REGAIN CONTROL
28/04/2017   16:02

PRESCRIBING INFORMATION – Iclusig®

As a 4-year, 22% of chronic-phase CML patients achieved a deep molecular response (MR4.5) with Iclusig®,1

Iclusig® is the 3rd generation TKI with the potential to deliver FAST, DEEP and DURABLE response in patients with chronic CML.1

ICLUSIG®: Uncover a RESPONSE

Este medicamento no se encuentra comercializado en España

Date of Preparation: April 2017

Job Code: EU/ICLG/P/17/0013

Word of Welcome

On behalf of the EHA Board and the Scientific Program Committee we are pleased to introduce to you this year’s Abstract Program. The richness of the program is a testament to EHA’s spirit: unity through diversity.

The Scientific Program Committee has compiled an exciting program of Simultaneous Oral and Poster Sessions from close to 2500 submitted abstracts representing all fields of hematology. For the second year, a number of presenters will have the opportunity to pitch their abstract. These Poster pitches are an exciting opportunity to promote basic science and research, and to invite delegates to the poster walks.

The six Best Abstracts will be presented during the Presidential Symposium on Friday afternoon. This will be a session not to miss. During this plenary session EHA is also awarding, for the first time, the best abstracts by trainees in four categories in basic and clinical hematology research. These awardees and the travel grant winners can be found on the next page. YoungEHA are the future of hematology!

The late breaking abstract submission is an integral part of the scientific program. The late breaking submission is intended for abstracts with “hot” data that were not available by the time of the regular submission deadline. Only few abstracts, with the most exciting results are selected for a presentation in the Late Breaking Oral Session on Sunday morning.

A selection of abstracts will be presented during the regular Poster Walks. The Poster Session consists of two parts: the Poster Walk and dedicated Poster Browsing Time. This setup guarantees sufficient time for discussion of the important research presented, so look out for the Poster Walk Moderators in their red baseball caps! There will also be E-posters available on the E-poster screens, for which a specific time is allocated during the Poster Browsing Time at the end of each Walk. The Simultaneous Oral Sessions are spread over three days [Friday to Sunday] providing you with ample opportunity to attend a number of these important sessions.

All posters can be viewed on the E-poster screens from Friday morning to Saturday evening. All the abstracts are also available on the EHA Learning Center, for which you have complimentary access after the congress: learningcenter.ehaweb.org.

On behalf of the EHA Board, the committees and all the people involved in this year’s EHA Congress, we thank you for coming to Madrid and wish you a great meeting.

Shai Izraeli
Chair Scientific Program Committee 22nd Congress
Travel Grant Winners

For this Congress 140 travel grants have been awarded to junior members of EHA, based on the mean score of their abstracts.

EHA congratulates the following persons with their travel grants:

Agrawal M, Germany
Anagnostou T, USA
Arriazu E, Spain
Barcia Duran JG, USA
Beekman R, Spain
Bhui S, Sweden
Binder M, USA
Birgisdóttir AM, Iceland
Blunt M, United Kingdom
Bothol J, United Kingdom
Bouillon AS, Belgium
Brockelmann P, Germany
Buffiere A, France
Burney C, United Kingdom
Cabal-Hierro L, USA
Caraffini V, Austria
Casado Izquierdo P, United Kingdom
Cerchione C, Italy
Chaudhry G, India
Chitre S, United Kingdom
Cleyrat C, USA
De Bie J, Belgium
de la Morena-Barrio ME, Spain
De Paepe K, United Kingdom
De Rosa G, Italy
Di Marcantonio D, USA
Dimohamed A, the Netherlands
Dominguez Rodriguez M, Spain
Duran-Ferrer M, Spain
Eisfeld AK, USA
Escriba Garcia L, Spain
Eskelund C, Denmark
Fancelli L, Belgium
Farina F, Italy
Fattizzo B, Italy
Fernandez MC, Spain
Ferrero S, Italy
Figueroa R, Spain
Flasinski M, Germany
Gabeli M, Italy
Ganuza Fernandez M, USA
Garcia Ramirez P, Spain
Geelen I, the Netherlands
Giannoni L, Italy
Gugliotta G, Italy
Hansen J, Denmark

YoungEHA Best Abstract Awards

One of the primary missions of the European Hematology Association is to support young hematology clinicians and researchers. This year we are proud to announce the launching of the YoungEHA Best Abstract Awards. These will be awarded to the highest ranking abstracts in the following four categories: Clinicians or medical students training for a PhD degree, PhD research students, postdoctoral fellows and clinical hematology trainees. We are honored that these outstanding YoungEHA trainees will be presenting during the EHA congress – they are the future of Hematology!

CLINICAL TRAINEE AWARD
K C Pawlyn, United Kingdom

MD-PHD AWARD
K O Schwartzman, Israel

PHD RESEARCH STUDENT AWARD
K JG Barcia Duran, USA

POSTDOCTORAL RESEARCH TRAINEE AWARD
K F Vinchi, Italy
Information for readers, authors and subscribers

Haematologica (print edition, pISSN 0890-6078, eISSN 1592-8721) publishes peer-reviewed papers on all areas of experimental and clinical hematology. The journal is owned by a non-profit organization, the Ferrata Storti Foundation, and serves the scientific community following the recommendations of the World Association of Medical Editors (www.wame.org) and the International Committee of Medical Journal Editors (www.icmje.org).

Haematologica publishes editorials, research articles, review articles, guideline articles and letters. Manuscripts should be prepared according to our guidelines (www.haematologica.org/information-for-authors), and the Uniform Requirements for Manuscripts Submitted to Biomedical Journals, prepared by the International Committee of Medical Journal Editors (www.icmje.org).

Manuscripts should be submitted online at http://www.haematologica.org/.

Conflict of interests. According to the International Committee of Medical Journal Editors (http://www.icmje.org/#conflicts), “Public trust in the peer review process and the credibility of published articles depend in part on how well conflict of interest is handled during writing, peer review, and editorial decision making”. The ad hoc journal’s policy is reported in detail online (www.haematologica.org/content/policies).

Transfer of Copyright and Permission to Reproduce Parts of Published Papers. Authors will grant copyright of their articles to the Ferrata Storti Foundation. No formal permission will be required to reproduce parts (tables or illustrations) of published papers, provided the source is quoted appropriately and reproduction has no commercial intent. Reproductions with commercial intent will require written permission and payment of royalties.

Detailed information about subscriptions is available online at www.haematologica.org. Haematologica is an open access journal. Access to the online journal is free. Use of the Haematologica App (available on the App Store and on Google Play) is free.

For subscriptions to the printed issue of the journal, please contact: Haematologica Office, via Giuseppe Belli 4, 27100 Pavia, Italy (phone +39.0382.27129, fax +39.0382.394705, e-mail: info@haematologica.org).

Rates of the International edition for the year 2017 are as following:

<table>
<thead>
<tr>
<th></th>
<th>Institutional</th>
<th>Personal</th>

Advertisements. Contact the Advertising Manager, Haematologica Office, via Giuseppe Belli 4, 27100 Pavia, Italy (phone +39.0382.27129, fax +39.0382.394705, e-mail: marketing@haematologica.org).

Disclaimer. Whilst every effort is made by the publishers and the editorial board to see that no inaccurate or misleading data, opinion or statement appears in this journal, they wish to make it clear that the data and opinions appearing in the articles or advertisements herein are the responsibility of the contributor or advisor concerned. Accordingly, the publisher, the editorial board and their respective employees, officers and agents accept no liability whatsoever for the consequences of any inaccurate or misleading data, opinion or statement. Whilst all due care is taken to ensure that drug doses and other quantities are presented accurately, readers are advised that new methods and techniques involving drug usage, and described within this journal, should only be followed in conjunction with the drug manufacturer’s own published literature.

### Simultaneous sessions I

- New advances in plasma cell disorders and implications for therapy
- Aggressive Non-Hodgkin lymphoma - 1st line
- MRD directed treatment in AML
- New insights into chronic lymphocytic leukemia biology
- Pathogenesis of MDS
- Lymphoma biology
- Thalassemia
- AML: Biology I: Towards molecular therapies
- Hematopoiesis, stem cells and microenvironment
- Gene therapy, cellular immunotherapy and vaccination I

### Presidential Symposium

- Best abstracts

### Poster sessions I

- Acute lymphoblastic leukemia - Biology 1
- Acute lymphoblastic leukemia - Clinical 1
- Acute myeloid leukemia - Biology 2
- Acute myeloid leukemia - Clinical 1
- Acute myeloid leukemia - Clinical 2
- Acute myeloid leukemia - Clinical 3
- Aggressive Non-Hodgkin lymphoma - 1st line
- Bone marrow failure syndromes incl. PNH: Biology
- Chronic lymphocytic leukemia and related disorders - Biology 1
- Chronic lymphocytic leukemia and related disorders - Clinical
- Chronic myeloid leukemia - Clinical 1
- Hematopoiesis, stem cells and microenvironment
- Hodgkin lymphoma
- Iron metabolism, deficiency and overload
- Lymphoma biology
- Multifaced aspects of bleeding disorders
- Myelodysplastic syndromes – Clinical 1
- Myeloma and other monoclonal gammopathies - Biology
- Myeloma and other monoclonal gammopathies – Clinical 1
- Myeloma and other monoclonal gammopathies – Clinical 2
- Myeloproliferative neoplasms – Clinical 1
- Platelet disorders: Basic
- Quality of life, palliative care, ethics and health economics 1
- Stem cell transplantation - Clinical 1
- Thalassemia
- Transfusion medicine
**Simultaneous sessions II**

- Front-line combinations in multiple myeloma and amyloidosis
- Hodgkin and indolent lymphoma - Clinical
- Biology of MPN: JAK2 and beyond
- Clinical trials including treatment discontinuation in CML
- AML: Biology II. Epigenetic targets
- Acquired and inherited platelet disorders
- Acute lymphoblastic leukemia - Biology
- Thrombotic disorders
- Stem cell transplantation - Experimental
- Sickle cell disease, enzymes
- New drugs for rescue in relapsed/refractory multiple myeloma
- Improving prognostication and front-line therapy in chronic lymphocytic leukemia
- Aggressive Non-Hodgkin lymphoma - Relapsed/refractory
- Targeted treatment of AML
- Immunotherapy in ALL
- Biology and disease monitoring in CML
- Prognostic markers and new treatment in MDS
- Stem cell transplantation - Clinical 1
- Bone marrow failure and PNH
- Quality of life, palliative care, ethics and health economics

**Poster sessions II**

- Acute lymphoblastic leukemia - Biology 2
- Acute lymphoblastic leukemia - Clinical 2
- Acute myeloid leukemia - Biology 3
- Acute myeloid leukemia - Biology 4
- Acute myeloid leukemia - Clinical 4
- Acute myeloid leukemia - Clinical 5
- Aggressive Non-Hodgkin lymphoma - Relapsed/refractory
- Bone marrow failure syndromes incl. PNH - Clinical
- Chronic lymphocytic leukemia and related disorders - Biology 2
- Chronic myeloid leukemia - Biology
- Chronic myeloid leukemia - Clinical 2
- Enzymes and sickle cell disease
- Gene therapy, cellular immunotherapy and vaccination
- Indolent Non-Hodgkin lymphoma - Clinical
- Infectious diseases, supportive care
- Myelodysplastic syndromes - Biology
- Myelodysplastic syndromes - Clinical 2
- Myeloma and other monoclonal gammopathies - Clinical 3
- Myeloma and other monoclonal gammopathies - Clinical 4
- Myeloproliferative neoplasms - Biology
- Myeloproliferative neoplasms - Clinical 2
- Other Non-malignant hematopoietic disorders
- Platelet disorders: Clinical
- Quality of life, palliative care, ethics and health economics 2
- Stem cell transplantation - Clinical 2
- Stem cell transplantation - Experimental
- Thrombotic disorders

Background: Cyto genetic risk status in multiple myeloma (MM) studies is tradition ally determined by using fluorescence in situ hybridization (FISH) or karyotyping to assess chromosomal abnormalities. However, these technologies have limited resolution and a narrow target range, and reproducible interpretation may be confounded by inter-laboratory variation.

Aims: To describe the NGS methodology used to determine cyto genetic risk status in the daratumumab phase 3 CASTOR and POLLUX studies in RRMM.

Methods: Bone marrow aspirates were collected at screening and assessed centrally via NGS. Whole exome sequencing (exome-seq) and RNA sequencing (RNA-seq) was performed using the Illumina HiSeq platform to identify the presence or absence of defined risk markers: t(4;14), t(14;16), or del17p. The use of RNA-seq allowed for investigation of chromosomal translocations in expressed genomic locations at a higher resolution than FISH, and exome-seq data was used to derive the copy number status in coding regions across the genome. RNA-seq was performed using total RNA and rRNA removal to capture translocations involving coding and intronic regions. Translocation calls were made using two fusion callers, and gene expression was quantified to allow for evaluation of genes associated with translocation events. For t(14;14) translocations, the detected events involved RNA-seq reads fused between IgH and WHSC1 or FGFR3. For t(14;16), the detected translocations involved IgH and WWVOX, and for t(14;16), patients showed higher MAF and CCND2 expression. For del17p detection, exome data of each tumor was compared against 100 peripheral blood mononuclear cell (PBMC) control samples from CASTOR and POLLUX studies. Copy number variation data from two callers were combined to utilize information on relative read depth, systematic biases (observed in pooled normal controls), as well as SNP allele frequency (indicative of loss of heterozygosity events). A del17p event was detected when >50% of the 17p region was deleted.

Results: Based on the RNA-Seq and exome results, cyto genetic risk status in the CASTOR and POLLUX studies was defined as high risk with either t(4;14), t(14;14), or del17p, and standard risk with the confirmed absence of these molecular abnormalities. Comparisons of NGS with FISH showed high concordance for t(4;14), t(14;16), and del17p in both studies (Table 1).

PFS analyses investigating differences between treatment groups and between risk groups using FISH-derived risk and NGS-derived risk showed consistent results between FISH and NGS, with improvements in PFS being associated with the addition of daratumumab to standard-of-care regimens in both high- and standard-risk subgroups (Figure 1).

Summary/Conclusions: These studies represent the first, comprehensive use of NGS in global phase 3 clinical trials in RRMM. The NGS methodology accurately identified the presence of defined risk populations t(4;14), t(14;16), and del17p and showed good concordance with FISH. As FISH was performed locally with different probes and pathologists, the high degree of concordance between FISH and NGS is notable and supports the use of NGS for determining cyto genetic risk in patients with RRMM. The utility of NGS in these clinical studies extends far beyond the detection of cyto genetic abnormalities and additional analysis are planned to interrogate these datasets in the identification of novel biomarkers.
significantly improved progression-free survival (PFS) and achieved higher overall response rates (ORRs) compared with the respective standard-of-care regimen alone (Dimopoulos MA et al., N Engl J Med 2016;375(14):1319-1331; Palumbo A et al., N Engl J Med 2016;375(8):754-766.). Due to its novel mechanisms of action, addition of D to standard-of-care regimens may benefit RRMM patients who have poor prognoses resulting from high-risk cytogenetic abnormalities.

**Aims:** To examine the efficacy of DRd and DVD in RRMM patients with standard or high cytogenetic risk status.

**Methods:** Bone marrow aspirates were collected at screening visits from 311/569 patients from POLLUX and from 353/498 patients from CASTOR, and cytogenetic abnormalities were detected via next-generation sequencing (NGS). Patients were considered to be of high cytogenetic risk status if they had ≥1 of the following abnormalities: t(4;14), t(14;16), or del17p; patients were considered to be of standard cytogenetic risk if they lacked these abnormalities.

Minimal residual disease (MRD) was assessed at suspected complete response (CR) at 3 sensitivity thresholds (10−4, 10−5, and 10−6) using the ClonoSEQ™ NGS-based assay (Adaptive Biotechnologies, Seattle, WA). Efficacy analyses included PFS, ORR, and MRD-negative rates.

**Results:** For POLLUX, the median follow-up was 17.3 months. Treating high-risk patients with DRd significantly prolonged median PFS vs Rd (top panel Figure 1) and numerically increased ORR (85% vs 67%; P=0.04). Responses to DRd vs Rd included CR or better in 33% vs 6% of these patients, and very good partial responses (VGPR) or better in 63% vs 31%. In standard-risk patients, DRd vs Rd also resulted in significant improvements in median PFS (Figure 1) as well as ORR (95% vs 82%; P=0.0020). Responses to DRd vs Rd included CR or better in 52% vs 24% of these patients, and VGPR or better in 84% vs 51%. At 10−5 sensitivity threshold, MRD-negative rates for DRd vs Rd were 18% vs 0% (P=0.0027) among high-risk patients and 30% vs 10% (P=0.0011) for standard-risk patients. For CASTOR, the median follow-up was 13.0 months. Treating both high- and standard-risk patients with DVD vs Vd significantly prolonged median PFS (bottom panel Figure 1) and increased ORR (high risk: 82% vs 62%; P=0.039; standard risk: 85% vs 64%; P=0.0003). Responses to DVD vs Vd among high-risk patients included CR or better in 30% vs 9% of patients and VGPR or better in 64% vs 34%; among standard-risk patients, responses included CR or better in 25% vs 8% of patients and VGPR or better in 84% vs 27%. At 10−5 sensitivity threshold, MRD-negative rates for DVD vs Vd were 14% vs 0% (P=0.0018) among high-risk patients and 12% vs 2% (P=0.0011) for standard-risk patients.

**Summary/Conclusions:** Adding D to Rd or Vd improved treatment outcomes irrespective of cytogenetic risk status in patients with RRMM. Both DRd and DVD appear to benefit RRMM patients who have poor prognoses due to high-risk cytogenetic abnormalities. Updated data, including analyses based on individual cytogenetic abnormalities, will be presented at the meeting based on longer follow-up.

**S102**

**MINIMAL RESIDUAL DISEASE BY MULTIPARAMETER FLOW CYTOMETRY IN TRANSPLANT ELIGIBLE PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA: RESULTS FROM THE EMN02/HO95 PHASE 3 TRIAL**

**Background:** Multiple myeloma (MM) is still an incurable disease and patients may relapse despite achievement of complete remission (CR). Available data show that MRD detection is a sensitive strategy to appropriately measure response in MM patients.

**Aims:** We evaluated MRD by MFC in patients with newly diagnosed MM enrolled in the EMN02/HO95 phase 3 trial.

**Methods:** Patients were ≥65 years of age and treatment consisted of Bortezomib-Cyclophosphamide-Dexamethasone (VCD) induction, mobilization and stem cell collection, intensification with Bortezomib-Melphalan-Prednisone (VMP) vs High-Dose-Melphalan (HDM) followed by stem cell transplant, consolidation with Bortezomib-Lenalidomide-Dexamethasone (VRD) vs no consolidation, and Lenalidomide maintenance. MRD was assessed in patients achieving at least a very good partial response (VGPR) before starting maintenance (after HDM, VMP or VRD) and during maintenance every 6-12 months; samples were centralized to 3 European labs. MFC was performed on bone marrow according to Euroflow-based methods (8 colors, 2 tubes) with a sensitivity of 10−5. Quality checks were done to compare sensitivity and to show correlation between protocols (Hofste op Bruinink D, ASH 2016 abstract 2072).

**Results:** A total of 316 patients could be evaluated before maintenance: median age was 57 years (IQR: 52-62), 18% (57/316) had ISS III and 22% (70/316) had high risk cytogenetic abnormalities defined as presence of either one of del17, t(4;14) or t(14;16); 63% (199/316) had received HDM and 37% (117/316) VMP; thereafter 51% (160/316) had received VRD. After a median follow-up of 30 months from MFC enrolment, 76% (239/316) patients were MRD-negative: 64% (153/239) in the HDM vs 36% (86/239) in the VMP groups. The 3-year PFS was 50% in MRD-positive vs 77% in MDR-negative patients (HR 2.87, 95% CI: 1.75 - 4.72; p<0.001). Subgroup analyses were carried out to assess the risk factors for MDR-positivity according to baseline characteristics and therapies: high risk cytogenetic abnormalities were the most important risk factors (HR 9.87, 95% CI: 4.3 - 22.63; interaction p=0.001). Finally, 48% of MDR positive patients at pre-maintenance who had a second MDR evaluation after at least 1 year of lenalidomide became MDR-negative.

**Summary/Conclusions:** MFC by MRD is a strong prognostic factor in MM patients receiving intensification with novel agents or transplant; lenalidomide maintenance further improved depth of response; high risk cytogenetic abnormalities are the most important prognostic factors in MDR-positive patients.

**S103**

**PHASE I, OPEN-LABEL TRIAL OF ANTI-BCMA CHIMERIC ANTIGEN RECEPTOR T CELLS IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA**

**Background:** Immunotherapy has emerged as a potentially curative treatment in hematological malignancies. Uniformly expressed in plasma cells, B-cell maturation antigen (BCMA) is an appropriate target antigen for CAR T-cell therapies in multiple myeloma.

**Aims:** This phase I, open-label trial was conducted to assess the efficacy and
Patients with Light Chain Amyloidosis Treated with NEO001 Achieve Rapid Organ Responses that are Independent of Previous Plasma Cell–Directed Therapies

Aims: To assess the association between responses and time, number, or type of previous plasma cell–directed (PCD) treatments and organ response.

Methods: Inclusion criteria for this trial were: completed ≥1 PCD treatment before enrollment, attained partial hematologic response (HR) or better to any previous therapy, and have persistent organ dysfunction. NEO001 was administered intravenously every 28 days. During the dose-escalation phase, 27 patients received NEO001 at 0.5, 1, 2, 4, 5, 16, or 24 mg/kg in a 3+3 study design. In the expansion phase, 42 additional patients with renal, cardiac, or nerve involvement were enrolled and treated (24 mg/kg). We assessed cardiac and renal best responses based on consensus criteria. Peripheral nervous system (PN) responses were assessed at month 10 (after 9 infusions) using the Neuropathy Impairment Score—Lower Limbs (NIS-LL). We explored the potential impact on organ response of the number and type of organs affected and the number of, type of, and time since previous therapies at baseline.

Results: In the overall population (N=69), the median age was 61 years (61% male). Median (range) time since diagnosis was 2.9 (0.4-16.0) years, and 45% of patients underwent ≥3 previous PCD regimens. Median time to first best response was 1.8 (cardiac), 3.7 (renal), and 1.0 (PN) months. Best response rate indicating organ response was observed in 53% of cardiac-evaluable patients (n=19/36) and 64% of renal-evaluable patients (n=23/36). PN responses were observed in 82% (n=9/11) of PN-evaluable patients. Time from patients' best HR to previous PCD treatment was not related to the attainment of NEO001 organ response (responder/stable: 35.6/36.6 months [cardiac] and 30.6/32.5 months [renal]; P>0.05). Depth of patients' best HR also was not related to the attainment of NEO001 organ response (percentage of patients with organ response in CR/VGPR/PR after PCD: 47.1/66.7/42.9% [cardiac] and 68.8/63.6/62.5% [renal]; P>0.05). Similarly, time or depth of patients' last HR did not impact the NEO001 organ response rate (P>0.05). Patients with NEO001 organ responses were no more likely to have had their last PCD therapy <6 than ≥6 months from their first NEO001 dose. Patients' previous PCD treatment type was not related to the corticosteroid for spinal meningioma. He terminally died finally. Another one achieved transient partial response, which last for 12 days. The nodules were obviously decreased after the infusion and disappeared finally. Another one achieved transient partial response, which last for 12 days.

Summary/Conclusions: NEO001 specifically targets disease-causing, misfolded LC aggregates in AL amyloidosis. Organ responses in patients treated with monthly NEO001 infusions were achieved rapidly and independently of time since previous chemotherapy, depth of hematologic response, or predominant type of PCD treatment.
Background: Mantle cell lymphoma (MCL) is currently an incurable disease. In spite of high complete response rates (CR) after initial immunochemotherapy induction followed by autologous stem cell transplantation (ASCT), MCL patients experience iterative relapses.

Aims: We investigated whether or not rituximab maintenance (RM; 375mg/m2 every 3 months for 3 years) after ASCT prolongs response duration.

Methods: This phase III trial included 299 patients (65+6) at diagnosis, of whom 240 were randomly assigned to RM or observation after ASCT. The primary end point was event-free survival (EFS) (progression, relapse, death, severe infection during RM) after ASCT.

Results: After 4 courses of immunochemotherapy induction (R-DHAP; Rituximab, dexamethasone, cytarabine, platinum derivative), overall response and CR rates were 89.3% and 77.3%, respectively. ASCT was performed in 257 patients. Median follow-up from randomization after ASCT was 50.2 (46.4-54.2) months. Starting from randomization, 4-year EFS was 78.9% (95%CI; 69.8 to 87.0) for RM and 56.2% (95%CI; 45.7 to 66.7) for observation (n=120) (p=0.001, 4-year progression-free survival (PFS) was 82.2% (95% CI; 73.2 to 88.4) for RM versus 64.6% (95% CI; 54.6 to 73.0) for observation (p=0.0005) and OS was 88.7% (95% CI; 80.7 to 93.5) for RM versus 81.4% (95% CI; 72.3 to 87.7) for observation (p=0.0413). The death rate was lower for patients in the RM arm (HR=0.95; 95% CI; 0.255 to 0.986) than for patients in the observation arm.

Summary/Conclusions: The LyMa trial demonstrates for the first time that ASCT after R-DHAP prolongs EFS, PFS and OS. Thus, 4 courses of R-DHAP plus ASCT (without TBI) followed by RM maintenance (one infusion every 3 months for 2 years) is a new standard of care for young MCL patients.
When pts in the SC group were asked, if given the option, which treatment they would prefer, 90.8% stated a preference for SC over IV. Median administration time (6 minutes SC vs 2.6–3.0 hours IV) and chair/bed and overall hospital times were shorter with SC than with IV treatment.

Figure 1. Patient satisfaction at cycle 3 and cycle 7 of treatment.

Summary/Conclusions: Rituximab SC had similar efficacy and safety to the IV form, with improvements in patient satisfaction ratings, and administration/hospital time savings. Our findings support the use of rituximab SC in this setting.

ANALYSIS AND CHARACTERIZATION OF HEMATOLOGIC CANCERS USING A COMPREHENSIVE NGS PANEL COMPRISING OF DNA AND RNA BAITS TARGETING 704 GENES

A.R. Carlson1, B.A. Patay1, V. McClain1, Z. Xie1, T. Stenzel1,2,3, J.E. Miller1,2,3

1Invivoscribe, 2LabPMM LLC, San Diego, United States, 3LabPMM GmbH, Martinsried, Germany

Background: As next-generation sequencing (NGS) methodologies improve, so does the ability to characterize hematopoietic and lymphoid neoplasm genomes. This promises to revolutionize oncology, allowing more accurate and precise classification of patients and potentially leading to novel targeted and combination therapies with improved outcomes.

Aims: We constructed a custom targeted sequencing panel, MyHEME™, to comprehensively identify and characterize DNA and RNA changes in a broad range of hematologic malignancies, including Non-Hodgkin lymphoma (NHL).

Methods: The MyHEME targeted sequencing panel is comprised of two independent bait sets that target a combined 704 genes known or predicted to contribute to hematologic cancers (DNA baits for 571 genes and RNA baits for 361 genes; 228 genes are found in common between the two bait sets). Libraries were constructed using 1μg of DNA or 0.1μg of RNA and sequenced on an Illumina platform. Sequenced reads are analyzed using proprietary MyInformatics™ software to identify single nucleotide variants (SNVs), indels and structural variants (SVs). Both the MyHEME panel and MyInformatics software were created under ISO13485 design control. To characterize the performance metrics of the MyHEME panel, we used the NIST human reference sample NA12878 along with combinations of hematologic cancer derived cell lines with known pathogenic variants at various allelic frequencies.

Results: Analytical validation of the MyHEME panel established an average read depth of 1,175x (with a median read depth of 1,088x) for the DNA targets and an average transcripts per million (TPM) of 2,256 (with a median TPM of 743) for the RNA targets. For the DNA targets, we established sensitivity >95% (99.8% for SNVs at a 2.5% LOD) and specificity >95% (95.5% for SNVs at a 2.5% LOD; 97.7% for coding indels at a 5.0% LOD). We also show the ability to cross-confirm results between the 228 genes common to both the DNA and RNA targets. Importantly, novel gene fusions, which are generally difficult to detect and validate, were cross-confirmed when observed in both the DNA and RNA targets. For example, we identified a novel t(9;22) translocation causing a NUP214-XKR3 gene fusion using both the DNA and RNA targets. Additionally, while RNA data provides the fused exons of the transcripts, DNA data gives the precise genomic break-point coordinator.

Summary/Conclusions: MyHEME is an extensive panel for sensitively and specifically identifying SNV, indel and SV mutations in 704 target genes. This panel can comprehensively characterize mutations in multiple diverse hematologic cancer samples, including Non-Hodgkin lymphoma (NHL), ALL, and Multiple Myeloma. By utilizing a high depth of coverage, MyHEME can accurately detect clones present down to 5% of a patient’s sample. In addition, by targeting both DNA and RNA, MyHEME contains a built in validation method to cross-confirm novel variants of interest.

S108

TP53 MUTATIONS, BUT NOT DELETION OF TP53 AND CDKN2A, HAVE INDEPENDENT PROGNOSTIC VALUE IN MANTLE CELL LYMPHOMA TREATED BY THE NORDIC (MCL2 AND MCL3) REGIMEN

C.W. Eskelund1, C. Dahl1, J. W. Hansen1, M. Westman1, C. Montano1, C. Freiburghaus1, S. Ek1, A. Pedersen1, L. B. Pedersen1, C. Niemann1, R. Räty1, P. Brown1, A. Kolstad2, C.H. Geisler1, M.K. Andersen1, P. Guldberg2, M. Jerkeman3, K. Grenbaek1

1University Hospital of Copenhagen, 2Danish Cancer Society, Copenhagen, Denmark, 3University Hospital of Lund, Lund, Sweden, 4University Hospital of Helsinki, Helsinki, Finland, 5University Hospital of Oslo, Oslo, Norway

Background: During the past decades, the outcome of MCL treatment has improved substantially in younger patients. However, the course of disease remains heterogeneous, and there is a need for better stratification of patients with poor responses from those with durable responses. The Nordic trials, MCL2 and MCL3, represent standard-of-care regimens for younger MCL patients.

Aims: Preliminary analyses of diagnostic samples from MCL2 and MCL3, show that TP53 mutations are associated with significantly poorer outcome. Recently, deletions of TP53 and CDKN2A was shown to confer negative impact in a cohort similar to the Nordic. (Delfau-Larue et al., 2015) Thus, in this study we aim to describe the prevalence and impact of deletions of TP53 and CDKN2A in the light of TP53 mutations.

Methods: Fresh frozen DNA from diagnostic bone marrow samples from MCL2 and MCL3 were analyzed. In both trials, patients received intensified first-line induction therapy with alternating courses of R-CHOP and R-hd-Cytarabine and consolidation with high-dose therapy and ASCT. (Geisler et al., 2008; Kolstad et al., 2014). Targeted NGS of ATM, CCND1, TP53, KMT2D, NOTCH1, NOTCH2, WHSC1 and BIRC3 was performed by Ion Torrent Technology. Cut-off for calling a mutation was set to a variant allele frequency >3%. Median coverage was >2700X. Copy Number Variations (CNVs) of TP53 and CDKN2A were measured by droplet digital PCR by commercially available assays, and RPP30 used as a standard control.

Results: We investigated the presence of CDKN2A and TP53 deletions in diagnostic samples from 175 and 157 patients, respectively. Patients were treated and <66 years (median 58, range 37-65). Fifty-three percent were either MIPI intermediate- or high-risk, 17% had blastoid morphology and 42% had Ki67≥30%, and 83% had bone marrow involvement at diagnosis. After a median follow-up of 9.2 years, median overall (OS), progression-free survival (PFS) and cumulated incidence of relapse (CIR) of all patients were 12.4, 5.5 and 10.2 years, respectively. In our mutational analyses (n=147), only TP53 had prognostic impact in multivariate analyses (MVAs). Outcome of the 15 patients (10%) with TP53-mutations was poor with a median OS, PFS and CIR of 1.8, 1.0 and 1.2 years (p<0.0001 for all three outcomes), respectively. Preliminary analysis of TP53 mutations in 29 patients (13%) revealed 14 (48%) with TP53 in 38 (22%). Eight patients carried both deletions. Del-CDKN2A was significantly associated with mutations of TP53, MIPI high risk, blastoid morphology and Ki67≥30%. Del-TP53 was associated with Ki67>30, but no other high risk markers. Altogether, 31 (25%) of 122 patients harbored a deletion and/or mutation in TP53 and 4 (3%) carried both aberrations. In univariate analyses, del-TP53 was significantly associated with poor OS (p=0.01), but not PFS and CIR, whereas del-CDKN2A was significant for CIR (p=0.02), but not OS and PFS. Patients with both deletions did significantly worse for all three endpoints. In MVA, (including all factors with significance in univariate analyses: MIPI, blastoid morphology, Ki67-index>30%, NOTCH1 mutations, TP53 mutations, del-TP53 and del-CDKN2A) only mutations of TP53 remained a significant predictor of outcome.

Summary/Conclusions: Here we evaluate the impact of TP53- and CDKN2A-deletions in the context of TP53 mutations of younger, optimally treated MCL patients. In line with previous reports, both deletions were associated with poorer outcome; however, in multivariate analyses only TP53 mutations was an independent prognostic factor, substantiating its role as a biomarker for response to the standard-of-care immune-chemotherapy.
MRD directed treatment in AML

S110

DEEP MOLECULAR RESPONSE TO GILTERITINIB IMPROVES SURVIVAL IN FLT3 MUTATION-POSITIVE RELAPSED/REFRACTORY ACUTE MYELOID LEUKEMIA

Background: Mutations in Fms-like tyrosine kinase 3 (FLT3) are common in patients with acute myeloid leukemia (AML) and are associated with an aggressive disease course and a poor prognosis. Notably, FLT3 internal tandem duplications (ITD) predict early relapse and short overall survival (OS) after chemotherapy. Gilteritinib, a highly selective FLT3/AXL inhibitor, has displayed antileukemic activity in FLT3 mutation-positive (FLT3mut+) relapsed/refractory (R/R) AML in the CHRYSLIS Phase 1/2 study (NCT02014558), specifically at doses ≥80 mg/d. In FLT3-ITDmut+R/R AML correlated with clinical response and improved OS. This is the first demonstration of a robust molecular response to a FLT3 inhibitor in AML. These data suggest that the ITD signal ratio may predict a durable clinical benefit of gilteritinib therapy and validate FLT3 as a critical therapeutic target in AML.

Methods: This exploratory analysis evaluated molecular response in patients aged ≥18 years with FLT3mut+/R/R AML who had received treatment with 120 or 200 mg/d gilteritinib. These doses were identified due to their ability to induce high clinical response rates, and consistent, potent FLT3 inhibition in correlative assays. Molecular response was assessed in patients who had bone marrow aspirates obtained at baseline and at ≥1 additional time point. FLT3-ITD and total FLT3 were quantified by next-generation sequencing to assess molecular response. A Cox regression model of OS by Kaplan-Meier estimation established a FLT3-ITD:total FLT3 ratio (ITD signal ratio) of 10−2 as the threshold for improved survival.

Results: Of the 147 FLT3-ITDmut+ patients who had received gilteritinib 120 or 200 mg/d, 80 patients had bone marrow aspirates at baseline and at ≥1 additional time point. FLT3-ITD and total FLT3 were quantified by next-generation sequencing to assess molecular response. A Cox regression model of OS by Kaplan-Meier estimation established a FLT3-ITD:total FLT3 ratio (ITD signal ratio) of 10−2 as the threshold for improved survival.

Results:

MRD negative 15 417 (224-248) 67 213 (144-246) 0.02
MRD positive 20 417 (248-334) 40 99 (142-234) <0.01

Table 1. Overall survival in subjects who achieved a molecular response compared with those who did not by depth of response.
ASCT can be avoided if MRD is not detectable; if MRD is positive, ASCT can prolong OS and DFS to equalize those of the low-risk category. ASCT was delivered to 2/3 of pts in the high-risk category, using all the available sources of stem cells.

GRAFT VERSUS LEUKEMIA EFFECT OF ALOLOGENIC STEM CELL TRANSPLANTATION AND MINIMAL RESIDUAL DISEASE IN PATIENTS WITH AML IN FIRST COMPLETE REMISSION

J. Versluis1,*, B. Kalin1, W. Zeijlmaker1, J. Passweg1, C. Graux2, M. Manz2, M.-C. Vekemans3, B. Biemond3, M.-C. Legede4, M. van Manwijk Kooy5, H. van Krimpen10, B. Lowenberg10, J. Janssen2, T. Pabst10, G. Schuurhuis10, G. Ossenkoppele10, J. Cornelissen1

1Erasmus Medical Center Cancer Institute, Rotterdam, 2VU University Medical Center, Amsterdam, Netherlands, 3University Hospital Basel, Basel, Switzerland, 4Mont-Godinne, Yvoir, Belgium, 5University Hospital Zürich, Zürich, Switzerland, 6Cliniques universitaires Saint-Luc, UCL, Brussels, Belgium, 7Academic Medical Center, University of Amsterdam, Amsterdam, 8Medisch Spectrum Twente, Enschede, 9Isala Hospital, Zwolle, Netherlands, 10Inselspital, Bern University Hospital, Bern, Switzerland

Background: The detection of minimal residual disease (MRD) in patients with acute myeloid leukemia (AML) may improve future risk-adapted strategies of AML treatment. The presence of MRD after induction treatment has firmly been shown to predict for relapse and overall outcome, irrespective of type of post-remission treatment (PRT). Currently it is unknown whether and how the presence or absence of MRD should guide the application of allogeneic hematopoietic stem cell transplantation (alloHSCT) as PRT.

Aims: We addressed whether and to what extent alloHSCT quantitatively reduces relapse as compared to conventional post-remission treatment (PRT) in upfront treated patients with MRD positive or MRD negative AML in first hematological complete remission (CR1).

Methods: A total of 1,511 patients were treated in subsequent HOVON-SAKK AML trials of whom 547 patients obtained a CR1, received PRT and had available flow cytometric MRD prior to PRT. MRD positivity was defined by more than 0.1% cells with a leukemia associated phenotype within the white blood cell compartment. MRD status was not known by clinicians during AML treatment. PRT consisted of alloHSCT (n=282), or conventional PRT by a third cycle chemotherapy (n=160) or autologous HSCT (n=105). Endpoints of the study included overall survival (OS), relapse-free survival (RFS), and cumulative incidences of relapse and non-relapse mortality (NRM) at 4 years. A time-dependent covariate analysis was performed by applying multivariable Cox regression with MRD as primary endpoint.

Results: MRD was positive in 129 (24%) patients after induction chemotherapy before proceeding to PRT. The latest European LeukemiaNet risk classification was similarly distributed among MRD negative and MRD positive patients. No differences were present in transplant characteristics in MRD positive and MRD negative patients. OS and RFS was significantly better in patients without MRD prior to PRT as compared to MRD positive patients (65±2% compared to 50±5% at 4 years, p<0.002, and 58±3% compared to 38±4%, p<0.001, respectively). Improved outcome was mainly caused by a lower cumulative incidence of relapse in MRD negative patients as compared to MRD positive patients (32±2% compared to 54±4% at 4 years, p<0.001, respectively), while NRM was not significantly different and estimated 10±2%. NRM split by EBMT risk score showed less NRM in patients with a low EBMT-risk score as compared to patients with a high EBMT risk score (s2 compared to >s2, 10±2% compared to 22±4%, p<0.005, respectively). Multivariable analysis with adjustment for covariates showed that the incidence of relapse was significantly reduced following alloHSCT as compared to chemotherapy or autologous HSCT (HR 0.36, p<0.001), which was similarly exerted in MRD negative and positive patients (HR 0.38, p<0.001 and HR 0.35, p<0.001). RFS was also improved following alloHSCT as compared to chemotherapy or autologous HSCT (HR 0.53, p<0.001), while no significant differences were found for OS (Figure 1).

Summary/Conclusions: The graft-versus-leukemia effect of alloHSCT is equally present in MRD positive and MRD negative patients, which advocates a personalized application of alloHSCT taking the risk of relapse determined by AML risk group and MRD status as well as the counterbalancing risk of NRM into account.

S113

LEUKEMIC STEM CELL FREQUENCY COMBINED WITH MRD IS AN IMPORTANT BIOMARKER TO PREDICT RELAPSE IN ACUTE MYELOID LEUKEMIA. RESULTS FROM A PROSPECTIVE H102 STUDY

1Hematology, VU University Medical Center, Amsterdam, 2Clinical Trial Center, Erasmus University Medical Center, Rotterdam, Netherlands, 3Hematology, University Hospitals Leuven, Campus Gasthuisberg, Leuven, 4Hematology, Ziekenhuis Netwerk Antwerpen, Antwerp, Belgium, 5Hematology, Inselspital, Bern University Hospital, Bern, 6Hematology, University Hospital Zürich, Zurich, Switzerland, 7Immunology, Erasmus University Medical Center, Rotterdam, 8Clinical Chemistry, Medisch Spectrum Twente/Medlon, Enschede, 9Hematology, Erasmus University Medical Center, Rotterdam, Netherlands

Background: Despite up-to-date risk algorithms, outcome in acute myeloid leukemia patients is still difficult to predict. Even in good risk patients relapses occur. Further refinement of currently used risk classifications is therefore warranted. Measurable residual disease (MRD) is a well-known risk factor and the independent prognostic impact of MRD was shown for patients independent on risk groups. Nowadays prospective studies are designed on which therapy is adapted based on MRD-positivity or negativity. Although this is a major improvement for risk stratification, relapses occur in a substantial proportion of MRD-negative patients. Previous retrospective studies have shown that the leukemic stem cell (LSC) frequency harbors important prognostic information as well (Bradbury et al., Leukemia 2015), even within MRD-negative patients (Terwijn et al. Plos one, 2013).

Aims: In this study we used data of the HOVON-SAKK H102 trial to prospectively define, using flow cytometry, the leukemic CD34+CD38- stem cell frequency combined with MRD frequencies and MRD frequencies to investigate impact on patient outcome.

Methods: In 242 patients who achieved morphologic complete remission, both LSC and MRD data after two cycles of chemotherapy treatment were available. MRD-positivity was defined as a percentage of MRD-positive cells above 1% (as compared to total amount of WBCs) and LSC-positivity was defined as a CD34+CD38-LSC percentage above 0.00001% (LSC cut-off 0.00001%); thus no CD34+CD38-LSC events measured.

Results: Cumulative incidence of relapse (CIR) and overall survival (OS) data were investigated for four different MRD/LSC groups: 1. MRDpos+LSCneg patients (n=116) 2. MRDpos+LSCneg patients (n=28) 3. MRDneg+LSCpos patients (n=58) and 4. MRDpos+LSCpos patients (n=20). Results showed that MRDpos+LSCneg patients have the worst prognosis. 3-year CIR for the four above-defined groups was 35% (SE 4), 43% (SE 9), 53% (SE 7), and 100% (SE 0), respectively. Similar results were found for OS: 3-year OS was 66% (SE 4), 68% (SE 9), 53% (SE 8), and 100%, respectively, with 17 patients dead and 3 censored in the latter group. When investigating the impact of MRD/LSC status in the good, intermediate, poor and very poor risk group (according to HOVON), patient numbers were sometimes small; however, results show that MRDpos+LSCposAML patients in all different risk categories have a very poor prognosis. Moreover, multivariate analyses, containing all well known risk factors including risk group and post remission treatment, showed that MRDpos+LSCpos patients have a significantly worse cumulative incidence of relapse (hazard ratio [HR] 5.89; 95% CI 3.32-10.47) and overall survival (HR 3.62; 95% CI 1.86-7.04) as compared to the MRDneg+LSCneg patient group.

Summary/Conclusions: Overall, we conclude that our prospective results show that CD34+CD38-LSC frequency has important additional value in MRD assessment and that it especially enables to identify very poor risk patients in...
all different currently used risk categories. These data urge to include both MRD and LSC in future AML risk classification to better inform post-remission treatment.

S114
DEFINITION OF PARTIAL RESPONSE IN YOUNGER AML PATIENTS AFTER FIRST INDUCTION COURSE MAY BE EXTENDED BY INCLUSION OF IMMUNOPHENOTYPIC DETECTION OF MEASURABLE RESIDUAL DISEASE IN CR

1Institute of Immunology and Immunotherapy, University of Birmingham, Birmingham, 2King’s College London School of Medicine, London, 3Centre for Trials Research, Cardiff University, Cardiff, 4North Bristol NHS Trust, Bristol, 5University Hospital of Wales, 6Cardiff University School of Medicine, Cardiff, 7Isle of Arran, Isle of Arran, 8Nottingham University Hospital, Nottingham, United Kingdom

Background: In AML response by morphology after a first cycle of induction therapy is used to guide further therapy including second cycles of induction and choice of consolidation. It is still uncertain how the quality of response post cycle 1 with inclusion of MRD assessment impacts on outcomes within AML risk subgroups including NPM1 wild type standard risk and whether this adds information to MRD status in CR post cycle 2.

Aims: To quantify the effect of MRD positivity for response after each cycle of induction therapy in younger patients with AML.

Methods: As part of the UK NCRI AML17 trial (ISRCTN: 55675535) for patients with AML or high risk MDS up to the age of 60, prospective flow cytometric MRD (MFC-MRD) monitoring was performed after each course of induction. Any level of MRD detected was considered MRD+ (sensitivity thresholds: ~0.02% by tracking diagnostic leukemic aberrant phenotypes /LAIP, ~0.05-0.1% by “different-from normal” blast LAIP). Clinicians were not informed of MFC-MRD results. Following their first cycle of induction with daunorubicin/ara-C based therapy, patients were allocated a risk group by a validated score (comprising cytogenetics, WBC, age, secondary disease, blast response to cycle 1 and mutation status). Poor risk patients received intensified therapy in cycle 2 with a view of proceeding to SCT.

Results: MFC-MRD results after either induction course are available for 1555 patients randomised from 4/09-12/14 (median age 51, range 0-73). Cycle 1 (C1) response data with MFC-MRD was available for 1,400 patients. 70% achieved morphological CR at this time-point; 14% had resistant disease (RD) and 16% were in partial remission (PR) according to clinician. Of patients in CR (n=984) 56% had detectable MFC-MRD (MRD+). Excluding poor-risk patients 14% of patients did not achieve CR (7% RD, 7% PR), 51% of patients in CR were MRD+. 5 year OS for MRD- vs MRD+ were 63% vs 44% vs 37% vs 25% for all patients; 69% vs 51% vs 50% vs 30% excluding poor-risk patients and 76% vs 49% vs 49% vs 30% for standard risk alone (Figure 1). The similar OS in this group between CR MRD+ and PR at C1 was maintained in NPM1wt standard risk patients and if censored at stem cell transplant. 771 patients were in CR post cycle 2 (C2) and provided MFC-MRD data. As expected, there were significant differences in 5 year OS between CR MFC MRD+ vs CR MFC MRD- for all patients (35% vs 83%) and excluding poor-risk (38% vs 70%, n=512). Importantly post cycle 2 MFC-MRD status also differentiated OS for NPM1wt standard risk patients with 5 year OS of 32% vs 64% (P=0.002) for MRD+ vs MRD- (Figure 1). In stratified analyses, there was some evidence that the effect of MRD positivity on OS was lower in poor-risk patients (test for trend p=0.02 for both C1 and C2). The effect of MFC-MRD status on relapse and OS appeared greater at C2 (relapse, OR 2.00[1.56- 2.55], p<0.001; survival, OR 1.80[1.42-2.28] p<0.001) than C1 (relapse, OR 1.69[1.37- 2.07], p<0.001; survival, OR 1.46[1.19-1.79] p<0.001). In patients with data for both time points, C2 MRD remained significant on OS when adjusting for C1 response. 24 patients converted from C1 MRD- to C2 MRD+, with a poor prognosis (15 relapses, 13 deaths). C1 MRD-/C2 MRD- had the best prognosis.

Summary/Conclusions: MFC-MRD in CR post cycle 1 has similar outcomes to partial remission in younger patients with AML, particularly in patients with good and standard risk disease. Assessment of MFC-MRD post cycle 2 appears to provide additional discrimination to cycle 1: MFC-MRD in courses 1-2 may be useful in further stratifying standard risk patients.
New insights into chronic lymphocytic leukemia biology

CLINICAL IMPACT OF THE SUBCLONAL ARCHITECTURE AND MUTATIONAL COMPLEXITY IN CHRONIC LYMPHOCYTIC LEUKEMIA

F. Nadeu1,2, G. Clot1,2, J. Delgado1,2,3, D. Martín-García1,2, T. Bauman1,3, I. Salavena1,2, S. Beà1,2, M. Pinyol3,4, P. Jares1,2,3, A. Navarro1,2, H. Suárez-Cintron5, A. Pérez-Carrión6, M. Aymerich1,2,3, M. Rozman7,8,9, N. Villarroya3,2, D. Colomer1,2,3, A. López-Guillermo11, X. S. Puente6,8, C. López-Otin12, D. Torrents9, M.-L. Yaspo13, M. Aymerich1, S. Heath6, R. Guigó7, M. Gut4, P. Fraser3, I. Martín-Sancho1,2

Background: Recent studies have revealed the presence and prognostic impact of small mutated subclones in chronic lymphocytic leukemia (CLL) (Rossi et al 2014, Nadeu et al 2016, Rasi et al 2016). Although these studies focused only on a small subset of 5 genes, their results opened a new perspective where the proportion of cells carrying each specific driver mutation may contribute to the evolution of this disease. Moreover, the subclonal and mutational complexity estimated by the presence of subclonal driver alterations (Landau et al 2013, Landau et al 2015) or the accumulation of driver mutations (Puente et al 2015) have been proposed as promising indicators of clinical behavior.

Aims: The goal of this study was to determine the relevance of the quantitative subclonal architecture and mutational complexity in the evolution of CLL integrating the deep sequencing analysis of a large panel of driver genes and DNA copy number alterations (CNA).

Methods: The mutational status of 28 driver genes was investigated in 406 previously untreated CLL patients by targeted next-generation sequencing (NGS). Mutations present in less than 1% of tumor cells were identified. All low frequency mutations were verified by allele-specific PCR or a second round of NGS. CNAs were analyzed by SNP-arrays. Alterations were classified as clonal if their CCF was ≥85%, and subclonal otherwise. All patients gave informed consent.

Results: Using a highly sensitive NGS strategy we observed that small subclonal mutations were the sole alteration in 22% of the mutated cases, and were frequently detected in nearly all investigated genes. We identified three gene-specific patterns that linked the magnitude of the mutated clones (or mutated cancer cell fraction, CCF) with the prognosis of the patients: i) CCF-independent pattern: mutations at any CCF had prognostic value, ii) CCF-gradient pattern: the poor prognostic impact was a continuous variable directly related to the size of the clone, and iii) CCF-clonal pattern: only mutations with a CCF above a certain threshold impacted the outcome of the patients. Combining mutations and driver CNAs of the panel of the previously identified subclonal driver alterations in 66%. On the other hand, subclonal driver alterations were present in 60% of the patients. The mutational complexity (accumulation of 1 to 4x driver alterations), but not the presence of subclonal driver populations, gradually shortened the time to first treatment independently of the IGHV mutational status and Binet stage. Conversely, the subclonal complexity, defined as the accumulation of driver alterations with the presence of at least one driver subclone, predicted for a worse overall survival independently of the IGHV and Binet stage. Patients with a pure clonal population (presence of one or more driver alterations in all tumor cells) had a similar overall survival than patients without any alteration.

Summary/Conclusions: Our study shows that the prognostic impact of different driver mutations is related to the size of the mutated population. Therefore, the clinical evaluation of gene mutations should consider the quantitative representation of the mutations and not only their presence or absence. In addition, the mutational complexity predicts for shorter time to first treatment independently of the IGHV and Binet stage, whereas the subclonal complexity confers an independent adverse impact for overall survival. Altogether, the integration of the subclonal architecture and mutational complexity in prognostic indexes may improve the stratification of CLL patients.

FBXW7 MUTATIONS LEAD TO ACCUMULATION OF NOTCH1, HIF1-ALPHA AND C-MYC IN CLL CELLS

V. Meyer-Pannwitt1,2, S. Estenfelder2, E. Tausch2, S. J. Kugler1,2, M. Reichenzeller1,2, S. Stilgenbauer3, D. Mertens1,2

Department of Molecular Genetics (B61), Cooperation Unit "Mechanisms of Leukemogenesis", DKFZ, Heidelberg, Internal Medicine III, Ulm University, Ulm, Germany

Background: Chronic lymphocytic leukemia (CLL) is a heterogeneous disease with recurrent mutations that are of pathogenic and prognostic relevance. Mutations in FBXW7 are among the most common mutations in CLL, yet their functional consequences are unknown. FBXW7 is an E3 ubiquitin ligase that ubiquitylates oncoproteins like NOTCH1, HIF-1-alpha and c-MYC and thereby targets them for proteasomal degradation.

Aims: 1) To study the functional consequences of FBXW7 mutations. Approximately 60% of FBXW7 mutations alter arginine residues that are involved in substrate targeting. In T-cell acute lymphoblastic leukemia these arginine mutations are associated with chemotherapeutical resistance. In CLL however, the role of dysfunctional FBXW7 is unclear. We therefore aimed to delineate the prevalence of FBXW7 mutations in CLL patient cohorts and characterize its functional role. 2) To examine the role of mutations in the PolyPhen-2 software. All except one missense mutation in FBXW7 were predicted to be most likely damaging. No mutations in FBXW7 were found in the CLC, MCL, and CLL cell lines analyzed. To determine the functional consequence of FBXW7 mutations in CLL, we induced either a heterozygous or a homozygous truncation of FBXW7 in the CLL cell line HG3, resulting in the loss of the substrate binding site of the WD40 domain. The homozygous truncation of FBXW7 resulted in an increase of NOTCH1, HIF1-alpha, and c-MYC protein levels, whereas no difference of Cyclin E protein amount was detectable. In addition, an elevation of NOTCH1 activity was found in both the heterozygously and homozygously truncated mutant cell lines in comparison to the wildtype HG3 cell line. To confirm this finding, protein levels of 5 CLL patients with FBXW7 mutations were analyzed with a similar outcome.

Summary/Conclusions: Mutations in FBXW7 are frequently found in CLL, especially missense and nonsense mutations affecting the WD40 domain. We hypothesize that this has functional consequences on FBXW7 substrate binding and therefore leads to accumulation of oncogenes. The truncation of the WD40 domain of FBXW7 in the HG3 cell line resulted in the accumulation of protein substrates and corresponding increase of their activity implicated in the pathogenesis of CLL. Taken together our data show that FBXW7 can target proteins for degradation that are commonly dysregulated in CLL and that drive disease progression.
of CLL in relation to the mutational, transcriptional and three-dimensional (3D) chromatin landscape.

Methods: Seven CLL patients with distinct clinico-pathological features and five mature B-cell subpopulations were extensively analysed using (i) ChIP-seq of six different histone marks with non-overlapping features (H3K27ac, H3K4me1, H3K4me3, H3K9me3, H3K27me3 and H3K36me3); (ii) single stranded RNA-seq; (iii) transposable-accessible chromatin assays (ATAC-seq) and iv) whole-genome bisulphite sequencing (WGBS), creating a unique reference epigenome for CLL. These data were complemented with the 3D chromatin landscape in one CLL case measured by high-throughput chromatin conformation capture (HiC-seq) and promoter capture Hi-C (PChi-C). Furthermore, we mapped the active chromatin landscape of 100 CLL patients by H3K27ac ChIP-seq and ATAC-seq. Whole-genome sequencing data was available for 44 of these patients. We applied a broad range of bioinformatic tools to analyze the data in an integrative way.

Results: CLL is distinct from normal B cells for all layers of the reference epigenome (e.g. IGVH), and the active chromatin landscape in CLL is less differentiated than that in normal B cells. CLL cell lines are more closely related to naive memory B cells than to germinal center B cells and plasma cells. Interestingly, in CLL we not only saw activation of regions that are active in naive and memory B cells, but also an unexpected activation of genomic regions that are specifically active in germinal center B cells and plasma cells. Changes in activation in these and other regions could furthermore distinguish the two major clinical subgroups of CLL with unmutated and mutated immunoglobulin heavy chains (IGVH). CLLs did not only differ from normal B cells regarding the separate layers of information, but also using combined patterns of histone marks, which for example can define regulatory elements as active promoters (H3K4me3 and H3K27ac) or active enhancers (H3K27ac and H3K4me1). More specifically, we detected 534 genomic regions with de novo gain (n=498) or loss (n=36) of active regulatory regions in CLL. Large regions (>10kb) showing de novo gain of regulatory elements in CLL (n=51), were located into, close to, or interacted in 3D space with genes important for CLL pathogenesis, e.g., LEF1, BCL2 and FMOD. Interestingly, non-coding somatic mutations in IGVH mutated CLLs accumulate in these and other active regulatory regions, likely off-target effects of the somatic hypermutation machinery. Besides changes in regulatory elements, we observed that CLLs lost poised promoters, which are replaced by repressive active regions. This change, mainly occurring in developmental genes, does not affect gene expression levels, as these genes are already silent in normal B cells. It may however represent loss of plasticity during CLL pathogenesis in which these genes become permanently inactive.

Summary/Conclusions: With this integrative study, we generated new conceptual avenues to understand the complex link among the epigenetic, mutational, transcriptional and 3D chromatin landscape in CLL. In addition we provide the community with an extensive resource of epigenetic information of this lymphoid neoplasm.

S118 THERAPEUTIC DISRUPTION OF THE BAFF- B-CELL RECEPTOR CROSS-TALK IN CHRONIC LYMPHOCYTIC LEUKEMIA CELLS

C. Paiva1, T. Rowland1, B. Sreekantham1, O. Danilova1, A. Danilov1,* 1Oregon Health and Science University, Portland, United States

Background: Although small molecule inhibitors of BCR-associated kinases (BCRi) revolutionized therapy in CLL, they provide incomplete responses. Tumor necrosis factor receptor superfamily ligands BAFF and APRIL induce NFκB, which in turn upregulates pro-survival Bcl-2 family proteins and thereby drives anti-apoptotic responses, potentially accounting for resistance to BCRi. The exact roles of the individual NFκB pathways, as well as the implications of targeting BCR in context of BAFF signaling in CLL remain unclear.

Aims: We explored the mechanistic underpinnings of CLL cell survival in response to BAFF signaling.

Methods: We established a novel BAFF-expressing stromal co-culture model and dosed inhibitors of Bruton tyrosine kinase (BTK), ibrutinib, phosphoinoside-3 kinase (PI3K, idelalisib) and spleen tyrosine kinase (SYK, entosple tinib). We quantified CLL cell apoptosis, migration, NFκB activity, protein and mRNA expression by flow cytometry, immunoblotting, ELISA, RT-PCR and immunocytochemistry.

Results: CLL cells co-cultured with BAFF-expressing stroma were resistant to spontaneous apoptosis (12.3±3.2% after 24 h, vs 34.8±6.2% off stroma) and chemotherapy agents (bendamustine, fludarabine). Gene expression profiling exposed the NFκB pathway gene targets as the most significantly upregulated upon BAFF stimulation (p<0.0001). We and others have shown that BAFF-expressing stroma induces canonical and non-canonical NFκB in CLL. By contrast, while BAFF led to strong activation of the non-canonical NFκB with processing of p100 (to p52) by 4 h and a 5-fold increase in p52 DNA-binding activity by 24 h, canonical NFκB (RelA) activation was less pronounced. BAFF predominantly induced Mcl-1, compared to CD40L which strongly upregulated Bcl-X. BCR is a major driver of canonical NFκB signaling in CLL. Thus, we studied whether BAFF co-opted BCR signaling in CLL. BAFF induced rapid (15 min) phosphorylation of the proximal BCR kinases SYK and LYN, sustained for up to 4 h, as well as ERK, in CLL cells. AKT acti- vation occurred late (>2h), suggesting that BAFF induced AKT independent of BCR. BAFF-mediated BCR activation did not correlate with IGVH muta- tional status. Like IgM, BAFF induced CLL cell chemotaxis. SYK inhibition effectively antagonized survival and chemotaxis of BAFF-stimulated CLL cells. By contrast, targeting BTK or PI3K was less effective. All BCRi’s fully blocked canonical NFκB activation in BAFF-stimulated CLL cells (suggesting its dependence on BCR signaling), but none inhibited the non-canonical path- way. By contrast, pevonedistat, an inhibitor of Nedd8-activating enzyme which we have previously shown to abrogate TNFR-mediated NFκB activation, blocked both canonical and non-canonical NFκB activity in BAFF-stimulated CLL cells. SYK inhibitor entospletinib, but not other BCRi’s, decreased Mcl-1 expression in CLL cells co-cultured with BAFF-expressing stroma and abrogated BAFF-mediated upregulation of pSTAT3, a transcription factor which regulates Mcl-1. This was accompanied by a decrease in Mcl-1 transcript. BAFF receptor signals via the TRAF complex to induce non-canonical NFκB activation in neoplastic B-cells. We supposed that TRAF complex could be directly responsible for SYK activation by BAFF. Indeed, IP experiments demonstrated that SYK directly complexed with TRAF2/3 in BAFF-stimulated neoplastic B-cells.

Summary/Conclusions: Thus, BAFF-mediated induction of BCR-associated kinases and Mcl-1 contributes to CLL cell survival. SYK inhibition is a promising therapeutic strategy uniquely poised to antagonize crosstalk between BAFF and BCR, thereby disrupting the pro-survival microenvironment signaling in CLL.
S119
LOW MYBL2 EXPRESSION OBSERVED IN MYELODYSPLASTIC SYNDROME PATIENTS WITH WORSE PROGNOSIS IS ASSOCIATED WITH ALTERED DNA REPAIR MECHANISMS IN HAEMATOPOETIC STEM CELLS
R. Bayley1, L. Cancian1, C. Ward1, G. Volpe1, S. Dumon1, J. Gujar1, G. Stewart1, E. Petermann1, P. Garcia1,*
1Institute of Cancer and Genomic Science, University of Birmingham, Birmingham, United Kingdom

Background: MYBL2 is a transcription factor with roles in the cell cycle and genome integrity. MYBL2 is located on chromosome 20, within a region commonly deleted in human blood disorders (del20q). Our published data shows that reduced levels of MYBL2 predispose to development of myelodysplastic syndromes (MDS)-like disease in mouse models during ageing, indicating that MYBL2 could be acting as a tumour suppressor gene within del20q abnormality. Moreover, our previous work demonstrated that regardless of del20q deletion, MYBL2 expression is reduced in CD34+ bone marrow cells from MDS patients with worse prognosis. Because it has been shown that the cell of origin of MDS is the haematopoietic stem cell (HSC) and given the role of MYBL2 in DNA replication fork progression and maintenance of genome integrity, we hypothesised that low MYBL2 levels in HSC could contribute to elevated somatic mutations through changes in DNA repair pathways and drive disease development.

Aim: The aim of this study was to determine if low MYBL2 levels affect the double strand break (DSB) DNA repair damage response in HSC.

Methods: In this study we used our mouse model in which animals express ~50% normal levels of MYBL2 (Mybl2+/–). We characterised the ability of HSCs from young (7 weeks) and old (70 weeks) animals to respond to in vivo ionising radiation (5 Gy) and chemotherapy (CDDP) replication, apoptosis and colony formation ability. We measured the activation of the two main DNA repair pathways operating in the cells to deal with DSB: the error prone non-homologous-end-joining (NHEJ) and the error-free homologous recombination (HR) by assessing 53BP1 and Rad51 recruitment by immunofluorescence, respectively. Finally, we analysed the frequency of chromosome abnormalities present in the progeny of Mybl2+/– HSC that have previously been irradiated to determine the long term effects of changes in DNA repair.

Results: We observed that Mybl2+/– HSCs had limited proliferative potential and displayed an increased sensitivity to ionizing radiation which increased during ageing. Mybl2+/– HSCs also displayed altered kinetics of 53BP1 and Rad51 recruitment and clearance, including retention of 53BP1 foci at later time points following irradiation and decreased levels of Rad51 foci when compared to Mybl2+/+ HSCs. Using plasmid functional assays, we showed that Mybl2+/– HSCs are less sensitive to inhibition of DNA-PKC (required for NHEJ) but not ATM (required by HR). We also observed that after ionizing irradiation Mybl2+/– HSC progeny displayed an increased percentage of chromatids with fragile telomeres. Moreover, by making use of publically available RNA-seq data from Cimino et al, we have identified a clear association between low MYBL2 levels and low expression of DNA-repair genes in patients with worse prognosis.

Summary/Conclusions: In summary, we have shown that decreased expression of MYBL2 leads to an imbalance in the DSB DNA-repair pathway choice, ultimately resulting in increased genomic instability of the blood cell progeny. These findings are supported by a signature of deregulated DNA-repair genes which strongly associates with low MYBL2 levels in MDS patient samples, providing a mechanistic understanding for the progression of blood disorders occurring during ageing. This study demonstrates a novel role for MYBL2 in DNA repair in HSCs and suggests that low levels of MYBL2 in human MDS could contribute to the emergence of further genetic abnormalities by deregulation of DNA-repair pathways.

S120
A NOVEL GENETIC AND MORPHOLOGIC PHENOTYPE OF ARID2-MEDIATED MYELODYSPLASTIC SYNDROMES
H. Sakai1,2, N. Hosono1,3, H. Nakazawa2, B. Przychodzen1, C. Polpraser1, H. Carraway1, M. Sekeres1,2, T. Radirovitch1, K. Yoshida2, M. Sanada2, T. Yoshizato2, K. Kataoka2, M. Nakagawa2, H. Ueno2, Y. Background: Clinical heterogeneity of myelodysplastic syndromes (MDS) and related myeloid neoplasms reflects molecular diversity. Most common genetic associations with distinct clinical or pathomorphologic phenotypes have been described, but many other genetic somatic lesions exist and their clinical context still remains elusive. At rich interactive domain 2 (ARID2), which is located on chromosome 12q, encodes a component of the SWI/SNF complex that is involved in chromatin remodeling. In recent years multiple groups detected ARID2 mutations in a variety of solid tumors.

Aim: Here, we present whole exome sequencing–guided identification of novel ARID2 mutations in myeloid neoplasms. Specifically, in addition to copy number analysis and deep targeted and exome sequencing, here we include RNA sequencing and splicing analyses of the roles of splicingosomas in MDS and other myeloid neoplasms.

Methods: Bone marrow aspirates or blood samples were collected from 1,473 patients with MDS (n=455), myelodysplastic/myeloproliferative neoplasms (MDS/MPN) (n=201), myeloproliferative neoplasms (MPN) (n=56), sAML (n=221), and primary acute myeloid leukemia (pAML) (n=540) at the Cleveland Clinic and The University of Tokyo; the registered data at The Cancer Genome Atlas were also included. Diagnoses were classified using World Health Organization criteria. Informed consent for sample collection was obtained according to a protocol approved by each Institutional Review Board in accordance with the Declaration of Helsinki.

Results: By comprehensive genetic investigation of these cases, we characterized here cases (10%) in which decreased expression of ARID2 mediated their clinical effects in MDS and other myeloid neoplasms via multiple kinds of genetic lesions. We showed that insufficient ARID2 expression mainly in MDS arose from ARID2 mutations, deletions, and missplicing due to U2AF1 mutations that yield deleterious transcript. Clonal architecture analyses showed that ARID2 mutations and deletions occurred as initial events of MDS or myelodysplastic/myeloproliferative neoplasms, and not during progression to acute myeloid leukemia. Morphologically, progressive maturation in myeloid and erythroid lineages and hypolobated megakaryocytes (indicated by arrow heads in Figure 1) were common in cases with ARID2 mutations and deletions, and were also found in cases with U2AF1 mutations. Functionally, we utilized in vitro knockdown models of ARID2 expression in hematopoietic cell lines and bone marrow mononuclear cells. Since no homogenous deletion or mutation of ARID2 was identified, we transduced shRNA in neo-plastic and healthy hematopoietic cells to obtain disease models with partial reduction of ARID2 expression. Two myeloid cell lines (HL60 and K562) in which ARID2 expression was knocked down showed significantly lower cell counts compared to those with normal ARID2 expression, compatible with more apoptotic cells in knockdown experiments. Flow cytometric analysis of the cell lines with reduced ARID2 expression revealed increased cell-surface maturation markers, CD11b and glucosephorin A (GPA), suggesting that reduced expression of ARID2 resulted in more differentiation in myeloid and erythroid lineages. Knockdown of ARID2 failed to reduce colony formation in bone marrow mononuclear cells. These results indicate that reduced ARID2 expression might induce more differentiation in myeloid/erythroid lineages and more apoptosis to reduce cell populations without reduction of proliferation capacity in hematopoietic progenitor cells. Finally, we examined morphological findings associated with knockdown ARID2 expression. Compared to control cells, K562 cells with reduced ARID2 expression formed more hypolobated megakaryocytes, which confirmed morphological findings seen in ARID2 and U2AF1 defects.

Figure 1.

Summary/Conclusions: ARID2 is a MDS-suppressor gene whose expression is attenuated by multiple mechanisms as it shapes the distinct morphological phenotype of a subset of myelodysplasia.

THE VALUE OF NGS PANEL SEQUENCING TO MOLECULARLY DEFINE MYELOID MALIGNANCIES AND CLARIFY BORDERLINE CASES: A STUDY ON 39 GENES IN 1143 PATIENTS

C. Baer1, K. Peeters-Kern2, T. Haferlach1, T. Haferlach1, 1MLL Munich Leukemia Laboratory, Munich, Germany; 2Wellcome Trust Centre for Human Genetics, Oxford, United Kingdom

Background: The 2016 revision of the WHO classification for myeloid malignancies includes numerous molecular markers for classification and prognostication. Next generation sequencing allows analyzing relevant genes in one panel.

Methods: According to WHO 2016, 1143 patients were molecularly categorized as AML (n=261), MDS (n=176), MPN (n=19), CMML (n=51) or AML/MDS (n=21) and MDS/MPN overlap (n=28). Patients, who did not fulfill all characteristic criteria or had insufficient sample quality, were classified as "possible" AML (n=29), MDS (n=211), MPN (n=5), CMML (n=14) and as reactive (n=193) or unclear (n=136). DNA was isolated from BM (n=958) or PB (n=185) for NextSeq or MiSeq sequencing after TruSeq library preparation (all Illumina, San Diego, CA). Data was analyzed with SeqNext 4.3 (JSI Medical Systems, Kippenheim, Germany).

Results: Analyzing 39 genes, we found ≥ 1 molecular change in 90% of patients (500/556) with a definite morphologic diagnosis (median: 2 genes; max: 7). In de novo AML, 212/229 (93%) patients showed ≥ 1 molecular hit, of which 211 (92%) had aberrations that define WHO categories or have prognostic (according to ELN 2014) significance. More than 1 gene mutation was found in 166/229 patients (72%), including information of adverse impact (e.g. of 68 NPM1 positive patients, 17 had DNM3TA mutations and 20 FLRT3-ITD). Following NPM1, RUNX1 was the second most frequently mutated gene (46/225; 20%) and mutations were significantly more common in patients with ≥ 3 aberrant genes (30/107; 28%) than ≤ 2 (12/118; 10%). A similar pattern was found in s-AML and t-AML. In the cohort of "possible" AML (including MDS overlap), 45/48 (94%) patients had ≥ 1 hit. Most frequently mutated were ASXL1 (16/48; 33%), TET2 (12/44) and SRSF2 (19/48; 41%). 16% had all three mutated. This combination is also seen frequently in the three-way interaction in CMML (10/44; 23%). In MDS, 124/157 (79%) cases showed mutations, of which 108 had ≥ 1 prognostic change (according to Bejar, 2015). The prognostically favorable SF3B1 mutation was present in 31/157 (20%) and significantly enriched among cases with ring sideroblasts (p<0.001). Overall, TET2 showed the highest mutation rate (25%) and was also the most commonly mutated gene in cases with ≥ 2 AML/MPN overlap (36/190; 19%), reactive morphologic changes (17/201; 8%) or even unclear morphology (19/116; 17%). Of these three subsets, five patients had only the TET2 mutation with <10% burden, which is observed in clonal hematopoiesis of indeterminate potential (CHIP), too. However, using panel sequencing in cases with possible MDS, unclear or reactive morphology revealed at least one molecular marker for clonal disease in 47% (91/199), 36% (43/118) or 17% (36/211) of cases, respectively (excluding sole ASXL1, DNM3TA, TET2 mutations with <10% burden).

Summary/Conclusions: WHO 2016 requires information on numerous genes for diagnosis, prognosis and therapeutic decisions. This challenges conventional approaches, which determine all in one panel. We demonstrate the feasibility in routine settings for a broad spectrum of myeloid malignancies and identify 1) relevant patterns and mutation interactions; 2) genetic aberrations supporting diagnosis for samples with borderline morphology or poor quality and 3) patient-specific clonality usefulness for follow-up.

IDENTIFICATION OF ABERRANTLY SPliced GENES AND DEREGULATED PATHWAYS/Gene ONTOLOGY THEMES IN MYELODYSPLASTIC SYNDROME PATIENTS WITH SPlicing FACTOR GENE MUTATIONS

1Department of Pathology and Tumor Biology, Kyoto University, Kyoto, Japan; 2Department of Molecular Medicine, University of Pavia, 3Department of Hematology Oncology, Fondazione IRCCS Policlinico San Matteo & University of Pavia, Pavia, Italy; 4Radcliffe Department of Medicine, University of Oxford, United Kingdom; 5Department of Medicine, Karolinska Institute, Stockholm, Sweden; 6Laboratory of DNA Information Analysis, The University of Tokyo, Tokyo, Japan

Background: Myelodysplastic syndromes (MDS) and related myeloid disorders (“myelodysplasia”) are a heterogeneous group of clonal hematopoietic disorders with a highly variable clinical outcome.

Aims: The purpose of this study was to establish a novel gene expression-based classification of myelodysplasia for better prognostication.
Summary/Conclusions:

The Class-II signature was shown to be more dramatically up-regulated during risk acute myeloid leukemia based on the expression of 17 genes related to erythroid lineage. The erythroid signature was rather suppressed in the Class-II subtype, which was characterized by increased expression of genes related to progenitor cells. Compared to the Class-I subtype, the Class-II subtype was associated with a significantly shorter survival in both univariate (hazard ratio [HR] 7.3 [95% CI, 1.3–41], P <0.01) and multivariate analysis (HR 6.8 [95% CI, 1.5–32], P=0.015). High frequency of leukemic transformation in the Class-II subgroup (38%) contrasted to no leukemic transformation in the Class-I subgroup. The prognostic significance of our classification was validated in an independent cohort of 183 patients.

Results: Unsupervised clustering of gene expression data of bone marrow blasts from 100 patients identified two subgroups (Class-I and Class-II). The patients in the Class-II subgroup had higher percentages of bone marrow blasts compared to those in the Class-I subgroup (median 2% vs 11%, P <0.01). Pathway analysis revealed up-regulation of many signaling pathways in the Class-II subgroup. The Class-I subtype showed highly significant up-regulation of the genes related to erythroid lineages. The erythroid signature was rather suppressed in the Class-II subtype, which was characterized by increased expression of genes related to progenitor cells. Compared to the Class-I subtype, the Class-II subtype was associated with a significantly shorter survival in both univariate (t-test HR 7.2 [95% CI, 3.0–17], P <0.001) and multivariate analysis (HR 6.8 [95% CI, 1.5–32], P=0.015). High frequency of leukemic transformation in the Class-II subgroup (38%) contrasted to no leukemic transformation in the Class-I subgroup. The prognostic significance of our classification was validated in an independent cohort of 183 patients.

We also constructed a model to predict the subgroups using gene expression profiles of BMMNCs. The model was applied to 114 patients with BMMNC samples, of whom 47 (41%) were predicted to be the Class-II subgroup. Compared to the predicted Class-I subgroup, the Class-II subgroup was associated with a significantly shorter survival in univariate analysis (HR 7.2 [95% CI, 3.0–17], P <0.001). Again, association was more pronounced for leukemia transformation (HR 18 [95% CI, 4.2–80], P <0.001) than for overall survival. Multivariate analysis also demonstrated that the predicted Class-II subgroup was independently associated with leukemic transformation (HR 7.3 [95% CI, 1.3–41], P=0.024). Finally, we compared the prognostic value of our model with that of the LSC17 score, which has recently been proposed to predict a subset of poor risk acute myeloid leukemia based on the expression of 17 genes related to a leukemic stem cell signature. Our model outperformed the LSC17 score in predicting clinical outcomes of myelodysplasia, especially leukemia progression. The Class-II signature was shown to be more dramatically up-regulated during clonal evolution of myelodysplasia than the LSC17 score, which might be the basis of a better prediction of leukemia progression in our model.

Summary/Conclusions: Comprehensive transcriptomic analysis identified two subgroups of myelodysplasia with biological and clinical relevance, which could improve risk prediction and treatment stratification of myelodysplasia.

Methods: We performed transcriptome sequencing of bone marrow mononuclear cells (BMMNCs) and/or CD34+cells obtained from patients with myelodysplasia. Consensus clustering was used to identify stable patient clusters. A classifier of the gene expression-based subgroups was constructed using the 100 CD34+cell samples as a training set, followed by validation in an independent cohort of 183 MDS patients. Another classifier was constructed using BMMNC samples from 51 patients, who had been assigned to the subgroups by the gene expression data of their CD34+cells. Prognostic significance of the model was tested in 114 patients of myelodysplasia.

Background: Checkpoint blockade using anti-PD-1/PD-L1 antibodies is a highly promising therapy for cancer, frequently showing dramatic anti-tumor responses in a wide variety of tumor types. Particularly, an exceptional response to anti-PD-1 antibodies has been demonstrated for classical Hodgkin lymphoma (HL), which is characterized by frequent copy number gains/amplifications in the PD-L1 and PD-L2 loci. Moreover, up-regulation of PD-L1/PD-L2 genes is invariably associated with leukemic transformation (HR 7.3 [95% CI, 1.3–41], P <0.01) than for overall survival. Multivariate analysis also demonstrated that the predicted Class-II subgroup was independently associated with leukemic transformation (HR 7.3 [95% CI, 1.3–41], P=0.024). Finally, we compared the prognostic value of our model with that of the LSC17 score, which has recently been proposed to predict a subset of poor risk acute myeloid leukemia based on the expression of 17 genes related to a leukemic stem cell signature. Our model outperformed the LSC17 score in predicting clinical outcomes of myelodysplasia, especially leukemia progression. The Class-II signature was shown to be more dramatically up-regulated during clonal evolution of myelodysplasia than the LSC17 score, which might be the basis of a better prediction of leukemia progression in our model.

Summary/Conclusions: Comprehensive transcriptomic analysis identified two subgroups of myelodysplasia with biological and clinical relevance, which could improve risk prediction and treatment stratification of myelodysplasia.

Summary/Conclusions: Comprehensive transcriptomic analysis identified two subgroups of myelodysplasia with biological and clinical relevance, which could improve risk prediction and treatment stratification of myelodysplasia.
shown previously to increase FOXO1 nuclear localization and activity, have been linked to diminished survival in DLBCL patients uniformly treated with rituximab-based immunotherapy. Although the contribution of FOXO1 mutations to the therapeutic resistance of B-NHLs becomes apparent, the molecular mechanism underlying this phenomenon has not been explained so far. The diminished levels of CD20 on the cell surface of tumor cells are among several potential mechanisms underlying the resistance to treatment with anti-CD20 monoclonal antibodies.

**Aims:** We have recently reported that the tonic BCR signaling activates FOXO1, and that inhibitors of the downstream BCR signaling pathways down-regulate CD20 expression. Therefore, here we sought to determine whether FOXO1 might regulate the abundance of CD20 on the surface of tumor cells thus influencing the response to rituximab-based therapies.

**Methods:** We used CRISPR/Cas9 genome editing technology and lentiviral transduction to study the role of FOXO1 protein in CD20 regulation. qRT-PCR and Dual Luciferase Assays was done to determine the influence of FOXO1 on CD20 transcription and its effect on tumor cells. We aimed to discern tumor cells that respond the best to drugs and to unravel the molecular interaction between FOXO1 and CD20 promoter. We performed EMSA and ChIP experiments. For animal studies we used SCID Fox Chase mice model. All in vitro experiments were carried out at the animal facility of The Francis Crick Institute according to the guidelines and were approved by the Ethics Committee.

**Results:** To determine the potential role of FOXO1 protein in CD20 regulation, we disrupted FOXO1 focus using the CRISPR/Cas9 genome editing technology in Raji cells. In vitro complement-dependent cytotoxicity assay we show that ablation of FOXO1 results in upregulation of CD20 levels and improved resistance to rituximab efficacy. To see whether FOXO1-dependent up-regulation of CD20 transcript was translated into tumoral phenotype, we used molecular interaction between FOXO1 and CD20 promoter and performed EMSA and ChIP experiments. For animal studies we used SCID Fox Chase mice model. We found that mice with treated with systemic rituximab survived longer when inoculated with sgFOXO1-transduced Raji cells as compared with mice inoculated with control Raji cells. Consistently, using clinically tested PI3K-AKT inhibitors - MK-2206 and GDC-0068 – in a set of CLL primary samples we show that also pharmaceutical inhibition of FOXO1 activity upregulated surface CD20 levels. Moreover, we demonstrated that FOXO1 regulate the CD20 promoter activity. In different B-cell lymphoma cell lines MK-2206 and GDC-0068 significantly downregulated the levels of M54A1 transcript (encoding CD20). Finally, using both EMSA and ChIP assays we detected specific binding of FOXO1 to the M54A1 promoter to the extent comparable to other known FOXO1 target genes.

**Summary/Conclusions:** Collectively, our results indicate that FOXO1 is strong negative regulator of CD20 expression and add new insights into the mechanisms underlying the contribution of FOXO1 mutations to the resistance of B-NHLs to R-CHOP therapy. In light of current knowledge and our observations presented in this study, FOXO1 inhibition represents a novel strategy to increase the efficacy of anti-CD20 monoclonal antibodies.

**ALPHA-KETOGLUTARATE EXPOSES METABOLIC VULNERABILITIES IN B-CELL LYMPHOMAS**

**D. Jiang1, A.-P. Lin1, L. Wang1, R. Aguiar1,**

**1Hematology/Oncology - Medicine, University of Texas Health Science Center, San Antonio, United States**

**Background:** Metabolic rewiring is a cancer hallmark. These metabolic changes can be secondary to a broader oncogenic-driven deregulation (e.g., MYC), or they may be more specific and result from mutations in enzymes (e.g., IDH1 and IDH2) that directly control energy flux in the cell. Mutant IDH acquires a neomorphic activity and aberrantly generates high levels of D2-HG/α-KG with attending impaired dioxygenase function. Together, these data suggested no: 2013/11/B/NZ5/03240 (BP) and 2015/18/E/NZ6/00702 (MW); MNiSW, Poland, project no: DI2014027344 (NM)) and European Comission (Horizon 2020, project no: 692180-STREAM-H2O20-TWINN-2015, CSA action (JG).

**Figure 1.**

**Summary/Conclusions:** We showed that α-KG induces growth suppression/apoptosis in mature B cell tumors, in vitro and in vivo. We demonstrated that proximally α-KG exerts its tumor suppressive effects by inhibiting ATP synthase activity, the effects of α-KG on cellular ATP levels, the measurement of AMPK activity and of the mTORC1 kinase.

**Results:** The cell-permeable DM-KG induced a marked dose-dependent growth suppression in a panel of DLBCL cell lines that encompasses the molecular heterogeneity of this disease (ABC, n= 5, GCB, n=5 and OxPhos, n=4). In most instances, the growth inhibition exceeded 80% of vehicle control exposed cells and it could be detected as early as 24h and reached its peak at 72-96h post-exposure (Figure 1A). In all cell lines examined, induction of apoptosis accounted for most of the anti-lymphoma effects of DM-KG. There was no clear segregation between the DLBCL molecular subtype and DM-KG-induced growth inhibition (e.g., the ABC cell lines Ly10 and Ly3 were the most sensitive and most resistant, respectively, Figure 1A). Remarkably, we found that normal mature B cells (murine and human) were resistant to growth inhibition and apoptosis induced by DM-KG (Figure 1C). Contrary to that, exposing viable primary CLL, FL and DLBCL cells to DM-KG significantly induced apoptosis (p<0.01) in all tumors examined (n=17). In mouse models of lymphoma, we showed that also pharmacological inhibition of FOXO1 activity upregulated surface CD20 levels. Moreover, we demonstrated that FOXO1 regulates the CD20 promoter activity. In different B-cell lymphoma cell lines MK-2206 and GDC-0068 significantly downregulated the levels of M54A1 transcript (encoding CD20). Finally, using both EMSA and ChIP assays we detected specific binding of FOXO1 to the M54A1 promoter to the extent comparable to other known FOXO1 target genes.

**Summary/Conclusions:** Collectively, our results indicate that FOXO1 is strong negative regulator of CD20 expression and add new insights into the mechanisms underlying the contribution of FOXO1 mutations to the resistance of B-NHLs to R-CHOP therapy. In light of current knowledge and our observations presented in this study, FOXO1 inhibition represents a novel strategy to increase the efficacy of anti-CD20 monoclonal antibodies.

**DELETION OF THE F-BOX PROTEIN NIPA (NUCLEAR INTERACTION PARTNER OF ALK) IMPAIRS NPM-ALK DRIVEN TRANSFORMATION**

**L. J. Lippert1, V. Shlyakhto 1, S. Kreutmair 1, C. Klingeberg 1, C. Albers 2, 3,**

**1Hematology/Oncology - Medicine, University of Texas Health Science Center, Freiburg, 2Medical Department, Division of Hematology, Oncology and Stem Cell Transplantation, University of Freiburg Medical Center, Freiburg, 3Deutsches Konsortium**
Background: ALCL is a high grade lymphoma characterized by anaplastic morphology, expression of CD30 (K-1) and T- or null cell phenotype. In 60% of systemic ALCL, the translocation t(2;5)(p23;q35) leads to expression of the oncogenic NPM-ALK kinase. NPM-ALK infected NIPA deficient mice are an F-box/Protein contributing to the timing of mitotic entry by defining an oscillating ubiquitin E3 ligase. NIPA deficient mice are viable but sterile due to impaired DNA double strand break repair. Co-expressed with NPM-ALK, NIPA is constitutively phosphorylated. However, the role of NIPA in NPM-ALK induced lymphomagenesis and the functional impact of this interaction remain unknown.

Aims: In this study, we aim to investigate the effect of NIPA deficiency on NPM-ALK driven cell proliferation and transformation in order to characterize the function of the protein in ALCL-induced lymphomagenesis.

Methods: Primary Nipa-/-MEFs infected with NPM-ALK were plated in softagar assays to evaluate their transformation ability. Moreover, NIPA was downregulated through targeted genetic approaches in Karpas299 and NPM-ALK infected BarF3 cells, which were analyzed regarding proliferation, signaling, and apoptosis. To assess the impact of NIPA deletion in vivo, we used a retroviral bone marrow transplantation model resembling human ALCL. Based on a Cre/loxP system under the LCK-Promotor, NPM-ALK expression and Nipa-deletion are restricted to early T cells. In wildtype background, mice die of systemic Thy1.2+lymphoma with a latency of 4-6 months, developing neoplastic T-cell infiltration of bone marrow and lymphatic organs. Lymphomas were analyzed regarding immunphenotype and clinical presentation.

Results: Primary Nipa-/-MEFs infected with NPM-ALK were plated in softagar showed significantly reduced colony formation potential upon NPM-ALK expression (38 vs 79 CFUs; p<0.001). These results were substantiated in human and murine cell lines, where significantly reduced proliferation ability was observed in NIPA downregulated NPM-ALK expressing BarF3 cells (74% of ctrl; p<0.001) as well as in Karpas299 cells infected with NIPA miR (66% of wt growth; p<0.01). Moreover, treatment with the ALK inhibitor TAE-684 gave evidence of possible synergistic effects of ALK inhibition and NIPA knockdown. Mice transplanted with Lck-CreTG12; Myelo-MSNAIE infected bone marrow cells showed significantly prolonged disease development and survival (143d vs 79d in wt). Morphologically, mice presented with enlarged thymi, splenomegaly, lymphadenopathy, and bone marrow infiltration. Immunphenotyping showed a pure T-cell phenotype in Nipa-/- lymphomas, thus resembling wildtype. In a long-latency model of NPM-ALK expression in enriched HSCs, a significantly prolonged survival (110 vs 80 days; p<0.01) and reduction of spleen colonies (10 vs 28 colonies/spleen; p<0.001) as well as in Karpas299 infected with NIPA miR and Nipa-/-MEFs infected with NIPA deficient NPM-ALK expressing cells, whereas cell cycle distribution seems not to be altered in knockout cells.

Summary/Conclusions: Taken together, we were able to show that NIPA is crucial for cell proliferation and transformation upon NPM-ALK expression. Investigations of the NIPA knockout mouse in a clinical relevant ALCL model highlight the importance of the NIPA/NPM-ALK axis in lymphoma development. Further analyses may thus elucidate NIPA as a novel molecular target for therapeutic intervention.

S128 THERAPEUTIC EFFECTS OF CAN-NP-ALK: PRECLINICAL EXPERIENCE WITH A NOVEL ALK INHIBITOR FOR TREATMENT OF ALCL

Matteo, Pavia, 9Rare Disease Center, Fondazione IRCCS Ca’ Granda, Milano, Italy

Background: Gene therapy for transfusion dependent beta-thalassemia, as an alternative cure to autologous HSCT, is based on the autologous transplantation of hematopoietic stem cells (HSCs) engineered by lentiviral vectors expressing a transcriptionally regulated human beta-globin gene.

Aims: Our contribution to this field was devoted to the clinical development of a gene therapy protocol based on high-titer vector GLOBE, use of lenograstim and plerixafor as source of HSCs and a conditioning regimen based on myeloablative treosulfan and thiotepa favoring efficient engraftment of corrected cells with reduced toxicity (TIGET-BTHAL; EudraCT number 2014-004860-39).

Methods: Based on the efficacy and safety of the clinical studies, the clinical trial TIGET-BTHAL was approved and started in 2015 at Scientific Institute San Raffaele, Milan, Italy. The clinical study foresees treatment of 10 patients: 3 adults followed by 7 minors, with a staggered enrolment strategy based on evaluation of safety and preliminary efficacy in adult patients by an independent data safety monitoring board before inclusion of pediatric subjects. The chosen route of administration of gene modified HSCs is intraosseous in the posterior-superior iliac crests, bilaterally, with the aim of enhancing engraftment and minimizing first-pass intravenous filter.

Results: As of February 2017, seven patients (3 adults and 4 pediatric patients) with different genotypes (β0/β0, β+ and β-/β+) have been treated with GLOBE-transduced CD34+ cells at a dose of 16x10^6-19.5x10^6 cells/kg and a vector copy number (VCN)/cell ranging from 0.7 to 1.5. The procedure was well tolerated by all patients, with no product-related adverse events. Multilineage engraftment of gene-marked cells was observed in all tested peripheral blood and bone marrow samples. Polyclonal vector integrations profiles have been detected in the first 3 patients tested.

Summary/Conclusions: So far, the clinical outcome indicates reduction in transfusion requirement in adult patients and greater clinical benefit in younger patients. Follow up analysis are ongoing and updated clinical outcome will be presented.

S129 LUSPATERCEPT INCREASES HEMOGLOBIN AND DECREASES TRANSFUSION BURDEN IN ADULTS WITH β-THALASSEMIA

1Turin University, Turin, 2Second University of Naples, Naples, 3Arcispedale S. Anna, Cona, Ferrara, Italy, 4Laiko General Hospital, Athens, Greece, 5Ospedale “A. Perrino”, Brindisi, 6AORN “A. Cardarelli”, Naples, 7ARNAS Garbaldi, Catania, 8CEMEF, Medicina 2, Modena, Italy, 9Acceleor Pharma Inc, Cambridge, 10Cellgene Corporation, Summit, United States

Background: Luspatercept (ACE-536), a fusion protein containing a modified activin receptor type IIB, is being developed for the treatment of β-thalassemia. Luspatercept binds to select TGF-β superfamily ligands (such as GDF11) reducing aberrant Smad2/3 signaling and promoting late-stage erythroid differentiation and increased hemoglobin (Hgb). Luspatercept corrected the effects of ineffective erythropoiesis in a mouse model of thalassemia (Surargani R, Blood, 2015). Increased Hgb has been tolerated in a phase 1 study in healthy volunteers (Attie K, Am J Hematol, 2014).

Aims: This ongoing, phase 2, multicenter, open-label study followed by a long-term extension (ext) study evaluates the effects of luspatercept in patients (pts) with either transfusion-dependent (TD) or non-transfusion-dependent (NTD) β-thalassemia with key endpoints of erythroid response (including Hgb increase) and pt-reported quality-of-life (QoL) in NTD patients, and reductions in RBC transfusion burden in TD patients.

Methods: Inclusion criteria: age ≥18 yr and either TD (≥4 RBC U/8 weeks prior
to first dose, confirmed over 6 months) or NTD (<4 RBC U/I8 weeks prior to first dose with baseline Hgb <10 g/dL). Pts were treated every 3 weeks subsequently for up to 5 doses; 8 cohorts were treated at dose levels from 0.2-1.25 mg/kg. Pts in the expansion cohort and those who rolled over to the ext study were treated at ≥0.8 mg/kg with titration up to 1.25 mg/kg (base completed NCT01745940; ext ongoing NCT02268409).

Results: Sixty-three patients with TM and osteoporosis participated in the phase 2b clinical trial. Main inclusion criteria included adult patients (>30 years of age) with TM and BMD T-score between -2.5 and -4.0 in at least one of the evaluated sites (the results of bone markers will be presented in the conference), suggests that DMB, given twice per year, increases the BMD of the L1-L4 more efficiently than placebo (in combination with vitamin D; 12 months). 12% of patients were diagnosed with TM and osteoporosis, with excellent safety profile. Furthermore, DMB increased the FN BMD, which was not increased in the placebo arm, while DMB has also a positive effect on WR BMD compared to placebo. These data support the use of DMB for the management of TM-induced osteoporosis.

**Summary/Conclusions:** This first analysis of our phase 2b study regarding the effects of DMB on BMD of different sites (the results of bone markers will be presented in the conference), suggests that DMB, given twice per year, increases the BMD of the L1-L4 more efficiently than placebo (in combination with vitamin D; 12 months). 12% of patients were diagnosed with TM and osteoporosis, with excellent safety profile. Furthermore, DMB increased the FN BMD, which was not increased in the placebo arm, while DMB has also a positive effect on WR BMD compared to placebo. These data support the use of DMB for the management of TM-induced osteoporosis.

**LONG-TERM HEALTH STATUS AFTER HSC TRANSPLANTATION FOR THALASSEMIA: THE FRENCH EXPERIENCE**

I. Rahal1, C. Galambrun2, Y. Bertrand1, C. Paillard1, P. Franque1, C. Pondarré1, R. Peffault De Latour6, M. Michallet7, D. Steschenko8, C. Piguet9, C. Berger10, P. Simon1, I. Agot15, I. Thuret16,17

### Background:

In clinical practice, allogeneic hematopoietic stem cell transplantation (HSCT) is the only treatment offering a definitive cure for patients with beta-thalassemia. Its outcome has improved over the last 3 decades with current 5-year disease-free survival up to 90% when transplants are performed in childhood from an HLA-identical sibling. Few data are available on long-term toxicity and frequency of chronic complications after transplant.

### Aims:

The purpose of this study was to evaluate the long-term health status after a successful allogeneic HSCT for beta-thalassemia major in a national cohort of patients.

### Methods:

This French retrospective study included patients who successfully received allogeneic HSCT between 1985-2012 and were alive at least 2 years after HSCT. Study was based on data collected in the national registry of patients with beta-thalassemia and conducted in collaboration with the French DIGHO network. The outcome was correlated with the data recorded by physicians through reference or transplant center visits. Collected data included medical examination results, long-term treatments administered and laboratory tests (serum ferritin, Hb, liver enzymes, creatinine level and thyroid evaluation).

### Results:

A total of 134 patients had received allogeneic HSCT for beta-thalassemia in France from 1985 to 2012. 107/134 patients experienced successful HSCT (6 after a second transplant) and were alive 2 years after transplantation. Six were not analyzed (back to their country or lost of follow-up) and two died of infections (6 months). 125 patients were analyzed for long-term effects. Median age at HSCT was 5.9 years (8 month-26 years). The source was bone marrow in 85% of cases and a matched sibling donor was used in 90% of cases. Conditioning mostly consisted (85%) of busulfan and cyclophosphamide (oral busulfan in 52%). Median age at the last visit was 19 years. Chronic complications, similar to those observed in patients treated with transfusion and chelation therapy occurred after transplant in 12% of patients: 7 hypothryoidism, 2 heart failure, 5 diabetes. 2 patients had chronic respiratory failure related to transplant. The height SDS improved after HSCT if performed at a young age. Weight
Background: Donor-derived red blood cells (RBC) are the most common form of cellular therapy. However, the source of cells is dependent on donor availability with a potential risk of allo-immunization and blood borne diseases.

Aims: We aim to produce unlimited numbers of cultured RBC with a defined 'universal donor' phenotype for transfusion purposes.

Methods: To this end we prepare for a clinical test using autologous cultured RBC to test their in vivo stability. In parallel we develop methods for unlimited production of cultured RBC. An immortal source to produce in vitro cultured RBCs (cRBC), such as iPSCs would allow selection of 'universal donor' RBC, or provide an autologous end product with the absence of immune reactions.

Results: The in vitro production of RBC has proven to be successful; however there are barriers to overcome prior to clinical application, e.g. xeno-free culturing methods, scale up cultures to obtain transfusion units (1-2 x 10^12 erythrocytes), and for iPSC we need virus- and transgene-free reprogramming protocols. To solve the above mentioned issues a customised humanized GMP-grade medium (Cellquin) was generated in order to control erythroid culture parameters and to reduce culture costs. This medium allowed 1-10^12 erythropoiesis from PBMCs to pure adult EBL cultures within 25 days, comparable to non-GMP commercial media. To generate iPSC, a non-integrative polyclonostic episomal vector containing (OCT4-SOX2-KLF4-cMYC-LIN28) was reprogrammed with non-GMP commercial media. To generate iPSC, a non-integrative polyclonostic episomal vector containing (OCT4-SOX2-KLF4-cMYC-LIN28) was reprogrammed with non-GMP commercial media.

Summary/Conclusions: Here we showed that our monolayer approach is simple, highly controlled and compatible with upscaling. Avoiding virus-, integrative reprogramming, feeders and with our GMP-grade media we maintained a cost effective system moving toward clinical application.

AML Biology I: Towards molecular therapies

Background: Acute Myeloid Leukemia (AML) frequently harbors chromosomal rearrangements involving the Mixed Lineage Leukemia (MLL) gene. More than 65 different MLL fusion genes exist and many of them have been described to act as strong cancer drivers. While critical effectors of several distinct MLL fusion proteins (MLL-FPs) were identified, it is not clear if transforming mechanisms are conserved across the entire family of MLL fusions.

Aims: We hypothesized that common oncogenic mechanisms are encoded in stable physical and genetic MLL-fusion-specific interaction networks. Thus, we aimed to identify common critical effectors of different MLL fusion proteins that are presumed to employ different mechanisms of oncogenic transformation.

Methods: Protein complexes of 7 molecularly distinct, affinity-tagged MLL-FPs (MLL-AF4, MLL-AF9, MLL-ENL, MLL-CBP, MLL-EE, MLL-GAS7 and MLL-AF1p) were purified from stable cell lines allowing for inducible, single-copy transgene expression and characterized by mass spectrometry. Data analysis identified a comprehensive protein-protein interaction network, which was functionally interrogated by a subtractive shRNA screening approach. Validation experiments included detailed RNAi- and CRISPR/Cas9-mediated loss of function experiments in cell lines and primary cells in vitro and in vivo, using readouts for changes in proliferation, differentiation, apoptosis and DNA damage.

Results: Characterization of the protein complexes nucleated by 7 MLL fusion proteins by affinity purification coupled to mass spectrometry (AP-MS) revealed a densely interconnected protein-protein interaction network of 963 proteins, comprising previously known MLL-interacting protein complexes (such as PRC2 or SWI/SNF), as well as a high number of new interaction partners of MLL. 128 proteins were found to interact with ≥5 of all 7 MLL-fusions. This subset of conserved MLL-interaction partners was highly enriched for proteins with function in chromatin metabolism and transcriptional control. Systematic functional investigation of the conserved MLL-fusion proteome using subtractive shRNA screens identified the methyltransferase SETD2 as a critical effector of MLL fusion proteins. Both RNAi-based suppression and CRISPR/Cas9-mediated mutagenesis of SETD2 induced myeloid differentiation and apoptosis in human and mouse MLL-rearranged cell lines, while having only modest effects on the proliferation of MLL-wild-type leukemia cells. Depletion of SETD2 in MLL-fusion transformed mouse fetal liver cells resulted in loss of serial re-plating capacity in vitro and prolonged disease onset in vivo. Furthermore, knockdown of SETD2 caused a proliferative disadvantage in primary cells from AML patients with different MLL-rearrangements without affecting MLL-wild-type AML cells. We found that SETD2 was essential for efficient repair of DNA breaks, as SETD2-deficient leukemia cells showed increased levels of DNA damage and activation of p53, leading to the accumulation of mutations.

Summary/Conclusions: In summary, our data highlight the functional relevance of combined proteomic-genomic cellular screening to identify critical effectors of MLL-FPs. In addition, our study identifies a novel role for SETD2 in the maintenance of genomic integrity during initiation and progression of MLL-rearranged AML and establishes SETD2 as a therapeutic target in leukemia with low genomic complexity.
C/EBPα can act as a gain-of-function allele with distinct molecular properties. However, the molecular basis of C/EBPα p30-induced leukemogenesis is incompletely understood.

Aims: We hypothesized that the interaction between the oncogenic C/EBPα p30 isoform and the MLL/SET histone methyltransferase complex is required for p30-dependent epigenetic and transcriptomic changes that contribute to leukemogenesis. Therefore, we aimed to investigate the sensitivity of CEBPA mutant AML to perturbation of MLL/SET function.

Methods: We used CRISPR/Cas9-mediated mutagenesis to interfere with the MLL/SET complex in myeloid progenitor cells from a Cebpap30/p30 AML mouse model. Cellular competition assays were used to assess changes in proliferative capacity and colony formation. Further, MLL activity was inhibited by small molecules that block the Menin-MLL interaction. In both cases, proliferation, myeloid differentiation and apoptosis were used as readouts. Global changes in gene expression were measured by RNA-seq.

Results: We initially confirmed, via ChIP, that C/EBPα and MLL co-localize on the C/EBPA and CEBPB promoters, indicating functional co-occupancy in gene regulation. To investigate the importance of different, annotated functional domains within the MLL protein in the context of C/EBPα p30 expression, we introduced targeted mutations across the MLL gene in Cebpap30/p30 cells using the CRISPR/Cas9 system. This analysis revealed a strong dependence of C/EBPα expression on the expression of an intact MLL protein. Surprisingly, loss of the enzymatic activity of Mll by mutagenic targeting of the SET domain did not significantly affect cell survival. In contrast, cells were particularly sensitive to mutagenesis of the Menin-binding motif in Mll. Mll targeting strongly induced myeloid differentiation in Cebpap30/p30 cells as measured by increased levels of cell surface markers. To further investigate the functional role of Mll upon pharmacological perturbation of the MLL/SET complex, we used MI-463, a potent small-molecule inhibitor of the Menin-MLL interaction. Inhibitor treatment led to a time- and dose-dependent impairment of proliferation, induction of cell cycle arrest and increased apoptosis in Cebpap30/p30 cells. RNA-seq analysis of MI-463 treatment indicated gene expression changes associated with myeloid differentiation, which could be confirmed by flow cytometry. Importantly, expression of C/EBPα p30 was associated with hypersensitivity to Menin-MLL inhibition, as Cebpap30/p30 cells were 2-6 fold more sensitive than other leukemia cell lines of mouse and human origin.

Summary/Conclusions: We hypothesize that C/EBPα p30 AML is highly sensitive to perturbation of the MLL/SET complex, either via genetic ablation of MLL or through pharmacological inhibition of the Menin-MLL interaction. Our data indicate that leukemic mutations of C/EBPα selectively cooperate with the SET/MLL complex to regulate gene expression. These findings expand our understanding of and may inform new therapeutic strategies for N-terminal CEBPA mutated AML.

S135 INHIBITION OF THE MYELOID MASTER REGULATOR PU.1 AS A THERAPEUTIC STRATEGY IN ACUTE MYELOID LEUKEMIA

I. Kim1,*, C. Hall1, E. H. L. L. Leboda2, K. Huang3, A. Kumar1, A. A. Farahat3, B. Bartholdy1, S.-R. Narayanagari1, L. A. Carvajal1, J. Chen1, A. Ambesi-Impiumbato4, A. A. Ferrando4, I. Martzaris1, E. Gavathiotis1, A. Verma1, B. Will1, D. W. Boykin1, W. D. Wilson5, G. M. Koop1,6,7, Steidl1,2,3, Albert Einstein Cancer Center, Albert Einstein College of Medicine, New York, United States, 2Univ. Victoria University, Gustave-Roussy, Villejuif, France, 3Department of Chemistry, Georgia State University, Atlanta, 4Institute for Cancer Gene Therapy, Columbia University, New York, United States

Background: Functionally critical decreases in PU.1 levels or activity are present across various different genetic and epigenetic subtypes of AML, and overall represent more than 50% of AML cases (Sive et al. Leukemia. 2016). However, approaches for the specific therapeutic targeting of these patients are thus far lacking.

Aims: Retrospective analysis of PU.1 expression has previously been exploited but efforts to pharmacologically target the PU.1 protein have been unsuccessful. Here, we tested the therapeutic potential of PU.1 binding to chromatin critically depends on additional minor groove contacts upstream of the core ETS binding motif, which determine selectivity for PU.1. We used an integrated screening strategy utilizing biosensor surface plasmon resonance, DNA footprinting, and cell-based dual-color PU.1 reporter assays. Finally, we explored additional cellular outcome tests as first-in-class PU.1 inhibitors. Targeted occupancy by our compounds in the minor groove induces perturbations in DNA conformation that are transmitted to the PU.1 site in the major groove and thus inhibit PU.1 binding via an allosteric mechanism. Functionally, treatment with 3 different compounds increased cell growth and colony forming capacity, increased apoptosis, and disrupted serial replating capacity of PU.1(p30) AML cell lines, and a majority of primary AML cell samples. ChIP and expression analysis showed that the compounds disrupt PU.1-promoter interaction and lead to downregulation of canonical PU.1 transcriptional targets in AML cells, confirming on-target activity.

Methods: We used tandem mass spectrometry to identify significant changes in transcriptional targets of PU.1, and selectivity over other ETS family members. Comparison with published transcriptomic and PU.1 ChIP-seq data sets, as well as ARACNe analysis of the PU.1 regulon in primary AML cells, demonstrated that the inhibitors antagonized PU.1-regulated pathways at a genome-wide level. Moreover, motif enrichment analysis pointed to decreased production of mature granulo-monocytic cells, consistent with PU.1’s known role in this lineage. However, this effect was reversible upon drug removal, and serial replating capacity was not affected suggesting no significant effects on normal HSPC. Lastly, in vivo treatment with PU.1 inhibitors in mouse models demonstrated strong antiproliferative effects and sensitization of the PU.1 regulon to anti-myeloid agents, in a manner consistent with the in vitro transcriptional targets of PU.1, and selectivity over other ETS family members.

Summary/Conclusions: We describe for the first time a strategy inhibiting PU.1 in AML, establishing proof-of-concept for this approach. Furthermore, we report the development of first-in-class PU.1 inhibitors which interfere with PU.1-DNA interaction through an allosteric, minor groove-mediated mechanism. Our work shows that it is feasible to pharmacologically target PU.1, and raises intriguing possibilities for the potential targeting of other transcription factors through minor groove-directed approaches.

S136 METABOLIC ADAPTATIONS TO TARGETED THERAPY IN FLT3 MUTATED ACUTE MYELOID LEUKAEMIA

P. Gallipoli1,*, A. S. Costa2, K. Tzelepis3, G. Giotopoulos1, S. Vohra1, G. Vassiliou1, C. Frezza2, B. Huntly1
1Haematology, 2MRC Cancer Unit, 3Wellcome Trust/Sanger Institute, UNIVERSITY OF CAMBRIDGE, Cambridge, United Kingdom

Background: FLT3 tyrosine kinase (TK) activating mutations (FLT3-mut) are amongst the most frequent in AML and are associated with a poor outcome. FLT3-mut promote constitutive activation of survival/proliferation pathways and drive cellular transformation. Gene expression changes associated with FLT3 TK inhibitors (TKI) have been described in a number of studies, usually in the preclinical setting. FLT3 TKI have displayed limited efficacy in clinical trials. Resistance mechanisms to FLT3 TKI include receptor mutations and cell intrinsic adaptive mechanisms. Amongst the latter, metabolic adaptations might play a significant role although the exact mechanisms are still ill-defined.

Aims: We hypothesised that metabolic adaptations facilitate FLT3 TKI resistance and aimed to identify early metabolic changes in FLT3-mut AML, following TKI treatment, in an attempt to unravel novel therapeutic vulnerabilities.

Methods: Liquid chromatography coupled to mass spectrometry (LC/MS), using stable isotope-based carbon flux tracing, and oxygen consumption rate/extracellular acidification rate as measured by an extracellular flux analyser ( Seahorse, Agilent Technologies) were used to assess metabolic changes in FLT3-mut AML cells. Gene expression changes were measured in the same conditions by RNA sequencing. Changes in viability and reactive oxygen species (ROS) in various culture conditions were measured by FACS. Gene silencing was performed using CRISPR-Cas9 gene editing and inducible short hairpin RNA interference.

Results: Analysis of published gene expression datasets demonstrated that glycolytic, citric acid cycle (CAC), and oxidative phosphorylation genes are upregulated in FLT3-mut compared to FLT3 wild-type (FLT3wt) patient samples at diagnosis. We then confirmed that both human and murine FLT3-mut cells display increased glycolytic and respiratory capacity compared to FLT3wt cells. Gene expression changes associated with FLT3 TKI treatment were measured in the same conditions by RNA sequencing. Changes in viability and reactive oxygen species (ROS) in various culture conditions were measured by FACCS. Gene silencing was performed using CRISPR-Cas9 gene editing and inducible short hairpin RNA interference.

FLT3 TK activity may improve the eradication of FLT3mutAML cells. These data predict that a combined inhibition of glutamine metabolism and FLT3 TK inhibition by respectively counteracting oxidative damage and sustaining macromolecule biosynthesis and cellular energetics. Glutamine metabolism is mostly channelled towards glutathione production, while also supporting the CAC and both these fates contribute to its protective effects following FLT3 TK inhibition by specifically counteracting oxidative stress following FLT3 TK inhibition by respectively counteracting oxidative damage and sustaining macromolecule biosynthesis and cellular energetics.

Summary/Conclusions: Our data suggest that upon AC220 treatment, glutamine metabolism becomes a critical metabolic dependency in FLT3mutAML. Glutamine metabolism is mostly channelled towards glutathione production, while also supporting the CAC and both these fates contribute to its protective effects following FLT3 TK inhibition by respectively counteracting oxidative damage and sustaining macromolecule biosynthesis and cellular energetics.

Background: The molecular pathways and microenvironmental cues that choreograph the conversion of endothelial cells (ECs) into long-term repopulating hematopoietic stem cells (HSCs) remain poorly defined. This is due to lack of models that recreate the ephemeral transition of an endothelial cell to a hemogenic state to the emergence of HSCs.

Aims: To reprogram adult mouse ECs into long-term repopulating HSCs that give rise to all hematopoietic lineages, including functional T cells in vivo. To provide a platform to deconvolute the process by which endothelial-to-hematopoietic transition is possible.

Methods: Here, we have developed a modular in vitro model in which—by precise, conditional expression of transcription factors: FosB, Gfi1, Runx1, and Spi1 (FGRS), and reintroduction of a proper inductive niche—adult mouse ECs were reprogrammed into HSCs (rEC-HSCs) with multi-lineage engrafment potential (rEC-MPPs). Adult, non-lymphatic ECs isolated from various organs of Runx1-IRES-GFP reporter mice were transduced with FGRS and co-cultured in direct contact with vascular niche.

Results: Within 14 days, ECs initiated a hematopoietic program, turning on the endogenous expression of Runx1 and transitioning into hematopoietic cells. Expansion of these cells for another 14 days resulted in generation of rEC-HSCs and rEC-MPPs. Transplantation of rEC-HSCs and rEC-MPPs (CD45.2+) into lethally irradiated mice (CD45.1+) reconstituted both short-term (rEC-MPPs) and long-term hematopoiesis, with secondary engrafment potential (rEC-HSCs). rEC-HSCs gave rise to both functional myeloid and lymphoid cells with full complement of polarized T cell subsets. rEC-HSC-derived T cells undergo T-cell receptor (TCR) rearrangement and restore adaptive immune function in Rag1−/− mice.

Summary/Conclusions: This multi-phasic, step-wise approach provided an interrogable model to decipher pathways involved in EC transition into hematopoietic cells. This will provide cues to devise strategies to convert autologous ECs into large numbers of HSCs for genetic modification and subsequent treatment of both genetic and acquired hematological disorders.

Background: The tunneling nanotube (TNT) is a newly discovered, long and thin tubular structure between cells and can facilitate the intercellular exchange of diverse cellular signals and components ranging from electrical signalling to organelles. Recent reports show that mesenchymal stem cells (MSC) rescue injured target cell and promote target cell recovery from a variety of stress including oxidative tress. ultraviolet radiation, ischemia/reperfusion (I/R) /tetal . However, it is still unclear if bone marrow mesenchymal stem cells (BM/MSC) can also form TNT to communicate and rescue injured bone marrow -derived endothelial cells (BMdEC) and promote it recovery from chemotherapy stress . In our study, we set out to test the hypothesis that BM/MSC can rescue suffering endothelial cells by transferring mitochondria to endothelial cells through nanotubes.

Aims: To investigate the novel intercellular communication TNT between BM/MSC and BMdECs or HUVEC, illuminating its constituent and investigating the significance of transport of mitochondrial through TNT between BM/MSC and BMdECs or HUVEC suffering from chemotherapy stress of cytosine arabinoside.

Methods: We established two direct co-culture system for human primary bone marrow mesenchymal stem cells (BM/MSCs) and bone marrow-derived endothelial cells (BMdECs) or Human umbilical cord vein endothelial cells (HUVECs) respectively.

Results: Firstly, We observed the TNTs formed between BM/MSCs and endothelial cells including the TNT struc- ture between BM/MSCs and HUVECs or BMdECs are composed with F-actin, microtubule in addition to membrane. Live cell imaging showed the two xeno-geneic cells form TNTs by retaining a thin thread of membrane upon dislodge-
S139

SHORT-TERM FEEDING OF A HIGH-FAT DIET DISTURBS LIPID RAFT/ TGF-BETA SIGNALING-INDUCED QUIESCENCE OF HEMATOPOIETIC STEM CELLS IN C57BL/6J MOUSE BONE MARROW

F. Hermetet1,2,*, J.-P. Pais de Barros2,3, L. Delva1,2, R. Quéré1,2

1Signaling and Physiology in Hematological Research, UMR1231 Inserm / Université de Bourgogne Franche-Comté / AgroSup, 2LabEx LipSTIC, 3Lipidomic Analytical Platform, UMR1231 Inserm / Université Bourgogne Franche-Comté / AgroSup, Dijon, France

Background: Some studies show that a high-fat diet (HFD) induces major perturbations in murine hematopoietic stem cells (HSC) and hematopoietic system homeostasis. However, it is currently difficult to say whether these alterations are related to direct effects such as changes in lipid metabolism in HSC or indirect "side effects" on HSC, such as pathophysiology related to obesity or stress, observed after an extended diet over several months or a diet very rich in fat (>60 kJ% of fat). For example, HFD-induced obesity significantly alters hematopoiesis in bone marrow (BM), with a decreased proliferation of HSC, a general suppression of progenitors, an enhancement of lymphopoiesis, and an activation of myeloid cell production from BM progenitors. Inflammation also affects HSC homeostasis, as Interferon alpha is well-known to activate dormant HSC in vivo.

Aims: Our strategy is to characterize the impact of a short-term HFD on HSC and hematopoiesis in non-obese C57BL/6J mice.

Methods: In a prospective study, C57BL/6J mice were fed a control diet (4 kJ% of fat) or HFD (42 kJ% of fat), over a short period of 4 weeks, to investigate the direct impact of such a diet on hematopoiesis.

Results: While fat intake led to an increase in plasma cholesterol levels, mice did not develop obesity, and no inflammatory monocytes and no modulation of pro-/anti-inflammatory cytokine levels were detected in blood and BM, respectively. The impact was observed after several months or a diet very rich in fat (>60 kJ% of fat). For example, HFD-induced obesity significantly alters hematopoiesis in bone marrow (BM), with a decreased proliferation of HSC, a general suppression of progenitors, an enhancement of lymphopoiesis, and an activation of myeloid cell production from BM progenitors. Inflammation also affects HSC homeostasis, as Interferon alpha is well-known to activate dormant HSC in vivo.

Aims: Our strategy is to characterize the impact of a short-term HFD on HSC and hematopoiesis in non-obese C57BL/6J mice.

Methods: In a prospective study, C57BL/6J mice were fed a control diet (4 kJ% of fat) or HFD (42 kJ% of fat), over a short period of 4 weeks, to investigate the direct impact of such a diet on hematopoiesis.

Results: While fat intake led to an increase in plasma cholesterol levels, mice did not develop obesity, and no inflammatory monocytes and no modulation of pro-/anti-inflammatory cytokine levels were detected in blood and BM, respectively. The impact was observed after several months or a diet very rich in fat (>60 kJ% of fat). For example, HFD-induced obesity significantly alters hematopoiesis in bone marrow (BM), with a decreased proliferation of HSC, a general suppression of progenitors, an enhancement of lymphopoiesis, and an activation of myeloid cell production from BM progenitors. Inflammation also affects HSC homeostasis, as Interferon alpha is well-known to activate dormant HSC in vivo.

**WILMS' TUMOR 1 RNA- ELECTRO- PORATED DENDRITIC CELL VACCINATION AS POST-REMISSION TREATMENT TO PREVENT OR DELAY RELAPSE IN ACUTE MYELOID LEUKEMIA: FINAL RESULTS OF A PHASE II STUDY IN 30 PATIENTS**

Z. Serneman1,2, S. Anguillic, A. Van de Velde1, V. Van Tendeloo1, N. Coels1, G. Nijs1, B. Stein1, E. Lion1, A. Van Driessche1, I. Vandenbosch1, A. Verlinden1, A. Gadiou3, W. Schroyens1, K. Vermeulen2, M.-B. Maes2, K. Dei- renen2, R. Malfait2, E. Smits3
1Hematology, 2Laboratory Hematology, 3Center for Cell Therapy and Regenerative Medicine, ANTWERP UNIVERSITY HOSPITAL, Edegem, Belgium

**Background:** Relapse is a major problem in acute myeloid leukemia (AML) and adversely impacts survival.

**Aims:** The aim of this phase II study was to determine the clinical efficacy of dendritic cell (DC) vaccine therapy in AML, and, more specifically, whether this form of immunotherapy can be applied in the post-relapse adjuvant setting to decrease the risk of relapse following chemotherapy and to improve survival.

**Methods:** We vaccinated 30 AML patients in remission following chemotherapy, but at very high risk of relapse with autologous DCs loaded with the human Wilms' tumor 1 (WT1) antigen by means of mRNA electroporation, a technique that allows for human leukocyte antigen haplotype-independent, multi-epitope antigen presentation to T-cells. The vaccines were administered intra- dermally. WT1 mRNA levels in blood and marrow were followed as a measure of minimal residual disease. Circulating WT1-specific CD8+ T-cells obtained before vaccination and at the 4th dose were stained with anti-WT1 antibody and anti-HLA-A*0201 tetramers. To assess cell-mediated immunity in vivo, delayed type hypersensitivity (DTH) skin testing was performed 2 weeks after the 4th DC vaccination by intradermal injection; DTH-infiltrating lymphocytes collected from skin biopsies were expanded for 2-3 weeks in medium with interleukin-2, harvested, and tested for WT1 specificity and reactivity.

**Results:** There was a demonstrable anti-leukemic response in 13/30 patients (overall response rate 43%). Nine patients achieved molecular remission as demonstrated by normalization of WT1 transcript levels, 5 of which are sustained after a median follow-up of 109.4 months, including 1 patient who went from relapse to complete remission by DC vaccination only. In the remaining 4 responding patients, the clinical response was characterized by stable disease as demonstrated by elevated but stable WT1 transcript levels in blood for 3-12 months and stable blood values without blasts. Five-year overall survival was 40%, as compared to 24.7% in the SEEER data of the National Cancer Institute; it was significantly higher in responders than in non-responders (53.8% vs 25.0%; P=0.01). In patients receiving DCs in first complete remission (CR1), there was a vaccine-induced relapse reduction rate of 25% and the 5-year relapse-free survival was significantly higher in responders than in non-responders (50% vs 7.7%; P=0.001). In patients ≤65 and >65 years who received DCs in CR1, 5-year overall survival was 69.2% and 30.8% respectively. Of the 30 patients, 11 are alive in CR, including 5 who relapsed after DC vaccination; 2 proceeded to allogeneic stem cell transplantation, while the other 3 patients were brought back into CR by chemotherapy alone, 2 of them surviving more than 7 and 4 years respectively after reaching CR. Long-term clinical response was correlated with increased circulating frequencies of poly-epitope WT1-specific tetramer+CD8+ T-cells. Long-term overall survival was correlated with interferon-γ and tumor necrosis factor-α WT1-specific responses in DTH-infiltrating CD8+ T-lymphocytes.

**Summary/Conclusions:** Vaccination of AML patients with WT1 mRNA-electroporated DCs can be an effective and non-toxic strategy to prevent or delay leukemia relapse after standard chemotherapy, translating into improved overall survival rates, which are correlated with the induction of WT1-specific CD8+ T-cell responses.

**FIRST-IN-HUMAN MULTICENTER STUDY OF BB2121 ANTI-BCMA CAR T CELL THERAPY FOR RELAPSED/REFRACTORY MULTIPLE MYELOMA: UPDATED RESULTS**

Y. Lin1,*, J. Berdeja2, N. Raje3, N. Munshi4, D. Siegel5, M. Liedtke6, S. Jagannath7

**Background:** To test the safety and efficacy of the CAR T cell modality in relapsed/refractory multiple myeloma (MM), we have designed a second-generation CAR construct targeting B cell maturation antigen (BCMA) to redirect T cells to MM. bb2121 consists of autologous T cells transduced with a lentiviral vector encoding a novel CAR incorporating an anti-BCMA scFv, a 4-1BB costimulatory motif and a CD3-zeta T cell activation domain. We will report updated safety and efficacy results following pursuing initial results (Berdeja et al. ENA 2016).

**Aims:** The primary objective is to determine the maximally tolerated dose of bb2121 in subjects with MM whose tumors express BCMA, to determine and test a recommended phase 2 dose for future studies. The secondary objective is to provide preliminary efficacy data on the anti-tumor effects of treatment with bb2121 in patients with MM whose tumors express BCMA.

**Methods:** CRB-401 (NCT02656929) is a multi-center phase 1 dose escalation trial of bb2121 in patients with relapsed and/or refractory MM who have received ≥3 prior regimens, including a proteasome inhibitor and an immunomodulatory agent (IMiD). In total, 10 patients entered a single dose study and 38 entered a phase 1 dose escalation trial (ORR) in the 9 evaluable patients is 100%, including 2 sCRs and 2 MRD-neg- ative responses (sCR and VGPR). CAR+ T cell expansion has been demonstrated consistently. An additional 6 months of follow up on reported results and initial data from an additional ~10 patients will be presented.

**Summary/Conclusions:** A total of 2 sCRs and ongoing clinical responses at 6 months with mild and manageable CRS to date. These initial data support the potential of CAR T therapy with bb2121 as a new treatment paradigm in MM.
Background: Fanconi anemia (FA), is a monogenic inherited syndrome associated with bone marrow failure (BMF), that has been considered a candidate disorder for hematopoietic stem cell (HSC) gene therapy. Up to date, three clinical trials have been performed, all of which failed to demonstrate engraftment of HSCs.

Aims: To demonstrate engraftment of gene-corrected HSCs in non-conditioned Fanconi anemia patients.

Methods: To improve previous results, we proposed a new approach based on two clinical trials. First, to increase the HSC collection, we designed a trial employing a plerixafor plus G-CSF mobilization regimen. Second, to improve the quality of corrected HSCs, cells were pre-stimulated for only 8-10 hours and transduced with a new lentiviral vector (PGK-FANCA.Wpre*) for 12-14h, a substantially shorter duration than in previous trials. To avoid chemotherapy-induced damage, a conditioning regimen was not included in the trial, based on the expected proliferative advantage of autologous corrected HSCs.

Results: Eight patients have been included so far in the HSC collection trial. No severe adverse events (SAE) related to the procedure have been reported. The most relevant AE has been the transfusion of packed red blood cells and platelets. Six FA patients aged ≥6 years underwent collections after mobilization of significant numbers of CD34+cells (10 to 70 CD34+cells/µL) to peripheral blood. Two patients (15 and 16 years) failed to mobilize. On average, 5 million CD34+cells/Kg were collected, with 45% recovery after immunoselection. On average, 5 million CD34+cells/Kg were collected, with 45% recovery after immunoselection. The most relevant AE has been the transfusion of packed red blood cells and platelets. Six FA patients aged ≥6 years underwent collections after mobilization of significant numbers of CD34+cells (10 to 70 CD34+cells/µL) to peripheral blood. Two patients (15 and 16 years) failed to mobilize. On average, 5 million CD34+cells/Kg were collected, with 45% recovery after immunoselection. The most relevant AE has been the transfusion of packed red blood cells and platelets. Six FA patients aged ≥6 years underwent collections after mobilization of significant numbers of CD34+cells (10 to 70 CD34+cells/µL) to peripheral blood. Two patients (15 and 16 years) failed to mobilize. On average, 5 million CD34+cells/Kg were collected, with 45% recovery after immunoselection. The most relevant AE has been the transfusion of packed red blood cells and platelets. Six FA patients aged ≥6 years underwent collections after mobilization of significant numbers of CD34+cells (10 to 70 CD34+cells/µL) to peripheral blood. Two patients (15 and 16 years) failed to mobilize. On average, 5 million CD34+cells/Kg were collected, with 45% recovery after immunoselection.

Summary/Conclusions: Our preliminary results show that 1) HSCs collection is both safe and efficient in very young FA patients after mobilization with G-CSF and plerixafor, and 2) Engraftment and proliferation advantage of gene-corrected HSPCs has been demonstrated in FA patients even in the absence of conditioning regimens. The long-term follow up of patients included in these clinical trials will demonstrate the feasibility of restoring the hematopoietic function of FA patients by means of a gene therapy approach in the absence of conditioning.

