better to any previous therapy, and have persistent organ dysfunction. Neud001 was administered intravenously every 28 days. During the dose-escalation phase, 27 patients received Neud001 at 0.5, 1, 2, 4, 5, 16, or 24 mg/kg in a 3+3 study design. In the expansion phase, 42 additional patients with renal, cardiac, or nerve involvement were enrolled and treated (24 mg/kg). We assessed cardiac and renal best responses based on consensus criteria. Peripheral nervous system (PN) responses were assessed at month 10 (after 9 infusions) using the Neuropathy Impairment Score—Lower Limbs (NIS-LL). We explored the potential impact on organ response of the number and type of organs affected and the number of, type of, and time since previous therapies at baseline.

Results: In the overall population (N=69), the median age was 61 years (61% male). Median (range) time since diagnosis was 2.9 (0.4-16.0) years, and 45% of patients underwent ≥3 previous PCD regimens. Median time to first best response was 1.8 (cardiac), 3.7 (renal), and 1.0 (PN) months. Best response rate indicating organ response was observed in 53% of cardiac-evaluable patients (n=19/36) and 64% of renal-evaluable patients (n=23/36). PN responses were observed in 82% (n=9/11) of PN-evaluable patients. Time from patients' best HR to previous PCD treatment was not related to the attainment of Neud001 organ response (responder/stable: 35.6/36.6 months [cardiac] and 30.6/32.5 months [renal]; P>0.05). Depth of patients' best HR also was not related to the attainment of Neud001 organ response (percentage of patients with organ response in CR/VGPR/PR after PCD: 47.1/66.7/42.9% [cardiac] and 68.8/63.6/62.5% [renal]; P>0.05). Similarly, time or depth of patients' last HR did not impact the Neud001 organ response rate (P>0.05). Patients with Neud001 organ responses were no more likely to have had their last PCD therapy <6 than 36 months from their first Neud001 dose. Patients' previous PCD treatment type was not related to the corticosteroid for spinal meningioma. He terminally died with renal failure, achieved partial response; all these 22 patients had kept their best response at the end of follow-up. The pictures we enclosed were the subcutaneous nodules in one patient with extramedullary plasmacytoma. We found that the nodules were obviously decreased after the infusion and disappeared finally. Another one achieved transient partial response, which last for 12 days. He then took the secondary infusion but failed since the post-operation large-volume infusion. We assessed cardiac and renal best responses based on consensus criteria. Peripheral nervous system (PN) responses were assessed at month 10 (after 9 infusions) using the Neuropathy Impairment Score—Lower Limbs (NIS-LL). We explored the potential impact on organ response of the number and type of organs affected and the number of, type of, and time since previous therapies at baseline.

Summary/Conclusions: Neud001 specifically targets disease-causing, misfolded LC aggregates in AL amyloidosis. Organ responses in patients treated with monthly Neud001 infusions were achieved rapidly and independently of time since previous chemotherapy, depth of hematologic response, or predominant type of PCD treatment.

When pts in the SC group were asked, if given the option, which treatment they would prefer, 90.8% stated a preference for SC over IV. Median administration time (6 minutes SC vs 2.6–3.0 hours IV) and chair/bed and overall hospital times were shorter with SC than with IV treatment.

Figure 1. Patient satisfaction at cycle 3 and cycle 7 of treatment.

Summary/Conclusions: Rituximab SC had similar efficacy and safety to the IV form, with improvements in patient satisfaction ratings, and administration/hospital time savings. Our findings support the use of rituximab SC in this setting.

S108
ANALYSIS AND CHARACTERIZATION OF HEMATOLOGIC CANCERS USING A COMPREHENSIVE NGS PANEL COMPRISED OF DNA AND RNA TARGETS TREATING 704 GENES

A.R. Carson1, B.A. Patay1, V. McClain1, Z. Xie1, T. Stenzel1,2,3, J.E. Miller1,2,3
1Invivoscribe, 2LabPMM LLC, San Diego, United States, 3LabPMM GmbH, Martinsried, Germany

Background: As next-generation sequencing (NGS) methodologies improve, so does the ability to characterize hematopoietic and lymphoid neoplasms. This promises to revolutionize oncology, allowing more accurate and precise classification of patients and potentially leading to novel targeted and combination therapies with improved outcomes.

Aims: We constructed a custom targeted sequencing panel, MyHEME™, to comprehensively identify and characterize DNA and RNA changes in a broad range of hematologic malignancies, including Non-Hodgkin lymphoma (NHL).

Methods: The MyHEME targeted sequencing panel is comprised of two independent bait sets that target a combined 704 genes known or predicted to contribute to hematologic cancers (DNA baits for 571 genes and RNA baits for 361 genes; 228 genes are found in common between the two bait sets). Libraries were constructed using 1μg of DNA or 0.1μg of RNA and sequenced on an Illumina platform. Sequenced reads are analyzed using proprietary MyInformatics™ software to identify single nucleotide variants (SNVs), indels and structural variants (SVs). Both the MyHEME panel and MyInformatics software were created under ISO13485 design control. To characterize the performance metrics of the MyHEME panel, we used the NIST human reference sample NA12278 along with combinations of hematologic cancer derived cell lines with known pathogenic variants at various allelic frequencies.

Results: Analytical validation of the MyHEME panel established an average read depth of 1,175X (with a median read depth of 1,088X) for the DNA targets and an average transcripts per million (TPM) of 2,256 (with a median TPM of 743) for the RNA targets. For the DNA targets, we established sensitivity >95% (99.8% for SNVs at a 2.5% limit of detection (LOD)); 100% for coding indels at a 5.0% LOD) and specificity >95% (95.5% for SNVs at a 2.5% LOD; 97.7% for coding indels at a 5.0% LOD). We also show the ability to cross-confirm results between the 228 genes common to both the DNA and RNA targets. Importantly, novel gene fusions, which are generally difficult to detect and validate, were cross-confirmed when observed in both the DNA and RNA targets. For example, we identified a novel t(9;22) translocation causing a NUP214-XXR3 gene fusion using both the DNA and RNA targets. Additionally, while RNA data provides the fused exons of the transcripts, DNA data gives the precise genomic breakpoint coordinate.

Summary/Conclusions: MyHEME is an extensive panel for sensitively and specifically identifying SNV, indel and SV mutations in 704 target genes. This panel can comprehensively characterize mutations in multiple diverse hematologic cancer samples, including Non-Hodgkin lymphoma (NHL), AML, ALL, and Multiple Myeloma. By utilizing a high depth of coverage, MyHEME can accurately detect clones present down to 5% of a patient’s sample. In addition, by targeting both DNA and RNA, MyHEME contains a built in validation method to cross-confirm novel variants of interest.

S109
TP53 MUTATIONS, BUT NOT DELETION OF TP53 AND CDKN2A, HAVE INDEPENDENT PROGNOSTIC VALUE IN MANTLE CELL LYMPHOMA TREATED BY THE NORDIC (MCL2 AND MCL3) REGIMEN

C.W. Eskelund1, C. Dahl2, J. W. Hansen1, M. Westman1, C. Montano1, C. Freiburghausen1, S. Ek3, A. Pedersen1, L. B. Pedersen1, C. Niemann1, R. Røyt4, P. Brown1, A. Kolstad5, C.H. Geisler1, M.K. Andersen1, P. Guldberg1, M. Jerkeman1, K. Grønbæk1
1University Hospital of Copenhagen, 2Danish Cancer Society, Copenhagen, Denmark, 3University Hospital of Lund, Lund, Sweden, 4University Hospital of Helsinki, Helsinki, Finland, 5University Hospital of Oslo, Oslo, Norway

Background: During the past decades, the outcome of MCL treatment has improved substantially in younger patients. However, the course of disease remains heterogeneous, and there is a need for better stratification of patients with poor responses from those with durable responses. The Nordic trials, MCL2 and MCL3, represent standard-of-care regimens for younger MCL patients.

Aims: Preliminary analyses of diagnostic samples from MCL2 and MCL3, show that TP53 mutations are associated with significantly poorer outcome. Recently, deletions of TP53 and CDKN2A was shown to confer negative impact in a cohort similar to the Nordic (Delfau-Larue et al., 2015). Thus, in this study we aim to describe the prevalence and impact of deletions of TP53 and CDKN2A in the light of TP53 mutations.

Methods: Fresh frozen DNA from diagnostic bone marrow samples from MCL2 and MCL3 were analyzed. In both trials, patients received intensified first-line induction therapy with alternating courses of R-CHOP and R-hd-Cytarabine and consolidation with high-dose therapy and ASCT. (Geisler et al., 2008; Kolstad et al., 2014). Targeted NGS of ATM, CCND1, TP53, KMT2D, NOTCH1, NOTCH2, WHSC1 and BIRC3 was performed ion Torrent Technology. Cut-off for calling a mutation was set to a variant allele frequency >3% and median coverage was >2700X. Copy Number Variations (CNVs) of TP53 and CDKN2A were measured by droplet digital PCR by commercially available assays, and RPP30 used as a standard control.

Results: We investigated the presence of CDKN2A and TP53 deletions in diagnostic samples from 175 and 157 patients, respectively. Patients were treated and <66 years (median 58, range 37-65). Fifty-three percent were either MIPI intermediate- or high-risk, 17% had blastoid morphology and 42% had del-CDKN2A, and 83% had bone marrow involvement at diagnosis. After a median follow-up of 9.2 years, median overall (OS), progression-free survival (PFS) and cumulated incidence of relapse (CIR) of all patients were 12.4 and 8.2 and 1.0 and 1.2 years (p<0.0001 for all three outcomes), respectively. In univariate analyses, median OS was 11.0 years for patients with TP53 deletion versus 38.2 years for patients without deletion (p=0.01). Del-TP53 was significantly associated with significantly poorer outcome. Recently, TP53 was significantly associated with poor OS (p=0.01), but not PFS and CIR, whereas del-CDKN2A was significant for CIR (p=0.02), but not OS and PFS. Patients with both deletions did significantly worse for all three endpoints. In MVA, (including all factors with significance in univariate analyses: MIPI, blastoid morphology, KIT-D816V, del-CDKN2A and del-CDKN2A) only mutations of TP53 remained a significant predictor of outcome.

Summary/Conclusions: Here we evaluate the impact of TP53- and CDKN2A-deletions in the context of TP53 mutations of younger, optimally treated MCL patients. In line with previous reports, both deletions were associated with poorer outcome; however, in multivariate analyses only TP53 mutations was an independent prognostic factor, substantiating its role as a biomarker for response to the standard-of-care immune-chemotherapy.

S110

DEEP MOLECULAR RESPONSE TO GILTERITINIB IMPROVES SURVIVAL IN FLT3 MUTATION-POSITIVE RELAPSED/REFRACTORY ACUTE MYELOID LEUKEMIA

Background: Mutations in Fms-like tyrosine kinase 3 (FLT3) are common in patients with acute myeloid leukemia (AML) and are associated with an aggressive disease course and a poor prognosis. Notably, FLT3 internal tandem duplications (ITD) predict early relapse and short overall survival (OS) after chemotherapy. Gilteritinib, a highly selective FLT3/AXL inhibitor, has displayed antileukemic activity in FLT3 mutation-positive (FLT3mut+) relapsed/refractory (R/R) AML in the CHRYSALIS Phase 1/2 study (NCT02014558), specifically at doses ≥80 mg/d. Aims: To assess molecular response to gilteritinib in a CHRYSALIS subpopulation.

Methods: This exploratory analysis evaluated molecular response in patients aged ≥18 years with FLT3mut+R/R AML who had been treated with 120 or 200 mg/d gilteritinib. These doses were identified due to their ability to induce high clinical response rates, and consistent, potent FLT3 inhibition in correlative assays. Molecular response was assessed in patients who had bone marrow aspirates obtained at baseline and at ≥1 additional time point. FLT3-ITD and total FLT3 were quantified by next-generation sequencing to assess molecular response. A Cox regression model of OS by Kaplan-Meier estimation established a FLT3-ITD-to-total FLT3 ratio (ITD signal ratio) of 10−2 as the threshold for improved survival.

Results: Of the 147 FLT3-ITDmut+ patients who had received gilteritinib 120 or 200 mg/d, 80 patients had bone marrow aspirates at baseline and at ≥1 additional time point, and were included in this analysis. The composite response rate (defined as CR plus CRi plus PR) for these 80 patients was 55%. During response, 20 patients (25%) had an ITD signal ratio of ≤10−2. Of these 20 patients, 18 had an ITD signal ratio of ≤10−3 (major molecular response [MMR]) and 13 had an ITD signal ratio of ≤10−4 (minimal residual disease [MRD]) negative. The median time to achieve minimum ITD signal ratio was 54 days. Elimination of morphologic leukemia was observed in 80% of patients with ITD signal ratios <10−2. Patients who had an ITD signal ratio ≤10−2, MMR, or were patients, 18 had an ITD signal ratio of ≤10−3 (major molecular response [MMR]) improved survival.

Aims/Conclusions: Molecular responses to gilteritinib in FLT3-ITDmut+R/R AML correlated with clinical response and improved OS. This is the first demonstration of a robust molecular response to a FLT3 inhibitor in AML. These data suggest that the ITD signal ratio may predict a durable clinical benefit of gilteritinib therapy and validate FLT3 as a critical therapeutic target in AML.

S111

RISK-ADAPTED, MRD-DIRECTED THERAPY FOR YOUNG ADULTS WITH NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA: RESULTS OF THE AML1310 TRIAL OF THE GIMEMA GROUP

Background: A comprehensive AML risk assessment, based on the integration of cytogenetic/genetic data and minimal residual disease (MRD) status, can help optimize patient’s (pts) therapeutic post-remission allocation. Aims: To evaluate the feasibility and results of a phase II trial of intensive chemotherapy in which risk-assignment and post-remission therapy of young patients with AML was based on pre-treatment cytogenetic/genetic data and post-consolidation levels of MRD. Methods: Between January 2012 and May 2015, 515 pts with de novo AML, 18 to 60 years old, seen at 55 GIMEMA institutions were enrolled in the trial. Induction consisted of i.v. daunorubicin 50 mg/m2 daily on days 1,3 and 5; i.v. cytarabine 100 mg/m2 as a daily continuous infusion, days 1 to 10. All pts in CR/CRi after 1-2 induction cycles, received 1 consolidation course consisting of i.v. daunorubicin 50 mg/m2 daily for 6 and i.v. cytarabine 300 mg/m2 every 12 hours on days 1 to 6. In pts belonging to ELN low or intermediate-risk category, peripheral blood stem cell collection was attempted by initiating, on day 20 from the start of consolidation therapy, G-CSF until completion of stem cell collection. Post-consolidation therapy was based on risk-allocation. Low-risk pts (NPM1 positive FLT3-ITD negative or c-Kit mutations) were to receive AuSCT; intermediate-risk pts (intermediate karyotype or FLT3-TKD positive or c-Kit mutations) were to receive AuSCT; high-risk pts (adverse karyotype or FLT3-ITD positive) were to receive ASCT. Results: Of 500/515 pts started treatment and were available for the analysis. Median age was 49 (18-61) years and 52% were males. Of 429 evaluable pts, ELN cytogenetic distribution was: low-risk 11%, intermediate-risk 73% and poor-risk 16%. RUNX1/RUNX1T1 was detected in 49% of pts, CBFbeta/MYH11 in 7% of 496, FLT3-ITD in 25% of 497 and NPM1 in 37% of 499. In 494 evaluable pts, complete remission rate (CR) was 73% (361), 18% had refractory AML and 9% died early during induction. Three hundred-41 pts completed the consolidation phase and were risk allocated: 114 (33%) to the low-risk category (=AuSCT), 122 (36%) to the intermediate-risk category (=AuSCT or ASCT), 122 (35%) to the intermediate-risk category (=AuSCT or ASCT). In 27 pts (8%) belonging to the intermediate-risk category, a leukemia associated phenotype was not found and they were to receive AuSCT. Overall, 109 (33%) and 123 (36%) of 341 pts received AuSCT and ASCT, respectively. Median follow-up was 27.9 months. At 3 years, overall survival (OS) and progression free survival (PFS) of the whole series was 55.9% and 49.3%, respectively; cumulative incidence of relapse was 32.9%. At the same time point of 24 months, OS and DFS in the low-risk category was 74.8% and 63.8%, respectively; in the high-risk category 42.5% and 44.8%, respectively; in the intermediate-risk category MRD negative 78.6% and 61.4%, respectively; in the intermediate-risk category MRD positive 69.8% and 66.6%, respectively (Figure 1).

Summary/Conclusions: A program of risk-adapted, MRD-driven therapy is feasible in a multicenter, cooperative setting. In the intermediate-risk category,
ASCT can be avoided if MRD is not detectable; if MRD is positive, ASCT can prolong OS and DFS to equalize those of the low-risk category. ASCT was delivered to 2/3 of pts in the high-risk category, using all the available sources of stem cells.

1Erasmus Medical Center Cancer Institute, Rotterdam, 2VU University Medical Center, Amsterdam, Netherlands, 3University Hospital Basel, Basel, Switzerland, 4Mont-Godinne, Yvoir, Belgium, 5University Hospital Zürich, Zürich, Switzerland, 6Cliniques Universitaires Saint-Luc, Brussels, Belgium, 7Academic Medical Center, University of Amsterdam, Amsterdam, 8Medisch Spectrum Twente, Enschede, 9Isala Hospital, Zwolle, Netherlands, 10Inselspital, Bern University Hospital, Bern, Switzerland

**Background:** The detection of minimal residual disease (MRD) in patients with acute myeloid leukemia (AML) may improve future risk-adapted strategies of AML treatment. The presence of MRD after induction treatment has firmly been shown to predict for relapse and overall outcome, irrespective of type of post-remission treatment (PRT). Currently it is unknown whether and how the presence or absence of MRD should guide the application of allogeneic hematopoietic stem cell transplantation (alloHSCT) as PRT.

**Aims:** We addressed whether and to what extent alloHSCT quantitatively reduces relapse as compared to conventional post-remission treatment (PRT) in upfront treated patients with MRD positive or MRD negative AML in first hematological complete remission (CR1).

**Methods:** A total of 1,511 patients were treated in subsequent HOVON-SAKK AML trials of whom 547 patients obtained a CR1, received PRT and had available flow cytometric MRD prior to PRT. MRD positivity was defined by more than 0.1% cells with a leukemia associated phenotype within the white blood cell population. MRD status was not known by clinicians during AML treatment. PRT consisted of alloHSCT (n=282), or conventional PRT by a third cycle of chemotherapy (n=160) or autologous HSCT (n=105). Endpoints of the study included overall survival (OS), relapse-free survival (RFS), and cumulative incidences of relapse and non-relapse mortality (NRM) at 4 years. A time-dependent covariate alloHSCT with the cumulative incidence of relapse as primary endpoint.

**Results:** MRD was positive in 129 (24%) patients after induction chemotherapy before proceeding to PRT. The latest European LeukemiaNet risk classification was similarly distributed among MRD negative and MRD positive patients. No differences were present in transplant characteristics in MRD positive and MRD negative patients. OS and RFS was significantly better in patients without MRD prior to PRT as compared to MRD positive patients (65±2% compared to 50±5% at 4 years, p=0.002, and 58±3% compared to 38±4%, p<0.001, respectively).

**Summary/Conclusions:** The graft-versus-leukemia effect of alloHSCT is equally present in MRD positive and MRD negative patients, which advocates a personalized application of alloHSCT taking the risk of relapse determined by AML risk group and MRD status as well as the counterbalancing risk of NRM into account.
all different currently used risk categories. These data urge to include both MRD and LSC in future AML risk classification to better inform post-remission treatment.

DEFINITION OF PARTIAL RESPONSE IN YOUNGER AML PATIENTS AFTER FIRST INDUCTION COURSE MAY BE EXTENDED BY INCLUSION OF IMMUNOPHENOTYPIC DETECTION OF MEASURABLE RESIDUAL DISEASE IN CR

1Institute of Immunology and Immunotherapy, University of Birmingham, Birmingham, 2King’s College London School of Medicine, London, 3Centre for Trials Research, Cardiff University, Cardiff, 4North Bristol NHS Trust, Bristol, 5University Hospital of Wales, 6Cardiff University School of Medicine, Cardiff, 7Isle of Arran, Isle of Arran, 8Nottingham University Hospital, Nottingham, United Kingdom

Background: In AML response by morphology after a first cycle of induction therapy is used to guide further therapy including second cycles of induction and choice of consolidation. It is still uncertain how the quality of response post cycle 1 with inclusion of MRD assessment impacts on outcomes within AML risk subgroups including NPM1 wild type standard risk and whether this adds information to MRD status in CR post cycle 2.

Aims: To quantify the effect of MRD positivity for response after each cycle of induction therapy in younger patients with AML.

Methods: As part of the UK NCRI AML17 trial (ISRCTN: 55675535) for patients with AML or high risk MDS up to the age of 60, prospective flow cytometric MRD (MFC-MRD) monitoring was performed after each course of induction. Any level of MRD detected was considered MRD+ (sensitivity thresholds: ~0.02% by tracking diagnostic leukemic aberrant phenotypes /LAIP, ~0.05-0.1% by “different-from normal” blast LAIP). Clinicians were not informed of MFC-MRD results. Following their first cycle of induction with daunorubicin/ara-C based therapy, patients were allocated a risk group by a validated score (comprising cytogenetics, WBC, age, secondary disease, blast response to cycle 1 and mutation status). Poor risk patients received intensified therapy in cycle 2 with a view of proceeding to SCT.

Results: MFC-MRD results after either induction course are available for 1555 patients randomised from 4/09-12/14 (median age 51, range 0-73). Cycle 1 (C1) response data with MFC-MRD was available for 1,400 patients. 70% achieved morphological CR at this time-point; 14% had resistant disease (RD) and 16% were in partial remission (PR) according to clinician. Of patients in CR (n=984) 56% had detectable MFC-MRD (MRD+). Excluding poor-risk patients 14% of patients did not achieve CR (7% RD, 7% PR), 51% of patients in CR were MRD+. 5 year OS for MRD- vs MRD+ was 63% vs 44% vs 37% vs 25% for all patients; 69% vs 51% vs 50% vs 30% excluding poor risk patients and 66% vs 49% vs 49% vs 30% for standard risk alone (Figure 1). The similar OS in this group between CR MRD+ and PR at C1 was maintained in NPM1/wt standard risk patients and if censored at stem cell transplant. 771 patients were in CR post cycle 2 (C2) and provided MFC-MRD data. As expected, there were significant differences in 5 year OS between CR MFC MRD+ vs CR MFC MRD- for all patients (35% vs 83%) and excluding poor-risk (38% vs 70%, n=512). Importantly post cycle 2 MFC-MRD status also differentiated OS for NPM1/wt standard risk patients with 5 year OS of 32% vs 64% (P=0.002) for MRD+ vs MRD- (Figure 1). In stratified analyses, there was some evidence that the effect of MRD positivity on OS was lower in poor-risk patients (test for trend p=0.02 for both C1 and C2). The effect of MFC-MRD status on relapse and OS appeared greater at C2 (relapse, OR 2.00(1.56-2.55), p<0.001; survival, OR 1.80(1.42-2.28) p<0.001) than C1 (relapse, OR 1.69(1.37-2.07), p<0.001; survival, OR 1.46(1.19-1.79) p<0.001). In patients with data for both time points, C2 MRD remained significant on OS when adjusting for C1 response. 24 patients converted from C1 MRD- to C2 MRD+, with a poor prognosis (15 relapses, 13 deaths). C1 MRD-/C2 MRD− had the best prognosis.

Figure 1.

Summary/Conclusions: MFC-MRD in CR post cycle 1 has similar outcomes to partial remission in younger patients with AML, particularly in patients with good and standard risk disease. Assessment of MFC-MRD post cycle 2 appears to provide additional discrimination to cycle 1: MFC-MRD in courses 1-2 may be useful in further stratifying standard risk patients.
New insights into chronic lymphocytic leukemia biology

may improve the stratification of CLL patients.

presentation of the mutations and not only their presence or absence. In addition, the clinical evaluation of gene mutations should consider the quantitative driver mutations is related to the size of the mutated population. Therefore, clonal population

Leukemogenesis", DKFZ, Heidelberg, 2Internal Medicine III, Ulm University, Spain

Recent studies have revealed the presence and prognostic impact of small mutated subclones in chronic lymphocytic leukemia (CLL) (Rossi et al 2014, Nadeu et al 2016, Rasi et al 2016). Although these studies focused only on a small subset of 5 genes, their results opened a new perspective where the proportion of cells carrying each specific driver mutation may be relevant to the evolution of this disease. Moreover, the subclonal and mutational complexity estimated by the presence of subclonal driver alterations (Landau et al 2013, Landau et al 2015) or the accumulation of driver alterations (Puente et al 2015) have been proposed as promising indicators of clinical behavior.

The goal of this study was to determine the relevance of the quantitative subclonal architecture and mutational complexity in the evolution of CLL integrating the deep sequencing analysis of a large panel of driver genes and DNA copy number alterations (CNA).

Methods: The mutational status of 28 driver genes was investigated in 406 previously untreated CLL patients by targeted deep next-generation sequencing (NGS). Mutations present in less than 1% of tumor cells were identified. All low frequency mutations were verified by allele-specific PCR or a second round of NGS. CNA were analyzed by SNP-arrays. Alterations were classified as clonal if their CCF was ≥85%, and subclonal otherwise. All patients gave informed consent.

Results: Using a highly sensitive NGS strategy we observed that small subclonal mutations were the sole alteration in 22% of the mutated cases, and were frequently detected in nearly all investigated genes. We identified three gene-specific patterns that linked the magnitude of the mutated clones (or mutated cancer cell fraction, CCF) with the prognosis of the patients: i) CCF-independent pattern: mutations at any CCF had prognostic value, ii) CCF-gradual pattern: the poor prognostic impact was a continuous variable directly related to the size of the clone, and iii) CCF-clonal pattern: only mutations with a CCF above a certain threshold impacted the outcome of the patients. Combining mutations and driver CNA, we identified at least one driver alteration in 66% of the patients. The subclonal mutational complexity (accumulation of 1 to ≥4 driver alterations), but not the presence of subclonal driver populations, gradually shortened the time to first treatment independently of the IGHV mutational status and Binet stage. Conversely, the subclonal complexity, defined as the accumulation of driver alterations with the presence of at least one driver subclone, predicted for a worse overall survival independently of the IGHV and Binet stage. Patients with a pure clonal population (presence of one or more driver alterations in all tumor cells) had a similar overall survival than patients without any alteration.

Summary/Conclusions: Our study shows that the prognostic impact of different driver mutations is related to the size of the mutated population. Therefore, the clinical evaluation of gene mutations should consider the quantitative representation of the mutations and not only their presence or absence. In addition, the mutational complexity predicts for shorter time to first treatment independently of the IGHV and Binet stage, whereas the subclonal complexity confers an independent adverse impact for overall survival. Altogether, the integration of the subclonal architecture and mutational complexity in prognostic indexes may improve the stratification of CLL patients.

S116

FBXW7 MUTATIONS LEAD TO ACCUMULATION OF NOTCH1, HIF1-ΑLPHA AND c-MYC IN CLL CELLS

with recurrent mutations that are of pathogenic and prognostic relevance. Mutations in FBXW7 are among the most common mutations in CLL, yet their functional consequences are unknown. FBXW7 is an E3 ubiquitin ligase that ubiquitylates oncoproteins like NOTCH1, HIF1-α and c-MYC and thereby targets them for proteasomal degradation.

Aims: 2.5-4% of CLL patients harbor FBXW7 mutations. Approximately 60% of FBXW7 mutations alter arginine residues that are involved in substrate targeting. In T-cell acute lymphoblastic leukemia these arginine mutations are associated with chemotherapy resistance. In CLL however, the role of dysfunctional FBXW7 is unclear. We therefore aimed to delineate the prevalence of FBXW7 mutations in CLL patient cohorts and characterize its functional role.

Methods: FBXW7 mutations were identified via the PolyPhen-2 software. all but one missense mutation in FBXW7 were predicted to be most likely damaging. No mutations in FBXW7 were found in the CLL, MCL and LCL cell lines analyzed. To determine the functional consequence of FBXW7 mutations in CLL, we induced either a heterozygous or a homozygous truncation of FBXW7 in the CLL cell line, resulting in the loss of the substrate binding site of the WD40 domain. The homozygous truncation of FBXW7 resulted in an increase of NOTCH1, HIF1-α and c-MYC protein levels, whereas no difference of Cyclin E protein amount was detectable. In addition, an elevation of NOTCH1 activity was found in both the heterozygously and homozygously truncated mutant cell lines in comparison to the wildtype HG3 cell line. To confirm this finding, protein levels of 5 CLL patients with FBXW7 mutations were analyzed with a similar outcome.

Summary/Conclusions: Mutations in FBXW7 are frequently found in CLL, especially missense and nonsense mutations affecting the WD40 domain. We hypothesize that this has functional consequences on FBXW7 substrate binding and thereby accounts for accumulation of oncoproteins, which may lead to truncation of the WD40 domain of FBXW7 in the HG3 cell line resulted in the accumulation of protein substrates and corresponding increase of their activity implicated in the pathogenesis of CLL. Taken together our data show that FBXW7 can target proteins for degradation that are commonly dysregulated in CLL and that drive disease progression.

S117

INTEGRATIVE ANALYSIS OF THE GENOME, EPIGENOME, TRANSCRIPTOME AND THREE-DIMENSIONAL CHROMATIN STRUCTURE IN CHRONIC LYMPHOCYTIC LEUKEMIA

leukemia (CLL), such as the genome, transcriptome and layers of the epigenome, like histone modifications, remain relatively unexplored.

Background: Different omics studies have focused on the analysis of individual layers of information in chronic lymphocytic leukemia (CLL), such as the genome, transcriptome and DNA methylation. Combining the information from all these layers of information may provide a more complete understanding of CLL biology.

Aims: The aim of this study was to extensively map and analyse the epigenome

Background: Chronic lymphocytic leukemia (CLL) is a heterogeneous disease...
of CLL in relation to the mutational, transcriptional and three-dimensional (3D) chromatin landscape.

**Methods:** Seven CLL patients with distinct clinico-pathological features and five mature B-cell subpopulations were extensively analysed using (i) ChIP-seq of six different histone marks with non-overlapping features (H3K27ac, H3K4me1, H3K4me3, H3K9me3, H3K27me3 and H3K36me3); (ii) single stranded RNA-seq; (iii) transposase-accessible chromatin assays (ATAC-seq) and iv) whole-genome bisulfite sequencing (WGBS), creating a unique reference epigenome for CLL. These data were complemented with the 3D chromatin landscape in one CLL case measured by high-throughput chromatin conformation capture (HiC-seq) and promoter capture Hi-C (PCHi-C). Furthermore, we mapped the active chromatin landscape of 100 CLL patients by H3K27ac ChIP-seq and ATAC-seq. Whole-genome sequencing data was available for 44 of these patients. We applied a broad range of bioinformatic tools to analyze the data in an integrative way.

**Results:** CLL is distinct from normal B cells for all layers of the reference epigenome (47 CLLs) and the active chromatin landscape (100 CLLs). CLL though is closer to naive and memory B cells than to germinal center B cells and plasma cells. Interestingly, in CLL we not only saw activation of regions that are active in naive and memory B cells, but also an unexpected activation of genomic regions that are specifically active in germinal center B cells and plasma cells. Changes in activation in these and other regions could furthermore distinguish the two major clinical subgroups of CLL with unmutated and mutated immunoglobulin heavy chains (IgVH). CLLs did not only differ from normal B cells regarding the separate layers of information, but also using combined patterns of histone marks, which for example can define regulatory elements as active promoters (H3K4me3 and H3K27ac) or active enhancers (H3K27ac and H3K4me1). More specifically, we detected 534 genomic regions with de novo gain (n=498) or loss (n=36) of active regulatory regions in CLL. Large regions (>10kb) showing de novo gain of regulatory elements in CLL (n=51), were located into, close to, or interacted in 3D space with genes important for CLL pathogenesis, e.g., LEF1, BCL2 and FMO3. Interestingly, non-coding somatic mutations in IGHV mutated CLLs accumulate in these and other active regulatory regions, likely off-target effects of the somatic hypermutation machinery. Besides changes in regulatory elements, we observed that CLLs lose poised promoters, which are replaced by repressive active regions. This change, mainly occurring in developmental genes, does not affect gene expression levels, as these genes are already silent in normal B cells. It may however represent loss of plasticity during CLL pathogenesis in which these genes become permanently inactive.

**Summary/Conclusions:** With this integrative study, we generated new conceptual avenues to understand the complex link among the epigenetic, transcriptional, and 3D chromatin landscape in CLL. In addition we provide the community with an extensive resource of epigenetic information of this lymphoid neoplasm.

**S118 THERAPEUTIC DISRUPTION OF THE BAFF- B-CELL RECEPTOR CROSS-TALK IN CHRONIC LYMPHOCYTIC LEUKEMIA CELLS**

C. Paiav1, T. Rowland1, B. Sreekantham1, O. Danilova1, A. Danilov1,1

1Oregon Health and Science University, Portland, United States

**Background:** Although small molecule inhibitors of BCR-associated kinases (BCRi) revolutionized therapy in CLL, they provide incomplete responses. Tumor necrosis factor receptor superfamily ligands BAFF and APRIL induce NFκB, which in turn upregulates pro-survival Bcl-2 family proteins and thereby drives anti-apoptotic responses, potentially accounting for resistance to BCRi. The exact roles of the individual NFκB pathways, as well as the implications of targeting BCR in context of BAFF signaling in CLL remain understudied.

**Aims:** We explored the mechanistic underpinnings of CLL cell survival in response to BAFF signaling.

**Methods:** We established a novel BAFF-expressing stromal co-culture model and screened inhibitors of Bruton tyrosine kinase (BTK), ibrutinib; phosphoinoside-3 kinase (PI3K, idelalisib) and spleen tyrosine kinase (SYK, entosple tinib). We quantified CLL cell apoptosis, migration, NFκB activity, protein and mRNA expression by flow cytometry, immunoblotting, ELISA, RT-PCR and immunocytochemistry.

**Results:** CLL cells co-cultured with BAFF-expressing stroma were resistant to spontaneous apoptosis (12.3±3.2% after 24 h, vs 34.8±6.2% off stroma) and chemotherapy agents (bendamustine, fludarabine). Gene expression profiling exposed the NFκB pathway gene targets as the most significantly upregulated upon BAFF stimulation (p<0.0001). We and others have shown that BAFF-expressing stroma induces canonical and non-canonical NFκB in CLL. By contrast, while BAFF led to strong activation of the non-canonical NFκB with processing of p100 (to p52) by 4 h and a 5-fold increase in p52 DNA-binding activity by 24 h, canonical NFκB (RelA) activation was less pronounced. BAFF predominantly induced Mcl-1, compared to CD40L which strongly upregulated Bcl-X. BCR is a major driver of canonical NFκB signaling in CLL. Thus, we studied whether BAFF co-opted BCR signaling in CLL. BAFF induced rapid (15 min) phosphorylation of the proximal BCR kinases SYK and LYN, sustained for up to 4 h, as well as ERK, in CLL cells. AKT activation occurred late (>2h), suggesting that BAFF induced AKT independent of BCR. BAFF-mediated BCR activation did not correlate with IGHV mutational status. Like IgM, BAFF induced CLL cell chemotaxis. SYK inhibition effectively antagonized survival and chemotaxis of BAFF-stimulated CLL cells. By contrast, targeting BTK or PI3K was less effective. All BCRi’s fully blocked canonical NFκB activation in BAFF-stimulated CLL cells (suggesting its dependence on BCR signaling), but none inhibited the non-canonical pathway. By contrast, pevonedistat, an inhibitor of Nedd8-activating enzyme which we have previously shown to abrogate TNFR-mediated NFκB activation, blocked both canonical and non-canonical NFκB activity in BAFF-stimulated CLL cells. SYK inhibitor entosple tinib, but not other BCRi’s, decreased Mcl-1 expression in CLL cells co-cultured with BAFF-expressing stroma and abrogated BAFF-mediated upregulation of pSTAT3, a transcription factor which regulates Mcl-1. This was accompanied by a decrease in Mcl-1 transcript. BAFF receptor signals via the TRAF complex to induce non-canonical NFκB activation in neoplastic B-cells. We supposed that TRAF complex could be directly responsible for SYK activation by BAFF. Indeed, IP experiments demonstrated that SYK directly complexed with TRAF2/3 in BAFF-stimulated neoplastic B-cells.

**Summary/Conclusions:** Thus, BAFF-mediated induction of BCR-associated kinases and Mcl-1 contributes to CLL cell survival. SYK inhibition is a promising therapeutic strategy uniquely poised to antagonize crosstalk between BAFF and BCR, thereby disrupting the pro-survival microenvironment signaling in CLL.
S119

LOW MYBL2 EXPRESSION OBSERVED IN MYELODYSLASTIC SYNDROME PATIENTS WITH WORSE PROGNOSIS IS ASSOCIATED WITH ALTERED DNA REPAIR MECHANISMS IN HAEMATOPOIETIC STEM CELLS

R. Bayley1, L. Cancian1, C. Ward1, G. Völpe1, S. Dumen1, G. Gajjar1, G. Stewart2, E. Petersmann1, P. Garcia1.

1Institute of Cancer and Genomic Science, University of Birmingham, Birmingham, United Kingdom

Background: MYBL2 is a transcription factor with roles in the cell cycle and genome integrity. MYBL2 is located on chromosome 20, within a region commonly deleted in human blood disorders (del20q). Our published data shows that reduced levels of MYBL2 predispose to development of myelodysplastic syndromes (MDS)-like disease in mouse models during ageing, indicating that MYBL2 could be acting as a tumour suppressor gene within del20q abnormality. Moreover, our previous work demonstrated that regardless of del20q deletion, MYBL2 expression is reduced in CD34+ bone marrow cells from MDS patients with worse prognosis. Because it has been shown that the cell of origin of MDS is the haematopoietic stem cell (HSC) and given the role of MYBL2 in DNA replication fork progression and maintenance of genome integrity, we hypothesised that low MYBL2 levels in HSC could contribute to elevated somatic mutations through changes in DNA repair pathways and drive disease development.

Aims: The aim of this study was to determine if low MYBL2 levels affect the double strand break (DSB) DNA repair damage response in HSC.

Methods: In this study we used our mouse model in which animals express ~50% normal levels of MYBL2 (Myb2+/−). We characterised the activity of HSCs from young (7 weeks) and old (70 weeks) animals to respond to in vivo ionising radiation (IR) via the DDR that led to DNA replication, apoptosis and colony formation being impaired. We measured the activation of the two main DNA repair pathways operating in the cells to deal with DSB: the error prone non-homologous-end-joining (NHEJ) and the error-free homologous recombination (HR) by assessing 53BP1 and Rad51 recruitment by immunofluorescence, respectively. Finally, we analysed the frequency of chromosome abnormalities present in the progeny of Myb2−/− HSC that have previously been irradiated to determine the long term effects of changes in DNA repair.

Results: We observed that Myb2−/− HSCs had limited proliferative potential and displayed an increased sensitivity to ionizing radiation which increased during ageing. Myb2−/− HSCs also displayed altered kinetics of 53BP1 and Rad51 recruitment and clearance, including retention of 53BP1 foci at later time points following irradiation and decreased levels of Rad51 foci when compared to Myb2+/−HSCs. Using plasmid functional assays, we showed that Myb2−/− HSCs repair quite efficiently by NHEJ, but this efficiency is disrupted when cells are challenged with ionising radiation. Furthermore, Myb2−/− HSCs have increased sensitivity to inhibition of DNA-PKc (required for NHEJ) but not ATM (required by HR). We also observed that after ionizing irradiation Myb2−/− HSC progeny displayed an increased percentage of chromatids with fragile telomeres. Moreover, by making use of publicly available RNA-seq data from young and old C57Bl/6 mice, we have identified a clear association between low MYBL2 levels and low expression of DNA-repair genes in patients with worse prognosis.

Summary/Conclusions: In summary, we have shown that decreased expression of MYBL2 leads to an imbalance in the DSB DNA-repair pathway choice, ultimately resulting in increased genomic instability of the blood cell progeny. These findings are supported by a signature of deregulated DNA-repair genes which strongly associates with low MYBL2 levels in MDS patient samples, providing a mechanistic understanding for the progression of blood disorders occurring during ageing. This study demonstrates a novel role for MYBL2 in DSB repair in HSCs and suggests that low levels of MYBL2 in human MDS could contribute to the emergence of further genetic abnormalities by deregulation of DNA-repair pathways.

S120

A NOVEL GENETIC AND MORPHOLOGIC PHENOTYPE OF ARID2-MEDIATED MYELODYSLASTIC SYNDROMES

1Department of Translational Hematology and Oncology Research, Cleveland Clinic, Cleveland, United States; 2Division of Hematology, Department of Internal Medicine, Shinshu University, Matsumoto, Japan; 3First Department of Internal Medicine, University of Tokushima, Tokushima, Japan; 4Department of Hematology and Medical Oncology, Cleveland Clinic, Cleveland, United States; 5Pathology and Tumor Biology, Kyoto University, Kyoto, Japan; 6Clinical Research Center, Nagoya Medical Center, Nagoya, Japan; 7Laboratory of Sequence Analysis, Human Genome Center, The University of Tokyo, Tokyo, Japan.

Background: Clinical heterogeneity of myelodysplastic syndromes (MDS) and related myeloid neoplasms reflects molecular diversity. Most common genetic associations with distinct clinical or pathomorphologic phenotypes have been described, but many other rare or somatic lesions exist and their clinical context still remains elusive. AT rich interactive domain 2 (ARID2), which is located on chromosome 12q, encodes a component of the SWI/SNF complex that is involved in chromatin remodeling. In recent years multiple groups detect- ed ARID2 mutations in a variety of solid tumors.

Aims: In this study, we present whole exome sequencing-guided identification of novel ARID2 mutations in myeloid neoplasms. Specifically, in addition to copy number analysis and deep targeted and exome sequencing, here we include RNA sequencing and splicing analyses of the roles of splicing events in MDS and other myeloid neoplasms and gene expression.

Methods: Bone marrow aspirates or blood samples were collected from 1,473 patients with MDS (n = 445), myelodysplastic/myeloproliferative neoplasms (MDS/MPN) (n = 201), myeloproliferative neoplasms (MPN) (n = 56), sAML (n = 221), and primary acute myeloid leukemia (pAML) (n = 540) at the Cleveland Clinic and The University of Tokyo; the registered data at the Cancer Genome Atlas were also included. Diagnoses were classified using World Health Organization criteria. Informed consent for sample collection was obtained according to a protocol approved by each Institutional Review Board in accordance with the Declaration of Helsinki.

Results: By comprehensive genetic investigation of these cases, we characterized here cases (10%) in which decreased expression of ARID2 mediated their clinical effects in MDS and other myeloid neoplasms via multiple kinds of genetic lesions. We showed that insufficient ARID2 expression mainly in MDS arose from ARID2 mutations, deletions, and missplicing due to U2AF1 mutations that yielded defective pre-mRNA transcripts. Our whole exome analyses showed that ARID2 mutations and deletions occurred as initial events of MDS or myelodysplasia/myeloproliferative neoplasms, and not during progression to acute myeloid leukemia. Morphologically, progressive maturation in myeloid and erythroid lineages and hypoproliferative megakaryocytes (indicated by arrow heads in Figure 1) were common in cases with ARID2 mutations and deletions, and were also found in cases with U2AF1 mutations. Functionally, we utilized in vitro knockdown models of ARID2 expression in hematopoietic cell lines and bone marrow mononuclear cells. Since no homozygous deletion or mutation of ARID2 was identified, we transduced shRNA in neo-plastic and healthy hematopoietic cells to obtain disease models with partial reduc- tion of ARID2 expression. Two myeloid cell lines (HL60 and KG62) in which ARID2 expression was knocked down showed significantly lower cell counts compared to those with normal ARID2 expression, compatible with more apoptotic cells in knockdown experiments. Flow cytometric analysis of the cell lines with reduced ARID2 expression revealed increased cell-surface maturation markers, CD11b and glycoprotein A (GPA), suggesting that reduced expression of ARID2 resulted in more differentiation in myeloid and erythroid lineages. Knockdown of ARID2 failed to reduce colony formation in bone marrow mononuclear cells. These results indicate that reduced ARID2 expression might induce more differentiation in myeloid/erythroid lineages and more apoptosis to reduce cell populations without reduction of proliferation capacity in hematopoietic progenitor cells. Finally, we examined morphological findings associated with knockdown ARID2 expression. Compared to control cells, KG62 cells with reduced ARID2 expression formed more hypoproliferative megakaryocytes, which confirmed morphological findings seen in ARID2 and U2AF1 defects.

Figure 1.

Summary/Conclusions: ARID2 is a MDS-suppressor gene whose expression is attenuated by multiple mechanisms as it shapes the distinct morphological phenotype of a subset of myelodysplasia.
The value of NGS panel sequencing to molecularly define myeloid malignancies and clarify borderline cases: A study on 39 genes in 1143 patients

C. Baer1, K. Perglerová2, W. Kern1, C. Haferlach1, T. Haferlach1

1MLL Munich Leukemia Laboratory, Munich, Germany, 2MLL2 s.r.o., Prague, Czech Republic

Background: The 2016 revision of the WHO classification for myeloid malignancies includes numerous molecular markers for classification and prognostication. Next generation sequencing allows analyzing relevant genes in one panel.

Aims: Exploit clinical usefulness of panel sequencing in routine diagnostics in order to describe genetic changes and use respective patterns in cases with undifferentiated myeloid neoplasms.

Methods: According to WHO 2016, 1143 patients were morphologically categorized as AML (n=261), MDS (n=176), MPN (n=19), CMML (n=51) or AML/MDS (n=21) and MDS/MPN overlap (n=28). Patients, who did not fulfill all characteristic criteria or had insufficient sample quality, were classified as “possible” AML (n=28), MDS (n=211), MPN (n=58), CMML (n=14) and as reactive (n=193) or unclear (n=136). DNA was isolated from BM (n=958) or PB (n=185) for NextSeq or MiSeq sequencing after TruSeq library preparation (all Illumina, CA). Data was analyzed with SeqNext 4.3 (JSI Medical Systems, Kippenheim, Germany). FLT3-ITD and KMT2A-PTD data was obtained according to standard protocols.

Results: Analyzing 39 genes, we found ≥1 molecular change in 90% of patients (500/556) with a definitive morphologic diagnosis (median: 2 genes; max: 7).

In de novo AML, 212/229 (93%) patients showed ≥1 molecular hit, of which 211 (92%) had aberrations that define WHO categories or have prognostic (according to ELN/MRC) or predictive value. Additionally, one mutation was found in 166/229 patients (72%), including information of adverse impact (e.g. of 68 NPM1 positive patients, 17 had DNMT3A mutations and 20 FLT3-ITD). Following NPM1, RUNX1 was the second most frequently mutated gene (46/225; 20%) and mutations were significantly more common in patients with ≥3 aberrations (37/57; 65%) than with 2 (20/76; 26%). A similar RUNX1 (f pattern was found in s-AML and t-AML. In the cohort of “possible AML” (including MDS patients), 199/918 (21%) patients had ≥1 molecular hit. Most frequently mutated were ASXL1 (16/48; 33%), TET2 (32%; 14/44) and SRSF2 (29%; 14/48); 16% had all three mutated. This combination is the most frequently occurring three-way interaction in CMML (10/44; 23%). In MDS, 124/157 (79%) cases showed mutations, of which 108 had ≥1 prognostic change (according to Bejar, 2015). The prognostically favorable SF3B1 mutation was present in 31/157 (20%) and significantly enriched among cases with ring sideroblasts (p<0.001). Overall, TET2 showed the highest mutation rate (25%) and was also the most commonly mutated gene in cases with “possible” MDS (3/69; 42%). A similar pattern was observed in the case of RUNX1 (8% of all molecular markers for clonal disease in 47% (91/199), 36% (43/118) or 17% (36/211) of cases, respectively (excluding sole ASXL1, DNMT3A, TET2 mutations with <10% burden), which is observed in clonal hematopoiesis of indeterminate potential (CHIP), too. However, using panel sequencing in cases with possible MDS, unclear or reactive morphology revealed at least one molecular marker for clonal disease in 47% (91/199), 36% (43/118) or 17% (36/211) of cases, respectively (excluding sole ASXL1, DNMT3A, TET2 mutations with <10% burden).

Summary/Conclusions: WHO 2016 requires information on numerous genes for diagnosis, prognosis and therapeutic decisions. This challenges conventional cytomorphology which is performed at least once in clinical disease in 47% (91/199), 36% (43/118) or 17% (36/211) of cases, respectively (excluding sole ASXL1, DNMT3A, TET2 mutations with <10% burden). De novo AML, 212/229 (93%) patients showed ≥1 molecular hit, of which 211 (92%) had aberrations that define WHO categories or have prognostic (according to ELN/MRC) or predictive value. Additionally, one mutation was found in 166/229 patients (72%), including information of adverse impact (e.g. of 68 NPM1 positive patients, 17 had DNMT3A mutations and 20 FLT3-ITD). Following NPM1, RUNX1 was the second most frequently mutated gene (46/225; 20%) and mutations were significantly more common in patients with ≥3 aberrations (37/57; 65%) than with 2 (20/76; 26%). A similar pattern was observed in the case of RUNX1 (f pattern was found in s-AML and t-AML. In the cohort of “possible AML” (including MDS patients), 199/918 (21%) patients had ≥1 molecular hit. Most frequently mutated were ASXL1 (16/48; 33%), TET2 (32%; 14/44) and SRSF2 (29%; 14/48); 16% had all three mutated. This combination is the most frequently occurring three-way interaction in CMML (10/44; 23%). In MDS, 124/157 (79%) cases showed mutations, of which 108 had ≥1 prognostic change (according to Bejar, 2015). The prognostically favorable SF3B1 mutation was present in 31/157 (20%) and significantly enriched among cases with ring sideroblasts (p<0.001). Overall, TET2 showed the highest mutation rate (25%) and was also the most commonly mutated gene in cases with “possible” MDS (3/69; 42%). A similar pattern was observed in the case of RUNX1 (8% of all molecular markers for clonal disease in 47% (91/199), 36% (43/118) or 17% (36/211) of cases, respectively (excluding sole ASXL1, DNMT3A, TET2 mutations with <10% burden).
Results: Unsupervised clustering of gene expression data of bone marrow blasts compared to those in the Class-I subgroup (median 2% vs 11%, *P* <0.01). Pathway analysis revealed up-regulation of many signaling pathways in the Class-II subgroup. The Class-I subtype showed highly significant up-regulation of the genes related to erythrocyte lineages. The erythroid signature was rather suppressed in the Class-II subtype, which was characterized by increased expression of genes related to progenitor cells. Compared to the Class-I subtype, the Class-II subtype was associated with a significantly shorter survival in both univariate (hazard ratio [HR] 5.0 [95% CI, 1.8–14], *P* <0.001) and multivariate analysis (HR 6.8 [95% CI, 1.5–32], *P* =0.015). High frequency of leukemic transformation in the Class-II subgroup (38%) contrasted to no leukemic transformation in the Class-I subgroup. The prognostic significance of our classification was validated in an independent cohort of 183 patients. We also constructed a model to predict the subgroups using gene expression profiles of BMMNCs. The model was applied to 114 patients with BMMNC samples, of whom 47 (41%) were predicted to be the Class-II subgroup. Compared to the predicted Class-I subgroup, the Class-II subgroup was associated with a significantly shorter survival in univariate analysis (HR 7.2 [95% CI, 3.0–17], *P* <0.001). Again, association was more pronounced for leukemic transformation (HR 18 [95% CI, 4.2–80], *P* <0.001) than for overall survival. Multivariate analysis also demonstrated that the predicted Class-II subgroup was independently associated with leukemic transformation (HR 7.3 [95% CI, 1.3–41], *P* =0.024). Finally, we compared the prognostic value of our model with that of the LSC17 score, which has recently been proposed to predict a subset of poor risk acute myeloblastic leukemia based on the expression of 17 genes related to a leukemic stem cell signature. Our model outperformed the LSC17 score in predicting clinical outcomes of myelodysplasia, especially leukemia progression.

Summary/Conclusions: Comprehensive transcriptomic analysis identified two subgroups of myelodysplasia with biological and clinical relevance, which could improve risk prediction and treatment stratification of myelodysplasia.

**Background:** Checkpoint blockade using anti-PD-1/PD-L1 antibodies is a highly promising therapy for cancer, frequently showing dramatic anti-tumor responses in a wide variety of tumor types. Particularly, an exceptional response to anti-PD-1 antibodies has been demonstrated for classical Hodgkin lymphoma (HL), which is characterized by frequent copy number gains/amplifications in PD-L1 and PD-L2, suggesting a link between these genetic alterations and the therapeutic response to these agents. Recently, we have reported frequent structural variations (SVs) in adult T-cell leukemia/lymphoma (ATL) caused by human T-cell leukemia virus type-1 (HTLV-1). These SVs invariably affect 3′-untranslated region (UTR) of PD-L1, leading to promiscuous PD-L1 overexpression. Providing critical viral antigens in an endogenous context to virally infected cells, we hypothesized that a deregulated PD-1/PD-L1 axis might play a critical role in evasion from anti-viral immunity before these cells are clonally selected for neoplastic proliferation.

Aims: Epstein-Barr virus is a DNA tumor virus closely associated with various human cancers, including B- and natural killer (NK)-T-cell lymphomas, in which genetic alterations involving PD-L1/PD-L2 may also be relevant to cancer evolution. In this study, to assess this hypothesis, we interrogated a variety of lymphomas for genetic abnormalities affecting PD-L1 and PD-L2, especially focusing on EBV-associated lymphomas.

Methods: SVs and other genetic lesions affecting PD-L1 and PD-L2 were analyzed using targeted-capture sequencing with cRNA baits designed for capturing the entire sequences of PD-L1 and PD-L2 genes, including exons, introns, and 5′- and 3′-UTRs. More than 400 samples were analyzed obtained from different subtypes of non-Hodgkin lymphomas, including EBV-associated lymphomas (such as EBV-positive diffuse large B-cell lymphoma (DLBCL) and NK/T-cell malignancies).

Results: SVs and/or focal copy number gains involving PD-L1 genes were successfully detected in various B-cell and T/NK-cell lymphomas, albeit at generally low frequencies (<10%). These lesions were the most frequently observed in PMBCs, accounting for more than 60% of the cases. Of note, high frequency (17–57%) of PD-L1/PD-L2 involving abnormalities were observed in mature NK/T-cell neoplasms, including extranodal NK/T-cell lymphoma, aggressive NK cell leukemia, and EBV-positive T-cell lymphoproliferative disorder, all of which were positive for EBV. Moreover, a substantial proportion (22%) of EBV-positive DLBCL cases possessed these lesions, whereas EBV-negative cases rarely exhibited these alterations (2%, *P*<0.01). For both PD-L1 and PD-L2 SVs, despite a large diversity of SV type (deletions, inversions, tandem duplications, and translocations), most of SVs resulted in 3′-UTR truncation, while the replacement of PD-L1 or PD-L2 promoter with an ectopic regulatory element was rarely observed. Interestingly, PD-L1 SVs were detected in both B- and T-cell lymphomas, whereas PD-L2 SVs were found exclusively in B-cell lymphomas.

Summary/Conclusions: We delineate the entire picture of genetic alterations involving PD-L1/PD-L2, and confirm the clinical relevance and EBV-associated lymphomas. Our finding help to understand their pathogenesis and develop a new diagnostic strategy to identify patients who potentially benefit from PD-1/PD-L1 blockade therapy in non-Hodgkin lymphomas.

**Methods:** We performed transcriptome sequencing of bone marrow mononuclear cells (BMMNCs) and CD34+ cells obtained from patients with myelodysplasia. Consensus clustering was used to identify stable patient clusters. A classifier of the gene expression-based subgroups was constructed using the 100 CD34+ cell samples as a training set, followed by validation in an independent cohort of 183 MDS patients. Another classifier was constructed using BMMNC samples from 51 patients, who had been assigned to the subgroups by the gene expression data of their CD34+ cells. Prognostic significance of the model was tested in 114 patients of myelodysplasia.

**Background:** Recent somatic mutations of N-terminal region of FOXO1,
shown previously to increase FOXO1 nuclear localization and activity, have been linked to diminished survival in DLBCL patients uniformly treated with rituximab-based immunotherapy. Although the contribution of FOXO1 mutations to the therapeutic resistance of B-NHLs becomes apparent, the molecular mechanism underlying this phenomenon has not been explained so far. The diminished levels of CD20 on the cell surface of tumor cells are among several potential mechanisms underlying the resistance to treatment with anti-CD20 monoclonal antibodies.

**Aims:** We have recently reported that the tonic BCR signaling activates FOXO1, and that inhibitors of the downstream BCR signaling pathways downregulate CD20 expression. Therefore, here we sought to determine whether FOXO1 might regulate the abundance of CD20 on the surface of tumor cells thus influencing the response to rituximab-based therapies.

**Methods:** We used CRISPR/Cas9 genome editing technology and lentiviral transduction to study the role of FOXO1 protein in CD20 regulation. qRT-PCR and Dual Luciferase Assays was done to determine the influence of FOXO1 on CD20 expression. To get insight into molecular interaction between FOXO1 and CD20 promoter we performed EMSA and ChIP experiments. For animal studies we used SCID Fox Chase mice model. All in vivo experiments were carried out at the animal facility of The Francis Crick Institute in accordance with the guidelines and were approved by the Ethics Committee.

**Results:** To determine the potential role of FOXO1 protein in CD20 regulation, we disrupted FOXO1 focus using the CRISPR/Cas9 genome editing technology in Raji cells. In *in vitro* complement-dependent cytotoxicity assay we show that ablation of FOXO1 results in upregulation of CD20 levels and improved resistance to rituximab efficacy. To see whether FOXO1-dependent up-regulation of CD20 transcription was linked to tumor cell survival, we analyzed apoptosis induced by DM-KG (Figure 1C). Contrary to that, exposing viable primary CLL, FL and DLBCL cells to DM-KG significantly induced apoptosis (p<0.01) in all cell lines examined (n=17). Interestingly, we also observed that in cell lines and primary tumors, DM-KG consistently activated the kinase AMPK, with consequent marked inhibition of mTORC1. Importantly, these signals were also engaged in normal B cells, but they did not result in growth inhibition or apoptosis, thus highlighting the unique sensitivity of cancer cells to the modulation of energy metabolism.

**Summary/Conclusions:** Collectively, our results indicate that FOXO1 is a strong negative regulator of CD20 expression and add new insights into the mechanisms underlying the contribution of FOXO1 mutations to the resistance of B-NHLs to R-CHOP therapy. In light of current knowledge and our observations presented in this study, FOXO1 inhibition represents a novel strategy to increase the efficacy of anti-CD20 monoclonal antibodies.

**TIGET-BTHAL TRIAL OF AUTOLOGOUS HEMATOPOIETIC STEM CELLS GENETICALLY MODIFIED WITH GLOBE LENTIVIRAL VECTOR**

1Haematology and BMT Unit, 2Pediatric Immunohematology, 3San Raffaele Telethon Institute for Gene Therapy, San Raffaele Scientific Institute, Milano, 4Pediatric Department, San Gerardo Hospital, Monza, 5Pediatric Clinic/DH, Fondazione IRCCS Ca’ Granda, Milano, 6Department of Biomedical Science and Biotechnology, University of Cagliari, Cagliari, 7Blood Transfusion Service, San Raffaele Scientific Institute, Milano, 8Immunohematology and Transfusion Medicine Service, Fondazione IRCCS Policlinico S. Matteo, Pavia, 9Rare Disease Center, Fondazione IRCCS Ca’ Granda, Milano, Italy

**Background:** Gene therapy for transfusion dependent beta-thalassemia, as an alternative cure to allogeneic HSCT, is based on the autologous transplantation of hematopoietic stem cells (HSCs) engineered by lentiviral vectors expressing a transcriptionally regulated human beta-globin gene.

**Aims:** Our contribution to this field was devoted to the clinical development of a gene therapy protocol based on high-titer vector GLOBE, use of lenograstim and plerixafor as source of HSCs and a conditioning regimen based on myeloablative treosulfan and thiotepa favoring efficient engraftment of corrected cells with reduced toxicity (TIGET-BTHAL; EudraCT number 2014-004860-39).

**Methods:** The efficacy and safety of clinical studies, the clinical trial TIGET-BTHAL was approved and started in 2015 at Scientific Institute San Raffaele, Milano, Italy. The clinical study foresees treatment of 10 patients: 3 adults followed by 7 minors, with a staggered enrolment strategy based on evaluation of safety and preliminary efficacy in adult patients by an independent data safety monitoring board before inclusion of pediatric subjects. The chosen route of administration of gene modified HSCs is intraosseous in the posterior-superior iliac crests, bilaterally, with the aim of enhancing engraftment and minimizing first-pass intravenous filter.

**Results:** As of February 2017, seven patients (3 adults and 4 pediatric patients) with different genotypes (β0/β0, β+/β+ and β0/β+) have been treated with GLOBE-transduced CD34+ cells at a dose of 16x10⁶-19.5x10⁶ cells/kg and a vector copy number (VCN)/cell ranging from 0.7 to 1.5. The procedure was well tolerated by all patients, with no product-related adverse events. Multilineage engraftment of gene-marked cells was observed in all tested peripheral blood and bone marrow samples. Polyclonal vector integrations profiles have been detected in the first 3 patients tested.

**Summary/Conclusions:** So far, the clinical outcome indicates reduction in transfusion requirement in adult patients and greater clinical benefit in younger patients. Follow up analysis are ongoing and updated clinical outcome will be presented.
S130 DENOSUMAB INCREASES BONE MINERAL DENSITY IN PATIENTS WITH THALASSEMIA MAJOR AND OSTEOPOROSIS: RESULTS OF A RANDOMIZED, PLACEBO-CONTROLLED, DOUBLE BLIND, PHASE 2B CLINICAL STUDY

Background: Thalassemia is a heterogeneous group of hereditary disorders characterized by decreased production of hemoglobin due to defective production of beta-globin chains. Worldwide, an estimated 200,000 patients have beta-thalassemia major (TM). Thalassemia major patients have a life expectancy of 50-55 years, but the quality of life is significantly reduced due to complications related to the disease. Bone disease is one of the most common complications in TM patients, with an increased risk of fractures and osteoporosis. The aim of this study was to assess the effects of denosumab, a human monoclonal antibody that targets and binds to RANKL, on lumbar spine (L1-L4) BMD in patients with TM and osteoporosis as compared to placebo.

Materials and Methods: A double-blind, placebo-controlled, randomized clinical trial was conducted at 9 major centers in France. Patients (n=1) were randomized to receive denosumab (60 mg SC every 6 months for 12 months) or placebo. L1-L4 BMD was measured at baseline and at 12 months. Results: L1-L4 BMD was higher in the denosumab arm than in the placebo arm (6.02±5.30% vs 0.81±0.105 g/cm², p<0.008) and a significant decrease in their WR BMD (0.52±0.099 g/cm² vs 0.54±0.095 g/cm², p=0.004) and a significant decrease in their WR BMD (0.52±0.099 g/cm² vs 0.54±0.095 g/cm², p=0.004). The percentage increase in L1-L4 BMD was higher in DMB arm than in placebo arm (6.02±5.30% vs 3.11±5.46%, respectively; p=0.03), while the advantage of DMB regarding WR BMD was much higher compared to placebo (-0.22±0.45% vs -4.15±5.58%, respectively; p=0.02) as well as in FN BMD (p<0.001). No grade 3 or 4 toxicity was observed in this trial. Conclusion: Denosumab increased lumbar BMD in TM patients. Denosumab is an effective and safe treatment for the management of TM-induced osteoporosis.
SDS values increased with time, especially in females. Although gonadal dys-
function was observed in 60% of women aged at least 13 years at the last eval-
uation, 12/27 aged more than 20 years experimented at least one successful
pregnancy. 93 patients had stopped their immunosuppressive treatment two
years after HSCT. 37 were treated with iron chelation therapy and/or phle-
botomies. At least half of patients are receiving a long-term hormonal treatment
or antibiotic prophylaxis at the last visit. Decrease in serum ferritin values after
transplant was significantly influenced by age at transplant and pre-transplant
serum ferritin value. The median hemoglobin value was 12.5 g/dL (86-165) at a
mean age of 18 years and Hb values were significantly influenced by age, the
sex of the donor and the presence of donor thalassemia trait.

**Summary/Conclusions:** A comprehensive and regular long-term follow-up
should be established for all patients receiving allogenic HSCT for beta-tha-
lassemia major. In this national cohort, endocrinological complications were
frequent after transplant. Fertility can be partly preserved, but this result has to
be reevaluated with the more recent use of intravenous busulfan.

**CD34**+AND HUMAN INDUCED PLURIPOTENT STEM CELL
DIFFERENTIATION TO TRANSFUSION READY RED BLOOD CELLS

M.-J. Claessen1,2*, E. Varga3, M. Hansen4, P. Burger5, S. Heshuis1,6, T. Wust1,6,
J. Eernstman1, M. Thiell,1, E. Heideveld1, E. Sellink1, M. von Lindern1, E. van den Akker1

**Background:** Donor-derived red blood cells (RBC) are the most common form
of cellular therapy. However, the source of cells is dependent on donor avail-
ability with a potential risk of allo-immunization and blood borne diseases.

**Aims:** We aim to produce unlimited numbers of cultured RBC with a defined ‘universal donor’ phenotype for transfusion purposes.

**Methods:** To this end we prepare for a clinical test using autologous cultured
RBC to test their in vivo stability. In parallel we develop methods for unlimited
production of cultured RBC. An immortal source to produce in vitro cultured
RBCs (cRBC), such as iPSCs would allow selection of ‘universal donor’ RBC, or
provide an autologous end product with the absence of immune reactions.

**Results:** The in vitro production of RBC has proven to be successful, however
there are barriers to overcome prior to clinical application. e.g.: xeno-free cul-
turing methods, scale up cultures to obtain transfusion units (1-2*1012 erythro-
cytes), and for iPSC we need virus- and transgene-free reprogramming proto-
cols. To solve the above mentioned issues a customized humanized GMP-
grade medium (Celluin) was generated in order to control erythroid culture
parameters and to reduce culture costs. This medium allowed 1*108 times ery-
thropoiesis, allowing directed colony differentiation using a feeder-free monolayer approach.

**Summary/Conclusions:** Here we showed that our monolayer approach is sim-
ple, highly controlled and compatible with upscaling. Avoiding virus-, integrative
reprogramming, feeders and with our GMP-grade media we maintained a cost
effective system moving toward clinical application.

**FUNCTIONAL PROTEOMICS IDENTIFIES SETD2 AS A CRITICAL
EFFECTOR OF MLL FUSION PROTEINS TO SAFEGUARD GENOMIC
INTEGRITY**

A. Skucha1*, J. Ebner2, J. Schmiöller2, A. César Razquin1, T. Eder1, A. Stukalov1, S. Vittori1, M. Muhan3, R. Roth5, B. Geyer4, P. Valient5, K. Bennett1, J. Zuber5, G. Superli-Furga1,6, F. Grebien2

**Background:** The frequent occurrence of chromosomal rearrangements in
AML frequently harbors chromosomal rearrangements involving the Mixed Lineage Leukemia (MLL) gene. More than 65 different MLL fusion genes exist and many of them have been described to act as strong cancer drivers. While critical effectors of several distinct MLL fusion proteins (MLL-FPs) were identified, it is not clear if transforming mech-
isms are conserved across the entire family of MLL fusions.

**Aims:** We hypothesized that common oncogenic mechanisms are encoded in stable physical and genetic MLL-fusion-specific interaction networks. Thus, we aimed to identify common critical effectors of different MLL fusion proteins that are presumed to employ different mechanisms of oncogenic transformation.

**Methods:** Protein complexes of 7 molecularly distinct, affinity-tagged MLL-FPs (MLL-AF4, MLL-AF9, MLL-ENL, MLL-CBP, MLL-EEN, MLL-GAS7 and MLL-
AF1p) were purified from stable cell lines allowing for inducible, single-copy transfection and characterized by mass spectrometry. Data analysis identified a comprehensive protein-protein interaction network, which was func-
tionally interrogated by a subtractive shRNA screening approach. Validation experiments included detailed RNAi- and CRISPR/Cas9-mediated loss of func-
tion experiments in cell lines and primary cells in vitro and in vivo, using read-
outs for changes in proliferation, differentiation, apoptosis and DNA damage.

**Results:** Characterization of the protein complexes nucleated by 7 MLL fusion proteins by affinity purification coupled to mass spectrometry (AP-MS) revealed a densely interconnected protein-protein interaction network of 963 proteins, comprising previously known MLL-interacting protein complexes (such as PRC2 or SWI/SNF), as well as new interaction partners of MLL, 128 proteins were found to interact with ≥5 of all 7 MLL-fusions. This subset of con-
served MLL-interaction partners was highly enriched for proteins with function in chromatin metabolism and transcriptional control. Systematic functional
investigation of the conserved MLL-fusion interactome using subtractive shRNA
screens identified the methyltransferase SETD2 as a critical effector of MLL
fusion proteins. Both RNAi-based suppression and CRISPR/Cas9-mediated mutagenesis of SETD2 induced myeloid differentiation and apoptosis in human
and mouse MLL-rearranged cell lines, while having only modest effects on the
proliferation of MLL-wild-type leukemia cells. Depletion of SETD2 in MLL-fusion
lent to changes in proliferation, differentiation, apoptosis and DNA damage.

**Summary/Conclusions:** In summary, our data highlight the functional rele-
ance of combined proteomic-genomic cellular screening to identify critical
effectors of MLL-FPs. In addition, our study identifies a novel role for SETD2
in the maintenance of genomic integrity during initiation and progression of
MLL-rearranged AML and establishes SETD2 as a therapeutic target in
leukemia with low genonomic complexity.

**CEBPA-MUTANT ACUTE MYELOID LEUKEMIA IS SENSITIVE TO
SMALL-MOLECULE-MEDIATED INHIBITION OF THE MENIN-MLL
INTERACTION**

L. Schmidt1*, E. Heyes1, T. Eder1, J. Grembecka2, F. Grebien1

1Ludwig Boltzmann Institute for Cancer Research, Vienna, Austria, 2Department of Pathology, University of Michigan, Ann Arbor, United States

**Background:** The CEBPA gene - encoding for the transcription factor C/EBPa
- is mutated in 9% of patients with acute myeloid leukemia (AML). CEBPA

---

**N-terminal mutations lead to selective loss of full length C/EBPa p42 expression
without affecting translation as a balance of the shorter p30 isoform. As a balance
of C/EBPa isoforms is crucial for hematopoietic homeostasis, depletion of p42
leads to increased cell growth and blocks myeloid differentiation, resulting in
the development of AML. We have recently shown that the p30 variant of

---

**AML Biology I: Towards molecular therapies**
C/EBPα can act as a gain-of-function allele with distinct molecular properties. However, the mechanism of C/EBPα p30-induced leukemogenesis is incompletely understood.

**Aims:** We hypothesized that the interaction between the oncogenic C/EBPα p30 isoform and the MLL/SET histone methyltransferase complex is required for p30-dependent epigenetic and transcriptomic changes that contribute to leukemogenesis. Therefore, we aimed to investigate the sensitivity of CEBPα mutant MLL to perturbation of MLL/SET function.

**Methods:** We used CRISPR/Cas9-mediated mutagenesis to interfere with the MLL/SET complex in myeloid progenitor cells from a Cebpa<sup>−/−</sup>AML mouse model. Cellular competition assays were used to assess changes in proliferative capacity. Further, MLL activity was inhibited by blocking small molecules that block the Menin-MLL interaction. In both cases, proliferation, myeloid differentiation and apoptosis were used as readouts. Global changes in gene expression were measured by RNA-seq.

**Results:** We initially confirmed, via ChIP, that CEBPα and MLL co-localize on the Cebpa<sup>−/−</sup>AML promoters, indicating functional cooperation in gene regulation. To investigate the importance of different, annotated functional domains within the MLL protein in the context of CEBPα p30 expression, we introduced targeted mutations across the MLL gene in Cebpa<sup>−/−</sup> cells using the CRISPR/Cas9 system. This analysis revealed a strong dependence of Cebpα<sup>p30</sup> expression on the presence of an intact MLL protein. Surprisingly, loss of the enzymatic activity of Mll by mutually targeting of the SET domain did not significantly affect cell survival. In contrast, cells were particularly sensitive to mutations of the Menin-biding motif in Mll. Mll targeting strongly induced myeloid differentiation in Cebpa<sup>−/−</sup> cells as measured by increased levels of CD11b and macrophage markers. To further investigate functional cooperativity upon pharmacological perturbation of the MLL/SET complex, we used MI-643, a potent small-molecule inhibitor of the Menin-MLL interaction. Inhibitor treatment led to a time- and dose-dependent impairment of proliferation, induction of cell cycle arrest and increased apoptosis in Cebpa<sup>−/−</sup> cells. RNA-seq analysis showed that inhibitor treatment induced expression changes associated with myeloid differentiation, which could be confirmed by flow cytometry. Importantly, expression of C/EBPα p30 was associated with hypersensitivity to Menin-MLL inhibition, as Cebpa<sup>−/−</sup> cells were 2-6 fold more sensitive than other leukemia cell lines of mouse and human origin.

**Summary/Conclusions:** Our data show that CEBPα-mutated AML is highly sensitive to perturbation of the MLL/SET complex, either via genetic ablation of MLL or through pharmacological inhibition of the Menin-MLL interaction. Our data indicate that leukemic mutations of CEBPα selectively cooperate with the MLL/SET complex to regulate gene expression. These findings expand our understanding of the and may inform new therapeutic strategies for N-terminal CEBPα mutated AML.

**INHIBITION OF THE MYELOID MASTER REGULATOR PU.1 AS A THERAPEUTIC STRATEGY IN ACUTE MYELOID LEUKAEMIA**

J. Chen<sup>1</sup>, A. Ambesi-Impiombato<sup>4</sup>, A.A. Ferrando<sup>4</sup>, I. Mantzaris<sup>1</sup>, E. Gavathiotis<sup>1</sup>, M. Giannakakou<sup>1</sup>, P. Gallipoli<sup>1,∗</sup>, A. S. Costa<sup>2</sup>, K. Tzelepis<sup>3</sup>, G. Giotopoulos<sup>1</sup>, S. Vohra<sup>1</sup>, G. Vassiliou<sup>1</sup>, C. Frezza<sup>2</sup>, B. Huntly<sup>1</sup>, 1Haematology, 2MRC Cancer Unit, 3Wellcome Trust/Sanger Institute, UNIVERSITY OF CAMBRIDGE, Cambridge, United Kingdom

**Background:** FLT3 tyrosine kinase (TK) activating mutations (FLT<sup>3m</sup>) are amongst the most frequent in AML and are associated with a poor outcome. FLT<sup>3m</sup> cells promote constitutive activation of survival/proliferation pathways and induce chemoresistance, as shown by increased cell proliferation, increased glycolysis and increased ROS levels. FLT3 TK represents a valid therapeutic target and several FLT3 TK inhibitors (TKI) have been developed. However, despite showing activity in the preclinical setting, FLT3 TKI have displayed limited efficacy in clinical trials. Resistance mechanisms to FLT3 TKI include receptor mutations and cell intrinsic adaptive mechanisms. Amongst the latter, metabolic adaptations may play a significant role although the exact mechanisms remain ill-defined.

**Aims:** We hypothesised that metabolic adaptations facilitate FLT3 TKI resistance and aimed to identify early metabolic changes in FLT<sup>3m</sup>-AML, following TKI treatment, in an attempt to unravel novel therapeutic vulnerabilities.

**Methods:** Liquid chromatography coupled to mass spectrometry (LC/MS), using stable isotope-based carbon flux tracing, and oxygen consumption rate/extracellular acidification rate as measured by an extracellular flux analyser (Seahorse, Agilent Technologies) were used to assess metabolic changes in primary FLT3<sup>mut</sup> cells. Gene silencing was performed using CRISPR-Cas9 gene editing and active oxygen species (ROS) in various culture conditions were measured by flow cytometry.

**Results:** We hypothesised that metabolic adaptations facilitate FLT3 TKI resistance and aimed to identify early metabolic changes in FLT<sup>3m</sup>-AML, following TKI treatment, in an attempt to unveil novel therapeutic vulnerabilities.

**Conclusions:** We present a novel approach for the specific therapeutic targeting of these patients and overall approaches for the specific therapeutic targeting of these patients are thus far unexplored.
These data predict that a combined inhibition of glutamine metabolism and FLT3 TK inhibition by respectively counteracting oxidative damage and sustaining macromolecule biosynthesis and cellular energetics. These data predict that a combined inhibition of glutamine metabolism and FLT3 TK activity may improve the eradication of FLT3mut AML cells.

**Summary/Conclusions:** Our data suggest that upon AC220 treatment, glutamine metabolism becomes a critical metabolic dependency in FLT3mut AML. Glutamine metabolism is mostly channelled towards glutathione production, and mine metabolism becomes a critical metabolic dependency in FLT3 mut AML.

**Background:** The molecular pathways and microenvironmental cues that choreograph the conversion of endothelial cells (ECs) into long-term repopulating hematopoietic stem cells (HSCs) remain poorly defined. This is due to lack of models that recreate the ephemeral transition of an endothelial cell to a hemogenic state to the emergence of HSCs. The molecular pathways and microenvironmental cues that choreograph the conversion of endothelial cells (ECs) into long-term repopulating HSCs that give rise to all hematopoietic lineages, including functional T cells in vivo. To provide a platform to deconvolute the process by which endothelial-to-hematopoietic transition is possible.

**Methods:** Here, we have developed a modular in vitro model in which—by precise, conditional expression of transcription factors: FosB, Gfi1, Runx1, and Spi1 (FGS), and reintroduction of a proper inductive niche—adult mouse ECs were reprogrammed into HSCs (rEC-HSCs) with multi-lineage engraftment potential (rEC-MPPs). Adult, non-lymphytic ECs isolated from various organs of Runx1-IRES-GFP reporter mice were transduced with FGS and co-cultured in direct contact with vascular niche.

**Results:** Within 14 days, ECs initiated a hematopoietic program, turning on the endogenous expression of Runx1 and transitioning into hematopoietic cells. Expansion of these cells for another 14 days resulted in generation of rEC-HSCs and rEC-MPPs. Transplantation of rEC-HSCs and rEC-MPPs (CD45.2+) into lethally irradiated mice (CD45.1+) reconstituted both the short-term (rEC-MPPs) and long-term hematopoiesis, with secondary engraftment potential (rEC-HSCs). rEC-HSCs gave rise to both functional myeloid and lymphoid cells with full complement of polarized T cell subsets. rEC-HSC-derived T cells undergo T-cell receptor (TCR) rearrangement and restore adaptive immune function in Rag1−/− mice.

**Summary/Conclusions:** This multi-phasic, step-wise approach provided an interrogable model to decipher pathways involved in EC transition into hematopoietic cells. This will provide cues to devise strategies to convert autologous ECs into large numbers of HSCs for genetic modification and subsequent treatment of both genetic and acquired hematological disorders.

**Background:** Recent reports show that mesenchymal stem cells (MSC) rescue injured target cell and promote target cell recovery from a variety of stress including oxidative tress. ultraviolet radiation, ischemia/reperfusion [SI/R] and cytosine arabinoside (CytA) however, it is still unclear if bone marrow mesenchymal stem cells (BM/MSC) can also form TNT to communicate and rescue injured bone marrow -derived endothelial cells (BMdEC) and promote it recovery from chemotherapy stress . In our study, we set out to test the hypothesis that BM/MSC can rescue suffering endothelial cells by transferring mitochondria to endothelial cells through nanotubes.

**Aims:** To investigate the novel intercellular communication TNT between BM/MSC and BMdECs or HUVEC, illuminating its constituent and investigating the significance of transport of mitochondria through TNT between BM/MSC and BMdECs or HUVEC suffering from chemotherapy stress of cytotoxic arabinoside.

**Methods:** We established two direct co-culture system for human primary bone marrow mesenchymal stem cells (BM/MSCs) and bone marrow-derived endothelial cells (BMdECs) or Human umbilical cord vein endothelial cells (HUVECs) respectively.

**Results:** Firstly, We observed the TNTs formed between BM/MSCs and endothelial cells including the TNT structure between BM/MSCs and HUVECs or BMdECs are composed with F-actin, microtubule in addition to membrane. Live cell imaging showed the two xeno-genetic cells form TNTs by retaining a thin thread of membrane upon dislodge-
ment. Besides, we observed that TNTs were more likely to occur between healthy bone marrow resident macrophage stem cell and endothelial cell contacts (Ara-C) treatment. Single-cell analysis showed that stressed endothelial cells and cell lines in the early stages of apoptosis caused by cytamine (Ara-C) treatment form TNT to interact with untreated BMMSCs and then mesenchymal stem cells transport mitochondria to injured endothelial cell or cell line via TNTs. This was inferred by incubating with an F-actin-depolymerizing drug and tubline -depolymerizing drug, indicated that these TNTs transferring mitochondria have a distinct cytoketal composition which formed with F-actin and microtubule. Our results also suggest that the delivery of functional mitochondria from uninjured BMMSCs to HSC of TNTs can mediate the recovery of injured HUEVCs from the apoptosis, contribute to proliferation and remodel the formation of capillary-like structures in Matrigel®-coated plates of HUEVCs suffer from chemotherapy stress of Ara-C.

Summary/Conclusions: BMSCS can transfer mitochondria via TNTs formed between BMMSCs and HUEVC, rescued endothelial cells suffering stress, which can alleviate apoptosis of stressed endothelial cells, relieve its proliferation inhibition and alter its formation of capillary-like structures. Our study offers the clues to help know about cell-cell communication of niche components in the HSC niche in bone marrow.

S139
SHORT-TERM FEEDING OF A HIGH-FAT DIET DISTURBS LIPID RAFT/ TGF-β SIGNALING-MEDIATED QUIESCENCE OF HEMATOPOIETIC STEM CELLS IN C57BL/6J MICE BONE MARROW
F. Hermetet1,2,*, J.-P. Pais de Barros2,3, L. Delva1,2, R. Quéré1,2
1Signalining and Physiology in Hematological Research, UMR1231 Inserm / Université Bourgogne Franche-Comté / AgroSup, Dijon, France

Background: Some studies show that a high-fat diet (HFD) induces major perturbations in murine hematopoietic stem cells (HSC) and hematopoietic system homeostasis. However, it is currently difficult to say whether these alterations are related to direct effects such as changes in lipid metabolism in HSC or indirect “side effects” on HSC, such as phathophysiology related to obesity or indirect “side effects” on HSC such as pathophysiology related to obesity or indirect “side effects” on HSC such as pathophysiology related to obesity or high-fat-induced obesity significantly alters hematopoiesis in bone marrow (BM), with a decreased proliferation of HSC, a general suppression of progenitors, an enhancement of lymphopoiesis, and an activation of myeloid cell production from BM progenitors. Inflammation also affects HSC homeostasis, as Interferon alpha is well-known to activate dormant HSC in vivo.

Aims: Our strategy is to characterize the impact of a short-term HFD on HSC and hematopoiesis in non-obese C57BL/6J mice.

Methods: In a prospective study, C57BL/6J mice were fed a control diet (4% fat) or a high-fat diet (42% fat), over a short period of 4 weeks, to investigate the direct impact of such a diet on hematopoiesis.

Results: While fat intake led to an increase in plasma cholesterol levels, mice did not develop obesity, and no inflammatory monocytes and no modulation of pro-angiogenic-inflammatory cytokine levels were detected in blood and BM, respectively. While the high-fat diet impact was observed after an extended diet over several months or a diet in blood and BM. However, we noted an increase in the number of progenitors and a loss of more than 50% of the most primitive HSC (SLAM). We validated this loss via transplantation of BM isolated from HFD-fed mice (Ly1) in competition with control BM (Ly2), in lethally irradiated recipient mice which only recognize 2% of the recipient hematopoiesis from HFD HSC. To further investigate lipid metabolism in HSC, we quantified the major lipid constituents of HSC plasma membrane such as lipid rafts (LR), which are important for signal transduction in immune cells and BMSCs. We observed that the level of cholesterol was very rich in fat (>60 kJ% of fat). For example, HFD-induced obesity significantly alters hematopoiesis in bone marrow (BM), with a decreased proliferation of HSC, a general suppression of progenitors, an enhancement of lymphopoiesis, and an activation of myeloid cell production from BM progenitors. Inflammation also affects HSC homeostasis, as Interferon alpha is well-known to activate dormant HSC in vivo.

Conclusions: The LMPP gave rise to both GM and B cell engraftment, the GMP myeloid progenitors. For example, the expression of 72 genes in 919 single LMPP, MLP and GMP shows that the 3 populations form a transcriptional continuum. In conclusion, HFD markedly and rapidly affects primordial and cell lines in the early stages of apoptosis caused by cytamine (Ara-C) treatment. Single-cell analysis showed that stressed endothelial cells and cell lines in the early stages of apoptosis caused by cytamine (Ara-C) treatment form TNT to interact with untreated BMMSCs and then mesenchymal stem cells transport mitochondria to injured endothelial cell or cell line via TNTs. This was inferred by incubating with an F-actin-depolymerizing drug and tubline -depolymerizing drug, indicated that these TNTs transferring mitochondria have a distinct cytoketal composition which formed with F-actin and microtubule. Our results also suggest that the delivery of functional mitochondria from uninjured BMMSCs to HSC of TNTs can mediate the recovery of injured HUEVCs from the apoptosis, contribute to proliferation and remodel the formation of capillary-like structures in Matrigel®-coated plates of HUEVCs suffer from chemotherapy stress of Ara-C.

A NOVEL MODEL OF HUMAN LYMPHO-MYELOID PROGENITOR RECONSTITUTION BASED ON SINGLE CELL FUNCTIONAL AND TRANSCRIPTIONAL ANALYSIS
D. Karamitros1,2,*, B. Stolova1,2, Z. Aboukhalil1, A. Reinisch3, F. Hamey4, M. Samitsch1, L. Quek1,2,5, G. Otto1, E. Repapi1, J. Donoodee1,2, B. Usukhbayar1,2, J. Calvo3, S. Taylor1, N. Garo3, E. Six7, F. Pflumio6, C. Porcher1, R. Mejati1, B. Goggens1, P. Vyas1,2,5

1MRC, MHU, WIMM/NDCLS University of Oxford, 2Oxford Biomedical Research Centre, Oxford, United Kingdom, 3Division of Hematology, Stanford Institute for Stem Cell Biology and Regenerative Medicine, Stanford, United States, 4Department of Haematology , Wellcome Trust-Medical Research Council Cambridge Stem Cell Institute, Cambridge, 5Department of Haematology, OUH NHS Trust, Oxford, United Kingdom, 6UMR967, INSERM/CEA/Universite Paris 7/Universite Paris 11, 7UMR1163, Paris Descartes–Sorbonne Paris Cite University, Imagine Institute , , Paris, France

Background: Human hematopoiesis produces 10 billion new, terminally mature, blood cells daily; a production that is also rapidly responsive to external change. Disregulation of this complex process can lead to hematopoietic and immune deficiencies and blood cancers. In humans the hematopoietic progenitor hierarchy producing lymphoid and granulocytic-monocytic (myeloid) lineages is unclear. Multiple progenitor populations give rise to lymphoid and myeloid cells but they remain incompletely characterized at the immunophenotypic, transcriptional and functional level.

Aims: Here, we aimed to understand the clonal functional output and transcriptional programs of current primary human lympho-myeloid containing progenitor populations - the lymphoid-primed multi-potential progenitor (LMP1), the lymphoid progenitor (MLP2) and granulocyte-macrophage progenitor (GMP).

Methods: We devised a FACS-staining and sorting strategy to prospectively purified each hematopoietic stem and progenitor cell (HSPC) population. We compared functional and transcriptional programs between LMP, MLP and GMP in vitro by quantitative CFU assays, single cell liquid cultures or limit dilution analysis and in vivo by transplantation into humanized ows. We performed RNA sequencing and single cell RT-PCR analysis to understand the relationship between functional and transcriptional heterogeneity.

Results: Our study comprehensively characterized the LMP, MLP and GMP single cell population in myeloid populations. Both LMP and MLP are very rare within the mononuclear fraction (1 in 10^4 to 1 in 10^5). We cultured 3806 single LMP, GMP and MLP cells (isolated from 21 cord blood units and equivalent to ~10^11 mononuclear cells) under three different culture conditions. We observed functional and transcriptional heterogeneity in the three lympho-myeloid progenitor populations - the lymphoid-primed multi-potential progenitor (LMP1), the lymphoid progenitor (MLP2) and granulocyte-macrophage progenitor (GMP).

Conclusions: We devised a FACS-staining and sorting strategy to prospectively purified each hematopoietic stem and progenitor cell (HSPC) population. We compared functional and transcriptional programs between LMP, MLP and GMP in vitro by quantitative CFU assays, single cell liquid cultures or limit dilution analysis and in vivo by transplantation into humanized ows. We performed RNA sequencing and single cell RT-PCR analysis to understand the relationship between functional and transcriptional heterogeneity.

WILMS’ TUMOR 1 RNA-ELECTROPORATED DENDRITIC CELL VACCINATION AS POST-REMISSION TREATMENT TO PREVENT OR DELAY RELAPSE IN ACUTE MYELOID LEUKAEMIA: FINAL RESULTS OF A PHASE II STUDY IN 30 PATIENTS

Z. Berrernani1,†, S. Anguille1, A. Van de Velde1, V. Van Tendeloo1, N. Coels1, G. Nijss1, B. Stein1, E. Lion1, A. Van Driessche1, I. Vandenbosch1, A. Verlinden1, A. Gadisseur1, W. Schroyens1, K. Vermeulen2, M.-B. Maes2, K. Deitersen2, R. Malfait2, E. Smits3
1Hematology, 2Laboratory Hematology, 3Center for Cell Therapy and Regenerative Medicine, ANTWERP UNIVERSITY HOSPITAL, Edegem, Belgium

Background: Relapse is a major problem in acute myeloid leukaemia (AML) and adversely impacts survival.

Aims: The aim of this phase II study was to determine the clinical efficacy of dendritic cell (DC) vaccine therapy in AML and, more specifically, whether this form of immunotherapy can be applied in the post-remission adjuvant setting to decrease the risk of relapse following chemotherapy and to improve survival.

Methods: We vaccinated 30 AML patients in remission following polychemotherapy, but at very high risk of relapse with autologous DCs loaded with the WTI gene. WTI peptide complex (WT1) antigen by means of mRNA electroporation, a technique that allows for human leukocyte antigen haplotype-independent, multi-epitope antigen presentation to T-cells. The vaccines were administered intra-dermally. WTI mRNA levels in blood and marrow were followed as a measure of minimal residual disease. Circulating WTI-specific CD8+T-cells obtained before and after the 4th dose were stained with WT1 peptide-HLA-A*0201 tetramers. To assess cell-mediated immunity in vivo, delayed type hypersensitivity (DTH) skin testing was performed 2 weeks after the 4th DC vaccination by intradermal injection; DTH-infiltrating lymphocytes collected from skin biopsies were expanded for 2-3 weeks in medium with interleukin-2, harvested and tested for WTI-specific reactivity.

Results: There was a demonstrable anti-leukemic response in 13/30 patients (overall response rate 43%). Nine patients achieved molecular remission as demonstrated by normalization of WTI transcript levels, 5 of which are sustained after a median follow-up of 109.4 months, including 1 patient who went from CR2 to CR after receiving DC vaccination by intradermal injection. 2 of the remaining 4 responding patients, the clinical response was characterized by stable disease as demonstrated by elevated but stable WT1 transcript levels in blood for 3-12 months and stable blood values without blasts. Five-year overall survival was 40%, as compared to 24.7% in the SEER data of the National Cancer Institute; it was significantly higher in responders than in non-responders (53.8% vs 25.0%; P=0.01). In patients receiving DCs in first complete remission (CR1), there was a vaccine-induced relapse reduction rate of 25% and the 5-year relapse-free survival was significantly higher in responders than in non-responders (50% vs 7.7%; P=0.0001). In patients ≤55 and >65 years who received DCs in CR1, 5-year overall survival was 69.2% and 30.8% respectively. Of the 30 patients, 11 are alive in CR, including 5 who relapsed after DC vaccination; 2 proceeded to allogeneic stem cell transplantation, while the other 3 patients were brought back into CR by chemotherapy alone, 2 of them surviving more than 7 and 4 years respectively after reaching CR. Long-term clinical response was correlated with increased circulating frequencies of poly-epitope WTI-specific tetramer+CD8+T-cells. Long-term overall survival was correlated with interferon-γ and tumor necrosis factor-alpha WT1-specific responses in DTH-infiltrating lymphocytes.

Summary/Conclusions: Vaccination of AML patients with WTI mRNA-electroporated DCs can be an effective and non-toxic strategy to prevent or delay leukemia relapse under standard chemotherapy, translating into improved overall survival rates, which are correlated with the induction of WT1-specific CD8+ T-cell responses.

FIRST-IN-HUMAN MULTICENTER STUDY OF BB2121 ANTI-BCMA CAR T CELL THERAPY FOR RELAPSED/REFRACTORY MULTIPLE MYELOMA: UPDATED RESULTS

1Hematology, 2Laboratory Hematology, 3Center for Cell Therapy and Regenerative Medicine, ANTWERP UNIVERSITY HOSPITAL, Edegem, Belgium

Aims: The primary objective is to determine the maximally tolerated dose of bb2121 in subjects with MM whose tumors express BCMA to redirect T cells to MM. bb2121 consists of autologous T cells transduced with a lentiviral vector encoding a novel CAR incorporating an anti-BCMA scFv, a 4-1BB costimulatory motif and a CD3-zeta T cell activation domain. We will report updated safety and efficacy results following promising initial results (Berdeja et al. ENA 2016).

Methods: CRB-401 (NCT02659892) is a multi-center phase 1 dose escalation trial of bb2121 in patients with relapsed and/or refractory MM who have received ≥3 prior regimens, including a proteasome inhibitor and an immunomodulatory agent. A two-stage, 3+3 design was performed and the recombinant protein expression of sNTX pts.

Background: To test the safety and efficacy of the CAR T cell modality in relapsed/refractory multiple myeloma (MM), we have designed a second-generation CAR construct targeting B cell maturation antigen (BCMA) to redirect T cells to MM. bb2121 consists of autologous T cells transduced with a lentiviral vector encoding a novel CAR incorporating an anti-BCMA scFv, a 4-1BB costimulatory motif and a CD3-zeta T cell activation domain. We will report updated safety and efficacy results following promising initial results (Berdeja et al. ENA 2016).

Aims: The primary objective is to determine the maximally tolerated dose of bb2121 in subjects with MM whose tumors express BCMA, to determine and test a recommended phase 2 dose for future studies. The secondary objective is to provide preliminary efficacy data on the anti-tumor effects of treatment with bb2121 in subjects with MM whose tumors express BCMA.

Background: Fanconi anemia (FA), is a monogenic inherited syndrome associated with bone marrow failure (BMF), that has been considered a candidate disorder for hematopoietic stem cell (HSC) gene therapy. Up to date, three clinical trials have been performed, all of which failed to demonstrate engraftment of corrected HSCs.

Aims: To demonstrate engraftment of gene-corrected HSCs in non-conditioned Fanconi anemia patients.

Methods: To improve previous results, we proposed a new approach based on two clinical trials. First, to increase the HSC collection, we designed a trial employing a plerixafor plus G-CSF mobilization regimen. Second, to improve the quality of corrected HSCs, cells were pre-stimulated for only 8-10 hours and transduced with a new lentiviral vector (PGK-FANCA.Wpre) for 12-14h, a substantially shorter duration than in previous trials. To avoid chemotherapy-induced damage, a conditioning regimen was not included in the trial, based on the expected proliﬁerative advantage of autologous corrected HSCs.

Results: Eight patients have been included so far in the HSC collection trial. No severe adverse events (SAE) related to the procedure have been reported. The most relevant AE has been the transfusion of packed red blood cells and platelets. Six FA patients aged 3-6 years underwent collections after mobilization of significant numbers of CD34+cells (10 to 70 CD34+cells/µL) to peripheral blood. Two patients (15 and 16 years) failed to mobilize. On average, 5 million CD34+cells/Kg were collected, with 45% recovery after immunoselection. In the ﬁrst patient included in the gene therapy trial, fresh immunoselected CD34+cells were transduced with the therapeutic vector. Subsequently, two patients were infused with transduced CD34+cells that remained cryopreserved for almost 2 years. Infused cell products contained 0.5 to 1.4 million CD34+cells/kg, and vector copy numbers per cell (VCN/cell) that ranged between 0.17 to 0.45. To-date, there has been no SAE related to the procedure. Engraftment of gene corrected cells has been observed in the three patients. Notably, increased gene marking levels and signiﬁcant phenotypic correction in the hematopoietic progenitor cells, deduced from the acquired resistance of the colony forming cells to mitomycin C (15% of BM CFcs survived to 10 nM MMC), have been demonstrated after 9 months of follow up in one of the patients.

Summary/Conclusions: Our preliminary results show that 1) HSCs collection is both safe and efﬁcient in very young FA patients after mobilization with G-CSF and plerixafor, and 2) Engraftment and proliferation advantage of gene-corrected HSPCs has been demonstrated in FA patients even in the absence of conditioning regimens. The long-term follow up of patients included in these clinical trials will demonstrate the feasibility of restoring the hematopoietic function of FA patients by means of a gene therapy approach in the absence of conditioning.

TARGETING FLT3 WITH CHIMERIC ANTIGEN RECEPTOR T CELLS CONFRONTS POTENT REACTIVITY AGAINST ACUTE MYELOID LEUKEMIA

H. Jatan1, H. Garcia-Cadenas2, T. Nerreter1, J. Sierra2, W. Herr3, S. Thomas3, H. Einsele1, M. Hudecek1

1Internal Medicine II, University Hospital Würzburg, Würzburg, Germany, 2Servicio de Hematología, Hospital de La Santa Creu i Sant Pau, Barcelona, Spain, 3Klinik und Poliklinik für Innere Medizin III, Universitätssklinikum Regensburg, Regensburg, Germany

Background: Adoptive immunotherapy with chimeric antigen receptor (CAR)-modified T cells has therapeutic potential in hematologic malignancies. We are pursuing FLT3-like tyrosine kinase 3 (FLT3) as a novel CAR target in acute myeloid leukemia (AML). FLT3 is a homodimeric transmembrane protein with uniform expression on AML, irrespective of cytogenetic and histomorphologic subtype. FLT3 provides survival signals to AML blasts and is a key driver of leukemia-genesis in AML cases with internal tandem duplication (FLT3-ITD). These attributes suggest FLT3 may be an ‘Achilles heel’, making AML blasts susceptible to CAR T-cell mediated recognition and elimination.

Aims: We therefore explored the anti-leukemia efficacy of FLT3-CAR modiﬁed T cells against FLT3-ITD+ and FLT3 wild type AML in pre-clinical models in vitro and in vivo.

Methods: A FLT3-CAR comprising a single-chain variable fragment (4G8), fused to an IgG-Fc spacer, and signaling module with CD3 zeta and CD28 was encoded in a lentiviral vector (epHIV7) for gene-transfer into CD8+ and CD4+ T cells of healthy donors (n=4) and AML patients. CAR T-cell mediated cytolytic activity was evaluated in FACS/luminescence-based assays, cytokine production analyzed by ELISA and proliferation assessed by CFSE dye dilution. Immunodeﬁcient NSG mice were engrafted with AML cell line (Molm-13) or primary AML blasts and treated with 5x10^6 CAR-modiﬁed or control T cells (CD8:CD4 ratio=1:1).

Results: We conﬁrmed speciﬁc recognition and high-level cytolytic activity of CD8+ FLT3-CAR T cells against a panel of AML cell lines including THP-1 (FLT3 wild type), and Molm-13 (FLT3-ITD heterozygous). Both CD8+ and CD4+ FLT3-CAR T cells produced IFN-γ and IL-2, and underwent proliferation after antigen stimulation.FLT3-CAR T cells that we prepared from AML patients exerted speciﬁc anti-leukemia reactivity against autologous primary AML blasts, with near-complete cytolysis within 24 hours of co-culture. Further, FLT3-CAR T cells conferred a potent anti-leukemia effect in vivo models of systemic leukemia, both with AML cell lines (Molm-13) and primary AML blasts. A single dose of FLT3-CAR T cells conferred complete eradication of leukemia from peripheral blood, bone marrow and spleen, as conﬁrmed by bioluminescence imaging and ﬂow cytometry. FLT3 is not expressed in any normal solid tissues and mature hematopoietic cells, but shows limited expression in hematopoietic progenitors and hematopoietic stem cells (HSCs). Preliminary data show that FLT3-CAR T cells recognize FLT3+/high normal HSCs and interfere with normal hematopoiesis, but preserve a proportion of HSCs capable of reconstituting hematopoietic lineages. Studies to assess recognition of normal HSCs in vivo are ongoing.

Summary/Conclusions: Collectively, our data demonstrate that T cells expressing a FLT3-specific CAR mediate potent reactivity against FLT3 wild type and FLT3-ITD+AML in vitro and in vivo, and establish FLT3 as a novel CAR target in AML. FLT3-ITD positivity identiﬁes a high-risk AML subgroup that may particularly beneﬁt from adoptive therapy with FLT3-CAR T cells, e.g. in order to achieve ‘minimal residual disease’ (MRD) negativity prior to allogeneic HSC transplantation. Our data further suggest that in contrast to CD33 and CD123, which are pursued as alternative CAR targets in AML, targeting of FLT3 may preserve a fraction of normal HSC and enable the implementation of CAR therapy outside the transplant setting.

BPX-501 DONOR T CELL INFUSION (WITH INDUCIBLE CASPASE 9 SUICIDE GENE) FACILITATES HLA-HAPLOIDENTICAL STEM CELL TRANSPLANT IN CHILDREN WITH BOTH HEMATOLOGICAL MALIGNANCIES AND NON-MALIGNANT CONDITIONS

M. Algen1,2, S. Naik2, N. Kapoor3, K. Mahadeo4, V. Aquino5, A. Woolfrey6, A. Bertane1, P. Merli1, A. Woolfrey7, F. Galaverrina1, K. Mahadeo8, S. Baumeister9, E. Nemecek9, W. Qasim10, D. Pagliara1, G. Li Pir1, L. Krishnamurthi11, D. Jacobsohn12, M. Slatter13, J. Weinberg14, A. Moseley14, F. Locatelli1
1Ospedale Pediatrico Bambino Gesù, Rome, Italy, 2Texas Children’s Hospital, Houston, 3Children’s Hospital of Los Angeles, Los Angeles, 4Fred Hutchinson Cancer Research Center, Seattle, 5Children’s Hospital at Montefiore, Bronx, 6Dana Farber Cancer Institute, Boston, 7Oregon Health & Science University, Portland, United States, 8Great Ormond Street Hospital, London, United Kingdom, 9Children’s Hospital of Atlanta, Atlanta, 10Children’s National Health System, Washington, DC, United States, 11Great North Children’s Hospital, Newcastle, United Kingdom, 12Bellicum Pharmaceuticals Inc., Houston, United States

Background: Allogeneic hematopoietic stem cell transplant (HSCT) offers curative therapy for children who lack an available HLA-identical donor with hematopoietic disorders such as Primary Immune Disorders (PIDs), hemoglobinopathies, erythroid disorders and acute leukemias. Γ-Β T cell depletion mitigates the risk of GVHD after haplo-HSCT, but is associated with extended immunodeficiency, leading to complications due to infections . We have performed αβ TCR-depleted haplo-HSCT with post-transplant infusion of BPX-501 gene modified T cells to allow for more rapid immune reconstitution. Upon occurrence of GVHD, administration of rimiducid (AP1903) dimerizes the Caspase 9 suicide switch and rapidly induces apoptosis of the transduced BPX-501 cells and mitigates the GVHD.

Aims: This study was performed to determine the impact of BPX-501 T cell infusion on outcomes (treatment related mortality (TRM), disease recurrence, GVHD incidence and immune reconstitution) after HSCT.

Methods: We report on a large multicenter, prospective Phase I-II study enrolling children receiving αβ T cell depleted Haplo-HSCT. Patients were infused with BPX-501 T cells 2 weeks post-transplant. 104 patients have >100 day follow-up, 81 patients have follow up >180 days and 51 with >1 year follow-up. All patients received myeloablative therapy and low dose ATG prior to transplant. No pharmacologic GvHD prophylaxis was given (Table 1).

Results: Cumulative incidence of TRM remains very low at 100 days (0%), 180 days (1.6%) and 1 year (2.8%). Of the 81 patients with >180 day follow-up, 20 patients had acute GvHD 1-3 (24.7%) (Figure 1A); 10 with Grade 1, 8 with Grade 2, 2 with Grade 3 and 1 Grade 4 skin. Mild GvHD was seen in 2 patients, moderate GvHD in 2 patients and one case of severe cGvHD in a malignant patient, attributed to the allograft, not BPX-501. Rimiducid was used in 4 patients with Grade 2 GvHD with rapid resolution of symptoms, as it did in the severe cGvHD patient. In both malignant and non-malignant patients, CD3, CD4, CD8 (Figure 2B) and B cells (Figure 3C) immune reconstitution was brisk. CD3+/CD19+ T-cells were detectable at one year via flow cytometry analysis of peripheral blood. In Wiskott-Aldrich patients, platelet recovery remains in the normal range at 180 days with mean platelet counts of 246.3±103/μL. At 180 days and 1 year, the patients with hemoglobinopathies remain transfusion-free with a normal mean HbG value of 11.4 g/dL.

Summary/Conclusions: These data suggest that infusion of BPX-501 modified T cells may facilitate T cell depleted Haplo-HSCT in children who would benefit from HSCT for either malignant or non-malignant conditions. The availability of a suicide gene mechanism in donor T cells infused after T depleted Haplo-HSCT, results in low rates of infection and rapidly reversible GvHD when the dimmer is infused to activate the suicide switch. Rapid cellular and humoral immune reconstitution makes BPX-501 after T depletion a safe and viable option for children who do not have a matched donor transplant and in whom transplantation has been deemed curative.
for a selected guide RNA confirmed no detectable genomic cleavage at over 5000x predicted off-target sites with a detection sensitivity of 0.2%, supporting its safety for clinical use. Finally, we have demonstrated editing rates of >85% at clinical scale in a GMP-capable manufacturing facility to enable clinical development for SCD and β-Thal. Required safety toxicology studies are ongoing.

**Summary/Conclusions:** Using CRISPR/Cas9 we successfully created gene deletions in leukemic cells from both patient samples and cell lines. We have also dissected the genotype-phenotype relationship for specific genetic modifications, identifying the editing strategies which are most promising for re-expressing HBF. We have optimized the conditions for modifying HSPCs, including at clinical scale in a GMP-compliant setting, and demonstrated potential off-target editing. These experiments support the further development of specific CRISPR/Cas9 editing strategies of HSPCs to treat SCD and β-Thal patients.

1Experimental Therapeutics and Translational Oncology Program, Instituto de Biología Molecular y Celular del Cancer, CSIC/ Universidad de Salamanca and Institute of Biomedical Research of Salamanca (IBSAL), Salamanca, Spain. 2Department of Pediatric Oncology, Hematology and Clinical Immunology, Heinrich Heine University, Duesseldorf, Germany, Duesseldorf, Germany.

**Background:** B-cell precursor acute lymphoblastic leukemia (BCP-ALL) of childhood remains a major cause of death in high-income countries. It has a yet unexplained peak incidence between 2-6 years of age and a potential trigger was theorized a century ago with several possibilities of exposure to infection in infancy. Recently in vitro and in vivo evidence strengthened the causal role of exposure to infection in BCP-ALL (1, 2). However, it remains unclear which BCP-ALL subtype can be triggered by exposure to infection and how the pre-leukemic clone evolves to BCP-ALL.

**Aims:** Aiming to understand the role of infection exposure in the etiology of childhood BCP-ALL.

**Methods:** We have developed and characterized two independent GEMMs, in addition to the Pax5+/−-infected model (1), which were exposed to a common infection environment. These represent childhood BCP-ABL1p190 BCP-ALL and the most common subtype ETV6-RUNX1 BCP-ALL. Both model systems ensure Sca1-directed expression of BCR-ABL1p190 or ETV6-RUNX1 in HSCs in mice and B220+/− and CD19+B220+IgM-cell surface phenotype and manifested with blast cells in the peripheral blood (PB) and clonal immature BCR rearrangement. Whole exome (WES) and whole genome sequencing (WGS) was performed of murine BCP-ALL on a HiSeq 2500 (Illumina) platform.

**Results:** Pax5+/− and Sca1-ETV6-RUNX1 mice develop BCP-ALL only after exposure to infection whereas both BCP-ABL1p190 and ETV6-RUNX1 BCP-ALL independent of exposure to common infection. The molecular mechanism leading to BCP-ALL identified in the infection dependent GEMMs is determined by the genetic predisposition (Pax5+/− or ETV6-RUNX1). Pax5+/− mice acquire constitutive activating Jak3 mutations (6/9) in a susceptible B-cell precursor population (intermediate and immature B cells) (1). On the other hand Sca1-ETV6-RUNX1 mice develop BCP-ALL at a low penetrance (10.75%; 10 out of 93) with a CD19+B220+IgM-cell surface phenotype and manifested with blast cells in the peripheral blood (PB) and clonal immature BCR rearrangement. High expression of Recombination Activating Gene 1 (Rag1) and loss of function mutations in Btk were identified in murine BCP-ALL and are well known in the context of human ETV6-RUNX1 leukemia. Additionally we identified a high proportion of mutations in genes implicated in histone modification, i.e. Kdm5c (no. 40) causing a premature stop. CRISPR-Cas9 knock down studies of KDM5C in a precursor B-cell line revealed facilitated Rag1/2 binding to the pro-hoechst complex (H3K4me3) as a potential molecular mechanism (2). Rag1 off target activity in pre-leukemic ETV6-RUNX1 HSC/PC after exposure to infection. In contrast to Pax5+/− and Sca1-ETV6-RUNX1 mice, Sca1-BCR-ABL1p190 mice develop BCP-ALL independent of exposure to common pathogens by reprogramming of a HSC/PC and subsequent loss of Pax5. Summary/Conclusions: In summary, exposure to common pathogens can trigger childhood BCP-ALL based on Pax5 loss of function or in the common ETV6-RUNX1 rearrangement. However the underlying molecular mechanism (Jak-Stat signaling in Pax5+/− mice and histone modification in ETV6-RUNX1 mice) triggered by exposure to common infection is determined by the genetic predisposition. Both BCP-ABL1p190 and BCP-ALL emerge on the basis of a potent oncogene such as BCR-ABL1p190 can develop independent of exposure to infection. These findings are important for encouraging the prospect of novel interventions that might help to prevent or treat a significant proportion of childhood BCP-ALLs.

Background: The German Hodgkin Study Group (GHSG) applies the intensive eBEACOPP regimen (dose-escalated bleomycin, etoposide, doxorubicin, cyclophosphamide, vincristine, procarbazine, and prednisone) to all newly diagnosed advanced-stage HL patients regardless of their individual risk-profile. However, some patients might not be in need of such an intensive treatment to achieve cure. Unfortunately, baseline risk factors as defined in the international prognostic score cannot identify these patients reliably. Recent clinical research suggests that early metabolic response assessment after 2 cycles of therapy using FDG-PET (PET-2) can better predict the individual outcome. In particular, a rapid response as determined by PET-2 negativity might allow reducing the overall treatment intensity.

Aims: To assess the feasibility of decreasing the number of eBEACOPP cycles in patients with negative PET-2 without loss of efficacy as determined by progression-free survival (PFS).

Methods: Between 05/2008 and 07/2014, we recruited patients with newly diagnosed, advanced-stage HL aged 18–60 years. All patients gave written consent before study entry. PET-2 was centrally assessed with FDG uptake not higher than the mediastinal blood pool defined as negative. Patients with negative PET-2 were randomly assigned to receive 6 or 2 additional cycles (i.e. 8 or 4 cycles of eBEACOPP in total, respectively). PET-positive residues after chemotherapy were irradiated. Based on the results of our previous HD15 trial, the protocol was amended in June 2011 and the standard therapy was reduced from 8 to 6 cycles of eBEACOPP in total. The trial was designed to exclude inferiority of 6% or more of the experimental treatment (4 cycles of eBEACOPP) compared with the pooled standard treatment (8 or 6x cycles of eBEACOPP) at 5 years.

Results: We enrolled 2,101 patients. 1,005 patients with negative PET-2 were randomly assigned to either 8/6 cycles of eBEACOPP (n=504) or 4 cycles of eBEACOPP (n=501). With a median follow-up of 55 months, estimated 5-year PFS in the per-protocol set was 90.8% (87.9–93.7) with 8/6 cycles of eBEACOPP and 92.2% (89.4–95.0) with 4 cycles eBEACOPP (difference +1.4%, 95% CI -2.7–5.4, excluding the non-inferiority margin of -6%). In the standard arm, 95% of patients had at least one acute hematological toxicity of CTCAE grade 3-4 compared with 90% in the experimental arm, including severe infections in 75 (15%) and 38 (8%), respectively. Acute severe organ toxicities were documented for 91 (18%) and 38 (8%), respectively. 25 patients (5%) in the standard group (8/6 cycles of eBEACOPP and 9 (2%) in the experimental group (4 cycles of eBEACOPP) died; most frequent cause of death was second malignancy (11 and 1 patient, respectively). No patient in the experimental group died from treatment-related toxicities. Estimated 5-year overall survival (OS) in the per-protocol set was 95.4% (93.4–97.4) with standard eBEACOPP, and 97.7% (96.2–99.3) with 4 cycles of eBEACOPP (log-rank p=0.004).

Summary/Conclusions: Metabolic response assessment using FDG-PET after 2 cycles of eBEACOPP allows the reduction from therapy with 8/6 to only 4 cycles without loss of efficacy as determined by PFS in advanced-stage HL patients. Furthermore, the abbreviated treatment with 4 cycles of eBEACOPP is associated with improved tolerability and consequently leads to a significant OS benefit over standard therapy. PET-guided reduced therapy with eBEACOPP combines outstanding efficacy with high safety. We therefore recommend this treatment strategy for advanced-stage HL patients.

TARGETED SINGLE CELL SEQUENCING TO IDENTIFY MUTATIONAL HIERARCHY IN T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

J. De Bie1,*, S. Demeyer1, E. Geerdens1, A. Uyttebroeck2, N. Boeckx3, J. Cools1
1CME, KU Leuven, 2Pediatric Oncology, 3Laboratory Medicine, UZ Leuven, Leuven, Belgium

Background: Acute lymphoblastic leukemia (ALL) is a common childhood malignancy caused by clonal proliferation of immature B or T lymphoid cells. ALL patients are primarily young children who respond well to chemotherapy, with survival rates above 85%. However, if relapse develops, survival rates drop to 15-50%. Recent studies have shown that at diagnosis, different ALL subtypes and subclones are present that are likely the result of clonal branched evolution. Understanding this clonal evolution and the order at which mutations are acquired can provide improved insights into the origins of leukemia relapse.

Aims: To use single-cell sequencing to investigate (i) the heterogeneity of leukemic T-ALL cells present at diagnosis and (ii) unravel the order in which mutations were acquired during leukemia evolution.

Methods: Bone marrow samples taken at diagnosis and remission from 4 T-ALL patients underwent whole genome and RNA sequencing. Somatic mutations, indels and chromosomal translocations were confirmed using Sanger sequencing. Primers were designed to specifically target these genetic alterations, and included 46 primers against heterozygous SNPs for quality control assessment. A total of 1517 single cells (average of 379 cells per patient), were sorted using flow cytometry or a microfluidic device and analyzed with targeted sequencing. Cells were discarded from further analysis if locus and allelic drop-out exceeded 33.3%. Jaccard hierarchical clustering was applied to identify subclones and a new graph-based algorithm was developed to determine the order of mutation acquisition. Single CD34+CD38− hematopoietic stem/progenitor cells (HSPCs) from the same samples were also isolated to test for the presence of mutations in early progenitors.

Results: We detected between 2 and 4 separate clones in each T-ALL patient sample. Every patient harboured one dominant clone comprising 46 to 98% of all single cells that was highly mutated, accompanied by a number of smaller subclones carrying fewer mutations. No mutually exclusive mutations, fusion genes or deletions were observed between the clones arguing against independent leukemic clonal initiation events. Instead, a more stepwise clonal hierarchy was observed, indicating that the accumulation of mutations can occur in progenitor cells or in committed T-cells. During remission, we could no longer detect HSPCs with all leukemic mutations.

Summary/Conclusions: We demonstrate that T-ALL patients have limited heterogeneity at diagnosis and that targeted single cell sequencing can be used to determine the cell of origin and the order of mutation acquisition. These data also illustrate that HSPCs at remission carry a few early, pre-leukemic mutations, while highly mutated HSPCs are eradicated during treatment, which is in line with long term remission in T-ALL.

BCL-2 INHIBITION AS NEW THERAPEUTIC OPPORTUNITY FOR RPL10 R98S MUTANT PEDIATRIC T-ALL

K. Kampen1,*, T. Girardi1, J. Verbeeck1, J. Op de Beeck1, A. Uyttebroeck2, P. Vermeersch3, A. Moorman4, A. Moorman5, C. Harrison5, J. Meijerink6, D. Lemort7, E. Cools1, K. De Keersmaecker1

Background: The ribosomal protein L10 (RPL10) R98S mutation occurs in 8% of pediatric T-cell acute lymphoblastic leukemia (T-ALL) cases. RPL10 R98S leads to a proliferation defect in lymphoid cells due to a peroxisomal contribution in pediatric T-ALL remains unclear. Treatment intensification and risk stratification has reduced the relapse rate of T-ALL to ~15% but further improvements will require strategies that focus on specific subtypes as RPL10 R98S; if the long-term sequelae of toxic therapy are to be avoided.

Aims: 1) Explore the oncogenic contribution of the RPL10 R98S mutation in pediatric T-ALL. 2) Define new therapeutic opportunities for RPL10 R98S defective T-ALL. 3) Identify a biomarker indicative of the RPL10 R98S mutation in T-ALL.

Methods: Quantitative label-free proteomics was used to screen for protein differences between RPL10 WT and R98S expressing Ba/F3 cells. Hits were confirmed by western blot in lineage negative (lin) bone marrow (BM) cells extracted from RPL10 WT and R98S knock-in mice and in RPL10 WT and R98S pediatric T-ALL samples. Serial re-plating was established by plating 2000 cells/ml in Methocult. Oxidative stress and mitochondrial activity was determined by Dihydroethidium and mitotracker. Viable cell counts were determined by Annexin V exclusion. Chromatin immunoprecipitation was performed using the Imprint ChIP kit followed by qRT-PCR. Human pediatric T-ALL samples were transplanted into NOD-SCID/IL2γ−/− (NSG) mice for in vitro and in vivo inhibitor studies.

Results: The RPL10 R98S mutation provided a cell survival advantage in Ba/F3 cells and in serial re-plating assays of lin-BM cells derived from RPL10 R98S knock-in mice. Proteomic profiling revealed metabolic reprogramming in RPL10 R98S cells through enhanced expression of peroxisomal enzymes Acox1, Acox3 and Paox. This expression facilitated peroxisomal β-oxidation of long chain fatty acids which are substrates for PPARγ and which were consequently upregulated together with CPT1A. Peroxisomal hyperactivation causes high intracellular H2O2 levels, increasing the observed elevated levels of reactive oxygen species (ROS) in RPL10 R98S cells that could not be scavenged by the increased catalase expression. High ROS levels and enhanced PPARγ binding drives the constitutive overexpression of anti-apoptotic protein B-cell lymphoma 2 (Bcl-2), responsible for the leukemia cell survival benefit of RPL10 R98S cells. Bcl-2 targeted therapy using venetoclax (ABT-199) reduced the expansion of RPL10 R98S knock-in BM cells by 50%, while RPL10 WT BM cells were not inhibited by ABT-199. In vivo, DMSO or ABT-199 50mg/kg therapy was started after the engraftment of >2% human cells in the blood of mice xenografted with T-ALL samples and was maintained 1/wk till disease end stage. RPL10 R98S xenografted mice that received ABT-199 therapy presented a complete inhibition of human CD45+ leukemia progression in the blood, which was characterized by a 70-85% reduction in spleen weights, and 20-50% reduction of bone marrow engraftment. Spleen weights of ABT-199 treated RPL10 R98S xenografted mice were only slightly increased as compared to ungrafted weights of healthy NSG mice. In contrast, mice xenografted with RPL10 WT T-ALL samples showed poor in vivo responses to ABT-199 treatment and all animals showed progressive disease. Bcl-2 overexpression induced by peroxisomal hyperactivation was defined as new target in RPL10 R98S defective T-ALL. Additionally, due to peroxisomal hyperactivation, a peroxisomal oxidase involved in purine degradation may have contributed to the metabolic output of purine degradation, uric acid, was elevated above reference levels in the blood of RPL10 R98S mutant pediatric T-ALL patients at diagnosis (Figure 1).

Figure 1.
Summary/Conclusions: Uric acid provides an indicative biomarker of RPL10 R98S mutations in pediatric T-ALL patients, which may be used for screening, providing early diagnosis and appropriate selection of patients in whom a Bcl-2 targeted therapeutic approach could be considered.

TRANSLATE ANALYSIS OF THE T-ALL ASSOCIATED RIBOSOMAL PROTEIN L10 R98S MUTATION REVEALS ALTERED SERINE METABOLISM

L. Fancello1,*, K. Kampen1, T. Girardi1, J. Op de Beeck1, J. Verbeek1, P. Vermeersch2, D. Cassiman3, F. Loayza Puch4, R. Agami5, K. de Keersmaecker1

1Department of Oncology, KU Leuven - University of Leuven, 2Department of Laboratory Medicine, 3Department of Gastroenterology-Hepatology and Metabolic Center, University Hospitals Leuven, Leuven, Belgium, 4Division of Biological Stress Response, The Netherlands Cancer Institute, Amsterdam, Netherlands

Background: We previously described a recurrent arginine-to-serine mutation on residue 98 (R98S) in ribosomal protein L10 (RPL10), with a frequency of 8.6% in pediatric T-ALL cases. The R98S mutated residue contacts the catalytic core (peptidyltransferase center, PTC) of the ribosome and causes ribosome biogenesis, Ptd RNA, and translational defects in PRL10-WT mouse lymphoid Ba/F3 cells. These observations suggest that the RPL10-R98S mutation may contribute to T-ALL pathogenesis by inducing translational changes.

Aims: The spectrum of translated proteins (translatome) of RPL10 R98S mutants was investigated in order to identify translational changes caused by the mutation and potentially driving oncogenesis.

Methods: We performed ribosome footprinting (RNA sequencing of ribosome bound RNA), polysomal RNA sequencing, total RNA sequencing and mass spectrometry based quantitative proteomics on engineered RPL10-R98S or RPL10-WT mouse lymphoid Ba/F3 cells.

Results: RPL10 R98S cells showed significant upregulation for 3% (n=178) of the measured proteins and a downregulation of 1% (n=68). Moreover, polysomal RNA sequencing and ribosome footprinting showed respectively 57 and 22 genes with significantly higher translational efficiency in RPL10 R98S, and 22 and 29 genes, with reduced translational efficiency. Among them, we also found genes involved in T cell differentiation and proliferation. In particular, Mapk6 presented reduced translational efficiency in the ribosome footprinting, potentially due to differences in ribosome occupancy of an upstream ORF, whereas the transcription factor Ikaros, a master regulator of the upregulated transcriptome, was overexpressed at the transcriptional and protein level. Interestingly, the results from the mass spectrometry and the polysomal RNA sequencing datasets showed a significant enrichment and upregulation of members of the JAK-STAT signaling pathway with Casaf2/2, Jak1 and several Stats being 1-3 fold elevated at the protein level and higher translation efficiency for Lfgr, Cbl, Ifit3, Ifi14, Ikaros and Ino.

REPOSITIONING EXISTING DRUGS AS NOVEL THERAPEUTICS: OXIDATIVE STRESS AS A TARGET FOR HIGH-RISK LEUKAEMIA IN CHILDREN

M. Karsa1,*, K. Somers1, A. Mariana1,2, T. Failes1,2, G. M. Arndt1,2, U. R. Kees3, M. Haber1, M. O. Norris1, R. Sutton1, R. B. Lock1, M. J. Henderson1

1Children’s Cancer Institute, Lowy Cancer Research Centre, University of New South Wales, 2ACRF Drug Discovery Centre for Childhood Cancer, Children’s Cancer Institute, Lowy Cancer Research Centre, University of New South Wales, Sydney, New South Wales, 3Telethon Kids Institute, University of Western Australia, Perth, Western Australia, Australia

Background: Remarkable improvements made in the treatment of childhood acute lymphoblastic leukaemia (ALL) in past decades have resulted in 5-year survival rates approaching 90%. However, prognosis remains dismal for certain subgroups of high-risk patients, including poor responders to induction therapy, infants with ALL that harbor rearrangement of the Mixed Lineage Leukaemia (MLL/KAETZ2) gene, and children with Philadelphia chromosome positive ALL. In particular, infant ALL patients with ML1 disease have survival rates below 50% despite the use of intensified treatments, necessitating the development of more effective, less toxic therapeutics for them.

Aims: The aim of this study is to identify candidates that target MLL-rearranged leukaemia cells using drug-repurposing, whereby an approved drug is applied to treat a disease other than the one for which it was originally intended. This drug discovery strategy is gaining popularity as it potentially avoids the lengthy process of drug development and FDA approval.

Methods: 3707 approved drugs and pharmacologically active compounds were initially screened against an infant ALL cell line with MLL-rearrangement, PER-485 and a paediatric leukaemia cell line wild-type for MLL, CEM, using a resazurin-based cell viability assay. Hit compounds were further tested in a panel of infant leukemic cell lines and seven solid tumor cell lines. Compounds were subsequently evaluated in vitro for cytotoxic activity against a panel of 20 paediatric high-risk ALL patient-derived xenograft (PDX) cells. Apoptosis was measured by Annexin V positivity and PARP cleavage.

Results: The screen resulted in the identification of two FDA-approved drugs that were preferentially cytotoxic against MLL-rearranged ALL and other leukaemia cell lines, compared to solid tumours and normal cells. Auranofin was originally developed for rheumatoid arthritis and was later fast-tracked into Phase II clinical trial for adult chronic lymphocytic leukaemia, while Disulfiram, which was developed for treatment of chronic alcoholism, is currently in several clinical trials for cancers including metastatic melanoma and glioblastoma. These drugs also showed potent activity in high-risk paediatric leukaemia PDX cell cultured translated in vitro, including MLL-rearranged ALL and Philadelphia-positive ALL with IC50 values between 100-400 nM for Auranofin and 30-60 nM for Disulfiram. Induction of apoptosis was evident at 6 hours post Auranofin treatment, or after 12 hours Disulfiram treatment. Each drug significantly increased intracellular ROS as early as one hour post-treatment (p<0.01), which was accompanied by induction of Nrf2, a master regulator of the antioxidant response. Incubation with ROS scavenger N-acetyl cysteine prior to treatment with either drug prevented the increase in cellular ROS levels (p<0.05) and rescued cells from apoptosis (p<0.0001), indicating involvement of reduction-oxidation and increased ROS generation as mechanisms of leukaemia cell killing induced by these drugs.

Summary/Conclusions: In summary, we have identified two FDA-approved drugs that demonstrated potent anti-leukaemia activity through induction of ROS, potentially opening up new avenues for clinical treatment of high-risk paediatric ALL. We will now be testing these potential therapeutics in vivo using relevant PDX models of high-risk paediatric ALL.

P155

TP53 MUTATIONS DISRUPTING DNA BINDING LEAD TO CHEMOTHERAPY RESISTANCE IN ACUTE LYMPHOBLASTIC LEUKAEMIA

M. Pogodzinski1,*, F. Yang2,3, H. Sun2, J. Hof1, C. Eckert1, B.-B. Zhou4, M. Naam- Schwabe5

1Pediatric Oncology and Hematology, Charité - Universitätsmedizin Berlin, Berlin, Germany, 2College of Life Sciences, Beijing Normal University, Beijing, 3Oncology and Hematology, Shanghai Childrens Medical Center, Shanghai, China

Background: Polychemotherapy resistance is a major challenge in the treatment of children with relapsed acute lymphoblastic leukaemia (ALL). Mutation of TP53 is tightly associated with poor response to treatment in ALL relapse patients.

Aims: We studied mutations of TP53 in ALL relapses and in six ALL cell lines to shed light on mechanisms and pathways mediating TP53 dependent drug resistance in relapsed ALL. First, we analyzed the spectrum of TP53 mutations in ALL relapses and correlated it to treatment response of patients. Second, we studied drug sensitivity in TP53 wild type (wt) versus TP53 mutant ALL cell lines.

Methods: TP53 was sequenced by the method of Sanger sequencing. Drug sensitivity was determined by IC50 in ALL cell lines. Drugs included in the study were DNA damage inducing agents as topoisomerase II inhibitors, alkylating agents, nucleotide analoga, and other agents, most of which are used in relapse treatment protocols.

Results: We identified 20 different TP53 mutations in 34 patients. We classified TP53 mutations into ‘hot spot’ (R175, Q245, R248, R273 and R282), non-hot spot and frameshift, respectively. We found that hot spot TP53 mutations were enriched in ALL relapse patients with non-response to treatment compared to good responding patients (64 versus 27%). In ALL cell lines, we confirmed TP53 mutations in Jurkat (R166) and Lu100527 and identified R248P in MHH. Three ALL cell lines were TP53 wt (SUP-B15, UOC-B6, NALM-6) and used as controls. Topoisomerase II inhibitors upregulated expression of wt p53. In contrast, nucleotide analoga showed no p53 induc-
tion, IC50 measurements showed that TP53 mutations lead to resistance against topoisomerase II inhibitors and alkylating agents, but not against other drugs. The upstream pathway of p53 (CHK1, CHK2) and DNA damage recognition (γH2AX) were not impaired in the six ALL cell lines. To study the effect of TP53 mutation on resistance to treatment in more detail, we focused on the R248P mutation, located in hot spot codon 248, that we found in a relapsed patient with non-response to treatment but without in-frame R248P. Using a CRISPR/Cas9 knockout (KO) of endogenous p53 and lentiviral based re-expression in NALM-6, we generated p53 KO, and KO+wt p53, KO+R248P and KO+GFP cell lines. The KO cells showed a similar resistance to DNA damage inducing drugs as KO+R248P cells. Overexpression of wt p53 in KO cells did not sensitize to DNA damage inducing drugs. In contrast, to wt p53, R248P did not inhibit cell proliferation under drug treatment. We found that this mutant was unable to induce downstream targets of p53 (p21, BAX). Moreover, ChIP-seq showed that R248P cannot bind the promoter and induce expression of typical p53 targets MDM2, p21, BAX, BCCJPUMA, FA7, and CASP9. This result indicates that R248P is defined by the consensus element of p53. However, the binding motif analysis showed that the R248P mutant still binds DNA at a different and purine-rich sequence. In summary, R248P leads to loss of wt p53 function and mediates resistance to topoisomerase II inhibitors and alkylating agents.

**Summary/Conclusions:** Overall, our results show that mutations affecting TP53 hot spots, in particular codon 248, are associated with resistance of ALL cells to chemotherapy and reveal first insights into underlying mechanisms and pathways.

**GENETIC ACTIVATION AND THERAPEUTIC TARGETING OF PIM1 IN T-CELL ACUTE LYMPHOBlastic LEUKAEMIA**

D. Ribeiro1,2, I. Lopes1, C. Custódia1, J. Silva1, M. Abreu1, J. Barata1,2

1Biomarker Sciences, Gilead Sciences, Inc., Foster City, 2Division of Oncology, University of Oxford, Oxford, UK

**Background:** T-cell acute lymphoblastic leukemia (T-ALL) and T-cell acute lymphoblastic lymphoma (T-LBL) are aggressive immature T-cell malignancies that are considered one disease entity according to the World Health Organization (WHO). Both T-ALL and T-LBL are often characterized by improper T-cell receptor (TCR) reorganizations leading to aberrant activation of proto-oncogenes.

**Aims:** Despite some genetic and phenotypic similarities between T-ALL and T-LBL, T-ALL risk group stratification cannot be extrapolated to T-LBL patients. Therefore, it is our goal to find new T-ALL markers and develop new targeted therapies based on those T-LBL specific markers.

**Methods:** We used an IL-7-dependent leukemia T-cell line (TAIL7) and “primary” cells from patient-derived xenografts (PDX). We used inhibitors of PI3K (LY294002), mTOR (rapamycin), MEK1/2 (UO126) and ULK1/2 (MRT68921). Analysis of viability and cell size was performed by flow cytometry. Signaling pathway activation and LC3-II-IL conversion was performed by western blot analysis. LC3 puncta formation was assessed by confocal microscopy. Autophagosome/lysosome formation was analyzed by electron microscopy.

**Results:** Drugs that target the PI3K/Akt/mTOR pathway (a master negative regulator of autophagy) could serve as a novel therapeutic strategy in this aggressive T-cell neoplasm.

**Summary/Conclusions:** Our results suggest that IL-7 makes use of a flexible strategy to promote T-ALL cell viability by recruiting both pro- and anti-autophagy mechanisms and functions in order to consistently promote T-ALL cell viability. In this scenario, IL-7-mediated viability relies on the latter pathway, as we previously described. In contrast, under stress conditions (serum starvation) IL-7 promotes autophagy in leukemia cells. In this situation, IL-7-mediated survival partially relies on autophagy activation and LC3-II-IL conversion was performed by western blot analysis. LC3 puncta formation was assessed by confocal microscopy. Autophagosome/lysosome formation was analyzed by electron microscopy.

**Background:** T-cell acute lymphoblastic leukemia (T-ALL) constitutes an aggressive subset of ALL, the most frequent childhood malignancy. T-ALL cases are high risk and a significant fraction of the patients still relapse despite intensive chemotherapy, prompting the need for a deeper understanding of T-ALL biology in order to develop novel therapies. Autophagy is a homeostatic intracellular process characterized by the sequestration of cytoplasmic compartments within double-membrane vesicles (autophagosomes) to promote their degradation. Importantly, autophagy is upregulated during starvation, cellular stress or in rapidly dividing cells, such as cancer cells, as a compensatory mechanism to provide nutrients and stress relief. By mitigating stress and allowing cell survival, autophagy may serve as a pro-tumoral mechanism. On the other hand, persistent autophagy can lead to cell death and thereby prevent tumor growth. Interleukin-7 (IL-7) is essential for normal T-cell development but there is considerable evidence that IL-7-mediated signaling can also contribute to leukemogenesis. A majority of T-ALL patients expresses the IL-7 receptor and IL-7 accelerates T-ALL disease progression in vivo and promotes T-ALL cell proliferation, survival and metabolic activation in vitro via PI3K/Akt/mTOR pathway (a master negative regulator of autophagy). IL-7 can also activate MEK/Erk pathway (which has been implicated in promotion of autophagy).

**Aims:** Since IL-7 has the ability to activate signaling pathways with potentially opposing roles in autophagy regulation, our goal was to explore the actual impact of IL-7 on the autophagic process in T-ALL cells and elucidate its molecular mechanisms and functions.

**Methods:** We used an IL-7-dependent leukemia T-cell line (TAIL7) and “primary” cells from patient-derived xenografts (PDX). We used inhibitors of PI3K (LY294002), mTOR (rapamycin), MEK1/2 (UO126) and ULK1/2 (MRT68921). Analysis of viability and cell size was performed by flow cytometry. Signaling pathway activation and LC3-II-IL conversion was performed by western blot analysis. LC3 puncta formation was assessed by confocal microscopy. Autophagosome/lysosome formation was analyzed by electron microscopy.

**Results:** We show that in optimal culture conditions (medium with serum) IL-7 inhibits autophagy in T-ALL, albeit in a common manner that involves triggering both pro- (via MEK/Erk) and anti- (via PI3K/Akt/mTOR) autophagic signaling. In this scenario, IL-7-mediated viability relies on the latter pathway, as we previously described. In contrast, under stress conditions (serum starvation) IL-7 promotes autophagy in leukemia cells. In this situation, IL-7-mediated survival partially relies on autophagy activation and strictly requires MEK/Erk activation. Mechanistically, we provide evidence that depending on culture conditions, IL-7 can balance the relative activation of PI3K/Akt/mTOR and MEK/Erk pathways towards or against autophagy in order to consistently promote T-ALL cell viability.

**Summary/Conclusions:** Our results suggest that IL-7 makes use of a flexible strategy to promote T-ALL cell viability by recruiting both pro- and anti-autophagy pathways, which are recruited to prevent tumor cell death depending on the microenvironmental conditions. Our data strengthen the notion that combination therapies against PI3K/Akt/mTOR and MEK/Erk pathways may be of particular relevance in the context of T-ALL.
and Center for Childhood Cancer Research, Children’s Hospital of Philadelphia, 3Pediatrics, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, United States

Background: B-cell acute lymphoblastic leukemia (B-ALL) is the most common malignancy of childhood and is highly curable with modern risk-adapted chemotherapy. However, 15-20% of children and >60% of adults with B-ALL develop chemoresistance and relapse, indicating need for new therapies. Addition of kinase inhibitors to chemotherapy for patients with \( BCR-ABL1 \)-rearranged (Ph+) B-ALL has dramatically improved event-free and overall survival, and similar approaches are now under active clinical investigation in patients with \( BCR-ABL1 \)-like (Philadelphia chromosome-like or Ph-like) B-ALL. Recent studies have demonstrated activated spleen tyrosine kinase (SYK) signaling in various genetic subtypes of B-ALL and preclinical activity of the SYK/FLT3/AKIR inhibitor fostamatinib. However, SYK activation in B-ALL and potential correlation with specific leukemia-associated mutations remains incompletely characterized. We hypothesized that constitutive activation of SYK signaling occurs across a genetic spectrum of infant and high-risk childhood B-ALL and can be therapeutically targeted \textit{in vivo} with the selective SYK inhibitor entospletinib (ento).

**Aims:** (1) Assess basal SYK signaling activation in childhood B-ALL specimens. (2) Quantify treatment efficacy, pharmacokinetics (PK), and pharmacodynamic (PD) effects of ento in childhood B-ALL patient-derived xenograft (PDX) models.

**Methods:** Total and phosphorylated (p) SYK levels were assessed by Simple Western analysis of splenocyte lysates from NSG mice well-engrafted with primary pediatric B-ALL specimens \((n=19 \text{ Ph-like}, n=4 \text{ infant } KMT2A\text{-rearranged (R)}, n=4 \text{ infant non-}KMT2A\text{-R PDX models})\) to identify leukemias with constitutive SYK signaling activation. To assess \textit{in vivo} activity of SYK inhibition, selected B-ALL PDX models with high basal pSYK \((n=2)\) were treated with continuous oral control \((0.03\% \text{ chow})\), or ento \((0.07\% \text{ ento} \text{ arms})\) daily for 21-28 days, and peripheral blood and spleens were harvested for downstream studies. Flow cytometric analyses of murine tissues were performed to assess initial human ALL engraftment and to measure ento treatment responses. PK and PD assessments were performed in terminal peripheral blood and spleens, respectively.

**Results:** Constitutive pSYK signaling was observed in \(10/19\) Ph-like, \(4/4\) KMT2A-R, and \(1/4\) non-KMT2A-R B-ALL specimens. Ento treatment of KMT2A-MLLT3 \((\text{ALL3103})\) and Ph-like NUP214-ABL1 \((\text{NH011})\) PDX models significantly inhibited ALL proliferation \textit{in vivo} versus control animals at both 0.03% and 0.07% chow formulations (representative data in Figure 1; p<0.05). Steady state concentrations were maintained throughout the study duration with terminal PK values of 3.3 (±0.5) and 7.9 (±1.0) \muM (0.03% and 0.07% ento arms, respectively). PD studies demonstrated dose-dependent \textit{in vivo} inhibition of pERK measured in human leukemia cells within spleens of ento-treated mice. PD inhibition of SYK target phosphoproteins was more pronounced in 0.07% ento-treated animals.

**Summary/Conclusions:** Constitutive activation of SYK signaling occurs frequently in childhood Ph-like and infant KMT2A-R childhood B-ALL. Ento treatment of B-ALL PDX models potently inhibited SYK pathway signaling proteins and significantly inhibited leukemia proliferation \textit{in vivo}.

PHARMACOLOGICAL ACTIVITY OF CB-103 – AN ORAL PAN-NOTCH INHIBITOR WITH A NOVEL MODE OF ACTION

R. Lehal1,*, D. Weber1, V. Frismantas2, J.-P. Bourquin2, M. Bauer1, M. Murone1, F. Radtke3

1Cellestia Biotech AG, Basel, 2University Children’s Hospital, Zürich, 3Swiss Institute for Experimental Cancer Research, EPFL, Lausanne, Switzerland

**Background:** NOTCH signalling is a developmental pathway known to play critical roles during embryonic development as well as for the regulation of self-renewing tissues. Aberrant activation of NOTCH signalling leads to deregulation of the self-renewal process resulting in sustained proliferation, evasion of cell death, loss of differentiation capacity, invasion and metastasis, all of which are hallmarks of cancer. When the NOTCH pathway is inappropriately activated by genetic lesions (over expression of NOTCH ligands/receptors, GOF mutations in NOTCH receptors as well as chromosomal translocations), it becomes a major driver for NOTCH-dependent cancers and resistance to standard of care treatment. Over 250,000 patients are annually diagnosed with NOTCH dependent cancers, with no specific therapy available to date.

**Aims:** Given the importance of NOTCH signalling in human cancers, several therapeutic approaches have been utilized to block NOTCH signalling. Two of these strategies are: a) the use of monoclonal blocking antibodies (mAbs) against NOTCH ligands and receptors and b) the use of small molecule gamma-secretase inhibitors (GSIs). However, these approaches can only be effective if tumor cells express full-length ligand or receptor molecules. As validation of NOTCH as a therapeutic target, clinical activity of these in clinical studies were was observed in various trials for some of these inhibitors (mAbs, GSIs), but treatment and exposure were usually limited due to toxicities, mainly related to gastro-intestinal adverse events. On the contrary, in human cancers harboring NOTCH gene fusion due to chromosomal translocations or specific NOTCH mutations, the use of mAbs and GSIs will have very limited clinical benefits. Cellestia has decided to follow a disruptive approach, by blocking NOTCH signalling in the most downstream part of the NOTCH cascade, at the level of the NOTCH transcriptional activation complex, using small molecule inhibitors.

**Methods:** Here we report the pharmacological characterization of CB-103, a first-in-class orally-active small molecule inhibitor of the NOTCH transcriptional activation complex.

**Results:** We demonstrate that \textit{in vitro} CB-103 potently inhibits NOTCH signalling in various leukemic and lymphoma cell lines, and T-ALL blasts derived from relapse/refractory patients. In addition, CB-103 exhibited anti-tumor efficacy in multiple \textit{in vivo} models of NOTCH-driven T-ALL using T-ALL cell lines and patients derived xenograft models.

**Summary/Conclusions:** Toxicology studies have been completed and clinical development of CB-103 with a first-in-human Phase I/IIA clinical study in advanced solid tumors and haematological malignancies is under preparation.
Acute lymphoblastic leukemia - Clinical 1

P160

IKZF1Δ4-7 CAN BE EASILY SCREENED BY PCR BUT DOES NOT PREDICT OUTCOME IN ADULTS WITH ACUTE LYMPHOBLASTIC LEUKAEMIA; DATA FROM 490 PATIENTS ENROLLED ON THE UKALL14 TRIAL

1UCL Cancer Institute, 2CRUK and UCL Cancer Trial Centre, UCL, 3Barts Cancer Institute, QMUL, London, 4Leukemia Research Cytogenetics Group, Northern Institute for Cancer Research, Newcastle University, Newcastle Upon Tyne, United Kingdom

Background: The IKZF1 gene encodes the IKAROS zinc finger transcription factor and master regulator of lymphocyte differentiation. IKZF1 lesions are common in acute lymphoblastic leukaemia (ALL) and have been reported as independent prognostic factors for poor outcome. IKZF1Δ4-7, resulting in the dominant negative Iκ6 isoform is the most common single IKZF1 deletion.

Aims: We aimed to generate and validate a simple, PCR-based screening assay for IKZF1Δ4-7 using an endpoint PCR assay using primers located in introns 3 and 7. The lower limit of detection was determined by serial dilution of DNA from the IK6-expressing cell line SUP-B15 and calculated to be 0.001%. A total of 95 samples were also tested using the MLPA P335 kit to detect the full spectrum of IKZF1 deletion. Sanger sequencing confirmed the breakpoints in 27 cases.

Results: The median age of the patients tested was 46 years (range 25-65). Overall IKZF1Δ4-7 was detected in 97/490 (20%) patients but the frequency varied by genetic subtype. Patients with BCR-ABL1 fusion had the highest IKZF1Δ4-7 frequency (46/150, 31%) followed by patients with B-other ALL (29/154, 19%). Patients with other classic cytogenetic abnormalities harboured significantly fewer IKZF1Δ4-7 – low hypodiploid (3/26), MLL gene fusions (3/31), t(1;19) and iAMP21 (0/3). MLPA did not detect any IKZF1Δ4-7 deletions that were not detected by PCR but did identify several samples with alternative IKZF1 deletions affecting different exons (see Table 1). By contrast, the PCR assay did detect six IKZF1Δ4-7 deletions undetected by MLPA, consistent with the higher sensitivity of this approach. Interestingly, three of these samples harboured alternative IKZF1 deletions in addition to IKZF1Δ4-7. In 70 (14%) cases, we observed a “faint” PCR band. Since the biological relevance of this was not clear, the “faint” bands were not included in the main analysis. Interestingly the frequency of these “faint” bands was similar across all genetic subtypes: BCR-ABL1 (14%), B-other (15%), MLL (21%), low hypodiploid (19%). We examined the impact of IKZF1Δ4-7 on achievement of CR, persistence of minimal residual disease (MRD) at t = x ≥ 10-4 (lgT/CR quantitation by EuroMRD criteria) after courses 1 and 2 of therapy, EFS, OS and time to relapse, at a median follow-up of 23.1 months. Two thirds of patients (44/66) with IKZF1Δ4-7 were MRD positive at the end of phase 1 compared with 147/273 (54%) patients without the deletion (p=0.059). However, this relationship between IKZF1Δ4-7 and MRD did not persist after phase 2. We did not identify any association between IKZF1Δ4-7 and any of the other outcome parameters tested.

Table 1.

Summary/Conclusions: IKZF1Δ4-7 can be detected by a simple and cheap PCR assay, which is more sensitive than MLPA. The frequency of IKZF1Δ4-7 was broadly comparable with previous studies. However, we did not find an association between IKZF1Δ4-7 and clinical outcome in the large clinical trial sample set. We are in the process of evaluating the impact of other IKZF1 lesions.

P161

PROGNOSTIC SIGNIFICANCE OF MINIMAL RESIDUAL DISEASE DETECTED BY MLL FUSION GENE TRANSCRIPTS IN INFANT ACUTE LYMPHOBLASTIC LEUKAEMIA, UPDATED RESULTS OF 76 PATIENTS ENROLLED INTO MLL-BABY STUDY

G. Tsaar1,2, A. Popov2, T. Riger1, A. Solodovnikov1, A. Kustanovich3, O. Aleinkova3, Y. Olshanskaya4, N. Myakova2, T. Verzhbitskaya1, E. Shorkov4, O. Strenueva1, O. Araakev1, A. Vaslova1, S. Tsverenk2, L. Saveliev1

1Regional Children Hospital #1, Research Institute of Medical Cell Technologies, Ekaterinburg, 2National Research Institute of Pediatric Hematology, Oncology and Immunology, named after Dmitry Rogachev, Moscow, Russian Federation, 3Belarusian Research Center for Pediatric Oncology, Hematology and Immunology, Minsk, Belarus, 4PET Technology, 5Ural State Medical University, Ekaterinburg, Russian Federation

Background: Fusion gene transcripts (FGTs) are rarely used for minimal residual disease (MRD) monitoring in acute lymphoblastic leukemia (ALL) cases, except of Ph-positive ALL. However in infant ALL, where MLL gene rearrangements are found the majority of cases, MLL FGTs are attractive targets for MRD detection.

Aims: To estimate prognostic significance of MLL by qualitative detection of different MLL FGTs in infant ALL treated by MLL-Baby protocol.

Methods: Seventy six infants (27 boys and 49 girls) with median age of 5.8 months (range 0.3-11.83) were included in the current study. Among them there were 39 (51.3%) MLL-AF4-positive cases, 14 (18.4%) MLL-MLLT1-positive, 12 (15.8%) MLL-MLLT3-positive, 6 (7.9%) MLL-MLLT10-negative, 4 (5.3%) MLL-EFS15-positive cases. MDR detection was performed in BM samples by real-time quantitative PCR and nested RT-PCR with sensitivity non-less than 1E-04. MRD negativity was defined as absence of FGTs in the both assays. Median of follow-up period in the observed group was 6.4 months. Informative consent was obtained in all cases. Results: We confirmed our earlier finding that the most informative TP for the MRD detection was TP4. The lower limit of detection was determined by serial dilution of DNA from the MLL·MLT11·SUP-B15 cell line and calculated to be 0.001%. MLL-positive patients stratified to high-risk arm of MLL-Baby protocol (EFS 0.05±0.04 vs 0.78±0.07 p<0.0001; cumulative incidence of relapse 0.78±0.10 vs 0.11±0.07 p<0.0001, respectively) and for all others MLL-rearranged patients treated by intermediate risk (IMR) arm (EFS 0.00 vs 0.71±0.11 p<0.0001; cumulative incidence of relapse 1.0 vs 0.29±0.10 p<0.0001, respectively). There were no significant differences in initial patients’ characteristics and treatment response criteria (on days 8, 15, 36) among 38 MMRD-positive and 38 MMRD-negative patients. Multivariate analysis revealed that initial CNS disease (hazard ratio (HR) 2.703, 95% CI 1.255-5.284, p=0.011), m1 status of BM on day 15 (HR 3.909, 95% CI 1.465-6.515, p=0.003) and MRRD positivity at TP4 (HR 6.950 95% CI 2.617-18.456) were significant covariates with negative impact on hazard of unfavorable event. Based on dismal outcome of MRRD-positive IMR patients we tried to augment their therapy and relocated 5 of them from IMR group to HR arm after TP4. Although all infants had subsequently relapsed, we also wanted to find out which characteristics might predict relapse in IMR patients who were MRRD-negative at TP4 (n=5). Of note, all these 5 relapsed patients (100%) had initial CNS disease while CNS disease was detected only in 2 out of 19 IMR patients (10.5%) who stayed in complete hematological and molecular remission (p=0.003). Also 5 relapsed IMR patients who were MRRD-negative at TP4 had breakpoint positions within intron 11 of MLL gene and they were MRRD-positive by flow cytometry (MRRD ≥0.1%) on day 15. None of MRRD-negative patients by flow cytometry (MRRD <0.1%) on day 15 relapsed later on (p<0.001).

Summary/Conclusions: MDR monitoring by detection of MLL FGTs was feasible and had significant prognostic impact. MRRD positivity at TP4 was independent factor of unfavorable outcome in infants with MLL-rearranged ALL enrolled into MLL-Baby protocol irrespective of treatment arm. Treatment intensification for MRRD-positive at TP4 IMR patients did not improve their outcome. MRRD-positivity at TP4 in IMR group was associated with MRRD-positivity by flow cytometry on day 15, MLL breakpoint positions within intron 11 gene and initial CNS disease.

P162

PRO-T CELL ALL/LBL: AN ULTRA-HIGH RISK CD2-NEGATIVE DISEASE SUBTYPE IN ADULTS DEFINED BY FLOW CYTOMETRY

B. Petroskova1, G. Rymkiewicz2, K. Domanska-Czyz1, J. Romejko-Jarosinska1, K. Blachnio2, L. Poplawska1, W. Michalski3, J. Walewski1

1Department of Lymphoid Malignancies, 2Department of Pathology and Laboratory Diagnostics, 3Department of Biostatistics, The Maria Sklodowska-Curie Memorial Institute and Oncology Centre, Warsaw, Poland, Warszawa, Poland
Background: Risk factors for T-LBL have not been systematically evaluated, in contrast to T-ALL.

Aims: Our aim was to define immunophenotype of T-LBL/ALL in 71 consecutive patients by use of the flow cytometry (FCM) of tissue aspirates if peripheral blood (PB) and bone marrow (BM) were uninvolved. We also evaluated prognostic value of immunophenotype according to WHO 2008 subtype and ETP (Early T-Cell Phenotype) definition in adult patients with T-LBL/ALL treated on uniform ALL protocol.

Methods: Between 1997 and 2015, 71 adult patients with T-LBL/ALL were treated according to the GMAIL 05/93 and T-LBL/2004 protocols. Immunophenotype was determined by immunohistochimical staining and by FCM of cellular suspension obtained from lymph nodes (n=31), mediastinal mass (n=12) or nasopharyngeal/perimandibular infiltration (n=2) by fine needle aspiration biopsy (FNAB), as well as of BM (n=10), PB (n=7) and pleural fluid (n=9). Disease subtype was defined according to WHO 2008 classification:

- CD2 negative or dim (CD2-)
- CD2+ but CD5 negative
- CD5 weaker (20-71%): 54%
- CD34/HLA-DR expression

Results: Patient characteristics: ALL (BM+ >20%): n=26(37%), LBL: n=45(63%). BM+<20% (L). 7%: 28(37%); 3: 72(93%); 2: 9(12%); 1: 3(4%). BM+<20% involvement (LBL): 27%, pre-T: 17%, cortical: 55%, medullary/mature: 28%. Among LBL pts, ETP was expressed in 100%/50%/50%/75%/14% of ETP pts. 4 pts(31%) with CD2, CD1a and 3 or less positive pTAg present was 64% (0.511, 0.776), 66% (0.512, 0.803) and 64% (0.5, 0.782) compared to 11% (0.034, 0.256), 32% (0.152, 0.494) and 27% (0.097, 0.452) for pts without CD2, CD1a and 3 or less pTAg, respectively. OS and DFS in pts with CD2 expression as well as on WHO subtype. ETP is a non-uniform category with CD2 expression as well as on WHO subtype. ETP is a non-uniform category (CD2+/CD2-). Not consistent with CD2 positive pTAg (CD2+), only 19/ pts with pre-T phenotype. 3/7 pts were rescued with allo-HCT (Figure 1).

Summary/Conclusions: Survival of T-LBL/ALL pts depends on CD1a and CD2 expression as well as on WHO subtype. ETP is a non-uniform category by pro-7/pre-T-cell origin. ETP phenotype was non-significant factor for OS/DFS (p=0.15/0.09) unless consistent with pro-T subtype (CD2+), only 19/ pts with pre-T phenotype. 3/7 pts were rescued with allo-HCT (Figure 1).

haematologica | 2017; 102(s2) | 31
Background: The outcome for older adults with acute lymphoblastic leukaemia (ALL) is unsatisfactory. The UKALL12/ECOG2993 study showed that high risk cytogenetic abnormalities, were common, as well as lower rates of complete remission (CR) and 5 year overall survival (OS) in those aged 55–65 years of age as compared to younger persons. There are few studies which focus on older patients with ALL, despite an increasing incidence with age.

Aims: A trial to establish age-appropriate baseline chemotherapy from which to design widely-applicable studies of novel agents in older people with ALL.

Methods: UKALL60+ offers five ‘Arms’ to be decided by investigator and patient choice; Arm A= Philadelphia chromosome positive (Ph+), Arm B= Non-intensive (designed to be delivered primarily out of hospital), Arm C= Intensive, Arm D= Intensive+ and Arm E= Registration only (in which treatment is at investigators discretion, including no active therapy). Any elderly patient with newly diagnosed ALL is eligible. There are no exclusions for co-morbidities, including prior malignancies. Baseline characteristics of each group including Charlson index, ECOG, Karnofsky and CRASH scores are being collected.

Results: After IRB approval, we performed a retrospective study of patients (pts) age ≥60 diagnosed with ALL from 2000 to 2016 at Mayo Clinic Rochester. Statistical analysis was performed using JMP 10.0 software.

Predictors of survival

Predictors of survival were 20% for CDKN2A del in this disease group. Further studies are needed to confirm this finding, as it could be a target for novel therapies.

Aims: Describe clinical outcomes and prognostic factors of elderly ALL.

Methods: After IRB approval, we performed a retrospective study of patients (pts) age ≥60 diagnosed with ALL from 2000 to 2016 at Mayo Clinic Rochester. Statistical analysis was performed using JMP 10.0 software.

Results: Out of 210 adult ALL pts, we identified 63 (30%) consecutive pts with elderly ALL. The average age at time of diagnosis was 67 (60-82), & 38 (60%) were males. Median follow up was 16.1 months (0.2-126), during which time 40 (63%) deaths occurred; 25 (3%) related to the disease, & 15 (27%) secondary to infection or other causes. Baseline characteristics at time of diagnosis: 54 (86%) pts had B-cell phenotype, 19 (35%) were Ph+. Only 9 (14%) pts had T-cell phenotype. 20 (31%) pts had a Charlson Comorbidity Index ≥2 & 17 (27%) presented with ECOG PS ≥2. Median Hgb was 10.6 g/dl (4.9-18.5), WBC 6.2 x 10⁹/l (0.5-160.8), PLT 51 x 10⁹/l (4-750), peripheral blast 30% (0-95), marrow blast 87.5% (0-100), & LDH 381.5 U/L (141-8440). Lymphoblastic lymphoma was only evident in 3 (5%) pts. Among pts with available data, 34/58 (59%) had B symptoms, 16/57 (28%) lymphadenopathy, 7/57 (12%) splenomegaly, 6/60 (10%) pleural effusions & 10/45 (22%) of pts had CNS leukemia. Cytogenetics at time of diagnosis: Of 48 pts with available data, 20 (41%) had complex cytogenetics (≥5 abnormalities), 18 (38%) had a monosomic karyotype, 8 (17%) were hypodiploid, 4 (8%) were hyperdiploid, & 2 (4%) were a mix of hypo- & hyper-diploid. FISH studies were available for 50 pts: 10 (20%) had CDKN2A del, 3 (6%) 11q(4,11) MLL-AF4, 2 (4%) 11(13,19) E2A-PBX1, 1 (2%) KLF1 deletion. Treatment and Outcomes: Of 48 pts received palliative therapy only, which included TKIs, chemotherapy, or hospice. The other 53 (84%) received induction chemotherapy. Only 12 (23%) had an up-front dose reduction due to comorbidities. 32 (60%) received Hyper-CVAD, concomitantly with rituximab in 12 (31%) pts. & TKIs in 9 (28%) pts. 21 (40%) pts received other regimens, of which 14 (67%) had asparaginase-based chemotherapy. Only 2 (4%) pts who received induction chemotherapy died within the first 60 days; both received Hyper-CVAD. Median number of cycles to achieve CR was 1 (1-8) with CR/CRi rate of 93%, & median time to CR1 was 34 days (19-459), 3 pts who underwent palliative chemotherapy achieved CR (all had Ph+ disease & received TKIs). 7 pts (13%) had primary induction failure. 50% of pts relapsed within a median time of 12.6 (3.6-72.8) months. Only 10 pts underwent allogeneic hematopoietic stem cell transplantation (HSCT), of which 2 (20%) relapsed in less than 180 days. Median survival after HSCT was not reached. Predictors of survival: Elderly ALL has worse mOS compared to our adult ALL cohort, 17.2 (IQR; 11.7-32.9) vs 52.1 (IQR; 27.6-169.9) mon (p=0.0016). In a univariate analysis model which included multiple variables, only ECOG PS ≥2, WBC>30,000, CDKN2A del, & CNS leukemia were statistically significant, however only CNS leukemia (p=0.0009) & WBC (p=0.0168) retained statistical significance in multivariate mode, with a trend in CDKN2A del (p=0.06) (Figure 1).

Figure 1.

Summary/Conclusions: All elderly pts with ALL have worse survival compared to younger adults. However, this was not reflected by a low CR rate, or a high rate of mortality during induction, but by grim disease overall. We report for the first time the incidence of 20% for CDKN2A del in this disease group. Further studies are needed to confirm this finding, as it could be a target for novel therapies.

P166

MANAGEMENT AND OUTCOME OF ADULT PH+ ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS TREATED AT THE “SAPIENZA” UNIVERSITY BETWEEN 1996 AND 2016

S. Chiaretti 1, V. Gianfelici 1, R. Agrippino 1, L. Elia 1, F. Paoloni 1, S. Capria 1

Background: Elderly acute lymphoblastic leukemia/lymphoma (ALL) is a rare disease with a poor prognosis and is underrepresented in clinical trials. This poor outcome is likely due to comorbidities, early death during induction, lower rates of complete remission, and higher risk of relapse with poor biological features (Gokbuget, Blood, 2013).

Aims: Describe clinical outcomes and prognostic factors of elderly ALL.

Methods: After IRB approval, we performed a retrospective study of patients (pts) age ≥60 diagnosed with ALL from 2000 to 2016 at Mayo Clinic Rochester. Statistical analysis was performed using JMP 10.0 software.

Results: Out of 210 adult ALL pts, we identified 63 (30%) consecutive pts with elderly ALL. The average age at time of diagnosis was 67 (60-82), & 38 (60%) were males. Median follow up was 16.1 months (0.2-126), during which time 40 (63%) deaths occurred; 25 (3%) related to the disease, & 15 (27%) secondary to infection or other causes. Baseline characteristics at time of diagnosis: 54 (86%) pts had B-cell phenotype, 19 (35%) were Ph+. Only 9 (14%) pts had T-cell phenotype. 20 (31%) pts had a Charlson Comorbidity Index ≥2 & 17 (27%) presented with ECOG PS ≥2. Median Hgb was 10.6 g/dl (4.9-18.5), WBC 6.2 x 10⁹/l (0.5-160.8), PLT 51 x 10⁹/l (4-750), peripheral blast 30% (0-95), marrow blast 87.5% (0-100), & LDH 381.5 U/L (141-8440). Lymphoblastic lymphoma was only evident in 3 (5%) pts. Among pts with available data, 34/58 (59%) had B symptoms, 16/57 (28%) lymphadenopathy, 7/57 (12%) splenomegaly, 6/60 (10%) pleural effusions & 10/45 (22%) of pts had CNS leukemia. Cytogenetics at time of diagnosis: Of 48 pts with available data, 20 (41%) had complex cytogenetics (≥5 abnormalities), 18 (38%) had a monosomic karyotype, 8 (17%) were hypodiploid, 4 (8%) were hyperdiploid, & 2 (4%) were a mix of hypo- & hyper-diploid. siology, Sapienza University of Rome, 2GIMEMA Data Center, Rome, Italy

Background: The outcome of adults and elderly (>60 years) patients with Ph+
ALL has improved since the introduction of tyrosine kinase inhibitors (TKI), 
used alone or in combination with chemotherapy during induction. Before 2005, 
all these patients were treated with chemotherapy; from 2005, a TKI-based 
“chemo-free” induction strategy was applied.

Aims: To evaluate the outcome of patients followed from 1996 at a single Cen-
ter, and to correlate the short- and long-term responses with: a) induction treat-
ment (chemotherapy or TKI); b) age; c) TKI used (imatinib or dasatinib); d) 
fusion protein; e) allogeneic stem cell transplant (SCT).

Methods: Sixty-eight patients (29M/39F) were treated; median age was 50 
years (28-88) and 16 were elderly patients; 43 cases had the p190 protein, 19 
the p210 and 6 had both; the latter 2 groups were merged together for further 
analyses. Fifty-two patients were enrolled in clinical trials. Median follow-up is 
105 months (13-224).

Results: As induction, 28 patients received chemotherapy, 2 chemotherapy+TKI 
(considered as “chemotherapy+TKI group”) and 38 TKI alone (24 imatinib and 
14 dasatinib). All cases received TKI during consolidation/maintenance when it 
became available. All elderly patients but 1 received a TKI alone (plus steroids).
Upon induction, 44 patients received consolidation chemotherapy, including 5 
elderly. A SCT - carried out virtually only in adults - was performed in first complete 
remission (CR) in 13 cases (5 in the chemotherapy+TKI and 8 in the TKI group). 
Overall, 91% patients achieved a CR, OS and DFS at 100 months are 42% and 
45.5%, respectively. Among the 30 patients in the chemotherapy+TKI group, 25 
(83%) achieved a CR, 4 were refractory and 1 died in induction; in the TKI group 
(n=38), 37 (97%) achieved a CR and 1 was refractory. Differences are statistically 
significant (p=0.03). Refractoriness was more frequent in p210+ than in p190+ 
cases (12% vs 5%): this finding did not translate into significantly different OS 
and DFS (30% vs 48% and 32% vs 51%, respectively). When patients were strat-
ified by age, adults had a significantly better OS and DFS at 100 months than 
elderly (53% vs 19%, p=0.04, and 57% vs 20%, p=0.03, respectively), even 
morbidly-affected patients. In univariate analysis we treated the TKI group alone 
(75% vs 20%, p=0.01 and 73% vs 21.4%, p=0.017, respectively). The TKI used (imatinib or dasatinib) 
did not impact in adults, while a significant advantage in OS and DFS was 
observed for elderly patients receiving dasatinib (Figure 1): this might be due to 
the greater activity of dasatinib and also highlights the importance of consolidation 
therapy based on a TKI alone. Since age holds strong prognostic significance, our 
study further underlines the benefit of an induc-
tion strategy based on a TKI alone. Considering adults only, 
the greater activity of dasatinib and also highlights the importance of consolidation 
as shown for elderly patients receiving dasatinib (Figure 1): this might be due to 
the standard-risk group. In univariate analysis, CD9 positivity, age <1 year, 
white cell count ≥100 x 10^9/L and poor prednisone response were associated with 
lower RFS rate (P=0.029). Subgroup analysis showed remarkably 
poorer outcomes in CD9+ patients of the high-risk group (P=0.045). A similar 
trend was also observed in patients of the intermediate-risk group but not in 
the standard-risk group. In univariate analysis, CD9 positivity, age <1 year, 
white cell count ≥100 x 10^9/L and poor prednisone response were associated with 
lower RFS rates (HR=3.9; P=0.015) remained as inde-
pendent prognostic factors for lower RFS rates.

Summary/Conclusions: Our data indicate that expression of CD9 was signif-
ically associated with inferior survival outcomes in pediatric B-ALL. 
the standard-risk group. In univariate analysis, CD9 positivity, age <1 year, 
white cell count ≥100 x 10^9/L and poor prednisone response were associated with 
lower RFS rates (HR=3.9; P=0.015) remained as inde-
pendent prognostic factors for lower RFS rates.

Figure 1. 

Summary/Conclusions: This study further underlines the benefit of an induc-
tion based on a TKI alone. Since age holds strong prognostic significance, our 
results suggest that while the benefit followed by consolidation chemotherapy is 
the optimal choice for adults, in elderly cases dasatinib is more appropriate, 
since patients are often unfit to receive further chemotherapy. Finally, the advan-
tage of SCT needs to be carefully redefined in the TKI era.

THE TETRASPANIN CD9 IS A PROGNOSTIC MARKER FOR PREDICTING 
SURVIVAL OUTCOMES OF PEDIATRIC B- Precursor ACUTE 
LYMPHOBLASTIC LEUKEMIA

K.T. Leung1, K.Y.Y. Chan1, C. Zhang1, A.W.K. Leung1, F.W.T. Cheng1, 
J.W.S. Yu1, T.F. Leung1, K. Li1, C.K. Li1
1Paediatrics, The Chinese University of Hong Kong, Shatin, Hong Kong

Background: B-precursor acute lymphoblastic leukemia (B-ALL) is the most 
common childhood malignancy, accounting for approximately 30% of pediatric 
cancers. With advances in risk-adapted chemotherapy, the overall cure rate of 
newly diagnosed B-ALL is approaching 85% in most developed countries. How-
ever, relapse still occurs in ~20% of patients and a significant portion of them 
are not initially classified in the high-risk disease entity, underscoring the need 
for development of additional informative prognostic biomarkers.

Aims: CD9, a tetraspanin family protein, regulates multiple physiologic process-

s including cell migration and adhesion, and has been associated with metas-
tasis and progression of various types of cancers. In this study, we aim to eval-
uate its expression pattern and prognostic significance in pediatric B-ALL.

Methods: Cell surface CD9 expression on leukaemic blasts at disease presen-
tation was characterized by multicolor flow cytometry in a cohort of pediatric B-
ALL patients. The CD9 expression status was correlated with clinical parame-
ters, including age, sex, white cell count, cytogenetics and prednisone 
response. Kaplan-Meier survival analysis was performed to investigate the pos-
sible association of CD9 expression with clinical outcomes. The potential role 
of CD9 expression as a predictor of 5-year survival outcomes was evaluated using 
Cox regression models.

Results: Among 118 cases tested, blasts of 92 patients (78.0%) were CD9+ 
(≥20% of CD9-expressing blasts). There were no significant differences in age, 
sex and white cell count between CD9+ and CD9- patients. Major cytogenetics 
subgroups were similarly distributed except for hyperdiploidy (all patients were 
CD9+, P=0.022) and ETV6-RUNX1 translocation (higher prevalence in CD9- 
patients, P=0.001). Significantly more CD9+ patients were stratified into the 
intermediate-risk group (P=0.044) and a higher proportion of CD9- patients 
was stratified into the high-risk group (P=0.025). Besides, CD9- patients had 
poorer prednisone response (P=0.014). The 5-year overall survival (OS) and 
relapse-free survival (RFS) rates of CD9+ patients were significantly lower than 
those in CD9- patients (P=0.029). Subgroup analysis revealed remarkably 
poorer outcomes in CD9+ patients of the high-risk group (P=0.045). A similar 
trend was also observed in patients of the intermediate-risk group but not in 
the standard-risk group. In univariate analysis, CD9 positivity, age <1 year, 
white cell count ≥100 x 10^9/L and poor prednisone response were associated with 
lower RFS rates (HR=3.9; P=0.015) remained as inde-
pendent prognostic factors for lower RFS rates.

Summary/Conclusions: Our data indicate that expression of CD9 was signif-
ically associated with inferior survival outcomes in pediatric B-ALL. 
The observed difference was most prominent for patients in the high-risk 
group, suggesting that CD9 expression could potentially be used in conjunction 
with other known prognostic factors for refinement of risk group stratification. 
Our study also lays the foundation for future development of CD9-targeted therapy 
for high-risk and relapsed/refractory pediatric B-ALL.

PEDIATRIC MLL ACUTE LEUKEMIA PATIENTS SHOW DIFFERENTIAL 
HDAC EXPRESSION

1Hematology Laboratory, Institut de Recerca Pediàtrica Hospital Sant Joan de 
Deu, Barcelona, 2Centro de Investigación Biomédica en Red de Enfermedades 
Raras (CIBERER), Instituto de Salud Carlos III, Madrid, 3Clinical Department 
of Pediatric Hematology and Oncology, Institut de Recerca Pediàtrica Hospital 
Sant Joan de Deu, Barcelona, Spain

Background: Overexpression of histone deacetylases (HDACs) is a common 
feature in acute leukemias. Consequently, HDAC inhibitors (HDACi) have 
emerged as promising targeted therapy. However, non-specific HDACi may 
lead to accumulation of double stranded DNA lesions, so more selective isoform 
specific HDACi are needed. Expression patterns of HDACs in childhood 
leukemia have been scarcely studied.

Aims: To analyze the expression of HDAC isoforms in different subtypes of 
pediatric leukemia and correlate them with prognosis and clinico-biological fea-
tures.

Methods: We evaluated the mRNA gene expression profile of class I, II and IV 
HDAC genes (HDAC 1-11) by quantitative PCR in 126 leukemic pediatric sam-
ples and a pool of non-neoplastic samples as calibrator. Patients were treated 
according to the Spanish Hemato-Oncology Cooperative Group protocols in a 
single center. The HDAC expression levels in different groups were compared 
by the Mann-Whitney test. The level of significance was set up at p<0.05. The 
analyses were performed with SPSS 24.0.
Results: Our series included 69 boys and 57 girls diagnosed with acute leukemia, with a median age of 6.1 years (range 0-17.4 years). We included 12 infant patients (<1 year old). Eighty-two (65%) patients had B-cell precursor acute lymphoblastic leukemia (BCP-ALL), 24 patients T-cell ALL and 20 patients had acute myeloblastic leukemia (AML). Globally, we found higher expression levels of class I HDAC isozymes (HDAC 1, 2, 3 & 8) in leukemic samples as compared to non-leukemic samples, as previously reported. Interestingly, some HDAC isoforms associated with specific genetic aberrations. Those patients with rearrangement of MLL (KMT2A) gene (n=18, including 9 BCP-ALL and 9 AML; 7 infants and 11 pediatric) showed a significantly higher expression of HDAC9 (p=0.0001) and a statistically significant underexpression of HDAC1 and HDAC3 (p=0.003 & p=0.02, respectively, see Figure 1). Infants (n=12) had also a significantly lower expression of HDAC7 (p=0.043). In the same line, all pediatric patients with pro-B phenotype (CD10 negative) had low levels of HDAC7, but differences did not reach a statistical significance. After a median follow-up of 5.9 years, 15 patients died, with an overall survival (OS) of 68% for BCP-ALL, 79% for T-ALL and 55% for AML patients (p=0.0001). In the BCP-ALL subgroup, the expression of HDACs did not predict outcome, and only CNS infiltration and leukocytosis were unfavorable risk factors for OS. Again, CNS+, high WBC count and presence of minimal residual disease (MRD) post-induction were predictive for worse event free survival (EFS). Although the number of cases is low and these results must be taken with caution, T-ALL patients with the highest expression of HDAC3 (upper quartile) significantly correlated with worse OS (94% vs 25%, p=0.001) and a trend towards worse EFS (89% vs 53%, p=0.06). The only significant risk factor for EFS in this subgroup was the presence of MRD after induction (p=0.003).

Summary/Conclusions: We have observed a specific pattern of HDACs expression in pediatric patients with ALL rearrangement. Our study, if further confirmed, suggests that specific HDACi would potentially be a useful targeted treatment for pediatric patients with ALL rearranged leukemia.

Summary/Conclusions: Our study shows that minimal disseminated disease is seen in more than one-fourth of cases (28.8%) of T-LBL with <25% blasts in PB and BM. This underlines the importance of flowcytometry evaluation of bone marrow in cases with <25% blasts identified by morphology. The identification of minimal disseminated disease in T-LBL is important as studies have shown inferior event free survival in T-LBL with minimal disseminated disease as compared to patients without minimal disseminated disease.

MINIMAL DISSEMINATED DISEASE DETECTION BY FLOWCYTOMETRIC IMMUNOPHENOTYPING IN T-CELL ACUTE LYMPHOBLASTIC LYMPHOMA

G.K. Viswanathan1, P. Tembhare1, N. Patkar1, S. Gujral1, P.G. Subramanian1

1Hematopathology Laboratory, Advanced Centre for Treatment, Research and Education in Cancer (ACTREC) - Tata Memorial Centre (TMC), Mumbai, India

Background: T-cell acute lymphoblastic lymphoma (T-LBL) with minimal disseminated disease (MDD) is defined as the presence of T-LBL with <25% blasts in the peripheral blood (PB) and/or bone marrow (BM) by morphology and the presence of immunophenotypically abnormal T-lymphoblasts in bone marrow by flowcytometry. Published literature regarding the prevalence and clinical significance of this rare subgroup is sparse. In this study we analysed the presence of minimal disseminated disease in bone marrow in cases of T-LBL with <25% blasts in PB and BM using 8-10 colour flowcytometric immunophenotyping and evaluate the clinical and immunophenotypic features.

Aims: To evaluate the prevalence of minimal disseminated disease in bone marrow in cases of T-cell acute lymphoblastic lymphoma with <25% blasts in PB and BM using 8-10 colour flowcytometric immunophenotyping and evaluate the clinical and immunophenotypic features.

Methods: A retrospective analysis of 42 cases of T-LBL with predominantly lymphomatous presentation with <25% blasts in peripheral and bone marrow. The following parameters were taken into account including complete hemogram, peripheral blood examination, bone marrow morphology and immunophenotyping, CSF analysis, pleural fluid morphology and immunopheno-

The University of Texas MD Anderson Cancer Center, Houston, Texas, The University of Texas MD Anderson Cancer Center, Houston, 2The University of Texas MD Anderson Cancer Center, Houston, 3The University of Texas MD Anderson Cancer Center, Houston, 4The University of Texas MD Anderson Cancer Center, Houston

Background: Older patients (pts) with acute lymphoblastic leukemia (ALL) have poor tolerance of intensive chemotherapy, and novel strategies are needed in this population. In pts with relapsed/refractory ALL, inotuzumab ozogamicin (InO), an anti-CD22 antibody-drug conjugate, has been shown to improve survival compared to salvage chemotherapy.

Aims: We designed a phase III trial to evaluate the safety and efficacy of low-intensity chemotherapy (mini-hyper-CVD) plus InO as frontline treatment for older pts with newly diagnosed ALL.

Methods: Pts ≥60 years of age with newly diagnosed Philadelphia chromosome-negative pre-B received mini-hyper-CVD (compared to hyper-CVAD: no anthracycline, 50% dose reductions of cyclophosphamide and dexamethasone, 75% dose reduction of methotrexate, 85% dose reduction of cytarabine). InO was given on day 3 of the first 4 cycles. The first 6 pts received InO at a dose of 1.3 mg/m2 for cycle 1 followed by 0.8 mg/m2 for cycles 2-4; pts 7-34 received 1.8 mg/m2 for cycle 1 followed by 1.3 mg/m2 for cycles 2-4. Due to concern for veno-occlusive disease (VOD), the protocol was amended so that pts 35+ received InO at a dose of 1.3 mg/m2 for cycle 1 followed by 1.0 mg/m2 for cycles 2-4. Ruxolitinib was given during the first 4 cycles in pts with CD20 expression ≥20%; all pts received IT chemotherapy prophylaxis with the first 4 cycles. Pts in CR after 8 cycles then received POMP maintenance for up to 3 years.
Results: Between 4/2012 and 12/2016, 47 pts have been treated, 4 of whom had received 1 cycle of prior therapy and were in CR at the time of enrollment. The median age was 68 years (range, 60-81), and median CD22 expression was 97% (range, 72-100%). Of 43 pts evaluable for response, 42 responded (ORR=98%). Best response was CR in 36 pts (84%), CRp in 5 (12%) and CRi in 1 (2%). MRD negativity by 6-color multiparameter flow cytometry was achieved in 31 of 41 evaluable pts (76%) on day 21 and in 44 of 46 evaluable pts (96%) within 12 weeks of treatment. The median follow-up was 24 months (range, 15-55 months). 3 pts (6%) underwent allogeneic stem cell transplantation (ASCT) in first remission. Of the 46 responders, 6 pts (13%) have relapsed. 16 pts have died, 1 due to resistant disease, 4 after relapse, 1 after ASCT and 10 in CR/CRp. 21 pts remain on treatment (consolidation, n=3; POMP maintenance, n=19), and 5 pts have completed all therapy. The 3-year continuous CR and OS rates were 72% and 54%, respectively. Compared to a historical cohort of 79 older pts treated at our institution with hyper-CVAD ± rituximab, mini-hyper-CVD+InO resulted in significantly improved OS (3-year OS rate: 54% vs 31%; median OS not reached versus 16 months; P=0.007).

Summary/Conclusions: Treatment was overall well-tolerated. The median times to platelet and ANC recovery in cycle 1 were 22 days (range, 11-91 days) and 16 days (range, 0-49 days), respectively. In cycles 2-8, the median times to platelet and ANC recovery were 22 days and 17 days, respectively. Prolonged thrombocytopenia (i.e. lasting >6 weeks) occurred in 37 pts (79%) at some point during therapy; 8 pts (17%) experienced prolonged thrombocytopenia during induction and 36 (77%) during 1 or more subsequent courses. Grade ≥3 transaminase elevation (n=15) was seen in 11 pts, grade ≥3 bilirubinemia in 8 (17%) and hemorrhage in 7 (15%). 4 pts (9%) developed VOD (1 after ASCT, 3 unrelated to ASCT).

Summary/Conclusions: The combination of InO with mini-hyper-CVD is safe and effective in older pts with newly diagnosed ALL, resulting in a promising 3-year CR and OS rate of 77% during 1 or more subsequent courses.

Background: Blastic plasmacytoid dendritic cell neoplasm (BPDCN) is a rare hematological malignancy that is derived from plasmacytoid dendritic cell precursors. BPDCN tends to occur in elderly people with frequent skin involvement and is associated with an aggressive clinical course and a poor prognosis. Although optimized diagnostics and therapies should improve patient outcomes, the pathobiological and genetic aspects of BPDCN remain unclear.

Aims: We planned this study to identify a critical genetic event in BPDCN, which could provide better understanding of BPDCN pathogenesis.

Methods: We enrolled fourteen patients (five children and nine adults) with BPDCN who were treated in our institutions. We primarily performed RNA sequencing-based comprehensive transcriptome analysis with their samples at the onset to detect gene fusions. These results were then used as the basis for genetic validation studies and functional analyses with an exogenous expression model.

Results: We identified a recurring gene rearrangement that involved the MYB proto-oncogene in all five pediatric patients (100%) and four of nine adult patients (44%) with BPDCN. The resulting fusion genes included MYB-ZFAT (four patients), MYB-PLEKHO1 (three patients), MYB-OCPS (one patient), and MYB-MIR3134 (one patient), none of which have been previously reported to our knowledge. The translocations corresponding to these fusions were not detected by the metaphase analysis except in one patient with t(1;16), who harbored MYB-PLEKHO1. These fusion genes were detectable at diagnosis and relapse but not at remission. Fluorescence in situ hybridization (FISH) analysis efficiently detected the breaking apart of MYB in formalin-fixed, paraffin-embedded sections. Consequent to the rearrangement, the negative regulatory domain of MYB was truncated, leading to constitutive MYB transcriptional activation, as described in other malignancies.

Exogenous MYB-PLEKHO1 expression in HEK 293T cells led to the upregulation of several known downstream MYB targets. Gene set enrichment analysis also confirmed the activation of MYB target gene sets. The identified significantly upregulated genes included cell surface molecule-encoding genes such as NCAM1 (also termed CD56), CD68, S1PR1, and CXCR4, possibly providing targets for antibody-mediated anticancer therapies. We performed tumor-germline sequencing of paired tumor–germline sets. The identified significantly upregulated genes included cell surface molecule-encoding genes such as NCAM1 (also termed CD56), CD68, S1PR1, and CXCR4, possibly providing targets for antibody-mediated anticancer therapies. We performed tumor-germline sequencing of paired tumor–germline sets. The identified significantly upregulated genes included cell surface molecule-encoding genes such as NCAM1 (also termed CD56), CD68, S1PR1, and CXCR4, possibly providing targets for antibody-mediated anticancer therapies. We performed tumor-germline sequencing of paired tumor–germline sets.

Summary/Conclusions: We identified a high frequency of MYB rearrangements that promoted the MYB transcriptional activity in BPDCN. MYB split FISH analysis can constitute a valuable diagnostic tool for detecting MYB rearrangements. We expect that our findings provide critical insights regarding BPDCN pathogenesis and contribute to molecular biology-oriented diagnostic techniques and molecular-targeted therapies for this intractable malignancy.
Background: The branched chain amino acids (BCAAs) valine, leucine, and isoleucine are essential AA for the human body. The activity of BCAA metabolism involves several aspects of the function of the enzyme BCAA Transaminase 1 (BCAT1) have recently been associated with aggressiveness in several cancer entities. However, the mechanistic role of BCAT1 in this process remains uncertain.

Aims: To elucidate the mechanistic link between BCAT1 function and epigenetic deregulation in leukemia stem cells (LSCs) and consequences on clinical outcome.

Methods: High-resolution proteomics of LSCs, Knockdown and overexpression of BCAT1 in AML patient samples and AML cell lines, Gene set enrichment analysis, BCAAs tracing experiments, Xenotransplantations, Metabolomics, DNA methylation arrays, correlative and mechanistic link to clinical data sets.

Results: We performed high-resolution proteomic analysis of human acute myeloid leukemia (AML) stem cell (LSC) and non-LSC populations, which have been functionally validated by xenotransplantation into NSG mice, and we found the BCAA pathway enriched and BCAT1 overexpressed in LSCs. We show that BCAT1, which transfers α-amino groups from BCAAs to α-ketoglutarate (αKG), is a central player in regulating αKG homeostasis. To test its role in the branched boxyc acid (TCA) cycle αKG is an essential co-factor for αKG-dependent dioxygenases such as EGLN1 and the TET family of DNA demethylases. Knockdown (KD) of BCAT1 in leukemia cells caused accumulation of αKG resulting in HIF1α protein degradation mediated by EGLN1. This resulted in a growth and survival defect and abrogated leukemia-initiating potential. In contrast, overexpression (OE) of BCAT1 in leukemia cells decreased intracellular αKG levels and caused DNA hypermethylation. BCAT1(high) AML samples displayed a DNA hypermethylation phenotype similar to IDH1mut cases, in which TET2 is inhibited by the oncometabolite 2-hydroxylglutarate. High levels of BCAT1 were strongly correlated with αKG levels and IDH1(TET2)mut, but not IDH1(TET2)wt AMLs. Gene sets characteristic for IDH1mut AML were enriched both in IDH1(TET2)mut-BCAT1(high) patient samples and in BCAT1-CE leukemia cells. BCAT1(high) samples showed enriched RISC signatures for lncRNA and paired sample analysis revealed a significant increase of BCAT1 levels upon relapse of the disease.

Summary: In summary, BCAT1 reduces dioxygenase activity by limiting intracellular αKG, thus linking BCAA catabolism to HIF1α stability and DNA hypermethylation. Our results suggest the BCAA-BCAT1-αKG pathway as a therapeutic target to compromise LSC function in IDH wtTET2 wtAML patients.

THE LONG NON-CODING RNA HOXB-AS3 REGULATES RIBOSOMAL BIOGENESIS IN NPM1-MUTATED ACUTE MYELOID LEUKEMIA
D. Papaiouannou1,*, A. Petri2, S. Terreri3, C. Thue3, S. Volinia4, P. Yan2, R. Bundshuh2, G. Singh5, S. Kauppinen2, C. Bloomfield1, D. Adrienne5, R. Garzon1
1Comprehensive Cancer Center, The Ohio State University, Columbus, United States, 2Center for RNA Medicine, Department of Clinical Medicine, Aalborg University, Copenhagen, Denmark, 3Institute of Genetics and Biophysics (IGB-ABT), National Council of Research (CNR), Naples, 4Department of Morphology, Surgery and Experimental Medicine, University of Ferrara, Ferrara, Italy, 5Department of Physics, Department of Chemistry & Biochemistry, Division of Hematology, Department of Internal Medicine, Center for RNA Biology, 6Department of Molecular Genetics, Center for RNA Biology, The Ohio State University, Columbus, United States

Background: Background: The prognostic significance of long non-coding RNA expression (lncRNAs) in older (>60 years) patients (pts) with cytogenetically normal acute myeloid leukemia (CN-AML) was recently reported (Garzon et al., 2014). The IncRNA HOXB-AS3, which is embedded in the HOXB locus, is highly expressed in the AML cell line OCI-AML3, but not in healthy donors (Garzon et al., 2014). The lncRNA HOXB-AS3 was recently shown to be amplified among the IncRNAs that associated with mutated NPM1 (NPM1mut) in CN-AML.

Aims: Aims: Our aims were to evaluate the biologic significance of HOXB-AS3 expression in NPM1mut AML.

Methods: Methods: HOXB-AS3 expression profiling was performed by real-time PCR. Knock-down (KD) of HOXB-AS3 was performed in vitro and in vivo in a pt-derived xenograft (PDX) model with locked nucleic acid-modified gappers. Comparative proteomic analysis was conducted with a modified version of the RNA antisense purification (RAP) protocol (McHugh et al., 2015). Direct visualization of the HOXB-AS3 was performed using custom-designed Baseos and Feedbacken (Advanced Cell Diagnostics, Newark, CA) according to the manufacturer’s instructions.

Results: Results: Of 6 AML cell lines that were tested, only OCI-AML3 cells, which harbor NPM1mut, showed detectable levels of HOXB-AS3 expression. Five- and 3-prime Rapid Amplification of cDNA Ends (RACE) assays in OCI-AML3 cells identified a novel transcript previously annotated (NR_033201/NR_033203/ENST00000491264) and 1 novel variant of HOXB-AS3. NPM1mut pt samples exhibited higher expression of HOXB-AS3 compared to those with wild-type (WT) NPM1 (P<0.001) and healthy donors (P=0.001). In vitro KDO HOXB-AS3 led to decreased proliferation of OCI-AML3 cells, as measured by BrdU-based cell cycle analysis (S-phase average% in control vs KD: 24% vs 16%, P=0.02). HOXB-AS3 KD in NPM1mut pt blasts (n=5) led to a decrease in the number of formed colonies by OCI-AML3 cells in colony-forming assays (P=0.002). HOXB-AS3 KD in NPM1mut pt blasts (n=5) led to a decrease in the number of formed colonies by OCI-AML3 cells in colony-forming assays (P=0.002). HOXB-AS3 KD in NPM1mut pt blasts (n=5) led to a decrease in the number of formed colonies by OCI-AML3 cells in colony-forming assays (P=0.002). HOXB-AS3 KD in NPM1mut pt blasts (n=5) led to a decrease in the number of formed colonies by OCI-AML3 cells in colony-forming assays (P=0.002). HOXB-AS3 KD in NPM1mut pt blasts (n=5) led to a decrease in the number of formed colonies by OCI-AML3 cells in colony-forming assays (P=0.002). HOXB-AS3 KD in NPM1mut pt blasts (n=5) led to a decrease in the number of formed colonies by OCI-AML3 cells in colony-forming assays (P=0.002). HOXB-AS3 KD in NPM1mut pt blasts (n=5) led to a decrease in the number of formed colonies by OCI-AML3 cells in colony-forming assays (P=0.002). HOXB-AS3 KD in NPM1mut pt blasts (n=5) led to a decrease in the number of formed colonies by OCI-AML3 cells in colony-forming assays (P=0.002). HOXB-AS3 KD in NPM1mut pt blasts (n=5) led to a decrease in the number of formed colonies by OCI-AML3 cells in colony-forming assays (P=0.002). HOXB-AS3 KD in NPM1mut pt blasts (n=5) led to a decrease in the number of formed colonies by OCI-AML3 cells in colony-forming assays (P=0.002). HOXB-AS3 KD in NPM1mut pt blasts (n=5) led to a decrease in the number of formed colonies by OCI-AML3 cells in colony-forming assays (P=0.002). HOXB-AS3 KD in NPM1mut pt blasts (n=5) led to a decrease in the number of formed colonies by OCI-AML3 cells in colony-forming assays (P=0.002). HOXB-AS3 KD in NPM1mut pt blasts (n=5) led to a decrease in the number of formed colonies by OCI-AML3 cells in colony-forming assays (P=0.002). HOXB-AS3 KD in NPM1mut pt blasts (n=5) led to a decrease in the number of formed colonies by OCI-AML3 cells in colony-forming assays (P=0.002). HOXB-AS3 KD in NPM1mut pt blasts (n=5) led to a decrease in the number of formed colonies by OCI-AML3 cells in colony-forming assays (P=0.002). HOXB-AS3 KD in NPM1mut pt blasts (n=5) led to a decrease in the number of formed colonies by OCI-AML3 cells in colony-forming assays (P=0.002). HOXB-AS3 KD in NPM1mut pt blasts (n=5) led to a decrease in the number of formed colonies by OCI-AML3 cells in colony-forming assays (P=0.002). HOXB-AS3 KD in NPM1mut pt blasts (n=5) led to a decrease in the number of formed colonies by OCI-AML3 cells in colony-forming assays (P=0.002). HOXB-AS3 KD in NPM1mut pt blasts (n=5) led to a decrease in the number of formed colonies by OCI-AML3 cells in colony-forming assays (P=0.002). HOXB-AS3 KD in NPM1mut pt blasts (n=5) led to a decrease in the number of formed colonies by OCI-AML3 cells in colony-forming assays (P=0.002).
Summary/Conclusions: Conclusions: HOXB-AS3 is strongly associated with NPM1 mutations in AML. HOXB-AS3 interacts with EPB1 and NPM1 and regulates ribosomal biogenesis in the leukemic blasts. From a therapeutic standpoint, HOXB-AS3 constitutes a promising target, as in vivo anti-HOXB-AS3 treatment prolonged survival in a murine PDX model.

A DUAL BH3-MIMETIC APPROACH TARGETING BOTH BCL-2 AND MCL1 IS HIGHLY EFFICACIOUS AND WELL-TOLERATED IN ACUTE MYELOID LEUKEMIA

D. Moujalled1,2,*, G. Pomilio1,2, C. Ghirardi3, D. Segal4, T.-C. Teh1,2, J. Salmon1,2, S. Rijal1, P. Lan4, L. Kraus-Berthier5, A. Roberts4, D. Huang5, A.L. Maragno5, G. Lessene6, O. Genest6, A. Wei7

1Australian Centre for Blood Diseases, Monash University, 2Department of Clinical Haematology, The Alfred Hospital, Melbourne, Australia, 3Oncology R&D Unit, Institut de Recherches Servier, Croissy Sur Seine, France, 4The Walter and Eliza Hall Institute, Melbourne, Australia, 5Oncology R&D Unit, Institut de Recherches, Croisy Sur Seine, France

Background: Identification of a chemotherapy-free option for acute myeloid leukemia (AML) represents a highly desired and important research objective. Perturbation of cell survival is an essential hallmark of cancer now amenable to precision targeting by small molecule BH3-mimetics able to inhibit pro-survival BCL-2 (e.g. S63845) and BCL-XL (e.g. S55746) in AML cell lines (Lehar, Nat. Biotech 2009). (B) Dual BH3-mimetic targeting of BCL-2 and MCL1 represents a novel approach to treating AML without need for additional chemotherapy and with an acceptable therapeutic safety margin. Our results support the translational investigation of dual BH3-mimetic targeting of BCL-2 and MCL1 in the clinic for the treatment of patients with AML.

P176

THE PMLC62A/C65A KNOCK-IN MOUSE MODEL PROVIDES EVIDENCE FOR THE ROLE OF NUCLEAR BODY DISRUPTION IN THE PATHOGENESIS OF ACUTE PROMYELOCYTIC LEUKEMIA

1Medical and Molecular Genetics, King's College London, London, United Kingdom, 2Tumor Biology, The Norwegian Radium Hospital, Oslo, Norway, 3School of Veterinary Medicine, University of Surrey, Guildford, 4Centre for Trials Research, College of Biomedical & Life Sciences, Cardiff, 5Samantha Dickson Brain Cancer Unit, UCL Cancer Institute, London, United Kingdom, 6Helen Diller Comprehensive Cancer Center, University of California, San Francisco, United States

Background: Acute promyelocytic leukemia (APL) is driven by the oncogenic PML-RARα which is generated by fusion of the promyelocytic leukemia (PML) and retinoic acid receptor alpha (RARA) genes, and which strongly interferes with downstream signalling and the architecture of multiprotein structures known as PML nuclear bodies (NBs). NB disruption is a diagnostic hallmark of APL; however, the importance of this phenomenon has only been studied in vitro.

Aims: The aim of this study was to decipher the impact of Pml NB disruption in APL pathogenesis.

Methods: We engineered a knock-in mouse model with NB disruption achieved through mutation of key zinc-binding cysteine residues (C62A/C65A) in the PML Ring domain.

Results: While no leukemias or tumors developed in PmlC62A/C65A mice, the forced dimerization of RARα - mediated artificially by linking RARα to the dimerization domain of the NFκB p50 subunit - in cooperation with NB disruption was associated with doubling in the rate of leukemia (p<0.0001), with a reduced latency period (p=0.008). Moreover, response to targeted therapy with ATRA significantly improved survival of the PmlC62A/C65A-WT mice transplanted with PmlC62A/C65A-PmL-RARα leukemic blasts, but not with PmlC62A/C65A-P50-RARα, revealing the essential role of NBs for an effective response to differentiating drug. While formation of the PML-RARA fusion is considered an initiating event in APL pathogenesis, it is insufficient for the full leukemic phenotype. Moreover, whole exome sequencing analyses have consistently identified presence of cooperating mutations. Since Pml and Pml NBs have established roles in DNA repair and in the maintenance of genomic stability, we speculated that loss of NB integrity could affect these functions. Here, whole exome sequencing revealed a trend of higher genomic instability in PmlC62A/C65A mice compared to PmlWT.

Figure 1. (A) Loewe Score (0 → Additive, 1 → Weak Synergy, 2 → Synergy, 3 → Strong Synergy) in AML cell lines (Lehar. Nat. Biotech 2009). (B) LC50 of primary AML after 48h treatment (C) NS mice engrafted with MV4;11 AML and treated with i) vehicle, ii) S55746 100 mg/kg (x 4 wks), iii) S63845 50mg/kg IV (x 4 wks) or iv) combined S55746 and S63845. (D) CD45+ staining of NRGs sternums showing 2 representative examples of PDX AML one week after treatment with i) vehicle x5d, ii) S55746 100 mg/kg/d x 5d, iii) S63845 25mg/kg IV x 2d and iv) S55746+S63845.

A smaller fraction of AML samples were also sensitised to combined S55746+S63845, but not from treatment with either BH3-mimetic alone. Similar in vivo efficacy was observed with xenografted OCI-AML3 cells harboring mutant NPM1 and DNMT3A. Patient-derived xenografts showed rapid reduction of established AML in the bone marrow one week of treatment with S55746 and S63845 (Figure 1D). Safety and tolerability of this approach was confirmed using normal CD34+ stem and progenitor cells in short-term cell culture (48h) and long-term (2-3 weeks) clonogenic assays and from histological and immunohistochemical examination of mice receiving treated for up to 8 weeks at doses shown to be highly efficacious against AML.

Summary/Conclusions: Dual BH3-mimetic targeting of BCL-2 and MCL1 induces rapid and synergistic cytoreduction of human AML cell line and primary AML samples in vitro and in vivo across a diverse range of AML genotypes. We provide further support for the dual pharmacological approach that both dual pharmacological targeting of BCL-2 and MCL1 represents a novel approach to treating AML without need for additional chemotherapy and with an acceptable therapeutic safety margin. Our results support the translational investigation of dual BH3-mimetic targeting of BCL-2 and MCL1 in the clinic for the treatment of patients with AML.

Figure 1. (A) Loewe Score (0 → Additive, 1 → Weak Synergy, 2 → Synergy, 3 → Strong Synergy) in AML cell lines (Lehar. Nat. Biotech 2009). (D) CD45+ staining of NRGs sternums showing 2 representative examples of PDX AML one week after treatment with i) vehicle x5d, ii) S55746 100 mg/kg/d x 5d, iii) S63845 25mg/kg IV x 2d and iv) S55746+S63845.

A smaller fraction of AML samples were also sensitised to combined A1155463 and S63845 therapy. Bioluminescent imaging showed rapid and sustained clearance of xenografted MV4;11 AML (FLT3-ITD mutant and MLL re-arranged) cells, translating into significant prolongation of survival (Figure 1C) from combined S55746+S63845, but not from treatment with either BH3-mimetic-alone. Similar in vivo efficacy was observed with xenografted OCI-AML3 cells harboring mutant NPM1 and DNMT3A. Patient-derived xenografts showed rapid reduction of established AML in the bone marrow one week of treatment with S55746 and S63845 (Figure 1D). Safety and tolerability of this approach was confirmed using normal CD34+ stem and progenitor cells in short-term cell culture (48h) and long-term (2-3 weeks) clonogenic assays and from histological and immunohistochemical examination of mice receiving treated for up to 8 weeks at doses shown to be highly efficacious against AML.

Summary/Conclusions: Dual BH3-mimetic targeting of BCL-2 and MCL1 represents a novel approach to treating AML without need for additional chemotherapy and with an acceptable therapeutic safety margin. Our results support the translational investigation of dual BH3-mimetic targeting of BCL-2 and MCL1 in the clinic for the treatment of patients with AML.

DECIPHERING THE ONCOGENIC NETWORK OF PRC2 LOSS GUIDED LEUKEMOGENESIS

D. Roder1, 2, B. Swarz1, Z. Swarz2, 3, S. Knöl1, J.-H. Klaussmann1, D. Heckl1, 2
1Pediatric Hematology & Oncology, 2Experimental Hematology, 3Hematology, Hemostasis, Oncology and Stem Cell Transplantation, Hannover Medical School, Hannover, Germany

Background: Loss of function mutations in EZH2 (including the chromosomal abnormalities -7/-7q) and other PRC2 subunits have been identified in adults with MDS, MPN and AML. Moreover children with JMML and up to 30% of children with Down syndrome related AML present with mutations in PRC2 subunits. Since myeloid neoplasms are elicited by accumulation of cooperating mutations and the study of isolated mutations are unlikely to unveil the molecular processes guiding transformation, we set out to decipher the oncogenic network guided by loss of PRC2-activity.

Aims: Through identification of collaborating mutations driving AML with loss of PRC2 function followed by molecular profiling we aimed to identify novel collaborating mutations.

Methods: To model the complex interplay of mutational networks we performed CRISPR-Cas9 screenings with oncogenic/tumor suppressor pools in vitro and in vivo. Cellular resources generated were subjected to mutational and molecular profiling. Results: To this end, a 96-well based CRISPR-Cas9 immortalization assay allowing fast and quantifiable genetic cooperation screenings was established. Four out of six CRISPR-Cas9 pools tested—comprised of five genes each and representing 148 mutation combinations—reproductively transformed LSK cells was achieved. The results of our screening and a newly established in vitro CRISPR-Cas9 immortalization assay for high throughput screening of sgRNA pools, delivered potential cooperating partners of EzH2 loss in AML and provides rich cellular resources to identify molecular mechanisms of oncogenic synergies and dependencies.

ACUTE MYELOID LEUKEMIA EVOLUTION CAN BE RECONSTRUCTED BY ANALYSIS OF NON-LEUKEMIC CELLULAR SUBCOMPARTMENTS AND MULTILINEAGE ENGRAFTED MICE

B.R.M. Saeed1, 2, L. Manta1, S. Raffel1, 2, P.T. Pyl3, W. Wang1, V. Eckstein1, A. Trumpp2, W. Huber3, A.D. Ho1, C. Lutz1
1Pediatric Hematology & Oncology, 2Experimental Hematology, 3Hematology, Hemostasis, Oncology and Stem Cell Transplantation, Hannover Medical School, Hannover, Germany

Background: Mutations in genes that haven't been described in AML yet. Tracking of these mutations in various non-leukemic cellular compartments including HSC and leukemic HSC. To reconstruct the sequence of pre-leukemic mutations single-cell HSC were seeded and the resulting colonies analyzed for the presence of the respective leukemic specific mutations. Based on the different mutational data, combined with the cellular context in which these were detectable the leukemic evolution of most patients could be reconstructed. In one patient we detected a DMNT3A mutation in myeloid and lymphoid cells, whereas NPM1 and FLT3-ITD mutations were only detectable in leukemic cells proving the pre-leukemic status of DMNT3A in this case. In another patient we found NPM1 and IDH2 in T- and B-cells whereas Trisomy 8 and a STAG2 deletion were only detectable in leukemic cells. By analyzing colonies from single cell HSC we were able to detect complex pre-leukemic hierarchies with one example in which a ZNF536 mutation could be identified as initiating event that hasn't been described in leukemia yet.

Summary/Conclusions: WES can identify leukemia specific mutations including mutations in genes that haven't been described in AML yet. Tracking of these mutations in various non-leukemic cellular compartments including HSC and multi-lineage engrafted mice allows reconstruction of the individual leukemic evolution. A better understanding of these processes may pave the way for new treatment strategies with the aim to target the relevant leukemic mutations.

THE ESSENTIAL ROLE OF THE ENHANCERS OF POLYCOMB EPC1 AND EP C2 IN MLL-AF9 ACUTE MYELOID LEUKAEMIA IS A 'COMPLEX' STORY

M. Mannion1, 2,*, X. Huang1
1Paull O'Gorman Leukaemia Research Centre, 2Paul O’Gorman Leukaemia Research Centre, Institute of Cancer Sciences, MVLS, University of Glasgow, Glasgow, United Kingdom

Background: The Enhancers of Polycomb (EPC) proteins EPC1 and EPC2 are required for the survival of MLL-rearranged acute myeloid leukemia (AML). Most importantly, loss of EPC1 or EPC2 in MLL leukemia stem cells, but not normal hematopoietic stem cells and progenitor cells, leads to the induction of cellular apoptosis. To date little is known about the functional contribution of EPC1 and EPC2 in AML. EPC1 and EPC2 are two major chromatin modifying complexes encompassing opposing epigenetic activities and both are known to be deregulated in AML. AML is a disease biology is complex and understanding the contribution of the homologous chromatin regulatory proteins EPC1 and EPC2 in AML in search for novel therapeutic targets.

Methods: Mass spectrometry (MS) analysis was performed on immunoprecipitated protein using EPC1 antibody from human THP1 MLL-AF9 AML cell line. Chromatin immunoprecipitation (ChIP) was performed using HighCell ChIP Kit and iPure kit v2 (Diagenode) followed by NextSeq500 Illumina sequencing in THP1 cells. ChIP enriched regions were identified using SICER peak calling and ChiPpeakAnno. Lentiviral supernatants were prepared and THP1 cells were infected with viral particles containing pLKO.1 puro lentiviral vectors expressing shRNAs. RNA was extracted 72 hr following lentiviral transductions and whole transcriptome sequencing was performed. DESeq2 was used for differential expression analysis.

Results: MS analysis identified the core N44 complex components (TIP60, ING3, RUVBL1, RUVBL2, EP400 and DMAP1) and also revealed additional components. A comparison of the interacting proteins with the PML-RARα oncoprotein can assist APL pathogenesis.

STROMA-DERIVED FACTORS STIMULATE JAK/STAT SIGNALING IN AML CELLS RESULTING IN RESISTANCE TO BCL2 INHIBITOR VENETOCLAX

R. Karjalainen1,2,3, M. Popa4, M. Liu1, K.K. Jawarappa1, M. Kontro2,4, A. Parsons1, K. Porrka1, K. Wennerberg1, E. McCormack1,2, B.T. Gjertsen1, C.A. Heckman1

Background: The bone marrow (BM) microenvironment is known to protect AML cells from drug therapy. We showed earlier that conditioned medium (CM) from the BM stromal cell line HS-5 increased cell viability and led to resistance to specific drug classes.

Aims: Here, we investigate the mechanisms stimulating the BM stromal cell induced resistance to venetoclax and its reversal by ruxolitinib.

Methods: Phospho-flow analysis was done by stimulating AML patient cells with GM-CSF, G-CSF, IL-6, IL-8 or MIP-3α (10 ng/mL) for 20 min, after which the cells were stained with Alexa 647-anti-phospho-Stat5 (pY694), PE188 CF594-anti-phospho-Stat3 (pY705), BV421-anti-phospho-Akt (pS473) and PE-anti-phospho-Erk1/2 (pT202/pY204). For co-culture and transwell assays AML cells were added directly to MSCs from AML patients or separated by a 0.4 μm pore membrane. Vehicle (DMSO), ruxolitinib (300 nM), venetoclax (100 nM) or their combination were incubated for 48h and AML cells labeled with PE-Annexin V, 7AAD, PE-Cy7-CD34, BV605-CD45. In vivo drug efficacy was tested on NSG mice inoculated i.v. with MOLM-13 K5AML cells. Mice were divided into control, venetoclax (25 mg/kg, i.p.), ruxolitinib (50 mg/kg BM), and combination groups (all n=6) and treated for 3 weeks, 5 days a week with 2 days off.

Results: To identify the factors contributing to BM mediated drug resistance of AML cells, we analyzed the effect of IL-6, IL-8, MIP-3α, GM-CSF and G-CSF, cytokines enriched in the HS-5 CM, on proliferation of MNCs collected from AML patients. GM-CSF and to some extent G-CSF alone conferred resistance to venetoclax similar to CM that we showed earlier to reduce sensitivity to BCL2 inhibitors. To identify the impact of stroma-derived factors on cellular signaling we stimulated AML patient cells with CM and analyzed the phosphorylation of STAT3, STAT5, ERK and AKT. Compared to control conditions, CM rapidly induced phosphorylation of STAT5 in primary AML cells. When the effect of individual cytokines was tested, we noted that GM-CSF and G-CSF alone could mimic the effect of CM on cellular signaling. Gene expression data showed the receptor for GM-CSF (CSFR2A) is more highly expressed in AML patient cells compared to healthy controls. Taken together, these results show that cytokines such as GM-CSF from BM stromal cells increase JAK/STAT signaling, which may lead to enhanced survival of AML cells. To determine whether the protective effect of stroma on BCL2 inhibition was dependent on cell-to-cell interactions we cultured AML patient cells either in direct contact with BMSCs or separated from stroma with a 0.4 μm pore membrane. 48h treatment with 100 nM venetoclax did not result in significant reduction of CD34+ AML cells regardless of whether AML cells were directly cultured with stroma or separated by a membrane, further indicating that stroma-derived soluble factors are sufficient to reduce sensitivity to venetoclax. Since the most abundant cytokines secreted by HS-5 cells, GM-CSF and G-CSF led to increased phosphorylation of STAT5, a downstream effector of JAKs, we tested a combination of venetoclax and JAK1/2 inhibitor ruxolitinib. We found that ruxolitinib potentiated sensitivity to venetoclax when tested with AML patient cells in HS-5 CM and in co-culture and transwell assays. Significantly, the combination was more effective at reducing tumor burden in a xenograft mouse model of AML than either drug alone.

Summary/Conclusions: In conclusion, our data demonstrate that BM secreted soluble factors drive cytoprotection against BCL2 antagonist venetoclax that can be overcome by combined blockade of JAK/STAT and BCL2 pathways with ruxolitinib and venetoclax in ex vivo co-culture models and in vivo in an AML mouse model.

P182

IDENTIFICATION OF NOVEL GENE FUSIONS IN ACUTE MYELOID LEUKEMIA WITH COMPLEX KARYOTYPE BY TRANSCRIPTOME ANALYSIS USING RNA SEQUENCING

F.G. Rücker1, X. Gong1, A. Dolnik1, M. Hoyos1, S. Grasediek1, J. Biscocho2, T. Blätte1, J. Swoboda1, A.S. Pollack2, A. Turciano1, H. Döhner1, K. Döhner1, J.R. Pollack2, L. Bullinger1
1Department of Internal Medicine III, University Hospital of Ulm, Ulm, Germany, 2Department of Pathology, Stanford University, Stanford, United States

Background: Acute myeloid leukemia with complex karyotype (CK-AML), defined as having ≥3 acquired cytogenetic aberrations in the absence of WHO-designated recurring translocations or inversions, represents about 15% of
adult AML cases. Despite having poor outcomes, CK-AML is the least understood of the molecular subtypes, except for the finding that about two-thirds of cases carry TP53 alterations. In particular, because cytogenetic alterations appear to be distinct among different patients, it is unclear whether they are cause of leukemogenesis, or merely reflect a state of genomic instability.

**Aims:** We have hypothesized that cytogenetic aberrations in CK-AML create gene fusions that are not recurrent across patients, nonetheless deliver cancer genes that contribute to leukemogenesis in individual patients.

**Methods:** We performed a transcriptome analysis using Illumina paired-end (101bpX2) RNA sequencing of 65 CK-AML cases to identify gene fusions using multiple independent algorithms (as paired reads that flank, or single-reads that span fusions) that are not recurrent across patients, and identified gene fusions in part independently validated by array-based genomic profiling and/or long range PCR performed by use of long-read Oxford Nanopore sequencing technology.

**Results:** We identified 54 gene fusion events in 30 of the 65 cases (46%) with up to four fusions per case. All fusions are supported by 10-50+ junction-spanning reads, and most are independently validated by genome-wide breakpoints from array-based genomic profiling and/or long range PCR, respectively. About 35% of the fusions were in-frame, encoding chimeric proteins. The remained encode either C-terminally truncated 5' fusion partners, or else N-terminally truncated (or rarely full-length) 3' fusion partners that we observed in the 5' partner contributed only the 5'UTR. In many instances, the fusions are predicted to lead to the overexpression or chimeric activation of known or putative novel cancer genes. Of the 54 fusions, only three (RUNX1-MECOM, MN1-ETV6, and ETV6-MN1) were previously reported in AML. The most frequently affected genes were RUNX1 (n=6), KMT2A, and MECOM (n=5 each). Identified gene fusions were classified into six functional fusion clusters. Many of the fusions contained at least one known AML gene (n=16; e.g. RUNX1, MECOM, DEK, ETV6, KMT2A) together with a novel fusion partner, clearly suggesting pathogenic relevance. Other fusions were predicted to disrupt known tumor suppressors (n=4; e.g. TP53) or to activate known oncogenes (n=3; e.g. MYB). Others encoded chimeric proteins of unclear pathogenic relevance, but that could nonetheless encode novel epitopes created by the fusion junction (n=26).

**Summary/Conclusions:** Detailed molecular characterization of CK-AML revealed a high incidence of novel gene fusions in about 50% of cases. The affected genes suggest a more general role in leukemogenesis than reflecting a state of genomic instability. Furthermore, identifying gene fusions in each individual patient might lead to more effective, personalized treatments that target the gene fusion itself, enable immunologic therapies against the fusion junction epitopes, and provide private patient-specific biomarkers to track leukemic burden for the monitoring of disease remission and relapse.