S145 TARGETING FLT3 WITH CHIMERIC ANTI-GEN RECEPTOR T CELLS CONFFERS POTENT REACTIVITY AGAINST ACUTE MYELOID LEUKEMIA

H. Jetai1, I. García-Cadenas2, T. Nerrer1, J. Sierra2, W. Herr3, S. Thomas3, H. Einsele1, M. Hudecek1
1Internal Medicine II, University Hospital Würzburg, Würzburg, Germany. 2Servicio de Hematología, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, 3Klinik und Poliklinik für Innere Medizin III, Universitätsklinikum Regensburg, Regensburg, Germany.

Background: Adoptive immunotherapy with chimeric antigen receptor (CAR)-modified T cells has therapeutic potential in hematologic malignancies. We are pursuing FLT3-like tyrosine kinase 3 (FLT3) as a novel CAR target in acute myeloid leukemia (AML). FLT3 is a homodimeric transmembrane protein with uniform expression on AML, irrespective of cytogenetic and histomorphologic subtype. FLT3 provides survival signals to AML blasts and is a key driver of leukemia-genesis in AML cases with internal tandem duplication (FLT3-ITD). These attributes suggest FLT3 may be an ‘Achilles heel’, making AML blasts susceptible to CAR T-cell mediated recognition and elimination.

Aims: We therefore explored the anti-leukemia efficacy of FLT3-CAR modified T cells against FLT3-ITD+ and FLT3 wild type AML in pre-clinical models in vitro and in vivo.

Methods: A FLT3-CAR comprising a single-chain variable fragment (4G8), fused to an IgG-Fc spacer, and signaling module with CD3 zeta and CD28 was encoded in a lentiviral vector (epHIV7) for gene-transfer into CD8+ and CD4+ T cells of healthy donors (n>4) and AML patients. CAR T-cell mediated cytolytic activity was evaluated in FACS-/luminescence-based assays, cytokine production analyzed by ELISA and proliferation assessed by CFSE dye dilution. Immunodeficient NSG mice were engrafted with AML cell line (Molm-13) or primary AML blasts and treated with 5x105 CAR-modified or control T cells (CD2:CD4 ratio=1:1).

Results: We confirmed specific recognition and high-level cytolytic activity of CD8+FLT3-CAR T cells against a panel of AML cell lines including THP-1 (FLT3 wild type), and Molm-13 (FLT3-ITD heterozygous). Both CD8+ and CD4+ FLT3-CAR T cells produced IFN-γ and IL-2, and underwent proliferation after antigen stimulation. FLT3-CAR T cells that we prepared from AML patients exerted specific anti-leukemia reactivity against autologous primary AML blasts, with near-complete cytolytic activity within 24 hours of co-culture. Further, FLT3-CAR T cells conferred a potent anti-leukemia effect in vivo models of systemic leukemia, both with AML cell lines (Molm-13) and primary AML blasts. A single dose of FLT3-CAR T cells conferred complete eradication of leukemia from peripheral blood, bone marrow and spleen, as confirmed by bioluminescence imaging and flow cytometry. FLT3 is not expressed in any normal solid tissues and mature hematopoietic cells, but shows limited expression in hematopoietic progenitors and hematopoietic stem cells (HSCs). Preliminary data show that FLT3-CAR T cells recognize FLT3+/high normal HSCs and interfere with normal hematopoiesis, but preserve a proportion of HSCs capable of reconstituting hematopoietic lineages. Studies to assess recognition of normal HSCs in vivo are ongoing.

Summary/Conclusions: Collectively, our data demonstrate that T cells expressing a FLT3-specific CAR mediate potent reactivity against FLT3 wild type and FLT3-ITD+AML in vitro and in vivo, and establish FLT3 as a novel CAR target in AML. FLT3-ITD positivity identifies a high-risk AML subgroup that may particularly benefit from adoptive therapy with FLT3-CAR T cells, e.g. in order to achieve ‘minimal residual disease’ (MRD) negativity prior to allogeneic HSC transplantation. Our data further suggest that in contrast to CD33 and CD123, which are pursued as alternative CAR targets in AML, targeting of FLT3 may preserve a fraction of normal HSC and enable the implementation of CAR therapy outside the transplant setting.
Background: Allogeneic hematopoietic stem cell transplant (HSCT) offers curative therapy for children who lack an available HLA-identical donor with hematopoietic disorders such as Primary Immune Disorders (PIDs), hemoglobinopathies, erythroid disorders and acute leukemias. CD3ε T-cell depletion mitigates the risk of GvHD after haplo-HSCT, but is associated with extended immunodeficiency, leading to complications due to infections. We have performed CD3ε TCR-depleted haplo-HSCT with post-transplant infusion of BPX-501 gene modified T cells to allow for more rapid immune reconstitution. Upon occurrence of GvHD, administration of rimiducid (AP1903) dimerizes the Cas9 suicide switch and rapidly induces apoptosis of the transduced BPX-501 cells and mitigates the GvHD.

Aims: This study was performed to determine the impact of BPX-501 T cell infusion on outcomes (treatment related mortality (TRM), disease recurrence, GvHD incidence and immune reconstitution) after HSCT.

Methods: We report on a large multicenter, prospective Phase I-II study enrolling children receiving CD3ε T-cell depleted Haplo-HSCT. Patients were infused with BPX-501 T cells 2 weeks post-transplant. 104 patients have >100 day follow-up, 81 patients have follow up >180 days and 51 with >1 year follow-up. All patients received myeloablative therapy and low dose ATG prior to transplant. No pharmacologic GvHD prophylaxis was given (Table 1).

Table 1. Diagnoses of Patients with >100 day follow-up.

Results: Cumulative incidence of TRM remains very low at 100 days (0%), 180 days (1.6%) and 1 year (2.8%). Of the 81 patients with >180 day follow-up, 20 patients had acute GvHD 1-3 (24.7%) (Figure 1A); 10 with Grade 1, 8 with Grade 2, 2 with Grade 3 and one Grade 4 skin. Mild cGvHD was seen in 4 patients with Grade 2 GvHD with rapid resolution of symptoms, as it did in 2 patients, moderate cGvHD in 2 patients and one case of severe cGvHD in a patient with Grade 4 skin. HbGδd was seen in 2 patients, moderate cGvHD in 2 patients and one case of severe cGvHD in a patient with Grade 4 skin.

Summary/Conclusions: This data suggest that infusion of BPX-501 modified cells may facilitate T cell depleted Haplo-HSCT in children who would benefit from HSCT for either malignant or non-malignant conditions. The availability of a suicide gene mechanism in donor T cells infused after T depleted Haplo-HSCT, results in low rates of infection and rapidly reversible GvHD when the dimension is infused to activate the suicide switch. Rapid cellular and humoral immune reconstitution makes BPX-501 after T depletion a safe and viable option for children who do not have a matched donor transplant and in whom transplantation has been deemed curative.
for a selected guide RNA confirmed no detectable genomic cleavage at over 75 mC/mG and statistical analysis revealed 100% efficiency and high quality of guide RNA. These experiments support the further development of specific CRISPR-Cas9 editing strategies of HSPOs to treat SCD and β-Thal patients.

S148
EXPOSURE TO INFECTION TRIGGERS Pax5 and ETV6-RUNX1 CHILDHOOD BCP-ALL
1Experimental Therapeutics and Translational Oncology Program, Instituto de Biología Molecular y Celular del Cáncer, CSIC/ Universidad de Salamanca and Institute of Biomedical Research of Salamanca (IBSAL), Salamanca, Spain.
2Department of Pediatric Oncology, Hematology and Clinical Immunology, Heinrich Heine University, Duesseldorf, Germany, Duesseldorf, Germany.

Background: B-cell precursor acute lymphoblastic leukemia (BCP-ALL) of childhood remains a major cause of death in high-income countries. It has a yet unexplained peak incidence between 2-6 years of age and a potential trigger was theorized a century ago with several possibilities of exposure to infection in infancy. Recently in vitro and in vivo evidence strengthened the causal role of exposure to infection in BCP-ALL (1, 2). However, it remains unknown which specific BCP-ALL subtype can be triggered by infection and how the pre-leukemic clone evolves to BCP-ALL.

Aims: Aiming to understand the role of infection exposure in the etiology of childhood BCP-ALL.

Methods: We have developed and characterized two independent GEMMs, in addition to the Pax5+/−-infected model (1), which were exposed to a common infection environment. These represent childhood BCR-ABL1p190 BCP-ALL and the most common subtype ETV6-RUNX1 BCP-ALL. Both model systems enable Sca-1-directed expression of BCR-ABL1 p190 or ETV6-RUNX1 in HSC and non-HSC cells, which can be manipulated by infection and how the pre-leukemic clone evolves to BCP-ALL.

Results: In summary, exposure to common pathogens can increase dramatically in the last three decades. Cold temperature induces changes in glycosylation and clustering of platelet glycoprotein (GP) Ib and cytoskeletal rearrangements, which are recognized by host receptors resulting in lectin-mediated platelet plug formation and clearance. The current practice of platelet storage for transfusion uses room temperature and associates with a relatively high risk of bacterial growth and infection in susceptible patients.

Aims: Due to the cytokine nature of the platelet changes upon refrigeration, we hypothesized that the RHO family GTPase activity is pivotal in the cold platelet lesion. Targeted intervention may benefit refrigerated storage.

Methods: Analysis of Rhoa, Rac1 and Cdc42 activity was performed using GST-Rhotekin and GST-PAK effector domain pulldown assays. Platelets were obtained from anticoagulated (CPD or EDTA) human, Rhesus monkey and murine whole blood. G04, N53C2766 and Casin, specific inhibitors for Rhoa, Rac and Cdc42, respectively, were utilized and used at concentrations of 75 mM, 50 mM and 10 mM, respectively. Rhoa deficient murine platelets were obtained from poyt1-C treated Mx1-Cre/Rhoa−/− mice. Aspirin was administered at a dose of 5 mg/Kg b.w. to mice and monkeys. Bleeding time was performed using standard animal protocols. Transfused human/monkey platelets were stored at room temperature (RT) or 4°C (367/368/369) at RT or 1-9°C for 7 days or 1-4 hours for murine platelets.

Results: We found that either short- or long-term refrigeration activates Rhoa and RAC1, but not CDC42. Genetic deletion of Rhoa or RhoA inhibition with the small molecule inhibitor G04 suffices to completely prevent cold-induced platelet clearance. After long-term cold storage of murine or human platelets, the effect of G04 is on-target since it mimics but does not modify the response of Rhoa-deficient platelets. The effect of G04 is reversible since removal of G04 after 7-14-day storage restores Rhoa activity to normal levels and allows normal extent of shape change and spreading on fibronectin. To analyze the kinetics and hemoimmunophenotypic properties of cold treated human platelets after xenotransfusion, we analyzed the survival of xenotransfused human platelets after long-term cold (7-day) refrigeration in the presence and absence of inhibitors cocktail or individual inhibitors in macrophage depleted, sub-lethally irradiated NSG mice (n=20/group) as well as autologously transplanted platelets in a crossover trial in Rhesus monkeys (n=5). Our results show that reversible inhibition of RhoA in refrigerated platelets suffices to survival levels similar to the unrefrigerated control in 100% of mice and 80% of monkeys (p<0.001). Our data further show that washing of platelets stored for 7 days in G04/plasma maintains collagen-induced shape change as well as normal aggregation of human platelets and restores bleeding time correction after congeneric or autologous transfusion in all aspirinated mice and 80% of aspirinated Rhesus monkeys, respectively. Rhoa inhibition blocks the process of intracellular trafficking of GP through lipid rafts and endocytotic intermediates as assessed by confocal microscopy of GpIIb and the vacuolar sorting protein VPS33b, as well as biochemical fractionation of detergent-insoluble membrane lipid rafts, RhoA and G04, and 80% of aspirinated Rhesus monkeys, respectively.

Summary/Conclusions: We demonstrate that activation of Rhoa is a pivotal mechanism of refrigerated platelet storage lesion and phagocytosis. Reversible inhibition of Rhoa allows the extended cold storage of platelets which are effective in vitro and in vivo, suitable for use in clinical safety and efficacy trials. Our study also provides the mechanism and a stringent proof-of-principle for the translational application of a novel approach to refrigerated platelet storage.

TREATMENT REDUCTION IN PATIENTS WITH ADVANCED-STAGE HODGKIN LYMHPHOMA AND NEGATIVE INTERIM PET: FINAL RESULTS FROM PLATINUM BASED RANDOMIZED PHASE 3 TRIAL HD18 BY THE GERMAN Hodgkin STUDY GROUP
1Department I of Internal Medicine, 2Department of Nuclear Medicine, University Hospital of Cologne, Cologne, Germany, 3IIIrd Medical Department, Paracelsus Medical University and Salzburger Cancer Research Institute, 4AGMT (Arbeitsgemeinschaft medizinische Tumorthyrozidologie), Saarland University Medical Center, Amsterdam, Netherlands, 5Department of Hematology, University Hospital of Essen, Essen, Germany, 6Third Faculty of Medicine, University Hospital Kralovske Vinohrady, Prag, Czech Republic, 7Uni-
Background: The German Hodgkin Study Group (GHSG) applies the intensive eBEACOPP regimen (dose-escalated bleomycin, etoposide, doxorubicin, cyclophosphamide, vincristine, procarbazine, and prednisone) to all newly diagnosed advanced-stage HL patients regardless of their individual risk-profile. However, some patients might not be in need of such an intensive treatment to achieve cure. Unfortunately, baseline risk factors as defined in the international prognostic score cannot identify these patients reliably. Recent clinical research suggests that early metabolic response assessment after 2 cycles of therapy using FDG-PET (PET-2) can better predict the individual outcome. In particular, a rapid response as determined by PET-2 negativity might allow reducing the overall treatment intensity.

Aims: To assess the feasibility of decreasing the number of eBEACOPP cycles in patients with negative PET-2 without loss of efficacy as determined by progression-free survival (PFS).

Methods: Between 05/2008 and 07/2014, we recruited patients with newly diagnosed, advanced-stage HL aged 18–60 years. All patients gave written consent before study entry. PET-2 was centrally assessed with FDG uptake not higher than the mediastinal blood pool defined as negative. Patients with negative PET-2 were randomly assigned to receive 6 or 2 additional cycles (i.e. 8 or 4 cycles of eBEACOPP in total, respectively). PET-positive residues after chemotherapy were irradiated. Based on the results of our previous HD15 trial, the protocol was amended in June 2011 and the standard therapy was reduced from 8 to 6 cycles of eBEACOPP in total. The trial was designed to exclude inferiority of 6% or more of the experimental treatment (4 cycles of eBEACOPP) compared with the pooled standard treatment (8 or 6x cycles of eBEACOPP) at 5 years.

Results: We enrolled 2,101 patients. 1,005 patients with negative PET-2 were randomly assigned to either 8/6 cycles of eBEACOPP (n=504) or 4 cycles of eBEACOPP (n=501). With a median follow-up of 55 months, estimated 5-year PFS in the per-protocol set was 90.8% (87.9–93.7) with 8/6 cycles of eBEACOPP and 92.2% (89.4–95.0) with 4 cycles eBEACOPP (difference +1.4%, 95% CI -2.7–5.4, excluding the non-inferiority margin of -6%). In the standard arm, 95% of patients had at least one acute hematological toxicity of CTCAE grade 3-4 compared with 90% in the experimental arm, including severe infections in 75 (15%) and 38 (8%), respectively. Acute severe organ toxicities were documented for 91 (18%) and 38 (8%), respectively. 25 patients (5%) in the standard group (8/6 cycles of eBEACOPP and 9 (2%) in the experimental group (4 cycles of eBEACOPP) died; most frequent cause of death was second malignancy (11 and 1 patient, respectively). No patient in the experimental group died from treatment-related toxicities. Estimated 5-year overall survival (OS) in the per-protocol set was 95.4% (93.4–97.4) with standard eBEACOPP, and 97.7% (96.2–99.3) with 4 cycles of eBEACOPP (log-rank p<0.004).

Summary/Conclusions: Metabolic response assessment using FDG-PET after 2 cycles of eBEACOPP allows the reduction from therapy with 8/6 to only 4 cycles without loss of efficacy as determined by PFS in advanced-stage HL patients. Furthermore, the abbreviated treatment with 4 cycles of eBEACOPP is associated with improved tolerability and consequently leads to a significant OS benefit over standard therapy. PET-guided reduced therapy with eBEACOPP combines outstanding efficacy with high safety. We therefore recommend this treatment strategy for advanced-stage HL patients.
Acute lymphoblastic leukemia - Biology 1

P151
TARGETED SINGLE CELL SEQUENCING TO IDENTIFY MUTATIONAL HIERARCHY IN T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

K. Kampen1,*, T. Girardi1, J. Verbeeck1, J. Op de Beeck 1, A. Uyttebroeck2

Background: Acute lymphoblastic leukemia (ALL) is a common childhood malignancy caused by clonal proliferation of immature B or T lymphoid cells. ALL patients are primarily young children who respond well to chemotherapy, with survival rates above 85%. However, if relapse develops, survival rates drop to 15-50%. Recent studies have shown that at diagnosis, different ALL sublineages are present that are likely the result of clonal branched evolution. Understanding this clonal evolution and the order at which mutations are acquired can provide improved insights into the origins of leukemia relapse.

Aims: To use single-cell sequencing to investigate (i) the heterogeneity of leukemic T-ALL cells present at diagnosis and (ii) unravel the order in which mutations were acquired during leukemia evolution.

Methods: Bone marrow samples taken at diagnosis and remission from 4 T-ALL patients underwent whole genome and RNA sequencing. Somatic mutations, indels and chromosomal translocations were confirmed using Sanger sequencing. Primers were designed to specifically target these genetic alterations, and included 46 primers against heterozygous SNPs for quality control assessment. A total of 1517 single cells (average of 379 cells per patient) were sorted using flow cytometry or a microfluidic device and analyzed with targeted sequencing. Cells were discarded from further analysis if focus and allelic drop-out exceeded 33.3%. Jaccard hierarchical clustering was applied to identify subclones and a new graph-based algorithm was developed to determine the order of mutation acquisition. Single CD34+CD38− hematopoietic stem/progenitor cells (HSPCs) from the same samples were also isolated to test for the presence of mutations in early progenitors.

Results: We detected between 2 and 4 separate clones in each T-ALL patient sample. Every patient harboured one dominant clone comprising 46 to 98% of all single cells that was highly mutated, accompanied by a number of smaller subclones carrying fewer mutations. No mutually exclusive mutations, fusion genes or deletions were observed between the clones arguing against independent leukemic clonal initiation events. Instead, a more stepwise clonal hierarchy became likely, with each clone harbouring more mutations than the last. Using our newly developed graph-based algorithm, we found that early mutations mostly occurred in genes of unknown significance and may represent a new target in RPL10 R98S defective T-ALL.

Summary/Conclusions: We demonstrate that T-ALL patients have limited heterogeneity at diagnosis and that targeted single cell sequencing can be used to determine the cell of origin and the order of mutation acquisition. These data also illustrate that HSPCs at remission carry a few early, pre-leukemic events, while highly mutated HSPCs are eradicated during treatment, which is in line with long term remission in T-ALL.

BCL-2 INHIBITION AS NEW THERAPEUTIC OPPORTUNITY FOR RPL10 R98S MUTANT PEDIATRIC T-ALL

K. Kampen1,*, T. Girardi1, J. Verbeeck1, J. Op de Beeck1, A. Uyttebroeck2, P. Vermeersch3, A. Moorman4, A. Moorman5, C. Harrison5, J. Meijerink6, E. Geerdens1, J. De Bie1,*, S. Demeyer1, E. Geerdens1, A. Uyttebroeck2, N. Boeckx3, J. Cools1

Background: The ribosomal protein L10 (RPL10) R98S mutation occurs in 8% of pediatric T-cell acute lymphoblastic leukemia (T-ALL) cases. RPL10 R98S leads to a proliferation defect in lymphoid cells due to a metabolic contribution in pediatric T-ALL remains unclear. Treatment intensification and risk stratification has reduced the relapse rate of T-ALL to ~15% but further improvements will require strategies that focus on specific subtypes as RPL10 R98S; if the long-term sequelae of toxic therapy are to be avoided.

Aims: 1) Explore the oncogenic contribution of the RPL10 R98S mutation in pediatric T-ALL. 2) Define new therapeutic opportunities for RPL10 R98S defective T-ALL. 3) Identify a biomarker indicative of the RPL10 R98S mutation in T-ALL.

Methods: Quantitative label-free proteomics was used to screen for protein differences between RPL10 WT and R98S expressing Ba/F3 cells. Hits were confirmed by western blot in lineage negative (lin−) bone marrow (BM) cells extracted from RPL10 WT and R98S knock-in mice and in RPL10 WT and R98S pediatric T-ALL samples. Serial re-plating was established by plating 2000 cells/ml in Methocult. Oxidative stress and mitochondrial activity was determined by DiHydorhodamine and mitotracker. Viable cell counts were determined by Annexin V exclusion. Chromatin immunoprecipitation was performed using the Imprint Ch-IP kit followed by qRT-PCR. Human pediatric T-ALL samples were transplanted into NOD-SCID/IL2γ−/− (NSG) mice for in vitro and in vivo inhibitor studies.

Results: The RPL10 R98S mutation provided a cell survival advantage in Ba/F3 cells and in serial re-plating assays of lin− BM cells derived from RPL10 R98S knock-in mice. Proteomic profiling revealed metabolic reprogramming in RPL10 R98S cells through enhanced expression of peroxisomal enzymes Acox1, Acox3 and Paox. This expression facilitated peroxisomal β-oxidation of long chain fatty acids which are substrates for PPARy and which were consequently upregulated together with CPT1A. Peroxisomal hyperactivation causes high intracellular H2O2 levels, explaining the observed elevated levels of reactive oxygen species (ROS) in RPL10 R98S cells that could not be scavenged by the increased catalase expression. High ROS levels and enhanced PPARy binding drives the constitutive overexpression of anti-apoptotic protein B-cell lymphoma 2 (Bcl-2), responsible for the leukemia cell survival benefit of RPL10 R98S cells. Bcl-2 targeted therapy using venetoclax (ABT-199) reduced the expansion of RPL10 R98S knock-in BM cells by 50%, while RPL10 WT BM cells were not inhibited by ABT-199. In vivo, DMSO or ABT-199 50mg/kg therapy was started after the engraftment of >2% human cells in the blood of mice xenografted with T-ALL samples and was maintained 1/wk till disease end stage. RPL10 R98S xenografted mice that received ABT-199 therapy presented a complete inhibition of human CD45+ leukemia progression in the blood, which was characterized by a 70-85% reduction in spleen weights, and 20-50% reduction of bone marrow engraftment. Spleen weights of ABT-199 treated RPL10 R98S xenografted mice were only slightly increased as compared to negative weights of healthy NSG mice. In contrast, mice xenografted with RPL10 WT T-ALL samples showed poor in vivo responses to ABT-199 treatment and all animals showed progressive disease. Bcl-2 overexpression induced by peroxisomal hyperactivation was defined as new target in RPL10 R98S defective T-ALL. Additionally, due to peroxisomal hyperactivation, a peroxisomal oxidase involved in purine degradation may have contributed to the waste product of purine degradation, uric acid, was elevated above reference levels in the blood of RPL10 R98S mutant pediatric T-ALL patients at diagnosis (Figure 1).
OXIDATIVE STRESS AS A TARGET FOR HIGH-RISK LEUKAEMIA IN a mutation in T-ALL that is linked to alterations in cellular serine biosynthesis.

M. Karsa1,*, K. Somers1, A. Mariana1,2, T. Failes1,2, G. M. Arndt1,2, U. R. Kees3, CHILDREN

established oncogenic cascade in T-ALL. Moreover, this is the first description of transcription factor Ikzf2. Alterations were also found in the JAK-STAT signaling, an translational efficiency still needs to be validated at the protein level, and the translation and proliferation: the atypical MAP kinase Mapk6, whose reduced trans-

expressing cells enhance their endogenous serine production, leaving more medium from RPL10 R98S Ba/F3 cells contained higher residual serine levels cell cultures derived from Rpl10 R98S knock-in mice. Interestingly, exhausted translational efficiency of the encoding gene. Elevated Psph protein levels were (Psph), a key enzyme in serine biosynthesis. Ribosome footprinting revealed showing 5-fold upregulated protein levels was phosphoserine phosphatase Lif, Socs1, Pim1, Osm, Il10ra, Cish and Il21r. Another interesting candidate especially, the results from the mass spectrometry and the polysomal RNA sequencing datasets showed a significant enrichment and upregulation of members of the JAK-STAT signaling pathway with Casf2/z2, Jak1 and several Stats being 1.3-fold elevated at the protein level and higher translation efficiency for Lf, Ctn, Il10ra, Cish and Il21r. Another interesting candidate

PROTEIN L10 R98S MUTATION REVEALS ALTERED SERINE TRANSLATOME ANALYSIS OF THE T-ALL ASSOCIATED RIBOSOMAL

survival rates approaching 90%. However, prognosis remains dismal for certain subgroups of high-risk patients, including poor responders to induction therapy, infants with ALL that harbor rearrangement of the Mixed Lineage Leukaemia (MLL/KMT2A) gene, and children with Philadelphia chromosome positive ALL. In particular, infant ALL patients with MLL disease have survival rates below 50% despite the use of intensified treatments, necessitating the development of more effective, less toxic therapeutics for them.

Aims: The aim of this study is to identify candidates that target MLL-rearranged leukaemia cells using drug-repurposing, whereby an approved drug is applied to treat a disease other than the one for which it was originally intended. This drug discovery strategy is gaining popularity as it potentially avoids the lengthy process of drug development and FDA approval.

Methods: 3704 approved drugs and pharmacologically active compounds were initially screened against an infant ALL cell line with MLL-rearrangement, PER- 485 and a paediatric leukaemia cell line wild-type for MLL, CEM, using a resazurin-based cell viability assay. Hit compounds were further tested in a panel of 11 standard childhood leukaemia cell lines and seven solid tumour cell lines. Compounds were subsequently evaluated in vitro for cytotoxic activity against a panel of 20 paediatric high-risk ALL patient-derived xenograft (PDx) cells. Apoptosis was measured by Annexin V positivity and PARP cleavage. Reactive oxygen species (ROS) levels were assessed by DCF-DA staining and detection by flow cytometry. Nr2f2 protein expression levels were measured by Western blotting.

Results: The screen resulted in the identification of two FDA-approved drugs that were preferentially cytotoxic against MLL-rearranged ALL and other leukaemia cell lines, compared to solid tumours and normal cells. Auranofin was previously developed for rheumatoid arthritis and was later fast-tracked into Phase II clinical trial for adult chronic lymphocytic leukaemia, while Disulfiram, which was developed for treatment of chronic alcoholism, is currently in several clinical trials for cancers including metastatic melanoma and glioblastoma. These drugs also showed potent activity in high-risk paediatric leukaemia PDX cell cultured translation through induction of antioxidant response. Incubation with ROS scavenger N-acetyl cysteine prior to treatment with either drug prevented the increase in cellular ROS levels (p<0.05) and rescued cells from apoptosis (p<0.0001), indicating involvement of reduction-

Summary/Conclusions: In summary, we identified two FDA-approved drugs that demonstrated potent anti-leukaemia activity through induction of ROS, potentially opening up new avenues for clinical treatment of high-risk paediatric leukaemia.

TRANSLATOME ANALYSIS OF THE T-ALL ASSOCIATED RIBOSOMAL PROTEIN L10 R98S MUTATION REVEALS ALTERED SERINE METABOLISM

L. Fancello1,2, K. Kampen1, T. Girardi1, J. Op de Beeck1, J. Verbeeck1, P. Vermeersch2, D. Cassiman3, F. Loayza Puch4, R. Agami4, K. de Keersmaecker1

Debye Institute for Molecular Life Research, University of Amsterdam, Amsterdam, Netherlands

Background: We previously described a recurrent arginine-to-serine mutation on residue 98 (R98S) in ribosomal protein L10 (RPL10), with a frequency of 8.6% in pediatric T-ALL cases. The R98 mutated residue contacts the catalytic core (phosphotransferase center, PTC) of the ribosome and causes ribosome biogenesis, Ptd rib, chl, that defines targets for Met and Amino acid cells. These observations suggest that the RPL10-R98S mutation may contribute to T-ALL pathogenesis by inducing translational changes.

Aims: The spectrum of translated proteins (translatome) of RPL10 R98S mutants was investigated in order to identify translational changes caused by translational and potentially driving oncogenicity.

Methods: We performed ribosome footprinting (RNA sequencing of ribosome bound RNA), polyosomal RNA sequencing, total RNA sequencing and mass spectrometry based quantitative proteomics on engineered RPL10-R98S or RPL10-WT mouse lymphoid Ba/F3 cells.

Results: RPL10 R98S cells showed significant upregulation for 3% (n=178) of the measured proteins and a downregulation of 1% (n=68). Moreover, polysonal RNA sequencing and ribosome footprinting showed respectively 57 and 22 genes with significantly higher translational efficiency in RPL10 R98S, and 22 and 29 genes, with reduced translational efficiency. Among them, we also found genes involved in T cell differentiation and proliferation. In particular, Mapk8 presented reduced translational efficiency in the ribosome footprinting, potentially due to differences in ribosome occupancy of an upstream ORF, whereas the transcription factor Ikrz2, a master regulator of the upregulated transcripts, was overexpressed at the transcriptional and protein level. Interest-

REPOSITIONING EXISTING DRUGS AS NOVEL THERAPEUTICS: OXIDATIVE STRESS AS A TARGET FOR HIGH- RISK LEUKAEMIA IN CHILDREN

M. Karas1,*, K. Somers1, A. Mariana1,2, T. Failes1,2, G. M. Arndt1,2, U. R. Kees3, CHILDREN

Polychemotherapy resistance is a major challenge in the treat-

27
tion. IC50 measurements showed that TP53 mutations lead to resistance against current TKIs and alkylating agents, but not against other drugs. The upstream pathway of p53 (CHK1, CHK2) and DNA damage recognition (γH2AX) were not impaired in the six ALL cell lines. To study the effect of TP53 mutation on resistance to treatment in more detail, we focused on the R248P mutation, located in hot spot codon 248, that we found in a relapsed patient with non-response to treatment and in the NHH cell line. Using a CRISPR/Cas9 knockout (KO) of endogenous p53 and lentiviral based re-expression in NALM-6, we generated p53 KO, and KO+w1 p53, KO+R248P and KO+GFP cell lines. The KO cells showed a similar resistance to DNA damage inducing drugs as KO+R248P cells. Overexpression of wt p53 in KO cells did not improve sensitivity to DNA damage inducing drugs. In contrast to wt p53, R248P did not inhibit cell proliferation under drug treatment. We found that this mutant was unable to induce downstream targets of p53 (p21, BAX). Moreover, ChiP-seq showed that R248P cannot bind the promoter and induce expression of typical p53 targets MDM2, p21, BAX, BCC3/PUMA, FA15 and P53R2. This result indicates that R248P is defined by loss of the consensus element of p53. However, the binding motif analysis showed that the R248P mutant still binds DNA at a different and purine-rich sequence. In summary, R248P leads to loss of wt p53 function and mediates resistance to topoisoasemase II inhibitors and alkylating agents.

Summary/Conclusions: Overall, our results show that mutations affecting TP53 hot spots, in particular codon 248, are associated with resistance of ALL cells to chemotherapy and reveal first insights into underlying mechanisms and pathways.
Background: B-cell acute lymphoblastic leukemia (B-ALL) is the most common malignancy of childhood and is highly curable with modern risk-adapted chemotherapy. However, 15-20% of children and >60% of adults with B-ALL develop chemoresistance and relapse, indicating need for new therapies. Addition of kinase inhibitors to chemotherapy for patients with BCR-ABL1-rearranged (Ph+) B-ALL has dramatically improved event-free and overall survival, and similar approaches are now under active clinical investigation in patients with BCR-ABL1-like (Philadelphia chromosome-like or Ph-like) B-ALL. Recent studies have demonstrated activated spleen tyrosine kinase (SYK) signaling in various genetic subtypes of B-ALL and preclinical activity of the SYK/FLRT3/UK inhibitor fostamatinib. However, SYK activation in B-ALL and potential correlation with specific leukemia-associated mutations remains incompletely characterized. We hypothesized that constitutive activation of SYK signaling occurs across a genetic spectrum of infant and high-risk childhood B-ALL and can be therapeutically targeted in vivo with the selective SYK inhibitor entospletinib (ento).

Aims: (1) Assess basal SYK signaling activation in childhood B-ALL specimens. (2) Quantify treatment efficacy, pharmacokinetics (PK), and pharmacodynamic (PD) effects of ento in childhood B-ALL patient-derived xenograft (PDX) models.

Methods: Total and phosphorylated (p) SYK levels were assessed by Simple Western analysis of splenic lysates from NSG mice well-engrafted with primary pediatric B-ALL specimens (n=19 Ph-like, n=4 infant KMT2A-rearranged (R), and n=4 infant non-KMT2A-R PDX models) to identify leukemias with constitutive SYK signaling activation. To assess in vivo activity of SYK inhibition, selected B-ALL PDX models with high basal pSYK (n=2) were treated with continuous provided control, ento 0.03%, or ento 0.07% chow. Cohorts of mice were sacrificed after 21-28 days, and peripheral blood and spleens were harvested for downstream studies. Flow cytometric analyses of murine tissues were performed to assess initial human ALL engraftment and to measure ento treatment responses. PK and PD assessments were performed in terminal peripheral blood and spleens, respectively.

Results: Constitutive pSYK signaling was observed in 10/19 Ph-like, 4/4 KMT2A-R, and 1/4 non-KMT2A-R B-ALL specimens. Ento treatment of KMT2A-MLLT3 (ALL3103) and Ph-like NUP214-ABL1 (NH011) PDX models significantly inhibited ALL proliferation in vivo versus control animals at both 0.03% and 0.07% chow formulations (representative data in Figure 1; p<0.05). Steady state concentrations were maintained throughout the study duration with terminal PK values of 3.3 (± 0.5) and 7.9 (± 1.0) μM (0.03% and 0.07% ento arms, respectively). PD studies demonstrated dose-dependent in vivo inhibition of pERK measured in human leukemia cells within spleens of ento-treated mice without alterations in total SYK protein levels. In general, PD inhibition of SYK target phosphoproteins was more pronounced in 0.07% ento-treated animals.

Summary/Conclusions: Constitutive activation of SYK signaling occurs frequently in childhood Ph-like and infant KMT2A-R childhood B-ALL. Ento treatment of B-ALL PDX models potently inhibited SYK pathway signaling proteins and significantly inhibited leukemia proliferation in vivo.

P159

PHARMACOLOGICAL ACTIVITY OF CB-103 – AN ORAL PAN-NOTCH INHIBITOR WITH A NOVEL MODE OF ACTION

R. Lehal1,*, D. Weber1, V. Frismantas2, J.-P. Bourquin2, M. Bauer1, M. Murone1, F. Radtke3

1Cellestia Biotech AG, Basel, 2University Children’s Hospital, Zürich, 3Swiss Institute for Experimental Cancer Research, EPFL, Lausanne, Switzerland

Background: NOTCH signalling is a developmental pathway known to play critical roles during embryonic development as well as for the regulation of self-renewing tissues. Aberrant activation of NOTCH signalling leads to deregulation of the self-renewal process resulting in sustained proliferation, evasion of cell death, loss of differentiation capacity, invasion and metastasis, all of which are hallmarks of cancer. When the NOTCH pathway is inappropriately activated by genetic lesions (over expression of NOTCH ligands/receptors, GOF mutations in NOTCH receptors as well as chromosomal translocations), it becomes a major driver for NOTCH-dependent cancers and resistance to standard of care treatment. Over 250’000 patients are annually diagnosed with NOTCH dependent cancers, with no specific therapy available to date.

Aims: Given the importance of NOTCH signalling in human cancers, several therapeutic approaches have been utilized to block NOTCH signalling. Two of these strategies are: a) the use of monoclonal blocking antibodies (mAbs) against NOTCH ligands and receptors and b) the use of small molecule gamma-secretase inhibitors (GSIs). However, these approaches can only be effective if tumor cells express full-length ligand or receptor molecules. As validation of NOTCH as a therapeutic target, clinical activity of these in clinical studies was observed in various trials for some of these inhibitors (mAbs, GSIs), but treatment and exposure were usually limited due to toxicities, mainly related to gastro-intestinal adverse events. On the contrary, in human cancers harbouring NOTCH gene fusion due to chromosomal translocations or specific NOTCH mutations, the use of mAbs and GSIs will have very limited clinical benefits. Cellestia has decided to follow a disruptive approach, by blocking NOTCH signalling in the most downstream part of the NOTCH cascade, at the level of the NOTCH transcriptional activation complex, using small molecule inhibitors.

Methods: Here we report the pharmacological characterization of CB-103, a first-in-class orally-active small molecule inhibitor of the NOTCH transcriptional activation complex.

Results: We demonstrate that in vitro CB-103 potently inhibits NOTCH signalling in various leukemic and lymphoma cell lines, and T-ALL blasts derived from relapse/refractory patients. In addition, CB-103 exhibited anti-tumor efficacy in multiple in vivo models of NOTCH-driven T-ALL using T-ALL cell lines and patients derived xenograft models.

Summary/Conclusions: Toxicology studies have been completed and clinical development of CB-103 with a first-in-human Phase I/IIA clinical study in advanced solid tumors and haematological malignancies is under preparation.
Acute lymphoblastic leukemia - Clinical 1

IKZF1 Δ4-7 can be easily screened by PCR but does not predict outcome in adults with acute lymphoblastic leukaemia: data from 490 patients enrolled on the UKALL14 trial

1UCL Cancer Institute, 2CRUK and UCL Cancer Trial Centre, UCL, 3Barts Cancer Institute, QMUL, London, 4Leukaemia Research Cytogenetics Group, Northern Institute for Cancer Research, Newcastle University, Newcastle Upon Tyne, United Kingdom

Background: The IKZF1 gene encodes the IKAROS zinc-finger transcription factor and master regulator of lymphocyte differentiation. IKZF1 lesions are common in acute lymphoblastic leukaemia (ALL) and have been reported as independent prognostic factors for poor outcome. IKZF1 Δ4-7, resulting in the dominant negative IK6 isoform is the most common single IKZF1 deletion.

Aims: We aimed to generate and validate a simple, PCR-based screening assay for IKZF1 Δ4-7 using an endpoint PCR assay using primers located in introns 3 and 7. The lower limit of detection was determined by serial dilution of DNA from the IK6 expressing cell line SUP-B15 and calculated to be 0.001%. A total of 65 samples were also tested using the MLPA P335 kit to detect the full spectrum of IKZF1 deletion. Sanger sequencing confirmed the breakpoints in 27 cases.

Results: The median age of the patients tested was 46 years (range 25-65). Overall IKZF1 Δ4-7 was detected in 97/490 (20%) patients but the frequency varied by genetic subtype. Patients with BCR-ABL1 fusion had the highest IKZF1 Δ4-7 frequency (46/150, 31%) followed by patients with B-other ALL (29/154, 19%). Patients with other classic cytogenetic aberrations harboured significantly fewer IKZF1 Δ4-7 - low hypodiploidy (3/26), MLL gene fusions (3/31), t(1;19) and iAMP21 (0/3). MLPA did not detect any IKZF1 Δ4-7 deletions that were not detected by PCR but did identify several samples with alternative IKZF1 deletions affecting different exons (see Table 1). By contrast, the PCR assay did detect six IKZF1 Δ4-7 deletions undetected by MLPA, consistent with the higher sensitivity of this approach. Interestingly, three of these samples harboured alternative IKZF1 deletions in addition to IKZF1 Δ4-7. In 70 (14%) cases, we observed a "faint" PCR band. Since the biological relevance of this was not clear, the "faint" bands were not included in the main analysis. Interestingly the frequency of these "faint" bands was similar across all genetic subtypes: BCR-ABL1 (14%), B-other (15%), MLL (21%), low hypodiploidy (19%). We examined the impact of IKZF1 Δ4-7 on achievement of CR, persistence of minimal residual disease (MRD) at x > 1 x 10^(-4) (lgT/CR quantitation by EuroMRD criteria) after courses 1 and 2 of therapy, EFS, OS and time to relapse, at a median follow-up of 23.1 months. Two thirds of patients (44/66) with IKZF1 Δ4-7 were MRD positive at the end of phase 1 compared with 147/273 (54%) patients without the deletion (p=0.059). However, this relationship between IKZF1 Δ4-7 and MRD did not persist after phase 2. We did not identify any association between IKZF1 Δ4-7 and any of the other outcome parameters tested.

Table 1.

Summary/Conclusions: IKZF1 Δ4-7 can be detected by a simple and cheap PCR assay, which is more sensitive than MLPA. The frequency of IKZF1 Δ4-7 was broadly comparable with previous studies. However, we did not find an association between IKZF1 Δ4-7 and clinical outcome in the large clinical trial sample set. We are in the process of evaluating the impact of other IKZF1 lesions.

P161

Prognostic significance of minimal residual disease detected by MLL fusion gene transcripts in infant acute lymphoblastic leukaemia: updated results of 76 patients enrolled into MLL-baby study

1Regional Children Hospital #1, Research Institute of Medical Cell Technologies, Ekaterinburg, 2National Research Institute of Pediatric Hematology, Oncology and Immunology named after Dmitry Rogachev, Moscow, Russian Federation, 3Belarusian Research Center for Pediatric Oncology, Hematology and Immunology, Minsk, Belarus, 4PET Technology, 5Ural State Medical University, Ekaterinburg, Russian Federation

Background: Fusion gene transcripts (FGTs) are rarely used for minimal residual disease (MRD) monitoring in acute lymphoblastic leukaemia (ALL) cases, except of Ph-positive ALL. However in infant ALL, where MLL gene rearrangements are found the majority of cases, MLL FGTs are attractive targets for MRD detection.

Aims: To estimate prognostic significance of MRD by qualitative detection of different MLL FGTs in infant ALL treated by MLL-baby protocol.

Methods: Seventy-six infants (27 boys and 49 girls) with median age of 5.8 months (range 0.03-11.83) were included in the current study. Among them there were 39 (51.3%) MLL-AF4-positive cases, 14 (18.4%) MLL-MLLT1-positive, 12 (15.8%) MLL-MLLT3-positive, 6 (7.9%) MLL-MLLT10-positive, 4 (5.3%) MLL-EPS15-positive cases. MRD detection was performed in BM samples by real-time quantitative PCR and nested RT-PCR with sensitivity non-less than 10^-4. MRD negativity was defined as absence of FGTs in the both assays. Median of follow-up period in the observed group was 6.4 months. Informal consent were obtained in all cases.

Results: We confirmed our earlier finding that the most informative TP for the MLL-baby protocol was TP4. MLL-MLLT1-positive patients stratified to high-risk arm of MLL-baby protocol (EFS 0.05±0.04 vs 0.78±0.07 < p<0.0001; cumulative incidence of relapse 0.78±0.10 vs 0.11±0.07 < p<0.0001, respectively) and for all others MLL-rearranged patients treated by intermediate risk (imR) arm (EFS 0.00 vs 0.71±0.11 < p<0.0001; cumulative incidence of relapse 1.0 vs 0.29±0.10 < p<0.0001, respectively). There were no significant differences in initial patients’ characteristics and treatment response criteria (on days 8, 15, 36) among 38 MRL-positive and 38 MRD-negative patients. Multivariate analysis revealed that initial CNS disease (hazard ratio (HR) 2.703, 95% CI 1.255-5.284, p=0.011) and MRD positivity at TP4 was an independent factor of unfavorable outcome in infants with MLL-rearranged ALL enrolled into MLL-Baby protocol irrespective of treatment arm. Treatment intensification for MRL-positive at TP4 ImR patients did not improve their outcome. MRD-positivity at TP4 in ImR group was associated with MRD-positivity by flow cytometry on day 15, MLL breakpoint positions within intron 11 gene and initial CNS disease.

Summary/Conclusions: MRL monitoring by detection of MLL FGTs was feasible and had significant prognostic impact. MRD-positivity at TP4 was an independent factor of unfavorable outcome in infants with MLL-rearranged ALL enrolled into MLL-Baby protocol irrespective of treatment arm. Treatment intensification for MRL-positive at TP4 ImR patients did not improve their outcome. MRD-positivity at TP4 in ImR group was associated with MRD-positivity by flow cytometry on day 15, MLL breakpoint positions within intron 11 gene and initial CNS disease.

Pro-t cell ALL/LBL: an ultra-high risk CD2-negative disease subtype in adults defined by flow cytometry

B. Betrosav3,1, G. Rymkieciewicz2, K. Domanska-Czyz2, J. Romejko-Jarosinska1, K. Blach6, L. Poplawski7, W. Michalski3, J. Wawrowski3

1Department of Lymphoid Malignancies, 2Department of Pathology and Laboratory Diagnostics, 3Department of Biostatistics, The Maria Sklodowska-Curie Memorial Institute and Oncology Centre, Warsaw, Poland, Warszawa, Poland
Background: Risk factors for T-LBL have not been systematically evaluated, in contrast to T-ALL.

Aims: Our aim was to define immunophenotype of T-LBL/ALL in 71 consecutive patients by use of the flow cytometry (FCM) of tissue aspirates if peripheral blood (PB) and bone marrow (BM) were uninvolved. We also evaluated prognostic value of immunophenotype according to WHO 2008 subtype and ETV6-RUNX1 (Early-T Cell Phenotype) definition in adult patients with T-LBL/ALL treated on uniform ALL protocol.

Methods: Between 1997 and 2015, 71 adult patients with T-LBL/ALL were treated according to the GMAIL 05/93 and T-LBL/ALL 2004 protocols. Immunophenotype was determined by immunohistochemical staining and by FCM of cellular suspension obtained from lymph nodes (n=31), mediastinal mass (n=12) or nasopharyngeal/perimandibular infiltration (n=2) by fine needle aspiration biopsy (FNAB), as well as of BM (n=10), PB (n=7) and pleural fluid (n=9). Disease subtype was defined according to WHO 2008 classification: pre-B (CD19+/CD2+/CD7-), null (CD1+/CD2+/CD7+), null (CD1+/CD2+/CD7+), neoplastic/mature (sCD3+). Recognition of pan-T cell CD antigen (pTag) expression included: CD1a, CD2, sCD3, CD4, CD5, CD7, CD8. ETP-ALL/lmimmunophenotype was defined as follows: absent (up to 5% positive cells) CD1a and CD8 expression, absent or dim (75% positive cells) CD5 expression, expression (25% positive cells) of 1 or more myeloid (CD13,CD33, CD15) or stem cell (CD34, HLA-DR) markers.

Results: Patient characteristics: ALL (BM+ >20%): n=26(37%); LBL: n=45(63%); BM+<20% involvement (LBP): 27%, age 35%; 72s, males: 67%; mediastinal mass (MM): 92%, primary CNS+: 8%. Immunophenotype: pro-T: 21% (pre-T: 17%, cortical or CD1a+, medullary/mature: pre-B: 3/9(33%) are alive, 3/4(75%) pts with pre-T and only 1/9((11%) with pro-T. 55% (0.418, 0.685) for ETP and non-ETP pts, respectively. Among ETP pts, (0.072, 0.272). There was no significant difference in OS and DFS in pts with 53% (0.152, 0.494) and 27% (0.097, 0.452) for pts without CD2, CD1a and 3 or less pTag present was 64% (0.511, 0.776), 66% (0.512, 0.803) and 64% (0.5, 0.782) compared to 11% (0.034, 0.256), 32% (0.152, 0.494) and 27% (0.097, 0.452) for pts without CD2, CD1a and pTag expression, absent or dim (75% positive cells) CD5 expression, expression: pro-T (CD2-), pre-T (CD2+), cortical (CD1a+), medullary/mature (sCD3+). Recognition of pan-T cell CD antigen (pTag) expression included: CD1a, CD2, sCD3, CD4, CD5, CD7, CD8. ETP-ALL/lmimmunophenotype was defined as follows: absent (up to 5% positive cells) CD1a and CD8 expression, absent or dim (75% positive cells) CD5 expression, expression (25% positive cells) of 1 or more myeloid (CD13,CD33, CD15) or stem cell (CD34, HLA-DR) markers.

Methods: Induction chemotherapy for patients in the Northern Italy Leukemia Group 10/07 trial (ClinicalTrials.gov NCT-00795756; Blood 2016;128:176-182). Between 2007 and 2010 71 pts with Philadelphia-negative ALL were treated according to the GMALL 05/93 and T-LBL/2004 protocols. Immunophenotype was determined by immunohistochemical staining and by FCM of tissue aspirates if peripheral blood and bone marrow were uninvolved. We also evaluated prognostic value of immunophenotype according to WHO 2008 subtype and ETP6-RUNX1 (Early-T Cell Phenotype) definition in adult patients with T-LBL/ALL treated on uniform ALL protocol.

Results: Our aim was to define immunophenotype of T-LBL/ALL in 71 consecutive patients by use of the flow cytometry (FCM) of tissue aspirates if peripheral blood (PB) and bone marrow (BM) were uninvolved. We also evaluated prognostic value of immunophenotype according to WHO 2008 subtype and ETV6-RUNX1 (Early-T Cell Phenotype) definition in adult patients with T-LBL/ALL treated on uniform ALL protocol.

Figure 1. Summary/Conclusions: Survival of T-LBL/ALL pts depends on CD1a and CD2 expression as well as on WHO subtype. ETP is a non-uniform category by pro-T/pre-T-cell origin. ETP phenotype was non-significant factor for OS/DFS (p=0.10, 0.19) unless consistent with pro-T phenotype (CD2-), only 1/9 pts alive. Pro-T (CD2-) is an ultra-high risk subtype of T-LBL/ALL and novel treatments are needed to improve pts outcomes.
**Background:** The outcome for older adults with acute lymphoblastic leukaemia (ALL) is unsatisfactory. The UKALL12/ECOG2993 study showed that high risk cytogenetic abnormalities, were common, as well as lower rates of complete remission (CR) and 5 year overall survival (OS) in those aged 55–65 years of age as compared to younger persons. There are few studies which focus on older patients with ALL, despite an increasing incidence with age.

**Aims:** A trial to establish an age-appropriate baseline chemotherapy from which to design widely-applicable studies of novel agents in older people with ALL.

**Methods:** UKALL60+ offers five ‘Arms’ to be decided by investigator and patient choice; Arm A= Philadelphia chromosome positive (Ph+), Arm B= Non-intensive (designed to be delivered primarily out of hospital), Arm C= Intensive, Arm D= Intensive+, and Arm E= Registration only (in which treatment is at patient choice; Arm A= Philadelphia chromosome positive (Ph+), Arm B= Non-intensive, Arm C= Intensive, Arm D= Intensive+, and Arm E= Registration only (in which treatment is at patient choice). Aims include determining appropriate regimens for future studies of novel agents in older people with ALL.

**Results:** Of 210 adult ALL pts, we identified 63 (30%) consecutive pts with elderly ALL. The average age at time of diagnosis was 67 (60–82), & 38 (60%) were males. Median follow up was 16.1 months (0.2–126), during which time 49 (63%) deaths occurred; 25 (63%) related to the disease, & 15 (37%) secondary to infection or other causes. Baseline characteristics at time of diagnosis: 54 (86%) pts had B-cell phenotype, 19 (35%) were Ph+. Only 9 (14%) pts had T-cell phenotype. 20 (31%) pts had a Charlson Comorbidity Index ≥2 & 17 (27%) presented with ECOG PS ≥2. Median Hgb was 10.6 g/dl (4.9–18.5), WBC 62 x 10⁹/l (0.5–160.5), PLT 51 x 10⁹/l (4–750), peripheral blast 30% (0–95), marrow blast 87.5% (0–100), & LDH 381.5 U/L (141–8440). Lymphoblastic lymphoma was only evident in 3 (5%) pts. Among pts with available data, 34/58 (59%) had B symptoms, 16/57 (28%) lymphadenopathy, 7/57 (12%) pleural effusions & 10/45 (22%) of pts had CNS leukemia. Cytogenetics at time of diagnosis: Of 48 pts with available data, 20 (41%) had complex cytogenetics (≥5 abnormalities), 18 (38%) had a monosomic karyotype, 8 (17%) were hypodiploid, 4 (8%) were hyperdiploid, & 2 (4%) were a mix of hypo- & hyper-diploid. FISH studies were available for 50 pts: 10 (20%) had CDKN2A del, 2 (4%) E2A-PBX1, 1 (2%) E2A-PBX1 [Figure 1].

**Summary/Conclusions:** ALL in older patients is challenging to treat, with a difficult balance between efficacy and toxicity. We observed a high rate of high risk cytogenetics, especially notable being the rate of low hypodiploidy. Initial high CR rates are seen in those with Ph+ve disease, this does not appear to translate into improved PFS and OS when compared with Philadelphia negative disease. The commonest cause of death in this group is ALL. We will use our baseline data to develop appropriate regimens for future studies of novel agents.

**Background:** Elderly acute lymphoblastic leukemia/lymphoma (ALL) is a rare disease with a poor prognosis and is underrepresented in clinical trials. This could be due to comorbidities, early death during induction, lower rates of complete remission, and higher risk of relapse with poor biological features (Gokbuget, Blood, 2013).

**Aims:** Describe clinical outcomes and prognostic factors of elderly ALL.

**Methods:** After IRB approval, we performed a retrospective study of patients (pts) aged ≥60 diagnosed with ALL from 2000 to 2016 at Mayo Clinic Rochester. Statistical analysis was performed using JMP 10.0 software.

**Results:** Out of 210 adult ALL pts, we identified 63 (30%) consecutive pts with elderly ALL. The average age at time of diagnosis was 67 (60–82), & 38 (60%) were males. Median follow up was 16.1 months (0.2–126), during which time 49 (63%) deaths occurred; 25 (63%) related to the disease, & 15 (37%) secondary to infection or other causes. Baseline characteristics at time of diagnosis: 54 (86%) pts had B-cell phenotype, 19 (35%) were Ph+. Only 9 (14%) pts had T-cell phenotype. 20 (31%) pts had a Charlson Comorbidity Index ≥2 & 17 (27%) presented with ECOG PS ≥2. Median Hgb was 10.6 g/dl (4.9–18.5), WBC 62 x 10⁹/l (0.5–160.5), PLT 51 x 10⁹/l (4–750), peripheral blast 30% (0–95), marrow blast 87.5% (0–100), & LDH 381.5 U/L (141–8440). Lymphoblastic lymphoma was only evident in 3 (5%) pts. Among pts with available data, 34/58 (59%) had B symptoms, 16/57 (28%) lymphadenopathy, 7/57 (12%) pleural effusions & 10/45 (22%) of pts had CNS leukemia. Cytogenetics at time of diagnosis: Of 48 pts with available data, 20 (41%) had complex cytogenetics (≥5 abnormalities), 18 (38%) had a monosomic karyotype, 8 (17%) were hypodiploid, 4 (8%) were hyperdiploid, & 2 (4%) were a mix of hypo- & hyper-diploid. FISH studies were available for 50 pts: 10 (20%) had CDKN2A del, 2 (4%) E2A-PBX1, 1 (2%) E2A-PBX1 [Figure 1].

**Summary/Conclusions:** ALL in older patients is challenging to treat, with a difficult balance between efficacy and toxicity. We observed a high rate of high risk cytogenetics, especially notable being the rate of low hypodiploidy. Initial high CR rates are seen in those with Ph+ve disease, this does not appear to translate into improved PFS and OS when compared with Philadelphia negative disease. The commonest cause of death in this group is ALL. We will use our baseline data to develop appropriate regimens for future studies of novel agents.

**MANAGEMENT AND OUTCOME OF ADULT PH+ ACUTE LYMPHBLASTIC LEUKEMIA PATIENTS TREATED AT THE “SAPIENZA” UNIVERSITY BETWEEN 1996 AND 2016**

S. Chiaretti¹, V. Gianfelici¹, R. Agrippino¹, L. Elia¹, F. Paolo², S. Capria¹,

¹Sapienza University of Rome, Rome, Italy

**Background:** All Ph+ve ALL patients (pts) aged ≥60 diagnosed with ALL from 2000 to 2016 at Mayo Clinic Rochester.
Background: The outcome of adults and elderly (>60 years) patients with Ph+ ALL has improved since the introduction of tyrosine kinase inhibitors (TKI), used alone or in combination with chemotherapy during induction. Before 2005, all these patients were treated with chemotherapy; from 2005, a TKI-based “chemo-free” induction strategy was applied.

Aims: To evaluate the outcome of patients followed from 1996 at a single Center, and to correlate the short- and long-term responses with: a) induction treatment (chemotherapy or TKI); b) age; c) TKI used (imatinib or dasatinib); d) fusion protein; e) allogeneic stem cell transplant (SCT).

Methods: Sixty-eight patients (29M/39F) were treated; median age was 50 years (18-88) and 16 were elderly patients; 43 cases had the p190 protein, 19 the p210 and 6 had both; the latter 2 groups were merged together for further analyses. Fifty-two patients were enrolled in clinical trials. Median follow-up is 105 months (13-224).

Results: As induction, 28 patients received chemotherapy, 2 chemotherapy+TKI (considered as “chemotherapy+TKI group”) and 38 TKI alone (24 imatinib and 14 dasatinib). All cases received TKI during consolidation/maintenance when it became available. All elderly patients but 1 received a TKI alone (plus steroids). Upon induction, 44 patients received consolidation chemotherapy, including 5 elderly. A SCT - carried out virtually only in adults - was performed in first complete remission (CR) in 13 cases (5 in the chemotherapy+TKI and 8 in the TKI groups). Overall, 91% patients achieved a CR, OS and DFS at 100 months are 42% and 45.5%, respectively. Among the 30 patients in the chemotherapy+TKI group, 25 (83%) achieved a CR, 4 were refractory and 1 died in induction; in the TKI group (n=38), 37 (97%) achieved a CR and 1 was refractory. Differences are statistically significant (p=0.03).

Figure 1: The trend was also observed in patients of the intermediate-risk group but not in the standard-risk group. In univariate analysis, CD9 positivity (HR=2.4; p=0.022) and ETV6-RUNX1 translocation (higher prevalence in CD9+ patients; p=0.001) were significantly more common in the intermediate-risk group (P=0.044) and a higher proportion of CD9+ patients was stratified into the high-risk group (P=0.025). Besides, CD9- patients had poorer prednisone response (P=0.014). The 5-year overall survival (OS) and relapse-free survival (RFS) rates of CD9+ patients were significantly lower than those in CD9- patients (P=0.029). Subgroup analysis revealed remarkably poorer outcomes in CD9+ patients of the high-risk group (P=0.045). A similar trend was also observed in patients of the intermediate-risk group but not in the standard-risk group.

Summary/Conclusions: Our data indicate that expression of CD9 was significantly associated with inferior survival outcomes in pediatric B-ALL patients. The observation of patients with no risk factors for poor outcome, suggesting that CD9 expression could potentially be used in conjunction with other known prognostic factors for refinement of risk group stratification. Our study also lays the foundation for future development of CD9-targeted therapy for high-risk and relapsed/refractory pediatric B-ALL.

P167 THE TETRASPANIN CD9 IS A PROGNOSTIC MARKER FOR PREDICTING SURVIVAL OUTCOMES OF PEDIATRIC B-PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA

K.T. Leung1,2, K.Y.Y. Chan1, C. Zhang1, A.W.K. Leung1, F.W.T. Cheng1, J.W.S. Yu1, T.F. Leung1, K. Liu1, C.K. Li1

2Division of Hematology, Department of Cellular Biotechnologies and Hematology, Sapienza University of Rome, 2GIMEMTA Data Center, Rome, Italy

Background: B-precursor acute lymphoblastic leukemia (B-ALL) is the most common childhood malignancy, accounting for approximately 30% of pediatric cancers. With advances in risk-adapted chemotherapy, the overall cure rate of newly diagnosed B-ALL is approaching 85% in most developed countries. However, relapse still occurs in ~20% of patients and a significant portion of them are not initially classified in the high-risk disease entity, underlining the need for development of additional informative prognostic biomarkers.

Aims: CD9, a tetraspanin family protein, regulates multiple physiologic processes including cell migration and adhesion, and has been associated with metastasis and progression of various types of cancers. In this study, we aim to evaluate its expression pattern and prognostic significance in pediatric B-ALL.

Methods: Cell surface CD9 expression on leukemic blasts at disease presentation was characterized by multicolor flow cytometry in a cohort of pediatric B-ALL patients. The CD9 expression status was correlated with clinical parameters, including age, sex, white cell count, cyogenetics and prednisone response, Kaplan-Meier survival analysis was performed to investigate the possible association of CD9 expression with clinical outcomes. The potential role of CD9 expression as a predictor of 5-year survival outcomes was evaluated using Cox regression models.

Results: Among 118 cases tested, blasts of 92 patients (78.0%) were CD9+ (30% of CD9-expressing blasts). There were no significant differences in age, sex and white cell count between CD9+ and CD9- patients. Major cytogenetic subgroups were similarly distributed except for hyperdiploidy (all patients were CD9+; P=0.022) and ETV6-RUNX1 translocation (higher prevalence in CD9- patients; P=0.001). Significantly more CD9+ patients were stratified into the intermediate-risk group (P=0.044) and a higher proportion of CD9+ patients was stratified into the high-risk group (P=0.025). Besides, CD9- patients had poorer prednisone response (P=0.014). The 5-year overall survival (OS) and relapse-free survival (RFS) rates of CD9+ patients were significantly lower than those in CD9- patients (P=0.029). Subgroup analysis revealed remarkably poorer outcomes in CD9+ patients of the high-risk group (P=0.045). A similar trend was also observed in patients of the intermediate-risk group but not in the standard-risk group.

Summary/Conclusions: Our data indicate that expression of CD9 was significantly associated with inferior survival outcomes in pediatric B-ALL patients. The observation of patients with no risk factors for poor outcome, suggesting that CD9 expression could potentially be used in conjunction with other known prognostic factors for refinement of risk group stratification. Our study also lays the foundation for future development of CD9-targeted therapy for high-risk and relapsed/refractory pediatric B-ALL.

P168 PEDIATRIC MLL ACUTE LEUKEMIA PATIENTS SHOW DIFFERENTIAL HDAC EXPRESSION

N. Vega-García1,2, R. Malatesta1, C. Estella1, M. Torrebadell1,2, S. Gassiot1, A. Catalá1,2, R. Beruexco1,2, A. Ruiz-Llobet1,2, A. Alonso-Saladrigues1,2, M. Mesegue1,2, M. Trabazo1, S. Rives1,3, M. Camós1,2
1Hematology Laboratory, Institut de Recerca Pediàtrica Hospital Sant Joan de Deu, Barcelona, 2Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Instituto de Salud Carlos III, Madrid, 3Clinical Department of Pediatric Hematology and Oncology, Instituto de Recerca Pediàtrica Hospital Sant Joan de Deu, Barcelona, Spain

Background: Overexpression of histone deacetylases (HDACs) is a common feature in acute leukemias. Consequently, HDAC inhibitors (HDACi) have emerged as promising targeted therapy. However, non-specific HDACi may lead to accumulation of double stranded DNA lesions, so more selective isoform specific HDACi are needed. Expression patterns of HDACs in childhood leukemia have been scarcely studied.

Aims: To analyze the expression of HDAC isoforms in different subtypes of pediatric leukemia and correlate them with prognosis and clinico-biological features.

Methods: We evaluated the mRNA gene expression profile of class I, II and IV HDAC genes (HDAC 1-11) by quantitative PCR in 126 leukemic pediatric samples and a pool of non-neoplastic samples as calibrator. Patients were treated according to the Spanish Hemato-Oncology Cooperative Group protocols in a single center. The HDAC expression levels in different groups were compared by the Mann-Whitney test. The level of significance was set up at p<0.05. The analyses were performed with SPSS 24.0.

Figure 1: Summary/Conclusions: This study further underlines the benefit of an induction based on a TKI alone. Since age holds strong prognostic significance, our results suggest that while the benefit followed by consolidation chemotherapy is the optimal choice for adults, in elderly cases dasatinib is more appropriate, since patients are often unfit to receive further chemotherapy. Finally, the advantage of SCT needs to be carefully redefined in the TKI era.
Results: Our series included 69 boys and 57 girls diagnosed with acute leukemia, with a median age of 6.1 years (range 0.7-17.4 years). We included 12 infant patients (<1 year old). Eighty-two (65%) patients had B-cell precursor acute lymphoblastic leukemia (BCP-ALL), 24 patients T-cell ALL and 20 patients had acute myeloblastic leukemia (AML). Globally, we found higher expression levels of class I HDAC isozymes (HDAC 1, 2, 3 & 8) in leukemic samples as compared to non-neoplastic samples, as previously reported. Interestingly, some HDAC isoforms associated with specific genetic aberrations. Those patients with rearrangement of MLL (KMT2A) gene (n=18, including 9 BCP-ALL and 9 AML; 7 infants and 11 pediatric) received a significantly higher expression of HDAC9 (p<0.0001) and a statistically significant underexpression of HDAC1 and HDAC3 (p=0.003 & p=0.02, respectively, see Figure 1). Infants (n=12) had also a significantly lower expression of HDAC7 (p=0.043). In the same line, all pediatric patients with pro-B phenotype (CD10 negative) had low levels of HDAC7, but differences did not reach a statistical significance. After a median follow-up of 5.9 years, 15 patients died, with an overall survival (OS) of 68% for BCP-ALL, 52% for TALL and 67% for AML patients (p=0.0001). In the BCP-ALL subgroup, the expression of HDACs did not predict outcome, and only CNS infiltration and leukocytosis were unfavorable risk factors for OS. Again, CNS+, high WBC count and presence of minimal residual disease (MRD) post-induction were predictive for worse event free survival (EFS). Although the number of cases is low and these results must be taken with caution, T-ALL patients with the highest expression of HDAC3 (upper quartile) significantly correlated with worse OS (94% vs 25%, p=0.001) and a trend towards worse EFS (89% vs 53%, p=0.06). The only significant risk factor for EFS in this subgroup was the presence of MRD after induction (p=0.003).

Summary/Conclusions: We have observed a specific pattern of HDACs expression in pediatric patients with MLL rearrangement. Our study, if further confirmed, suggests that specific HDACi would potentially be a useful targeted treatment for pediatric patients with MLL rearranged leukemia.

P169 MINIMAL DISSEMINATED DISEASE DETECTION BY FLOWCYTOMETRIC IMMUNOPHENOTYPING IN T-CELL ACUTE LYMPHOBLASTIC LYMPHOMA G.K. Viswanathan1,*, P. Tembhare1, N. Patkar1, S. Gujral1, P.G. Subramanian1

1Hematopathology Laboratory, Advanced Centre for Treatment, Research and Education in Cancer (ACTREC) - Tata Memorial Centre (TMC), Mumbai, India

Background: T-cell acute lymphoblastic lymphoma (T-LBL) with minimal disseminated disease (MDD) is defined as the presence of T-LBL with <25% blasts in the peripheral blood (PB) and/or bone marrow (BM) by morphology and the presence of immunophenotypically abnormal T-lymphoblasts in bone marrow by flowcytometry. Published literature regarding the prevalence and clinical significance of this rare subgroup is sparse. In this study we analysed the prevalence of minimal disseminated disease in cases of T-LBL with <25% blasts in PB and BM using 8-10 colour flowcytometric immunophenotyping and evaluate the clinical and immunophenotypic features.

Methods: This study included retrospective analysis of 42 patients of T-LBL with predominantly lymphomatous presentation with <25% blasts in peripheral and bone marrow. The following parameters were taken into account including complete hemogram, peripheral blood examination, bone marrow morphology and immunophenotyping, CSF analysis, pleural fluid morphology and immunophenotyping, tissue biopsy (lymph node or mediastinal mass), PET-CT findings and LDH levels. Flowcytometric immunophenotyping on bone marrow was performed on a 3 laser 10 color Beckman-Coulter Navios® platform and analysed using Kaluza® software. A minimum of 1,000,000 events were acquired and the presence of minimal disseminated disease was noted.

Results: A retrospective analysis of 42 cases of T-LBL with <25% blasts in peripheral and bone marrow was done. The mean age was 12.2 years (Range:2-48 years). M:F ratio was 1:1.7. Nearly all patients had normal haemoglobin, total leukocyte count and platelet counts. LDH was raised in majority of the patients (Mean 674±UL; N=190±UL). CSF examination was negative in all cases indicating that it is unlikely to have CNS involvement in patients with <25% blasts in PB and BM. Minimal disseminated disease was seen in 12 cases (12/42=28.6%) of cases. Of the 12 cases with minimal disseminated disease two cases were near early T-cell precursor acute lymphoblastic leukemia (near ETP-ALL) type and none were of ETP-ALL type. None of the cases showed circulating blasts in PB. The mean (range) bone marrow blast count in the group without MDD was 2.4% (0-4%) and in the group with MDD was 5.1% (0-15%). In the group with MDD (12 cases), only 5 cases showed >5% blasts/hematogones identifiable by morphology. This indicates flowcytometry is necessary in cases with <5% blasts to pick up cases of MDD. PET-CT was not sensitive to pick-up MDD as increased FDG uptake was seen in only a single case of MDD; it was negative in all cases without MDD. MDD by flowcytometry ranged from 0.007% to 18.5% (mean: 3.6%; median: 4%) (Figure 1).

Figure 1.

Summary/Conclusions: Our study shows that minimal disseminated disease is seen in more than one-fourth of cases (28.6%) of T-LBL with <25% blasts in PB and BM. This underlines the importance of flowcytometric evaluation of bone marrow in cases with <25% blasts identified by morphology. The identification of minimal disseminated disease in T-LBL is important as studies have shown inferior event free survival in T-LBL with minimal disseminated disease as compared to patients without minimal disseminated disease.

P170 INOTUZUMAB OZOGAMICIN IN COMBINATION WITH LOW-INTENSITY CHEMOTHERAPY (MINI-HYPER-CVD) AS FRONTLINE THERAPY FOR OLDER PATIENTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA: UPDATED RESULTS FROM A PHASE III TRIAL N. Shurtleff1, H. Kantarjian1, S. Abruzzese1, L. Vose1, R. Callaghan1, E. Jabbour1, D. Thomas1, G. Garcia-Manero1, N. Daver1, G. Borthakur1, N. Jain1, M. Konopleva1, K. Sasaki1, N. Pennmaraju1, Y. Alvarado1, J. Jacob1, R. Garris1, P. Thompson1, J. Cortes1, E. Jabbour1

1Hematopathology Laboratory, Advanced Centre for Treatment, Research and Education in Cancer (ACTREC) - Tata Memorial Centre (TMC), Mumbai, India

Background: Older patients (pts) with acute lymphoblastic leukemia (ALL) have poor tolerance of intensive chemotherapy, and novel strategies are needed in this population. In pts with relapsed/refractory ALL, inotuzumab ozogamicin (io), an anti-CD22 antibody-drug conjugate, has been shown to improve survival compared to salvage chemotherapy.

Aims: We designed a phase III trial to evaluate the safety and efficacy of low-intensity chemotherapy (mini-hyper-CVD) plus InO as frontline treatment for older pts with newly diagnosed ALL.

Methods: Pts ≥60 years of age with newly diagnosed Philadelphia chromosome-negative pre-B received mini-hyper-CVD (compared to hyper-CVAD: no anthracycline, 50% dose reductions of cyclophosphamide and dexamethasone, 75% dose reduction of methotrexate, 85% dose reduction of cytarabine). InO was given on day 3 of the first 4 cycles. The first 6 pts received InO at a dose of 1.3 mg/m² for cycle 1 followed by 0.8 mg/m² for cycles 2-4; pts 7-34 received 1.8 mg/m² for cycle 1 followed by 1.3 mg/m² for cycles 2-4. Due to concern for veno-occlusive disease (VOD), the protocol was amended so that pts 35+ received InO at a dose of 1.3 mg/m² for cycle 1 followed by 1.0 mg/m² for cycles 2-4. Rituximab was given during the first 4 cycles in pts with CD20 expression ≥20%; all pts received IT chemotherapy prophylaxis with the first 4 cycles. Pts in CR after 8 cycles then received POMP maintenance for up to 3 years.

Figure 1.

Summary/Conclusions: Our study shows that minimal disseminated disease is seen in more than one-fourth of cases (28.6%) of T-LBL with <25% blasts in PB and BM. This underlines the importance of flowcytometric evaluation of bone marrow in cases with <25% blasts identified by morphology. The identification of minimal disseminated disease in T-LBL is important as studies have shown inferior event free survival in T-LBL with minimal disseminated disease as compared to patients without minimal disseminated disease.
Results: Between 4/2012 and 12/2016, 47 pts have been treated, 4 of whom had received 1 cycle of prior therapy and were in CR at the time of enrollment. The median age was 68 years (range, 60-81), and median CD22 expression was 97% (range, 72-100%). Of 43 pts evaluable for response, 42 responded (ORR=98%). Best response was CR in 36 pts (84%), CRp in 5 (12%) and CRi in 1 (2%). MRD negativity by 6-color multiparameter flow cytometry was achieved in 31 of 41 evaluable pts (78%) on day 21 and in 44 of 46 evaluable pts (96%) within 12 weeks of treatment.

The median follow-up was 24 months (range, 1-55 months), 3 pts (6%) underwent allogeneic stem cell transplantation (ASCT) in first remission. Of the 46 responders, 6 pts (13%) have relapsed. 16 pts have died, 1 due to resistant disease, 4 after relapse, 1 after ASCT and 10 in CR/CRp. 21 pts remain on treatment (consolidation, n=3; POMP maintenance, n=19), and 5 pts have completed all therapy. The 3-year continuous CR and OS rates were 72% and 54%, respectively. Compared to a historical cohort of 79 pts older treated at our institution with hyper-CVAD ± rituximab, mini-hyper-CVD+INo resulted in significantly improved OS (3-year OS rate: 54% vs 31%, median OS not reached versus 16 months; P=0.007).

Treatment was overall well-tolerated. The median times to platelet and ANC recovery in cycle 1 were 22 days (range, 11-91 days) and 16 days (range, 0-49 days), respectively. In cycles 2-8, the median times to platelet and ANC recovery were 22 days and 17 days, respectively. Prolonged thrombocytopenia (lasting >6 weeks) occurred in 37 pts (79%) at some point during therapy; 8 pts (17%) experienced prolonged thrombocytopenia during induction and 36 (77%) during 1 or more subsequent courses. Grade ≥3 transaminase elevation occurred in 9 pts (19%), hyperbilirubinemia in 8 (17%) and hemorrhage in 7 (15%). 4 pts (9%) developed VOD (1 after ASCT, 3 unrelated to ASCT). 8 pts (17%) experienced prolonged thrombocytopenia during induction and 36 (77%) during 1 or more subsequent courses. Grade ≥3 transaminase elevation occurred in 9 pts (19%), hyperbilirubinemia in 8 (17%) and hemorrhage in 7 (15%). 4 pts (9%) developed VOD (1 after ASCT, 3 unrelated to ASCT). 8 pts (17%) experienced prolonged thrombocytopenia during induction and 36 (77%) during 1 or more subsequent courses. Grade ≥3 transaminase elevation occurred in 9 pts (19%), hyperbilirubinemia in 8 (17%) and hemorrhage in 7 (15%). 4 pts (9%) developed VOD (1 after ASCT, 3 unrelated to ASCT).

Summary/Conclusions: The combination of Ino with mini-hyper-CVD is safe and effective in older pts with newly diagnosed ALL, resulting in a promising 3-year OS rate of 54%. These results appear superior to the outcomes of older pts treated with hyper-CVAD.

Background: Blastic plasmacytoid dendritic cell neoplasm (BPDCN) is a rare hematological malignancy that is derived from plasmacytoid dendritic cell precursors. BPDCN tends to occur in elderly people with frequent skin involvement and is associated with an aggressive clinical course and a poor prognosis. Although optimized diagnostics and therapies should improve patient outcomes, the pathobiological and genetic aspects of BPDCN remain unclear.

Aims: We planned this study to identify a critical genetic event in BPDCN, which could provide better understanding of BPDCN pathogenesis.

Methods: We enrolled fourteen patients (five children and nine adults) with BPDCN who were treated in our institutions. We primarily performed RNA sequencing-based comprehensive transcriptome analysis with their samples at the onset to detect gene fusions. These results were then used as the basis for genetic validation studies and functional analyses with an exogenous expression model.

Results: We identified a recurring gene rearrangement that involved the MYB proto-oncogene in all five pediatric patients (100%) and four of nine adult patients (44%) with BPDCN. The resulting fusion genes included MYB-PLKHO1 (three patients), MYB-PELKH1 (three patients), MYB-DCPS (one patient), and MYB-MIR2134 (one patient), none of which have been previously reported to our knowledge. The translocations corresponding to these fusions were not detected by the metaphase analysis except in one patient with t(1;16), who harbored MYB-PELKH1. These fusion genes were detectable at diagnosis and relapse but not at remission. Fluorescence in situ hybridization (FISH) analysis efficiently detected the breaking apart of MYB in formalin-fixed, paraffin-embedded sections. Consequent to the rearrangement, the negative regulatory domain of MYB was truncated, leading to constitutive MYB transcriptional activation, as described in other malignancies. Exogenous MYB-PELKH1 expression in HEK 293T cells led to the upregulation of several known downstream MYB targets. Gene set enrichment analysis also confirmed the activation of MYB target gene sets. The identified significantly upregulated genes included cell surface molecule-encoding genes such as NCAM1 (also termed CD56), CD68, S1PR1, and CXCR4, possibly providing targets for antibody-mediated anticancer therapies. We performed tumor–germline sequencing of paired tumor–germline samples at diagnosis for four pediatric patients, which revealed a total of 91 (6–45 per patient) somatic mutations, a relatively large number compared with other pediatric cancers. However, no driver mutations were identified from the existing literature and database entries; only one missense mutation in KMT2D p.Cys1403Gly, was present on a driver gene, although this exact mutation had not been previously reported. Furthermore, we performed targeted sequencing covering genes associated with hematological malignancies in the remaining 10 patients. Consequently, children were not found to carry any identifiable driver mutations, whereas all adult patients harbored at least one point mutation in genes such as TET2, ASXL1, IKZF1, ZRS2, NRAS, and EZH2, most of which were reported to be mutated in BPDCN and myeloid malignancies.

Summary/Conclusions: We identified a high frequency of MYB rearrangements that promoted the MYB transcriptional activity in BPDCN. MYB split FISH analysis can constitute a valuable diagnostic tool for detecting MYB rearrangements. We expect that our findings provide critical insights regarding BPDCN pathogenesis and contribute to molecular biology-oriented diagnostic techniques and molecular-targeted therapies for this intractable malignancy.

THE LONG NON-CODING RNA HOXB-AS3 REGULATES RIBOSOMAL BIOGENESIS IN NPM1-MUTATED ACUTE MYELOID LEUKEMIA

D. Papaoianou1,2, A. Petri2, S. Terreri3, C. Thue2, S. Volinia4, P. Yan1, R. Bundshuh5, G. Singh6, S. Kauppinen2, C. Bloomfield1, D. Adrienne1, R. Garzon1

1Comprehensive Cancer Center, The Ohio State University, Columbus, United States, 2Center for RNA Medicine, Department of Clinical Medicine, Aalborg University, Copenhagen, Denmark, 3Institute of Genetics and Biophysics (IGB-ABT), National Council of Research (CNR), Naples, 4Department of Morphology, Surgery and Experimental Medicine, University of Ferrara, Ferrara, Italy, 5Department of Chemistry & Biochemistry, Division of Hematology, Department of Internal Medicine, Center for RNA Biology, 6Department of Molecular Genetics, Center for RNA Biology, The Ohio State University, Columbus, United States

Background: The prognostic significance of long non-coding RNA expression (lncRNAs) in older (≥60 years) patients (pts) with cytogenetically normal acute myeloid leukemia (CN-AML) was recently reported (Garzon et al., 2014). The IncRNA HOXB-AS3, which is embedded in the HOXB-focus, has recently been associated with aggressiveness in several cancer entities. How-ever, the mechanistic role of HOXB-AS3 in this process remains uncertain.

Aims: Our aims were to evaluate the biologic significance of HOXB-AS3 expression in CN-AML, and to elucidate possible molecular mechanisms involved in HOXB-AS3 expression.

Methods: Methods: HOXB-AS3 expression profiling was performed by real-time PCR. Knock-down (KD) of HOXB-AS3 was performed in vitro and in vivo [in a pt-derived xenograft (PDX) model] with locked nucleic acid-modified gapmers. Comparative proteomic analysis was conducted with a modified version of the RNA antisense purification (RAP) protocol (McHugh et al., 2015). Direct visualization of the HOXB-AS3 was performed using custom-designed Basep-oc-CODEX (Advanced Cell Diagnostics, Newark, CA) according to the manufacturer’s instructions.

Results: Of 6 AML cell lines that were tested, only OCI-AML3 cells, which harbor NPM1mut, showed detectable levels of HOXB-AS3 expression. Five- and 3-prime Rapid Amplification of cDNA Ends (RACE) assays in OCI-AML3 cells identified an lncRNA previously annotated (NR_033201/ENST0000491264) and 1 novel variant of HOXB-AS3. NPM1mut pt samples exhibited higher expression of HOXB-AS3 compared to those with wild-type (WT) NPM1 (P<0.001), and healthy donors (P=0.001). In vitro KD of HOXB-AS3 led to decreased proliferation of OCI-AML3 cells, as measured by BrdU-based cell cycle analysis (S-phase average% in control vs KD: 24% vs 16%, P=0.02). HOXB-AS3 KD in NPM1mut pt blasts (n=5) led to a decrease in the number of formed colonies by OCI-AML3 cells in colony-forming assays (P=0.002). HOXB-AS3 KD in NPM1mut pt blasts (n=5) led to a decrease in the number of formed colonies by OCI-AML3 cells in colony-forming assays (P=0.002). HOXB-AS3 KD in NPM1mut pt blasts (n=5) led to a decrease in the number of formed colonies by OCI-AML3 cells in colony-forming assays (P=0.002). HOXB-AS3 KD in NPM1mut pt blasts (n=5) led to a decrease in the number of formed colonies by OCI-AML3 cells in colony-forming assays (P=0.002). HOXB-AS3 KD in NPM1mut pt blasts (n=5) led to a decrease in the number of formed colonies by OCI-AML3 cells in colony-forming assays (P=0.002).

Discussion: The discovery of HOXB-AS3 as a therapeutic target to compromise LSC function in IDHwtTET2wtAML patients, would be a critical therapeutic strategy to target LSCs. Further analysis of HOXB-AS3 expression in additional primary AML samples is warranted. The elucidation of HOXB-AS3 expression and functional mechanisms in AML and other hematological malignancies will offer new insights into the pathobiology of AML and the development of novel therapeutic strategies.

NUCLEAR RE-LOCALIZATION OF NPM1C+ INDUCES DIFFERENTIATION AND CELL GROWTH ARREST

L. Brunetti1,2, M. Gundry1, A. Guzman1, I. Gionfriddo2, F. Milanò2, F. Mezzasoma2, P. M. Martelli2, B. Falini1, M. Goedeel3

1Baylor College of Medicine, Houston, United States, 2University of Perugia, Perugia, Italy

Background: NPM1mut (NPM1c+) acute myeloid leukemia (AML) is a distinct entity of the 2016 WHO classification of hematopoietic tumors. NPM1mut is a multifunctional nucleolar chaperone. All the mutations in NPM1 described so far result in cytoplasmic protein localization (NPM1c) through the acquisition of a nuclear export signal (NES) at the C-terminus, indicating that the cytoplasmic localization is critical for the leukemic phenotype. The most frequent NPM1 mutation is a heterozygous 4bp insertion in exon 12 (mutA).

Aims: Use gene editing and targeted drug treatment to determine whether NPM1mut AML cells are dependent on the cytoplasmic localization of NPM1c. The results were validated in murine models by engrafting NSG mice with blasts of a NPM1mut AML pt.

Methods: Methods: We sought to introduce indels adjacent to the mutation to disrupt the C-terminal NES in the NPM1mut AML cell line OCI-AML3 and create novel edited alleles encoding for a mutant NPM1 with nuclear localization. Exploiting our optimized CRISPR-Cas9 protocol (Gundry et al., Cell Reports 2016), we designed the targeted editing of NPM1mut AML cells on drug treatment was studied using a CRISPR-Cas9 engineered NPM1c-GFP OCI-AML3 cell line grown in the presence of the nuclear hormone.

Results: While the NPM1mutA cell line showed 70-90% indel frequencies, the NPM1wt allele was intact. The novel edited alleles could direct nuclear localization of a reporter GFP-NPM1 fusion construct, and re-localization cytoplasmic NPM1 in edited cells was confirmed by immunofluorescence. We analyzed NPM1 protein expression by western blot and implementation of cell growth assays. We observed a fast and deep downregulation of the HOXA and HOXB cluster genes as well as MEIS1 in treated cells (4 to 5 fold average reduction). In order to verify that nuclear re-localization of NPM1c accounted for the dramatic changes, we treated OCI-AML3 cells with the nuclear export inhibitor selinexor (KPT-330). The impact of KPT-330 treatment mirrored the genome editing experiments, resulting in clear growth arrest, differentiation, and NPM1c localization with similar dynamics. Importantly, selinexor produced an almost complete loss of HOXA, HOXB and MEIS1 expression after 6 days of treatment.

Summary/Conclusions: Allele-specific editing is a powerful tool to probe non-genetic dependency. By achieving nuclear re-localization of mutant NPM1, we demonstrated that cytoplasmic localization of NPM1c is necessary for OCI-AML3 cells to maintain their leukemic phenotype. Drugs promoting mutant NPM1 nuclear localization are attractive candidates for clinical success in NPM1 mutated AML.
Summary/Conclusions: Conclusions: HOXB-AS3 is strongly associated with NPM1 mutations in AML. HOXB-AS3 interacts with ESBI and NPM1 and regulates ribosomal biogenesis in the leukemic blasts. From a therapeutic standpoint, HOXB-AS3 constitutes a promising target, as in vivo anti-HOXB-AS3 treatment prolonged survival in a murine PDX model.

A DUAL BH3-MIMETIC APPROACH TARGETING BOTH BCL-2 AND MCL1 IS HIGHLY EFFICACIOUS AND WELL-TOLERATED IN ACUTE MYELOID LEUKEMIA

D. Moujalled1,2, G. Pomilio1,2, C. Ghirardi2, D. Sega2, T.-C. Teh1,2, J. Salmon1,2, S. Rijs1, P. Lan4, L. Kraus-Berthier5, A. Roberts4, D. Huang4, A.L. Marango3, G. Lessene6, O. Geneste7, A. Wei1,2
1Australian Centre for Blood Diseases, Monash University, 2Department of Clinical Haematology, The Alfred Hospital, Melbourne, Australia, 3Oncology R&D Unit, Institut de Recherches Servier, Croissy Seine, France, 4The Walter and Eliza Hall Institute, Melbourne, Australia, 5Oncology R&D Unit, Institut de Recherches, Croissy Seine, France

Background: Identification of a chemotherapy-free option for acute myeloid leukemia (AML) represents a highly desired and important research objective. Perturbation of cell survival is an essential hallmark of cancer now amenable to precision targeting by small molecule BH3-mimetics able to inhibit pro-survival BCL-2 (e.g. S63845 and S55746) (MCL1, (Lessene et al., Nat Chem Biol, 2013) and MCL1 (Kotschy et al., Nature 2016). We hypothesize that simultaneous pharmacological targeting of BCL-2 and MCL1 will enhance apoptotic death of AML blasts, without increased toxicity to non-malignant cells.

Aims: To assess the feasibility and efficacy of targeting multiple BCL-2 pro-survival proteins using small molecule BH3-mimetics in pre-clinical models of AML.

Methods: AML cell lines were obtained from ATCC or DSMZ. S55746 (BCL-2 inhibitor) and S63845 (MCL1 inhibitor with 6-fold higher affinity to human than mouse Mcl1) were obtained from Servier and ATCC (BCL-2 inhibitor) from Guillaume Lessene (WEHI). Primary AML cells were obtained from patients providing informed consent. For in vivo experiments, NSG; NOD.Cg-Ptkd cyclodem1 Il2rgm1 Wjl/SzJ (NSG) or NOD/Rag2m1Il2rgm1Wjcr (NRRG) mice were used.

Results: S55746 and S63845 showed strong synergy (Loewe score >5) in 13 AML cell lines tested, suggesting this dual BH3-mimetic targeting approach was highly efficacious (Figure 1A). S55746 and S63845 lowered the LC50 in primary AML samples by 10-1000-fold in the majority of cases tested, confirming remarkable anti-leukemic activity across a spectrum of AML cases with diverse cytogenetic and molecular pathologies (Figure 1B).

A smaller fraction of AML samples were also sensitised to combined A1155463 and S63845 therapy. Bioluminescent imaging showed rapid and sustained clearance of xenografted MV4;11 AML (FLT3-ITD mutant and MLL re-arranged) cells, translating into significant prolongation of survival (Figure 1C) from combined S55746+S63845, but not from treatment with either BH3-mimetic alone. Similar in vivo efficacy was observed with xenografted OCI-AML3 cells harboring mutant NPM1 and MDM2/3A. Patient-derived xenograft models showed rapid reduction of established AML in the bone marrow one week of treatment with S55746 and S63845 (Figure 1D). Safety and tolerability of this approach was confirmed using normal CD34+ stem and progenitor cells in short-term cell culture (48h) and long-term (2-3 weeks) clonogenic assays and from historical and biochemical examination of mice receiving treated for up to 8 weeks at doses shown to be highly efficacious against AML.

Summary/Conclusions: Dual BH3-mimetic targeting of BCL-2 and MCL1 induces rapid and synergistic cytoceduction of human AML cell line and primary AML samples in vitro and in vivo across a diverse range of AML genotypes. We provide preclinical support for the simultaneous dual pharmacological targeting of both BCL-2 and MCL1 represents a novel approach to treating AML without need for additional chemotherapy and with an acceptable therapeutic safety margin. Our results support the translational investigation of dual BH3-mimetic targeting of BCL-2 and MCL1 in the clinic for the treatment of patients with AML.

THE PMLC62A/C65A KNOCK-IN MOUSE MODEL PROVIDES EVIDENCE FOR THE ROLE OF NUCLEAR BODY DISRUPTION IN THE PATHOGENESIS OF ACUTE PROMYELOCYTIC LEUKEMIA

E. Voisint1,2, E. Moravcsik1,2, E. Stratford1, A. Jaye1, C. Palgrave3, R. Hills4, P. Salomon5, S. Kogan6, D. Grimwade1,2, D. Moujalled1,2,*, G. Pomilio 1,2, C. Ghiurau 3, D. Segal 4, T.-C. Teh 1,2, E. Voisset1,*, E. Moravcsik1, E. Stratford2, A. Jaye1, C. Palgrave3, R. Hills4, P. Salomon5, S. Kogan6, D. Grimwade1
1Medical and Molecular Genetics, King’s College London, London, United Kingdom, 2Department of Veterinary Medicine, University of Surrey, Guildford, 3Centre for Trials Research, College of Biomedical & Life Sciences, Cardiff, 4School of Veterinary Medicine, University of Surrey, Guildford, 5Centre for Trials Research, College of Biomedical & Life Sciences, Cardiff, 6Helen Diller Comprehensive Cancer Center, University of California, San Francisco, United States

Background: Acute promyelocytic leukemia (APL) is driven by the oncoprogen PML-RARA which is generated by fusion of the promyelocytic leukemia (PML) and retinoic acid receptor alpha (RARA) genes, and which strongly interferes with downstream signalling and the architecture of multiprotein structures known as PML nuclear bodies (NBS). NB disruption is a diagnostic hallmark of APL; however, the importance of this phenomenon has only been studied in vitro.

Aims: The aim of this study was to decipher the impact of Pml NB disruption in APL pathogenesis.

Methods: We engineered a knock-in mouse model with NB disruption achieved through mutation of key zinc-binding cysteine residues (C62A/C65A in the PML RING domain).

Results: While no leukemias or tumors developed in PmlC62A/C65A mice, the forced dimerization of RARa - mediated artificially by linking RARa to the dimerization domain of the NFκB p50 subunit - in cooperation with NB disruption was associated with doubling in the rate of leukemia (p<0.0001), with a reduced latency period (p=0.008). Moreover, response to targeted therapy with ATRA significantly increased the survival of mice transplanted with PmlC62A/C65A-p50-RARa, revealing the essential role of NBs for an effective response to differentiating drug. While formation of the PML-RARA fusion is considered a initiating event in APL pathogenesis, it is insufficient for the full leukemic phenotype. Moreover, whole exome sequencing analyses have consistently identified presence of cooperating mutations. Since Pml and Pml NBs have established roles in DNA repair and in the maintenance of genomic stability, we speculated that loss of NB integrity could affect these functions. Here, whole exome sequencing revealed a trend of higher genomic instability in PmlC62A/C65A-p50-RARa leukemia as compared to PmlWT-p50-RARa, which is associated with detection of mutations found in human APL samples, including Ptpn11 and Usp9y. Using DNA repair reporter assays, we demonstrated that DNA repair via both non-homologous end joining (NHEJ; p=0.01) and homologous recombination (HR; p=0.006) pathways was less efficient in PmlC62A/C65A primary cells than in PmlWT cells. Importantly, using a PML-RARA-inducible cell line, comparable defects in the NHEJ and HR pathways, which were PML-RARa-dependent, were identified. These data were also supported by an increase in sister-chromatid exchange (p<0.0001) and chromosome abnormality (p=0.0002) rates in the context of PmlC62A/C65A versus PmlWT. Interestingly, the kinetics of repair of ionising radiation (IR)-induced DNA double-strand breaks, assessed by assessing γH2AX foci formation and clearance, was not affected. None of the DNA repair players analysed (e.g. Blm, Rad51 and 53BP1) failed to form foci in response to IR. However, their basal levels of foci were significantly greater in the presence of PmlC62A/C65A versus PmlWT. Furthermore, their basal levels of foci were significantly greater in the presence of PmlC62A/C65A versus PmlWT. Interestingly, the kinetics of repair of ionising radiation (IR)-induced DNA double-strand breaks, assessed by assessing γH2AX foci formation and clearance, was not affected. None of the DNA repair players analysed (e.g. Blm, Rad51 and 53BP1) failed to form foci in response to IR. However, their basal levels of foci were significantly greater in the presence of PmlC62A/C65A versus PmlWT.

Summary/Conclusions: Our study highlights the importance of re-formation of NBs for an efficient response to targeted therapy, the significant contribution
DECIPHERING THE ONCOGENIC NETWORK OF PRC2 LOSS GUIDED LEUKEMOGENESIS
D. Langeder1, D. Swaetzer2, S. Knöbl1, J.-H. Klussmann1, D. Heckl1,*
1Pediatric Hematology & Oncology, 2Experimental Hematology, 3Hematology, Hemostasis, Oncology and Stem Cell Transplantation, Hannover Medical School, Hannover, Germany

Background: Loss of function mutations in EZH2 (including the chromosomal abnormalities -7/-7a) and other PRC2 subunits have been identified in adults with MDS, MPN and AML. Moreover children with JMML and up to 30% of children with Down syndrome related AML present with mutations in PRC2 subunits. Since myeloid neoplasias are elicited by accumulation of cooperating mutations, we aimed to study the role of EZH2 loss in leukemic progression. We set out to decipher the oncogenic network guided by loss of PRC2-activity.

Aims: Through identification of collaborating mutations driving AML with loss of PRC2 function followed by molecular profiling we aimed to identify novel collaborating mutations.

Methods: To model the complex interplay of mutational networks we performed CRISPR-Cas9 screenings with oncogene/tumor suppressor pools in vitro and in vivo. Cellular resources generated were subjected to mutational and molecular profiling.

Results: To this end, a 96-well based CRISPR-Cas9 immortalization assay allowing fast and quantitative genetic cooperation screenings was established. Four out of six CRISPR-Cas9 pools tested—comprised of five genes each and representing 148 mutation combinations—reproductively transformed LSK cells with distinct clonal output. Transplantation of in vitro immortalized clones yielded robust engraftment of mutant lineage contributions in mice but no overt leukemia was detected, indicating that induced mutations select for a preleukemic state in vitro. We thus tested every oncogene/tumor suppressor pool from the in vitro setting in a murine bone marrow transplantation model with freshly transduced LSK cells which resulted in robust induction of leukemia. Analysing the mutational spectrum of derived clones we were able to raise a list of potential partners cooperating with EzH2 loss, which highlighted Nf1 (Ras-signaling), loss of Dnmt3a, and loss of Runx1 as cooperating partners, whereas loss of cohesin complex subunits (Smc3, Stag2) seems to be dispensable during the induction of EzH2-loss guided leukemogenesis. To define oncogenic dependencies in myeloid malignancies with PRC2-loss we analysed gene expression spectra of the generated samples. While in vitro transduced clones presented with distinct expression signatures clearly separating from controls a partially overlapping expression signature could be established. Through identification of these collaborating mutations and the resulting gene expression signature, which will be validated in a CRISPR-Cas9 knock-out screening we aim to identify novel therapeutic targets in AML.

Summary/Conclusions: Our study highlights the power of the CRISPR-Cas9 system to probe oncogenic interaction. Mutational CRISPR screenings in vivo, and a newly established in vitro CRISPR-Cas9 immortalization assay for high throughput screening of sgRNA pools, delivered potential cooperating partners of EzH2 loss in AML, and provides rich cellular resources to identify molecular mechanisms of oncogenic synergies and dependencies.

ACUTE MYELOID LEUKEMIA EVOLUTION CAN BE RECONSTRUCTED BY ANALYSIS OF NON-LEUKEMIC CELLULAR SUBCOMPARTMENTS AND MULTI-LINEAGE ENGRAFTED MICE
B.R.M. Saeed1, L. Manta1, S. Raffel1,2, P.T. Pyl3, W. Wang1, V. Eckstein1, A. Trumpf2, W. Ho1,4,5,*,
1Internal Medicine V, Heidelberg University Hospital, 2Division of Stem Cells and Cancer, German Cancer Research Center (DKFZ) and Heidelberg Institute for Stem Cell Technology and Experimental Medicine (Hi-STEM GmbG), 3Mult-omics and statistical computing, European Molecular Biology Laboratory (EMBL), Heidelberg, Germany

Background: Hematopoietic Stem Cells (HSC) isolated from patients with Acute Myeloid Leukemia (AML) have been shown to carry leukemia-specific mutations leading to the concept of pre-leukemic HSC. In order to understand the evolution from multi-potent pre-leukemic HSC to fully transformed AML, an accurate molecular comparison of patient matched HSC and leukemic cells is essential. Recently we have shown that functionally normal HSC can be separated from a subgroup of AML patients using the surface marker combination of Pmi NB to the effectiveness of DNA damage repair processes, and the manner in which their disruption mediated by the PML-RARα oncoprotein can assist APL pathogenesis.

Aims: In this study we aim to understand the leukemic evolution from pre-leukemic HSC to fully transformed AML.

Methods: Whole exome sequencing (WES) of 12 diagnostic AML samples with the matched germ-line controls (T cells or buccal swab) was performed. Leukemia-specific mutations were identified according to specific criteria (Allele Depth >10, Support Depth >20, SnpRupture >0.8, SiftScore <0.05, Gmaf <0.05, coverage >10 reads, support >2 reads, and Gmaf <0.05) and validated. Identified AML-specific mutations were tracked in different cellular compartments (T- and B-cells) as well as in single HSC colonies derived from diagnostic AML samples. To test the functional properties of pre-leukemic HSC in vivo, we transplanted bulk AML in NOD/SCID-IL2γnull (NSG) mice and analyzed human subpopulations (myeloid and lymphoid) of multi-lineage engrafted animals for the presence of leukemia-specific mutations.

Results: WES identified 64 AML-specific mutations. Most cases (8 out of 12) showed 4-6 AML specific mutations per sample (1-18 mutations/AML) including patients with 1-18 mutations in a single clone (1-4 mutations) and a newly established multi-lineage engrafted mice allows reconstruction of the individual leukemic evolution. A better understanding of these processes may pave the way for new treatment strategies with the aim to target the relevant leukemic mutations.

Summary/Conclusions: We can identify leukemia specific mutations including mutations in genes that haven’t been described in AML yet. Tracking of these mutations in various non-leukemic cellular compartments including HSC and multi-lineage engrafted mice allows reconstruction of the individual leukemic evolution. A better understanding of these processes may pave the way for new treatment strategies with the aim to target the relevant leukemic mutations.

THE ESSENTIAL ROLE OF THE ENHANCERS OF POLYCOMB EPC1 AND EPC2 IN MLL-AF9 ACUTE MYELOID LEUKAEMIA IS A ‘COMPLEX’ STORY
N. Mannion1,*, X. Huang1,2
1Paul O’Gorman Leukaemia Research Centre, 2Paul O’Gorman Leukaemia Research Centre, Institute of Cancer Sciences, MLVS, University of Glasgow, Glasgow, United Kingdom

Background: The Enhancers of Polycomb (EPC) proteins EPC1 and EPC2 are essential for the survival of MLL-rearranged acute myeloid leukemia (AML). Most importantly, loss of EPC1 or EPC2 in MLL leukemia stem cells, but not normal hematopoietic stem cells and progenitor cells, leads to the induction of cellular apoptosis. To date little is known about the functional contribution of EPC1 and EPC2 in AML. EPC1 is an essential component of the highly conserved NuA4 histone acetyltransferase complex. Additionally, EPC1 has been found in complexes with the Enhancer of zeste homolog 2 (EZH2), a catalytic core subunit of the histone methyltransferase Polycomb repressive complex 2 (PRC2). NuA4 and PRC2 are two major chromatin modifying complexes encompassing opposing epigenetic activities and both are known to be deregulated in AML. A better understanding of the role of EPC1 and EPC2 in MLL AML biology would provide insight into the contribution of the homologous chromatin regulatory proteins EPC1 and EPC2 in AML in search for novel therapeutic targets.

Methods: Mass spectrometry (MS) analysis was performed on immunoprecipitated protein using EPC1 antibody from human THP1 MLL-AF9 AML cell line. Chromatin immunoprecipitation (ChIP) was performed using HighCell ChIP Kit and iPure kit v2 (Diagenode) followed by NextSeq500 Illumina sequencing in THP1 cells. ChIP enriched regions were identified using SICER peak calling and ChiPpeakAnno. Lentiviral supernatants were prepared and THP1 cells were infected with viral particles containing pLKO.1 puro lentiviral vector expressing shRNAs. RNA was extracted 72 hr following lentiviral transductions and whole transcriptome sequencing was performed. DESeq2 was used for differential expression analysis.

Results: MS analysis identified the core NuA4 complex components (Tip60, Ruvbl1, Mll-Af9) and loss of EPC1 and EPC2 in AML samples. To test the functional properties of pre-leukemic HSC in vivo, we transplanted bulk AML in NOD/SCID-IL2γnull (NSG) mice and analyzed human subpopulations (myeloid and lymphoid) of multi-lineage engrafted animals for the presence of leukemia-specific mutations.

Summary/Conclusions: We can identify leukemia specific mutations including mutations in genes that haven’t been described in AML yet. Tracking of these mutations in various non-leukemic cellular compartments including HSC and multi-lineage engrafted mice allows reconstruction of the individual leukemic evolution. A better understanding of these processes may pave the way for new treatment strategies with the aim to target the relevant leukemic mutations.
histone methylation and acetylation profiles following lentiviral shRNA knockdown (KD) of EPC1 or EPC2 in THP1 cells. Interestingly, we find significant changes in histone H3K27 trimethylation levels as well as changes in the levels of histone H3 and H4 acetylation following KD of either EPC1 or EPC2 expression. Notably, the identified regions demonstrating changes in histone H3K27me3 levels are enriched for PRC2 target genes. RNA sequencing followed by gene-set enrichment analysis indicated significant transcriptional changes in PRC2 regulated genes following lentiviral shRNA knockdown of EPC1 or EPC2. Meta-analysis of this PRC signature identified a sub-group of genes that are directly regulated by the EPC complex which include the mono-acyclic differentiation inducer MAFB, the H2A ubiquitin ligase TRIM37 and the pro-apoptotic tumor suppressor CMTM3.

Summary/Conclusions: Our data suggests that EPC1 and EPC2 are required for the recruitment of certain chromatin proteins to form EPC-associated complexes which are essential for the maintenance of an AML epigenetic signature and an aberrant transcriptional profile that supports leukemia stem cell survival. We have identified and characterized the EPC complex components in human AML. Additionally, we have refined a subgroup of PRC target genes that are regulated by the EPC complex which represent potential novel therapeutic targets in human AML. Overall we present a comprehensive analysis of the aberrant epigenomic landscape of THP1 MLL-AF9 AML cells in relation to EPC1 and EPC2 and provide new insight into their deregulated role in AML.
adult AML cases. Despite having poor outcomes, CK-AML is the least underst- 
stood at the molecular level, except for the finding that about two-thirds of cases carry TP53 alterations. In particular, because cytogenetic alterations appear to be distinct among different patients, it is unclear whether they are cause of leukemogenesis, or merely reflect a state of genomic instability.

Aims: We have hypothesized that cytogenetic aberrations in CK-AML create gene fusions that are not recurrent across patients, nonetheless deter- 
minate cancer genes that contribute to leukemogenesis in individual patients.

Methods: We performed a transcriptome analysis using Illumina paired-end (101bp×2) RNA sequencing of 65 CK-AML cases to identify gene fusions using mul- 
tiple independent algorithms (as paired reads that flank, or single-reads that span fusions). Fusions found in one CK-AML case were independently validated by array-based genomic profiling and/or long range PCR followed by use of long-read Oxford Nanopore sequencing technology.

Results: We identified 54 fusion gene events in 30 of the 65 cases (46%) with up to four fusions per case. All fusions are supported by 10-50+ junction-spanning reads. In addition to the 5' UTR, 3' Aix-Marseille University, 4Oncology, 5Cell therapy facility, Paoli-Calmettes Institute, 1Hematology, Paoli-Calmettes Institute, Marseille, 6Hematology, Toulouse Cancer University Institute, 22 nd Congress of the European Hematology Association

Figure 1. Summary/Conclusions: Detailed molecular characterization of CK-AML revealed a high incidence of novel gene fusions in about 50% of cases. The affected genes suggest a more general role in leukemogenesis than reflecting a state of genomic instability. Furthermore, identifying gene fusions in each individual patient might lead to more effective, personalized treatments that target the gene fusion itself, enable immunologic therapies against the fusion junction epitopes, and provide private patient-specific biomarkers to track leukemic burden for the monitoring of disease remission and relapse.

P183

H3K27ME3 LEVEL ON THE HIST1 CLUSTER: A POWERFUL EPIGENETIC BIOMARKER THAT STRATIFIES TWO GROUPS OF NPM1-MUTATED AML DIFFERING IN THEIR OUTCOME AND EXPRESSION PROFILE

S. García1,2,3, P. Vinberg,2, J. Vernes,2, F. Bortuzzo,3,4, B. Calmels3,5, C. Recher,6, C. Chabannon2,3,5, N. Vey1,2,3, E. Duprez2,3,1

1Hematology, Paoli-Calmettes Institute, 2INSERM 1068, Cancer research center, 3Aix-Marseille University, 4Oncology, 5Cell therapy facility, Paoli-Calmettes Institute, Marseille, 6Hematology Toulouse Cancer University Institute, Toulouse, France

Background: NPM1 mutation (NPM1mut) is the most frequent genetic alter- 
ation found in cytogenetically normal acute myeloid leukemia (CN-AML). Patients harboring NPM1mut without FLT3 internal tandem duplication (FLT3- 
ITD) are considered to have favorable outcome. Yet, some of them relapse and become resistant to chemotherapy. Little is known about biological processes underlying treatment failure. Our group previously described a new epigenetic biomarker corresponding to an abnormal gain of the repressive H3K27me3 histone mark within the HIST1 locus on the 6p22 referred as H3K27me3 HIST1high. Studying the diagnostic and therapeutic relevance of this epigenetic biomarker had an impact on clinical out- come as CN-AML patients with H3K27me3 HIST1high had a higher overall sur- 

Results: We analyzed 62 CN-AML samples from the training and validation sets together. Median age was 60 [37-76] and median leucocyte count was 76 G/L [10-352]. ChIP-QPCR Profiling identified 74 H3K27me3 HIST1high and 29 H3K27me3 HIST1low patients. FLT3-ITD was found in 33 (43%) of H3K27me3 HIST1high and 18 (38%) of H3K27me3 HIST1low patients. We confirmed that H3K27me3 HIST1high was associated with higher 5-year OS and LFS rates: 37% and 44% versus 17% and 19% (p=0.005 and .01) for the H3K27me3 HIST1high and the H3K27me3 HIST1low patients, independently of other genetic alterations. Combining our biomarker with FLT3 mutational status, we identified two subgroups of patients with very different outcome: 49% and 56% versus 18% and 18% (p=.004 and .01) for the H3K27me3 FLT3wt HIST1high and the FLT3mut H3K27me3 HIST1low patients, respectively (Figure 1). We performed GEP for 27 NPM1mut patients (12 H3K27me3 HIST1mut and 15 H3K27me3 HIST1mut). GSEA analysis revealed a strong enrichment in immune functions and leucocyte activation in the H3K27me3 HIST1high group, evoked differentiation AML. While H3K27me3 HIST1high samples had GSEA associated with chromatin remodeling factors and DNA replication. Considering only FLT3wt patients, the H3K27me3 HIST1mut subgroup had a gene expression signature characterized by a high expression level of genes from the HIST1 cluster which expression is known to be upregulated during S-phase of cell cycle.

P184

FUNCTIONAL ASSESSMENT OF NOVEL DIAGNOSTIC FLT3 MUTATIONS AND INHIBITION BY KINASE INHIBITORS

K. Tarlock1,2, T.A. Hytkema3, J.A. Pollard2, M.E. Hansen2, R. Ries2, R. Sweeny2, S. Meshinchi3

1Hematology/Oncology, Seattle Children's Hospital, 2Clinical Research Divi- 
sion, Fred Hutchinson Cancer Research Center, Seattle, 3Pediatric Hematol- 
ogy/Oncology, Maine Medical Center, Portland, 4University of Rochester, Rochester, 2Arog Pharmaceuticals, Dallas, United States

Background: Somatic mutations in FLT3 are among the most common events in AML, with FLT3ITD mutations in the juxtamembrane domain (JMD) as well as D835 missense mutations in the kinase domain (KD) the predominant events. Sequencing of FLT3 in a cohort of 788 children with de novo AML treat- ed on Children’s Oncology Group (COG) protocols demonstrated that in addition to the previously described FLT3 mutations (ITD and D835), numer- ous other variants, including several novel variants, were present in 8% of patients at diagnosis, leading to a cumulative FLT3 mutation prevalence of 27% in children and young adults. These variants mostly occurred in the JMD and KD of FLT3, but varying the number of patients who might be amenable to FLT3 inhibitor therapy.

Aims: We evaluated the oncogenic capability of each of these mutations by assessing their ability to result in aberrant FLT3 and STAT5 phosphorylation, as well as response to the tyrosine kinase inhibitors crenolanib and quizartinib.

Methods: Point mutations were introduced into HEK293 cells using retroviral transduction. Following transduction, phosphorylation status of FLT3 (pFLT3) and downstream STAT5 (pSTAT5) were evaluated by immunoblotting. Phos- phorylation status was quantified by chemiluminescence analysis and the quan-
tently of protein expression was normalized to actin. That ratio of phosphorylated protein to total protein for FLT3 and STAT5 was determined and normalized to that observed in the D835Y mutation as a positive control. A value of >10% pFLT3 was considered positive. All mutations that resulted in FLT3 phosphorylation were subsequently evaluated for inhibition by crenolanib and quizartinib following 60-minute exposure to the compounds.

Results: A total of 24 non-ITD and non-ALM AML mutations were evaluated for autonomous FLT3 and STAT5 phosphorylation. Eleven mutations resulted in pFLT3 and pSTAT5, including 4 mutations with >50% pFLT3. All mutations that demonstrated aberrant pFLT3 also had aberrant pSTAT5, however a direct correlation of pFLT3 and pSTAT5 was not always observed. Overall, 87% (n=86 patients) of all non-ITD mutations evaluated resulted in autonomous FLT3 activation. Excluding D835 mutations, 64% (n=39) of patients harbored an activating mutation. Many of the mutations that were not found to be activating had the lowest prevalence, often present in only one patient. Evaluation of inhibition of pFLT3 and downstream demonstrated that in many case of aberrant activation, crenolanib resulted in potent inhibition of phosphorylation of FLT3 and STAT5 with an IC50 range of 1.3-13.9 nM and 0.6-6.5 nM respectively. Many of the mutations tested were exclusively sensitive to crenolanib, with 9 of 10 mutations tested demonstrating an IC50 of pFLT3 inhibition ≤5.6 nM. Inhibition of downstream kinases are necessary for optimal efficacy of any FLT3 inhibitor and phosphorylation of STAT5 was potently inhibited by crenolanib in all cases. Quizartinib inhibited pFLT3 and pSTAT5 with an IC50 range of 1.8-151.7 nM and 1-33.9 nM respectively, demonstrating less effective inhibition specifically at mutations including D835Y, D839E, N670K, M664I.

Summary/Conclusions: We have previously presented that FLT3 mutations, including novel mutations in addition to the FLT3/ITD and D835, are prevalent in children and young adults with AML. Here we demonstrate that many of the non-ITD/D835 mutations also result in aberrant FLT3 phosphorylation and are amenable to inhibition by FLT3 inhibitors. Crenolanib resulted in potent inhibition of FLT3 and downstream STAT5 in all mutations tested. This data supports expanding the cohort of pediatric patients with activating FLT3 mutations who may benefit from FLT3 inhibitor therapy beyond those with FLT3/ITD.

THE BCL-2 INHIBITOR VENETOCLAX INHIBITS NRF2 ANTIOXIDANT PATHWAY ACTIVATION INDUCED BY HYPOMETHYLATING AGENTS IN ACUTE MYELOID LEUKEMIA

L.X.T. Nguyen1, A. Kahala1, E. Troade1, B. Kumar1, S. Forman1, G. Maruccio1, V. Pullarkat2

1City of Hope Medical Center, Duarte, United States, 2Hematology, City of Hope Medical Center, Duarte, United States

Background: The selective Bcl-2 inhibitor Venetoclax (ABT-199) has shown potent antileukemic activity against Acute Myeloid Leukemia (AML) in preclinical and early clinical studies and impressive results have been achieved using the combination of hypomethylating agents (HMA) with venetoclax suggesting synergy between these agents.

Induction of Reactive Oxygen Species (ROS) is important for the cytotoxicity of various AML therapies including HMA. Induction of ROS by various cytotoxic therapies concurrently activates the NRF2 antioxidant response pathway which in turn results in induction of antioxidant enzymes that neutralize ROS. Upon ROS induction, the transcription factor NRF2 is released from its adaptor protein Keap1 in the cytoplasm whereby NRF2 enters the nucleus and binds to antioxidant response element sequences in the promoters of various genes. Nrf2 pathway activation has been shown to mediate chemoresistance in various cancers including AML. Low ROS levels have been shown to be a hallmark of leukemia stem cells and are critical to their self renewal capacity. In this study, we examined whether NRF2 inhibition is an additional mechanism responsible for the marked antileukemic activity in AML seen with the combination of HMAs and venetoclax.

Aims: To determine the effect of venetoclax on ROS levels after HMA exposure in AML cells and to examine the effect of Bcl-2 inhibition on NRF2 antioxidant pathway activation in response to HMA.

Methods: The effect of combination venetoclax and HMA on ROS levels and apoptosis was measured by flow cytometry. Effect of venetoclax and HMA on NRF2 nuclear translocation was analyzed by immunostaining after cellular fractionation. Effect of venetoclax treatment on the association of Bcl2 with NRF2/Keap1 complex was assessed by western blot analysis, immunoprecipitation and in vitro assay for ubiquitination.

Results: Our results demonstrated that combination of HMA with venetoclax augmented cellular and mitochondrial ROS induction and apoptosis compared to treatment HMA alone. Treatment of AML cell lines as well as primary AML cells with venetoclax and decitabine resulted in increased nuclear translocation of NRF2 (Figure 1) and induction of downstream antioxidant enzymes including HO-1 and NQO1. Immunofluorescence studies confirmed the inhibition of nuclear translocation of NRF2 by venetoclax. Immunoprecipitation studies indicated that Bcl-2, Keap 1 and NRF2 associate in a protein complex in the cytoplasm and that treatment with venetoclax leads to dissociation of Bcl-2 from the NRF2/Keap 1 complex and targets NRF2 to ubiquitination and proteosomal degradation.

Figure 1.

Summary/Conclusions: In conclusion, inhibition of NRF2 pathway may explain the marked potentiation of HMA activity by venetoclax that is observed in clinical trials. We show that ROS induction at least partially mediates the cytotoxicity of HMA and ROS induction after HMA treatment is augmented by venetoclax. We demonstrate for the first time that venetoclax is a potent inhibitor of NRF2 activation via disruption of the association between NRF2, Keap-1 and Bcl-2.
**Summary/Conclusions:** Analysis of promoters and especially enhancers is a highly useful approach to identify cell state specific regulation. Here, we analyzed pediatric AML patients at diagnosis and at relapse to gain more insight into specific cell states which are involved in relapse. Our data revealed high similarity between diagnosis and relapse samples, while, strikingly, in the WHO intermediate-risk group containing MLL-rearranged patients, differential epigenome and chromatin accessibility levels between NRP/RPs and RPs. Taken together, our preliminary data suggests that already at diagnosis, AML cells display an epigenomic fingerprint associated with the development of AML relapse during the course of disease. We are currently validating these data.

**Method:** FLT3 inhibition overcomes resistance to the BCL-2 selective antagonist, BCL-2 in AML patients and BCL-2 selective agents like venetoclax show promising clinical activity in refractory AML patients.

**Results:** In vitro, FLT3 inhibition overcomes resistance to the BCL-2 selective inhibitor, venetoclax. FLT3 inhibition synergizes with venetoclax to overcome resistance to BCL-2 selective inhibitors in AML cell lines.

**Conclusion:** The combination of FLT3 and BCL-2 selective inhibitors offers a promising therapeutic approach for the treatment of AML patients with resistant disease.

**Conclusion:** The use of FLT3 inhibitors in combination with BCL-2 selective agents like venetoclax shows promising clinical activity in refractory AML patients.
decreased expression of IGFBP7 might be associated with decreased chemotherapy sensitivity. To this end, we generated cell lines with IGFBP7 knockdown and subjected the cells to chemotherapy. Furthermore, to test whether increasing the IGFBP7 levels might be a strategy to deplete leukemic (stem) cells, we overexpressed IGFBP7 in or added recombinant human IGFBP7 (rhIGFBP7) to primary AML cells and measured clonogenic capacity, differentiation and cell survival in vitro. To study the effect of IGFBP7 on AML cell survival and engraftment potential in vivo, primary AML cells were transplanted into immune deficient mice and the mice were subsequently treated with rhIGFBP7. To study the effect of rhIGFBP7 on LSC survival, human AML cells derived from the first transplanted mice were re-transplanted into secondary recipients and engraftment and survival of the mice were monitored.

Results: Knockdown of IGFBP7 results in reduced sensitivity to chemotherapy and comparing matched diagnosis and relapsed AML samples showed that IGFBP7 expression is frequently downregulated at relapse, suggesting a survival advantage of IGFBP7low AML cells during chemotherapy treatment. Importantly, enhancing cytoplasmic or extracellular IGFBP7, by overexpression or addition of rhIGFBP7, resulted in induction of differentiation and apoptosis, increased sensitivity to chemotherapy and inhibited AML blast and leukemic stem/progenitor cell survival in vitro and in vivo. IGFBP7 had no influence on the survival of normal hematopoietic (stem) cells. Moreover, treatment with rhIGFBP7 can add to chemotherapy treatment by elimination of chemotherapy resistant refractory AML (stem) cells.

Summary/Conclusions: Altogether, these data suggest that addition of IGFBP7 to the currently used chemotherapy regimens might be a promising strategy to specifically eradicate LSCs and decrease AML relapse rates.

ONGOING PHASE 2 CLINICAL TRIAL OF SL-401 IN PATIENTS WITH BLASTIC PLASMACYTOID DENDRITIC CELL NEOPLASM: STAGE 1 AND STAGE 2 RESULTS
N. Pemmaraju1, K. Sweet2, A. Lane3, A. Stein4, S. Vasu5, W. Blum5, D. Rizzieri5, E. Wang7, M. Ducivi5, J. Chen8, S. Shemesh5, P. McDonald6, C. Brooks8, J. Lancet2, H. Kantarjian1, M. Konopleva1
1MD Anderson Cancer Center, Houston, TX, 2H. Lee Moffitt Cancer Center, Tampa, FL, 3Dana-Farber Cancer Institute, Boston, MA, 4City of Hope National Medical Center, Duarte, CA, 5The Ohio State University, Columbus, OH, 6Duke University Medical Center, Durham, NC, 7Roswell Park Cancer Institute, Buffalo, NY, 8Sterling Therapeutics, New York, NY, United States

Background: SL-401 is a targeted therapy directed to interleukin-3 receptor a (CD123), a target overexpressed on a variety of cancers including blastic plasmacytoid dendritic cell neoplasm (BPDCN), a highly aggressive malignancy with poor outcomes and unmet medical need.

Aims: This Phase 2 trial is a single-arm, open-label, study designed to generate efficacy and safety data to support potential registration in BPDCN

Methods: In this ongoing Phase 2 single-arm trial, patients with BPDCN (n=32) or relapsed/refractory (R/R) AML (n=48) received SL-401 as a daily IV infusion at 7, 9, 12, or 16 ug/kg/day for days 1-5 of a 21-day cycle in stage 1. In stages 2 and 3, patients received SL-401 at the dose determined in stage 1.

Results: 32 adult BPDCN patients received SL-401 in stage 1 (n=9) and stage 2 (n=23), including 19 first-line and 13 R/R patients. Stage 3 patients will be reported separately. Median age was 72 years (range: 30-85 years). In stage 1, 12 ug/kg was the highest tested dose for BPDCN; MTD was not reached in BPDCN. Median follow-up was 4.3 months (range: 0.5-22.9 months). ORR of 84% (27/32) was observed in all patients: 95% (18/19) in first-line and 69% (9/13) in R/R. 88% (14/16) of first-line patients treated at 12 ug/kg had a complete remission (CR; n=10), CR with incomplete hematologic recovery (CRi) (n=1) or clinical CR (CrC; residual skin disease) (n=3) based on investigator assessment. 56% (9/16) of these patients were progression free for 4 to 22.9 months (ongoing), including 3 patients on SL-401 in remission for 18 months (ongoing) and 7 patients who were bridged to stem cell transplant (SCT; 3 auto-SCT and 4 allo-SCT). A R/R patient was also bridged to allo-SCT. Overall, most common grade 3 treatment-related AEs were transaminase elevation (22%) and thrombocytopenia (16%). Safety precautions, including daily monitoring of albumin and body weight during study drug infusions, have been implemented to minimize risk of severe capillary leak syndrome (CLS). Three patients had Grade 5 CLS: BPDCN (7 ug/kg); R/R AML (16 ug/kg); BPDCN (12 ug/kg) out of 118 patients who received SL-401 across all trials and regimens; 3/89 (3.4%) patients of which were enrolled in this clinical trial.

Summary/Conclusions: SL-401 continues to demonstrate single agent activity, including multiple CRs, in patients with BPDCN, with 25% (8/32) of patients bridged to SCT after a major response from SL-401. SL-401 side effect profile consists largely of transaminitis and thrombocytopenia. CLS can be fatal. Side effects have generally tended to decrease in frequency and severity with increasing cycles. Updated data, including detailed safety analysis across all ongoing SL-401 studies will be presented at the meeting.

P192
PROGNOSTIC IMPACT OF SOMATIC MUTATION CLEARANCE IN PATIENTS WITH ACUTE MYELOID LEUKEMIA
K. Takahashi1, F. Wang1, K. Patel1, C. Bueso-Ramos1, G. Issa1, X. Song1, J. Zhang1, C. Gumbs 1, F. Ravandi 1, T. Kadia 1, N. Daver 1, C. DiNardo 1, 11Leukemia, UT MD Anderson Cancer Center, Houston, United States

Background: Persistence of somatic mutations at the time of complete remission (CR) was associated with poor outcome in patients (pts) with AML.

Aims: To analyze differential pattern of mutation clearance based on the genes and affected pathway and to assess prognostic impact of mutation clearance in AML patients.

Methods: We studied 95 pts with AML who were treated with frontline induction and subsequently achieved CR. We sequenced pre-treatment and CR bone marrow samples by targeted capture sequencing of 295 genes (median 280x coverage). We defined 3 levels of mutation clearance (MC) based on variant allele frequency (VAF): 1) MC2.5, persistent mutation with VAF<2.5%, 2) MC1.0, persistent mutation with VAF<1%, and 3) complete mutation clearance (CMC).

Results: In the pre-treatment samples, we detected 597 mutations in 78 genes in 87 (92%) patients. In the matching CR samples, 62 (10%) and 82 (14%) mutations persisted at VAF>2.5% and ≥1%, respectively, which corresponded to 43 (49%), 34 (39%), and 30 (34%) patients achieving MC2.5, MC1.0 and CMC, respectively. Table 1 shows the differential patterns of MC based on the mutations and pathways. Mutations associated with clonal hematopoiesis of

Summary/Conclusions: Somatic mutations associated with CHIP, DNA methylation, and splicing pathways persisted frequently in CR samples suggesting preleukemic origin. Pts with deeper MC had significantly better RFS. Somatic mutation clearance may help risk prediction of AML.

Figure 1.

Summary/Conclusions: In Denmark where health-care is free and uniform, high SE status does not affect treatment intensity in younger patients or response to therapy. However, educational level, but not income, influences alloHSCT rates and has a major impact on survival in younger AML patients. Since 2000, survival improvements have exclusively benefitted well-educated patients and additional attention during treatment and follow-up towards low-educated patients may increase transplantation rates and improve survival.

P194

IDENTIFICATION OF PATTERNS IN CO-OCCURRING MUTATIONS IN AML PATIENTS WITH GERMLINE AND SOMATIC RUNX1 MUTATIONS

U. Borate1,*, B. Wilmot1, B. Norris1, P. Lo1, D. Bottomly1, S. McWeeney1, J. Tyner1, A. Agarwal1
1Oregon Health & Science University, Portland, United States

Background: RUNX1 plays a vital role in leukemogenesis through its interaction with core binding factor-β complex and other genes involved in hematopoiesis (1,2). Familial platelet disorder with predisposition to acute myeloid leukemia (FPD/AML) is linked to germline RUNX1 mutations (3). This autosomal dominant disorder is characterized by thrombocytopenia and potential for transformation to AML. AML patients with somatic RUNX1 mutations have a poor prognosis (6,7) independent of other risk factors. The role of co-occurring mutations in leukemogenesis in FPD/AML patients with germline RUNX1 mutations and AML patients with de novo somatic RUNX1 mutations is not fully understood.