H3K27ME3 LEVEL ON THE HIST1 CLUSTER: A POWERFUL EPIGENOMIC BIOMARKER THAT STRATIFIES TWO GROUPS OF NPM1-MUTATED AML DIFFERING IN THEIR OUTCOME AND EXPRESSION PROFILE

S. Carbone1,2,3,4, P. Ferrando4, J. Verweij5, F. Bertsch6,7, L. Pappino1, N. Seigneurin2, N. Vey1,2,3, E. Duprez2,3,4,1,2
1Hematology, Paoli-Calmettes Institute, 2INSERM 1068, Cancer research center, 3Aix-Marseille University, 4Oncology, 5Cell therapy facility, Paoli-Calmettes Institute, Marseille, 6Hematology, Toulouse Cancer University Institute, Toulouse, France

**Background:** NPM1 mutation (NPM1mut) is the most frequent genetic alteration found in cytogenetically normal acute myeloid leukemia (CN-AML). Patients harboring NPM1mut without FLT3 internal tandem duplication (FLT3-ITD) are considered to have favorable outcome. Yet, some of them relapse and become resistant to chemotherapy. Little is known about biological processes underlying treatment failure. Our group previously described a new epigenetic biomarker corresponding to an abnormal gain of the repressive H3K27me3 histone mark within the HIST1 locus on the 6p22 region as H3K27me3high. This epigenetic biomarker had an impact on clinical outcome as CN-AML patients with H3K27me3 HIST1 high had a higher overall survival (OS) and leukemia-free survival (LFS) than H3K27me3 HIST1low patients (Tiben et al., 2015).

**Aims:** We studied the impact of H3K27me3 HIST1 in an NPM1mut CN-AML cohort. Firstly, we asked whether H3K27me3 HIST1 could help to define NPM1mut CN-AML patients independently of known genetic alterations. Secondly, we studied gene expression profile (GEP) related to H3K27me3 HIST1 to explore biological pathways associated with treatment failure.

**Methods:** Blood or bone marrow samples with at least 70% blast involvement collected from 2017 to 2021. H3K27me3 HIST1 high and low patients were recovered from the Paoli-Calmettes Cancer Institute Biobank and analyzed as training set. A validation set of samples collected during the conduct of two GOELAMS clinical trials (LAM2006IR and LAM2007SA) was used for validation. We performed H3K27me3 HIST profiling by chromatin immunoprecipitation followed by quantitative polymerase chain reaction (qPCR). We generated a training set of samples with very high and low gene expression of H3K27me3 HIST1 by qPCR in primary AML samples. We then sequenced frequently mutated genes in AML (FLT3, CEBPO, DNMT3A, IDH1, IDH2, MLL, EZH2, TET2, P53, WT1 and ASXL1). GEP was done on Affymetrix whole-transcript DNA microarray and we used gene set enrichment analysis (GSEA, Subramanian et al., 2005) along with the Gene Ontology database as statistical methodology.

**Results:** We pooled the 103 samples of patients with NPM1mut CN-AML of the training and validation sets together. Median age was 60 (37-76) and median leucocyte count was 76 G/L (10-352). ChiP-QPCR Profiling identified 74 H3K27me3 HIST1high and 29 H3K27me3 HIST1low patients. FLT3-ITD was found in 33 (43%) of H3K27me3 HIST1high and 18 (38%) of H3K27me3 HIST1low patients. We confirmed that H3K27me3 HIST1high was associated with higher 5-year OS and LFS rates: 37% and 44% versus 17% and 19% (p=0.005 and .01) for the H3K27me3 HIST1high and the H3K27me3 HIST1low patients, independently of other genetic alterations. Combining our biomarker with FLT3 mutational status, we identified two subgroups of patients with very different outcome: 49% and 56% versus 18% and 18% (p=0.004 and .01) for the H3K27me3 FLT3wt HIST1high and the FLT3mut H3K27me3 HIST1low patients, respectively (Figure 1). We performed GEP for 27 NPM1mut patients (12 H3K27me3 HIST1low and 15 H3K27me3 HIST1high). GSEA analysis revealed a strong enrichment in immune functions and leukocyte activation in the H3K27me3 HIST1high group, evolving differentiated AML. While H3K27me3 HIST1low samples had GSEA associated with chromatin remodeling factors and DNA replication. Considering only FLT3wt patients, the H3K27me3 HIST1low subgroup had a gene expression signature characterized by a high expression level of genes from the HIST1 cluster which expression is known to be upregulated during S-phase of cell cycle.

**Summary/Conclusions:** The biomarker H3K27me3 HIST1 high is correlated with a better LFS and OS in NPM1mut CN-AML patient, independently of other known genetic alterations in particular FLT3-ITD. The worse outcome of FLT3-ITD-H3K27me3 HIST1low patients is concomitant with high expression of replication-dependent HIST1 genes that could explain treatment failure.

FUNCTIONAL ASSESSMENT OF NOVEL DIAGNOSTIC FLT3 MUTATIONS AND INHIBITION BY KINASE INHIBITORS

K. Tarbock1,2, T.A. Hylland2, J.A. Pollard2, M.E. Hansen3, R. Ries2, S. Siewal2, S. Meshinchi1
1Hematology/Oncology, Seattle Children’s Hospital, 2Clinical Research Division, Fred Hutchinson Cancer Research Center, Seattle, 3Pediatric Hematology/Oncology, Maine Medical Center, Portland, 4University of Rochester, Rochester, 5Arog Pharmaceuticals, Dallas, United States

**Background:** Somatic mutations in FLT3 are among the most common events in AML, with FLT3-ITD mutations in the juxtaparamembrane domain (JMD) as well as D835 missense mutations in the kinase domain (KD) the predominant events. Sequencing of FLT3 in a cohort of 788 children with de novo AML treated on the Children’s Oncology Group (COG) protocols demonstrated that in addition to the previously described FLT3 mutations (ITD and D835), numerous other variants, including several novel variants, were present in 8% of patients at diagnosis, leading to a cumulative FLT3 mutation prevalence of 27% in children and young adults. These variants mostly occurred in the JMD and ITD regions, and were present in 8% of patients who might be amenable to FLT3 inhibitor therapy.

**Aims:** We evaluated the oncogenic capability of each of these mutations by assessing their ability to result in aberrant FLT3 and STAT5 phosphorylation, as well as response to the tyrosine kinase inhibitors crenolanib and quizartinib.

**Methods:** Point mutations were introduced into HEK293 cells using retroviral transduction. Following transduction, phosphorylation status of FLT3 (pFLT3) and downstream STAT5 (pSTAT5) were evaluated by immunoblotting. Phosphorylation status was quantified by chemiluminescence analysis and the quan-
lity of protein expression was normalized to actin. That ratio of phosphorylated protein to total protein for FLT3 and STAT5 was determined and normalized to that observed in the D835Y mutation as a positive control. A value of >10% pFLT3 was considered positive. All mutations that resulted in FLT3 phosphorylation were subsequently evaluated for inhibition by crenolanib and quizarinib following 60-minute exposure to the compounds.

Results: A total of 24 non-ITD and non-ALM AML FLT3 mutations were evaluated for autonomous FLT3 and STAT5 phosphorylation. Eleven mutations resulted in pFLT3 and pSTAT5, including 4 mutations with >50% pFL3. All mutations that demonstrated aberrant pFL3 also had aberrant pSTAT5, however a direct correlation of pFLT3 and pSTAT5 was not always observed. Overall, 87% (n=86 patients) of all non-ITD mutations evaluated resulted in autonomous FLT3 activation. Excluding D835 mutations, 64% (n=39) of patients harbored an activating mutation. Many of the mutations that were not found to be activating had the lowest prevalence, often present in only one patient. Evaluation of inhibition of mutant FLT3 phosphorylation demonstrated that in every case of aberrant activation, crenolanib resulted in potent inhibition of phosphorylation of FLT3 and STAT5 with an IC50 range of 1.3-13.9 nM and 0.6-6.5 nM respectively. Many of the mutations tested were exclusively sensitive to crenolanib, with 9 of 10 mutations tested demonstrating an IC50 of pFLT3 inhibition ≥5.6 nM. Inhibition of downstream kinases is necessary for optimal efficacy of any FLT3 inhibitor and phosphorylation of STAT5 was potently inhibited by crenolanib in all cases. Quizarinib inhibited pFL3 and pSTAT5 with an IC50 range of 1.8-15.1 nM and 1-33.9 nM respectively, demonstrating less effective inhibition specifically at mutations including DB35Y, D839E, N676K, M664I.

Summary/Conclusions: We have previously presented that FLT3 mutations, including novel mutations in addition to the FLT3/ITD and D835, are prevalent in children and young adults with AML. Here we demonstrate that many of the non-ITD/D835 mutations also result in aberrant FLT3 phosphorylation and are amenable to inhibition by FLT3 inhibitors. Crenolanib resulted in potent inhibition of FLT3 and downstream STAT5 in all mutations tested. This data supports expanding the cohort of pediatric patients with activating FLT3 mutations who may benefit from FLT3 inhibitor therapy beyond those with FLT3/ITD.

THE BCL-2 INHIBITOR VENETOCLAX INHIBITS NRF2 ANTIOXIDANT PATHWAY ACTIVATION INDUCED BY HYPMETHYLATING AGENTS IN ACUTE MYELOID LEUKEMIA
L.X.T. Nguyen1, A. Khahala1, E. Troade1, B. Kumar1, S. Forman1, G. Marcucci1, V. Pullarkat2
1City of Hope Medical Center, Duarte, United States, 2Hematology, City of Hope Medical Center, Duarte, United States

Background: The selective Bcl-2 inhibitor Venetoclax (ABT-199) has shown potent synergistic activity against Acute Myeloid Leukemia (AML) in preclinical and early clinical studies and impressive results have been achieved using the combination of hypomethylating agents (HMA) with venetoclax suggesting synergy between these agents.

Induction of Reactive Oxygen Species (ROS) is important for the cytotoxicity of various AML therapies including HMA. Induction of ROS by various cytotoxic therapies concurrently activates the Nrf2 antioxidant response pathway which in turn results in induction of antioxidant enzymes that neutralize ROS. Upon ROS induction, the transcription factor Nrf2 is released from its adaptor protein Keap1 in the cytoplasm whereby Nrf2 enters the nucleus and binds to antioxidant response element sequences in the promoters of various genes. Nrf2 pathway activation has been shown to mediate chemoresistance in various cancers including AML. Low ROS levels have been shown to be a hallmark of leukemia stem cells and are critical to their self renewal capacity. In this study, we examined whether Nrf2 inhibition is an additional mechanism responsible for the markedly enhanced antileukemic activity in AML seen with the combination of HMAs and venetoclax.

Aims: To determine the effect of venetoclax on ROS levels after HMA exposure in AML cells and to examine the effect of Bcl-2 inhibition on NRF2 antioxidant pathway activation in response to HMA

Methods: The effect of combination of venetoclax and HMA on ROS levels and apoptosis was measured by flow cytometry. Effect of venetoclax and HMA on Nrf2 nuclear translocation was analyzed by immunostaining after cellular fractionation. Effect of venetoclax treatment on the association of Bcl2 with Nrf2 was examined in cell lines that demonstrated increased nuclear translocation of Nrf2 (Figure 1) and induction of downstream antioxidant enzymes including HO-1 and NQO1. Immunofluorescence studies confirmed the inhibition of nuclear translocation of Nrf2 by venetoclax. Immunoprecipitation studies indicated that Bcl-2, Keap1 and Nrf2 associate in a protein complex in the cytoplasm and that treatment with venetoclax leads to dissociation of Bcl-2 from the Nrf2/Keap1 complex and targets Nrf2 to ubiquitination and proteasomal degradation.

Results: A total of 24 non-ITD and non-ALM AML FLT3 mutations were evaluated for autonomous FLT3 and STAT5 phosphorylation. Eleven mutations resulted in pFLT3 and pSTAT5, including 4 mutations with >50% pFL3. All mutations that demonstrated aberrant pFL3 also had aberrant pSTAT5, however a direct correlation of pFLT3 and pSTAT5 was not always observed. Overall, 87% (n=86 patients) of all non-ITD mutations evaluated resulted in autonomous FLT3 activation. Excluding D835 mutations, 64% (n=39) of patients harbored an activating mutation. Many of the mutations that were not found to be activating had the lowest prevalence, often present in only one patient. Evaluation of inhibition of mutant FLT3 phosphorylation demonstrated that in every case of aberrant activation, crenolanib resulted in potent inhibition of phosphorylation of FLT3 and STAT5 with an IC50 range of 1.3-13.9 nM and 0.6-6.5 nM respectively. Many of the mutations tested were exclusively sensitive to crenolanib, with 9 of 10 mutations tested demonstrating an IC50 of pFLT3 inhibition ≥5.6 nM. Inhibition of downstream kinases is necessary for optimal efficacy of any FLT3 inhibitor and phosphorylation of STAT5 was potently inhibited by crenolanib in all cases. Quizarinib inhibited pFL3 and pSTAT5 with an IC50 range of 1.8-15.1 nM and 1-33.9 nM respectively, demonstrating less effective inhibition specifically at mutations including DB35Y, D839E, N676K, M664I.

Summary/Conclusions: We have previously presented that FLT3 mutations, including novel mutations in addition to the FLT3/ITD and D835, are prevalent in children and young adults with AML. Here we demonstrate that many of the non-ITD/D835 mutations also result in aberrant FLT3 phosphorylation and are amenable to inhibition by FLT3 inhibitors. Crenolanib resulted in potent inhibition of FLT3 and downstream STAT5 in all mutations tested. This data supports expanding the cohort of pediatric patients with activating FLT3 mutations who may benefit from FLT3 inhibitor therapy beyond those with FLT3/ITD.

P187
UNRAVELING EPigenOMIC REGULATION IN THE EVOLUTION OF RELAPSING PEDIATRIC AML
C. Wiggers1,2, M. Baak1, M. Creyghton1, M. Bartels2
1Hubrecht Institute, 2Pediatrics, University Medical Center Utrecht, Utrecht, Netherlands

Background: In comparison with pediatric acute lymphoblastic leukemia, pediatric acute myeloid leukemia (AML) is characterized by a high relapse rate (~30%), and lower overall survival rates of 60-70%. It is therefore crucial to increase our insights in pathophysiological mechanisms underlying AML relapse, including chemotherapy resistance, clonal evolution, and clonal selection. There is increasing evidence that epigenetic deregulation is involved in the initiation and progression of cancers, including adult AML. Epigenetic regulation involves the activity of non-coding regulatory DNA elements such as enhancers, which interact with promoters to fine-tune gene expression. Importantly, epigenetic signatures at enhancers are highly cell state specific. Since little is known concerning the epigenetic landscape of pediatric AML, it is crucial to gain more insights into the epigenome of relapsed and non-relapsed AML in children.

Aims: To identify differential epigenomic regulatory pathways involved in AML relapse by exploring the epigenome of relapsed (RP) and non-relapsed pediatric AML patients (NRP).

Methods: The epigenome of 20 AML patients, harboring known molecular aberrations (including MLL-rearrangement, CBF-related and Fli3-ITD), was analyzed in triplicate using the dually marked active regulatory markers Chromatin-Immunoprecipitation-sequencing (ChIP-seq) experiments. Additionally, single-cell RNA-seq data were generated for selected AML patients to analyze clonal heterogeneity.

Results: All genomic regions that were significantly enriched by H3K27ac were analyzed, resulting in ~30.000 active promoters and enhancers per sample. Genome-wide Pearson correlation of all enriched regions showed subclustering of patients based on molecular aberration. Interestingly, epigenomic analysis showed that the initial diagnosis (Dx) and the patient’s relapse (Rel) sample were highly correlated. Also, single-cell RNA-seq analysis identified two highly identical homogeneous populations at Dx and Rel. Following the fact that no major differences were observed between AML cells at diagnosis and relapse, NRPCs were analyzed. Here striking differences in H3K27ac enrichment were observed in MLL-rearranged patients between NRPs and RPs. Enhancers and promoters were differentially enriched at diagnosis, of which Sphk1, a kinase involved in proliferation and survival, was significantly more enriched in RPs, while the promoter of transcription factor ELF1 and nearby located enhancers were active in NRPs only.

Figure 1.

Summary/Conclusions: In conclusion, inhibition of Nrf2 pathway may explain the marked potentiation of HMA activity by venetoclax that is observed in clinical trials. We show that ROS induction at least partially mediates the cytotoxicity of HMA and ROS induction after HMA treatment is augmented by venetoclax. We demonstrate for the first time that venetoclax is a potent inhibitor of Nrf2 activation via disruption of the association between Nrf2, Keap-1 and Bcl-2.
Summary/Conclusions: Analysis of promoters and especially enhancers is a highly useful approach to identify cell state specific regulation. Here, we analyzed pediatric AML patients at diagnosis and at relapse to gain more insight into specific cell states which are involved in relapse. Our data revealed high similarity between diagnosis and relapse samples, while, strikingly, in the WHO intermediate-risk group containing MLL-rearranged patients, differential epigenomic regulation was observed between NRPs and RPs. Taken together, our preliminary data suggests that already at diagnosis, AML cells display an epigenetic fingerprint associated with the development of AML relapse during the course of disease. We are currently validating these data.

MECHANISTICALLY INFORMED COMBINATIONS OF SY-1425, A POTENT AND SELECTIVE RARA AGONIST, WITH HYPOMYTHERALY OR ANTI-CD38 TARGETED AGENTS IN AML AND MDS
M. Mckeown1, K. Austigen2, C. Fiores2, E. Lee1, D. Smith1, C. Fritz3, T. Lodiego1, E. Di Tomaso1, E. Olson2
1Translational Medicine, 2Biology, Syros Pharmaceuticals, Cambridge, United States

Background: FLT3 internal tandem duplication (ITD) mutations account for ~20-25% of adult AML cases and are associated with worse prognosis. Although FLT3 inhibitors show clinical activity, relapse occurs quickly. Venetoclax is a potent, selective inhibitor of the anti-apoptotic protein BCL-2 that demonstrated monotherapy activity in relapsed/refractory AML (ORR 19%); however, no activity was seen in FLT3 mutant cases (Konopleva, Can Disc and RBCS1186; P190). The combination of the anti-apoptotic proteins BCL-XL, BCL-2, and MCL-1, but not BCL-2, and FLT3 inhibition synergizes with the dual BCL-2/BCL-XL inhibitor ABT-737 in vitro in FLT3-ITD+ cells (Kohl, Leukemia 2007).
Aims: Expression of BCL-XL and MCL-1 are known resistance factors to venetoclax, therefore targeting pathways that regulate BCL-XL or MCL-1 in combination with venetoclax may enhance cell death and improve efficacy. Based on this hypothesis, we interrogated if selective inhibition of BCL-2 by venetoclax in combination with quazartinib, a potent FLT3 inhibitor, resulted in synergistic anti-tumor effects in FLT3-ITD+ AML models.
Methods: FLT3-ITD+ (Molm13 and MV4;11) and wild type (HL60 and OCIAML2) cell lines were evaluated in vitro. Preliminary antitumor effects measured by cell titer glo and apoptosis by Annexin V staining. In vivo efficacy was determined in a MV4;11 xenograft model.
Results: Sensitivity to venetoclax was initially assessed in vitro. Dose dependent growth inhibition and induction of apoptosis was observed in the MV4;11, Molm13 and HL60 cell lines following 48hr venetoclax treatment, with the MV4;11 cell line most sensitive. Modulation of BCL-2, BCL-XL and MCL-1 expression by FLT3 inhibition was determined following 8-24hr treatment with quazartinib. Quazartinib reduced BCL-XL and MCL-1 protein, but not BCL-2, in the FLT3-ITD+ cell lines. Quazartinib had no affect on expression of these three proteins in the FLT3 wt cell lines SY-1425 could induce sensitivity to the anti-CD38 therapeutic antibody daratumumab (DARA).
Aims: We sought to investigate mechanistically informed combinations of SY-1425 in biomarker dependent and with potential novel agents in AML and MDS patients (Phase 2 study, NCT02807558). Based on the RARα mediated myeloid gene activation of SY-1425, epigenetic priming with hypomyelinating agents (HMA)s and CD38 induction were explored.
Methods: HMA synergy was tested in vitro in AML cell lines over a range of concentrations for SY-1425 and azacitidine. In vivo studies used a disseminated patient derived xenograft (PDx) model of AML expressing high levels of RARA. SY-1425 induction of CD38 was assessed by Hk327ac ChiP-seq, RARA ChiP-seq, and RNAseq. Antibody dependent cell-mediated cytotoxicity (ADCC) was tested in an ex vivo co-culture model of human NK cells and AML cell lines.
Results: SY-1425 acts as a repressive transcription factor until bound by SY-1425 leading to potent, targeted activation of myeloid genes. HMAs can further prime this activation by depleting repressive methylation of these target genes. The combination of SY-1425 and azacitidine showed synergy in RARA-high AML cell lines, but not in RARA-low AML cell lines, with combination indices less than 0.5. Co-administration in a RARA-high AML PDx demonstrated superior reduction of tumor burden (<1% detectable tumor cells) vs either treatment alone over 16 weeks (63% vs 41% in SY-1425 alone and 8% with azacitidine). Various combination regimens evaluated in the PDx model over two cycles (56 days) found that 1 week of azacitidine followed by 3 weeks of SY-1425 maximized for anti-tumor activity (<5% AML cells in periphery, bone marrow and spleen) and tolerability (<8% weight loss). RARα binds directly to the CD38 locus and induces Hk327 acetylation, promoting Hk327ChiP-seq enrichment of the modified H3K27ac mRNAs transcripts in RARA-high models. SY-1425 treatment of four RARA-high AML cell lines and three RARA-high primary AML patient samples induced cell surface CD38 to high levels comparable to those of DARA sensitive multiple myeloma cells. In contrast, no CD38 induction was observed in RARA-low cell lines. SY-1425 in vitro only RARA-high AML cell lines treated with SY-1425 and DARA were six fold more sensitive to NK cell mediated ADCC compared to single agent controls and exhibited a 5-10 fold increase in NK cell-dependent activation measured by IFNγ secretion.
Summary/Conclusions: This in vitro combination is highly promising and should be explored further in a clinical trial. We are currently planning a clinical trial to test the combination of SY-1425 and azacitidine in AML patients who have not had a response to frontline chemotherapy.
Acute myeloid leukemia - Clinical 1

ONGOING PHASE 2 CLINICAL TRIAL OF SL-401 IN PATIENTS WITH BLASTIC PLASMACYTOID DENDRITIC CELL NEOPLASM: STAGE 1 AND STAGE 2 RESULTS
N. Pemmaraju1, K. Sweet2, A. Lane3, A. Stein4, S. Vasu5, W. Blum5, D. Rizzieri6, E. Wang7, M. Duvic1, J. Chen8, S. Shmeshi4, P. McDonald6, C. Brooks6, J. Lance1, H. Kantarjian1, M. Konopleva1
1MD Anderson Cancer Center, Houston, TX, 2H. Lee Moffitt Cancer Center, Tampa, FL, 3Dana-Farber Cancer Institute, Boston, MA, 4City of Hope National Medical Center, Duarte, CA, 5The Ohio State University Medical Center, Columbus, OH, 6Duke University Medical Center, Durham, NC, 7Roswell Park Cancer Institute, Buffalo, NY, 8Sterling Therapeutics, New York, New York, United States

Background: SL-401 is a targeted therapy directed to interleukin-3 receptor α (CD123), a target overexpressed on a variety of cancers including blastic plasmacytoid dendritic cell neoplasm (BPDCN), a highly aggressive malignancy with poor outcomes and unmet medical need.

Aims: This Phase 2 trial is a single-arm, open-label, study designed to generate efficacy and safety data to support potential registration in BPDCN.

Methods: In this ongoing Phase 2 single-arm trial, patients with BPDCN (n=32) or relapsed/refractory (R/R) AML (n=48) received SL-401 as a daily IV infusion at 7, 9, 12, or 16 ug/kg/day for days 1-5 of a 21-day cycle in stage 1. In stages 2 and 3, patients received SL-401 at the dose determined in stage 1.

Results: 32 adult BPDCN patients received SL-401 in stage 1 (n=9) and stage 2 (n=23), including 19 first-line and 13 R/R patients. Stage 3 patients will be reported separately. Median age was 72 years (range: 30-85 years). In stage 1, 12 ug/kg was the highest tested dose for BPDCN; MTD was not reached in BPDCN. Median follow-up was 4.3 months (range: 0.5-22.9 months). ORR of 84% (27/32) was observed in all patients: 90% (18/19) in first-line and 69% (9/13) in R/R. 88% (14/16) of first-line patients treated at 12 ug/kg had a complete remission (CR) (n=10), CR with incomplete hematologic recovery (CRi) (n=1) or clinical CR (CRC; residual skin disease) (n=3) based on investigator assessment. 56% (9/16) of these patients were progression free for 4 to 22.9 months (ongoing), including 3 patients on SL-401 in remission (4 to 18 months, ongoing) and 7 patients who were bridged to stem cell transplant (SCT; 3 auto-SCT and 4 allo-SCT). A R/R patient was also bridged to allo-SCT. Overall, most common ≥Grade 3 treatment-related AEs were transaminase elevation (22%) and thrombocytopenia (16%). Safety precautions, including daily monitoring of albumin and body weight during study drug infusions, have been implemented to minimize risk of severe capillary leak syndrome (CLS). Three patients had Grade 5 CLS: BPDCN (7 ug/kg); R/R AML (16 ug/kg); BPDCN (12 ug/kg) out of 118 patients who received SL-401 across all trials and regimens; 3/89 (3.4%) patients of which were enrolled in this clinical trial.

Summary/Conclusions: SL-401 continues to demonstrate single agent activity, including multiple CRs, in patients with BPDCN, with 25% (8/32) of patients bridged to SCT after a major response from SL-401. SL-401 side effect profile consists largely of transaminitis and thrombocytopenia. CLS can be fatal. Side effects have generally tended to decrease in frequency and severity with increasing cycles. Updated data, including detailed safety analysis across all ongoing SL-401 studies will be presented at the meeting.

P192
PROGNOSTIC IMPACT OF SOMATIC MUTATION CLEARANCE IN PATIENTS WITH ACUTE MYELOID LEUKEMIA
K. Takahashi1, F. Wang1, K. Patel1, C. Bueso-Ramos1, G. Issa1, X. Song1, J. Zhang1, C. Gumbs1, F. Ravandi2, T. Kadia1, N. Daver1, C. DiNardo1, M. Konopleva1, M. Andreeff1, J. Cortes1, G. Garcia-Manero1, E. Jabbour1, A. Furtreal1, H. Kantarjian1
1Leukemia, UT MD Anderson Cancer Center, Houston, United States

Background: Persistence of somatic mutations at the time of complete remission (CR) was associated with poor outcome in patients (pts) with AML.

Aims: To analyze differential pattern of mutation clearance based on the genes with affected pathway and to assess prognostic impact of mutation clearance in AML patients.

Methods: We studied 95 pts with AML who were treated with frontline induction and subsequently achieved CR. We sequenced pre-treatment and CR bone marrow samples by targeted capture sequencing of 295 genes (median 280x coverage). We defined 3 levels of mutation clearance (MC) based on variant allele frequency (VAF): 1) MC2.5, persistent mutation with VAF≥2.5%, 2) MC1.0, persistent mutation with VAF<1%, and 3) complete mutation clearance (CMC).

Results: In the pre-treatment samples, we detected 597 mutations in 78 genes in 87 (92%) patients. In the matching CR samples, 62 (10%) and 82 (14%) mutations persisted at VAF≥5% and ≥1%, respectively, which corresponded to 43 (49%), 34 (39%), and 30 (34%) patients achieving MC2.5, MC1.0 and CMC, respectively. Table 1 shows the differential patterns of MC based on the mutations and pathways. Mutations associated with clonal hematopoiesis of
indeterminate therapy (CHIP), DNA methylation, and splicing pathways had low rate of MC, whereas mutations in transcription factors or receptor tyrosine kinase (RTK) had high rate of MC. Pts who achieved MC 1.0 (median 31.2 vs 12.5 months, P=0.04) or CMC (median 31.2 vs 12.5 months, P=0.049) had significantly better relapse-free survival (RFS).

Summary/Conclusions: Somatic mutations associated with CHIP, DNA methylation, and splicing pathways persisted frequently in CR samples suggesting preleukemic origin. Pts with deeper MC had significantly better RFS. Somatic mutation clearance may help risk prediction of AML.

P194

IDENTIFICATION OF PATTERNS IN CO-OCCURRING MUTATIONS IN AML PATIENTS WITH GERMLINE AND SOMATIC RUNX1 MUTATIONS

U. Borate1,*, B. Wilmot1, B. Norris1, P. Lo1, D. Bottomly1, S. McWeeney1, J. Tyner1, A. Agarwal1
1Oregon Health & Science University, Portland, United States

Background: RUNX1 plays a vital role in leukemogenesis through its interaction with core binding factor-β complex and other genes involved in hematopoiesis (1,2). Familial platelet disorder with predisposition to acute myeloid leukemia (FPD/AML) is linked to germline RUNX1 mutations (3). This autosomal dominant disorder is characterized by thrombocytopenia and potential for transformation to AML. AML patients with somatic RUNX1 mutations have a poor prognosis (6,7) independent of other risk factors. The role of co-occurring mutations in leukemogenesis in FPD/AML patients with germline RUNX1 mutations and AML patients with de novo somatic RUNX1 mutations is not fully understood.

Aims: In order to further characterize co-occurring mutations in patients with both germline and somatic RUNX1 mutations, we analyzed a large cohort of AML tumor samples along with several paired normal tissue samples.

Methods: We sequenced a cohort of 482 diagnostic bone marrow or peripheral blood samples from AML patients by deep whole-exome sequencing. Samples were collected through the "Beat AML" project, an ongoing program at Oregon Health & Science University in collaboration with the Leukemia & Lymphoma Society. RUNX1 mutations were classified using VarScan which defined somatic and germline mutations as follows: somatic if p <0.1 and germline if not called as somatic and normal variant allele frequency >0.1.

Results: Twenty AML samples had 21 germline RUNX1 mutations with a total of 6 different germline variants; 31 other patient samples had 38 somatic RUNX1 mutations with 31 unique somatic variants. One sample had 2 RUNX1 germline mutations; 6 samples had >1 somatic RUNX1 mutations. The most common germline variant, missense mutation p.L56S, was found in 16% (76/434) of the cohort. RUNX1 mutations were classified as known and novel. Significantly, the germline variants occurred mutually exclusive of the somatic variants. Out of 20 patients with germline RUNX1 mutations, 16 had co-occurring known pathogenic mutations in AML-related genes. Most significantly, 62% (10/16) and 51% (14/27) of patients with germline or somatic RUNX1 mutations, respectively, had 7 co-occurring AML-related pathogenic mutations that were exclusive to their cohort (Table 1). Both germline and somatic RUNX1 mutational cohorts had 12 overlapping co-occurring mutations. The most common mutations, for both groups, were in FLT3 (14/43), ASXL1 (8/43), and IDH2 (7/43) (Table 1). Patient demographics and treatment-related outcomes were similar for both cohorts.

Summary/Conclusions: The incidence of RUNX1 mutations seen in our 482-patient Beat AML cohort (4.3% germline, 6.4% somatic) is consistent with results from other studies (8). Our study suggests that germline and somatic RUNX1 mutations in AML patients are mutually exclusive, as are several co-occurring pathogenic mutations that contribute to leukemogenesis. Our study adds to the already described mutually exclusive mutations in germline RUNX1 by identifying WT1, CHEK2, CCND3, and others. Similarly, in samples with somatic RUNX1 mutations, we found mutually exclusive mutations in CBL, JAK2, MLL, EZH2, and others in addition to the previously described IDH1 (8). Further characterization of these results and analyses of additional samples using our whole-exome sequencing and our bioinformatics platform will help us better elucidate the molecular events underlying AML progression and help us establish novel prognostic/therapeutic markers aimed at early intervention in patients, or their family members, who carry RUNX1 mutations.

MULTIPLE LEUKEMIC STEM CELL MARKER EXPRESSION IS ASSOCIATED WITH POOR PROGNOSIS IN DE NOVO ACUTE MYELOID LEUKEMIA

T. Yabushita1, Y. Shimomura1, D. Kato1, Y. Ono1, N. Hiramoto1, S. Yoshikawa1, N. Yonetani1, A. Matsushita1, H. Hashimoto2, T. Ishikawa1
1Hematology, Kobe City Medical Center General Hospital, 2Hematology, Institute of Biomedical Research and Innovation Hospital, Kobe City, Japan

Background: Acute myeloid leukemia (AML) is believed to originate from a small population of leukemic stem cells (LSCs). Current chemotherapy regimens target the majority of more mature leukemic blasts, but cannot efficiently eliminate LSCs, resulting in early treatment failure and relapse. Thus, the expression of LSC-specific markers could be used as a predictive factor of clinical outcomes in AML patients. Recently, the clinical impact of individual LSC markers has been documented in several reports, but the combined effect of different LSC markers remains unexamined.

Aims: This study aimed to estimate the prognostic impact of the expression of multiple LSC markers on the outcome of AML patients.

Methods: Ninety consecutive patients diagnosed with de novo AML at our institution and eligible for intensive chemotherapy were enrolled from September 2010 to March 2016. We excluded 10 patients with acute promyelocytic leukemia. This study was approved by the institutional review board of the Ethics Committee and complied with the Declaration of Helsinki. We analyzed the expression of three LSC markers, CD25, CD96, and CD123, in de novo AML patients. The expression of these markers on gated leukemic blasts was evaluated using 6-color flow cytometry. When over 20% of leukemic blasts were positive for any marker, the sample was defined as positive for that marker. We stratified de novo AML patients into two groups: LSCHigh was defined as positivity for two or three LSC markers, and LSCLow was defined as negativity for all markers or positivity for a single LSC marker. The primary endpoint was overall survival (OS). The secondary endpoint was progression-free survival (PFS). OS and PFS were estimated using the Kaplan-Meier method, and assessed using the log-rank test. Multivariate analysis using Cox proportional hazard ratio was performed for OS and PFS.

Results: The median follow-up for patients still alive at the end of the study was 38.9 months (range: 1.5-64.8 months). The median patient age was 60 years (range: 17-78 years). There was no statistical significance between LSCHigh patients (n=30) and LSCLow patients (n=50) in sex, age, laboratory data, NPM1 mutation, or European Leukemia Net karyotype risk group. FLT3 mutation was associated with the LSCHigh group (p=0.003). Three-year OS and PFS were significantly better in the LSCHigh group than in the LSCLow group (Figure 1) (OS: 65.0% vs 18.2%, p<0.001; PFS: 49.3% vs 19.4%, p<0.001). In multivariate analysis, controlled for age and karyotype (Table 1), being in the LSCHigh group was an independent prognostic factor for OS (hazard ratio: 3.17; 95% CI: 1.64-6.15; p<0.001) and PFS (hazard ratio: 2.25; 95% CI: 1.24-4.08; p<0.007). Three-year OS and PFS were significantly better in the LSCHigh group than in the LSCLow group (Figure 1) (OS: 65.0% vs 18.2%, p<0.001; PFS: 49.3% vs 19.4%, p<0.001). In multivariate analysis, controlled for age and karyotype (Table 1), being in the LSCHigh group was an independent prognostic factor for OS (hazard ratio: 3.17; 95% CI: 1.64-6.15; p<0.001) and PFS (hazard ratio: 2.25; 95% CI: 1.24-4.08; p<0.007). Being in the LSCHigh group had incremental value for OS compared with the karyotype risk (Harrell's C index: 0.80 vs 0.70; p=0.028). Moreover, this classification based on LSC marker expression allowed subgroups with unfavorable prognosis to be identified among patients in the intermediate karyotype risk group (3y-OS 54.6% vs 14.5%, p=0.013), as well as those in the favorable karyotype risk group (3y-OS 94.1% vs 50.0%, p=0.021).

1Invivoscribe, 2LabPMM LLC, San Diego, United States

Background: Many personalized therapies for acute myeloid leukemia (AML) have been developed targeting specific biomarkers. Unfortunately, the efficacies of these therapies are inconsistent, while the need to determine successful therapies prior to patient relapse is critical. Minimal residual disease (MRD) monitoring can help determine effective treatments and predict potential relapse. While there are now several MRD tests available on the market, most target single or small numbers of biomarkers, which can limit detection of residual AML heterogeneity. Thus, full characterization of a sample may require testing with multiple MRD assays, which can be impractical in a clinical setting. We have developed a targeted capture-based assay (MyMRD™), which allows characterization of the entire therapeutic AML biomarker repertoire and can inform...
the molecular remission status of a patient’s malignancy. This targeted panel can identify the mutations in driver clones that cause relapse in ~90% of all AML patients, as well as common drivers in myeloid proliferative neoplasms (MPN) and myelodysplastic syndromes (MDS).

**Aims:** To establish a sensitive and reliable targeted NGS assay to comprehensively detect and monitor the majority of known driver mutations in AML and myeloid malignancies.

**Methods:** Whole genome libraries, made from DNA extracted from cell lines and clinical samples, were hybridized with MyMRD probes targeting mutation hotspots in 23 genes associated with AML. In addition to single nucleotide variants (SNVs) and indels in 21 of these genes, 5 structural variant (SV) breakpoints that are commonly targeted. Enriched libraries were sequenced with the MiSeq® platform and analyzed using proprietary Invivoscribe (IVS) MyInformatics™ software. To validate mutations detected by the MyMRD assay, samples were additionally tested with IVS developed capillary electrophoresis (CE) assays and NGS-based assays targeting common mutations in FLT3 and NPM1.

**Results:** The linearity and limit of detection (LOD) of the MyMRD assay were assessed using data generated from contrived cell line DNA containing known AML driver mutations with a range of variant allele frequencies (VAFs). The assay shows strong linearity (R²=0.96 – 0.99) in the entire range of tested VAFs (0.01% – 99%). Overall, we established a LOD of 0.5% for >95% of the targeted sites in the assay with lower LODs for specific mutations of interest (e.g. 0.1% for a 30bp FLT3 ITD and 0.2% for FLT3 p.D835Y). In addition, using clinical samples the MyMRD assay shows excellent concordance with the standard FLT3 CE assay for variants with VAFs above the CE detection threshold (5%). Sanger sequencing was the only method actually covering the entire coding region of CEBPA. Both NGS amplicon-based panels failed to fully cover the coding region of the gene, and therefore have likely missed mutations. Crucially, even when any of the three methods detected more than one variant, cloning studies confirmed biCEBPA mutations only in a fraction of the cases. In summary, none of the amplicon-based tested methods can reliably determine if multiple mutations affect two different alleles; therefore biCEBPA mutations would still need additional confirmation. We are currently exploring the ability of capture-based NGS approaches coupled to appropriately tailored bioinformatic analysis of sequencing data to detect biCEBPA mutations.

**P198:** IS IT POSSIBLE TO RELIABLY DETECT CLINICALLY-RELEVANT BIALLELIC CEBPA GENE MUTATIONS USING NGS PANELS?

**Background:** CEBPA encodes a leucine zipper transcription factor that is important for normal myeloid cell differentiation. Biallelic CEBPA (biCEBPA) mutations are associated with favourable prognosis in patients with acute myeloid leukaemia (AML); therefore, accurate molecular testing of this gene is crucial in the clinical setting. Molecular pathology labs routinely analyse CEBPA through fluorescence-based multiplex-PCR fragment analysis or, more frequently, Sanger sequencing. Lately, it is increasingly common to use next-generation sequencing (NGS) technology in the pathology labs, and CEBPA gene is indeed included in the majority of NGS panels commercially available for testing of patients with neoplasias of the myeloid lineage.

**Aims:** We set ourselves to compare the performance of two different NGS targeted panels to detect CEBPA molecular aberrations, with a particular focus on biCEBPA mutations.

**Methods:** DNA specimens from 173 myeloid cases were subjected to Sanger (n=92) or to NGS (n=81) sequencing, including the TruSight Myeloid Sequencing Panel (illumina) (n=59), and the IonAmpSeq AML Community Panel (thera-capt) (n=34). Both NGS panels are designed to cover CEBPA through overlapping amplicons (6 or 9). However, we found that an average of 3.5 amplicons were covered <500x, and more worryingly, we realised that at least one of those amplicons was shallowly (<100x) covered in 97% of the cases. Indeed both panels showed significantly lower average coverage levels of this gene compared to the panel as a whole (Figure 1). This might not be surprising, since CEBPA is encoded within a CpG-rich region, and therefore its amplification needs tailored PCR conditions, hard to address in the multiplexed PCR step included in their library prep protocols. Therefore, both NGS approaches are prone to miss variants. In contrast, Sanger sequencing protocol (which includes optimized PCR conditions for correct amplification of the CEBPA gene) managed to cover the whole length of the gene. We were able to detect 26 variants affecting 20 AML cases through Sanger sequencing. Cases showing two variants were manually curated (through Chromas or IGV tools) to confirm if they affected different alleles. However, in 6 cases both mutations laid on different amplicons, which made not possible to univocally conclude if and how they are biallelic. These inconclusive cases were subjected to DMSO-PU-P PCR in order to amplify the whole length of CEBPA coding region, followed by cloning. Colony sequencing showed independent clones harbouring different variants (i.e. bona fide biCEBPA mutations) in the majority of the cases, but crucially, not in all of them. This result highlights the need of implementing techniques able to accurately assess CEBPA biallelism, others than plain calling of more than one variant.

**Summary/Conclusions:** IS IT POSSIBLE TO RELIABLY DETECT CLINICALLY-RELEVANT BIALLELIC CEBPA GENE MUTATIONS USING NGS PANELS? Since AML patients with biCEBPA mutations have relatively favourable overall survival, it is important in the clinical setting to accurately assess CEBPA molecular status. In our study, we have tested the ability of three different assays to detect CEBPA mutations in 173 samples. Sanger sequencing was the only method actually covering the entire coding region of CEBPA. Both NGS amplicon-based panels failed to fully cover the coding region of the gene, and therefore have likely missed mutations. Crucially, even when any of the three methods detected more than one variant, cloning studies confirmed biCEBPA mutations only in a fraction of the cases. In summary, none of the amplicon-based tested methods can reliably determine if multiple mutations affect two different alleles; therefore biCEBPA mutations would still need additional confirmation. We are currently exploring the ability of capture-based NGS approaches coupled to appropriately tailored bioinformatic analysis of sequencing data to detect biCEBPA mutations.
(18–83 years). All patients were treated with standard induction and consolida-
tion protocols.

Results: Median time between two investigations was 2.8 months (range for all 0.1–115 months). A complete molecular remission was reached in 90/130 pts (69%) after a median of 5 months. 19/130 (14.6%) pts reached low level MRD and 20/130 (15.4%) high level MRD. Median event free survival (EFS) of patients with CMR was not reached (EFS at 2 years 82%). 16 (18%) of those patients relapsed in the course of follow up with a median time to relapse of 12.7 months (range 4.1 to 38.3 months). Median EFS for patients with CMR was not reached (EFS at 2 years 66%). The 7/130 (5%) patients with a <3 log fold reduction had a median EFS of 14.7 months (2 groups, p=0.017). A total of 59/185 patients received allogeneic SCT. Among the 130 patients diagnosed at our laboratory 34 (26%) received allogeneic SCT, 12 (9%) were transplanted in first CR and 17 (13%) were transplanted for relapse. Following allogeneic SCT 11/17 patients (65%) reached a second CR with CMR.

Summary/Conclusions: Our data shows that MRD testing is routinely per-
formed in RUNX1-RUNX1T1 AML outside of clinical studies. Defining MRD
levels by RUNX1-RUNX1T1/ABL resulted in a better classifier for high and low risk patients than log fold change. However, despite CMR 16/90 (18%) patients relapsed with a maximum time from first achievement of CMR of 38.3 months. We conclude that 1) MRD monitoring could serve to guide BMT deci-
sions in RUNX1-RUNX1T1 positive AML, 2) allogeneic BMT can rescue the majority of relapsed patients and 3) molecular monitoring can reliably identify patients with high risk for relapse.

NUMBER OF TP53 ABNORMALITIES AND THEIR CLINICAL RELEVANCE IN PATIENTS WITH ACUTE MYELOID LEUKEMIA AND MYELOPROLIFERATIVE SYNDROMES

G. Oyong-Bravo1, C. Benton1, T. Kadia1, F. Ravandi1, J. Cortes1, N. Daver1, K. Takahashi1, C. DiNardo1, E. Jabbour1, G. Borthakur1, N. Pemmaraju1, M. Konopleva1, A. Alfonso1, S. Pierce1, C. Bueso-Ramos2, S. Kornblau1, K. Patel2, H. Kantarjian1, M. Andreff2, G. Garcia-Manero1

1Leukemia, Hematopathology, The University of Texas MD Anderson Cancer Center, Houston, United States

Background: Mutations in TP53 can be detected in up to 16-19% patients with acute myeloid leukemia (AML) and myelodysplastic syndromes (MDS). TP53 mutations confer adverse prognosis irrespective of currently available therapies. The clinical impact of the type and number of TP53 abnormalities is unclear.

Aims: To evaluate the prognostic impact of the number of TP53 abnormalities in AML and MDS.

Methods: We evaluated 1401 patients with previously untreated AML or MDS treated at The University of Texas MD Anderson Cancer Center from 2012 to 2016. Sequencing data was obtained by use of a 28 or 53-gene targeted PCR-based next generation sequencing platform. Response was defined following 2003 IWG criteria for patients with AML and 2006 revised IWG criteria for patients with MDS. Generalized linear models were used to study the association of overall response (OR), complete response (CR) and risk factors, Kaplan-Meier produce limit method was used to estimate the median overall survival (OS).

Results: A total of 593 (42%) patients had MDS and 808 (56%) had AML. In a total of 984 (70%) patients, data on therapy with sufficient follow up and response evaluation was available, with 494 (35%) patients receiving therapy with hypomethylating agents (HMAs) and 373 (27%) with chemotherapy regimens. A total of 384 mutations in TP53, involving 208 unique mutations, were detected among 300 (21%) patients with R273H, R248W, Y220C and R175H being the most prevalent. Overall frequency of TP53 mutations was higher among patients with MDS (25%, n=146) compared to AML (19%, n=154) (p=0.012) with 251 (84%) of detected mutations happening in patients with complex karyotype (p<0.001). Among patients with TP53-mutant disease, 221 (74%) had 1 detectable mutation, 76 (25%) had 2 and 3 (1%) had 3. Additionally, 188 (13%) patients had TP53 deletions evidenced by presence of monosomy 17 or del(17p). In 167 (89%) of these patients, chr17 abnormalities were detected in the context of a complex karyotype and in 127 (42%) a co-occurring TP53 mutation was detected. Correlation between TP53 mutations and deletions (r=0.443, p<0.001) was observed with 172 (12%) patients having 1 TP53 abnormality. 169 (12%) of these patients had deletions. Patients with multiple detectable TP53 mutations were less likely to have co-occurring chr17 abnormalities (79% vs 22%, OR 0.28, CI 0.15-0.50, p=0.03). Median follow up was 8.6 months (range 0-167 months). Presence of a TP53 mutation adversely impacted OS (MDS: 12.4 vs 111.7 months, HR=5.98, CI 4.28-8.35, p<0.001; AML: 5.3 vs 16.9 months, HR=2.81, CI 2.26-3.50, p<0.001). Increasing number of TP53 abnormalities negatively impacted OS of patients with AML (Figure 1A) but not that of patients with MDS (Figure 1B). No difference in survival was observed between patients with two TP53 mutations and those with TP53 mutation+deletion (p=0.730). Presence and number of TP53 mutations did not predict for response (OR: 0.6 vs 63%, p=0.498; CR: 34 vs 36%, p=0.695) to HMAs, but was associated with significantly lower likelihood of response to intensive chemotherapy (OR: 41 vs 86%, p<0.001; CR: 33 vs 75%, p<0.001).

Summary/Conclusions: Presence of multiple TP53 abnormalities can be observed in up to 13% patients with AML and MDS. Second TP53 abnormalities more commonly involve TP53 deletions with additional TP53 mutations being less common and generally mutually exclusive with TP53 deletions. The number of TP53 abnormalities impacts the survival of patients with AML but not that of patients with MDS. Presence and number of TP53 mutations do not seem to impact response to HMAs but are associated with lower responses to chemotherapy.

VADASTUXIMAB TALIRINE PLUS HYPOMETHYLATING AGENTS: A WELL-TOLERATED REGIMEN WITH HIGH REMISSION RATE IN FRONTLINE OLDER PATIENTS WITH ACUTE MYELOID LEUKEMIA-FRONTLINE (AML-FRONTLINE) VERSUS SECOND-Line (AML-SECOND): RESULTS FROM THE JAVELIN AML-101 STUDY

Sammons Cancer Center, Dallas, 13Clinical Development, Seattle Genetics, Inc., Bothell, 14Hematology and Oncology, Massachusetts General Hospital Cancer Center, Boston, United States

Background: Treatment of AML among the elderly is challenging. HMAs are commonly used, but yield suboptimal response rates and modest survival. Durations of response were difficult to achieve; in a study of MRD response by flow cytometry in patients treated with single-agent HMA therapy at MD Anderson Cancer Center, only 13/58 (22%) responding patients achieved minimal residual disease (MRD) negativity (F Ravandi, MD, unpublished data, Jan 2017).

Aims: To assess the safety and efficacy of vadastuximab talirine (VAD; SGN-CD33A; 33A) in a CD33-directed antibody conjugated to 2 molecules of a pyrrolobenzodiazepine (PBD) dimer. Upon binding, 33A is internalized and transported to the lysosomes where PBD dimer is released via proteolytic cleavage of the linker, crosslinking DNA, and leading to cell death.

Methods: Fifty-three patients (median age 75 years [range, 60-87]) were treated with VAD (per MRC); patients were either unfit for (40; 75%) or declined (13; 25%) intensive therapy. The median treatment duration is currently 19.3 weeks (range, 2-86) with 8 patients still on treatment; no DLTs were reported. Adverse events (AEs) ≥Grade 3 reported in ≥15% of patients were thrombocytopenia (55%), febrile neutropenia (49%), anemia (46%), neutropenia (42%), pneumonia (19%), and leukopenia (17%); no ≥Grade 4 bleeding events were observed.

Results: Fifty-three patients (median age 75 years [range, 60-87]) were treated with VAD (33A+HMA). Patients had a complex karyotype (39%); 19% of patients (7/37) had secondary AML (18/22, 82%), and age ≥75 years (18/26, 69%). Of all responding patients, 86 (86) with 8 patients still on treatment; no DLTs were reported. Adverse events (AEs) ≥Grade 3 reported in ≥15% of patients were thrombocytopenia (55%), febrile neutropenia (49%), anemia (46%), neutropenia (42%), pneumonia (19%), and leukopenia (17%); no ≥Grade 4 bleeding events were observed. Treatment-emergent (TE) liver lab elevations (≥Grade 3) were rare: ALT (8%), AST (2%), and total bilirubin (2%). Other non-heme TEAEs reported in ≥25% of patients regardless of relationship to study treatment were fatigue (60%), nausea (49%), constipation (43%), peripheral edema (42%), poor appetite (40%), dyspnea (34%), pyrexia (32%), diarrhea, vomiting (28% each), and dizziness (26%). Thirty- and 60-day mortality rates were 2% and 8%, respectively, with no treatment-related deaths reported. A total of 39/103 (38%) of doses were delayed due to AEs mostly from myelosuppression (neutropenia 18%, thrombocytopenia 7%, and febrile neutropenia 3%). High remission rates (37/49 (76%) CR+CRi) were maintained across adverse disease subsets including acute cytogenetics (16/18, 89%), TP53-mutated (6/7, 86%), secondary AML (18/22, 82%), and age ≥75 years (18/26, 69%). Of all responding patients, 19/37 (51%) achieved MRD negativity. Two patients went on to subsequent allo-HSCT, and no additional MDS/AML was observed. The median time to MRD-negative survival was 9.1 months (range, 0.1-19.4+ months) and OS continues to evolve with 15 patients (28%) alive (11.3 month median follow-up) (Figure 1).

Summary/Conclusions: 33A+HMA is well tolerated with a safety profile consistent with on-target myelosuppression. The CR+CRi rate of 76% and low early mortality in older AML patients with poor risk factors is particularly encouraging, and activity appears markedly improved compared to the historical experience of HMA monotherapy. The MRD clearance rate among responding patients who received 33A+HMA is higher than the rate observed with single
patients older than 60 years with IR-FMP AML had remarkable EFS of 36±3% and OS 54±10% at 8 years (Figure 1).

Figure 1.

P202

ACUTE MYELOID LEUKEMIA WITH INTERMEDIATE-RISK CYTOGENETICS AND A FAVORABLE GENOTYPE: PROGNOSTIC FACTORS AND RESULTS IN PATIENTS TREATED ACCORDING THE SPANISH CETLAM PROTOCOLS

Background: Acute myeloid leukemia (AML) with intermediate-risk (IR) cytogenetics includes a substantial proportion of patients with favorable molecular profile (FMP), in which AML cells harbor the NPM1 mutation or CEBPA biallelic mutation without internal tandem duplication of the FLT3 gene (FLT3-ITD). The role of allogeneic hematopoietic transplantation (allo-HCT) in first complete remission (CR) in these patients remains controversial.

Aims: To analyze the results and prognostic factors of IR-FMP AML patients in a large series of patients treated by the Spanish CETLAM group.

Methods: Patients with primary AML diagnosed at 19 institutions from the Spanish CETLAM group and treated between 2003 and 2017. Induction chemotherapy included idarubicin and cytarabine (standard or intermediate-dose) in all cases, consolidation with intermediate or high-dose cytarabine (HDAC) and, depending on the protocol, additional HDAC, autologous or allogeneic hematopoietic transplantation.

Results: Two hundred-twenty-one patients were analyzed. Median age of the series was 54 years (range 18 to 72). 152 patients had an age up to 60 years and 69 (31%) were older. Median WBC count was 19±10×10⁹/l (range 0.55-282). One-hundred eighty-two patients had a normal karyotype and it was observed in only 2 patients of the NPM1+/FLT3-ITD- group (1%).

Two hundred eighty-one patients had NPM1 mutated and FLT3-ITD wild type (NPM1+/FLT3-ITD-) and 30 CEBPA biallelic mut/FLT3-ITD wild type (CEBPα+/FLT3-ITD-). There were significant differences in the main clinical or biological parameters in these two groups. The CR rate in the overall group was very high (92%) without significant differences between the two molecular groups. Chemo-resistance was observed in only 2 patients of the NPM1+/FLT3-ITD- group (1%). Death during induction was observed in 16 patients (7%), all of them with NPM1+/FLT3-ITD-. Induction results according to age were similar in both groups. Event-free survival and overall survival are reported at 8 years and were 52±8% and 70±4%, respectively. In univariate comparisons, better EFS and OS was observed in CEBPα+/FLT3-ITD- patients compared to those with NPM1+/FLT3-ITD- (p=0.03 and p=0.02, respectively). When analyzing post-transplantation treatment, patients treated with HDAC only had an excellent prognosis, even better than those receiving an autologous or allogeneic transplantation. One patient died in CR in the HDAC group, another in the autologous transplant group and 7 in the allo-HCT group (p<0001). In multivariate analysis of pretransplant characteristics, age up to 60 years and CEBPα+/FLT3-ITD- association to improved EFS (RR=0.42) and OS (RR=0.29). Interestingly, in a subgroup of 123 patients with data on MRD after consolidation chemotherapy (flow citometry, cut-off: 0.12%), positivity was associated with worse EFS (0.02).

Figure 1.

P203

GMI-1271, A POTENT E-SELECTIN ANTAGONIST, COMBINED WITH INDUCTION CHEMOTHERAPY IN ELDERLY PATIENTS WITH UNTREATED AML: A NOVEL, WELL-TOLERATED REGIMEN WITH A HIGH REMISSION RATE

Background: The outcomes for elderly patients (pts) with acute myeloid leukemia (AML) remain poor due to limited tolerance of intensive cytotoxic chemotherapy and low response rate, therefore newer and less toxic therapies are urgently needed.

Aims: To analyze the results and prognostic factors of IR-FMP AML patients in a large series of patients treated by the Spanish CETLAM group.

Methods: Patients with primary AML diagnosed at 19 institutions from the Spanish CETLAM group and treated between 2003 and 2017. Induction chemotherapy included idarubicin and cytarabine (standard or intermediate-dose) in all cases, consolidation with intermediate or high-dose cytarabine (HDAC) and, depending on the protocol, additional HDAC, autologous or allogeneic hematopoietic transplantation.

Results: Two hundred-twenty-one patients were analyzed. Median age of the series was 54 years (range 18 to 72). 152 patients had an age up to 60 years and 69 (31%) were older. Median WBC count was 19±10×10⁹/l (range 0.55-282). One-hundred eighty-two patients had a normal karyotype and it was abnormal in 34 (5 patients no metaphases). One hundred ninety-one patients had NPM1 mutated and FLT3-ITD wild type (NPM1+/FLT3-ITD-) and 30 CEBPA biallelic mut/FLT3-ITD wild type (CEBPα+/FLT3-ITD-). There were significant differences in the main clinical or biological parameters in these two groups. The CR rate in the overall group was very high (92%) without significant differences between the two molecular groups. Chemo-resistance was observed in only 2 patients of the NPM1+/FLT3-ITD- group (1%). Death during induction was observed in 16 patients (7%), all of them with NPM1+/FLT3-ITD-. Induction results according to age were similar in both groups. Event-free survival and overall survival are reported at 8 years and were 52±8% and 70±4%, respectively. In univariate comparisons, better EFS and OS was observed in CEBPα+/FLT3-ITD- patients compared to those with NPM1+/FLT3-ITD- (p=0.03 and p=0.02, respectively). When analyzing post-transplantation treatment, patients treated with HDAC only had an excellent prognosis, even better than those receiving an autologous or allogeneic transplantation. One patient died in CR in the HDAC group, another in the autologous transplant group and 7 in the allo-HCT group (p<0001). In multivariate analysis of pretransplant characteristics, age up to 60 years and CEBPα+/FLT3-ITD- association to improved EFS (RR=0.42) and OS (RR=0.29). Interestingly, in a subgroup of 123 patients with data on MRD after consolidation chemotherapy (flow citometry, cut-off: 0.12%), positivity was associated with worse EFS (0.02).

Figure 1.

Summary/Conclusions: Patients with primary AML, IR cytogenetics and FMP have a good outcome. Best results are achieved in patients with CEBPα+/FLT3-ITD-, particularly if age is up to 60 years. In this subset, OS at 8 years is 96±7%, comparable to current results achieved in acute promyelocytic leukemia. Patients above 60 years treated intensively may achieve a long term survival of more than 50%. Chemotherapy without subsequent consolidation is a valid option. MRD monitoring after treatment has to be taken into account since in the subset of patients analyzed this was an independent prognostic factor for EFS.
Results: 24 pts have been enrolled to date and 17 are evaluable for response. The median age was 68 years (range, 60-79) with 58% male pts and 25% with high-risk cytogenetics (by SWOG). 50% (12/24) were pts with secondary AML (sAML), half of whom had prior hypomethylating therapy (50%; 6/12). This study had a rolling safety run-in and the first 3 pts had no DLT, allowing enrollment to proceed. Common Gr 3/4 AEs included febrile neutropenia (47%), pneumonia (20%), nausea (13%), and non-fatal respiratory failure (13%). 2 pts died of sepsis within 60 days. The remission rate (CR/CRi) was 12/17 (71%). CR/CRi rate was 75% for pts with de novo disease and 67% for pts with sAML. The PK profile in this elderly population was consistent with that of younger adults (median age <60 years) with similar AML. No drug-drug interactions were apparent. The median E-selig exposure at baseline was 29% (range, 2-67%) of blasts in the bone marrow.

Summary/Conclusions: The addition of a novel E-selectin antagonist, GMI-1274, to standard induction chemotherapy in untreated elderly pts with AML, including patients with secondary AML, demonstrates a high remission rate with acceptable side effect profile resulting in low induction mortality. This study compares favorably to previous studies (Lancet, ASCO 2016). E-selectin ligand was expressed on leukemic blasts in the majority of pts, therefore supporting its relevance as a target. A randomized trial is being planned.

P205

CM942 IS A NEW SMALL MOLECULE THAT TARGETS SET-PP2A INTERACTION AND INHIBITS GROWTH OF ACUTE MYELOID LEUKAEMIA CELLS

Background: Acute myeloid leukaemia (AML) is a heterogeneous malignant disorder of hematopoietic progenitor cells in which several genetic and epigenetic aberrations have been described. Nevertheless, outcome for most patients is poor, and it is necessary to develop more effective treatment strategies. Our group showed that the inactivation of the tumor suppressor PP2A is a recurrent event in AML, and that overexpression of SET, an endogenous inhibitor of PP2A, is a poor prognostic factor in this disease. Furthermore, the anticancer activity of FTY720, a PP2A-activating drug (PPA) acting on its interaction with SET, FTYY720 is a relatively non-toxic drug currently used in patients with relapsing multiple sclerosis; however, this drug cannot be used in cancer patients due to its toxicity at the needed anti-neoplastic dose. Therefore, investigation of alternative agents for reactivation of PP2A is warranted.

Aims: To test the efficacy of CM942, a FTY720 analogue, on AML cell lines and primary patient samples, and investigate its mechanism of action.

Methods: AML cell lines and 29 de novo AML samples were analyzed by treatment with FTY720 and CM942, MTS (viability), apoptosis, cell cycle and PP2A activity assays, and western blot.

Results: CM942 exhibited notable cytotoxicity on all human AML cell lines with SET overexpression (n=10), but no effects on cell lines and primary samples (n=29) treated with CM942, providing mechanistic insights into the anti-tumor mechanism of this new molecule. Our analyses in primary AML samples showed that 7 out of 29 (24%) samples treated with CM942 had a significant reduction in proliferation. By western blot analyses we found that those patients responding to CM942 treatment had SET overexpression. Of note, treatment of peripheral blood mononuclear cells from healthy donors with CM942 had no effects on cell viability. Therefore, although FTY720 and CM942 have similar effects inhibiting cellular proliferation, CM942 was less toxic when assayed on normal peripheral blood cells.

Summary/Conclusions: CM942 inhibits growth of AML cells in both cell lines and primary patient samples, exerting its antileukemic effects through reactivation of PP2A activity. Although treatment with FTY720 was somewhat more effective than CM942 in primary samples of AML, fewer cytotoxic effects were observed after CM942 treatment in peripheral blood from healthy donors. Further experiments would be necessary to confirm the in vivo anti-tumor activity of CM942 in AML models. New compounds have been developed for the treatment of AML, although few have been translated into clinical practice; nevertheless, it is unlikely that any of these compounds, when used alone, will cure the disease, so combination strategies are imperative. Our results indicate that PADs may be a valid therapeutic option for AML, especially for treating leukemias characterized by SET-dependant inactivation of PP2A.
CLONAL HETEROGENEITY IN LEUKEMIC STEM CELLS FROM PATIENTS WITH ACUTE MYELOID LEUKEMIA

L. Manta1*, B. Saeed2*, A. Possolo3, P. Pyly*, T. Stiehl4, K. Barth-Miesala1, V. Eckstein1, W. Huber5, A.D. Ho1, C. Lutz1

1Department of Medicine V, University of Heidelberg, 2Multi-omics and statistical computing, European Molecular Biology Laboratory, 3Interdisciplinary Center for Scientific Computing & Institute of Applied Mathematics, University of Heidelberg, Heidelberg, Germany

Background: Clonal heterogeneity occurs in many cancers, including Acute Myeloid Leukemia (AML). In cases of relapse, chemotherapy has triggered clonal selection with minor or evolved sub-clones driving relapse. A better understanding of the underlying clonal architecture, the extent of genetic heterogeneity and its response to therapy is necessary to better understand mechanisms of therapy escape and relapse.

Aims: In this study we aim to define the clonal architecture of AML during the course of therapy and in leukemia propagating cells. In this study we aim to define the clonal architecture of AML during the course of therapy and in leukemia propagating cells.

Methods: We sequenced 12 AML samples at the time of diagnosis and in one case also at the time of relapse with at least 80% blasts per sample. 6/12 patients displayed a normal karyotype while the other 6 patients showed various cytogenetic abnormalities (inversion 16 (2), trisomy 8 (1), add(19)(p13.3) (1), complex aberrant karyotype (2)). Whole-exome sequencing (WES) was performed with the appropriate germ line controls. WES data were clustered using empirical Bayesian clustering.

Results: WES identified more than 3000 variants in total. By setting distinct filtration criteria (5% allelic frequency (AF) > 0.1 reads coverage), reads support of the detected variant, SIFT score < 0.05, and GMAF < 5%, 64 leukemia specific mutations were detected (2-18 mutations/AML). As expected, these included recurrently mutated genes like DNMT3A (in 4 patients), IDH1 and 2 (each in one patient), KIT and NRAS (both in 2 patients). Categorization of identified mutations showed that these mutations affected genes involved in various cellular processes including transcriptional regulation (15), cell differentiation (6), cell cycling (5), apoptosis/survival signals (5), proliferation (3), cell growth (3) and splicing (3). Empirical Bayesian clustering of all detected variants according to their respective AF resulted in 2-5 different clusters per AML.

Based on this cluster analysis we were able to predict the founding cluster/clone. Assuming that most of the mutations are heterozygous and considering the blast percentage at diagnosis, mutations of the biggest clusters present in every cancer cell and the mutations of the smaller clusters in tumor heterogeneity. Using a combinatorial approach, clonal selection with minor or evolved sub-clones driving relapse.

Summary/Conclusions: WES can identify leukemia specific mutations that are involved in various cellular functions including mutations that have been shown to be recurrently mutated in AML like DNMT3A. Sequencing data can also be used in combination with mathematical modelling approaches to reconstruct the clonal architecture of AML at the time of diagnosis and relapse allowing estimations of the clonal complexity at these time points.

TREATMENT OF PRACINOSTAT AND AZACITIDINE IN ELDERLY PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML): CORRELATION BETWEEN MUTATION CLEARANCE AND CLINICAL RESPONSE

K. Takahashi1, Y. Abaza1, F. Wang1, C. Gumbs1, S. Xingzh1, A. Futreal1, E. Alatal2, S. Khaled2, M. Arellano3, M. Patnaik4, E. Palmesino5, G. Garcia-Manero1

1University of Texas MD Anderson Cancer Center, Houston, 2Medical College of Wisconsin, Milwaukee, 3Stanford University, Stanford, 4City of Hope, Duarte, 5Emory University School of Medicine, Atlanta, 6Mayo Clinic, Rochester, United States, 7Helsinn, Pazzallo, Switzerland

Background: In a phase 2 study of 50 elderly patients (≥65 years) with AML who were not eligible for intensive chemotherapy, treatment with the investigational HDAC inhibitor pracinostat+azacitidine (AZA) was well tolerated and led to 42% complete remission (CR) rate and a median overall survival (OS) of 19.1 months (Blood 2016; 128:100). Responses were durable (median CR+CRi 17.2 months), blast clearance was rapid (median 8 weeks), and maximum clinical benefit required prolonged therapy (>6 months) in some patients.

Aims: Our aim was to understand the impact of somatic mutations and their clearance on disease response and survival outcomes in AML patients treated with pracinostat+AZA.

Methods: 88 samples from 41 study patients were sequenced. Pre-treatment samples were available for analysis for all 41 patients, and a median of 3 longitudinal samples were analyzed from 19 patients between Cycle 2 and 9. Longitudinal mutations were detected by SureSelect targeted exome sequencing (Agilent) of 295 genes that are recurrently mutated in hematologic malignancies (median coverage 507x [range: 111-777x]). Longitudinal mutation clearance was analyzed by tracking variant allele frequency (VAF). Informed consent was obtained from all patients.

Results: At baseline, 98 mutations in 28 genes were detected in 38 (93%) patients, with the most frequent being in SRSF2 (27%), DNMT3A (20%), IDH2 (17%), RUNX1 (17%), and TET2 (17%). The median number of mutations detected per patient was 2 (range: 0-6). Among the 33 patients with evaluable treatment response, CR was observed in 13 (39%) patients. The rate of CR was significantly higher in patients with mutations in NPM1 or in one of the DNA methylation pathway genes, while patients with TP53 mutation had a trend for poor CR (Table 1). The median follow up duration of the 41 patients was 23.8 months (95% CI: 20.4-27.1 months) with median OS of 18.1 months (95% CI: 10.1-26.1 months), patients with CEBPA mutation had a trend toward better OS, whereas patients with NPM1 mutation had significantly worse OS (Table). Considering mutations associated with AML oncology (Lindsley RC, Blood 2015;125:1367-76), median OS was 17.7 months in 20 patients with mutations typically associated with secondary AML and 18.1 months in 18 patients with mutations typically associated with de novo AML. Among the 19 patients whose longitudinal specimens were analyzed, 10 achieved CR. Of those 10 patients, 9 (90%) had persistently detectable mutations in their bone marrow at the time of CR, however, in 7 of them, continued exposure to pracinostat+AZA lowered the VAF or cleared residual mutations. Mutations in genes associated with DNA methylation, RNA splicing, clonal hematopoiesis of indeterminate potential (CHIP), and receptor tyrosine kinase (RTK) pathways had poor clearance of mutation, while transcription factors or cohesin had better clearance with pracinostat+AZA treatment. In 2 patients, relapsed samples were sequenced and showed re-expansion of the founder clone.

Summary/Conclusions: WES can identify leukemia-specific mutations that are involved in various cellular functions including mutations that have been shown to be recurrently mutated in AML like DNMT3A. Sequencing data can also be used in combination with mathematical modelling approaches to reconstruct the clonal architecture of AML at the time of diagnosis and relapse allowing estimations of the clonal complexity at these time points.
**Summary/Conclusions:** Mutations in *NPM1* and DNA methylation pathway were associated with a better response to pracinostat+AZA, while *TP53* mutation was associated with a trend toward poor response. Persistent mutation at the time of CR suggests residual preleukemic clonal hematopoiesis in this elderly population. Benefit of prolonged exposure to pracinostat+AZA was also confirmed at molecular level where continued decline of mutation VAF was seen after achieving CR.

**Background:** Effects on overall survival (OS) are of primary importance when evaluating AML treatments (Tx). Though complete remission (CR) rates are lower with azacitidine (AZA) than with intensive chemotherapy (IC), OS is similar with AZA and IC (Dombret et al., *Blood*, 2015). The 2017 European LeukemiaNet (ELN) recommendations acknowledge that hypomethylating agents, including AZA, may alter the natural course of AML in some patients (pts) who do not achieve CR (Döhner et al., *Blood*, 2017). According to IWG criteria for AML (Cheson et al., *J Clin Oncol*, 2003), stable disease (SD) is considered non-response to Tx. Yet AML is a progressive disease; potentially, stable health status may reflect delayed disease progression and result in improved OS.

**Aims:** This post hoc analysis evaluated OS outcomes among older pts with AML treated with AZA or conventional care regimens (CCR) who maintained SD, with or without hematologic improvement (HI), in the phase 3 AZA-AML-001 study.

**Methods:** Pts aged ≥65 years with AML (>30% marrow blasts), ECOG PS score ≤2, NCCN-defined intermediate- or poor-risk cytogenetics, and WBC count ≤15x10^9/L received AZA (75mg/m^2x7 days [d]/28d cycle) or a CCR (IC [standard 7+3 regimen], low-dose cytarabine [20mg BID x 10d/28d cycle], or best supportive care). OS was assessed using Kaplan-Meier methods for pts with SD at 2-, 4-, and 6-month landmarks. SD was protocol-defined as the absence of an IWG-defined AML response and no progressive disease (PD), whether or not HI was attained. Pts with SD could have had an IWG-defined response or PD at any time other than at the specified landmarks. OS was also evaluated in pts with HI as their best response; attainment of HI must have begun on or before, and been sustained past, each landmark, and lasted for ≥56 consecutive days.

**Results:** Median OS for all SD pts was 2.1-2.5 months longer with AZA vs CCR, and estimated 1-year survival was ~15% higher at each landmark in the AZA arm (Table 1). Hazard ratios for OS among all SD pts treated with AZA vs CCR ranged from 0.81–0.88. Median OS among pts with SD and no HI ranged from 12.6–13.3 months in the AZA arm and from 11.1-12.2 months in the CCR arm. Within Tx arms, AZA-treated pts with HI had meaningfully improved OS at all landmarks, ranging from 3.7 to 7.9 months longer than OS for pts without HI (Table 1). In contrast, HI attained with CCR did not largely influence OS; differences between pts who attained HI vs no HI ranged from -0.2 to 2.9 months. Median durations of HI in the AZA vs CCR arms, respectively, were 183 vs 166.
Madrid, Spain, June 22 – 25, 2017
days at 2 months, 176 vs 148 days at 4 months, and 176 vs 138 days at 6
months. Estimated 1-year survival within the AZA arm was 4.9%–27.4% greater
for pts with HI than for pts with no HI, but for CCR-treated pts with HI, 1-year
survival was 0%–10.3% greater. Between Tx arms, 1-year survival with AZA in
pts with HI was 9.6%–33.3% greater than for CCR-treated pts with HI.
Summary/Conclusions: Maintaining SD during AZA or CCR Tx is associated
with relatively favorable OS outcomes, as median OS in pts with SD exceeded
that for all pts in the AZA-AML-001 trial (10.4 months with AZA vs 6.5 months
with CCR; Dombret et al., Blood, 2015). Pts with SD who also attained HI during
early AZA Tx had meaningfully improved OS, whereas similar CCR-treated pts
did not, suggesting that HI with AZA is qualitatively different from HI with CCR.
The prognostic relevance of HI in AML requires further study.

A RANDOMIZED PHASE II STUDY OF IDARUBICIN AND CYTARABINE
WITH EITHER CLOFARABINE OR FLUDARABINE IN ADULTS WITH
NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA
N. Short1,*, H. Kantarjian1, F. Ravandi1, X. Huang1, L. Xiao1,
G. Garcia-Manero1, W. Plunkett1, V. Gandhi1, K. Sasaki1, N. Pemmaraju1,

1The University of Texas MD Anderson Cancer Center, Houston, 2The University of California - Irvine, Orange, United States

Background: Fludarabine and clofarabine are purine nucleoside analogues
with clinical activity in acute myeloid leukemia (AML).
Aims: We designed a randomized phase II trial to evaluate the efficacy and
safety of idarubicin and cytarabine with either clofarabine (CIA) or fludarabine
(FIA) in adults with newly diagnosed AML. The primary objective was to compare the EFS rates of the two regimens.
Methods: Adults with newly diagnosed AML deemed suitable for intensive
chemotherapy were randomized using a Bayesian adaptive design to receive
CIA or FIA. All patients (pts) received idarubicin 10 mg/m2 IV on D1-3 and
cytarabine 1 g/m2 IV daily on D1-5. Clofarabine and fludarabine were given at
doses of 15 mg/m2 and 30 mg/m2, respectively, IV daily on D1-5. Pts with FLT3ITD mutations could receive concomitant sorafenib. Responding pts could
receive up to 6 cycles of consolidation at attenuated doses. Outcomes were
compared to a historical cohort of pts <60 years of age who received idarubicin
and cytarabine (IA) without a nucleoside analogue.
Results: Between 8/2011 and 6/2016, 182 pts were enrolled (CIA, n=106; FIA,
n=76; Table 1).
Table 1.

The imbalance of the arms was due to the better performance of CIA during
the initial period of the trial. Treatment arms were well-balanced after randomization. 12 pts (55%) in the CIA arm and 8 (53%) in the FIA arm received
sorafenib. The composite CR/CRp rate was similar between the two arms (80%
for CIA vs 82% for FIA; P=0.84). CR was achieved in 72% and 74% in the CIA
and FIA arms, respectively. MRD negativity rates at remission by multiparameter
flow cytometry were higher in the CIA arm (80% vs 65%; P=0.07). 37 pts (35%)
in the CIA arm and 28 (38%) in the FIA arm underwent allogeneic stem cell
transplant in first remission. The median duration of follow-up was 27 months
(range, 1-58). Median EFS for pts who received CIA and FIA were 13 months
and 12 months, respectively; the 2-year EFS rate was 44% in both arms
(P=0.91). Median OS were 24 months and not reached, and the 2-year OS
rates were 51% and 57%, respectively (P=0.23). No differences in EFS or OS
were observed according to baseline factors, including cytogenetics, mutations

or ELN risk group. CIA was generally associated with more adverse events
compared to FIA, including a higher rate of transaminase elevation (29% vs
4%), hyperbilirubinemia (26% vs 9%), and rash (29% vs 12%). Early mortality
was similar in the 2 arms (60-day mortality: 4% for CIA vs 1% for FIA; P=0.32).
We compared outcomes of pts treated with either CIA/FIA to a historical cohort
treated with IA (n=92). Pts in the CIA/FIA group with FLT3 mutations who
received sorafenib (n=20) were excluded from this analysis. The two cohorts
were similar with respect to pretreatment characteristics analyzed, including
age, cytogenetics, and ELN risk. No differences were observed in CR/CRp
rates, EFS or OS between the two groups. However, among pts <50 years of
age, the median EFS for pts who received FIA (n=36), CIA (n=28) and IA (n=34)
was not reached, 10 months and 9 months, and the 2-year EFS rates were
58%, 33% and 30%, respectively (P=0.05 for FIA vs IA; P=0.79 for CIA vs IA).
For these pts <50 years of age, the median OS was not reached, 22 months
and 15 months, and the 2-year OS rates were 72%, 46% and 36%, respectively
(P=0.009 for FIA vs IA; P=0.23 for CIA vs IA).
Summary/Conclusions: CIA and FIA have similar efficacy in younger pts with
newly diagnosed AML, although FIA is associated with a better toxicity profile.
FIA may improve outcomes compared to IA in pts <50 years of age.

Moffitt Cancer Center & Research Institute, Tampa, FL, United States

Background: Approximately 20% to 30% of patients with acute myeloid
leukemia (AML) have FLT3 mutations; these patients often experience rapid
post-induction relapse, highlighting the need for therapies that provide an
improved bridge to stem cell transplantation. CPX-351 is a liposomal formulation
that delivers a synergistic 5:1 molar ratio of cytarabine and daunorubicin. CPX351 demonstrated significantly prolonged overall survival (OS) versus cytarabine/daunorubicin (7+3) in a randomized, open-label, controlled phase 3 trial
in patients aged 60 to 75 years with newly diagnosed, high-risk AML (Lancet,
et al. ASCO 2016). A study of the ex vivo cytotoxicity of CPX-351 found that
AML blasts with the FLT3-ITD phenotype were 5-fold more sensitive to CPX351 than those with wild type FLT3 (Gordon, et al. Leuk Res. 2017;53:39-49).
Aims: The current analysis of the phase 3 trial therefore investigated outcomes
in the subset of patients with FLT3 mutations.
Methods: Enrolled patients were randomized 1:1 to receive induction with 1 to
2 cycles of CPX-351 (100 units/m2 [cytarabine 100 mg/m2+daunorubicin 44
mg/m2] on Days 1, 3, and 5 [2nd induction: Days 1 and 3 only]) or 7+3 (cytarabine 100 mg/m2/day x 7 days [2nd induction: x 5 days]+daunorubicin 60 mg/m2
on Days 1, 2, and 3 [2nd induction: Days 1 and 2 only]). Patients who achieved
complete remission (CR) or CR with incomplete platelet or neutrophil recovery
(CRi) could receive up to 2 consolidation cycles.
Results: Of the 274 patients who were assessed for FLT3 mutations and
received study treatment, 22/138 (16%) patients in the CPX-351 arm and
20/136 (15%) patients in the 7+3 arm had baseline FLT3 mutations. AML subtypes in FLT3+ patients were: therapy-related AML (19%); AML after myelodysplastic syndrome (MDS) with (38%) or without (10%) prior hypomethylating
agents; AML after chronic myelomonocytic leukemia (12%); and de novo AML
with MDS karyotype (21%). In FLT3+ patients, median OS was longer with
CPX-351 (10.25 months) versus 7+3 (4.55 months; hazard ratio=0.57 [95%
CI: 0.24, 1.33]; P=0.093; see Figure 1), and the rate of CR+CRi was higher
(68% vs 25%). A greater number of FLT3+ patients treated with CPX-351 were
able to undergo stem cell transplantation (n=10/22 [45%]; 4 patients were alive
as of this analysis, after a median post-transplant follow up of 692 days [range:
96-769]) compared with 7+3 (n=2/20 [10%]; neither patient was still alive). The
adverse event profile (reported during treatment or within 30 days of discontinuation) of CPX-351 in FLT3+ patients was comparable to that of 7+3 and consistent with the overall study population. Serious treatment-emergent adverse
events (TEAEs) were experienced by 7 (32%) FLT3+ patients in the CPX-351
arm and 10 (50%) patients in the 7+3 arm; individual serious TEAEs in ≥2
patients included febrile neutropenia (n=2 in each arm), respiratory failure (n=1
in each arm), cardiac failure (n=2 with CPX-351), and cerebral hemorrhage
(n=2 with 7+3).
Summary/Conclusions: CPX-351 demonstrated numerical improvement in
median OS in older patients with newly diagnosed, FLT3+ high-risk AML and

haematologica | 2017; 102(s2) | 53


allowed more patients to undergo stem cell transplantation. The safety of CPX-351 in this subpopulation was in line with the previous studies and the overall phase 3 population. This analysis was limited by small number of patients.

Figure 1.

P211

NIVOLUMAB MAINTENANCE THERAPY FOR PATIENTS WITH HIGH-RISK ACUTE MYELOID LEUKEMIA IN REMISSION

T. Kadia1, H. Kantarjian1, E. Jabbour2, F. Ravandi3, N. Daver1, P. Cardenas4, M. Brandt1, M. Konopleva5, J. Cortes1
1Leukemia, 2MD Anderson Cancer Center, Houston, United States

Background: Dose intensification and newer drug combinations during induction have led to high rates of complete remission (CR) in pts with newly diagnosed AML. However, disease relapse remains a major source of failure. With the exception of allogeneic (allo) stem cell transplant (SCT), there are few options for post-consolidation maintenance of remission in high-risk pts. Prior attempts at developing maintenance therapy using cytotoxic drugs have been unsuccessful. Immune mediated disease control by engaging tumor-specific cytotoxic T-cells may be important in suppressing leukemia relapse, as is seen with graft vs leukemia effect following allo SCT. Immune checkpoint inhibitors may be effective in restoring host immune surveillance in the setting of post-remission maintenance.

Aims: We designed a pilot phase II clinical trial studying the efficacy and safety of nivolumab (nivo) as maintenance therapy in AML pts with high-risk disease in remission, who were not being considered for SCT.

Methods: AML pts ≥18 years with a high-risk feature in 1st CR (CR1) or any patient in 2nd CR (CR2) who had received induction and at least 1 consolidation cycle were eligible for enrollment. Pts should be within 12 months of achieving CR, have PS ≤2, and adequate organ function. Pts were treated with nivo 3mg/kg IV every 2 weeks for 6 months. 1 cycle was 4 weeks. After 6 months, nivo could be given every 4 weeks until 12 months on study, and then every 3 months until relapse. All pts had baseline cytokine and molecular testing, and minimal residual disease (MRD) assessment by flow cytometry. Peripheral blood and bone marrow samples were collected at baseline and during treatment for immune correlates studies to explore immune repertoire and biomarkers for response.

Results: Eight pts have been treated, with a median age of 60 years (range, 49-71). 7 pts were in CR and 1 in CRi at the time of enrollment; 5 pts (63%) were in CR1, 2 pts (25%) were in CR2, and 1 pt (13%) in CR4 was inadvertently enrolled and treated on the trial. Baseline characteristics are outlined in Table 1. AML-related mutations detected at start of therapy include: IDH2 (n=2), NPM1 (2), TET2 (1), and DNMT3a. High risk features at the time of enrollment were as follows: 2 (25%) persistent MRD, 2 (25%) adverse karyotype, 1 (13%) adverse mutational profile, and 3 pts (38%) in CR2 or beyond. Pts have received a median of 4 (1 – 13) cycles of therapy. With a median followup of 6+ months (1 – 14), the 6- and 12-month estimated RFS were 88% and 73%, respectively. The 6- and 12-month estimated OS were 100% (Figure 1). The one patient who died was discovered to actually be in CR4. This patient relapsed approximately 8 months after achieving CR4. The regimen was well tolerated overall, with 4 pts having possible immune-related events. 1 patient had grade 3 pneumonitis leading to hypothyroidism, treated successfully with steroids and thyroid hormone supplementation, who continues on treatment. 1 patient had grade 4 transaminase elevation which responded to dose interruption and who continues on treatment (Table 1).

Summary/Conclusions: Nivo appears to be a feasible maintenance strategy in high-risk AML pts who are not candidates for SCT. The study continues to surpass the pre-specified expected rate of 6-month relapse-free survival of high-risk pts based on a historical cohort. Correlative studies profiling the immune repertoire of pts before and during treatment are being finalized and will be summarized.

P212

HIGHER EXPRESSION OF LONG NON-CODING RNA KIAA0125 IS ASSOCIATED WITH CHARACTERISTIC CLINICAL AND BIOLOGICAL FEATURES AND IS AN INDEPENDENT POOR PROGNOSTIC FACTOR IN ACUTE MYELOID LEUKEMIA

S.-Y. Hung1, C.-C. Lin1,2,3, H.-A. Hou1, W.-C. Chou1,2, H.-F. Tien1
1Division of Hematology, Department of Internal Medicine, 2Department of Laboratory medicine, National Taiwan University Hospital, 3Graduate Institute of Clinical Medicine, College of Medicine, National Taiwan University, Taipei City, Taiwan, Republic of China

Background: Long non-coding RNAs (IncRNAs) are non-protein coding RNAs longer than 200 nucleotides. Recently, a number of IncRNAs have been shown to play important roles in cancer biology. IncRNA KIAA0125 is one of the 11 genes in an expression signature significantly associated with prognosis in cytogenetically normal acute myeloid leukemia (AML) patients as shown in our previous report. It is also among another set of 17 leukemia stem cell (LSC) genes, identified through xenotransplantation model in NSG mice, which predict inferior treatment response in AML.

Aims: KIAA0125 gene is localized on chromosome 14q32.33; its functions remain unexplored. One study reported that it might be involved in neurogenesis including induction of astrocytosis, preventing formation of dopaminergic neurons. Another study showed that it could potentiate cell invasion and migration in gallbladder cancer. Its clinical significance in hematologic malignancies has not been explored yet. Since independent studies have reported KIAA0125 as an important gene for unfavorable prognosis, in this study we aimed to investigate its clinical relevance in AML.

Methods: We performed global mRNA arrays for bone marrow samples from 347 newly diagnosed de novo AML patients in the National Taiwan University Hospital, who had adequate cryopreserved cells and detailed demographic, clinical, and genetic data for analysis. The KIAA0125 expression level extracted from the array data was analyzed for its clinical relevance. We also validated our findings by analyzing the public databases of AML.

Results: The 347 patients were divided into two groups based on the median level of KIAA0125 expression on the arrays. Higher KIAA0125 expression was inversely associated with favorable karyotypes including t(8;21) and t(15;17). Patients with M1 by the French-American-British classification more frequently had higher KIAA0125 expression (p < 0.001), while those with M3 (acute promyelocytic leukemia) had significantly lower levels of KIAA0125 expression (p < 0.001). To investigate the association of gene mutations with KIAA0125 expression in AML, we analyzed mutations of 17 AML-associated genes. We found that patients with higher KIAA0125 expression had significantly higher incidence of FLT3-ITD (28.7% vs 19.7%, p=0.048), and mutations of RUNX1 (18.4% vs 10.4%, p=0.034), and DNMT3A (24.1% vs 13.9%, p=0.015), compared to those with lower KIAA0125 expression. Among the 227 patients who received standard chemotherapy, those with higher KIAA0125 expression had a lower complete remission rate (61.2% vs 84.7%, p < 0.001), and shorter overall survival (median OS, 23.7 months vs 116.8 months, p < 0.001) than those with lower KIAA0125 expression after a median follow-up of 57.0 months. The prognostic significance could be validated in another two independent cohorts, TCGA and GSE12417. In multivariate analyses, higher expression of KIAA0125 remained to be an unfavorable prognostic factor for OS independent of age, white blood cell counts, karyotype, FLT3-ITD, CEBPA double mutations,
RUNX1 mutation, MLL-PTD, WT1 mutation, and TP53 mutation (p=0.011).

Summary/Conclusions: Higher expression of KIAA0125 in AML patients was correlated with mutations of RUNX1, NMT3A, and FLT3-ITD but negatively associated with favorable karyotypes such as t(8;21) and t(15;17). Higher expression of KIAA0125 appeared to be an independent unfavorable prognostic factor in our cohort, and its negative prognostic impact could be validated in another two large independent cohorts of AML. The close association of KIAA0125 expression with LSC signatures might in part explain its unfavorable impact on the survival of AML patients.

P213
LEUKEMIC STEM CELLS CAN BE DETECTED IN A CONSIDERABLE PERCENTAGE OF PATIENTS WITH ACUTE MYELOID LEUKEMIA AT DIAGNOSIS AND IS A SIGNIFICANT PROGNOSTIC FACTOR

O. Pérez-López1,*, T. Caballero-Velázquez1, I. Álvarez-Laderas1, P. Hernández-Díaz1, A. M. Márquez-Mattio1, J. González-Campos1, R. Morales-Camacho1, C. Prats-Martín1, M.T. Vargas-de los Monteros1, R. Bernai-Ruíz2, J.A. Pérez-Simón1

1Virgen del Rocío University Hospital, Sevilla, Spain

Background: There is a growing interest on the identification of leukemic stem cells (SC) as a potential prognostic factor in patients with acute myeloid leukemia (AML). Several studies identify these cells as CD34+CD38-Lin- although there is a controversy about its phenotypic identification and prognostic value.

Aims: To identify SC in a cohort of patients with AML and evaluate their prognostic value in a series of newly diagnosed AML patients.

Methods: The presence of SC (CD34+CD38-Lin-) in bone marrow samples was prospectively evaluated in a consecutive series of 67 newly diagnosed AML patients by flow cytometry, between May 2013 and June 2016. All patients received intensive chemotherapy according to PETHEMA protocol. We evaluated response, relapse rate and overall survival (OS) and event free survival (EFS).

Results: Out of the 67 patients [34 men/33 women; median age 54 (0-78)], 58 (86.6%) have SC at diagnosis, 37.9% of them (n=22) achieved complete remission (CR) with a negative minimal residual disease (MRD) vs 77.8% (7/9) among patients without SC (p=0.03). Among patients who obtained CR with a negative MRD (n=29), no one suffer a leukemic relapse in the non SC vs 5/22 (22.7%) in the SC group (p=0.02). Considering the intermediate risk group according to cytogenetic/ molecular features, 100% of patients without SC at diagnosis achieve a negative MRD (5/15 vs 14/41; 34.1%) among those in the SC group (p=0.008). OS at 9 months was 89 vs 56% (p=0.043), and the EFS 78 vs 48% (p=0.054) in the non SC and SC group, respectively (Figure 1).

Figure 1.

Summary/Conclusions: SC can be detected in a considerable group of patients with AML at diagnosis. The presence of SC is a prognostic factor in terms of response, OS and EFS. Accordingly, SC detection could help to identify prognosis subgroup of patients with different prognostic among those in the intermediate risk group by genetics/molecular assays.

P214
POST-REMISSIONAL AND PRE-TRANSPLANT ROLE OF MINIMAL RESIDUAL DISEASE DETECTED BY WT1 IN ACUTE MYELOID LEUKEMIA: A RETROSPECTIVE COHORT STUDY

C. Frairia1,*, S. Aydin1, E. Audisio1, L. Riera2, S. Aliberti2, B. Allione3, R. Morales-Camacho1, C. Prats-Martín1, M.T. Vargas-de los Monteros1, R. Bernai-Ruíz2, J.A. Pérez-Simón1

1Virgen del Rocío University Hospital, Sevilla, Spain

Background: In acute myeloid leukemia (AML) the detection of residual leukemic cells at a submicroscopic level (minimal residual disease - MRD) is still under investigation. In about 30-40% of AML lacking a specific molecular target, quantitative real-time polymerase chain reaction (QRT-PCR) has been used to detect transcripts commonly overexpressed in AML. Among a large number of candidates, Wilms tumor gene 1 (WT1) has been proposed as a promising MRD marker.

After the standardization of QRT-PCR on behalf of the European LeukemiaNet (ELN), subsequent studies investigated the role of WT1 expression in AML with controversial results.

Aims: To assess the role of WT1 expression as a MRD marker after intensive induction chemotherapy and before allogeneic hematopoietic cell transplantation HCT (allo-HCT) in a large cohort of AML patients treated in a single institution.

Methods: The present retrospective cohort study included adult patients with untreated AML consecutively diagnosed between 2004 and 2014 in the Hematology Unit of the University-Hospital Città della Salute e della Scienza di Torino, Italy. The study was approved by the Ethical Committee and was registered at www.clinicaltrials.gov as NCT02714790. Among 255 enrolled patients, MRD was investigated in those in first complete remission (CR) with an available diagnosis and at two further time-points: after induction (n=117) and prior allo-HCT (n=65).

Results: Patients with baseline WT1 <250 copies were excluded. All patients underwent intensive induction chemotherapy with curative intent and subsequent consolidation chemotherapy according to the AML risk assessment (autologous peripheral stem cell transplantation for low risk and allo-HCT for intermediate and high risk patients). Effect of post induction WT1 expression on disease-free survival (DFS) and overall survival (OS) and of pre allo-HCT WT1 expression on relapse (CIR) were investigated.

Results: Baseline WT1 expression were not found significantly associated with demographical, clinical and disease biological features at diagnosis. Baseline BM WT1 expression lacked even to show an association with response to induction chemotherapy (CR 1.16; 95% CI 0.90-1.50, p<0.244).

OS and DFS were significantly shorter in patients in first CR with >350 WT1 copies after induction compared to those with ≤350 (OS 17 vs 95 months vs <150 copies; p=0.018 and 3-year DFS rates 15% vs 55% with a HR of 2.81; 95% CI 1.14-6.93, p=0.025).

Adding the BM WT1 in the model along with other factors determines an increase of the C-statistic from 0.696 to 0.7193 for OS (NR=0.384) and from 0.7413 to 0.7920 (NR=0.4037) for DFS. Before allo-HCT, patients with WT1 >150 copies (n=18) had a significantly higher CIR compared to those with WT1 ≤150 (n=47), HR 4.61; 95% CI 1.72-12.31, p=0.002.

Summary/Conclusions: The results of the present study showed that BM WT1 is associated with survival in patients in CR in two decisive time-point for treatment planning: after induction treatment and before allo-HCT. The prognostic role of WT1 resulted independent from other well-established risk factors. Therefore, WT1 may represent an additional MRD tool for risk stratification in patients nowadays classified in CR, especially in the high risk MRD positive subgroup which may have a role. Published evidences so far supported these suggestions, but mainly due to methodological issues, the role of WT1 is still a matter of debate. Perspective randomized studies are required to confirm these results.

P215
DIFFERENTIATION SYNDROME ASSOCIATED WITH ENASIDENIB (AG-221), A SELECTIVE INHIBITOR OF MUTANT ISOCITRATE DEHYDROGENASE 2 (MIDH2)

A.T. Fathi1,2,*, C.D. DiNardo 3, I. Kline4, L. Kenvin4, I. Gupta4, E.C. Attar5, E.M. Stein67, S. de Botton8

1Massachusetts General Hospital Cancer Center, 2Harvard Medical School, Boston, 3The University of Texas MD Anderson Cancer Center, Houston, 4Cellgene Corporation, Summit, 5Agios Pharmaceuticals, Inc, Cambridge, 6Memorial Sloan Kettering Cancer Center, 7Weill Cornell Medical College, New York, United States, 8Institut Gustave Roussy, Villejuif, France

Background: Enasidenib (AG-221) is an oral, selective, small-molecule inhibitor of miDH2 enzymes. Preclinical studies showed that exposing myeloblasts from patients (pts) with acute myeloid leukemia (AML) to enasidenib ex vivo resulted in differentiation of leukemic marrow blasts into mature, fully functional neutrophils (Yen et al, 2017). Enasidenib can inhibit 100 mg daily in a phase 1 dose-escalation and expansion study (NCT01915498). This dose is currently used in a多中心 multicenter, randomized, phase 3 trial comparing enasidenib with conventional care regimens in R/R AML pts (NCT02577406).
Methods: An independent Differentiation Syndrome Review Committee (DSRC) was formed to review potential cases of IDH-DS. The DSRC identified and agreed upon a series of signs and symptoms possibly characteristic of IDH-DS, including fever, lung infiltrates, pleural or pericardial effusions, rapid weight gain, edema, and azotemia. In all, 27 cases (8 of investigator-reported IDH-DS and 19 with characteristics suggestive of IDH-DS) were identified and retrospectively reviewed by the DSRC to determine their consistency with IDH-DS.

Results: The DSRC determined 13 cases (11.9% of 109 R/R AML pts in the enasidenib 100 mg/day dosing cohort) to be consistent with IDH-DS. Median time to onset was 30 days (range 7-116). Manifestations of IDH-DS in >2 pts were dyspnea (n=10), pyrexia (9), lung infiltrates (8), pleural effusion (5), and kidney injury (3). IDH-DS was effectively managed with systemic corticosteroids in 12/13 cases. Leukocytosis accompanied 4/13 cases, for which hydroxyurea was employed for cytoreduction. Enasidenib was interrupted for 9 pts (for a median of 7 days), but dose reductions or enasidenib discontinuation were not required for pts with IDH-DS. Six of the 13 pts had clinical responses (2 complete remissions [CR], 2 CRs with incomplete hematologic recovery, 1 partial remission, and 1 morphologic leukemia-free state), 6 pts had stable disease, and 1 pt had progressive disease.

Summary/Conclusions: Systemic corticosteroids, close hemodynamic management, and hydroxyurea (in the presence of leukocytosis) are effective IDH-DS management strategies; they should be administered promptly when IDH-DS is suspected, and continued until improvement. Enasidenib interruption can be considered if initial intervention is unsuccessful. IDH-DS represents a novel clinical finding in pts with mAML treated with enasidenib, and is likely due to its suggested mechanism of action, myeloblast differentiation.

Aggressive Non-Hodgkin lymphoma - 1st line

P217

OUTCOME OF PATIENTS WITH INTRAVASCULAR B-CELL LYMPHOMA, A RETROSPECTIVE STUDY CONDUCTED ON BEHALF OF THE LYMPHOMA STUDY ASSOCIATION GROUP

1Hematology, University Hospital Hôtel-Dieu, Nantes, 2Hematology, CHU, Montpellier, 3Hematology, La Pitié Salpêtrière APHP, Paris, 4Anatomopathology, University Hospital Hôtel-Dieu, Nantes, 5Hematology, CHU, Lyon, 6Hematology, Saint Antoine APHP, Paris, 7Hematology, CHU, Rennes, 11Hematology, CHU, Strasbourg, 12Hematology, Loire Cancerology Institute, Saint Etienne, 13Hematology, CHU, Clermont-Ferrand, 14Hematology, CHD, La Roche sur Yon, 15Hematology, CHU, Angers, 16Hematology, Hospital, Bayonne, 17Hematology, Polyclinic Bordeaux Nord Aquitaine, Bordeaux, 18Hematology, Hospital, Le Mans, 19Hematology, CHU, Limoges, 20Hematology, Paoli Calmette Institute, Marseille, 21Hematology, Catherine de Sienne Centre, Nantes, 22Hematology, Cancerology Centre, Mougins, 23Hematology, Hospital, Pau, 24Hematology, CHU, Tours, 25Anatomopathology, CHU, Lyon, 26Statistic, University Hospital Hôtel-Dieu, Nantes, France

Background: Intravascular large B-cell lymphoma (IVLBCL) is a rare type of extranodal large B-cell lymphoma characterized by the selective growth of lymphoma cells within the lumina of vessels, classically reported with poor responses to chemotherapy. Due to its low incidence and rarity of tumor cells, diagnosis of IVLBCL remains difficult and many issues remain unresolved, regarding both clinical features and therapeutic strategies.

Aims: Our work aims to describe clinical presentation and outcome of IVLBCL patients treated in French LYSA centers between 2000 and 2016.

Methods: All LYSA centers were asked to report and update clinical data about IVLBCL patients treated. No central pathology review was performed for the present study, but all cases were classified by LYSA pathologists. Local investigators reported disease characteristics and updated patients’ outcome (clinical examination, standard biological parameters, bone marrow biopsy, CT scan at baseline, CT response evaluation and outcome).

Results: We identify 65 IVLBCL patients treated in 23 LYSA centers during the studied period. Median age was 67.8 years (range 22-91). In note, two third of patients presented with IP3 score >3 (67%) and all patients had a stage IV disease. As expected in Western patients, cutaneous and CNS involvement were highly frequent, respectively 33% and 39%. But interestingly, hemophagocytic syndrome were observed in nearly half of the patients (41%), while it was mainly described in Asian series. Despite classically delayed diagnosis in IVLBCL, only 2 cases were confirmed post-mortem and almost all alive patients at diagnosis (n=58) were treated with rituximab-containing chemotherapy regimen (92%). Regarding first line treatment, 83% of patients were treated with anthracycline-based regimens, with CNS prophylaxis for half of them (47%), and seven patients underwent autologous stem cell transplantation upfront. The median progression free survival was 28.4 months and median overall survival was 63.8 months (Figure 1). Pathological features (including cell of origin characterization, C-MYC expression, adhesion protein expression level) investigation is ongoing and will be presented at the time of the meeting.

Figure 1.
Summary/Conclusions: The present study is the largest European IVLBCL series. It shows that despite the use of modern immune-chemotherapy, IVLBCL remains an aggressive lymphoma entity. In particular, these patients are highly exposed to early relapse and therefore should be considered for innovative frontline therapies.

P218

OUTCOME OF ELDERLY DLBCL PATIENTS (≥80 YEARS) TREATED WITH ANTHRACCYLINE BASED CHEMOTHERAPY: R-CHOP DOSE REDUCTION IS NOT NECESSARY FOR EVERYBODY

1Charles University Hospital, Prague, 2University Hospital, Brno, 3University Hospital, Hradec Kralove, 4University Hospital, Olomouc, 5University Hospital Kralovske Vinohrady, 6CLSG Data Center, Prague, 7University Hospital, Pilsen, 8University Hospital Motol, Prague, Czech Republic

Background: Management of elderly patients (above ≥80y) is difficult and only limited number of patients could be treated by curative approach with anthracyline based chemotherapy. Dose reduction of particular drugs is used very often and it varies based on pts characteristics and center preferences. There is however lack of randomized or at least non-randomized historical comparisons.

Aims: The objective of this study is to analyze elderly DLBCL patients prospectively registered in NiHL Lymphoma Project and treated anthracyline based regimen in real world outside of clinical trials.

Methods: Patients (pts.) with informed consent are prospectively followed in multicenter Lymphoma Project since 1999. Diagnostic, therapeutic and follow up data are prospectively collected. There were 399 DLBL pts older than 80year diagnosed in period 1999-2014 identified. Among 372 pts. with pathology review and essential data there were 112 pts. (30.1%) treated with R-CHOPlike chemotherapy. Analysis of clinical prognostic factors, therapy and toxicity was performed. Pearson, Kaplan-Meier and log rank tests were used.

Results: Median age was 81 years (80-88), 51.8% of men. Proportion of pts ≥85 was 14.3%, with PS ≥2 (ECOG) 34.0%, with higher LDH 64.3%, with high or intermediate high IPI 49.1%, with bulky disease (≥10 cm) 17.0%, with lower albumin 27.7%, with Charlson Comorbidity Score (CCS) ≥25%. According to treatment choice of physician (intent to treat), pts. could be divided into 3 groups R-CHOP (CHOPlike chemotherapy). Analysis of clinical prognostic factors, therapy and toxicity was performed. Pearson, Kaplan-Meier and log rank tests were used.

Summary/Conclusions: According to treatment choice of physician (intent to treat), pts. could be divided into 3 groups R-CHOP (CHOPlike chemotherapy) – A - 50 mg/m2) or R-MiniCHOP (miniCH) (CF 400 mg/ m2, A 25 mg/m2, Peyrade 2011) or modified R-CHOP (modiCH) (CF 750 mg/m2 and A 25 mg/m2) for any other dose between CHOP and miniCHOP. There were 21 pts (15.8%) treated with CH, 38 (33.9%) with miniCH and 53 (47.3%) with modiCH. There were no significant differences between the subgroups, except higher proportion of bulk in modiCH vs miniCH and CH (35% vs 12.9% vs 7.7% resp.; p 0.04) and cardiac comorbidity (60.5% vs 33.3% vs 30.2% resp.; p 0.02). Six and more cycles were administered in 71.4%, 63.1% and 58.5% pts. in CH, miniCH and modiCH resp. Following proportion of pts. received >80% (>50%) of original CHOP dose. For cyclophosphamide it was 66.7% (81%), 0% (50%) and 62.2% (79.2%) resp. and for A it was 57% (76.1%), 2.6% (15.8%) and 13.2% (49%) resp. for CH, miniCH and modiCH resp. There were observed 11 treatment related deaths (6 cardiac toxicity and infection), 5 in miniCH and 6 in modiCH groups. The overall response rate was 76.8% with 58.9% CR/CRu. Median PFS and OS were 2.8y and 4.6y vs 3.5y vs 0.8 y. There was numerically (not significantly) better OS median for R-CHOP (4.6y) vs R-miniCHOP (3.2y) and R-modiCHOP (2.9y) (Figure 1B).

Figure 1.

Summary/Conclusions: Only one third of elderly DLBCL pts (≥80y) is treated with anthracycline based regimen. Performance status, albumin and beta2microglobulin levels were significantly associated with prognosis. In minority of these pts full dose of R-CHOP could be safely used and there is trend to better overall survival. Supported by AZV 16-31092A.

P219

IMPROVED SURVIVAL IN PRIMARY CENTRAL NERVOUS SYSTEM LYMPHOMA UP TO AGE 70 ONLY: A POPULATION-BASED STUDY ON INCIDENCE, PRIMARY TREATMENT AND SURVIVAL IN THE NETHERLANDS, 1989-2015

A. Dinnohamed1,2,3,4, M. van der Meulen4, O. Visser2, J. Doorduin3, J. Bromberg4

1Research, Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht, 2Public Health, Erasmus University Medical Center, 3Hematology, 4Neuro-oncology, Erasmus MC Cancer Institute, Rotterdam, 4Registration, Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht, Netherlands

Background: PCNSL is a rare, aggressive form of an extranodal non-Hodgkin lymphoma that exclusively affects the CNS. Recent findings from the few available prospective studies demonstrated improved outcome in PCNSL. However, the results from such studies are inherent to patient selection. Population-based studies that assess long-term patterns of incidence, treatment and survival in PCNSL are virtually lacking.

Aims: The aim of this comprehensive nationwide population-based study was to assess trends in incidence, primary treatment and survival among adult PCNSL patients (pts) diagnosed during a 27-year period in the Netherlands.

Methods: We selected all adult (≥18 years) pts diagnosed with PCNSL of the diffuse large-B-cell type in the Netherlands between 1989-2015 from the nationwide Netherlands Cancer Registry with survival follow-up through February, 2016. Pts diagnosed without pathological or cytological confirmation (n=50) and pts diagnosed at autopsy were excluded (n=32). Age-standardized incidence rates (ASIR) were calculated per 1,000,000 person-years and standardized according to the European standard population. Data on primary treatment (i.e. no therapy, chemotherapy (CT) alone, radiotherapy (RT) alone, and CT+RT) were available for individual pts. Pts were categorized into 4 periods (1989-1994, 1995-2000, 2001-2007 and 2008-2014) and 3 age groups (18-60, 61-70 and >70 years). We calculated relative survival (RS) and the relative excess risk of mortality as measures of disease-specific survival.

Results: We included a total of 1,673 newly diagnosed PCNSL pts in the study (median age, 65 years; age range, 19-89 years; 53% males). The ASIR of PCNSL increased from 3.0 in the first period (1989-1996) to 4.4 in the last period (2009-2015), which was consistently higher among males than in females throughout the entire study (4.8 vs 4.0 in the last period). The age-specific incidence rates were 2.3, 9.0 and 10.9 in the first period for the three age groups (18-60, 61-70 and >70 years), as compared with 2.7, 18.7 and 19.5 in the last period. The application of CT+RT increased exclusively among pts age 18-60. More specifically, the proportions for the three age groups were 26, 18 and 4% in the first period, as compared with 60, 10 and 4% in the last period. The use of RT alone among pts age >60 decreased with each period, following the wider use of CT alone over time, especially for pts age 61-70 years. The proportions of CT alone for the three age groups were 11, 8 and 2% in the first period, as compared with 31, 64 and 32% in the last period. Of note, 38 and 26% of pts age >70 received no therapy, chemotherapy (CT) alone, radiotherapy (RT) alone, and CT+RT were available for individual pts. Pts were categorized into 4 periods (1989-1994, 1995-2000, 2001-2007 and 2008-2014) and 3 age groups (18-60, 61-70 and >70 years). We calculated relative survival (RS) and the relative excess risk of mortality as measures of disease-specific survival.

Figure 1.

Summary/Conclusions: The incidence of PCNSL steadily increases among
PT20

CLINICAL CHARACTERISTICS AND LONG-TERM RESULTS OF TREATMENT OF DIFFUSE LARGE HEPATITIS C-ASSOCIATED NON-HODGKIN LYMPHOMA (DLBCL+C)

1Russian National Research Medical University named after N.I. Pirogov, 2National Research Center for Haematology, 3National Research Center for Oncology named after N.N. Blochin, 4City Clinical Hospital named after C.P. Botkin, 5City Clinical Hospital named after V.M. Buyanov, Moscow, Russian Federation

Background: In the WHO classification (2008), hepatitis C virus distinguishes as one of the etiological factors of multistage etiopathogenesis DLBCL.

Aims: The purpose of this study was an evaluation of clinical features and results of treatment of diffuse krepnokletochnoy lymphoma associated with hepatitis C in comparison with a control group of patients with diffuse large lymphoma without viral hepatitis markers.

Methods: It was included 521 patients with DLBCL: 98 patients with DLBCL and markers of hepatitis C (DLBCL+C) and a control group of 422 patients with DLBCL without markers of hepatitis C (DLBCL-C).

Results: Patient’s age ranged from 21 to 76 years (median was 47 years) in DLBCL+C; ranged from 23 to 81 years (median 61) in DLBCL-C (p=0.02). The male:female ratio was 1:1.3 in patients with DLBCL+C; 1:1.7 in the group DLBCL-C. Stage I and II were in 11% patients with DLBCL+C; and 48% patients with DLBCL-C; III and stage IV were detected in 89% patients with DLBCL+C and 52% of DLBCL-C(p=0.00002). Extranodal lesions detected in 72% in DLBCL+C and in 26% in C DLBCL-C (p=0.006). In comparable groups localization of extranodal lesions was: spleen (52% to 23%), bone marrow involvement (43% and 27%), liver involvement (36% and 64%) in DLBCL-C; 36% and 64% in DLBCL-C. Hepatitis C virus RNA in blood was detected by PCR. Viral RNA was found in 78% (74 patients). High viral load was in 21% of patients. In 22% of cases markers of hepatitis C virus in blood were identified by ELISA. All patients received chemotherapy according to the scheme CHOP/R-CHOP. The frequency of complete remission was 60% in the group of patients with DLBCL+C and 63% of DLBCL-C. Median overall survival (OS) was 46 months in group DLBCL+C and 71 months in DLBCL-C (p=0.0003).

Median progression-free survival (PFS) was 28 months in DLBCL+C 47 months in the control group (p=0.0002). According to the immunohistochemical variant of DLBCL-C Group A was in 19% of cases in DLBCL+C; 11% in controls. Group B was in 24% in DLBCL+C and 73% in controls (p=0.00002). In the comparison group of patients with markers of hepatitis C in the group DLBCL +C and in controls the difference was statistically significant (p=0.0002). GCB non-GCB histological variants ratio was 55%/45% in DLBCL-C; 36%/64% in DLBCL-C group (p=0.001). Hepatitis C virus RNA in blood was detected by PCR. Viral RNA was found in 78% (74 patients). High viral load was in 21% of patients. In 22% of cases markers of hepatitis C virus in blood were identified by ELISA. All patients received chemotherapy according to the scheme CHOP/R-CHOP. The frequency of complete remission was 60% in the group of patients with DLBCL+C and 63% of DLBCL-C. Median overall survival (OS) was 46 months in group DLBCL+C and 71 months in DLBCL-C (p=0.0003).

Conclusion: The study is a prospective, clinical, single-centre study. The study aims to include 70 consecutive chemotherapy-naive lymphoma patients scheduled for intended curative chemotherapy without planned mediastinal radiation therapy. All patients undergo routine clinical examinations, but with supplementary imaging, including 1) baseline 82Rb PET and MR (prior to treatment); 2) acute 82Rb PET and MR (within 1 week of the first treatment); 3) subacute 123I-MIBG (after 2-3 months of therapy) and (4) late MR (1 year after the start of treatment). 82Rb PET imaging is performed at rest and during pharmacological stress testing with adenosine. It is primarily used to evaluate the acute effects of doxorubicin on myocardial perfusion. 123I MIBG is used for detection of doxorubicin-induced subacute changes in the myocardial adrenergic neurons. Cardiac MR is performed with late gadolinium enhancement and provides information on acute and late changes in left ventricular, atrial and ventricular volumes, myocardial mass and interstitial fibrosis. Statistical analyses were done in R (version 3.2.0) as paired difference tests using Wilcoxon signed rank test. P-values <0.05 were considered significant.

Results: As of March 1st 2017, 61 patients have been included. In 33 cases, the time of intended follow-up has been reached. Four patients died prior to follow-up, including one patient who died before the acute imaging procedures. Four patients were excluded due to compliance problems. One patient was excluded due to disease downstaging resulting in omission of doxorubicin from the treatment plan. Of the 24 patients with complete data from both the baseline and late MR scans, 16 had lower LVEF values at follow-up: 0-5% (n=3), 6-10% (n=8), 10-15% (n=4) and >20% (n=1). Mean LVEF at follow-up was significantly lower (57.1%) compared to baseline LVEF. (62.0%; p<0.01) and acute LVEF (64.3%; p<0.002). The LVEF decline from baseline to follow-up was paralleled by an increase in mean left ventricular end diastolic volume (LVEDV) of 10.0ml (p=0.03). Interestingly, an increase in LVEDV was already registered at the acute MR scan (7.3ml; p<0.03). The increase in LVEDV from the acute MR to follow-up was not significant. We also registered an acute increase of 7.4ml in mean stroke volume (SV) (p<0.02). However, from the acute MR to follow-up we found a significant decline in SV (p<0.02). There was no difference in SV from baseline to follow-up (p=0.7). The acute changes in LVEDV did not predict LV EF declines from baseline to follow-up (Figure 1).

Figure 1.

Summary/Conclusions: Our preliminary show that cardiac MR can be used for detection of declining LV function 1 year after after doxorubicin exposure. It appears that cardiac MR may also provide information on acute functional changes in LVEDV and SV. We hope that our 82 Rb PET and 123I MIBG data will provide additional early signs of doxorubicin cardiodotoxicity that can be used to predict subsequent development of HF.
Background: We conducted this clinical trial to address the efficacy and safety of our regiment for newly diagnosed stage IV (n=49) and relapsed (n=11) ENKTL from 2010 to 2016. The median age at recruitment was 38 years and the median follow-up period was 13.4 months. Patients were treated with GLIDE (gemcitabine 800 mg/m2 D1, L-asparaginase 6000 U/m2 D1, L-asparaginase 6000 U/m2 D4,D8,12 or peg-asparaginase 2500 u/m2 D4,11; ifosfamide 1000 mg/m2 D1-3; dexamethasone 20mg D1-4; etoposide 100 mg/m2 D1-3) every 4 weeks, and responses were evaluated with PET/CT every 2 cycles. Patients achieving CR underwent ASCT or continued with GLIDE up to 6 cycles. Others finished 6 cycles of GLIDE. Overall response rate (ORR), CR, OS and progression free survival (PFS) were calculated using standard methods. Statistical analysis was done using Fishers exact test or Chi-square test / Kruskal-Wallis test. Kaplan-Meier method was used for time-to-event analysis including overall survival and progression free survival. The Log-rank test was used to evaluate the difference in time-to-event endpoints between patient groups.

Results: Fifty-seven patients had finished planned treatment with 1 withdraw of informed consent after cycle 1, and 2 death of sepsis during cycle 1 and cycle 2 respectively. Twenty-one patients underwent ASCT. The ORR was 81.4% and the CR was 69.5% with early CR (CR after 2 cycles) of 57.6%. Estimated 5-year OS and PFS rates of the whole cohort and patients underwent ASCT were 68.7%, 54.0%, 79.6% and 85.2% respectively. Univariate analysis revealed that ECOG ≤1, IPI≤2, early CR and ASCT were associated with less relapse and death. Multivariate analysis showed ECOG ≥2 was an independent risk factor for disease progression (HR=4.321, 95% CI 1.127–16.572, P=0.033) and death (HR=4.265, 2.150–993.190, P=0.014) and ASCT was associated with better OS, PFS and DFS (HR=0.058, 95% CI 0.007–0.495, P=0.009) and OS (HR=0.019, 95% CI 0.001–0.596, P=0.024). Figure 1 highlights the OS and PFS of whole cohort (A) and ASCT patients (B). Myelosuppression was the most common adverse reaction (AE). The incidences of level 4 neutropenia, thrombocytopenia and anemia were 46.6%, 28.6% and 5.3% respectively. The most common non-hematologic AE was fever with neutropenia (36.8% of total cycles), while others were mild and manageable.

Summary/Conclusions: GLIDE is an effective regimen for newly diagnosed stage IV and relapsed ENKTL. Up-front ASCT after achieving CR can reduce relapse and prolong survival. Treatment related adverse reactions and support care need concerns.

Bone marrow failure syndromes incl. PNH - Biology

P226
IDENTIFICATION OF A NOVEL GERMLINE MECOM / EV1 VARIANT THAT RUNS IN A PEDIGREE WITH RADIULNAR SYNOSTOSIS AND AMEGAKARYOCYTIC THROMBOCYTOPENIA AND PREDISPOSES TO ADULT ONSET MYELOID MALIGNANCY

T. Ripperger1,2,3, W. Hofmann1, J.C. Koch1, K. Shireeshan3, H. Haase3, G. Wull3, P.R. Issing4, M. Karnebogen5, G. Schmidt1, B. Auber1, B. Schlegelberger1, T. Illig1,2,4, B. Zirm5, D. Steiennann1

1Department of Human Genetics, Hannover Medical School, Hannover, 2Department of Neurology, 3Department of Hematology and Oncology, University Medical Centre, Goettingen, 4Department of Orthoholymphology, Head, Neck and Facial Plastic Surgery, Klinikum Bad Hersfeld, Bad Hersfeld, 5Healthpark Lengern, Division of Surgery and Orthopedics, Bovenden, 6Unified Biobank, Hannover Medical School, Hannover, 7Genetic Counseling and Diagnostics, Genetikum, Stuttgart, Germany

Background: Radioulnar synostosis and amegakaryocytic thrombocytopenia (RUSAT), one of the rare bone marrow failure syndromes, is caused by a point mutation in HOXA11. In three simplex patients, de novo missense variants in MECOM have recently been reported as an alternative cause in individuals with RUSAT. MECOM, identified as a common ecotropic viral integration site 1 (EV1) in murine myeloid leukemia, is known as a key transcriptional regulator in hematopoiesis and is frequently involved in sporadic myeloid leukemia.

Aims: To screen for the causative genetic alteration in a family with four affected individuals out of three generations with radioulnar synostosis, incompletely penetrant congenital thrombocytopenia, hearing impairment due to dysplastic middle ear bones, patellar hypoplasia, and hand and foot dysmorphisms. Notably, two of four affected individuals in our family developed adult onset myeloid malignancies (i.e. myelodysplastic syndrome (MDS) with excess blasts and MDS/myeloproliferative neoplasm-unclassifiable). No HOXA11 mutation was identified in this family.

Methods: Whole exome sequencing was performed in three affected individuals using a Nextera Rapid Capture kit and a NextSeq 500 instrument (Illumina, Munich, Germany). Identified sequence variants were filtered for those that are de novo by carrier analysis. In all three subjects, it was decided to be diagnostic of MECOM. Autosomal dominant inheritance was assumed and the following filter criteria were applied: (i) presence in both affected family members and two of the four affected individuals; (ii) not being a known variant (gVCF, 1000G, ESP6500, ExAC), and (iv) not listed in our in-house database of recurrent variants.

Results: Following this approach, a novel MECOM missense variant (i.e. Cys766Gly, UniProtKB Q03112-1) was identified. The missense mutation affects a heavily conserved cysteine residue in C2-H2-zinc finger motif 9 in the C-terminal zinc finger domain of MECOM. This residue is crucial for the tetrahedral coordination of a zinc ion stabilizing the zinc finger conformation and thus, is essential for DNA binding of the C-terminal zinc finger domain.

Summary/Conclusions: Our findings confirm the causality of MECOM missense mutations targeting the C-terminal zinc finger domain in subjects with RUSAT and indicate that MECOM needs to be considered in RUSAT pedigrees with no HOXA11 mutation. We report here for the first time that MECOM germline mutations are associated with an increased risk for adult onset myeloid malignancies. This extends the RUSAT-associated phenotype and proposes that MECOM germline mutations can cause a genetic predisposition to adult onset myeloid malignancy.

[BZ and DS contributed equally to this work].
generated by ENU mutagenesis were characterized in terms of their hematopoietic and non-hematopoietic phenotypes during embryonic development and adulthood.

**Results:** The rad51f mutant fish developed key features of FA, including hypocellular kidney marrow (equivalent to mammalian bone marrow), sensitivity to crosslinking agents and decreased size. Interestingly, although mutants can survive to adulthood, they develop exclusively as sterile males. We show that some of the hematological symptoms stem from both decreased proliferation and increased apoptosis of embryonic hematopoietic stem and progenitor cells. Co-mutation of p53 was able to rescue the embryonic and adult hematopoietic defects seen in the single mutants, but led to early tumor development in the adult double mutants. We further establish that prolonged inflammatory stress can exacerbate the hematological impairment, leading to an additional decrease in kidney marrow cell numbers linked to excess p53 expression (Figure 1).

![Figure 1. Example image of a p53, rad51 double mutant fish with a tumor behind the eye (A). Histological analysis showed the tumour to be a malignant peripheral nerve sheath tumor (B). The scale bar is 500 and 10μm respectively.](image)

**Summary/Conclusions:** We demonstrate that zebrafish lacking functional rad51f can be viable and develop symptoms resembling FA. These findings strengthen the assignment of RAD51F as a Fanconi gene and provide more evidence for the notion that aberrant p53 signaling during embryogenesis leads to the hematological defects seen during later stages of life in FA patients. Further research on this novel zebrafish FA model will lead to a deeper understanding of the molecular basis of bone marrow failure in FA and the cellular role of the RAD51F protein.

**A NOVEL TELOMERASE RNA COMPONENT VARIANT IN A FAMILY WITH MACROCYTOSIS AND MILD VARIABLE CYTOPENIAS**

C. Burney1,2, A. Mumford2, N. Roy3, A. Schuh3, M. Proven3, A. Mumford2, N. Roy3

1Department of Haematology, University Hospitals Bristol NHS Trust, 2School of cellular and molecular medicine, University of Bristol, Bristol, 3BRC Blood Theme and BRC/NHS Translational Molecular Diagnostics Centre, John Radcliffe Hospital, 4Molecular Haematology Unit, Weatherall Institute of Molecular Medicine, John Radcliffe Hospital, Oxford, United Kingdom

**Background:** Telomerase RNA component (TERC), encoded by the TERC gene, is an essential component of telomerase, a polymerase that adds the telomeric repeat to the 3’ lagging strand of DNA during cell replication. TERC variants have been causally associated with several hematological disorders, including autosomal dominant dyskeratosis congenita (DKC), aplastic anaemia, myelodysplastic syndrome and acute leukaemia, sometimes accompanied by non-hematological phenotypes. In order to determine the pathogenicity of this variant, telomere lengths were assessed and found to be short in both Case I.1 and II.2 (Table 1). There were no other likely pathogenic variants in the Oxford Red Cell Panel genes. Together, these observations suggest that the n.181A>C substitution is causally associated with the macrocytosis phenotype.

**Summary/Conclusions:** This report demonstrates a likely causal association between a newly identified TERC variant, short telomere length and a relatively mild hematological phenotype that is largely restricted to red cells. This emphasizes the phenotypic heterogeneity associated with TERC variants, justifies the rationale of screening multiple genes simultaneously and suggests that TERC variant could potentially underlie a broader range of unexplained heritable blood cell abnormalities.

**GENERATION OF X-LINKED DYSKERATOSIS CONGENITA-LIKE HUMAN HEMATOPOIETIC STEM CELLS**

C. Carrascoso1,2, H.A. Zittersteijn1,2, L. Pintado-Berniches3, M.L. Lozano1,2, L. Sastre3, J.A. Buener1,2, R. Perona23, G. Guenchea1,2

1Division of HematoPOietic Innovative Therapies, Centro de Investigaciones Estructurales Medicinales (CIBMED and CEBARMAT) and Instituto de Investigación Sanitaria Fundación Jiménez Díaz (IIS-FJD/UAM), 2Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), 3Instituto de Investigaciones Biomédicas Alberto Sols (CSIC/UAM), Madrid, Spain

**Background:** X-linked Dyskeratosis congenita (XDC) is an inherited syndrome caused by mutations in the DKC1 gene that encodes for the dyskerin nucleolar protein. These mutations reduce the telomerase activity leading to premature telomere length attrition. Several organs can be affected in these patients, although the bone marrow failure (BMF) is the main cause of death in XDC patients. Other mutations have also been causally associated with telomere shortening and a more severe hematopoietic phenotypic spectrum. These mutations may cause an early onset of clinical symptoms, and there is an urgent need for new treatments that could delay the onset of BMF. Since hematopoietic stem cells (HSCs) are the building blocks of the hematopoietic system, they must be studied to develop new therapeutic strategies for XDC patients.

**Methods:** In this study, we generated functional hematopoietic stem cells (HSCs) in vitro from XDC patients using the human umbilical cord blood (HUCB) as a source of HSCs. We used the plasmid pCMV-hTERT to overexpress telomerase reverse transcriptase (TERT) in the HUCB cells, and we also used the plasmid pCMV-hDKC1 to overexpress dyskerin. After transfection, the HUCB cells were cultured under conditions that promote hematopoietic cell differentiation. We then isolated the HSCs from the differentiated cells and characterized their hematopoietic potential.

**Results:** We were able to generate functional HSCs from XDC patients using the plasmids pCMV-hTERT and pCMV-hDKC1. The HSCs showed normal hematopoietic differentiation potential, and we were able to generate all hematopoietic lineages. We also observed an increase in the telomere length of the HSCs, which was consistent with the overexpression of TERT and DKC1.

**Summary/Conclusions:** This study demonstrates the potential of using gene therapy to generate functional HSCs from XDC patients. This approach could provide a new therapeutic strategy for XDC patients and may lead to the development of new treatments for other hematopoietic disorders.
Aims: Because of the difficulties associated to the use of primary HSCs from DC patients for experimental studies, this study was focused on the generation of X-DC-like human HSCs by flow cytometry. The generated X-DC-HSCs showed an inhibited telomerase activity, as well as a reduced clonogenic and hematopoietic reconstitutuion potential in NSG mice. Additionally, an increase in DNA damage and senescence was observed in DKC1-interfered CD34+ cells.

Methods: CD34+ cells were obtained by immunomagnetic purification from healthy human umbilical cord blood samples. The generated X-DC-HSCs were then selected for 2 days with puromycin, and cultured in vitro or transplanted into immunodeficient NSG mice to evaluate the effects of shRNAs.

Results: Based on the inhibition of DKC1 gene expression, 3 shRNAs were selected among 7 designed shRNAs. Interted HSCs showed an inhibited telomerase activity, as well as a reduced clonogenic and hematopoietic reconstitutuion potential in NSG mice. Additionally, an increase in DNA damage and senescence was observed in DKC1-interfered CD34+ cells.

Summary/Conclusions: In vitro and in vivo data obtained from DKC1-interfered X-DC-HSCs suggested that these cells will be useful in the study of primary X-DC-HSCs. The generation of X-DC-like HSCs will facilitate the understanding of the molecular basis of the HSCS defects characteristic of X-DC and contribute to the development of new experimental therapies for the treatment of the BMF of X-DC patients.

P230 STUDY OF EXTRACELLULAR VESICLES ROLES IN THE PATHOPHYSIOLOGY OF THROMBOSIS IN PAROXYSMAL NOCTURNAL HEMOGLOBINURIA PATIENTS DURING ECUILIZUMAB TREATMENT: A PILOT PROSPECTIVE LONGITUDINAL CLINICAL STUDY

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a disease characterized by complement-mediated hemolysis (Brodsky et al., Br J Haematol, 2004; Hugel et al., Blood, 1999). Eculizumab, a human anti-C5 monoclonal antibody, used in the treatment of PNH seems to decrease the thrombosis frequency (relative reduction of 85% of thromboembolic event rate with the introduction of the treatment in the patients) (Hillmen et al., Blood, 2007; Kelly et al., Ther Clin Risk Manag, 2009; Weitz et al. Thromb Res, 2012; Al-Jafar et al. Hemato Rep, 2015).

Aims: The general purpose of this project is a better understanding about the role of EVs in thrombosis in the context of PNH patients under eculizumab. We aimed to study whether eculizumab can modulate EV production and on their procoagulant activity, in order to check, if the antithrombotic activity of the eculizumab could be in part explained by its interaction with the EVs.

Methods: We conducted a pilot prospective open label longitudinal clinical study with six PNH patients treated with eculizumab. The study was led according to the Declaration of Helsinki and approved by the local Ethics Committee. Informed consent was obtained for each patient. The aim was to measure, by flow cytometry, the production of EVs in patient’s platelet-free plasma (PFP) before the start of eculizumab, after 4 weeks and after 11 weeks of treatment. We also assessed the procoagulant activity in PFP by STA®-Procoag-PPL assay and by thrombin generation assay (TGA). A more sensitive version of TGA was also performed to study the procoagulant profile induced by the EVs (use of EVs pelleted from PFP). We used mixed-effects linear regression for flow cytometry results. We compared the results after 4 weeks or 11 weeks of treatment against the inclusion value.

Results: We observed a decrease in platelet EVs with the eculizumab treatment (p<0.05). STA®-Procoag-PPL assay showed a decrease of the procoagulant profile induced by procoagulant phospholipids (PL) with the treatment. These results were not confirmed by TGA on PFP, due to a lack of sensitivity. By this way, we performed a more sensitive version of TGA that allows to observe variation in the procoagulant profile induced by the EV with the eculizumab (p<0.05).

Summary/Conclusions: Eculizumab has an impact on the amount and the procoagulant profile induced by the procoagulant PL and the EVs. The anti-thrombotic performance of the eculizumab can be in part explained by its action on EVs.

P231 TELOMERE LENGTH SCREENING TRIGGERED BY CLINICAL SUSPICION FOR CLASSICAL AND/OR CRYPTIC DYSKERATOSIS CONGENITA – PROSPECTIVE RESULTS FROM THE AACHEN TELOMEROPATHY REGISTRY

F. Beier1,*, M. Kirschner1, A.-S. Bouillon1, I. Halfmeyer1, M.S. Ventura Ferreira1, S. Giammarco1,*, S. Simona2, C. Dufour3, R. Peffault de Latour4, G. Socie5, J. Passweg6, A. Baigalupoi1

1Hematology, Università Cattolica del Sacro Cuore, Rome, 2Hematology, University of Florence, 3Department of Medicine and Surgery, University of Pisa, 4Hematology, Hôpital Saint-Antoine, AP-HP, Paris, 5Hematology, Hôpital Necker-Enfants Malades, Assistance Publique - Hôpitaux de Paris, 6Hematology, University Hospital Regensburg, Regensburg, Germany

Background: Classical Dyskeratosis Congenita (DKC) is a multisystem disorder caused by defective telomere maintenance, mostly due to mutations in genes related to functional activity of telomerase or accessibility of the telomeres themselves. Clinical characteristics are mucocutaneous abnormalities, bone marrow failure, an increased predisposition to cancer and other variable features. While classical DKC is typically diagnosed in childhood or adolescence, the incidence of cryptic DKC variants typically presenting with a clinically more heterogeneous picture within the spectrum of bone marrow failure, is currently unknown. The prevalence of DKC in the general population is unknown. Accelerated shortening of Telomere length (TL) in peripheral blood leukocytes represents the functional read-out of altered telomere maintenance and thus allows for a screening of patients with suspected DKC. On the basis of TL measured below the 1% percentile of age adjusted healthy controls, next-generation-sequencing (NGS) analysis for underlying mutations was triggered.

Aims: In this study, we report the first results of such a clinical routine screening for telomeropathies carried out within the Aachen Telomeropathy Registry (ATR).

Methods: 184 patients from 52 participating centers (80% academic centers) within Germany, Austria and Switzerland were screened for premature telomere shortening and included with informed consent into the ATR since November 2014. Inclusion criteria and reason for screening was either the clinical suspicion of the treating physician for a telomere maintenance disorder and/or the recommendations of the German Society of Hematology and Oncology (DGHO) published via Onkopedia. TL analysis of peripheral blood granulocytes and lymphocytes was carried out using combined fluorescence in situ hybridization and flow cytometry (flow-FISH). Mutations in genes suspected to cause telomeropathies (i.e. TERT, TERC, DKC1, NOP10, NHP2, US2, TERT, RTLE1, TIN2, TCAB1) were analyzed by NGS using customized primer panels and amplicon-based sequencing on a Miseq sequencer (Illumina) in all patients with TL in lymphocytes below the 1% percentile of healthy controls.

Results: Underlying initial diagnosis by the treating physician for screening was aplastic anemia (AA, n=72, 39% of cases), unexplained cytopenia (UC, n=66, 36%), myelodysplastic syndrome (MDS, n=34, 18%), atypical squamous cell carcinoma of the head-and-neck (SCCHN, n=10, 6%), paroxysmal nocturnal hemoglobinuria (PNH, n=9, 5%), acute myeloid leukemia (AML, n=5, 3%) as well as other disorders (e.g. lung fibrosis, Dragon-Blackfan-Anemia, LGMD, etc.). Median age at diagnosis was 57.0 (range 1.5 to 88) years. TL screening revealed 20% (38/184) patients with lymphocyte TL and 16% (30/184) of patients with granulocyte TL below the 1% percentile. NGS screening identified typical mutations associated with altered telomere maintenance in 15 out of 38 patients (40%) representing 8.2% of the total patient population. Median age of patients with mutations was 45.0 y (range 21 to 68 y). 12 of 20 patients with mutations were detected in RTLE1 (n=3), TERC (n=6), TERT (n=2), DKC1 (n=3). Mutations were observed in 5% of all AA, 12% of all UC, 50% of all MDS, 13% of all SCCHN, 20% of all screened AML patients.

Summary/Conclusions: We provide the first analysis of a routine TL screening that started in the Aachen Telomeropathy Registry in patients up to the age of 88 y. TL screening is feasible in a routine clinical setting identifying approximately 20% of all samples to reside below the 1% percentile. Genetic testing confirmed the diagnosis of cryptic DKC in a variety of initial diagnoses. This study highlights both the diagnostic value of TL screening for cryptic DKC as well as the importance of comprehensively underlined patients. Preliminary mapping of DKC however is of utmost importance given its significant clinical implications towards prognosis, treatment and family counseling.
versità Cattolica del Sacro Cuore, roma, 1Hematology, Istituto Giannina Gaslini, Genova, Italy, 2Hematology, Hôpital St Louis, 3Hematology, Hôpital Saint-Louis, Paris, France, 4Hematology, Universitätsspital Basel, Basel, Switzerland

Background: Mortality following HSCT in SAA pts over the age of 40 is reported to be in the order of 50%, without taking in to account long term sequelae such as chronic GvHD, known to be more frequent in older patients. This has prompted international guidelines to recommend first line immunosuppressive therapy above 40 years of age. The question is whether this is still true in 2017.

Aims: Assess whether TRM in SAA patients grafted 2010-2015 is reduced, as compared to the era 2001-2009.

Methods: We used the WPSAA-EBMT registry, and identified 748 pts aged 40 years or more, with acquired SAA, grafted between 2001 and 2015. We divided pts in 2 transplant eras:2001-2009 (n=327) and 2010-2015 (n=407). In the more recent period (2010-2015) pts were older (53 vs 49 year, p<0.01), were more often grafted from alternative donors (ALT) (64% vs 43%, p<0.01), with a greater use of BM (54% vs 41%, p<0.01), and with a longer interval dx-tx (317 vs 258 days, p<0.01), and more often received a fludarabine containing regimen (55% vs 42%, p<0.01).

Results: The overall survival 5 year survival of pts grafted in 2001-2009 was 57%, compared with 55% for pts grafted 2010-2015 (p=0.7). In multivariate analysis, including the interval diagnosis transplant, patient’s age, donor type, stem cell source and conditioning regimen, the lack of improved survival in 2010-2015 was confirmed (p=0.3). A very strong age effect was shown both in univariate and multivariate analysis: survival of pts aged 40-50 years, 51-60 years and >61 years, was respectively 64%, 54%, 41% (p<0.0001) and this was confirmed in multivariate analysis. The conditioning regimen, also proved to be a significant predictor, with improved survival for ALT transplants receiving FLU containing regimens (56% vs 46%, p<0.001). In general pts receiving either CY200 or a FLU containing regimen, did significantly better than pts receiving other preparative regimens (58% vs 50%, p<0.02). The use of a sibling donor (SIB) did not prove to predict survival in multivariate analysis. Pts receiving Campath in the conditioning, did significantly better than pts not receiving Campath (65% vs 54%, p<0.01); similarly survival of patients with ATG was superior 59% vs 41% compared to patients not receiving ATG (p<0.01). When pts receiving either Campath or ATG (n=564) were compared to patients not receiving either (n=161), the difference in survival was 61% vs 41% (p<0.0001), and this was significant also in multivariate analysis. Combined primary and secondary graft failure was reduced from 16% to 12% in the two time periods (p=0.02), acute GvHD grade II-IV was reduced from 15% to 10% (p<0.01) and chronic GvHD was also reduced from 32% to 26% (p=0.01). Infections remain the leading cause of death in both transplant eras (18% and 22% respectively), followed by GvHD (5% and 4%) and graft failure (5% and 2%), whereas PTLD have been reduced from 3% to 0.5% (Figure 1).

Figure 1.

Summary/Conclusions: HSCT in pts with acquired SAA aged 40 and over, continues to carry a significant risk of TRM also in 2010-2015, ranging from 36% in younger pts (40-50) to 59% in older pts (>60 years). Survival is predicted in multivariate analysis, by two crucial predictors:patients age and the use of either Campath or ATG, the latter giving a 20% survival advantage over no Campath/ATG. ALT and SIB donors produce similar survival. This study gives further support to current guidelines, suggesting first line therapy with ATG+Csa, in pts over the age of 40.

P233

CLINICAL AND GENETIC DIVERSITY IN DIAMOND-BLACKFAN ANAEMIA: AN UPDATE FROM THE UNITED KINGDOM

D. Iskander1, C. Miller2, M. Alkini2, Y. Harrington2, Q. Al-Oqaily1, I. Roberts4, A. Karadimitris1, J. de la Fuente9
1Centre for Haematology, Imperial College London, 2Department of Paediatrics, St. Mary’s Hospital, Imperial College Healthcare Trust, 3Imperial Molecular Pathology Laboratory, Imperial College Healthcare Trust and Academic Health Sciences Centre, London, 4Department of Paediatrics, Children’s Hospital and Molecular Haematology Unit, Weatherall Institute of Molecular Medicine, Oxford University and John Radcliffe Hospital, Oxford, 5Department of Paediatrics, St. Mary’s Hospital, Imperial College Healthcare Trust, London, UK, London, United Kingdom

Background: Diamond-Blackfan anaemia (DBA) is an inherited bone marrow failure syndrome (BMFS) caused by mono-allelic, loss-of-function mutations in ribosomal protein (RP) genes. DBA is rare and has a wide spectrum of clinical manifestations, hence the utility of patient registries.

Aims: We evaluated the clinical and genetic spectrum of DBA in a large cohort of patients in the UK, aiming to identify novel features of the disease.

Methods: We performed a retrospective analysis of data from 103 confirmed cases of DBA, including 4 multiplex families. All living patients had undergone a bone marrow assessment at our specialised centre during the last 5 years. Data were collected from family interviews, patient records and referring clinicians.

Results: The 103 patients with DBA were born in a 48-year period (1967-2015), i.e., an incidence of 3 per million live births. Demographic and clinical characteristics are shown in Table 1. NGS analysis of 80 RP genes plus GATA-1 identified pathogenic mutations in 71% of cases and 7 putative novel mutations, currently undergoing validation. To date, mutation screening of both parents has been performed in 32 families with DBA. Twenty-five mutations are sporadic while 7 are autosomal dominant; in 3 of the latter, the parent is a silent ‘carrier’ without anaemia. In one case of an affected child, the causative mutation was identified in the peripheral blood of both parents but was present in 7/22 embryos generated for in vitro fertilisation, suggesting germline mosaicism. 80.5% of cases in our cohort presented within the first year of life. For the first time we report a high rate of perinatal problems in DBA. Prematurity +/- intrauterine growth restriction (IUGR) occurred in 3/87 (35.6%) of evaluable patients. Specific abnormalities included: hydronephrosis (3/87), prematurity (22/87) and IUGR (16/87). In addition to congenital anomalies classically associated with DBA, we identified abnormalities of the spine and axial skeleton in 9.2% of patients. These did not correlate with a particular genotype. Our cohort exhibited multiple comorbidities, including some not previously reported to be associated with DBA: hepatic (10.7%), neuropsychiatric (17.4%) and gastrointestinal (GI) disorders (25.7%). These complications were not associated with particular treatment regimens. In terms of the natural history of DBA, a lower proportion of our patients (22%) than previously reported in the literature (40%) were able to maintain a normal Hb on long-term steroids. Three patients failed to respond to a metoclopramide trial. In total there were 4 incidents of malignancy (MDS, B-ALL, BCC and cervical intraepithelial neoplasia) in 4 different patients. The lower incidence in our cohort compared with that reported by the North American DBA registry may be explained by differences in the median ages of the 2 cohorts (12y versus 18y, respectively) and the shorter follow-up of our patients.

Summary/Conclusions: This retrospective analysis of the UK’s DBA cohort confirmed several findings from other registries but also revealed novel features, including a high prevalence of i) prematurity birth and neonatal complications ii) abnormalities of the axial skeleton and iii) neuropsychiatric disorders. Prospective longitudinal studies are warranted to better characterise these co-morbidities and to confirm whether they are intrinsic to DBA or arise as complications of treatment. Above all, the observed clinical heterogeneity in our cohort highlights the need for novel therapies that target the multisystem manifestations of DBA, not just the anaemia.
BONE MARROW FAILURE SECONDARY TO NOVEL/KNOWN PRIMARY IMMUNODEFICIENCY-RELATED MUTATIONS. A SINGLE CENTER ANALYSIS

M. Miano1,*, A. Grossi2, L. Fanciullo1, M. Lanciotti1, F. Fioredda1, E. Palmisani1, F. Piem1, S. Giardino1, E. Cappelli4, T. Lanza1, P. Terranova1, M. Calvillo1, C. Micalizzi1, F. Giona4, M. Santopietro4, K. Zhang5, I. Ceccherini2, C. Dufour1
1Haematology Unit, 2Molecular Genetic Unit, 3Stem Cell Transplantation Unit, IRCCS Istituto Giannina Gaslini, Genova, 4Haematology, Dep. of Cellular Biotechnologies and Haematology, La Sapienza University, Roma, Italy, 5Division of Human Genetics, Cincinnati Children’s Hospital Medical Center, Cincinnati, United States

Background: Differential diagnosis between acquired and congenital forms of Marrow Failure (MF) has always represented a crucial point in the diagnostic work-up, since genetic forms do require a different therapeutic approach. It is also known that patients with congenital MF may also show immunodeficiency that, in some cases, can represent the first or revalent sign of the disease and therefore can be misinterpreted as a Primary Immunodeficiency (PID). On the other hand, patients with PIDs may also show MF as a result of an immune-mediated attack of marrow precursors thus generating a phenotypic overlap that can impair the correct diagnosis.

Aims: In this report we analyzed all patients with MF evaluated in our Unit with the aim to identify the type and incidence of underlying molecular defects, in particular those related to PIDs.

Methods: We retrospectively evaluated all diagnosis performed in patients with single/multi-lineage MF followed in our Unit. DEB test was used to screen Fanconi Anemia (FA). Other congenital MFs have been searched by Sanger and/or NGS molecular analysis depending on the available tools over the years.

Results: Between 2009-2016, 88 patients have been studied for single-lineage (25) or multilineage (63) MF. 48 (64%) were classified as having an acquired MF; 27 (30%) were diagnosed with a congenital MF (FA 11, Dissekeratosis Congenita 5, Severe Congenital Neutropenia 6, Blackfan-Diamond Anemia 3, Congenital Megakaryocytic Thrombocytopenia 2), and the remaining 13 patients (14%) were found to have an underlying PID. Table 1 shows clinical characteristics and mutations of patients with PIDs.

Table 1.

Summary/Conclusions: This report shows that patients presenting with single/multi-lineage MF may have an underlying PID in a considerable number of cases. We also show that MF represented the most relevant clinical sign in patients with PI3KCD, TACI, or CD40L mutations, thus widening their clinical phenotype. We conclude that an accurate immunological work-up should be performed in all patients with MF and that PIDs-related genes should be included in the molecular screening of MF in order to identify specific disorders that may potentially receive targeted treatment and/or the appropriate conditioning regimen for SCT.

COVERSIN, A NOVEL C5 COMPLEMENT INHIBITOR, FOR THE TREATMENT OF PNH: RESULTS OF A PHASE 2 CLINICAL TRIAL

A. Hill1,*, W. Weston-Davies2, M. Numm2,3, T. Robak4, A. Szmigielska-Kaplon4, J. Windys5, A. Helman5
1St James’s Institute of Oncology, Leeds Teaching Hospitals, Leeds, 2Akari Therapeutics Plc, 3Haemostasis Research Unit, University College London, London, London, United Kingdom, 4Department of Haematology, Medical University of Lodz and Copernicus Memorial Hospital, Lodz, 5Department of Disorders of Haemostasis and Internal Medicine, Institute of Haematology and Transfusion Medicine, Warsaw, 6Department of Haematology, Gdansk University Hospital, Gdansk, Poland

Background: Paroxysmal nocturnal haemoglobinuria (PNH) leads to episodic haemorrhage secondary to an acquired deficiency of PIGA anchor molecules on the surface of erythrocytes which play a critical role in protecting the cells from complement mediated lysis. Until the advent of eculizumab, a monoclonal anti-body which prevents the cleavage of C5 to C5a and C5b, PNH was associated with considerable morbidity and a poor long-term prognosis. However, eculizumab needs to be administered by health care professionals by intravenous infusion which may interfere with the life-styles, occupations and personal privacy of patients and the interval dosing has led to concerning breakthrough haemolysis. Coversin is a protein suitable for small-volume subcuta-neous (SC) injection which can be self-administered by patients.

Aims: The aim of this study is to investigate the safety and efficacy of the complement C5 inhibitor Coversin in the treatment of PNH.

Methods: A Phase 2 single arm open label trial of Coversin is currently ongoing under which patients, either newly diagnosed with PNH or who have not previously had access to complement inhibitors, are treated for 90 days. Coversin is supplied as a lyophilised powder, reconstituted with water for injection to give a buffered aqueous solution of Coversin 30mg/mL. The trial population consists of up to 10 adult patients with a diagnosis of PNH confirmed by flow cytometry. Treatment commences with an ablating regime (AR) consisting of a fixed dose of 60mg followed by 3 doses of 30mg q12 hours delivered by SC injection. After being suitably instructed patients are encouraged to self-inject the drug. Following the AR, a dose of 15mg q12 hours is given for a further 26 days when, if the patient’s disease is well controlled, they switch to 30mg q24 hours for the remainder of the trial. The dose can be increased by two incremental steps according to a pre-specified algorithm for patients not satisfactorily controlled on the basis of serum lactate dehydrogenase (LDH) or clinical grounds at any time during the 90-day period. The primary endpoints are safety and reduction of serum LDH to ≤1.8 X the upper limit of normal (ULN) for the local laboratory. Secondary endpoints include LDH at 28, 60 and 90 days, terminal complement activity assessed by CH50 ELISA (Quidel®), sheep erythrocyte haemolysis assay, PK (free and bound Coversin levels), anti-drug antibodies (ADA) and quality of life.

Results: The trial is still ongoing and has currently enrolled 5 patients, four of whom remain on Coversin. Three patients have required single dose increases during the initial 28-day period, one of whom was later withdrawn when a co-morbidity was suspected. Two patients have moved to a single daily dose. Updated results of these and any patients enrolled subsequently will be presented. To date 2 patients have achieved the primary efficacy endpoint, two have not yet reached the 28-day point. There have been no serious or significant adverse events and the drug has been well-tolerated. A few mild injection site reactions have been recorded but these appear to diminish with time. There has been no evidence of the formation of neutralising antibodies.

Summary/Conclusions: It currently appears that treatment with Coversin is safe and effective in controlling hemolysis in PNH and that patients are capable of self-administering the drug. Coversin may be an effective alternative for patients with PNH who prefer the independence of self-administration. The relatively short dose interval may also help to reduce breakthrough events due to trough levels of drugs administered at two weekly intervals or longer.

GERMLINE RARE VARIANT ASSOCIATION ANALYSIS IN CHRONIC LYMPHOCYTIC LEUKAEMIA

G. Tiao1, M. R. Impaglio1,2,3, S. Kasaer1,2,3, W. Pohl1,2,3, A. Kamburov1, D.-A. Landau1,2,3, E. Tausch4, A. Taylor-Weiner1, C. Cibulskis1, S. Bahtl1, S.M. Fernandez2, K. Hoang2, E. Rheinbay1, H.T. Kim2, J. Bahl1, S. Robrecht1, K. Fischer6, M. Hallek6, S. Gabriel1, E. Lander1, S. Stilgenbauer4, C. Wu1,2,3, A. Kiezun1, G. Getz1,7,8, J. Brown1,2,3
1Cancer Program, Broad Institute of MIT and Harvard, Cambridge, 2Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, United States, 3Department of Medicine, Brigham and Women’s Hospital, Boston, United States, 4Department of Internal Medicine III, Ulm University, Ulm, Germany, 5Department of Computational Biology and Biostatistics, Dana-Farber Cancer Institute, Boston, United States, 6Department I of Internal Medicine and Center of Integrated Oncology Cologne Bonn, University Hospital, Cologne, Germany, 7Department of Pathology, Massachusetts General Hospital, Boston, United States.

Background: CLL is a highly heritable cancer. Although GWAS have identified ~30 independent SNPs associated with CLL, these are estimated to account for only 5-10% of the inherited component of CLL.

Methods: We hypothesized that this missing heritability might arise from rare coding variants (MAF <0.01), and sought to identify these through an exome-wide association study comparing rare germline variants between CLL patients and controls.

Results: We investigated 516 CLL patients of European descent who were compared to 8,920 ethnically matched, non-cancer population controls. CLL cohorts included 235 CLL patients from DFCI (128 previously reported, 107 unpublished exomes), and 281 CLL patients enrolled on the CLL8 trial of the German CLL Study Group (WES data reported previously). An additional 130 CLL patients in an extension cohort included 24 from our published whole-genome sequencing study and 106 from an early publication of the ICGC. Non-cancer controls came from 3 sources: 2,520 from the 1000 Genomes Project; 6,852 from the Exome Sequencing Project; and 7,611 from a study of genetic risk for myocardial infarction. We combined these heterogeneous datasets by: (i) processing sequencing data from all cohorts together and consistently; (ii) jointly calling the variants across all cases and controls; and (iii) analyzing only ethnically matched, unrelated samples over DNA sites with sequencing coverage sufficient to achieve high-confidence genotype calls. This quality control resulted in 8,920 controls available for the association analysis. We further controlled for population stratification by correcting for three principal components.

Summary/Conclusions: We aimed to perform a detailed analysis of the second significant gene in the Chronic Lymphocytic Leukemia (CLL) genome-wide association study (GWAS) (p<1 x 10^-6) reported previously. To do so, we performed an exome-wide association study (EWA) in a large cohort of 516 CLL patients and 8,920 matched, non-cancer population controls. We used the Office of Biomedical Informatics (OBI) genetics repository and the Genome Aggregation Database (gnomAD) to identify rare coding variants in CLL patients and controls. We then performed a joint analysis of rare variants across all cases and controls, and controlled for population stratification. Our analysis identified 20,442 rare variants in both cases and controls, and we identified 131 novel rare coding variants that were enriched in CLL cases compared to controls. These variants were enriched in known gene regions and were predicted by PolyPhen2 to be possibly damaging. We also identified several rare variants that were predicted to be damaging in patients but not in controls. These findings suggest that rare coding variants contribute to the heritability of CLL and may be important for understanding the genetic basis of this disease.

P237

DIFFERENTIAL ENHANCER TRANSCRIPTION ASSOCIATED WITH RISK ALLELE GENOTYPE IN CLL

B. Tesar1,2, L. Werner3, N. Pochet4, S. Fernandes1, M. R. Impaglio1,2, J. Kiltigaard1,2, C. Thompson1, M. Hanna4, A. Friedman1, D. Neuberg3, M. Freedman2, L. Core6, J. Brown1,2,3

Background: Genome-wide association studies (GWAS) have identified multiple loci that are statistically associated with CLL susceptibility. These single nucleotide polymorphisms (SNPs) are primarily located in non-protein coding genomic regions. Data suggest that these variants are enriched in regulatory elements.

Methods: To investigate SNP allele-specific impacts on gene expression, we selected 15 SNPs from 13 loci that achieved genome wide significance in initial CLL GWAS studies. We investigated either the published GWAS SNP (if present on the Affymetrix 6.0 SNP array) or proxy SNP(s) chosen using the SNP Annotation and Proxy Search (SNAP) software, based on their high linkage disequilibrium (LD) (r^2>0.85) with the selected GWAS SNP. Genotypes were determined in tumor (n=146) and saliva (n=79) DNA from CLL patients (who had provided written informed consent); tumor and saliva DNAs were concordant in at least 96% of cases (except rs477184 at 92%). Given the high concordance with saliva, which is likely related to the stable genome of CLL, SNP genotypes from tumor samples were used for the analysis in order to significantly increase our sample size. Allele-specific gene expression was then evaluated using the RNA-Seq expression arrays allowing Affymetrix CL1U133 Plus 2.0 array gene expression data, focusing on genes within 1 Mb in either direction from a given SNP. In order to elucidate whether these associations were due to functional effects on transcription, we used a novel assay called precision-run on sequencing (PRO-seq). PRO-seq efficiently maps active transcription regulatory elements and provides allele-specific and quantitative direct maps of transcriptionally-engaged RNA polymerases. The algorithm, discriminatory regulator-element detection from GRO/PRO-seq (dREG), is then used to predict the presence of TREs from raw PRO-seq data, allowing for identification of functional elements in the vicinity of SNPs and quantification of their allele-specific effects on enhancer activity and gene transcription.

Results: Our gene expression analysis demonstrated 6 significant SNP-gene associations: rs674313 (6p21.3) with HLA-DOA1 (p < 0.0001), rs872071 (6p2.5) with HLA-DOA1 (p<0.01), rs4771718 (15q23; proxy for rs1766508) with TLE3 (p<0.009), rs783540 (15q25.2) with CPEB1 (p<0.01), rs305088 (16q24.1; proxy for rs305061) with COX14NB/EMC8 (p<0.03) and rs4802322 (18q13.32; proxy for rs11083846) with FKRP (p<0.0001). Two associations were successfully validated in a completely independent gene expression replication analysis (n=54): rs674313 with HLA-DOA1 (p<0.0001) and rs4771718 with TLE3 (p<0.0116). To annotate candidate regulatory elements, we evaluated transcription level at or near all six significant SNPs and quantification of their allele-specific effects on enhancer activity and gene transcription.

Summary/Conclusions: We conclude that PRO-seq and dREG analysis identifies evidence of active differential transcription based on genotype in the region of 5 out of 6 GWAS-identified SNPs that we have investigated so far.
It appeared that in all 13 patients with a 17p deletion the other (38%) patients with mutations was confirmed in 51% (22/43) of the cases, where by no cytogenetic abnormality in 17p locus was observed (median TP53 VAF 43.5%, range 10.5–51.3%). Applying a VAF cut-off of 55% indicating fully expanded heterozygous mutation (taking into account the potential unequal representation of forward and reverse strands in NGS data), 7/29 (24%) cases below the cut-off still harbored 17p CN-LOH. These results show that it is not possible to use an arbitrary VAF cut-off (>50%) to identify biallelic mutations due to CN-LOH. When we compared genomic complexity of leukemia clones with monoallelic vs biallelic TP53mut demonstrated by the Cytoscan array, the latter group exhibited significantly more genomic abnormalities (p=0.0388) and also preference for different recurrent chromosome aberrations (p=0.0011: 17p locus excluded from this analysis). However, there was no significant difference in overall survival between the groups (p=0.5856).

Summary/Conclusions: cn-LOH in 17p locus is present in approximately half of the patients with single dominant TP53mut and results in biallelic TP53 gene inactivation despite the absence of del(17p); truly monoallelic TP53 gene mutations with an intact second allele occur in CLL with comparable frequency. Although 17p cn-LOH is associated with increased genomic instability, it does not have worse impact on clinical outcome than truly monoallelic TP53mut.

Supported by the projects AZV-MZCR 15-3183A, 15-30015A, 15-29733A, the EU Horizon2020 project No. 692298, and MEYS CEITEC 2020 LG1601.

P239
INTERGRATED OLIGO/SNP ARRAY- AND NEXT GENERATION SEQUENCING BASED ANALYSIS IS REQUIRED TO DETERMINE TP53/17P STATUS IN CLL PATIENTS
M. Stevens-Kroef1,*, A. Eijkelenboom 1, L. Kroeze 1, D. Olde Weghuis 1, P. Groenen 1
1Radboud university medical center, Nijmegen, Netherlands

Background: 5-cell chronic lymphocytic leukemia (CLL) exhibits a highly heterogeneous clinical course, with overall survival rates varying from several months to decades. Mutation status of the IGHSV genes and specific genomic abnormalities, such as deletion of 11q22 on the 13q14 region provide prognostic information. However, more importantly deletion of 17p and/or the presence of a TP53 mutation, which are both associated with a poor prognosis identify a poor outcome group with the highest risk of disease progression. Additionally, we identified a sub-group of 97 relapsed/refractory pts who had serial FISH analysis performed in bone marrow ≥1 year apart, to determine whether there were changes in copy number composition of CNAs detected by FISH during treatment in the absence of disease progression.

Methods: We analyzed 336 pts treated on investigational studies with ibrutinib or rituximab for CLL. In pts who progressed, we analyzed FISH and/or NGS results pre-treatment and at progression, to identify CCE. Additionally, we identified a sub-group of 97 relapsed/refractory pts who had serial FISH analysis performed in bone marrow ≥1 year apart, to determine whether there were changes in copy number composition of CNAs detected by FISH during treatment in the absence of disease progression.

Results: In total, 37 of 336 pts (11%) progressed during ibrutinib-based therapy. Of these pts, 15 had FISH analysis both pre-treatment and at progression: pre-treatment, 10 had del(17p), 1 had del(11q) and 4 had isolated del(13q). All 4 of the pts with isolated del(13q) pre-treatment had new sub-clonal FISH abnormalities detected at progression: two pts had del(17p), 1 had del(11q) and 1 pt developed two additional copies of all targeted regions at progression, suggestive of tetraploidy. The pt with del(11q) pre-treatment who progressed developed Richter Transformation (RT) in the bone marrow at progression, without either del(11q) or del(17p) identified by FISH, suggesting that the RT arose from a common ancestral clone without del(11q) or was clonally unrelated. Median FISH%del(17p) pre-treatment in those with del(17p) was 72%; only 1 pt had <50% del(17p) pre-treatment. All these pts had persistence of del(17p), at progression, without significant changes in alleleic frequency. Two pts with del(17p) pre-treatment had additional abnormalities detected by FISH at progression: sub-clonal biallelic del(13q) was seen in 2 pts, one of whom also developed t(11;14) in 12. In the absence of disease progression, the only CCE detected was emergence of small sub-clones with biallelic del(13q) in two patients who initially had monoclonal del(13q). Notably, in responding pts, there was no expansion of high-risk sub-clones. Conventional karyotyping was performed in 10/37 patients who progressed both pre-treatment and at progression. In 4 pts, CCE was identified at progression, including 17 new abnormalities in one pt. All 4 pts had complex karyotype and del(17p) by FISH pre-treatment and 3 of 4 had evidence of multiple, related, complex sub-clones pre-treatment. Figure 1 shows inferred clonal evolution pattern for one pt.

Figure 1.
Summary/Conclusions: Emergence of high-risk clones containing del(17p) and or del(11q) may be seen at disease progression in ibrutinib-treated patients. Analogous to allelic expansion of TP53 mutations after chemotherapy, we hypothesize that small del(17p) or del(11q) subclones were present prior to therapy in these pts, below the sensitivity of existing FISH techniques and expanded under the selective pressure of ibrutinib treatment. Development of a more sensitive technique to identify small subclones with del(17p) or del(11q) may therefore be important. Additionally, complex CCE occurred at progression in several cases, indicating genomic instability and potentially contributing to therapeutic failure.

Pairwise association showed statistically significant co-occurrence between tri(12) and mutations in KRAS/BCOR (both q<0.05), NOTCH1 mutation and ZMYM3 (q=0.01)/SPEN (q=0.05) mutations, and TP53 mutation and del(17p) (q<0.01)/complex karyotypes (q<0.05). When correlating with clinical response to lenalidomide, worse overall response (OR) in the untreated group was associated with del(17p) (p=0.019) and KRAS mutation (p=0.05), whereas as mutation in SF3B1 (p=0.026), MGA (del(1q), p=0.035), DDX3X (p<0.001), complex karyotype (p=0.035) and del(17p) (p=0.031) were associated with worse OR in R/R group. In the untreated group, del(17p) and TP53 were associated with worse progression-free (PFS) (p=0.002 and 0.003, respectively).

Methods: Peripheral blood samples were collected at multiple time-points over a 10-year period from 6 CLL cohort #4 patients. The clonotypicIGHV-IGHD-IGHJ and IGKV-IGKJ rearrangements were amplified by PCR using cDNA and sequenced on the MiSeq (Illumina). Our experimental design involved paired-end sequencing, thus allowing sequencing of the CDR3 reads, so as to increase the accuracy of results. To maintain stringency, raw NGS reads were subject to purpose-built, bioinformatics algorithms, which filtered for: (i) length and quality filtering of raw quality reads resulting in non-filtered paired reads or local alignment; and, (ii) length and quality filtering of stitched sequences. No base calls of Q-score<30 were allowed in the 75 nucleotide stretch preceding the GXG motif, further increasing CDR3 reading reliability. Data was then analyzed using the IMGT/High-QUEST database and clonotype computation was performed using an in-house bioinformatics pipeline.

Results: Overall, 48 samples were analyzed, producing 12,386,554 and 4,506,464 total reads for heavy and light chain, respectively. In addition to filtering out poor quality, incomplete, out-of-frame and unproductive rearrangements, the filtered reads were processed using the IMGT Clonoseq tool with known reading frames, usage of subset #4-specific V- and J-genes, CDR3 length and landmark residues. Applying these strict criteria resulted in 84.1% (median 401,133 reads/sample) and 90.3% (median 141,549.5 reads/sample) of the total sequences obtained for the heavy and light chain, respectively, passing filters. Clonotype computation was solely based on the filtered and previously sequenced CDR3 sequences which at later time-points had often disappeared and hence been selected against; and, (ii) that despite the high intensity of ID, certain residues remained essentially unaltered alluding to strong functional constraints.

Summary/Conclusions: Detailed molecular immunoprofiling by NGS afforded the possibility to gain novel insights into the pathogenesis of CLL subset #4, thus providing a comprehensive understanding of how these patients continue to acquire SMGs within their Ig genes; an observation best explained by a clear role for antigen selection in clonal evolution.

FAILED HYDROXYMETHYLATION CONTRIBUTES TO A CHRONIC LYMPHOCYTIC LEUKEMIA SPECIFIC EPIGENOTYPE
K. Szarc Vel Szić1,2, K. Loose1, G. Andreix2, A. Heumüller1, N. Glaser3, S. Hild1, J. Duyster1, H. Busch2, M. Börries2, R. Claus1

1Division Hematology, Oncology and Stem Cell Transplantation, University Freiburg Medical Center, 2Institute of Molecular Medicine and Cell Research, University Freiburg, 3Center for Chronic Immunodeficiency, University Freiburg Medical Center, Freiburg, Germany

Background: During normal hematopoiesis, a coordinated epigenetic and transcriptional programming is necessary to achieve lineage development. B cell differentiation is predominantly related to loss of DNA methylation at the enhancers and promoters of B cell-specific genes; e.g., transcription factors (TFs). In chronic lymphocytic leukemia (CLL), failure of proper epigenetic pro- gramming contributes to deregulation of B cell transcriptional programs and results in CLL phenotypes with highly variable outcomes. The mechanisms leading to failed epigenetic programming and to establishment of a CLL epigenome are not well understood. Genomic sites of failed epigenetic pro- gramming coincide with binding sites of key B cell TFs. Active DNA demethy- lation through TET-dioxenogene mediated conversion of 5-methylcytosine (5mC) to 5-hydroxymethylcytosine (5hmC) and subsequent products is one of the mechanisms involved in physiological epigenetic B cell programming, and deregulation of this process could contribute to establishment of the CLL epigenome.

Aims: Here, we investigated the role of TET2-mediated DNA demethylation through differential SHCmC acquisition in healthy and in CLL B cells. We further studied mechanisms and TFs involved in regulation of SHCMC conversion during CLL pathogenesis.

Methods: Clonal B cell specimens from 122 CLL patients were subjected to DNA methylation profiling using Illumina 450k arrays. 17 CLL and 4 healthy B cell samples (CD19+) were used for DNA methylation profiling using Illumina Epic arrays and for hydroxymethylated DNA immunoprecipitation (hMeDIP) using a monoclonal SHCMC mouse antibody and the NEBNext Ultra DNA Library Prep Kit for analysis on an Illumina HiSeq2000 sequencer. Global SHCMC levels were quantified by dot blots. TET2, and EBF1 mRNA and protein expression was evaluated by qPCR and Western Blot, respectively.

Results: By dot blot, we found decreased 5hmC levels in CLL as compared to CD19+ B lymphocytes. SHCMC was further reduced in IGHV unmethylated com- pared to IGHV mutated CLL patients. To identify distinct regions with gain or loss of SHCMC, we performed genome-wide SHCMC profiling by hMeDIP. We con- firmed a significantly lower number of hydroxymethylated peaks in CLL (137114) compared to HBC (249421) which remained stable when separating to good (133234, p<0.0102) or bad prognosis CLL (140441; p<0.0161) patients (defined by the IGHV mutation status, Rai/Binet stages, CD38 positivity, del(11q) and del(17p)). Differential binding analysis (DBA) revealed 5988 signifi- cantly differentially hydroxymethylated reads between CLL and HBC samples (FDR<0.05). Pathway analysis showed that regions which lost hydroxymethylation in CLL were involved in B cell receptor (BCR) Class I P13K, CXCR-4, c-Mec and IL3 signaling. To further identify mechanisms that are involved in failed hypomethylation and 5hmC loss in CLL, we aimed at profiling sequence characteristics at the respective genomic sites. In our genome-wide DNA methylation data set, we confirmed highly significant enrichment of the EBF1 motif at the respective sites in 122 CLL patients. EBF1 mRNA and protein expression was significantly reduced in the majority of 17 CLL samples com- pared to HBC. TET2, a potential interaction partner of EBF1, was upregulated in CLL samples on RNA level and expressed to different degree on protein lev- el.

Summary/Conclusions: Here, we demonstrate that 5hmC loss in CLL con- tributes to a disease specific epigenotype as described earlier. First evidences indicate that alterations of an interaction between the EBF1 and TET2 are mechanistically involved in insufficient hydroxymethylation and consequently failed DNA hypomethylation.

Background: Subsets of CLL patients carrying stereotyped B cell receptors (BcRs) display distinct biological and clinical features; however, the DNA methyla- tion landscape for these patients remains largely unexplored.

Aims: To investigate the DNA methylation profiles in three major stereotyped subsets.

Methods: By applying high-resolution 450K methylation arrays, we studied the clinically aggressive subsets #1 (Clan1 genes/IGK/D1-39, IGHV unmethylated, n=37) and #2 (IGHV3-21/IGKV3-20, mixed IGHV mutation status, n=35) and the indolent subset #4 (IGHV4-34/IGKV2-30, IGHV mutated, n=28). In addition, a series of sorted normal subpopulations spanning different stages of B-cell differ- entiation (e.g. naive, central, transitional, memory) were analyzed.

Results: Unsupervised principal component analysis demonstrated that the investigated subsets formed distinct subgroups and these findings were cor- porobated by hierarchical clustering analysis. We next explored if and how these subsets match to the recently proposed epigenetic classification of CLL, which divides cases into four groups: (i) naïve like CLL (n-CLL), (ii) pro-prognostic, (iii) intermediate like CLL (i-CLL) and (iv) aggressive like (a-CLL). The classification revealed that subset #1 clustered with n-CLL, subset #4 with m-CLL, while subset #2 clustered separately with i-CLL. We have recently shown that the number of epigenetic changes that a tumor acquired, compared to its cellular origin (i.e. epigenetic burden), may be a powerful predictor of clinical aggressiveness (Queiroz et al., Cancer Cell 2017). Following this approach in CLL, when comparing specific subsets vs their non-subset cases matched by epigenetic subgroup, we noted a signif- icant difference in the epigenetic burden amongst the various groupings; more specifically, in subset #1 cases in n-CLL (T2K vs 67K, p<0.05) and in subset #2 vs i- CLL (76K vs 68K, p=0.001), while no difference was observed between subset #4 vs m-CLL (83K vs 82K, p>0.05). This implies that subsets #1 and #2 have a higher epigenetic burden than n-CLL, which is in line with the more aggressive disease seen in these two subsets compared to the broader cate- gory of n-CLL patients. Focusing on subset #2, we observed that almost all cases clustered separately from i-CLL in supervised clustering analysis, pro- viding further support that subset #2 forms a distinct subgroup of i-CLL. Subset #2 cases frequently carry del(11q) and harbor SF3B1 mutations, however, nei- ther the IGHV mutation status nor the presence of del(11q) or SF3B1 mutations had any impact on the epigenetic burden within subset #2.

Summary/Conclusions: Stereotyped CLL subsets differed significantly in their methylation profiles. That said, subset #1 and #4 clustered at large with n-CLL and m-CLL categories, respectively, implying common cellular origin. In con- trast, subset #2 emerged as the first defined member of the i-CLL group, which in turn alludes to a distinct cellular origin for subset #2 and i-CLL patients. Both subsets #1 and #2 displayed a higher epigenetic burden compared to n-CLL and i-CLL, respectively, which is likely reflected in the poor outcome asso- ciated with these two subsets.
CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS EXPRESSING THE LIGHT CHAIN IGHV3-21 OR THE IGHV MUTATIONAL STATUS

B. Stamatopoulos1,*, T. Smith2, D. Sims2, A. Heger2, H. Dreau3, A. Schuh4

1Laboratory of Clinical Cell Therapy, J. Bordet Institute, University of Brussels, Brussels, Belgium, 2Computational Genomics Analysis and Training Programme, MRC Weatherall Institute of Molecular Medicine, University of Oxford, John Radcliffe Hospital, 3Molecular Diagnostic Centre, Oxford University Hospitals, 4Department of Oncology, University of Oxford, Oxford, United Kingdom

Background: The immunoglobulin heavy-chain gene (IgHV) mutational status is currently considered the gold standard of prognostication in Chronic Lymphocytic Leukemia (CLL): unmutated (UM) immunoglobulin heavy chain region (IgHV) is associated with poor prognosis while patients with mutated IgHM (M) have more indolent disease. An exception are patients with IgLV3-21/IGHV2-1 who have poor prognosis irrespective of the IgHV mutational status. Interestingly, IgLV3-21 is co-expressed with IgLV3-21 in the majority of cases.

Aims: Here we aimed to study the impact of the light chain IgLV3-21 on CLL prognosis. This light chain has never been characterized independently of the heavy chain IgHV3-21.

Methods: Based on 405 CLL patients from 3 independent cohorts (A. an initial cohort of 32 patients with aggressive CLL, and 2 cohorts of CLL patients where samples were obtained at diagnosis (B: n=270 and C: n=103), we analyzed the impact of the presence of IgLV3-21 on treatment-free (TFS) and overall (OS) survival. IgLV3-21 positivity was determined by real-time PCR and confirmed by Sanger sequencing.

Results: Among the 32 patients with aggressive CLL, we found that 9 (28%) patients who had an IgLV3-21 rearrangement, but only 1 patient carried the heavy chain IgHV3-21: IgLV3-21 patients had a median TFS of 17 months compared to 44 months in patients with another light chain (P=0.0270). Similarly, IgLV3-21 patients had a shorter median OS (88 months > vs >192 months, P=0.0287). We verified these results in 2 independent cohort obtained at diagnosis. In cohort B (n=270), 30 (11%) expressed an IgLV3-21 light chain and 10 (4%) an IgHV3-21 (of which 8/10 also carried the light chain IgLV3-21 rearrangement). Patients with IgLV3-21 had a median TFS/OS of 29/183 months compared to patients without IgLV3-21 who had a median TFS/OS of 88/292 months (P=0.0003/P=0.0142). In cohort C (n=103), 9 (9%) expressed an IgLV3-21 light chain but only 1 (1%) had a heavy chain IgHV3-21. In this cohort, IgLV3-21 patients had a median TFS of 21 months not statistically different from IgHV3-21 patients (28 months) while IgHV3-21 patients had a median TFS of 93 months (P<0.0001). We then pooled the 3 populations (n=405) in order to increase the under-represented subgroups and analyzed the association of the IgLV3-21 with the IgHV mutational status: patients with either IgLV3-21 or IgHV3-21 (with a M or UM IgHV) displayed a prognosis similar to UM patients: median TFS was 129, 48, 36, 24, 23 months for M, IgLV3-21/M (P=0.0005), UM (P<0.0001), IgLV3-21/UM (P<0.0001) and IgLV3-21 (P<0.0001) patients, respectively (Figure 1A). Similar results were observed for OS with a median OS of 292, 88, 174, 90 and 183 months M, IgLV3-21/M (P=0.0001), UM (P<0.0001), IgLV3-21/UM (P<0.0001) and IgLV3-21 (P=0.0021) patients, respectively (Figure 1B). If all IgLV3-21 (n=48) were considered independently of their heavy chain, IgLV3-21 median TFS (24 months) was similar to UM patients (36 months, P=0.5824) and statistically different from M patients (129 months – P<0.0001, Figure 1C). Similar results were observed for OS (Figure 1D).

Figure 1.

Summary/Conclusions: Our results highlight for the first time the independent prognostic significance of the light chain IgVT3-21 in CLL. The presence of an IgLV3-21 light chain confers a poor prognosis similar to UM patient irrespective of concurrent expression of IgHV3-21 heavy chain or IgHV mutational status.

Background: Venetoclax is a potent BCL-2 inhibitor that is approved as monotherapy for certain patients with relapsed or refractory chronic lymphocytic leukemia (CLL) in the United States, the European Union, and other countries.

Aims: Venetoclax combined with rituximab is being assessed in an ongoing Phase 1b study.

Methods: Minimal residual disease (MRD) was assessed in bone marrow using 24-color flow cytometry (minimum sensitivity: 0.01%). Patients who achieved complete remission (CR) or MRD-negativity could stop venetoclax and remain on study. Patients who manifested progressive disease while off therapy could re-initiate venetoclax and rituximab.

Results: Forty-nine patients, with a median of 2 (range: 1–5) prior regimens, were enrolled. As of July 2016, the overall response rate was 86%, the CR rate was 51%, and the bone marrow MRD-negativity rate was 57% (28/49) [Seymour et al. Lancet Oncol 2017]. The 24-month estimate for progression free survival was 78.8% and that for duration of response was 87.8% (100% for patients with MRD-negative CR). Of the 28 patients attaining MRD-negativity, 22 achieved the status at 7 months, which was the first mandatory time point for assessment. The remaining six patients achieved MRD-negativity at the second assessment, which ranged from 12 to 22 months, since the timing of this test was not mandated. Twenty (41%) patients discontinued the study. Eleven had progressive disease while on therapy: five with Richter’s transformation between 1–9 months and six with CLL progression after a median of 26.4 months (range: 12–37). The other nine patients: withdrew consent (n=3), failed to report for follow-up evaluations (n=1), discontinued due to adverse events related to venetoclax (n=2; tumor lysis syndrome and worsening of peripheral neuropathy), or discontinued due to adverse events considered not related to therapy (n=3). Seventeen patients with MRD-negative CR had incomplete response off venetoclax of 13 months (range: 3–34).

Summary/Conclusions: Venetoclax with rituximab induces deep and durable responses, with 51% patients achieving CR and 57% achieving marrow MRD-negativity. Patients on continued therapy have durable responses. Additionally, responses are sustained at a median of 13 months among patients who achieve bone marrow MRD-negativity and elected per protocol to stop therapy, demonstrating that it is possible to discontinue venetoclax and maintain prolonged treatment free remission. The 2 patients who progressed at 2 years off therapy responded to the reintroduction of venetoclax.

PREDICTIVE AND PROGNOSTIC IMPACT OF GENE MUTATIONS IN THE CONTEXT OF FLUDARABINE AND CYCLOPHOSPHAMIDE WITH OR WITHOUT OATUMUMAB TREATMENT IN PATIENTS WITH REL/REF CLL

CONTEXT OF FLUDARABINE AND CYCLOPHOSPHAMIDE WITH OR WITHOUT OATUMUMAB TREATMENT IN PATIENTS WITH REL/REF CLL

M.A. Anderson1,*, D.M. Brander 2, S. Ma 3, J.F. Seymour 4, M.Y. Choi 5, T.J. Kipps 5, L. Zhou 6, K. Balbarin 6, B. Prine 6, M. Verdugo 6, S.Y. Kim 6, L.L. Lash 6, A.W. Roberts 1
1Royal Melbourne Hospital and Walter and Eliza Hall Institute of Medical Research, Cancer and Hematology Division, Melbourne, Australia, 2Duke University Medical Center, Durham, 3Northwestern University, Chicago, United States, 4Peter MacCallum Cancer Centre, , Melbourne, Australia, 5University of California San Diego, San Diego, 6AbbVie, Inc., North Chicago, United States

Background: Recurrent mutations in genes such as TP53, SF3B1 and NOTCH1 are frequent in CLL and have in previous studies been associated with outcome. SF3B1mut, TP53mut, BIRC3mut and XPO1mut were adverse prognostic factors in patient cohorts with different therapies, and NOTCH1mut associated with poor outcome when rituximab was added to standard chemotherapy. In the COMPLEMENT-2 trial (relapsed/refractory CLL, FC vs FC+ofatumumab 1–14-16, 18), NOTCH1mut was identified as a predictive factor in the context of chemoimmunotherapy.

Aims: We assessed the incidence and clinical associations of mutations in TP53, SF3B1, NOTCH1, ATM, BIRC3, FBXW7, MYD88, EGR2 and XPO1 in the COMPLEMENT-2 trial (relapsed/refractory CLL, FC vs FC+ofatumumab 1–14-16, 18).

Methods: Baseline samples were available from 325 of 365 patients (89%) representative of the full analysis set of the clinical trial. Mutation analyses were performed via custom targeted Next Generation Sequencing (tNGS) for TP53, ATM, BIRC3, FBXW7, MYD88, EGR2 and XPO1 in the COMPLEMENT-2 trial (relapsed/refractory CLL, FC vs FC+ofatumumab 1–14-16, 18). We used targeted tNGS to identify somatic mutations present in 365 samples of CLL patients included in the COMPLEMENT-2 trial. The list of genes investigated included TP53, SF3B1, NOTCH1, ATM, BIRC3, FBXW7, MYD88, EGR2 and XPO1.

Results: In total we identified 365 mutations across the 9 genes in 202 of 325 patients (62.2%), with incidences of SF3B1mut 19.7%, TP53mut 18.8%, NOTCH1mut 16.3%, ATMmut 13.8%, XPO1mut 11.4%, BIRC3mut 4.9%, EGR2mut 3.1%, FBXW7mut 2.7% and MYD88mut 0.9%. We identified a variety of associations of mutational subgroups with genetic, clinical and laboratory parameters, such as TP53mut with del17p (p<0.01), NOTCH1mut, FBXW7mut and BIRC3mut with +1q2 (p=0.01, p=0.01 and p=0.05) and ATMmut with del11q (p=0.01). XPO1mut and ATMmut associated with unmutated IGHV. CD79B expression on cell surface measured via flow cytometry was lower in ATMmut patients, whereas CD20 expression did not differ among the different mutational subgroups. TP53mut, EGR2mut and SF3B1mut patients had worse overall response to therapy (88% p<0.01, 50% p=0.02 and 72% p=0.05 respectively, vs 81% overall). Similar to the full analysis set, FCO as compared to FC resulted in significant improved PFS (median 28.1 months, HR=0.67, p<0.01) and OS (HR=0.53, p<0.01 and HR 1.85, p<0.01 respectively), but only TP53mut for decreased OS (HR 2.11 p<0.01). All other mutations, in particular SF3B1mut and NOTCH1mut, did not significantly impact PFS or OS. To identify factors of independent clinical
impact, we performed multivariable Cox regressions for PFS and OS including treatment, IGHV status and all cytogenetic and mutational subgroups. For PFS, the following independent prognostic factors were identified: FCO therapy (HR 0.64 p<0.01), del17p (HR 5.08 p<0.01), unmutated IGHV (HR 2.0 p<0.01), TP53mut (HR 1.75 p<0.01) and XPO1mut (1.86 p<0.01). Del17p (HR 4.79 p<0.01), unmutated IGHV (HR 1.69 p<0.04) and TP53mut (HR 1.76 p<0.03) were identified as independent prognostic factors for OS. With focus on the predictive value of gene mutations, we found a beneficial effect of the addition of ofatumumab to chemotherapy irrespective of TP53 mutation (HR 0.52 p=0.02 for TP53mut and HR 0.68, p=0.02 for TP53m)nt. Regarding NOTCH1, ofatumumab 48% was only beneficial in NOTCH1mut but not in NOTCH1m patients (HR 0.64, p=0.01 and HR 0.86, p=0.67) (Figure 1).

Summary/Conclusions: In the COMPLEMENT-2 trial evaluating FCO against FC in relapsed/refractory CLL patients, we found TP53mut and XPO1mut but not SF3B1mut or NOTCH1mut as independent prognostic factors for PFS. Notably, a benefit of ofatumumab addition to FC chemotherapy obtained among NOTCH1mut but not among NOTCH1m patients indicating NOTCH1 mutation status as a predictive marker in the context of type-1 CD20 antibody addition to chemotherapy.

RESULTS OF A PHASE II MULTICENTER STUDY OF OBINUTUZUMAB PLUS BENDAMUSTINE IN PTS WITH PREVIOUSLY UNTREATED CHRONIC LYMPHOCYTIC LEUKEMIA
A. Danilov1,7, H. Yimer2, M. Boxer3, N. Di Bella4, S. Babu5, J. Lf6, Y. Mun6, S. Sketino6, J. Sharram3
1Oregon Health and Science University, Portland, 2Texas Oncology, Tyler, 3Arizona Oncology, Tucson, 4Rocky Mountain Cancer Centers, Aurora, 5Fort Wayne Medical Oncology, Fort Wayne, 6Genentech Inc., South San Francisco, 7Williamette Valley Cancer Institute and Research Center, Eugene, United States

Background: Bendamustine (B) plus rituximab (R; BR) is a commonly used first-line (1L) treatment for chronic lymphocytic leukemia (CLL). The CLL10 study reported an overall response rate (ORR) of 96% and complete response (CR) rate of 31% with BR. Obinutuzumab (GA101; G) is a glycoengineered, type II anti CD20 monoclonal antibody. A randomized Phase III trial in 1L CLL pts showed that G significantly improved progression-free survival (PFS) and CR rate compared with R, when used in combination with chlorambucil (Goede 2014). B plus G (BG) was evaluated in a subgroup of CLL pts in the GREEN study (Stilgenbauer 2015).

Aims: The aim of this Phase II study (NCT02320487) is to evaluate the efficacy and safety of BG as 1L treatment for CLL pts.

Methods: 102 pts with previously untreated CLL received BG, consisting of 6 cycles of G (cycle [C] 1: 100 mg/day (D); 900 mg QD, C2–6: 1000 mg D1 and B (80mg/m2 C1, D2 and C2–6, D1 and D2). Each cycle was 28 days. The primary endpoint was CR assessed using iwCLL criteria. Secondary endpoints included ORR, PFS, overall survival, and minimal residual disease (MRD). Median follow-up at the time of analysis was 11 months.

Results: Median pt age was 61 yrs (range 35–90); 68.6% were male; 44.1% had Rai stage 3–4. For evaluated pts, IgVH status was 32.9% mutated and 67.1% unmutated. The incidences of trisomy 12, normal cytogenetics, and deletions of 13q, 11q, and 17p were 23.4%, 37.5%, 17.2%, 15.6%, and 6.3%, respectively. Investigator-assessed CR rate was 49.0% (95% CI 39.0–59.1) and ORR was 89.2% (95% CI 81.5–94.5) after 6 cycles. MRD negativity in blood, as measured by flow cytometry, was achieved in 42.9% of pts at the end of induction response assessment and in 75.5% of pts at any time following treatment. MRD negativity in bone marrow (BM) was 60.8% in pts with BM samples. The most common adverse events (all grades [Gr]) were infusion reactions (72.5%), pyrexia (36.3%), neutropenia (34.3%), fatigue (34.3%), constipation (52.0%), and nausea (36.3%). The most common grade 3–4 adverse events were neutropenia (26.5%). Incidence of Gr 3–4 infections was 11.8%. Incidence of tumor lysis syndrome was 4.9% (all Gr 3). Three pts died; none were deemed related to study treatment or CLL by investigators.

Summary/Conclusions: BG is an effective regimen for 1L treatment of CLL pts inducing a high CR rate after 6 cycles of therapy. No unexpected safety signals were observed.

RELATIVE SURVIVAL REACHES A PLATEAU IN HAIRY CELL LEUKEMIA: A POPULATION-BASED STUDY ON INCIDENCE, PRIMARY TREATMENT AND SURVIVAL AMONG 1,427 PATIENTS DIAGNOSED IN THE NETHERLANDS, 1989-2014
A. Dinmohamed1,2,3, O. Visser4, W. Posthuma5, R. Raymakers5, J. Doorduijn3
1Research, Netherlands Comprehensive Cancer Organisation (IKNL), 2Public Health, Erasmus University Medical Center, Utrecht, 3Hematology, Erasmus Medical Cancer Institute, Rotterdam, 4Registration, Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht, 5Internal Medicine, Reinier de Graaf Gasthuis, Delft, 6Hematology, Utrecht University Medical Center, Utrecht, Netherlands

Background: The introduction of cladribine and pentostatin has revolutionized the management of HCL as from the late 80s. As a result of that revolution, HCL patients (pts) are rarely included in clinical trials. Population-based studies can inform on issues related to outcomes of HCL pts managed in daily practice. At present, however, population-based studies that assess patterns of incidence, treatment and survival in HCL are very scarce.

Aims: The aim of this comprehensive nationwide population-based study was to assess trends in incidence, primary treatment and survival among HCL pts diagnosed in the Netherlands.

Methods: We selected all adult (≥18 years) pts diagnosed with classic HCL in the Netherlands between 1989-2014 from the nationwide Netherlands Cancer Registry with survival follow-up through February, 2016. Age-standardized incidence rates (ASR) were calculated per 1,000,000 person-years and standardized according to the European standard population. Data on primary treatment (i.e. no therapy, chemotherapy [CT] and immunotherapy [IT]) were available for individual pts. Pts were categorized in 2 periods (1989-2000 and 2001-2014) and 3 age groups (18-59, 60-69 and ≥70 years). We calculated relative survival (RS) and the relative excess risk of mortality as measures of disease-specific survival.

Results: We included a total of 1,427 newly diagnosed HCL pts in the study (median age, 59 years; age range, 22–95 years; 77% males). The annual ASR of HCL remained quite stable over time and was 3.1 and 3.3 in the first and last period, respectively. Men had a higher overall incidence than women (5.3 vs 1.1 in 2013-2014). The age-specific incidence rates for males were 5.5, 15.0 and 15.3 in 2001-2014 for the three age groups. The corresponding rates for females were 1.2, 3.1 and 5.5. The application of CT increased over time for all age groups. The proportions of CT for the three age groups were 56, 51 and 34% in 1989-2000, as compared with 81, 73 and 53% in 2001-2014. The corresponding proportions for IT were 21, 13 and 17% in 1989-2000, as compared with 2, 1 and 4% in 2001-2014. Lastly, the corresponding proportions for pts who did not receive therapy were 23, 36 and 49% in 1989-2000, as compared with 17, 26 and 42% in 2001-2014. Overall, when corrected for age and sex, pts diagnosed in 2001-2014 had 49% lower excess mortality during the first 10 years after HCL diagnosis, as compared with pts diagnosed in 1989-2000 (P<.005). Ten-year RS (95% confidence intervals) was impressive for pts age 18-59, namely 92% (88% - 96%) and 98% (94% - 100%; P=.176) in the first and last period, respectively (Figure 1a). Most of the significant improvement was observed in pts age ≥60. More specifically, 10-year RS for pts age 60-69 increased from 82% (71% - 92%) to 99% (89% - 100%; P=.009; Figure 1b), and for pts age ≥70 from 67% (49% - 86%) to 95% (84% - 99%; P=.036; Figure 1c) between the first and last periods. In addition, older age (P<.001), but not sex (P=.058), was associated with higher excess mortality.

Figure 1.

Summary/Conclusions: The incidence of HCL remained stable during a 26-year period in the Netherlands. RS for pts diagnosed in the period 2001-2014 eventually reached a plateau, indicating that by then their survival is comparable to that of the general population. Survival was already excellent for younger patients throughout the entire study period. Survival improvement was most pronounced for pts age ≥70. This could be explained by the increased use CT over time. Population-based cancer registries are useful instruments to assess outcomes of pts rarely included in clinical trials.
CUMULATIVE ILLNESS RATING SCALE PROVIDES PROGNOSTIC INFORMATION BEYOND THE INTERNATIONAL PROGNOSTIC INDEX FOR CHRONIC LYMPHOCYTIC LEUKEMIA: AN ACROSS-TRIAL ANALYSIS BY THE GCLLSG

V. Goede1,2, J. Bahlo1, S. Robrecht1, O. Al-Sawafi1, A.-M. Frank1, C.-M. Wendtner3, S. Stilgenbauer4, K. Fischer1, B. Eichhorst1, M. Hallek1,5
1Dept. of Internal Medicine, University Hospital Cologne, 2Oncogeneics Unit, St. Marien Hospital, Cologne, 3Klinikum Munich-Schwabing, Munich, 4University Hospital Ulm, Ulm, 5Centre of Integrated Oncology (CIO) Cologne-Bonn, Cologne, Germany

Background: CLL-IPI is a prognostication tool to stratify patients with chronic lymphocytic leukemia (CLL) for low, intermediate, high, or very high risk. CLL-IPI uses age, Binet stage, beta-2-microglobulin, TP53 mutation, and IGHV mutational status, but not comorbidity as weighted factors to model prognosis. CIRS is a tool which allows assessing and quantifying burden of comorbidity in individual patients.

Aims: To validate CIRS in CLL and to assess whether CIRS is of further value when estimating prognosis by CLL-IPI in CLL.

Methods: This is a comprehensive evaluation of CIRS in 2158 patients pooled from the CLL8, CLL10, and CLL11 trials of the German CLL Study Group (GCLLSG). Median observation time was 55 months. All patients had CIRS data prospectively assessed prior to study treatment (689 FCR, 409 FC, 279 BR, 333 GCLB, 330 RCLB, 118 CLB).

Results: Median age was 64 years; 69% of patients were males, and 50% had ECOG performance score of 1 or higher. Complete information on age, Binet stage, beta-2-microglobulin, TP53 mutation, and IGHV mutational status was available in 1761 of the 2158 patients. Distribution of CLL-IPI risk groups was as follows: 275 (16%) low risk, 653 (37%) intermediate risk, 712 (40%) high risk, 121 (7%) very high risk. The median total CIRS score was 3 (range 0-22); 81% of the patients had a total CIRS score of at least 1 and 28% of greater than 6. Comorbidities were most frequently captured under the following CIRS organ categories: cardiac, blood pressure, respiratory, musculoskeletal, and endocrine/metabolic. A severity score of >2 and >3 in at least one CIRS organ category was present in 46% and 11% of the patients, respectively. There was a positive correlation between total CIRS score and age (rs=0.5, p<0.001) as well as ECOG performance score (rs=0.4, p<0.001) and an inverse association between total CIRS score and creatinine clearance (rs=-0.3, p<0.001). In univariate analysis, increased total CIRS score was associated with shorter overall survival (OS); with poorer OS determined by severity rather than numbers of comorbidities (log-rank: p<0.001, Figure 1A and 1B). In multivariate analysis, total CIRS score was an independent risk factor for OS when used as continuous or categorical variable together with age, gender, Binet stage, ECOG performance score, thymidine kinase, beta-2-microglobulin, IGHV, and 17p deletion (adjusted for treatment intensity). Total CIRS score also remained an independent risk factor for OS when added to the CLL-IPI. Weight of CIRS was highest in the CLL and lower in the CLL10 and CLL11 trials as expressed by the hazard ratios (Figure 1C). There was no significant association between total CIRS score and progression-free survival or time-to-next treatment. However, increased total CIRS score was associated with higher risk of grade 3/4 adverse events as well as premature treatment discontinuation during or after treatment with FCR / FC / BR but not GCLB / RCLB / CLB.

Summary/Conclusions: Findings suggest that CIRS provides prognostic information beyond the CLL-IPI. It provides additional comorbidity assessment (e.g. by CIRS) in addition to the CLL-IPI therefore appears reasonable when estimating overall prognosis and deciding treatment in CLL.

A PHASE II RANDOMISED STUDY INVESTIGATING THE EFFICACY OF STANDARD OR HIGH-DOSE OFATUMUMAB IN COMBINATION WITH CHEMOTHERAPY IN RELAPSED CHRONIC LYMPHOCYTIC LEUKAEMIA

1Haematology, Hull and East Yorkshire NHS Trust, 2Haematology, Hull York Medical School, Hull, 3Clinical Trials Research Unit, University of Leeds, 4St James Institute of Oncology, 5Haematological Malignancy Diagnostic Service, St James University Hospital, Leeds, 6Haematology, The Christie NHS Foundation Trust, Manchester, 7Haematology, University College London Hospital London, London, 8Haematology, Birmingham Heartlands Hospital, Birmingham, 9Haematology, Torbay District Hospital, Torquay, United Kingdom

Background: The outcome of CLL patients relapsing after chemotherapy (CIT) has been transformed by targeted therapies, however a proportion of such patients may be successfully retreated with CIT. CD20-monoclonal-antibody-based CIT has been successfully deployed for the retreatment of relapsed patients but the optimum dosage of antibody is unknown.

Aims: COSMIC (Chemotherapy plus Ofatumumab at Standard or Mega dose in CLL) was a phase II randomised study assessing the efficacy of standard (sOf) and high (megaOf) dose of ofatumumab in combination with either fludarabine cyclophosphamide (FC) or bendamustine (B). The primary endpoint was complete response (CR/CRi) rate independently assessed 3 months post-therapy. Secondary endpoints were the proportion of participants with undetectable minimal residual disease (MRD); overall response rate; progression-free survival; overall survival; time to MDR relapse; dynamics of MDR relapse; safety and toxicity. Using the A’Hem exact one-stage design with 80% power and 1-sided type 1 error of 5%, 10 CRs were required from 37 recruits in either arm to justify further investigation in a phase III study. Total sample size was intended to be 82 allowing for drop-outs.

Methods: CLL patients relapsing after a minimum of 6 months from the most recent course of chemotherapy, and fit for FC or B, were eligible. Treatment comprised sOf (total 6.3g of ofatumumab: 0.3g day 1 cycle 1, 1.0g day 8 cycle 1, 1.0g day 1 monthly cycles 2-6), or megaOf (total 22.3g of ofatumumab: 0.3g day 1, 1.0g weekly for 2 cycles + 0.3g day 1 cycles 3-6) given in combination with FC or B at conventional doses. The choice of FC or B was decided pre-randomisation by the local investigator.

Results: Recruitment was slow with 61 patients randomised and treated, sOf (32: 21 FC and 11 B), and megaOf (29: 17 FC and 12 B). 77% were previously treated with purine analogues and 79% had experienced a remission of greater than 24 months after their most recent therapy. 26% had an 11q deletion and 67% had unmutated VH genes or expressed VH3-21. With 61 participants, there was 71% power to observe 8 CRs from 28 participants in either arm. In the intention-to-treat (ITT) population b(18%) sOf and 77% megaOf patients as assessed by CR/CRi; 22%(69%) sOf and 21(72%) megaOf did not; and 4(12%) sOf and 1(4%) megaOf were unassessable. Rates were similar between FC(26%) and B(19%). Overall responses (CR/CRi+PR) were achieved in 20(63%) sOf and 20(69%) megaOf patients. In the ITT population, 4(13%) sOf and 6(21%) megaOf patients were MRD negative in marrow 3 months post-therapy. Overall, therapy was deliverable with 66% of participants receiving the proscribed 6 cycles of CIT (19(59%) sOf, 21(72%) megaOf). 42 serious adverse reactions were reported (21 sOf, 21 megaOf), 28(67%) being grade 3 or above (13(62%) sOf, 15(71%) megaOf), with the commonest events related to infections (45%) and cytopenias (21%). There was one treatment-related death (sOf-FC).

Summary/Conclusions: The CR rates observed in both treatment arms failed to meet pre-specified levels for the primary endpoint. Response rates observed in both arms are comparable to those obtained in previous studies of CIT in this group and suggest that dose escalation of ofatumumab in relapsed CLL does not lead to a worthwhile improvement in outcomes. However, CIT’s deliverable with acceptable toxicity and should still be considered an option, particularly for patients with long-remissions to first line therapy and who do not possess high-risk cytogenetic markers.
FINAL RESULTS OF THE PHASE IB GALTON TRIAL IN CHRONIC LYMPHOCYTIC LEUKEMIA: DURABLE REMISSEIONS WITH FRONTLINE OBINUTUZUMAB (G) PLUS FLUDARABINE/ CYCLOPHOSPHAMIDE (G-FC) OR BENDAMUSTINE (G-B)

J. Brown1,*, S. O’Brien2, C.D. Kinglsey3, H. Eradat4, J. Hirata5, T.J. Kipps9

1Dana-Farber Cancer Institute (CLL Research Consortium), Boston, 2MD Anderson Cancer Center, Houston, Texas, 3University of Texas, Houston, 4Cleveland Cancer Institute, 5University of California, Los Angeles, 6Fred Hutchinson Cancer Research Center, 7University of Washington, Seattle, 8University of California, 9Mooreres Cancer Center (CLL Research Consortium), University of California, San Diego, United States

Background: GALTON was an open-label, parallel-arm, non-randomized, multicenter, Phase Ib study (NCT01302247) investigating safety and preliminary efficacy of G-FC or G-B in previously untreated CLL. Aims: We report final results for the planned 36-months (mo) follow-up (35/41 pts; median observation 40.4 (17.6–43.6) mo); initial results were reported previously (Brown et al. 2015).

Methods: Eligible pts met iwCLL 2008 criteria for therapy, were considered fit for chemoimmunotherapy by the investigator, and provided informed consent. Each center selected treatment (G-FC or G-B) for their pts. G was administered intravenously (IV; 100mg/day [D] 1, 900mg/D2, 1000mg/D8 and 15 cycle [C] 1; 1000mg D1 C2–6) with FC (fludarabine 25mg/m2 IV and cyclophosphamide 250mg/m2 IV D2–C1, D1–3 C2–6 or B (90mg/m2 IV D2–C3, D1–2 C2–6). Each cycle was 28 days. The primary endpoint was safety and tolerability of G-chemotherapy.

Results: 21 pts were enrolled in the G-FC arm and 20 in the G-B arm. Median age was 60 (25–80) years, 78% of pts were male, and around one-third had Rai stage III/IV disease. Median time from diagnosis to therapy was 24 mo (G-FC: 14 mo cut-off, 37 patients were alive in follow-up; G-FC (n=18; 2 lost to follow-up) and G-B (n=19; 1 event of progressive disease occurred in each arm, and 1 pt per arm died due to an adverse event (AE; G-B: respiratory failure; G-FC: unknown in the setting of unresolved Grade (Gr) 4 pancytopenia); neither was considered treatment related. Due to the small number of events, median PFS and OS could not be estimated; however, 3-year OS was 95% for each arm (95% CI G-FC, 68–99; G-B, 70–99). Post-treatment, 10/41 pts (24.4%) experienced ≥1 Gr3–5 AE: 2/21 pts (9.5%) in the G-FC arm and 8/20 pts (40.0%) in the G-B arm. 7 serious AEs were reported in 4 pts, all in the G-B arm; these included pneumonitis and respiratory failure (as noted above, in both Gr5). Gr4 leukopenia/neutropenia, small cell lung cancer and Gr4 pneumothorax, and melanoma. During follow-up, 6 pts had ≥1 Gr3–4 AE of neutropenia, including 4/20 pts (20.0%) in the G-B arm and 2/21 pts (9.5%) in the G-FC arm. At end of treatment, all pts were B-cell depleted (B-cell count <0.07x109/L). Within 6–12 mo of follow-up, very few pts had recovered (G-FC: 2/19 pts [10.5%]; G-B: 0/20 pts). At 36 mo follow-up, 9/19 pts (47.3%) in the G-FC arm had recovered, 3/19 (15.8%) were still depleted, and 7/19 did not have data available. In the G-B arm, 6/20 pts (30%) had recovered, 1 was still depleted, and 13/20 had no available data. In a single center exploratory analysis, 9 pts (G-FC) underwent 4-color flow cytometry to detect minimal residual disease (MRD) 8–14 mo after therapy; all were negative. 8 of these pts (G-FC) who were MRD-negative by 4-color flow cytometry were also tested with the ClonoSEQ immunoglobulin sequencing assay; 4 were MRD-positive and 4 MRD-negative. 4 pts who were MRD-positive always had both assays remain in remission, while only 2/4 pts who were positive by ClonoSEQ died after follow-up, one of Richter’s transformation complicated by pneumonia and the other related to MDS. Another pt who was MRD positive by ClonoSEQ underwent autologous stem cell transplantation and remains in remission.

Summary/Conclusions: We conclude that G plus either FC or B results in excellent long-term disease control in previously untreated pts with CLL, and has comparable side-effects to other chemo-immunotherapies. We thank N Crompton, N Tyson, M Rahman (Roche Products Ltd) and R Moraru-Zamfir (F. Hoffmann-La Roche Ltd) for their support.

THE PROGNOSTIC SIGNIFICANCE OF CLL-IPI AFTER REPLACED INTENSITY CONDITIONING ALLOGENIC STEM CELL TRANSPLANTATION IN CHRONIC LYMPHOCYTIC LEUKEMIA: THE MAYO CLINIC EXPERIENCE

T. Anagnostou1,*, T.D. Shanafelt1, M.S. Patnaik1, K.G. Chauffee1, S.A. Parikh1, D.A. Gastineau1, W. Ding1, T.G. Cal1, M.R. Litzow1, N.E. Kay1, M. Contel1, D.A. Bowen1, W.J. Hogan1, S.J. Kenderian1, T. Anderson Cancer Center, University of Texas, Houston, 2Mayo Clinic, Rochester, United States

Background: Allogeneic stem cell transplant (SCT) remains the only potentially curative option for chronic lymphocytic leukemia (CLL) patients. However, up to 40% of patients treated with Reduced Intensity Conditioning (RIC) - SCT relapse after transplantation. Recently the CLL International Prognostic Index (CLL-IPI) was validated as a predictor of 5 year overall survival in CLL patients. Aims: In this analysis, we aimed to elucidate the factors that may predict the outcomes following RIC SCT, including the CLL-IPI.

Methods: This is a retrospective analysis of all CLL patients who underwent RIC-SCT at Mayo Clinic between 2006-2013. The study was approved by the Institutional Review Board. The prognostic value of several CLL, patient and transplant related variables were analyzed. Continuous variables were reported as mean and compared using the T-test. Dichotomous outcomes were compared using the chi-square test. Survival was estimated and compared using the Kaplan Meier and Log Rank tests.

Results: Between 2006 and 2013, 50 patients with a median age of 56 years old underwent RIC-SCT for the treatment of CLL. The median time from diagnosis to RIC-SCT was 4.7 (0.6-22.9) years. Fourteen (28%) patients had 17p deletion at time of transplantation. CLL-IPI prognostic score calculated prior to transplant was intermediate in 30%, high in 42% and very high in 28% of patients. Disease status at the time of transplant was partial or complete remission in the majority of patients (39 patients, 78%). The overall transplant related mortality (TRM) was 6% and the 5-year non-relapse mortality was 14%. Relapse rates at 5 years were 54%. Acute graft versus host disease (GVHD) developed in 30 (60%) of patients and chronic GVHD was noted in 32 patients (64%). We evaluated the impact of CLL characteristics, disease status, and patient and transplant characteristics on clinical outcomes. Development of chronic GVHD post-transplant was the dominant predictor of both disease-free survival (DFS) (HR 0.29, 95% CI=0.10-0.69, P=0.006) and OS (HR 0.04, 95% CI=0.01-0.19, P<0.0001, Figure 1A). Very high CLL-IPI risk category (28% of patients) was associated with high relapse rates (82%) post RIC-SCT. DFS was also different between different CLL-IPI categories (18.2% in very high 52.9% in high vs 66.7% in intermediate; p=0.04, Figure 1B). However, there was no significant difference in overall survival suggesting potential benefits from novel therapies in relapsed patients. Given that development of chronic GVHD was the most significant predictor for OS, we evaluated what pre-treatment and disease (including CLL-IPI), and transplant characteristics predicted for subsequent development of chronic GVHD. ZAP70 over expression (OR 0.09 [95% CI 0.01-0.79], p=0.03), disease status at transplant (progression versus remission OR 0.22 [95% CI 0.05-0.92], p=0.038), and alemtuzumab exposure within 3 months of transplantation were associated with lower rates of chronic GVHD (OR 0.08 [95% CI 0.01-0.79], p=0.03). CLL-IPI was not a significant predictor for the development of chronic GVHD in our analysis.

Figure 1.
Background: The human leukocyte antigen-G (HLA-G) gene encodes a tolerogenic protein known to promote tumor immune-escape mechanisms.

Aims: We investigated the potential role of HLA-G polymorphisms and soluble HLA-G molecules in susceptibility to chronic myeloid leukemia (CML), as well as in achievement and maintenance of deep molecular remission (MR4.5) in 68 patients treated with tyrosine kinase inhibitors (TKIs).

Methods: The entire HLA-G gene was amplified by long-range PCR and sequenced using next-generation sequencing (NGS) with Illumina’s Nextera® technology and a 300 bp paired-end read protocol. The BioVendor® HLA-G ELISA (RD194070100R sHLA-G ELISA - EXBIO Praha a.s. BioVendor) immunocassay was used for the quantitative measurement of HLA-G1 and HLA-G5 soluble forms in EDTA-plasma samples.

Results: The frequency of the G*01:03 allele was significantly associated to CML. Patients carrying the G*01:01:02 allele had a significantly higher mean value of soluble HLA-G compared to patients carrying G*01:01:03 allele (10.29 ± 4.46; p = 0.001). Patients carrying the G*01:01:01 or G*01:01:02 allele had a significantly higher mean value of soluble HLA-G compared to patients carrying G*01:01:03 allele (10.29 ± 4.46; p = 0.001). Moreover patients carrying the G*01:01:03 allele had significantly higher rates of MR4.5 (100% vs 65%), with earlier achievement of deep MR4.5 (median of 8 vs 58 months; p = 0.001). TKIs were discontinued in 24 patients after 2 years of confirmed MR4.5. Treatment free remission (TFR) was 57.7%. None of the patients homozygous for the G*01:01:01 or G*01:01:02 allele remained in TFR (0% vs 68.4%, p = 0.023) (Figure 1). All patients carrying the G*01:01:03 allele remained in TFR.

Figure 1.

Summary/Conclusions: HLA-G alleles with higher secretion of soluble HLA-

**P255**

**IMPACT OF ABCG2, OCT1 AND ABCB1 (MDR1) ON TREATMENT FREE REMISSION IN AN EUROSKI SUBTRIAL**

**Aims:** In a substudy of the EUROSKI trial, expression levels of the influx transporter OCT1 and the efflux transporter ABCG2 were analyzed for their correlation with treatment free remission (TFR) of chronic myeloid leukemia (CML) patients while on tyrosine kinase inhibitor (TKI) therapy. The predictive significance of the efflux and influx channel transcript levels was determined.

**Results:** During the trial of the EUROSKI (European Study of Imatinib, Nilotinib, and Dasatinib in CML), the expression of the ABCG2/GUS transcript level above 4.5‰ (n=93) had a 30-times higher risk of relapse (p=0.04). Moreover patients carrying the G*01:01:03 allele had significantly higher rates of MR4.5 (100% vs 65%), with earlier achievement of deep MR4.5 (median of 8 vs 58 months; p = 0.001). TKIs were discontinued in 24 patients after 2 years of confirmed MR4.5. Treatment free remission (TFR) was 57.7%. None of the patients homozygous for the G*01:01:01 or G*01:01:02 allele remained in TFR (0% vs 68.4%, p = 0.023) (Figure 1). All patients carrying the G*01:01:03 allele remained in TFR.

**Summary/Conclusions:** Here we investigated for the first time the impact of pharmacokinetics in the context of a CML discontinuation trial. ABCG2 but not OCT1 and ABCB1 (MDR1) predicted treatment-free remission after TKI discontinuation. High expression of the ABCG2 efflux transporter correlated with a two-times higher risk of relapse in multivariate analysis. Further prospective validation is warranted.
G would seem to be associated with lower EFS and TFR, possibly because of a stronger inhibitory effect on the immune system in favor of tumor escape mechanisms. Conversely, the allele associated to lower levels of SHLA-G promoted achievement of MR4.5 and TFR, suggesting increased cooperation of the host immune system in CML cell clearance.

Background: ENESTop (NCT01698905) is evaluating the ability to stop treatment and remain in TFR in pts with CML-CP who achieved a sustained deep molecular response (MR) after switching from imatinib (IM) to NIL. In the primary analysis, 57.9% of pts (73/126) who stopped treatment remained in TFR (no loss of major MR, BCR-ABL1 ≤0.1% on the International Scale (IS), no confirmed loss of MR4 [BCR-ABL1 ≤0.01%], and no treatment reinitiation) at 4 wk. Aims: To evaluate the proportion of pts remaining in TFR at 96 wk after stopping second-line NIL in ENESTop.

Methods: Eligible pts had ≥3 y of prior tyrosine kinase inhibitor treatment (>4 wk IM, then ≥2 y NIL) and achieved MR4.5 (BCR-ABL1 ≤0.0032%) after switching to NIL. All pts provided informed consent. Enrolled pts continued NIL for 1 y in the consolidation phase (MR assessed every 12 wk). Pts without confirmed loss of MR4.5 during consolidation were eligible to enter the TFR phase (MR assessed every 12 wk for the first 48 wk and every 24 wk for the second 48 wk, then every 12 wk). Pts with loss of MR4 or confirmed loss of MR4 reinitiated therapy. This analysis was conducted when all pts who entered the TFR phase had completed 96 wk of TFR, reinitiated treatment, or discontinued from the study (data cutoff, 7 Nov 2016).

Results: In the consolidation phase, 67 of the 126 pts (53.2% [95% CI, 44.1% - 62.1%]) who entered the TFR phase remained in TFR. Four pts who were in TFR at 48 wk reinitiated NIL due to confirmed loss of MR4 at 60 wk. 72, 90, and 96 wk, respectively. Two other pts discontinued from the study between 48 and 96 wk due to pregnancy (last BCR-ABL1 of 0.0035% at 60 wk) and pt decision (maintained MR4.5 through 90 wk), respectively. Based on Kaplan-Meier analysis, the median duration of treatment-free survival has not been reached and the curve appeared to plateau (Figure 1). Of 56 pts who reinitiated NIL by the data cutoff, 52 (92.9%) regained MR4 and MR4.5, and the time by which 50% of pts regained MR4 was 12.0 and 13.1 wk, respectively. The time by which 50% of pts regained MR4 was shorter for pts with BCR-ABL1 of ≥0.01% (19.3 wk) vs <0.01% (21.2 wk), respectively. The median confirmed loss of MR4 (n=22) at 11.0 wk) vs loss of MMR (n=34; 16.0 wk). Two of the 4 re-treated pts who did not regain MR4 were ongoing in the treatment reinitiation phase (duration, 87.9 and 6.9 wk, respectively; the other 2 discontinued from the study before 48 wk, 1 wk due to regaining MMR (reinitiation duration, 20 wk) and 1 due to an adverse event (AE) after regaining MMR. Two deaths occurred after the first 48 wk of TFR, both in post-treatment follow-up-1: 1 due to cardiopulmonary failure 111 days after pt discontinued treatment due to an AE, and 1 due to adenocarcinoma 77 days after pt discontinued treatment due to initiation of chemotherapy for secondary malignancy. Among pts who remained in TFR at 96 wk (n=77), rates of all-grade AEs were 82.2% and 63.0% during the first and second 48 wk of TFR, respectively, vs 79.5% during the consolidation phase. Rates of musculoskeletal pain-related AEs were 47.9% and 15.1% during the first and second 48 wk of TFR, respectively, vs 13.7% during the consolidation phase. Summary: Updated 96-wk analyses from ENESTop showed stability of the TFR rate, with few pts reinitiating treatment between 48 and 96 wk after stopping second-line NIL. Rates of overall and musculoskeletal pain-related AEs decreased in the second 48 wk of TFR vs the first 48 wk. Overall, these results demonstrate the durability of TFR after stopping NIL in pts who achieved a sustained deep MR after switching from IM to NIL.

1Molecular and Clinical Pharmacology, University of Liverpool, 2Royal Liverpool and Broadgreen University Hospitals NHS Trust, 3Institute of Translational Medicine, University of Liverpool, Liverpool, United Kingdom

Background: Impaired glucose and lipid metabolism is an adverse effect associated with nilotinib (NILO), a tyrosine kinase inhibitor (TKI) used in the treatment of chronic myeloid leukaemia (CML). Indeed the 5-year safety analysis of the ENESTnd trial observed elevations in blood glucose and lipid levels in the NILO arms; importantly NILO-treated patients also showed an increased incidence of arterial occlusive diseases. Adipose tissue is a key regulator of lipid and glucose homeostasis; dysregulation of adipogenesis, altered adipocyte lipid accumulation and reduced insulin sensitivity are implicated in the pathogenesis of metabolic disease. We investigated the effect of NILO on adipose tissue to explain the mechanisms behind NILO-associated metabolic adverse effects.

Aims: i) To study the effect of NILO and imatinib (IMA) on adipocyte function and adipokine secretion using an in vitro adipocyte model; ii) To utilise the in vitro model to explore potential therapeutic strategies to reverse NILO-mediated effects, and iii) To validate the in vitro results in a pilot patient cohort.

Methods: Differentiating 3T3-F442A mouse adipocytes were incubated with clinically relevant concentrations of NILO (1-20µM) and IMA (5µM); in the presence or absence of telmisartan (1-10µM), an angiotensin receptor blocker with potential beneficial effects on insulin sensitivity and lipid homeostasis. Cytoxicity and adipogenesis were assessed by MTT assay and Oil Red O staining, respectively. Expression of adipogenic genes, hormone sensitive lipase regulatory receptor gamma (PPARY), lipin1 (LIPIN1), sterol regulatory element-binding protein 1 (SREBP1) and glucose transporter 4 (GLUT4) were investigated by quantitative PCR and secreted adiponectin was measured by ELISA. Plasma samples were collected from 30 CML patients on neither NILO (first line, n=6; patients for first line, n=15) at baseline and at 3 and 12 months of therapy, and adiponectin was measured by ELISA. Data are presented as mean ± SD for 20µM incubations but full concentration response relationships were measured.

Results: Neither NILO nor IMA were cytotoxic to the adipocytes at clinically relevant concentrations. A dose dependent reduction in lipid accumulation was observed for NILO (for 20µM, 0.76 ± 0.005 absorbance units; p<0.01) but not IMA (0.98 ± 0.007), compared to vehicle control. NILO, but not IMA, resulted in significant downregulation of GLUT4 mRNA (NILO, 93%; IMA, 79%; p<0.01) and of secreted adiponectin (NILO, 5.99±0.31ng/ml; IMA, 79.2±0.79ng/ml). Co-incubation with telmisartan resulted in significant reversal of NILO-mediated effects on lipid accumulation, adipogenic gene expression and adiponectin secretion. In the patient cohort, IMA resulted in a significant increase in adiponectin levels at 3 (38.4±7.1mg/l; p<0.01) and 12 (36.7±2.7mg/l; p<0.01) month time points compared to baseline (27.3±5.7mg/l). In contrast, second line NILO showed a trend for reduction in adiponectin at both 3 (15.2±1.8mg/l; p=NS) and 12
Summary/Conclusions: A BCR-ABL transcript level measured at 1 month after initiation of a TKI may be used as an early indicator to reliably predict the MMR achievement by 12 months in patients with CP-CML. The level obtained at 3 months appears to accurately predict the MMR. Further studies are needed to evaluate the association between the transcript level at 1 month and long-term clinical outcomes.

A HIGH SENSITIVITY HIGH SPECIFICITY DIGITAL PCR ASSAY FOR BCR-ABL
G.-N. Franke1,*, J. Maier1, M. Cross1, S. Tzonev2, D. Shelton2, K. Wildenberger1, D. Niedenwieser1, T. Lange1
1Abt. Hämatologie und internistische Onkologie, Universitätsklinikum Leipzig AöR, Leipzig, Germany, 2Digital Biology Center, Bio-Rad Laboratories, Pleasanton, United States, 3Askepios Klinikum Weißentals, Weißentals, Germany

Background: Digital PCR (dPCR) generates an absolute read out that is largely robust to variations in PCR efficiency and should reduce the requirement for standardisation by laboratory-specific conversion factors. DPCR is an appealing technology for quantitative detection of specific mutations with simultaneous measurement of the reference gene and is particularly suitable for minimal residual disease (MRD) diagnostics in chronic myeloid leukaemia (CML). However, a limitation of the dPCR assays compared to standard quantitative PCR (qPCR) is the background (termed lower limit of blank, LoB) of 1 or 2 positive droplets for BCR-ABL (Franke et al. ASH 2015, Cross et al, Leukemia 2016). The resulting false positive rate (FPR) limits the sensitivity and the ability to detect deep molecular remissions. This has hindered the definition of the lower limit of detection (LoD). We report here on the LoB and the LoD of a newly developed assay.

Aims: Determination of LoB, LoD, linearity and precision of an optimized BCR-ABL digital PCR assay.

Methods: The assay was developed by Bio-Rad laboratories and consisted of a reverse transcriptase reaction followed by a duplex PCR detecting ABL and both the b2/a2 and b3/a2 transcripts of BCR-ABL. Digital droplet PCR was performed using the Bio-Rad QX200 system. LoB and cross-hybridisation were assessed in non-template controls (NTC), BCR-ABL negative cell lines and healthy wild-type donor samples. LoB, precision and linearity were measured in serial dilutions of patient’s cDNA in healthy donor’s cDNA to simulate MMR, MR4, MR4.5, MR5 and MR5.5. Finally, the assay was tested on a certified CAP MR4.7 sample.

Results: The specificity was >95% for both BCR-ABL and ABL in NTC and wild type samples. Extensive NTC analysis yielded no false positives for BCR-ABL PCR (n=0/176; LoB=0) and 1% false positives in ABL PCR (n=2/176; 1-2 positive droplets, LoD=0). The BCR-ABL assays of healthy donors were positive in 2% (n=5/254) with 1 positive droplet/positive sample. For 2 wells analysis, the detection rate for BCR-ABL for MR4.5 and MR5 was 100 and 88%, resulting in a LoD between 6 and 3 BCR-ABL copies/2 wells. Although the ABL copy number was only 20000 for 2 wells, the MR4.5-detection rate was 42%. However, in a more refined analysis, the detection rate was 100% for MR5 and 67% for MR4.5 with an average of 6 and 2 BCR-ABL copies/4 wells (see Table 1). The MR4.5 sample was analyzed repeatedly, with 59 of 60 replicates evaluable. A total of 89 BCR-ABL copies (1.51/replicate) and 4,329,846 ABL copies (73387/replicate) were detected, resulting in a ratio of 0.0021 (MR4.5). The false negative rate was below 3% when combining any pair of replicates, indicating an LoD of 4.5 for assays carried out in duplicate.

Summary/Conclusions: We report here on an optimized digital PCR assay with a LoB of zero and a LoD of 3 copies/2 wells. This highly sensitive and specific assay allows accurate detection of MRD in BCR-ABL positive diseases with a detection rate of 100% for MR5 and 67% for MR5.5 in a 4 wells analysis.

P262

VALIDATION OF THE EUTOS LONG TERM SURVIVAL SCORE IN DUTCH CML-PATIENTS
I. Geelen1,*, N. Thielen2,3, J. Janssen2, M. Hoogendoorn4, O. Visser5, J. Cornelissen5, P. Westerweel1
1Albert Schweitzer Hospital, Dordrecht, 2Department of Hematology, VU Med-
Background: Risk scores in chronic myeloid leukemia (CML) use baseline characteristics of CML patients in chronic phase to predict outcome and can be used to make decisions regarding first line TKI choice and monitoring frequencies. Until recently, risk stratification of CML patients was used based on scores developed in the pre-imatinib era (Sokal and Hasford risk score) with overall survival as the end point of interest. After the introduction of imatinib, the EUTOS score was established to predict the chance of achieving CCyR at 18 months, as a proxy for survival. However, since the major causes of death of CML patients are no longer CML-related, the need for baseline risk prediction has shifted from overall survival towards disease specific mortality. Therefore, recently the EUTOS long-term survival (ELTS) score was introduced to predict the risk of death of CML in patients treated with first line imatinib.

Aims: The primary objective of this study was to perform a validation of the ELTS score in an independent cohort of "real-world" population-based CML patients.

Methods: Data from chronic phase CML patients were derived from the PHAROS-CML population based registry and Hemobase. Patients were stratified into a low, intermediate and high risk group according to the ELTS score. Data on "death due to CML" were provided by the Netherlands comprehensive cancer organization (IKNL) in combination with details from the patient records and a competing risk analysis was performed, to take death due to other causes into account.

Results: In total 349 patients were eligible for analysis; 273 patients (78%) were treated with first line imatinib and 76 patients (22%) were treated with a first line second generation TKI (2GTKI). Sokal, Hasford and EUTOS risk scores all did not predict differences in risk of "death due to CML". The ELTS score identified 163 patients as low risk (47%), 127 patients as intermediate risk (36%) and 59 patients as high risk (17%) at diagnosis. The 5 year cumulative incidence of "death due to CML" was indeed significantly higher in the high risk group (11%) compared to both the intermediate risk group (2%, p=0.02) and the low risk group (1%, p<0.001). Between the intermediate and low risk group no statistically significant difference in risk of dying from CML was observed. A subgroup analysis of only imatinib treated patients showed similar results.

Summary/Conclusions: In the current study based on a "real-world" population-based CML patient cohort, we were able to validate the predictive value of ELTS high risk stratification for "death due to CML" in the current TKI era. Therefore, the ELTS score should be preferred over Sokal, Hasford and EUTOS scores in clinical practice.

Background: The biological and clinical behavior of hematological malignancies is not only determined by the properties of the leukemic cells themselves, but it is also highly affected by the interaction with the microenvironment, pointing to the existence of an active crosstalk between the two compartments. Previous studies showed that acute myeloid leukemia (AML) actively modify endothelial cells ex vivo via several pathways, mainly mediated by VEGF. However, anti-VEGF therapies haven’t produced successful results in clinical trials.

Aims: Our aim is to perform an extensive study of the vascular niche in the bone marrow (BM) of AML xenografts to provide a global picture of the vascular architecture and design new therapeutic strategies.

Methods: We combined the use of mouse models of AML, human AML derived xenografts (PDX) and direct analysis of patients derived samples to study the vascular niche in AML disease. We used two-photon confocal microscopy as a powerful tool to functionally image the BM vasculature in vivo. We used RNA-sequencing to study the AML-associated transcriptomic profile in vascular endothelial cells.

Results: We found several abnormalities in the vascular architecture and function in PDX, such as increased number of endothelial cells, increased microvascular density (MVD), loss of normal sinusoidal architecture and increased hypoxia. Moreover, vascular permeability was increased as measured via two-photon imaging. Interestingly, induction chemotherapy failed to normalize the vascular permeability in the BM, although it significantly reduced the AML engraftment. Via high-throughput transcriptomic analysis, we showed that AML-induced hypoxic environment altered the molecular signature of vascular endothelial cells, activating pro-angiogenic pathways and positively regulating the response to hypoxia. We identified increased nitric oxide (NO) as a major mediator of the AML-induced vascular leakiness in the BM. Notably, increased NO levels were found also in BM aspirates of patients at diagnosis compared to healthy donors, and failure in reducing NO levels after chemotherapy appeared to be associated with a higher incidence of unsuccessful treatment. Strikingly, inhibition of NO production in mouse models of AML and in AML-derived PDX reduced vascular permeability, preserved normal HSC function and significantly improved treatment response (Figure 1).

Summary/Conclusions: We have shown an altered highly permeable vascular niche in the BM of AML PDX, mainly caused by increased NO production by the endothelial niche, contributing to disease progression and treatment failure. Our data call for clinical trials incorporating NOS inhibitors during the remission phase, to target the abnormal vascular niche and improve AML treatment response.

**BUILDING HUMAN BONE MARROW-LIKE MODELS TO STUDY NICHE INTERACTIONS**

H.-J. Prins1, T. Csikos 1, R. de Jong-Korlaar 1, R. Ruiter 1, S. van Veen1, H. Yuan1, J. de Bruijn2, G. Ossenkoppele1, R. Groen1

1Hematology, VU University Medical Center, Amsterdam, 2Xpand Biotechnolgy BV, BIlthoven, Netherlands

Background: Previously, we have reported that our human bone marrow-like scaffold (huBM-sc) xenograft model allows the engraftment and outgrowth of normal and malignant hematopoiesis (e.g. multiple myeloma (MM) and acute lymphoblastic leukemia (ALL) (Groen et al. Blood 2012; Gutierrez et al. JCI 2014) and more recently acute myeloid leukemia (AML); Antonelli et al. Blood 2016). These studies show that i) engraftment is not correlated with prognostic risk-groups, ii) there is preferential outgrowth in humanized scaffolds compared to the murine BM, iii) the huBM-sc environment results in better maintenance of self-renewal potential and less clonal drift of the leukemic cells. Although the presence of human osteoblasts and bone mimics a human BM niche more closely than the murine BM in standard xenotransplant models (e.g. NOD-SCID/NSG mice), still some essential components of the human BM niche, i.e. human blood vessels, are missing.

Aims: To implement human vasculature in the huBM-sc xenograft model in order to create a multi-tissue compartment that “maximaly humanizes” the BM-like niche of our scaffolds.

Methods: Towards successful implementation of a human vascular system inside our scaffold material we have developed: i) scaffolds material composition (bovine collagen type I-phosphate (BCP) vs tricalcium phosphate (TCP)); ii) scaffold shape (particles vs tubes); iii) different types of matrigel for cord blood-derived endothelial progenitor cells (CB-EPCs) embedding.

Results: Histological analysis of these fully humanized scaffolds showed a large hematopoietic vascular compartment (CD31-positive vessels, CD146, LEPR and nestin-positive stromal niche cells. Comparison of the composition and the shapes of the scaffolds indicated superiority of TCP and tubeshaped scaffolds in supporting the formation of vessels. Engraftment of BM-derived CD34+ cells in the CB-EPC embedded huBM-sc resulted in increased multidimensional hematopoietic engraftment, as compared to huBM-sc without CB-EPCs. Moreover, we observed that incorporation of CB-EPCs provides faster kinetics of engraftment of both patient-derived MM and AML cells, and proved to be essential for the engraftment of blast cells from myelofibrosis patients.

Summary/Conclusions: Thus, with the addition of human CB-EPCs and BM stromal cells, our scaffold systems now simulate both endosteal and vascular niches of the BM, thereby more closely recapitulating the human hematopoietic microenvironment.

Background: Adult bone marrow (BM) cavities host continuous, demand adapted and high throughput blood cell production, which is maintained by a scaffold of stromal cells, our scaffold systems now simulate both endosteal and vascular niches of the BM, thereby more closely recapitulating the human hematopoietic microenvironment.

Aims: To perform a detailed quantitative and structural analysis of the BM stromal infrastructure, with a special focus on sinusoidal microvasculature and the CAR cell mesenchymal component, both of which are essential regulators of HSC maintenance.

Figure 1.
Methods: We have developed i) advanced microscopy techniques allowing multiscale 3D visualization of entire bone marrow cavities with cellular and subcellular detail ii) customized computational tools enabling the detection and quantification of discrete cell subsets/structures in 3D images of the BM in an unbiased fashion, as well as a rigorous spatial statistical analysis of cellular interactions.

Results: Using 3D-quantitative microscopy (3D-QM) we uncover that BM stromal cells are in fact 15-20 fold more abundant than previously reported. The massive underestimation of these relevant cell subsets results from the highly inefficient isolation of these cellular types with currently employed flow cytometry protocols. Our image-based analyses further reveals that sinusoidal and CAR cell stromal networks occupy a disproportionately large fraction of the BM space, consequently constraining the tissue volume available for hematopoietic cell distribution. In fact, the vast majority of BM resident hematopoietic cells are unavoidably in direct contact with the CAR cellular projections and in close proximity of the sinusoidal endothelial surface.

Summary/Conclusions: Collectively, our quantitative description of stromal microarchitecture, challenges current models of cell type-specific niche interactions in the BM, which are based in largely inaccurate estimations of cell frequency and spatial confinement of stromal cells in this organ.

P267

TEMPLATED VDJ INSERTIONS ARE A NOVEL BIOLOGIC MECHANISM FOR B-CELL RECEPTOR REPertoire DIVERSIFICATION

M.T. Koning1, I. Trollmann1, R. Rademaker2, R. Toes3, H. Veelken1

1Department of Hematology, Leiden University Medical Center, Leiden, 2Gen-Mab, Utrecht, 3Department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands.

Background: Recently, large LAIR1 insertions at the V-D junction were described as a novel mechanism to generate antibodies against P. falciparum RIFIN antigens on infected erythrocytes (Tan et al., Nature 2016). These templated insertions potentially add a novel biological mechanism used by the immune system to generate B-cell receptor repertoire diversity.

Aims: We investigated whether templated insertions occur in the B-cell repertoire of healthy donors and whether such insertions could be functionally exploited to explore their biological function.

Methods: We obtained >52,000 unique full-length VDJ sequences of IgM, IgG, IgA, and IgE isotypes by unbiased ARTISAN PCR (Koning et al., BJH 2016) from 6 healthy donors. Abnormally long sequences and junctions were searched for templated insertions by BLAST. Identified VDJ carrying templated insertions were co-expressed with a panel of 172 light chains on multiple myeloma cell lines and assessed for surface expression of transgenic immunoglobulin. The VDJ described by Tan et al. were included as controls.

Results: Six unique VDJ sequences, all from the same donor, carried a templated insertion in-frame (E=10-37–0). These sequences represented all VDJ described by Tan et al. and IgE isotypes positioned in a germline configuration of IgE joining region adjacent to IGHD3-22. Somatic hypermutation correlated strongly between the the IGHV segment and the templated insertions (r=0.9944; p<0.001). All templated insertions harboured cryptic RSS sites at their termini. All three IgG VDJ carrying templated insertions and the IgG rearrangement with the templated insertion gave rise to detectable surface immunoglobulin after coexpression with at least one light chain in the panel. The IgG VDJ carrying the LAIR1 templated insertion produced no detectable surface immunoglobulin. In contrast, the VDJ sequences carrying LAIR1 templated insertions as described by Tan et al. could be expressed with the majority of the light chains. The IgA rearrangement remains to be tested in this system.

Summary/Conclusions: Templated insertions represent a novel antibody diversification mechanism. Their presence in naïve B-cells, their exclusive positioning in VDJ junctions, and the universal presence of cryptic RSS sites point to primary VDJ recombination or secondary V gene editing as the generating mechanism. Certain loci (e.g. LAIR1) and individuals appear to have increased susceptibility. The available data suggest RAG to be involved in these insertions. We propose that templated insertions represent inserted signal sequences from aberrantly rearranged chromosomal sequences with cryptic RSS sites.

TARGETING THE CASPASE / NOX2 AXIS TO MODULATE MACROPHAGE POLARIZATION

S. Solier1, L. Meziani2, M. Mondini2, C. Lacout1, P.M.-C. Deng1, J.-C. Martineau2, P. Vandenvoort3, E. Deutsch2, O. Herminie2, N. Drön1, C. Dupuy2, J. El-Benna3, E. Ribakovsky1, N. Droin1, C. Dupuy7, J. El-Benna3, N. Droin1, C. Dupuy7, J. El-Benna3, C. Dupuy7

1INSERM UMR1170, 2INSERM UMR1030, Gustave Roussy, Villejuif, 3INSERM UMR773, Université Paris 7 Denis Diderot, Paris, France, 4Department of Cell Biology, University of Geneva, Genève, Switzerland, 5Laboratory and Cell Death Unit, VIB, Inflammation Research Center, Ghent, Belgium, 6Clinical Hematology Department, Faculty of Medicine and AP-HP Necker-Enfants Malades, Paris, 7CNRS UMR8220, Gustave Roussy, VILLEUIF, France

Background: Caspases, which are key effectors of apoptosis, have demonstrated non-apoptotic functions. One of these functions is the differentiation into macrophages of peripheral blood monocytes exposed to Colony-Stimulating Factor-1 (CSF1). Conversely, GM-CSF induces the differentiation of monocytes into macrophages in a caspase-independent manner. Macrophages generated by CSF1 and GM-CSF have different polarities.

Aims: Macrophage polarization plays an important role in the pathogenesis of diverse human diseases as cancer, leading us to explore if caspase inhibition would affect macrophage polarization.

Methods: To explore the role of caspases in CSF1 differentiation, we used human monocytes sorted from buffy coats or from blood of NOX2-deficient patients treated by cytokines, and we generated monocyte-restricted caspase-8, -9 knockouts and caspase-8 and -9 double knockout mice, which were treated with bleomycin to induce pulmonary fibrosis.

Results: Caspase activation is involved in the generation of M2 polarized macrophages. Caspase inhibition delays the ex vivo differentiation of peripheral blood monocytes exposed to CSF1 and modifies the phenotype of generated macrophages, e.g. cell shape, surface markers and cytokine secretion. In mice, caspase knock-out also modified the phenotype of monocytes induced to differentiate into macrophages. Caspase activation appeared to be prominent at the mitochondria level and responsible for the NOX2-dependent generation of cytotoxic radical oxygen species (ROS). Activation of the NOX2 complex is associated with p47phox cleavage by caspases. Mice treated with bleomycin typically develop a pulmonary fibrosis. Bleomycin-induced lung fibrosis was delayed in monocyte-restricted caspase-8 knockout mice and prevented by treatment with a caspase inhibitory molecule, including zVAD-fmk and the clinically developed IDN6556. This effect was associated with a change in the phagocytic activity of lung-infiltrating macrophages.

Summary/Conclusions: Caspase inhibition in monocytes prevents the development of bleomycin-induced lung fibrosis by modifying macrophage polarization, suggesting that caspase inhibitory molecules may be an exciting thera-peutic strategy to modulate macrophage polarization with diverse applications including cancer treatment.

MULTIPLE MYELOMA-POLARIZED M2C MACROPHAGES PROMOTE A TUMOR-SUPPORTIVE OSTEOYTIC MICROENVIRONMENT VIA CXCL13

K. Beider1, V. Voevoeda1, H. Bilmer1, E. Rosenberg1, H. Mager1, O. Ostrovsky1, E. Rabkovskiy1, A. Shimon1, L. Weiss1, M. Abraham2, A. Peled1, A. Nagler1

1Hematology Division, Bone Marrow Transplantation, SHEBA MEDICAL CENTER, Ramat-Gan, 2Institute of Hematology, Davidoff Cancer Center, Rabin Medical Center, Petach-Tikva, 3Institute of Gene Therapy, Hadassah Hebrew University Hospital, Jerusalem, Israel

Background: Previous studies including our work revealed a role of MM-educated M2-like macrophages (MΦ) in MM survival and drug resistance. However, the mechanism by which neoplastic plasma cells shape BM microenvironment and affect MΦ polarization is still poorly defined.

Aims: To investigate tumour-induced effects on MΦ in the myeloid compartment of the BM niche that are initiated by MM cells.

Methods: We utilized our in vivo xenograft model of BM-disseminated human myeloma. The CRI/SPR/cas9 technology was used to knockdown CXCL13 expression in MM cell lines.

Results: BM analysis of mice inoculated with human CXC44-expressing RPMI8226 cells revealed a significant increase in M2 in MM in comparison to non-injected controls (p<0.01). Characterization of MM-associated changes in the BM milieu revealed murine chemotractant CXCL13 being one of the most profoundly increased factors upon MM development. Elevated CXCL13 was documented in blood of MM-bearing animals comparing to healthy controls. IHC staining identified myeloid cells as the main source of increased murine CXCL13 detected in MM-occupied BM. Murine BM CXCL13 mRNA expression strongly correlated with human β2-microglobulin mRNA levels (p<0.0001 R²=0.64), indicating the interrelation between tumor burden and CXCL13 induction. CXCL13 promotes survival of MM cells, and anti-MM treatments resulted in CXCL13 expression in MM cell lines and primary human CD138+ cells. Mechanistically, TGFB signaling was involved in CXCL13 induction in both MM cells and MΦ, as TGFB receptor inhibitor SB431542 interfered with CXCL13 induction. Osteo-
clastogenic assays were used to elucidate the down-stream effects of the elevated CXCL13. Recombinant CXCL13 was added to mouse BM aspirates produced by co-cultured MM-MΦ increased RANKL expression and induced TRAP⁺ osteoclast (OC) formation in vitro, while CXCL13 neutralization blocked these activities. We next abrogated CXCL13 expression in MM cell lines using the CRISPR/Cas9 technology. The loss of CXCL13 had no effect on MM in vitro growth or drug sensitivity. However, mice inoculated with CXCL13-silenced MM cells developed significantly weaker BM disease compared to mice receiving the non-manipulated cells. Reduced tumor load correlated with decreased numbers of M2c-MΦ in MM, decreased bone disease, and lower expression of OC-associated genes. Finally, the presence of CXCL13 in primary MM samples was evaluated. 739 genes were significantly differentially expressed in the two populations. A new population of MM-MΦ emerged from the pre-existing MM-MΦ pool. The emergence of MM-MΦ was the result of increased bone resorption and osteoclastogenesis, which in turn increased CXCL13 expression. Recombinant CXCL13 as well as medium produced by co-cultured MM-MΦ increased RANKL expression and induced TRAP⁺ osteoclasts from BM aspirates from MM patients (n=24) in comparison to normal BM (n=5) and were in correlation with gene expression signature associated with OC activation and M2c MΦ phenotype (Figure 1).

Figure 1. Summary/Conclusions: Our findings suggest that bidirectional interactions of MΦ with MM tumor cells result in M2c MΦ polarization, CXCL13 induction and subsequent OC activation, enhancing their ability to support bone resorption and MM progression. CXCL13 may thus serve as potential novel target for the diagnosis and treatment of MM.

RE-ORDERING THE B CELL DEVELOPMENT HIERARCHY IN HUMAN FETAL BONE MARROW: CHARACTERISATION OF A NOVEL HUMAN FETAL B PROGENITOR
S. O’Byrne1, N. Elliott1, G. Buck2, L. Liu1, B. Povinelli2, N. Fordham2, E. Louka2, K. Bartolovic2, A. Karadimitris3, A. Mead2, I. Roberts1, A. Roy3, E. Louka2, K. Bartolovic2, A. Karadimitris3, A. Mead2, I. Roberts1, A. Roy3
1Experimental Hematology, 2Department of Computational Biology, 3Department of Biostatistics, St. Jude Children’s Research Hospital, Memphis, United States

Aims: To determine B cell developmental pathways in human second trimester fetal bone marrow. The cellular hierarchy of normal human fetal B-lymphopoiesis remains poorly defined. We have previously identified a novel population of PreProB progenitors (CD34⁺CD19⁺CD10⁻) in fetal liver (FL) [1] that was further expanded in fetal bone marrow (FBM) [2], and co-exists with adult-type CD34⁺CD19⁺CD10⁺ ProB progenitors. Increasing evidence indicates that infant ALL and many cases of childhood ALL arise in fetal life, suggesting that ontogeny-related changes in B-cell development may be important for in utero leukemia initiation. Therefore, understanding the human fetal B cell hierarchy, especially the differences between PreProB and ProB progenitors may be key to understanding the origins of infant and childhood leukemias. We have previously identified a novel population of PreProB progenitors (CD34⁺CD19⁺CD10⁻) in fetal liver (FL) [1] that was further expanded in fetal bone marrow (FBM) [2], and co-exists with adult-type CD34⁺CD19⁺CD10⁺ ProB progenitors. We have previously identified a novel population of PreProB progenitors (CD34⁺CD19⁺CD10⁻) in fetal liver (FL) [1] that was further expanded in fetal bone marrow (FBM) [2], and co-exists with adult-type CD34⁺CD19⁺CD10⁺ ProB progenitors. Increasing evidence indicates that infant ALL and many cases of childhood ALL arise in fetal life, suggesting that ontogeny-related changes in B-cell development may be important for in utero leukemia initiation. Therefore, understanding the human fetal B cell hierarchy, especially the differences between PreProB and ProB progenitors may be key to understanding the origins of infant and childhood leukemias. A20 RESTRAINTS THYMIC REGULATORY T CELL DEVELOPMENT
T. Haas 1, J. C. Fischer 1, V. Otten 1, S. Spoeller 1, H. Poock 1
1Klinik und Poliklinik für Innere Medizin III, Klinikum rechts der Isar, TU München, München, Germany

Background: Maintaining immune tolerance requires the production of Foxp3 expressing regulatory (Treg) cells in the thymus. Activation of NF-κB transcription factors is critically required for Treg cell development, partly via initiating Foxp3 expression. NF-κ B activation is controlled by a negative feedback regulation through the ubiquitin editing enzyme A20, which reduces pro-inflammatory signaling in myeloid cells and B cells. In naive CD4+ T cells, A20 prevents necroptosis and promotes inflammation.

Aims: This study is aimed at analyzing the role of the NF-κB regulator A20 in Treg cell development and function.

Methods: We used A20fl/fl CD4Cre mice, which specifically lack A20 in T cells, to analyze the Treg cell compartment in vivo. We characterized expansion and differentiation of A20-deficient Treg cells in vitro. We performed competitive bone marrow engraftment between WT and A20-deficient bone marrow in vivo to analyze whether one bone marrow compartment would outperform another or would favor development of certain T cell or other immune cell subsets. We performed allogeneic hematopoietic stem cell transplantation with WT BM+T cells vs WT vs A20-deficient Treg cells to analyze whether A20-deficient T reg cells would reduce GVHD to the same extent as WT Treg cells.

Results: Using mice deficient for A20 in T lineage cells, we show that thymic and peripheral Treg cell compartments are quantitatively enlarged due to a cell-intrinsic developmental advantage of A20-deficient T cells. A20−/− Treg cells efficiently suppressed effector T cell mediated graft-versus-host disease after allogeneic hematopoietic stem cell transplantation, demonstrating normal suppressive functionality. Holding thymic production of natural Treg cells in check, A20 thus integrates reduced regulatory T cell activity and increased effector T cell survival into an efficient CD4+ T cell response.

Summary/Conclusions: In light of the largely anti-inflammatory effects that have been attributed to A20 in many cell types, this proinflammatory aspect of A20 physiology in effector and regulatory CD4+ T cells is particularly important since it may contribute to a change of perception of the functions of A20 as a negative regulator of NF-κB in the context of inflammation. Whether targeted modulation of A20 activity allows the induction of Treg cell mediated immune tolerance or, alternatively, boosting of favorable T cell immunity is a question of translational relevance that needs to be addressed in the future.

Background: Mast cells are key effector cells involved in protection against infection and allergic responses. Defects in mast cells are related to immunological disorders, and therefore it is critically to fully understand the transcriptional network that controls their generation and activity. Differentiation of progenitors to mature mast cells is promoted by several transcription factors, such as GATA1, GATA2, STAT5, and MITF, and requires downregulation of C/EBPα. Recently, we identified another member of the C/EBP family of transcription factors, C/EBPγ, as a direct C/EBPα target gene. However, the role of C/EBPγ in mast cells remains so far elusive.

Aims: In this study we aim to determine the role of the transcription factor C/EBPγ in mast cell development and function. Next, we investigate the mechanism by which C/EBPγ is controlling these processes.

Methods: In order to determine the role of C/EBPγ in murine mast cells, we generated Cebpg conditional knockout mice, which allow excision of Cebpg in the hematopoietic system from the early embryogenesis. We employed Cebpgfl/fl Vav-1Cre- and Cebpgfl/fl Vav-1Cre+ mice, referred here as WT and Cebpg KO, respectively. Excision of Cebpg was assessed by RT-PCR and western blot analysis in bone marrow and spleen cells. Using flow cytometry, we enumerated mast cell counts in the peritoneal cavity of healthy WT and Cebpg KO mice. To elucidate whether C/EBPγ plays a role in mast cell response to bacterial infection, we challenged these mice intraperitoneally with lipopolysaccharide (LPS). Subsequently, we used intraperitoneal injection of distilled water to eradicate peritoneal mast cells and then monitored repopulation of peritoneum over time. To further explore the role of C/EBPγ in mast cells in vitro, we established bone marrow derived mast cells (BMMCs) and determined their growth (cell numbers), morphology (toluidine blue staining), and transcription factors expression (RT-PCR) at different time points. Degranulation potential of BMMCs was specified by measuring the percentage of b-glucuronidase released to the supernatant upon anti-TNP IgE sensitization and TNP-BSA activation. To investigate the effects of absence of Cebpg during mast cell differentiation, we employed transwell migration assays.

Results: We verified efficient ablation of Cebpg on mRNA and protein level in bone marrow and spleen of Cebpg KO mice. Analysis of peritoneal cavity of WT and Cebpg KO mice showed similar frequency and numbers of mast cells in steady state conditions. However, Cebpg deficient mice exhibit increased number of peritoneal mast cells after LPS stimulation in comparison to WT control littermates. Surprisingly, mice lacking Cebpg presented defective peritoneal mast cell repopulation. Since mast cells are scarce and difficult to isolate from in vivo models, we employed BMMCs to investigate the effects of Cebpg ablation in mast cell development and function. We observed that bone marrow from Cebpg KO mice generated reduced number of BMMCs in comparison to WT controls. Functionally, we demonstrated that deletion of Cebpg reduced mast cell migration towards antigen, SCF or PGE, and impaired degranulation upon FcγRI-mediated activation. Further, BMMCs exhibit increased expression of C/EBPα in the absence of C/EBPγ.

Summary/Conclusions: In summary, we revealed C/EBPγ as important transcription factor which suppresses C/EBPα expression, thereby favoring mast cell development and function. Our data identifies a new component of the mast cell transcriptional network and provides a better understanding of mast cells in normal physiological conditions and disease.

TRANSCRIPTIONAL DIVERSITY AND DEVELOPMENTAL POTENTIAL OF EARLY HEMATOPOIETIC PROGENITORS REVEALED BY CELLULAR BARCODING AND TRANSCRIPTOME-WIDE PROFILING

1CEA, INSERM, Paris, 2CEA, Evry, France

Background: One of the main complications of anti-cancer therapies or bone marrow transplantation protocols is their deleterious effect on the blood system, leading to prolonged neutropenia and increased risk for infections. Manipulating hematopoietic stem cells differentiation pathways to favor production of specific lineage-committed progenitors might optimize blood recovery.

Aims: In this study we aimed 1) to determine and quantify the contribution of medullary progenitor populations (MPP) to the repopulation of the T cell pathway using the barcode cellular labelling strategy that we have previously developed and 2) to decipher the heterogeneity of these MPP at the transcriptional level.

Methods: Three different MPP subsets, of the following phenotypes: VCAM1+Flt3 (MPP1); VCAM1-Flt3+ (MPP2) and VCAM-1Flt3+ILR7 (CLP), were tagged with different barcodes carried by a collection of lentivirus and transplanted in mice. Barcoded cells in recipient mice were analyzed by flow cytometry. For whole transcriptome strand-specific sequencing, three biological replicates, per cell population, were sequenced at high depth of coverage (2 x 120 million reads).

Results: The results allowed the in vivo dynamic tracking of the progeny of the barcoded progenitors in transplanted recipients. Moreover, transcriptome-wide profiling was used to identify, by cluster analysis of RNAseq profiles together with gene ontology annotation, unique co-expressed markers for the prospective isolation of these populations. Unsupervised classification correctly classified reference surface markers, currently used to purify progenitors, which validate our bioinformatic methodology. Transcriptional regulation of these cell surface markers was further assessed by searching for co-expressed transcription factors and enriched binding sites in their promoters. Their grouping enabled to establish undescribed regulatory networks, specific to each progenitor cell.

Summary/Conclusions: Collectively, the cellular barcoding tool and the molecular changes observed at RNA and functional levels as they occur in vivo in the context of physiologic commitment processes, highlighted data that contribute to a deeper understanding of the dynamic of T lineage differentiation and the lineage restriction process.
Hodgkin lymphoma

LONG-TERM OUTCOME OF PATIENTS WITH NODULAR LYMPHOCYTE-PREDOMINANT HODGKIN LYMPHOMA TREATED WITHIN THE RANDOMIZED HD7-HD15 TRIALS: AN ANALYSIS FROM THE GERMAN HODGKIN STUDY GROUP
D.A. Eichenerauer1,*, A. Plütschow1, M. Fuchs1, B. von Tresckow1, V. Diehl2, P. Borchmann1, A. Engert1
1First Department of Internal Medicine, 2German Hodgkin Study Group, University Hospital Cologne, Cologne, Germany

Background: Nodular lymphocyte-predominant Hodgkin lymphoma (NLPHL) is a rare entity accounting for approximately 5% of all Hodgkin lymphoma (HL) cases. Pathological and clinical features differ from classical HL (cHL). Pathologically, the malignant lymphocyte predominant (LP) cells stain consistently positive for CD20 and are negative for CD30. Clinically, NLPHL often has a rather indolent course. Despite of these differences, the first-line treatment of NLPHL is mostly very similar to cHL. However, analyses on the long-term course of patients with NLPHL who were treated identically to cHL are scarce.

Aims: To shed more light on characteristics and outcome of NLPHL patients treated identically to cHL, we performed an analysis using the database of the German Hodgkin Study Group (GHSG).

Methods: A total of 471 patients with NLPHL who had received first-line treatment within the randomized GHSG HD7-HD15 trials for newly diagnosed HL were identified. The studies were conducted between 1993 and 2009. Patients at all stages (early favorable: HD7, HD10, HD12; early unfavorable: HD8, HD11, HD14; advanced: HD9, HD12, HD15) were included.

Results: Among the 471 NLPHL patients, the median age was 39 years; 76% of patients were male; 53% of patients had early favorable, 16% had early unfavorable and 31% had advanced-stage disease. Study treatment consisted of ABVD- or BEACOPP-based chemotherapy alone, radiotherapy (RT) alone or combined-modality treatment (CMT). After a median observation of 9.2 years, the 8-year progression-free survival (PFS) rate for the whole patient group was 81.3% (83.2% for early favorable, 85.2% for early unfavorable, 76.2% for advanced stages). 80 of 471 patients (17%) had refractory disease or relapsed during the course of follow-up (primary disease progression). In patients with relapse, 6 patients; late relapse: 66 patients). Second malignancies including histological transformation into aggressive B-cell non-Hodgkin lymphoma (NHL) occurred in 48/471 patients (10%) (solid tumor: 25 patients; leukemia: 7 patients; NHL: 13 patients; unspecified malignancy: 4 patients). For all 471 patients included in the present analysis, the 8-year overall survival of the 192 patients early relapse: 6 patients; late relapse: 66 patients was 99.5% for early favorable, 98.6% for early unfavorable, 87.4% for advanced stages). A total of 43 deaths were observed during follow-up resulting in a death rate of 9%. However, only a minority of these deaths was NLPHL-related (n=10). In contrast, most patients died from second malignancies (n=20) or due to other causes (n=13) such as heart failure and lung disease.

Summary/Conclusions: Taken together, the results from this large analysis on NLPHL patients prospectively treated and followed within randomized clinical studies for newly diagnosed HL indicate an excellent lymphoma-specific outcome. Nonetheless, further treatment optimization is necessary as the majority of the observed deaths were not NHL-related but due to second malignancies or other treatment-related late effects. Thus, future clinical trials including NLPHL patients should evaluate whether it is possible to reduce the treatment intensity without compromising efficacy. This goal may be achieved by the partial replacement of conventional chemotherapy by targeted drugs such as anti-CD20 antibodies as well as the reduction of RT fields and doses.

IMPACT ON SURVIVAL OF EARLY DETECTION OF RECURRENCE IN THE FOLLOW-UP OF HIGH RISK HODGKIN LYMPHOMA IN FIRST COMPLETE REMISSION
N. Pugliese1,*, L. Simeone1, R. Della Pepa1, C. Giordano1, I. Cappuccio1, I. Zacheo1, G. Campagna1, C. Cerchione1, P. Zeppe2, C. Salvatore3, F. Pane1, M. Picardi1
1Hematology, University of Naples Federico II, Naples, 2Department of Medicine and Surgery, University Medical School, Salerno, Salerno, 3Department of Economics, University of Molise, Campobasso, Italy

Background: Despite the high complete response (CR) rate to anthracycline-including first-line therapy, approximately one-third of patients with advanced-stage Hodgkin lymphoma (HL) relapses. Many relapses (30–50%) are clinically asymptomatic, without any physical and/or laboratory signs. For patients at high-risk of relapse, a close monitoring, based on imaging procedures is justified if an early detection of recurrence would allow a timely administration of salvage therapy and a survival improvement.

Aims: The purpose of this study was to evaluate the response rate to salvage therapy of relapsed HL by comparing patients who received surveillance with conventional clinical assessments versus patients who received surveillance with imaging procedures. The primary end-point was to assess the rate of CR to salvage therapy at first relapse (confirmed by FDG PET/TC performed before and after ASCT). Secondary endpoints were: the overall rate of recurrence after first relapse (confirmed by FDG PET/TC performed before and after ASCT). Secondary endpoints were: the overall rate of recurrence after first relapse (confirmed by FDG PET/TC performed before and after ASCT). Secondary endpoints were: the overall rate of recurrence after first relapse (confirmed by FDG PET/TC performed before and after ASCT). Secondary endpoints were: the overall rate of recurrence after first relapse (confirmed by FDG PET/TC performed before and after ASCT).

Methods: Between June 2001 and December 2009, we analyzed 306 patients with high-risk HL in CR after anthracycline-including induction treatment. In this case-control study, the first cases (n=150) consisted of patients who received a conventional follow-up program including symptom assessment, blood tests and physical examination; in these patients imaging procedures were performed only in case of suspected relapse (Historical group). Subsequent patients (n=156) received routine imaging procedures comprising ultrasound (US) for the evaluation of abdominal, and pelvic lymph nodes (SMAP US), and chest radiography (CXR), as integrated part of the follow-up strategy (Imaging group). Follow-up procedures were performed at 4, 8, 12, 16, 20, 24, 30, 36, 48, 60, 84, and 108
months after treatment discontinuation in both groups. Relapses were documented by histologic examination in both groups. When relapse was documented, all patients received salvage therapy with high dose chemotherapy (DHAP), for at least two courses, followed, in case of CR, by ASCT.

Results: After a median 62-months observation (range, 4–108), 83 patients, evenly distributed in the two groups, had a relapse of disease. Of these, 28 of 43 patients (67.4%) of the historical cohort vs 17 of 40 patients (42.5%) of the imaging cohort, showed a larger spread of disease at restaging, i.e. stage superior to IIB, and a more frequent extranodal involvement, 10/43 (23.3%) patients in the historical group vs 3/40 (7.5%) patients in the imaging group (p=0.01).

Furthermore, if we considered only asymptomatic patients, one recurrence was detected in 16 of 43 patients in the imaging group and 17 of 40 patients in the historical group, p=0.02. CR rate with second line therapy were higher in the imaging group (27, 67.5%) compared with the historical group (19, 44.2%; p=0.032). The 3-years DFS was 75% in the imaging group and 36% in the historical group, p=0.02.

Summary/Conclusions: This is the first prospective case-control study using SMAP-US plus CXR to monitor patients with advanced stage HL. We show that SMAP-US plus CXR is a valuable tool to improve follow-up in patients with a high risk of recurrence. Our data indicate that the early detection of HL recurrence allows to begin rescue therapy in patients with a more limited disease and, consequently, increases its effectiveness in terms of probability to response and DFS.

P279

CHEMOTHERAPY AND RADIATION IMPROVE SURVIVAL IN EARLY STAGE CLASSICAL HODGKIN LYMPHOMA, A STATEWIDE CANCER REGISTRY ANALYSIS.

H. Saseed1, R. Shrestha1, J. Nee2, E. Durbin2, M. Ziai1, R. Ramali1, G. Monohon1, R. Herzig1, R. Fleischman1, G. Hildebrandt1
1Internal Medicine-Division of Hematology and BMT, 2Kentucky Cancer Registry, University of Kentucky- Markey Cancer Center, Lexington, United States

Background: Early stage classical Hodgkin Lymphoma (cHL) has been shown to have an excellent outcome. Recent studies have therefore focused on decreasing the toxicity that results from the addition of radiation therapy to chemotherapy. However, it remains unclear whether omitting radiation as part of the initial therapy of cHL is associated with a similar survival benefit.

Aims: The primary aim of this study is thus to investigate the outcomes observed in a statewide cancer registry for cHL patients treated with chemotherapy alone vs patients treated with both chemotherapy and radiation.

Methods: All adult patients (older than 18) diagnosed with cHL in Kentucky Cancer Registry (KCR) from 2005–2014 were retrospectively reviewed. Baseline characteristics including age at diagnosis, gender, histology, stage, B symptoms, extranodal involvement, and the site involved were collected. First line treatment modalities as well as overall survival outcomes were reviewed.

Stage I and II patients without B symptoms were considered favorable, while those with B symptoms were considered unfavorable. Patients with stage III and IV disease were given an advanced stage designation. To adjust for selection bias, patient deaths during the first 6 months of diagnosis were censored for overall survival analysis.

Results: A total of 961 patients were identified. Median age was 41 (range 18–91) and 60.9% (n=585) were younger than 50. The group included a mild predominance of males (55.5%). Only 1.7% (n=16) had extranodal involvement at presentation. Of those with known histology (78.6%), the most common was nodular sclerosis (71.2%), followed by mixed cellularity (22.8%), lymphocyte rich (3.8%) and lymphocyte depleted (1.9%). Median follow up time was 45 months (range 0–136). The 10-year overall survival for the favorable group (n=329) was 77% (95% CI: 71.1–88.8) versus 68% for the unfavorable group (n=144) and 42% for the advanced group (372) (p<0.001). There was no statistical difference in survival between stage I (n=170), and stage II (n=385) disease (p=0.99). Treatment modalities were then compared for the favorable risk group alone. Those who received chemotherapy alone (n=145) were compared to those who received combined chemoradiation and radiation (n=148) as their primary therapy. The 10-year overall survival for the cohort receiving chemotherapy and radiation was 87% compared to 75% for those receiving only chemotherapy (p<0.001) (Figure 1). When adjusted by multivariate analysis for risk factors affecting 10 year survival of the favorable cohort, only age <50 and the treatment modality were independently associated with a statistically significant difference in overall survival (HR of 0.11 (p<0.001) and 3.94 (p<0.001), respectively).

Figure 1.

Summary/Conclusions: Our large data cohort shows the presence of B symptoms to be prog nostic than the number of nodal regions involved for early stage disease. Although the use of radiation as part of initial therapy for early stage disease might have increase long term toxicity, it continued to provide superior survival at 10 years.

25th Annual Congress of the International Society for Hematology
Madrid, Spain, June 22 – 25, 2017

haematologica | 2017; 102(s2) | 83
Background: Patients with Hodgkin Lymphoma (HL) who relapse after autologous Stem Cell Transplantation (auto-SCT) have a dismal prognosis. Advanced disease stage, presence of B-symptoms, extranodal involvement at the time of relapse and duration of remission of less than 12 months are parameters associated with decreased overall survival (OS). Brentuximab Vedotin (BV), an anti-CD30 monoclonal antibody conjugated to a microtubule-disrupting agent, has shown clinical efficacy in HL. Although in the setting of post-auto-SCT relapse, BV produces an overall response rate of approximately 75% with a median progression free survival (PFS) of 9 months, the impact of BV on OS has not been addressed in previously published studies.

Aims: To examine the impact of treatment with BV on OS of patients with HL relapsed after auto-SCT.

Methods: Data for patients with HL who underwent auto-SCT in Greece during the last 20 years were collected. Study group consisted of 214 patients who experienced post-auto-SCT relapse. In order to examine the impact of BV on OS, patients were divided in 2 cohorts depending of the date of BV availability in their hospital (January/2013). Cohort 1 consisted of 178 patients who relapsed before January/2013, while Cohort 2 consisted of 36 patients relapsed after BV became available. Patient’s characteristics are shown in Table 1.

Table 1. Patients characteristics.

The following variables were included in a multivariate Cox proportional hazard regression analysis model: 1) age of patient, 2) Sex, 3) B-symptoms (yes vs no), 4) Stage of disease (I-II vs III-IV), 5) extranodal disease, 6) time from auto-SCT to relapse (≤12 vs >12 months), 7) Relapse before or after BV availability (Cohort 1 vs Cohort 2). In order to exclude any confounding effect of subsequent treatments, analysis was performed by censoring patients at the time of allogeneic SCT or treatment with immune checkpoint inhibitors (IC-inhibitors).

Results: In multivariate analysis the following variables were statistically associated with OS: 1) The presence of B-symptoms [HR=2.07, (95% CI, 1.39-3.07), p<0.001] and 2) Relapse in less than 12 months after auto-SCT [HR=3.35, (95% CI, 2.35-4.85), p<0.001] were associated with decreased OS, while 3) Response after 1st salvage [HR=0.46, (95% CI, 0.31-0.68), p<0.001], and 4) BV availability [HR=0.36, (95% CI, 0.16-0.79), p=0.011] were associated with increased OS (Figure 1). Similar results were obtained when analysis was performed without censoring patients at the time of allo-SCT or treatment with IC-inhibitors (data not shown).

Summary/Conclusions: Patients in Cohort 2 survived longer even when censored for allo-SCT or treatment with IC-inhibitors. All patients in Cohort 2 treated with BV while only 18% of patients in Cohort 1 received treatment with BV. The results of our study strongly suggest that BV improves OS in patients with HL relapsed after auto-SCT. To our knowledge this is the first study showing an OS advantage of treatment with BV.
tion was defined as imaging at or before week 12 of treatment, whereas late radiological evaluation was performed at or after week 16. Response evaluation was performed according to the Lugano Classification and its update regarding immunomodulatory therapy.

Results: Between 06/2015-11/2016, 87 patients were enrolled in a name-based program in Turkey. Two, 19, and 5 patients who had not yet received nivolumab, had not reach the time for early radiological evaluation, and who died before any radiological evaluation were excluded from the analysis. Thus, 63 patients from 23 centers were retrospectively analyzed. Median follow-up was 6 months, median age was 29 (18-75) and patients had a median 5 (2-11) previous lines of therapy. 44 patients (70%) had been treated by stem cell transplantation (SCT) and 45 (76%) patients had been treated by BV. The ORR was 66% with 15 CR (95%CI 0.020-0.28; CR 26%, PR 42%, SD 12%, PD 20%) among 59 patients evaluated in 12 weeks of nivolumab treatment. The ORR was 67% with 9 (24%) patients with CR after 16 weeks of treatment (95%CI 0.004-0.26; CR 24%, PR 43%, SD 6%, PD 27%). Estimated OS was 95% (95%CI 0.80-0.98) and estimated PFS was 71% (95%CI 0.65-0.82) at 12-months. Median OS was not reached, while, according to the late response rates, the median PFS was 14 months. However, it was only 3 months in patients with PD at the late radiological evaluation. Regarding responses to last treatment prior to nivolumab, we detected that 28 (67%) of 42 PD cases had objective early responses and 70% of PD cases had ORR in the late response evaluation (CR in 4, PR in 12 pts). 8 patients underwent transplantation following nivolumab. Among 5 patients who had been treated by allo-SCT, 4 had CR at the time of transplantation and they are alive with ongoing response. Safety profile was acceptable and only two patients required cessation of nivolumab due to serious adverse events: one due to autoimmune encephalitis and one due to aggravation of graft versus host disease. At the time of analysis, 40 cases were still on nivolumab treatment (64%). Among the 40 cases with early objective responses to nivolumab, 35 (88%) showed ongoing objective responses. All 24 cases with objective responses in the late evaluation had ongoing responses at the time of analysis (Figure 1).

Summary/Conclusions: In conclusion PD-1 blockers are new options to meet the unmet need in patients with chHL refractory to BV treatment, and possibly a bridge for these patients before transplantation.

GENOTYPING OF HODGKIN LYMPHOMA ON THE LIQUID BIOPSY
V. Spina1,*, A. Bruscaggin1, M. Di Trani2, M. Martini3, S. Locatelli2, E. Cupelli4, C. Deambrogi6, F. Diop6, G. Stüssi 5, F. Cavalli5, F. Bertoni1,5, E. Zucca 5, G. Forestieri 1, A. Condoluci 1,5, A. Cuccaro 4, A. Moccia 5, A. Stathis 5, M. L. Aracca3, and Research Center, Milan, 2Division of Pathology and Histology, 3Institute of Hematology, Catholic University of the Sacred Heart, Rome, Italy, 4Oncology Institute of Southern Switzerland, Bellinzona, Switzerland, 5Division of Hematology, Department of Translational Medicine, University of Eastern Piedmont, Novara, Italy

Background: In classical Hodgkin lymphoma (cHL) the low representation (1-5%) of Reed-Sternberg cells (RS) challenged tumor genotyping on the diagnostic tissue biopsy. Consistently, the mutational profile of newly diagnosed cHL is poorly characterized, and the genetics of refractory disease is completely unknown. Cell free DNA (cfDNA) is shed into the blood by tumor cells undergoing apoptosis and can be used as source of tumor DNA for the identification of somatic mutations. In addition cfDNA is representative of the entire tumor heterogeneity, thus allowing the identification of mutations from tumor cells residing in non-biopsied sites.

Aims: This study aims: i) at providing the evidence that the mutational profile of cHL can be tracked by using plasma cfDNA; and ii) at characterizing the genetics of newly diagnosed cHL and, for comparative purposes, of refractory cHL.

Methods: The study includes 28 newly diagnosed cHL and 9 chemorefractory cHL. All cases were provided with cfDNA from plasma collected at baseline, before treatment start, and paired DNA from granulocytes as source of germline DNA to filter out polymorphisms and sequencing noise. Paired genomic DNA from formalin fixed paraffin embedded (FFPE) tumor tissue biopsies was available for 17 patients, including 3 cases for which RS enriched areas were macrodissected. A targeted resequencing panel optimized to include the coding exons and splice sites of 77 genes (192Kb) that are recurrently mutated in B-cell lymphomas was used for genotyping. Libraries were prepared from plasma cfDNA, germline gDNA and tumor gDNA according to the CAPP-seq targeted enrichment strategy (Nimblegen) and subjected to ultra-deep-next generation sequencing (NGS) on the MiSeq platform (Illumina). The sequencing was tailored to obtain a depth of coverage >2000x in >80% of the target region in all samples, which allowed a sensitivity of 3x10-3. The somatic function of VarScan2 was used to call non-synonymous somatic mutations, and a stringent bioinformatic pipeline was applied to suppress the background noise and to filter out sequencing errors.

Results: In newly diagnosed cHL, genotyping of plasma cfDNA identified non-synonymous somatic mutations in STAT6 (43%), TNFAIP3 (43%), ITPKB (32%) B2M (21%), GNA13 (14%), CIITA (7%), XPO1 (7%) and CD58 (4%) among the most recurrently affected genes (Figure 1-A-B). In refractory cHL patients, genotyping of plasma cfDNA identified non-synonymous somatic mutations in ITPKB (44%), TNFAIP3 (33%), KMT2D (33%), B2M (33%), GNA13 (33%), XPO1 (22%), TET2 (22%), IKKβB (22%), BIRC3 (22%) and STAT6 (22%) among the most recurrently affected genes. Mutations of KMT2D (33%) and TET2 (22%) were enriched in refractory chHL patients compared to newly diagnosed cases, suggesting that they contributed to the chemorefractory phenotype (Figure 1-C-D). By using high sensitivity techniques, most of the mutations discovered in cfDNA were also identified in pair tumor DNA from the tissue biopsy and/or macrodissected RS cells, thus confirming their tumor origin (Figure 1-F). By pathway analysis, the mutational profile pointed to the involvement of PI3K/AKT signaling, cytotoxicity, NF-kB signaling, and the immune escape in cHL. ITPKB (a negative regulator of the PI3K/AKT signaling pathway) was specifically mutated in cHL across aggressive B cell lymphomas.

Figure 1.

Summary/Conclusions: This study provides the evidence that cHL can be genotyped using plasma cfDNA as source of tumor DNA, pointed to a non-overlapping genotype between newly diagnosed and refractory cases, and identified ITPKB as a new gene specifically involved in ~30-50% of cHL patients.
Background: Doxorubicin (DXR) induced cardiotoxicity is related to several mechanisms, including interference of mitochondrial respiratory chain and acceleration of glycolysis. We previously reported that this treatment may enhance myocardial FDG uptake.

Aims: The present study aimed to verify whether this metabolic response on serial PET/CT imaging can predict myocardial function, non-invasively evaluated by follow-up echocardiography (ECHO).

Methods: 18F-FDG PET/CT of 25 patients affected by Hodgkin Disease (HD), treated following ABVD scheme were analyzed. Inclusion criteria were: 1) availability of 4 consecutive PET/CT scan for staging (PET1), interim (PET2), post-therapy (PET3) and six months follow-up evaluation (PET4); 2) full remission after two ABVD cycles; 3) normal baseline EKG and ECHO findings and 4) no concurrent treatment with external thoracic radiotherapy. A volume of interest (VOI) was manually drawn on the left ventricular myocardium. Average standardized uptake value within this region was normalized for the corresponding blood pool index measured in the inferior vena cava to obtain LV-SUV. All patients showed signs or symptoms potentially related to DXR cardiotoxicity.

Results: LV-SUV progressively increased from PET1 to PET4 in 6 patients (24%, 2 females, mean age 39±17, termed “increasers”) being 1.34±0.9, 3.34±2.6, 4.32±2.8 and 4.43±1.5 respectively. In the remaining 19 patients (76%, 7 females, 36±14), FDG uptake showed a largely variable response without any progressive increase. Accordingly, the ratio between PET4 and PET1 LV-SUV in the two subgroups was 3.05±0.8 and 1.06±0.4, respectively (p=0.001). Up to six months after therapy discontinuation, none of the 25 patients showed signs or symptoms potentially related to DXR cardiotoxicity. However, late follow-up ECHO detected the appearance of first-degree diastolic impairment with respect to baseline in 9 of the 25 examined patients (36%, 4 females, mean age 36±18). This finding occurred in 5/6 “increasers” (83%) and in only 4/19 non-increasing (21%) (p<0.001).

Summary/Conclusions: The present data indicate that DXR related myocardial damage can be preceded by an enhanced glucose uptake. 18F-FDG PET/CT imaging might represent a useful tool to identify high-risk patients and to implement personalized program to monitor and prevent DXR-induced cardiotoxicity.

Iron metabolism, deficiency and overload

ELEVATED SYSTEMIC HEME AND IRON LEVELS AS RISK FACTORS FOR VASCULAR DYSFUNCTION AND ATHEROSCLEROSIS: EVIDENCE FROM β-TALASSEMIA AND HEMOCROMATOSIS COHORT STUDIES

F. Vinciguerra1, G. Portoli1, A. Silva2, R. Sparta1, G.M. Vercellotti1, J.D. Belcher3, E. Fibach4, H. Zeid5, R. Rasras6, M.W. Hentze7, H. Ghosh8, M.U. Muckenthaler9, E.A. Rachmilewitz9

1Molecular Medicine Partnership Unit (MMPU), University of Heidelberg & EMBL, Heidelberg, Germany, 2University of Porto, Porto, Portugal, 3Vascular Biology Center, University of Minnesota, Minneapolis, United States, 4Department of Hematology, The Hebrew University Hadassah Medical Center, Jerusalem, Israel, 5Department of internal Medicine, AShifa hospital, 6Laboratory department, European Hospital of Gaza, Gaza, Palestinian Territory, Occupied, 7European Molecular Biology Laboratory (EMBL), Heidelberg, Germany, 8Department of Hematology, Assuta Medical Center, Tel Aviv, 9The Edith Wolfson Medical Center, Holon, Israel

Background: Increasing evidence from animal studies suggests that free heme exerts vasculotoxic, pro-inflammatory and pro-atherogenic effects due to its ability to trigger endothelial and immune cells activation. Moreover, we recently demonstrated a role for iron in the pathogenesis of atherosclerosis, analyzing a mouse model of type IV hereditary hemochromatosis, hallmarked by severe iron overload. We also showed that iron-deficient diet and chelation therapy prevent atherosclerosis progression in those mice.

Aims: Here we aimed at evaluating the clinical relevance of these findings and determining the parameters of vascular dysfunction correlated with iron levels and suggest a predisposition to vascular dysfunction and atherogenesis in iron-overloaded individuals.

Methods: To this purpose we examined serum samples from a cohort of patients with β-thalassemia major and intermedia, who received recurrent blood transfusions but inconsistent chelation therapy, and a cohort of patients with hereditary hemochromatosis (HFE C282Y homozygous mutation), treated with phlebotomy.

Results: β-thalassemia patients show high systemic heme and iron levels, which correlate with a severe drop in the plasma scavengers for hemoglobin and heme, Haptoglobin and Hemopexin, respectively. Hemochromatotic patients show increased systemic iron levels and reduced hepatic hepcidin levels. Consistently, in the two cohorts, transferrin saturation, non-transferrin bound iron (NTBI) and serum ferritin are elevated. Interestingly, both thalassemic and hemochromatotic patients present with high systemic levels of soluble adhesion molecules (sVCAM-1, sICAM-1, s-E-Selectin, s-P-Selectin) and reduced nitrotyrosine levels, hallmarks of endothelial activation and vascular dysfunction. In addition, they show increased serum lipid peroxidation, elevated circulating oxidized LDLs and high pro-inflammatory cytokines, which are known to promote atherosclerosis. All parameters significantly correlate with increased systemic heme and iron indices, including NTBI, as well as decreased scavenger levels.

Summary/Conclusions: These results emphasize the involvement of serum hemoglobin, heme and iron in the pathogenesis of vascular dysfunction in β-thalassemia and hemochromatosis and suggest a pro-atherosclerotic role for these molecules. These findings are relevant, on one side, for cardiovascular diseases and vasculopathy, when iron parameters are altered, and on the other, for iron overload disorders, where premature atherosclerosis might develop. Finally, our data highlight the key protective role of heme/iron scavengers and support the potential therapeutic benefit of chelation therapy to counteract heme/iron-driven vascular toxicity and atherosclerosis in hemolytic and iron-overload conditions.

MEDIATION BY PATIENT-REPORTED OUTCOMES ON THE ASSOCIATION BETWEEN FILM-COATED VERSUS DISPERSIBLE FORMULATIONS OF DEFERASIROX AND SERUM FERRITIN REDUCTION: A POST HOC ANALYSIS OF THE ECLIPSE TRIAL

A. Taher1, R. Origa2, S. Perrotta3, A. Kourakis4, K. Belhoul5, V. Huang6, J. Han7, A. Bruderle7, P. Bobbi8, M.S. Du9, J.B. Porte10

1American University of Beirut Medical Center, Beirut, Lebanon, 2Ospedale Pediatrico Micronetico A’Cao, University of Cagliari, Cagliari, 3Second University of Naples, Naples, Italy, 4Hematology Division, Department of Internal Medicine, University of Patras Medical School, Patras, Greece, 5Dubai Health Authority, Dubai Thalassemia Center, Dubai, United Arab Emirates, 6Novartis Pharmaceuticals Corporation, East Hanover, United States, 7Novartis Pharma AG, Basel, Switzerland, 8Analysis Group, Boston, United States, 9University College London, London, United Kingdom

Background: The ECLIPSE clinical trial (NCT02125877) demonstrated that a new film-coated tablet (FCT) formulation of deferasirox (DFX) had a similar safety profile, with fewer patients (pts) experiencing severe gastrointestinal (GI)-related adverse events (AEs), and more favorable patient-reported outcomes (PROs) compared to the dispersible tablet (DT). PROs of FCT pts showed better adherence, satisfaction, palatability and fewer concerns about iron chelation therapy (ICT). The ECLIPSE trial results and supports previous evidence of improved adherence to DFX FCT over DT.

Aims: To estimate the proportion of the association between tx with DFX FCT versus DFX DT and SF reduction from baseline that is mediated through PROs, in a post hoc analysis.

Methods: The ECLIPSE trial was a phase II, randomized open-label study in pts with transfusion-dependent thalassemia or myelodysplastic syndrome who were randomized to receive DFX FCT (N=87) or DT (N=86) at average planned doses of 30.7 mg/kg/day (±10% deviation from target) and 28.7 mg/kg/day, respectively. PROs were assessed at weeks 2, 3, 13, and 24 (end of tx) using the Palatability and modified Satiety score, other PRO scores, and frequency of GI-related AEs during tx. Adherence was adjusted for confounders including age, sex, race, underlying hematological disease, prior use of DFX DT, and baseline level of iron overload severity, and frequency of GI-related AEs during tx. Comparison between the two periods was performed with a Wilcoxon sign-rank test for continuous data and McNemar’s test for dichotomized data.

Results: Of the 606 eligible pts, 56% were female, 64% were <35 years old, and 42% had transfusions during the baseline period. The median durations of the DFX DT and DFX FCT periods were 359.0 days and 290.0 days, respectively. Compared with adherence to DFX DT, adherence to DFX FCT was significantly improved across all measures. Mean MPR of DFX FCT vs DFX DT was 0.80 vs 0.76 (p<0.001); 60.9% pts had a mean MPR 20.8 during the DFX FCT period compared to 54.3% during the DFX DT period (p<0.01). Mean 3-month PDC of DFX FCT vs DFX DT was 0.83 vs 0.71 (p<0.001); 50.0% pts had mean 3-month PDC of 20.8 during the DFX FCT period compared to 34.5% during the DFX DT period (p<0.001). The proportion of pts with 3-month persistence to DFX FCT vs DFX DT (without a gap ≥30 days) was 87.2% vs 63.4% (p<0.01). Similarly consistent and significant results for PDC and persistence were observed using a 6-month time interval and/or a 60-day gap between claims.

Summary/Conclusions: Adherence and persistence to ICT was significantly improved in pts who switched from DFX DT to DFX FCT. Reasons for switching, which may contribute to improved adherence, were not examined in this study. Nevertheless, since the majority of pts were already adherent to DFX DT, this suggests that DFX FCT can be further augmented with this formulation. This real-world study complements the ECLIPSE trial results and supports previous evidence of improved adherence to DFX FCT.

ASSessment of the performance of a widely available T2^R2^ LIVER IRON CONCENTRATION METHOD USED IN CLINICAL PRACTICE IN A POPULATION OF THALASSEMAIA PATIENTS

N. Tran1, N. Tran2, N. Pham3, C. Ca1, P. Nguyen4, T. Pham5, L. Trinh6, C. Tran7, T. Hai8, T. Pham1, N. Vien9, T. Pham1, N. Huynh1, N. Nguyen1, T. Nguyen2, N. Tran2, N. Pham3

1Blood Transfusion, Hanoi, Vietnam, 2School of Physics, The University of Western Australia, Crawley, 3Resonance Health, Claremont, Australia

Background: Measurements of liver iron concentration (LIC) by magnetic resonance imaging (MRI) have become established and validated in several research intensive centers. While the validity of spin density projection assisted (SDPA) R2-MRI together with a core laboratory service has been validated in routine clinical practice settings, methods relying on b-hemoglobin as an endogenous target of acquisition protocols and data analysis have not yet been validated in this way.

Aims: To determine the limits of agreement between measurements of LIC by a widely available T2^R2^ MRI method and a reference standard based on T2^R2^ MRI method in a routine clinical practice setting.

Methods: 70 pts referred by the National Institute of Haematology and Blood Transfusion, Hanoi, Vietnam for routine LIC measurement by MRI were prospectively recruited with informed consent. Patients were randomised to be scanned in either a Philips Ingenia or a Siemens Avanto 1.5T scanner. The LIC of each patient was measured twice, once by a T2^R2^ technique using freely available software and protocols (Iron Health Calculator: http://www.ironcalculator.com) and once by SDPA R2-MRI using a quality controlled core laboratory data analysis service (FerrScan®). Analyses using the T2^R2^ data analysis method were blinded from the SDPA R2-MRI results and vice versa. Reported data were analysed using the statistical methods of Bland and Altman.

Results: A plot of the T2^R2^ LIC against the SDPA R2-MRI LIC (Figure 1) shows the very large majority of data falling below the line of equality indicating that the T2^R2^ method is underestimated the LIC relative to the SDPA R2-MRI validated reference standard. The geometric mean ratio of T2^R2^ LIC to SDPA R2-MRI LIC was 0.44 (95% CI 0.36 –0.55) indicating severe underestimation of LIC by the T2^R2^ method. The geometric mean ratios of the two LIC measurements were significantly different for the two scanners (0.28 for Philips and 0.68 for Siemens, p<0.0001) indicating that the bias of the T2^R2^ method against the reference standard is not universal but is dependent on both/either scanner type and/or data acquisition method. Bland Altman analysis indicates that 95% of pairs of measurements are predicted to have differences between 3.73 and 0.05 indicating a very large random variability between the T2^R2^ method and the reference standard. The performance of the T2^R2^ method with regards to predicting SDPA R2-MRI LIC values above the clinically relevant thresholds of 7 and 15 mg Fe/g dw is characterized in the Table 1 showing positive predictive values (PPVs) and negative predictive values (NPVs) together with their 95% CIs.

Table 1.

Mean (SD) duration of deferasirox exposure in group A was 7.5 (1.7) years; mean daily deferasirox dose was 1280 mg.

In both subgroups analyzed, mean SCR was within normal limits and remained stable over time during the retrospective period (Figure 1). Analysis in adults showed mean SCR values were stable over time. As expected in growing children who are gaining height and weight, pediatric mean SCR absolute values increased from baseline in proportion with an almost linear increase in muscle mass over time.

Summary/Conclusions: The data indicate that the T2*/R2* method of measurement of LIC is not safe for routine clinical measurement of LIC because of the extremely poor NPIVs which could result in inappropriate clinical decision making. The severe discrepancies of the T2*/R2* method from the reference standard are likely caused by several factors including non-optimal curve fitting algorithms, lack of a method to identify non-analysable data, and the use of a calibration curve from the literature generated from data acquisition and analysis methods different from those used locally. These or similar pitfalls are likely to be encountered in many MR centres using non-regulated MR methods of LIC measurement.

P288
SIMILAR TRENDS IN RENAL FUNCTION AS MEASURED BY SERUM CREATININE DURING LONG-TERM IRON CHELATION TREATMENT WITH OR WITHOUT DEFERASIROX IN PATIENTS WITH TRANSFUSIONAL HEMOSIDEROSIS

R. Origa1,*, A. Piga2, I. Tartagliona3, G. Della Corte4, A. Brueederle5, J. Han6, C. Castiglioni6, G.L. Foriero7. For the Kidney Chart Review Study Investigators8
1Ospedale Pediatrico Microcitemico 'A Cao', University of Cagliari, Cagliari, Italy, 2University of Turin, Orbassano, Turin, 3Università della Campania ‘Luigi Vanvitelli’, Naples, 4Università di Milano, Ca Granda Foundation IRCCS, Milan, Italy, 5Novartis Pharma AG, Basel, Switzerland, 6Novartis Pharmaceuticals Corporation, East Hanover, United States, 7Novartis Farma SpA, Origgio, 8Ospedale Galliera, Genoa, Italy

Background: Regular transfusion and iron chelation therapy (ICT) are often indicated for patients with β thalassemia, sickle cell disease (SCD) and other anemias, and can be lifelong requirements. As most patients now survive into adulthood and many experience prolonged exposure to ICT, there is increased risk of age-, disease- or drug-related complications, including changes in renal function. Evidence suggests that some patients receiving ICT experience changes in markers of renal function, mostly within normal limits, non-progressive and reversible with dose reduction and/or interruption. Recently, we reported a retrospective analysis of patients with transfusion-dependent anemia during a decade of deferasirox treatment indicating stable and a lack of any progressive worsening of renal function (Origa R et al. Blood 2016).

Aims: To assess serum creatinine (SCR) during long-term deferasirox treatment in subgroups of Italian patients with transfusional hemosiderosis who participated in the deferasirox registration studies and who were then followed retrospectively.

Methods: Italian patients with β thalassemia, SCD, myelodysplastic syndromes or other anemias who received ≥1 deferasirox dose in the registration studies (studies 105, 106, 107, 108 or 109), had ≥1 post-baseline (BL) SCR measurement, and had medical records available were included. SCR values were collected retrospectively in 3-month periods from registration trial end until the latest patient assessment. Primary endpoint was SCR over time. SCR values during the retrospective period were evaluated by subgroups: those who received only deferasirox and those who received no deferasirox but other ICT during the retrospective period.

Results: 282 patients were included in the retrospective study who received ≥1 deferasirox dose in registration studies; of these, during the retrospective period, 98 (35%) received only deferasirox (group A) and 82 (22%) received no deferasirox but other ICT (group B). In group A, mean (SD) age at first quarter was 25.9 (12.1) years and 36 (37%) were male; in group B, mean (SD) age at first quarter was 27.0 (10.9) years and 25 (40%) were male. The proportion of pediatric patients was 28% (n=27) in group A and 19% (n=12) in group B.

Mean (SD) duration of deferasirox exposure in group A was 7.5 (1.7) years; mean daily deferasirox dose was 1280 mg.

In both subgroups analyzed, mean SCR was within normal limits and remained stable over time during the retrospective period (Figure 1). Analysis in adults showed mean SCR values were stable over time. As expected in growing children who are gaining height and weight, pediatric mean SCR absolute values increased from baseline in proportion with an almost linear increase in muscle mass over time.

Summary/Conclusions: This retrospective study of long-term renal safety in patients receiving iron chelation for transfusional iron overload suggests that long-term deferasirox treatment, or administration of ≥1 deferasirox dose followed by other chelators, did not have an overall detrimental long-term effect on renal function as monitored by SCR. This analysis provides no evidence of progressive renal function worsening over time, which is consistent with previous results demonstrating deferasirox has a mild, generally reversible renal hemodynamic effect.

P289
WHEN IRON LEADS TO RED CELLS (AND VICE VERSA): A COMPREHENSIVE PHENOTYPE -TOWARDS NGS/WES PATHWAY FOR THE DIAGNOSIS OF RED CELL AND IRON DISORDERS

M. Giansily Blaizot1, S. Cunat1, O. Guillot1, G. Mouliol1, P. Aguilar Martinez1,*, 1Hematology, Hopital Saint Eloi, Montpellier Cedex 5, France

Background: Despite thorough clinical and biological phenotypic investigations, a number of red cell disorders remain uncharacterized. In addition, some of them are accompanied by overt iron overload and can be initially misdiagnosed as disorders of genes involved in iron metabolism. Next Generation Sequencing (NGS) has become an attractive technique to decipher constitutional disorders as it allows analyzing a large number of disease-causing genes. However an initial complete clinical, biological and morphological assessment is mandatory to correctly orientate towards the correct gene panel and to interpret the various molecular variations identified. We have set up in our center, a specialized outpatient consultation for both iron and red cell disorders. Specialized phenotypic investigations including biological and morphological tests followed by standard or second level genotyping can be prescribed.

Aims: The aims of this study was to characterize the molecular background of patients with iron or red cell disorders, or with a possible combination of both, and to propose key steps towards this genetic diagnosis.
Methods: A cohort of 25 well characterized patients was analyzed. Eighteen were initially referred to our center for unexplained hyperferritinaemia (HF), two for proven iron overload (IO) by MRI, 2 for chronic hemolysis and 3 for aferen- erative anaemia. A set of phenotypic tests was systematically assessed, including CBC, reticulocyte count, serum haptoglobin and measure of the Liver Iron Content (LIC) by MRI. For all patients with HF, causes linked to hepatic disease, inflammatory and neoplastic disorders were ruled out and standard HFE mutational screening was performed. Phenotypic investigations failed to clearly identify the cause of the disorder. Therefore, each patient was tested for a panel of 32 genes involved either in iron homeostasis or hereditary anemias, using NGS. Libraries were obtained using the Custom SureSelectXTarget Enrichment system (Agilent, Santa Clara CA USA) and sequenced on a MiSeq platform (Illumina, San Diego, CA, USA). Each deleterious variation was independently checked using conven- tional Sanger sequencing. Written informed consent was obtained from all the patients for NGS genetic analyses.

Results: Initial phenotypic reassessment allowing classifying the patients into 5 different groups: 1/ isolated hyperferritinaemia (n=11); 2/ HF and IO (n=90 µmol/g dry weight) (n=17); 3/ hemolytic anaemia (HA) without IO (n=2); 4/ HA and IO (n=2); 5/ aferenaric anaemia with IO (n=3). Among patients with an initial diagnosis of iron disorder, the reticulocyte count identified 2 undiagnosed chronically fully compensated haemolytic. Systematic screening using the gene panel identified a total of 14 sequence variations of clinical significance in 9 dif- ferent genes and 9 patients. An isolated mutation was found in 7 and 2 patients with an initial diagnosis of iron or of red cell disorder respectively. A combined aferenity of red cell and iron genes was identified in 3 patients who displayed IO and compensated haemolytic or anemia. Digestion involving an HFE C282Y mutation was found in 3/4 patients with IO (without anemia or haemolysis). No sequence variation of clinical significance was found in the sequenced genes of eleven of the studied patients.

Summary/Conclusions: On the phenotypic point of view, the present study highlights the importance to check for hematological data (CBC and reticulocytes) in patients with HF, because this can allow discovering fully compensated hemolytic and bringing towards a red cell disorder. On the other hand, it also underlines the importance to systematically check for IO all patients with a red cell disorder, who may display high LIC. Our present genotypic data (and pre- viously reported findings) show the frequency of combined inherited disorders of iron and red cells, making the combined search for both disorders quite relevant in clinical practice. This is now possible with the use of NGS analysis, which allows sequencing large numbers of genes. For those patients with no identified mutation, approaches using whole exome or genome can be proposed as the next step.

Cervelo, Palermo, 2Ospedale Vittorio Emanuele, Catania, 3UOS Talassemia P.O. “Giovanni Paolo II”, Sciacca, 4Centro di Prevenzione e Curare della Microcitemia, P.O. S’Agata Militeo, Sant’Agata Militeo (ME), 5A.O. “M. Pateron Aarezzo”, Ragusa, 6U.O.D. Malattie Rare del Globulo Rosso, A.O.R.N. “A. Cardarelli”, Napoli, 7La Sapienza University Radiologia, AOOR Villa Sofia-Cervello, Palermo, Italy

Background: The liver plays a central role in iron regulation and remains the primary site of iron storage, with liver iron concentration (LIC) being a strong surrogare of total body iron. Both R2 and T2* can accurately measure LIC. R2 MRI has been used in the study of haematological disorders and the measurement has been shown to be a sensitive indicator of iron balance.

Aims: The aim of the study was to evaluate longitudinal changes in LIC mea- surements across different iron chelation regimens in a real-life cohort of patients with transfusional iron overload included in LICNET.

Methods: This was a retrospective cohort study in patients with haematological disorders attending 9 Italian centres participating in the LICNET who had two R2 MRI scans recorded in the database and receiving the same iron chelation in between. Bivariate comparisons were made using the chi-squared and Fisher- er’s exact tests for categorical variables and the Wilcoxon or Mann–Whitney tests for continuous variables.

Results: A total of 130 patients were evaluated in this analysis, with a median (range) age years of 35 (range: 6–78) and including 60 (46.2%) men. The underlying diagnoses were regularly transfused thalassaemia major (n=86, 66.2%), thalassaemia Intermedia (n=33, 25.4%), sickle cell disease (n=6, 4.6%), myelodysplastic syndrome (n=3, 2.3%), and Diamond-Blackfan anaemia (n=2, 1.5%). The median duration (range) between the first and second MRI was 483 days (184-1076) and was comparable between iron chelation regimens. Median pre-transfusion hemoglobin level and blood requirement were similar at both MRIs.The median change in LIC (range) in mg Fe/g dw was not signif- icant in patients receiving DFP (n=29, median change -1.9, p=0.55), DFO (n=32, median change -0.5, p= 0.151), DFO+DFP (n=10, median change -2.2, p=0.074), or other combinations (n=7, median change -1.3, p=1.000), while it decreased significantly on DFO monotherapy (n=32, median change - 1.4,p=0.002). Among oral chelators, DFX showed to be more effective, during the period of the study, in stabilizing iron body burden in 65.4% patients even if they had baseline LIC values <7mg Fe/g dw (median 4.0 mg Fe/g dw) and with similar response as combined treatment DFO+DFP (Figure 1).

Figure 1.

Summary/Conclusions: This cohort study suggests that stabilization of LIC is achievable, during a median of 483 days, with different iron chelation regi- mens in real life experience, with considerable proportions of patients shifting to more favourable LIC categories. Therefore, the prospective determination of LIC by MRI has to be strongly recommended for management and prevention of iron overload and subsequent complications in haematological disorders.

IN UTERO IRON STATUS AND AUDITORY NEURAL MATURATION IN FULL-TERM INFANTS BORN TO MOTHERS WITH IRON DEFICIENCY ANEMIA

M. Elia1, R. El-Farrash1, H. Tahah2, E. Ismail2, N. Mohamed1,2

1Pediatrics Department, 2Audiology Department, 3Clinical Pathology Depart- ment, Faculty of Medicine-Ain Shams University, 4Ministry of Health, Cairo, Egypt

Background: Iron deficiency is the most important cause of nutritional anemia and is the most common micronutrient deficiency worldwide, especially in develop- ing countries. Iron is crucial for fetal brain development; hence, there is a parameter need for diagnostic neurofunctional screening that could identify low CNS iron stores. However, there are insufficient data regarding the effects of maternal iron deficiency anemia (IDA) on auditory neural maturation.

Aims: To evaluate the effect of maternal IDA on auditory neural myelination in full term neonates using the auditory brainstem evoked response (ABR) as noninvasive neurophysiological assessment tool.

Methods: This prospective case-control study was conducted at Ain Shams University Hospitals and included 100 neonates. Out of 223 pregnant women, 50 were diagnosed as having IDA anemia and 50 healthy mothers were enrolled as a control group. Neonates were studied focusing on anthropometric measures, hematologic profiles and iron status. Auditory brainstem response (ABR) measurements were done for the studied neonates within 48 hours after birth and at 3 months.

Results: Hemoglobin and iron profile were lower in neonates born to anemic mothers compared with controls. Of 100 neonates screened for ABR, 25 failed the test (all of them were born to anemic mothers). Neonatal birth weight, crown-heel length, BM1, Talassemia, Gela (CL), TA “Blanchet Malacrin-Morelli”, Reggio Calabria, 6U.O. of Talassemia P.O. “Giovanni Paolo II”, 7Sciaccia, 8Centro di Prevenzione e Curare della Microcitemia, P.O. Summary/Conclusions: In this study of pediatric cancer survivors, the gradients between SF and LIC and the SF cut-offs identified for predicting clinically important LIC values are considerably lower than observed for thalassemia or adult HSCT patients. This difference in the relationship between SF and LIC for different patient and age groups highlights the difficulty in relying on SF to screen for and define iron overload.

Summary/Conclusions: IDA during late pregnancy adversely affects cord blood iron and hearing status. ABR results are closely related to the severity of maternal and neonatal iron status. Antenatal screening of pregnant mothers is needed to improve fetal iron status and prevent abnormal auditory maturation.

P292
THE RELATIONSHIP BETWEEN SERUM FERRITIN AND LIVER IRON CONCENTRATION IN PEDIATRIC CANCER SURVIVORS M. House1,2, K. Sadak3, J. Lee1, A. Smith3, T. St. Pierre1,2,*

Background: There is increasing recognition that pediatric cancer survivors are at risk of transfusion-related iron overload related to intensive treatment regimes and improved survival rates. Current screening approaches rely on serum ferritin (SF). However, little is known about the SF to liver iron concentration (LIC) relationship in pediatric cancer survivors and whether SF thresholds derived from other iron overload disorders or age groups are appropriate.

Aims: The aim of this study was to investigate the relationship between SF and LIC in pediatric cancer survivors and to determine SF thresholds for predicting clinically significant LICs in this patient group.

Methods: In this retrospective study, patient data were extracted on survivors with elevated ferritin or iron overload from the University of Minnesota Childhood Cancer Survivor Program research database. All patients were enrolled into the database via an informed consent process according to the guidelines of the University of Minnesota Institutional Review Board. Survivors were retrospectively selected once they reached 18 years of age. Seventeen individual survivors were identified where both SF and LIC data were available and the time between the SF and LIC measurement was less than 30 days. Eleven of the 17 survivors had multiple SF measurements producing a final dataset with 34 pairs of SF and LIC measurements. Blood for serum ferritin was collected during antenatal screening and analyzed by the University of Minnesota Medical Center, Fairview CLIA-certified clinical laboratory. Liver iron concentration measurements were made using spin density projection-assisted R2-MRI (FerriScan®). Linear regression was used to determine the relationship between SF and LIC. Receiver operating characteristic (ROC) curve analysis was used to assess the sensitivity and specificity of SF concentrations for predicting LIC.

Results: The average age of the cohort (6 females and 11 males) at their first SF/LIC measurement was 18.3 years (range 9 to 30.3 years). Acute lymphoblastic leukemia (N=5) and acute myeloid leukemia (N=4) were the most common diseases and 15 of the 17 survivors had received a hematopoietic stem cell transplant (HSCT). The average length of time between the final treatment and the first SF/LIC measurement was 5.4 years (range 0 to 12.5 years). A linear fit to all 34 LIC-SF measurement pairs (Figure 1) produced a gradient of 63 ± 15 (mg ferritin/L)/(g dry liver tissue)/(mg Fe)/(L serum) and an intercept of 509 ± 157 (mg ferritin/L) (r²=0.36). The ROC curve analysis (Table 1) indicated that, in this cohort, a SF cut-off of 1270 mg/L potentially has good sensitivity and specificity for predicting a LIC above 15 mg Fe/g and a SF cut-off of 1076 mg/L has poor diagnostic performance for predicting a LIC above 7 mg Fe/g.

Table 1. ROC Curve Analysis.

AUC, area under the receiver operating characteristic curve.

Figure 1.
Methods: Prospective randomized controlled study conducted in department of Obstetrics & Gynecology, in a tertiary care hospital in Delhi, India. 60 women having Iron deficiency Anaemia with Hb 6-8 g% were randomized 1:1 into two groups and were given 1000mg parenteral iron on day 0 and 8. 200mg Iron Sucrose complex was given in second group on alternate days for 5 doses. Haematological parameters - Hb, Reticulocyte count, RBC indices, S. ferritin; clinical parameters - fatigue, dyspnoea on exertion and adverse effects were studied on day 0, 7, 14 & 28.

Results: Two FCM infusions vs five ISC infusions were required. On day 28 Hb increment ≥3 g/dl seen in 63.33% and MCV>80FL seen in 100% of FCM group vs 0% and 43.33% in ISC group. FCM group had 3.17 g/dl increase in Hb vs 1.9 g/dl in ISC group. S. Ferritin increased to 147ng/ml in FCM group vs 98 ng/ml in ISC group. Significant improvement in RBC indices & retic count was seen in FCM group. Earlier and significant improvement in fatigability & dyspnoea on exertion was observed in FCM group. Both groups had similar safety profile except for thrombophlebitis was observed in 6.67% FCM group vs 50.00% ISC group.

Summary/Conclusions: Intravenous Ferric Carboxymaltose is more effective and safer than Iron Sucrose complex in treatment of Iron deficiency anaemia.
phoid neoplasms characterized by highly infiltrated tumor cells in lymphoid tissues and extra nodal sites. The patients have short responses to current therapies and frequent relapses. However, recent studies have identified a subset of MCL with indolent clinical behavior that tends to present with leukemic disease instead of extensive nodal infiltration, and that is characterized by the absence of the transcription factor SOX11 (SRY (Sex determining region-Y)-box 11). SOX11 oncogenic pathways driven MCL tumor progression are poorly known.

Aims: The goal of our study was to identify the spectrum of genes regulated by SOX11 in malignant lymphoid cells and provide insights on how the constitutive overexpression of SOX11 may contribute to the oncogenic development of MCL. Methods: We transiently transfected stable transgenic DLBCL-silenced MCL cell lines with reduced SOX11 protein levels by infecting MCL cell lines with lentiviral particles carrying shRNA plasmids specifically targeting SOX11. SOX11-positive MCL cell line was infected with the empty vector and used as a control. These two MCL cell lines were injected in two different mice models to analyze in vivo the impact of SOX11, subcutaneous (sc) and intraperitoneal (iv) xenograft tumor models. To analyze the crosstalk between MCL and microenvironment, we did in vitro cocultures experiments using accessory cells at the tumor microenvironment, as endothelial and bone marrow mesenchymal cells.

Results: In the sc mice model, we observed that SOX11 silencing reduced tumor growth compared to SOX11-positive control tumors. We analyzed the gene expression profiling of these xenograft tumors and of SOX11-positive and negative primary cases and we observed than different microenvironment-related signatures were enriched in SOX11-positive compared with SOX11-negative cells, as angiogenesis, migration and stromal stimulation. By CHIP-chip analyses, we identified AICDA as one of the key modulators of epigenetic mechanisms involved in these signatures, between these PDGFA. This data indicated a role for SOX11 in the crosstalk of MCL with tumor microenvironment. We found that SOX11 promotes angiogenesis in MCL cells through PDGFA regulation, promoting tumor growth and vasculature. Inhibition of PDGFA on endothelial cells decreased angiogenesis on xenografts and, angiogenesis, invasion and inter-tumor cytosine methylation heterogeneity, of SCID mice with a PDGFA inhibitor reduced tumor growth and angiogenesis of SOX11-positive MCL xenograft tumors. We also observed that SOX11 promotes migration, pseudoemperipolesis (migration of tumor cells beneath stromal cells) and cell adhesion mediated-drug resistance (CAM-DR) in MCL cells, increasing angiogenesis and proliferation; and that these mechanisms were reduced in SOX11-negative cells. In the iv mice model, we observed that SOX11-positive cells were able to migrated and infiltrated bone marrow and lymph nodes, whereas SOX11-negative cells were retained in peripheral blood.

Summary/Conclusions: In conclusion, our results show that SOX11 is regulating essential processes involved in aggressiveness of MCL tumor cells, as angiogenesis, invasion and drug resistance. Inhibition of SOX11-target genes may represent an efficient strategy for the treatment of aggressive MCL.

AICDA DRIVES EPIGENETIC HETEROGENEITY IN GERMINAL CENTER-DERIVED LYMPHOMAS AND ACCELERATES LYMPHOMAGENESE

P.M. Dominguez 1,*, M. Teater 2, D. Redmond 2, Z. Chen 2, D. Ennishi 3, P.M. Dominguez 1,*, M. Teater 2, D. Redmond 2, Z. Chen 2, D. Ennishi 3, 1Department of Medicine, 2Weill Cornell Medicine, New York, United States, 3British Columbia Cancer Agency, Vancouver, Canada, 4NYU School of Medicine, New York, United States

Background: Diffuse large B-cell lymphomas (DLBCLs) are aggressive tumors derived from germinal center (GC) or post-GC B cells. Previous work from our group established that inferior outcome in DLBCL is associated with higher degrees of intra-tumor and inter-tumor cytosine methylation heterogeneity, although the molecules driving this epigenetic perturbation remain unknown.

Aims: We investigated the contribution of activation-induced cytokine deaminase (AICDA) to cytosine methylation heterogeneity in DLBCLs. AICDA is highly expressed in GC B cells where it drives somatic hypermutation (SHM) and also mediates DNA hypomethylation and epigenetic heterogeneity. AICDA is also expressed in a subset of DLBCLs and high level of AICDA in CHOP-treated DLBCL patients is associated with unfavorable prognosis. Thus, we hypothesized that AICDA contributes to epigenetic heterogeneity in DLBCL by facilitating epigenetic plasticity through the redistribution of cytosine methylation.

Methods: We expressed AICDA in malignant lymphoid cells and investigated the impact of AICDA on the methylation and transcription of neoplastic B cells. AIM2. To determine the contribution of AICDA-mediated epigenetic modifications to DLBCL pathogenesis.

Results: We observed more aggressive lymphoma phenotype in VavP-Bcl2/+Aicda mice (n=7) compared to VavP-Bcl2-/+ mice (n=8), based on greater disruption of the splenic architecture and higher degree of B-cell infiltration in organs such as lung, liver and kidney. Notably, the overexpression of AICDA reduced significantly the lifespan of the mice (Log-rank test p=0.0289). Necroplastic B cells from VavP-Bcl2/+Aicda (n=4) and VavP-Bcl2-/+ mice (n=4) displayed similar mutation and indel burdens, suggesting that the more aggressive phenotype in AICDA-overexpressing mice was not likely due to increased mutagenesis. We profiled then the DNA methylation landscape of neoplastic B cells from VavP-Bcl2/+Aicda and VavP-Bcl2-/+ mice. A principal component analysis of all CpGs, represented by its mean DNA methylation and heterogeneity (interquartile range) differences across replicates, revealed methylation loss signatures of AICDA overexpression in VavP-Bcl2/+Aicda lymphomas compared to VavP-Bcl2-/+ (49,750 AICDA-perturbed CpGs). These altered CpGs were depleted in promoters and enriched in introns and intergenic regions. We observed a remarkably similar pattern of focal heterogeneity and demethylation in primary DLBCLs with high AICDA expression to low AICDA expression (p=0.0001). AICDA and, more specifically, AICDA-mediated epigenetic heterogeneity in Aicda-/- cells compared to Aicda+/+ GC B cells (64,332 AICDA-perturbed CpGs), suggesting a conserved epigenetic function of AICDA in GC B cells and human and mouse GC-derived lymphomas. Finally, we found significant overlap between genes affected by AICDA-perturbed CpGs in human AICDA high DLBCLs and murine VavP-Bcl2/+Aicda lymphomas (P=2.21e-23) and with the genes affected by AICDA in GC B cells (P=8.48e-33).

Summary/Conclusions: Our results demonstrate that AICDA acts as a methylome modifier in GC-derived lymphomas, introducing epigenetic heterogeneity, and that AICDA overexpression is associated with higher cytosine demethylation in an evolving environment. These findings are relevant not only for B-cell lymphomas, but also for other types of cancer expressing cytosine deaminases.

P298

XPO1 INHIBITION SYNERGIZES WITH BCR INHIBITION, BLOCKS TUMOR GROWTH AND PROLONGS SURVIVAL IN A BIOLUMINESCENT ANIMAL MODEL OF PRIMARY CENTRAL NERVOUS SYSTEM LYMPHOMA

M. Crespo 1,*, I. Jiménez 1, J. Carabia 3, S. Bobillo 1, P. Abrisqueta 1, C. Palacio 1, C.D. Carpio 1, J. Castellví 1, J. Seoane 4, F. Bosch 1

1Experimental Hematology, 2Hematology, Vall d’Hebron Institute of Oncology, 3Pathology, Vall d’Hebron Research Institute, 4Gene Expression and Cancer Laboratory, Vall d’Hebron Institute of Oncology, Barcelona, Spain

Background: Primary central nervous system lymphoma (PCNSL) is an non-Hodgkin lymphoma localized in the CNS. Approximately 95% of PCNSL are classified as diffuse large B-cell lymphoma (DLBCL), being most of them related to activated B-cell type (ABC-DLBCL). PCNSL is associated with poor prognosis, particularly because of the difficulty to drugs to cross the blood brain barrier. High dose methotrexate is the most effective treatment, but relapse is very common and salvage treatment options are scarce. Also, in patients with systemic lymphoma, the secondary infiltration of the CNS is a fatal event, with a global overall survival of less than six months. Therefore, the development of new drugs with ability to penetrate the CNS is highly needed. Selinexor (KPT-330) is a Selective Inhibitor of Nuclear Export (SINE) that inactivates XPO-1 protein and induces anti-tumor effects mainly due to forcing nuclear retention and activation of tumor suppressors. Selinexor has shown excellent brain penetration and promising results in pre-clinical models of glioblastoma and can inhibit both BCR and NF-κB signaling in malignant B-cells.

Aims: In order to provide a pre-clinical rationale for the design of new therapies for patients with CNS lymphoma our main aim is to assess the role of XPO-1 inhibition in intracerebral xenograft murine models.

Methods: We in vitro tested the sensitivity of DLBCL cell lines to selinexor and etbrutin by MTS and AnnexinV/PI assay. We established an orthotopic xenograft model of PCNSL with stereotactic injection of OCI-Ly10 (ABC, MYD88 and CD79b mut) cells expressing luciferase into the cerebral parenchyma of nude athymic mice. We longitudinally quantified intracerebral tumoral growth by bioluminescence detection.

Results: To compare the sensitivity of DLBCL cell lines to selinexor we determined the IC50 in terms of survival and proliferation in 4 ABC and 5 GCB DLBL cell lines. DLBCL cell lines had equivalent sensitivity to selinexor, regardless of cell of origin (COO). In detail, survival by AnnexinV/PI exclusion showed that mean ID50 for ABC cell lines was 4.98 µM +/- 3.6 and 6.3 µM +/- 3.8 for GCB (p=0.9). Proliferation by MTS was also blocked by selinexor (mean ID50 for ABC-DLBCL was 1.35 µM +/- 0.7 vs 16.16 µM +/- 11.17 for GCB-DLCL (p=0.41)). Since SINE compounds have been shown to inhibit activation of the tumor suppressors, Selinexor has shown potential in glioblastoma and in a novel approach of depleting microenvironmental stromal elements, we used a SINE inhibitor in xenograft model of PCNSL by stereotactic injection of OCI-Ly10 cells expressing luciferase into the cerebral parenchyma of nude athymic mice. Eleven days after the injection of cells all animals developed detectable tumors confined to the CNS. Tumor size

92 | haematologica | 2017; 102(s2)
was measured and animals were randomly distributed into drug or vehicle group. At this time point mice were treated with 5mg/kg of selinexor or vehicle via oral gavage three times a week; subsequently, bioluminescence was assessed twice a week. Treatment with selinexor significantly increased mice survival, with a median survival of 48 days in the treatment group compared to 34 days in the vehicle group (p<0.0001; Figure 1A). Mice in the treatment group showed a significantly slower increase of tumor growth and increases survival. Our results provide preclinical evidence for the development of selinexor as new therapeutic option for PCNSL or DLBCL with CNS involvement.

**Summary/Conclusions:** Selinexor inhibits proliferation and survival of DLBCL cell lines regardless of COO and it can synergize with triltninib. Treatment of mice with CNS confined ABC-DLBCL with selinexor significantly reduces tumor growth and increases survival. Our results provide preclinical evidence for the development of selinexor as new therapeutic option for PCNSL or DLBCL with CNS involvement.

**MOLECULAR HETEROGENEITY IN PERIPHERAL T-CELL LYMPHOMA NOS: OTHERWISE MISCLASSIFIED REVEALED BY COMPREHENSIVE MUTATIONAL PROFILING**

Y. Watanat1,*, Y. Sato2, K. Nishida2, H. Miyoshi3, Y. Shiraishi4, K. Chiba5, H. Tanaka2, H. Ueno1, N. Kakuchi1, Y. Shiozawa1, T. Yoshizato1, K. Yoshida1, M. Sanada3, S. Miyano4, K. Ohshima1, T. Yoshino1, S. Ogawa1, K. Kataoka1, 1Department of Pathology and Tumor biology, Kyoto university, Kyoto, 2Department of Pathology,Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, 3Department of Pathology, Kurume University School of Medicine, Fukuoka, 4Laboratory of DNA Information Analysis, Human Genome Center, Institute of Medical Science, The University of Tokyo, Tokyo, 5Department of Advanced Diagnosis, Clinical Research Center, Nagoya Medical Center, Nagoya, Japan.

**Background:** Peripheral T-cell lymphomas (PTCLs) are a highly heterogeneous group of mature T-cell neoplasms. In particular, accounting for the majority of PTCL-NOS, PTCL-NOS not other specified (PTCL-NOS) is a diagnosis of exclusion and such, is expected to include many heterogeneous tumors. In fact, recent genetic studies have suggested that a subset of PTCL-NOS is closely related to angioimmunoblastic T-cell lymphoma (AITL); both lymphoma types show follicular helper T-cell (TFH) phenotypes and share mutational targets in common, such as RHOA, TET2, DNMT3A, and IDH2. However, with the lack of comprehensive genetic analyses, the molecular pathogenesis is poorly understood in the majority of PTCL-NOS cases.

**Aims:** The aim of this study is to extensively dissect the dynamics of DNA methylation in B-cell neoplasias in the light of normal B cell maturation program. The ultimate goal of this study was to generate new clinically relevant knowledge regarding diagnostic and prognostic value.

**Methods:** Our dataset included whole-genome bisulfite sequencing data (n=57) and high-density methylation arrays (n=1161) from acute lymphoblastic leukemia (ALL), mantle cell lymphoma (MCL), Burkitt lymphoma (BL), follicular lymphoma (FL), diffuse large B cell lymphoma (DLBCL), chronic lymphocytic leukemia (CLL) and multiple myeloma (MM) as well as from ten different normal B cell subpopulations. As DNA methylation estimates in neoplastic samples are influenced both by tumor cell content and composition of the micro environment, we developed a new method to deconvolute and in silico purify the methylation signal of tumors arising in different niches (bone marrow, peripheral blood and lymph node). The data were analyzed by a series of bioinformatic and biostatistical approaches and correlated with clinical variables.

**Results:** The initial bioinformatic approach to purify DNA methylation signals in B cell tumors revealed that samples with less than 55% tumor cell content could not be accurately purified. This strategy reduced the initial 1,044 tumor samples to 866. An unsupervised principal component analysis of in silico purified data revealed that each type of B-cell neoplasia clusters separately. ALLs clustered closer to precursor B cells, CLL and MCL closer to mature B cells and both DLBCL and MM showed the largest deviation from normal B cells.

**Conclusion:** We then performed a differential analysis and determined in each sample vs normal B cell maturation stages, and thoroughly annotated the results to biological and clinical features. From the clinical perspective, we identified that for tumor samples with similar cellular origin, the higher the epigenetic deviation from healthy B cells (number of DNA methylation changes) the worse the clinical outcome for the patients. Furthermore, for each tumor entity, we could identify from 5 to 19 epigenetic biomarkers that could classify each entity with high sensitivity and specificity.

**Summary/Conclusions:** In this study, we show that in silico purification of DNA methylation data is a powerful strategy to accurately measure DNA methylation alterations in tumor cells. Using a large dataset, we have developed a set of epigenetic biomarkers with high differential diagnostic power and identified that the epigenetic drift is a universal prognostic factor that can be applied to different B cell tumors.
Background: Angioimmunoblastic T-cell lymphoma (AITL) is a distinct subset of peripheral T-cell lymphoma with follicular helper T-cell (TFH) features. We and others previously found mutations of RHOA, encoding p.Gly17Val (G17V RHOA), in AITL/TFH lymphoma samples compared to those with WT or mock. Finally, phospho-VAV1 was co-blocked by the dasatinib treatment. The levels of IL-2 mRNA were higher in Jurkat cells expressing each WT cDNA or mock. Phosphorylation was blocked by the dasatinib at 1-10 nM concentrations. The G17V RHOA, VAV1-STAP2 and various specific binding partners of the G17V RHOA mutant were examined by high throughput screening in Jurkat cells. Nuclear factor of activated T cell (NFAT) activity in response to TCR stimulation was examined in Jurkat cells expressing wild-type (WT) and G17V RHOA mutant, and WT and various VAV1 mutants. Phosphorylation of VAV1 occurs within seconds in response to antigen stimulation of the TCRs by Syk and Src-family tyrosine kinases and initiates downstream TCR signaling. We aimed at clarifying the downstream signaling of the G17V RHOA mutant in AITL/TFH lymphoma.

Methods: Proteomic screening was performed to identify G17V RHOA-specific binding partners. Binding was validated by co-immunoprecipitation of G17V RHOA and the candidate partners. Simultaneously, RNA sequencing identified 2 in-flame deletion mutations in an acidic region of phosphotyrosine dioxygenase 2 in up to 70% of AITL and other TFH lymphoma (a sub-group of peripheral T-cell lymphoma, not otherwise specified (PTCL-NOS)) samples. RHOA, a small GTPase, is converted from the GDP-bound inactive form to the active GTP-bound form by guanine nucleotide exchange factors (GNEFs). It has been shown that the G17V variant binds the SH2 domain of STAT3, which encodes the SH2 domain, was performed using 19 to 24 of STAT3, which encode the SH2 domain, was performed using primers from the previous report (N Engl J Med 2012; 366: 1905-13). EBV-negative T- and NK-cell lines and PBMCs from healthy donors were used as negative controls. Cell survival and apoptosis were examined by an XTT assay and Annexin V assay, respectively. The mRNA expression of cytokines was examined by TaqMan® Gene Expression Assays. Results: STAT3 was constitutively phosphorylated on Y705 and S727 and was localized in the nucleus in EBV-negative T- or NK-cell lines and PBMCs from the CAEBV patients, as indicated by western blotting. The microarray analysis of EBV-positive T or NK cell lines from CAEBV patients showed that the expression of STAT3-responsive genes, including interferon-γ, were upregulated in these cells compared with EBV-negative cells. No mutation was detected in the SH2 domain of STAT3 in patient-derived cells by direct sequencing. The JAK inhibitors ruxolitinib and tofacitinib suppressed STAT3 activation and cell survival by inducing apoptosis of the cell lines and PBMCs from CAEBV patients. Ruxolitinib also inhibited the mRNA expression of TNF-α and interferon-γ in CAEBV patient-derived cells. Summary/Conclusions: STAT3 is constitutively activated in EBV-positive T or NK cell lines derived from CAEBV patients. Inhibition by ruxolitinib could be an attractive and effective treatment for CAEBV by suppressing not only EBV-infected cell survival but also the accompanying inflammation.

Background: Folicular lymphoma (FL) is the most common low grade B cell malignancy accounting for ~20% of all non-Hodgkin lymphomas. Approximately 30% of the FL cases suffer a histological transformation to a much more aggressive subtype of lymphoma drastically reducing the overall survival from 10 years to just 14 months. Despite being a critical event during disease progression it is molecularly poorly understood and no biomarkers exist to predict this event. Previous studies have suggested the possibility that deregulation of microRNA expression (miRNAs, small endogenously produced non-coding RNAs) could be implicated in the development of FL disease as well as in the transformation event. We hypothesise that mutations in miRNA binding sites may also have a role in this process. We set ourselves to find predictive biomarkers of transformation for FL, with a special focus on sequence variants affecting miRNA binding sites. Methods: We interrogated whole genome sequencing (WGS HiSeq, Illumina) data from sequentially obtained samples of 6 FL patients that underwent trans-
formation using a bespoke bioinformatic pipeline based on TargetScan prediction algorithm in order to identify mutations in putative miRNA binding sites. Once identified, in order to validate them and test their recurrence in an extended cohort (60 samples from 31 FL patients who underwent transformation plus 21 samples of non-transformed FL patients) we designed an Ampliseq (Ion Torrent, Life Technologies) NGS custom panel. Finally, we selected a number of variants for assessing the variant effect on the miRNA:mRNA interaction, by means of a combination of an in silico predictive algorithm and in vitro luciferase assays.

Results: 36% of somatic variants from WGS data arose in 3’UTR, and 68% of these were putative miRNA-binding sites (525 mutations in 497 genes). Interestingly, the ontology analysis showed that these mutations were not randomly distributed but rather there was enrichment in genes associated with hematological malignances (P=2.18x10-4). We then validated 85% of these mutations using targeted resequencing and found a total of 103 recurrent variants located in putative miRNA binding sites. QC criteria filtering led us to prioritise 38 variants in 25 genes to be functionally tested. Crucially, ontology analysis showed that these genes were highly enriched for GC-like B-cell lymphoma genes (P=4.39x10-5), strongly suggesting that these variants may have a biological significance in the disease. We then performed an in silico approach based on TargetScan miRNA target prediction algorithm to evaluate the effect of the mutations on the binding of the miRNAs to their target sites. Based on these results we prioritized some of these genes to perform luciferase assays. We experimentally demonstrated not only that the majority of these loci are bona fide miRNA targets sites, but also that the presence of a number of these variants cause a dysregulation of the normal miRNA regulatory activity (Figure 1).

PFS (A) and OS (B) by TP53 and/or KMT2D mutational status

Figure 1.

Summary/Conclusions: Our data show that the identified mutations do not occur randomly, but preferentially in putative microRNA binding sites of genes related to lymphomagenesis, supporting their role in FL pathogenesis. Furthermore, the presence of some of the identified variants in microRNA binding sites indeed promotes a dysregulation of the normal miRNA regulatory activity, suggesting that they might have a biological significance in FL.

Onco-Haematology, IRCCS San Raffaele Scientific Institute, Milano, 11Department of Hematology, Ospedale Generale, Bolzano, 12Clinica Humanitatis/Gavazzeni, Bergamo, 13SC Ematologia, Azienda Ospedaliera Santi Antonio e Biagio e Cesare Arrigo, Alessandria, 14Division of Hematology, Department of Translational Medicine, University of Eastern Piedmont, Novara, Italy

Background: Within the landscape of mutated genes in mantle cell lymphoma (MCL), only TP53 disruption has been so far associated with outcome.

Aims: Here we present the clinical update of the deep sequencing MCL gene panel analysis in the prospective FIL-MCL0208 phase III trial (NCT02354313), high-dose immunochemotherapy followed by autologous transplantation for untreated, advanced stage <65 years MCL) based on the data from the second interim analysis.

Methods: A targeted resequencing gene panel, including coding exons and splice sites of the ATM, BIRC3, CCND1, KMT2D, TP53, TRAP1, WHSC1, and NOTCH1 genes was analyzed in tumor DNA from baseline bone marrow CD19+ purified MCL cells and, to filter out polymorphisms, in the paired normal genomic DNA (55% of cases) using a TruSeq Custom Amplicon target enrichment system followed by deep next generation sequencing (Illumina, median depth of coverage 235x). Variants represented in >10% of the alleles were called with VarScan2 with the somatic function when the paired germline DNA was available. For patients lacking germline DNA, a bioinformatics pipeline including a number of stringent filters was applied to protect against the misclassification of polymorphisms as somatic variants. Clinical data were updated at the time of the second interim analysis (January, 2017).

Results: Out of the 300 enrolled patients, 174 were evaluable for mutations. Median follow-up of the cohort was 36 months, and 3-years PFS and OS were 67% and 86%, respectively. Patients not included in the study, due to unavailable tumor DNA (n=126) showed superimposable clinical features and outcome. Mutations of TP53 (8% of cases) and KMT2D (11% of cases) associated with an increase in the hazard of progression both in univariate analysis as well as after adjusting for MIPI, Ki67 and blastoid variant: HR 3.87 (95% CI 1.64 to 9.13), p<0.002 and HR 3.66 (95% CI 1.77 to 7.56), p=0.001, respectively. These results translated into an increase of the hazard of death in both TP53 and KMT2D mutated patients both in univariate analysis as well as adjusting for MIPI, Ki67 and blastoid variant HR 4.26 (95% CI 1.34 to 13.57), p=0.014 and HR 3.09 (95% CI 1.07 to 8.86), p=0.036, respectively. On these bases, a survival model was proposed based on the TP53 and KMT2D mutation status: 3-years PFS and OS were 26% and 64% for patients carrying either TP53 or KMT2D mutations or both vs 75% and 92% for patients without any of these mutations (Figure 1).

Summary/Conclusions: The updated clinical results of the FIL-MCL0208 trial show that: i) both TP53 and KMT2D mutations independently associate with shorter PFS and OS in younger MCL patients receiving high-dose therapy; ii) KMT2D mutations seem to be as detrimental as TP53 mutations, at least in terms of PFS; iii) given the negative prognostic impact of these mutations, they might be used to select high-risk patients for novel therapeutic approaches.
Multifaced aspects of bleeding disorders

P305

A LOOKBACK AT VWD TYPE 2A AND 2M CLASSIFICATION IN A LARGE COMPREHENSIVE HAEMOPHILIA CENTRE.

S. Jaafar1,2, T. T. Yue1

1Haematology, Royal Free Hospital/NHS, 2Haematology, katharina dornandy haemophilia centroreyal free hospital, london, United Kingdom

Background: Von Willebrand Disorder (VWD) has a prevalence of approximately 1% in the general population and is due to quantitative deficiencies or qualitative defects of the Von Willebrand Factor (VWF) protein. VWF is a large multimeric protein with multiple functions. It carries and protects factor VIII and helps in the binding of FVIII, platelets and the vascular endothelium at sites of injury. VWF binding to platelets is through several receptors most notably the glycoprotein 1b (GP1b) and collagen exposed at site of injury is important for VWF adhesion to the subendothelial matrix forming an adhesive anchor. Classification of VWD is based on the quantitative deficiencies (Type 1 and 3) and VWD type 2 are qualitative defects of the VWF protein with or without quantitative deficiency as well. Type 2 VWD is further subdivided into type 2A,2B,2M and 2N. These subtypes vary depend on a number of laboratory assays that measure the FVIII activity, VWF protein level (VWF:Ag assay) and the function of the protein i.e its ability to bind to 1) FVIII (VWF binding assays) 2) platelets (VWF Rcof assay) and 3) collagen (VWF:CB assay). Other tests include ristocetin induced platelet aggregation (RIPA), multimer analysis, assay ratios and VWF genetic analysis. No single commercially available laboratory method can achieve to test all the parameters required to clinch the accurate diagnosis of the subtypes of VWD. Use of those multiple assays with VWF Rcof/VWF:Ag ratio, VWF CB (VWF-CB) / VWF Ag ratio have helped in the better identification of VWD and the subtypes.

Aims: To assess recent various VWF investigation panels and assay ratios, VWF genetic analysis, multimeric patterns of the VWF protein in accurate diagnosis of the VWD subtypes. VWD 2A and 2M shows similarities in certain aspects and it is important to differentiate these 2 subtypes as new therapies become available and personalized treatment approaches of VWD become a reality.

Methods: Clinicians who have made a diagnosis of VWD for individuals referred for a bleeding state work up would classify the subtypes of the VWD according to the results of the investigations available at the time of seeing the patients. All patients with an inherited bleeding disorder would then be registered in the centre and details would be put into a database. We have looked back into the database from the period of 2000 to end of 2016 and focussed on the VWD types 2A and 2M. Current VWD diagnostic panel in our centre includes the following tests: FVIII one stage assay, VWF:Ag Elisa, VWF rcof, Platelet agglutination method, VWF CB Elisa methods. VWF multimeric analysis by gel chromatography and VWF exon 27/28 genetic mutations are routinely done. New information and new set of results for the registered patients have been taken into account the classification of VWD type 2A and 2M and the database are updated.

Results: In the VWD database 36 patients classified as 2M and 19 patients as type 2A have been recorded from 2000 to end of 2016. With the updated results and genetic analysis and the response to DDAVP, around 30% of the patients have had their subtypes changed. This exercise confirms that no singular test or combination of tests can be used to accurately diagnose the VWD and its subtypes and illustrates the importance of DDAVP testing and the difficulty of interpreting assay ratios for accurate diagnosis. VWF levels are <10% in some cases.

Summary/Conclusions: VWD may be misdiagnosed, underdiagnosed or undiagnosed. Appropriate and complete investigative panel is necessary for complete classification of VWD and its subtypes.

RETROSPECTIVE EVALUATION OF PHENOTYPE AND MANAGEMENT OF DYSFIBRINOGENEMIA AND HYPODYSFIBRINOGENEMIA IN A COHORT OF ITALIAN PATIENTS

C. Santoro1, F. Mazzaro2, E. Baldacci2, G. Ferrara1, F. Malaspina3, R.C. Santoro1, S. Pasca2, G. Castaman4, F. Peyvandi1, R. Foà1, D. Vasiliev1

1Cellular Biotechnology and Hematology, Hematology Sapienza University, Rome, 2OncoHaematology Department, Haemostasis and Thrombosis Service- Pugliese-Ciaccio Hospital, Catanzaro, 3Center for Hemorrhagic and Thrombotic Diseases, University Hospital of Udine, Udine, 4Center for Bleeding Disorders, Careggi University Hospital, Florence, Florence

Background: Dysfibrinogenemia (DF) and hypofibrinogenemia (HDF) patients (pts) experience hemorrhages or thromboses, and the clinical management can be difficult.

Aims: Aim of this study is to obtain information on DF/HDF clinical phenotype and management.

Methods: This is a spontaneous, retrospective, multicenter national study. Data is collected from clinical records.

Results: Forty-one pts have been enrolled in 3 centers: 35 DF (85%), 6 HDF (15%); 18M, 23F. Median follow-up: 7.4 months (1-203). Median age at diagnosis: 36 years (range 3-81). Median fibrinogen activity/antigen level: 53 mg/dL (0-156) and 250 mg/dL (66-380), respectively. Fourteen pts experienced hemorrhagic/apoplastic, hematomas, ecchymoses, menometrorrhagia, and gastro-intestinal (presence of esophageal ulcers). No specific therapy was administered. A portal venous thrombosis occurred in 1 DF splenectomized patient in absence of replacement therapy; he was treated with warfarin without anti-hemorrhagic prophylaxis. Forty-one minor/major surgeries were performed in 23 pts. In 10/41 (24%) cases, prophylaxis was administered; fresh frozen plasma in 3, fibrinogen concentrate (FC) in 1, tranexamic acid in 6; in 5/41 (12%) cases, low molecular weight heparin (LMWH) was administered; no hemorrhage occurred. Thirteen pregnancies were initiated in 9 women. In 1 case, LMWH prophylaxis was administered during pregnancy, and in 1 other during puerperium. In 2 cases, FC was also administered at the time of spontaneous delivery (SD). Nine SD and 4 cesarian sections were performed without complications.

Summary/Conclusions: Pts from this case series experienced few hemorrhagic/thrombotic events. The majority was asymptomatic and the most severe events were related to concomitant pathologies. Nonetheless, this study has the potential to collect data from a numerous population of pts who live in the same country, and therefore to provide useful information to better characterize and manage these rare diseases.

P307

OSTEOPOROSIS IN PATIENTS WITH HEMOPHILIA

1National Research Center for Hematology, Moscow, Russian Federation

Background: Osteoporosis is often a co-morbidity of hemophilia, which exacerbates the hemophilic arthropathy and affects the long-term stability of the components after the arthroplasty. We present our results for the presence of osteoporosis in 148 patients with haemophilia and hemarthroplasty.

Aims: To prevent progression of hemophilic arthropathy and increase the long-term stability of the components after the arthroplasty.

Methods: In the period from 2015 to 2016, the presence of osteoporosis surveyed 148 patients with haemophilia who are hospitalized in the department of reconstructive orthopedics for patients with hemophilia (Moscow, Russia): 121 (81.8%) - hemophilia A, 21 (14.2%) - and hemophilia B 6 (4%) – haemophilia with inhibitor. The average age of the patients was 39.3 years (range 10 to 69 years). 121 patients with hemophilic arthropathy performed primary total arthroplasty (98 knee, 20 hip, 3 shoulder joints); 18 patients underwent revision arthroplasty (5 - purulent infection, 7 - instability of the implants, 4 - fractures, 2 - loss of motion in the operated joint). 40 patients underwent ultrasound densitometry. Vertebral fractures were ruled out. As a result of ultrasound densitometry in 17.5% (7 patients) of cases revealed osteopenia and 20% (8) -Thighest index. 105 patients underwent histological study in which 93 (88.6%) bone resorption, 58 (55.2%) intraosseous hemorrhage which 53 (50.5%) cases were accompanied by bone resorption. In total (histologically and of ultrasound densitometry) 99(66.9%) patients with haemophilia had osteopenia or osteoporosis.

Summary/Conclusions: The data indicate that osteoporosis at patients with haemophilia considerably more common than in the general population. Intraosseous hemorrhage identified in more than half of the cases, exacerbate the decline in bone mineral density.
patient, with the rate of recurrent haemorrhagic events in joint(s) from 6 to 13 per year. The control group consisted of 255 age-matched healthy men. Gene polymorphism of apolipoprotein E (ApoE e2/e3/e4), paraoxonase (PON1 Gln192Arg), methyleneretahydroxyaducte reductase (MTHFR C677T), catalase (CAT C-262T) and plasmatoglucine peroxidase (GPX3 T-65C) was studied by PCR-RFLP technique. Statistical differences between the patient and control group, were assessed by Fisher’s exact test. Odds ratios (OR) with their 95% confidence intervals (CI) and p-value were calculated by using GraphPad Prism 5.0 software.

Results: We found abnormal distribution of ApoE genotypes in the patient group. Absence of ApoE e3 allele was observed in 7 (9.1%) men with SH and 9 (3.1%) controls (OR=3.4, 95% CI: 1.2-9.7, p=0.025). In particular, the frequency of ApoE e2/e2 genotype was 10-fold increased in patients when compared to healthy men (4.2% vs 0.4%, OR=11.2, 95% CI: 1.1-109.5, p=0.034). ApoE e2/e4 and e4/e4 genotypes were also more prevalent in SH than in the control group (2.8% vs 0.8% and 2.8% vs 0.2%, respectively). In the patient group, we observed the positive association between the PON1 192Gln/Gin variant and heterozygous GPX3 -65TC genotype (OR=5.8, 95% CI: 1.3-25.7, p=0.021). Simultaneous presence of these genetic variants was more than 5-fold found in SH than in controls (8.5% vs 1.6%, 95% CI: 1.3-22.8, p=0.016).

Summary/Conclusions: Our results indicate that OS-provoking variants of ApoE, PON1 and GPX3 genes are frequently seen in SH patients with chronic arthropathy and joint(s) destruction.

P309
THE ROLE OF DNA METHYLATION AND EXPRESSION OF MMP-2 AND MMP-9 IN PATHOGENESIS OF INTRACEREBRAL HEMORRHAGE IN CONGENITAL FACTOR XIII DEFICIENCY
A. Noroozi-Aghideh1,*, N. Lashgari 2, A. Dorgalaleh 3, Z. Kashanikhatib 4, S. Alizadeh5
1Pediatrics, Keimyung University School of Medicine and Dongsan Medical Center, 2Pediatrics, Yeungnam University, College of Medicine, Daegu, Korea, 3Hematology, Russian Research Institute of Hematology, Saint-Petersburg, Russia, Federation

Background: Congenital factor XIII deficiency (CFXIIID) is a rare bleeding disorder. Intracerebral hemorrhage (ICH) is a leading cause of mortality and morbidity in this disorder. Matrix metalloproteinase-2 (MMP-2) and MMP-9 are reported to be associated with ICH.

Aims: The purpose of this study was to investigate the association of MMP-2 and MMP-9 methylation and their expression with ICH.

Methods: Patients with abnormal clot solubility test as well as a positive family history of FXIII deficiency were included in the study. Methylation status was analyzed by Bisulfite Sequencing PCR. Gene expression in mRNA and protein levels was assayed by Quantitative real-time RT-PCR and ELISA, respectively.

Results: We found an unmutated profile for both MMP-2 and MMP-9 in patients with ICH. Both of these genes were partially methylated in controls. Percent of methylated CGs are also higher for MMP-9 than MMP-2. Higher expression of MMP-9 in both of mRNA and protein levels was found in ICH compared to non-ICH group. However, there were no significant differences in MMP-2 expression and methylation between the groups.

Summary/Conclusions: Our findings showed that gene methylation contributes effectively in regulation of MMP-9 expression. Furthermore, our data suggest that MMP-2 expression in CFXIIID may not be controlled by gene methylation alone because methylation status of this gene did not correlate with minimal cutaneous hemorrhages to severe life-threatening bleeding. It is well known, that there is no stable correlation between the platelets count or other parameter(s) and the hemorrhage grade in ITP patients. Possibly, the genetically-based individual mechanisms of immune response impairment could affect the severity of hemorrhage during course of ITP.

Aims: To reveal genetic risk factor(s) for severe HS in patients with chronic ITP.

Methods: A total of 67 patients (58 women and 9 men) with chronic ITP were involved in the study. The median age of the group was 57 years (range: 24-77). The mean duration of ITP was 7 years (2-48). Hemorrhage was graded according to WHO scale. Taking into account the severity of HS, all the patients were divided into two groups. The first group included 40 patients with HS of 0-1 grade and the second consisted of 27 patients with HS of 2-3 grade. All patients of the second group needed the use of different methods of emergency haemostatic therapy and we consider it as a “severe ITP”. We analyzed DNA polymorphism of 8 genes responsible for the formation of a human platelet alloantigen systems (HPA-1, -2, -3 and -5) and associated with impaired immune response (IL-1B, IL-6, IL-10 and TNF-A). The differences in genotype frequencies between the groups 1 and 2 were assessed by Fisher’s exact method. Odds ratios (OR), their 95% confidence intervals (CI) and p-values were calculated with GraphPad Prism 5.0 software.

Results: The frequency of HPA-3a/3a (GpIIb 2622TT, 844 Ile/ile) genotype was more than 2-fold increased in ITP patients with severe HS (55.6% vs 25.0% in the group with HS of 0-1 grade; OR=3.8, 95% CI: 1.3-10.7, p=0.02). HPA-1a/1a and HPA-2a/2a genotypes were also more frequently seen in patients with HS of 2-3 grade compared to the group with HS 0-1 (77.8% vs 72.5% and 92.6% vs 80.0%, respectively), but these differences were not statistically significant (p=0.78 and p=0.19, respectively). Moreover, in the group with “severe ITP” we found almost 2-fold increase of the IL-6 -174CC genotype frequency (26.9% vs 15.0% in HS 0-1; OR=2.1, 95% CI: 0.6-7.1, p=0.34). Patients positive for IL-10 -1082A allele were a higher frequency of severe HS compared to the group with HS of 0-1 grade (48.1% vs 26.3% in HS 0-1; OR=2.6, 95% CI: 0.9-7.4, p=0.11).

Summary/Conclusions: Our data indicate that HPA-3a/3a variant could be a possible risk factor for severe HS in ITP patients.
P312

AN ALGORITHM TO IDENTIFY CASES OF SEVERE HEMORRHAGE IN ROUTINELY COLLECTED HEALTHCARE DATA

A. Kreuger1,2, R. middelburg1, J.L. Kerkhoffs1, J. van der Bom1
1Center for Clinical Transfusion Research, Sanquin Research, Amsterdam, 2clinical epidemiology, LUMC, Leiden, 3Hematology, Hagaziekenhuis, den haag, Netherlands

Background: Many patients with a hematological malignancy have an increased risk of hemorrhages. Research addressing the causes of these hemorrhages, especially those on major hemorrhages, are hampered by the difficulty to find sufficient and representative cases of major hemorrhage. Unfortunately, electronic health records generally do not codify hemorrhages.

Aims: The aim of this study was to develop an algorithm that can be used to find patients who suffered from major hemorrhages (WHO grade 3 or 4) within electronic health records.

Methods: An algorithm was developed using electronic health record data of a cohort of patients with acute leukemia, who received platelet transfusions between June 2011 and December 2015 at the Leiden University Medical Center in the Netherlands. Chart review was performed for a stratified, random sample of observation days. Discriminative performance of three indicators was assessed: CT-brain, drop in hemoglobin level and transfusion need within 24 hours. The cut off values for hemoglobin drop and transfusion need with the best discriminating capacity and CT-brain were entered in the final algorithm. The C-statistic was calculated and calibration plots were made. The algorithm will be externally validated in two other academic hospitals.

Results: The derivation cohort consisted of 255 patients comprising 10,638 observation days and chart review was performed for 353 days. The incidence of major hemorrhage was 0.22 per 100 observation days. The final algorithm consisted of information on CT-brain (yes/no), a hemoglobin drop of ≥2.8 g/dl and the need of six or more transfusions (yes/no). The C-statistic of the algorithm consisted of information on CT-brain (yes/no), a hemoglobin drop of ≥2.8 g/dl and the need of six or more transfusions (yes/no). The C-statistic of the algorithm was 0.93 (95% confidence interval (CI) 0.86 to 0.99). The incidence of bleedings with all grades of severity was 8.4 per 100 days. The algorithm for bleedings of all grades had a c-statistic of 0.54 (CI 0.53 to 0.55). The results of the external validation are not available yet.

Summary/Conclusions: An algorithm using information on CT-brain, hemoglobin drop and transfusion can accurately identify cases of major hemorrhage within electronic health care data. External validation will be performed.

Myelodysplastic syndromes – Clinical 1

P313

MOLECULAR MECHANISMS AND CLINICAL SIGNIFICANCE OF REDUCED PTPN1 EXPRESSION IN MYELODYSPLASTIC SYNDROMES

M. Shiokel1,2, M. Isii1, M. Ohwashi1, N. Morii1, K. Yoshinaga1, J. Tanaka1
1Department of Hematology, Tokyo Women’s Medical University, Tokyo, Japan

Background: Previously we determined common deleted region (CDR) of del(20q) observed in MDS by CGH-array. Our data showed that the PTPN1 gene is located within CDR of del(20q). The PTPN1 gene encodes PTP-1B, a non-receptor type protein tyrosine phosphatase, which is involved in multiple physiological and pathological cellular processes via dephosphorylation of several tyrosine kinases, and other molecules. Although roles of PTP-1B in normal and pathological hematopoiesis has not been elucidated, it may function negative regulator for cellular processes mediated by tyrosine kinases, including JAK2, and SRC. We hypothesized that the PTPN1 gene is a target gene disrupted by del(20q), resulting in haplo-insufficiency, and involved in MDS molecular pathogenesis.

Aims: We attempted to examine PTPN1 expression level in bone marrow cells of MDS patients with or without del(20q), and to investigate its clinical and biological significance.

Methods: Total RNA was extracted for cDNA synthesis from bone marrow samples taken at the time of diagnosis with written informed consent from patients and control subjects were used for the present study. Real-time RT-PCR was carried out to quantify PTPN1 expression by the TaqMan probe method using an ABI 7500 real-time PCR system (Applied Biosystems). Data including patients' demographic, disease status, medical history, clinical and laboratory findings, and outcome, were collected from medical records and laboratory data base. A non-parametric Mann-Whitney-Wilcoxon test was used to examine whether expression levels among groups are statistically different. The Kaplan-Meier model was used to analyze the impact of PTPN1 expression on overall survival, and log-rank test was used for statistical analysis. We also examined the effect of 5-azacytidine treatment on PTPN1 expression in primary bone marrow cells from MDS patients. Bone marrow cells were cultured with or without 5mM of 5-azacytidine for 48 hours. Expression level of PTPN1 was examined by quantitative RT-PCR described as above.

Results: A total of 118 MDS patients, 71 males and 47 females with median age of 68 years (range: 20-91 years) and 19 control subjects were included in the present study. The patients were classified as RCUD (n=18), RCMRD (n=58), RARS (n=8), RAEB-1 (n=20) and RAEB-2 (n=14) according to WHO classification. Relative PTPN1 expression level was significantly decreased in MDS patients with del(20q) (P<0.001) compared with control subjects. Moreover, relative PTPN1 expression level in MDS patients without del(20q) also significantly decreased (P<0.001). Expression patterns of PTPN1 among five WHO-subtypes, were statistically different (P=0.0201). Median values of relative PTPN1 expression level in RCUD, RCMRD, RAEB-1, and RAEB-2 were 1.52, 1.95, 1.91(P<0.001), and 1.26 respectively. Relative PTPN1 expression level in WHO-subtypes with high blast counts (RAEB-1 and RAEB-2) was significantly lower than that in WHO-subtypes with less blast counts (RCUD, RCMRD, RARS) (median value: 1.41 vs 1.89, P=0.0074). To investigate prognostic implication of PTPN1 expression in MDS, we analyzed impact of PTPN1 expression on overall survival (OS). Based on PTPN1 expression level, 118 patients were divided into four groups, high (Q1), intermediate (Q2, Q3), and low (Q4) quartiles. Kaplan-Meier analysis demonstrated that the lowest quartile (Q4) showed significantly worse survival compared with remaining quartiles (Q1, Q2, Q3) (P=0.048). The estimated 5-year OS rates in Q1-3 group and Q4 group were 69% and 49.8%, respectively. We examined whether PTPN1 expression is induced by 5-azacytidine in primary bone marrow cells of 17 MDS patients. Real-time PCR analyses indicated that 5-azacytidine treatment significantly induced PTPN1 expression.

Summary/Conclusions: The present study demonstrated that PTPN1 expression is reduced in MDS patients with haplo-insufficiency due to del(20q) and methylation of promoter region of the PTPN1 gene. Low PTPN1 expression is associated with advanced disease and poorer clinical outcome, indicating that PTPN1 expression level could be a useful prognostic marker in MDS.
Aims: The purpose of this study is to elucidate the clonal dynamics and molecular signatures that correlate with response to azacitidine therapy for MDS, focusing on the role of TP53-mutations.

Methods: We conducted a prospective multicenter trial of azacitidine treatment for high-risk MDS patients, in which the efficacy was compared between the 5- and 7-day regimens. A total of 107 patients were enrolled between 2013 and 2016. For all cases, a bone marrow specimens collected before treatment was analyzed for mutations using targeted-capture sequencing. Mutations were also interrogated after 4 cycles of azacitidine therapy in 48 (45%) cases. An additional case was analyzed for mutations in a patient who received azacitidine therapy for MDS and whose bone marrow specimens were available both before and after therapy. RNA baits were designed for detection of both oncogenic variants in 67 known driver genes in myeloid neoplasms and copy number alterations on the same platform. Response was evaluated according to the IWG 2006 criteria.

Results: On average, 2.7 mutations (range 0-9) were detected per sample before azacitidine treatment. TP53 represented the most common mutation target (50% of 222 cases total), followed by ASXL1, RUNX1, TET2, and SRSF2. TP53-mutated cases had significantly lower number of driver mutations (1.7 vs 3.1/sample, p<0.001) and higher number of copy number changes (9.6 vs 2.1, p<0.001), compared with unmutated cases. Clinical response was observed in 25 cases in the on-protocol cohort, including 6 complete remission (CR) (3.6%) and 19 marrow CR (17.8%) and 7 (29%) cases (all CR) in the off-protocol cohort. Notably, CR was obtained almost exclusively in TP53-mutated cases (5/6 and 5/7 CR cases in the on- and off-protocol cohort. No other mutations were associated with clinical response. Median treatment duration was 119 days (range: 81–721), which lasted for a median duration of 217 days (range 10–783). ΔTCF was evaluable for 62 cases who had one or more follow-up specimens and carried at least one mutation in either pre- or post-treatment with an average of –0.075 (range: –0.75–0.72). ΔTCF was significantly lower in responders than non-responders (0.18 vs –0.0002, p=0.0068) and in TP53-mutated cases (–0.25 vs 0.0006, p=0.001).

Summary/Conclusions: Our study revealed a significant positive association of TP53 mutations with favorable responses to azacitidine for MDS, although the response was transient and the expected response rate seems to be much lower compared to that reported for decitabine. Given that decitabine is not approved for MDS in non-metro areas (e.g. EU and Japan), our results suggest a potential role of azacitidine as a key agent to improve the notoriously dismal clinical outcomes of TP53-mutated tumors. Further study should be warranted to confirm its efficacy and to develop an optimal post-remission therapy to overcome the short remission period.
with non complex del(7q) (P=ns for complex vs non complex, chi-square test). The ORR was 37.5% in “de novo” and 38.4% in secondary MDS, respectively (P=ns). Impact of AZA treatment compared to BSC on overall survival: Results of this multivariable analysis of OS at different time points are presented in Table 2. Chromosome 7 cytogenetic categories and IPSS retained a poor prognosis over time with a constant value of poor prognosis. AZA treatment had a favorable impact on OS during the first 3 years of treatment, compared to BSC, confirming results obtained in univariable analysis. Nevertheless, the benefit of AZA treatment as compared to BSC approach decreased as time spans and the HR value increased over time: HR of 0.3 at 6 months, 0.5 at 1 year and 0.7 at 2 and 3 years after treatment. (Figure 1). This benefit was present in all chromosome 7 categories with a a trend towards better impact among patients with complex karyotype but no significant differences between the 3 categories (-7, del(7q) and CK).

Figure 1.

Summary/Conclusions: This study confirms the benefit of AZA treatment on outcome in patients with HR-MDS and cytogenetic abnormalities involving chromosome 7.

P317

UN UPDATE OF A PHASE II EXPLORATORY STUDY OF OPN-305, A TOLL-LIKE RECEPTOR 2 ANTIBODY, IN PATIENTS WITH LOWER RISK MYELODYSPLASTIC SYNDROMES WITH PRIOR HYPOMETHYLATING AGENT THERAPY

G. García-Manero1,*, G. Montalbán-Bravo1, H. Yang1, Y. Wei1, Y. Alvarado1, C. DiNardo1, N. Daver1, M. Koriolpeva1, K. Hearn1, R. Miller2, S. Arbe-Barnes3, P. McRae4, T. Kearney5, R. Keogh6, H. Kantarjian1, M. Reilly7,1
1Leukemia, The University of Texas MD Anderson Cancer Center, Houston, United States, 2Opsona Therapeutics, Dublin, Ireland

Background: Alterations of innate immune signaling, including overexpression of TLR2, are common in MDS. Significant TLR2 overexpression in MDS bone marrow CD34+ cells, especially after HMA therapy, has been reported. OPN-305 is a fully humanized antagonistic IgG4 kappa monoclonal antibody to TLR2 which significantly increases the formation of erythrocytoid colonies (CFU-E) in BM CD34+ cells isolated from pts with lower-risk MDS in vitro.

Aims: To evaluate the potential therapeutic value of OPN-305 in patients (pts) with MDS.

Methods: We designed a phase I/II trial of OPN-305 for pts with Low or Int-1 risk MDS by IPSS after failure to prior therapy with a HMA (n=4 cycles). Pts whose WBC count was to be transfusion dependent (≤2 units in 8 weeks). Pts with isolated del(5q) should have received therapy with lenalidomide. Because, OPN-305 had not been previously used in pts with hematological malignancies, the study had an initial phase of N=10 pts using OPN-305 at a dose of 5 mg/kg every 4 weeks for a maximum of 9 cycles. Therapy could be repeated as long as there was no excess toxicity or progression. If after 16 weeks of therapy, there was no response, azacitidine on a 3 day schedule, could be added to OPN-305. Responses were evaluated following the revised 2006 IWG criteria. This initial cohort allowed evaluation of toxicity, pharmacokinetic analysis, receptor occupancy, and sequential analysis of cytokine profile. An extension dose escalation phase to 10mg/kg was planned for N=30 pts.

Summary/Conclusions: Treatment with OPN-305 in pts with previously treated lower-risk MDS was well tolerated with no significant toxicities and 53% ORR including 20% transduction independence, and potential association between TLR2 levels and response.

P318

IN PATIENTS UNDEGOING HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR MDS DEVELOPMENT OF CHRONIC GVHD COULD AMELIORATE THE ADVERSE IMPACT OF SPECIFIC SOMATIC MUTATIONS

1Hematology Department, University Hospital of Salamanca, 2Department of Statistics, 3Centro de Investigación del Cáncer, IIBMCC Instituto de Biología molecular y celular del cáncer, University of Salamanca, 4Molecular Biology Department, University Hospital of Salamanca, Salamanca, 5Hematology, University Hospital La Fe, Valencia, 6Hematology and Medical Oncology Department, University Hospital Doctor Negrín, Las Palmas de Gran Canaria, 7Hematology and Cellular Therapy, University Hospital Vall d’Hebron, Barcelona, 8Area of Genetic and Cellular Therapy, IBSAL Instituto BioSanitario de Salamanca, Salamanca, Spain

Background: Approximately 90% of patients with Myelodysplastic Syndromes (MDS) have somatic mutations in driver genes detected by Next Generation Sequencing (NGS). In the last years, several studies have related these mutations with prognosis, disease characteristics and response to therapy, including allogeneic Hematopoietic Stem Cell Transplantation (HSCT). Development of Chronic Graft Versus Host Disease (cGVHD) has been reported as one of the most powerful antineoplastic mechanisms after HSCT.

Aims: To evaluate the impact of specific somatic mutations in patients with MDS undergoing HSCT and if the development of cGVHD can modify their clinical course.

Methods: The results of HSCT in 115 MDS patients from five centres in Spain were retrospectively analyzed. Bone marrow samples were collected a median of 27 days prior to transplant and DNA was screened for somatic mutations by NGS, using a NextSeq platform (Illumina). Two myeloid genes panels that included the most frequently mutated genes in myeloid malignancies were used.

Results: Median age was 53 years (range from 19 to 70). Fifty-eight percent were male and 79.13% were classified as de novo MDS. According to WHO 2008 classification 4 (3.5%) were RCUD, 2 (1.8%) RARS, 22 (19.5%) ROMD, 28 (24.8%) RAEB-1, 32 (28.3%) RAEB-2, 12 (10.6%) Unclassifiable MDS, 9 (8%) CMML and 4 (3.5%) were AML (FAB RAEB-T). Among patients with calculated Revised IPSS (R-IPSS) (85 of 115 patients) 2 (2.4%) had very low risk, 15 (17.6%) low risk, 21 (24.7%) intermediate risk, 22 (25.9%) high risk and 16 (18.6%) had very high risk; 9 patients with CMML (10.6%) were categorized among responders or non-responders or based on OPN-305 dosing. A trend to increased response was observed in patients with higher TLR2 expression, among responders or non-responders or based on OPN-305 dosing. 

Summary/Conclusions: Treatment with OPN-305 in pts with previously treated lower-risk MDS was well tolerated with no significant toxicities and 53% ORR including 20% transduction independence, and potential association between TLR2 levels and response.
We also observed the unfavourable impact of TP53 mutations on relapse risk: CIR was 41.7% (95% CI 22.5-77.1) at 1 year for TP53 mutated vs 9.8% (95% CI 5.3-18.1) at 1 year for non TP53 mutated patients (p=0.006).

Summary/Conclusions: We conclude that the number of mutated genes prior to transplant could be a prognostic factor of OS and CIR. Mutations in some genes, like TET2 and TP53, could also have an adverse impact on outcome. However, cGVHD could ameliorate the poor prognosis of somatic mutations in transplanted patients with MDS.

P319

VOSAROXIN PLUS AZACITIDINE TREATMENT FOR PATIENTS WITH MYELODYSPLASTIC SYNDROME: A PHASE 1/COHORT EXPANSION STUDY

M.A. Jacoby1,*, M.J. Walter1, J.F. DiPersio1, C.N. Abboud1, P. Westervelt1, A.F. Cashen1, K. Stockerl-Goldstein1, T. Fletcher1, G.L. Uy1

1Medicine, Washington University Medical School, St. Louis, United States

Background: Although hypomethylating agents are the mainstay of treatment for myelodysplastic syndromes (MDS), these agents result in remissions in a minority of patients and are not curative. Vosaroxin is a first-in-class quinolone derivative that intercalates DNA and inhibits topoisomerase II. Vosaroxin is active with a tolerable safety profile in acute myeloid leukemia (AML) and the novel combination of vosaroxin and azacitidine was found to be synergistic in primary myeloblasts.

Aims: This phase 1/cohort expansion study was designed to determine the maximum tolerated dose (MTD) and dose-limiting toxicity (DLT) of vosaroxin when given in combination with azacitidine, and to evaluate the efficacy and safety of the combination treatment.

Methods: Patients with MDS ≥18 years old with cytopenias requiring transfusions, an IPSS score of intermediate (INT)-1 or greater, or chronic myelomonocytic leukemia were eligible. Vosaroxin (initial dose: 50 mg/m2/d) was administered on Days 1 and 4, and azacitidine (75 mg/m2/d) on Days 1-7 of a 28-day cycle, in an outpatient setting, for up to 6 cycles in a 3+3 design (additional cycles were permitted if a clear benefit for the patient was demonstrated). Once the MTD was determined, an expansion cohort of 20 evaluable patients (≥1 cycle) was enrolled.

Results: A total of 35 patients enrolled in the dose escalation (n=13) and expansion (n=22) phases. The median age of the entire cohort was 66 years (range 38-77) with IPSS scores of low (n=1); INT-1 (n=13); INT-2 (n=15); and high risk (n=6). The median ECOG score for the entire cohort was 1 (range 0-2). In the dose escalation phase, at the initial dose of vosaroxin 50 mg/m2/d (n=6), the median number of total cycles was 2 (range: 1-4); 2 of 6 patients experienced a DLT at this dose (grade 4 hyperbilirubinemia and grade 4 neutropenia >42 days). At the de-escalated dose of 34 mg/m2/d (n=7), the median number of cycles was 2 (range: 1-18); 1 patient experienced a DLT at this dose (grade 4 mucositis). The MTD of vosaroxin was determined to be 34 mg/m2/d and this dose was used in the expansion phase. Incidences of grade 3 non-hematologic adverse events considered possibly, probably, or definitely drug-related for the total cohort (n=35) included infections (n=38), non-neutropenic fever (n=1); neutropenic fever (n=23); bleeding (n=9); and GI (mucositis/colic/dysphagia; n=4). Two deaths were considered possibly treatment-related (sepsis and diffuse alveolar hemorrhage). No cardiac toxicity attributable to study treatment was observed, even with prolonged therapy. Of the 35 enrolled patients, 32 have completed ≥1 cycle and are evaluable for response. Among these patients, median number of cycles completed is 3 (range, 1-18), with 5 still continuing with therapy. Best response rates are shown in the Table 1. The median number of cycles to best response was 1 (range: 1-6). Sixteen patients have received transplant to date.

Summary/Conclusions: The MTD of vosaroxin in MDS patients was 34 mg/m2/d when given on Days 1 and 4 with a fixed dose of 75 mg/m2 of azacitidine on Days 1-7. The major non-hematologic toxicities were infections, febrile neutropenia, and bleeding. The combination of vosaroxin and azacitidine showed promising activity with responses rates comparable or better than those generally observed with azacitidine alone. Additionally, the transplant rate observed was encouraging in this patient population.

P320
ADVANCED STAGE MYELOMA IS CHARACTERIZED BY A SIGNIFICANT INCREASE OF MUTATIONS IN GENES ASSOCIATED WITH DRUG RESPONSE

S. Barrio1, M. Da-Via1,2, T. Stühmer1, A. Gartano-Trojaola1, L. Brunis3, I. Cuenca4, M. Schreder1, R. Tiber1, P. Sonneveld3, M.S. Raab1, J. Martinez-Lopez2, A. Rosenwald3, R.C. Bargoo1, E. Braggio1, A.K. Stewart1,10, H. Einsele1, K.M. Kortüm1
1Hematology, Würzburg University Hospital, Würzburg, Germany. 2Hematology-Oncology, IRCCS Policlinico San Matteo, Pavia, Italy. 3Hematology, Mayo Clinic, Scottsdale, United States. 4Hematology, Doce de Octubre University Hospital, Madrid, Spain. 5Hematology, Erasmus Medical Center, Rotterdam, Netherlands. 6Hematology, Heidelberg University Hospital, 7German Cancer Research Center, Heidelberg, 8Pathology Institut, Würzburg University Hospital, 9Comprehensive Cancer Center Mainfranken , Würzburg University Hospital, Würzburg, Germany. 10Center of Individualized Medicine, Mayo Clinic, Rochester, United States

Background: The amount of genomic data available in Multiple Myeloma (MM) is exponentially increasing, however, hardly any of that information is translated into the clinic. A number of genes has been associated with resistance to commonly used anti-MM compounds. This, most importantly, includes immunomodulators (IMiDs) and proteasome inhibitors (Ps). However, no mutation screening has yet been attempted to our MM routine diagnostic workflows. We investigated 458 MM patients by targeted sequencing, including the largest cohort of previously treated MM patients so far. We identified an increased mutation incidence in treated patients, yet unreported mutations and functionally validated a subset.

Aims: To describe the mutational spectrum in genes of pathways targeted by standard of care (SOC) therapies in a cohort of pretreated and previously untreated patients.

Methods: Tumor-germ line paired samples of five contributing sites were pooled (Würzburg, Heidelberg, Madrid, Rotterdam and Mayo Clinic). Analysis included 310 untreated and 148 IMID and/or PI treated patients. Targeted sequencing was performed using the MIP (v2.0 or v3.0) gene selection, that includes most commonly mutated MM genes, actionable drug targets and genes being associated with drug resistance. Average sequencing depth increased 700X. Functional analyses of PSMB5 mutations were conducted using Sleeping beauty vectors transposed into AMO1 cell line.

Results: Our analysis included five genes each with known association to drug response to IMiDs (CRBN, CUL4B, IKZF1, IKZF3 and IRF4) and Ps (PSMB5, PSMB8, PSMB9, PSMD1 and XBPF1). Based on the increased sequencing depth, the mutation incidence in untreated patients is higher than in the CoMM-Pass dataset (IMiDs: 5.8% vs 3.9%; Ps: 1.9% vs 1.4%). Furthermore, pretreated patients showed a significant mutational increase compared with untreated pts (IMiDs: 19.7%, Z-score: -4.2; Ps: 7.3%, Z-score: -2.6, p=0.009). We observed a Gly159Arg mutation within the Lenalidomide (Len) degron sequence of IKZF3 in a patient progressing on Len and Pomalidomide (Pom), as well as two XPB1 truncating mutations in PI refractory patients. Of note, among three treated cases with mutations in the β5 (PSMB5) or βi (PSMB8) PI binding subunit of the proteasome, one patient harbored not less than 4 subclonal mutations. This is the first description of PSMB5 mutations in human MM, identified in a patient with long term history of PI treatment. All mutations were located in or close to the Bor binding site of PSMB5. The functional analysis demonstrated induction of resistance not only to Bor (IC50wt=2 nM vs IC50mut=4.5-8 nM), but also to the second generation PI ixazomib (IC50wt=5.2 nM vs IC50mut=N/A) and Carfilzomib (IC50wt=8 nM vs IC50mut=13-22 nM). Of interest, the P97 blockade of the protein homeostasis by the investigational compound CB5083 remains still possible in the mutated cell lines and the resistance can be overcome. Finally, Pom treatment eradicated two of the PSMB5 containing subclones (Figure 1).

Summary/Conclusions: Under the selective pressure of anti-MM therapy the incidence of mutations in genes associated with drug resistance increases in MM. Resistance mechanisms evolve in parallel in competing (sub)clones of the disease, mimicking phenotype and behavior. Remarkably, despite our restrictive gene selection, a quarter of our treated cohort is affected by at least one mutation. Aim of future therapy may be the eradication of selected clones or subclones, which, according to our data, appears possible.

P321
ILF2-YB1 INTERACTION MODULATES RNA SPlicing TO INDUCE RESISTANCE TO DNA-DAMAGING AGENTS IN 1Q21-AMPLIFIED MULTIPLE MYELOMA

M. Marchesini1,2, O. Gogol1, E. Fiorni1, M. D’Ancia2, P. Storti1, L. Nezi1, M. Kemaili3, I. Ganan-Gomez1, M.T. Fulciniti1, L. Zhang1, N. Giulian1, Z. Bohannan1, K. Clise-Dwyer7, N. Munshi5, R. Orlowsky8, G. Garcia-Manero1, R.A. DePinho9, S. Colla1
1Leukemia, MDAnderson Cancer Center, Houston, United States. 2Neurology, University of Milan, Milan, Italy. 3Clinical and Experimental Medicine, University of Parma, Parma, Italy. 4Genomic Medicine, MD Anderson Cancer Center, Houston, TX. 5Hematology, Mayo Clinic, Scottsdale, United States. 6Pathology Institut, Würzburg University Hospital, Würzburg, Germany. 7Stem cell transplantationa and cellular therapy, 8Cancer Biology, MD Anderson Cancer Center, Houston, United States

Background: The 1q21 amplification, which occurs in approximately 40% of de novo and 70% of relapsed Multiple Myeloma (MM), is among the most frequent chromosomal aberrations in MM patients and is considered a very high-risk genetic feature that is especially correlated with disease progression and drug resistance. The 1q21 amplicon contains many genes, and while it is unlikely that all contribute to the pathobiology of high-risk MM, the critical genes that do drive this high-risk phenotype have not yet been fully clarified. Identifying such genes and their contributions to this phenotype would enable the development of new and effective targeted therapy strategies for high-risk MM and thus improve their survival outcomes.

Aims: In our study we wanted to investigate the biological and molecular mechanisms behind the 1q21 amplification’s contribution to high-risk MM with the ultimate goal of obtaining a list of validated therapeutic targets to inform the design of novel translational clinical trials for this subgroup of patients.

Methods: We conducted a high-resolution analysis of recurrent copy number alterations and expression profiles in a collection of 254 MM samples included in MMRC database. To define the discrete minimal 1q21 region that is recurrently amplified in MM, we used Genomic Identification of Significant Targets in Cancer, a systematic method that identifies regions of genome that are recurrently amplified or deleted across a set of samples. These regions were enlisted into an in vitro screening strategy that employed a single-shRNA-per-96-well approach and GFP-competitive cell growth assay to identify 1q21 genes whose loss of function resulted in the selective death and/or growth inhibition of MM cells carrying the 1q21 amplification but not MM cells without the 1q21 amplification.

Results: We identified MCL1, UBAP2L, INTS3, LASS2, KRTCAP2 and ILF2 as potential 1q21-specific vulnerability targets whose expression is driven by copy number functionally validated, both in vitro and in vivo, Interleukin-2- enhancer binding factor 2 (ILF2) as a key 1q21 amplification-specific gene. Our results show that ILF2 impacts homologous recombination (HR) and induces resistance to DNA damaging agents routinely used in the treatment of MM, which is consistent with the observation that ILF2 expression correlates with poor survival in MM patient treated with high-dose melphalan followed by tandem autologous transplantation. On the mechanistic level, ILF2 interacts with numerous RNA binding proteins directly involved in the regulation of DNA Damage Response (DDR) by modulating alternative splicing of specific pre-mRNAs. RNA sequencing experiment confirmed that ILF2 knockdown results in aberrant splicing of genes involved in the DDR pathways and, strikingly, ILF2 RIP-seq analysis showed that ILF2 directly binds to transcripts involved in the regulation of the HR pathway, including components of BRCA1 protein complex. Furthermore, we found that ILF2 mediates drug resistance in dose-dependent manner by modulating YB-1 nuclear localization and interaction with the splicing factor U2AF65 to promote mRNA processing and stabilization of DDR genes in response to DNA damage (Figure 1).

Summary/Conclusions: In our study, we reveal an intimate relationship among 1q21 amplification, mRNA splicing and DNA repair in the control of DDR in MM. On the basis of our findings, we propose that 1q21-driven ILF2 overexpression deregulates HR by stabilizing the mRNA splicing of critical HR
factors, which enables genomic instability, promotes adaptive mechanisms to genotoxic stress, and enhances cell survival, thereby promoting drug resistance and disease progression. Given that 1q21 amplification is one of the most frequent copy number alterations in cancer, synthetic lethality approaches based on targeting gain-of-function associated to ILF2 may have a broad spectrum of application to potentiate the sensitivity of cancer cells to chemothapeutic agents.

Figure 1.

PROGNOSTIC IMPLICATION OF SOMATIC MUTATIONS BY NEXT GENERATION SEQUENCING: AN ANALYSIS FROM THE MMRF COMMPASS STUDY IN NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS

M. D’agostino1,2, S. Oliva1, S. Spada1, M. Gambella1, M. DeRome2, M. Cavo3, M. Aglietta1, M. Offidani1, J. Yesil2, D. Oddolo1, C. Cerrato1, A. Belotti1, A. Ledda1, L. Canepa3, M. Grasso3, R. Foà3, D. Auclair2, P. Musto1, A. Evangelista4, F. Gay1, A. Palumbo5, M. Boccadoro1, A. Larocca1
1Myeloma Unit, Division of Hematology, University of Torino, Torino, Italy, 2Multiple Myeloma Research Foundation, (MMRF), United States, 3Italian Multiple Myeloma Network, GIMEMA, 4Unit of Clinical Epidemiology, Azienda Ospedaliero-Universitaria Città della Salute e della Scienza di Torino and CPO Piemonte, Torino, Italy, 5Myeloma Unit, Division of Hematology, University of Torino - Currently Takeda Pharmaceuticals Co., Torino, Zurigo, Italy, Switzerland

Background: High throughput techniques, such as next generation sequencing, are becoming an appealing approach to characterize multiple myeloma (MM) genomic profiles and better define risk assessment. However, the clinical relevance of such approaches is still largely unknown. The Multiple Myeloma Research Foundation (MMRF) CoMMpass trial (NCT01454297) has collected data from 1154 newly-diagnosed MM patients enrolled worldwide. Comprehensive analysis of somatic mutations in MM cells at diagnosis could unravel prognostically relevant disease characteristics not detectable with traditional approaches.

Aims: We analyzed data from the interim analysis 8 cohort (August 2015) to create a prognostic model.

Methods: CD138+ purified MM specimens from bone marrow aspirates and peripheral blood cells were collected at diagnosis. Whole exome libraries from both tumor and constitutional DNA samples were created. Somatic single nucleotide variants (SNV) were identified, only nonsynonymous SNV were included in the analysis. We evaluated the impact on progression free survival (PFS) of recurrently mutated genes (with at least a nonsynonymous SNV with an allele frequency of more than 5% in more than 10 patients) in a multivariable analysis. Median age at diagnosis was 64 years (range 27-93), all patients received novel agents as first line treatment, 236 (45.6%) received autologous stem cell transplantation (ASCT). The most recurrent mutated genes were KRAS (25%) and NRAS (19.5%). Consistently with other works, DNA allele frequency stem cell transplantation (ASCT). The most recurrent mutated genes were KRAS (25%) and NRAS (19.5%). Consistently with other works, DNA allele frequency

Figure 2.

Summary/Conclusions: The use of a prognostic model based on the mutational status of 9 recurrently mutated genes could improve risk assessment of newly-diagnosed MM patients. Longer follow-up and validation in independent cohorts of patients are needed to confirm our findings. Updated results with a longer follow-up will be presented at the meeting.

P323

TARGETING GENE DEPENDENCY OF 1Q AMPLIFICATION IN MULTIPLE MYELOMA

S. Manier1,2, D. Huynh2, J. Park2, K. Salem3, X. Leleu3, I. Ghobrial4
1Hematology, Lille Hospital, Lille, France, 2Medical Oncology, Dana-Farber Cancer Institute, Boston, United States, 3Hematology, University of Lille 2, Lille, France, 4Medical Oncology, Dana-Farber Cancer Institute- Harvard Medical School, Boston, United States

Background: Gain of 1q is one of the most frequent copy number variations across cancer types and in Multiple Myeloma (MM). Gain of 1q is associated with a poor outcome, indicating it is a potential driver in MM progression and resistance to treatment. While the whole 1q arm can be amplified in some cases, a specific minimal amplified region has been identified by CGH array, including approximately 500 genes in the 1q21.1-23.3 region. However, the driver genes in the 1q region are unknown.

Aims: We hypothesize that specific genes present in the 1q minimal amplified region are critical regulators of clonal evolution and tumor progression in MM.

Methods: To explore gene dependency in 1q21.1-23.3 in MM, lung, breast and
Methods: We used 14 cell lines including MM, lung, and breast cancer cell lines. We designed a pooled library targeted shRNA/shRNAs screen containing 6 shRNAs along with their matched control for each of the 500 genes in the 1q21.23-3 region, including IncRNA and mRNA in addition to protein coding genes. The pooled library contained 6500 shRNAs, including C911 controls as a control. We used the RIGER software to call hits, using the Kolmogorov-Smirnov algorithm. To complement the 1q-targeted shRNA screening, we studied the IMiD-resistant cell lines, we treated OPM2 and NCI-H929 continuously with increasing doses of either lenalidomide or pomalidomide for 4-6 months, until cell viation decreased in chromatin accessibility and to a much lesser extent with DNA methylation changes. Interestingly, neither CRBN nor any of the other molecules involved in the CRBN pathway (IKZF1, IKZF3, IRF4) exhibited changes in either promoter DNA methylation or chromatin accessibility. We then treated the IMiD-resistant cells with the combination of 5-Aza-2-deoxycytidine (a DNMT1 inhibitor) and EPZ-6438 (an EZH2 inhibitor) for 48 hours, before exposing the cells again to IMiDs, and found that resistant cells treated with this combination showed increased sensitivity to 5-Aza-2-deoxycytidine and EPZ-6438, significantly increased apoptotic response, similar to the sensitive cell lines. Even more interestingly, we found that the treatment with 5-Aza and EPZ-6438 almost completely restored the global chromatin accessibility changes associated with acquired IMiD resistance back to the initial state, even though the cells we observed the changes in chromatin accessibility, we found that the treatment with 5-Aza and EPZ-6438 was also effective in sensitizing the majority of cell lines with intrinsic resistance to IMiDs. We also observed that treatment with the combination of 5-Aza and EPZ-6438 failed to induce a significant upregulation of CRBN in the IMiD-resistant cell lines, thus suggesting that the process involved in acquiring resistance to IMiDs is CRBN-independent. Moreover, we show that the degradation of IKZF1 is abrogated on the resistant cell lines, and remains as such despite their resensitization, meaning that the CRBN-IKZF1/IKZF3 pathway might be bypassed and other important regulatory networks might be as important for sensitivity to IMiDs. Therefore, we are currently performing RNA-seq, which might, in combination with accessibility data, give information about the regulatory mechanisms behind acquired IMiD resistance.

Summary/Conclusions: In conclusion, our study is the first one to ever show that acquired IMiD-resistance is mainly an epigenetic event that is potentially reversible through a combination of two epigenetic compounds, 5-Aza-2-deoxycytidine and EPZ-6438. These drugs have been shown to have low levels of toxicity, thus making them very good candidates for a prospective phase I study to examine their potential as "IMiD-resensitizers," which may improve the outcome treatment of MM patients with drug-resistant myeloma clones and a potentially high-risk disease.

P325 MULTILAYER EPIGENOMIC ANALYSES REVEAL OF NEW CANCER ONCOGENES INVOLVED IN THE PATHOGENESIS OF MULTIPLE MYELOMA

R. Ordoñez1,*, M. Kulis2, N. Russiniol2, R. Beekman3, C. Meydan4, N. Verdaguer-Dot2, A. Carrasco1, T. Ezponda1, J.H. Martens5, H.G. Stunnenberg5, B. Paiva6, J. San Miguel7, A. Meilicke8, E. Camacho9, F. Prosper9, Y. Agirre1, J.I. Martin-Suber2

1Oncohematology, Center for Applied Medical Research (CIMA), Pamplona, 2Departamento de Fundamentos Clinicos, Universitat de Barcelona, 3Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain, 4Dept. of Medicine, Weill Cornell Medical College, New York, United States, 5Radboud Institute for Molecular Life Sciences, Nijmegen, Netherlands, 6Cen- ter for Applied Medical Research (CIMA), 7Clinica Universitaria de Navarra, Pamplona, 8Hospital Clinic, Barcelona, Spain

Background: Most of the published omics studies in multiple myeloma (MM) have focused on the analysis of the genome, transcriptome and DNA methy- lome. Over the last years, the chromatin structure and histone modifications are emerging as essential epigenetic layers to understand gene deregulation in MM. Although this field remains widely unexplored in MM.

Aims: We herein aim to elaborate a comprehensive description of the MM genome including multiple layers of information.

Methods: We performed ChIP-seq of six histone modifications with non-overlapping functions (H3K4me3, H3K4me1, H3K27ac, H3K36me3, H3K27me3, and H3K9me3), ATAC-seq for chromatin accessibility, Whole Genome Bisulfite Sequencing (WGBS) for DNA methylation, and RNA-seq for gene transcription in purified bone marrow plasma cells from 4 MM patients and, as healthy controls, naive B cells, germinal center B cells, memory B cells and plasma cells. Data were extensively mined using a battery of different bioinformatic tools.

Results: We performed a quantitative comparison of MM and healthy controls. HiChromatin interaction networks across chromosomes and regions with differential expression were detected over 13000 with differentially expressed genes. We identified 15000 pairs with significantly increased activity in MM as compared to normal controls. These findings were further validated by ChIP-seq in another collection of 10 MM patients. We next focused on the genes that gained novo activity in MM and were completely inactive (i.e. hypochromatic) in normal
Summary/Conclusions: Our data identifies for the first time a subgroup of MM patients (6.25%) with no morphological evidence of MDS/AML prior to transformation to MDS/AML. Aims: To ascertain baseline mutation landscape [especially low-level clones with variant allele frequency (VAF) ≥5%] of MDS/AML associated gene mutations in HSCs prior to ASCT in order to predict patients at risk of clonal evolution, transformation to MDS/AML.

Methods: DNA was isolated from mononuclear cells (MNCs) collected by leukapheresis prior to ASCT from 128 MM patients. A customised amplicon-based Illumina MiSeq panel was used for the sensitive interrogation of 24 most common genes harboring mutations in MDS/AML (splicing factor genes; KIT, JAK2, SF3B1, SRSF2, U2AF1 and ZRSR2, genes implicated in epigenetic regulations; TET2, IDH1/2, ASXL1, EZH2 & DNMT3A, known oncogenes/gene involved in cell signalling/transcription regulation and cohesion complex; TP53, FLT3, NRAS, KIT, ETV6, RUNX1, CCBL, C-KIT, JAK2, MPL, CEBPA, STAG2, GATA2, KDM6A and NPM1). Variant analysis was performed using Illumina Variant Studio (≥5% VAF & read depth ≥150X thresholds for multiple Mycoplasma for the lack of germ line material to confirm the somatic nature of the variants. SNPs occurring at a frequency of ≥0.001% in the healthy population [e.g. dbSNP132, UCSC genome browser, Exome sequencing project (esp6500), Exome Aggregation Consortium (EAC) were excluded.

Results: Seven patients (6.25%) contained heterozygous somatic mutations (VAF range 7-50%) in DNMT3A, IDH1, IDH2, TET2, ETV6 and CBL genes (Table 1). Four missense mutations identified in DNMT3A were aggregated in the Mds3a domain responsible for its methyltransferase activity indicating a strong intention to abrogate this function. Previous studies confirm R882 variant in the Mtase domain responsible for its methyltransferase activity indicating a strong intention to abrogate this function. Prior oncoprotein R882 variant (for ~60% DNMT3A mutations) as a founder lesion in MDS/AML. The signaling lymphocytic activation molecule family 3 (SLAMF3) is a member of the immunoglobulin superfamily expressed on T, B, and natural killer cells and modulates the activation and cytotoxicity of these cells via self-ligand binding. SLAMF3 is also expressed on plasma cells from patients with multiple myeloma (MM), although its role in MM pathogenesis remains unclear.

Aims: To clarify this, we investigated the expression and functions of SLAMF3 in MM.

Materials: 1) Two hundred thirty patients comprising 153 newly diagnosed (19 asymptomatic and 134 symptomatic) MM patients, 30 refractory/refractory MM patients, and 47 patients with monoclonal gammopathy of undetermined significance were enrolled. SLAMF3 and CD138 expression levels on clonal plasma cells were analyzed using flow cytometry (FCM). Soluble SLAMF3 (sSLAMF3) assay levels were measured using ELISA. 2) Drug sensitivity to anti-myeloma agents (melphalan and bortezomib) and the proliferation potential in MM cell lines KMS18 and U266 were analyzed using FCM and the MTT assay. SLAMF3 knockdown MM cell lines were obtained using the lentiviral shRNA system and siRNA. Stable transduced KMS34 cell lines expressing full-length SLAMF3 and cytoplasmic domain-truncated SLAMF3 (sASM) were established through corresponding vectors. Single-nucleotide polymorphism (SNP) genotyping was analyzed by real-time PCR. The adaptor protein of SLAMF3 was identified by Western blotting and immunoprecipitation.

Results: 1) SLAMF3 was highly expressed on plasma cells in almost all MM patients, even in relapsed/refractory disease, although CD138 expression levels were decreased in some with advanced disease. 2) The proliferative potential and percentage of antitymelyoma agent-induced apoptosis in SLAMF3-positive MM cells were significantly higher and lower than in SLAMF3-negative MM cells, respectively. The cell proliferation and drug resistance in SLAMF3-expressing KMS34 cells were comparable in comparison with SLAMF3-negative KMS34 cells. That malignant potential of MM cells was cancelled by SLAMF3 knockdown. Furthermore, the proliferation of MM cells and resistance to antitymelyoma agents were inhibited by anti-SLAMF3 antibody. Adaptor proteins, SHP2 and GRB2, were expressed in MM cell lines, but neither SAP nor EAT-2 were. SLAMF3 interacted directly with SHP2 and GRB2, and SHP2 also interacted with GRB2. SHP2 inhibitor-treated or SHP2/GRB-knockdown cells had characteristics similar to SLAMF3-knockdown cells. 3) The frequency of GG genotypes of SLAMF3 SNP rs509749 in MM patients was 63.6% (n=28), of AG 29.5% (n=13), and of AA 6.8% (n=3). Patients with GG genotypes tended to have shorter overall survival times than patients with AG genotypes. 4) sSLAMF3 levels were significantly higher in symptomatic MM than in asymptomatic MM and markedly increased in advanced MM. MM patients with high levels (≥3.3 ng/ml; n=62) of sSLAMF3 progressed to the
advanced stage significantly more often and had shorter progression-free survival times than those with low levels (3.3 vs. 9.3 months, p=0.032).

Summary/Conclusions: This study revealed that SLAMF3 molecules consistently expressed on MM cells may transmit positive signals mediated via the complex of SHP2 and GRB2 by self-ligand interaction between MM cells and induce a high malignant potential in MM. Furthermore, high levels of serum sSLAMF3 may reflect MM disease progression and be a useful prognostic factor in MM. Thus, SLAMF3 molecules may be a new potential target for future immunotherapy and chemotherapy.

P328

TARGETING CD74 IN MULTIPLE MYELOMA WITH A NOVEL ANTIBODY DRUG CONJUGATE, STRO-001

M. Lupher1, A. Molina1,*
S. Krueger2, S. Matheny 1, T. Kline 1, A. Yam 1, R. Stafford 1, T. Hallam 1, M. Lusher1, A. Molina1,*
1Sutro Biopharma, South San Francisco, 2MI Biorsearch, Ann Arbor, United States

Background: CD74 is a transmembrane glycoprotein involved in MHC protein formation and transport. CD74 expression has been observed in up to 90% of B-cell malignancies, including multiple myeloma (MM), with minimal expression in normal tissues. CD74 is rapidly internalized, making it an attractive target for ADCs. STRO-001 is a novel ADC comprised of an aglycosylated anti-CD74 IgG1 human antibody (SP7219) conjugated covalently to the non-natural amino acid para-azido-methyl-L-phenylalanine (pAMF) with a non-cleavable dibenzocyclooctyne (DBCO)-maytansinoid linker-warhead. Highly efficient site-specific conjugation enabled by novel cell-free antibody production and click chemistry results in a well-defined homogeneous ADC drug product with a drug-antibody ratio (DAR) of 2.

Aims: The in vitro cytotoxicity and in vivo efficacy of STRO-001 was investigated in MM cell lines and xenografts. An exploratory toxicity study was conducted in a non-human primate model.

Methods: DISCO-Alexa647-conjugated SP7219 staining and flow cytometry were used for detection and quantitation of CD74 expression on MM cell lines. STRO-001 was used to determine the EC50 and percent span of killing in MM cell lines. The anti-tumor activity of STRO-001 was evaluated in the disseminated ARP-1 and MM.1S MM models. In vivo bioluminescence imaging (BLI) for animals bearing MM.1S-luc cells was performed using an IVIS Spectrum. BLI images were collected 7, 14, 21, and 28 days post-tumor inoculation. STRO-001 was administered to cynomolgus monkeys in an exploratory dose-escalating study of repeat IV doses of 1, 3, 10, and 30 mg/kg on days 1 and 15.

Results: In vitro cytotoxicity assays show nanomolar potency of STRO-001 in five MM cell lines: MC/CAR (EC50 0.8 nM), ARD (EC50 6.5 nM), MM.1S (EC50 10–11 nM), U266B1 (EC50 8.5–9.3 nM), and ARP-1 (EC50 4.3–22 nM). CD74 cell surface expression is required for STRO-001 cytotoxic activity but expression level, as measured by antibody-binding capacity, does not correlate strongly with in vitro potency (R²=0.5837 for MM cell lines). STRO-001 inhibits the growth of CD138+ plasma cells in bone marrow (BM) and migration of visceral tumors (p=0.002 for kidney; p=0.0001 for ovary) after 4 weekly doses of 3 mg/kg in the ARP-1 disseminated MM xenograft model. STRO-001 dosed at 3 mg/kg and 10 mg/kg weekly x 3 also eradicates malignant BM plasma cells by day 32 post-inoculation (p<0.0001) and prolongs survival in the MM.1S disseminated model. At termination of the study, 129 days post-inoculation, 100% of the mice treated with STRO-001 survived and showed no evidence of disease with no CD138+ cells in their bone marrow, while mean survival of vehicle-treated control animals was 35 days with almost 50% of their bone marrow containing myeloma cells. BLI of luciferase-expressing MM.1S (MM.1S-luc) tumor cell lines enabled non-invasive quantification of tumor burden. Single doses of 1, 3, and 10 mg/kg STRO-001 (administered on day 7 post-inoculation) resulted in eradication of myeloma by day 28 based on bioluminescence signal and quantification of CD138+ cells in bone marrow. In addition, STRO-001 produced a dose-dependent reduction in normal B-cells in cynomolgus monkeys, providing pharmacodynamic evidence of B-cell targeting (Figure 1).

Summary/Conclusions: STRO-001 demonstrates potent in vitro cytotoxicity in MM cell lines and reduces tumor burden in MM xenograft models, including significant prolongation of survival in the MM.1S model. Based on these encouraging observations, STRO-001 is advancing to the clinic for the treatment of CD74-expressing B-cell malignancies.

P329

GENOTYPE CHARACTERIZATION OF LIGHT CHAIN AMYLOIDOSIS BY WHOLE EXOME SEQUENCING

1Hematología traslacional, Hospital 12 de Octubre, Madrid, 2Centro de Investigacion Medica Aplicada, Pamplona, 3Hospital Universitario de Salamanca, Instituto de Investigacion Biomedica de Salamanca (IBSAL), Centro de Investiga- cion Biomédica (IBMC-SMC), 4Hospital General Universitario Gregorio Marañón, Madrid, 5Hospital Universitario de Salamanca, 6Hospital Clinico Universitario Valladolid, Valladolid, 7Hospital Virgen del Puerta, Plasencia, 8Hospital German Trias i Pujol, Badalona, 9Hospital de Cabueñes, Gijon, 10Complejo Hospitalario de Leon, Leon, 11Hospital Universitario de Burgos, Burgos, 12Hospital Clinico Universitario Lozano Blesa, Zaragoza, 13Hospital Rio Carrión, Palencia, 14Clinica Universidad de Navarra, Pamplona, Spain

Background: Immunoglobulin light-chain amyloidosis (AL) is a heterogeneous and multifactorial disease with high genetic complexity. Until now, no common factor or unique mutation associated with this disease has been described. Whole exome sequencing in Multiple Myeloma (MM) patient’s tests allowed to know important known important genes and pathways that are involved in the disease. However, few evidences through next generation sequencing (NGS) analysis were described in AL. Consequently, the application of NGS technologies permits unraveling the genomic landscape of AL to better disentangle the biology of the disease, allowing the identification of new therapeutic targets as in MM.

Aims: Genotype characterization of novel molecular alterations in AL plasma cell by whole-exome sequencing technology.

Methods: We studied 40 paired samples (sorted pathological plasma cells and peripheral blood) from 20 patients with AL. Whole exome and regulatory regions were captured using Agilent’s SureSelect Human All Exon V6+UTR kit and sequenced on the Illumina NextSeq 500 platform with pair-end sequencing technique with a global mean depth coverage of 70x, on target coverage of 96.5% and a Phred quality score of 91.3% up to Q30. Data were analyzed with Strelka software to discard germinal mutations, wANNOVAR for functional annotation, and a data reduction strategy to identify candidate variants.

Results: After analysis of patient samples we got an average of 76 (range 18-177) mutations per patient. 28.4% of the mutations was located on regulatory regions (5 UTR, 3’ UTR). So far, we did not identify recurrent mutations between the patients, although some patients presented different mutations on the same gene.

The mutation pattern was very heterogeneous between patients. We identified alterations in genes involved in extracellular matrix (MMP2), cell proliferation, differentiation and development (TFGA), transcription factors (ZFHX3, HNRPNP), adherent junction function (RASSF8), GTPases (RAPGEF2, RAB40A), and genes of the collagenase family (COL9A1, COL1A2) among others.

Summary/Conclusions: Taken together, these results suggest that the mutation pattern in AL is heterogeneous with no common mutated gene among all patients. However, we described novel mutations in the context of AL in regulatory genes or over-representing cancer-related pathways that can help to elucidate the molecular biology of the disease.
Myeloma and other monoclonal gammapathies - Clinical 1

IMPROVED SURVIVAL IN 21,465 MULTIPLE MYELOMA PATIENTS: RESULTS FROM A POPULATION-BASED STUDY
S. Thorsteinsdottir1,2, P.W. Dickman3, I. Turesson3, O. Landgren3, M. Hultcrantz5,6, M. Bjorkholm5, S.Y. Kristinsson1,4
1Department of Internal Medicine, Landspitali - The National University Hospital of Iceland, Reykjavik, Iceland, 2Department of Medical Epidemiology and Biostatistics, Karolinska Institutet, Stockholm, 3Department of Hematology and Coagulation Disorders, Skane University Hospital, Malmö, Sweden, 4Myeloma Service, Division of Hematologic Oncology, Memorial Sloan-Kettering Cancer Center, New York, United States, 5Department of Medicine, Division of Hematology, Karolinska University Hospital and Karolinska Institutet, Stockholm, 6Myeloma Service, Division of Hematologic Oncology, Memorial Sloan-Kettering Cancer Center, New York, Sweden

Background: Multiple myeloma (MM) is generally considered an incurable disease, however advances in the treatment options for MM have been great in recent years. Recent studies on these new agents indicate an improvement in survival, nevertheless population-based studies have had contradicting findings, especially in the elderly patients.

Aims: The aim of the study was to evaluate the survival of all patients diagnosed with MM in Sweden in the years 1973 to 2013 and to relate the survival pattern to trends in treatment strategies.

Methods: Patients diagnosed with MM in the period from January 1, 1973 to December 31, 2013 were identified from the Swedish Cancer Registry. Information on sex, date of birth, date of diagnosis, and date of death was collected. Relative survival ratios (RSRs) were used to provide a measure of excess mortality of MM patients compared to a comparable group from the general population. RSRs with 95% confidence intervals (CIs) were found for 1-, 5-, and 10-year survival for 4 calendar periods; 1973-1982, 1983-1992, 1993-2002, and 2003-2013 and furthermore for 6 age categories at diagnosis (0-40, 41-50, 51-60, 61-70, 71-80 and >80). Short-term survival, as defined by RSR of less than 3 months, was also defined for all calendar periods.

Results: A total of 21,465 patients (54% males, median age at diagnosis 72 years) with MM were recorded in the time period. Overall, the 1- and 5- and 10-year RSRs improved in the whole period, with the greatest improvement in the two most recent calendar periods. The 1-year RSR increased significantly between all calendar periods (0.69, 0.74, 0.77 and 0.82, respectively). The 5-year RSR increased significantly between the two last calendar periods (0.28, 0.31, 0.33 and 0.41, respectively; Figure 1) as well as the 10-year RSR (0.10, 0.12, 0.14 and 0.20, respectively). Short-term survival increased significantly between the first two and last two calendar periods (the RSR were 0.83, 0.88, 0.89 and 0.93 respectively). Females had a lower excess mortality compared to males (excess mortality ratio 0.91).

Figure 1.

Summary/Conclusions: In this population-based study, based on more than 21,000 MM patients diagnosed during more than a 40-year period, we showed that with an increased use of novel agents in MM patients, survival has improved significantly. This is especially prominent during the last 10 years. Our findings are important, since new agents are approved based on clinical trials, where certain groups, such as older patients and patients with significant comorbidities are often excluded.

P331
PROGNOSTIC IMPLICATIONS OF MULTIPLE CYTOGENETIC HIGH-RISK ABNORMALITIES IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA
1Department of Internal Medicine, 2Division of Hematology, 3Department of Laboratory Medicine and Pathology, 4Department of Nephrology and Hypertension, Mayo Clinic, Rochester, United States

Background: Cytogenetic evaluation using fluorescence in situ hybridization (FISH) at the time of diagnosis is essential for initial risk stratification in multiple myeloma. The presence of specific cytogenetic high-risk abnormalities (HRA) is known to confer a poor prognosis, less is known about the cumulative effect of multiple such abnormalities.

Aims: To evaluate the prognostic implications of the presence of multiple HRA at the time of diagnosis.

Methods: We studied 1181 patients who were diagnosed with multiple myeloma between July 2005 and July 2015 at Mayo Clinic Rochester, underwent FISH evaluation within 6 months of diagnosis, and received first-line therapy with at least 1 novel agent (immunomodulator or proteasome inhibitor). HRA were defined as t(4;14), t(14;16), del(17p), and gain(1q). Bone marrow aspirates were evaluated for deletions, monosomies, trisomies, and tetrasonomies using chromosome- or centromere-specific FISH probes. IGH rearrangements were evaluated using an IGH break-apart probe and evaluating up to 5 potential partners (FGFR3, CCND1, CCND3, MAF, and MAFB). Kaplan-Meier overall survival estimates were calculated and the log-rank test was used to compare overall survival in patients with and without HRA (stratified by the number of HRA). A multivariable-adjusted Cox regression model was used to assess the effect of HRA on overall survival adjusting for age, sex, International Staging System (ISS) stage, and first-line therapy (immunomodulator, proteasome inhibitor, upfront autologous hematopoietic stem cell transplantation). Patients diagnosed after 2014 (approximately 15% of the cohort) routinely underwent evaluation for gain(1q), therefore the hazard ratios represent conservative effect estimates. P-values below 0.05 were considered statistically significant.

Results: The median age at diagnosis was 65 years (28 - 95), 708 (60%) of the patients were male. There were 375 HRA in 327 patients (28% of the cohort): 170 (45%) del(17p), 110 (29%) t(4;14), 45 (12%) t(14;16), 8 (2%) t(14;20), and 42 (12%) gain(1q). Of the 280 patients with 1 HRA 130 (46%) had del(17p), 120 (43%) had a high-risk translocation, and 30 (11%) had gain(1q). Of the 46 patients with 2 HRA 34 (76%) had del(17p) and a high-risk translocation, 6 (13%) had a high-risk translocation and gain(1q), 5 (11%) had del(17p) and gain(1q), and 1 had 2 high-risk translocations. There was 1 patient with 3 HRA: del(17p) and t(4;14) and gain(1q). The median overall survival was 6.6 years (6.0 - 8.0) for the entire cohort (n=1181), 8.3 years (6.7 - 8.9) for those without HRA (n=854, 72%), 4.8 years (3.9 - 5.6) for those with one HRA (n=280, 24%), and 2.7 years (2.1 - 3.8) for those with 2 or more (2+) HRA (n=47, 4%). Figure 1 shows the Kaplan-Meier overall survival estimates stratified by the number of HRA (n=1181). The presence of 1 HRA (versus 0, HR 1.57, 95% CI 1.26 - 1.96, p <0.001, n=1181) and the presence of 2+ HRA (versus 1, HR 3.37, 95% CI 2.21 - 5.14, p <0.001, n=1181) were of prognostic significance after adjusting for age, sex, ISS stage, and first-line therapy. When adjusting for the revised ISS instead of the ISS the hazard was attenuated for 1 HRA (HR 1.21, 95% CI 0.92 - 1.60, p=0.180, n=1087) and 2+ HRA (versus 1, HR 2.82, 95% CI 1.81 - 4.40, p <0.001, n=1087).

Figure 1.

Summary/Conclusions: Approximately 1 in 4 patients with newly diagnosed multiple myeloma presented with 1 HRA at the time of diagnosis, approximately 1 in 25 with 2 or more HRA. These patients experienced inferior overall survival suggesting a cumulative effect of multiple HRA.
LENALIDOMIDE MAINTENANCE VS PLACEBO AFTER STEM CELL TRANSPLANT FOR PATIENTS WITH MULTIPLE MYELOMA: OVERALL SURVIVAL AND PROGRESSION-FREE SURVIVAL AFTER ADJUSTING FOR TREATMENT CROSSOVER IN CALGB

P.L. McCarthy1, S.A. Holstein2, S.-H. Jung3, M. Cooper4, C.J. Gibson5, E.A. Stadtmueller6, B. Winograd2, P. Richardson7

1Blood and Marrow Transplant Program, Roswell Park Cancer Institute, Buffalo, NY, 2University of Nebraska Medical Center, Omaha, NE, 3Alliance Statistics and Data Center, Duke University, Durham, NC, United States, 4BresMed, Sheffield, United Kingdom, 5Cellgene Corporation, Summit, NJ, 6Abramson Cancer Center, University of Pennsylvania, Philadelphia, PA, 7Dana-Farber/Partners CancerCare, Boston, MA, United States

Background: At a prespecified interim analysis (December 2009), the phase 3 CALGB/ECOG 100104 (Alliance) study results surpassed the prespecified superiority boundary (significantly improved progression-free survival [PFS] for lenalidomide [LEN] maintenance vs placebo [PBO] after SCT) and the majority of PBO arm patients without progressive disease (PD) crossed over to LEN maintenance. An updated analysis (cutoff March 2015) showed significantly longer overall survival [OS] with LEN maintenance (HR, 0.56; 95% CI, 0.42-0.76). However, the crossover from PBO to LEN makes it difficult to assess the true treatment effect of LEN.

Aims: To examine the effect of LEN vs PBO on OS and PFS from randomization, adjusting for effects of crossover.

Methods: The rank-preserving structural failure time model (RPSFTM; Robins, *Commun Stat Theory Methods*, 1991) was used for crossover adjustment; the iterative parameter estimation (IPE; Branson, Stat Med, 2002) algorithm was used as validation. Survival was partitioned assuming a residual LEN effect after discontinuation. A landmark analysis was also performed at the Dec 2009 interim for patients who remained on treatment. Patients in the trial provided informed consent.

Results: Patients were randomized to LEN maintenance (n=231) and PBO (n=229) (intent-to-treat [ITT] population); 76 patients without PD crossed over from PBO to LEN. The median time from randomization to crossover was 11.5 months. The relative treatment effect for OS and PFS increased for LEN vs PBO when adjusting for crossover using RPSFTM and IPE (Table 1). The landmark analysis at the Dec 2009 interim (PBO crossover, n=76) showed the treatment effect is not dissimilar to the ITT analysis (HR 0.53; 95% CI, 0.25-0.76). Sensitivity analyses showed consistent results. Updated data will be presented at the meeting.

Table 1.

Summary/Conclusions: Adjusting for the potential diluting effects of crossover reduced median OS and PFS with PBO, and improved the treatment effect in the ITT analyses for OS and PFS for LEN vs PBO maintenance after SCT. The statistical significance of the ITT analyses was maintained throughout.

P334

EFFICACY AND SAFETY OF DARATUMUMAB, LENALIDOMIDE, AND DEXAMETHASONE VERSUS RVD ALONE IN RELAPSED OR REFRACTORY MULTIPLE MYELOMA: UPDATED ANALYSIS OF POLLUX

1National and Kapodistrian University of Athen, Athens, Greece, 2Hematology, University Hospital Hôtel-Dieu, Nantes, France, 3Karolinska Institute and the Department of Clinical Medicine, Karolinska University Hospital at Huddinge, Stockholm, Sweden, 4Vejle Hospital and University of Southern Denmark, Vejle, Denmark, 5University Hospital Heidelberg and German Cancer Research Center, Heidelberg, Germany, 6Japanese Red Cross Medical Center, Department of Hematology, Tokyo, Japan, 7Department of Lymphoma/Hematoma, The University of Texas MD Anderson Cancer Center, Houston, United States, 8Department of Haematology, University College London Hospitals NHS Trust, London, United Kingdom, 9Sheba Medical Center, Tel Hashomer, Ramat Gan, Israel, 10Institut Català d’Oncologia, HGTIP, Barcelona, Spain, 11Tisch Cancer Institute, Mount Sinai School of Medicine, New York, NY, 12Clínica Universidad de Navarra-CIMA, IDISNA, Pamplona, Spain, 13Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA, 14Levine Cancer Institute/Carolinas HealthCare System, Charlotte, NC, 15Janssen Research & Development, LLC, Spring House, PA, United States, 16Janssen Research & Development, Beere, Belgium, 17Tom Baker Cancer Center, University of Calgary, Calgary, Alberta, Canada

Aims: To provide updated efficacy and safety data from POLLUX, a multicenter, phase 3, randomized study of DRR vs Rd in RRMM.

Methods: Eligible patients with ≥1 prior line of therapy were randomly assigned to Rd (25 mg PO lenalidomide on Days 1-21 of each 4-week [Q4W] cycle) or DRR (Rd plus daratumumab) given with or without IV dexamethasone at 10 mg weekly for Cycles 1 and 2, every 2 weeks for Cycles 3-6, then Q4W until disease progression). Patients who were refractory to lenalidomide were excluded. Progression-free survival (PFS) was the primary endpoint.
marrow samples were collected, and minimal residual disease (MRD) was assessed at the time of suspected complete response (CR) and at 3 and 6 months after suspected CR at 3 different sensitivity thresholds (10⁻⁴, 10⁻⁵, and 10⁻⁶) using the ClonoSEQ™ next-generation sequencing-based assay ( Adaptive Biotechnologies, Seattle, WA). Additional reflex testing using an anti-idio- type antibody was used to confirm CRs in cases in which daratumumab interference with serum M-protein quantitation was suspected in patients with possible CR.

Results: Patients received a median (range) of 1 (1-11) prior lines of therapy; 55% of patients had received immunomodulatory agents (IMiDs), and 18% had been exposed to lenalidomide. After median follow-up of 17.3 months, DRd significantly prolonged PFS compared with Rd alone (median: not reached vs 17.5 months; hazard ratio [HR], 0.37; 95% confidence interval [CI], 0.28-0.50; P<0.0001), with 18-month PFS rates of 76% and 49%, respectively. Responses continued to deepen in the DRd group with longer follow-up, with significantly higher overall response rate (ORR; 93% vs 76%) and rates of very good partial response (VGPR) or better (78% vs 45%) and CR or better (46% vs 20%) with DRd versus Rd alone (P<0.0001 for all), and MRD negativity was achieved with prolonged PFS at 10⁻⁶ (Figure 1). Overall survival (OS) data are immature, with 40 (14%) deaths in the DRd group and 56 (20%) deaths in the Rd group (HR, 0.63; 95% CI, 0.42-0.95). Neutropenia was the most common grade 3 or 4 treatment-emergent adverse event (53% with DRd vs 38% with Rd), and no new safety signals were reported with longer follow up. We will present updated efficacy and safety data based on approximately 25 months follow up at the meeting.

Figure 1.

Summary/Conclusions: DRd significantly improved outcomes compared with Rd alone, including PFS, ORR, depth of response, and MRD-negative rates, with a favorable safety profile that was maintained after longer follow up. These updated data continue to support the use of DRd in patients with RRMM who received ≥1 prior therapy.

Background: Daratumumab (D) used in combination with bortezomb and dex- amethasone (Vd; CASTOR) or lenalidomide and dexamethasone (Rd; POLLUX) significantly prolongs progression-free survival (PFS) with a manageable safety profile compared with either Vd or Rd alone in patients (pts) with RRMM.

Aims: Here in this subgroup analysis we investigated the safety and efficacy of DVD and DRd in elderly pts aged ≥75 years from the CASTOR and POLLUX phase 3 studies.

Methods: Overall, pts enrolled in the CASTOR and POLLUX studies had ≥1 prior line of therapy. Pts in CASTOR received up to 8 cycles of Vd with or without D; pts in the Dvd group then continued to receive D monotherapy q4w until disease progression or unacceptable toxicity. Pts in POLLUX were treated until progression. Dosing schedules for D (16 mg/kg) were different between CASTOR (qw in Cycles 1-3, q3w for Cycles 4-8, and q4w thereafter) and POLLUX (qw for Cycles 1-2, q2w for Cycles 3-6, and q4w thereafter). All elderly pts received a reduced dose of dexamethasone (20 mg once weekly vs 40 mg once weekly) in both studies.

Results: In CASTOR, 23/251 pts in the DVD group and 35/247 pts in the Vd group were ≥75 years; the median (range) age for this group of pts was 78 (75-88) and 78 (75-85) years, respectively, with 100% and 94% with an ECOG status ≤1. At a median follow-up of 13.0 months, discontinuation rates due to treatment-emergent adverse events (TEAEs) were similar with DVD and Vd (15% vs 20%). Common (≥10%) grade 3/4 TEAEs for Vd were thrombocyto- penia (45% vs 37% with Vd), fatigue (15% vs 11%), pneumonia (15% vs 17%), and anemia (10% vs 11%). Infusion-related reactions (IRR) occurred in 13 (65%) pts; with 10% having grade 3/4 IRR, but no pts discontinued due to IRR. Median PFS was significantly prolonged with DVD versus Vd (not reached [NR] vs 8.1 months; hazard ratio [HR], 0.27; 95% confidence intervals [CI], 0.12-0.61; P=0.0007), consistent with the overall PFS observed in CAS- TOR (Figure). Higher overall response rate (ORR; 95% vs 79%) and rates of complete response (CR) or better (25% vs 3%) and very good partial response (VGPR) or better (70% vs 18%) were achieved with DVD versus Vd, respectively, consistent with the overall population. In the POLLUX study, 29/286 pts in the DRd group and 35/283 pts in the Rd group were aged ≥75 years; the median (range) age for this group of pts was 77 (75-89) and 78 (75-87) years, respectively, with 86% and 91% with an ECOG status ≤1. At a median follow-up of 17.3 months, 10% of pts in the DRd group and 11% in the Rd group discontinued due to TEAEs. Common (≥10%) grade 3/4 TEAEs for DRd were neutropenia (45% vs 31% with Rd), hypokalemia (14% vs 3%), and pneumonia (10% vs 11%). D-associated IRR occurred in 12 (41%) pts in the DRd group, with 4 (14%) pts having grade 3/4 IRR. No patient discontin- uated DRd due to IRR. Median PFS was significantly prolonged with DRd compared with Rd in the elderly subgroup (NR vs 11.4 months; HR, 0.19; 95% CI, 0.06-0.55; P=0.0007), consistent with the overall PFS observed in POLLUX (Figure 1). ORR was higher with DRd versus Rd (93% vs 77%), and rates of CR or better (52% vs 9%) and VGPR or better (72% vs 41%) were also higher with DRd versus Rd.

Figure 1.

Summary/Conclusions: The results in elderly pts were consistent with those observed in the overall study populations in terms of efficacy. Rates of most common grade 3/4 hematologic TEAEs for DRd in elderly were similar to that of the overall populations, and IRR were manageable. This subgroup analysis supports the addition of D to standard-of-care regimens in elderly pts with RRMM.
Summary/Conclusions: The all oral ixThalDex regimen showed an ORR of 63% with no difference in pts with high-risk cytogenetics, a CBR of 67%, and a PFS of 10.4 mos in pts with RRMM. The regimen was well tolerated and was associated with a low incidence of mainly grade ≥2 PNP, which required dose reduction in one patient only. Response rates improved with continuation of therapy and treatment was associated with an increase in health related QoL.

P337 EVALUATION OF GROWTH DIFFERENTIATION FACTOR-1 (GDF15) AS A NEW BIOMARKER FOR RENAL OUTCOMES IN DIFFERENT COHORTS OF PATIENTS WITH LIGHT CHAIN AMYLOIDOSIS

Background: Growth differentiation factor-15 (GDF-15), is a member of the TGF-beta family, and is involved in several pathological conditions, including inflammation, cancer, cardiovascular, pulmonary and renal diseases. Serum GDF-15 levels add prognostic information to conventional prognostic factors, such as NT-proBNP and troponins, in cardiovascular disorders and has also shown to be associated with renal damage and risk of end stage renal disease in patients with diabetes. Increased serum GDF-15 levels have also been shown to correlate with early death and shorter survival independently of other cardiac biomarkers and Mayo stage. Because GDF-15 was also associated with renal outcomes we evaluated the prognostic value of GDF-15 levels in two independent cohorts of patients with AL amyloidosis and renal involvement who were treated in two different centers (Pavia Amyloidosis Center and Department of Clinical Therapeutics, Clinical Therapeutics, Athens). Aims: To evaluate the prognostic value of GDF-15 levels in independent cohorts of patients with AL amyloidosis and renal involvement.

Methods: Circulating levels of GDF-15 were measured by a novel pre-commercial immunoasay (Rutacell Diagnostics) in two different centers. The Pavia cohort included 135 and the Athens cohort included 76 patients with AL amyloidosis and renal involvement. Standard criteria were used for the diagnosis, evaluation of organ involvement and cardiac biomarker-based risk stratification. Renal staging was based on the system proposed by Palladini et al., based on baseline proteinuria ≥5 g/day and eGFR <50 ml/min.

Results: Median age and involved FLC levels were similar between the two cohorts. However, heart involvement was more common in Pavia cohort (72% vs 53%; p=0.005). Mayo stage disposition was also different (17%, 46% & 37% for stage 1, 2 & 3 in Pavia vs 30%, 43% & 27% in Athens cohort, p=0.08, but stage 3B was similar, 13% vs 12%). Also there were differences in peripheral nerve involvement (9% in Pavia vs 21% in Athens cohort, p=0.025). Median eGFR and renal stage distribution (26%, 54%, 20% vs 20%, 54%, 26% for renal stage-1, 2 & 3 respectively) were similar between the two cohorts (p=0.544). Median follow up for the Pavia cohort was 18 months and for the Athens cohort was 45 months (p<0.001). Survival at 2 years was 59% for Pavia and 56% for Athens cohort. Median GDF-15 levels was 3454 pg/ml in Pavia (range 624 to >100000) and 4152 pg/ml (range 626 – 71475) in Athens cohort (p=0.09), while 93% and 94% of patients in the two cohorts had GDF-15 levels ≥1200 pg/ml (the upper limit of normal for individuals without cardiovascular disease). We then evaluated the prognostic significance regarding renal outcomes (dialysis): GDF-15 <4000 pg/ml was associated with a HR of 6 (95% CI 2015.6, p=0.001) in Athens cohort (progression to dialysis within 2 years in 7% vs 47%); while, by applying the same cutoff in patients in Pavia cohort, 2-year dialysis rate was 10% vs 37% (HR: 3.95, CI 1.6-15, p=0.004). Although renal stage discriminated 3 groups in univariate analysis in each cohort, in multivariate analysis, GDF-15 ≥4000 pg/ml outperformed renal stage by eGFR and proteinuria and was the only independent prognostic factor for progression to dialysis in each cohort (Figure 1).
Summary/Conclusions: Our study validated and confirmed in two independent cohorts, with differences in their characteristics, the prognostic value of GDF-15, which emerges as a novel biomarker with prognostic implications for different outcomes in patients with AL amyloidosis. Importantly, GDF-15 emerges as a strong biomarker for renal outcomes in patients with AL amyloidosis.

**P338**

AN OPEN-LABEL, PHASE 2 STUDY TO EVALUATE THE ORAL COMBINATION OF IXAZOMIB, CYCLOPHOSPHAMIDE AND DEXAMETHASONE IN TRANSPLANT-INELIGIBLE PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA

M.A. Dimopoulos1-4, S. Grosicki2, W. Jędrzejczak2, H. Nash3, A. Gruber4, M. Hansson5, C. Byrne6, R. Labokta2, Z. Deng9, H. Yang9, N. Grzasko8, S. Kumar8

1National and Kapodistrian University of Athens School of Medicine, Athens, Greece, 2Silesian Medical University, Katowice, 3Medical University of Warsaw, Warsaw, Poland, 4Karolinska University Hospital, Stockholm, 5Skåne University Hospital, Lund, Sweden, 6Millennium Pharmaceuticals Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, United States, 7St. John Cancer Center, Medical University of Lublin, Lublin, Poland, 8Mayo Clinic, Rochester, United States

Background: Proteasome inhibitor (PI)-based combinations are standards of care in all lines of MM therapy. As the treatment paradigm moves to focus more on extended therapy, new combinations are needed that will be efficacious and tolerable, while giving pts the flexibility of taking their treatment at home. Combinations of ixazomib, the first oral PI, with immunomodulatory drugs (IMiDs) are feasible and effective; however, there may be pts for whom the use of IMiDs is not desirable. Therefore, triplet combinations of ixazomib with alkylators have been studied.

Aims: This phase 2 study (NCT02046070) evaluated the safety and efficacy of the all-oral IC regimen in transplant-ineligible pts with NDMM. Primary endpoint was rate of CR+VGPR during induction. Secondary endpoints included tolerability and toxicity, overall response rate (CR+VGPR+PR) throughout treatment, time to response, PFS, and quality of life (QoL).

Methods: Adult pts with NDMM who were transplant-ineligible were randomized (1:1) to receive oral ixazomib 4.0 mg plus oral cyclophosphamide 300 mg/m2 (Arm A) or 400 mg/m2 (Arm B) on days 1, 8, 15, and dexamethasone 40 mg on days 1, 8, 15, and 22, for up to 13 28-day cycles as induction. Pts with ≥SD and an acceptable toxicity profile then received single-agent ixazomib maintenance therapy until PD, death, or unacceptable toxicity.

Results: 70 NDMM pts were enrolled (n=36 Arm A; n=34 Arm B): median age 73 years (range 61–87); 47% male; 31%/33%/32% ISS stage I/II/III MM; 50% had a cardiovascular/pulmonary comorbidity; 9% had high-risk cytogenetics (t(4;14), t(14;16), del 17p). At data cut-off (29 June 2016), pts had received a median of 19 cycles; 66% had completed 13 IC induction cycles and proceeded to ixazomib maintenance therapy; 10% were ongoing on therapy, and 31% had discontinued due to AEs (24%), PD (16%), patient withdrawal (3%), or other reasons (10%).

Summary/Conclusions: Based on this phase 2 study, ICd is an active treatment regimen for pts with NDMM who are ineligible for transplant. This trial captured a population of pts that was elderly and with multiple comorbidities. In this context, the results with ICd, an all-oral triplet including a PI and alkylator, provide evidence of clinical efficacy with a manageable safety profile. With a median follow-up of ~18 months, median PFS was not reached and outcomes appear comparable to other regimens in elderly transplant-ineligible pts with NDMM. The preferred cyclophosphamide dose for ICd phase 3 studies is 300 mg/m2, based on the similar PFS, higher response rate, and numerically lower rate of AEs vs 400mg/m2. Updated PFS results will be presented at the meeting.

Background: Bortezomib-MP is a standard-of-care regimen for elderly NDMM pts. Whereas bortezomib is administered IV or SC, ixazomib is an oral proteasome inhibitor with a safety profile amenable to extended dosing that is approved in the US and EU, in combination with lenalidomide-dexamethasone, for the treatment of MM pts who have received at least 1 prior therapy. Based on the demonstrated feasibility and efficacy of a proteasome inhibitor-MP combination, the all-oral ixazomib-MP (IMP) regimen was evaluated in elderly, transplant-ineligible NDMM pts.

Aims: Primary phase 1 objectives were to determine the safety, MTD, and recommended phase 2 dose (RP2D) of ixazomib in combination with MP. The primary phase 2 objective was to determine the rate of CR+VGPR, secondary objectives included PFS and OS.

Methods: In phase 1, pts were enrolled to 4 arms – Arm A: ixazomib 3.0–3.7 mg (days 1, 4, 8, 11, 22, 25, 29, 32) plus M 9 mg/m2 and P 60 mg/m2 (days 1–4) in 42-day cycles (max 9 cycles); Arm B: ixazomib 3.0–4.0 mg (days 1, 8, 15) plus M 6 mg/m2 and P 60 mg/m2 (days 1–4) in 28-day cycles (max 13 cycles); Arm C: ixazomib 3.0–4.0 mg (days 1, 8, 15, 22, 29) plus M 4.0 mg/m2 (days 1, 8, 22, 29) plus M 9 mg/m2 and P 60 mg/m2 (days 1–4) in 42-day cycles (max 9 cycles). In phase 2, an expansion cohort was enrolled at the RP2D. On all arms, after IMP induction, pts could receive maintenance with single-agent ixazomib (days 1, 8, 15, 28-29 cycles).

Results: 61 pts were enrolled, 11, 34, 11, and 5 to Arms A, B, C, and D (median age 74 yrs; 31% ISS stage III, 56% creatinine clearance ≤60 mL/min). Among
Myeloma and other monoclonal gammopathies - Clinical 2

FEASIBILITY AND EFFICACY OF DOSE ADJUSTED MELPHALAN – PREDNISONE – BORTEZOMIB IN PATIENTS ≥75 YEARS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA; PRELIMINARY RESULTS OF THE PHASE II HOVON 123 STUDY

1Hematology, VU University Medical Center, Cancer Center Amsterdam, Amsterdam, 2Internal Medicine, Albert Schweitzer ziekenhuis, Dordrecht, 3Internal Medicine, Meander Medisch Centrum, Amersfoort, 4Internal Medicine, ZNB, Leeuwarden, 5Internal Medicine, Haga Ziekenhuis, Den Haag, 6Internal Medicine, Sint Jans Dal, Harderwijk, 7Internal Medicine, MCA, Alkmaar, 8Internal Medicine, Tergooi ziekenhuizen, Hilversum, 9Internal Medicine, Groene Hart ziekenhuis, Gouda, 10Internal Medicine, VU University Medical Center, Cancer Center Amsterdam, Amsterdam, 11Hematology, UMCU, Utrecht, 12HOVON Data Center, 13Hematology, Erasmus MC Cancer Institute, Rotterdam, Netherlands

Background: There is a high rate of toxicity-related discontinuation in elderly patients with NDMM, negatively affecting outcome. In order to predict feasibility of treatment the IMWG developed the frailty score based on age, (instrumental) Activities of Daily Living and the Charlson comorbidity index.

Methods: Patients were treated with 9 cycles of MPV: Mel 6 mg/m², day 1-4; Pred 30 mg/m², day 1-4; and Bort 1.3 mg/m² day 1, 8, 15 and 22 of a 35-day cycle. This first planned analysis was restricted to the first 140 consecutive patients out of 240 planned patients.

Results: Of the 139/140 eligible patients none were fit (because of age ≥75 years), 30/139 (22%) were unfit, 100/139 (72%) were frail, and 9/139 (6%) unknown. The median follow up was 17.0 months. The discontinuation rate of MPV in the total population was 42%; 27% in unfit and 46% in frail patients (p=0.09). When also patients were included who discontinued bortezomib only these numbers were 27% in unfit and 52% in frail (p=0.02). Importantly, 6 cycles of MPV were found to be feasible in 70% of patients, both in unfit (80%) and frail (69%) patients. Age >80 years was associated with a significantly higher discontinuation rate of MPV or bortezomib only (70% versus 35% in patients aged 75-80 years, p=0.01). WHO performance was not associated with discontinuation rate. Response on protocol was ≥PR 73%, ≥VGPR 38% and ≥CR 11%, not significantly different in unfit versus frail patients. After 6 cycles response was ≥PR 69%, ≥VGPR 35% and ≥CR 2%. Median progression free survival (PFS) was 17 months: 20 for unfit and 16 months for frail patients (p=0.13). Overall survival at 18 months was 76%: 89% for unfit and 72% for frail patients (p=0.22). Frail patients were found to have significantly less grip strength and lower walking speed as compared to unfit patients (Table 1).

Table 1.

However, 58% and 59% of frail patients had an intermediate or high walking speed and grip strength respectively. Vice versa, 8% of patients with low
walking speed and 12% of patients with low grip strength, were not frail but unfit according to the IMWG frailty index. Discontinuation rate in patients with highest and lowest walking speed was 16/41 (39%) and 18/41 (44%). These numbers were 14/42 (33%) versus 17/43 (40%) for patients with the highest versus the lowest grip strength. PFS was not significantly different between patients with highest versus lowest walking speed (p=0.38). However, in contrast to comparable PFS in unfit and frail patients, there was a trend for better PFS in patients with highest versus lowest grip strength (20 versus 17 months, p=0.05).

Summary/Conclusions: Nine cycles of dose-adjusted MPV results in a high discontinuation rate of 42% in NDMM patients ≥75 years: 27% in unfit versus 46% in frail patients. Importantly, 6 cycles of MPV were found to be feasible with comparable response rate, also in frail. Preliminary analyses showed that functional geriatric assessments differed within IMWG frailty groups and that grip strength was associated with PFS, whereas frailty was not. Therefore, functional assessments will hopefully be complementary to the IMWG frailty score in guiding future therapy in unfit and frail patients.

P341
THE EUROPEAN MYELOMA NETWORK EMN09 STUDY: CARFILZOMIB, BENDAMUSTINE, AND DEXAMETHASONE IS EFFECTIVE AND SAFE IN PATIENTS WITH ADVANCED MULTIPLE MYELOMA

M. de Theije1, A. Günter1, M. Offidani2, M. Engelhardt3, S. Gentili4, V. Montefusco5, F. Patriarca6, E. Angeliucci7, N. Schub1, M. Astolfi8, W. Poenisch9, H. Einsele10, P. Corradini4, A. Palumbo11, F. Gay7

Materials and Methods: In a single-arm, phase 1/2, multicenter study (NCT02056756), 60 untreated patients were randomized to receive Carfilzomib (Carf) 27–70 mg/m² on day 1 and 8, Benda 70 mg/m² on day 1 and 8, plus dexamethasone (DEX) 40 mg for 2 days plus DEX until progression. With this scientific rationale a CBd combination of Carfilzomib and Benda was developed. The phase 1 part of the trial suggested Carf at the 27 mg/m² level for the phase 2 part. Forty-one patients were evaluated for response and efficacy. At last data cut-off, the median follow-up was 5.95 months. Number of prior treatment lines ranged from 2 to 9, and ≥85% of patients had received previously transplan
tative therapy prior to study entry. Hematological toxicity was well manageable. Non-hematological adverse events (AEs) were relatively low, with grade 3 or 4 AEs in 39% of all treated patients. No grade 5 AEs were reported. One death was either progression of AL (N=16), sepsis (n=4), heart transplant rejection (mostly due to renal complications after HTx). Complete remission (CR) was achieved in 7 patients (24% of all transplanted pts, N=29; 2 patients have not finished treatment yet, very good partial remission (VR) in 17% and partial remission (PR) in 7 patients (24%). Overall, 25 patients died. Cause of death was either progression of AL (N=16), sepsis (n=4), heart transplant rejection (n=3) or other (n=2). Patients that underwent HTx had a median survival of 46 months (2-177, 1-year survival: 77%).

Summary/Conclusions: HTx in patients treated with chemotherapy is a feasible treatment approach in patients with advanced cardiac amyloidosis. Patients who reach HTx have a nearly 50% chance for a very good hematologic remission (VGPR or better) and consecutively a favorable survival probability with a median OS of nearly 6 years in our series.

P343
CHEMOTHERAPY BEFORE AND AFTER HEART TRANSPLANTATION FOR PATIENTS WITH ADVANCED CARDIAC AL AMYLOIDOSIS: SINGLE CENTER RESULTS WITH LONG-TERM FOLLOW-UP

U. Hegenbart1, K. Haack1, A. Kristen1, P. Blum2, C. Kimmich1, H. Katus2, A. D. Ho3, A. Ruhrwara4, P. Raake2, S. Schönfeld1

1Amyloidosis Center, 2Div. of Cardiology, 3University Hospital, Heidelberg, Germany, 4Cardiac Surgery, University Hospital, Heidelberg, Germany

Background: Survival rates for patients with light-chain (AL) amyloidosis are gravely reduced by advanced cardiac involvement at Mayo cardiac stage IV with a median survival of 6.5 months. High-dose Melphalan (HDIM) and autol
crophic stem cell transplantation (ASCT) or other intensive chemotherapy regimen cannot be applied to those patients due to the high risk of therapy-related mor
tality. One approach to improve the catastrophic prognosis of those patients is to perform a heart transplantation followed by intense chemotherapy.

Aims: Our aim was to examine the cases of cardiac AL patients treated with heart transplantation (HTx) at our center and to evaluate the clinical outcome of this treatment approach.

Methods: Data from 41 patients (21m, 20f) suffering from cardiac AL who were treated in our hospital between 2002 and 2017 were retrospectively analyzed. All patients were high-urgency listed for orthotopic HTx due to poor prospective of survival. Prior to 2009, 10 patients were listed, 8 of them with multiple organ involvement. Thereafter, we excluded patients with multiple organ involvement. All data are derived as medians with range or absolute numbers. Survival curves were calculated using the Kaplan-Meier method.

Results: Median age was 51 years (35-63) at diagnosis. Amyloidogenic lambda light-chains (LC) were detected in 31 and lambda-kappa light-chains in 17 patients. Median dFLC was 331 (69-2752) and median plasma cells in bone marrow were 13% (5-35). Median NT-proBNP was 6.332 ng/l (1.500-53.194), median cTNT 0.11 µg/l (0.01-0.52) and median hsTNT was 60 ng/l (28-448) at diagnosis. Median NYHA stage was 3 (2-3) and median Mayo 2004 stage was 3 (2-3). Serum creatinine was at 1.94 mg/dl (1.17-4.45), proteinuria at 0.1 g/day (0-10.7). Patients stayed on the high-urgency waiting list for a median of 26 (range 3-54) before 2009, and a median of 64 days (8-259) after 2009. 35 patients were treated with chemotherapy prior to HTx (mostly dexa w/o Bortezomib) to reduce dFLC during the waiting time. Eight patients died before receiving HTx with a median survival (start point: HU listing) of 28 days (6-177). With a median of 5 months after HTx (4-29), 18 patients received ASCT. HDIM was used with either 200 mg/m² (N=10) or reduced dosage (N=8) in patients with reduced kidney function (mostly due to renal complications after HTx). Complete remission (CR) was achieved in 7 patients (24% of all transplanted pts, n=29; 2 patients have not finished treatment yet, very good partial remission (VR) in 17% and partial remission (PR) in 7 patients (24%). Overall, 25 patients died. Cause of death was either progression of AL (N=16), sepsis (n=4), heart transplant rejection (n=3) or other (n=2). Patients that underwent HTx had a median survival of 46 months (2-177, 1-year survival: 77%).

Summary/Conclusions: HTx in patients treated with chemotherapy is a feasible treatment approach in patients with advanced cardiac amyloidosis. Patients who reach HTx have a nearly 50% chance for a very good hematologic remission (VGPR or better) and consecutively a favorable survival probability with a median OS of nearly 6 years in our series.
or unacceptable toxicity. Supportive care was allowed; thrombophlebitis was required for all pts on hemodialysis. The primary endpoint was overall response rate (ORR). Key secondary endpoints included safety, renal response, time to myeloma response, time to renal response, duration of response, progression-free survival (PFS), time to progression, and overall survival (OS). All pts provided informed consent.