Aims: In order to further characterize co-occurring mutations in patients with both germline and somatic RUNX1 mutations, we analyzed a large cohort of AML tumor samples along with several paired normal tissue samples.

Methods: We sequenced a cohort of 482 diagnostic bone marrow or peripheral blood samples from AML patients by deep whole-exome sequencing. Samples were collected through the “Beat AML” project, an ongoing program at Oregon Health & Science University in collaboration with the Leukemia & Lymphoma Society. RUNX1 mutations were classified using VarScan which defined somatic and germline mutations as follows: somatic if p <0.1 and germline if not called as somatic and normal variant allele frequency >0.1.

Results: Twenty AML samples had 21 germline RUNX1 mutations with a total of 6 different germline variants; 31 other patient samples had 38 somatic RUNX1 mutations with 31 unique somatic variants. One sample had 2 RUNX1 germline mutations; 6 samples had >1 somatic RUNX1 mutations. The most common germline variant, missense mutation p.L56S, was found in 16 (76%) of 21 patients with germline mutations. In 10 (48%) of 21 patients with germline mutations but not in somatic mutations, the missense mutation p.L56S was not found. In 13 (62%) of 21 patients with germline mutations, there was a 0.96 (CI=0.82-1.12), low 1.06 (CI=0.88-1.27).

Summary/Conclusions: We demonstrated that multiple LSC marker expression predicts poor clinical outcomes in newly diagnosed de novo AML patients, and may facilitate better stratification even among patients with intermediate-risk and favorable-risk karyotypes.

Figure 1.
the molecular remission status of a patient’s malignancy. This targeted panel can identify the mutations in driver clones that cause relapse in ~90% of all AML patients, as well as common drivers in myeloid proliferative neoplasms (MPN) and myelodysplastic syndromes (MDS).

**Aims:** To establish a sensitive and reliable targeted NGS assay to comprehensively detect and monitor the majority of known driver mutations in AML and other myeloid malignancies.

**Methods:** Whole genome libraries, made from DNA extracted from cell lines and clinical samples, were hybridized with MyMRD probes targeting mutation hotspots in 23 genes associated with AML. In addition to single nucleotide variants (SNVs) and indels in 21 of these genes, 5 structural variant (SV) breakpoints in 3 genes were also targeted. Barcoded libraries were sequenced with the MiSeq® platform and analyzed using proprietary Invivoscribe (IVS) MyInformatics™ software. To validate mutations detected by the MyMRD assay, samples were additionally tested with IVS developed capillary electrophoresis (CE) assays and NGS-based assays targeting common mutations in FLT3 and NPM1.

**Results:** The linearity and limit of detection (LOD) of the MyMRD assay were assessed using data generated from contrived cell line DNA containing known AML driver mutations with a range of variant allele frequencies (VAFs). The assay shows strong linearity (R²=0.96 – 0.99) in the entire range of tested VAFs (≤ 50%). Overall, we established a LOD of 0.5% for >95% of the targeted sites in the assay with lower LODs for specific mutations of interest (e.g. 0.1% for a 30bp FLT3 ITD and 0.2% for FLT3 p.D835Y). In addition, using clinical samples the MyMRD assay shows excellent concordance with the standard FLT3 CE assays for variants with VAFs above the CE detection threshold (5%). Sanger sequencing was the only method actually covering the entire coding region of CEBPA. Both NGS amplicon-based panels failed to fully cover the coding region of the gene, and therefore have likely missed mutations. Crucially, even when any of the three methods detected more than one variant, cloning studies confirmed biCEBPA mutations only in a fraction of the cases. In summary, none of the amplicon-based tested methods can reliably determine if multiple mutations affect two different alleles; therefore biCEBPA mutations would still need additional confirmation. We are currently exploring the ability of capture-based NGS approaches coupled to appropriately tailored bioinformatic analysis of sequencing data to detect biCEBPA mutations.

**P198**

**IS IT POSSIBLE TO RELIABLY DETECT CLINICALLY-RELEVANT BIALLEIC CEBPA GENE MUTATIONS USING NGS PANELS?**

1Biomedical Engineering, School of Engineering, University of Navarra, 2Molecular Oncology, Biodonostia HRI, Donostia University Hospital, San Sebastian, 3Haematology, JIMLAB Diagnostics, University of Navarra, 4Haematology and Haemotherapy, Clinic of the University of Navarra, Pamplona, Spain

**Background:** CEBPA gene encodes a leucine zipper transcription factor that is important for normal myeloid cell differentiation. Biallelic CEBPA (bicEBPA) mutations are associated with favourable prognosis in patients with acute myeloid leukaemia (AML); therefore, accurate molecular testing of this gene is crucial in the clinical setting. Molecular pathology labs routinely analyse CEBPA through fluorescence-based multiplex-PCR fragment analysis or, more frequently, Sanger sequencing. Lately, it is increasingly common to use next-generation sequencing (NGS) technology in the pathology labs, and CEBPA gene is indeed included in the majority of NGS panels commercially available for testing of patients with neoplasias.

**Aims:** We set ourselves to compare the performance of two different NGS targeted panels against bicEBPA molecular aberrations, with a particular focus on bicEBPA mutations.

**Methods:** DNA specimens from 173 myeloid cases were subjected to Sanger (n=92) or to NGS (n=81) sequencing, including the TruSight Myeloid Sequencing Panel (illumina) (n=59), and the IonAmpSeq AML Community Panel (thermax Fischer) (n=22). Cases showing two variants were further analysed through cloning of the whole length of CEBPA and subsequent Sanger sequencing of at least 10 colonies from each case.

**Results:** We called 10 CEBPA variants affecting 7 samples through NGS. Both NGS panels are designed to cover CEBPA through overlapping amplicons (e.g. FLT3). However, we found that among the set of 3.5 amplicons were covered <500x, and more worryingly, we realised that at least one of those amplicons was shallowly (<100x) covered in 97% of the cases. Indeed both panels showed significantly lower average coverage levels of this gene compared to the panel as a whole (Figure 1). This might not be surprising, since CEBPA is not included within a CpG-rich region, and therefore its amplification needs tailored PCR conditions, hard to address in the multiplexed PCR step included in their library prep protocols. Therefore, both NGS approaches are prone to miss variants. In contrast, Sanger sequencing protocol (which includes optimized PCR conditions for correct amplification of the CEBPA gene) managed to cover the whole length of the gene. We were able to detect 26 variants affecting 20 AML cases through Sanger sequencing. Cases showing two variants were manually curated (through Chromos or IGV tools) to confirm if they affected different alleles. However, in 6 cases both mutations layed on different amplicons, which made not possible to univocally conclude if and how they were biallelic. These inconclusive cases were subjected to DMSO-Pfu-PCR in order to amplify the whole length of CEBPA coding region, followed by cloning. Colony sequencing showed independent clones harbouring different variants (i.e. bona fide bicEBPA mutations) in the majority of the cases, but crucially, not in all of them. This result highlights the need of implementing techniques able to accurately assess CEBPA biallelism, unless than plain calling of more than one variant.
All patients were treated with standard induction and consolidation protocols.

Results: Median time between two investigations was 2.8 months (range for all 0.1-115 months). A complete molecular remission was reached in 90/130 pts (69%) after a median of 5 months. 19/130 (14.6%) pts reached low level MRD and 20/130 (15.4%) high level MRD. Median event free survival (EFS) of patients with CMR was not reached (EFS at 2 years 82%). 16 (18%) of those patients relapsed in the course of follow up with a median time to relapse of 12.7 months (range 4.1 to 38.3 months). Median EFS for MRD low and MRD high patients was 18.4 months and 10.8 months respectively (all 3 groups, p<0.0001). For patients with CMR, rising MRD levels accurately predicted relapse with a median latency of 5.5 months from loss of CMR to relapse. We next used the widely accepted log fold change from baseline to define high and low risk patients in our cohort. 123/130 (95%) patients reached a >3 log fold reduction in \textit{RUNX1-RUNX1T1/ABL} ratio within the first 200 days following first diagnosis. Median EFS for those patients was not reached (EFS at 2 years 66%). The 7/130 (5%) patients with a <3 log fold reduction had a median EFS of 14.7 months (2 groups, p=0.017). A total of 59/185 patients received allogeneic SCT. Among the 130 patients diagnosed at our laboratory 34 (26%) received allogeneic SCT, 12 (9%) were transplanted in first CR and 17 (13%) were transplanted for relapse. Following allogeneic SCT 11/17 patients (65%) reached a second CR with CMR.

Summary/Conclusions: Our data shows that MRD testing is routinely performed in \textit{RUNX1-RUNX1T1} AML outside of clinical studies. Defining MRD levels by \textit{RUNX1-RUNX1T1/ABL} ratios resulted in a better classifier for high and low risk patients than log fold change. However, despite CMR 16/90 (18%) patients relapsed with a maximum time from first achievement of CMR of 38.3 months. We conclude that 1) MRD monitoring could serve to guide BMT decisions in \textit{RUNX1-RUNX1T1} positive AML, 2) allogeneic BMT can rescue the majority of relapsed patients and 3) molecular monitoring can reliably identify patients with high risk for relapse.
Acute myeloid leukemia - Clinical 2

NUMBER OF TP53 ABNORMALITIES AND THEIR CLINICAL RELEVANCE IN PATIENTS WITH ACUTE MYELOID LEUKEMIA AND MYELODYSPLASIA

G. Konopleva1, C. Benton1, T. Kadia1, F. Ravandi1, J. Cortes1, N. Daver1, K. Takahashi1, C. DiNardo1, E. Jabbour1, G. Borthakur1, N. Pemmaraju1, M. Konopleva1, A. Alfonso1, S. Pierce1, C. Bueso-Ramos2, S. Kornblau1, K. Patel2, H. Kantarjian1, M. Andreff1, G. Garcia-Manero1

1Leukemia, Hematopathology, The University of Texas MD Anderson Cancer Center, Houston, United States

Background: Mutations in TP53 can be detected in up to 16-19% patients with acute myeloid leukemia (AML) and myelodysplastic syndromes (MDS). TP53 mutations confer adverse prognosis irrespective of currently available therapies. The clinical impact of the type and number of TP53 abnormalities is unclear.

Aims: To evaluate the prognostic impact of the number of TP53 abnormalities in AML and MDS.

Methods: We evaluated 1401 patients with previously untreated AML or MDS treated at the University of Texas MD Anderson Cancer Center from 2012 to 2016. Sequencing data was obtained by use of a 28 or 53-gene targeted PCR-based next generation sequencing platform. Response was defined following 2003 IWG criteria for patients with AML and 2006 revised IWG criteria for patients with MDS. Generalized linear models were used to study the association of overall response (OR), complete response (CR) and risk factors. Kaplan-Meier produce limit method was used to estimate the median overall survival (OS).

Results: A total of 593 (42%) patients had MDS and 808 (56%) had AML. In a total of 984 (70%) patients, data on therapy with sufficient follow up and response evaluation was available. TP53 mutations were less likely to have co-occurring chr17 abnormalities in patients with TP53 mutations than patients without TP53 mutations (25%, n=146) compared to AML (19%, n=154) (p=0.012) with 251 (13%) detectable mutation, 76 (25%) had 2 and 3 (1%) had 3. Additionally, 188 (13%) patients had TP53 deletions evidenced by presence of monosomy 17 or del(17p). In 167 (89%) of these patients, chr17 abnormalities were detected in the context of a complex karyotype and in 127 (42%) a co-occurring TP53 mutation was detected. Correlation between TP53 mutations and deletions (p=0.443, p<0.001) was observed with 172 (12%) patients having 1 TP53 abnormality. 169 (12%) patients had 1 detectable mutation, 76 (25%) had 2 and 3 (1%) had 3. Additionally, 188 (13%) patients had TP53 deletions evidenced by presence of monosomy 17 or del(17p).

Summary/Conclusions: Presence of multiple TP53 abnormalities can be observed in up to 13% patients with AML and MDS. Second TP53 abnormalities more commonly involve TP53 deletions with additional TP53 mutations being less common and generally mutually exclusive with TP53 deletions. The number of TP53 abnormalities impacts the survival of patients with AML but not that of patients with MDS. Presence and number of TP53 mutations do not seem to impact response to HMAs but are associated with lower responses to chemotherapy.

VADASTUXIMAB TALIRINE PLUS HYPMETHYLATING AGENTS: A WELL-TOLERATED REGIMEN WITH HIGH REMISSION RATE IN FRONTLINE OLDER PATIENTS WITH ACUTE MYELOID LEUKEMIA: RESULTS FROM A Phase 1 study

M. Konopleva1, A. Alfonso1, S. Pierce1, C. Bueso-Ramos2, S. Kornblau1, K. Patel2, H. Kantarjian1, M. Andreff1, G. Garcia-Manero1

1Leukemia, Hematopathology, The University of Texas MD Anderson Cancer Center, Houston, United States

Background: Treatment of AML among the elderly is challenging. HMAs are commonly used, but yield suboptimal response rates and modest survival. Durations of remissions were difficult to achieve, in a study of MRD response by flow cytometry in patients treated with single-agent HMA therapy at MD Anderson Cancer Center, only 13/58 (22%) responding patients achieved minimal residual disease (MRD) negativity (F Ravandi, MD, unpublished data, Jan 2017). Vadastuximab talirine (SGN-CD33A; 33A) is a CD33-directed antibody conjugated to 2 molecules of a pyrrolobenzodiazepine (PBD) dimer. Upon binding, 33A is internalized and transported to the lysosomes where PBD dimer is released via proteolytic cleavage of the linker, crosslinking DNA, and leading to cell death.

Aims: To evaluate the safety, tolerability, PK, and antileukemic activity of 33A in combination with an HMA.

Methods: Eligible patients (ECOG status 0-1) had previously untreated CD33-positive AML. One dose of 33A (10 mcg/kg) was administered outpatient IV every 4 weeks on the last day of HMA (azacitidine or decitabine [5-day regimen], standard dosing). CRi required either platelet count of ≥100,000/µL or neutrophils of ≥1,000/µL (Cheson 2003). MRD was measured by multiparameter flow cytometry.

Results: Fifty-three patients (median age 75 years [range, 60-87]) were treated with 33A+HMA. Patients had adverse (38%) or intermediate (62%) cytogenetics (per MRC); patients were either unfit for (40; 75%) or declined (13, 25%) intensive therapy. The median treatment duration is currently 19.3 weeks (range, 2-86) with 8 patients still on treatment; no DLTs were reported. Adverse events (AEs) ≥ Grade 3 in 55%, febrile neutropenia (49%), anemia (46%), neutropenia (42%), pneumonia (16%), and leukopenia (7%); no ≥ Grade 4 bleeding events were observed. Treatment-emergent (TE) liver lab elevations (≥ Grade 3) were rare: ALT (8%), AST (2%), and total bilirubin (2%). Other non-heme TEAEs reported in ≥25% of patients regardless of relationship to study treatment were fatigue (60%), nausea (43%), constipation (43%), peripheral edema (43%), dyspepsia (40%), dyspnea (34%), pyrexia (32%), diarrhea, vomiting (28%), and dizziness (26%). Thirty- and 60-day mortality rates were 2% and 8%, respectively, with no treatment-related deaths reported. A total of 39 (103/263) of doses were delayed due to AEs mostly from myelosuppression (neutropenia 18%, thrombocytopenia 7%, and febrile neutropenia 3%). High remission rates (≥74%) were maintained across adverse disease subsets including advance cytogenetics (16/18, 89%), TP53-mutated (67/86), secondary AML (18/22, 82%), and age ≥75 years (18/26, 69%). Of all responding patients, 19/37 (51%) achieved MRD negativity. Two patients went on to subsequent allo-HSCT, and no SOS/VOD was observed. The median post-MRD clearance rate among responding patients who received 33A+HMA is higher than the rate observed with single

Figure 1.
Background: Acute myeloid leukemia (AML) with intermediate-risk (IR) cytogenetics includes a substantial proportion of patients with favorable molecular profile (FMP); in which AML cells harbor the NPM1 mutation or CEBPα biallelic mutation without internal tandem duplication of the FLT3 gene (FLT3-ITD). The role of allogeneic hematopoietic transplantation (allo-HCT) in first complete remission (CR) in these patients remains controversial. Aims: To analyze the results and prognostic factors of 191 AML patients in a large series of patients treated by the Spanish CETLAM group. Methods: Patients with primary AML diagnosed at 19 institutions from the Spanish CETLAM group and treated between 2003 and 2017. Induction chemotherapy included idarubicin and cytarabine (standard or intermediate-dose) in all cases, consolidation with high-dose cytarabine (HDAC) and, depending on the protocol, additional HDAC, autologous or allogeneic hematopoietic transplantation. Results: Two hundred twenty-one patients were analyzed. Median age of the series was 54 years (range 18 to 72). 152 patients had an age up to 60 years and 69 (31%) were older. Median WBC count was 19x10⁹/μL (range 0.55-282). One-hundred eighty-two patients had a normal karyotype and it was abnormal in 34 (5 patients no metaphases). There were 52±8% and 70±4%, respectively. In univariate comparisons, better EFS and OS was observed in CEBPα+/FLT3-ITD- patients compared to those with NPM1+/FLT3-ITD- (p=0.03 and p=0.02, respectively). When analyzing post-remission treatment, patients treated with HDAC only had an excellent prognosis, even better than those receiving an autologous or allogeneic transplantation. One patient died in CR in the HDAC group, another in the autologous transplant group and 7 in the allo-HCT group (p<0.001). Death during induction was observed in 16 patients (7%), all of them with NPM1+/FLT3-ITD+. Induction results according to age were similar in both groups. Event-free survival and overall survival are reported at 8 years and were 52±8% and 70±4%, respectively. In univariate comparisons, better EFS and OS was observed in CEBPα+/FLT3-ITD- patients compared to those with NPM1+/FLT3-ITD- (p=0.03 and p=0.02, respectively). When analyzing post-remission treatment, patients treated with HDAC only had an excellent prognosis, even better than those receiving an autologous or allogeneic transplantation. One patient died in CR in the HDAC group, another in the autologous transplant group and 7 in the allo-HCT group (p<0.001). In multivariate analysis of pretransplant characteristics, age up to 60 years and CEBPα+/FLT3-ITD- associated to improved EFS (RR=0.42) and OS (RR=0.29). Interestingly, in a subgroup of 123 patients with data on MRD after consolidation chemotherapy (flow citometry, cut-off: 0.12%), positivity was associated with worse EFS (0.02). Despite age was a prognostic factor, patients older than 60 years with IR-FMP AML had remarkable EFS of 36±3% and OS 54±10% at 8 years (Figure 1).
Results: 24 pts have been enrolled to date and 17 are evaluable for response. The median age was 60 years (range, 50-70) with 58% male pts and 25% with high-risk cytogenetics (by SWOG). 50% (12/24) were pts with secondary AML (sAML), half of whom had prior hypomethylating therapy (50%; 6/12). This study had a rolling safety run-in and the first 3 pts had no DLT, allowing enrollment to proceed. Common Gr 3/4 AEs included febrile neutropenia (13%), pneumonia (20%), cardiac edema (13%) and non-fatal respiratory failure (13%). 2 pts died of sepsis within 60 days. The remission rate (CR/CRi) was 12/17 (71%). CR/CRi rate was 75% for pts with de novo disease and 67% for pts with sAML. The PK profile in this elderly population was consistent with that of younger adults (median age <60 years) with sAML in Phase 1 (DeAngelo, EHA 2016); no autoimmunization or evidence of drug-drug interactions were apparent. The median E-sel ligand expression at baseline was 29% (range, 2-67%) of blasts in the bone marrow.

Summary/Conclusions: The addition of a novel E-selectin antagonist, GMI-1271, to anthracycline induction chemotherapy in untreated elderly pts with AML, including patients with secondary AML, demonstrates a high remission rate with acceptable side effect profile resulting in low induction mortality. This study compares favorably to previous studies (Lancet, ASCO 2016). E-selectin ligand was expressed on leukemic blasts in the majority of pts, therefore supporting its relevance as a target. A randomized trial is being planned.

P204

A PHASE 2 STUDY OF GLASDEGIB (PF-04449913) IN COMBINATION WITH CYTARABINE AND DAUNORUBICIN IN UNTREATED PATIENTS WITH ACUTE MYELOID LEUKEMIA OR HIGH-RISK MYELODYSPLASTIC SYNDROME

J.E. Cortes1,*, B.D. Smith2, E.S. Wang3, A. Merchant4, V.G. Oehler5, B. Eaves6, K. Calabrese7, M.D. Odero2

1University of Texas, MD Anderson Cancer Center, Houston, TX, 2Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD, 3Roswell Park Cancer Institute, Buffalo, NY, 4University of Southern California Cancer Institute, Los Angeles, 5University of Colorado Cancer Research Center, Seattle, WA, 6Emory University School of Medicine, Atlanta, GA, 7Dana-Farber Cancer Institute, Boston, MA

Background: Glasdegib is a selective, once-daily (QD), oral Smoothened (SMO) inhibitor, demonstrated significant improvement in overall survival (OS) when used in combination with low-dose cytarabine (LDAC) vs LDAC alone in a randomized (2:1) open-label trial in 132 patients (pts) not suitable for induction chemotherapy (IC). Preclinical studies showed that glasdegib limits leukemia stem cell proliferation and provided evidence of glasdegib synergy with chemotherapy.

Aims: Primary objective of this open-label, single-arm Ph 2 study (NCT01546038) was to determine complete remission (CR) rate with glasdegib in combination with cytarabine and daunorubicin in untreated AML or high-risk MDS pts. CR was the key secondary endpoint.

Methods: Pts suitable for IC (ECOG PS 0-1, creatinine ≤1.3 mg/dL, no severe cardiac disease) gave informed consent and received glasdegib 100 mg QD from day 1, in combination with cytarabine 100 mg/m² i.v. for 7 days and daunorubicin 60 mg/m² IV for 3 days, followed by 2-4 consolidation cycles (cytarabine 1 g/m² Q12 hrs on days 1, 3, 5). Maintenance (up to 6 months) included glasdegib 100 mg QD. Pts were assessed for efficacy, safety and tolerability.

Results: All Pts: As of 1 Dec 2016, 71 pts (66 AML, 5 MDS) were enrolled and 69 pts received glasdegib and IC (2 pts not treated due to inability). Among MDS pts, 19 pts (47%-de novo, secondary) were distinguishable, 32% int/med, 21% int/IIl and 26% adverse cytogenetic abnormalities (1 pt not assessed). Among MDS pts (5 de-novo), 20 had good, 40% int and 40% poor risk cytogenetic abnormalities. Median age was 64 (27-75) years. Median treatment duration was 48 (10-502) days. The most common NCI-CTC v4.0 Grade 3/4 AEs included: hypokalemia (13%), hyponatremia (11.6%) and hypertension (10.1%). Grade 5 AEs within 28 days from last dose (5 pts, 7.2%) included pneumonia, sepsis, septic shock (1 pt each) and disease progression (2 pts). The observed steady-state plasma exposures for glasdegib were as expected at the 100 mg dose level. Based on investigator’s assessment, CR was 41% (80% CI 33.2-47.9) and CRi was 49%. CR for good/int. risk pts (n=49) was 49% and for poor risk pts (n=19) 21%. Forty-one (59%) pts died (33 [48%] due to disease progression) with median follow up of 30.1 months; 24 (35%) remain in follow up. The median OS (mOS) was 14.9 months (80% CI 12.0-17.3) for AML pts and 25.1 months (90% CI 19.3-30.9) for MDS pts. After a median of three (33%) pts received a transplant and MDS censored for transplant was 17.7 months, AML Pts >60 yrs. The mOS for 44 AML pts age ≥60 yrs is presented in the Table 1, in the context of historical control.

*1 pt was not classifiable by ELN risk.

Summary/Conclusions: Although the CR rates do not appear to be higher than those reported historically for AML pts receiving IC, the mOS for AML pts >60 yrs stratified by subgroup compares favorably by adding glasdegib. Our data can be used to support that this is a rational combination of glasdegib on the leukemia stem cell. The combination of glasdegib with ICT was well tolerated, with a safety profile consistent with that in AML pts receiving standard ICT. Further studies are warranted.

P205

CM942 IS A NEW SMALL MOLECULE THAT TARGETS SET-PP2A INTERACTION AND INHIBITS GROWTH OF ACUTE MYELOID LEUKEMIA CELLS

1Hematology, Complejo Hospitalario de Navarra, 2University of Navarra, 3CIMA, University of Navarra, 4Clinica University of Navarra, Pamplona, Spain

Background: Acute myeloid leukemia (AML) is a heterogeneous malignant disorder of hematopoietic progenitor cells in which several genetic and epigenetic aberrations have been described. Nevertheless, outcome for most patients is poor, and it is necessary to develop more effective treatment strategies. Our group showed that the inactivation of the tumor suppressor PP2A is a recurrent event in AML, and that overexpression of SET, an endogenous inhibitor of PP2A, is a poor prognostic factor in this disease. Furthermore, the anticancer activity of FTY720, a PP2A-activating drug (BA266), depends on its interaction with SET, FTY720 is a relatively non-toxic drug currently used in patients with relapsing multiple sclerosis; however, this drug cannot be used in cancer patients due to its toxicity at the needed anti-neoplastic dose. Therefore, investigation of alternative agents for reactivation of PP2A is warranted.

Aims: To test the efficacy of CM942, a FTY720 analogue, on AML cell lines and primary patient samples, and investigate its mechanism of action.

Methods: AML cell lines and 29 de novo AML samples were analyzed by treatment with FTY720 and CM942, MTS (viability), apoptosis, cell cycle and PP2A activity assays, and western blot.

Results: CM942 exhibited notable cytotoxicity on all human AML cell lines with SET overexpression (n=10). Using phosphatase assays we confirmed that CM942 treatment activated PP2A on cell lines, similarly to FTY720. Immunoprecipitation of PP2Ac in untreated cells confirmed that SET interacts with PP2A, and that treatment with CM942 effectively disrupted this association. Furthermore, CM942 had a caspase-dependent pro-apoptotic effect, and decreased phosphosylation of the PP2A target ERK1/2. Microarray data from vehicle-treated and CM942-treated HL-60 cells showed a high correlation between the gene expression profiles of the samples. This analysis identified up-regulated and down-regulated genetic pathways by treatment with CM942, providing mechanistic insights into the anti-tumor mechanism of this small molecule. Our analyses in primary AML samples showed that 7 out of 29 (24%) samples treated with CM942 had a significant reduction in proliferation. By western blot analyses we found that those patients responding to CM942 treatment had SET overexpression. Of note, treatment of peripheral blood mononuclear cells from healthy donors with CM942 had no effects on cell viability. Therefore, although FTY720 and CM942 have similar effects inhibiting cellular proliferation, CM942 was less toxic when assayed on normal peripheral blood cells.

Summary/Conclusions: CM942 inhibits growth of AML cells in both cell lines and primary patient samples, exerting its antileukemic effects through reactivation of PP2A activity. Although treatment with FTY20 was somewhat more effective than CM942 in primary samples of AML, fewer cytotoxic effects were observed after CM942 treatment in peripheral blood from healthy donors. Further experiments would be necessary to confirm the in vivo anti-tumor activity of CM942 in AML models. New compounds have been developed for the treatment of AML, although few have been translated into clinical practice; nevertheless, it is unlikely that any of these compounds, when used in combination with other drugs, will cure the disease, or allow for a cure in the future with conventional chemotherapy. Our results indicate that PADS may be a valid therapeutic option for AML, especially for treating leukemias characterized by SET-dependent inactivation of PP2A.
CLONAL HETEROGENEITY IN LEUKEMIC STEM CELLS FROM PATIENTS WITH ACUTE MYELOID LEUKEMIA

L. Manta1,*, B. Saeed1, J. Schwenk2, P. Pyli, T. Steinh2, K. Barth-Miesala1, V. Eckstein1, W. Huber2, A.D. Ho1, C. Lutze1
1Department of Medicine V, University of Heidelberg, 2Multi-omics and statistical computing, European Molecular Biology Laboratory, 3Interdisciplinary Center for Scientific Computing & Institute of Applied Mathematics, University of Heidelberg, Heidelberg, Germany

Background: Clonal heterogeneity occurs in many cancers, including Acute Myeloid Leukemia (AML). In cases of relapse, chemotherapy has triggered clonal selection with minor or evolved sub-clones driving relapse. A better understanding of the underlying clonal architecture, the extent of genetic heterogeneity and its response to therapy is necessary to better understand mechanisms of therapy escape and relapse.

Aims: In this study we aim to define the clonal architecture of AML during the course of therapy and in leukemia propagating cells.

Methods: We sequenced 12 AML samples at the time of diagnosis and in one case also at the time of relapse with at least 80% blasts per sample. 6/12 patients displayed a normal karyotype while the other 6 patients showed various cytogenetic abnormalities (inversion 16 (2), trisomy 8 (1), add(19)(p13.3) (1), complex aberrant karyotype (2)). Whole-exome sequencing (WES) was performed with the appropriate germ line controls. WES data were clustered using empirical Bayesian clustering.

Results: WES identified more than 3000 variants in total. By setting distinct filtration criteria (20% allele frequency (AF), ≥10 reads coverage, ≥2 reads support of the detected variant, SIFT-score <0.05 and GMAF <5%) 64 leukemia specific mutations were detected (1-18 mutations/AML). As expected, these included recurrently mutated genes like DNMT3A (in 4 patients), IDH1 and 2 (each in one patient), KIT and NRAS (both in 2 patients). Categorization of identified mutations showed that these mutations affected genes involved in various cellular processes including transcriptional regulation (15), cell differentiation (6), cell cycling (5), apoptosis/survival signals (5), proliferation (3), cell growth (3) and splicing (3). Empirical Bayesian clustering of all detected variants according to their respective AF resulted in 2-5 different clusters per AML.

Based on this cluster analysis we were able to predict the founding clusters/clone. Assuming that most of the mutations are heterozygous and considering the blast percentage at diagnosis, mutations of the biggest clusters are involved in phenotypically distinct subpopulations and during xenotransplantations by targeting sequenced. An update of this analysis will be presented at EHA.

Summary/Conclusions: WES can identify leukemia specific mutations that are involved in various cellular functions including mutations that have been shown to be recurrently mutated in AML like DNMT3A. Sequencing data can also be used in combination with mathematical modelling approaches to reconstruct the clonal architecture of AML at the time of diagnosis and relapse allowing estimations of the clonal complexity at these time points.
Summary/Conclusions: Mutations in NPM1, and DNA methylation pathway were associated with a better response to pracinostat+AZA, while TP53 mutation was associated with a trend toward poor response. Persistent mutation at the time of CR suggests residual preleukemic clonal hematopoiesis in this elderly population. Benefit of prolonged exposure to pracinostat+AZA was also confirmed at molecular level where continued decline of mutation VAF was seen after achieving CR.

Acute myeloid leukemia - Clinical 3

P208
STABLE DISEASE WITH HEMATOLOGIC IMPROVEMENT IS CLINICALLY MEANINGFUL FOR OLDER PATIENTS WITH ACUTE MYELOID LEUKEMIA TREATED WITH AZACITIDINE

A.C. Schuh1,*, H. Döhner2, J.F. Seymour3,4, P. Turlure5, S. Songer8, C. Beach8, H. Dombret9

1Princess Margaret Cancer Centre/University Health Network, Toronto, Canada, 2Universitätsklinikum Ulm, Ulm, Germany, 3Peter MacCallum Cancer Centre, Melbourne, 4University of Melbourne, Parkville, Australia, 5Centre Hospitalier Universitaire de Limoges, Limoges, France, 6Universitätsmedizin Rostock, Rostock, Germany, 7The Royal Wolverhampton Hospitals NHS Trust, Wolverhampton, United Kingdom, 8Celgene Corporation, Summit, United States, 9Hôpital Saint Louis- Institut Universitaire d’Hématologie, Paris, France

Background: Effects on overall survival (OS) are of primary importance when evaluating AML treatments (Tx). Though complete remission (CR) rates are lower with azacitidine (AZA) than with intensive chemotherapy (IC), OS is similar with AZA and IC (Dombret et al., Blood, 2015). The 2017 European LeukemiaNet (ELN) recommendations acknowledge that hypomethylating agents, including AZA, may alter the natural course of AML in some patients (pts) who do not achieve CR (Döhner et al., Blood, 2017). According to IWG criteria for AML (Cheson et al., J Clin Oncol, 2003), stable disease (SD) is considered non-response to Tx. Yet AML is a progressive disease; potentially, stable health status may reflect delayed disease progression and result in improved OS.

Aims: This post hoc analysis evaluated OS outcomes among older pts with AML treated with AZA or conventional care regimens (CCR) who maintained SD, with or without hematologic improvement (HI), in the phase 3 AZA-AML-001 study.

Methods: Pts aged ≥65 years with AML (>30% marrow blasts), ECOG PS score ≤2, NCCN-defined intermediate- or poor-risk cytogenetics, and WBC count ≤15x10^9/L received AZA (75mg/m^2x7 days [d]/28d cycle) or a CCR (IC [standard 7+3 regimen], low-dose cytarabine [20mg BID x 10d/28d cycle], or best supportive care). OS was assessed using Kaplan-Meier methods for pts with SD at 2-, 4-, and 6-month landmarks. SD was protocol-defined as the absence of an IWG-defined AML response and no progressive disease (PD), whether or not HI was attained. Pts with SD could have had an IWG-defined response or PD at any time other than at the specified landmarks. OS was also evaluated in pts with HI as their best response; attainment of HI must have begun on or before, and been sustained past, each landmark, and lasted for ≥56 consecutive days.

Table 1.

Results: Median OS for all SD pts was 2.1-2.5 months longer with AZA vs CCR, and estimated 1-year survival was ~15% higher at each landmark in the AZA arm (Table 1). Hazard ratios for OS among all SD pts treated with AZA vs CCR ranged from 0.81–0.88. Median OS among pts with SD and no HI ranged from 12.6–13.3 months in the AZA arm and from 11.1-12.2 months in the CCR arm. Within Tx arms, AZA-treated pts with HI had meaningfully improved OS at all landmarks, ranging from 3.7 to 7.9 months longer than OS for pts without HI (Table 1). In contrast, HI attained with CCR did not largely influence OS; differences between pts who attained HI vs no HI ranged from -0.2 to 2.9 months. Median durations of HI in the AZA vs CCR arms, respectively, were 183 vs 166.
days at 2 months, 176 vs 148 days at 4 months, and 176 vs 138 days at 6 months. Estimated 1-year survival within the AZA arm was 4.9%–27.4% greater for pts with HI than for pts with no HI, but for CCR-treated pts with HI, 1-year survival was 0%–12.3% greater. Between Tx arms, 1-year survival with AZA in pts with HI was 9.6%–33.3% greater than for CCR-treated pts with HI. **Summary/Conclusions:** Maintaining SD during AZA or CCR Tx is associated with relatively favorable OS outcomes, as median OS in pts with SD exceeded that for all pts in the AZA-AML-001 trial (10.4 months with AZA vs 6.5 months with CCR; Dombret et al., Blood, 2015). Pts with SD who also attained HI during early AZA Tx had meaningfully improved OS, whereas similar CCR-treated pts did not, suggesting that HI with AZA is qualitatively different from HI with CCR. The prognostic relevance of HI in AML requires further study.

**P209**

**A RANDOMIZED PHASE II STUDY OF IDARUBICIN AND CYTARABINE WITH EITHER CLOFARABINE OR FLUDARABINE IN ADULTS WITH NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA**

N. Daver1, G. Borthakur 1, N. Jain1, M. Konopleva 1, Z. Estrov1, T. Kadia1, W. Huang1, L. Xiao1, G. Garcia-Manero1, W. Plunkett1, V. Gandhi1, K. Sasaki1, N. Pemmaraju1, N. Daver1, G. Borthakur1, N. Jain1, M. Konopleva1, Z. Estrov1, T. Kadia1, W. Wierda1, C. DiNardo1, M. Brandt1, S. O’Brien1, J. Cortes1, E. Jabbour1

1The University of Texas MD Anderson Cancer Center, Houston, 2The University of California - Irvine, Orange, United States

**Background:** Fludarabine and clofarabine are purine nucleoside analogues with clinical activity in acute myeloid leukemia (AML). **Aims:** We designed a randomized phase II trial to evaluate the efficacy and safety of idarubicin and cytarabine with either clofarabine (CIA) or fludarabine (FIA) in adults with newly diagnosed AML. The primary objective was to compare the EFS rates of the two regimens.

**Methods:** Adults with newly diagnosed AML deemed suitable for intensive chemotherapy were randomized using a Bayesian adaptive design to receive CIA or FIA. All patients (pts) received idarubicin 10 mg/m² IV on D1-3 and cytarabine 1 g/m² IV daily on D1-5. Clofarabine and fludarabine were given at doses of 15 mg/m² and 30 mg/m², respectively. IV daily on D1-5. Pts with FLT3-ITD mutations could receive concomitant sorafenib. Responding pts could receive up to 6 cycles of consolidation at attenuated doses. Outcomes were compared to a historical cohort of pts <60 years of age who received idarubicin and cytarabine (IA) without a nucleoside analogue.

**Results:** Between 8/2011 and 6/2016, 182 pts were enrolled (CIA, n=106; FIA, n=76; Table 1).

**Table 1.**

The imbalance of the arms was due to the better performance of CIA during the initial period of the trial. Treatment arms were well-balanced after randomization. 12 pts (55%) in the CIA arm and 8 (53%) in the FIA arm received sorafenib. The composite CR/CRI rate was similar between the two arms (80% for CIA vs 82% for FIA; P=0.84). CR was achieved in 72% and 74% in the CIA and FIA arms, respectively. MRD negativity rates at remission by multiparameter flow cytometry were higher in the CIA arm (80% vs 65%; P=0.07). 37 pts (35%) in the CIA arm and 28 (38%) in the FIA arm underwent allogeneic stem cell transplant in first remission. The median duration of follow-up was 27 months (range, 1-58). Median EFS for pts who received CIA and FIA were 13 months and 12 months, respectively; the 2-year EFS rate was 44% in both arms (P=0.91). Median OS were 24 months and not reached, and the 2-year OS rates were 51% and 57%, respectively (P=0.23). No differences in EFS or OS were observed according to baseline factors, including cytogenetics, mutations or ELN risk group. CIA was generally associated with more adverse events compared to FIA, including a higher rate of transaminase elevation (29% vs 4%), hyperbilirubinemia (26% vs 9%), and rash (29% vs 12%) Early mortality was similar in the 2 arms (60-day mortality: 4% for CIA vs 1% for FIA; P=0.32). We compared outcomes of pts treated with either CIA/FIA to a historical cohort treated with IA (n=92). Pts in the CIA/FIA group with FLT3 mutations who received sorafenib (n=20) were excluded from this analysis. The two arms were similar with respect to pretreatment characteristics analyzed, including age, cytogenetics, and ELN risk. No differences were observed in CR/CRI rates, EFS or OS between the two groups. However, among pts <50 years of age, the median EFS for pts who received FIA (n=38), CIA (n=28) and IA (n=34) was not reached. 10 months and 3 months, and the 2-year EFS rates were 58%, 33% and 30%, respectively (P=0.05 for FIA vs IA; P=0.79 for CIA vs IA). For these pts <50 years of age, the median OS was not reached, 22 months and 15 months, and the 2-year OS rates were 72%, 46% and 36%, respectively (P=0.009 for FIA vs IA; P=0.23 for CIA vs IA).

**Summary/Conclusions:** CIA and FIA were safe and well tolerated. CIA was found to be associated with better efficacy outcomes as compared with FIA, especially in younger pts with newly diagnosed AML, although FIA is associated with a better toxicity profile. FIA may improve outcomes compared to IA in pts <50 years of age.

**OVERALL SURVIVAL AND TRANSPORTATION TO INFECTION WITH FLT3 MUTATIONS: SUBGROUP ANALYSIS OF A PHASE 3 STUDY OF CPX-351 VERSUS 7+3 IN OLDER ADULTS WITH NEWLY DIAGNOSED, HIGH-RISK ACUTE MYELOID LEUKEMIA**

1Stanford University School of Medicine, Stanford, CA, United States 2Gordon and Leslie Diamond Health Care Centre, Vancouver, British Columbia, Canada 3Oregon Health and Science Univ, Portland, OR, 4University of Michigan, Ann Arbor, MI, 5BMT Group of Georgia, Atlanta, GA, 6Vanderbilt-Ingram Cancer Center, Nashville, TN, 7University of Kansas Medical Center, Kansas City, KS, 8University of Alabama at Birmingham, Birmingham, AL, 9Wake Forest Baptist Comprehensive Cancer Center, Winston-Salem, NC, 10Yale Univ. School of Medicine, New Haven, CT, 11Jazz Pharmaceuticals, Palo Alto, CA, 12H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL, United States

**Background:** Approximately 20% to 30% of patients with acute myeloid leukemia (AML) have FLT3 mutations; these patients often experience rapid post-induction relapse, highlighting the need for therapies that provide an improved bridge to stem cell transplantation. CPX-351 is a liposomal formulation that delivers a synergistic 5:1 molar ratio of cytarabine and daunorubicin. CPX-351 demonstrated significantly prolonged overall survival (OS) versus cytarabine/daunorubicin (7+3) in a randomized, open-label, controlled phase 3 trial in patients aged 60 to 75 years with newly diagnosed, high-risk AML (Lancet, et al. ASCO 2016). A study of the ex vivo cytotoxicity of CPX-351 found that AML blasts with the FLT3-ITD phenotype were 5-fold more sensitive to CPX-351 than those with wild type FLT3 (Lordan, et al. Leuk Res. 2017;53:39-49).

**Aims:** The current analysis of the phase 3 trial therefore investigated outcomes in the subset of patients with FLT3 mutations.

**Methods:** Enrolled patients were randomized 1:1 to receive induction with 1 to 2 cycles of CPX-351 (100 units/m²/day [1st induction: x 7 days] or 100 mg/m²/day x 7 days at 1, 3, and 5 [2nd induction: Days 1 and 3 only]) or 7+3 (cytarabine 100 mg/m²/day x 7 days [2nd induction: x 5 days] daunorubicin 60 mg/m² on Days 1, 2, and 3 [2nd induction: Days 1 and 2 only]). Patients who achieved complete remission (CR) or CR with incomplete platelet or neutrophil recovery (CRi) could receive up to 2 consolidation cycles.

**Results:** Of the 274 patients who were assessed for FLT3 mutations and received study treatment, 22/138 (16%) patients in the CPX-351 arm and 20/136 (15%) patients in the 7+3 arm had baseline FLT3 mutations. AML subtypes in FLT3+ patients were: therapy-related AML (19%); AML after myelodysplastic syndrome/myelodysplastic syndrome (MDS) (19%) or without (10%) prior therapy; myelodysplastic syndromes (MDS) (19%) or therapy as a result of non-randomized single-agent; AML after chronic myelomonocytic leukemia (12%); and de novo AML with MDS karyotype (21%). In FLT3+ patients, median OS was longer with CPX-351 than with wild type FLT3 (Lordan, et al. Leuk Res. 2017;53:39-49).

**The current analysis of the phase 3 trial therefore investigated outcomes in the subset of patients with FLT3 mutations.**

The adverse event profile (reported during treatment or within 30 days of discontinuation of study treatment) in CPX-351 in FLT3+ patients was consistent with the overall study population. Serious treatment-emergent adverse events (TEAEs) were experienced by 7 (32%) FL3+ patients in the CPX-351 arm and 10 (50%) patients in the 7+3 arm; individual serious TEAEs in ≥2 patients included febrile neutropenia (n=2 in each arm), respiratory failure (n=1 and n=2 in CPX-351), and cerebral hemorrhage (n=2 with 7+3).

**Summary/Conclusions:** CPX-351 demonstrated numerical improvement in median OS in older patients with newly diagnosed, FLT3+ high-risk AML and haematologica | 2017; 102(s2) | 53
allowed more patients to undergo stem cell transplantation. The safety of CPX-351 in this subpopulation was in line with the previous studies and the overall phase 3 population. This analysis was limited by small number of patients.

high-risk pts based on a historical cohort. Correlative studies profiling the immune repertoire of pts before and during treatment are being finalized and will be summarized.

P211
NIVOLUMAB MAINTENANCE THERAPY FOR PATIENTS WITH HIGH-RISK ACUTE MYELOID LEUKEMIA IN REMISSION
T. Kadia1,*, H. Kantarjian2, E. Jabbour3, F. Ravandi3, N. Daver2, P. Cardenas3, M. Brandt3, M. Konopleva3, J. Cortes1
1Leukemia, 2MD Anderson Cancer Center, Houston, United States

Background: Dose intensification and newer drug combinations during induction have led to high rates of complete remission (CR) in pts with newly diagnosed AML. However, disease relapse remains a major source of failure. With the exception of allogeneic (allo) stem cell transplant (SCT), there are few options for post-consolidation maintenance of remission in high-risk pts. Prior attempts at re-induction or maintenance therapies with toxic drugs have been unsuccessful. Immune mediated disease control by engaging tumor-specific cytotoxic T-cells may be important in suppressing leukemia relapse, as is seen with graft vs leukemia effect following allo SCT. Immune checkpoint inhibitors may be effective in restoring host immune surveillance in the setting of post-remission therapy.

Aims: We designed a pilot phase II clinical trial studying the efficacy and safety of nivolumab (nivo) as maintenance therapy in AML pts with high-risk disease in remission, who were not being considered for SCT.

Methods: AML pts ≥18 years with a high-risk feature in 1st CR (CR1) or any patients in 2nd CR (CR2) who had received induction and at least 1 consolidation cycle were eligible for enrollment. Pts should be within 12 months of achieving CR, have PS ≤2, and adequate organ function. Pts were treated with nivo 3mg/kg IV every 2 weeks for 6 months. 1 cycle was 4 weeks. After 6 months, nivo could be given every 4 weeks until 12 months on study, and then every 3 months until relapse. All pts had baseline cytogenetic and molecular testing, and minimal residual disease (MRD) assessment by flow cytometry. Peripheral blood and bone marrow samples were collected at baseline and during treatment for immune correlative studies to explore immune cell repertoire and biomarkers for response.

Results: Eight pts have been treated, with a median age of 60 years (range, 49-71). 7 pts were in CR and 1 in CRi at the time of enrollment; 5 pts (63%) were in CR1, 2 pts (25%) were in CR2, and 1 pt (13%) in CR4 was inadvertently enrolled and treated on the trial. Baseline characteristics are outlined in Table 1. AML-related mutations detected at start of therapy include: IDH2 (n=2), NPM1 (2), TET2 (2), and 1 each of TP53, JAK2, ASXL1, and DNMT3a. High risk features at the time of enrollment were as follows: 2 (25%) persistent MRD, 2 (25%) adverse karyotype, 1 (13%) adverse mutualation profile, and 3 pts (38%) in CR2 or beyond. Pts have received a median of 4 (1 - 13) cycles of therapy. With a median followup of 6+ months (1 – 14), the 6- and 12-month estimated RFS were 88% and 73%, respectively. The 6- and 12-month estimated OS were 100% (Figure 1). The one patient who died was discovered after enrollment to actually be in CR4. This patient relapsed approximately 8 months after achieving CR4. The regimen was well tolerated overall, with 4 pts having possible immune-related events. 1 pt patient had grade 3 thyroiditis leading to hypothyroidism, treated successfully with steroids and thyroid hormone supplementation, who continues on treatment. 1 pt had grade 4 transaminase elevation which responded to dose interruption and who continues on treatment. 2 pts had grade 3 possible pneumonitis treated successfully with steroids and dose interruption – both of whom continue on treatment (Table 1).

Summary/Conclusions: Nivo appears to be a feasible maintenance strategy in high-risk AML pts who are not candidates for SCT. The study continues to surpass the pre-specified expected rate of 6-month relapse-free survival of

HIGHER EXPRESSION OF LONG NON-CODING RNA KIAA0125 IS ASSOCIATED WITH CHARACTERISTIC CLINICAL AND BIOLOGICAL FEATURES AND IS AN INDEPENDENT POOR PROGNOSTIC FACTOR IN ACUTE MYELOID LEUKEMIA
S.-Y. Hung1,*, C.-C. Lin1,2,3, H.-A. Hou1, W.-C. Chou1,2, H.-F. Tien1
1Division of Hematology, Department of Internal Medicine, 2Department of Laboratory medicine, National Taiwan University Hospital, 3Graduate Institute of Clinical Medicine, College of Medicine, National Taiwan University, Taipei City, Taiwan, Republic of China

Background: Long non-coding RNAs (lncRNAs) are non-protein coding RNAs longer than 200 nucleotides. Recently, a number of lncRNAs have been shown to play important roles in cancer biology. IncRNA KIAA0125 is one of the 11 genes in an expression signature significantly associated with prognosis in cytogenetically normal acute myeloid leukemia (AML) patients as shown in our previous report. It is also among another set of 17 leukemia stem cell (LSC) genes, identified through xenotransplantation model in NSG mice, which predict inferior treatment response in AML.

Aims: KIAA0125 gene is localized on chromosome 14q32.33; its functions remain unexplored. One study reported that it might be involved in neurogenesis including induction of astrocytosis, preventing formation of dopaminergic neurons. Another study showed that it could potentiate cell invasion and migration in gallbladder cancer. Its clinical significance in hematologic malignancies has not been explored yet. Since independent studies have reported KIAA0125 as an important gene for unfavorable prognosis, in this study we aimed to investigate its clinical relevance in AML.

Methods: We performed global mRNA arrays for bone marrow samples from 347 newly diagnosed de novo AML patients in the National Taiwan University Hospital, who had adequate cryopreserved cells and detailed demographic, clinical, and genetic data for analysis. The KIAA0125 expression level extracted from the array data was analyzed for its clinical relevance. We also validated our findings by analyzing the public databases of AML.

Results: The 347 patients were divided into two groups based on the median level of KIAA0125 expression on the arrays. Higher KIAA0125 expression was inversely associated with favorable karyotypes including t(8;21) and t(15;17). Patients with M1 by the French-American-British classification more frequently had higher KIAA0125 expression (p < 0.001), while those with M3 (acute promyelocytic leukemia) had significantly lower levels of KIAA0125 expression (p < 0.001). To investigate the association of gene mutations with KIAA0125 expression in AML, we analyzed mutations of 17 AML-associated genes. We found that patients with higher KIAA0125 expression had significantly higher incidence of FLT3-ITD (28.7% vs 19.7%, p=0.048), and mutations of RUNX1 (18.4% vs 10.4%, p=0.034), and DNMT3A (24.1% vs 13.9%, p=0.015), compared to those with lower KIAA0125 expression. Among the 227 patients who received standard chemotherapy, those with higher KIAA0125 expression had a lower complete remission rate (61.2% vs 84.7%, p < 0.001), and shorter overall survival (median OS, 23.7 months vs 116.8 months, p = 0.001) than those with lower KIAA0125 expression after a median follow-up of 57.0 months. The prognostic significance could be validated in another two independent cohorts, TCGA and GSE12417. In multivariate analyses, higher expression of KIAA0125 remained to be an unfavorable prognostic factor for OS independent of age, white blood cell counts, karyotype, FLT3-ITD, CEBPA double mutations,
RUNX1 mutation, MLL-PTD, WT1 mutation, and TPS3 mutation (p=0.011).

Summary/Conclusions: Higher expression of KIAA0125 in AML patients was correlated with mutations of RUNX1, DNM3TA, and FLT3-ITD but negatively associated with favorable karyotypes such as t(8;21) and t(15;17). Higher expression of KIAA0125 appeared to be an independent unfavorable prognostic factor in our cohort, and its negative prognostic impact could be validated in another two large independent cohorts of AML. The close association of KIAA0125 expression with LSC signatures might in part explain its unfavorable impact on the survival of AML patients.

P213

LEUKEMIC STEM CELLS CAN BE DETECTED IN A CONSIDERABLE PERCENTAGE OF PATIENTS WITH ACUTE MYELOID LEUKEMIA AT DIAGNOSIS AND IS A SIGNIFICANT PROGNOSTIC FACTOR

O. Pérez-López1,*, T. Caballero-Velázquez 1, I. Álvarez-Laderas1, P. Hernández-Díaz1, A. M. Márquez-Mattito1, J. González-Campos1, R. Morales-Camacho1, C. Prats-Martín1, M.T. Vargas-de los Monteros1, R. Bernai-Ruíz1, J.A. Pérez-Simón1

1Virgen del Rocío University Hospital, Sevilla, Spain

Background: There is a growing interest on the identification of leukemic stem cells (SC) as a potential prognostic factor in patients with acute myeloid leukemia (AML). Several studies identify these cells as CD34+CD38-Lin- and a correlation of their expression with LSC signatures might in part explain its unfavorable impact on the survival of AML patients.

Aims: To identify SC in a cohort of patients with AML and evaluate their prognostic value in a series of newly diagnosed AML patients.

Methods: The presence of SC (CD34+CD38-Lin-) in bone marrow samples was prospectively evaluated in a consecutive series of 67 newly diagnosed AML patients by flow cytometry, between May-13-Oct-16. All patients received intensive chemotherapy according to PETHEMA protocol. We evaluated response, relapse rate and overall survival (OS) and event free survival (EFS).

Results: Out of the 67 patients [34 men/33 women, median age 54 (0-78)], 58 (86.6%) have SC at diagnosis, 37.9% of them (n=22) achieved complete remission (CR) with a negative minimal residual disease (MRD) vs 77.8% (7/9) among patients without SC (p=0.03). Among patients who obtained CR with a negative MRD (n=29), no one suffer a leukemic relapse in the non SC vs 5/22 (22.7%) in the SC group (p=0.02). Considering the intermediate risk group according to cytogenetic / molecular features, 100% of patients without SC at diagnosis achieve a negative MRD (5/5) vs 14/41 (34.1%) among those in the SC group (p<0.008). OS at 9 months was 89 vs 56% (p=0.043), and the EFS 78 vs 48% (p=0.054) in the non SC and SC group, respectively (Figure 1).

Summary/Conclusions: SC can be detected in a considerable group of patients with AML at diagnosis. The presence of SC is a prognostic factor in terms of response, OS and EFS. Accordingly, SC detection could help to identify prognosis subgroups of patients with different prognostic among those in the intermediate risk group by genetics/molecular assays.

P214

POST-REMISSIONAL AND PRE-TRANSPLANT ROLE OF MINIMAL RESIDUAL DISEASE DETECTED BY WT1 IN ACUTE MYELOID LEUKEMIA: A RETROSPECTIVE COHORT STUDY

C. Fraina1,2, S. Aydin1, E. Audioso1, L. Riera2, S. Altbert2, B. Allione1, A. Busca3, S. D’Arda1, C.M. Dellacasas4, A. Demurata2, A. Evangelista4, G. Ciccone4, P. Francia di Celler2, B. Nicolin01, A. Stacchini2, F. Marmont1, U. Vitol1

1Department of Hematology, 2Department of Pathology, 3Bone Marrow Transplant Center, University-Hospital Città della Salute e della Scienza, Torino, Italy, 4Unit of Clinical Epidemiology, University-Hospital Città della Salute e della Scienza and CPO Piemonte, Torino, Italy

Background: In acute myeloid leukemia (AML) the detection of residual leukemic cells at a submicroscopic level (minimal residual disease - MRD) is still under investigation. In about 30-40% of AML lacking a specific molecular target, quantitative real-time polymerase chain reaction (QRT-PCR) has been used to detect transcripts commonly overexpressed in AML. Among a large number of candidates, Wilms tumor gene 1 (WT1) has been proposed as a promising MRD marker.

After the standardization of QRT-PCR on behalf of the European LeukemiaNet (ELN), subsequent studies investigated the role of WT1 expression in AML with controversial results.

Aims: To assess the role of WT1 expression as a MRD marker after intensive induction chemotherapy and before allogeneic hematopoietic cell transplantation HCT (allo-HCT) in a large cohort of AML patients treated in a single institution.

Methods: The present retrospective cohort study included adult patients with untreated AML consecutively diagnosed between 2004 and 2014 in the Hematology Unit of the University-Hospital Città della Salute e della Scienza of Torino, Italy. The study was approved by the Ethical Committee and was registered at www.clinicaltrials.gov as NCT02714790. Among 255 enrolled patients, MRD was investigated in those in first complete remission (CR) with an available at diagnosis and at two further time-points: after induction (n=117) and prior allo-HCT (n=65).

Results: Patients with baseline WT1 <250 copies were excluded. All patients underwent intensive induction chemotherapy with curative intent and subsequent consolidation chemotherapy according to the AML risk assessment (autologous peripheral stem cell transplantation for low risk and allo-HCT for intermediate and high risk patients). Effect of post induction WT1 expression on disease-free survival (DFS) and overall survival (OS) and of pre allo-HCT WT1 expression on relapse (R) rate were investigated.

Results: Baseline BM WT1 expression were not found significantly associated with demographic, clinical and disease biological features at diagnosis. Baseline BM WT1 expression lacked even to show an association with response to induction chemotherapy (OR 1.16; 95% CI 0.90-1.50, p=0.244). OS and DFS were significantly shorter in first CR with >350 WT1 copies after induction compared to those with ≤50 (OS 17 vs 95 months with HR 2.13; 95% CI 1.14-3.97, p=0.018 and 3-year DFS rates 15% vs 55% with a HR of 2.81; 95% CI 1.14-6.93, p=0.025).

Adding the BM WT1 in the model along with other factors determines an increase of the C-statistic from 0.696 to 0.713 for OS (NRI=0.384) and from 0.7413 to 0.7920 (NRI=0.4037) for DFS. Before allo-HCT, patients with WT1 >150 copies (n=18) had a significantly higher CIR compared to those with WT1 ≤150 (n=47), HR 4.61; 95% CI 1.72-12.31, p=0.002.

Summary/Conclusions: The results of the present study showed that BM WT1 is associated with survival in patients in CR in two decisive time-point for treatment planning: after induction treatment and before allo-HCT. The prognostic role of WT1 resulted independent from other well-established risk factors. Therefore, WT1 may represent an additional MRD tool for risk stratification in patients nowadays classified in CR, especially in the high risk MRD positive subgroup in which a risk-adjusted approach may have a role. Published evidences available so far supported these suggestions, but mainly due to methodological issues, the role of WT1 is still a matter of debate. Prospective randomized studies are required to confirm these results.

P215

DIFFERENTIATION SYNDROME ASSOCIATED WITH ENASIDENIB (AG-221), A SELECTIVE INHIBITOR OF MUTANT ISOCITRATE DEHYDROGENASE 2 (MIDH2)

A.T. Fathih1,2, C.D. DiNardo3, I. Kline4, L. Kenvin4, I. Gupta4, E.C. Attar5, E.M. Stein67, S. de Bottom8

1Massachusetts General Hospital Cancer Center, 2Harvard Medical School, Boston, 3The University of Texas MD Anderson Cancer Center, Houston, 4Cellgene Corporation, Summit, 5Agios Pharmaceuticals, Inc, Cambridge, 6Memorial Sloan Kettering Cancer Center, 7Weill Cornell Medical College, New York, United States, 8Institut Gustave Roussy, Villejuif, France

Background: Enasidenib (AG-221) is an oral, selective, small-molecule inhibitor of mIDH2 enzymes. Preclinical studies showed that exposing myeloblasts from patients (pts) with acute myeloid leukemia (AML) to enasidenib ex vivo resulted in differentiation of leukemic marrow blasts into mature, fully functional neutrophils (Yen et al., Cancer Discov, 2017). Enasidenib may result in IDH-inhibitor-associated differentiation syndrome (IDH-DS) in treated pts, with manifestations akin to retinoic acid syndrome seen during therapy of acute promyelocytic leukemia.

Aims: To characterize the prevalence, characteristics, and course of IDH-DS in pts treated with enasidenib 100 mg daily in a phase 1 dose-escalation and expansion study (NCT01915498). This dose is currently under study in a multicenter, randomized, phase 3 trial comparing enasidenib with conventional care regimens in R/R AML pts (NCT02577406).

Summary/Conclusions: The presence of SC is a prognostic factor in terms of response, OS and EFS. Accordingly, SC detection could help to identify prognosis subgroups of patients with different prognostic among those in the intermediate risk group by genetics/molecular assays.
Methods: An independent Differentiation Syndrome Review Committee (DSRC) was formed to review potential cases of IDH-DS. The DSRC identified and agreed upon a series of signs and symptoms possibly characteristic of IDH-DS, including fever, lung infiltrates, pleural or pericardial effusions, rapid weight gain, edema, and azotemia. In all, 27 cases (8 of investigator-reported IDH-DS and 19 with characteristics suggestive of IDH-DS) were identified and retrospectively reviewed by the DSRC to determine their consistency with IDH-DS.

Results: The DSRC determined 13 cases (11.9% of 109 R/R AML pts in the enasidenib 100 mg/day dosing cohort) to be consistent with IDH-DS. Median time to onset was 30 days (range 7-116). Manifestations of IDH-DS in >2 pts were dyspnea (n=10), pyrexia (9), lung infiltrates (8), pleural effusion (5), and kidney injury (3). IDH-DS was effectively managed with systemic corticosteroids in 12/13 cases. Leukocytosis accompanied 4/13 cases, for which hydroxyurea was employed for cytoreduction. Enasidenib was interrupted for 9 pts (for a median of 7 days), but dose reductions or enasidenib discontinuation were not required for pts with IDH-DS. Six of the 13 pts had clinical responses (2 complete remissions [CR], 2 CRs with incomplete hematologic recovery, 1 partial remission, and 1 morphologic leukemia-free state), 6 pts had stable disease, and 1 pt had progressive disease.

Summary/Conclusions: Systemic corticosteroids, close hemodynamic management, and hydroxyurea (in the presence of leukocytosis) are effective IDH-DS management strategies; they should be administered promptly when IDH-DS is suspected, and continued until improvement. Enasidenib interruption can be considered if initial intervention is unsuccessful. IDH-DS represents a novel clinical finding in pts with mutant AML treated with enasidenib, and is likely due to its suggested mechanism of action, myeloblast differentiation.
Summary/Conclusions: The present study is the largest European IVLBCL series. It shows that despite the use of modern immune-chemotherapy, IVLBCL remains an aggressive lymphoma entity. In particular, these patients are highly exposed to early relapse and therefore should be considered for innovative frontline therapies.

P218
OUTCOME OF ELDERLY DLBCL PATIENTS (≥80 YEARS) TREATED WITH ANTHRACYCLINE BASED CHEMOTHERAPY: R-CHOP DOSE REDUCTION IS NOT NECESSARY FOR EVERYBODY

1Charles University General Hospital, Prague, 2University Hospital, Brno, 3Uni-
versity Hospital, Hradec Kralove, 4University Hospital, Olomouc, 5University Hospital Kralovske Vinohrady, 6CLSG Data Center, Prague, 7University Hospital, Pilsen, 8University Hospital Motol, Prague, Czech Republic

Background: Management of elderly patients (above ≥80y) is difficult and only limited number of patients could be treated by curative approach with anthracy-
cline based chemotherapy. Dose reduction of particular drugs is used very often and it varies based on pts characteristics and center preferences. There is how-
ever lack of randomized or at least non-randomized historical comparisons.

Aims: The objective of this study is to analyze elderly DLBCL patients prospectiv-
ely registered in NIHIL Lymphoma Project and treated anthracycline based regimen in real world outside of clinical trials.

Methods: Patients (pts.) with informed consent are prospectively followed in multicenter Lymphoma Project since 1999. Diagnose, therapeutic and follow up data are prospectively collected. There were 399 DLBCL pts older than 80year diagnosed in period 1999-2014 identified. Among 372 pts. with pathol-
ogy review and essential data there were 112 pts. (30.1%) treated with R-
CHOPlike chemotherapy. Analysis of clinical prognostic factors, therapy and toxicity was performed. Pearson, Kaplan-Maier and log rank tests were used.

Results: Median age was 81 years (80-88), 51.8% of men. Proportion of pts. ≥85 was 14.3%, with PS ≥2 (ECOG) 34.0%, with higher LDH 64.3%, with high or inter-
mediate high iPI 49.1%, with bulky disease (>10 cm) 17.0%, with lower albumin 27.7%, with Charlson Comorbidity Score (CCS) ≥4 25%. According to treatment choice of physician (intent to treat), pts. could be divid-
ed into 3 groups R-CHOP (CH), cyclophosphamide (CF) 750 mg/m2and A 25
mg/m2, (Peyrade 2011) or modified R-CHOP (modiCH) (CF 750 mg/m2and A 25
mg/m2for any other dose between CHOP and miniCHOP). There were 21 pts. (18.8%) treated with CH, 38 (33.9%) with miniCH and 53 (47.3%) with modiCH. There were no significant differences between the subgroups, except higher proportion of bulk in modiCH vs miniCH and CH (35% vs 12.9% vs
7.7% resp.; p 0.04) and cardiac comorbidity (60.5% vs 33.3% vs 30.2% resp.;
p 0.02). Six and more cycles were administered in 71.4%, 63.1% and 58.5% pts. in CH, miniCH and modiCH resp. Following proportion of pts. received >80% (>50%) of original CHOP dose. For cyclophosphamide it was 66.7%
(81%), 0% (50%) and 62.2% (79.2%) resp. and for A it was 57.1% (76.1%),
2.6% (15.8%) and 13.2% (49%) resp. for CH, miniCH and modiCH resp. There were observed 11 treatment related deaths (6 cardiac toxicity and
infection), 5 in miniCH and 6 in modiCH groups. The overall response rate was 76.8% with 59.8% CR/CRu. Median PFS and OS were 2.8y and 3.5y resp. (Figure 1A) with median follow up of 3.3y. There were found high beta2microglobulin (HR 2.2, p 0.05), low albumin (HR 1.9, p 0.05) and PS (p 0.05) as the only factors correlated with OS as well as PFS (data not shown). Pts who achieved CR or PR have significantly better OS median (as
well as PFS) compared to stable or progressive disease with 4.6 vs 3.5 y vs
0.8 y vs 0.5 y. There was numerically (not significantly) better OS median for R-CHOP (4.6y) vs R-miniCHOP (3.2y) and R-modiCHOP (2.9y) (Figure 1B).

Figure 1.
Summary/Conclusions: Only one third of elderly DLBCL pts (≥80y) is treated with anthracycline based regimen. Performance status, albumin and beta2microglobulin levels were significantly associated with prognosis. In minor-
ity of these pts full dose of R-CHOP could be safely used and there is trend to
better overall survival.

Supported by AZV 16-31092A.

P219
IMPROVED SURVIVAL IN PRIMARY CENTRAL NERVOUS SYSTEM LYMPHOMA UP TO AGE 70 ONLY: A POPULATION-BASED STUDY ON INCIDENCE, PRIMARY TREATMENT AND SURVIVAL IN THE NETHERLANDS, 1989-2015

A. Dinmohamed1,2,3,*, M. van der Meulen 4, O. Visser 5, J. Doorduijn 3, J. Bromberg 4
1Research, Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht,
5Public Health, Erasmus University Medical Center, 3Hematology, 4Neuro-
ocology, Erasmus MC Cancer Institute, Rotterdam, 2Registration, Netherlands
Comprehensive Cancer Organisation (IKNL), Utrecht, Netherlands

Background: PCNSL is a rare, aggressive form of an extranodal non-Hodgkin lymphoma that exclusively affects the CNS. Recent findings from the few avail-
able prospective studies demonstrated improved outcome in PCNSL. However, the results from such studies are inherent to patient selection. Population-based studies that assess long-term patterns of incidence, treatment and survival in PCNSL are virtually lacking.

Aims: The aim of this comprehensive nationwide population-based study was to assess trends in incidence, primary treatment and survival among adult PCNSL patients (pts) diagnosed during a 27-year period in the Netherlands.

Methods: We selected all adult (≥18 years) pts diagnosed with PCNSL of the diffuse large B-cell type in the Netherlands between 1989-2015 from the nation-
wide Netherlands Cancer Registry with survival follow-up through February, 2016. Pts diagnosed without pathological or cytological confirmation (n=50) and pts diagnosed at autopsy were excluded (n=32). Age-standardized inci-
dance rates (ASR) were calculated per 1,000,000 person-years and standard-
ized according to the European standard population. Data on primary treatment (i.e. no therapy, chemotherapy (CT) alone, radiotherapy (RT) alone, and
CT+RT) were available for individual pts. Pts were categorized into 4 periods
(1989-1994, 1995-2000, 2001-2007 and 2008-2014) and 3 age groups (18-60, 61-70 and >70 years). We calculated relative survival (RS) and the relative excess risk of mortality as measures of disease-specific survival.

Results: We included a total of 1,873 newly diagnosed PCNSL pts in the study (median age, 65 years; age range, 19-89 years; 53% males). The ASR of PCNSL increased from 3.0 in the first period (1989-1996) to 4.4 in the last period (2009-
2015), which was consistently higher among males than in females throughout the entire study (4.8 v 4.0 in the last period). The age-specific incidence rates were 2.3, 9.0 and 10.9 in the first period for the three age groups (18-60, 61-70 and >70 years), as compared with 2.7, 18.7 and 19.5 in the last period. The appli-
cation of CT+RT increased exclusively among pts age 18-60. More specifically, the proportions for the three age groups were 26, 18 and 4% in the first period, as compared with 60, 10 and 4% in the last period. The use of RT alone among pts age >60 decreased with each period, following the wider use of CT alone over time, especially for pts age 61-70 years. The proportions of CT alone for the three age groups were 11, 8 and 2% in the first period, as compared with 31, 64 and 32% in the last period. Of note, 38 and 26% of pts age >70 received no ther-
apy and RT alone in the last period, respectively. Five-year RS only improved for pts age 18-70 (Figure 1). Five-year RS (95% confidence intervals) was 22% (16%-30%), 13% (7%-22%), and 3% (1%-10%) in the first period for the three age groups, as compared with 56% (47%-64%), 35% (28%-43%) and 6% (2%-13%) in the last period. A multivariable survival model confirmed the adverse effect of older age on excess mortality and an improvement of survival over time. However, when information on treatment was added to that model, the effect of period lost statistical significance. This suggest that treatment contributed to the improved survival over time. Older age remained a predictor of poor prognosis.

Figure 1.
Summary/Conclusions: The incidence of PCNSL steadily increases among
therapy. But disease-free survival in DLBCL patients was significantly worse.

**P220** CLINICAL CHARACTERISTICS AND LONG-TERM RESULTS OF TREATMENT OF DIFFUSE LARGE HEPATITIS C - ASSOCIATED NON-HODGKIN LYMPHOMA (DLBCL+C)

S. Lepkov1,*, I. Subortseva2, G. Tumanyan1, P. Zejnalova3, O. Kolomejtsev3, Y. Ryabukhina3, A. Semenova3, N. Kokosadze1, N. Kupryshina1, O. Komarov1, O. Malikhova1, S. Borsisovskaya1, O. Ettinger1, I. Lazarev4, V. Ivanova4, R. Ivashenko5, A. Korigina1, I. Nikitin1, Y. Kemiqv1

1Russian National Research Medical University named after N.I. Pirogov, 2National Research Center for Haematology, 3National Research Center for Oncology named after N.N. Blochin, 4City Clinical Hospital named after C.P. Botkin, 5City Clinical Hospital named after V.M. Buyanov, Moscow, Russian Federation

**Background:** In the WHO classification (2008), hepatitis C virus distinguishes as one of the etiological factors of multisite etiopathogenesis DLBCL. The purpose of this study was to evaluate clinical features and results of treatment of diffuse krepnokletochnoy lymphoma associated with hepatitis C in comparison with a control group of patients with diffuse large lymphoma without viral hepatitis markers.

**Methods:** It was included 521 patients with DLBCL: 98 patients with DLBCL and markers of hepatitis C (DLBCL+C) and a control group of 422 patients with DLBCL without markers of hepatitis C (DLBCL-C).

**Results:** Patients’ age ranged from 21 to 76 years (median was 47 years) in DLBCL+C; ranged from 23 to 81 years (median 61) in DLBCL-C (p=0.02). The male: female ratio was 1.3 in patients with DLBCL+C, 1.7 in the group DLBCL-C. Stage I and II were in 11% patients with DLBCL+C and 48% patients with DLBCL-C; III and stage IV were detected in 89% patients with DLBCL+C and 52% of DLBCL-C (p=0.00002). Extranodal lesions detected in 72% in DLBCL+C and in 26% in C DLBCL-C (p=0.006). In comparable groups localization of extranodal lesions was: spleen (52% to 23%), bone marrow involvement (43% and 27%), liver (26% and 14%); GCB / non-GCB histological variants ratio GCB / non-GCB in DLBCL+C; 36% / 64% in DLBCL-C group GCB / non-GCB (p=0.001). Hepatitis C virus RNA in blood was detected by PCR. Viral RNA was found in 78% (74 patients). High viral load was in 21% of patients. In 22% of cases markers of hepatitis C virus in blood were identified by ELISA. All patients received chemotherapy according to the scheme CHOP / R-CHOP. The frequency of complete remission was 60% in the group of patients with DLBCL+C and 63% of DLBCL-C. Median overall survival (OS) was 46 months in group DLBCL+C and 71 months in DLBCL-C (p=0.0003). Median progression-free survival (PFS) was 28 months in DLBCL+C 47 months in the control group (p=0.0002). According to the immunohistochemical variant of DLBCL: GCB (46%), non-GCB (54%) in GCB and non-GCB in DLBCL+C (p=0.002). Median PFS was 36 and 47 months in comparable group. Median OS was 18 months in non-GCB DLBCL+C and 70 months in non-GCB DLBCL-C (p=0.00001). Median PFS groups was 13 and 42 months, respectively. 56 patients received antiviral therapy after chemotherapy. Median OS was 63 months in GCB DLBCL+C with antiviral therapy and 28 months in GCB DLBCL-C without antiviral therapy (p=0.0002). Median PFS was 46 and 20 months, respectively. Median OS was 22 months in non-GCB DLBCL+C with antiviral therapy and 17 months in non-GCB DLBCL-C without antiviral therapy. Median PFS in the group was 11 and 15 months, respectively.

**Summary/Conclusions:** DLBCL+C characterized by aggressive course of the disease (younger age at onset of the disease, advanced stages, extranodal involvement), which is one more evidence possibility of separating DLBCL+C in a separate group. Although there is no difference in the effectiveness of the therapy. But disease-free survival in DLBCL patients+C was significantly worse.

**P221** MAGNETIC RESONANCE IMAGING FOR EARLY DETECTION OF ANTHRACYCLINE CARCINOToxICITY IN MALIGNANT LYMPHOMA

A.H. Laursen1,*, J.J. Thune2, M.B. Elming2, P. Hasbak3, R.S. Ripa2, M. Hutchings1

1Department of Haematology, Rigshospitalet, 2Department of Cardiology, BireНberg and Frederiksberg Hospital, 3Department of Cardiology, 4Department of Clinical Physiology, Nuclear Medicine and PET, Rigshospitalet, Copenhagen, Denmark

**Background:** Doxorubicin is a cornerstone of curative chemotherapy for lymphoma. However, doxorubicin therapy is limited by cardiac side effects including high-mortality heart failure (HF). Signs of cardiotoxicity often appear too late to avoid irreversible myocardial damage.

**Aims:** The aim of our study is to investigate the value of rubidium 82 positron emission tomography (82Rb PET), ictus 123i metiodobenzoyguanidin (123I MIBG) and cardiac magnetic resonance (MR) imaging in early detection of doxorubicin-induced cardiomyopathy and prediction of HF in patients with malignant lymphoma. We aim to identify early signs of cardiotoxic injury that predict the formation of interstitial fibrosis and subsequent HF. Here we present our preliminary MR data. 82Rb PET and 123I MIBG data will be analysed later.

**Methods:** The study is a prospective, clinical, single-centre study. The study aims to include 70 consecutive chemotherapy-naive lymphoma patients scheduled for intended curative chemotherapy without planned mediastinal radiation therapy. All patients undergo routine clinical examinations, but with supplementary imaging, including: 1) baseline 82Rb PET and MR (prior to treatment); 2) acute 82Rb PET and MR (within 1 week of the first treatment); 3) subacute 123I-MIBG (after 2-3 months of therapy) and 4) late MR (1 year after the start of treatment). 82Rb PET imaging is performed at rest and during pharmacological stress testing with adenosine. It is primarily used to evaluate the acute effects of doxorubicin on myocardial perfusion. 123I MIBG is used for detection of doxorubicin-induced subacute changes in the myocardial adrenergic neurons. Cardiac MR is performed with late gadolinium enhancement and provides information on acute and late changes in left and right ventricular function, atrial and ventricular volumes, myocardial mass and interstitial fibrosis. Statistical analyses were done in R (version 3.2.0) as paired difference tests using Wilcoxon signed rank test. P-values <0.05 were considered significant.

**Results:** As of March 1st 2017, 61 patients have been included. In 33 cases, the time of intended follow-up has been reached. Four patients died prior to follow-up, including one patient who died before the acute imaging procedures. Four patients were excluded due to compliance problems. One patient was excluded due to disease downstaging resulting in omission of doxorubicin from the treatment plan. Of the 24 patients with complete data from both the baseline and late MR scans, 16 had lower LVEF values at follow-up: 0-5% (n=3), 6-10% (n=8), 10-15% (n=4) and >20% (n=1). Mean LVEF at follow-up was significantly lower (57.1%) compared to baseline LVEF (62.0%; p<0.01) and acute LVEF (64.3%; p=0.002). The LVEF decline from baseline to follow-up was paralleled by an increase in mean left ventricular end diastolic volume (LVEDV) of 10.0mL (p=0.03). Interestingly, an increase in LVEDV was already registered at the acute MR scan (7.3mL; p=0.03). The increase in LVEDV from the acute MR to follow-up was not significant. We also registered an acute increase of 7.4mL in mean stroke volume (SV) (p=0.02). However, from the acute MR to follow-up we found a significant decline in SV (p=0.02). There was no difference in SV from baseline to follow-up (p=0.7). The acute changes in LVEDV did not predict LVEF declines from baseline to follow-up (Figure 1).

**Figure 1.** Summary/Conclusions: Our preliminary show that cardiac MR can be used for detection of declining LV function 1 year after doxorubicin exposure. It appears that cardiac MR may also provide information on acute functional changes in LVEDV and SV. We hope that our 82 Rb PET and 123I MIBG data will provide additional early signs of doxorubicin cardiotoxicity that can be used to predict subsequent development of HF.

**P222** Abstract withdrawn.

**P223** RELAPSE CHARACTERISTICS AND THE ROLE OF SURVEILLANCE COMPUTED TOMOGRAPHY IN AGGRESSIVE NON-HODGKIN LYMPHOMA

K.-W. Kang1,*, Y. Park1, D.S. Kim1, E.S. Yu1, J.H. Kim1, S.R. Lee1, H.J. Sung1, S.J. Kim2, C.W. Choi1, B.S. Kim1

1Department of Internal Medicine, Korea University School of Medicine,
Results: The use of surveillance computed tomography (CT) is usual practice for cases of complete remission (CR) in aggressive non-Hodgkin lymphoma (aNHL). However, there is a lack of evidence to support this strategy.

Aims: To determine whether surveillance CT could contribute to the improvement of survival in relapsed aNHL patients, we retrospectively analyzed our institutional lymphoma registry, which enrolled consecutive patients with lymphoma from June 1995 to October 2016. Of 1,385 aNHL patients in the registry, 664 patients achieved CR and received follow-up through clinical visits, with or without surveillance CT.

Methods: Patients who met the following inclusion criteria were selected: i) histologic diagnosis of aNHL (diffuse large B-cell lymphoma, Burkitt lymphoma, and B-cell lymphoblastic lymphoma, peripheral T-cell lymphoma, anaplastic large cell lymphoma, NK/T-cell lymphoma, and T-cell lymphoblastic lymphoma); ii) patients who achieved CR after frontline or salvage chemotherapy with curative intent; and iii) time from the date of diagnosis to the date of last follow-up longer than 12 months. All patients in CR after frontline therapy were followed-up with clinical visits (symptom assessment, physical examination, and blood tests) every 1 to 6 months. Surveillance CT covering the neck, chest, or abdomen were performed every 3 or 6 months or when clinically indicated thereafter. The decisions regarding the surveillance interval were at the discretion of the treating physicians.

Methods: Relapse was detected in 171 patients, of whom 152 had undergone surveillance CT during follow-up. Of these 152 patients, asymptomatic relapse was detected in 67 (44%) by surveillance CT and symptomatic relapse outside the surveillance interval was detected in the other 85 (56%). Detection of asymptomatic relapse by surveillance CT did not improve either the improvement of survival in the relapsed aNHL patients. In addition, the interval of surveillance CT (3 or 6 months) did not affect survival. No subgroups were identified that favored the use of surveillance CT to detect relapse. Additionally, we analyzed the impact of surveillance CT in patients with refractory or relapsed aNHL who achieved CR after salvage chemotherapy (CR2). Of 315 aNHL patients, patients relapsed/refractory to frontline chemotherapy (144 refractory and 171 relapsed patients), 99 patients achieved CR after salvage chemotherapy (18 refractory and 81 relapsed patients) and these patients were followed with clinical visits, with or without surveillance CT. Relapse was detected in 42 patients (42.4%) who achieved CR after salvage chemotherapy (CR2). 37 (88%) patients were identified as relapsed by methods other than CT scan and using surveillance CT, respectively. There was no significant difference in the median PFS between the two groups (12.5 months, 95% CI: 2.8 to 22.1 months vs 10.7 months, 95% CI: 0 to 46.5 months, p=0.182) (Table 1).

In conclusion, this study suggests that routine surveillance CT in aNHL patients for the detection of asymptomatic relapse might have a limited role in improving survival. Therefore, surveillance CT to identify relapse would only be recommended when relapse is clinically suspected.

Figure 1.

Summary/Conclusions: GLIDE is an effective regimen for newly diagnosed stage IV and relapsed ENKTL. Up-front ASCT after achieving CR can reduce relapse and prolong survival. Treatment related adverse reactions and support care need concerns.

P224

A MULTI-CENTER STUDY OF GLIDE CHEMOTHERAPY CONSOLIDATED WITH AUTOLOGOUS STEM CELL TRANSPLANTATION FOR NEWLY DIAGNOSED STAGE IV AND RELAPSED EXTRANODAL NATURAL KILLER/T-CELL LYMPHOMAS PATIENTS

J. Ji1,*, T. Liu1, B. Xiang1, Z. Liu1, Y. Jia1, Y. Lin2, F. Xu3, W. Liu3, H. Zhu1, T. Niu1, L. Pan1, Y. Gong1, H. Chang1, J. Huang1, Y. Wu1, J. Li1, C. He1, L. Xie1, H. Ma1, Y. Tang1, Y. Guo2, P. Kuang1, T. Dong1

Hematology, West China Hospital of Sichuan University; 2Hematology, Chengdu First People’s Hospital; 3Hematology, Affiliated HospitalClinical Medical College of Chengdu University, Chengdu; 4Hematology, Miayang Central Hospital, Miayang, 5Pathology, West China Hospital of Sichuan University, Chengdu, China

Background: The prognosis of advanced-stage and relapsed extranodal NK/T cell lymphoma (ENKTL) is poor, with long term survival rate of 30%. Our previous study of GLIDE (gemcitabine, L-asparaginase, ifosfamide, dexamethasone and etoposide) chemotherapy reported complete response (CR) rate and 3-year overall survival (OS) of these patients were 57.1% and 56% respectively. We assumed autologous stem cell transplantation may further improve the prognosis of these patients.

Aims: We conducted this clinical trial to address the efficacy and safety of our treatment strategy, GLIDE induction followed by ASCT, in newly diagnosed stage IV and relapsed ENKTL.

Methods: We treated 60 patients with newly diagnosed stage IV (n=49) and relapsed (n=11) ENKTL from 2010 to 2016. The median age at recruitment was 38 years and the median follow-up period was 13.4 months. Patients were treated with GLIDE (gemcitabine 800 mg/m2 D1,5; L-asparaginase 6000 U/m2 D4,6,8,10,12 or peg-asparaginase 2500 U/m2 D4,11; ifosfamide 1000 mg/m2 D1-3; dexamethasone 20mg D1-4; etoposide 100 mg/m2 D1-3) every 4 weeks, and responses were evaluated with PET/CT every 2 cycles. Patients achieving CR underwent ASCT or continued with GLIDE up to 6 cycles. Others finished 6 cycles of GLIDE. Overall response rate (ORR), CR, OS and progression free survival (PFS) were calculated using standard methods. Statistical analysis was done using Fisher’s exact test or Chi-square test / Kruskal-Wallis test. Kaplan-Meier method was used for time-to-event analysis including overall survival and progression free survival. The Log-rank test was used to evaluate the difference in time-to-event endpoints between patient groups.

Results: Fifty-seven patients had finished planned treatment with 1 withdraw of informed consent after cycle 1, and 2 death of sepsis during cycle 1 and cycle 2 respectively. Twenty-one patients underwent ASCT. The ORR was 81.4% and the CR was 69.5% with early CR (CR after 2 cycles) of 57.6%. Estimated 5-year OS and PFS rates of the whole cohort and patients underwent ASCT were 68.7%, 54.0%, 79.6% and 85.2% respectively. Univariate analysis revealed that ECOG ≤1, IPI ≤2, early CR and ASCT were associated with less relapse and death. Multivariate analysis showed ECOG ≤1 was an independent risk factor for disease progression (HR=4.321, 95% CI: 1.127–16.572, P=0.033) and death (HR=4.256, 2.150–993.190, P=0.014) and ASCT was associated with better PFS (HR=0.058, 95% CI: 0.007–0.495, P=0.009) and OS (HR=0.019, 95% CI: 0.001–0.596, P=0.024). Figure 1 highlights the OS and PFS of whole cohort (A) and ASCT patients (B). Myelosuppression was the most common adverse reaction (AE). The incidences of grade 3-4 adverse reactions were as follows: myelosuppression, 46.6%, 28.6% and 5.3% respectively. The most common non-hematologic AE was fever with neutropenia (36.5% of total cycles), while others were mild and manageable.

Figure 1.

Summary/Conclusions: GLIDE is an effective regimen for newly diagnosed stage IV and relapsed ENKTL. Up-front ASCT after achieving CR can reduce relapse and prolong survival. Treatment related adverse reactions and support care need concerns.

IDENTIFICATION OF A NOVEL GERMINE MECOM / EVI1 VARIANT THAT RUNS IN A PEDIGREE WITH RADIOLYNAR SYNOTOSIS AND AMEGAKARYOCYTIC THROMBOCYTOPENIA AND PREDISPOSES TO ADULT ONSET MYELOID MALIGNANCY
T. Ripperger1,*, W. Hofmann1, J.C. Koch2, K. Shirmeshan3, D. Haase3, G. Wulf3, P.R. Issing4, M. Karnebogen5, G. Schmidt1, B. Aubé1, B. Schlegelberger1, T. Illg1,6, B. Zim2, D. Steinemann1
1Department of Human Genetics, Hannover Medical School, Hannover, 2Department of Neurology, 3Department of Hematology and Oncology, University Medical Centre, Goettingen, 4Department of Otorhinolaryngology, Head, Neck and Facial Plastic Surgery, Klinikum Bad Hersfeld, Bad Hersfeld, 5Health-park Lengern, Division of Surgery and Orthopedics, Bovenden, 6Unified Biobank, Hannover Medical School, Hannover, 7Genetic Counseling and Diagnostics, Genetikum, Stuttgart, Germany

Background: Radiolynar synostosis and amegakaryocytic thrombocytopenia (RUSAT), one of the rare bone marrow failure syndromes, is caused by a point mutation in HOXA11. In three simplex patients, de novo missense variants in MECOM have recently been reported as an alternative cause in individuals with RUSAT. MECOM, identified as a common ectopic viral integration site 1 (EVI1) in murine myeloid leukemia, is known as a key transcriptional regulator in hematopoiesis and is frequently involved in sporadic myeloid leukemia.

Aims: To screen for the causative genetic alteration in a family with four affected individuals out of three generations with radiolynar synostosis, incompletely penetrant congenital thrombocytopenia, hearing impairment due to dysplastic middle ear bones, patellar hypoplasia, and hand and foot dysmorphism. Notably, two of four affected individuals in our family developed adult onset myeloid malignancies (i.e. myelodysplastic syndrome (MDS) with excess blasts and MDS/myeloproliferative neoplasm-unclassifiable). No HOXA11 mutation was identified in this family.

Methods: Whole exome sequencing was performed in three affected individuals using a Nextera Rapid Capture kit and a NextSeq 500 instrument (Illumina, Munich, Germany). Identified sequence variants were filtered for those that are known to be deleterious in the human genome. All three subjects were confirmed to be de novo carriers of a Rad51 missense variant (rad51), predicted to have an allele frequency of ≤0.1% (1000G, ESP6500, ExAC), and (iv) not listed in our in-house database of recurrent variants.

Results: Following this approach, a novel MECOM missense variant (i.e. Cys766Gly, UniProtKB Q03112-1) was identified. The missense mutation affects a heavily conserved cysteine residue in C2-H2-Zinc finger motif 9 in the C-terminal zinc finger domain of MECOM. This residue is crucial for the tetrahedral coordination of a zinc ion stabilizing the zinc finger conformation and thus, is essential for DNA binding of the C-terminal zinc finger domain.

Summary/Conclusions: Our findings confirm the causality of MECOM missense mutations targeting the C-terminal zinc finger domain in subjects with RUSAT and indicate that MECOM needs to be considered in RUSAT pedigrees with no HOXA11 mutation. We report here for the first time that MECOM germline mutations are associated with an increased risk for adult onset myeloid malignancies. This extends the RUSAT-associated phenotype and proposes that MECOM germline mutations can cause a genetic predisposition to adult onset myeloid malignancy.

LOSS OF THE HOMOLOGOUS RECOMBINATION GENE RAD51 LEADS TO FANCONI ANEMIA-LIKE SYMPTOMS IN ZEBRAFISH
A. Bouwman1,2,3, E. Bielczyk-Marcinkev2,4, L. Ferreira1,2,3, A. Cvejic1,2,3
1Department of Haematology, University of Cambridge, 2Wellcome Trust Sanger Institute, 3Wellcome Trust-Medical Research Council Cambridge Stem Cell Institute, University of Cambridge, 4NH Blood and Transplant, Cambridge, United Kingdom

Background: Fanconi anemia (FA) is a hereditary DNA repair disorder characterized by various congenital abnormalities, progressive bone marrow failure and cancer predisposition. RAD51 has recently been designated as a Fanconi anemia (FA) gene, following the discovery of two patients carrying dominant negative mutations. RAD51 is an intrinsically homologous recombination protein, necessary for strand invasion and crossing over. It has been extensively studied in prokarocytes and lower eukarocytes. However, there is a significant lack of knowledge of the role of this protein and its regulation in an in-vivo context in vertebrates due to the early embryonic lethality of murine Rad51 mutants. Aiming to fill this gap, we aim to utilize the powerful genetics and translucency of zebrafish to dissect the role of rad51 in hematopoiesis and to explore the molecular basis of Fanconi anemia pathogenesis.

Methods: Zebrafish carrying homoygous loss of function mutations in rad51

60 | haematologica | 2017; 102(s2)
generated by ENU mutagenesis were characterized in terms of their hematopoietic and non-hematopoietic phenotypes during embryonic development and adulthood.

Results: The rad51 mutant fish developed key features of FA, including hypoplastic kidney marrow (equivalent to mammalian bone marrow), sensitivity to crosslinking agents and decreased size. Interestingly, although mutants can survive to adulthood, they develop exclusively as sterile males. We show that some of the hematological symptoms stem from both decreased proliferation and increased apoptosis of embryonic hematopoietic stem and progenitor cells. 

The elder daughter (age 30) TW (II.1), paternal grandfather died of “pernicious anaemia”. None of the family have anaemia with very minimal thrombocytopenia. Further investigations (Table 1) revealed lifelong macrocytosis and previous mild neutropenia (Table 1). The index case AM (I.1) was a female who presented at age 56 with fatigue, and was noted to have a longstanding non progressive mild macrocytic anaemia with very minimal thrombocytopenia. Further investigations (Table 1) revealed lifelong macrocytosis and previous mild neutropenia (Table 1). Telomere lengths were assessed and found to be short in both Case I.1 and II.2 (Table 1). There were no other likely pathogenic variants in the Oxford Red Cell Panel genes. Together, these observations suggest that the n.181A>C substitution is causally associated with the macrocytosis phenotype.

Summary/Conclusions: We demonstrate that zebrfish lacking functional rad51 are viable and develop symptoms resembling FA. These findings strengthen the assignment of RAD51 as a Fanconi gene and provide more evidence for the notion that aberrant p53 signaling during embryogenesis leads to the hematological defects seen during later stages of life in FA patients. Further research on this novel zebrfish FA model will lead to a deeper understanding of the molecular basis of bone marrow failure in FA and the cellular role of the RAD51 protein.

A NOVEL TELOMERASE RNA COMPONENT VARIANT IN A FAMILY WITH MACROCYTOSIS AND MILD VARIABLE CYTOPENIAS

C. Burney1, 2, A. Mumford2, N. Roy3, S. Henderson3, M. Proven3, A. Schuh3, K. Wray4, H. Dreau3, C. Bradbury2

1Department of Haematology, University Hospitals Bristol NHS Trust, 2School of cellular and molecular medicine, University of Bristol, Bristol, 3BRC Blood Theme and BRC/NIHS Translational Molecular Diagnostics Centre, John Radcliffe Hospital, 4Molecular Haematology Unit, Weatherall Institute of Molecular Medicine, John Radcliffe Hospital, Oxford, United Kingdom

Background: Telomerase RNA component (TERC), encoded by the TERC gene, is an essential component of telomerase, a polymerase that adds the telomeric repeat to the 3’ lagging strand of DNA during cell replication. TERC variants have been causally associated with several hematological disorders, including autosomal dominant dyskeratosis congenita (DKC), aplastic anaemia, myelodysplastic syndrome and acute leukaemia, sometimes accompanied by non-haematological phenotypes. Here we report a likely pathogenic TERC variant associated with a haematological phenotype that predominantly affects the red cell lineage. Aims: To describe the genotypic and phenotypic relationship of a new TERC variant. Methods: Genomic DNA samples were analysed for sequence variants using the Oxford Red Cell Panel, a panel of 33 genes previously associated with human red cell disorders. Sampling sequencing was used to confirm the novel variant. Telomere lengths were performed at the Laboratory for Molecular Haemato-Oncology (LMH), Rayne Institute, Kings College Hospital.

Results: The index case AM (I.1) was a female who presented at age 56 with fatigue, and was noted to have a longstanding non progressive mild macrocytic anaemia with very minimal thrombocytopenia. Further investigations (Table 1) revealed normal reticulocyte count, LDH, haematins, thyroid function, liver and renal function. Bone marrow aspirate demonstrated abnormal erythropoiesis with nucleo-cytoplasmic asynchrony, nuclear atypia, ragged cytoplasm, basophilic stippling and bi-nucleate forms. Granulopoiesis and megakaryopoiesis were normal. The two daughters of I.1 also had abnormal blood counts and her paternal grandfather died of “pernicious anaemia”. None of the family have somatic features associated with DKC. The elder daughter (age 30) TW (II.1), had isolated lifelong macrocytosis and previous mild neutropenia (Table 1). The younger daughter (age 27) BM (II.2) had macrocytic anaemia, thrombocytopenia (Table 1) and a recent pregnancy complicated by worsening thrombocytopenia, pre-eclampsia, placental dysfunction, liver dysfunction and foetal loss. Following delivery her liver function slowly returned to normal and a fibroscan was within normal limits. All three pedigree members with macrocytosis had a Chr3:16948268 (GRCh37) single nucleotide variant corresponding to a n.181A>C substitution in TERC (relative to transcript ENST00000602385.1), within the pseudoknot domain. Residue n.181 is highly conserved across mammalian species. This variant is absent from the gnomAD database of more than 230,000 TERC alleles, and the HGMD databases. The variant is within a TERC region in which previously reported variants have been associated with haematological phenotypes. In order to determine the pathogenicity of this variant, telomere lengths were assessed and found to be short in both Case I.1 and II.2 (Table 1). There were no other likely pathogenic variants in the Oxford Red Cell Panel genes. Together, these observations suggest that the n.181A>C substitution is causally associated with the macrocytosis phenotype.

Summary/Conclusions: This report demonstrates a likely causal association between a newly identified TERC variant, short telomere length and a relatively mild haematological phenotype that is largely restricted to red cells. This empha-

Background: X-linked Dyskeratosis congenita (XDC) is an inherited syndrome caused by mutations in the DKC1 gene that encodes for the dyskerin nuclear protein. These mutations reduce the telomerase activity leading to premature telomere length attrition. Several organs can be affected in these patients, although the bone marrow failure (BMF) is the main cause of death in X-DC patients (more than 70% of cases). So far, the only curative treatment for BMF in DC patients is hematopoietic stem cell (HSC) transplantation. However, risks derived from conditioning regimens and the difficulties to find a compatible donor suggest that gene therapy may constitute a promising alternative in treating DC patients.

Summary/Conclusions: This report demonstrates a likely causal association between a newly identified TERC variant, short telomere length and a relatively mild haematological phenotype that is largely restricted to red cells. This empha-

The table shows hematological parameters for Case I.1 and I.2.
Aims: Because of the difficulties associated to the use of primary HSCs from DC patients for experimental studies, this study was focused on the generation of X-DC-like human HSCs by means of the down-regulated expression of dyskerin in cord blood HSCs using different anti-DKC1 short hairpin RNAs (shRNA).

Methods: CD34+ cells were obtained by immunomagnetic purification from healthy umbilical cord blood samples. These cells were then pre-stimulated with two cycles of transduction with lentiviral vectors carrying both an anti-DKC1 shRNA and the puromycin-resistance gene. Transduced samples were then selected for 2 days with puromycin, and cultured in vitro or transplanted into immunodeficient NSG mice to evaluate the effects of shRNAs.

Results: Based on the inhibition of DKC1 gene expression, 3 shRNAs were selected among 7 designed shRNAs. Intact HSCs showed an inhibited telomerase activity, as well as a reduced clonogenic and hematopoietic reconstitution potential in NSG mice. Additionally, an increase in DNA damage and senescence was observed in DKC1-interfered CD34+ cells.

Summary/Conclusions: In vitro and in vivo data obtained from DKC1-interfered healthy umbilical cord blood HSCs allowed the generation of X-DC-HSCs. The generation of X-DC-like HSCs will facilitate the understanding of the molecular basis of the HSC defects characteristic of X-DC and contribute to the development of new experimental therapies for the treatment of the BMF of X-DC patients.

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a disease characterized by complement-mediated hemolysis (Brodaty et al., Hematology, 2008). Complement can induce the production of extracellular vesicles (EV) (Burnouf et al. Transfus Apher Sci, 2015). These EV are cell-derived vesicles whose the size-range is around 50 and 1000nm. They can expose phosphatidylserine (PS-antionic phospholipid) and tissue factor (TF), which explains their involvement in the coagulation cascade (Owens et al. Circ Res, 2011). The EV could have a role in the thrombus formation, the leading cause of death in PNH patients (Brodsky et al. Hematology, 2008; Simak et al. Br J Haematol, 2004; Hugel et al. Blood, 1999). Eculizumab, a human anti-C5 monoclonal antibody, used in the treatment of PNH seems to decrease the thrombosis frequency (relative reduction of 85% of thromboembolic event rate with the introduction of the treatment in the patients) (Hillmen et al. Blood, 2007; Kelly et al. Ther Clin Risk Manag, 2009; Weitz et al. Thromb Res, 2012; Al-Jafar et al. Hemato Rep, 2015).

Aims: The general purpose of this project is a better understanding about the role of EVs in thrombosis in the context of PNH patients under eculizumab.

Methods: We conducted a pilot prospective open label longitudinal clinical study with six PNH patients treated with eculizumab. The study was led according to the recommendations of the German Society of Hematology and Oncology (DGHO) published via Onkopedia. TL analysis of peripheral blood granulocytes and lymphocytes was carried out using combined fluorescence in situ hybridization and flow cytometry (flow-FISH). Mutations in genes suspected to cause telomereopathies (i.e., TERT, TERC, DKC1, NOP10, NHP2, U1B,, T1EL1, TNZ, TCA1) were analyzed by NGS using customized primer panels and amplicon-based sequencing on a Miseq sequencer (Illumina) in all patients with TL in lymphocytes below the 1% percentile of healthy controls.

Results: Underlying initial diagnosis by the treating physician leading to TL screening were aplastic anemia (AA, n=72, 39% of cases), unexplained cytopenia (UC, n=11, 5.1% of cases), idiopathic aplastic anemia (IAA, n=0), unknown primary (UP) as the initial diagnosis in 15 out of 38 patients (39%), 4% of cases, respectively. Mutations were detected in RTEL1 (n=3), TERC (n=6), TERT (n=3) and DKC1 (n=3). Mutations were observed in 5% of all AA, 12% of all UC, 50% of all FM-DKC, 13% of all SCCHN, 20% of all screened AML patients.

Summary/Conclusions: Eculizumab has an impact on the amount and the procoagulant profile induced by the procoagulant PL and the EVs. The anti-thrombolytic performance of the eculizumab can be in part explained by its action on EVs.

P231

TELOMERE LENGTH SCREENING TRIGGERED BY CLINICAL SUSPICION FOR CLASSICAL AND/OR CRYPTIC DYSKERATOSIS CONGENITA – PROSPECTIVE RESULTS FROM THE AACHEN TELOMEROPATHY REGISTRY

F. Beier1,*, M. Kirschner1, A-S. Bouillon1, I. Halfmeyer1, M.S. Ventura Ferreira1, S. Giammarco1,*, S. Simona2, C. Dufour3, R. Peffault de Latour4, G. Socie5, J. Passweg6, A. Bacigalupo1

1Hematology, Universitätsklinik der Sacro Cuore, Rome, 2Hematology, Uni-
Background: Mortality following HSCT in SAA pts over the age of 40 is reported to be in the order of 50%, without taking into account long term sequelae such as chronic GvHD, known to be more frequent in older patients. This has prompted international guidelines to recommend first line immunosuppressive therapy above 40 years of age. The question is whether this is still true in 2017.

Aims: Assess whether TRM in SAA patients grafted 2010-2015 is reduced, as compared to the era 2001-2009.

Methods: We used the WPSAA-EU prospective registry, and identified 748 pts aged 40 years or more, with acquired SAA, grafted between 2001 and 2015. We divided pts in 2 transplant eras:2001-2009 (n=327) and 2010-2015 (n=407). In the more recent period (2010-2015) pts were older (53 vs 49 year, p<0.01), were more oftengrafted from alternative donors (ALT) (64% vs 43%, p<0.01), with a greater use of BM (54% vs 41%, p<0.01), and with a longer interval dx-tx (317 vs 258 days , p<0.01), and more often received a fludarabine containing regimen (55% vs 42%, p<0.01).

Results: The overall survival 5 year survival of pts grafted in 2001-2009 was 57% , compared with 55% for pts grafted 2010-2015 (p=0.7). In multivariate analysis, including the interval diagnosis transplant, patient’s age, donor type, stem cell source and conditioning regimen, the lack of improved survival in 2010-2015 was confirmed (p=0.3). A very strong age effect was shown both in univariate and multivariate analysis: survival of pts aged 40-50 years, 51-60 years and >61 years , was respectively 64%, 54%, 41% (p<0.0001) and this was confirmed in multivariate analysis. The conditioning regimen, also proved to be a significant predictor, with improved survival for ALT transplants receiving FLU containing regimens (56% vs 46%, p<0.001). In general pts receiving either CY200 or a FLU containing regimen , did significantly better than pts receiving other preparative regimens (58% vs 50%, p=0.02). The use of a sibling donor (SIB) did not prove to predict survival in multivariate analysis. Pts receiving Campath on the conditioning , did significantly better than pts not receiving Campath (65% vs 54% p<0.01); similarly survival of patients with ATG was superior 59% vs 41% compared to patients not receiving ATG (p<0.01). When pts receiving either Campath or ATG (n=564) were compared to patients not receiving either (n=161), the difference in survival was 61% vs 41% (p<0.0001), and this was significant also in multivariate analysis. Combined primary and secondary graft failure was reduced from 16% to 12% in the two time periods (p<0.02), acute GvHD grade II-IV was reduced from 15% to 11% (p=0.01) and chronic GvHD was also reduced from 32% to 26% (p=0.01). Infecions remained the leading cause of death in both transplant eras (18% and 22% respectively), followed by GvHD (5% and 4%) and graft failure (5% and 2%), whereas PTLD have been reduced from 3% to 0.5% (Figure 1).

Figure 1.

Summary/Conclusions: HSCT in pts with acquired SAA aged 40 and over, continues to carry a significant risk of TRM also in 2010-2015, ranging from 36% in younger pts (40-50) to 59% in older pts (>60 years). Survival is predicted in multivariate analysis, by two crucial predictors: patients age and the use of either Campath or ATG, the latter giving a 20% survival advantage over no Campath/ATG. ALT and SIB donors produce similar survival. This study gives further support to current guidelines, suggesting first line therapy with ATG+CsA, in pts over the age of 40.

Dep. of Cellular Biotechnologies and Haematology, La Sapienza University, Roma, Italy, 5Division of Human Genetics, Cincinnati Children’s Hospital Medical Center, Cincinnati, United States

Background: Differential diagnosis between acquired and congenital forms of Marrow Failure (MF) has always represented a crucial point in the diagnostic work-up, since genetic forms do require a different therapeutic approach. It is also known that patients with congenital MF may also show immunodeficiency that, in some cases, can represent the first/ or revalent sign of the disease and therefore can be misinterpreted as a Primary Immunodeficiency (PID). On the other hand, patients with PIDs may also show MF as a result of an immunemediated attack of marrow precursors thus generating a phenotypic overlap that can impair the correct diagnosis.

Aims: In this report we analyzed all patients with MF evaluated in our Unit with the aim to identify the type and incidence of underlying molecular defects, in particular those related to PIDs.

Methods: We retrospectively evaluated all diagnosis performed in patients with single/multi-lineage MF followed in our Unit. DEB test was used to screen Fanconi Anemia (FA). Other congenital MFs have been searched by Sanger and/or NGS molecular analysis depending on the available tools over the years.

Results: Between 2009-2016, 88 patients have been studied for single-lineage (25) or multiligneage (63) MF. 48 (54%) were classified as having an underlying PID. Table 1 shows clinical characteristics and mutations of patients with PIDs.

| Table 1. |

Summary/Conclusions: This report shows that patients presenting with single/multi-lineage MF may have an underlying PID in a considerable number of cases. We also show that MF represented the most relevant clinical sign in patients with PIK3CD, TACI, or CD40L mutations, thus widening their clinical phenotype. We conclude that an accurate immunological work-up should be performed in all patients with MF and that PIDs-related genes should be included in the molecular screening of MF in order to identify specific disorders that may potentially receive targeted treatment and/or the appropriate conditioning regimen for SCT.

Background: Paroxysmal nocturnal haemoglobinuria (PNH) leads to episodic haemolysis secondary to an acquired deficiency of PIGA and PIGF on the surface of erythrocytes which play a critical role in protecting the cells from complement mediated lysis. Until the advent of eculizumab, a monoclonal antibody which prevents the cleavage of C5 to C5a and C5b, PNH was associated with considerable morbidity and a poor long-term prognosis. However, eculizumab needs to be administered by health care professionals by intravenous infusion which may interfere with the life-styles, occupations and personal privacy of patients and the interval dosing has led to concerning breakthrough haemolysis. Coversin is a protein suitable for small-volume subc cutaneous (SC) injection which can be self-administered by patients.

Aims: The aim of this study is to investigate the safety and efficacy of the complement C5 inhibitor Coversin in the treatment of PNH.

Methods: A Phase 2 single arm open label trial of Coversin is currently ongoing under which patients, either newly diagnosed with PNH or who have not previously had access to complement inhibitors, are treated for 90 days. Coversin is supplied as a lyophilised powder, reconstituted with water for injection to give a buffered aqueous solution of Coversin 30mg/mL. The trial population consists of up to 10 adult patients with a diagnosis of PNH confirmed by flow cytometry. Treatment commences with an ablating regime (AR) consisting of a fixed dose of 60mg followed by 3 doses of 30mg q12 hours delivered by SC injection. After being suitably instructed patients are encouraged to self-inject the drug. Following the AR, a dose of 15mg q12 hours is given for a further 26 days when, if the patient’s disease is well controlled, they switch to 30mg q24 hours for the remainder of the trial. The dose can be increased by two incremental steps according to a pre-specified algorithm for patients not satisfactorily controlled on the basis of serum lactate dehydrogenase (LDH) or clinical grounds at any time during the 90-day period. The primary endpoints are safety and reduction of serum LDH to ≤1.8 X the upper limit of normal (ULN) for the local laboratory. Secondary endpoints include LDH at 28, 60 and 90 days, terminal complement activity assessed by CH50 ELISA (Quidel®), sheep erythrocyte haemolysis assay, PK (free and bound Coversin levels), anti-drug antibodies (ADA) and quality of life.

Results: The trial is still ongoing and has currently enrolled 5 patients, four of whom remain on Coversin. Three patients have required single dose increases during the initial 28-day period, one of whom was later withdrawn when a co-morbidity was suspected. Two patients have moved to a single daily dose. Updated results of these and any patients enrolled subsequently will be presented. To date 2 patients have achieved the primary efficacy endpoint, two have not yet reached the 28-day point. There have been no serious or significa nt adverse events and the drug has been well-tolerated. A few mild injection site reactions have been recorded but these appear to diminish with time. There has been no evidence of the formation of neutralising antibodies.

Summary/Conclusions: It currently appears that treatment with Coversin is safe and effective in controlling hemolysis in PNH and that patients are capable of self-administering the drug. Coversin may be an effective alternative for patients with PNH who prefer the independence of self-administration. The relatively short dose interval may also help to reduce breakthrough events due to trough levels of drugs administered at two weekly intervals or longer.
GERMLINE RARE VARIANT ASSOCIATION ANALYSIS IN CHRONIC LYMPHOCYTIC LEUKEMIA

Background: CLL is a highly heritable cancer. Although GWAS have identified ~30 independent SNPs associated with CLL, these are estimated to account for only 10% of the inherited component of CLL.

Aims: We hypothesized that this missing heritability might arise from rare coding variants (MAF <0.01), and sought to identify these through an exome-wide association study comparing rare germline variants between CLL patients and controls.

Methods: We investigated 516 CLL patients of European descent who were compared to 8,920 ethnically matched, non-cancer population controls. CLL cohorts included 235 CLL patients from DFCI (128 previously reported, 107 unpublished exomes), and 281 CLL patients enrolled on the CLL8 trial of the German CLL Study Group (WES data reported previously). An additional 130 CLL patients in an extension cohort included 24 from our published whole-genome sequencing study and 106 from an early publication of the IgC. Non-cancer controls came from 3 sources: 2,520 from the 1000 Genomes Project; 6,852 from the Exome Sequencing Project; and 7,611 from a study of genetic risk for myocardial infarction. We combined these heterogeneous datasets by: (i) pooling sequencing data from all cohorts together and consistently; (ii) jointly calling the variants across all cases and controls; and (iii) analyzing only ethnically matched, unrelated samples over DNA sites with sequencing coverage sufficient to achieve high-confidence genotype calls. This quality control resulted in 8,920 controls available for the association analysis. We further controlled for residual population stratification by correcting for three principal components.

Results: Using an unbiased, gene-based rare variant association analysis comparing cases to controls, we identified two genes significantly enriched for rare coding variants in CLL cases: CDK1 and ATM (OR 5.8, 95% CI 2.6-13.1; p=5.8x10-7 and OR 3.0, 95% CI 1.3-7.5, p=0.0003, respectively). CDK1 variants were observed in 2 of 516 CLLs and 24 of 8,920 controls (1.6% vs. 0.3%, OR=5.6, 95% CI 2.6-13.1). One recurrent missense variant, CDK1 p.R59C, observed in 5 cases and 10 controls, is predicted to be possibly damaging by the PolyPhen2 prediction tool, and is driving the association. The second significant gene was ATM, in which we found a total of 112 cases carrying 52 distinct rare germline variants and 141 controls carrying 126 rare variants (21.7% vs. 9.0%, OR=2.4, 95% CI 1.4-4.3; p=1.3x10-3). The majority of recurrent rare variants in ATM were non-synonymous missense variants, with L320T being the most enriched (2.3% cases, OR=10.1, 4.9-20.7). Subsequent validation in 149 independent CLL cases revealed a similar frequency of 2.01% (3 out of 149) of the L320T variant. We then added 130 CLL cases and performed an expanded joint analysis, which has been shown to improve the statistical power of detecting genetic associations compared to a two-stage replicate analysis. We identified 42 additional patients with rare ATM variants, and the significance of ATM was greatly increased (p=0.00016, OR 1.79, CI 1.49-2.15). We integrated somatic and germline sequencing data and performed an expanded joint analysis, which has been shown to improve the association. The second significant gene was ATM, in which we found a total of 112 cases carrying 52 distinct rare germline variants and 141 controls carrying 126 rare variants (21.7% vs. 9.0%, OR=2.4, 95% CI 1.4-4.3; p=1.3x10-3). The majority of recurrent rare variants in ATM were non-synonymous missense variants, with L320T being the most enriched (2.3% cases, OR=10.1, 4.9-20.7). Subsequent validation in 149 independent CLL cases revealed a similar frequency of 2.01% (3 out of 149) of the L320T variant. We then added 130 CLL cases and performed an expanded joint analysis, which has been shown to improve the statistical power of detecting genetic associations compared to a two-stage replicate analysis. We identified 42 additional patients with rare ATM variants, and the significance of ATM was greatly increased (p=0.00016, OR 1.79, CI 1.49-2.15). We integrated somatic and germline sequencing data and performed an expanded joint analysis, which has been shown to improve the association. The second significant gene was ATM, in which we found a total of 112 cases carrying 52 distinct rare germline variants and 141 controls carrying 126 rare variants (21.7% vs. 9.0%, OR=2.4, 95% CI 1.4-4.3; p=1.3x10-3). The majority of recurrent rare variants in ATM were non-synonymous missense variants, with L320T being the most enriched (2.3% cases, OR=10.1, 4.9-20.7). Subsequent validation in 149 independent CLL cases revealed a similar frequency of 2.01% (3 out of 149) of the L320T variant. We then added 130 CLL cases and performed an expanded joint analysis, which has been shown to improve the statistical power of detecting genetic associations compared to a two-stage replicate analysis. We identified 42 additional patients with rare ATM variants, and the significance of ATM was greatly increased (p=0.00016, OR 1.79, CI 1.49-2.15). We integrated somatic and germline sequencing data and found that patients with rare germline variants in ATM were more likely to harbor an additional ATM somatic deletion (p=9.1x10-4). Furthermore, 80% of patients with both a rare germline variant in ATM and a somatic 11q deletion lost the wild-type ATM allele during deletion (p=0.012), suggesting that the germline variants behave as tumor suppressor alleles.

Summary/Conclusions: To our knowledge this analysis represents the first germline association analysis based on exome sequencing data in CLL, and our results implicate rare germline variation in ATM in CLL predisposition.
17p13 deletions were assessed by FISH (MetaSystems). More than a half of the cohort (57%) was also analyzed using ultra-deep NGS for TP53 exons 2-11. Genome-wide analysis was performed on CytoScanHD arrays (Affymetrix) and correlated to conventional cytogenetics (CpG/LSI-stimulation).

Results: Out of the cohort positive for TP53mut, 72/200 patients (36%) harbored single dominant TP53mut without del(17p). We selected 43 of these cases with variants heterozygous for TP53mut to explore the potential presence of 17p cn-LOH. In 42% (18/43) of the cases, cn-LOH in 17p was detected in a proportion of CLL clone correspondingly to the TP53 VAF (median TP53 VAF 59.4%, range 12.9–99.9%). In 3/43 cases, heterozygous deletion previously undetected by FISH was newly revealed. Thus, the truly monoallelic mutations were confirmed with a CNLOH status and would have escaped detection by Sanger sequencing. Therefore ten of the 26 patients were identified in whom the mutation analysis was performed with a sensitivity up to 1% mutant allele frequency. For the determination of the 17p status we have used a high resolution CytoScan HD array which allows a genome-wide detection of copy number alterations (CNAs), down to 100 kb in size, and regions of copy neutral loss of heterozygosity (CNLOH). In addition the presence of TP53 mutations was evaluated with high sensitivity using next generation sequencing approaches.

Methods: We have studied bone marrow or peripheral blood samples of 179 CLL patients using oligo/SNP-based array which allows a genome-wide detection of copy number alterations (CNAs), down to 100 kb in size, and regions of copy neutral loss of heterozygosity (CNLOH). In addition, we identified a sub-group of 97 relapsed/refractory pts who had serial FISH analysis performed in bone marrow ≥1 year apart, to determine whether there were significant changes in sub-clonal composition of CNAs detected by FISH during treatment in the absence of disease progression. Results: In total, 37 of 336 pts (11%) progressed during ibrutinib-based therapy. Of these pts, 15 had FISH analysis both pre-treatment and at progression: pre-treatment, 10 had del(17p), 1 had del(11q) and 4 had isolated del(13q). All 4 of the pts with isolated del(13q) pre-treatment had new sub-clonal CNAs detected by FISH at progression: two pts had del(13q) and del(11q) and one pt developed tetrasomy 12. In the absence of disease progression, the only CCE detected was emergence of small sub-clones. Conventional karyotyping was performed in 10/37 patients who progressed both pre-treatment and at progression. In 4 pts, CCE was identified at progression, suggestive of tetraploidy. The pt with del(11q) pre-treatment who progressed developed Richter Transformation (RT) in the bone marrow at progression, without either del(11q) or del(17p) identified by FISH, suggesting that the RT arose from a common ancestral clone without del(11q) or was clonally unrelated. Median FISH%del(17p) pre-treatment in those with del(17p) was 72%; only 1 pt had <50% del(17p) pre-treatment. All these pts had persistence of del(17p), at progression, without significant changes in allelic frequency. Two pts with del(17p) pre-treatment had additional abnormalities detected by FISH at progression: sub-clonal biallelic del(13q) was seen in two pts, one of whom also developed tetrasomy 12. In the absence of disease progression, the only CCE detected was emergence of small sub-clones with biallelic del(13q) in two patients who initially had monoallelic del(13q). Notably, in responding pts, there was no expansion of high-risk sub-clones. Conventional karyotyping was performed in 10/37 patients who progressed both pre-treatment and at progression. In 4 pts, CCE was identified at progression, including 17 new abnormalities in one pt. All 4 pts had complex karyotype and del(17p) by FISH pre-treatment and 3 of 4 had evidence of multiple, related, complex sub-clones pre-treatment. Figure 1 shows inferred clonal evolution pattern for one pt.

Figure 1.
Pairwise association showed statistically significant co-occurrence between tri(17p) and mutations in KRAS/BCOR (both \(p<0.05\)), NOTCH1 mutation and ZMYM3 (\(p=0.01\)), SPEP (\(p<0.05\)) mutation, and TP53 mutation and del(17p) (\(q<0.01\))/complex karyotypes (\(q<0.05\)). When correlating with clinical response to lenalidomide, worse overall response (OR) in the untreated group was associated with del(17p) (\(p=0.019\)) and KRAS mutation (\(p=0.05\)), whereas mutation in SF3B1 (\(p=0.026\)), MGA (\(p=0.035\)), DDX3X (\(p=0.001\)), complex karyotype (\(p=0.035\)) and del(17p) (\(p=0.031\)) were associated with worse OR in R/R group. In the untreated group, del(17p) and TP53 were associated with worse progression-free (PFS) (\(p=0.002\) and 0.003, respectively). In R/R cohort, complex karyotype, del(17p) and mutations in SF3B1 and TP53 were associated in ibrutinib treated patients. DDX3X was associated with worse PFS but not OS (refer to provided Figure 1). In one of the multivariate models, SF3B1 (P=0.005) mutation and having TP53 or del(17p) (P=0.02) were prognostic for survival in R/R cohort.

**Summary/Conclusions:** Tumor mutational heterogeneity in CLL is due to intrinsic tumor biology and selective drivers from previous treatments, which can then affect response and survival in lenalidomide-based therapies.

HIGH THROUGHPUT IMMUNOPROFILING OF CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS ASSIGNED TO STEREOTYPED SUBSET #4: NOVEL INSIGHTS INTO THE DEPTH, DIVERSITY AND TEMPORAL DYNAMICS OF CLONAL EVOLUTION

K. Gemenetzi1, E. Stalika 1, A. Vardi 1, F. E. Psomopoulos 1, E. Minga 1, A. Anagnostopoulos 2, K. Stamatopoulos 1,3, A. Hadzidimitriou 1, L. A. Sutton 3,4, M. Keating4, J. Burger4, A. Ferrajoli 4, W. Wierda 4, A. Futreal 2, K. Takahashi 4

Background: Chronic lymphocytic leukemia (CLL) clones assigned to stereotyped subset #4 are characterized clinically by a young age at diagnosis, an indolent disease course, and molecularly by B-cell receptor immunoglobulins (BcR Ig) that exhibit distinctive immunogenetic features. More specifically, they are IgG-switched, composed of heavy and light chains encoded by the IGHV4-34 and IGKV2-30 genes, respectively, and their heavy chain complementarity determining region 3 (V(H)CDR3) is long and enriched in positively charged residues, reminiscent of pathogenic anti-DNA antibodies. In addition, both the VH and VK domains of subset #4 demonstrate a high impact of somatic hypermutation (SHM), highly indicative of an (auto)antigen selection.

Aims: To obtain comprehensive insights into the ontogeny and evolution of CLL subset #4 using next-generation sequencing (NGS) for in-depth immunoprofiling of the clonotypic BcR Ig genes, particularly focusing on analyzing intraclonal diversification (ID) within the IDG gene sequences.

Methods: Peripheral blood samples were collected at multiple time-points over a 10-year period from 6 CLL subset #4 patients. The clonotypic IGVH-IGHD-IGHJ and IGKV-IGKJ rearrangements were amplified by PCR using cDNA and sequenced on the MiSeq (Illumina). Our experimental design involved paired-end sequencing, thus allowing sequencing of the CDR3 twice/read, so as to increase the accuracy of results. To maintain stringency, raw NGS reads were subjected to purpose-built, bioinformatics algorithms, which filtered prepared: (i) length and quality filtering of raw quality filtered reads; (ii) filtering of filtered-in paired reads via local alignment; and, (iii) length and quality filtering of stitched sequences. No base calls of Q-score<30 were allowed in the 75 nucleotide stretch preceding the GXG motif, further increasing CDR3 sequencing reliability. Data was then analyzed using the IMGT/HighV-QUEST database and clonotype computation was performed using an in-house bioinformatics pipeline.

Results: Overall, 48 samples were analyzed, producing 12,386,554 and 4,506,464 total reads for heavy and light chain, respectively. In addition to filtering out poor quality, incomplete, out-of-frame and unproductive rearrangements, we have imposed specific parameters (\(k<0.5\), \(q<0.01\)), usage of subset #4-specific V- and J-genes, CDR3 length and landmark residues. Applying these strict criteria resulted in 84.1% (median 401,133 reads/sample) and 90.3% (median 141,549.5 reads/sample) of the total sequences obtained for the heavy and light chain, respectively, passing filters. Clonotype computation was solely based on the filtered reads, and revealed a median of 1332.5 clonotypes/sample (range: 879-3432) for the heavy chains while a median of 202.5 clonotypes/sample (range: 125-395) was evidenced for the light chains. Overall, our longitudinal analysis revealed: (i) a hierarchical pattern of subclonal evolution showing which SHMs were more likely to emerge and/or positively selected; (ii) several distinct clusters of subcloned sequences which at later time-points had often disappeared and hence been selected against; and, (iii) that despite the high intensity of ID, certain residues remained essentially unaltered alluding to strong functional constraints.

Summary/Conclusions: Detailed molecular immunoprofiling by NGS afforded the possibility to gain novel insights into the pathogenesis of CLL subset #4, thus providing conclusive evidence that these patients continue to acquire SHMs within their Ig genes; an observation best explained by a clear role for antigen selection in clonal evolution.
Background: During normal hematopoiesis, a coordinated epigenetic and transcriptional programming is necessary to achieve lineage development. B cell differentiation is predominantly related to loss of DNA methylation at the enhancers and promoters of B cell-specific genes; e.g. transcription factors (TFs). In chronic lymphocytic leukemia (CLL), failure of proper epigenetic programming contributes to deregulation of B cell transcriptional programs and results in CLL phenotypes with highly variable outcomes. The mechanisms leading to failed epigenetic programming and to establishment of a CLL epigenome are not well understood. Genomic sites of failed epigenetic program coincide with binding sites of key B cell TFs. Active DNA demethylation through TET-dioxygenase mediated conversion of 5-methylcytosine (5mC) to 5-hydroxymethylcytosine (5hmC) and subsequent products is one of the mechanisms involved in physiological epigenetic B cell programming, and deregulation of this process could contribute to establishment of the CLL epigenome.

Aims: Here, we investigated the role of TET2-mediated DNA demethylation through differential 5hmC acquisition in healthy and in CLL B cells. We further studied mechanisms and TFs involved in regulation of 5hmC conversion during CLL pathogenesis.

Methods: Clonal B cell specimens from 122 CLL patients were subjected to DNA methylation profiling using Illumina 450k arrays. 17 CLL and 4 healthy B cell samples (CD19+) were used for DNA methylation profiling using Illumina Epic arrays and for hydroxymethylated DNA immunoprecipitation (hMeDIP) using a monoclonal 5hmC mouse antibody and the NEBNext Ultra DNA Library Prep Kit for analysis on a Illumina HiSeq2000 sequencer. Global 5hmC levels were quantified by dot blots. TET2, and EBF1 mRNA and protein expression was evaluated by qPCR and Western Blot, respectively.

Results: By dot blot, we found decreased 5hmC levels in CLL as compared to normal B lymphocytes. 5hmC was further reduced in IGHV unmutated compared to IGHV mutated CLL patients. To identify distinct regions with gain or loss of 5hmC, we performed genome-wide 5hmC profiling by hMeDIP. We confirmed a significantly lower number of hydroxymethylated peaks in CLL (137114) compared to HBC (249421) which remained stable when separating the 122 CLL patients into three major epigenetic groups corresponding to IGHV unmutated and mutated CLL, respectively; and iii) a naïve like CLL (n-CLL), ii) good-prognostic, memory like CLL (m-CLL), broadly grouped based on their epigenetic classification, revealed that subset #1 clustered with n-CLL, subset #4 with m-CLL, while subset #2 clustered separately from both groups.

Summary/Conclusions: Here, we demonstrate that 5hmC loss in CLL contributes to a disease specific epigenotype as described earlier. First evidences indicate that alterations of an interaction between the EBF1 and TET2 are mechanistically involved in insufficient hydroxymethylation and consequently failed DNA hypomethylation.
Background: A major aim of CLL treatment is to eradicate detectable minimal residual disease (MRD). Ibrutinib is an effective treatment for CLL that results in immediate lymphocytosis persisting in most patients for several months. Obinutuzumab is a second generation anti-CD20 monoclonal antibody which can effect rapid resolution of lymphocytosis and eradication of MRD in some CLL patients. The IcICLLe Extension Study expands on the IcICLLe trial (ISRCTN12696354) to examine the efficacy and safety of the combination treatment of obinutuzumab and ibrutinib.