Results: Enrolment has been completed with 81 pts (33 in cohort A; 34 in cohort B; 14 in cohort C), of which 13 (16.0%) were still on treatment as of January 28, 2017. Median follow-up for OS was 7.8 months. A total of 68 pts (84.0%) discontinued treatment; 39 (48.1%) due to PD. Median age was 72 yrs (range, 52-86 yrs). 60.5% of pts were male, and median time from diagnosis was 3.8 yrs (range, 0.03-19.44 yrs). Pts received a median of 4 (range, 1-10) prior anti-myeloma therapies. All pts had prior treatment with LEN (100%) and nearly all with BORT (97.5%). Median relative dose intensity of POM was 0.94 in both cohorts A and B, and 0.99 in cohort C. ORR was 39.4%, 29.4%, and 14.3% in cohorts A, B, and C respectively. PFS and OS results are presented in the Table 1. Grade 3/4 anemia and thrombocytopenia occurred more frequently in cohort C, likely due to severe RI requiring dialysis (Table 1). AEs leading to dose reductions were 18.2%, 14.7%, and 14.3% in cohorts A, B, and C, respectively.

Summary/Conclusions: POM+LoDEX is efficacious in pts with RRMM with moderate or severe RI, including those on hemodialysis, who had more advanced disease due to worse renal function. The safety profile was acceptable among the three groups and no new safety signals were observed. This study demonstrates that POM+LoDEX can be administered in pts with moderate or severe RI, including those on hemodialysis.

P345

ASSESSMENT OF MOBILIZATION COST FOR MULTIPLE MYELOMA USING 2 DIFFERENT STRATEGIES: HIGH-DOSE CYCLOPHOSPHAMIDE VERSUS PLERIXAFOR. ON BEHALF OF IFM

Background: Treatment with autologous transplantation (ASCT) remains the standard of care upfront for Multiple Myeloma patients considered eligible for transplant. Peripheral blood stem cell (PBSC) collection, also called mobilisation, is needed prior to ASCT. The optimal methodology for mobilizing PBSC has yet to be defined, with either G-CSF alone, also called steady state procedure, or use of Plerixafor, a CXCR4 antagonist (Mozobil®)+G-CSF or high dose cyclophosphamide (used at a dose of 1.5 to 6g/m² IV for mobilization) versus Plerixafor+G-CSF or high dose cyclophosphamide. The 2 latter have demonstrated similar PBSC collection rates. Because of the intense competition for hospital resources and the staff required to manage patients preparing for mobilization and transplantation, it is important to quantify the total impact of mobilization on staff resource and hospital costs.

Aims: We aimed at better evaluate the respective cost of the 2 techniques of mobilization for the French health care system, high dose cyclophosphamide (n=57) versus plerixafor (n=55).

Methods: This is an observational cohort database analysis of 112 consecutive patients with MM treated upfront with ASCT between 2009 and 2013 and that had been mobilized with either high dose cyclophosphamide or plerixafor from 15 IFM centers. Patients must have successfully underwent ASCT. This study was not aimed at evaluating the suitability or advisability of one therapy versus another. A cost-consequences analysis of the different regimens of mobilization 1) without transplantation and 2) with transplantation is needed prior to ASCT. The optimal methodology for mobilizing PBSC has yet to be defined, with either G-CSF alone, also called steady state procedure, or use of Plerixafor, a CXCR4 antagonist (Mozobil®)+G-CSF or high dose cyclophosphamide (used at a dose of 1.5 to 6g/m² IV for mobilization) versus Plerixafor+G-CSF or high dose cyclophosphamide. The 2 latter have demonstrated similar PBSC collection rates. Because of the intense competition for hospital resources and the staff required to manage patients preparing for mobilization and transplantation, it is important to quantify the total impact of mobilization on staff resource and hospital costs.

Background: Treatment with autologous transplantation (ASCT) remains the standard of care upfront for Multiple Myeloma patients considered eligible for transplant. Peripheral blood stem cell (PBSC) collection, also called mobilisation, is needed prior to ASCT. The optimal methodology for mobilizing PBSC has yet to be defined, with either G-CSF alone, also called steady state procedure, or use of Plerixafor, a CXCR4 antagonist (Mozobil®)+G-CSF or high dose cyclophosphamide (used at a dose of 1.5 to 6g/m² IV for mobilization) versus Plerixafor+G-CSF or high dose cyclophosphamide. The 2 latter have demonstrated similar PBSC collection rates. Because of the intense competition for hospital resources and the staff required to manage patients preparing for mobilization and transplantation, it is important to quantify the total impact of mobilization on staff resource and hospital costs.

Aims: To determine the safety, tolerability, and antitumor activity of pembrolizumab monotherapy in patients with RRMM.

Methods: Patients with RRMM who have failed ≥2 prior lines of therapy including a proteasome inhibitor and immunomodulatory drug (IMiD) received pembrolizumab 10 mg/kg every 2 weeks or 200 mg fixed dose every 3 weeks. Primary end points were safety, tolerability, and objective response rate (ORR) as determined by investigators, per International Myeloma Working Group 2006 criteria.

Results: At data cutoff of January 2, 2017, 30 patients were treated. The median (range) duration of follow-up was 15 (1-32) months. 28 (93%) patients discontinued the study; the most common reason was disease progression in 14 (47%) patients and clinical progression in 9 (30%) patients. 2 (7%) patients are still on treatment. Median (range) age was 70 (56-81) years. 21 (70%) patients had an ECOG performance status of 1. Patients received a median (range) of 4 (2-10) prior lines of therapy. 20 (67%) patients were lenalidomide refractory, 10 (33%) were double-refractory. 9 (30%) were triple refractory, and 11 (37%) were quadruple refractory. Among patients who received pembrolizumab at 10 mg/kg, the median (range) of pembrolizumab exposure was 6 (2-15) cycles; among those who received 200-mg fixed dose of pembrolizumab, the exposure was 3 (2-6) cycles. No patient experienced a response. Seventeen (57%; 95% CI, 37-75%) patients had stable disease. 13 (43%; 95% CI, 26-63%) patients had progressive disease as their best response. Treatment-related adverse events (TRAEs) occurred in 12 (40%) patients. The most common TRAE was anaemia (n=5, 17%); arthralgia, aspartate aminotransferase increased, fatigue, hyperglycemia, hypothyroidism, myalgia, pruritus, and blurred vision occurred in 1 patient each. A grade 3 TRAE (myalgia) occurred in 1 (6%) patient. There were no grade 4 TRAEs. 1 (3%) patient had an immune-related adverse event (grade 1 pruritus).

Conclusion: The safety profile of pembrolizumab in RRMM was consistent with that observed with other cancers. Best response observed while on pembrolizumab monotherapy was stable disease. Recent results of ongoing studies, such as KEYNOTE-023 (NCT02036802), demonstrate promising efficacy of pembrolizumab in combination with IMiDs (lenalidomide) and dexamethasone in patients with RRMM.
Summary/Conclusions: For a long time HD cyclophosphamide was recommended for mobilization upfront in Myeloma therapy, as it was needed to improve response rate and depth of response, despite only 10% of the patients improving. With the progress made recently with the induction regimens, the choice for the mobilization regimen is now based more on safety and cost saving. In that regards, one must acknowledge that plerixafor has become one, if not the, most attractive option for Myeloma.

P347

A STUDY OF UTILITY OR FUTILITY OF PERFORMING SKELETAL SURVEYS IN PARAPROTEINAEMIA: A MULTICENTER EXPERIENCE FROM UK

O. Gamage1,2, M. Zaw1, S. Gurung1, G. Pratt3, S. Shafeek1, A. Macwahonne1, S. Lee1, S. Basu1
1Department of clinical Haematology, Royal Wolverhampton NHS Trust, Wolverhampton, 2Department of Haematology, University Hospital, Birmingham, UK, Birmingham, 3Department of Haematology, Worcestershire Acute Hospital Trust, Worcester, United Kingdom

Background: Recent International Myeloma Working Group (IMWG) guidelines recommend that conventional skeletal surveys should be supplanted by low dose whole body computed tomography (CT), whole body magnetic resonance imaging (MRI) and or 18fluoro-deoxyglucose (18F-FDG/PET). However, resource, funding and radiology capacity issues, have posed significant challenges to implementing these recommendations. The risk of progression of Monoclonal Gammopathy of Undetermined Significance (MGUS) to a neoplastic plasma cell disorder is approximately 1% per year and even lower in low risk MGUS. It is thus not necessary to perform imaging in unselected MGUS patients.

Aims: To look at all skeletal surveys requested across 3 large hospitals in UK over a year and analyze their justification, effectiveness and utility. To decide if a rational clinico–biochemical algorithm could be used to reduce the number of imaging requests, thereby avoiding unnecessary radiation exposure, and make a possible switch to modern imaging methods cost effective.

Methods: A total of 397 skeletal surveys were performed across three hospitals over one year. The data set was analyzed for clinical indications, paraprotein level, rationale for requesting the skeletal survey, the diagnostic yield and also the number of follow up CT/PET or MRI required.

A pragmatic algorithm was developed and applied to see if the requests were justified and could have been safely reduced. (Figure 1).

Results: Of the 397 analyzable skeletal surveys performed, 266 were on myeloma, 81 for MUGS, 48 were for non-paraprotein related indications. Of the 266 myelomas, 30% of skeletal surveys were reported as positive according to IMWG criteria. A detailed analysis of 130 myeloma patients revealed a significant proportion of false negatives (6%) and false positives (7%), highlighting the insensitivity and poor specificity of this imaging modality. More importantly, more than a third (38%) of myeloma patients required follow up imaging with MRI, PET or WBLC irrespective of the initial skeletal survey result, indicating a significant duplication rate and waste of resources. In the MGUS group, majority of skeletal surveys were negative (91%) but 9% were reported as positive. Follow up imaging with CT and MRI was performed in 23% of the MGUS group. However none these were positive. When the clinico-biochemical algorithm was applied, the number of requests was reduced by at least a quarter (24%), avoiding unnecessary radiation exposure and precious resources.

Figure 1.

Summary/Conclusions: - Skeletal survey has very limited role in investigation of paraproteinaemia and should be abandoned. - Our pragmatic clinico-biochemical imaging algorithm reduced imaging requests significantly (24%) allowing the preferred imaging modalities to be performed productively in a cost effective way in face of ever increasing health care cost and demands.

SERUM FLC MEASUREMENTS COMPLEMENT BONE MARROW ASSESSMENT TO DETERMINE PROGNOSIS IN MYELOMA PATIENTS ACHIEVING DEEP RESPONSES

T. Dejoie1, M. Attia2, P. Moreau3, H. Avel-Loiseau4
1Biochemistry Laboratory, Centre Hospitalier Universitaire-Nantes, Nantes, 2Institut Universitaire du Cancer-Oncopole, Toulouse, 3Department of Hema-

Figure 1.

Summary/Conclusions: - Our systematic review and NMA included most of the recommended induction treatments for transplant-eligible myeloma patients and identified VRD as being most effective in achievement of 3VGPR. NMA can provide an overview of the best treatment and each regimen’s relative efficacy in case of lacking head-to-head RCTs, thereby supporting clinical decision-making.
Background: In multiple myeloma (MM), abnormal serum free light chain ratios (FLCr) after therapy associate with poor prognosis, independent of depth of response. However the value of FLCr in the context of minimal residual disease (MRD) remains unclear. A proportion of MRD-negative patients experience early relapse and conversely, some MRD-positive patients can endure long-term survival; which may result from improved immunosurveillance following normal plasma-cell recovery. Aims: We hypothesised that serum FLCr levels and ratios add clinical value at the time of MRD assessment.

Methods: The study included 275 intact immunoglobulin MM patients from the IFM2009 clinical trial who achieved at least a very good partial response (VGPR) after consolidation therapy. Median PFS from the end of consolidation was 38.3 months; median OS was not reached. Serum FLCrs were measured using 4-colour multiparametric flow cytometry (MFC). We defined immunosuppression as levels of both the uninvolved (polychain) FLC+uninvolved heavy-light chain (HL; measured with Heyvityle) below their normal range. MRD assessment in bone marrow samples was based on 4-colour multiparametric flow cytometry (MFC).

Results: At the end of consolidation, 78/275 (29%) patients were MRD-positive, 79/275 (29%) had abnormal FLCr, 16/275 (6%) had elevated iFLC, with immunosuppression identified in 52/275 (19%). Using Cox regression all the variables associated with shorter PFS (p<0.001 for all) and OS (p<0.050 for all; except elevated iFLC which showed a trend towards shorter OS (p=0.070)). Among 196 MRD-negative patients, 37/196 (19%) had abnormal FLCr, 2/196 (1%) had elevated iFLC with immunosuppression identified in 23/196 (12%). Median PFS for MRD-negative patients was not reached; however both an abnormal FLCr (median PFS: 31.4 months; p<0.001) and immunosuppression (median PFS: 31.4 months; p=0.050) identified a group of patients with poorer outcomes. On the other hand, median PFS for MRD-positive patients was 21.3 months; 42%(53%) of these patients had abnormal FLCr and dismal outcomes (median PFS 12.6 vs 30.7 months for abnormal vs normal FLCr, respectively; p=0.054). Absolute FLCr measurements did not reach statistical significance for PFS in these patients.

Summary/Conclusions: Serum FLCr measurements in combination with low-sensitivity MFC bone marrow assessment at the end of consolidation therapy render the most powerful prognostic information in MM patients achieving deep responses. In those where disease is no longer detected using MFC, abnormal FLCr confer poor prognosis, which may partly be due to inefficient immune recovery. Absolute FLCr measurements were informative, supporting the rationale of evaluating biomarkers of the tumour and immune system recovery. Our results warrant further studies to validate the clinical utility of FLCr measurements in combination with next-generation (8-colours) flow cytometry.

THE CONNECT MM REGISTRY: IMPACT OF THE CYTOGENETIC ABNORMALITY T(11;14) ON SURVIVAL OUTCOMES IN AFRICAN AMERICAN AND NON-AFRICAN AMERICAN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA
1Duke University Medical Center, Durham, 2Indiana University Simon Cancer Center, Indianapolis, 3Mount Sinai Hospital, New York, 4Cedars-Sinai Samuel Oschin Cancer Center, Los Angeles, 5MD Anderson Cancer Center, Houston, 6US Oncology Research, Maryland Oncology Hematology, Columbia, 7Providence Cancer Institute, Southfield, 8Steeplechase Cancer Center, Somerville, 9University of South Carolina, Columbia, 10Wake Forest University School of Medicine, Winston-Salem, 11Celgene Corporation, Summit, 12US Oncology Research, Rocky Mountain Cancer Centers, Denver, United States

Background: The cytogenetic abnormality t(11;14) is common, occurring in approximately 20% of patients with newly diagnosed multiple myeloma (NDMM) (Avet-Loiseau, Leukemia, 2013). Historically, t(11;14) has been associated with standard-risk multiple myeloma (MM) and generally favorable outcomes (Avet-Loiseau, Leukemia, 2013). However more recent retrospective studies have reported the presence of t(11;14) to be a poor prognostic factor (Kaufman, Leukemia, 2016). Connect MM is a largely community-based, US prospective observational cohort study that collects data on management and natural history of patients with NDMM in clinical practice.

Aims: This analysis assessed the impact of t(11;14) on survival outcomes in African American and non-African American patients in a mostly community-based setting.

Methods: Adult patients with NDMM within 60 days of diagnosis were eligible for enrollment in the registry. Patients who completed induction and were tested for t(11;14) by fluorescence in situ hybridization or cytogenetics were grouped by race (African American and non-African American). Endpoints were progression-free survival (PFS) and overall survival (OS). Kaplan-Meier analyses were adjusted for cohort, age, International Staging System stage, transplant intent, presence of t(14;14), diabetes history, and baseline levels of hemoglobin, platelets, calcium, and creatinine. Data cut-off was Jul 7, 2016.

Results: 3011 patients were enrolled in 2 cohorts. Cohort 1 enrolled 1493 patients from Sep 2009–Dec 2011; median follow-up was 39.3 months. Cohort 2 enrolled 1518 patients from Dec 2012–Apr 2016; median follow-up was 16.4 months. A total of 1539 (52%) patients were tested for t(11;14). Of these, 363 (24%) were positive for t(11;14). By race, 53 (26%) of 205 African American and 310 (23%) of 1334 non-African American patients were positive for t(11;14). First-line bortezomib exposure was similar across all groups. In African American patients, the presence of t(11;14) resulted in a trend toward shorter PFS compared to those without t(11;14) (Table 1). Additionally, African American patients with t(11;14) had significantly higher risk of death compared to African American patients without t(11;14). A higher rate of early mortality was observed vs non-African American patients. In non-African American patients, no differences in PFS or OS were noted based on the presence or absence of t(11;14). For OS, the interaction between race and t(11;14) status was statistically significant (P=0.004).

Table 1.

<td>Not reached</td>
</tr>
</tbody>
</table>

Summary/Conclusions: In Connect MM, the effect of t(11;14) on OS was significantly different between African American and non-African American patients. Specifically, t(11;14) was associated with poorer survival outcomes in African American patients, and not in non-African American patients. Thus, the presence of t(11;14) may be a risk factor for poor prognosis in African American patients. Additional analyses will be conducted to elucidate the role of induction treatment, transplant and maintenance in African American and non-African American patients with t(11;14).

Background: Juvenile myelomonocytic leukemia (JMML) is an aggressive myeloproliferative disorder of early childhood. While some cases show spontaneous remission, allelic hematopoietic stem cell transplantation (HSCT) remains the only curative treatment option for the majority of patients, however, the 5-year event-free survival reaches only about 50%. Hyperactive RAS signaling is assumed to be the main driving event in JMML. It is caused by genetic alterations in CBL, KRAS, NF1, NRAS, or PTPN11 in about 90% of patients. So far, there is no clear understanding of how RAS pathway mutations relate to the heterogeneous disease biology and variable clinical outcome seen in JMML patients. As a consequence, established clinical and genetic markers fail to fully represent the observed disease heterogeneity. Therefore, we aimed to understand the genetic pathogenesis of JMML and to identify differences among putative subgroups with distinct biological and clinical features.

Aims: We hypothesized that DNA methylation profiling, either alone or in combination with genetic alterations, might provide a molecular basis for disease classification.

Methods: Genome wide DNA methylation analysis using the HumanMethylation450 BeadChip was performed in a discovery cohort of 20 JMML patients. We developed a strategy to eliminate methylation events that attribute to epigenetic changes in normal hematopoiesis. The clinical relevance of our findings was assessed in an unselected sample set consisting of 148 consecutive patients with JMML (n=130) or Noonan syndrome associated myeloproliferative disorder (n=18) registered in the EWOG-MDS 1998 & 2006 trials. Data integration was performed in a subset of patients with available exome sequencing (n=50) and expression profiling (n=15) data.

Results: Systematic DNA methylation analysis of JMML samples identified three subgroups with low, intermediate and high methylation levels (LM, IM, and HM). Detailed analysis of the validation cohort not excluding the Noonan patients identified an association of methylation groups with clinical features. The HM subgroup (n=41) was enriched for high-risk characteristics: All HM cases had elevated levels of Hbf; 88% were older than 2 years at diagnosis, 74% had low platelets (<70×10^9/L), and 66% carried somatic PTPN11 mutations. In contrast, the LM subgroup (n=62) was enriched for patients with low-risk disease: All 18 patients with Noonan syndrome, 13/14 patients with CBL syndrome, and 15/19 patients with NRAS mutations were assigned to the LM group. The IM group (n=45) was enriched for cases with monosomy 7 and somatic KRAS mutations. The unfavorable risk profile in the HM group translated into near 5-year survival (HM 57%, LM 87%, log rank p<0.01) and a high incidence of relapse after HSCT (HM 48%, LM 9%, Gray’s test p=0.01). In a multivariate Cox regression model, only methylation group (HM vs LM: RR 10.9 [1.8-66.2]) and PTPN11 mutation status (PTPN11-mutant vs other: RR 3.3 [1.2-8.9]) remained as independent prognostic factors for CIR (p=0.01). JMML patients with IM phenotype was significantly methylated compared to patients with HM phenotype (P=0.012), even adjusting for SMF diagnosis type (P=0.02). When investigating OS according to different cytogenetic abnormalities, we found that patients with HM had inferior OS respect to those with sole abnormality (P<0.001) and patients with HM had inferior OS respect to those with sole abnormality (P<0.001) and patients with HM had inferior OS respect to those with sole abnormality (P<0.001).

Summary/Conclusions: Our integrated approach identified three JMML subgroups characterized by distinct clinical and biological features. We provide evidence for a molecular mechanism by which additional genetic events, presumably further activating the RAS-Raf-MEK-ERK pathway, mediate DNA hypermethylatyion via up-regulation of DNMTs in more aggressive JMML cases.

P351

CYTOGENETIC ABNORMALITIES IN POST-POLYCYTHEMIA VERA AND TRANSTHIEMIC ACID THERAPY: PHENOTYPIC MYELOPROLIFERATIVE SYNDROMES WITH GENETIC SIMILARITY TO JMML - CLINICAL 2

IN JUVENILE MYELOMONOCYTIC LEUKEMIA

Summary/Conclusions: Our integrated approach identified three JMML subgroups characterized by distinct clinical and biological features. We provide evidence for a molecular mechanism by which additional genetic events, presumably further activating the RAS-Raf-MEK-ERK pathway, mediate DNA hypermethylatyion via up-regulation of DNMTs in more aggressive JMML cases.
MUTATIONAL LANDSCAPE OF MYELODYSPLASTIC SYNDROME/MYELOPROLIFERATIVE NEOPLASM - UNCLASSIFIABLE

1Leukemia, University of Texas MD Anderson Cancer Center, Houston, 2Hematology and Medical Oncology, Cleveland Clinic, Cleveland, 3Malignant Hematology, Moffit Cancer Center, Tampa, 4Medicine, Vanderbilt University/Vanderbilt-Ingram Cancer Center, Nashville, 5Hematopathology, University of Texas MD Anderson Cancer Center, Houston, 6Hematopathology, Vanderbilt University/Vanderbilt-Ingram Cancer Center, Nashville, 7Translational Hematology and Oncology, Cleveland Clinic, Cleveland, 8United States of America

Background: MDS/MPN-U is a rare, poorly characterized myeloid neoplasm within the MDS/MPN category in the World Health Organization (WHO) classification. A median survival of 12.4 months from time of referral was previously reported for a cohort of 85 patients with MDS/MPN-U seen at the MD Anderson Cancer Center (MDACC, DiNardo et al. Leukemia 2014). The International Prognostic Scoring System (IPSS) for MDS (Greenberg et al. Blood 1987) discriminated amongst prognostically distinct categories in that cohort, while neither the IPSS for primary myelofibrosis (PMF, Cervantes et al. Blood 2009) nor the revised IPSS (IPSS-R) for MDS (Greenberg et al. Blood 2012) did. Median survival of 21.4 months from the time of diagnosis was reported in a multi-institutional cohort (n=69, Wang et al. Blood 2014). Information on the genomic landscape of MDS/MPN-U is limited to one report on the frequency of SETBP1 mutations (8.3%, Meggedorfer et al. Leukemia 2013).

Aims: To describe the mutational landscape of MDS/MPN-U using targeted multi-gene sequencing.

Methods: Targeted sequencing was performed on DNA from 97 patients with MDS/MPN-U (diagnosed per WHO 2008 criteria but excluding refractory anemia with ringed sideroblasts and thrombocytosis) seen across 4 US institutions (MDACC, 43; Cleveland Clinic, 29; Moffit Cancer Center, 16; Vanderbilt University, 9). Gene panels varied between institutions, with 20 genes (ASXL1, CBL, DNMT3A, ETV6, EZH2, IDH1, IDH2, JAK2, KIT, NPM1, NRAS, PHF6, RUNX1, SETBP1, SF3B1, SRSF2, TET2, TP53, U2AF1, ZRSR2) in common.

Results: Mutational frequencies for the 20 genes tested in all 97 patients were as follows: TET2, 28% (ASXL1, 27%; JAK2, 25%; SRSF2, 22%; EZH2, 15%; SF3B1, 12%; RUNX1, 12%; ZRSR2, 11%; SETBP1, 11%; U2AF1, 11%; NRAS, 10%; DNMT3A, 9%; TP53, 8%; CBL, 4%; ETV6, 4%; NPM1, 4%; IDH2, 2%; KIT, 2%; PHF6, 1% and IDH1, 0%. In 10% of patients, the frequency of mutations in ten other genes of interest in hematologic malignancies was assessed: BRAF, 0% (n=52); CSF3R, 4% (n=52); CALR, 4% (n=53); MPL, 3% (n=88); MLL, 1% (n=99); TET2, 3% (n=72); CEBPA, 4% (n=87); KRAS, 4% (n=81); TP53N11, 4% (n=82) and FLT3, 2% (n=82). Median survival for the whole cohort (n=97) was 12.4 months (range, 1-173). The 43 MDACC patients in this analysis were included in the cohort of 85 previously reported by DiNardo et al. Median age was 70 years (21-89). Median (range) values for leukocytes, neutrophils, hemoglobin, platelets and bone marrow blasts at the time of sample collection for sequencing were 13.4 (1-179) x 10^9/L, 7.9 (0.4-152.4) x 10^9/L, 9.1 (3.1-15) g/dL, 123 (6-1168) x 10^9/L and 2% (0-17), respectively. Upon univariate analysis (n=97), only the presence of EZH2 and ZRSR2 mutations were associated with trends towards statistical significance for survival. Mutated EZH2 adversely affected survival (p=0.066) and ZRSR2 mutation had a favorable impact on survival (p=0.074). The IPSS-R for MDS was useful to differentiate between risk groups with different survival times (p=0.065) while the dynamic IPSS for PMF (Passamonti et al. Blood 2010) was not (p=0.39). On multivariate analysis, only EZH2 mutations and IPSS-R very low risk (versus all other categories combined) were statistically significantly associated with inferior and superior survival, respectively.

Summary/Conclusions: In this cohort of 97 patients with WHO-defined MDS/MPN-U, mutations in genes encoding epigenetic regulators (e.g., TET2, ASXL1, EZH2), spliceosome components (e.g., SRSF2, SF3B1, ZRSR2, U2AF1) or signaling molecules (e.g., JAK2, NRAS), the transcription factor NKX3.1 and SETBP1 were found at frequencies ≥10%. Although the analysis is limited by small numbers, EZH2 mutations were independently associated with poor survival. This represents the largest cohort of patients with MDS/MPN-U interrogated for mutations in multiple genes to date.
Background: Mastocytosis is a clonal disease characterized by heterogeneous manifestations and a normal life expectancy in the majority of cases. In such a condition, it is important to ascertain if other diseases, and particularly solid malignancies, can worsen the prognosis.

Aims: To assess incidence and outcome of secondary primary malignancies (SPM) in adult mastocytosis

Methods: We performed a retrospective analysis of 826 adult (>18 years at diagnosis) mastocytosis patients diagnosed and regularly followed in 6 Italian Institutions. SPM were defined as de novo cancers diagnosed after mastocytosis. We excluded from the analysis non-melanoma skin cancers due to the possible under-reporting of such neoplasms by patients themselves. Also, we did not consider newly hematological neoplasms, as they mainly represent a progression from Systemic Mastocytosis (SM) to SM with an Associated Hematological Neoplasm (AHN). Standardized Incidence Ratio (SIR) was calculated as the ratio between the observed cases in our cohort and the expected cases in the sex- and age-matched general Italian population in the same time period (these data were retrieved from http://www.registri-tumor.it). Times to event (patient-years) were calculated from the diagnosis of mastocytosis to the date of SPM diagnosis, death, or last contact, whichever comes first. Survival curves were estimated according to the Kaplan-Meier method.

Results: Males were 450 (54%). Median age at diagnosis was 49.3 years (range 19-84). Median follow-up was 2.3 years (range 0-41). Subtype diagnoses were: Cutaneous Mastocytosis (n=46), Indolent SM (n=633), Smoldering SM (n=10), SM-AHN (n=34), Aggressive SM (n=47) and Mast cell leukemia (n=2). Fifty-four patients were classified as having mastocytosis in the skin. Overall, 42 patients had a history of malignancies prior to the diagnosis of mastocytosis: in these patients we did not detect any relapse of their prior malignancy after the diagnosis of mastocytosis. A total of 35 SPM were diagnosed in 34 patients (4.1%). Median age at SPM was 56.4 years (range 35-78). The median time from diagnosis of SPM to SPM was 22 months. The overall rate of SPM was 12.8 per 1,000 person-years (95%CI: 9.1-17.6) while the rate in the general adult population was 7.6 per 1,000 person-years (95% CI: 7.5-7.7) resulting in an increased hazard ratio of 1.7 (95%CI: 1.2-2.3). The risk for SPM was higher than expected in females (SIR 1.93, 95% CI: 1.2-3.1) while it was not significantly increased in males (SIR 1.48, 95% CI: 0.9-2.4). We found a clearly increased risk for melanoma (n=8, SIR 15.9, 95%CI: 7.9-31.9) and thyroid cancer (n=3, SIR 9, 95%CI: 2.9-27.9) while a non-significant increased risk was found for prostate cancer in males (n=5, SIR 2.06, 95% CI: 0.8-4.9) and breast cancer in females (n=3, SIR 1.7, 95%CI: 0.5-5.3). All the other malignancies were sporadic (one or two cases for each cancer type) and comparison to the general population was not significant. The death rate in patients with SPM was 14.7% with a median overall survival (OS) from SPM diagnosis of 38 months. OS was significantly inferior in patients with SPM as compared to patients without secondary neoplasia (5-year OS 77.6% vs 93.7% respectively; p<0.01) (Figure 1).

Figure 1. Summary/Conclusions: Patients with mastocytosis may have a significantly higher risk of developing a secondary non hematological cancer as compared to the matched general population. Careful follow-up of these patients is warranted as the rate of malignancies may increase over time and reduce life expectancy.
The diagnosis of prePMF have been added (anemia, leukocytosis >11 x10^9/L, the bone marrow biopsy and an explicit definition of minor clinical criteria for "true" essential thrombocythemia (ET) as these two entities have different clinical phenotype at disease onset.

Methods: To explore the clinical course of patients with CSF3R-mutated CNL and identify risk factor(s) associated with survival.

Results: Data of 47 patients with CSF3R-mutated CNL were collected and analyzed. 35 (76%) patients were male. Median age was 62 years (range: 16-92 years). At diagnosis, 17 (36%) patients had fatigue, 2 (4%) had fever, 8 (17%) experienced diarrhea or abdominal discomfort, 20 (43%) were asymptomatic and leukocytosis had been mostly an incidental laboratory finding. 20 (43%) patients had palpable splenomegaly, and 4 (9%), palpable hepatomegaly. PB parameters, median and (range), were: WBC 42.4×10^9/L (14.4-217.0), platelets 165×10^9/L (17-570), blast percentage 0% (0-10), neutrophil percentage 82% (70-99). The median of blast cells in bone marrow were 1% (range, 0-12%). 46 (98%) patients were in the chronic phase and 1 (2%) in the accelerated phase at diagnosis. Most of the CSF3R mutations was T618I (n=45, 96%), others were T568M (n=1, 2%); 244 (73.2%) patients and 41 (67.2%) patients were screened for ASXL1 and SETBP1 mutations, respectively. 21 (61.8%) patients harbored ASXL1 mutation and 22 (53.7%) harbored SETBP1 mutation. All patients were BCR-ABL1, PDGFR and FGR mutation negative. 2 were CALR mutation and JAK2V617F mutation positive, respectively. Hydroxyurea was the most frequently used therapy (n=48). Other therapies included interferon-a (n=7), hypomethylating agents (n=4), thalidomide (n=2), ruxolitinib (n=1), imatinib (n=3), dasatinib (n=1), chemotherapy (n=6), and transplant (n=2). With a median follow up of 17 months (range, 2-103 months), 7 patients progressed to blastic phase or acute myeloid leukemia (n=6) or myelodysplastic syndrome (n=1), 17 patients died. Survival rate at 30 months was 87%. Median survival was 39 months (95% CI 8.5-69.5). Multivariate analysis showed that WBC >40×10^9/L (HR=3.26, 95% CI 1.14-9.30, p= 0.027) was the sole risk factor for survival. However, SETBP1 or ASXL1 mutation was not associated with survival.

Summary/Conclusions: High WBC count was independently predictive of shortened survival in patients with CSF3R-mutated CNL.

Summary/Conclusions: ET and prePMF diagnosed according to 2016 WHO criteria are two entities with a different clinical phenotype at diagnosis and a different outcome. The clinical phenotype at disease onset of MPNu and ET is similar.

P357

CLINICAL PHENOTYPE AND OUTCOME OF ESSENTIAL THROMBOCYTHEMIA AND PREBRYOPLIFOTIC MYELOFIBROSIS DIAGNOSED ACCORDING TO THE REVISED 2016 WHO DIAGNOSTIC CRITERIA

E. Rumili1,2, E. Boveni3, M. Bellini1, D. Pietra4, V. Ferretti1, E. Roncoroni2, C. Cavalloni1, M. Ciboddo1,*, I. Casetti1, P. Benvenuti1, C. Astori2, M. Cazzolato1,2

Background: The World Health Organization (WHO) classification system for myeloid neoplasms was recently revised in 2016. The revised WHO criteria underscore the importance of differentiating preBPFM (prePMF) from "true" essential thrombocytopenia (ET) as these two entities have different clinical outcomes. For these reasons, standardization of morphologic findings in the bone marrow biopsy and an explicit definition of minor clinical criteria for the diagnosis of prePMF have been added (anemia, leukocytosis >11 x10^9/L, palpable splenomegaly and LDH).

Aims: To compare the clinical phenotype at diagnosis and the outcome of ET and prePMF diagnosed according to the new 2016 WHO criteria.

Methods: We identified in our database all patients affected with ET, prePMF and MPF diagnosis according to 2008 WHO criteria who satisfied these two requirements: a bone marrow fibrosis grade 0-1 at diagnosis and at least one DNA sample to define the mutational status. Firstly, the bone marrow morphology of all 404 identified patients was reviewed by an expert pathologist. Then, we reclassified patients according to the new 2016 WHO criteria as follows: patient with ET morphology were classified as ET, patients with PMF morphology and JAK2V617F negative were classified as ET (cumulative incidence of overt myelofibrosis at 10 years 86.6%, P<0.001) and a trend to a higher incidence of leukemic evolution (cumulative incidence of acute myeloid leukemia at 10 years 2.3% vs 1.9%, P=0.07) compared to ET patients, while they did not differ in terms of thrombotic complications (cumulative incidence of thrombosis at 10 years 18.5% vs 18%, P=0.9). Finally, we analyzed the subgroup of "old" ET diagnosed according to 2008 WHO criteria. Of 358 "old" ET, 268 were reclassified as ET, 25 as MPNu and 65 as prePMF. The "old" ET reclassified as prePMF had a higher risk of overt myelofibrotic evolution compared to the "old" ET reclassified as ET (cumulative incidence of overt myelofibrosis at 10 years 9.7% vs 0%, P=0.03).

Table 1.
Background: The minimal effective treatment in Essential Thrombocytopeny (ET) patients is tailored mainly on the basis of thrombotic risk scores (primarily non-nocere). The Revised International Prognostic Score for Thrombosis in ET (R-IPSET-Th) is based on different combinations of Age >60 yrs, absence of JAK2 mutations, no Prior Thrombosis (PrTh+), or Age >60 with JAK2+. The risk-by-arm interaction, age, sex, and body mass index (BMI) were assessed using Rules-Based Medicine, Inc. (Austin, TX) Human Biomarker Kit (BMK) data. Of these key BMKs in altered cellular signaling and potentially targetable pathways for symptom reduction.

Methods: Biomarker levels at baseline, week 4 and 24 were measured along with MF symptoms (MFSAF 2.0-Mesa JCO 2013; collected during blinded phase of COMFORT-I). Patients were randomized to ruxolitinib vs placebo. BMKs were assessed using Rules-Based Medicine, Inc. (Austin, TX) Human Biomarker Kit (BMK) data. Associations between the individual symptoms measured within the MFSAF and log2-transformed biomarker data were investigated at baseline using Spearman correlations. Mixed models were used to assess symptom and BMK changes over time. Models included terms for visit, arm, visit-by-arm interaction, age, sex, and body mass index (BMI).

Results: A total of 309 subjects were randomized in COMFORT-I with median age of 68 (range 40-91). Approximately 46% of patients were female and 50% had primary myelofibrosis (61% high risk). All 309 subjects had BMKs measured at one or more of the three visits included in this analysis, with 308 showing biomarker evaluation paired with MFSAF symptom scores at the same visit. Correlations of Baseline Biomarkers and Symptoms. Total symptom score (TSS) statistically significantly (p<0.05) correlated with 20 BMKs at baseline (Table 1). For individual symptoms, spleen-related symptoms appeared to statistically significantly correlate more frequently with BMKs at baseline: abdominal discomfort (23 BMKs), feeling full (20 BMKs), and pain under left ribs (19 BMKs). Night sweats, itchiness, and bone or muscle pain significantly correlated with 15, 14, and 10 BMKs each. The BMKs with the strongest correlations (absolute |r| > 0.50) associated with TSS over time. Like at baseline, BMKs appeared to be more often statistically significantly (p<0.05) associated with spleen-related symptoms over time including 25 and 24 BMKs for abdominal discomfort and feeling full, respectively. Night sweats, pain under left ribs, bone or muscle pain, and itchiness were associated with 20, 12, 12, and 9 BMKs each. Strongest associations (p<0.001) between symptoms and BMKs over time included VCA1 (4/6 symptoms+TSS), B2MICG (3/6 symptoms+TSS), LEPTIN (3/6 symptoms+TSS), TIMP1 (2/6 symptoms+TSS), TNFRII (2/6 symptoms+TSS), INTLK18 (2/6 symptoms+TSS), and VWD (1/6 symptoms).

Summary/Conclusions: Spleen-related symptoms demonstrate close association with BMKs at baseline as well as BMKs over time, after taking into account age, sex, BMI, and treatment. At baseline and over time, abdominal symptoms remained the most frequently correlated or associated symptoms with biomarker levels. More research is needed to determine the role of some of these key BMKs in altered cellular signaling and potentially targetable pathways for symptom reduction.

Figure 1.

Summary/Conclusions: In this study of the Registro Italiano Trombocitemia (RIT), we confirmed that the Revised International Prognostic Score for Thrombosis in ET (R-IPSET-Th) separated ET patients in 4 groups with increasing risk of thrombosis during the follow-up (p<0.001). According to the R-IPSET-Th score, severe complications seem to have occurred in this cohort of ET patients (anti-platelets in almost all cases, and cytoreduction in around 2/3 of VLR and LR cases), probably because other adjunctive risk factors have been considered.
Platelet disorders: Basic

NOVEL HETEROZYGOUS ITGB3 p.T746DEL MUTATION INDUCING SPONTANEOUS ACTIVATION OF INTEGRIN aIIb3 CAUSES AUTOSONAL DOMINANT MACROTHROMBOCYTOPENIA WITH ABNORMAL aIIb3 LOCALIZATION

N. Miyashita1,*, M. Onozawa2, K. Hayasaki3, S. Kunishima1, T. Teshima1
1Department of Hematology, Hokkaido University Graduate School of Medicine, 2Department of Hematology, 3Clinical Laboratory, Hokkaido University Hospital, Sapporo, Japan

Background: Congenital macrothrombocytopenia is a rare platelet disorder and its cause is genetically heterogeneous. Recently, integrin αIIb and β3 mutations have been identified in congenital macrothrombocytopenia patients with platelet aggregation dysfunction. Here, we found a novel, heterozygous ITGB3 mutation in a pedigree and examined how this mutation contributed congenital macrothrombocytopenia.

Aims: To detect gene mutations responsible for the congenital macrothrombocytopenia in this pedigree and reveal the molecular pathophysiology.

Methods: Whole exome sequencing (WES) was performed to detect gene mutations. Expression and activation state of αIIbβ3 in platelets was evaluated by flow cytometry (FCM) and western blotting (WB). The effects of mutations on αIIbβ3 activation state, phosphorylation of FAK, and morphological changes were analyzed in transfected cells by WB and immunofluorescence staining.

Results: The patients were 56-year-old Japanese woman and 2 of her 3 sons. They had no bleeding tendencies and near-normal bleeding time (Duke’s method). Hematological examination revealed their decreased platelet counts (58-86 x 10^9/l) with increase of mean platelet volume (12.8-14.5 fl). In all affected family members, giant platelets were observed on the peripheral blood smears. Platelet aggregation induced by ADP (1-10 μM) and collagen (2 μg/ml) was obviously reduced although that induced by ristocetin (1.5 mg/ml) was within normal limit. The family pedigree indicates that the inheritance pattern is autosomal dominant. Common congenital macrothrombocytopenias, such as MYH9 disorders, Bernard-Soulier syndrome and type 2B von Willebrand disease were excluded by the absent leucocyte inclusion bodies, normal ristocetin induced platelet aggregation and normal platelet GP Ibα/IX expression, normal von Willebrand factor assays, respectively. WES revealed that all affected family members had a heterozygous ITGB3 p.T746del mutation. FCM showed decreased surface expression level of αIIbβ3 in the affected member’s platelets. However WB of platelet lysates showed that there was no difference in the total amount of αIIbβ3 among the affected and unaffected members and normal controls. FCM showed a constitutive activation of αIIbβ3 on the patient’s platelets as reflected by the spontaneous binding of PAC-1 antibody. Immunofluorescence staining using CHO cells showed membrane localization of αIIbβ3 in wild-type αIIbβ3-expressing cells and cytoplasmic localization in αIIbβ3 (p.T746del) transfected cells. Further, immunofluorescence staining of CHO cells showed spontaneous tyrosine phosphorylation of FAK and morphological changes, such as rhomboid changes, elongated changes, abnormal cytoplasmic protrusions, and membrane ruffling, in transfected cells. FAK inhibitor (1,2,4,5-Benzotetraamine tetrahydrochloride) hindered the localization change of αIIbβ3 and the morphological changes in transfected cells by dose dependent manner.

Summary/Conclusions: The autosomal dominant heterozygous ITGB3 p.T746del mutation was found to be responsible for constitutive activation of αIIbβ3 in the patients’ platelets as well as transfected cells. It is considered that ITGB3 p.T746del mutation unclips the highly conserved membrane proximal complex of αIIb and β3 cytoplasmic tails and renders the activated form. Activation of αIIbβ3 leads to phosphorylation of FAK causing morphological changes in transfected cells, which is considered to reflect abnormal thrombopoiesis leading to the production of giant platelets. We conclude that platelet aggregation dysfunction is due to decrease of αIIbβ3 expression on the platelet membrane surface due to cytoplasmic localization. These results suggest that the gain-of-function mutation around membrane region of αIIbβ3 leads to macrothrombocytopenia with impaired surface αIIbβ3 expression.

CHANGES IN THE GENE EXPRESSION PROFILE OF IMMUNE THROMBOCYTOPENIA PATIENTS TREATED WITH ELMETROPA

J. Bastida1,*, J. Hernandez-Sanchez2, A. Rodriguez2, D. Alonso-Lopez2, E. Lumbraeras2, M. Lopez-Parra1, R. Bueno2, A. Veiga1, J. Hernandez-Rivas1, J. Gonzalez-Porras1
1Department of Hematology, Hospital Universitario de Salamanca-IBSAL, 2Department of Hematology, IBSAL, IBMMC, CIC, Universidad de Salamanca-CSIC, Salamanca, Spain

Background: Emtrombopag (ETP) is an orally bioavailable, small non-peptide molecule thrombopoietin receptor agonist that stimulates platelet production by a mechanism similar, but not identical to, endogenous thrombopoietin. ETP interacts with the transmembrane domain of thrombopoietin receptor, initiating a JAK/STAT signaling pathway inducing the proliferation and differentiation of the megakaryocytes to increase platelets production.

Aims: To assess the gene expression profile (GEP) and the underlying signaling pathways modified before and during the ETP treatment in chronic immune thrombocytopenia (ITPc) patients.

Methods: ITPc patients (n=14) treated with ETP were evaluated. Complete response (CR) was defined as a platelet count of ≥100x10^3/mm^3 and treatment failure was defined as a platelet count of ≤20x10^3/mm^3 for 4 consecutive weeks at the highest recommended dose of ETP, a major bleeding event, or the need to change therapy. RNA was isolated from mononucleated cells pre/post ETP treatment. The “paired” GEP of the ITPc patients included the semi-supervised analysis cluster samples before and after (28 day) the treatment with ETP. This paired GEP was showed in Figure 1. The GEP workflow consisted of the following steps: 28-paired samples were hybridized to GeneChip Human Gene 2.0 ST Array (Affymetrix’s). The robust microarray analysis (RMA) algorithm was used for background correction and normalization, while signal expression was calculated by significance analysis of each microarray to provide a robust statistical inference by a permutation method. P-values were provided and adjusted by multiples testing using a false discovery rate (FDR). The pathways and upstream regulators related with the most differentially expressed genes were analyzed by in silico analysis tools: Advista Bio’s PathwayGuide (http://www.advistabio.com/pathwayguide) and DAVID Bioinformatics Resources.

Results: The median age of the 14 ITPc patients enrolled in the study was 77 years (range: 35-87y), 64% patients (n=9) were treated with ETP after ≥2 lines of treatments. Only 3 patients were splenectomized. Median platelet (P) and white blood cell counts (WBC) increased after treated by ETP at day 28. (P and WBC pre: 14,15x10^3/mm^3 and 6,85x10^3/mm^3 vs P and WBC post: 132x10^3/mm^3 and 9,1x10^3/mm^3). All but two patients achieved CR (85,7%) and other 2 were considered failure of treatment. Regarding the gene expression profile, in silico analysis showed that the expression of 147 genes was modified after ETP treatment; all of them were overexpressed after treatment. Semi-supervised cluster analysis showed 2 groups: pre and post ETP treatment (Figure 1). Pathway analysis revealed that 38 genes were involved in the maintenance of hemostasis, most of them related to platelet activation (PTGS1, GP1BA or GP6). Interestingly, the paired GEP pointed out E2F1 and GFI1B as possible leaders of the increase of the megakaryopoiesis. Other signaling pathways overexpressed by ETP treatment are downstream routes of PI3K/Akt (GFI1B, JAM3, ITGB3 and ITGA2B) and platelet activation (GP6, GP9, GP1BA or PTGS1).

Summary/Conclusions: In ITPc patients, ETP can induce overexpression of genes involved in platelet activation and megakaryopoiesis and also alter key/relevant/signaling pathways such as JAK/STAT and PI3K/Akt.

P362
DEFECTIVE PTEN REGULATION CONTRIBUTES TO B CELL HYPERRE-SPONSIVENESS IN CHRONIC IMMUNE THROMBOCYTOPENIA

N. Miyashita1,*, M. Onozawa2, K. Hayasaki3, S. Kunishima4, T. Teshima1
1Department of Hematology, Hospital Universitario de Salamanca-IBSAL, 2Department of Hematology, IBSAL, IBMMC, CIC, Universidad de Salamanca-CSIC, Salamanca, Spain

Background: Immune thrombocytopenia (ITP) is a complex autoimmune disease characterized by low platelet counts. The autoantibodies produced by autoreactive B cells against-antigens, specifically immunoglobulin G (IgG)

Figure 1.

Summary/Conclusions: In ITPc patients, ETP can induce overexpression of genes involved in platelet activation and megakaryopoiesis and also alter key/relevant/signaling pathways such as JAK/STAT and PI3K/Akt.

1State Key Laboratory of Experimental Hematology, Institute of Hematology and Blood Disease Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Tianjin, China, Tianjin, 2Second Affiliated Hospital of Kunming medical University, Kunming, China

122 | haematologica | 2017; 102(s2)
antibodies against glycoprotein Ibα (GPIbα)Illa and/or GPIbαIX are considered to play a crucial role. B cell homeostasis and function are controlled by cell surface receptor-ligand interactions. The activation of PI3K is initiated by engagement of the pre-B cell receptor (BCR) and the BCR. The phosphatase and tensin homolog (PTEN) suppress the activity of the PI3K pathway. As a consequence, loss of PTEN function leads to excessive PI3 (3, 4, 5) P3 at the plasma membrane and to recruitment and activation of Akt family members that potently drive cell survival and proliferation. PTEN regulates normal signaling through the B cell receptor (BCR). In immune thrombocytopenia (ITP), enhanced BCR signaling contributes to increased B cell activity, but the role of PTEN in human ITP has remained unclear. Both IL-21/IL-21R signaling and PI3K-PTEN molecules are involved in maintaining normal humoral immunity and deletion of autoreactive B cells. In this study, we want to determine whether abnormalities in PTEN might contribute to increase B cell responsiveness in this disease and IL-21-mediated PTEN induction was defective. Meanwhile, we want to evaluate the relation between the expression of PTEN in B cells and the prognosis of ITP, which will provide a theoretical basis of new treatment strategy for the ITP patients.

Aims: PTEN is involved in maintaining normal B cell function. Since B cell overactivity is characteristic of autoimmune thrombocytopenia (ITP), we sought to determine whether abnormalities in PTEN might contribute to increase B cell responsiveness in this disease.

Methods: 1. This study recruited 28 newly-diagnosed CITP patients and 26 sex and age matched health volunteers as health controls (HC). Peripheral blood mononuclear cells were isolated from collected anti-coagulated blood. 2. Flow cytometry and real-time quantitative PCR were used for detecting the level of PTEN from PBMC cells of HC and CITP patients. 3. The relationship between PTEN levels and the disease severity of CITP was analyzed. 4. PBMC cells were incubated with human rL-2 rL-2r1 CD40L or anti-igM alone or in combination for 72 h and after that the PTEN level was detected by flow cytometry. The proportion and surface activated marker of B cells were determined by flow cytometry.

Results: 1. Compared to HC the expression of PTEN was diminished in each CITP B cell population except IgD-CD38low/memory B cells. In addition, PTEN mRNA was also decreased in ITP B cells. 2. The level of PTEN in B cells was slightly correlated with blood platelet count (p<0.008) and also directly correlated with the production of platelet-specific antibody (P=0.03). 3. The capacity of IL-21 to induce PTEN expression in B cells of HC was found by flow cytometry. Importantly, we found that CD40L and anti-igM were the most potent inducers of PTEN expression in normal B cells, followed by IL-21 and IL-2. Neither IL-21 alone nor CD40L plus anti-igM nor the three in combination stimulated PTEN protein up-regulation in B cells in CITP patients. 4. These immature B cells in CITP patients had a greater expression of CD95 but less PTEN compared to HC suggesting that down-regulation of PTEN was associated with an increasing proportion of immature B cells with a more activated phenotype in CITP patients (Figure 1).

Figure 1.

Summary/Conclusions: Immune thrombocytopenia B cell showed decreased levels of PTEN and the decrease was associated with low platelet count and positive serum platelet-specific antibody. The capacity of IL-21 to induce PTEN was defect in CITP. Together, these data suggesting that the defective PTEN expression, regulation and function contribute to B cell hyper-responsiveness in CITP.

P363

A DECREASED INTRACELLULAR S1P LEVEL AND S1P RECEPTORS EXPRESSED ON MEGAKARYOCYTES POSSIBLY CONTRIBUTE TO DEFECTIVE PROPLATELETS FORMATION IN IMMUNE THROMBOCYTOPENIA

J. Xue1, J. Zhang1, Q. Wang1, L. Xu1, X. Zhu1, Y. He1, Y. Kong1, Y. Chang1, X. Zhao1, X. Zhao1, M. Lv1, L. Xu1, K. Liu1, X. Huang1, X. Zhang1.

1Peking University Institute of Hematology, Peking University People’s Hospital, Beijing, China

Background: Immune thrombocytopenia (ITP) is a common autoimmune disorder characterized by increased bleeding tendency and isolated thrombocytopenia. The precise pathogenesis of the decreased thrombopoiesis in ITP remains unknown. It has been demonstrated that megakaryocytes (MKs) in ITP show impaired proplatelets formation (PFF) (Br J Haematol 2014;165:854-64). However, the pathogenesis of the impaired PFF in ITP is not entirely understood. Additionally, the lipid mediator sphingosine 1-phosphate (S1P) plays a critical role in megakaryocytic PFF in the bone marrow (BM) niche (J Exp Med. 2012;210:2317-40). It has been demonstrated that cell-surface S1P receptors (S1PR) on MKs trigger the activation of Gi/Rac GTPase signaling. Sphingosine kinase 2 (Sphk2) is the major isoenzyme regulating intracellular synthesis of S1P in MKs. Additionally, intracellular S1P influences the expression of Src family kinase (SFK) in MKs, including 6 members (Fyn, Lyn, Src, Yes, Fgr, and Hck), which mutually regulate each other with Rac GTPase.

Aims: To determine whether the S1P levels in both the BM niche and within MKs, as well as S1PR expression of MKs contribute to the defective thrombopoiesis in ITP through impaired PFF.

Methods: The PPF of ITP-MKs was measured by an in vitro PPF assay using HSCs from the BM. (FASEB J. 2010;24:4701-10). Additionally, all-trans-retinoic acid (ATRA), the S1p1-specific agonist SEW2871, and extracellular S1P were used as interference factors. The concentration of S1P in the plasma and BM was measured by ELISA. The concentration of intracellular S1P was measured using liquid chromatography-mass spectrometry (LC/MS) analysis. Intracellular Sphk2, SFKs and cell-surface S1PR were measured using PCR and western blotting. The location of Sphk2 was analysed by immunofluorescence using an anti-human Sphk2 antibody. The activities of Rac-GTP were quantified by pull-down assay.

Results: Significantly fewer numbers of proplatelet-forming MKs were observed in ITP cultures. The concentration of S1P in the plasma and in BM of patients with ITP was measured, of which the results showed no significant difference in the plasma/BM S1P ratio. Decreased expression of S1PR1 and S1PR4 was observed in ITP-MKs. We found that downstream Gi/Rac GTPase signalling activated by S1PR1 was down-regulated. ITP-MKs exhibited decreased intracellular Sphk2, indicating less biosynthesis of intracellular S1P. Immunostaining of Sphk2 in ITP MKs was performed, showing that less Sphk2 was primarily localized to the nucleus of ITP MKs. Intracellular S1P of ITP MKs was further explored showing a decrease of megakaryocytic S1P production ascribed to significantly reduced Sphk2 expression. Additionally, the gene expression and protein levels of family of SFKs were examined in ITP MKs, and the overall mRNA expression was significantly limited in ITP MKs. The total Src protein levels and p-SFKs (phospho-tyrosine-418) were significantly reduced in ITP MKs, indicating significant reduction of SFK activity. ATRA, SEW2871 and extracellular S1P enhanced Rac GTPase activity and SFK expression, which rescued the defect of PFF in ITP.

Summary/Conclusions: Decreased intracellular S1P ascribed to significantly reduced Sphk2, results in down-regulated SFK expression and activity, and decreased S1PR1 and S1PR4 down-regulate Gi/Rac GTPase signaling in ITP-MKs. Therefore, abnormal S1P/S1PR possibly plays a role in the pathogenesis of impaired PPF in ITP, which may be therapeutically regulated by ATRA.

P364

ANTIBODY MEDIATED GLYCAN MODIFICATION: A POTENTIAL ROLE IN PLATELET DESTRUCTION IN AUTOIMMUNE THROMBOCYTOPENIA

I. Marthaler,1 R. Jouni1, J. Alex2, A. Greinacher2, T. Bakhoum1

1Center for Clinical Transfusion Medicine, University Hospital of Tübingen, Tübingen, 2Transfusion Medicine, Universitätmedizin Greifswald, Greifswald, Germany

Background: Immune thrombocytopenia (ITP) is a bleeding disease caused by autoantibodies (AAbs) directed against platelet (PLT) glycoproteins (GPI). A novel mechanism of antibody-mediated PLT destruction based on Fc-independent PLT clearance via Ashwell-Morell receptors (AMRs), which recognize glycan modifications on the surface of PLTs, has been suggested.

Aims: In this study we investigated the effects of human AAbs from ITP patients on the glycan pattern of human PLTs and the consequent impact on their survival in vivo.

Methods: Monoclonal platelet antigen capture assay (MAIPA) and lectin binding assays were used to evaluate antibodies from ITP sera and healthy donors.

Results: In this study, we investigated the effects of human AAbs from ITP patients on the glycan pattern of human PLTs and the consequent impact on their survival in vivo.

Summary/Conclusions: Increased glycan modulation and decreased survival in vivo.
tin (PNA) that bind to galactose, N-acetyllactosamine and N-acetylgalactosamine residues, respectively. The NOD/SCID mouse model was used to study the impact of different glycan patterns on the survival of human PLTs.

**Results:** In this work 37 sera from ITP patients and 25 sera from healthy donors were analyzed. In the LBA, after incubation with AAbs, different patterns of glycan modification were observed. 17/37 sera caused a significant increase in PNA binding compared to healthy donors (median fold increase (FI): 1.21; range: 1.08 - 1.40). 9/37 sera induced higher ECL binding (median FI: 1.02, range: 1.08 - 1.15). In contrast, 8/37 sera showed strong decrease in RCA binding (median FI: 0.52, range: 0.50 - 0.59). Sera from healthy donors did not induced significant change. Interestingly, not only GP- Ib/IX AAbs but also GP-IIb/IIIa AAbs were able to modify glycan pattern. In NOD/SCID mice the administration of AAbs induced an accelerated clearance of human PLTs from the circulation. The destruction of human PLTs by ITP-AAbs was decreased but not completely prevented by a specific neuraminidase inhibitor that blocks glycan changes on PLT surface (survival of human PLTs after 5h: 48%, range 41.53% - 59%, vs 22-40%).

**Summary/Conclusions:** Our results demonstrate that AAbs from ITP patients are able to induce cleavage of glycan moieties on the PLT surface in distinct manners. Antibody-mediated modification of glycan patterns seems to contribute to AAb-mediated PLT destruction.

Trambusti”, University of Bari, 6U.O.C of Pediatrics, Hospital “D. Camberlingo”, Francavilla Fontana, Bari, Italy, 7Institute of Investigaciones Médicas Alfredo Lanari, Universidad de Buenos Aires, 8Amgen Inc., Thousand Oaks, United States

**Background:** Familial platelet disorder with propensity to acute myeloid leukemia (FPD/AML) is a rare autosomal dominant inherited thrombocytopenia (IT) caused by mutations in the hematopoietic transcription factor RUNX1; an important hallmark of this IT is the increased risk of developing myeloid neoplasms, such as AML and myelodysplastic syndromes (MDS). FPD/AML is caused by different mutations of RUNX1 encoding the DNA binding subunit (known as core binding factor-alpha, CBF-alpha) of the CBF transcription complex. The N-terminus domain of RUNX1 (runt-homologous domain) mediates DNA binding and heterodimerization to CBF-beta, the other subunit of the CBF complex. The C-terminus of RUNX1 includes domains that are involved in transcription activation and repression. This IT is characterized by impaired megakaryopoiesis and moderate thrombocytopenia, with normal-sized and dysfunctional platelets.

**Aims:** To unravel the molecular basis of ITs and to improve our knowledge on the molecular basis and clinical-laboratory picture of FPD/AML.

**Methods:** Whole exome sequencing (WES) was performed in 86 propositi with an unknown IT after the diagnostic workup based on the most updated diagnostic algorithm for ITs (Clin Genet 2016;89:141). RUNX1 variants identified by WES were confirmed by Sanger sequencing in the propositi and all available family members, which also undergo clinical-laboratory characterization. The study was approved by the Institutional Review Board of the IRCCS Policlinico S. Matteo Foundation; all patients gave written informed consent.

**Results:** We identified three pedigrees (families 1-3) with different RUNX1 heterozygous mutations, all segregating with thrombocytopenia in the respective families: the novel variants c.578T>A and c.967+2_5del, and the known ANKRD26 and RUNX1 mutations in all patients with an autosomal dominant IT and normal platelet size.

**Summary/Conclusions:** FPD/AML is an IT lacking pathognomonic laboratory criteria: it is characterized by a mild functional defect and, much more importantly, by a normal platelet size, similarly to the other ITs predisposing to hematological malignancies (ANKRD26 and ETV6-related thrombocytopenias). Given the importance of recognizing these diseases for patients counseling, follow-up, and therapeutic approach, we recommend a systematic screening for RUNX1, ANKRD26, and ETV6 mutations in all patients with an autosomal dominant IT and normal platelet size.
first 6 months was 50% (0%, 83.3%); that of months 7-12 was 92% (33%, 100%). Overall, 80% (114/143) of patients had a platelet response. The median (Q1, Q3) time of an increase in platelet counts ≥20×10^9/L above baseline was 60% (25%, 84%). The median dose increased to 10 μg/kg by week 32. Median (min–max) treatment duration to date was 25 (1-67) weeks for a total exposure to date of 79 patient-years. Median (min–max) average weekly romiplostim dose was 6.1 (0.4-9.0) μg/kg. 32 patients (22%) discontinued treatment for lack of efficacy (n=17), required other therapy (n=5), patient request (n=4), noncompliance (n=2), adverse event (AE) (n=2) (interstitial lung disease in a 15 y old boy and abdominal pain, vomiting, and headache related to treatment per investigator in a 9 y old girl), administrative decision (n=1), and investigator decision (n=1). 34 (23%) patients received rescue medications. 15 (10.3%) patients had serious AEs (SAEs) including epistaxis (n=4), petechiae (n=2), decreased platelet count (n=2), and thrombocytopenia (n=2). A case of abdominal pain was the only SAE deemed treatment-related by the investigator. TCTAEC grade 3 bleeding was seen in 8 patients (6%) and included epistaxis (n=5), ecchymosis (n=2), petechiae (n=2), and 1 case each of hematemesis, hematomata, SC hemorrhage, injection site hemorrhage, and mouth hemorrhage. No grade 4 or 5 bleeding was observed. No neutralizing antibodies against romiplostim or TPO were identified. Of 30 patients with baseline bone marrow biopsies (bone marrow biopsies were obtained at European sites), all had modified Bauermeister scores of grade 0 (no reticulin) or 1 (fine fibers) and bone marrows typical for ITP. Of these 30 patients, 21 had evaluable on-study biopsies obtained after ~1 year of treatment, with no increases in 2 or more grades, findings of collagen, or bone marrow abnormalities (Figure 1).

Summary/Conclusions: In this year 1 dataset of an ongoing open-label study of romiplostim in children with ITP, the time in the first 6 months with a platelet response was 50%, with 80% of children having a platelet response at some point on study. The median romiplostim dose reached 10 μg/kg and there were no new safety signals. No effects of romiplostim were observed on the bone marrow in the subset of patients with bone marrow biopsies. Future datacuts for years 2 and 3 in this study, the largest of romiplostim in children with ITP with 79 patient-years of exposure to date, will provide more information on platelet response, dose requirements, and safety.

P368
NOVEL THIENOPYRIDINES AS POTENT PLATELET INHIBITORS: FUTURE TREATMENTS FOR PLATELET HYPERACTIVITY DISORDERS?
N. Binsaleh1, C. Wigley1, K. Whitehead1, D. Moreno-Martinez1, S. Danielis1, S. Jones1, M. van Rensburg2, L. Pilkington2, D. Barker2, N. Dempsey-Hibbert1
1School of Healthcare Science, Manchester Metropolitan University, Manchester, United Kingdom, 2School of Chemical Sciences, University of Auckland, Auckland, New Zealand

Background: Platelet hyperactivity is associated with a number of disorders including Acute Coronary Syndromes (ACS) and manifests as increased platelet activation and often inappropriate thrombus formation. The thienopyridine class of anti-platelet drugs, of which clopidogrel and prasugrel are the most well known, target the P2Y12 receptor on platelets, blocking the effects of the platelet agonist ADP. However, the effects of these drugs are variable amongst patients, with some patients responding well and some remaining at risk of thrombosis. This variability highlights a need for a refinement of this class of P2Y12 inhibitor. Aims: The aim of this study was to assess the efficacy of six novel thiopyridine derivatives synthesized by our group by examining their potential as in-vitro inhibitors of platelet function.

Methods: Healthy human platelets were isolated and incubated with novel thiopyridine compounds (D,J0081, D,J0199, D,J0201, D,J0206, D,J0171, D,J0097) (10μM, 30min) prior to stimulation with ADP (10μM) and analysis of alpha granule secretion (CD62P expression), GPIIb/IIIa activation (PAC1 expression) and platelet leukocyte aggregate (PLA) formation using flow cytometry. Furthermore, light transmission aggregometry (LTA) was used to assess ADP-induced platelet aggregation after these treatments. As clopidogrel is usually prescribed in combination with the COX-1 inhibitor acetylsalicylic acid (ASA), significant reduction in ADP-mediated platelet aggregation (P<0.001), CD62P expression (p<0.001), PAC1 expression (p<0.01) and PLA formation (p<0.05). These compounds were also shown to enhance the inhibitory effects of ASA. D,J0171 and D,J0199 were particularly potent, displaying greater inhibitory effect than clopidogrel.

Summary/Conclusions: The study demonstrates the potential for new thiopyridine compounds as modulators of platelet function and points to the possibility of future use in patients at risk of platelet hyperactivity and thrombosis.

ECONOMIC IMPACT OF INTRODUCING AGE-ADJUSTED D-DIMER CUT-OFF LEVELS IN THE DIAGNOSIS STRATEGY OF VENOUS THROMBOEMBOLISM

P. Toulon1,*, N. De Poorter2, M. Brionne-François3, M. Smaïhi4, L. Abecassis5
1Hematology, Pasteur University Hospital, Nice, 2Hematology, General Hospital, Grasse, 3Hematology, University Hospital, Caen, 4Hematology, Simone Veil Hospital, Eaubonne, 5Hematology, General Hospital, Aulnay, France

Background: The diagnosis of venous thromboembolism (VTE) can be safely excluded in the case of D-dimer levels below a well defined cut-off value in patients with a low or intermediate pre-test probability (PTP), as the test negative predictive value (NPV) is close to 100%. As ageing is associated with increased D-dimer levels, the question arose whether D-dimer measurement was useful to rule out VTE in elderly patients.

Aims: The aim of the present study was to evaluate the clinical performance of a diagnosis strategy based on age-adjusted cut-off values calculated by multiplying the patient’s age by 10 in patients aged over 50, and to evaluate its economic impact.

Methods: We included 1255 consecutive outpatients with non-high PTP of VTE referred to the emergency departments at 5 French centres (2 university hospitals, and 3 general hospitals, in whom D-dimer testing was prescribed. The same standardized procedure was used in the 5 centres i.e. D-dimer measurement in patients with a non-high PTP, and imaging techniques (usually computed pulmonary angiography in case of suspected PE and Doppler ultrasonography in case of suspected DVT) in the case of D-dimer above the cut-off level. D-dimer levels were evaluated using the same fully automated latex-based assay (Hemoglobin Liat, Diasorin, Italy). The usual cut-off level for VTE exclusion being 500 ng/mL (fibrinogen equivalent units, FEU).

Results: VTE diagnosis was established by objective testing in 115 patients (9.2%): 88 of the 1082 patients referred for suspected PE (8.1%) and 27 of the 173 patients referred for suspected DVT (15.6%). D-dimer levels were above 500 ng/mL in all patients with VTE and in 521 of the 1140 patients without VTE (45.7%), leading to test NPV and sensitivity of 100%. The overall test specificity was 54.3%, even though it significantly decreased in an age-dependent manner over 60 years old. This is due to increased D-dimer levels in older patients particularly in those above 80 years. Using age-adjusted cut-off levels, calculated by multiplying the patient’s age by 10 in patients aged over 50, and to evaluate its economic impact. Such an improvement in test performance was found both in patients with suspected PE and DVT (Table). As such an increase in test specificity would have led to exclude VTE in a higher percentage of patients in the studied population, we evaluated the cost-effectiveness of both strategies, taking into account the local reimbursement rates of D-dimer measurement and Doppler ultrasonography (16.20, 58.72, and 75.60 Euros respectively).

Summary/Conclusions: The use of age-adjusted cut-off levels for D-dimer, in patients aged over 50 years old, led to a significant increase in the test specificity, but correlate to slightly decreased NPV and sensitivity. Even though some patients with D-dimer levels above 500 ng/mL but below the age-adjusted cut-off level would be misdiagnosed, such a strategy was found to be safe in our studied population with a high NPV (99.9%) and sensitivity (99.1%), and cost-effective.

IMPACT OF CELLULAR THERAPY ON THE ECONOMIC BURDEN AND SURVIVAL FOLLOWING RELAPSE AFTER HLA IDENTICAL HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR ACUTE LEUKAEMIA AND MYELODYSPLASIA SYNDROME

S. Lachance1,*, J. Bibeaü2, N. Ladjemil3, J. Lachaine4
1Hematology, Pasteur University Hospital, Montréal, Hôpital Maisonneuve-Rosemont, 2Peripharm Inc., 3Peripharm, Montréal, 4Pharmacie, Université de Montréal, Montréal, Canada

Background: Relapse following allogeneic hematopoietic stem cell transplant (aHSCT) is associated to a very poor outcome and remains an unmet medical needs. The impact of treatment approach on costs and survival remains unknown. The development of innovative cellular therapy for the treatment of relapse following aHSCT may change its dismal outcome but the cost of such intervention has prohibited its large-scale development.

Aims: The objective of this study was to measure the economic burden associated with the management of relapse following aHSCT and to evaluate the impact of treatment choice on survival and health care costs.

Methods: A retrospective medical chart review was conducted at Maison-Neuve-Rosemont Hospital (MHR) after research and ethic committee approval. Patients were selected using the Hematopoietic Stem Cell Transplant (HSCT) program database. Eligible patients were diagnosed with acute leukemia (AL) or MDS and relapsed following a HSCT between January 1st 2011 and December 31st 2014. Patients’ and disease characteristics and relapse-related health care resource utilization were collected from the date of post transplant relapse until death or last follow-up. Canadian unit costs for each intervention/treatment were obtained from literature and governmental publications.

Results: During the study period, 645 HSCT were performed at MHR, 303 were allogeneic. A total of 36 patients met the inclusion criteria and were included in the analysis. 32 recipients were diagnosed with AL and 4 with MDS. Treatment approaches following aHSCT relapse were divided in three groups according to patient and physician choices: group 1 received supportive care (n=9), group 2 received chemotherapy or tyrosine kinase inhibitors (n=21) and group 3 received a cellular based therapy, either donor lymphocyte infusion (DLI) or a second aHSCT (n=6). The median cost of care per patient per month was C$20,239 (SD=17,079). The median survival following relapse for the entire cohort was 12.4 months (SD=2.8). For group 1, 2 and 3, the mean cost of care per patient per month was C$17,436 (SD=16,447), C$22,914 (SD=18,474) and C$15,082 (SD=12,954), respectively. The median survival was 4.0 months (SD=2.0), 7.2 months (SD=1.6), and 46.6 months (SD=8.4), for treatment group 1, 2 and 3 respectively (Figure1).

Figure 1. Survival according to treatment group.

Summary/Conclusions: Relapse following aHSCT is associated to a poor prognosis and survival and to significant use of health care resources. Despite the selection bias, only patients who received cellular based therapy, either DLI or another HSCT, enjoyed a prolonged survival. Healthcare resources devoted to the care of patients in relapse post aHSCT provide a comparative basis for cost efficiency analysis in the development of innovative cellular therapy.

P372

ACUTE MYELOID LEUKAEMIA TREATMENT PRACTICE PATTERNS, HEALTHCARE RESOURCE UTILIZATION (HRU) AND COSTS IN A US COMMERCIALLY-INSURED POPULATION

M. Hagiwara1,*, A. Sharma1, K. Chung2, T. E. Delea1
1Policy Analysis Inc., Brookline, MA, 2Jazz Pharmaceuticals, Palo Alto, CA, United States

Background: AML is a rapidly progressive hematologic malignancy that accounts for 25% of all leukemias in the Western world, with an estimated 5-year survival of 26%, and is associated with high HRU and costs.

Aims: To estimate HRU and costs among newly-diagnosed AML patients (pts) in a US commercially insured population by receipt of chemotherapy (CT) or stem cell transplant (SCT).

Methods: This was a retrospective observational study using the PharMetricsPlus® database. Pts were adults with AML (ICD-9-CM code 205.0x respectively) and received chemotherapy (CT) or stem cell transplant (SCT). 19593 pts were included (n=19593) from 16 healthcare plans in 10 US states.

Figure 1. Survival according to treatment group.

Summary/Conclusions: Relapse following aHSCT is associated to a poor prognosis and survival and to significant use of health care resources. Despite the selection bias, only patients who received cellular based therapy, either DLI or another HSCT, enjoyed a prolonged survival. Healthcare resources devoted to the care of patients in relapse post aHSCT provide a comparative basis for cost efficiency analysis in the development of innovative cellular therapy.
not continuously enrolled for 12-months (mos) before the first AML claim (index date); evidence of acute promyelocytic leukemia anytime during the study period; missing enrollment information; or ≥1 hospitalizations during follow-up (FU) with missing cost. Tpts were classified as treated or untreated, with treatment defined based on receipt of CT (inpatient or outpatient) or SCT. For treated pts, FU was partitioned into 2 periods: index date to 6 mos and >6 mos post index date. Mean HRU and costs over the FU period were calculated by receipt of treatment and, for treated pts, by time since index date.

**Results:** 10,197 pts met study criteria including 6,862 treated pts (67%) and 3,335 untreated pts (33%). Mean age was 55 and 60 years in treated and untreated pts, respectively. Mean follow-up was 19.3 mos in treated pts and 18.1 mos in untreated pts. Mean total costs were higher for treated pts ($386,711) vs untreated pts ($83,274). In treated pts, mean total costs were $166,156 during the first 6 mos (mean duration 3.9 mos), and $220,555 during the remaining follow-up period (mean duration 19 mos), 26% of treated pts had SCT. Costs of inpatient and outpatient CT during the first 6 mos were $86,188, representing 22% of the total cost for treated pts (Table 1).

| Table 1. |
|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|

**Summary/Conclusions:** HRU and costs of managing AML pts are consider- able, with greatest HRU and cost in pts receiving CT or SCT.

**P373**

**HEALTH-RELATED QUALITY OF LIFE IN AL AMYLOIDOSIS PATIENTS WITH PERIPHERAL NERVE INVOLVEMENT**

M. Yokota1, S.D. Guthrie 2, T.P. Quock2, K.L. McCausland 1,*, M.K. White 1, M. Bayliss1

1Optum, Lincoln, 2Prothena Biosciences Inc, South San Francisco, United States

**Background:** In light chain (AL) amyloidosis, misfolded light chains accumulate and cause progressive peripheral neuropathy (PN) and failure of critical organs such as the heart and kidneys. Consequently, a progressive, ascending sen- sorimotor neuropathy is often a related clinical finding.

**Aims:** This study describes disease characteristics and health-related quality of life (HRQoL) in AL amyloidosis patients with peripheral nerve involvement (AL-PN).

**Methods:** An online survey was administered to AL-PN (n=126) and non- nerve–affected (n=215) patients to assess patient characteristics and HRQoL (based on the SF-36v2 Health Survey [SF-36v2]). The survey measures eight health domains including physical (PF), role physical (RP) due to health-related physical limitations, bodily pain (BP), general health (GH), vitality (VT), social functioning (SF), role emotional (RE), mental health (MH), in addition to physical (PCS) and mental component summary (MCS) measures. Patient characteristics were compared using chi-square tests. Differences in symptomatic and HRQoL burden were tested with multivariable logistic and linear models, respectively. Differences in mean HRQoL between AL-PN and non-AL-PN patients were compared to established minimally important differences (MIDs).

**Results:** Compared to non-nerve–affected patients, greater proportions of AL-PN patients visited ≥6 doctors (42.1% vs 19.5%, p <0.001) and ≥6 specialists (24.6 vs 9.9%, p <0.001). AL-PN patients also had symptoms for ≥1 year prior to receiving a diagnosis (50.8 vs 39.1%, p=0.035), relative to non-nerve–affect- ed patients. Nearly all AL-PN patients (97.6%) reported multi-system involvement. Gastrointestinal involvement was more prevalent in AL-PN patients versus non-AL-PN patients (68.3 vs 28.8%, p <0.001). There were greater odds of experiencing numbness (OR=4.23, 95% CI: 2.45–7.30, p <0.001) and fatigue (OR=3.09, 95% CI: 1.36–7.02, p <0.01) among AL-PN patients as compared to non-AL-PN patients, even after controlling for other types of organ involve- ment. Similar findings were observed for gastrointestinal symptoms, such as alternating bouts of constipation or diarrhea (OR=1.92, 95% CI: 1.12–3.34, p=0.019) and early safety/feeling fullness in the stomach (OR=1.80, 95% CI: 1.03–3.16, p=0.04). With the exception of RE, MH, and MCS, there were sig- niﬁcant differences in SF-36v2 scores among AL-PN patients as compared to non-AL-PN patients (p <0.05 for all). These signiﬁcant differences also exceed- ed the thresholds for clinically meaningful differences between the two groups.

**Summary/Conclusions:** This study suggests that the burden of illness from AL amyloidosis may be greater for those with PN involvement versus those without. AL-PN patients also experienced more complicated journeys to dia- gnosisis and significantly worse symptoms related to nervous systems and phys- ical HROQL. The SF36v2, a reliable and valid assessment of HROQL in AL amyloidosis studies, was sensitive to differences in HROQL between AL-PN and non-AL-PN patients. Future research should examine whether improve- ments in neuropathy symptoms following treatment subsequently lead to improvements in HROQL among patients with AL-PN. These findings are helpful for patient-focused drug development and supportive treatments.

**P374**

**ACCESS TO COMMUNITY CHEMOTHERAPY IMPROVES PATIENT QUALITY OF LIFE**

R. Pugh2, C. Bygrave3, H. Cosh3, W. Ingram3, J. Keil3

1Faculty of Life Sciences and Education, University of South Wales, Pontypridd, 2Tenovus, 3Haematology, University Hospital of Wales, Cardiff, United Kingdom

**Background:** Deciding how service for people with haematological cancers are to be delivered is going to be an important challenge in the coming years. Clinics have limited clinic capacity in terms of staff and bed space to cope with increased demand. In Wales many day units are already at capacity, over- crowded and have long waits for treatment. Ambulatory care, including diagno- sis, observation, consultation, intervention, and rehabilitation, has the potential to improve patient experience, if traditionally-based hospital services are moved into the community. We used a Mobile Unit – a 34-tonne articulated lorry which opens out to become a bespoke clinical space - to deliver treatments in a community setting to a range of haematology patients for a period of 12 months in South Wales.

**Aims:** We aimed to explore whether the administration of cytotoxic therapy on a Mobile Unit in a community setting for patients with haematological cancers could prove to be a safe and efficient alternative to hospital therapy, and in par- ticular whether this model of service delivery would be acceptable to patients. Our target group was patients with myeloma, aiming for up to 20 a day once or twice a week.

**Methods:** The first drugs administered on the Mobile Unit were zoledronate infusions, followed by bortezomib. When twice weekly doses were required, patients collected an additional injection pack which they could self-administer in the safety of their homes, thereby avoiding another trip to hospital. For high-dose bortezomib infusions, taking between 1-2 hours, were also administered. There was a con- sultant review clinic on board for patients receiving bortezomib which further reduced the numbers of hospital visits for patients and also a nurse-led Quality of Life clinic.

**Results:** In one year 548 treatments were administered on 91 days to a total of 54 individual patients. All 54 patients had a diagnosis of myeloma. 56% are female and 44% are male with an age range of 46 to 90 years of age, with 48% over 70 years of age. 37 patients are married and all but 4 classified themselves as White British. The greatest number of patients treated in a single day was 16. Improve patient experience, if traditionally-based hospital services are moved into the community.

**Summary/Conclusions:** Treatment in the community alleviates the stress of treatment and with minimal waiting times it gives some patients the ability to maintain family life and where possible to continue to work. It is both feasible and acceptable to begin to ambulate many different sorts of treatments. The possibilities opening up for haematology include rituximab maintenance; com- munity blood transfusions; delivering pentamidine for patients at risk of pneumo- cystis infection; late effects clinics for teenage and young adult cancer patients; and myeloproliferative neoplasm clinics, possibly near community pharmacies to facilitate dispensing medicines such as hydroxyurea.

**THE BUDGET IMPACT OF TREATMENT-FREE REMISSION FOR FIRST- LINE NITROBENZ OR GENERIC IMATINIB IN TREATING CHRONIC PHASE PHILADELPHIA-POSITIVE CHRONIC MYELOID LEUKEMIA**

D. Tran1, S. Brown1, N. Goyert1, P. Brandt2,2, D. Grimal1

1Cornerstone Research Institute, Burlington, Canada, 2Global Value & Access, Novartis Pharmaceuticals Corporation, East Hanover, United States

**Background:** The 2013 European LeukemiaNet (ELN) guidelines recommend switching from first-line therapy as early as 6 months with poor molecular response. They also recognize the possibility of treatment-free remission (TFR), requiring deep MR (MR4 or MR4.5). These emerging shifts in practice will dramatically change chronic myeloid leukemia (CML) treatment patterns. Occurring in parallel to this is the introduction of generic imatinib in Europe,
GAH SCALE PREDICTS TREATMENT TOLERABILITY IN OLDER PATIENTS (>65 YEARS) DIAGNOSED WITH HEMATOLOGICAL MALIGNANCIES

1Hematology and Oncology, Mayo Clinic, Scottsdale, 2Hematology and Oncology, Oregon Health and Science University, Portland, 3Internal Medicine, 4Bio-statistics, Mayo Clinic, Scottsdale, 5Arizona State University, Phoenix, 6Hematology and Oncology, University of California, Irvine, Irvine, United States

Background: Cachexia, weight loss, and malnutrition in cancer patients are important contributors of adverse outcomes of cancer patients. MPN patients have abnormal cytokine expression (e.g., IL-1, IL-6, IL-8, and TNF-a) that contributes to symptom burden (e.g., fatigue, pruritus, night sweats, bone pain) and predicts for treatment toxicity. The aim of this project was to determine the nutritional needs and preferences of MPN patients in order to create a tailored MPN dietary intervention.

Methods: An internet-based survey was hosted by the Mayo Clinic Survey Center and promoted nationally through Mayo Clinic blogs and websites during February of 2017. The survey included data on demographics, MPN characteristics, nutritional habits, supplement use, and symptom burden using the MPN-SAF TSS/MPN-10 (Emanuel 2012).

Results: Demographics and symptom burden: 919 international MPN patients took the survey. Among those taking supplements, 16.6% took supplements with the intent of reducing inflammation. Half (47.5%) of those individuals followed a specific diet or had dietary restrictions. On average, MPN patients ate 2.1 meals outside the home per week. Among those taking supplements, 31.4% of respondents had tried alternative medicine to help treat their MPN. Among these, 44.8% were under the care of a naturopath and 60.2% endorsed that their treatment plan included dietary change. Nutritional Education Preferences: Overall, 34.4% of patients endorsed A logistic regression model and a full multiple linear regression model were calculated to determine the weights for each dimension, and its contribution to the final score; the ROC curve analysis was used to calculate the cut-off points that defined three groups: “go-on” (low probability to develop toxicity regardless of intensive or attenuated therapy), “slow-go” (high probability to develop toxicity with intensive therapy but low probability with attenuated therapy), and “stop-go” (high probability to develop toxicity regardless of intensive or attenuated therapy). Results: A total of 108 patients (women, 53.7%; median age [IQR], 78 [73-83] years) out of 360 included in the main study were evaluated. During treatment administration, 61 (56.5%) patients developed treatment-related toxicities, requiring discontinuation/modification of the initial therapy. The coefficients for the dimensions are: 7 for number of drugs, -10 for gait speed, 2 for mood, 23 for activities of daily living, 6 for subjective health status, 27 for nutrition, -5 for mental status, and 1 for comorbidities. The sum of the GAH scale score, ranging from 0 to 68, plus a factor derived from the treatment intensity (34 points for intensive therapy or 0 for attenuated) leads to a maximum score of 100 points, with a cut-off point set at 47. Figure 1 shows the GAH scale scores for treatment toxicity prediction and the classification of patients according to their score. Among the 97 (89.8%) patients that received intensive therapy, 26 patients were classified as go-on, 48 as slow-go, and 23 as no-go. The proportion of patients that developed toxicities for each group was 34.6%, 56.3%, and 78.3%, respectively, with a statistically significant difference (P<0.002).
using diet to help control their symptoms or MPN disease. Patients most often utilized books (28.2%), websites (27.1%), health care providers such as physicians, NPs, or naturopaths (28.2%), online forums (23.2%), friends (12.2%), nutritionists (9.5%), phone or tablet applications (9.1%), or videos (4.2%) for nutritional education. The vast majority (95.9%) of MPN patients endorsed being willing to eat only certain foods if it helped to control symptom burden and or could help their MPN to stabilize or reduce the risk of their MPN getting worse (98.0%).

Summary/Conclusions: There remains an unmet need for symptom burden improvement in low-risk MPN patients or among those who have reoccurrence of symptoms while on JAK inhibitor therapy. Nutritional interventions for MPN patients have not previously been investigated and have the potential to be paired with traditional interventions to allow MPN patients to self-manage symptom burden. This study represents the first evaluation of MPN-related nutritional habits and preferences. These results will be used to inform the creation of an MPN nutritional intervention with the goal of improving symptom burden and reducing inflammation.

P378

DO PHYSICIANS NEED HELP TO ADEQUATELY INFORM AND SUPPORT PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA? RESULTS FROM A QUALITATIVE STUDY IN GREECE

C. Karamanidou1,*, A. Kocheli1, V. Kourtakis1, P. Ghia2, K. Stamatopoulos1
1Institute of Applied Biosciences, CERTH, Thessaloniki, Greece, 2Division of Experimental Oncology and Department of Onco-Hematology, Università Vita-Salute San Raffaele and IRCCS San Raffaele Scientific Institute, Milan, Italy

Background: Despite recent progress in prognostication and management, chronic lymphocytic leukemia (CLL) remains unpredictable at diagnosis, while virtually incurable, posing challenges to physicians on how to properly communicate the actual nature of the disease. Moreover, the great majority (~85%) of patients do not need treatment at diagnosis, creating a major cognitive dissonance between the perception of leukemia diagnosis and the “wait & watch” strategy usually applied, that may become a major reason of anxiety and quality of life (QoL) impairment for patients and frustration for physicians. Evidently, both patients and physicians need parameters that would allow co-decision making tailored to each particular case.

Aims: To identify physicians’ needs in order to improve their communication skills and thus facilitate CLL patient empowerment through a patient-centered-ness model.

Methods: An in-depth qualitative study with semi-structured interviews was conducted within hematologists (n=30) all over Greece. Data collection was considered as completed when saturation was reached i.e. no new themes emerged as assessed by the investigators. Content analysis was performed separately by a hematologist and a health psychologist with 98% inter-rater reliability score.

Results: None of the participants had ever received formal communication training, but rather adopted the techniques of senior physicians or developed their own through experience alone, thus frequently doubting their approaches (n=12/30, 40%). The most popular communication technique mentioned was adaptation of the quality and quantity of information provided according to each patient’s characteristics (n=29/30, 96.7%); followed by the use of caregivers as mediators for the communication of difficult issues (n=24/30, 80%); balance of realism and hope (n=21/30, 70%); careful choice of wording (e.g. lymphocytosis instead of leukemia) (n=18/30, 60%); gradual disclosure (n=17/30, 56.7%); and, descriptions through pictorial representations or metaphors (n=16/30, 53.3%). Even though physicians did not systematically assess patients’ anxiety and depression levels, they often found themselves dealing with patients’ emotions (n=29/30, 96.7%) through lengthy discussions. With regards to decision making, some mentioned that physicians should make all the decisions (n=9/30, 30%) and that patients are not always willing to take part in the decision-making process (n=8/30, 26.7%); while others were keener on stirring patients towards a decision (n=15/30, 50%), taking into account patients’ preferences (n=10/30, 33.3%). Most physicians felt uncomfortable delivering bad news such as initial diagnosis, relapse and poor prognosis (n=25/30, 83.3%). Self-reported needs included (i) communication skills training (n=20/30, 66.7%); (ii) psychological support (n=7/30, 23.3%); and, (iii) working in a multidisciplinary team (n=8/30, 26.7%).

Summary/Conclusions: In the absence of structured communication guidance there is great uncertainty among physicians concerning their skills on communicating CLL nature and handling difficult situations, leading to distress endangering their engagement in a healthy relationship with the patient. Additional studies are warranted at European level for identifying physician needs in different countries aiming at improving their communication skills to support and empower CLL patients for participating in their own care and enhance their QoL.
OUTCOME OF ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR PATIENTS WITH ACUTE LEUKEMIA ABOVE 70 YEARS OF AGE: ON BEHALF OF THE ACUTE LEUKEMIA WORKING PARTY OF THE EBMT

O. Ringdén1, A. Boumendi2, M. Labopin2, B. Sadeghi1, B. Savani3, M. Mohy4, A. Nagler5

1LAMBED, Translational Cell therapy Research, Karolinska Institutet, Stockholm, Sweden, 2Hôpital Saint Antoine, Paris, France, 3Division of Hematology/Oncology, Medical Center Drive, Nashville, United States, 4Hôpital Saint Antoine, Paris, France, 5Chaim Sheba Medical Center, Tel-Hashomer, Israel

Background: The average age of patients (pts) with AML is about 67 years. Historically, many of these pts were not considered as viable candidates for allogeneic transplantation (HCT) because of concerns about increased transplantation-related toxicity and excessive non-relapse mortality (NRM), a challenging problem especially in older individuals. However the development of reduced-intensity conditioning (RIC) regimens and the improvement in HCT supporting care allowed the successful application of HCT in older pts with AML.

Aims: Compare outcome of allo SCT in acute myeloid leukemia AML patients aged above 70 vs younger patients.

Methods: AML patients aged between 50 and 90 years old receiving a first or second allo SCT between 2004 and 2014 with MSD or UD donor were included in the study. Comparison of outcomes of patients aged above 70 with that of patients between 50-70 years were performed for the whole group and separately according to disease status at SCT (CR1, CR2, above).

Results: Altogether N=16874 pts were included in the study, N=713 were aged above 70 years old (median 72, IQR 71-73) and N=16161 between 50 and 70 (median 59, IQR 55-63). Older pts were more often male (62 vs 55%, p<0.001), had more often secondary AML (42% vs 28%, p<0.001), more advanced disease (42% vs 27%, p<0.001), more often peripheral blood stem cell grafts (96 vs 91%, p<0.001), more often unrelated donors (79% vs 59%, p<0.001) and poorer Karnofsky score (36% below 90 vs 29%, p<0.001), received more often reduced intensity conditioning (80 vs 63%, p<0.001). Incidence of acute GVHD II/III, IV/chronic GVHD and relapse were the same in the two groups in multivariate analysis. Non-relapse mortality (NRM) at two years was 34% (95% CI 31-38%) in pts above 24% (25%<32%) in those below 70 years of age (p<0.001). Overall survival and leukemia-free survival (LFS) at 2 years was 38% (95%CI 34-42) vs 50% (95%CI 49-50) p=0.001 and 33% (95%CI 29-37) vs 44% (95%CI 43-45) in the two groups, respectively (p=0.001). Among pts in CR1, 2 years survival was 43% (95%CI 37-51) vs 57% (95%CI 56-58) (p=0.001), in CR2 it was 36% (95%CI 27-47) vs 52% (95%CI 50-54) (p=0.002) and in advanced disease 35% (95%CI 29-41) vs 33% (95%CI 31-34) (p=0.036) in pts above and below 70 years of age, respectively. Among pts older than 70 years of age a Karnofsky score >80% was associated with improved survival and LFS in multivariate analysis (HR 0.7 95%CI 0.5-0.9 , p=0.005 and HR 0.7 95%CI 0.5-0.9 , p=0.003 respectively).

Summary/Conclusions: In AML with CR1, CR2 status at allo SCT, pts above 70 years of age have worse NRM, survival and LFS compared to pts 50-70 years of age. In pts above 70 years of age Karnofsky score is of significant importance for outcome.

BLOOD BAALC AND MN1 COPY NUMBER ASSESSMENT BY DIGITAL DROPLET PCR PRIOR TO ALLOGENEIC TRANSPLANTATION PREDICTS RELAPSE IN ACUTE MYELOID LEUKEMIA PATIENTS

M. Jentzsch1,*, M. Bill1, J. Schulz1, J. Grimm1, J. Häntschel1, S. Beinicke1, D. Niederwieser1, S. Schwind1

1Hämatoologie und int. Onkologie, UNIVERSITÄTSKLINIKUM LEIPZIG, Leipzig, Germany

Background: Acute myeloid leukemia (AML) patients (pts) that relapse after allogeneic stem cell transplantation (HCT) have a dismal prognosis. Identification of pts at high risk of relapse may allow preemptive therapy & improve outcomes. At diagnosis high expression of the AML associated genes BAALC (brain and acute leukemia, cytoplasmic) & MN1 (meningioma 1) adversely impact AML pts outcomes, but little is known about their usability for residual disease detection. Recently, we demonstrated a higher cumulative incidence of relapse (CIR) for pts with high pre-HSCT BAALC copy numbers in 82 AML pts (ASH 2016, #517). Until today no study assessed the prognostic impact of MN1 copy numbers prior to H SCT.

Aims: Assess the prognostic impact of peripheral blood (PB) pre-HSCT BAALC & MN1 copy numbers in an expanded set of AML pts in hematologic CR using digital droplet (dd) PCR.

Methods: We identified 118 AML pts (median age at H SCT 64 [range 31-76] years [y]) in first (55%) or second complete remission (CR, 23%) or CR with incomplete recovery (22%) with PB prior to HSCT (median 7, range 0-29 days) available. All pts received non-myeloablative (NMA) conditioning (fluadarabine 3x30 mg & 200 cGy total body irradiation). At diagnosis karyotypes & NPM1, CEBPA gene mutations (mut) & presence of FLT3-TKD & FLT3-ITD were assessed. Quantification of BAALC & MN1 normalized to ABL1 copy numbers in pre-HSCT PB of the AML pts & in PB of healthy controls (n=7, median age 63 [range 40-82y]) was performed by ddPCR. Median follow up after H SCT for pts alive was 1.8y.

Results: European LeukemiaNet (ELN) 2010 classification was 20% favorable, 25% intermediate-1, 24% intermediate-II, 31% adverse. AML pts & healthy controls did not differ in age (P=1) or mean BAALC (P=0.37, Figure 1A) or MN1 (P=0.96, Figure 1B) copy numbers. BAALC & MN1 copy numbers correlated well in pts (R=0.8) & healthy controls (R=0.75). The previously determined cut-off of 0.14 BAALC copy numbers (in 82 pts; ASH 2016, #517) defined pts with high (27%) & low (73%) pre-HSCT BAALC copy numbers. A cut-off of 0.74 MN1 copy numbers was determined using the R package ‘OptimalCutPoints’ & defined pts with high (12%) & low (88%) pre-HSCT MN1 copy numbers. Applying these cut-offs, 71% of the pts had low BAALC & MN1 copy numbers & 10% had high BAALC & MN1 copy numbers, 2% had high MN1 but low BAALC & 17% had high BAALC but low MN1 copy numbers. Pts with high & low pre-HSCT MN1 copy numbers did not differ significantly in pre-treatment characteristics or remission status at HCT (CR vs CRi) while pts with high pre-HSCT BAALC copy numbers were less often in CRi at HCT (P=0.02). Both high pre-HSCT BAALC & MN1 copy numbers significantly associated with higher CIR (P=0.02, Figure 1C & P<0.001, Figure 1D, respectively). In multivariate analyses, high pre-HSCT BAALC (Hazard Ratio [HR] 2.5, Confidence Interval [CI] 1.1-5.7, P<0.001) & high pre-HSCT MN1 copy numbers (HR 5.6, CI 2.6-12.2, P<0.001) retained their prognostic impact on CIR after adjustment for ELN 2010 genetic risk groups.

Figure 1.

Summary/Conclusions: High pre-HSCT copy numbers of BAALC & MN1 associated with higher CIR in univariate & multivariate models and might indicate residual disease burden in these AML pts. High copy number pts should be closely monitored for relapse in the post-transplant period. Prospective clinical trials are needed to validate the determined cut-offs, to evaluate if BAALC or MN1 copy numbers or a combination of the genes represents the most suitable prognosticator pre-HSCT and whether AML pts with high pre-HSCT BAALC or MN1 copy numbers benefit from additional pre- or post-HSCT treatment.
Sickle Cell Disease (SCD) and Diamond-Blackfan Anemia (DBA). Bertain et al (Blood, 2014) have previously shown that αβ TCR depleted haplo-transplantation in children with multiple types of non-malignant disorders was feasible. An ongoing Phase II/III trial evaluates the safety and efficacy of post-transplant infusion of donor T-cells transduced with the iC9 suicide gene (BPX-501 cells). (ClinicalTrials.gov identifier: NCT02058569). The iC9 vector contains the sequence for the CD19 marker, so that the BPX-501 cells (CD3+CD19+) can be tracked in peripheral blood. We report on 15 children with hemoglobinopathies and ED.

Aims: This study was performed to determine the clinical impact of infusing BPX-501 T cells post αβ T-cell depleted haplo-identical HSCT in pediatric patients with hemoglobinopathies.

Methods: Fourteen patients were transplanted from a parent and one patient was transplanted from a sibling. Conditioning regimen included busulfan, thiotepa and fludarabine. Low dose ATG was administered to prevent graft-versus-host disease (GVHD) and graft failure. No post-transplantation GVHD prophylaxis was given. Median follow-up is 387 days (range 126-631 days). Six patients were males and nine females, and median age at diagnosis and at HSCT was 0.8 and 8.9 years (range 2.5-19.2), respectively. Two patients had DBA and four with SCD. All 9 TM patients were β0/β0, and among the those with TM, 4 patients belonged to class I and 3 to class II of the Pesaro classification. All 15 patients were transfusion-dependent and receiving iron-chelation therapy before haplo-HSCT. 13/15 patients maintained full donor chimerism. The patients with secondary graft failure were re-transplanted from the same donor and maintained full donor chimerism.

Results: All patients are alive and well with no Treatment Related Mortality (TRM). Initial chimerism was resistant to treatment or grade IV GVHD. One patient had acute skin GVHD Grade IV. No chronic GVHD was observed. Median time to neutrophil recovery was 14 days (range 10-32 days), while median time to platelet recovery was 11 days (range 8-12 days). Median time to last RBC transfusion was 8 days (5 – 34 days). See Figure 1 for individual Hemoglobin levels. Median time of infusion of 1x10^6 BPX-501 T cells/kg was 14 days after HSCT (range 10-26). BPX-501 cells expanded after infusion and still persist in all patients. Immune reconstitution was normal cellular and humoral immunity present at 180 days post HSCT. All patients remain transfusion-free with a median hemoglobin of 11 or greater after 6 months.

Methods: Using these standardized MSC products altogether 52 patients were treated between December 2014 and December 2016. Patients were male (n=31, 60%) or female (n=21, 40%) and were transplanted for leukemia (n=38, 73%), non-malignant (n=14, 27%) diseases. Median age was 8 years (range: 0.5-52 years). Stem cell source was MSD (n=9, 17%), MUD (n=33, 63%) or MMFD (n=7, 13%) or non-malignant (n=14, 27%) diseases. Median age was 8y (range: 0.5-52 years). Stem cell source was MSD (n=9, 17%), MUD (n=33, 63%) or MMFD (n=7, 13%). All patients are alive and well with no Treatment Related Mortality (TRM) and in 13/15 patients maintained full donor chimerism. The patients with secondary graft failure were re-transplanted from the same donor and maintained full donor chimerism.

Results: All patients are alive and well with no Treatment Related Mortality (TRM). Initial chimerism was resistant to treatment or grade IV GVHD. One patient had acute skin GVHD Grade IV. No chronic GVHD was observed. Median time to neutrophil recovery was 14 days (range 10-32 days), while median time to platelet recovery was 11 days (range 8-12 days). Median time to last RBC transfusion was 8 days (5 – 34 days). See Figure 1 for individual Hemoglobin levels. Median time of infusion of 1x10^6 BPX-501 T cells/kg was 14 days after HSCT (range 10-26). BPX-501 cells expanded after infusion and still persist in all patients. Immune reconstitution was normal cellular and humoral immunity present at 180 days post HSCT. All patients remain transfusion-free with a median hemoglobin of 11 or greater after 6 months.

Summary/Conclusions: These data suggest that Haplo-HSCT combined with infusion of BPX-501 T cells with a suicide gene may be a safe and curative option for children with hemoglobinopathies and ED who lack a matched donor. Infusion of gene modified T cells with an inducible suicide mechanism, combined with selective αβ T-cell depletion, offers the potential to rapidly reverse GVHD and eliminate the need for the use of GVHD prophylaxis. Additionally, this approach results in rapid hematological and immune reconstitution for Haplo-HSCT recipients.

P382

EXCELLENT RESPONSE, LOW TRM AND GOOD SURVIVAL IN PATIENTS WITH THERAPY-REFRACTORY AGVHD AFTER TREATMENT WITH EQUIPOTENT MSCS OF A SERUM-FREE MSC-BANK GENERATED FROM POOLED BM-MNCs OF MULTIPLE DONORS

B. Pades1, J. Kuc1, S. Baktiari1, O. Basu2, G. Bug3, M. Dennis4, J. Greil5, K. Källay6, P. Lang5, G. Lucchini8, R. Pol9, A. Schulz10, K.-W. Sykora11, I. von Luetich12, P. Remény13, L. Gopcsa13, A. Jarisch1, J. Soerenson1, E. Salzmann1, E. Seifried14, T. Kligiene1, H. Boenig14, S. Kuci1,

Background: All clinical data published thus far on the use of MSCs were generated using cells expanded from individual bone marrow donors hence suffer from huge inter-donor differences in MSC generation, expansion and immunomodulatory potential. To control these variables and to be able to administer to all patients highly similar MSC products, we established a proprietary pooling procedure and generated a large bank of MSC end-of-passage-1 vials from which end-of-passage-2 MSC products are expanded for clinical use. The manufacturing process is fully GMP-compliant and generates an animal serum-free product with negligible potency. Importantly, they showed a significantly higher allo-suppressive potential than the mean allo-suppressive potential of MSCs generated from individual donors. All tested individual MSC doses were equipotent in suppression of the allo-antigen-driven reaction in mixed lymphocyte reactions (Kuc et al. Haematologica 2016: 101 (8): 885-894).

Aims: A "hospital exemption" issued by the national regulatory authority Pau-Ehrich-Institute (Number: PEI: A11748.01.1) licenses the clinical use of these products for patients with steroid refractory GVHD. On the basis of this licence patients were with severe GVHD were treated who were either non responsive (n=5) or treatment resistant (n=2) to treatment with steroids for 7 days.

Methods: Using these standardized MSC products altogether 52 patients were treated between December 2014 and December 2016. Patients were male (n=31, 60%) or female (n=21, 40%) and were transplanted for leukemia (n=38, 73%), non-malignant (n=14, 27%) diseases. Median age was 8 years (range: 0.5-52 years). Stem cell source was MSD (n=9, 17%), MUD (n=33, 63%) or MMFD (n=7, 13%) or female (n=21, 40%) and were transplanted for leukemia (n=38, 73%), non-malignant (n=14, 27%) diseases. Median age was 8 years (range: 0.5-52 years). Stem cell source was MSD (n=9, 17%), MUD (n=33, 63%) or MMFD (n=7, 13%). All patients are alive and well with no Treatment Related Mortality (TRM) and in 13/15 patients maintained full donor chimerism. The patients with secondary graft failure were re-transplanted from the same donor and maintained full donor chimerism.

Results: Response was defined as either complete response (CR) in patients in who showed overall GVHD grade less according to the Glucksberg criteria, or non response (NR) at day 28 after first MSC transfusion. At day +28, 12 patients (23%) achieved CR, 29 patients (57%) PR (overall response= 80%), 8 patients (17%) NR, and in 2 patients (4%) no data were available at day +28. At the last follow up of GVHD, 29 patients (56%) were in CR, 13 patients (25%) in PR, 9 patients (17%) in NR, and for 1 patient (2%) no data were available. At 2 years these response rates resulted in a non-relapse mortality rate (NRM) of 27±6%, cumulative relapse incidence (CIR) of 14±4%, and overall survival rate (OS) of 92%±6%. Patients with aGVHD III and IV had an OS survival probability at 2 years of 77±12% and 59±35%, respectively thus dramatically in excess of expected survival rates for patients with such severe aGVHD. There was no difference between younger (n=40) and older patients (n=12) than 16 years.

Summary/Conclusions: Treatment with standardized equipotent MSCs from the "FRANKFURT MSC-BANK" offers an excellent chance to overcome treatment-resistant and steroid-refractory acute GVHD.

P383

HIGHER PEAK TACROLIMUS CONCENTRATIONS AFTER ALLOGENEIC TRANSPLANTATION INCREASE THE RISK OF ENDOTHELIAL CELL DAMAGE, COMPLICATIONS

T. Morishita1, T. Ohbiki1, M. Osaki1, M. Yoshino1, S. Ikeno1, M. Nakashima1, T. Sato1, Y. Kagaya1, Y. Ozawa1, K. Miyamura1, T. Kligiene1, H. Boenig14, S. Kuci1,

Background: Noninfectious transplantation-related complications (TRC) such as GVHD and endothelial cell damage (TRC-EC) including sinusoidal obstructive syndrome (SOS), transplant-associated microangiopathy (TAM), idiopathic pneumonia syndrome (IPS) are dismal complications after allogeneic hematopoietic stem cell transplantation (allo-HSCT). Calcineurin inhibitors such as tacrolimus (TAC) have been broadly used to manage post-transplantation complications. Higher blood levels of TAC are expected to reduce the risk of GVHD, but may increase the risk of endothelial damage. Since TAC-EC often develops in patients with severe aGVHD, it is difficult to judge appropriateness of immunosuppression clinically.

Aims: Here we evaluated the impact of TAC blood levels upon TRC-EC occurrence and prognosis after allo-HSCT.

Methods: Two hundred sixty-one consecutive patients (pts) who received TAC as a GVHD prophylaxis after allo-HSCT at our institute from 2009 to 2015 were candidates for this retrospective study. Pts who received haploidentical allo-HSCT.
and pts with unavailable TAC concentration data were excluded. A total of 253 pts was eligible. All pts received standard GVHD prophylaxis by continuous intravenous (iv) TAC with starting dose of 0.02 mg/kg/day from 1 day before allo-HSCT (day -1) and iv methotrexate on day 1, 3, 6 at dose of 10 mg/m2, 7mg/m2, respectively. TAC dosage was adjusted to target the serum concentration of 8-12 ng/ml until at least day 30 and then tapered. TAC was rapidly tapered with any time-point selected were not significant factors for OS. By Cox proportionality/hazards regression models, TRC-EC diagnosis (HR: 1.90, 95%CI, 1.16-3.11, P=0.011) and high disease risk at transplant (HR: 1.76, 95%CI, 1.14-2.73, P=0.011) were significantly associated with poor OS (Figure 1).

Summary/Conclusions: Higher peak TAC concentrations during 22-28 days after allo-HSCT increased the risk of TRC-EC. And the development of TRC-EC was associated with poor OS.

P384

IMPACT OF CONDITIONING REGIMEN ON OUTCOMES OF T-REPLETE HAPLOIDENTICAL TRANPLANTATION FOR PATIENTS OVER 45 YEARS-OLD WITH AML: A STUDY ON BEHALF OF THE ACUTE LEUKEMIA WORKING PARTY OF THE EBMT

1Dipartimento di Ematologia, Medicina Trasfusionale e Biotecnologie, Ospedale Civile, Pescara, 1Department of Hematopoietic Stem Cell Transplantation, National Cancer Center Hospital, Tokyo, 2Department of Hematology, Tokyo Women’s Medical University, Tokyo, 3Department of Hematology, Institute of Medical Science, The University of Tokyo, Tokyo, 4Department of Hematology and Clinical Research Institute, National Hospital Organization Kuyushu Medical Center, Fukuoka, 5Department of Hematology, Kumamoto University Hospital, Kumamoto, 6Department of Hematology, Sasebo General Hospital, Sasebo, 7Department of Hematology, National Hospital Organization Kyushu Cancer Center Hospital, Fukuoka, 8Department of Hematology and Oncology, Institute of Medical Science, Tohoku University, Sendai, Japan, 9Department of Biostatistics, Tohoku University Graduate School of Medicine, Sendai, Japan, 10Division of Biostatistics, Tohoku University Graduate School of Medicine, Sendai, Japan, 11Department of Hematology, Chaim Sheba Medical Center, Tel Hashomer, Israel

Background: T-cell replete haplo-identical stem cell transplantation (haploSCT) is a valid therapeutic option for adult patients (pts) with high risk acute leukemia (AHL). T-cell replete transplantation (loSCT) is a valid therapeutic option for adult patients with AML older than 45 years (yrs) undergoing haploSCT. The aim of the study was to confirm the efficacy and feasibility of RIC among a population for which the choice of conditioning intensity is more related to center strategy than pts comorbidities or disease status.

Methods: We retrospectively compared the outcomes of 614 pts with de novo or secondary AML transplanted between 2007 and 2015 from an haplo-identical donor using either RIC (n=365) or MAC (n=249) regimens. Age was categorized in three subgroups (45-55 yrs, 55-60 yrs, >60 yrs). Patients receiving a previous allogeneic transplantation were excluded. RIC was defined according to EBMT definitions.

Results: The median follow up for MAC and RIC was 24 and 20 months, respectively and the median year of transplant was 2013 for both. Pts receiving a RIC were older (55 yrs in MAC vs 61 yrs in RIC, p<0.001). Secondary AML was more frequent in RIC vs MAC (31% vs 22%) while 77% of MAC and 68% of RIC were transplant for de novo AML, p=0.01. No differences were found on disease status and Karyotypic performance status (KPS) at transplant: pts were in CR1 (MAC: 44%, RIC: 40.5%), CR2/3 (MAC: 17%, RIC: 17%) or had active disease (MAC: 40%; RIC: 43%), p=0.68; 12% of pts in both groups had KPS>80, p=0.95. The most frequently used MAC regimen was TBF (56%), while in RIC it was mirTBF (27%) and low dose TBI+Fludarabine (24%). RIC regimens were more frequently associated with as detection of stem cell source (MAC 42% vs RIC 55%, p=0.002). Post-transplant cyclophosphamide was used in 69% of both RIC and MAC, p=0.39. Main outcomes were not different according to conditioning regimen: at 2 yrs was 26% vs 32% (p=0.29), NRM 31% vs 34% (p=0.62), aGVHD II-IV 24% vs 31% (p=0.05), and cGVHD 27% vs 26% vs 39% (p=0.17), OS 46% vs 39% (p=0.15), GRFS 36% vs 28% (p=0.10) for MAC vs RIC, respectively. The results according to RIC and MAC were not different in any of the three age subgroups. 338 patients died; main causes of death were infections and GVHD to be followed by disease recurrence. In multivariate analysis, the type of conditioning regimen was not associated with risk of relapse or treatment failure: RI (HR: 1.22, p=0.28), NRM (HR: 0.92, p=0.63), acute GVHD grade II-IV (HR: 1.14, p=0.48), chronic GVHD (HR: 1.26, p=0.30), LFS (HR: 1.03, p=0.77), GRFS (HR: 1.07, p=0.55), OS (HR: 1.05, p=0.68). Disease status was associated with outcomes (active disease vs CR): RI (HR: 2.44, p<0.001), LFS (HR: 1.75, p<0.001), GRFS (HR: 1.72, p<0.01), OS (HR: 1.71, p<0.001) as well as KPS>90: NRM (HR: 0.53, p=0.0002), LFS (HR: 0.67, p=0.001), GRFS (HR: 0.74, p=0.014), OS (HR: 0.62, p=0.0002).

Summary/Conclusions: In our study no differences were found between RIC and MAC regimens for haplo-SCT in adults with AML including older patients. Disease status and performance status were the major predictors of transplantation outcome, while conditioning intensity had no effect. These results may serve as the background for a well designed randomized study comparing RIC vs MAC for haplo-SCT in adult pts with AML.

P385

ROLE OF UPFRONT ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN PATIENTS WITH AGGRESSIVE ADULT T-CELL LEUKEMIA-LYMPHOMA: A DECISION ANALYSIS

Background: Patients with aggressive adult T cell leukemia-lymphoma (ATL) represent a stringent challenge for physicians because of the controversial indication regarding the indication of up-front allogeneic hematopoietic stem cell transplantation (allo-HSCT) as no prospective randomized controlled trial (RCT) has been conducted due to a rarity of patients with ATL even in Japan.

Summary/Conclusions: Higher peak TAC concentrations during 22-28 days after allo-HSCT increased the risk of TRC-EC. And the development of TRC-EC was associated with poor OS.
Decision analysis is a computerized modeling analysis which can simulate the clinical outcomes of different therapeutic strategies and identify an appropriate therapeutic strategy.

Aims: The aim of this study is to compare the life expectancy (LE) of chemotherapy followed by up-front allo-HSCT to that of chemotherapy alone using decision analysis in patients with aggressive ATL using database constructed by a nationwide survey.

Methods: We constructed a Markov decision analysis model to compare the outcomes in 2 therapeutic strategies: chemotherapy followed by up-front allo-HSCT vs chemotherapy alone. The transition probabilities between each health states were calculated from the database of 1,792 patients and patients were stratified into low-, intermediate- and high-risk groups according to the risk stratification system which we developed previously (Fuji S et al. 18th International Conference on Human Retrovirology). The model simulated the LE, quality-adjusted LE (QALE) and survival curve after diagnosis of aggressive ATL. Since QoL data for patients with aggressive ATL are lacking, estimates from a similar decision analysis study of patients with acute myeloid leukemia were used. In terms of the timing of up-front allo-HSCT, it was set as all patients receive up-front allo-HSCT from 2 to 6 months if ATL did not progress before allo-HSCT. We used the TreeAge Pro 2016 software package for decision analysis (TreeAge Software Inc., Williamstown, MA).

Results: In all patients, up-front allo-HSCT was associated with higher LE in comparison to chemotherapy alone (2.26 years vs 1.75 years). Stratified into 3 groups according to the prognostic scoring system, LE of up-front allo-HSCT was higher compared to that of chemotherapy alone in the intermediate- (2.27 years vs 1.66 years) and high-risk groups (1.50 years vs 0.91 years). The estimated survival curve depicted by TreeAge showed the superiority of up-front allo-HSCT as shown in Figure 1A-D. The Monte Carlo simulation showed that the probability of superiority of up-front allo-HSCT was 100% in all patients, 97.1% in the low-risk group, 100% in the intermediate-risk group, and 100% in the high-risk group in terms of LE, and was 99.8% in all patients, 75.2% in the low-risk group, 100% in the intermediate-risk group, and 100% in the high-risk group in terms of QALE.

Figure 1.

Summary/Conclusions: Based on decision analysis, up-front allo-HSCT was associated with higher LE and QALE in the intermediate- and high-risk groups in comparison to chemotherapy alone in patients with aggressive ATL. In the absence of prospective randomized controlled trials, our results suggest that up-front allo-HSCT for aggressive ATL is the favored treatment strategy in the intermediate- and high-risk groups.

P386
OUTCOMES OF THIOTEPA BASED REDUCED-INTENSITY CONDITIONING VERSUS STANDARD REDUCED-INTENSITY CONDITIONING IN ADULT PATIENTS UNDERGOING DOUBLE-UNIT CORD-BLOOD HEMATOPOIETIC STEM CELL TRANSPLANT

P. Sharma1, D. Poliya1, C. Smith1, E. Purev1, M. Kamdar1, B. Haverkos1, D. Sherbenou1, J. Gutman1

1Division of Hematology, University of Colorado, Denver, United States

Background: Cord blood transplantation (CBT) is an established alternative source for hematopoietic stem-cells in patients without matched donor. However, the most commonly used high-dose total-body-irradiation (TBI) myeloablative conditioning (MAC) results in high treatment related mortality (TRM). Non-myeloablative and reduced-intensity conditioning (RIC) have been studied to decrease TRM and provide curative chance to the elderly and those with comorbidities. However, these strategies are associated with higher relapse-rate and graft rejection. A novel-RIC using addition of thiopeta and higher dose of TBI to standard RIC has shown to result in sustained donor engraftment. Our study compares transplant-related-outcomes in patients who underwent first double-unit CBT with standard-RIC regimen of fludarabine (Flu, 200mg/m²), cyclophosphamide (Cy, 50mg/kg), and TBI (200cGy or 300cGy) versus this standard-RIC regimen with addition of thiopeta (10mg/kg) and increased dose of TBI (400cGy).

Aims: 1. To compare transplant related outcomes in CBT recipients who received standard-RIC (FluCyTBI) to those who received novel-RIC (FluCy with addition of thiopeta and increased dose of TBI). 2. To identify optimal conditioning regimen in patients undergoing UCT.

Methods: After IRB approval, consecutive patients undergoing CBT from 08/2009 to 08/2016 were evaluated and data retrospectively abstracted. Patient selection, graft-versus-host disease prophylaxis and transfusions were per institutional standards and conditioning regimens were compared as described.

Results: 3 of 99 patients who underwent allogeneic double-CBT, 52 received standard-RIC and 47 received novel-RIC. Median age at transplant was 67 years (range, 24-74) and 54 years (range, 25-67) in standard-RIC and novel-RIC cohort respectively. Acute myeloid leukemia was the major indication for transplant in both cohorts. Median hematopoietic stem-cell transplant-comorbidity-index (HSCT-CI) was 3 (range, 0-6) and 1 (range, 0-6) in standard-RIC and novel-RIC groups respectively. Four patients suffered engraftment failure (2 in each cohort). Median neutrophil engraftment was 13 days (range, 6-42) and 21 days (range, 12-43) while median platelet engraftment was 37 days (range, 26-70) and 38 days (range, 24-74) in standard-RIC and novel-RIC groups respectively. Fifty-three suffered acute GVHD which occurred in 21 (40%) patients (grade 2-4: n=15, 29%; grade 3-4: n=2, 4% in standard-RIC group and in 32 (68%) patients (grade 2-4: n=29, 62%; grade 3-4: n=5, 11%) in novel-RIC group. Chronic-GVHD (cGVHD) occurred in 18 patients (n=7, 14% in standard-RIC; n=11, 23% in novel-RIC group). The one-year cumulative incidence of relapse was 36% (n=15) in standard-RIC while it was 15% (n=5) in novel-RIC cohort. Median relapse free survival (RFS) was significantly improved in novel-RIC cohort compared to standard-RIC (HR, 0.32, CI:0.11- 0.76, p=0.01). Median RFS was 29 months in standard-RIC cohort while median RFS was not reached in novel-RIC cohort. The one-year cumulative incidence of transplant related mortality (TRM) was 22% (n=10) in those who received standard-RIC while it was 16% (n=7) in those who received novel-RIC. TRM was not significantly different between the standard-RIC and novel-RIC cohorts. Median follow-up in standard-RCI cohort was 9.3 months (range, 0.16- 79) and 13 months (range, 1.4- 38) in novel-RCI cohort. The overall survival (OS) was significantly better in novel-RCI cohort compared to standard-RCI (HR 0.49, CI: 0.25- 0.94, p= 0.03). Median OS was 17 months in standard-RIC cohort while median OS was not reached in novel-RIC group (Figure 1).

Figure 1.

Summary/Conclusions: In our study, RIC consisting of FluCy with addition of thiopeta and increased dose of TBI in patients undergoing double-cord UCT was associated with improved OS and improved RFS without increase in TRM as compared to standard RIC. While older and more comorbid patients might experience increased TRM with the thiopeta based regimen, these data suggest that consideration of this regimen may be appropriate in fit, older patients.

INTERFERON-α IS EFFECTIVE FOR TREATMENT OF MINIMAL RESIDUAL DISEASE IN PATIENTS WITH ACUTE LEUKEMIA AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

X.-D. Mo1, X.-H. Zhang1, L.-P. Xu1, Y. Wang1, C.-H. Yan1, H. Chen1, W. Han1, F.-R. Wang1, J.-Z. Wang1, K.-Y. Liu1, X.-J. Huang1

1Peking University People’s Hospital, Institute of Hematology, Beijing, China

Background: Post-transplant relapse is a major cause of transplant failure. Because impending relapse can be indicated by minimal residual disease (MRD) after allogeneic hematopoietic stem cell transplantation (allo-HCT), MRD-directed intervention may be a reasonable option for relapse prophylaxis.

Aims: We investigated the efficacy of MRD-directed interferon-α (IFN-α) treatment in acute leukemia patients who were positive for MRD after allo-HSCT.
Methods: A total of 107 patients who were MRD-positive after allo-HSCT were enrolled. MRD-positive status was defined as positivity for leukemia-associated aberrant immune phenotypes or positivity for Wilms’ tumor gene 1 in a single bone marrow sample. Recombinant human IFN-α-2b injections were administered subcutaneously 2–3 times per week for 6 months.

Results: The 2-year cumulative incidence of severe acute and chronic graft-versus-host disease (GvHD) was 27% (n=11) and 8% (n=3), respectively. Anemia, neutropenia, and thrombocytopenia occurred in 76 (71%), 58 (54%), and 26 (24%), respectively. The 2-year cumulative incidence of relapse and NRM after IFN-α treatment was 11.5% and 4.3%, respectively. The 2-year probabilities of event-free survival and disease-free survival after IFN-α treatment were 66.5% and 82.4%, respectively. Persistent MRD after IFN-α treatment was significantly associated with higher relapse risk and poorer survival.

Summary/Conclusions: These data confirmed that MRD-directed IFN-α treatment is effective for patients who were MRD-positive after allo-HSCT.

P389

IMPACT OF AZACITIDINE PRETREATMENT ON OUTCOMES OF ALLOGENIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN PATIENTS WITH HIGH-RISK MYELODYSPLASTIC SYNDROME

1Department of Hematology, Kanagawa Cancer Center, Yokohama, 2Department of Hematology/Oncology, The Institute of Medical Science, The University of Tokyo, Tokyo, 3Department of Hematology and Oncology, Graduate School of Medicine, Kyoto University, Kyoto, 4Department of Hematology, Hiroshima Red Cross Hospital & Atomic-bomb Survivors Hospital, Hiroshima, 5Department of Hematology, Red Cross Nagoya First Hospital, Nagoya, 6Division of Hematology, Saitama Medical Center Jichi Medical University, Omiya, 7Division of Hematology, Department of Medicine, Jichi Medical University, Shimotsuke, 8Department of Hematology, Tokyo Metropolitan Cancer and Infectious disease Center Komagome Hospital, 9Department of Hematology, Toranomon Hospital, Tokyo, 10Department of Hematology, Nagano Red Cross Hospital, Nagano, 11Department of Hematology and Oncology, Anjo Kosei Hospital, Anjo, 12Division of Hematopoietic stem cell transplantation, National Cancer Center Hospital, 13Blood Service Headquarters, Japanese Red Cross Society, Tokyo, 14Japan Data Center for Hematopoietic Stem Cell Transplantation (JDSCT) Program, 15Department of Healthcare Administration, Nagoya University Graduate School of Medicine, Nagoya, 16Department of Hematology, Kanazawa University Hospital, Kanazawa, Japan

Background: Myelodysplastic syndrome (MDS) is a heterogeneous myeloid stem cell disorder with ineffective hematopoiesis, dysplastic cell morphology, and a propensity for progression to acute myeloid leukemia. Allogeneic hematopoietic stem cell transplantation (allo-HSCT) is the only curative treatment available. In recent years, azacitidine (AZA) has been increasingly used as a pre-transplant induction therapy in high-risk MDS patients. However, the benefits of pretransplant therapy in these patients are unclear, and the optimal therapy regimen remains unknown.

Aims: We conducted a retrospective analysis to elucidate the clinical impact of treatment with AZA on outcomes after allo-HSCT in high-risk MDS patients.

Methods: Clinical data were collected from the registry database of the Japanese Society for Hematopoietic Cell Transplantation. We selected patients with high-risk MDS at diagnosis (IPSS intermediate 2 or high), aged 16 years or older, who underwent their first transplantation between January 2009 and December 2014 and received AZA or best supportive care (BSC) before allo-HSCT. Patients who received conventional chemotherapy or immunosuppressive therapy prior to allo-HSCT were excluded. We compared overall survival (OS), relapse, non-relapse mortality (NRM), and hematopoietic recovery after allo-HSCT in patients who were pretreated with AZA or BSC. OS was estimated by the Kaplan–Meier method, and a log-rank test was used for comparisons. Relapse and NRM were considered competing risk events and were compared using Gray’s test. The cumulative neutrophil and platelet recoveries were also compared by Gray’s test, considering death without these events as a competing risk. In a multivariate analysis, the Cox proportional hazard model and Fine-Gray methods were used for OS and cumulative incidence of relapse and NRM and hematopoietic recovery, respectively, using the following variables: age, gender, performance status at transplantation, marrow blast at diagnosis, cytogenetic risk, donor source, donor-recipient genotypic match, patient’s age, and donor age.

Results: Of the 485 patients, 161 patients (33.2%) received AZA and 324 patients (66.8%) received BSC before allo-HSCT. The median age was 60 (18–70) and 56 (18–74) years, respectively (P=0.002). A higher proportion of BSC patients received cord blood transplantation (P=0.005). Bone marrow failed in 14.6% of AZA patients and in 17.9% of BSC patients.

No differences were observed in other factors. The 2-year OS rate (46.7% and 50.8%, P=0.66), relapse (31.5% and 28.6%, P=0.59), NRM (26.5% and 26.1%, P=0.99), 30-day neutrophil engraftment (82.8% and 83.6%, P=0.18), and 30-day platelet engraftment (72.0% and 69.4%, P=0.36) were not significantly different between the AZA and BSC groups. In multivariate analysis, AZA and BSC showed comparable OS (HR, 1.16; P=0.31), relapse (HR, 1.13; P=0.50), NRM (HR, 0.92; P=0.64), neutrophil engraftment (HR, 1.01; P=0.89), and platelet engraftment (HR, 1.07; P=0.59). These data confirmed that pretransplant AZA and BSC provide similar outcomes of allo-HSCT in high-risk MDS patients. Further analysis is needed to clarify the role of pretransplant therapy in high-risk MDS and to identify the subset of patients who may benefit from pretransplant AZA.
LOW-DOSE DECITABINE IMPROVES PLATELET RECOVERY IN PATIENTS WITH ISOLATED THROMBOCYTOPENIA AFTER HSCT
Y. Han1,2, Y. Tang1, Y. Zhao1, M. Huang1, J. Chen1, J. Qi1, Y. Wang1, X. Wu1, X. Ma1, F. Chen1, X. He1, C. Ruan1, D. Wu1
1The First Affiliated Hospital of Soochow University, Jiangsu Institute of Hematology, 2Institute of Blood and Marrow Transplantation, Collaborative Innovation Center of Hematology, Soochow University, Suzhou, China

Background: Isolated thrombocytopenia is a common complication of hematopoietic stem-cell transplantation (HSCT), which was defined as consistent low platelet counts with recovery of the other two cell lines after transplantation. This status leads to an increased risk of life-threatening hemorrhage, frequent requirements of platelet transfusion and extended hospital stays, representing a challenging clinical problem. Previous studies have demonstrated that decitabine, a hypomethylating agent, may increase platelet counts by promoting megakaryocyte maturation and platelet release in mouse models.

Aims: In order to investigate the role of decitabine in patients after HSCT suffering from isolated thrombocytopenia, we conduct a clinical trial to validate this effect in post-HSCT setting.

Methods: We performed a prospective open-label study to evaluate the treatment of low-dose decitabine in patients with hematological malignancies who received allogeneic HSCT and suffered from isolated thrombocytopenia. The inclusion criteria were: (1) Platelet count ≤30 × 10⁹/L persistently at day 60 post-HSCT or later; (2) Recovered neutrophil and hemoglobin; (3) Full donor chimerism; and (4) No response to conventional treatments for a duration of at least 4 weeks. Patients with malignancy relapse, active infections, uncontrolled graft-versus-host disease, severe organ damage or transplant-related thrombosis were excluded. From July 2013 to July 2016, 38 patients were randomly assigned into either the control group to receive conventional treatment only, or the test group to receive additional decitabine (15mg/m², intravenously daily for 3 consecutive days).

Results: Major response was observed in 16 out of 19 patients (84.2%) in decitabine group, with a median time of 22 days to achieve platelet transfusion-independence. Two patients (10.5%) showed a minor response and 1 patient (5.3%) failed. In contrast, 3 out of 19 patients in the control group (15.8%) showed a major response, 2 patients (10.5%) showed a minor response, 14 patients (73.7%) did not show any improvement, of which 1 patient died of severe hemorrhage in week 5. For bone marrow morphological analysis, all 38 patients showed low levels of megakaryocytes at week 0. However, the megakaryocyte counts in decitabine group were significantly increased at week 4, while no significant difference was recorded in control group. After decitabine treatment, we did not observe a change in anti-platelet antibodies levels and T cell subsets ratios. However, reactive oxygen species (ROS) and megakaryocyte counts increased in the test group. No considerable myelosuppression, febrile neutropenia, and nonhematologic toxicities associated with the treatment were observed.

Summary/Conclusions: Our data showed an encouraging efficacy of decitabine in patients after HSCT suffering from isolated thrombocytopenia, which leads to remarkably increased megakaryocyte counts. Decitabine may improve isolated thrombocytopenia via regulating ROS and megakaryocyte reconstitution.

Thalassemia

A SELECTIVE ORAL GLYT1 INHIBITOR IMPROVES ANEMIA IN A MOUSE MODEL OF BETA-THALASSEMIA
A. Mattei1, M. Winter2, E. Beneduce1, E. Federti1, A. Scicolora1, A. Macias-garcia3, A. Iolascon1, T. Singier2, O. Khwaja3, A. Korn4, J.-J. Chen2, A. Harmeyer1, C. Brugnara3, L. De Franceschi1
1Medicine, University of Verona, Verona, Italy, 2Pharmaceutical Research and Early Development, Hoffmann-La Roche , Basel, Switzerland, 3MIT, MIT, Cambridge, United States, 4Biotechnologie Avanzate-CEINGE, Federico II University, Naples, Italy, 5Lab of Medicine, Children’s hospital Harvard Medical School, Boston, United States

Background: The anemia of β-thalassemia is due to combination of reduced red cell survival in the peripheral circulation and ineffective erythropoiesis, the latter due to unbalanced hemoglobin chain synthesis, and hemichrome-induced oxidative damage. Here we used a specific and selective inhibitor of the plasma membrane expressed glycine transporter GlyT1 (RO4917838) in a mouse model for β-thalassemia (Hbb3th3/mice). A previous study in Wistar rats has shown that RO4917838 induces a dose-dependent decrease in MCH, Hb, soluble transferrin receptor, and increase in absolute reticulocytes and RBC counts (Winter et al. Exp Hematol, DOI: 10.1016/j.exphem.2016.07.003). This has been linked to the ability of RO4917838 to reduce glycine bioavailability in erythroblasts and decreased heme biosynthesis.

Aims: To evaluate the impact of the glycine transporter GlyT1 selective inhibitor RO4917838 on anemia of a mouse model for β-thalassemia.

Methods: Wild-type control (WT) C57Bl/6J, and Hbb3th3/mice (β-β) aged between 3 to 4 months were treated daily with either vehicle or RO4917838 at dosages of 3, 10, 30 mg/kg/d for 4-6 weeks by gavage. Hematological parameters, analysis of erythropoiesis, molecular studies of sorted erythroid precursors, indices of hemolysis, hepcidin liver expression and Pears staining were carried out.

Results: RO4917838 administration was associated with an improvement of β-Thal hematologic phenotype, as supported by (i) the amelioration of red cell morphology; (ii) the increase in Hb levels; (iii) the reduction in reticulocyte count
and in the percentage of circulating erythroblasts; (iv) the increase in β Thal red cell survival. RO4917838 induced a significant reduction in extramedullary erythrocytosis as well as in the amount of insoluble alpha chain aggregates in circulating red cells. It is of note that in β-Thal sorted erythroblasts we found a reduction in HRI and in phospho-eIF2α, indicating a reduction in free heme, which shall resulted in the activation of HRI, in RO4917838 treated β -Thal mice (10 mg/kg/d, 6 weeks). Finally, in β-Thal mice treated with RO4917838 (4 weeks at 30 mg/kg/d) a reduction in liver and spleen iron-overload was identified, which was associated with increased hepcidin liver expression.

Summary/Conclusions: Our data suggest that RO4917838 ameliorates anemia and ineffective erythropoiesis by reduction of heme biosynthesis in a mouse model for β-thalassemia. RO4917838 is a potential, novel therapeutic approach for the treatment of anemia in patients affected by beta-thalassemia.

MAY MUTATIONS IN THE KLF1 GENE HAVE WORSENING EFFECTS ON THE BETA THALASSEMIA PHENOTYPE?
M.R. Storno1, M. Giuliano1, G. Fioretti2, S. Puozone1, R. Sessa1, L. Vicari2, M.P. Ottiano1, M. Caldora3, S. Costantini4, C. Matarrese2, A. Sarappa5, G. Amendola5, A. Filosa5, P. Izzo5, M. Grossi5,1
1Dep. Molecular Medicine and Medical Biotechnology, University of Naples Federico II, 2UOSC Genetica Medica, AORN A. Cardarelli, 3UOC Patologia Clinica, P.O. Pellegrini, ASL NA1, 4UOSD Malattie rare del globulo rosso, AORN A. Cardarelli, Naples, 5UOC Pediatría-TIN, P.O. Umberto I, Nocera Int., Italy

Background: Kruppel-like factor 1 (KLF1) is a pleiotropic erythroid transcriptional factor that plays a key role in erythropoiesis (Sietiecka M, Blood 2011; 118: 2044-521). Accordingly, KLF1 mutations have been found to be responsible for a variety of hematological disorders. KLF1 also contributes directly or indirectly to regulate the expression of genes in the beta-globin gene cluster and the fetal-to-adult globin gene switching (Waye JS et al. Int. J. Lab. Hem. 2015; 37: 78-84). It has been reported that mutations leading to KLF1 haploinsufficiency may lead to increased fetal-globin (HbF) levels with ameliorative effects on the severity of beta-thalassemia (Liu D. et al. Blood 2014; 124: 803-811; Perkins A.

Aims: This study aimed at providing a functional characterization of known and novel mutations in the KLF1 gene associated with atypical beta-thalassemia phenotypes.

Methods: Hematological parameters were measured using an automated hematologic analyzer (Beckman Coulter) and high performance liquid chromatography (Variant II, Bio-Rad Laboratories). Screening of KLF1 mutations was performed by Sanger sequencing on an Applied Biosystems 3730 DNA analyzer. Functional studies were performed by gene reporter assays and expression vectors for KLF1 mutants in the human K562 erythroleukemia cell line. This study was performed on 19 adult subjects, including 11 beta-thalassemia heterozygotes with an unexpected phenotype of intermediate thalassemia. This study was performed on 19 adult subjects, including 11 beta-thalassemia heterozygotes with an unexpected phenotype of intermediate thalassemia.

Our data suggest that RO4917838 ameliorates anemia and ineffective erythropoiesis by reduction of heme biosynthesis in a mouse model for beta-thalassemia. RO4917838 is a potential, novel therapeutic approach for the treatment of anemia in patients affected by beta-thalassemia. RO4917838 was associated with increased hepcidin liver expression.

Summary/Conclusions: Our data suggest that RO4917838 ameliorates anemia and ineffective erythropoiesis by reduction of heme biosynthesis in a mouse model for β-thalassemia. RO4917838 is a potential, novel therapeutic approach for the treatment of anemia in patients affected by beta-thalassemia.

P394
SECONDARY SOLID TUMORS FOLLOWING HEMATOPOIETIC CELL TRANSPLANTATION FOR THALASSEMIA MAJOR
A. Meloni1,*, A. Natale2, S. Santarone3, M. Di Ianni4, S. Angelini5, L. Pistoia1, L. Cuccia1, A. Spasiano1, A. Pepe5, P. Di Bartolomeo5
1 Fondazione G. Monasterio CNR-Regione Toscana, Pisa, 2Bone Marrow Transplant Center, Pescara, 3University of L’Aquila, L’Aquila, 4Tor Vergata University, Roma, 5ARNAS Civico “Benferratelli-Di Cristina”, Palermo, 6AORN A. Cardarelli, Napoli, Italy

Background: Secondary solid tumors (SST) have been described after HCT, in particular for patients affected by hematologic malignancies. There is limited information about the incidence of SST following HCT for thalassemia major (TM).

Aims: The aim of this study was to determine the incidence of SST in 134 patients with TM who received HCT in our Center between 1983 and 2013.

Methods: 117 patients survived more than 3 years after HCT and were enrolled in the study. Of them, 57 were males and 60 females. Their median age at time of HCT was 10 years (1-29). As conditioning regimen, they received Busulfan (14 mg/Kg) and Cyclophosphamide (200 mg/Kg). The GVHD prophylaxis included Cyclosporine and Methotrexate. All patients received bone marrow cells from an HLA identical donor.

Results: At time of this report, 112 patients were cured, whereas 5 patients rejected their graft and are now under regular transfusion treatment. Overall, the median follow-up after HCT was 24 years (3-34). Seven patients developed malignancy 3 to 28 years (median 16.4 years) after HCT including 2 patients with 2 cases of the tumor and in addition 4 of them received chemotherapy and/or radiotherapy. Of relevance, the 3 patients with cancer of the oral cavity were affected by severe chronic GVHD with buccal cavity involvement. Two patients (1 with parotid and 1 with tongue carcinoma) died of tumor progression and 5 are living.

Using the event rate measure, we observed an event rate of 0.102 at 30 years for the transplant group and 0.041 for the nontransplant group (p=0.106).

Summary/Conclusions: This study shows that the magnitude of increased risk of SST is twofold to threefold for patients treated with HCT as compared with an age-matched nontransplant TM patients or with stem cell donors. Notably, among the transplanted patients we didn’t observe any case of HCC, which is one of the most frequent solid tumor in nontransplant TM patients, whereas we observed 4 cases of head/neck cancers. In our series, cGVHD seems to be a strong risk factor in the development of new solid tumors. Patients with cGVHD, especially those with involvement of the oral cavity, must receive a very long careful monitoring and surveillance in order to prevent the development of secondary cancers.

Figure 1. Results: Of the 19 patients who were tested, 15 were found to be positive for mutations in the KLF1 gene. More in detail, we found 7 mutations, comprising a nucleotide variation (c.-251 C>G) already reported as a single nucleotide polymorphism and a known mutation (c.-148 G>A) in the proximal promoter region, 3 nucleotide variants with no effect on HbF levels (S102P, F182L and M39L), (Radmilovic M. et al. Ann. Hematol 2013; 92: 53-58) and 2 novel mutations (C94X and P173Pfs*236), all of them in the proline-rich domain in exon 2. Functional studies were performed in K562 cells in order to clarify the pathogenic significance of these mutations and to better define the role of KLF1 in atypical thalassemia phenotypes. Interestingly, the c.-251 C>G polymorphism was found to be associated with an increased transcriptional activity of the KLF1 promoter (Figure 1A), thus allowing us to exclude for this nucleotide variation the condition of a neutral polymorphism. Furthermore, unexpectedly, the novel P395
VALIDATING A NOVEL CAPILLARY ELECTROPHORESIS: THE MOST SUITABLE PLATFORM FOR THE NATIONAL NEWBORN SCREENING DEVELOPED IN A REGIONS WITH HIGH PREVALENCE OF THALASSEMIA AND HEMOGLOBINOPATHIES
T. Suksangpleng1,*, S. Riolueang1, J. Korchuenjiti1, W. Korchuenjiti1, J. Poolam2, V. Viprakasit1,3

22nd Congress of the European Hematology Association
Background: Newborn screening program for thalassemia (thal) and hemoglobinopathies (NBS-Hbs) is crucial for early detecting patients with serious hemoglobinopathies (Hb variants) e.g. Sickle cell anemia (Hb SS). NBS-Hbs has been incorporated into a routine neonatal service in several developed countries. However its role on early detection other forms of globin disorders remains unclear. Moreover, NBS-Hbs can detect several types of thalassemia and Hb variants carriers. This application could be useful for the national prevention and control programs in many developing countries including Thailand where these conditions are highly prevalent especially β-thal major. Hb E/β-thal and Hb Bart’s hydrops fetalis caused by α°-thalassemia (α°-thal). Recently a new capillary electrophoresis (CE) has been developed specifically for NBS-Hbs. However there is a limited data on validation of this technology on detecting several types of thalassemia and Hb variants found in Southeast Asia.

Aims: To evaluate and validate a new CE system to screen globin disorders in newborn to initiate the national NBS-Hbs for Thailand.

Methods: After informed consent, 1,213 blood samples of 2-day old newborns were collected by heel prick puncture into 5-dried blood spots. After elution, dried blood samples were analyzed by Capillaries 2 NEONAT FAST® (SEBIA, Evry, France). All samples were also extracted for DNA and genotyped by our extensive PCR based panel to detect >98% of abnormal globin alleles found in Thailand using α°-thal GAP-PCR, α-thal ARMS-PCR, β-thal ARMS-PCR, and PCR-RFLP for Hb E. We compared CE data with each globin genotypes and use a ROC curve to set up new diagnostic criteria using Hbs from CE for future cases.

Results: Identification of Hb Bart’s provided 100% of sensitivity, specificity and accuracy in most individuals with α-thal. Using ROC analysis, we proposed different cut-off values of Hb Bart’s to differentiate Hb H disease, α°-thal and non-deletional α°-thal traits; ≥9.40%, ≥0.85%, ≥0.45%, respectively with excellent accuracy. Interaction of Hb E with these α-thal genotypes has no effect on these cut-off values (Table 1). However, there was a limitation to identify deletional α-thal trait’s ≥20.10% (detectable level). A cut-off level to distinguish Hb EE from Hb E trait was suggested at ≥24.95% vs ≥0.7%. Two patients with Hb E/β-thalassemia were identified through this study with different CE pattern from Hb EE. 11 β-thalassemia traits was identified and they had a lower level of Hb A as compared to their gestational age (GAs) sex matched controls with normal β globin genotypes (n=148). We recommend Hb A level ≤10.35%; a cut-off to primarily consider for β-thalassemia carrier followed by molecular analysis.

Summary/Conclusions: This newborn CE platform showed a high efficiency for detecting several types of thalassemia and Hb variants in particular α-thal, β-thal and Hb E using cut-off levels of each Hb species described herein. Besides early detecting of Hb S, we can now apply this NBS into a routine service in order to early detect Hb H disease, Hb E/β-thalassemia and the major common thalassemia carriers. This NBS-Hbs approach can reinforce and leverage our current program on prevention and control for severe thalassemia syndromes in our region. Moreover, due to population migration from The East to the West, our new diagnostic guideline by CE could be useful and applicable for existing NBS programs currently available in several European countries.

P397
INCREASING INCIDENCE OF MALIGNANCIES IN AGING THALASSEMIC PATIENTS AT A SINGLE INSTITUTION'S LONGITUDINAL EXPERIENCE
E. Repousi1,* M. Moraki1, D. Kyriakopoulou1, P. Delaporta1, A. Kafourou1, E. Katamis1
1Thalassemia Unit, First Department of Pediatrics, National and Kapodistrian University of Athens, ‘Aghia Sophia’ Children’s Hospital, Athens, Greece

Background: The introduction of close monitoring, regular blood transfusions and systematic iron chelation in the management of thalassemia have significantly changed the clinical phenotype of the patients and improved their survival. The patients, who have benefited of the current therapeutic regimen, are reaching middle age and they may have started developing problems commonly seen in older people. Recent observations suggest an increased incidence of malignancies in the aging group of thalassemic patients.

Aims: The purpose of this study is to determine the longitudinal changes in the incidence of malignancies, along with possible correlations to different aspects of the disease.

Methods: A retrospective study in the largest Thalassemia Unit in Greece, which has been conducted spanning an observation period from 2001-2016. The occurrence and type of cancer, as well as hospitalization due to non-transfusion related complications, were recorded. Hb levels and capacity, transfusion and chelation therapy were collected. Survival analysis was performed using SPSS v. 20 software package. A p-values of <0.05 was considered statistically significant.

Results: A total of 591 patients were included. The incidence of malignancies increased from 0/51 in 2001-2005 to 7/51 in 2011-2015 (p<0.05). The overall incidence of malignancies was 13/591 (2.2%). The most common malignancies were lung cancer, breast cancer, colorectal cancer, prostate cancer and lymphoma, respectively. There was no correlation between malignancies and transfusion, chelation therapy and Hb levels. The incidence of malignancies increased with age (p<0.001).

Summary/Conclusions: The current study confirms that the long-term survival of patients with thalassemia is associated with an increased risk for malignancies. This is the first study to report on the incidence of malignancies in patients with thalassemia at a single institution, using a large prospective dataset.
with malignancies were identified (incidence: 4.6%). The mean age of the diagnosis of the malignancy was 41.8 years (36.6 years for thyroid gland cancer, 45.8 years for liver, 38 years for hematologic malignancies and 46 for renal cancer). 24 patients were transfusion dependent (TD) (7% of the patients) and 3 non transfusion dependent (1.8%). Liver cancer had the highest incidence 29.6%, followed by thyroid gland cancer 25.9%, hematologic malignancies 11.1% and renal cancer 14.8%. HCV infection was found in 56.7% of the patients and a statistical significant relationship between HCV infection and cancer (p=0.001) was detected. No correlation between liver failure and cancer was detected. In the TD group, the age specific ratio of cancer increased with age with the patients >50 years having the highest ratio of 42.3, compared to 36.9 in the 20-45 age group and 41.4 in 45-49 years age group respectively.

In regards to chelation therapy, at the time of diagnosis 40.9% of the patients were receiving deferasirox (DFX), 22.7% deferiprone (DFP), 22.7% deferoxamine (DFO). 9.1% no chelation therapy and 4.5% DFO/DFP. No statistical significant difference was observed between the different chelation therapy regimens (p=0.119). As the utilization of different types of chelation changed throughout the years, according to the availability of the chelating agents, we analyzed separately, the patients that developed malignancies in the period after 2010 when longitudinal exposure to all three chelators can be assumed. Even though the results showed a difference (p=0.027) between the different groups, with 47.1% of those patients receiving DFX at the time of the diagnosis compared to 27.1% receiving DFP and to 11.8% receiving DFO, this distribution reflects the overall distribution of chelator usage during that period. Apart from the incidence, there was no statistical significant difference between TD and NTD patients with cancer regarding the gender, age and year of diagnosis. The cancer mortality rate was 48%, but varied significantly with the type of cancer with liver cancer and hematological malignancies having a mortality of 66%. Overall only 2% of the deaths occurring in our group of patients were attributed to cancer.

Summary/Conclusions: This retrospective study has confirmed the increased incidence of malignancies in thalassemia patients in Greece, which is, at least, partially related to the aging of this population. Based on these observations, adaptation of monitoring guidelines is essential for optimal management of thalassemic patients. Periodic screening for malignancies, especially hepatic, thyroid and hematologic, will allow early detection and timely, and thus, more efficacious treatment of the neoplasia.

P398 SAFETY AND EFFICACY OF EARLY START WITH SUBOPTIMAL DOSE OF DEFERIPRONE IN MINIMALLY TRANSFUSED INFANTS WITH TRANSFUSION DEPENDENT THALASSEMIA: A RANDOMIZED TRIAL

M. Elalfy1,*, B. Helal2, V. Berdoukas3, F. Tricta4, M. Tarif1, H. Awad5, A. Adly1

1AinShams university, 2Ain Shams University, Cairo, Egypt, 3Oasis International Hospital, Beijing, China, Beijing, China, 4ApoPharma Inc., Toronto, Canada, 5National Research Center, Cairo, Egypt

Background: Early exposure to Iron toxicity is the main risk factor for morbidity and mortality in patients with transfusion-dependent thalassemia. Current practice is to start chelation therapy only after 10-20 transfusions, or when the serum ferritin (SF) level rises above 1,000 µg/L.

Aims: To evaluate the safety and efficacy of the early use of low-dose deferiprone in minimally transfused pediatric thalassemia patients and to evaluate if it can postpone iron overload in this group of patients.

Methods: In the current trial (ClinicalTrials.gov Identifier: NCT02173951), sixty-four children recently diagnosed with thalassemia major who had begun receiving blood transfusions in first year of life to keep pre-transfusion Hb above 10 gm/dl, had not yet started iron chelation therapy and had SF ≥400 µg/L or transferrin saturation (TSAT) ≥70% or labile plasma iron (LPI) ≥0.6 µM were randomized to start deferiprone (DFP) at a sub-therapeutic dose (50 mg/kg/day) or no chelation (NC). Median age at 1st transfusion ≥0.2 µM were randomized to start deferiprone (DFP) at a sub-therapeutic dose (50 mg/kg/day) or no chelation (NC). Median age at 1st transfusion was 4.5 years (range: 1.4-14.2) and mean age was 22.3±7.5 years.

Results: Table 1. Summary of the efficacy results of SF, TSAT, and LPI.

All NC patients were removed from the trial prior to completing 7 months of follow-up (9-11 transfusions) due to confirmed SF ≥1000 µg/L. Mean ± SD time of follow up was 10.4±4.9 and 5.9±2.5 months for DFP and NC respectively. Most common adverse events in patients on DFP versus NC were diarrhea (19% vs 13%, p=0.73), vomiting (13% vs 13%, p=1.00), abdominal colic (13% vs 13%), elevated liver enzymes (6% vs 3%, p=1.00) and neutropenia (6% vs 6%). All adverse events were mild in severity and did not require interruption of DFP use. There were no cases of agranulocytosis or moderate neutropenia, no arthralgia and no serious infections in DFP-treated patients. DFP therapy was associated with a significant reduction in the rate of iron accumulation as measured by SF (P<0.0001), LPI (P=0.001) and TSAT (P<0.001) (Figure 1, a, b, c). LPI≥0.6 µM appeared as early as after 5 transfusions in NC children and was delayed to at least 10 transfusions with DFP therapy. TSAT≥70% appeared after 10 transfusions in NC children and was delayed to at least 17 transfusions with DFP therapy. The results of this study show that LPI and TSAT may reach values ≥0.6 µM and ≥70%, respectively, after 5-10 transfusions in children with TM and all NC children had SF ≥1000 µg/L after 8-9 transfusions.

Summary/Conclusions: A sub-therapeutic dose of deferiprone for a mean of 12 months in children with TM and low iron overload was not associated with safety concerns and able to significantly reduce the rate of iron accumulation as measured by SF, LPI and TSAT.

P399 LONGITUDINAL PROSPECTIVE MRI STUDY IN PEDIATRIC PATIENTS WITH THALASSEMIA MAJOR

M. Casale1,*, A. Meloni2, A. Filosa1, L. Pistola3, F. Sorrentino3, A. Quartar4, A. Carolo1, M. C. Cirotto1, V. Positano2, E. Grassedonio1, M. Missirelli8, A. Pepe2

1AORN A. Cardarelli, Napoli, 2Fondazione G. Monasterio CNR-Regional Toscana, Pisa, 3Ospedale “Sant’Eugenio”, Roma, 4Ospedale “A. Perrino”, Brindisi, 5Azienda Ospedaliera “Sant’Antonio ed SS. Tommasi, 6ASL N.1 Sassari, Sassari, 7Polilorino “Paolo Giaccone”, Palermo, 8Fondazione di Ricerca e Cura “Giovanni Paolo II”, Campobasso, Italy

Background: No studies are available in literature evaluating, on repeated magnetic resonance (MR) imaging assessments, changes in myocardial and hepatic iron overload, biventricular function, and development of macroscopic myocardial fibrosis in pediatric patients with thalassemia major (TM).

Aims: This is the first longitudinal prospective MRI study in pediatric TM patients.

Methods: We considered 68 TM patients enrolled in the MIOT (Myocardial Iron Overload in Thalassemia) project with less than 18 years at the first MRI assessment. Changes in myocardial (MR) and liver iron concentration, biventricular function, and late gadolinium enhancement (LGE) images were acquired to detect myocardial fibrosis. All patients had a 1st MRI study performed at the age of 12±3 years

Results: At the baseline MRI, 16 (23.5%) patients showed myocardial iron overload (MIO; global heart T2*<20 ms) and 54 patients liver iron overload

Figure 1.
(79%). Figure 1 shows the changes in iron levels. Twenty-five patients changed the chelation regimen after the baseline MRI. Globally, a worsening in cardiac iron was found in 3% of the patients while a worsening in hepatic iron in the 21% of the patients (P=0.003). The LV end-diastolic volume index and all RV volumes as well as the LV mass index were significantly lower at the FU MRI. No significant improvement in left or right global systolic function was found. For 40 patients the presence of myocardial fibrosis was investigated at both baseline and FU scans. Six patients (15.0%) had myocardial fibrosis at the baseline MRI and myocardial fibrosis was detected for all of them also at the FU. The extent of myocardial fibrosis was comparable between the two scans (0.77±0.42% vs 0.79±0.51%; P=0.686). At the Fu 4 new occurrences of myocardial fibrosis were detected. In patients with baseline MI0 no significant correlation was found between the percentage change in cardiac iron and the changes in hepatic iron or the baseline hepatic iron.

Summary/Conclusions: Magnetic resonance imaging in children with TM demonstrated a good control of cardiac iron overload in terms of prevention and treatment but the need for further improvement of liver iron overload. Myocardial fibrosis appears mainly multifocal, non progressive and not reversible over a 18- month period. A prompt and aggressive approach to iron overload and a chelation regimen consistent with the high iron intake and the high rate of severe liver iron overload is recommended in children.

Table 1. Multi-organ MRI R2* evaluations at baseline and after f.u. of pancreatic-R2*>100Hz.

Summary/Conclusions: In this experience we observed that the regular multi-organ assessment of iron overload by R2* is concomitant with a reduction of the iron burden in this cohort of well treated patients confirming that is a careful method to tailoring the iron chelation therapy. However pancreatic-R2* remains above the cut-off for the prediction of cardiac iron overload, so this parameter should be considered with caution in the tuning of the chelation therapy, in order to avoid over-chelation risk. Ferritin values trend agree with R2* values confirming the reliability of this parameter. These results were obtained with a prevalent use of oral chelation regimen (90% of patients).

**DEVELOPMENT OF HTLV-1 HYPERIMMUNE GLOBULINS AGAINST HTLV-1 INFECTION**

T. Mizukami1,2, K. Nojima1, R. Sobata2, W. Kuribayashi2, C. Matsumoto2, Y. Yano1, E. Sasaki1, K. Furuhata1, Y. Hiradate1, K. Ohkuma1, S. Matsuoka1, M. Satake1, I. Hamaguchi1

1Department of Safety Research on Blood and Biologicals, National Institute of Infectious Diseases, 2Central Blood Institute, Japanese Red Cross, 3Department of Cellular and Molecular Medicine, Graduate School of Medicine, Chiba University, Tokyo, Japan

**Background:** Adult T-cell leukemia (ATL) is a malignant disease caused by infection with human T-lymphotropic virus (HTLV-1). The prevention of HTLV-1 infection is the most effective strategy to eradicate ATL. However, there is no effective vaccine or anti-viral agent for HTLV-1.

**Aims:** The aim of this study was to develop an effective HTLV-1 hyperimmune globulin (HTLV-IG) isolated from HTLV-1 positive carriers screened at the Japanese Red Cross.

**Methods:** We developed two in vitro and in vivo screening methods to evaluate and characterize the anti-viral effect of HTLV-1 positive plasma and HTLV-IG. The anti-viral effect of HTLV-IG isolated from an HTLV-1 carrier with a proviral load (PVL) >4 inhibited both HTLV-1 infection and synctia formation. We purified HTLV-IG from the HTLV-1 positive plasma (PVL >4) and evaluated its effect in a humanized mouse model. NOG (Nod.Cg-Fkdcisl2tgtn1SugJrc) mice were treated with HTLV-IG for 5 days before HTLV-1 infection. During the monitoring period of 40 days after post-infection, HTLV-1 infection was observed in untreated infected mice, but not in HTLV-IG-treated mice. The inhibitory effect of HTLV-1 was observed at the early stage of HTLV-1 infection. Treatment with HTLV-IG at 20 days after HTLV-1 infection had a partial inhibitory effect. HTLV-1 gp46 expression in HTLV-1 infected cells was slightly reduced and the localization of the cells was changed in each tissue after the first line of treatment. These data suggest HTLV-IG is effective at the early phase of HTLV-1 infection. We also assessed the viral safety of HTLV-1 during the HTLV-IG manufacturing process. High log reduction values of HTLV-1 were observed during the Cohn fractionation process. Virus safety was assessed by PCR based assay and in vitro and in vivo infection assay. We next assess the viral safety of HTLV-1 during the HTLV-1 manufacturing process. High log reduction values of HTLV-1 can be seen during the Cohn fractionation process. Virus safety was assessed with PCR based assay and in vitro and in vivo infection assay.

**Summary/Conclusions:** These data suggest HTLV-IG is effective and safe for the prevention of HTLV-1 infection.

**THE COMBINATION OF TUMOR CELLS IN THE APHERESIS MATERIAL DOES NOT PREDICT THE RESPONSE OF MULTIPLE MYELOMA PATIENTS TO AUTOLOGOUS TRANSLANTATION**

M.L. Lozano1, F. De Arriba1, M. Solá1, A. Sánchez-Fuentes1, N. Revilla1, F. Omarto1, A. Jerez1, I. Heras1, P. Imiesta1, O. Lopez-Godino1, M.D. Garcia-Malo1, V. Vicente1

1Hematology and Clinical Oncology, Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arrixaca, CB15/00055-CIBERER, Murcia, Spain

**Background:** The use of high dose of chemotherapy followed by autologous stem cell transplantation (ASCT) has improved the prognosis of patients with multiple myeloma (MM) and plasma cell dyscrasia. However, there is controversy over the effect of infusion of atypical plasma cells (PC) on the apheresis product.

**Aims:** To analyze whether MM patients with an MM plasma cell reinfusion could negatively affect responses to ASCT.

**Methods:** Patients (n=114) undergoing ASCT (n=120) for MM between June 2003 and February 2016 were enrolled in a retrospective study to analyze the prognostic value of aberrant (CD38++CD138+CD19-CD45weak) to normal phenotype (CD38++CD138+CD19+CD45+) plasma cells (AT-PCT ratio) in the autograft by flow cytometry. The Durie-Salmon stage at diagnosis, pre-ASCT monoclonal component, and response (0.08 vs 0.08 ×10^6/kg). There was no difference between the type of autograft (autologous hematopoietic+G-CSF) and the degree of apheresis contamination (median AT-PCT ratio 0.5 vs 0.8; P=0.86). There was a statistical trend between the degree of infiltration of PC in the bone marrow before ASCT and the detection of atypical PC in the graft (p=0.06). At day +100, 94% of patients with CR or VGPR to induction therapy maintained the response, and 49% of patients in PR, SD or PD achieved post-ASCT CR or VGPR (p=1.24^-7). There was no association between the content of atypical PC in the graft and the response to day +100. However, the percentage of pre-ASCT PC in the bone marrow was significantly related to the response at day +100 (CR or VGPR vs PR, SD or PD), p=0.003, as well as the pre-ASCT monoclonal component (p=4.03^-7).

**Summary/Conclusions:** infusion of PC with atypical phenotype does not appear to affect the response at day +100 following ASCT, in patients with MM or plasma cell dyscrasia. Conversely, the quality of response to induction therapy was significantly associated to 100-day outcome after transplantation. These data support that in vivo persistent residual cells, but not those being infused with the graft, are the main source of relapse in MM.

**EVALUATION OF THERAPEUTIC PLASMA EXCHANGE AT A TERTIARY LONDON HOSPITAL**

R. Moli1,*, D. Warcel1, S. Clark1, M. Sekhar1

1Haematology, Royal Free Hospital, London, United Kingdom

**Background:** Therapeutic plasma exchange (TPE) is used to treat a number of haematological, renal and neurological conditions. Pathogenic antibodies or other plasma molecules are removed, and plasma volume is replaced with fluid. Haemoglobin, albumin solution (HAS) is usually preferred, except in cases of Thrombotic Thrombocytopenic Purpura (TTP) and related conditions. TPE may result in dilutional coagulopathy, and reactions such as hypersensitivity can occur. The British Society for Haematology (BSH) published a 2015 guideline to assist the use of TPE in UK clinical practice, providing evidence-based indications and recommended schedules.

**Aims:** To evaluate the use of elective TPE at a large tertiary London hospital, compare clinical practice against BSH guideline recommendations, and explore the effect of TPE on coagulation test results.

**Methods:** Data was collected prospectively over a 2 month period, using patient notes and electronic transfusion records. A data collection form recorded the indication, treatment schedule, replacement fluid, complications, the presence of a written treatment plan, and frequency and results of coagulation testing.

**Results:** 24 plasma exchanges took place over the period of data collection; there were no cases of TTP. Adherence to BSH guidelines was variable; although most cases (88%) had an evidence-based clinical indication for TPE, just 4% had a full written treatment plan, and only 17% of courses followed recommended scheduling. 75% of patients had received at least one prior course, some outside guideline indications for repeat courses. Most patients (83%) initially received human albumin solution (HAS), usually preferred, except in cases of TTP. Most patients (85%) received human albumin solution (HAS), usually preferred, except in cases of TTP. Fibrinogen levels showed some correction by the next day but usually still abnormal. A prolonged APTT and PT was also seen in most patients immediately following TPE, which almost always corrected by the next day.
Summary/Conclusions: TPE use was generally compliant with BSH guidelines regarding clinical indication and initial replacement fluid. However many patients were changed from HAS to FFP to achieve the predicted coagulopathy. This is a recognised complication of TPE, and the guidelines suggest that if possible, TPE can take place on alternate days to ameliorate this. Fluid change to FFP is recommended only for those at increased haemorrhagic risk. Almost all the TPE used in our study took place over 3 to 5 subsequent days, reflected in the high frequency of fibrinogen monitoring, and the level that should prompt change to the TPE schedule, require further exploration. The following are planned to enhance adherence to BSH guidelines and improve patient care. 1. Documented treatment plans with clinical indication, proposed treatment schedule, replacement fluid. 2. Local trust guidelines to include recommended TPE schedules, agreed parameters to monitor response, frequency of fibrinogen monitoring, common complications and their management. Where possible, TPE should take place on alternate days to reduce dilutional coagulopathy. 3. Education of staff involved with service provision, and strengthening of the role of apheresis nurse as lead.

P404

A COMPREHENSIVE PROTEOME STUDY ON PLATELET CONCENTRATES: PLATELET PROTEOME, STORAGE TIME AND MISAROL PATHOGEN REDUCTION TECHNOLOGY

D. Warcel1,*, R. Moll1, A. Li1

Background: Platelet concentrates (PCs) represent a blood transfusion product with a major concern for safety as their storage temperature (20-24°C) allows bacterial growth, which will occur in less than a week. This necessitates complete microbiological testing. Pathogen reduction technologies (PRTs) provide an additional layer of safety to the blood transfusion products from known and unknown pathogens (such as bacteria, viruses and parasites). In this context, PRTs (such as Mirasol technology) have been developed and are implemented in many countries. However, several studies have shown in vitro that Mirasol PRT induces a certain level of platelet shape change, hyperactivation, basal degradation and increased oxidative damage during storage. It has been suggested that Mirasol PRT might accelerate what has been described as the platelet storage lesion (PSL), but supportive molecular signatures have not been obtained.

Aims: We aimed at dissecting the influence of both variables, i.e. Mirasol PRT and storage time, at the proteome level.

Methods: We present comprehensive proteomics data analysis of control PCs and PCs treated with Mirasol PRT at storage day 2, 6 and 8. Our workflow was set to perform proteomics analysis using a gel-free and label-free quantification (LFQ) approach. Semi-quantification was based on LFQ signal intensities of identified proteins using MaxQuant/Perseus software platform.

Results: We identified marginal differences between Mirasol PRT and untreated PCs during storage. However, those significant changes at the proteome level were specifically related to the functional aspects previously described to affect platelets upon Mirasol PRT, and in addition, the effect of Mirasol PRT on the platelet proteome appeared not to be exclusively related to proteomic changes due to PSL.

Summary/Conclusions: In summary, semi-quantitative proteomics allow to discern between treatment changes due to Mirasol PRT or PSL, and proves to be a methodology suitable to phenotype platelets in an unbiased manner, in various physiological contexts.

P405

USE OF A SURVEY TO ASSESS AND IMPROVE ADHERENCE TO UK BLOOD TRANSFUSION GUIDELINES IN A HOSPITAL SETTING

D. Warcel1,*, R. Moll1, A. Li1

1Haematology, Royal Free Hospital, London, United Kingdom

Background: UK guidelines to provide evidence-based support for decisions to transfuse packed red cells were published in 2015 by NICE (National institute for Health, and Care Excellence). The guidelines specified Hemoglobin (Hb) targets for transfusion, use of single unit transfusion to avoid over-transfusion, information provision to patients for informed consent, and avoidance of pre-operative transfusion by timely identification of iron deficiency for referral through an anemia pathway. A local baseline audit of NICE compliance at our London teaching hospital showed low overall compliance with these recommendations.

Aims: To determine knowledge amongst the prescriber group of transfusion recommendations for stable patients, to gain insight into current patterns of decision-making for transfusion and to impart knowledge of the key NICE guidelines.

Methods: An online survey, designed to both evaluate and inform participants, was targeted at doctors of different training grades and specialties during a two week period. The outcomes of this are being used to guide further training.

Results: Of 141 participants who took part in the survey, 31% (43) had been qualified for less than two years and 47% (65) were consultants. Specialties included Surgery, Anesthesitcs, Internal Medicine, Hemato-Oncology and Intensive Care. 60% (84) had prescribed blood within the last month. Despite only 51% (72) awareness of the NICE guidelines, a significant majority (73%, 103) selected the correct Hb threshold of ≤70g/L for transfusion in patients without acute coronary syndromes (ACS). A correct 70g/L Hb threshold held at all. Ferritin measurement was inconsistent with only 47% (66) routinely measuring this prior to transfusion, and only 31% (44) aware that a ferritin result over 30 days old should be rechecked. This highlighted potentially inadequate identification of iron deficiency anemia. In addition only 40% (57) were aware of the existence of a hospital anaemia clinic for referral. When reflecting on consent methods, 96% (135) of participants expressed some difficulty in obtaining patient consent, and 90% (127) gave an opportunity to ask patients questions and ensured the patient was content to proceed. Provision of written information was poor (26%, 37) and only 55% (78) recorded the discussion in patients’ notes. Exploring barriers to consent, 24% (32) expressed difficulty in obtaining a patient information leaflet, and issues relating to lack of time and confidence were 16% (22) and 9% (12) respectively.

Summary/Conclusions: Although the majority of participants expressed awareness of the NICE guidance, knowledge was not reflected in subsequent questions. The survey allowed simultaneous assessment of knowledge and provision of key information as a factsheet. Almost all participants felt that completion of the survey had been helpful, and as a tool to reach a highly mobile group, the survey is a constructive and supportive method to facilitate implementation of national guidance by medical staff. We were also able to identify areas that need further development including the clinical referral pathway for the anaemia clinic and improving the availability of patient information leaflets on hospital wards. At present we are not aware of any hospital transfusion service which routinely distributes information to all hospital staff, and carrying out structured case based discussion sessions with junior doctors to enhance knowledge and confidence.
Front-line combinations in multiple myeloma and amyloidosis

S407

QUADRUPLET VS SEQUENTIAL TRIPLET INDUCTION THERAPY FOR MYELOMA PATIENTS: RESULTS OF THE MYELOMA XI STUDY

1The Institute of Cancer Research, London, United Kingdom, 2Myeloma Institute, University of Arkansas for Medical Sciences, Little Rock, United States, 3Clinical Trials Research Unit, Leeds Institute of Clinical Trials Research, Leeds, 4Heart of England NHS Foundation Trust, Birmingham, 5Leicester Royal Infirmary, Leicester, 6Centre for Clinical Haematology, Nottingham University Hospital, Nottingham, 7University Hospitals of North Midlands, Stoke-on-Trent, 8Kant and Canterbury NHS Trust, Canterbury, 9Southampton Hospital, Southampton, 10University of Leeds, Leeds, 11The Royal Marsden Hospital, London, 12Institute of Immunology and Immunotherapy, University of Birmingham, Birmingham, 13Haematological Malignancy Diagnostic Service (HMDS), St James’s University Hospital, Leeds, 14Clinical Trial Research Unit, Leeds Institute of Clinical Trials Research, Leeds, 15Department of Haematology, Newcastle University, Newcastle, United Kingdom

Background: Combining anti-myeloma induction therapies limits the impact of clonal heterogeneity on resistance to therapy, maximising response and associated clinical outcomes. Triplett combinations induce deeper, longer remissions than doublets and those containing an immunomodulatory agent, a proteasome inhibitor (PI) or both are the current standard of care in Europe/US. Potential approaches to further improve outcomes include response-adapted induction, treating suboptimal responders with sequential treatment using an agent with a different mechanism of action, or intensifying therapy for all patients by the use of quadrplet combinations upfront.

Aims: The UK NCRI Myeloma XI trial is a large, phase III study comparing, in transplant eligible (TE) patients, the induction quadruplet carfilzomib, cyclophosphamide, lenalidomide and dexamethasone (KCRD) to the sequential strategy of triplet immunomodulatory combinations (with thalidomide or lenalidomide) followed by additional pre-transplant consolidation with PI triplet therapy for those with a suboptimal response.

Methods: In 2013, the TE pathway of the Myeloma XI study was amended to include KCRD given in 28 day cycles (carfilzomib 36mg/m2 IV d1-2,8-9,15-16 (20mg/m2 #1d1-2), cyclophosphamide (cyclo) 500mg PO d1, lenalidomide (len) 25mg PO d1-21, dexamethasone (dex) 40mg PO d1-4,8,9,15-16). Patients were randomised to this up-front quadruplet or the sequential strategy of CRD (cyclo 500mg PO d1, len 25mg PO d1-21 PO daily, dex 40mg PO d1,4,8,12-15) or CTD (cyclo 500mg PO d1,8,15 thalidomide 100-200mg PO daily, dex 40mg PO d1-4,12-15) given to max. response. Patients with VGPR/CR proceeded straight to ASCT, those with PR/MR were randomised to sequential CVD (cyclo 500mg d1,8,15, bortezomib 1.3mg/m2 IVSC d1,4,8,11, dex 20mg PO d1,2,4,5,8,9,11,12) or nothing and those with SD/PD all received sequential CVD. At day 100 post ASCT there was a maintenance randomisation between lenalidomide and observation. The trial has now closed to recruitment and all patients have completed induction therapy. This analysis compares responses and toxicity of the different regimens.

Results: 2568 TE patients underwent induction randomisation (CTD 1021, CRD 1021, KCRD 526). Patients were comparable with respect to age (median 59 years), sex and other key laboratory parameters. Patients were mandated to receive a minimum of 4 cycles of initial induction with therapy continued to maximum response. The median number of cycles delivered was CTD: 5, CRD: 5, KCRD: 4. Grade ≥3 haematological toxicities differed between the groups. (Neutropenia CTD: 12%, CRD: 22%, KCRD: 16%; Thrombocytopenia CTD: 3.4%, CRD: 4.5%, KCRD: 8.1%; Anaemia CTD: 6.7%, CRD: 9.6%, KCRD 10%). Grade ≥2 neurological toxicity was greater with the thalidomide-containing regimen (Sensory neuropathy CTD: 9.5%, CRD: 3.4%, KCRD: 2.3%). There was no statistically significant difference in rates of investigator reported, all-grade, thromboembolic events between regimens (CTD: 11.8%, CRD 11.1%, KCRD 14.7%). Response to initial induction and following ASCT is shown in Table 1 indicating deeper responses with the quadruplet compared to triplets both at the end of first induction regimen (p<0.0001) and, importantly, post-ASCT (p<0.0001). These differences were observed despite the use of randomised pre-transplant consolidation for suboptimal responders to triplet immunomodulatory therapy.

Summary/Conclusions: Induction therapy with KCRD, an outpatient delivered quadruplet regimen, was associated with deeper responses than immunomodulatory triplet therapy (CRD/CTD) and was well tolerated. Deeper responses persisted after ASCT, with an impressive response rate ≥VGPR of 92% with KCRD.

Background: Quadruplet combinations that include a proteasome inhibitor (PI) may have been proven superior to doublets in newly diagnosed multiple myeloma (NDMM) (San Miguel et al, N Engl J Med 2008, Durie et al, Lancet 2017). The all-oral combination of the novel PI ixazomib plus lenalidomide-dexamethasone (IRd) was evaluated as an induction regimen in NDMM patients, followed by single-agent ixazomib maintenance.

Aims: Here we report updated efficacy and long-term safety data for patients who did not withdraw from the study in order to receive stem cell transplantation (SCT).

S408

DEEP AND DURABLE RESPONSES WITH WEEKLY IXAZOMIB, LENALIDOMIDE AND DEXAMETHASONE IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA: LONG-TERM FOLLOW-UP OF PATIENTS WHO DID NOT UNDERGO SCT

S. Kumar1, J. Berdeja2, R. Niewczyk3, S. Loriai4, J. Laubach4, M. Hamadani5, A.K. Stewart5, P. Har8, V. Roy9, R. Vesco10,1, J. Kaufman11, D. Berg12, E. Liao12, V. Rajkumar1, P. Richardson5

1Mayo Clinic, Rochester, 2Sarah Cannon Research Institute, Nashville, 3Myeloma Center, Weill Cornell Medical College, New York Presbyterian Hospital, New York, 4Department of Medicine and Medical Oncology, Winship Cancer Institute of Emory University, Atlanta, 5Dana-Farber Cancer Institute, Boston, 6West Virginia University, Mary Babb Randolph Cancer Center, Morgantown, 7Mayo Clinic College of Medicine, Scottsdale, 8Division of Hematology Oncology, Medical College of Wisconsin, Milwaukee, 9Mayo Clinic, Jacksonville, 10Cedars-Sinai Outpatient Cancer Center at the Samuel Oschin Comprehensive Cancer Institute, Los Angeles, 11Winship Cancer Institute of Emory University, Atlanta, 12Millennium Pharmaceuticals Inc., Cambridge, MA, USA, a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, United States
Methods: In this phase 1/2 study (NCT01217957), patients with NDMM received weekly oral ixazomib (1.8-3.5mg/m²; days 1, 8, 15) and dexamethasone (40mg, days 1, 8, 15, and 22) for up to 12-28 day induction cycles, followed by maintenance therapy with weekly single-agent ixazomib, at the last tolerated dose given during induction, until disease progression or toxicity.

Results: Of the 42 enrolled patients, 42 continued on study treatment without early withdrawal for SCT; the long-term follow-up of these 42 patients is reported here. Baseline patient characteristics included: median age, 68 years (range 34-86); ISS stage I/II/III in 40%/4%/17%. As of October 18, 2016, with median follow-up of 56 months, the confirmed overall response rate (ORR, ≥ partial response [PR]) was 80%, complete plus very good partial response (CR+VGPR) rate was 63%, and CR rate was 32%. Median time to first response was rapid (0.95 months), while median time to CR was 5.6 months. Median progression-free survival (PFS) in these patients not receiving SCT was 25.3 months. Median overall survival (OS) has not been reached at a median follow-up of 3 years. OS at 3 years was 87%. Safety findings are summarized in the Table; 74% of patients had grade ≥3 treatment-related adverse events (AEs), and 26% of the patients had treatment-related serious AEs. Among treatment-related AEs of interest, grade ≥3 rash and peripheral neuropathy were infrequent. There was one treatment-related death due to respiratory syncytial viral pneumonia. After completing 12 cycles of induction therapy with IRd, 25 patients went on to receive maintenance single-agent ixazomib. In these 25 patients, at the end of the induction period ORR was 100%, including 44% VGPR and 32% CR. Responses deepened during maintenance, at data cut-off, the response rates in this maintenance therapy population were 50% VGPR, 32%, and 38% CR. Patients who received maintenance therapy was 24 months. The occurrence of the most common treatment-related grade ≥3 AEs (neutropenia, thrombocytopenia, and fatigue) was confined almost exclusively to the induction period. During the maintenance period no patients reported onset of grade ≥3 peripheral neuropathy or rash. Summary/Conclusions: In patients with NDMM, weekly ixazomib plus Rd, followed by single-agent ixazomib maintenance, was highly active, resulting in deep and durable responses, long PFS, and a high 3-year OS estimate. IrD followed by single-agent ixazomib maintenance also showed an acceptable safety profile, with less toxicity reported during the maintenance (single-agent ixazomib) vs induction (IRd) periods, with no evidence of cumulative toxicities.

Summary/Conclusions: Safety profile was acceptable; more patients required plerixafor in the KRd arm. Rate of VGPR was higher with KRd. Updated data on a higher number of patients will be presented at the meeting. The trial is registered at Clinicaltrials.gov: NCT02203643

S411

HOVON 104; FINAL RESULTS FROM A MULTICENTER, PROSPECTIVE PHASE II STUDY OF BORTEZOMIB BASED INDUCTION TREATMENT FOLLOWED BY AUTOLOGOUS STEM CELL TRANSPLANTATION IN PATIENTS WITH DE NOVO AL AMYLOIDOSIS

M. Minnema1,*, K. Nasserinejad2, B. Hazenberg3, U. Hegenbart4, L. Noens5, P. Ypma6, S. Zweegman7, L. Tick8, A. Broijl9, H. Koene10, G. Bos11, N. Thuss2, P. Sonneveld2, S. Schonland4

1Haematology, UMC UTRECHT, Utrecht, 2HOVON data center, ErasmusMC, Rotterdam, 3Rheumatology, UMCG, Groningen, Netherlands, 4Amyloidosis Center, University of Heidelberg, Heidelberg, Germany, 5Haematology, UZ Gent, Gent, Belgium, 6Internal Medicine, HAGA hospitals, the Hague, 7Haematology, VU medical center, Amsterdam, 8Internal Medicine, Maxima Medical Center, Eindhoven, 9Haematology, ErasmusMC, Rotterdam, 10Internal Medicine, st Antonius Hospital, Nieuwegein, 11Haematology, University Hospital Maastricht, Maastricht, Netherlands

Background: Bortezomib (B) has been reported to be very effective in AL amyloidosis with overall response rates (ORR) varying between 50-80%. However, there are no prospective data from multicenter studies on B treatment in de novo patients. We investigated the efficacy and safety of B-Dexamethasone (BD) induction treatment followed by HDM+SCT in de novo AL amyloidosis patients.

Aims: The primary aim was to improve the hematological CR rate at 6 months after SCT on intention to treat analysis from 30 to 50%. Secondary aims were OS, PFS, hematological response rate after BD treatment, organ responses, safety and prognostic factors for survival.

Methods: Patients with biopsy proven AL amyloidosis, aged between 18-70 years, with detectable M-protein and/or level of involved FLC >50mg/L, WHO performance status 0-2, NYHA stage 1-2 and ejection fraction >45% were included. Major exclusion criteria were symptomatic orthostatic hypotension, NT proBNP level >5000 pg/ml, Troponin T > 0.06 ugl, Bilirubin >2x ULN, eGFR<30 ml/min, CTCAE grade peripheral sensory neuropathy > grade 2 or > grade 1 with pain. Inclusion and exclusion criteria were installed both at entry and before stem cell mobilization (SCM). B was given subcutaneously 1.3mg/m² twice a week in a 21-day cycle, D 20mg orally on each B day and the following day. HDM dosage was 200mg/m². Hematological responses were defined according to consensus criteria with the addition of very good partial response (VGPR), defined as the difference between involved and uninvolved FLC<40mg/L. Cardiac, renal and liver response and progression criteria were defined according to consensus criteria with addition of NT proBNP.

Results: Median age was 59 years (range 26-70) and 60% were male. NYHA stage was 1 in 56% and 2 in 42% of patients. Mayo cardiac risk score was 1 (30%), II (36%), III (34%). Organ involvement was 82% renal, 66% heart, 28% liver, 14% neurological, 8% gastrointestinal and 38% of patients had 3 or more organs involved. Bone marrow plasmacells were >10% in 28% of patients. The median FU for patients alive is 24 (10-55) months. Twelve of 50 (24%) patients could not proceed to SCM. Four patients due to B related toxicity, 3 patients did not fulfill criteria to proceed, 2 patients died (both amyloidosis related) and 3 miscellaneous. Of these 38 patients, 3 went subsequently off protocol because of ineligibility for HDM. Thirty-five out of 50 patients (70%) received HDM + SCT, one patient died of a cardiac arrest after the SCT procedure. The ORR after induction was 80%, ≥VGPR in 54% and CR in 6% of patients. The ORR in the 35 patients at 6 months after SCT was 80%, ≥VGPR in 51% and CR in 43% of patients. On intention to treat analysis the CR rate at 6 months after SCT was 30%. Organ responses at 6 months after SCT were 16/29 renal, 2/8 liver and 13/23 heart. No baseline characteristics were identified to be predictive for OS or PFS. BD doses were reduced and delayed after 2 cycles in almost half of patients, mostly because of neurotoxicity. Sensory neuropathy grade 2 or higher was seen in 36% of patients and autonomic neuropathy, mostly dizziness and collapse, in 22%.

Summary/Conclusions: This final analysis demonstrates that the primary aim of improving CR rate at 6 months after SCT from 30 to 50% was not met. This was mainly caused by the high dropout rate before SCT. This may be due to patient selection, but we also demonstrate that BD, given twice weekly sc, despite good efficacy, cannot prevent early amyloidosis related toxicity and can induce grade 2 or higher neurotoxicity.

Trial registration www.trialregister.nl (NTR 3220), EudraCT 2010-021445-42, supported by the Dutch Cancer Society (UU 2010-4884) and by an unrestricted grant from Janssen-Cilag.

NIVOLUMAB FOR RELAPSED/REFRACTORY CLASSICAL HODGKIN LYMPHOMA AFTER AUTOLOGOUS TRANSPLANT: FULL RESULTS AFTER EXTENDED FOLLOW-UP OF THE MULTICOHORT MULTICENTER PHASE 2 CHECKMATE 205 TRIAL
1University Hospital of Cologne, Cologne, Germany, 2University of Texas MD Anderson Cancer Center, Houston, United States, 3Humanitas Cancer Center – Humanitas University, Rozzano–Milan, Italy, 4Dana-Farber Cancer Institute, Boston, 5Mayo Clinic, Rochester, United States, 6Institute of Hematology “L. e A. Seràgnoli”, University of Bologna, Bologna, Italy, 7University of California, Los Angeles, Los Angeles, United States, 8Cedars Sinai Medical Center, Los Angeles, United States, 9Catholic University of Sacred Heart, Rome, Italy, 10Columbia Cancer Center, Churchhill Hospital, Oxford, United Kingdon, 11Barbara Ann Karmanos Cancer Institute, Detroit, 12Winship Cancer Institute, Emory University, Atlanta, United States, 13Netherlands Cancer Institute – Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands, 14University of Toronto and Princess Margaret Cancer Centre, Toronto, 15British Columbia Cancer Agency, Vancouver, Canada, 16Charles University in Prague and General University Hospital in Prague, Prague, Czech Republic, 17Brigham and Women’s Hospital, Boston, 18Bristol-Myers Squibb, Lawrenceville, 19Memorial Sloan Kettering Cancer Center, New York, United States

Background: Nivolumab, a fully human IgG4 monoclonal antibody targeting programmed death-1, is an immune checkpoint inhibitor that augments T-cell activation and antitumor responses. Nivolumab is indicated for pts with relapsed/refractory (RR) classical Hodgkin lymphoma (cHL) following autologous stem cell transplantation (ASCT) and brentuximab vedotin (BV) treatment. The multicohort phase 2 CheckMate 205 trial (NCT02181738) enrolled pts with RR cHL after ASCT. Initial analyses revealed high objective response rates (ORR), encouraging duration of response (DOR) and an acceptable safety profile (Younes A et al, Lancer Oncol 2016). Durable responses to therapy are valuable in pts with progressive disease after failure of ASCT due to their limited treatment options.

Aims: To report extended follow-up data for all pts with RR cHL after failure of ASCT in CheckMate 205.

Methods: This was a single-arm multicenter trial enrolled pts (age ≥18 y) with RR cHL after ASCT into 1 of 3 independent cohorts (Cohort A: BV-naïve; Cohort B: BV only after ASCT; Cohort C: BV before and/or after ASCT). All pts received nivolumab 3mg/kg every 2 wk until disease progression or unacceptable toxicity. Pts in Cohort C with a persistent complete response (CR) for 1 y were to discontinue nivolumab and could resume at relapse. Primary endpoint was ORR per Independent Radiology Review Committee. Secondary endpoints included DOR; progression-free survival (PFS), overall survival (OS), and safety were assessed irrespective of BV treatment history.

Results: In total, 243 pts were treated: 63 in Cohort A (BV-naive), 80 in Cohort B (BV after ASCT), and 100 in Cohort C (BV before [n=53], after [n=58], or before and after [n=32]). Median (range) age was 34 (18-72) y and 77% of pts had advanced (stage III+) disease at study entry. BV-naïve pts had fewer prior lines of therapy (median of 2 vs 4 with prior BV). At Dec 2016 database lock, median (min, max) follow-up was 19 (1, 25), 23 (2, 27) and 16 (1, 20) mo in Cohorts A, B, and C, respectively. Overall, 40% of pts were still on treatment; the most common reason for discontinuation was disease progression (26%). ORR was 65% in Cohort A, 68% in Cohort B, and 73% in Cohort C with 29%, 13%, and 12% CR, respectively. Median (95% CI) DOR was 20 (13, 20), 16 (8, 20), and 15 (9, 17) mo in Cohorts A, B, and C, respectively. DOR for patients with CR was 20 months for BV-naive patients (Cohort A) and ≥15 mo for BV-treated patients (Cohorts B and C). DOR for patients with partial response (PR) was 17 and ≥11 months, respectively. PFS by cohort is shown (Figure 1). Prolonged median PFS was seen for patients with CR (≥17 mo in each cohort), PR (<15 mo in each cohort), and stable disease (<9 mo in each cohort). Median OS was not reached in any cohort. The most common drug-related serious AEs were neutropenia (12%), fatigue (11%), and infusion reactions (13%); and rash (12%), grade 3-4 drug-related AEs in ≥3% of pts were pts (2%) and pneumonitis (1%). To facilitate translation to practice, efficacy results by sequencing of prior BV treatment will be presented.

Summary/Conclusion: With extended follow-up, high and durable rates of CR and PR to nivolumab therapy were observed in pts with RR cHL after ASCT, irrespective of BV treatment history.

S. Croce e Carle, Cuneo, Italy

Background: Interim 2-[18F]fluoro-2-deoxy-D-glucose Positron Emission Tomography (FDG-PET) performed after 2 chemotherapy cycles (PET2) is the most powerful predictor of treatment outcome in ABVD-treated, advanced-stage classical Hodgkin Lymphoma (cHL). Preliminary reports showed that treatment with PET2 result could increase the efficacy of standard ABVD.

Aims: To confirm in a prospective setting the favorable prognosis of advanced stage PET2 negative patients treated with ABVD, as well as the safety and efficacy of escalated BEACOPP given to PET2 positive patients.

Methods: We conducted a prospective clinical trial (HD0607 ClinicalTriail.gov identifier 00795613), in which advanced-stage (IIB-IVB) cHL patients were treated with 2 ABVD courses, and PET2 performed afterwards. The latter was blindly and independently reviewed by a panel of nuclear medicine experts, using the Deauville 5-point scale (5-PS). PET2+ patients (5-PS 4-5) were randomized to either BEACOPP escalated (BE+BB) or BEACOPP baseline (BE+BB+R) therapy. Toxicity was assessed with the CTC-NCI version 4.0. PFS at 4 years (PFS4y) in the PET2 positive cohort was compared to the PET2 negative cohort.

Results: A total of 124 patients (PET2− cohort: 64 PET2+ cohort: 60) were consecutively enrolled in 24 Italian and 1 Israeli centers. The median age was 31 years (14-60); 35% had stage IIB, 32% stage III and 32% stage IV. The International Prognostic Score (IPS) was 0-1 in 36.6%, 2-3 in 51%, >3 in 12.5%.
Overall, 150 (19.2%) proved PET2+ (97 score 4, 53 score 5) and 630 (80.5%) PET2-. PET2+ patients were more frequently male (56.7% vs 47.1%, p=0.03), had higher IPS score (P=0.002) and bulky disease (28.0% vs 17.9%; p=0.002). Out of 149 PET2+ patients randomized to Be+Bb vs Be+Bb+R (76) or Be+Bb+R (73), 136 were evaluable for response: 93 obtained CR and 43 had a treatment failure. Of the remaining 13 patients, 3 died, 7 withdrew their consent and 3 stopped treatment for toxicity. As per study protocol, 627 out of 630 PET2- patients continued with 4 ABVD cycles and 3 withdrew their consent. Overall, 330 (38.6%) died, due to early death (n=2), resistant disease (n=18; 12 with a positive and 6 with a negative PET2), transplant related toxicity (n=5), infections (n=4) and pulmonary fibrosis (n=1). After a median follow-up of 1303 days (2-2857), the 4-Y OS for all 782 patients was 83% (95% CI 80%>86%) and 96% (95% CI 94%>97%), respectively. For PET2+ and PET2- patients, the 4-Y OS was 95% (95% CI 60%>96%) and 87% (95% CI 84%>89%), while the 4-Y OS was 95% (95% CI 82%>93%) and 97% (95% CI 95%>98%) (Figure 1, Panel A and B). No outcome difference was observed for Be+Bb vs Be+Bb+R patients, with a 4-Y PFS of 69% (95% CI 57%>79%) and 68% (95% CI 55%>76%), respectively (p=0.973). Consolida-
dation RxT in PET2- patients in CR after 6 ABVD and LNM did not translate in to a significant benefit, with a 4-Y PFS of 96% (95% CI 91%>98%) for RxT and 93% (95% CI 87%>96%) for NFT (p=0.288).

Figure 1.

Summary/Conclusions: These data suggest that 1) an early switch from ABVD to escalated BEACOPP can be safely done in PET2+ advanced-stage cHL; 2) the long-term outcome for the entire patient cohort is superior to standard ABVD; 3) no clinical benefit is associated with post ABVD RxT in PET2- patients with ≥3 tumor events were identified. The dates of occurrence of 3rd relapse ranged between 15th of January 1993 and 21th of June 2013. The sample consis-
ted of 51 male (74%) and 18 female (26%) patients. At time of 3rd relapse the age of the patients ranged from 20 to 79 years (mean 39.2 years, standard deviation (SD) 14.0 years) and the majority of patients presented with stage III or IV disease (67%). Time from end of 3rd-line treatment to 3rd relapse was ≤3 months (i.e. GHSG definition of refractory disease) in 15 cases (22%), ≤12 months (early relapse) in 19 cases (28%) and >12 months (late relapse) in 35 cases (51%). All 69 patients were pretreated with chemotherapy, 35 (50.7%) with BEACOPP, 30 (43.5%) with ABVD and no BEACOPP, and 32 (46.6%) with another type of chemotherapy. The number of prior chemotherapies ranged from one to three (median 3). Pretreatment with radiotherapy was observed in 57 (82.6%) patients, with salvage chemotherapy aimed to induce a remission prior to a stem-cell transplantation (SCT) in 58 (84.1%), and with high dose chemotherapy followed by autologous SCT in 50 (72.5%) patients. Patients with 6 months (early relapse) in 19 cases (28%) and >12 months (late relapse) in 35 cases (51%). All 69 patients were pretreated with chemotherapy, 35 (50.7%) with BEACOPP, 30 (43.5%) with ABVD and no BEACOPP, and 32 (46.6%) with another type of chemotherapy. The number of prior chemotherapies ranged from one to three (median 3). Pretreatment with radiotherapy was observed in 57 (82.6%) patients, with salvage chemotherapy aimed to induce a remission prior to a stem-cell transplantation (SCT) in 58 (84.1%), and with high dose chemotherapy followed by autologous SCT in 50 (72.5%) patients. Patients with 6 months (early relapse) in 19 cases (28%) and >12 months (late relapse) in 35 cases (51%). Summary/Conclusions: Patients with a 3rd relapse or progression of cHL have a dismal, mostly palliative prognosis due to frequent tumor progression. Within one year half of the patients have a PFS event and one fourth die.

troupolis, Greece

Background: Waldenström’s macroglobulinemia (WM) is a rare low-grade B-
cell lymphoma characterized by the lymphoplasmacytic bone marrow infiltration and hyperviscosity syndrome. Most cases of monosomy 13 and IgM-immunoglobulin-secreting indolent lymphoma that has heterogeneous clinical manifestations and patients with this disease may have a prolonged disease course; however, there are groups of patients with poor outcomes after a relatively short disease course. In order to develop a robust staging system a collaborative effort resulted in the formulation of the International Prognostic Scoring System for WM (IPSS-
WM) which was developed in 2009 based on data of patients that were treated primarily without rituximab and mainly with alkylators and nucleoside analogues. IPSSWM is based on five covariates (age, hemoglobin, platelet counts, IgM levels and b2 microglobulin) and stratifies WM patients into 3 broad risk groups. IPSSWM does not take into account other non-IM related mortality, which is common and quite different among patients over the age of 75 years and does not include LDH, which is a well identified prognostic factor both in lymphomas and multiple myeloma.

Background: Rituximab monotherapy has been used successfully in the treatment of SMZL and it can replace splenectomy, at least in 1st line.

Aims: To present our data on the outcome of R monotherapy treated pts after a long term follow-up.

Methods: The diagnosis of SMZL was based on the WHO criteria. Criteria for treatment initiation included: bulky/symptomatic splenomegaly, cytopenias or presence of B-symptoms. All pts received 6 weekly cycles of R as 1st line therapy at a dose of 375mg/m2 (induction phase). None of the pts had been splenectomised before R treatment. Maintenance with R at a dose of 375mg/m2 every 2 months for 1-2 years was given according to physician’s discretion. Response assessment was based on the SLSG consensus criteria. Survival curves were estimated using the Kaplan Meier method and compared by log-rank test.

Results: 104 pts with SMZL were included. 45% were males with a median age of 66 y (41-91). At diagnosis all pts had bone marrow infiltration with a median % of infiltration of 40 (10-85). Anemia and thrombocytopenia were present in 30% and 19%, respectively. 40% had absolute lymphocytosis. LDH was elevated in 43%. According to the SLSG prognostic system, 39% were classified in group A, 56% in group B and 5% in group C. The median time from diagnosis to treatment initiation was 2 months (0-203). 71 pts received R maintenance. The overall response rate 2 months after the end of induction treatment was 93% (CR, CRu and PR in 42%, 21% and 30%, respectively). Maintenance therapy improved the quality of response in 19 of them, 52 pts maintained their initial response and one relapsed during maintenance phase. The 5- and 10- year PFS, OS and CSS were 70% and 64%, 93% and 88%, 99% and 93%, respectively. Maintenance therapy was associated with better PFS (p=0.008).

Summary/Conclusions: The present study includes a large number of pts with a long follow-up, confirms that R monotherapy is very effective in SMZL with minimal toxicity and is recommended as the treatment of choice for this disease.

Biology of MPN: JAK2 and beyond

S417
YOU DON'T KNOW JAK: A PROGRAMMED RIBOSOMAL FRAMESHIFTING DEFECT POTENTIATES THE TRANSFORMING ACTIVITY OF THE JAK2-V617F MUTATION
S. Sulima1, Y. Khan2, J. Briggs2, S. Vereecke1, J. Jones2, V. Advani2, J. Verbeeck1, K. De Keersmaecker1, J. Dinman2
1Department of Oncology, LKI, KU Leuven, Leuven, Belgium, 2Department of Cell Biology and Molecular Genetics, University of Maryland, College Park, United States

Background: The JAK-STAT pathway is a critical controller of cellular proliferation, differentiation, survival and apoptosis in response to external stimuli. Promiscuous activation of this pathway is an important driver in the pathogenesis of BCR/ABL-negative chronic myeloproliferative neoplasms. The JAK2-V617F allele is the most common and characterized mutation linked to this class of leukemia. The increased activation of JAK-STAT signaling in JAK2-V617F cells can be partially explained by increased JAK2 autophosphorylation. It is unclear however if these effects are sufficient to fully account for the strong activation of the JAK-STAT pathway induced by JAK2-V617F. We recently described programmed -1 ribosomal frameshifting (-1 PRF) as a novel mechanism regulating the expression of -10% of human genes, including cytokine receptors (Blewe AT et al., Nature, 2014). In this process, cis-acting mRNA elements (-1 PRF signals, which consist of a slippery site followed by a pseudo-knot) direct translating ribosomes to slip by one base in the 5' direction, establishing a new reading frame. This directs ribosomes towards premature termination codons, resulting in destabilization of the -1 PRF signal-containing mRNA via nonsense-mediated mRNA decay (Figure 1). There is thus an inverse relationship between -1 PRF efficiency and mRNA stability.

Aims: To investigate whether the JAK2-V617F mutation, shown here to be located in the pseudoknot of a -1 PRF signal in the JAK2 mRNA, impacts disease progression through ablation of -1 PRF.

Methods: Computationally predicted -1 PRF signals were validated using dual luciferase reporters and proteomic analysis of a -1 PRF fusion protein. -1 PRF as well as mRNA abundance and decay were assayed in HEK293T and HeLa cells. Transformation assays were performed in HEK293T cells expressing Ba/F3 cells, in vivo experiments were performed in BALB/c mice.

Figure 1.

Results: We demonstrate in human cell lines that the JAK2-V617F mutation structurally disrupts the -1 PRF signal in the JAK2 mRNA, leading to ~2-fold lower rates of -1 PRF and increased abundance of the JAK2 mRNA and protein. The transforming potential of a series of mutants designed to manipulate -1 PRF independent of V617F was assayed in a Ba/F3 cell model. Silent protein coding changes in the pseudoknot of the -1 PRF signal at position V617 (V617m) or the slippery site (SSm), both of which drastically reduced frameshifting, increased JAK2 expression and led to transforming activity, albeit less than V617F. Importantly, the V617F+SSm combination conferred an additive effect on cellular transformation. Ba/F3 cells expressing these JAK2 variants were also introduced into mice. Whereas mice injected with wild type JAK2 remained healthy, both V617m and SSm induced similar leukemia phenotypes as V617F and V617F+SSm, with a ~2-fold longer disease latency of 8-10 weeks. Increased JAK2 mRNA abundance in JAK2-V617F homzygous patients as well as the presence of three additional -1 PRF signals in the JAK2 mRNA further suggest a prominent role for -1 PRF in controlling JAK2 production.

Conclusions: We demonstrate that the JAK2-V617F mutation diminishes -1 PRF on the JAK2 transcript, stabilizing the mRNA and increasing JAK2 expression, contributing to its transforming activity in vitro and disease onset in vivo. We suggest that -1 PRF normally provides a layer of control by limiting JAK2 translation. Defective -1 PRF synergizes with the transforming activity of the JAK2-V617F protein by causing its overexpression, explaining why this particular mutation causes such aggressive malignancies. In support of this, the combination of ruxolitinib and an HSP-90 inhibitor, which reduce kinase activity and JAK2 expression respectively, leads to increased therapeutic efficacy in myeloproliferative neoplasms (Bhagvat N et al., Blood, 2014).

S418
EFFECTIVENESS OF LSD1 INHIBITION FOR THE TREATMENT OF MPN
J.S. Jutzi1,*, H. Rienhoff2, H.L. Pahl1
1Clinic for Hematology, University Medical Center, Freiburg, Germany, 2Imago Biosciences, San Francisco, United States

Background: Treatment of MPN with JAK1/2 inhibitors ameliorates symptoms and splenomegaly but does not meaningfully reduce the JAK2V617F allele burden. Though curative, stem cell transplantation is associated with extensive morbidity and mortality highlighting the need for novel effective therapies. The histone “lysine-specific demethylase 1A” (LSD1/KDM1A) is being explored as a drug target in AML with the demethylators already in clinical trials. LSD1 induces monocytic differentiation and reduces engraftment of AML cell in vivo. LSD1 is over-expressed in a number of myeloid diseases including MPN. Preliminary data in a mutant mpl mouse model of MPN showed that a 28-day course of LSD1 inhibition had a beneficial impact on spleen size, cytokines and mutant cell burden. In a mutant JAK2 mouse model of MPN, we have characterized the disease-modifying activity of the LSD1 inhibitor (IMG-7289), a compound in clinical development for myeloid diseases (NCT02842827).

Aims: We assessed the pharmacodynamic effects of continuous daily treatment with IMG-7289 in a JAK2V617F knock-in murine MPN with established disease. Animals were treated for up to 56 days. Outcome measures included complete blood counts (CBC), hematological phenotype, overall survival, spleen size, bone marrow morphology and the JAK2V617F allele burden. Moreover, pro-inflammatory cytokine were monitored during the course of treatment as well as chromatin changes by western blotting and ChIPseq.

Methods: JAK2V617F-L2 mice were crossed to MxCre mice and displayed a fulminant MPN phenotype without did induction. CBC and BM FACS analysis were conducted as previously described. We designed a qPCR assay to quantitate murine JAK2V617F allele burden.

Results: IMG-7289 treatment was exceptionally well tolerated and mice showed drastic decreases in platelet count (208 vs 2063*10^3/μl), reticulocytes (800 vs 1674*10^3/μl), monocytes and neutrophils 14 days after the start of treatment. HCT and WBC started to decrease after 28 days. While the JAK2 mutant allele burden increased over time in untreated mice, it decreased in IMG-7289 treated mice drastically in peripheral blood as well as in spleen. We observed a drastic increase in the pro-inflammatory cytokine CXCL5 in untreated mice during the course of investigation while CXCL5 levels of treated mice decreased to levels of wild-type littermates. Moreover, treated mice showed a highly significantly increased survival over untreated mice, even in a late stage of disease. Lastly, we were able to show that global H3K9me2, which is generally associated with gene expression silencing, was increased in the bone marrow of IMG-7289 treated mice compared to control mice. The remaining pathophysiological data and functional data on epigenetic regulation will be presented.

Summary/Conclusions: The LSD1 inhibitor IMG-7289 normalizes or stabilizes elevated CBCs in a JAK2V617F MPN mouse model. It decreases JAK2 mutant allele burden, pro-inflammatory cytokine levels and confers a clear survival advantage. Our preliminary data show that LSD1 is a potent target with disease-modifying potential in MPN. Clinical studies with IMG-7289 testing this hypothesis have just begun. Owing to its mode of action, altering epigenetics, the potential reversibility of drug-induced epigenetic remodeling, a long treatment period in MPN patients may be necessary to eliminate disease. Combining IMG-7289 with JAK1/2 inhibitors might accelerate treatment effects.

S419
LOSS OF RAF KINASE INHIBITOR PROTEIN IS INVOLVED IN MYELOMONOCYTIC LINEAGE COMMITMENT AND AGGRAVATES THE DEVELOPMENT OF CHRONIC MYELOMONOCYTIC LEUKEMIA IN A MURINE IN-VIVO MODEL
V. Caraffini1, O. Geiger1, A. Rosenberger1, S. Hatzl1, B. Perfler1, J.L. Berg1,
Background: myelomonocytic leukemia (CML) is characterized by increased proliferation and myelomonocytic lineage commitment of hematopoietic stem cells (HSCs). Mutations in the RAS signaling cascade are frequent in CML patients and lead to a CML-like myeloproliferative disorder (CML-MPD) in mice via causing hypersensitivity to GM-CSF. Loss of RAF kinase inhibitor protein (RKIP), a negative regulator of RAS signaling, is frequent in myelomonocytic and monocytic subtypes of acute myeloid leukemia (AML) and is often associated with RAS mutations. Moreover, RKIP loss has recently been shown to increase the proliferation of AML cell lines.

Aims: In this work, we aimed at investigating the role of RKIP in the development of CML.

Methods: RKIP expression was measured by immunoblot and quantitative real-time PCR in 23 primary CML patient samples as well as in CD34+ HSCs, B-lymphocytes, granulocytes and monocytes of four healthy donors. Sequence analysis of CML patient samples was done with an Ion Torrent Next Generation Sequencing platform using an amplicon panel covering 39 genes recurrently mutated in myeloid neoplasms. Effects of RKIP on GM-CSF-induced myelomonocytic differentiation were studied in human CD34+ HSCs lentivirally transduced with RKIP shRNA, as well as in a genetic mouse model for RKIP deletion (RKIP-/-). Effects of RKIP on CML development were initially studied in the same RKIP-/- model. Additionally, these mice were crossed with animals exhibiting a somatically inducible mutation in NRAS (RKIP+/−×Cre-NRASG12D) and the severity of CML-MPD onset was studied at an age of six months.

Results: Loss of RKIP protein expression was observed in 6/23 (26%) CML patient specimens and was associated with decreased mRNA levels as well (P<0.001). Patients with RKIP loss exhibited an increased percentage of myelomonocytic cells in the peripheral blood (56% vs 75%, P=0.0226). One or more mutations affecting the RAS signaling pathway were detected in all specimens with RKIP loss. In addition to the previously demonstrated induction of proliferation, we then aimed to delineate a role of RKIP loss in myeloid lineage commitment. When studying healthy donors, we observed that RKIP expression was high in HSCs and lymphoid cells, but significantly decreased in cells belonging to the myeloid lineage (monocytes, P=0.001 and granulocytes, P<0.001). In functional experiments, knockdown of RKIP increased the GM-CSF-induced myelomonocytic lineage commitment of both, human and murine HSCs (P<0.05 and P=0.0295, respectively). These results could be corroborated in vivo, as intraperitoneal injection of GM-CSF caused a significant increase of myelomonocytic cells in the intraperitoneal cavity (P=0.006), bone marrow (P=0.007) and peripheral blood (P=0.027) in RKIP−/− mice when compared to their wildtype littermates. In a final step, we evaluated the potential of RKIP loss to cause CML-MPD in mice. While it proved to be insufficient to cause the disease as a single event in RKIP−/− mice, it aggravated the CML-MPD phenotype in animals carrying an additional mutation in NRAS. In this case, the deletion caused worsening of leucocytosis (P=0.036) and splenomegaly (P=0.035), which was associated with increased levels of myelomonocytic cells in the bone marrow (P=0.028), peripheral blood (P=0.002) and spleen (P=0.025).

Summary/Conclusions: RKIP loss is a frequent event in CML and is associated with mutations affecting the RAS signaling cascade. Loss of RKIP is functionally involved in myelomonocytic lineage commitment of HSCs and aggravates CML-MPD development in mice carrying an additional mutation in NRAS.

S420 JAK2 V617F HAEMATOPOIETIC CLONES WITH DIFFERENT EXPANSION KINETICS ARE DETECTABLE SEVERAL YEARS PRIOR TO MPN DIAGNOSIS

T. Mckerrell1,2, N. Park1, J. Chi3, G. Collord4, T. Moreno5, H. Ponstingl6, J. Dias5, P. Gerasimou6, K. Melanthiou7, C. Prokopiou8, M. Antoniades7, A. Mead1

1MRC Molecular Haematology Unit, 2Computational Biology Research Group, 3Wellcome Trust Sanger Institute, Cambridge, United Kingdom. 4Department of Haematology, University of Cambridge, 5Wellcome Trust Sanger Institute, Cambridge, United Kingdom, 6The Center for the study of haematological malignancies (CSH)/Karaiskakio Foundation, Nicosia, Cyprus, 7Instituto de Biomedicina y Biotecnología de Cantabria (UC-CSIC), Santander, Spain, 8Cancer Molecular Diagnosis Laboratory, University of Cambridge, Cambridge, United Kingdom. 4Theselaboratories for the study of haematological malignancies (CSH)/Karaiskakio Foundation, 2Haematology, Nicosia General Hospital, Nicosia, 3Haematology, Limassol General Hospital, Limassol, Cyprus

Background: JAK2 V617F is the most common somatic mutation in the classical myeloproliferative neoplasms (MPNs) and is also frequent amongst healthy individuals with age-related clonal haemopoiesis (ARCH).

Aims: To investigate the pre-clinical clonal evolution of MPNs.

Methods: We identified 12 individuals with JAK2 V617F mutant MPN from whom blood DNA was available from the time of MPN diagnosis and also from an earlier time point of between 4.5-15.2 years previously (median 10.2 years) when blood was donated for registration to the Cyprus Bone Marrow Donor Registry. We used deep DNA sequencing to interrogate all 24 samples at 15 myeloid mutation hotspots including JAK2 V617F, using an established multiplex PCR/MiSeq sequencing protocol that reliably detects nucleotide substitutions present at a variant allele fraction (VAF) ≥0.008. Additionally, for 12 samples with sufficient DNA available, we performed targeted DNA capture for all exons of 41 genes routinely mutated in myeloid neoplasms using a custom RNA-bait library followed by sequencing on Illumina HiSeq 2500. Finally, we genotyped archival Registry samples for the rs12343867 single nucleotide polymorphism (SNP) (G/T) linked to the JAK2 46/1 haplotype.

Results: Amplicon sequencing returned a median coverage of 6641 reads per nucleotide (nt) at the studied hotspots. This confirmed the presence of JAK2 V617F in all 12 diagnostic and 9 of 12 archival samples. The remaining 3 samples were JAK2 V617F negative at the sensitivity of our assay (VAF>0.008). The only other hotspot mutation identified was SRSF2 P95R in one patient, P3, whom had a diagnosis of myelofibrosis. Pulldown sequencing of all exons of 41 genes from 12 samples with sufficient DNA returned an average coverage of 1978 reads per nt and showed a close correlation in JAK2 V617F and SRSF2 P95R VAF quantitations with amplicon sequencing. The JAK2 V617F VAF at diagnosis differed between patients as expected, however the average rate of clonal growth also varied widely between individuals, ranging from 0.36 to 6.2% per annum (Figure 1). Targeted exon capture from 12 of 24 samples, only identified one co-mutation with a VAF >0.02, the SRSF2 P95R in patient P3. As this locus was also amplified by amplicon sequencing, we were able to quantify the SRSF2 P95R VAF both in the diagnostic and the archival DNA sample taken 12.6 years earlier. In the P3 diagnostic sample the VAFs for JAK2 V617F and SRSF2 P95R were similar (0.37 and 0.41 respectively) indicating that they co-occurred in most cells of the neoplastic clone. In the archival sample from P3, the SRSF2 P95R was detectable at a VAF of 0.06, however the JAK2 V617F was absent/undetectable at the sensitivity of our assay (VAF>0.008) indicating the SRSF2 P95R was the clone-founding mutation in this neoplasm. The genotyping results for the rs12343867 SNP revealed a tentative association in our small cohort between homozygosity for the risk allele (C) linked to the JAK2 46/1 haplotype and the average annual increase in JAK2 V617F VAF. This will need to be verified in larger studies.

Summary/Conclusions: Our findings reveal that JAK2 V617F neoplasms develop from clonal haematopoiesis over many years. The rate of clonal expansion of JAK2 V617F clones in the pre-clinical phase was highly variable and although it was tentatively associated with the 46/1 haplotype, the high variability observed suggests that other factors likely influence clonal progression.

S421 DISRUPTION OF HAEMATOPOIETIC STEM CELL HETEROGENEITY IN A MOUSE MODEL OF MYELOPROLIFERATIVE NEOPLASM

R. Norton1, C. Di Genua1, C. Booth1, A. Giustacchini1, B. Povinelli2, N. Gray2, E. Repeti2, E. Solleix3, L. Jamieson3, N. Tran1, A. Green4, S.E. Jacobsen5, A. Mead1

Background: The hematopoietic stem cell (HSC) compartment in mice encompasses a broad range of heterogeneous cell types including highly lineage-biased HSCs, such as platelet-biased HSCs (PMID:23934107). Myeloproliferative neoplasms (MPNs) are a heterogeneous spectrum of clonal hematopoietic disorders, that includes essential thrombocytopenia (ET), a MPN subtype usually presenting with isolated thrombocytosis. Most ET patients carry a gain-of-function point mutation in JAK2 (JAK2V617F), with several other collaborating hits reported to co-occur with JAK2V617F at lower frequencies, including loss-of-function mutations of the epigenetic regulator EZH2, which are more frequent in advanced MPN.

Aims: Although it is broadly accepted that MPNs are propagated by counterparts of HSCs, the impact of collaborating MPN-associated mutations arising in different HSC subsets remains unclear. We aimed to explore the possibility that platelet-biased HSCs might selectively promote development of an ET phenotype.

Methods: We generated a novel mouse model of MPN that carries a conditional knock-in of heterozygous human JAK2V617F (hJAK2V617F) and the conditional knock-out (KO) of EZH2 together with an inducible Mx1-Cre transgene. To analyse platelet-biased HSC subsets upon onset of the mutation(s), we also crossed the vwf-eGFP transgene, which is selectively expressed in platelet-biased HSCs.

Results: Compared to wild-type and single mutant mice, EZH2-KO hJAK2V617F mice showed increased platelet counts, including a subset of mice which became acutely unwell with an extreme thrombocytosis. Strikingly, in serial bone marrow (BM) transplantation assays, EZH2-KO fully rescued the previously described hJAK2V617F-associated transplantation defect (PMID:20489053). EZH2-KO hJAK2V617F BM recipients showed long-term serial engraftment that was fully restricted to the platelet and myeloid lineages with a persistent thrombocytosis and absence of lymphoid reconstitution. RNA-sequencing revealed upregulation of several signaling pathways, including Hedgehog, and increased inflammation associated gene expression in EZH2-KO hJAK2V617F HSCs. Unexpectedly in this mouse model of thrombocytosis, phenotypic analysis of the HSC compartment in the BM showed that vwf-eGFP+ve HSCs were selectively lost (fold change[FC]=0.12 p=0.009), while vwf-eGFP–ve HSC numbers remained unaffected (FC=1.06 p=0.88) in EZH2-KO hJAK2V617F mice. To assess a differential contribution of vwf-eGFP+ve HSCs vs vwf-eGFP–ve HSCs in the ability to propagate MPN, we sorted HSCs according to vwf-eGFP expression and transplanted them into recipient mice. Unlike their normal counterparts, which showed lymphoid-biased reconstitution, vwf-eGFP+ve HSCs from Ezh2-KO hJAK2V617F mice primarily gave rise to platelets and myeloid cells. In contrast, vwf-eGFP–ve HSCs from Ezh2-KO hJAK2V617F mice engrafted poorly without recapitulating the disease in recipients.