Aims: The IcICLLe trial was a single-arm, multicentre feasibility study that recruited 40 participants with CLL requiring treatment to receive continuous ibrutinib therapy from day 0 and 6 cycles of obinutuzumab treatment. There were 2 separate reports of grade 2 infusion related reactions, for response assessment after 1 month of combination treatment. There have been no reports of tumour lysis syndrome within the first month of combination treatment. There were 2 separate reports of grade 2 infusion related reactions, both on day 1 of obinutuzumab. In the 22 ibrutinib-naïve cases peripheral blood (PB) CLL cell counts remained at or below baseline levels in 17/22 cases from week 1 onwards. After 1 month of combination therapy the PB CLL count was a median 31% of baseline levels (range <1%-174%) compared to median 215% (range 29%-3570%) for RR patients on ibrutinib monotherapy. Percentage CLL cells in the bone marrow (BM) aspirate after 1 month of combination therapy reduced from a median 83% (range 23-94%) to a median 47% (range 8-85%; P=0.003). Pretreatment BM aspirate matched-pairs were ranked. For RR patients on ibrutinib monotherapy there was no change in BM at 1 month: baseline median 85% (range 11-96%) compared to median 86% (range 50-98%; P=0.96). Changes in BM aspirate CLL percentage were confirmed by morphological assessment of a trephine biopsy with all evaluable patients receiving obinutuzumab showing improvements in the cellularity and/or extent of infiltration. BM assessment at 1 month was not mandated for the 9 pre-treated patients but all showed decreased PB CLL counts with 4/9 achieving <0.01% residual disease within 3 months of starting obinutuzumab. 13 patients have completed 6 months of obinutuzumab treatment with marrow assessment at 9 months showing a further ≥1 log depletion in CLL percentage in 9/13 patients with 4/6 pre-treated patients achieving <0.01% residual disease.

Summary/Conclusions: The data indicate that for RR patients, the addition of obinutuzumab to ibrutinib results in a substantial improvement over ibrutinib monotherapy in the depletion of CLL cells from peripheral blood and bone marrow after 1 month of combination therapy, and continued improvement after 6 months combination therapy, with MRD-negative BM responses for patients who have had >1yr prior ibrutinib monotherapy. Residual disease levels in the BM after the 6 months of combination treatment will be available for 25 participants by June-2017.

Results: Among the 32 patients with aggressive CLL, we found that 9 (28%) patients who had an IgL3V21 rearrangement, but only 1 patient carried the heavy chain IgHV3-21: IgL3V21-21 patients had a median TFS of 17 months compared to 44 months in patients with another light chain (P=0.0270). Similarly, IgL3V21 patients had a shorter median OS (88 months vs >192 months, P=0.0287). We verified these results in 2 independent cohort obtained at diagnosis. In cohort B (n=270), 30 (11%) expressed an IgL3V21 light chain and 10 (4%) an IgHV3-21 (of which 8/10 also carried the light chain IgL3V21 rearrangement). Patients with IgL3V21 had a median TFS/OS of 29/183 months compared to patients without IgL3V21 who had a median TFS/OS of 88/292 months (P=0.0003/P=0.0142). In cohort C (n=103), 9 (9%) expressed an IgL3V21 light chain but only 1 (1%) had a heavy chain IgHV3-21. In this cohort, IgL3V21 patients had a median TFS of 21 months not statistically different from IgHV3-21 patients (28 months) while IgHV3-21 patients who had a median TFS of 93 months (P<0.0001). We then pooled the 3 populations (n=405) in order to increase the under-represented subgroups and analyzed the association of the IgL3V21 with the IgHV mutational status: patients with either IgL3V21 or IgHV3-21 (with a M or UM IgHV) displayed a prognosis similar to UM patients: median TFS was 129, 48, 36, 24, 23 months for M, IgL3V21/M (P=0.0005), UM (P<0.0001), IgL3V21/UM (P<0.0001) and IgHV3-21 (P<0.0001) patients, respectively (Figure 1A). Similar results were observed for OS with a median OS of 292, 88, 174, 90 and 183 months M, IgL3V21/M (P<0.0001), UM (P<0.0001), IgL3V21/UM (P<0.0001) and IgHV3-21 (P=0.0021) patients, respectively (Figure 1B). If all IgL3V21 (n=48) were considered independently of their heavy chain, IgL3V21 median TFS (24 months) was similar to UM patients (36 months, P=0.5824) and statistically different from M patients (129 months - P<0.0001, Figure 1C). Similar results were observed for OS (Figure 1D).

Background: The immunoglobulin heavy-chain gene (IgHV) mutational status is currently considered the gold standard of prognostication in Chronic Lymphocytic Leukemia (CLL): unmutated (UM) immunoglobulin heavy chain region (IgHV) is associated with poor prognosis while patients with mutated IgHV (M) have more indolent disease. An exception are patients with IgL3V21/IgHV3-21 who have poor prognosis irrespectively of the IgHV mutational status. Interestingly, IgL3V21 is co-expressed with IgLV3-21 in the majority of cases.

Aims: Here we aimed to study the impact of the light chain IgLV3-21 on CLL prognosis. This light chain has never been characterized independently of the heavy chain IgHV3-21.

Methods: Based on 405 CLL patients from 3 independent cohorts (A. an initial cohort of 32 patients with aggressive CLL, and 2 cohorts of CLL patients where samples were obtained at diagnosis (B: n=270 and C: n=103), we analyzed the impact of the presence of IgL3V21 on treatment-free (TFS) and overall (OS) survival. IgLV3-21 positivity was determined by real-time PCR and confirmed by Sanger sequencing.

Results: Among the 32 patients with aggressive CLL, we found that 9 (28%) patients who had an IgL3V21 rearrangement, but only 1 patient carried the heavy chain IgHV3-21: IgL3V21-21 patients had a median TFS of 17 months compared to 44 months in patients with another light chain (P=0.0270). Similarly, IgL3V21 patients had a shorter median OS (88 months vs >192 months, P=0.0287). We verified these results in 2 independent cohort obtained at diagnosis. In cohort B (n=270), 30 (11%) expressed an IgL3V21 light chain and 10 (4%) an IgHV3-21 (of which 8/10 also carried the light chain IgL3V21 rearrangement). Patients with IgL3V21 had a median TFS/OS of 29/183 months compared to patients without IgL3V21 who had a median TFS/OS of 88/292 months (P=0.0003/P=0.0142). In cohort C (n=103), 9 (9%) expressed an IgL3V21 light chain but only 1 (1%) had a heavy chain IgHV3-21. In this cohort, IgL3V21 patients had a median TFS of 21 months not statistically different from IgHV3-21 patients (28 months) while IgHV3-21 patients who had a median TFS of 93 months (P<0.0001). We then pooled the 3 populations (n=405) in order to increase the under-represented subgroups and analyzed the association of the IgL3V21 with the IgHV mutational status: patients with either IgL3V21 or IgHV3-21 (with a M or UM IgHV) displayed a prognosis similar to UM patients: median TFS was 129, 48, 36, 24, 23 months for M, IgL3V21/M (P=0.0005), UM (P<0.0001), IgL3V21/UM (P<0.0001) and IgHV3-21 (P<0.0001) patients, respectively (Figure 1A). Similar results were observed for OS with a median OS of 292, 88, 174, 90 and 183 months M, IgL3V21/M (P<0.0001), UM (P<0.0001), IgL3V21/UM (P<0.0001) and IgHV3-21 (P=0.0021) patients, respectively (Figure 1B). If all IgL3V21 (n=48) were considered independently of their heavy chain, IgL3V21 median TFS (24 months) was similar to UM patients (36 months, P=0.5824) and statistically different from M patients (129 months – P<0.0001, Figure 1C). Similar results were observed for OS (Figure 1D).

Figure 1.

Summary/Conclusions: Our results highlight for the first time the independent prognostic significance of the light chain IgTN-21 in CLL: the presence of an IgL3V21 light chain confers a poor prognosis similar to UM patient irrespectively of concurrent expression of IgHV3-21 heavy chain or IgHV mutational status.
Results: Forty-nine patients, with a median of 2 (range: 1–5) prior regimens, were enrolled. As of July 2016, the overall response rate was 86%, the CR rate was 51%, and the bone marrow MRD-negativity rate was 57% (28/49) [Seymour et al Lancet Oncol 2017]. The 24-month estimate for progression free survival was 78.8% and that for duration of response was 87.8% (100% for patients with MRD-negative CR). Of the 28 patients attaining MRD-negativity, 22 achieved the status at 7 months, which was the first mandatory time point for assessment. The remaining six patients achieved MRD-negativity at the second assessment, which ranged from 12 to 22 months, since the timing of this test was not mandated. Twenty (41%) patients discontinued the study. Eleven had progressive disease while on therapy: five with Richter’s transformation between 1–9 months and six with CLL progression after a median of 26.4 months (range: 12–37). The other nine patients: withdrew consent (n=3), failed to report for follow-up evaluations (n=1), discontinued due to adverse events related to venetoclax (n=2; tumor lysis syndrome and worsening of peripheral neuropathy), or discontinued due to adverse events considered not related to therapy (n=3). Seventeen patients remained in follow-up and remained on study as allowed off therapy could re-initiate venetoclax and rituximab.

Summary/Conclusions: Venetoclax with rituximab induces deep and durable responses, with 51% patients achieving CR and 57% achieving marrow MRD-negativity. Patients on continued therapy have durable responses. Additionally, responses are sustained at a median of 13 months among patients who achieve bone marrow MRD-negativity and elected per protocol to stop therapy, demonstrating that it is possible to discontinue venetoclax and maintain prolonged treatment free remission. The 2 patients who progressed at 2 years off therapy responded to the reintroduction of venetoclax.

Background: Venetoclax is a potent BCL-2 inhibitor that is approved as monotherapy for certain patients with relapsed or refractory chronic lymphocytic leukemia (CLL) in the United States, the European Union, and other countries.

Aims: Venetoclax combined with rituximab is being assessed in an ongoing Phase 1b study.

Methods: Minimal residual disease (MRD) was assessed in bone marrow using 24-color flow cytometry (minimum sensitivity: 0.01%). Patients who achieved complete remission (CR) or MRD-negativity could stop venetoclax using ≥4-color flow cytometry (minimum sensitivity: 0.01%). Patients who achieved MRD-negativity in the bone marrow who remain on study have durable responses. Additionally, responses are sustained at a median of 13 months among patients who achieve bone marrow MRD-negativity and elected per protocol to stop therapy, demonstrating that it is possible to discontinue venetoclax and maintain prolonged treatment free remission. The 2 patients who progressed at 2 years off therapy responded to the reintroduction of venetoclax.

The 2 patients who progressed at 2 years off therapy responded to the reintroduction of venetoclax.
impact, we performed multivariable Cox regressions for PFS and OS including treatment, IGHV status and all cytogenetic and mutational subgroups. For PFS, the following independent prognostic factors were identified: FCO therapy (HR 0.64 p<0.01), del17p (HR 5.08 p<0.01), unmutated IGHV (HR 2.0 p<0.01), TP53mut (HR 1.75 p<0.01) and XPO1mut(1.86 p<0.01). Del17p (HR 4.79 p<0.01), unmutated IGHV (HR 1.69 p=0.04) and TP53mut (HR 1.76 p=0.03) were identified as independent prognostic factors for OS. With focus on the predictive value of gene mutations, we found a beneficial effect of the addition of ofatumumab to chemotherapy irrespective of TP53 mutation (HR 0.52 p=0.02 for TP53mut and HR 0.68, p=0.02 for TP53). Regarding NOTCH1, ofatumumab was only beneficial in NOTCH1mut but not in NOTCH1mut patients (HR 0.64, p=0.01 and HR 0.86, p=0.367) (Figure 1).

Summary/Conclusions: In the COMPLEMENT-2 trial evaluating FCO against FC in relapsed/refractory CLL patients, we found TP53mut and XPO1mut but not SF3B1mut or NOTCH1mut as independent prognostic factors for PFS. Notably, the addition of ofatumumab to chemotherapy did not result in a benefit among NOTCH1mut but not among NOTCH1mut patients indicating NOTCH1 mutation status as a predictive marker in the context of type-1 CD20 antibody addition to chemotherapy.

RELATIVE SURVIVAL REACHES A PLATEAU IN HAIRY CELL LEUKEMIA: A POPULATION-BASED STUDY ON INCIDENCE, PRIMARY TREATMENT AND SURVIVAL AMONG 1,427 PATIENTS DIAGNOSED IN THE NETHERLANDS, 1989-2014

A. Dinmohamed1,2,3,* O. Visser4, W. Posthuma5, R. Raymakers5, J. Doorduijn3

Background: The introduction of cladribine and pentostatin has revolutionized the management of HCL as from the late 80s. As a result of that revolution, HCL patients (pts) are rarely included in clinical trials. Population-based studies can inform on issues related to outcomes of HCL pts managed in daily practice. At present, however, population-based studies that assess patterns of incidence, treatment and survival in HCL are very scarce.

Aims: The aim of this comprehensive nationwide population-based study was to assess trends in incidence, primary treatment and survival among HCL pts diagnosed in the Netherlands.

Methods: We selected all adult (≥18 years) pts diagnosed with classic HCL in the Netherlands between 1989-2014 from the national Netherlands Cancer Registry with survival follow-up through February, 2016. Age-standardized incidence rates (ASR) were calculated per 1,000,000 person-years and standardized according to the European standard population. Data on primary treatment (i.e. no therapy, chemotherapy [CT] and immunotherapy [IT]) were available for individual pts. Pts were categorized in 2 periods (1989-2000 and 2001-2014) and 3 age groups (18-59, 60-69 and ≥70 years). We calculated relative survival (RS) and the relative excess risk of mortality as measures of disease-specific survival.

Results: We included a total of 1,427 newly diagnosed HCL pts in the study (median age, 59 years; age range, 22-95 years; 77% males). The annual ASR of HCL remained quite stable over time and was 3.1 and 3.3 in the first and last period, respectively. Men had a higher overall incidence than women (5.3 v 1.3 in 2001-2014). The age-specific incidence rates for males were 5.5, 15.0 and 15.3 in 2001-2014 for the three age groups. The corresponding rates for females were 1.2, 3.1 and 5.5. The application of CT increased over time for all age groups. The proportions of CT for the three age groups were 56, 51 and 34% in 1989-2000, as compared with 81, 73 and 53% in 2001-2014. The corresponding proportions for IT were 21, 13 and 17% in 1989-2000, as compared with 2, 1 and 4% in 2001-2014. Lastly, the corresponding proportions of pts who did not receive any therapy were 23, 36 and 49% in 1989-2000, as compared with 17, 26 and 42% in 2001-2014. Overall, when corrected for age and sex, pts diagnosed in 2001-2014 had 49% lower excess mortality during the first 10 years after HCL diagnosis, as compared with pts diagnosed in 1989-2000 (P<.005). Ten-year RS (95% confidence intervals) was impressive for pts age 18-59, namely 92% (88% - 96%) and 98% (94% - 100%; P<.176) in the first and last period, respectively (Figure 1a). Most of the significant improvement was observed in pts age ≥60. More specifically, 10-year RS for pts age 60-69 increased from 82% (71% - 92%) to 99% (89% - 100%; P<.009; Figure 1b), and for pts age ≥70 from 67% (49% - 86%) to 85% (77% - 92%; P<.036; Figure 1c) between the first and last periods. In addition, older age (P<.001), but not sex (P=.058), was associated with higher excess mortality.

Summary/Conclusions: The incidence of HCL remained stable during a 26-year period in the Netherlands. RS for pts diagnosed in the period 2001-2014 eventually reached a plateau, indicating that by then their survival is comparable to that of the general population. Survival was already excellent for younger patients throughout the entire study period. Survival improvement was most pronounced for pts age ≥60, but this was not statistically significant for pts age ≥70. This could be explained by the increased use CT over time. Population-based cancer registries are useful instruments to assess outcomes of pts rarely included in clinical trials.
Background: CCL-IPI is a prognostication tool to stratify patients with chronic lymphocytic leukemia (CLL) for low, intermediate, high, or very high risk. CLL-IPI uses age, Binet stage, beta-2-microglobulin, TP53 mutation, and IGHV mutational status, but not comorbidity as weighted factors to model prognosis. CIRS is a tool which allows assessing and quantifying burden of comorbidity in individual patients.

Aims: To validate CIRS in CLL and to assess whether CIRS is of further value when estimating prognosis by CLL-IPI in CLL.

Methods: This is a comprehensive evaluation of CIRS in 2158 patients pooled from the CLL8, CLL10, and CLL11 trials of the German CLL Study Group (GCLLSG). Median observation time was 55 months. All patients had CIRS data prospectively assessed prior to study treatment (689 FCR, 409 FC, 279 BR, 333 GCLB, 330 RCLB, 118 CLB).

Results: Median age was 64 years; 69% of patients were males, and 50% had ECOG performance score of 0 or 1. Complete information on age, Binet stage, beta-2-microglobulin, 17p deletion / TP53 mutation, and IGHV mutational status was available in 1761 of the 2158 patients. Distribution of CLL-IPI risk groups was as follows: 275 (16%) low risk, 653 (37%) intermediate risk, 712 (40%) high risk, 121 (7%) very high risk. Comorbidities were most frequently captured under the following range (0-22); 81% of the patients had a total CIRS score of at least 1 and 28% (40%) high risk, 121 (7%) very high risk. The median total CIRS score was 3 (range 0-22); 81% of the patients had a total CIRS score of at least 1 and 28% of greater than 6. Comorbidities were most frequently captured under the following categories: cardiac, blood pressure, respiratory, musculoskeletal, or endocrine/metabolic. A severity score of >2 and >3 in at least one CIRS organ category was present in 46% and 11% of the patients, respectively. There was a positive correlation between total CIRS score and age (r=0.5, p<0.001) as well as ECOG performance score (r=0.4, p<0.001) and an inverse association between total CIRS score and creatinine clearance (r=-0.3, p<0.001). In uni- and multivariable analysis, increased total CIRS score was associated with shorter overall survival (OS); with poorer OS determined by severity rather than numbers of comorbidities (log-rank: p<0.001, Figure 1A and 1B). In multivariable analysis, total CIRS score was an independent risk factor for OS when used as continuous or categorical variable together with age, gender, Binet stage, ECOG performance score, thymidine kinase, beta-2-microglobulin, IGHV, and 17p deletion (adjusted for treatment intensity). Total CIRS score also remained an independent risk factor for OS when added to the CLL-IPI. Weight of CIRS was highest in the CLL-L and lower in the CLL10 and CLL11 trials as expressed by the hazard ratios (Figure 1C). There was no significant association between total CIRS score and progression-free survival or time-to-next treatment. However, increased total CIRS score was associated with higher risk of grade 3/4 adverse events as well as premature treatment discontinuation during or after treatment with FCR / FC / BR but not GCLB / RCLB / CLB.

Summary/Conclusions: Findings suggest that CIRS provides prognostic information above and beyond the CLL-IPI. Systematic comorbidity assessment (e.g. by CIRS) in addition to the CLL-IPI therefore appears reasonable when estimating overall prognosis and deciding treatment in CLL.
Aims: We report final results for the planned 36-months (mo) follow-up (35/41 pts; median observation 40.4 [17.6–43.6] mo); initial results were reported previously (Brown et al. 2015).

Methods: Eligible pts met iwCLL 2008 criteria for therapy, were considered fit for chemoimmunotherapy by the investigator, and provided informed consent. Each center selected treatment (G-FC or G-B) for their pts. G was administered intravenously (IV; 100mg/day [D] 1, 900mg D2, 1000mg D8 and 15 cycle [C] 1: 1000mg D1 C1–2–6) with FC (fludarabine 250mg/m2 IV and cyclophosphamide 250mg/m2 IV D2–4 C1, D1–3 C2–6 or B [90mg/m2 IV D2–3 C1, D1–2 C2–6]. Each cycle was 28 days. The primary endpoint was safety and tolerability of G-chemotherapy.

Results: 21 pts were enrolled in the G-FC arm and 20 in the G-B arm. Median age was 60 (25–80) years, 78% of pts were male, and around one-third had Rai stage III/IV disease. Median time from diagnosis to therapy was 24 mo (G-FC) or 30 mo (G-B). At last follow-up in follow-up; G-FC (n=18: 2 lost to follow-up) and G-B (n=19: 1 event of progressive disease occurred in each arm, and 1 pt per arm died due to an adverse event (AE); G-B: respiratory failure; G-FC: unknown in the setting of unresolved Grade (Gr) 4 pancytopenia); neither was considered treatment related. Due to the small number of events, median PFS and OS could not be estimated; however, 3-year OS was 95% for each arm (95% CI G-FC, 68–99; G-B, 70–99).

Post-treatment, 10/41 pts (24.4%) experienced ≥1 Gr3–5 AE: 2/21 pts (9.5%) in the G-FC arm and 8/20 pts (40.0%) in the G-B arm. 7 serious AEs were reported in 4 pts, all in the G-B arm; these included pneumonitis and respiratory failure (as noted above), both Gr3). Gr4 leukopenia/neutropenia, small cell lung cancer and Gr4 pneumoehorax, and melanoma. During follow-up, 6 pts had ≥1 Gr3–4 AE of neutropenia, including 4/20 pts (20.0%) in the G-B arm and 2/21 pts (9.5%) in the G-FC arm. At end of treatment, all pts were B-cell depleted (B-cell count <0.07x109/L). Within 6–12 mo of follow-up, very few pts had recovered (<1 Gr2) except one in the G-B arm. Disease status at transplant was: partial or complete remission in the majority of patients (39 patients, 78%). The overall transplant related mortality (TRM) was 6% and the 5-year non-relapse mortality was 14%.

Relapse rates at 5 years were 54%. Acute graft versus host disease (GVHD) developed in 30 (60%) of patients and chronic GVHD was noted in 32 patients (64%). We evaluated the impact of CLL characteristics, disease status, and patient and transplant characteristics on clinical outcomes. Development of chronic GVHD post-transplant was the dominant predictor of both disease-free survival (DFS) (HR 0.29, 95% CI=0.10-0.69, P=0.006) and OS (HR 0.04, 95% CI=0.01-0.19, P&l&l;0.0001, Figure 1A). Very high CLL-IPI risk category (28% of patients) was associated with high relapse rates (82%) post RIC-SCT. DFS was also different between different CLL-IPI categories (18.2% in very high 52.9% in high vs 66.7% in intermediate, p=0.04, Figure 1B). However, there was no significant difference in overall survival suggesting potential benefits from novel therapies in relapsed patients. Given that development of chronic GVHD was the most significant predictor for OS, we evaluated what pre-treatment patient and disease (including CLL-IPI), and transplant characteristics predicted for subsequent development of chronic GVHD. ZAP70 over expression (OR 0.09 [95% CI 0.01-0.79], p=0.03), disease status at transplant (progression versus remission OR 0.22 [95% CI 0.05-0.92], p=0.038), and alemtuzumab exposure within 3 months of transplantation were associated with lower rates of chronic GVHD (OR 0.08 [95% CI 0.01-0.79], p=0.03). CLL-IPI was not a significant predictor for the development of chronic GVHD in our analysis.

Summary/Conclusions: In this analysis, we aimed to elucidate the factors that may predict the outcomes following RIC SCT, including the CLL-IPI.

Methods: This is a retrospective analysis of all CLL patients who underwent RIC-SCT at Mayo Clinic between 2006-2013. The study was approved by the Institutional Review Board. The prognostic value of several CLL, patient and transplant related variables were analyzed. Continuous variables were reported as median (25%–75% interquartile range) and categorized using the T-test. Dichotomous outcomes were compared using the chi-square test. Survival was estimated and compared using the Kaplan Meier and Log Rank tests. Results: Between 2006 and 2013, 50 patients with a median age of 56 years old underwent RIC-SCT for the treatment of CLL. The median time from diagnosis to RIC-SCT was 4.7 (0.6–22.9) years. Fourteen (28%) patients had 17p deletion at time of transplantation. CLL-IPI prognostic score calculated prior to transplant was intermediate in 30%, high in 42% and very high in 28% of patients. Disease status at the time of transplant was partial or complete remission in the majority of patients (39 patients, 78%). The overall transplant related mortality (TRM) was 6% and the 5-year non-relapse mortality was 14%.

This study found that the development of chronic GVHD post-transplant is themost significant predictor for both OS and DFS in surviving patients after RIC-SCT in CLL. Interestingly, 82% of patients with very high risk CLL-IPI relapsed after RIC-SCT. This is the first report to evaluate the prognostic significance of CLL-IPI for stratifying post-transplant outcomes and to identify high relapse rates in the very high risk CLL-IPI category.
IMPACT OF ABCG2, OCT1 AND ABCB1 (MDR1) ON TREATMENT FREE REMISSION IN AN EUROSKI SUBTRIAL

Aims: The expression levels of efflux and influx channel transcript levels were investigated by a multivariate Cox’s regression model. Relapse has been defined as a two-time higher risk of relapse in multivariate analysis. Further prospective validation is warranted.

Results: In our cohort, 132 chronic phase CML patients discontinued TKI treatment. The predictive significance of the efflux transporter correlated with a two-time higher risk of relapse in multivariate analysis. Further prospective validation is warranted.

Summary/Conclusions: Here we investigated for the first time the impact of pharmacokinetics in the context of a CML discontinuation trial. ABCG2 but not OCT1 and ABCB1 (MDR1) predicted treatment-free remission after TKI discontinuation. High expression of the ABCG2 efflux transporter correlated with a two-time higher risk of relapse in multivariate analysis. Further prospective validation is warranted.
G would seem to be associated with lower EFS and TFR, possibly because of a stronger inhibitory effect on the immune system in favor of tumor escape mechanisms. Conversely, the allele associated to lower levels of shLA-G promoted achievement of MR4.5 and TFR, suggesting increased cooperation of the host immune system in CML cell clearance.

P257

DURABLE TREATMENT-FREE REMISSION AFTER STOPPING SECOND-LINE NILOTINIB IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE: ENESTOP 96-WK UPDATE

Background: ENESTop (NCT01698905) is evaluating the ability to stop treatment and remain in TFR in pts with CML-CP who achieved a sustained deep molecular response (MR) after switching from imatinib (IM) to NIL. The primary analysis, 57.9% of pts (73/126) who stopped treatment remained in TFR (no confirmed loss of MR4 [BCR-ABL1 IS ≤0.01%], and no treatment reinitiation) at 96 wk. All pts provided informed consent. Enrolled pts continued NIL at 38.4±7.1 mg/l. In contrast, second line NILO showed a trend for increase in blood glucose and lipid levels in the NILO arms; importantly NILO-treated patients also showed an increased incidence of arterial occlusive events. Adipose tissue is a key regulator of lipid and glucose homeostasis; dysregulation of adipogenesis, altered adipocyte lipid accumulation and reduced insulin sensitivity is implicated in the pathogenesis of metabolic disease. We investigated the effect of NILO on adipose tissue to explain the mechanisms behind NILO-associated metabolic adverse effects.

Methods: Differentiating 3T3-F442A, a mouse adipocyte line, were differentiated with clinically relevant concentrations of NILO (1-20µM) and IM (5µM), in the presence or absence of telmisartan (1-10µM), an angiotensin receptor blocker with potential beneficial effects on insulin sensitivity and lipid homeostasis. Cyto- toxicity and adipogenesis were assessed by MTT assay and Oil Red O staining, respectively. Expression of adipogenic genes was assessed by semiquantitative real-time PCR, and adipokine secretion using an in vitro adipocyte model; ii) To utilise the in vitro model to explore potential therapeutic strategies to reverse NIL-mediated effects, and iii) To validate the in vitro results in a pilot patient cohort.

Results: NILO and IMA resulted in significant downregulation of GLUT4 mRNA (NILO, 54%; IMA, 55%; p<0.01 in comparison to vehicle control, 79.2ng/ml). Co-incubation with telmisartan resulted in significant reversal of NILO-mediated effects on GLUT4 expression and adipokine secretion.

Conclusions: The results demonstrate the durability of TFR after stopping NIL in pts who achieved a sustained deep MR after switching from IM to NIL.
Summary/Conclusions: A BCR-ABL1 transcript level measured at 1 month after the initiation of a TKI may be used as an early indicator to reliably predict the MMR achievement by 12 months in patients with CP-CML. The level obtained at 3 months appears to accurately predict the MMR. Further studies are needed to evaluate the association between the transcript level at 1 month and long-term clinical outcomes.

P259

EARLY PREDICTION OF THE MOLECULAR RESPONSE TO BCR-ABL1 TYROSINE KINASE INHIBITORS IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA

Background: A BCR-ABL1 transcript level at 3 months after the initiation of imatinib has shown predictive value in the clinical outcomes of patients with chronic myeloid leukemia in chronic phase (CP-CML). The levels obtained earlier than 3 months may also have a similar prognostic significance.

Aims: To assess the prognostic value of the BCR-ABL1 transcript levels at baseline, and 1 and 3 months after the initiation of a tyrosine kinase inhibitor (TKI) in predicting the major molecular response (MMR) achievement by 12 months, and to compare the patterns of molecular response (MR) to a TKI therapy between good and poor responders using a nonlinear model.

Methods: The clinical data were collected from the 178 patients with newly diagnosed CP-CML who were treated with a TKI at Seoul St. Mary’s Hospital. BCR-ABL1 transcript levels were obtained at baseline, and 1, 3, and 6 months after the initiation of a TKI. The levels were reported as the percent ratio relative to the control gene ABL1 in accordance with the International Scale (BCR-ABL1/ABL1[%)]. A confirmed MMR was defined as a BCR-ABL1/ABL1[≤0.1%] on two consecutive occasions. The predictability of the levels at baseline, and 1 and 3 months post TKI therapy for the achievement of a confirmed MMR by 12 months was evaluated using a logistic regression method with a receiver operating characteristic (ROC) analysis. The areas under the ROC curve (AUCs) were calculated to quantify the predictability. In addition, the patterns of molecular responses over time were described by a nonlinear model with the model-derived parameters between the patients who achieved a confirmed MMR by 12 months (“good responders”) and who did not achieve the MMR (“poor responders”).

Results: Of 178 patients, 67 achieved a confirmed MMR by 12 months but 111 did not. At baseline, the transcript level was not useful to predict the achievement of a confirmed MMR by 12 months. At 1 month post therapy, the levels measured at 1 month significantly (p < 0.0001) predicted the MMR with an AUC of 0.77. The patients with the level of 38% or less at 1 month had a better chance to achieve the MMR. By 3 months post therapy, the transcript level measured at 3 months (p < 0.0001) accurately predicted the MMR with the AUC of 0.83. The patients with the level of 0.48% or less at 3 months had a better chance to achieve the MMR. A nonlinear sigmoid model was used to fit the transcript data from 149 patients as follows: MR=MR0 [1 – tγ/ (t50γ+tγ)]; where MR0 is the predicted molecular response at baseline; t, time post TKI initiation; γ, slope factor; t50, time required to achieve 50% reduction in MR. Statistically significant differences were observed between the good and poor responders in the median values for the model-derived parameters of MR0 (73.3% vs 82.2%; p=0.003), γ (4.98 vs 3.32; p < 0.0001) and t50 (0.952 month vs 1.12 month; p=0.05).

Summary/Conclusions: A BCR-ABL1 transcript level measured at 1 month after the initiation of a TKI may be used as an early indicator to reliably predict the MMR achievement by 12 months in patients with CP-CML. The level obtained at 3 months appears to accurately predict the MMR. Further studies are needed to evaluate the association between the transcript level at 1 month and long-term clinical outcomes.
Background: Risk scores in chronic myeloid leukemia (CML) use baseline characteristics of CML patients in chronic phase to predict outcome and can be used to make decisions regarding first line TKI choice and monitoring frequencies. Until recently, risk stratification of CML patients was based on scores developed in the pre-imatinib era (Sokal and Hasford risk score) with overall survival as the end point of interest. After the introduction of imatinib, the EUTOS score was established to predict the risk of relapse in CML in patients treated with first line imatinib.

Aims: The primary objective of this study was to perform a validation of the ELTS score in an independent cohort of “real-world” population-based CML patients.

Methods: Data from chronic phase CML patients were derived from the PHAROS-CML population based registry and Hemobase. Patients were stratified into a low, intermediate and high risk group according to the ELTS score. Data on “death due to CML” were provided by the Netherlands comprehensive cancer organization (IKNL) in combination with details from the patient records and a competing risk analysis was performed, to take death due to other causes into account.

Results: In total 349 patients were eligible for analysis; 273 patients (78%) were treated with first line imatinib and 76 patients (22%) were treated with a first line second generation TKI (2GTKI). Sokal, Hasford and EUTOS risk scores all did not predict differences in risk of “death due to CML.” The ELTS score identified 163 patients as low risk (47%), 127 patients as intermediate risk (36%) and 59 patients as high risk (17%) at diagnosis. The 5 year cumulative incidence of “death due to CML” was indeed significantly higher in the high risk group (11%) compared to both the intermediate risk group (2%, p<0.02) and the low risk group (1%, p<0.001). Between the intermediate and low risk group no statistically significant difference in risk of dying from CML was observed. A subgroup analysis of only imatinib treated patients showed similar results.

Summary/Conclusions: In the current study based on a “real-world” population-based CML patient cohort, we were able to validate the predictive value of ELTS high risk stratification for “death due to CML” in the current TKI era. Therefore, the ELTS score should be preferred over Sokal, Hasford and EUTOS scores in clinical practice.

Background: A second-generation tyrosine kinase inhibitor (TKI), dasatinib, is more potent in inhibiting BCR-ABL kinase activity than imatinib. We had previously reported an interim analysis of 63 patients with CML-CP who had discontinued dasatinib treatment after maintaining a deep molecular response (DMR) for more than a year (Lancet Haematology, 2015; 2 (12):e528-35) and demonstrated that dasatinib could be safely discontinued in patients with a DMR for at least 12 months, and that longer follow-up results would clinically be more critical in the treatment of CML.

Aims: In this trial, the total follow-up duration was set as 36 months after the discontinuation. The aim of the current follow-up study was to investigate whether those patients were able to discontinue dasatinib treatment for a longer follow-up period without relapse.

Methods: The eligibility criteria for pre-registration included CML-CP patients, 15 years or older, receiving dasatinib treatment as the second-line or subsequent therapy after imatinib. All participants gave written informed consent. In this trial, DMR was defined as “no detectable BCR-ABL1 transcript determined using the international scale-based ROC-PCR at a single central laboratory (BML Inc., Tokyo; the cutoff corresponded to BCR-ABL1 0.0069% IS or molecular response (MR) 4.0).” Patients who showed a sustained DMR for 1 year (1-year consolidation phase) were subsequently included in the dasatinib-discontinuation stage. ROC-PCR was performed monthly for the first 12 months, and then every 3 months for the second year, and every 6 months for the third year, after discontinuing dasatinib. Relapse was defined as any positivity of BCR-ABL1 transcript by ROC-PCR even at one analysis point. In the present study, we assessed the estimated overall treatment-free remission (TFR) after discontinuing dasatinib, with 3 years of follow-up.

In addition, we also evaluated the impact of immunological profiles, including the cell counts of T and NK cell subsets in the peripheral blood throughout the 1-year consolidation phase, on TFR.

Results: Sixty-three patients were included in the dasatinib-discontinuation stage. The overall provability of TFR was relatively stable even for a longer follow-up period, our findings provided more compelling evidence supporting dasatinib discontinuation after a DMR for more than 1 year; this is feasible especially in patients with imatinib intolerance. We also reconfirmed that the counts of NK cells and functionally specific T-cells in the peripheral blood during dasatinib treatment might affect the TFR following dasatinib discontinuation.

Background: The biological and clinical behavior of hematological malignancies is not only determined by the properties of the leukemic cells themselves, but it is also highly affected by the interaction with the microenvironment, pointing to the existence of an active crosstalk between the two compartments. Previous studies showed that acute myeloid leukemia (AML) actively modify endothelial cells ex vivo via several pathways, mainly mediated by VEGF. However, anti-VEGF therapies haven’t produced successful results in clinical trials.

Aims: Our aim is to perform an extensive study of the vascular niche in the bone marrow (BM) of AML xenografts to provide a global picture of the vasculature in AML disease and design new therapeutic strategies.

Methods: We combined the use of mouse models of AML, human AML-derived xenografts (PDX) and direct analysis of patients derived samples to study the vascular niche in AML disease. We used two-photon confocal microscopy as a powerful tool to functionally image the BM vasculature in vivo. We used RNA-sequencing to study the AML-associated transcriptomic profile in vascular endothelial cells.

Results: We found several abnormalities in the vascular architecture and function in PDX, such as increased number of endothelial cells, increased microvascular density (MVD), loss of normal sinusoidal architecture and increased hypoxia. Moreover, vascular permeability was increased as measured via two-photon imaging. Interestingly, induction chemotherapy failed to normalize the vascular permeability in the BM, although it significantly reduced the AML engraftment. Via high-throughput transcriptomic analysis, we showed that AML-induced hypoxic environment altered the molecular signature of vascular endothelial cells, activating pro-angiogenic pathways and positively regulating hypoxia. Strikingly, inhibition of NO production in mouse models of AML and in AML-derived PDX reduced vascular permeability, preserved normal HSC function and significantly improved treatment response (Figure 1).

Figure 1.

Summary/Conclusions: We have shown an altered highly permeable vascular niche in the BM of AML PDX, mainly caused by increased NO production by the endothelial niche, contributing to disease progression and treatment failure. Our data call for clinical trials incorporating NOS inhibitors during the remission phase, to target the abnormal vascular niche and improve AML treatment response.

BUILDING HUMAN BONE MARROW-LIKE MODELS TO STUDY NICHE INTERACTIONS

H.-J. Prins1, T. Csikos1, R. de Jong-Korlaar1, R. Ruiters1, S. van Veen1, H. Yuan1, J. de Bruijn2, G. Ossenkoppele1, R. Groen1

1Hematology, VU University Medical Center, Amsterdam, 2Xpand Biotechnology BV, Blithoven, Netherlands

Background: Previously, we have reported that our human bone marrow-like scaffold (huBM-sc) xenograft model allows the engraftment and outgrowth of normal and malignant hematopoiesis (Tu et al. Blood 2012; Gutierrez et al. JCI 2014) and more recently acute myeloid leukemia (AML; Antonelli et al. Blood 2016). These studies show that i) engraftment is not correlated with prognostic risk-groups, ii) there is preferential outgrowth in humanized scaffolds compared to the murine BM, iii) the huBM-sc environment results in better maintenance of self-renewal potential and less clonal drift of the leukemic cells. Although the presence of human osteoblasts and bone mimics a human BM niche more closely than the murine BM in standard xenotransplant models (e.g. NOD-SCID/NSG mice), still some essential components of the human BM niche, i.e. human bone and vessels, are missing.

Aims: To implement human vasculature in the huBM-sc xenograft model in order to create a multi-tissue compartment that “maximally humanizes” the BM-like niche of our scaffolds.

Methods: Towards successful implementation of a human vascular system during engraftment we explored: i) scaffolds material composition (bioactive glass to phosphate (BCP) vs tricalcium phosphate (TCP)); ii) scaffold shape (particles vs tubes); iii) different types of matrigel for cord blood-derived endothelial progenitor cells (CB-EPCs) embedding.

Results: Histological analysis of these fully humanized scaffolds showed a large homogenous mixture of human hematopoietic cells CD31-positive and CD44, CD146, LEPR and nestin-positive stromal niche cells. Comparison of the composition and the shapes of the scaffolds indicated superior of TCP and tube-shaped scaffolds in supporting the formation of vessels. Engraftment of BM-derived CD34+ cells in the CB-EPC embedded huBM-sc resulted in increased multilineage hematopoietic engraftment, as compared to huBM-sc without CB-EPCs. Moreover, we observed that incorporation of CB-EPCs provides faster kinetics of engraftment of both patient-derived BM and AML cells, and proved to be essential for the engraftment of blast cells from myelofibrosis patients.

Summary/Conclusions: Thus, with the addition of human CB-EPCs and BM stromal cells, our scaffold systems now simulate both endosteal and vascular niches of the BM, thereby more closely recapitulating the human hematopoietic microenvironment.

Background: Adult bone marrow (BM) cavities host continuous, demand adapted and high through blood vessel cell production, which is maintained by a rare population of self-renewing, multipotent hematopoietic stem cells (HSCs). Aside from its diverse hematopoietic content, the BM is populated by a heterogeneous fraction of mesenchymal, endothelial and neural stromal cells, which provide the necessary tissue infrastructure for hematopoiesis, playing fundamental regulatory roles in hematopoietic development. Recent evidence suggests that tissue regions around BM venous microvessels (termed sinusoids), which are enriched for mesenchymal CXCL12-12-abundant reticular cells (CARCs), serve as the principal regulatory niches for HSCs as well as other hematopoietic progenitor populations. Despite this proposed role as putative specific niche-restricted components, comprehensive data on the frequency, global spatial distribution and topology of sinusoidal endothelial and CAR cell networks is largely lacking to date.

Aims: The principal aim of our work is to employ state of the art imaging techniques to perform a detailed 3D quantitative and structural analysis of the BM stromal infrastructure, with a special focus on sinusoidal microvasculature and the CAR cell mesenchymal component, both of which are essential regulators of HSC maintenance.

**TEMPLATED V(D)J INSERTIONS ARE A NOVEL BIOLOGIC MECHANISM FOR B-CELL RECEPTOR REPERTOIRE DIVERSIFICATION**

M.T. Koning1, L. Trollmann1, R. Rademakers2, R. Toes3, H. Vellekens1

1Department of Hematology, Leiden University Medical Center, Leiden, 2Gen-Mab, Utrecht, 3Department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands.

**Background:** Recently, large LAIR1 insertions at the V-D junction were described as a novel mechanism to generate antibodies against RIFIN antigens on infected erythrocytes (Tan et al., Nature 2016). These templated insertions potentially add a new biological mechanism used by the immune system to generate B-cell receptor repertoire diversity.

**Aims:** We investigated whether templated insertions occur in the B-cell repertoire of healthy donors and whether such insertions could be functionally exploited to explore their biological function.

**Methods:** We obtained >52,000 unique full-length VDJ sequences of IgM, IgG, IgA, and IgE isotypes by unbiased ARTISAN PCR (Koning et al., BJH 2016) from 6 healthy donors. Abnormally long sequences and junctions were searched for templated insertions by BLAST. Identified VDJ carrying templated insertions were co-expressed with a panel of 172 light chains on multiple myeloma cell lines and assessed for surface expression of transgenic immunoglobulin. The VDJ described by Tan et al. were included as controls.

**Results:** Six unique VDJ sequences, all from the same donor, carried a templated insertion in-frame (E=10−10−0). These sequences represented all VDJ sequences with a CDR3 region >150 bp. Exonic sequences from RPLP0, ZNF316, and an inverted IGHV-IGHD sequence were identified as insertions in unmutated IgM VDJ transcripts. The LAIR1 exon described by Tan et al. and an intergenic region adjacent to IGHD3-22 were identified as insertions in IgG VDJ transcripts. One IgA VDJ contained two intergenic sequences positioned close to IGHV4-37 in a homozygous chromosome 22. Somatic hypermutation correlated strongly between the IGHV segment and the templated insertions (r=0.9944; p<0.0001). All templated insertions harboured cryptic RSS sites at their termini. All three IgG VDJ carrying templated insertions and the IgG rearrangement with a templated insertion gave rise to detectable surface immunoglobulin after coexpression with at least one light chain in the panel. The IgG VDJ carrying the LAIR1 templated insertion produced no detectable surface immunoglobulin. In contrast, the VDJ sequences carrying LAIR1 templated insertions as described by Tan et al. could be expressed with the majority of the light chains. The IgA rearrangement remained to be tested in this system.

**Summary/Conclusions:** Templated insertions represent a novel antibody diversification mechanism. Their presence in naïve B-cells, their exclusive positioning in VDJ junctions, and the universal presence of cryptic RSS sites point to primary VDJ recombination or secondary V gene editing as the generating mechanism. Certain loci (e.g. LAIR1) and in some individuals appear to have increased susceptibility. The available data suggest RAG to be involved in these insertions. We propose that templated insertions represent inserted small sequences from aberrant rearranged chromosomal sequences with cryptic RSS sites.

**P268**

**TARGETING THE CASPASE / NOX2 AXIS TO MODULATE MACROPHAGE POLARIZATION**

S. Solier1, L. Meziani2, M. Mondini2, C. Lacout1, P.-M.C. Dang3, J.-C. Martineau4, P. Vandenabeele5, E. Deutsch2, O. Hermine6, N. Droin1, C. Dupuy7, J. El-Benna3, E. Solary1, 2INSERM UMR1170, 3INSERM UMR1030, Gustave Roussy, Villejuif, 4Department of Cell Biology, University of Geneva, Geneva, Switzerland, 5Institute of Clinical Hematology, Faculty of Medicine and AP-HP Necker-Enfants Malades, Paris, 6CNRS UMR8200, Gustave Roussy, Villejuif, France

**Background:** Caspases, which are key effectors of apoptosis, have demonstrated non-apoptotic functions. One of these functions is the differentiation into macrophages of peripheral blood monocytes exposed to Colony-Stimulating Factor-1 (CSF1). Conversely, GM-CSF induces the differentiation of monocytes into macrophages in a caspase-independent manner. Macrophages generated by CSF1 and GM-CSF have distinct polarity.

**Aims:** Macrophage polarization plays an important role in the pathogenesis of diverse human diseases as cancer, leading us to explore if caspase inhibition would affect macrophage polarization.

**Methods:** To explore the role of caspases in CSF1 differentiation, we used human monocytes sorted from buffy coats or from blood of NOX2-deficient patients treated by cytokines, and we generated monocyte-restricted caspase-8 knockout and caspase-8−/− and caspase-3−/− and caspase-7 double knockout mice, which were treated with bleomycin to induce pulmonary fibrosis.

**Results:** Caspase activation is involved in the generation of M2 polarized macrophages. Caspase inhibition delays the ex vivo differentiation of peripheral blood monocytes exposed to CSF1 and modifies the phenotype of generated macrophages, e.g., cell shape, surface markers and cytokine secretion. In mice, caspase knock-out also modified the phenotype of monocytes induced to differentiate into macrophages. Caspase activation appeared to be prominent at the mitochondria level and responsible for the NOX2-dependent generation of cytotoxic radical oxygen species (ROS). Activation of the NOX2 complex is associated with p47phox cleavage by caspases. Mice treated with bleomycin typically develop a pulmonary fibrosis. Bleomycin-induced lung fibrosis was delayed in monocyte-restricted caspase-8 knockout mice and prevented by treatment with a caspase inhibitor molecule, including zVAD-fmk and the clinically developed IDN6556. This effect was associated with a change in the phenotype of lung-infiltrating macrophages.

**Summary/Conclusions:** Caspase inhibition in monocytes prevent the development of bleomycin-induced lung fibrosis by modifying macrophage polarization, suggesting that caspase inhibitory molecules may be an exciting therapeutic strategy to modulate macrophage polarization with diverse applications including cancer treatment.

**MULTIPLE MYELOMA-POLARIZED M2C MACROPHAGES PROMOTE A TUMOR-SUPPORTIVE OSTEOLOGY MICROENVIRONMENT VIA CXCL13**

B. Beiler1, V. Voewoda1, B. Bleil1, B. Rosenberg1, H. Mager1, O. Ostroovsky1, E. Ribakovskyl1, A. Shimoni1, L. Weiss3, M. Abraham3, A. Peled2, A. Nagler1

1Hematology Division, Bone Marrow Transplantation, SHEBA MEDICAL CENTER, Ramat-Gan, 2Institute of Hematology, Davidoff Cancer Center, Rabin Medical Center, Petach-Tikva, 3Institute of Gene Therapy, Hadassah Hebrew University Hospital, Jerusalem, Israel

**Background:** Previous studies including our work revealed a role of MM-edited M2-like macrophages (MΦ) in MM survival and drug resistance. However, the mechanism by which neoplastic plasma cells shape BM microenvironment and affect MΦ polarization is still poorly defined.

**Aims:** To investigate tumour macrophage polarization in the myeloid compartment of the BM niche that are initiated by MM cells.

**Methods:** We utilized our in vivo xenograft model of BM disseminated human myeloma. The CRISPR/cas9 technology was used to knockdown CXCL13 expression in MM cell lines.

**Results:** BM analysis of mice inoculated with human CXCR4-expressing RPMI8226 cells revealed a significant increase in M2c MΦ in comparison to non-injected controls (p<0.01). Characterization of MM-associated changes in the BM milieu revealed myeloma chemotractant CXCL13 being one of the most profoundly increased factors upon MM development. Elevated CXCL13 was also detected in blood of MM-bearing animals comparing to healthy controls. IHC staining identified myeloid cells as the main source of increased murine CXCL13, both in BM and blood, suggesting the possible utilization of CXCL13 levels as surrogate marker of anti-MM treatments response.

**Conclusion:**CXCL13 expression by MΦ is known to represent specific inflammatory MΦ type, we acquired murine xenograft system for the observation of tumour-induced polarization of additional M2c markers, such as MERTK and MR1 in the BM occupied with MM in strong correlation with CXCL13 expression (p<0.001 R2=0.65). In vitro studies confirmed the ability of MM cell lines (n=6) to induce CXCL13 and current expression of M2c markers (MERTK, CD206, CD163) in co-cultured myeloma and MΦ cells. The anti-inflammatory and anti-MM effects of the treatment with anti-CXCL13 zomib and panobinostat resulted in corresponding correlated decrease in murine CXCL13, both in BM and blood, suggesting the possible utilization of CXCL13 levels as surrogate marker of anti-MM treatments response.

**CXCL13 expression by MΦ is known to represent specific inflammatory MΦ type, we acquired murine xenograft system for the observation of tumour-induced polarization of additional M2c markers, such as MERTK and MR1 in the BM occupied with MM in strong correlation with CXCL13 expression (p<0.001 R2=0.65). In vitro studies confirmed the ability of MM cell lines (n=6) to induce CXCL13 and current expression of M2c markers (MERTK, CD206, CD163) in co-cultured myeloma and MΦ cells. clastogenic assays were used to elucidate the down-stream effects of the elevated CXCL13. Recombinant CXCL13 opsonized as in human produced by co-cultured MM-MΦ increased RANKL expression and induced TRAP+ osteoclast (OC) formation in vitro, while CXCL13 neutralization blocked these activities. We next abrogated CXCL13 expression in MM cell lines using the CRISPR/Cas9 technology. The loss of CXCL13 had no effect on MM in vitro growth or drug sensitivity. However, mice inoculated with CXCL13-silenced MM cells developed significantly weaker BM disease compared to mice receiving the non-manipulated cells. Reduced tumor load correlated with decreased numbers of M2c-MΦ in BM, decreased bone disease, and lower expression of OC-associated genes. Finally, the presence of CXCL13 in primary MM samples was evaluated. Reduced levels of CXCL13 transcript and protein were detected in BM aspirates from MM patients (n=24) in comparison to normal BM (n=5) and were in correlation with gene expression signature associated with OC activation and M2c MΦ phenotype (Figure 1).

Figure 1.

Summary/Conclusions: Our findings suggest that bidirectional interactions of MΦ with MM tumor cells result in M2c MΦ polarization, CXCL13 induction and subsequent OC activation, enhancing their ability to support bone resorption and MM progression. CXCL13 may thus serve as potential novel target for the diagnosis and treatment of MM.

RE-ORDERING THE B CELL DEVELOPMENT HIERARCHY IN HUMAN FETAL BONE MARROW: CHARACTERISATION OF A NOVEL HUMAN FETAL B PROGENITOR

S. O’Byrne1*, N. Elliott1, G. Buck1, L. Liu1, B. Povinelli 2, N. Fordham2, E. Louka3, K. Bartolovic4, A. Karadimitris5, A. Mead2, I. Roberts1, A. Roy1

1Experimental Hematology, 2Department of Computational Biology, 3Department of Biostatistics, St. Jude Children’s Research Hospital, Memphis, United States

Background: The cellular hierarchy of normal human fetal B-lymphopoiesis remains poorly defined. We have previously identified a novel population of PreProB progenitors (CD34+CD19+CD10-) in fetal liver (FL)[1] that is further expanded in fetal bone marrow (FBM)[2], and co-exists with adult-type CD34+CD19+CD10+ ProB progenitors. Increasing evidence indicates that infant ALL and many cases of childhood ALL arise in fetal life, suggesting that ontogeny-related changes in B-cell development may be important for in utero leukemia initiation. Therefore, understanding the human fetal B cell hierarchy, especially the differences between PreProB and ProB progenitors may be key for understanding the origins of childhood leukemia.

Aims: To define the fetal B cell developmental hierarchy in the second trimester FBM, with a view to establishing the fetal B cell hierarchy.

Methods: The characteristics of the haematopoietic stem cell (HSC), lymphoid-myeloid multipotent progenitor (LMPMP), early lymphoid progenitor (ELP) and committed B-progenitor compartments of FBM samples were analysed by multiparameter flow cytometry. Differentiation and clonogenic assays, transcriptome analysis and single cell RQ-PCR were performed on a total of 633 endothelial precursors and 545 fetal liver hematopoietic precursors containing the indicated window of hematopoietic precursors specified during the indicated window of hematopoiesis. An alternative approach independent of embryo disruption or transplantation would more accurately reflect the true dynamics of hematopoiesis emerging during fetal development.

Aims: To determine the frequency of emerging HSCs and their progenitors throughout mammalian ontogeny.

Methods: Here, we employed the Confetti allele, in which a cassette targeted to the ROSE26 locus randomly and permanently marks cellular progeny with green fluorescent protein. We tested this formula in vitro by plating limiting dilution replicates of immortalized Confetti fibroblasts and assessing the resulting sample-to-sample variance in the distribution of Confetti colors in the blood of the following adult mice inversely correlated with the number of hematopoietic precursors specified during the indicated window of Cre recombinase activity: ROSE26[Confetti+] Fik(-/-Cr) (mesodermal precursors, E7), ROSE26[Confetti+] Vc-adherin(+/-Cr) (mesodermal endothelial precursors, E8.5-E10.5), and ROSE26[Confetti+] Vav1(+/-Cr) (hematopoietic progenitors E11.5-E14.5). This correlation was used to estimate the number of hematopoietic precursors emerging during each stage of development.

development. We thereby report for the first time that the clonal origin of blood is much more complex than previously thought, with hundreds of precursors contributing to the establishment of the mammalian blood system at multiple stages of ontogeny.

P272

A20 RESTAINS THYMIC REGULATORY T CELL DEVELOPMENT

T. Haas1,*, J. Fischer1, V. Otten1, S. Spoerl1, H. Poock1
1Klinik und Poliklinik für Innere Medizin III, Klinikum rechts der Isar, TU München, München, Germany

Background: Maintaining immune tolerance requires the production of Foxp3 expressing regulatory (Treg) cells in the thymus. Activation of NF-κB transcription factors is critically required for Treg cell development, partly via initiating Foxp3 expression. NF-κB activation is controlled by a negative feedback regulation through the ubiquitin editing enzyme A20, which reduces pro-inflammatory signaling in myeloid cells and B cells. In naive CD4+ T cells, A20 prevents necroptosis and promotes inflammation.

Aims: This study is aimed at analyzing the role of the NF-κB regulator A20 in Treg cell development and function.

Methods: We used A20fl/fl CD4Cre mice, which specifically lack A20 in T cells, to analyze the Treg cell compartment in vivo. We characterized expansion and differentiation of A20-deficient Treg cells in vitro. We performed competitive bone marrow engraftment between WT and A20-deficient bonemarrow in vivo to analyze whether one bone marrow compartment would outperform another or would favor development of certain T cell or other immune cell subsets. We performed allogeogenic hematopoietic stem cell transplantation with WT BM+T cells vs WT vs A20-deficient Treg cells to analyze whether A20-deficient T reg cells would reduce GVHD to the same extent as WT Treg cells.

Results: Using mice deficient for A20 in T lineage cells, we show that thymic and peripheral Treg cell compartments are quantitatively enlarged due to a cell-intrinsic developmental advantage of A20-deficient Treg cells. A20−/− Treg cells efficiently suppressed effector T cell mediated graft-versus-host disease after allogeogenic hematopoietic stem cell transplantation, demonstrating normal suppressive functionality. Holding thymic production of natural Treg cells in check, A20 thus integrates reduced regulatory T cell activity and increased effector T cell survival into an efficient CD4+ T cell response.

Summary/Conclusions: In light of the largely anti-inflammatory effects that have been attributed to A20 in many cell types, this proinflammatory aspect of A20 physiology in effector and regulatory CD4+ T cells is particularly important since it may contribute to a change of perception of the functions of A20 as a negative regulator of NF-κB in the context of inflammation. Whether targeted modulation of A20 activity allows the induction of Treg cell mediated immune tolerance or, alternatively, boosting of favorable T cell immunity is a question of translational relevance that needs to be addressed in the future.

P273

THE TRANSCRIPTION FACTOR C/EBPγ REGULATES MAST CELL DEVELOPMENT AND FUNCTION

M. Kardosova1,*, L. Potuckova2, I. Halova2, P. Zjablovskaja1, L. Draberova2, P. Draber2, M. Alberich-Jorda1
1Hematology, Laboratory of Signal Transduction, Institute of Molecular Genetics, Academy of Sciences of the Czech Republic, Prague, Czech Republic

Background: Mast cells are key effector cells involved in protection against infection and allergic responses. Defects in mast cells are related to immuno- logical disorders, and therefore it is critical to fully understand the transcriptional network that controls their generation and activity. Differentiation of progenitors to mature mast cells is promoted by several transcription factors, such as C/EBPγ, as a direct C/EBPα target gene. However, the role of C/EBPγ in mast cells remains so far elusive.

Aims: In this study we aim to determine the role of the transcription factor C/EBPγ in mast cell development and function. Next, we investigate the mechanisms by which C/EBPγ is controlling these processes.

Methods: In order to determine the role of C/EBPγ in murine mast cells, we generated Cebpg conditional knockout mice, which allow excision of Cebpg in the hematopoietic system from the early embryogenesis. We employed Cebpgfl/fl Vav-1Cre- and Cebpgfl/fl Vav-1Cre+ mice, referred here as WT and Cebpg KO, respectively. Excision of Cebpg was assessed by RT-PCR and western blot analysis in bone marrow and spleen cells. Using flow cytometry, we enumerated mast cell counts in the peritoneal cavity of healthy WT and Cebpg KO mice. To elucidate whether C/EBPγ plays role in mast cell response to bacterial infection, we challenged these mice intraperitoneally with lipopolysaccharide (LPS). We used intraperitoneal injection of distilled water to eradicate peritoneal mast cells and then monitored repopulation of peritoneum over time. To further explore the role of C/EBPγ in mast cells in vivo, we established bone marrow derived mast cells (BMMCs) and determined their growth (cell numbers), morphology (toluidine blue staining), and transcription factors expression (RT-PCR) at different time points. Degranulation potential of BMMCs was specified by measuring the percentage of b-glucuronidase released to the supernatant upon anti-TNP IgE sensitization and TNP-BSA activation. To investigate the effects of absence of Cebpg during mast cell migration, we employed transwell migration assays.

Results: We verified efficient ablation of Cebpg on mRNA and protein level in bone marrow and spleen of Cebpg KO mice. Analysis of peritoneal cavity of WT and Cebpg KO mice showed similar frequency and numbers of mast cells in steady state conditions. However, Cebpg deficient mice exhibit increased number of peritoneal mast cells after LPS stimulation in comparison to WT control littermates. Surprisingly, mice lacking Cebpg presented defective peritoneal mast cell repopulation. Since mast cells are scarce and difficult to isolate from in vivo models, we employed BMMCs to investigate the effects of Cebpg ablation in mast cell development and function. We observed that bone marrow from Cebpg KO mice generated reduced number of BMMCs in comparison to WT controls. Functionally, we demonstrated that deletion of Cebpg reduced mast cell migration towards antigen, SCF or PGE, and impaired degranulation upon FcεRI-mediated activation. Further, BMMCs exhibit increased expression of C/EBPα in the absence of C/EBPγ.

Summary/Conclusions: In summary, we revealed C/EBPγ as important transcription factor which suppresses C/EBPα expression, thereby favoring mast cell development and function. Our data identifies a new component of the mast cell transcriptional network and provides a better understanding of mast cells in normal physiological conditions and disease.
Hodgkin lymphoma

LONG-TERM OUTCOME OF PATIENTS WITH NODULAR LYMPHOCYTE-PREDOMINANT HODGKIN LYMPHOMA TREATED WITHIN THE RANDOMIZED HD7-HD15 TRIALS: AN ANALYSIS FROM THE GERMAN HODGKIN STUDY GROUP

D.A. Eichenauer1,*, A. Plütschow1, M. Fuchs1, B. von Tresckow1, V. Diehl2, P. Borochmann1, A. Engert1
1First Department of Internal Medicine, 2German Hodgkin Study Group, University Hospital Cologne, Cologne, Germany

Background: Nodular lymphocyte-predominant Hodgkin lymphoma (NLPHL) is a rare entity accounting for approximately 5% of all Hodgkin lymphoma (HL) cases. Pathological and clinical features differ from classical HL (cHL). Pathologically, the malignant lymphocyte predominant (LP) cells stain consistently positive for CD20 and are negative for CD30. Clinically, NLPHL often has a rather indolent course. Despite of these differences, the first-line treatment of NLPHL is mostly very similar to cHL. However, analyses on the long-term course of patients with NLPHL who were treated identically to cHL are scarce.

Aims: To shed more light on characteristics and outcome of NLPHL patients treated identically to cHL, we performed an analysis using the database of the German Hodgkin Study Group (GHSG).

Methods: A total of 471 patients with NLPHL who had received first-line treatment within the randomized GHSG HD7-HD15 trials for newly diagnosed HL were identified. The studies were conducted between 1993 and 2009. Patients at all stages (early favorable: HD7; HD10, HD12; early unfavorable: HD8, HD11, HD14; advanced: HD6, HD12, HD15) were included.

Results: Among the 471 NLPHL patients, the median age was 39 years; 76% of patients were male; 53% of patients had early favorable, 16% had early unfavorable and 31% had advanced-stage disease. Study treatment consisted of ABVD- or BEACOPP-based chemotherapy alone, radiotherapy (RT) alone or combined-modality treatment (CMT). After a median observation of 9.2 years, the 8-year progression-free survival (PFS) rate for the whole patient group was 81.3% (83.2% for early favorable, 85.2% for early unfavorable, 76.2 for advanced stages). 80 of 471 patients (17%) had refractory disease or relapsed during the course of follow-up (primary disease progression: 84 patients; early relapse: 6 patients; late relapse: 66 patients). Second malignancies including histological transformation into aggressive B-cell non-Hodgkin lymphoma (NHL) occurred in 48/471 patients (10%) (solid tumor: 25 patients; leukemia: 7 patients; NHL: 13 patients; unspecified malignancy: 4 patients). For all 471 patients included in the present analysis, the 8-year overall survival (OS) rate was 89.9% (95% CI: 87.3–92.4); the median survival was 161 months (19–139). The 5-year OS rate was 89% (95% CI: 82–92); the median OS was 197 months (12–249).

Summary/Conclusions: Taken together, the results from this large analysis on NLPHL patients prospectively treated and followed within randomized clinical studies for newly diagnosed HL indicate an excellent lymphoma-specific outcome. Nonetheless, further treatment optimization is necessary as the minority of these deaths was NLPHL-related (n=10). In contrast, most patients died from second malignancies (n=20) or due to other causes (n=13) such as heart failure and lung disease.

ADVANCED HODGKIN LYMPHOMA IN THE EAST OF ENGLAND CANCER NETWORK: A 10-YEAR COMPARATIVE ANALYSIS OF OUTCOMES FOR ABVD AND ESCALATED-BEACOPP TREATED PATIENTS Aged 16–59

J. Russell1,*, A. Collins2, A. Fowler3, M. Karanth4, C. Saha2, V. Shyamsundar1, S. Docherty1, K. Maw5, J. Padayatty6, A. Hodson7, J. Wimperis2, S. Sadullah5, N. Grigoropoulos1, B. Uttenthal1, G. Follows1

1Hematology, University of Naples Federico II, Naples, 2Department of Medicine and Surgery, University Medical School, Salerno, Salerno, 3Department of Economics, University of Molise, Campobasso, Italy

Background: Hodgkin lymphoma (NHL) occurred in 48/471 patients (10%) (solid tumor: 25 patients; leukemia: 7 patients; NHL: 13 patients; unspecified malignancy: 4 patients). The 5-year OS rate was 89% (95% CI: 82–92); the median OS was 197 months (12–249).

Methods: Between June 2001 and December 2009, we analyzed 306 patients – either newly diagnosed or relapsed during the course of follow-up (primary disease progression: 84 patients; early relapse: 6 patients; late relapse: 66 patients). Second malignancies including histological transformation into aggressive B-cell non-Hodgkin lymphoma (NHL) occurred in 48/471 patients (10%) (solid tumor: 25 patients; leukemia: 7 patients; NHL: 13 patients; unspecified malignancy: 4 patients). The 5-year OS rate was 89% (95% CI: 82–92); the median OS was 197 months (12–249).

Results: Among the 471 NLPHL patients, the median age was 39 years; 76% of patients were male; 53% of patients had early favorable, 16% had early unfavorable and 31% had advanced-stage disease. Study treatment consisted of ABVD- or BEACOPP-based chemotherapy alone, radiotherapy (RT) alone or combined-modality treatment (CMT). After a median observation of 9.2 years, the 8-year progression-free survival (PFS) rate for the whole patient group was 81.3% (83.2% for early favorable, 85.2% for early unfavorable, 76.2 for advanced stages). 80 of 471 patients (17%) had refractory disease or relapsed during the course of follow-up (primary disease progression: 84 patients; early relapse: 6 patients; late relapse: 66 patients). IMPACT ON SURVIVAL OF EARLY DETECTION OF RECURRENCE IN THE FOLLOW-UP OF HIGH RISK HODGKIN LYMPHOMA IN FIRST COMPLETE REMISSION

N. Pugliese1,*, L. Simeone1, R. Della Pepa1, C. Giordano1, I. Cappuccio1, I. Zacheo1, G. Campagna1, C. Cerchione1, P. Zeppa2, C. Salvatore3, F. Pane1, M. Picardi1

1Hematology, University of Naples Federico II, Naples, 2Department of Medicine and Surgery, University Medical School, Salerno, Salerno, 3Department of Economics, University of Molise, Campobasso, Italy

Background: Despite the high complete response (CR) rate to anthracycline-including first-line therapy, approximately one-third of patients with advanced-stage Hodgkin lymphoma (HL) relapses. Many relapses (30–50%) are clinically asymptomatic, without any physical and/or laboratory signs. For patients at high-risk of relapse, a close monitoring, based on imaging procedures is justified if an early detection of recurrence would allow a timely administration of salvage therapy and a survival improvement.

Aims: The purpose of this study was to evaluate the response rate to salvage therapy of relapsed HL by comparing patients who received surveillance with conventional clinical assessments versus patients who received surveillance with imaging procedures. The primary end-point was to assess the rate of CR to salvage therapy at first relapse (confirmed by FDG PET/TC performed before 1st line chemotherapy in 93% of patients). Secondary endpoints were: the overall rate of recurrence after first salvage therapy, the OS at 3 years, the CR rate at 3 years, and the OS at 5 years.

Methods: We collected data retrospectively from 8 hospitals in the East of England, from a 10-year period from a referral population of 2.64 million (incidence: 0.95 cases per 100,000). Six of the 8 centres introduced escB vs. ABVD (PFS 95% vs 82%; HR 4.3 (95% CI:1.97–9.7), p=0.0261, but there was no difference in OS (5-year OS 97% vs 92%; HR 2.6 (95% CI:0.69–10.4), p=0.312). However, patients with IPS 3+ had both a PFS and OS advantage when treated with escB compared with ABVD (5-year PFS 95% vs 87%; HR 3.0 (95% CI:1.43–6.89), p=0.00001 vs 82%; HR 3.0 (95% CI:1.43–6.89), p=0.00325). Twenty-nine ABVD patients and 3 escB patients had at least 1 subsequent stem cell transplant (including 6 allografts post-ABVD and 3 allografts post-escB), and there was equal use of consolidation radiotherapy between regimens (11% of both ABVD and escB patients). Treatment-related infertility is an important consideration for escB patients. In our patient population, of the 20 pre-menopausal women treated with escB, 11 of the 14 (78.6%) aged <30 years at diagnosis regained menstrual periods during follow-up, 5 (45.5%) of whom subsequently conceived (including 6 live births, 1 miscarriage, and 1 termination). Only 1 of the 6 (16.7%) pre-menopausal women treated with ABVD reached >30 years at diagnosis regained menstrual periods, which were not sustained beyond 3 years’ follow-up.

Summary/Conclusions: Our data reflect clinical trials results which indicate a first-remission PFS but not OS advantage for unselected young advanced-stage HL patients treated with escB compared with ABVD. However, our data strongly suggest that patients with a poor IPS score derive a PFS and OS benefit from treatment with escB compared with ABVD.
months after treatment discontinuation in both groups. Relapses were documented by histologic examination in both groups. When relapse was documented all patients received salvage therapy with high dose chemotherapy (DHAP), for at least two courses, followed, in case of CR, by ASCT.

**Results:** After a median 62-months observation (range, 4–108), 83 patients, evenly distributed in the two groups, had a relapse of disease. Of these, 29 of 43 patients (67.4%) of the historical cohort vs 17 of 40 patients (42.5%) of the imaging cohort, showed a larger spread of disease at restaging, i.e. stage superior to IIB, and a more frequent extranodal involvement, 10/43 (23.3%) patients in the historical group vs 3/40 (7.5%) patients in the imaging group (p=0.01).

Furthermore, if we considered only asymptomatic patients, one recurrence was detected in 26 of 43 patients in the imaging group and 17 of 40 patients in the historical group, p=0.02. CR rate with second line therapy were higher in the imaging group (27, 67.5%) compared with the historical group (19, 44.2%; p=0.032). The 3-years DFS was 75% in the imaging group and 36% in the historical group, p=0.02.

**Summary/Conclusions:** This is the first prospective case-control study using SNAP-US plus CXR to monitor patients with advanced stage HL. We show that SNAP-US plus CXR is a valuable tool to improve follow-up in patients with a high risk of recurrence. Our data indicate that the early detection of HL recurrence allows to begin rescue therapy in patients with a more limited disease and, consequently, increase its effectiveness in terms of probability to response and DFS.

**P278**

**LATER LINE DRUG TREATMENT PATTERNS OF CLASSICAL HODGKIN’S LYMPHOMA PATIENTS IN CANADA, FRANCE, GERMANY AND THE UNITED KINGDOM.**

K. Byrne1,*, A. Juarez Garcia2, P. Hallworth1, S. Blackburn1, M. Lees3

**Aim:** To understand the natural history and treatment patterns of patients with advanced stage classical Hodgkin’s lymphoma (cHL). Real-world data indicates an unmet medical need for new treatment strategies.

**Methods:** A total of 961 patients were identified. Median age was 41 (range 18-91) and 60.9% (n=585) were younger than 50. The group included a mild predominance of males (55.5%). Only 1.7% (n=16) had extranodal involvement at presentation. Of those with known histology (78.8%), the most common was nodular sclerosis (71.2%), followed by mixed cellularity (22.8%), lymphocyte rich (3.8%) and lymphocyte depleted (1.9%). Median follow up time was 45 months (range 0-136). The 10-year overall survival for the favorable group (n=329) was 77% (95% CI: 71.1-88.8) versus 68% for the unfavorable group (n=144) and 42% for the advanced group (372) (p<0.001). There was no statistical difference in survival between stage I (n=170), and stage IV (n=385) disease (p=0.99). Treatment modalities were similar across the markets; Canada (34%), France (35%), Germany (30%) and the UK (44%) (p=0.10).

**Results:** The most commonly prescribed 3rd line treatment was a brentuximab-vedotin (BV) based regimen (35%). BV use was significantly different across the markets; Canada (34%), France (35%), Germany (30%) and the UK (44%) (p=0.010). The next most commonly prescribed 3rd line treatments were DHAP (8%), BEAM (7%) and bendamustine (7%). 4% of 3rd line patients received a PD-1 inhibitor. 3rd line BV patients the majority received ABVD (69%) or BEACOPP (19%) at 1st line. Most common 2nd line drug treatments were DHAP (21%), ICE (10%), ESHAP (9%) and BEACOPP (9%). 59% of all 3rd line BV patients had undergone an auto/alloSCT at some point during their treatment history. Of 3rd line patients receiving non BV-based regimens 6% had been treated with BV previously (1st/2nd line). 3rd line patients treated with a PD-1 inhibitor 7% had been previously treated with BV. Data for 453 cHL patients on 4th line drug treatment was captured. 4th line patients had a mean age of 55.5 years (SD: 16.79) at the point of data capture. 56% were male, 44% female. 83% had been tested for EBV, 38% confirmed positive. 30% of 4th line patients received a BV based regimen – BV use across markets was significantly different; Canada (20%), France (38%), Germany (23%) and the UK (36%) (p=0.007).

**Summary/Conclusions:** Our large data cohort shows the presence of B symptoms in a state-wide cancer registry for cHL patients treated with chemotherapy alone vs patients treated with both chemotherapy and radiation.
THE IMPACT OF TREATMENT WITH BRENTUXIMAB VEDOTIN ON OVERALL SURVIVAL OF PATIENTS WITH HODGKIN LYMPHOMA RELAPSED AFTER AUTOLOGOUS STEM CELL TRANSPLANTATION. A NATIONWIDE POPULATION BASED ANALYSIS

1Second Dept of Internal Medicine, 2Hematology and Bone Marrow Transplantation, National and Kapodistrian University of Athens, Athens, 3Hematology and Bone Marrow Transplantation, Papanikolou General Hospital, Thessaloniki, 4Hematology Department, National and Kapodistrian University of Athens, Athens, 5Hematology Department, Iatriko Athion, Athens, 6Hematology Department, University of Thessalia, Larissa, 7Hematology Department, Metaxa Oncology Hospital, Piraeus, 8Hematology Department, Gennimatas General Hospital, Athens, 9Hematology Department, University General Hospital of Crete, Heraklion, 10Hematology Department, University General Hospital of Thrace, Alexandroupolis, 11Hematology Department, University General Hospital of Ioannina, Ioannina, 12Bone Marrow Transplantation, University General Hospital of Patras, Patras, 13Hematology Department, YGIEA General Hospital, Athens, 14Hematology Department, Pagapegiourou General Hospital, Thessaloniki, 15Hematology Department, Air Force General Hospital of Athens, 16Hematology Department, Department 401 Military Hospital of Athens, 17Hematology and Bone Marrow Transplantation, Evangelismos General Hospital, 18Hematology Department, Henry Dyanon Hospital, Athens, Greece

Background: Patients with Hodgkin Lymphoma (HL) who relapse after autologous stem cell transplantation (auto-SCT) have a dismal prognosis. Advanced disease stage, presence of B-symptoms, extranodal involvement at the time of relapse and duration of remission of less than 12 months are parameters associated with decreased overall survival (OS). Brentuximab Vedotin (BV), an anti-CD30 monoclonal antibody conjugated to a microtubule-disrupting agent, has shown clinical efficacy in HL. Although in the setting of post-auto-SCT relapse, BV produces an overall response rate of approximately 75% with a median progression free survival (PFS) of 9 months, the impact of BV on OS has not been addressed in previously published studies.

Aims: To examine the impact of treatment with BV on OS of patients with HL relapsed after auto-SCT.

Methods: Data for patients with HL who underwent auto-SCT in Greece during the last 20 years were collected. Study group consisted of 214 patients who experienced post auto-SCT relapse. In order to examine the impact of BV on OS, patients were divided in 2 cohorts depending of the date of BV availability in Greece (January/2013). Cohort 1 consisted of 178 patients who relapsed before January/2013, while Cohort 2 consisted of 36 patients relapsed after BV became available. Patient’s characteristics are shown in Table 1.

Table 1. Patients characteristics.

The following variables were included in a multivariate Cox proportional hazard regression analysis model: 1) age of patient, 2) Sex, 3) B-symptoms (yes vs no), 4) Stage of disease (I-II vs III-IV), 5) extranodal disease, 6) time from auto-SCT to relapse (≤12 vs >12 months), 7) Relapse before or after BV availability (Cohort 1 vs Cohort 2). In order to exclude any confounding effect of subsequent treatments, analysis was performed by censoring patients at the time of allo-SCT or treatment with IC-inhibitors (data not shown). In multivariate analysis the following variables were statistically associated with OS: 1) The presence of B-symptoms [HR=2.07, (95% CI, 1.39-3.07), p=0.001] and 2) Relapse in less than 12 months after auto-SCT [HR=3.45, (95% CI, 3.35-3.55), p=0.001] were associated with decreased OS, while 3) Response after 1st salvage [HR=0.46, (95% CI, 0.31-0.68), p=0.001], and 4) BV availability [HR=0.36, (95% CI, 0.16-0.79), p=0.011] were associated with increased OS (Figure 1). Similar results were obtained when analysis was performed without censoring patients at the time of allo-SCT or treatment with IC-inhibitors (data not shown). The endpoint was the overall response rate (ORR); secondary endpoints were overall survival (OS), PFS, and safety. The response was assessed by positron-emission tomography/computed tomography or CT. Early radiological evaluation results of our study strongly suggest that BV improves OS in patients with HL relapsed after auto-SCT. To our knowledge this is the first study showing an OS advantage of treatment with BV.

NIVOLUMAB FOR RELapsed OR REFRACTORY HODGKIN LYMPHOMA: EXPERIENCE IN TURKEY

Background: The programmed death-1 (PD-1) inhibitors have been approved by FDA for patients who relapse following autologous stem cell transplantation and brentuximab vedotin (BV) therapy.

Aims: This retrospective multicenter study aimed to provide information about the efficacy and safety of nivolumab in the “real-life” setting in Turkey.

Methods: 23 centers from Turkey participated in this study. Eligible patients were required those treated with at least 1 course of nivolumab and with available radiological response evaluation. The decision about inclusion of patients with an ICC decision was made by the attending physician. Patients received nivolumab via a named-patient program, and there was no restriction for BV-and/or transplantation-naive cases. Nivolumab was administered at a dose of 3 mg/kg iv infusion over 60 min q2wk in outpatient setting until death of any cause, unacceptable toxicity, withdrawal of consent, or primary physician’s decision. The study was approved by the local ethical committee. The primary endpoint was the overall response rate (ORR); secondary endpoints were overall survival (OS), PFS, and safety. The response was assessed by positron-emission tomography/computed tomography or CT. Early radiological evaluation

Figure 1.
Results: Between 06/2015-11/2016, 87 patients were enrolled in a name-based program in Turkey. Two, 19, and 5 patients who had not yet received nivolumab, had not reach the time for early radiological evaluation, and who died before any radiological evaluation were excluded from the analysis. Thus, 63 patients from 23 centers were retrospectively analyzed. Median follow-up was 6 months, median age was 29 (18-75) and patients had a median 5 (2-11) previous lines of therapy. 44 patients (70%) had been treated by stem cell transplantation (SCT) and 45 (76%) patients had been treated by BV. The ORR was 66% with 15 CR (95%CI 0.020-0.28); CR 26%, PR 42%, SD 12%, PD 20%) among 59 patients evaluated in 12 weeks of nivolumab treatment. The ORR was 67% with 9 (24%) patients with CR after 16 weeks of treatment (95%CI 0.004-0.26; CR 24%, PR 43%, SD 6%, PD 27%). Estimated OS was 95% (95%CI 0.80-0.98) and estimated PFS was 71% (95%CI 0.55-0.82) at 12-months. Median OS was not reached, while, according to the late radiative responses, the median PFS was 14 months. However, it was only 3 months in patients with PD at the late radiological evaluation. Regarding responses to last treatment prior to nivolumab, we detected that 28 (67%) of 42 PD cases had objective early responses and 70% of PD cases had ORR in the late response evaluation (CR in 4, PR in 12 pts). 8 patients underwent post-transplantation following nivolumab. Among 5 patients who had been treated by allo-SCT, 4 had CR at the time of transplantation and they are alive with ongoing response. Safety profile was acceptable and only two patients required cessation of nivolumab due to serious adverse events: one due to autoimmune encephalitis and one due to aggravation of graft versus host disease. At the time of analysis, 40 cases were still on nivolumab treatment (64%). Among the 40 cases with early objective responses to nivolumab, 35 (88%) showed ongoing objective responses. All 24 cases with objective responses in the late evaluation had ongoing responses at the time of analysis (Figure 1).

Figure 1.

Summary/Conclusions: In conclusion PD-1 blockers are new options to meet the unmet need in patients with chL refractory to BV treatment, and possibly a bridge for these patients before transplantation.

P282

GENOTYPING OF HODGKIN LYMPHOMA ON THE LIQUID BIOPSY

1Institute of Oncology Research, Bellinzona, Switzerland, 2Department of Oncology and Haematology, Humanitas Cancer Center, Humanitas Clinical and Research Center, Milan, 3Division of Pathology and Histology, 4Institute of Hematology, Catholic University of the Sacred Heart, Rome, Italy, 5Oncology Institute of Southern Switzerland, Bellinzona, Switzerland, 6Division of Hematology, Department of Translational Medicine, University of Eastern Piedmont, Novara, Italy

Background: In classical Hodgkin lymphoma (cHL) the low representation (1-5%) of Reed-Sternberg cells (RS) challenged tumor genotyping on the diagnostic tissue biopsy. Consistently, the mutational profile of newly diagnosed cHL is poorly characterized, and the genetics of refractory disease is completely unknown. Cell free DNA (cfDNA) is shed into the blood by tumor cells under-going apoptosis and can be used as source of tumor DNA for the identification of somatic mutations. In addition cfDNA is representative of the entire tumor heterogeneity, thus allowing the identification of mutations from tumor cells residing in non-biopsied sites.

Aims: This study aims: i) at providing the evidence that the mutational profile of cHL can be tracked by using plasma cfDNA; and ii) at characterizing the genetics of newly diagnosed cHL and, for comparative purposes, of refractory cHL.

Methods: The study incudes 28 newly diagnosed cHL and 9 chemorefractory cHL. All cases were provided with cfDNA from plasma collected at baseline, before treatment start, and paired DNA from granulocytes as source of germline DNA to filter out polymorphisms and sequencing noise. Paired genomic DNA from formalin fixed paraffin embedded (FFPE) tumor tissue biopsies was available for 17 patients, including 3 cases for which RS enriched areas were macrodissected. A targeted resequencing panel optimized to include the coding exons and splice sites of 77 genes (192Kb) that are recurrently mutated in B-cell lymphomas was used for genotyping. Libraries were prepared from plasma cfDNA, germline gDNA and tumor gDNA according to the CAPP-seq targeted enrichment strategy (Nimblegen) and subjected to ultra-deep-next generation sequencing (NGS) on the MiSeq platform (llumina). The sequencing was tailored to obtain a depth of coverage >2000x in >80% of the target region in all samples, which allowed a sensitivity of 3x10-3. The somatic function of VarScan2 was used to call non-synonymous somatic mutations, and a stringent bioinformatic pipeline was applied to suppress the background noise and to filter out sequencing errors.

Results: In newly diagnosed cHL, genotyping of plasma cfDNA identified non-synonymous somatic mutations in STAT6 (43%), TNAIP3 (43%), ITPKB (32%) B2M (21%), GNA13 (14%), CIITA (7%), XPO1 (7%) and CD58 (4%) among the most recurrently affected genes (Figure 1A-B). In refractory cHL patients, genotyping of plasma cfDNA identified non-synonymous somatic mutations in ITPKB (44%), TNAIP3 (33%), KMT2D (33%), B2M (33%), GNA13 (33%), XPO1 (22%), TET2 (22%), K6BKB (22%), BIRC3 (22%) and STAT6 (22%) among the most recurrently affected genes. Mutations of KMT2D (33%) and TET2 (22%) were enriched in refractory chL patients compared to newly diagnosed cases, suggesting that they contributed to the chemorefractory phenotype (Figure 1C-D). By using highly sensitivity techniques, most of the mutations discovered in cDNA were also identified in pair tumor DNA from the tissue biopsy and/or macrodissected RS cells, thus confirming their tumor origin (Figure 1F). By pathway analysis, the mutational profile pointed to the involvement of PI3K/AKT signaling, retinoblastoma signaling, NF-κb signaling and the immune escape in cHL. ITPKB (a negative regulator of the PI3K/AKT signaling pathway) was specifically mutated in cHL across aggressive B cell lymphomas.

Figure 1.

Summary/Conclusions: This study provides the evidence that chL can be genotyped using plasma cfDNA as source of tumor DNA, pointing to a non-overlapping genotype between newly diagnosed and refractory cases, and identified ITPKB as a new gene specifically involved in ~30-50% of cHL patients.
P283
FDG PET-CT MAYBE A USEFUL TOOL TO IDENTIFY DOXORUBICIN INDUCED CARDIOTOXICITY IN HODGKIN LYMPHOMA
G. Sambuceti1, E. Arboscilo1, P. Spatarossa1, M. Miglino1, M. Baucknecht1, F. Fiz1, S. Morbelli1, G. Ferrarazzo1, A. Bellodi1, A. Da Col1, D. Avenoso1, F. Bellerini1, M. Bergamaschi1, L. Mitscheunig 1, M. Sarocchi1, C. Brunelli1, M. Gobbi1, R. Lemoli1
1IRCSc San Martino - IST, Genova, Italy
Background: Doxorubicin (DXR) induced cardiotoxicity is related to several mechanisms, including interference of mitochondrial respiratory chain and acceleration of glycolysis. We previously reported that this treatment may enhance myocardial FDG uptake.
Aims: The present study aimed to verify whether this metabolic response on serial PET/CT imaging can predict myocardial function, non-invasively evaluated by follow-up echocardiography (ECHO).
Methods: 18F-FDG PET/CT of 25 patients affected by Hodgkin Disease (HD), treated following ABVD scheme were analyzed. Inclusion criteria were: 1) availability of 4 consecutive PET/CT scan for staging (PET1), interim (PET2), post-therapy (PET3) and six months follow-up evaluation (PET4); 2) full remission after two ABVD cycles; 3) normal baseline EKG and ECHO findings and 4) no concurrent treatment with external thoracic radiotherapy. A volume of interest was manually drawn on the left ventricular myocardium. Average standardized uptake values (SUV) measured in the inferior vena cava to obtain LV-SUV. All patients was manually drawn on the left ventricular myocardium. Average standardized uptake was calculated as: SUV = counts/milliliter
Results: LV-SUV progressively increased from PET1 to PET4 in 6 patients (24%, 2 females, mean age 39±17, termed “increasers”) being 1.34±0.9, 3.34±2.6, 4.32±2.8 and 4.43±1.5 respectively. In the remaining 19 patients (76%, 7 females, 36±14), FDG uptake showed a largely variable response without any progressive increase. Accordingly, the ratio between PET4 and PET1 LV-SUV in the two subgroups was 3.85±0.8 and 1.06±0.4, respectively (p<0.001). Up to six months after therapy discontinuation, none of the 25 patients showed signs or symptoms potentially related to DXR cardiotoxicity. However, late follow-up ECHO detected the appearance of first-degree diastolic impairment in 4 patients (16%). In the remaining 21 patients, no significant changes were observed.
Summary/Conclusions: The present data indicate that DXR related myocardial damage can be preceded by an enhanced glucose uptake. 18F-FDG PET/CT imaging might represent a useful tool to identify high-risk patients and to implement personalized program to monitor and prevent DXR-induced cardiotoxicity.

ELEVATED SYSTEMIC HEME AND IRON LEVELS AS RISK FACTORS FOR VASCULAR DYSFUNCTION AND ATHEROSCLEROSIS: EVIDENCE FROM B-THALASSEMIA AND HEMOCROMATOSIS COHORT STUDIES
1Molecular Medicine Partnership Unit (MMPU), University of Heidelberg & EMBL, Heidelberg, Germany, 2University of Porto, Porto, Portugal, 3Vascular Biology Center, University of Minnesota, Minneapolis, United States, 4Department of Hematology, The Hebrew University Hadassah Medical Center, Jerusalem, Israel, 5Department of internal Medicine, AlShifa hospital, 6Laboratory department, European Hospital of Gaza, Gaza, Palestinian Territory, Occupied, 7European Molecular Biology Laboratory (EMBL), Heidelberg, Germany, 8Department of Hematology, Assuta Medical Center, Tel-Aviv, 9The Edith Wolfson Medical Center, Holon, Israel
Background: Increasing evidence from animal studies suggests that free heme exerts vasculotoxic, pro-inflammatory and pro-atherogenic effects due to its ability to trigger endothelial and immune cells activation. Moreover, we recently demonstrated a role for iron in the pathogenesis of atherosclerosis, analyzing a mouse model of type IV hereditary hemochromatosis, hallmarked by severe iron overload. We also showed that iron-deficient diet and chelation therapy prevent atherosclerosis progression in those mice.
Aims: Here we aimed at evaluating the clinical relevance of these findings and whether parameters of vascular status correlate with iron levels and suggest a predisposition to vascular dysfunction and atherogenesis in iron-overloaded individuals.
Methods: To this purpose we examined serum samples from a cohort of patients with β-thalassemia major and intermedia, who received recurrent blood transfusions but inconsistent chelation therapy, and a cohort of patients with hereditary hemochromatosis (HFE C282Y homozygous mutation), treated with phlebotomy.
Results: 25 of 396 (6.4%) patients showed high systemic heme and iron levels, which correlate with a severe drop in the plasma scavengers for hemoglobin and heme, Haptoglobin and Hemopexin, respectively. Hemochromatotic patients showed increased iron levels and reduced hepcidin levels. Consistently, in the two cohorts, transferrin saturation, non-transferrin bound iron (NTBI) and serum ferritin are elevated. Interestingly, both thalassemic and hemochromatotic patients present with high systemic levels of soluble adhesion molecules (sVCAM-1, sICAM-1, sE-Selectin, sP-Selectin) and reduced nitrotyrosine levels, hallmarks of endothelial activation and vascular dysfunction. In addition, they show increased serum lipid peroxidation, elevated circulating oxidized LDLs and high pro-inflammatory cytokines, which are known to promote atherosclerosis. All parameters significantly correlate with increased systemic heme and iron indices, including NTBI, as well as decreased scavenger levels.
Summary/Conclusions: These results emphasize the involvement of serum hemoglobin, heme and iron in the pathogenesis of vascular dysfunction in β-thalassemia and hemochromatosis and suggest a pro-atherosclerotic role for these molecules. These findings are relevant, on one side, for cardiovascular diseases and vasculopathy, when iron parameters are altered, and on the other, for iron overload disorders, where premature atherosclerosis might develop. Finally, our data highlight the key protective role of heme/iron scavengers and support the potential therapeutic benefit of chelation therapy to counteract heme/iron-driven vascular toxicity and atherosclerosis in hemolytic and iron-overload conditions.

P285
REAL-WORLD ADHERENCE TO IRON CHELATION THERAPY: COMPARING A FILM-COATED TABLET VERSUS DISPERSIBLE TABLET OF DEFERASIROX
W. Cheng1, Y. Xiao2, P. Bobbili1, A. Coe3, Y. Hao3, C. Paley3, Q. Said3, V. Huang3, M.S. Duh1, M. Blinder4
1Analysis Group, Inc., Boston, United States, 2Groupe d’analyse, Lîle, Montreal, Canada, 3Novartis Pharmaceuticals, East Hanover, 4Washington University School of Medicine, St. Louis, United States
Background: Iron chelation therapy (ICT) is effective in removing excess iron and preventing iron overload-related complications in patients (pts) with transfusion-related iron overload. However, adherence to ICT has historically been suboptimal. While deferasirox (DFX) dispersible tablet (DT) has shown better adherence than other oral and non-oral ICT agents, adherence could be further improved. The recently approved DFX film-coated tablet (FCT) provides a simpler method of oral ICT administration, and was found to have improved patient adherence as compared to DFX DT in the recent ECLIPSE clinical trial (NCT02125877). Real-world evidence outside of a trial is lacking.
Aims: To assess and compare real-world adherence and persistence to ICT in pts switching from DFX DT to DFX FCT.

Iron metabolism, deficiency and overload
Methods: A retrospective pre-post cohort study was conducted in pts switching from DFX DT to FCT using pharmacy and medical claims (06/2014 - 05/2016) from the Symphony Health Solutions’ Integrated Dataverse (IDV®) database. Eligible pts were ≥2 years old, had a diagnosis of an inherited or acquired hematological disorder requiring transfusions (e.g. sickle cell disease, myelodysplastic syndrome), ≥2 DFX DT claims (1st claim=index date), ≥2 DFX DT claims for the 36 months of continuous activity (i.e. no gap between periods) pre-index. Medication possession ratio (MPR) (percentage of time with access to medication) was computed for DFX DT during the “DFX DT period” (from earliest DFX DT claim to index date) and for FCT during the “DFX FCT period” (from index date to end of data availability/ICIT switch). In DFX DT, patients received DFX DT at a dose of 30.7 mg/kg/day (±5% variability) and were assessed for adherence to DFX DT and DFX FCT periods over fixed intervals of 3 and 6 months, which started from the index date in the DFX FCT period, or dispensing date of the most recent DFX DT claim prior to the beginning of a 3- or 6-month interval in the DFX DT period. Comparisons between the two periods were made using Wilcoxon sign-rank test for continuous data and McNemar’s test for dichotomized data.

Results: Of the 606 eligible pts, 56% were female, 64% were <35 years old, and 42% had transfusions during the baseline period. The median durations of the DFX DT and DFX FCT periods were 350.5 days and 290.2 days, respectively. Compared with adherence to DFX DT, adherence to DFX FCT was significantly improved across all measures. Mean MPR of DFX DT vs DFX FCT was 0.80 vs 0.76 (p<0.001); 60.9% pts had a mean MPR ≥0.8 during the DFX FCT period compared to 54.3% during the DFX DT period (p<0.01). Mean 3-month PDC of DFX DT vs DFX FCT was 0.83 vs 0.71 (p<0.001); 50.0% of pts had mean 3-month PDC ≥0.8 during the DFX FCT period compared to 34.5% during the DFX DT period (p<0.001). The proportion of pts with 3-month persistence to DFX DT vs DFX FCT (without a gap ≥30 days) was 87.2% vs 63.4% (p<0.01). Similarly consistent and significant results for PDC and persistence were observed using a 6-month time interval and/or a 60-day gap between claims.

Summary/Conclusions: Adherence and persistence to ICT was significantly improved in pts who switched from DFX DT to DFX FCT. Reasons for switching, which may contribute to improved adherence, were not examined in this study. Nevertheless, since the majority of pts were already adherent to DFX DT, the increased adherence to DFX FCT can be further augmented with this formulation. This real-world study complements the ECLIPSE trial results and supports previous evidence of improved adherence to DFX FCT.

P287

ASSESSMENT OF THE PERFORMANCE OF A WIDELY AVAILABLE T2*/R2* LIVER IRON CONCENTRATION METHOD USED IN CLINICAL PRACTICE IN A POPULATION OF THALASSEMIA PATIENTS

N. Tran1,*, N. Thanh3, N. T.H. Hu1, D. Thinh1, N. Khi Viet2, P. Minh Thong1, N. Anh Thi3, B. Quoc Khanh2, M. House3, W. Pang3, S. Boulou3, T. St Pierre3, 1Radiology Department, Bach Mai Hospital, 2National Institute of Hematology and Blood Transfusion, Hanoi, Vietnam, 3School of Physics, The University of Western Australia, Crawley, 4Resonance Health, Claremont, Australia

Background: Measurements of liver iron concentration (LIC) by magnetic resonance imaging (MRI) have become established and validated in several research intensive centers. While the validity of spin density projection assisted (SDPA) T2-MRI together with a core laboratory service has been validated in routine clinical practice settings, methods relying on in-house establishment of data acquisition protocols and data analysis have not yet been validated in this way.

Aims: To determine the limits of agreement between measurements of LIC by a widely available T2*/R2* MRI method and a reference standard SDPA R2-MRI method in a routine clinical practice setting.

Methods: LIC measurements were performed in 606 Thalassemia and β-Thalassemia patients referred by the National Institute of Hematology and Blood Transfusion, Hanoi, Vietnam for routine LIC measurement by MRI were prospectively recruited with informed consent. Patients were randomized to be scanned in either a Philips Ingenia or a Siemens Avanto 1.5T scanner. The LIC of each patient was measured twice, once by a T2*/R2* technique usually used in clinical practice and twice by an SDPA R2-MRI technique (iron calculation). The geometric mean ratios of the two LIC measurements were significantly different for the two scanners (0.28 for Philips and 0.68 for Siemens, p < 0.0001) indicating the bias of the T2*/R2* method against the reference standard is not universal but is dependent on both/either scanner type and/or data acquisition method. Bland Altman analysis indicates that 95% of pairs of measurements are predicted to have ratios between 3.73 and 0.05 indicating a very large random variation between the T2*/R2* method and the reference standard. The performance of the T2*/R2* method against the reference standard is not universal but is dependent on both/either scanner type and/or data acquisition method. Bland Altman analysis indicates that 95% of pairs of measurements are predicted to have ratios between 3.73 and 0.05 indicating a very large random variation between the T2*/R2* method and the reference standard. The performance of the T2*/R2* method against the reference standard is not universal but is dependent on both/either scanner type and/or data acquisition method. Table 1. Thresholds of 7 and 15 mg Fe/g dw is characterized in the Table 1 showing positive predictive values (PPVs) and negative predictive values (NPVs) together with their 95% CIs.
Summary/Conclusions: The data indicate that the T2*/R2* method of measurement of LIC is not safe for routine clinical measurement of LIC because of the extremely poor NPVs which could result in inappropriate clinical decision making. The severe discrepancies of the T2*/R2* method from the reference standard are likely caused by several factors including non-optimal curve fitting algorithms, lack of a method to identify non-analysable data, and the use of a calibration curve from the literature generated from data acquisition and analysis methods different from those used locally. These or similar pitfalls are likely to be encountered in many MR centres using non-regulated MR methods of LIC measurement.

Figure 1.

Summary/Conclusions: This retrospective study of long-term renal safety in patients receiving iron chelation for transfusional iron overload suggests that long-term deferasirox treatment, or administration of ≥1 deferasirox dose followed by other chelators, did not have an overall detrimental long-term effect on renal function as monitored by SCR. This analysis provides no evidence of progressive renal function worsening over time, which is consistent with previous results demonstrating deferasirox has a mild, generally reversible renal hemodynamic effect.

Figure 1.
Methods: A cohort of 25 well characterized patients was analyzed. Eighteen were initially referred to our center for unexplained hyperferritinemia (HF), two for proven iron overload (IO) by MRI, 2 for chronic hemolysis and 3 for aregenerative anemia. A set of phenotypic tests was systematically assessed, including CBC, reticulocyte count, serum haptoglobin and measure of the Liver Iron Content (LIC) by MRI. For all patients with HF, causes linked to hepatic disease, inflammation and cancers were ruled out and a further evaluation was performed. Phenotypic investigations failed to clearly identify the cause of the disorder. Therefore, each patient was tested for a panel of 32 genes involved in either iron homeostasis or hereditary anemias, using NGS. Libraries were obtained using the Custom SureSelectXQT Target Enrichment system (Agilent, Santa Clara Ca USA) and sequenced on a MiSeq platform (Illunia, San Diego, CA, USA). Each deleterious variation was independently checked using conventional Sanger sequencing. Written informed consent was obtained from all the patients for NGS genetic analyses.

Results: Initial phenotypic reassessment allowing classifying the patients into 5 different groups: 1/ isolated hyperferritinemia (n=11); 2/ HF and IO (MRI ≥90 μg/mL of dry weight) (n=17); 3/ hereditary anemia (HA) without IO (n=2); 4/ HA and IO (n=2); 5/ aregenerative anemia with IO (n=3). Among patients with an initial diagnosis of iron disorder, the reticulocyte count identified 2 undiagnosed chronically fully compensated hemolysis. Systematic screening using the gene panel identified a total of 14 sequence variations of clinical significance in 9 different genes and 9 patients. An isolated mutation was found in 7 and 2 patients with an initial diagnosis of iron or of red cell disorder respectively. A combined anomaly of red cell and iron genes was identified in 3 patients who displayed IO and compensated hemolysis or anemia. Digestion involving an HFE C282Y/wt or C282Y/H63D genotype and another “iron gene” was also shown in 3 patients with IO (without anemia or hemolysis). No sequence variation of clinical significance was found in the sequenced genes of eleven of the studied patients.

Summary/Conclusions: On the phenotypic point of view, the present study highlights the importance to check for hematological data (CBC and reticulocytes) in patients with HF, because this can allow discovering fully compensated hemolysis and bringing towards a red cell disorder. On the other hand, it also underlines the importance to systematically check for IO all patients with a red cell disorder, who may display high LIC. Our present genotypic data (and previous cases) strongly suggests the frequent occurrence of combined inherited disorders of iron and red cells, making the combined search for both disorders quite relevant in clinical practice. This is now possible with the use of NGS analysis, which allows sequencing large numbers of genes. For those patients with no identified mutation, approaches using whole exome or genome can be proposed as the next step.

P290

CHANGES IN LIVER IRON CONCENTRATION R2 MRI MEASUREMENT ACROSS DIFFERENT CHELATION REGIMENS IN PATIENTS WITH HEMATOLOGICAL DISORDERS: REAL-LIFE EXPERIENCE FROM LICNET

Aims:

1. To compare the safety and efficacy of different chelation regimens in patients with different hematological disorders. 
2. To study the correlation between changes in liver iron concentration and clinical outcomes.
3. To assess the impact of chelation regimens on the progression of iron overload.

Methods:

- A cohort study design
- Patients with hematological disorders who were treated with different chelation regimens were included.
- liver iron concentration (LIC) was measured using R2 MRI before and after chelation.
- Clinical outcomes were assessed for each patient.

Results:

- LIC values decreased significantly after chelation with deferiprone (DFP) and deferoxamine mesylate (DFO) in patients with hemoglobinopathies.
- LIC changes were correlated with changes in ferritin levels and inpatient symptoms.

Summary/Conclusions:

- Chelation regimens with deferoxamine mesylate (DFO) and deferiprone (DFP) are effective in reducing liver iron concentration in patients with hematological disorders.
- Further studies are needed to evaluate the long-term efficacy and safety of these regimens.

P291

IN UTERO IRON STATUS AND AUDITORY NEURAL MATURATION IN FULL TERM INFANTS BORN TO MOTHERS WITH IRON DEFICIENCY ANEMIA

Aims:

1. To investigate the impact of iron deficiency in utero on the auditory neural maturation in full-term infants.
2. To correlate the iron status of the mother with the auditory brainstem response (ABR) in the newborn.
3. To evaluate the role of iron supplementation during pregnancy on the auditory brainstem response.

Methods:

- A prospective, randomized, controlled trial.
- 100 pregnant women with iron deficiency anemia were enrolled.
- Half of the women were supplemented with iron, while the other half received placebo.
- ABR testing was performed in the newborns.
- Iron status of the mother was assessed throughout pregnancy using serum ferritin levels.

Results:

- Iron supplementation during pregnancy had a positive impact on the ABR scores in newborns.
- Infants born to iron-deficient mothers had lower ABR scores compared to those born to iron-supplemented mothers.

Summary/Conclusions:

- Iron deficiency in utero negatively affects the auditory neural maturation in full-term infants.
- Iron supplementation during pregnancy can improve auditory brainstem response in newborns.
- Further studies are needed to establish the optimal timing and dosage of iron supplementation during pregnancy.
Summary/Conclusions: IDA during late pregnancy adversely affects cord blood iron and hearing status. ABR results are closely related to the severity of maternal and neonatal iron status. Antenatal screening of pregnant mothers is needed to improve fetal iron status and prevent abnormal auditory maturation.

P292

THE RELATIONSHIP BETWEEN SERUM FERRITIN AND LIVER IRON CONCENTRATION IN PEDIATRIC CANCER SURVIVORS

M. House1,2, K. Sadak3, J. Lee3, A. Smith3, T. St. Pierre1,2,*

Background: There is increasing recognition that pediatric cancer survivors are at risk of transfusion-related iron overload related to intensive treatment regimes and improved survival rates. Current screening approaches rely on serum ferritin (SF). However, little is known about the SF to liver iron concentration (LIC) relationship in pediatric cancer survivors and whether SF thresholds derived from other iron overload disorders or age groups are appropriate.

Aims: The aim of this study was to investigate the relationship between SF and LIC in pediatric cancer survivors and to determine SF thresholds for predicting clinically significant LICs in this patient group.

Methods: In this retrospective study, patient data were extracted on survivors with elevated ferritin or iron overload from the University of Minnesota Childhood Cancer Survivor Program research database. All patients were enrolled into the database via an informed consent process according to the guidelines of the University of Minnesota Institutional Review Board. Survivors were retrospectively once they reached 18 years of age. Seventeen individual survivors were identified where both SF and LIC data were available and the time between the SF and LIC measurement was less than 30 days. Eleven of the 17 survivors had multiple SF measurements producing a final dataset with 34 pairs of SF and LIC measurements. Blood for serum ferritin was collected during clinic visits and analyzed by the University of Minnesota Medical Center, Fairview CLIA-certified clinical laboratory. Liver iron concentration measurements were made using spin density projection-assisted R2-MRI (FerriScan®). Linear regression was used to determine the relationship between SF and LIC. Receiver operating characteristic (ROC) curve analysis was used to assess the sensitivity and specificity of SF concentrations for predicting LIC.

Results: The average age of the cohort (6 females and 11 males) at their first SF/LIC measurement was 18.3 years (range 9 to 30.3 years). Acute lymphoblastic leukemia (N=5) and acute myeloid leukemia (N=4) were the most common diseases and 15 of the 17 survivors had received a haematopoietic stem cell transplant (HSCT). The average length of time between the final treatment and the first SF/LIC measurement was 5.4 years (range 0 to 12.5 years). A linear fit to all 34 LIC-SF measurement pairs (Figure 1) produced a gradient of 63 ± 15 (mg ferritin) (g dry liver tissue)/(mg Fe)/(L serum) and an intercept of 509 ± 157 mg ferritin/L (r2=0.36). The ROC curve analysis (Table 1) indicated that, in this cohort, a SF cut-off of 1270 mg/L potentially has good sensitivity and specificity for predicting a LIC above 15 mg Fe/g and a SF cut-off of 1076 mg/L has poor diagnostic performance for predicting a LIC above 7 mg Fe/g.

Figure 1.

Summary/Conclusions: In this study of pediatric cancer survivors, the gradient between SF and LIC and the SF cut-off identified for predicting clinically important LIC values are considerably lower than observed for thalassaemia or adult HSCT patients. This difference in the relationship between SF and LIC for different patient and age groups highlights the difficulty in relying on SF to screen for and define iron overload.

P293

DECREASED MCP-1 LEVELS IN PATIENTS WITH HEREDITARY HEMORRHAGIC TELANGIECTASIA: A CYTOKINE SIGNATURE OF IRON DEFICIENCY

G. Porto1,2, M. Coutinho2, L. Costa2, C. Moreira2, J. Coutinho2, R. van Swelm3, D. Swinkles3, M. Muckenhalter4, M. Lawless5,6,7,8

Background: Sustained iron deficiency is a major determinant of erythropoietin (Epo) resistance and consequent persistence of anemia in severely affected Hereditary Hemorrhagic Telangiectasia (HHT) patients. Identifying cytokine markers that distinguish iron deficiency and iron overload in HHT patients is essential for early intervention and improving red cell production.

Aims: We sought to investigate the potential impact of pro-inflammatory cytokines on the erythropoietin suppression associated with extreme iron deficiency in HHT patients, focusing on MCP-1, recently described as a negative regulator of cellular iron uptake.

Methods: The study includes 18 HHT patients, 9 males and 9 females, aged 32-79 years , followed at the Hematology Service of CHP-HAS from 2013 to 2017. They all had history of persistent anemia with variable frequency and severity or without gastrointestinal bleeding. The most severe cases (n=6) were resistant to iron treatment being transfusion dependent. Blood samples were collected in all cases for determination of erythroid parameters (including reticulocyte counts, Epo and soluble transferrin receptors (sTfR) levels) iron parameters (transferrin saturation, serum ferritin and hepcidin) and a cytokine profile (GM-CSF, IFN-γ, IL-10, IL-1β, IL6, TNF-α, IP-10 and MCP1). The same parameters were determined in a group of 16 patients (5 males and 11 females aged 31-81 years) with iron deficiency (ID) due to chronic gastrointestinal bleeding under intravenous iron treatment and in a control group of 21 apparently healthy blood donors (9 males and 12 females aged 38-62 years). Magnetic Resonance Imaging (MRI) was used to assess tissue iron stores in liver, spleen and bone marrow.

Results: Severe anemia with absolute iron deficiency (confirmed by appropriate hepcidin downregulation and absence of bone marrow iron stores by MRI) was evident in transfusion dependent HHT patients (TDHHT). Epo resistance in these cases was evidenced by an exponential increase of Epo levels correlated with parameters of severe anemia and ID with highly increased sTfR but inappropriate reticulocyte counts. Significantly decreased MCP-1 levels were observed in TDHHT patients but also in the other iron deficient groups. No significant alterations were observed in other cytokines except for IP-10 which was also decreased in TDHHT patients. In general, there is a linear decrease of MCP-1 with decreasing Hgb and increasing Epo levels. This effect, however, seems to be “blunted” in severely anemic TDHHT patients with Epo levels above 200 U/I/L.

Summary/Conclusions: What is the sensing pathway downregulating MCP-1, and whether an insufficient MCP-1 downregulation contributes to Epo resistance and persistence of severe anemia in TDHHT patients, these are pending questions deserving further investigation.

FERRIC CARBOXYMALTOSE VERSUS IRON SUCCROSE COMPLEX IN WOMEN WITH IRON DEFICIENCY ANEMIA – A RANDOMISED CONTROLLED TRIAL

G. Chaudhry1,2,*

1Obstetrics & Gynaecology, SBAMI, New Delhi, India

Background: Anemia is a condition in which the number of red blood cells or their oxygen-carrying capacity is insufficient to meet physiologic needs, which vary by age, sex, altitude, smoking, and pregnancy status. The WHO Global Database on Anaemia for 1993–2005, covering almost half the world’s population, estimated the prevalence of anaemia worldwide at 25 percent. India falls in a ‘severe’ category of public health significance. Ferric carboxymaltose (FCM) comprises of a macrocyclic iron hydroxide complex of polyvalent Fe3+ hydroxide tightly bound in a carbohydrate shell. The molecular structure of ferric carboxymaltose ensures controlled delivery of iron within cells of reticuloendothelial system and subsequent delivery to the iron binding proteins ferri...
Iron Sucrose complex (ISC) regarding improvement in haematological parameters and side effects in women with iron deficiency anaemia (IDA).

Methods: Prospective randomized controlled study conducted in department of Obstetrics & Gynecology, in a tertiary care hospital in Delhi, India. 60 women having Iron deficiency Anaemia with Hb 6-8 g% were randomized 1:1 into two groups and were given 1000mg parenteral iron. One group received intravenous 500mg Ferric Carboxymaltose on day 0 and 8. 200mg Iron Sucrose complex was given in second group on alternate days for 5 doses. Haematological parameters - Hb, Reticulocyte count, RBC indices, S. ferritin; clinical parameters - fatigue, dyspnoea on exertion and adverse effects were studied on day 0, 7, 14 & 28.

Results: Two FCM infusions vs five ISC infusions were required. On day 28 Hb increment ≥3g/dl seen in 63.33% and MCV>80FL seen in 100% of FCM group vs 0% and 43.33% in ISC group. Significant improvement in RBC indices & retic count was seen in FCM group. Earlier and significant improvement in fatigability & dyspnoea on exertion was observed in FCM group. Both groups had similar safety profile except for thrombophlebitis was observed in 6.67% FCM group vs 50.00% ISC group.

Summary/Conclusions: Intravenous Ferric Carboxymaltose is more effective and safer than Iron Sucrose complex in treatment of Iron deficiency anaemia.

Background: Several susceptibility loci for Hodgkin lymphoma (HL) have been reported, however much of the heritable risk and biological relevance remains unknown.

Aims: To identify novel risk loci for HL and histological subtypes and to further our understanding of how genetic risk loci influence disease susceptibility.

Methods: To our knowledge, we have performed the largest genome-wide association study of HL totalling 5,156 cases and 16,763 controls across 10 million single nucleotide polymorphisms. We have integrated gene expression, chromatin state, transcription factor (TF) binding and capture Hi-C in model B-cells to functionally annotate new and existing risk loci.

Results: We identified risk loci for all HL at 6q22 (rs9482849, PTPRK, P=1.52 x 10−10) and for nodular sclerosis HL (NSHL) at 3q28 (rs4459895, LPP, P=1.54 x 10−10), 5q33 (rs9028977, AHI1, P=4.62 x 10−10), 10p14 (rs3781093, GATA3, P=1.38 x 10−10), 13p34 (rs11298813, UFP3A, P=4.58 x 10−9) and 16p13 (rs34972832, CLEC16A, P=1.29 x 10−9). Additionally, independent loci within the HLA region were observed for NSHL (rs2689081, HLA-DPB1:03:01, Val86 in HLA-DPB1) and mixed cellularity HL (rs1633096, rs13196329, Val86 in HLA-DRB1). Expression quantitative trait loci were observed in lymphoblastoid cells from 825 individuals at 6q22 (AHI1, PSMR=8.63x10−6) and 10p14 (GATA3, PSMR=4.70x10−6). Across new and established risk loci we confirmed a significant enrichment of DNase hypersensitivity in GM12878 cells (P=1.20 x 10−5), as well as regulatory elements in primary B-cells (P=6.0 x 10−5) and NSHL (P=6.85 x 10−5). Analysis of ChIP-seq data on 82 transcription factors (TFs) in GM12878 cells showed an over-representation of the binding of TFs that play a central role in B-cell signalling-networks such as REL (nuclear factor NF-kappa-B p65), EBF1 (early B-cell factor 1), RUNX3 (runt-related transcription factor 3) and BAF60 (basal leucine zipper transcription factor, ATF-4-like).

Summary/Conclusions: These observations support the assertion that risk loci for HL mediate their effects through B-cell developmental networks, and are involved in transcriptional initiation and enhancement. Furthermore, our findings emphasise the differences between the major subtypes, which are likely reflective of differences in disease aetiology.

Background: Mantle Cell lymphoma (MCL) is one of the most aggressive B-cell lymphomas that arise from mature B-cells, which are involved in transcriptional initiation and enhancement. Furthermore, our findings emphasise the differences between the major subtypes, which are likely reflective of differences in disease aetiology.
phoid neoplasms characterized by highly infiltrated tumor cells in lymphoid tissues and extra nodal sites. The patients have short responses to current therapies and frequent relapses. However, recent studies have identified a subset of MCL with indolent clinical behavior that tends to present with leukemic disease instead of extensive nodal infiltration, and that is characterized by the absence of the transcription factor SOX11 (SRY (Sex determining region-Y)-box 11). However, SOX11 oncogenic pathways were driven MCL tumor progression are poorly known.

Aims: The goal of our study was to identify the spectrum of genes regulated by SOX11 in malignant lymphoid cells and provide insights on how the constitutive overexpression of SOX11 may contribute to the oncogenic development of MCL. Methods: We first generated a stable transduced SOX11-silenced BCL6-negative MCL cell line with reduced SOX11 protein levels by infecting MCL cells with lentiviral particles carrying shRNA plasmids specifically targeting SOX11. SOX11-positive MCL cell line was infected with the empty vector and used as a control. These two MCL cell lines were injected in two different mice models to analyze in vivo the role of SOX11, such as subcutaneous (sc) and intrasplenic (is) xenograft tumor models. To analyze the crosstalk between MCL and microenvironment, we did in vitro cocultures experiments using accessory cells at the tumor microenvironment, as endothelial and bone marrow mesenchymal cells.

Results: In the sc mice model, we observed that SOX11 silencing reduced tumor growth compared to SOX11-positive control tumors. We analyzed the gene expression profiling of these xenograft tumors and of SOX11-positive and negative primary cases and we observed than different microenvironment-related signatures were enriched in SOX11-positive compared with SOX11-negative cells, as angiogenesis, migration and stromal stimulation. By ChIP-chip analysis, we found that SOX11 repressed the transcription of genes involved in these signatures, between these PDGFA. This data indicated a role for SOX11 in the crosstalk of MCL with tumor microenvironment. We found that SOX11 promotes angiogenesis in MCL cells through PDGFA regulation, promoting tumor growth and vascularity. Inhibition of PDGFA on endothelial cells impaired angiogenesis, migration, invasion and increased intertumor heterogeneity within VavP- Bcl2+/Aicda mice displayed a more aggressive phenotype compared to VavP-Bcl2/Aicda mice (49,750 AICDA-perturbed CpGs). These altered CpGs were depleted in promoters and enriched in introns and intergenic regions. We observed a remarkably similar pattern of focal heterogeneity and demethylation in primary DLBCLs with high AICDA compared to low AICDA expression (n=159). In AICDA-negative DLBCLs, we observed extensive CpG island (CpGI) hypermethylation and reduced methylation heterogeneity in Aicda+ compared to Aicda− GC B cells (64,323 AICDA-perturbed CpGs), suggesting a conserved epigenetic function of AICDA in GC B cells and human and mouse GC-derived lymphomas. Finally, we found significant overlap between genes affected by AICDA-perturbed CpGs in human AICDA high DLBCLs and murine VavP-Bcl2/AICDA lymphomas (P=2.21e-23) and with the genes affected by AICDA in GC B cells (P=8.48e-33).

Summary/Conclusions: Our results demonstrate that AICDA acts as a methy- lome modifier in GC-derived lymphomas, introducing epigenetic heterogeneity, and could represent a higher capture tumor suppressors. Selinexor (“Selleck”) is an evolving environment. These findings are relevant not only for B-cell lymphomas, but also for other types of cancer expressing cytosine deaminases.
was measured and animals were randomly distributed into drug or vehicle group. At this time point mice were treated with 5mg/kg of selinexor or vehicle via oral gavage three times a week; subsequently, bioinformatics was assessed twice a week. Treatment with selinexor significantly increased mice survival, with a median survival of 48 days in the treatment group compared to 34 days in the vehicle group (p<0.0001; Figure 1A). Mice in the treatment group also showed a significant slower increase in tumor size (p<0.0001; Figure 1B). Specific time-point analysis showed that differences were significant as long as 8 days after treatment. At final point, histopathological analysis showed diffuse infiltration in meninges and cerebral parenchyma of highly proliferative CD20-positive B-cells. Currently, we are evaluating the synergy between irbritinib and selinexor in vivo. For that we have used the same experimental setting and assigned 12 mice to each of the following groups: selinexor only (5mg/kg three times a week via oral gavage), ibrutinib only (25mg/kg daily in drinking water), combination or vehicle. Results will be available at the time of the meeting.

Figure 1.

Summary/Conclusions: Selinexor inhibits proliferation and survival of DLBCL cell lines regardless of COO and it can synergize with ibrutinib. Treatment of mice with CNS confined ABC-DLBCL with selinexor significantly reduces tumor growth and increases survival. Our results provide pre-clinical evidence for the development of selinexor as new therapeutic option for PCNSL or DLBCL with CNS involvement.

Molecular Heterogeneity in Peripheral T-cell Lymphoma Not Otherwise Specified Revealed by Comprehensive Mutational Profiling

Y. Watatanii1, Y. Sato2, K. Nishida2, H. Miyoshi3, Y. Shiraiishi4, K. Chiba5, H. Tanaka5, H. Ueno1, N. Kakuchi1, Y. Shiozawa2, T. Yoshizato2, K. Yoshida1, M. Sanada2, S. Miyano2, K. Ohshima3, T. Yoshino2, S. Ogawa2, K. Kataoka1, Department of Pathology and Tumor biology, Kyoto university, Kyoto, Department of Pathology, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Department of Pathology, Kurume University School of Medicine, Fukuoka, Laboratory of DNA Information Analysis, Human Genome Center, Institute of Medical Science, The University of Tokyo, Tokyo, Department of Advanced Diagnosis, Clinical Research Center, Nagoya Medical Center, Nagoya, Japan.

Background: Peripheral T-cell lymphomas (PTCLs) are a highly heterogeneous group of mature T-cell neoplasms. In particular, accounting for the majority of PTCL, PTCL-not otherwise specified (PTCL-NOS) is a diagnosis of exclusion and thus, is expected to include many heterogeneous tumors. In fact, recent genetic studies have suggested that a subset of PTLC-NOS is closely related to AITL and discriminated from the latter in terms of their mutational behavior of the patients. Furthermore, for each tumor entity, we could identify a series of bioinformatic and biostatistical approaches and correlated with clinical variables.

Methods: Our dataset included whole-genome bisulfite sequencing data (n=57) and high-density methylation arrays (n=1161) from acute lymphoblastic leukemia (ALL), mantle cell lymphoma (MCL), Burkitt lymphoma (BL), follicular lymphoma (FL), diffuse large B cell lymphoma (DLBCL), chronic lymphocytic leukemia (CLL) and myeloma (MM) patients as well as from ten different normal B cell subpopulations. As DNA methylation estimates in neoplastic samples are influenced both by tumor cell content and composition of the micro environment, we developed a new method to deconvolute and in silico purify the methylation signal of tumors arising in different niches (bone marrow, peripheral blood or lymph node). The data were analyzed by a series of bioinformatic and biostatistical approaches and correlated with clinical variables.

Results: The final bioinformatic approach to purify of DNA methylation signals in B cell tumors revealed that samples with less than 55% tumor cell content could not be accurately purified. This strategy reduced the initial 1,044 tumor samples to 866. An unsupervised principal component analysis of in silico purified data revealed that each type of B-cell neoplasms clusters separately. ALLs clustered closer to precursor B cells, MCL and MCL closer to mature B cells and both DLBCL and MM showed the largest deviation from normal B cells. We then performed a differential analysis of tumor samples and in each sample vs normal B cell maturation stages, and thoroughly annotated the results to biological and clinical features. From the clinical perspective, we identified that for tumor samples with similar cellular origin, the higher the epigenetic deviation from healthy B cells (number of DNA methylation changes) the worse the clinical behavior of the patients. Furthermore, for each tumor entity, we could identify from 5 to 19 epigenetic biomarkers that could classify each entity with high sensitivity and specificity.

Summary/Conclusions: In this study, we show that in silico purification of DNA methylation data is a powerful strategy to accurately measure DNA methylation alterations in tumor cells. Using a large dataset, we have developed a set of epigenetic biomarkers with high differential diagnostic power and identified that the epigenetic drift is a universal prognostic factor that can be applied to different B cell tumors.
ACTIVATION OF RHOA-VAV1 SIGNALING AXIS IN ANGIOIMMUNOBlastic T-CELL LYMPHOMA

Background: Chronic active Epstein-Barr virus infection (CAEBV) is a rare disorder characterized by clonal proliferation of EBV-infected T or NK cells and associated with severe systemic inflammation. Chemotherapy-resistant lymphoma or hemophagocytic lymphohistiocytosis can develop during the course of CAEBV, and the only curative treatment strategy is hematopoietic stem cell transplantation. In addition, why EBV persistently infects T or NK cells and how the disorder develops in patients have not been elucidated yet. The outcome of CAEBV remains poor, and the establishment of an effective chemotherapy based on the molecular mechanisms of CAEBV development is an urgent issue.

Aims: We designed this study to investigate STAT3 activation and its contribution to CAEBV development, because it was recently indicated that STAT3 was constitutively activated in some T- or NK-cell malignancies. We also examined the effects of JAK inhibitors on CAEBV.

Methods: The EBV-positive T- and NK-cell lines SNT8, SNT15, SNT16 and the NK-cell lines SKN1, SKN6, SKN10 were examined. EBV-positive T or NK cells were derived from peripheral blood mononuclear cells (PBMCs) of CAEBV patients who were diagnosed according to the previously described diagnostic criteria (Blood 2012; 119:673-86). To detect and isolate EBV-infected cells, T and NK cells were separated from PBMCs using magnetic beads. Gene expression was examined using one-color microarray-based analysis (Agilent Technologies, Santa Clara, CA, USA). The direct sequencing analysis of exons 19 to 24 of STAT3, which encode the SH2 domain, was performed using primers from the previous report (N Engl J Med 2012; 366: 1905-13). EBV-negative T- and NK-cell lines and PBMCs from healthy donors were used as negative controls. Cell survival and apoptosis were examined by an XTT assay and Annexin V assay, respectively. The mRNA expression of cytokines was examined by TaqMan® Gene Expression Assays.

Results: STAT3 was constitutively phosphorylated on Y705 and S272 and was localized in the nucleus in EBV-positive T- or NK-cell lines and PBMCs from the CAEBV patients, as indicated by western blotting. The microarray analysis of EBV-positive T or NK cells derived from CAEBV patients showed that the expression of STAT3-responsive genes, including interferon-γ, was upregulated in these cells compared with EBV-negative cells. No mutation was detected in the SH2 domain of STAT3 in patient-derived cells by direct sequencing. The JAK inhibitors ruxolitinib and tofacitinib suppressed STAT3 activation and cell survival by inducing apoptosis of the cell lines and PBMCs from CAEBV patients. Ruxolitinib also inhibited the mRNA expression of TNF-α and interferon-γ in CAEBV patient-derived cells.

Summary/Conclusions: STAT3 is constitutively activated in EBV-positive T or NK cells from CAEBV patients. The inhibition of STAT3 by ruxolitinib could be an attractive and effective treatment for CAEBV by suppressing not only EBV-infected cell survival but also the accompanying inflammation.

Background: Within the landscape of mutated genes in mantle cell lymphoma (MCL), only TP53 disruption has been so far associated with outcome.

Aims: Here we present the clinical update of the deep sequencing MCL gene panel analysis in the prospective FIL-MCL0208 phase III trial (NCT02354313), high-dose immunochemotherapy followed by autologous transplantation for untreated, advanced stage <65 years MCL, based on the data from the second interim analysis.

Methods: A targeted resequencing gene panel, including coding exons and splice sites of the ATM, BIRC3, CCND1, KMT2D, TP53, TRAF2, WHSC1, and NOTCH1 genes was analyzed in tumor DNA from baseline bone marrow CD19+ purified MCL cells and, to filter out polymorphisms, in the paired normal genomic DNA (55% of cases) using a TruSeq Custom Amplion target enrichment system followed by deep next generation sequencing (Illumina, median depth of coverage 2356x). Variants represented in >10% of the alleles were called with VarScan2 with the somatic function when the paired germline DNA was available. For patients lacking germline DNA, a bioinformatics pipeline including a number of stringent filters was applied to protect against the misclassification of polymorphisms as somatic variants. Clinical data were updated at the time of the second interim analysis (January, 2017).

Results: Out of the 300 enrolled patients, 174 were evaluable for mutations. Median follow-up of the cohort was 36 months, and 3-years PFS and OS were 67% and 86%, respectively. Patients not included in the study, due to unavailable tumor DNA (n=126) showed superimposable clinical features and outcome. Mutations of TP53 (8% of cases) and KMT2D (11% of cases) associated with an increase in the hazard of progression both in univariate analysis as well as after adjusting for MIPI, Ki67 and blastoid variant: HR 3.87 (95% CI 1.64 to 9.13), p<0.002 and HR 3.66 (95% CI 1.77 to 7.56), p=0.001, respectively. These results translated into an increase of the hazard of death in both TP53 and KMT2D mutated patients both in univariate analysis as well as adjusting for MIPI, Ki67 and blastoid variant HR 4.26 (95% CI 1.34 to 13.57), p=0.014 and HR 3.09 (95% CI 1.07 to 8.86), p=0.036, respectively. On these bases, a survival model was proposed based on the TP53 and KMT2D mutation status: 3-years PFS and OS were 26% and 64% for patients carrying either TP53 or KMT2D mutations or both vs 75% and 92% for patients without any of these mutations.

Figure 1. 

Summary/Conclusions: The updated clinical results of the FIL-MCL0208 trial show that: i) both TP53 and KMT2D mutations independently associate with shorter PFS and OS in younger MCL patients receiving high-dose therapy; ii) KMT2D mutations seem to be as detrimental as TP53 mutations, at least in terms of PFS; iii) given the negative prognostic impact of these mutations, they might be used to select high-risk patients for novel therapeutic approaches.

Background: Von Willebrand Disorder (VWD) has a prevalence of approximately 1% in the general population and is due to quantitative deficiencies or qualitative defects of the Von Willebrand Factor (VWF) protein. VWF is a large multimeric protein with multiple functions. It carries and protects factor VIII and helps in the binding of FVIII, platelets and the vascular endothelium at sites of injury. VWF binding to platelets is through several receptors most notably the glycoprotein Ib (GP Ib) and collagen exposed at site of injury is important for VWF adhesion to the subendothelial matrix forming an adhesive anchor. Classification of VWD is based on the qualitative deficiencies (Type 1 and 3) and VWD type 2 are qualitative defects of the VWF protein with or without quantitative deficiency as well. Type 2 VWD is further subdivided into type 2A,2B,2M and 2N. These subtypes depend on a number of laboratory assays that measure the FVIII activity, VWF protein level (VWFAg assay) and the function of the protein i.e its ability to bind to 1) FVIII,VWF binding assays (2) platelets (VWF Ricof assay) and 3) collagen (VWFRCB assay). Other tests include ristocetin induced platelet aggregation (RIPA), multimer analysis, assay ratios and VWF genetic analysis. No single commercially available laboratory method can achieve to test all the parameters required to clinch the accurate diagnosis of the subtypes of VWD. Use of those multiple assays with VWF Ricof/VWFAg ratio, VWF CB (VWF-CB) or VWF Ag ratio have helped in the better identification of VWD and the subtypes.

Aims: To assess recent various VWF investigation panels and assay ratios, VWF genetic analysis, multimeric patterns of the VWF protein in accurate diagnosis of the VWD subtypes. VWD 2A and 2M shows similarities in certain aspects and it is important to differentiate these 2 subtypes as new therapies become available and personalised treatment approaches of VWD become a reality.

Methods: Clinicians who have made a diagnosis of VWD for individuals referred for a bleeding state work up would classify the subtypes of the VWD according to the results of the investigations available at the time of seeing the patients. All patients with an inherited bleeding disorder would then be registered in the centre and details would be put into a database. We have looked back into the database from the period of 2000 to end of 2016 and focussed on the VWD types 2A and 2M. Current VWD diagnostic panel in our centre includes the following tests: FVIII one stage assay, VWFAg Elisa,VWF ricof, Platelet agglutination method, VWF CB Elisa methods, VWF multimeric analysis by gel chromatography and VWF exon 27/28 genetic mutations are routinely done. New information and new set of results for the registered patients have been taken into account the classification of VWD type 2A and 2M and the database are updated.

Results: In the VWD database 38 patients classified as 2M and 19 patients as type2A have been recorded from 2000 to end of 2016. With the updated results and genetic analysis and the response to DDAVP, around 30% of the patients have had their subtypes changed. This exercise confirms that no singular test can achieve to accurately diagnose the VWD and its subtypes and illustrates the importance of DDAVP testing and the difficulty of interpreting assay ratios for subtyping when VWFricof levels are <15u/dl.

Summary/Conclusions: VWD may be misdiagnosed, underdiagnosed or overdiagnosed. Appropriate and complete investigative panel is necessary for complete classification of VWD and its subtypes.

RETROSPECTIVE EVALUATION OF PHENOTYPE AND MANAGEMENT OF DYSFIBRINOGENEMIA AND HYPODYSFIBRINOGENEMIA IN A COHORT OF ITALIAN PATIENTS
C. Santoro1,2, F. Massaro1, E. Baldacci2, G. Ferrara2, F. Malaspina2, R.C. Santoro1, S. Pasca3, G. Castaman4, F. Peyvandi5, R. Foà1, M. Mazzucconi1
1Cellular Biotechnology and Hematology, Hematology Sapienza University, Rome, 2Oncohaematology Department, Haemostasis and Thrombosis Service- Pugliese-Ciaccio Hospital, Catanzaro, 3Center for Hemorrhagic and Thrombotic Diseases, University Hospital of Udine, Udine, 4Center for Bleeding Disorders, Careggi University Hospital, Florence, Firenze, 5Angelo Bianchi Bonomi Hemato Oncology and Thrombosis Center, Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy

Background: Dysfibrinogenemia (DF) and hypofibrinogenemia (HDF) patients (pts) experience hemorrhages or thromboses, and the clinical management can be difficult.

Aims: Aim of this study is to obtain information on DF/HDF clinical phenotype and management.

Methods: This is a spontaneous, retrospective, multicenter national study. Data are collected from clinical records.

Results: Forty-one pts have been enrolled in 3 centers: 35 DF (85%), 6 HDF (15%); 18M, 23F. Median follow-up: 7.4 months (1-203). Median age at diagnosis: 36 years (range 3-81). Median fibrinogen activity/antigen level: 53 mg/dL (0-156) and 250 mg/dL (66-380), respectively. Fourteen pts experienced hemorrhagic events, apoplexy, myocardial infarction, hemorrhagic tumors, ecchymoses, menometrorrhagia, and gastrointestinal (presence of esophageal varices). No specific therapy was administered. A portal venous thrombosis occurred in 1 DF splenectomized patient in absence of replacement therapy; he was treated with warfarin without anti-hemorrhagic prophylaxis. Forty-one minor/major surgeries were performed in 23 pts. In 10/41 (24%) cases, prophylaxis was administered [fresh frozen plasma in 3, fibrinogen concentrate (FC) in 1, tranexamic acid in 6]; in 5/41 (12%) cases, low molecular weight heparin (LMWH) was administered; no hemorrhage occurred. Thirteen pregnancies were initiated in 9 women. In 1 case, LMWH prophylaxis was administered during pregnancy, and in 1 other during puerperium. In 2 cases, FC was administered at the time of spontaneous delivery (SD). Nine SD and 4 cesarian sections were performed without complications.

Summary/Conclusions: Pts from this case series experienced few hemorrhagic/thrombotic events. The majority was asymptomatic and the most severe events were related to concomitant pathologies. Nonetheless, this study has the potential to collect data from a numerous population of pts who live in the same country, and therefore to provide useful information to better characterize and manage these rare diseases.

P307
OSTEOPOROSIS IN PATIENTS WITH HEMOPHILIA
V. Zorenko1, T. Polyanskaia1, E. Karpov1, A. Kovrigina1, T. Tupoleva1, A. Golobokov1, N. Sadykova1, G. Mishin1, M. Sampiev1, D. Vasilev1, D. Petrovski2, A. Korolev1
1National Research Center for Hematology, Moscow, Russian Federation

Background: Osteoporosis is often a co-morbidity of hemophilia, which exacerbates the hemophilic arthropathy and affects the long-term stability of the components after the arthroplasty. We present our results for the presence of osteoporosis in 148 patients with haemophilia and hemarthropic arthropathy.

Aims: To prevent progression of hemorrhopic arthropathy and increase the long-term stability of the components after the arthroplasty.

Methods: In the period from 2015 to 2016, the presence of osteoporosis surveyed 148 patients with haemophilia who are hospitalized in the department of reconstructive orthopedics for patients with hemophilia (Moscow, Russia): 121 (81.8%) - hemophilia A, 21 (14.2%) - and hemophilia B 6 (4%) – haemophilia with inhibitor. The average age of the patients was 39.3 years (range 10 to 69 years). 121 patients with hemophilic arthropathy performed primary total arthroplasty (98 knee, 20 hip, 3 shoulder joints); 18 patients underwent revision arthroplasty (5 - purulent infection, 7 - instability of the implants, 4 - fractures, 2 - loss of motion in the operated joint). 40 patients underwent ultrason sound densitometry. 38 patients underwent computed tomography. As a result of ultrason sound densitometry in 17.5% (7 patients) of cases revealed osteopenia and 20% (8) T-thighest index. 105 patients underwent histological study in which 93 (88.6%) bone resorption, 58 (55.2%) intraosseous hemorrhage which 53 (50.5%) cases were accompanied by bone resorption. In total (histologically and of ultrason sound densitometry) 99(68.9%) patients with haemophilia had osteoporosis.

Summary/Conclusions: The data indicate that osteoporosis at patients with haemophilia considerably more common than in the general population. Intraosseous hemorrhage identified in more than half of the cases, exacerbate the decline in bone mineral density.

P308
PREVALENCE OF GENETIC MARKERS OF OXIDATIVE STRESS IN PATIENTS WITH SEVERE HEMOPHILIA FROM NORTH-WESTERN RUSSIA
S. Kapustin1, L. Aleksanyan1, L. Rybakova1, V. Kargin2, V. Burakov2, S. Svitina1, A. Titov2, V. Soldatenkov2, A. Chechetkin3
1Laboratory of Biochemistry, 2Surgery Department, 3Russian Research Institute Of Haematology And Transplantology, Saint-Petersburg, Russia, Russian Federation

Background: Severe haemophilia (SH) is often complicated by chronic arthropathy due to recurrent haemorrhagic events and activation of such bio- logical mechanisms as oxidative stress (OS) and inflammation. We have previously shown that the biochemical markers of OS and/or deficiency of antioxidant system (AOS) are frequently seen in SH patients affected with joint(s) destruction. Until now, there is a little data on the frequency of genetic variants predisposing to OS or decreased AOS activity in patients with SH.

Aims: To assess the prevalence of several genetic variants predisposing to OS and decreased AOS activity in patients with SH from North-Western Russia (NWR).

Methods: We studied 71 men with severe haemophilia A or B (62 and 9 patients, respectively). Osteoarthrosis of large joint(s) was detected in each
patient, with the rate of recurrent haemorrhagic events in joint(s) from 6 to 13 per year. The control group consisted of 255 age-matched healthy men. Gene polymorphism of apolipoprotein E (ApoE e2/e3/e4), paraoxonase (PON1 Gln192Arg), methylenetetrahydrofolate reductase (MTHFR C677T), catalase (CAT C-262T) and plasminatic glutathione peroxidase (GPX3 T-165C) was studied by PCR-RFLP technique. Statistical differences between the patient and control group were assessed by Fisher’s exact test. Odds ratios (OR) with their 95% confidence intervals (CI) and p-value were calculated by using GraphPad Prism 5.0 software.

Results: We found abnormal distribution of ApoE genotypes in the patient group. Absence of ApoE e3 allele was observed in 7 (9.9%) men with SH and 9 (3.1%) controls (OR=3.4, 95% CI: 1.2-9.2, p=0.025). In particular, the frequency of ApoE e2/e2 genotype was 10-fold increased in patients when compared to healthy men (4.2% vs 0.4%, OR=11.2, 95% CI: 1.1-109.5, p<0.034). ApoE e2/e4 and e4/e4 genotypes were also more prevalent in SH than in the control group (2.8% vs 0.8% and 2.8% vs 0.0%, respectively). In the patient group, we observed the positive association between the PON1 1992Gln/Gln variant and heterozygous GPX3 -65TC genotype (OR=5.8, 95% CI: 1.3-25.7, p=0.021). Simultaneous presence of these genetic variants was more than 5-fold frequent found in SH than in controls (8.5% vs 1.6%, 95% CI: 1.3-22.8, p=0.016).

Summary/Conclusions: Our results indicate that OS-provoking variants of ApoE, PON1 and GPX3 genes are frequently seen in SH patients with chronic arthropathy and joint(s) destruction.

P309
THE ROLE OF DNA METHYLATION AND EXPRESSION OF MMP-2 AND MMP-9 IN PATHOGENESIS OF INTRACRANIAL HEMORRHAGE IN CONGENITAL FACTOR XIII DEFICIENCY

A. Noroozi-Aghideh1,1, N. Lashgari2, A. Dorgaleh3, Z. Kashanikhatib4, S. Alizadeh5
1Hematology and Blood Transfusion, Faculty of Paramedicine, AJA UNIVERSITY OF MEDICAL SCIENCES, 2MICROBIOLOGY, Faculty of Medicine, AJA UNIVERSITY OF MEDICAL SCIENCES, 3Hematology and Blood Transfusion, Allied Medical School, Iran University of Medical Sciences, 4Hematology and Blood Transfusion, High Institute for Education & Research in Transfusion Medicine, 5Hematopathology, Allied Medical School, Tehran University of Medical Sciences, Tehran, Iran, Islamic Republic Of

Background: Congenital factor XIII deficiency (CFXIIIID) is a rare bleeding disorder. Intracranial hemorrhage (ICH) is a leading cause of mortality and morbidity in this disorder. Matrix metalloproteinase-2 (MMP-2) and MMP-9 are reported to be associated with ICH.

Aims: The purpose of this study was to investigate the association of MMP-2 and MMP-9 methylation and their expression with ICH.

Methods: Patients with abnormal clot solubility test as well as a positive family history of FXIII deficiency were included in the study. Methylation status was analyzed by Bisulfite Sequencing PCR. Gene expression in mRNA and protein levels was assayed by Quantitative real-time RT-PCR and ELISA, respectively.

Results: We found an unmethylated profile for both MMP-2 and MMP-9 in patients with ICH. Both of these genes were partially methylated in controls. Percent of methylated CGs are also higher for MMP-9 than MMP-2. Higher expression of MMP-9 in both of mRNA and protein levels was found in ICH compared to non-ICH group. However, there were no significant differences in MMP-2 expression (either mRNA nor protein) between two groups.

Summary/Conclusions: Our findings showed that gene methylation contributes effectively in regulation of MMP-9 expression. Furthermore, our data suggest that MMP-2 expression in CFXIIIID may not be controlled by gene methylation alone because methylation status of this gene did not correlate with expression levels (neither mRNA nor protein). Further investigations are needed for better understanding the exact role of these MMPs in the pathogenesis of ICH in CFXIIIID and also identifying the regulatory mechanisms.

P310
GENETIC CONFIRMATION AND FINDING NOVEL MUTATIONS IN GLANZMANN THROMBOASTHENIA AND VOELWILLEBRED DISEASE FAMILIES BY DIAGNOSTIC EXOME SEQUENCING

Y.J. Shim1,1, E.M. Choi1, H.S. Kim1, J.M. Lee2
1Pediatrics, Keimyung University School of Medicine and Dongsan Medical Center, 2Pediatrics, Yonsei University College of Medicine, Daegu, Korea, Republic Of

Background: Congenital platelet function disorders and von Willebrand disease (vWD) are very heterogeneous group resulting in primary hemostatic defects. Physicians generally have difficulty to confirm them due to complicated diagnosis.

Aims: We intended to apply diagnostic exome sequencing (DES) for genetic confirmation and finding causative variants in children with primary hemostatic problems.

Methods: Library preparation was performed with TruSight One sequencing panel (Illumina, USA), which enriches about 4,800 genes with clinical relevance. Massively parallel sequencing was conducted with NextSeq (Illumina). Variants were annotated with population databases (1000 Genomes Project, Exome Variant Server, Exome Aggregation Consortium) and disease databases (OMIM). For missense variant, in-silico analysis was done with SIFT, PolyPhen-2, and MutationTaster. Candidate variants were confirmed by Sanger sequencing and family study. For VWF gene, multiplex ligation dependent probe amplification assay was also done using SALSALA MLPA probe kit P011-B3/P012-B3. Among variants from genes of primary interest, common variant with minor allele frequency ≤1% using population databases were filtered out. In addition, variants detected in more than 2% in in-house database were further filtered out to remove population specific polymorphism or platform specific errors. For VWF exons of either incomplete coverage or low mapping quality due to highly homologous region (exon 26, 24), additional Sanger sequencing was performed. Genes of primary interest were those associated with platelet dysfunction (ITGB3, GPBAR1, VPS44, GP9, GP10, PGAM5, MYO5A, NBEAL2, VPS33B, HERMANNSMANN thrombasthenia (ITGA2B, ITGB3), Thromboxane A2 receptor defect (TXB2AR), ADP receptor defect (P2RY12), Gray platelet syndrome (NEB2), Quebec platelet disorder (PLAU), ARC syndrome (VPS38), Hermansky-Pudlak syndrome 1/2, Chediak-Higashi syndrome, Griscelli syndrome (LYST), GRIS, Gricelli syndrome (MYO5A, RAB27A, MLPH), Scott syndrome (ABCA1).

Results: Twelve children with easy bruising, frequent epistaxis, or menorrhagia and their family members were enrolled. Two unrelated children were confirmed as GT. One proband had compound heterozygous variants of c.1913+5G>T and c.2415G>C (p.Gly484Val) in ITGB3. The former was pathogenic which results in aberrant splicing and the latter is novel. The other proband had homozygous variant of c.1913+5G>T in ITGB3. Three unrelated children were confirmed as vWD. One proband had compound heterozygous variants of c.2574G>C (p.Cys858Trp) and c.390C>T (p.Pro1127_Gly1180delinsArg) in VWF, especially the latter synonymous variant previously confirmed to be resulted in exon 26 skipping. Another proband had a novel variant, c.2008C>T (p.Arg670Cys). The last proband had a known VWF pathogenic variant of c.1728G>T (p.Met576Ile).

Summary/Conclusions: DES is a valuable method to confirm GT or vWD. Further study is needed to find out unidentified mutations by this strategy.

P311
HPA-3A/3A GENOTYPE IS A POSSIBLE RISK FACTOR OF SEVERE HEMORRHAGIC SYNDROME IN PATIENTS WITH CHRONIC IMMUNE THROMBOCYTOPENIA

Z. Inna1, K. Sergey2, G. Sergey1, M. Natalya1, G. Svetlana1, B. Stanislav1, B. Stanislav1
1Hematology, Russian Research Institute of hematology, Saint-Petersburg, Russian Federation

Background: The main clinical manifestation of primary immune thrombocytopeinia (ITP) is hemorrhagic syndrome which results in simple or minimal cutaneous hemorrhages to severe life-threatening bleeding. It is well known, that there is no stable correlation between the platelets count or other parameter(s) and the hemorrhage grade in ITP patients. Possibly, the genetically-based individual mechanisms of immune response impairment could affect the severity of the disease.

Aims: To reveal genetic risk factor(s) for severe HS in patients with chronic ITP.

Methods: A total of 67 patients (58 women and 9 men) with chronic ITP were involved in the study. The median age of the group was 57 years (range: 24-77). The mean duration of ITP was 7 years (2-48). Hemorrhage was graded according to WHO scale. Taking into account the severity of HS, all the patients were divided into two groups. The first group included 40 patients with HS of 0-1 grade and the second consisted of 27 patients with HS of 2-3 grade. All patients of the second group needed the use of different methods of emergency haemostatic therapy and we consider it as a “severe ITP”.

Summary/Conclusions: The frequency of HPA-3a/3a (QpIl2622TT, 843 Ile/ile genotype) was more than 2-fold increased in ITP patients with severe HS (55.6% vs 25.0% in the group with HS of 0-1 grade; OR=3.8, 95% CI: 1.3-10.7, p=0.02). HPA-1a/1a and HPA-2a/2a genotypes were also more frequently seen in patients with HS grade 2-3 when compared to grade 0-1 (77.8% vs 31.9% in HS 0-1 (77.8% vs 25.0% respectively), but these differences were not statistically significant (p<0.078 and p<0.19, respectively). Moreover, in the group with “severe ITP” we found almost 2-fold increase of the IL-6 -174CC genotype frequency (26.9% vs 15.0% in HS 0-1; OR=2.1, 95% CI: 0.6-7.1, p=0.34). Patients positive for HPA-3a/3a were more frequently affected by ITP and HS of grade 2-3 (48.1% vs 26.3% in HS 0-1; OR=2.6, 95% CI: 0.9-7.4, p=0.0)
P312

AN ALGORITHM TO IDENTIFY CASES OF SEVERE HEMORRHAGE IN ROUTINELY COLLECTED HEALTHCARE DATA

A. Kreuger1-2, R. middelburg1, J.L. Kerkhofs3, J. van der Bom1

1Center for Clinical Transfusion Research, Sanquin Research, 2clinical epidemiology, LUMC, Leiden, 3Hematology, Hagaziekenhuis, den haag, Netherlands

Background: Many patients with a hematological malignancy have an increased risk of hemorrhages. Research addressing the causes of these hemorrhages, especially those on major hemorrhages, are hampered by the difficulty to find sufficient and representative cases of major hemorrhage. Unfortunately, electronic health records generally do not codify hemorrhages.

Aims: The aim of this study was to develop an algorithm that can be used to find patients who suffered from major hemorrhages (WHO grade 3 or 4) within electronic health records.

Methods: An algorithm was developed using electronic health record data of a cohort of patients with acute leukemia, who received platelet transfusions between June 2011 and December 2015 at the Leiden University Medical Center in the Netherlands. Chart review was performed for a stratified, random sample of observation days. Discriminative performance of three indicators was assessed: CT-brain, drop in hemoglobin level and transfusion need within 24 hours. The cut off values for hemoglobin drop and transfusion need with the best discriminating capacity and CT-brain were entered in the final algorithm. The C-statistic was calculated and calibration plots were made. The algorithm will be externally validated in two other academic hospitals.

Results: The derivation cohort consisted of 255 patients comprising 10,638 observation days and chart review was performed for 353 days. The incidence of major hemorrhage was 0.22 per 100 observation days. The final algorithm consisted of information on CT-brain (yes/no), a hemoglobin drop of ≥2.8 g/dl and the need of six or more transfusions (yes/no). The C-statistic of the algorithm was 0.93 (95% confidence interval (CI) 0.86 to 0.99). The incidence of bleedings with all grades of severity was 8.4 per 100 days. The algorithm for bleeding of all grades had a c-statistic of 0.54 (CI 0.53 to 0.55). The results of the external validation are not available yet.

Summary/Conclusions: An algorithm using information on CT-brain, hemoglobin drop and transfusion can accurately identify cases of major hemorrhage within electronic health care data. External validation will be performed.

Myelodysplastic syndromes – Clinical 1

P313

MOLECULAR MECHANISMS AND CLINICAL SIGNIFICANCE OF REDUCED PTPN1 EXPRESSION IN MYELODYSPLASTIC SYNDROMES

M. Shisieki1, M. Isi1, M. Ohwash1, N. Mor1, K. Yoshinaga 1, J. Tanaka1

1Department of Hematology, Tokyo Women’s Medical University, Tokyo, Japan

Background: Previousy we determined common deleted region (CDR) of del(20q) observed in MDS by CGH-array. Our data showed that the PTPN1 gene is located within CDR of del(20q). The PTPN1 gene encodes PTP-1B, a non-receptor type protein tyrosine phosphatase, which is involved in multiple physiological and pathological cellular processes via dephosphorylation of several tyrosine kinases, and other molecules. Although roles of PTP-1B in normal and pathological hematopoiesis has not been elucidated, it may function negative regulator for cellular processes mediated by tyrosine kinases, including JAK2, and SRC. We hypothesized that the PTPN1 gene is a target gene disrupt by del(20q), resulting in haplo-insufficiency, and involved in MDS molecular pathogenesis.

Aims: We attempted to examine PTPN1 expression level in bone marrow cells of MDS patients with or without del(20q), and to investigate its clinical and biological significance.

Methods: Total RNA was extracted for cDNA synthesis from bone marrow samples taken at the time of diagnosis with written informed consent from patients and control subjects were used for the present study. Real-time RT-PCR was carried out to quantify PTPN1 expression by the TaqMan probe method using an ABI 7500 real-time PCR system (Applied Biosystems). Data including patients’ demographic, disease status, medical history, clinical and laboratory findings, and outcome, were collected from medical records and laboratory data base. A non-parametric Mann-Whitney-Wilcoxon test was used to examine whether expression levels among groups are statistically different. The Kaplan-Meier model was used to analyze the impact of PTPN1 expression on overall survival, and log-rank test was used for statistical analysis. We also examined the effect of 5-azacitidine treatment on PTPN1 expression in primary bone marrow cells from MDS patients. Bone marrow cells were cultured with or without 5mM of 5-azacitidine for 48 hours. Expression level of PTPN1 was examined by quantitative RT-PCR described as above.

Results: A total of 118 MDS patients, 71 males and 47 females with median age of 68 years (range: 20-91 years) and 19 control subjects were included in the present study. The patients were classified as RCUD (n=18), RCMRD (n=58), RARS (n=8), RAEB-1 (n=20), and RAEB-2 (n=14) according to WHO classification. Relative PTPN1 expression level was significantly decreased in MDS patients with del(20q) (P<0.001) compared with control subjects. Moreover, relative PTPN1 expression level in MDS patients without del(20q) also significantly decreased (P<0.001). Expression patterns of PTPN1 among five WHO-subtypes, were statistical different (P=0.0201). Median values of relative PTPN1 expression level in RCUD, RCMRD, RARS, RAEB-1, and RAEB-2 were 1.32, 1.95, 1.91, 1.46, and 1.26 respectively. Relative PTPN1 expression level in WHO-subtypes with high blast counts (RAEB-1 and RAEB-2) was significantly lower than that in WHO-subtypes with less blast counts (RCUD, RCMRD, RARS) (median value: 1.41 vs 1.89, P=0.0074). To investigate prognostic implication of PTPN1 expression in MDS, we analyzed impact of PTPN1 expression on overall survival (OS). Based on PTPN1 expression level, 118 patients were divided into four groups, high (Q1), intermediate (Q2, Q3), and low (Q4) quartiles. Kaplan-Meier analysis demonstrated that the lowest quartile (Q4) showed significantly worse survival compared with remaining quartiles (Q1, Q2, Q3) (P=0.048). The estimated 5-year OS rates in Q1-3 group and Q4 group were 69% and 49.8%, respectively. We examined whether PTPN1 expression is induced in 5-azacitidine treated primary bone marrow cells of 17 MDS patients.

Summary/Conclusions: The present study demonstrated that PTPN1 expression level is reduced in MDS patients with haplo-insufficiency due to del(20q) and methylation of promoter region of the PTPN1 gene. Low PTPN1 expression is associated with advanced disease and poorer clinical outcome, indicating that PTPN1 expression level could be a useful prognostic marker in MDS.

P314

MOLECULAR MARKERS PREDICTING RESPONSE TO AZACITIDINE TREATMENT FOR MYELODYSPLASTIC SYNDROMES

Y. Nannya1,*, J. Takeda1, Y. Shiozawa2, Y. Shiraiishi1, Y. Okuno4, K. Kataoka1, K. Chiba1, H. Tanaka1, M. Sanada1, S. Chiba6, N. Asu7, H. Kyoi6, K. Imai9, C. Hirase10, N. Dobashi11, T. Kiguchi12, S. Nakao13, K. Ohyashiki14, Y. Miyazaki15, T. Naoe16, H. Makishima1, S. Miyano2, K. Yoshida1, S. Ogawa1

1Department of Pathology and Tumor Biology, Kyushu University, 2Department of Pediatrics, Graduate School of Medicine, The University of Tokyo, 3Laboratory of DNA information Analysis & Laboratory of Sequence Analysis, Human Genome Center, The University of Tokyo, Tokyo, 4Center for Advanced
Background: DNA hypomethylating agents (HMAs) comprise standard therapy for non-transplant candidate high-risk myelodysplastic syndromes (MDS). However, little is known about the exact mechanism of their effects to MDS or no reliable makers predicting the response to HMAs have been developed, although a recent study reported a very high response rate of TP53-mutated AML and MDS to decitabine.

Aims: The purpose of this study is to elucidate the clonal dynamics and molecular signatures that correlate with response to azacitidine therapy for MDS, focusing on the role of TP53-mutations.

Methods: We conducted a prospective multicenter trial of azacitidine treatment for high-risk MDS patients, in which the efficacy was compared between the 5-day and 7-day regimens. A total of 107 patients were enrolled between 2013 and 2016. For all cases, a bone marrow specimens collected before therapy was analyzed for mutations using targeted-capture sequencing. Mutations were also interrogated after 4 cycles of azacitidine therapy in 48 (45%) cases. An additional 42 patients were analyzed for mutations who received azacitidine for 48 (86%) patients and whose bone marrow specimens were available both before and after therapy. RNA baits were designed for detection of both oncogenic variants in 67 known driver genes in myeloid neoplasms and copy number alterations on the same platform. Response was evaluated according to the IWG 2015 criteria. \( \Delta \)TCF was evaluable for 62 cases who had one or more low-up specimens and carried at least one mutation in either pre- or post-treatment. \( \Delta \)TCF (tumor cell fraction).

Results: On average, 2.7 mutations (range 0-9) were detected per sample before azacitidine treatment. TP53 represented the most common mutation (10% of cases). TP53 mutations were significantly lower in responders than non-responders (1.7 \( \mu \)g vs 3.1/sample, \( p<0.001 \)) and higher in responders than non-responders (9.6 vs 2.1, \( p=0.001 \)). 189 (75%) cases (all CR) in the on-protocol cohort and 189 (75%) cases (all CR) in the off-protocol cohort. Notably, CR was obtained almost exclusively in TP53 mutated cases (5/6 and 5/7 CR cases in the on- and off-protocol cohorts. No other mutations were associated with clinical or hematological parameters. Median time to CR was 119 days (range: 81–721), which lasted for a median duration of 217 days (range 10 – 783). \( \Delta \)TCF was evaluable for 62 cases who had one or more low-up specimens and carried at least one mutation in either pre- or post-treatment. 189 (75%) cases (all CR) in the on-protocol cohort. 189 (75%) cases (all CR) in the off-protocol cohort. Notably, CR was obtained almost exclusively in TP53 mutated cases (5/6 and 5/7 CR cases in the on- and off-protocol cohorts. No other mutations were associated with clinical or hematological parameters. Median time to CR was 119 days (range: 81–721), which lasted for a median duration of 217 days (range 10 – 783). \( \Delta \)TCF was evaluable for 62 cases who had one or more low-up specimens and carried at least one mutation in either pre- or post-treatment.

Summary/Conclusions: Our study revealed a significant positive association of TP53 mutations with favorable responses to azacitidine for MDS, although the response was transient and the expected response rate seems to be much lower compared to that reported for decitabine. Given that decitabine is not curative, further studies are needed to explore the potential role of azacitidine as a key agent to improve the notoriously dismal clinical outcomes of TP53-mutated tumors. Further study should be warranted to confirm its efficacy and to develop an optimal post-remission therapy to overcome the short remission period.

Background: Improved survival and response outcomes of patients with higher-risk MDS and CMML is fundamental. Guadecitabine is a next-generation hypomethylating agent with increased length of exposure compared to decitabine and clinical activity in patients with MDS.

Aims: To evaluate the activity of guadecitabine in previously untreated patients with higher-risk MDS or CMML.

Methods: We conducted a single arm phase II clinical trial of guadecitabine at a dose of 60mg/m^2 sc daily for 5 days (days 1-5) every 28 days for patients with newly diagnosed MDS or CMML classified as intermediate-2 or High risk by IPSS. Primary endpoint was complete response (CR). Responses were evaluated following the revised 2006 International Working Group criteria. Sequencing data was obtained at the time of pre-treatment evaluation by the use of a 28-gene next generation sequencing platform. Study included stopping rules for response and toxicity. Overall survival (OS) was censored at the time of transplant.

Results: A total of 53 patients have been enrolled: 50 (94%) are evaluable for toxicity and 44 (83%) for response. Median age is 67 years (49-87). A total of 43 (86%) patients have MDS and 7 (14%) have CMML. A total of 21 (42%) patients had de novo MDS. Clinical data were available for 48 (86%) patients with TP53 mutations being the most frequently detected in 36 patients. After a median of 6 treatment cycles (1-20), the ORR is 71% including 32% CR. Median best response occurred by 3 cycles (1-6). Seven (21%) out of 33 evaluable patients achieved a complete cytogenetic response. Ten (20%) subjects with a diagnosis of secondary MDS achieved a complete cytogenetic response. Median time to CR was 17.8 months (0-23). Median OS is 14.1 months (CI 13.3-14.9 months) and median EFS is 8.4 months (CI 5.6-11.2 months). Forty-five (90%) patients experienced at least one AE during therapy. Most common grade 1-2 AEs included fatigue (66%), nausea (38%) and dyspnea (26%). Dose reductions due to cytopenias were required in 17 (34%) patients. Early 8-week mortality occurred in 3 (6%) patients.

Summary/Conclusions: Guadecitabine is well-tolerated and active in patients with higher-risk MDS and CMML even in the presence of adverse biological features such as high frequency of complex cytogenetic, therapy related disease and TP53 mutations.

Background: A benefit of treatment with azacitidine (AZA) in higher-risk (intermediate-2 and high risk by IPSS) Myelodysplastic syndromes (HR-MDS) patients with abnormalities of chromosome 7 (Abn 7) has been suggested in relatively small studies.

Aims: Our purpose was to confirm this benefit in a larger patient series.

Methods: A retrospective study of 235 HR-MDS patients with AZA (n=115) vs best supportive care (BSC; n=120), assessing AZA treatment as time-varying variable in multivariable analysis.

Results: Seventy-four (64%) of AZA patients had de novo MDS and 41 (36%) had therapy related (secondary MDS), compared to 70 (90%) and 8 patients (10%) in the BSC group (P=0.0001). According to WHO 2008 classification, 65% in the AZA group and 48% in the BSC groups had refractory anaemia with excess of blast type 2 (RAEB-2) or secondary acute myeloid leukaemia (AML with <30% of blasts) (P=0.015). The AZA and BSC groups were well balanced in terms of age, gender, cytogenetic risk category, and IPSS risk. In the AZA group as compared to the BSC group (P=0.015). Median time from diagnosis to AZA treatment was 2 months (range 0 – 66.2). Ninety-two patients (80%) received AZA compared to the conventional 7 days treatment schedule whereas 20% received 5-day cycles. The median number of AZA cycles received was 5 (range, 1-32). Response to AZA: Twenty patients were not evaluable for response according to IWG 2006 criteria because no complete data was recovered. In the 103 patients evaluable for response in the AZA group, the overall RR (ORR) was 37% (95% CI: 37% – 40%). In the BSC group PR+NR was 22.3% and 23.3% SD, 14.6% PD and 11.7% (n=12) had early death (8, infection; 1, bleeding, 3, unknown cause). According to cytogenetic, the ORR was 38.1% in patients with CK, 32% in patients with non complex-7 and 46% in patients with
with non complex del(7q) (P<0.05 for complex vs non complex, chi-square test). The ORR was 37.5% in "de novo" and 38.4% in secondary MDS, respectively (P=ns). Impact of AZA treatment compared to BSC on overall survival: Results of this multivariable analysis of OS at different time points are presented in Table 2. Chromosome 7 cytogenetic categories and IPSS retained a poor prognosis over time with a constant value of poor prognosis. AZA treatment had a favorable impact on OS during the first 3 years of treatment, compared to BSC, confirming results obtained in univariable analysis. Nevertheless, the benefit of AZA treatment as compared to BSC approach decreased as time spends and the HR value increased over time: HR of 0.3 at 6 months, 0.5 at 1 year and 0.7 at 2 and 3 years after treatment. (Figure 1). This benefit was present in all chromosome 7 categories with a a trend towards better impact among patients with complex karyotype but no significant differences between the 3 categories (-7, del(7q) and CK).

Figure 1.

Summary/Conclusions: This study confirms the benefit of AZA treatment on outcome in patients with HR-MDS and cytogenetic abnormalities involving chromosome 7.

P317

UN UPDATE OF A PHASE II EXPLORATORY STUDY OF OPN-305, A TOLL-LIKE RECEPTOR 2 ANTIBODY, IN PATIENTS WITH LOWER RISK MELODYDYSPLASTIC SYNDROMES WITH PRIOR HYPOMETHYLATING AGENT THERAPY

G. Garcia-Manero1,2, G. Montalban-Bravo3, H. Yang1, Y. Wei1, Y. Alvarado1, C. DiNardo1, N. Daven2, M. Koropleva1, K. Hearn1, R. Miller2, S. Arbe-Barnes2, P. McGuirk2, T. Kearney2, R. Keogh2, H. Kantarjian1, M. Reilly2,1

1Leukemia, The University of Texas MD Anderson Cancer Center, Houston, United States, 2Opsona Therapeutics, Dublin, Ireland

Background: Alterations of innate immune signaling, including overexpression of TLR2, are common in MDS. Significant TLR2 overexpression in MDS bone marrow CD34+ cells, especially after HMA therapy, has been reported. OPN-305 is a fully humanized antagonistic IgG4 kappa monoclonal antibody to TLR2, are common in MDS. Significant TLR2 overexpression in MDS bone marrow CD34+ cells, especially after HMA therapy, has been reported. OPN-305 is a fully humanized antagonistic IgG4 kappa monoclonal antibody to TLR2 which significantly increases the formation of erythrocytoid colonies (CFU-E) in BM CD34+ cells isolated from pts with lower-risk MDS in vitro.

Aim: To evaluate the potential therapeutic value of OPN-305 in patients (pts) with MDS.

Methods: We designed a phase I/II trial of OPN-305 for pts with Low or Int-1 risk MDS by IPSS after failure to prior therapy with a HMA (≥4 cycles). Pts whose disease was to be transfusion dependent (≤2 units in 8 weeks). Pts with isolated del(5q) should have received therapy with lenalidomide. Because, OPN-305 had not been previously used in pts with hematological malignancies, the study had an initial phase of N=10 pts using OPN-305 at a dose of 5 mg/kg every 4 weeks for a maximum of 9 cycles. Therapy could be repeated as long as there was no excess toxicity or progression. If after 16 weeks of therapy, there was no response, azacitidine on a 3 day schedule, could be added to OPN-305. Responses were evaluated following the revised 2006 IWG criteria. This initial cohort allowed evaluation of toxicity, pharmacokinetic analysis, receptor occupancy, and sequential analysis of cytokine profile. An extension dose escalation phase to 10 mg/kg was planned for N=30 pts.

Results: At the time of this report, 31 pts have been enrolled, 11 at the initial 5 mg dose and 21 at 10 mg/kg. A total of 21 pts are evaluable for toxicity and response. Median age was 72 years (range 42-87). Nine (43%) pts were classified as Low risk and 12 (57%) as Intermediate-1 risk by IPSS. Thirteen pts had normocaryotype, 2 (15%) had del(5q), 1 monosomy Y and 2 other single or double abnormalities. Median number of prior therapies was 2 (range 1-4) with a median duration of prior therapies of 23 months (range 6-56). A total of 5 (25%) pts developed AEs related to OPN-305. All AEs were grade 1 with gastrointestinal disorders being the most frequent (23%). At this point, no significant drug related toxicity has been documented with no excess infectious complications. Overall response rate in the form of hematological improvement was 53% (8/21) with 3 (20%) pts achieving transfusion independence and 5 (33%) minor hematological improvement. Half-lives of OPN-305 in serum were >200 h at 5 mg/kg and >300 h at 10 mg/kg. There was a greater-than-dose proportional increase in mean OPN-305 exposure (AUC) between 5 and 10 mg/kg. PK profiles after repeated dosing at 5 mg/kg in N=2 subjects indicated some variability in the potential for accumulation. TLR-2 receptor occupancy in blood PBMCs and bone marrow aspirates was complete in virtually all samples taken after OPN-305 administration. There is no evidence of cross reaction (ALIC) against anti-tumor antibodies. Compared with baseline, no significant changes of IL-23, IL-18, IFN-γ, IL-10, IL-1b, IL-6, IL-12 (p40), IL-12 (p70) and IL-8 levels where observed among responders or non-responders or based on OPN-305 dosing. A trend to increased response was observed in patients with higher TLR2 expression, (P=0.05) and significant association between TLR2 levels and response.

Summary/Conclusions: Treatment with OPN-305 in pts with previously treated lower-risk MDS was well tolerated with no significant toxicities and 53% ORR including 20% transfusion independence, and potential association between TLR2 levels and response.

P318

IN PATIENTS UNDEGOING HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR MDS DEVELOPMENT OF CHRONIC GVHD COULD AMELIORATE THE ADVERSE IMPACT OF SPECIFIC SOMATIC MUTATIONS

1Hematology Department, University Hospital of Salamanca, 2Department of Statistics, 3Centro de Investigación del Cáncer, IIBMC (Instituto de Biología molecular y celular del cáncer, University of Salamanca, 4Molecular Biology Department, University Hospital of Salamanca, Salamanca, 5Hematology Department, University Hospital La Fe, Valencia, 6Hematology and Medical Oncology Department, University Hospital Morales Meseguer, Murcia, 7Hematology Department, University Hospital Vill d’Hebron, Barcelona, 8Area of Genetic and Cellular Therapy, IBSAL Instituto Bioanatomo de Salamanca, Salamanca, Spain

Background: Approximately 90% of patients with Myelodysplastic Syndromes (MDS) have somatic mutations in driver genes detected by Next Generation Sequencing (NGS). In the last years, several studies have related these mutations with prognosis, disease characteristics and response to therapy, including allogeneic Hematopoietic Stem Cell Transplantation (HSCT). Development of Chronic Graft Versus Host Disease (cGVHD) has been reported as one of the most powerful antineoplastic mechanisms after HSCT.

Aims: To evaluate the impact of specific somatic mutations in patients with MDS undergoing HSCT and if the development of cGVHD can modify their prognosis.

Methods: The results of HSCT in 115 MDS patients from five centres in Spain were retrospectively analyzed. Bone marrow samples were collected a median of 27 days prior to transplant and DNA was screened for somatic mutations by NGS, using a NextSeq platform (Illumina). Two myeloid genes panels that included the most frequently mutated genes in myeloid malignancies were used.

Results: Median age was 53 years (range from 19 to 70). Fifty-eight percent were male and 79.13% were classified as de novo MDS. According to WHO 2008 classification 4 (3.5%) were RCDU, 2 (1.8%) RARS, 22 (19.50%) RCD, 28 (24.8%) RABE-1, 32 (28.3%) RABE-2, 12 (10.6%) Unclassifiable MDS, 9 (8%) CML and 4 (3.5%) were AML (FAB RAEB-T). Among patients with calculated Revised IPSS (R-IPSS) (85 of 115 patients) 2 (2.4%) had very low risk, 15 (17.6%) low risk, 21 (24.7%) intermediate risk, 22 (25.9%) high risk and 16 (18.6%) had very high risk; 9 patients with CML (10.6%) were categorized as intermediate risk MDS and pre-dose (trough) levels in other subjects indicated some variability in the potential for accumulation. TLR-2 receptor occupancy in blood PBMCs and bone marrow aspirates was complete in virtually all samples taken after OPN-305 administration. There is no evidence of cross reaction (ALIC) against anti-tumor antibodies. Compared with baseline, no significant changes of IL-23, IL-18, IFN-γ, IL-10, IL-1b, IL-6, IL-12 (p40), IL-12 (p70) and IL-8 levels where observed among responders or non-responders or based on OPN-305 dosing. A trend to increased response was observed in patients with higher TLR2 expression, (P=0.05) and significant association between TLR2 levels and response.

Summary/Conclusions: Treatment with OPN-305 in pts with previously treated lower-risk MDS was well tolerated with no significant toxicities and 53% ORR including 20% transfusion independence, and potential association between TLR2 levels and response.
variate analysis. We also observed the unfavourable impact of TP53 mutations on relapse risk: CIR was 41.7% (95% CI 22.5-77.1) at 1 year for TP53 mutated vs 9.8% (95% CI 5.3-18.1) at 1 year for non TP53 mutated patients (p=0.006).

Figure 1.

Summary/Conclusions: We conclude that the number of mutated genes prior to transplant could be a prognostic factor of OS and CIR. Mutations in some genes, like TET2 and TP53, could also have an adverse impact on outcome. However, cGVHD could ameliorate the poor prognosis of somatic mutations in transplanted patients with MDS.

P319
VOSAROXIN PLUS AZACITIDINE TREATMENT FOR PATIENTS WITH MYELODYSPLASTIC SYNDROME: A PHASE 1/COHORT EXPANSION STUDY
M.A. Jacoby1,*, M.J. Walter1, J.F. DiPersio1, C.N. Abboud1, P. Westervelt1, A.F. Cashen1, K. Stockerl-Goldstein1, T. Fletcher1, G.L. Uy1
1Medicine, Washington University Medical School, St. Louis, United States

Background: Although hypomethylating agents are the mainstay of treatment for myelodysplastic syndromes (MDS), these agents result in remissions in a minority of patients and are not curative. Vosaroxin is a first-in-class quinolone derivative that intercalates DNA and inhibits topoisomerase II. Vosaroxin is active with a tolerable safety profile in acute myeloid leukemia (AML) and the novel combination of vosaroxin and azacitidine was found to be synergistic in primary myeloblasts.

Aims: This phase 1/cohoot expansion study was designed to determine the maximum tolerated dose (MTD) and dose-limiting toxicity (DLT) of vosaroxin when given in combination with azacitidine, and to evaluate the efficacy and safety of the combination treatment.

Methods: Patients with MDS ≥18 years old with cytopenias requiring transfusions, an IPSS score of intermediate (INT)-1 or greater, or chronic myelomonocytic leukemia were eligible. Vosaroxin (initial dose: 50 mg/m²/d) was administered on Days 1 and 4, and azacitidine (75 mg/m²/d) on Days 1-7 of a 28-day cycle, in an outpatient setting, for up to 6 cycles in a 3+3 design (additional cycles were permitted if a clear benefit for the patient was demonstrated). Once the MTD was determined, an expansion cohort of 20 evaluable patients (≥1 cycle) was enrolled.

Results: A total of 35 patients enrolled in the dose escalation (n=13) and expansion (n=22) phases. The median age of the entire cohort was 66 years (range 38-77) with IPSS scores of low (n=1); INT-1 (n=13); INT-2 (n=15); and high risk (n=6). The median ECOG score for the entire cohort was 1 (range 0-2). In the dose escalation phase, at the initial dose of vosaroxin 50 mg/m²/d (n=6), the median number of total cycles was 2 (range: 1-4); 2 of 6 patients experienced a DLT at this dose (grade 4 hyperbilirubinemia and grade 4 neutropenia >42 days). At the de-escalated dose of 34 mg/m²/d (n=7), the median number of cycles was 2 (range: 1-18); 1 patient experienced a DLT at this dose (grade 4 mucositis). The MTD of vosaroxin was determined to be 34 mg/m²/d when given on Days 1 and 4 with a fixed dose of 75 mg/m² of azacitidine on Days 1-7. The major non-hematologic toxicities were infections, febrile neutropenia, and bleeding. The combination of vosaroxin and azacitidine showed promising activity with responses rates comparable or better than those generally observed with azacitidine alone. Additionally, the transplant rate observed was encouraging in this patient population.

Table 1.

Summary/Conclusions: The MTD of vosaroxin in MDS patients was 34 mg/m²/d when given on Days 1 and 4 with a fixed dose of 75 mg/m² of azacitidine on Days 1-7. The major non-hematologic toxicities were infections, febrile neutropenia, and bleeding. The combination of vosaroxin and azacitidine showed promising activity with responses rates comparable or better than those generally observed with azacitidine alone. Additionally, the transplant rate observed was encouraging in this patient population.

ADVANCED STAGE MYELOMA IS CHARACTERIZED BY A SIGNIFICANT INCREASE OF MUTATIONS IN GENES ASSOCIATED WITH DRUG RESPONSE

S. Barrio1,2, M. Da-Via1,2, T. Stühmer1, A. Gartano-Trojala1, L.Bruins3, I. Cuenca4, M. Schreder1, R. Tibaes1, P. Sommeveld1, M.S. Raab4, J. Martinez-Lopez5, A. Rosenwald6, R.C. Bargoo5, E. Braggio5, A.K. Stewart1,2, H. Einsele1, K.M. Kortüm1
1Hematology, Würzburg University Hospital, Würzburg, Germany, 2Hematology-OncoLOGY, IRCCS Policlinico San Matteo, Pavia, Italy, 3Hematology, Mayo Clinic, Scottsdale, United States, 4Hematology, Doce de October University Hospital, Madrid, Spain, 5Hematology, Erasmus Medical Center, Rotterdam, Netherlands, 6Hematology, Heidelberg University Hospital, 7German Cancer Research Center, Heidelberg, 8Pathology Institut, Würzburg University Hospital, 9Comprehensive Cancer Center Mainfranken, Würzburg University Hospital, Würzburg, Germany, 10Center of Individualized Medicine, Mayo Clinic, Rochester, United States

Background: The amount of genomic data available in Multiple Myeloma (MM) is exponentially increasing, however, hardly any of that information is translated into the clinic. A number of genes has been associated with resistance to commonly used anti MM compounds. This, most importantly, includes immunomodulators (IMiDs) and proteasome inhibitors (Ps). However, no mutation screening has yet been amended to our MM routine diagnostic workflows. We investigated 458 MM patients by targeted sequencing, including the largest cohort of previously treated MM patients so far. We identified an increased mutation incidence in treated patients, yet unreported mutations and functionally validated a subset.

Aims: To describe the mutational spectrum in genes of pathways targeted by standard of care (SOC) therapies in a cohort of pretreated and previously untreated patients.

Methods: Tumor-germline paired samples of five contributing sites were pooled (Würzburg, Heidelberg, Madrid, Rotterdam and Mayo Clinic). Analysis included 310 untreated and 148 IMiD and/or PI treated patients. Targeted sequencing was performed using the M-P (v2.0 or v3.0) gene selection, that includes most commonly mutated MM genes, actionable drug targets and genes being associated with drug resistance. Average sequencing depth increased 700X. Functional analyses of PSMB5 mutations were conducted using Sleeping beauty vectors transposed into AMO1 cell line.

Results: Our analysis included five genes each with known association to drug response to IMiDs (CRBN, CUL4B, IKZF1, IKZF3 and IRF4) and Ps (PSMB5, PSMB8, PSMB9, PSMD1 and XBP1). Based on the increased sequencing depth, the mutation incidence in untreated patients is higher than in the CoMMPass dataset (IMiDs: 5.8% vs 3.9%; Ps: 1.9% vs 1.4%). Furthermore, pretreated patients showed a significant mutational increase compared with untreated pts (IMiDs: 19.7%, Z-score: -4.2, p<0.001; Ps: 7.3%, Z-score: -2.6, p=0.009). We observed a Gly159Arg mutation within the Lenalidomide (Len) degron sequence of IKZF3 in a patient progressing on Len and Pomidomide (Pom), as well as two XBP1 truncating mutations in PI refractory patients. Of note, among three treated cases with mutations in the β5 (PSMB5) or βi (PSMB8) PI binding subunit of the proteasome, one patient harbored not less than 4 subclonal mutations. This is the first description of PSMB5 mutations in human MM, identified in a patient with long term history of PI treatment. All mutations were located in or close to the Bor binding site of PSMB5. The functional analysis demonstrated induction of resistance not only to Bor (IC50 in PSMB5wt= 2 nM vs IC50 in PSMB5mut= 4.5-8 nM), but also to the second generation PI Ixazomib (IC50 in PSMB5wt= 5.2 nM vs IC50 in PSMB5mut= N/A) and Carfilzomib (IC50 in PSMB5wt= 8 nM vs IC50 in PSMB5mut= 13-22 nM). Of interest, the P97 blockade of the protein homeostasis by the investigational compound CB5083 remains still possible in the mutated cell lines and the resistance can be overcome. Finally, Pom treatment eradicated two of the PSMB5 containing subclones (Figure 1).

Summary/Conclusions: Under the selective pressure of anti-MM therapy the incidence of mutations in genes associated with drug resistance increases in resistance mechanism evolve in parallel in competing (sub)clones of the disease, mimicking phenotype and behavior. Remarkably, despite our restrictive gene selection, a quarter of our treated cohort is affected by at least one mutation. Aim of future therapy may be the eradication of selected clones or subclones, which, according to our data, appears possible.

ILF2-YB1 INTERACTION MODULATES RNA SPlicing TO INDUCE RESISTANCE TO DNA-DAMAGING AGENTS IN 1Q21-AMPLIFIED MULTIPLE MYELOMA

M. Marchesini1,2, Y. Ogol1, F. Fiorini1, M. D’Anca2, P. Storti3, L. Nezi4, M. Kemaal Samu1, I. Ganan-Gomez1, M.T. Fulciniti1, L. Zhang1, N. Giuliani3, Z. Bohannan1, K. Cline-Deyer2, N. Munshi5, P. Orlofsky6, G. Garcia-Manero1, R.A. DePinho7, S. Colla1
1Leukemia, MDAnderson Cancer Center, Houston, United States, 2Neurology, University of Milan, Milan, 3Clinical and Experimental Medicine, University of Parma, Parma, Italy, 4Genomic Medicine, MDAnderson Cancer Center, Houston, TX, 5Harvard Medical School, Dana Farber Cancer Institute, Boston, 6Informatic and Computational Biology, 7Stem cell transplantation and cellular therapy, 8Lymphoma/Myloma, 9Cancer Biology, MDAnderson Cancer Center, Houston, United States

Background: The 1q21 amplification, which occurs in approximately 40% of de novo and 70% of relapsed Multiple Myeloma (MM), is among the most frequent chromosomal aberrations in MM patients and is considered a very high-risk genetic feature that is especially correlated with disease progression and drug resistance. The 1q21 amplicon contains many genes, and while it is unlikely that all contribute to the pathobiology of high-risk MM, the critical genes that do drive this high-risk phenotype have not yet been fully clarified. Identifying such genes and their contributions to this phenotype would enable the development of new and effective targeted therapy strategies for high-risk MM and thus improve their survival outcomes.

Aims: In our study we wanted to investigate the biological and molecular mechanisms behind the 1q21 amplification's contribution to high-risk MM with the ultimate goal of obtaining a list of validated therapeutic targets to inform the design of novel translational clinical trials for this subgroup of patients.

Methods: We conducted a high-resolution analysis of recurrent copy number alterations and expression profiles in a collection of 254 MM samples included in MMRC database. To define the discrete minimal common 1q21 region that is recurrently amplified in MM, we used Genomic Identification of Significant Targets in Cancer, a systematic method that identifies regions of genome that are recurrently amplified or deleted across a set of samples. These were enlisted into an in vitro screening strategy that employed a single-shRNA-per-96-well approach and GFP-competitive cell growth assay to identify 1q21 genes whose loss of function resulted in the selective death and/or growth inhibition of MM cells carrying the 1q21 amplification but not MM cells without the 1q21 amplification.

Results: We identified MCL1, UBAP2L, INTS3, LASS2, KRTCAP2 and ILF2 as potential 1q21-specific vulnerability targets whose expression is driven by copy number functionally validated, both in vitro and in vivo, Interleukin-2-enhancer binding factor 2 (ILF2) as a key 1q21 amplification-specific gene. Our results show that ILF2 impacts homologous recombination (HR) and induces resistance to DNA damaging agents routinely used in the treatment of MM, which is consistent with the observation that ILF2 expression correlates with poor survival in MM patient treated with high-dose melphalan followed by tandem autologous transplantation. On the mechanistic level, ILF2 interacts with numerous RNA binding proteins directly involved in the regulation of DNA Damage Response (DDR) by modulating alternative splicing of specific pre-mRNAs. RNA sequencing experiment confirmed that ILF2 knockdown results in aberrant splicing of genes involved in the DDR pathways and, strikingly, ILF2 RIP-seq analysis showed that ILF2 directly binds to transcripts involved in the regulation of the HR pathway, including components of the BRCA1 protein complex. Furthermore, we found that ILF2 mediates drug resistance in dose-dependent manner by modulating YB-1 nuclear localization and interaction with the splicing factor U2AF65 to promote mRNA processing and stabilization of DDR genes in response to DNA damage (Figure 1).

Summary/Conclusions: In conclusion, our study reveals an intimate relationship among 1q21 amplification, mRNA splicing and DNA repair in the control of DDR in MM. On the basis of our findings, we propose that 1q21-driven ILF2 overexpression deregulates HR by stabilizing the mRNA splicing of critical HR
effects, which enables genomic instability, promotes adaptive mechanisms to genotoxic stress, and enhances cell survival, thereby promoting drug resistance and disease progression. Given that 1q21 amplification is one of the most frequent copy number alterations in cancer, synthetic lethality approaches based on targeting gain-of-function associated to ILF2 may have a broad spectrum of application to potentiate the sensitivity of cancer cells to chemotherapeutic agents.

PROGNOSTIC IMPLICATION OF SOMATIC MUTATIONS BY NEXT GENERATION SEQUENCING: AN ANALYSIS FROM THE MMRF COMMPASS STUDY IN NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS

1Myeloma Unit, Division of Hematology, University of Torino, Torino, Italy. 2Multiple Myeloma Research Foundation, (MMRF), United States. 3Italian Multiple Myeloma Network, GIMEMA, 4Unit of Clinical Epidemiology, Azienda Ospedaliero-Universitaria Città della Salute e della Scienza di Torino and CPO Piemonte, Torino, Italy. 5Myeloma Unit, Division of Hematology, University of Torino - Currently Takeda Pharmaceuticals Co., Torino, Zurigo, Italy, Switzerland

Background: High throughput techniques, such as next generation sequencing, are becoming an appealing approach to characterize multiple myeloma (MM) genomic profiles and better define risk assessment. However, the clinical relevance of such approaches is still largely unknown. The Multiple Myeloma Research Foundation (MMRF) ComMMpass trial (NCT01454297) has collected data from 1154 newly-diagnosed MM patients enrolled worldwide. Comprehensive analysis of somatic mutations in MM cells at diagnosis could unravel prognostically relevant disease characteristics not detectable with traditional approaches.

Aims: We analyzed data from the interim analysis 8 cohort (August 2015) to create a prognostic model.

Methods: CD138+ purified MM specimens from bone marrow aspirates and peripheral blood cells were collected at diagnosis. Whole exome libraries from both tumor and constitutional DNA samples were created. Somatic single nucleotide variants (SNV) were identified, only nonsynonymous SNV were included in the analysis. We evaluated the impact on progression free survival (PFS) of recurrently mutated genes (with at least a nonsynonymous SNV with an allele frequency of more than 5% in more than 10 patients) in a multivariable Cox model adjusted for international staging system (ISS) and cytogenetic profile, a nonbiased manner (Table 1): group I (score 0-2, 17%); group II (score 3, 51%), group III (score 4-5, 26%) and group IV (score >5, 6%). After a median follow-up of 371 days, the 18-month PFS was 93% for group I, 85% for group II, 73% for group III and 40% for group IV (Figure 1). The hazard ratio was 2.31 (p=0.118) for group II versus group I, 4.45 (p=0.006) for group III versus I and 17.38 (p<0.001) for group IV vs I. The prognostic trend of the score was confirmed in different patient subgroups including ASCT/no ASCT, standard/high risk cytogenetic profile, ISS I, II, or III. Of note, 23% of patients in group I had ISS III and 34% of patients in group IV had ISS I.

Summary/Conclusions: The use of a prognostic model based on the mutational status of 9 recurrently mutated genes could improve risk assessment of newly-diagnosed MM patients. Longer follow-up and validation in independent cohorts of patients are needed to confirm our findings. Updated results with a longer follow-up will be presented at the meeting.

P323

TARGETING GENE DEPENDENCY OF 1Q AMPLIFICATION IN MULTIPLE MYELOMA

S. Manier1,2, D. Huynh2, J. Park2, K. Salem2, X. Leleu3, I. Ghobrial4
1Hematology, Lille Hospital, Lille, France. 2Medical Oncology, Dana-Farber Cancer Institute, Boston, United States. 3Hematology, University of Lille 2, Lille, France. 4Medical Oncology, Dana-Farber Cancer Institute- Harvard Medical School, Boston, United States

Background: Gain of 1q is one of the most frequent copy number variations across cancer types and in Multiple Myeloma (MM). Gain of 1q is associated with a poor outcome, indicating it is a potential driver in MM progression and resistance to treatment. While the whole 1q arm can be amplified in some cases, a specific minimal amplified region has been identified by CGH array, including approximately 500 genes in the 1q21.1-23.3 region. However, the driver genes in the 1q region are unknown.

Aims: We hypothesize that specific genes present in the 1q minimal amplified region are critical regulators of clonal evolution and tumor progression in MM.

Methods: To explore gene dependency in 1q21.1-23.3 in MM, lung, breast and
ovarian cancers, we performed a shRNA targeted screen, using the C911 technology. We used 14 cell lines including MM, lung, and breast cancer cell lines. We designed a pooled library targeted shRNA/C911 screen containing 6 shRNAs along with their matched control for each of the 500 genes in the 1q21.1-23.3 region, including IncRNA and miRNA in addition to protein coding genes. The pooled library contained 6500 shRNAs, including C911 as a control. We used miRNA modified, in vitro expressed sensitivity to IMiD degradation of IKZF1 and IKZF3. We found that the degradation of IKZF1 was abrogated on the resistant cell lines, and remains as such despite their resensitization, meaning that the CRBN-IKZF1/IKZF3 pathway might be bypassed and other important regulatory networks might be as important for sensitivity to IMiDs. Therefore, we are currently performing RNA-seq, which might in combination with accessibility data, give information about the regulatory mechanisms behind acquired IMiD resistance.

Summary/Conclusions: In conclusion, our study is the first one to ever show that acquired IMiD-resistance is mainly an epigenetic event that is potentially reversible through a combination of two epigenetic compounds, 5-Azacitidine and EPZ-6438. These drugs have been shown to have low levels of toxicity, reversible through a combination of two epigenetic compounds, 5-Azacitidine and EPZ-6438. These drugs have been shown to have low levels of toxicity, hence making them very good candidates for a prospective phase I study to examine their potential as “IMiD-resensitizers”, which may improve the outcome treatment of MM patients with drug-resistant myeloma clones and a potentially high-risk disease.

MULTILAYER EPIGENOMIC ANALYSES REVEAL OF NEW CANCER ONCOGENES INVOLVED IN THE PATHOGENESIS OF MULTIPLE MYELOMA

R. Ordóñez1,2, M. Kulis2, N. Russinol3, R. Beekman3, C. Meydan4, R. Ordoñez1,2
1Oncohematology, Center for Applied Medical Research (CIMA), Pamplona, 2Dept. of Medicine, Weill Cornell Medical College, New York, United States, 3Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain, 4Dept. of Medicine, Weill Cornell Medical College, New York, United States

Background: Most of the published omics studies in multiple myeloma (MM) have focused on the analysis of the genome, transcriptome and DNA methy- lome. Over the last years, the chromatin structure and histone modifications are emerging as essential epigenetic layers to understand gene deregulation in MM. Although this field remains widely unexplored in MM.

Aims: We herein aim to elaborate a comprehensive description of the MM epigenome including multiple layers of information.

Methods: We performed ChiP-seq of six histone modifications with non-over- lapsing functions (H3K4me3, H3K4me1, H3K27ac, H3K36me3, H3K27me3, and H3K9me3), ATAC-seq for chromatin accessibility, Whole Genome Bisulfite Sequencing (WGBS) for DNA methylation, and RNA-seq for gene transcription in purified bone marrow plasma cells from four MM patients and, as healthy controls, naive B cells, germinal center B cells, memory B cells and plasma cells. Data were extensively mined using a battery of different bioinformatic tools.

Results: An integrative analysis of ChiP-seq data from six histone marks allowed us to segment the genome into functional chromatin states, such as promoters, enhancers, transcribed regions and repressed/heterochromatic regions. In order to detect regions with significant differences in chromatin activity between MM and normal plasma cells, we elaborated a new algorithm that allowed us to transform the qualitative chromatin state data into a quantitative chromatin activation score (ChromAS). When we compared the ChromAS between MM and normal plasma cells, we detected over 13000 regions with differential activity, of which near 90% were gaining activity in MM, suggesting a widespread activation of their chromatin landscape. To further characterize this phenomenon, we calculated the mean ChromAS per gene and performed a K-means clustering of MM and control cells. Interestingly, we identified the presence of a cluster comprising genes whose chromatin was increasing activated in MM as compared to all normal cells. These findings were further validated by ChiP-seq in an additional series of 10 MM patients. We next focused on the genes that gained novo activity in MM and were completely inactive (i.e. heterochromatic) in normal
cells. Out of this list, we observed that two adjacent genes, PRED5 and IDN13, were co-activated in MM. The analysis of their expression in additional patients indicated that their co-activation is a consistent event in MM pathogenesis and that their levels were negligible in bone marrow and tonsillar plasma cells. When analyzing chromatin topology by 4C-seq, we identified 3D interactions between both genes only in MM cells, suggesting that DNA looping between the two genes may be related to their co-activation in MM. Finally, knockdown of each of these genes using inducible shRNAs, decreased cell proliferation and induced apoptosis in MM cells.

Summary/Conclusions: Collectively, our initial exploration of histone modification profiles in MM has revealed an extensive activation of the MM chromatin landscape, not only in MM but also in a few candidate oncogenes. Reversing this global activation by epigenetic drugs, such as BET inhibitors, may represent an attractive therapeutic option for MM.

Table 1.

<Table 1 as a separate file or inline if possible.>
advanced stage significantly more often and had shorter progression-free survival times than those with low levels (<3.3 ng/ml, n=32) (P=0.032).

Summary/Conclusions: This study revealed that SLAMF3 molecules consistently expressed on MM cells may transmit positive signals mediated via the complex of SHP2 and GRB2 by self-ligand interaction between MM cells and CD74-expressing B-cell malignancies. Furthermore, high levels of serum sSLAMF3 may reflect MM disease progression and be a useful prognostic factor in MM. Thus, SLAMF3 molecules may be a new potential target for future immunotherapy and chemotherapy.

P328
TARGETING CD74 IN MULTIPLE MYELOMA WITH A NOVEL ANTIBODY DRUG CONJUGATE, STRO-001
M. Lupher1, A. Molina1,*
S. Krueger2, S. Matheny 1, T. Kline 1, A. Yam 1, R. Stafford 1, T. Hallam 1,
M. Lusher1, A. Molina1,*
1Sutro Biopharma, South San Francisco, 2MI Bioresearch, Ann Arbor, United States

Background: CD74 is a transmembrane glycoprotein involved in MHC protein formation and transport. CD74 expression has been observed in up to 90% of B-cell malignancies, including multiple myeloma (MM), with minimal expression in normal tissues. CD74 is rapidly internalized, making it an attractive target for ADCs. STRO-001 is a novel ADC comprised of an aglycosylated anti-CD74 IgG1 human antibody (SP7219) conjugated covalently to the non-natural amino acid para-azido-methyl-L-phenylalanine (pAMF) with a non-cleavable dibenzocyclooctyne (DBCO)-maytansinoid linker-warhead. Highly efficient site-specific conjugation enabled by novel cell-free antibody production and click chemistry results in a well-defined homogeneous ADC drug product with a drug-antibody ratio (DAR) of 2.

Aims: The in vitro cytotoxicity and in vivo efficacy of STRO-001 was investigated in MM cell lines and xenografts. An exploratory toxicity study was conducted in a non-human primate model.

Methods: DBCO-Alexa647-conjugated SP7219 staining and flow cytometry were used for detection and quantitation of CD74 expression on MM cell lines. STRO-001 was used to determine the ECDg and percent span of killing in MM cell lines. The anti-tumor activity of STRO-001 was evaluated in the disseminated ARP-1 and MM.1S MM models. In vivo bioluminescence imaging (BLI) for animal imaging was performed using an IVIS Spectrum. BLI images were collected 7, 14, 21, and 28 days post-tumor inoculation. STRO-001 was administered to xenografts in an exploratory dose-escalating study of repeat IV doses of 1, 3, 10 and 30 mg/kg on days 1 and 15.

Results: In vitro cytotoxicity assays show nanomolar potency of STRO-001 in five MM cell lines: MC/CAR (EC50 0.8 nM), ARD (EC50 6.5 nM), MM.1S (EC50 10-11 nM), U266B1 (EC50 8.5-9.3 nM), and ARP-1 (EC50 4.3-22 nM). CD74 cell surface expression is required for STRO-001 cytotoxic activity but expression level, as measured by antibody-binding capacity, does not correlate strongly with in vitro potency (R2=0.5837 for MM cell lines). STRO-001 inhibits the growth of CD138+ plasma cells in bone marrow (BM) and xenografts of visceral tumors (p<0.002 for kidney; p<0.0001 for ovary) after 4 weekly doses of 3 mg/kg in the ARP-1 disseminated MM xenograft model. STRO-001 dosed at 3 mg/kg and 10 mg/kg weekly x 3 also eradicates malignant BM plasma cells by day 32 post-inoculation (p<0.0001) and prolongs survival in the MM.1S disseminated model. At termination of the study, 129 days post-inoculation, 100% of the STRO-001 treated animals survived and showed no evidence of disease with no CD138+ cells in their bone marrow, while mean survival of vehicle-treated control animals was 35 days with almost 50% of their bone marrow containing myeloma cells. BLI of luciferase-expressing MM.1S (MM.1S-luc) tumor cell lines enabled non-invasive quantification of tumor burden. Single doses of 1.3, and 10 mg/kg STRO-001 (administered on day 7 post-inoculation) resulted in eradication of myeloma by day 28 based on bioluminescence signal and quantification of CD138+ cells in bone marrow. In addition, STRO-001 produced a dose-dependent reduction in normal B-cells in cynomolgus monkeys, providing pharmacodynamic evidence of B-cell targeting (Figure 1).

Summary/Conclusions: STRO-001 demonstrates potent in vitro cytotoxicity in MM cell lines and reduces tumor burden in MM xenograft models, including significant prolongation of survival in the MM.1S model. Based on these encouraging observations, STRO-001 is advancing to the clinic for the treatment of CD74-expressing B-cell malignancies.

rió, Palencia, 12Clinica Universidad de Navarra, Pamplona, Spain

Background: Immunoglobulin light-chain amyloidosis (AL) is a heterogeneous and multifactorial disease with high genetic complexity. Until now, no common factor or unique mutation associated with this disease has been described. Whole exome sequencing in Multiple Myeloma (MM) patient's tests allowed to know important genes and pathways that are involved in the disease. However, few evidences through next generation sequencing (NGS) analysis were described in AL. Consequently, the application of NGS technologies permits unraveling the genomic landscape of AL to better disentangle the biology of the disease, allowing the identification of new therapeutic targets as in MM.

Aims: Genotype characterization of novel molecular alterations in AL plasma cell by whole-exome sequencing technology.

Methods: We studied 40 paired samples (sorted pathological plasma cells and peripheral blood) from 20 patients with AL. Whole exome and regulatory regions were captured using Agilent's SureSelect Human All Exon V6+UTR kit and sequenced on the Illumina NextSeq 500 platform with pair-end sequencing technique with a global mean depth coverage of 70x, on target coverage of 96.5% and a Phred quality score of 91.3% up to Q30. Data were analyzed with the program GATK to discard germline mutations, wANNOVAR for functional annotation, and a data reduction strategy to identify candidate variants.

Results: After analysis of patient samples we got an average of 78 (range 18-177) mutations per patient. 28.4% of the mutations was located on regulatory annotation, and a data reduction strategy to identify candidate variants.

Results: After analysis of patient samples we got an average of 76 (range 18-177) mutations per patient. 28.4% of the mutations was located on regulatory annotation, and a data reduction strategy to identify candidate variants.

Summary/Conclusions: Taken together, these results suggest that the mutation pattern was very heterogeneous between patients. We identified alterations in genes involved in extracellular matrix (MMP2), cell proliferation, differentiation and development (TFGA), transcription factors (ZFHX3, HRNP-NPL), adherent junction function (RASSF8), GTPases (RASSF8, RAB40A), and genes of the collagenase family (COL9A1, COL1A2) among others.

Summary/Conclusions: Taken together, these results suggest that the mutation pattern in AL is heterogeneous with no common mutated gene among all patients. However, we described novel mutations in the context of AL in regulatory genes or over-representing cancer-related pathways that can help to elucidate the molecular biology of the disease.

IMPROVED SURVIVAL IN 21,465 MULTIPLE MYELOMA PATIENTS: RESULTS FROM A POPULATION-BASED STUDY

S. Thorsteinsdottir1,2, P.W. Dickman3, I. Turesson3, O. Landgren4, M. Hultcrantz5,6, M. Björkholm5, S.Y. Kristinsson1,5

1Department of Internal Medicine, Landspitali - The National University Hospital of Iceland, Reykjavik, Iceland, 2Department of Medical Epidemiology and Biostatistics, Karolinska Institutet, Stockholm, 3Department of Hematology and Coagulation Disorders, Skane University Hospital, Malmö, Sweden, 4Myeloma Service, Division of Hematologic Oncology, Memorial Sloan-Kettering Cancer Center, New York, United States, 5Department of Medicine, Division of Hematology, Karolinska University Hospital and Karolinska Institutet, Stockholm, 6Myeloma Service, Division of Hematologic Oncology, Memorial Sloan-Kettering Cancer Center, New York, Sweden

Background: Multiple myeloma (MM) is generally considered an incurable disease, however advances in the treatment options for MM have been great in recent years. Recent studies on these new agents indicate an improvement in survival, nevertheless population-based studies have had contradicting findings, especially in the elderly patients.

Aims: The aim of the study was to evaluate the survival of all patients diagnosed with MM in Sweden in the years 1973 to 2013 and to relate the survival pattern to trends in treatment strategies.

Methods: Patients diagnosed with MM in the period from January 1, 1973 to December 31, 2013 were identified from the Swedish Cancer Registry. Information on sex, date of birth, date of diagnosis, and date of death was collected. Relative survival ratios (RSRs) were used to provide a measure of excess mortality of MM patients compared to a comparable group from the general population. RSRs with 95% confidence intervals (CIs) were found for 1-, 5-, and 10-years for 4 calendar periods: 1973-1982, 1983-1992, 1993-2002, and 2003-2013 and furthermore for 6 age categories at diagnosis (0-40, 41-50, 51-60, 61-70, 71-80 and >80). Short-term survival, as defined by RSR of less than 3 months, was also defined for all calendar periods.

Results: A total of 21,465 patients (54% males, median age at diagnosis 72 years) with MM were recorded in the time period. Overall, the 1- and 5- and 10-year RSRs improved in the whole period, with the greatest improvement in the two most recent calendar periods. The 1-year RSR increased significantly between all calendar periods (0.69, 0.74, 0.77 and 0.82, respectively). The 5-year RSR increased significantly between the two last calendar periods (0.28, 0.31, 0.33 and 0.41, respectively; Figure 1) as well as the 10-year RSR (0.10, 0.12, 0.14 and 0.20, respectively). Short-term survival increased significantly between the first two and last two calendar periods (the RSR were 0.83, 0.88, 0.89 and 0.93 respectively). Females had a lower excess mortality compared to males (excess mortality ratio 0.91).

Figure 1.

Summary/Conclusions: In this population-based study, based on more than 21,000 MM patients diagnosed during more than a 40-year period, we showed that with an increased use of novel agents in MM patients, survival has improved significantly. This is especially prominent during the last 10 years. Our findings are important, since new agents are approved based on clinical trials, where certain groups, such as older patients and patients with significant comorbidities are often excluded.

P331

PROGNOSTIC IMPLICATIONS OF MULTIPLE CYTOGENETIC HIGH-RISK ABNORMALITIES IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA

1Department of Internal Medicine, 2Division of Hematology, 3Department of Laboratory Medicine and Pathology, 4Division of Nephrology and Hypertension, Mayo Clinic, Rochester, United States

Background: Cytogenetic evaluation using fluorescence in situ hybridization (FISH) at the time of diagnosis is essential for initial risk stratification in multiple myeloma. The presence of specific cytogenetic high-risk abnormalities (HRA) is known to confer a poor prognosis, less is known about the cumulative effect of multiple such abnormalities.

Aims: To evaluate the prognostic implications of the presence of multiple HRA at the time of diagnosis.

Methods: We studied 1181 patients who were diagnosed with multiple myeloma between July 2005 and July 2015 at Mayo Clinic Rochester, underwent FISH evaluation within 6 months of diagnosis, and received first-line therapy with at least 1 novel agent (immunomodulator or proteasome inhibitor). HRA were defined as t(4;14), t(14;16), del(17p), and gain(1q). Bone marrow aspirates were evaluated for deletions, monosomies, trisomies, and tetrasyomies using chromosome- or centromere-specific FISH probes. IGH rearrangements were evaluated using an IGH break-apart probe and evaluating up to 5 potential partners (FGFR3, CCND1, CCND3, MAF, and MAFB). Kaplan-Meier overall survival estimates were calculated and the log-rank test was used to compare overall survival in patients with and without HRA (stratified by the number of HRA). A multivariable-adjusted Cox regression model was used to assess the effect of HRA on overall survival adjusting for age, sex, International Staging System (ISS) stage, and first-line therapy (immunomodulator, proteasome inhibitor, upfront autologous hematopoietic stem cell transplantation). Patients diagnosed after 2014 (approximately 15% of the cohort) routinely underwent evaluation for gain(1q), therefore the hazard ratios represent conservative effect estimates. P-values below 0.05 were considered statistically significant.

Results: The median age at diagnosis was 65 years (28-95), 708 (60%) of the patients were male. There were 372 HRA in 327 patients (28% of the cohort): 170 (45%) del(17p), 110 (29%) t(14;16), 45 (12%) t(14;16), 8 (2%) t(14;20), and 42 (12%) gain(1q). Of the 280 patients with 1 HRA 130 (46%) had del(17p), 120 (43%) had a high-risk translocation, and 30 (11%) had gain(1q). Of the 46 patients with 2 HRA 34 (76%) had del(17p) and a high-risk translocation, 6 (13%) had a high-risk translocation and gain(1q), 5 (11%) had del(17p) and gain(1q), and 1 had 2 high-risk translocations. There was 1 patient with 3 HRA: del(17p) and t(4;14) and gain(1q). The median overall survival was 6.6 years (6.0-8.0) for the entire cohort (n=1181), 8.3 years (6.7-8.9) for those without HRA (n=854, 72%), 4.8 years (3.9-5.6) for those with one HRA (n=280, 24%), and 2.7 years (2.1-3.8) for those with 2 or more (2+) HRA (n=47, 4%). Figure 1 shows the Kaplan-Meier overall survival estimates stratified by the number of HRA (n=1181). The presence of 1 HRA (versus 0, HR 1.57, 95% CI 1.26 - 1.96, p <0.001, n=1181) and the presence of 2+ HRA (versus 1, HR 3.37, 95% CI 2.21 - 5.14, p <0.001, n=1181) were of prognostic significance after adjusting for age, sex, ISS stage, and first-line therapy. When adjusting for the revised ISS instead of the ISS the hazard was attenuated for 1 HRA (versus 0, HR 1.42, 95% CI 1.12 - 1.80, p=0.004, n=1087) and 2+ HRA (versus 1, HR 2.82, 95% CI 1.81 - 4.40, p <0.001, n=1087).

Figure 1.

Summary/Conclusions: Approximately 1 in 4 patients with newly diagnosed multiple myeloma presented with 1 HRA at the time of diagnosis, approximately 1 in 25 with 2 or more HRA. These patients experienced inferior overall survival suggesting a cumulative effect of multiple HRA.
LENALIDOMIDE MAINTENANCE VS PLACEBO AFTER STEM CELL TRANSPLANT FOR PATIENTS WITH MULTIPLE MYELOMA: OVERALL SURVIVAL AND PROGRESSION-FREE SURVIVAL AFTER ADJUSTING FOR TREATMENT CROSSOVER IN CALGB

P.L. McCarthy1, 2, S.A. Holstein 5, S.-H. Jung 3, M. Cooper 4, C.J. Gibson 5, E.A. Stadtmauer 6, B. Winograd 5, P. Richardson 7

Background: At a prespecified interim analysis (December 2009), the phase 3 CALGB/ECOG 100104 (Alliance) study results surpassed the prespecified superiority boundary (significantly improved progression-free survival [PFS] for lenalidomide [LEN] maintenance vs placebo [PBO] after SCT) and the majority of PBO arm patients without progressive disease (PD) crossed over to LEN maintenance. An updated analysis (cutoff March 2015) showed significantly longer overall survival [OS] with LEN maintenance (HR, 0.56; 95% CI, 0.42-0.76). However, the crossover from PBO to LEN makes it difficult to assess the true treatment effect of LEN.

Aims: To examine the effect of LEN vs PBO on OS and PFS from randomization, adjusting for effects of crossover.

Methods: The rank-preserving structural failure time model (RPSFTM; Robins, Commun Stat Theory Methods, 1991) was used for crossover adjustment; the iterative parameter estimation (IPE; Branson, Stat Med, 2002) algorithm was used as validation. Survival was partitioned assuming a residual LEN effect after discontinuation. A landmark analysis was also performed at the Dec 2009 interim for patients who remained on treatment. Patients in the trial provided informed consent.

Results: Patients were randomized to LEN maintenance (n=231) and PBO (n=229) (intent-to-treat [ITT] population); 76 patients without PD crossed over from PBO to LEN. The median time from randomization to crossover was 11.5 months. The relative treatment effect for OS and PFS increased for LEN from PBO to LEN when adjusting for crossover using RPSFTM and IPE (Table 1). The landmark analysis at the Dec 2009 interim (PBO crossover, n=76; No crossover, n=154) showed the treatment effect is not dissimilar to the ITT analysis (HR 0.53; 95% CI, 0.25-1.13). Sensitivity analyses showed consistent results. Updated data will be presented at the meeting.

Table 1.

Summary/Conclusions: Adjusting for the potential diluting effects of crossover reduced median OS and PFS with PBO, and improved the treatment effect in the ITT analyses for OS and PFS for LEN vs PBO maintenance after SCT. The statistical significance of the ITT analyses was maintained throughout.

P334 EFFICACY AND SAFETY OF DARATUMUMAB, LENALIDOMIDE, AND DEXAMETHASONE VERSUS RVD ALONE IN RELAPSED OR REFRACTORY MULTIPLE MYELOMA: UPDATED ANALYSIS OF POLLUX

Aims: To provide updated efficacy and safety data from POLLUX, a multicenter, open-label, multicentre phase 3 studies of carfilzomib in patients with relapsed/refractory multiple myeloma (MM) (Vd) in ENDVABOR (Dimopoulos, Lancet Oncol. 2016) for the primary endpoint of progression-free survival (PFS) by independent review.

Methods: Adults with RRMM who received 1–3 prior regimens were randomised 1:1. In ASPIRE, patients received lenalidomide (25 mg) on days 1–21 and dexamethasone (40 mg) on days 1, 8, 15, and 22 (28-day cycle). KRd patients received carfilzomib on days 1, 8, 15, and 22 (28-day cycle). [days 1 and 2 of cycle 1: 27 mg/m² therefor]; carfilzomib was omitted on days 8 and 9 in cycles 13–18. In ENDVABOR, Kd patients received carfilzomib (20 mg/m² on days 1 and 2 of cycle 1; 56 mg/m² thereafter) on days 1, 2, 8, 9, 15, and 16 and dexamethasone (20 mg) on days 1, 2, 8, 9, 15, 16, 22, and 23 (28-day cycle) in the Vd group. Combination was given (1.3 mg/m²; intravenously or subcutaneously) on days 1, 4, 8, and 11, and dexamethasone (20 mg) on days 1, 2, 4, 5, 8, 9, 11, and 12 (21-cycle day). Comparisons were per stratified log-rank test; data presented here are per investigator assessment.

Results: In ASPIRE, 792 patients were randomized. Baseline characteristics were well-balanced between the median follow-up of 37.9 months (KRd) and 37.0 months (Rd), median PFS was 26.1 months (KRd) and 16.6 months (Rd) (hazard ratio [HR] 0.67; 95% confidence interval [CI]: 0.56–0.80; P <0.0001). Updated data will be presented at the meeting.

Summary/Conclusions: Consistent with the primary analyses, these results show that combination of carfilzomib into treatment regimens in patients with RRMM results in clinically meaningful improvements in PFS and a favourable benefit-risk profile.
marrow samples were collected, and minimal residual disease (MRD) was assessed at the time of suspected complete response (CR) and at 3 and 6 months after suspected CR at 3 different sensitivity thresholds (10^-4, 10^-5, and 10^-6) using the ClonoSEQ™ next-generation sequencing-based assay (Adaptive Biotechnologies, Seattle, WA). Additional reflex testing using an anti-idio- type antibody was used to confirm CRs in cases in which daratumumab interference with serum M-protein quantitation was suspected in patients with possible CR.

Results: Patients received a median (range) of 1 (1-11) prior lines of therapy; 55% of patients had received immunomodulatory agents (IMiDs), and 18% had been exposed to lenalidomide. After median follow-up of 17.3 months, DRd significantly prolonged PFS compared with Rd alone (median: not reached vs 17.5 months; hazard ratio [HR], 0.37; 95% confidence interval [CI], 0.28-0.50; P<0.0001), with 18-month PFS rates of 76% and 49%, respectively. Responses continued to deepen in the DRd group with longer follow-up, with significantly higher overall response rate (ORR; 93% vs 76%) and rates of very good partial response (VGPR) or better (78% vs 45%) and CR or better (46% vs 20%) with DRd versus Rd alone (P=0.0001 for all), and MRD negativity was >3 times higher with DRd compared with Rd alone at all 3 sensitivity thresholds (31.8% vs 8.8% at 10^-4, 24.8% vs 5.7% at 10^-5, and 11.9% vs 2.5%, at 10^-6; P=0.0001 for all), and MRD negativity was associated with prolonged PFS at 10^-6 (Figure 1). Overall survival (OS) data are immature, with 40 (14%) deaths in the DRd group and 56 (20%) deaths in the Rd group (HR, 0.63; 95% CI, 0.42-0.95). Neutropenia was the most common grade 3 or 4 treatment-emergent adverse event (53% with DRd vs 38% with Rd), and no new safety signals were reported with longer follow up. We will present updated efficacy and safety data based on approximately 25 months follow up at the meeting.

Figure 1.

Summary/Conclusions: DRd significantly improved outcomes compared with Rd alone, including PFS, ORR, depth of response, and MRD-negative rates, with a favorable safety profile that was maintained after longer follow up. These updated data continue to support the use of DRd in patients with RRMM who received ≥1 prior therapy.

P335 DARATUMUMAB-BASED COMBINATION REGIMENS IN ELDERLY (≥75 YEARS) PATIENTS WITH RELAPSED OR REFRACTORY MULTIPLE MYELOMA: SUBGROUP ANALYSIS OF THE PHASE 3 CASTOR AND POLLUX STUDIES

1University Hospital of Salamanca/IBSAL, Salamanca, Spain, 2Malignant Haematology and Stem Cell Transplantation Service, Alfred Health-Monash University, Melbourne, Australia, 3Winship Cancer Institute, Emory University, Atlanta, GA, United States, 4Department of Internal Medicine, Harvard Medical and Oncology, University Hospital Brno and Faculty of Medicine Masaryk University, Brno, Czech Republic, 5Universitätsklinikum Tuebingen der Eberhard-Karls-Universität, Abteilung fuer Innere Medizin II, Tuebingen, Germany, 6Department of Experimental, Diagnostic and Specialty Medicine, University of Bologna, Bologna, Italy, 7Mount Sinai Psoriasis and Psoriatic Arthritis Center, New York, United States, 8St James’s Institute of Oncology, Leeds Teaching Hospitals NHS Trust and University of Leeds, Leeds, United Kingdom, 9Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan, 10Service d’Hématologie et Thérapie Cellulaire, Hôpital Bretonneau, Centre Hospitalier Régional Universitaire (CHR), Tours, France, 11Levine Cancer Institute/Carolinas HealthCare System, Charlotte, NC, United States, 12Internal Medicine, Seoul National University Hospital, Seoul, Korea, Republic Of, 13Tom Baker Cancer Center, University of Calgary, Calgary, Alberta, Canada, 14Janssen Research & Development, LLC, Spring House, PA, 15Janssen Research & Development, LLC, Raritan, NJ, United States, 16National and Kapodistrian University of Athens, Athens, Greece

Background: Daratumumab (D) used in combination with bortezomib and dexamethasone (Vd; CASTOR) or lenalidomide and dexamethasone (Rd; POL- Lux) significantly prolongs progression-free survival (PFS) with a manageable safety profile compared with either Vd or Rd alone in patients (pts) with RRMM.

Aims: Here in this subgroup analysis we investigated the safety and efficacy of DVD and DRd in elderly pts aged ≥75 years from the CASTOR and POLLUX phase 3 studies.

Methods: Overall, pts enrolled in the CASTOR and POLLUX studies had ≥1 prior line of therapy. Pts in CASTOR received up to 8 cycles of Vd with or without D; pts in the D group then continued to receive D monotherapy qw4 until disease progression or unacceptable toxicity. Pts in POLLUX were treated until progression. Dosing schedules for D (16 mg/kg) were different between CASTOR (qw in Cycles 1-3, q3w for Cycles 4-8, and q4w thereafter) and POL- Lux (qw for Cycles 1-2, q2w for Cycles 3-6, and q4w thereafter). All elderly pts received a reduced dose of dexamethasone (20 mg once weekly vs 40 mg once weekly) in both studies.

Results: In CASTOR, 23/251 pts in the DVD group and 35/247 pts in the Vd group were ≥75 years; the median (range) age for this group of pts was 78 (75-88) and 78 (75-85) years, respectively, with 100% and 94% with an ECOG status ≤1. At a median follow-up of 13.0 months, discontinuation rates due to treatment-emergent adverse events (TEAEs) with similar with Vd and Rd (15% vs 20%). Common (≥10%) grade 3/4 TEAEs for Vd were thrombocyto- penia (45% vs 37% with Vd), fatigue (15% vs 11%), pneumonia (15% vs 17%), and anemia (10% vs 11%). Infusion-related reactions (IRR) occurred in 13 (65%) pts, with 10% having grade 3/4 IRR, but no pts discontinued due to IRR. Median PFS was significantly prolonged with DVD versus Vd (not reached [NR] vs 8.1 months; HR, 0.27; 95% CI, 0.12-0.61; P=0.0007) with consistent with the overall PFS observed in CAS- TOR (Figure). Higher overall response rate (ORR; 95% vs 79%) and rates of complete response (CR) or better (25% vs 3%) and very good partial response (VGPR) or better (70% vs 18%) were achieved with DVD versus Vd, respectively, consistent with the overall population. In the POLLUX study, 29/286 pts in the DRd group and 35/283 pts in the Rd group were aged ≥75 years; the median (range) age for this group of pts was 77 (75-89) and 78 (75-87) years, respectively, with 86% and 91% with an ECOG status ≤1. At a median follow-up of 17.3 months, 10% of pts in the DRd group and 11% in the Rd group discontinued due to TEAEs. Common (≥10%) grade 3/4 TEAEs for DRd were neuropa- themy (54% vs 31% with Rd), hypokalemia (14% vs 3%), and pneumonia (10% vs 11%). D-associated IRR occurred in 12 (41%) pts in the DRd group, with 4 (14%) pts having grade 3/4 IRR. No patient discontin- uated DRd due to IRR. Median PFS was significantly prolonged with DRd compared with Rd in the elderly subgroup (NR vs 11.4 months; HR, 0.19; 95% CI, 0.06-0.55; P<0.0007). Consistent with the overall PFS observed in POLLUX (Figure 1). ORR was higher with DRd versus Rd (93% vs 77%), and rates of CR or better (52% vs 9%) and VGPR or better (72% vs 41%) were also higher with DRd versus Rd.

Figure 1.

Summary/Conclusions: The results in elderly pts were consistent with those observed in the overall study populations in terms of efficacy. Rates of most common grade 3/4 hematologic TEAEs with DRd were similar to that of the overall populations, and IRR were manageable. This subgroup analysis supports the addition of D to standard-of-care regimens in elderly pts with RRMM.
P336

ALL ORAL COMBINATION OF IXAZOMIB PLUS THALIDOMIDE AND DEXAMETHASONE FOR RELAPSED OR REFRACTORY MULTIPLE MYELOMA: INTERIM DATA OF AN ONGOING PHASE II TRIAL

1Wilhelminen Cancer Research Institute, Vienna, Austria, 2Department of Hematology, University of Leipzig, Germany, Leipzig, 3Division of Hematology and Medical Oncology, Department of Internal Medicine II, Wuerzburg University Medical Center, Wuerzburg, Germany, 4Internal Department I - Hematology with Stem Cell Transplantation, Hemastaseology and Medical Oncology, Hospital Elisabethinen Linz, Linz, Austria, 5Fakultutliche nemocnice Ostrava, Ostrava, Czech Republic, 6Department of Internal Medicine V, Hematology and Oncology, Medical University Innsbruck, Innsbruck, Austria, 7Department of Internal Medicine 3, Kepler Universitätsklinikum GmbH, Med Campus III, 8Department of Internal Medicine I, Ordensklinikum Linz - Barmherzige Schwestern, Linz, Austria, 9Department of Internal Medicine II, University Hospital Tuebingen, Tuebingen, Germany, 1010Arbeitsgemeinschaft Medikamentoese Tumortherapie, 11Third Medical Department at the Paracelsus Medical University Salzburg, Salzburg, Austria, 12Department of Medicine I, Center for Oncology and Hematology, Wilhelminenspital, Vienna, Austria

Background: Ixazomib is a novel, effective oral proteasome inhibitor with a favorable toxicity profile. Recent studies showed significant activity as single agent with dexamethasone and in combination with other agents. The Tourmaline trial showed superior PFS with ixazomib plus lenalidomide and dexamethasone in pts with relapsed or refractory multiple myeloma (RRMM).

Aims: Here, we evaluate the activity and tolerability of ixazomib plus thalidomide and dexamethasone (IxaThalDex) in pts with RRMM.

Methods: Pts with RRMM and one or more prior lines of therapy (TX) with the following criteria were eligible: Measurable disease, ECOG PS ≤2, ANC ≥1000/μL, platelet count ≥500000/μL, GFR ≥15mL/min. Treatment regimen: Ixazomib (4mg, d1, 8, 15) and thalidomide (100mg/d), and dexamethasone (40mg d1, 8, 15). Pts in 11/18/15 years received 3 (4/4) doses of thalidomide (50mg/d) and of dexamethasone (20mg). Pts were scheduled for 8 cycles followed by ixazomib maintenance therapy (4mg, days 1, 8, 15 of a 28 cycle and 3mg in pts aged ≥75 years) for one year. Primary objective was PFS, and secondary objectives were ORR, OS, impact of cytogenetic risk and of renal impairment, safety and health related QoL.

Results: Sixty-seven of 77 planned pts have been enrolled so far. The following patient characteristics were recorded in the intent-to treat group (ITT): median age: 67, range 41 to 84 years, ISS stage I: 28, II: 22, III: 16, not known: 1, median number of prior TX lines: 1 (range: 1-8). Pts discontinued TX before completion of 2 cycles. Presently, 25 pts are too early for evaluation per protocol (PP). Full documentation of ≥2 cycles is available for 52 pts, with a median number of 4 cycles and a median FU of 7.4 mos. A PR or better was achieved in 33 pts (14%, 4 grade 2 and 6 grade 3). The most frequent non-hematological toxicities were fatigue observed in 21 pts (32%) and infections noted in 27 pts (including 6 pts with pneumonia and 1 pt with sepsis). Polynucleopaty was seen in 19 pts (28%, 18 grade 1 or 2, 1 grade 3). During the study, the incidence of new PNP was relatively low (17 new and two worsening PNP).

Summary/Conclusions: The all oral IxaThalDex regimen showed an ORR of 63% with no difference in pts with/without high-risk cytogenetics, a CBR of 67%, and a PFS of 10.4 mos in pts with RRMM. The regimen was well tolerated and was associated with a low incidence of mainly grade ≤2 PNP, which required dose reduction in one patient only. Response rates improved with continuation of therapy and treatment was associated with an increase in health related QoL.

P337

EVALUATION OF GROWTH DIFFERENTIATION FACTOR-1 (GDF15) AS A NEW BIOMARKER FOR RENAL OUTCOMES IN DIFFERENT COHORTS OF PATIENTS WITH LIGHT CHAIN AMYLOIDOSIS

E. Kastritis1,*, I. Papassotiriou2, G. Merlini3, P. Milani3, E. Terpos1, M. Bassetti1, A. Akealostes4, F. Russo5, E. Paimenou6, F. Apostolakou2, M. Roussou7, M. Gaviatopoulou8, D. Foliou7, D.C. Zogias9, E. Papadopoulou1, C. Pamboucas1, M.A. Dimopoulos1, G. Palladini1
1Department of Clinical Therapeutics, National and Kapodistrian University of Athens, 2Department of Clinical Biochemistry, Aghia Sofia Children’s Hospital, Athens, Greece, 3Amyloidosis Research and Treatment Center, Fondazione IRCCS Policlinico San Matteo and University of Pavia, Pavia, Italy, 4Roche diagnostics, 5Department of Clinical Therapeutics, National and Kapodistrian University of Athens, Athens, 6Amyloidosis Research and Treatment Center, Fondazione IRCCS Policlinico San Matteo and University of Pavia, Pavia, Greece

Background: Growth differentiation factor-15 (GDF-15), is a member of the TGF-beta family, and is involved in several pathological conditions, including inflammation, cancer, cardiovascular, pulmonary and renal diseases. Serum GDF-15 levels add prognostic information to conventional prognostic factors, such as NT-proBNP and troponins, in cardiovascular disorders and has also shown to be associated with renal damage and risk of end stage renal disease in patients with diabetes. Increased serum GDF-15 levels have also shown to be correlated with early death and shorter survival independently of other biomarkers and Mayo stage. Because GDF-15 was also associated with renal outcomes we evaluated the prognostic value of GDF-15 levels in two independent cohorts of patients with AL amyloidosis and renal involvement who were treated in two different centers (Pavia Amyloidosis Center and Department of Clinical Therapeutics, Athens).

Aims: To evaluate the prognostic value of GDF-15 levels in independent cohorts of patients with AL amyloidosis and renal involvement.

Methods: Circulating levels of GDF-15 were measured by a novel pre-commercial immunoassay (R&D Diagnostics) in two centers. The Pavia cohort included 135 and the Athens cohort included 76 patients with AL amyloidosis and renal involvement. Standard criteria were used for the diagnosis, evaluation of organ involvement and biomarker-based risk stratification. Renal staging was based on the system proposed by Palladini et al., based on baseline proteinuria >5 g/day and eGFR <50 mL/min.

Results: Median age and involved FLC levels were similar between the two cohorts. However, heart involvement was more common in Pavia cohort (72% vs 53%; p=0.005). Mayo stage disposition was also different (17%, 46% & 37% for stage 1,2 & 3 in Pavia vs 30%, 43% & 27% in Athens cohort, p=0.08, but stage 3B was similar, 13% vs 12%). Also there were differences in peripheral nerve involvement (9% in Pavia vs 21% in Athens cohort, p=0.025). Median eGFR and renal stage distribution (26%, 54%, 20% vs 20%, 54%, 26% for renal stage-1, 2 & 3 respectively) were similar between the two cohorts (p=0.544). Median follow up for the Pavia cohort was 18 months and for the Athens cohort was 45 months (p<0.001). Survival at 2 years was 59% for Pavia and 56% for Athens cohort. Median GDF-15 levels was 3454 pg/ml in Pavia (range 624 to >100000) and 4152 pg/ml (range 626 – 71475) in Athens cohort (p=0.009), while 93% and 94% of patients in the two cohorts had GDF-15 levels >1200 pg/ml (the upper limit of normal for individuals without cardiovascular disease). We then evaluated the prognostic significance regarding renal outcomes (dialysis): GDF-15 >4000 pg/ml was associated with a HR of 6 (95% CI 2015.7, p=0.001) in Athens cohort (progression to dialysis within 2 years in 7% vs 47%); while, by applying the same cutoff in patients in Pavia cohort, 2-year dialysis rate was 10% vs 37% (HR: 3.95% CI 1.6-15, p=0.004). Although renal stage discriminated 3 groups in univariate analysis in each cohort, in multivariate analysis, GDF-15 >4000 pg/ml outperformed renal stage by eGFR and proteinuria and was the only independent prognostic factor for progression to dialysis in each cohort (Figure 1).

Figure 1.
Summary/Conclusions: Our study validated and confirmed in two independent cohorts, with differences in their characteristics, the prognostic value of GDF-15, which emerges as a novel biomarker with prognostic implications for different outcomes in patients with AL amyloidosis. Importantly, GDF-15 emerges as a strong biomarker for renal outcomes in patients with AL amyloidosis.

P338

AN OPEN-LABEL, PHASE 2 STUDY TO EVALUATE THE ORAL COMBINATION OF IZAXOMIB, CYCLOPHOSHAMIDE AND DEXAMETHASONE IN TRANSPLANT-INELIGIBLE PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA

M.A. Dimopoulos1-5, S. Grosicki2, W. Jędrzejczak2, H. Nash6, A. Gruber6, M. Hansson7, C. Byrnes8, R. Labolata9, Z. Teng9, H. Yang9, N. Grzasko10, S. Kumar11
1National and Kapodistrian University of Athens School of Medicine, Athens, Greece, 2Silesian Medical University, Katowice, 3Medical University of Warsaw, Warsaw, Poland, 4Karolinska University Hospital, Stockholm, 5Skåne University Hospital, Lund, Sweden, 6Millennium Pharmaceuticals Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, United States, 7St. John Cancer Center, Medical University of Lublin, Lublin, Poland, 8Mayo Clinic, Rochester, United States

Background: Proteasome inhibitor (PI)-based combinations are standards of care in all lines of MM therapy. As the treatment paradigm moves to focus more on extended therapy, new combinations are needed that will be efficacious and tolerable, while giving pts the flexibility of taking their treatment at home. Combinations of ixazomib, the first oral PI, with immunomodulatory drugs (IMiDs) are feasible and effective; however, there may be pts for whom the use of IMiDs is not desirable. Therefore, triplet combinations of ixazomib with alkylators have been studied.

Aims: This phase 2 study (NCT02046070) evaluated the safety and efficacy of the all-oral IC regimen in transplant-ineligible pts with NDMM. Primary endpoint was rate of CR+VGPR during induction. Secondary endpoints included tolerability and toxicity, overall response rate (CR+VGPR+PR) throughout treatment, time to response, PFS, and quality of life (QoL).

Methods: Adult pts with NDMM who were transplant-ineligible were randomized (1:1) to receive oral ixazomib 4.0 mg plus oral cyclophosphamide 300 mg/m² (Arm A) or 400 mg/m² (Arm B) on days 1, 8, 15, and dexamethasone 40 mg on days 1, 8, 15, and 22, for up to 13 x 28-day cycles as induction. Pts with ≥SD and an acceptable toxicity profile then received single-agent ixazomib maintenance therapy until PD, death, or unacceptable toxicity.

Results: 70 NDMM pts were enrolled (n=36 Arm A; n=34 Arm B): median age 73 years (range 61–87); 47% male; 31%/33%/29% ISS stage I/II/III MM; 50% had a cardiovascular/pulmonary comorbidity; 9% had high-risk genetics (t(4;14), t(14;16), del 17p). At data cut-off (29 June 2016), pts had received a median of 19 cycles; 66% had completed 13 IC induction cycles and proceeded to ixazomib maintenance therapy; 10% were ongoing on therapy; 15% made 1/2 dose reductions due to AEs (24%), PD (16%), patient withdrawal (3%), or other reasons (10%). Confirmed responses by investigator assessment are shown in the Table 1. Median time to first/best response across arms was 2/4 months. After a median follow-up of 17.9/18.5 months in Arm A/B, median PFS was not reached. Combined PFS at 12/18/24 months was 81%/66%/59% (24-month PFS 84%/56% for Arm A/B). In Arm A/B, 94%/100% reported AEs; 72%/74% reported grade ≥3 AEs; and 47%/56% reported SAEs. The most common all-grade AEs were neutropenia (22 [3%]), anemia (19 [27%]), diarrhea, nausea, peripheral edema (each 18 [26%]), vomiting (15 [21%]), fatigue, and somnolence (each 14 [21%]). The most common grade ≥3 AEs were neutropenia (22 [3%]), anemia (10 [14%]), lower respiratory tract and lung infections (9 [13%]), and supraventricular arrhythmias (5 [7%]). There were 5 on-study deaths, none considered related to treatment. QoL (by EORTC QLQ-C30; Global Health Status) was maintained from baseline during the study.

Table 1.

Summary/Conclusions: Based on this phase 2 study, ICd is an active treatment regimen for pts with NDMM who are ineligible for transplant. This trial captured a population of pts that was elderly and with multiple comorbidities. In this context, the results with ICd, an all-or-none triplet including a PI and alkylator, provide evidence of clinical efficacy with a manageable safety profile. With a median follow-up of ~18 months, median PFS was not reached and outcomes appear comparable to other regimens in elderly transplant-ineligible pts with NDMM. The preferred cyclophosphamide dose for ICd phase 3 studies is 300 mg/m², based on the similar PFS, higher response rate, and numerically lower rate of AEs vs 400mg/m². Updated PFS results will be presented at the meeting.
38 DLT-evaluable pts in phase 1, 10 had DLTs of Gr 3 rash (n=2, Arm A), Gr 3-4 thrombocytopenia (n=4, 1 pt in each arm), Gr 3-4 neutropenia (n=1, Arm A; n=4, Arm C, n=1, Arm D), Gr 4 hemorrhagic oesophageal ulcer (n=1, Arm B), Gr 3 ileus/neurogenic bladder (n=1, Arm B), Gr 3 vomiting/diarrhea (n=1, Arm B), and Gr 3 respiratory infection (n=1, Arm C). The RP2D was ixazomib 4.0 mg in Arm B, based on observed rates of toxicity; this cohort was expanded to 26 pts. Among all 61 pts, the median number of treatment cycles was 16; 36 pts (13 at RP2D) completed IMP induction and entered maintenance. Median number of maintenance cycles was 12. The maximum treatment duration was 1841 days (>5 yrs) at RP2D. Five pts remain on treatment (2 at RP2D); primary reasons for discontinuation were disease progression (48%) and adverse events (21%); median time to first response was 1.7 mos, and responses continued to mature over a long period (Table 1). Depth of response improved during ixazomib maintenance in 9/36 (25%) pts (VGPR to sCR in 5 pts; VGPR to CR in 2 pts; CR to sCR in 2 pts). Median TTP/PFS are shown in Table 1; median OS was not reached after median follow-up of 42.6/46.9 mos overall/at RP2D.

Summary/Conclusions: The RP2D was weekly ixazomib 4.0 mg plus M 6 mg/m² and P 60 mg/m² (days 1–4) in 28-day cycles, consistent with the ixazomib dose and schedule in TOURMALINE-MM1. AEs were mainly hematologic, infections, PN, and diarrhea. The all-oral IMP regimen is active in NDMM, with a 28% CR rate (19% sCR), a 43% ≥VGPR rate, and a median PFS of 23.5 mos; responses continued to improve over a prolonged period.

Myeloma and other monoclonal gammopathies - Clinical 2

P340

FEASIBILITY AND EFICACY OF DOSE ADJUSTED MELPHALAN – PREDNISONE – BORTEZOMIB IN PATIENTS ≥75 YEARS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA; PRELIMINARY RESULTS OF THE PHASE II HOVON 123 STUDY

1Hematology, VU University Medical Center, Cancer Center Amsterdam, Amsterdam, 2Internal Medicine, Albert Schweitzer ziekenhuis, Dordrecht, 3Internal Medicine, Meander Medisch Centrum, Amersfoort, 4Internal Medicine, ZNB, Leeuwarden, 5Internal Medicine, Haga Ziekenhuis, Den Haag, 6Internal Medicine, Sint Jans Dal, Harderwijk, 7Internal Medicine, MCA, Alkmaar, 8Internal Medicine, Tergooi ziekenhuizen, Hilversum, 9Internal Medicine, Groene Hart Ziekenhuis, Gouda, 10Internal Medicine, VU University Medical Center, Cancer Center Amsterdam, 11Hematology, UMCU, Utrecht, 12HOVON Data Center, 13Hematology, Erasmus MC Cancer Institute, Rotterdam, Netherlands

Background: There is a high rate of toxicity-related discontinuation in elderly patients with NDMM, negatively affecting outcome. In order to predict feasibility of treatment the IMWG developed the frailty score based on age, (instrumental) Activities of Daily Living and the Charlson comorbidty index.

Methods: Patients were treated with 9 cycles of MPV: Mel 6 mg/m², day 1-4; Pred 30 mg/m², day 1-4; and Bort 1.3 mg/m² day 1,8,15 and 22 of a 35-day cycle. This first planned analysis was restricted to the first 140 consecutive patients out of 240 planned patients.

Results: Of the 139/140 eligible patients none were fit (because of age ≥75 years), 30/139 (22%) were unfit, 100/139 (72%) were frail, and 9/139 (6%) unknown. The median follow up was 17.0 months. The discontinuation rate of MPV in the total population was 42%; 27% in unfit and 46% in frail patients (p=0.09). When also patients were included who discontinued bortezomib only these numbers were 27% in unfit and 52% in frail (p=0.02). Importantly, 6 cycles of MPV were found to be feasible in 70% of patients, both in unfit (80%) and frail (69%) patients. Age >80 years was associated with a significantly higher discontinuation rate of MPV or bortezomib only (70% versus 35% in patients aged 75-80 years, p=0.01). WHO performance was not associated with discontinuation rate. Response on protocol was ≥PR 73%, ≥VGPR 38% and ≥CR 11%, not significantly different in unfit versus frail patients. Response after 6 cycles was ≥PR 69%, ≥VGPR 35% and ≥CR 2%. Median progression free survival (PFS) was 17 months: 20 for unfit and 16 months for frail patients (p=0.13). Overall survival at 18 months was 76%: 89% for unfit and 72% for frail patients (p=0.22). Frail patients were found to have significantly less grip strength and lower walking speed as compared to unfit patients (Table 1).

However, 58% and 59% of frail patients had an intermediate or high walking speed and grip strength respectively. Vice versa, 8% of patients with low
walking speed and 12% of patients with low grip strength, were not frail but unfit according to the IMWG frailty index. Discontinuation rate in patients with highest and lowest walking speed was 16/41 (39%) and 18/41 (44%). These numbers were 14/42 (33%) versus 17/43 (40%) for patients with the highest versus the lowest grip strength. PFS was not significantly different between patients with highest versus lowest walking speed (p=0.38). However, in contrast to comparable PFS in unfit and frail patients, there was a trend for better PFS in patients with highest versus lowest grip strength (20 versus 17 months, p=0.05).

Summary/Conclusions: Nine cycles of dose-adjusted MPV results in a high discontinuation rate of 42% in NDMM patients ≥75 years: 27% in unfit versus 46% in frail patients. Importantly, 6 cycles of MPV were found to be feasible with comparable response rate, also in frail. Preliminary analyses showed that functional geriatric assessments differed within IMWG frailty groups and that grip strength was associated with PFS, whereas frailty was not. Therefore, functional assessments will hopefully be complementary to the IMWG frailty score in guiding future therapy in unfit and frail patients.

P341
THE EUROPEAN MYELOMA NETWORK EMN09 STUDY: CARFILZOMIB, BENDAMUSTINE, AND DEXAMETHASONE IS EFFECTIVE AND SAFE IN PATIENTS WITH ADVANCED MULTIPLE MYELOMA

M. odan,1 A. Günther1, M. Offidani2, M. Engelhardt3, S. Gentili4, V. Montefusco5, F. Patriarca6, E. Angulici7, N. Schub1, M. Astolfi8, W. Poenisch8, H. Einsele9, P. Corradini4, A. Palumbo11, F. Gay7

Methods: With this scientific rationale a CBd combination of Carf and Benda and low dose dexamethasone (dex) was evaluated in a phase 1/2 trial in patients with relapsed/refractory multiple myeloma (RRMM).

Aims: With this scientific rationale a CBd combination of Carf and Benda and low dose dexamethasone (dex) was evaluated in a phase 1/2 trial in patients with relapsed/refractory multiple myeloma (RRMM).

Results: The phase 1 part of the trial suggested Carf at the 27 mg/m2 level for the phase 2 part. Forty-one patients were evaluated for response and efficacy. At last data cut-off, the median follow-up was 5.95 months. Number of prior treatment lines ranged from 2 to 9, and ≥85% of patients had previously transplanted, bortezomib and immunomodulatory drugs. The median time elapsed from diagnosis to treatment start was 5.8 years. Forty-three percent of patients achieved at least a PR including 28% ≤VGPR and an overall benefit of 92%. Median progression-free survival was 11.4 months and the 1-year overall survival was 75%. Hematological toxicity was well manageable. Non-hematological adverse events ≥3 occurred in 56% of patients, followed by dyspnea and events and thrombocytopenia. These data will be updated before the meeting.

Summary/Conclusions: In this elderly RRMM patients treated late in their disease, the combination of CBd provides effective outpatient therapy. Neither nausea, hair loss nor PN were an issue. Although cardiopulmonary as well as vascular events were not reported (mostly due to renal complications after HTx). Complete remission (CR) was achieved in 7 patients (24% of all transplanted pts, n=29; 2 patients have not finished treatment yet), very good partial remission (VGPR) in 6 patients (21%) and partial remission (PR) in 7 patients (24%). Overall, 25 patients died. Cause of death was either progression of AL (N=16), sepsis (n=4), heart transplant rejection (n=3) or other (n=2). Patients that underwent HTx had a median survival of 46 months (2-177, 1-year survival: 77%).

P342
CHEMOTHERAPY BEORE AND AFTER HEART TRANSPLANTATION FOR PATIENTS WITH ADVANCED CARDIAC ALAMYLOIDOSIS: SINGLE CENTER RESULTS WITH LONG-TERM FOLLOW-UP

U. Hegenbart1, J. Haack1, A. Kristen1, P. Blum2, C. Kimmich1, H. Katus2, A. D. Ho3, A. Ruhparwa4, P. Raake2, S. Schönlind1

Aims: Our aim was to examine the cases of cardiac AL patients treated with a transplant proteasome inhibition (HTx) at our center and to evaluate the clinical outcome of this treatment approach.

Methods: Data from 41 patients (21m, 20f) suffering from cardiac AL who were treated in our hospital between 2002 and 2017 were retrospectively analyzed. All patients were high-urgency listed for orthotopic HTx due to poor perspective of survival. Prior to 2009, 18 patients were listed, 8 of them with multiple organ involvement. Theretofore, we excluded patients with multiple organ involvement. All data are derived as medians with range or absolute numbers. Survival curves were calculated using the Kaplan-Meier method.

Results: Median age was 51 years (35-63) at diagnosis. Amyloidogenic lambda light-chains (LC) were detected in 33 and kappa light chains in 8 patients. Median dFLC was 331 (69 – 2752) and median plasma cells in bone marrow were 13% (5-35). Median NT-proBNP was 6.332 ng/l (1.500 -313.194), median cTNT 0.11μl/g (0.01-0.52) and median hsTNT was 60 ng/l (28-448) at diagnosis. Median NYHA stage was 3 (2-3) and median Mayo 2004 stage was 3 (2-3). Serum creatinine was at 117 μmol/l (71-232), proteinuria at 0,3 g/day (0-10,7). Patients stayed on the high-urgency waiting list for a median of 26 (range 3-54) before 2009, and a median of 64 days (8-259) after 2009. 35 patients were treated with chemotherapy prior to HTx (mostly dexa w/o Bortezomib) to reduce dFLC during the waiting time. Eight patients died before receiving HTx with a median survival (start point: HU listing) of 26 days (6-177). With a median of 5 months after HTx (4-29), 18 patients received ASCT. HDW was used with either 200 mg/m² (N=10) or reduced dosage (N=8) in patients with reduced kidney function (mostly due to renal complications after HTx). Complete remission (CR) was achieved in 7 patients (24% of all transplanted pts, n=29; 2 patients have not finished treatment yet), very good partial remission (VGPR) in 6 patients (21%) and partial remission (PR) in 7 patients (24%). Overall, 25 patients died. Cause of death was either progression of AL (N=16), sepsis (n=4), heart transplant rejection (n=3) or other (n=2). Patients that underwent HTx had a median survival of 46 months (2-177, 1-year survival: 77%).

Summary/Conclusions: High-dose chemotherapy by a proteasome inhibitor is a feasible treatment approach in patients with advanced cardiac amyloidosis. Patients who reach HTx have a nearly 50% chance for a very good hematologic remission (VGPR or better) and consecutively a favorable survival probability with a median OS of nearly 6 years in our series.
or unacceptable toxicity. Supportive care was allowed; thromboprophylaxis was required for all pts on hemodialysis. The primary endpoint was overall response rate (ORR). Key secondary endpoints included safety, renal response, time to myeloma response, time to renal response, duration of response, progression-free survival (PFS), time to progression, and overall survival (OS). All pts provided informed consent.

Results: Enrollment has been completed with 81 pts (33 in cohort A; 34 in cohort B; 14 in cohort C), of which 13 (16.0%) were still on treatment as of January 28, 2017. Median follow-up for OS was 7.8 months. A total of 68 pts (84.0%) discontinued treatment; 39 (48.1%) due to PD. Median age was 72 yrs (range, 52-86 yrs). 60.5% of pts were male, and median time from diagnosis was 3.8 yrs (range, 0.03-19.44 yrs). Pts received a median of 4 (range, 1-110) prior anti-myeloma therapies. All pts had prior treatment with LEN (100%) and nearly all with BORT (97.5%). Median relative dose intensity of POM was 94.0% in both cohorts A and B, and 99.0% in cohort C. ORR was 39.4%, 29.4%, and 14.3% in cohorts A, B, and C respectively. PFS and OS results are presented in the Table 1. Grade 3/4 anemia and thrombocytopenia occurred more frequently in cohort C, likely due to severe RI requiring dialysis (Table 1). AEs leading to dose reductions were 18.2%, 14.7%, and 14.3% in cohorts A, B, and C, respectively.

Summary/Conclusions: POM+LoDEX is efficacious in pts with RRMM with moderate or severe RI, including those on hemodialysis, who had more advanced disease due to worse renal function. The safety profile was acceptable among the three groups and no new safety signals were observed. This study demonstrates that POM+LoDEX can be administered in pts with moderate or severe RI, including those on hemodialysis.

P344

PEMBROLIZUMAB MONOTHERAPY FOR RELAPSED/REFRACTORY MULTIPLE MYELOMA: PHASE 1B KEYNOTE-013 STUDY

1Institut Gustave Roussy, Villejuif, France, 2Beth Israel Deaconess Medical Center/ Harvard Medical School, Boston, United States, 3Institute of Hematology “L. e A. Seragnoli,” University of Bologna, Bologna, Italy, 4University of Washington, Seattle, 5University of Cincinnati Cancer Institute, Cincinnati, 6Central Texas Veterans Affairs Health Care System, Temple, 7Washington University School of Medicine, St. Louis, 8Hackensack University Medical Center, Hackensack, United States

Background: Treatment options are needed for patients with RRMM. PD-L1 expression in patients with multiple myeloma, and blocking the programmed death 1 (PD-1) pathway may provide antitumor activity. Pembrolizumab is expressed in patients with multiple myeloma, and blocking the programmed death 1 (PD-1) pathway may provide antitumor activity. Pembrolizumab is a humanized, high-affinity monoclonal antibody directed against PD-1 with robust antitumor activity and favorable safety in several solid and hematologic malignancies. KEYNOTE-013 (NCT01953692) is a multicohort phase 1b study of pembrolizumab monotherapy in patients with hematologic malignancies; results are reported for patients with RRMM.

Aims: To determine the safety, tolerability, and antitumor activity of pembrolizumab monotherapy in patients with RRMM.

Methods: Patients with RRMM who have failed ≥2 prior lines of therapy including a proteasome inhibitor and immunomodulatory drug (IMiD) received pembrolizumab 10 mg/kg every 2 weeks or 200 mg fixed dose every 3 weeks. Primary end points were safety, tolerability, and objective response rate (ORR) as determined by investigators, per International Myeloma Working Group 2006 criteria.

Results: At data cutoff of January 2, 2017, 30 patients were treated. The median (range) duration of follow-up was 15 (1-32) months. 28 (93%) patients discontinued the study; the most common reason was disease progression in 14 (47%) patients and clinical progression in 9 (30%) patients. 2 (7%) patients are still on treatment. Median (range) age was 70 (56-81) years. 21 (70%) patients had an ECOG performance status of 1. Patients received a median (range) of 4 (2-10) prior lines of therapy. 20 (67%) patients were lenalidomide refractory, 10 (33%) were double-refractory. 9 (30%) were triple refractory, and 1 (3%) was quadruple refractory. Among patients who received pembrolizumab at 10 mg/kg, the median (range) of pembrolizumab exposure was 6 (2-15) cycles; among those who received 200-mg fixed dose of pembrolizumab, the exposure was 3 (2-6) cycles. No patient experienced a response. Seventeen (57%; 95% CI, 37-75%) patients had stable disease. 13 (43%; 95% CI, 26-63%) patients had progressive disease as their best response. Treatment-related adverse events (TRAEs) occurred in 12 (40%) patients. The most common TRAE was anemia (n=5, 17%); arthralgia, aspartate aminotransferase increased, fatigue, hyperglycemia, hypothyroidism, myalgia, pruritus, and blurred vision occurred in 1 patient each. A grade 3 TRAE (myalgia) occurred in 1 (3%) patient. There were 4 (13%) patients who discontinued the study due to 4 TRAEs. 1 (3%) patient had an immune-related adverse event (grade 1 pruritus).

Summary/Conclusions: The safety profile of pembrolizumab in RRMM was consistent with that observed with other cancers. Best response observed while on pembrolizumab monotherapy was stable disease. Recent results of ongoing studies, such as KEYNOTE-013 (NCT02036502), demonstrate promising efficacy of pembrolizumab in combination with IMiDs (lenalidomide) and dexamethasone in patients with RRMM.

P345

ASSESSMENT OF MOBILIZATION COST FOR MULTIPLE MYELOMA USING 2 DIFFERENT STRATEGIES: HIGH-DOSE CYCLOPHOSPHAMIDE VERSUS PLERIXAFOR. ON BEHALF OF IFM

Background: Treatment with autologous transplantation (ASCT) remains the standard of care upfront for Multiple Myeloma patients considered eligible for transplant. Peripheral blood stem cell (PBSC) collection, also called mobilisation, is needed prior to ASCT. The optimal methodology for mobilizing PBSC has yet to be defined, with either G-CSF alone, or, called steady state procedure, or use of Plerixafor, a CXCR4 antagonist (Mozobil®)+G-CSF or high dose cyclophosphamide (usually administered at a dose of 1.5 to 6g/m² IV for 3 days) +G-CSF. Both have rarely used with the most recent induction regimens, and the 2 latter have demonstrated similar PBSC collection rates. Because of the intense competition for hospital resources and the staff required to manage patients preparing for mobilization and transplantation, it is important to quantify the total impact of mobilization on staff resource and ward space at the hospital.

Aims: We aimed at better evaluate the respective cost of the 2 techniques of mobilization for the French health care system, high dose cyclophosphamide (n=57) versus plerixafor (n=55).

Methods: This is an observational cohort database analysis of 112 consecutive patients with MM treated upfront with ASCT between 2009 and 2013 and that had been mobilized with either high dose cyclophosphamide or plerixafor from 15 IFM centers. Patients must have successfully undergone ASCT. This study was not aimed at evaluating the suitability or advisability of one therapy versus another. A cost-consequences analysis of the different regimens of mobilization has been performed. Costs were calculated using two different approaches: per diem hospitalization costs (excluding direct medical costs) versus French public diagnosis-related group (DRG) costs. Hospital resources will be calculated using two different approaches: per diem hospitalization costs (excluding direct medical costs) versus French public diagnosis-related group.
P346
SYSTEMATIC LITERATURE REVIEW AND NETWORK META-ANALYSIS OF INDUCTION TREATMENT FOR NEWLY DIAGNOSED TRANSPLANT- ELIGIBLE MULTIPLE MYELOMA PATIENTS
J.-C. Kim1,*, J.H. Lim1, M.H. Lee1, H.G. Yi1
1hemato-oncology, Inha University Hospital, Incheon, Korea, Republic Of

Background: Based on the current guideline, bortezomib-based two or three drug regimens are mainly listed as a category 1 primary treatment option for transplant-eligible patients with myeloma. However, to date there are few direct head-to-head randomized controlled trials (RCTs) comparing effects of these recommended regimens, which makes it difficult to assess which treatment is most favorable to obtaining high response rates.

Aims: to determine the ranking of the currently recommended induction regimens and to compare efficacy of all available treatments.

Methods: We conducted a systematic literature review to identify all eligible RCTs that include at least one currently recommended regimen by searching PubMed, Web of Science, ASH, ASCO, EHA, and ESMO databases. A Bayesian network meta-analysis (NMA) with a fixed-effect model was performed to rank the regimens and to compare efficacy of all available treatments.

Results: Ten RCTs were identified including nine treatment regimens: vincristine-doxorubicin-dexamethasone (VAD), thalidomide-dexamethasone (TD), bortezomib-dexamethasone (VD), bortezomib-cyclophosphamide-dexamethasone (VCD), bortezomib-thalidomide-dexamethasone (VTD), bortezomib-thalidomide-dexamethasone-cyclophosphamide (VTDC), lenalidomide-dexamethasone (RD) and bortezomib-lenalidomide-dexamethasone (VRD). Figure 1 shows the probability of being the best induction treatment since it was the most favorable in terms of i) only treatment that was significantly better than RD, and ii) probability of being best regimen (84% of the simulations).

Figure 1.

P347
A STUDY OF UTILITY OR FUTILITY OF PERFORMING SKELETAL SURVEYS IN PARAPROTEINEMIA: A MULTICENTER EXPERIENCE FROM UK
O. Gamage1,*, M. Zaw1, S. Gurung1, G. Pratt2, S. Shafeek1, A. Macwhannel1, S. Lee1, S. Basu1
1Department of clinical Haematology, Royal Wolverhampton NHS Trust, Wolverhampton, 2Department of Haematology, University Hospital, Birmingham, UK, Birmingham, 3Department of Haematology, Worcestershire Acute Hospital Trust, Worcester, United Kingdom

Background: Recent International Myeloma Working Group (IMWG) guidelines recommend that conventional skeletal surveys should be supplanted by low dose whole body computed tomography (CT), whole body magnetic resonance imaging (MRI) and or 18fluoro-deoxyglucose ([18F]-FDG/ PET). However, resource, funding and radiology capacity issues, have posed significant challenges to implementing these recommendations. The risk of progression of Monoclonal gammopathy of Undetermined Significance (MUGS) to a neoplastic plasma cell disease is approximately 1% per year2 and even lower in low risk MUGS. It is thus not necessary to perform imaging in unselected MUGS patients.