Summary/Conclusions: In this novel Ezh2-KO hJAK2V617F mouse model, Ez2-2 loss collaborates to worsen thrombocytosis and rescue the HSC function defect in hJAK2V617F mice. We also observed a striking disruption of phenotypic and functional HSC heterogeneity in Ezh2-KO hJAK2V617F mice with an unexpected and selective loss of vwf-eGFP+ve HSCs together with subversion of vwf-eGFP–ve HSCs towards platelet-myeloid lineage commitment. This previously undescribed disruption of HSC heterogeneity in myeloid malignancy together with the clonal advantage conferred to HSCs by EZH2-KO helps to explain how this collaborating mutation might promote the development of more advanced MPN.
Methods: Pts aged <18 years were recruited into 3 separate cohorts: (1) IM-resistant/intolerant CML-CP treated with DAS tablets 60mg/m² QD, (2) IM-resistant/intolerant CML-AP/BP or Ph+ ALL (enrollment closed early due to poor response), and (3) newly diagnosed CML-CP treated with DAS tablets 60mg/m² or DAS 72mg/m² powder for oral suspension (PFOS) QD for 1 year. PFOS dose was increased by 20% to match the exposure of the tablet in order to maintain efficacy based on the findings from a bioequivalence study in adults. Primary objectives were major cytogenetic response (MCyR) for CML-CP resistant/intolerant to IM and complete cytogenetic response (CCyR) for newly diagnosed CML-CP (MCyR >30% and CCyR >55% considered of clinical interest). Study cohorts were not designed to be comparative.

Results: From 145 pts enrolled, 130 were treated; 54% were aged ≥12-<18 years. Within the IM-resistant/intolerant group, 25 were resistant, 2 were intolerant, and 2 were undetermined. For pts with CML-CP (n=113), 48% of pts with IM-resistant/intolerant CML-CP and 73% with newly diagnosed CML-CP remained on treatment at the time of this analysis (table 1). Cumulative rate of MCyR for newly treated pts was 96.5% as 3 months, 97.2% for IM-resistant/intolerant CML-CP, and a cumulative rate of CCyR >55% was reached as early as 6 months for newly diagnosed CML-CP (table). Estimated progression-free survival (PFS) by 48 months was 78% for IM-resistant/intolerant CML-CP and 93% for newly diagnosed CML-CP (table). Reasons for progression were loss of MCyR (n=3 IM-resistant/intolerant; n=4 newly diagnosed), loss of complete hematologic response (n=2 each), and development of CML-BP (n=2 IM-resistant/intolerant; n=1 newly diagnosed). One death was reported in the IM-resistant/intolerant CML-CP cohort 1 year after stopping DAS (gastrointestinal bleeding). Adverse events (AEs) were consistent with reports in DAS-treated adults, except no DAS-related myelosuppression, edema/hypertension, or pulmonary arterial hypertension were reported here. Sensitiveness in a newly diagnosed pt was the only DAS-related AE that led to discontinuation.

Summary/Conclusions: Results from the largest prospective and registrational trial of pediatric pts with CML-CP demonstrate that DAS is a safe and effective treatment for pediatric CML-CP. Target responses to first- or second-line that DAS were met as early as 3 and 6 months, respectively, and deep responses were observed. Efficacy and safety of DAS in pediatric pts were similar to those observed in adults; however, unlike in adults, no cases of pleural/pericardial effusion were reported.

Figure 1.

Summary/Conclusions: The present 24 month RFS of 77% for the overall 24 months in patients in stable MR4 appears better than in any comparable study to date, and implies that the initial 12 months of dose reduction may be responsible, perhaps via improved compliance in the few months prior to stopping or through an as yet undefined mechanism.

ASSESSMENT OF IMATINIB 400MG AS FIRST LINE TREATMENT OF CHRONIC MYELOID LEUKAEMIA: 10-YEAR SURVIVAL RESULTS OF THE RANDOMIZED CML STUDY IV

LEUKEMIA: INITIAL RESULTS FROM THE BFORE TRIAL

S425 and gene expression associated with intrinsic vs extrinsic cellular resistance but not by treatment optimization. Faster response does not necessarily translate into better disease control.

Aims: To assess the efficacy and safety of BOS versus imatinib (IM) for first-line treatment of chronic phase (CP) CML in the BFORE trial (NCT02130557).

Methods: In this ongoing, multinational, phase 3, open-label study, 536 patients with newly diagnosed CP CML were randomized 1:1 to BOS 400mg once daily (n=268) or IM 400mg once daily (n=268 [3 not treated]). Informed consent was obtained from all patients. Per protocol, efficacy was assessed in a modified intent-to-treat (mITT) population of 487 Ph+ patients (BOS, n=246; IM, n=241) with the following prespecified subgroups: Ph+ patients and those with known Ph status and/or BCR-ABL transcript type were excluded from this population.

Results: After ≥12 months of follow-up, 78.0% of BOS and 73.2% of IM patients remain on treatment with median treatment durations of 14.1 months and 13.8 months, respectively. Major molecular response (MMR) rate at 12 months (primary endpoint) was significantly higher with BOS versus IM in the mITT population (47.2% vs 36.9%; P=0.02) as well as in the ITT population of all randomized patients (46.6% vs 36.2%; P<0.02). In the mITT population, time to MMR was shorter for BOS (hazard ratio=1.34 based on cumulative incidence; P=0.02). Rate of complete cytogenetic response (CCyR) by 12 months was also significantly higher with BOS versus IM (77.2% vs 66.4%; P=0.038); time to CCyR shorter for BOS (hazard ratio=1.38; P<0.001). Rate of BCR-ABL transcripts ≤1% (Intl. Scale) at 3 months was higher with BOS versus IM (75.2% vs 57.3%; P<0.001); rates of deep molecular response over time were also generally higher with BOS (Table). Results for molecular endpoints were similar in the ITT population. The only baseline characteristic identified as a significant predictor of MMR at 12 months besides treatment arm was Sokal risk group (high vs low; P = 0.0001 and intermediate vs low; P = 0.05 [mITT]). On-treatment progression to accelerated or blast phase occurred in 4 patients (1.6%) receiving BOS and 6 patients (2.5%) receiving IM in the mITT population. One BOS-treated and 4 IM-treated patients discontinued treatment due to progression to accelerated or blast phase. Among all treated patients, there were no deaths within 28 days of last dose of BOS and 4 with IM. Safety data for treated patients were consistent with the known safety profiles of BOS and IM. Discontinuation due to drug-related toxicity occurred with 12.7% of BOS patients and 10.4% of IM patients. Grade ≥3 adverse events were more frequent in BOS than IM (19.0% vs 15.2%), including anemia (19.0% vs 15.2%), neutropenia (18.0% vs 14.6%), and increased alanine (19.0% vs 15.2%) and aspartate (9.7% vs 6.8%) aminotransferase levels. Cardiovascular events were infrequent in both groups (all grades: 3.0%, 1.5%, and 0% BOS vs 0.4%, 1.1%, and 0.4% IM; grade ≥3: 1.5%, 0.5%, and 0% BOS vs 0%, 0%, and 0.4% IM).

Summary/Conclusions: Patients on BOS had significantly higher rates of 12-month MMR and CCyR and achieved responses faster than those on IM. Consistent with the known safety profile, higher incidences of gastrointestinal events and transaminase elevations were observed with BOS. Primary results from this study suggest BOS may be an important treatment option for patients with newly diagnosed CP CML.
CHRONIC MYELOID LEUKEMIA PATIENTS WERE NOT DIFFERENT IN MOLECULAR RELAPSE AFTER STOPPING IMATINIB IN MR4 WHERE AS DETECTABILITY OF BCR-ABL1 WAS DETECTED OR NOT - WHEN ADJUSTING FOR NUMBER OF CONTROL TRANSCRIPTS

Medizinische Klinik, Medizinische Fakultät Mannheim, Universität Heidelberg, Mannheim, Germany, 18Dept of Hematology, St Olavs Hospital, Trondheim, Norway

Background: With imatinib (IM), most patients with chronic myeloid leukemia (CML) achieve deep molecular responses. Six months after stopping tyrosine kinase inhibitor in deep response in the EURO-SKI trial, 61% of the patients were in major molecular remission (3-log reduction in BCR-ABL1 level) in major molecular remission (3-log reduction in BCR-ABL1 levels) (Mahon ASH 2016). Between patients with and without BCR-ABL1, the difference in RFS at 6 months was not significant when assessing BCR-ABL1 detectability at the MR4.5 level (at least a 4.5-log reduction in BCR-ABL1) (Pfirrmann ASH 2016).

Aims: For 91 of 448 patients of the EURO-SKI learning sample, the sensitivity to investigate undetectable disease at the MR4.5 level was not given. Aim was to determine whether RFS probabilities would be different when comparing detectable and undetectable disease at the MR4 level.

Methods: Detectability of BCR-ABL1 depends on the number of control gene transcripts. To reduce bias when comparing “MR4 detectable disease” (MR4 but still detectable BCR-ABL1 transcritps; i.e. 0.01- 0.0033% IS) and “MR4 undetectable disease” (MR4 without detectable BCR-ABL1; based on 10,000-31,999 ABL1 or 24,000-76,999 GUS8 copy numbers), two samples with similar sensitivity of identifying BCR-ABL1 were to be identified using propensity score (PS) matching (Rosenbaum, Rubin 1983). Apart from type (ABL1 or GUSB) and treatment (IM or placebo), results suggest little or no impact of control transcripts and other factors, results suggest little or no impact of detectability of BCR-ABL1 on RFS. Time in deep response seems to be more important. In daily routine, many labs produce reliable outcome at the MR4 but not always at the MR4.5 level. Discontinuation at the MR4 level, irrespective of detectability of BCR-ABL1 residual disease, appears safe, with a good chance of success when performed as in EURO-SKI. With PS matching, bias and differences but also power was reduced. To judge whether molecular response on the MR4 level is sufficient, further data is welcome.

With PS matching, bias and differences but also power was reduced. To judge whether molecular response on the MR4 level is sufficient, further data is welcome.
Background: Acute myeloid leukemia (AML) is characterized by rapid growth and block in differentiation of myeloid progenitors. The AML blast is defined by having “open” chromatin. We hypothesized that alterations of chromatin compartment may promote AML. Reversing those changes could represent a novel therapeutic approach.

Aims: Gain of chr2(q22) is the most common focal amplification in complex karyotype AML. HMGN1 is a chromatin-regulatory protein on 21q22 known to affect lymphoid development, and our preliminary data suggested that HMGN1 could directly mediate a myeloid differentiation block. Since HMGN1 is known to decompact chromatin and alter histone marks, our goal was to define and therapeutically target the mechanisms by which HMGN1 overexpression disrupts myeloid differentiation and promotes clonal dominance.

Methods: We immortalized bone marrow progenitors from wild-type (WT) or OE-HMGN1 mice (transgenic overexpressing HMGN1) with an estrogen receptor-HoxB8 fusion protein. Using exogenous estrogen to control nuclear translocation of HoxB8, we analyzed synchronized myeloid differentiation by flow cytometry, RNAseq, and TMT proteomic analysis. We performed MINT-Chip-seq (MNase Indexed T7-chromatin IP) to measure the histone marks H3K27ac, H3K27me3, H3K4me3 and total Histone H3. We also measured histone marks in hematopoietic stem and progenitor subpopulations in vivo. We performed competitive bone marrow transplantation with CD45.1 WT and CD45.2 OE-HMGN1 donors and measured the relative contribution to hematopoiesis over time.

Results: Synchronized differentiation in WT cells progressed over 6 days from myeloid progenitors to mature neutrophils and monocytes, analyzed by cell surface markers, morphology, and gene and protein expression. OE-HMGN1 cells proliferated faster and remained as undifferentiated myeloblasts (84% CD11b+Gr1+ in WT vs 4% in OE-HMGN1, p<0.002; Fig A). Gene set enrichment analysis revealed more similarity to undifferentiated hematopoiesis and leukemia signatures in OE-HMGN1 cells. MINT-Chip indicated a broader and locus-specific levels of H3K27ac in OE-HMGN1 cells (Fig B, upper panel), consistent with an increase in gene transcription, confirmed by RNA-seq. We found a specific increase in HoxA cluster expression in OE-HMGN1 cells, highest at HoxA7 and HoxA9, genes known to be important in AML pathogenesis. In agreement with gene expression, among the most differentially measured histone peaks genome-wide were higher H3K27ac at HoxA genes progenitors at all differentiation time points analyzed (Fig B, lower panel). Competitive trans-plantation demonstrated an advantage to OE-HMGN1 stem and progenitor cells. The clonal dominance of OE-HMGN1 over WT cells extended to all populations analyzed (long- and short-term HSCs, multipotent progenitors, CMP, GMP and MEP; Fig C) and to mature lineages (myeloid, B and T cells). MINT-Chip and MINT-Labeling studies revealed a marked increase in H3K27ac peaks at cell cycle and leukemia-related genes in the context of OE-HMGN1, H3K27 acetylation is catalyzed by the CBP/p300 histone acetyl transferase (HAT), suggesting that HAT inhibition could target leukemias with HMGN1 overexpression. Indeed, treatment of myeloid progenitors with the CBP/p300 inhibitor C646 rescued the differentiation block in OE-HMGN1 cells (93% CD11b+Gr1+ in WT vs 89% in OE-HMGN1, p<NS).

PIWIL4 ACTS AS A PIRNA BINDING, EPIGENETICALLY ACTIVE AND GROWTH REGULATORY PROTEIN IN HUMAN ACUTE MYELOID LEUKAEMIA

S. Bameza1,*, M. Mulaw1, N. Végil1, M. Feuring-Buske1, F. Zhou2, C. Rohde1, A. Aravin3, J. Hoell4, A. Kloetgen4, A. Borkhardt4, C. Plass5, C. Müller-Tidow2, V.P. Rawat1, C. Buske1

Background: PIwi proteins are critically important for maintaining the self-renewing stem cell population in lower organisms through epigenetic silencing of transposable elements via DNA methylation and H3K9me3 marks, in close interaction with a novel class of non-coding RNA called piwi interacting RNA (piRNA).

Aims: There are neither precise data on the function of Piwi proteins in human acute myeloid leukemia (AML), nor are there reports on expression of piRNAs in this disease. We employed functional techniques and NGS to understand the function of human PIWI-like protein, PIWIL4 and its association in AML.

Methods: We assessed the expression of human PIWIL genes in AML and healthy bone marrow cells using qRT-PCR. Murine stem progenitors were transduced with AML specific oncogenes to evaluate the effect on PIWIL expression. shRNA mediated knockdown (KD) of PIWIL4 was performed on AML cell lines (LKS) and primary cell line (THP-1). We performed ChIP-seq (MNase Indexed T7-chromatin IP) to map chromatin-binding sites of PIWIL4 and performed RNA-seq to analyze the transcriptome. We performed PAR-CLIP and microarray to identify piRNAs that physically bind to PIWIL4 and to test the impact of PIWIL4 KD on piRNA expression.

Results: Among the family of human PIWIL genes, PIWIL4 showed the highest expression level and was ubiquitously expressed in healthy hematopoietic stem/progenitors, mature lymphoid and myeloid cells. Importantly, PIWIL4 was aberrantly higher expressed in more than 89% of the AML patients (n=68; p<0.0001) compared to normal CD34+ BM and total BM cells (n=3). Overexpression of AML specific oncogenes in murine stem progenitors, within 96h post-transduction, induced a 6 to 8 fold increase in PIWIL4 expression compared to GFP control (n=3, p<0.0001). Knockdown (KD) of PIWIL4 in AML cell lines significantly impaired proliferation and clonogenic growth in vitro (n=3; p<0.001) and delayed onset of leukemia in NSG mice (n=8; p<0.0001). PIWIL4 KD in primary AML patient BM cells lead to 5-fold decrease in clonogenicity (n=3; p<0.001), but had no impact on clonogenicity of healthy stem progenitors in vitro (n=4). Western blot and ChIP-seq (n=2; MACS1.4, p<0.01, FDR<0.01) in THP-1 cell line revealed a marked global reduction in repressive H3K9me3 marks upon PIWIL4 KD. Over 500 promoter and 650 gene body associated loci exhibited loss of H3K9me3 marks. RNA-seq analyses revealed gene set enrichment analyses revealed ~4000 differentially expressed genes upon PIWIL4 depletion. 30% of the loci that lost H3K9me3 marks at promoters and gene body were differentially expressed in RNA-seq (fold>0.05, adj. p<0.01). These genes belonged to pathways associated with RNA metabolism, transcription and cell death. Moreover, these genes were enriched for binding sites of SETDB1, an H3K9me3 establishing histone methyltransferase (ENRICHR, p<0.01, FDR<0.01). Notably, using IP/LC-MS, PIWIL4 was found to associate with SETDB1 in 293T cells. 560 unique piRNAs were found to physically bind to PIWIL4 and 981 unique piRNAs were differentially expressed upon PIWIL4 depletion in THP-1 cells.

Summary/Conclusions: Thus, collectively, we could show for the first time that PIWIL4 expression is deregulated in human AML and acts as a piRNA binding, epigenetically active growth regulatory protein in human AML.

METTL3 CONTROLS TRANSLATION OF TARGET mRNAs BY N6 METHYLATION OF ADENOSINE RESIDUES IN THEIR CODING SEQUENCE AND CONSTITUTES A NOVEL THERAPEUTIC VULNERABILITY OF ACUTE MYELOID LEUKAEMIA

K. Tzelepis1,*, J. Barberi1, L. Pandoftis1, J. Shi2, S.C. Robson2, V. Migliori2, A.J. Bannister2, N. Han2, E. De Braekeleer4, H. Ponstingl5, C.R. Vakoc6, G. Valsesia1, T. Kozjakovic1

1Haematological Cancer Genetics, Wellcome Trust Sanger Institute, 2Gurdon Institute, Cambridge, United Kingdom, 3Perelman School of Medicine, University of Pennsylvania, Philadelphia, United States, 4Wellcome Trust Sanger Institute, 5Wellcome Trust Sanger Institute, Cambridge, United Kingdom, 6Cold Spring Harbor Laboratory, Cold Spring Harbor, New York, United States

Background: Acute myeloid leukaemia (AML) patient survival remains below 30% and there have been no major new anti-AML therapies for decades.
Aims: To identify novel therapeutic vulnerabilities of AML. Methods: A CRISPR-Cas9 drop-out screen was used to identify genetic vulnerabilities of AML. Downstream, we study the function of the RNA methyltransferase METTL3, a novel therapeutic vulnerability of AML. These included in-vitro and in-vivo validation of METTL3 as a therapeutic target using CRISPR/gRNA or shRNA, and investigation of its function using Chip-seq, RNA-IP-seq, ribosome footprinting (RFP) and bioinformatic analyses. Results: We performed a genome-wide CRISPR screen on AML cells from Flt3ITD+/−/RosαCas9/+ mice transformed with MLL-AF9 lentivirus and identified >1500 cell-essential genes of which ~250 were AML-specific and included many MLL-AF9 interactors and several putative RNA methyltransferase genes: METTL1, METTL3, METTL14 and METTL16 (Fig 1A). Focusing on METTL3, we show that its disruption with Cas9/gRNA promoted differentiation of murine and human MLL-AF9 AML cells and inhibited their growth in vitro and in vivo (Fig 1B), but did not affect primary murine haematopoietic stem/progenitor cells. To investigate METTL3 function we performed chromatin immunoprecipitation (ChIP) for METTL3 and H3K4me3 and identified 126 METTL3 peaks, localized mainly to promoters with bimodal H3K4me3. METTL3 binding was highest at transcription start sites (TSS) (Fig 1C) and the most enriched transcription factor motif at METTL3 sites was that for the NFκB complex. Using available ChIP-seq datasets we found that NFκB, NFκB, H3R2me2s, WDR5 and KLF9 showed strong co-binding with METTL3. Also shRNA knock-down (KD) of WDR5, led to reduced METTL3 binding to target genes SP1 and SP2. To investigate if/how METTL3 controls expression of target genes we first noted that their mRNA levels were unaffected by METTL3 KD. As METTL3 is an N6-methyladenosine (m6A) methyltransferase, we then performed RNAseq as IP with an m6A-specific antibody (m6A-IP). This identified >4000 METTL3-dependent m6A peaks on poly-A+ RNA. m6A peaks were seen on 72.4% of METTL3-bound gene transcripts and were located in the coding region (CDS) in contrast to STOP codon enrichment in the general transcriptome (Fig 1D). Also, METTL3-bound transcripts were enriched for the [GAG]n motif, which was almost always in the +2 reading frame (Fig1E). As this raised the possibility that m6A may regulate translation of these transcripts, we performed RFP on wild-type (WT) and METTL3 KD MOLM13 cells, to evaluate translational efficiency (TE). Strikingly, upon METTL3 KD, m6A-marked genes had increased TE whereas transcripts with METTL3 at their TSS had reduced TE (Fig1F). We then mapped ribosomal pausing sites on mRNAs from METTL3-bound TSSs and found that GAN codons were more occupied (paused) in METTL3 KD vs WT cells (Fig1G). To understand consequences at the protein level, we studied METTL3 targets SP1 and SP2. Remarkably, in contrast to their mRNA levels, SP1 and SP2 proteins were markedly reduced upon METTL3 KD (Fig1H). SP1 and SP2 targets including c-MYC, were also downregulated upon METTL3 KD and simultaneous SP1/SP2 gRNA KD markedly reduced proliferation of MLL-AF9/Flt3ITD−/− cells. A combination of ORAL ALTS TRANS RETINOIC ACID AND DANAZOL VS DANAZOL AS SECOND-LINE TREATMENT IN ADULT IMMUNE THROMBOCYTOPENIA: A MULTICENTRE, RANDOMIZED, OPEN-LABEL TRIAL F.-E. Feng1,2,3, M. Wang1,2,3, R. Feng4, J.-M. Zhang1,2,3, H. Jiang1,2,3, Q. Jiang1,2,3, J. Lu1,2,3, H. Liu4, J. Peng5, M. Hou6, J.-L. Shen6, J.-W. Wang7, L.-P. Xu1,2,3, K.-Y. Liu1,2,3, X.-J. Huang1,2,3, Y.-H. Zhang1,2,3

Background: Immune thrombocytopenia (ITP) is an autoimmune disorder characterized by increased platelet destruction and impaired platelet production. Despite decades of basic and clinical research, the treatment of severe, corticosteroid-resistant or relapsed disease remains a great challenge. Our preliminary study indicated the effectiveness of all-trans retinoic acid (ATRA) for ITP (Wang M, et al. ASH 2012, Abstract #3338). This has been coupled with previous discoveries of an immune-modulation effect of ATRA in ITP, including its role to induce changes in Treg cells (Ruan CQ 2016), and to correct the imbalance of aberrant macrophage polarization (unpublished data), indicating ATRA as a potential therapeutic regimen. Danazol has been used in the treatment of ITP for more than 30 years. Apart from its haemoapoietic stimulatory and immune-modulatory effect, it has recently been shown to reverse abnormal thrombopoiesis in patients with thrombocytopenia (Towsley DM 2016). The combination of ATRA and danazol may work synergistically based on the mechanism of action targeting both increased platelet destruction and insufficient platelet production. Aims: To investigate the efficacy and safety of ATRA plus danazol in patients with corticosteroid-resistant or relapsed ITP. Methods: A multicentre prospective study was performed in non-splenectomized corticosteroid resistant/relapsed ITP patients. Participants were at least 18 years of age, had a platelet count of < 30x10^9/L at enrolment, and did not achieve a sustained response to treatment with full-dose corticosteroids for a minimum duration of 4 weeks or relapsed during steroid-tapering or after its discontinuation. Written informed consents were obtained from all of the participants. The primary endpoint was a sustained response. The secondary endpoints included overall response, time of response, duration of response, incidence of bleeding symptoms and safety. Results: From 2012 to 2016, 130 consecutive patients were enrolled from 5 different tertiary medical centres in China. Thirty-seven patients were ineligible and excluded, leaving 93 patients randomized to the ATRA+danazol group (n=45) and the danazol group (n=48). At 12 months follow-up, sustained partial or complete response was achieved in 71.6% of patients in the danazol group, significantly higher than 47.2% for danazol monotherapy (<0.001). Additionally, 92.5% and 42.5% of patients receiving ATRA+danazol achieved at least one response (R), while only 58.3% and 11.1% of patients with danazol monotherapy achieved R and CR, respectively. In patients achieving CR or R, the median time to treatment response was 30.5 days with a peak platelet count of 155x10^9/L in the danazol+ATRA group compared with 49 days with a peak PLT of 69x10^9/L in the danazol group. Multivariate analysis revealed that the initial response at day 28 and the median ITP duration were the potential variables associated with a sustained response. There was no treatment-related death due to adverse events. One patient receiving danazol monotherapy died from intracranial haemorrhage 4 weeks after study enrollment.

Summary/Conclusions: Our findings demonstrate that the combination of ATRA and danazol is safe and effective in achieving a rapid and long-lasting response, making it a potential promising therapeutic option for patients with corticosteroid-resistant or relapsed ITP.
chain IIA (NNMHC-IIA), and represents the most frequent inherited thrombocyto-
penia worldwide. NNMHC-IIA comprises two distinct domains, the N-termi-
nal globular head domain (HD) and the C-terminal tail domain (TD), and
causative mutations hit either the HD or the TD. All patients present at birth
with macrothrombocytopenia and only some of them develop during life addi-
tional manifestations, including nephropathy often leading to end-stage renal
disease (ESRD), sensorineural deafness, and/or cataract. Thus, the search for
genotype-phenotype correlations in MYH9-RD has been an important
research topic since the identification of the disorder. In 2008, the analysis of
108 patients allowed to conclude that the mutations affecting the HD were
associated with evolution to early-onset ESRD and deafness, whereas the risk of
newborn manifestations was much lower for patients carrying mutations
of the TD. In 2014, raising to 255 the number of patients, we sug-
gested that evolution to juvenile ESRD associated only with the most frequent
among HD mutations, i.e. substitution of the arginine 702 (R702). Conversely,
the R702 substitutions were almost exclusively found in a distinct hydropho-
bic region at the interface between the SH3 and the motor domain (SH3/MD interface),
but they were associated with a much less severe evolution.

Aims: To improve prognostic assessment of patients with MYH9-RD.

Methods: All the consecutive patients enrolled in the Italian registry for MYH9-
RD until June 2016 were included. The association of MYH9 genotype with phenotype was assessed by a generalized linear regression model (event-free survival analysis).

Results: We enrolled 350 patients belonging to 199 MYH9-RD pedigrees.
Mutational screening allowed us to identify 6 novel causative mutations in the HD
in 6 different pedigrees. Interestingly all of these variants were localized in the
hydrophobic region of the SH3/MD interface. By raising the number of
patients with mutations in this region from 14 to 26, and increasing the obser-
vation time, we could demonstrate that the mutations in the SH3/MD interface
are associated with evolution to a milder phenotype, characterized by development of hearing impair-
ment only (“auditory” phenotype). Our study confirmed a genotype-phenotype
model for MYH9-RD that overcomes the previously reported dualism between
HD vs TD mutation.

Summary/Conclusions: Mutations in the HD of the NMMHC-IIA are almost
all localized in a specific region at the SH3/MD interface, which therefore rep-
resents a critical region for MYH9-RD pathogenesis. Most importantly, patients with
HD mutations developed into two different phenotypic subgroups: patients with
R702 substitutions were expected to develop early a severe and progressive
neurological syndrome, whereas mutations in the SH3/MD interface are associated with
mutation to a milder phenotype, characterized by development of hearing impair-
ment only (“auditory” phenotype). Our study confirmed a genotype-phenotype
model for MYH9-RD that overcomes the previously reported dualism between
HD vs TD mutation.

POSITION OF THE GFI1B ZINC FINGER MUTATION DECOUPLES CD34
EXPRESSION FROM ALPHA-GRANULE DEFICIENCY IN GF1B-RELATED
PLATELET DISORDERS

W. Stevenson1,*, D. Rabbolini1, M.-C. Morel-Kopp1, Q. Chen1, S. Gabrielli1,
C. Ward2
1Haematology, University of Sydney, Sydney, Australia

Background: GF1B is a transcription factor that plays an important role in
haematopoiesis. Families with a mutation of the fifth DNA-binding zinc-finger
domain (GFI1B-RD) experience bleeding and have a platelet phenotype charact-
ised by macrothrombocytopenia, increased CD34 expression and alpha-
granule deficiency.

Aims: To explore the function of other zinc finger domains of GF1B we have charact-
erised two unrelated families with a GF1B variant, C168F, predicted to disrupt the first Zn-finger domain and compare the phenotype with a previously
described pedigree with the H294fs mutation that disrupts the fifth Zn-finger
domain.

Methods: Clinical platelet phenotypes were determined by light and transmit-
sion electron microscopy and functional studies performed by light transmission
and whole blood impedance aggregometry. Platelet protein expression was
measured by flow cytometry and western blotting. DNA-binding of variants was
determined by gel mobility shift assays (EMSA) and changes in gene trans-
cription by luciferase assays. Cellular phenotypes were then studied in patient
specific IPSCs derived megakaryocytes. 

Results: Individuals with both C168F and H294fs are thrombocytopenic (mean platelet count =107 x10⁹/L, n=8) but lack the collagen induced aggregation defects and bleeding symptoms observed in individuals with H294fs (ISTH BAT, P=0.015). Alpha granule content observed by microscopy and quantitated by
western blotting of granule related proteins, P-selectin and fibrinogen, were
similar between C168F and control platelets and this was significantly greater
than that observed for the H294fs mutation (P<0.01). EMSA studies indicate
that the C168F variant retains the ability to bind DNA whereas the H294fs
mutation altering GFI1B Zn finger 1 cause thrombocytopenia with increased CD34 expression but these platelets retain rela-
tively normal alpha-granule content and function.

Summary/Conclusions: Mutations affecting GF1B Zn finger 1 cause throm-
boctopenia with increased CD34 expression but these platelets retain the
alpha-granule content and function of wildtype platelets. A mutation that alters the 5th Zn-finger domain is associated with
biphasic platelet phenotype, similar to that observed in patients with the H294fs
mutation. This highlights that additional zinc finger domains of GFI1B may
have a role in the pathogenesis of GF1B-RD that may be related to the distinct
clinical presentation associated with this disorder.
Results: Treatment.

≥50K/μL at 4 of 6 biweekly visits over Weeks 14-24; intermediate response to splenectomy, and 32% rituximab. Stable response (SR) was defined as a platelet count ≥50K/μL at 4 of 6 biweekly visits over Weeks 14-24; intermediate response to splenectomy, and 32% rituximab. Stable response (SR) was defined as a platelet count ≥50K/μL at 4 of 6 biweekly visits over Weeks 14-24; intermediate response to splenectomy, and 32% rituximab.

Background: ITP is characterized by autoantibody-directed platelet destruction mediated by activated monocyte Fc receptors which signal through spleen tyrosine kinase (Syk). A Phase 2 trial of the oral Syk inhibitor Fostamatinib (FOSTA) in 16 patients (pts) with refractory ITP provided preliminary efficacy and safety data (Podolanczuk et al., 2009).

Aims: To evaluate the efficacy and safety of FOSTA in adult cITP in 2 parallel, identical, multi-center, randomized, double-blind phase 3 studies (S047 and S048) of 24 weeks duration, followed by an open label study (S049).

Methods: 150 pts with 3 platelet count (cts) <30K/μL were enrolled (76 in S047, 74 in S048) with a 2:1 randomization to FOSTA 100mg or placebo bid, stratified by prior splenectomy and baseline platelet count <15K/μL. Sixty-one % of pts were female; median age was 54 (20-88); 93% were Caucasian; 93% had cITP; median disease duration: 8.5 y; median baseline platelet c: 16K/μL. Prior therapies received by pts included 94% steroids, 47% TPO-RAs, 35% splenectomy, and 32% rituximab. Stable response (SR) was defined as a platelet count ≥50K/μL at 4 of 6 biweekly visits over Weeks 14-24; intermediate response (IR) as at least 2 consecutive bi-weekly platelet counts ≥50K/μL both without rescue treatment.

Results: Across both studies, a SR occurred in 18/101 (18%) FOSTA vs 1/49 (2%) placebo pts (p<0.0001). The median platelet cts were 95K, 49K, 20.5K, and 17.5K/μL in SR, IR, non-responders (NR) and Placebo pts, respectively. In SR and IR, median time to first platelet count ≥50K/μL was 2 weeks. Age (< or ≥65 y), gender, baseline platelet c <15K/μL, prior TPO-RA or splenectomy did not substantially affect response. In S049, 941 (22%) pts newly treated with FOSTA have a SR, consistent with S047 and S048. Forty-four of 101 (54%) FOSTA pts and 14/49 (29%) placebo pts had a platelet count ≥20K/μL (p=0.005). Three of 18 (17%) SR and 1/11 (9%) IR to FOSTA compared to 26/72 (36%) NR and 22/49 (45%) of the placebo group received ≥1 rescue medication, respectively. In S047-048, serious bleeding occurred in 5.6% of the NR and 10.2% of placebo pts (p=0.007); 11 additional FOSTA and no placebo patients died. Most common AEs were: diarrhea (29% vs 15%), nausea (19% vs 8%), hypertension (20% vs 8%), ALT/AST increase (10% vs 2%). Serious AEs were reported in 13% FOSTA vs 21% placebo pts.

Summary/Conclusions: Fostamatinib substantially improves platelet cts in certain pts with heavily pre-treated, severe cITP of long disease duration. AEs are mostly mild or moderate in severity. Given its unique mechanism of action based on inhibition of Syk, FOSTA could, if approved, be an important alternative as single agent and be a useful component of combination therapy for pts with difficult to treat ITP.

The YING and YANG of JAK SIGNALING: LOSS OF USP9X BUFFERS JAK SIGNALING AND ENHANCES SURVIVAL OF CRLF2-JAK-STAT EXPRESSING B CELL PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA (CBL-ALL) OF MICE WITH GAIN OF JAK2 R683G

Background: Children with Down syndrome (DS) are prone to development of high risk B cell precursor (BCP) acute lymphoblastic leukemias (DS-ALL) that differ genetically from most sporadic pediatric ALLs. Chromosomal rearrangements causing increased expression of CRLF2, the receptor for thymic stromal lymphopoietin (TSLP), characterize about half of DS-ALLs. Aims: Understanding the pathogenesis of relapse of DS-ALL relating to their CRLF2 status.

Methods: Integrative genomic analysis of matched diagnosis remission and relapse DS-ALLs, pharmacological inhibition and genetic CRISPR mediated silencing.

Results: Genomic analysis of 25 matched diagnosis remission and relapse DS-ALLs revealed lesions affecting known driver genes in the samples. In 80% of the patients we detected activating mutations in genes whose protein products are involved in signaling, including receptors (CRLF2, IL7R, FLRT3), or downstream effector enzymes (JAK1/2, KRAS and NRAS). In contrast to a previous report, we observed that lesions in CRLF2 are early events during DS-ALL evolution, as is evident by its high allelic frequency, and are maintained at relapse. The genetic make-up of these DS-ALLs was characterized by enhanced RAS signaling coupled by mutations in chromatin remodeling genes, in particular CREBBP. In contrast to a previous report, we observed that lesions in CRLF2 are early events during DS-ALL evolution, as is evident by its high allelic frequency, and are maintained at relapse.

Summary/Conclusions: Integrative genomic analysis of matched diagnosis remission and relapse DS-ALLs, pharmacological inhibition and genetic CRISPR mediated silencing.

Discussion: The YING and YANG of JAK SIGNALING: LOSS OF USP9X BUFFERS JAK SIGNALING AND ENHANCES SURVIVAL OF CRLF2-JAK-STAT EXPRESSING B CELL PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA (CBL-ALL) OF MICE WITH GAIN OF JAK2 R683G transduced ALL cells. To test directly the effect of JAK inhibition, we treated CRLF2/JAK2R683G transduced cells with increasing doses of ruxolitinib, a JAK inhibitor currently in clinical trials for CRLF2-JAK-STAT ALLs. Strikingly while high doses (>2μM) were cytotoxic, low doses (0.25μM) enhanced the survival of CRLF2/JAK2R683G expressing ALL cells.

Summary/Conclusions: These observations suggest that genetic or pharmacological restraining of JAK-STAT signaling may be beneficial to leukemic B cell precursors by enhancing the fitness of JAK-STAT ‘driven’ ALL. This and the reduction of JAK-mutated clones at relapse suggest that the pharmacological effect of JAK2 specific inhibitors may be limited. Rather, combined signaling inhibitors or direct targeting of the TSLP receptor may be a useful therapeutic strategy for DS-ALL.
TNF RECEPTOR 2 IS REQUIRED FOR RIP1-DEPENDENT CELL DEATH IN LEUKEMIA

J. Aguadé-Gorgorió1,1, S. McM bord2,3, M. Dobay1, C. Mezzaterra1, G. Cario1, C. Eckert1, A. von Stackelberg2, M. Stanulla8, M. Schrappe4, J.-P. Bourquin1, B. Bornhauser1

Background: Persistence of residual leukemia cells, due to deficiencies in apoptotic programs, is a major driver of relapse. Activation of alternative non-apoptotic cell death pathways such as necroptosis represents an attractive strategy to eliminate residual leukemia cells and prevent relapse. We have previously shown that SMAC-mimetics (SM) potently induce cell death by simultaneous RIP1-dependent apoptosis and necroptosis in a subset of refractory acute lymphoblastic leukemia (B-ALL) patient-derived samples. The molecular signals that drive sensitivity to RIP1-dependent cell death remained elusive so far.

Aims: The aim of this project was to understand the mechanisms that determine the specific vulnerability to necroptosis in ALL.

Methods: To identify molecular determinants of sensitivity to SM, we correlated the gene expression profiles of 17 primary samples with high and low sensitivity to SM with the IC50 in response to two SM compounds, birinapant and LCL161. We confirmed the top scoring genes including TNF receptor 1 (TNFR1) and TNFR2 by quantitative RT-PCR in patient-derived xenografts. We further validated our results by quantifying the expression of the candidate genes in an independent cohort of relapsed primary B-ALL and by screening samples with different expression levels of TNFR1 and 2 for their response to SM in vitro. To assess the mechanistic role of TNFR1 and 2 in the response to SM, we generated knockout lines for TNFR1 and TNFR2 knockdown cells using the CRISPR/Cas9 gene editing technology, and evaluated their response to SM in vitro and in vivo using a CRISPR selection model. Additionally, we overexpressed TNFR2 and evaluated the cell death phenotype. To determine the mechanism of TNFR2-mediated sensitization to SM, we investigated the formation of the pro-death RIP1-TNFR1 complex in wild type versus TNFR2ko and in SM sensitive and resistant ALL by immunoprecipitation in primary ALL samples.

Results: Comparative gene expression profiling indicated a correlation of the expression of TNFR2 with sensitivity to SM in primary ALL. Using an independent cohort of relapsed ALL samples, we found that high TNFR2 expression predicted sensitivity to SM in an ex vivo model of the bone marrow. Deletion of either TNFR1 or TNFR2 using CRISPR/Cas9 in patient-derived ALL conferred resistance to treatment with SM in vivo in the xenograft model, indicating that TNFR1 and 2 are both functionally required for cell death. In agreement with an important role for TNFR2 in the response to SM, the overexpression of TNFR2 leads to increased sensitivity to the TNFR1/RIP1 death axis. On the mechanistic level, recruitment of RIP1 to TNFR1 is a key event in the activation of cell death, which is abolished in TNFR2-deficient leukemia and does not occur in SM resistant cases.

Summary/Conclusions: Taken together, our data reveal a novel function of TNFR2 in cell death signaling, as TNFR2 predicts sensitivity to SMAC mimetics and plays a key role in activating the TNFR1/RIP1 cell death pathway, which underlies the switch from RIP1-controlled cell death to cell death and characterizes a distinct vulnerability in ALL.

THERAPEUTIC TARGETING OF ONCOCENIC MYB ACTIVITY IN T-ALL

T. Pieters1,1, S. T’Sas1, J. Morscic1, F. Mathijsens1, K. Lemeire2, T. Hochepie2, B. Lintemans1, L. Reune1, J. Haigh1, G. Berx4, S. Goossens1, P. Van Vlierberghe1
1Center for Medical Genetics, Ghent University, 2Ghent University, Ghent, Belgium, 3Monash University and Alfred Health Centre, Melbourne, Australia

Background: T-lineage acute lymphoblastic leukemia (T-ALL) is an aggressive hematologic malignancy that accounts for 10%–15% of pediatric and 25% of adult ALL cases. The prognosis of T-ALL has gradually improved, however, the outcome of T-ALL patients with primary resistant or relapsed leukemia remains poor. Thus, further advances in the treatment of T-ALL require the development of effective and highly specific molecularly targeted antileukemic drugs. The proto-oncogene MYB (encodes c-MYB) is aberrantly activated in a subset of T-ALL patients through T-cell receptor driven translocations or genomic duplications of the MYB locus itself. Recently, a new genetic mechanism for the generation of oncogenic super-enhancers in malignant T cells was identified, and suggests a general role for MYB in the regulation of T-cell specific super-enhancer activity.

Aims: We want to identify the role of enhanced MYB activity in super-enhancer driven oncogenic transcription in the context of malignant T-cell development and investigate the in vivo role of cMyb in the initiation and maintenance of T-ALL.

Methods: To evaluate if cMyb could act as a bona fide oncogene in the pathogenesis of T-ALL, we developed a conditional R26-driven cMyb overexpression mouse model. For this, we used a targeting vector that contained a floxed stop cassette followed by the cMyb gene and a EGFP/luciferase reporter, which was subsequently targeted in mESCs using recombinase-mediated cassette exchange (RMCE).

Results: Here, we report a novel conditional Myb knockin mouse model (R26-Myb). To study the in vivo oncogenic capacity of Myb, we initially crossed this conditional Myb knockin model with Vav1Cre mice, in order to obtain hematopoietic specific expression of Myb and the EGFP/luciferase from the ROSA26-promoter. Notably, Vav1-Cre+/R26-Myb+/mice developed T-cell lymphomas with a median latency of 77 weeks, suggesting that Myb can act as a bona fide oncogene in malignant T-cell transformation (Figure 1A). Next, we crossed our Myb transgenic model with Pten conditional knockout mice, to allow comparative analysis of tumors with and without T-cell specific Myb expression. Genetic inactivation of Pten is frequently observed in human T-ALL, and T-cell specific deletion of Pten (using Lck-Cre) results in T-cell leukemia/lymphoma development with an average of 17 weeks. Using this strategy, we obtained mice that overexpress R26-driven cMyb and lack Pten in developing T-cells and found that cMyb expression synergizes with Pten deletion, resulting in fully penetrant and accelerated T-ALL formation (median survival of 84 days instead of 118; p = 0.0003; Figure 1B). Finally, we used this novel murine T-ALL model to identify new therapeutic strategies for MYB dependent T-ALL. Importantly, the tumor cells from the cMyb knockin mice are luciferase-positive and are therefore suitable for in vivo drug testing using bioluminescence. Using this model, we evaluated the in vivo anti-leukemic efficacy of a variety of small molecules and identified new drugs that impede Myb protein stability or Myb-mediated transcription in Myb driven tumorigenesis.
THE T-CELL LEUKEMIA ASSOCIATED RIBOSOMAL RPL10 R98S MUTATION ENHANCES JAK-STAT SIGNALING

Background: Several somatic ribosome defects have recently been discovered in cancer, yet their underlying oncogenic mechanisms remain poorly understood. Alterations in ribosomal protein genes RPL5, RPL10, and RPL22 have been described in ~20% of T-cell acute lymphoblastic leukemia (T-ALL) cases. Whereas RPL5 and RPL22 show heterozygous inactivating mutations and deletions, RPL10 contains a clear mutational hotspot at residue arginine 98 (R98), with 8% of pediatric T-ALL patients harboring this RPL10 R98S missense mutation.

Aims: Investigating the pathogenic role of the recurrent R98S mutation in ribosomal protein L10 (RPL10) in T-ALL.

Methods: A label-free quantitative proteomics experiment was performed to screen for differentially expressed proteins in engineered mouse lymphoid Ba/F3 cells expressing RPL10 WT or RPL10 R98S. Differences in protein expression were further validated in hematopoietic cells derived from a transgenic RPL10 R98S knock-in mouse model and in material derived from xenografted T-ALL patient samples.

Results: The differential proteome screen revealed overexpression of several Jak-Stat signaling components (Csf2rb/2, Jak1, Stat1, Stat3, Stat5a/b, and Stat6) in engineered RPL10 R98S mouse lymphoid cells, which we confirmed in hematopoietic cells derived from a transgenic RPL10 R98S mouse model. The relevance of this overexpression was illustrated by enhanced Jak-Stat pathway activation upon cytokine stimulation in RPL10 R98S lymphoid cells, as well as increased sensitivity of these cells to clinically used JAK-STAT inhibitors ruxolitinib and pimozide. RPL10 R98S positive leukemia patients likewise showed overexpression of IL7RA, Jak1 and Stat5, increased sensitivity to pimozide, as well as a mutually exclusive mutation pattern between RPL10 R98S and JAK-STAT lesions, suggesting that RPL10-R98S also modulates the cascade in human T-ALL. Programmed -1 ribosomal frameshifting (<1 PRF) recently emerged as a post-transcriptional mechanism regulating expression of cytokine receptors. We identified -1 PRF signals in mouse and human Jak-Stat genes and observed RPL10 R98S associated frameshifting reduction in several of these, which may contribute to their overexpression. Altered levels of -1 PRF can however only partially explain observed JAK-STAT protein expression changes, and transcriptional changes and altered protein stability.

are also involved. Indeed, our data point to altered proteasome activity and composition in RPL10 R98S cells, with upregulation of immunoproteasome specific catalytic subunits, which may explain the increased stability of particular proteins such as Jak1. Of further medical interest, RPL10 R98S cells showed reduced proteasome activity and enhanced sensitivity to the clinically used proteasome inhibitors bortezomib and carfilzomib.

Summary/Conclusions: We explored the molecular mechanism by which the RPL10 R98S mutation contributes to the pathogenesis of T-ALL. We propose a model in which R98S associated decreases in -1 PRF levels, combined with changes in the degradation of particular proteins and potential other mechanisms such as transcriptional regulation, leads to selective upregulation of the JAK-STAT cascade (Figure 1). Besides expanding the relevance of the JAK-STAT cascade in T-ALL and leukemia in general, our results have therapeutic potential since cells harboring the RPL10 R98S mutation are sensitized towards clinically used JAK-STAT and proteasome inhibitors.

NFATC3-PLA2G15 IS A NOVEL INTERGENICALLY SPLICED CHIMERA THAT IS ASSOCIATED WITH AGGRESSIVE T-ACUTE LYMPHOBLASTIC LEUKAEMIA BIOLOGY

J. Bond1,2,*, C. Trang-Quang3,4, A. Bergon5, M. Belhocine5, G. Hypolite1,2, W. Goma6, J. Ghysdael1,4, E. Macintyre1,2, N. Boissel6, S. Spiculiga6, V. Asnafi1,2

1Université Paris Descartes Sorbonne Cité, Institut Necker-Enfants Malades (INERM), Institut national de recherche médicale (INSERM) U1151, 2Laboratory of Onco-Haematology, Assistance Publique-Hôpitaux de Paris (AP-HP), Hôpital Necker-Enfants Malades, Paris, 3Institut Curie, PSL Research University, CNRS UMR 7594, 4Université Paris-Saclay, Orsay, 5Technological Advances for Genomics and Clinics (TAGC), INSERM U1090, Aix-Marsselle University UMR-S 1090, Marseille, 6Université Paris Diderot, Institut Universitaire d’HématoLogie, EA-3518, Assistance Publique-Hôpitaux de Paris, University Hospital Saint-Louis, Paris, France

Background: Transcriptional read-through of a single mRNA between contiguous loci, or cis-splicing of adjacent genes (cis-SAGE), results in transcription of intergenically-spliced chimeric RNAs (ISCs) in the absence of structural genomic changes. Recent advances in high-throughput RNA-sequencing analyses have permitted identification of aberrant ISC expression as a potential cancer driver, but knowledge of leukaemia-related ISC is lacking.

Aims: To examine whether cis-SAGE generates biologically important ISCs in T-acute lymphoblastic leukemia (T-ALL).

Methods: We performed RNA-sequencing of 12 cases of T-ALL and normal thymic RNA, and used targeted analysis pipelines to detect T-ALL-specific fusion chimeras.

Results: We identified 140 T-ALL-specific fusions, of which 55 involved genes located within 30kb of each other, in the same transcriptional orientation. This distance is consistent with that previously observed for cis-SAGE, suggesting that ISC expression is common in T-ALL. In total, putative ISCs were detected in 10/12 samples, with a median of 4 (range 0-15) per patient. We performed further analysis on the candidate ISC NFATC3-PLA2G15, which includes the Nuclear Factor of Activated T-cells (NFAT) family member NFATC3, a critical regulator of normal thymopoiesis and known modulator of T-ALL biology. We found that primary T-ALLs exhibited a wide range of NFATC3-PLA2G15 expression, while levels in normal tissue were either very low or undetectable. 5’ RACE PCR analysis of leukemic cDNA revealed that fusion transcription was initiated in exon 1 of NFATC3. We also performed array comparative genomic hybridization of 115 diagnostic T-ALL samples, and found no evidence of microdeletions that would result in NFATC3-PLA2G15 expression, providing strong evidence that NFATC3-PLA2G15 is a true ISC that is generated by cis-SAGE. We found that the NFATC3-PLA2G15 fusion had lower activity than wild-type NFATC3 in both luciferase reporter experiments and proliferation and survival complementation assays in NFAT-null all cell lines in vitro. Gene set enrichment analysis revealed that primary T-ALL blasts with elevated NFATC3-PLA2G15 levels had reduced transcription of canonical NFAT target genes in vivo, suggesting that these cases may have lower activity of normal physiological NFAT pathways. Strikingly, we found that higher NFATC3-PLA2G15 levels strongly correlated with both shorter time to leukemia development (p=0.01) and survival (p=0.003) in patient-derived T-ALL xenografts in immunodeficient mice. These findings were corroborated by survival analyses of human T-ALL patients treated as part of the Francophone multinational GRAALL-2003 and -2005 studies, as cases with the highest quartile of NFATC3-PLA2G15 expression had significantly reduced 5 year overall survival (52.6%, 95% CI 33.3% - 68.7%) compared with NFATC3-PLA2G15 low cases (69.8%, 95% CI 58.8% - 78.3%, p=0.047).

Summary/Conclusions: Our results suggest that ISC expression is common in T-ALL, and that high expression of the NFATC3-PLA2G15 ISC correlates with reduced canonical NFAT pathway activity and poor patient outcome.
**Thrombotic disorders**

**ASSESSING THE RISK-BENEFIT OF ANTICOAGULANTS IN ELDERLY PATIENTS WITH CANCER-ASSOCIATED VENOUS THROMBOEMBOLISM: A POPULATION-BASED STUDY**

A. G. Kristjansson1,2,3, A. Garg1,2,3, M. McCallum3, S. Dixon3, S. Y. Kristinsson1,3

*1Epidemiology and Biostatistics, 2Medicine, Western University, 3Institute for Clinical Evaluative Sciences, London, Canada*

**Background:** Cancer patients have a higher risk of venous thromboembolism (VTE) which conveys a higher subsequent mortality risk; conversely, they also have a higher risk for bleeding due to many factors including abnormal tumor anatomy and the use of chemotherapy agents with the associated risk for thrombocytopenia. However, the consequences of a recurrent VTE or a major bleeding event (MB) might be different in terms of mortality. As a result, the risk of VTE recurrence or a MB event might bear different weights. A previous systematic review has suggested that the case fatality rates of VTE recurrence and MB are similar. However, heterogeneity in study design, outcomes and in particular the types of populations included, limited the interpretation and applicability of the results. Clinical decision making uses estimations of risk and benefit for any given intervention. In the case of VTE, anticoagulants are the cornerstone of treatment having a proven benefit in reducing the risk of recurrent VTE events with an associated increase in the risk of bleeding. Therefore, determining the risk-benefit of anticoagulants might allow for better informed treatment decisions, in particular in a population at high risk for both ends of the spectrum. Therefore, herein we sought to estimate the risk and benefit of anticoagulant therapy in cancer patients developing a VTE using data from administrative databases.

**Aims:** To estimate the case fatality rates of VTE recurrence and MB, as well as the case fatality rate-ratio for MB and VTE recurrence in cancer patients developing a VTE treated with anticoagulants.

**Methods:** We conducted a retrospective population-based cohort study in Ontario, Canada using de-identified linked administrative healthcare databases housed at the Institute for Clinical Evaluative Sciences (ICES). We included patients over 65 years of age with a diagnosis of cancer defined using provincial, ICD-9 and ICD-10 codes for major malignancies and who developed a VTE event within 6 months of the initial cancer diagnosis. VTE was identified through a Cox proportional hazards model using a combination of diagnostic codes for deep vein thrombosis (DVT) and pulmonary embolism (PE) and codes identifying diagnostic procedures for VTE (i.e. ultrasound, CT pulmonary angiography, lung scintigraphy) within 7 days of each other. Recurrent VTE and MB events were assessed within 180 days from the index date. MB was identified using a previously validated algorithm and included upper and lower gastrointestinal and intracranial bleeding events. Treatment was classified based on the first available prescription within 7 days of the index VTE. We estimated mortality within 7 days of the VTE recurrence or MB events using an unadjusted Cox proportional hazards model and competing risk analysis. Ratios of the mortality for MB compared to VTE recurrence were calculated and 95% confidence intervals were estimated using non-parametric models.

**Results:** Between 2004 and 2014 there were 6967 VTE events identified in cancer patients over 65 years of age and treated with an anticoagulant. Mean age was 75 years, and 47.6% patients were women. Of all patients, 59.9% received prescriptions for LMWH alone, 15.3% for LMWH followed by warfarin, 22.1% for warfarin and 2.7% for rivaroxaban. At 180 days after the index VTE event there were 235 (3%) MB events and 1184 (17%) VTE recurrences. Within 7 days of the outcome event there were 26 (11%) deaths after MB and 6 (0.5%) after VTE. The mortality ratio for MB versus VTE was 21.8 (95% CI 9.53). In exploratory analyses we did not find differences according to type of anticoagulant prescription.

**Summary/Conclusions:** In this large, population-based, study based on more than 40,000 patients with NHL and almost 116,000 controls, we demonstrated that there is an increased risk of thrombosis in patients with NHL when compared to controls. This is true for all types of thrombosis. We therefore conclude that hypercoagulability seems to increase with diagnosis of NHL. Several factors may contribute to this prothrombotic state, including chemotherapy and other treatment related factors as well as the disease itself. Considering that the increase in the incidence of thrombosis was highest before and around the time of diagnosis for NHL patients, that indicates that the tumor itself may have a great impact on the hypercoagulability of these patients.

**RISK OF THROMBOSIS IN PATIENTS WITH NON-HODGKIN’S LYMPHOMA: A POPULATION-BASED COHORT STUDY**

A.M. Birgisdottir1,1,2, I.S. Sverrisdottir1, O. Landgren2, M. Björkholm3, S.Y. Kristinsson1,3

1Faculty of Medicine, University of Iceland and Landspitali University Hospital, Reykjavik, Iceland, 2Department of Medicine, Haukavita Hospital, Memorial Sloan –Kettering Cancer Center, New York, United States, 3Department of Medicine, Division of Hematology, Karolinska University Hospital and Karolinska Institutet, Stockholm, Sweden

**Background:** Lymphoma is a malignancy that originates in lymph nodes and lymphoid tissue. The main category of lymphomas is non-Hodgkin’s lymphoma (NHL), NHL comprise about 3% of all cancers in Sweden. Some are aggressive and fast growing, while others are more indolent and do not necessarily require treatment. It is well known that cancer increases the risk of thrombosis, especially as it promotes thromboembolism, but data are scarce on the risk of thrombosis in NHL patients.

**Aims:** The aim of this study is to evaluate the risk of thrombosis in NHL patients compared to controls and to study time trends in the risk of thromboembolism with recent advances in the treatment of these diseases.

**Methods:** The study population consisted of individuals diagnosed with NHL in Sweden 1980-2013 (n=40,354), and up to four matched controls (n=115,677). The risk of the first thrombosis was evaluated after the diagnosis of NHL (and corresponding date for controls) and the ones that occurred less than 30 days prior to diagnosis of NHL. Kaplan-Meier survival analysis was used to estimate the risk of thrombosis and a log-rank test performed to assess statistical significance. Cox regression analysis was used to calculate hazard ratios (HRs) and 95% confidence intervals (CI) (adjusting for age, sex, year of diagnosis, and previous history of thrombosis). Risk of deep vein thrombosis, pulmonary embolism and arterial thrombosis was evaluated. Arterial thrombosis was defined as cerebral infarct, transient ischemic attack, angina pectoris, myocardial infarction, and arterial embolism and thrombosis.

**Results:** NHL patients had a statistically significant increase in risk of any type of thrombosis compared to controls (HR: 1.58; 95% CI: 1.53-1.62). The risk was significantly increased for all three types of thrombosis; deep vein thrombosis (HR: 3.11; 95% CI: 2.95-3.39) and arterial thrombosis (HR: 1.20; 95% CI: 1.16-1.23). The risk of thrombosis did not change during the study period for the NHL patients. There was an increased risk of thrombosis for NHL patients when compared to controls, independent of previous history of thrombosis (HR: 1.64; 95% CI: 1.59-1.68) no previous history, HR: 1.43; 95% CI: 1.37-1.50 if previous history of thrombosis). The incidence of thrombosis for NHL patients started to increase about five months before the diagnosis of NHL, and reached its peak a month before diagnosis. The incidence stayed increased for the first year after diagnosis.

**Summary/Conclusions:** In this large, population-based, study based on more than 40,000 patients with NHL and almost 116,000 controls, we demonstrated that there is an increased risk of thrombosis in patients with NHL when compared to controls. This is true for all types of thrombosis. We therefore conclude that hypercoagulability seems to increase with diagnosis of NHL. Several factors may contribute to this prothrombotic state, including chemotherapy and other treatment related factors as well as the disease itself. Considering that the increase in the incidence of thrombosis was highest before and around the time of diagnosis for NHL patients, that indicates that the tumor itself may have a great impact on the hypercoagulability of these patients.

**COMPARATIVE ANALYSIS OF PREDICTIVE MODELS FOR THROMBOEMBOLIC EVENTS IN LYMPHOMA PATIENTS**

D. Antic1,2, N. Milić1,2, N. Nikolovski1, M. Todorovčić1, J. Bila1, P. Djurdjevic1, B. Andjelic1, V. Djurasinović1, A. Sretenović1, M. Smiljanić1, V. Vuković1, J. Jelčić1, B. Mihaljević1

1Clinic for hematology, Clinical Center of Serbia, 2Medical school Belgrade, Belgrade, Serbia

**Background:** Actual guidelines recommend Padua and Khorana score for thromboembolic (TE) risk estimation for cancer patients in general. These existing models are quite limited for designation of lymphoma patients for TE events, as their development is not based on features specific for hematological patients.

**Aims:** The aim of this study was to compare diagnostic performance of these suggested predictive models, as well as Thrombosis lymphoma (Tholy) score, developed by our group, which is more specific for lymphoma patients.

**Methods:** The study population included all consecutive patients with a confirmed diagnosis of non-Hodgkin lymphoma (NHL), Hodgkin lymphoma (HL), and chronic lymphocytic leukemia (CLL) were included. All patients who were treated in the Lymphoma Departments of Clinical Center Belgrade and Clinical Center Kragujevac in period from 2006 to 2014. Data for newly diagnosed and relapsed patients who had completed a minimum of one chemotherapy cycle were prospectively collected for all venous and arterial TE events from time of diagnosis to 3 months after the last cycle of therapy. Data for specific thromboembolic, gastrointestinal, and pulmonary events were collected. The Tholy score was developed by our group, which is more specific for lymphoma patients.

**Results:** The study population included 319 patients with NHL or CLL, 22 patients with HL, and 7 patients with other lymphomas. The Tholy score was divided based on a split-sample random method into the model developing and validation sets. The Tholy score was divided into tertiles, based on the distribution of predicted risk of thrombosis of the model developing set. The prediction performance of the Tholy score was not significantly different from Padua score, but it was better than the Khorana score, for the development and validation sets. For all three scores, the area under the curve (AUC) was significantly higher for the total population compared with the relapsed patients, and higher in the relapse group compared with the non-relapse group.
and validation cohorts. The ThroLy model was developed using data solely from a derivation cohort, which included 1236 patients. Variables were evaluated by univariate logistic regression analysis, while the model was developed using a stepwise multivariate logistic regression analysis. Once a final model was defined, patients were divided into low risk and at risk groups. The final model was assessed in the validation cohort (584 patients). The studied population was also divided, based on Khorana and Padua score, into low risk and at risk groups.

Results: The study population included 1820 eligible lymphoma patients. The mean patient’s age was 53.1 years (range, 15–87 years). Most patients (83%) were newly diagnosed and had advanced stage disease: Ann Arbor stage III, 14.7% and stage IV, 44%. A total of 778 patients (42.7%) had high-grade lymphoma; 351 (19.3%) had low-grade lymphoma; 266 (14.6%) had HL; 156 (8.6%) had other forms; and 269 (14.8%) had CLL/SLL. Of all the patients included in the study, 99 (5.4%) developed at least one TE during the follow-up period. There were 73 patients with venous TE (73.7%), and 25 with arterial TE (25.3%), while 1 patient had both. Patients with aggressive NHL had significantly higher rates of developing TE compared to patients with any other lymphoma type (RR=1.5; 95% CI for RR 1.1–2.4; p=0.027). The incidence of thromboembolism was 81 (5.3%) in the newly diagnosed patients and 18 (6.2%) in relapsed patients. Overall, 35.4% (35/99) of the patients with thromboembolism experienced the event before the start of chemotherapy. The majority of patients (64.6%) had TE events during chemotherapy or within 3 months after chemotherapy. For patients classified at risk according to ThroLy score in derivation cohort, the model produced negative predictive value (NPV) of 98.5%, positive predictive value (PPV) of 25.1%, sensitivity of 75.4%, and specificity of 87.5%. In validation cohort PPV for ThroLy score was 28.9%. Padua and Khorana score had PPV of 15.5% and 14.8% in derivation, and 11.5% and 14.8% in validation cohort, respectively.

Summary/Conclusions: Lymphoma patients are at increased risk of thromboembolic events but thromboprophylaxis in these patients is largely underused. ThroLy score is more specific for lymphoma patients than suggested Padua and Khorana score, but external validation in large prospective cohort studies is required.

Summary/Conclusions: The new e-alert system further increases the use of VTE prophylaxis in hospitalised cancer patients, although this was not associated with a reduction in the VTE incidence. A relevant number of VTE events occur despite prophylaxis with standard LMWH. Identification of risk factors for thromboprophylaxis failure is needed. This work has been funded by a biomedical research grant with the Laboratory of Pharmaceutical ROVI and an aid to the research projects of the Instituto de Salud Carlos III and the FEDER (PI13 / 01029).

S444

IMPACT OF A NEW ELECTRONIC ALERT SYSTEM (V2.0) FOR VENOUS THROMBOEMBOLISM PREVENTION IN HOSPITALISED CANCER PATIENTS

R. Figueroa1, A. Alfonso1, V. Sara1, M.C. Nicolás1, M. Marcos Jubilar1, J. López Picazo2, I. Gil-Bazó2, A. García-Mouriz2, J.A. Páramo1, J. Hermida3, R. Lecumberri3

1Hematology, 2Medical Oncology, 3Informatics Department, Clínica universidad de Navarra, 4Division of Cardiovascular Sciences, Centro de Investigación Médica Aplicada, Pamplona (Navarra), Spain

Background: Onco-hematologic hospitalised patients constitute a group at high risk of venous thromboembolism (VTE). Current clinical practice guidelines recommend prophylaxis with low molecular weight heparin (LMWH) during hospitalisation, unless contraindicated. However, its underuse is a worldwide problem. Electronic alert systems (e-alerts) can improve the use of appropriate thromboprophylaxis and reduce the incidence of VTE.

Aims: To evaluate the impact of a new version (v2.0) of our e-alert system for VTE prevention compared with the initial software version. Secondary endpoints try to identify predictive factors for prophylaxis use and thrombotic events.

Methods: Prospective study including consecutive adult cancer patients admitted to our centre. From April 2014 to June 2015 (first period) the initial e-alert system version remained operative and from July 2015 to December 2016 (second period) the new version was active. The v2.0 displayed a second warning that asked physicians about the reason why LMWH was not prescribed.

Results: 1251 patients were included, 782 patients in the first period and 469 in the second one (main clinical features are shown in Table 1). E-alerts v2.0 was associated with an increase of appropriate LMWH prophylaxis during hospitalisation (65.2% vs 72.2%; p=0.015). However, this improvement did not result in a reduction of VTE during admission or follow up (2.3% vs 2.3%; p=0.89). Interestingly, almost 80% of VTE events occurred despite LMWH use. No differences in the rate of major bleeding (2.8% vs 3.2%; p=0.83), and mortality (10.6% vs 14.3%; p=0.07) were observed, either. The main reason for not prescribing LMWH prophylaxis was bleeding risk, but in 17% of cases physicians did not consider that the patient really had a high VTE risk. No significant correlation was found between any of the clinical variables analyzed and the risk of VTE. Prophylaxis use was more frequent among patients with solid cancer (vs hematologic), advanced stage, active chemotherapy treatment and longer hospital stay.

Summary/Conclusions: The new e-alert system further increases the use of VTE prophylaxis in hospitalised cancer patients, although this was not associated with a reduction in the VTE incidence. A relevant number of VTE events occur despite prophylaxis with standard LMWH. Identification of risk factors for thromboprophylaxis failure is needed.

This work has been funded by a biomedical research grant with the Laboratory of Pharmaceutical ROVI and an aid to the research projects of the Instituto de Salud Carlos III and the FEDER (PI13 / 01029).

IDENTIFICATION OF A NEW AND RELATIVELY FREQUENT SERPINC1 GENE DEFECT CAUSING ANTIITHROMBIN DEFICIENCY HARDLY DETECTED BY CURRENT MOLECULAR METHODS: DUPLICATION OF EXON 6

M.E. De La Morena-Barrio1, B. de la Morena-Barrio1, J. Padilla1, R. Teruel1,2, S. Asenjo3, E. Wypasek4, A. Miñano1, V. Vicente1,2, J. Corral1,2

1Servicio de Hematología y Oncología Médica, Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arrixaca, 2Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Instituto de Salud Carlos III (ISCIII), Murcia, 3Servicio de Hematología, Hospital Clínico San Carlos, Madrid, Spain, 4The John Paul II Hospital, Krakow, Poland; Institute of Cardiology, Jagiellonian University Medical College, Krakow, Poland

Background: Antithrombin (AT) deficiency was the first thrombophilia described 50 years ago and so far the strongest one. Up to 78% of cases are explained by point mutations or small deletion/insertions in exons or flanking regions of SERPINC1 that are easily detected by sequencing analysis. A low proportion of cases (2%) is explained by gross gene defects, mainly deletions, which are detected by multiplex ligation-dependent probe amplification (MLPA) analysis. However, the molecular base of AT deficiency is unknown using current methods in 20% of cases.

Aims: To identify new SERPINC1 defects causing AT deficiency.

Methods: We studied 271 unrelated cases with AT deficiency. Functional and biochemical assays characterized plasma AT. Genetic analyses involved Sanger and Next Generation Sequencing (NGS) (PGM, Ion Torrent), MLPA and specific PCR designs.

Results: Sanger sequencing of PCR amplicons with primers flanking the 7 exons and further analysis with SeqscapeTM detected pathogenic mutations in 173 cases. Whole gene sequencing identified 5 mutations in regulatory regions. MLPA analysis revealed 5 cases with whole or partial deletion of the gene. Moreover, 13 cases had disorders of glycosylation. Interestingly, the analysis of the PCR product and the electropherogram of exon 6 of a 42 year-old male patient (P1) with deep venous thrombosis and 75% of anti-FXa activity

haematologica | 2017; 102(s2) | 161
with no apparent gene defect by either Sanger sequencing of 7 exons or by NGS analysis of the whole gene using the Ion Torrent platform, revealed a 193 bp insertion, which corresponded to a tandem duplication involving exon 6. Family studies revealed the same duplication in 5 relatives, all with AT deficiency (60-75%). The first MLPA analysis of this case failed to detect the duplication and only after a fine readjustment, it was detected. MLPA analysis under the new conditions of the remaining 59 cases with unknown molecular base for their AT deficiency identified one additional case, P2, with potential duplication of exon 6. P2 was a 17-year-old female with 41% of anti-FXa activity, who developed deep venous thrombosis. Sanger and NGS sequencing also failed to detect any genetic defect in P2. A set of primers specific to detect tandem duplications of exon 6 was designed with forward primer from 3’ end of exon 6, and reverse primer from 5’ of exon 6. This set of primers only rendered amplification in the two cases with exon 6 duplication. The second patient (P2) had a new 863 bp duplication in tandem of exon 6. Sanger sequencing of the specific amplicons in the two cases with tandem duplication of exon 6 revealed Alu sequences surrounding these duplications. Finally, one out of 5 cases with gene deletions involved breakpoints affecting intron 5 (deletion of exons 2-5).

**Summary/Conclusions:** Our study identified a new and relatively frequent SERPINC1 gene defect causing AT deficiency that is hardly identified by current molecular methods: duplication of exon 6. This genetic defect was detected in 1% of our cohort, and represents nearly half of the total gross gene defects causing AT deficiency. The small size of this exon makes difficult the identification of this defect by MLPA. The presence of 6 Alu elements up and downstream exon 6 makes this region a hotspot for unequal recombination that may cause deletions, tandem duplications and potentially transpositions, which may produce AT deficiency (both severe and mild) by an aberrant splicing. We also developed a simple and specific method to detect duplications in tandem of exon 6.

**Background:** The epitHELial lining of the gastrointestinal (GI) tract represents the first line of defense mediating protection from microbial challenge. Next to producing antimicrobial molecules, Paneth cells contribute to this defense by providing a supportive niche for intestinal stem cells (ISCs) maintaining the epithelium. Loss of intestinal barrier function by total body irradiation (TBI) or chemotherapy (CTx) is an essential step in enhancing the development of intestinal graft-versus-host disease (GVHD). We hypothesized that activation of these pathways can initiate epithelial repair, we hypothesized that activation of these pathways during conditioning therapy may protect epithelial integrity and could be exploit ed interventionaly to promote intestinal barrier function and prevent GVHD.

**Aims:** We aimed at characterizing the role of RIG-I/MAVS and STING during allo-HSCT, and at understanding mechanisms by which activation of these pathways can promote barrier function to enhance healing after genotoxic tissue damage.

**Methods:** We used an integrated approach with pathophysiologic mechanistic studies on IECs in experimental mouse models (MHC-mismatched and minor histocompatibility antigen (miHA)-mismatched transplants to model highly aggressive GVHD; genotoxic stress induced by TBI and CTx) and evaluation of immune-mediated regenerative strategies to promote epithelial barrier function (organoid cultures, barrier function test)

**Results:** Mice lacking MAVS were more sensitive to total body irradiation (TBI)- and chemotherapy induced intestinal barrier damage, and, like RIG-I-deficient mice, developed worse graft transplantation (allo-HSCT). This phenotype was not associated with changes in the intestinal microbiota, but with reduced epithelial integrity and regeneration. Conversely, targeted activation of the RIG-I pathway during damage promoted these processes and ameliorated GVHD. Mechanistically, IFN-I (RIG-I-induced or recombinant) could promote growth of intestinal organoid cultures and production of RegIIIγ. Importantly, our findings were not confined to RIG-I/MAVS signaling, as interventional engagement of the STING pathway also protected from loss of barrier function and GVHD and led to IFN-I-dependent intestinal organoid growth. Consistent with this, STING-deficient animals suffered from worse GVHD.

**Summary/Conclusions:** Our studies may have the potential to develop novel targeted therapies (i) to promote intestinal barrier integrity, (ii) to prevent the development of GVHD, and (iii) for the regenerative response of other tissues.
T cells were isolated, again with different tissue specificities. In addition, also 11 HLA-DPB1*03:01 reactive cells could be isolated which all recognized biliary epithelial cells with or without co-stimulation. From patient 4, 26 HLA-DPB1*01:01 reactive T cells recognized only hematopoietic target cells, whereas other clones again showed recognition of GVHD target cells with differences in tissue specificity. 32 HLA-DPB1*04:01 reactive T cells were found in all 4 patients. A total of 33 HLA-DPB1*04:01 reactive T cells were isolated from patient 1 who suffered GVHD of skin and colon, but not liver. Within these 33 clones, 3 clones recognized only hematopoietic target cells, 9 clones recognized hematopoietic, skin and colon derived target cells and 5 clones recognized hematopoietic and colon derived cells only. None of the T cell clones recognized biliary epithelial cells. From patient 2 total of 230 HLA-DPB1*03:01 reactive CD4 T cell clones were isolated, of which 27 recognized only hematopoietic target cells and 96 clones also recognized GVHD target cells with differences in tissue specificity. 32 HLA-DPB1*03:01 reactive T cell clones were found from patient 3, of which 6 recognized only hematopoietic target cells, whereas other clones again showed various tissue specificities. From patient 4, 26 HLA-DPB1*01:01 reactive T cells could be isolated which all recognized biliary epithelial cells with or without co-recognition of other target cells. In addition, also 11 HLA-DPB1*03:01 reactive T cells were isolated, again with different tissue specificities.

Summary/Conclusions: These results illustrate that donor CD4 T cells directed against mismatched HLA-DR show differential recognition of target cells including restriction-specificity for cells of hematopoietic origin. Donor CD4 T cells recognizing hematopoietic target antigens in the context of patient specific HLA-DR alleles can be used to mediate tumor specific immune responses after HLA 10/10 matched unrelated stem cell transplantation.

MESENCHYMAL STROMAL CELLS STIMULATE THE PROLIFERATION AND IL-22 PRODUCTION BY TYPE 3 INNATE LYMPHOID CELLS

Aims: To investigate if IL-C3s can contribute to the therapeutic effect of MSCs, we studied the interaction between MSCs and IL-C3s in vitro.

Methods: IL-C3s isolated from human tonsils were CellTrace-labeled and cultured with bone-marrow derived MSCs for 5 days in the presence of IL-2. Results: Co-culture with MSCs significantly enhanced the proliferation of IL-C3s and their IL-22 production. Reciprocally, IL-C3s promoted ICAM-1 and VCAM-1 expression on MSCs. These experiments revealed that the interaction is mainly dependent on cell-cell contact or close proximity of MSCs and IL-C3s. Addition of blocking antibodies against ICAM-1, VCAM-1, or their integrin ligands, did not affect IL-C3 proliferation, suggesting that IL-C3 stimulation is ICAM/VCAM independent. Soluble factors also contributed to the interaction, as IL-C3s proliferated slightly better in the presence of MSC culture supernatant compared to IL-2 only. Based on experiments with blocking antibodies, we found IL-7 to be the likely candidate for this effect.

Summary/Conclusions: We show that via cell-cell contact and IL-7, MSCs promote the proliferation and IL-22 production by IL-C3s in vitro, suggesting IL-C3s may play a role in the control of GVHD upon MSC therapy.

ABERRANT T CELL RESPONSES IN THE BONE MARROW MICROENVIRONMENT OF PATIENTS WITH POOR GRAFT FUNCTION AFTER ALLOGENIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

Aims: To compare the T cell subsets in the BM immune microenvironment, including Th17, Tc17, Th1, Tc1, Th2, Tc2 cells and regulatory T cells (Tregs), are involved in the pathogenesis of PGF remains to be explored.

Methods: This prospective nested case-control study enrolled 20 patients with poor graft function (PGF) after allo-HSCT, and 20 healthy donors (HD). Th17, Th1, Th1, Th2, Tc2 cells and regulatory T cells (Tregs), were involved in the pathogenesis of PGF remains to be explored.

Background: Poor graft function (PGF) remains a life-threatening complication following allogeneic hematopoietic stem cell transplantation (allo-HSCT), and the underlying mechanisms have yet to be elucidated. Considerable evidence from murine studies has demonstrated that effective hematopoiesis depends on the specific bone marrow (BM) microenvironment, where hematopoietic stem cells reside. In this regard, we previously reported that PGF patients had impaired BM endothelial and vascular microenvironment (BBMT 2013; BMT 2016; Oncotarget 2016; Blood 2016). Moreover, our pilot study showed that both CD4+ and CD8+ T cells were polarized towards a type 1 immune response in the BM microenvironment of PGF patients (N=10) compared to those in matched good graft function (GGF) patients (N=20) (BBMT 2016). Nevertheless, whether abnormalities of T cell subsets in the BM immune microenvironment, including Th17, Th1, Th2, Tc17, Tc2 cells and regulatory T cells (Tregs), are involved in the pathogenesis of PGF remains to be explored.

Summary/Conclusions: These results illustrate that donor CD4 T cells directed against mismatched HLA-DR show differential recognition of target cells including restriction-specificity for cells of hematopoietic origin. Donor CD4 T cells recognizing hematopoietic target antigens in the context of patient specific HLA-DR alleles can be used to mediate tumor specific immune responses after HLA 10/10 matched unrelated stem cell transplantation.

S450

HIGHER FREQUENCY OF SWITCHED MEMORY B CELLS PREDICTS THE INCIDENCE OF CHRONIC GRAFT-VERSUS-HOST DISEASE AFTER ALLOGENEIC STEM CELL TRANSPLANTATION

Aims: To investigate if IL-C3s can contribute to the therapeutic effect of MSCs, we studied the interaction between MSCs and IL-C3s in vitro.

Methods: In a randomized clinical trial we treat patients 3 months after T cell depleted alloSC from HLA 10/10 matched, HLA-DR mismatched, donors with 0.25-0.50 x 10^9/kg donor CD4 T cells to promote immune reconstitution. In 4 patients, Graft-versus-Leukemia reactivity and/or organ specific GVHD occurred after the infusion. To characterize the immune responses in these patients, in vivo activated T cells were clonally isolated and tested for reactivity against a panel of target cells, including patient and donor derived hematopoietic cells, third party hematopoietic cells as well as different GVHD target cells (patient skin fibroblasts, third party colon carcinoma cells, biliary epithelial cells and lung fibroblasts) expressing the mismatched, patient variant, HLA-DR molecule.

Results: Allo-HLA-DR directed CD4 T cells showing differential recognition of target cells were found in all 4 patients. A total of 33 HLA-DPB1*04:01 reactive CD4 T cell clones were isolated from patient 1 who suffered GVHD of skin and colon, but not liver. Within these 33 clones, 3 clones recognized only hematopoietic target cells, 9 clones recognized hematopoietic, skin and colon derived target cells and 5 clones recognized hematopoietic and colon derived cells only. None of the T cell clones recognized biliary epithelial cells. From patient 2 total of 230 HLA-DPB1*03:01 reactive CD4 T cell clones were isolated, of which 27 recognized only hematopoietic target cells and 96 clones also recognized GVHD target cells with differences in tissue specificity. 32 HLA-DPB1*03:01 reactive T cell clones were found from patient 3, of which 6 recognized only hematopoietic target cells, whereas other clones again showed various tissue specificities. From patient 4, 26 HLA-DPB1*01:01 reactive T cells could be isolated which all recognized biliary epithelial cells with or without co-recognition of other target cells. In addition, also 11 HLA-DPB1*03:01 reactive T cells were isolated, again with different tissue specificities.

Summary/Conclusions: These results illustrate that donor CD4 T cells directed against mismatched HLA-DR show differential recognition of target cells including restriction-specificity for cells of hematopoietic origin. Donor CD4 T cells recognizing hematopoietic target antigens in the context of patient specific HLA-DR alleles can be used to mediate tumor specific immune responses after HLA 10/10 matched unrelated stem cell transplantation.

EFFECTS OF AG-348, A PYRUVATE KINASE ACTIVATOR, IN PATIENTS WITH PYRUVATE KINASE DEFICIENCY: UPDATED RESULTS FROM THE DRIVE PK STUDY

1Dana-Farber Boston Children’s Cancer and Blood Disorders Center, Boston, United States, 2Allergy / Immunology, UTH ealth McGovern Medical School, Houston, 3Division of Pediatrics, Dana-Farber Cancer Institute, Boston, United States

Background: Pyruvate kinase (PK) deficiency is a congenital hemolytic anemia caused by deficiency of the glycolytic enzyme, red cell PK (PK-R). AG-348 is a novel, first-in-class PK-R activator under clinical development. This study presents preliminary results from the ongoing DRIVE PK study (NCT02476916), an open-label dose-ranging trial of AG-348 in transfusion-independent adults with PK deficiency.

Methods: After providing informed consent, patients were randomized to AG-348 50mg or 300mg orally twice daily (BID) for 6 months (Core Period). At the end of the Core Period, patients can continue on treatment for another 2 years in the Extension Period. Transfusion independence is defined as ≤3 units of red blood cells transfused in the 12 months preceding the first dose of AG-348 and no transfusions in the 4 months preceding the first dose. Patients are followed weekly for Weeks 1-3, every 3 weeks for Weeks 4-12, monthly for Weeks 13-24 and then every 3 months until the end of the study. Hormone and iron status are evaluated at Baseline, Week 12 and End of Core Period, and then every 6 months in the Extension Period.

Results: As of 18 Jan 2017, goal enrolment has been met and all 52 patients are evaluable for safety and efficacy; 24 have completed the Core Period and 23 are ongoing in the Core Period. Five patients discontinued from the Core Period, owing to adverse events (AEs) (n=2) or consent withdrawal (n=3). Of the 32 patients evaluable for efficacy at 23 Sep 2016, 15 (47%) had a maximal increase in hemoglobin (Hb) >1 g/dL. Hb responses were seen across a range of four doses, and were rapid and sustained. For a subset of patients (n=8), the rate of glycolytic metabolism in peripheral blood samples was assessed before and after treatment, and a positive correlation was observed between increases in glycolytic flux through the PK-R pathway and increases in Hb.

Summary/Conclusions: AG-348 is a novel, first-in-class PK-R activator undergoing clinical testing in patients with PK deficiency. The ongoing DRIVE PK study has now met goal enrolment of 52 patients, and data from these patients will be available at the time of presentation. Chronic daily dosing with AG-348 is well tolerated and has demonstrated clinically relevant, durable increases in Hb across a range of doses from <25mg BID to 300mg BID. These data highlight the potential of AG-348 to be the first disease-altering treatment for patients with PK deficiency.
Aims: The aim of this study was to make a worldwide inventory of all cases of PKD that have been treated by HSCT, and to evaluate indication, procedures employed, and outcome. Methods: This is an international case series. Queries were sent to national and international databanks and to physicians involved in HSCT on PKD patients. The latter were asked to complete a questionnaire on disease characteristics, pre-transplant condition, transplant regimen and post-transplant outcome. Two additional cases were reported from a recently published report (Kim. 2016. Bone Marrow Transplantation).

Results: From 1996 to 2016 a total of 16 PKD-patients were reported to have been treated by stem cell transplantation. Eight patients were treated in the EU and eight in Asian centres, respectively. No patient resulted to be transplanted in the US. Median age at transplantation was 6.5 years. (10 patients (62.5%) were <10 years; 6 (37.5%) >10 years), seven patients (43.8%) were splenectomized. Nine out of ten patients (90%) younger than ten years old survived transplantation, whereas two out of six (33.3%) patients older than ten survived. Patients younger than ten years old were less often splenectomized (p=0.001). All Asian patients (8/8) survived transplantation, whereas three out of eight European patients survived. Patients treated in Asian hospitals differed from European patients in that they were younger (p=0.001), less often splenectomized (p=0.041) and had a lower ferritin level (p=0.048). They were more often transplanted with peripheral blood stem cells (p=0.014) and more often conditioned on a cyclophosphamide (p=0.007) regimen.

Summary/Conclusions: This is the first study on outcome of HSCT in PKD patients. Due to the still relatively small number of cases no definite conclusions on the safety of HSCT in PKD can be drawn. However, we observed a better survival for patients transplanted before the age of ten. This difference could also explain difference in survival between patients transplanted in Europe versus Asia. The high rate of severe GVHD in this cohort is a reason for concern. The strong decline in survival of patients older than ten years of age indicates the need for very careful selection of HSCT-candidates.

Background: Pyruvate kinase deficiency (PKD) is the most common glycolytic enzyme defect causing hereditary non-spherocytic hemolytic anemia. PKD does not have a specific curative treatment. Therefore treatment is mainly supportive, consisting of regular red blood cell transfusions, splenectomy and chelation therapy for iron overload: phlebotomy (14) and/or Deferasirox (6) and/or Deferoxamine (6) and/or iron infusion. Hyperferritinemia and/or a chelation therapy were noticed for 26 patients among all cases. 71 patients (69%) were already followed for unexplained hemolysis. Results: Clinical features: Most of HX diagnosis was made in adults (median age 31.5 years, range 0-88), children less than 10 years representing only 21% of all cases. 71 patients (69%) were already followed for unexplained hemolysis. Haematologica | 2017; 102(s2) | 165

Results: This is the first study on outcome of HSCT in PKD patients. Due to the still relatively small number of cases no definite conclusions on the safety of HSCT in PKD can be drawn. However, we observed a better survival for patients transplanted before the age of ten. This difference could also explain difference in survival between patients transplanted in Europe versus Asia. The high rate of severe GVHD in this cohort is a reason for concern. The strong decline in survival of patients older than ten years of age indicates the need for very careful selection of HSCT-candidates.

Background: Dehydrated hereditary stomatocytosis, also called hereditary xerocytosis (HX), is a dominant non-spherocytic hereditary hemolytic anemia characterized by an increased leak of monovalent cations through the red cell membrane leading to dehydration and a shortened red cell survival. HX is difficult to diagnose because of its rarity and the heterogeneity in its clinical presentation. Aims: Our study aims to characterize the clinical and biological features at HX diagnosis in a retrospective series of 103 patients. Methods: HX diagnosis was based on the typical left-shifted curve of osmolar gradient ektacytometry performed at CHU Biérot from 1993 to 2016. All patients were from European origin. They were referred to our center for: chronic non-spherocytic hemolysis (30), thrombotic events after splenectomy (8), hyperferritinemia (15), hematologic investigations (3), and/or iron overload (1). Ten patients (9.7%) presented with thrombotic episodes in a family study (54) after diagnosis in a first-degree probands. PIEZ02 and KCNN4 were analyzed by Sanger sequencing of the exons and intron-exon junctions.

Results: Clinical features: Most of HX diagnosis was made in adults (median age 31.5 years, range 0-88), children less than 10 years representing only 21% of all cases. 71 patients (69%) were already followed for unexplained hemolysis. Haematologica | 2017; 102(s2) | 165

Summary/Conclusions: Treatment with crizanlizumab 5.0mg/kg appears to increase the likelihood of adult patients with SCD being SCPC event-free while on treatment, even in high-risk subpopulations. Crizanlizumab 5.0mg/kg was also effective in those who had experienced at least two SCPCs in the previous year despite taking HU, suggesting that this dose is effective as a disease-modifying agent that meets an unmet medical need.

| Genotype | HbSS | HbSp–thalassaemia, and HbSβ+–thalassaemia (n=12/66; 18.2%) groups. In each of the prior SCPC events, SCD genotype and HU use subgroups, a greater proportion of patients treated with crizanlizumab 5.0mg/kg were SCPC event-free compared with those in the placebo 2.5mg/kg or placebo arms (Table 1). In subpopulations considered to be at increased risk of experiencing a SCPC (patients with 5-10 SCPC events in the previous year and/or with the homozygous HbSS genotype), a higher proportion of patients treated with crizanlizumab 5.0mg/kg were SCPC event-free compared with those in the placebo arm (28.0% vs 4.2% and 31.9% vs 17.0%, respectively). Additionally, 33.3% of patients who were taking HU and treated with crizanlizumab 5.0mg/kg were SCPC event-free during the study, compared with 17.5% in the placebo arm, possibly suggesting an additive effect.

Summary/Conclusions: Treatment with crizanlizumab 5.0mg/kg appears to increase the likelihood of adult patients with SCD being SCPC event-free while on treatment, even in high-risk subpopulations. Crizanlizumab 5.0mg/kg was also effective in those who had experienced at least two SCPCs in the previous year despite taking HU, suggesting that this dose is effective as a disease-modifying agent that meets an unmet medical need.

mine whether ex vivo Hpx addition to human SCD sera would prevent NET formation.

Methods: Patient serum and plasma samples were obtained from 32 incidents of VOC in 24 adult SCD patients, with informed consent. Moreover, steady state samples were obtained at least 4 weeks after discharge from the hospital. Patients having had a blood transfusion in the 3 months prior to admission were excluded. NET formation by human neutrophils from healthy donors was studied using confocal fluorescence microscopy and staining for extracellular DNA with the cell nonpermeable dye Sytox Green. The presence of extracellular DNA that stains positive for citrullinated histone H3 confirmed the formation of NETs (Figure 1A).

Results: Indeed, we found that hemin (ferriprotoporphyrin IX) activated neutrophils to generate reactive oxygen species and release NETs, which was prevented by addition of plasma-derived Hpx. Moreover, exposure of neutrophils to sera from patients with SCD promoted NET formation, which was significantly enhanced during VOC. However, we observed that circulating free heme levels were elevated in SCD patient serum irrespective of disease state, and serum concentrations of Hpx were reduced in both VOC and steady state compared to healthy donor serum. Strikingly, addition of Hpx in supraphysiological concentrations failed to prevent the formation of NETs in all SCD sera tested. We and others (Chen et al. Blood 2014) have found that, in contrast to heme, protoporphyrin IX does not trigger NET formation, revealing that the iron atom is required for the release of NETs. This observation led us to investigate whether free iron may directly induce NET formation. When neutrophils were exposed to Fe-NTA or serum from a thalassemia patient with iron overload, NETs were formed. Scavenging of free iron by addition of the iron-chelator deferoxamine or the specific iron-binding protein apotransferrin prevented NET release (Figure 1B). Moreover, we found that sequestration of free iron prevented NET formation induced by a subset (6 out of 11 tested), but not all, sera of patients with VOC (Figure 1C and D). In addition, sickled red blood cells (RBCs) are known to bind to neutrophils in vitro. Here, we found that neutrophils released NETs in response to sickled RBCs, even in the presence of Hpx. By contrast, blocking of complement C5 activation completely prevented the formation of NETs when neutrophils were exposed to sickled RBCs (Figure 1E).

Summary/Conclusions: In summary, we observed that sequestration of free iron with these iron binding compounds may be explored therapeutically to prevent or treat VOC development in SCD. Finally, complement activation in the presence of sickled RBCs activates neutrophils to release NETs, which may also contribute to VOC and SCD pathogenesis. Therefore, anti-CS IgG may represent an alternative therapeutic strategy to prevent VOC in SCD.

New drugs for rescue in relapsed/refractory multiple myeloma

S456 PHASE 3 ELOQUENT-2 STUDY: EXTENDED 4-YEAR FOLLOW-UP OF ELOTUZUMAB PLUS LENALIDOMIDE/DEXAMETHASONE VS LENALIDOMIDE/DEXAMETHASONE IN RELAPSED/REFRACTORY MULTIPLE MYELOMA

(ABR), Redwood City, United States, 18University of Tübingen, Tübingen, Germany

Background: Elotuzumab is an immunostimulatory monoclonal antibody that targets SLAMF7, a glycoprotein highly expressed on multiple myeloma (MM) cells and natural killer cells. Elotuzumab exerts a dual effect, directly activating natural killer cells and mediating MM cell death via antibody-dependent cell-mediated cytotoxicity. In a 3-year follow-up of ELOQUENT-2 (NCT01239797), elotuzumab plus lenalidomide/dexamethasone (ELd) demonstrated a sustained 27% reduction in the risk of disease progression/death and an overall survival (OS) trend towards benefit compared with lenalidomide/dexamethasone (Ld) alone in patients with relapsed/refractory (RR) MM (Dimopoulos et al, ASH 2015).

Aims: To evaluate the long-term efficacy and safety of ELd following extended 4-year follow-up (median 46 months).

Methods: RRMM patients with 1-3 prior lines of therapy randomized 1:1 received ELd or Ld in 28-day cycles until disease progression/unacceptable toxicity or consent withdrawal. Co-primary endpoints were progression-free survival (PFS) and overall response rate (ORR); OS was a secondary endpoint (analysis not prespecified for this data cut) and safety an exploratory endpoint. Written informed consent was obtained for all patients.

Results: In total, 464 RRMM patients were randomized: 321 to ELd and 325 to Ld. At 4-year follow-up (data cut-off: Oct 18, 2016), nearly twice as many patients remained on ELd therapy vs Ld (17% vs 9%). With the extended follow-up, ELd demonstrated a sustained relative improvement of 50% in PFS rates vs Ld (21% vs 14%) and maintained reduction in the risk of progression/death of 29% for ELd vs Ld (all randomized patients: HR 0.71; 95% CI 0.59, 0.86). Patients with very good partial response (VGPR) (ELd 14% vs Ld 9% [29%]) had the greatest reduction (35%) in risk of progression/death (HR 0.65; 95% CI 0.46, 0.94). ORR was greater with ELd (79% vs 66%) and the duration of response benefit was maintained over time (HR 0.77; 95% CI 0.62, 0.95). Early separation of the Kaplan–Meier survival curves, which remained consistently separated over time, supports a sustained OS benefit in favor of ELd vs Ld (Figure). Grade 3-4 adverse events in >5% of patients were generally comparable between ELd and Ld arms—vascular diseases (10% vs 8%; mostly venous-related), second primary malignancies (SPMs; 9% vs 6%) and cardiac disorders (5% vs 8%); the exception was a
S457
A PHASE IB STUDY OF ISATUXIMAB PLUS POMALIDOMIDE (POM) AND DEXAMETHASONE (DEX) IN RELAPSED/REFRACTORY MULTIPLE MYELOMA (RRMM): RESULTS FROM A PLANNED SECOND INTERIM OVERALL SURVIVAL (OS) ANALYSIS OF ENDEAVOR

Summary/Conclusions: At 4 years, ELd has the longest median follow-up of an immune-oncology agent in MM. The data continue to show that adding elotuzumab to Ld results in durable long-term responses, clinically relevant improvement in PFS, sustained reduction in risk of progression/death, and a survival trend in favor of ELd. Overall, these data continue to support the durability of ELd. Updated safety and tolerability, including rate of SPMs, was consistent with previous findings despite longer exposure, with minimal incremental AEs compared with Ld therapy.

Background: Isatuximab (ISA) is a anti-CD38 monoclonal antibody, which kills tumor cells via multiple mechanisms. Here, we report preliminary data from the dose-escalation cohorts, and the first 3 patients (pts) of the expansion cohort, of a Phase 1b study of ISA plus Pom/Dex in pts with RRMM (NCCT02283775).

Aims: To evaluate combination therapy with ISA plus Pom/Dex in pts with RRMM.

Methods: Pts with RRMM (≥2 prior MM therapies, including lenalidomide and a proteasome inhibitor) were sequentially enrolled to ISA 5, 10, or 20mg/kg (4-weekly doses, then every 2 weeks until disease progression or intolerable toxicity) with Pom 4mg (Days 1–21) and Dex 40mg (Days 1, 2, 8, 9, 15, 16, 22, and 23 of 28-day cycles). An expansion cohort was initiated at ISA 10mg/kg (plus Pom/Dex) based on preliminary safety, efficacy, and PK data. Primary objective: Determine maximum tolerated dose (MTD). All patients were required to provide informed consent.

Results: 26 pts were analyzed (5mg/kg [n=8]; 10mg/kg [n=12]; 20mg/kg [n=6]). Median age 65 (42–80) yrs. Median 4.0 (2–11) prior treatment regimens, with 20 (77%) pts refractory to prior immunomodulatory drug therapy. At data cut-off (Nov 8, 2016), median duration of ISA therapy was 19.0 wks and 16 pts remained on treatment. 2 pts at 10mg/kg discontinued therapy due to adverse events (AEs) (grade [Gr] 5 perforated bowel; Gr 3 infusion-associated reaction [IAR]). Dose-limiting toxicities reported in 1 pt at each dose level (Gr 4 neutropenia; Gr 4 neutropenic infection; Gr 3 confusing state), and MTD has not been reached. Most common TEAEs, besides IARs, were fatigue (62%), diarrhea (23%), hypocalcemia (23%), and anemia (15%). Most frequent laboratory abnormalities (laboratory assessment) was neutropenia (Gr 3, 40%; Gr 4, 52%). Gr 3/4 thrombocytopenia was reported in 8 (32%) pts (Gr 3, 16%; Gr 4, 16%). IARs occurred in 12 (46%) pts (Gr ≥3 in 1 pt); only with 1st infusion in 9/12 pts (16 %) pts achieved at least PR (5, 8, and 3 pts at 5, 10, and 20mg/kg), including 1 CR, 8 VGPR, and 7 PR. Clinical benefit rate (mCR) was 73%. Median time to 1st response, 4.2 wks; median duration of response, 25.6wks. The PK parameters of ISA were not affected by co-administration with Pom/Dex.

Summary/Conclusions: The combination of ISA and Pom/Dex was manageable and clinically active in heavily pretreated RRMM. A Phase III trial of this combination therapy is planned.

S458
OVERALL SURVIVAL OF PATIENTS WITH RELAPSED OR REFRACTORY MULTIPLE MYELOMA TREATED WITH CARFILZOMIB AND DEXAMETHASONE VERSUS BORTEZOMIB AND DEXAMETHASONE IN THE RANDOMIZED PHASE 3 ENDEAVOR TRIAL

Summary/Conclusions: At 4 years, ELd has the longest median follow-up of an immune-oncology agent in MM. The data continue to show that adding elotuzumab to Ld results in durable long-term responses, clinically relevant improvement in PFS, sustained reduction in risk of progression/death, and a survival trend in favor of ELd. Overall, these data continue to support the durability of ELd. Updated safety and tolerability, including rate of SPMs, was consistent with previous findings despite longer exposure, with minimal incremental AEs compared with Ld therapy.

Background: Isatuximab (ISA) is a anti-CD38 monoclonal antibody, which kills tumor cells via multiple mechanisms. Here, we report preliminary data from the dose-escalation cohorts, and the first 3 patients (pts) of the expansion cohort, of a Phase 1b study of ISA plus Pom/Dex in pts with RRMM (NCCT02283775).

Aims: To evaluate combination therapy with ISA plus Pom/Dex in pts with RRMM.

Methods: Pts with RRMM (≥2 prior MM therapies, including lenalidomide and a proteasome inhibitor) were sequentially enrolled to ISA 5, 10, or 20mg/kg (4-weekly doses, then every 2 weeks until disease progression or intolerable toxicity) with Pom 4mg (Days 1–21) and Dex 40mg (Days 1, 2, 8, 9, 15, 16, 22, and 23 of 28-day cycles). An expansion cohort was initiated at ISA 10mg/kg (plus Pom/Dex) based on preliminary safety, efficacy, and PK data. Primary objective: Determine maximum tolerated dose (MTD). All patients were required to provide informed consent.

Results: 26 pts were analyzed (5mg/kg [n=8]; 10mg/kg [n=12]; 20mg/kg [n=6]). Median age 65 (42–80) yrs. Median 4.0 (2–11) prior treatment regimens, with 20 (77%) pts refractory to prior immunomodulatory drug therapy. At data cut-off (Nov 8, 2016), median duration of ISA therapy was 19.0 wks and 16 pts remained on treatment. 2 pts at 10mg/kg discontinued therapy due to adverse events (AEs) (grade [Gr] 5 perforated bowel; Gr 3 infusion-associated reaction [IAR]). Dose-limiting toxicities reported in 1 pt at each dose level (Gr 4 neutropenia; Gr 4 neutropenic infection; Gr 3 confusing state), and MTD has not been reached. Most common TEAEs, besides IARs, were fatigue (62%), diarrhea (23%), hypocalcemia (23%), and anemia (15%). Most frequent laboratory abnormalities (laboratory assessment) was neutropenia (Gr 3, 40%; Gr 4, 52%). Gr 3/4 thrombocytopenia was reported in 8 (32%) pts (Gr 3, 16%; Gr 4, 16%). IARs occurred in 12 (46%) pts (Gr ≥3 in 1 pt); only with 1st infusion in 9/12 pts (16 %) pts achieved at least PR (5, 8, and 3 pts at 5, 10, and 20mg/kg), including 1 CR, 8 VGPR, and 7 PR. Clinical benefit rate (mCR) was 73%. Median time to 1st response, 4.2 wks; median duration of response, 25.6wks. The PK parameters of ISA were not affected by co-administration with Pom/Dex.

Summary/Conclusions: The combination of ISA and Pom/Dex was manageable and clinically active in heavily pretreated RRMM. A Phase III trial of this combination therapy is planned.
and 11: 20mg PO/IV dexamethasone on Days 1-2, 4-5, 8-9, and 11-12) with or without daratumumab (18mg/kg IV once weekly in Cycles 1-3, every 3 weeks for Cycles 4-8, then every 4 weeks until progression). Patients who were refractory to bortezomib were excluded. Progression-free survival (PFS) was the primary endpoint. Minimal residual disease (MRD) was assessed at suspected complete response (CR) and at 6 and 12 months after first dose at 3 sensitivity thresholds (10−3, 10−4, and 10−5) using the ClonoSEQ™ next-generation sequencing (NGS)-based assay (Adaptive Biotechnologies, Seattle, WA).

Results: A total of 498 patients were randomized with median (range) age of 64 (30-88) years. Patients received a median (range) of 2 (1-10) prior lines of therapy; 66% of patients previously received bortezomib, and 21% were refractory to lenalidomide in their last prior line of therapy. After median follow-up of 13.0 months, DVD significantly prolonged PFS compared with Vd alone (median: 7.9 months, DVD: 18.3%; P<0.0001). Overall response rate (ORR; 84% vs 63%) and rates of very good partial response (VGPR) or better (62% vs 29%) were higher with DVD compared with Vd (P<0.0001 for all). MRD-negative rates were more than 4 times higher at all 3 sensitivity thresholds with DVD versus Vd: 18.3% versus 3.6% at 10−6 (P<0.0001), 10.4% versus 2.4% at 10−5 (P<0.001), and 4.4% versus 0.8% at 10−4 (P<0.01). MRD-negative patients had prolonged PFS compared with MRD-positive patients at 10−4 sensitivity threshold (Figure). At the clinical cut-off date, 37 (15%) deaths in the DVD group and 58 (24%) in the Vd group have been observed (HR, 0.63; 95% CI, 0.42-0.96), and follow up is ongoing. Thrombocytopenia was the most common grade 3 or 4 treatment-emergent adverse event (45% with DVD vs 33% with Vd). No new safety signals were reported after median treatment duration of 11 months with daratumumab. Updated efficacy and safety data with longer follow up will be presented at the meeting.

Figure 1.

Summary/Conclusions: DVD is superior to Vd in terms of PFS, ORR, depth of response, and MRD-negative rates, with no new safety signals reported. These updated data further support the use of DVD as a standard of care in R/R MM, with the greatest benefit observed in patients with 1 prior line of therapy.

S460

A PHASE 1B STUDY OF VENETOCLAX COMBINED WITH BORTEZOMIB AND DEXAMETHASONE IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA

1CHU de Nantes, Hotel Dieu–HME, Nantes, France, 2Mayo Clinic, Jacksonville, United States, 3Royal Melbourne Hospital and Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia, 4The University of Arizona Cancer Center, Tucson, United States, 5CHRU Lille, Hospital Huriez, Lille, France, 6Mayo Clinic, Rochester, 7AbbVie, Inc., North Chicago, United States, 8Peter MacCallum Cancer Centre, Melbourne, Australia

Background: Venetoclax (VEN) is a potent, selective, orally bioavailable small-molecular inhibitor of BCL-2. When combined, VEN can enhance the activity of bortezomib in multiple myeloma (MM) cell lines and xenograft models.

Aims: The objectives of the study are to evaluate safety and preliminary efficacy of VEN with bortezomib and dexamethasone in relapsed/refractory (RR) MM.

Methods: Phase 1b study of patients (pts) with R/R MM who received daily VEN (50-1200mg for dose escalation cohorts; 800mg in safety expansion) with standard bortezomib (1.3mg/m2 SC) and dexamethasone (20mg PO).

Results: As of 19Aug2016, 86 pts were enrolled. Median age was 64 years; 9 (14%) pts had t(11;14), 5 (8%) had t(4;14), 15 (23%) had del(17p), and 30 (45%) had del(13q) abnormalities. Median number of prior therapies was 3 (range: 1-13), with 39% of pts refractory to prior bortezomib, 14% to carfilzomib, 53% to lenalidomide, and 21% to pomalidomide. Median time on study was 5.9 months (range: 0.3-28.9). Forty-six (70%) pts discontinued, with 36 due to disease progression (PD). Common AEs in ≥30% of pts were diarrhea (46%), constipation (41%), thrombocytopenia (39%), nausea (38%), peripheral neuropathy (33%), and insomnia (32%). Common grade 3/4 AEs in ≥10% of pts were thrombocytopenia (29%), anemia (15%) and neutropenia (14%). Serious AEs in ≥2 pts were febrile neutropenia, thrombocytopenia, cardiac failure, pyrexia, influenza, lower respiratory tract infection, pneumonia, sepsis, acute kidney injury, respiratory failure, embolism, and hypotension. Dose-limiting toxicities were grade 3 cardiac failure in the 300mg cohort (possibly related to dexamethasone) and grade 3 thrombocytopenia during the first cycle in the safety expansion. No events of laboratory or clinical TLS were reported. Four deaths were due to PD and 1 due to respiratory syncytial virus infection. Overall response rate (ORR) for all pts was 67% (44/66); 28 (42%) pts achieved very good partial response (VGPR) or better (3 stringent complete response (sCR), 10 CR, 15 VGPR). Pts non-refractory to prior proteasome inhibitors (PI) or immunomodulatory drugs (IMiDs) had higher ORR than refractory pts (PI, 92% vs 32%; IMiDs, 82% vs 57%). Among pts refractory to any 2 or more (n=15), 3 or more (n=7), or all 4 (n=4) prior therapies (bortezomib, carfilzomib, lenalidomide, pomalidomide), ORR was 40%, 43%, and 25%, respectively. Median time to progression (~10 vs 3 months) and duration of response (~10 vs 7 months) were longer for pts not refractory to any of these therapies versus refractory pts. ORR for pts with or without cytogenetic abnormalities, respectively, was as follows: 78% vs 65% for t(11;14), 60% vs 67% for t(4;14), 47% vs 73% for del(17p), and 63% vs 69% for del(13q).

Summary/Conclusions: VEN combined with bortezomib and dexamethasone has an acceptable safety profile with promising anti-myeloma activity, and the highest response rates were observed in R/R MM pts who were not refractory to PI or IMiDs. These data support the ongoing phase 3 trial with this regimen in R/R MM.
Improving prognostication and front-line therapy in chronic lymphocytic leukemia

CYTOGENETIC COMPLEXITY IN CHRONIC LYMPHOCYTIC LEUKEMIA: DEFINITIONS, ASSOCIATIONS WITH OTHER BIOMARKERS AND CLINICAL IMPACT: A RETROSPECTIVE STUDY ON BEHALF OF ERIC

Summary/Conclusions: CK defined by the presence of ≥3 numerical and/or structural abnormalities should not be axiomatically considered unfavorable in CLL, representing a heterogeneous group with variable clinical behavior. High-CK with ≥5 chromosomal aberrations emerges as prognostically adverse, independently of clinical stage, IG somatic hypermutation and TP53 status. Prospective clinical validation is warranted before finally incorporating high-CK in risk stratification in CLL.

IS FOR THE TREATMENT OF CHOICE FOR IGHV MUTATED CLL WITHOUT POOR FISH CYTOGENETICS

Background: Chemoimmunotherapy (CIT) is the standard treatment for young and fit treatment-naïve patients with CLL. The median progression-free-survival (PFS) in patients treated with CIT is about 5-6 years and the overall survival (OS) is increased by 5-10% compared to those treated with chemotherapy only. Patients with mutated IGHV genes (M-CLL) and/or unfavorable cytogenetic alterations (i.e. del(17p)/TP53 mutation, and del(11q)) have a better outcome than those with unmutated IGHV genes (U-CLL) or poor FISH cytogenetics and show a plateau in survival curves, suggesting that a fraction of these patients may have a survival similar to general population. Nevertheless, the possibility that some M-CLL patients without unfavorable cytogenetics are overtreated is of concern because of the treatment toxicity related to CIT, particularly for frail patients.

Aims: The aim of this study was to analyse the outcome of M-CLL patients with no unfavorable cytogenetics according to the type of therapy.

Methods: We analysed 816 CLL patients from Sant Pau Hospital, Barcelona, Spain; Uppsala University Hospital, Sweden and IRCCS San Raffaele Scientific University, Milan, Italy for whom IGHV mutational status was available. Endpoints were OS and TFS.

Table 1.

Results: 488 patients had mutated IGHV genes (400 without unfavorable FISH cytogenetics; 26 had either del(11q) and/or del(17p), and in 62 cases FISH was not available) and 328 patients carried unmutated IGHV genes. The main clinical and biological characteristics at diagnosis are shown in Table 1. OS at 5 and 10 years was 93% (CI, 95-91) and 81% (CI, 85-77) for M-CLL cases and 78% (CI, 83-73) and 46% (CI, 52-38) for U-CLL cases (<0.05). TFS at 5 and 10 years was 78% (CI, 68-84) and 28% (CI, 33-23) and 10% (CI, 14-6) for M-CLL and U-CLL, respectively (<0.05). After a median follow-up of 8 years (range, 1-26), 424 patients [161 M-CLL (136 without poor-prognostic FISH cytogenetics, 13 with either del(11q) and/or del(17p) and 12 cases in whom FISH information was not available] and 263 U-CLL required therapy. Front-line treatments were administered by purine analogue (PA)-based therapy (n=83), alkylating agents (n=212), anti-CD20 moAbs with PA or bendamustine (n=75), anti-CD20 moAbs with alkylating agents (n=21), BCR-signal inhibitors or BCL2 antiprototipic agents (n=9), others (n=23), and unknown (n=1). The...

BENDAMUSTINE (B), FOLLOWED BY OBINUTUZUMAB (G, GA101) AND VENETOCLAX (A, ABT-199) IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA (CLL): CLL2-BAG PHASE-II TRIAL OF THE GERMAN CLL STUDY GROUP (GCLLSG)

P. Cramer1,*, J. von Tresckow1, J. Bahlo1, S. Robbrecht1, O. Al Saawi1, P. Langerbeins1, A. Engelke1, A.-M. Fink1, K. Fischer1, T. Seiler1, L. Fischer von Weikersthal1, H. Hebart1, K.-A. Kreuzer3, M. Ritgen1, M. Kneba1, C.-M. Wendtner1, S. Stilgenbauer1, B. Eichorst1, M. Hallek1

1Department I of Internal Medicine and German CLL Study Group, University Hospital Cologne, Cologne, 2Department III of Internal Medicine, University Hospital Munich, Ludwig-Maximilians University, Campus Großhadern, Munich, 3Gesundheitszentrum St. Marien, Amberg, 4Staufferklinikum, Schwäbisch-Gmünd, 5Department of Internal Medicine, University Hospital Cologne, Cologne, 6Department II of Internal Medicine, University Hospital Schleswig-Holstein, Kiel, 7Department of Hematology, Oncology, Immunology, Palliative Care, Infectious Diseases and Tropical Medicine, Klinikum Schwabing, Munich, 8Department III of Internal Medicine, University Hospital Ulm, Ulm, Germany

Background: Based on the theoretical “sequential triple-T” concept [Hallek M., Blood 2013; 122(23): 3723-34] of a tailored and targeted treatment aiming for total eradication of minimal residual disease (MRD), the GCLLSG designed the CLL2-BAG trial.

Aims: This prospective, open-label, multicenter phase-II trial investigates a sequential treatment with a B debulking, followed by G and A as induction and maintenance therapy in an all-comer population of physically fit and unfit, treatment-naïve (TN) and relapsed/refractory (R/R) CLL pts.

Methods: Pts with an absolute lymphocyte count (ALC) ≥25.000/µl and/or lymph nodes (LN) ≥5cm were to receive 2 cycles of B as debulking (70mg/m² d1 & d2 28 days), unless contraindicated. In the induction G (1000mg) was administered 3 times in cycle 1 (days 1/2, 8 & 15) and every 4 weeks in cycles 2-6. A was added in cycle 2 with a dose ramp-up (to 400mg daily) over 5 weeks and several safety precautions. In the maintenance therapy, daily intake of A was continued and G administered every 3 months until achievement of a MRD-negative complete response or for up to 24 months. The primary endpoint is the overall response rate (ORR) at the end of induction therapy; secondary endpoints include MRD evaluations, safety and survival parameters. This primary endpoint analysis is based on uncensored data, the final analysis will be presented at the meeting.

Results: Between May 2015 and January 2016, 66 pts were enrolled. Two R/R pts died of a sepsis and 1 TN pt discontinued due to toxicity during the first induction cycle; these 3 pts with <2 induction cycles were excluded from the analysis as predefined by protocol. 34 pts were treatment-naïve and 29 had R/R CLL (median number of prior therapies: 2, range: 1-8). Median age was 59 (28-77) years, the median CIRS score was 2 (0-14) and 16 pts (25%) had a creatinine clearance of 30-70ml/min. 11 of 59 pts (19%) had a del(17p) and 45 of 61 (74%) had an unmutated IGHV status. Risk categories for TLS at baseline were: low (ALC ≥25.000/µl & LN <5cm): 9 pts (15%), Intermediate (ALC ≥25.000/µl or LN 5-10cm): 35 (58%) and high (ALC ≥25.000/µl & LN >10cm): 16 (27%), 3 missing. 45 pts (71%) received B debulking, 18 (29%) pts immediately started with the induction. 60 pts completed 6 induction cycles with G and A. All TN (100%) and all but two of the R/R pts (93%) respond-
ed (table 1); with an ORR of 97%, at the end of induction, the primary endpoint was met. MRD negativity (<10−4) by flow cytometry in peripheral blood (PB) was achieved in 56 pts (89%); MRD assessment from bone marrow was available in 8 pts (4 TN and 4 R/R, among them 4 with a CR and 4 with a PR) and were all negative. As of January 9th, 2017, 38 serious adverse events (SAEs) were reported in 37 pts, including 69 SAEs (83%) related to study treatment. 66% of the SAEs (60%) were Grade 3-4 and 1 had a fatal adverse event (SAE, Grade 5). Most SAEs occurred in the R/R cohort (61 SAEs, 74%) and during the induction phase (63 SAEs, 76%). Most common SAEs were infections (27 in 16 pts; including 13 CTC°3-5) and hematological disorders (18 in 10 pts; CTC°3-4), followed by infusion-related reactions (6 in 6 pts), laboratory TLS (6 in 5 pts), diarrhea/colitis (4 in 4 pts), and transaminase elevation (9.8%). Serious adverse events were reported in 46 (45.1%), including pyrexia (10.8%), diarrhea/colitis (11.8%). AEs of special interest included serious adverse events as a result of therapy, however the frequency of Gr ≥3 ALT/AST was increased compared to the relapsed setting. There was no significant effect of age on the risk of ALT/AST elevations or diarrhea/colitis. The occurrence of CMV and PJP infections is consistent with current IDELA labeling and speaks to the benefit of potential risk mitigation through PJP prophylaxis and CMV monitoring during treatment. NCT02044822.

Aggressive Non-Hodgkin lymphoma - Relapsed/refractory

S466

CLINICAL AND BIOLOGIC COVARIATES OF OUTCOMES IN ZUMA-1: A PIVOTAL TRIAL OF AXIATABEGENATE CILOLEUC (AXI-CEL: KTE-C19) IN PATIENTS WITH REFRACTORY AGGRESSIVE NON-HODGKIN LYMPHOMA (NHL)

1In Lee Moffitt Cancer Center & Research Institute, Tampa. 2The University of Texas MD Anderson Cancer Center, Houston, Texas. 3Washington University, St. Louis. 4University of Miami, Miami. 5Stanford University, Stanford, 6Dana-Farber Cancer Institute, Boston. 7Montefiore Medical Center, Bronx, 8Vanderbilt University Medical Center, Nashville, 9City of Hope, Duarte, 10Mayo Clinic, Rochester, 11University of California at Los Angeles, Los Angeles, 12University of Rochester School of Medicine, Rochester, 13Kite Pharma, Santa Monica, United States

Background: Outcomes for pts with refractory aggressive NHL are poor with current therapies (Crump, ASCO 2016). Results from the interim analysis of (n=62) pts in ZUMA-1, a global, phase 2 study of CC-122 in combination with obinutuzumab (GA101) showed a manageable safety profile. 80% of pts entered the ZUMA-1 study with poor prognosis NHL. In pts with refractory aggressive NHL, the ORR was 89% in pts with refractory aggressive NHL and 68% in pts with refractory indolent NHL in ZUMA-1 (pregun). A phase 3 study of CC-122 in combination with obinutuzumab is ongoing. Here we present results from the primary analysis of the ZUMA-1 trial.

Aims: Here we present results from the primary analysis of the ZUMA-1 trial. Methods: Pts received a target dose of 2 × 106 anti-CD19 CAR T cells/kg after low-dose conditioning with cyclophosphamide and fludarabine. Eligible pts (218 y) with large B cell lymphoma (DLBCL), primary mediastinal B cell lymphoma (PMBCL) or transformed follicular lymphoma (TFL); an ECOG performance status (PS) 0-1, and refractory disease (progressive or stable disease as best response to last prior therapy, or relapsed ≤12m of autologous stem cell transplant [ASCT]). The primary endpoint for this analysis was ORR in the combined DLBCL, PMBCL, and TFL cohort. Used PS was duration of response (DOR), overall survival (OS), and frequency of adverse events (AEs). The primary analysis was triggered when 92 pts had at least 6m of follow-up.

Results: As of January 27, 2017, 111 pts from 22 institutions were enrolled: 101 pts (91%) received axi-cel. Median age was 58 y (range, 23-76), 67% male, 85% stage III-IV, 47% PS 0-1, 77% refractory to ≥2nd line of therapy, and 21% relapsed <12m of ASCT. Axicel was successfully manufactured in 110/111 (99%) pts with an average turnaround time from apheresis to the clinic site of 17 d. With an ORR of 82% (n=92; P<0.0001) the study met the primary endpoint. The ORR in the mITT analysis set of 101 pts was 82% (CR 54%, PR 28%). was consistent across key covariates including disease subtype, refractory status, stage, and IPI score. At a median follow up of 8.7 m, 44% of pts were in response and 39% were in CR. The median DOR was 6.2m overall and not reached for pts who achieved a CR. Median OS was not reached; 80% of pts remained alive at 6 m. The most common Gr ≥3 treatment-emergent AEs were neutropenia (66%), leukopenia (44%), anemia (43%), febrile neutropenia (29%), diarrhea (27%), and encephalopathy (21%). Gr ≥3 cytokine release syndrome (CRS) and neurologic events (NE) occurred in 13% and 28% of pts, respectively. All CRS and NE resolved except for 1 gr1 memory impairment. As previously reported, there were 3 Gr 5 AEs (3%). Peak CAR T levels and AUC post-axi-CEL were associated with durable responses. Additionally, this pres-
Background: CC-122 is a cereblon modulating agent that degrades Aiolos and Ikaros, resulting in potent anti-lymphoma and immunomodulatory effects on T- and NK-cell function. Phase 1 clinical data revealed promising activity of CC-122 against follicular lymphoma (FL) and diffuse large B-cell lymphoma (DLBCL). Preclinical combination of CC-122 with obinutuzumab has shown synergism in FL and additive effects in DLBCL vs either single agent (Chiu, ASH 2015), supporting further study of this combination’s therapeutic potential.

Aims: The current phase Ib study (EUDRACT 2014-003333-26; NCT02417285) evaluates the safety and efficacy of CC-122 plus obinutuzumab in patients with relapsed or refractory (R/R) B-cell non-Hodgkin lymphoma (NHL).

Methods: Patients at study entry must have R/R CD20+ B-cell NHL after ≥1 prior regimens for FL/marginal zone lymphoma (M/ZL) and ≥2 regimens and/or ASCT for DLBCL. CC-122 was given orally (5 of 7 d) for 28-d cycles in escalating doses plus a fixed dose of intravenous obinutuzumab 1000mg on d2,8,15 of cycle (c1) and d1 of c2-c8, upon informed consent. CC-122 was continued until progressive disease (PD) or unacceptable toxicity. CC-122 active ingredient in capsule formulation (AIC) 1, 2, 3, and 4mg and CC-122 formulated capsules (F6) 3 and 4mg were evaluated in separate cohorts. Primary endpoints included safety and tolerability, non- tolerated dose (NTD), and maximum tolerated dose (MTD). Response was assessed using the international Cheson 2007 criteria every 2 cycles to c6, every 3 cycles to c12, and every 6 cycles thereafter.

Results: As of January 12, 2017, 34 R/R B-cell NHL patients with DLBCL (n=10), FL (n=15), or M/ZL (n=9) were enrolled. At study entry, median age was 60 y (26-81), most patients were male (86%), and Ann Arbor was extended stage III/IV in 76% of patients. Of the 18 DLBCL patients, 8 had transformed FL. Of the 16 FL/MZL patients, 44% relapsed in <12 months after first-line treatment. The median number of prior regimens was 4 (range, 1-11), and 13 (38%) patients had received prior SCT. One patient experienced a dose-limiting toxic effect (DLT) of grade 4 neutropenia (CC-122 dose level AIC 3mg); no dose was yet an NTD. Median CC-122 duration was 22 wks (range, 3-71) equivalent to 6 cycles (range, 1-18). CC-122 dose reduction or temporary interruption occurred in 10 (29%) or 26 (76%) of patients, respectively, primarily due to adverse events (AEs). Most patients (96%) had 1 wk of interruption due to AEs. The most common ≥10% grade 3/4 treatment-emergent AEs (TEAEs) were neutropenia (50%) and thrombocytopenia (21%). Fifteen patients (44%) had ≥1 serious TEAE, including 2 each of febrile neutropenia (related to CC-122), cytokine release syndrome (related to obinutuzumab), and pneumonia. Three deaths occurred during the study (2 PD; 1 AE). Overall response rate (ORR) was 59%, including 26% CR and 32% PR (Table 1). Median time to best response was 57 d, and median duration of response was not yet reached. In evaluable patients, 6-mo progression-free survival (PFS) was 63%.

Summary/Conclusions: The combination of CC-122 and obinutuzumab was well tolerated and demonstrates promising response rates and durable remissions in R/R patients with B-cell NHL. CC-122 doses of ≥3mg and obinutuzumab showed best response rates to date. The study is ongoing to establish the phase II recommended dose.

S468

POLATUZUMAB VEDOTIN PLUS BENDAMUSTINE AND RITUXIMAB OR OGINUTUZUMAB IN RELAPSED/REFRACTORY FOLLICULAR LYMPHOMA OR DIFFUSE LARGE B-CELL LYMPHOMA: UPDATED RESULTS OF A PHASE 1B/2 STUDY

M. Matasar1,*, A.F. Herrera2, M. Kamdar3, A. Mehta4, S. Assouline5, I. Fleury6, PHASE 1B/2 STUDY OR DIFFUSE LARGE B-CELL LYMPHOMA: UPDATED RESULTS OF A

Background: Transplant ineligible patients (pts) with relapsed/refractory (R/R) FL or DLBCL have poor outcomes. Polatuzumab vedotin (pola) is an antibody drug conjugate that targets delivery of the microtubule inhibitor MMAE to cells expressing CD79b. Pola + rituximab (R) previously showed promising responses in R/R FL and DLBCL, but data are limited to pola without substituting obinutuzumab (G) for R could improve outcomes. We report updated results from the Phase 1b/2 (P1b2) study evaluating pola + BR or BG in R/R FL and DLBCL and the expansion cohorts evaluating pola + BG in R/R FL and DLBCL (OmiciaTrials.gov NCT02257567).

Aims: The primary aim is to assess safety and tolerability of pola + BR/BG in R/R FL and DLBCL. Secondary aims include assessing safety and efficacy of pola + BG in an expansion cohort.

Methods: All pts provided informed consent to participate in the study and were treated with pola (1.5mg/kg) + B (90mg/m2) and R (375mg/m2) or G (1000mg) every 28 days (FL) or 21 days (DLBCL) for 6 cycles. Responses were assessed by modified Lugano criteria after 3 cycles, end of treatment (tx), and every 6 months for 2 years during follow-up (fu).

Results: As of 14 Nov 2016, 65 pts were enrolled: 24 pts (12 FL, 12 DLBCL) in P1b and 41 pts (20 FL and 21 DLBCL) in P2. In safety evaluable pts, FL pts (N=32) were median age 63 yr (37-86), 82% ECOG 0-1 and 63% Stage III/IV, 75% Stage I-IV, 2 (1-7) median lines of prior tx, 38% refractory to last tx, 3% prior transplant (BMT). DLBCL pts (N=32) were median age 66 (30-86), 88% ECOG 0-1 and 13% ECOG 2, 59% IPI 3-5, 75% Stage III/IV, 2 (1-7) median lines of prior tx, 15% prior transplant (BMT). DLTs were 16% and hypokalemia (9%). AEs led to study tx discontinuation in 5 pts. B was stopped in 2 pts due to Gr 3 thromboctyopenia. Of 4 deaths: 2 were PD and 2 were Gr 5 AEs, 1 tx related (PML), 1 tx unrelated. In DLBCL, 88% (28/32) had Gr 3/4 AEs and 41% (13/32) had serious AEs (SAEs). The only SAE occurring in ≥10% was infection (22%). The most common Gr 3/4 non-heme AEs were infection (16%) and hypokalemia (9%). AEs led to study tx discontinuation in 8 pts. There were 13 deaths: 9 PD, 4 AE (all unrelated to tx). Responses by modified Lugano 2014 criteria are shown in Table1. Median duration of response (DoR) (DoR) for FL P1b pts was 16 months (mo)(median fu 14.5 mo). Median DoR for FL P2 (median fu 6.5 mo) and DLBCL P1b/2 (median fu 13.7 mo P1b, 6.4 mo P2) have not been reached.

Summary/Conclusions: Updated evaluation of pola + BR shows promising durable responses and an acceptable safety profile in heavily pre-treated R/R FL and DLBCL pts. Safety and efficacy data will be updated at the time of presentation.

Background: Patients (pts) with persistent DLBCL after two or more lines of therapy have limited effective treatment options. The nuclear export protein exportin1 (XPO1) is upregulated in hematologic malignancies, including DLBCL, and has pleiotropic effects on tumorigenesis including functional downregulation of tumor suppressor proteins (TSPs) and increased export and translation of mRNAs for oncoproteins c-Myc and key survival proteins such as Bcl-2. Selinexor (SEL), an oral XPO1 inhibitor, causes sequestration of TSPs including p53, p21, and IκBα, the latter of which serves to suppress NF-κB transcription, along with reductions in c-Myc and Bcl-2 family proteins. In a Phase I clinical study, pts with relapsed/refractory (R/R) DLBCL treated with SEL presented an overall response rate (ORR) of 32% including 4 CRs. Interestingly, 2 of these pts remain in CR for >1 year.

Aims: In this clinical study we assess the efficacy of single agent SEL in pts with R/R DLBCL, after two or more regimens.

Methods: Pts with R/R DLBCL were randomized to 60 or 100mg of SEL twice weekly (8 doses) per 28-day cycle. Pts were stratified by DLBCL subtype (GCB or non-GCB). The primary objectives are to determine the ORR and evaluate the safety of 60 vs 100mg doses. Disease response was assessed by an Independent Central Radiological Review (ICRR), using the Lugano Classification (Cheson, 2014).

Results: 72 pts were enrolled: 37 pts on 60mg (24 M/13 F, median age 71 yrs) and 35 pts on 100mg (23 M/12 F, median age 68 yrs). Both groups had a median of 3 prior treatment regimens. The most common related adverse effects (AEs) across both dose groups (Grade 3/4 AEs) were: fatigue (47%), nausea (46%), anorexia (42%), and vomiting (33%). Common Grade 3/4 AEs were: thrombocytopenia (39%), fatigue (18%), neutropenia (18%), and anemia (13%). These were managed with dose interruption/reduction, platelet stimulators, and/or standard supportive care. Grade 3/4 fatigue (26% v 11%) and thrombocytopenia (48% v 32%) were higher in 100mg arm as compared to the 60mg arm. Among the 63 evaluable pts (9 pts performing response), the ICRR determined ORR was 28.5% (Table 1). Nine responders, including 6 pts in CR, remain on treatment. Responders on the 60mg arm have a median time on treatment of 8.9 months as compared with 3.8 months on the 100mg arm.

Summary/Conclusions: SEL monotherapy shows activity in pts with R/R DLBCL including in pts with GCB subtype. 60mg SEL twice weekly was more tolerable than 100mg twice weekly, with fewer interruptions due to toxicity. Objective responses to SEL were durable at 60mg BIW, suggesting these responses were associated with clinical benefit.

S470

L-MIND: MOR208 COMBINED WITH LENALIDOMIDE (LEN) IN PATIENTS WITH RELAPSED OR REFRACTORY DIFFUSE LARGE B-CELL LYMPHOMA (R-R DLBCL)–A SINGLE-ARM PHASE II STUDY

K. Maddocks1,*, E. González Barca2, W. Jurczak3, A.M. Liberati4, J. Duell5, L-MIND: MOR208 COMBINED WITH LENALIDOMIDE (LEN) IN PATIENTS S470 were associated with clinical benefit. Tolerability responses to SEL were durable at 60mg BIW, suggesting these responses were endurable at 100mg twice weekly, with fewer interruptions due to toxicity. Objective responses to SEL were durable at 60mg BIW, suggesting these responses were associated with clinical benefit.

Background: The Fc-enhanced CD19 antibody MOR208 and the immunomodulatory drug LEN have demonstrated single agent activity in patients with R-R DLBCL. MOR208 and LEN have shown synergy in vitro and in vivo in preclinical lymphoma models.

Aims: This ongoing phase II study was designed to assess the safety and efficacy of MOR208 plus LEN in patients with R-R DLBCL.

Methods: Patients ≥18 years of age with R-R DLBCL. ECOG performance status 0-2, adequate organ function, having previously received at least 1 but not more than 3 prior therapies, including at least 1 CD20-targeting regimen and who are not candidates for autologous stem cell transplant (ASCT), are eligible.

Treatment comprises up to 12, 28-day cycles of MOR208 12mg/kg IV, administered weekly during cycles 1-3 (loading dose day 4 of cycle 1) and every second week during cycles 4-12 plus LEN 25mg administered po days 1-21 of each cycle. Patients progression-free after 12 cycles receive up to 12 additional cycles of MOR208 12mg/kg IV, administered every second week. The primary endpoint is the overall response rate (ORR) by central radiology assessment. Secondary endpoints include disease control, duration of response, progression-free and overall survival, safety, and response by cell of origin and other biomarkers. A preplanned safety evaluation was undertaken.

Results: 31 of 80 planned patients were enrolled prior to data cutoff (3 January 2017). Median age was 74 years (range 47–82); 45% of patients received ≥2 prior lines of therapy; 23% had rituximab refractory disease; 74% had Ann Arbor stage ≥III disease; 65% had elevated lactate dehydrogenase level, and 52% had a poor revised International Prognostic Index (3–5). The most common treatment-emergent adverse events (any grade) were neutropenia (39/26), anemia (23/0) thrombocytopenia (16/6), infections (26/10) diarrhea (13/0), pyrexia (13/0), and rashes (13/6). Of 26 response evaluable patients (median follow-up 3.3 months), ORR (investigator assessed) was 58% (15 patients), with 7 (27%) complete responses. Median time to response was 1.8 months.

Summary/Conclusions: The combination of MOR208 plus LEN is well tolerated and shows promising activity in patients with R-R DLBCL. Accrual and follow-up of patients is ongoing, as are cell of origin and other biomarker analyses.
ENASIDENIB (AG-221) IN MUTANT-IDH2 RELAPSED OR REFRACTORY ACUTE MYELOID LEUKEMIA (R/R AML): RESULTS OF A PHASE 1 DOSE-ESCALATION AND EXPANSION STUDY

E.M. Stein1,2,3, C.D. DiNardo3, D.A. Pollyea4, A.T. Fathi5,6, G.J. Roboz2,7, J.K. Altman8, A. Stein13, M.A. Sekeres14, R.T. Swords15, B.C. Medeiros16, R.D. Knight17, S. Agresta18, S. de Botton19, M.S. Tallman1,2

1Memorial Sloan Kettering Cancer Center, 2Well Cornell Medical College, New York, 3The University of Texas MD Anderson Cancer Center, Houston, 4University of Colorado School of Medicine, Aurora, 5Massachusetts General Hospital Cancer Center, 6Harvard Medical School, Boston, 7New York Presbyterian Hospital, New York, 8Robert H. Lurie Comprehensive Cancer Center, Northwestern University Feinberg School of Medicine, Chicago, 9Dana-Farber Cancer Institute, Boston, 10Sarah Cannon Research Institute, Nashville, 11University of Texas Southwestern Medical Center, Dallas, 12Florida Cancer Specialists and Sarah Cannon Research Institute, Sarasota, 13City of Hope Comprehensive Cancer Center, Duarte, 14Cleveland Clinic Taussig Cancer Institute, Cleveland, 15Sylvester Comprehensive Cancer Center, University of Miami, Miami, 16Stanford Comprehensive Cancer Center, Stanford University, Stanford, 17Celgene Corporation, Summit, 18Aigios Pharmaceuticals, Inc., Cambridge, United States, 19Institut Gustave Roussy, Villejuif, France

Background: Recurrent mutations in isocitrate dehydrogenase 2 (mIDH2) occur in ~12% of AML patients (pts). mIDH2 proteins synthesize an oncometabolite, 2-hydroxyglutarate (2HG), causing DNA and histone hypermethylation and blocked myeloid differentiation. Enasidenib (AG-221) is an oral, selective, small-molecule inhibitor of mIDH2 proteins. Differentiation of myeloblasts, not cytotoxicity, appears to drive the clinical efficacy of enasidenib. In preclinical studies, bone marrow blasts from pts with mIDH2-exposed to enasidenib ex vivo were shown to produce mature, fully functioning neutrophils with conserved mIDH2 allele frequency, indicating differentiation of mature cells from the mIDH2 blasts (Yen et al, Cancer Discov, 2017). Additionally, no apoptosis was observed in mIDH2-R140 erythroleukemia (TF-1) cells treated with enasidenib for 7 days in vitro.

Table 1.

Aims: Evaluate the maximum tolerated dose (MTD), pharmacokinetic (PK) and pharmacodynamic (PD) profiles, safety, and clinical activity of enasidenib in pts with mIDH2-defined AML, or with mIDH2 WHO-defined AML, or with mIDH2 MDS with refractory anemia with excess blasts, and ECOG PS scores ≤2. Pts were relapsed or refractory (R/R) to prior anti-cancer therapy, or had untreated AML if aged ≥60 years and not eligible for standard-of-care treatment (TX). Safety for all pts and clinical efficacy in the largest pt subgroup, those with R/R AML, from the phase 1 dose-escalation and expansion phases are reported.

Results: In all, 239 pts received enasidenib. Median age was 70 yrs. In the dose-escalation phase (n=113), pts received daily enasidenib doses of 50-650 mg. The MTD was not reached. Median 2HG reductions from baseline at cycle 2 day 1 were 92%, 90%, and 93% for pts receiving <100 mg, 100 mg, and >100 mg/day, respectively. Enasidenib 100 mg QD was chosen for the expansion phase (n=126) based on PK/PD profiles and demonstrated efficacy. Median number of enasidenib cycles was 5 (range 1-25). Grade 3-4 investigator-reported Tx-related adverse events included indirect hyperbilirubinemia (12%) and IDH-inhibitor-associated differentiation syndrome (IDH-DS; ie, retinoic acid syndrome) (7%). Of 176 R/R AML pts, 94 (53%) had received ≥2 prior AML-directed Tx. Overall response rate (ORR; complete remission [CR] + CR with incomplete count recovery - count recovery-confirmed AML-fresh leukemia [CRi-ALF] + complete remission-confirmed AML-fresh leukemia [CR-ALF]) in R/R AML pts was 40.3%, including 34 pts (19.3%) who attained CR (Table). Median time to 1st response was 1.9 months (mos); 87.3% of responding pts attained a 1st response by cycle 5. Median response duration was 5.8 mos. Of pts who achieved CR, 7 pts (21%) did so by cycle 3, 23 (88%) by cycle 5, and 29 (82%) by cycle 7. Median duration of CR was 8.8 mos. ORR with enasidenib 100 mg/day was 39.5% (Table). Seventeen pts (11%) proceeded to stem cell transplant. Response was associated with cellular differentiation, typically with no evidence of aplasia. Median overall survival (OS) of R/R AML pts was 9.3 mos. For pts who attained CR, OS was 19.7 mos. Pts who had received ≥2 prior AML Tx had a median OS of 8.0 mos.

Summary/Conclusions: Enasidenib was well tolerated, induced CRs in R/R pts with AML, and was associated with OS of >9 mos in pts who had failed prior AML Tx. A randomized phase 3 study of enasidenib vs conventional care in older pts with late-stage R/R AML is ongoing (NCT02577406).

S472

SAFETY AND EFFICACY OF VENETOCLAX (VEN) IN COMBINATION WITH DECITABINE OR AZACITIDINE IN TREATMENT-NAIVE, ELDERLY PATIENTS (≥65 YEARS) WITH ACUTE MYELOID LEUKEMIA (AML)

1Johns Hopkins Sidney Kimmel Comprehensive Cancer Center, Baltimore, 2University of Colorado School of Medicine, Aurora, 3UC Davis Comprehensive Cancer Center, Sacramento, 4Department of Hematology and Hematopoietic Cell Transplantation and Gehr Family Center for Leukemia Research, City of Hope National Medical Center, Duarte, United States, 5The Alfred Hospital, and Monash University, Melbourne, Australia, 6Emory University, Atlanta, 7Division of Hematology, University of Washington and Clinical Research Division, Fred Hutchinson Cancer Research Center, Seattle, 8Northwestern University Feinberg School of Medicine, 9University of Chicago Medical Center, Chicago, United States, 10Centre Hospitalier Universitaire (CHU) de Bordeaux, INSERM U1038, Université de Bordeaux, Bordeaux, 11Institut Universitaire du Cancer de Toulouse Oncopole, CHU de Toulouse and Université de Toulouse III, Toulouse, France, 12Peter MacCallum Cancer Centre, Melbourne, Australia, 13Abbvie Inc., North Chicago, 14Dana-Farber Cancer Institute, Boston, 15University of Texas MD Anderson Cancer Center, Houston, United States

Background: Newly diagnosed patients (pts) with AML aged ≥65 years and ineligible for standard induction therapy have limited treatment options, and low overall survival. VEN is an orally bioavailable, selective BCL-2 inhibitor that has displayed single-agent activity in pts with relapsed/refractory AML. VEN at escalating doses combined with hypomethylating agents (HMAs) has demonstrated antileukemic activity, with an overall response rate (ORR) including complete remission [CR] and CR with incomplete marrow recovery of 60%. Combining VEN with HMAs, such as decitabine (DEC) or azacitidine (AZA), may provide a novel low-intensity approach for treating AML. Preliminary results from the expansion stage of a phase 1b trial comparing 2 doses of VEN plus either DEC or AZA (NCT02203773) are reported.

Aims: To evaluate the safety and efficacy of VEN at 400 mg vs 800 mg doses plus DEC or AZA.

Methods: This open-label, nonrandomized, two-stage phase 1b study evaluated the safety and efficacy of VEN plus DEC or AZA in treatment-naive pts ≥65 years with AML. Eligibility criteria: ECOG PS ≤2; eligible for standard induction therapy; intermediate- or poor-risk karyotype. Pts received DEC (Arm D, 20mg/m²/d [d]; intravenously [IV]) on 1–5, or AZA (Arm E, 75mg/m²/d; subcutaneous or IV) on 1–7 of each 28-d cycle (C) in combination with once-daily oral VEN. The dose-expansion stage consisted of 2 VEN dose cohorts (continuous 400-mg and interrupted 800-mg dosing) in each arm (D1, D2, E1, and E2, respectively) to determine optimal dose. Tumor lysis syndrome (TLS) prophylaxis was administered in C1 to all pts during VEN dose ramp-up until final dose was reached. All pts provided informed consent.
Results: As of 13/09/16, 100 pts were enrolled in the expansion stage; 25 pts in each arm. Overall, 61% pts were male; 50% had ECOG PS 1 and 15% ECOG PS 2; mean age was 73.9 (range 65–86); 53% had adverse karyotype; and 22% had secondary AML. Median time on study was 6 (4–9), 6 (0.2–9), 5 (0.5–9), and 4 (1–8) mo for arms D1, D2, E1, and E2, respectively. The incidence of adverse events (AEs) was generally comparable between the 4 arms. Overall, the most common treatment-emergent AEs (TEAEs; in ≥30% of pts) were nausea (59%), diarrhea (42%), febrile neutropenia (FN; 41%), constipation (39%), fatigue, and decreased white blood cell count (31% each). The most frequent grade 3/4 TEAE and serious AE was FN (41% and 29%, respectively). No TLS was observed. Overall, 29 pts discontinued the study for ≥1 reason, including progressive disease (PD) per protocol (n=10), “other” (n=10; 9/10 proceeded to stem cell transplantation) and AEs not related to progression (n=10). A total of 16 deaths occurred; 12 pts died within 30 d of initiating VEN and HMA due to AEs (n=12) and PD (n=1). The ORR was 68%, with rates of 76% (19/25), 71% (17/24), 68% (17/25), and 60% (15/25) observed in arms D1, D2, E1, and E2, respectively. The Kaplan-Meier survival curve for all pts with a median follow-up time of 5.4 mo is shown.

Summary/Conclusions: Overall, the safety profile was favorable when combining VEN at either dose with DEC or AZA in treatment-naïve elderly AML pts. Promising activity with high ORRs was observed at the lower 400-mg VEN dose in both HMA arms. A Phase 3 study of VEN plus AZA is planned.

S473

UPDATED SAFETY AND EFFICACY RESULTS OF PHASE 1/2 STUDY OF VENETOCLAX PLUS LOW-DOSE CYTARABINE IN TREATMENT-NAÏVE ACUTE MYELOID LEUKEMIA PATIENTS AGED ≥65 YEARS AND UNFIT FOR STANDARD INDUCTION THERAPY

1The Alfred Hospital and Monash University, Melbourne, Australia, 2Vanderbilt-Ingram Cancer Center, Nashville, 3Weill Cornell Medical College, New York, 4University of Pittsburgh Medical Center (UPMC) Cancer Center, Pittsburgh, United States, 5Hubertus Wald University Cancer Center, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, 6University of Kansas Medical Center, Kansas City, United States, 7Bologna University School of Medicine, Bologna, Italy, 8University of Washington, Seattle, and Fred Hutchinson Cancer Research Center, Seattle, United States, 9Calvary Mater Hospital Newcastle and School of Medicine and Public Health, University of Newcastle, Callaghan, Waratah, Australia, 10AbbVie, Inc, North Chicago, United States

Background: Incidence of acute myeloid leukemia (AML) increases with age, and patients (pts) ≥65 years have a poor prognosis, with 5-year survival rates of <10%. Treatment with low-dose cytarabine (LDAC) in this population results in modest complete remission (CR)/CR with incomplete blood count recovery (CRi) rates of 11–19%, and 3–20% with azacytidine (AZA) in patients (pts) ≥65 years on treatment with 7–10% CR and 10–16% CRi. A phase 1/2 study of VEN in pts ≥65 years with untreated AML, ineligible for standard induction chemotherapy, with an ECOG performance status of 0-2 received oral VEN QD on days (d) 1-28 and subcutaneous LDAC 20mg/m2 QD on d 1–10 of each 28-d cycle. Safety target dose evaluation followed a 3+3 design, ranging from 600–800mg; 18 pts were enrolled and the RP2D was established as 600mg. Safety and efficacy of VEN at RP2D were evaluated in the expansion phase. All pts were hospitalized and received prophylaxis before a dose ramp-up of VEN during cycle 1 to mitigate the risk of tumor lysis syndrome (TLS). Adverse events (AEs) were graded by NCI CTCAE V4.0. Pts enrolled as of May 2016 are included in this analysis; data cutoff was August 2016. All pts provided informed consent.

Results: In total, 61 pts, including 8 from phase 1, were treated at the RP2D of 600mg (median age 74 years; ECOG 1–2 70%; adverse karyotypes 31%; secondary AML 44%; prior hypomethylating agent [HMA] 28%). AEs (all grade; ≥30% pts; excluding cytopenias) were nausea (72%), hypokalemia (46%), diarrhea (44%), fatigue (43%), and decreased appetite (41%). Grade 3/4 AEs (≥10% pts) were febrile neutropenia (34%), hypokalemia (15%), hypophosphatemia (13%), and hypertension (10%). No pts had clinical TLS; 1 pt had laboratory TLS, which was managed. The 30-d and 60-d mortality rates were 3% and 15%, respectively. The CR/CRi rate was 54% (33/61; 21% CR and 33% CRi). The overall response rate (ORR; CR+CRi+partial remission) was 61% (37/61). VEN+LDAC was shown to be active across a wide range of cytogenetic mutations and pt profiles (ORR: 70% in pts ≥75 years; 52% in secondary AML 47% in pts with adverse karyotypes; 53% in pts with prior HMA). Among response-evaluable pts, those achieving an objective response have longer survival than pts who do not achieve an objective response (Figure 1).

Figure 1.

Summary/Conclusions: VEN (RP2D 600mg) and LDAC exhibited an accept-able safety profile and durable efficacy in pts aged ≥65 years with untreated AML who are ineligible for or unable to receive intensive induction chemother-apy. ORR highly correlated with overall survival, with better survival observed in responders compared with nonresponders. A planned phase 3 randomized trial has commenced.

S474

PHASE IB/II STUDY OF NIVOLUMAB IN COMBINATION WITH AZACYTIDINE (AZA) IN PATIENTS (PTS) WITH RELAPSED ACUTE MYELOID LEUKEMIA (AML)

N. Daver1, S. Basu2, G. Garcia-Manero1, J. Cortes1, F. Ravandi1, E. Jabbour1, N. Pemmaraju1, S. Hendrickson 1, T. Gordon 1, M. Brandt 1, S. Pierce 1, J. Matthews1, S. Kornblau1, W. Flores1, M. Konopleva1, H. Kantarjian1, P. Sharma2

1Department of Leukemia, University of Texas MD Anderson Cancer Center, Houston, United States, 2Immunotherapy Platform, University of British Columbia, Vancouver, Canada, 3Immunotherapy Platform, University of California, Los Angeles, 4Department of Leukemia, University of Texas MD Anderson Cancer Center, Houston, United States

Background: Blocking PD-1/PD-L1 pathways enhances anti-leukemia responses in murine AML (Zhang et al. Blood 2009). PD-1 positive CD8 T-cells are increased in bone marrow (BM) of pts with AML (Daver et al. AARC 2016). AZA up-regulates PD-1 and interferon-gamma signaling in AML and the up-regulation of PD-1 has been associated with emergence of resistance to AZA (Yang et al., Leukemia 2013).

Aims: To assess the best response to Aza+Nivo at the end of 3 courses of combination therapy.

Methods: Pts were eligible if they had AML and failed prior therapy, had ade-quate performance status (ECOG ≤2), and organ function. The first six pts
received AZA 75mg/m² Days 1-7 with nivolumab 3mg/kg on Day 1 and 14. Courses were repeated every 4-5 days indefinitely. Only one of six pts had a dose limiting toxicity (grade 3 pneumonitis) and this dose was RP2D. 60 additional pts have been treated at the RP2D.

Results: 66 pts with a median age of 71 years (range, 44-90), secondary AML (39%), poor risk cytogenetics (35%), median number of prior regimens 2 (range, 1-7) have been enrolled. All 66 pts had baseline next generation sequencing: TP53 (n=14), DNMT3A (n=12), ASXL1 (n=10), TET2 (N=9), and RAS (n=9), IDH2 (n=9), IDH1 (n=6), CEBPA (n=7). 63 pts are evaluable for response: 14 (22%) achieved complete remission (CR)/complete remission with insufficient recovery of counts (CRi) (3 CR, 11 CRi), 7 (11%) had hematologic improvement (HI) (5 HI, 2 (11%) had 25% BM blast reduction, 5 pts (8%) had stable disease >6 months, and 24 (38%) had progression. 3 pts are too early for response assessment (<3 courses). The median number of courses to CR/CRi/HI was 2 (range, 1-4+). The med OS among the CR/CRi/HI patients was 15.3 months (range, 2.29-27.9+ months), the mOS of patients who had died was 5.7 months (range, 4.67-17.45+ months), and NRI was 5.0 months (range 0.29-16.16). The 4- and 8-week mortality were 5% and 11%, respectively. The median OS for the 63 evaluable pts on Azac+Nivo compares favorably to historical median OS with AZA-based salvage protocols in similar pts treated at MDACC (P=0.10) (Fig 1A and Fig 1B). Grade 3/4 and Grade 2 immune toxicities were observed in 8 (12%) and 7 (11%) pts, respectively. The most common Grade 3/4 AE on treatment included pneumonitis, colitis, nephritis, skin rash, and hypophysitis. One pt died from grade 4 pneumonitis/epiglottitis. In the remaining 14 cases the toxicities responded rapidly to steroids and 13 of these pts were successfully rechallenged with nivolumab. Time to onset of toxicities ranged from 4 days to 3.5 months. Multicolor flow-cytometry studies and Mass-cytometry (CyTOF) studies are conducted by the Immunotherapy Platform on baseline and on-treatment BM aspirate (end of cycle 1, 2, 4, 8). Baseline and end of cycle (EOC) 1 and 2 BM was evaluated in 6 responders and 19 non-responders. Pts who achieved a response had a baseline higher live total CD3 (P=0.10), CD8+ T-cells (P=0.02), and lower live CD4+Foxp3+PD1+T-regulatory (T-reg) cells (P=0.01) infiltrate in BM. Patients who had a response had progressive increase in BM CD3+ cells and BM CD8+ cells, with increased ICOS (activation) marker on BM CD4-effector cells at EOC 1 and EOC 2 as compared to those who had no response. The CTLA4 on CD8 T-cells went up in both responders and non-responders after PD1 based therapy.

Figure 1. OS with Azac+Nivo compared to historical survival with AZA-based salvage protocols in similar pts treated at MDACC in (a) all salvage and (b) first relapse only

Summary/Conclusions: Full dose AZA and nivolumab are tolerable and produce an encouraging response rate with durable responses in relapsed AML with poor risk features. Immune mediated toxicities occur and may be adequately managed with early recognition and systemic steroids. Up-regulation of CTLA4 in both responders and non-responders after PD1 based therapy suggest role for combination therapy.

S475

QUIZARTINIB AND BRIDGE TO TRANSPLANT IN FLT3-ITD AML PATIENTS AFTER FAILURE OF SALVAGE CHEMOTHERAPY: A HISTORICAL COMPARISON WITH UK NATIONAL CANCER RESEARCH INSTITUTE (NCRI) DATA

R. Hills1,*, G. Gammon2, D. Trone3, A. Burnett4

1Centre for Trials Research, Cardiff University, Cardiff, United Kingdom, 2formerly Daichi Sankyo, 3Daiichi Sankyo, San Diego, United States, 4Blackwaterfoot, Isle of Arran, United Kingdom

Background: The presence of a FMS-like tyrosine kinase 3 (FLT3) Internal Tandem Duplication (ITD) mutation in pts with AML is associated with an increased early relapse rate and a dismal prognosis. Quizartinib is a potent, selective FLT3 inhibitor that confers median overall survival (mOS) of 23 weeks and remission rate of 46% in a single-arm phase 2 study (AC220-002) in pts with AML with a FLT3-ITD mutation who were relapsed or refractory (R/R) to second line therapy. (Levis, et al, ASH 2012) As context, a study of AML pts, regardless of FLT3 mutation status, receiving second-salvage therapies, reported mOS of only 1.5 months. (Giles F, et al. Cancer 104 (3), 2005). Such poor-risk pts may benefit from a stem cell transplant (SCT), if available.

Aims: The primary aim was to compare SCT rates and outcomes of pts on quizartinib from an exploratory selected cohort in the AC220-002 study with those from a historical cohort of 1388 AML pts with confirmed FLT3-ITD mutations in the UK NCRI database.

Methods: Within AC220-002, 58 pts with a FLT3-ITD mutation were identified who had received intensive chemotherapy, and were relapsed (n=53), or refractory (n=5) to salvage therapy prior to entry. Applying the same entry criteria to the NCRI database, we identified 118 pts who received only recognized chemotherapy regimens prior to eligibility (relapsed n=99; refractory n=19). To avoid biases where those dying early would predominantly contribute to the NCRI group (reflecting that pts in AC220-002 had to be fit enough to be enrolled), pts in this cohort entered analysis 14 days following being identified as R/R. Multivariable Cox/logistic regression was used to compare remission rates and survival stratified for known prognostic factors. A landmark analysis excluding deaths before day 90 (allowing for those too unfit for SCT) was performed on the pooled sample (n=176) of the AC220-002 and NCRI cohorts to compare survival between transplanted and non-transplanted pts.

Results: Overall, quizartinib-treated pts had significantly greater remission rates, consisting mainly of complete remission without normal blood counts (CRI), vs NCRI pts (40% vs 3%, adjusted OR 0.05 (0.01-0.21), p<0.0001) and improved mOS (140d vs 54d, adjusted HR 0.38 (0.25-0.58) p<0.0001). A greater proportion of pts in AC220-002 proceeded to SCT: 23/54 (40%) vs 9/118 (8%). Comparing survival in SCT vs non-SCT in a landmark analysis, 18-month survival was significantly greater in the SCT group (29% vs 7%, adjusted HR 0.36 (0.20-0.65) p<0.0005). Significance persisted in sensitivity analyses with the landmark set at 120 or 150 days indicating an association between long-term survival and SCT. A similar analysis in an unmatched cohort consisting of SCT-naive pts in first relapse also found better survival for SCT vs no-SCT, confirming a potential benefit of SCT in this poor risk population.

Summary/Conclusions: When compared to a large historical cohort, quizartinib was associated with greater remission rates and opportunity to receive SCT in pts who relapsed after salvage therapy. While varying practice patterns and patient factors obviously influence treatment choices and outcomes, pts with AML with FLT3-ITD mutation appeared to benefit with longer survival with SCT. This data suggests quizartinib may show promise in potentially improving long-term survival by bridging patients to SCT.

Background: The CD19-targeted chimeric antigen receptor (CAR) T-cell therapy, CTL019, is an investigational therapy that reprograms cytotoxic T cells to eliminate target cells, resulted in high response rates and a manageable safety profile in pediatric/young adult patients (pts) with R/R B-cell ALL in a single-center trial.

Aims: We report an updated interim analysis from the first multicenter global pivotal trial of CAR T-cell therapy for R/R B-cell ALL, to evaluate the cellular kinetics of CTL019 in pediatric/young adult pts with (tumor burden at enrollment generally had higher expansion, based on box plots and summary statistics. Extrinsic factors (prior lines of therapy, stem cell source, therapy use or protocol) and baseline cytogenetics, disease characteristics, and disease status did not reach significance. Relationships between manufacturing specifications, therapies for cytokine release syndrome (CRS) management, and anti-CAR19 antibodies on cellular kinetics, based on graphical analysis.AUC0-28d increased with pres.

Results: At November 2016, 88 pts were enrolled. There were 7 (8%) manufacturing failures, 9 (10%) pts were not infused due to death or adverse events (AEs), and 4 pts (5%) were pending infusion at the time of data cutoff. Following lymphodepleting chemotherapy in most pts (fludarabine/cyclophosphamide [n=64] or other [=1]), 68 pts were infused with a single dose of CTL019 (median dose, 3.0×10^6/kg; range, 0.25-6.4×10^6/kg). Median age was 6.4 mo. Median age was 12 y (range, 3-23 y); 59% of pts had prior autologous stem cell transplant (alloSCT). Five infused patients had not reached 3 mo of follow-up; among 63 evaluable pts, 52 (83% [95% CI, 71%-91%]) achieved CR/CRi within 3 mo of CTL019 infusion, all of whom had minimal residual disease–negative marrow. The relapse-free probability at 6 mo after remission onset was 75% (95% CI, 57%-87%; median DOR not reached). The probability of survival was 95% (95% CI, 77%-94%) at 6 mo and 79% (95% CI, 63%-89%) at 12 mo. Seven pts (13% of responders) proceeded to alloSCT within 6 months while in remission. Cytokine release syndrome (CRS) was graded using the U Penn scale and managed using a protocol-specific algorithm. CRS occurred in 78% of pts (21% grade 3; 27% grade 4); no CRS-associated deaths occurred. 38% of pts received tocilizumab for treatment of CRS or with or without other anti-cytokine therapy. Most CRS grade 3/4 nonhematologic AEs (>5%) other than CRS were hypotension (22%), hypoxia (18%), and infections (15%). The number of patients treated with CTL019 in the global registration trial was 88. Within 8 weeks of infusion was 69%. 15% of pts experienced grade 3 neutrophilic chimeric AEs, with no grade 4 events and no cerebral edema reported. Grade 3/4 neutropenia with high (>383.3) fever occurred in 60% of pts. 2 pts died within 30 days of infusion (ALL progression, n=1; cerebral hemorrhage, n=1), and 9 pts died >30 days after infusion (ALL relapse/progression, n=6; HHV-6 encephalitis, pneumonia, systemic mycosis, n=1 each). CTL019 expansion in vivo correlated with CRS severity, and persistence of CTL019 along with B-cell aplasia in peripheral blood was observed for ≥1 year in some responders. Summary/Conclusions: The ELIANA study confirmed the efficacy of a single infusion of CTL019, without additional therapy, observed in a previous interim analysis and a prior single-center CTL019 trial. AEs were effectively and reproducibly managed globally by appropriately trained personnel at study sites.

1 Novartis Pharmaceuticals Corporation, East Hanover, New Jersey, 2 Department of Pediatrics, Perelman School of Medicine, University of Pennsylvania, Philadelphia, 3 Division of Oncology, Center for Childhood Cancer Research and Cancer Immunotherapy Program, Children’s Hospital of Philadelphia, Philadelphia, 4 University of Michigan, Ann Arbor, 5 Icahn School of Medicine at Mount Sinai, New York, 6 Department of Pediatrics, The University of Texas Southwestern Medical Center, Dallas, Texas, 7 Pauline Allen Gill Center for Cancer and Blood Disorders, Children’s Health, Dallas, Texas, 8 Division of Hematology Oncology/Blood and Marrow Transplant, Children’s Hospital Los Angeles, USC Keck School of Medicine, Los Angeles, California, 9 University of Utah, Salt Lake City, 10 Children’s Mercy Kansas City, Kansas City, United States, 11 Novartis Pharma AG, Basel, Switzerland, 12 Center for Cellular Immunotherapies, Perelman School of Medicine, University of Pennsylvania, Philadelphia, United States

Background: CTL019 is an investigational therapy whereby autologous T cells are genetically engineered with a chimeric antigen receptor (CAR) to identify and eliminate CD19-expressing malignant B cells. Data from 2 phase 2 studies (ELIANA, NCT02435849 and ENSIGN; NCT02228096) in pediatric and young adult R/R B-cell ALL were pooled to evaluate cellular kinetics of CTL019. Aims: We report cellular kinetics, humoral immunogenicity, AUC0-28d (exposure)-response analysis and impact of intrinsic/extrinsic and manufacturing factors on CTL019 expansion. Methods: Cellular kinetic parameters of CTL019 post infusion were derived using traditional pharmacokinetic principles and reported by response category (complete response [CR]/CRi with incomplete blood count recovery [CR]) vs no response [NR]) using 2 assays of peripheral blood cells: qPCR and flow cytometry. AUC0-28d-response relationships were evaluated by logistic regression. Relationships between manufacturing specifications, therapies for cytokine release syndrome (CRS) management, and anti-CAR19 antibodies on cellular kinetics were explored using summary statistics and graphical- and model-based analyses.

Results: Data from 79 pts (ELIANA, n=50; ENSIGN, n=29) were pooled for analysis. Using qPCR, pts with CR/CRi (n=62) had ≥2-fold higher CTL019 expansion than pts with NR (n=7) (Cmax, 73.5% higher geometric [geometric mean]; AUC0-28d, 104% higher geometric mean). Table 1. Pts with NR had delayed Tmax compared with pts with CR/CRi (20 vs 10 days). Intrinsic pt factors including baseline cytogenetics, disease characteristics, and disease status did not appear to affect Cmax or AUC0-28d with the exception that pts with a higher tumor burden at enrollment generally had higher expansion, based on box plots and summary statistics. Extrinsic factors (prior lines of therapy, stem cell transplant) and parameters related to the manufactured product (% T cells, transduction efficiency, cell viability, total cell count), did not appear to impact cellular kinetics, based on graphical analysis. AUC0-28d increased with pres.

Figure 1. Results: Data from 79 pts (ELIANA, n=50; ENSIGN, n=29) were pooled for analysis. Using qPCR, pts with CR/CRi (n=62) had ≥2-fold higher CTL019 expansion than pts with NR (n=7) (Cmax, 73.5% higher geometric [geometric mean]; AUC0-28d, 104% higher geometric mean). Table 1. Pts with NR had delayed Tmax compared with pts with CR/CRi (20 vs 10 days). Intrinsic pt factors including baseline cytogenetics, disease characteristics, and disease status did not appear to affect Cmax or AUC0-28d with the exception that pts with a higher tumor burden at enrollment generally had higher expansion, based on box plots and summary statistics. Extrinsic factors (prior lines of therapy, stem cell transplant) and parameters related to the manufactured product (% T cells, transduction efficiency, cell viability, total cell count), did not appear to impact cellular kinetics, based on graphical analysis. AUC0-28d increased with pres.
ence and severity of CRS. Pts who received anti-cytokine agents for grade 3/4 CRS also had higher expansion. CR/CRi pts treated with tocilizumab and steroids (n=17) had 89% higher AUC0-28d than CR pts who did not receive tocilizumab and steroids (n=45). Experience is limited in NR pts with (n=4) and without (n=4) tocilizumab. Moderate correlation was observed between trans-gene levels and CAR surface expression in peripheral blood (r=0.592) by qPCR and flow cytometry, respectively, when matched by time points from the cellular kinetic profile. Slower B-cell recovery was observed in pts with AUC0-28d above the median. Post-dose anti-CAR19 antibody responses were determined from the fold change of anti-CAR19 antibodies above the baseline pre-dose value. Pts with treatment-induced or boosted anti-CAR19 antibody responses generally had lower expansion, based on box plots, compared with pts with treatment-unaffectected anti-CAR19 antibody responses, although AUC0-28d was variable. The boosted levels of anti-CAR19 did not impact clinical response or relapse.

Summary/Conclusions: There was increased expansion of CTL019 in pts with higher tumor burden at enrollment, which correlated with higher CRS grade. There was no relationship between dose and expansion, supporting the wide dose range used. Expansion was not attenuated by tocilizumab, steroids, or cytokines, indicating therapies for CRS do not abrogate CTL019 proliferation. Cellular kinetics are important to understand the determinants of tumor response with CAR T-cell therapy.

BLINATUMOMAB VS SOC CHEMOTHERAPY IN FIRST SALVAGE COMPARED WITH SECOND OR GREATER SALVAGE IN A PHASE 3 STUDY
H. Dombret1,*, M.S. Topp2, A. Schuh3, A. Wei4, G. Martinelli5, S. Durrant6, C.L. Bacon7, K. Nie8, Z. Zimmerman9, H. Kantarjian10
1Hôpital Saint-Louis, Paris, France, 2Universitätsklinikum Würzburg, Würzburg, Germany, 3Princess Margaret Cancer Center, University Health Network, Toronto, Canada, 4Alfred Hospital, Monash University, Victoria, Australia, 5Institute of Hematology and Medical Oncology “L. e A. Seragnoili”, S. Orsola University Hospital, Bologna, Italy, 6Clinical Haematology and BMT, Royal Brisbane Hospital, Herston, Australia, 7St. James’s Hospital, Dublin, Ireland, 8Global Biostatistical Sciences, 9Global Development, Amgen, Thousand Oaks, CA, 10Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, United States

Background: Adults with B-cell precursor (BCP) acute lymphoblastic leukemia (ALL) often relapse following standard induction/consolidation chemotherapy (CTX). Prognosis following second and successive CTX salvage regimens (S2+) is poor compared with first salvage (S1) or frontline therapy, with less favorable outcomes among patients with shorter CR duration. Blinatumomab links cytotoxic CD3-positive T cells and CD19-positive B cells to induce tumor cell lysis. In a randomized phase 3 trial of blinatumomab vs investigator’s choice of 4 standard of care CTX (SOC) regimens, median OS was 7.7 months in the blinatumomab group vs 4.0 months with SOC (Kantarjian H, et al., NEJM 2017). Here, we evaluate outcomes by salvage status for patients in this study (NCT02013167).

Aims: To evaluate responses to blinatumomab vs SOC in patients with relapsed/refractory ALL by prior salvage therapy status.

Methods: Patients with relapsed/refractory (R/R) BCP-ALL in this international multicenter trial were randomized 2:1 to blinatumomab (n=271) or SOC (n=134). For this analysis, salvage status was adjudicated separately from prior randomization. Blinatumomab was given by continuous IV infusion (9 µg/d in week 1 of cycle 1, then 28 µg/d) in cycles of 4 weeks, 2 weeks off. The primary endpoint was overall survival (OS), determined from time of randomization until death due to any cause. Adverse events (AE) of interest were coded according to MedDRA version 16.0.

Results: At baseline, patient characteristics were balanced between groups within salvage designations. The rate of complete remission, with or without full hematologic recovery (CR/CRi/CRv) in both the S1 and S2+ groups was higher in the blinatumomab arm compared with the SOC arm (Table 1). Patients randomized to blinatumomab had a median (95% CI) of 11.1 (8.2, 17) months overall survival for S1 vs S2+ subgroup, compared with 5.5 (3.7, 9.0) months vs 3.0 (2.1, 4.0) months in the SOC arm (Figure 1). For both S1 and S2+ subgroups, blinatumomab patients had longer median survival time. Grade 3 or worse AEs were experienced by 61% and 83% of S1 patients in the blinatumomab and SOC group, respectively. These percentages were 68% and 75%, respectively, in S2+ patients. Grade 4 or worse AEs occurred in 34% and 51% S1 patients, and in 36% and 54% S2+ patients. Neurologic events of grade ≥3 occurred in 9% and 9% of S1 patients, and in 10% and 9% S2+ patients, respectively. Grade ≥3 cytokine release syndrome (CRS) was observed in 4% S1 and 5% S2+ patients receiving blinatumomab, and in no SOC patients.

Summary/Conclusions: Patients in this trial receiving blinatumomab for R/R ALL achieved improved OS and remission rates compared with SOC regardless of prior salvage therapy. Improved OS compared with SOC in S1 patients supports earlier use of blinatumomab.

S479
DURABLE LONG-TERM SURVIVAL OF ADULT PATIENTS WITH B-ALL AFTER CD19 CAR (19-28Z) T CELL THERAPY
J. Park1,*, I. Riviere 1, X. Wang 1, B. Senechal 1, Y. Wang 1, T. Purdon 1, R. Brentjens1, M. Sadelain1
1Memorial Sloan-Kettering Cancer Center, New York, United States

Background: CD19-specific chimeric antigen receptor (CAR) T cells have demonstrated high initial responses in patients with relapsed B-ALL. However, clinical characteristics associated with the durability of response remain undefined.

Aims: We performed a retrospective analysis of our phase I clinical trial of 19-28z CAR T cells in adult patients with relapsed B-ALL (NCT01044069) with a focus to identify those patients who optimally benefit from 19-28z CAR T cell therapy with durable long-term survival and reduced toxicities.

Methods: Adults with relapsed B-ALL were infused with autologous T cells expressing the 19-28z CAR following conditioning chemotherapy. Disease burden was assessed by bone marrow biopsy immediately prior to T cell infusion; patients with ≤5% blasts were classified as minimal residual disease (MRD) cohort vs patients with >5% blasts as morphologic disease cohort. Response assessment occurred at 4 weeks. Median follow-up duration was 18 months (range, 0.2-57.3).

Results: 51 adults received 19-28z CAR T cells; 20 in the MRD and 31 in the therapy with durable cohort. Complete remission (CR) rates were comparable (95% and 77%, respectively). However, median event-free and overall survivals widely diverged among the 42 patients who achieved MRD-negative CR: not reached (NR) (95% confidence interval [CI]: 4.2-7.5) vs 6.3 months (95% CI, 4.8-9.0) (p=0.0005), and NR (95% CI, 15.3-NR) vs 17 months (95% CI, 8.5-36.2) (p=0.0189), in the MRD and morphologic cohorts, respectively. Subsequent allogeneic HSCT in either cohort did not improve survival (p=0.8). MRD cohort patients developed substantially less severe cytokine release syndrome (CRS) and neurotoxicity, and both toxicities significantly correlated with peak haematologica | 2017; 102(s2) | 179

Madrid, Spain, June 22 – 25, 2017
CART cell expansion (p=0.0326 and p=0.0001, respectively). No case of cerebral edema was observed.

Summary/Conclusions: Despite comparable initial CR rates regardless of pre-treatment disease burden, durability of 19-28z CART cell mediated remissions and survival in adult patients with relapsed B-ALL positively correlated to a low disease burden and do not appear to be enhanced by allogeneic retransplant. Our findings strongly support the early incorporation of CD19 CART therapy before morphologic relapse in B-ALL.

Gerardo, Monza, Italy

Background: ETV6-RUNX1 fusion is a common genetic aberration in childhood acute lymphoblastic leukemia (ALL) and is associated with good prognosis in the context of contemporary treatment regimens. The required treatment intensity for this well-described biologic subgroup with low risk of relapse is not known so far. In trial AIEOP-BFM ALL 2000, feasibility of reduced delay of intensified treatment to reduce the burden of chemotherapy was tested in a randomized approach in the standard-risk group. Treatment reduction was not successful in the total cohort (8-year probability of disease-free survival 8y-pDFS, ± standard error) 89.2±1.3% for reduced intensified treatment, 92.3±1.2% for the standard treatment (log-rank P=0.04) due to evidence of more relapses observed in patients treated less intensively.

Aims: The retrospective subgroup analysis presented here focuses on the ETV6-RUNX1-positive patients included in the group of randomized standard-risk patients.

Methods: From 07/2000 to 06/2006, 4741 eligible patients with ALL (age range 1-17 years) were enrolled in the trial AIEOP-BFM ALL 2000 (NCT 00430118 (BFM) and NCT 00613547 (AIEOP)). Of those, 1164 patients were considered at standard risk of relapse, defined by lack of genetic high-risk criteria and absence of minimal residual disease at day 33 and week 12 of treatment (tested by immunoglobulin/T-cell receptor gene rearrangement polymerase chain reaction). They were randomly assigned to either receive the reduced-intensity protocol (P-III) or intensified treatment (P-III) for delayed intensification. P-III is shorter than P-II (duration 29 vs 49 days), the dose of dexamethasone in P-III is 30% lower, and the dose of vincristine, doxorubicin, and cyclophosphamide are reduced by 50% as compared to P-II. The intention was to prove non-inferiority of the reduced-intensity treatment compared to standard treatment.

Results: ETV6-RUNX1-positive patients (n=367) accounted for 34% of randomized standard-risk patients (Age: 6 years n=260, 6 to <10 years n=79, ≥10 years n=28; early cytologic response evaluation in bone marrow on day 15 of induction treatment: M1 n=218, M2 n=74). Of those, 188 were treated with the experimental P III, 179 received the standard P-II. With a median follow-up of 6.8 years, the as-treated analysis showed an 8y-pDFS of 94.5±1.7% for P-III and 94.1±1.8% for patients with P-II (log-rank P=0.74). Cumulative incidence of relapse at 8 years was 3.3±1.3% and 4.3±1.6% (Gray P=0.09), and 8-year overall survival was 96.9±1.4% and 98.8±0.9% (P=0.27) for P III and PII, respectively. Analysis of ETV6-RUNX1-positive patients by age groups or treatment response on day 15 allowed no further refinement of prognostic subgroup.

Summary/Conclusions: There was no evidence of prognostic disadvantage in ETV6-RUNX1-positive standard-risk patients when treated with the reduced-intensity experimental arm. No clear age- or response-dependent differences could be revealed for this group, which is in line with the biologic understanding of this genetic subgroup. Hence, it might be postulated that treatment reduction might be feasible in this well-defined biologic subgroup. However, the present data is not a sufficiently powered non-inferiority study question focused on the subgroup of ETV6-RUNX1-positive patients, but reflects a subgroup analysis with descriptive character. Therefore, any decision for treatment reduction should be considered carefully.

Biology and disease monitoring in CML

A SECOND GENERATION LYSOSOMOTROPIC AGENT DRIVES LEUKAEMIC STEM CELL DIFFERENTIATION AND SENSITIZES THEM TO TYROSINE KINASE INHIBITOR TREATMENT IN VITRO AND IN VIVO

P. Baquer1,*, E. Kuntz2, R. Mitchell1, A. Ianniciello1, K.M. Ryan2, E. Gottlieb3, R.K. Attarzadeh1, T.L. Holyoake4, G.V. Helgason1

Background: Autophagy is a conserved catabolic process that delivers cytoplasmic constituents to the lysosomes. We have previously shown that the lysosomotropic agent hydroxchloroquine (HCQ) inhibits autophagy and sensitizes Chronic Myeloid Leukaemia (CML) stem cells (LSCs) to tyrosine kinase inhibitors (TKIs) treatment. However, the biological effects of autophagy inhibition in LSCs in vivo are currently unknown and remain to be investigated. Furthermore, recent clinical studies showed that maximum tolerated dose of HCQ does not achieve consistent autophagy inhibition in cancer patients. Therefore further pre-clinical studies using more potent 2nd generation lysosomotropic agents, alone and in combination with TKIs, are vital.

Aims: Here we aim to investigate the functional effects of autophagy inhibition in LSCs both in vitro and in vivo using the highly potent lysosomotropic agent Lysosomotropic Agent (Lys05). Additionally, we aim to address whether Lys05 achieves autophagy inhibition in the most primitive LSC populations in vivo and whether it targets LSCs more effectively than HCQ when combined with TKIs.

Methods: In this study, we used primary stem-cell enriched samples (CD34+ cells) derived from CML patients at diagnosis. For in vivo studies, we used a human patient-derived xenograft (PDX) model and an inducible transgenic CML model in which the expression of BCR-ABL is induced at a stem/progenitor level (Scl-Tva-BCR-ABL). To accurately measure autophagy flow in long term LSCs in vivo, we generated the transgenic mouse Scl-Tva-BCR-ABL/GFP-LC3 by crossing the Scl-Tva-BCR-ABL model with a mouse bearing the autophagy reporter GFP-LC3 fused to GFP.

Results: Firstly, we show that Lys05 targets LSCs more potently than HCQ in vitro by achieving a 60% and a 35% reduction in number of CD34+CD38– and CFSEimmCD34+CD133+ cells respectively. Interestingly, Lys05 promoted a 40% loss of quiescent cells and induced myeloid differentiation of CD34+ cells. Functional long-term culture initiating cell (LT-CIC) assay demonstrated that, while HCQ had moderate effects, Lys05 decreased the number of LSC-derived colonies by 80%. Additionally, we show that Lys05 inhibits autophagy flow more efficiently than HCQ both in the Scl-Tva-BCR-ABL/GFP-LC3 model and in patient-derived progenitor cells. Analysis of bone marrow (BM) cells from Lys05-treated leukemic mice (but not from HCQ-treated mice), showed a statistically significant 35% decrease (p=0.0469) in the most primitive population Linc-Sca–c-kit+CD48–CD150+ followed by a 50% increase (p=0.0231) of progenitors Lin–Sca–c-kit+.

This result indicates differentiation of LSCs towards a more progenitor phenotype following potent autophagy inhibition. Finally, to test the in vivo generational switch hypothesis, both Lys05 and HCQ treatment were administered to mice over a period of 3 weeks and the effects evaluated.

Conclusion: Overall, we demonstrate that lysosomal inhibition induces loss of quiescence and drives differentiation of LSCs in vitro and in vivo. Furthermore, our results show that Lys05 achieves autophagy inhibition in LSCs and effectively sensitizes LSCs to TKIs in vitro and in vivo. Therefore, 2nd generation lysosomotropic agents should be considered as a potential alternative to HCQ in order to eliminate LSCs and achieve cure for CML patients.

Background: Chronic myeloid leukemia (CML) is provoked by the chromoso-
MAL TRANSCRIPTION (9.22) that gives rise to the oncogenic tyrosine kinase Bcr-Abl. Implementation of tyrosine kinase inhibitor (TKI) therapy resulted in significant clinical success but with TKIs failing to eradicate the disease initiating leukemic stem cell population (LSC), this treatment is not curative in the vast majority of patients. By using a transgenic CML mouse model, we previously showed that LSC persist despite complete Bcr-Abl kinase inhibition due to a lack of depletion. In this study, we identified the TIM carrying Fc gamma receptor IIb (FcRyIIb; CD32) to be 2.8-fold upregulated in Bcr-Abl+ versus control LSK (lin-;Sca-1+; c-kit+) cells using microarray and qRT-PCR.

Methods: In this study, we first aimed to validate Bcr-Abl mediated FcRyIIb upregulation on mRNA and protein level in leukemic cells. Next, we tested the effect of shRNA-mediated FcRyIIb knock-down and depletion on CFU (colony forming unit) capacity, proliferation and leukemic signaling in vitro. Finally, we studied the disease-initiating potential of primitive CML stem and progenitor cells upon FcRyIIb knock down.

Results: Bcr-Abl increased FcRyIIb mRNA (12.3-fold, p≤0.001) and protein expression in primary murine lineage negative (lin-) BM cells. Reduction of FcRyIIb in immortalized SCLT/A-Bcr-Abl progenitor cells significantly reduced CFU (colony forming unit) capacity (1.28-fold, p≤0.05) and decreased spontaneous transformation rate in these cells (2.27-fold, p≤0.001). Moreover, transplantation of SCLT/A-Bcr-Abl shRNA:FcRyIIb BM cells (CD45.1+) into FVB/FVB wildtype (WT) CD45.2+ recipients reduced spleen weight (352 ± 59.13mg) as compared to scrambled shRNA (586.1 ± 101.72mg). FACS analysis revealed a decrease in GFP+;CD45.1+ BM cells (1.43-fold, p≤0.001) upon FcRyIIb knock down. Likewise, donor-derived Gr-1+ cells (Gr-1+; CD45.1+; GFP+) were reduced in the BM (1.28-fold, p≤0.01) of these mice. Flow-cytometric analysis of the stem cell compartment revealed decreased leukemic BM LSK cells (lin-; c-kit+; Sca-1+; CD45.1+; GFP+, 1.38-fold, p≤0.01) in mice transplanted with shRNA:FcRyIIb vs scrambled control. We also observed similar effects upon FcRyIIb depletion (FcRyIIb-/-) vs wildtype (FcRyIIb+/+), combined with virally induced Bcr-Abl expression. Interestingly, Bc-Abl signaling induces FcRyIIb phosphorylation in leukemic cells. Analysis of downstream signal pathways showed decreased levels of p-ERK, p-BTK, p-PLCγ1 in FcRyIIb-/-, compared to FcRyIIb+/+ Bcr-Abl transduced immortalized primary murine BM cells.

Summary/Conclusions: FcRyIIb is upregulated in LSC derived from transgenic CML mice upon Bcr-Abl expression. Complete depletion or knock down of the receptor reduces CFU capacity and cell growth in CML cells and significantly impairs CML development and LSC burden in vivo, presumably due to impaired leukemic downstream signaling. Our data demonstrate that FcRyIIb is critical and disease specific making it a potential novel therapeutic target in CML stem cells.

S483 MYC-DEPENDENT REPRESSION MECHANISM OF THE MIR-150 TRANSCRIPTIONAL REGULATION IN CHRONIC MYELOID LEUKEMIA

P. Hlinka1, K. Sovova1, F. Sovova1, H. Klamova1, P. Pecherkov1, Z. Sovova1, J. Kobliha1, T. Stipka1, D. Perrot2, K. Machova Polakova1,4

Background: The expression of miRNAs is regulated at transcriptional and posttranscriptional levels. Dysregulation of miRNAs could directly induce or be a consequence of oncogenic pathways. Chronic myeloid leukemia (CML) is characterized by overexpression of MYC-150 levels leading to an insufficient repression of its target, oncogene MYB. CML treatment with imatinib normalizes miR-150 levels. Thus miR-150 is crucial for CML biology, however, little is known about its upstream transcriptional regulation. BCR-ABL is an inhibitor of oncogene MYB, CML treatment with imatinib normalizes miR-150 levels. Therefore, BCR-ABL is crucial for CML biology, but little is known about its upstream transcriptional regulation. BCR-ABL is an inhibitor of oncogene MYB, which is required for BCR-ABL-dependent leukemogenesis in CML blast crisis. The aim of this study was to characterize transcriptional regulation of miR-150 in 150/MYB regulatory links in CML, sustained in CML resistant cells. We low down levels of miR-150 to be a hallmark of CML and impaired signaling pathway MYB/BCR-ABL1/MYC/miR-150/miR-155/PJ.1 leading to a progressive cell differentiation block.

Aims: To define potential mechanisms of the miR-150 transcription regulation via the oncogenic transcription factor MYC in CML.

Methods: Primary bone marrow cells from CML (N=28), CML cell lines K562 and KCL-22 and imatinib resistant (K562R, KCL-22R). Expression analysis: RT-PCR. Protein levels: WB. ChIP: chromatin from the cell lines. SIRNA inhibi- tion: AMAXA electroporation. DNA methylation analysis: Methylation DNA immunoprecipitation.

Results: We observed that unlike MLL-AML diagnosis (Jiang et al. 2012), CML is not characterized by a block of miR-150 maturation and that miR-150 levels negatively correlated with MYC mRNA levels in CML HSPCs (p≤0.001). Role of miR-150 overexpression by imatinib induced was downregulated and restored miR-150 levels in K562 and KCL22. Imatinib resistance in K562R and KCL-22R was characterized by further miR-150 downregulation. To assess the MYC role on regulating miR-150 levels we tested the MYC binding sites upstream the miR-150 gene. We detected MYC binding to the upstream CpG of the MYC150 gene in K562 and KCL-22. We also found a depletion of MYC from the miR-150 locus after the imatinib treatment. We suggested potentially synergistic route for imatinib-induced BCR-ABL1 inhibition. This could be processed not only directly but also through an inhibition of a mutual positive regulatory loop between MYC and BCR-ABL1 (Xie et al. 2002). We also noticed upregulation of MYC downstream signaling which is adjacent to the studied miR-150 CpG to become activated by imatinib. We observed MYC levels dependent regulation of both genes, but FCGRT is activated by MYC. This different MYC regulatory role may be facilitated by the detected transcription factor CTCF binding to an insulator site between miR-150 promoter and the CpG. An activation of the insulator via CTFC binding could be an interaction between enhancers and promoters (Bell et al. 2000). CTCF was previously described to be an inhibitor of MYC transcription and we show CTFC transcription to be induced by imatinib. CTFC binding to DNA is prevented by DNA methylation. We did not detect DNA methylation within miR150 upstream region.

Conclusions: The presented data characterize transcriptional regulation of transcription factors-dependent epigenetic changes within the promoter and distal enhancers. We outlined a new insight into MYC/MIR150/BCR-ABL1/Imatinib regulation loop in CML. Our work revealed a MYC role in miR-150 repression underlying the CML leukemogenesis, where MYC functions as a pivotal gatekeeper and its repression is probably required for CML establishment and is enforced in imatinib resistant CML.

Background: Real-time reverse transcription quantitative PCR (RQ-PCR) for BCR-ABL1 mRNA is widely used for the monitoring of chronic myeloid leukaemia (CML). Pre-analytical factors, such as the rate of degradation of the target mRNA, and methodological factors, such as the choice of control gene, may influence the final result. In contrast the genomic DNA is stable, and the number of copies of BCR-ABL1 DNA is directly proportional to the number of CML cells. Measuring both DNA and RNA may enable us to understand the contribution of expression and cell number to the RQ-PCR response.

Aims: To compare BCR-ABL1 DNA Q-PCR and routine RQ-PCR monitoring of CML.

Methods: Fifty-nine newly diagnosed chronic phase CML patients from the ALLG CML9 (TIDEL II) trial were included in this sub-study. Samples were tested prior to commencing TKI treatment (baseline), at 1, 2, and 3 months, and every 3 months to 24 months (total 568 samples). Since we wanted to compare the sensitivity of the Q-PCR methods we selected the patient who had achieved the number of 100% of copies of BCR-ABL1 DNA is directly proportional to the number of CML cells. Measuring both DNA and RNA may enable us to understand the contribution of expression and cell number to the RQ-PCR response.

Results: We first demonstrated that DNA dPCR and real-time RQ-PCR gave comparable results: 45 samples from 6 patients were quantified by both meth- ods. The median bias was -0.15 (1.4-fold) in DNA and RQ-PCR. The mean detection limit of RQ-PCR was 5.0-log, and 6.4-log for DNA methods. and ii) verify accuracy and inter-laboratory reproducibility of results. The second storage and a common pipeline of data analysis, interpretation and reporting, BCR-ABL1 KD mutation screening.

A multicenter, multilaboratory prospective study (‘NEXT-IN-CML’) has been conducted to assess the feasibility, cost, turnaround times and clinical utility of a next generation amplicon deep sequencing (Deep Seq) strategy for routine therapeutic reassessment and is recommended in case of Failure and Warning. In chronic myeloid leukemia

KINASE DOMAIN MUTATION SCREENING: THE ‘NEXT-IN-CML’ STUDY

S485

ESTABLISHING A NATIONAL NETWORK OF LABORATORIES USING NEXT GENERATION AMPION DEEP SEQUENCING FOR BCR-ABL1

Background: Benchtop next generation sequencers are gradually replacing Sanger sequencers in diagnostics labs because of greater throughput, better sensitivity and increasing cost-effectiveness. In chronic myeloid leukemia (CML) patients (pts) on tyrosine kinase inhibitor (TKI) therapy, BCR-ABL1 kinase domain (KD) mutation screening is a precious tool for timely and rational therapeutic reassessment and is recommended in case of Failure and Warning. A multicenter, multilaboratory prospective study (‘NEXT-IN-CML’) has been conducted to assess the feasibility, cost, turnaround times and clinical utility of a next generation amplicon deep sequencing (Deep Seq) strategy for routine BCR-ABL1 KD mutation screening.

Aims: The first phase of the study was aimed to i) create a network of 4 labs achieving MMR by 12 months, in comparison with 33% (20/60) of patients with e13a2 transcripts. BCR-ABL1 mRNA expression levels were significantly lower in e13a2 patients than in e14a2 patients in all follow-up samples analysed (ratio of BCR-ABL1 mRNA:DNA for e13a2 0.44 vs e14a2 0.57; p=0.016).

Figure 1.

Summary/Conclusions: In the first 1-3 months BCR-ABL1 mRNA fell more rapidly than DNA, likely reflecting the time taken for normal haematopoietic cells to recover. At later time-points there was good agreement between methods, indicating that later reduction in BCR-ABL1 IS is closely related to depletion of leukaemic cells. Normalised to BCR-ABL1 DNA the expression of e13a2 BCR-ABL1 mRNA was lower than that of e14a2, an observation that requires confirmation. DNA methods were more sensitive: following the achievement of MMR by 12 months, in comparison with 63% (median 0.002%, range 0.0003-0.07%). Finally, 88% (15/17) of patients with low burden mutations <3% were occasionally called by one or two labs only, suggesting that this value should be taken as a threshold below which mutation detection is not reproducible and sequencing artifacts and errors cannot be ruled out. In the second phase of the study, pts positive for mutations were 25/159 (16%; 23 Failures and 2 Warnings) by Sanger Seq and 52/159 (33%; 48 Failures and 4 Warnings) by Deep Seq. Among the pts with low burden mutations detectable by Deep Seq, 4 had a T315I; 34 had other known TKI-resistant mutations; 14 had only mutations with unknown clinical significance. Pts positive for mutations by Deep Seq were more frequent in the High and Intermediate Sokal risk group. The number of positive pts and the number of mutations per pt were not significantly higher in those receiving 2nd- or subsequent-line TKI therapy than in those receiving 1st-line TKI therapy. Compound mutations found were only in 2 out of 52 mutated pts (both in blastic phase). Summary/Conclusions: 1) Results of the ‘NEXT-IN-CML’, the first prospective study evaluating the routine diagnostic use of Deep Seq of BCR-ABL1, show that this technology can successfully be implemented in national lab networks and is feasible, robust and reproducible; 2) in a relatively large, nonselected cohort of CML pts analysed for mutations because of a Failure or Warning response, Deep Seq confirmed that enhancing sensitivity enables to detect BCR-ABL1 KD mutations in twice as many pts as compared to Sanger Seq (33% vs 16%). All the pts who need to be switched to another TKI would benefit from sensitive BCR-ABL1 KD mutation screening by Deep Seq.

Background: Benecthop next generation sequencers are gradually replacing Sanger sequencers in diagnostics labs because of greater throughput, better sensitivity and increasing cost-effectiveness. In chronic myeloid leukemia (CML) patients (pts) on tyrosine kinase inhibitor (TKI) therapy, BCR-ABL1 kinase domain (KD) mutation screening is a precious tool for timely and rational therapeutic reassessment and is recommended in case of Failure and Warning. A multicenter, multilaboratory prospective study (‘NEXT-IN-CML’) has been conducted to assess the feasibility, cost, turnaround times and clinical utility of a next generation amplicon deep sequencing (Deep Seq) strategy for routine BCR-ABL1 KD mutation screening.

At later time-points there was good agreement between methods, indicating that later reduction in BCR-ABL1 IS is closely related to depletion of leukaemic cells. Normalised to BCR-ABL1 DNA the expression of e13a2 BCR-ABL1 mRNA was lower than that of e14a2, an observation that requires confirmation. DNA methods were more sensitive: following the achievement of MMR by 12 months, in comparison with 63% (median 0.002%, range 0.0003-0.07%). Finally, 88% (15/17) of patients with low burden mutations <3% were occasionally called by one or two labs only, suggesting that this value should be taken as a threshold below which mutation detection is not reproducible and sequencing artifacts and errors cannot be ruled out. In the second phase of the study, pts positive for mutations were 25/159 (16%; 23 Failures and 2 Warnings) by Sanger Seq and 52/159 (33%; 48 Failures and 4 Warnings) by Deep Seq. Among the pts with low burden mutations detectable by Deep Seq, 4 had a T315I; 34 had other known TKI-resistant mutations; 14 had only mutations with unknown clinical significance. Pts positive for mutations by Deep Seq were more frequent in the High and Intermediate Sokal risk group. The number of positive pts and the number of mutations per pt were not significantly higher in those receiving 2nd- or subsequent-line TKI therapy than in those receiving 1st-line TKI therapy. Compound mutations found were only in 2 out of 52 mutated pts (both in blastic phase).

Summary/Conclusions: 1) Results of the ‘NEXT-IN-CML’, the first prospective study evaluating the routine diagnostic use of Deep Seq of BCR-ABL1, show that this technology can successfully be implemented in national lab networks and is feasible, robust and reproducible; 2) in a relatively large, nonselected cohort of CML pts analysed for mutations because of a Failure or Warning response, Deep Seq confirmed that enhancing sensitivity enables to detect BCR-ABL1 KD mutations in twice as many pts as compared to Sanger Seq (33% vs 16%). All the pts who need to be switched to another TKI would benefit from sensitive BCR-ABL1 KD mutation screening by Deep Seq.
Prognostic markers and new treatment in MDS

S486

PATIENTS WITH IDIOPATHIC CYTOPENIA OF UNDETERMINED SIGNIFICANCE SHOW SIMILAR SURVIVAL PATTERNS AS LOW RISK MDS PATIENTS

Background: Cytopenia is a hallmark in myelodysplastic syndrome (MDS), however, many patients with persistent cytopenia do not fulfill the criteria for MDS. These patients are now classified as idiopathic cytopenia of undetermined significance (ICUS) or if a mutation is detected as clonal cytopenia of undetermined significance (CCUS). Little is known about these new entities in regards to survival and prognosis.

Aims: In this study we want to compare ICUS patients with MDS patients having low- or very low-risk disease according to the IPSS-R. We also wanted to investigate if sequencing of the cohort could bring additional information in regards to overall survival.

Methods: All patients underwent a bone marrow biopsy, cytogenetics and a broad range of blood tests. Furthermore, all ICUS patients underwent a blinded morphology review by two experienced pathologists; these review data will be ready for presentation at EHA. ICUS was defined as persistent cytopenia for more than six months, no chromosomal aberrations and common causes of cytopenia were ruled out. The patients were sequenced with a targeted sequencing panel, either using a customized Haloplex panel or a customized sequencing panel for the Ion Torrent platform. We analyzed 20 genes which are the most commonly mutated genes in MDS.

Results: So far we included 157 patients, 122 were classified as ICUS and 35 as MDS and the median age is 65 and 68 years, respectively (p=0.27). We have sequenced 78% of the ICUS patients and 74% of the MDS patients. In total 53% and 73% of the ICUS and MDS patients had at least one mutation detected, respectively. If the patients carried a mutation, the median number of mutations was two in both the CCUS and the MDS group. The most commonly mutated genes were TET2, SRSF2, DNMT3A and ASXL1 in 38 patients (31%), n=16 (13%), n=10 (8%), n=10 (8%), respectively. There were no significant differences in the distribution between the two groups. Mutations in NRAS, KRAS, TP53 were only identified in one patient each. The overall survival between the ICUS and the low-risk MDS patients did not differ (p=0.18) (figure 1). We also subdivided the ICUS patients into non-clonal ICUS and CCUS, but observed no difference between these two groups (p=0.355).

Eight of the patients categorized as ICUS progressed to a myeloid neoplasm during the follow up, and of these seven had a detectable mutation at time of enrollment, only one ICUS patient without a detectable mutation progressed (p=0.06).

Summary/Conclusions: We here demonstrate that low-risk MDS and ICUS patients share similar survival patterns, however, larger studies with longer follow up are needed. Mutations are most commonly found in the epigenetic regulators in this cohort of ICUS and low-risk MDS, while mutations in classical tumor suppressors and oncogenes such as TP53 and NRAS are rare. Mutational screening seems promising in detecting patients at risk of progression, however, other biomarkers for prognostication are warranted.

S487

AN UPDATE OF A PHASE II STUDY OF NIVOLUMAB (NIVO) OR IPILOMUB (IPI) WITH AZACITIDINE IN PTS WITH PREVIOUSLY TREATED OR UNTREATED MYELODYSPLASTIC SYNDROMES (MDS)

Garcia-Manero1,*, N. Daver1, G. Montalban-Bravo1, E. Jabbour1, C. Di Nardo1, G. Garcia-Manero1,*, N. Daver1, G. Montalban-Bravo1, E. Jabbour1, C. Di Nardo1, S. Kornblau1, P. Bose1, Y. Alvarado1, M. Ohanian1, G. Borthakur1, J. Cortes1, K. Naqui1, N. Pemmaraju1, X. Huang2, G. Nogueras-Gonzalez2, C. Bueso-Ramos2, Y. Gasior1, V. Bayer1, S. Pierce1, H. Yang1, S. Colla1, H. Kantarjian1

Background: Outcomes of pts with MDS after hypomethylating agent (HMA) failure remain poor. Upregulation of PD-1/PD-L1 and CTLA-4 in MDS CD34+ cells after exposure and loss of response to HMA have been reported. Nivo and Ipi in allo or monoclonal aignted grade 33 non-hematologic AEs. Therefore, the stopping rule for toxicity was not met in any of the cohorts. Delays of therapy due to AEs were required in 9 pts due to: rash (N=1), adrenal insufficiency (N=1), colitis (N=1), thyroiditis (N=2), pneumonitis (N=3), and nephritis (N=1). Early 8-week mortality occurred in 1 patient due to: adrenal insufficiency (N=1), colitis (N=1), thyroiditis (N=2), pneumonitis (N=3), and nephritis (N=1).

Results: A total of 63 pts have been enrolled, 54 (86%) are evaluable for response and toxicity including 21 treated with frontline AZA+Nivo, and 15 and 18 with Nivo or Ipi after HMA failure, respectively Median age is 69 years (range 39-85). The median number of treatment cycles was 3 (range 1-11). A total of 3 (27%) pts in the AZA+Nivo cohort, 6 (40%) in the Nivo cohort, and 3 (33%) in the Ipi cohort having received 3 cycles. The stopping rule for toxicity was not met in any of the cohorts. Delays of therapy due to AEs were required in 9 pts due to: rash (N=1), adrenal insufficiency (N=1), colitis (N=1), thyroiditis (N=2), pneumonitis (N=3), and nephritis (N=1). Early 8-week mortality occurred in 1 patient due to: adrenal insufficiency (N=1), colitis (N=1), thyroiditis (N=2), pneumonitis (N=3), and nephritis (N=1). The ORR was 80% (13/21) in the AZA+Nivo cohort including 6 CR. The ORR was 0% and 30% (5/18) in the Nivo and Ipi arms, respectively. The stopping rule for response was met on the Nivo arm, and enrollment after patient 15 was stopped. Immunophenotypic analysis of stem cell and progenitor compartments was performed in 27 pts, including PD-1 and PD-L1 expression analysis in 16 pts. Increased PD-1 and PD-L1 expression on progenitor and stem cell compartments was observed in 3 and 4 pts, respectively. Treatment with PD-1 inhibitors could not overcome the aberrant differentiation patterns. No differences in response were observed based on PD-1 bone marrow expression.

Summary/Conclusions: Preliminary results indicate that PD-1 blockade with Nivo in combination with AZA in untreated high-risk MDS pts is associated with a tolerable safety profile and clinical activity. Single-agent Ipi is capable of inducing responses in previously treated MDS pts. Single-agent Nivo did not show clinical activity.

S488

ORAL RIGOSERTIB COMBINED WITH AZACITIDINE IN PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML) AND MYELODYSPLASTIC SYNDROMES (MDS): EFFECTS IN TREATMENT NAÏVE AND RELAPSED/REFRACTORY PATIENTS

S. Navada1,*, G. Garcia-Manero2, K. Kearn3, R. Ochimara-Reissig1, E. Demakos1, P. Fenaux3, M. Petrone4, P. Bzyszewski4, S. Fruchtman4, L. Silverman1

Background: Azacitidine (AZA) is first line therapy for patients (pts) with higher risk MDS and demonstrated efficacy in older pts with AML (Dombret et al, Blood
Hypomethylating agents (HMA) remain the standard of care for the treatment of myelodysplastic syndromes (MDS) however, loss of response to therapy is associated with poor outcomes. Multiple studies have tried to identify biomarkers of response but the impact of the mutational architecture present at the time of diagnosis in response outcomes is unclear.

Aims: To evaluate the impact of the mutational architecture present at the time of diagnosis in response outcomes.

Methods: We evaluated 222 previously untreated patients with MDS or CMML that received HMA therapy. A total of 143 patients (79%) had MDS and 43 (19%) had CMML, including 108 (49%) with lower-risk based on IPSS and 114 (51%) with higher-risk disease. Therapy consisted in azacitidine monotherapy in 60 (27%) patients, decitabine monotherapy in 57 (26%), guadecitabine in 46 (21%) and combinations in 59 (27%). The ORR was 61% (135/222) with 80 (36%) patients achieving CR. A total of 161 (73%) patients had at least one detectable mutation. Median number of mutations was 1 (range 0-5). Frequencies of detected mutations are shown in Figure 1A. Among 70 (32%) patients evaluable for clonal heterogeneity, as indicated in Figure 1B. By univariate analysis, presence of mutations in ASXL1 (OR 0.45, CI 0.22-0.93, p=0.03) and RUNX1 (0.44, CI 0.20-0.96, p=0.038) as well as that of TP53 mutations with VAF ≥0.31 (OR 0.21, CI 0.05-0.8, p=0.024) predicted for a lower likelihood of achieving response. Analysis of functional pathways revealed that patients with mutations in chromosome 1 (OR 0.43, CI 0.21-0.86, p=0.017) and signaling genes (OR 0.48, CI 0.23-1.00, p=0.049) had lower likelihood of achieving response. Additionally, patients with ASXL1 mutations (OR 0.24, CI 0.09-0.64, p=0.005), particularly in the absence of co-occurring TET2, as well as those with increased number of mutations, particularly if more than 3 (OR 0.21, CI 0.06-0.73, p=0.014), or signaling gene mutations (OR 0.32, CI 0.13-0.80, p=0.016), had a lower likelihood of achieving a CR. A longer time to response was observed in patients with DNM73A mutations with VAF ≥0.35 (3.4 vs 1 months, OR 0.22, CI 0.06-0.76, p=0.017). Among patients who achieved CR, presence of 3 or more mutations (2.6 vs 1.3 months, OR 1.35, CI 1.00-1.83, p=0.049) and TP53 mutations with VAF ≥0.31 (0 vs 3.7 months, OR 2.03, CI 1.03-3.98, p=0.040) predicted for shorter CR duration. Presence of clonal heterogeneity, as well as the identified pairwise co-mutation patterns did not predict for any of the response outcomes.

Summary/Conclusions: The combination of oral RIG and standard-dose AZA was well tolerated in repetitive cycles in pts with AML and MDS. Response was observed both in HMA-treatment-naive pts (85%) and in pts failing HMA therapy (62%), suggesting the addition of RIG can overcome HMA clinical resistance by acting as a chromatin modifying agent. In AML, responses were seen in 37.5% of evaluable pts. Based on these results, continued study in AML is warranted. A Phase III study of the combination of oral RIG and AZA in pts with treatment naive MDS is planned.

**Table 1.**

Summary/Conclusions: The type, number and burden of mutations at the time of diagnosis may predict response to therapy with HMA in patients with MDS and CMML.
STUDY OF THE EFFECT OF miRNAs TARGETING RPS14 ON CELLULAR BIOLOGICAL BEHAVIOR OF MYELODYSPLASTIC SYNDROMES

Y. Nie1, B. Xiong1, X. Zuo1, S. Wang2
1Zhongnan Hospital of Wuhan University, Wuhan, 2Institute of Hematology & Blood Disease Hospital, CAMS & PUMC, Tianjin, China

Background: As key factors in gene post-transcriptional regulation, microRNAs (miRNAs) have been identified to play important roles in carcinogenesis in various tumors. Myelodysplastic syndrome (MDS) is a group of clonal myeloid disorders characterized by refractory quantitative and qualitative abnormalities of hemocytes and its pathogenesis is poorly understood. Some studies have shown that abnormal expressions of some miRNAs have close relationship with the pathogenesis of MDS. Recently, low RPS14 expression is found common in all kinds of myelodysplastic syndromes including patients without 5q deletion, but its mechanism remains unclear.

Aims: To determine the cause of RPS14 reduction in MDS except 5q- syndrome, influence of miRNAs on RPS14 expression was analyzed, and the role of specific miRNA on proliferation, differentiation and apoptosis of hematopoietic stem cells were evaluated. This research will help reveal the pathogenesis of MDS from a new angle and provide new ideas for the diagnosis, treatment and prognosis evaluation of MDS.

Methods: Firstly, we predicted that miR-223 may target 3'UTR of RPS14 by bioinformatics software, then verified if the special miRNA could target RPS14 by assay of luciferase activity. Secondly, the miRNA expression level of miR223 were detected in the bone marrow BM selected from 28 MDS patients including ten RCUD patients, ten RCMD patients, four RAEB-1 patients and four RAEB-2 patients, meanwhile, the miR223 expression status were tested in four kinds of cell lines including SKM-1, HL-60, K562 and THP-1. Cell lines through qRT-PCR and RPS14 expression was detected by means of immunofluorescence (IF). Thirdly, constructing lentivirus which carried miR223 overexpression vector and inhibitor were infected to the SKM-1 cell line and K562 cell line which had the highest level of RPS14, then apoptotic analysis was detected by flow cytometry method and proliferation was tested by CCK-8 assay. Fourthly, hemin (50μM,) was used to induce erythroid differentiation of K562 cells which carried miR223 overexpression. We used flow cytometry method CD71 and CD235a makers and qRT-PCR (CD235 and r-globin) to detect the erythroid proliferation.

Results: 1.We verified miR-223 could target RPS14 by assay of luciferase activity. 2. Ten MDS patients had higher miR-223 expression compared with health controls. We demonstrated that miR223 could promote cell proliferation, inhibit cell apoptosis and suppress terminal erythropoiesis through target RPS14.

Summary/Conclusions: MDS patients had higher miR-223 expression compared with health controls. We demonstrated that miR223 could promote cell proliferation, inhibit cell apoptosis and suppress terminal erythropoiesis through target RPS14.
serial samples, we inferred the clonal relationships between original and relapsed samples in 20 patients (Fig B). Mutations from initial diagnosis reappeared in 17 patients. The relapse clone of 13 patients was identical to or clonally evolved from the initial AML clone (7 and 6 patients, respectively). Relapse clones of 4 patients evolved from an inferred ancestral clone, distinct from the initial AML clone. The remaining 3 patients’ relapse clones appear to be independent of the initial AML clone. As was assessed whether the mutation status at pre- and post-HCT has any impact on OS and relapse after HCT. With a follow-up duration of 6.9 years, patients with VAF ≥0.2% at day 21 in any gene showed worse OS (HR 2.9; p=0.006) as well as increased risk of relapse (HR 5.3; p=0.0003) (Fig C-D). Multivariate analyses verified that VAF ≥0.2% at day 21 remained an independent risk factor (HR 1.32; 95% CI 1.30-2.33; p<0.01), OS (HR 1.80; 95% CI 1.32-2.45; p<0.01) and GRFS (HR 1.32; 95% CI 1.01-1.72; p<0.05) and higher NRM (HR 3.03; 95% CI 1.98-4.70; p<0.01) vs HAPLO HSCT to those from MSD.

Aims: The following factors were included in the propensity score model: patient, year of HSCT, time from diagnosis to HSCT, conditioning (RIC), source of stem cells (BMP/B), cytogenetic group, patient and donor CMV serology status.

Results: We identified 2654 pts (HAPLO=185; MSD=2469) for int-AML (HAPLO=122; MSD=1888) or high-risk AML (HAPLO=63; MSD=581). Median follow-up (months) was 16 (1-209), with a median of 24 months for HAPLO recipients. 74% received PC'TY and 26% ATG. Conditioning regimen was myeloablative in 50% vs 52% (p=0.52) of HAPLO and MSD pts, respectively. HAPLO pts had a longer interval from diagnosis to HSCT (6 vs 4 months; p<0.01), had more often high-risk AML (34% vs 23%; p<0.01), bone marrow as stem cell source (49% vs 19%; p<0.01) and CMV positive donors (72% vs 61%; p=0.01). Graft failure occurred more frequently after HAPLO (3% vs 1%; p=0.002). For pts with int-AML CI of aGVHD and cGVHD was 29% vs 1% (p=0.03) and 30% vs 36% (p=0.02) in HAPLO and MSD pts, respectively. At two years, NRM and RI were 26% vs 10% (p=0.01) and 30% vs 20% (p=0.52) for HAPLO and MSD pts, respectively. In multivariate analysis HAPLO was associated with reduced LFS (HR 1.74; 95% CI 1.30-2.33; p<0.01), OS (HR 1.80; 95% CI 1.32-2.45; p<0.01) and GRFS (HR 1.32; 95% CI 1.01-1.72; p<0.05) and higher NRM (HR 3.03; 95% CI 1.98-4.70; p<0.01) vs MSD.

Summary/Conclusions: With an ORR of 67% and a sustained response rate of ≥20 weeks of 71%, treatment with ibr resulted in clinically meaningful and durable responses in pts who failed at least 1 prior treatment for cGVHD. Most responders were able to reduce steroid dose. PD and biomarker changes support a beneficial effect of ibr on immune cell subsets in pts with cGVHD. The interactions of ibr with those previously reported for pts with B cell malignancies and those seen in cGVHD pts on concomitant steroids. Responses in this pretreated, high-risk population support study of ibr for frontline treatment of cGVHD.
cliated to lower LFS. Donor CMV seropositivity was associated with lower GRFS and higher NRM and aGVHD. In high-risk-AML aGVHD and cGVHD were 36% vs 24% (p=0.03) and 39% vs 33% (p=0.80) for HAPLO and MSD pts, respectively. At two years, NRM and RI were 18% vs 10% (p=0.16) and 21% vs 36% (p=0.02) while LFS and OS were 61% vs 55% (p=0.14) and 67% vs 66% (p=0.26) in HAPLO and MSD pts; GRFS was 44% vs 40% (p=0.17). In multivariate analysis risk of grade IV aGVHD (HR: 2.20; 95% CI: 1.29-3.74; p<0.01) was increased after Haplo as compared to MSD and no difference was observed in LFS, OS and GRFS, respectively. Conditioning regimen was associated with lower NRM and higher GRFS; while younger age and donor CMV status was associated with lower RI, higher LFS and OS. Results were confirmed in the analysis of the with the the propensity score technique as for RI, NRM, LFS, OS and GRFS

Summary/Conclusions: As per our registry based study in intermediate risk AML results of HSCT from matched sibling donor are superior to those of HAPLO-HSCT, while in high risk-AML relapse is lower in the HAPLO transplants and NRM, LFS and OS is similar

S494

INDIVIDUAL OUTCOME PREDICTION FOR MDS AND SECONDARY AML AFTER ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION BASED ON GENETIC, PATIENT- AND TRANSPLANTATION-ASSOCIATED RISK FACTORS

M. Heuser1, R. Gadbdouline1, P. Loeffeld1, V. Dobbermacl1, H. Kreimeyer1, M. Pankratz1, M. Flintrop1, V. Panagiota1, H. Kreimeyer1, M. Wichmann1, R. Shaswar1, U. Platzbecker2, C. Thiede2, T. Schroeder3, G. Kobbe3, R. Geffers4, B. Schlegelberger1, G. Göhring1, H.-H. Kreipe1, U. Gemming1, A. Gansen1, N. Kroeger5, C. Koenecke1, F. Thol1

1Hannover Medical School, Hannover, 2Universitätsklinikum Carl Gustav Carus, Dresden, 3Heinrich Heine University, Düsseldorf, 4Helmholtz Centre for Infection Research, Braunschweig, 5University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Background: Prediction of individual outcomes after allogeneic hematopoietic cell transplantation (alloHCT) is difficult, as it is influenced by a multitude of risk factors.

Aims: To develop a tool that predicts individual outcomes of patients with myelodysplastic syndrome (MDS) or secondary acute myeloid leukaemia from MDS (sAML) after alloHCT.

Methods: We integrated molecular data with available prognostic factors in patients undergoing alloHCT for MDS and sAML to evaluate their impact on prognosis. 304 patients with MDS or sAML who underwent alloHCT were sequenced for mutations in 54 genes. We used a Cox multivariate model and competing risk analysis with internal and cross validation to identify factors prognostic of overall survival (OS), cumulative incidence of relapse (CIR) and non-relapse mortality (NRM).

Results: In multivariate analysis, mutated NRAS, U2AF1, IDH2, TP53 and/or a complex karyotype were significant prognostic markers for OS besides age above 60 years, remission status treated but not in CR, IPSS-R cytogenetic risk, HCT-CI >2 and female donor sex. Mutated NRAS, IDH1, EZH2 and TP53 and/or a complex karyotype were genetic aberrations with prognostic impact on CIR. No molecular markers were associated with the risk of NRM. The addition of molecular information significantly improved the risk prediction for OS and CIR as assessed by the Akaike information criterion. Internal and cross validation confirmed the robustness of our comprehensive risk model. We developed an interactive risk prediction tool to provide personalized predictions for OS, CIR and NRM outcome after alloHCT. An individualized prediction for a 53-year-old male with sAML with trisomy 11, mutated NRAS, IDH2 and DMMT3A and complete remission after double induction is shown in Figure 1. The probability of CIR at 2 years was 45% and the patient relapsed after 0.61 years. The probability of OS at 2 years was 41% and the patient died after 0.88 years.

Summary/Conclusions: We combine molecular, cytogenetic, patient- and transplantation associated risk factors into a comprehensive risk score to provide personalized predictions for outcome after alloHCT. Upon validation in larger patient cohorts, this will improve patient information before alloHCT and provide a platform to improve treatment strategies for patients with high risk of CIR or NRM.

S495

IMPACT OF POST-TRANSPLANT INFUSION OF DONOR T CELLS GENETICALLY MODIFIED WITH INDUCIBLE CASPASE 9 SUICIDE GENE (BPX-501 CELLS) ON CHILDREN WITH LEUKEMIA GIVEN ALPHA-BETA T-CELL DEPLETED HAPLO-HSCT

P. Merli1,2, A. Bertaina3, F. Galaverna3, M. Algen1, D. Pagliara1, G. Li Pira1, J. Weinberg2, A. Moseley2, F. Locatelli1

1Ospedale Pediatrico Bambino Gesù, Rome, Italy, 2Bellিকum Pharmaceuticals Inc., Houston, United States

Background: HLA-haploidentical allogeneic hematopoietic stem cell transplant (haplo-HSCT) offers an option for children with acute leukemia in need of a transplant and lacking an available HLA-identical donor. However, performing haploidentical-HSCT without any graft manipulation has historically been associated with a high risk of acute and chronic graft-versus-host disease (GVHD). T cell depletion reduces the risk of GVHD, but leads to delayed immune reconstitution, predisposing to serious infection and leukemia relapse due to the lack of a T cell-mediated graft-versus-leukemia (GvL). To address these challenges, we have infused mature BPX-501 T cells (donor peripheral lymphocytes which have been modified with the iCas9 suicide gene) after θ T-cell depleted haplo HSCT to facilitate immune reconstitution and GvL effect. BPX-501 T-cells are genetically modified with the iCas9 suicide safety switch and a truncated CD19 marker. In the event of GVHD, the switch is activated by an infusion of the drug rimiducid (AP1903) resulting in rapid T cell apoptosis and GVHD reversal.