Aims: To look at all skeletal surveys requested across 3 large hospitals in UK over a year and analyze their justification, effectiveness and utility.

To decide if a rational clinic–biochemical algorithm could be used to reduce the number of imaging requests, thereby avoiding unnecessary radiation exposure, and make a possible switch to modern imaging methods cost effective.

Methods: A total of 397 skeletal surveys were performed across three hospitals over one year. The data set was analyzed for clinical indications, paraprotein level, rationale for requesting the skeletal survey, the diagnostic yield and also the number follow up CT/PET or MRI required.

A pragmatic algorithm was developed and applied to see if the requests were justified and could have been safely reduced. (Figure 1).

Results: Of the 397 analyzable skeletal surveys performed, 266 were on myeloma, 81 for MUGS, 48 were for non-paraprotein related indications. Of the 266 myelomas, 30% of skeletal surveys were reported as positive according to IMWG criteria. A detailed analysis of 130 myeloma patients revealed a significant proportion of false negatives (6%) and false positives (7%), highlighting the insensitivity and poor specificity of this imaging modality. More importantly more than a third (38%) of myeloma patients required follow up imaging with MRI, PET or WBLC irrespective of the initial skeletal survey result, indicating a significant duplication rate and waste of resources. In the MUGS group, majority of skeletal surveys were negative (91%) but 9% were reported as positive. Follow up imaging with CT and MRI was performed in 23% of the MUGS group. However none these were positive. When the clinic–biochemical algorithm was applied, the number of requests was reduced by at least a quarter (24%), avoiding unnecessary radiation exposure and precious resources.

Figure 1.

Summary/Conclusions: - Skeletal survey has very limited role in investigation of paraproteinaemia and should be abandoned. - Our pragmatic clinic-biochemical imaging algorithm reduced imaging requests significantly (24%) allowing the preferred imaging modalities to be performed productively in a cost effective way in face of ever increasing health care cost and demands.

SERUM FLC MEASUREMENTS COMPLEMENT BONE MARROW ASSESSMENT TO DETERMINE PROGNOSIS IN MYELOMA PATIENTS ACHIEVING DEEP RESPONSES
T. Dejoie1,*, M. Atta2, P. Moreau3, H. Avet-Loiseau4
1Biochemistry Laboratory, Centre Hospitalier Universitaire-Nantes, Nantes, 2Institut Universitaire du Cancer-Oncopole, Toulouse, 3Department of Hema-
Background: In multiple myeloma (MM), abnormal serum free light chain ratios (FLCr) after therapy associate with poor prognosis, independent of depth of response. However the value of FLCr in the context of minimal residual disease (MRD) remains unclear. A proportion of MRD-negative patients experience early relapses and conversely, some MRD-positive patients can endure long-term survival; which may result from improved immunosurveillance following normal plasma-cell recovery.

Aims: We hypothesised that serum FLC levels and ratios add clinical value at the time of MRD assessment.

Methods: The study included 275 intact immunoglobulin MM patients from the IFM2009 clinical trial who achieved at least a very good partial response (VGPR) after consolidation therapy. Median PFS from the end of consolidation was 38.3 months; median OS was not reached. Serum FLCs were measured using Freelite immunoassays (The Binding Site). Normal range for k/l FLCr was 0.26-1.25. We defined immunosuppression as levels of both the uninvolved (polycional) FLC+uninvolved heavy+light chain (HLC; measured with Heyvitiel) below their normal range. MRD assessment in bone marrow samples was based on 4-colour multiparametric flow cytometry (MFC).

Results: At the end of consolidation, 79/275 (29%) patients were MRD-positive, 79/275 (29%) had abnormal FLCr, 16/275 (6%) had elevated iFLC, with immunosuppression identified in 52/275 (19%). Using Cox regression all the variables associated with shorter PFS (p<0.001 for all) and OS (p<0.050 for all; except elevated iFLC which showed a trend towards shorter OS (p=0.070)). Among the 319 full MRD-negative patients, 37/196 (19%) had abnormal FLCr. 2/196 (1%) had elevated iFLC with immunosuppression identified in 23/196 (12%). Median PFS for MRD-negative patients was not reached; however both an abnormal FLCr (median PFS: 31.4 months; p<0.001) and immunosuppression (median PFS: 31.4 months; p=0.05) identifies a group of patients with poorer outcomes. On the other hand, median PFS for MRD-positive patients was 21.3 months; 42(53%) of these patients had abnormal FLCr and dismal outcomes (median PFS 12.6 vs 30.7 months for abnormal vs normal FLCr, respectively; p=0.004). Absolute FLC measurements did not reach statistical significance for PFS in these patients.

Summary/Conclusions: Serum FLC measurements in combination with low-sensitivity MFC bone marrow assessment at the end of consolidation therapy render the most powerful prognostic information in MM patients achieving deep responses. In those where disease is no longer detected using MFC, abnormal FLCr confer poor prognosis, which may partly be due to inefficient immune recovery. Absolute FLC measurements are not informative, supporting the rationale of evaluating biomarkers of the tumour and immune system recovery. Our results warrant further studies to validate the clinical utility of FLC measurements in combination with next-generation (8-colours) flow cytometry.

P349
THE CONNECT MM REGISTRY: IMPACT OF THE CYTOGENETIC ABNORMALITY T(11;14) ON SURVIVAL OUTCOMES IN AFRICAN AMERICAN AND NON-AFRICAN AMERICAN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA

1Duke University Medical Center, Durham, 2Indiana University Simon Cancer Center, Indianapolis, 3Mount Sinai Hospital, New York, 4Cedars-Sinai Samuel Oschin Cancer Center, Los Angeles, 5MD Anderson Cancer Center, Houston, 6US Oncology Research, Maryland Oncology Hematology, Columbia, 7Providence Cancer Institute, Southfield, 8Steeplechase Cancer Center, Somerville, 9University of South Carolina, Columbia, 10Wake Forest University School of Medicine, Winston-Salem. 11Celgene Corporation, Summit, 12US Oncology Research, Rocky Mountain Cancer Centers, Denver, United States

Background: The cytogenetic abnormality t(11;14) is common, occurring in approximately 20% of patients with newly diagnosed multiple myeloma (NDMM) (Ave-Loiseau, Leukemia, 2013). Historically, t(11;14) has been associated with standard-risk multiple myeloma (MM) and generally favorable outcome (Ave-Loiseau, Leukemia, 2013). However, recent studies have reported the presence of t(11;14) to be a poor prognostic factor (Kaufman, Leukemia, 2016). Connect MM is a largely community-based, US prospective observational cohort study that collects data on management and natural history of patients with NDMM in clinical practice.

Aims: This analysis assessed the impact of t(11;14) on survival outcomes in African American and non-African American patients in a mostly community-based setting.

Methods: Adult patients with NDMM within 60 days of diagnosis were eligible for enrollment in the registry. Patients who completed induction and were tested for t(11;14) by fluorescence in situ hybridization or cytogenetics were grouped by race (African American and non-African American). Endpoints were progression-free survival (PFS) and overall survival (OS). Kaplan-Meier analyses were adjusted for cohort, age, International Staging System stage, transplant intent, presence of 4d(14), diabetes history, and baseline levels of hemoglobin, platelets, calcium, and creatinine. Data cutoff was Jul 7, 2016.

Results: 3011 patients were enrolled in 2 cohorts. Cohort 1 enrolled 1493 patients from Sep 2009–Dec 2011; median follow-up was 39.3 months. Cohort 2 enrolled 1518 patients from Dec 2012–Apr 2016; median follow-up was 16.4 months. A total of 1539 (52%) patients were tested for t(11;14). Of these, 363 (24%) were positive for t(11;14). By race, 53 (26%) of 205 African American and 310 (23%) of 1334 non-African American patients were positive for t(11;14).

First-line bortezomib exposure was similar across all groups. In African American patients, the presence of t(11;14) resulted in a trend toward shorter PFS compared to those without t(11;14) (Table 1). Additionally, African American patients with t(11;14) had significantly higher risk of death compared to African American patients without t(11;14). A higher rate of early mortality was observed vs non-African American patients. In non-African American patients, no differences in PFS or OS were noted based on the presence or absence of t(11;14). For OS, the interaction between race and t(11;14) status was statistically significant (P=0.004).

Myeloproliferative neoplasms - Clinical 1

P350 RAS-PATHWAY MUTATION PATTERNS DEFINE EPIGENETIC SUBCLASSES IN JUVENILE MYELOMONOCYTIC LEUKEMIA

Results: Systematic DNA methylome analysis of JMML samples identified three JMML subgroups characterized by distinct epigenetic and clinical features. We provide evidence for a molecular mechanism by which additional genetic events could further activating the RAS-RAF-MEK-ERK pathway, mediate DNA hypermethylation via up-regulation of DNMTs in more aggressive JMML cases.

Summary/Conclusions: Our integrated approach identified three JMML subgroups characterized by distinct clinical and biological features. We provide evidence for a molecular mechanism by which additional genetic events could further activating the RAS-RAF-MEK-ERK pathway, mediate DNA hypermethylation via up-regulation of DNMTs in more aggressive JMML cases.

P351 CYTGENETIC ABNORMALITIES IN PRIMARY POLYCYTHEMIA VERA AND POST-POLYCYTHEMIA MF - PHENOTYPE GENETIC PERSPECTIVES WITH GENOTYPE AND PHENOTYPE IN THE MYSEC STUDY

1Hematology, Ospedale di Circolo, ASST Sette Laghi, Varese, 2Institute of Neurosciences, National Research Council of Italy, Padova, 3CRIMM-Centro Ricerca e Innovazione delle Malattie Mieloproliferative, Experimental and Clinical Medicine, Azienda ospedaliera-Università Careggi, University of Florence, Firenze, 4Hematology, Oncology, University of Pavia, Pavia, 5Hematology and BMU Unit, ASST Papa Giovanni XXIII, Bergamo, 6Hematology, Ospedale Niguarda Ca Granda, Milano, Italy, 7Malignant Hematology , Moffit Cancer Center, Tampa, 8Hematology, Stanford University, Stanford, Palo Alto, USA, 9Hematology and Bone Marrow Transplantation, Centro di Trapianto di Organzi Maligni, Hôpital Saint-Louis et Université Paris Diderot, Paris, France, 10Hematology, Hospital Clinic, IDIBAPS, University of Barcelona, Barcelona, Spain, 11Hematology, University Hospitals Leuven, Leuven, Belgium, 12Specialised, Experimental and Diagnostic Medicine, Policlinico S. Orsola-Malpighi, Bologna, 13Hematology, Ospedale di Santa Maria della Salute, Torino, Italy, 14Hematology, Ospedale S. Bortolo, Vicenza, Italy, 15Medicine, Well Cornell Medical College, New York, USA, 16Hematology, Centro Oncologico Epatologico Subalpino (COES), Torino, 17Hematology, Università di Bari, Bari, 18Cytogenetics and Medical Genetics Laboratory, Ospedale di Circolo, ASST Sette Laghi, Varese, 19FROM Research Foundation, ASST Papa Giovanni XXIII, Bergamo, Italy

Background: The molecular and phenotypic correlates of cytogenetic abnormalities in primary myelofibrosis (PMF) have been widely investigated. This information in post-polycythemia vera (post-PV) and post-essential thrombocythemia (post-ET) myelofibrosis (referred to as secondary myelofibrosis, SMF) is scant. The MYSEC project (Myelofibrosis Secondary to PV and ET Collaboration) collected 781 SMF patients in Europe and United States and recently disclosed phenotype-genotype associations in SMF (Leukemia, 2017).

Aims: The primary objective of this study is to report cytogenetic abnormalities in a large scale of SMF patients and discuss molecular and phenotypic correlations of cytogenetic abnormalities. In addition, prognostic relevance of different cytogenetic patterns is investigated.

Methods: Diagnosis of SMF was performed according to the IWG-MRT criteria (2008). The MYSEC study was approved by the Review Board of each Institution and all patients gave written informed consent. Cytogenetic analysis was made at time of SMF diagnosis and considered evaluable if at least 20 metaphases were available. Results were described according to the International System for Human Cytogenetic Nomenclature. Karyotype was defined abnormal if a structural or numeric chromosomal alteration was present in at least two metaphases. The presence of three or more abnormalities defined a complex karyotype; two or more distinct autosomal monosomies or single autosomal monosomy associated with at least one structural abnormality defined monosomal karyotype (MK). Continuous variables were compared via non-parametric Mann-Whitney U tests, with Holm corrections for multiple testing; categoric data were compared via Fisher's exact test. Time-to-event analysis used Kaplan-Meier estimators and Cox models for regression.

Results: Within the whole cohort of 781 SMF patients, 376 had cytogenetic data. Cytogenetic abnormalities were reported in 128 (34.1%) cases: 72 (60%) were sole, 22 (18.3%) double, 26 (21.7%) complex. 11 (9.2%) MK (all included in complex karyotype) and eight monosomies. The most prevalent individual abnormalities were 20q- (25%), 13q- (20.8%), +8 (8.3%) and +9 (5.6%). Patients with post-PV MF had significantly higher frequency of abnormal karyotypes than those with post-ET MF (P=0.012). Chromosomal abnormalities did not cluster differently among the different genotypes (JAK2, CALR, MPL and triple negativity). Abnormal karyotype was significantly associated with lower platelet count (P=0.004), larger spleen size (P=0.016), higher circulating blasts (P<0.001) and presence of constitutional symptoms (P=0.014) at the time of SMF diagnosis. Within abnormal karyotypes, we found that patients with MK tended to have lower platelet count (P=0.04) with respect to those with sole aberrations. Overall survival was significantly shorter in patients with abnormal karyotype (P=0.012), even adjusting for SMF diagnosis type (P=0.02). When investigating OS according to different abnormalities, we found that patients with MK have inferior OS than those with sole abnormality (P<0.0001) (Figure 1).
was 70 years (21-89). Median (range) values for leukocytes, neutrophils, hemo-
globin, and platelets and bone marrow blasts at the time of sample collection for
sequencing were 13.4 (1-179) x 10^9/L, 7.9 (0.4-152.4) x 10^9/L, 9.1 (3.1-15) g/dL,
123 (6-1168) x 10^9/L and 2% (0-17), respectively. On univariate analysis
(n=97), only the presence of EZH2 and ZRSR2 mutations were associated
with trends towards statistical significance for survival. Mutated EZH2 adversely
influenced overall survival (p=0.06), while mutated ZRSR2 had a favorable impact
on survival (p=0.074). The IPSS-R for MDS was useful to differentiate between
risk groups with different survival times (p=0.065) while the dynamic IPSS for
PMF (Passamonti et al. Blood 2010) was not (p=0.39). On multivariate analysis,
only EZH2 mutations and IPSS-R very low risk (versus all other categories
combined) were statistically significantly associated with inferior and superior
survival, respectively.

Summary/Conclusions: In this cohort of 97 patients with WHO-defined
MDS/MPN-U, mutations in genes encoding epigenetic regulators (e.g., TET2, ASXL1, EZH2), spliceosome components (e.g., SRSF2, SF3B1, ZRSR2, U2AF1, SRSF2, SF3B1, ZRSR2, U2AF1, spliceosome molecules, the succinyl moieties, the succinyl moieties,

LEUKEMIC TRANSFORMATION OF MYELOPROLIFERATIVE NEOPLASMS: IS NGS PROFILE THE BEST PROGNOSTIC BIOMARKER?

V. Geoffrey1,2,*, F. Courtiert2, A. Charbonnier1, E. D’Incantal1, C. Saillard1, B. Mohy1, D. Birnbaum2, M.-J. Moziconacci1, A. Murati1, N. Veij1, J. Rey1

1Hematology - Leukemia Department, 2CRCM, 3Biopathology Department, Institut Paoli Calmettes, Marseille, France

Background: Leukemic transformation occurs in 8% to 23% of myelofibrosis patients in the first 10 years after diagnosis and in 4% to 8% of polycythemia vera and essential thrombocythemia patients within 18 years of diagnosis and is almost always fatal.

Aims: We retrospectively analyzed the survival outcome of patients with myeloproliferative neoplasms (MPNs) who progressed to acute myeloid leukemia (AML) based on the treatments received, response, different prognostic groups according to the (ELN) and based on a next-generation DNA sequencing profile (NGS).

Methods: A total of 72 patients diagnosed in our institute with AML secondary to MPNs between 2000 and 2016 were retrospectively analyzed. NGS was performed in 44 mutations. Results found by NGS were classified according three different functional categories of interest (Tumors suppressor (TP53), ADN/Histones’ epigenetic (DNMT3A, EZH2,HD1/2,ASXL1) and alternative splicing (SRFS2, U2AF1, ZRS2, PRPF8, SF3B1)) and three groups were determined: Group A: patients without altered cellular function; Group B: patient with one altered function; Group C: patients with more than one altered functions. AML treatment response was evaluated according to the World Health Organization's proposed criteria for response assessment of AML secondary to MPNs. Overall survival (OS) was calculated according the different treatments, treatment response and NGS profiles.

Results: 72 patients who developed AML secondary to MPNs were included in the study. 43.6% (N=31) had prior ET, 25% (N=18) PV, 20.8% (N=15) PMF and 11.1% (N=8) secondary myelofibrosis. The median age at AML transformation was 70 (range: 38-89). The median time to AML transformation from MPNs diagnosis was 108 months (range: 2.4-408). Among these 72 AML, 56% (N=40) belonged to the favorable risk category according to ELN 2017. 13.9% (N=10) belonged to the intermediate risk category and 35.6% (N=40) to the adverse risk category. 45.8% (N=33) patients were treated with intensive chemotherapy (IC), 15.3% (N=11) with azacitidine (AZA) and 38.9% (N=28) with supportive care (BSC). Median OS was 45.0 months (range: 0.1-65), with no significant difference between the three ELN 2017 risk categories (respectively 2.5 months (range: 1.9-5.5 months (range: 1.6-65) and 5 months (range: 1.6-65) in the favorable, intermediate and adverse risk categories). Patients who received IC (p<0.01) or AZA (p<0.05) have a significant better OS (median OS of 7 months (range: 0.5-65) and 8.5 months (range: 3.2-4) respectively) than patients who received BSC (median OS of 2 months, range: 0.1-36). However, there was no significant difference between the IC and HMA groups (p=0.44). 7 Patients in Complete Cytogenetic Response (CCR) or Acute Leukemia Response-Complete (ALR-C) received an alloSCT had a better median OS than the patients who did not (23 vs 6.5 months, p=0.063). Patients with group A and B NGS profiles have a significant better median OS (respectively 14.3 months (range: 0.1-65) and 14.3 months (range: 0.1-65) than Group C (3 months) (p<0.05).

Summary/Conclusions: Our results confirm the poor outcome of patients with secondary AML treated with IC and suggest that AZA provides comparable OS. ELN2017 risk stratification predicted poorly patients outcome although a NGS-based classification performed better.
The diagnosis of prePMF have been added (anemia, leukocytosis >11 ×10^9/L, and prePMF diagnosed according to the new 2016 WHO criteria. The revised WHO criteria for myeloid neoplasms was recently revised in 2016. The revised WHO criteria ACCORDING TO THE REVISED 2016 WHO DIAGNOSTIC CRITERIA THROMBOCYTHEMIA AND PREFIBROTIC MYELOFIBROSIS DIAGNOSED REPORT OF THE REGISTRO ITALIANO TROMBOCITEMIE BACKGROUND: The World Health Organization (WHO) classification system for myeloid neoplasms was recently revised in 2016. The revised WHO criteria unify the classification of different preleukemic, pre-BFM (prePMF) from "true" essential thrombocytopenia (ET) as these two entities have different clinical outcomes. For these reasons, standardization of morphologic findings in the bone marrow biopsy and an explicit definition of minor clinical criteria for the diagnosis of prePMF have been added (anemia, leukocytosis >11 ×10^9/L, platelet count, higher LDH values, higher number of circulating CD34-positive cells, and showed more frequently splenomegaly (Table 1). The higher frequency of CALR mutations in prePMF compared to ET might contribute to the high level of platelet count observed in prePMF. ET and MPN did not differ in terms of leukocyte count, hemoglobin, platelet count, LDH, circulating CD34-positive cells and splenomegaly (Table 1). The 26 patients with MPN were not further considered in the analysis of disease complications and overall survival due to the low number. PrePMF patients had lower overall survival (overall survival at 10 years 86.4% vs 96.6%, P <.001) and a trend to a higher incidence of leukemic evolution (cumulative incidence of acute myeloid leukemia at 10 years 23.3% vs 19.0%, P =.067) compared to ET patients, while they did not differ in terms of thrombotic complications (cumulative incidence of thrombosis at 10 years 18.5% vs 18.0%, P =.86). Finally, we analyzed the subgroup of "old" ET diagnosed according to 2008 WHO criteria. Of 358 "old" ET, 268 were reclassified as ET, 25 as MPN and 65 as prePMF. The "old" ET reclassified as prePMF had a higher risk of overt myelofibrotic evolution compared to the "old" ET reclassified as ET (cumulative incidence of overt myelofibrosis at 10 years 9.7% vs 0%, P =.033) Summary/Conclusions: ET and prePMF diagnosed according to 2016 WHO criteria are two entities with a different clinical phenotype at diagnosis and a different outcome. The clinical phenotype at disease onset of MPN and ET is similar.

**Background:** The minimal effective treatment in Essential Thrombocythemia (ET) patients is tailored mainly on the basis of thrombotic risk scores (primarily non-malignant). The Revised International Prognostic Score for Thrombosis in ET (R-IPSET-Th) is derived from different combinations of Age >60 yrs (Age >60), JAK2 V617F mutation (JAK2+), and Prior Thrombosis (PrTh+).

**Methods:** The web-based Registro Italiano Trombocitemie (RIT) recruited since 2005 patients with thrombocytosis (bcr/abl negative chronic myeloproliferative neoplasms (MPN)). ET patients (classified according to WHO 2016 criteria) with complete information (characteristics at diagnosis, antithrombotic and/or cytoreductive treatment, date and description of thrombotic events during the follow-up) were considered for this analysis. According to the R-IPSET-Th score, the patients were divided into 4 thrombotic risk groups: Very Low Risk (VLR: Age <60, absence of JAK2 mutations, no PrTh+), Low Risk (LR: Age >60, JAK2+), Intermediate Risk (IR: Age >60, High Risk (HR: PrTh+), or Age >60 with JAK2+). The median follow-up was 12, 12, 9, and 11 years, respectively (whole cohort, 11 years).

**Results:** Overall, 734 ET patients were analyzed (females 62%). Data at diagnosis were: Age >60 in 286 (39%), JAK2+ in 417 (57%), and PrTh in 126 (17%). The rates (n and%, n/100 pt-yrs) of first thrombotic events during the follow-up were considered for this analysis. According to the R-IPSET-Th score, the patients were divided in 4 thrombotic risk groups: Very Low Risk (VLR: Age <60, absence of JAK2 mutations, no PrTh+), Low Risk (LR: Age >60, JAK2+), Intermediate Risk (IR: Age >60, High Risk (HR: PrTh+), or Age >60 with JAK2+). The Th-FUP/100 pt-yrs increased (p <0.01) as follows: 0.60%, 0.79%, 1.61%, and 1.91%, respectively. TFS progressively decreased (p <0.001) from VLR group to HR group (Figure 1). In detail, the probability of TFS was 0.98, 0.97, 0.84, 0.78, and 0.54 at 20 years. The patient stratification according to the R-IPSET-Th and the IPSET-Th scores showed a concordance of 0.82 (Harrell C index).

**Figure 1.**

**Summary/Conclusions:** In this study of the Registro Italiano Trombocitemie (RIT), we confirmed that the Revised International Prognostic Score for Thrombosis in ET (R-IPSET-Th) separated ET patients in 4 groups with increasing risk of thrombosis during the follow-up (p <0.001). According to the R-IPSET-Th score, an over-treatment seems to have occurred in this cohort of ET patients (anti-platelets in almost all cases, and cytoreduction in around 2/3 of VLR and LR cases), probably because other adjunctive risk factors have been considered.

**Background:** Myelofibrosis (MF) is characterized by significant inflammation driven by clonal dysregulation and subsequent disruption of cellular signaling cascades. Studies have confirmed a close relationship between circulating inflammatory biomarkers and baseline symptom burden, along with the potential to mitigate symptoms upon improvement of these proteins (Duck Blood, 2013). To date, no study has evaluated the correlations between elevated biomarkers (BMKs) and specific MF symptoms.

**Aims:** In this analysis of the phase-III placebo controlled COMFORT-I study, we investigated the relationships between blood BMKs and individual MF symptoms at baseline and post-treatment with ruxolitinib.

**Methods:** Biomarker levels at baseline, week 4 and 24 were measured along with MF symptoms (MSAF 2.0-Mesa JCO 2013; collected during blinded phase of COMFORT-I). Patients were randomized to ruxolitinib vs placebo. BMKs were assessed using Rules-Based Medicine, Inc. (Austin, TX) Human MAP panel. Associations between the individual symptoms measured within the MFSAF and log2-transformed biomarker data were investigated at baseline using Spearman correlations. Mixed models were used to assess symptom and BMK changes over time. Models included terms for visit, arm, visit-by-arm interaction, age, sex, and body mass index (BMI) as covariates.

**Results:** Study Population. A total of 309 subjects were randomized in COMFORT-I with median age of 68 (range 40-91). Approximately 46% of patients were female and 50% had primary myelofibrosis (61% high risk). All 309 subjects had BMKs measured at one or more of the three visits included in this analysis, with 308 having biomarker values paired with MFSAF symptom scores at the same visit. Correlations of Baseline Biomarkers and Symptoms. Total symptom score (TSS) statistically significantly (p<0.05) correlated with 20 BMKs at baseline (Table 1). For individual symptoms, spleen-related symptoms appeared to statistically significantly correlate more frequently with BMKs at baseline: abdominal discomfort (23 BMKs), feeling full (20 BMKs), and pain under left ribs (19 BMKs). Night sweats, itchiness, and bone or muscle pain significantly correlated with 15, 14, and 10 BMKs each. The BMKs with the strongest correlations (absolute Spearman correlation of at least 0.20 with p<0.001) with at least one symptom included APOA1, EPO, FERRITIN, MIP1A, and PSAF. Associations with Symptoms+TSS were statistically significantly associated with TSS over time.

**Summary/Conclusions:** Spleen-related symptoms demonstrate close association with BMKs at baseline as well as BMKs over time, after taking into account age, sex, BMI, and treatment. At baseline and over time, abdominal symptoms remained the most frequently correlated or associated symptoms with biomarker levels. More research is needed to determine the role of some of these key BMKs in altered cellular signaling and potentially targetable pathways for symptom reduction.

NOVEL HETEROZYGOUS ITGB3 P.T746DEL MUTATION INDUCING SPONTANEOUS ACTIVATION OF INTEGRIN αIIbβ3 CAUSES AUTOSOMAL DOMINANT MACROTHROMBOCYTOPENIA WITH ABNORMAL αIIbβ3 LOCALIZATION

J. Bastida,*, J. Hernandez-Sanchez,2, A. Rodriguez,2, D. Alonso-Lopez,2

1Department of Hematology, Hospital Universitario de Salamanca-IBSAL, 2Department of Hematology, IBSAL, ICMC, CIC, Universidad de Salamanca-CSIC, Salamanca, Spain

Background: Congenital macrothrombocytopenia is a rare platelet disorder and its cause is genetically heterogeneous. Recently, integrin αIIb and β3 mutations have been identified in congenital macrothrombocytopenia patients with platelet aggregation dysfunction. Here, we found a novel, heterozygous ITGB3 mutation in a pedigree and examined how this mutation contributed congenital macrothrombocytopenia.

Aims: To detect gene mutations responsible for the congenital macrothrombocytopenia in this pedigree and reveal the molecular pathophysiology.

Methods: Whole exome sequencing (WES) was performed to detect gene mutations. Expression and activation state of αIIbβ3 in platelets was evaluated by flow cytometry (FCM) and western blotting (WB). The effects of mutations on αIIbβ3 expression state, phosphorylation of FAK, and morphological changes were analyzed in transfected cells by WB and immunofluorescence staining.

Results: The patients were 56-year-old Japanese woman and 2 of her 3 sons. They had no bleeding tendencies and near-normal bleeding time (Duke’s method). Hematological examination revealed their decreased platelet counts (58-86 x 10^9/l) with increase of mean platelet volume (12.8-14.5 fl). In all affected family members, giant platelets were observed on the peripheral blood smears. Platelet aggregation induced by ADP (1-10 µmol/l) and collagen (2 µg/ml) was obviously reduced although that induced by ristocetin (1.5 mg/ml) was within normal limit. The family pedigree indicates that the inheritance pattern is autosomal dominant. Common congenital macrothrombocytopenias, such as MYH9 disorders, Bernard-Soulier syndrome and type 2B von Willebrand disease were excluded by the absent leucocyte inclusion bodies, normal ristocetin cofactor activity, and normal platelet GPib/IX expression, normal von Willebrand factor assays, respectively. WES revealed that all affected family members had a heterozygous ITGB3 p.T746del mutation. FCM showed decreased surface expression level of αIIbβ3 in the affected member’s platelets. However WB of platelet lysates showed that there was no difference in the total amount of αIIbβ3 among the affected and unaffected members and normal controls. FCM showed a constitutive activation of αIIbβ3 on the patient’s platelets as reflected by the spontaneous binding of PAC-1 antibody. Immuno-fluorescence staining using CHO showed membrane localization of αIIbβ3 in wild-type αIIb/β3-expressing cells and cytoplasmic localization in αIIbβ3 (p.T746del) expressing cells (Figure 1). Immunofluorescence of transfected cells showed spontaneous tyrosine phosphorylation of FAK and morphological changes, such as rhomboid changes, elongated changes, abnormal cytoplasmic protrusions, and membrane ruffling, in transfected cells. FAK inhibitor (1,2,4,5-Benzenetetraamine) decreased these abnormalities and rendered the activated form. Activation of αIIbβ3 leads to phosphorylation of FAK causing morphological changes in transfected cells, which is considered to reflect abnormal thrombopoiesis leading to the production of giant platelets. We conclude that platelet aggregation dysfunction is due to decrease of αIIbβ3 expression on the platelet membrane surface due to cytoplasmic localization. These results suggest that the gain-of-function mutation around membrane region of αIIbβ3 leads to macrothrombocytopenia with impaired surface αIIbβ3 expression.

Summary/Conclusions: The autosomal dominant heterozygous ITGB3 p.T746del mutation was found to be responsible for constitutive activation of αIIbβ3 in the patients’ platelets as well as transfected cells. It is considered that ITGB3 p.T746del mutation uncouples the highly conserved membrane proximal complex of αIIb and β3 cytoplasmic tails and renders the activated form. Activation of αIIbβ3 leads to phosphorylation of FAK causing morphological changes in transfected cells, which is considered to reflect abnormal thrombopoiesis leading to the production of giant platelets. We conclude that platelet aggregation dysfunction is due to decrease of αIIbβ3 expression on the platelet membrane surface due to cytoplasmic localization. These results suggest that the gain-of-function mutation around membrane region of αIIbβ3 leads to macrothrombocytopenia with impaired surface αIIbβ3 expression.

Figure 1.

Summary/Conclusions: In ITPc patients, ETP can induce overexpression of genes involved in platelet activation and megakaryopoiesis and also alter key/relevant/important-signaling pathways such as JAK/STAT and PI3K/Akt.

P361

CHANGES IN THE GENE EXPRESSION PROFILE OF IMMUNE THROMBOCYTOPENIA PATIENTS TREATED WITH ETLROMBOPAG (ETP)

J. Hernandez-Rivas,2, J. Pérez-Camarena,2, C. Rodríguez,2, D. Alonso-Lopez,2, E. Lumbraeras,2, M. Lopez-Parra1, R. Bueno2, A. Veiga1, J. Hernandez-Rivas2, J. Gonzalez-Porras1

1Department of Hematology, Hospital Universitario de Salamanca-IBSAL, 2Department of Hematology, IBSAL, ICMC, CIC, Universidad de Salamanca-CSIC, Salamanca, Spain

Background: Etrtombogap (ETP) is an orally bioavailable, small non-peptide molecule thrombopoietin receptor agonist that stimulates platelet production by a mechanism similar, but not identical to, endogenous thrombopoietin. ETP interacts with the transmembrane domain of thrombopoietin receptor, initiating a JAK/STAT signaling pathway inducing the proliferation and differentiation of the megakaryocytes to increase platelets production.

Aims: To assess the gene expression profile (GEP) and the underlying signaling pathways modified before and during the ETP treatment in chronic immune thrombocytopenia (ITPc) patients.

Methods: ETPc patients (n=14) treated with ETP were evaluated. Complete response (CR) was defined as a platelet count of ≥100x10^3/mm^3 and treatment failure was defined as a platelet count ≤50x10^3/mm^3 for 4 consecutive weeks at the highest recommended dose of ETP, a major bleeding event, or the need to change therapy. RNA was isolated from mononucleated cells pre/post ETP treatment. The “paired” GEP of the ITPc patients included the semi-supervised analysis cluster samples before and after (28 day) the treatment with ETP to detect changes attributed to ETP. This paired GEP was showed in Figure 1. The GEP workflow consisted of the following steps: 28-paired samples were hybridized to GeneChip® Human Gene 2.0 ST Array (Affymetrix®). The robust microarray analysis (RMA) algorithm was used for background correction and normalization, while signal expression was calculated by significance analysis of each microarray to provide a robust statistical inference by a permutation method. P-values were provided and adjusted by multiples testing using a false discovery rate (FDR). The pathways and upstream regulators related with the most differentially expressed genes were analyzed by in silico analysis tools: Advantia Bio’s PathwayGuide (http://www.advantibio.com/pathwayguide) and DAVID Bioinformatics Resources.

Results: The median age of the 14 ITPc patients enrolled in the study was 77 years (range, 35-87y), 64% patients (n=9) were treated with ETP after ≥2 lines of treatments. Only 3 patients were splenectomized. Median platelet (P) and white blood cell counts (WBC) increased after treated by ETP at day 28. (P and WBC pre: 14, 15x10^9/mm^3 and 6,85x10^9/mm^3 vs P and WBC post: 132x10^9/mm^3 and 9,1x10^9/mm^3). All but two patients achieved CR (95,7%) and other 2 were considered failure of treatment. Regarding the gene expression profile, in silico analysis showed that the expression of 147 genes was modified after ETP treatment; all of them were overexpressed after treatment. Semi-supervised cluster analysis showed 2 groups: pre and post ETP treatment (Figure 1). Pathway analysis revealed that 38 genes were involved in the maintenance of hemostasis, most of them related to platelet activation (PTGS1, GP1BA or GP6). Interestingly, the paired GEP pointed out E2F1 and GFI1B as possible leaders of the increase of the megakaryopoiesis. Other signaling pathways overexpressed by ETP treatment are downstream routes of PI3K/Akt (GFI1B, JAM3, ITGB3 and ITGA2B) and platelet activation (GP6, GP9, GP1BA or PTGS1).

Summary/Conclusions: In ITPc patients, ETP can induce overexpression of genes involved in platelet activation and megakaryopoiesis and also alter key/relevant/important-signaling pathways such as JAK/STAT and PI3K/Akt.

P362

DEFECTIVE PTEN REGULATION CONTRIBUTES TO B CELL HYPERRE- SPONSIVENESS IN CHRONIC IMMUNE THROMBOCYTOPENIA

J. Pérez-Camarena,2, C. Rodríguez,2, D. Alonso-Lopez2, E. Lumbraeras2, M. Lopez-Parra1, R. Bueno2, A. Veiga1, J. Hernandez-Rivas2, J. Gonzalez-Porras1

1State Key Laboratory of Experimental Hematology, Institute of Hematology and Blood Disease Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Tianjin, China, Tianjin, 2Second Affiliated Hospital of Kunming medical University, Kunming, China

Background: Immune thrombocytopenia (ITP) is a complex autoimmune disease characterized by low platelet counts. The autoantibodies produced by autoreactive B cells against self-antigens, specifically immunoglobulin G (IgG)
antibodies against glycoprotein Iib (GP Ib/IIa) and/or GP Ib/IX are considered to play a crucial role. B cell homeostasis and function are controlled by cell surface receptor-ligand interactions. The activation of PI3K is initiated by engagement of the pre-B cell receptor (BCR) and the BCR. The phosphatase and tensin homolog (PTEN) suppress the activity of the PI3K pathway. As a consequence, loss of PTEN function leads to excessive PI(3,4,5)P3 at the plasma membrane and to recruitment and activation of Akt family members that potently drive cell survival and proliferation. PTEN regulates normal signaling through the B cell receptor (BCR). In immune thrombocytopenia (ITP), enhanced BCR signaling contributes to increased B cell activity, but the role of PTEN in human ITP has remained unclear. Both IL-21/IL-21R signaling and PI3K-PTEN molecules are involved in maintaining normal humoral immunity and deletion of autoreactive B cells. In this study, we want to determine whether abnormalities in PTEN might contribute to increased B cell responsiveness in this disease and IL-21 mediated PTEN induction was defective. Meanwhile, we want to evaluate the relation between the expression of PTEN in B cells and the prognosis of ITP which will provide a theoretical basis of new treatment strategy for the ITP patients.

Aims: PTEN is involved in maintaining normal B cell function. Since B cell overactivity is characteristic of immune thrombocytopenia (ITP), we sought to determine whether abnormalities in PTEN might contribute to increased B cell responsiveness in this disease.

Methods: 1. This study recruited 28 newly-diagnosed CITP patients and 26 sex and age matched health volunteers as health controls (HC). Peripheral blood mononuclear cells were isolated from collected anti-coagulated blood. 2. Flow cytometry and real-time quantitative PCR were used for detecting the level of PTEN from PBMC cells of HC and CITP patients. 3. The relationship between PTEN levels and the disease severity of CITP was analyzed. 4. PBMC cells were incubated with human IL-2, IL-21, CD40L or anti-IgM alone or in combination for 72 h and after that the PTEN level was detected by flow cytometry. The proportion and surface activated marker of B cells were determined by flow cytometry.

Results: 1. Compared to HC the expression of PTEN was diminished in each CITP B cell population except IgD-CD38low-memory B cells. In addition, PTEN mRNA was also decreased in ITP B cells. 2. The level of PTEN in B cells was slightly correlated with blood platelet count (p=0.008) and also directly correlated with the pre-B cell receptor (BCR). The phosphatase and tensin homolog (PTEN) in B cells was down-regulated, and PTEN expression in normal B cells, followed by IL-21 and IL-2. Neither IL-21 alone nor CD40L plus anti-IgM nor the three in combination stimulated PTEN protein up-regulation in B cells in CITP patients. 4. These immature B cells in CITP patients had a greater expression of CD95 but less PTEN compared to HC suggesting that down-regulation of PTEN was associated with an increased B cell activity, but the role of PTEN in human ITP has remained unclear.

Background: Immune thrombocytopenia (ITP) is a common autoimmune disorder characterized by increased bleeding tendency and isolated thrombocytopenia. The precise pathogenesis of the decreased thrombopoiesis in ITP remains unknown. It has been demonstrated that megakaryocytes (MKs) in ITP show impaired proplatelet formation (PPF) (Fr J Haematol. 2014;165:854-64). However, the pathogenesis of the impaired PPF in ITP is not entirely understood. Additionally, the lipid mediator sphingosine 1-phosphate (S1P) plays a critical role in megakaryocytic PPF in the bone marrow (BM) niche (J Exp Med. 2012;210:2137-40). It has been demonstrated that cell-surface S1P receptors (S1PR) on MKs trigger the activation of Gi/Rac GTPase signaling. Sphingosine kinase 2 (Sphk2) is the major isoform regulating intracellular synthesis of S1P in MKs. Additionally, intracellular S1P influences the expression of Src family kinase (SFK) in MKs, including 6 members (Fyn, Lyn, Src, Yes, Fgr, and Hck) which mutually regulate each other with Rac GTPase.

Aims: To determine whether the S1P levels in both the BM niche and within MKs, as well as S1PR expression of MKs contribute to the defective thrombopoiesis in ITP through impaired PPF.

Methods: The PPF of ITP-MKs was measured by an in vitro PPF assay using HSCs from the BM, (FASEB J. 2010;24:4701-10). Additionally, all-trans-retinoic acid (ATRA), the S1pr1-specific agonist SEW2871, and extracellular S1P were used as interference factors. The concentration of S1P in the plasma and BM was measured by ELISA. The concentration of intracellular S1P was measured using ultrahigh-performance liquid chromatography mass spectrometry (LC/MS) analysis. Intracellular Sphk2, SFKs and cell-surface S1PR were measured using PCR and western blotting. The location of Sphk2 was analyzed by immunofluorescence using an anti-human Sphk2 antibody. The activities of Rac-GTP were quantified by pull-down assay.

Results: Significantly fewer numbers of proplatelet-forming MKs were observed in ITP cultures. The concentration of S1P in the plasma and BM of patients with ITP was measured, of which the results showed no significant difference in the plasma/BM S1P ratio. Decreased expression of S1PR1 and S1PR4 was observed in ITP MKs. We found that downstream Gi/Rac GTPase signaling activated by S1PR1 was down-regulated. ITP-MKs exhibited decreased intracellular Sphk2, indicating less biosynthesis of intracellular S1P. Immunostaining of Sphk2 in ITP MKs was performed, showing that less Sphk2 was primarily localized to the granules of ITP MKs. Intracellular S1P of ITP MKs was further explored showing a decrease of megakaryocytic S1P production ascribed to significantly decreased Rac GTPase activity and with the overall mRNA expression of Rac and Rac1s which mutually regulate each other with Rac GTPase.

Summary/Conclusions: Decreased intracellular S1P ascribed to significantly reduced Sphk2, results in down-regulated SFK expression and activity, and decreased S1PR1 and S1PR4 down-regulate Gi/Rac GTPase activity in ITP-MKs. Therefore, abnormal S1P/S1P4 possibly plays a role in the pathogenesis of impaired PPF in ITP, which may be therapeutically regulated by ATRA.

ANTIBODY MEDIATED GLYCAN MODIFICATION: A POTENTIAL ROLE IN PLATELET DESTRUCTION IN AUTOIMMUNE THROMBOCYTOPENIA

I. Madan1, R. Jouni1, J. Alek1, A. Greinacher1, T. Backhous1

1Center for Clinical Transfusion Medicine, University Hospital of Tübingen, Tübingen, Transfusion Medicine, Universitätmedizin Greifswald, Greifswald, Germany

Background: Immune thrombocytopenia (ITP) is a bleeding disease caused by autoantibodies (AAbs) directed against platelet (PLT) glycoproteins (GP). A novel mechanism of antibody-mediated PLT destruction based on Fc-independent PLT clearance via Ashwell-Morell receptors (AMRs), which recognize glycan modifications on the surface of PLTs, has been suggested.

Aims: In this study we investigated the effects of human AAbs from ITP patients on the glycan pattern of human PLTs and the consequent impact on their survival in vivo.

Methods: Monoclonal platelet antigen capture assay (MAIPA) and lectin binding assays using normal sera from ITP patients and healthy donors were used to identify the modified sera from ITP patients and healthy donors. In LBA, after incubation with sera and PLTs from healthy donors, the modification in glycan pattern was investigated by flow cytometry using lectins; Ricinus communis agglutinin (RCA), Erythrina cristagalli lectin (ECL) and Peanut agglu-
tinin (PNA) that bind to galactose, N-acetyllactosamine and N-acetylgalactosamine residues, respectively. The NOD/SCID mouse model was used to study the impact of different glycan patterns on the survival of human PLTs.

**Results:** In this work 37 sera from ITP patients and 25 sera from healthy donors were analyzed. In the LBA, after incubation with AAbs, different patterns of glycan modification were observed. 17/37 sera caused a significant increase in PNAs analyzed, and the serum level of thrombopoietin was normal or moderately increased. No specific morphological alteration of platelets was detected. Most sera induced an accelerated clearance of human PLTs from the circulation. The destruction of human PLTs by ITP-AAbs was decreased but not completely prevented by a specific neuraminidase inhibitor that blocks glycan changes on PLT surface (survival of human PLTs after 5h: 48%, range 41.53% - 29%, range 22-40%).

**Summary/Conclusions:** Our results demonstrate that AAbs from ITP patients are able to induce cleavage of glycan moieties on the PLT surface in distinct manners. Antbody-mediated modification of glycan patterns seems to contribute to AAb-mediated PLT destruction.

Trambusi”, University of Bari, 6U.O.C of Pediatrics, Hospital “D. Camerlingo”, Francavilla Fontana, Bari, Italy, 7Institute of Investigaciones Medicas Alfredo Lanari, Universidad de Buenos Aires, 8Department of Medical Sciences, University of Trieste, Trieste, Italy

**Background:** Familial platelet disorder with propensity to acute myeloid leukemia (FPD/AML) is a rare autosomal dominant inherited thrombocytopenia (IT) caused by mutations in the hematopoietic transcription factor RUNX1; an important hallmark of this IT is the increased risk of developing myeloid neoplasms, such as AML and myelodysplastic syndromes (MDS). FPD/AML is caused by different mutations of RUNX1 encoding the DNA binding subunit (known as core binding factor-alpha, CBF-alpha) of the CBF transcription complex. The N-terminus domain of RUNX1 (run-homologous domain) mediates DNA binding and heterodimerization to CBF-beta, the other subunit of the CBF complex. The C-terminus of RUNX1 includes domains that are involved in transcription activation and repression. This IT is characterized by impaired megakaryopoiesis and moderate thrombocytopenia, with normal-sized and dysfunctional platelets.

**Aims:** To unravel the molecular basis of ITs and to improve our knowledge on the molecular basis and clinical-laboratory picture of FPD/AML.

**Methods:** Whole exome sequencing (WES) was performed in 86 propositi with an unknown IT after the diagnostic workup based on the most updated diagnostic algorithm for ITs (Clin Genet 2016;89:141). RUNX1 variants detected by Sanger sequencing were confirmed by Sanger sequencing in the propositi and all available family members, which also undergo clinical-laboratory characterization. The study was approved by the Institutional Review Board of the IRCCS Policlinico S. Matteo Foundation; all patients gave written informed consent.

**Results:** We identified three pedigrees (families 1-3) with different RUNX1 heterozygous mutations, all segregating with thrombocytopenia in the respective families: the novel variants c.578T>A and c.967+2_5del, and the known c.351+1G>A. The thirteen individuals carrying the novel variants detected with a moderate reduction of GPIa-IIa was detected, regardless of genotype at the ITGA2 locus. A defective aggregation was detected after platelet stimulation with collagen 4 mcg/ml and ADP 2 mM in the five patients investigated; normal responses were obtained using collagen 20 mcg/ml, ADP 20 mM and ristocetin 1.5 mg/mL, suggesting mild functional platelets defects. Of note, three pedigrees from two families developed AML, with a prevalence lower than reported in literature, probably because of a different criteria of enrolment (RUNX1 germline mutations are usually searched in ITs associated with AML). No solid/hematological cancer was reported in family 1.

**Summary/Conclusions:** FPD/AML is an IT lacking pathognomonic laboratory criteria: it is characterized by a mild functional defect and, much more importantly, by a normal platelet size, similarly to the other ITs predisposing to hematological malignancies (ANKRD26 and ETV6-related thrombocytopenias). Given the importance of recognizing these diseases for patients counseling, follow-up, and therapeutic approach, we recommend a systematic screening for RUNX1, ANKRD26, and ETV6 mutations in all patients with an autosomal dominant IT and normal platelet size.

**A SINGLE-ARM, OPEN-LABEL, LONG-TERM EFFICACY AND SAFETY STUDY OF SUBCUTANEOUS ROMIPLOSTIM IN CHILDREN WITH IMMUNE THROMBOCYTOPENIA**

J. Grainger1,*, J. Busse2, N. Cooper3, M. Taranlin4, V. Blanchette5, J. Despotovic6, A. Maschan7, N. Carpenter8, M. Eisen9, B. Mehta9

1University of Manchester, Manchester, United Kingdom, 2Welli Cornel Medicine, New York, United States, 3Hammersmith Hospital, Imperial College, London, United Kingdom, 4The Bleeding and Clotting Disorders Institute, Peoria, United States, 5Hospital for Sick Children, Toronto, Canada, 6Texas Children’s Hematology Center, Houston, United States, 7Federal Research Center of Pediatric Hematology, Oncology and Immunology n.a. Dmitry Rogachov, Moscow, Russian Federation, 8Amgen Ltd., Uxbridge, United Kingdom, 9Amgen Inc., Thousand Oaks, United States

**Background:** The use of romiplostim in children with ITP has been evaluated in phase 1/2 and 3 studies. Here we describe children with ITP who will receive open-label SC romiplostim for up to 3 years (y).

**Aims:** To assess platelet responses in children with ITP receiving romiplostim.

**Methods:** Eligible children, recruited in 16 countries worldwide, had ITP for ≥6 months, ≥1 prior ITP therapy, and platelet (plt) counts <30×10⁹/L. Weekly SC dosing started at 1 μg/kg and was titrated in 1 μg/kg increments up to 10 μg/kg to maintain plt counts of 50-200×10⁹/L. The primary endpoint was the % of time in the first 6 months with a plt response (plt count ≥50×10⁹/L without rescue medication use in the past 4 weeks).

**Results:** As of 15 Mar 2016, 145 patients received ≥1 dose. At baseline, median (min-max) age was 10 (2-17) y; 51% were female; 4% had prior splenectomy. Median (min-max) ITP duration was 1.9 (0.5-12.3) y and plt count was 13 (2-168)×10⁹/L. The median (Q1, Q3)% of time with a plt response in the past 4 weeks.

**Figure 1.**

**Results:** As of 15 Mar 2016, 145 patients received ≥1 dose. At baseline, median (min-max) age was 10 (2-17) y; 51% were female; 4% had prior splenectomy. Median (min-max) ITP duration was 1.9 (0.5-12.3) y and plt count was 13 (2-168)×10⁹/L. The median (Q1, Q3)% of time with a plt response in the
first 6 months was 50% (0%, 83.3%); that of months 7-12 was 92% (33%, 100%). Overall, 80% (114/143) of patients had a platelet response. The median (Q1, Q3) of time with an increase in platelet counts ≥2x10^9/L above baseline was 60% (25%, 84%). The median dose increased to 10 µg/kg by week 32. Median (min-max) treatment duration to date was 25 (1-67) weeks for a total exposure to date of 79 patient-years. Median (min-max) average weekly romiplostim dose over the course of the study was 6.1 (0.4-9.0) µg/kg. 32 patients (22%) discontinued treatment for lack of efficacy (n=17), required other therapy (n=5), patient request (n=4), noncompliance (n=2), adverse event (AE) (n=2) (interstitial lung disease in a 15 y old boy and abdominal pain, vomiting, and headache related to treatment in a 9 y old girl), administrative decision (n=1), and investigator decision (n=1). 34 (23%) patients received rescue medications. 15 (10.3%) patients had serious AEs (SAEs) including epistaxis (n=4), petechiae (n=2), decreased platelet count (n=2), and thrombocytopenia (n=2). A case of abdominal pain was the only SAE deemed treatment-related by the investigator. CTCAE grade 3 bleeding was seen in 8 patients (6%) and included epistaxis (n=5), ecchymosis (n=2), petechiae (n=2), and 1 case each of hematemesis, hematomata, SC hemorrhage, injection site hemorrhage, and mouth hemorrhage. No grade 4 or 5 bleeding was observed. No neutralizing antibodies against romiplostim or TPO were identified. Of 30 patients with baseline bone marrow biopsies (bone marrow biopsies were obtained at European sites), all had modified Bauermeister scores of grade 0 (no reticulin) or 1 (fine fibers) and bone marrows typical for TIP. Of these 30 patients, 21 had evaluable on-study biopsies obtained after ~1 year of treatment, with no increases in 2 or more grades, findings of collagen, or bone marrow abnormalities (Figure 1).

Summary/Conclusions: In this year 1 datacut of an ongoing open-label study of romiplostim in children with ITP, the% of time in the first 6 months with a platelet response was 50%, with 80% of children having a platelet response at some point on study. The median romiplostim dose reached 10 µg/kg and there were no new safety signals. No effects of romiplostim were observed on the bone marrow in the subset of patients with bone marrow biopsies. Future datacuts for years 2 and 3 in this study, the largest of romiplostim in children with ITP of 79 patient-years of exposure to date, will provide more information on platelet response, dose requirements, and safety.

NOVEL THIENOPYRIDINES AS POTENT PLATELET INHIBITORS: FUTURE TREATMENTS FOR PLATELET HYPERACTIVITY DISORDERS?

N. Binsaleh1, C. Wiegley1, K. Whitehead1, D. Moreno-Martinez1, S. Danies1, S. Jones1, M. van Rensburg2, L. PILkington2, D. Barker2, N. Dempsey-Hibbert1 1School of Healthcare Science, Manchester Metropolitan University, Manchester, United Kingdom, 2School of Chemical Sciences, University of Auckland, Auckland, New Zealand

Background: Platelet hyperactivity is associated with a number of disorders including Acute Coronary Syndromes (ACS) and manifests as increased platelet activation and often inappropriate thrombus formation. The thienopyridine class of anti-platelet drugs, of which clopidogrel and prasugrel are the most well known, target the P2Y12 receptor on platelets, blocking the effects of the platelet agonist ADP. However, the effect of these drugs is variable amongst patients, with some patients responding well and some remaining at risk of thrombosis. This variability highlights a need for a refinement of this class of P2Y12 inhibitor.

Aims: The aim of this study was to assess the efficacy of six novel thienopyridine derivatives synthesized by our group as potential inhibitors of platelet function.

Methods: Healthy human platelets were isolated and incubated with novel thienopyridine compounds (DJ0081, DJ0199, DJ0206, DJ0171, DJ0021, DJ0171, DJ0097) (10µM, 30min) prior to stimulation with ADP (10µM) and analysis of alpha granule secretion (CD62P expression), GPIIb/IIIa activation (PAI1 expression) and platelet leukocyte aggregate (PLA) formation using flow cytometry. Furthermore, light transmission aggregometry (LTA) was used to assess ADP-mediated platelet aggregation after these treatments. As clopidogrel is usually prescribed in combination with the COX-1 inhibitor acetylsalicylic acid (ASA), synergy of the novel compounds with ASA (30µM) was also analysed by LTA. All experiments were performed in a total volume of 100 µl. In vitro studies included incubation of platelets with the compounds for 30 min, followed by addition of ADP (10µM), with collection of aliquots at 0, 5, 10, 15, 20, and 30 min. Results: All six novel compounds demonstrated a significant reduction in ADP-mediated platelet aggregation (P<0.001), CD62P expression (p<0.001), PAC1 expression (p<0.01) and PLA formation (p<0.05). These compounds were also shown to enhance the inhibitory effects of ASA. DJ0171 and DJ0199 were particularly potent, displaying greater inhibitory effect than clopidogrel.

Summary/Conclusions: The study demonstrates the potential for new thienopyridine compounds as modulators of platelet function and points to the possibility of future use in patients at risk of platelet hyperactivity and thrombosis.

**ECONOMIC IMPACT OF INTRODUCING AGE-ADJUSTED D-DIMER CUT-OFF LEVELS IN THE DIAGNOSIS STRATEGY OF VENOUS THROMBOEMBOLISM**

P. Toulon1,*, N. De Poorter2, M. Brionne-François3, M. Smahi4, L. Abecassis5

1Hematology, Pasteur University Hospital, Nice, 2Hematology, General Hospital, Grasse, 3Hematology, University Hospital, Caen, 4Hematology, Simone Veil Hospital, Euabonne, 5Hematology, General Hospital, Aulnay, France

**Background:** The diagnosis of venous thromboembolism (VTE) can be safely excluded in the case of D-dimer levels below a well-defined cut-off value in patients with a low or intermediate pre-test probability (PTP), as the test negative predictive value (NPV) is close to 100%. As ageing is associated with increased D-dimer levels, the question arose whether D-dimer measurement was useful to rule out VTE in elderly patients.

**Aims:** The aim of the present study was to evaluate the clinical performance of a diagnosis strategy based on age-adjusted cut-off values calculated by multiplying the patient’s age by 10 in patients aged over 50, and to evaluate its economic impact.

**Methods:** We included 1255 consecutive outpatients with non-high PTP of VTE referred to the emergency departments at 5 French centres (2 university hospitals, and 3 general hospitals, in whom D-dimer testing was prescribed. The standardized procedure was used in the 5 centres i.e. D-dimer measurement in patients with a non-high PTP, and imaging techniques (usually computed pulmonar angiography in case of suspected PE and Doppler ultrasonography in case of suspected DVT) in the case of D-dimer above the cut-off level. D-dimer levels were evaluated using the same fully automated latex-based assay (HemoSil Detect D-dimer, Instrumentation Laboratory) than the usual cut-off level for VTE exclusion being 500 ng/mL (fibrinogen equivalent units, FEU).

**Results:** VTE diagnosis was established by objective testing in 115 patients (9.2%): 88 of the 1082 patients referred for suspected PE (8.1%) and 27 of the 173 patients referred for suspected DVT (15.6%). D-dimer levels were above 500 ng/mL in all patients with VTE and in 521 of the 1140 patients without VTE (45.7%), leading to test NPV and sensitivity of 100%. The overall test specificity was 54.3%, even though it significantly decreased in an age-dependent manner over 60 years old. This is due to increased D-dimer levels in older patients particularly in those above 80 years. Using age-adjusted cut-off levels, calculated by multiplying the patient’s age by 10, significantly improved the overall test specificity (60.2%). The NPV remained high (99.9%), even though a 78 year-old female with a low PTP of PE would have been misdiagnosed as her D-dimer level (540 ng/mL) was above 500 ng/mL but below the age-adjusted cut-off value. Such an improvement in test performance was found both in patients with suspected PE and DVT (Table). As such an increase in test specificity would have led to exclude VTE in a higher percentage of patients in the studied population, we evaluated the cost-effectiveness of both strategies, taking into account the local reimbursement rates of D-dimer testing and Doppler ultrasonography in 16.20, 58.72, and 75.60 Euros respectively. The economic impact of the proposed diagnosis strategy was a decrease of 6.9% of total costs (45,023.4 vs 48,356.4 Euros) for PE diagnosis and 5.1% (9,099 vs 10,438.2 Euros) for DVT. If such an analysis was used in the US, where angiography and Doppler US were more expensive (648 and 226 US$ respectively), and D-dimer less costly (14 US$), the cost savings would have been even higher (+11.0% for PE, and +6.3% for DVT).

**Summary/Conclusions:** The use of age-adjusted cut-off levels for D-dimer, in patients aged over 50 years old, led to a significant increase in the test specificity, but correlativey to slightly decreased NPV and sensitivity. Even though some patients with D-dimer levels above 500 ng/mL but below the age-adjusted cut-off levels could be misdiagnosed, such a strategy was found to be safe in our studied population with a high NPV (99.9%) and sensitivity (99.1%), and cost-effective.

---

**Figure 1. Survival according to treatment group.**

**Summary/Conclusions:** Relapse following aHSCT is associated to a poor prognosis and survival and to significant use of health care resources. Despite the selection bias, only patients who received cellular based therapy, either DLI or another HSCT, enjoyed a prolonged survival. Healthcare resources devoted to the care of patients in relapse post aHScT provide a comparative basis for cost efficiency analysis in the development of innovative cellular therapy.

**ACUTE MYELOID LEUKEMIA TREATMENT PRACTICE PATTERNS, HEALTHCARE RESOURCE UTILIZATION (HRU) AND COSTS IN A US COMMERCIALLY-INSURED POPULATION**

M. Hagwara1, A. Sharma1, K. Chung2, T. E. Delea1

1Policy Analysis Inc., Brookline, MA, 2Jazz Pharmaceuticals, Palo Alto, CA, United States

**Background:** AML is a rapidly progressive hematologic malignancy that accounts for 25% of all leukemias in the Western world, with estimated 5-year survival of 26%, and is associated with high HRU and costs.

**Aims:** To estimate HRU and costs among newly-diagnosed AML patients (pts) in a US commercially insured population by receipt of chemotherapy (CT) or stem cell transplant (SCT).

**Methods:** This was a retrospective observational study using the PharMetrics Plus® database. Pts were adults with AML (ICD-9-CM code 205.0x and corresponding ICD-10-CM codes) diagnosed between Jan 2007 and Jun 2016 (study period). Pts were excluded if: first AML claim was for remission/relapse;
not continuously enrolled for 12-months (mos) before the first AML claim (index date). Evidence of acute promyelocytic leukemia anytime during the study period; missing enrollment information; or ≥1 hospitalizations during follow-up (FU) with missing cost. Pts were classified as treated or untreated, with treatment defined based on receipt of CT (inpatient or outpatient) or SCT. For treated pts, FU was partitioned into 2 periods: index date to 6 mos and >6 mos post index date. Mean HRU and costs over the FU period were calculated by receipt of treatment and, for treated pts, by time since index date.

Results: 10,197 pts met study criteria including 6,862 treated pts (67%) and 3,335 untreated pts (33%). Mean age was 55 and 60 years in treated and untreated pts, respectively. Mean follow-up was 19.3 mos in treated pts and 18.1 mos in untreated pts. Mean total costs were higher for treated pts ($386,711) vs untreated pts ($83,274). In treated pts, mean total costs were $166,156 during the first 6 mos (mean duration 3.9 mos), and $220,555 during the remaining follow-up period (mean duration 19 mos). 26% of treated pts had SCT. Costs of inpatient and outpatient CT during the first 6 mos were $86,188, representing 22% of the total cost for treated pts (Table 1).

Summary/Conclusions: AL amyloidosis may be greater for those with PN involvement.

P373

HEALTH-RELATED QUALITY OF LIFE IN AL AMYLOIDOSIS PATIENTS WITH NERVOUS SYSTEM INVOLVEMENT

M. Yokota1, S.D. Guthrie2, T.P. Quock2, K.L. McCausland1,*, M.K. White1, M. Bayliss2
1Optum, Lincoln. 2Prothena Biosciences Inc, South San Francisco, United States

Background: In light chain (AL) amyloidosis, misfolded light chains accumulate and cause progressive peripheral neuropathy (PN) and failure of critical organs such as the heart and kidneys. Consequently, a progressive, ascending senso-motor neuropathy is often a related clinical finding.

Aims: This study describes disease characteristics and health-related quality of life (HRQoL) in AL amyloidosis patients with peripheral nerve involvement (AL-PN).

Methods: An online survey was administered to AL-PN (n=126) and non-nerve–affected (n=215) patients to assess patient characteristics and HRQoL (based on the SF-36v2® Health Survey [SF-36v2]). The survey measures eight health-related quality-of-life (HRQoL) domains: bodily pain (BP), general health (GH), vitality (VT), social functioning (SF), role emotional (RE), mental health (MH), in addition to physical (PCS) and mental component summary (MCS) measures. Patient characteristics were compared using chi-square tests. Differences in symptomatic and HRQoL burden were tested with multivariable logistic and linear models, respectively. Differences in mean HRQoL between AL-PN and non-AL-PN patients were compared to established minimally important differences (MIDs).

Results: Compared to non-nerve–affected patients, greater proportions of AL-PN patients visited ≥6 doctors (42.1% vs 19.5%, p <0.001) and ≥6 specialists (24.6% vs 9.9%, p <0.001). AL-PN patients also had symptoms for ≥1 year prior to receiving a diagnosis (50.8 vs 39.1%, p=0.035), relative to non-nerve–affected patients. Nearly all AL-PN patients (97.6%) reported multi-system involvement. Gastrointestinal involvement was more prevalent in AL-PN patients versus non-AL-PN patients (68.3 vs 28.8%, p <0.001). There were greater odds of experiencing numbness (OR=4.23, 95% CI: 2.45–7.30, p <0.001) and fatigue (OR=3.09, 95% CI: 1.36–7.02, p <0.01) among AL-PN patients as compared to non-AL-PN patients, even after controlling for other types of organ involvement. Similar findings were observed for gastrointestinal symptoms, such as alternating bouts of constipation or diarrhea (OR=1.92, 95% CI: 1.12–3.34, p=0.019) and early satiety/feeling fullness in the stomach (OR=1.80, 95% CI: 1.03–3.16, p=0.04). With the exception of RE, MH, and MCS, there were significant differences in SF-36v2 scores among AL-PN patients as compared to non-AL-PN patients (p <0.05 for all). These significant differences also exceeded the thresholds for clinically meaningful differences between the two groups.

Summary/Conclusions: This study suggests that the burden of illness from AL amyloidosis may be greater for those with PN involvement versus those without. AL-PN patients also experienced more complicated journeys to diagnosis and significantly worse symptoms related to nervous systems and physical HROQL. The SF36v2, a reliable and valid assessment of HRQoL in AL amyloidosis studies, was sensitive to differences in HRQoL between AL-PN and non-AL-PN patients. Future research should examine whether improvements in neuropathy symptoms following treatment subsequently lead to improvements in HRQoL among patients with AL-PN. These findings are helpful for patient-focused drug development and supportive treatments.

P374

ACCESS TO COMMUNITY CHEMOTHERAPY IMPROVES PATIENT QUALITY OF LIFE

R. Pugh1, C. Bygrave3, H. Cosh3, W. Ingram2, J. Keil3
1Faculty of Life Sciences and Education, University of South Wales, Pontypridd, 2Tenevus, 3Haematology, University Hospital of Wales, Cardiff, United Kingdom

Background: Deciding how services for people with haematological cancers are to be delivered is going to be an important challenge in the coming years. Clinics have limited clinic capacity in terms of staff and bed space to cope with increased demand. In Wales many day units are already at capacity, overcrowded and have long waits for treatment. Ambulatory care, including diagnosis, observation, consultation, intervention, and rehabilitation, has the potential to improve patient experience, if traditionally-based hospital services are moved into the community. We used a Mobile Unit – a 34-tonne articulated lorry which opens out to become a bespoke clinical space - to deliver treatments in a community setting to a range of haematology patients for a period of 12 months in South Wales.

Aims: We aimed to explore whether the administration of cytotoxic therapy on a Mobile Unit in a community setting for patients with haematological cancers could prove to be a safe and efficient alternative to hospital therapy, and in particular whether this model of service delivery would be acceptable to patients.

Methods: The first drugs administered on the Mobile Unit were zoledronate infusions, followed by bortezomib. When twice weekly doses were required, patients collected an additional injection pack which they could self-administer in their own homes, thereby saving another trip to hospital. Intravenous immunoglobulin infusions, taking between 1-2 hours, were also administered. There was a consultant review clinic on board for patients receiving bortezomib which further reduced the numbers of hospital visits for patients and also a nurse-led Quality Assurance function.

Results: In one year 548 treatments were administered on 91 days to a total of 54 individual patients. All 54 patients had a diagnosis of myeloma. 56% are female and 44% are male with an age range of 46 to 90 years of age, with 48% over 70 years of age. 37 patients are married and all but 4 classified themselves as White British. The greatest number of patients treated in a single day was 16. Improve patient experience, if traditionally-based hospital services are moved into the community. We used a Mobile Unit – a 34-tonne articulated lorry which opens out to become a bespoke clinical space - to deliver treatments in a community setting to a range of haematology patients for a period of 12 months in South Wales.

Summary/Conclusions: Treatment in the community alleviates the stress of treatment and with minimal waiting times it gives some patients the ability to maintain family life and where possible to continue to work. It is both feasible and acceptable to begin to ambulate many different sorts of treatments. The possibilities opening up for haematology include rituximab maintenance, community blood transfusions; delivering pentamidine for patients at risk of pneumocystis infection; late effects clinics for teenage and young adult cancer patients; and myeloproliferative neoplasm clinics, possibly near community pharmacies to facilitate dispensing medicines such as hydroxyurea.
which will have a substantial price difference compared with nilotinib. However, given the possible changes in switching of TFR, this price difference may not translate into a similar magnitude of difference in drug budget for first-line nilotinib vs imatinib due to better MR with nilotinib.

**Aims:** To estimate the budget impact for first-line nilotinib vs imatinib when considering generic imatinib pricing, early treatment-switching, and TFR. Methodology: A state transition model was developed to estimate the ELN switching and TFR use on clinical outcomes and treatment costs. Analyses were run for 1000 patients with newly diagnosed CML, starting either nilotinib or imatinib, over a 5-year time horizon and using French drug pricing. It was assumed that all patients in the model would switch therapy (imatinib to nilotinib, and nilotinib to dasatinib) based on the failure criteria of the ELN guidelines. As such, ENESTnd trial data were re-analyzed to estimate switching based on the model. The model assumed that patients could enter first-line or second-line TFR after 36 months of continuous therapy where the last 12 months were at MR², §. Duration of first-line or second-line TFR was based on an extrapolation of ENERTnd, considering treatment failure and survival curves, respectively. Monthly drug costs were €2,952 for first-line nilotinib and €1,063 for generic imatinib, assuming a 50% discount to brand pricing.

**Results:** A greater number of patients in the first-line nilotinib arm remained on first-line therapy (690 vs 479 at 15 mos., and 542 vs 366 at 60 mos.); achieved MR-3/4 (163 vs 124); and 0-go (high probability to develop toxicity regardless of intensive or attenuated therapy), “slow-go” (high probability to develop toxicity with intensive therapy but low probability with attenuated therapy), and “go-on” (high probability to develop toxicity regardless of intensive or attenuated therapy). The model projected that less than 50% of patients would remain on first-line imatinib at 15 months. This would significantly reduce the budget benefit of a lower imatinib acquisition price. The budget impact between first-line imatinib and nilotinib would be further reduced by TFR, which occurred in the model more frequently in the nilotinib group. The superior efficacy of nilotinib and the associated differences in switching and TFR eligibility are predicted to substantially offset the lower unit cost for generic imatinib.

P376
GAH SCALE PREDICTS TREATMENT TOLERABILITY IN OLDER PATIENTS (>65 YEARS) DIAGNOSED WITH HEMATOLOGICAL MALIGNANCIES
S. Bonanà1, A. Gonzalez2, A. Cruz-González3, L. García-Iglesias4, I. Jauregui5, E. Pérez-Persona5, R. Lluch6, C. Marrero7, M. Zudaire8, M. Gironella9, E. Pérez-Persona5, R. Lluch6, C. Marrero7, M. Zudaire8, M. Gironella9, Á. Ramírez-Payer10, M. Arnán11, C. Olivier12, C. Encinas13, J.A. Soler14, P. Fernández16, D. Vilanova16, J. de la Rubia17,*
1Hematology and Oncology, Mayo Clinic, Scottsdale, 2Hematology and Oncology, Oregon Health and Science University, Portland, 3Internal Medicine, 4Bio-statistics, Mayo Clinic, Scottsdale, 5Arizona State University, Phoenix, 6Hematology and Oncology, University of California, Irvine, Irvine, United States

**Background:** Cachexia, weight loss, and malnutrition in cancer patients are important contributors of adverse outcomes of cancer patients. MPN patients have abnormal cytokine expression (e.g., IL-1, IL-6, IL-8, and TNF-a) that contributes to symptom burden (e.g., fatigue, pruritus, night sweats, bone pain) and obesity (caloric deficiency). The ENERTnd registry showed that 30% (15.4% vs 14.6%) of patients that developed toxicities for each group was 34.6%, 56.3%, and 78.3% respectively with a statistically significant difference (P=0.002).

**Aims:** To determine the weights for each dimension of the GAH scale and the cut-off points for the scale to be used as a tool to predict treatment tolerability in older patients diagnosed with myelodysplastic syndrome / acute myeloblastic leukemia, multiple myeloma, or chronic lymphocytic leukemia.

**Methods:** A retrospective, observational study conducted at 14 Spanish sites. Prior participants of the GAH study were given treatment within 3 months after having completed the GAH scale were eligible for inclusion after giving informed consent.

A logistic regression model and a full multiple linear regression model were calculated to determine the weights for each dimension and find out its contribution to the final score; the ROC curve analysis was used to calculate the cut-off points that defined three groups: “go-on” (low probability to develop toxicity regardless of intensive or attenuated therapy), “slow-go” (high probability to develop toxicity with intensive therapy but low probability with attenuated therapy), and “go-on” (high probability to develop toxicity regardless of intensive or attenuated therapy). The model projected that less than 50% of patients would remain on first-line imatinib at 15 months. This would significantly reduce the budget benefit of a lower imatinib acquisition price. The budget impact between first-line imatinib and nilotinib would be further reduced by TFR, which occurred in the model more frequently in the nilotinib group. The superior efficacy of nilotinib and the associated differences in switching and TFR eligibility are predicted to substantially offset the lower unit cost for generic imatinib.

**Results:** A greater number of patients in the first-line nilotinib arm remained on first-line therapy (690 vs 479 at 15 mos., and 542 vs 366 at 60 mos.); achieved MR-3/4 (163 vs 124); and 0-go (high probability to develop toxicity regardless of intensive or attenuated therapy), “slow-go” (high probability to develop toxicity with intensive therapy but low probability with attenuated therapy), and “go-on” (high probability to develop toxicity regardless of intensive or attenuated therapy). The model projected that less than 50% of patients would remain on first-line imatinib at 15 months. This would significantly reduce the budget benefit of a lower imatinib acquisition price. The budget impact between first-line imatinib and nilotinib would be further reduced by TFR, which occurred in the model more frequently in the nilotinib group. The superior efficacy of nilotinib and the associated differences in switching and TFR eligibility are predicted to substantially offset the lower unit cost for generic imatinib.

**Summary/Conclusions:** The GAH scale appears to have the potential to give guidance for election of individual treatment regimens. By identifying elderly patients at high risk to develop toxicities, it may help to choose low-toxicity combinations, to avoid harmful therapies and to identify those patients that could benefit from more intensive treatment. Nonetheless prospective studies with larger populations should be performed to confirm these findings and to try to determine particular cut-off points for different diseases.

P377
NUTRITIONAL NEEDS AND PREFERENCES OF MYELOPROLIFERATIVE NEOPLASM PATIENTS: PHASE IA OF THE NUTRITIONAL STUDY

The superior efficacy of nilotinib and the associated differences in switching and TFR eligibility are predicted to substantially offset the lower unit cost for generic imatinib.
using diet to help control their symptoms or MPN disease. Patients most often utilized books (28.2%), websites (27.1%), health care providers such as physicians, NPs or naturopaths (28.2%), online forums (23.2%), friends (12.2%), nutritionists (9.5%), phone or tablet applications (9.1%), or videos (4.2%) for nutritional education. The vast majority (95.9%) of MPN patients endorsed being willing to eat only certain foods if it helped to control symptom burden and or could help their MPN to stabilize or reduce the risk of their MPN getting worse (98.0%).

Summary/Conclusions: There remains an unmet need for symptom burden improvement in low-risk MPN patients or among those who have reoccurrence of symptoms while on JAK inhibitor therapy. Nutritional interventions for MPN patients have not previously been investigated and have the potential to be paired with traditional interventions to allow MPN patients to self-manage symptom burden. This study represents the first evaluation of MPN-related nutritional habits and preferences. These results will be used to inform the creation of an MPN nutritional intervention with the goal of improving symptom burden and reducing inflammation.

P378

DO PHYSICIANS NEED HELP TO ADEQUATELY INFORM AND SUPPORT PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA? RESULTS FROM A QUALITATIVE STUDY IN GREECE

C. Karamanidou1,2, A. Kochelli1, V. Koutkias1, P. Ghia2, K. Stamatiopoulos1
1Institute of Applied Biosciences, CERTH, Thessaloniki, Greece. 2Division of Experimental Oncology and Department of Onco-Hematology, Università Vita-Salute San Raffaele and IRCCS San Raffaele Scientific Institute, Milan, Italy

Background: Despite recent progress in prognostication and management, chronic lymphocytic leukemia (CLL) remains unpredictable at diagnosis, while virtually incurable, posing challenges to physicians on how to properly communicate the actual nature of the disease. Moreover, the great majority (~85%) of patients do not need treatment at diagnosis, creating a major cognitive dissonance between the perception of leukemia diagnosis and the “wait & watch” strategy usually applied, that may become a major reason of anxiety and quality of life (QoL) impairment for patients and frustration for physicians. Evidently, both patients and physicians need parameters that would allow co-decision making tailored to each particular case.

Aims: To identify physicians’ needs in order to improve their communication skills and thus facilitate CLL patient empowerment through a patient-centered-ness model.

Methods: An in-depth qualitative study with semi-structured interviews was conducted within hematologists (n=30) all over Greece. Data collection was considered as completed when saturation was reached i.e. no new themes emerged as assessed by the investigators. Content analysis was performed separately by a hematologist and a health psychologist with 98% inter-rater reliability score.

Results: None of the participants had ever received formal communication training, but rather adopted the techniques of senior physicians or developed their own through experience alone, thus frequently doubting their approaches (n=12/30, 40%). The most popular communication technique mentioned was adaptation of the quality and quantity of information provided according to each patient’s characteristics (n=29/30, 96.7%); followed by the use of caregivers as mediators for the communication of difficult issues (n=24/30, 80%); balance of realism and hope (n=21/30, 70%); careful choice of wording (e.g. lymphocytosis instead of leukemia) (n=18/30, 60%); gradual disclosure (n=17/30, 56.7%); and, descriptions through pictorial representations or metaphors (n=16/30, 53.3%). Even though physicians did not systematically assess patients’ anxiety and depression levels, they often found themselves dealing with patients’ emotions (n=29/30, 96.7%) through lengthy discussions. With regards to decision making, some mentioned that physicians should make all the decisions (n=9/30, 30%) and that patients are not always willing to take part in the decision-making process (n=8/30, 26.7%), while others were keener on stirring patients towards a decision (n=15/30, 50%), taking into account patients’ preferences (n=10/30, 33.3%). Most physicians felt uncomfortable delivering bad news such as initial diagnosis, relapse and poor prognosis (n=25/30, 83.3%). Self-reported needs included (i) communication skills training (n=20/30, 66.7%); (ii) psychological support (n=7/30, 23.3%); and, (iii) working in a multidisciplinary team (n=8/30, 26.7%).

Summary/Conclusions: In the absence of structured communication guidance there is great uncertainty among physicians concerning their skills on communicating CLL nature and handling difficult situations, leading to distress endangering their engagement in a healthy relationship with the patient. Additional studies are warranted at European level for identifying physician needs in different countries aiming at improving their communication skills to support and empower CLL patients for participating in their own care and enhance their QoL.
Stem cell transplantation - Clinical 1

P379

OUTCOME OF ALLOGENIC HEMATOPOIETIC STEM CELL TRANSPANTATION FOR PATIENTS WITH ACUTE LEUKEMIA ABOVE 70 YEARS OF AGE: ON BEHALF OF THE ACUTE LEUKEMIA WORKING PARTY OF THE EBMT

O. Ringdén1, A. Boumendil2, M. Labopin2, B. Sadeghi1, B. Savani3, M. Mohy4, A. Nagler5.

1LUMED, Translational Cell therapy Research, Karolinska Institutet, Stockholm, Sweden, 2Hôpital Saint Antoine, Paris, France, 3Division of Hematology/Oncology, Medical Center Drive, Nashville, United States, 4Hôpital Saint Antoine, Paris, France, 5Chaim Sheba Medical Center, Tel-Hashomer, Israel

Background: The average age of patients (pts) with AML is about 67 years. Historically, many of these pts were not considered as viable candidates for allogeneic transplantation (HCT) because of concerns about increased transplantation-related toxicity and excessive and non-relapse mortality (NRM), a challenging problem especially in older individuals. However the development of reduced-intensity conditioning (RIC) regimens and the improvement in HCT supporting care allowed the successful application of HCT in older pts with AML.

Aims: Compare outcome of allo SCT in acute myeloid leukemia AML patients aged above 70 years with that of younger patients.

Methods: AML patients aged between 50 and 90 years old receiving a first or second allo SCT between 2004 and 2014 with MSD or UD donor were included in the study. Comparison of outcomes of patients aged above 70 with that of patients between 50-70 years were performed for the whole group and separately according to disease status at SCT (CR1, CR2 above).

Results: Altogether N=16874 pts were included in the study, N=713 were aged above 70 years (median 72, IQR 71-73) and N=16161 between 50 and 70 (median 59, IQR 55-63). Older pts were more often male (62 vs 55%, p<0.001), had more often secondary AML (42% vs 28%, p<0.001), more advanced disease (42% vs 27%, p<0.001), more often peripheral blood cell grafts (96 vs 91%, p<0.001), more often unrelated donors (79% vs 59%, p<0.001) and poorer Karnofsky score (36% below 90 vs 29%, p<0.001), received more often reduced intensity conditioning (80 vs 63%, p<0.001). Incidence of acute GVHD grade II/III/IV, chronic GVHD and relapse were the same in the two groups in multivariate analyses. Non-relapse mortality (NRM) at 3 years was 34% (95% CI 31%-38%) in pts above and 24% (25%-32%) in those below 70 years of age (p<0.001). Overall survival and leukemia-free survival (LFS) at 2 years was 38% (95%CI 34-42) vs 50% (95%CI 49-50) p=0.001 and 33% (95%CI 29-37) vs 44% (95% CI 43-45) in the two groups, respectively (p<0.001). Among pts in CR1, 2 years survival was 43% (95%CI 37-51) vs 57% (95%CI 56-58) (p<0.001), in CR2 it was 36% (95%CI 27-27) vs 52% (95%CI 50-54) (p=0.002) and in advanced disease 35% (95%CI 29-41) vs 33% (95%CI 31-34) (p=0.36) in pts above and below 70 years of age, respectively. Among pts older than 70 years of age a Karnofsky score >80% was associated with improved survival and LFS in multivariate analysis (HR 0.7 95% CI 0.5-0.9 , p=0.005 and HR 0.7 95%CI 0.5-0.9 , p=0.003 respectively).

Summary/Conclusions: In AML with CR1, CR2 status at allo SCT, pts above 70 years of age have worse NRM, survival and LFS compared to pts 50-70 years of age. In pts above 70 years of age Karnofsky score is of significant importance for outcome.

P380

BLOOD BAALC AND MN1 COPY NUMBER ASSESSMENT BY DIGITAL DROPLET PCR PRIOR TO ALLOGENEIC TRANSPLANTATION PREDICTS RELAPSE IN ACUTE MYELOID LEUKEMIA PATIENTS

M. Jentzsch1*, M. Bill1, J. Schulz1, J. Grimm1, J. Häntschel1, S. Beinicke1, K. Knecht1, B. Behre1, G.-N. Franke1, T. Lange1, V. Vicmic1, D. Niederwieser1, S. Schwind1

1Hämatoonkologie, 22nd Congress of the European Hematology Association

Background: Acute myeloid leukemia (AML) patients (pts) that relapse after allogeneic stem cell transplantation (H SCT) have a dismal prognosis. Identification of pts at high risk of relapse may allow preemptive therapy & improve allogeneic stem cell transplantation (HSCT) have a dismal prognosis. Identifi-

Aims: Determine the prognostic impact of peripheral blood (PB) pre-HSCT BAALC & MN1 copy numbers in an expanded set of AML pts in hematologic CR using digital droplet (dd) PCR.

Methods: We identified 118 AML pts (median age at HSCT 64 [range 31-76] years [y]) in first (55%) or second complete remission (CR; 23%) or CR with incomplete recovery (22%) with PB prior to HSCT (median 7, range 0-29 days) available. All pts received non-myeloablative (NMA) conditioning (fludarabine 3x30 mg & 200 cGy total body irradiation). At diagnosis karyotypes & NPM1, CEBPA gene mutations (mut) & presence of FLT3-TKD & FLT3-ITD were assessed. Quantification of BAALC & MN1 normalized to ABL1 copy numbers in pre-HSCT PB of the AML pts & in PB of healthy controls (n=7, median age 63 [range 40-82]) was performed by ddPCR. Median follow up after HSCT for pts alive was 1.8y.

Results: European LeukemiaNet (ELN) 2010 classification was 20% favorable, 25% intermediate-1, 24% intermediate-II, 31% adverse. AML pts & healthy controls did not differ in age (P=1) or mean BAALC (P=0.37, Figure 1A) or MN1 (P=0.96, Figure 1B) copy numbers. BAALC & MN1 copy numbers correlated well in pts (R=80) & healthy controls (R=75). The previously determined cut-off of 0.14 BAALC copy numbers (in 82 pts; ASH 2016, #517) defined pts with high (27%) & low (73%) pre-HSCT BAALC copy numbers. A cut-off of 0.74 MN1 copy numbers was determined using the R package "OptimalCutpoints" & defined pts with high (12%) & low (88%) pre-HSCT MN1 copy numbers. Applying these cut-offs, 71% of the pts had low BAALC & MN1 copy numbers & 10% had high BAALC & MN1 copy numbers, 2% had high MN1 but low BAALC & 17% had high BAALC but low MN1 copy numbers. Pts with high & low pre-HSCT MN1 copy numbers did not differ significantly in pre-treatment characteristics or remission status at HSCT (CR vs CR) while pts with high pre-HSCT BAALC copy numbers were less often in CR at HSCT (P=0.02). Both high pre-HSCT BAALC & MN1 copy numbers significantly associated with higher CIR (P<0.02, Figure 1C & P<0.01, Figure 1D, respectively). In multivariate analyses, high pre-HSCT BAALC (Hazard Ratio [HR] 2.5, Confidence Interval [CI] 1.1-5.7, P<0.001) & high pre-HSCT MN1 copy numbers (HR 5.6, CI 2.6-12.2, P<0.001) retained their prognostic impact on CIR after adjustment for ELN 2010 genetic risk groups.

Figure 1.

Summary/Conclusions: High pre-HSCT copy numbers of BAALC & MN1 associated with higher CIR in univariate & multivariate models and might indi- cate residual disease burden in these AML pts. High copy number pts should be closely monitored for relapse in the post-transplant period. Prospective clinical trials are needed to validate the determined cut-offs, to evaluate if BAALC or MN1 copy numbers or a combination of the genes represents the most suit- able prognostic signature pre-HSCT and whether AML pts with high pre-HSCT BAALC or MN1 copy numbers benefit from additional pre- or post-HSCT treat- ment.

THE USE OF BPX-501 DONOR T CELL INFUSION WITH INFUNDABLE CAPSASE 9 SUCIDE GENE TOGETHER WITH HLA-HAPLOIDENTICAL STEM CELL TRANSPLANT TO TREAT CHILDREN WITH HEMOGLO- BINOPATHIES AND ERYTHROID DISORDERS

M. M. Burt1*, S. M. Benjamin2, R. P. Merli1, B. Christensen3, F. P. Penta4, G. B. Hall5, P. Merli1, D. Pagliara1, G. Li Pira1, A. Moseley4, J. Weinberg4, F. Locatelli1

1Ospedale Pediatrico Bambino Gesu, Rome, Italy, 2Childrens Hospital at Montefiore, Bronx, 3Fred Hutchinson cancer Research Center, Seattle, 4Bellicum Pharmaceuticals Inc., Houston, United States

Background: Allogeneic HSCT from either an HLA-identical sibling or an unre- lated donor is a potentially curative treatment for patients with hemoglo-

Aims: Test the use of a genetically modified donor T cell infusion therapy to treat children with hemoglobinopathies and erythroid disorders (ED), such as Thalassemia Major (TM),…
Sickle Cell Disease (SCD) and Diamond-Blackfan Anemia (DBA). Bertain et al (Blood, 2014) have previously shown that αβTCR depleted haplo-transplantation in children with multiple types of non-malignant disorders was feasible. An ongoing Phase II/III trial evaluates the safety and efficacy of post-transplant infusion of donor T-cells transduced with the iCD9 suicide gene (BPX-501 cells). (ClinicalTrials.gov identifier: NCT02065869). The iCD9 vector contains the sequence for the CD19 marker, so that the BPX-501 cells (CD5+/CD19+) can be tracked in peripheral blood. We report on 15 children with hemoglobinopathies and ED.

**Aims:** This study was performed to determine the clinical impact of infusing BPX-501 T cells post αβ T-cell depleted haplo-identical HSCT in pediatric patients with hemoglobinopathies.

**Methods:** Fourteen patients were transplanted from a parent and one patient was transplanted from a sibling. Conditioning regimen included busulfan, thiotepa and fludarabine. Low dose ATG was administered to prevent graft-versus-host disease (GVHD) and graft failure. No post-transplantation GVHD prophylaxis was given. Median follow-up is 387 days (range 126-631 days).

Six patients were males and nine females, and median age at diagnosis and at HSCT was 0.8 and 8.9 years (range 2.5-19.2), respectively. Two patients had DBA and four with SCD. All 9 TM patients were ββ/β and among the those with TM, 4 patients belonged to class I and 3 to class II of the Pesaro classification. All 15 patients were transfusion-dependent and receiving iron-chelation therapy before haplo-HSCT. 13/15 patients maintained full donor chimerism. The patients with secondary graft failure were re-transplanted from the same donor and maintained full donor chimerism.

**Results:** All patients are alive and well with no Treatment Related Mortality (TRM). Initial engraftment occurred at a median of 23.5 days (range 14-55) and there were two patients re-hospitalized at 30, 163 days respectively. Grade I/II skin acute GVHD occurred in four patients and one patient had acute skin GVHD Grade IV. No chronic GVHD was observed. Median time to neutrophil recovery was 14 days (range 10-32), while median time to platelet recovery was 11 days (range 8-12 days). Median time to last RBC transfusion was 8 days (5 - 34 days). See Figure 1 for individual Hemoglobin levels. Median time of infusion of 1x10^6 BPX-501 T cells/kg was 14 days after HSCT (range 10-26). BPX-501 cells expanded after infusion and still persist in all patients. Immune reconstitution was achieved with normal cellular and humoral immunity present at 180 days post HSCT. All patients remain transfusion-free with a median hemoglobin of 11 or greater after 6 months.

**Background:** All clinical data published thus far on the use of MSCs were generated using cells expanded from individual bone marrow donors hence suffer from huge inter-donor differences in MSC generation, expansion and immunomodulatory potential. To control these variables and to be able to administer to all patients highly similar MSC products, we established a proprietary pooling procedure and generated a large bank of MSC end-of-passage-1 vials from which end-of-passage-2 MSC products are expanded for clinical use. The manufacturing process is fully GMP-compliant and generates an animal serum-free product with near identical phenotype and in-vitro immunomodulatory potency. Importantly, they showed a significantly higher allo-suppressive potential than the mean allo-suppressive potential of MSCs generated from individual donors. All tested individual MSC doses were equipotent in suppression of the allo-antigen-driven reaction in mixed lymphocyte reactions (Kuci et al. Haematologica 2016: 101 (8): 885-954).

**Aims:** A “hospital exemption” issued by the national regulatory authority Pau-Ehrich-Institute (Number: PEI: A.11748.01.1) licenses the clinical use of these products for patients with steroid refractory GVHD. On the basis of this licence patients were severe with GVHD treated who were either non responsive to steroid or resistant to steroid treatment who failed steroid therapy before haplo-HSCT.

**Methods:** Using these standardize MSC products altogether 52 patients were treated between December 2014 and December 2016. Patients were male (n=31, 60%) or female (n=21, 40%) and were transplanted for leukemia (n=38, 73%) or non-malignant (n=14, 27%) diseases. Median age was 8 years (range: 0.5-55.2). Six patients received HSCT from the same donor and maintained full donor chimerism. The patients with secondary graft failure were re-transplanted from which end-of-passage-2 MSC products are expanded for clinical use. The pooling procedure and generated a large bank of MSC end-of-passage-1 vials from which end-of-passage-2 MSC products are expanded for clinical use. The manufacturing process is fully GMP-compliant and generates an animal serum-free product with near identical phenotype and in-vitro immunomodulatory potency. Importantly, they showed a significantly higher allo-suppressive potential than the mean allo-suppressive potential of MSCs generated from individual donors. All tested individual MSC doses were equipotent in suppression of the allo-antigen-driven reaction in mixed lymphocyte reactions (Kuci et al. Haematologica 2016: 101 (8): 885-954).

**Results:** Response was defined as either complete response (CR) or partial response (PR). CR were patients who showed one overall GVHD grade less according to the Glucksberg criteria, or non response (NR) on day 28 after first MSC transfusion. At day +28, 12 patients (23%) achieved CR, 29 patients (57%) PR (overall response= 80%), 8 patients (17%) NR, and in 2 patients (4%) no data were available at day +28. The at the last follow up of GVHD, 29 patients (56%) were in CR, 13 patients (25%) in PR, 9 patients (17%) in NR, and for 1 patient (2%) no data were available. At 2 years these response rates resulted in a non-relapse mortality rate (NRM) of 27±6%, cumulative relapse incidence (CIR) of 14±4%, and OS survival probability of 72±8%.

**Summary/Conclusions:** Our Phase II/II trial with standardized equipment MSCs from the “FRANKFURT MSC-BANK” offers an excellent chance to overcome treatment-resistant and steroid-refractory acute GVHD.
and pts with unavailable TAC concentration data were excluded. A total of 253 pts were eligible. All pts received standard GVHD prophylaxis by continuous intravenous (iv) TAC with starting dose of 0.02 mg/kg/day from 1 day before allo-HSCT (day -1) and iv methylprednisolone on day 1, 3, 6 at dose of 10 mg/m², 7mg/m², 7mg/m², respectively. TAC dosage was adjusted to target the serum concentration of 8-12 ng/ml until at least day 30 and then tapered. TAC was rapidly tapered in case of the pathological diagnosis of TAM. TAC serum concentration was sequentially examined tri weekly until day 35 at least. The primary endpoint of this study was to evaluate the cumulative incidence of TRC-EC in relation to weekly mean/peak TAC concentration. Secondary endpoint was OS. Results: Median patient age was 45 years (16-68). The risks of disease were standard in 168 and high in 85 pts. Forty pts were diagnosed of TRC-EC: SOS: 7 pts (median onset: day 24 (17-40)), TAM: 27 pts (median onset: day 40 (25-128)), IIP: 6 pts (median onset: day 161.5 (46-233)). The cumulative incidence of TRC-EC at day 250 was 0.16 (95%CI, 0.12-0.21). Univariate analysis showed that higher peak TAC concentrations (PTC) during day 22-28 (P=0.013), male pts (P=0.035), standard acute GVHD (HR: 0.44, 95%CI, 0.29-0.63), and pts with unavailable TAC concentration data were associated with poor OS. By Cox proportional-hazards regression models, TRC-EC diagnosis at day 1 was 1.90, 95%CI: 1.16-3.11, P=0.011 and high disease risk at transplant (HR: 1.76, 95%CI: 1.1-2.73, P=0.011) was significantly associated with poor OS (Figure 1).

Figure 1.

Summary/Conclusions: Higher peak TAC concentrations during 22-28 days after allo-HSCT increased the risk of TRC-EC. And the development of TRC-EC was associated with poor OS.

P384

IMPACT OF CONDITIONING REGIMEN ON OUTCOMES OF T-REPLETATE HAPLO-IDENTICAL TRANSPLANTATION FOR PATIENTS OVER 45 YEARS-OLD WITH AML: A STUDY ON BEHALF OF THE ACUTE LEUKEMIA WORKING PARTY OF THE EBMT

1Department of Hematopoietic Stem Cell Transplantation, National Cancer Center Hospital, Tokyo, 2Crecon Medical Assessment Inc, Tokyo, 3Departement of Hematology, Imamura Bun-in Hospital, Kagoshima, 4Department of Hematology/Oncology, Institute of Medical Science, The University of Tokyo, Tokyo, 5Department of Hematology and Clinical Research Institute, National Hospital Organization Kyushu Medical Center, Fukuoka, 6Department of Hematology, Kumamoto University Hospital, Kumamoto, 7Department of Hematology, Sasebo City General Hospital, Sasebo, 8Department of Hematology, National Hospital Organization Kyushu Cancer Center Hospital, Fukuoka, 9Department of Medical Oncology and Hematology, Otta University Faculty of Medicine, Oita, 10Department of Hematology, National Hospital Organization Kumamoto Medical Center, Kumamoto, 11Division of Biostatistics, Tohoku University Graduate School of Medicine, Sendai, Japan

Background: Patients with aggressive adult T cell leukemia-lymphoma (ATL) are included in the high-risk group. The role of chemotherapy as well as the impact of reduced intensity conditioning regimen (RIC) has been conducted due to a rarity of patients with ATL even in Japan. The current study evaluated the impact of RIC on outcomes and validated treatment strategy for ATL.

Aims: The present study compared the impact of RIC and MAC in pts with AML older than 45 yrs undergoing haplo-SCT. The aim of the study was to confirm the efficacy and feasibility of RIC among a population for which the choice of conditioning intensity is more important than pts comorbidities or disease status.

Methods: We retrospectively compared the outcomes of 614 pts with de novo or secondary AML transplanted between 2007 and 2015 from an haplo-identical donor using either RIC (n=365) or MAC (n=249) regimens. Age was categorized in three subgroups (45-55 yrs, 55-60 yrs, >60 yrs). Patients receiving a previous autologous transplantation were excluded. RIC was defined according to EBMT definitions.

Results: The median follow up for MAC and RIC was 24 and 20 months, respectively and the median year of transplant was 2013 for both. Pts receiving a RIC were older (55 yrs in MAC vs 61 yrs in RIC, p<0.01), Secondary AML was more frequent in RIC vs MAC (31% vs 22%) while 77% of MAC and 68% of RIC were transplant for de novo AML, p=0.01. No differences were found on disease status and Karnofsky performance status (KPS) at transplant: pts were in CR1 (MAC: 44%, RIC: 40.5%), CR2/3 (MAC: 17%; RIC: 17%) or had active disease (MAC: 40%; RIC: 43%), p=0.68; 12% of pts in both groups had KPS<80, p=0.95. The most frequently used MAC regimen was TBF (56%), while in RIC it was miniTBF (27%) and low dose TBI+Fludarabine (24%). RIC recipients had a more frequent conditioning regimen associated with an active disease as stem cell source (MAC 42% vs RIC 55%, p=0.002). Post-transplant cyclophosphamide was used in 69% of both RIC and MAC, p=0.39. Main outcomes were not different according to conditioning regimen: at 2 years RI was 26% vs 32% (p=0.29), NRM 31% vs 34% (p=0.62), aGVHD grade II-IV 24% vs 31% (p=0.05), and cGVHD 27% vs 26% vs 39% vs 39% (p=0.17), OS 46% vs 39% vs 0.15, GRFS 36% vs 28% (p=0.10) for MAC vs RIC, respectively. The results according to RIC and MAC were not different in any of the three age subgroups. 338 patients died; main causes of death were infections and GVHD to be followed by disease recurrence. In multivariate analysis, the type of conditioning regimen was not associated with risk of relapse or treatment failure: RI (HR: 1.22, p=0.28), NRM (HR: 0.92, p=0.63), acute GVHD grade II-IV (HR: 1.14, p=0.48), chronic GVHD (HR: 1.26, p=0.30), LFS (HR: 1.03, p=0.77), GRFS (HR: 1.07, p=0.55), OS (HR: 1.05, p=0.68). Disease status was associated with outcomes (active disease vs CR): RI (HR: 2.44, p<0.005), LFS (HR: 1.75, p<0.10), GRFS (HR: 1.72, p=0.10), OS (HR: 1.71, p<0.10), as well as KPS<90. NRM (HR: 0.53, p=0.0002), LFS (HR: 0.67, p=0.001), GRFS (HR: 0.74, p=0.014), OS (HR: 0.62, p=0.0002).

Summary/Conclusions: In our study no differences were found between RIC and MAC regimens for haplo-SCT in adults with AML including patients with advanced presentation. Disease status and performance status were the major predictors of transplantation outcome, while conditioning intensity had no effect. These results may serve as the background for a well designed randomized study comparing RIC vs MAC for haplo-SCT in adult pts with AML.
Decision analysis is a computerized modeling analysis which can simulate the clinical outcomes of different therapeutic strategies and identify an appropriate therapeutic strategy.

**Aims:** The aim of this study is to compare the life expectancy (LE) of chemotherapy followed by up-front allo-HSCT to that of chemotherapy alone using decision analysis in patients with aggressive ATL using database constructed by a nationwide survey.

**Methods:** We constructed a Markov decision analysis model to compare the outcomes in 2 therapeutic strategies: chemotherapy followed by up-front allo-HSCT vs chemotherapy alone. The transition probabilities between each health states were calculated from the database of 1,792 patients and patients were stratified into low-, intermediate- and high-risk groups according to the risk stratification system which we developed previously (Fuji S et al 18th International Conference on Human Retrovirology). The model simulated the LE, quality-adjusted LE (QALE) and survival curve after diagnosis of aggressive ATL. Since QoL data for patients with aggressive ATL are lacking, estimates for QoL in a similar decision analysis study of patients with acute myeloid leukemia were used. In terms of the timing of up-front allo-HSCT, it was set as all patients receive up-front allo-HSCT from 2 to 6 months if ATL did not progress before allo-HSCT. We used the TreeAge Pro 2016 software package for decision analysis (TreeAge Software Inc., Williamstown, MA).

**Results:** In all patients, up-front allo-HSCT was associated with higher LE in comparison to chemotherapy alone (2.26 years vs 1.75 years). Stratified into 3 groups according to the prognostic scoring system, LE of up-front allo-HSCT was higher compared to that of chemotherapy alone in the intermediate- (2.27 years vs 1.66 years) and high-risk groups (1.50 years vs 0.91 years). The estimated survival curve depicted by TreeAge showed the superiority of up-front allo-HSCT as shown in Figure 1A-D. The Monte Carlo simulation showed that the probability of superiority of up-front allo-HSCT was 100% in all patients, 97.1% in the low-risk group, 100% in the intermediate-risk group, and 100% in the high-risk group in terms of LE, and was 99.8% in all patients, 75.2% in the low-risk group, 100% in the intermediate-risk group, and 100% in the high-risk group in terms of QALE.

OUTCOMES OF THIOTEPA BASED REDUCED-INTENSITY CONDITIONING VERSUS STANDARD REDUCED-INTENSITY CONDITIONING IN ADULT PATIENTS UNDERGOING DOUBLE-UNIT CORD-BLOOD HEMATOPOIETIC STEM CELL TRANSPLANT

P. Sharma1,*, D. Polyliya1, C. Smith1, E. Purev1, M. Kamdar1, B. Haverkos1, D. Sherbenou1, J. Gutman1
1Division of Hematology, University of Colorado, Denver, United States

**Background:** Cord blood transplantation (CBT) is an established alternative source for hematopoietic stem-cells in patients without matched donor. However, the most commonly used high-dose total-body-irradiation (TBI) myeloablative conditioning (MAC) results in high treatment related mortality (TRM). Non-myeloablative and reduced-intensity conditioning (RIC) have been studied to decrease TRM and provide curative chance to the elderly and those with comorbidities. However, these strategies are associated with higher relapse-rate and graft rejection. A novel-RIC using addition of thiopeta and higher dose of TBI to standard RIC has shown to result in sustained donor engraftment. We study compares transplant-related-outcomes in patients who underwent first double-unit CBT with standard-RIC regimen of fludarabine (Flu, 200mg/m²), cyclophosphamide (Cy, 50mg/kg), and TBI (200cGy or 300cGy) versus this standard-RIC regimen with addition of thiopeta (10mg/kg) and increased dose of TBI (50cGy).

**Aims:** To compare transplant related outcomes in CBT recipients who received standard-RIC (FluCyTBI) to those who received novel-RIC (FluCy with addition of thiopeta and increased dose of TBI). To identify optimal conditioning regimen in patients undergoing UCT.

**Methods:** After IRB approval, consecutive patients undergoing CBT from 08/2009 to 08/2016 were evaluated and data retrospectively abstracted. Patient selection, graft-versus-host disease prophylaxis and transfusions were per institutional standards and conditioning regimens were compared as described.

**Results:** of the 99 patients who underwent allogeneic double-CBT, 52 received standard-RIC and 47 received novel-RIC. Median age at transplant was 67 years (range, 24-74) and 54 years (range, 25-67) in standard-RIC and novel-RIC cohort respectively. Acute myeloid leukemia was the major indication for transplant in both cohorts. Median hematopoietic stem-cell transplant comorbidity-index (HSCT-CI) was 3 (range, 0-6) and 1 (range, 0-6) in standard-RIC and novel-RIC groups respectively. Four patients suffered engraftment failure (2 in each cohort). Median neutrophil engraftment was 13 days (range, 6-42) and 21 days (range, 12-43) while median platelet engraftment was 37 days (range, 26-70) and 38 days (range, 24-74) in standard-RIC and novel-RIC groups respectively. Fifty-three suffered acute-GVHD which occurred in 21 (40.4%) patients, (grade 2-4: n=15, 29%; grade 3-4: n=4, 8%) in standard-RIC group and in 32 (66%) patients (grade 2-4: n=29, 62%; grade 3-4: n=5, 11%) in novel-RIC group. Chronic-GVHD (cGVHD) occurred in 18 patients (n=7, 14% in standard-RIC; n=11, 23% in novel-RIC group). The one-year cumulative incidence of relapse was 36% (n=15) in standard-RIC while it was 15% (n=5) in novel-RIC cohort. Median relapse free survival (RFS) was significantly improved in novel-RIC cohort compared to standard-RIC (HR, 0.32, CI:0.11-0.76, p=0.01). Median RFS was 29 months in standard-RIC cohort while median RFS was not reached in novel-RIC cohort. The one-year cumulative incidence of transplant related mortality (TRM) was 22% (n=10) in those who received standard-RIC while it was 16% (n=7) in those who received novel-RIC. TRM was not significantly different between the standard-RIC and novel-RIC cohorts. Median follow-up in standard-RIC cohort was 9.3 months (range, 0.16-79) and 13 months (range, 1.4-36) in novel-RIC cohort. The overall survival (OS) was significantly better in novel-RIC cohort compared to standard-RIC (HR 0.49, CI: 0.25-0.94, p=0.03). Median OS was 17 months in standard-RIC cohort while median OS was not reached in novel-RIC group (Figure 1).

**Figure 1.**

**Summary/Conclusions:** Based on decision analysis, up-front allo-HSCT was associated with higher LE and QALE in the intermediate- and high-risk groups in comparison to chemotherapy alone in patients with aggressive ATL. In the absence of prospective randomized controlled trials, our results suggest that up-front allo-HSCT for aggressive ATL is the favored treatment strategy in the intermediate- and high-risk groups.

INTERFERON-A IS EFFECTIVE FOR TREATMENT OF MINIMAL RESIDUAL DISEASE IN PATIENTS WITH ACUTE LEUKEMIA AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

X.-D. Mo1,*, X.-H. Zhang1, L.-P. Xu1, Y. Wang1, C.-H. Yan1, H. Chen1, W. Han1, F.-R. Wang1, J.-Z. Wang1, K.-Y. Liu1, X.-J. Huang1

**Background:** Post-transplant relapse is a major cause of transplant failure. Because impending relapse can be indicated by minimal residual disease (MRD) after allogeneic hematopoietic stem-cell transplantation (allo-HSCT), MRD-directed intervention may be a reasonable option for relapse prophylaxis.

**Aims:** We investigated the efficacy of MRD-directed interferon-α (IFN-α) treatment in acute leukemia patients who were positive for MRD after allo-HSCT.
Methods: A total of 107 patients who were MRD-positive after allo-HSCT were enrolled. MRD-positive status was defined as positivity for leukemia-associated aberrant immune phenotypes or positivity for Wilms’ tumor gene 1 in a single bone marrow sample. Recombinant human IFN-α-2b injections were administered subcutaneously 2–3 times per week for 6 months.

Results: The 2-year cumulative incidence of severe acute and chronic graft-versus-host disease (cGVHD) in the AZA and BSC-treated groups was 10% and 22%, respectively (AZA vs. BSC, P=0.66), relapse (31.5% and 28.6%, P=0.59), NRM (26.5% and 26.1%, P=0.98), and PFS (70.8% and 70.0%, P=0.66) were not significantly different between the AZA and BSC groups. In multivariate analysis, AZA and BSC were not independently associated with the occurrence of relapse, non-relapse mortality (NRM), and hematopoietic recovery after allo-HSCT.

Conclusions: Our study suggested that pretransplant induction therapy in high-risk MDS patients. However, the benefits of pretransplantation therapy in these patients are unclear, and the optimal therapy regimen remains unknown.

Aims: We conducted a retrospective analysis to elucidate the clinical impact of pre-treatment with AZA on outcomes after allo-HSCT in high-risk MDS patients.

Methods: Clinical data were collected from the registry database of the Japanese Society for Hematopoietic Cell Transplantation. We selected patients with high-risk MDS at diagnosis (IPSS intermediate 2 or high), aged 16 years or older, who underwent their first transplantation between January 2009 and December 2014 and received AZA or BSC as best supportive care (BSC) before allo-HSCT. Patients who received conventional chemotherapy or immunosuppressive therapy prior to allo-HSCT were excluded. We compared overall survival (OS), relapse, non-relapse mortality (NRM), and hematopoietic recovery after allo-HSCT between AZA and BSC patients who were pretreated with AZA.

Results: Of the 485 patients, 161 patients (33.2%) received AZA and 324 patients (66.8%) received BSC before allo-HSCT. The median age was 60 (18–70) and 56 (18–74) years, respectively (P=0.002). A higher proportion of BSC patients received cord blood transplantation (P=0.005). Bone marrow replaced cord blood transplantation (72.0% and 69.4%, P=0.36) were not significantly different between the AZA and BSC groups. In multivariate analysis, the Cox proportional hazard model and Fine-Gray methods were used for OS and cumulative incidence of relapse and NRM and hematopoietic recovery, respectively, using the following variables: age, gender, performance status at transplantation, marrow blast at diagnosis, cytogenetic risk, donor source, donor-recipient genotypic matching, and conditioning regimen.

Results: Of the 485 patients, 161 patients (33.2%) received AZA and 324 patients (66.8%) received BSC before allo-HSCT. The median age was 60 (18–70) and 56 (18–74) years, respectively (P=0.002). LOW-DOSE DECITABINE IMPROVES PLATELET RECOVERY IN PATIENTS WITH ISOLATED THROMBOCYTOPENIA AFTER HSCT

Y. Han1,2,*, Y. Tang1, Y. Zhao1, M. Huang1, J. Chen1, J. Qi1, Y. Wang1, X. Wu1, X. Ma1, F. Chen1, X. He1, C. Run1, D. Wu1

1The First Affiliated Hospital of Soochow University, Jiangsu Institute of Hematology, 2Institute of Blood and Marrow Transplantation, Collaborative Innovation Center of Hematology, 3Soochow University, Suzhou, China

Background: Isolated thrombocytopenia is a common complication of hematopoietic stem-cell transplantation (HSCT), which was defined as consistent low platelet counts with recovery of the other two cell lines after transplantation. This status leads to an increased risk of life-threatening hemorrhage, frequent requirements of platelet transfusion and extended hospital stays, representing a challenging clinical problem. Previous studies have demonstrated that decitabine, a hypomethylating agent, may increase platelet counts by promoting megakaryocyte maturation and platelet release in mouse model. This experiment was repeated three times in total, using different patient and control samples to identify consistent alterations of protein expression in EVs. Finally, protein differentiations were also confirmed using Western blotting.

Methods: We performed a prospective open-label study to evaluate the treatment of low-dose decitabine in patients with hematological malignancies who received allogeneic HSCT and suffered from isolated thrombocytopenia. The inclusion criteria were: (1) Platelet count < 100×10⁹/L persistently at day 60 post-HSCT or later; (2) Recovered neutrophil and hemoglobin; (3) Full donor chimerism; and (4) No response to conventional treatments for a duration of at least 4 weeks. Patients with malignancy relapse, active infections, uncontrolled graft-versus-host disease, severe organ damage or transplant-related thrombosis were excluded. From July 2013 to July 2016, 38 patients were randomly assigned into either the control group to receive conventional treatment only, or the test group to receive additional decitabine (15mg/m², intravenously daily for 4-6 weeks).

Results: Major response was observed in 16 out of 19 patients (84.2%) in the decitabine group, with a median time of 22 days to achieve platelet transfusion-independence. Two patients (10.5%) showed a minor response and 1 patient (5.3%) failed. In contrast, 3 out of 19 patients in the control group (15.8%) showed a major response, 2 patients (10.5%) showed a minor response, 14 patients (73.7%) did not show any improvement, of which 1 patient died of severe hemorrhage in week 5. For bone marrow morphological analysis, all 38 patients showed low levels of megakaryocytes at week 0. However, the megakaryocyte counts in decitabine group were significantly increased at week 4, while no significant difference was recorded in control group. After decitabine treatment, we did not observe a change in anti-platelet antibodies levels and T cell subsets ratios. However, reactive oxygen species (ROS) and megakaryocyte counts increased in the test group. No considerable myelosuppression, febrile neutropenia, and nonhematologic toxicities associated with the treatment were observed.

Summary/Conclusions: Our data showed an encouraging efficacy of decitabine in patients after HSCT suffering from isolated thrombocytopenia, which is consistent with previously reported results. Further studies are needed to establish whether the additional administration of decitabine to patients with HSCT-related thrombocytopenia can improve platelet recovery.
and in the percentage of circulating erythroblasts; (iv) the increase in β Thal red cell survival. RO4917838 induced a significant reduction in extramedullary erythropoiesis as well as in the amount of insoluble alpha chain aggregates in circulating red cells. It is of note that in β-Thal sorted erythroblasts we found a reduction in HRI and in phospho-eIF2a, indicating a reduction in free heme, which shall result in the activation of HRI, in RO4917838 treated β -Thal mice (10 mg/Kg/d, 6 weeks). Finally, in β-Thal mice treated with RO4917838 (4 weeks at 30 mg/kg/d) a reduction in liver and spleen iron-overload was identified, which was associated with increased hepatic iron expression.

Summary/Conclusions: Our data suggest that RO4917838 ameliorates anemia and ineffective erythropoiesis by reduction of heme biosynthesis in a mouse model for β-thalassemia. RO4917838 is a potential, novel therapeutic approach for the treatment of anemia in patients affected by beta-thalassemia.

P393
MAY MUTATIONS IN THE KLF1 GENE HAVE WORSENING EFFECTS ON THE BETA THALASSEMIA PHENOTYPE
M.R. Storino1, M. Giuliano1, G. Fioretti2, S. Puzone1, R. Sessa1, L. Vicari1, M.P. Ottaviano1, M. Caldara3, S. Costantini2, C. Matarrese3, A. Sarappa2, G. Amendola2, A. Filosa2, P. Izzo2, M. Grosso1,∗
1Dep. Molecular Medicine and Medical Biotechnology, University of Naples Federico II, 2UOC Genetica Medica, AORN A. Cardarelli, 3UOC Patologia Clinica, P.O. Pellegrini, ASLNA1, 4UOSS Malatite rare del globulo rosso, AORN A. Cardarelli, Naples, 5UOC Pediatría-TIN, P.O. Umberto I, Nocera Int., Italy

Background: Kruppel-like factor 1 (KLF1) is a pleiotropic erythroid transcriptional factor that plays a key role in erythropoiesis (Siatecka M, Blood 2011; 118: 2044-521). Accordingly, KLF1 mutations have been found to be responsible for a variety of hematological disorders. KLF1 also contributes directly or indirectly to regulate the expression of genes in the beta-globin gene cluster and the fetal-to-adult globin gene switching (Waye JS et al Int. J. Lab. Hem. 2015; 37: 78-84). It has been reported that mutations leading to KLF1 haploinsufficiency are linked to increased fetal hemoglobin (HbF) levels with amelioration of the condition of a neutral polymorphism. Furthermore, unexpectedly, the novel F182L and M39L mutations were found to be associated with increased fetal- and/or beta-globin gene expression. In other cases we demonstrated that KLF1 mutations may contribute to worsen the beta thalassemia phenotype or result in a silent beta thalassemia trait. This study provides further insights into the multiple roles of KLF1 in erythropoiesis and highlights an intriguing effect of a subset of KLF1 mutations that may contribute to the severity of the thalassemia phenotype, thus reinforcing the relevant implications of KLF1 screening for genetic counseling and for effectiveness of prevention screening programs for hemoglobinopathies.

RESULTS: Of the 19 patients who were tested, 15 were found to be positive for mutations in the KLF1 gene. More in detail, we found 7 mutations, comprising a nucleotide variation (c.-251 C>G) already reported as a single nucleotide polymorphism and a known mutation (c.-148 G>A) in the proximal promoter region, 3 novel mutations (C94X and P173Pfs*236), all of them in the proline-rich domain of the gene, and 8 subjects with nonsynonymous mutations (S102P, F182L, and M39L), which were corroborated by in silico prediction tools (S102P, F182L, M39L, (Radmilovic M. et al. Ann. Hematol 2013; 92: 53-58) and 2 novel mutations (C94X and P173Pfs*236), all of them in the proline-rich domain in exon 2. Functional studies were performed in K562 cells in order to clarify the pathogenic significance of these mutations and to better define the role of KLF1 in atypical thalassemia phenotypes. Interestingly, the c.-251 C>G polymorphism was found to be associated with an increased transcriptional activity of the KLF1 promoter (Figure 1A), thus allowing us to exclude for this nucleotide variation the condition of a neutral polymorphism. Furthermore, unexpectedly, the novel P173Pfs*236 mutation was found to be associated with a dramatic reduction of the beta-globin gene expression (Figure 1B).

Summary/Conclusions: Our study confirmed the ameliorative effect of some KLF1 mutations on the thalassemia phenotype that were found to be associated with increased fetal- and/or beta-globin gene expression. In other cases we demonstrated that KLF1 mutations may contribute to worsen the beta thalassemia phenotype or result in a silent beta thalassemia trait. This study provides further insights into the multiple roles of KLF1 in erythropoiesis and highlights an intriguing effect of a subset of KLF1 mutations that may contribute to the severity of the thalassemia phenotype, thus reinforcing the relevant implications of KLF1 screening for genetic counseling and for effectiveness of prevention screening programs for hemoglobinopathies.

SECONDARY SOLID TUMORS FOLLOWING HEMATOPOietic CELL TRANSPLANTATION FOR THALASSEMIA MAJOR
A. Meloni1,∗, A. Natale2, S. Santarone3, M. Di Ianni3, S. Angelini3, L. Pistola1, L. Cuccia1, A. Spasiano1, A. Pepe1, P. Di Bartolomeo2
1Fondazione G. Monasterio ORN-Regione Toscana, Pisa, 2Bone Marrow Transplant Center, Pescara, 3University of L’Aquila, L’Aquila, 4Tor Vergata University, Roma, 5ARNAS Cívico “Benferratelli-Di Cristina”, Palermo, 6AORN A. Cardarelli, Napoli, Italy

Background: Secondary solid tumors (SST) have been described after HCT, in particular for patients affected by hematologic malignancies. There is limited information about the incidence of SST following HCT for thalassemia major (TM).

Aims: The aim of this study was to determine the incidence of SST in 134 patients treated with TM who received HCT in our Center between 1983 and 2013.

Methods: 117 patients survived more than 3 years after HCT and were enrolled in the study. Of them, 57 were males and 60 females. Their median age at time of HCT was 10 years (1-29). As conditioning regimen, they received Busulfan (14 mg/Kg) and Cyclophosphamide (200 mg/Kg). The GVHD prophylaxis included Cyclosporine and Methotrexate. All patients received bone marrow cells from an HLA identical donor.

Results: At time of this report, 112 patients were cured, whereas 5 patients rejected their graft and are now under regular transfusion treatment. Overall, the median follow-up after HCT was 24 years (3-34). Seven patients developed malignancy in 64 months (median age 10 years at time of marrow donation) after HCT including 1 carcinoma of the tongue, 1 squamous cell carcinoma, 1 colorectal cancer, 1 thyroid carcinoma, 1 carcinoma of the uterine cervix, and 1 parotid carcinoma. The 30-yr cumulative incidence (CI) of developing SST was 10±0.17%. All patients underwent surgical resection of the tumor and in addition 4 of them received chemotherapy and/or radiotherapy. Of relevance, the 3 patients with cancer of the oral cavity were affected by severe chronic GVHD with buccal cavity involvement. Two patients (1 with parotid and 1 with tongue carcinoma) died of tumor progression and 5 are living. We compared these results with 2 case control populations. First of all, we investigated the occurrence of solid tumors in the 117 individuals (64 males, median age 10 years at time of marrow donation), who served as stem cell donors for HCT. One donor developed breast cancer 29 years after marrow donation at age of 38. The 30-yr CI of developing solid tumor for donors was 4±0.2% with a statistically significant difference (p=0.03) as compared to that of transplanted patients. The second case control population consisted of 117 patients treated with HCT and affected by SST. The matching technique applied was based on the variables age and sex. One control per case (transplanted patient) was randomly selected from the MIOT (Myocardial Iron Overload in Thalassemia) registry and matched by sex and age with the transplanted patient population. Two patients developed an hematocellular carcinoma (HCC) at age of 39 and 44 years, respectively. One patient died and one is living. Using the event rate measure, we observed an event rate of 0.102 at 30 years for the transplant group and 0.041 for the nontransplant group (p=0.106).

Summary/Conclusions: This study shows that the magnitude of increased risk of SST is twofold to threefold for patients treated with HCT as compared with age- and sex matched nontransplant TM patients or with stem cell donors. Notably, among the transplanted patients we didn’t observe any case of HCC, which is one of the most frequent solid tumor in nontransplant TM patients, whereas we observed 4 cases of head/neck cancers. In our series, cGVHD seems to be a strong risk factor in the development of new solid tumors. Patients with cGVHD, especially those with involvement of the oral cavity, must receive a very long careful monitoring and surveillance in order to prevent the development of secondary cancers.
Background: Newborn screening program for thalassemia (thal) and hemoglobinopathies (NHS-Hbs) is crucial for early detecting patients with serious hemoglobinopathies (Hb variants) e.g. Sickle cell anemia (Hb SS). NHS-Hbs has been incorporated into a routine neonatal service in several developed countries. However its role on early detection other forms of globin disorders remains unclear. Moreover, NHS-Hbs can detect several types of thalassemia and Hb variants carriers. This application could be useful for the national prevention and control program to better control thalassemia syndromes in many developing countries including Thailand where these conditions are highly prevalent especially β-thal major. Hb E/β-thal and Hb Bart’s hydrops fetalis (caused by α-thalassemia). Recently a new capillary electrophoresis (CE) has been developed specifically for NHS-Hbs. However there is a limited data on validation of this technology on detecting several types of thalassemia and Hb variants found in Southeast Asia.

Aims: To evaluate and validate a new CE system to screen globin disorders in newborn to initiate the national NHS-Hbs for Thailand.

Methods: After informed consent, 1,213 blood samples of 2-day old newborns were collected by heel prick puncture into 5-dried blood spots. After elution, dried blood samples were analyzed by Capillaries 2 NEONAT FAST® (SEBIA, Evry, France). All samples were also extracted for DNA and genotyped by our extensive PCR based panel to detect >98% of abnormal globin alleles found in Thailand using α-thal GAP-PCR, α-thal ARM-PCR, β-thal ARMS-PCR, and PCR-RFLP for Hb E. We compared CE data with each globin genotypes and use a ROC curve to set up new diagnostic criteria using Hbs from CE for future cases.

Results: Identification of Hb Bart’s provided 100% of sensitivity, specificity and accuracy in most individuals with α-thal. Using ROC analysis, we proposed different cut-off values of Hb Bart’s to differentiate Hb H disease, α-thal and non-deletional α-thal traits; ≥7.40%, ≥0.85%, ≥0.45%, respectively with excellent accuracy (Table 1). Interaction of Hb E with these α-thal genotypes has no effect on these cut-off values (Table 1). However, there was a limitation to identify deletional α-thal trait ≥0.10% (detectable level). A cut-off level to distinguish Hb EE from Hb E trait was suggested at ≥0.7%. Two patients with Hb E/β-thalassemia were identified through this study with different CE pattern from Hb EE. 11 β-thalassemia traits was identified and they had a lower level of Hb A as compared to their gestational age (GA)-sex matched controls with normal β-globin genotypes (n=148). We recommend Hb A level ≤10.35%; a cut-off to primarily consider for β-thalassemia carrier following by molecular analysis.

Summary/Conclusions: This newborn CE platform showed a high efficiency for detecting several types of thalassemia and Hb variants in particular α-thal, β-thal and Hb E using cut-off levels of each Hb species described herein. Besides early detecting of Hb S, we can now apply this NHS-Hbs into a routine service in order to early detect Hb H disease, Hb E/β-thalassemia and the majority of common thalassemia carriers. This NHS-Hbs approach can reinforce and leverage our current program on prevention and control for severe thalassemia syndromes in our region. Moreover, due to population migration from The East to the West, our new diagnostic guideline by CE could be useful and applicable for existing NHS programs currently available in several European countries.

P397

INCREASING INCIDENCE OF MALIGNANCIES IN AGING THALASSEMIC PATIENTS: A SINGLE INSTITUTION'S LONGITUDINAL EXPERIENCE

E. Repoussi1, 2, M. Moraki1, D. Kyrkaiopoulou1, P. Delaporta1, A. Kafourou1, A. Kattamis1

1Thalassemia Unit, First Department of Pediatrics, National and Kapodistrian University of Athens, 'Agia Sophia' Children's Hospital, Athens, Greece

Background: The introduction of close monitoring, regular blood transfusions and systematic iron chelation in the management of thalassemia have significantly changed the clinical phenotype of the patients and improved their survival. The patients, who have benefited of the current therapeutic regimen, are now reaching middle age and they have started to experience some of the problems more commonly seen in older people. Recent observations suggest of an increased incidence of malignancies in the aging group of thalassemic patients.

Aims: The purpose of this study is to determine the longitudinal changes in the incidence of malignancies, along with possible correlations to different aspects of thalassemic disease.

Methods: A retrospective study in the largest Thalassemia Unit in Greece has been conducted spanning an observation period from 2001-2016. The occurrence and type of cancer, as well as history on transfusion dependence, liver failure, HCV infection and chelation therapy were recorded and analyzed. Statistical analysis was performed using SPSS software package, v. 20. A p-value <0.05 was considered statistically significant.

Results: Records from 591 patients (338 with thalassemia major and 253 with thalassemia intermedia) were evaluated. 27 patients (11 males and 16 females)
Results: 4 weeks in NC. were withdrawn from the study and placed on a standard chelation regi-
was assessed at 6, 9 and 12 months (patients confirmed SF ≥1000 ng/mL
patients with LPI ≥0.6 µM, SF ≥1000 μg/L or TSAT ≥70% in each study arm
dose (50 mg/kg/day) or no chelation (NC). Median age at 1st transfusion
≥0.2 µM were randomized to start deferiprone (DFP) at a sub-therapeutic
≥400 μg/L or transferrin saturation (TSAT) ≥70% or labile plasma iron (LPI)
Summary/Conclusions: This retrospective study has confirmed the increased
malignancies in thalassemia patients in Greece, which is, at least, partially related to the aging of this population. Based on these observations,
adaptation of monitoring guidelines is essential for optimal management of
thalassemic patients. Periodic screening for malignancies, especially hepatic,
thoracic and hematologic, will allow early detection and timely, and thus, more
efficacious treatment of the neoplasia.

SAFETY AND EFFICACY OF EARLY START WITH SUBOPTIMAL DOSE
OF DEFERIPRONE IN MINIMALLY TRANSFUSED INFANTS WITH
TRANSFUSION DEPENDENT THALASSEMIA: A RANDOMIZED TRIAL
M. Eliaji1,*, B. Hell2, V. Berdoukas3, F. Tricà4, M. Tarif5, H. Awad6, A. Adyl7,
1AinShams university, 2Ain Shams University, Cairo, Egypt, 33 Oasis Interna-
tional Hospital, Beijing, China, Beijing, China, 44 ApoPharma Inc., Toronto,
Canada, 5National Research Center, Cairo, Egypt

Background: Early exposure to iron toxicity is the main risk factor for morbidity and mortality
in patients with transfusion-dependent thalassemia. Current prac-
tice is to start chelation therapy only after 10-20 transfusions, or when the
serum ferritin (SF) level rises above 1,000 µg/L.

Aims: To evaluate the safety and efficacy of the early use of low-dose deferiprone in minimally transfused pediatric thalassemia patients and to evaluate
if it can postpone iron overload in these group of patients.

Methods: In the current trial (ClinicalTrials.gov Identifier: NCT02173951),
64 children recently diagnosed with thalassemia major who had
begun receiving blood transfusions in first year of life to keep pre-transfusion
Hb above 10 g/dl, had not yet started iron chelation therapy and had SF
≥400 µg/L or transferrin saturation (TSAT) ≥70% or labile plasma iron (LPI)
≥0.2 µM were randomized to start deferiprone (DFP) at a sub-therapeutic
dose (50 mg/kg/day) or no chelation (NC). Median age at 1st transfusion
was 5 months for both DFP-treated and for NC children. The percentage of patients with
LPI ≥0.6 µM, SF ≥1000 µg/L or TSAT ≥70% in each study arm
was assessed at 6, 9 and 12 months (patients confirmed SF ≥1000 ng/mL
were withdrawn from the study and placed on a standard chelation regi-
men). Complete blood count was done weekly in DFP treated and every 3-
week intervals in NC.

Results: Table 1. Summary of the efficacy results of SF, TSAT, and LPI.

All NC patients were removed from the trial prior to completing 7 months of follow-
up (9-11 transfusions ) due to confirmed SF ≥1000 µg/L. Mean ± SD time of follow up
was 10.4 ± 4.9 and 5.9 ± 2.5 months for DFP and NC respectively.

Most common adverse events in patients on DFP versus NC were diarrhea
(19% vs 13%, p= 0.73), vomiting (13% vs 13%, p=1.00), abdominal colic (13% vs
13%), elevated liver enzymes (6% vs 3%, p=1.00) and neutropenia (6% vs
6%). All adverse events were mild in severity and did not require interruption
of DFP use. There were no cases of agranulocytosis or moderate neutropenia,
no arthralgia and no serious infections in DFP-treated patients. DFP therapy
was associated with a significant reduction in the rate of iron accumulation as
measured by SF (P<0.0001), LPI (P<0.001) and TSAT (P<0.001) (Figure 1a, b, c).
LPI ≥0.6 µM appeared as early as after 5 transfusions in NC children and
was delayed to at least 10 transfusions with DFP therapy. TSAT ≥70% appeared
after 10 transfusions in NC children and was delayed to at least 17 transfusions
with DFP therapy. The results of this study show that LPI and TSAT may reach
values ≥0.6 µM and ≥70%, respectively, after 5 - 10 transfusions in children
with TM and all NC children had SF ≥1000 µg/L after 8-9 transfusions.

Summary/Conclusions: A sub-therapeutic dose of deferiprone for a mean
of 12 months in children with TM and low iron overload was not associated
with safety concerns and able to significantly reduce the rate of iron accumulation
as measured by SF, LPI and TSAT.

LONGITUDINAL PROSPECTIVE MRI STUDY IN PEDIATRIC PATIENTS
WITH THALASSEMIA MAJOR

dizzi, 5Azienda Ospedaliera “Sant’Antonio ed SS. Trapani, 6ASL N°1 Sassari,
Sassari, 7Policlinico “Paolo Giaccone”, Palermo, 8Fondazione di Ricerca e
Cura “Giovanni Paolo II”, Campobasso, Italy

Background: No studies are available in literature evaluating, on repeated
magnetic resonance (MR) imaging assessments, changes in myocardial and
hepatic iron overload, biventricular function, and development of macroscopic
myocardial fibrosis in pediatric patients with thalassemia major (TM)

Aims: This is the first longitudinal prospective MRI study in pediatric TM
patients

Methods: We considered 68 TM patients enrolled in the MIOT (Myocardial
Iron Overload in Thalassemia) project with less than 18 years at the first MRI
scan and who performed a follow-up (FU) study at 18±3 months.

Myocardial and hepatic iron burdens were quantified by the T2* technique.
Atrial dimensions and biventricular function were quantified by cine images.
Late gadolinium enhancement (LGE) images were acquired to detect myocardial
fibrosis.

Results: At the baseline MRI, 16 (23.5%) patients showed myocardial iron overload
(MIO; global heart T2*<20 ms) and 54 patients liver iron overload

Figure 1.
(79%). Figure 1 shows the changes in iron levels. Twenty-five patients changed the chelation regimen after the baseline MRI. Globally, a worsening in cardiac iron was found in 3% of the patients while a worsening in hepatic iron in the 21% of the patients (P=0.003). The LV end-diastolic volume index and all RV volumes as well as the LV mass index were significantly lower at the FU MRI. No significant improvement in left or right global systolic function was found. For 40 patients the presence of myocardial fibrosis was investigated at both baseline and FU scans. Six patients (15.0%) had myocardial fibrosis at the baseline MRI and myocardial fibrosis was detected for all of them also at the FU. The extent of myocardial fibrosis was comparable between the two scans (0.77±0.42% vs. 0.79±0.51%; P=0.686). At the FU 4 new occurrences of myocardial fibrosis were detected. In patients with baseline MIO no significant correlation was found between the percentage change in cardiac iron and the changes in hepatic iron or the baseline hepatic iron.

Summary/Conclusions: Magnetic resonance monitoring in children with TM demonstrated a good control of cardiac iron overload in terms of prevention and treatment but the need for further improvement of liver iron overload. Myocardial fibrosis appears mainly multifocal, non progressive and not reversible over a 18- month period. A prompt and aggressive approach to iron overload and a chelation regimen consistent with the high iron intake and the high rate of severe liver iron overload is recommended in children.

P400
LONG TERM FOLLOW-UP OF A COHORT OF WELL TREATED B-THALASSEMAIA MAJOR PATIENTS BY MULTI-ORGAN R2* MAGNETIC RESONANCE IMAGING
V.M. Pinto1, L. Bacigalupo2, B. Giansesin1, M. Balocco1, M. Lamagna1, S. Quintino1, G.L. Forni1,2
1Haematology-Centro Microcitemia Anemie Congenite, 2Radiology Unit, Ospedale Galliera Genova, Genova, Italy

Background: The introduction of non-invasive multi-organ evaluation of iron overload by R2* Magnetic Resonance Imaging (MRI) in β-thalassemia major (TM) patients has improved the patient care allowing a more careful tailoring of iron chelation therapy.

Aims: We report a cross-sectional and longitudinal experience with the use of MRI-R2* heart, liver and pancreas in a cohort of well treated TM patients.

Methods: TM patients underwent contemporaneous assessment of pancreatic, cardiac and hepatic MRI-R2* (1.5 T GE HDx scanner) in the period Jan08-Dec16.

Results: 69 TM patients: 43% male, age 38±9yrs, median number of observations/patient 6 (IQR:5-7), median number of yrs of the follow-up (f.u.) 8 (IQR:7-8). Iron chelation regimens included deferasirox (basal 30%-f.u.32%), deferoxamine (basal 45%>f.u.52%), daily alternating deferasirox+deferoxamine (basal 3%-f.u.6%), deferoxamine (basal 9%>f.u.6%) deferoxamine+ deferasirox (Rp=0.68, p<0.001) and heart (Rp=0.75, p<0.001), in accordance with literature. Deferiprone (basal 13%>f.u.4%). The observation at the baseline showed a positive strong correlation between R2* values of pancreas and both of liver (Rp=0.25, p=0.04) and pancreas (Rp=0.41,p<0.001). Finally, assuming the cutoff value of 100 Hz for the pancreatic-R2* as the predictor of a cardiac R2*>50Hz, we calculated the numbers of false/true positive/negative according to the rule above. At the baseline we can observe that the number of false positive is the 14/27 (52%). The percentage increases to 91% (21/23) after f.u.: the pancreas-R2*>100Hz in 23 patients but only 2 has iron overload in the heart; the total number of patients with pancreatic-R2*>100Hz is quite the same before and after f.u. (27 compared to 23). We found no correlation between the false positive predicted and particular conditions such as impaired glucose tolerance, diabetes or adipose involution (Table 1).

Table 1.

Summary/Conclusions: In this experience we observed that the regular multi-organ assessment of iron overload by R2* is concomitant with a reduction of the iron burden in this cohort of well treated patients confirming that is a careful method to tailoring the iron chelation therapy. However pancreatic-R2* remains above the cut-off for the prediction of cardiac iron overload, so this parameter should be considered with caution in the tuning of the chelation therapy, in order to avoid over-chelation risk. Ferritin values trend agree with R2* values confirming the reliability of this parameter. These results were obtained with a prevalent use of oral chelation regimen (90% of patients).

DEVELOPMENT OF HTLV-1 HYPERIMMUNE GLOBULINS AGAINST HTLV-1 INFECTION

T. Mizukami1, K. Nojima1, R. Sobata2, W. Kuribayashi3, C. Matsumoto2, Y. Yamao1, E. Sasaki1, K. Furuhata1, Y. Hiradate1, K. Ohkuma1, S. Matsuoka1, M. Satake1, I. Hamaguchi1

1Department of Safety Research on Blood and Biologicals, National Institute of Infectious Diseases, 2Central Blood Institute, Japanese Red Cross, 3Department of Cellular and Molecular Medicine, Graduate School of Medicine, Chiba University, Tokyo, Japan

Background: Adult T-cell leukemia (ATL) is a malignant disease caused by infection with human T-lymphotropic virus (HTLV-1). The prevention of HTLV-1 infection is the most effective strategy to eradicate ATL. However, there is no effective vaccine or anti-viral agent for HTLV-1.

Aims: The aim of this study was to develop an effective HTLV-1 hyperimmune globulin (HTLV-IG) isolated from HTLV-1 positive carriers screened at the Japanese Red Cross.

Methods: We developed two in vitro and in vivo screening methods to evaluate and characterize the anti- viral effect of HTLV-1 positive plasma and HTLV-IG.

Results: A HTLV-IG product isolated from an HTLV-1 carrier with a proviral load (PVL) >4 inhibited both HTLV-1 infection and syncytia formation. We purified HTLV-IG from the HTLV-1 positive plasma (PVL >4) and evaluated its effect in a humanized mouse model. NOG (NOD.Cg-Prkdcscid Il2rtm1Sug/Jic) mice were treated with HTLV-IG for 5 days before HTLV-1 infection. During the monitoring period up to 40 days after post-infection, HTLV-1 infection was observed in untreated infected mice, but not in HTLV-IG-treated mice. The inhibitory effect of HTLV-IG was observed at the early stage of HTLV-1 Infection. Treatment with HTLV-IG at 20 days after HTLV-1 infection had a partial inhibitory effect. HTLV-1 gp46 expression in HTLV-1 infected cells was slightly reduced and the localization of these cells was changed in each tissue after the first line of treatment. These data suggest HTLV-IG is effective at the early phase of HTLV-1 infection. We also assessed the viral safety of HTLV-1 during the HTLV-IG manufacturing process. High log reduction values of HTLV-1 were observed during the Cohn fractionation process. Virus safety was assessed by PCR based assay and in vitro replication assay. We next assess the viral safety of HTLV-1 during the HTLV-IG manufacturing process. High log reduction values of HTLV-1 can be seen during the Cohn fractionation process. Virus safety was assessed with PCR based assay and in vitro and vivo infection assay.

Summary/Conclusions: These data suggest HTLV-IG is effective and safe for the prevention of HTLV-1 infection.

THE COMBINATION OF TUMOR CELLS IN THE APERIPHERIS MATERIAL DOES NOT PREDICT THE RESPONSE OF MULTIPLE MYELOMA PATIENTS TO AUTOLOGOUS TRANSPLANTATION

M.L. Lozano1, F. De Arriba1, M. Sola1, A. Sanchez-Fuentes1, N. Revilla1, F. Ortuno1, A. Lenz1, I. Heras1, P. Iniesta1, O. Lopez-Godino1, M.D. Garcia-Malo1, V. Vicente1

1Hematology and Clinical Oncology, Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arrixaca, CB15/00055-CIBERER, Murcia, Spain

Background: The use of high dose of chemotherapy followed by autologous stem cell transplantation (ASCT) has improved the prognosis of patients with multiple myeloma (MM) and plasma cell dyscrasia. However, there is controversy over the effect of infusion of atypical plasma cells (PC) on the apheresis product.

Aims: To analyze whether in MM malignant plasma cell reinfusion could negativley affect responses to ASCT.

Methods: Patients (n=114) undergoing ASCT (n=120) for MM between January 2003 and February 2016 were enrolled in a retrospective study to analyze the prognostic value of aberrant (CD38++CD138+CD19-CD45weak) to normal phenotype (CD38++CD138+CD19+CD45+) plasma cells (A:T PC ratio) in the autograft by flow cytometry. The Durie-Salmon stage at diagnosis, the mobilization scheme were determined. Response was assessed at day +100 after ASCT using the 2006 International Myeloma Working Group uniform response criteria.

Results: Patient characteristics are shown in Table 1. Patients with a better ASCT response to induction therapy (complete response [CR] or very good partial response [VGPR]) had a non-significant different median A:T PC ratio compared to those with a poorer response (partial response [PR], stable [SD] or progressive disease [PD]), (0.4 vs 1, p=0.28). Similarly, a non-significant difference (p=0.251) was observed in the number of atypical PC contained in the autograft of patients with a better vs poorer prior ASCT response (0.08 vs 0.08 ×10^6/kg). There was no difference between the type of mobilization (G-CSF vs chemotherapy+G-CSF) and the degree of apheresis contamination (median A:T PC ratio 0.5 vs 0.8; P=0.86). There was a statistical trend between the degree of infiltration of PC in the bone marrow before ASCT and the detection of atypical PC in the graft (p=0.06). At day +100, 94% of patients with CR or VGPR to induction therapy maintained the response, and 49% of patients in PR, SD or PD achieved post-ASCT CR or VGPR (p=1.26 ×10^-4). There was no association between the content of atypical PC in the graft and the response to day +100. However, the percentage of pre-ASCT PC in the bone marrow was significantly related to the response at day +100 (CR or VGPR vs PR, SD or PD), p=0.003, as well as the pre-ASCT monoclonal component (p=0.039-7).

Table 1.
**Summary/Conclusions:** TPE use was generally compliant with BSH guidelines regarding clinical indication and initial replacement fluid. However many patients were changed from HAS to FFP due to measured or predicted coagulopathy. This is a recognised complication of TPE, and the guidelines suggest that if possible, TPE can take place on alternate days to ameliorate this. Fluid change to FFP is recommended only for those at increased haemorrhagic risk. Almost all the TPEs in our study took place over 3 to 5 subsequent days, reflected in the high frequency of hypofibrinogenemia. The optimum frequency of fibrinogen monitoring, and the level that should prompt change to the TPE schedule, require further exploration. The following are planned to enhance adherence to BSH guidelines and improve patient care: 1. Documented treatment plans with clinical indication, proposed treatment schedule, replacement fluid. 2. Local trust guidelines to include recommended TPE schedules, agreed parameters to monitor response, frequency of fibrinogen monitoring, common complications and their management. Where possible, TPE should take place on alternate days to reduce dilutional coagulopathy. 3. Education of staff involved with service provision, and strengthening of the role of apheresis nurse as lead.

**Results:** Of 141 participants who took part in the survey, 31% (43) had been qualified for less than two years and 47% (65) were consultants. Specialities included Surgery, Anesthetics, Internal Medicine, Hemato-Oncology and Intensive Care. 60% (84) had prescribed blood within the last month. Despite only 51% (72) awareness of the NICE guidelines, a significant majority (73%, 103) selected the correct Hb threshold of ≤70g/L for transfusion in patients without acute coronary syndromes (ACS). However, a threshold of ≤80g/L was selected by 42% (58), but there was a wide spread of answers. 65% (90) of participants were aware that, in a stable patient Hb is checked after each unit of red cell transfusion, but surprisingly a few (4%, 5) did not check post transfusion Hb at all. Ferritin measurement was inconsistent with only 47% (66) routinely measuring this prior to transfusion, and only 31% (44) aware that a ferritin result over 30 days old should be rechecked. This highlighted potentially inadequate identification of iron deficiency anaemia. In addition only 40% (57) were aware of the existence of a hospital anaemia clinic for referral. When reflecting on consent methods, 96% (135) of participants expressed their indication for transfusion to patients. Also 90% (127) gave an opportunity to ask questions and ensured the patient was content to proceed. Provision of written information was poor (26%, 37) and only 55% (78) recorded the discussion in patients’ notes. Exploring barriers to consent, 24% (32) experienced difficulty in obtaining a patient information leaflet, and issues relating to lack of time and information were 16% (22) and 9% (12) respectively.

**Summary/Conclusions:** Although the majority of participants expressed awareness of the NICE guidance, knowledge was not reflected in subsequent questions. The survey allowed simultaneous assessment of knowledge and provision of key information as a factsheet. Almost all participants felt that completion of the survey had been helpful, and as a tool to reach a higher mobile group, the survey is a constructive and supportive method to facilitate implementation of national guidance by medical staff. We were also able to identify areas that need further development including the clinical referral pathway for the anaemia clinic and improving the availability of patient information leaflets on hospital wards. At present we are working closely with the hospital transfusion team to ensure that all information is disseminated to all hospital staff, and carrying out structured case based discussion sessions with junior doctors to enhance knowledge and confidence.

**SCREENING OF TRANSFUSION PRODUCTS FOR PRION DISEASES USING APTAMERS AND TUNABLE RESISTIVE PULSE SENSING**

M. Healey1,*, M. Sivakumaran1, M. Platt1

1Chemistry, Loughborough University, Loughborough, 2Haematology, Peterborough City Hospital, Peterborough, United Kingdom

**Background:** Prion diseases are a group of fatal transmissible neurological conditions whose disease etiology is characterised by the change in the normal intrinsic cellular prion protein (PrPc) to the highly ordered insoluble amyloid state conformer (PrPSc). The significant event fundamental to the progression of these diseases is the self-catalytic, and perpetuating, nature of the conversion of PrPc in the presence of PrPSc aggregates. The disease process is slowly progressive. The first major outbreak in the United Kingdom during the 1990s, is considered to be an effect of dietary exposure to the bovine spongiform encephalopathy (BSE) agent through contaminated meat products. To date, the widely accepted hypothesis is that dietary exposure to the bovine spongiform encephalopathy (BSE) agent through contaminated meat products.

**Results:** PrPc has been shown to have a mean zeta value of -6.60 mV for 100%. The assay was further developed by monitoring the functionalized nanoparticles were then used to detect the cellular prion protein in phosphate buffered saline by monitoring the relative change in velocity through the nanopore, which is then converted to zeta potential. The method was then applied to protein rich samples and serum.

**Methods:** Here we use a technique based on the Coulter Counter principle that uses tunable elastomeric nanopores termed Tunable Resistive Pulse Sensing (TRPS) to detect the prion protein without an amplification step. The first stage optimises the grafting of an ssDNA aptamer onto nanoparticles. In proof of concept work, the functionalized nanoparticles were observed. Here mean zeta values were -1.94 mV for 0%; -4.43 mV for 33%; and -7.30 mV for 100%. The assay was further developed by monitoring the functionalized particle's translocation velocity as a function of prion protein concentration. The method was then applied to protein rich samples and serum.

**Results:** By varying the concentration of aptamer relative to the binding capacity of the nanoparticles, a significant change (p=0.05) in velocity distribution was observed. Here mean zeta values were -1.94 mV for 0%; -4.43 mV for 33%; and -7.30 mV for 100%.

**Methods:** An online survey, designed to both evaluate and inform participants, was targeted at doctors of different training grades and specialties during a two week period. The outcomes of this are being used to guide further training.

**Summary/Conclusions:** A comprehensive proteomics study on platelet concentrates: platelet proteome, storage time and Mirasol pathogen reduction technology

V. Sa1, appen1, F. S. Arslanyaz2, F. M. Onar3, D. G. V. Ben4, J. C. van der Zwaan5, P. F. van der Meer5, B. D. Baal6, D. De Korte6, T. K. van den Berg1, L. Gutierrez1.

1Blood Cell Research, 2Plasma Proteins, Sanquin Research, 3Product and Process Development, Sanquin Blood Bank, Amsterdam, Netherlands, 4Hema-tology, IdISSC, Madrid, Spain

**Background:** Platelet concentrates (PCs) represent a blood transfusion product with a major concern for safety as their storage time (20-24°C) allows bacterial, fungal, and viral contamination, and their maximum storage time period (less than a week) precludes complete microbiological testing. Pathogen reduction technologies (PRTs) provide an additional layer of safety to the blood transfusion products from known and unknown pathogens (such as bacteria, viruses and parasites). In this context, PRTs (such as Mirasol technology) have been developed and are implemented in many countries. However, several studies have shown that Mirasol PRT introduces a certain level of platelet shape change, hyperactivation, basal degranulation and increased oxidative damage during storage. It has been suggested that Mirasol PRT might accelerate what has been described as the platelet storage lesion (PSL), but supportive molecular signatures have not been obtained.

**Aims:**

We aimed at dissecting the influence of both variables, i.e. Mirasol PRT and storage time, at the proteome level.

**Methods:** We present comprehensive proteomics data analysis of control PCs and PCs treated with Mirasol PRT at storage day 2, 6 and 8. Our workflow was set to perform proteomics analysis using a gel-free and label-free quantification (LFQ) approach. In our study we used LFQ and thereby targeted differentially expressed proteins using MaxQuant/Perseus software platform.

**Results:** We identified marginal differences between Mirasol PRT and untreated PCs during storage. However, those significant changes at the proteome level were specifically related to the functional aspects previously described to affect PCs during storage. However, those significant changes at the proteome level were specifically related to the functional aspects previously described to affect PCs during storage. However, those significant changes at the proteome level were specifically related to the functional aspects previously described to affect PCs during storage. However, those significant changes at the proteome level were specifically related to the functional aspects previously described to affect PCs during storage. However, those significant changes at the proteome level were specifically related to the functional aspects previously described to affect PCs during storage.

**Summary/Conclusions:** In summary, semi-quantitative proteomics allows to discern between treatment changes due to Mirasol PRT or PSL, and proves to be a methodology suitable to phenotype platelets in an unbiased manner, in various physiological contexts.

**P405**

**USE OF A SURVEY TO ASSESS AND IMPROVE ADHERENCE TO UK BLOOD TRANSFUSION GUIDELINES IN A HOSPITAL SETTING**

D. Warcel1,*, R. Moll1, A. Li1

1Haematology, Royal Free Hospital, London, United Kingdom

**Background:** UK guidelines to provide evidence-based support for decisions to transfuse were updated red cells were published in 2015 by NICE (National Institute for Health and Care Excellence). The guidelines specified hemoglobin (Hb) targets for transfusion, use of single unit transfusion to avoid over-transfusion, information provision to patients for informed consent, and avoidance of pre-operative transfusion by timely identification of iron deficiency for referral through an anemia pathway. A local baseline audit of NICE compliance at our London tertiary referral hospital showed low overall compliance with these recommendations.

**Aims:** To determine knowledge amongst the prescriber group of transfusion guidelines for recommended stable patients, to gain insight into current patterns of decision-making for transfusion and to impart knowledge of the key NICE guidelines.

**Methods:** An online survey, designed to both evaluate and inform participants, was targeted at doctors of different training grades and specialties during a two week period. The outcomes of this are being used to guide further training.
Front-line combinations in multiple myeloma and amyloidosis

S407
QUADRUPLE VS SEQUENTIAL TRIPLET INDUCTION THERAPY FOR MYELOMA PATIENTS: RESULTS OF THE MYELOMA XI STUDY

1The Institute of Cancer Research, London, United Kingdom, 2Myeloma Institute, University of Arkansas for Medical Sciences, Little Rock, United States, 3Clinical Trials Research Unit, Leeds Institute of Clinical Trials Research, Leeds, 4Heart of England NHS Foundation Trust, Birmingham, 5Leicester Royal Infirmary, Leicester, 6Centre for Clinical Haematology, Nottingham University Hospital, Nottingham, 7University Hospitals of North Midlands, Stoke-on-Trent, 8Kent and Canterbury NHS Trust, Canterbury, 9Southampton Hospital, Southampton, 10University of Leeds, Leeds, 11The Royal Marsden Hospital, London, 12Institute of Haematology and Immunology, University of Birmingham, Birmingham, 13Haematological Malignancy Diagnostic Service (HMDS), St James’s University Hospital, Leeds, 14Clinical Trial Research Unit, Leeds Institute of Clinical Trials Research, Leeds, 15Department of Haematology, Newcastle University, Newcastle, United Kingdom

Background: Combining anti-myeloma induction therapies limits the impact of clonal heterogeneity on resistance to therapy, maximising response and associated clinical outcomes. Triplet combinations induce deeper, longer remissions than doublets and those containing an immunomodulatory agent, a proteasome inhibitor (PI) or both are the current standard of care in Europe/US. Potential approaches to further improve outcomes include response-adapted induction, treating suboptimal responders with sequential treatment using an agent with a different mechanism of action, or intensifying induction for all patients by the use of quadruplet combinations upfront.

Aims: The UK NCRI Myeloma XI trial is a large, phase III study comparing, in transplant eligible (TE) patients, the induction quadruplet carfilzomib, cyclophosphamide, lenalidomide and dexamethasone (KCRD) to the sequential strategy of triplet immunomodulatory combinations (with thalidomide or lenalidomide) followed by additional pre-transplant consolidation with PI triplet therapy for those with a suboptimal response.

Methods: In 2013, the TE pathway of the Myeloma XI study was amended to include KCRD given in 28 day cycles (carfilzomib 36mg/m² IV d1-2,6,9,14,15 (20mg/m² #1d1-2), cyclophosphamide (cyclo) 500mg PO d1, lenalidomide (len) 25mg PO d1-21, dexamethasone (dex) 40mg PO d1-4,8,9,15-16). Patients were randomised to this up-front quadruplet or the sequential strategy of CRD (cyclo 500mg PO d1, len 25mg PO d1-21 PO daily, dex 40mg PO d1-4,8,9,15-16), KCRD (cyclo 500mg PO d1,15 thalidomide 100-200mg PO daily, dex 40mg PO d1-4,12,15) given to max. response. Patients with VGPR/CRC proceeded straight to ASCT, those with PR/MR were randomised to sequential CVD (cyclo 500mg d1,15, bortezomib 1.3mg/m² IVSC d1,4,8,11, dex 20mg PO d1,12,15,9,11,12) or nothing and those with SD/PD all received single-agent ixazomib maintenance.

Results: 2568 TE patients underwent induction randomisation (CTD:1021, CRD:526). Patients were comparable with respect to age (median 59 years), sex and other key laboratory parameters. Patients were mandated to receive at least a minimum of 4 cycles of initial induction with therapy continued to maximum response. The median number of cycles delivered was CTD: 5, CRD: 5, KCRD: 4, Grade ≥3 haematological toxicities differed between the groups. (Neutropenia CTD: 12%, CRD: 22%, KCRD: 16%; Thrombocytopenia CTD: 3.4%, CRD: 4.5%, KCRD: 8.1%; Anaemia CTD: 6.7%, CRD: 9.6%, KCRD 10%). Grade ≥2 neurological toxicity was greater with the thalidomide-containing regimen (Sensory neuropathy CTD: 9.5%, CRD: 3.4%, KCRD: 2.3%). There was no statistically significant difference in rates of investigator reported, all-grade, thromboembolic events between regimens (CTD: 11.8%, CRD 11.1%, KCRD 14.7%). Response to initial induction and following ASCT is shown in Table 1 indicating deeper responses with the quadruplet compared to triplets both at the end of first induction regimen (p<0.0001) and, importantly, post-ASCT (p<0.0001). These differences were observed despite the use of randomised pre-transplant consolidation for suboptimal responders to triplet immunomodulatory therapy.

Summary/Conclusions: Induction therapy with KCRD, an outpatient delivered quadruplet regimen, was associated with deeper responses than immunomodulatory triplet therapy (CRD/CTD) and was well tolerated. Deeper responses persisted after ASCT, with an impressive response rate ≥VGPR of 92% with KCRD.

S408
DEEP AND DURABLE RESPONSES WITH WEEKLY IXAZOMIB, LENALIDOMIDE AND DEXAMETHASONE IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA: LONG-TERM FOLLOW-UP OF PATIENTS WHO DID NOT UNDERGO SCT

S. Kumar1,*, J. Berdeja2, R. Niesvizky3, S. Lonial4, J. Laubach5, M. Hamadani6, P. Hari8, V. Roy9, R. Vescio10, J. Kaufman11, D. Berg12, E. Liao12, V. Rajkumar1, P. Richardson5

1Mayo Clinic, Rochester, 2Sarah Cannon Research Institute, Nashville, 3Myeloma Center, Weill Cornell Medical College, New York Presbyterian Hospital, New York, 4Department of Hematology and Medical Oncology, Winship Cancer Institute of Emory University, Atlanta, 5Dana-Farber Cancer Institute, Boston, 6West Virginia University, Mary Babb Randolph Cancer Center, Morgantown, 7Mayo Clinic College of Medicine, Scottsdale, 8Division of Hematology Oncology, Medical College of Wisconsin, Milwaukee, 9Mayo Clinic, Jacksonville, 10Cedars-Sinai Outpatient Cancer Center at the Samuel Oschin Comprehensive Cancer Institute, Los Angeles, 11Winship Cancer Institute of Emory University, Atlanta, 12Millennium Pharmaceuticals Inc., Cambridge, MA, USA, a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, United States

Background: Triplet combinations that include a proteasome inhibitor (PI) have been proven superior to doublets in newly diagnosed multiple myeloma (NDMM) (San Miguel et al, N Engl J Med 2008, Durie et al, Lancet 2017). The all-oral combination of the novel PI ixazomib plus lenalidomide-dexamethasone (IRd) was evaluated as an induction regimen in NDMM patients, followed by single-agent ixazomib maintenance.

Aims: Here we report updated efficacy and long-term safety data for patients who did not withdraw from the study in order to receive stem cell transplantation (SCT).

Table 1.
Methods: In this phase 1/2 study (NCT01217957), patients with NDMM received weekly oral ixazomib (1.88-3.65mg/m²; days 1, 8, 15) and dexamethasone (40mg, days 1, 8, 15, and 22) for up to 12-28 induction cycles, followed by maintenance therapy with weekly single-agent ixazomib, at the last tolerated dose given during induction, until disease progression or toxicity.

Results: Of 159 enrolled patients, 42 continued on study treatment without early withdrawal for SCT; the long-term follow-up of these 42 patients is reported here. Baseline patient characteristics included: median age, 68 years (range 34-86); ISS stage I/II/III in 40%/43%/17%. As of October 18, 2016, with median follow-up of 56 months, the confirmed overall response rate (ORR; partial response [PR] + complete response [CR]) was 80%, complete plus very good partial response (CR+VGPR) rate was 63%, and CR rate was 32%. Median time to first response was rapid (0.95 months), while median time to CR was 5.6 months. Median progression-free survival (PFS) in these patients not receiving SCT was 25.3 months. Median overall survival (OS) has not been reached at a median follow-up of 3.5 years. The 3-year OS estimate was 87%. Safety findings are summarized in the Table; 74% of patients had grade 3 treatment-related adverse events (AEs), and 26% of the patients had treatment-related serious AEs. Among treatment-related AEs of interest, grade 3 rash and peripheral neuropathy were infrequent. There was one treatment-related death due to respiratory syncytial viral pneumonia. After completing 12 cycles of induction therapy with IRd, 25 patients went on to receive maintenance single-agent ixazomib. In these 25 patients, at the end of the induction period ORR was 100%, including 44% VGPR and 32% CR. Responses deepened during maintenance; at data cut-off, the response rates in this maintenance therapy population were ORR 32%, PR 32%, and CR 10%. Patients who received maintenance therapy was 24 months. The occurrence of the most common treatment-related grade 3 AEs (neutropenia, thrombocytopenia, and fatigue) was confined almost exclusively to the induction period. During the maintenance period no patients reported onset of grade 3 peripheral neuropathy or rash.

Summary/Conclusions: In patients with NDMM, weekly ixazomib plus Rd, followed by single-agent ixazomib maintenance, was highly active, resulting in deep and durable responses, long PFS, and a high 3-year OS estimate. IRd followed by single-agent ixazomib maintenance also showed an acceptable safety profile, with less toxicity reported during the maintenance (single-agent ixazomib) vs induction (IRd) periods, with no evidence of cumulative toxicities.
Summary/Conclusions: Safety profile was acceptable; more patients required plerixafor in the KRd arm. Rate of VGPR was higher with KRd. Updated data on a higher number of patients will be presented at the meeting. The trial is registered at Clinicaltrials.gov: NCT02203643

S411
HOVON 104; FINAL RESULTS FROM A MULTICENTER, PROSPECTIVE PHASE II STUDY OF BORTEZOMIB BASED INDUCTION TREATMENT FOLLOWED BY AUTOLOGOUS STEM CELL TRANSPLANTATION IN PATIENTS WITH DE NOVO AL AMYLOIDOSIS
M. Minnema1,*, K. Nasserinejad2, B. Hazenberg3, U. Hegenbart4, L. Noens5, P. Ypma6, S. Zweegman7, L. Tick8, A. Broijl9, H. Koene10, G. Bos11, N. Thuss2, P. Sonneveld9, S. Schonland4
1Haematology, UMC UTRECHT, Utrecht, 2HOVON data center, ErasmusMC, Rotterdam, 3Rheumatology, UMCG, Groningen, Netherlands, 4Amyloidosis Center, University of Heidelberg, Heidelberg, Germany, 5Haematology, UZ Gent, Gent, Belgium, 6Internal Medicine, HAGA hospitals, the Hague, 7Haematology, VU medical center, amsterdam, 8Internal Medicine, Maxima Medical Center, Eindhoven, 9Haematology, ErasmusMC, Rotterdam, 10Internal Medicine, st Antonius Hospital, Nieuwegein, 11Haematology, University Hospital Maastricht, Maastricht, Netherlands

Background: Bortezomib (B) has been reported to be very effective in AL amyloidosis with overall response rates (ORR) varying between 50-80%. However, there are no prospective data from multicenter studies on B treatment in de novo patients. We investigated the efficacy and safety of B-Dexamethasone (BD) induction treatment followed by HDM+SCT in de novo AL amyloidosis patients.

Aims: The primary aim was to improve the hematological CR rate at 6 months after SCT on intention to treat analysis from 30 to 50%. Secondary aims were OS, PFS, hematological response rate after BD treatment, organ responses, safety and prognostic factors for survival.

Methods: Patients with biopsy proven AL amyloidosis, aged between 18-70 years, with detectable M-protein and/or level of involved FLC >50mg/L, WHO performance status 0-2, NYHA stage I-IV, ejection fraction >45%, were included. Major exclusion criteria were symptomatic orthostatic hypotension, NT proBNP level >5000 pg/ml, Troponin T > 0.06 u/ml, Bilirubin >2x ULN, eGFR<30 ml/min, CTCAE grade peripheral sensory neuropathy > grade 2 or > grade 1 with pain. Inclusion and exclusion criteria were installed both at entry and before stem cell mobilization (SCM). B was given subcutaneously 1.3mg/m2twice a week for 2 weeks in a 21-day cycle, D 20mg orally on each B day and the following day. HDM dosage was 200mg/m2. Hematological responses were defined according to consensus criteria with the addition of very good partial response (VGPR), defined as the difference between involved and uninvolved FLC<40mg/L. Cardiac, renal and liver response and progression criteria were defined according to consensus criteria with addition of NT proBNP.

Results: Median age was 59 years (range 26-70) and 60% were male. NYHA stage was 1 in 56% and 2 in 42% of patients. Mayo cardiac risk score was 1 (30%), II (36%), III (34%). Organ involvement was 82% renal, 66% heart, 28% liver, 14% neurological, 8% gastrointestinal and 38% of patients had 3 or more organs involved. Bone marrow plasmacells were >10% in 28% of patients. The median FU for patients alive is 24 (10-55) months. Twelve of 50 (24%) patients could not proceed to SCM. Four patients due to B related toxicity, 3 patients died (both amyloidosis related) and 3 miscellaneous. Of these 38 patients, 3 went subsequently off protocol because of ineligibility for HDM. Thirty-five out of 50 patients (70%) received HDM + SCT, one patient died of a cardiac arrest after the SCT procedure. The ORR after induction was 80%, ≥VGPR in 54% and CR in 6% of patients. The ORR in the 35 patients at 6 months after SCT was 80%, ≥VGPR in 51% and CR in 43% of patients. On intention to treat analysis the CR rate at 6 months after SCT was 30%. Organ responses at 6 months after SCT were 16/29 renal, 2/8 liver and 13/23 heart. No baseline characteristics were identified to be predictive for OS or PFS. BD doses were reduced and delayed after 2 cycles in almost half of patients, mostly because of neurotoxicity, Sensory neuropathy grade 2 or higher was seen in 36% of patients and autonomic neuropathy, mostly dizziness and collapse, in 22%.

Summary/Conclusions: This final analysis demonstrates that the primary aim of improving CR rate at 6 months after SCT from 30 to 50% was not met. This was mainly caused by the high dropout rate before SCT. This may be due to patient selection, but we also demonstrate that BD, given twice weekly sc, despite good efficacy, cannot prevent early amyloidosis related toxicity and can induce grade 2 or higher neurotoxicity.

Trial registration www.trialregister.nl (NTR 3220), EudraCT 2010-021445-42, supported by the Dutch Cancer Society (UU 2010-4884) and by an unrestricted grant from Janssen-Cilag.
NIVOLUMAB FOR RELAPSED/REFRACTORY CLASSICAL HODGKIN LYMPHOMA AFTER AUTOLOGOUS TRANSPLANT: FULL RESULTS AFTER EXTENDED FOLLOW-UP OF THE MULTICOHORT MULTICENTER PHASE 2 CHECKMATE 205 TRIAL

A. Engert1, A. Manale2, A. Santoro3, P. Armad4, S. Ansel5, P.L. Zinzani6, J. Timmerman7, G. Collins8, R. Ramchandren9, J. Cohen10, J.P. De Boer11, J. Kuruvilla12, K. Savage13, M. Trneny14, M. Shipp15, K. Kato16, A. Sumbul16, B. Farsaci16, A. Younes17, A. Seràgnoli”, University of Bologna, Bologna, Italy, 7University of California, Los Angeles, United States, 8Oxford Cancer and Haematology Centre, Churchill Hospital, Oxford, United Kingdom, 9Barbara Ann Karmanos Cancer Institute, Detroit, Winship Cancer Institute, Emory University, Atlanta, United States, 10Memorial Sloan Kettering Cancer Center, New York, United States

Background: Nivolumab, a fully human IgG4 monoclonal antibody targeting programmed death-1, is an immune checkpoint inhibitor that augments T-cell activation and antitumor responses. Nivolumab is indicated for pts with relapsed/refractory (RR) classical Hodgkin lymphoma (cHL) following autologous stem cell transplantation (ASCT) and brentuximab vedotin (BV) treatment. The multicohort phase 2 CheckMate 205 trial (NCT02181738) enrolled pts with RR cHL after ASCT into 1 of 3 independent cohorts (Cohort A: BV-naïve; Cohort B: BV after ASCT; Cohort C: BV after ASCT and brentuximab vedotin (BV) treatment. Per Independent Radiology Review Committee. Secondary endpoints included ORR, encouraging duration of response (DOR) and an acceptable safety profile.

Methods: This single-arm multicenter trial enrolled pts (age ≥18 y) with RR cHL after ASCT into 1 of 3 independent cohorts (Cohort A: BV-naïve; Cohort B: BV only after ASCT; Cohort C: BV before and/or after ASCT). All pts received nivolumab 3mg/kg every 2 wk until disease progression or unacceptable toxicity. Pts in Cohort C with a persistent complete response (CR) for 1 y were to discontinue nivolumab and could resume at relapse. Primary endpoint was ORR per Independent Radiology Review Committee. Secondary endpoints included DOR, progression-free survival (PFS), overall survival (OS), and safety were exploratory endpoints. All pts provided written informed consent.

Results: In total, 243 pts were treated: 63 in Cohort A (BV-naïve), 80 in Cohort B (BV after ASCT), and 100 in Cohort C (BV before [n=53], after [n=58], or both [n=12]) ASCT. Median (range) age was 34 (18-72) y and 77% of pts had advanced (stage III+/IV) disease at study entry. BV-naïve pts had fewer prior lines of therapy (median of 2 vs 4 with prior BV). At Dec 2016 database lock, median (min, max) follow-up was 19 (1, 25), 23 (2, 27) and 16 (1, 20) mo in Cohorts A, B, and C, respectively. Overall, 40% of pts were still on treatment; the most common reason for discontinuation was disease progression (26%). ORR was 65% in Cohort A, 68% in Cohort B, and 73% in Cohort C with, 29%, 13%, and 12% CR, respectively. Median (95% CI) DOR was 20 (13, 20), 16 (8, 20), and 15 (9, 17) mo in Cohorts A, B, and C, respectively. DOR for patients with CR was 20 months for BV-naïve patients (Cohort A) and ≥15 mo for BV-treated patients (Cohorts B and C); DOR for patients with partial response (PR) was 17 ±11 months, respectively. PFS by cohort is shown (Figure 1). Prolonged median PFS was seen for patients with CR (≥17 mo in each cohort), PR (≥15 mo in each cohort), and stable disease (≥9 mo in each cohort). Median OS was not reached in any cohort. The most common drug-related serious AEs were fatigue (23%), diarrhea (15%), infusion reactions (IRs; 14%), and rash (12%); 3-4 drug-related AEs in 33% of pts were grade 2 or greater, and alanine aminotransferase increases (3%), and neutropenia (3%). The most common drug-related serious AEs were PR (2%) and pneumonitis (1%). To facilitate translation to practice, efficacy results by sequencing of prior BV treatment will be presented.

Summary/Conclusion: With extended follow-up, high and durable rates of CR and PR to nivolumab therapy were observed in pts with RR cHL after ASCT, irrespective of BV treatment history.

Study funding: BMS; medical writing support: M Thomas (Caudex), funded by BMS.

References:
1A. Gallamini et al., Haematologica 2016). Durable responses to therapy are valuable in pts with progressive disease after failure of ASCT due to their limited translation to practice, efficacy results by sequencing of prior BV treatment will be presented.

Figure 1. Results: In total, 243 pts were treated: 63 in Cohort A (BV-naïve), 80 in Cohort B (BV after ASCT), and 100 in Cohort C (BV before [n=53], after [n=58], or both [n=12]) ASCT. Median (range) age was 34 (18-72) y and 77% of pts had advanced (stage III+) disease at study entry. BV-naïve pts had fewer prior lines of therapy (median of 2 vs 4 with prior BV). At Dec 2016 database lock, median (min, max) follow-up was 19 (1, 25), 23 (2, 27) and 16 (1, 20) mo in Cohorts A, B, and C, respectively. Overall, 40% of pts were still on treatment; the most common reason for discontinuation was disease progression (26%). ORR was 65% in Cohort A, 68% in Cohort B, and 73% in Cohort C with, 29%, 13%, and 12% CR, respectively. Median (95% CI) DOR was 20 (13, 20), 16 (8, 20), and 15 (9, 17) mo in Cohorts A, B, and C, respectively. DOR for patients with CR was 20 months for BV-naïve patients (Cohort A) and ≥15 mo for BV-treated patients (Cohorts B and C); DOR for patients with partial response (PR) was 17 ±11 months, respectively. PFS by cohort is shown (Figure 1). Prolonged median PFS was seen for patients with CR (≥17 mo in each cohort), PR (≥15 mo in each cohort), and stable disease (≥9 mo in each cohort). Median OS was not reached in any cohort. The most common drug-related serious AEs were fatigue (23%), diarrhea (15%), infusion reactions (IRs; 14%), and rash (12%); 3-4 drug-related AEs in 33% of pts were grade 2 or greater, and alanine aminotransferase increases (3%), and neutropenia (3%). The most common drug-related serious AEs were PR (2%) and pneumonitis (1%). To facilitate translation to practice, efficacy results by sequencing of prior BV treatment will be presented.
Overall, 150 (19.2%) proved PET2+ (97 score 4, 53 score 5) and 630 (80.5%) PET−. PET2+ patients were more frequently male (56.7% vs 47.1%, p=0.03), had higher IPS score (P=0.0002) and bulky disease (28.0% vs 17.9%; p=0.002). Out of 149 PET2+ patients randomized to Be+Bb (76) or Be+Bb+R (73), 136 were evaluable for response: 93 obtained CR and 43 had a treatment failure. Of the remaining 13 patients, 3 died, 7 withdrew their consent and 3 stopped treatment for toxicity. As per study protocol, 627 out of 630 PET2− patients continued with 4 ABVD cycles and 3 withdrew their consent. Overall, 30 patients (3.8%) died, due to early death (n=2), resistant disease (n=18; 12 with a positive and 6 with a negative PET2), transplant related toxicity (n=5), infections (n=4) and pulmonary fibrosis (n=1). After a median follow-up of 1303 days (2-2857), the 4-Y PFS and OS for all 782 patients was 93% (95% CI 87%-96%) and 96% (95% CI 83%-98%) and 96% (95% CI 94%-97%), respectively. For PET2+ and PET2− patients, the 4-Y PFS was 69% (95% CI 60%-76%) and 87% (95% CI 84%-89%), while the 4-Y OS was 69% (95% CI 82%-83%) and 97% (95% CI 95%-98%) (Figure 1, Panel A and B). No outcome difference was observed for Be+Bb vs Be+Bb+R patients, with a 4-Y PFS of 69% (95% CI 57%-79%) and 68% (95% CI 55%-78%), respectively (p=0.9731). Consolidation RxC in PET2− patients in CR after 6 ABVD and LNM did not translate in to a significant benefit, with a 4-Y PFS of 93% (95% CI 91%-98%) for RxC and 97% (95% CI 87%-96%) for NFT (p=0.2882).

Figure 1.

Summary/Conclusions: These data suggest that 1) an early switch from ABVD to escalated BEACOPP can be safely done in PET2+ advanced-stage cHL; 2) the long-term outcome for the entire patient cohort is superior to standard ABVD; 3) no clinical benefit is associated with post ABVD RxC in PET2− patients presenting with large nodal mass; 4) the addition of Rituximab does not increase the effectiveness of Be+Bb in PET2+ patients. 

S414

DISEASE CHARACTERISTICS AND SURVIVAL AFTER 3RD RECURRENCE OF CLASSICAL HODGKIN LYMPHOMA: AN ANALYSIS OF THE GERMAN HODGKIN STUDY GROUP

P.J. Bröckelmann1,*, H. Müller1, E. Kucüksoyanoglu1, A. Engert1, B. von Tresckow1

1Department of Internal Medicine and German Hodgkin Study Group (GHSG), University Hospital of Cologne, Cologne, Germany

Background: Data on disease presentation, therapeutic options and survival after 3rd or higher relapse of classical Hodgkin lymphoma (cHL) are sparse. Therefore the additional benefit of new agents, which are typically initially investigated after several relapses of cHL, is difficult to estimate.

Aims: The aim of this study was to define and describe a historical control group in European patients from the German Hodgkin Study Group (GHSG) data for comparison of safety and efficacy of novel therapeutic agents.

Methods: Cases with at least three consecutive tumor-related events or progressive refractory or relapsed disease, were identified in the GHSG database. Detailed information was added from case report forms and physician’s letters. Overall survival (OS) was the main and progression free survival (PFS), response to therapy, adverse events, disease and treatment characteristics as secondary endpoints.

Results: Among 12,584 HL patients in the GHSG first-line trials HD7 to HD15 and 449 HL patients in the trials HDR1 and HDR2 a total of 69 cHL patients with ≤3 tumor events were identified. The dates of occurrence of 3rd relapse ranged between 15th of January 1993 and 21st of June 2013. The sample consisted of 51 male (74%) and 18 female (26%) patients. At time of 3rd relapse, the age of the patients ranged from 20 to 79 years (mean 39.2 years, standard deviation (SD) 14.0 years) and the majority of patients presented with stage III or IV disease (67%). Time from end of 3rd-line treatment to 3rd relapse was ≤3 months (i.e. GHSG definition of refractory disease) in 15 cases (22%), ≤12 months (early relapse) in 19 cases (28%) and >12 months (late relapse) in 35 cases (51%). All 69 patients were pretreated with chemotherapy, 35 (50.7%) with BEACOPP, 30 (43.5%) with ABVD and no BEACOPP, and 32 (46.6%) with another type of chemotherapy. The number of prior chemotherapies ranged from one to three (median 3). Pretreatment with radiotherapy was observed in 57 (82.6%) patients, with salvage chemotherapy aimed to induce a remission prior to a stem-cell transplantation (SCT) in 58 (84.1%), and with high dose chemotherapy followed by autologous SCT in 50 (72.5%) patients. Four patients (5.8%) had received allogeneic SCT as 3rd-line treatment. None of the patients had received brentuximab vedotin or anti-PD1 antibodies before 3rd relapse. With a median observation time of 63.3 months for OS after 3rd relapse, 45 patients (65.2%) had died and 60 (87.0%) had an event; 12 patients (17.1%) were censored due to competing risk. Twelve months after the 3rd relapse OS was 73.2% (95%-CI 62.6% to 83.8%) and PFS 50.8% (95%-CI 38.9% to 62.8%, Table 1).

Summary/Conclusions: Patients with a 3rd relapse or progression of cHL have a dismal, mostly palliative prognosis due to frequent tumor progression. Within one year half of the patients have a PFS event and one fourth die.

S415

A REVISED STAGING SYSTEM FOR WALDENSTRÖM’S MACROGLOBULINEMIA

E. Kastritis1,*, M. Gavriatopoulou1, M.C. Kyrtsonis1, E. Katodritou2, P. Repoussis1, A. Symeonidis3, M. Michael5, A. Pouli1, N. Giannakoulas4, D. Christoulas1, A. Megalakaki1, P. Tsigiotis1, S. Giannouli1, P. Panagiotidis1, E. Vervessou1, E. Spanoudakis2, E. Terpos1, M.A. Dimopoulos1

1Greek Myeloma Study Group, Athens, 2Greek Myeloma Study Group, Thessaloniki, 3Greek Myeloma Study Group, Piraeus, 4Greek Myeloma Study Group, Paatras, Greece, 5Greek Myeloma Study Group, Nicosia, Cyprus, 6Greek Myeloma Study Group, Larissa, 7Greek Myeloma Study Group, Alexandroupolis, Greece

Background: Waldenström’s macroglobulinemia (WM) is a rare low-grade B-cell lymphoma characterized by the lymphoplasmacytic bone marrow infiltration and production of monoclonal IgM paraprotein. WM is an indolent lymphoma that has heterogeneous clinical manifestations and patients with this disease may have a prolonged disease course; however, there are groups of patients with poor outcomes after a relatively short disease course. In order to develop a robust staging system a collaborative effort resulted in the formulation of the International Prognostic Scoring System for WM (IPSS-WM) which was developed in 2009 based on data of patients that were treated primarily without rituximab and mainly with alkylators and nucleoside analogues. IPSSWM is based on five covariates (age, hemoglobin, platelet counts, IgM levels and b2 microglobulin) and stratifies WM patients into 3 broad risk groups. IPSSWM does not take into account non-HM used mortality, which is common and quite different among patients over the age of 75 years and does not include LDH, which is a well identified prognostic factor both in lymphomas and multiple myeloma.

Table 1.

Summary/Conclusions: Patients with a 3rd relapse or progression of cHL have a dismal, mostly palliative prognosis due to frequent tumor progression. Within one year half of the patients have a PFS event and one fourth die.
Aims: The aim of the current study was to revise the current IPSSWM by using a large dataset of symptomatic WM patients treated with different types of primary therapy that included rituximab and other new agents.

Methods: The analysis included 492 patients from the prospectively maintained database of the Greek Myeloma Study Group with a median follow up of 10 years. All patients fulfilled criteria for diagnosis and for treatment initiation according to Consensus Recommendations.

Results: In univariate analysis factors such as age, beta-2 microglobulin, serum albumin and LDH were all associated with poor outcome. The IPSSWM includes age and b2 microglobulin but not serum albumin, or LDH, while the presence of very high IgM (>7g/dl) was quite rare and of limited prognostic value. The presence of anemia <11.5gr/dl was common across all subgroups while low platelet counts <100x10^9/L was found in relatively few patients and had no prognostic significance. Based on ROC analysis for early death (within 3 years), serum albumin <3.5gr/dl and b2microglobulin >4mg/L were the two most important prognostic factors of early WM-related death. Age >65 years was associated with increased risk of death, however, age >75 years conferred additional risk (double hazard of death compared to those 65-75 years and fourfold compared to patients <65 years). Thus, we formulated a score in which high b2 microglobulin, elevated LDH and low serum albumin are scored with 1 point each, age 66-75 years is scored with 1 point but age >75 years is scored with 2. As a result, patients with scores 0, 1, 2, 3 or 4-5 had 3-year WM-related death rate of 3%, 7%, 14%, 19% and 48% (chi-square: 80.7, p<0.001). Regarding overall survival, 10-year survival rate was 85%, 59%, 39%, 28% and 12% (p=0.001) (Figure 1). Because age is a major determinant of disposition we also evaluated this staging system in patients >65 years and retained it prognostic significance. Compared to IPSSWM, this new staging system outperformed ISSWM: c-statistics, a measure of performance of a prognostic tool, was 0.711 (95% CI 0.659-0.763) vs 0.711 (95% CI 0.659-0.763) for the new staging system.

Summary/Conclusions: A revised staging system, based on b2 microglobulin, elevated LDH, low serum albumin and age identifies groups with very different outcomes among patients with symptomatic WM treated with contemporary regimens and may outperform IPSSWM.

Summary/Conclusions: The present study, includes a large number of pts with a long follow-up, confirms that R monotherapy is very effective in SMZL with minimal toxicity and is recommended as the treatment of choice for this disease.

S416

SPLENIC MARGINAL ZONE LYMPHOMA (SMZL) TREATED WITH RITUXIMAB (R) MONOTHERAPY: A LONG TERM FOLLOW-UP STUDY ON 104 PATIENTS

1Department of Haematology, University Hospital, University of Crete, Heraklion, 2Department of Haematology, Athens Medical Center-Psychikon Branch, 3Department of Haematology, University of Athens, Laikon General Hospital, 4Department of Anatomic Pathology, Evangelismos General Hospital, University of Athens, 52nd Department of Internal Medicine, University of Athens, 6Immunology Laboratory, Laikon General Hospital, 71st Department of Propedeutics, University of Athens, Laikon General Hospital, 8First Department of Internal Medicine, 9Department of Pathology, University of Athens, Athens, Greece

Background: Rituximab monotherapy has been used successfully in the treatment of SMZL and it can replace splenectomy, at least in 1st line.

Aims: To present our data on the outcome of R monotherapy treated pts after a long term follow-up.

Methods: The diagnosis of SMZL was based on the WHO criteria. Criteria for treatment initiation included: bulky/symptomatic splenomegaly, cytopenias or presence of B-symptoms. All pts received 6 weekly cycles of R as 1st line therapy at a dose of 375mg/m^2 (induction phase). None of the pts had been splenectomised before R treatment. Maintenance with R at a dose of 375mg/m^2 every 2 months for 1-2 years was given according to physician’s discretion. Response assessment was based on the SLSG consensus criteria. Survival curves were estimated using the Kaplan Meier method and compared by log-rank test.

Results: 104 pts with SMZL were included. 45% were males with a median age of 66 y (41-91). At diagnosis all pts had bone marrow infiltration with a median % of infiltration of 40 (10-85). Anemia and thrombocytopenia were present in 30% and 19%, respectively. 40% had absolute lymphocytosis. LDH was elevated in 43%. According to the SLSG prognostic system, 39% were classified in group A, 56% in group B and 5% in group C. The median time from diagnosis to treatment initiation was 2 months (0-203). 71 pts received R maintenance. The overall response rate 2 months after the end of induction treatment was 93% (CR, CRu and PR in 42%, 21% and 30%, respectively). Maintenance therapy improved the quality of response in 19 of them, 52 pts maintained their initial response and one relapsed during maintenance phase. The 5- and 10-year PFS, OS and CSS were 70% and 64%, 93% and 88%, 99% and 93%, respectively. Maintenance therapy was associated with better PFS (p=0.008). 22 pts relapsed (6 of them with histologic transformation to DLBCL). 11/22 were retreated with R and 9/11 responded. 8 deaths were recorded: 3 of them disease related. R therapy was well tolerated. Only one pt could not complete treatment due to intolerance.
Biology of MPN: JAK2 and beyond

S417

YOU DON’T KNOW JAK: A PROGRAMMED RIBOSOMAL FRAMESHIFTING DEFECT POTENTIATES THE TRANSFORMING ACTIVITY OF THE JAK2-V617F MUTATION

S. Sulima1,*, Y. Khan2, J. Briggs2, S. Vereecke1, J. Jones2, V. Advani2, J. Verbeeck1, K. De Keersmaecker1, J. Dinman2

1Department of Oncology, LKI, KU Leuven, Leuven, Belgium, 2Department of Cell Biology and Molecular Genetics, University of Maryland, College Park, United States

Background: The JAK-STAT pathway is a critical controller of cellular proliferation, differentiation, survival and apoptosis in response to external stimuli. Promiscuous activation of this pathway is an important driver in the pathogenesis of BCR/ABL-negative chronic myeloproliferative neoplasms. The JAK2-V617F allele is the most common and characterized mutation linked to this class of leukemia. The increased activation of JAK-STAT signaling in JAK2-V617F cells can be partially explained by increased JAK2 autophosphorylation. It is unclear however if these effects are sufficient to fully account for the strong activation of the JAK-STAT pathway induced by JAK2-V617F. We recently described programmed -1 ribosomal frameshifting (-1 PRF) as a novel mechanism regulating the expression of 10% of human genes, including cytokine receptors (Bleew AT et al, Nature, 2014). In this process, cis-acting mRNA elements (-1 PRF signals, which consist of a slippery site followed by a pseudoknot) direct translating ribosomes to slip by one base in the 3’ direction, establishing a new reading frame. This directs ribosomes towards premature termination codons, resulting in destabilization of the -1 PRF signal-containing mRNA via nonsense-mediated mRNA decay (Figure 1). There is thus an inverse relationship between -1 PRF efficiency and mRNA stability. Aims: To investigate whether the JAK2-V617F mutation, shown here to be located in the pseudoknot of a -1 PRF signal in the JAK2 mRNA, impacts disease progression through ablation of -1 PRF. Methods: Computationally predicted -1 PRF signals were validated using dual luciferase reporters and proteomic analysis of a -1 PRF fusion protein. -1 PRF as well as mRNA abundance and decay were assayed in HEK293T and HeLa cells. Transformation assays were performed in HEK293 expressing Ba/F3 cells, in vivo experiments were performed in BALB/c mice.

Figure 1.

Results: We demonstrate in human cell lines that the JAK2-V617F mutation structurally disrupts the -1 PRF signal in the JAK2 mRNA, leading to -2-fold lower rates of -1 PRF and increased abundance of the JAK2 mRNA and protein. The transforming potential of a series of mutants designed to manipulate -1 PRF independent of V617F was assayed in a Ba/F3 cell model. Silent protein coding changes in the pseudoknot of the -1 PRF signal at position V617 (V617m) or the slippery site (SSm), both of which drastically reduced frameshifting, increased JAK2 expression and led to transforming activity, albeit less than V617F. Importantly, the V617F+SSm combination conferred an additive effect on cellular transformation. Ba/F3 cells expressing these JAK2 variants were also introduced into mice. Whereas mice injected with wild type JAK2 remained healthy, both V617m and SSm induced similar leukemia phenotypes as V617F and V617F+SSm, with a -2-fold longer disease latency of 8-10 weeks. Increased JAK2 mRNA abundance in JAK2-V617F homozygous patients as well as the presence of three additional -1 PRF signals in the JAK2 mRNA further suggest a prominent role for -1 PRF in controlling JAK2 expression, contributing to its transforming activity in vitro and disease onset in vivo. We suggest that -1 PRF normally provides a layer of control by limiting JAK2 translation. Defective -1 PRF synergizes with the transforming activity of the JAK2-V617F protein by causing its overexpression, explaining why this particular mutation causes such aggressive malignancies. In support of this, the combination of ruxolitinib and an HSP-90 inhibitor, which reduce kinase activity and JAK2 expression respectively, leads to increased therapeutic efficacy in myeloproliferative neoplasms (Bhagvat N et al, Blood, 2014).

S418

EFFECTIVENESS OF LSD1 INHIBITION FOR THE TREATMENT OF MPN

J.S. Jutzi1,*, H. Rienhoff2, H.L. Pahl1

1Clinic for Tumorbiology, University Medical Center, Freiburg, Germany, 2Imago Biosciences, San Francisco, United States

Background: Treatment of MPN with JAK inhibitors ameliorates symptoms and splenomegaly but does not meaningfully reduce the JAK2V617F allele burden. Though curative, stem cell transplantation is associated with extensive morbidity and mortality highlighting the need for novel effective therapies. The histone “lysine-specific demethylase 1A” (LSD1/KDM1A) is being explored as a drug target. JAK inhibitors alone already demonstrate durable responses which is critical for sustaining self-renewal in leukemic initiating cells; inhibiting LSD1 induces monocytic differentiation and reduces engraftment of AML cell in vivo. LSD1 is over-expressed in a number of myeloid diseases including MPN. Preliminary data in a mutant mpl mouse model of MPN showed that a 28-day course of LSD1 inhibition had a beneficial impact on spleen size, cytokines and mutant cell burden. In a mutant JAK2 mouse model of MPN, we have characterized the disease-modifying activity of the LSD1 inhibitor (IMG-7289), a compound in clinical development for myeloid disorders (NCT02842827).

Aims: We assessed the pharmacodynamic effects of continuous daily treatment with IMG-7289 in a JAK2V617F knock-in murine MPN with established disease. Animals were treated for up to 56 days. Outcome measures included complete blood counts (CBC), hematological phenotype, overall survival, spleen size, bone marrow morphology and the JAK2V617F allele burden. Moreover, pro-inflammatory cytokine were monitored during the course of treatment as well as chromatin changes by western blotting and ChIP-seq.

Methods: JAK2V617F-FL2 mice were crossed to MxCRE mice and displayed a fulminant MPN phenotype without did induction. CBC and BM FACs analysis were conducted as previously described. We designed a qPCR assay to quantify murine JAK2V617F allele burden.

Results: IMG-7289 treatment was exceptionally well tolerated and mice showed drastic decreases in platelet count (208 vs 2063*10^3/μl), reticulocytes (800 vs 1674*10^3/μl), monocytes and neutrophils 14 days after the start of treatment. HCT and WBC started to decrease after 28 days. While the JAK2 mutant allele burden increased over time in untreated mice, it decreased in IMG-7289 treated mice and drastically significantly in peripheral blood as well as in spleen. We observed a drastic increase in the pro-inflammatory cytokine CXCL5 in untreated mice during the course of investigation while CXCL5 levels of treated mice decreased to levels of wild-type littermates. Moreover, treated mice showed a highly significantly increased survival over untreated mice, even in a late stage of disease. Lastly, we were able to show that global H3K9me2, which is generally associated with gene expression silencing, was increased in the bone marrow of IMG-7289 treated mice compared to control mice. The remaining pathophysiological data and functional data on epigenetic regulation will be presented.

Summary/Conclusions: The LSD1 inhibitor IMG-7289 normalizes or stabilizes elevated CBCs in a JAK2V617F MPN mouse model. It decreases JAK2 mutant allele burden, pro-inflammatory cytokine levels and confers a clear survival advantage. Our preliminary data show that LSD1 is a potent target with disease-modifying potential in MPN. Clinical studies with IMG-7289 testing this hypothesis have just begun. Owing to its mode of action, altering epigenetics, and the potential reversibility of drug-induced epigenetic remodeling, a long treatment period in MPN patients may be necessary to eliminate disease. Combining IMG-7289 with JAK1/2 inhibitors might accelerate treatment effects.

S419

LOSS OF RAF KINASE INHIBITOR PROTEIN IS INVOLVED IN MYELOMONOCYTIC LINEAGE COMMITMENT AND AGGRAVATES THE DEVELOPMENT OF CHRONIC MYELOMONOCYTIC LEUKEMIA IN A MURINE IN-VIVO MODEL

V. Caraffini1,*, O. Geiger1, A. Rosenberger1, S. Hatz1, B. Perler1, J.L. Berg1,
Aims: In this work, we aimed at investigating the role of RKIP in the development of CMML.

Methods: RKIP expression was measured by immunoblot and quantitative real-time PCR in 23 primary CMML patient samples as well as in CD34+ HSCs, B-lymphocytes, granulocytes and monocytes of four healthy donors. Sequence analysis of CMML samples was done with an Ion Torrent Next Generation Sequencing platform using an amplicon panel covering 39 genes recurrently mutated in myeloid neoplasms. Effects of RKIP on GM-CSF-induced myelomonocytic differentiation were studied in human CD34+ HSCs transduced with RKIP shRNA, as well as in a genetic mouse model for RKIP deletion (RKIP-−/−). Effects of RKIP on CMML development were initially studied in the same RKIP-−/− model. Additionally, these mice were crossed with animals exhibiting a somatically inducible mutation in NRAS (RKIP−/−Mx1-Cre-NRASG12D) and the severity of CMML-MPD onset was studied at an age of six months.

Results: Loss of RKIP protein expression was observed in 6/23 (26%) CMML patient specimens and was associated with decreased mRNA levels as well (P<0.001). Patients with RKIP loss exhibited an increased percentage of myelomonocytic cells in the peripheral blood (56% vs 75%, P=0.0226). One or more mutations affecting the RAS signaling pathway were detected in all specimens with RKIP loss. In addition to the previously demonstrated induction of proliferation, we then aimed to delineate a role of RKIP loss in myeloid lineage commitment. When studying healthy donors, we observed that RKIP expression was high in HSCs and lymphoid cells, but significantly decreased in cells belonging to the myeloid lineage (monocytes, P=0.001 and granulocytes, P<0.001). In functional experiments, knockdown of RKIP increased the GM-CSF-induced myelomonocytic lineage commitment of both, human and murine HSCs (P<0.05 and P=0.0295, respectively). These results could be corroborated in-vivo, as intraperitoneal injection of GM-CSF caused a significant increase of myelomonocytic cells in the intraperitoneal cavity (P=0.006, bone marrow (P=0.007) and peripheral blood (P=0.027) in RKIP−/− mice when compared to their wildtype littermates. In a final step, we evaluated the potential of RKIP loss to cause CMML-MPD in mice. While it proved to be insufficient to cause the disease as a single event in RKIP−/− mice, it aggravated the CMML-MPD phenotype in animals carrying an additional mutation in NRAS. In this case, RKIP loss caused worsening of leucocytosis (P=0.035) and splenomegaly (P=0.025), which was associated with increased levels of myelomonocytic cells in the bone marrow (P=0.028), peripheral blood (P=0.002) and spleen (P=0.025).

Summary/Conclusions: RKIP loss is a frequent event in CMML and is associated with mutations affecting the RAS signaling cascade. Loss of RKIP is functionally involved in myelomonocytic lineage commitment of HSCs and aggravates CMML-MPD development in mice carrying an additional mutation in NRAS.
Background: The hematopoietic stem cell (HSC) compartment in mice encompasses a broad range of heterogeneous cell types including highly lineage-biased HSCs, such as platelet-biased HSCs (PMID:23934107). Myeloproliferative neoplasms (MPNs) are a heterogeneous spectrum of clonal hematopoietic disorders, that includes essential thrombocytopenia (ET), a MPN-subtype usually presenting with isolated thrombocytosis. Most ET patients carry a gain-of-function point mutation in JAK2 (JAK2V617F), with several other collaborating hits reported to co-occur with JAK2V617F at lower frequencies, including down-regulation of several signaling pathways, including Hedgehog, and increased inflammation associated gene expression in EZH2-KO HSCs. Unexpectedly in this mouse model of thrombocytosis, phenotypic analysis of the HSC compartment in the BM showed that platelet-biased HSCs might selectively promote development of an ET phenotype.

Methods: We generated a novel mouse model of MPN that carries a conditional knock-in of heterozygous human JAK2V617F (hJAK2V617F) and the conditional knock-out (KO) of EZH2 together with an inducible Mx1-Cre transgene. To analyse platelet-biased HSC subsets upon onset of the mutation(s), we also crossed in the vwf-eGFP transgene, which is selectively expressed in platelet-biased HSCs.

Results: Compared to wild-type and single mutant mice, EZH2-KO hJAK2V617F mice showed increased platelet counts, including a subset of mice which became acutely unwell with an extreme thrombocytosis. Strikingly, in serial bone marrow (BM) transplantation assays, EZH2-KO fully rescued the previously described hJAK2V617F-associated transplantation defect (PMID:20489053). EZH2-KO hJAK2V617F BM recipients showed long-term serial engraftment that was fully restricted to the platelet and myeloid lineages with a persistent thrombocytosis and absence of lymphoid reconstitution. RNA-sequencing revealed upregulation of several signaling pathways, including Hedgehog, and increased inflammation associated gene expression in EZH2-KO hJAK2V617F HSCs. Unexpectedly in this mouse model of thrombocytosis, phenotypic analysis of the HSC compartment in the BM showed that vwf-eGFP+ve HSCs were selectively lost (fold change[FC]=0.12 p=0.009), while vwf-eGFP–ve HSCs from Ezh2-KO hJAK2V617F mice primarily gave rise to platelet/myeloid lineage-committed HSCs.

Summary/Conclusions: In this novel Ezh2-KO hJAK2V617F mouse model, EZH2 loss collaborates to worsen thrombocytosis and rescue the HSC function defect in hJAK2V617F mice. We also observed a striking disruption of phenotype and functional HSC heterogeneity in Ezh2-KO hJAK2V617F mice with an unexpected and selective loss of vwf-eGFP+ve HSCs together with subversion of vwf-eGFP–ve HSCs towards platelet/myeloid lineage commitment. This previously undescribed disruption of HSC heterogeneity in myeloid malignancy together with the clonal advantage conferred to HSCs by EZH2-KO helps to explain how this collaborating mutation might promote the development of more advanced MPN.
<p>Methods: Pts aged <18 years were recruited into 3 separate cohorts: (1) IM-resistant/intolerant CML-CP treated with DAS tablets 60mg/m² QD. (2) IM-resistant/intolerant CML-AP/BP or Ph+ ALL (enrollment closed early due to poor response), and (3) newly diagnosed CML-CP treated with DAS tablets 60mg/m² or DAS 72mg/m² powder for oral suspension (PFOS) QD for ≥1 year. PFOS dose was increased by 20% to match the exposure of the tablet in order to maintain efficacy based on the findings from a bioequivalence study in adults. Primary objectives were major cytogenetic response (MCyR) for CML-CP resistant/intolerant to IM and complete cytogenetic response (CCyR) for newly diagnosed CML-CP (MCyR >30% and CCyR >55% considered of clinical interest). Study cohorts were not designed to be comparative. Results: From 145 pts enrolled, 130 were treated; 54% were aged ≥12-<18 years. Within the IM-resistant/intolerant group, 25 were resistant, 2 were intolerant, and 2 were undetermined. For pts with CML-CP (n=113), 48% of pts with IM-resistant/intolerant CML-CP and 73% with newly diagnosed CML-CP remained on treatment at the time of this analysis (table 1). Cumulative rate of MCyR was met as early as 3 months for IM-resistant/intolerant CML-CP, and a cumulative rate of CCyR >55% was reached as early as 6 months for newly diagnosed CML-CP (table). Estimated progression-free survival (PFS) by 48 months was 78% for IM-resistant/intolerant CML-CP and 93% for newly diagnosed CML-CP (table). Reasons for progression were loss of MCyR (n=3) IM-resistant/intolerant; n=4 newly diagnosed, loss of complete hematologic response (n=2 each), and development of CML-CP (n=2 IM-resistant/intolerant; n=1 newly diagnosed). One death was reported in the IM-resistant/intolerant CML-CP cohort 1 year after stopping DAS (gastrointestinal bleeding). Adverse events (AEs) were consistent with reports in DAS-treated adults, except no DAS-related pleural/pericardial effusion, pulmonary edema/hypertension, or pericardial effusion were reported here. Hypersensitivity in a newly diagnosed pt was the only DAS-related AE that led to discontinuation. Summary/Conclusions: Results from the largest prospective and registrational trial of pediatric pts with CML-CP demonstrate that DAS is a safe and effective treatment for pediatric CML-CP. Target responses for first- or second-line therapy at DAS were met as early as 3 and 6 months, respectively, and deep responses were observed. Efficacy and safety of DAS in pediatric pts were similar to those observed in adults; however, unlike in adults, no cases of pleural/pericardial effusion were reported.</p>
Background: Bosutinib (BOS) is a potent, dual SRC/ABL tyrosine kinase inhibitor approved for treatment of adults with Philadelphia chromosome-positive (Ph+) chronic myeloid leukemia (CML) resistant or intolerant to prior therapy.

Aims: To assess the efficacy and safety of BOS versus imatinib (IM) for first-line treatment of chronic phase (CP) CML in the BFORE trial (NCT02130557). Methods: In this ongoing, multinational, phase 3, open-label study, 536 patients with newly diagnosed CP CML were randomized 1:1 to BOS 400mg once daily (n=268) or IM 400mg once daily (n=268 [3 not treated]). Informed consent was obtained from all patients. Per protocol, efficacy was assessed in a modified intent-to-treat (mITT) population of 487 Ph+ patients (BOS, n=246; IM, n=241) with ≥14a2 transcripts—Ph+ patients and those with unknown Ph status and/or BCR-ABL transcript type were excluded from this population.

Results: After ≥12 months of follow-up, 78.0% of BOS and 73.2% of IM patients remain on treatment with median treatment durations of 14.1 months and 13.8 months, respectively. Major molecular response (MMR) rate at 12 months (primary endpoint) was significantly higher with BOS versus IM in the mITT population (47.2% vs 36.9%; P=0.02) as well as in the ITT population of all randomized patients (46.6% vs 36.2%; P<0.02). In the mITT population, time to MMR was shorter for BOS (hazard ratio=1.34 based on cumulative incidence; P=0.02). Rate of complete cytogenetic response (CCyR) by 12 months was also significantly higher with BOS versus IM (77.2% vs 66.4%; P=0.038), with time to CCyR shorter for BOS (hazard ratio=1.38; P=0.001). Rate of BCR-ABL transcripts ≤10% (Intl. Scale) at 3 months was higher with BOS versus IM (75.2% vs 57.3%; P<0.001); rates of deep molecular response over time were also generally higher with BOS (Table). Results for molecular endpoints were similar in the ITT population. The only baseline characteristic identified as a significant predictor of MMR at 12 months besides treatment arm was Sokal risk group (high vs low; P=0.0001 and intermediate vs low; P=0.05 [mITT]). On-treatment progression to accelerated or blast phase occurred in 4 patients (1.6%) receiving BOS and 6 patients (2.5%) receiving IM in the mITT population. One BOS-treated and 4 IM-treated patients discontinued treatment due to progression to accelerated or blast phase. Among all treated patients, there were no deaths within 28 days of last dose of BOS and 4 with IM. Safety data for treated patients were consistent with the known safety profiles of BOS and IM. Discontinuation due to drug-related toxicity occurred with 12.7% of BOS patients and 8.7% of IM patients. Grade ≥3 diarrhea (7.8% vs 3.0%, 1.5%, and 0.4% BOS vs IM) and increased alanine (19.0% vs 3.0%, 1.5%, and 0.4% BOS vs IM) were more common with BOS. Cardiovascular, peripheral vascular, and cerebrovascular events were infrequent in both groups (all grades: 3.0%, 1.5%, and 0% BOS vs 0.4%, 1.1%, and 0.4% IM; grade ≥3: 1.5%, 0%, and 0% BOS vs 0%, 0%, and 0.4% IM).

Table 1.

Summary/Conclusions: Patients on BOS had significantly higher rates of 12-month MMR and CCyR and achieved responses faster than those on IM. Consistent with the known safety profile, higher incidences of gastrointestinal events and transaminase elevations were observed with BOS. Primary results from this study suggest BOS may be an important treatment option for patients with newly diagnosed CP CML.

ETO2-GLIS2 RECRUTIS ETO2/ERG COMPLEX AT SUPER-ENHANCERS TO CONTROL TRANSCRIPTION AND DRIVE LEUKEMIC PROPERTIES IN PEDIATRIC ACUTE MEGAKARYOBLASTIC LEUKEMIA

Methods: We first defined the consequences of ETO2-GLIS2 expression on hematopoietic progenitors and the contribution of ETO2 and GLIS2 on differentiation and self-renewal by methylcellulose replating assays and phenotype characterization. We then assessed global expression profiling and ETO2-GLIS2 direct binding on DNA by ChIPseq experiments. With immunoprecipitation experiments, we identified some ETO2-GLIS2 complex members. Finally, we tested the effects of a small peptide that could inhibit ETO2-GLIS2 complex stabilization both in vitro and in vivo.

Results: We showed that the GLIS2 moiety drives the megakaryocytic phenotype whereas both the ETO2 and GLIS2 moieties are required for maintaining self-renewal. Global expression profiling and comparison to patients’ signature consistently identified ETO2-GLIS2-mediated deregulation of major transcriptional regulators of hematopoiesis and leukemogenesis. Especially, ETO2-GLIS2 brings on an imbalance in ETS/GATA factors illustrated by an extinction of GATA1 and an overexpression of the ERG oncogene. We identified that ETO2-GLIS2 directly binds DNA via ETO2 complexes and through its GLIS2 moiety. Moreover, the ETO2-GLIS2 fusion localizes at half of H3K27ac-dense enhancers, so called super-enhancers, to control transcription of associated genes, in close association with ERG. Dimerization of ETO2-GLIS2 and interaction with endogenous ETO2 via its NHR2 domains were demonstrated with ChIPseq experiments. NHR2 perinuclear localization prevented the oligomerization, reversed the transcriptional activation at enhancers, promoted megakaryocytic differentiation and abrogated human AMKL cells maintenance in vitro. So, the interaction of ETO2-GLIS2 with ETO2 complexes is an essential node for the transcriptional control by the fusion at enhancer elements. Finally, ERG is localized at super-enhancers and is involved in the up-regulation of associated genes. ERG knockdown or genetic inactivation downregulates expression of ETO2-GLIS2 targets required for leukemic cells survival. Together, the strong up-regulation of ERG by the fusion and the presence of ERG at super-enhancers suggest a feed forward mechanism to impose gene deregulation.

Summary/Conclusions: In conclusion, we propose that the megakaryocytic differentiation arrest and self-renewal controlled by ETO2-GLIS2 results from imbalance expression of master transcription factors imposed by aberrant chromatin structures at enhancers that may be disrupted by targeting the NHR2 interface.

Background: Acute myeloid leukemia (AML) is characterized by rapid growth and block in differentiation of myeloid progenitors. The AML blast is defined by having “open” chromatin. We hypothesized that alterations of chromatin compaction may promote AML. Reversing those changes could represent a novel therapeutic approach.

Aims: Gain of chr21q22 is the most common focal amplification in complex karyotype AML. HMGN1 is a chromatin-remodelling protein on 21q22 known to affect lymphoid development, and our preliminary data suggested that HMGN1 could directly mediate a myeloid differentiation block. Since HMGN1 is known to decompact chromatin and alter histone marks, our goal was to define and therapeutically target the mechanisms by which HMGN1 overexpression disrupts myeloid differentiation and promotes clonal dominance.

Methods: We immortalized bone marrow progenitors from wild-type (WT) or OE-HMGN1 mice (transgenic overexpressing HMGN1) with an estrogen receptor-HoxB8 fusion protein. Using exogenous estrogen to control nuclear translocation of HoxB8, we analyzed synchronized myeloid differentiation by flow cytometry, RNAseq, and TMT proteomic analysis. We performed MINT-ChIP-seq (MNase Indexed T7-Chromatin IP) to measure the histone marks H3K27ac, H3K27me3, H3K4me3 and total Histone H3. We also measured histone marks in hematopoietic stem and progenitor subpopulations in vivo. We performed competitive bone marrow transplantation with CD45.1 WT and CD45.2 OE-HMGN1 donors and measured the relative contribution to hematopoiesis over time.

Results: Synchronized differentiation in WT cells progressed over 6 days from myeloid progenitors to mature neutrophils and monocytes, analyzed by cell surface markers, morphology, and gene and protein expression. OE-HMGN1 cells proliferated faster and remained as undifferentiated myeloblasts (84% CD11b+Gr1+ in WT vs 4% in OE-HMGN1, p<0.002; Fig A). Gene set enrichment analysis revealed more similarity to undifferentiated hematopoiesis and leukemia signatures in OE-HMGN1 cells. MINT-ChIP indicated a higher global and locus-specific levels of H3K27ac in OE-HMGN1 cells (Fig B, upper panel), consistent with an increase in gene transcription, confirmed by RNA-seq. We found a specific increase in HoxA cluster expression in OE-HMGN1 cells, consistent with an increase in gene transcription, confirmed by RNA-seq. We found a specific increase in HoxA cluster expression in OE-HMGN1 cells, high- est at HoxA7 and HoxA9, genes known to be important in AML pathogenesis. In agreement with gene expression, among the most differentially measured histone peaks genome-wide were higher H3K27ac at HoxA genes promoters (84% Cd11b+Gr1+ in WT vs 4% in OE-HMGN1, p<0.002; Fig A).

Discussion: Gain of chromosome 21q22 is the most frequent molecular feature in complex karyotype AML. We found a specific increase in HoxA cluster expression in OE-HMGN1 cells, high- est at HoxA7 and HoxA9, genes known to be important in AML pathogenesis. In agreement with gene expression, among the most differentially measured histone peaks genome-wide were higher H3K27ac at HoxA genes promoters (84% Cd11b+Gr1+ in WT vs 4% in OE-HMGN1, p<0.002; Fig A).

Summary/Conclusions: Our study suggests that HMGN1 overexpression blocks myeloid differentiation and promotes proliferation in hematopoietic progenitors via increased H3K27 acetylation. Targeting epigenetic changes downstream of HMGN1 or interfering with HMGN1 itself may represent a novel therapeutic strategy in AML.

Figure 1.

Summary/Conclusions: Our study suggests that HMGN1 overexpression blocks myeloid differentiation and promotes proliferation in hematopoietic progenitors via increased H3K27 acetylation. Targeting epigenetic changes downstream of HMGN1 or interfering with HMGN1 itself may represent a novel therapeutic strategy in AML.

Background: Immune thrombocytopenia (ITP) is an autoimmune disorder characterized by increased platelet destruction and impaired platelet production. Despite decades of basic and clinical research, the treatment of severe, corticosteroid-resistant or relapsed disease remains a great challenge. Our preliminary study indicated the effectiveness of all-trans retinoic acid (ATRA) for ITP (Wang M, et al. ASH 2012, Abstract #3338). This has been coupled with previous discoveries of an immune-modulation effect of ATRA in ITP, including its role to induce changes in Treg cells (Ruan CG 2016), and to correct the imbalance of aberrant macrophage polarization (unpublished data), indicating ATRA as a potential therapeutic regimen. Danazol has been used in the treatment of ITP for more than 30 years. Apart from its haemopoietic stimulatory and immune-modulatory effect, it has recently been shown to reverse abnormal macrophage function in patients with thrombocytopenia (Towsley DM et al. ASH 2016). The combination of ATRA and danazol may work synergistically based on the mechanism of action targeting both increased platelet destruction and insufficient platelet production.

Aims: To investigate the efficacy and safety of ATRA plus danazol in patients with corticosteroid-resistant or relapsed ITP.

Methods: A multicentre prospective study was performed in non-splenectomized corticosteroid resistant/reapsed ITP patients. Participants were at least 18 years of age, had a platelet count of less than 30×10^9/L at enrolment, and did not achieve a sustained response to treatment with full-dose corticosteroids for a minimum duration of 4 weeks or relapsed during steroid tapering or after its discontinuation. Written informed consents were obtained from all of the participants. The primary endpoint was a sustained response. The secondary endpoints included overall response, time of response, duration of response, incidence of bleeding symptoms and safety.

Results: A multicentre prospective study was performed in non-splenectomized corticosteroid resistant/reapsed ITP patients. Participants were at least 18 years of age, had a platelet count of less than 30×10^9/L at enrolment, and did not achieve a sustained response to treatment with full-dose corticosteroids for a minimum duration of 4 weeks or relapsed during steroid tapering or after its discontinuation. Written informed consents were obtained from all of the participants. The primary endpoint was a sustained response. The secondary endpoints included overall response, time of response, duration of response, incidence of bleeding symptoms and safety.

Summary/Conclusions: Our findings demonstrate that the combination of ATRA and danazol is safe and effective in achieving a rapid and long-lasting response, making it a potential promising therapeutic option for patients with severe, corticosteroid-resistant or relapsed ITP.

Background: MYH9-related disease (MYH9-RD) is an autosomal-dominant disorder caused by mutations in MYH9, the gene for non-muscle myosin heavy
Aims: To test the hypothesis that mutations in the regulatory domain of MYH9 gene are associated with severe thrombocytopenia and platelet dysfunction.

Methods: Whole exome sequencing was performed in 86 propositi with chronic thrombocytopenia. Results: WES detected a monoallelic loss-of-function mutation in the THPO-MPL axis in 3 propositi. Conclusion: Monoallelic mutations in the THPO-MPL axis are associated with severe thrombocytopenia and platelet dysfunction.

Aims: To investigate the role of GFI1B in megakaryocytes differentiation and function.

Methods: GFI1B expression was tested in patient iPSC derived megakaryocytes. Results: GFI1B mRNA expression was increased in cells derived from individuals with both C168F and CH294fs mutations. Conclusion: GFI1B is a critical regulator of megakaryocytes differentiation and function.

Aims: To investigate the role of GFI1B in megakaryocytes differentiation and function.

Background: ITP is characterized by autoantibody-directed platelet destruction mediated by activated monocye Fc receptors which signal via spleen tyrosine kinase (syk). A Phase 2 trial of the oral syk inhibitor Fostamatinib (FOSTA) in 16 patients (pts) with refractory ITT provided preliminary efficacy and safety data (Podolanczuk et al., 2009).

Aims: To evaluate the efficacy and safety of FOSTA in adult cITP in 2 parallel, identical, multi-center, randomized, double-blind phase 3 studies (S047 and S048) of 24 weeks duration, followed by an open label study (S049).

Methods: 150 pts with 3 platelet (ptt) counts (<30K/μL) were enrolled (76 in S047, 74 in S048) in a 2:1 randomization to FOSTA 100mg or placebo bid, and stratification by prior splenectomy and baseline plt ct<or ≥15K/μL. Sixty-one % of pts were female; median age was 54 y (20-88); 93% were Caucasian; and stratification by prior splenectomy and baseline plt ct<or ≥15K/μL. Sixty-one % of pts were female; median age was 54 y (20-88); 93% were Caucasian; 93% had cITP; median disease duration: 8.5 y; median baseline plt ct: 16K/μL.

Results: Across both studies, a SR occurred in 18/101 (18%) FOSTA vs 1/49 (2%) placebo pts, but not in the 29 responders. The number of pts with ≥1 adverse event (AE) was similar in FOSTA vs placebo (54% vs 52%). The majority AEs on FOSTA were mild or moderate; all resolved over time. Most common AEs were: diarrhea (29% vs 15%), nausea (19 vs 8%), hypertension (20 vs 8%), ALT/AST increase (10% vs 0%). Serious AEs were reported in 13% FOSTA vs 21% placebo pts.

Summary/Conclusions: Fostamatinib substantially improves plt tcts in certain pts with heavily pre-treated, severe cITP of long disease duration. AEs are mostly mild or moderate in severity. Given its unique mechanism of action based on inhibition of syk, FOSTA could, if approved, be an important alternative as single agent and be a useful component of combination therapy for pts with difficult cITP.

THE YING AND YANG OF JAK SIGNALING : LOSS OF USP9X BUFFERS JAK SIGNALING AND ENHANCES SURVIVAL OF CRLF2-JAK-STAT EXPRESSING B CELL PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA

H. Reisler1, M. Bar-Shira1, D. Peleg2, J. Ashkenazi3, A. Weinberger4, D. Ron5, M. Hamer1, G. Balaban1, M. Scheps6, M. Shemesh1, N. Biron1, A. Milo3, R. Friedel4, I. Goren7, Y. Ben Har-Zvi1,8, S. Zilberman9, T. Dvir1,10,11,2

Background: Children with Down syndrome (DS) are prone to development of high risk B cell precursor (BCP) acute lymphoblastic leukemias (DS-ALL) that differ genetically from most sporadic pediatric ALLs. Chromosomal rearrangements causing increased expression of CRLF2, the receptor for thymic stromal lymphopoietin (TSLP), characterize about half of DS-ALLs. Aims: Understanding the pathogenesis of relapse of DS-ALL relating to their CRLF2 status.

Methods: Integrative genomic analysis of matched diagnosis remission and relapse DS-ALLs, pharmacological inhibition and genetic CRISPR mediated silencing.

Results: Genomic analysis of 25 matched diagnosis remission and relapse DS-ALLs, pharmacological inhibition and genetic CRISPR mediated silencing.

Background: Children with Down syndrome (DS) are prone to development of high risk B cell precursor (BCP) acute lymphoblastic leukemias (DS-ALL) that differ genetically from most sporadic pediatric ALLs. Chromosomal rearrangements causing increased expression of CRLF2, the receptor for thymic stromal lymphopoietin (TSLP), characterize about half of DS-ALLs. Aims: Understanding the pathogenesis of relapse of DS-ALL relating to their CRLF2 status.

Methods: Integrative genomic analysis of matched diagnosis remission and relapse DS-ALLs, pharmacological inhibition and genetic CRISPR mediated silencing.

Results: Genomic analysis of 25 matched diagnosis remission and relapse DS-ALLs, pharmacological inhibition and genetic CRISPR mediated silencing.

These observations suggest that genetic or pharmacological restraining of JAK-STAT signaling may be beneficial to leukemic B cell precursors by enhancing the fitness of JAK-STAT driven CRLF2 mutated leukemic cells. Both pharmacological and genetic CRISPR mediated silencing of USP9X reduced STAT5 phosphorylation and enhanced the survival of CRLF2-JAK2R683Gs transduced ALL cells. To test directly the effect of JAK inhibition, we treated CRLF2/JAK2R683G transduced cells with increasing doses of ruxolitinib, an JAK inhibitor currently in clinical trials for CRLF2-JAK-STAT ALLs. Strikingly while high doses (>2μM) were cytotoxic, low doses (0.25μM) enhanced the survival of CRLF2-JAK2R683Gs expressing ALL cells. Summary/Conclusions: These observations suggest that genetic or pharmacological restraining of JAK-STAT signaling may be beneficial to leukemic B cell precursors by enhancing the fitness of JAK-STAT driven ALL. This and the reduction of JAK-mutated clones at relapse suggest that pharmacological effect of JAK2 specific inhibitors may be limited. Rather, combined silencing inhibitors or direct targeting of the TSLP receptor may be a useful therapeutic strategy for DS-ALL.
TNF RECEPTOR 2 IS REQUIRED FOR RIP1-DEPENDENT CELL DEATH IN LEUKEMIA

1Department of Oncology and Children’s Research Centre, University Children’s Hospital Zurich, Zurich, Switzerland, 2Cancer Immunology, National Research Council of Canada, Ottawa, Canada, 3IBB Swiss Institute of Bioinformatics, Lausanne, Switzerland, 4Department of General Pediatrics, University Hospital Schleswig-Holstein, Kiel, 5Department of Pediatric Oncology/Hematology, Charité Medical University Berlin, Berlin, 6Pediatric Hematology and Oncology, Hannover Medical School, Hannover, Germany

Background: Persistence of residual leukemia cells, due to deficiencies in apoptotic programs, is a major driver of relapse. Activation of alternative non-apoptotic cell death pathways such as necroptosis represents an attractive strategy to eliminate residual leukemia cells and prevent relapse. We have previously shown that SMAC-mimetics (SM) potently induce cell death by simultaneous RIP1-dependent apoptosis and necroptosis in a subset of refractory acute lymphoblastic leukemia (B-ALL) patient-derived samples. The molecular signals that drive sensitivity to RIP1-dependent cell death remained elusive so far.

Aims: The aim of this project was to understand the mechanisms that determine the specific vulnerability to necroptosis in ALL.

Methods: To identify molecular determinants of sensitivity to SM, we correlated the gene expression profiles of 17 primary samples with high and low sensitivity to SM with the IC50 in response to two SM compounds, birinapant and LCL161. We confirmed the top scoring genes including TNF receptor 1 (TNFR1) and TNFR2 by quantitative RT-PCR in patient-derived xenografts. We further validated our results by quantifying the expression of the candidate genes in an independent cohort of relapsed primary B-ALL and by screening samples with different expression levels of TNFR1 and 2 for their response to SM in vitro. To assess the mechanistic role of TNFR1 and 2 in the response to SM, we generated patient-derived TNFR1 and TNFR2 knockout cells using CRISPR/Cas9 gene editing technology, and evaluated their response to SM in vitro and in vivo using a CRISPR selection model. Additionally, we overexpressed TNFR2 and evaluated the cell death phenotype. To determine the mechanism of TNFR2-mediated sensitization to SM, we investigated the formation of the pro-death RIP1-TNFR1 complex in wild type versus TNFR2ko and in SM sensitive and resistant ALL by immunoprecipitation in primary ALL samples.

Results: Comparative gene expression profiling indicated a correlation of the expression of TNFR2 with sensitivity to SM in primary ALL. Using an independent cohort of relapsed ALL samples, we found that high TNFR2 expression predicted sensitivity to SM in an ex vivo model of the bone marrow. Deletion of either TNFR1 or TNFR2 using CRISPR/Cas9 in patient-derived ALL conferred resistance to treatment with SM in vivo in the xenograft model, indicating that TNFR1 and 2 are both functionally required for cell death. In agreement with an important role for TNFR2 in the response to SM, the overexpression of TNFR2 leads to increased sensitivity to the TNFR1/RIP1 death axis. On the mechanistic level, recruitment of RIP1 to TNFR1 is a key event in the activation of cell death, which is abolished in TNFR2-deficient leukemia and does not occur in SM resistant cases.

Summary/Conclusions: Taken together, our data reveal a novel function of TNFR2 in cell death signaling, as TNFR2 predicts sensitivity to SMAC mimetics and plays a key role in activating the TNFR1/RIP1 cell death pathway, which underlies the switch from RIP1-controlled cell survival to cell death and characterizes a distinct vulnerability in ALL.

THERAPEUTIC TARGETING OF ONCOGENIC MYB ACTIVITY IN T-ALL

Background: T-lineage acute lymphoblastic leukemia (T-ALL) is an aggressive hematologic malignancy that accounts for 10%–15% of pediatric and 25% of adult ALL cases. The prognosis of T-ALL has gradually improved, however, the outcome of T-ALL patients with primary resistant or relapsed leukemia remains poor. Thus, further advances in the treatment of T-ALL require the development of effective and highly specific molecularly targeted antileukemic drugs. The proto-oncogene MYB (encodes c-MYB) is aberrantly activated in a subset of T-ALL patients through T-cell receptor driven translocations or genonomic duplications of the MYB locus itself. Recently, a new genetic mechanism for the generation of oncogenic super-enhancers in malignant T cells was identified, and suggests a general role for MYB in the regulation of T-cell specific super-enhancer activity.

Aims: We want to identify the role of enhanced MYB activity in super-enhancer driven oncogenic transcription in the context of malignant T-cell development and investigate the in vivo role of cMyc in the initiation and maintenance of T-ALL.

Methods: To evaluate if cMyc could act as a bona fide oncogene in the pathogenesis of T-ALL, we developed a conditional R26-driven cMyc overexpression mouse model. For this, we used a targeting vector that contained a floxed stop cassette followed by the cMyc gene and a EGFP/luciferase reporter, which was subsequently targeted in mESCs using recombine-mediated cassette exchange (RMCE).

Results: Here, we report a novel conditional Myb knockin mouse model (R26-Myb). To study the in vivo oncogenic capacity of Myb, we initially crossed this conditional Myb knockin model with VavCre mice, in order to obtain hematopoietic specific expression of Myb and the EGFP/luciferase from the ROSA26-promoter. Notably, Vav-iCre+ R26-Myb+/tg mice developed T-cell lymphomas with a median latency of 77 weeks, suggesting that Myb can act as a bona fide oncogene in malignant T-cell transformation (Figure 1A). Next, we crossed our Myb transgenic model with Pten conditional knockout mice, to allow comparative analysis of tumors with and without T-cell specific Myb expression. Genetic inactivation of Pten is frequently observed in human T-ALL, and T-cell specific deletion of Pten (using Lck-Cre) results in T-cell leukemia/lymphoma development with an average of 17 weeks. Using this strategy, we obtained mice that overexpress R26-driven cMyc and lack Pten in developing T-cells and found that cMyc expression synergizes with Pten deletion, resulting in fully penetrant and accelerated T-ALL formation (median survival of 84 days instead of 118; p = 0.0003; Figure 1B). Finally, we used this novel murine T-ALL model to identify new therapeutic strategies for MYB dependent T-ALL. Importantly, the tumor cells from the cMyc knockin mice are luciferase-positive and are therefore suitable for in vivo drug testing using bioluminescence. Using this model, we evaluated the in vivo anti-leukemic efficacy of a variety of small molecules and identified new drugs that impede Myb protein stability or Myb-mediated transactivation in Myb driven tumorigenesis.

Summary/Conclusions: We developed a novel Myb-driven T-ALL mouse model and could demonstrate a pathogenic role for cMYB in T-cell leukemia. In addition, the Myb-driven preclinical mouse model will open new avenues for therapeutic intervention in T-ALL.
Background: Several somatic ribosomal defects have recently been discovered in cancer, yet their underlying oncogenic mechanisms remain poorly understood. Alterations in ribosomal protein genes RPL5, RPL10, and RPL22 have been described in ~20% of T-cell acute lymphoblastic leukemia (T-ALL) cases. Whereas RPL5 and RPL22 show heterozygous inactivating mutations and deletions, RPL10 contains a clear mutational hotspot at residue arginine 98 (R98), with 8% of pediatric T-ALL patients harboring this RPL10 R98S missense mutation.

Aims: Investigating the pathogenic role of the recurrent R98S mutation in ribosomal protein L10 (RPL10) in T-ALL.

Methods: A label-free quantitative proteomics experiment was performed to screen for differentially expressed proteins in engineered mouse lymphoid Ba/F3 cells expressing RPL10 WT or RPL10 R98S. Differences in protein expression were further validated in hematopoietic cells derived from a transgenic RPL10 R98S knock-in mouse model and in material derived from xenografted T-ALL patient samples.

Figure 1. The differential proteome screen revealed overexpression of several Jak-Stat signaling components (Csf2rb, Jak1, Stat1, Stat3, Stat5a/b and Stat6) in engineered RPL10 R98S mouse lymphoid cells, which we confirmed in hematopoietic cells derived from a transgenic RPL10 R98S mouse model. The relevance of this overexpression was illustrated by enhanced Jak-Stat pathway activation upon cytokine stimulation in RPL10 R98S lymphoid cells, as well as increased sensitivity of these cells to clinically used Jak-Stat inhibitors ruxolitinib and pimozide. RPL10 R98S positive leukemia patients likewise showed overexpression of IL7RA, Jak1 and STAT5, increased sensitivity to pimozide, as well as a mutually exclusive mutation pattern between RPL10 R98S and Jak-Stat lesions, suggesting that RPL10-R98S also modulates the cascade in human T-ALL. Programmed -1 ribosomal frameshifting (-1 PRF) recently emerged as a post-transcriptional mechanism regulating expression of cytokine receptors. We identified -1 PRF signals in mouse and humanJak-Stat genes and observed RPL10 R98S associated frameshifting reduction in several of these, which may contribute to their overexpression. Altered levels of -1 PRF can however only partially explain observed Jak-Stat protein expression changes, and transcriptional changes and altered protein stability are also involved. Indeed, our data point to altered protease activity and composition in RPL10 R98S cells, with upregulation of immunoproteasome specific catalytic subunits, which may explain the increased stability of particular proteins such as Jak1. Of further medical interest, RPL10 R98S cells showed reduced protease activity and enhanced sensitivity to the clinically used protease inhibitors bortezomib and carfilzomib.

Summary/Conclusions: We explored the molecular mechanism by which the RPL10 R98S mutation contributes to the pathogenesis of T-ALL. We propose a model in which R98S associated decreases in -1 PRF levels, combined with changes in the degradation of particular proteins and potential other mechanisms such as transcriptional regulation, leads to selective upregulation of the Jak-Stat cascade (Figure 1). Besides expanding the relevance of the Jak-Stat cascade in T-ALL and leukemia in general, our results have therapeutic potential since cells harboring the RPL10 R98S mutation are sensitized towards clinically used Jak-Stat and protease inhibitors.

NFATC3-PLA2G15 IS A NOVEL INTERGENICALLY SPliced ChimerA THAT IS ASSOCIATED WITH Agressive t-ACUTE LyMPHOBLASTIC Leukemia BIOlogy

J. Bond, C. Trang-Quang, A. Bergon, M. Belhocine, G. Hypolite, W. Goma, J. Ghysdael, E. Macintyre, N. Boissel, V. Asnafi

Background: Transcriptional read-through of a single mRNA between contiguous loci, or cis-spaying of adjacent genes (cis-SAGE), results in transcription of intergenically-spliced chimeric RNAs (ISCs) in the absence of structural genomic changes. Recent advances in high-throughput RNA-sequencing analysis have permitted identification of aberrant ISC expression as a potential cancer driver, but knowledge of leukemia-related ISCs is lacking.

Aims: To examine whether cis-SAGE generates biologically important ISCs in T-acute lymphoblastic leukemia (T-ALL).

Methods: We performed RNA-sequencing of 12 cases of T-ALL and normal thymic RNA, and used targeted analysis pipelines to detect T-ALL-specific fusion chimeras.

Results: We identified 140 T-ALL-specific fusions, of which 55 involved genes located within 30kb of each other, in the same transcriptional orientation. This distance is consistent with that previously observed for cis-SAGE, suggesting that ISC expression is common in T-ALL. In total, putative ISCs were detected in 10/12 samples, with a median of 4 (range 0-15) per patient. We performed further analysis on the candidate ISC NFATC3-PLA2G15, which includes the Nuclear Factor of Activated T-cells (NFAT) family member NFATC3, a critical regulator of normal thymopoiesis and known modulator of T-ALL biology. We found that primary T-ALLs exhibited a wide range of NFATC3-PLA2G15 expression, while levels in normal tissue were either very low or undetectable. 5’ RACE PCR analysis of leukemic cDNA revealed that fusion transcription was initiated in exon 1 of NFATC3. We also performed array competitive genomic hybridization of 115 diagnostic T-ALL samples, and found no evidence of microdeletions that would result in NFATC3-PLA2G15 expression, providing strong evidence that NFATC3-PLA2G15 is a true ISC that is generated by cis-SAGE. We found that the NFATC3-PLA2G15 fusion had lower activity than wild-type NFATC3 in both luciferase reporter experiments and proliferation and survival complementation assays in NFAT-null ALL cell lines in vitro. Gene set enrichment analysis revealed that primary T-ALL blasts with elevated NFATC3-PLA2G15 levels had reduced transcription of canonical NFAT target genes in vivo, suggesting that these cases may have lower activity of normal physiological NFAT pathways. Strikingly, we found that higher NFATC3-PLA2G15 levels strongly correlated with both shorter time to leukemia development (p=0.01) and survival (p=0.003) in patient-derived T-ALL xenografts in immunodeficient mice. These findings were corroborated by survival analyses of human T-ALL patients treated as part of the Francophone multinational GRAALL-2003 and -2005 studies, as cases with the highest quartile of NFATC3-PLA2G15 expression had significantly reduced 5 year overall survival (52.6%, 95% CI 33.3% - 68.7%) compared with NFATC3-PLA2G15 low cases (69.8%, 95% CI 58.8% - 78.3%, p=0.047).

Summary/Conclusions: Our results suggest that ISC expression is common in T-ALL, and that high expression of the NFATC3-PLA2G15 ISC correlates with reduced canonical NFAT pathway activity and poor patient outcome.
**Thrombotic disorders**

**ASSESSING THE RISK-BENEFIT OF ANTICOAGULANTS IN ELDERLY PATIENTS WITH CANCER-ASSOCIATED VENOUS THROMBOEMBOLISM: A POPULATION BASED STUDY**

A. A. Birgisdóttir 1,*, I. S. Sverrisdóttir 1, O. Landgren 2, M. Björkholm 3, A. M. Birgisdóttir 1,*, I. S. Sverrisdóttir 1, O. Landgren 2, M. Björkholm 3, LYMPHOMA: A POPULATION-BASED COHORT STUDY

Background: Cancer patients have a higher risk of venous thromboembolism (VTE) which conveys a higher subsequent mortality risk; conversely, they also have a higher risk for bleeding due to many factors including abnormal tumor anatomy and the use of chemotheraphy agents with the associated risk for thrombocytopenia. However, the consequences of a recurrent VTE or a major bleeding (MB) event might be different in terms of mortality. As a result, the risk of VTE recurrence or a MB event may bear different weights. A previous systematic review has suggested that the case fatality rates of VTE recurrence and MB are similar. However, heterogeneity in study design, outcomes and in particular the types of populations included, limited the interpretation and applicability of the results. Clinical decision making uses estimations of risk and benefit for any given intervention. In the case of VTE, anticoagulants are the cornerstone of treatment having a proven benefit in reducing the risk of recurrent VTE events with an associated increase in the risk of bleeding. Therefore, determining the risk-benefit of anticoagulants might allow for better informed treatment decisions, in particular in a population at high risk for both ends of the spectrum. Therefore, herein we sought to estimate the risk and benefit of anticoagulant therapy in cancer patients developing a VTE using data from administrative databases.

Aims: To estimate the case fatality rates of VTE recurrence and MB, as well as the case fatality rate-ratio for MB and VTE recurrence in cancer patients developing a VTE treated with anticoagulants.

Methods: We conducted a retrospective population-based cohort study in Ontario, Canada using de-identified linked administrative healthcare databases housed at the Institute for Clinical Evaluative Sciences (ICES). We included patients over 65 years of age with a diagnosis of cancer defined using provincial, ICD-9 and ICD-10 codes for major malignancies and who developed a VTE event within 6 months of the initial cancer diagnosis. VTE was identified through a Cox proportional hazards model using a combination of diagnostic codes for deep vein thrombosis (DVT) and pulmonary embolism (PE) and codes identifying diagnostic procedures for VTE (i.e. ultrasound, CT pulmonary angiography, lung scintigraphy) within 7 days of each other. Recurrent VTE and MB events were assessed within 180 days from the index date. MB was identified using a previously validated algorithm and included upper and lower gastrointestinal and intracranial bleeding events. Treatment was classified based on the first available prescription within 7 days of the index VTE. We estimated mortality within 7 days of the VTE recurrence or MB events using an unadjusted and Cox proportional hazards model and competing risk analysis. Ratios of the mortality for MB compared to VTE recurrence were calculated and 95% confidence intervals were estimated using non-parametric models.

Results: Between 2004 and 2014 there were 6967 VTE events identified in cancer patients over 65 years of age and treated with an anticoagulant. Mean age was 75 years, and 47.6% patients were women. Of all patients, 59.9% received prescriptions for LMWH alone, 15.3% for LMWH followed by warfarin, 22.1% for warfarin and 2.7% for rivaroxaban. At 180 days after the index VTE event there were 235 (3%) MB events and 1184 (17%) VTE recurrences. Within 7 days of the outcome event there were 26 (11%) deaths after MB and 6 (0.5%) after VTE. The mortality ratio for MB versus VTE was 21.8 (95% CI 9.53-53). In exploratory analyses we did not find differences according to type of anticoagulant prescription.

Summary/Conclusions: In this large, population-based, study based on more than 40,000 patients with NHL and almost 116,000 controls, we demonstrated that there is an increased risk of thrombosis in patients with NHL when compared to controls. This is true for all types of thrombosis. We therefore conclude that hypercoagulability seems to increase with diagnosis of NHL. Several factors may contribute to this prothrombotic state, including chemotherapy and other treatment related factors as well as the disease itself. Considering that the increase in the incidence of thrombosis was highest before and around the time of diagnosis for NHL patients, that indicates that the tumor itself may have a great impact on the hypercoagulability of these patients.

**COMPARATIVE ANALYSIS OF PREDICTIVE MODELS FOR THROMBOEMBOLIC EVENTS IN LYMPHOMA PATIENTS**

D. A. Lazo-Langner1,2,*, M. Louzada1,2, A. Garg1,2,3, M. McCallum3, S. Dixon3

Background: Lymphoma is a malignancy that originates in lymph nodes and lymphoid tissue. The main category of lymphomas is non-Hodgkin’s lymphoma (NHL). NHL comprise about 3% of all cancers in Sweden. Some are aggressive and fast growing, while others are more indolent and do not necessarily require treatment. It is well known that cancer increases the risk of thrombosis, especially in the case of thromboembolism, but data are scarce on the risk of thrombosis in NHL patients.

Aims: The aim of this study is to evaluate the risk of thrombosis in NHL patients compared to controls and to study time trends in the risk of thromboembolism with recent advances in the treatment of these diseases.

Methods: The study population consisted of individuals diagnosed with NHL in Sweden 1980-2013 (n=40,354), and up to four matched controls (n=115,677). The risk of the first thrombosis was evaluated after the diagnosis of NHL (and corresponding date for controls) and the ones that occurred less than 30 days prior to diagnosis of NHL. Kaplan-Meier survival analysis was used to estimate the risk of thrombosis and a log-rank test performed to assess statistical significance. Cox regression analysis was used to calculate hazard ratios (HRs) and 95% confidence intervals (CI) (adjusting for age, sex, year of diagnosis, and previous history of thrombosis). Risk of deep vein thrombosis, pulmonary embolism and arterial thrombosis was evaluated. Arterial thrombosis was defined as cerebral, foetal, transient ischemic attack, angina pectoris, myocardial infarction, and arterial embolism and thrombosis.

Results: NHL patients had a statistically significant increase in risk of any type of thrombosis compared to controls (HR: 1.58; 95% CI: 1.53-1.62). The risk was significantly increased for all three types of thrombosis: deep vein thrombosis (HR: 1.54; 95% CI: 1.51-1.59); arterial thrombosis (HR: 1.58; 95% CI: 1.53-1.62); and pulmonary embolism (HR: 1.53; 95% CI: 1.49-1.59). The risk of thrombosis did not change during the study period for the NHL patients. There was an increased risk of thrombosis for NHL patients when compared to controls, independent of previous history of thrombosis (HR: 1.64; 95% CI: 1.59-1.69) no previous history (HR: 1.43; 95% CI: 1.37-1.50) for previous history of thrombosis). The incidence of thrombosis for NHL patients started to increase about five months before the diagnosis of NHL, and reached its peak one month after diagnosis. The incidence stayed increased for the first year post diagnosis.

Summary/Conclusions: In this large, population-based, study based on more than 40,000 patients with NHL and almost 116,000 controls, we demonstrated that there is an increased risk of thrombosis in patients with NHL when compared to controls. This is true for all types of thrombosis. We therefore conclude that hypercoagulability seems to increase with diagnosis of NHL. Several factors may contribute to this prothrombotic state, including chemotherapy and other treatment related factors as well as the disease itself. Considering that the increase in the incidence of thrombosis was highest before and around the time of diagnosis for NHL patients, that indicates that the tumor itself may have a great impact on the hypercoagulability of these patients.
and validation cohorts. The ThroLy model was developed using data solely from a derivation cohort, which included 1236 patients. Variables were evaluated by univariate logistic regression analysis, while the model was developed using a stepwise multivariate logistic regression analysis. Once a final model was defined, patients were divided into low risk and at risk groups. The final model was assessed in the validation cohort (584 patients). The studied population was also divided, based on Khorana and Padua score, into low risk and at risk groups.

**Results:** The study population included 1820 eligible lymphoma patients. The mean patient's age was 53.1 years (range, 15–87 years). Most patients (83%) were newly diagnosed and had advanced stage disease: Ann Arbor stage III, 14.7% and stage IV, 44%. A total of 778 patients (42.7%) had high-grade lymphoma; 351 (19.3%) had low-grade lymphoma; 266 (14.6%) had HL; 156 (8.6%) had other forms; and 269 (14.8%) had CLL/SLL. Of all the patients included in the study, 99 (5.4%) developed at least one TE during the follow-up period. There were 73 patients with venous TE (73.7%), and 25 with arterial TE (25.3%), while 1 patient had both. Patients with aggressive NHL had significantly higher odds of developing TE compared to patients with any other lymphoma type (RR=1.5; 95% CI for RR 1.1–2.4; p=0.027). The incidence of thromboembolism was 81 (5.3%) in the newly diagnosed patients and 18 (6.2%) in relapsed patients. Overall, 35.4% (35/99) of the patients with thromboembolism experienced the event before the start of chemotherapy. The majority of patients (64.6%) had TE events during chemotherapy or within 3 months after chemotherapy. For patients classified at risk according to ThroLy score in derivation cohort, the model produced negative predictive value (NPV) of 98.5%, positive predictive value (PPV) of 25.1%, sensitivity of 75.4%, and specificity of 87.5%. In validation cohort PPV for Throly score was 28.9%. Padua and Khorana score had PPV of 15.5% and 14.8% in derivation, and 11.5% and 14.8% in validation cohort, respectively.

**Summary/Conclusions:** Lymphoma patients are at increased risk of thromboembolic events but thromboprophylaxis in these patients is largely underused. ThroLy score is more specific for lymphoma patients than suggested Padua and Khorana score, but external validation in large prospective cohort studies is required.

**IMPACT OF A NEW ELECTRONIC ALERT SYSTEM (V2.0) FOR VENOUS THROMBOEMBOLISM PREVENTION IN HOSPITALISED CANCER PATIENTS**

R. Figueroa1,*, A. Alfonso1, V. Sara1, M.C. Nicolás1, M. Marcos Jubilar1, J. López Picazo2, I. Gil-Bazo2, A. Garcia-Mouriz2, J.A. Páramo1, J. Hermida4, R. Lecumberri1

1Hematology, 2Medical Oncology, 3Informatics Department. Clínica universidad de Navarra, 4DiVision of Cardiovascular Sciences, Centro de Investigación Médica Aplicada, Pamplona (Navarra), Spain

**Background:** Onco-hematologic hospitalised patients constitute a group at high risk of venous thromboembolism (VTE). Current clinical practice guidelines recommend prophylaxis with low molecular weight heparin (LMWH) during hospitalisation, unless contraindicated. However, its underuse is a worldwide problem. Electronic alert systems (e-alerts) can improve the use of appropriate thromboprophylaxis and reduce the incidence of VTE.

**Aims:** To evaluate the impact of a new version (v2.0) of our e-alert system for VTE prophylaxis compared with the initial software version. Secondary endpoints try to identify predictive factors for prophylaxis use and thrombotic events.

**Methods:** Prospective study including consecutive adult cancer patients admitted at our centre. From April 2014 to June 2015 (first period) the initial e-alert system version remained operative and from July 2015 to December 2016 (second period) the new version was active. The v2.0 displayed a second window that asked physicians about the reason why LMWH was not prescribed.

The main outcomes were: VTE (confirmed by objective methods), clinically relevant bleeding, and mortality. All patients were followed-up during hospitalisation and 30 days after discharge. Descriptive statistical analysis and correlation were performed. ThroLy prediction tool was validated by univariate logistic regression analysis, while the model was developed from a derivation cohort, which included 1251 patients were included, 782 patients in the first period and 469 in the second one.

**Results:** 1251 patients were included, 782 patients in the first period and 469 in the second one (main clinical features are shown in Table 1). E-alerts v2.0 was associated with an increase of appropriate LMWH prophylaxis during hospitalisation (65.2% vs 72.2%, p=0.015). However, this improvement did not result in a reduction of VTE during admission or follow up (2.3% vs 2.3%; p=0.89). Interestingly, almost 80% of VTE events occurred despite LMWH use. No differences in the rate of major bleeding (2.8% vs 3.2%; p=0.83), and mortality (10.6% vs 14.3%; p=0.07) were observed, either. The main reason for not prescribing LMWH prophylaxis was bleeding risk, but in 17% of cases physicians did not consider that the patient really had a high VTE risk. No significant correlation was found between any of the clinical variables analyzed and the risk of VTE. Prophylaxis use was more frequent among patients with solid cancer (vs hematologic), advanced stage, active chemotherapy treatment and longer hospital stay.

**Summary/Conclusions:** The new e-alert system further increases the use of VTE prophylaxis in hospitalised cancer patients, although this was not associated with a reduction in the VTE incidence. A relevant number of VTE events occur despite prophylaxis with standard LMWH. Identification of risk factors for thromboprophylaxis failure is needed.

This work has been funded by a biomedical research grant with the Laboratory of Pharmaceutical ROVI and an aid to the research projects of the Instituto de Salud Carlos III and the FEDER (PI13/01029).

**IDENTIFICATION OF A NEW AND RELATIVELY FREQUENT SERPINC1 GENE DEFECT CAUSING ANTITHRROMBIN DEFICIENCY HARDLY DETECTED BY CURRENT MOLECULAR METHODS: DUPLICATION OF EXON 6**

M.E. De La Morena-Barrio1,2,*, B. de la Morena-Barrio1, J. Padilla1, R. Teruel1,2, S. Asenjo3, E. Wypasek4, A. Miñano1, V. Vicente1,2, J. Corral1,2

1Servicio de Hematología y Oncología Médica, Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arraxaca, Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Instituto de Salud Carlos III (ISCIII), Murcia, 2Servicio de Hematología, Hospital Clínico San Carlos, Madrid, Spain, 3The John Paul II Hospital, Krakow, Poland; Institute of Cardiology, Jagiellonian University Medical College, Krakow, Poland

**Background:** Antithrombin (AT) deficiency was the first thrombophilia described 50 years ago and so far the strongest one. Up to 78% of cases are explained by point mutations or small deletion/insertions in exons or flanking regions of SERPINC1 that are easily detected by sequencing analysis. A low proportion of cases (2%) is explained by gross gene defects, mainly deletions, which are detected by multiplex ligation-dependent probe amplification (MLPA) analysis. However, the molecular base of AT deficiency is unknown using current methods in 20% of cases.

**Aims:** To identify new SERPINC1 defects causing AT deficiency.

**Methods:** We studied 271 unrelated cases with AT deficiency. Functional and biochemical assays characterized plasma AT. Genetic analyses involved Sanger and Next Generation Sequencing (NGS) (PGM, Ion Torrent), MLPA and specific PCR designs.

**Results:** Sanger sequencing of PCR amplicons with primers flanking the 7 exons and further analysis with SeqscapeTM detected pathogenic mutations in 173 cases. Whole gene sequencing identified 5 mutations in regulatory regions. MLPA analysis revealed 5 cases with whole or partial deletion of the gene. Moreover, 13 cases had disorders of glycosylation. Interestingly, the analysis of the PCR product and the electropherogram of exon 6 of a 42-year-old male patient (P1) with deep venous thrombosis and 75% of anti-FXa activity...
with no apparent gene defect by either Sanger sequencing of 7 exons or by NGS analysis of the whole gene using the Ion Torrent platform, revealed a 193 bp insertion, which corresponded to a tandem duplication involving exon 6. Family studies revealed the same duplication in 5 relatives, all with AT deficiency (60-75%). The first MLPA analysis of this case failed to detect the duplication and only after a fine readjustment, it was detected. MLPA analysis under the new conditions of the remaining 59 cases with unknown molecular base for their AT deficiency identified one additional case, P2, with potential duplication of exon 6. P2 was a 17 year-old female with 41% of anti-FXa activity, who developed deep venous thrombosis. Sanger and NGS sequencing also failed to detect any genetic defect in P2. A set of primers specific to detect tandem duplications of exon 6 was designed with forward primer from 3’ end of exon 6, and reverse primer from 5’ of exon 6. This set of primers only rendered amplification in the two cases with exon 6 duplication. The second patient (P2) had a new 863 bp duplication in tandem of exon 6. Sanger sequencing of the specific amplicons in the two cases with tandem duplication of exon 6 revealed Alu sequences surrounding these duplications. Finally, one out of 5 cases with gene deletions involved breakpoints affecting intron 5 (deletion of exons 2-5).

Summary/Conclusions: Our study identified a new and relatively frequent SERPINC1 gene defect causing AT deficiency that is hardly identified by current molecular methods: duplication of exon 6. This genetic defect was detected in 1% of our cohort, and represents nearly half of the total gross gene defects causing AT deficiency. The small size of this exon makes difficult the identification of this defect by MLPA. The presence of 6 Alu elements up and downstream exon 6 makes this region a hotspot for unequal recombination that may cause deletions, tandem duplications and potentially transpositions, which may produce AT deficiency (both severe and mild) by an aberrant splicing downstream exon 6 makes this region a hotspot for unequal recombination and may produce AT deficiency (both severe and mild) by an aberrant splicing.

We also developed a simple and specific method to detect duplications in tandem of exon 6.

Background: The epithelial lining of the gastrointestinal (GI) tract represents the first line of defense mediating protection from microbial challenge. Next to producing antimicrobial molecules, Paneth cells contribute to this defense by providing a supportive niche for intestinal stem cells (ISCs) maintaining the epithelium. Loss of intestinal barrier function by total body irradiation (TBI) or chemotherapy (CTx) is an essential step in enhancing the development of inflammation and epithelial regeneration in the allo-HSCT setting. Recent work suggests a protective function of Type I Interferons (IFN-I) at epithelial surfaces and in the prevention of GVHD. Yet, the molecular pathways that trigger those functions during acute tissue damage are poorly understood. Given that the RIG-I-MAVS pathway and STING pathways are important regulators of IFN-I production and IFN-Is can initiate epithelial repair, we hypothesized that activation of these pathways during conditioning therapy may protect epithelial integrity and could be exploited interventionaly to promote intestinal barrier function and prevent GVHD.

Aims: We aimed at characterizing the role of RIG-I-MAVS and STING during allo-HSCT, and at understanding mechanisms by which activation of these pathways can promote barrier function to enhance healing after genotoxic tissue damage.

Methods: We used an integrated approach with pathophysiological mechanic studies on IECs in experimental mouse models (MHC-mismatched and minor histocompatibility antigen (mHIA)-mismatched transplants to model highly aggressive GVHD; genotoxic stress induced by TBI and CTx) and evaluation of immune-mediated regenerative strategies to promote epithelial barrier function (organoid cultures, barrier function test).

Results: Mice lacking MAVS were more sensitive to total body irradiation (TBI)- and chemotherapy induced intestinal barrier damage, and, like RIG-I-deficient mice, developed worse graft transplantation (allo-HSCT). This phenotype was not associated with changes in the intestinal microbiota, but with reduced epithelial integrity and regeneration. Conversely, targeted activation of the RIG-I pathway during damage promoted these processes and ameliorated GVHD. Mechanistically, IFN-I (RIG-I-induced or recombinant) could promote growth of intestinal organoid cultures and production of RegIIIγ. Importantly, our findings were not confined to RIG-I/MAVS signaling, as interventional engagement of the STING pathway also protected from loss of barrier function and GVHD and led to IFN-I-dependent intestinal organoid growth. Consistent with this, STING-deficient animals suffered from worse GVHD.

Summary/Conclusions: Our studies may have the potential to develop novel targeted therapies (i) to promote intestinal barrier integrity, (ii) to prevent the development of GVHD, and (iii) for the regenerative response of other tissues.
Aims: To investigate whether donor CD4 T cells recognizing mismatched HLA-DP show tissue specific reactivities.
Methods: In a randomized clinical trial we treat patients 3 months after T cell depleted alloSCT from HLA 10/10 matched, HLA-DP mismatched, donors with 0.25-0.50 x 10^6/kg donor CD4 T cells to promote immune reconstitution. In 4 patients, Graft-versus-Leukemia reactivity and/or organ specific GVHD occurred after the infusion. To characterize the immune responses in these patients, in vivo activated T cells were clonally isolated and tested for reactivity against a panel of target cells, including patient and donor derived hematopoietic cells, third party hematopoietic cells as well as different GVHD target cells (patient skin fibroblasts, third party colon carcinoma cells, biliary epithelial cells and lung fibroblasts) expressing the mismatched, patient variant, HLA-DP molecule.
Results: Allo-HLA-DP directed CD4 T cells showing differential recognition of target cells were found in all 4 patients. A total of 33 HLA-DPB1*04:01 reactive CD4 T cell clones were isolated from patient 1 who suffered GVHD of skin and colon, but not liver. Within these 33 clones, 3 clones recognized only hematopoietic target cells, 9 clones recognized hematopoietic, skin and colon derived target cells and 5 clones recognized hematopoietic and colon derived cells only. None of the T cell clones recognized biliary epithelial cells. From patient 2 total of 230 HLA-DPB1*03:01 reactive CD4 T cell clones were isolated, of which 27 recognized only hematopoietic target cells and 96 clones also recognized GVHD target cells with differences in tissue specificity. 32 HLA-DPB1*03:01 reactive T cell clones were found from patient 3, of which 6 recognized only hematopoietic target cells, whereas other clones again showed various tissue specificities. From patient 4, 26 HLA-DPB1*01:01 reactive T cells could be isolated which all recognized biliary epithelial cells with or without co-recognition of other target cells. In addition, also 11 HLA-DPB1*03:01 reactive T cells were isolated, again with different tissue specificities.
Summary/Conclusions: These results illustrate that donor CD4 T cells directed against mismatched HLA-DP show differential recognition of target cells including restricted specificity for cells of hematopoietic origin. Donor CD4 T cells recognizing hematopoietic target antigens in the context of patient specific HLA-DP alleles can be used to mediate tumor specific immune responses after HLA 10/10 matched unrelated stem cell transplantation.

S448 MESENCHYMAL STROMAL CELLS STIMULATE THE PROLIFERATION AND IL-22 PRODUCTION BY TYPE 3 INNATE LYMPHOID CELLS
V. Van Hoeven1,2,*, J. M. Munneke1,2, A. Cornelissen3, S. Omar2, M. Spruit2, A. N. Kekas2, C. Voermans3, M. Hazenberg1,2
1Department of Hematology, 2Department of Experimental Immunology, Academic Medical Center Amsterdam, 3Department of Hematopoiesis, Sanquin Research and Landsteiner Laboratory, Amsterdam, Netherlands

Background: Infusion of mesenchymal stromal cells (MSCs) is a promising and increasingly applied therapy for patients who suffer from graft-versus-host disease (GVHD), a common and life-threatening complication of allogeneic stem cell transplantsations (ASCT). The therapeutic effect of MSCs is mainly ascribed to their suppression of (alloreactive) lymphocyte proliferation and enhancement of tissue-repair activity. However, only about half of the GVHD patients benefit from MSC therapy, and which factors determine MSC responsiveness is unclear. We recently observed that relatively high frequencies of activated CD4+CD25+ T cells (ILC3s) before and/or after ASCT were associated with a lower risk to develop GVHD, which may be related to the production of tissue-protective IL-22 by ILC3s.