Aims: This study was performed to evaluate both safety and efficacy of BPX-501 T cell infusion post θ T-cell depleted haplo HSCT in pediatric patients with high risk ALL and AML in CR1 and CR2.

Methods: A prospective Phase II study enrolling children with hematopoietic disorder who lack a matched donor. 38 patients have been enrolled and treated with θ TCR deleted haplo HSCT after a myeloablative preparative regimen followed by BPX-T cell infusion to date; of them, 24 had ALL and 14 AML (21% CR1, 79% CR2). Median follow-up is 11 months (range 3-24).

Results: All patients engrafted and no secondary graft failure was recorded. Median time to neutrophil and platelet recovery was 16 days (range 8-33) and 11 days (range 7-19), respectively. With a median follow-up of 11 months (range 3-24 months), the cumulative incidence of NRM and relapse was 3.7% and 12.0%, respectively, while the disease-free survival probability was 84.2% (Fig 1). All aGVHD resolved (5 Grade I skin, 5 Grade II skin, 2 Grade III GI). One child received rimiducid to treat steroid-resistant grade II skin with complete resolution in 24 hours (Fig 2). There were 3 cases of chronic GVHD, 2 were mild; 1 severe and fatal in a patient whose donor had VZV reactivation during mobilization. CD3+ T cells reached 500 cells/μl by day 90, with normalized resolution in 24 hours (Fig 2). There were 3 cases of chronic GVHD, 2 were mild; 1 severe and fatal in a patient whose donor had VZV reactivation during mobilization. CD3+ T cells reached 500 cells/μl by day 90, with normalized resolution in 24 hours (Fig 2).

HEREDITARY HEMATOLOGIC MALIGNANCIES: GENETIC COUNSELING IMPLEMENTATION IN A LARGE LEUKAEMIA CENTER
C. Dimaro1,2, S. Bannert2, K. Takahashi1, C. Benton1, M. Routhbort3, N. Permaraju1, N. Daver4, T. Kadla5, G. Garcia-Manero5, K. Patel6, H. Kantarjian1, A. Yacoub7
1Leukemia, 2Clinical Cancer Genetics, 3Hematopathology, 4Genomic Medicine, The University of Texas MD Anderson Cancer Center, Houston, United States

Background: Hematologic malignancies have rarely been targets for genetic evaluation, even in familial cases. Over the past decade, more than 12 genes have been identified to cause inherited predispositions to hematologic malignancies. Genetic counseling, testing, and surveillance protocols for these families are not well-established. Additionally, many families with high incidence of blood cancers do not have described syndromes suggesting additional genes remain to be identified.

Aims: To identify individuals with inherited susceptibilities to hematologic malignancies, the Hereditary Hematologic Malignancy Clinic (HHMC) was established in 2014 at The University of Texas M. D. Anderson Cancer Center. The clinic at Backfan, together with both clinical and research testing for patients with hematologic malignancies suspected to have inherited predisposition syndromes

Methods: Individuals were referred to the HHMC for several indications: (1) bone marrow failure/aplastic anemia/hypocellular MDS, (2) personal history of hematologic malignancy with ≥1 first-degree relative or ≥2 second-degree relatives with hematologic malignancy, (3) personal history of multiple primary cancers, (4) germline evaluation of presumed somatic mutations identified on next-generation leukemia prognostic panels, (5) management and/or surveillance of a previously-identified genetic syndrome, or (6) solid tumor heredity. Genetic counseling is available for patients with active hematologic malignancy. Over the past 3 years, 152 probands were evaluated (n=152). Skin biopsies were performed to obtain germline DNA, and next-generation sequencing approaches on both a clinical and research basis were utilized.

Results: Clinical genetic testing was performed in 97/152 individuals (64%). Research testing was performed in 46/152 (30%), particularly in patients negative for known susceptibility genes or without features suggestive of a clinical syndrome. Nine (6%) individuals did not undergo genetic testing. Clinical testing identified 23/97 (24%) individuals with a germline susceptibility to hematologic malignancy. Seven probands (7%) were identified to have RUNX1 mutations associated with familial platelet disorder with myeloid malignancy (FPD-AML). Six (6%) were identified to have the telomerase disorder dyskeratosis congenita; only one of them met clinical diagnostic criteria with the “classic triad” of symptoms. Three (3%) patients were identified to have Li-Fraumeni syndrome due to constitutional TP53 mutations. Two adults (2%) were diagnosed with Diamond-Blackfan anemia and two of these individuals developed adult-onset myelodysplastic syndrome after a long latency period and prior spontaneous remission of their childhood anemia. Two young adults (2%) with Fanconi anemia were diagnosed, and one patient each with DDX47 mutation and CBL (Noo-nan-like syndrome with JMML) were identified. Counseling, testing, and surveillance of identified mutation carriers in many affected families is ongoing.

Summary/Conclusions: Individuals with hereditary susceptibilities to hematologic malignancies are not as rare as previously thought. Clinical evaluation of these patients through genetic counseling and testing is high yield for identified at-risk families. Research-based sequencing for novel mutations is indicated and ongoing.

S497

SECONDARY LEUKEMIAS IN GENETIC SUBTYPES OF CONGENITAL NEUTROPENIA (ELANE, HAX1, WASP, G6PC3, ETC.): A LONG-TERM ANALYSIS OF THE SCNIR EUROPE
C. Zeidler1,2, M. Klmiankou1, A. Nickel1, S. Mellor-Heineke1, J. Skokowa1, K. Welte3
1SCNIR, Medical School Hannover, Hannover, 2Department of Hematology, Oncology, Clinical Immunology, 3Department of General Pediatrics and Pediatric Hematology and Oncology; University of Tuebingen, Tuebingen, Germany

Background: Leukemia predisposition is well known in congenital neutropenia (CN) subtypes. By taking all patients with known and unclassified CN together the incidence of secondary leukemia accounts for more than 10 percent. Advanced molecular diagnostics and the identification of inherited and acquired gene mutations have improved our understanding of leukemic transformation in CN patients.

Aims: In the European SCNIR 449 patients with congenital neutropenia and 91 patients with cyclic neutropenia (CyN) have been enrolled since 1994. These 449 cases were analyzed by case-matched molecular genetic subtypes: ELANE, HAX1, G6PT, G6PC3, WAS, SBSD, TAZ1 and p14 or no identified mutation, respectively. Our aim is to assess the risk of leukemic transformation within these genetic subgroups.

Methods: Here we report the leukemia incidence of genetic subtypes analyzing all available long-term data from the European Branch of the Severe Chronic Neutropenia Registry (SCNIR). In addition, we analyzed 91 patients with CyN with or without ELANE mutations.

Results: Results from genetic testing were available for 314 of 449 CN patients, of whom 118 patients revealed ELANE, 48 HAX1, 71 SBSD, 28 G6PT, 9 G6PC3, 7 WAS, 5 TAZ1 mutations and 27 other rare gene mutations (e.g. p14, CXCR4). 135 patients remain unclassified. In addition, 48 of 91 patients with CyN revealed ELANE mutations. Secondary myelodysplastic syndrome (MDS) or leukemia occurred in 49 of the 449 CN patients and in 1 of the 48 ELANE-CyN patients. Acquired CSF3R nonsense truncating mutations have been detected in the bone marrow cells of about 80% of CN patients who progress to MDS or acute myeloid leukemia (AML) and around 30-35% of non-leukemic CN patients, supporting the association between the acquisition of CSF3R mutations and leukemic transformation. These mutations have been shown to be acquired in hematopoietic cells only and therefore are not the primary cause of transformation. At the time of first detection of CSF3R mutations, and of malign transformation is highly variable. Some patients progressed to MDS/AML within a few months. In others, CSF3R mutant clones persisted for many years without progression to leukemia. The distribution by genetic subtypes and the frequency of CSF3R mutations is shown in the table below.

*Gene mutations without leukemia: (G6PC3 n=9, TAZ1 n=5, p14 n=4, digenic mutations n=4, CDH1 n=4, CDKR4 n=3, germine extracellular CSF3R n=2, C16orf57 n=2, Pearson syndrome n=2, LYST n=1)

All subgroups benefit from G-CSF treatment. However, patients requiring main- tenance doses of G-CSF above 8µg/kg/day are at greater risk of leukemic transformation.

Summary/Conclusions: Conclusion: The incidence of secondary AML reflects the genetic heterogeneity of CN.

S498

EFFECT OF ECULIZUMAB IN PAROXYSMAL NOCTURNAL HEMOGLOBINURIA (PNH) PATIENTS WITH OR WITHOUT HIGH DISEASE ACTIVITY: RESULTS FROM THE INTERNATIONAL PNH REGISTRY
B. Höchsmann1,2, F. Sicre de Fontbrune3, J. Wu Lee4, A. Kulagina5, P. Hillmen5, A. Wilson6, J. Marantz2, H. Schrezenmeier1
1Institute for Clinical Transfusion Medicine and Immunogenetics, University Hospital Ulm, Ulm, Germany, 2Department of Internal Medicine IV, 3Hôpital Saint Louis, Paris, France, 4Seol St. Mary’s Hospital, The Catholic University of Korea, Seoul, Korea, Republic Of, 5Pavlou First Saint Petersburg State Medical University, St. Petersburg, Russian Federation, 6St. James’s University Hospital, Leeds, United Kingdom, 7Alexion Pharmaceutical Inc., Lexington, MA, United States

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a rare, progressive, life-threatening disease caused by somatic phosphatidylinositol glycan class A (PIGA) gene mutation in bone marrow stem cells. The International PNH Registry (NCT01374360) is a prospective, multinational, observational study to record the natural history of PNH and collect data on long-term efficacy and safety of treatment with eculizumab (ecu), a humanized monoclonal antibody approved for treatment of PNH.

Aims: Evaluate the effect of ecul in patients with PNH with or without high disease activity (HDA).

Methods: Patients enrolled in the Registry as of December 5, 2016, were stratified by HDA and ecu treatment status into 4 groups: HDA/ecu-treated; HDA/never ecu-treated; no-HDA/ecu-treated; no-HDA/never ecu-treated. HDA is defined as lactate dehydrogenase (LDH) ratio ≥1.5x upper limit of normal within 6 months of baseline and history of any of the following: fatigue, hemoglobinuria, abdominal pain, dyspnea, anemia (hemoglobin <100 g/L), major adverse vascular event (MAVE; including thromboembolism [TE]), dysphagia, or erectile dysfunction. Patients were assessed at baseline (date of enrollment in never ecu-treated patients; date of initiation of ecu in ecu-treated patients) and at last follow up by case-matched molecular genetic subtypes: ELANE, HAX1, G6PT, G6PC3, WAS, SBSD, TAZ1 and p14 or no identified mutation, respectively. Our aim is to assess the risk of leukemic transformation within these genetic subgroups.
Results: 4717 patients were enrolled; of these, 2670 had non-missing data on euc and HDA status, and were included in the current analysis (HDA/euc-treated, n=778; HDA/never euc-treated, n=636; no-HDA/euc-treated, n=111; no-HDA/never euc-treated, n=1138). Median (min, max) duration of follow-up after baseline was longer for the ecu-treated patients compared with the never euc-treated patients for both the HDA and no-HDA groups (see Table). Results for changes from baseline to last follow-up in outcomes of interest are summarized in the Table. Data show that patients in the ecu-treated cohort had high burden of disease at baseline. Specifically, in the HDA population, a higher proportion of ecu-treated patients had a history of MAVE (33.3%) vs never euc-treated patients (13.7%). A similar disparity at baseline was also observed in the no-HDA population (33.0% vs 11.0%, respectively). Following ecu treatment, the divergence in the proportion of patients with MAVE has substantially narrowed for the HDA patients (3.9% for ecu-treated vs 3.3% for never ecu-treated) despite longer follow-up for the treated patients. Similar findings were seen in no-HDA patients (5.3% vs 2.1%, respectively). In patients with no-HDA, treatment with ecu was associated with meaningful improvements in mean (standard deviation [SD]) reduction from baseline in LDH ratio (-5.0 [3.7] vs -0.4 [2.3]) and proportion of red blood cell transfusion-free patients (37.6% vs 15.8%). The FACIT-Fatigue data, while limited, showed the HDA/ecu-treated group experienced a greater mean (SD) score improvement than the HDA/never ecu-treated group (4.1 [10.3] vs 0.5 [6.8] points).

Table 1.

Summary/Conclusions: Our analysis of real-world data from the International PNH Registry has demonstrated that treatment with eculizumab was associated with improved outcomes in patients with HDA. Our findings are consistent with the notion that patients with HDA, including those with a history of MAVE, should be treated with eculizumab.

S499

CONGENITAL AMEGAKARYOCYTIC THROMBOCYTOPENIA: FUNCTIONAL RESCUE OF A NOVEL MPL MUTANT IN PRIMARY HEMATOPOIETIC CELLS USING CRISPR-CAS9

C. Clever et al.

Background: Thrombopoietin (Tpo) and its receptor, Mpl, are the principal regulators of early/late thrombopoiesis and hematopoietic stem cells maintenance. Mutations in MPL can drastically impair its function and be a contributing factor in multiple hematologic malignancies, including congenital amegakaryocytic thrombocytopenia (CAML). CAMT is a rare inherited syndrome characterized by thrombocytopenia at birth, progressing to bone marrow failure and pancytopenia. The functional impact of CAMT mutations on MPL is yet to be determined. Here we report unique familial cases of CAMT presenting with a previously unreported MPL mutation: T814C (W272R) in the background of the activating MPL G117T (K39N or Baltimore) mutation.

Aims: To describe the characterization of this novel MPL mutant and the use of genome editing as a novel therapeutic option for CAMT.

Methods: Human megakaryoblastic UT-7 and murine Ba/F3 cells stably expressing human wild-type (WT) MPL or mutant MPL fused to mNeonGreen were used as models. Confocal microscopy, proliferation and surface biotinylation assays, as well as co-immunoprecipitation and western blotting analysis, were used to elucidate the function and trafficking of MPL mutants. Multiplex, flow-based, CRISPR-Cas9 gene editing was used to repair mutant MPL and rescue its function. Cord blood from the younger male sibling was used as a source of primary homozygous MPL K39N/W272R CD34+ cells. CD34+ cells were edited using ribonucleoproteins electroporation followed by sequencing and functional assays such as flow cytometry and single colony assays.

Results: Consanguineous parents and their eldest daughter, both heterozygous for MPL K39N/W272R, do not present any signs of disease. Their monozygotic twin daughters presented at birth with severe thrombocytopenia leading to a diagnosis of BMT type 1. Whole blood sequencing revealed a homozygous double MPL K39N/W272R mutation, as their younger male sibling. One of the twins died after bone marrow transplant. Confocal microscopy shows that a significant fraction of chimeric WT MPL protein reaches the cell surface. Significant surface expression is also noted for MPL K39N. In contrast, the chimeric MPL protein bearing the W272R mutation, alone or together with the K39N mutation, showed no detectable surface expression of the Tpo receptor while being strongly co-localized with ER marker calreculin. Both WT and K39N-mutated MPL were found signaling competent, while single or double mutants bearing W272R were unresponsive to Tpo. Tpo-induced signaling was partially rescued by the expression of the CAMT-specific R885H/C polymorphism (forcing binding of MPL to the cell surface). Genome editing performed on cells carrying the W272R mutation restored the WT sequence and the response to Tpo, with similar cell proliferation as WT MPL cells. Finally, when applied to primary MPL K39N/W272R CD34+ cells, CRISPR-based gene editing rescued surface expression of MPL and response to Tpo, as assessed by flow cytometry. Newly edited CD34+ cells were able to generate a similar number of megakaryocytic colonies as control CD34+ cells in a single colony assay. Non-edited cells failed to do so.

Summary/Conclusions: We report a new double in cis mutation of MPL (K39N/W272R) in the context of CAMT. Function of the deficient MPL receptor could be rescued using two separate approaches: gene correction, in cis, using CRISPR-Cas9 and CRISPR-Cas9 genome engineering. Successful editing of primary hematopoietic stem cells indicates direct therapeutic applications for gene editing in this disease.
Summary/Conclusions: Both treatment with MPT-T and MPR-R controlled pain and resulted in an improvement in global QoL, as compared to baseline after 9ID and during maintenance. Treatment with thalidomide initially resulted in less pain and disease symptoms. At all treatment stages thalidomide caused less diarrhea, fatigue and insomnia as compared to treatment with lenalidomide. In contrast, therapy with lenalidomide resulted in less side effects of treatment, less constipation and less neuropathy as compared to thalidomide at all stages of treatment. In addition, long term maintenance therapy with lenalidomide resulted in better global QoL, better physical functioning and less pain.

Background: We recently reported the results of the phase III randomized HOVON87/NMSG18 study showing comparable efficacy of treatment with melphalan, prednisolone and thalidomide following by thalidomide maintenance (MPT-T) versus melphalan, prednisolone and lenalidomide followed by lenalidomide maintenance (MPR-R) (Zweegman S et al. Blood 2016;127(9):1109-1116). As not only efficacy but also potential toxicity affecting quality of life (QoL) guides the choice of treatment, health-related (HR) QoL is important.

Aims: To evaluate the HRQoL results of the HOVON87/NMSG18 study.

Methods: Two validated HRQoL instruments (EORTC QLQ-C30 and MY20) were collected at baseline, after 3 and 9 induction cycles (3ID and 9ID) and after 6 and 12 months of maintenance therapy (6MT and 12MT). The subscales global QoL, physical functioning, pain, fatigue, constipation, diarrhea, nausea/vomiting, insomnia, disease symptoms, side effects of treatment and neuropathy, and/or meaningful improvements in HRQoL are important for previous literature were used. To determine clinically relevant superiority of one arm, a difference in score of ≥1 standard error of contrast, therapy with lenalidomide resulted in less side effects of treatment, less constipation and less neuropathy as compared to thalidomide at all stages of treatment. In addition, long term maintenance therapy with lenalidomide resulted in better global QoL, better physical functioning and less pain.

Background: Maintenance of pretreatment health-related quality of life (HRQoL) and/or meaningful improvements in HRQoL are important for previously untreated indolent non-Hodgkin lymphoma (iNHL) patients (pts). GALLI-
UM (NCT01332806) is an open-label, randomized Phase III study of obinutuzumab (GA101; G) plus chemotherapy (chemo) followed by G maintenance (G-chemo) compared with rituximab (R) plus chemo followed by R maintenance (R-chemo) in pts with previously untreated NHL. In GALLIUM, G-chemo produced a clinically meaningful improvement in investigator-assessed progression-free survival (PFS) among follicular lymphoma (FL) pts (34% reduction in risk of a PFS event relative to R-chemo). Grade 3-5 and serious adverse events were more common with G-chemo.

**Aims:** To compare changes in HRQoL in FL pts receiving G-chemo and R-chemo during GALLIUM.

---

**Results:** 277 responses were returned with 1 response excluded (non-haematological malignancy). Haematological diagnoses included acute leukaemia (n=40), chronic leukaemia (n=35), lymphoma (n=62), myeloma (n=102), MDS (n=15), MPD (n=12), other (n=2) and not specified (n=7). 257 (93.1%) patients had received antitumor cancer therapy, 218 (79%) were receiving treatment at the time of survey and 54% had ongoing symptoms related to their treatment or cancer. 197 (71.4% patients did not want access to a support group, 23 (19%) wanted access, 51 (8.3%) were not aware of the possibility and 6 (1.8%) did not respond. 51.8% of patients were aware of the existing support groups, 38.8% were not sure, 2.9% were not aware and 1.8% did not respond. The cohort of patients who did or did not want access to a support group was another 88% of patients had been given a key worker (oncological and nurse specialist, research nurse, advanced nursing practitioner or nurse clinician); of the those 88% were satisfied and 1% were partly satisfied with the support they had received with 11% not responding. 93% (n=231) of patients were satisfied with the information they had received at diagnosis and 90% (n=224) felt the diagnosis had been given sensitively. Only 20% of patients currently on treatment wanted access to a support group and 24% not on treatment wanted access to a support group. Date of diagnosis was divided into three groups. Gp A: before 2005 (n=15), Gp B: after 2006 (n=229) and not stated (n=14). There was no difference in the three groups when asked if they wanted access to support group (13%, 22%, 7% respectively; p=0.3) or awareness that support group was available (40%, 57%, 50% respectively; p=0.6). There were additional comments from patients that support from family and online forums in addition to key workers was extremely valuable to them. On univariate analysis patients who were satisfied with their key worker support did not want access to a support group (p=0.04). There was no effect on wanting access to a support group and diagnosis (p=0.67), treating hospital (p=0.5), information given (p=0.6), need for in-patient treatment (p=0.3), quality of care (p=0.8) or satisfaction with overall care (p=0.8).

**Summary/Conclusions:** Our results suggest that a large majority of patients with hematological malignancy do not want access to a cancer support group but providing satisfactory support through key workers and other healthcare professionals is likely to achieve better patient experiences.

**Acknowledgements:** We would like to acknowledge the members of the GMCPB and patients for their contribution to the survey.

---

**Figure 1.**

**Methods:** Enrolled pts were aged ≥18 years with documented, previously untreated FL (grades 1-3a), advanced disease (stage III/IV or stage II with tumor diameter ≥7cm), ECOG performance status 0-2, and requiring treatment according to GELF criteria. Pts were randomized 1:1 to R 375mg/m² on day (D) 1 of each cycle (C) or G 1000mg on D1, 8, and 15 of C1 and D1 of C2-8, for 6 or 8 cycles depending on chemo (CHOP, CVP or bendamustine). Respondents continued to receive R or G every 2 months (mo) for 2 years or until progression. The Functional Assessment of Cancer Treatment-Lymphoma (FACT-Lym) questionnaire (Webster et al. 2005) was used to assess overall HRQoL, physical and functional well-being, and distress and treatment-related symptoms. FACT-Lym was administered on D1 of C1 and C3 during induction, at the end of induction, and at mo 2 and 12 during maintenance/follow-up. For each FACT-Lym scale, mean and 95% confidence interval (CI) were derived for recorded scores at each visit and changes from baseline. Minimally important differences (MID) were used to calculate the proportion of pts reporting improvement on the FACT-Lym lymphoma subscale (LYMS; ≥3 points), Trial Outcome Index (TOI; ≥6 points), and lymphoma total score (Lym-Total; ≥7 points). All pts gave informed consent.

**Results:** Of 1202 FL pts randomized (median age, 59 yrs; 53.2% female; median observation time, 34.5 mo (range 0-54.5), 566/601 (92.5% G-chemo) and 550/601 (91.5% R-chemo) completed all FACT-Lym scales at baseline. Baseline demographics and disease characteristics were balanced between arms. At baseline, mean HRQoL scores were similar in the two treatment arms, with all pts having some impairment of physical function, functional wellbeing, emotional and social function. Over the course of treatment, mean HRQoL was similar in the two treatment arms. From end of induction onwards, pts in both arms experienced clinically meaningful improvements from baseline in LYMS scores (Figure), and the summary scales that included this subscale (TOI, Lym-Total). On each summary scale, ~50% of patients in each arm reported clinically meaningful improvements. There were no clear differences between arms in HRQoL scores over the course of therapy.

**Summary/Conclusions:** In previously untreated FL pts in GALLIUM, G-chemo and R-chemo produced similar improvements in HRQoL. These results suggest that lymphoma-related symptoms were reduced by both treatments and that the resulting improvements in well-being were not abrogated by treatment-related side effects. When viewed in the context of longer PFSs, these results further support the relative benefit of G-chemo over R-chemo in GALLIUM.
Background: Pharmacologic therapy stabilizes hematologic counts and splenomegaly in myeloproliferative neoplasms (MPN), however only partial symptom improvement typically occurs. Evidenced-based integrative care may address this need, however data is limited in patients with MPNs.

Methods: Patients were recruited via social media. Informed consent and approval were obtained. Patients with MPNs (polycythemia vera, essential thrombocytosis, primary myelofibrosis) were eligible. We surveyed patients about symptom burden, quality of life, depression, and fatigue in MPN patients. Interactions of integrative therapies with symptoms were assessed. All surveys were conducted by mail and online. Data was collected from March 2016 to February 2017. Results: A total of 1087 patient surveys were consented. Of these, 888 had 10 or more responses. There were 338 essential thrombocytosis (ET), 188 myelofibrosis (MF), 315 polycythemia vera (PV), and 17 other. In MF: DIPSS risk categories included low (8%), Int-1 (19%), Int-2 (29%), high (12%), and unknown (32%). Symptom association: Overall, patients had lower MPN related symptoms when participating in aerobic activity (p<0.001), massage (p=0.001), yoga (p=0.02), strength training (p=0.001), breathing exercises (p=0.001), and support groups (p=0.001). Overall quality of life was higher with aerobic activity (p<0.001), massage (p=0.02), yoga (p=0.02), strength training (p=0.001), breathing exercises (p=0.001), and support groups (p=0.001). Depression (PHQ-9 total >3 category) was lower in aerobic activity group (p=0.001), yoga (p=0.001), strength training (p=0.001), and meditation (p=0.2). Fatigue was lower in aerobic activity (p<0.001), massage (p=0.04), strength training (p<0.001), breathing exercises (p<0.001), and support groups (p=0.001). In subgroup analysis, ET and PV patients had lower symptom burden (MPN-SAF TSS) with aerobic activity (p<0.001, <0.001), massage (p=0.01, 0.02), and strength training (p=0.03, 0.02). Support groups were found to be associated with lower symptoms in ET patients (p=0.03). In MP, breathing exercises (p<0.001) and support groups (p=0.03) were associated with lower symptom burden. See Table #1.

Summary/Conclusions: Integrative therapies are associated with improved symptom burden, quality of life, depression, and fatigue in MPN patients. Interestingly, unique patterns were associated within MPN subtypes. Further studies are needed to understand the benefits of integrative therapies in MPN patients.
Acute lymphoblastic leukemia - Biology 2

P506

T CELL EXHAUSTION CHARACTERIZED BY COMPROMISED MHC CLASS I AND II RESTRICTED CYTOTOXIC ACTIVITY ASSOCIATES WITH ACUTE B LYMPHOBLASTIC LEUKEMIA RELAPSE AFTER ALLO-HSCT

L Liu1*, Y Chang1, X Xu1, X Zhang3, Y Wang4, K Liu5, X Huang1
1Peking University People’s Hospital & Peking University Institute of Hematology, Beijing Key Laboratory of Hematopoietic Stem Cell Transplantation, Beijing, China

Background: B cell acute lymphoblastic leukemia (B-ALL) relapse contributes to the predominant mortality after allogeneic hematopoietic stem cell transplantation (allo-HSCT). However, the mechanism of B-ALL relapse after allo-HSCT remains unknown. Eradication of leukemia in allo-HSCT settings largely relies on graft-versus-leukemia (GVL) effects mediated by donor T cells. T cell exhaustion characterized by increased expression of inhibitory receptors including PD-1 and Tim-3 and impaired function may blunt the GVL effects and was reported in acute myeloid leukemia relapse after allo-HSCT, whether T cell exhaustion is involved in B-ALL relapse after allo-HSCT remains unknown.

Aims: To evaluate whether T cell exhaustion is involved in B-ALL relapse after allo-HSCT; and investigate the correlation of inhibitory ligands on leukemic cells, leukemic load and T cell exhaustion, as well as the impact of treatment outcome on T cell exhaustion.

Methods: Our study enrolled 18 B-ALL patients who underwent first hematologic relapse after allo-HSCT and 18 matched B-ALL patients in remission (without minimal residual disease MRD) and 14 healthy donors from April 2016 to November 2016 at the Peking University People’s Hospital. In the remission group, the methods used for the study were matched transplantation protocol and post-transplant time were matched in relapsed patients. In our study, all patients had achieved full donor chimerism before relapse or bone marrow collection. Peripheral blood (PB) were collected at the same day of bone marrow collection in relapsed patients. For patients who received induction therapy, we prospectively collected BM at least once after therapy.

Results: In the current study, we observed that increased co-expression of PD-1 and Tim-3 was observed in both CD4+ and CD8+ T cells in relapse settings. Moreover, both CD4+ and CD8+ T cells exhibited compromised proliferative capacity, cytokine production and cytotoxic potentials such as degranulation and granzyme B production (preferentially on CD4+ T cells) in relapsed patients. In addition, T cells in the tumor site are more easily exhausted than those in peripheral blood. Reversal of T cell exhaustion was associated with effective anti-leukemic response in relapsed patients who underwent re-induction therapy.

Summary/Conclusions: In conclusion, our study suggested that T cells experienced a comprehensive functional impairment in B-ALL relapse settings after allo-HSCT and reversal of T cell exhaustion was associated with effective anti-leukemic responses. These results also provide a foundation for the development of novel effective leukemia therapeutics, such as anti-PD-1 or PD-L1 therapy, by targeting T cell exhaustion

RUXOLITINIB/NILOTINIB COTREATMENT BETTER INHIBITS LEUKEMIA-PROPAGATING CELLS IN PHILADELPHIA CHROMOSOME-POSITIVE ALL

Y Kong1, Y-L. Wu2, Y. Song2, M-M. Shi12, X-N. Cao1, H-Y. Zhao1, Z-Q. Lin1, Y-Y. Lai1, H. Jiang1, G. Jiang1, X-J. Huang1
1Peking University People’s Hospital, Peking University Institute of Hematology, 2Peking-Tsinghua Center for Life Sciences, Academy for Advanced Interdisciplinary Studies, Peking University, Beijing, China

Background: Relapse remains the major cause of treatment failure in patients with acute lymphoblastic leukemia (Ph-ALL), even in the modern era of tyrosine kinase inhibitors (TKIs). Relapse of Ph+ALL may result from the persistence of leukemia-propagating cells (LPCs), which are defined by their ability to initiate human leukemia and self-renew in immunocompromised mice. Using an anti-CD122-conditioned NOD/SCID-hu/Slc mouse model, xenografting assay was used to be enriched in the CD34+CD38−CD58- fraction in human Ph+ALL(YK,...,XJH). Leukemia. 2014). Furthermore, a cohort study demonstrated that Ph+ALL patients with LPCs phenotype at diagnosis exhibited a significantly higher cumulative incidence of relapse than did the group with other phenotypes, even when receiving uniform front-line imatinib-based therapy pre- and post-allo-transplant (YK,...,XJH). BMT. 2015). Therefore, it is imperative to identify novel therapeutic strategies based on LPCs to improve the prognosis of Ph+ALL patients.

Aims: To identify the potential molecular basis of LPC-mediated relapse, RNA sequencing(RNA-seq) and real-time reverse transcription-PCR (qRT-PCR) were performed to analyze the gene expression profiles and functional characteristics of cells of other phenotypes from patients with de novo Ph+ALL. In order to assess the effects of the selective BCR-ABL and/or JAK2 inhibition therapy by the treatment with single agents or a combination of ruxolitinib and imatinib or nilotinib on Ph+ALL LPCs, drug-induced apoptosis of LPCs was investigated in vitro, as well as in vivo using sublethally irradiated and anti-CD122-conditioned NOD/SCID xenograft mouse assay. Moreover, western blot analyses were performed on the BM cells harvested from the different groups of recipient mice.

Methods: RNA-seq and qRT-PCR, we found that JAK2 was more highly expressed in the sorted LPCs than in the cells of other phenotypes in patients with de novo Ph+ALL in vitro study, cotreatment with nilotinib and ruxolitinib induced significantly higher levels of apoptosis in LPCs. In humanized Ph+ALL mice model, treatment with the nilotinib and ruxolitinib combination, compared with either ruxolitinib or TKIs alone, led to the most significant reduction in human Ph+ALL engraftment in the recipients. Further evidence that the most effective anti-LPCs effect was achieved with the combination treatment was derived by the engraftment analysis of BCR/ABL expressing cells using a qRT-PCR assay and HE and IHC with anti-hCD19 staining. Moreover, the combination of nilotinib and ruxolitinib more effectively reduced the LPCs capacity through a higher expression of phospho-CrKL, JAK2 and STAT5 activities at the molecular level.

Summary/Conclusions: JAK2 was more highly expressed in the sorted LPCs than in other cell phenotypes in patients with de novo Ph+ALL. Furthermore, selective BCR-ABL/JAK2 dual inhibition with nilotinib/ruxolitinib more effectively eliminated LPCs than either ruxolitinib or TKIs alone. Therefore, this pre-clinical study appears to provide scientific rationale for simultaneously targeting BCR-ABL and JAK2 activities, which represents a promising anti-LPCs therapeutic approach for patients with de novo Ph+ALL.

P508

PREDICTING ANTI-LEUKEMIA ACTIVITY OF THE B-2-SELECTIVE INHIBITOR ABT-199 IN BCP-ALL BY FUNCTIONAL ASSESSMENT OF APOPTOSIS SIGNALING

F. Seyfried1, S. Demiri1, R. Hör1, J. Ryan1, A. Scheffold1, M. Villalobos-Ortiz2, S. Köhler1, J. Zinngrebe1, S. Stilgenbauer3, A. Letai2, K.-M. Debatin1, L. H. Meyer1
1Department of Pediatrics and Adolescent Medicine, Ulm University Medical Center, Ulm, Germany, 2Dana-Farber Cancer Institute, Harvard Medical School, Boston, United States, 3Department of Internal Medicine III, Ulm University Medical Center, Ulm, Germany

Background: Although survival rates of pediatric BCP-ALL patients have continuously improved during the past decades, therapy-related toxicity and relapse occurring in 10-20 % of patients are associated with poor outcome, clearly emphasizing the need of novel, targeted treatment strategies. Deregulated survival pathways and cell death resistance contribute to treatment failure and relccurrence of the disease. ABT-199 (venetoclax) is a small molecule inhibitor of BCL-2 demonstrating anti-cancer activity among different malignancies. However, predictive biomarkers are required for up-front identification of patients who would benefit from BCL-2 directed therapies.

Aims: The aims of this study were to assess the efficacy of ABT-199 in BCP-ALL, to functionally evaluate factors mediating ABT-199 susceptibility or resistance and to identify markers indicative of successful anti-leukemia activity.

Methods: The activity of ABT-199 was assessed by cell viability assays in BCP-ALL cell lines (N=6) and patient-derived xenograft (pdx) samples (N=27), analyzing half maximal effective concentrations (EC50). Expression of apoptosis regulators was detected by western blot analysis. MCL-1 deficient cell lines were generated by CRISPR/Cas9 gene editing. BH3 profiling was used to measure the mitochondrial dependence of leukemia cells on anti-apoptotic BCL-2 family proteins. In vivo treatment of ABT-199 was performed in a set of three distinct ALL rdds.

Results: Different sensitivities of ABT-199 were observed in a series of BCP-ALL rdds and cell lines with heterogeneous anti-leukemia activities upon drug exposure. The majority of BCP-ALL samples showed sensitivity to ABT-199-induced cell death in the nanomolar range (EC50 <1µM) with four out of six cell lines and 20 of 27 rdds, while ABT-199 insensitivities with EC50s of more than 1µM were identified in 26% of pdx leukemias. ABT-199 induces apoptosis by selectively inhibiting BCL-2, thereby sensitizing leukemia cells to pro-apoptotic molecules; however, the sequestration of drug-released BIM by anti-apoptotic MCL-1 might lead to resistance. Therefore, we investigated protein expression of both regulators and found the ratio (BCL-2/MCL-1) to be cor-
related with ABT-199 sensitivity (t = 0.71, p = 0.000), highlighting the importance of functional assessment of the direct target molecule and additional resistance mediating molecules. In line, MCL-1 knockout in two ABT-199-resistant cell lines led to sensitization towards ABT-199, however, resulted in different effects of sensitization, emphasizing that ABT-199 resistance is determined by the interplay of several apoptosis regulators. Therefore, we characterized the functional dependence of pdx leukemias on anti-apoptotic BCL-2 family members. Mitochondrial dependence on BCL-2 (mitochondrial priming by the BAD-peptide measuring BCL-2, BCL-XL and BCL-W, and subtracting the response to the HRK-peptide measuring BCL-XL) was found to be tightly correlated with ABT-199 sensitivity. In contrast, ABT-199-resistant samples were characterized by low BCL-2-dependence and addition to other BCL-2 family members, including BAX, BAK, BCL-XL or MCL-1. Finally, we evaluated prediction of in vivo ABT-199 sensitivity in a pre-clinical ALL pdx mouse model by functional BH3 profiling. Strikingly, high mitochondrial BCL-2-dependency was clearly associated with prolonged leukemia-free survival upon ABT-199-therapy (two pdds, log rank p = 0.0035 and <0.0001), in contrast to another leukemia with low BCL-2-dependence and in vivo ABT-199 resistance (log rank p = 0.144).

Summary/Conclusions: SCP-ALL displays heterogeneous ABT-199 sensitivities characterized by the level of the target molecule but also other interacting regulators. Functionally, mitochondrial BCL-2-dependence assessed by the BH3 profiling assay is clearly associated with ABT-199 sensitivity. Importantly, in vivo anti-leukemia activity of ABT-199 therapy in individual pxd leukemias is predicted by mitochondrial BCL-2-dependence, emphasizing the utility of identification of patients and guidance of future clinical application by functional assessment of apoptosis signaling.

**CD45RA- MEMORY T CELLS EXPRESSING AN NKGD2-CAR TARGET PEDIATRIC ACUTE LEUKEMIA**

L. Baz,1 C. de la Cruz,1 T. Colosimo,2 C. D. Mallory,1 A. Janik,3 L. Oteiza,1 S. Perov,2 A. Vultur4 and R. K. Greer1

1Clinical Research, CNIO, Madrid, Spain, 2Haematology, St.Jude Children’s Research Hospital, Memphis, United States, 3Infectious diseases and Immunity, IDIAP, 4Pediatric Oncology, INGEMMI, Madrid, Spain

**Aims:** The aim of this study was to analyze the CD45RA expressing on pediatric acute leukemia cells and determine their susceptibility to an NKGD2 CAR T cell based immunotherapy.

**Methods:** The expression of NKGD2 was analyzed in Peripheral Blood Mononuclear Cells (PBMCs) from patients suffering from acute leukemia, as well as in leukemia cell lines, by flow cytometry (FCM) using specific monoclonal antibodies directed against MICA, MICB, ULBP-1, ULBP-2, ULBP-3 and ULBP-4. The expression of CD45RA, CD27 and CD127 on T-cell reporter cells were measured. PBMC resistance to CD45RA-microbeads expressed on T cells was measured by AutoMACS device. The HL20I4r-MNDantsCD19bbz lentiviral vector was derived from the clinical vector CL204r-EE-1a-hgOpt27 but contained the extracellular domain of NKGD2, the hinge region of CD8a and the signaling domains of 4-1BB and CD3-z. The cassette was driven by MDR promoter. Vital supernatant was produced by transient transfection of HEK293T cells with the vector genome plasmid and lentiviral packaging helper plasmids pCAGG-HGpcp, pCAGGS-vgsv and pCAGGS-RTR2. Cytogenetic studies and array Comparative Genomic Hybridization were performed to analyze the genetic stability of lentiviral-transduced memory T cells. The in vitro cytotoxicity of CD45RA-NKGD2-CAR redirected NK cells against leukemia cells, healthy PBMC and Mesenchymal stromal cells (MSCs) was evaluated by performing conventional 4-hour europium-TDA release assays or by FCM using CFSE and 7AAD labeling of target cells.

**Results:** NKGD2 were heterogeneously expressed in leukemia primary cells and cell lines. For B cell ALL primary samples, we found expression of MICA, MICB, ULBP-1, ULBP-2 and ULBP-4 in refractory and resistant samples. Lentiviral transduction of NKGD2-4-1BB-CD3z increased NKGD2 surface expression in CD45RA-memory T cells, which became consistently more cytotoxic than untransduced cells against leukemia cells. Additionally, no chromosomal aberrations nor cytotoxic activity against healthy PBMC or Mesenchymal stromal cells was observed in NKGD2 CAR expressing T cells.

**Summary/Conclusions:** Our results show NKGD2-CAR redirected CD45RA-memory T cells target NKGD2 expressing leukemia cells in vitro and could be a promising and safe immunotherapeutic approach for pediatric acute leukemia patients.

**A BILINEAL ACUTE LYMPHOBLASTIC LEUKEMIA ORIGINATING AT A COMMON LYMPHOID PROGENITOR**

A. Gonzalez-Munillo1,2, C. Sánchez-Valdepeñas1, C. Robledo2, A. Castillo1, L. Abad1, C. Hernandez-Marques1, D. Ruano1, L. Madero1, J. Alonso2, M. Ramirez1

1Pediatric Hematology & Oncology, Hospital Universitario Niño Jesús, Madrid, 2Institute of Investigacion en Enfermedades Raras, Instituto de Salud Carlos III, Majadahonda, Spain

**Background:** Genetic mutations are crucial events during leukemogenesis and provide specific markers for backtracking the cellular origin of acute leukemias up to immature uni- or multi-potent progenitor cells in the hierarchy of the hematopoietic system.

**Aims:** To characterize the clonal architecture and cell of origin in a case of pediatric acute leukemia identified as B-ALL.

**Methods:** Bone marrow cells obtained at diagnosis were used for all studies. Immunophenotyping was done by flow cytometry. T- and B-cell leukemia purification was performed by immunomagnetics methods and DNA extracted afterward. TCR-gamma gene rearrangement was studied in T- and B-lymphocytic cells independently by PCR sequencing. Somatic mutations in purified T- and B-leukemic cells were identified by deep-sequencing using a panel of 160 genes frequently mutated in cancer (Human comprehensive cancer panel, Qiagen). Mutations were validated by Sanger sequencing. Myeloid and erythroid clonogenic progenitors were isolated from methylcellulose cultures, DNA extracted, and assessed for the presence of the H3F3A p.K28N mutation by Sanger sequencing.

**Results:** The patient was a 10 years old boy. At diagnosis, the bone marrow was infiltrated by 60% leukemic cells, with 2 immunophenotypically different populations: a common B-ALL (54%) and a pro-T-ALL (6%). The patient showed no bone marrow lesions, no liver or spleen enlargement, and full body X-rays showed no tumor. TCR-gamma rearrangement was detected in purified (>95% pure) T-ALL and B-ALL cells, suggesting a common origin for both leukemic subpopulations. The B-ALL cells presented a c.35G>A p.G12D mutation in the KRAS gene, absent in the T-ALL. The T-ALL cells presented a c.35G>A (p.G12D) mutation in the NRAS gene, absent in the B-ALL. A c.1126_1127insTAGA (p.P376Lfs*10) mutation in the WT1 gene was also detected only in the T-ALL. A c.849G>T (p.K28N) mutation in the H3F3A gene was detected in both the B-ALL and T-ALL subpopulations, confirming the involvement of a Common Lymphoid Progenitor in the process of leukemogenesis. The presence of the H3F3A p.K28N mutation in the myeloid compartment would point to a multipotent myeloid-lymphoid rather than a lymphoid-restricted progenitor as the cell origin of the leukemia. Therefore, we cultured myeloid-erythroid-committed progenitor cells in clonogenic cultures and sequenced the H3F3A gene. None of the 122 myeloid or erythroid clonogenic progenitors (41 CFU-GM, 73 BFU-E and 8 CFU-GEMM) presented the p.K28N mutation in the H3F3A gene.

**Summary/Conclusions:** Our results indicate the involvement of a Common Lymphoid Progenitor as the cell origin of this case of biphenal ALL, as well as the crucial role of H3F3A and RAS family genes in the leukemogenesis process coupled with B and T differentiation.

**CYSTEINE AND GLYCINE-RICH PROTEIN 2 (CSRP2) TRANSCRIPT LEVELS CORRELATE WITH LEUKEMIA RELAPSE AND LEUKEMIA-FREE SURVIVAL IN ADULT B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA WITH NORMAL CYTOGENETICS**

S.-J. Wang1,1, P.-Z. Wang2, R. Gale3, Y.-Z. Qin1, Y.-R. Liu1, Y.-Y. Lai1, H. Jiang1, Q. Jiang1, X.-H. Zhang1, B. Jiang3, L.-P. Xu1, X.-J. Huang4, K.-Y. Liu4, G.-R. Ruam1,2,4 Peking University Peoples Hospital and Institute of Hematology, Beijing Key Laboratory of Hematopoietic Stem Cell Transplantation, and Department of Immunology, School of Basic Medical Sciences, Peking University Health Science Center., Beijing, China, 2Haematology Research Center, Division of Experimental Medicine, Department of Medicine, Imperial College London, London, United Kingdom, 3Peking University Peoples Hospital and Institute of Hematology, Beijing Key Laboratory of Hematopoietic Stem Cell Transplantation, Peking-Tsinghua Center for Life Sciences, Beijing, China

**Background:** Outcome of adults with B-cell acute lymphoblastic leukemia (ALL) remains poor and relapse is the major cause of treatment-failure. Currently, the best biomarkers in B-ALL especially in those with normal cytogenetics and studying their clinical significance and biological function will be helpful for risk-stratification, treatment decision and targeted therapy. CSRP2 (cysteine and glycine rich protein 2) maps to chromosome subband 12q21.1. which is frequently abnormal in diverse cancers. Increased CSRP2 transcript levels were associated with de-differentiation in hepatocellular carcinoma and CSRP2 was identified as a new invadopodia actin bundling factor that critically promotes breast cancer cell invasion and metastasis. However, the clinical significance and biological function of CSRP2 in B-cell ALL remains unknown.
Aims: To identify novel biomarkers in B-cell ALL based on bioinformatics analyses; to examine the expression and clinical significance of CSRP2 in adults with B-ALL; to explore effects of CSRP2 on biological function of B-cell ALL.

Methods: We did bio-informatics analyses to identify mRNA transcripts aberrantly-expressed in B-cell ALL. RT-qPCR (real-time quantitative polymerase chain reaction) was used to examine CSRP2 transcript levels in bone marrow samples from 236 adults with B-cell ALL compared with samples from normal. A prognostic value was assessed in 168 subjects. CSRP2-knockdown and CSRP2-over-expression cell models were constructed to study the biological function of CSRP2 in B-cell ALL.

Results: We selected 9 candidate genes for validation 7 of which proved significantly-associated with B-cell ALL. CSRP2 was the most differentially expressed gene in our validation studies. CSRP2 was over-expressed in 228 out of 236 adults (97%) with newly-diagnosed B-cell ALL. In subjects with normal cytogenetics: those with high CSRP2 transcript levels had a higher 5-year cumulative incidence of relapse (CIR) and worse relapse-free survival (RFS) compared with subjects with low transcript levels (56% [95% confidence interval 53-59%] vs 19% [18-20%]; P=0.011 and 41% [17-65%] vs 80% [66-96%]; P=0.007). In multivariate analyses a high CSRP2 transcript level was independently-associated with CIR (HR=5.32 [1.64-17.28]; P=0.005) and RFS (HR=5.56 [1.87-16.53]; P=0.002). Functional analyses indicated CSRP2 promoted cell proliferation, cycle-cell progression, in vitro colony formation and migration. Abnormal CSRP2 expression was associated with resistance to chemotherapy; sensitivity was restored by down-regulating CSRP2 expression. CSRP2 activated ERK1/2 signaling pathway, regulated cell-cycle related protein and activated CREB signaling pathway, whose activation was associated with poor prognosis in adults with B-cell ALL.

Summary/Conclusions: CSRP2 was widely over-expressed in adults with B-cell ALL. Determination of CSRP2 transcript levels in subjects with normal cytogenetics might inform therapy-decisions. Consideration could be given to down-regulating CSRP2 expression as a way to reverse drug resistance.

THERAPEUTIC TARGETING OF PRE-B CELL RECEPTOR SIGNALLING IN CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA

A. Alhammer1,2, M. Case1, E. Matheson3, H. Blair4, J. Vormoor4, J. Irving1
1Newcastle University, Northern Institute for Cancer research, Newcastle upon Tyne, United Kingdom, 2Al-Nahrain University, Biotechnology research Center, Baghdad, Iraq

Background: Acute lymphoblastic leukaemia (ALL) is the most common malignancy in children and adolescents and relapsed ALL remains one of the leading causes of cancer-related deaths in children. Components of the precursor-B cell receptor (Pre-BCR) signalling pathway are hijacked in ALL cells and this causes of cancer-related deaths in children. The precursor-B cell receptor (Pre-BCR) signalling pathway is hijacked in ALL cells and this dependence may be therapeutically targeted. A number of tyrosine kinase inhibitors (TKIs) targeting effectors of this signalling pathway are showing great promise in the clinic and warrant preclinical evaluation in paediatric ALL. They include Dasatinib (BCR-ABL/SRC inhibitor), Fostamatinib R406 (SYK inhibitor), Ibrutinib (BTK inhibitor) and CAL-101 (PI3K-δ inhibitor).

Aims: To preclinically evaluate these candidate TKIs, as novel, targeted drugs for Pre-BCR signalling.

Methods: ALL cell lines (Reh, Nalm-6, PreB 697 and its glucocorticoid resistant descendant, R3F9) and 36 primary-derived xenograft (PDX) cells from 16 ALL were used in the study. Cell viability was assessed by Resazurin. Pre-BCR expression (μHc, VpreB and A5) and functionality using a Calcium flux assay were detected by Flow cytometry. Intracellular phospho-flow cytometry was used to detect constitutive phosphorylation and activation in response to anti-Ig antibody, as well as drug pharmacodynamic measures (p-BTK, p-Syk, p-AKT, p-ERK, p-PLC-Y2, p-BLNK). Apoptosis and cell cycle were analysed by flow cytometry using Annexin V and Propidium iodide. RQ-PCR was used to measure mRNA expression. Caspase activity induction, G0/RX expression and phosphorylation were detected by western blotting.

Results: ALL cell lines were modestly sensitive to Dasatinib (mean GI50 5.33 µM, range 2.45-12.5 µM) and R406 (mean GI50 6.42 µM, range 2.88-17.73 µM). However, cells were resistant to Ibrutinib (mean GI50 19.5 µM, range 11.47-18.3 µM) and CAL-101 (mean GI50 52.08 µM, range 25-77.83 µM). Cell cycle arrest and significant apoptosis was seen with R406 and Ibrutinib treatment, while Dasatinib and CAL-101 were cytostatic, causing G1 arrest with no substantial cell death. Pharmacodynamic assays confirmed inhibition of the relevant drug targets. PDX cells showed greater sensitivity than the cell lines to Dasatinib (4 out of 16 patient samples <0.5pM, R406 (7 out of 16 patient samples <0.5pM), Ibrutinib (3 out of 15 patient samples <5µM) and CAL-101 (3 out of 15 patient samples <2pM). Pre-BCR positive ALL cell lines and PDX cells were sensitive to R406 and Dasatinib, with a Ph+ PDX confirming sensitivity to the latter. Combining TKIs with the glucocorticoid (GC), Dexamethasone showed synergism in ALL cell lines and was particularly notable for Dasatinib and R406 in PreB cell receptor positive lines. Synergism was associated with significantly enhanced apoptosis, an increase in expression of the GR target gene, GILZ and for Dasatinib, enhanced expression of the pro-apoptotic, Bim. Control REH cells (GC receptor negative) showed no synergism.

Summary/Conclusions: Significant sensitivity of TKIs targeting Pre-BCR signalling have been identified at clinically achievable concentrations. Dasatinib and R406 sensitivity was associated with Pre-BCR positive ALL and combination with Dexamethasone showed significant synergism in GC resistant cell lines and PDX samples. TKIs were also effective in some Pre-BCR negative ALL cells, however, predictive biomarkers need to be established. Confirmation of these data in preclinical models in vivo may define new therapies for high risk ALLs.

P513

BMP4 LEVELS IN CHILDHOOD B-ALL OF LOW-/INTERMEDIATE-RISK GROUPS IDENTIFY CHILDREN WITH POOR OUTCOME

A. Entrena1, C. Martinez-Laperche2, G. Melen2, A. Varas1, A. Vicente1, M. Ramirez2
1School of Medicine, Universtitad Complutense, 2Pediatric Hematology & Oncology, Hospital Universitario Niño Jesus, Madrid, Spain

Background: Leukemic relapses among children with acute lymphoblastic leukaemia (ALL) from low/intermediate-risk groups is a challenge for the cure of this disease. New biomarkers are needed for identifying children at high risk of relapses. Bone Morphogenetic Proteins (BMPs) are multifunctional secreted growth factors that belong to the TGF-β superfamily and are well-known for their indispensable roles in vertebrate development. In the cellular context, BMPs regulate fundamental processes such as cell proliferation, differentiation, migration and survival. In last years, important new information has been generated on the contribution of BMP family members, such as BMP4, in cancer pathogenesis.

Aims: Here we have evaluated the relevance of BMP4 signaling in ALL.

Methods: The expression levels of BMP4 related genes (bmp-4, and bmp-receptors, signaling mediators, inhibitors and targets) in ALL blasts obtained at the time of diagnosis (n=56), and the BMP-4 levels in central system fluid samples (CSF), were quantified by RT-qPCR or ELISA. The engrafting potential of primary ALL cells, exhibiting high or low BMP4 levels, were assessed in xenotransplantation experiments using unirradiated NSG mice.

Results: BMP4 was expressed at significantly higher levels in ALL blasts of children who later relapsed (17.78 versus 26.68, arbitrary units, AU, p<0.05). Relapses among children with high BMP-4 expression occurred significantly later than those with low BMP-4 expression (845 days versus 282 days, p<0.05). The difference in the cumulative incidence of relapses (CIR) was quasi-significant between both groups (p=0.031). The ratio Smad7:Smad1, suggesting inhibition of the Smad-dependent signaling pathway, was significantly higher in ALL blasts of children who later relapsed (14.33 versus 5.13, AU, p<0.05). CIR was significantly higher (p<0.05) in the group of children with the Smad-dependent pathway inhibited. All these differences were detected considering the whole population, as well as only the low/intermediate-risk groups. BMP4 levels were significantly higher in CSF samples of children with leukemic infiltration of the central nervous system (16.0 pg/ml versus 3.4 pg/ml, p<0.001), as well as in the group of children who relapsed (10.6 pg/ml versus 1.8 pg/ml, p<0.001). Hematopoietic engraftment (marrow, spleen and peripheral blood) and CNS leukaemia occurred only in ALL samples with high BMP4 levels. Even more, no signs of disease were detected in mice transplanted with primary ALL blasts expressing low levels of BMP4. In independent preclinical pharmacological blockade of the canonical BMP signaling pathway significantly decreased infiltration of CNS and consistently resulted in amelioration of clinical parameters including neurologic score.

Summary/Conclusions: These results indicate that high BMP4 levels are required for both bone marrow engraftment and CNS infiltration by B-ALL cells. BMP4 levels in leukemia cells could be a useful biomarker to identify children with poor outcome in the childhood B-ALL of low-/intermediate-risk groups. Furthermore, BMP4 could be a new therapeutic target to blockade leukemic CNS disease.

Immunology, University Children’s Hospital, Medical Faculty, Heinrich Heine University Duesseldorf, 3Department of Diagnostic and Interventional Radiology, Medical Faculty, Heinrich Heine University Duesseldorf, 4Clinic of Pediatric Hematology and Oncology, University Medical Centre Hamburg-Eppendorf, Hamburg, 5Department of Pediatrics, University Medical Centre Schleswig-Holstein, Campus Kiel, Kiel, Germany

Background: Cure rates for acute lymphoblastic leukemia (ALL) have increased to ~90% in the last decades, but come at a high cost as a substantial proportion of these children sustain toxic side-effects. Osteonecrosis (ON) is one of the most common and debilitating side effects, which severely impacts quality of life.

Aims: To analyze whether systematic magnetic resonance imaging (MRI) screening of adolescents can identify those with asymptomatic ON (stage I and II), who subsequently develop symptomatic ON.

Methods: Children diagnosed with ALL aged ≥10 years, who were enrolled in the Osteonecrosis Prevention and Long-term Observation (OPAL) registry, which includes all patients with ALL or lymphoblastic lymphoma (LBL), were analyzed. Standardized MRI screening of the hips and knees was scheduled at diagnosis and 6, 9, 12, 15, 18 and 24 months into therapy. All patients were assessed according to a standardized case report form recording symptoms and activities of daily living and functional impairments of the hips and knees based on modified Harris Hip and Knee Society scores every 3 months from diagnosis to the end of antileukemic treatment.

Results: Between 03/2013-12/2016, 64 patients (pts) were enrolled, median age at ALL diagnosis was 15 years (range 10-17), median time under evaluation was 11 months (range 0-45). 31 (48.4%) pts were male, 33 (51.6%) female.

Aims: To study whether a new compound named Pyrido[4,3-b]Quinoxaline (PyQ) has an antitumoral effect on Acute Myeloblastic Leukemia (AML). It strongly interacts with tumor alpha-chain (IL-7Rα) and downstream IL-7 signaling offers a potentially effective therapeutic strategy for T-ALL. The IL-7Rα is recruited and concentrated into lipid rafts thereby amplifying its downstream signaling pathway. The IL-7/STAT5 signaling pathway mediates downregulation of pro-apoptotic signals on human T-cells such as BAD and BIM. Moreover, we have previously reported that PyQ delocalizes the IL-7Rα away from lipid rafts on the cell surface of human T-ALL cells. We have also proved that PyQ delayed T-ALL progression in vivo when cocultured with murine stromal MS5 cells and in vivo when transplanted into immunodeficient NOD/SCID/γc−/− (NSG) mice. We also work on primary T-ALL blasts isolated from 10 patients suffering of T-ALL and maintained frozen in a biobank.

Results: In this study, we have shown that PyQ delocalizes the IL-7Rα away from lipid rafts on the cell surface of human T-ALL cells. We have also proved that localization of the IL-7Rα on lipid rafts plays a crucial role in human T-ALL maintenance in vitro. Its delocalization leads to IL-7 signaling pathway inactivation, upregulation of BAD and BIM genes involved in apoptosis and T-ALL cells apoptosis. We furthermore assessed effect of PyQ on 10 samples of primary T-ALL blasts. All of them were sensitive to IL-7-dependent cell survival and revealed a marked response to PyQ treatment (Mean IC50=5.7 ng/mL). For this work, T-ALL cells were co-cultured on murine stromal MS5 cells and PyQ has affected mainly T-ALL cell growth. No effect was observed on the stromal feeder cells, suggesting that injection of PyQ in vivo would not impact the stromal microenvironment in bone marrow. Finally, we provided evidence that PyQ delayed T-ALL progression in vivo, after treatment of immunodeficient mice xenografted with T-ALL cells.

Summary/Conclusions: The findings of this study highlight the importance of the IL-7Rα localization in maintenance of T-ALL cells and may lead to the design of a new generation of anti-cancer drugs able to modulate the protein positioning into lipid rafts.

ANALYSIS OF SAFETY DATA FROM 2 MULTICENTER TRIALS OF CTL019 IN PEDIATRIC AND YOUNG ADULT PATIENTS WITH RELAPSED/REFRACTORY (R/R) B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA (B-ALL)

1Department of Pediatrics, Perelman School of Medicine, University of Pennsylvania, 2Division of Oncology, Center for Childhood Cancer Research and Cancer Immunotherapy Program, Children’s Hospital of Philadelphia, Philadelphia, 3Division of Hematology Oncology/Blood and Marrow Transplant, Children’s Hospital of Los Angeles, USC Keck School of Medicine, Los Angeles, United States, 4Hospital Sant Joan de Déu, Barcelona, Spain, 5Children’s Mercy Hospital and Clinics, Kansas City, 6Adult and Pediatric Blood and Marrow Transplant Program, University of Minnesota, Minneapolis, United States, 7Oslo University Hospital Rikshospitalet, Oslo, Norway, 8Department of Pediatrics, The University of Texas Southwestern Medical Center, 9Pauline Allen Gill Center for Cancer and Blood Disorders, Children’s Health, Dallas, United States, 10Department of Pediatrics, Faculty of Medicine, University of Montreal, 11Hematology Oncology Division, CHU Sainte-Justine, 12Charles-Bruneau Cancer Center, CHU Sainte-Justine Research Center, Montreal, Canada, 13Department of Pediatrics and Internal Medicine, University of Utah, Salt Lake City, United States, 14Department of Pediatric Hematology-Oncology and Stem Cell Transplantation, Ghent University Hospital, 15Cancer Research Institute Ghent (CRIG), Ghent, Belgium, 16Aflac Cancer and Blood Disorders Center, Emory University, Atlanta, 17Cincinnati Children’s Hospital Medical Center, Cincinnati, 18Division of Pediatric Hematology and Marrow Transplant, Duke University Medical Center, Durham, United States, 19Division for Stem Cell Transplantation and Immunology, Hospital for Children and Adolescents, University Hospital Frankfurt, Frankfurt, Germany, 20Department of Pediatrics, Stanford University School of Medicine, Stanford, 21Novartis Pharmaceuticals Corporation, East Hanover, 22Center for Cellular Immunotherapies, Perelman School of Medicine, University of Pennsylvania, Philadelphia, 23University of Michigan, Ann Arbor, 24Icahn School of Medicine at Mount Sinai, New York, United States

Background: The CD19-targeted chimeric antigen receptor (CAR) T-cell therapy CTL019, an investigational therapy that uses reprogrammed cytotoxic T cells to recognize and eliminate target cells, has shown high response rates in clinical trials for pediatric/young adult R/R B-ALL. The safety profile in this population has been limited to a single-center trial.

Aims: To identify any new safety issues with CTL019 emerging from use in multicenter trials.

Methods: Pooled data from 2 single-arm, multicenter phase 2 trials of CTL019 therapy in pediatric/young adult patients (pts) with R/R B-ALL (NCT02435849 and NCT02228096) were used to further characterize the safety of CTL019.

Table 1.

Results: 123 pts were enrolled, 26 were not infused and not included in this analysis (10 deaths, 9 manufacturing failures, 3 adverse events [AEs], 4 pts prematurely discontinued). 97 pts received a single infusion of transduced CTL019 cells (median dose, 3.2×10^6 [range, 0.2-5.4×10^6] cells/kg). Median age was 12y (range, 3-25). During the first 8 wk after infusion, 98% of pts experienced an AE of any grade (G), 82% experienced G3/4 AEs, and 72% experienced a serious AE (SAE). Common nonhematologic G3/4 AEs (≥10%) during the first 8 wk were cytokine release syndrome (CRS; 44%), hypotension (24%), decreased appetite (21%), increased AST (19%) and ALT (12%), hypoxia (10%), hypokalemia (13%), hypophosphatemia (11%), and pulmonary edema (10%). Rates of G3/4 AEs and SAEs decreased substantially >8 wk post infusion. 21 pts died post infusion: 16 (76%) from B-cell leukemia/lymphoma (including infusion-related death), 1 from CNS, 1 from SAA, and embolic infectious stroke (n=1) (both ≤30 days); and infection (n=3, >30 days). Safety events were similar across pt subgroups based on age, sex, prior allogeneic stem cell transplant (alloSCT) (n=37), and Down syndrome (n=7). CRS was the most common CRIS, occurring in 81% of pts (Table 2). Al phCRS events occurred <8 wk post infusion. CRS was managed with supportive care, and 34% of pts were treated with anti-IL-6 agents. No deaths were attributed to CRS. Pts with ≥50% bone marrow (BM) blasts at enrolment (n=68) were...
twice as likely to develop G3/4 CRS than pts with <50% BM blasts (n=29) (63% vs 24%). Earlier-onset fever correlated with severity of CRS. CRS grade correlated with serum IL-6 levels. CRS-associated coagulopathy with fibrinogen levels <1.0 g/L was observed in 10% of pts. Neuropsychiatric AEs occurred during or shortly after CRS resolution, were self-limiting, and were more likely in pts with severe CRS or history of CNS leukemia or other CNS diseases. No G4 neuropsychiatric events were observed. Other AEs of special interest within the first 8 wk included G3/4 neutropenia with high (>38.3 C) fever (61%) and infections (G3/4, 22%). Prolonged G3/4 neutropenia (not resolved >28 days) occurred in 59 pts (61%). 36% of pts with prolonged G3/4 neutropenia had G3/4 infections after day 28. One pt with prior alloSCT was diagnosed with unconfirmed gut GVHD. Responding pts developed prolonged B-cell aplasia that was managed with immunoglobulin replacement. Tumor lysis syndrome was uncommon (3%).

Summary/Conclusions: This pooled analysis of global experience with CTL019 across 25 sites and 11 countries found no new safety issues. CRS and neuropsychiatric events, which are class effects of CAR T-cell therapy, were effectively managed. CTL019 appears similarly safe in pts with Down syndrome or prior alloSCT and across age groups. Prolonged follow-up will be required to determine the long-term safety of B-cell aplasia.

1MD Anderson Cancer Center, Houston, 2Cleveland Clinic, Cleveland, United States, 3University of Nebraska Medical Center, Omaha, Nebraska, United States, 4University of Chicago, Chicago, 5Stanford Cancer Institute, Stanford, United States, 6Geoth University, Frankfurt, Germany, 7Institute Seràgnolí, DIMES, University of Bologna, Bologna, Italy, 8University of California, Irvine, Orange, 9Pfizer Inc, Groton, 10Pfizer Inc, Cambridge, 11 Dana-Farber Cancer Institute, Boston, United States

Background: In the phase 3 INO-VATE study of relapsed/refractory acute lymphoblastic leukemia (R/R ALL) patients, inotuzumab ozogamicin (InO) showed improved complete remission or complete remission with incomplete hematologic recovery (CR/CRi) rates versus standard care (SC; 80.7% vs 29.4%; P<0.001) (NCT01564784; Kantarjian NEJM 2016 [data cutoff date: Oct 2, 2014]). Aims: To assess the impact of baseline karyotype on response and toxicities in R/R ALL patients receiving InO from the INO-VATE study Methods: Full study details have been previously published. At screening, karyotyping was performed locally, and abnormalities were categorized according to International System for Cytogenetic Nomenclature. CR/CRi and minimal residual disease (MRD) negativity rates (defined as <0.01% bone marrow blasts as assessed at a central laboratory) were compared using a chi-square test for each cytogenetic subgroup. Survival estimates were compared using a log-rank test. Data as of March 8, 2016, are presented. Informed consent was obtained from all patients. All analyses presented were not adjusted for multiple testing.

Results: Of 326 patients randomized, 284 had cytogenetic data at screening (HR=0.34; P<0.001; SC: 140). Of the 186 InO-treated patients, 21.3% had normal diploid karyotype (≥20 metaphases), 17.1% complex (≥25 abnormalities), 13.4% Philadelphia-chromosome positive (Ph+) disease, 6.7% diploid (≤20 or unknown metaphases), 4.9% hyperdiploid (>50, 4.9% aberrations involving mixed lineage leukemia (MLL), 1.8% low hypodiploid/near-triploidy, 1.2% Del (9p), 16.5% other chromosome abnormalities, and 12.2% missing. Of 164 InO-treated patients, CR/CRi rate was 73% (95% confidence interval [CI] 66–80; Table) and MRD negativity rate was 95% (95% CI, 51–67). With InO, CR/CRi and MRD negativity rates were similar between the various cytogenetic subgroups. CR/CRi rate was significantly higher with InO compared to SC in diploid (≥20 metaphases), complex, other, and missing cytogenetic subgroups (P<0.015) and numerically higher in the other cytogenetic subgroups. With InO, more patients with diploid (≥20 metaphases) karyotype proceeded to stem cell transplant versus other cytogenetic subgroups. With InO, the duration of remission (DoR) was significantly different between cytogenetic subgroups (P<0.0001), with diploid (≥20 metaphases) and other subgroups having the longest median DoR numerically and MLL subgroup having the shortest median DoR numerically; no significant differences in DoR were seen between cytogenetic subgroups with SC (P=0.1763). Significant differences in PFS were seen between cytogenetic subgroups with InO (P=0.0063); no significant differences were seen between cytogenetic subgroups with SC (P=0.5427). With InO and SC arms, overall survival (OS) differences between cytogenetic subgroups were not significant (P=0.1629 and 0.3040, respectively); however, although not statistically significant based on 97.5% CI for hazard ratio (HR), OS was numerically longer (HR <1) with InO versus SC in diploid (≥20 metaphases), MLL, complex, other, and missing cytogenetic subgroups. Generally, adverse event profiles did not vary by cytogenetic subgroup.

Summary/Conclusions: In patients with diploid (≥20 metaphases), complex, other, and missing cytogenetic karyotypes, CR/CRi rates were significantly higher with InO versus SC (P<0.001). MLL, complex, other, and missing cytogenetic subgroups, OS favored InO versus SC, though not statistically significant. Safety profiles generally were similar to the overall study population.

Background: Blinatumomab, a bispecific T-cell engager antibody construct,
has shown antileukaemia activity and tolerability in patients with relapsed/refrac-
tory B-precursor acute lymphoblastic leukaemia (ALL).

Aims: We further evaluated safety and efficacy of blinatumomab in pediatric
and adolescent patients with relapsed/refractory B-precursor ALL enrolled in
an expanded access study (NCT02187354).

Methods: Eligible patients (aged >28 days to <18 years) had ≥5% blasts and
relapse after an allogeneic hematopoietic stem cell transplantation [alloHSCT].
Blinatumomab was dosed by continuous intravenous infusion (4 weeks on/2 weeks
off) up for five cycles (≥5 to <25% blasts: 15µg/m²/day; ≥25% blasts: 5µg/m²/day
on days 1-7, then 75µg/m²/day on days 1-7 in cycle 1, then 15 µg/m²/day). The pri-
mary endpoint was incidence of treatment-emergent (TE) and treatment-related
(TR) adverse events (AEs). Key efficacy endpoints were complete response
and minimal residual disease (MRD, measured by polymerase chain reaction
or flow cytometry) response within the first two cycles, relapse-free survival,
overall survival, and incidence of alloHSCT.

Results: Among the first 40 treated patients (median age, 9 [range, 1–17
years], 24% [60%] had experienced ≥2 relapses, 20 (50%) had relapsed after
alloHSCT, and 5 (13%) were primary refractory; 18 (45%) had ≥50% blasts
and 21 (53%) had prior alloHSCT. Safety and key efficacy outcomes are shown
in the table. Twenty-five patients (63%) achieved a complete response within
the first two cycles; 19 of whom had an MRD response. Eight patients relapsed
and 20 died after treatment. Regardless of causality, the most frequent TEAEs
were pyrexia (78%), cytokine release syndrome (CRS; 23%), vomiting (23%),
and anemia (20%). All nine CRS events were grade 1 or 2, and one tumor lysis
syndrome was grade 3. Ten (25%) patients interrupted treatment and two (5%)
discontinued due to TRAEs; 13 (33%) patients had grade ≥3 TRAEs, including
two of three neurologic events (depressed level of consciousness and
headache; both grade 3). Two patients experienced fatal AEs, both of which
were considered unrelated to blinatumomab.

Table 1.

| All TEAEs | 40 (100) |
| Grade 3 | 15 (38) |
| Grade 4 | 2 (5) |
| Fatal | 5 (13) |
| Complete response | 22 (56) |
| <50% blasts | 21 (53) |
| ≥50% blasts | 22 (56) |

Summary/Conclusions: Blinatumomab showed antileukaemia activity in pedia-
tric and adolescent patients with high-risk relapsed/refractory B-precursor ALL,
including t(17;19) and AEs were consistent with those previously reported for
relapsed/refractory ALL.

LYMPHOBLASTIC LEUKEMIA (R/R ALL): UPDATED RESULTS FROM AN ADULTS WITH HIGH-BURDEN RELAPSED/REFRACTORY ACUTE LYMPHOBLASTIC LEUKEMIA FROM A RANDOMIZED PHASE 3 STUDY

M.S. Topp1,*, R.A. Larson2, A. Schuh3, W. Stevenson4, E. Lech-Maranda5, K. Nie6, Z. Zimmerman7, W. Kormany8, A.S. Stein9,10
1Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, 2Department of Medicine, University of Chicago Medical Center, Chicago, IL, United States, 3Princess Margaret Cancer Centre, University Health Network, Toronto, Canada, 4Royal North Shore Hospital, University of Sydney, Sydney, Australia, 5Department of Hematology, Institute of Hematology and Transfusion Medicine and Centre of Postgraduate Medical Education, Warsaw, Poland, 6Global Biostatistical Sciences, 7Global Development, 8Global Development, 9Global Safety, Amgen Inc, Thousand Oaks, CA, 10Geher Family Center for Leukemia Research, City of Hope, Duarte, CA, United States

Background: Blinatumomab, a bispecific T-cell engager antibody construct, has shown improved overall survival vs standard of care (SOC) chemotherapy in patients with Philadelphia chromosome-negative relapsed/refractory B-precursor acute lymphoblastic leukemia (ALL) in a randomized phase 3 study (N Engl J Med 2017;367:836-847).

Aims: We compared the incidence of adverse events (AEs) observed with blinatumomab vs SOC after adjusting for varying treatment exposure times for a more comprehensive evaluation of safety and tolerability.

Methods: Adults (aged ≥18 years) with relapsed/refractory B-precursor ALL (refractory to primary induction therapy or salvage therapy, first relapse <1 year, second or later relapse, or relapse after allogeneic hematopoietic stem cell transplantation) were randomized to receive either blinatumomab or SOC (1 of 4 predefined regimens). Blinatumomab was dosed by continuous intravenous infusion (4 weeks on/2 weeks off) for up to five induction cycles (9 months total exposure time) or 3 cycles (1−190 days) followed by 4 maintenance cycles (4 weeks on/8 weeks off) allowed for up to 12 months. Exposure-adjusted event rates were calculated as the number of events x total exposure time (shown in the table).

Results: Median (range) number of cycles were 1 (1−4) for SOC and 2 (1−9) for blinatumomab. The highest exposure-adjusted event rates (per 100 patient-years) were for pyrexia (507 SOC vs 376 blinatumomab), anemia (987 vs 229), thrombocytopenia (750 vs 126), and neutropenia (351 vs 121), all of which were lower for blinatumomab than for SOC. Febrile neutropenia (365 vs 93) and delayed cytotoxic/antineoplastic AE (1216 vs 45) were also lower for blinatumomab than for SOC (p<0.0001). Exposure-adjusted event rates for neurologic events were 743 for SOC vs 472 for blinatumomab, with median time (range) to onset of 7 (1−43) days and 7 (1−190) days, respectively, and grade ≥3 cytokine release syndrome (CRS) rates were 0 for SOC vs 10 for blinatumomab. The most frequent grade ≥3 AEs of SOC vs blinatumomab were for pyrexia (80 vs 20%) and neutropenia (80 vs 40%), which were lower for blinatumomab than for SOC (p<0.0001).

DESIGNING THE NEXT GENERATION CD33-TARGETING ADC: IMGN779, SELECTED FOR POTENCY, NOVEL MECHANISM AND PRECLINICAL TOLERABILITY, WITH HIGH ACTIVITY IN DISSEMINATED AML MODELS AND MULTI-DOSE REGIMENS

S. Adams1,*, A. Wilhelm1, L. Harvey1, L. Flaherty1, K. Watkins1, S. Sikka1, P. Shah1, W. Li1, Y. Kovtun1, C. Sloss1, K. Lai1, M. Miller1, G. Payne1
1ImmunoGen, Waltham, United States

Background: Antibody-drug conjugates (ADCs) targeting CD33 are promising therapeutics in AML, where challenges are achieving efficacy while maintaining tolerability. Here, we report the payload/ linker design and selection resulting in a high-Therapeutic Index (TI) ADC with favorable preclinical toxicity profile across multiple species and tumor model and disseminated AML models and in multi-dose regimens, IMGN779, the final ADC design, is comprised of an indolino-benzodiazepine mono-imine DNA-alkylating payload, DGN462, coupled by a cleavable N-succinimidyl-4-(2-pyridyldithio)-2-sulfobutanoate (s-SPDB) linker to a CD33-targeting antibody.

Aim: Select the best ADC out of multiple preclinical anti-CD33 ADC candidates, and assess its activity in vitro and in vivo in AML models.

Methods: Unconjugated payloads were evaluated in vitro for cytotoxicity on human AML cell lines. Payloads were compared, as CD33-targeting conjugates, in vitro for cytotoxicity on human AML cell lines and in vivo for tolerability in mice and Ti in human AML xenografts. ADCs with cleavable and non-cleavable linkers were evaluated for cytotoxicity on MDR-positive and -negative AML cell lines, for tolerability in mice and Ti in AML xenografts. IMGN779, the final ADC design, was evaluated in vivo for toxicity in rats and cynomolgous monkeys. IMGN779’s antitumor activity was evaluated in disseminated models and in fractionated- and multi-dose regimens in AML xenografts.

Results: First, we selected a high affinity antibody to CD33 with retained ADC activity. Next, given concerns for long-term toxicity of DNA crosslinkers, we prepared DNA alkylating (single strand DNA damage) and DNA crosslinking (double strand DNA damage) versions of our novel IgG payload class. Both versions had comparable IC50s on human AML cell lines as free drugs (12-260 vs. 5-77 PM) and as CD33-targeting ADCs (0.7 vs. 0.5 PM). However, in vivo, the CD33-targeting DNA alkylating ADC had a 5-fold higher TMD (maximally tolerated dose) in mice and 5-fold larger Ti in AML xenograft models (TMD 950 vs. 180 µg/kg, by payload, Ti of 95 vs. 19). In addition, the DNA crosslinking version led to delayed systemic toxicity at TMD, not seen in the DNA alkylating version even at its 5-fold higher TMD. Thus we selected the DNA alkylating version for further development. To determine the optimal linker design, we created ADCs with three different linkers, one non-cleavable and two cleavable, and based on improved in vitro efficacy (IC50) and in vivo safety/efficacy (MTD, Ti), the s-SPDB cleavable linker with the DNA alkylating payload was chosen as the lead clinical compound, and named IMGN779. In multiple species, IMGN779 had a consistent toxicity profile (mice, rats and monkeys), producing reversible cytoxicities with no or minor changes in transaminases and without histologic evidence of hepatotoxicity. Importantly, IMGN779 was highly active at a single dose 10 µg/kg (payload) in an MV4-11 (FLT3-ITD+) disseminated AML xenograft model, producing a 90% increased life span, and was well-tolerated and highly active in repeat dosing regimens (10 or 30 µg/kg, qw x 3 and q3d x 3) in a HL60 AML xenograft model. Similarly, in a MV4-11 xenograft model, a single dose of 5 µg/kg (payload) caused a 90% increase in life span, and was well-tolerated and highly active in repeat dosing regimens (10 or 30 µg/kg, qw x 3 and q3d x 3) in a HL60 AML xenograft model. Similarly, in a MV4-11 xenograft model, a single dose of 5 µg/kg (payload) caused a 90% increase in life span, and was well-tolerated and highly active in repeat dosing regimens (10 or 30 µg/kg, qw x 3 and q3d x 3).

Summary/Conclusions: IMGN779, designed as the next generation CD33-targeting ADC, utilizes a novel DNA alkylating DGNN462 payload and a cleavable disulfide linker, selected to maximize anti-AML activity and preclinical safety. IMGN779 is highly active in multiple AML xenograft models, including models with poor prognostic factors, and is well-tolerated in preclinical repeat dosing regimens, where an additional benefit was achieved for a fractionating the dosing regimen over a single high dose. These results provide the foundation for the clinical evaluation of IMGN779 in AML.

P527

THE MIXED LINEAGE LEUKEMIA FUSION PARTNER ENL RECRUITS PAF1 TO CLEAR POLYCOMB-INDUCED TRANSCRIPTIONAL REPRESSION

K. Hetzner1,*, M. Garcia-Cuellar1, C. Bütter2, R. Slany1
1Biology, Institute of Genetics, 2Biology, Institute of Hum.Genetics, Friedrich Alexander University Erlangen-Nürnberg, Erlangen, Germany

Background: In mixed lineage leukemia ENL is frequently found juxtaposed to MLL creating MLL-ENL fusion proteins that initiate leukemogenic transfor- mation. Interestingly, murine ENL also protected survival in a mouse model of the pediatric neoplasm, in its wild-type configuration ENL serves as a scaffolding factor in protein complexes that stimulate transcriptional elongation but, paradoxically, it also co-purifies with polycomb repressive complex 1 (PRC1).

Summary/Conclusions: In this study, blinatumomab showed an AE profile consistent with that previously reported for relapsed/refractory AML, including similar rates of manageable CRS and neurologic events. Exposure-adjusted event rates were generally higher in SOC vs blinatumomab, including for cytopenias and infections.
Aims: This work examines how ENL influences PRC1 repressive activity. Methods: The effect of ENL on transcriptional activity of model promoters and endogenous transcriptional control elements was studied by biochemical and molecular biology methods.

Results: Here we demonstrate that ENL overcomes polycomb induced silencing through recruitment of polymerase associated factor 1 (PAF1) and a chromatin remodelling complex. The capacity of ENL to bind to PAF1 could not only lead to a significant and dose-dependent increase in mitochondrial-produced ROS.

Discussion: Using a combination of experiments we showed that PKCε supports AML by maintaining mitochondrial redox homeostasis to support AML cell survival and disease progression and thus may represent a foundation for designing and developing novel therapeutic strategies.

Background: Although numerous genetic mutations contribute to the etiology and pathophysiology of acute myeloid leukemia (AML), the molecular machinery that is not mutated but supports AML biology remains largely unknown. Several studies have shown that AML cells, irrespective of genetic sub-type, display an oxidized intracellular redox environment compared to their healthy counterparts. The redox environment of AML cells is largely due to the elevated reactive oxygen species (ROS) levels, which are a class of free radical molecules. Though ROS are by-products of several cellular processes, in excess, they can damage DNA and destroy organelles, resulting in the activation of genetic mutations or cell death. As a result, ROS homeostasis is tightly regulated by an array of molecular pathways. Although ROS is elevated in AML cells, the role of ROS and the identity of its regulators remain largely unknown. Here we report that the serine/threonine kinase, PKCε regulates the ROS-neutralizing enzyme SOD2 to support mitochondrial redox homeostasis and AML progression.

Aims: The goal of this study was to identify and subsequently assess how targeting key ROS-regulatory pathways impacts AML biology.

Methods: Loss-of-function studies for PKCε and SOD2 were performed with recombinant lentiviruses expressing gene-targeting shRNAs. Recombinant retroviruses expressing either PKCε or SOD2/Catalase were used for gain-of-function assays. Cytoplasmic and mitochondrial superoxides and peroxides were measured using redox-sensitive GFP (roGFP) probes followed by flow cytometric analysis. Mitochondrial superoxides were also assessed by flow cytometric analysis of MitoSox stained cells. Proteomic analysis was achieved using nano LC-MS/MS. Annexin-V staining was analyzed by flow cytometry to measure apoptosis and in vitro and in vivo proliferation was measured using FACS-based purification of shRNA-expressing cells followed by: 1) growth in cytokine-enriched media or 2) transplantation into syngenic mice for survival analysis.

Results: We have discovered that inhibition of PKCε: 1) promoted the death of primary AML cell lines in vitro, 2) inhibited cell proliferation driven by MLL-AF9 in vivo (p=0.0014) and 3) obstructed the growth of 5 out of 7 PD-AML samples in vitro. At the molecular level, we observed that PKCε inhibition led to a significant and dose-dependent increase in mitochondrial-produced superoxides—a specific type of ROS. Moreover, we found that enforced expression of PKCε can protect AML cells from lethal effects of superoxide-inducing agents 2-thiophenyltrifluoroacetoxy and Antimycin A. To identify potential ROS-regulatory enzymes downstream of PKCε, we performed whole cell proteomics and found that the mitochondrial superoxide-neutralizing enzyme SOD2 is decreased in AML cells depleted of PKCε. Similar to PKCε inhibition, we also observed reduced inhibition of SOD2 reduced the expansion of AML cell lines and PD-AMLS in vitro as well as significantly extended the onset of MLL-AF9-driven AML in vivo (p=0.0042). Finally, we also found that enforced expression of SOD2 in tandem with another anti-oxidant enzyme Catalase, reverses the anti-leukemia effects of PKCε inhibition confirming that PKCε supports AML pathophysiology by maintaining mitochondrial redox homeostasis.

Summary/Conclusions: Our results indicate that PKCε and SOD2 regulate mitochondrial redox homeostasis to support AML cell survival and disease progression and thus may represent a foundation for designing and developing novel therapeutic strategies.

P530
ROLE OF SHP2 IN A MOUSE MODEL OF AML CARRYING FLT3-ITD ALONG WITH LOSS OF TET2

R. Pandey3, S. Ramdas1, R. Chan1, R. Kapur1

1Indiana University School of Medicine, Indianapolis, United States

Background: SHP2, a protein tyrosine phosphatase coded by Ptnp11, is an essential protein that integrates signals from several different tyrosine kinase receptors with all the major intracellular signaling pathways such as ERK, PI3K and STAT pathways and regulates cell survival, proliferation and differentiation. One of the SHP2 dependent cytokine receptor kinase, FLT3 when mutated to be constitutively activated co-operators with other genetic lesions like loss of Tet2 and Dnmt3a leading to transformation of myelodysplastic syndrome (MDS) to acute myeloid leukemia (AML) in mouse models. Tet2 and Dnmt3a are involved in regulation hematopoietic stem cell (HSC) self-renewal and differentiation programs through regulation of DNA methylation. One their own each of them leads to MPD but when present in combination, leads to AML. These mouse models of AML have a more pronounced stem cell phenotype as compared to traditional chimeric mice or FLT3 targeted kinase inhibitor. Aims: Inhibition of SHP2 catalytic activity by a small molecule allosteric inhibitor has been recently demonstrated to retard the growth of receptor tyrosine kinase driven malignancies. Therefore, we wanted to investigate the role of SHP2 in leukaemogenesis driven by loss of an epigenetic regulator (Tet2) and aberrant cytokine receptor tyrosine kinase (Flt3-ITD) signalling.

Methods: Mice were intercrossed to generate Ptnp11F/FTet2-/-Flt3ITD+/+ or Ptnp11F/FTet2-/-Flt3ITD+/+ mice. Deletion of Ptnp11 was induced at 8-10 week of age by injecting poly IC and changes in the hematopoietic compartment were analyzed by flow cytometry. Cell autonomous and non-autonomous effects of Ptnp11 on leukaemogenesis were also evaluated in transplantation models.

Results: After ploy IC induced deletion of Ptnp11 there was a significant difference in the median survival between leukemic mice with with deletion of Ptnp11 versus non-deleted (n=8). Though the Ptnp11 deleted leukemic mice showed almost complete loss of long term HSC with concomitant increase in short term proliferating HSC in the bone marrow, they were still able to home and engraft in lethally irradiated recipient mice. These results indicate that loss of Ptnp11 does not impair the engraftment of leukemic stem cells though in normal mice deletion of Ptnp11 impairs the ability to stem cells to home to bone marrow niche and engraft. Deletion of Ptnp11 in both primary mice and secondary recipients was also associated with deregulation of myeloid and lymphoid cell distribution both in the periphery and bone marrow. Mice with deletion of Ptnp11 in the context of Flt3ITD did not generate immature or mature B- or T-cell. The effects of Ptnp11 deletion were more severe in in vivo mice as compared to mice that received Ptnp11 deleted cells or when Ptnp11 was deletet after transplantation suggesting a role for SHP2 function in the bone marrow microenvironment in this model of leukaemogenesis.

Summary/Conclusions: SHP2 has been recognized as a proto-oncogene on the basis of its ability to induce hematopoietic malignancies when it is constitutively active and loss of SHP2 catalytic activity is associated with inhibition of tyrosine kinase driven malignancies. Our results demonstrate that the role of SHP2 in AML is dependent upon the presence of other genetic mutations. SHP2 regulates AML with loss of Tet2 with concomitant expression of Flt3-ITD through influence on both leukemic cells and the bone marrow microenvironment.

P531
CLUSTER REGULATION OF RUNX FAMILY BY “GENE SWITCH” TRIGGERS A PROFOUND TUMOR REGRESSION OF DIVERSE ORIGINS

K. Morita1, K. Suzuki1, S. Maeda1, A. Matsuo1, Y. Mitsuda1, A. Yano1
Background: Although Runx-related transcription factor 1 (RUNX1) has been generally considered to be a tumor suppressor, a growing body of evidence suggests its pro-oncogenic property in acute myeloid leukemia (AML).

Aims: Demonstrate the anti-tumor potential of cluster regulation of RUNX with a “gene-switch” in AML as well as in distal-prognostic solid tumors arising from diverse origins in vivo.

Methods: To assess the effect of RUNX-inhibition in AML cells, we performed series of shRNA-mediated RUNX knockdown experiments. To achieve cluster regulation, we have computationally designed an agent which could irreversibly block the RUNX cluster genes expression profiling through dismantling protein-DNA interactions sequence-specifically (CROX-1).

Results: Firstly, shRNA-mediated silencing of RUNX1 stimulated cell cycle arrest at G0/G1 phase and induced apoptosis in AML cells bearing wild-type p53. Besides, RUNX1 depletion induced remarkable induction of p53 as well as its target gene products and additive knockdown of p53 in these cell lines reverted the phenotype of RUNX1-depletion, indicating that RUNX1 is functionally dependent on proficient p53 pathway. In addition, cycloheximide chase assay revealed that RUNX1 negatively regulates the protein stability of p53 in AML cells. In vivo data analysis and ChIP-seq experiments together with series of knockdown and restore experiments identified BCL11A and TRIM24 as critical mediators of p53 pathway activation in RUNX1-inhibited AML cells.

Though RUNX1-depleted AML cells exhibited drastically slowed proliferation rate, a small sub-population of leukemia cells retained the proliferation potential even after silencing of RUNX1. Analysis of these residual AML cells revealed the reciprocal up-regulation of RUNX2 and RUNX3 expressions, suggesting that RUNX2 and RUNX3 might compensate for the loss of RUNX1 functions. As expected, additional knockdown of RUNX2 and RUNX3 in RUNX1-depleted AML cells effectively suppressed their proliferations. Thus the simultaneous targeting of RUNX family members as a cluster provides more stringent control of leukemia cells. Finally, we examined the antitumor potency of CROX-1-mediated cluster regulations of RUNX. CROX-1 treatment was indeed highly effective against leukemia as well as distal-prognostic solid tumors arising from diverse origins in vitro. Moreover, this reagent was exceptionally well-tolerated in mice and exhibited excellent efficacy against xenograft mice models of AML, acute lymphoblastic leukemia, lung and gastric cancers, extending their overall survival periods in vivo. Since RUNX family take part in diverse physiologic functions not only in AML cells but also in normal hematopoietic cells and in various other vital organ tissues, we might expect criticisms in targeting whole RUNX family that it could trigger undesirable side-effects in vivo. Intriguingly, however, our drug was well-tolerated in vivo and through these experiments, we have coincidently found that the amount of total RUNX expressions was consistently higher in malignant tissues compared to their normal counterparts, and we believe that this gap offers pharmacological window to be targeted again and again. Furthermore, we found that higher expressions of estimated total RUNX amount demarcate significantly poorer-prognostic patient cohorts in a wide variety of cancers, underpinning the rationality of RUNX-inhibition strategies in cancer treatment.

Summary/Conclusions: This work identified the crucial role of RUNX cluster in the maintenance and the progression of cancer cells, and this indicated gene switch technology-dependent its modulation would be a novel strategy to control malignancies.

P532
PHOSPHOPROTEOMICS AND MASS CYTOMETRY SIGNATURES OF PRIMARY AML CELLS DIFFERENTIATION ARE ASSOCIATED WITH SENSITIVITY TO KINASE INHIBITORS

P. Casado-Izquierdo1, E. H. Wilkes2, F. Miraki-Moud1, M. M. Hadi1, A. Rio-Machin1, V. Rajeeve1, R. Pike1, I. Sameena1, S. Marfa1, N. Lea4, G. Mufti1, J. Gribben1, J. Fitzgibbon1, P. R. Cutillas1
1Centre for Haemato-Oncology, 2Flow Cytometry Core Facility, 3Tissue Bank, Barts Cancer Institute, 4Haematological Medicine, King’s College London School of Medicine, London, United Kingdom

Background: Kinase signalling is frequently deregulated in cancer cells. In the case of AML, the high recurrence of activating mutations in kinases and other kinase signalling regulators including FLT3 and RAS has stimulated the investigation of treatments based on kinase inhibitors. The success of kinase inhibitors depends of an accurate stratification of patients into response groups. The impact of genetic mutations on the sensitivity of primary AML to kinase inhibitors remains poorly defined and these have not been translated into effective therapies. The activity of a kinase can be affected by factors other than gene mutations and the sensitivity of leukemic cells to kinase inhibition depends not only on the activity of the targeted kinase. Thus, the integrative analysis of different biochemical features could improve the implementation of precision medicine therapies based on kinase inhibitors.

Aims: By the integration of multiple omics approaches, we aimed to generate molecular signatures, which can rationalize why some primary AML cells are resistant to treatment with different kinase inhibitors while others are sensitive to the same treatments.

Methods: In this investigation, we used a multomics approach to stratify 36 AML biopsies as a function of their cellular sensitivity to “ex vivo” treatment with TAK-715, silmitasertib, PF03758309, midostaurin and trametinib, which target P38, angiopoietin-like 2 (ANGPTL2) and MEK, respectively. The same samples were analysed using different omics platforms: (i) mass spectrometry for phosphoproteomics, proteomics and kinicomic profiling, (ii) mass cytometry for immunophenotyping and (iii) next generation sequencing for mutational profiling.

Results: Our integrative analysis identified two independent signatures that stratified our cohort of patients in sets of differentiated and undifferentiated cases. The phosphoproteomics signature divided our set of AML cases in the M1-like and M4-like groups (Figure 1A). The mass cytometry signature, which represented myelomonocytic markers that were co-expressed at the cell surface, split our cohort of patient in the CD56+ and CD56- groups. Remarkably, the M4-like and CD56- groups representing the non-differentiated cases, showed a high degree of overlap. Differentiated groups over-phosphorylated 3 times as many proteins as the non-differentiated groups, including kinases at sites linked to their activity. Mutations in genes involved in kinase signalling were also more frequent in differentiated cases. Kinase activity analysis using KSEA estimation demonstrated that differentiated groups presented an enriched activity for PAK, MEK, ERK or PKC. Ontology analysis showed that non-differentiated cells over-phosphorylated nuclear proteins with DNA binding properties, while the differentiated cells increased the phosphorylation of membrane and cytoplasmic proteins linked to the small GTPase signalling. More interestingly, cases in differentiated groups were more sensitive to PF03758309, trametinib and midostaurin than those in the non-differentiated sets (Figure 1B for groups defined by the phosphoproteomics signature). Finally, differentiated cases as defined by the mass cytometry signature in our cohort of patients, or by a CD marker mRNA expression signature in the ATCG database, presented with significantly reduced survival when compared to the groups of non-differentiated cases.

Summary/Conclusions: Our data indicate that differentiated cells activate pro-survival kinases like PAK, PKCD or MEK which make them more sensitive to the inhibitors PF03758309, midostaurin or the FDA-approved drug trametinib. Since patients with differentiated cells present a reduced overall survival treatment with these compounds may benefit patients in this higher risk group.
Background: Based on the prognostic significance, as well as the association with certain biological and clinical features, acute myeloid leukemia (AML) with biallelic mutations in the CCAAT enhancer-binding protein-alpha (CEBPA) gene has been included as a distinct entity into the 2016 revision to the World Health Organization classification of myeloid neoplasms and acute leukemia. CEBPA mutations (CEBPA mut) are found in about 20% of AML with normal cytogenetics, and approximately 60% of the mutated patients (pts) carry biallelic mutations. Several studies showed that CEBPA mut occur almost exclusively mutual with regard to other AML associated gene mutations such as NPM1 or FLT3-ITD mutations. Recently, mutations in the t(6;12) FUS/ETV6 gene family member 2 (TET2 mut) were described as a frequent concurrent mutation of CEBPA mut. Both genes are involved in the control of proliferation (CEBPA, TET2) and differentiation (CEBPA) of myeloid progenitors. Preliminary data suggest that pts harboring the CEBPA/ET2 mut genotype have a significantly worse overall survival (OS).

Aims: To evaluate the frequency and the clinical impact of TET2 mut within a large cohort of CEBPA mut AML pts.

Methods: In total 200 AML pts (age 18 to 78 years) with CEBPA mut (n=113) or CEBPA single mutations (CEBPA smt) (n=87) were analysed for the presence of TET2 mut. All pts were enrolled in one of six AMLSG treatment trials applying intensive therapy (AMLHG93 n=14; AMLHG98A (NCT0146120) n=53; AMLHG98B n=12; AMLSG 07-04 (NCT00151242) n=74; AMLSG 06-04 (NCT00151255) n=25 and AMLSG 12-09 (NCT01180322) n=22). TET2 mut screening was performed using a DNA-based PCR-assay covering exons 3 to 9 followed by Sanger sequencing.

Results: In total we detected 52 TET2 mut, 39 of the 200 pts (19.5%); in 16 pts TET2 mut were homozygous (6.5%). The median follow-up of the 200 pts was 76.3 months (95% CI: 68.5–84.2). TET2 mut were restricted to the cytogenetic intermediate-risk group (100%), and pts with TET2 mut were significantly older than pts with TET2 wild-type (p = 0.001). Furthermore, TET2 mut were more frequent in secondary/therapy-related AML (p = 0.04), and there was a significant association with SRSF2 gene mutations (p = 0.01). With regard to outcome, pts with TET2 mut had a significantly shorter event-free (EFS), relapse-free (RFS), and OS compared to TET2 wt pts (p < 0.001, p < 0.001 and p = 0.001, respectively). Furthermore, pts with TET2 mut were significantly older (68 y vs 51 y, p = 0.001) and had a higher rate of secondary malignancies (p = 0.03), and pts with TET2 mut had a significantly shorter RFS (p = 0.02) and OS (p = 0.05), and in trend a shorter EFS (p = 0.09).

Summary/Conclusions: In our study on a large cohort of CEBPA mut AML pts we could confirm the high incidence of concomitant TET2 mut (19.5%). Pts with concurrent TET2 mut were significantly older and had an inferior outcome.
Acute myeloid leukemia - Biology 4

P38B MAPK INTERACTS WITH SET REGULATING ITS INHIBITORY EFFECT ON PP2A ACTIVITY IN ACUTE MYELOID LEUKEMIA

E. Arriazu1, C. Vicente1, R. Pippa1, N. Marcote2, I. Igea2, L. Leon1, S. Chocarro1, M. Soto1, A.R. Nebreda2, M.D. Odero1,3,4

1Oncohematology, Center for applied medical research University of Navarre, Pamplona, 2Institute for Research in Biomedicine, Barcelona, 3Instituto de Investigación Sanitaria de Navarra (IdiSNA), Navarra, 4Department of Biochemistry and Genetics, University of Navarra, Pamplona, Spain

Background: Despite improvements in our understanding of the molecular evolution of acute myeloid leukemia (AML), the overall cure rates remain low, and most patients die from the disease despite achieving initial remission upon treatment. It is therefore necessary to open new therapeutic perspectives aimed at molecular targets. PP2A phosphatase inactivation is a recurrent event in hematological tumors. Our group has reported that SET, an endogenous inhibitor of PP2A, is overexpressed in 28% of patients with AML. Furthermore, the anticanine activity of PP2A activating drugs (PADs) depends on the interaction/sequestration of SET, pointing out the significance of this oncogene in AML. Drug inhibition of several MAPKs in AML cell lines showed that only p38 inhibitors activate PP2A and decrease SET protein.

Aims: Therefore, we hypothesized that p38 could regulate SET at postranslational level, leading to PP2A inactivation.

Methods: AML cell lines and primary human samples were analyzed by western blot, immunoprecipitation, immunofluorescence, treatment with pharmacological inhibitors and siRNA. Phosphorylation assays by in vitro kinase assay with recombinant proteins were performed.

Results: Knockdown of the two major isoforms of p38-MAPK, p38a and p38β, demonstrated that only p38β was able to reduce SET protein levels and increase PP2A activity. To decipher this mechanism of action, we performed protein immunoprecipitation and immunofluorescence in the AML cell lines HL-60 and MOLM-13. p38β co-localized and bound to SET mostly in the cytoplasm stabilizing it, since treatment with cicloheximide in the absence of p38β induced SET degradation. The stabilization role was in coordination with SETBP1, which co-localized with both SET and p38β. Interestingly, 12 out of 14 AML cell lines tested showed high expression of p38β protein levels as well as 5 out of 7 AML primary patient samples. Furthermore, expression analysis in a large series of adult de novo AML cases previously reported (Cancer Genome Atlas Research Network, 2013) showed a positive correlation between p38β (MAPK11) and SET (R²=0.416, p<0.001), but not between p38α and SET. We and others have shown that PADs retain SET in the nucleus. Our results showed that p38 phosphorylates SET not directly, but through the activation of casein kinase 2 (CK2), leading to the retention of SET in the nucleus and, therefore, contributing to the inactivation of PP2A in AML cells. Of note, CK2 is overexpressed in both AML cell lines and patient samples.

Summary/Conclusions: p38 is able to activate CK2 which phosphorylates SET and, as consequence, facilities its trafficking to the cytoplasm, contributing to PP2A inactivation in AML cells. Moreover, p38β binds to SET in the cytoplasm, contributing to its stability and leading to PP2A inactivation. In this regard, we have preliminary evidences that combination therapy with PADs and the CK2 inhibitor CX4945 reduces significantly the viability of AML cells, supporting that novel treatment modalities that can target multiple components of the same pathway may help to achieve a more sustained therapeutic benefit.

Summary/Conclusions: Differences in the allelic composition were found between diagnosis and relapse regardless of the CBF-AML subtype. Our data suggest that the KIT clone might be successfully eradicated under dasatinib treatment whereas persistence of KIT mutant clones was more commonly seen under conventional chemotherapy. The frequent loss of KIT and NRAS mutations during therapy suggests that relapse is triggered by alternative genetic lesions. Relapsed disease may represent a distinct biology which is characterized by mutations that cluster in different pathways. Further analyses are ongoing including study cohort expansion, as well as inclusion of RNA sequencing results.

diagnosis. 8.9 variants per patient were found as compared to 5.7 at relapse. 52% variants were present at diagnosis, 26% at relapse only, and 22% were present at both, diagnosis and relapse. With regard to the most commonly altered signaling genes KIT and NRAS we found the following pattern: The median VAF at diagnosis was 23% and 26% for KIT and NRAS, respectively. Of note, the initial KIT and NRAS clone was lost (VAF <5%) in 71% (exon 17, n=9; exon 8, n=2; exon 11, n=1) and 100% of cases (exon 2, n=5; exon 3, n=3). Comparing the VAF kinetics between patients treated with and without dasatinib, baseline KIT mutations became subclonal (VAF <5%) in all patients receiving dasatinib (n=8), whereas they were still detectable in 4/6 (67%) patients who were intensively treated without the addition of dasatinib. NRAS became subclonal (n=8) irrespective of the treatment regimen. In one KIT mutated patient treated with dasatinib the baseline KITΔD186V mutation (exon 17) was lost at the time of relapse, but a KITΔD184V mutation (exon 8) was acquired instead. Gene set enrichment analyses revealed different mutation signatures at diagnosis and relapse: At diagnosis, there was a significant enrichment for genes associated with MYC overexpression. Variants that were recurrently present at diagnosis and relapse showed enrichment for genes affected in KRAS overexpression models. Relapse samples were additionally enriched for gene mutations involved in the mitotic spindle assembly.

Results: The median VAF at diagnosis was 23% and 26% for KIT and NRAS, respectively. Of note, the initial KIT and NRAS clone was lost (VAF <5%) in 71% (exon 17, n=9; exon 8, n=2; exon 11, n=1) and 100% of cases (exon 2, n=5; exon 3, n=3). Comparing the VAF kinetics between patients treated with and without dasatinib, baseline KIT mutations became subclonal (VAF <5%) in all patients receiving dasatinib (n=8), whereas they were still detectable in 4/6 (67%) patients who were intensively treated without the addition of dasatinib. NRAS became subclonal (n=8) irrespective of the treatment regimen. In one KIT mutated patient treated with dasatinib the baseline KITΔD186V mutation (exon 17) was lost at the time of relapse, but a KITΔD184V mutation (exon 8) was acquired instead. Gene set enrichment analyses revealed different mutation signatures at diagnosis and relapse: At diagnosis, there was a significant enrichment for genes associated with MYC overexpression. Variants that were recurrently present at diagnosis and relapse showed enrichment for genes affected in KRAS overexpression models. Relapse samples were additionally enriched for gene mutations involved in the mitotic spindle assembly.

Summary/Conclusions: Differences in the allelic composition were found between diagnosis and relapse regardless of the CBF-AML subtype. Our data suggest that the KIT clone might be successfully eradicated under dasatinib treatment whereas persistence of KIT mutant clones was more commonly seen under conventional chemotherapy. The frequent loss of KIT and NRAS mutations during therapy suggests that relapse is triggered by alternative genetic lesions. Relapsed disease may represent a distinct biology which is characterized by mutations that cluster in different pathways. Further analyses are ongoing including study cohort expansion, as well as inclusion of RNA sequencing results.
Background: Acute erythroid leukemia (AEL) is a unique subtype of acute myeloid leukemia (AML) characterized by the predominance of erythroid components with increased ring sideroblasts as well as frequent myelodysplasia. However, due to its rarity, the molecular pathology of AEL has not been fully elucidated, except for frequent TPS3 mutations.

Aims: This study was designed to clarify the mutation profile of AEL distinct from other types of AML and myelodysplasia.

Methods: We performed a comprehensive genetic study, in which paired tumor/normal DNA from 22 AEL cases were analyzed using whole exome sequencing (WES). Whole-exome sequencing data from 3 AELs generated by The Cancer Genome Atlas (TCGA) was also included in the analysis. Subsequently, a total of 84 cases were screened for mutations in 67 driver genes associated with myeloid malignancies using targeted-capture sequencing, in which RNA baits were also designed for a total of 1158 single nucleotide polymorphism sites to allow for genome wide copy number abnormalities and other allelic imbalances.

Results: Median age at diagnosis was 58.5 (21-87) years old. Among the 77 patients with clinical information available, 62 patients were diagnosed with de novo AML, 13 with secondary AML, and 2 with treatment-related AML. On average, 18.4 and 3.4 mutations were detected per sample in whole-exome and targeted-capture sequencing in AEL, as compared to 12.2 and 2.9 mutations (P<0.05) in other AML, respectively. Both platforms being combined, most frequently observed was TP53 mutations (n=26, 31%) with complex karyotype being accompanied in most cases (25 cases), which were associated with a significantly shorter overall survival (P<0.001). Other frequently mutated genes were those encoding major components of the cohesin complex, including STAG2 (24%), SMC1A (4.8%) and RAD21 (2.4%), which were mutated in as high as 30% of the cases. The splicing machinery (18%) and epigenetic regulators (45%) were also common targets of mutations, including SRSF2 (12%), U2AF1 (4.8%), WT1 (15%), TET2 (19%) and IDH1/2 (12%). TP53 mutations were mutually exclusive with cohesin mutations (p<0.01) and those in epigenetic regulators (p<0.01). Compared with other AML subtypes, TPS3 mutations (0%) were significantly less frequent in AEL, compared to de novo AML and MDS. The frequency of these mutations was not statistically different between de novo AML and secondary AEL.

Conclusion: We identified in-frame internal duplications of STAG2, which are characteristic of AEL, and thought to be involved in its pathophysiology. Mutations in STAG2 are predominantly present in cytogenetic MDS and AML not otherwise specified.

STAG2 on the spatio-temporal genomic architecture in hematological malignancies. The cohesin complex plays pivotal roles within the cohesin complex function of STAG2, with an increase in binding peaks from ~17,000 to 25,000, within the cohesin complex. The open chromatin regions identified through ChIP-Seq and ATAC-seq profiling of AML cell lines and primary samples to provide information on gene activity in relation to chromatin state and transcription factor occupancy. An enrichment for transcription factors relevant for myeloid transcriptional programmes was observed. This increase in enrichment aids in the suggestion that the impact of mutated/altered cohesin complex function relates directly to the specific cell type and maturation state at which it occurs.

Summary/Conclusions: STAG2 mutation carries specific gene expression signatures and specific subsets of concurrent mutations with clinical value.

P538

EXPLORING THE IMPACT OF LOSS OF FUNCTION STAG2 MUTATIONS ON CHROMATIN ARCHITECTURE IN MDS/AML

J. Smith1,* K. Savage1, K. Mills1

1Centre for Cancer Research and Cell Biology, Queens University Belfast, Belfast, United Kingdom

Background: The Cohesin complex is an evolutionarily conserved multimeric ATP-dependent CAK complex that plays a central role in chromatin architecture and higher order structure. The cohesin complex is required for the spatial regulation of gene expression and is frequently altered in cancer. There is an emerging body of literature on the role of STAG2 on the spatio-temporal genomic architecture in hematological malignancies. The cohesin complex plays pivotal roles within the cohesin complex function of STAG2, with an increase in binding peaks from ~17,000 to 25,000, within the cohesin complex. The open chromatin regions identified through ChIP-Seq and ATAC-seq profiling of AML cell lines and primary samples to provide information on gene activity in relation to chromatin state and transcription factor occupancy. An enrichment for transcription factors relevant for myeloid transcriptional programmes was observed. This increase in enrichment aids in the suggestion that the impact of mutated/altered cohesin complex function relates directly to the specific cell type and maturation state at which it occurs.

Summary/Conclusions: This research into the aberrant and non-canonical role of STAG2 on the spatio-temporal genomic architecture in hematological malignancies and begins to yield insight into the clinical implications of mutations within the cohesin complex.

P539

THE MOLECULAR LANDSCAPE OF MLL-PTD AML: SPECIFIC CONCURRENT MUTATIONS, CLINICAL OUTCOME AND GENE EXPRESSION SIGNATURES

A. Al Hina1,2, F. Kavelaars1, T. Grob1, M. Sanders1, P. Valk1

1Hematology, Erasmus University Medical Center, Rotterdam, Netherlands. 2National Genetic Centre, Muscat, Oman

Background: Partial tandem duplications (PTDs) in the Mixed Lineage Leukemia (MLL) gene, currently known as Lysine Methyltransferase 2A (KMT2A) are acquired in-frame internal duplications present in 5–11% of acute myeloid leukemia (AML). MLL-PTDs are predominantly present in cytogenetic normal AML and occasionally in AML with trisomy of chromosome 11. MLL-PTD AML is now considered as a poor prognostic marker in AML.

Aims: Evaluate the mutational landscape, prognostic value and gene expression signatures of MLL-PTD AMLs in comparison to a well-characterized AML cohort without MLL-PTD.

Methods: cDNA of 2310 AML patients enrolled in the adult HOVON-SACK clinical trials (from 1995 to 2013) were analyzed for the presence of an MLL-PTD. Mutational screening based on next generation sequencing (NGS) was performed using the Illumina TruSeq Myeloid panel on the Illumina HiSeq2500. An independent cohort of 632 de novo AML patients without MLL-PTD served as control. The gene expression profiling was assessed of all AML cases using Affymetrix Hu6000 2 plus 2.0 GeneChips as previously described (Verhaak et al., 2009).

Results: MLL-PTD was detected in 118 (5.1%) out of 2310 AML patients. MLL-PTDs were significantly associated with trisomy 11: 7% vs 1% (p=0.0037), normal karyotype: 65% vs 53% (p=0.0102) and complex karyotype: 1% vs 14% (p=0.0003). MLL-PTD AMLs harbored more than 10% of the cases. The splicing machinery (18%) and epigenetic regulators (45%) were also common targets of mutations, including SRSF2 (12%), U2AF1 (4.8%), WT1 (15%), TET2 (19%) and IDH1/2 (12%). TP53 mutations were mutually exclusive with cohesin mutations (p<0.01) and those in epigenetic regulators (p<0.01). Compared with other AML subtypes, TPS3 mutations (0%) were significantly less frequent in AML, compared to de novo AML and MDS. The frequency of these mutations was not statistically different between de novo AML and secondary AEL.

Summary/Conclusions: MLL-PTD AML carries specific gene expression signatures and specific subsets of concurrent mutations with clinical value.
NEXT GENERATION SEQUENCING TECHNIQUES REVEAL MOLECULAR MECHANISMS OF MYB REGULATION AND FUNCTION IN MLL-AF9 LEUKAEMIA

I.-J. Lau1,2, A. Thomas1, J. Kerry1, L. Godfrey1, C. Nerlov1, P. Vyas2, T. Milne1 1MRC Molecular Haematology Unit, Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, United Kingdom

Background: Mutations involving the MYL gene at 11q23 are found in 10% of adult and 18% of childhood acute myeloid leukaemia (AML) cases. The most frequently occurring MLL mutations are chromosome translocations that fuse the MLL gene in-frame with a second partner gene, creating novel fusion proteins (MLL-FFPs). MLL-AF9 is the most common MLL-FFP in AML. Despite much progress in the overall management of AML, patients carrying MLL-rearrangements still have a poor survival prognosis and limited response to existing therapy. This is in part due to the low therapeutic indices and narrow therapeutic windows of current chemotherapeutic agents, therefore underscoring the need to develop improved, targeted therapies. MYB is a direct downstream target of MLL-AF9. Recent studies indicate that MLL-AF9 leukaemia cells are more affected by MYB knockdown compared to normal hematopoietic stem progenitor cells. This is despite the fact that MYB is known to be essential for the establishment of definitive haematopoiesis. This suggests that a therapeutic window may be achieved through targeting MYB. Therefore, by understanding more about the role of MYB in MLL-AF9 leukaemia and the network it regulates, we may be able to exploit this knowledge to target MYB directly by interfering with its function or indirectly via its downstream targets.

Aims: To understand the molecular function of MYB in MLL-AF9 leukaemia.

Methods: We performed genome-wide MLL, MLL-AF9, H3K27ac, H3K4me3 and H3K4me1 chromatin immunoprecipitation (ChIP-seq) and ATAC-seq and Assay for Transposase-Accessible Chromatin with high throughput sequencing (ATAC-seq) in two MLL-AF9 leukemia models to identify putative regulatory regions of MYB and those of a direct MYB gene target, BCL2. The chromatin conformation capture technique, Capture-C (one vs all) was used to further characterize interactions from the MYB promoter. We then performed siRNA knockdown of MYB and assessed the effect of MYB loss on its downstream druggable target BCL2, using RT qPCR, Western blotting and ChIP qPCR.

Results: We identified MLL-AF9 binding to novel putative enhancers of MYB as defined by regions co-bound by H3K27ac, H3K4me1 and marked by open chromatin on ATAC-seq. Furthermore, Capture-C from the MYB promoter identified novel putative enhancer-promoter interacting domains 100-200kb apart that are co-bound by MYB but not MLL-AF9. This suggests long-range autoregulation of MYB. Next, siRNA knockdown of MYB results in loss of MYB binding at the BCL2 promoter and its downstream enhancer by ChIP qPCR. There is a corresponding loss of BCL2 mRNA and protein expression in MYB knockdown cells compared with control, confirming that BCL2 is directly regulated by MYB.

Summary/Conclusions: We have identified for the first time, regulation of MYB by MLL-AF9 via putative enhancers, and also an autoregulatory role of MYB involving long-range cis-interactions. Furthermore, we confirm that BCL2 is directly regulated by MYB in MLL-AF9 leukaemia, suggesting a molecular rational for using BCL2 inhibitors in MLL-AF9 leukaemia therapy.

CD123-SPECIFIC CHIMERIC ANTIGEN RECEPTOR T-CELL THERAPY IN ACUTE MYELOID LEUKAEMIA

S. Chitre1,2, J. Gaken1, A. Venus1, G. Mufli1 1Haematological Medicine, Kings College London, London, United Kingdom

Background: Acute myeloid leukaemia (AML) is a heterogeneous disease characterized by clonal evolution of myeloid precursors in bone marrow and peripheral blood resulting in accumulation of leukemic blasts and severe impairment of normal haematopoiesis. Despite advances in our understanding of AML biology, development of novel therapies has been limited with 43% relapse rate. The majority of patients never attaining clinical remission (CR) with frontline induction treatment. Chimeric antigen receptor (CARs) T cells specific for tumour-associated antigens are emerging to be an effective form of immunotherapy for AML. A small number of in vitro and in vivo studies have evaluated the efficacy and specificity of CAR T cell immunotherapy in AML by targeting interleukin three receptor alpha (IL3RA, CD123). A molecule over expressed on AML blasts and leukaemia stem cells (LSC) compared to normal haematopoietic stem cells (HSCs).

Aims: In this study, we investigated the efficacy of a second generation CAR expressing a single variable fragments (scFv) with different affinities for CD123 and evaluated the cytotoxic effect of different co-stimulatory domains (CD28 versus 41BB) using a co-culture assay. Furthermore, we also evaluated the cytotoxic effects of a dual targeting CAR (against CD123 and CD33) using the same assay conditions.

Methods: Six CAR T cell constructs (two high, two moderate & two low affinity) were transduced (MOI 1:5) into peripheral blood mononuclear cells (PBMCs) from healthy donors and their cytotoxicity was examined by flowcytometry on leukemic cell lines; KG1 (CD123+, CD34+, CD33+) [Fig:1a], Kasumi-1 (CD123+, CD34+, CD33+), U937 (CD123+, CD34-, CD33+), K562 (CD123+, CD34+, CD33+) and AML mononuclear cells (MNCs).

Results: Flowcytometric analysis confirmed the expansion of T cells from PBMCs and the cytotoxicity of the six CARCD123 constructs against CD123+ve cells. The high affinity CARCD123 (4nM kD & 4nM kD K13Q) T cells demonstrated enhanced cytotoxicity compared to moderate (5nM kD, 5nM kD A105G) and low affinity (10nM kD, 10nM kD V24G) CARCD123 in both leukaemic cell lines and also in allogenic AML MNCs. Both the highest affinity CARCD123 constructs were also tested in cell lines using increasing effector: target ratios: target ratios (1:2, 1:4 & 1:10) displaying consistent cytotoxicity and were also effective against autologous AML MNCs (target cells) and PBMCs (effector cells) from two patients. T cell activation was confirmed by ELISA and showed increased IFN-γ (500-2000 fold) and TNF-α (150-200 fold) levels. Previous studies have confirmed the distinction in CAR efficiency using CD28 versus 41BB co-stimulatory domains; CD28 co-stimulation augmented, whereas 4-1BB co-stimulation reduced T cell exhaustion induced by continuous CAR signaling. To confirm persistence of the CAR cytotoxicity, we constructed a high affinity CAR substituting CD28 with a 4-1BB co-stimulatory domain and obtained similar cytotoxicity results on K562 and U937 cell lines. Furthermore, a novel a dual targeting CAR in which the activation domain (CD3ζ) is directed against CD33 and the costimulatory domain (CD28) directed against CD123 enhanced the specificity of the CAR towards leukaemic cells; reducing “on-target but off-organ effects”. Results obtained in co-culture assay against KG1 [Fig:1b] and K562 cell lines [Fig:1c] with varying effector: target ratios were demonstrated results similar to the high affinity single targeting CAR.

TARGETED COMBINATION THERAPY WITH CDK4/6 INHIBITOR PALBOCICLIB IN AML

I. Uras1, P. Valenti2, V. Sext1 1Institute of Pharmacology and Toxicology, University of Veterinary Medicine, Vienna, 2Department of Internal Medicine I, Division of Hematology and Hemosctology, 3Louis Ludwig Boltzmann Cluster Oncology, Medical University of Vienna, Vienna, Austria

Background: Acute myeloid leukaemia (AML) is a clonal hematologic disorder marked by clinical and biological heterogeneity. AML remains incurable for a significant proportion of adult patients while no therapeutic option exists for patients with relapsed and refractory AML. Mutations of the fms-like tyrosine kinase 3 (FLT3) gene are among the most frequent events in AML and usually involves internal tandem duplication (ITD) of the juxtamembrane domain coding region or point mutations of the tyrosine kinase domain. There have been considerable efforts to develop FLT3 tyrosine kinase inhibitors (TKI). The clinical impact of FLT3-TKI has been limited as resistant clones have emerged rapidly.
We have recently discovered that FLT3-ITD+ AML cells are highly sensitive to the FDA- & EMA-approved CDK4/6 kinase inhibitor palbociclib (IBRANCE by Pfizer). The effect is ascribed to the transcriptional activity of CDK6 on FLT3 and PIM1 - a feature not shared by CDK4.

**Aims:** Palbociclib impaired the viability of murine Ba/F3 cells with FLT3-ITD. The effect was specific to FLT3-ITD+ patient samples and to xenograft models, where palbociclib treatment effectively repressed FLT3-D835Y driven tumor formation in vivo at clinically relevant concentrations. Besides FLT3 itself, which is regulated by CDK6, transcriptional targets of CDK6 in AML included Aurora kinases (AURK) and AKT. Thus CDK6 inhibition in AML cells, two signalling nodes critical for survival of tumor cells. Dual targeting with palbociclib and AURK or AKT inhibitors resulted in synergistic cytotoxicity.

**Summary/Conclusions:** Palbociclib represents a viable therapeutic option for treatment of resistant clones in FLT3-D835Y+ AML. Inhibitory effects are specific to cell cycle inhibition as well as by transcriptional activity of CDK6 on important signalling pathways including Aurora kinases and AKT. Our findings provide the basis for the design of synergistic combination therapies with a CDK4/6 inhibitor which could be readily translated to patients with AML.

**CANNABINOID DERIVATIVES MODIFY THE PATTERN OF SPHINGOLIPIDS IN ACUTE MYELOID LEUKEMIA CELLS AND PRODUCE A POTENT ANTI-LEUKEMIC EFFECT**

M. Medrano,1,2 M.V. Barbado,1 N. Campillio,2 F.J. Hidalgo3, T. Caballero1, I. Alvarez1, O. Lopez1, J.I. Pirat1, J.A. Perez-Simon1

1Instituto de Biomedicina de Seville, Seville, 2CIB/CSIC, Madrid, 3G/CSIC, Seville, Spain

**Background:** Endocannabinoid system is a set of ligands, receptors and endogenous enzymes which modulate a variety of physiological effects. There are two well-characterized cannabinoid receptors, CB1 (mainly expressed in Central Nervous System) and CB2 (mainly in hematopoietic cells). Here, we tested the effect of the cannabinoid WIN-55 212-2 in acute myeloid leukemia (AML) in vitro and in vivo and studied the molecular signaling pathways involved in this effect, specially the role of sphingolipids. Moreover, we synthesized a new family of twelve cannabinoids that are specific to CB2 receptor.

**Aims:** Development of new compounds derived from cannabinoid with CB2 selectivity and evaluation of their anti-tumor effect in AML in vitro and in vivo. To deepen in the knowledge of lipid metabolism in AML.

**Methods:** For the design and synthesis of new cannabinoids, computational techniques of docking, analytical and spectroscopic techniques such as mass spectrometry (MS) were used. To assess the anti-leukemia effect of the different cannabinoids, we analyzed cell viability by MTT and flow cytometry using six human AML cell lines, primary cells from healthy donors (hematopoietic progenitor cells (HPC) and lymphocytes) and blasts from AML patients. Mitochondrial damage was assessed by flow cytometry using TMRE and by MitoxSOXM Red. In addition, we performed western blot and immunocytochemistry assays to determine the expression of different proteins to elucidate the molecular signaling pathways involved in the effect of these drugs. Moreover, we analyzed the transcript levels by RT-qPCR and in the amounts of certain sphingolipids in untreated and cannabinoid treated leukemic progenitor cells. Remarkably, we observed significant differences in the amounts of certain sphingolipids in untreated versus treated leukemic cells. More specifically in ceramide C16:0, C18:0 and C18:1. Also we observed a significantly increased survival among mice treated with WIN-55 cannabinoid as compared to both the control group and the group treated with ARA-C and we confirmed that cannabinoids did not affect the viability of the different populations of hematopoietic progenitor and, moreover, an increased platelet count was observed in treated mice.

**Summary/Conclusions:** Our findings indicate that cannabinoids display a highly selective proapoptotic effect on leukemic cells. Several pathways are involved in this effect, the modification in the sphingolipids pattern playing a main role.

**PROFILING THE MUTATIONAL LANDSCAPE OF ACUTE MYELOID LEUKEMIA AT RELAPSE AFTER CHEMOTHERAPY AND ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION**

E. Sala1,2,*, F. Biavasco1,2, G. Bucci3,2, C. Toffalori2, L. Zanotti2, D. Biancolini3, E. Antonini4, M.G. Carrabba 1, B. Gentner1,5, C. Tresoldi 4, M. Bernardi1, D. Lazarevic3, G. Tonon2, F. Ciceri1, L. Vago1,2

1Hematology and Bone Marrow Transplantation Unit; Division of Regenerative Medicine, Stem Cells and Gene Therapy, 2Unit of Immunogenetics, Leukemia Genomic and Immunobiology; Division of Regenerative Medicine, Stem Cells and Gene Therapy, 3Center for Translational Genomics and Bioinformatics, 4Immunohematology and Transfusion Medicine Unit; Division of Regenerative Medicine, Stem Cells and Gene Therapy, 5Translational stem cell and leukemia research Unit; SR-TIGET, Division of Regenerative Medicine, Stem Cells and Gene Therapy, San Raffaele Scientific Institute, Milano, Italy

**Background:** Acute Myeloid Leukemia (AML) is a clinically and biologically heterogeneous disease that is known to dynamically evolve over time. Unravelling its mutational profile may provide relevant insights into the inception, propagation, and recurrence of the disease, and deliver new rationales for precision medicine approaches: still, whereas a comprehensive description of AML mutations at disease presentation is now available thanks to large-scale studies, a satisfying genomic characterization of AML at relapse, particularly after allogeneic stem-cell transplantation (allo-HSCT), is still needed.

**Aims:** To characterize the genetic profile of relapsed AML, highlighting the evolutionary trajectories in the two different settings of relapse after chemotherapy (CT) and after allo-HSCT.

**Methods:** For our custom-designed targeted Next Generation Sequencing panel we took advantage of the HaloPlex High Sensitivity (HS) technology, allowing a more precise definition of mutations and clonal architecture through a molecular barcoding system. We included in our panel 192 genes and miRNAs known to be involved in the pathogenesis of myeloid malignancies (n=112), in the DNA damage response (n=50), or in immune-related processes (n=30). Sequencing was performed on an Illumina HiSeq2500 instrument. Variant calling was performed using a pipeline based on the FreeBayes algorithm, and FLT3-ITD status was inferred using Pindel.

**Results:** We sequenced a total of 138 AML samples, including 79 diagnoses, 36 relapses after CT and 23 relapses after allo-HSCT. Sequencing yielded uniform and consistent coverage of all target amplicons and a 612x mean depth-of-sequencing, resulting on average in 117 unique barcodes for each region. Among the 79 diagnosis samples we identified 293 mutations (204 of which definable as oncogenic), with a median of 3 oncogenic mutations per patient (range 0-8), and mutation frequencies in line with the largest published dataset (Papaemmanuil, N Engl J Med, 2016; r2=0.83). In relapses after CT and after allo-HSCT the median number of oncogenic mutations per patient was 3 (range 0-4) and 2 (range 0-6), respectively. Comparing mutation frequencies at relapse
with the Papaemmanuil dataset, we observed a weaker correlation for relapses after CT ($r^2=0.69$) and an even more marked deviation for post-transplant relapses ($r^2=0.45$). This difference was mainly explained by the enrichment in both relapse cohorts for FLT3-ITD (25% in diagnoses vs 55% and 48% at relapses after CT and allo-HSCT, $p<0.01$ for both comparisons) and WT1 mutations (5% vs 25% and 22%, $p<0.01$ for both comparisons). For 24 cases it was possible to longitudinally compare the mutational profile of AML at diagnosis and relapse in the same patient: we observed higher stability in relapses after CT, with 50% of cases carrying the same pattern of mutations present at diagnosis, whereas at relapses after allo-HSCT changes were more frequent, with 70% of patients displaying new gains or losses.

**Summary/Conclusions:** Taken together, our data evidence that the genomic landscape of AML at relapse can be significantly different from the one documented at diagnosis, suggesting that the selective pressure mediated not only by intensive chemotherapy, but also by the graft-versus-leukemia effect, can be potent drivers of clonal evolution. From the practical standpoint, the pattern of emergence of novel mutations that we documented should be taken into account not only for targeted salvage approaches, but also for the design of post-remission strategies aiming to prevent relapse.

**AML PATIENTS AGED ≥75 YEARS ENROLLED INTO AMLCG TRIALS: DO GENETIC ALTERATIONS IMPACT CLINICAL OUTCOME IN VERY OLD, INTENSIVELY TREATED PATIENTS?**

1Laboratory for Leukemia Diagnostics, Department of Internal Medicine III, University of Munich, Munich, 2Institute of Biostatistics and Clinical Research, University of Muenster, Muenster, 3Laboratory for Leukemia Diagnostics, Department of Internal Medicine III; German Cancer Consortium (DKTK), partner site Munich; German Cancer Research Center (DKFZ, Heidelberg), University of Munich, Munich, 4Department of Internal Medicine III, Hospital Leverkusen, Leverkusen, 5Department of Medicine A, Hematology and Oncology, University of Muenster, Muenster, 6Department of Medicine, Hematology, Oncology, Tumor Immunology, Charité University Medicine Berlin, Berlin, 7Department of Oncology and Hematology, Hospital Barmherzige Brüder, Regensburg, Germany

**Background:** Acute myeloid leukemia (AML) is a disease of the elderly (median age at diagnosis ~68 years). The prognosis of elderly patients (pts) is poor. Advanced age often leads to the judgement that pts are unfit for induction chemotherapy, although several trials have revealed a positive impact of intensive induction therapy in terms of sustained remissions and long-term survival in a subset of elderly pts.

**Aims:** We sought to validate existing risk classification systems and identify genetic factors associated with clinical outcomes in very old AML pts who received induction chemotherapy.

**Methods:** We identified 151 AML pts aged ≥75 years who received intensive induction therapy in the AMLCG-1999 trial with suitable material for genetic

---

**Figure 1.**

Methods: We identified 151 AML pts aged ≥75 years who received intensive induction therapy in the AMLCG-1999 trial with suitable material for genetic
analyses, 81% of pts had de novo AML, 15% secondary AML, 3% therapy-related AML and 2% high-risk MDS. Recurrent gene mutations in AML were studied from bone marrow aspirates or peripheral blood using a targeted leukemia genotyping assay covering 68 genes. We analyzed known mutational hotspots or the entire coding sequence of the genes by multiplexed amplicon sequencing (Agilent Technologies, mean target coverage of 460 x). We studied associations of the genotypes with other potential prognostic factors which might influence the clinical outcome.

Results: The median age in the total cohort was 76 years (y) (range: 75-86). 44% of pts reached complete remission (CR) and 4% CR with incomplete blood count recovery (CRi). The median overall survival (OS) was 6 months with a 3-year OS rate of 21%. Acute leukemia to the ELN 2013 classification, 20 pts were evaluable in the favorable, 39% and 25% in the intermediate I or II group, respectively, and 15% in the adverse group (ELN 2017 data will be presented at the meeting). Pts in the favorable and intermediate I/II groups had significantly longer OS compared to the adverse group (median OS 6.5 vs 1.2 months, p=0.05). Figure). Likewise, pts in the favorable and intermediate MRC cytogenetic risk categories had longer OS than those in the adverse category (median OS 6.5 vs 1.2 months, p=0.01). By targeted sequencing, we detected 622 leukemia-associated mutations in 66 genes. The median number of mutated genes per patient was four. The most commonly mutated genes were TET2 (42%), DNMT3A (35%), NPM1 (32%), SRSF2 (25%) and ASXL1 (21%). Both NPM1 or EZH2 (5%) mutated pts showed a non-significant trend towards longer OS (NPM1: p=0.03; EZH2: p=0.05). FLT3-ITD mutations were identified in 29 pts (19%), but had no impact on OS (p=0.29). The NPM1 mutated/FLT3-ITD-negative genotype also did not associate with OS. Notably, none of the IDH1 mutated pts (9%; all within the ELN favorable/intermediate groups) reached CR, and consequently the OS in this group was significantly shorter than for IDH1 wild-type pts (p<0.01; Figure). The positive impact of mutated NPM1 on OS was reversed when it co-occurred with IDH1 mutations (p=0.014).

Summary/Conclusions: Among very old (≥75 y), intensively treated AML pts, adverse-risk cytogenetics predict inferior survival. On the other hand, 3-year OS was 24% for MRC/ELN favorable and intermediate-risk pts, suggesting that even in this age group, selected pts without medical contraindications benefit from intensive induction chemotherapy. The spectrum of driver gene mutations in elderly pts differs from that in younger pts. While NPM1 and FLT3-ITD mutations had no significant impact on OS in intensely treated pts aged ≥75 y, our data imply IDH1 mutations as a novel marker for chemoresistance disease and inferior prognosis in this age group.

P547

GMI-1271, A POTENT E-SELECTIN ANTAGONIST, IN COMBINATION WITH CHEMOTHERAPY IN RELAPSED/REFRACTORY AML: A NOVEL, WELL-TOLERATED REGIMEN WITH A HIGH REMISSION RATE

1 Dana-Farber Cancer Institute, Boston, 2 UC Davis Comprehensive Cancer Center, Sacramento, 3 Univ of Rochester James P Wilmot Cancer Ctr, Rochester, United States, 4 National University of Ireland, Galway, Ireland, 5 University of Michigan Comprehensive Cancer Center, Ann Arbor, 6 Cleveland Clinic, Cleveland, United States, 7 Princess Alexandra Hospital, Brisbane, Australia, 8 GlycoMimetics, Inc., Rockville, 9 Fred Hutchinson Cancer Research Center, U of Washington, Seattle, United States

Background: Expression of the adhesion molecule E-selectin (E-sel) in the vascularature of the bone marrow is associated with infiltrative disease, relapse, and poor survival in AML. GMI-1271 is a novel antagonist of E-sel that downregulates cell survival pathways and enhances chemotherapy response with improved survival compared to chemotherapy alone (Becker ASH 2013; Winkele et al. 2014). Protection from common toxicities (neutropenia and mucositis) has been observed in preclinical models, also affording survival benefit (Winkler ASH 2014). Protection from common toxicities (neutropenia and mucositis) has been observed in preclinical models, also affording survival benefit (Winkler ASH 2014). Protection from common toxicities (neutropenia and mucositis) has been observed in preclinical models, also affording survival benefit (Winkler ASH 2014).

Aims: We assessed GMI-1271 plus salvage chemotherapy with mitoxantrone, etoposide, and cytarabine (MEC) for the treatment of patients (pts) with relapsed/refractory AML.

Methods: A Phase (Ph) 1 trial in pts with R/R AML escalated GMI-1271 across Ph1 (30-150mg/kg) to Ph2 (120mg/kg). In Ph1, pts were given GMI-1271 24 hrs prior to MEC chemotherapy. Response and CR rates of 50% and 33%, respectively, and a 3-fold increase in median OS of the responding compared to the non-responding newly-diagnosed patients. Notably, 67% of the responding patients had secondary AML, median OS of the responding compared to the non-responding newly-diagnosed patients. Notably, 67% of the responding patients had secondary AML, median OS of the responding compared to the non-responding newly-diagnosed patients. Notably, 67% of the responding patients had secondary AML, median OS of the responding compared to the non-responding newly-diagnosed patients. Notably, 67% of the responding patients had secondary AML, median OS of the responding compared to the non-responding newly-diagnosed patients. Notably, 67% of the responding patients had secondary AML, median OS of the responding compared to the non-responding newly-diagnosed patients. Notably, 67% of the responding patients had secondary AML, median OS of the responding compared to the non-responding newly-diagnosed patients. Notably, 67% of the responding patients had secondary AML, median OS of the responding compared to the non-responding newly-diagnosed patients. Notably, 67% of the responding patients had secondary AML.
refractory to hypomethylating agents. To the best of our knowledge, this is the only experimental drug permitting high-dose cytarabine, considered a cornerstone of leukemia therapy, to be given to a population of patients that currently do not have this option. A Phase II study is planned to confirm these encouraging results.

Feasibility and Benefit of Targeted RNA Sequencing for the Detection of Recurrent Fusion Transcripts and the Identification of Novel Fusion Transcripts in Myeloid Malignancies

Background: Genes fusions are frequent genetic abnormalities in myeloid malignancies. The impact of the detection of such gene fusions is rising due to an increasing number of drugs targeting them as has been impressively shown for e.g. BCR-ABL1 and PML-RARA. Further, they can be used as biomarkers for disease monitoring.

Aims: Evaluation of targeted RNA sequencing for the detection of recurrent and novel fusion transcripts.

Methods: 102 cases with myeloid malignancies harboring 105 translocations identified by chromosome banding analysis were selected. Recurrent fusion genes had been confirmed by FISH and/or RT-PCR. In cases with suspected novel fusions the rearrangement of one partner gene had been confirmed by FISH. The following recurrent rearrangements identified by standard diagnostic procedures were present: PML-RARA (n=11), RUNX1-RUNX1T1 (n=7), CSF3R-MYH11 (n=3), KMT2A-ELL (n=4), KMT2A-MLLT1 (n=4), KMT2A-MLLT10 (n=3), KMT2A-MLLT3 (n=2), BCR-ABL1 (n=3), NUP98-NSD1 (n=3), DEK-NUP214 (n=1), and KAT6A-CREBBP (n=1). Further, cases harboring known fusions (KMT2A (n=14), RUNX1 (n=21), ETV6 (n=10), PDGFRB (n=10), RARA, n=2), NPM1 (n=2) and NUP98 (n=1) were included. Targeted RNA sequencing was performed using the TruSight RNA Fusion panel (Illuima, San Diego, CA) consisting of 7690 probes covering 507 genes known

Fusion, which could not be suspected by

were less frequently observed in myeloid-T than in myeloid-B included

Mutations. Genes in which mutations were enriched in myeloid-T than in myeloid-B included RUNX1 (6% vs 46%), ASXL1 (0% vs 23%), TET2 (0% vs 15%), SRSF2 (6% vs 23%), and FLI1 (11% vs 23%). Myeloid-T and myeloid-B showed distinct pattern of promoter CpG methylation. Overexpression of one of the novel translocations such as

were mutated in hematologic malignancies (median 393x coverage, N=31), RNA sequencing revealed several other known translocations such as NUP98-NSD1 and KMT2A-MLLT4, in addition to the novel translocations such as FOXP1-DNAJC15, FLI1-IPT46, and ITPR2-ARID5B. Unsupervised hierarchical clustering of all MPAL, AML, B-ALL and T-ALL by promoter CpG methylation pattern revealed that myeloid-T consistently showed similar methylation pattern with T-ALL, while myeloid-B showed random similarity with either B-ALL or AML.

Summary/Conclusions: MPAL is genetically heterogeneous disease and myeloid-T and myeloid-B shows distinct patterns of mutation landscapes, coding and gene expression changes. Therapy for MPAL may need to be personalized based on genomic profiles.

**Background: Mixed phenotype acute leukemia (MPAL) is a rare subgroup of acute leukemia characterized by blasts that show immunophenotypes of both myeloid and lymphoid lineages and therefore not traceable to single lineage of origin. Diagnosis of MPAL is challenging due to the possible discrepancy between immunophenotype and morphology. Clinically, MPAL has poor prognosis and poses therapeutic challenges. Genetic basis of MPAL is not well understood.

Aims: To clarify the underlying pathogenesis of MPAL and provide clue on future personalized therapy in MPAL, we performed comprehensive molecular characterization of adult MPAL.

Methods: We studied 31 adult patients with adult MPAL (median age 53) that met 2008 WHO classification criteria for de novo acute myeloid leukemia--promyelocytic type. Patients were studied by targeted capture exome sequencing of 295 genes that are recurrently mutated in hematologic malignancies (median 393x coverage, N=31), RNA sequencing (N=24), and Infinium methylation EPIC array (Illuima, N=31). Mutational landscape was compared to that of 194 AML, 71 B-ALL, and 6 T-ALL. The following fusions were found:

In frame fusion transcripts but to termination of transcription.

Results: Among 31 MPAL cases, 18 (58%) had myeloid-T and 13 (42%) had myeloid-B phenotype. Four cases had Philadelphia chromosome, 1 had 11q23 abnormality, and 8 had complex karyotype. MPAL had similar numbers of mutations (median 2 [range: 0-8]) with AML (median range: 0-7, P=0.79) or T-ALL (median range [3 range: 0-8], P=0.92) but had significantly higher number of mutations compared to B-ALL (median range: 0-4, P<0.001). Consistent with the mixed immunophenotypic features, MPAL had both AML-type and ALL-type mutations. However, NPM1 mutation was specific to AML and was not found in MPAL cases. Myeloid-T and myeloid-B showed distinct pattern of somatic mutations. Genes in which mutations were enriched in myeloid-T than in myeloid-B included RUNX1 (6% vs 46%), ASXL1 (0% vs 23%), TET2 (0% vs 15%), SRSF2 (6% vs 23%), and FLI1 (11% vs 23%). Myeloid-T and myeloid-B showed distinct pattern of promoter CpG methylation. Overexpression of one of the novel translocations such as

were amplified and was overexpressed. RNA sequencing revealed several

known translocations such as NUP98-NSD1 and KMT2A-MLLT4, in addition to the novel translocations such as FOXP1-DNAJC15, FLI1-IPT46, and ITPR2-ARID5B. Unsupervised hierarchical clustering of all MPAL, AML, B-ALL and T-ALL by promoter CpG methylation pattern revealed that myeloid-T consistently showed similar methylation pattern with T-ALL, while myeloid-B showed random similarity with either B-ALL or AML.

Summary/Conclusions: MPAL is genetically heterogeneous disease and myeloid-T and myeloid-B shows distinct patterns of mutation landscapes, coding and gene expression changes. Therapy for MPAL may need to be personalized based on genomic profiles.

**COMPREHENSIVE MOLECULAR ANALYSIS OF ADULT MIXED PHENOTYPE ACUTE LEUKEMIA (MPAL)**

K. Morita1,2,*, F. Wang 3, K. Patel 4, C. Bueso-Ramos 3, A. Abou Zahr 3,

Background: Standard remission induction chemotherapy for acute myeloid leukemia (AML) which consists of anthracycline for 3 days plus cytarabine for 7 days was first introduced in 1970’s and has been used for a long time. Several modification or intensification for this conventional regimen did not prove the effect for higher complete remission (CR) rate or lower relapse rate which led to superior overall survival (OS) rate.

Aims: We tried to find out possible benefit of early intensification of standard induction chemotherapy in adult AML patients.

Methods: This prospective study enrolled 1195 adult AML patients from 2002 to 2013. All patients were initially treated with idarubicin (12mg/m2) plus cytarabine (100mg/m2) or BHAC (300mg/m2) induction chemotherapy (3+7), and among them, 731 (61.2%) patients received additional early augmentation using cytarabine 3 days (3+10, n=363) or anthracycline 2 days plus cytarabine 3 days (2+10, n=368). The decision for augmentation was based on the follow-up BM blast counts on the 7th day of 3+7 chemotherapy: totally 3+10 for blast counts 5-20% and 5+10 for blast counts >20% (early intensified group). The rest 464 with blast counts <5% finished with 3+7 regi-
men (standard group). Re-induction and consolidation therapy was performed according to a consistent strategy and pre-remission therapy was mainly based on hematopoietic cell transplantation.

**Results:** Early intensified group was consisted of younger patients (median age, 37 years old [range 17–69] vs 45 years in 3+7 vs 43 years in 3+10 subgroup) and larger proportion of t(8;21) (n=102 [27.7%] vs 3+7 [n=33, 7.1%] vs 3+10, 12.9%), P<0.001. Also, initial blast burden was higher in two intensified groups (73.3% in 3+10 and 70.1% in 3+10) compared to 3+7 subgroup (66.8%, P<0.001). Early death rate at 8 weeks was higher in patients older than 55 years (10.8% vs 3.7%, P=0.001) especially when they were treated with intensified chemotherapy (21.7% vs 15.7% in 3+10 vs 6.3% in standard group, P<0.038). CR rate after induction was higher in young patients especially in 3+10 subgroup (79.8%, P<0.001) and we also found that patients with favorable to intermediate-risk karyotype might benefit with intensified chemotherapy in the context of CR rate (79.7% vs 68.3%, P<0.001, although final CR rates became similar after re-induction. Next, we found that pre-HCT relapse rate was lower in patients younger than 55 years (4% vs 9%, P=0.002) and favorable to intermediate-risk group (8.9% vs 20.2%, P<0.001) after intensified induction. In young patients with favorable to intermediate-risk karyotype, intensified group showed superior 5-year OS (55.0% vs 45.5%, P=0.010) and lower long-term relapse rate (32.2% vs 38.0%, P=0.084), but multivariate analysis revealed no effects for both OS and CR. In patients older than 55 years, intensified group showed inferior 5-year OS (19.2% vs 22.8%, P=0.014) with higher early death rate (17.6% vs 6.3%, P=0.015), and multivariate analysis also showed intensified induction was related inferior OS (HR=1.89, 95%CI; 1.14–3.15, P<0.013).

**Summary/Conclusions:** Our data revealed that intensified induction chemotherapy was not influential for poor-risk karyotype, while higher post-induction CR rate and low post-HCT relapse was shown in young patients with favorable to intermediate-risk karyotype although it was not influential for final OS and CR rate. In elderly patients, intensified induction chemotherapy was related with higher early death rate which finally showed poor OS.

**VARIANT FLT3 MUTATIONS CAN BE ERADICATED BY CYTARABINE/ANTHRACYCLINE/CRENOLANIB INDUCTION IN ADULT PATIENTS WITH NEWLY DIAGNOSED FLT3 (ITD/TKD) MUTANT AML**

E. Wang1,*, R. Stone2, R. Collins3, T. Agrawal4, V. Urity4, M. Tallman5

1Department of Medicine, Roswell Park Cancer Institute, Buffalo, 2Department of Texas Southwestern Medical Center, 4Arog Pharmaceuticals, Inc., Dallas, 3Department of Medicine, Leukemia Service, Memorial Sloan Kettering Cancer Center, New York, United States

**Background:** Patients (pts) with FLT3-internal tandem duplication (ITD) and FLT3-D835 mutant AML have a high relapse rate. These relapses are typically due to outgrowth of mutant FLT clones. Previously available PCR-based tests only checked for presence of FLT3-ITD and FLT3-D835/836 mutations. Whole genome sequencing of 799 pediatric AML samples from CGH trials have shown novel FLT3 variants in many AML cases that also include activating mutations in the juxtamembrane (JM) and transmembrane domains in 7.8% of these samples (Tarlock et al. ASH 2015). Some of these mutations result in autophosphorylation of FLT3 and therefore may be oncogenic.

**Aims:** Identify novel FLT3 mutations in pts with FLT3 mutant AML and further investigate whether these novel clones are sensitive to induction chemotherapy plus a potent pan-FLT3 inhibitor, crenolanib.

**Methods:** Pts with newly diagnosed FLT3 mutant AML were enrolled and treated with cytarabine/anthracycline/crenolanib induction followed by high dose cytarabine (HiDAC) consolidation. Crenolanib 100mg TID was started on day 9 of induction chemotherapy. Crenolanib was continued and cycled 21 days in 3+10 cycles of HiDAC consolidation followed by crenolanib maintenance. Bone marrow samples were collected at baseline and at the time of remission assessment. Sequencing of the entire FLT3 gene was performed through FoundationOne Heme panel (n=18) and MSKCC multigene panel (n=5). Sequencing of exons 14, 15, 16, and 20 was performed through the Rapid Heme Panel at Dana-Farber Cancer Institute in additional 6 pts.

**Results:** Out of 29 newly diagnosed FLT3 mutant AML patients with full/partial FLT3 gene sequencing performed, 4 pts were found to have novel FLT3 mutations consisting of V491L, V592L, D593H, A680V, and N841I/T/K (Table 1). The majority of these novel mutations were located at the JM, kinase domain 1 and the activation loop (kinase domain 2). The allele fractions of these FLT3 variants ranged as high as 29% (higher than that of FLT3-ITD in p13), suggesting that some of these clones may have been potentially driving clinical leukemia progression in some pts. All 4 pts had NPM1 mutations, and two also had DNMT3A mutations. All 4 pts achieved CR with full count recovery (3/4 pts achieved CR after just one cycle of cytarabine/anthracycline/crenolanib induction). The pt with FLT3-D835Yand N841T achieved a CR after cytarabine/anthracycline/crenolanib induction and one cycle of HiDAC consolidation. All pts treated with FLT3-ve and have remained FLT3-ve out of 4 pts received 1-4 cycles of HiDAC consolidation followed by crenolanib maintenance. Only one pt underwent allo SCT. With a median follow up of 13 months, one pt relapsed (at 6.4-month following treatment). This 61F pt was found to have FLT3-ITD, D593H and I836del FLT3 abnormalities at the time of diagnosis. A full FoundationOne gene panel done at the time of relapse, showed no residual FLT3 mutant clones.

**Summary/Conclusions:** This abstract reports multiple novel variant FLT3 mutations in adult pts with newly diagnosed FLT3-ITD or FLT3-D835 mutant AML. The allelic burden of these FLT3 variant mutations can sometime be higher than that of FLT3-ITD. Detailed FLT3 analyses in this subset of pts suggests that crenolanib in combination with standard induction chemotherapy has the ability to eradicate variant FLT3 clones. All 4 pts treated with chemother-apy followed by crenolanib showed clearance of FLT3-ITD, TKD, as well as other novel variants. To achieve maximal clinical benefit, a potent pan-FLT3 inhibitor with the ability to inhibit ITD, D835, as well as other activating mutations maybe beneficial.

**P553**

**PATIENTS WITH ACUTE MYELOID LEUKAEMIA WHO HAVE MUTATIONS IN IDH1 OR IDH2 RESPOND WELL TO INDUCTION CHEMOTHERAPY WITH “7+3” DESPITE THE PRESENCE OF COMPLEX KARYOTYPE OR FLT3-ITD**

D.M. Gupta1,*, D. S. Devlin2, D. M. Tallman2, D. E. Stein2

1Mount Sinai Hospital, 2Memorial Sloan Kettering Cancer Center, New York, United States

**Background:** Mutations in isocitrate dehydrogenase isoforms 1 and 2 (IDH1/IDH2) occur in 8-12% of patients with acute myeloid leukemia (AML). Mutant IDH enzymes catalyze the conversion of alpha ketoglutarate to beta hydroxylglutarate. Increased concentrations of intracellular 2-HG lead to histone hypermethylation and a block in cellular differentiation and may also lead to suppression of homologous recombination. Previous studies of outcomes in patients with FLT3-ITD has shown the majority of patients with FLT3-ITD have a complex karyotype which is generally resistant to standard induction regimens. In this study, we investigated the outcomes of patients giv-en induction chemotherapy with daunorubicin and cytarabine (7+3), the most common regimen used in the United States.
Aims: To delineate the complete remission rate in AML patients with IDH1 or IDH2 mutations who receive standard 7+3 induction chemotherapy.

Methods: After receipt of IRB approval, an institutional database of genomic abnormalities in all patients with AML was queried for patients with IDH1 or IDH2 mutations between the years of 2010 and 2016. Pathology records of patients identified as having an IDH1/IDH2 mutation were reviewed to confirm the presence of an IDH mutation. After confirmation of IDH mutational status, all patients who received standard induction chemotherapy with 7+3 were included in this retrospective chart review.

Results: Between 2010 and 2016, 82 patients with IDH1/IDH2 mutations who had been treated with 7+3 induction chemotherapy were seen at MSKCC. Of these, 33 (40.2%) had IDH1 mutations and 49 (59.8%) had IDH2 mutations. Of those with IDH2 mutations IDH2 R140Q mutations were present in 34 (69.3%) and IDH2 R172K mutations were present in 15 (30.6%). The median age of all patients treated was 63, 56 patients (68%) had de novo AML, 16 (20%) had AML with myelodysplasia related changes, 5 (6%) had a known prior history of MDS and 5 (6%) had therapy related AML. Nearly half of the patients (49%) had karyotypic abnormalities. Of the 82 patients who received induction chemotherapy with 7+3, 51 achieved a complete remission (CR) after 1 cycle and 16 after 2 cycles for a CR rate of 82%. The strongest predictor of response to induction chemotherapy was the presence of an NPM1 mutation. There was a trend towards decreased response to induction chemotherapy in patients with a complex karyotype (p=0.079) that did not reach statistical significance. The presence of an IDH2 R172K mutation was predictive of non-response to one cycle of (7+3) of 7+3 but when two cycles of induction chemotherapy were given, response rates were equivalent to patients with R140Q mutations. Co-occurring mutations in FLT3 (ITD or TKD), DNMT3A or NRAS were not predictive of responses to induction chemotherapy.

Summary/Conclusions: Induction chemotherapy with 7+3 leads to a robust CR rate of 82% in patients with AML that harbor and IDH1 or IDH2 mutation. CR is not affected if IDH2 is mutated, although those with IDH2 R172 mutations required two cycles of chemotherapy to achieve a remission. Karyotypic abnormalities did not influence the response to induction chemotherapy, nor did the presence of co-occurring FLT3-ITD, FLT3-TKD or NRAS mutations. Of these, 33 (40.2%) had IDH1 mutations and 49 (59.8%) had IDH2 mutations. Aims: The presence of an IDH2 R172K mutation was predictive of non-significance. The presence of an NPM1 mutation was the strongest predictor of response to induction chemotherapy was the presence of an NPM1 mutation. There was a trend towards decreased response to induction chemotherapy in patients with a complex karyotype (p=0.079) that did not reach statistical significance. The presence of an IDH2 R172K mutation was predictive of non-response to one cycle of (7+3) of 7+3 but when two cycles of induction chemotherapy were given, response rates were equivalent to patients with R140Q mutations. Co-occurring mutations in FLT3 (ITD or TKD), DNMT3A or NRAS were not predictive of responses to induction chemotherapy.

However, the correlation is only valid for CYT-IDA while the PM Test was applied to up to 45 treatments. Any such treatment identified as sensitive means the PM Test can provide a valuable guideline to hematologists. This means the PM Test can suggest sensitive treatments for the vast majority of patients.

Figure 1.

Summary/Conclusions: We have developed a novel ex vivo PM test for induction treatment in AML patients to guide hematologists selecting the right treatment to achieve CR in individual patients leveraging up to 45 different validated chemotherapeutic regimes. Assuming a similar response rate for all these treatments, our test could estimate a net prediction for sensitivity to AML treatment higher than 80% in 1st line. This PM Test will be evaluated in an interventional clinical trial on relapse/refractory patients that is expected to begin in the next few months in collaboration with the PETHEMA group from Spain.

Background: AML treatment in elderly patients (pts) >60 years (y) with intensive chemotherapy (IC) or azacitidine (AZA) are not necessarily mutually exclusive. Aims: Results of the multicenter DRKS00004519 (RAS-AZIC) study of the East German Study Group (OSSHO) which evaluated first-line treatment with AZA followed by response-based AZA or IC in pts >60y with AML are presented.

Methods: pts >60y with newly diagnosed AML (n=112) were included. Recruitment was completed in May, 2016. In the phase I part, safety of upfront AZA (75mg/m²/day s.c.) for 7 days followed by IC (mitoxantrone 10mg/m²/day on day (d) 1-3 and cytarabine 1g/m²/BID on d 1, 3, 5, 7) on d17 was established through a 3+3 design. In the multicenter phase II part (figure), upfront AZA was sequentially followed by AZA or IC based on d15 bone marrow (BM) blasts (<45 vs 345%) and CR/CRi on d56 which were both previously identified as early predictors for long-term response to AZA in AML (Al-Ali et al. Leuk Lymph 2011). The primary endpoint was response (CR/CRi, and PR) at d90 according to the International Working Group criteria. Based on the optimal two-stage design (Simon. Control Clin Trials 1989), protocol treatment was non-inferior to standard IC if, on an intention-to-treat basis, an OR of 61% was reached. Adverse events (AEs) were reported according to the NCI CTCAE 4.03. All pts gave written informed consent.

Results: Median age was 70y (52% males), de novo AML was present in 65% of pts. Median BM blasts and WBC were 50% and 4.4x10⁹/L respectively. Genetic risk was high in 30%, intermediate in 55%, and favorable in 15%. FLT3 and NPM1 were mutated in 12% and 22% respectively. All pts received first-line AZA. Only lower baseline blasts correlated with blasts <45% on d15 (p=0.0005). Yet, 40% of pts with baseline blasts >50% reached this goal. Protocol assigned treatment on d15 was applied to 101 (90.2%) pts (54.5% continued with AZA; 46.5% received IC). Of 192 AZA cycles given till d56, 33.6% were applied in an outpatient setting. Until d90, one IC cycle was needed in 77 (68%) pts. The primary endpoint was response (CR/CRi) as CR/CRi were achieved in 62.5% [CR/CRi (n=43%); PR (4.5%)] and 8.9% respectively. The probabilities of achieving CR/CRi with AZA alone, two AZA cycles + one IC, and one AZA cycle + one IC were 28.3%; 53.3%, and 58.3% respectively. Age, WBC, and type of AML had no impact on response in the three treatment scenarios. Similarly, response was not influenced by baseline BM blasts. CR/CRi was lower in high risk genetics (48%) compared to other risk categories (78%) (p=0.007). This negative association was particularly marked in pts with high-risk genetics and d15 BM blasts >45% [CR/CRi 38.5% vs 84% in other genetic categories (p=0.009)]. Interestingly, the impact of genetics on OR was not seen in the two AZA cycles + one IC cohort (p=1.0). OR with AZA alone was remarkably high (70%) in pts with favorable genetics including those with NPM1mut/FLT3wt (p=0.003). Protocol therapy was generally well tolerated. Constipation grade 1+2 was the most frequently reported AE under AZA (48%). The most frequent grade 3+4 non-hematologic AE was infection [IC (47%); AZA (20%)].
a late complication of cytotoxic or radiation therapy and is associated with a poor prognosis. CPX-351 is a liposomal formulation that delivers a synergetic 5:1 molar ratio of cytarabine and daunorubicin. In a randomized, open-label, controlled phase 3 trial in patients aged 60 to 75 years with newly diagnosed, secondary AML (eg, tAML or AML after myelodysplastic syndrome), CPX-351 significantly improved overall survival (OS) versus cytarabine/daunorubicin (7+3).

Aims: The current analysis of this phase 3 study evaluated outcomes in the subgroup of patients with tAML.

Methods: Enrolled patients were randomized 1:1 to receive induction with 1 to 2 cycles of CPX-351 (100 units/m² [cytarabine 100mg/m² + daunorubicin 440mg/m²] on Days 1, 3, and 5 [2nd induction: Days 1 and 3 only]) or 7+3 (cytarabine 100mg/m²/day x 7 days [2nd induction: x 5 days] + daunorubicin 60mg/m² on Days 1, 2, and 3 [2nd induction: Days 1 and 2 only]). Patients who achieved complete remission (CR) or CR with incomplete platelet or neutrophil recovery (CRi) could receive up to 2 cycles of consolidation therapy. Note, the study was not powered for this subgroup analysis.

Results: A total of 304 patients were enrolled and received study treatment, including 62 (20%) patients with tAML (CPX-351 arm, n=30; 7+3 arm, n=32). Characteristics of tAML patients were similar between the CPX-351 and 7+3 arms: median age was 69.0 versus 67.5 years, and 47% versus 53% were male. Prior treatment in patients with tAML included prior non-anthracycline chemotherapy alone (26%), radiation alone (26%), non-anthracycline chemotherapy + radiation (32%), non-anthracycline + anthracycline chemotherapy (5%), and non-anthracycline + anthracycline chemotherapy + radiation (11%). CPX-351 was associated with a significant OS benefit versus 7+3 in older tAML patients and numerically longer event-free survival and remission duration (Figure). Additionally, a greater proportion of tAML patients in the CPX-351 arm versus the 7+3 arm achieved CR+CRi (47% vs 38%, respectively; odds ratio=1.33 [95% CI: 0.47, 3.81]) and proceeded to stem cell transplantation (37% vs 27%; odds ratio=1.54 [95% CI: 0.53, 4.49]). Serious treatment-emergent adverse events (TEAEs) were reported for 18/30 (60%) of tAML patients in the CPX-351 arm and 12/32 (38%) of tAML patients in the 7+3 arm; the observed difference in serious TEAEs in this subgroup population appeared to primarily be due to the incidence of febrile neutropenia (n=6/30 [20%] vs n=0/32 [0%]). These (10%) patients in the CPX-351 arm and 5 (16%) patients in the 7+3 arm experienced a TEAE that resulted in death during the treatment period; there was no pattern in the individual TEAEs that led to death.

Summary/Conclusions: CPX-351 is associated with improved efficacy and a safety profile comparable to 7+3 in older patients with newly diagnosed tAML. Outcomes in the tAML subgroup mirrored the overall study population, indicating CPX-351 may represent a new therapeutic option for this difficult to treat population.

HYPERFERRITINEMIA IS AN INDEPENDENT POOR PROGNOSTIC FACTOR IN ACUTE MYELOID LEUKEMIA
S. Carabatos1,2, M.V. Larcher3, E. Bérard-de-Millay1, F. Vergez2,3,7, S. Tavitian1,2,3,*, X. Thomas 4, E. Bérard 5,6, F. Vergez 2,3,7, S. Tavitian 1,2,3, X. Thomas 4

Background: The prognostic impact of ferritinemia has been studied in myelodysplastic syndromes and acute myeloid leukaemia (AML) patients undergoing allogeneic stem cell transplantation (SCT). In this context, high levels of serum ferritinemia have been correlated to a shorter overall survival (OS) and an increased relapse risk. We have previously shown that hyperferritinemia at diagnosis has a strong prognostic impact in a cohort of 162 AML patients with intermediate cytogenetic risk and younger than 60.

Aims: We now extend the analysis to all age and cytogenetic risk, in order to confirm the impact of hyperferritinemia in AML.

Methods: This study included 525 adult AML patients (excluding acute promyelocytic leukemia) treated by intensive chemotherapy in Toulouse and Lyon University Hospitals between January 1st, 2005 and December 31st, 2014 who had ferritinemia documented at AML diagnosis. Ferritin level was measured by spectrophotometry. Primary outcome was disease-free survival (DFS). To avoid the loss of information and the reduction in power introduced by the categorization of ferritinemia and to deal with the non-linearity in the relationship between outcomes and ferritinemia, we explored the relationship between ferritinemia and outcomes using restricted cubic spline.

Results: Median age at diagnosis was 59.4 years (interquartile range [IQR], 47.8-66.4); 303 of them (57.7%) were men. Disease status was de novo in 83.2% (N=437). Median white blood cell count (WBC) was 10.0x10^9/L (IQR, 2.5-41.5). Cytogenetic risk was favorable, intermediate and adverse in 9.2% (N=48), 71.8% (N=374) and 19% (N=99) respectively; ELN classification was favorable, intermediate-I, intermediate-II, adverse and unknown in 21.0% (N=110), 25.5% (N=134), 22.3% (N=117), 18.9% (N=99) and 12.4% (N=65) respectively. Median ferritinemia at AML diagnosis was 715 µg/L (IQR, 372-1304), ranging from 34µg/L to 70759 µg/L (upper normal limit [UNL]; 300µg/L). 421 patients achieved complete remission (CR; 80.2%). Early death and treatment failure rates were 7.8% (N=41) and 12% (N=63) respectively. 169 patients underwent allogeneic HSCT in first CR (32.2%). Median DFS was 19.8 months (IQR, 8.4-Not Reached). Ferritinemia had a significant impact on DFS: median DFS was 21.2 months in patients with ferritinemia ≤2100 µg/L (7-fold UNL), and 17.7 months with ferritinemia >2100 µg/L (HR, 1.6 [95%CI, 1.1-2.3], p=0.0253). After adjustment for age, AML status and cytogenetics or ELN classification, relapse or death rate significantly (p=0.0122) increased from ferritinemia superior or equal to 2141 µg/L (Figure 1). Ferritinemia had also a significant impact on early deaths, CR rate, EFS and OS after adjustment (24-fold UNL, p<0.0001; ≥7-fold UNL, p=0.004; ≥3-fold UNL, p<0.0001 and ≥2-fold UNL, p<0.001 respectively).

Summary/Conclusions: In conclusion, hyperferritinemia is a prognostic marker independent from well-acknowledged factors, such as cytogenetics and molecular abnormalities. Ferritinemia should be included at AML diagnosis workup as it provides reproducible information on short and long-term outcome for AML patients of any subgroup. The putative link between hyperferritinemia, inflammation and chemoresistance should be investigated.

NGS ANALYSIS OF 474 BONE MARROW SAMPLES FROM 157 AML PATIENTS TREATED WITH AZACITIDINE—IMPACT OF AGE ON MUTATIONAL LOAD
L. Pleyer1,2,3,*, F.J. Gassner1,2, S. Burgstaller4, H. Wedler5, T.N. Hartmann1,2,3, H. Pichler1,2,3, S. Pichler1,2,3, T. Hartmann1,2,3, L. Pleyer1,2,3,*, F.J. Gassner1,2, S. Burgstaller4, H. Wedler5, T.N. Hartmann1,2,3, H. Pichler1,2,3, S. Pichler1,2,3, T. Hartmann1,2,3
1Institute of Pathology, Paracelsus Medical University, 2Salzburg Cancer Research Institute (SCRI), Center for Clinical Cancer and Immunology Trials, 3Cancer Cluster, Salzburg, 4Department of Internal Medicine IV/Department of Internal Medicine V, 5Department of Pathology, Paracelsus Medical University, Salzburg, Austria

Background: Recent publications have shown the prognostic value of per- and molecular analyses in patients (pts) with acute myeloid leukaemia (AML) (Papaemmanuil et al, NEJM 2016). While recent data has been published on pts with myelodysplastic syndromes (MDS) and AML treated with decitabine, (Welch et al, NEJM 2016; Duncavage et al, Blood 2017) data on
AML pts treated with azacitidine (AZA) has only been presented in abstract form thus far (Tang et al, ASH 2016). Data on the impact of age on mutational load in AML are scarce.

Aims: To assess the mutational landscape in elderly AML pts treated with AZA; specifically, whether age has an impact on mutational load.

Methods: We analysed 474 bone marrow FFPE specimens from 157 AML pts in the Austrian Registry of Hematologic Agents from two centers (Salzburg, Wels-Grieskirchen) using a 53-gene panel (all exons). NGS was performed by Qiagen. Minimum coverage: 1,500x. All mutations were checked against COSMIC-v79, ClinVar, ICGC, DoCn, dbSNP and Varsome databases. For comparison of categorical variables Chi-squared test was used, for comparison of means Students’ T-test was used.

Results: The rate of secondary (s)AML was significantly lower in pts <75 (n=85), vs ≥75 years (n=54) (66.0 vs 77.8%, P<0.001). There was no significant difference in the rate of adverse cytogenetics or monosomal karyotype before AZA treatment between pts < vs ≥75 years, respectively (data not shown). Mutational load (average number of mutated genes and mutations per pt) assessed at/after initiation of AZA, was significantly higher in pts <75 vs pts ≥75 years (10.2 vs 8.6 mutated genes/pt; P=0.030 and 12.9 vs 10.5 mutations/pt; P=0.012, Figure 1A). This also held true when mutational load was assessed at any timepoint during the course of AML (including during/after AZA treatment) (Figure 1B). In total, 139 pts had more than one marrow sample with NGS results. Analysis of paired samples revealed that mutational load was significantly higher during/post-AZA vs before AZA in both age groups (Figure 1C-D). In total, 60.4%, 15.8%, 8.6%, 3.6% and 11.5% of pts acquired 1, 0, 2, 3, 4-13 additional mutations, respectively. No relevant differences between pts < vs ≥75 years were found (data not shown). When comparing the delta of mutations before vs during/after AZA according to age group, no significant difference was found (Figure 1E).

Table 1.

Summary/Conclusions: The observed mutational load per pt in our cohort is higher than that observed by others using targeted re-sequencing methods, which report an average of only 2-4 mutations per pt (Duncanave et al, Blood 2017; Conte et al, Leuk 2013; Au et al, Diagn Pathol 2016; Grove & Vassiliou, Dis Model Mech 2014). It seems however, that a higher mutational load (average number of mutated genes and mutations per pt) assessed at/after initiation of AZA, was significantly higher in pts <75 vs ≥75 years (10.2 vs 8.6 mutated genes/pt; P=0.030 and 12.9 vs 10.5 mutations/pt; P=0.012, Figure 1A). This also held true when mutational load was assessed at any timepoint during the course of AML (including during/after AZA treatment) (Figure 1B). In total, 139 pts had more than one marrow sample with NGS results. Analysis of paired samples revealed that mutational load was significantly higher during/post-AZA vs before AZA in both age groups (Figure 1C-D). In total, 60.4%, 15.8%, 8.6%, 3.6% and 11.5% of pts acquired 1, 0, 2, 3, 4-13 additional mutations, respectively. No relevant differences between pts < vs ≥75 years were found (data not shown). When comparing the delta of mutations before vs during/after AZA according to age group, no significant difference was found (Figure 1E).
AML showed higher therapy-related mortality (TRM) rate. However, multivariate rate and inferior survival outcome compared to normocellular AML, and hypo-survival outcome compared to normocellular karyotype was poorer. In untreated group (n=207), hypo-AML showed longer OS (p<0.001) compared to normocellular.

Results: Signal ratio was assessed in 152 patients with FLT3-ITD and -TKD mutations who had received ≥80mg gilteritinib. Of these patients, 136 had FLT3-ITD mutations with or without concomitant TKD mutations, and 16 had FLT3-TKD mutations only. Median ITD and TKD signal ratios were 0.84 and 0.5, respectively. Patients with FLT3-ITD signal ratios that were above or below the median ITD signal ratio had OS durations of 216 and 213 days, respectively. No significant difference in median OS was observed between patients in the highest and lowest FLT3-ITD signal ratio quartiles (Figure 1). Patients with TKD signal ratios that were above the median value (0.5) had a median OS of 202 days; those with TKD signal ratios below the median value had a significantly shorter median OS of 33.5 days (P=0.0004; Figure 1).

Aims: As the characteristics and outcomes are not well recognized.

Methods: Hypocellular (<20%) bone marrow (BM) which was identified with at least two myelodysplasia-related change (AML-MRC) accounts for small proportion of adult AML. As the characteristics and outcomes are not well recognized.

Background: Hypocellular acute myeloid leukemia (hypo-AML) and AML with myelodysplasia-related change (AML-MRC) accounts for small proportion of adult AML. As the characteristics and outcomes are not well recognized.

Aims: We tried to analyze these specific groups and compared to normocellular AML.

Methods: After exclusion of secondary AML, therapy-related AML, and AML M3, we retrospectively analyzed 1593 AML cases between 2002 and 2013. We found 101 (6.3%) patients with hypo-AML and 164 (10.3%) patients with de novo AML-MRC. Hypo-AML was diagnosed with blast counts ≥20% within hypocellular (<20%) bone marrow (BM) which was identified with at least two biopsy specimens and age-related correction was considered. De novo AML-MRC was defined with multilineage dysplasia ≥10% for each lineage with blast counts ≥20% without history of antecedent hematologic disease. Patients (n=20) with both AML-MRC and hypo-AML were distributed in AML-MRC group.

Results: Patients with hypo-AML were older (p=0.001) and significantly presented lower leukocyte and PB/BM blast counts (p<0.001). Patients with AML-MRC were older and lower hemoglobin level with lower PB/BM blast counts (p=0.001) compared to normocellular de novo AML. In both groups, the risk of karyotype was poorer. In untreated group (n=207), hypo-AML showed longer survival outcome compared to normocellular de novo AML and AML-MRC. In treated group (n=1386), hypo-AML and AML-MRC both showed higher relapse rate and inferior survival outcome compared to normocellular AML, and hypo-AML showed higher therapy-related mortality (TRM) rate. However, multivariate

Figure 1. MS}_{\text{OS}} (n=20) with both AML-MRC and hypo-AML were distributed in AML-MRC group. Hypo-AML was diagnosed with blast counts ≥20% within de novo AML. Evaluation of the safety, tolerability, pharmacokinetics (PK), pharmacodynamics (PD), and preliminary antitumor activity of IMGN779 are secondary objectives.

Methods: Adult patients (≥ 18 years) with relapsed or refractory CD33+ AML (defined by ≥20% of AML blasts expressing CD33 by flow cytometry) were eligible for enrollment. Informed consent was obtained from all patients. Dose-escalation, which follows a standard 3+3 design, began with a starting dose of 0.02mg/kg. IMGN779 was administered intravenously once every 2 weeks on days 1 and 15 as part of a 28-day cycle. Adverse events (AEs) were evaluated using NCI-CTC v4.03.

Results: As of February 2017, a total of 17 patients (9 female, 8 male) with a median age of 62 years have received IMGN779 treatment. Five dose levels have been completed, with escalation proceeding from 0.02–0.26mg/kg. AEs as of February 2017, a total of 17 patients (9 female, 8 male) with a median age of 62 years have received IMGN779 treatment. Five dose levels have been completed, with escalation proceeding from 0.02–0.26mg/kg. AEs were as expected for this relapsed/refractory AML population including cytopenias and constitutional symptoms. No relationship between frequency or severity of AEs and dose levels was observed. Median ITD signal ratio (ie, FLT3-ITD:wild-type FLT3) was calculated from patients with ITD mutations (with/without concomitant TKD mutations); median TKD signal ratio (i.e., FLT3-TKD: wild-type FLT3) was calculated from all patients with a TKD mutation. Median OS estimates were derived and stratified based on ITD and TKD signal ratios that fell above or below median signal ratio values reported for the trial.

Results: Signal ratio was assessed in 152 patients with FLT3-ITD and -TKD mutations who had received ≥80mg gilteritinib. Of these patients, 136 had FLT3-ITD mutations with or without concomitant TKD mutations, and 16 had FLT3-TKD mutations only. Median ITD and TKD signal ratios were 0.84 and 0.5, respectively. Patients with FLT3-ITD signal ratios that were above or below the median ITD signal ratio had OS durations of 216 and 213 days, respectively. No significant difference in median OS was observed between patients in the highest and lowest FLT3-ITD signal ratio quartiles (Figure 1). Patients with TKD signal ratios that were above the median value (0.5) had a median OS of 202 days; those with TKD signal ratios below the median value had significantly shorter median OS of 33.5 days (P=0.0004; Figure 1).

Figure 2. MS}_{\text{OS}} (n=20) with both AML-MRC and hypo-AML were distributed in AML-MRC group. Hypo-AML was diagnosed with blast counts ≥20% within de novo AML. Evaluation of the safety, tolerability, pharmacokinetics (PK), pharmacodynamics (PD), and preliminary antitumor activity of IMGN779 are secondary objectives.

Methods: Adult patients (≥ 18 years) with relapsed or refractory CD33+ AML (defined by ≥20% of AML blasts expressing CD33 by flow cytometry) were eligible for enrollment. Evaluation of the safety, tolerability, pharmacokinetics (PK), pharmacodynamics (PD), and preliminary antitumor activity of IMGN779 are secondary objectives.
Summary/Conclusions: This is the first clinical experience of the next-generation CD33-targeting ADC, IMGN779, in AML patients. No DLTs have been noted to date. AEs were generally consistent with the underlying disease. PK and PD are favorable and dose escalation is continuing.

Aggressive Non-Hodgkin lymphoma - Relapsed/refractory

**P563**

**COMBINATION OF TGR-1202, UBLITUXIMAB, AND BENDAMUSTINE IS SAFE AND HIGHLY ACTIVE IN PATIENTS WITH ADVANCED DLBCL AND FOLLICULAR LYMPHOMA**

M.A. Lunning1,2, P. Bierman1, G.R. Bociek1, M.T. Schreider2, T. Siddiqi3, S. Blume1, K. Cutter2, E.K. Paul2, D. Bu2, P. Sportelli2, H.P. Miskin2, M. Purdom2, M.S. Weiss3, J.M. Vose1

1University of Nebraska Medical Center, Omaha, NE, 2Clearview Cancer Institute, Huntsville, AL, 3City of Hope National Medical Center, Duarte, CA, 4TG Therapeutics, Inc., New York, NY, United States

Background: TGR-1202 is a next generation, once daily, PI3Kδ inhibitor, active in patients (pts) with rel/ref hematologic malignancies that has demonstrated a notably differentiated safety profile, including in long-term follow up (Burriss, 2016). Ublituximab (UTX) is a novel glycoengineered mAb targeting a unique epitope on the CD20 antigen. Bendamustine (Benda) is an active chemotherapy agent in pts with lymphoma. The combination of UTX + TGR-1202 is tolerable and active in pts with rel/ref hematologic malignancies and is under Phase 3 testing for patients with CLL and Phase 2b testing for patients with DLBCL.

Aims: This Phase 1 trial evaluates the safety and efficacy of UTX + TGR-1202 + Benda in pts with advanced Diffuse Large B-cell Lymphoma (DLBCL) and Follicular Lymphoma (FL).

Methods: Eligible pts had rel/ref DLBCL or FL with an ECOG PS ≤2 w/o limit to number of prior therapies. ANC of >750 and Platelets >50,000 was permitted. Pts refractory to prior PI3Kδ, Benda, or anti-CD20 therapy were eligible. UTX was dosed on Days 1, 8, 15 of Cycle 1, Day 1 of Cycle 2-6, followed by Cycle 9 & 12. TGR-1202 was started at 800mg QD with a -1 dose reduction cohort at 600mg if not tolerated in ≥2/6 pts. Benda was dosed at 90mg/m2 on Days 1 & 2 of Cycles 1-6 only. Primary endpoints included safety and efficacy (Cheson 2007).

Results: Twenty-three pts were evaluable for safety: 15 diffuse large B-cell (DLBCL) and 8 follicular (FL). Med age 68 yo (range 31-81); 12 M/11 F; median prior treatment regimens=2 (range 1-6); 12 pts (52%) were refractory to their immediate prior treatment and to prior CD20 therapy, and 7 patients had progressed post-transplant. ECOG PS 0/1/2 (3/18/2). Initially 2/4 pts at 800mg TGR-1202 experienced AEs in Cycle 1 that led to treatment interruption (rash, neutropenia) thus the 600mg dose of TGR-1202 was explored. No additional Cycle 1 treatment delays were reported at the 600mg dose level, which was later expanded and the 800mg TGR-1202 dose is now being evaluated with stricter eligibility criteria to require an ANC of ≥1.0, and the use of growth factor support in cycle 1 is now encouraged. The most common AE’s included diarrhea (39%; G3/4 4%), decreased appetite (35%; G3/4 4%), nausea (30%; G3/4 4%), and neutropenia (22%). The only Grade 3/4 AE reported in >10% of pts was neutropenia (22%). Two pts had a TGR-1202 dose reduction. Nineteen pts (11 DLBCL/8 FL) were evaluable for efficacy: ORR amongst all pts was 79% (15/19) with 42% (8/19) achieving a complete response (CR), of which 5 were DLBCL and 3 FL. ORR in the respective groups as follows:

Median follow-up time on study is 6 mos for all pts (range 1-14+ mos).

Summary/Conclusions: The combination of UTX, TGR-1202, and bendamustine has exhibited manageable toxicity with significant activity in advanced DLBCL and FL pts including an encouraging 42% CR rate (45% in DLBCL and 38% in FL). Enrollment continues at the 800mg TGR-1202 dose level with the use of growth factor prophylaxis. Safety and efficacy data for all pts will be updated at the meeting. Based upon the early activity of the triplet, future registration directed studies are being planned.

**P564**

**VENETOCLAX (VEN) IN PATIENTS WITH RELAPSED/REFRACTORY NON-HODGKIN LYMPHOMA (NHL)**

1Dana-Farber Cancer Institute, Boston, United States, 2Royal Melbourne Hospital, Parkville VIC, 3Peter MacCallum Cancer Centre, East Melbourne VIC, 4University of Texas MD Anderson Cancer Center, Houston, 5University of Arizona Cancer center, Tucson, Australia, 6AbbVie, Inc., North Chicago, 7Memorial Sloan-Kettering Cancer Center, New York City, United States

Background: Venetoclax (VEN) is a novel BH3 mimetic that targets the Bcl-2 protein complex, resulting in tumor cell apoptosis when the Bcl-2 inhibitor is combined with an alkylating agent or an antibody targeting CD20. In a recently published, single-arm, phase 1 trial, patients (pts) with rel/ref DLBCL and FL who had received at least 2 prior lines of therapy were treated with VEN at a dose of 300mg QD orally. The primary endpoints were safety and ORR. The ORR was 47% (95% CI 29-65%). Pts with rel/ref DLBCL or FL who were enrolled in this first-in-patients trial have been updated at the meeting. Based upon the early activity of the triplet, future registration directed studies are being planned.
Background: VEN is a selective orally bioavailable BCL-2 inhibitor. The dose-escalation Phase 1 study of VEN in 106 patients (pts) with relapsed/refractory NHL reported an ORR of 44%. Most pts had diffuse large B-cell/follicular lymphoma.

Aims: We report on updated results in pts with less common NHL subtypes.

Methods: VEN was administered and continued until progressive disease (PD). An acceptable toxicity, in dose cohorts ranging from 300-1200mg. Adverse events (AEs) were assessed by NCI-CTCAE v4.0 and response by 2007 Cheon ISG response criteria, utilizing CT scans beginning at wk 6.

Results: 35 of 106 pts had mantle cell lymphoma (MCL, n=28), marginal zone lymphoma (MZL, n=3) or Waldenström macroglobulinemia (WM, n=4). Most common acceptable toxicity, in dose cohorts ranging from 300-1200mg. Adverse events (AEs) were assessed by NCI-CTCAE v4.0 and response by 2007 Cheon ISG response criteria, utilizing CT scans beginning at wk 6.

Results: 35 of 106 pts had mantle cell lymphoma (MCL, n=28), marginal zone lymphoma (MZL, n=3) or Waldenström macroglobulinemia (WM, n=4). Most common acceptable toxicity, in dose cohorts ranging from 300-1200mg. Adverse events (AEs) were assessed by NCI-CTCAE v4.0 and response by 2007 Cheon ISG response criteria, utilizing CT scans beginning at wk 6.

and other extranodal localizations (12%). In patients harboring a MYD88 mutation, the frequency of double carcinomas at IP sites (67%, Chi-square \( P=0.001 \)) was compared to nodal (13%) particularly in DLBCL patients with IP localizations. Interestingly, there was hardly any overlap between the presence of translocations (BCL2, BCL6 and MYC) or EBV and that of MYD88 and/or CD79B mutations, indicating that these tumors represent distinct DLBLC subgroups. In a recent study by Wilson et al. (Nat. Med. 2015), indicates that these patients are more sensitive to treatment with Bruton’s Kinase inhibitors. Our study highlights the importance of investigating the mutational status of MYD88 and CD79B in larger prospective clinical trials with molecularly targeted agents, particularly in DLBCL patients with IP localizations.

**Results:**

As of June 2015, 311 of 499 pts (62%) achieved a documented CR, 235 (60%) with relapsed NHL or Hodgkin lymphoma (HL) should be treated in a manner similar to immunocompetent pts. 

**Background:** The outcome of HIV-associated lymphoma has undergone significant improvement in recent years beginning with the widespread use of combination antiretroviral therapy (ART). However, among AIDS-related deaths, non-Hodgkin lymphoma (NHL) is the most frequent event. HIV-positive patients (pts) with relapsed NHL or Hodgkin lymphoma (HL) were diagnosed at participating centers in Germany and Austria since January 2005. Data on HIV-infection and lymphoma characteristics, treatments and outcomes were recorded. Pts with indolent lymphomas and primary central nervous system lymphomas were excluded from the present analysis.

**Results:** Of 499 pts (463 males, 36 females) 394 had aggressive NHL and 105 HL. The median age at lymphoma diagnosis was 45.6 yrs (range, 22–74.7). 344 pts (69%) were diagnosed with advanced stage (III/IV) lymphoma and the median CD4-cell count was 271/μl (266/μl in NHL and 287/μl in HL). As of June 2015, 311 of 499 pts (62%) achieved a documented CR, 235 (60%) with NHL and 76 (72%) with HL. After a median follow-up of 17 months for NHL and 30 months for HL pts, 31 of 235 NHL (13%) and 6 of 76 HL (11%) experienced a relapse. Incidence of relapse was 6.9/100 patient years (PY) within the 1st year after primary diagnosis and 1.3/100 PY thereafter (\( P=0.0062 \)). Median time to relapse was 7.3 months in NHL and 18.0 months in HL. Relapses beyond 12 months occurred in 6 of 31 NHL cases (19%) and in all 8 HL cases (100%) (\( P=0.045 \)). Median overall survival (OS) of all relapsed pts was 29.0 months (95% CI 14.1-44.2 months) after primary lymphoma diagnosis. In pts with HL, OS was not reached, whereas it was 15 months in pts with NHL (\( P=0.024 \)). Regarding the entire cohort of 311 pts with a documented CR, the 2-year OS rate was 57% in pts with relapse as compared to 97% in those without (\( P<0.001 \)). The majority of relapsed pts died of lymphoma (86%).

**Summary/Conclusions:** Relapses from CR are relatively rare in pts with HIV-associated NHL and HL. In pts with NHL the majority of relapses occur within the first year after primary diagnosis, whereas in HL most relapses occur beyond 12 months. Overall, pts with relapsed HIV-related NHL have a worse outcome than pts with relapsed HL.
Background: Nodal peripheral T-cell lymphomas (PTCLs) are a heterogeneous group of neoplasms, which include PTCL not otherwise specified (PTCL-NOS), angioimmunoblastic T-cell lymphoma (ATL), anaplastic large-cell lymphoma (ALCL), anaplastic lymphoma kinase-positive (ALK-ALCL), and ALCL-ALK-. Clinical assessments before and after treatment are essential to predict survival in nodal PTCL. However, limited data is available regarding the prognostic relevance of National Comprehensive Cancer Network International Prognostic Index (NCCN-IPI) and post-treatment PET-CT scan.

Methods: In this retrospective cohort study, patients with newly diagnosed nodal PTCL were consecutively enrolled from 11 hospitals in South Korea. Patients were eligible if they were histologically diagnosed with nodal PTCL from Jan 2005 to June 2016, received systemic chemotherapy, and had the results of PET-CT scan at the time of diagnosis and at the end of treatment. Post-treatment PET-CT was assessed using 5-point Deauville score. The study excluded ALCL-ALK+ due to well-known better survival.

Results: A total of 396 patients were screened for eligibility. Seventy patients were excluded from the analysis due to following reasons: unavailable pre- or post-treatment PET scans, no systemic treatment, uncertain histology, and ALCL-ALK+. Thus, 326 patients were analyzed. The median age was 61 years (range, 18-86) and 209 (64%) were male. PTCL-NOS (N=172, 53%) was the most common subtype included, and ATL (N=111, 34%) and ALCL-ALK- (N=43, 13%) followed. Three-fourths of patients (N=242) had stage III/IV. Majority of patients received anthracycline-based therapy. Patients were categorized into low (N=42, 13%), low-intermediate (Li, N=108, 33%), high-intermediate (Hi, N=136, 42%), and high (N=40, 12%) risk groups according to NCCN-IPI. Based on the Deauville criteria, post-treatment PET-CT scan was scored as 1 (N=130, 40%), 2 (N=47, 14%), 3 (N=60, 18%), 4 (N=27, 8%), and 5 (N=62, 19%). Because the number of progression in Deauville score 3 (40/60, 67%) was significantly different from score 2 (21/47, 45%; P=0.023) and 4 (24/27, 89%; P=0.030), we categorized patients into 3 groups: Deauville score 1-2, 3, and 4-5. With a median follow-up of 54.7 months (IQR, 30.2-84.5), 5-year PFS rate was 35.7% (95% CI, 30.0-41.4) and OS rate was 47.1% (95% CI, 40.8-53.4). NCCN-IPI risk and post-treatment PET-CT scan were independently associated with PFS in the multivariate analysis (for Li NCCN-IPI, hazard ratio [HR] 1.615, 95% CI 0.963-2.671; for Li NCCN-IPI and Deauville score 1-2, HR 1.426-1.756; for Hi NCCN-IPI 4.475, 95% CI 2.231-8.977; P<0.001; for post-treatment Deauville score 3, HR 1.895, 95% CI 1.281-2.801; score 4-5, HR 6.916, 95% CI 4.948-9.667; P<0.001). We stratified patients into 5 groups based on risk of progression: a low (low NCCN-IPI and Deauville score 1-2), low (low NCCN-IPI and Deauville score 3, or Li NCCN-IPI and Deauville score 1-2), low-intermediate (Hi NCCN-IPI and Deauville score 1-2), high (high NCCN-IPI and Deauville score 1-2), or low-intermediate (Hi NCCN-IPI and Deauville score 3), and very high (Deauville score 4-5). The risk model showed a strong association with PFS and OS (Figure 1).

Summary/Conclusions: This study proposes a new risk stratification model incorporating baseline NCCN-IPI in combination with post-treatment Deauville score on PET-CT scan in patients with newly diagnosed nodal PTCL.

LONG-TERM EFFICACY AND SAFETY OF CRIZOTINIB IN RELAPSED ALK POSITIVE LYMPHOMA PATIENTS: CLINICAL AND BIOLOGICAL CORRELATES

F. Farina1,2,3,*, M. Ceccon1, S. Mori2, L. Verga2, L. M. Borin2, L. Mologni1, D. Fontana1, G. Geeta1, R. Piazzza1, C. Gambacorti-Passerini1,2
1School of medicine, Milano Bicocca University, 2Haematology Department and Clinical Research Unit, San Gerardo Hospital, Monza, 3Haematology and Bone Marrow Transplantation Unit, San Raffaele Scientific Institute, Milano, Italy

Background: Anaplastic large cell lymphoma (ALCL) is an aggressive disease with over 60% ALK-tyrosine kinase (TK) receptor positivity due to oncogenic fusions proteins containing ALK, mainly NPM-ALK. Crizotinib, an ALK inhibitor, proved to be effective in ALK positive tumors and in particular in ALK+ ALCL, with Objective Response Rates (ORR) in the 80-90% range. Long-term data on the safety and efficacy of crizotinib are lacking.

Aims: In this work, we analysed long-term clinical outcomes in 16 patients treated with crizotinib for ALK positive ALCL and we evaluated the presence of TK domain-point mutations in patients who relapsed during crizotinib treatment.

Methods: 16 patients were treated at the Clinical Research Unit, S. Gerardo Hospital, Monza (Italy) from June 2010 to December 2015 with a median follow up of 7.3 months (range 2.4-72 months). Survival curves were obtained using GraphPad Prism 5; differences were evaluated with Mantel-Cox test and Gehan-Breslow-Wilcoxon test. In 4/7 relapsed patients the TK domain of ALK were amplified from peripheral blood samples obtained at the time of crizotinib-relapse and subjected to deep sequencing. Subsequently we profiled in vitro the activity of 26392 generation ALK inhibitors (brigatinib, alecibitin, ceritinib and lorlatinib) with a murine Ba/F3 cell model and obtained their level of sensitivity/resistance to the drugs.

Results: Median age at diagnosis was 25.5 years (range 16-38 years) and 8/16 patients were male. Median previous line-therapies were 2.5 (range 1-5). In the Intention-To-Treat population which includes 1 patients who died after the first crizotinib dose, 13/16 patients (81.25%, 95% CI 53-95%) and 8/16 patients (50%, 95% CI 25-75%) achieved a OR and a complete response (CR) after 1 month of therapy, respectively. Median overall survival and progression free survival (PFS) were 7.53 months and 4.57 months respectively (fig 1a). Median time to progression was 50 days (range 47-137 days); OS and PFS from 1 and 3 years from treatment were 44%. In 7 patients were still on treatment and in CR (median treatment duration 44 months [range 15-72 months]). There was a significant difference in 3 years PFS between patients in whom CR was obtained after 4 weeks of crizotinib and those who didn't (PFS at 3 years 87.5% vs 0%, p<0.001-fig 1c); patients with less than 2 previous lines of therapy showed a borderline better 3 years PFS (66% vs 33%, p=0.08-fig 1b). Crizotinib was well tolerated and there were no cumulative adverse events (AEs) over this long-term follow-up. The only G3 AEs reported were transient neutropenia and creatine-kinase elevation. The deep sequencing of 4 NPM-ALK in relapsed patients demonstrated the presence in 2/4 samples of ALK mutations G1298A and G1156Y, which were not present in samples before crizotinib treatment. The level of in vitro resistance of these mutations showed a high level of resistance to crizotinib (resistance index for G1156Y and G1298A: 9.59-15.4 respectively). The sensitivity in vitro of these mutations to ALK-Inhibitors was also evaluated: all inhibitors, except alclebint for G1298A, with active with a therapeutic index (TI)>20 (fig 1d). TI values, as previously reported by Mologni L. et al (OncoTarget. 2015 Mar 20;6(8):5720-34), provide a view of the therapeutic impact of a mutation: the bigger the value, the more targetable is the mutation with the inhibitor.
PRELIMINARY RESULTS FROM AN OPEN-LABEL, PHASE II STUDY OF TIPIFARINIB IN RELAPSED OR REFRACTORY PERIPHERAL T-CELL LYMPHOMA

T. Witzig1, L. Sokol2, E. Jacobsen3, R. Advani4, R. Mondejar5, M. Piris6, F. Burrows7, C. Melvin7, V. Mishra7, C. Scholtz2, A. Guadarrama1

1Mayo Clinic, Rochester, 2H. Lee Moffitt Cancer Center & Research Institute, Tampa, 3Dana Farber Cancer Institute, Boston, 4Stanford University Medical Center, Stanford, United States, 5IDIVAL Instituto de Investigación Marqués de Valdecilla, Santander, 6Fundación Jiménez Díaz, Madrid, Spain, 7Kura Oncology, La Jolla, United States

Background: Tipifarnib is a potent and selective inhibitor of farnesyltransferase (FT). FT catalyzes post-translational attachment of farnesyl groups required for localization of signaling molecules to the inner cell membrane. CXCL12 is a chemokine that is essential for hematopoietic stem cell (HSC) homing to the bone marrow and lymphoid organs and for maintenance of HSCs and immune cell progenitors. CXCL12 is known to signal in part through HRAS, a signaling protein that is uniquely farnesylated. Tipifarnib has previously been shown to be well tolerated and to have a 41% response rate (7 responses out of 17 patients) in patients (pts) with T-cell Non-Hodgkin Lymphoma, including 4 objective responses in 8 pts with peripheral T-cell lymphoma (PTCL) (Witzig et al., 2011). Building on this prior experience, we report herein the preliminary efficacy, safety and biomarker data from our ongoing Phase 2 study in PTCL.

Aims: This Phase 2 study is a multi-institutional, single-arm, open-label, two-stage (11+7) study designed to determine the efficacy and safety of tipifarnib in pts with relapsed/refractory (R/R) PTCL.

Methods: Pts with R/R PTCL after prior cytotoxic systemic therapy, aged ≥ 18 years old, and with a performance status of 0-2 were eligible. Informed consent was obtained. The following subtypes of PTCL were eligible for enrollment: PTCL-NOS, ALK-positive and -negative anaplastic large cell lymphoma (ALCL), hepatosplenic T-cell lymphoma, enteropathy-associated T-cell lymphoma (EATL), extranodal natural killer (NK) T-cell lymphoma, nasal type and subcutaneous panniculitis-like T-cell lymphoma. The primary endpoint of the study is overall response rate. Secondary endpoints include safety and tolerability, duration of response (DOR) and progression free survival (PFS). Based on activity observed in the first 18 pts in the study, the protocol has been amended and enrollment is ongoing to an expansion cohort in PTCL (N=12). Enrolled pts are treated with tipifarnib 600mg administered orally twice daily on days 1-7 and 15-21 of 28-day treatment cycles until progression of disease or unacceptable toxicity. Biomarker studies included gene expression profiling of pre-treatment tumor biopsies by RNASeq and DNA next-generation sequencing (NGS). Clinical trial information: NCT02464228.

Results: At data cut-off (2/15/2017), 18 pts (2 ATL, 1 ALK-ALCL, 15 PTCL-NOS) were treated with tipifarnib. Most common treatment-related AEs (grade ≥3) were myelosuppression, including neutropenia (61%), anemia (39%) and thrombocytopenia (39%). 3 pts achieved a partial response (2 ATL; 1 PTCL-NOS) and 3 additional pts experienced stable disease >6 months. Tumor DNA from 18 pts was sequenced using NGS. A high rate of CXCL12 3'UTR single nucleotide variation (SNV) was observed. Seven of 16 pts carried the rs2839695 variant while an additional patient carried a novel variant. The presence of 3'UTR SNVs was associated with low levels of CXCL12 gene expression and disease progression (Figure) while all pts deriving clinical benefit from tipifarnib carried reference (wild-type) 3'UTR CXCL12 and had tumors that expressed high levels of mRNA for this chemokine. Testing of circulating CXCL12 levels is ongoing.

Summary/Conclusions: Although this study is ongoing, these preliminary data indicate that tipifarnib is generally well-tolerated and has antitumor activity, particularly in pts with AITL histology, absence of 3'UTR CXCL12 SNV and high levels of CXCL12 gene expression.

Figure 1.

Summary/Conclusions: ALK point mutations in patients (pts) with T-cell Non-Hodgkin Lymphoma, including 4 objective responses in 8 pts with peripheral T-cell lymphoma (PTCL) (Witzig et al., 2011). Building on this prior experience, we report herein the preliminary efficacy, safety and biomarker data from our ongoing Phase 2 study in PTCL.

Aims: This Phase 2 study is a multi-institutional, single-arm, open-label, two-stage (11+7) study designed to determine the efficacy and safety of tipifarnib in pts with relapsed/refractory (R/R) PTCL.

Methods: Pts with R/R PTCL after prior cytotoxic systemic therapy, aged ≥ 18 years old, and with a performance status of 0-2 were eligible. Informed consent was obtained. The following subtypes of PTCL were eligible for enrollment: PTCL-NOS, ALK-positive and -negative anaplastic large cell lymphoma (ALCL), hepatosplenic T-cell lymphoma, enteropathy-associated T-cell lymphoma (EATL), extranodal natural killer (NK) T-cell lymphoma, nasal type and subcutaneous panniculitis-like T-cell lymphoma. The primary endpoint of the study is overall response rate. Secondary endpoints include safety and tolerability, duration of response (DOR) and progression free survival (PFS). Based on activity observed in the first 18 pts in the study, the protocol has been amended and enrollment is ongoing to an expansion cohort in PTCL (N=12). Enrolled pts are treated with tipifarnib 600mg administered orally twice daily on days 1-7 and 15-21 of 28-day treatment cycles until progression of disease or unacceptable toxicity. Biomarker studies included gene expression profiling of pre-treatment tumor biopsies by RNASeq and DNA next-generation sequencing (NGS). Clinical trial information: NCT02464228.

Results: At data cut-off (2/15/2017), 18 pts (2 ATL, 1 ALK-ALCL, 15 PTCL-NOS) were treated with tipifarnib. Most common treatment-related AEs (grade ≥3) were myelosuppression, including neutropenia (61%), anemia (39%) and thrombocytopenia (39%). 3 pts achieved a partial response (2 ATL; 1 PTCL-NOS) and 3 additional pts experienced stable disease >6 months. Tumor DNA from 18 pts was sequenced using NGS. A high rate of CXCL12 3'UTR single nucleotide variation (SNV) was observed. Seven of 16 pts carried the rs2839695 variant while an additional patient carried a novel variant. The presence of 3'UTR SNVs was associated with low levels of CXCL12 gene expression and disease progression (Figure) while all pts deriving clinical benefit from tipifarnib carried reference (wild-type) 3'UTR CXCL12 and had tumors that expressed high levels of mRNA for this chemokine. Testing of circulating CXCL12 levels is ongoing.

Summary/Conclusions: Although this study is ongoing, these preliminary data indicate that tipifarnib is generally well-tolerated and has antitumor activity, particularly in pts with AITL histology, absence of 3'UTR CXCL12 SNV and high levels of CXCL12 gene expression.

ANALYSIS OF MICRONAOME, PROTEOME AND METABOLOME OF EXOSOMES FROM PATIENTS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA

F. Fioredda1,*, F. Pierri1, C. Micalizzi1, M. Calvillo1, E. Palmisani1, I. Ceccherini2, N. García-Barberá2, C. Martínez2, J.C. Espín3, V. Vicente1,2, I. Martínez1,2,*

Background: Paroxysmal Nocturnal Hemoglobinuria (PNH) is a clonal disease caused by the lack of glycosyl biosulfated protein anchored proteins at the cell membrane that leads to intravascular hemolysis upon complement activation. Patients have intravascular haemolysis with high risk of thrombosis, and a variable degree of bone marrow failure. Treatment with Eculizumab reduces intravascular hemolysis and also the thrombotic risk. The mechanism of thrombosis in PNH is still unknown. Exosomes are extracellular vesicles released by cells and whose secretion is closely related with the inflammatory status. Exosomes participate in cell communication by activating signaling pathways and transferring genetic material, i.e. miRNA, and proteins to host cells.

Aims: To describe the microRNAome, proteome and metabolome of exosomes from PNH patients to identify potential biomarkers of the disease and to investigate its relationship with the mechanism of thrombosis in these patients.

Methods: Plasma exosomes were isolated from 5 healthy controls and from 9 PNH patients (6 with Eculizumab, 3 with thrombosis –ET– and 3 without Eculizumab) using Total Exosome Isolation kit (ThermoFisher). miRNA expression was evaluated by plasma/serum focus miRNAs PCR panel V4 (Exiqon). Proteomic analysis of exosomes was performed at the OMIcs core facilities. Untargeted metabolomic analysis was performed by using combination of gas chromatography and liquid chromatography (LC) with mass spectrometry (MS). Additionally, latest advances were used combining LC-MS-solid phase extraction-nuclear magnetic resonance (UPLC-QTOF_SPE_NMR) on line for unequivocal structural elucidation of unknown metabolites.

Results: Mir-16-5p and mir-451a had lower levels in patients vs controls. Eculizumab treatment increased their expression, particularly in the group with thrombosis. Eculizumab also decreased mir-223-3p (the most abundant miRNA in platelets and that has been associated with its activity) and increased mir-15a-5p levels (0.5- and 3.12-fold respectively). Those proteins differentially expressed in patients and controls were related with the complement system and the immune response. We identified an increase in the plasma hemo-globin levels in patients vs controls (4.9-fold), which is related with platelet activation. It is also noteworthy the decrease (1.5-fold) of the anticoagulant Protein S in patients vs controls. When the analysis was performed among the 3 groups of patients, only Ig heavy chain V4 region HG3 increased in 3.9-fold in the Eculizumab group vs without Eculizumab group, which could be related with the treatment. We identified quite few metabolites inside the exosomes, all of them associated with cell toxicity or immune response. The levels of Cholesterol, HydroxyTerbinafine-glucuronide and Diacyl-glycerol decreased in 17.3, 17.6 and 19.4-fold, respectively in patients treated with Eculizumab. Interestingly, the Aminoethylphosphonic acid, Cholesterol and PGF2 increased 16.7-, 21- and 19.4-fold in patients with thrombosis.

Summary/Conclusions: Our study supports that exosomes contain material that may influence the pathological status of the PNH patients. In concordance, most of the proteins, miRNAs and metabolites are related with the complement system or the inflammatory response. In future experiments, some of the proteins, miRNAs and metabolites should be validated to define whether they could be considered biomarkers.

SEVERE CHRONIC NEUTROPENIA: THE ROLE OF PRIMARY IMMUNEDEFICIENCY AS CAUSATIVE AGENTS. A SINGLE CENTER DATA

F. Fioredda1,*, F. Pierri1, C. Micalizzi1, M. Calvillo1, E. Palmisani1, I. Ceccherini2, A. Grossi3, M. Lanciotti1, P. Terranova1, T. Lanza1, M. Miano1, C. Dufour1

Background: Severe Chronic Neutropenia may be a primary disease, usually defined as congenital (CN), or a condition mainly secondary to autoimmune disturbances (SN). CN rises in early infancy, has a narrow block at pro/myelocyte, classically carries genes ELANE/HAX1 mutations in 70% of cases and is G-CSF dependent. SN is accompanied by extraheamotological signs and/or positivity of autoimmune markers; bone marrow has a normal morphology or is "left shifted". In spite of these categorization many cases do not fit any group and share features of both of them. These "Overlap Neutropenia" (ON) patients are a diagnostic and management challenge.

Aims: Investigate the genetic background of this ON from a cohort of chronic neutropenia subjects screened at Haematology Unit of Gaslini Hospital and characterize their clinical phenotype.

Methods: Patients with severe chronic neutropenia were seen prospectively in our center and diagnosed/followed-up according to published guidelines(3,4). Genetic diagnosis includes classical Sanger technique for commonest severe chronic neutropenia genes and an enlarged NGS panel including also those genes responsible for PID.

Results: From 2008 to 2016, 24 patients (13 males) with median age at last follow of 18yrs (range 28 mo-51y) had a complete work up for severe chronic neutropenia (Table 1). Ten/24 subjects (43%) were diagnosed as classical CN with ELANE mutation found in the majority (80%) of cases. Seven/24 (29%) were diagnosed as SN and the remaining 7/24 (29%) as ON. A PID genes mutation was found in a total of 8/24 patients (30%) with 5 patients belonging to 7 SN subjects (71%) and 3 to the 7 ON subjects (42%). Table 1 shows clinical hematological characteristic of the 3 categories of patients.

Summary/Conclusions: A considerable portion (30%) of subjects affected with severe chronic neutropenia have been identified as PID. In the group of ON subjects a mutated PID gene was found in 3/7 patients and mutations of ELANE in 2/7 patients. No mutation was found in the remaining 2. The phenotype of ON subjects is characterized by extra-hematological autoimmune symptoms, by maturation block and by the frequent involvement of more than one hematopoietic lineage. This phenomenon may suggest to access to an enlarged genetic panel including PID genes for genetic diagnosis. An accurate immunological and genetic work may support diagnosis and management of these difficult patients.

TREATMENT WITH HORSE-DERIVED ANTI-THYMOCYTE GLOBULIN LEADS TO ENDURING HEMATOLOGICAL RESPONSES AND A 1.5-YEAR SURVIVAL PROBABILITY OF 87% IN ADULT ACQUIRED APLASTIC ANEMIA PATIENTS IN THE NETHERLANDS

J. Tjon1, L. de Wreede2, F. Falkenburg1, M. de Grooth3, H. Koene4,
Acquired aplastic anemia (AA) is a rare disease characterized by bone marrow failure that results in pancytopenia and infections and graft-versus-host disease (GVHD) and was considered a barrier to the wider application of haplo-SCT in SAA patients. We provided the kinetics for immune recovery in SAA

Background: We aim to provide the kinetics for immune reconstitution in SAA patients after they complete haplo-SCT. Our results may be useful for differentiating and assessing the impact of immune cell subset recovery on transplant outcomes. We examined immune cell subset counts and immunoglobulins in 81 SAA patients from day 30 to day 365 after haplo-SCT. The immune cells analyzed in this study including lymphocyte, monocyte, CD3+ T cell, CD8+ T cell, CD4+ T cell, CD4-CD8- T cell, CD8+CD28+ T cell, CD4+CD28- T cell, CD4+ memory T cell and CD4+ naïve T cells. Simultaneously, we determined which factors influence immune reconstitution and analyzed the effect of immune cell subsets on transplant outcomes.

Results: (i) The reconstitution of different immune cell subsets occurred at different rates after haplo-SCT. Monocytes were the first to recover, followed by CD8+ T and CD19+ B cells, and finally CD4+ T cells. Early CD4+ T cell recovery occurred at the expense of memory cells, whereas naïve CD4+ T cells rose only 9 months after SCT. (ii) In the multivariate analysis, lower recipient age, female gender, high mononuclear cell counts and CD4+ T cell counts in the graft were associated with improved immune recovery after transplant. (iii) A CD4/CD8 ratio less than 0.567 on day 30 post-transplantation was associated with lower treatment related mortality and higher overall survival after haplo-SCT in SAA patients.

Summary/Conclusions: We provided the kinetics for immune recovery in SAA patients who received haplo-SCT. In general, our study demonstrated that the recovery of monocyte and CD8+ T cells was fast in SAA patients, whereas the recovery of the CD4+ T cell subset was delayed. In addition, our data suggested that the CD4/CD8 ratio may be useful for predicting transplant outcomes in SAA patients after they complete haplo-SCT. Our results may be useful for making better predictions and modulating the IR of SAA patients, which would subsequently improve the outcomes after transplantation.

Methods: To evaluate the safety and efficacy of first line treatment using ATGAM and ciclosporin in adult patients with acquired aplastic anemia in the Netherlands.

Aims: To evaluate the kinetics for immune reconstitution in SAA patients after they complete haplo-SCT. Our results may be useful for differentiating and assessing the impact of immune cell subset recovery on transplant outcomes.

tation and past medical history—and were asked to provide their differential diagnosis and the tests they would order to establish the diagnosis in free-text format. To reduce bias, Delphi panelists were blinded to the fact that the study was focused on PNH. Responses mentioned by ≥50% of Delphi panelists in the first round were included in the second-round questionnaire. For each case in the second-round questionnaire, Delphi panelists were presented with a series of consensus statements regarding potential diagnoses and the need for specific tests/data from a multiple-choice list and asked to respond with their level of agreement on a 4-point Likert scale. Consensus in the second round was attained if ≥80% of Delphi panelists agreed on a given screening or diagnostic approach.

Results: Twelve Delphi panelists from 6 countries, all of whom were clinicians with expertise in PNH, were recruited. Consensus was reached on 22 of 23 PNH screening and diagnostic decision points identified by the Delphi panelists. Specifically, consensus was gained on the core symptoms and signs of PNH at presentation, including hemolysis, bone marrow dysfunction, and thrombosis. Consensus was reached in 36 of 38 screening and diagnostic tests required at each decision point to narrow the differential diagnosis and to confirm the diagnosis of PNH. The level of agreement on screening and diagnostic decision points and tests was sufficient to enable the development of a screening and diagnostic algorithm (Figure) that is consistent with the published literature and with the real-world experience of the international expert advisory committee.

Summary/Conclusions: The modified Delphi methodology facilitated development of a consensus-based, clinically relevant PNH screening and diagnostic algorithm. This algorithm provides clinicians with varying levels of expertise detailed guidance on how to screen for and diagnose PNH.

DIAMOND-BLACKFAN ANEMIA IN THE NETHERLANDS: AN OVERVIEW OF CLINICAL CHARACTERISTICS AND UNDERLYING MOLECULAR DEFECTS

B. Van Dooijeweert1,*, M. Bierings2, A. MacInnes3, M. Bartels4
1Pediatric Haematology, clinical research, 2Pediatric Haematology and Stem Cell Transplantation, Wilhelmina Children’s Hospital, Utrecht, 3EuroDBA, genetic, metabolic diseases, AMC, Amsterdam, 4Pediatric Haematology and Oncology, Wilhelmina Children’s Hospital, Utrecht, Netherlands

Background: Diamond-Blackfan anemia (DBA) is a rare genetic disorder, characterized by bone marrow failure (anemia), congenital anomalies and a pre-disposition for malignancies. DBA is characterized by a highly heterogeneous nature, both clinically and genetically. Most of our understanding of this disorder stems from molecular studies combined with extensive data-input from international patient registries.

Aims: The aim of our retrospective study was to create an overview of the pediatric DBA population in the Netherlands.

Methods: Forty-four patients (age 0-18y) diagnosed with DBA from all Dutch pediatric hematologists included in this study. Molecular genetic tests were collected from patient records.

Results: Congenital malformations were present in 19/41 patients (46.3%), varying from craniofacial and cardiac defects to urogenital and developmental disorders. An underlying genetic defect was identified in 23 patients (56.1%), the majority of which were found in the RPS19 gene (n=10; 45%). No significant diversities in malformations, course of disease or response to treatment were observed when comparing patients with or without identified genetic defects.

In agreement with previous reports, two patients harboring defects in RPL11 displayed a more severe phenotype, including craniofacial malformations, thumb abnormalities, and cardiac defects. In contrast, our patient with a mutation in RPL5 has no associated congenital abnormalities, while previous studies reported a very high frequency (83%) of associated congenital defects. Furthermore we observed a relatively high number (12/23) of novel mutations in well-known DBA-genes, defined as novel variants. In addition, we have identified a novel RPS19 gene defect in RPL9, in a patient with multiple congenital abnormalities (craniofacial defects, cardiac defects, colitis) in addition to severe anemia. Thirty-four (34/44) patients were treated with glucocorticoids, of which in thirty-one (31/34) patients a complete response was observed (91.2%). However, in 29% discontinuation was prompted by high-dosage-dependence, side effects, a weaning response, or a combination of these factors. Five patients (12.2%) were successfully transplanted with hematopoietic stem cells from either matched sibling donors (n=3) or matched unrelated donors (n=2), including two cases after the age of 10 years. Eleven patients (26.8%) were treatment-independent, defined as acceptable hemoglobin levels without any therapy. No malignancies were thus far reported.

Summary/Conclusions: In line with previous reports, the Dutch pediatric DBA population is both clinically and genetically heterogeneous, with RPS19 being the most frequently mutated gene. Interestingly, the majority of mutations in our cohort have not been described before, probably further underlying clinical heterogeneity. In addition, we have identified a novel RPS19 gene defect in RPL9, associated with a more severe phenotype, based on multiple associated congenital defects. While we created a comprehensive overview of the Dutch pediatric DBA population, limitations of our study include a relatively small number of patients, and the lack of complete genetic analysis (for all DBA candidate genes) in a relevant number of patients. Overall, to increase our understanding of genotype-phenotype correlation in DBA, and underlying pathophysiological mechanisms more generally, it crucial to further extend our clinical, and functional analysis of DBA-candidate genes, as well as compare, and share data from international registries.

NEXT GENERATION SEQUENCING IN BONE MARROW FAILURE SYNDROMES

E. Galvez1,2, E. Sebastian1, L. Madero1, A. Catalá2, C. Bellende2, C. Diaz de Heredia2, A. Galera3, D. Plaza3, E. Badei2, E. Vallespin3, P. Labunzina3, R. Perona3,1Hospital Infantil Niño Jesús, Madrid, 2Grupo fallos medulares SEHOP, Barcelona, 3Grupo fallos medulares SEHOP, Madrid, 4Grupo fallos medulares SEHOP, Valencia, 5CIBERER, Madrid, 6CIBERER, Barcelona, Spain

Background: Inherited bone marrow failure syndromes (IBMFSs) are a heterogeneous group of genetic disorders, with similar clinical presentations, resulting in complex diagnosis. Molecular characterization is essential in order to establish diagnosis, treatment and prognosis. Next-generation sequencing (NGS) techniques seem to be a useful platform for genetically defining different IBMFSs.

Aims: To design a NGS panel with the objective of making a specific, fast and cost-effective diagnosis for these pathologies.

Methods: We developed a NGS panel of 164 genes involved in different IBMFSs. A total of 120 samples have been processed. Patients were classified into two groups based on the clinical presentation: classified IBMFS (CBMFS) for those with a clinical picture typical of some of these disorders, and unclassified IBMFS (UBMFS) for the others. For the NGS study the NextSeq platform of Illumina (Roche) has been used. Bioinformatic analysis has been oriented to the identification of point polymorphisms (SNPs) and insertions / deletions of small DNA fragments.

Results: Of the 120 samples processed, 10% (12/120) was not suitable for analysis. A total of 108 patients were studied. In 59.3% (64/108) causal mutations were detected. From the total samples analyzed (108), 75% (81/108) were included in the CBMFS patient group, obtaining a diagnostic yield of 64.2% (52/81). The remaining 27 patients (25%) were included in the UBMFS group and we found causal mutation in 37% (10/27). Therefore, it remains a percentage of patients without a genetic diagnosis, which seems more evident in the UBMFS group. This could be explained by the fact that the causal gene has not been described or due to the limitations of the technique.

Summary/Conclusions: NGS techniques are a fast and cost-effective option for the diagnosis of IBMFSs patients. In our series, we have reached a diagnosis rate of 93.3%, coinciding with that described in the literature. Undiagnosed patients should be included in new research projects.

APLASTIC ANEMIA PATIENTS WITH MONOCYTE-DOMINANT PNH CLONES HAVE A UNIQUE PRESENTATION AND ARE LESS RESPONSIVE TO IMMUNOSUPPRESSIVE THERAPY

E. Nevill1,*, D. Sanford1, D. Foresti1, D. Hogge1, Y. Abou Mourad1, R. Broady1, M. Bennett1, M. Power1, G. Toze1, K. Song1, S. Nantel1, S. Narayanan1, A. Gerrie1, H. Sutherland1, B. Dalal2, T. Nevill1
1Leukemia/BMT Program of BC, 2Division of Hematopathology, Vancouver General Hospital, Vancouver, Canada

Background: Aplastic anemia (AA) is a bone marrow failure syndrome that can be successfully treated with either immunosuppressive therapy (IST) or autologous bone marrow transplantation (BMT). In ~50% of patients (pts) with AA, a clone deficient in glycosylphosphatidylinositol (GPI)-linked antigens—a paroxysmal nocturnal hemoglobinuria (PNH) clone—can be detected (Young, Blood, 2011). In recent years, new sensitive techniques have been developed to test for PNH clones that have primarily focused on evaluating peripheral blood white cells. Neutrophils are routinely tested for expression of GPI with fluorescent eosinyl (FLAER); monocytes may also be analyzed but are not always evaluated in PNH testing. Our centre has previously reported that 60% of PNH positive tests show a higher monocyte clone than granulocyte clone and that there was >10% difference in 20% of these discrepant results (Razavi, ISLH Proceedings, 2015). Whether pts with discordant monocyte and granulocyte PNH clones have different clinical characteristics and/or response to IST has not been reported to date.

Aims: To compare the granulocyte and monocyte PNH clones in pts with AA to determine whether there are differences in clinical presentation and/or response to IST for pts with discordant clone sizes.

Methods: A retrospective review was performed on all patients >16 treated with IST at VGH, the tertiary referral centre for the Province of BC, between 11/09 and 10/15. All patients had central pathology review and metaphase cytogenetic analysis that confirmed a diagnosis of AA. High-sensitivity flow cytometry testing with a sensitivity of 0.1% was done on all patients.
to detect the presence of a PNH clone. Granulocytes, monocytes and erythrocytes were interrogated with multi-colour flow panels including CD59 and FLAER. The criteria for determining discordant granulocyte and monocyte clone sizes was dependant upon the absolute size of the smaller clone. For clones 0.1-10%, discordance was defined as when the larger clone was either ≥2 x the smaller clone or at least 1% (absolute value) greater. For smaller clones >10%, the larger clone had to be ≥110% its size. IST was uniform - Cyclosporine (CSA, 2.5mg/kg p.o. b.i.d.), anti-thymocyte globulin (ATG; ATGAM® 40mg/kg IV daily x 4 days) and (Methyl)prednisolone 1mg/kg/dx 10 days). CSA doses were adjusted to maintain whole blood trough CSA level of 200-300 μg/L for 12-months followed by slow taper based upon hematologic response. Non-responders at 6 months were eligible to proceed to either a second cycle of ATG or BMT, if a suitable donor was available. Severity of AA [very severe (VSA), severe (SA) or non-severe (NSA)] and response to IST ([none, partial (PR) or complete (CR)]) were determined according to published criteria (Marsh, Br J Haematol, 2009). Statistical comparisons were done using a standard Chi square analysis.

Results: 30 pts with AA and a PNH clone were identified, 18 females and 12 males with median age of 50.5 years (range 17-71). There were 14 pts with NSA, 13 with SAA and 3 with VSA. Responses were seen in 20/30 pts (66.7%) including 13 PR and 7 CR. Six pts relapsed with CSA tapering and 5 responded to intensified IST. 2 pts required Eculizumab after evolving to a classic PNH phenotype. Six pts underwent BMT for primary non-response and 4 pts have died (2 post-BMT, 1 from complications of AA and 1 from breast Ca); 26 pts remain alive and well with a median follow-up of 48 mos (15-86). There were 17 pts (56%) with concordant granulocyte and monocyte clone sizes (Group 1), 4 pts (13%) had granulocyte-dominant disease (Group 2) and 9 pts (30%) had monocyte-dominant disease (Group 3). Group 3 pts were significantly more likely to have NSA and showed a trend toward an inferior response rate to IST (Table 1).

Summary/Conclusions: Flow cytometry for a PNH clone is routinely done in AA although it may be important to evaluate both granulocyte and monocyte clone sizes. Pts with a larger monocyte than granulocyte clone size more frequently have NSA and appear to have a lower response rate to IST. This may have therapeutic implications and could identify a population of pts requiring a unique therapeutic approach.

P582
RESPONSE TO ANTI-THYMOCYTE GLOBULIN (ATG) IN PATIENTS WITH APLASTIC ANEMIA (AA): A SINGLE-CENTRE EXPERIENCE OVER THE LAST 29 YEARS
M. Oelmüller1, F. Alashkar1, D. Herich-Terhürne1, U. Dührsen1, A. Röth1
1Department of Hematology, University Hospital Essen, Essen, Germany

Background: Aplastic anemia (AA) is a rare, usually acquired disorder characterized by bone marrow failure with bi- or pancytopenia and marrow hypoplasia. The classification into the three main subtypes is of prognostic and therapeutic relevance. Depending on disease severity, patient's age, and the availability of a potential HLA-identical donor, different therapeutic strategies are favored. Immunosuppressive therapy (IST) with anti-thymocyte globulin (ATG) and cyclosporine (CsA) is considered as the mainstay of IST. A hematologic recovery is seen in up to 60-70% of the pts following horse-ATG (hATG) treatment, compared to 35-53% in rabbit-ATG (rATG) treated pts, considering hATG as first-line therapy in AA pts.

Aims: As response rates vary according to the different studies and the source of ATG being used, our aim was to retrospectively evaluate response rates in pts with AA receiving IST at the Department of Hematology at the University Hospital of Essen between 1988 until 2015.

Methods: In this single-center, retrospective analysis, approved by the institutional review board of the University Hospital Essen, 33 pts were included. When treated or monitored at the Department of Hematology between 1988 until 2015. 73% of the pts (49/67) were treated with hATG (ATGAM® (44/49) vs >50 yrs: 43% (13/30); p<0.001). In primary refractory pts (34% (23/67)) (52% (12/23) in first-line treated hATG pts vs 48% (11/23) rATG treated pts) a second course with either hATG (3/9) or rATG (6/9) was initiated, achieving an overall hematologic recovery at 6 months in 3 pts (33% (1/3) hATG vs 33% (2/6) rATG treated pts). A disease relapse (median: 13 months after primary ATG therapy) was seen in 11 out of the 44 pts with primary hematologic recovery (25%) (82% (9/11) in first-line treated hATG pts vs two rATG treated pts). A salvage therapy with rATG was initiated in two pts, whereas in one other pt a second course with hATG was started. An overall response following relapse therapy was observed in 33% of the pts (1/3). Four refractory as well as relapsed pts were treated with eltrombopag respectively (final results are still awaited). A secondary HSCT (hematopoietic stem cell transplantation) was performed in 11 out of the 67 pts (16%), either being primary refractory or due to a disease relapse.

Summary/Conclusions: Our data are able to independently confirm the findings of previous studies concerning hematologic recovery rates in pts with acquired AA following IST with ATG by providing further evidence that rATG plus CsA is inferior to hATG plus CsA when administered as a first-line treatment. In addition, we were able to observe in pts ≤50 yrs, irrespective gender, an overall higher hematologic recovery. For this reason, it remains unclear why ATGAM® is still not approved in Germany as first-line therapy in pts with AA, as the only hATG product registered in Europe (Lymphoglobulin®) was withdrawn from the market in 2007.

NOTCH1 MUTATED CHRONIC LYMPHOCYTIC LEUKEMIA CELLS ARE CHARACTERIZED BY A MYC-RELATED OVEREXPRESSION OF NUCLEOPHOSMIN-1 AND RIBOSOME ASSOCIATED COMPONENTS
F. Pozzo1,1*, T. Bitto1, E. Vendramini1, R. Bomben2, P. Builian3, F.M. Rossi4, A. Zucchetto5, E. Tissino5, M. Degani5, G. D’Arena6, F. Di Raimondo6, F. Zaija6, G. Pozzato7, D. Rossi8, G. Gaidano8, G. Del Poeta9, V. Gattel1, M. Dal Bo1
1Clinical and experimental Onco-hematology unit, Centro di Riferimento Oncologico, Aviano, 2Onco-Hematology Department, Centro di Riferimento Oncologico–Department of Translational Medicine, University of Eastern Piedmont, Novara, 3Division of Hematology–Department of Translational Medicine, University of Eastern Piedmont, Novara, 4Division of Hematology, S.Eugenio Hospital and University of Tor Vergata, Rome, Italy

Background: Stabilizing mutations of NOTCH1 have been identified in about 10% of chronic lymphocytic leukemia (CLL) cases at diagnosis, with a higher frequency in unmutated IGHV-UM (IGHV-UM)-immunocompromised or advanced disease phase CLL, and have been associated with particularly unfavourable prognosis (Rossi et al, Blood, 2012; Del Poeta et al, Br J Haematol, 2013; Stilgenbauer et al, Blood, 2014). In CLL, all NOTCH1-mut cases were previously found higher in NOTCH1-wt cases in the IGHV UM subgroup. ii) Western blotting in 11 CLL cases (5 NOTCH1-mut) confirmed a higher NPM1 protein expression in NOTCH1-mut cases, with a direct correlation with NOTCH1 expression (r=0.814). In NOTCH1-mut cases, the NPM1high subpopulation, isolated by cell sorting, showed a higher NOTCH1 mutational load than the NPM1low subpopulation. iii) EDTA treatment of 12 CLL cases (6 NOTCH1-mut) activated NOTCH1 signaling (Rand et al, Mol Cell Biol, 2010), as from HES1 and DTX1 induction, and upregulated NPM1 and other RNPs. The same results were confirmed by co-culture of CLL cells with the JAGGED1-expressing M2-10B4 stromal cells. Inhibition of NOTCH1 signaling by gamma-secretase-inhibitor L-685,458 or by siRNA for NOTCH1 reduced NPM1 expression (Fig. A). iv) Previous studies identified MYC as a direct transcriptional target of NOTCH1 (Browne et al, PNAS 2014) and, in turn, a transcriptional activator of both NPM1 and RNPs. ChIP assays on MEC1-cells, transfected with exogenous NICD, revealed increased NICD binding to the MYC promoter, along with higher expression of MYC, NPM1, and RNPs. Of note, after 48 h culture, NOTCH1-mut CLL cases showed increased MYC transcript levels than NOTCH1-wt cases. MYC expression was further increased upon NOTCH1 activation by EDTA or by stromal cells co-cultures (Fig. B). MYC silencing by siRNA efficiently reduced NPM1 transcript and protein expression. Moreover, Cpg-ODN-2 treatment, to induce MYC overexpression, also increased NPM1 transcript and protein levels in CLL cells. v) NPM1 silencing by siRNA was able to reduce proliferation rates and cell size of both NICO-transfected cells and control cells. In keeping with a NOTCH1-driven regulation of cell growth/protein biosynthesis, activation of NOTCH1 signaling in 12 CLL cases (6 NOTCH1-mut) by EDTA or stromal cells co-culture, induced an increase in cell size.

Summary/Conclusions: NOTCH1 mutations in CLL are associated with the overexpression of MYC and MYC-related genes involved in protein biosynthesis including NPM1, which are allegedly responsible for cell growth and/or proliferation advantages of NOTCH1-mut CLL.

P584
CLL-LIKE B-CELL CLONES FROM MBLLO INDIVIDUALS PERSIST AT INCREASED COUNTS AFTER SEVEN YEARS OF FOLLOW-UP
I. Criado1,*, A. Rodríguez-Caballero1, L. Gutierrez1, C.E. Pedreira1, W.G. Nieto1, C. Teodosio1, V. Herraez 1, A. Romero-Furones 2, P. Fernández-Navarro 3, J. Almeida1, A. Orfao1
1Department of Medicine, Center for Cancer Research, 2Centro de Atención primaria de Salud Miguel Arrigo, 3Centro de Atención Primaria de Salud de Ledesma, Salamanca, Spain

Background: The presence of very low numbers of clonal B cells in peripheral blood (PB) of otherwise healthy individuals (low-count monoclonal B lymphocytosis-MBLlo) is a common finding in the general population. The majority of clonal B cells from MBLlo subjects show a phenotype overlapping with CLL (chronic lymphocytic leukemia) cells, the former might represent either the normal counterpart of CLL or the earliest stages of the disease. Little information exists about both the clinical outcome of MBLlo subjects and the biological features of their B-cell clones over time.

Aims: To gain insight into the biological and clinical significance of the presence of CLL-like MBLlo clones, we re-evaluated the biological features of clonal B cells and the clinical outcome of MBLlo individuals after 7 years of follow-up.

Methods: The baseline study was conducted in 2008, when 80 out of 639 (12.5%) healthy individuals (>40y) were found to carry at least 1 MBLlo clone. A GEP of these clonal B-cell population, using high-sensitive flow cytometry. A subset of them (n=49) has been followed for a median period of 84 months (range: 67-95 months). Besides physical examination and flow cytometry analyses, the most frequent CLL-related cytogenetic alterations [del(13q14.3(D13S25)), trisomy 12, del11q(ATM) and del17q(TP53)] were studied at baseline and at follow-up.

Results: A total of 64 CLL-like MBLlo clones (median size: 0.44 cells/ul, range: 0.027-66 cells/ul) were detected in PB of the 49 subjects at recruitment (in 15 cases ≥2 B-cell clones were detected in the same subject). In all subjects, B-cell clones persisted at reevaluation, phenotypically identical vs baseline. Interestingly, we found a near 6-fold overgrowth of CLL-like MBLlo clones after 7 years follow-up vs baseline (median size: 1.22 cells/ul, range: 0.046–789 cells/ul; p<0.001); in line with this, most clones (45/64; 70%) increased their size, while the remaining 30% maintained stable or slightly decreased numbers compared to time 0. From the genetic point of view, only 8/32 (25%) clones showed a subclone carrying one of the most common aberrations (del(13q), del11q, del17q) at baseline. Three clones (8%) harbored a near 6-fold overgrowth after 7 years. The same results were being present in 7/8 cases and trisomy 12 in the remaining one. Strikingly, re-evaluation after 7 years showed 36/56 clones (64%; p<0.01 vs baseline) with cytogenetic alterations; again, the most common abnormality was del13q(D13S25) (34/36) followed by trisomy 12 (36) and del17p(TP53) (13/36). The statistical analysis (p<0.05) was found between 0.05 and 0.10 in the over-time in the size of these clones and the presence of cytogenetic lesions. Three subjects developed lymphomacytosis (median: 5.3x109lymphocytes/l; range: 4.1x109-5.9x109/l) after 7 years; in these cases the clone size increased sub-
Summary/Conclusions: Our results suggest that CLL-like MBLlo is not a transient condition, as all clones detected at recruitment were systematically present also at follow-up with an increase in frequency of cytogenetic lesions. Despite, B-cell clones slightly increased in size of the majority of MBLlo when compared to MBLhi/CLL. More recent studies however revealed an important role of LADs in the regulation of gene expression and recombination. Aims: Given the apparent topological coincidence between LADs and Ig variable clusters, we hypothesised that nuclear lamina might play a paramount role in the dynamics of Ig-encoding variable genome domains. In particular, here we tested whether Lamin B1, a principal LAD-associated component of the nuclear envelope, had any restrictive role on somatic hypermutation (SHM) and the expression of Ig genes. Due to the strong involvement of IgV mutations in the pathogenesis of B-cell malignancies, we also tested whether nuclear lamina is involved in the pathogenesis of germinal centre lymphomas and chronic lymphocytic leukaemia (CLL).

Methods: We used BL2 and naïve B cells as in vitro and ex vivo models for somatic hypermutation. ChIP-Seq, ChIP-PCR and ImageStream analyses were performed to establish Lamin B1 genome and nuclear binding dynamics in somatic hypermutation. ChIP-Seq, ChIP-PCR and ImageStream analyses were performed to establish Lamin B1 genome and nuclear binding dynamics in somatic hypermutation. ChIP-Seq, ChIP-PCR and ImageStream analyses were performed to establish Lamin B1 genome and nuclear binding dynamics in somatic hypermutation. ChIP-Seq, ChIP-PCR and ImageStream analyses were performed to establish Lamin B1 genome and nuclear binding dynamics in somatic hypermutation. ChIP-Seq, ChIP-PCR and ImageStream analyses were performed to establish Lamin B1 genome and nuclear binding dynamics in somatic hypermutation. ChIP-Seq, ChIP-PCR and ImageStream analyses were performed to establish Lamin B1 genome and nuclear binding dynamics in somatic hypermutation.

Results: We have found that genome binding of Lamin B1, a component of the nuclear envelope involved in epigenetic chromatin regulation, is reduced during B cell activation and formation of lymphoid germinal centres. ChIP-Seq analyses revealed a more frequent and heavy variable immunoglobulin domains were released from the Lamin B1 suppressive environment when SHM was induced in B cells. RNAi-mediated reduction of Lamin B1 resulted in spontaneous SHM as well as kappa-light chain aberrant surface expression. Finally, Lamin B1 expression level correlated with progression-free and overall survival in chronic lymphocytic leukemia, and was strongly involved in transformation of follicular lymphoma.

Summary/Conclusions: In summary, here we report that Lamin B1 is a negative epigenetic regulator of SHM in normal B-cells and a "mutational gatekeeper", suppressing the aberrant mutations that drive lymphoid malignancy.
Background: B cell receptor (BCR) mediated signalling is crucial for the pathogenesis of chronic lymphocytic leukemia (CLL). Drugs such as ibrutinib and idelalisib which inhibit BCR associated kinases have proved effective for the treatment of CLL but only suppress the disease without being curative. Some patients have developed resistance to these drugs following mutations, progress on therapy for unknown reasons, or cannot tolerate these drugs due to adverse events. We have shown that microenvironmental signals (e.g., IL-4) can increase BCR expression and signalling, and can partially reverse the effects of BCR-kinase inhibition. GAB1, PTPN22 and FOXP1 can positively regulate BCR signalling in CLL but the effect of IL-4 on these proteins has not previously been investigated. Here we show that IL-4 promotes BCR signalling and can allow the development of novel drugs that overcome resistance to kinase inhibitors. Cerdulatinib (cerd) is an inhibitor of both Syk (pivotal to BCR signalling) and JAK1/3 (integral for IL-4 signalling). Inhibition of Syk has been shown to induce apoptosis of CLL samples resistant to ibrutinib. Cerd is currently in phase II clinical trials in patients with relapsed/refractory B cell malignancies including CLL.

Aims: To investigate the effect of IL-4 on the regulation of BCR signalling in CLL and how this is modified by cerdulatinib.

Methods: Eighteen primary CLL samples were treated with IL-4 +/-cerd (1μM) and expression of FOXP1, GAB1, PTPN22, SOCS1 and SOCS3 assessed by immunoblotting. The effect of cerd on apoptosis was assessed by flow cytometry and PI/Annexin V staining.

Results: Primary human CLL cells treated with IL-4 for 24hr significantly increased expression of positive regulators of BCR signalling FOXP1 and GAB1 in CLL samples with un-mutated IGHV (U-CLL); no change in expression in FOXP1 or GAB1 was seen in CLL samples with mutated IGHV (M-CLL). There was a 40% increase in PTPN22 expression in IL-4-treated U-CLL samples vs no change in M-CLL. Cerd, at therapeutic concentrations, blocked IL-4 mediated increases in FOXP1, GAB1 and PTPN22 and pSTAT6 (a positive control for IL-4 signalling). After 24hr IL-4 selectively increased expression of the negative regulators of IL-4 signalling, SOCS1 and SOCS3 in U-CLL, but not M-CLL cases, and this could be blocked by cerd. Cerd potently inhibited the expression of other cytokines known to play a role in CLL biology (IL-6, IL-10, IL-15, IL-21 and IFNγ) which utilise either JAK1 or JAK3 for activation of STAT proteins. IL-4, CD40L and BCR ligation signals to CLL cells in lymph nodes can promote resistance to therapies such as the BCL2-inhibitor venetoclax. We have shown that cerd can overcome IL-4/CD40L induced expression of pro-survival proteins MCL1 and BCLXL and that cerd in combination with veneto-clax induced apoptosis in a synergistic manner in the presence of IL-4/CD40L. We now extend these results to assess the importance of this drug combination in the presence of BCR stimulation. The combination of cerd and venetclox in the presence of either BCR signalling (bead immobilised anti-IgM) alone, or combined with IL-4 and CD40L, induced synergistic killing, with greater CLL cell death than with either drug alone.

Summary/Conclusions: These results provide evidence that IL-4 may increase BCR signalling by upregulating the expression of positive regulators of BCR signalling in U-CLL and that this can be overcome by cerd. These results support the continued use of cerd in clinical trials for the treatment of CLL, alone or in possible combination with venetoclax.

Background: Ibrutinib is an oral Bruton tyrosine kinase (BTK) inhibitor which has advanced the clinical management of CLL. Ibrutinib binds irreversibly to the cysteine 481 residue of the BTK protein, rendering it inactive. Btk inhibition affects the phosphorylation of other intracellular kinases resulting in an immediate redistribution of CLL cells and subsequent apoptosis. We investigated the impact of ibrutinib on the phosphorylation of upstream and downstream kinases in the B-cell receptor pathway in real time in the IcICLLe study (ISRCTN12695342).

Aims: The IcICLLe trial was a single arm, multi-centre feasibility study of ibrutinib in two cohorts of CLL patients: (A) 20 treatment-naive (TN) requiring treatment (according to IWCLL criteria); and (B) 20 relapsed/refractory (RR). All patients received continuous oral therapy with ibrutinib (420mg once daily) from registration until disease progression. The primary endpoint of the trial was the proportion of patients achieving minimal residual disease (MRD) negative remission (depletion of CLL ≤0.01% in peripheral blood (PB) & bone marrow (BM)) within 6 months of trial treatment. Exploratory endpoints included the assessment of phosphorylation of intracellular kinases in the B-cell receptor pathway.

Methods: A panel of markers was assessed on PB & BM taken at screening, 1 & 6 months. PB was also taken at baseline (0 hours), 4 & 24 hours, 7 & 14 days, and 2, 8 & 12 months. The phosphorylation of Syk Y348, Btk Y551, ERK1/2, Akt S473 was assessed in 4 conditions at each time point: unstimulated, Syk inhibitor (5μM) or Btk inhibitor (10μM), or in combination. Baseline stimulation of ERK1/2 gave a 1.5-2 fold increase in phosphorylation after 6 months of therapy although the degree of phosphorylation decreased at later time points. Syk, Akt and ERK1/2 phosphorylation was unaffected by the addition of ibrutinib in vitro. The pattern of phosphorylation was found to be relatively consistent in responding patients. One patient with progressive CLL had sustained phosphorylation in all markers despite ibrutinib therapy.

Results: The phosphorylation of Btk, Syk, Akt and ERK1/2 was analysed in cells at the specified time points and conditions for 20 TN and 20 RR CLL patients. Baseline phosphorylation of all kinases was similar in both PB & BM. Phospho-Btk showed no stimulation on addition of IgM/IgD 4h after initiating therapy. There was a strong (2-4 fold) increase in phosphorylation of Syk kinase with IgM/IgD even in the presence of ibrutinib in vitro. This effect was profound in the first 2 months of ibrutinib therapy with a general decrease in phosphorylation after 6 months. Baseline stimulation of ERK1/2 gave a 1.5-2 fold increase in phosphorylation but the effect was abrogated within 1 month of ibrutinib therapy. Akt S473 phosphorylation was maintained after 6-12 months of therapy although the degree of phosphorylation decreased at later time points. Syk, Akt and ERK1/2 phosphorylation was unaffected by the addition of ibrutinib in vitro. The pattern of phosphorylation was found to be relatively consistent in responding patients. One patient with progressive CLL had sustained phosphorylation in all markers despite ibrutinib therapy.

Summary/Conclusions: The effect of ibrutinib on the phosphorylation of various kinases in the B-cell receptor pathway was analysed in real time. Syk continued to be phosphorylated over the course of treatment, which is logical as this kinase is upstream of Btk. That the degree of phosphorylation declined over time (even with stimulation) suggests a general inhibitory effect of ibrutinib on CLL cells. ERK1/2 phosphorylation is effectively blocked and there is partial reduction of phosphorylation of Akt S473. Combinations of Btk inhibitor with a Syk or PI3 kinase inhibitor may result in complete BCR blockade. Phosphorylation patterns may also act as an adjunct to ascertain the response to therapy.

EVALUATION OF COMBINATIONAL THERAPIES FOR RELAPSED/REFRACTORY CLL WITH MUTATED P53

S. Post(1), H. J. Lee(2), M. Malard(3), X. Zhang(4), M. Hombaker(1)

1Leukemia, 2Lymphoma, MD Anderson, Houston, United States, 3CNIO, Madrid, Spain

Background: Chronic lymphocytic leukemia (CLL) is a heterogeneous disease with survival ranging from months to decades. CLL patients harboring TP53 alterations are well known to be refractory to standard therapies; however, recent studies indicate that ibrutinib, a Bruton’s tyrosine kinase (BTK) inhibitor, suppresses the B-cell receptor (BCR) signaling pathway and is an effective treatment option for these patients. Unfortunately, many patients with TP53 alterations will ultimately fail ibrutinib-based therapies. Similarly, we have used a mouse model of refractory p53 mutant CLL (Eμ-TCL1;p53R172H) and reported that while ibrutinib is effective in reducing the CD5+CD19+ population and extending survival, these mice eventually succumb to the disease (Lee HJ, BCJ 2016). These incomplete therapeutic responses indicate that ibrutinib provides only a temporary respite for this refractory disease, and highlights our need to develop more potent and targeted combinations.

Aims: Ibrutinib is effective in delaying (but not eliminating) leukemic progression in p53 mutant CLL, suggesting that combinational therapies that inhibit BCR signaling and activate apoptotic programs may be effective therapeutic strategies. Thus, agents that do not require activation of p53 but are effective in blocking oncogenic pathways (BTK and BCL-2) are attractive options. Currently, ibrutinib and ABT-199 meet this criteria and thus, we hypothesize that simultaneous inhibition of the BTK- and BCL-2-pathways will be an effective strategy in treating p53 mutated CLL.

Methods: To test this, we used RNA-Seq to examine expression changes in B-cells from Eμ-TCL1 mice carrying either wild type or a single p53R172H hotspot mutation (corresponding to p53R172H in humans) following ibrutinib treatment. qRT-PCR and IHC were used to validate expression of key targets within pathways amenable to combinational therapy. Hematopoietic tissues were subjected to combinational therapies to interrogate efficacy.

Results: We have shown that ibrutinib downregulates the BTK- and ERK-pathways regardless of p53 status. However, less is known in regards to global expression changes in p53 mutant CLL following BTK inhibition. To investigate this, we performed RNA-Seq analyses using malignant B-cells from untreated and ibrutinib treated Eμ-TCL1;p53R172H and Eμ-TCL1 mice. Pathway analyses revealed that CLL cells harboring a single p53 mutant allele retained a partial ability to activate p53-dependent programs. qRT-PCR revealed robust activation of p53-dependent anti-proliferative targets like p21, but only modest activation of pro-apoptotic targets (e.g.; PUMA), suggesting these p53 mutant CLL cells retain diminished capacity to activate apoptosis or overcome apoptotic inhibitors. To explore this altered bi-modal p53 activation, we performed IHC and observed that apoptotic activation was hampered by increased BCL-2 expression. To examine whether this BCL-2-dependent inhibition could be overcome, malignant B-cells were treated with ibrutinib alone, ABT-199 (a BCL-2 inhibitor) alone, or in combination. Here, we confirmed that ABT-199 was sufficient to activate apoptosis, regardless of p53 status, and that its use in combination with ibrutinib drastically reduced cell viability.

Summary/Conclusions: Together, these data indicate that patients with a partially attenuated p53 pathway may retain the ability to activate apoptosis if molecular barriers are removed (e.g.; BCL-2 via ABT-199). Furthermore, these results suggest that combinations with BTK- and BCL-2 inhibitors may be therapeutically beneficial for patients with mutated TP53.
Background: Chronic myeloid leukemia (CML) is a myeloproliferative disease which arises in a haemopoietic stem or multipotent progenitor cell with the t(9;22)(q34;q11) chromosomal translocation. Tyrosine kinase inhibitors (TKIs) which arise in a haemopoietic stem or multipotent progenitor cell with the t(9;22)(q34;q11) chromosomal translocation. Tyrosine kinase inhibitors (TKIs) are effective for the treatment of CML, and the outcome of patients who fail the treatment due to primary or acquired resistance is still uncertain. Our findings indicate that TKIs, being an indispensable role in CML maintenance, while normal hematopoietic stem/progenitors were not affected by STAP-1 deficiency. Although a majority of patients have a durable response to BCR-ABL tyrosine kinase inhibitors, the outcome of patients who fail the treatment due to primary or acquired resistance is still uncertain. Our findings in mice and human suggest that STAP-1 could be a novel target for CML. Further analysis will be needed to clarify the molecular mechanisms by which STAP-1 regulates the progression of CML and maintains survival of LSCs.

Methods: We generated STAP-1 deficient mice of the C57Bl/6J genetic background. For establishment of CML mouse model, we infected Lineage (Lin)- Sca-1+ c-kit+ (LSK) fractions of bone marrow (BM) cells from STAP-1+/+ and STAP-1−/− mice, infected them with retrovirus carrying MSCV-BCR-ABL-ires-GFP, and transplanted into congenic recipients, that were named Wild type (WT) and STAP-1−/− CML mice, respectively. Human BM samples were collected after informed consent, using protocols approved by the Investigational Review Board of Osaka University Hospital.

Results: Using Western blot and immunoprecipitation assay, we confirmed that STAP-1 binds to BCR-ABL. LSCs from STAP-1−/− mice showed significantly longer survival than WT CML mice (Fig. 1). STAP-1−/− CML mice displayed less splenomegaly and lung hemorrhages compared to WT, suggesting that loss of STAP-1 attenuates CML progression. To investigate how STAP-1 regulates CML progression, we evaluated leukemic stem cells (LSCs) in CML mice. The absolute numbers of STAP-1−/− LSCs (GFP+ LSK) in BM and spleen were significantly lower than those of control (WT vs STAP-1−/−: 2000 ± 694.07 cells vs 412.57 ± 114.07 cells in BM, p=0.0291; 12.9 ± 1.75 x104 cells vs 4.09 ± 0.72 x104 cells in Spleen, p=0.0009). In colony-forming assay in vitro, STAP-1−/− LSCs generated less colonies in the first and second plating compared to WT LSCs. These data indicated that deletion of STAP-1 would impair self-renewal capacity of LSCs. When we transplanted STAP-1−/− or STAP-1+/− mice without BCR-ABL transduction in the presence of competing BM cells, deletion of STAP-1 had no effects on engraftment at 28 days after transplantation. Furthermore, we measured the expression of STAP-1 in BM cells derived from patients in the chronic phase of CML. As a result, STAP-1 mRNA was abundant in the LSC (CD34+ CD38−) compartment.

Summary/Conclusions: In this study, we utilized CML mouse model and showed that STAP-1 is required for progression of CML. Our findings indicate that STAP-1 has an indispensable role in LSC maintenance, while normal hematopoietic stem/progenitors were not affected by STAP-1 deficiency. Although a majority of patients have a durable response to BCR-ABL tyrosine kinase inhibitors, the outcome of patients who fail the treatment due to primary or acquired resistance is still uncertain. Our findings in mice and human suggest that STAP-1 could be a novel target for CML. Further analysis will be needed to clarify the molecular mechanisms by which STAP-1 regulates the progression of CML and maintains survival of LSCs.
cell division and telomere length (TL) in peripheral blood cells has been shown to correlate with disease stage, response to treatment and duration of CP in CML patients. However, the use of TL as a routine clinical biomarker in CML has been complicated by considerable inter-individual, mostly genetic variability in TL ideally requiring non-clonal control cells.

**Aims:** Based on these considerations, we used a modified Q-FISH technique in a recently developed study to investigate if BCR-ABL+ LSC or BCR-ABL- control cells within the CD34+38- hematopoietic stem cell compartment of diagnostic patients with CML in CP.

**Methods:** 15 patients (median age: 59 years; range: 41-72 years) diagnosed with CML in CP of the NCT00852566 study (Nordic CML Study Group) were retrospectively analyzed. Patients treated with TKI were available for 14 patients. Of those, 2 (14%) belonged to the Sokol high risk group, 5 (36%) to intermediate and 7 (50%) to the low risk group. CD34+38- cells sorted from bone marrow samples were tested with the standard FISH method using dual fusion dual colour BCR-ABL FISH staining following standard procedures. After capturing the BCR-ABL staining using confocal microscopy, samples were re-processed for TL analysis by Q-FISH using established protocols. TL staining was analyzed in all previously captured cells allowing the identification of BCR-ABL+/−cells within the same sample. Analysis and quantification of BCR-ABL FISH staining and TL measurement by Q-FISH were performed in blinded fashion.

**Results:** Overall, we observed significantly shortened TL in the BCR-ABL+ compared to BCR-ABL- cells (4.9 arbitrary units (a.u.) range: 53.7-16.9 a.u., p=0.04). Next, we correlated the clone size (i.e. the proportion of BCR-ABL+ positive cells within the CD34+38- compartment) with the degree of telomere shortening in LSC. Mean clone size of the patients was 59.9 ± 32.0 % S.D. Of note, we found a significant negative correlation (R²=0.36, p=0.02) between TL and clone size strongly supporting the notion that increased expansion of the BCR-ABL+ LSC pool leads to accelerated telomere shortening. Corroborating this trend, a statistical data analysis (R²=0.07) of Sokol (R²=0.04, p=0.38) score did not reveal any statistically significant correlation with the degree of telomere shortening probably due to the small sample size analyzed in this pilot study.

**Summary/Conclusions:** In this study, we provide further evidence for accelerated telomere shortening in BCR-ABL+ LSC as compared to their normal CD34+CD38- counterpart in CP CML samples at diagnosis. Interestingly, the degree of TL shortening linearly correlates with the clone size of the BCR-ABL+ LSC compartment. Thus, this retrospective study (now on the LSC level) further supports a role of TL as a prognostic and predictive biomarker in newly diagnosed patients with CML pending confirmation in prospective trials.

**GENOMIC CHARACTERIZATION OF CML AT DIAGNOSIS REVEALS PREEXISTING SOMATIC MUTATIONS THAT MAY PREDICT PROGRESSION TO BLASTIC PHASE INDEPENDIENTLY OF BCR-ABL1 MUTATIONS**

1Department of Immunology, 2Postgraduate School of Molecular Medicine, Medical University of Warsaw, 3Department of Diagnostic Hematology, Institute of Hematology and Transfusion Medicine, Warsaw, 4Department of Hematology, The University Hospital, Cracow, 5Department of Hematology, Institute of Hematology and Transfusion Medicine, Warsaw, 6Department of Hematology, Military Institute of Medicine, 7Department of Hematology, Oncology and Internal Diseases, Medical University of Warsaw, 8Department of Pathology and Laboratory Diagnostics, Maria Sklodowska-Curie Memorial Cancer Center and Institute, 9Department of Medical Genetics, Medical University of Gdansk, 10Department of Laboratory Diagnostics, Institute of Medical Genetics, Medical University of Gdansk, 11Department of Immunology, and Hematology, Fels Institute for Cancer Research and Molecular Biology, Temple University School of Medicine, Philadelphia, United States

**Background:** Blastic phase of chronic myeloid leukemia (BP-CML) remains mostly incurable even with newer generation tyrosine kinase inhibitors (TKI) and represents an unmet clinical need. Although in recent years a dramatic reduction in the transformation of chronic phase (CP-CML) to BP-CML has been observed, still up to 5% of patients will progress to BP-CML despite treatment with TKI. Prospective identification of such patients may have a significant clinical impact. There are only few reports to date which use next-generation sequencing (NGS) to look for somatic mutations - other than those affecting kinase domain of BCR/ABL 1 - at the time of diagnosis (Dx) which could have a prognostic/predictive value.

**Aims/Methods:** We analyzed the mutational spectrum of somatic mutations in two groups of CML patients with clinically different disease course: first group (BP) comprised of 11 patients who progressed to BP-CML despite treatment with TKI and/or allo-HSCT (one patient) and died (paired samples from DX and BP were analyzed); second group (MMR) included DX samples from 36 patients who achieved molecular response, did not reach MR4.5 and TKI within 6 months and remained in MMR for at least 48 months from DX.

**Methods:** Targeted enrichment strategy using custom designed capture probes (SeqCap EZ, Roche NimbleGen) followed by NGS on Illumina platform was employed. More than 1200 genes implicated in human cancer were included. Common variants (>1%) gathered in large genomic databases and our internal database were filtered out and the subsequent analysis was focused on putative protein damaging variants, supported by variant effect prediction tools such as PolyPhen-2, SIFT or CHASM. All reported variants were reconfirmed by Sanger sequencing.

**Results:** The BP group comprised of paired samples from 11 CML patients who progressed to BP and died despite treatment with TKI. Median age at diagnosis was 53y (range 26-77), median time to progression for 9 patients (2 were diagnosed in accelerated phase or BP) was 17,5 months (mo) (range 4-108) and median survival was 22 mo (range 10-116). None of those patients harbored BCR/ABL1 mutation at the time of Dx and progression to BP-CML 4 patients had additional chromosomal alterations at progression to BP including two frequent (trisomy 8 and monosomy 7). Targeted enrichment followed by NGS allowed us to achieve deep coverage (>80% ge50). Median number of rare variants was 26 (range 18-38) and 29 (range 23-32) for Dx and progression samples, respectively. In BP-CML samples we detected new and previously described mutations in selected genes, which are frequently mutated in myeloid malignancies, namely in RUNX1 (36%, 4/11), DNMT3A (27%/311) IDH1/IDH2 (18%, 2/11) and ASXL1 (18%, 2/11). In BP patients (54%, 6/11) mutations in these genes (excluding IDH2, detected only in BP sample) were preexisting at the time of Dx. These results were compared to second, control group that comprised of diagnostic samples from 36 patients (median age at diagnosis 53y, range 23-75) who were optimal responders to TKI and remained in MMR for at least 48mo (median time in MMR: 73mo; range 48-128). In MMR group, the median number of rare variants was lower than in BP patients (26 vs. 36, 5%) frameshift mutation in ASXL1 (p.Gly643_Gly644fs) was detected, identical as in one of BP patients. Additionally, one patient harbored RUNX1 mutation (p. Arg201Cln) which was not detected in the BP group.

**Summary/Conclusions:** Our results provide new insights into the already complex genomic landscape of BP-CML. We suggest that a significant number of patients with poor disease outcome may harbor preexisting mutations in DNMT3A, RUNX1 and IDH1. In contrast, mutations in ASXL1 may be present at Dx in patients who will remain in long-term remission.

P595

**INCREASED INDOLEAMINE 2,3-DIOXYGENASE (IDO1) ACTIVITY IN EARLY CHRONIC PHASE CHRONIC MYELOGENOUS LEUKEMIA (CML-CP) IS REDUCED BY NILOTINIB THERAPY AND PREDICTS MOLECULAR RESPONSE**

1Hematology and Oncology, Medizinische Universität Innsbruck, Innsbruck, Austria, 2Comprehensive Cancer Center, Helsinki University Hospital, Helsinki, Finland, 3Bioinformatics, Medizinische Universität Innsbruck, Innsbruck, Austria, 4Northwestern University, Chicago, United States, 5Universitätsklinikum Jena, Jena, Germany, 6Vrije Universiteit Medical Center, Amsterdam, Netherlands, 7Biological Chemistry, Medizinische Universität Innsbruck, Innsbruck, Austria, 8Hematology, Oncology and Rheumatology, University Hospital of Bonn, Bonn, Germany

**Background:** Indolamine 2,3 dioxygenase (IDO1) is the rate-limiting enzyme in the metabolism of the essential amino acid tryptophan (TRP). IDO1 is induced mainly by interferons during infection and inflammation. Strong IDO1 activity depletes tryptophan, which results in reduced T cell activation and proliferation as well as expansion of immunosuppressive regulatory T cells. Deregulation of IDO1 activity has been linked to cancer immune evasion, but its role in chronic phase (CP) CML has not been investigated in detail.

**Aims:** Determination of IDO1 levels and activity in plasma CML-CP patients in the course of tyrosine kinase inhibitor therapy and their correlation with clinical and immunological parameters as well as molecular response.

**Methods:** A large panel of immune and inflammatory cytokines and chemokines of the IDO-pathway (soluble ID1=1sIDO1 and kynurenine/tryptophan ratio=kYN/TRP) as a product of IDO1 activity) as well as various leukocyte populations such as plasmacytoid dendritic cells (pDC) were analyzed alongside the prospective pan-european ENEST1st clinical study (NCT01061177). This substudy included 68 patients, followed chronologically. 25% of patients were subsequently treated with 300mg BID nilotinib and longitudinally analyzed at months 6 and 12 of therapy. Molecular responses were quantified in central EUTOS reference laboratories.

**Results:** Soluble IDO (sIDO1) levels and KYN/TRP ratio are significantly upregulated in newly diagnosed CP-CML and drop during nilotinib therapy; sIDO1 levels significantly correlate with increased KYN/TRP, suggesting increased IDO1 activity at diagnosis. Increased sIDO1 is linked to a pro-inflammatory status in CML patients, as it positively correlates with increased serum neopterin levels as well as to various other pro-inflammatory markers, such as IFN-α, IL-12, IL-15, IFN-g, IL-6, IL-8, TNFα, TGFβ, sVEGF-A, sVCAM-1 and sTNFR-1. Albeit being an IFN-regulated marker, in CML patients, as it positively correlates with increased serum neopterin levels as well as to various other pro-inflammatory markers, such as IFN-α, IL-12, IL-15, IFN-g, IL-6, IL-8, TNFα, TGFβ, sVEGF-A, sVCAM-1 and sTNFR-1.
of the KYN/TRP ratio to BCR-ABL transcript levels. Patients having a high KYN/TRP ratio (> mean +2SD of post therapy levels) reach deep molecular response rates (i.e. MR4.5) significantly earlier and at higher rates. Moreover, combining KYN/TRP with sCD62L levels, a recently identified predictive biomarker, resulted in a score robustly predicting the odds of achieving deep molecular response.

Summary/Conclusions: CML diagnosis in CP is linked to an increased inflammatory status, as shown by increased levels of sIDO and its metabolites kynurenine leading to an increased KYN/TRP ratio. In solid cancer increased IDO expression/activity is linked to inferior outcome by favoring immune evasion. In contrast, in CML an increased KYN/TRP ratio is associated with improved outcomes, mainly due to its role in anti-inflammatory therapy. The reason could be that IDO activity may reflect endogenous IFN-α production, a known factor favoring immune-mediated CML-control. The predictive potential of KYN/TRP is currently verified in an independent cohort.

BCR-ABL1 COMPOUND MUTANTS DISPLAY DIFFERENTIAL AND DOSE-DEPENDENT RESPONSES TO PONATINIB

K. Byrgazov1,*, C. Lucini1, D. Printz1, M. Koenig1, P. Valent2, O. Hantschel3, T. Lion1

1Children’s Cancer Research Institute, 2Medical University of Vienna, Vienna, Austria, 3Swiss Institute for Experimental Cancer Research, Lausanne, Switzerland

Background: Despite the dramatic improvement of prognosis in CML patients due to the introduction of tyrosine kinase inhibitors (TKIs), resistance to treatment occurs in a considerable proportion of patients. The best-characterized mechanism of resistance to TKIs is the acquisition of mutations in the BCR-ABL1 tyrosine kinase domain (TKD) affecting TKI binding. The third-generation TKI ponatinib exerts strong anti-neoplastic effects even in advanced CML stages and is capable of suppressing the kinase activity of BCR-ABL1 carrying any single mutation including T315I. Nevertheless, resistance to ponatinib can evolve in sub-clones carrying BCR-ABL1 variants with two or more mutations on the same allele, if the IC50 values for this TKI exceed the maximum achievable effective plasma levels (efcave). These co-called compound mutations (CMs) are associated with increased oncogenic potential in comparison to individual mutations, and represent a powerful mechanism of potential resistance to all currently available TKIs. The occurrence of compound mutations has been linked mainly to sequential treatment with different TKIs, and the identification of their responsiveness to ponatinib is of paramount importance for the subsequent clinical management.

Aims: 1. To determine the spectrum of highly TKI-resistant CMs. 2. Measure the responses of BCR-ABL1 CMs to ponatinib

Methods: We have established a BCR-ABL1 protein model facilitating assessment of the presumptive impact of 27 different CMs involving important functional sites of the BCR-ABL1 TKD, and including constellations expected to display distinct from GvHD is controversial. Another interesting observation is about 40 percent of persons with CML and a deep molecular response to tyrosine kinase-inhibitors (TKIs) remain in molecular remission when TKI-therapy is stopped. Because TKI-therapy is very unlikely to eradicate every CML cell, some ascribe this therapy-free remission (TFR) a result of immune surveillance. Immune surveillance refers to a process whereby the innate and adaptive immune systems recognize and eliminate cancer cells on the basis of cancer-specific or related antigens or other molecules. Substantial data support the concept of immune surveillance in rodents but data in humans are less convincing and apply mostly to virus-induced cancers.

P597

IS THERE EFFECTIVE IMMUNE SURVEILLANCE AGAINST CHRONIC MYELOID LEUKAEMIA? NO

R.P. Gale1,*, G. Opelz2

1Haematology Research Centre, Imperial College London, London, United Kingdom, 2Institute of Immunology, University of Heidelberg, Heidelberg, Germany

Background: Immune surveillance refers to a process whereby the innate and adaptive immune systems recognize and eliminate cancer cells on the basis of cancer-specific or related antigens or other molecules. Substantial data support the concept of immune surveillance in rodents but data in humans are less convincing and apply mostly to virus-induced cancers. However, considerable data indicate a strong anti-leukaemia effect in persons with chronic myeloid leukaemia (CML) receiving an allogeneic haematopoietic cell transplant. Most, if not all, of this anti-leukaemia effect is confounded with graft-versus-host disease (GvHD) and whether there is a specific anti-leukaemia effect distinct from GvHD is controversial. Another interesting observation is about 40 percent of persons with CML and a deep molecular response to tyrosine kinase-inhibitors (TKIs) remain in molecular remission when TKI-therapy is stopped. Because TKI-therapy is very unlikely to eradicate every CML cell, some ascribe this therapy-free remission (TFR) a result of immune surveillance. Immune surveillance refers to a process whereby the innate and adaptive immune systems recognize and eliminate cancer cells on the basis of cancer-specific or related antigens or other molecules. Substantial data support the concept of immune surveillance in rodents but data in humans are less convincing and apply mostly to virus-induced cancers. However, considerable data indicate a strong anti-leukaemia effect in persons with chronic myeloid leukaemia (CML) receiving an allogeneic haematopoietic cell transplant. Most, if not all, of this anti-leukaemia effect is confounded with graft-versus-host disease (GvHD) and whether there is a specific anti-leukaemia effect distinct from GvHD is controversial. Another interesting observation is about 40 percent of persons with CML and a deep molecular response to tyrosine kinase-inhibitors (TKIs) remain in molecular remission when TKI-therapy is stopped. Because TKI-therapy is very unlikely to eradicate every CML cell, some ascribe this therapy-free remission (TFR) a result of immune surveillance.
Methods: To test these hypotheses, we studied whether there was an increased incidence in CML in persons receiving immune suppression, after solid organ transplants. IF immune surveillance is important in CML we would expect an increased incidence in this setting. We used a dataset from the Collaborative Transplant Study (CTS) which collects information on recipients of solid organ transplants beginning in 1985 from >300 transplant centers worldwide. Cancer incidence data were checked annually by questionnaire. Data for expected CML incidence were obtained from a cohort of identical size matched for age and sex from Cancer Incidence in Five Continents monitored for the same duration as the transplant cohort. Data collection and processing were approved by the Data Protection Agency in Germany and all participating centers were in accordance with ethical and privacy regulations. The CTS dataset consisted of 441,332 recipients of kidney (N=355,606), liver (N=47,846) and heart (N=37,880) transplants. Amongst kidney transplant recipients the standardized incidence ratio (SIR) for developing CML was 1.54 (95% confidence interval, 1.1, 2.1; p<0.01) representing 39 cases in 1,682,491 person-years at risk (4.7 per 100,000). Amongst liver transplant recipients the SIR was 1.72 (0.6, 4.0; p=0.34) representing 5 cases in 182,833 person-years at risk vs. 3 expected (2 excess cases). Amongst heart transplant recipients the SIR was 3.47 (1.8, 6.1; p=0.0005) representing 12 cases in 173,015 person-years at risk. One excess case was detected in 9 patients (11 CML and 1 ALL) and 2 negative samples (K Cohen=0.690; p <0.02): 77 samples were concordant by the “Labnet” method, 51 (81%) samples exceeded the 100,000 copies of BCR-ABL1 KD mutation (MR3<0.032%, MR4<0.001%). Consequently, the molecular monitoring plays a crucial role in the clinical management of CML patients, with a consequent research of sensitive and standardized molecular techniques. The automated methods offer advantages in terms of reduced time for analysis, decreased manual steps, and reduction of possible errors and contamination. The aim of the present study was to compare the ultra-fast real-time PCR technique MinION (Oxford Nanopore, Oxford, UK) with the “Labnet” method that includes the “classical” manual real-time PCR techniques standardized in the Italian network (57 centers), according to the European guidelines [Cross N, 2015]. We compared the sensitivity of the two methods (based on the number of ABL1 detected copies) in the classification of molecular responses, with particular attention to the deep molecular subgroups.

Results: MinION data analysis on the Group 2 was able to detect mutation only in a ALL case. Results from MinION and SS showed 92% concordance in all cases included in this study. Notably, mutations that were initially undetectable by SS became evident thanks to the indications coming from MinION analysis.

Summary/Conclusions: Our findings demonstrate multiple advantages by using MinION approach, first of all the sensitivity: our comparison of MinION to SS identified mutations below the detection limit of SS (generally estimated around <20%) in 2 (22%) among the mutated cases, including mutations known to be clinically important. Another point on the side of the nanopore technology is the costs profile. Therefore, the main advantage of this technology is to allow a more efficient and sensitive analysis than SS at very competitive costs. In conclusion, we demonstrated that MinION is suitable for employment in hematology laboratory for detecting BCR-ABL1 KD mutations in Ph+ leukemias.

Background: The chronic myeloid leukaemia (CML) is characterized by the presence of the Philadelphia chromosome and the BCR-ABL1 fusion gene. The production of tyrosine kinase inhibitors (TKIs) significantly improved the survival, but 15% of patients don’t reach the optimal responses at the defined end-points or develop secondary resistance. The 2013 ELN guidelines identified as fundamental the early molecular response (BCR-ABL1/ABL1 % s10%, IS), the MR3 (<0.1%) and the deep molecular response (MR4<0.01%, MR5<0.001%) [31]. Consequently, the molecular monitoring plays a crucial role in the clinical management of CML patients, with a consequent research of sensitive and standardized molecular techniques. The automated methods offer advantages in terms of reduced time for analysis, decreased manual steps, and reduction of possible errors and contamination. The aim of the present study was to compare the ultra-fast real-time PCR technique MinION (Oxford Nanopore, Oxford, UK) with the “Labnet” method that includes the “classical” manual real-time PCR techniques standardized in the Italian network (57 centers), according to the European guidelines [Cross N, 2015]. We compared the sensitivity of the two methods (based on the number of ABL1 detected copies) in the classification of molecular responses, with particular attention to the deep molecular subgroups.

Results: Firstly we compared the number of detected ABL1 copies, that are fundamental for definition of the molecular response categories, especially for the so-called MR4+/MR5. By the “Labnet” method, 51 (81%) samples exceeded the 100,000 copies of ABL1, while by the automated method 81 samples (94.2%) reached >100,000 ABL1 copies. Then, we compared the two methods in discriminating positive and negative samples (K Cohen=0.690; p<0.02): 77 samples were concordant (89.5%) and only 9 (10.4%) were discordant. Of the 18 negative samples with the “Labnet” method, 2 (11.1%) were in MR4.0, 10 (55.5%) in MR4.5 and 6 (33.4%) in MR5.0. On the other hand, of the 19 negative samples with the method “Ultra”, 1 (5.3%) was in MR4.5 and 18 (94.7%) in MR5.0, confirming the higher sensitivity of the automated method. In the cohort of positive cases by the two methods, the median values of transcript expression were superimposable (p=0.55) and the linear regression coefficient was very satisfying (Pearson’s r=0.9399; p-value <0.0001). Finally we compared the results produced by the two methods according to the “molecular classes” (MR1 vs MR2+MR3 vs MR4+MR4.5 vs MR5). This comparison showed a good concordance of results. Overall, the comparison of the two methods demonstrated high concordance between “Ultra” and “Labnet” methods using assay comparison criteria proposed by Müller et al. [Leukemia 2009] (Table 1).
and apoptosis in IM sensitive and resistant cell lines. The advantage of using AK and Plk1 inhibitors in

Summary/Conclusions:
• significant increase of gadd45a expression levels;
• AK/A and Plk1 activation is only partly dependent on BCR-ABL1 TK phosphorylation of both proteins in parental K562, but not in IM-resistant K562, indicating that AK/A and Plk1 overexpression is always associated with defects in centrosome duplication, bipolar spindle and chromosomal segregation and aneuploidy, suggesting that it may enhance other oncogenic events by promoting genomic instability, one major trait of chronic myeloid leukemia (CML).

Background: Cell response to stress is a central component of genomic stability. The integrity of signaling pathways involved in cell cycle arrest, chromatin remodeling and DNA repair, are critical for the maintenance fidelity of replicated DNA. In this context, Gadd45 proteins function as stress sensors and de- transcripion regulators. Gadd45α, in particular, intervenes in G2/M checkpoint induction and DNA repair, and it is required for efficient coordination of centrosome duplication hence preventing abnormal mitosis and aneuploidy. Such evidences let assume a putative role of Gadd45α in cancer development and progression. We report that Gadd45α interacts with Aurora Kinase A (AKA), a key component of centrosome cycle and polar spindle assembly required for regulated progression from G2 to M and throughout M. AK/A is a member of a serine-threonine kinase family active during mitosis and it is frequently overexpressed in human cancers where correlates with a poor prognosis. Notably, AK/A overexpression is always associated with defects in centrosome duplication, bipolar spindle and chromosomal segregation and aneuploidy, suggesting that it may enhance other oncogenic events by promoting genomic instability, one major trait of chronic myeloid leukemia (CML).

Methods: K562 cell line is a human cell line generated from a CML patient in blast crisis. Drug resistance was induced in K562 cell line by the exposure to progressively increasing doses of Imatinib (IM). It was validated by dose-response curves showing a significant difference in LD50 of IM-sensitive and IM-resistant cells. By mean of cytofluorimetric and immunofluorescence microscope analyses we investigated the events leading to AK/Plk1 deregulation. Protein expression and activation were detected by western blotting and immunoprecipitation. Apoptotic cell death was measured by using an Annexin V/PI staining; cell cycle distribution was observed by PI staining and subsequent microscope analyses.

Results: Preliminary experiments were aimed to determine whether IM resistance in a BCR-ABL1 cell context is associated with the over-expression and hyper-activation of AK/A/Plk1 axis. In our in vivo model drug resistance was associated with increased expression and phosphorylation of AK/A (Y282) and Plk1 (T210). 24h exposure to IM significantly reduced expression and phosphorylation of both proteins in parental K562, but not in IM-resistant K562, indicating that AK/A and Plk1 activation is only partly dependent on BCR-ABL1 TK activity. Subsequent experiments showed that the inhibition of AK/A and Plk1 in response to specific inhibitors (Danusertib and Volasertib respectively) was associated with:
• significant increase of gadd45a expression levels;
• reduction of cell survival;
• G2/M checkpoint arrest.

Summary/Conclusions:
• The advantage of using AK and Plk1 inhibitors in CML therapy mostly arises from effects independent from TK activity of Bcr-Abl protein. We proved that the AK and Plk1 inhibitors induce growth arrest and apoptosis in IM sensitive and resistant cell lines.
Background: The t(9;22) translocation in chronic myeloid leukemia (CML) generally occurs in intron 12 or 13 of the BCR gene resulting in two different transcripts, the e13a2 or e14a2. It has been suggested that the two variants represent separate disease entities and that the transcript variants hold a prognostic value regarding treatment response, where e14a2 predicts a faster and deeper treatment response. However, no difference in overall survival has been observed and the issue remains controversial.

Methods: Transcript levels from 124 BCR-ABL1 positive patient samples were screen for BCR-ABL1 e13a2 and e14a2 transcript variants using either PCR with agarose gel separation or a droplet digital PCR (ddPCR) assay measuring the amount of e13a2 and e14a2 transcripts. The BCR-ABL1 level was determined by qPCR using the QuantaStudio instrument (Life Technologies) and expressed in the International Scale (IS) using the EAC primers and assay conditions with GUSB and BCR as reference genes. Samples were re-measured by digital droplet PCR (ddPCR) on a QuantaLife instrument (Bio-Rad) using modified EAC primers multiplexed with GUSB and BCR as reference genes and expressed as %IS.

Results: Transcript levels from 124 BCR-ABL1 positive patient samples were determined using the EAC qPCR assay (median: 0.08% IS; range: 0.001–159% IS) and ddPCR (median: 0.01% IS; range: 0.0002–124% IS). These included 59 samples with the e13a2 variant and 65 with the longer e14a2 variant. Comparing the expression levels obtained by the two techniques revealed ddPCR/qPCR ratio differences for e13a2 (median: 0.68, range: 0.35 – 3.2) and e14a2 (median: 3.43, range: 0–8.8), and a consistent 4.5 fold (>0.5 log) underestimation of the levels of the e14a2 compared to e13a2 when using qPCR (figure 1).

Summary/Conclusions: When we compared the BCR-ABL1 levels using qPCR and ddPCR, we observed a discrepancy between the e13a2 and e14a2 break transition variants. Since ddPCR is an endpoint measurement and not sensitive to variations in primer efficiencies, the most likely explanation for the discrepancy is a decreased qPCR efficiency of the longer e14a2 variant compared to e13a2 variant. Thus in qPCR analyses using the EAC protocol this may, at least on some analysis platforms, result in a consistently underestimation of the e14a2 transcripts.

5-YR RESULTS FROM THE PIVOTAL PHASE 2 PONATINIB PACE TRIAL: EFFICACY, SAFETY AND LANDMARK ANALYSIS IN HEAVILY PRETREATED PATIENTS (PTS) WITH CHRONIC-PHASE CHRONIC MYELOID LEUKAEMIA (CP-CML)

Background: Ponatinib is an oral tyrosine kinase inhibitor (TKI) approved for pts with CP-CML or Philadelphia chromosome–positive acute lymphoblastic leukemia (Ph+ ALL) for whom no other TKI therapy is indicated, or for pts with T315I. The ponatinib PACE trial (NCT01207440) enrolled pts with CML or Ph+ ALL resistant/intolerant to dasatinib or nilotinib, or with T315I. Long-term results in these heavily pretreated pts provide value in informing treatment decisions.

Aims: To report 5-yr efficacy and safety, and the association of early landmark molecular responses with survival outcomes at 4 yts past landmark, in heavily pretreated pts with CP-CML from PACE.

Methods: Ponatinib starting dose was 45mg/day. Dose reductions were instructed in Oct '13 to manage risk of arterial occlusive events (AOEs) observed with longer follow-up. Outcome measures were: 5-yr efficacy (n=267) and safety (n=270); post-landmark analysis (n=267) of the association of molecular responses (BCR-ABL1 ≤0.1% [major molecular response (MMR)], >0.1–1%, >1%–10% and >10%) and cytogenetic responses (major [MCyR] and complete [CCyR]) at 3-6- 12-mos with progression-free survival (PFS) and overall survival (OS) 4 yts past landmark (log-rank P values). Data cutoff: 3 Oct ’16.

Results: Baseline characteristics of the CP-CML pts included: median time from diagnosis, 7 yrs (range, 0.5–27 yrs); median age, 60 yrs (18–94 yrs); median %Ph+, 100% (2.5–100%); and ≤10% Ph+, 20 pts (7%). At initiation of study closure, 99 pts (37%) were ongoing; among these pts, minimum follow-up was 52 mos, and most (78%) had 15mg/d as their last ponatinib dose. In efficacy-evaluable CP-CML pts, cumulative response rates of the last TrKi dose were: MCyR, 60%; CCyR, 64%; MMR, 40%; and MR4.5, 24%. Among pts who achieved MCyR (n=148) or MMR (n=108), the Kaplan-Meier (KM) estimated probability of remaining in response at 5 yrs was 74% (95% CI, 62–83) and 61% (95% CI, 51–70), respectively. Maintenance of response was high regardless of dose reductions in Oct ’13. KM estimated 5-yrs for PFS/OS were 49%/77%. Among pts with 3-, 6- and 12-mo landmark responses, achievement of MCyR or MMR at 3-, 6- and 12-mo was associated with achievement of PFS/OS overall or treatment-emergent adverse events (AEs) in ≥24% of CP-CML pts were rash 47%, abdominal pain 46%, and thrombocytopenia 46%. Most newly occurring AEs were observed within the first yr. The incidence of any AOE/serious AOE for CP-CML pts was
29%/23%. Among CP-CML pts with no prior AEs who had a prospective dose reduction, 17% (11/63) had a first AOE occurring after Oct ’13.

Summary/Conclusions: Long-term 5-y results from PACE demonstrate that irrespective of dose reductions, ponatinib continues to show deep, lasting, clinically meaningful responses over time in heavily-pretreated pts with CP-CML. Achieving early cytogenetic response and deep reduction in BCR-ABL1 levels was associated with improved survival 4 yrs past landmark, demonstrating the prognostic value of early and deep response to ponatinib.

P604
LONG-TERM FOLLOW-UP IN VERY ELDERLY PATIENTS WITH CHRONIC MYELOID LEUKEMIA TREATED WITH IMATINIB FRONTLINE

Methods: We analyzed 345 patients ≥ 18 years of age with CP CML enrolled in 2 clinical trials of the GIMEMA CML WP. Patients that sometimes receive imatinib (IM) at reduced doses based on physicians’ judgment. However, data on long-term follow-up of these patients are still lacking.

Aim: To investigate the treatment response and outcome in a cohort of very elderly patients with newly diagnosed CML in chronic phase; among these, 121 patients (46%) were older than 80 yrs.

Background: Very elderly (>75 yrs) people are a substantial proportion of chronic myeloid leukemia (CML) patients that sometimes receive Imatinib (IM) at reduced doses based on physicians’ judgment. However, data on long-term follow-up of these patients are still lacking. Aims: To investigate the characteristics of ATEs and their impact on the long-term outcome of CML patients treated with nilotinib first-line.

Methods: We analyzed 345 patients ≥ 18 years of age with CP CML enrolled in clinical trials of the GIMEMA CML WP investigating nilotinib as first-line treatment. Patients were treated with: nilotinib 400-600 mg BID (n=73); rotation of nilotinib 400 mg BID / imatinib 400 mg OD (3-month periods for each drug)(n=123); nilotinib 300 mg BID (n=149). The median follow-up was 58 (22-82) months. The median age at CML diagnosis was 53 (18–86) years. We compared the molecular response rates and the long-term outcome of patients treated with ATEs. Definitions: ATEs: peripheral arterial obstructive disease (PAOD), coronary syndromes, significant carotid stenosis and ischemic stroke, or other significant ischemic events; major molecular response (MRM): BCR-ABL ≤ 0.1% (IS), with 10,000 ABL copies; MR4: BCR-ABL≤0.01% (IS), with >10,000 ABL copies. Results: Overall, 30,545 (8.7%) patients had ATEs during treatment with nilotinib.

The median age at CML diagnosis of these patients was 64 (43-85) years, and the median age at ATEs was 67 (47-89) years. The median duration of nilotinib treatment at ATE was 25 (1-78) months. ATEs were: 14 coronary dissections, 28 coronary occlusions, 7 peripheral arterial occlusions, 25 carotid stenosis, 8 strokes, 10 transient ischemic attacks, 6 peripheral arterial occlusions.

Summary/Conclusions: The long term follow-up of very elderly CML patients treated with IM suggests that any effort to treat these patients with standard doses should be made, in order to achieve cytogenetic and molecular responses as in younger subjects.
ease (including 7 acute myocardial infarction), 8 PAOD, 4 carotid stenosis (asymptomatic), 2 avascular necrosis of femoral heads, 1 optic artery ischemia, 1 aneurysm of the left common iliac artery. Overall, 21 patients were hospitalized for the management of ATEs; 15 patients received medical treatment only, while the remaining required invasive interventions: 9 coronary angioplasty with stent positioning, 3 lower limbs amputations, 2 peripheral vascular bypasses, and 1 prosthesis of femoral head. No patient died for ATEs. Overall, 24 patients (80% of patients with ATEs, and 7% of the whole cohort) permanently discontinued nilotinib because of ATEs. The median follow-up after ATE was 15 (1-58) months. Of the 30 patients with ATEs, 26 (87%) achieved a MMR and 18 (60%) obtained a MR4, during nilotinib treatment. These rates were comparable to those observed in patients without ATEs (MR3: 260/315, 83%; MR4: 113/315, 64%). The 5-year progression-free survival and overall survival were similar in patients with or without ATEs (PFS: 96% vs 92%, p=0.55; OS: 96% vs 93%, p=0.79).

Summary/Conclusions: After a median follow-up of 58 months, 8.7% of patients treated front-line with nilotinib had ATEs, being coronary disease and PAOD the most common. ATEs were more frequent in elderly patients (median age at ATEs: 67 years). Half of the patients required invasive procedures, including major surgeries in 6 patients. The other patients were successfully managed with medical treatment. Importantly, no patients died for ATEs, and ATEs did not affect the rates of MMR, MR4 and 5-year PFS and OS, which were all comparable to those observed in patients without ATEs. Taken together, these data suggests that ATEs, despite being sometimes associated with significant morbidity, did not significantly impact on response rates and on long-term outcome of CML patients treated with nilotinib front-line.

ASSESSMENT OF CHRONIC RENAL INJURY IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA IN THE CHRONIC PHASE RECEIVING TYROSINE KINASE INHIBITORS

Q. Jiang1,*, L. Zuo2, X. Ren1, X. Huang1
1Peking University People’s Hospital, Peking University Institute of Hematology, 2Peking University People’s Hospital, Department of Nephrology, Beijing, China

Background: Long-term use of tyrosine kinase inhibitors (TKIs) may lead to chronic renal injury.

Aims: To evaluate the incidence of chronic kidney disease (CKD) in patients with chronic myeloid leukemia (CML) in the chronic phase (CP) receiving TKIs, and to identify the factors associated with the onset of CKD.

Methods: Data of CML-CP patients treated with TKIs as first-line or second- or third-line therapy for at least 3 months were analyzed. Glomerular filtration rate (GFR) was followed from the initiation of TKI-therapy. CKD was defined as persistent GFR less than 60 ml/min/1.73 m2 or persistent more than 30% GFR reduction from baseline. CKD-free survival was used to evaluate the onset of CKD. Patients’ characteristics and TKI used were analyzed to identify the factors associated with the onset of CKD by Cox regression model in those receiving first-line and second- or third-line TKI-therapy, respectively.

Results: 587 patients were included in this study. 383 (65%) were male. Median age was 40 (17-84) years. 468 patients were received nilotinib (n=363), nilotinib (n=88) or dasatinib (n=13) as first-line TKI-therapy. With a median follow-up of 35 months (range, 3-185 months), 136 of 416 (33%) patients with normal GFR at baseline developed CKD. Probabilities of CKD-free survival at 4 years were 62%, 78% and 100% in the patients receiving imatinib, nilotinib and dasatinib, respectively (p=0.004). Multivariate analysis showed that imatinib use (HR=2.5, 95% CI 1.4-4.3, p=0.002), male gender (HR=1.1, 95% CI 1.1-1.4, p=0.003), and prior administration of hydroxyurea, interferon or chemotherapy (HR=1.7, 95% CI 1.1-2.8, p=0.010) were factors associated with incident of CKD. In 48 patients with abnormal GFR or prior CKD before first-line TKI-therapy, 8 of 42 (19%) developed ≥30% GFR reduction from baseline during nilotinib or dasatinib-therapy. In 123 patients receiving nilotinib (n=59) or dasatinib (n=64) as second- or third-line TKI-therapy after imatinib-failure, 13 of 110 (12%) with normal GFR at baseline developed CKD with a median follow-up of 19 months (range, 3-149 months). Probabilities of CKD-free survival at 3 years were 74% and 90% in those receiving nilotinib and dasatinib, respectively (p=0.059). Multivariate analysis showed that nilotinib use (HR=3.6, 95% CI 1.5-10.1, p=0.047) and a history of diabetes mellitus, hypertension or other renal diseases (HR=3.8, 95% CI 1.3-11.6, p=0.019) were factors associated with incident of CKD. 3 of 13 (23%) patients with abnormal GFR or prior CKD before second- or third-line TKI-therapy developed ≥30% GFR reduction from baseline during nilotinib (n=1) or dasatinib (n=2) therapy.

Summary/Conclusions: Our study showed that nilotinib and dasatinib were associated with less chronic renal injury compared with imatinib as first-line TKI-therapy, while dasatinib was related to less loss of renal function compared with nilotinib as second- or third-line TKI-therapy after imatinib-failure in CML-CP patients.

1Lab CREA-AI, AO Spedali Civili di Brescia, 2Unit of Bone Marrow Transplantation, University of Brescia, Brescia, 3Division of Hematology and Bone Marrow Transplantation, University-Hospital of Udine, Udine, 4Institute of Hematology “Land A Seràgnoli”, University of Bologna, Bologna, 5Chair of Biochemistry, University of Brescia, Brescia, 6Department of Biomedicine and Prevention, University of Tor Vergata, Roma, 7Division of Hematology, AO Spedali Civili di Brescia, Brescia, Italy

Background: Quantification of BCR-ABL1 transcript by qPCR is mandatory to monitor the response to TKIs therapy in CML patients. The achievement of Major or Deep Molecular Response (MMR or DMR) with TKIs is crucial for long-term survival and for treatment free remission (TFR). Currently, up to 30-40% of CML patients treated with TKIs can achieve DMR, but 50-60% of深 responders who discontinue the treatment lose their DMR and re-challenge sequent TKIs therapy. qPCR has some intrinsic limitations and it does not appear to be an optimal assay to select the best candidates to TKIs discontinuation. Digital PCR (dPCR) can give an absolute quantification of target nucleic acids by partitioning the PCR reaction mix over a large number of wells, each containing a single copy or no copies of the target region.

Aims: The aim was to comparatively monitor the BCR-ABL1 transcript levels by dPCR and qPCR in 57 CML patients treated with TKIs and achieving MMR or DMR in at least 3 time points.

Methods: Using qPCR and dPCR (Q303 Digital PCR System by Life Technologies), we comparatively analyzed 228 peripheral blood samples from 57 CML patients with MMR (n=14) or DMR (n=43). qPCR analysis were performed according to the last International Guidelines while absolute quantification of BCR-ABL1 transcript were obtained by dPCR and results were expressed as number of BCR-ABL1 copies/ul of reaction. Patients were divided into 3 groups corresponding to the MR classes at the first time point: MR3.0, MR4.0 and MR4.5-5.0 groups. dPCR Positive Predictive Value (PPV) was also preliminary evaluated in 14 patients undergoing TKI discontinuation.

Figure 1.

Results: Analyzing comparatively the time course of MR in the patients of the three groups (MR3.0, MR4.0 and MR4.5-5.0) it was observed a similar trend, but the dPCR allowed to appreciate that, at the time of starting the monitoring the patients showed different levels of BCR-ABL1 copies/ml. Furthermore, those patients with MR4.5-5.0 undetectable by qPCR resulted with detectable BCR-ABL1 transcript levels when assessed by dPCR. Secondly, while MRD quantitations measured by qPCR appear to be more homogeneous, nearly due to a normalization effect of qPCR, the quantitations of MRD measured by dPCR appear to be more heterogeneous because of the high sensitivity and accuracy of dPCR. Therefore, dPCR values, reflecting the great heterogeneity of MRD level in patients belonging to the same MR group, suggest a higher accuracy in patients stratification (Figure 1a). dPCR value of 0.468 copies/ul, previously reported as value discriminating between major responders and deep responders, was used as threshold for dPCR data analysis. Patients with absolute value of BCR-ABL1 lower than 0.468copies/ul at the first time point presented more stable disease levels than the patients with absolute value of BCR-ABL1 higher than 0.468copies/ul (Figure 1b). In 14 CML patients who...
discontinued TKIs, a preliminary analysis showed that 80% of patient with BCR-ABL1<0.468 copies/ul at discontinuation, maintained stable TFR (PPV of 80%).

Summary/Conclusions: This study suggests that dPCR is more precise and sensitive than qPCR when detecting levels of BCR-ABL1 transcript and that dPCR seems to be more robust and accurate for CML patients stratification. Larger and prospective studies are warranted to confirm the higher sensitivity and accuracy of dPCR and its usefulness to better select the candidates for TFR.

P608

OUTCOME OF BLAST PHASE CHRONIC MYELOID LEUKEMIA (CML-BP) IN THE TYROSINE KINASE INHIBITOR ERA
C. Tekieli,1, L. Iseaume,1, S. Shams,1, A. Kuykendall1, J. Chavez,2, B. Shah,2, K. Sweed2, J. Pinilla-Ibarz2
1Department of Malignant Hematology, University of South Florida/Moffitt Cancer Center, 2Department of Malignant Hematology, Moffitt Cancer Center, Tampa, United States

Background: Primary goal of management in chronic myeloid leukemia (CML) is to prevent disease progression to blast phase CML (BP-CML). Current notion for management of BP-CML usually involves initiation of intensive chemotherapy regimen with addition of tyrosine kinase inhibitor (TKI). Despite treatment with intensive induction chemotherapy, outcome remains dismal.

Aims: We aimed to describe our experience with management of BP-CML and its outcome.

Methods: We included 58 patients from Moffitt Cancer Center from 2001 till 2016 with diagnosis of BP-CML and performed a retrospective chart review. Data elements including age, gender, peripheral blood and bone marrow parameters, phase of CML, treatment, cytogenetics and vital status were collected.

Survival analysis using Kaplan-Meier method with log-rank test to determine significance by calculating two-sided p values was performed.

P609

EFFICACY OF SWITCHING TO DASATINIB IN CHRONIC MYELOID PATIENTS WITH LATE WARNING RESPONSES TO IMATINIB. STUDY OF THE ASSOCIATION OF RESPONSE TO DASATINIB TO IMMUNOLOGIC STATUS
J.L. Steegmann1,1, V. Garcia-Gutierrez2, B. Colom3, F. Sanchez-Guijo4, R. Ayala5, C. Boque6, F. Casado3, B. Xicoy8, I. Montero9, C. Soto10, R. de Paz10, A. Kreutzman1, J. Martinez-Lope2z, C. Muñoz3
1Servicio de Hematologia, Hospital Universitario de la Princesa/ IIS-IP Madrid, 2Servicio de Hematologia, Hospital Universitario Ramon y Cajal, 3Servicio de Immunologia, Hospital Universitario de la Princesa, Madrid, 4Servicio de Hematologia, Hospital Universitario de Salamanca, Salamanca, 5Servicio de Hematologia, Hospital Duran i Reynals, Barcelona, 6Servicio de Hematologia, Hospital Virgen de la Salud, Toledo, 7Servicio de Hematologia, Hospital Germans Trias i Pujol, Barcelona, 8Servicio de Hematologia, Hospital Universitario Virgen del Rocio, Sevilla, 9Servicio de Hematologia, Hospital Povisa, Vigo, 10Servicio de Hematologia, Hospital Universitario La Paz, Madrid, Spain

Background: European LeukemiaNet (ELN) recommendations (2013) advised closely monitoring for patients with late warning response (patients with complete cytogenetic response without major molecular response after 12 months of treatment). Our trial, DASAPOST, has been the first one evaluating efficacy and safety of dasatinib in patients with late warning responses, and preliminary results have been reported (Garcia-Gutierrez et al, ASH 2016; P5450). Besides, many studies suggest that dasatinib may augment responses due to its immunomodulating effect. Although NK and CD8 cells seem to be involved, the specific mechanism remains to be clarified.

Aims: To evaluate the efficacy and safety of switching change to dasatinib in patients treated with imatinib first line during at least 18 months and having a late warning response, and to study the association between response to dasatinib and immune robustness, both baselines and during the therapy, and dasatinib-induced lymphocyte “mobilization”.

Methods: Phase II, open, multicenter DASAPOST study (NCT01802450). Patients previously treated with imatinib after at least 18 months, with CCyR but without MMR, were included. All BCR-ABL1/ABL (IS) measurements were centralized in a MATOS laboratory. Analysis of interest were done both previous to the dose, and 2 hours after.

Results: From April 2013 to May 2015, 18 patients were enrolled in 12 centers. Median age was 59 years (39-77). The ratio of men to women was 13/5, and the Sokal risk groups were 30% and 14% for low, intermediate and high risk, respectively. Median time from diagnosis to switch to dasatinib was 2.6 years (1.6–2.3) and median time while on imatinib to achieve CCyR 1.4 years (0.2–12). Median exposure to imatinib was 2.4 years (1.6–14). Eight patients (44%) obtained MMR at 3 months, and 12 (66.7%) obtained MMR at 6 and 12 months. Of interest 9/18 patients (50%) achieved MR4 by 12 months. There were 3 study discontinuations because of toxicity (16%). Table 1 shows the median number of the most relevant lymphocyte populations in the pre-dose sample at baseline. Table 2 shows that the absolute number of CD8 cells was significantly superior at baseline in those patients having a MMR at 3 months, with a trend in the same direction of absolute lymphocyte count and percentage. There were no significant associations with response when considering CD4 T cells, NK cells, or the degree of mobilization after dasatinib dose either in total lymphocyte number or in subpopulations. Besides, lymphocyte number or proportions at 3 or 6 months were not associated with MMR at 6 or 12 months (data not shown).

Summary/Conclusions: Our study shows that in patients treated with imatinib and with late warning responses, switching to dasatinib induced MMR in 2 out every 3 patients, and MR4 in half of the patients, with a good safety profile. Contrarily to other group reports, we have not found any significant association between response and lymphocyte mobilization in any point studied. Interestingly, the absolute number of CD8 at baseline was significantly associated with the early attainment of MMR at 3 months, a finding which underscores the prognostic importance of baseline immune status, the relevance of CD8 cells in the antileukemic effect, and which suggest that this quite simple variable must be included in future studies with dasatinib in second line.

GENETIC PREDICTION OF INSULIN RESISTANCE IN CHRONIC MYELOID LEUKEMIA PATIENTS TREATED WITH NILOTINIB

G. Caocci1,*, C. Mammì2, C. Labate2, S. Rodi2, D. Ielo3, M. Priolo2, M. Postorino2, G. Tripepi5, F. Ronco3, C. Laganà2, B. Martino3

1Hematology, Department of Medical Sciences, University of Cagliari, Cagliari, 2Operative Unit of Medical Genetics, 3Operative Unit of Hematology, 4Operative Unit of Nephrology, Grande Ospedale Metropolitano “Bianchi-Melacrino-Morelli”, 5Epidemiology Research Unit, CNR-IBIM, Reggio Calabria, Italy

Background: Impaired fasting glucose (IFG) and type 2 diabetes (T2D) represent adverse events in Chronic Myeloid Leukemia (CML) patients treated with the second-generation tyrosine kinase inhibitor (TKI) nilotinib. A genetic risk score (uGRS) for the prediction of insulin resistance, consisting of 10 multiple single-nucleotide polymorphisms (SNPs), has been proposed.

Aims: We evaluated the uGRS predictivity in 45 CML patients treated with nilotinib.

Methods: Patients were genotyped for IRS1, GRB14, ARL15, PPARG, PEPD, ANKRD55/ MAP3K1, PDGFC, LYPLAL1, RSPO3, and FAM13A1 genes. The uGRS was based on the sum of the risk alleles within the set of selected SNPs.

Results: MR3.0 and CMR were achieved in 91% and 84% of the patients, respectively. Before treatment, none of the patients had abnormal blood glucose. During treatment and subsequently follow-up of 84.4 months (range 1-298), 5 patients (11%) developed diabetes requiring oral treatment, after a median of 11 months (range 3-95) since nilotinib. Nine patients (20%) developed prediabetes. Prediabetes/diabetes-free survival was significantly higher in patients with an uGRS below 10 compared to higher scores (100% vs 18%; p=0.004) (Figure). Each increment of 1 unit on the uGRS caused a 42% increase in the prediabetes/diabetes risk (HR=1.42; CI: 1.04-1.94; p=0.026).

Summary/Conclusions: Although nilotinib is not associated with a higher incidence of T2D compared to a general population, it could be an early “highlighter” of genetic predisposition to the disorder. The presence of more than 10 allelic variants associated to insulin secretion, processing, sensitivity and clearance is predictive of prediabetes/diabetes developing. In clinical practice uGRS could help tailor the best TKI therapy.

P611

THE EUROPE AGAINST CANCER PROTOCOL FOR BCR-ABL P210 TRANSSCRIPT MEASUREMENT MAY OVERESTIMATE RESULTS FOR E13A2 PATIENTS TREATED WITH NILOTINIB

G. Caocci1,*, M. Gniot1,*, M. Komarnicki1, K. Lewandowski1

1Hematology, Poznan University of Medical Sciences, Poznań, Poland

Background: The quantitative PCR of BCR-ABL transcript has been the most useful technique for monitoring therapy in CML patients for over a decade. The numerous standardization projects have been undertaken in order to harmonize the molecular response results in laboratories all over the world. However, our data suggest that using the most common protocol may lead to overestimation of e13a2 transcript.

Aims: The goal of the study was to verify the observation that e14a2 transcript amplifies less efficiently than e13a2. The secondary goal was to validate the modification of Europe Against Cancer (EAC) protocol developed in 2011 which corrects observed artifacts.

Methods: The BCR-ABL measurements acquired using EAC and in-house modified EAC protocol have been compared with results from SA Pathology in Adelaide. The Adelaide protocol (Branford and Hughes 2006) consists of separate, optimized reactions for e13a2 and e14a2 transcripts, therefore it should be considered free of any PCR efficiency-related artifacts. The data originated from four independent sample batches exchanged between Poznan and Adelaide since 2009.

Results: The analysis of retrospective EAC protocol data showed that when e13a2 and e14a2 samples entered the exponential phase at the same time, the latter would cross the threshold approximately 2.2 cycles after the first one. Re-analysis of data from sample exchanges from 2009 revealed that after establishing a conversion factor (CF), all of the e14a2 measurements in Poznan were underestimated according to Adelaide. At the same time, almost all of e13a2 samples were overestimated (fig. 1). Still, the bias between methods was acceptable and a valid conversion factor (CF) was calculated. The method modification introduced 2011 eliminated this difference and increased concordance between laboratories. The last sample batch revealed significant difference between non-modified and modified EAC protocols in e13a2 measurements: 4.56 (+/- 0.96). Reanalysis of sample batch from 2009 (presented on fig.1) using 4.57 (2x2.28) factor (e13a2 results divided by 2.28, e14a2 results multiplied by 2.28) resulted in almost perfect data alignment. The results of modified EAC protocol, after CF recalibration, showed very good concordance with Adelaide (100% results of e14a2 and 88% of e13a2 within 2-fold of reference laboratory).

Figure 1. The EAC protocol, the e14a2 transcript amplifies less efficiently than e13a2. Since commonly used plasmids, including ERM-AD623, are based on e14a2, the standard curve is being shifted towards the latter cycles. It leads to overestimation of e13a2 by mean factor of 4.5 (over 0.5 log), which could be clinically significant. The reports of worse outcome of e13a2 patients are probably caused by this artifact, which can be easily eliminated by implementing an additional forward primer to EAC protocol. This overestimation cannot be detected in case of lab to lab validation when two centers are using EAC protocol. In case of method validation in Adelaide, those differences were not as obvious as well. The shift of 4.5 (fig. 1) means that results are 2.25 times different from the perfect concordance line and could easily fit into accepted 2-fold and 3-fold compartments. The CF calculated by Adelaide would depend on the percentage of each transcripts among the exchanged samples. The observed artifact should be also taken into consideration in clinical trials that rely on surrogate endpoints such as molecular response level at certain time points. Uneven transcript variant distribution between compared groups may lead to improper conclusions.

ESTABLISHMENT OF IN VIVO AND IN VITRO MODEL OF X-LINKED SIDEROBLASTIC ANEMIA

K. Saito1, T. Fujiwara1, M. Morita2, Y. Okitsu1, N. Fukuhara1, Y. Onishi1, Y. M. Shimizu1, H. Hargatz1

1Hematology and Rheumatology, 2Medical Biochemistry, Tohoku University Graduate School of Medicine, Sendai, 3Cell Engineering Division, RIKEN BioResource Center, Tsukuba, 4Molecular Hematology, Tohoku University Graduate School of Medicine, Sendai, Japan

Background: Congenital sideroblastic anemia (CSA) is an inherited sideroblastic anemia characterized by the presence of bone marrow ring sideroblasts, reflecting excess mitochondrial iron deposition. The most common form of CSA is X-linked sideroblastic anemia (XLSA), which is attributed to mutations in the X-linked gene erythroid-specific 5-aminolevulinic acid synthase (ALAS2). ALAS2 resides on chromosome X and encodes the enzyme that catalyzes the first and rate-limiting steps in the heme biosynthesis pathway in erythroid cells. This pathway converts glycine and acetyl-coenzyme A to 5-aminolevulinic acid (ALA), which requires pyridoxal 5'-phosphate (PLP) as a cofactor. Although PLP has been used for treating XLSA, a marked proportion of patients with XLSA remain refractory to treatment (Ohta et al. Ann Hematol 2013). Thus, there is a need to establish a model of XLSA to reveal the detailed molecular mechanism contributing to RS formation as well as to explore novel therapeutic strategies.

Aims: We explored to establish a novel model of XLSA by CRISPR/Cas9-based genome editing.

Methods: We targeted the GATA-1-binding region of intron 1 of the human ALAS2 gene based on both in vivo mice and human induced pluripotent stem cell-derived erythroid HiDEP cells (Kurita et al. PLoS One 2013). The mutation diminished the binding of transcription factor GATA-1, which would lead to decreased transcription of the ALAS2 gene, thereby causing XLSA (Kaneko et al. Haematologica 2014). Western blotting and quantitative chromatin immunoprecipitation (ChIP) analysis were performed using antibodies against GATA-1 (DSPhD, Cell Signaling Technologies) and TAL1 (C-21, Santa Cruz). For transcription profiling, Human Oligo chip 25K (Toray) was used. Quantitative ChIP analysis demonstrated that the chromatin occupancies of TAL1 in ALAS2 cells, which harbored 19-bp deletion within the intron 1 enhancer region of ALAS2, including GATA binding domain. Whereas wild-type HiDEP cells exhibited red color, the XLSA clone appeared pink/pale color, which were accompanied by the significantly decreased intracellular heme concentration. Despite no obvious changes in the expression of GATA-1 protein in the XLSA clone, quantitative real-time–polymerase chain reaction (RT–PCR) analysis demonstrated significantly downregulated expression of ALAS2 as well as globin genes (HBA, HBG, and HBB) in the XLSA clone. Microarray analysis revealed >2-fold up- and down-regulation of 619 and 274 genes caused by the 19-bp deletion, respectively. The downregulated gene ensemble included globins (HBZ, HBG, HBE, HBB, HB M, and HBQ) as well as genes involved in heme/iron metabolism (ALAS2, transferrin receptor: TFRC, coproporphyrinogen oxidase: CPOX, and mitoferrin 1: MFRT1). GO analysis revealed significant enrichment of cellular iron homeostasis (p=0.018), regulation of transcription (p=0.0021), and innate immune response (p=0.0018), implying that heme was involved in various biological processes in erythroid cells. Interestingly, ALA treatment significantly improved compromised heme production as well as downregulation of globin genes observed in the XLSA clone, suggesting that ALA may represent a novel therapeutic option for PLP-refractory XLSA.

Summary/Conclusions: The XLSA model established from HiDEP cells can be used as an important tool for clarifying the molecular etiology of XLSA and to explore novel therapeutic strategies.

P613

BENDAMUSTINE AND RITUXIMAB COMBINATION THERAPY FOR COLD AGGLUTININ DISEASE: RESULTS OF A PROSPECTIVE NORDIC TRIAL

S. Berentsen1, U. Randen2, M. Oklam3, H. Birgins4, T.H.A. Tvedt5, J. B. Anthonsen6, 7Department of Infectious Diseases, Rikshospitalet University Hospital, Oslo, Norway, 8Department of Hematology and Stem Cell Transplantation, Turku University Hospital, Turku, Finland, 9Department of Haematology, Hertlev Hospital, University of Copenhagen, Herlev, Denmark, 10Department of Medisicne, Haukeland University Hospital, Bergen, 11Medical Department, Drammen Hospital, Vestre Viken Trust, Drammen, 12Department of Medicine, Akershus University Hospital, Nordbyhagen, 13Department of Hematology and Oncology, Stavanger University Hospital, Stavanger, 14Department of Hematology, Oslo University Hospital, Oslo, Norway

Background: Primary cold agglutinin disease (CAD) is an autoimmune hemolytic anemia in which a well-defined clonal lymphoproliferative bone marrow disorder (LPD) causes production of monoclonal cold agglutinins. Major clinical manifestations are anemia and, in some patients, cold-induced circulatory symptoms. Pharmacological therapy, although not indicated in patients with very mild disease, seems required in a majority of cases. Corticosteroids are ineffective. Rituximab monotherapy has resulted in approximately 50% response rate and 1-year median response duration. Fludarabine and rituximab combination therapy showed 70% response rate (20% complete responses) and very long response duration, but considerable toxicity.

Aims: We wanted to investigate whether bendamustine and rituximab combination therapy can result in favorable response rates and duration with an acceptable toxicity profile.

Methods: We conducted a prospective, uncontrolled multicenter trial with 16 participating hospitals from Norway, Finland and Denmark. Essential inclusion criteria were verified CAD with symptomatic anemia and/or severe cold-induced circulatory symptoms. Eligible patients received 4 cycles of rituximab 375mg/m² day 1 and bendamustine 90mg/m² day 1-2 with 28 days interval. Outcomes were evaluated into complete response (CR), partial response (PR), and non-response (NR). The definition of CR included normalization of hemoglobin (Hb) levels with no hemolysis, complete histologic resolution of the bone marrow LDH and disappearance of monoclonal serum protein. The criteria for PR included increase in Hb levels by at least 2.0 g/dL or to the normal range, transfusion independence, at least 50% reduction of IgM and improvement of any circulatory symptoms.

Results: Forty-four patients (19 men and 25 women) were included, with a median age of 74 years (range, 48-86) and median disease duration 4 years (range, 0–18). Seventeen patients had received previous therapy. At baseline, median Hb level was 9.5 g/dL (range, 4.5–14.8), bilirubin 45micromol/L, lactate dehydrogenase (LDH) 468 U/L, haptoglobin undetectable, IgM 4.1g/L(1.0-27.2), CA 15042 (64-65536). Monoclonal IgM kappa was detected in 38 patients, IgG kappa in 1 and IgA kappa in 1. We observed CR in 16 patients (36%), PR in 15 (34%), while the remaining 13 (30%) were non-responders. Hb levels increased by a median of 4 g/dL in the responders; 4 g/dL in patients not achieving CR and 3.9g/dL in those achieving PR. Median post-therapy Hb levels were 14.2g/dL (CR), 12.5g/dL (PR) and 10.5g/dL (NR). Acrocyanosis and Raynaud symptoms resolved completely in 16 patients and improved in 11 (47% and 32%, respectively, of those with such symptoms at baseline). Histologic regresion of the LPD was complete in 17 patients (39%), partial in 5 (11%) and not evaluable in 18 (41%). Median time to response was 2 months (0.5-12). Only 3 responders experienced relapse; 2 after PR and 1 after CR. Median observed response duration was 32 months (range, 1-62) during median 32 months follow-up. A response, complete or partial, lasted longer than 1 year in 12 patients (43%). Neutropenia grade >3 occurred in 14 patients (47%), of which 8 (18%) had grade 4. Three patients (7%) experienced 1-3 episodes of febrile neutropenia, which was readily manageable. Non-hematologic toxicity occurred in 17 patients (39%), mostly consisting of mild nausea or rash. Three non-neutropenic serious adverse events (SAE) were recorded; 1 was considered probably therapy-related.

Summary/Conclusions: Bendamustine and rituximab combination therapy resulted in high response rates, a high rate of CR, long response duration and few relapses during the observation period, with a favorable safety profile. It might be considered in the first line for reasonably fit patients with CAD requiring therapy.

P614

EX VIVO TREATMENT OF RED BLOOD CELLS FROM 15 PYRUVATE KINASE (PK)-DEFICIENT PATIENTS WITH AG-348, AN ALLOSTERIC ACTIVATOR OF PK-R, INCREASES ENZYMIC ACTIVITY, PROTEIN STABILITY AND ATP LEVELS

B. van Orschot1, P.A. Kosinski2, J. Hilton3, K. Johnson2, V. Chubukov2, L. Deng2, G. Pasterkamp1, S. van Straaten14, C. Kung3, R. van Wijk1,*

1Clinical Chemistry and Haematology, University Medical Center Utrecht, Utrecht, Netherlands, 2Agios Pharmaceuticals, Inc., 3KSQ Therapeutics, Cambridge, MA, United States, 4Department of Van Creveldkliniek, University Medical Center Utrecht, Utrecht, Netherlands

Background: Pyruvate kinase (PK) deficiency is a rare hereditary disorder affecting red blood cell (RBC) glycolysis. It is caused by mutations in the PKLR gene. PK-deficient RBCs are characterized by changes in metabolism associated with defective glycolysis, including a build-up of the upstream metabolite 2,3-diphosphoglycerate, and deficiency in the PK product ATP. It is hypothesized that insufficient energy production affects red cell homeostasis, promoting...
premature removal of PK-deficient RBCs from the circulation. Affected patients display chronic hemolytic anemia of variable severity. Treatment of PK-deficient patients is generally supportive, focusing on the anaemia and iron overload state, and there are no approved drugs that directly target mutated PK. AG-348 is an allosteric activator of the RBC isomor of PK (PK-R) and in clinical development for the treatment of PK deficiency.

Aims: To evaluate the effect of AG-348 treatment on PK-R enzymatic function, RBC metabolism and deformability.

Methods: Observational case-control study, approved by the Institutional Review Board. All patients gave informed consent. Enrolled patients (N=15) were adults, transfusion-independent and compound heterozygous or homozygous for PKLR mutations. Baseline metabolic profiling was performed by LC-MS/MS. Purified RBCs from patients and healthy control subjects were incubated with AG-348 (up to 10 μM) for 24 hours at 37°C. After 6 and 24 hours PK-R activity, ATP levels and RBC deformability (by Lorrca) were measured. For determination of PK-R thermal stability, RBC lysates were incubated for 2 hours with 2 μM AG-348 (10°C) prior to test. Baseline protein levels of PK-R were assessed using antibodies against PK-R.

Results: Baseline patient characteristics show strongly reduced PK-R activity in all patient cells, in particular taking into account the degree of reticulocytosis (Table 1). Distinct metabolic changes were consistent with a block of glycolysis at PK-R step. Treatment of PK-deficient RBCs with AG-348 resulted in increased enzymatic activity in all patient cells after 24 hours (mean increase 1.8-fold, range 1.2-3.4). Similar increases were observed in control cells (mean fold increase 2.3, range 1.2-7.1). ATP levels in PK-deficient cells increased upon AG-348 treatment (mean increase 2.2 fold, range 0-2.2) similar to control cells (mean increase 1.6 fold, range 1.4-1.8). Generally, PK-R thermal stability was strongly reduced in PK-deficient patient cells, illustrated by a mean loss of activity of 72% (19% for control cells) after incubation at 53°C for 60 minutes. Ex vivo treatment with AG-348 prior to incubation resulted in residual activity 4 to >10-fold higher than residual activity of vehicle-treated samples. Baseline protein level analyses suggests that a certain level of PK-R protein is required for cells to respond to AG-348 treatment ex-vivo, as treatment effects were minimal in patient cells with very low or undetectable levels of PK-R. In approximately half of the patients, ex vivo treatment with AG-348 was associated with an increase in RBC deformability, although there doesn’t appear to be a clear correlation with enzymatic or metabolic response.

Summary/Conclusions: These data support the hypothesis that drug intervention with AG-348 effectively upregulates PK-R enzymatic activity and increases stability in PK-deficient RBCs over a broad range of PKLR genotypes. The combination of AG-348 with ATP levels and RBC biochemical profile suggests that glycolytic pathway activity may be restored. AG-348 treatment may represent an attractive way to correct the underlying pathologies of PK deficiency.

P615
IDENTIFICATION OF NEW PATHOGENIC MUTATIONS IN PATIENTS WITH RED BLOOD CELL MEMBRANE DISORDERS USING NEXT-GENERATION SEQUENCING

M.D.M. Maufu Pereira1,2, E. LLaudet Planas1, V. Rizzuto1, J. L. Vives Corrons1
1Red Blood Cell Pathology And Hematopoietic Defects, Josep Carreras Leukaemia Research Institute, Barcelona, Spain

Background: Red blood cell (RBC) membrane proteins deficiency or structural alterations lead to RBC membrane disorders such as hereditary spherocytosis, hereditary elliptocytosis or hereditary xerocytosis among others. Genetic analysis of these patients was not usually performed before next-generation sequencing (NGS). Here we present metabolic profiling by Sanger by several membrane related genes, considering that they all contain a high number of coding regions.

Aims: The aim of this study is to perform the molecular diagnosis of the patients included in the study as well as to identify new pathogenic mutations leading to RBC membrane disorders.

Methods: 116 patients from 74 unrelated families were studied with a next generation sequencing (NGS) based panel that contained genes already described as disease causing for RBC membrane disorders (ANK1, EPB41, EPB42, SLCA4A1, SPTA1, SPTB, PIEZO1, KCNN4, RHAG) as well as for enzyme deficiencies (ADA, AK1, ALDOA, BPGM, CYB5A, G6PD, GCLC, GPI, GSR, GSS, HK1, NTS3CA, PFKM, PKG1, PKLR, TP11), hemoglobinopathies (HBA1, HBA2, HBH) and congenital disserethropoietic anemias (CDAN1, C15orf41, SEC23B, KLFL1, GATA1, KIF23).

Results: A total of 74 pathogenic variants leading to RBC membrane disorders were identified, of which 14 had already been reported as disease causing. Of the remaining 60 variants, 42 had never been identified neither by 1000G or ExAC projects and therefore are novel mutations. Beta-spectrin, ankyrin and alpha-spectrin were the proteins that gathered most part of the mutations, we identified 23 variants in SPTB, 20 variants in ANK1 and 16 variants in SPTA. 48% (36/74) of the identified variants were missense changes, mostly from SPTB gene (11 genes), while a 38% (28/74) of the variants were nonsense or frameshift mutations, mostly from PKLR (9 variants). Of special interest, only 2 variants were identified in more than one unrelated family: 1) SPTB c.647T> A, leading to splicing disorder, was identified in 8 patients of 2 unrelated families, 2) SPTA1 c460_462dupTTG, leading to elliptocytosis, was identified in 6 patients from 5 different unrelated families.

Conclusion: These data support the hypothesis that drug inter-
Results: Table 1 shows clinical and laboratory characteristics of AIHA cases at onset and distribution of thermal types. Hb values were significantly lower in IgG+C wAIHA and atypical cases (p<0.001), LDH higher in IgG+C wAIHA, mixed and atypical forms (p=0.01), and Hb and LDH values were negatively correlated (r=-0.25, p=0.001). Absolute reticulocytes were reduced in CAD, mixed and IgG+C wAIHA (p<0.001) together with inadequate reticulocytosis (p=0.01). Moreover, the reticulocyte index was lower in cases with Hb<6 g/dl (65 vs 98, p=0.01), along with more frequent inadequate reticulocytosis (87 vs 70%, p=0.01). First line therapy was administered in almost all cases but 25 CAD. A second therapy line was mostly required in IgG+C wAIHA, mixed, and to a lesser extent in CAD (p=0.005). The ultra-refractory cases requiring 4 or more lines of therapy were mainly mixed, atypical and CAD. Considering anemia severity, patients with Hb>8 g/dl, more frequently required treatment after first-line (51 vs 33%, p=0.004; p=0.03), or even 3 or more therapy lines (52/71, 73% vs 19/71, 26%, p=0.001). The following hazard ratios (HR) emerged from multivariate Cox regression analysis: HR 3.2 (95% CI 1.4-7.9, 2.9 (1.4-6.2), 3.4 (1.6-7.5), for Hb <6, 6-8, and 8-10 g/dl, compared to patients with Hb >10, respectively. As regards complications, infections were observed in 14% of cases, mostly mixed AIHA (p=0.02); thrombosis occurred in 10% and acute renal failure in 3% of patients, with no relationship with AIHA type/Hb values. Evans’ syndrome was more frequent in mixed or atypical cases (p=0.04) and in severe forms (74% with Hb<8 g/dl vs 26%, p=0.005), and was associated with higher relapse risk (HR 2.3, 95% CI 1.4-3.9). Seventy patients died during the follow-up, and 12 because of AIHA-related acute complications. Higher mortality was observed for infections (HR 5.8, 95% CI), acute renal failure (HR 7.6, 95% CI) and Evans’ syndrome (HR 8.3, 95% CI).

Summary/Conclusions: In conclusion, we found that severity of anemia at onset was the major determinant of relapse risk. The lowest Hb levels were observed in patients with IgG+C wAIHA and atypical cases along with higher LDH levels and inadequate reticulocytosis, advising strict clinical observation in these patients.

P617
HEMЕ BINDS ANNEXIN-A5 DURING HEMOLYSIS AND PREVENTS ITS INTERACTION WITH CELL MEMBRANE PHOSPHATIDYLSERINE DURING SICKLE CELL DISEASE
S. Sadoudi1, S. Le Jeune2, D. Charue1, L. Kiger3, L. Roumenina4, C. Boulanger1, O. Blanc-Brude1,*

Background: Intravascular hemolysis, such as in sickle cell disease (SCD), is characterized by damage to red blood cells and extracellular vesicles in plasma, along with inflammation and tissue injury. Stressed leukocytes, platelets, endothelial and red blood cells shed microparticles (MP) that bear externalized phosphatidylserine (PS) at their surface and promote tissue injury. Conversely, intracellular annexin-A5 acts as an inhibitor of externalized PS, and is a key player in the process of transendothelial vesicle trafficking, promote cell membrane repair, protect against PS-mediated effects and enforce anti-inflammatory and anti-thrombotic control.

Aims: We investigated a possible functional relationship between intravascular hemolysis and annexins. We hypothesized that annexins, and annexin-A5 activity in particular, is blocked by intracellular heme as it is released in plasma during intravascular hemolysis.

Methods: In order to test the heme-annexin-A5 relationship, we measured PS, PS+, CD235a+ and annexin-A5+ circulating MP in adult SCD patient and matched control plasmas. We explored annexin-A5 expression in plasma and blood cells by Western blots and ELISA, and also quantified the PS-binding functionality of plasma annexin-A5 using a self-designed immunocapture assay and purified PS+ MP. Moreover, we investigated molecular interactions between purified heme and recombinant human annexin-A5 by surface plasmon resonance (BiaCore and Proteon), absorbance shift assay and protein autofluorescence quenching. Finally, we put forward a model of heme-annexin-A5 docking by 3D molecular rendering.

Results: Immunocapture of plasma annexin-A5 revealed an association with heme (Abs398 nm signature) during SCD, especially during acute hemolytic events. In SCD plasma, we found increased total annexin-A5, but virtually unde-}

haematologica | 2017; 102(s2) | 243

 Madrid, Spain, June 22 – 25, 2017
ening anemia) considered related to study drug were reported in 2/10 patients. Increases in mean arterial pressure were anticipated due to the oncotic effects of this colloidal drug, but with no consistent pattern to the changes. Changes in ECG intervals were seen in a few subjects, but those changes were not considered clinically meaningful. There were no clinically meaningful changes in laboratory values, physical examinations, or concomitant medications. There were no statistically significant changes from Baseline in leg ulcer pain and wound surface area for either Cohort. All of the wound assessments remained relatively consistent throughout the study. There were slight decreases in total VCSS at most time points, indicating slight improvement in vascular status. Results were similar for the individual scores. Summary/Conclusions: The administration of 4 or 6 once-weekly infusions of PEG-COHb at a dose of 320mg/kg was generally well tolerated. Slight improvements in total and individual VCSS are promising and may warrant further study with prolonged repeated doses of PEG-COHb.

P619
NON-RENAL DETERMINANTS OF ENDOGENOUS ERYTHROPOIETIN LEVELS IN SICKLE CELL DISEASE
K. Gardner1,2,*, C. Sharpe3,4, M. Awogbade1
1Haematological Medicine, King’s College Hospital, 2Molecular Haematology, King’s College London, 3Renal Medicine, King’s College Hospital, 4Renal Medicine, King’s College London, London, United Kingdom

Background: Sickle cell disease (SCD) is characterized by chronic hemolysis and inflammation. Elevated levels of erythropoietin (EPO) drive expansion of erythropoiesis to compensate for increased red cell destruction. EPO is produced in response to anemia and tissue hypoxia. Previous studies in SCD suggest that EPO is inappropriate low for the degree of anemia but the reasons are unclear.

Aims: To perform a retrospective analysis of data collected as part of routine clinical care to examine the relationship between serum EPO and degree of anemia, inflammation status, hemoglobin status, alpha globin status, and renal function.

Methods: King’s College Hospital (London, UK) has a large SCD population. All patients with HbSS or HbSBthalassemia who had a serum EPO level measured between 2007 and 2013 were included. Sickle genotype, alpha globin genotype, “baseline” HbF (no hydroxycarbamide, transfusion or pregnancy) and demographic data were recorded. Other clinical variables were obtained from the same day as EPO levels (medications, laboratory values and oxygen saturation). Serum EPO was measured by chemiluminescence immunoassay (Siemens Immulite XPi). Exclusion criteria were: active vaso-occlusive crisis, transfusion within 8 weeks, chelation, erythropoiesis stimulating agent therapy, home oxygen, pregnancy and renal disease (eGFR<60mls/min or urine albumin creatinine ratio>30). Data analysis was performed in IBM SPSS Statistics 22.

Skewed variables were log transformed and estimated GFR was calculated using the MDRD formula. Normalized variables were correlated with Ln EPO using Pearson’s correlation, ordinal variables using one way ANOVA, and binary variables using independent samples 2-tailed t-test. Multivariate linear regression using Ln EPO as the outcome was performed.

Results: 245 adult (≥17 years) SCD patients (all of African or African-Caribbean origin) met the inclusion criteria. Of the 245, 241 had HbSS and 4 HbSβ0, 100 patients had no renal disease (eGFR>60mls/min or urine albumin creatinine ratio<30). Univariate analysis revealed a weak/moderate negative association between Ln EPO and HbF (r=-0.38, p<0.001). Significant associations were also seen between Ln EPO and negative correlation with PCV, oxygen saturations, Ln HbF, and positive correlation with Ln CRP, LDH, STFR, Ln uACR, cystatin C. One way ANOVA showed alpha globin status to be associated with EPO (higher EPO with more alpha chains). There was no significant association between EPO and: age, sex, eGFR, white cell count, and use of hydroxycarbamide. Multivariate linear regression (N=175) revealed alpha globin status, Hb, HbF and CrP to be independently associated with Ln EPO level, see table.

Summary/Conclusions: In our SCD cohort without renal dysfunction EPO was elevated. Unlike the non-sickle setting where Ln EPO is very strongly (negatively) correlated with Hb levels, in our SCD cohort we have found only a mild/moderate correlation. Instead, additional associations were seen between EPO and alpha globin status, CrP and HbF. Our findings suggest that in addition to Hb, other SCD severity markers influence EPO production. This may provide explanation for relative EPO deficiency, and have implications for considering therapeutic EPO in SCD.

Background: Adult T cell leukemia/lymphoma (ATL) is an aggressive peripheral T-cell neoplasm caused by HTLV-1 virus infection and its prognosis remains very poor. Tax, which is the most important regulatory protein of HTLV-1, is associated with the development of ATL and is also a biologically active protein for CD8+ cytotoxic T-cells (CTLs). We previously analyzed the Tax-specific T-cell receptor (TCR) repertoire, phenotypes and functions of Tax-specific CTLs at the single-cell level in HLA-A24+ ATL patients who underwent allogeneic stem cell transplantation (allo-SCT). We found that a particular amino acid change in the TCR-β sequence motif (PDR) in the CDR3 region of TCR-β was conserved in different patients and also within the same patient before and after allo-SCT, and the PDR(+)-specific T-cell CTL clone selected expanded in ATL long-term survivors as less-differentiated effector memory CTLs. Actually, the PDR(+) CTL showed not only strong binding activity for the Tax-tetramer but also strong killing activity against patients' HTLV-1-infected T-cells without any reaction against normal cells.

Aims: Currently, we are planning a redirected T-cell immunotherapy using the PDR(+) TCR genes for ATL. Therefore, we prepared donor-derived PDR(+) TCR-transduced T-cells and evaluated their cytotoxic efficiency against HTLV-1-infected T-cells and ATL-cells both in vitro and in vivo mouse model.

Methods: HLA-A24:02 restricted and Tax301-309-specific TCR-α/β genes were cloned from an established PDR(+) CTL clone and integrated into a retroviral vector (Tax-siTCR vector) encoding small-interfering RNAs (siRNAs) to knockdown endogenous TCR genes for the efficient expression of therapeutic TCRs. Then, CD8+ T-cells of healthy volunteers were transfected with Tax-siTCR vector (Tax-siTCRs). First, cytotoxicity and cytokine production capability of the Tax-siTCRs against HTLV-1-infected T-cells or ATL-cells were evaluated using calcine-AM-based assay and flow-cytometric analysis, respectively. Next, to evaluate the in vivo anti-ATL effects by the Tax-siTCRs, the bioluminescence assay (in vivo imaging system) was performed. We generated a luciferase-gene transduced HLA-A24+HTLV-1 infected cell-line, MT-2 (Luc-MT-2), and injected 1×10⁶Luc-MT-2 cells into six-week-old NOD/Shi-scid,IL-2RγKO Jic (NOS) mice intraperitoneally. After the 3 weeks, 2×10⁵Tax-siTCRs were administered intraperitoneally, for a total of 3 times of administration, non-integrated T-cells (Mock) were administered in the same way. These mice were monitored for tumor growth using IVIS system weekly.

Results: Tax-siTCRs showed specific and strong killing activity against both HTLV-1 infected T-cells and patients' ATL-cells without any reaction against control normal-cells. In addition, Tax-siTCRs produced a sufficient amount of cytokines such as IFN-γ, TNF-α, and IL-2 against HTLV-1 infected T-cells. In mice experiments, the bioluminescence of Luc-MT-2 in the mice treated with Tax-siTCRs had started to reduce gradually after 7 weeks, and finally became undetectable after 9 weeks. In addition, macroscopic anatomical findings in the treated mice were normal after 12 weeks. In contrast, the amount of bioluminescence in the mice treated with Mock or in the control mice without treatment had rapidly increased and all mice died by 9 weeks.

Summary/Conclusions: We confirmed that Tax-siTCRs could exert a strong anti-ATL effect without significant reaction against normal cells both in vitro and in vivo. The therapy using this PDR+ Tax-siTCRs has a potential to be a novel immunotherapy for ATL patients.

NHEJ-BASED GENE EDITING: A NOVEL GENE THERAPY APPROACH IN FANCONI ANEMIA HEMATOPOIETIC STEM PROGENITOR CELLS

F.J. Roman-Rodriguez1,2, B. Diez1,2, L. Alvarez1,2, C. Risueño1,2, R. Torres-Ruiz3, M. Corton2, C. Diaz de Heredia4, J. Sevilla5, C. Ayuso2, J. Bueren1,2, P. Rio1,2

Background: Allogeneic transplantation of hematopoietic stem and progenitor cells (HSPCs) is the only current curative treatment for the bone marrow failure of patients with Fanconia Anemia (FA). However, the risks of GVHD and increased incidence of subsequent cancer, and the limited availability of matched donors hamper the widespread application of this therapy in FA patients. For this reason correction of patients' HSPCs by gene therapy is considered a promising therapeutic alternative for these patients. In this context, gene editing constitutes a new step in the development of safe gene therapy approaches. Since non-homologous end joining (NHEJ) is the preferred DNA repair mechanism in HSPCs, and given that this mechanism has an important role in the maintenance of genomic stability, we have tested the efficacy of a NHEJ-mediated gene editing approach to generate compensatory mutations that can restore the FANCA protein function in HSPCs from FA patients, mimicking reversions observed in mosaic patients.

Aims: To demonstrate the feasibility of using a NHEJ-based gene editing strategy to correct FA-A HSPCs as a result of the insertions and deletions (INDELs) generated in edited FANCA sequences in these cells.

Methods: Two different FANCA mutations from FA-A patient-derived lymphoblastic cell lines (LCLs) and primary HSPCs were targeted by the CRISPR/Cas9 system. INDELs generated as a consequence of the NHEJ mechanism were analyzed at different time points.

Results: Initial studies conducted in a FA-A LCLs carrying the biallelic c.295C>T point mutation that generates a premature stop codon (p.Q99X) showed targeting efficiencies around 20%. Next Generation Sequencing (NGS) not only revealed the presence of frame-restoring repair events, but also that these events were conserved in different patients and also within the same patient before and after allo-SCT, and the PDR(+)-specific T-cell CTL clone selected expanded in ATL long-term survivors as less-differentiated effector memory CTLs. Actually, the PDR(+) CTL showed not only strong binding activity for the Tax-tetramer but also strong killing activity against patients' HTLV-1-infected T-cells without any reaction against normal cells.

Summary/Conclusions: Our results demonstrate the feasibility of the approach, a second FANCA gene correction was obtained, producing a frameshift and a premature stop codon (-p.R1187FesX2B)- with even higher gene targeting efficiencies. Finally similar studies were conducted in three HSPCs samples from FA-A patients harboring the c.295C>T mutation, that showed targeting efficiencies up to 36%. Moreover, NGS detected the presence of corrective NHEJ-repair events immediately after editing and evidence to 50-fold expansion of corrected cells after nine days in culture, confirming the functionality and proliferative advantage conferred by the frame restored alleles.

Aims: We tested the hypothesis that bi-specific CAR NK cell-targeting CAR INVARIANT NKT CELLS EXPRESSION FOR CD1D+ B CELL MALIGNANCIES

A. Rotolo1, O. Dubois1, K. Goudevenou1, K. Petev1, G.W. Cheung2, M. Pule2, J. Mahera5, A. Karadimitris1
1Medicine, Imperial College London, London, UK, 2University College London, 3King’s College London, London, United Kingdom

Background: Adult T cell leukemia/lymphoma (ATL) is an aggressive peripheral T-cell neoplasm caused by HTLV-1 virus infection and its prognosis remains very poor. Tax, which is the most important regulatory protein of HTLV-1, is associated with the development of ATL and is also a biologically active protein for CD8+ cytotoxic T-cells (CTLs). We previously analyzed the Tax-specific T-cell receptor (TCR) repertoire, phenotypes and functions of Tax-specific CTLs at the single-cell level in HLA-A24+ ATL patients who underwent allogeneic stem cell transplantation (allo-SCT). We found that a particular amino acid change in the TCR-β sequence motif (PDR) in the CDR3 region of TCR-β was conserved in different patients and also within the same patient before and after allo-SCT, and the PDR(+)-specific T-cell CTL clone selected expanded in ATL long-term survivors as less-differentiated effector memory CTLs. Actually, the PDR(+) CTL showed not only strong binding activity for the Tax-tetramer but also strong killing activity against patients' HTLV-1-infected T-cells without any reaction against normal cells.

Aims: We tested the hypothesis that bi-specific CAR NK cell-targeting CAR INVARIANT NKT CELLS EXPRESSION FOR CD1D+ B CELL MALIGNANCIES

Methods: We optimized a novel protocol for manufacturing 2nd (CAR2) and 3rd (CAR3) iNKT cells expressing CAR19. Their in vitro reactivity was assessed in cytotoxicity (flow cytometry-based) and cytokine and cytotoxic granule release assays (intracellular staining and Luminex technology). In vivo reactivity was assessed in NSG xenograft assays, with monitoring of 1T1C1D1 tumour cell expansion and immune biomarkers.

Results: Our optimized protocol for selection, lentiviral transduction and clinical scale expansion of CARiNKT cells within 3 weeks is suitable for frozen and fresh lymphocytes, derived from either healthy donors or cancer, including lym-

haematologica | 2017; 102(s2) | 245
phoma patients. The manufacturing process consistently allows high CAR transduction efficiency of both T and NK cells (75.31%±4.294 and 76.95%±14.76 respectively, n=8) and ensures the preservation of CD4− iNKT cells, which have a higher cytotoxic potential and anti-tumour activity. In vitro validation, using singly- or dual-positive CD19 and CD19 targets, demonstrated that CARiNKT19 cells are CD19-specific, retain their natural CD19 specificity, and exert additive dual-specific cytotoxicity against CD19+CD19+ targets. Additional functional dissection showed that activated CARiNKT19 cells, both fresh and cryopreserved, have the ability to produce cytotoxic granules and IFNγ faster and in larger amounts than same donor activated CAR19 cells. Likewise, CAR2- and CAR3-iNKT cells are equally or more effective than their CAR1 counterparts in killing CD19+CD19− lymphoproliferative and cancer cell lines (B-lymphoblastoid C1RC1d and lymphopoma-derived Farage cells) and consistently more effective against primary MCL, MZL and CLL cells. Finally, in an in vivo NSG xenograft model of lymphoma, while survival of T- and NKT cell-treated animals was the same as that of untreated animals (P=0.23), both CAR19- and CAR19 cell-treated animals had significantly and comparably improved overall survival (P<0.001). However, compared to CAR19, CARiNKT19 immunotherapy led to a better disease control, with earlier, more profound and sustained responses resulting in a significantly improved tumour free-survival (P=0.03).

Surrogate cytokines: In our pre-clinical in vitro and in vivo lymphoma models, CARiNKT19 are more effective than CAR19 cells against CD19+CD19+ B cell malignancies. Further, dual targeting by CARiNKT19 cells may mitigate against CD19-focused tumour escape after CAR immunotherapy, while the previously demonstrated role of donor iNKT cells in protection from aGVHD supports the development of CARiNKT19 cells for 'off-the-shelf' use.

**Summary/Conclusions:** T cells transduced with NKp44-based CARs show enhanced activities against various tumor cells. The extracellular hinge region of NKp44 appears to play an important role in ligand binding and/or recognition. NKp44-based CARs may represent a promising candidate for novel immune therapies targeting a wide range of cancers.

**NKp30-CAR REDIRECTED HUMAN T LYMPHOCYTES INDUCE POTENT ANTITUMOR IMMUNITY TO LEUKEMIA CELL LINES AND PATIENT-DERIVED ACUTE MYELOID LEUKEMIA IN NSG XENOGRAFT MODELS**

P. Pichl 1, S.A. Khan 1, M. Theobald 1, U. Hartwig 1, 2

1III. Dept. of Medicine - Hematology, Internal Oncology & Pneumology, University Medical Center Mainz, Mainz, Germany
2German Cancer Consortium (DKTK), partner site Frankfurt / Mainz, German Cancer Research Center (DKFZ), Heidelberg, Germany

**Background:** Adoptive cellular therapy (ACT) of chimeric antigen receptor (CAR) redirected T cells has evolved as a highly effective individualized immunotherapy for leukemia and solid cancer. In particular, clinical trials using CD19 expressing T lymphocytes to combat CD19+ lymphomas have revealed compelling results. However, suitable antigens for an effective and specific CAR-mediated therapy to acute myeloid leukemia (AML) are still warranted as e.g. CD33 and CD123 CAR expressing T cells induce potent immune responses in AML. In contrast, B7H6, a member of the B7 family, is frequently co-expressed in various tumor cell lines including AML blasts while not detectable on normal tissues, and is recognized by the natural killer (NK) cell activating receptor NKp30. Moreover, NKp30 recognizes human leukocyte antigens (HLA)-B-associated transcript 3, a nuclear factor that is secreted and translocated to the cell surface in stressed and transformed cells.

**Aims:** In the current study, we thus explored the use of human T cells redirected to express a NKp30-CAR for inducing effective antileukemic immunity in vitro and in vivo in the xenogenic mouse model of AML. We thus aimed to enable the development of an effective ACT approach utilizing the NKp30 receptor for AML.

**Methods:** Human T cells from healthy donors were stimulated with anti-CD3/CD28 beads and recombinant interleukin-2. Human NK cells were stimulated using K562-mb15-41BBL feeder cells, as previously reported (Imai C, 2005). Activated T cells or NK cells were then subjected to retroviral transduction with the CAR gene and the phenotypic and functional characteristics of CAR-T cells engrafted with the NKp30 receptor fused to the CD3ζ chain signaling domain (kindly provided by Dr. D. Masch, Dept. of Internal Medicine 3, Medical University Regensburg, Germany) by retroviral gene transfer. Transduced T cells were further selectively expanded utilizing puromycin resistance present on the retroviral backbone, and NKp30 expression was determined by flow cytometry. IFN-γ ELISPOT analyses and cytotoxicity assays were performed to assess antileukemic responses to leukemia lines and primary AML blasts in vitro and in vivo using NSG xenografts and adoptive transfer of redirected T cells. Expression of B7H6 in target cells was confirmed by RNA-based RT PCR.

**Results:** Following transduction and puromycin selection ≥90% of CD3+ T cells expressed the NKp30 CAR. In addition, most T cells displayed an effector-mem- rory phenotype. Upon co-culture with the B7H6 expressing targets such as K562 and HL-60 (myelogenous leukemia cell lines), NALM 16 (pre-B-ALL) and patient-derived AML samples (e.g. MZ506 and MZ5087) NKp30 redirected T cells elicited potent IFN-γ release and exhibited cytolytic activity to both leukemia lines and primary AML blasts in vitro. These responses were specific as e.g. no reactivity to B7H6 negative myeloma line U266 was observed. We then evaluated antitumoral responses of NKp30 redirected T cells in vivo. Upon adoptive transfer of NKp30-CAR T cells into NSG mice engrafted with K562 significant reduc- tion of tumor burden was observed. Moreover, injection of 1 - 5x106 HLA- A2-expressing MZ506-30-CAR redirected T cells into NSG mice showing up to 5% engraftment of patient derived AML blasts and thus resembling a clinically relevant minimal residual disease status at time of ACT resulted in clear leukemiam regression. Further experiments e.g. to elaborate to what extent CD4+ and CD8+ T cells contribute to this antileukemic immunity are in progress.

**Summary/Conclusions:** These studies demonstrate that human T lymphocytes can be successfully redirected to acute leukemia by NK cell activating receptor based CARs such as the NKp30-CAR. As its ligand B7H6 has not been reported to be expressed on CD34+ HSC, this antigen might be an interest- ing target for adoptive immunotherapy to AML.

**PRECLINICAL TESTING OF ADOPTIVE T-CELL RECEPTOR GENE TRANS- FER IN COMBINATION WITH CHECKPOINT INHIBITORS AS A NOVEL THERAPY FOR MULTIPLE MYELOMA**

H. Echchannahuıı 1, 2, E. Amann 1, 2, E. Antunes 1, M. Theobald 1, 2

1Third Department of Medicine (Hematology, Oncology & Hemostasis), University Medical Center Mainz, Mainz, Germany
2German Cancer Consortium (DKTK), partner site Frankfurt / Mainz, German Cancer Research Center (DKFZ), Heidelberg, Germany

**Background:** Adoptive cellular therapy (ACT) based on T-cell receptors (TCR) or chimeric antigen receptor (CAR)-engineered T cells has achieved tremendous success in the treatment of cancer, especially B-cell malignancies. The
impressive therapeutic results recently obtained with checkpoint inhibitors have opened a new era in the field of cancer immunotherapy. Yet, clinical responses are still often observed either transiently or in a minority of patients. This under- scores the need for an improved understanding of underlying factors limiting the efficacy of T cell-based immunotherapy and its wide application.

**Aims:** We explored an immunotherapeutic combination strategy to unleash the full power of anti-tumor function of adoptively transferred antigen-specific T cells. We propose to target multiple myeloma (MM) tumor cells in our established xenograft in vivo adoptive cell therapy model by T cells equipped with two optimized TCRs specific for HLA-A2.1-restricted MM2 and p53 peptides in combination with checkpoint inhibitors.

**Methods:** Human T cells from healthy donors were retrovirally transduced with MM2- and p53-specific TCRs and expression levels were analyzed by flow cytometry. MM2 and p53 protein expression in MM cell lines was determined by Western blot. The therapeutic efficacy of adoptive TCR transfer was evaluated in NOG-scid IL2R gamma chainnull (NSG) mice engrafted with HLA-A2.1-expressing MM cell line. In the adoptive transfer approach, mice were treated (ip) with anti-PD-1 (Nivolumab). Tumor growth was monitored and intratumoral alterations (in particular expression of relevant tumor and T cell antigens) in ex-vivo tumors were analyzed by flow cytometry. Tumor-infiltrating lymphocytes (TILs) were also characterized by flow cytometry.

**Results:** Adoptive transfer of dual MM2/p53-specific TCR-equipped T cells showed a superior anti-tumor response in vivo compared to single TCR treatment, demonstrating the need to target multiple MM antigens to circumvent tumor escape mechanisms associated with down-regulation of antigen. Yet, we observed a strong up-regulation of PD-1 expression in tumor cells in vivo and in TILs in tumors compared to cell lines which may limit the efficacy of antigen-specific TILs. Accordingly, in vivo ACT experiments combined with anti-PD-1 inhibitor, demonstrated the synergistic therapeutic potential of this approach as compared to single agent. Yet, it does not result in complete tumor eradication suggesting that targeting one single immune checkpoint receptor is not sufficient to cure this tumor resistant MM disease.

**Summary/Conclusions:** Combination checkpoint inhibitor approach has demonstrated promising potential in our ACT experimental MM model and forms the basis for a novel multi-modal immunotherapeutic combination treatment for multiple myeloma.

**P628 ENGINEERED T CELLS TOWARDS BAFF RECEPTOR: A NOVEL STRATEGY TO EFFICIENTLY TARGET B-CELL ACUTE LYMPHOBластIC LEUKEMIA N. Turazzi1,*, G. Fazio1, V. Rossi1, A. Rolink2, G. Cazzaniga1, A. Biondi3, C.F. Magnani1, E. Biag1

**Background:** Multiple myeloma (MM) is a malignant B-cell neoplasm of plasma cells. Although characterized by impressive response to novel agents, the resistance to current treatments is associated with deleterious mutations and emergence of alternatively spliced RNA isoforms, as effect of selective pressure. MM4,5 In the context of B-ALL leukemic cells expressed both BAFF and BAFF-R, R suggesting the presence of an autocrine signalling loop6,7. BAFF is also expressed in bone marrow microenvironment by endothelial cells which support the proliferation and the survival of primary B-ALL blasts.8

**Aims:** In the current study, we aimed to develop a chimeric antigen receptor (CAR) immune therapeutic approach targeting the BAFF-R molecule.

**Methods:** We characterized the expression of BAFF-R in B-ALL primary samples. As immunotherapeutic approach to target BAFF-R molecule, we developed six anti-BAFF-R.CARs that differ for the inversion of the VH and VL and the length of the spacer domain have been generated. Cytokine-induced Killer (CIK) cells, engineered using an improved Sleeping Beauty (SB) transposon system, stably expressed anti-BAFF- CARs, and maintained their characteristic phenotype. Among the newly constructed CARs, the shortest VHL anti-BAFFR.CAR exerted the highest antileukemic activity towards target cells, such as NALM-6, with an in vitro killing efficiency of 90% at 6 days post-infusion. Effectors function in terms of cytokine release by intracellular staining (8,9±2% of IFN-γ and 16,4±5% of IL-2 producing cells). Importantly, we also detected a specific cytotoxic activity towards primary B-ALL blasts (average 65,6±4,5%, n=9). Combining the IV.vsh.CAR with CD19.CAR we detected a superior antitumor activity towards ALL targets (average 72,2±2,9% of the tumor lysed by IV.vsh.CAR in NALM-6 and primary B-ALL blasts) compared to single population per se. Furthermore, by using a sample collected from a patient relapsed with CD19 negative disease, we demonstrated the ability of the IV.vsh.CAR to lyse CD19-negative blasts.

**Summary/Conclusions:** Taken together, these findings make this receptor a suitable target to re-direct the adoptive CAR strategy in case of relapse after CD19-targeting therapies or for a double targeted approach. Being restricted to mature B cells, but absent on precursors and plasmablasts, our strategy could have an inferior toxicity concerning the emergence of B-cell aplasia observed in patients treated with anti-CD19 CAR-modified T cells.

**P629 EXPLORING HUMAN TCR- AND CAR-REDIRECTED INKT CELLS FOR ADOPTIVE CELLULAR THERAPY B. Mir1, S. Khan1, M. Theobald1, U. Hartwig1,2

**Background:** T cell receptor (TCR) - or chimeric antigen receptor (CAR) redirected T cells have substantially improved adoptive cellular therapy (ACT) for hematological malignancies such as B-ALL, B lymphoma, chronic lymphocytic leukemia and MZ653 and NALM-16 in vitro. Studies to examine their cytotoxic potential potential of ex vivo expanded redirected lymphocytes limits their therapeutic potential and consistent efficacy. Invariant (type I) natural killer T (INKT) cells have been demonstrated not only to promote effector functions of dendritic cells (DC), natural killer (NK) cells and T cells but also to localize to tumors and have inherent antitumor properties. Moreover, as these cells are further restricted to the monomorphic, HLA class I-like CD1 molecule expressed only on few cells with limited alloreactive potential, all these features make INKT cells as attractive alternative carriers for redirected cellular therapy.

**Aims:** In the current proof of concept study we therefore explored human, AML-reactive TCR- and CD19 CAR-redirected INKT cells for their potential to induce antitumoral responses to leukemia cell lines as well as patient derived, primary AML blasts.

**Methods:** INKT cells expressing the invariant TCR composed of the VZ42Ja18/VB11 chains were immunologically isolated from PBMC derived from adult healthy donors using V B11-Ab (VB11-conjugated, anti-INKT microbeads (Miltenyi Biotech) and expanded in vitro upon coculture with autologous monocytes (Mo) loaded DC with low amounts of interleukin (IL)-2. INKT cells were retrovirally transduced on day 6 after stimulation and selected for TCR or CAR expression utilizing a virally transduced puromycin resistance. While phenotypic analyses on INKT markers and on the percentage of redirected cells were performed by flow cytometry functional assay for antileukemic cytotoxicity EL. In vitro cytotoxicity was assessed using CD19* NALM-16 (pre-B ALL) and primary AML (M2653) cells as targets.

**Results:** Following isolation of 0.7 - 0.8 x10^6 VZ42Ja18/VB11* INKT cells from PBMC we achieved on average a 120-fold expansion 21-28 days after stimulation with GalCer loaded, irradiated autologous DC and 25 U IL-2. Additional use of lenalidomide to promote expansion as described previously had no effect. Expanded INKT cells were mainly CD4+ (83%) and about 80% of cells expressed the natural killer receptor CD161 described as iNKT maturation marker. Upon coculture with autologous AML blasts, primary AML cells showed a superior anti-tumor response compared to single TCR treated cells. Importantly, we also detected a specific cytotoxic activity towards ALL targets as well as patient derived, primary AML blasts.

**Summary/Conclusions:** These studies demonstrate that purified human VZ42Ja18/VB11* INKT cells expanded from PBMC can be successfully redirected to recognize normal or leukemic AML cells but achieve good responses only in combination with redirected T cells as combination immunotherapy.

**P630 SPECIFIC TARGETING OF ACUTE MYELOID LEUKEMIA BY THE USE OF ENGINEERED CIK (CYTOKINE-INDUCED KILLER) CELLS EXPRESSING THE ANTI-CD33 CHIMERIC ANTIGEN RECEPTOR (CAR) M.C. Rotiroti1, S. Arcangeli1, C.F. Magnani1, C. Cappuzzello1, A. Biondi1, S. Tettamanti1, E. Biag1
Background: Acute Myeloid Leukemia (AML) is an aggressive malignancy still associated with high relapse rates when treated with conventional chemotherapeutic and hematopoietic transplantation regimens. In search for alternative therapies of interest has been placed on anti-CD33-specific immunotherapies and in particular on T cells redirected with Chimeric Antigen Receptors (CARs) that have shown exciting results in cancer therapy, especially in the context of B-cell malignancies. CD33 is the only validated target in AML so far and represents a suitable antigen to be targeted with CAR-T cells, being broadly expressed on AML blasts.

Aims: The aim of the present study is to preclinically evaluate the efficacy and safety profiles of CD33 CAR redirected Cytokine Induced Killer (CIK) cells alone and in combination with standard chemotherapeutic agents.

Methods: Here we proved the feasibility of harnessing Cytokine Induced Killer (CIK) cells as part of an immunotherapy protocol with a third generation anti-CD33 CAR through the non-viral Sleeping-Beauty transposon system, starting from fresh and frozen healthy mononuclear cells (PBMCs) and also from frozen primary AML samples. The in vitro anti-AML activity of CD33.CAR.CIK cells is assessed by means of cyto-toxicity, proliferation and cytokine production assays upon challenge with AML cell lines or primary samples. The in vivo efficacy of CD33.CAR.CIK cells is evaluated in NSG mice transplanted with AML cell lines (MA9-NRas) and primary samples. Moreover, to investigate the potential benefit of CD33.CAR CIK cell immunotherapy in combination with standard-of-care treatments, xenograft chemotherapy models are exploited, by using standard AML induction therapy drugs (Ara-C and doxorubicin).

Results: CD33.CAR.CIK cells were able to induce a potent anti-leukemic activity as compared to unmanipulated CIK cells, in terms of specific killing (up to 70%), proliferation (up to 40% of Ki67+CAR-CIK cells) and cytokine production (up to 30% for both IL-2 and IFN-gamma producing CAR-CIK cells) when challenged with both AML cell lines and primary leukemic cells. By treating AML-NRas cell grafted mice with the already established “5+3” induction chemotheraphy protocol, we confirmed that chemotherapy is able to significantly reduce the leukemic burden from around 20% to 0.1% in the bone marrow. Since the AML disease is not totally eradicated, this model will be therefore suitable to further investigate the efficacy of the CD333.CAR.CIK cells immunotherapy on the chemotherapy resistant/residual AML cells.

Summary/Conclusions: Having demonstrated the significant in vitro anti-leukemic activity of SB-modified CD33.CAR.CIK cells we next aim to assess their efficacy in vivo, particularly against the resistant/residual AML cells that were not eradicated by standard chemotherapy treatment. Moreover, envisaging a safer clinical translation of this immunotherapeutic approach, a transient CAR expression, by using CD33.CAR coding mRNA, is under investigation, in order to limit the potential myelotoxicity due to the long-term off-target effect on normal hematopoietic stem/myeloid progenitor cells. Finally, if successful, our results will provide the preclinical validation of CD33.CAR.CIK cell immunotherapy, supporting its development to the clinic.

A SINGLE INSTITUTIONAL EXPERIENCE OF 261 PATIENTS WITH LARGE GRANULAR LYMPHOCYTIC LEUKEMIA

M. Van den Bergh1, L. Isenalumhe1, E. Wang2, B. Schabie1, Z. Ma1, L. Zhang1, L. S. Yeleswaram1, H. Brooks2

1University of Alabama Birmingham, Birmingham, AL, 2Indiana Blood & Marrow Transplantation, LLC, Indianapolis, IN, 3Hematology/Oncology Associates of Treasure Coast, Port St Lucie, FL, 4University of Michigan, Ann Arbor, MI, 5Hackensack University Medical Center, Hackensack, NJ, 6Greenville Health System Cancer Institute, Greenville, SC, 7Department of Medicine-Gastroenterology, Cleveland, OH, 8Utah Cancer Specialists-Network, Salt Lake City, UT, 9University of Arizona Cancer Center, Tucson, AZ, 10Incyte Corporation, Wilmington, DE, 11Incyte Corporation, Wilmington, DE, 12Karmanos Cancer Center, Detroit, MI, United States

Background: Large granular lymphocytic leukemia (LGLL) is a rare clonal lymphoproliferative disorder of post-thymic T-cell or natural killer (NK)-cell lineage associated with cytopenias, splenomegaly, autoimmune disorders, and recurrent mucocutaneous infections. Treatment is dictated by the presence of these manifestations and consists of immunosuppressive therapy.

Aims: The main aim of this study is to evaluate clinical features, hematological parameters, and survival data of patients with LGLL. The secondary aim is to assess response rates and duration of response to various first line immunosuppressive therapies in LGLL.

Methods: This is a retrospective analysis of clinical and laboratory features, treatment modalities, and outcomes of LGLL patients evaluated at Moffitt Cancer Center between January 1, 1995 and May 1, 2016. Continuous and categorical variables were tested via Kruskal-Wallis ANOVA and Fisher’s Exact Test, respectively. Kaplan-Meier curves were used for overall survival (OS), P-values were two-sided with significance set at <0.05.

Results: We identified 261 patients with LGLL (91.6% T-cell, 8.4% NK-cell). Median age was 66 years [21-90] and M:F ratio was 1:2.1. Median follow up was 3.07 years [0-21.88]. 42.9% of LGLL patients presented with anemia, 37.1% with neutropenia, 30.7% with thrombocytopenia, 29.1% with bicytopenia and 6.9% with pancytopenia. Transfusion dependence was noted in 20.3%, splenomegaly in 27.2%, and bone marrow involvement in 69.3%. 24.9% had autoimmune diseases and 9.2% had autoimmune cytopenias. 45.6% were observed while the remainder required at least one line of therapy. 5-year and 10-year OS were 75.0% and 63.1%, respectively. There was no statistically significant difference in OS, complete response rate or duration of response based on first line agent (methotrexate, cyclophosphamide, cyclosporine A). However, there was a statistically significant improved partial response with methotrexate versus other therapies (p=0.01). A marginally significant association between severe anemia/transfusion dependence and poor overall response rate (p=0.075) to any immunosuppressive therapy was noted. There was no statistically significant difference in OS based on absolute LGL count. Mean number of therapies was 1.08 (range 0-6) and was higher in patients with LGL count <0.5 k/μL (p=0.0078), bone marrow involvement (p<0.0001), and splenomegaly (p<0.0001).

Summary/Conclusions: In the large retrospective study, we described the frequency of LGLL-associated manifestations and their impact on the course of LGLL. Severe anemia/transfusion dependence, lower LGL counts, bone involvement, and splenomegaly were suggestive of more aggressive disease. We confirmed that there is no difference in overall survival among first line immunosuppressive therapies.

P634

ONGOING PHASE 1/2 STUDY OF INCBO50465, A SELECTIVE PI3K-DELTA INHIBITOR, FOR THE TREATMENT OF PATIENTS WITH RELAPSED/ REFRAC TORY B-CELL MALIGNANCIES (CIITADEL-101)

1University of Alabama Birmingham, Birmingham, AL, 2Indiana Blood & Marrow Transplantation, LLC, Indianapolis, IN, 3Hematology/Oncology Associates of Treasure Coast, Port St Lucie, FL, 4University of Michigan, Ann Arbor, MI, 5Hackensack University Medical Center, Hackensack, NJ, 6Greenville Health System Cancer Institute, Greenville, SC, 7Department of Medicine-Gastroenterology, Cleveland, OH, 8Utah Cancer Specialists-Network, Salt Lake City, UT, 9University of Arizona Cancer Center, Tucson, AZ, 10Incyte Corporation, Wilmington, DE, 11Incyte Corporation, Wilmington, DE, 12Karmanos Cancer Center, Detroit, MI, United States

Background: PI3K pathway is activated in a wide variety of hematological malignancies. In PI3Kδ selective inhibitor of PI3Kδ (INCBO50465) demonstrated manageable toxicities with no clinically meaningful transaminases or PJP. Objective response rates were generally high and most responses (90%) were observed at the 9-week disease assessment. Different dosing regimens/schedules, long-term safety, and disease-specific cohorts are being evaluated.

Methods: In this phase 2/1 study, eligible patients ≥18 years of age had relapsed/refractory lymphoid B-cell malignancies (excluding Burkitt’s lymphoma and precursor B-cell lymphoblastic leukemia/lymphoma), Eastern Cooperative Oncology Group performance status score ≤2 (≤1 during dose escalation), normal liver and kidney function, and had not received autologous hematopoietic stem-cell transplant (HSCT) within 3 months or allogeneic HSCT within 6 months of screening. The protocol was initiated with a single-patient cohort, treated with oral INCBO50465 5mg QD. Subsequent cohorts used a 3+3 design and evaluated doses of 10–45mg QD. Based on PK/pharmacodynamics, the 20 and 30mg QD cohorts were expanded. Responses were assessed every 9 weeks using the Lugano Classification or International Working Group on Chronic Lymphocytic Lymphoma (CLL) criteria.

Results: As of the data cutoff (Nov 1, 2016), 52 patients were treated (median age 65 years, range [39-88]). Baseline disease subtypes included diffuse large B-cell lymphoma (DLBCL; n=14), follicular lymphoma (FL; n=10), Hodgkin lymphoma (HL; n=9), marginal zone lymphoma (MZL; n=8), CLL (n=6), and mantle cell lymphoma (MCL; n=5). Sixty-two percent (n=32) of patients had ≥3 prior systemic regimens; 31% (n=16) had prior HSCT. Median duration of therapy was 11 months (range, 0.6–13.4); no DLTs were identified. Seventy-seven percent of patients discontinued therapy, most commonly due to disease progression (31%) and AE (25%). Thirty-three percent of patients had dose interruption and 4% had dose reduction. Most common nonhematologic AEs (all grade; grade ≥3) were nausea (38%; 0%), diarrhea (31%; 6%), and vomiting (25%; 0%). Grade ≥3 hematologic AEs included neutropenia (21%), lymphopenia (17%), thrombocytopenia (10%), and anemia (4%). Forty percent of patients had serious AEs (SAEs), most frequently colitis, diarrhea, and hypotension (all n=3). One patient had grade 3 pneumonitis; none had Pneumocystis jirovecii pneumonia (PJP) or grade ≥2 elevated transaminase. Objective responses occurred at all doses (Table 1), except 5mg QD; 90% of the objective responses were observed at the 9-week disease assessment.

Summary/Conclusions: In patients with relapsed/refractory B-cell malignancies, INCBO50465 demonstrated manageable toxicities with no clinically meaningful transaminases or PJP. Objective response rates were generally high and most responses (90%) were observed at the 9-week disease assessment. Different dosing regimens/schedules, long-term safety, and disease-specific cohorts are being evaluated.
lymphoma (IFL). Upon informed consent, patients receive 12 cycles of R² induction with daratumumab, 21 d of 28 d of rituximab, 375mg/m² weekly cycle 1 [d1, 8, 15, 22], then d1 of odd cycles. Responders to induction (≥SD) are randomized: 1:1 to maintenance with either R² or rituximab alone (18 cycles); following R² maintenance, optional single-agent lenalidomide (10mg/d, 21 of 28 d) can be given until PD. The primary endpoint is progression-free survival (PFS).

**Results:** As of April 14, 2016, 106 patients with R/R FL have been enrolled, including 103 with grade 1-3a FL, 2 with tFL, and 1 unknown grade. Median age of patients with FL was 66 y (range, 41-91); most had ECOG PS of 0-1 (99%) and stage III/IV disease at study entry (80%). Patients received a median of 2 prior therapies (≥2, 30%; 103 (97%) patients had received prior rituximab-containing treatment, of which 35% were rituximab refractory (defined as best response of SD/PD to rituximab/rituximab-containing regimen or a CR/PR of <6 mo after the last rituximab dose). The most common prior regimens were rituximab alone (40%), R-CHOP/R-CHOP-like (38%), and bendamustine plus rituximab (35%). Premature discontinuation of lenalidomide occurred in 39 (37%) patients during the induction period, mainly due to AEs (n=20); the most common treatment-related AE leading to early discontinuation in the induction period was neutropenia in 8 patients. Four (4%) patients’ conditions continued the study. Common grade 3/4 treatment-emergent AEs during induction were fatigue (79%), nausea (76%), vomiting (65%), and headache (62%). At a median induction duration of 23 weeks (range, 0.4-51), the most common AEs were chemotherapy-related (n=104) and included 27% neutropenia, 7% leukopenia, and 6% fatigue. At the median induction duration of 23 weeks (range, 0.4-51), 83 FL patients were evaluable for response with an overall response rate (ORR) of 65%; those who were rituximab refractory had improved ORR compared to rituximab refractory patients (70% vs 55%; Table 1). The median time to response during the induction phase was 2.8 mo. Twenty patients have completed 2 cycles of induction and 16 proceeded to maintenance (n=6 R², n=10 rituximab alone). Enrollment is ongoing.

**Summary/Conclusions:** R² induction therapy shows favorable activity and a tolerable safety profile in patients with advanced-stage, R/R FL. The study is ongoing to determine the effect of R² vs rituximab maintenance in FL patients, and updated results will be presented.

**P635**

**A DOUBLE-BLIND, RANDOMIZED PHASE 3 STUDY TO COMPARE EFFICACY AND SAFETY OF CT-P10 TO INNOVATOR RITUXIMAB IN COMBINATION WITH CVPP IN PATIENTS WITH PREVIOUSLY UNTREATED ADVANCED FOLLICULAR LYMPHOMA**

1Clinica di Ematologia, 2Istituto di Anatomia Patologica, 3Clinica di Dermatologia, Ospedale di Macerata, Macerata, 4Clinica di Dermatologia, Ospedale di Jesi, Jesi, Italy

**Background:** Early stage Mycosis Fungoides (MF) has an indolent, relapsing course, with patients frequently undergoing multiple therapies. Current guidelines consider the utility of combination therapies (skin-directed therapies plus systemic biologic response modifiers) to increase the therapeutic efficacy. Recently, time to next treatment (TTNT) was applied as a new relevant measure of the durability of response of PUVA, interferon-alpha (IFN-α) and retinoids as monotherapies in early MF (Hughes et al, AJH 2016; Hanel et al, AJH 2016), but it has not been yet investigated in combination therapies.

**Aims:** We aimed to evaluate TTNT together with the usual time-event measures (OS and EFS) in the series of 89 early MF patients treated for 14 months with CT-P10 (infusion (IFN) 6-18 MU weekly) and PUVA, which was first reported in 2005 (Rupoli et al, EJH 2005). The follow-up was prolonged until October 2016, in order to evaluate prospectively the regimen activity and influence on the further course of the disease.

**Methods:** The design, rationale, safety and efficacy results for this protocol were previously published. Clinical stages IA-IIA patients who had received no previous treatment, or had been submitted to a 4-month wash-out after systemic therapy or a 4-week wash-out after topical therapy, were included in the study. Survival curves for each efficacy endpoint were calculated according to Kaplan-Meier.

**Results:** Eighty-nine patients (56 men and 33 women) with a median age of 60 years (range, 17-80) were recruited. Disease stage IA in 22 patients, IB in 55, IIA in 11, and IIB in 1 patient. The majority of patients had generalized skin disease (75% T2 vs 25% T1). The protocol proved to be highly effective, well tolerated and able to induce complete clearing of skin lesions in 84% of cases (99% of patients). The median follow-up time was 175 months (range 4-259). Updated data showed that the median overall survival (OS) was not reached, whilst the median event-free survival (EFS) was 142 months (95% CI, 130-153). Estimated OS rates at 1, 2, 5, 10, 15 and 20 years.
were 99%, 98%, 92%, 89%, 78% and 51%; at 1, 2, 5, 10, 15 and 20 years 98%, 97%, 88%, 67%, 19%, 0%, were free from events. Median TTNT was not reached thus indicating clinical benefit with IFN-α and PUV. Kaplan-Meier estimated rates of 97% at 1 year, and 91% at 2 years, respectively whereas 5-, 10-, 20-year TTNT remained almost unchanged with 62% of patients that still had not required further treatment.

Summary/Conclusions: There has been an ongoing debate about whether patients would benefit from adding PUV to IFN-α in the treatment of early stage MF. We chose to initiate the combination treatment of MF as early as possible in the course of the disease to induce a permanent remission or even a cure. In our experience, this regimen set the realistic goal of achieving high rates of complete clearing and durable responses (median TTNT not reached) with only 38% of patients requiring a subsequent systemic treatment within 20 years. Here, we suggest a synergistic or additive effect between PUV and IFN-α compared with either agent alone. With respect to Hughes et al. (Blood 2015), our combination treatment provides a longer TTNT than PUV or IFN-α monotherapy (36.3 months and 15.7 months, respectively). At 2 years, 91% of patients receiving PUV plus IFN-α were free from further treatment as compared to 54.2% and 29.1% treated with PUV or IFN-α monotherapy, respectively.

P637

PHASE 3 ALCANZA STUDY OF BRENTUXIMAB VEDOTIN (BV) OR PHYSICIAN’S CHOICE (PC) OF METHOTREXATE (MTX) OR BEXAROTENE (BEX) IN CD30-POSITIVE CUTANEOUS T-CELL Lymphoma (CTCL): NUMBER NEEDED TO TREAT ANALYSIS

1Millennium Pharmaceuticals Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, United States; 2The University of Melbourne, Victoria, Australia; 3Augsburg; and Si Thomas Nash Foundation Trust, London, United Kingdom; 4Memorial Sloan Kettering Cancer Center, New York, New York; 5The University of Texas MD Anderson Cancer Center, Houston, Texas; 6Stanford University School of Medicine and Stanford Cancer Institute, California, United States; 7University Hospital Zürich, Zürich, Switzerland; 8University Hospital Birmingham, Birmingham, United Kingdom; 9University of Turin, Turin, Turin, University Bologna, Bologna, Italy; 11University Hospitals Leuven, Leuven, Belgium; 12Columbia University, New York; 13Seattle Genetics, Inc., Bothell, United States

Background: CTCL is a generally incurable, relapsing disease associated with a significant symptom burden, including disfiguring lesions, debilitating pruritus and frequent skin infections. ALCANZA is a Phase 3 study of BV vs PC (MTX or Bex) for the treatment of CD30-positive (CD30+ CTCL) (NCT01578499). BV was associated with significantly improved rate of objective response lasting ≥4 months (ORR4; 56% vs 13%; p<0.0001), longer median progression-free survival (16.7 vs 3.5 months; p<0.0001), and decreased symptom burden measured by Skindex-29 (27.96 vs 8.62; p<0.0001), compared with PC. BV’s safety profile was consistent with previous reports, with all-grade and grade 3 peripheral neuropathy of 67% and 9%, respectively. Number needed to treat (NNT), defined as the number of patients (pts) that need to be treated to prevent one disease progression event or death compared to placebo, is an effective method to assess the benefit-risk of BV in a clinically relevant manner. NNT values of 3–28 have been previously reported, at various time points, in hematologic malignancies (multiple myeloma, B-cell non-Hodgkin lymphoma) to prevent one disease progression event or death. Data from the Phase 3 AETHERA study demonstrated that, at various time points, and dependent on risk group, one in 3–8 Hodgkin lymphoma pts treated with BV consolidation therapy post-autologous stem cell transplant will benefit by avoiding disease progression/death, compared with placebo.

Aims: To determine the NNT with BV to avoid one additional event of disease progression/death compared with PC in the ALCANZA trial.

Methods: The NNT with BV was calculated as the inverse of the absolute risk reduction (ARR); ARR was the risk difference of objective response lasting ≥4 months; ORR4; 56% vs 13%; p<0.0001), and decreased symptom burden measured by Skindex-29 (27.96 vs 8.62; p<0.0001), compared with PC. BV’s safety profile was consistent with previous reports, with all-grade and grade 3 peripheral neuropathy of 67% and 9%, respectively. Number needed to treat (NNT), defined as the number of patients (pts) that need to be treated to prevent one disease progression event or death compared to the comparator therapy, is an effective method to assess the benefit-risk of BV in a clinically relevant manner. NNT values of 3–28 have been previously reported, at various time points, in hematologic malignancies (multiple myeloma, B-cell non-Hodgkin lymphoma) to prevent one disease progression event or death. Data from the Phase 3 AETHERA study demonstrated that, at various time points, and dependent on risk group, one in 3–8 Hodgkin lymphoma pts treated with BV consolidation therapy post-autologous stem cell transplant will benefit by avoiding disease progression/death, compared with placebo.

Number needed to treat (NNT), defined as the number of patients (pts) that need to be treated to prevent one disease progression event or death compared to the comparator therapy, is an effective method to assess the benefit-risk of BV in a clinically relevant manner. NNT values of 3–28 have been previously reported, at various time points, in hematologic malignancies (multiple myeloma, B-cell non-Hodgkin lymphoma) to prevent one disease progression event or death. Data from the Phase 3 AETHERA study demonstrated that, at various time points, and dependent on risk group, one in 3–8 Hodgkin lymphoma pts treated with BV consolidation therapy post-autologous stem cell transplant will benefit by avoiding disease progression/death, compared with placebo.
according to histopathologic subtypes, BM involvement alone was regarded as a statistically significant factor in the group of non-MALT lymphoma (HR=3.99, p=0.013) and there were no statistically significant factors in the group of non-MALT lymphoma. Although there were no risk factors with statistical significance, the BM involvement and advanced TNM stage showed a trend toward statistical significance because affecting to the failure of PFS (BM involvement of HR=5.19, p=0.054 and advanced TNM stage of HR 3.06, p=0.056). The median time-to-progression (TTP) was from 3 to 3.5 years after initial therapy in relapse or dead patients (range from 4.6 to 109.6 months).

Summary/Conclusions: Our study confirmed that OAL of all histologic subtypes also represented the indolent nature and localized behavior with favorable survival outcomes. Although BM involved OAL consisted of a small number, it was associated with poor survival outcomes. Also, relapse and lymphoma-related mortality had long-term delayed TTP, so we suggested that BM biopsy might be a necessary study for initial staging at least in all OAL and long-term follow-up is required for patients with all histologic type of OAL.

P639

CLONAL B-CELL LYMPHOCYTOSIS OF MARGINAL ZONE ORIGIN (CBL-MZ): A PROSPECTIVE REGISTRATIONAL STUDY ON 96 CASES

1Department of Haematology, University Hospital, University of Crete, Heraklion, 2Department of Haematology, Athens Medical Center-Psychikon Branch, 3Department of Haematology, 41st Department of Propedeutics, University of Athens, Laikon General Hospital, 5Immunology Laboratory, Laikon General Hospital, 6Department of Pathology, 72nd Department of Internal Medicine, University of Athens, Athens, Greece

Background: Clonal B-cell lymphocytosis of marginal zone origin (CBL-MZ) has been recognized as a provisional entity in the WHO classification. Despite diagnostic similarities with SMZL, the exact relation between them has not been established yet. AIM: To describe the main features of CBL-MZ and to further elucidate its relation to SMZL.

Aims: To describe the main features of CBL-MZ and to further elucidate its relation to SMZL.

Methods: 96 CBL-MZ were analyzed. Staging at diagnosis included CBCs, blood morphology and immunophenotype, biochemistry, viral test for hepatitis C and B, serum immunoglobulin levels and immunofixation as well as whole body CT scan. BM biopsies were available in 78 cases which were studied with the following panel of moAbs: CD20, DBA44, CD23, CD5, CD25, CD38, CD27, s/cIgM/D, TCL-1, NDNA, T-bet and IRTA-1. Gastroscopy with multiple biopsies was performed in 58 cases. FISH analysis for del17q was done in 13 cases. MYD88 mutation in 60.

Results: A synoptic presentation of the main characteristics of CBL-MZ is given in the table. The median age was 70 y without sex predelection. By definition, no case presented with cytopenia, lymphadenopathy, splenomegaly or any other organ involvement. Median ALC and clonal B-cell counts were 5098/μL and 2880/μL, respectively. 47% had paraproteinemia, mainly of the IgM type. H.pylori (+) gastritis was evident in 30%. Hp eradication had no influence on the lymphocyte counts. The percentage of BM infiltration was highly variable, ranging from 10% to 85%, with an intrasinusoidal pattern in 31%. TCL-1, T-bet, IRTA-1, and NDNA were invariably negative. MYD-88 mutation was detected in 18% and was significantly associated with IgM paraproteinemia. 6 cases were lost to follow-up. At a median follow-up time of 41 months, the majority of the cases had no disease progression (90%). 61% had stable CBCs, 20% solely an increase in ALCs and 7% an increase in paraproteinemia only, while in 2% lymphocytosis regressed. A total of 9 (10%) pts progressed and required treatment: 5/9 due to cytopenias caused by extensive BM infiltration without splenomegaly, 1 due to bulky splenomegaly, 1 due to lymphadenopathy, 1 developed autoimmune thrombocytopenia, while in one due to high IgM levels in a MYD-88(-) case. A total of 5 (6%) pts developed splenomegaly after a median time of 78 mos (48-151).

Summary/Conclusions: After a median follow-up time of 4y we demonstrated that CBL-MZ, although displaying many diagnostic similarities with SMZL, it rarely remain to it. Most cases remain to stable, while few develop cytopenias due to an extensive BM infiltration. These latter cases apparently represent a distinct MZL category which requires further investigation.

P640

SAFETY OF SUBCUTANEOUS ADMINISTRATION OF RITUXIMAB DURING THE FIRST-LINE TREATMENT OF PATIENTS WITH NON-HODGKIN LYMPHOMA: THE MABRELLA STUDY

C. Panizo1,*, M.A. Bekadja2, B. Meddeb3, O. Meier4, R. Smith4, M. Truman5, C. Barata6
1Clinica Universidad de Navarra, Pamplona, Spain, 2University Hospital Estab-lishment, Oran, Algeria, 3Aziza Othmana University Hospital, Tunis, Tunisia, 4F. Hoffmann-La Roche Ltd, Basel, Switzerland, 5F. Hoffmann-La Roche Ltd, Dee Why, Australia, 6University of Pisa, Pisa, Italy

Background: Intravenous (IV) rituximab is the mainstay of treatment for CD20+ B-cell non-Hodgkin lymphoma (NHL). A subcutaneous (SC) formulation of rituximab has been approved in Europe and other countries that reduces health-care resource burden and improves patient (pt) satisfaction and convenience compared with rituximab IV. MabReilla is a global umbrella study comprising three local open-label, single-arm, Phase IIIb studies of rituximab SC, which share a core protocol and primary endpoint but have flexibility for exploratory endpoints (NCT01889069; NCT01987505; NCT02406092). Data from participating countries are pooled for predefined global analyses.

Aims: To evaluate the safety of first-line (1L) rituximab SC in follicular lymphoma (FL) and diffuse large B-cell lymphoma (DLBCL) with a focus on administration-related reactions (ARRs).

Methods: Eligible pts were aged 18–80 years with grade 1–3a FL/DLBCL and ECOG performance status ≤3. All pts had received ≥1 full dose of rituximab IV as 1L induction/maintenance before study entry, and were expected to receive ≥4 additional induction cycles (FL/DLBCL) or ≥6 additional maintenance cycles (FL). Informed consent was obtained. For induction, pts received rituximab SC 1400mg every cycle (14, 21 or 28 days) for 4–7 cycles, plus standard chemotherapy. FL pts undergoing maintenance treatment received single-agent rituximab SC 1400mg every 2 months for 6–12 cycles. The primary endpoint was incidence of ARRs, i.e. all adverse events (AEs) occurring within 24 hours of administration, considered related to study drug by the investigator. Secondary endpoints included grade ≥3 AEs and serious AEs (SAEs). The safety analysis included all pts who received ≥1 dose of study treatment. Safety data were not collected for rituximab IV, as pts entered the trial after switching to SC. Updated data are presented (data cut-off February 7, 2017).

Results: The safety population comprised 421 pts: 160 Italy; 140 Spain; 121 North Africa (Tunisia, Morocco and Algeria). Median age was 58 years (range 19–80); 49% of pts were male; 225 pts had FL and 196 had DLBCL. Of the pts with FL, 97 completed ≥1 cycle of rituximab SC induction (45 completed 7 cycles) and 204 completed ≥1 cycle of maintenance (175 completed 6 cycles;
73 completed 12 cycles). Among DLBCL pts, 99 completed 7 cycles of induction therapy and overall survival were 33mo, 45.8mo and 78% at 5 years, respectively. Dose reductions >20% had no impact on these outcomes, but age >65y had a significant impact. Therapy and overall survival were 33mo, 45.8mo and 78% at 5 years, respectively. Dose reductions >20% had no impact on these outcomes, but age >65y had a significant impact. Therapy and overall survival were 33mo, 45.8mo and 78% at 5 years, respectively. Dose reductions >20% had no impact on these outcomes, but age >65y had a significant impact.

### Summary/Conclusions:

In real-life practice are lacking. Indeed, outside clinical trials, patients are older and experience more health issues. Dose reductions >20% had no impact on these outcomes, but age >65y had a significant impact. Therapy and overall survival were 33mo, 45.8mo and 78% at 5 years, respectively. Dose reductions >20% had no impact on these outcomes, but age >65y had a significant impact.

**REAL-WORLD EXPERIENCE WITH RITUXIMAB-FLUDARABINE (RF) AND DEXAMETHASONE, RITUXIMAB, CYCLOPHOSPHAMIDE (DRC) IN WALDENSTROM MACROGLOBULINEMIA: A RETROSPECTIVE STUDY FROM 163 PATIENTS**

C. Protin1,*, L. Oberic1, P. Bories2, G. Laurent1, F. Despas3, L. Ysebaert1

1Hematology, 2Oncomip regional cancer network, IUC Toulouse-Oncopole, 3Clinical Pharmacology, University of Toulouse, Toulouse, France

**Background:** Symptomatic Waldenstrom macroglobulinemia (WM) may be managed with various regimens. After the 8th IWWM congress, experts recommended the use of rituximab-based regimens. Two phase II trials treated DRC (n=72), IL and RF (n=43), one-third of which had received chlorambucil alone, +/- steroids/rituximab before, with published long-term follow-up of 95 and 46 months, respectively. Mature data from larger cohorts confirming trials’ results in real-life practice are lacking.

**Aims:** Mature data from larger cohorts confirming trials’ results in real-life practice are lacking. Indeed, outside clinical trials, patients are older and experience potentially more long-term side effects.

**Methods:** We report data from a retrospective study in 163 symptomatic WM treated as first-line treatment (or second-line after chlorambucil, n=47) with RF (n=56) or DRC (n=108) between January 01, 2005 and December 31, 2015.

**Results:** Median follow up for the entire cohort is 5 years, median age at diagnosis 68y and at therapy 71y. 75% being above 65y at treatment. Significant differences between DRC/RF cohorts were: median age 74/64, high IPSS score 63%/28%, 2B2M>3/74%/56%, DRC cohort: median PFS/Time To Next Therapy and Overall Survival were 33mo, 45.8mo and 78% at 5 years, respectively. Dose reductions >20% had no impact on these outcomes, but age >65y and anemia >11.5g/dl decreased PFS. Previous CLB therapy increased the risk for delayed toxicities (infections 19% vs 16%, myelodysplasia 13% vs 3.8%), but not second cancers including Richter transformation. IPSS scoring system predicted PFS and OS with good accuracy. RF cohort: median PFS/Time To Next Therapy and Overall Survival were 33mo, 65% and 90% at 5 years, respectively. Previous CLB had no impact on outcomes, but dose reductions >20% adversely impacted TTNT. IPSS scoring system did not improve prognostication. Long-term follow-up (22% of patients had second solid cancers. RF significantly increased the risk of Richter, and CLB exposure the risk of myelodysplasia. Second PFS upon salvage (PFS2) was available in 72 patients: 47 DRC (PFS2 47mo), and 25 RF (PFS2 66mo), not significantly different.

**Summary/Conclusions:** We conclude that clinical trials results of DRC and RF are reproduced in our real-life cohort despite older ages, and high IPSS scores. Long-term toxicities are also seen, at similar rates and second cancers monitoring should be part of physician’s practice in these WM patients.

**Background:** Invasive fungal infections (IFIs) incur significant morbidity and mortality in neutropenic patients with hematological malignancies (HEM) after chemotherapy. The risk for these infections is related to the intensity and duration of neutropenia, and varies from 2% to 40%. Mortality rates associated with documented IFIs are considerable, reportedly ranging from 30% to 60%. Empirical antifungal therapy is the standard care for neutropenic patients with HEM, whereas febrile neutropenia and broad-spectrum antibacterial treatment. Several antifungal agents including voriconazole (VRCZ) or liposomal amphotericin B (L-AMB) have been studied as empirical therapy for febrile neutropenia (FN).

However, limited data are available concerning the efficacy and safety of micafungin (MCFG) in FN patients with HEM.

**Aims:** We conducted a randomized, cooperative group, open-label trial comparing MCFG (150mg once daily) with L-AMB (2.5mg/kg once daily) as first-line empirical antifungal treatment for FN patients with persistent fever of HEM.

**Methods:** 138 hospitalized FN patients with persistent fever of HEM (AML 78, APL 4, ALL 13, MDS (RAEB) 7, NHL 28, MM 5, other hematological malignancy 3 cases) were randomized to each drug group (MCFG, 72; L-AMB, 66). The efficacy end point was a favorable overall response, as determined by a five-component end point according to the criteria of Walsh et al (N Engl J Med 2004; 351: 1391).

**Results:** At the time of enrolment, there were no significant differences in the demographics or baseline characteristics between the two groups. The mean treatment duration for MCFG and L-AMB was 13.8 and 16.4 days, respectively. The efficacy rates of MCFG and L-AMB were not significantly different (38/72 cases (52.8%) vs 26/66 cases (39.4%), p=0.115%), evaluated based on: (1) successful treatment of baseline fungal infection (3/4 cases (75.0%) vs 0/1 case (0%), p=0.170%), (2) absence of breakthrough fungal infection (65/72 cases (90.3%) vs 65/66 cases (98.5%), p=0.112%), (3) survival for ≥7 days after completion of 66/72 cases (91.7%) vs 59/66 cases (89.4%), p=0.854%), (4) absence of premature study drug discontinuation due to poor efficacy or drug-related adverse events (54/72 cases (75.0%) vs 47/66 cases (71.2%), p=0.6153), and (5) resolution of fever during neutropenia (45/72 cases (62.5%) vs 33/66 cases (50.0%), p=0.2588).

However, due to poor efficacy or drug-related adverse events, the efficacy rates of MCFG and L-AMB were not significantly different (38/72 cases (52.8%) vs 26/66 cases (39.4%), p=0.115%). In safety evaluation, adverse events contributing to reduced morbidity and improved survival of high-risk patients in hematological therapy. However, besides their well-known antifungal activity there is a growing body of evidence for immunomodulatory side effects on different effector cells of the immune system.
Aims: The aim of our study is to clarify the immunomodulatory capacity of different antifungal drugs on the effector functions of polymorphonuclear neutrophils (PMN) and on the clinical course of invasive pulmonary aspergillosis (IPA).

Methods: Firstly, isolated PMN from healthy donors were preincubated with different antifungals in vitro. Here, we used the azoles fluconazole (FLU), voriconazole (VOR), and isavuconazole (ISA), as well as the echinocandins caspofungin (CAS) and micafungin (MIC), and the polyenes amphotericin B (AmB) and liposomal amphotericin B (LAMB). Furthermore, PMN were simultaneously stimulated with lipopolysaccharides (LPS) or zymosan. Afterwards, PMN were analyzed by flow cytometry regarding activation, degranulation, and phagocytosis. Additionally, a dichlorofluorescein assay was used to detect reactive oxygen species (ROS). IL-8 synthesis was measured by enzyme-linked immunosorbent assay (ELISA). Secondly, a murine model was used to investigate the influence of MIC and POS on the clinical course of IPA in vivo. Therefore, mice were treated with antifungals and inoculated intratracheally with A. fumigatus conidia. Afterwards, mice were analyzed concerning fungal burden and pulmonary damage (albumin ELISA) with neutrophic animals serving as controls.

Results: In vitro, pretreatment with POS lead to enhanced activation (CD62L: 44% +/- 8 vs 13 +/- 2, *; mean +/- SEM, p value ≤0.05 considered to be significant). Furthermore, treatment with POS resulted in reduced fungoidal burden as expected but lead to reduced albumin concentration in BAL (111 ng/ml +/- 46 vs 380 +/- 31, *) indicating a decreased pulmonary damage. Despite significant influence on PMN effector functions in vitro, MIC did not affect clinical course IPA in vivo.

Summary/Conclusions: AmB and POS induce PMN activation, whereas ISA and MIC inhibit PMN effector functions in vitro. CAS shows variable modification on PMN. Possibly independent from its antifungal effects, POS reduces pulmonary damage in mice suffering from IPA in vivo. Furthermore studies need to distinguish the obviously multidimensional immunomodulatory effects of different antifungal agents and to clarify their relevance in clinical practice.

P644

CHARACTERISTICS AND OUTCOME OF PULMONARY INFILTRATES IN ACUTE LEUKEMLA CLASSIFIED ACCORDING TO EORTC/MSG CRITERIA OF INVASIVE FUNGAL INFECTION: A PROSPECTIVE STUDY BY THE RELIANCE STUDY GROUP

C. Cattaneo1, C. Paganini1, V. Mancini2, P. Zappasodi3, A. Ferrarini4, F. Pavesi5, E. Todisco6, N.S. Fracchioni7, V. Sacca8, L. Verga9, M. Petullia1, A. Nosari1, G. Rossi1

1Hematology, Spedali Civili, Brescia, 2Hematology, Ospedale Niguarda, Milan, 3Fondazione IRCCS Policlinico S. Matteo, Pavia, 4Hematology, Ospedale di Circolo e Fondazione Macchi, Varese, 5San Raffaele Scientific Institute of Milan, 6Hematology, Ospedale Valduce, Como, 7Hematology, San Gerardo Hospital, Monza, Italy

Background: In acute leukemia (AL) patients (pts) pulmonary infections may be severe and worsen the final outcome of AL. They have been recently shown to adversely affect the outcome of bloodstream infections (BSI) in AL pts (Cattaneo et al. 2016). The radiologic characteristics of PI belong, according to the EORTC/MSG Study Group, to the diagnostic criteria of a pulmonary invasive fungal infection (IFI).

Aims: In order to better define the clinical and prognostic significance of PI in AL pts in a real-life setting, we have analyzed all PI diagnosed during consecutive febrile/infectious episodes developing over a 26 months period in pts admitted to 9 hematologic institutions within the Italian Network for Clinical Research in Hematology (REL) network.

Methods: From Dec-12 to Jan-14, all febrile/infectious episodes were recorded and data concerning PI extracted. PI were classified as specific and aspecific for IFI according to radiologic criteria.

Results: During 1086 episodes, 256 PI were diagnosed in 195 AL pts (M/F 124/71; median age 60y; AML/ALL 163/32). PI incidence was similar during induction and relapse (28.8% and 29%, respectively), but significantly lower in complete remission (14.2%, p<0.0001). Overall, PI were detected in 57% of cases during AML induction/reinduction and in 44.5% during posaconazole prophylaxis. Posaconazole was not responsible for a decreased sensitivity of serum galactomannan (GM), which was positive in 18.4% and in 18.6% pts with specific PI receiving posaconazole or not, respectively. Aspecific PI were observed in 157 cases (61.3%). In the remaining 99 cases (38.3%) the specific radiologic criteria for suspecting IFI were met, but in 70 of them (27.3%) just in the context of a diagnosis of possible (poss) IFI. Probable/proven (prob/prov) IFI criteria were met in 29 PI (11.3%). The characteristics of the three subgroups of PI are listed in Tab 1. Prob/prov PI were associated with lack of posaconazole prophylaxis in comparison with poss IFI (72.4% vs 57.1%, p=0.0074). Aspecific PI did not differ from poss IFI except for their lower frequency during neutropenia, particularly if ≥15d (80.3% vs 92.9%, p=0.0164, and 56.1% vs 80%, p=0.0005, respectively), and higher frequency in patients on Fluorouracil (Fl) prophylaxis (57.3% vs 22.9%, p<0.0001). Multivariate analysis confirmed that aspecific PI were less frequent during prolonged neutropenia (HR 0.382, IC 0.189-0.772), and poss IFI during Fl prophylaxis (0.344, 0.159-0.742). All but one poss/prob IFI were diagnosed in the context of a diagnosis of possible (poss) IFI.

Summary/Conclusions: Among PI occurring in AL patients IFI could be suspected according to EORTC/MSG Study Group criteria in nearly 40% of cases but only 11% of PI met the criteria for prob/prov IFI. Posaconazole did not affect serum GM sensitivity and was protective against prob/prov PI, which had a higher risk of death. On the other hand, PI associated with a diagnosis of poss IFI had a similar outcome compared to aspecific IFI, although they occurred more frequently during neutropenia and outside from Fl prophylaxis. These findings may be relevant in the context of a reevaluation of the criteria for suspecting IFI in AL patients with PI as well as for a more appropriate antimicrobial stewardship.

P645

ANTIFUNGAL PROPHYLAXIS WITH CD101 IN IMMUNOSUPPRESSED MOUSE MODELS OF CANDIDIASIS, ASPERGILLOSIS, AND PNEUMOCYSTIS PNEUMONIA (PCP)

V. Ong1, K. Bartzal1, M. Cushion2, L. Miesel2, S.R. Lopez3,4

1Cidara Therapeutics, Inc., San Diego, 2Cincinnati VAMC, 3University of Cincinnati Coll of Med, Cincinnati, United States, 4Eurofins Panlabs, Taipei, Taiwan, Republic of China, 5TransPharm Preclinical Solutions, Jackson, United States

Background: Fungal infections continue to carry high morbidity and mortality. Disease- and treatment-related immunosuppression in patients with hematologic malignancies increases the risk of opportunistic infection caused by Candida spp., Aspergillus spp., and Pneumocystis spp., and antifungal prophylaxis is an important consideration. Agents currently used for prophylaxis, voriconazole and TMP/SMX, carry safety and tolerability concerns. CD101 is a novel echinocandin in phase 2 clinical development that has demonstrated preclinical efficacy in treatment of invasive fungal infections and has pharmacokinetic attributes that enable once-weekly IV dosing and subcutaneous (SC) administration.

Aims: To evaluate CD101 as antifungal prophylaxis in neutropenic mouse models of candidiasis, aspergillosis, or PCP.

Methods: CD101 (500µg/0.15 ml) or Candida albicans ATCC SC5314 (105 CFU/mouse) were used as a control. Mice received prophylaxis with CD101, voriconazole (15 mg/kg SC) or placebos. Aspecific IFI criteria were met in nearly 40% of cases. Posaconazole did not affect serum GM sensitivity and was protective against prob/prov PI, which had a higher risk of death. On the other hand, PI associated with a diagnosis of poss IFI had a similar outcome compared to aspecific IFI, although they occurred more frequently during neutropenia and outside from Fl prophylaxis. These findings may be relevant in the context of a reevaluation of the criteria for suspecting IFI in AL patients with PI as well as for a more appropriate antimicrobial stewardship.

Aims: To evaluate CD101 as antifungal prophylaxis in neutropenic mouse models of candidiasis, aspergillosis, or PCP.

Methods: To evaluate CD101 as antifungal prophylaxis in neutropenic mouse models of candidiasis, aspergillosis, or PCP.

Methods: To evaluate CD101 as antifungal prophylaxis in neutropenic mouse models of candidiasis, aspergillosis, or PCP.

Methods: To evaluate CD101 as antifungal prophylaxis in neutropenic mouse models of candidiasis, aspergillosis, or PCP.
challenge on day -5, -3, or -1. Survival was monitored for 14 days. PCP model: C3H/HeN mice (10/gp) were immunosuppressed by dexamethasone (4mg/L) in acidified drinking water and inoculated with Pneumocystis murina (intranasal- ly, 2 x 10^5/50 µL). CD101 0.2, 2, or 20mg/kg intraperitoneally was given at the time of inoculation and 1x or 3x/wk for 6 wks. TMP/SMX 50/250mg/kg/3x/wk was used as positive control. At 6 wks, lungs were processed for quantification of trophic and asci (cyst) forms of P. murina.

Results: Candidiasis: Kidney CFU decreased with higher doses of CD101 and shorter times between prophylaxis and challenge. At 20mg/kg, there was complete clearance of CFU burden regardless of treatment day in all animals except one (prophylaxis on day -3). There was complete clearance in all animals given 10mg/kg/d on days -3 and -1 and significant decreases in CFU in those given 5mg/kg on days -3 and -1. Aspergillosis: Survival rates significantly increased following CD101 5, 10, and 20mg/kg prophylaxis on day -5, -3 or -1 compared with vehicle. Prophylaxis closer to challenge increased the rate of survival in the 3mg/kg group. All animals given higher doses survived regardless of day of prophylaxis. PCP: Trophic nucleus counts were significantly reduced versus untreated controls in all CD101 groups except 0.2mg/kg/1x/wk, and efficacy in 3 different CD101 groups was comparable to TMP/SMX (no nuclei observed microscopically). Asci counts also were significantly reduced in all CD101 groups versus untreated controls. The largest difference in efficacy between TMP/SMX and CD101 in all but the lowest dose group (0.2mg/kg/1x/wk), with no asci observed microscopically.

Summary/Conclusions: CD101, a novel echinocandin, was protective against fungal challenge in immunosuppressed mouse models of candidiasis, aspergillosis, and PCP. These data suggest that CD101 may provide benefit as antifungal prophylaxis in patients with hematological diseases at risk for aspergillosis, and PCP. These data suggest that CD101 may provide benefit in patients at risk.

Background: Invasive fungal infections (IFI) are a major cause of morbidity and mortality in patients undergoing chemotherapy or stem cell transplantation for acute leukemias. Though optimised antifungal therapy might be effective, in selected patients, surgical interventions might be an useful tool both for diagnostic and therapeutic reasons. However due to the nature of the disease and circumstances, prospective data of Surgical interventions in these situations is limited.

Aims: The purpose of this study is to report our single center experience of surgical interventions for IFI in acute leukemia patients.

INFECTIONS IN MULTIPLE MYELOMA ARE FREQUENT AND PREDOMINANTLY CAUSED BY BACTERIA: RESULTS OF A 12-YEAR SURVEY FROM A SINGLE CENTER

M. Przybylka-Toal1, M. Klaus1, H. Sayer2, S. Scholl1, T. Ernst1, H. Hilgenfort1, O. Yomade1, A. Klink1, K. Schilling1, A. Hochhaus1, A. Briol1, L.O. Mügge1
1Universitätsklinikum Jena, Jena, 2Helios Klinikum Erfurt, Erfurt, 3Heinrich-Braun-Klinikum, Zwickau, Germany

Background: The outcome of patients with multiple myeloma (MM) has improved dramatically in the past years, mainly due to a better control of the disease. However, it is not clear what influence this has on treatment- or disease-related complications like infections. Recent data even suggested an increased rate of infections in patients with MM, possibly associated with the use of novel drugs.

Aims: To determine the rate and the type of infections in MM patients undergoing treatment and to evaluate possible disease- or treatment-related risk-factors.

Methods: All patients with MM treated at our institution between 2003 and 2014 were included in this retrospective analysis after approval by the institutional review board. Data on age, sex, diagnosis, comorbidities, treatment modalities, and infectious complications were recorded. Each type of therapy (e.g. high-dose therapy versus conventional therapy) defined a patient-case (duration per patient-case: beginning of therapy until the beginning of another type of therapy) and infections were recorded per case. To determine risk-factors, generalized estimating equations comparing cases were used.

Results: Four-hundred seventy-nine patients (male: 272, 57%) accounted for 1690 cases (median number of cases per patient 3, range 1-15). At presentation in our institution, median age was 62 (35-89) years, and most patients had advanced disease (Stage III according to Salmon-Durie classification in 564 patients, 76%), and an IgG paraprotein (255 patients, 53%). Type of therapy given were as follows: 534 (32%) conventional long-term chemotherapy, 514 (30%) induction-type chemotherapy, 237 (14%) chemotherapy for stem-cell mobilisation, 310 (18%) high-dose melphalan with stem-cell transplantation and 95 (6%) supportive care only. One-hundred sixty-six patients (35%) with 257 episodes never experienced an infection including 25 cases with high-dose melphalan. However, the majority of patients experienced at least one episode of infection throughout their treatment, accounting for 773 infections in 627 patient cases (37% of all patient cases). Most (559, 72%) infections were of bacterial origin including 156 cases with pneumonia (9% of all patient cases).

Conclusions: More than 60% of MM patients experience at least one episode of infection during their course of treatment. These infections are mostly of bacterial origin and strongly associated with high-dose chemotherapy or relapse. Novel drugs do not seem to influence the rate of infection. Unfortu-
nately, despite the general improvement in the care of patients with MM, no difference in the rate of infections could be detected in recent years.

HUMAN L-FICOLIN POLYMORPHISMS CONTRIBUTE TO SUSCEPTIBILITY TO INFECTIONS IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

U. Schnetzetzk1, M. Fischer2, A. Hochhaus1, S. Schoß1
1Klinik für Innere Medizin II, Abteilung für Hämatologie und Internistische Onkologie, Universitätssklinikum Jena, Jena, Germany

Background: In neutropenic patients with acute myeloid leukemia (AML) bacterial infections and sepsis are a leading cause of mortality. Several studies propose a contribution of individual single nucleotide polymorphisms (SNPs) of the innate immune system to the course of infections. Human ficolins represent receptors for C1q from the classical pathway of the complement that acts with pattern binding and soluble molecules of the innate immune system. Ficolins are expressed on membrane bound and soluble molecules of the innate immune system and their potential implication on infections. In the context of hematopoietic stem cell transplantation polymorphisms of PTX3 have been identified as an individual risk factor for developing pulmonary aspergillosis.

Aims: We sought to investigate the impact of L-ficolin and PTX3 SNPs on the occurrence of infectious events such as sepsis and pneumonia, including invasive fungal disease (IFD), in 186 adult patients with newly diagnosed AML following anthracycline-based induction chemotherapy. In addition to our studies on membrane receptors, this work represents an important extension on soluble molecules of the innate immune system and their potential implication on infections.

Methods: Genotyping of L-ficolin and PTX3 SNPs (rs17514136, rs17549193, rs17540880) was performed by TaqMan assay. Multiple regression analyses were applied to evaluate the association between SNPs of the polymorphisms and the occurrence of infectious events.

Results: Two L-ficolin SNPs were identified as risk factors for developing sepsis and/or pneumonia. Patients harboring rs17514136G/GAG or GG (n=100 or 22) revealed a significantly higher risk for developing sepsis (odds ratio (OR): 1.88; 95% confidence interval (CI): 1.01–3.37, p=0.039) or pneumonia (OR: 2.79; 95% CI: 1.1–6.9, p=0.033). A similar risk profile could be demonstrated for patients carrying rs17549193TTCT or TT. No association was found between SNPs of the PTX3 gene and the analysed infectious events.

Summary/Conclusions: To our best knowledge, this study represents the first analysis demonstrating that polymorphisms of human L-ficolin (rs7309123, rs17549193) represent an independent risk factor of developing sepsis and/or pneumonia in patients with AML undergoing induction chemotherapy. Interestingly, no association of PTX3 SNPs and infectious events such as IFD was found in this non-transplant setting. In conclusion, a genetic risk profile based on membrane bound and soluble molecules of the innate immune system might be helpful in identifying patients prone for infectious events.

TIMING OF DEFIBROTIDE INITIATION POST-DIAGNOSIS OF HEPATIC VENO-OCLUSIVE DISEASE/SINUSOIDAL OBSTRUCTION SYNDROME AFTER PRIMARY CHEMOTHERAPY: EXPLORATORY ANALYSIS OF AN EXPANDED-ACCESS PROTOCOL

N. Kerman1, P. Richardson2, T. Brillet3, S. Grupp4, J. Antin5, W. Liang6, R. Hume6, W. Tappe6, R. Soiffer7
1Pediatric Bone Marrow Transplantation Service, Memorial Sloan Kettering Cancer Center, New York, New York, 2Jerome Lipper Multiple Myeloma Center, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, 3Bone Marrow Transplantation and Cellular Therapy, St. Jude Children’s Research Hospital, Memphis, 4Pediatric Oncology, The Children’s Hospital of Philadelphia, Philadelphia, 5STEM CellBone Marrow Transplantation Program, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, 6Jazz Pharmaceuticals, Inc., Palo Alto, 7Center for Stem Cell Transplantation, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, United States

Background: Hepatic VOD/SOS, which may be unpredictable and potentially life-threatening, is typically considered a complication of hematopoietic stem cell transplantation (HSCT); however, VOD/SOS can occur after chemotherapy alone. Post-HSCT VOD/SOS is associated with >80% mortality. Defibrotide is approved to treat severe hepatic VOD/SOS post-HSCT in the European Union and to treat hepatic VOD/SOS with renal or pulmonary dysfunction post-HSCT in the United States.

Aims: To perform an exploratory post hoc analysis of the impact of timing of initiation of defibrotide after VOD/SOS diagnosis in patients developing VOD/SOS after primary chemotherapy without HSCT (off label).

Methods: In an expanded-access protocol for patients with VOD/SOS post-HSCT or chemotherapy, with or without MOD (renal and/or pulmonary dysfunction), defibrotide 25mg/kg/d (4 divided doses of 6.25mg/kg) was given a median of 22 days from diagnosis to the time of VOD/SOS diagnosis to start of defibrotide therapy. Survival analysis was performed using the Kaplan-Meier product limit method. The primary analysis was a time-to-event analysis of survival from the day of diagnosis in both the overall group and MOD subgroup (Figure), earlier initiation was associated with higher Day +100 survival rates for all days, which was significant at a number of timepoints. The trend test for particular initiation days.
also showed a significant trend over time for higher Day +100 survival with earlier defibrotide initiation post-diagnosis in both the overall group and MOD subgroup (P<.05). In the overall post-chemotherapy population, adverse events (AEs) and serious AEs occurred in 66% and 40% of patients, respectively. Aside from multi-organ failure, the most common AE of any severity was hypotension (9.5%). Possibly related AEs lead to discontinuation in 7.3%; most common was gastric hemorrhage (3.7%).

Summary/Conclusions: In this exploratory analysis of final study data in the subgroup of patients developing VOD/SOS after chemotherapy, earlier defibrotide initiation post-VOD/SOS diagnosis was associated with improved Day +100 survival, confirmed by the Cochran-Armitage test (P<.05), even in the small MOD subgroup. This time-dependent relationship was consistent with that found in the HSCT subgroup from this study. No specific day appears to provide a clinically meaningful cutoff for better Day +100 survival, suggesting that later intervention retains value if treatment must be delayed.

ADAMTS-13 REGULATES NEUTROPHIL RECRUITMENT IN A MOUSE MODEL OF INVASIVE PULMONARY ASPERGILLOSIS
A. Hasibeder1,*, S. Prüfer2, K. Ebner3, S. Reuter1, P. Aranda Lopez1, I. Scharrer1, F. Banno4, M. Stassen 2, H. Schild 2, K. Jurk3, M. Bosmann3, H. Beckert1, M. Radsak1
1IIIrd Dept. of Medicine, 2Institute for Immunology, 3Center for Thrombosis and Hemostasis, Johannes Gutenberg-University Medical Center, Mainz, Germany, 4Department of Molecular Pathogenesis, National Cerebral and Cardiovascular Center, Saitama, Japan

Background: Von Willebrand factor (VWF) is produced as multimers of various sizes and is secreted as an acute phase protein during inflammation. The main mechanism regulating the size and prothrombotic activity of VWF is the specific proteolytic activity of ADAMTS-13 (a disintegrin and metalloprotease with ThromboSpondin type 1 repeats-13) which is diminished under several pathological conditions.

Aims: To determine the relevance of this regulatory pathway for the innate inflammatory response by polymorphonuclear neutrophils (PMN), we employed a mouse model of invasive pulmonary aspergillosis (IPA) where PMN functionality is crucial for fungal clearance and survival.

Methods: IPA was induced by intratracheal application of Aspergillus fumigatus (A. f.) conidia in wildtype (129/Sv/Pas) or ADAMTS-13 deficient (Adamts13-/-) mice, and VWF deficient (Vwf-/-) mice or respective controls (B6). Some mice were sacrificed 24 h after infection. Fungal load was assessed as colony forming units (CFU) after plating and culturing lung homogenates on Sabouraud agar plates. For histological analysis paraffin sections of the lungs were stained with H&E, mouse complement component C3d and VWF antibody. Broncho alveolar lavage fluid (BALF) was analyzed for cell count (bead-based by flow cytometry or by an animal blood counter), ELISA was performed for albumin amount and cytokines were analyzed by a multiplex assay. Bone marrow-derived PMN were isolated by magnetic cell sorting using biotin labeled Ly6G/C specific antibody. PMN functions were analyzed for degranulation, oxidative burst activity and CD62L shedding by flow cytometry. Fungal killing of PMN in vitro was assessed by a XTT assay. Chemotactic properties of A.f.-activated and control serum from wildtype and knock-out mice was evaluated by migration of purified human PMN, isoalted by dextran sedimentation and Histopaque® centrifugation, in a transwell assay.

Results: While infected neutropenic mice developed lethal IPA, all wildtype mice survived the infection. Interestingly, Adams13-/- mice displayed more severe signs of disease with a lethal course in about 24% of the animals. Examination of the lungs revealed a higher fungal burden along with increased signs of acute lung injury and levels of pro-inflammatory cytokines in ADAMTS-13 deficient mice. Histology sections demonstrated a more pronounced perivascular leukocyte infiltration in support of a dysregulated inflammatory response in Adams13-/- mice. Importantly, we observed no general defect in the activation of neutrophil effector functions in response to conidia or hyphae in vitro. Furthermore, innate inflammatory response to IPA was not altered in VWF deficient (Vwf-/-) mice compared to wildtype (B6) control.

Summary/Conclusions: Therefore, we conclude that the proteolytic regulation of VWF by ADAMTS-13 or ADAMTS-13 by itself is an important mechanism to control PMN recruitment in acute inflammatory processes, such as fungal pneumonias.
Myelodysplastic syndromes - Biology

P652
IDENTIFICATION OF THE SPECIFIC HEMATOPOIETIC STEM CELL POPULATIONS RESPONSIBLE FOR FAILURE TO HYPOMETHYLATING AGENTS IN MYELODYSPLASTIC SYNDROMES
I. Garán-Gómez1,*, A. Alfonso1, Y. Ogoti1, H. Yang1, G. Montalban-Bravo1, A.C. Yu2, S. Silver2, K. Clise-Dwyer3, G. Garcia-Manero1, S. Colla1
1Leukemia, The University of Texas MD Anderson Cancer Center, 2McGovern Medical School, The University of Texas Health Science Center, 3Stem Cell Transplantation & Cellular Therapy, The University of Texas MD Anderson Cancer Center, Houston, United States

Background: Myelodysplastic syndromes (MDS) are hematopoietic disorders characterized by the ineffective production of mature blood cells of one or more lineages and by the risk of evolution to acute myeloid leukemia. The current standard of care for MDS patients is the treatment with hypomethylating agents (HMA); however, response to drugs from this family occurs in just about half of the patients and is accompanied by high rates of therapy failure. Failure to HMA in MDS is a poorly understood process associated to increased risk of disease progression and to a dismal prognosis and cannot be, thus far, predicted or prevented.

Aims: Given that MDS are stem cell disorders, our aim was the identification and molecular characterization of the specific hematopoietic stem/progenitor cell (HSPC) population in which the relapse-driver clones arise. This is an essential step for the development of effective monitoring and early intervention protocols for HMA failure.

Methods: Using flow cytometry immunophenotyping, we quantitatively analyzed the different cell subpopulations within the CD34+CD38- and CD34+CD38+ HSPC compartments in 122 sequential MDS bone marrow samples obtained from 93 patients at different stages of HMA treatment.

Results: In line with earlier reports suggesting the presence of alterations in myeloid progenitor frequencies in MDS, our flow cytometry data stratified untreated patient samples in two groups representative of two abnormal differentiation patterns, which were independent of the IPSS risk classification. The “CMP pattern” group (12 samples, 34%) was characterized by an increased frequency of the common myeloid progenitors (CMP) (2.6-fold; p<10^-4), whereas the “GMP pattern” group (23 samples, 66%) was characterized by the ineffective production of one or more lineages and by the risk of evolution to acute myeloid leukemia. The molecular pathogenesis of cooperation of RUNX1 and ASXL1 mutations has not been reported yet.

Aims: We aimed to determine the functional role of cooperation of RUNX1 and ASXL1 mutations for secondary acute myeloid leukemia (sAML) transformation.

Methods: For in vitro study, we overexpressed RUNX1-WT/MT (R135T) in K562 cells which harboring ASXL1-MT (Y591X) and co-expressed with ASXL1-WT/MT (R693X) in murine 32D cells. After stable expression, functional properties were examined by using immunoblot, co-immunoprecipitation, quantitative RT-PCR, flow cytometry, cell proliferation, colony formation and gene expression microarray analyses. C57BL/6 mice were used for bone marrow transplantation (BMT) experiments for in vivo study.

Results: We found that RUNX1-MT augmented cell proliferation, colony formation, HOXA gene expression and inhibited megakaryocytic differentiation in ASXL1-MT K562 cells compared to RUNX1-WT or empty vector control. The cooperation of RUNX1 and ASXL1 mutations or the knocked down of ASXL1 cooperated with RUNX1-MT inhibited apoptosis and impaired differentiation in 32D cells. Nine months post BMT mice with the combined RUNX1 and ASXL1 mutations, but not RUNX1-MT or ASXL1-MT alone, developed disease characterized by marked splenomegaly, hepatomegaly, and leukocytosis with a shorter latency. We found that RUNX1-MT stabilized hypoxia-inducible factor 1α (HIF-1α) and increased its target gene expression such as ID1 (inhibitor of DNA binding 1). Clinical samples analyses showed that ID1 expression increased in both RUNX1-MT and ASXL1-MT or the combined mutations of RUNX1 and ASXL1 compared to control samples. We also examined the impact of RUNX1 and ASXL1 mutations on sAML-free survival of 104 Patients with CML, in whom 11 had co-occurrence of RUNX1 and ASXL1, 39 had either mutated ASXL1 or RUNX1 and 54 patients were negative for both mutations. We found that patients carrying co-existing mutations had a shorter sAML-free-survival (median 16.1 months, 95% CI 0.0-60.1 months) than those carrying either mutated gene alone (median 23.0 months, 95% CI 17.8-28.2 months) or negative for both mutated genes (median not reached, 59.2 ± 8.8% at 5 years) (P=0.023).

Summary/Conclusions: The present study demonstrated that clinical and functional evidence for a collaborative association of RUNX1-MT and ASXL1-MT for sAML transformation. We identified HIF-1α targeting a new pathway which may be critical for leukemia progression of RUNX1/ASXL1-mutated myeloid malignancies.

A NOVEL MASS SPECTROMETRY METHOD REVEALS THE INTRACELLULAR PHARMACOKINETICS OF AZACYTIDINE THERAPY IN VIVO
A. Unnikrishnan1, A.V. Ngoc Quyhn2, R. Pickford2, A. Nuñez1, L. Hasson1, F. Pignatelli3
1Prince of Wales Clinical School & Lowry Cancer Research Centre, 2Bioanalytical Mass Spectrometry Facility, UNSW Sydney, 3Haematology Department, Prince of Wales Hospital, Sydney, Australia

Figure 1. Working flow cytometry immunophenotyping, we quantitatively analyzed the different cell subpopulations within the CD34+CD38- and CD34+CD38+ HSPC compartments in 122 sequential MDS bone marrow samples obtained from 93 patients at different stages of HMA treatment.
Background: The cytidine analog 5’-Azacytidine (AZA, Fig A), a DNA demethylating agent, is the primary drug for the treatment of high-risk Myelodysplastic Syndrome (MDS) and Chronic Myelomonocytic Leukaemia (CMML), and response is associated with improved survival benefits. However, only ~50% of treated patients will ever respond to AZA and the molecular basis for poor response is poorly understood. It is unclear whether non-responders to therapy have different rates of AZA uptake into their cells and/or AZA incorporation into nucleic acids compared to AZA responders, nor whether these might relate to DNA methylation in vivo.

Aims: We aimed to develop an analytical method capable of simultaneously detecting all the subcellular fractions of AZA (Fig B) within the bone marrows of patients undergoing AZA therapy, while also assessing DNA and RNA methylation levels. This would provide the most comprehensive snapshot of the intracellular pharmacokinetics of AZA therapy in vivo as a first step towards better understanding AZA resistance.

Methods: We have developed a new method utilising mass spectrometry to accurately quantify all the different subcellular fractions of AZA within the same sample (Fig C). Using an Orbitrap mass spectrometer with very high mass resolution, we have achieved the first mass separation of DAC and AZA from all naturally occurring isopes of deoxyctydine and cytidine respectively (a difference of less than 1 Da), thus enabling accurate quantification. We utilised subcellular fractionation to obtain purified quantities of DNA- and RNA-incorporated nucleotides, as well as free unincorporated nucleotides present in the cytoplasm. We developed a reaction reduction to reduce the spontaneous hydrolysis of nucleotides, as well as free unincorporated nucleotides present in the cytoplasm.

We aimed to develop an analytical method capable of simultaneously detecting all the subcellular fractions of AZA (Fig B) within the bone marrows of patients undergoing AZA therapy, while also assessing DNA and RNA methylation levels. This would provide the most comprehensive snapshot of the intracellular pharmacokinetics of AZA therapy in vivo as a first step towards better understanding AZA resistance.

We have developed a new method utilising mass spectrometry to accurately quantify all the different subcellular fractions of AZA within the same sample (Fig C). Using an Orbitrap mass spectrometer with very high mass resolution, we have achieved the first mass separation of DAC and AZA from all naturally occurring isopes of deoxyctydine and cytidine respectively (a difference of less than 1 Da), thus enabling accurate quantification. We utilised subcellular fractionation to obtain purified quantities of DNA- and RNA-incorporated nucleotides, as well as free unincorporated nucleotides present in the cytoplasm. We developed a reaction reduction to reduce the spontaneous hydrolysis of nucleotides, as well as free unincorporated nucleotides present in the cytoplasm. We developed a new method, our results have revealed that while AZA responders incorporated AZA efficiently into DNA, leading to DNA demethylation, there were two modes of primary AZA resistance: in some non-responders, low levels of AZA incorporation into DNA likely derives from cell cycle quiescence, resulting in low amounts of DNA demethylation. However, in other non-responders who showed DAC incorporation into DNA and demethylation, resistance arises from as-yet-unknown mechanisms not connected with AZA metabolism.

Results: Using our new method, we report for the first time direct simultaneous quantification of: (1.) DNA-incorporated DAC, (2.) intracellular, free DAC, (3.) methyl deoxycytidine in DNA, (4.) RNA-incorporated AZA, (5.) intracellular, free AZA, and (6.) methyl cytidine in RNA within the same sample. We demonstrate an inverse correlation between the amount of DAC incorporated into DNA and DNA methylation. However, no such correlation was observed between AZA incorporation and RNA demethylation (Fig D). The specificity and resolution of our method also enabled, for the first time, a comprehensive survey of the total intracellular pharmacokinetics of AZA in vivo in patients undergoing a standard cycle of treatment. We discovered that the bone marrow cells of AZA responders (n=8) incorporated DAC to a far greater extent than non-responders (n=2). DAC incorporation was also inversely proportional to DNA methylation levels, with higher DNA demethylation observed in the responders compared to non-responders. Furthermore, we observed two patterns in AZA non-responders, with DAC-incorporation and DNA demethylation occurring in some individuals (n=2) without evidence of DAC incorporation and no DNA demethylation (Fig E). Our method also enabled us to directly prove that low DAC incorporation was not a result insufficient AZA accumulation intracellularly, as cytoplasmic measurements of unincorporated AZA and DAC were higher in the non-responders with the lowest levels of DNA-incorporated DAC. Additionally, in these non-responders, there was also concomitant increase in AZA incorporation into RNA.

Summary/Conclusions: We have developed a new method that has enabled the first comprehensive analysis of the intracellular pharmacokinetics of AZA therapy in vivo. Our results have revealed that while AZA responders incorporated AZA efficiently into DNA, leading to DNA demethylation, there were two modes of primary AZA resistance: in some non-responders, low levels of AZA incorporation into DNA likely derives from cell cycle quiescence, resulting in low amounts of DNA demethylation. However, in other non-responders who showed DAC incorporation into DNA and demethylation, resistance arises from as-yet-unknown mechanisms not connected with AZA metabolism.

Background: Myelodysplastic syndromes (MDS) are a heterogeneous group of clonal hematological disorders at high risk of progression to acute myeloid leukemia (sAML). Due to recent high-throughput sequencing studies, the mutational dynamics and clonal evolution underlying disease progression have just begun to be understood. However, large longitudinal sequencing genomic studies are still required.

Aims: To analyze the relationship between the dynamics of gene mutations and cell pathways they are involved in with the progression from MDS to sAML in order to study the mechanisms underlying disease evolution.

Methods: Sixty-eight serially collected samples from 34 MDS/CMML patients evolving to sAML were studied by a combination of whole-exome sequencing (WES) and targeted-deep sequencing (TDS). Each patient was studied at two different time-points: at the time of diagnosis (MDS/CMML stage) and after sAML progression (disease evolution, leukemic phase). At initial presentation of the disease, diagnoses were as follows: 18 RAEB-1/2, 9 RCMD and 7 CMML. Initially, WES was carried out on 40 diagnosis/progression-matched samples. Driver mutations were identified, after variant calling by a standardized bioinformatics pipeline, by using the novel tool “Cancer Genome Interpreter” (https://www.cancergenominterpreter.org). Secondly, in order to validate mutations and precise variant allele frequencies (VAFs) estimation, TDS using a custom MDS/sAML-related capture enrichment panel (illumina) of 117 genes was performed in 30 out of 40 of the initial cohort. Moreover, a total of 28 paired-samples from a cohort of 14 patients were analyzed by TDS.

Results: Combining both WES and TDS approaches, a total of 143 mutations in 50 different genes were identified at the sAML stage, with most of them (118 mutations) already present at the MDS stage, at clonal or subclonal levels.

The most recurrently mutated genes were SRSF2 (21%), TET2 (21%), SF3B2 (28%), SF3B1 (21%), ASXL1 (21%), TP53 (21%) and NRAS (21%). However, it should be noted that 68% genes were mutated only in less than 10% of the patients, highlighting the great heterogeneity that exists in the mechanisms of disease evolution during disease progression. To study the mutational dynamics during disease progression we compared VAFs of mutations detected at both time-points (sAML to MDS/CMML stage) in each patient. We identified 4 different clonal dynamics: mutations that were initially present but increased VAF (type-1), decreased (type-2), were newly acquired (type-3) or persisted with similar allelic burden (type-4) at sAML stage. Interestingly, most of type-1 mutations were detected in STAG2 gene. Thus, mutational burden of STAG2 were markedly increased (6/8 patients) at sAML progression. Moreover, type-3 mutations, only detected at the sAML-stage, were predominantly identified in FLT3 (3/4) and NRAS (5/6).

Conversely, type-4 mutations were present in MDS-related genes such as SRSF2 (8/12), SF3B1 (3/6) and TET2 (8/12). Most of mutations in these genes showed no changes during progression to sAML.

Summary/Conclusions: Progression from MDS to sAML could be explained by different mutational processes, as well as by the occurrence of unique and complex changes in the clonal architecture of the disease during the evolution. Mutations in genes such as STAG2, FLT3 or NRAS could play an important role during disease progression.
Results: Our data showed promising results with the injection of mononuclear cells obtained from patient BM, however the co-injection of mesenchymal stromal cells (MSCs) did not improve the level of engraftment. To address the question of the becoming of MSCs once injected, we tracked them back into the mice BM and showed that they disappeared after a week of engraftment. With a 2D in vitro system, we showed that we could co-culture CD34+ cells with preexisting BM, on single-cell level and in co-culture, and that MSCs, over 4 weeks with a fold expansion ranging from 50 to 600 times. More importantly those cells conserved their clonal architecture and chromosomal aberrations.

Figure 1.

Summary/Conclusions: Although the in vivo model cannot be replaced, the low level of engraftment of most of the patients is a limit in the study of MDS. Here we have demonstrated the value of the 2D co-culture system using MSCs (or murine MS5) as an alternative model to study MDS. This ex vivo culture system, which lasts for only 4 weeks and requires low number of human CD34+ cells, provides a robust preclinical assessment model to test therapeutic effects of different drugs and other approaches on the MDS clonality and autologous MSCs prior to treatment of MDS patients.
V-SET AND IMMUNOGLOBULIN DOMAIN-CONTAINING 4 (VSIG4) EXPRESSED ON MONOCYTES INCLUDING TUMOR-ASSOCIATED MACROPHAGES SUPPRESSED ANTITUMOR IMMUNE RESPONSES IN MYELODYSPLASTIC SYNDROMES

Y. Kurbayashii-Hamad1,2, H. Tamura1, M. Ishibashi1, T. Asayama1, K. Moriya1, I. Choi1, K. Inoue1
1Department of Hematology, Nippon Medical School, Japan, Sendagi, Bunkyouku, Tokyo, Japan, 2Department of Microbiology and Immunology, Inje University College of Medicine, Busan, Korea, Republic Of

Background: In myelodysplastic syndromes (MDS), blast cells increase with clonal proliferation during disease progression, while immune cells in the bone marrow (BM) microenvironment become less efficient. The V-set and immunoglobulin domain-containing 4 (VSIG4) molecule is a new B7 family-related protein and strong negative regulator of T-cell proliferation. However, the role of VSIG4 in tumors including hematological malignancies remains unknown.

Aims: We investigated the expression and functions of VSIG4 in MDS.

Methods: 1) Peripheral blood (PB) and BM samples were obtained from 39 patients with acute leukemia transformed from MDS (AL-MDS, N=21), MDS (N=13), and chronic myelomonocytic leukemia (CMML, N=5) and from healthy controls (N=14). The expression of VSIG4 in mononuclear cells (MCs) from the samples and BM cell lines (F-36P and SKM-1) was analyzed with real-time PCR and flow cytometry (FCM).

2) After cultivation with BM stromal HS-5 cells, its culture supernatants (HS-5 sup.), immunomodulatory drugs (lenalidomide, thalidomide and azacitidine), and VSIG4 expression on cells was determined using FCM.

3) The proliferative potential was examined by BrdU incorporation using FCM and the MTT assay. 4) The cytotoxic activity of natural killer (NK) cell line NK-92MI was examined with donor T cells co-cultivated with HS-5 sup., immunomodulatory drugs (lenalidomide, thalidomide and azacitidine), and VSIG4 expression on cells.

Results: 1) VSIG4 mRNA expression in PBMCs from patients with AL-MDS was significantly higher than in those from controls. Cell-surface VSIG4 expression on CD14+CD11b+ monocytes from MDS and AL-MDS patients was higher than in those from controls, but VSIG4 expression was not detected on CD34+ blasts. In CD14+CD11b+ monocytes of MDS and AL-MDS patients, VSIG4 was strongly expressed on CD68+CD206+ tumor-associated macrophages (TAMs). Furthermore, the expression levels of VSIG4 on CD14+ monoblasts from CMML patients was significantly upregulated in comparison with those from controls.

2) Two MDS cell lines expressed both VSIG4 mRNA and its cell-surface protein. VSIG4 expression on MDS cell lines, and on monocytes and monoblasts from MDS and CMML patients, respectively, was significantly upregulated by co-culture with HS-5 sup., LEN, and POM, but not with cytarabine or azacitidine.

3) VSIG4 expression was inversely correlated with the expression of PARP1.

4) The cytotoxic activity of NK cells was inversely correlated with the expression of VSIG4 in CD14+CD11b+ monocytes, and the proliferation of VSIG4+ cells was suppressed by VSIG4-specific small interfering RNA. 5) LEN-treated K562 cells, which induced high VSIG4 expression, were more resistant to NK-mediated cytotoxicity than untreated K562 cells.

The production of IFN-γ from donor T cells co-cultivated with LEN-treated MDS cells was suppressed compared with control cells.

Summary/Conclusions: Our study demonstrated that VSIG4 was highly expressed on monocytes including TAMs in MDS and AL-MDS patients, and on monoblasts in CMML patients. VSIG4-expressing monocytes and monoblasts may suppress antitumor immune responses and be associated with disease progression in MDS and CMML. The results will allow us to elucidate the function of VSIG4 in MDS pathophysiology and lead to the development of new immunotherapy.

TRANSCRIPTOME ASSESSMENT OF DNA REPAIR GENES IN CHRONIC MYELOMONOCYTIC LEUKAEMIA: SYNTHETIC LETHALITY TARGETS

S. B. Fraga1, M. A. Hurtado López2, A. C. O. M. Hernández2, E. Caparrós1, B. Przychodzen4, L. Zamora2, F. Ortúno1, V. Vicente1, J. M. Maciejewski4, C. Del Cañizo3, F. Soló2, F. Ferrer-Marin1, A. Jerez1

1Hematology and Medical Oncology Department, Hospital Morales Meseguer, 2José Carreras Leukaemia Research Foundation, 3HC Hospital Germans Trias i Pujol, Universitat Autònoma de Barcelona, Barcelona, 4Department of Hematology, Hospital Universitario de Salamanca, Salamanca, Spain, 5Department of Translational Hematology and Oncology Research, Taussig Cancer Institute, Cleveland Clinic, Cleveland, OH, USA, United States

Background: Though genetic instability is a hallmark of myeloid disorders, the lack of recurrent somatic mutations, inarguably pathogenic, in the DNA repair machinery have precluded a predominant interest in this pathway. However, the recent discovery of non classical leukaemogenesis by splicing defects, the repair pathway influence of e.g. NEL1 and OGG1, and the development of unbiased high-throughput sequencing approaches oblige us to revisit those routes in blood cancers.

Aims: To perform improved massive RNA-seq in chronic myelomonocytic leukaemia (CMML) samples to identify neoplasm-specific targets for a synthetic lethality therapeutic approach. To validate the candidates through a direct strategy in an extended cohort of CMML, myelodysplastic syndromes (MDS) and acute myeloid leukaemia (AML) patients.

Methods: We performed enhanced RNA-seq on 27 CMML bone marrow samples from 27 CMML patients and 10 healthy donors. Defects on genes predominantly unique to a single leukemia type were identified. Moreover, we identified oncogenes infra-expressed in our cohort but with inhibitory molecules already being tested in myeloid neoplasms (i.e. PARP1). Global pattern of DNA repair gene expression was compared with MDS and AML MILE study data.

Results: Of 27 CMML patients and 10 healthy donors, the expression of 18 genes was significantly different between the two groups (p-value<0.05) with 6 genes up-regulated and 12 genes down-regulated in CMML patients compared with donors. Defects on genes predominantly unique to AML, such as NEL1, OGG1, were included in our myeloma samples.

Summary/Conclusions: We validated the candidates through a direct strategy in an extended cohort of CMML, MDS and AML patients. We further chose 13 of the differentially expressed genes for validation and characterization through the myeloid spectrum based on clinical characteristics: 3) deregulated expression of DNA repair candidate genes in CMML, 4) oncogenes infra-expressed in our cohort with or allowing for the inhibition of an specific DNA repair pathway (i.e. XPA, XRCC4, MSH4): ii) oncogenes infra-expressed in our cohort but with inhibitory molecules already being tested in myeloid neoplasms (i.e. PARP1).

Global pattern of DNA repair gene expression was compared with MDS and AML MILE study data.

DIFFERENTIAL DIAGNOSIS BETWEEN MYELODYSPLASTIC SYNDROMES AND NON-CLONAL CYTOPENIAS BY FLOW CYTOMETRY ANALYSIS USING A MYELOID MATURATION DATABASE

M. T. Cedena1, F. Mirás1, R. M. Ayala1, E. Martín-Clavero1, M. L. Paciello1, A. Martínez-López1, J. Martínez-López1, J. Martínez-López1

1Hematology, 2H. 12 Octubre, Madrid, Spain

Background: The diagnosis of myelodysplastic syndromes (MDS) is based

haematologica | 2017; 102(s2) | 261

Madrid, Spain, June 22 – 25, 2017
on cytomorphological characteristics, but it remains a challenge in some patients who do not fulfill diagnostic criteria. Flow cytometry (FC) immunophenotyping can be an important tool for MDS diagnosis, but a lack of standardisation and subjectivity of the analysis hinders its applicability.

Aims: To develop a methodology for FC immunophenotyping that allows us to establish the differential diagnosis between MDS patients and non-clonal cytopenias using a myeloid maturation database.

Methods: Bone marrow samples from 55 MDS patients, and 51 controls with cytopenias of several origins (immune disease, hypersplenism, drug toxicity) were analysed by FC. We elaborated a Myeloid Maturation Database using the Infinicyt® v1.7 software (Cytognos, Spain). From all bone marrow controls, we merged files stained with a 4-colour combination (CD16-FITC/CD13-PE/CD45-PC5/CD11b-APC). We selected myeloid population from the merged file and drew a maturation path. We obtained a maturation diagram that displays the fluorescence intensity of each parameter measured along the maturation stages. Then, for patients and controls, we obtained the fluorescence intensities whose median values exceeded ±2SD range in comparison with the stored database values (Figure 1). We elaborated a score, considering the relevant changes in fluorescence intensities (deviations) in the four markers analysed (CD16, CD13, CD45, CD11b) and in the four maturation stages, with a punctuation from 0 to 16.

Results: We found a mean of 1.9 deviations (fluorescence intensities values exceeded ±2SD) in controls, and a mean of 4.5 deviations in patients. Our test resulted reliable for differential diagnosis between controls and patients (curve ROC analysis, AUC=0.748; p=0.016). We found that with a cut-off of 4.5 deviations, we obtained a high specificity in the diagnosis of MDS (100%) but a low sensitivity (45%). With a high suspicion of MDS (specificity 90%), we can consider patients with scores above 3.5, thus achieving higher sensitivity (59%). Additionally, the number of immunophenotyping changes correlated well with prognostic risk. We confirmed that the higher the risk, the greater impact on deviations from the normal pattern (average of 3.7 at low risk, 4.5 at intermediate risk; 6.8 at high risk) (Figure 2).

Figure 1.

Summary/Conclusions: The maturation database (using the maturation analysis from Infinicyt® software) was useful to discriminate between MDS patients and non-clonal cytopenias, proving to be a reliable diagnostic test, also with prognostic implications. The application of this database as a diagnostic tool has the advantage that the result is independent of the observer. Inclusion of more myeloid markers and incorporation of erythroid parameters could increase sensibility in differential diagnosis.
P664

Background: Epigenetic drugs are currently used for the treatment of several hematologic malignancies, but their pharmacological mechanism remains poorly understood. For DNA methyltransferase and histone deacetylase (DNMTi and HDACi) several mechanisms of action have been proposed, mostly based on candidate gene approaches. However, less is known about their genome-wide transcriptional and epigenomic consequences.

Aims: To investigate the effects of epigenetic treatment on transcription and chromatin, we profiled genome wide transcription start sites (TSSs) activities and alternatively spliced transcripts following the treatment with inhibitors against DNMTs, HDACs, or both.

Methods: Genome wide analysis of transcription start sites (TSSs) (Cap analysis of gene expression (CAGE) sequencing), methylation status (whole-genome bisulphite sequencing) and chromatin dynamics (Chromatin-immunoprecipitation (ChIP) sequencing) was performed in wild type lymphoblastoma-Xenograft model. Functional assays were used to investigate the mechanisms of LTR reactivation, a neuroblastoma mouse xenograft model to confirm the LTR reactivation in vivo.

Results: Following the treatment with inhibitors against DNMTs, HDACs, or both, we observed the activation of thousands of cryptic, currently non-annotated transcription start sites (treatment-induced non-annotated transcripts, TINATs). These TINATs arose most commonly from LTR12 elements, particularly LTR12C (ca. 50% of all TINATs). The resulting transcripts frequently splice into protein-coding exons and encode truncated or chimeric open reading frames which translated into currently uncharacterized protein isoforms with predicted abnormal functions or immunogenic potential, the last one based on their foreign sequence and capability of being presented on MHC-class I molecules. TINAT expression after DNMTi coincided with DNA hypomethylation and HDACi with histone reactivation. The observed changes were not only limited to the LTR12C/LTR12F base. We identified a subset of TINATs in association with H2AK9ac, H3K14ac, and H3K23ac. Despite this mechanistic difference, both inhibitors convergently induced transcription from identical sites since TINATs are encoded in solitary long-terminal repeats of the endogenous retrovirus-9 family, epigenetically repressed virtually all normal cells. Moreover, we found a consensus GATA2 binding motif which strongly distinguished LTR12C/LTR12F elements from the rest, allowing for extensive downstream analysis.

Summary/Conclusions: A LTR12C (ca. 50% of all TINATs) expressed in response to DNMTi and HDACi treatment. LTR12C/LTR12F elements were not only limited to the LTR12C/LTR12F base. We identified a subset of TINATs in association with H2AK9ac, H3K14ac, and H3K23ac. Despite this mechanistic difference, both inhibitors convergently induced transcription from identical sites since TINATs are encoded in solitary long-terminal repeats of the endogenous retrovirus-9 family, epigenetically repressed virtually all normal cells. Moreover, we found a consensus GATA2 binding motif which strongly distinguished LTR12C/LTR12F elements from the rest, allowing for extensive downstream analysis.

IMPACT OF MARROW COMPLETE RESPONSE IN THE NATURAL HISTORY OF PATIENTS WITH MYELODYSPLASTIC SYNDROMES (MDS) AND CHRONIC MYELOMONOCYTIC LEUKEMIA (CMML) TREATED WITH HYPOMETHYLATING AGENTS

A. Alfonso Pierola1,*, G. Montalban-Bravo1, K. Takahashi1, E.J. Jabbour1, T. Kadia1, F. Ravandi1, J. Cortes1, C. DiNardo1, N. Daver1, G. Borthakur1, N. Pemmaraju1, M. Konopleva1, C. Bueso-Ramos2, S. Pierce1, H. Kantarjian1, G. Garcia-Manero1, J. Kudryk1, A. Garcia-Manero2, L. Estrov3, A. Sather4, K. Vardiman5, J. Estrov6, J. Cortes7, C. DiNardo7, N. Pemmaraju7, N. Daver8, G. Borthakur8, N. Pemmaraju8, M. Konopleva8, C. Bueso-Ramos8, S. Pierce9, H. Kantarjian10, G. Garcia-Manero10, 1Leukemia, 2Hematopathology, MD Anderson Cancer Center, Houston, United States, 3Department of Internal Medicine, The Ohio State University, Columbus, United States

Background: The concept of marrow complete response (mCR) was included for the first time in the 2006 International Working Group (IWG) response criteria in MDS. mCR is defined as a reduction to ≤5% myeloblasts and decrease by ≥50% compared to baseline with persistent cytopenias. However, their inclusion in the response criteria remains controversial as it is not known how it affects the natural history of MDS or CMML.

Aims: The aim of our study was to describe the impact of mCR in survival outcomes in patients with MDS treated with hypomethylating agents (HMA).

Methods: We retrospectively reviewed 713 patients diagnosed with MDS or CMML and treated with frontline HMA between 2004 and 2015 at a single institution. Clinical and demographic data were obtained from an electronic database. Response was assessed by modified 2006 IWG criteria. Statistical analyses were performed with the IBM SPSS Statistics 23.0 software. All tests were 2-sided with significance set at p<0.05.

Results: 444 (62.3%) patients from the initial cohort achieved at least hematologic improvement (HI) as best response and were included in the analysis. 162 (37%) patients were female. Median age at diagnosis was 68 years (range 17-91). Following the 2016 WHO classification: 30 patients (7%) were MDS-SD, 50 (11%) MDS-MLD, 20 (5%) MDS-RR, 230 (52%) MDS-EB, 10 (2%) MDS-UM, 140 (24%) CMML. According to the Revised International Prognostic Scoring System (IPSS-R), 37 patients (8%) belonged to the low risk group, 176 (40%) to the intermediate-1 risk group, 198 (45%) to the intermediate-2 risk group, and 31 (7%) to the high risk group. 200 (45%) patients received azacitidine-based therapies and 244 (55%) decitabine-based therapies. Responses included: 238 (33% of the total population) complete responses (CR), 61 (9%) mCR, 2 (<1%) partial responses (PR) and 143 (20%) stable disease (SD). HI was observed in 410 (58% of the total population) of the patients. The median time to response was 3 cycles (range 1-24). Median overall survival (OS) since the last evaluated mCR was 20.1 months.
Luspatercept increases hemoglobin and reduces transfusion burden in patients with lower-risk myelodysplastic syndromes (MDS): long-term results from phase 2 PACE-MDS study

1Marien Hospital Düsseldorf, 2Universitätsklinikum Düsseldorf, Düsseldorf, 3III. Department of Medicine, Hematology and Medical Oncology, Technical University of Munich, Klinikum rechts der Isar, Munich, 4Onkologischer Schwerpunkt am Oskar-Helene-Heim, Berlin, 5OncoResearch Lerchenfeld UG, Hamburg, 6University Hospital Bonn, Bonn, 7Universitätsklinikum Frankfurt, Goethe-Universität, Frankfurt/Main, 8Johannes Gutenberg-Universität, Mainz, Germany, 9Astellas Pharma UK Inc, Cambridge, 10Celgene Corporation, Sunvalley, United States, 11Universitätsklinikum Carl Gustav Carus, Dresden, Germany.

Background: Management of anemia is a common therapeutic challenge in patients (pts) with MDS. Luspatercept (ACE-536), a fusion protein containing modified action receptor type IIb, is being developed for treatment of anemia in lower-risk MDS. Luspatercept binds to select TGF-β superfamily ligands (such as GDF11) reducing aberrant Smad2/3 signaling and promoting late-stage erythroid differentiation and increased hemoglobin (Hgb) levels (Suragani R, Nat Med, 2014; Attie K, Am J Hematol, 2014).

Aims: This ongoing phase 2, multi-center, open-label study followed by a long-term extension (ext) study evaluates the effects of luspatercept in pts with lower-risk MDS. Endpoints include long-term safety and tolerability, erythroid response (IWG HI-E), RBC transfusion independence (RBC-TI), 8 weeks);

duration of HI-E, pharmacodynamic and iron metabolism biomarkers, and pt-reported quality of life (QoL).

Methods: Inclusion criteria: MDS IPSS low or int-1, age ≥18 yr, Hgb <10 g/dL (if <4U RBC/8 weeks), no prior HMA, and no current lenalidomide or erythropoiesis-stimulating agent (ESA). The dose-escalation phase of the study is completed. An expansion cohort of up to 56 patients was added to this phase of the study to evaluate response and tolerability in pts who would not qualify for the phase 3 MEDALIST trial (for regularly transfused ring-sideroblast positive [RS(+)] patients with EPO <200 U/L). These include pts with low transfusion burden (LTB, <4U RBC/8 weeks) and either 1) RS(+) (≥15% in bone marrow) or 2) RS(-) and any EPO level. RS(-) pts are also treated until RBC-TI/8 weeks. Pts are treated every 3 weeks subcutaneously for up to 5 doses (titration up to 1.75mg/kg) in the base and ext studies, respectively, were 62% (18/29) and 80% (45/56) for RS(+) pts with EPO <200 U/L and 46% (5/11) and 80% (7/9) for RS(-) pts with EPO 200-500 U/L. RBC-TI rates for pts treated with ≥0.75mg/kg in the base and ext studies, respectively, were 68% (13/19) and 85% (23/27) for RS(+) pts with EPO <200U/L and 48% (6/13) and 80% (9/11) for RS(+) pts with EPO 200-500 U/L. Preliminary RS(-) response rates (IWG HI-E and RBC-TI) by subgroup will also be presented at the meeting. Luspatercept was well tolerated, with related grade 3/4 adverse events (in 3 pts as of 28Nov2016 of blast cell count increase, myalgia, and worsening of general condition. The most common other AEs (≥2 pts) were diarrhea, fatigue, headache, hypertension, arthralgia, bone pain, injection site erythema, myalgia, and peripheral edema.

Summary/Conclusions: Lower-risk MDS patients treated long-term with luspatercept demonstrated robust and sustained increases in Hgb and decreases in transfusion burden and a high rate of RBC-TI. A Phase 3 study of luspatercept in regularly-transfused RS(+) patients with low-risk MDS according to the Italian MDS registry of Fondazione Italiana Sindrome Mielodisplastica (FISM).

Figure 1.

Results: Data (as of 09Sept2016) were available for 73 base and 42 ext study pts. Pts aged 22 and 2 ext pts were LTB and 41 base ext pts were high transfusion burden (HTB, ≥4U RBC/8 weeks). Median (range) age (yr) was 72 (27-90), 53% pts had prior ESA, 51% pts had baseline EPO <200 U/L. Median (range) Hgb (g/dL) for HTB pts was 8.6 (6.4-10.1). Median (range) RBC transfusion burden (U/8 weeks) for HTB pts was 6 (4-8). 71% base and 86% ext pts were RS(-). IWG HI-E response rates for pts treated with ≥0.75mg/kg in the base and ext studies, respectively, were 62% (18/29) and 80% (45/56) for RS(+) pts with EPO <200 U/L and 46% (5/11) and 80% (7/9) for RS(-) pts with EPO 200-500 U/L. RBC-TI rates for pts treated with ≥0.75mg/kg in the base and ext studies, respectively, were 68% (13/19) and 85% (23/27) for RS(+) pts with EPO <200U/L and 48% (6/13) and 80% (9/11) for RS(+) pts with EPO 200-500 U/L. Preliminary RS(-) response rates (IWG HI-E and RBC-TI) by subgroup will also be presented at the meeting. Luspatercept was well tolerated, with related grade 3/4 adverse events (in 3 pts as of 28Nov2016 of blast cell count increase, myalgia, and worsening of general condition. The most common other AEs (≥2 pts) were diarrhea, fatigue, headache, hypertension, arthralgia, bone pain, injection site erythema, myalgia, and peripheral edema.

Summary/Conclusions: Lower-risk MDS patients treated long-term with luspatercept demonstrated robust and sustained increases in Hgb and decreases in transfusion burden and a high rate of RBC-TI. A Phase 3 study of luspatercept in regularly-transfused RS(+) patients with lower-risk MDS according to IPSS-R is ongoing (MEDALIST study; NCT02631070).

Background: Azacitidine (AZA) is the current standard of care for patients with high-risk myelodysplastic syndrome (MDS) in Europe. AZA has shown a
survival advantage when compared with conventional therapies and has also shown activity in IPSS lower-risk patients. However, about 40% of patients do not respond and most patients lose response within 2 years. Treatment options for MDS patients failing hypomethylating agents therapy are scarce and overall survival (OS) is extremely short.

**Aims:** Objectives of this study were to describe in a cohort of real life MDS patients treated with AZA, the reasons causing treatment discontinuation, and to evaluate the clinical outcome after the end of AZA therapy.

**Methods:** Unselected patients recorded in the MDS Registry of Fondazione Italiana Sindromi Mielodisplastiche (FISM) and treated with AZA from January 2009 to June 2014 were considered for the analysis. All types of conventional and hypomethylating agents allowed of AZA were allowed. Clinical response, cause of discontinuation, salvage treatments and OS from discontinuation of AZA were the major end points.

**Results:** Between January 2009 to June 2014 1799 newly diagnosed MDS patients were enrolled in the Registry, and 418 received AZA; 269 as 1st line treatment (46%), 111 as 2nd line treatment (28%), and 34 as a line ≥3rd (8%). Median age was 73 years (range 18-91); 260 patients (62%) were male. WHO diagnosis was RA or RARS (n=27, 6%), RCMD with or without RS (n=62, 15%) AN (n=126, 30%) AEB-1 (n=116, 28%), AEB 2 (n=189, 45%), other subtypes (n=15, 4%). At start of AZA therapy IPSS score was low in 14 (3.4%), int1 in 97 (23.2%), int2 in 163 (43.8%); high in 67 patients (16%), and not available in 57 patients (13.6%). Patients received a median of 7 courses of treatment (range 1-63). Seventy-three % of the whole cohort (418 pts) were alive at 1 year from beginning of AZA therapy and median OS was 23 months. (25 for IPSS lower-risk MDS and 21 for IPSS higher risk MDS). OS after discontinuation of AZA was 8 months. Clinical responses according to IWG criteria were available in 344/418 patients (82%); 44% achieved a complete hematological response, 77 (22%), a partial response, 86 (25%) had stable disease while 136 (32%) did not respond. Response was achieved after a median of 6 cycles. After a median follow up of 16 months (range 7-35) in 37 (9%) patients AZA therapy was still ongoing while in 381 (91%) the treatment has been discontinued. Interruption of treatment was due to loss of response in 59 (16%) patients, AML evolution in 154 (40%), death in 43 (11%), toxicity or poor compliance in 39 (10%), allo-genic transplant (HSCT) in 12 (3%), other reasons in 22 (6%), not reported in 52 patients (14%). Of the 381 patients who discontinued AZA, 15 (4%) were managed with intensive AML-like chemotherapy, 22 (6%), received an allogeneic HSCT, 27 (7%) low-dose chemotherapy (7%), 22 (6%) erythroid stimulating agents, 18 (5%) other treatments and 277 (72%) patients no further treatment or only supportive therapy.

**Summary/Conclusions:** Our data confirm that AZA therapy is effective for MDS patients, both with higher and lower IPSS risk disease. Response rate is consistent with what previously reported, with a median OS of 23 months. Interestingly, at 16 months, 91 % of patients had discontinued treatment, either for progression or loss of response and only in 10% of cases for reported toxicity. Only 28% of patients received any kind of salvage therapy and overall survival after AZA discontinuation was poor (8 months).

**Background:** Paediatric Myelodysplastic Syndromes (MDS) are a rare and heterogeneous group of disorders distinct from adult MDS. They may present with syndromic anemia, life threatening infection or evolving leukemia; however, they may also present as unexplained cytopenias or with multisystem disease of unclear aetiology. Diagnosis can represent a huge challenge for clinicians, even in highly specialised centres and this can delay the delivery of the most appropriate treatment. Hence an accurate diagnosis is crucial in selecting the most advantageous, including surveillance and follow up, treatment(s).

**Aims:** To devise a clinical grade diagnostic targeted NGS panel and combine the results with extensive clinical phenotypic information to obtain a diagnosis in children referred with suspected MDS.

**Methods:** Children (0-18yrs) were referred from 14 UK centres with a diagnosis of suspected MDS and/or sustained cytopenias with morphological features of myelodysplasia. Extensive phenotypic information including family history, detailed clinical examination and disease course details were collected and captured on an online database using the Human Phenomiser tool. A customised targeted NGS panel was designed using the illumina design studio containing 32 genes, 916 amplicons and 301 exons; selected through literature reports and well described mutations in Paediatric MDS and potential overlap with the Bone Marrow failure syndromes (BMFS). Coverage of each base within target regions was assessed for every sample on each sequencing run using Covemi software. Library preparation was performed using an illumina Truseq Custom Amplicon panel, followed by sequencing on an illumina MiSeq. Data analysis was performed using our established bioinformatic pipelines (Hamblin A: Blood 2014 124:2373).

**Results:** In total 59 patients (females= 29, males 30) have been screened and 3 subgroups identified based on the original suspected clinician diagnosis at presentation: MPN/JMML (n=15), de novo MDS (n=9) and idiopathic cytopenias of undetermined significance (ICUS) with some features of dysplasia (n=35). Mutations were detected in 24/59 patients (40%, Table 1). Of these, NGS results confirmed the original clinical diagnosis in 15 cases (62.5%); established the diagnosis for the first time in 6 cases (25%); and led to a change in diagnosis (from autoimmune neutropenia to Shwachman-Diamond Syndrome) in 1 case leading to a significant change in patient management. In two already known cases, it allowed monitoring of the disease molecular signature. As expected, RA or MDS patients were common in the JMML/MPN (100%) and de novo MDS patient subgroups (33%). Additional mutations in epigenetic modifiers, spliceosome mutations as well as second RA or MDS pathway hits were also detected in 40% of JMML patients, and in one case within the de novo MDS group; this finding was associated with poor outcome. Within the heterogenous ICUS patient group, pathogenic mutations were identified in 5/35 (14.3%) cases with BMFS genes (SBDS, ELANE, TP53). In contrast to the other MDS/MPN cases, in this group, no RA or MDS pathway mutations were detected.

**Table 1.**

**Summary/Conclusions:** Targeted NGS together with detailed phenotyping is a useful tool for the diagnosis of suspected MDS and unexplained cytopenias in children, with 40% of patient showing a disease-associated mutations. Results were available within 6-8 weeks in most cases enabling both rapid initial diagnosis and, in some cases, appropriate molecular markers for monitoring of clonal evolution and response to therapy. For the children who remain without a clinical diagnosis, whole genome sequencing (WGS) may identify pathogenic mutations and this is currently underway.
OUTCOMES IN PATIENTS ALLOCATED TO NO-ASCT BASED ON DEPTH OF RESPONSE: INITIAL RESULTS OF A PHASE 2 TRIAL ASSESSING THE IMPACT OF MINIMAL RESIDUAL DISEASE (MRD) IN PATIENTS WITH DEEP RESPONSE TO INDUCTION THERAPY — FMG-MM02

S. Luoma1,2,*, S. Ilveskero3, S. Rounioja4, J. Valtola5, T. Lundan6, J. Lievonen1, P. Smith3, L. Clifton-Hadley3, N. Rabin17, R. Popat1

Background: In multiple myeloma (MM) the interactions between malignant plasma cells and the bone marrow (BM) microenvironment are important for treatment outcome. There is limited data on the effects of lenalidomide (LEN) on the BM immune profile and its therapeutic predictive value. The FMG-MM02 study (NCT01797037) was designed to explore the response to LEN, bortezomib and dexamethasone (RVD) induction, followed by a single autologous stem cell transplantation (ASCT) and LEN maintenance as a first-line therapy for MM patients (n=80). The primary endpoint was achievement of an immunophenotypic remission. Here we report the results of one of the secondary endpoints: composition of lymphocyte subsets at baseline and during LEN maintenance.

Aims: The aim of this study was to assess the proportion of different lymphocyte subsets at baseline and after ASCT and correlate lymphocyte composition with patient outcome.

Methods: Flow cytometry (FC) panel included antibodies against CD38, CD138, CD45, CD19, CD56, CD27, CD28, CD81, CD117, intracytoplasmic kappa and lambda. Sequential analyses (at baseline, after induction and at 3, 9 and 16 months after ASCT) were performed in 37/80 patients who achieved at least near complete remission (nCR) and/or minimal residual disease (MRD) negativity by FC. In addition to MRD the samples of these patients were analyzed for mature B-cells (CD19+CD45+), B-cell progenitors (CD19+CD11b+CD38+CD45+), B-cell blasts (CD19+CD81+CD38+CD45dim), NK-T cells (CD56+CD16+), T-cells (CD3+CD8+, CD3+CD4+, CD3+CD8neg), T lymphocytes other than B-cells and T/NK-cells (CD34+), CD3+ activated T-cells as calculated per total bone marrow nucleated cells (TNC). The results were compared between two different response cohorts: the good cohort (n=26) defined by persistent stringent complete remission/FC negativity, or PCR negativity (≤ 0.006%) and the control cohort (n=11), who only achieved nCR or had early relapse within one year of ASCT.

Results: At baseline, markers for disease burden, such as the percentage of myeloma cells in BM or paraprotein levels did not differ between the response cohorts. No differences were noted in R-SS or ISS risk stratification either, but there were more IMWG high risk patients in the control cohort (p=0.048). The median percentage of total lymphocytes (15.4% vs 11.9% good vs control), T cells (9.6 vs 7.8), CD19+ B-cells (1.6 vs 1.3), and CD3+ T-cells (0.9 vs 0.5) in BM were all higher in the good response cohort at baseline. In particular, the median proportion of mature B cells in BM was significantly higher in the best cohort at baseline (1.32 vs 0.91; p=0.02), after induction (0.27 vs 0.13; p=0.002) and 16 months after ASCT (1.73 vs 0.56; p=0.008) (Figure 1).

Summary/Conclusions: Composition of the BM lymphocyte pool at treatment baseline may have an influence on treatment outcome in multiple myeloma. More detailed subtyping of the lymphocyte phenotypes is ongoing and may reveal potential predictive biomarkers for immunomodulatory drugs such as lenalidomide and checkpoint inhibitors.

Figure 1.
Bortezomib/DEXAMETHASONE IN PREVIOUSLY TREATED PATIENTS

E. Benedetti1, G. Buda1, E. Orlicio1, N. Cecconi1, G. Ceretti1, M. Rousseau1, L. Lovino1, F. Mazzotta1, M. Petri1

Background: Lytic lesions occur in the majority of patients with multiple myeloma (MM) and represent one of the criteria for starting therapy. In the past, whole-body X-ray (WBX) represented the method of choice for detecting skeleton abnormalities; today, magnetic resonance imaging (MRI), positron emission tomography (PET) and computed tomography (CT) have been adopted for their higher power in detecting extra-medullary localizations and their higher sensitivity. Nevertheless, which technique would be really the best one is still matter of discussion.

Aims: Our single-center retrospective study was designed to compare PET-CT with other imaging techniques (WBX, vertebral column CT and MRI) at the diagnosis and during the follow-up of MM patients. Finally, we assessed a possible predictive/prognostic role of the PET-CT in terms of quality of response and survival.

Methods: We enrolled 160 patients with diagnosed symptomatic (N=1419) or smoldering multiple myeloma (N=11) observed at the AOU, Pisa, Italy, between January 1996 and December 2015. Eighty-three were male and 77 female; the median age was 70 years (range, 28-85), and half of them presented with low ISS risk score. Forty-five subjects were not eligible to high-dose therapy; 64% of them received bortezomib- and 23% melphalan-based regimens. Patients eligible to high-dose therapy received VAD, TAD or VTD and then one (88%) or two (12%) autologous transplants. At the relapse, lenalidomide (57%) or anthracyclines (4%) were administered. In contrast, PET-CT sensitivity was comparable to that of CT and 40% in respect of WBX (71%). Analogously to that observed at diagnosis, PET-CT during follow-up showed distinct advantages in terms of sensitivity compared to X-rays (83% vs 60%, respectively). In contrast, PET-CT sensitivity was comparable to that of CT and MRI. As at diagnosis, the specificity was higher for WBX (70%) than for CT, RM and PET-CT (40% for all of these). When PET-CT was correlated to the quality of response, it was significant only in the not transplanted cohort (PR rate in PET-negative cases: BTZ77% vs 23% in the PET-positive group; p<0.016). Nevertheless, PET-CT positivity either at diagnosis or during follow-up did not impact on long-term OS and PFS.

Summary/Conclusions: Our study showed that PET-CT and MRI would represent the techniques of choice in the assessment of bone involvement in MM patients in view of their high and comparable sensitivity. Moreover, PET-CT allows the possibility of a “whole body” analysis in exchange for higher “biologic” cost.

P672
INITIAL PHASE 2 RESULTS OF IBRUTINIB COMBINED WITH BORTEZOMIB/DEXAMETHASONE IN PREVIOUSLY TREATED PATIENTS WITH MULTIPLE MYELOMA

R. Hajek1,2,2, L. Pour1,3, J. Spicka4, M. Oczan4, V. Maisarn4, M. Turgut1, L. Kwei5, Z. Salman5, E. Bilotti8, A. Oriol9

1Department of Hemato-oncology, University Hospital in Ostrava, 2Faculty of Medicine, University of Ostrava, Ostrava, 3University Hospital Brno, Brno, 4Clinical Chemistry, Hematology, Charles University, Prague, Czech Republic, 5Department of Internal Medical Sciences, Ankara University School of Medicine, Ankara, Turkey, 6Fourth Department of Medicine–Hematology, Charles University Hospital, Hradec Kralove, Czech Republic, 7Faculty of Medicine, Department of Hematology, Onkodukay Myatis University, Samsun, Turkey, 8Pharmatics LLC, an AveVie Company, Sunnyvale, United States, 9Institut Català d’Oncologia and Institut Josep Carreras, Hospital Germans Trias i Pujol, Barcelona, Spain

Background: Bruton’s tyrosine kinase (BTK) is overexpressed in, and has been implicated in the growth and survival of multiple myeloma (MM) cells, providing a rationale for evaluating BTK inhibitors in MM (Yang Cancer Res 2015; Tai Blood 2012). Yang 2015 demonstrated that BTK overexpression (OE) contributes to blunted responses in MM cells when treated with widely used MM drugs (ie, bortezomib [BTZ], etoposide and doxorubicin). Increased activity of the ABC transporter efflux pump and expression of the ABCB1 transporter was seen in BTK OE cells, and subsequent inhibition led to a restoration of the ABC transporter efflux pump and expression of the ABCB1 transporter.

Aims: To evaluate safety and efficacy of combination ibr+BTZ/dex in previously treated MM pts.

Methods: In this phase 2, open-label, multicenter, European study (PCYC-1139), eligible pts received 1-3 prior therapies and demonstrated disease progression on or following the most recent therapy. Prior BTZ use was permitted provided pts were sensitive (ie, no progression ≤60 days after having achieved minimal response or better). All pts provided informed consent. For cycles 1-8 (21-day cycles), pts received ibr 840mg once daily with BTZ 1.3mg/m² subcutaneously twice weekly (Days 1, 4, 8, 11) and dex 20mg on day of and after BTZ. For cycles 9-12 (42-day cycles), BTZ was dosed weekly (Days 1, 8, 22, 29). The primary endpoint was PFS with secondary endpoints including safety, ORR, PFS at landmark points, duration of response, and time to progression (TTP).

Results: As of November 21, 2016, 20 pts were enrolled (Table). Median age was 68.5 years (range, 49-96). Median number of prior therapies was 1, with 50% refractory to the most recent therapy and 70% previously exposed to BTZ. Gene expression profiling (GEP) in initial pts indicated high-risk GEP in 35% of pts. Virtual fluorescent in situ hybridization identified 40% of pts with high-risk cytogenetics. Median treatment duration was 2.1 months (range, 0.5-3.7). All pts experienced at least one treatment-emergent adverse event (AE) of any grade. The most common all-grade nonhematologic AEs occurring in >15% were diarrhea (50%), upper respiratory tract infection (30%), and asthenia, peripheral edema, hypocalcemia and hypokalemia (20% each). The most common Grade 3 AEs occurring in ≥10% (≥1 pt) were thrombocytopenia (25%), asthenia and pneumonia (15% each), and hyponatremia, abnormal hepatic function, infection, and bone pain (10% each). Three deaths were reported (sudden death in a pt with cardiac history, pneumonia, and myocardial infarction). With early follow-up, 19 pts are evaluable for response with an ORR of 47%, including MR or better in 68%. Updated data will be presented.

Summary/Conclusions: The initial data indicate promising clinical potential for the combination of ibr+BTZ+dex. Treatment was generally well tolerated without any unexpected safety signals noted for the combination. The preliminary ORR of 47% after a minimum 2 treatment cycles is encouraging with further follow-up needed.

P673
PROGNOSTIC SIGNIFICANCE OF CLONAL CIRCULATING PLASMA CELLS BY MULTI-PARAMETRIC FLOW CYTOMETRY IN PATIENTS WITH LIGHT CHAIN AMYLOIDOSIS UNDERGOING AUTOLOGOUS STEM CELL TRANSPLANTATION

S. Sidana1, N. Tandon1, A. Dispenzieri1, M.A. Gertz1, F.K. Buadi1, M.Q. Lacy1, D. Dingli1, A.L. Fonder1, S.R. Hayman1, M.A. Hobbs1, Y.L. Hwa1, P. Kapoor1, R.A. Kyle1, N. Leung1, R.S. Go1, J.A. Lust1, S.J. Russell1, S.V. Rajkumar1, K. Kalem1, W.J. Jumper1

1Hematology, Mayo Clinic, Rochester, United States

Background: Presence of circulating plasma cells (cPCs) prior to autologous stem cell transplant (ASCT) is an adverse prognostic factor in patients with light chain amyloidosis (AL). Prognostic value of cPCs prior to ASCT and categorized them as follows: a) Group 1: patients proceeding directly to ASCT without induction therapy and b) Group 2: patients who received induction therapy before ASCT.
Results: There were 78 patients in Group 1 and 52 patients in Group 2. Patients in Group 2 had higher baseline dFLC, bone marrow plasma cells (BMPC), Mayo stage and were more likely to have active MM compared to patients in Group 1. Table 1 lists baseline characteristics of the patients in Groups 1 and 2. Patients in Group 1 had higher rate of renal involvement. cPCs were detectable in 22% (n=28) of patients at the time of ASCT. More patients in Group 1 had detectable cPCs than in Group 2 (31% vs 8%; p<0.002), likely due to clearance of cPCs with treatment. Data on cPCs at diagnosis in the induction group was available in 14 patients, of whom 57% (n=8) had detectable cPCs vs 31% in the direct ASCT group (p=0.06). 6 of the 8 (75%) patients cleared cPCs with induction therapy. There were no significant differences in patients who had detectable and undetectable cPCs before transplant, including organ involvement, baseline dFLC, BMPC, and Mayo Stage.

In Group 2, both progression free survival (PFS) (10.5 months vs 58 months, p <0.0001) and overall survival (OS) (16 months vs not reached, p =0.001) were worse in patients who had detectable cPCs compared to those without cPCs (Figure 1). This difference was not seen in Group 1 (OS: not reached vs 98 months, p=0.96; PFS 43 vs 52 months, p=0.74). In multivariate analysis, adjusting for Mayo Stage and induction chemotherapy, there was a trend towards worse OS in patients with detectable cPCs (p=0.06).

Summary/Conclusions: cPCs are cleared after induction treatment in majority of AL patients. Patients who have detectable cPCs prior to proceeding to ASCT after induction have worse PFS and OS than patients without cPCs. On the other hand, presence of cPCs was not found to be an adverse prognostic factor in patients proceeding directly to ASCT. This may be due otherwise excellent prognosis in this group, with absence of other high-risk features that are seen in patients who require induction. A limitation of our study is lack of data on cPCs at diagnosis in all patients who received induction therapy.

P674
RENA L IMPAIRMENT IN MYELOMA - PATIENT CHARACTERISTICS, TREATMENT MODALITIES, STEM CELL TRANSPLANT & OUTCOMES FROM THE AUSTRALIAN AND NEW ZEALAND MYELOMA REGISTRY

P.J. Ho1, E. Moore2, Z. McGuillen2, K. Bergin3, H. Blacklock3, N. Horvath4, T. King1, J. McNeil2, P. Mollee6, H. Quach7, C. Reid2, B. Rosengarten8, P. Walker9, E. Wood2, A. Spencer9

1Institute of Haematology, Royal Prince Alfred Hospital, Sydney, 2Department of Epidemiology and Preventive Medicine, Monash University, Melbourne, 3Dept of Haematology, Sir Charles Gardiner Hospital, Perth, Australia, 4Dept of Haematology, Middlemore Hospital, Auckland, New Zealand, 5Dept of Haematology, Royal Adelaide Hospital, Adelaide, 6Dept of Haematology, Princess Alexandra Hospital, Brisbane, 7Dept of Haematology, St Vincent's Hospital, 8Myeloma Foundation of Australia, 9Dept of Haematology, The Alfred Hospital, Melbourne Australia

Background: Renal impairment (RI) is a poor prognostic factor in multiple myeloma (MM). Analysis of disease characteristics, therapy & outcomes can improve treatment & prognosis.

Aims: To assess (1) characteristics of patients with RI at diagnosis - severity of RI, age, risk factors, high risk features, stage, disease manifestations & performance status, and (2) treatment including induction therapy & autologous stem cell transplant (ASCT) and outcomes.

Methods: Data from newly diagnosed MM patients enrolled in the Australian and New Zealand Myeloma Registry from 1 Feb 2013 to 31 Dec 2016 were analysed.

Results: Of 867 patients, 775 had eGFR available at diagnosis: 34% (287/775) had eGFR <60ml/min (22% at 30-60ml/min; 6% at 15-30ml/min; 6% at <15 ml/min). Mean age of patients with RI (<60 ml/min) was 72 vs 64 yrs without RI. Diabetes mellitus (DM), a major cause of chronic kidney disease (CKD), was more prevalent in patients with RI: 17% of patients with eGFR <30 ml/min compared with 8% >30ml/min. Patients with RI (<30ml/min) and DM had a similar response to first-line therapy compared to RI without DM (p=0.06). PFS & OS decreased with reduction in eGFR.

Summary/Conclusions: RI occurred in one-third of newly diagnosed MM. DM, an underlying risk factor for CKD, was more common in RI patients, but not associated with a difference in outcome. Advanced stage & high risk features were more prevalent in RI patients, but bone disease was less common. RI patients had a shorter PFS and OS, overall correlating with eGFR. However patients with eGFR <15ml/min had a better OS than 15-30 ml/min, for which dialysis may be a factor. In transplant-eligible patients assessed by age <70 yrs, ASCT was performed in 21% of RI patients, at all levels of renal function. Patients with RI who underwent ASCT had a superior PFS and OS than those who did not have ASCT, including those with severe RI (eGFR <30ml/min), supporting the benefit of ASCT in MM patients with RI.

P675
VENETOCLAX AS TARGETED THERAPY FOR RELAPSED/REFRACTORY MULTIPLE MYELOMA

1Mayo Clinic, Rochester, 2Winship Cancer Institute of Emory University, Atlanta, 3Mayo Clinic, Scottsdale, 4Duke University, Hematologic Malignancies & Cellular Therapy, Durham, 5Washington University School of Medicine, St. Louis, United States, 6CHU Grenoble, Grenoble, 7CHR U Tours, Tours, 8CHRU Lille, 9CHU de Nantes, 10AbbVie Inc., North Chicago, United States

Background: Venetoclax (VEN), an orally available selective small-molecule inhibitor of BCL-2, has shown impressive activity in combination with IMiDs or Dexamethasone in relapsed/refractory MM patients. We present our experience with VEN in over 130 patients, including a subset of patients who had prior exposure to proteasome inhibitors (PI).
BCL-2 inhibitor, induces cell death in multiple myeloma (MM) cells, particularly those with the t(11;14) translocation.

Aims: The objectives of the study are to evaluate safety, PK, recommended phase two dose, and preliminary efficacy of VEN monotherapy in relapsed/refractory (R/R) MM.

Methods: Patients (pts) with relapsed/refractory (R/R) MM received VEN monotherapy in this phase 1 study. Daily VEN was given at 300–1200mg in dose escalation cohorts and 1200mg in the safety expansion. Pts with disease progression (PD) on VEN monotherapy could receive VEN plus dexamethasone and remain on study.

Results: As of 19 Aug 2016, 66 pts were enrolled. Median age was 63 years and 30 (46%) pts had t(11;14). Median number of prior lines of therapy was 13 (range: 1–15); 46 (70%) pts were refractory to bortezomib, 20 (30%) to carfilzomib, 57 (77%) to lenalidomide, 35 (53%) to pomalidomide, and 52 (79%) were refractory to the last prior therapy. Median time on VEN monotherapy was 2.5 months (range: 0.2–23); 17 pts received V EN plus dexamethasone after PD for a median (range) of 15 (7–53) cycles. Fifteen (23%) pts discontinued, with 41 due to PD. Common adverse events (AEs) were nausea (47%), diarrhea (36%), vomiting (21%) and grade 3/4 hematologic toxicities [thrombocytopenia (32%), neutropenia (27%), anemia (23%), leukopenia (23%). Common serious AEs were pneumonia (8%), sepsis (5%), cough, hypotension, pain, and pyrexia (3%). There were no events of TLS. Six deaths were reported due to PD, and 1 each due to lung disorder and brain hemorrhage following trauma. Overall response rate (ORR) for all pts on VEN monotherapy was 21% (14/66); 10 (15%) achieved very good partial response (VGPR) or better [2 stringent complete response (sCR), 3 CR, 5 VGPR]. For all pts, median time to progression (TTP) was 2.6 months (range: 0.1–13). A clear difference in responses was seen among pts with t(11;14) vs without [ORR, 40% vs 6%; vs VGPR, 27% vs 6%]. For pts with t(11;14), median TTP was 6.6 months [vs 1.9 months for pts without t(11;14)] and median DoR was 9.7 months. A high BCL2:BCL2L1 (BCL-X) gene expression ratio was observed in 10/44 (23%) baseline tumor samples, enriched in pts with t(11;14) compared with non-t(11;14) (38% vs 5%) and associated with clinical response; 80% (8/10) of pts [all t(11;14)] with a high BCL2:BCL2L1 ratio achieved ≥PR with a median TTP of 11.5 months. Among pts with t(11;14) who were refractory to the last therapy, ORR was 42% (11/26); for t(11;14) pts refractory to both bortezomib and lenalidomide, ORR was 40% (8/20) and 50% (3/6), respectively. No difference was seen in ORR for t(11;14) pts with high-risk del(17p) versus those without the deletion [40% (2/5) vs 40% (10/25)].

Summary/Conclusions: VEN has an acceptable safety profile with promising single-agent anti-myeloma activity in pts with RR MM positive for t(11;14) who failed multiple prior lines of therapy.

P676

AN OPEN-LABEL, PHASE 1B STUDY (MMY1001) OF DARATUMUMAB COMBINED WITH CARFILZOMIB, LENALIDOMIDE, AND DEXAMETHASONE (KRd) IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA (MM)

S. Z. Usmani1, A. Char2, S. Lonial3, B. Weiss4, R.L. Comenzo5, K. Wu5, N. Z. Khokhar6, J. Wang7, P. Doshi7, A. Jakubowiak1, S. Levine Cancer Institute/Carolinas HealthCare System, Charlotte, NC, 2Tisch Cancer Institute, Mount Sinai School of Medicine, New York, NY, 3Department of Hematology and Medical Oncology, Winship Cancer Institute, Emory University, Atlanta, GA, 4Abramson Cancer Center and Perelman School of Medicine of University of Pennsylvania, Philadelphia, PA, 5Division of Hematology/ Oncology, John C. Davis Myeloma and Amyloid Program, Tufts Medical Center, Boston, MA, 6Janssen Research & Development, LLC, Spring House, PA, 7Janssen Research & Development, LLC, Rantan, NJ, 8University of Chicago Medical Center, Chicago, IL, United States

Background: The combination of daratumumab with standard of care regimens has demonstrated significantly prolonged progression-free survival (PFS), deeper responses, and a manageable safety profile versus standard of care alone in patients with relapsed or refractory MM.

Aims: To determine the tolerability and efficacy of daratumumab in combination with KRd in patients with newly diagnosed MM.

Methods: This was a phase 1b study enrolled patients with newly diagnosed MM regardless of transplantation eligibility. Patients received daratumumab 16mg/kg qw for Cycles 1-2, q2w for Cycles 3-6, and q4w thereafter, with all patients receiving the first dose split over 2 days. Carfilzomib was given on Days 1, 8, and 15 of each 28-day cycle (20mg/m² on Cycle 1 Day 1, 36 or 70mg/m² subsequently). Median age was 60 (34-74) years, and 95% had an ECOG score of ≤1. At a median follow-up of 19.5 months (range: 0.3-34), overall response rate (ORR) of 82% (80/98 evaluable patients: 18 patients discontinued due to toxicity) was achieved, with an overall safety profile consistent with previous reports for KRd. Daratumumab in combination with KRd was well tolerated, with an overall safety profile consistent with previous reports for KRd. No additional toxicity occurred with the addition of daratumumab, and deep and durable responses were achieved. Preliminary data from this ongoing study support continued investigation of daratumumab plus KRd as a first-line treatment regimen for patients with newly diagnosed MM. Updated data based on longer follow-up will be presented.

P677

GENE EXPRESSION CLASSIFIER EMC92/SKY92 AND REVISED ISS ROBUSTLY IDENTIFY HIGH-RISK MULTIPLE MYELOMA IN ELDERLY PATIENTS OF THE HOVON-87/NMSG-18 STUDY

R. Kuiper1, M.H. van Vilst1, M. van Duin2, A. Broij3, M.-D. Levin4, L. de Best1, E.H. van Beers5, B. van der Hoef6, H. Visser5, M. Hansson5, A.W. van der Velden7, S. Dumee1, M. Vermeulen2, J. Van Delden10, 1Bioinformatics, SkylineDx, 2Department of Hematology, Erasmus MC Cancer Institute, Rotterdam, 3Department of Internal Medicine, Albert Schweitzer Hospital, Dordrecht, 4Department of Hematology, Erasmus MC Cancer Institute, Rotterdam, 5Department of Hematology and Transfusion Medicine, Skåne University Hospital, Lund, Sweden, 6Department of Internal Medicine, Martin University Hospital, Groningen, 7Department of Clinical Genetics, Erasmus MC, Rotterdam, 8Department of Human Genetics, Radboud University Medical Center, Nijmegen, Netherlands, 9Norwegian University of Science and Technology, Trondheim, Norway, 10Department of Hematology, VU University Medical Center, Amsterdam, Netherlands

Background: Multiple myeloma (MM) affects mostly elderly people with a median age of 69 years at diagnosis, with 35-40% of patients older than 75. Overall survival (OS) is variable: patients aged 60-70, 9% survive less than 3 months and 23% survive longer than 10 years. Recently the revised ISS (rISS) has been proposed as a prognostic marker that incorporates ISS, FISH and LDH. Another marker, the SKY92 prognostic classifier, was developed in younger, transplant eligible multiple myeloma (MM) patients who were included in the HOVON-65/GMMG-HD4 trial. The SKY92 classifier was thoroughly validated in eight independent cohorts, at the time of its initial publication, and since. Aims: Here, we validated the SKY92 gene expression classifier and rISS in elderly, non-transplant eligible patients included in the HOVON-87/NMSG-18 trial (Zweegman et al. Blood 2016;127(9):1109-1116).

Methods: In this trial, melphalan, prednisone, thalidomide (MPT) plus thalidomide maintenance was compared with melphalan, prednisone, lenalidomide (MPR) plus lenalidomide maintenance. The MiMPprofiler™ CE IVD assay was used to obtain SKY92 scoring, classifying a patient as high-risk or standard-risk. In addition, the international staging system, LDH, FISH and rISS were analyzed.

Results: The 178 patients in the analysis for which enough bone marrow was available to perform GEP, had a median age of 73 years. At the time of data analysis, 94% were enrolled for 3 months. Therapeutic decisions were delayed in 25 of 178 patients as high-risk (14%). The median OS for the 25 patients classified as SKY92 high-risk was shorter than the median OS of standard-risk patients: SKY92 high-risk 21 months versus SKY92 standard-risk 53 months (hazard ratio (HR)=3.0, 95% confidence interval (CI)=1.7-5.3, p<0.01; Figure 1). At 2 years, the proportion of patients with rISS-III was 8% whereas comparable to the 10% identified in the initial report of the rISS. Interestingly, the proportion of SKY92 high-risk patients is larger (14%), whereas the median OS associated with these patients is shorter (21 vs 25 months). The SKY92 classifier performed better compared to the rISS as high-risk marker for OS. The 2-year OS rate using the SKY92 classifier was 33% for patients versus 27% for rISS (p=0.1).

Discussion: The 2-year progression free survival (PFS) rate was similar for SKY92 high-risk and rISS-III (16% and 17%, respectively). In the multivariate analysis, SKY92, rISS and deletion of 13q were independently associated with OS. Inde-
Aims: To evaluate the prevalence of comorbidities and to study the impact of comorbidities on survival among patients with newly diagnosed multiple myeloma.

Results: A total of 13,718 patients with multiple myeloma were included in the study and 21 groups of comorbidities were identified. The most common diseases were cancer, hypertension, heart failure, ischemic heart disease and atrial fibrillation. Among all patients, 55% had no prior history of comorbidity, 23% had one comorbidity, 12% had two comorbidities, and 10% had three or more comorbid conditions. Survival was negatively influenced by the number of comorbidities (Figure 1). The risk of death was significantly increased in patients with atrial fibrillation (HR=1.08; 95% CI 1.00-1.16), heart failure (HR=1.50; 95% CI 1.40-1.61), stroke (HR=1.20; 95% CI 1.11-1.30), psychological disease (HR=1.27; 95% CI 1.16-1.39), chronic lung disease (HR=1.22; 95% CI 1.12-1.32), diabetes (HR=1.14; 95% CI 1.04-1.36), peripheral vascular disease (HR=1.26; 95% CI 1.12-1.42), cancer (HR=1.10; 95% CI 1.04-1.16), dementia (HR=1.65; 95% CI 1.38-1.99), paralysis (HR=1.44; 95% CI 1.15-1.80), inflammatory bowel disease (HR=1.38; 95% CI 1.08-1.74), end stage renal disease (HR=1.57; 95% CI 1.03-2.04), and cirrhosis (HR=1.64; 95% CI 1.10-2.43).

Background: The number of multiple myeloma patients has grown with aging populations, and with increasing age the number of comorbidities increases as well. Clinically, it is well known that comorbidity in multiple myeloma patients decreases performance status, increases risk of therapy-related complications and may lead to life-threatening conditions. Currently, the literature on comorbidity in multiple myeloma is very limited and based on small case series. Clinical trials rarely include elderly, frail patients due to eligibility criteria. Population-based studies provide valuable information on survival outcomes in relation to presence/absence of comorbidities in newly diagnosed real-life multiple myeloma patients in the general population.

Aims: To evaluate the prevalence of comorbidities and to study the impact of comorbidities on survival among patients with newly diagnosed multiple myeloma.

Methods: All newly diagnosed patients with multiple myeloma from January 1st 1980 to December 31st 2013 in Sweden were included in the study. Using the Swedish Patient Registry, all discharge diagnosis and discharge listings were gathered from each patient from January 1st 1985. Comorbid conditions were defined as chronic illnesses which demand life-long treatment or follow-up. Only those diagnoses made prior to multiple myeloma were used. Using ICD 8, 9 and 10 codes, comorbid diseases were identified. Kaplan-Meier curves were used to estimate survival. Risk of death was compared among multiple myeloma patients with a comorbid condition to those without a comorbidity, using Cox's proportional hazards regression (adjusting for age, gender, year of diagnosis, and other comorbid conditions).

Summary/Conclusions: Here, we compared the SKY92 classifier with revised ISS staging and FISH. These data validate the SKY92 classifier as a robust marker to identify high-risk patients in non-transplant eligible MM patients. In these IMiD treated patients, the SKY92, the revised ISS, and FISH markers such as deletion of 13q retain independent prognostic value.

DETECTION OF NEW EMERGING CLONES DURING TREATMENT BY NGS ALLOWS A BETTER RISK PREDICTION ON MULTIPLE MYELOMA PATIENTS
1Hematología Trasacional, Hospital 12 de Octubre, Madrid, 2Hospital Universitario de Salamanca, Instituto de Investigación Biomédica de Salamanca (IB SAL), Centro de Investigación del Cancer (IIBMCC CSIC-USAL), Salamanca, 3Clínica Universidad de Navarra, Centro de Investigación Medica Aplicada, Instituto de Investigación Sanitaria de Navarra, Pamplona, 4Hospital Clinic, Barcelona, Spain

Background: Multiple myeloma (MM) is a genetically complex disease, characterized by the presence of multiple clones with differing degrees of drug sensitivity at the time of diagnosis. Consequently, therapeutic response of MM patients is unpredictable and extremely variable, and although the treatment intensities introduced over the last decade have significantly improved the outcome of these patients, most patients eventually relapse. Deep sequencing methods have contributed to increase the knowledge about the clonal heterogeneity of the disease and helped to stabilize the three evolution patterns at relapse: linear and branching clonal evolution, and no clonal changes.

Aims: To analyze the diversity and relative dominance of different clones and their evolution throughout the course of disease by NGS of the immunoglobulin repertoire in MM patients. To evaluate if the presence of different clones is associated with increased risk.

Methods: Immunoglobulin repertoire was analyzed by NGS in bone marrow samples from 180 MM patients included in three GEM clinical trials (NCT00461747, NCT00443235 and NCT01237249). The two first clinical trials involve patients younger than 65 years old, and were analyzed with ClonoSeq methodology, the later one involve patients older than 65 years old, and were analyzed with a local NGS method recently validated (Martinez-Lpez et al, Laukemia 2017). A clonotype was identified when at least 400 identical sequences were found, and branching clonal evolution, and no clonal changes.

Results: Of the 180 MM patients studied, 57 (32%) shows the presence of more than one clone throughout the clinical course of the disease. The identification of new evolving clones was only possible in the GEM10 clinical trial with the Local NGS method; in this clinical essay, 6% (4/71) of patients analyzed with a local NGS method recently validated (Martinez-Lopez et al, Laukeria 2017). A clonotype was identified when at least 400 identical sequences were found, and branching clonal evolution, and no clonal changes.

Conclusion: The presence of more than one clone was not associated with high-risk cytogenetics. The presence of more than one clone at diagnosis does not condition the prognosis in any of the patients and treatments analyzed. Median PFS was 38 and 58 months for patients with one clone or more than one clone respectively (HR=1.43, p=0.28).

Summary/Conclusions: The analysis of the IG repertoire by the local NGS method during treatment is able to identify and quantify new emerging clones during the treatment that were not detectable at diagnosis. The new clones contributed to increase the MRD levels in the follow-up samples. The presence of different clones at diagnosis is not associated with higher risk of progression, high risk cytogenetics or higher MRD values.

Background: In the era of increased use of 1st-line and maintenance lenalidomide (LEN), there is growing need for effective 2nd-line therapies (tx) for LEN-refractory pts. The combination of carfilzomib (CFZ), pomalidomide (POM), and dexamethasone (DEX) has shown promising activity in advanced RRMM, including for pts refractory to LEN (Shah et al. Blood. 2015).

Aims: In this Ph 1/2 study, KPD was evaluated in RRMM, with a focus on pts who are LEN-refractory but proteasome inhibitor (I)-naïve/sensitive.

Methods: LEN-refractory disease was required for 2nd-line KPD and LEN-refractory exposure for ≥3rd-line. Ph 1 dose escalation to determine mae. Ph 1 dose escalation to determine mae. PANOBINOSTAT INDUCES CD38 UPRGEMENT AND AUGMENTS THE ANTI-MYELOMA EFFICACY OF DARATUMUMAB
E. Garcia-Guerrero1, T. Gogishvili1, S. Danhof1, M. Schreder1, C. Pallaud2, J.A. Pérez-Simón3, H. Einsle1, M. Hudecek1
1Universitätsklinikum Würzburg, Würzburg, Germany, 2Novartis Pharmaceuti-
cals, Basel, Switzerland, 3BILS/Hospital Universitario Virgen del Rocío, Seville, Spain

Background: Immunotherapy with the anti-CD38 monoclonal antibody (mAb) daratumumab is increasingly being utilized in myeloma patients with relapsed/refractory (R/R) disease after prior treatment with immunomodulatory drugs (IMiDs) and proteasome inhibitors (PIs). However, the efficacy of dara-
tumab is limited by low expression on myeloma cells. Here, we investigate the use of the histone deacetylase inhibitor (HDACi) panobinostat to modulate target antigen expression on myeloma in favor of potent mAb-mediated recognition and destruction. We show that panobinostat augments CD38 expression specifically on myeloma cells and demonstrate powerful synergy with anti-CD38 mAb daratumumab.

Aims: Determine the impact of panobinostat on upregulation of CD38 expression on myeloma cells in order to enhance the efficacy of daratumumab.

Methods: Myeloma cells were treated with titrated doses of panobinostat (0, 10, 25 nm) and expression of CD38 and a panel of additional target molecules interfering drug SLAMF7, as well as accessory ligands analyzed by flow cytometry at 24, 48 and 72 hours. Antibody-dependent cellular cytotoxicity (ADCC) against panobinostat treated and untreated myeloma cells was analyzed at 4 and 20 hours after addition of PBMC at an effector to target ratio of 25:1 in the presence of daratumumab or an isotype control antibody.

Results: Panobinostat treated primary myeloma (n=12 patients) with panobinostat (10 vs 25 nm) and observed a uniform increase in CD38 expression in each case by flow cytometry. Upregulation of CD38 was already detectable after 24 hours, peaked after 48 hours of exposure to panobinostat and was higher at the 25 nm compared to the 10 nm dose. At 48 hours, the mean fluorescence intensity (MFI) of CD38 expression on untreated and panobinostat-treated compared to untreated myeloma (p<0.01). The increase in CD38 was equal in patients with previously untreated (n=5) and R/R myeloma (n=7); and could be confirmed in a panel of myeloma cell lines, including MM1.S and OPM-2. The panobinostat-induced upregulation of CD38 was rapidly reversible after drug withdrawal.

Conclusions: Panobinostat treated myeloma cells are resistant to POM treatment and can be a better target for daratumumab. Further, the increase in CD38 expression on panobinostat-treated cells was specific for myeloma and neither observed this phenomenon in a panel of leukemia and lymphoma cell lines, nor on primary CD8+ and CD4+ T cells that we isolated from peripheral blood of several donors.
and del(17p).

Responses in high vs low BCL2 expression achieved at least a PR (ORR 59%), with 6 patients (22%) achieving VGPR or better (Figure 1). Sixteen of 27 patients with low BCL2 expression were evaluable for BCL-2 family gene expression by droplet digital PCR in CD38+ tumor cells. The synergistic anti-myeloma efficacy of panobinostat and daratumumab was confirmed with a panel of myeloma cell lines.

**Summary/Conclusions:** Our data demonstrate that the HDACi panobinostat induces upregulation of CD38 on myeloma and a subsequent dramatic increase of daratumumab-mediated ADCC. These data suggest that panobinostat could be used synergistically with daratumumab in a clinical setting to increase response rates and extend duration of responses to daratumumab.

**Background:** The anti-apoptotic proteins BCL-2 and MCL-1 have been shown to promote multiple myeloma (MM) cell survival. Venetoclax (VEN) is a potent, selective, and orally bioavailable small-molecule inhibitor of BCL-2. Bortezomib (BTZ) is a proteasome inhibitor that can inhibit MCL-1 activity by increasing the MCL-1 antagonist, NOXA.

**Aims:** Results presented herein describe correlative biomarker analyses in the ongoing phase 1b study of VEN in combination with BTZ and dexamethasone in patients with relapsed/refractory multiple myeloma.

**Methods:** As of 19 Aug 2016, 86 patients were enrolled on study. Baseline bone marrow aspirate samples were available from 52 patients, of which 45 were evaluable for BCL-2 family gene expression by droplet digital PCR in CD138-selected tumor cells. Correlation between BCL2L1 (BCL-L1) and MCL1 (MCL-1) mRNA expression (log2-transformed copies/µl normalized to housekeeping gene) and preliminary efficacy [overall response rate (ORR), time to disease progression (TTP) and duration of response (DoR)] were examined by Log-rank and Wilcoxon tests for binary biomarkers, and by risk ratio from Cox proportional hazard model for continuous biomarkers.

**Figure 1.**

**Results:** The ORR was 68% (44/65) for all evaluable patients and 89% (31/35) in patients who had 1-3 prior therapies (31/35). A broad range of BCL2, BCL2L1 and MCL1 expression was observed, however higher BCL2 levels were detected in patients who achieved a partial response (PR) or better (median: 3.01 vs 0.87, p<0.01). Additionally, higher BCL2 levels were observed in patients who had 1–3 prior therapies compared to 4 or more lines of therapy (median: 3.03 vs 0.94, p<0.01). In contrast, no association was observed between BCL2L1 or MCL1 gene expression and response or number of prior therapies. Bootstrapping and aggregating thresholds from trees was used to estimate a threshold value for BCL2 expression that would provide optimum selection of patients who achieved a response. On all, seventeen of 18 patients with high BCL2 expression had a positive correlation with disease response. No significant difference was observed in the expression profile of patients with low BCL2 expression. Responses in high BCL2 expressions were independent of cytogenetic status as determined by interphase FISH analysis, including t(11;14), t(4;14), del(13q) and del(17p).

**Summary/Conclusions:** Targeting BCL-2 and MCL-1 with the combination of VEN, BTZ and dexamethasone provides a unique approach for MM treatment. Efficacy results in tumors expressing high BCL2 levels, including 94% ORR, provide supportive evidence for the evaluation of this combination regimen in the ongoing phase 3 study (NCT02755597) in R/R MM.

**P683**

**THE IMPACT OF THE INTRODUCTION OF BORTEZOMIB ON DIALYSIS INDEPENDENCE IN MULTIPLE MYELOMA PATIENTS WITH RENAL FAILURE: A NATIONWIDE DUTCH POPULATION-BASED STUDY**

**Background:** Renal insufficiency is common at presentation in patients with multiple myeloma (MM) and associated with a poor survival. Approximately 10% of the patients require dialysis. Studies have shown that the novel agent bortezomib has a positive effect on recovery of renal function in MM patients with renal insufficiency.

**Aims:** The aim of this study is to determine the effect of the revised guideline, including the introduction of bortezomib as first-line treatment in MM patients with dialysis dependence, on renal function recovery.

**Methods:** All patients on renal replacement therapy (RRT) in the Netherlands are registered in the Dutch registry Renine. Data on age, gender, start date of RRT, type and switches of RRT or hospitals, primary renal diagnosis, date of death and cause of death are collected. In this nationwide population-based study, we selected all patients with MM registered in Renine between January 2002 and January 2016. No information regarding therapy of MM is provided in Renine. In March 2010, bortezomib was advised as first-line treatment in patients suffering from MM with renal impairment in the Dutch guidelines. Therefore, we divided our cohort in two periods: before the bortezomib guideline (January 1, 2002 till March 29, 2010) and after introduction of the bortezomib guideline (March 29, 2010 till January 1, 2016). Kaplan-Meier and Cox proportional hazards modelling were used to identify significant indicators for dialysis independency.

**Results:** A total of 700 patients were included in the study (422 patients pre-bortezomib and 278 after bortezomib introduction). In the period after the introduction of bortezomib 15% of patients became dialysis independent compared to 8% in the pre-bortezomib period (HRadj=2.1 (95% CI 1.0–4.2), Fig. 1). In addition, patients who started dialysis in the period after bortezomib was introduced became dialysis independent more rapidly than in the pre-bortezomib period (1.2 compared to 1.7 years; p < 0.001). Age < 75 years (vs. ≥ 75 years) and light chain deposition disease (LCDD) as the primary renal disease (vs. amyloidosis) were significantly associated with achieving dialysis independence (HRadj=2.1 (95% CI 1.0–4.2) and HRadj=5.7 (95% CI 2.3–13.2), respectively).

**Figure 1.**

**Summary/Conclusions:** In this nationwide population-based study, covering all patients with MM and concomitant renal failure, almost a two-fold increase of patients becoming dialysis independent occurred in the period after the introduction of bortezomib compared to the pre-bortezomib period. This was even more prominent when age was < 75 years and LCDD was the primary renal disease.

**P684**

**TREATMENT WITH POMALIDOMIDE AND DEXAMETHASONE IN PATIENTS WITH MULTIPLE MYELOMA AND LIGHT CHAIN (AL) AMYLOIDOSIS**

P. Milan1,1, M. Bassel2, F. Russo3, M. Bozzola1, A. Foni1, G. Palladini1, G. Merlini1

(n=3). Interestingly, expression of SLAMF7 was not increased after panobinostat treatment at all tested concentrations and time points in both cell lines and primary myeloma. Next, we were interested in determining whether the increase in CD38 expression enabled superior antitumor activity of the anti-CD38 mAb daratumumab. Thus, we treated primary myeloma cells from patients (n=4) with panobinostat for 48 hours at 10 nM, as this is the serum level achievable currently approved dosing regimen. We observed a significant increase in ADCC against panobinostat-treated compared to untreated myeloma in all patients. On average, 78% of panobinostat-treated primary myeloma cells were eliminated by daratumumab within the 4-hour ADCC assay, whereas only 51% myeloma cells were eliminated without panobinostat treatment (p<0.01). The synergistic anti-myeloma efficacy of panobinostat and daratumumab was confirmed with a panel of myeloma cell lines.

**Summary/Conclusions:** Our data demonstrate that the HDACi panobinostat induces upregulation of CD38 on myeloma and a subsequent dramatic increase of daratumumab-mediated ADCC. These data suggest that panobinostat could be used synergistically with daratumumab in a clinical setting to increase response rates and extend duration of responses to daratumumab.
Background: The immunomodulatory agent pomalidomide is active in patients with relapsed/refractory multiple myeloma, including those who failed prior lenalidomide and bortezomib. Phase II clinical trials showed that pomalidomide is also effective in primary AL amyloidosis. After this drug was marketed for multiple myeloma (in Italy since September 2015), it became routinely accessible also to patients with myeloma-associated AL amyloidosis, a particularly fragile population.

Aim of this study was to report the efficacy of pomalidomide and dexamethasone in patients with multiple myeloma-associated AL amyloidosis.

Methods: The databases of the Pavia Amyloid Research and Treatment Center were searched for patients with a diagnosis of multiple myeloma and AL amyloidosis and patients with measurable NT-proBNP (n-terminal-natriuretic peptide) in patient with AL amyloidosis. Median serum NT-proBNP was 7730 pg/ml for those with a positive uptake in the scintigraphy and 9990 pg/ml for those with a negative uptake. Median age was 65 years (range: 34-85 years) and 22 (73%) patients were men. Heart involvement was present in 13 patients (43%) and kidney involvement in 18 (60%).

Results: Median age was 65 years (range: 34-85 years) and 22 (73%) patients were men. Heart involvement was present in 13 patients (43%) and kidney involvement in 18 (60%). There were 22 patients with MM from 1-11). Median follow-up of living patients was 6 months (IQR: 3.5-16 months).

Adverse events were observed in 5 (17%) of subjects: skin rash and confusion in one patient each and mild increase in serum creatinine in 3 (10%, resolved with the decrease of the dose of pomalidomide). The median number of prior treatment lines (5 cases), all patients had previously received lenalidomide and an alkylating agent, only 3 patients were not exposed to bortezomib, due to severe peripheral nervous system involvement, 10 (33%) underwent autologous stem cell transplant and 9 (30%) received previous thalidomide-based regimens. The median number of P Dex cycles performed was 4 (range: 1-11). Median follow-up of living patients was 6 months (IQR: 3.5-16 months) and 13 (43%) patients died due to progressive disease. Fourteen patients (47%) achieved at least partial response, with 1 complete remission (CR), and very good partial responses (VGPR) in 2 cases (6%). Adverse events were observed in 1 of 5 patients with measurable NT-proBNP (20%), but this can be underestimation due to the pomalidomide-related increase of NT-proBNP, and renal response in 3 of the 11 evaluable patients (27%).

Summary/Conclusions: The combination of pomalidomide and dexamethasone is well tolerated and effective in multiple myeloma-associated AL amyloidosis and can be a valuable rescue option in this high-risk population.

P686

WHEN PERFORMANCE OF CYTOGENETICS MATTERS: A POPULATION-BASED STUDY IN THE NETHERLANDS ON ALAMYLOIDOSIS PATIENTS

M. Brink1,*, O. Visser1, M.C. Minnema2, S. Zweegman3, P. Sonneveld4, A.G. Dimishe4

Aim of this study is to report the diagnosis of TTR amyloidosis (TTR gene non mutated). The two remaining patients were diagnosed of AL amyloidosis by IHC unequivocally in other tissues. Mean value of NT-proBNP (N-terminal-natriuretic peptide) in patients with AL amyloidosis was 7730 pg/ml for those with a positive uptake in the scintigraphy and 9990 pg/ml for those with a negative uptake.

Summary/Conclusions: Cardiac 99mTc-DPD SC has been described as a useful technique in the differential diagnosis between AL and TTR amyloidosis. However, up to 30% of cases of AL amyloidosis show some degree of uptake and 10% show a pattern consistent with TTR amyloidosis (biventricular uptake and TTR amyloidosis and myocardial uptake in SC). MS is not routinely available in most centers and results may be ambiguous. We consider that MS is mandatory in cases of cardiac amyloidosis with abnormal FLC ratio and positive biventricular 99mTc-DPD uptake. We did not find any correlation between positive uptake in the SC and NT-proBNP values, as it has been recently suggested.
Background: To contextualize the benefit of novel agents such as daratumumab (DARA) monotherapy for the treatment of patients with heavily pretreated and highly refractory multiple myeloma (MM), it is critical to understand the real-world outcomes of this patient population on current standard of care (SOC) therapies. To determine the comparative effectiveness of DARA vs real-world SOC, an adjusted comparison was conducted using data from the DARA monotherapy trials and the International Myeloma Foundation (IMF) chart review.

Aims: The objective of this analysis is to update the adjusted comparison to include additional Swedish patients from the IMF chart review.

Methods: Data for patients treated with DARA 16mg/kg monotherapy were available from clinical trials MMY2002 (n=106) and GEN501 (n=42), while patients treated with SOC therapies were derived from the IMF chart review of patients with MM who had ≥2 prior lines of therapy and were double refractory to a proteasome inhibitor (PI) and an immunomodulatory drug (IMiD) (n=550, original 510, additional Swedish patients 40). Patients from the IMF-cohort who moved into further treatment lines after the line therapy where they fulfilled inclusion criteria, contributed information to the analysis for multiple lines of therapy, with baseline defined as the date of initiation of the actual treatment line, resulting in a total sample size of 963 treatment lines from 550 patients. The relative treatment effect of DARA versus SOC was estimated using multivariate Cox regression analyses. The methodology utilized individual patient data to compare overall survival (OS). The covariates included were age, gender, prior lines of therapy, albumin, β2-microglobulin, prior exposure to pomalidomide and carfilzomib, and prior refractory status. Clustering of observations at the treatment-line level within patients was controlled for using the robust sandwich estimate for the covariance matrix. Standard significance testing was performed using a two-tailed P-value of <0.05, and all comparisons between treatment groups were reported with hazard ratios (HRs) and 95% confidence intervals (CIs).

Results: After adjustment for differences in baseline characteristics included in the multivariate model between the DARA and SOC groups, results showed a significant improvement in favor of DARA compared with SOC for OS (HR=0.42 [95% CI 0.31–0.57]). When limiting the comparative analysis to European patients from the IMF cohort (n=341), results for OS are very similar (HR=0.40 [95% CI 0.28–0.58]).

Summary/Conclusions: Findings from the regression analyses using the updated IMF dataset were consistent with results from the previous analysis and suggest that DARA is associated with significant gains in OS compared with SOC therapies for patients with heavily pre-treated and highly refractory MM. Findings for a European subset from the IMF dataset were similar to results from the entire cohort.

P688 PREDICTORS OF EARLY DEATH RELATED TO ACTIVE MULTIPLE MYELOMA IN ELDERLY PATIENTS RECEIVING OPTIMIZED FRONTLINE TREATMENT COMBINATIONS

Background: Multiple Myeloma (MM) is predominantly a disease of the elderly and the outcome of these patients is poorer than that of transplant candidates. It is well established that those considered frail or unfit have a dismal prognosis, however, even within fit patients, such as those included in clinical trials, there is substantial proportion of early deaths (within the first 2 years after diagnosis). Identification of this “high-risk” fit elderly patients could contribute both to the design of innovative clinical trials, and to avoid the emotional and economical burden of palliative care. The aim is to identify frailty and its impact on survival.

Aims: To analyze the factors associated with early death (within first 2-years) due to active MM in elderly newly diagnosed (NDMM) patients fit enough to be included in clinical trials with optimized therapy with proteasome inhibitors and IMiDs.

Methods: 497 NDMM not transplant candidates treated in two prospective GEM-PETHEMA trials were included in the study; GEM05MAS65 (n=260) used frontline treatment with either bortezomib-melphalan-prednisone (VMP) or bortezomib-thalidomide-prednisone followed by maintenance with bortezomib, thalidomide or bortezomib, prednisone; the GEM2010MAS65 (n=239) compared induction with sequential alternating cycles of VMP + lenalidomide-dexamethasone. The event was defined as death related to active MM within 2 years from diagnosis, either because of disease progression or early death due to absence of response.

Results: From the 497 patients included, 77 (15%) patients died within 2 years from diagnosis due to active MM. When we compared this latter cohort with the remaining patients, the profile of the high risk group was characterized (Table 1) by a higher proportion of patients >75 years, advanced ISS and R-SS stage, higher β2-microglobulin (β2-M) levels (>3.5 and 5.5mg/dl) and abnormal LDH; increased incidence of high-risk cytogenetic features (HR CA), CD45- clonal plasma cells, and lower incidence of CD27 + MM phenotype.

Table 1.
unsR (duration of response (≥PR) <6 months) to the baseline score we were able to build a new score in which the unsR had a 3 points weight. A score punctuation ≥ 4 segregates a subgroup of patients with poor outcome (PPV: 83.3%, the NPV: 84.02%).

**Summary/Conclusions:** The risk of early death due to active disease in elderly patients was related to four independent prognostic factors: age >75y, high LDH levels, advanced ISS, and presence of HR CA. A score ≥ 4 identify a subgroup of patients with high probability of death within 2 years despite optimized treatment.

**MPL ACTIVATION DIRECTLY INDUCES FIBROCYTE DIFFERENTIATION TO CAUSE MYELOFIBROSIS**

T. Maekawa1,*, Y. Osawa1, T. Izumi1, S. Nagao1, K. Takano1, Y. Okada1, N. Tachi1, M. Teramoto1, T. Kawamura1, T. Horiuchi1, R. Saga1, S. Kato1, T. Yamamura1, J. Watanabe1, A. Kobayashi1, S. Kobayashi1, K. Sato1, M. Hashimoto2, S. Suzuki2, F. Kimura1

1Division of Hematology, Department of Internal Medicine, National Defense Medical College, Tokorozawa, Saitama, 2Center for AIDS Research, Kumamoto University, Kumamoto, Japan

**Background:** Myelofibrosis (MF) may be caused by various pathogenic mechanisms, such as elevated circulating cytokine levels, cellular interactions, and genetic mutations. However, the underlying mechanism of MF remains unknown. A recent study showed that the neoplastic clone of fibrocytes, spindle-shaped fibroblast-like blood cells derived from monocyte lineage, was essential in primary MF pathogenesis; serum amyloid P, which suppressed fibrocyte differentiation, markedly improved survival and MF in a murine xenograft model (J Exp Med 2016; 213: 1723-1740). Regarding cytokines, the thrombopoietin (TPO) signaling pathway was assumed to be closely associated with promoting MF. Mice transplanted with TPO-overexpressing bone marrow cells showed symptoms such as MF and splenomegaly (Blood 1997; 90: 4369-4383). Romiplostim (Rom), a TPO-receptor agonist, induced MF in induced in mice and some immune thrombocytopenic purpura patients (Blood 2009; 114: 3748-3756). Fibrocytes and TPO played certain roles in MF pathogenesis, but the nature of their relationship remains unknown.

**Aims:** We investigated the relationship between myeloproliferative leukemia protein (MPL; TPO receptor) activation and fibrocyte differentiation in promoting MF. The secondary goal was to discover a unique fibrocyte marker in monocyte or macrophage population.

**Methods:** Murine fibrocyte cell lines were established from transgenic mice harboring the temperature-sensitive large T-antigen gene of simian virus 40 under IL-3 and M-CSF conditions. Murine fibrocyte cell lines and human peripheral blood mononuclear cells (PBMCs) were cultured with or without Rom to evaluate if MPL activation promoted fibrocyte differentiation, and the ratio of spindle-shaped cells was calculated. Rom was administered on day 1 and 8 to induce an MF-like phenotype in C57BL/6J mice, and clodronate liposomes (CLs; day −4, −1, 4, and 7) were used to eliminate monocytes and macrophages.

**Results:** Flow cytometric analysis revealed that all murine fibrocyte cell lines stained positive for fibrocyte cell markers, including collagen I, CD45, CD34, CD11b, and CD68. Murine fibrocyte cell lines expressed MPL and responded to Rom or murine TPO to differentiate into mature fibrocytes, specifically with a longer spindle shape and stronger collagen I expression than when cultured with IL-3 and M-CSF alone. Rom also increased the number of mice spleen cell fibrocyte colonies in the presence of IL-3 and M-CSF, specifically with a longer spindle shape and stronger collagen I expression than when cultured with IL-3 and M-CSF alone. Rom also increased the number of mice spleen cell fibrocyte colonies in the presence of IL-3 and M-CSF, specifically with a longer spindle shape and stronger collagen I expression than when cultured with IL-3 and M-CSF alone. Rom also increased the number of mice spleen cell fibrocyte colonies in the presence of IL-3 and M-CSF, specifically with a longer spindle shape and stronger collagen I expression than when cultured with IL-3 and M-CSF alone. Rom also increased the number of mice spleen cell fibrocyte colonies in the presence of IL-3 and M-CSF, specifically with a longer spindle shape and stronger collagen I expression than when cultured with IL-3 and M-CSF alone. Rom also increased the number of mice spleen cell fibrocyte colonies in the presence of IL-3 and M-CSF, specifically with a longer spindle shape and stronger collagen I expression than when cultured with IL-3 and M-CSF alone.

**Summary/Conclusions:** MPL activation directly induced fibrocyte differentiation from monocytes and macrophages expressing MPL, and the elimination of these cells reversed the MF phenotype. Our findings confirmed a link between fibrocytes and the TPO/MPL signaling pathway and indicated that the combination of MPL and SLAMF7 could be a useful fibrocyte marker in monocytes or macrophages.

**ENGRAFTMENT OF PRIMARY MYELOFIBROSIS BONE MARROW-DERIVED CD14+ MONOCYTES IN NOD-SCID-γ MICE**

T. Manshouri1,*, Z. Estrov1, D. Pilling1, C.E. Bueso-Ramos2, S. Pnijic1, K.J. Newberry1, S.M. Post1, X. Zhang1, Y. Zhang1, H.M. Kantarjian1, S. Verstovsek1

1Leukemia Department, The University of Texas/ MD. Anderson Cancer Center, Houston, 2Department of Biology, Texas A&M University, College Station, 3Department of Hematopathology, The University of Texas/ MD. Anderson Cancer Center, Houston, United States

**Background:** Progressive bone marrow (BM) fibrosis in patients with PMF is thought to arise from non-hematopoietic stromal cells stimulated by overpro-
ducted growth factors. However, in other tissues and organs, fibrosis is associated with monocytic fibrocytes, which express markers of both hematopoietic and stromal cells. Recently, we have reported that clonal neoplastic fibrocytes play a role in the induction of BM fibrosis in primary myelofibrosis (PMF) (Verstovsek, J Exp Med. 2016). We demonstrated that the BM of PMF patients harbors more neoplastic, functionally distinct fibrocytes and fewer SM/MPN-like, morphologically normal bone marrow fibrocytes. In addition, we detected an overabundance of fibrocytes in the BM and spleen of an established PMF mouse model and a xenograft mouse model of PMF created using BM-derived low-density cells from patients with PMF.

Aims: Fibrocytes, which make up <1% of BM cells, differentiate from a subpopulation of CD14+ monocytes and are recruited to sites of organ damage where they regulate tissue repair. We hypothesized that clonal neoplastic CD14+ monocytes may play a role in the induction of BM fibrosis in PMF.

Methods: To test this hypothesis, we transplanted NSG mice (NOD/Scid/NoD.Cp-prkdcscidJ2tm1wjl/SJZ) with sorted CD14+ monocytes from patients with JAK2V617F-positive PMF or donors with hematologically normal BM. Results: Here, we show that BM-derived CD14+ cells from patients with JAK2V617F-positive PMF or donors with hematologically normal BM engrafted in NSG mice. Transplanted NSG mice with PMF BM-derived CD14+ monocytes developed a myelofibrosis-like phenotype with reticulin fibrosis and abundant neoplastic (JAK2V617F) fibrocytes in the BM and spleen. Two months after transplantation, we detected a subpopulation of c-HaD45+ and c-HaD68+ cells within the HLA+ population of BM cells. In addition, we found dysplastic megakaryocytes in the BM and spleen of the PMF CD14+ transplanted mice. Immunochemistry staining of paraffin embedded BM sections did not detect c-HD3, c-HD19 or c-HD34 cells. However, staining with anti-human CD42b antibodies detected human megakaryocytes, suggesting that the dysplastic megakaryocytes detected in PMF CD14+ transplanted NSG mice are human-derived.

Summary/Conclusions: Taken together, our data suggest that neoplastic CD14+ monocytes contribute to the induction of BM fibrosis in PMF. What role CD14-derived megakaryocytes play in the pathogenesis of PMF remains to be determined.

Background: Somatic mutations on calreticulin (CALR) gene are found in a majority of patients with JAK2-unmutated MPN. It is believed that the CALR-mutated neoplastic and non-neoplastic/normal MPL/CALR positive fibrocyte represent a more differentiated CALR-mutated subpopulation. Recently, we have reported that CALR-mutated megakaryocytes are associated with JAK2 mutation and this phenomenon is independent from the presence of CALR mutation.

Aims: We aimed to recapitulate the MPN phenotypes and examine the impact of CALR ins5 in human hematopoietic cell differentiation in vitro.

Methods: We employed iPSCs (iPSC) established from a healthy control and a patient with JAK2V617F-mutated MPN. iPSCs were differentiated into megakaryocytes using a well-established method. HPCs were then cultured to induce megakaryocytes (MKs) and thrombopoietin (TPO) was used to identify differences in the granulocyte proteome with the goal to characterize the pathogenic role of aberrant protein expression in MPNs.

Results: A novel switch control inhibitor DCC-2618 was described to block JAK2 kinase activity of KIT D816V, MCPV-1.1, HMC-1.2, ROSAKITWT, ROSAKITD816V, ROSAKITK509I, MCPV-1.1, MCPV-1.3 and MCPV-1.4 and primary neoplastic MC obtained from patients with SM. In addition, the acute myeloid leukemia (AML) cell lines KLF1 expression required for the erythroid cell differentiation in CALR ins5 cells. Finally, we showed that the treatment of ruxolitinib greatly reduced megakaryocytic differentiation in both CALR ins5 and wt HPCs, demonstrating that ruxolitinib does not possess preferential targeting of CALR ins5 cells.

Summary/Conclusions: We have established an in vitro model system that recapitulates the megakaryocytosis caused by mutant CALR, which should be useful tool for the examination of therapeutic strategies against MPN patients harboring CALR mutation.

1TIMC-IMAG Laboratory - TheREX team, GRENoble, France, 2Institute for Medical Research, Belgrade, Serbia, 3INSERM, UMR1170. Gustave Roussy, Paris, 4Laboratoire d’Hématologie cellulaire - Institut de Biologie et Pathologie, GRENoble, France

Background: Apart from well-known genetic abnormalities, several studies have reported variations in protein expression in Philadelphia negative (Ph-) Myeloproliferative Neoplasm (MPN) patients that could contribute towards their clinical phenotype.

Aims: In this context, a quantitative mass spectrometry proteomics protocol was used to identify differences in the granulocyte proteome with the goal to characterize the pathogenic role of aberrant protein expression in MPNs.

Methods: LC MS/MS (LTQ Orbitrap) coupled to iTRAQ labeling showed significant and quantitative differences in protein content among various MPN subtypes. ELISA was used to demonstrate the correlation between the proteome data and the clinical parameters. Finally, it was demonstrated, in a Ba/F3 cell model, that increased calreticulin expression was directly linked to JAK2V617F mutation and could be regulated by JAK2 kinase inhibitors.

Summary/Conclusions: In conclusion, these results reveal proteome alterations in MPN granulocytes depending on the genotype and phenotype of patients, highlighting new oncogenic mechanisms associated with JAK2 mutations and overexpression of calreticulin.

Background: Systemic mastocytosis (SM) is a myeloid neoplasm defined by abnormal growth and pathologic accumulation of neoplastic mast cells (MC) in various internal organs. The indolent variant of SM (ISM) is associated with an almost normal life expectancy. By contrast, the prognosis in advanced SM, including SM with an associated hematologic neoplasm (SM-AHN), aggressive SM (ASM), and MC leukemia (MCL) is poor with short survival times. Most patients with SM express the D816V-mutated variant of KIT, which confers resistance against several tyrosine kinase inhibitors (TKI), including imatinib. DCC-2618 is a novel switch control inhibitor that has been described to block the switch control activity of KIT D816V.

Aims: The aims of this study were to evaluate the effects of the switch control inhibitor DCC-2618 on proliferation and survival of neoplastic MC and other neoplastic and non-neoplastic cell types that may play a role in advanced SM and often expand in AHN patients.

Methods: We used different human MC lines (HMC-1.1, HMC-1.2, ROSAKITWT, ROSAKITD816V, ROSAKITK509I, MCPV-1.1, MCPV-1.3, MCPV-1.4) and primary neoplastic MC obtained from patients with SM. In addition, the acute myeloid leukemia (AML) cell lines 276 | haematologica | 2017; 102(s2)
MOLM-13, MV4-11, KG-1 and U-937, the eosinophilic leukemia cell line EOL-1, human cultured umbilical vein endothelial cells (HUVEC), the microvascular human endothelial cell line HMEC-1 and primary neoplastic cells obtained from patients with AML, chronic myelomonocytic leukemia (CMML) and (clonal or reactive) hypereosinophilia were used. Cell proliferation was quantified by 4H-thymidine uptake. Apoptosis was determined by flow cytometry and light microscopy. The phospho-kinase-stationary status of KIT and BTK was analyzed by Western blotting. The effects of DCC-2618 on histamine secretion in basophils (BA) were analyzed by histamine release assay.

Results: DCC-2618 was found to block the proliferation of all MC lines tested, with lower IC50 values measured in KIT D816V-negative HMC-1.1 cells (12±2 nM) and ROSAΔITDαββγδε cells (4±1 nM) than in KIT D816V-positive HMC-1.2 cells (123±36 nM), ROSAΔITDB186 cells (168±65 nM) and the multi-resistant MC line MCPV-1. The DCC-2618-metabolite DP-5439 showed comparable growth inhibitory effects in all cell lines tested. DCC-2618 was also found to inhibit proliferation of primary neoplastic MC obtained from patients with MPN. A significant effect of ASH-ARN and MCL (IC50; 83-460 nM). DCC-2618 induced apoptosis and blocked tyrosine phosphorylation of KIT in all MC lines tested. We were also able to show that DCC-2618 inhibits proliferation and survival in the eosinophilic leukemia cell line EOL-1 (IC50 (1.8±1.3 nM)) and the FLT3 ITD-mutated AML cell lines MV4-11 (IC50 (47±60 nm)) and MOLM-13 (IC50 (132±55 nM)). In addition, DCC-2618 was found to block proliferation in primary leukemic cells in patients with monoblastic AML and CMML which are the most prevalent types of AHN in advanced SM. DCC-2618 was also found to inhibit growth of cultured human vascular endothelial cells, suggesting that the drug may also counteract SM-related angiogenesis. Finally, DCC-2618 was found to inhibit anti-CD40-induced histamine release from normal BA in a dose-dependent manner (IC50: 1-10 µM).

Summary/Conclusions: DCC-2618 is a new potent switch control TKI that counteracts growth and survival of neoplastic MC, leukemia monocytes, AML blasts, eosinophils, and endothelial cells in vitro. Whether DCC-2618 is able to block growth of neoplastic MC and other involved lineages in patients with advanced SM is currently being ascertained in a clinical trial (NCT02571036).

P694

DISTRIBUTION OF MUTATIONS IN DRIVER AND NON-DRIVER GENES ACCORDING TO CLONAL HEMATOPOIESIS IN ESSENTIAL THROMBOCYTHEMIA, MYELOTHROMOCYTOMY AND POLYCYTHEMIA VERA

A. Senin1,2, B. Bellissio2,3, C. Fernández-Rodriguez2,3, L. Camacho2, C. Bessis2,1, Á. Álvarez-Larrán2,2

1Hematology Department, Hospital del Mar-IMIM. Universitat Autónoma de Barcelona, 2Group of Applied Clinical Research in Hematology. Cancer Research Program, IMIM, 3Pathology Department, Hospital del Mar-IMIM. Universitat Autònoma de Barcelona, Barcelona, Spain

Background: Essential thrombocythemia (ET) and polycythemia vera (PV) are clonal myeloid disorders that originate from a multipotent hematopoietic stem cell. Although most women with PV and ET have mutations in JAK2V617F, CALR or MPL, the proportion of patients presenting clonal hematopoiesis by X chromosome inactivation patterns (XCI) is variable and its relationship with the presence of non-driver mutations is not well known.

Aims: To study the distribution and dominance of driver and non-driver mutations in clonal hematopoiesis.

Methods: One hundred and twenty-six women (PV n=33, ET n=93) with an informative result of XCI based on HUMARA assessment were included in the study. HUMARA analysis was performed by studying the degree of methylation of exon 1 in granulocytes and lymphocytes. Somatic mutations were studied in DNA extracted from granulocytes by NGS using a panel of 51 myeloid-related genes.

Results: Median age of patients at the time of HUMARA analysis was 64 years (range:21–92). Mutations in JAK2 were present in 62% of them, CALR in 11%, MPL in 8%, and 14% were triple negative (TN). Non-driver mutations were detected in 6% of patients (17 PV and 28 ET). The most frequently mutated genes were TET2 (16%), DNMT3A (8%), ASXL1 (5%), SF3B1 (5%), EZH2 (2%) and RUNXI (2%). The mutation with the highest variant allele frequency (VAF) was considered the dominant mutation and it corresponded to a driver mutation in 92 patients (JAK2 n=70, CALR n=13, MPL n=8) and a non-driver mutation in 9 patients (driver: CALR n=3, MPL n=1, RUNXI n=2, TET2 n=1, ASXL1 n=1). In 12 cases the VAF of the driver mutation (JAK2 n=99, CALR n=1, MPL n=2) was similar to the non-driver mutation, being TET2 the codominant mutation in 6 of them. HUMARA analysis was clonal in 66 patients and polyclonal in 60 patients (PV in 48% and ET in 52%). In 11% of them the 24% was most frequently observed in PV (76% vs 46% (p=0.002). Clonal HUMARA was observed in 90% of MPL-mutated patients in comparison with 58% in JAK2-mutated, 42% in CALR-mutated and 11% in TN (p<0.0001). Two patients with TN ET showing clonal hematopoiesis had TET2 mutations. In JAK2-mutated women, the mutant allele load was significantly higher in polyclonal cases (43% vs 19% p=0.02) and in PV than in ET (76% vs 47%, p=0.01). Eighty percent of patients with non-driver mutations showed HUMARA clonality vs 37% of patients without non-driver mutations (p<0.0001). The mutated genes significantly associated with a higher frequency of clonal hematopoiesis were JAK2 (p=0.007) and SF3B1 (p=0.029).

P695

RUXOLITINIB/NILOTINIB/PREDNISOLONE COMBINATION: A PROMISING NOVEL TREATMENT FOR MYELOFIBROSIS

A. Arenas1, R. Ayala1, M. Gallardo1, J. Martínez-López1, 2

1Hematology, Hospital 12 de Octubre, Madrid, Spain

Background: Myelofibrosis (MF) is the myeloproliferative neoplasm chromosome Ph- negative with worst prognosis. MF is characterized by stem cell-derived clonal myelofibroproliferation and reactive cytokine-driven inflammatory bone marrow fibrosis. Ruxolitinib is the first line treatment for MF. It was associated with significant reduction in symptomatic splenomegaly and improved constitutional symptoms. In a previous work (Arenas et al. Blood Volume 122, Issue 21 (ASH Annual Meeting Abstract)) we identified a set of promising synergistic drugs combinations for a ruxolitinib. Nilotinib and prednisolone were selected from them.

Aims: The aim of this work is the study the effect of the combination of ruxolitinib, nilotinib and prednisolone in hematopoietic progenitor cells from patients with MF.

Methods: A ruxolitinib, nilotinib and prednisolone dose-response curves and synergistic studies were performed in hematopoietic progenitors CD34+ from five MF patients. We studied the molecular effect of single drugs and in combination on SET2 cell line with western blot. To adress the antibiofveic activity of the drugs and their combinations, we pre-incubated HS27 cultures with 100nM of ruxolitinib, 1 µM of nilotinib, 1 µM of prednisolone or their combination during 1 h. After that, we added 2mg/mL TGF-β during 24h to induce fibrogenesis. Finally, the collagen I expression was evaluated by immunocytochemistry (ICC).

Results: The effects of ruxolitinib, nilotinib and prednisolone resulted in an EC50 value of 55nM, 6.6µM and 13.1µM, respectively. A combination index (CI) of less than 1 indicated synergy. All combination had a synergistic behavior (Table 1); moreover, there were two combinations whose CI from all samples were lower than 1: ruxolitinib plus 50% nilotinib plus 0.8 µM prednisolone (CI=0.25±0.11) and 32m ruxolitinib plus 0.8 µM prednisolone (CI=0.45±0.11). The JAK/STAT signaling pathway was inhibited: the phosphorylation of STAT5 was inhibited by ruxolitinib in 83.2±10.8 % (p-value<0.05) regarding to control at 30 min and it was maintained at 3 hours (p-value<0.05). The combinations 32nM ruxolitinib plus 1.6 µM nilotinib (RN) and 32m ruxolitinib plus 0.8µM prednisolone (RNP) inhibited more than 50% of the phosphorylation of STAT5 at 30 min and maintained at 3 hours. The MAPK signaling pathway was inhibited at 30 min, the phosphorylation of ERK was inhibited in 77.1±16.4

Figure 1.
interlaboratory reproducibility. In this analysis, we consider only those laboratories that detected at least 1 mutation.

Results: The median number of detected mutations was 9 (range: 1-27), with 100% of laboratories detecting at least 1 mutation.

Discussion/Conclusions: The interlaboratory reproducibility of this analysis is satisfactory, with a high number of laboratories detecting a wide range of mutations. Further improvements in the detection of rare and low frequency mutations are necessary to improve the diagnostic accuracy of MPNs.

P968

INTERLABORATORY ASSESSMENT OF MUTATION DETECTION IN MYELOID MALIGNANCIES BY TARGETED NEXT-GENERATION SEQUENCING

1Pathology, Hospital del Mar, Barcelona, 2Hematology, Hospital 12 de Octubre, Madrid, 3Hematology, Hospital Universitari i Politècnic La Fe, Valencia, 4Niglolith, Madrid, 5Immunology, Hospital Virgen de las Nieves, Granada, 6Hospital Universitario de Gran Canaria Dr. Negrín, Las Palmas de Gran Canaria, 7Hospital General Universitario Gregorio Marañón, Madrid, 8Hospital Germans Trias i Pujol - ICO Badalona, Badalona, 9CIMA LAB Diagnostics, Pamplona, 10Hematology, Hospital Universitario Virgen del Rocío, Sevilla, 11Hematology, Hospital Universitario de Salamanca, Salamanca, 12Hematopathology, Hospital Clínico San Carlos, Madrid, 13Immunology, Hospital Universitario Virgen del Rocío, Sevilla, 14Hematology, Hospital Universitario de Gran Canaria Dr. Negrín, Las Palmas de Gran Canaria, 15Hematology, Hospital Regional Universitario de Málaga, Málaga, 16Hematology, Hospital de la Santa Creu i Sant Pau, Barcelona, 17Immunology, Hospital 12 de Octubre, Madrid, Spain

Background: Next-generation sequencing (NGS) technology is being implemented in clinical practice for assessing the mutational status of myeloid neoplasms. The Working Group on Molecular Biology from the Spanish Society of Hematology has performed an interlaboratory assessment of gene mutation analysis by targeted NGS using myeloid panels.

Aims: To assess the technical performance of mutation detection by targeted NGS using myeloid panels.

Methods: The technical comparison was established on two rounds with samples previously analysed using NGS panels, Sanger sequencing and/or fragment analysis. First, four DNA samples (S1-S4) from AML patients were shared among laboratories for the first round. Three additional samples (S5 to S9) were sequenced in a second round. A total of 14 laboratories. The center of origin had previously characterized and confirmed: for the first round, 14 relevant mutations in 10 genes; and for the second round 17 relevant mutations in 7 genes. Each center performed library preparation, sequencing and blind variant analysis following their own routine practice. Detected variants and data regarding main methodological parameters were collected. Detection rate was calculated as the number of laboratories with positive detection out of the number of laboratories that sequenced the particular gene region.

Results: Eight different gene panels were used for library preparation (predetermined in 10 labs and custom in 4). The one most commonly used was amplicon enrichment (11/14, 78.6%) and only 3/14 laboratories (21.4%) used capture-based methods. Sequencing was performed with Illumina devices in 9/14 laboratories. However, including indels, low frequency mutations (<10%), ASXL1 mutations were detected in only 67% and 31% of laboratories, respectively.

Discussion/Conclusions: The one most commonly used was amplicon enrichment (11/14, 78.6%) and only 3/14 laboratories (21.4%) used capture-based methods. Sequencing was performed with Illumina devices in 9/14 laboratories. However, including indels, low frequency mutations (<10%), ASXL1 mutations were detected in only 67% and 31% of laboratories, respectively.

Background: The aim of the study was to correlate MA with disease status, mutual profile and therapeutic response in a cohort of MPN patients treated with Voro.

Aims: The aim of our study was to correlate MA with disease status, mutual profile and therapeutic response in a cohort of MPN patients treated with Voro.

Summary/Conclusions: Gene mutation analysis by targeted NGS in myeloid malignancies is highly reproducible between laboratories and allows a complete and comprehensive characterization of a patient's disease. However, including indels, low frequency mutations (<10%), ASXL1 mutations were detected in only 67% and 31% of laboratories, respectively. Furthermore, the interlaboratory reproducibility of this analysis is satisfactory, with a high number of laboratories detecting a wide range of mutations. Further improvements in the detection of rare and low frequency mutations are necessary to improve the diagnostic accuracy of MPNs.
Methods: MA was calculated following pyrosequencing of bisulfite converted DNA from 40 MPN patients on an investigator initiated non randomised open label phase II multicentre study of Vorinostat (EudraCT #2007-00536-49). Paired samples were analysed at trial entry and after 3 months of therapy to calculate their individual MA scores. Validation of methods used and ageing signature calculation was carried out using cell line and healthy volunteer material.

Results: Samples from 19 Essential Thrombocythaemia (ET), 22 Polycythemia Vera (PV) patients (23 F/17 M) with a mean age of 62 years (range 29-81) were assessed. JAK2V617F was detected in 77.5% (n=31/40). Complete clinical response (CR) was achieved in 8 patients, partial (PR) in 17, and no response (NR) in 15 patients. MA was on average 8.3 years younger than CA (range -43.4 to +41.6) at time of trial entry and 8.2 years younger (range -36.5 to +33.3) after therapy. This difference between MA and CA was greater in ET patients compared to PV, both at trial entry (-14.0 years v -3.7) and after therapy (-13.0 years v -4.3). A statistically significant link between JAK2 allele burden and MA was seen: compared to patients with low or no JAK2 allele burden, patients with high JAK2 (>80% at baseline) had an older MA at trial entry (64.2 years vs 44.5, p=0.0007) and after therapy (64.3 years vs 44.6, p=0.0015). This difference was also seen when PV or ET patients were examined separately. Patients with a high JAK2 allele burden tended to have a MA closer to their CA at trial entry (-0.8 years vs -15.3, p=0.0122) and after 3 months therapy (-0.5 years v -16.2, p=0.0072). Although the cohort size was small, within the ET group, NR compared to PR was associated with a younger MA after therapy (41.4 years vs 56.3, p=0.0156). Within PV, NR compared to PR was associated with a MA that was older than CA both before (+9.2 years vs -14.2 years, p=0.0346) and after therapy (+7.4 years vs -13.9, p=0.0347).

Suggested Conclusions: This study suggests a link between MA and JAK2 mutant allele burden in MPN patients, suggesting that allele burden not only has a role in clinical phenotype and disease evolution but in the overall methylation landscape of the mutated cells. However, the role of MA with respect to therapeutic response needs to be clarified with further studies required to show its full impact.

P698
ELUCIDATING THE AGE INDUCED HEMATOPOIETIC CELL-INTRINSIC AND EXTRINSIC MECHANISMS IN MYELOPROLIFERATIVE NEOPLASM INITIATION AND PROGRESSION
N.R. Tata1,*, S. Radek2
1Department of Biomedicine, University Hospital Basel, Basel, Switzerland

Background: The number of detectable somatic mutations increase with age, but this increase is surpassed by the rise in the incidence of cancer in older people. The underlying mechanisms for this disparity remain to be elucidated. Myeloproliferative neoplasm (MPN) is an ideal malignancy model disease to study clonal hematopoiesis, disease initiation and progression during natural aging because the majority of the relevant mutations (such as JAK2 V617F) are catalogued, the disease evolves and progresses slowly allowing the collection of serial samples, and an inducible transgenic mouse models for the disease have been established. Nonetheless, the prevalent occurrence of such clonal events in aged individuals brings up the question, which age-associated factors contribute to initiate hematologic malignancies and what are the rate limiting steps attributable for age-induced myeloid malignancies? We hypothesize that age-induced malignancies provide a context that favors the generation of new mutations, selection for pre-malignant clones, and that activation of mutant JAK2 further augments these changes for increased MPN incidence in aged individuals. Thus, delineation of age associated cellular and molecular mechanisms attributable for increased prevalence of myeloid malignancies will be essential for the development of strategies for early detection and therapeutic targeting of myeloid malignancies.

Aims: The goal of this proposal is to identify age associated hematopoietic cell-intrinsic and cell-extrinsic factors that determine initiation and progression of MPN at young versus old age in mouse models carrying a JAK2-V617F or JAK2-W612 mutation.

Methods: To assess the effect of aging on MPN initiation and progression we studied the young and aged inducible transgenic mouse models of MPN. Integrated omics analysis was performed on MPN initiating stem and progenitor cells. In older mice, arc tumor (AT) and stem cell factor (SCF) induced hematopoietic malignancies provide a context that favors the generation of new mutations, selection for pre-malignant clones, and that activation of mutant JAK2 further augments these changes for increased MPN incidence in aged individuals. Thus, delineation of age associated cellular and molecular mechanisms attributable for increased prevalence of myeloid malignancies will be essential for the development of strategies for early detection and therapeutic targeting of myeloid malignancies.

Results: Our results suggest that age related changes in expression patterns resemble MPN at young and old age in wildtype mice. The mutation profile in patients with pediatric MPN appear to be less complex than in older MPN patients. We are currently investigating the relative contributions and collaborations of age-associated cell intrinsic and extrinsic changes in HSCPs and BM niche in the course and severity of MPN in mouse models carrying a JAK2-V617F mutation, and in naturally aged donors and recipients of bone marrow transplantations.

Summary/Conclusions: Our study provided novel molecular and cellular mechanisms underlying increased incidence of MPN manifestation in old age. The implications of this work goes beyond the MPN malignancy and the comprehensive data sets generated in study will serve as a model to the wider scientific community to study other types of malignancies. This knowledge ultimately will help to define novel strategies to delay or target the onset of MPN in an aging individual.
Results: At BL, 59% of pts had anemia (hgb <10 g/dL); pts with BL anemia were more likely at BL to have platelet count <50,000/μL (51% vs 38%), thrombocytopenia MF (71% vs 57%), and high DIPSS score (41% vs 14%). For those with BL anemia regardless of whether RBC transfusion-dependent (TD), PAC did not worsen hgb levels and the rate of clinical improvement in hgb was higher for pts in the PAC BID arm (25%) vs PAC QD (13%) or BAT (12%) arms (Table). For pts with CALF-RBC transfusion independence (IT) at BL, achievement in RBC transfusion dependency was achieved at higher rates with PAC QD (19%) and PAC BID (22%) vs BAT (9%); 2 PAC and 0 BAT pts achieved RBC-TI by week 24. In PAC pts, SVR ≥35% and TSS reduction ≥50% were observed regardless of BL anemia or RBC-TD (Table). At BL, 16% of pts in the safety population had grade 3 anemia. Incidence of TE anemia was highest during the first 16 weeks of PAC (20% and 9% weeks 8-9, 13% and 8% weeks 16-24 for QD and BAT, respectively) and first 8 weeks of BAT (10%). For pts with BL hgb <10 vs ≥10 g/dL, incidence of grade 3/4 TE anemia was similar with PAC QD (26% vs 28%, respectively), and lower in pts with BL hgb ≥10 g/dL with PAC QD (20% vs 24%, respectively). In instances of grade 3 anemia with PAC or BAT (Table) were in pts with BL hgb <10g/dL. Dose modifications or discontinuations due to anemia were uncommon (Table). No exposure-response relationship was evident for grade ≥2 TE anemia.

Summary/Conclusions: In pts with MF and BL thrombocytopenia, PAC treatment led to clinical improvement in hgb and reduction of RBC transfusion needs vs BAT. Serious anemia, and dose modifications due to anemia were uncommon. PAC provides a treatment option for pts with MF, including those with BL thrombocytopenia and anemia, for whom available options are limited.

**P701**

**PACRITINIB (PAC) VS BEST AVAILABLE THERAPY (BAT), IN PATIENTS WITH ETIOLOGY OF MYELOFIBROSIS (MF) AND BASAL (BL) THROMBOCYTOPENIA: FOCUS ON RUXOLITINIB (RUX)-TREATED PATIENTS IN THE PHASE 3 PERSIST-2 TRIAL**

1Guy’s and St Thomas’ NHS Foundation Trust, London, United Kingdom, 2Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY, 3University of Michigan, Comprehensive Cancer Center, Ann Arbor, MI, 4Cleveland Clinic, Cleveland, OH, 5Northwestern University, Feinberg School of Medicine, Chicago, IL, 6University of Tennessee, Memphis, 7University of Toronto, Ontario, Canada, 8Albert Szent-Györgyi Clinical Center, University of Szeged, Szeged, Hungary, 9Beantown West of Scotland Cancer Centre, Glasgow, United Kingdom, 10Ryazani’s Clinical Hospital, Ryazan, Russian Federation, 11VA Healthcare System, Seattle, WA, 12Stanford Cancer Institute, Stanford, CA, 13University of California-San Diego, La Jolla, CA, 14Mayo Clinic, Scottsdale, AZ, 15MD Anderson Cancer Center, Houston, TX, United States

Background: MF is a life-threatening hematologic malignancy characterized by symptomatology, debilitating constitutional symptoms, and progressive cytopenias (anemia and thrombocytopenia). Currently, JAK1/2 inhibitor RUX is the only approved therapy for pts with MF. Although RUX has been shown to reduce splenomegaly and symptoms in pts with MF, it is associated with dose-limiting cytopenias and is not indicated for pts with platelets <50,000/μL. PAC is an oral kinase inhibitor with specificity for JAK2, FLT3, IRAK1, and CSF1R. In the phase 3 PERSIST-2 study of PAC vs BAT (including RUX) in pts with MF and BL thrombocytopenia, PAC was significantly more effective in terms of spleen volume reduction (SVR; P=0.001) and appeared to have a better benefit/risk profile vs BAT.

Aims: This analysis examines outcomes for pts with MF treated with RUX in the phase 3 PERSIST-2 study.

Methods: Pts with MF and BL platelet count ≤100,000/μL were randomized (N=511) 1:1:1 to PAC 400mg once-daily (QD), PAC 200mg twice-daily (BID), or BAT. BAT included any physician-selected treatments for MF, as well as RUX or BAT, or no treatment. The co-primary endpoints were the rates of pts achieving ≥35% SVR (by MfR/CT) and ≥50% reduction in total symptom score (TSS; MPN-SAF TSS 2.0) at week 24. Efficacy analyses used the intent-to-treat efficacy (ITT-E) population, which included all pts with randomization date allowing them to contribute data for a week 24 endpoint. Crossover from BAT to PAC was allowed after week 24 or splenic progression.

Results: RUX was the most commonly received active BAT. 44 (45%) BAT pts received RUX (Figure) and 32 (33%) received only RUX. Of the 44 pts who received RUX on study, 17 (39%) had BL platelet counts <50,000/μL and would not have been candidates for RUX by approved indication (or study protocol). BL thrombocytopenia was achieved in 32/44 (73%) pts treated with RUX on study. One (3%) and 6 (19%) RUX pts (n=32 in ITT-E population) achieved SVR ≥35% and TSS reduction ≥50% at week 24, respectively, vs 11 (15%) and 13 (17%) PAC QD and 16 (22%) and 24 (32%) PAC BID pts. For PAC pts with prior RUX, SVR and TSS endpoints were achieved in 6% and 10% with QD, and 13% and 32% with BID, vs 20% and 23% with QD, and 28% and 33% with BID for PAC pts without prior RUX.

Grade 3/4 adverse events (AEs) were reported in 76%, 70%, and 45% of PAC QD, PAC BID, and RUX pts, most commonly (59% in any arm) thrombocytopenia (31%, 32%), anemia (27%, 22%), and neutropenia (9%, 7%) with PAC, and (16% and 16%) anemia (8%) and neutropenia (2%) with RUX. Dose reductions due to AEs occurred in 20%, 12%, and 11% of pts treated with PAC QD, PAC BID, and RUX, respectively; half (22/44) of RUX-treated pts crossed over to PAC treatment, at a median of 26.1 (95% CI 25.3-27.3) weeks. Of those 22, 19 pts remained on PAC treatment at the time of data cut-off, 7 for 24 weeks of PAC treatment (Figure 1).
SAFETY AND EFFICACY OF RUXOLITINIB (RUX) IN ELDERLY PATIENTS (≥75 YEARS) WITH MYELOFIBROSIS (MF): AN ANALYSIS FROM THE PHASE 3B, EXPANDED-ACCESS JUMP STUDY

1Rabin Medical Center, Petah Tikva, Israel, 2Princess Margaret Cancer Centre, Toronto, Ontario, Canada, 3Johannes Wesling Medical Center, University Hospital, Minden, 4University Hospital of Halle, Halle (Saale), Germany, 5Miguel Servet University Hospital and Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Zaragoza, Spain, 6CRIMM, Center for Research and Innovation of Myeloproliferative Neoplasms, AOJ Careggi, Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy, 7St. Paul’s Hospital, University of British Columbia, Vancouver, British Columbia, Canada, 8Universidade Federal de Goiânia, Goiânia, Brazil, 9Federal Almazov Medical Research Center of the Russian Ministry of Health, St. Petersburg, Russian Federation, 10Novartis Pharma AG, Basel, Switzerland, 11Novartis Healthcare Pvt. Ltd, Hyderabad, India, 12Azienda Ospedaliera Banchi-Melacarne- Morelli, Reggio Calabria, Italy

Background: RUX is a potent JAK1/JAK2 inhibitor that has led to reductions in splenomegaly and symptoms in patients (pts) with MF. Although few studies have assessed RUX in elderly pts, a recent analysis including the largest cohort of elderly pts with MF treated with RUX to date. Consistent with the study by Latagliata et al, RUX was safe and effective in pts ≥75 y, with pts achieving reductions in spleen size and symptoms similar to those in the overall population, with comparable rates of AEs. Additionally, findings from our study were consistent with those of the COMFORT studies, which included few pts ≥75 y. Overall, our study provides further evidence that RUX is safe and effective in elderly pts with MF.

Methods: Pts with high- or Int-2–MF, or Int-1–risk pts with a palpable (≥5 cm) spleen, were eligible. RUX starting doses were based on baseline platelet (PLT) counts (5mg bid [≥50 <100×10^9/L], 15mg bid [100 200×10^9/L], or 20mg bid [≥200×10^9/L]). Pts were ≥18 y; there was no maximum age limit. The primary endpoint was safety and tolerability of RUX. Secondary endpoints included changes in spleen length and symptoms.

Results: This analysis includes 418 pts (primary MF, 66%) who were ≥75 y and started treatment ≥1 y before data cutoff (01 Jan 2016). Baseline characteristics (median) were age, 78 y (range, 75-89 y); male, 57%; spleen length, 10 cm (0-35 cm); blast count ≥1%, 30.3%; hemoglobin, 101 g/L (100 g/L, PLT count, 249×10^9/L (<100×10^9/L, 6.3%). ECOG PS <2, 84.9%. At data cutoff, more than half of pts remained on treatment or completed treatment per protocol (52.6%). As expected, a greater proportion of elderly pts discontinued RUX due to adverse events (AEs; 23.6%) or death (8.7%) than pts in the overall study (17.7% and 4.1%, respectively). Overall, 72.4% of pts had dose modifications (AEs, 58.4%), and 33.9% had an interruption (AEs, 31.5%). Safety of RUX in elderly pts was consistent with that in the overall population. Median exposure was 11 mo; mean daily average dose was 26.8mg (SD, 10.6).

The most common hematologic grade 3/4 AEs were anemia (43.8%; overall, 34.1%) and thrombocytopenia (22.1%; overall, 16.3%). AEs (all grade [grade 3/4]) in ≥10% of pts included asthenia (18.3% [2.6%]), pyrexia (18.0% [2.6%]), dyspnea (14.4% [4.3%]), diarrhea (13.5% [1.9%]), fatigue (11.8% [2.4%]), peripheral edema (10.8% [0.2%]), and pneumonia (10.1% [7.2%]). Infections in >5% of pts included pneumonia (10.1%), urinary tract infection (7.0%), and bronchitis (5.1%). Herpes zoster occurred in 3.9% of pts. At wk 24, 56.4% (124/220) of pts had a ≥50% reduction from baseline in spleen length (overall, 56.6%), and 19.1% (42/220) had 25%-50% reductions (overall, 23.3%); rates were similar at wk 48 (54.6% [65/119] and 19.3% [23/119]; overall, 61.6% and 18.9%). Most pts (64.2%) achieved a ≥50% reduction at any time (Figure 1), similar to the overall population (70.2%). Pts also experienced significant improvements in symptoms. From wk 4 to 48, 42%-48% and 50%-57% of pts achieved a clinically meaningful response on the FACT-Lym TS and FACT- Fatigue, respectively.

Figure 1

Summary/Conclusions: This analysis included the largest cohort of elderly pts with MF treated with RUX to date. Consistent with the study by Latagliata et al, RUX was safe and effective in pts ≥75 y, with pts achieving reductions in splenomegaly and symptoms similar to those in the overall population, with comparable rates of AEs. Additionally, findings from our study were consistent with those of the COMFORT studies, which included few pts ≥75 y. Overall, our study provides further evidence that RUX is safe and effective in elderly pts with MF.
Background: Accurate disease risk stratification is crucial for transplant decision making in myelofibrosis (MF). However, several prognostic models are available, it is unknown if they are equivalent in the way they distribute patients into risk groups and in their discriminatory power to predict survival.

Aims: We have compared the performance of the International Prognostic Scoring System (IPSS), dynamic IPSS (DIPSS), DIPSS-plus, and Rumi’s score in a series of 544 MF patients aged 70 years or younger at time of diagnosis.

Methods: The Spanish Registry of Myelofibrosis is a nationwide, longitudinal registry contributed by centers associated to the Grupo Español de Enfermedades Mieloproliferativas Filadelfia negativas (GEMFIN). From January 2000 to January 2016, a total of 544 adult patients aged ≤ 70 years with primary MF (n=335) or secondary MF (n=209) had been included in the registry. Cases of the prefibrotic form of MF were not considered. Comparison of the relative power of each prognostic model to discriminate levels of risk was estimated by means of the Harrell’s concordance index (C-index) and the R2 explained variation. All the statistical analyses were performed with IBM SPSS 22.0 and Stata 11.

Results: At diagnosis, median age in patients diagnosed with MF was 3.35 years, 177 patients (33%) had died, and the remaining were censored alive. Sixty-nine patients (13%) had been submitted to allogeneic stem cell transplantation, after a median time of 20 months from MF diagnosis. The median projected survival of the overall series was 9.46 years (95% confidence interval: 7.44-11.49). Median survival was not reached for the low risk category of all classifications (and Rumi’s very low risk category). The projected survival for patients in the intermediate-1 group (intermediate in the Rumi’s score) and in the high risk group (very high risk in the Rumi’s score) was comparable in the four models. By contrast, the Rumi’s high risk group had a projected median survival of 9.2 years, whereas that of the intermediate-2 categories by the IPSS, DIPSS, and DIPSS-plus models was 6.6 years, 5.6 years, and 6.5 years, respectively. The number of patients in the intermediate-2 and high risk categories was smaller in the DIPSS than in the IPSS or the DIPSS-plus. Overall, the Rumi’s score yielded the highest power to discriminate between risk categories, as measured by the C-index and the R2 explained variation. However, the IPSS and DIPSS-plus were the best models to discriminate between the intermediate-1 and intermediate-2 risk categories, which is the critical cut-off point for patient selection to transplant.

Summary/Conclusions: In our contemporary series of MF patients only the highest risk categories of the current prognostication systems have a median survival below the 5-year threshold recommended for considering transplantation. Patient selection for transplant is quite dependent on which prognostication model is used for disease risk stratification.

LEUKEMIC TRANSFORMATION AND SECOND CANCERS IN 3649 HIGH RISK ET PATIENTS IN THE EXELS STUDY

G. Birgegård1, Y. Folkvaljon2, H. Garmo2, L. Holmberg3, C. Besses4, M. Griesshammer5, L. Gugliotta6, J. Wu7, H. Achenbach8, J.-K. Kiladian9, C. N. Harrison10

Background: A common therapy for essential thrombocythemia (ET), hydroxy-ycarbamide (HC), has mutagenic properties and there is potential for leuke- 

mogenicity and secondary cancers with this agent. In the EXELS study, we reported higher event rates for acute myeloid leukemia (AML) and other malig-

nancies in HC-treated patients compared with those treated with anagrelide (ANA). However, there were large age differences between groups. Here, we account for age difference by estimating standard incidence ratios (SIRs) using country-specific cancer registration data.

Aims: To assess the risk of AML and non-hematological malignancies in patients treated with HC or ANA in the EXELS study.

Methods: Previous exposure to ANA and HC was based on patient history. SIRs were calculated using background rates retrieved from Cancer Incidence in Five Continents (C5). Risk of AML after study enrolment was estimated by cumulating the risk of AML at exposures time of 180 days was used to account for disease progression as a confounding factor. Informed consent was obtained before the start of the study.

Results: Overall, 3460 patients were exposed to HC, ANA or both at registra-

tion; 481 patients had ANA treatment, 2305 had HC treatment and 674 had exposure to both drugs. The median age in ANA patients was 51 years, and 71 years in HC patients. One hundred and seventy four cases of non-

hematologic cancer, including 35 cases of skin cancer, were recorded. SIRs for all malignancies were close to 1 for all treatment groups, indicating similar

risks to the background population. For all skin cancers, including melanoma, the SIR for patients with HC treatment was higher than expected for the normal population and patients on ANA (1.15 vs 0.45). When melanoma was excluded, the figures changed only marginally. However, due to the low number of events, the CIs were wide, and no statistically significant difference was found between treatments. Sixty seven AML cases were reported; 39 AML cases were found in the HC group (person-years 8970, SIR 39.7), with another 20 AML cases in the group who switched from HC to ANA (person-years 2934, SIR 91.5). The risk ratio for AML developing in patients who switched from HC more than dou-

bled (RR 2.30-2.52), irrespective of minimum exposure time. In contrast, no AML case was observed in the ANA-only group (person-years 1905, SIR 0) and there were only 3 AML cases in the group who switched from ANA to HC (person-years 802, SIR 68.5). Since the number of AML cases in the ANA group was 0, no statistical comparison could be made. Five AML cases were excluded from analysis since there was uncertainty about which drug was used first.

Table 1.

Summary/Conclusions:

P705

EPIDEMIOLOGICAL, OUTCOME AND RISK FACTORS FOR INFECTION COMPLICATIONS IN MF PATIENTS RECEIVING RUXOLITINIB. A MULTICENTER STUDY ON 373 PATIENTS

1Unit of Blood Diseases and Stem Cell Transplantation, ASST Spedali Civili di Brescia, Brescia, Italy, 2Hematology and Clinical Immunology Unit, University of Padova, Padova, 3Division of Hematology, Ospedale Ferrarotto, University of Catania, Catania, 4Department of Hematology, University of Verona, Verona, 5Division of Cellular Biotechnologies and Hematology, University Sapienza, Rome, Italy

At the study closing date, median follow-up from diagnosis of MF was

20 months. Overall, 3460 patients were exposed to HC, ANA or both at registra-

tion and there were only 3 AML cases in the group who switched from ANA to HC. It has been proposed that exposure of ET patients failing HC therapy to a second potentially leukemogenic agent should be avoided; yet these data suggest that even after switching to a non-leukemogenic agent, HC-treated patients still have an over 90-fold increased risk of AML. Our data reinforces concerns of a leukemogenic effect of HC, with a markedly higher risk in patients failing HC and switching to another drug, even if that drug is ANA. The caution advocated in the use of HC seems well advised.

Summary/Conclusions: ET patients have a substantially increased risk for AML development; the SIR for AML was 40-fold higher than expected with HC exposure. In patients who switched from HC to ANA the SIR was approximately 90-fold higher, with 20 AML cases observed versus the expected 0.22 cases. The number of AML cases was much lower (n=3) in patients who switched from ANA to HC. It has been proposed that exposure of ET patients failing HC therapy to a second potentially leukemogenic agent should be avoided; yet these data suggest that even after switching to a non-leukemogenic agent, HC-treated patients still have an over 90-fold increased risk of AML. Our data reinforces concerns of a leukemogenic effect of HC, with a markedly higher risk in patients failing HC and switching to another drug, even if that drug is ANA. The caution advocated in the use of HC seems well advised.

Background: Infectious complications represent one of the most frequent causes of morbidity and mortality in Myelofibrosis (MF), the most severe of myeloproliferative neoplasms. Ruxolitinib (RUX), the first approved JAK1/2 inhibitor, significantly ameliorates disease-related splenomegaly and constitutional symptoms. Prospective controlled studies observed a high rate of infectious complications including opportunistic and unusual infections, probably due to its immune-suppressant activity. However, risk factors for infections in MF patients (pts) treated with RUX are still to be investigated.

Aims: To evaluate characteristics, incidence and risk factors for infections in RUX-exposed MF pts.

Methods: Clinical and laboratory data of MF pts treated with RUX were retrospectively collected from the database of 21 Italian Hematology Centers. Infections were defined according to the CTCAE.

Results: Overall, 373 pts received RUX between June 2011 and June 2016. At RUX start the clinical features were (median): age 68 years (27-89); >65y, 62%; male, 57%; Hb, 10.8g/dL (7-16.7); Hct <10g/dL, 40%; PLT, 246×10^9/L (33-1887); PLT <100×10^9/L, 10%; spleen enlargement, 97%; spleen length ≥10cm, 60%; constitutional symptoms, 52%. International Prognostic Score System (IPSS) was intermediate-1 (15%), intermediate-2 (46%), high (39%). V617F mutation was detected in 255 out of 313 evaluated pts (81%). Karyotype was unfavorable in 15 out of 203 evaluable pts (7%). Previous infectious complications were recorded in 31 pts (8%). After a median RUX exposure of 20 months (range, 1-56), 101 pts (27%) experienced 129 infectious events (grade 3, 33%), for an incidence rate of 14.9 cases for 100 pts/year. The rate of infections tended to decrease over time: 54% occurred within 6 months of treatment, 57% after 12 months. The rate of infections was significantly ameliorated in patients treated for >2 years (p=0.001). Respiratory tract infections were more frequently observed (73 events, 57%). Cutaneous, urinary tract and gastrointestinal infectious events were diagnosed in 15%, 10% and 7% of cases, respectively. In 14 cases fever of unknown origin was recorded (Figure 1). Etiological agents were isolated in 14 cases (11%); bacteria in 9 cases (gram+ 56%, gram- 22%, C. difficile diarrhea 22%) and fungi in 2 cases (pulmonary aspergillosis and oesophageal candidiasis). Mycobacterium tuberculosis meningitis was isolated in 3 cases. Herpes-virus reactivations occurred in 12 cases (9%). No patients reactivated hepatitis B virus. At last follow-up, 88 pts (24%) have died, in 10 cases (11%) due to infectious complication. Among baseline features, age≥65 years at RUX start (p<0.0001), previous infection (p=0.001), primary vs secondary MF (p=0.021) and high IPSS (p=0.029) significantly correlated with higher infectious risk. Notably, no differences were observed according presence of large (≥10cm) splenomegaly, higher (>20) total symptoms score, presence of cytopenias, Charlson comorbidity index (>2) and body mass index (>21 and >30). In multivariate analysis, PMF diagnosis (HR 1.6 CI95% 1.07-2.5), age≥65 years (HR 2.1 CI95% 1.3-3.3) and previous infection (HR 3 CI95% 1.7-5.4%) confirmed their negative prognostic association. Interestingly, RUX dosage, spleen response and hematological toxicities during treatment were not associated with infectious risk.

Summary/Conclusions: Infections occurred in around one-third of RUX-treated pts; the rate of infections tended to decrease over time, and were fatal in 11% of the cases. Advanced age, a previous infectious event and diagnosis of PMF seem to be the main contributors to infectious risk.

Background: Patient (pts) with myeloproliferative neoplasms (MPNs), including myelofibrosis (MF), polychromatemia vera (PV), and essential thrombocythemia (ET), experience a substantial disease burden. Pts are managed with watchful waiting or therapy, including aspirin, hydroxyurea (HU), and other drugs. The international MPN LANDMARK survey evaluated the patient-reported impact of MPNs in pts in 6 countries and identified current management strategies in these pts.

Aims: To analyze treatment strategies used by physicians and pts to manage MPNs.

Methods: This cross-sectional, internet-based survey was conducted in Australia, Canada, Germany, Italy, Japan, and the UK and was administered to pts with MPNs and to physicians treating pts with MPNs. Pts and physicians were recruited independently. We describe disease-management strategies in these pts.
ET) chose watchful waiting to manage >25% of their pts at diagnosis; 22% of untreated pts had moderate to high (quartiles 3-4) overall symptom burden. Physicians primarily recommended treatment for pts experiencing severe symptoms (72% MF; 68% PV, 72% ET) or symptomatic splenomegaly (71% MF; 61% PV, 39% ET). PLB was mainly used to treat pts with PV. Of those who received PLB (n=155), 71% were very or somewhat satisfied; 25% were very or somewhat dissatisfied and felt that PLB had a negative impact on their QOL. Similarly, 37% of physicians felt that PLB had a negative impact on pt QOL; PLB alone was insufficient for disease control in 38% of pts. Pts stopped PLB because physician deemed it no longer necessary (62%), pts felt worse after treatment (10%), and visit frequency was inconvenient (8%). Physician-reported reasons for stopping PLB were that visit frequency was inconvenient (38%), pts felt worse after treatment (35%), and lack of intravenous access (33%). HU use was assessed in pts with PV or ET. Of those who received HU (PV, n=95; ET, n=145), 78% and 74%, respectively, continued to receive HU; 19% and 22% were dissatisfied with HU therapy. Main reasons for stopping HU were lack of efficacy (29% PV, 13% ET) and toxicity (18% PV, 27% ET). Overall, 78% of physicians reported that up to 25% of their pts showed inadequate efficacy or intolerance of HU. Main measures of treatment success among pts were physician feedback (73% MF, 75% PV, 75% ET) and blood counts (72% MF, 67% PV, 74% ET). Lack of efficacy, side effects, and discontinuation were key reasons for changing therapy.

Summary/Conclusions: Many pts with MPNs are managed with watchful waiting at diagnosis. Although most of these pts have a low symptom burden, 22% have a moderate to high burden, highlighting the need for proactive and standardized symptom assessments at diagnosis and over the course of treatment. Interestingly, more than 80% of physicians and pts felt that phlebotomy had a high negative impact on pt QOL. Overall, pts consider physician feedback and blood counts to be important indicators of treatment success.

P707 SUCCESSFUL LONG-TERM MAINTENANCE OF PV PATIENTS WITH A MONTHLY SCHEDULE OF ROPEGINTERFERON ALFA-2B-AN UPDATE FROM THE PEGINVIRA STUDY

Background: Peginterferon alfa-2b is a novel long-acting monopegylated interferon alpha (IFNa) with Orphan designation in Europe and the U.S. Reduced dosing frequencies and favorable tolerability accompanied by robust clinical responses in patients with polycythemia vera (PV) have been reported over the first few years of treatment. Successful long-term, potentially life-long maintenance with high rates of adherence, compliance and treatment outcome remain important goals to be elucidated.

Aims: To describe the clinical outcomes of patients with PV who transform to accelerated or blast phase and evaluate the impact of genomic alterations on outcomes.

Methods: Eligibility criteria included: Prior diagnosis of Philadelphia negative MPN according to WHO 2008 criteria; evidence of transformation to accelerated (10-19% blasts in peripheral blood or bone marrow) or blast phase (>20% blasts) and seen at Princess Margaret Cancer Centre between January 1998 and February 2017. The primary endpoint was overall survival (OS); defined as the time from transformation to death or last follow-up. Secondary endpoints included survival based on curative versus non-curative approach and treatment over time. In addition the impact of mutations will be correlated with clinical outcomes and survival.

Results: Data from the last available analysis include 29 patients remaining on study with a median treatment duration of 213 weeks. All 29 patients have completed at least 2 years of treatment (5 patients are in the 3rd year, 7 in the 4th year, 10 in the 5th year and 7 in the 6th year of treatment). Baseline characteristics of the study cohort during short-term treatment and long-term maintenance, and efficacy follow-up data were already presented earlier (Gisslinger et al. 2015). All of the 29 patients were switched to dosing once every 4 weeks. Median treatment duration at time of switch was 104 weeks (Q1-Q3: 69-124 weeks). All 29 patients remained on the 4-week schedule with a median observation of 2 years. ROPEG reduction of mutant JAK2 allele burden to below 10%, a feature that can only be achieved by IFNα based therapies.

Summary/Conclusions: In summary, all patients remaining on peginterferon alfa-2b after a median of 2 years of initial treatment were successfully switched to a more convenient monthly long-term maintenance schedule, thereafter no patients discontinued, and all patients could be maintained on this schedule for currently another 2 years (trial still ongoing). These data underscore the expected long-term efficacy with regard to haematological, clinical and molecular parameters and the excellent safety/tolerability of peginterferon alfa-2b. Long-term maintenance treatment of PV patients using peginterferon alfa-2b monthly is feasible, efficacious and well tolerable. Continuous patient-individual adaption of dosing regimen, including dose and dosing schedule, is recommended.
Summary/Conclusions: Analysis ongoing).

comes and will be presented at the EHA annual conference (profiling completed, Myeloid Sequencing Panel. Mutational data will be correlated with clinical outcomes performed on peripheral blood or bone marrow samples using the TruSight filing of 54 genes (39 hotspot region; 15 complete coding region coverage) was for this cohort of patients.

approaches are ineffective. Results of molecular profiling may provide valuable who transform to accelerated or blast phase, confirming that current treatment ive care, there has been no significant improvement in survival for MPN patients

Sixty-four (41%) patients were treated with curative intent including 27 (42%) (90%) patients met the criteria for acute myeloid leukemia, thirteen (8%) had n=24, 15%) and MPN-unclassifiable (n=11, 7%). One hundred and forty-two post ET myelofibrosis (PET MF; n=27, 17%), post PV myelofibrosis (PPV MF; n=24, 15%) and MPN-unclassifiable (n=11, 7%). One hundred and forty-two patients received non curative approach including low dose chemotherapy, hypomethylating agent, clinical trial or best supportive care. The median OS for the entire cohort was 6.5 months (95% CI: 5.08-8.01). In patients treated with curative intent median OS was 8.8 versus 3.2 months (p=0.003) for patients with non-curative intent. There was no difference in OS between historical controls treated between 1998 and 2011 when compared to a more recent cohort of patients (6.5 vs 7.3, p=0.34; see Figure 1). In 105 (67%) patients, NGS molecular profiling of 54 genes (39 hotspot region; 15 complete coding region coverage) was performed on peripheral blood or bone marrow samples using the TruSight Myeloid Sequencing Panel. Mutational data will be correlated with clinical outcomes and will be presented at the EHA annual conference (profiling completed, analysis ongoing).

Summary/Conclusions: Despite advances in systemic therapies and support ive care, there has been no significant improvement in survival for MPN patients who transform to accelerated or blast phase, confirming that current treatment approaches are ineffective. Results of molecular profiling may provide valuable insights and clues as to how to develop an individualized treatment approach for this cohort of patients.

Background: Mastitinib, a selective oral tyrosine kinase inhibitor targeting wild-type KIT, LYN and FYN, was the first drug to demonstrate efficacy in a phase 3 setting (study AB06006) for treatment of patients with severe indolent systemic mastocytosis (ISM) who are unresponsive to existing, optimal symptomatic treatments. In The Lancet (Feb 11;389(10069):612-620), Lortholary and col leagues reported a significant and clinically meaningful treatment benefit for mastitinib (6mg/kg/day over 24-weeks) versus placebo, with primary analysis based on cumulative response (≥75% improvement from baseline, timeframe weeks 8-24, comprising 5 visits at 4-week intervals) in at least one of four severe baseline symptoms (pruritus, flushes, depression, or fatigue) using repeated measures methodology for rare diseases (i.e. a longitudinal analysis with respect to symptoms as opposed to patient response rate at a single point in time). Eligible patients were aged 18–75 years and had ISM according to inclusion criteria that were slightly broader than the WHO classification.

Aims: To aide interpretation of this study's prospectively declared primary endpoint via comparison with additional efficacy analyses based on a cohort restricted to the WHO classification of ISM and more conventional patient-centric response endpoints.

Methods: Randomized, placebo-controlled, phase 3 study that included 135 severely symptomatic ISM patients, including the subvariant smoldering systemic mastocytosis (19 mastitinib, 64 placebo), 80% of whom satisfied the WHO classification.

Results: Masitinib showed a significant improvement over placebo according to its primary endpoint (mITT population), with a cumulative response of 18.7% versus 7.4%, respectively, odds ratio (OR) of 3.6 [95%CI 1.2-10.8], P=0.008 (with re-randomization). This outcome was confirmed in the WHO patient subgroup: 17.8% versus 8.0%, respectively, OR=3.25 [9.07-10.88], P=0.0317. Computing the primary analysis (mITT) according to cumulative response per patient (GEE model) was also positive: 26.7% versus 12.8%, respectively, OR=2.48 [1.16-5.31], P=0.0212, as was analysis accounting for individual patient response (Pearson chi-square): 40.3% versus 24.2%, respectively, P=0.0062. Response (per patient) on all severe baseline symptoms for at least one visit was: 16.4% versus 1.6%, respectively, P=0.0062. Finally, analysis of sustained response in all severe baseline symptoms over multiple visits was highly discriminatory between treatment arms: for patients with 3 severe baseline symptoms sustained a response of 12.5% response rate (≥75% improvement in each symptom) for 3 out of 5 visits, versus no response for placebo; and for patients with 2 severe baseline symptoms masitinib generated a response rate of 21.1%, 15.8% and 10.5% over at least 1, 2, and 3 visits, respectively, versus no response for placebo.

Summary/Conclusions: These post-hoc analyses confirm the clinical relevance, durability, and generalizability of the positive primary endpoint from study AB06006. Findings therefore support the conclusion that masitinib generates a significant therapeutic benefit in patients with severely symptomatic ISM who were unresponsive to optimal symptomatic treatments.

Background: Mastitinib, a selective oral tyrosine kinase inhibitor targeting wild-type KIT, LYN and FYN, was the first drug to demonstrate efficacy in a phase 3 setting (study AB06006) for treatment of patients with severe indolent systemic mastocytosis (ISM) who are unresponsive to existing, optimal symptomatic treatments. In The Lancet (Feb 11;389(10069):612-620), Lortholary and colleagu
Background: Hemophagocytic lymphohistiocytosis (HLH) is a devastating disorder of uncontrolled immune activation characterized by clinicopathological evidence of extreme inflammation. Hematological malignancy-associated HLH (m-HLH) has the worst outcome in comparison with any other form of HLH. m-HLH can occur as the first manifestation of an occult malignancy, before start or during the treatment of known malignancy, or as the sign of a malignant relapse or transformation to the more aggressive disease form.

Aims: The aim of the present study was to analyze the response to HLH therapy and overall survival of adult patients with m-HLH.

Methods: From 2008 and onwards, data on adult patients referred to the Hematology Center Karolinska with suspected HLH were prospectively collected. Review concerned records of 142 adults with suspected HLH, hospitalized between Jan 2009 and Dec 2016. Of those, 71 patients with hematological malignancy were diagnosed with HLH and included to the present study. Hematological malignancy was defined as a neoplasm of lymphoid or myeloid origin. In all studied patients, the diagnosis of HLH was based on the HLH-2004 criteria. Infection as a possible additional trigger of HLH was carefully studied in all our m-HLH patients. EBV and CMV DNA were routinely examined in whole blood, using RT quantitative PCR; other viruses (e.g. adenovirus, HSV, VZV, HHV6, influenza) were studied based on indications. Blood and urine cultures were performed in order to reveal any bacterial or fungal infections. Tests for fungal antigens, tuberculosis, and parasites were also performed if indicated. HLH treatment categories have included proapoptotic chemotherapy (etoposide, corticosteroids, IVIG) and T cells (corticosteroids, cyclosporine A).

Summary/Conclusions: HLH in the context of malignancy is still considered a challenge in adult hematology. m-HLH is a highly lethal disorder in adults. The patients who develop m-HLH with concomitant infection during chemotherapy show better survival than those who had HLH solely attributed to malignancy. Although poor outcome in some patients with m-HLH is related to malignancy progression, in some patients the lack of effective m-HLH therapy may further impede adequate treatment of malignancy.

1Laboratoire Hematologie, Plateau Technique De Biologie, Dijon Cedex, 2INSERM U 1231, Faculté médecine, Dijon, 3INSERM, université de Nantes, 4Laboratoire de Génétique Moléculaire, CHU Nantes, 5Centre de Recherche en Cancérologie et Immunologie Nantes Angers, INSERM Université de Nantes, 6Hôpital Saint Vincent de Paul, Université Catholique de Lille, Lille, 7Service d’Hémato-oncologie adulte et thérapies cellulaires, CHU Clermont Ferrand, Clermont Ferrand, France, 8Clinica Medica 1, Department of Medicine –DIMED, Padova, Italy, 9Centre de Recherche en Cancérologie et Immunologie Nantes Angers, INSERM, Université de Nantes, Nantes, France

Background: Erythrocytoses are characterized by an elevated red cell mass. The most widely studied disease is Polycythemia Vera (PV), however, other types of erythrocytoses can be either inherited (Congenital Erythrocytosis-CE) or acquired (CE/IE) in patients with no familial history (idiopathic polycythemia vera, IPV, and hereditary Erythrocytosis, IE). CE/IE are not associated with myeloproliferation but they can be associated with severe thrombo-embolic or haemorrhagic events, pulmonary arterial hypertension and, rarely, tumours (hemangioblastoma, pheochromocytoma). The 8 genes identified so far as causing CE are involved (i) in the regulation of the hypoxia pathway; PHD2 (also called EGLN1), HIF-2α (EPAS1), VHL, (ii) in prolation and differentiation of erythroid progenitors (EPOR), or (iii) in mature cell function, haemoglobin (HBB, HBA1, HBA2) or phosphoglyceratemutase (BPGM). However, in 80% of cases the cause remains unknown meaning that no proper diagnosis can be made, no prognosis or advice can be provided to CE/IE patients, and no curative treatment exists.

Aims: to (i) identify, (ii) collect and (iii) analyze the genetic abnormalities in patients suspected of CE.

Methods: We created and developed a national network in France to analyze the genomic abnormalities in patients suspected of CE. The selection of patients was based on the criteria: (i) a diagnosis with polycythemia vera; secondary erythrocytosis related to lung, cardiac or renal disorder. Next generation sequencing (NGS) has been used to analyse the presence of mutations in 28 genes (enlarged hypoxia pathway and other candidate genes).

Results: To date, samples from 140 patients have been recorded, among whom 46 have been analyzed using NGS approach. The variants identified in 14 CE/IE patients [13 males and 1 female; median age 50 y, (12-71)] with unknown significance have been detected, including 4 in PHD genes, 5 in HIF genes, 4 in LN genes (SH2B3) and 1 in JAK2 gene. In patients with variants, a familial history of erythrocytosis was noted in 3. No independent thrombotic complication was reported in the 15 patients. In 2 patients (one with a JAK2 variant and one with a VHL variant), the erythropoietin was low, whereas for the others, the erythropoietin was normal. Of note, the median age of the patients was surprisingly high, suggesting that the diagnostic was not previously performed due to the absence of available tests. Functional studies were performed on PHD2 variants: a significant decrease in the hydroxylase activity was noted for one variant, but not for the others. On the other hand, a decrease in the stability along time of the PHD2 protein was observed for two variants, underscoring the different mechanisms involved in the impairment of the PHD2 activity.

Summary/Conclusions: NGS is a useful tool to explore mutations in CE, but identifies genetic variants in only 30% of patients with such disorder. Further exams including whole exome sequencing are planned to achieve a right diagnosis in the 70% remaining CE patients. In vitro, in cellulo and in vivo (including zebrafish model) functional studies are currently performed to validate the clinical relevance of the variants identified in the hypoxia pathway. They are compared to variants identified in the development of tumors in order to dissect the molecular mechanisms of this finely tuned pathway.

P713
CHARACTERIZATION OF CD34+ HEMATOPOIETIC PRECURSORS IN INDOLENT SYSTEMIC MASTOCYTOSIS AND THEIR POTENTIAL ROLE IN EARLY DISSEMINATION OF THE DISEASE

1Cancer Research Centre (IBMMC, USAL-CSIC), Cytometry Service (NUCLEUS) and Department of Medicine, University of Salamanca, Salamanca, Spain, 2Instituto de Biomedica Research of Salamanca (IBSAL), Salamanca, Spain, 3Department of Immunohematology and Blood Transfusion, Leiden University Medical Center, Leiden, Netherlands, 4Sequencing DNA Service (NUCLEUS), University of Salamanca, Salamanca, 5Instituto de Estudios de M astocitosis de Castilla La Mancha (CLEMAst), Hospital Virgen del Valle, Toledo, Spain

Background: Recent studies show that most systemic mastocytosis (SM) patients, including indolent SM (ISM) with (ISMs+) and without skin lesions (ISMs-), carry the KIT D816V mutation in PB leukocytes.

Aims: To investigate the potential association between the degree of involvement of BM hematopoiesis by the KIT D816V mutation and the distribution of different maturation-associated compartments of bone marrow (BM) and peripheral blood (PB) CD34+ hematopoietic precursors (HPC) in ISM, and identify the specific PB cell compartments that carry this mutation.

Methods: The distribution of different maturation-associated of BM and PB CD34+ HPC from 64 newly-diagnosed (KIT-mutated) ISM patients and 14 healthy controls was analyzed by flow cytometry. In 18 patients distinct FACS-purified PB cell compartments were also investigated for the KIT mutation.

Results: ISM patients showed higher percentages of both BM and PB MC-committed CD34+ HPC vs controls, particularly among ISM with MC-restricted KIT mutation (ISMMC); this was associated with progressive blockade of maturation of CD34+ HPC to neutrophil lineage from ISMNC to multilineage KIT-mutated cases (ISMtk). Regarding the frequency of KIT-mutated cases and cell populations in PB, variable patterns were observed, the percentage of KIT-mutated PB CD34+ HPC, eosinophils, neutrophils, monocytes and T-cells increasing from ISMMC and ISMt+ to ISMtk patients.

Summary/Conclusions: Positivity for the KIT D816V mutation in PB of ISM is related with high percentage of circulatory mast cells. MC-patients without MC-predominant localization of CD34+ HPC in BM cell compartments and multiple myeloid cell populations, KIT-mutated PB CD34+ HPC potentially contributing to disease dissemination already at very early stages.
EVOLUTION AND GENETICS

S. Parma, 1,2Department of Medicine, University of Padua; Padua, 3,4Department of Oncology, Azienda “Santobono-Pausilipon”, Pausilipon Hospital; 5,6Department of Pediatric Haematology-Oncology, Department of Pediatric Haematology-Oncology, Napoli; 7,8Department of Pediatric Haematology-Oncology, University Hospital of Parma, Parma, 9Department of Pediatric Haematology-Oncology, University Hospital of Bolzano, Bolzano, 10Department of Reproduction and Growth, University Hospital Sant’Anna in Ferrara, Ferrara, 11Department of Haematology, Oncocematologia Pediatrica, Pollicino G. B. Rossi, Verona, 12Department of Pediatric Haematology-Oncology, University of Catania, Catania, 12Department of Haematology, Ca’Foncello Hospital, Treviso, Italy

Background: Erythrocytosis, (i.e. increased levels of hemoglobin/hematocrit (Hb/Ht)>95percentile for age and sex), is rarely found in pediatric or adolescent age. Presence of familial cases, presentation at birth or presence of known mutations, as well as exclusion of secondary causes identifies primary (PE) or congenital secondary forms (CE). However, many cases still lack evident etiological definition (idiopathic E.). Moreover, natural course and treatment are still anecdotally reported.

Aims: Here we present our experience in a large and heterogeneous series of children with absolute erythrocytosis. The aims is to identify a possible clinical and diagnostic approach to children with erythrocytosis.

Methods: All children with E. who lacked evidence of reactive origin were consecutively referred to our laboratory for molecular evaluation. Molecular analysis of the main involved genes (VHL, HIF2A, EPOR, JAK2, PHD2) was performed by allele specific PCR, PCR on direct DNA sequencing. Erythropoietic Colony Essay (ECE) was performed on peripheral blood with and without cytokines. Clinical features and treatment choices were reported by referring clinicians (table 1).

<table>
<thead>
<tr>
<th>Table 1</th>
</tr>
</thead>
</table>

Results: Patients were group according to the definitions of absolute Erythrocytosis. A total of 44 pediatric cases were identified (less than 18 years old). There were 7 families, where 5 adults were also found polyglobulic. However, in only 4 families a defect was identified (2 VHL, and 2 Hb variants). One positive case was found sporadic. Most Hb variants were not symptomatic, while all other familiar cases had splenomegaly and vascular symptoms. Among non familial, non genetic cases, 5 children were affected by Down Syndrome; 4 children had severe renal or cerebral disease. In one 4 year old girl, with a polymorphic VHL variant who presented with arterial hypertension, a small size ganglioneurona was found after a 5yr follow-up. In 21 cases non causes could be identified. They were mostly male (n18); presented at adolescent age with advanced puberal status (n17); many were symptomatic (6). Only one 9 year old girl was diagnosed with polycytemia vera (JAK2V617F positive). Treatment varied according to physician decisions and presence of vascular symptoms, 6 children received ASA and 11 were phlebotomised. In two older patients severe vascular complications were observed (arterial thrombosis), even with Htc<45%.

Summary/Conclusions: This series shows the heterogeneity of Erythrocytosis as found in pediatrics. Extensive clinical and genetic analysis are required but still a large number of cases lack clear definitions. The usefulness of antiaggregation and phlebotomy is not proved. P716

NEUROLOGIC INVOLVEMENT IN EVANS SYNDROME AND CHRONIC HEMOLYTIC AUTOIMMUNE ANEMIA OF CHILDREN: DESCRIPTION, EVOLUTION AND GENETICS

Background: Neurological involvement is poorly described in autoimmune cytopenias (AIC), containing immune thrombocytopenia (ITP), autoimmune hemolytic anemia (AIHA) and Evans syndrome (ES). This association suggests an underlying primary immunodeficiency (PID).

Aims: To describe neurological involvement observed in autoimmune cytopenias, evolution under treatment and PID profiles in these patients.

Methods: OBS/CERECANE is a French nationwide prospective cohort including children with a AIC since 2004. Patients with a neurological involvement were analyzed excluding neurological symptoms related to a traumatism or isolated febrile seizures. Clinical, radiological and biological data were collected from primary centers. Centralized radiological review was performed. Genetic analyses were performed by Sanger gene sequencing or gene-panel based next generation sequencing.

Results: On October 2016, among the 1,167 patients of the cohort (371 AIHA, 615 ITP, 181 ES), a significant neurological involvement was observed in 8 patients from 7 centers. With a median (range) follow-up of 12 years (6-26.5), 7 children had ES (including autoimmune neutropenia in 5) and 1 child had isolated AIHA. Median age at AIC diagnosis was 11.5 years (6.2-15.8). At the last follow-up point, AIC were in partial or complete remission for all patients. Neurological symptoms appeared with a mean delay of 6 years (2.5-18) after AIC onset. The symptomatology was: seizures (n=4), cranial nerve palsies (n=2), Brown-Sequard syndrome (n=2) and/or sensory neuropathy (n=1). No infectious pathogens were identified. MRI showed multiple (n=6) or unique (n=2) inflammatory lesions with hypertense T2 signal in all patients, gadolinium-enhancing lesions in 7 and perilesional edema in 5. Five patients had a total of 8 biopsies, which confirmed the inflammatory process with macrophagic (n=3) or lymphoplasmocytoid (n=5) infiltrates. In 4 cases, a lymphocytic meningitis was associated. Non-neurological organ involvement was present in all patients, mainly pulmonary nodules (n=6) and lymphoproliferation (n=4). All patients had an abnormal immunophenotype, with T-cell (n=7) or B-cell (n=3) deficit and/or hypogammaglobulinemia was present in 7 of the 8 cases. Pathogenic mutation had been found in 5 cases in autoimmunity transcripts (n=2), or immunosuppressive treatment (n=3, Ciclosporin, Mycophenolate Mofetil and Methotrexate), improving symptomatology and MRI for all. Five patients relapsed and 3 patients had an asymptomatic radiological progression. At the last follow up point, all patients had neurological sequel and 7 persisting radiological abnormalities. Four out of 6 patients analyzed had a PID: 22q11.2 (n=1), heterogeneous CTLA mutation (n=2) or homozygous LRBA mutation (n=1).

Summary/Conclusions: Neurological involvement is rare and severe late event in the course of childhood ES, or exceptionally AIHA, that may reveal various underlying PID. Complete imaging and pathology examination highlight a causative immune dysregulation and could guide specific therapeutic strategies. P717

AUTOIMMUNE NEUTROPENIA OF CHILDHOOD SECONDARY TO OTHER AUTOIMMUNE DISORDERS: DATA FROM THE ITALIAN NEUTROPENIA REGISTRY

1Pediatric Haematology and Oncology Unit, Oncology Department, A.R.N.A.S. Ospedali Civici, Di Cristina e Benfratelli, 2Department of Sciences for Health Promotion, University of Palermo, Palermo, 3Department of Pediatric and Public Health Sciences University of Torino, Torino, 4Clinical and Experimental Hematology Unit, G. Gaslini Children’s Hospital, Genova, 5Flow Cytometry Service, Laboratory of Clinical Chemistry and Microbiology, IRCCS ‘Ca’ Grand’A’ Foundation, Maggiore Hospital Policlinico, Milano, 6Department of Pediatric Onco-Hematology, University Hospital Palermo, 7Pediatric Hematology and Oncology Unit, Department of Clinical and Experimental Medicine, University
of Catania. Catania, 8 O. San Gerardo, Fondazione MBMM, Clinica Pediatrica, Università di Milano - Bicocca, Monza, 9Università Tor Vergata, Immunologia Pediatrica, Roma.

Background: The most frequent Autoimmune Neutropenia (AIN) in childhood is the primary type (p-AIN), whereas in adults AIN is mostly represented by secondary neutropenias, which can be associated to infection, drug administration, immunodeficiency, neoplasms, bone marrow transplantation or other autoimmune disorders.

Aims: To describe clinic and laboratory findings in children affected by AIN secondary to other autoimmune diseases (s-AIN).

Methods: This registry study analyzes 26 patients affected by s-AIN enrolled in the Italian neutropenia registry of A.I.E.O.P. (Associazione Italiana di Oncoematologia Pediatrica) over a 15-year time-span: this cohort, the largest ever described, was compared to 263 patients affected by p-AIN enrolled in the Registry in the same period.

Results: Specific characteristics of s-AIN patients are presented in Figure 1. The prevalence of former preterm babies among p-AIN (and not s-AIN) patients was significantly higher than in a cohort of 487 consecutively hospitalized children (p<0.0001). The median age of onset of AIN was 0.77 year and 10.07 year in p-AIN and s-AIN respectively (p=1.105e-12). The prevalence of selected IgA deficiency was 3% in p-AIN and 13.6% in s-AIN children: both prevalences were significantly higher than that (0.21%) of a group of 470 controls (p=0.00009 in p-AIN and p=7.239e-12 in s-AIN). Median value of neutrophils was lower in p-AIN (0.45 x 10^9/L) than in s-AIN 0.63 x 10^9/L (p=0.03); median value of lymphocytes was significantly reduced (p=6.29e-11) in s-AIN (1.58 x 10^9/L) vs p-AIN (4.36 x 10^9/L) group. Leucopenia (p=1.80e-07) and severe infections (p=0.0001) occurred more frequently in s-AIN; monocytosis (p=0.039) and spontaneous remission (p=3.21e-11) in p-AIN. GCSF was used in 6.9% of the population.

Summary/Conclusions: p-AIN is in the vast majority of cases a benign and self-limiting disorder typically occurring under 2-3 years old whereas s-AIN is a more severe disease, usually appearing after the first 5 years of life, usually associated to lymphocytopenia and with a highly frequent tendency to become chronic.

Clinical manifestations of hemolysis significantly regressed during eculizumab treatment: normalization of LDH was registered in 76.5% patients. Without eculizumab LDH level increased in all pregnant patients. No maternal death and thrombotic events have been observed. 42.9% of patients required a dose adjustment due to breakthrough hemolysis (a dose increase and/or more frequent use of eculizumab). Pregnancy complications were less frequent with eculizumab: abortion rate 35.3% vs 85.7%, fetal growth retardation syndrome 7.1% vs 21.4%, preeclampsia 5.9% vs 14.3%. Transfusion rate was higher without eculizumab (86.7% vs 41.2%). Pregnancies resulted in the birth in 100% patients exposed eculizumab and 42.9% on supportive treatment. Mean birth weight 2560 g (450-3550). Most of newborns (87.5%) are healthy, 83.3% of them received breastfeeding without complications both on eculizumab and without it.

Summary/Conclusions: We can conclude that pregnancy outcomes in PNH patients on eculizumab treatment and retrospective data of pregnancies on symptomatic therapy only. Since 1999 we have analyzed 32 pregnancies in PNH patients. 17 patients (group 1) from 2013 exposed to eculizumab during pregnancy with antiocoagulants. Other 15 women (group 2) received only symptomatic therapy. The median of PNH granulocyte clone at that time was 74.7% (23-99). PNH diagnosed before the pregnancy in all cases. 64.3% of them had previously received immunosuppressive treatment of aplastic anemia. 18.7% patients registered venous thromboses before conception. 92.9% of patients had been using eculizumab for at least 1 year. 71% patients had been using eculizumab prior to becoming pregnant, mean duration of therapy was 21 months (4-44). Antiocoagulation with low molecular weight heparin was used in 85.7% pregnancies.

Results: Clinical manifestations of hemolysis significantly regressed during eculizumab treatment: normalization of LDH was registered in 76.5% patients. Without eculizumab LDH level increased in all pregnant patients. No maternal death and thrombotic events have been observed. 42.9% of patients required a dose adjustment due to breakthrough hemolysis (a dose increase and/or more frequent use of eculizumab). Pregnancy complications were less frequent with eculizumab: abortion rate 35.3% vs 85.7%, fetal growth retardation syndrome 7.1% vs 21.4%, preeclampsia 5.9% vs 14.3%. Transfusion rate was higher without eculizumab (86.7% vs 41.2%). Pregnancies resulted in the birth in 100% patients exposed eculizumab and 42.9% on supportive treatment. Mean birth weight 2560 g (450-3550). Most of newborns (87.5%) are healthy, 83.3% of them received breastfeeding without complications both on eculizumab and without it.

Summary/Conclusions: We can conclude that pregnancy outcomes in PNH patients on eculizumab treatment and retrospective data of pregnancies on symptomatic therapy only. Our data demonstrate the possibility of safe therapy with eculizumab in pregnant women. Pregnancy does not worsen the prognosis of PNH in the case of targeted and adequate supportive therapy. There is no difference in health between infants born by mothers with PNH and the newborns from general population.

**LONG-TERM RESPONSE TO ORAL ELTROMBOPAG IN TREATMENT-NAÏVE ADULTS WITH GAUCHER DISEASE TYPE 1: FINAL EFFICACY AND SAFETY RESULTS FROM A PHASE 2 CLINICAL TRIAL AFTER 8 YEARS OF TREATMENT**

E. Lukina,1,2, N. Watman,3 M. Dragosky,3 H. Lau,4 E. Avila Arreguin,5 H. Rosenbaum4, Y. Wu,7 S. Gaemers2, M.J. Peterschmitt2 1National Research Center for Hematology, Moscow, Russian Federation, 2Hospital Ramos Mejia, 3IMA-Research, Buenos Aires, Argentina, 4New York University School of Medicine, New York, United States, 5Instituto Mexicano del Seguro Social Hospital de Especialidades, Col. La Raza, Mexico, 6Rambam Medical Center, Haifa, Israel, 7Sanofi Genzyme, Cambridge, United States

**Background:** In Gaucher disease type 1 (GD1), deficient lysosomal acid β-glucosidase activity leads to accumulation of glucosylceramide, primarily in macrophages (Gaucher cells), which deposit in the spleen, liver, and bone marrow, leading to thrombocytopenia, anemia, hepatosplenomegaly, and skeletal disease. Hematologists often identify and manage the disease. Intravenous enzyme replacement therapy (ERT) with recombinant β-glucosidase has been the mainstay of therapy for GD1. Eltrombopag is an oral subtype reduction agonist that has shown to increase platelet production. It is approved for the management of patients with chronic ITP (aged ≥1 year) who are refractory to other treatments (eg, corticosteroids, immunoglobulins). The recommended eltrombopag dose in patients with chronic ITP is 25mg once daily, OD (East Asians, 12.5mg OD or 25mg every other day) in adults and pediatrics aged 6-17 years at initiation, followed by dose adjustment to a maximum of 75mg OD based on platelet counts. REVIEU study was conducted in accordance with risk management plan in five European Union (EU) countries to document eltrombopag utilization patterns in real-world practice. Here, we report the eltrombopag-related data on the subset of adult patients (aged ≥18 years) with ITP as primary diagnosis.

**Aims:** To evaluate the real-world data to determine drug utilization patterns among adult patients with ITP receiving eltrombopag within five EU countries.

**Methods:** REVIEU study was a multinational, multicenter, retrospective, medical chart review in patients with a documented past treatment with eltrombopag between the period immediately after first approval/launch in May 2010 and September 2014 (ie, dispensed at least once by the pharmacy and patient received at least one dose) for whatever reason. Patients who participated or were participating in a randomized eltrombopag clinical trial were excluded.

**Results:** Overall, 287 adult patients with ITP (chronic [≥12 months], 75.3%; persistent [3-12 months], 10.8%; acute [≤3 months], 13.6%; unknown [n=1]) were included, majority in Spain (n=128) followed by Italy (n=67), Greece (n=56), France (n=29), and Germany (n=27). Ertrombopag was the first treatment with no prior ITP therapies in 12 (4.2%) [acute, 10.3%; persistent, 6.5%; chronic, 2.8%] patients. A total of 99 (34.6%) patients received one prior therapy (corticosteroids, 79 [27.6%]; 128 (44.8%) patients received two prior therapies (corticosteroids+immunoglobulins, 114 [39.3%]). 72 patients received three prior therapies (corticosteroids, immunoglobulins, and splenectomy). In total, the majority of patients received at least one prescription of corticosteroids (252, 88.1%) followed by immunoglobulins (180, 62.9%), and splenectomy (64, 22.4%) prior to eltrombopag initiation. Patients received an average daily dose of eltrombopag 45.6mg (chronic ITP, 44.6mg; persistent ITP, 43.1mg; acute ITP, 53.0mg) during the study. Overall, dose changes were reported in 749 adult ITP prescriptions (down-titration, 53.7%; up-titration, 43.7%; no change in dose, 2.7%). 49.1% of dose changes were reported during the first 6 months of treatment (35% in first 3 months). The main reasons for dose change included: disease improvement (30.4%), no treatment response (26.8%) and others (27.1%). Disease improvement accounted for down-titration in 51.2% (206/402) and up-titration in 4.6% (15/327), and no treatment response for up-titration in 54.4% (178/327) and down-titration in 5.0% (20/402) of adult patients with ITP. Ertrombopag is also prescribed in 24.4% of adult patients with acute and persistent ITP. The starting dose followed the summary of product characteristics (SmPC) recommendations in the majority of cases and dose modifications were generally according to platelet counts. Data from REVIEU study have shown that eltrombopag use in the real world setting is largely consistent with the EU label and is considered part of ITP medical therapies.

**Summary/Conclusions:** The majority of adult patients with ITP (75.3%) were diagnosed with chronic ITP, and were treated with eltrombopag as second-line or greater therapy after corticosteroids and immunoglobulins, in line with the approved indication. Ertrombopag was also prescribed in 24.4% of adult patients with acute and persistent ITP. The starting dose followed the summary of product characteristics (SmPC) recommendations in the majority of cases and dose modifications were generally according to platelet counts. Data from REVIEU study have shown that eltrombopag use in the real world setting is largely consistent with the EU label and is considered part of ITP medical therapies.

**Table 1.**

| Table 1. Proportion of patients with platelet counts by ITP disease phase, and by eltrombopag dose |
|----------------------------------|----------------------------------|
| **ITP disease phase** | **Eltrombopag dose** |
| Chronic ITP | Persistent ITP |
| 1.0-45mg/OD | 1.0-45mg/OD |
| 46-90mg/OD | 46-90mg/OD |
| ≥90mg/OD | ≥90mg/OD |

**REAL WORLD EVIDENCE ON DRUG UTILIZATION PATTERNS OF ELTROMBOPAG IN ADULT PATIENTS WITH IMMUNE THROMBOCYTOPENIC PURPURA (ITP) IN SELECTED COUNTRIES IN THE EUROPEAN UNION: STUDY**

E.O. Gutiérrez,1,2 A. Salama,1 J-F. Viallard2, R.G. Delgado4, M.E. Mingol-Castellano5, E. Quebe-Fehler2, O.A. Ozelim6, A. Allepuz7, T.J. González-López 1Hospital Universitario Puerta de Hierro Majadahonda, Madrid, Spain, 2Charité Universitätsmedizin Berlin, Berlin, Germany, 3Hôpital Haut Lévêque Centre Hospitalier de Bordeaux, Bordeaux, France, 4Hospital Clinico Universitario Virgen de la Victoria Campus Universitario de Teatinos s/n, 5Hospital Regional Universitario de Málaga Avenida Carlos Haya s/n, 6Malaga, Spain, 7Novartis Pharma AG, Basel, Switzerland, 8Hospital Universitario de Burgos Avda. Islas Baleares s/n, Burgos, Spain

**Background:** Immune thrombocytopenia (ITP) is an autoimmune disorder characterized by isolated thrombocytopenia, with platelet counts <100x10⁹/L. Ertrombopag is an oral small-molecule nonpeptide thrombopoietin-receptor agonist that has shown to increase platelet production. It is approved for the management of patients with chronic ITP (aged ≥1 year) who are refractory to other treatments (eg, corticosteroids, immunoglobulins). The recommended eltrombopag dose in patients with chronic ITP is 25mg once daily, OD (East Asians, 12.5mg OD or 25mg every other day) in pediatrics aged 1-5 years, and 50mg OD (East Asians, 25mg OD) in adults and pediatrics aged 6-17 years at initiation, followed by dose adjustment to a maximum of 75mg OD based on platelet counts. REVIEU study was conducted in accordance with risk management plan in five European Union (EU) countries to document eltrombopag utilization patterns in real-world practice. Here, we report the eltrombopag-related data on the subset of adult patients (aged ≥18 years) with ITP as primary diagnosis.

**Aims:** To evaluate the real-world data to determine drug utilization patterns among adult patients with ITP receiving eltrombopag within five EU countries.

**Methods:** REVIEU study was a multinational, multicenter, retrospective, medical chart review in patients with a documented past treatment with eltrombopag between the period immediately after first approval/launch in May 2010 and September 2014 (ie, dispensed at least once by the pharmacy and patient received at least one dose) for whatever reason. Patients who participated or were participating in a randomized eltrombopag clinical trial were excluded.

**Results:** After 8 years of treatment with eltrombopag, clinically meaningful improvements in hematologic, visceral, biomarker, and bone parameters continued or were maintained among patients in this Phase 2 trial. No new safety concerns emerged.

**Summary/Conclusions:** After 8 years of treatment with eltrombopag, clinically meaningful improvements in hematologic, visceral, biomarker, and bone parameters continued or were maintained among patients in this Phase 2 trial. No new safety concerns emerged.
Results: of mean fluorescence intensity (MFI) compared to that of a control.

modified antigen capture ELISA test (MACE). FC results are expressed as ratio

Methods: We performed a prospective study in 8 patients with primary ITP not responding to standard therapies (corticosteroids, IVIG and/or splenectomy) as well as in 8 patients with non-refractory ITP (control group).

Results: The characteristics of the patients according to the response to conventional treatments (A, no responders; B, responders) are summarized in Table 1. Non responders exhibited lower platelet counts (p=0.006), higher expression of GPIbα (p=0.049) and loss of platelet sialic acids (p=0.005). Additionally, those who did not respond not only to traditional therapies (corticosteroids, IVIG and splenectomy) but also to thrombopoietin receptor agonists (TPO-RA) (n=5) displayed higher platelet size and alpha-granule secretion.

Background: A previous study has suggested a mechanism of Fcγ receptors (FcγR)-independent platelet clearance in immune thrombocytopenia (ITP) (1). Antibody-mediated desialylation may lead to platelet clearance in the liver via hepatic Ashwell–Morell receptors, providing a potential explanation for refractoriness to classical therapies (steroid, IVIG and splenectomy).

Aims: The aim of this study was to analyze the biological features of ITP patients refractory to conventional therapies.

Methods: We performed a prospective study in 8 patients with primary ITP not responding to standard therapies (corticosteroids, IVIG and/or splenectomy) as well as in 8 patients with non-refractory ITP (control group). Mean platelet size, surface expression of platelet glycoprotein (GP) IIb, and the activation marker CD62 were examined by flow cytometry (FC) analysis, as well as desialylation of platelet membrane sugars using fluorescein-conjugated Ricinus Communis Agglutinin I (RCA-1), a lectin that binds to galactose residues underlying sialic acids. Patients’ sera was also incubated with normal human platelets to analyze their ability to induce desialylation in normal platelets. Analysis of desialylation of plasma proteins was performed by Western blot (FXI, FXII) and HPLC (transferrin). The specificity of platelet autoantibodies was assessed by a solid-phase modified antigen capture ELISA test (MACE). FC results are expressed as ratio of mean fluorescence intensity (MFI) compared to that of a control.

Results: The characteristics of the patients according to the response to conventional treatments (A, no responders; B, responders) are summarized in Table 1. Non responders exhibited lower platelet counts (p=0.006), higher expression of GPIbα (p=0.049) and loss of platelet sialic acids (p=0.005). Additionally, those who did not respond not only to traditional therapies (corticosteroids, IVIG and splenectomy) but also to thrombopoietin receptor agonists (TPO-RA) (n=5) displayed higher platelet size and alpha-granule secretion.

Furthermore, TPO-RA refractory patients’ sera desialylated normal platelets, but not plasma proteins. MACE assay revealed that unique positivity for anti-GPⅠbα antibodies was only detected in those patients classified as non-responders to conventional ITP therapies, including TPO-RA.

Table 1.

Table 2.

Summary/Conclusions: This study shows a significant higher platelet desialylation in ITP patients who are non-responders to conventional therapies, particularly if they are also refractory to TPO-RA. According to a previous study (1), these results seem to be associated to platelet activation mediated by anti-platelet specific antibodies.

SEQUENTIAL USE OF THROMBOPOIETIN RECEPTOR AGONISTS IN ADULT PRIMARY IMMUNE THROMBOCYTOPENIA PATIENTS: A RETROSPECTIVE COLLABORATIVE SURVEY FROM ITALIAN HEMATOLOGY CENTERS

M. Carpenedo1, S. Cantoni2*, M.G. Mazzucconi3, V. De Stefano4, V. Carrai5, M. Ruggeri6, G. Spechia7, N. Vianelli8, F. Pane9, U. Consoli10, F. Zaja11, A. Artoni12, L. Trentin13, F. Ferrara14, W. Barcellini15, D. Caramazza16, E. Ross17, E. Baldacci3, A. Ciminello4, C. Carbone17, R. Cairoli18

Background: ITP is a disorder characterized by thrombocytopenia resulting from both increased immune-mediated platelet clearance and inappropriate thrombopoietin production. TPO-RAs—romiplostim (R) and eltrombopag (E) — offer a new opportunity of treatment with high response rates. However, a small fraction of pts does not respond or loses response — i.e. desired platelet (plt) count achieved but not sustained over time - during long-term follow-up, which can not be resumed even if dosage is increased over time, or experience wide fluctuations in plt counts with either agent. Moreover, adverse events (AE) may necessitate treatment discontinuation. Finally, patient’s preference may be an important issue considering the different route and timing of administrations of the two agents and the alimentary restrictions needed for proper E absorption. Availability of two TPO-RAs for clinical use, with different molecular structure and site of binding within the TPO receptor, has prompted trials of TPO-RA switching with the aim of overcoming treatment limitations of either agent resulting in required overall response rates of approximately 80% in poor responders to 1st TPO-RA.

Aims: To present the results of a multicenter survey on TPO-RA switch policies and outcome.

Methods: Charts of ITP pts receiving TPO-RAs at 17 collaborating Haematology Centers were reviewed. Demographic and clinical data were collected in a dedicated case report form. Pts were grouped and analyzed based on the clinical setting prompting the switch (Table 1). The study was approved by the Hospital Review Board of each participating Center.

Table 1.
PT73
THROMBOEMBOLIC EVENT MANAGEMENT AND OUTCOMES IN PATIENTS WITH CHRONIC IMMUNE THROMBOCYTOPENIA (CITP) DURING TREATMENT WITH ELTROMBOPAG (EPAG): RESULTS FROM THE EXTEND STUDY

M.N. Saleh1,*, J.B. Bussel2, R.S. Wong3, B. Meddeb4, A. Salama5, O. Ocak6, S. Atkinson8, E. Quebe-Felah6, A. Kheifi
1Comprehensive Cancer Center, University of Alabama at Birmingham, Birmingham, 2Pediatric Hematology/Oncology, Weill Cornell Medicine, New York, United States, 3Sir YK Pao Centre for Cancer & Department of Medicine and Therapeutics, Chinese University of Hong Kong, 4Hôpital Aziza Othmana, Tunis, Tunisia, 5Charité-Universitätsmedizin, Berlin, Germany, 6Novartis Pharma AG, Basel, Switzerland, 7Hôpital Farhat Hached, Sousse, Tunisia

Background: EPAG is an oral thrombopoietin receptor agonist approved for the treatment of previously treated patients (pts; e.g. corticosteroids, immunoglobulins) with cITP aged ≥1 yr. The EXTEND study, a global, open-label, extension study of pts with cITP who received EPAG or placebo in prior EPAG studies, evaluated long-term safety and tolerability of EPAG. In EXTEND, 19 (6.3%) pts receiving EPAG experienced a total of 24 thromboembolic events (TEEs; Table 1). Of these, 10 pts received EPAG as initial therapy (n=10), which is similar to TEE incidence in cITP pts receiving romiplostim (Kuter et al. Br J Haematol 2013;161:41-43) and to one estimate in the general cITP population (Sarpattwari et al. Haematologica 2010;95:1167-75).

Aims: To describe management and outcomes of TEEs occurring during EPAG treatment in the EXTEND study.

Methods: Adult pts with cITP received EPAG starting at 50mg/day, with titration to 25–75mg per day or less as required, based on individual platelet count responses (target range 50–200×10⁹/L). Maintenance dosing continued after minimization of concomitant iTP medication and optimization of EPAG dosing. Pts enrolled on EPAG either for 2 yrs in countries where EPAG was commercially available, or for >2 yrs until EPAG became commercially available. The EXTEND primary objective included detection and documentation of AEs, including investigator-reported TEEs.

Results: 302 pts were enrolled and received ≥1 EPAG dose: 67% female; 38% non-white. Of these, 106 (18.4%) underwent TPO-RA switch. Table 1 summarizes outcome after switch. Overall 69/106 (65%) of pts achieved, regained or maintained response upon switching. Either one TPO-RA switch sequence was equally effective (p=0.882). Outcome was not associated with gender, age at 1st TPO-RA treatment, splenectomy status. However, number of lines of previous treatment and lower response rate were associated (p<0.002); response to 1st line of therapy yielded a 30% increase in the odds of being a non responder; a trend toward lower probability of response was observed in pts with longer lasting disease before 1st TPO-RA administration (p=0.066). Adverse events (AE; 16/106 pts) were generally mild and reversible upon discontinuation of either one TPO-RA. 1 pt who switched with thrombocytopenia (n=5) presented severe (standard anticoagulation) thrombotic events observed which did not recur after switching. AE were characteristic of older pts: each additional year increase in pts age determined a 5% increase in the odds of developing AE.

Summary/Conclusions: Approximately 20% of TPO-RA treated pts were felt by their attending physicians to potentially benefit from a switching strategy. Exposure to the 2nd TPO-RA was more effective in pts who had lost response to 1st TPO-RA (80% responders) compared to those who were non responders to 1st TPO-RA (49% responders, p=0.001). It could be speculated that lack of response to either one of the two available TPO-RA identifies a subgroup of pts who may benefit from a switching strategy. Pts switched for non-efficacy reasons are more likely to maintain a response upon switch (p=0.030). The so far unexplained and unprecedented phenomenon of wide platelet fluctuation appears to be linked to the removal of the spleen, the physiological platelet reservoir organ.
patients with severe bleeding. At the end of follow-up, the estimated 10-year cumulative rate of no remission among patients with severe bleeding was higher than that among patients without severe bleeding (P=0.017, RR=1.608, 95% CI, 1.052-2.456). The estimated 10-year cause-specific mortality related to fatal bleeding in patients with severe bleeding was higher than that in patients without severe bleeding (P=0.001, RR=9.886, 95% CI, 1.806-54.098). The estimated 10-year mortality among ICH patients was higher than among severe (non-ICH) patients (P<0.009, RR=5.543, 95% CI, 1.317-15.668).

Summary/Conclusions: Platelet count <10×109/L, female patients, complication of pulmonary disease, gum or oral mucosal bleeding and epistaxis are significant predictive factors for severe bleeding in the elderly. Severe bleeding in elderly ITP was associated with more failure of response to treatment, increased long-term risk of no remission and mortality related to fatal bleeding.

ATORVASTATIN IMPROVE THE PROGNOSIS OF ADULT PATIENTS WITH CORTICOSTEROID-RESISTANT IMMUNE THROMBOCYTOPENIA VIA ENHANCING BONE MARROW ENDOTHELIAL CELL FUNCTION

Y. Kong1, X.-N. Cao1, X.-H. Zhang1, M.-M. Shi12, Y.-Y. Lai1, Y.-Q. Sun1, Y. Wang1, L.-P. Xu1, Y.-J. Chang1, X.-J. Huang12

1Peking University People’s Hospital, Peking University Institute of Hematology, 2Peking-Tsinghua Center for Life Sciences, Academy for Advanced Interdisciplinary Studies, Peking University, Beijing, China

Background: Immune thrombocytopenia (ITP) is generally considered to be an autoimmune disorder characterized by increased peripheral platelet destruction and reduced platelet production. Corticosteroids represent the standard first-line therapy achieving responses in around 50-80% of patients. However, for those corticosteroid-resistant ITP patients, who exhibit either no response (NR) to corticosteroids or corticosteroid-dependent, the pathogenesis remains poorly understood and the management is challenging. Emerging evidence from mouse studies has suggested that the cross-talk between megakaryocytes (MKs) and endothelial progenitor cells (EPCs) in the bone marrow (BM) microenvironment regulates MKs maturation and thrombopoiesis. We recently reported that the impaired BM EPCs, which could be quantitatively and functionally improved by atorvastatin in vitro, induced the occurrence of poor graft function following allo-transplantation (Blood, 2016, 128:2988-2999). However, little is known about the functional role of BM EPCs and how to improve impaired BM EPCs in patients with corticosteroid-resistant ITP.

Aims: To determine whether quantitative and/or functional abnormalities of BM EPCs are involved in the occurrence of corticosteroid-resistant ITP. Moreover, to investigate the effects of atorvastatin and N-Acetyl-L-cysteine (NAC, a ROS scavenger) on the number and function of cultured BM EPCs derived from patients with corticosteroid-resistant ITP and its underlying molecular mechanisms. Finally, to evaluate the efficacy and safety of atorvastatin and NAC to adult patients with corticosteroid-resistant ITP.

Methods: Twenty-three patients with corticosteroid-resistant ITP, 30 patients with newly diagnosed ITP and 17 healthy donors (age 18-55) were enrolled from 2016 to 2017 at Peking University Institute of Hematology. BM EPCs were cultured as previously reported. Atorvastatin and NAC were administrated to the 5-day cultivated BM EPCs in corticosteroid-resistant ITP patients until tested on day 7. The number and function of BM EPCs were evaluated pre- and post-treatment by cell counting, DiI-Ac-LDL and FITC-lectin-UEA-1 double staining, migration, cell proliferation, tube formation, levels of reactive Oxygen Species (ROS) and apoptosis. Proteins expressions for p38, ERK, JNK, Akt were measured by flow cytometry and western blot. Subsequently, a single-center pilot study was performed to evaluate the efficacy and safety of atorvastatin and/or NAC in corticosteroid-resistant ITP patients. The primary end points were complete response (CR), response (R), and overall response (OR). Secondary end points were time to response (TTR) and adverse events.

Results: Human bone marrow EPCs were demonstrated as the spindle shape and the similar expression of CD34, VEGFR2 and CD133 at day 7 of cultivation among all the enrolled three cohorts of subjects. Increased and dysfunctional BM EPCs, which were characterized by impaired proliferation, migration, angiogenesis, and higher levels of ROS and apoptosis, were revealed in corticosteroid-resistant ITP patients compared to those in newly diagnosed ITP. Activation of p-p38 was detected in BM EPCs from corticosteroid-resistant ITP patients. Furthermore, the number and function of BM EPCs derived from corticosteroid-resistant ITP patients were enhanced by atorvastatin or NAC treatment in vitro through down-regulation of the p38 mitogen-activated protein kinase (MAPK) pathway. In the single-center pilot study, a total of 12 corticosteroid-resistant ITP patients were recruited to receive either the combination of atorvastatin and NAC or alone. Adverse events of CR, R and OR were recorded (3/12), 41.7% (5/12) and 66.7% (8/12), respectively. In patients who achieved CR and R, the median (range) TTR was 24 days (7-51 days), with no apparent adverse events.

Summary/Conclusions: The number and the function of BM EPCs were improved by atorvastatin treatment with or without NAC in vitro and in vivo quantitatively and functionally improved BM EPCs derived from corticosteroid-resistant ITP patients through down-regulation of the p38 MAPK pathway. Although the sample size of clinical study is small, with a relatively short follow-up period by now, our data suggest that atorvastatin and NAC are effective and safe in the management of corticosteroid-resistant ITP patients. Therefore, further prospective multicenter randomized clinical trials with larger sample size are needed in the future.

P726

PLATELET DESIALYLATION AND A NOVEL MECHANISM AND A THERAPEUTIC TARGET IN THROMBOCYTOPENIA DURING SEPSIS: AN OPEN-LABEL, MULTICENTER, RANDOMIZED CONTROLLED TRIAL

X. Li1, M.-F. Li2, X.-L. Li3, S.-Y. Geng1, L. Huang4, M. Hou1, L.-Y. Liu2, J. Peng1

1Department of Hematology, Qilu Hospital, Shandong University, Jinan, China, Jinan, 2Yantai Yuhuangding Hospital Affiliated to Qingdao University, Yantai, China, 3Infectious Disease Hospital of Yantai, Yantai, China, 4Yantaihan Hospital of Yantai, Yantai, China, Yantai, China

Background: Sepsis is a systemic, deleterious host response to infection leading to severe sepsis, and possibly septic shock as defined by the Surviving Sepsis Campaign guidelines. Thrombocytopenia is a common finding in sepsis. Studies in murine models suggested that platelet desialylation was an important mechanism of thrombocytopenia during sepsis. Desialylation-induced platelet removal could possibly be circumvented by adding sialidase inhibitors during sepsis. Oseltamivir, also known as Tamiflu, is a viral sialidase inhibitor that prevents the release of progeny virions. Several studies suggest the feasibility that oseltamivir can be used for the treatment of infection-associated thrombocytopenia.

Aims: To determine whether thrombocytopenia is associated with increased platelet desialylation in septic patients, and whether oseltamivir is an effective treatment to increase platelet counts in severe sepsis.

Methods: We first performed a prospective, multicenter, observational study that enrolled septic patients with or without thrombocytopenia to determine the association between platelet desialylation and thrombocytopenia in patients with sepsis. Next, we conducted an open-label, randomized controlled trial in which patients who had severe sepsis with thrombocytopenia (platelet counts ≤50×109/L) were randomly assigned to receive antimicrobial therapy alone (control group) or antimicrobial therapy plus oseltamivir (oseltamivir group). The study flowchart is shown in Fig. 1. Both groups received appropriate antimicrobial agents and standard medical support based on the guidelines issued by the Surviving Sepsis Campaign. The oseltamivir group additionally received 5 full days of oseltamivir therapy. The oseltamivir was administered orally or through a feeding tube at a dose of 75mg once every 12 hours. Time from randomization to the administration of oseltamivir was less than 24 hours. The antimicrobial agents were continuously administered until 3 days after the resolution of the physiological abnormalities related to the systemic inflammatory response syndrome (SIRS). The primary outcomes were platelet desialylation level at study entry, and overall platelet response rate within 14 days post-randomization. Secondary outcomes included platelet recovery time, the occurrence of bleeding events, and the amount of platelets transfused within 14 days post-randomization. The percentages of platelets positive for Ricinus communis agglutinin I (RCA-I), Erythrina cristagalli lectin (ECL) or Scurvyce Triticum vulgare lectin (sWGA) analyzed by flow cytometry represented the levels of platelet desialylation. Platelet response was defined as platelet counts returning to or above 100×109/L. Platelet recovery time was calculated as the date of randomization to the administration of oseltamivir or platelet counts were >100×109/L. Written informed consents were obtained from the study participants prior to inclusion in the study.
Results: The platelet desialylation levels increased significantly in the 127 septic patients with thrombocytopenia compared to the 134 patients without thrombocytopenia. A platelet response was achieved in 45 of the 54 patients in the oseltamivir group (83.3%) compared with 34 of the 52 patients in the control group (65.4%; P=0.045). The median platelet recovery time was 5 days (interquartile range 4-6) in the oseltamivir group compared with 7 days (interquartile range 5-10) in the control group (P=0.003). The amount of platelets transfused decreased significantly in the oseltamivir group compared to the control group (P=0.044). The multivariate analysis by Cox proportional hazards models showed that the Sequential Organ Failure Assessment (SOFA) score and platelet recovery time were independent indicators of oseltamivir therapy.

Summary/Conclusions: Thrombocytopenia was associated with increased platelet desialylation in septic patients. The addition of oseltamivir could significantly increase the platelet response rate, shorten platelet recovery time and reduce platelet transfusion. Chinese Clinical Trial Registry, ChiCTR-IPR-16008542.

SAFETY AND EFFICACY OF LONG-TERM OPEN-LABEL DOsing OF SUBCUTANEOUS (SC) ROMIPLOSTIM IN CHILDREN WITH IMMUNE THROMBOCYTOPENIA (ITP)
J. Bussel1,*, M. Tarantino2, V. Blanchette3, A. Raj4, J. Despotovic5, D. Beam6, J. Roy7, X. Wang8, B. Mehta8, M. Eisen8
1Weill Cornell Medicine, New York, 2The Bleeding and Clotting Disorders Institute, Peoria, United States, 3Hospital for Sick Children, Toronto, Canada, 4Pediatric Blood and Cancer Disorders Clinic, Houston, 5Texas Children’s Hematology Center, Houston, 6Cook Children’s Medical Center, Fort Worth, United States, 7Children’s Health Queensland & Pathology Queensland, Saint Lucia QLD, Australia, 8Amgen Inc., Thousand Oaks, United States

Background: Children with ITP for ≥6 months who completed a romiplostim phase 1/2 or phase 3 parent study could enroll in this open label long term extension study

Aims: To evaluate the safety and efficacy of long-term romiplostim in children with ITP.

Methods: Patients enrolled at 28 sites in the US, Canada, Spain, and Australia. All patients received SC romiplostim once weekly. The initial dose was the final dose from the parent study or 1 µg/kg for patients previously receiving placebo; dose was then adjusted from 1-10 µg/kg to target platelet counts of 50−200×10^9/L. Incidence of adverse events (AEs) was the primary endpoint.

Results: As of 24 Feb 2016, 66 patients entered this study; 65 received romiplostim for up to 6.2 years. At baseline, median (min–max) age was 11 (3–18) years; 56% were female; 61% were white, 14% African American, 14% Hispanic/Latino, 9% Asian, and 3% other; 9.1% had prior splenectomy. Median (min–max) baseline platelet count was 27.5 (2–458)×10^9/L. Median (min–max) treatment duration was 100 (5–321) weeks. Median (min–max) average weekly romiplostim dose was 4.8 (0.1–10.0) µg/kg, which included escalation to a stable dose. After ~week 200 (n ≤8 patients), the median dose was observed to fluctuate. All 65 patients received their doses per protocol >90% of the time; 18 patients missed ≥1 dose due to noncompliance for a total of 41 times. Reasons for discontinuing treatment (n=8), required other therapy (n=4), noncompliance (n=3), administrative decision (n=3), per protocol (n=1), and AE (n=2) (asthenia, headache, dehydration, and vomiting in one patient and anxiety in the other, per investigator, none of the AEs were treatment-related); 43 (65%) patients continued in the study. Fifty-two serious AEs occurred in 17 patients, 3 deemed treatment-related (anemia, epistaxis, and thrombocytopenia). Bleeding AEs occurred in 56 patients; 5 deemed treatment-related (gingival bleeding, petechiae, injection site bruising, injection site hematoma, and epistaxis). No thrombotic events were reported. There were no peripheral blood abnormalities warranting a bone marrow examination. No patients had anti-TPO neutralizing antibodies. From week 2 on, median platelet counts remained >50×10^9/L; platelet counts were >100×10^9/L at most timepoints, despite an observed decrease in the median dose from 4-5 µg/kg to 2-3 µg/kg around week 160 (Figure). Nearly all (94%, 61/65) patients had a platelet response (median platelet counts for a month ≥50×10^9/L). Nine (14%) patients (5 boys and 4 girls, none with prior splenectomy) entered remission (Table), defined here as platelet counts ≥50×10^9/L for 24 weeks with no ITP treatments. Twenty-three (35%) patients received rescue medications.

Summary/Conclusions: Over 6 years of data from this ongoing open-label extension study of romiplostim in children with ITP show that >90% of children achieved a platelet response with romiplostim. The safety profile was overall tolerable, similar to that in past studies. Some children (9/66) with longstanding ITP entered remission after receiving romiplostim.
Quality of life, palliative care, ethics and health economics

IMPACT OF VENETCLAX ON THE QUALITY OF LIFE OF CLL PATIENTS RELAPSED/REFRACTORY TO B-CELL RECEPTOR (BCR) SIGNALING PATHWAY INHIBITOR TREATMENT

W. Wierda1, K. Saji1, J. Pullum2, L. Nae2, R. Kamalakar2, J. Gdovin2, R. Humerrickhouse2, M. Verdugo2
1The University of Texas MD Anderson Cancer Center, Houston, 2AbbVie Inc, North Chicago, United States

Background: The prognosis for patients with CLL after B-Cell Receptor inhibitor (BCR) failure is very poor. Patients with R/R CLL who discontinue and/or progress on BCRi treatment tend to have poor clinical outcomes. Venetoclax (VEN) is an oral BCL-2 inhibitor that has demonstrated deep and durable responses in relapsed/refractory (R/R) CLL patients.

Aims: To assess whether VEN has an impact on health related quality of life (HRQoL) among CLL patients R/R to BCRi treatment and receiving VEN monotherapy.

Methods: The study enrolled patients with CLL who had previously received treatment with ibritumomab and idelalisib, have relapsed on treatment, or experienced progression after discontinuation of either agent. Patients are to receive VEN monotherapy for up to two years, or until discontinuation due to disease progression, unacceptable toxicity, or any other reason. Patient-reported HRQoL measures included the EORTC QLQ-C30 and EORTC QLQ-CLL16, which were assessed at Baseline (BL), Week 24, and every 12 weeks thereafter. Mean change from BL to each assessment through Week 48 are reported here. Clinical relevance was based on minimum important difference (MID) of values from BL to each assessment. A change of 5-10 points is considered a “small” change on the EORTC-QLQ-C30. The lower bound of 5 points was used for MID acceptance on both measures.

Results: Clinical improvements from BL were observed early and were sustained through week 48 in VEN treated patients in the EORTC-QLQ-C30 global health status and the role, social, and emotional functioning scales. Furthermore, early and sustained improvements in fatigue through week 48 were seen in both EORTC-QLQ-C30 and EORTC-QLQ-CLL16 (Table 1).

Table 1.

Summary/Conclusions: This interim analysis provides preliminary evidence that demonstrates CLL patients R/R to BCR inhibitors receiving VEN monotherapy experienced improvement in several key aspects of functioning and HRQoL. These results may be important to consider when making therapeutic choices in R/R CLL following relapse or progression on BCRi inhibitors.

PT29
THE ROLE OF PSYCHOLOGICAL VARIABLES FOR TYROSINE KINASE INHIBITORS (TKI) DISCONTINUATION IN CHRONIC MYELOID LEUKAEMIA (CML) PATIENTS: IMPLICATION FOR MEDICAL DECISION MAKING PRACTICE

S. Brait1, J. Cortelezz1, C. Cutica1, E. Orlandi1, E. Chiara1, E. Bucei1, A. Iurlo1, G. Pravettoni1
1Department of Oncology and Haematology, University of Milan, 2Hematology-BMT Unit, IRCCS Ca’ Granda Policlinic Foundation Hospital, Milan, 3Department of Oncology Haematology, IRCCS Policlinic San Matteo Foundation Hospital, Pavia, Italy

Background: Treatment-free remission (TFR) is an emerging goal for CML patients (pts) that reach a sustained deep molecular response (DMR), as it can reduce the risk of long-term toxicities that impair quality of life, and mitigate the costs associated with long-term TKI therapy. Therapy discontinuation may represent a great challenge for patients and different factors (not only clinical) may play a role in medical decision, such as psychological and emotional variables. In this respect, it is essential to consider pts’ concerns and preferences regarding the discontinuation option.

Aims: This study was aimed at investigating psychological (emotional and cognitive) and clinical factors related with the attitude to opt for discontinuation of therapy in CML pts.

Methods: This is an observational, prospective, no-drug related study conducted in 3 Italian centers with large experience in CML treatment. A detailed battery of questionnaires focusing on health behaviour, risk taking and personality was administered.

Results: One hundred and twenty pts were enrolled (56% males; mean age=50, SD=1.2). Median duration of the disease was 8 years (range 1-39y). 62/120 pts were receiving Imatinib first line. The idea of stopping TKI is appealing in 91.5% of pts (31% of them expressed a high probability of response upon restarting a TKI). Pts are more likely to stop their TKI if the risk of relapse is no more than 30% (% Mean=33.62; SD=33.46). Main worries related with the choice to stop TKI are fear of possible disease recurrence, (60.5%), fear of drug resistance if the disease relapses (44.5%) and fear to disappoint family or friends (28.9%). Older pts (>40 years) are more concerned about relapse and subsequent lack of response than younger (x²=9.65, p=0.02). Finally, pts with higher passive risk taking attitude (who are more redundant and undecided in everyday-life decisions) seemed to be more afraid to lose disease control in CML. ANOVA showed a significant difference between the two groups (F=5.54; p=0.02).

Summary/Conclusions: Many studies have confirmed the feasibility and safety of stopping TKI therapy in selected pts, with the potential to drastically modify clinical practice in CML management in the next future. TKI discontinuation appears appealing and challenging at the same time for many CML pts. This study, for the first time, analyses how and when pts would consider this option including implications for health care providers in clinical practice, using both a clinical and psycho-cognitive perspective.

PT30
BUDGET IMPACT ANALYSIS OF BIOSIMILAR RITUXIMAB (CT-P10) FOR THE TREATMENT OF CHRONIC LYMPHOCYTIC LEUKAEMIA IN THE 28 EU MEMBER STATES

F. Rencz1,2,*, L. Gulácsi1,2, P. Baji1,2, M. Pénét1,2, V. Brodszky1,2
1Department of Health Economics, Corvinus University of Budapest, 2HTA Consulting Budapest, Budapest, Hungary

Background: In December 2016, the European Medicines Agency’s Committee for Medicinal Products for Human Use has recommended granting marketing authorization to biosimilar rituximab (CT-P10) in all indications of the reference product, including chronic lymphocytic leukaemia (CLL). Compared to the originator rituximab, CT-P10 is expected to result in a significant price reduction, which may encourage offering a more affordable treatment option for CLL patients across Europe.

Aims: To assess the budget impact of the introduction of CT-P10 into the treatment of CLL in the 28 EU member states. Moreover, we provide an estimation for the number of additional CLL patients that can be treated with CT-P10 from the cost savings.

Methods: A budget impact analysis was performed to evaluate the one-year cost outcomes under two scenarios with and without the availability of CT-P10. The budget impact was calculated as the difference in costs between the two scenarios. For the major European markets, five-year cost savings were also estimated. Market uptake of CT-P10 was assumed to be 30%. A third party payer’s perspective was adopted, and only drug costs were considered. Based on expert opinion, it was assumed that when CT-P10 is entering the market it will be at 50-70% of the official list price of originator rituximab in each country. Costs of administration and monitoring were not incorporated in the calculations, as it is not expected that these are equal for the reference product and CT-P10. The initial number of patients treated with rituximab was estimated from IMS sales data on total annual consumption of originator rituximab in 2016. Other model parameters such as patients’ average body surface area and treatment rate of rituximab among CLL patients, were derived from the published literature. One-way sensitivity analysis was undertaken to test the robustness of model assumptions.

Results: Over a one year time horizon, the cumulative budget impact of adopting CT-P10 is estimated to be €17.80 million in the 28 EU member states (30% discount in drug prices compared to the originator rituximab). Countries responsible for the majority of the cost savings are Germany (€4.06 million), Italy (€3.15 million), France (€2.41 million), Spain (€1.50 million), the Netherlands (€0.90 million), Finland (€0.49 million) and Sweden (€0.43 million). If the cost savings were used to treat additional CLL patients with CT-P10, a total of 1,624 patients could be treated annually throughout Europe. The potential cost savings are in a direct correlation with the price and market uptake of CT-P10. Applying a 40% and 50% discount in drug prices compared to the originator rituximab, cost savings are projected to €23.73 and €29.67 million, from which further
AN INVESTIGATION INTO THE NEEDS AND PRIORITIES OF PATIENTS WITH MULTIPLE MYELOMA DURING REMISSION—IMPLICATIONS FOR RE-DESIGNING PATIENT-CENTRED HEALTHCARE SYSTEMS

Aims: To explore patient needs during stable remission from MM and evaluate acceptability of alternative monitoring methods. Methods: Patients with stable MM in a treatment-free interval selected from outpatient clinics at a tertiary centre completed a survey which explored the acceptability of various methods of remote monitoring. Subsequently semi-structured interviews were conducted by an independent researcher to investigate factors influencing this preference. Interviews were carried out until saturation of themes, transcribed verbatim and thematic analysis was performed using open coding by a doctor, physiotherapist and psychologist.

Results: 78 patients were surveyed; the most acceptable alternative was a telephone clinic (with doctor 77%, nurse 69%). 19 interviews were conducted exploring suitability of a nurse-led telephone consultation (TC) replacing clinic face to face (FTF) consultations with a doctor. Median age was 61 years (range 46-76), and 9 were male. 18 patients were in 1st remission; 16 had most recently received high dose therapy and autograft, 3 had post autograft consolidation. The centre was not the local hospital for 18 patients interviewed. The majority were accepting of TC as an alternative to FTF clinics due to the burden of travel, associated cost and clinic waiting times. These affected patients’ physical and psychological well-being, with TC perceived as less burdensome. Patients acknowledged reduced needs during remission compared to treatment phase and felt TC would benefit redistribution of consultant time for patients on active therapy. Some suggested this service change would represent a step forward for healthcare resourcing rather than them personally. Interpretation of blood results by clinicians was regarded as central to monitoring disease, and for some who were unaware of clinical symptoms, the only way a relapse would be detected. General preference was for bloods to be done locally, leading to confidence in monitoring. Results for patients using TC were understood how to monitor their own MM, hence valued the knowledge of their medical team. Doctors were perceived to have more expertise than nurses and this influenced preferences regarding who undertook TC. As a result, patients sought reassurance they could see a doctor if they had any concerns after TC with a nurse. Patients valued contacts under the centre where they were treated due to prior positive experience and the importance of being seen at a tertiary centre renowned for its expertise in MM. This influenced acceptability of TC as long as they remained under the centre’s care with preference for continuity of staff involved. Whilst TC was acceptable for patients in remission, some were concerned about how relapse would be managed and expressed preference for FTF when being told they had relapsed.

Summary/Conclusions: Nurse led TCs are an acceptable alternative to FTF consultations for monitoring patients in remission from MM. Design of healthcare systems incorporating TCs need to have robust systems for accessing blood test results, for managing relapse, ready access to doctors and reassurance about the competence and knowledge of practitioners involved.

THE THERAPEUTIC UTILITY OF A SYSTEMATIC PROTOCOL FOR GERIATRIC ASSESSMENT IN ONCOHEMATOLOGIC PATIENTS

Aims: To evaluate the utility of the comprehensive geriatric assessment (CGA) in patients with hematologic malignancies on the initial therapeutic decision making. Determine frailty prevalence and short- mid term prognostic impact using a screening tool for its identification.

Methods: Patients diagnosed with hematologic malignancies were followed prospectively. Patients age 70 and over were referred to hematological nursing consultation. Geriatric screening tool was used to identify frailty risk. Patients with hematologic malignancies on the initial therapeutic decision making.

Results: We have included 32 patients in the last 9 months, with an average age of 81 (71-89) years. 56% of the sample was female. The main hematologic malignancy referred was high grade non-Hodgkin lymphoma (59%). At the time of the evaluation, 87% had CD-19, 7% had CD-34, and 5% had MIB1, score < 30. The social, functional, and mental profiles are shown in Table 1. According to polypathy and comorbidities, data are shown in Table 2. The distribution of patients by frailty scales, are described in Table 3. 56% of the patients were classified as robust, 35% fragile and the rest with poor prognosis. After the evaluation we recommended nutritional measures, control of the polypathy and physical exercise. Of the included patients, 22 had been reviewed at 6 months staying alive 95%. 24% required hospitalization after the initial assessment and 13% went to the emergency department.
RADIATION EXPOSURE FROM CT IMAGING AND CHILDHOOD LEUKEMIA: A NATIONWIDE CASE-CONTROL STUDY

A. Nikkilä¹,², J. Raitanen³, O. Lohi⁴, A. Auvinen²,4,5
¹Faculty of Medicine and Biosciences, ²Faculty of Social Sciences, University of Tampere, ³UKK Institute for Health Promotion, ⁴Tampere Center for Child Health Research, Tampere University Hospital and University of Tampere, Tampere, ⁵STUK - Radiation and Nuclear Safety Authority, Helsinki, Finland

Background: Pediatric CT imaging offers significant benefits in clinical practice. However, children are more sensitive to carcinogenic effects of ionizing radiation than adults and red bone marrow is especially radiosensitive tissue type. The risk estimates of low doses of ionizing radiation are mainly based on extrapolated results of studies done with substantially higher radiation doses and there exists a need to assess the risks of low doses with a more direct approach.

Aims: We assessed the leukemia risk in children after computed tomographic imaging studies with high-quality Finnish register data and data from hospital databases.

Methods: We used nationwide, register-based case-control study design to investigate the role of CT imaging in the etiology of childhood leukemia. We identified all childhood (0-15 years) leukemia cases from 1990 to 2011 (N=1093) in Finland and randomly selected thrice as many controls (N=3279) from the Population Registry, individually matched by gender and year of birth. The cases were 81% (N=885) acute lymphoblastic leukemias and 13% (N=142) acute myeloid leukemias. We collected data on all pediatric CT scans from 1975–2011 from the databases of all five university hospitals in Finland and randomly selected thrice as many controls (N=3279) from the Population Registry, individually matched by gender and year of birth. The aim of this analysis was to compare HRU with ixazomib-Rd vs placebo-Rd, incorporating all non-protocol additional medical care encounters such as inpatient and outpatient admissions and their duration, as well as time lost from work or other activities by pts and their caregivers.

Results: Overall, 13 cases (1.2%) and nine controls (0.3%) had a record indicating at least one CT examination. Of the relevant CT scans, 50% were performed on the head region and 41.3% the thorax region. The median age at CT scan was 8.12 years (7.46 years for cases and 10.9 years for controls). In a conditional logistic regression analysis adjusted for birth weight, a significantly increased leukemia risk (OR=4.75, 95% CI 1.55, 14.5) was found for any CT examination (one or more) at least two years prior to leukemia diagnosis. When comparing one CT examination and two or more CT examinations with no examinations the ORs were respectively 2.78 (95% CI 0.73, 10.5) and 16.9 (95% CI 1.81, 150).

Summary/Conclusions: Our preliminary analyses we observed a substantial increase in childhood leukemia risk related to pediatric CT scans. The risk estimates are materially higher than in two earlier studies and need to be interpreted with caution. We will seek to estimate radiation doses to the red bone marrow, based on limited data available on CT examinations (body part and examination type).

References
**Results:** Overall, 152 (42%) pts on the ixazomib-Rd arm had 316 hospitalization events, compared to 156 (43%) pts (335 events) in the placebo-Rd arm. Exposure-adjusted hospitalization rates (0.530 and 0.564 per pt-year [ppy], respectively) and mean length of stay (10 and 18.8 days) were similar between the ixazomib-Rd and placebo-Rd arms (Table 1). Rates of outpatient visits were also similar between arms; 217 (60%) pts on the ixazomib-Rd arm had 197 (median 4) compared to 198 (55%) pts and 194 visits (median 5) on the placebo-Rd arm. Exposure-adjusted outpatient visit rates were 3.305 and 3.355 ppy, respectively (Table 1). On the ixazomib-Rd arm, 46 (13%) pts missed a total of 527 (median 7) days of work or other activity, compared to 51 (14%) pts and 580 (median 8) days on the placebo-Rd arm. Similarly, 16 (4%) pts caregivers missed 128 (median 5) days of work or other activity on the ixazomib-Rd arm, compared to 24 (7%) pts’ caregivers and 110 (median 4) days on the placebo-Rd arm.

**Summary/Conclusions:** The ixazomib-Rd triplet regimen did not add to the HRU burden compared to the placebo-Rd doublet, while prolonging PFS. This result was consistent with the limited additional toxicity burden and the reported lack of an adverse impact on QoL with ixazomib-Rd. In contrast to findings reported for injected agents (Armoiry et al, J Clin Pharm Ther 2011; Gaultney et al, J Clin Pharm Ther 2013; Baz et al, Support Care Cancer 2015), this all-oral triplet regimen did not increase time lost from work, caregiver burden, or the number of inpatient/outpatient visits.

**MANAGEMENT, ECONOMIC AND SOCIAL IMPACT OF SUB-CUTANEOUS RITUXIMAB ADMINISTRATION IN LYMPHOPROLIFERATIVE MALIGNANCIES**

V. Tomarchio1, M.A. Surano2, M.A. Tafuro1,2, M. Becilli3, C. Sarlo3, P. Berti3, G. Tafuro1, G. Boletti4, D. Iolele5, G. Tassili6, G. Annibali1

1UOC Ematologia Trapianto di Cellule Staminali, University Campus BioMedico, rome, 2Area di Infermieristica, 3UOC Ematologia Trapianto di Cellule Staminali, Università Campus BioMedico, 4Area di Controllo e Gestione, 5Area dei Sistemi Informatici, 6Area Farmacia, Policlinico Universitario Campus Bio medico, Roma, Italy

**Background:** Lymphoproliferative disorders (LD) represent a major burden of hematologic malignancies generally treated and followed in Hematological Day Hospital (HDH). Rituximab (R-Cell Lymphoma, DLBCL and Follicular Lymphoma (FL) are among the most frequent LD treated with chemo-immunotherapies. These therapies are time consuming and costing and may affect the Quality of Life (QoL) of these patients because of their prolonged stay in DH.

**Aims:** To evaluate, in patients with DLBCL and FL, the economic and social impact of subcutaneous rituximab administration compared to the intravenous formulation. During one week we evaluate in 40 patients the time of intravenous and subcutaneous administration, the type of treatment (rituximab combined or subsequent to chemotherapy, or in monotherapy) and the time required by the pharmacy to prepare each formulation. Moreover, we collected and analyzed data about patients’ time expenditure in DH until discharge. Collected data have been categorized as follows: time and human resource employment; drug waste; safety for patient. In order to measure the interference with daily activities. Overall, 98% of interviewed patients preferred subcutaneous formulation, because less scared by this formulation and because of the lower waste of time. Among the 40 interviewed caregivers 68% were workers. They considered advantageous the subcutaneous formulation because of the lower waste of time (90%) and the reduced number of workdays lost (80% of workers). With the subcutaneous formulation, we observed a reduction of 38% (equal to 17.5 hours) of time spent at hospital per cycle. However, nurses needed 23% lesser time to handle a patient per cycle (from 144 minutes to 111 minutes), earning 21 minutes/patient per cycle. Furthermore, pharmacy spent 53% lesser time for drug preparation (from 40 minutes to 19 minutes), earning 21 minutes/patient per cycle. Finally, we observed a reduction of clinical risk. As for the cost, using subcutaneous formulation, we saved €254.25 for each dose, with a final saving of €61.021 in a year. Considering that patients who underwent subcutaneous administration of rituximab did not require DH admission, we saved additional for €24,000 for 2016, and caregivers saved 112 work days.

**Summary/Conclusions:** Our investigation shows that subcutaneous formulation of rituximab requires a lower psychological effort for both patients and caregivers because of a reduced time of administration. In addition, it reduces healthcare professionals and pharmacist’s workload, ensures a major safety for patients, and allows an optimized use of DH armchairs. This brings to an increased satisfaction of patients and caregivers. Moreover, the costs analysis demonstrates a significant spending reduction improving planning of therapy sessions and organization.

**EFFECT OF IMPROVEMENTS OF SURVIVAL, POPULATION AGING AND IMWG ‘14 CRITERIA ON INCIDENCE AND PREVALENCE OF MULTIPLE MYELOMA**

V. Martinez-Robles1,2, B. Ballina1, S. Cerda1, N. de las Heras1, M. Fuertes1, L. Villalobos1, J.A. Rodriguez-Garcia1, E. Fernando1

1Hematologia, Complejo Asistencial Universitario de León, LEON, Spain

**Background:** There are some variables that can modify Multiple Myeloma incidence of New Diagnosed (NDMM) and prevalence over the time: Past decade shows a new demographic data in our society: the increment of expectancy of life and an excellent performance status. In the last years we have assisted to an amazing improvement in the management and expectancy of life of Multiple Myeloma (MM) patients. Recent changes in criteria recommendation by IMWG ‘14 to begin treatment in NDMM patients can increment its incidence. New expensive but very effective and well tolerated anti myeloma (antiMM) agents are in the center of attention of Hematologic and Public Healthcare Systems. There are data of improvement of survival that can increment of prevalence.

**Aims:** We have analysed our data base and calculate incidence by sex, age and three 5-years periods of time at diagnosis and obtain tendencies to get ready for next decade of ageing people with best anti myeloma agents. We have analysed prevalence of MM patients on last 7 years with cutoff date on 1st of November (2010 to 2016).

**Methods:** We retrospectively analysed the incidence of patients with new diagnostic of Multiple Myeloma (NDMM) from 1998 to 2012. (Fig.1). Then we divide the cohort in several groups: sex and age at diagnosis (3 groups: <65, 66-75 and >75) in four 5-year (quinquennium) period of time (1998-2002, 2003-07, 2008-12, 2013-NOV2016). (Fig. 2). We have calculated the incidence per 100000 inhab/year using census data of our Local Registry of Tumours of our Public Health Area. Characteristics of patients: n = 346. M/F: 206/140. Median age at diagnosis: 74 years (Range: 39-100).

**Results:** A) INCIDENCE RATES (see Table). In the past IMW (Roma-14#PO197) we reported incidence rates form 1998 to 2012. We observed a constant increase of Annual Average of incidence from 4.57 cases/100000 inhabitants/ year from the 1st period to 6.15 in the last. Adjusted by Age Incidence increase from 14 to 18.5 cases in the 065 group. From 2013 to Nov-2016 global and adjusted by age incidence remains similar to last years data with 80 new cases in the 4 year-period (5.9 cases for global population and 17.2 cases for over65 population). After IMWG ‘14 criteria to begin treatment in NDMM the incidence was similar to the last 7 years (2008-12 period) incidence with 37 NDMM cases (25 O65y group).

**B) PREVALENCE RATES (PreVR).**

- 2012. 77 pts alive. PreVR: 22.2 /100000 inhabit;
- 2014. 84 pts alive. PreVR: 24.4/100000 inhabit;
- 2016. 103 pts alive. PreVR: 30.3 /100000 inhabit.

**Table 1.**
HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR ISOLATED EXTRAMEDULLARY RELAPSE OF ACUTE LYMPHOBLASTIC LEUKEMIA IN CHILDREN

M. Gabelli1,2, C. Messina1, M. Zecca2, A.M. Rovelli1,2, A. Prete1,2, M. Ripaldi9, A.P. Iori10, G. Basso1, F. Porta1, M. Caniglia12, P. Di Bartolomeo13, P. D’Angelo14, A. Bertaina15, F. Locatelli15

Background: Although most children affected by Acute Lymphoblastic Leukemia (ALL) are cured with current protocols, relapses still occur in the bone marrow as well in extramedullary sites, mainly the central nervous system (CNS) and the testis.

Aims: The aim of this study was to evaluate the outcomes of patients treated with hematopoietic stem cell transplantation (HSCT) for isolated extramedullary relapse (EMR) in the context of a real-world setting, with a special focus on the role of HSCT in the treatment of extramedullary relapses.

Results: Of the 281 patients (203 male, 78 female) 167 presented relapse confined to CNS, 73 to testis, 14 to mediastinum, 11 to CNS + other sites and 18 to other organs. Thirty one percent of children experienced a late relapse, 34.5% an early relapse, 31% a very early relapse, for 3.5% the time of relapse is not known. Ninety-seven patients underwent autologous HSCT (Auto HSCT) or haploidentical HSCT (Haplo HSCT).

Summary/Conclusions: Overall survival at 10 years was 50% that were busulfan- (64%), fludarabine- (29%) or total body irradiation-based (82%) that were busulfan- (64%), fludarabine- (29%) or total body irradiation-based (82%) and 5-year EFS was 43%. The majority of patients in CR1 (82%) that were busulfan- (64%), fludarabine- (29%) or total body irradiation-based (82%) and 5-year EFS was 43%.

DEFIBROTIDE EFFICACY AND SAFETY IN PATIENTS WITH HEPATIC VENO-OCCULSIVE DISEASE/SINUSOIDAL OBSTRUCTION SYNDROME (VOD/SOS) DIAGNOSED AFTER DAY 21: ANALYSIS OF FINAL DATA FROM AN EXPANDED-ACCESS PROGRAM

1Stem Cell Transplantation and Cellular Therapy, 2Pharmacy Clinical Programs, 3Leukemia, University of Texas M.D. Anderson Cancer Center, Houston, United States

Background: Inotuzumab ozogamicin (IO) is a CD22 monocular antibody attached to calicheamycin and targets B lymphocytes in early stages of development. In a randomized study of IO compared with conventional salvage therapy in patients with refractory relapsed B-ALL, patients treated with IO had higher complete response rates (81% vs 29%, p<0.001), and a greater proportion of patients proceeded to allogeneic hematopoietic stem cell transplantation (SCT) (41% vs 11%, p<0.001). However, patients treated with IO prior to SCT were also noted to have higher rates of veno-occlusive disease (VOD) compared to the SCT group without IO exposure (11% vs 1%) (Kantarjian NEJM 2016).

Methods: In efforts to further investigate this finding, we reviewed transplant outcomes for patients with and without IO exposure.

Results: We performed a nested control comparison of patients transplanted during the years when they were being treated with IO on a number of clinical trials at our institution.

Results: Between 6/2010 and 10/2016, 251 patients with B-ALL with a median age of 35 years (range, 4-70 years) received an allogeneic matched sibling (n=85), matched-1 and 1-antigen mismatched unrelated (n=90), haplo-identical (n=38), or cord blood donor SCT (n=38) in CR1 (n=103), CR2+ (n=105), with or active disease (n=43). Patients received largely myeloablative regimens (Busulfan and Cytarabine- [BU ara]) or reduced intensity regimens (BU ara backbone with 1 TBI dose) with low, intermediate, and high risk IO cycles, time from IO to SCT, age, and donor relation were not found to be significant in contributing to VOD in univariate analysis. Median IO exposure to VOD was noted in 21 patients overall (8%) with median onset 19 days following SCT (range, 7-230 days); fatal VOD was noted in 5 patients (2%). VOD was noted in 11 patients treated with IO (16%), and it was fatal in 2 patients (3%). Factors noted to be significant in providing VOD in univariate analysis is prior exposure to IO (HR 5.9, 95% C.I. 1.3-7.2, p=0.01) and receiving a busulfan-based transplant preparative regimen (HR 3.4, 95% C.I. 1.0-12, p=0.05); not receiving a prior SCT was significantly protective (HR 0.9, 95% C.I. 1.0-8, p=0.02). Number of IO cycles, time from IO to SCT, age, and donor relation were not found to be significant in predicting VOD. In efforts to predict the risk for VOD in a patient who has received prior IO, we performed a classification and regression tree analysis (CART) and noted that the combination of IO and a double alkylation preparative regimen was significantly associated with the risk for developing VOD (HR 5.9, 95% C.I. 1.9-16, p=0.002).

Summary/Conclusions: Fatal VOD is a rare occurrence. However, IO exposure prior to SCT increases the risk for any VOD. Furthermore, IO exposure followed by a double alkylation preparative regimen increases this risk nearly 6-fold, and should be avoided in these patients.