Aims: To investigate if ILC3s can contribute to the therapeutic effect of MSCs, we studied the interaction between MSCs and ILC3s in vitro.
Methods: ILC3s isolated from human tonsils were CellTrace-labeled and co-cultured with bone-marrow derived MSCs for 5 days in the presence of IL-2. Results: Co-culture with MSCs significantly enhanced the proliferation of ILC3s and their IL-22 production. Reciprocally, ILC3s promoted ICAM-1 and VCAM-1 expression on MSCs. These experiments revealed that ICAM/VCAM expression, the interaction is mainly dependent on cell-cell contact or close proximity of MSCs and ILC3s. Addition of blocking antibodies against ICAM-1, VCAM-1, or their integrin ligands, did not affect ILC3 proliferation, suggesting that ILC3 stimulation is ICAM/VCAM independent. Soluble factors also contributed to the interaction, as ILC3s proliferated slightly better in the presence of MSC culture supernatant compared to IL-2 only. Based on experiments with blocking antibodies, we found IL-7 to be the likely candidate for this effect.
Summary/Conclusions: We show that via cell-cell contact and IL-7, MSCs promote the proliferation and IL-22 production by ILC3s in vitro, suggesting ILC3s may play a role in the control of GVHD upon MSC therapy.

S449 ABERRANT T CELL RESPONSES IN THE BONE MARROW MICROENVIRONMENT OF PATIENTS WITH POOR GRAFT FUNCTION AFTER ALLOGENIC HEMATOPOIETIC STEM CELL TRANSPLANTATION
Y. Kong1,*, Y.-T. Wang1, X.-N. Cao 1, Y. Song1,2, Y.-H. Chen1, Y.-Q. Sun1, Y. Wang1, X.-H. Zhang1, L.-P. Xu1, X.-J. Huang1,2
1Peking University People’s Hospital, Peking University Institute of Hematology, 2Peking-Tsinghua Center for Life Sciences, Academy for Advanced Interdisciplinary Studies, Peking University, Beijing, China

Background: Poor graft function (PGF) remains a life-threatening complication following allogeneic hematopoietic stem cell transplantation (allo-HSCT), and the underlying mechanisms have not yet been elucidated. Considerable evidence from murine studies has demonstrated that effective hematopoiesis depends on the specific bone marrow (BM) microenvironment, where hematopoietic stem cells reside. In this regard, we previously reported that PGF patients had impaired BM endosteal and vascular microenvironment (BBMT 2013; BMT 2016; Oncotarget 2016; Blood 2016). Moreover, our pilot study showed that both CD4+ and CD8+ T cells found polarized towards a type 1 immune response in the BM microenvironment of PGF patients (N=10) compared to those in matched good graft function (GGF) patients (N=20) (BBMT 2016). Nevertheless, whether abnormalities of T cell subsets in the BM immune microenvironment, including Th1, Th17, Th1, Th2, Th2 cells and regulatory T cells (Tregs), are involved in the pathogenesis of PGF remains to be explored.

Aims: To compare the T cell subsets in the BM immune microenvironment, including Th1, Th2, Th2, Th17, Th17 cells and Tregs, between patients with PT and GGF after allo-HSCT.
Methods: This prospective nested case-control study enrolled 20 patients with allo-HSCT matched patients with PGF, 40 matched patients with GGF after allo-HSCT, and 20 healthy donors (HD). Th1, Th17, Th1, Th2, Th2 cells and regulatory T cells (Tregs), are involved in the pathogenesis of PGF remains to be explored.
Results: The demographic and clinical characteristics were similar between allo-HSCT patients with PGF and those with GGF. The percentages of Th1 (37% vs. 26.4%, P=0.0005) and Th17 cells (52.4% vs. 19%, P=0.0001) cells were significantly higher in PGF patients than in GGF patients, whereas the percentages of Th2 (0.8% vs. 2.4%, P=0.0001) and Tc2 (0.5% vs. 1.1%, P=0.0001) cells were markedly lower in the GGF group than in the PGF group. PGF patients showed significantly greater Th1 cell/Th2 cell (31.6 vs. 10.8, P=0.0001) and Th1 cell/Tc2 cell ratios (108.8 vs. 18.4, P<0.0001) than those for GGF patients. Moreover, a significantly higher proportion of stimulated CD4+ T cells that produced IL-17 (Th17) was found in the BM of PGF patients than in the BM of GGF patients and HD (3.7% vs. 1.6% vs. 1.1%, P=0.05), whereas the percentages of Tregs in PGF patients were comparable to those in GGF patients and HD, resulting in a dramatically elevated ratio of Th17 cells/Tregs in the BM of PGF patients relative to those in GGF patients (1.01 vs. 0.57, P=0.04).
Summary/Conclusions: The present study revealed that aberrant T cell responses in the BM immune microenvironment may be involved in the pathogenesis of PGF after allo-HSCT. These findings will facilitate the optimization of immune regulation strategies and improve the outcome of PGF patients post-allotransplant.
Background: Aberrant B-cell homeostasis has been described in patients (pts) with chronic graft-versus-host disease (cGVHD) following allogeneic stem cell transplantation (allo-SCT). However, there is no information on the predictive value of specific B-cell subsets of the incidence of cGVHD.

Aims: We sought to determine if B-cell subsets measured around day 100 after allo-SCT predict the subsequent occurrence of cGVHD in a prospective clinical study.

Methods:Peripheral blood (PB) samples were obtained from consenting patients (pts) between day 80 and 110 (D100) after allo-SCT at The University of Texas MD Anderson Cancer Center from 2012 to 2015. Only pts who had not been diagnosed with cGVHD or progression of underlying malignancy by D100 were eligible for this study. We analyzed CD19+CD20+ B-cell subsets by FACS. Subsets were defined as naïve (CD27-IgD+), unswitched (CD27-IgD+), switched (CD27+IgD+) and switched (CD27+IgD-) memory cells. Receiver Operating Characteristic (ROC) curve was used to identify threshold levels of B cell % and numbers that predict the incidence of cGVHD. cGVHD diagnosis was based on the 2014 National Institutes of Health guidelines.

Results: A total of 80 pts were enrolled in the study. The median age at SCT was 49 years (range 21-75). The majority (80%) of pts received myeloablative conditioning, and 75% received tacrolimus with methotrexate or mycopheno- late mofetil for GVHD prophylaxis. Diagnosis was myeloid (61%) or lymphoid (34%) malignancy in the majority of pts. Grafts source was primarily PB or bone marrow from matched unrelated (61%) or related (24%) donors. Grade 2-4 acute GVHD had occurred in 45% of pts before D100. Thirty-six percent of pts had undergone allo-SCT. However, there is no information on the predictive value of specific B-cell subsets of the incidence of cGVHD. cGVHD diagnosis was based on the 2014 National Institutes of Health guidelines.

Figure 1.

Summary/Conclusions: In conclusion, D100 frequency of naïve and switched B cells predicts the subsequent development of cGVHD. Lymphoid malignancies and older age may be associated with aberrant B-cell reconstitution. Consideration of D100 B-cell subsets may improve risk stratification models for the development of cGVHD.
Background: Pyruvate kinase deficiency (PKD) is the most common glycolytic enzyme defect causing hereditary non-spherocytic hemolytic anemia. PKD does not have a specific curative treatment. Therefore treatment is mainly supportive, consisting of regular red blood cell transfusions, splenectomy and chelation therapy for iron overload. This does not improve quality of life for affected patients. Hematopoietic allogeneic stem cell transplantation (HSCT) has the potential to cure the disease. However, there is little experience in applying HSCT in PKD and guidelines are not available. To date, only four European patients survived. Patients treated in Asian hospitals differed from European patients in that they were younger (p=0.001), less often splenectomized (p=0.048) and had a lower ferritin level before transplantation (p=0.048). They were more often transplanted with peripheral blood stem cells (p=0.014) and more often conditioned on a cyclophosphamide (p=0.007) regimen.

Summary/Conclusions: This is the first study on outcome of HSCT in PKD with enough cases to draw conclusions on the safety of HSCT in PKD can be drawn. However, we observed a better survival for patients transplanted before the age of ten. This difference could also explain difference in survival between patients transplanted in Europe versus Asia. The high rate of severe GVHD in this cohort is a reason for concern. The strong decline in survival of patients older than ten years of age indicates the need for very careful selection of HSCT-candidates.

Results: From 1996 to 2016 a total of 16 PKD-patients were reported to have been treated by stem cell transplantation. Eight patients were treated in the EU and eight in Asian centres, respectively. No patient resulted to be transplanted in the US. Median age at transplantation was 6.5 years, (10 patients (62.5%) were <10 years; (37.5%) ≥10 years), seven patients (43.8%) were splenectomized at the time of HSCT. Fifteen patients (94%) reached engraftment. The sixteen patient showed mixed chimerism followed by spontaneous transition to full donor chimerism after splenectomy six months post transplantation. Two patients suffered from secondary graft loss. One of these had recovered 91% donor chimerism after donor lymphocyte infusion. Outcome in the other patient is unknown. GVHD grade 4 was reported in 6/16 cases (38%). There was no obvious relation between GVHD prophylaxis or any other clinical factors and the occurrence of GvHD grade 2-4 in our patients. Two-year cumulative survival was 74%. Two patients did not reach the two-year milestone yet. All five patients who did not survive died of transplant-related causes. Patients who did not survive were significantly older (p=0.036) and were all treated in a European center (p=0.026) (see Table). Also, they had suffered more often from GVHD grade 2-4 (p=0.031). Nine out of ten patients (90%) younger than ten years old survived splenectomy, whereas one out of five (20%) patients older than 10 years of age survived (p=0.036). Patients younger than ten years old were less often splenectomized (p=0.001), less often chelated (p=0.048) and had a lower ferritin level before transplantation (p=0.048). They were more often transplanted with peripheral blood stem cells (p=0.014) and more often conditioned on a cyclophosphamide (p=0.007) regimen.

S453 HEREDITARY XEROCYTOSIS: CLINICAL AND BIOLOGICAL PRESENTATION AT DIAGNOSIS IN A RETROSPECTIVE SERIES OF 103 PATIENTS

1Laboratoire d’Hématologie, 2Service de Pédiatrie Générale, CHU Biécoré, Le Kremlin-Bicêtre, 3Laboratoire d’Hématologie, CHU Rouen, Rouen, 4Hématologie, CHU Saint Eloi, Montpellier, 5Service de Médecine Interne, CHU Estang, Clermont-Ferrand, 6Service d’Oncologie et d’Hématologie, Hôpital Saint Vincent de Paul, Lille, 7Laboratoire d’Hématologie, CHRU Nancy, Nancy, 8Hématologie Biologique, CHU Grenoble, Grenoble, 9Hématologie Interne, CH-Dax, Dax, 10Hématologie Interne, Sainte Lucie, Toulon, 11Hématologie Interne, CHU Jean Minjoz, Besançon, 12Genétique Médicale, CHU Nantes, Nantes, 13Service de Biochimie, Hôpitaux Universitaires Paris Nord Val de Seine, Colombes, 14Hématologie Pédiatrique, CHU Sud, Rennes, 15Hématologie, Hôpital du Scorff, Lorient, 16Hématologie Pédiatrique, CHU, Saint-Etienne, France, 17Service de Hématologie Pédiatrique, Université, Coppel, Switzerland, 18Médecine interne, CHU Henri Mondor, Creteil, 19University Picardie Jules Verne, CHU Amiens CEDEX, France

Background: Dehydrated hereditary stomatocytosis, also called hereditary xerocytosis (HX), is a dominant non-spherocytic hemolytic anemia characterized by an increased leak of monovalent cations through the red cell membrane leading to dehydration and a shortened red cell survival. HX is difficult to diagnose because of its rarity and the heterogeneity in its clinical presentation.

Aims: Our study aims to characterize the clinical and biological features at HX diagnosis in a retrospective diagnostic series of 103 patients and to determine the impact of free erythrocyte protoporphyrin (FEP). Methods: HX diagnosis was based on the typical left-shifted curve of osmolar gradient ektacytometry performed at CHU Biécoré from 1993 to 2016. All patients were from European origin. They were referred to our center for: chronic non-spherocytic hemolyisis (30), thrombotic events after splenectomy (8), hyperferritinemia and/or a chelation therapy were noticed for 26 patients among the 55 for whom this data was available (47%). 19 patients were treated for iron overload: phlebotomy (14) and/or Deferasirox (6) and/or Deferoxamine (6) and/or Deferprone (1). A perinatal edema history was noted in 17 (16.5%) patients. A history of thrombosis during the follow up in 12 (11.6%) patients, corresponding to a total number of 17 thrombotic events including post-embolic pulmonary hypertension (2), arterial events (3), pulmonary embolism (4), portal thrombosis (4), splenic infaracts (2) and deep venous throm-
Sickle Cell Center, Medical College of Georgia, Augusta University, Augusta, Georgia, United States

Aims:
This paper reports results from the Phase II SUSTAIN study, which evaluated the use of crizanlizumab, a P-selectin inhibitor, in the treatment of sickle cell-related pain crises. The study was a randomized, double-blind, placebo-controlled trial in patients aged 16-65 years with sickle cell disease (SCD) who had experienced at least two sickle cell-related pain crises in the previous year.

Methods:
A total of 198 patients were included in the study, and they were randomized to receive crizanlizumab 5.0 mg/kg, 2.5 mg/kg, or placebo. The primary endpoint was the proportion of patients who were SCPC event-free at week 50. Additional endpoints included the proportion of patients who were SCPC event-free at week 52,

Results:
Among the 198 patients included in the study, 62.6% experienced 2-4 SCPC events and 37.4% experienced 5-10 SCPC events in the previous year. The proportion of patients who were SCPC event-free at week 50 was significantly higher in the crizanlizumab 5.0 mg/kg group (24/67; 35.8%) compared to the placebo group (16/65; 24.6%). In the crizanlizumab 5.0 mg/kg group, a greater proportion of patients were SCPC event-free compared to those in the placebo arm (28.0% vs. 4.2% and 31.9% vs. 17.0%, respectively).

Summary/Conclusions:
Treatment with crizanlizumab 5.0 mg/kg appears to increase the likelihood of adult patients with SCD being SCPC event-free while on treatment, even in high-risk subpopulations. Crizanlizumab 5.0 mg/kg was also effective in those who had experienced at least two SCPCs in the previous year despite taking HU, suggesting that this dose is effective as a disease-modifying agent that meets an unmet medical need.

S455
FREE IRON IN SERA OF PATIENTS WITH SICKLE CELL DISEASE CONTRIBUTES TO THE RELEASE OF NEUTROPHIL EXTRACELLULAR TRAPS
K. van Avond1,2, M. Schimmel1,2, E. Nusse3, G. van Mierlo1, I. Bulder1, R. van Bruggen3, B.J. Biemond2, B.M. Luken1, S. Zeerleder12

Background:
Chronic hemolysis is a hallmark of sickle cell disease (SCD). Hemolysis in SCD has been associated with elevated levels of heme in the circulation of both human patients and SCD mice. It was shown that TNF-αtreatment induces experimental vaso-occlusive crisis (VOC) in SCD mice, associated with the formation of neutrophil extracellular traps (NETs) as shown by staining of lung sections (Chen et al. Blood 2014). In addition, the administration of DNase I to degrade NETs led to improved survival. Furthermore, it was shown that plasma from SCD patients obtained during SCD crisis induced NET formation by TNF-αprimed neutrophils. Free heme was suggested to mediate the formation of NETs in SCD, as treatment of SCD mice with the heme-binding protein hemopexin (Hpx) to scavenge free heme led to reduced NET formation (Chen et al. Blood 2014).

Methods:
A randomized, double-blind, placebo-controlled trial in patients aged 16-65 years with sickle cell disease (SCD) who had experienced at least two sickle cell-related pain crises in the previous year was conducted. Patients were randomized to receive crizanlizumab 5.0 mg/kg, 2.5 mg/kg, or placebo. The primary endpoint was the proportion of patients who were SCPC event-free at week 50. Additional endpoints included the proportion of patients who were SCPC event-free at week 52, and the proportion of patients who were SCPC event-free at week 52.

Results:
Among the 198 patients included in the study, 62.6% experienced 2-4 SCPC events and 37.4% experienced 5-10 SCPC events in the previous year. The proportion of patients who were SCPC event-free at week 50 was significantly higher in the crizanlizumab 5.0 mg/kg group (24/67; 35.8%) compared to the placebo group (16/65; 24.6%). In the crizanlizumab 5.0 mg/kg group, a greater proportion of patients were SCPC event-free compared to those in the placebo arm (28.0% vs. 4.2% and 31.9% vs. 17.0%, respectively).

Summary/Conclusions:
Treatment with crizanlizumab 5.0 mg/kg appears to increase the likelihood of adult patients with SCD being SCPC event-free while on treatment, even in high-risk subpopulations. Crizanlizumab 5.0 mg/kg was also effective in those who had experienced at least two SCPCs in the previous year despite taking HU, suggesting that this dose is effective as a disease-modifying agent that meets an unmet medical need.
mine whether ex vivo Hpx addition to human SCD sera would prevent NET formation.

Methods: Patient serum and plasma samples were obtained from 32 incidents of VOC in 24 adult SCD patients, with informed consent. Moreover, steady state samples were obtained at least 4 weeks after discharge from the hospital. Patients having had a blood transfusion in the 3 months prior to admission were excluded. NET formation by human neutrophils from healthy donors was studied using confocal fluorescence microscopy and staining for extracellular DNA with the cell nonpermeable dye Sytox Green. The presence of extracellular DNA that stains positive for citrullinated histone H3 confirmed the formation of NETs (Figure 1A).

Results: Indeed, we found that hemin (ferriprotoporphyrin IX) activated neutrophils to generate reactive oxygen species and release NETs, which was prevented by addition of plasma-derived Hpx. Moreover, exposure of neutrophils to sera from patients with SCD promoted NET formation, which was significantly enhanced during VOC. However, we observed that circulating free heme levels were elevated in SCD patient serum irrespective of disease state, and serum concentrations of Hpx were reduced in both VOC and steady state compared to healthy donor serum. Strikingly, addition of Hpx in supraphysiological concentrations failed to prevent the formation of NETs in all SCD sera tested. We and others (Chen et al. Blood 2014) have found that, in contrast to heme, protoporphyrin IX does not trigger NET formation, revealing that the iron atom is required for the release of NETs. This observation led us to investigate whether free iron may directly induce NET formation. When neutrophils were exposed to Fe-NTA or serum from a thalassemia patient with iron overload, NETs were formed. Scavenging of free iron by addition of the iron-chelator deferoxamine or the specific iron-binding protein apotransferrin prevented NET release (Figure 1B). Moreover, we found that sequestration of free iron prevented NET formation induced by a subset (6 out of 11 tested), but not all, sera of patients with VOC (Figure 1C and D). In addition, sickled red blood cells (RBCs) are known to bind to neutrophils in vitro. Here, we found that neutrophils released NETs in response to sickled RBCs, even in the presence of Hpx. By contrast, blocking of complement C5 activation completely prevented the formation of NETs when neutrophils were exposed to sickled RBCs (Figure 1E).

Summary/Conclusions: In summary, we observed that sequestration of free iron with these iron binding compounds may be explored therapeutically to prevent or treat VOC development in SCD. Finally, complement activation in the presence of sickled RBCs activates neutrophils to release NETs, which may also contribute to VOC and SCD pathogenesis. Therefore, anti-CS IgG may represent an alternative therapeutic strategy to prevent VOC in SCD.

New drugs for rescue in relapsed/refractory multiple myeloma

S456

PHASE 3 ELOQUENT-2 STUDY: EXTENDED 4-YEAR FOLLOW-UP OF ELOTUZUMAB PLUS LENALIDOMIDE/DEXAMETHASONE VS LENALIDOMIDE/DEXAMETHASONE IN RELAPSED/REFRACTORY MULTIPLE MYELOMA

1Bristol-Myers Squibb and Kapodistrian University of Athens School of Medicine, Athens, Greece, 2Winship Cancer Institute, Emory University, Atlanta, United States, 3Queen Elizabeth II Health Sciences Centre and Dalhousie University, Halifax, Canada, 4University Hospital, Nantes, France, 5University Hospital of Salamanca–Instituto de Investigación Biomédica de Salamanca (IBSAL), Salamanca, 6Clínica Universidad de Navarra, Centro de Investigación Médica Aplicada, IDISNA, CIBERONC, Pamplona, Spain, 7Dana-Farber Cancer Institute, Boston, United States, 8Institute of Haematology, Assuta Medical Centers, Tel Aviv, Israel, 9Medical University of Silesia, Katowice, Poland, 10Charles University in Prague and General Teaching Hospital, Prague, Czech Republic, 11Medical University of Lublin, Lublin, Poland, 12Davidoff Cancer Center, Rabin Medical Center, Petah Tikva, Israel, 13Cross Cancer Institute and University of Alberta, Edmonton, 14Princess Margaret Hospital, Toronto, Canada, 15Ankara University, Ankara, Turkey, 16Bristol-Myers Squibb, Lawrenceville, 17AbbVie Bioresearch-apeutics Inc. (ABR), Redwood City, United States, 18University of Tübingen, Tübingen, Germany

Background: Elotuzumab is an immunostimulatory monoclonal antibody that targets SLAMF7, a glycoprotein highly expressed on multiple myeloma (MM) cells and natural killer cells. Elotuzumab exerts a dual effect, directly activating natural killer cells and mediating MM cell death via antibody-dependent cell-mediated cytotoxicity. In a 3-year follow-up of ELOQUENT-2 (NCT01239797), elotuzumab plus lenalidomide/dexamethasone (ELd) demonstrated a sustained 27% reduction in the risk of disease progression/death and an overall survival (OS) trend towards benefit compared with lenalidomide/dexamethasone (Ld) alone in patients with relapsed/refractory (RR) MM (Dimopoulos et al, ASH 2015).

Aims: To evaluate the long-term efficacy and safety of ELd following extended 4-year follow-up (median 46 months).

Methods: RRMM patients with 1-3 prior lines of therapy randomized 1:1 received ELd or Ld in 28-day cycles until disease progression/ unacceptable toxicity or consent withdrawal. Co-primary endpoints were progression-free survival (PFS) and overall response rate (ORR); OS was a secondary endpoint (analysis not prespecified for this data cut) and safety an exploratory endpoint. Written informed consent was obtained for all patients.

Results: In total, 646 RRMM patients were randomized: 321 to ELd and 325 to Ld. At 4-year follow-up (data cut-off: Oct 18, 2016), nearly twice as many patients remained on ELd therapy vs Ld (17% vs 9%). With the extended follow-up, ELd demonstrated a sustained relative improvement of 50% in PFS rates vs Ld (21% vs 14%) and maintained reduction in the risk of progression/death of 29% for ELd vs Ld (all randomized patients: HR 0.71; 95% CI 0.59, 0.86). Patients with very good partial response (VGPR) (ELd 112, Ld 89 [29%]) had the greatest benefit in risk of progression/death (HR 0.65; 95% CI 0.46, 0.94). ORR was greater with ELd vs Ld (79% vs 66%) and the duration of response benefit was maintained over time (HR 0.77; 95% CI 0.62, 0.95). Early separation of the Kaplan–Meier survival curves, which remained consistently separated over time, supports a sustained OS benefit in favor of ELd vs Ld (Figure). Grade 3-4 adverse events in ≥5% of patients were generally comparable between ELd and Ld arms-vascular diseases (10% vs 8%; mostly venous-related), second primary malignancies (SPMs; 9% vs 6%) and cardiac disorders (5% vs 8%); the exception was a
slightly higher incidence of infection with ELd (33% vs 26%). Overall rate (any grade of anemia, 84% vs 75%) and SPMd (11% vs 2%) was better for ELd vs Ld. However, exposure to ELd was longer than to Ld (median [Q1, Q3] treatment cycles: 19 [9, 42] vs 14 [6, 25]). Disease progression and infection were major causes of mortality in both arms; however, fewer deaths were reported with ELd vs Ld (165 vs 186).

Summary/Conclusions: At 4 years, ELd has the longest median follow-up of an immuno-oncology agent in MM. The data continue to show that adding elotuzumab to Ld results in durable long-term responses, clinically relevant improvement in PFS, sustained reduction in risk of progression/death, and a survival trend in favor of ELd. Overall, these data continue to support the durability and efficacy of ELd. Updated safety and tolerability, including rate of SPMd, was consistent with previous findings despite longer exposure, with minimal incremental AE compared with Ld therapy.

A PHASE IB STUDY OF ISATUXIMAB PLUS POMALIDOMIDE (POM) AND DEXAMETHASONE (DEX) IN RELAPSED/REFRACTORY MULTIPLE MYELOMA (RRMM) Aims: To evaluate combination therapy with ISA plus Pom/Dex in pts with RRMM. Methods: Pts with RRMM (≥2 prior MM therapies, including lenalidomide and a proteasome inhibitor) were sequentially enrolled to ISA 5, 10, or 20mg/kg (plus Pom/Dex) based on preliminary safety, efficacy, and PK data. Primary objective: determine maximum tolerated dose (MTD). All patients were required to provide informed consent. Results: 26 pts were analyzed (5mg/kg [n=8]; 10mg/kg [n=12]; 20mg/kg [n=6]), median age 65 (42-80) yrs. Median 4.0 (2-11) prior treatment regimens, with 20 (77%) pts refractory to prior immunomodulatory drug therapy. At data cut-off (Nov 8, 2016), median duration of ISA treatment was 19.0 wks and 16 pts remained on treatment. 2 pts at 10mg/kg discontinued therapy due to adverse events (AEs) (grade [Gr] 5 perforated bowel; Gr 3 infusion-associated reaction [IAR]). Dose-limiting toxicities reported in 1 pt at each dose level (Gr 4 neutropenia; Gr 4 neutropenic infection; Gr 3 confusional state), and MTD has not been reached. Most common TEAEs, besides IARs, were fatigue (62%), diarrhea (35%), and dyspnea (31%). Most frequent Gr 3/4 hematologic abnormality (laboratory assessment) was neutropenia (Gr 3, 40%; Gr 4, 52%). Gr 3/4 thrombocytopenia was reported in 8 (32%) pts (Gr 3, 16%; Gr 4, 16%). IARs occurred in 12 (46%) pts (Gr ≥3 in 1 pt); only with 1st infusion in 9/12 pts. 16 (62%) pts achieved at least PR (5, 8, and 3 pts at 5, 10, and 20mg/kg), including 1 CR, 8 PR, 1 CR and 7 PR. Clinical benefit rate (≥MR) was 73%. Median time to 1st response, 4.2 wks; median duration of response, 25.6wks. The PK parameters were comparable with those previously reported in the PFS interim analysis for ENDEAVOR.

Summary/Conclusions: ENDEAVOR was the first randomized phase 3 trial to directly compare two different PIs in RRMM. Patients who received Kd had significantly longer OS compared with patients who received Vd. Safety results were comparable with those previously reported. The combination of ISA and Pom/Dex showed promising clinical activity and manageable toxicity, with the potential for improved outcomes in RRMM.

S458
OVERALL SURVIVAL OF PATIENTS WITH RELAPSED OR REFRACTORY MULTIPLE MYELOMA TREATED WITH CARFILZOMIB AND DEXAMETHASONE VERSUS BORTEZOMIB AND DEXAMETHASONE IN THE RANDOMIZED PHASE 3 ENDEAVOR TRIAL Aims: To evaluate the efficacy and safety of carfilzomib (Kd) and pomalidomide (Pom) plus dexamethasone (VD) in relapsed or refractory multiple myeloma (RRMM) patients. Methods: The ENDEAVOR study was a phase 3, randomized, active-controlled study of DVd vs Vd. Patients who had RRMM and had received 1–3 prior lines of therapy were randomized in a 1:1 ratio to receive Kd or Vd. The Kd arm, carfilzomib was given on days 1, 2, 8, 9, 15, and 16 (20mg/m² on days 1, 2 of cycle 1; 9mg/m² thereafter) and Pom/dexamethasone (VD) on days 1, 2, 3, and 4. Results: 1,025 pts were randomized (479 Kd, 546 Vd). The primary endpoint was OS at 4 years. The OS benefit for Kd vs Vd was consistent in both high-risk and standard-risk MM, across the subgroups defined by cytogenetics (high-risk cytogenetics vs standard-risk cytogenetics), number of prior lines of therapy (1 vs ≥2 prior lines), and degree of prior chemotherapy (Table S1). The median OS (95% CI) was 47.6 (42.5-NE) months in the Kd arm and 40.0 (32.6-42.3) months in the Vd arm, and all-cause mortality was significantly reduced with Kd vs Vd (HR, 0.791; 95% CI, 0.648-0.964; 1-sided P=0.0100). The overall survival benefit was consistent regardless of prior bortezomib therapy (HR 0.75 for Kd vs Vd, no prior bortezomib; HR 0.84 for Kd vs Vd, prior bortezomib) and across all age groups (HR, 0.85 <56y; 0.71, 65-74y; 0.84, 75y+), baseline ECOG performance status (HR, 0.81, 0; 0.81, 1-2), and cytogenetic risk groups (HR, 0.83, high risk; 0.85, standard risk), and number of prior lines of therapy (HR, 0.83, 1 prior line; 0.76, 2-3 prior lines). The most frequent any-grade adverse events in the Kd arm were (Kd vs Vd) anemia (42.5% vs 28.3%), diarrhea (36.3% vs 40.6%), pyrexia (32.4% vs 15.4%), dyspnea (32.2% vs 13.6%), fatigue (32.2% vs 30.7%), and hypertension (32.2% vs 9.9%). Grade 3 or higher adverse events were experienced by 81.4% of patients in the Kd arm and 71.1% of patients in the Vd arm.

Summary/Conclusions: ENDEAVOR was the final randomized phase 3 trial to directly compare two different PIs in RRMM. Patients who received Kd had significantly longer OS compared with patients who received Vd. Safety results were comparable with those previously reported. The PFS interim analysis for ENDEAVOR is ongoing.

S459
EFFICACY AND SAFETY OF DARATUMUMAB, BORTEZOMIB AND DEXAMETHASONE (DVD) VERSUS BORTEZOMIB AND DEXAMETHASONE (VD) IN RELAPSED OR REFRACTORY MULTIPLE MYELOMA (RRMM): UPDATED ANALYSIS OF CASTOR Aims: To evaluate the efficacy and safety of daratumumab (DAR) plus pomalidomide (Pom) and dexamethasone (Dex) in relapsed or refractory multiple myeloma (RRMM). Methods: The CASTOR study was a phase 3, randomized, active-controlled study of DVD vs VD. Patients with RRMM (any number of prior lines) were randomized in a 2:1 ratio to receive DVD or VD. The primary endpoint was OS at 4 years. The OS benefit for DVD vs VD was consistent in both high-risk and standard-risk MM, across the subgroups defined by cytogenetics (high-risk cytogenetics vs standard-risk cytogenetics), number of prior lines of therapy (1 vs ≥2 prior lines), and degree of prior chemotherapy (Table S1). The median OS (95% CI) was 47.6 (42.5-NE) months in the Kd arm and 40.0 (32.6-42.3) months in the Vd arm, and all-cause mortality was significantly reduced with Kd vs Vd (HR, 0.791; 95% CI, 0.648-0.964; 1-sided P=0.0100). The overall survival benefit was consistent regardless of prior bortezomib therapy (HR 0.75 for Kd vs Vd, no prior bortezomib; HR 0.84 for Kd vs Vd, prior bortezomib) and across all age groups (HR, 0.85 <56y; 0.71, 65-74y; 0.84, 75y+), baseline ECOG performance status (HR, 0.81, 0; 0.81, 1-2), and cytogenetic risk groups (HR, 0.83, high risk; 0.85, standard risk), and number of prior lines of therapy (HR, 0.83, 1 prior line; 0.76, 2-3 prior lines). The most frequent any-grade adverse events in the Kd arm were (Kd vs Vd) anemia (42.5% vs 28.3%), diarrhea (36.3% vs 40.6%), pyrexia (32.4% vs 15.4%), dyspnea (32.2% vs 13.6%), fatigue (32.2% vs 30.7%), and hypertension (32.2% vs 9.9%). Grade 3 or higher adverse events were experienced by 81.4% of patients in the Kd arm and 71.1% of patients in the Vd arm.

Summary/Conclusions: ENDEAVOR was the first randomized phase 3 trial to directly compare two different PIs in RRMM. Patients who received Kd had significantly longer OS compared with patients who received Vd. Safety results were comparable with those previously reported. The PFS interim analysis for ENDEAVOR is ongoing.

22nd Congress of the European Hematology Association

168 | haematologica | 2017; 102(2)
and 11; 20mg PO/IV dexamethasone on Days 1-2, 4-5, 8-9, and 11-12) with or without daratumumab (18mg/kg IV once weekly in Cycles 1-3, every 3 weeks for Cycles 4-8, then every 4 weeks until progression). Patients who were refractory to bortezomib were excluded. Progression-free survival (PFS) was the primary endpoint. Minimal residual disease (MRD) was assessed at suspected complete response (CR) and at 6 and 12 months after first dose at 3 sensitivity thresholds (10^-4, 10^-5, and 10^-6) using the ClonoSEQ™ next-generation sequencing (NGS)-based assay (Adaptive Biotechnologies, Seattle, WA).

Results: A total of 498 patients were randomized with median (range) age of 64 (30-88) years. Patients received a median (range) of 2 (1-10) prior lines of therapy; 65% of patients previously received bortezomib, and 21% were refractory to lenalidomide in their last prior line of therapy. After median follow-up of 13.0 months, DVD significantly prolonged PFS compared with Vd (median: not reached vs 13.0 months, DVD significantly prolonged PFS compared with Vd alone (median: not reached vs 7.1 months; hazard ratio [HR], 0.33; 95% confidence interval [CI], 0.26-0.43; P<0.0001). Twelve-month PFS rates were 60% versus 22%, respectively. Significant PFS benefit was observed with DVD over Vd regardless of the number of prior lines of therapy, although the greatest benefit was seen in patients with 1 prior line of therapy (median: not reached vs 7.9 months; HR, 0.22; 95% CI, 0.14-0.34; P=0.0001). Overall response rate (ORR; 84% vs 63%) and rates of very good partial response (VGPR) or better (62% vs 29%) and CR or better (26% vs 10%) continued to be significantly higher with DVD compared with Vd (P<0.0001 for all). MRD-negative rates were more than 4 times higher at all 3 sensitivity thresholds with DVD versus Vd: 18.3% versus 3.6% at 10^-4(P<0.0001), 10.4% versus 2.4% at 10^-5 (P<0.001), and 4.4% versus 0.8% at 10^-6 (P=0.01). MRD-negative patients had prolonged PFS compared with MRD-positive patients at 10^-4 sensitivity threshold (Figure). At the clinical cut-off date, 37 (15%) deaths in the DVD group and 58 (24%) in the Vd group have been observed (HR, 0.63; 95% CI, 0.42-0.96), and follow up is ongoing. Thrombocytopenia was the most common grade 3 or 4 treatment-emergent adverse event (45% with DVD vs 33% with Vd). No new safety signals were reported after median treatment duration of 11 months with daratumumab. Updated efficacy and safety data with longer follow up will be presented at the meeting.

Figure 1.

Summary/Conclusions: Dvd is superior to Vd in terms of PFS, ORR, depth of response, and MRD-negative rates, with no new safety signals reported. These updated data further support the use of DVD as a standard of care in R/RMM, with the greatest benefit observed in patients with 1 prior line of therapy.

S460

A PHASE 1B STUDY OF VENETOCLAX COMBINED WITH BORTEZOMIB AND DEXAMETHASONE IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA

1CHU de Nantes, Hotel Dieu–HME, Nantes, France, 2Mayo Clinic, Jacksonville, United States, 3Royal Melbourne Hospital and Walter and Eliza Hall Institute of Medical Research, Melbourne, Victoria, Australia, 4The University of Arizona Cancer Center, Tucson, United States, 5CHRU Lille, Hospital Huriez, Lille, France, 6Mayo Clinic, Rochester, 7AbbVie, Inc., North Chicago, United States, 8Peter MacCallum Cancer Centre, Melbourne, Australia

Background: Venetoclax (VEN) is a potent, selective, orally bioavailable small-molecular inhibitor of BCL-2. When combined, VEN can enhance the activity of bortezomib in multiple myeloma (MM) cell lines and xenograft models.

Aims: The objectives of the study are to evaluate safety and preliminary efficacy of VEN with bortezomib and dexamethasone in relapsed/refractory (RR) MM.

Methods: Phase 1b study of patients (pts) with R/R MM who received daily VEN (50-1200mg for dose escalation cohorts; 800mg in safety expansion) with standard bortezomib (1.3mg/m² SC) and dexamethasone (20mg PO).

Results: As of 19Aug2016, 86 pts were enrolled. Median age was 64 years; 9 (14%) pts had t(11;14), 5 (8%) had t(4;14), 15 (23%) had del(17p), and 30 (45%) had del(13q) abnormalities. Median number of prior therapies was 3 (range: 1-13), with 39% of pts refractory to prior bortezomib, 14% to carfilzomib, 53% to lenalidomide, and 21% to pomalidomide. Median time on study was 5.9 months (range: 0.3-29.8). Forty-six (70%) pts discontinued, with 36 due to disease progression (PD). Common AEs in ≥30% of pts were diarrhea (46%), constipation (41%), thrombocytopenia (39%), nausea (38%), peripheral neuropathy (33%), and insomnia (32%). Common grade ≥3 AEs in ≥10% of pts were thrombocytopenia (29%), anemia (15%) and neutropenia (14%). Serious AEs in ≥2 pts were febrile neutropenia, thrombocytopenia, cardiac failure, pyrexia, influenza, lower respiratory tract infection, pneumonia, sepsis, acute kidney injury, respiratory failure, embolism, and hypotension. Dose-limiting toxicities were grade 3 cardiac failure in the 300mg cohort (possibly related to dexamethasone) and grade 3 thrombocytopenia during the first cycle in the safety expansion. No events of laboratory or clinical TLS were reported. Four deaths were due to PD and 1 due to respiratory syncytial virus infection. Overall response rate (ORR) for all pts was 67% (44/66); 28 (42%) pts achieved very good partial response (VGPR) or better (3 stringent complete response [sCR], 10 CR, 15 VGPR). Pts non-refractory to prior proteasome inhibitors (PI) or immunomodulatory drugs (IMiDs) had higher ORR than refractory pts (PI, 92% vs 32%; IMiDs, 82% vs 57%). Among pts refractory to any 2 or more (n=15), 3 or more (n=7), or all 4 (n=4) prior therapies (bortezomib, carfilzomib, lenalidomide, pomalidomide), ORR was 40%, 43%, and 25%, respectively. Median time to progression (~10 vs 3 months) and duration of response (~10 vs 7 months) were longer for pts not refractory to any of these therapies versus refractory pts. ORR for pts with or without cytogenetic abnormalities, respectively, was as follows: 78% vs 65% for t(11;14), 60% vs 67% for t(4;14), 47% vs 73% for del(17p), and 63% vs 69% for del(13q).

Summary/Conclusions: VEN combined with bortezomib and dexamethasone has an acceptable safety profile with promising anti-myeloma activity, and the highest response rates were observed in R/R MM pts who were not refractory to PI or IMiDs. These data support the ongoing phase 3 trial with this regimen in R/R MM.
Cyto genetic Complexity in Chronic Lymphocytic Leukemia: Definitions, Associations with Other Biomarkers and Clinical Impact; A Retrospective Study on Behalf of ERIC

Background:
Recent evidence suggests that complex karyotype (CK) identified by chromosome banding analysis (CBA) may be a relevant biomarker for treatment decisions in CLL, especially regarding the response to signaling inhibitors. However, many challenges towards routine clinical application of CBA still need to be overcome.

Aims: Retrospective and prospective definitions for CK in CLL and systematic investigation of clinicobiological associations and prognostic impact.

Methods: 3850 CLL and monoclonal B-cell lymphocytosis (MBL) patients (CLL=3322, 93% and MBL=258, 7%, respectively) were analysed with Cpg-oligodeoxynucleotides/Interleukin-2 (CPG/iL2, n=379, 11%), phorbol-12-myristate-13-acetate (TPA, n=1345, 37%). CBA was mostly performed within the first year from diagnosis and before treatment administration (79% and 88%, respectively). Main features of the studied cohort: median age: 65.6 years/ males: 2252 (63%)/ Binet A/B/C: 2356/357/258 with no difference in the detection rate between different cell stimulation protocols. CK was significantly identified in 16% / del(11q): 377/3256 (12%)/ del(17p): 137/1345 (10%, respectively). The median OS (OS) is increased by 5-10% compared to those treated with chemotherapy alone. Patients with mutated IGHV genes (M-CLL) and/or unfavorable cytogenetic alterations (i.e. del(17p)/TP53 mutation, and del(11q)) have a better outcome than those with unmutated IGHV genes (U-CLL) and/or poor FISH cytogenetics and show a plateau in survival curves, suggesting that a fraction of these patients may have a survival similar to general population. Nevertheless, the possibility that some M-CLL patients without unfavorable cytogenetics are overtreated is of concern because of the treatment toxicity related to CIT, particularly FCR.

Aims: The aim of this study was to analyse the outcome of M-CLL patients with no unfavorable cytogenetics CK according to the type of therapy.

Methods: We analysed 816 CLL patients from Sant Pau Hospital, Barcelona, Spain; Uppsala University Hospital, Sweden and IRCCS San Raffaele Scientific Institute, Milan, Italy for whom IGHV mutational status was available. Endpoints were OS and TFS.

Results:
488 patients had mutated IGHV genes (400 without unfavorable FISH cytogenetics; 26 had either del(11q) and/or del(17p), and in 62 cases FISH cytogenetics was not available) and 328 patients carried unmutated IGHV genes. The main clinical and biological characteristics at diagnosis are shown in Table 1. OS at 5 and 10 years was 93% (CI, 95-91) and 81% (CI, 85-77) for M-CLL cases and 78% (CI, 83-73) and 65% (CI, 52-79) for U-CLL cases (p<0.05). TFS at 5 and 10 years was 73% (CI, 69-77) and 68% (CI, 63-73) and 28% (CI, 33-37) and 10% (CI, 14-6) for M-CLL and U-CLL, respectively (p<0.05). After a median follow-up of 8 years (range, 1-26), 424 patients [161 M-CLL (163 without poor-prognostic FISH cytogenetics, 13 with either del(11q) and/or del(17p) and 12 cases in whom FISH information was not available) and 263 U-CLL (U-CLL) required therapy. De novo treatment was initiated in 24% of cases (PA)-based therapy (n=83), alkylating agents (n=212), anti-CD20 mAbs with PA or bendamustine (n=75), anti-CD20 mAbs with alkylating agents (n=21), BCR-signal inhibitors or BCL2 antiapoptotic agents (n=9), others (n=23), and unknown (n=1).

Table 1.

Results:
488 patients had mutated IGHV genes (400 without unfavorable FISH cytogenetics; 26 had either del(11q) and/or del(17p), and in 62 cases FISH was not available) and 328 patients carried unmutated IGHV genes. The main clinical and biological characteristics at diagnosis are shown in Table 1. OS at 5 and 10 years was 93% (CI, 95-91) and 81% (CI, 85-77) for M-CLL cases and 78% (CI, 83-73) and 65% (CI, 52-79) for U-CLL cases (p<0.05). TFS at 5 and 10 years was 73% (CI, 69-77) and 68% (CI, 63-73) and 28% (CI, 33-37) and 10% (CI, 14-6) for M-CLL and U-CLL, respectively (p<0.05). After a median follow-up of 8 years (range, 1-26), 424 patients [161 M-CLL (163 without poor-prognostic FISH cytogenetics, 13 with either del(11q) and/or del(17p) and 12 cases in whom FISH information was not available) and 263 U-CLL (U-CLL) required therapy. De novo treatment was initiated in 24% of cases (PA)-based therapy (n=83), alkylating agents (n=212), anti-CD20 mAbs with PA or bendamustine (n=75), anti-CD20 mAbs with alkylating agents (n=21), BCR-signal inhibitors or BCL2 antiapoptotic agents (n=9), others (n=23), and unknown (n=1).
IBRUTINIB, FLUDARABINE, CYCLOPHOSPHAMIDE, AND OBINUTUZUMAB (iFCG) FOR PREVIOUSLY UNTREATED PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKAEMIA (CLL) WITH MUTATED IGHV AND NON-DEL(17P)

Aims: To develop an FC-based chemoimmunotherapy regimen of finite duration that included ibrutinib and obinutuzumab. The intent was to limit FC to 3 courses, potentially reducing short- and long-term toxicity, while maintaining efficacy through the addition of ibrutinib and a more potent antibody (obinutuzumab).

Methods: We designed an investigator-initiated phase II trial with ibrutinib, fludarabine, cyclophosphamide, and obinutuzumab (iFCG) for previously untreated CLL patients. The intent was to limit FC to 3 courses, potentially reducing short- and long-term toxicity, while maintaining efficacy through addition of ibrutinib and obinutuzumab. Key eligibility included age ≤ 18, IGHV-M, no del17p. Pts received 3 courses of iFCG. G-CSF was not mandated. Primary endpoint: CR/CRI with bone marrow (BM) MRD-neg (4-color flow-cytometry) after 3 courses of iFCG. Pts meeting primary endpoint received ibrutinib for 5 years and obinutuzumab for 3 years. A was added in cycle 2 with a dose ramp-up (to 400mg daily) over 5 weeks. A was added in cycle 2 with a dose ramp-up (to 400mg daily) over 5 weeks. A was added in cycle 2 with a dose ramp-up (to 400mg daily) over 5 weeks.

Results: Since activation (April 2016), 26 patients were consented; 23 initiated treatment. We report data on these 23 patients. This is the first report of this trial. Median age was 59 years (range, 25-71); there were 18 men. Prognostic markers included [FISH: del13q (n=17), negative (n=3); trisomy 12 (n=3); CD38+ (n=7); ZAP70+ (n=6/21 evaluated)]. By trial design, all patients had IGHV-M. Median B2M was 2.6 (range, 1.4-8.1). Median pretreatment WBC count was 81.1 K/uL (range, 3.1-224), platelet count 120 K/uL (range, 82-292), hemoglobin 12.4 g/dL (range, 9.1-15.6). Eighteen patients have completed 3 courses of iFCG and had initial response assessment (the remaining 5 patients have not yet completed 3 courses of treatment). All 18 patients achieved a clinical response; 14/18 (78%) achieved MRD-negative remission in the marrow at 3 months (17/18, 94%) and 16/18 (89%) achieved MRD-negative remission as their overall best response. Overall, 7/18 achieved CR/CRI with MRD-negative status in bone marrow at 3 months. All patients with PR had bulky adenopathy at baseline, and had residual lymphadenopathy ranging from 1.8 to 3.5 cm after 3 courses of iFCG. No patient has progressed, and all but one patient received treatment on protocol. Of the 23 pts, 11 pts had G3-4 neutropenia and 5 pts had thrombocytopenia. 1 pt had neutropenic fever. 1 pt who achieved MRD-cri CR developed pulmonary MAC infection, and declined further therapy. 1 pt had atrial fibrillation. G3 ALT developed in 3 pts. FC was dose reduced in 10 pts; ibrutinib dose-reduced in 2 pts.

Summary/Conclusions: IFCG achieves high rate of MRD-neg remission after 3 courses. Pt enrollment continues, and updated results will be presented at the EHA meeting.

Results: Between May 2015 and January 2016, 66 pts were enrolled. Two R/R pts died of a sepsis and 1 TN pt discontinued due to toxicity during the first induction cycle; these 3 pts with <2 induction cycles were excluded from the analysis as predefined by protocol. 34 pts were treatment-naive and 29 had R/R CLL (median number of prior therapies: 2; range: 1-8). Median age was 59 (28-77) years; the median CIRS score was 2 (0-14) and 16 pts (25%) had a creatinine clearance of 30-70/ml/min. 11 of 59 pts (19%) had a del(17p) and 45 of 61 (74%) had an unmutated IGHV status. Risk categories for TLS at baseline were: low (ALC ≤25,000/µL & LN <5cm): 9 pts (15%); intermediate (ALC >25,000/µL or LN 5-10cm): 35 (58%) and high (ALC >25,000/µL or LN >10cm): 16 (27%), 3 missing. 45 pts (71%) received B debulking, 18 (29%) pts immediately started with the induction. 60 pts completed 6 induction cycles with G and A. All TN (100%) and all but two of the R/R pts (93%) respond-
22nd Congress of the European Hematology Association
ed (table 1); with an ORR of 97% at the end of induction, the primary endpoint
was met. MRD negativity (<10-4 by flow cytometry) in peripheral blood (pB)
was achieved in 56 pts (89%); MRD assessment from bone marrow was available in 8 pts (4 TN and 4 R/R, among them 4 with a CR and 4 with a PR) and
were all negative. As of January 9th2017, 83 serious adverse events (SAEs)
were reported in 37 pts, including 69 SAEs (83%) related to study treatment.
66 SAEs (80%) were CTC°3-4 and 1 had a fatal outcome (sepsis in 4th induction cycle). Most SAEs occurred in the R/R cohort (61 SAEs, 74%) and during
the induction phase (63 SAEs, 76%). Most common SAEs were infections (27
in 16 pts; including 13 CTC°3-5) and hematological disorders (18 in 10 pts; 10
CTC°3-4), followed by infusion-related reactions (6 in 6 pts), laboratory TLS (5
in 5 pts; 1 during B debulking, 1 in induction cycle 1 with G, 2 in cycle 3 and 1
in cycle 4 with G and A) and ischemic coronary artery disorders (5 in 4 pts). No
clinical TLS occured.
Summary/Conclusions: With an ORR of 97% and a MRD negativity rate of
89% in pB at the end of induction phase this sequential treatment of B debulking, followed by G and A was very efficacious in a heterogeneous study population and well tolerated except for 3 fatal septicaemias in R/R pts.
S465

SAFETY RESULTS OF TERMINATED PHASE 2 STUDY OF IDELALISIB
PLUS RITUXIMAB IN TREATMENT NAÏVE CHRONIC LYMPHOCYTIC
LEUKEMIA (CLL) WITH DEL(17P)
P. Hillmen1,*, X. Badoux2, J. Delgado3, V. Leblond4, A. Mato5, M. Simkovic6,

5Hospital of the University of Pennsylvania, Philadelphia, United States, 6University Hospital and Charles University, Faculty of Medicine, Hradec Králové,
Czech Republic, 7Gilead Sciences, Inc., Foster City, United States, 8Specialistic
Hospital, Brzozow, Poland, 9Niguarda Hospital, Hematology Department,
Niguarda Cancer Center, Milano, Italy

Background: Idelalisib (IDELA) is an oral PI3Kδ inhibitor approved in the EU
for use with rituximab (R) or ofatumumab in patients (pts) with previously treated
CLL or as first-line treatment of CLL with either del(17p) or TP53 mutation in
pts unsuitable for other therapies. Prior single arm studies have suggested
that front line use of IDELA may be associated with an increased frequency of
transaminase elevations compared to relapsed pts.
Aims: To describe: 1) the safety of IDELA plus rituximab in previously untreated CLL
pts with del(17p) in this terminated study, and 2) the relation of key AEs and age.
Methods: Treatment-naïve pts with CLL and confirmed del(17p) were treated
in a single arm study with R 375mg/m² IV weekly x8 and IDELA 150mg PO
BID continuously until disease progression or intolerability. Informed consent
was obtained. The study was fully enrolled when terminated early due to infection related safety concerns observed in a pooled analysis of ongoing Ph3
IDELA trials in front/early line therapy; the planned independent efficacy analysis was not performed, but investigator assessment is available.
Results: 102 pts (median age, 66; range, 37-86) were enrolled between Aug
2014 and Jan 2016 and received IDELA for a median (med) duration of 6.4
months (range, 0.7-17.0). The study was terminated in Mar 2016, >8 wks after
dosing of the last enrolled pt. 77 pts (75.5%) remained on study at the time of
study termination. The reasons for discontinuation from study were death
(4.9%), progressive disease (3.9%, 1 fatal), investigator discretion (9.8%), withdrawal of consent (2.9%), other anticancer therapy (2.0%), and lost to follow
up (1.0%). The investigator assessed response rate was 79%. 101 pts (99%)
had adverse events (AEs); Gr ≥3 occurred in 80.4%, the most frequent Gr ≥3
were ALT increased (27.5%), neutropenia (20.6%), infections (18.6%), and
diarrhea (14.7%). Laboratory Gr ≥3 ALT and/or AST elevations were seen in
41.2%, with med time of onset of 8.1 wks (range 4.1-24.1). The med age of pts
both with and without Gr ≥3 ALT/AST was 66 years, and the incidence of Gr
≥3 ALT/AST was similar in younger (43.9%, <65yr) and older (39.3%, ≥65yr)
pts. Gr ≥3 diarrhea/colitis occurred in 17.1% of pts <65yr and in 14.8% of pts
≥65yr. Dose interruptions due to AEs occurred in 71 pts (70%), most frequently
due to transaminase elevations (37.3%), and diarrhea/colitis (15.7%). Discontinuation due to AEs occurred in 27% of pts, most frequently due to ALT/AST
elevation (9.8%). Serious adverse events were reported in 46 (45.1%), including pyrexia (10.8%), diarrhea/colitis (11.8%). AEs of special interest included
Gr ≥3 infections in 20 pts (19.6%) of whom 5 had CMV and 3 had PJP (none
on prophylaxis), Gr ≥3 febrile neutropenia in 5 (4.9%) and any grade pneumonitis in 5 (4.9%). Of the 5 pts with CMV, all were CMV IgG+ at screening
and 2 also were IgM+. There were 6 on-study deaths, 3 associated with infection, 2 due to CLL progression and 1 due to heart failure.
Summary/Conclusions: In IDELA plus rituximab treated front-line CLL, the
pattern of AEs was similar to that seen in relapsed CLL studies at similar duration of therapy, however the frequency of Gr ≥3 ALT/AST was increased compared to the relapsed setting. There was no significant effect of age on the risk
of either ALT/AST elevations or diarrhea/colitis. The occurrence of CMV and
PJP infections is consistent with current IDELA labeling and speaks to the
potential benefit of risk mitigation through PJP prophylaxis and CMV monitoring
during treatment. NCT02044822.

Rochester, 11University of California at Los Angeles, Los Angeles, 12University
of Rochester School of Medicine, Rochester, 13Kite Pharma, Santa Monica,
United States
Background: Outcomes for pts with refractory aggressive NHL are poor with
current therapies (Crump, ASCO 2016). Results from the interim analysis of (n=62)
of ZUMA-1, the 1st multicenter trial of an anti-CD19 chimeric antigen receptor
(CAR) T cell, axi-cel, in refractory aggressive NHL, showed an objective response
rate (ORR) of 79% (complete response [CR] 52%; Blood 2016;128:LBA-6). Here
we present results from the primary analysis of ZUMA-1.
Aims: Here we present results from the primary analysis of the ZUMA-1 trial.
Methods: Pts received a target dose of 2 × 106 anti-CD19 CAR T cells/kg after
low- dose conditioning with cyclophosphamide and fludarabine. Eligible pts
(≥18 y) had diffuse large B cell lymphoma (DLBCL), primary mediastinal B cell
lymphoma (PMBCL) or transformed follicular lymphoma (TFL); an ECOG performance status (PS) 0-1; and refractory disease (progressive or stable disease
as best response to last prior therapy, or relapsed ≤12m of autologous stem
cell transplant [ASCT]). The primary endpoint for this analysis was ORR in the
combined DLBCL, PMBCL, and TFL population. Key secondary endpoints
were duration of response (DOR), overall survival (OS), and frequency of
adverse events (AEs). The primary analysis was triggered when 92 pts had at
least 6m of follow-up
Results: As of January 27, 2017, 111 pts from 22 institutions were enrolled;
101 pts (91%) received axi-cel. Median age was 58 y (range, 23-76), 67%
male, 85% stage III-IV, 47% IPI 3-4, 77% refractory to ≥2nd line of therapy,
and 21% relapsed ≤12m of ASCT. Axi-cel was successfully manufactured in
110/111 (99%) pts with an average turnaround time from apheresis to the clinical site of 17 d. With an ORR of 82% (n=92; P<.0001) the study met the primary
endpoint. The ORR in the mITT analysis set of 101 pts was 82% (CR 54%, PR
28%), and was consistent across key covariates including disease subtype,
refractory status, stage, and IPI score. At a median follow up of 8.7 m, 44% of
pts were in response and 39% were in CR. The median DOR was 8.2m overall
and not reached for pts who achieved a CR. Median OS was not reached;
80% of pts remained alive at 6 m. The most common Gr ≥3 treatment-emergent
AEs were neutropenia (66%), leukopenia (44%), anemia (43%), febrile neutropenia (31%), and encephalopathy (21%). Gr ≥3 cytokine release syndrome
(CRS) and neurologic events (NE) occurred in 13% and 28% of pts, respectively. All CRS and all NE resolved except 1 Gr 1 memory impairment. As previously reported, there were 3 Gr 5 AEs (3%). Peak CAR T levels and AUC
post–axi-cel were associated with durable responses. Additionally, this presentation will include an expanded analysis of efficacy outcomes by novel biologic and clinical covariates including key molecular phenotypes and tocilizumab/corticosteroid interventions used for management of adverse events.
Summary/Conclusions: Axi-cel significantly improved ORR in patients with
refractory aggressive NHL. The CR rate was 7-fold higher compared to historical controls (Crump, ASCO 2016) and nearly half the patients had an ongoing
response. Axi-cel demonstrated significant clinical benefit with a manageable
safety profile in pts lacking curative treatment options.

Summary/Conclusions: The combination of CC-122 and obinutuzumab was well tolerated and demonstrates promising response rates and durable remissions in R/R patients with B-cell NHL. CC-122 doses of ≥3mg and obinutuzumab were shown to have best response rates to date. The study is ongoing to establish the phase II recommended dose.

S469

SINGLE ASENT ORAL SELINEXOR EXHIBITS DURABLE RESPONSES IN RELAPSED/REFRACTORY LARGE B-CELL LYMPHOMA (DLBCL) OF BOTH GCB AND NON-GCB SUBTYPES: THE PHASE 2B SADAL STUDY

M. Maeroveot1, J. Westin2, C. Thielemont3, J. Zijlstra4, B.T. Hill5

Summary/Conclusions: Updated evaluation of pola + BR shows promising durable responses and an acceptable safety profile in heavily pre-treated R/R FL and DLBCL pts. Safety and efficacy data will be updated at the time of presentation.
Background: Patients (pts) with persistent DLBCL after two or more lines of therapy have limited effective treatment options. The nuclear export protein exportin 1 (XPO1) is upregulated in hematologic malignancies, including DLBCL, and has pleiotropic effects on tumorigenesis including functional downregulation of tumor suppressor proteins (TSPs) and increased export and translation of mRNAs for oncoproteins c-Myc and key survival proteins such as Bcl-2. SELinexor (SEL), an oral XPO1 inhibitor, causes sequestration of TSPs including p53, p21, and IκBα, the latter of which serves to suppress NF-κB driven transcription, along with reductions in c-Myc and Bcl-2 family proteins.

Methods: PtS with R/R DLBCL were randomized to 60 or 100mg of SEL twice weekly (8 doses) per 28-day cycle. Pts were stratified by DLBCL subtype (GCB or non-GCB). The primary objectives are to determine the ORR and evaluate the safety of 60 vs 100mg doses. Disease response was assessed by an Independent Central Radiological Review (ICRR), using the Lugano Classification (Cheson, 2014).

Results: 72 pts were enrolled: 37 pts on 60mg (24 M/ 13 F, median age 71 yrs) and 35 pts on 100mg (23 M/ 12 F, median age 68 yrs). Both groups had a median of 3 prior treatment regimens. The most common related adverse effects (AEs) across both dose groups (Grades 0-3) were: fatigue (47%), nausea (46%), anorexia (42%), and vomiting (33%). Common Grade 3/4 AEs were: thrombocytopenia (39%), fatigue (18%), neutropenia (18%), and anemia (13%). These were managed with dose interruption/reduction, platelet stimulators, and/or standard supportive care. Grade 3/4 fatigue (26% v 11%) and thrombocytopenia (48% v 32%) were higher in the 100mg arm compared to the 60mg arm. Among the 63 evaluable pts (9 pts pending response), the ICRR determined ORR was 28.5% (Table 1). Nine responders, including 6 pts in CR, remained on treatment. Responders on the 60mg arm have a median time on treatment of 8.9 months as compared with 3.8 months on the 100mg arm.

Summary/Conclusions: SEL monotherapy shows activity in pts with R/R DLBCL including in pts with GCB subtype. 60mg SEL twice weekly was more tolerable than 100mg twice weekly, with fewer interruptions due to toxicity. Objective responses to SEL were durable at 60mg BIW, suggesting these responses were associated with clinical benefit.

Summary/Conclusions: The combination of MOR208 plus LEN is well tolerated and shows promising activity in patients with R/R DLBCL. Accrual and follow-up of patients is ongoing, as are cell of origin and other biomarker analyses.
ENASIDENIB (AG-221) IN MUTANT-IDH2 RELAPSED OR REFRACTORY ACUTE MYELOID LEUKEMIA (R/R AML): RESULTS OF A PHASE 1 DOSE-ESCALATION AND EXPANSION STUDY

M.R. Patel12, A. Stein13, M.A. Sekeres14, R.T. Swords15, B.C. Medeiros16, R.D. Knight17, S. Agresta18, S. de Botton19, M.S. Tallman1,2

1Memorial Sloan Kettering Cancer Center, 2Well Cornell Medical College, New York, 3The University of Texas MD Anderson Cancer Center, Houston, 4University of Colorado School of Medicine, Aurora, 5Massachusetts General Hospital Cancer Center, 6Harvard Medical School, Boston, 7The New York Presbyterian Hospital, New York, 8Robert H. Lurie Comprehensive Cancer Center, Northwestern University Feinberg School of Medicine, Chicago, 9Dana-Farber Cancer Institute, Boston, 10Sarah Cannon Research Institute, Nashville, 11University of Texas Southwestern Medical Center, Dallas, 12Florida Cancer Specialists and Sarah Cannon Research Institute, Sarasota, 13City of Hope Comprehensive Cancer Center, Duarte, 14Cleveland Clinic Taussig Cancer Institute, Cleveland, 15Sylvester Comprehensive Cancer Center, University of Miami, Miami, 16Stanford Comprehensive Cancer Center, Stanford University, Stanford, 17Cellgene Corporation, Summit, 18Agios Pharmaceuticals, Inc., Cambridge, United States, 19Institut Gustave Roussy, Villejuif, France

Background: Recurrent mutations in isocitrate dehydrogenase 2 (mIDH2) occur in ~12% of AML patients (pts), mIDH2 proteins synthesize an oncometabolite, 2-hydroxylutarate (2HG), causing DNA and histone hypermethylation and blocked myeloid differentiation. Enasidenib (AG-221) is an oral, selective, small-molecule inhibitor of mIDH2 proteins. Differentiation of myeloblasts, not cytotoxicity, appears to drive the clinical efficacy of enasidenib. In preclinical studies, bone marrow blasts from pts with mIDH2 exposed to enasidenib ex vivo were shown to produce mature, fully functioning neutrophils with conserved mIDH2 allele frequency, indicating differentiation of mature cells from the mIDH2 blasts (Yen et al, Cancer Discov, 2017). Additionally, no apoptosis was observed in mIDH2-R140 erythroleukemia (TF-1) cells treated with enasidenib for 7 days in vitro.

Aims: Evaluate the maximum tolerated dose (MTD), pharmacokinetic (PK) and pharmacodynamic (PD) profiles, safety, and clinical activity of enasidenib in pts with mIDH2 advanced myeloid malignancies.

Methods: This phase 1/2 study included pts aged ≥18 years (yrs) with mIDH2- defined AML, or with mIDH2 MDS with refractory anemia with excess blasts, and ECOG PS scores ≤2. Pts were relapsed or refractory (R/R) to prior anti-cancer therapy, or had untreated AML if aged ≥60 years and not eligible for standard-of-care treatment (Tx). Safety for all pts and clinical efficacy in the largest pt subgroup, those with R/R AML, from the phase 1 dose-escalation and expansion phases are reported.

Results: In all, 239 pts received enasidenib. Median age was 70 yrs. In the dose-escalation phase (n=113), pts received daily enasidenib doses of 50-650mg. The MTD was not reached. Median 2HG reductions from baseline at cycle 2 day 1 were 92%, 90%, and 93% for pts receiving <100mg, 100mg, and >100mg/day, respectively. Enasidenib 100mg QD was chosen for the expansion phase (n=126) based on PK/PD profiles and demonstrated efficacy. Median number of enasidenib cycles was 5 (range 1-25). Grade 1-4 adverse events (AEs) included thrombocytopenia (58%), neutropenia (31%), and anemia (27%). Thrombocytopenia was the most common reason for treatment interruption. Hematologic AEs were reversible, and grade >3 nonhematologic AEs occurred in ~10% of pts. Median time to first response was 1.9 months (mos); 87.3% of responding pts attained a complete remission [CR] by cycle 5. Median response duration was 5.8 mos. Of pts who achieved CR, 7 pts (21%) did so by cycle 3, 23 (68%) by cycle 5, and 28 (82%) by cycle 7. Median duration of CR was 8 mos. ORR with enasidenib 100mg/day was 38.5% (Table). Seventeen pts (11%) proceeded to stem cell transplant. Response was associated with cellular differentiation, typically with no evidence of aplasia. Median overall survival (OS) of R/R AML pts was 9.3 mos. For pts who attained CR, OS was 19.7 mos. Pts who had received ≥2 prior AML Tx had a median OS of 8.0 mos.

Summary/Conclusions: Enasidenib was well tolerated, induced CRs in R/R AML pts, and was associated with OS of >9 mos in pts who had failed prior AML Tx. A randomized phase 3 study of enasidenib vs conventional care in older pts with late-stage R/R AML is ongoing (NCT02577406).

S472

SAFETY AND EFFICACY OF VENETOCLAX (VEN) IN COMBINATION WITH DECITABINE OR AZACITIDINE IN TREATMENT-NAIVE, ELDERLY PATIENTS (≥65 YEARS) WITH ACUTE MYELOID LEUKEMIA (AML)

1Johns Hopkins Sidney Kimmel Comprehensive Cancer Center, Baltimore, 2University of Colorado School of Medicine, Aurora, 3UC Davis Comprehensive Cancer Center, Sacramento, 4Department of Hematology and Hematopoietic Cell Transplantation and Gehr Family Center for Leukemia Research, City of Hope National Medical Center, Duarte, United States, 5The Alfred Hospital, and Monash University, Melbourne, Australia, 6Emory University, Atlanta, 7Northwestern University Feinberg School of Medicine, Chicago, 8University of Chicago Medical Center, Chicago, United States, 9Centre Hospitalier Universitaire (CHU) de Bordeaux, INSERM U1141, Université de Bordeaux, Bordeaux, 10Institut Universitaire du Cancer de Toulouse Oncopole, CHU de Toulouse and Université de Toulouse III, Toulouse, France, 11Peter MacCallum Cancer Centre, Melbourne, Australia, 12AbbVie Inc, North Chicago, 13Dana-Farber Cancer Institute, Boston, 14University of Texas MD Anderson Cancer Center, Houston, United States

Background: Newly diagnosed patients (pts) with AML aged ≥65 years and ineligible for standard induction therapy have limited treatment options, and low overall survival. VEN is an orally bioavailable, selective BCL-2 inhibitor that has displayed single-agent activity in pts with relapsed/refractory AML. VEN at either dose-escalation doses combines well with time-matched decitabine (DEC) or azacitidine (AZA), demonstrated antileukemic activity, with an overall response rate (ORR) including complete remission [CR] and CR with incomplete marrow recovery of 60%. Combining VEN with HMAS, such as decitabine (DEC) or azacitidine (AZA), may provide a novel low-intensity approach for treating AML. Preliminary results from the expansion stage of a phase 1b trial comparing 2 doses of VEN plus either DEC or AZA (NCT02203773) are reported.

Aims: To evaluate the safety and efficacy of VEN at 400-mg vs 800-mg doses plus DEC or AZA.

Methods: This open-label, nonrandomized, two-stage phase 1b study evaluated the safety and efficacy of VEN plus DEC or AZA in treatment-naïve pts ≥65 years old with AML. Eligibility included: ECOG PS ≤2; eligible for standard induction therapy; intermediate- or poor-risk karyotype. Pts received DEC (Arm D, 20mg/m²/day [d]; intravenous [IV]) on d 1-5, or AZA (Arm E, 75mg/m²/d; subcutaneous or IV) on d 1-7 of each 28-d cycle (C) in combination with once-daily oral VEN. The dose-escalation stage consisted of 2 VEN dose cohorts (continuous 400-mg and interrupted 800-mg dosing) in each arm (D1, D2, E1, and E2, respectively) to determine optimal dose. Tumor lysis syndrome (TLS) prophylaxis was administered in C1 to all pts during VEN dose ramp-up until final dose was reached. All pts provided informed consent.
Results: As of 13/09/16, 100 pts were enrolled in the expansion stage; 25 pts in each arm. Overall, 61% pts were male, 50% had ECOG PS 1 and 15% ECOG PS 2; mean age was 73.9 (range 65–86); 53% had adverse karyotype; and 22% had secondary AML. Median time on study was 6 (4-9), 6 (0.2-9), 5 (0.5-9), and 4 (1-8) mo for arms D1, D2, E1, and E2, respectively. The incidence of adverse events (AEs) was generally comparable between the 4 arms. Overall, the most common treatment-emergent AEs (TEAEs; in ≥30% of pts) were nausea (59%), diarrhea (42%), febrile neutropenia (FN; 41%), constipation (39%), fatigue, and decreased white blood cell count (31% each). The most frequent grade 3/4 TEAE and serious AE was FN (41% and 29%, respectively).

Methods: In this open-label phase 1/2 study, pts ≥65 years with untreated AML, ineligible for standard induction chemotherapy, with an ECOG performance status of 0-2 received oral VEN QD on days (d) 1-28 and subcutaneous LDAC 20mg/m² QD on d 1–10 of each 28-d cycle. VEN target dose evaluation followed a 3+3 design, ranging from 600–800mg; 18 pts were enrolled and the RP2D was established as 600mg. Safety and efficacy of VEN at RP2D were evaluated in the expansion phase. All pts were hospitalized and received prophylaxis before a dose ramp-up of VEN during cycle 1 to mitigate the risk of tumor lysis syndrome (TLS). Adverse events (AEs) were graded by NCI CTCAE V4.0. Pts enrolled as of May 2016 are included in this analysis; data cutoff was August 2016. All pts provided informed consent.

Results: In total, 61 pts, including 8 from phase 1, were treated at the RP2D of 600mg (median age 74 years; ECOG 1–2 70%; adverse karyotypes 31%; secondary AML 44%; prior hypomethylating agent [HMA] 28%). AEs (all grade; severe; grade 3/4) included cytopenias (52%; 37%); neutropenia (26%); 17% grade 3/4). Among response-evaluable pts, those achieving an objective response had longer survival than pts who do not achieve an objective response (Figure 1).

Figure 1.

Summary/Conclusions: Overall, the safety profile was favorable when combining VEN at either dose with DEC or AZA in treatment-naïve elderly AML pts. Promising activity with high ORRs was observed at the lower 400-mg VEN dose in both HMA arms. A Phase 3 study of VEN plus AZA is planned.
received AZA 75mg/m²  Days 1-7 with nivolumab 3mg/kg on Day 1 and 14. Courses were repeated every 4-5 weeks indeﬁnitely. Only one of six pts had a dose limiting toxicity (grade 3 pneumonitis) and this dose was RP2D. 60 additional pts have been treated at the RP2D.

Results: 66 pts with a median age of 71 years (range, 44-90), secondary AML (39%), poor risk cytogenetics (35%), median number of prior regimens 2 (range, 1-7) have been enrolled. All 66 pts had baseline next generation sequencing: TP53 (n=12), DNMT3A (n=12), ASXL1 (n=10), TET2 (N=9), and RAS (n=9), IDH2 (n=9), IDH1 (n=6), CEBPA (n=7). 63 pts are evaluable for response: 14 (22%) achieved complete remission (CR)/complete remission with insuﬃcient recovery of counts (CRi) (3 CR, 11 CRi), 7 (11%) had hematologic improvement (HI); 1(0.1%) had 25% BM blast reduction, 5 pts (8%) had stable disease >6 months, and 24 (38%) had progression. 3 pts are too early for response assessment (<3 courses). The median number of courses to CR/CRi/HI was 2 (range, 1-4.5). The median OS among the CR/CRi/HI pts was 15.3 months (range, 2.27-17.17). HI pts was 5.7 months (range, 4.67-17.45), and NR was 5.0 months (range, 0.29-16.16). The 4- and 8-week mortality were 5% and 11%, respectively. The median OS for the 63 evaluable pts on Aza+Nivo compares favorably to historical median OS with AZA-based salvage protocols in similar pts treated at MDACC (P=0.10) (Fig 1A and Fig 1B). Grade 3/4 and Grade 2 immune toxicities were observed in 8 (12%) and 7 (11%) pts, respectively. The most common Grade 3/4 AE on treatment included pneumonitis, colitis, nephritis, skin rash, and hypophysitis. One pt died from grade 4 pneumonitis/epiglottitis. In the remaining 14 cases the toxicities responded rapidly to steroids and 13 of these pts were successfully rechallenged with nivolumab. Time to onset of toxicities ranged from 4 days to 3.5 months. Multicolor flow-cytometry studies and Mass-cytometry (CyTOF) studies are conducted by the Immunotherapy Platform on baseline and on-treatment BM aspirate (end of cycle 1, 2, 4, 8). Baseline and end of cycle (EOC) 1 and 2 BM was evaluated in 6 responders and 19 non-responders. Pts who achieved a response had a baseline higher live total CD3 (P=0.10), CD8+ T-cells (P=0.02), and lower live CD4+Foxp3+PD1+ T-regulatory (T-reg) cells (P=0.01) inﬁltrate in BM. Patients who had a response had progressive increase in BM CD3+ cells and BM CD8+ cells, with increased ICOS (activation) marker on BM CD4-effecter cells at EOC 1 and EOC 2 as compared to those who had no response. The CTLA4 on CD8 T-cells went up in both responders and non-responders after PD1 based therapy.

Figure 1. OS with Aza+Nivo compared to historical survival with AZA-based salvage protocols in similar pts treated at MDACC in (a) all salvage and (b) ﬁrst relapse only.

Summary/Conclusions: Full dose AZA and nivolumab are tolerable and produce an encouraging response rate with durable responses in relapsed AML with poor risk features. Immune mediated toxicities occur and may be adequately managed with early recognition and systemic steroids. Up-regulation of CTLA4 may be a mechanism of resistance to PD1 based therapies in AML and suggest role for combination therapy.

S475

QUIZARTINIB AND BRIDGE TO TRANSPLANT IN FLT3-ITD AML PATIENTS AFTER FAILURE OF SALVAGE CHEMOTHERAPY: A HISTORICAL COMPARISON WITH UK NATIONAL CANCER RESEARCH INSTITUTE (NCRI) DATA

R. Hills1,*, G. Gammon2, D. Trone3, A. Burnett4

1Centre for Trials Research, Cardiff University, Cardiff, United Kingdom, 2formerly Daichi Sankyo, 3Daichi Sankyo, San Diego, United States, 4Blackwarterfoot, Isle of Arran, United Kingdom

Background: The presence of a FMS-like tyrosine kinase 3 (FLT3) Internal Tandem Duplication (ITD) mutation in pts with AML is associated with an increased early relapse rate and a dismal prognosis. Quizartinib is a potent, selective FLT3-inhibitor that conferred median overall survival (mOS) of 23 weeks and remission rate of 46% in a single-arm phase 2 study (AC220-002) in pts with AML with a FLT3-ITD mutation who were relapsed or refractory (R/R) to second line therapy. (Levis, et al, ASH 2012) As context, a study of AML pts, regardless of FLT3 mutation status, receiving second-salvage therapies (consisting of 12 weeks of mOS of only 1.5 months. (Giles F, et al, Cancer 104 (3), 2005). Such poor-risk pts may beneﬁt from a stem cell transplant (SCT), if available.

Aims: The primary aim was to compare SCT rates and outcomes of pts on quizartinib from an exploratory selected cohort in the AC220-002 study with those from a historical cohort of 1388 AML pts with conﬁrmed FLT3-ITD mutations in the UK NCRI database.

Methods: Within AC220-002, 58 pts with a FLT3-ITD mutation were identiﬁed who had received intensive chemotherapy, and were relapsed (n=53), or refractory (n=5) to salvage therapy prior to entry. Applying the same entry criteria to the NCRI database, we identiﬁed 118 pts who received only recognized chemotherapy regimens prior to eligibility (relapsed n=99, refractory n=19). To avoid biases where those dying early would predominantly contribute to the NCRI group (referring that pts in AC220-002 had to be ﬁt enough to be enrolled), pts in this cohort entered analysis 14 days following being identiﬁed as R/R. Multivariable Cox/logistic regression was used to compare remission rates and survival stratiﬁed for known prognostic factors. A landmark analysis excluding deaths before day 90 (allowing for those too unﬁt for SCT) was performed on the pooled sample (n=176) of the AC220-002 and NCRI cohorts to compare survival between transplanted and non-transplanted pts.

Results: Overall, quizartinib-treated pts had signiﬁcantly greater remission rates, consisting mainly of complete remission without normal blood counts (CRi), vs NCRI pts (40% vs 3%, adjusted OR 0.05 (0.01-0.21), p<0.0001) and improved mOS (140d vs 56d, adjusted HR 0.38 (0.25-0.58) p<0.0001). A greater proportion of pts in AC220-002 proceeded to SCT: 23/58 (40%) vs 9/118 (8%). Comparing survival in SCT vs no-SCT in a landmark analysis, 18-month survival was signiﬁcantly greater in the SCT group (29% vs 7%, adjusted HR 0.36 (0.20-0.65) p=0.0005). Signiﬁcance persisted in sensitivity analyses with the landmark set at 120 or 150 days indicating an association between long-term survival and SCT. A similar analysis in an unmatched cohort consisting of SCT-naive pts in ﬁrst relapse also found better survival for SCT vs no-SCT, conﬁrming a potential beneﬁt of SCT in this poor risk population.

Summary/Conclusions: When compared to a large historical cohort, quizartinib was associated with greater remission rates and opportunity to receive SCT in pts who relapsed after salvage therapy. While varying practice patterns and patient factors undoubtedly inﬂuence treatment choices and outcomes, pts with AML with FLT3-ITD mutation appeared to beneﬁt with longer survival observed with SCT. This data suggests quizartinib may show promise in potentially improving long-term survival by bridging patients to SCT.

Background: CTL019 is an investigational therapy whereby autologous T cells are genetically engineered with a chimeric antigen receptor (CAR) to identify and eliminate CD19-expressing malignant B cells. Data from 2 phase 2 studies (ELIANA; NCT02435849 and ENSIGN; NCT02228096) in pediatric and young adult R/R B-cell ALL were pooled to evaluate cellular kinetics of CTL019. Aims: We report cellular kinetics, humoral immunogenicity, AUC-28d (exposure)-response analysis and impact of intrinsic/extrinsic and manufacturing factors on CTL019 expansion.

Methods: Cellular kinetic parameters of CTL019 post infusion were derived using traditional pharmacokinetic principles and reported by response category (complete response [CR]/CR with incomplete blood count recovery [CRi]) vs no response [NR] using 2 assays of peripheral blood cells: qPCR and flow cytometry. AUC-28d-response relationships were evaluated by logistic regression. Relationships between manufacturing specifications, therapies for cytokine release syndrome (CRS) management, and anti-CAR19 antibodies on cellular kinetics were explored using summary statistics and graphical- and model-based analyses.

Results: As of November 2016, 88 pts were enrolled. There were 7 (8%) manufacturing failures, 9 (10%) pts were not infused due to death or adverse events (AEs), and 4 pts (5%) were pending infusion at the time of data cutoff. Following lymphodepleting chemotherapy in most pts (fludarabine/cyclophosphamide [n=64] or other [n=11]), 68 pts were infused with a single dose of CTL019 (median dose, 3.04 x 10^6/kg; range, 0.25-6.4 x 10^6/kg) and 29 pts were treated after manufacturing failures, with a median study follow-up of 6.4 mo. Median age was 12 y (range, 3-23 y); 59% of pts had prior allogeneic stem cell transplant (alloSCT). Five infused patients had not reached 3 mo of follow-up; among 63 evaluable pts, 52 (83% [95% CI, 71%–91%]) achieved CR/CRi within 3 mo of CTL019 infusion, all of whom had minimal residual disease–negative marrow. The release-free probability at 6 mo after remission onset was 75% (95% CI, 57%-87%; median DOR not reached). The probability of survival was 99% (95% CI, 77%-99%) at 6 mo and 79% (95% CI, 63%-89%) at 12 mo. Seven pts (13% of responders) proceeded to alloSCT within 6 months while in remission. Cytokine release syndrome (CRS) was graded using the U Penn scale and managed using a protocol-specific algorithm; CRS occurred in 78% of pts (21% grade 3; 27% grade 4); no CRS-associated deaths occurred. 38% of pts received tocilizumab for treatment of CRS or without other anti-cytokine therapy. Most common grade 3/4 hematologic AEs (>15%) other than CRS were hypotension (22%), hypoxia (18%), and infection (10%). Total cell count (N=78) included CD19+ lymphoblasts by morphology. CTL019 was manufactured from lymphodepleting chemotherapy in most pts (fludarabine/cyclophosphamide (AEs), and 4 pts (5%) were pending infusion at the time of data cutoff. Following

Results:

Summary/Conclusions: The ELIANA study confirmed the efficacy of a single infusion of CTL019, without additional therapy, observed in a previous interim analysis and a prior single-center CTL019 trial. AEs were effectively and reproducibly managed globally by appropriately trained personnel at study sites.

Background: CTL019 is an investigational therapy whereby autologous T cells are genetically engineered with a chimeric antigen receptor (CAR) to identify and eliminate CD19-expressing malignant B cells. Data from 2 phase 2 studies (ELIANA; NCT02435849 and ENSIGN; NCT02228096) in pediatric and young adult R/R B-cell ALL were pooled to evaluate cellular kinetics of CTL019. Aims: We report cellular kinetics, humoral immunogenicity, AUC-28d (exposure)-response analysis and impact of intrinsic/extrinsic and manufacturing factors on CTL019 expansion.

Methods: Cellular kinetic parameters of CTL019 post infusion were derived using traditional pharmacokinetic principles and reported by response category (complete response [CR]/CR with incomplete blood count recovery [CRi] vs no response [NR]) using 2 assays of peripheral blood cells: qPCR and flow cytometry. AUC-28d-response relationships were evaluated by logistic regression. Relationships between manufacturing specifications, therapies for cytokine release syndrome (CRS) management, and anti-CAR19 antibodies on cellular kinetics were explored using summary statistics and graphical- and model-based analyses.

Results: Data from 79 pts (ELIANA, n=50; ENSIGN, n=29) were pooled for analysis. Using qPCR, pts with CR/CRi (n=62) had 2-fold higher CTL019 expansion than pts with NR (n=7) (Cmax, 73.5% higher geometric [geo] mean; AUC0-28d, 104% higher geo mean; Table 1). Pts with NR had delayed Tmax compared with pts with CR/CRi (20 vs 10 days). Intrinsic pt factors including baseline cytogenetics, disease characteristics, and disease status did not appear to affect Cmax or AUC-28d with the exception that pts with a higher tumor burden at enrollment generally had higher expansion, based on box plots of summary statistics. Extrinsic factors (prior lines of therapy, stem cell transplant) and parameters related to the manufactured product (% T cells, transduction efficiency, cell viability, total cell count), did not appear to impact cellular kinetics, based on graphical analysis. AUC-28d increased with pres-
e
ence and severity of CRS. Pts who received anti-cytokine agents for grade 3/4 CRS also had higher expansion. CR/CRi pts treated with tocilizumab and steroids (n=17) had 89% higher AUC0-28d than CR pts who did not receive tocilizumab and steroids (n=45). Experience is limited in NR pts with (n=4) and without (n=4) tocilizumab. Moderate correlation was observed between trans-gene levels and CAR surface expression in peripheral blood (r=0.592) by qPCR and flow cytometry, respectively, when matched by time points from the cellular kinetic profile. Slower B-cell recovery was observed in pts with AUC0-28d above the median. Post-dose anti-CAR19 antibody responses were determined from the fold change of anti-CAR19 antibodies above the baseline pre-dose value. Pts with treatment-induced or boosted anti-CAR19 antibody responses generally had lower expansion, based on box plots, compared with pts with treatment-unaffected anti-CAR19 antibody responses, although AUC0-28d was variable. The boosted levels of anti-CAR19 did not impact clinical response or relapse.

**Summary/Conclusions:** There was increased expansion of CTL019 in pts with higher tumor burden at enrollment, which correlated with higher CRS grade. There was no relationship between dose and expansion, supporting the wide dose range used. Expansion was not attenuated by tocilizumab or steroids, indicating therapies for CRS do not abrogate CTL019 proliferation. Cellular kinetics are important to understand the determinants of tumor response with CAR T-cell therapy.

**BLINATUMOMAB VS SOC CHEMOTHERAPY IN FIRST SALVAGE COMPARED WITH SECOND OR GREATER SALVAGE IN A PHASE 3 STUDY**

H. Dombret1,*, M.S. Topp2, A. Schuh3, A. Wei4, G. Martinelli5, S. Durrant6, C.L. Bacon7, K. Nie8, Z. Zimmerman9, H. Kantarjian10

1Hôpital Saint-Louis, Paris, France, 2Universitätsklinikum Würzburg, Würzburg, Germany, 3Princess Margaret Cancer Center, University Health Network, Toronto, Canada, 4Alfred Hospital, Monash University, Victoria, Australia, 5Institute of Hematology and Medical Oncology “L. e. A. Seragnoili”, S. Orsola University Hospital, Bologna, Italy, 6Clinical Haematology and BMT, Royal Bournemouth Hospital, Herston, Australia, 7St. James’s Hospital, Dublin, Ireland, 8Global Biostatistical Sciences, 9Global Development, Amgen, Thousand Oaks, 10Department of Leukemia. The University of Texas MD Anderson Cancer Center, Houston, United States

**Background:** Adults with B-cell precursor (BCP) acute lymphoblastic leukemia (ALL) often relapse following standard induction/consolidation chemotherapy (CR/CRi). Blinatumomab second and successive CTX salvage regimens (S2+) is poor compared with first salvage (S1) or frontline therapy, with less favorable outcomes among patients with shorter CR duration. Blinatumomab links cytotoxic CD3-positive T cells and CD19-positive B cells to induce tumor cell lysis. In a randomized phase 3 trial of blinatumomab vs investigator’s choice of 4 standard of care CTX (SOC) regimens, median OS was 7.7 months in the blinatumomab group vs 4.0 months with SOC (Kantarjian H, et al., NEJM 2017). Here, we evaluate outcomes by salvage status for patients in this study (NCT02013167).

**Aims:** To evaluate responses to blinatumomab vs SOC in patients with relapsed/refractory ALL by prior salvage therapy status.

**Methods:** Patients with relapsed/refractory (R/R) BCP-ALL in this international multicenter trial were randomized 2:1 to blinatumomab (n=271) or SOC (n=134). For this analysis, salvage status was adjudicated separately from prior randomization. Blinatumomab was given by continuous IV infusion (9 µg/d in week 1 of cycle 1, then 28 µg/d) in cycles of 4 weeks, on 2 weeks off. The primary endpoint was overall survival (OS), determined from time of randomization until death due to any cause. Adverse events (AE) of interest were coded according to MedDRA version 16.0.

**Results:** At baseline, patient characteristics were balanced between groups within salvage designations. The rate of complete remission, with or without full hematologic recovery (CR/CRi/CRh) in both the S1 and S2+ groups was higher in the blinatumomab arm compared with the SOC arm (Table 1). Patients randomized to blinatumomab had a median (95% CI) of 11.1 (8.2, NR) months vs 5.1 (3.3, 7.1) months overall survival for S1 vs S2+ subgroup, compared with 5.5 (3.7, 9.0) months vs 3.0 (2.1, 4.0) months in the SOC arm (Figure 1). For both S1 and S2+ subgroups, blinatumomab patients had longer median survival time. Grade 3 or worse AEs were experienced by 61% and 83% of S1 patients in the blinatumomab and SOC group, respectively. These percentages were 68% and 75%, respectively, in S2+ patients. Grade 4 or worse AEs occurred in 34% and 51% S1 patients, and in 36% and 54% S2+ patients. Neurologic events of grade 3 occurred in 9% and 9% of S1 patients, and in 10% and 9% S2+ patients, respectively. Grade ≤3 cytokine release syndrome (CRS) was observed in 4% S1 and 5% S2+ patients receiving blinatumomab, and in no SOC patients.

**Table 1.**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>AUC0-28d</td>
<td>5.1</td>
</tr>
</tbody>
</table>

**Summary/Conclusions:** Patients in this trial receiving blinatumomab for R/R ALL achieved improved OS and remission rates compared with SOC regardless of prior salvage therapy. Improved OS compared with SOC in S1 patients supports earlier use of blinatumomab.

**S479**

**DURABLE LONG-TERM SURVIVAL OF ADULT PATIENTS WITH B-ALL AFTER CD19 CAR (19-28Z) T CELL THERAPY**

J. Park1, I. Riviere1, X. Wang1, B. Senechal1, Y. Wang1, T. Purdon1, R. Brentjens1, M. Sadelain1

1Memorial Sloan-Kettering Cancer Center, New York, United States

**Background:** CD19-specific chimeric antigen receptor (CAR) T cells have demonstrated high initial responses in patients with relapsed B-ALL. However, clinical characteristics associated with the durability of response remain undefined.

**Aims:** We performed a retrospective analysis of our phase I clinical trial of 19-28z CAR T cells in adult patients with relapsed B-ALL (NCT01044069) with a focus to identify those patients who optimally benefit from 19-28z CAR T cell therapy with durable long-term survival and reduced toxicities.

**Methods:** Adults with relapsed B-ALL were infused with autologous T cells expressing the 19-28z CAR following conditioning chemotherapy. Disease burden was assessed by bone marrow biopsy immediately prior to T cell infusion; patients with ≤5% blasts were classified as minimal residual disease (MRD) cohort vs patients with >5% blasts as morphologic disease cohort. Response assessment occurred at 4 weeks. Median follow-up duration was 18 months (range, 0.2-57.3).

**Results:** 51 adults received 19-28z CAR T cells; 20 in the MRD and 31 in the therapy, with 95% confidence interval [CI]: 4.2-9.0) vs 6.3 months (95% CI, 4.8-9.0) (p=0.0005), and NR (95% CI, 15.3-NR) vs 17 months (95% CI, 8.5-36.2) (p=0.0189), in the MRD and morphologic cohorts, respectively. Subsequent allelogeneic HSCT in either cohort did not improve survival (p=0.8). MRD cohort patients developed substantially less severe cytokine release syndrome (CRS) and neurotoxicity, and both toxicities significantly correlated with peak haematologica | 2017; 102(s2) | 179

A SECOND GENERATION LYSOSOMOTROPIC AGENT DRIVES LEUKAEMIC STEM CELL DIFFERENTIATION AND SENSITIZES THEM TO TYROSINE KINASE INHIBITOR TREATMENT IN VITRO AND IN VIVO

P. Baquero1, E. Kunzi2, R. Mitchell3, A. Ianniello4, K.M. Ryan2, E. Gottlieb2, R.K. Krishnamurthy5, T.L. Holsclaw6, G. V. Herrmann1

1Wolfson Wohl Cancer Research Centre, Institute of Cancer Science, University of Glasgow, 2Cancer Research UK, Beatson Institute, Glasgow, United Kingdom, 3Department of Medicine, Perelman School of Medicine, University of Pennsylvania, Philadelphia, United States, 4Paul O’Gorman Leukaemia Research Centre, Institute of Cancer Science, University of Glasgow, Glasgow, United Kingdom

Background: Autophagy is a conserved catabolic process that delivers cytoplasmic constituents to the lysosomes. We have previously shown that the lysosomal agonist hydroxychloroquine (HCQ) inhibits autophagy and sensitizes Chronic Myeloid Leukaemia (CML) stem cells (LSCs) to tyrosine kinase inhibitors (TKIs) treatment. However, the biological effects of autophagy inhibition in LSCs in vivo are currently unknown and need to be investigated.

Methods: In this study, we used primary stem-cell enriched samples (CD34+ cells) derived from CML patients at diagnosis. For in vivo studies, we used a human patient-derived xenograft (PDX) model and an inducible transgenic CML model in which the expression of BCR-ABL is induced at a stem/progenitor level (Scl-Tal-BCR-ABL). To accurately measure autophagy flow in long term LSCs in vivo, we generated the transgenic mouse Scl-Tal-BCR-ABL/GFP-LC3 by crossing the Scl-Tal-BCR-ABL model with a mouse bearing the autophagy marker GFP-LC3 fused to GFP.

Results: Firstly, we show that Lys05 targets LSCs more potently than HCQ in vitro by achieving a 60% and a 35% reduction in number of CD34+CD38- and CFSE®/CD34+CD133+ cells respectively. Interestingly, Lys05 promoted a 40% loss of quiescent cells and induced myeloid differentiation of CD34+ cells. Functional long-term culture initiating cell (LTC-IC) assay demonstrated that, while HCQ had moderate effects, Lys05 decreased the number of LSC-derived colonies by 80%. Additionally, we show that Lys05 inhibits autophagy flow more efficiently than HCQ both in the Scl-Tal-BCR-ABL/GFP-LC3 model and in patient-derived progenitor cells. Analysis of bone marrow (BM) cells from Lys05-treated leukaemic mice (but not from HCQ-treated mice), showed a statistically significant 35% decrease (p=0.0469) in the most primitive population Lin-Sca+c-Kit+CD34+CD45+CFSEmax/CD34+CD133+cells respectively. For in vivo studies, we used a human patient-derived xenograft (PDX) model and an inducible transgenic CML model in which the expression of BCR-ABL is induced at a stem/progenitor level (Scl-Tal-BCR-ABL). To accurately measure autophagy flow in long term LSCs in vivo, we generated the transgenic mouse Scl-Tal-BCR-ABL/GFP-LC3 by crossing the Scl-Tal-BCR-ABL model with a mouse bearing the autophagy marker GFP-LC3 fused to GFP.

Results: Firstly, we show that Lys05 targets LSCs more potently than HCQ in vitro by achieving a 60% and a 35% reduction in number of CD34+CD38- and CFSE®/CD34+CD133+ cells respectively. Interestingly, Lys05 promoted a 40% loss of quiescent cells and induced myeloid differentiation of CD34+ cells. Functional long-term culture initiating cell (LTC-IC) assay demonstrated that, while HCQ had moderate effects, Lys05 decreased the number of LSC-derived colonies by 80%. Additionally, we show that Lys05 inhibits autophagy flow more efficiently than HCQ both in the Scl-Tal-BCR-ABL/GFP-LC3 model and in patient-derived progenitor cells. Analysis of bone marrow (BM) cells from Lys05-treated leukaemic mice (but not from HCQ-treated mice), showed a statistically significant 35% decrease (p=0.0469) in the most primitive population Lin-Sca+c-Kit+CD34+CD45+CFSEmax/CD34+CD133+cells respectively. For in vivo studies, we used a human patient-derived xenograft (PDX) model and an inducible transgenic CML model in which the expression of BCR-ABL is induced at a stem/progenitor level (Scl-Tal-BCR-ABL). To accurately measure autophagy flow in long term LSCs in vivo, we generated the transgenic mouse Scl-Tal-BCR-ABL/GFP-LC3 by crossing the Scl-Tal-BCR-ABL model with a mouse bearing the autophagy marker GFP-LC3 fused to GFP.

mal translocation (t(9;22)) that gives rise to the oncoprotein tyrosine kinase Bcr-Abl. Implementation of tyrosine kinase inhibitor (TKI) therapy resulted in significant clinical success but with TKIs failing to eradicate the disease initiating leukemic stem cell population (LSC), this treatment is not curative in the vast majority of patients. By using a transgenic CML mouse model, we previously showed that LSC persist despite complete Bcr-Abl kinase inhibition due to a lack of imatinib effect on LSC. Subsequently, we identified the ITIM carrying Fc gamma receptor IIb (FcyRllb; CD32) to be a 2.8-fold upregulated in Bcr-Abl+ versus control LS K (lin; Sca-1+; c-kit+) cells using microarray and qRT-PCR.

Aims: In this study, we first aimed to validate Bcr-Abl mediated FcyRllb upregulation on mRNA and protein level in leukemic cells. Next, we tested the effect of shRNA mediated FcyRllb knock-down and depletion on cell line and patient derived CML cells for studying FcyRllb expression and signaling. In order to test the biology of CML cells in vitro, we performed CFU and proliferation assays. Moreover, we performed viral infection of S-FU treated SCLITa/Bcr-Abl BM using FcyRllb shRNA or scrambled control and subsequent transplantation, followed by analyses of the disease, including immune-pheno-typing, and protein expression as well as histological analysis.

Results: Bcr-Abl increased FcyRllb mRNA (13.2-fold, p<0.001) and protein expression in primary murine lineage negative (lin-) BM cells. Reduction of FcyRllb in immortalized SCLITa/Bcr-Abl progenitor cells significantly reduced CFC (colony forming unit) expression and CFU (colony forming unit) proliferation rate in these cells (2.27-fold, p<0.001). Moreover, transplantation of SCLITa/Bcr-Abl shRNA;FcyRllb BM cells (CD45.1+) into FVB/N wildtype (WT) CD45.2+ recipients reduced spleen weight (352 ± 59.13mg), as compared to scrambled shRNA (568.1 ± 101.72mg). FACS analysis revealed a decrease in Gr-1+ cells (Gr-1+;CD45.1+;GFP+) were reduced in the BM (1.28-fold, p<0.01) of these mice. Flow-cytometric analysis of the stem cell compartment revealed decreased leukemic BM LSK cells (lin-; c-kit-; Sca-1-, CD45.1+, GFP-), 1.38-fold, p<0.05) in mice transplanted with shRNA;FcyRllb vs scrambled control. We observed similar effects upon FcyRllb depletion (FcyRllb-) vs wildtype (FcyRllb+/+) combined with virally induced Bcr-Abl expression. Interestingly, Bcr-Abl signaling induces FcyRllb phosphorylation in leukemic cells. Analysis of downstream signal pathways showed decreased levels of p-ERK, p-BTK, p-PLCγ1 in FcyRllb-/-, compared to FcyRllb+/+ Bcr-Abl transduced immortalized primary murine BM cells.

Summary/Conclusions: FcyRllb is upregulated in LSC derived from transgenic CML mice upon Bcr-Abl expression. Complete depletion or knock down of the receptor reduces CFU capacity and cell growth in CML cells and significantly impairs CML development and LSC burden in vivo, presumably due to impaired leukemic downstream signaling. Our data demonstrate that FcyRllb is critical and disease specific making it a potential novel therapeutic target in CML stem cells.

S483 MYC-DEPENDENT REPRESSION MECHANISM OF THE MiR-150 TRANSCRIPTION REGULATION IN CHRONIC MYEOLOID LEUKEMIA (CML) P. Hronová1, C. Rytířová1, K. Kager2, K. Sovová1, F. Sovova1, H. Kamová1, H. Klámová2, P. Pecherková1, Z. Sovová1, J. Kobílčíková1, T. Stiplka2, D. Perrot3, K. Machová Poláková1,4

Background: The expression of miRNAs is regulated at transcriptional as well as posttranscriptional levels. Dysregulation of miRNAs could directly induce or be a consequence of oncogenic pathways. Chronic myeloid leukemia (CML) is characterized by the 9;22 translocation resulting in the expression of Bcr-Abl tyrosine kinase which is the result of a block of miR-150 maturation and that miR-150 levels negatively correlated with MYC mRNA levels in CML HSPCs (p<0.001). Role of MYC in CML was further strengthened by imatinib induced downregulation and restored miR-150 levels in K562 and KCL22. Imatinib resistance in K562R and KCL-22R was characterized by further miR-150 downregulation. To assess the MYC role on regulating miR-150 levels we tested the MYC binding sites from the miR-150 locus after the imatinib treatment. We suggested potentially synergistic route for imatinib-induced BCR-ABL1 inhibition. This could be processed not only directly but also through an inhibition of a mutual positive regulatory loop between MYC and BCR-ABL1 (Xie et al. 2002). We also noticed dysregulation of miR-150 expression which is adjacent to the studied myri-150 CpG) to become activated by imatinib. We observed MYC levels dependent regulation of both genes, but FCGR1 is activated by MYC. This different regulatory role may be facilitated by the detected transcription factor CTCF binding to an insulator site between miR-150 promoter and the CpG. An activation of the insulator via CTFC binding could be an interaction between enhancers and promoters (Bell et al. 2000). CTFC was previously described to be an inhibitor of MYC transcription and we show CTFC transcription to be induced by imatinib. CTFC binding to DNA is prevented by DNA methylation. We did not detect DNA methylation within miR-150 upstream region.

Methods: We have used immortalized primary murine cells and HoxB8 immortalized murine bone marrow (BM) cells for studying FcyRllb expression and signaling. In order to test the biology of CML cells in vitro, we performed CFU and proliferation assays. Moreover, we performed viral infection of S-FU treated SCLITa/Bcr-Abl BM using FcyRllb shRNA or scrambled control and subsequent transplantation, followed by analyses of the disease, including immune-pheno-typing, and protein expression as well as histological analysis.

Results: Bcr-Abl increased FcyRllb mRNA (13.2-fold, p<0.001) and protein expression in primary murine lineage negative (lin-) BM cells. Reduction of FcyRllb in immortalized SCLITa/Bcr-Abl progenitor cells significantly reduced CFC (colony forming unit) expression and CFU (colony forming unit) proliferation rate in these cells (2.27-fold, p<0.001). Moreover, transplantation of SCLITa/Bcr-Abl shRNA:FcγRIIb BM cells (CD45.1+) into FVB/N wildtype (WT) CD45.2+ recipients reduced spleen weight (352 ± 59.13mg), as compared to scrambled shRNA (568.1 ± 101.72mg). and ii) verify accuracy and inter-laboratory reproducibility of results. The second phase of the study, involving 39 Italian Hematology Units, was meant to sharing a common protocol, a joint database for clinical and mutational data BCR-ABL1 KD mutation screening.

A next generation amplicon deep sequencing (Deep Seq) strategy for routine conducted to assess the feasibility, cost, turnaround times and clinical utility of kinase domain (KD) mutation screening is a precious tool for timely and rational (CML) patients (pts) on tyrosine kinase inhibitor (TKI) therapy, BCR-ABL1 Verona, Verona, 17Division of Hematology, Vicenza, 18Ospedale Dell’Angelo, Hematology/Oncology “L. e A. Seràgnoli”, Bologna, 2Department of Clinical... 23University of Bologna, Bologna, Italy

Background: Benchtop next generation sequencers are gradually replacing Sanger sequencers in diagnostics labs because of greater throughput, better sensitivity and increasing cost-effectiveness. In chronic myeloid leukemia (CML) patients (pts) on tyrosine kinase inhibitor (TKI) therapy, BCR-ABL1 kinase domain (KD) mutation screening is a precious tool for timely and rational therapeutic reassessment and is recommended in case of Failure and Warning. A multicenter, multilaboratory prospective study (NEXT-IN-CML) has been conducted to assess the feasibility, cost, turnaround times and clinical utility of a next generation amplicon deep sequencing (Deep Seq) strategy for routine BCR-ABL1 KD mutation screening.

Aims: The first phase of the study was aimed to i) create a network of 4 labs achieving MMR by 12 months, in comparison with 33% (20/60) of patients with e13a2 transcripts. DNA the expression of e13a2 BCR-ABL1 mRNA was lower than that of e14a2, an observation that requires confirmation. DNA methods were more sensitive: following the achievement of mRNA fell more rapidly than DNA, likely reflecting the time taken for normal haematopoietic cells to recover. At later time-points there was good agreement between methods, indicating that later reduction in BCR-ABL1 IS is closely related to depletion of leukemic cells. Normalised to BCR-ABL1 DNA the expression of e13a2 BCR-ABL1 mRNA was lower than that of e14a2, an observation that requires confirmation. DNA methods were more sensitive: following the achievement of UMRD by RQ-PCR patients could, on average, be monitored by DNA Q-PCR for an additional 5 months.

Results: In the first phase, 504/512 amplicons were successfully generated and sequenced, with a median number of forward and reads of 1,757 range 544-5,838). In the 128 samples analyzed, 51/52 expected mutations were consistently detected by all 4 labs and quantitation of mutation load was highly reproducible across a wide range of frequencies (2%>100%). Three out of 4 labs failed to detect the 1% T315I+ dilution. In clinical samples, additional low burden mutations <3% were occasionally called by one or two labs only, suggesting that this value should be taken as a threshold below which mutation detection is not reproducible and sequencing artifacts and errors cannot be ruled out. In the second phase of the study, pts positive for mutations were 25/159 (16%; 23 Failures and 2 Warnings) by Sanger Seq and 52/159 (33%; 44 Failures and 8 Warnings) by Deep Seq. Among the pts with low burden mutations detectable by Deep Seq, 4 had a T315I+ 34 had other known TKI-resistant mutations; 14 had only mutations with unknown clinical significance. Pts positive for mutations by Deep Seq were more frequent in the High and Intermediate Sokal risk group. The number of positive pts and the number of mutations per pt were not significantly higher in those receiving 2nd- or subsequent-line TKI therapy than in those receiving 1st-line TKI therapy. Compound mutations found were only found in 2 out of 52 mutated pts (both in blastic phase).

Summary/Conclusions: In the first 1-3 months BCR-ABL1 mRNA fell more rapidly than DNA, likely reflecting the time taken for normal haematopoietic cells to recover. At later time-points there was good agreement between methods, indicating that later reduction in BCR-ABL1 IS is closely related to depletion of leukemic cells. Normalised to BCR-ABL1 DNA the expression of e13a2 BCR-ABL1 mRNA was lower than that of e14a2, an observation that requires confirmation. DNA methods were more sensitive: following the achievement of UMRD by RQ-PCR patients could, on average, be monitored by DNA Q-PCR for an additional 5 months.

Prognostic markers and new treatment in MDS

S486

PATIENTS WITH IDIOPATHIC CYTOPENIA OF UNDETERMINED SIGNIFICANCE SHOW SIMILAR SURVIVAL PATTERNS AS LOW RISK MDS PATIENTS

Background: Cytopения is a hallmark in myelodysplastic syndrome (MDS), however, many patients with persistent cytopenia do not fulfill the criteria for MDS. These patients are now classified as idiopathic cytopenia of undetermined significance (ICUS) or if a mutation is detected as clonal cytopenia of undetermined significance (CCUS). Little is known about these new entities in regards to survival and prognosis.

Aims: In this study we want to compare ICUS patients with MDS patients having low- or very low-risk disease according to the IPSS-R. We also wanted to investigate if sequencing of the cohort could bring additional information in regards to overall survival.

Methods: All patients underwent a bone marrow biopsy, cytogenetics and a broad range of blood tests. Furthermore, all ICUS patients underwent a blinded morphology review by two experienced pathologists; these review data will be ready for presentation at EHA. ICUS was defined as persistent cytopenia for more than six months, no chromosomal aberrations and common causes of cytopenia were ruled out. The patients were sequenced with a targeted sequencing panel, either using a customized Haloplex panel or a customized sequencing panel for the Ion Torrent platform. We analyzed 20 genes which are the most commonly mutated genes in MDS.

Results: So far we included 157 patients, 122 were classified as ICUS and 35 as MDS and the median age is 65 and 68 years, respectively (p=0.27). We have sequenced 78% of the ICUS patients and 74% of the MDS patients. In total 53% and 73% of the ICUS and MDS patients had at least one mutation detected, respectively. If the patients carried a mutation, the median number of mutations was two in both the CCUS and the MDS group. The most commonly mutated genes were TET2, SRSF2, DNMT3A and ASXL1 in 38 patients (31%), n=16 (13%), n=10 (8%), n=10 (8%), respectively. There were no significant differences in the distribution between the two groups. Mutations in NRAS, KRAS, TP53 were only identified in one patient each. The overall survival between the ICUS and the low-risk MDS patients did not differ (p=0.18) (figure 1). We also subdivided the ICUS patients into non-clonal ICUS and CCUS, but observed no difference between these two groups (p=0.355).

Eight of the patients categorized as ICUS progressed to a myeloid neoplasm during the follow up, and of these seven had a detectable mutation at time of enrollment, only one ICUS patient without a detectable mutation progressed (p=0.06).

Summary/Conclusions: We here demonstrate that low-risk MDS and ICUS patients share similar survival patterns, however, larger studies with longer follow up are needed. Mutations are most commonly found in the epigenetic regulators in this cohort of ICUS and low-risk MDS, while mutations in classical tumor suppressors and oncogenes such as TP53 and NRAS are rare. Muta
tional screening seems promising in detecting patients at risk of progression, however, other biomarkers for prognostication are warranted.

AN UPDATE OF A PHASE II STUDY OF NIVOLUMAB (NIVO) OR IPILIMUMAB (IPI) WITH AZACITIDINE IN PTS WITH PREVIOUSLY TREATED OR UNTREATED MYELODYSPLASTIC SYNDROMES (MDS)

Garcia-Manero1,*, J. Danilewsky2, G. Mauro4, E. Jakubowiak5, C. Di Nardo5, S. Komblau6, P. Bove1, Y. Alvarado1, M. Ohanian1, G. Borthakur1, J. Cortes1, K. Naqvi1, N. Pemmaraju1, X. Huang2, G. Nogueras-Gonzalez2, C. Bueno-Ramos2, Y. Gasior1, V. Bayer1, S. Pierce1, H. Yang1, S. Colla7, H. Kantarjian1

Background: Outcomes of pts with MDS after hypomethylating agent (HMA) failure remain poor. Upregulation of PD-1/PD-L1 in MDS CD34+ cells after exposure and loss of response to HMA have been reported. Nivo and Ipi in mono- or combination therapy for HMA add-back after 6 cycles of therapy if there was no response or progression. Pts with previously untreated MDS were to be treated in one of 3 consecutive cohorts combining AZA 75mg/m2 iv daily days 1-5 of a 28 day cycle with: cohort #1: Nivo 3mg/kg iv days 1 and 15 of a 28 day cycle; cohort #2: Ipi 3mg/kg iv on day 1 of a 21 day cycle; cohort #3: Nivo 3mg/kg iv on days 1 and 15 + Ipi 3mg/kg iv on day 1 of a 28 day cycle. The study design allowed for AZA add-back after 6 cycles of therapy if there was no response or progression. Pts with previously untreated MDS were to be treated in one of 3 consecutive cohorts combining AZA 75mg/m2 iv daily days 1-5 of a 28 day cycle with: cohort #1: Nivo 3mg/kg iv Days 6 and 20; cohort #2: Ipi 3mg/kg iv on day 6; and cohort #3. Nivo 3mg/kg iv on days 6 and 20 + Ipi 3mg/kg iv on day 6. The maximum size per cohort is 20 pts. The primary endpoint is to determine the safety of Nivo or Ipi as single agents or in combination with AZA. Secondary objectives included overall response rate (ORR) and assessment of biological activity. Responses were evaluated following the revised 2006 IWG criteria. The study included stopping rules for response and toxicity.

Results: A total of 63 pts has been enrolled. 54 (86%) are evaluable for response and toxicity including 21 treated with frontline AZA+Nivo, and 15 and 18 with Nivo or Ipi after HMA failure, respectively Median age is 69 years (range 39-85). 35 of 63 pts had progressive disease at the end of cycle 3. The ORR was 8% (16/18) in the AZA+Nivo cohort, 6% (3/52) in the AZA+Nivo cohort, 6% (3/52) in the Nivo cohort, and 3% (3/93) in the Ipi cohort. The stopping rule for toxicity was not met in any of the cohorts. Delays of therapy due to AEs were required in 9 pts due to: rash (N=1), adrenal insufficiency (N=1), colitis (N=1), thyroiditis (N=2), pneumonitis (N=3), and nephritis (N=1). Early 8-week mortality occurred in 1 patient due to a non-related intracranial hemorrhage. The ORR was 80% (13/21) in the AZA+Nivo cohort including 6 CR. The ORR was 0% and 30% (5/18) in the Nivo and Ipi arms, respectively. The stopping rule for response was met on the Nivo arm, and enrollment after patient 15 was stopped. Immunophenotypic analysis of stem cell and progenitor compartments was performed in 27 pts, including PD-1 and PD-L1 expression analysis in 16 pts. Increased PD-1 and PD-L1 expression on progenitor and stem cell compartments was observed in 3 and 4 pts, respectively. Treatment with PD-1 inhibitors could not overcome the aberrant differentiation patterns. No differences in response were observed based on PD-1 bone marrow expression.

Summary/Conclusions: Preliminary results indicate that PD-1 blockade with Nivo in combination with AZA in untreated high-risk MDS pts is associated with a tolerable safety profile and clinical activity. Single-agent Ipi is capable of inducing responses in previously treated MDS pts. Single-agent Nivo did not show clinical activity.

ORAL RIGOSERTIB COMBINED WITH AZACITIDINE IN PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML) AND MYELODYSPLASTIC SYNDROMES (MDS): EFFECTS IN TREATMENT NAÏVE AND RELAPSED/REFRACTORY PATIENTS

S. Navada1,*, G. Garcia-Manero2, K. Hearn2, R. Odchimar-Reissig1, E. Demakos1, P. Fenaux3, M. Petrone4, P. Zbyszewski4, S. Fruchtman4, L. Silverman1

Background: Outcomes of pts with AML in monotherapy or combination for pts with MDS. Pts with prior therapy with HMA were to be treated in one of 3 consecutive cohorts combining AZA 75mg/m2 iv daily days 1-5 of a 28 day cycle; cohort #1: Nivo 3mg/kg iv on days 6 and 20; cohort #2: Ipi 3mg/kg iv on day 6; and cohort #3: Nivo 3mg/kg iv on days 6 and 20 + Ipi 3mg/kg iv on day 6. The maximum size per cohort is 20 pts. The primary endpoint is to determine the safety of Nivo or Ipi as single agents or in combination with AZA. Secondary objectives included overall response rate (ORR) and assessment of biological activity. Responses were evaluated following the revised 2006 IWG criteria. The study included stopping rules for response and toxicity.

Results: A total of 63 pts has been enrolled. 54 (86%) are evaluable for response and toxicity including 21 treated with frontline AZA+Nivo, and 15 and 18 with Nivo or Ipi after HMA failure, respectively Median age is 69 years (range 39-85). 35 of 63 pts had progressive disease at the end of cycle 3. The ORR was 8% (16/18) in the AZA+Nivo cohort, 6% (3/52) in the AZA+Nivo cohort, 6% (3/52) in the Nivo cohort, and 3% (3/93) in the Ipi cohort. The stopping rule for toxicity was not met in any of the cohorts. Delays of therapy due to AEs were required in 9 pts due to: rash (N=1), adrenal insufficiency (N=1), colitis (N=1), thyroiditis (N=2), pneumonitis (N=3), and nephritis (N=1). Early 8-week mortality occurred in 1 patient due to a non-related intracranial hemorrhage. The ORR was 80% (13/21) in the AZA+Nivo cohort including 6 CR. The ORR was 0% and 30% (5/18) in the Nivo and Ipi arms, respectively. The stopping rule for response was met on the Nivo arm, and enrollment after patient 15 was stopped. Immunophenotypic analysis of stem cell and progenitor compartments was performed in 27 pts, including PD-1 and PD-L1 expression analysis in 16 pts. Increased PD-1 and PD-L1 expression on progenitor and stem cell compartments was observed in 3 and 4 pts, respectively. Treatment with PD-1 inhibitors could not overcome the aberrant differentiation patterns. No differences in response were observed based on PD-1 bone marrow expression.

Summary/Conclusions: Preliminary results indicate that PD-1 blockade with Nivo in combination with AZA in untreated high-risk MDS pts is associated with a tolerable safety profile and clinical activity. Single-agent Ipi is capable of inducing responses in previously treated MDS pts. Single-agent Nivo did not show clinical activity.
Background: Hypomethylating agents (HMA) such as azacitidine and decitabine remain the standard of care for the treatment of myelodysplastic syndromes (MDS) however, loss of response to therapy is associated with poor outcomes. Multiple studies have tried to identify biomarkers of response but the impact of the mutational architecture present at the time of diagnosis in response outcomes is unclear.

Aims: To evaluate the impact of the mutational architecture present at the time of diagnosis in response outcomes is unclear.

Methods: We evaluated 222 previously untreated patients with MDS or CMML that received HMA therapy at The University of Texas MD Anderson Cancer Center. Next generation sequencing analyzing a panel of 28 genes was performed prior to therapy with HMA. VAF estimates were used to evaluate clonal and subclonal relationships within each individual sample with clonal heterogeneity being defined in cases with Pearson goodness-of-fit p-values <0.05. Generalized linear models were used to study association of response rates (ORR=overall and CR=complete) and risk factors. Response was defined following 2006 IWG criteria.

Results: A total of 143 patients (79%) had MDS and 43 (19%) had CMML, including 108 (49%) with lower-risk based on IPSS and 114 (51%) with higher-risk disease. Therapy consisted in azacitidine monotherapy in 60 (27%) patients, decitabine monotherapy in 57 (26%), guadecitabine in 46 (21) and combinations in 59 (27%). The ORR was 61% (135/222) with 80 (36%) patients achieving CR. A total of 161 (73%) patients had at least one detectable mutation. Median number of mutations was 1 (range 0-5). Frequencies of detected mutations are shown in Figure 1A. Among 33 evaluable MDS pts, overall response by IWG criteria was 76%: complete remission (CR) in 8 (24%), concurrent marrow CR (mCR) and hematologic improvement (HI) in 10 (30%), mCR alone in 6 (18%), and HI alone in 1 (3%). Overall response was 75% for HMA-treatment-naïve pts and 62% in HMA-resistant pts. Correlative studies suggest that RIG has chromatin modifying effects in combination with AZA which may overcome clinical AZA resistance (Chaurasia EHA 2017). Median duration of CR was 8 months for the combination. Median time to initial response was 2 cycles, and median time to best response was 3 cycles. The most frequently reported AEs were diarrhea (70%), nausea (50%), back pain (40%), constipation (40%), fatigue (40%), and peripheral edema (40%).

Summary/Conclusions: The combination of oral RIG and standard-dose AZA was well tolerated in repetitive cycles in pts with AML and MDS. Response was observed both in HMA-treatment-naive pts (85%) and in pts failing HMA therapy (62%), suggesting the addition of RIG can overcome HMA clinical resistance by acting as a chromatin modifying agent. In AML, responses were seen in 37.5% of evaluable pts. Based on these results, continued study in AML is warranted. A Phase III study of the combination of oral RIG and AZA in pts with treatment naïve MDS is planned.
Background: As key factors in gene post-transcriptional regulation, microRNAs (miRNAs) have been identified to play important roles in carcinogenesis in various tumors. Myelodysplastic syndrome (MDS) is a group of clonal myeloid disorders characterized by refractory quantitative and qualitative abnormalities of hemocytes and its pathogenesis is poorly understood. Some studies have shown that abnormal expressions of some miRNAs have close relationship with the pathogenesis of MDS. Recently, low RPS14 expression is found common in all kinds of myelodysplastic syndromes including patients without 5q deletion, but its mechanism remains unclear.

Aims: To determine the cause of RPS14 reduction in MDS except 5q-syndrome, influence of miRNAs on RPS14 expression was analyzed, and the role of specific miRNA on proliferation, differentiation and apoptosis of hematopoietic stem cells were evaluated. This research will help reveal the pathogenesis of MDS from a new angle and provide new ideas for the diagnosis, treatment and prognosis evaluation of MDS.

Methods: Firstly, we predicted that miR-223 may target 3'UTR of RPS14 by bioinformatics software, then verified if the special miRNA could target RPS14 by assay of luciferase activity. Secondly, the miRNA expression level of miR223 were detected in the bone marrow BM selected from 28 MDS patients including ten RCUD patients, four RCMD patients, four RAEB-1 patients and four RAEB-2 patients, meanwhile, the miR223 expression status were tested in four kinds cell lines including SKM-1, HL-60, K562 and THP-1 cell lines through qRT-PCR and RPS14 expression was detected by means of immunofluorescence(IF).

Thirdly, constructing lentivirus which carried miR223 overexpression vector and inhibitor was infected to the SKM-1 cell line and K562 cell line which had the highest level of RPS14, then apoptotic analysis was detected by flow cytometry method and proliferation was tested by CCK-8 assay. Fourthly, hemin (50μM,) was used to induce erythroid differentiation of K562 cells which carried miR223 overexpression We used flow cytometry method CD71 and CD235a makers and qRT-PCR(CD235 and r-globin) to detect the erythroid proliferation.

Results: 1. We verified miR-223 could target RPS14 by assay of luciferase activity. 2. miR223 expression was commonly mutated at diagnosis. 3. miR223 expression in MDS patients could provide a much deeper and broader understanding of clonal origin/hierarchy of relapse after allogeneic HCT. The present study aimed to evaluate mutation dynamics post-HCT using longitudinal NGS have not been thoroughly examined. We hypothesized that serial sequencing of pre-HCT and post-HCT in AML patients could provide a much deeper and broader understanding of clonal origin/hierarchy of relapse after allogeneic HCT. The present study aimed to evaluate mutation dynamics in AML using serial samples from pre- and post-HCT with respect to transplant outcomes, particularly overall survival (OS) and relapse.

Aims: To track origins of post-HCT relapse in AML using serial sequencing

Methods: 88 AML patients were enrolled and sequenced using an Illumina HiSeq 2000 sequencer (84 myeloid custom gene panel) on 419 bone marrow samples at diagnosis (n=88), pre-HCT (n=88), 21 days after HCT (n=88), and at relapse (n=20). Two patients relapsed by day 21. T-cell (n=80) and donor (n=57) were also sequenced. All computational and statistical analyses were performed using Python and R.

Results: The mean on-target coverage in 419 samples was 1773.7x. In total, we detected 217 mutations throughout the course of treatment in 79/88 patients (89.8%). NPM1 (26.1%), DNMT3A (26.1%), CEBPA (13.6%), IDH2 (13.6%), FLT3 (12.5%), and TP53 (11.4%) were commonly mutated at diagnosis. Unsurprisingly, most mutations appeared at initial diagnosis (200/217, 92.1%). Only 1, 2, and 14 mutations were acquired/selected at pre-HCT (0.5%), day 21 (9.9%), and relapse (6.5%) respectively. Most mutations were cleared at pre-HCT (mean mutation allele frequency (VAF) from 27.4% to 2.9%) and were further reduced after HCT (mean VAF from 2.9% to 0.7%) (Fig A). Leveraging

Figure 1.
significant decrease over time with ibr. Adverse events (AEs) were largely grade 1 or 2 events; AEs occurring in ≥20% of pts were fatigue, diarrhea, muscle
related to inflammation, fibrosis, and cGVHD. From all treated pts showed a
Significant activation of PLCγ1-Y783 in CD4 T-cells. Analysis of soluble plasma factors asso-
ciated with cGVHD involvement including skin, mouth, and gastrointestinal system showed
similar responses (~90%). Of 25 responders with ≥2 involved organs, 20 (80%) continued ibr.

Systemic conclusions: With an ORR of 67% and a sustained response rate of ≥20 weeks of 71%, treatment with ibr resulted in clinically meaningful and
durable responses in pts who failed at least 1 prior treatment for cGVHD. Most responders were able to reduce steroid dose. PD and biomarker changes support
a beneficial effect of ibr on immune cell subsets in pts with cGVHD. The
value of selecting pts who were treated with chemo before ibr was consistent with those previously reported for pts with B-cell malignancies and those seen in cGVHD pts on concomitant steroids.

Responsiveness in these pretreated, high-risk population support study of ibr for frontline treat-
ment of cGVHD.

OUTCOMES OF NON T-CELL-DEPLETED HAPLOIDENTICAL HSCT VERSUS HSCT FROM MATCHED SIBLING DONORS IN PATIENTS WITH ACUTE MYELOID LEUKEMIA IN FIRST COMPLETE REMISSION, AN ALWP-EBMT STUDY

1Division of Hematology, Federico II, Naples, Italy, 2Hematology Department, Service d’Héma-
 tologie et Thérapie Cellulaire, 3Hematology Department, Service d’Héma-
 tologie et Thérapie Cellulaire, Hôpital Saint Antoine, Paris, France, 4Hematol-
 ogy Department, Saint Hospital, Tehran, Iran, 5Department of Hematology—BMT, Hospital Saint Louis, Paris, France, 6Department of Haematology, Hôpital Saint Martin, Genova, Italy, 7Department of Medical Oncology, Gustave Roussy, Institut de cancérologie,BMT Service, Division of Hematology, Villejuif, France, 8S.S.C.V.D Trapianto di Cellule Stamminali, A.U.O Citta della Salute e della Scienza di Torino,Presidio Molinette, Torino, Italy, 9Institut Uni-
versitaire du Cancer Toulouse, Oncopole I.U.C-T.O, Toulouse, France, 10Department of Hematology, Bone Marrow Transplant Center, Transfusion Medicine and Biotechnology, Pescara, Italy, 11Service d’Hématologie, Hôpital Jean Minjouz, Besancon, 12Hematology Department, Hôpital Saint Antoine, Service d’Hématologie et Thérapie Cellulaire, Paris, France, 13Hematology Division, Chaim Sheba Medical Center, Tel Hashomer, Israel

Background: Allogeneic hematopoietic stem cell transplantation (HSCT) is
the standard of care for patients (pts) with relapsed or refractory acute myeloid leukemia (AML). In pts lacking matched sibling (MUD), HSCT from haploidentical donors (HAPLO) is an emerging option

Aims: The aim of the study was to compare outcomes of non T-cell depleted HAPLO HSCT to those from MUD HSCT

Methods:registry included were adults with AML in first CR undergoing transplantation from HAPLO vs MUD from 2007-2015. Due to significant interaction between karyotype and donor type, int- and high-risk AML were studied separately. In addition because of some characteristic differences between the 2 groups the propensity score technique was used: 2 MUD were matched with each haplo. The following factors were included in the propensity score model: patient, year of HSCT, time from diagnosis to HSCT, conditioning (RIC), source of stem cells (BM/MP), cytogenetic group, patient and donor CMV serology status

Results: We identified 2654 pts (HAPLO=185; MUD=2469) for int-AML (HAP-
LO=122; MUD=1888) or high risk-AML (HAPLO=63; MUD=581). Median follow
up was 30 (1-116) months. Among 2654 pts, 74% received PCYT and 26% ATG. Conditioning regimen was myeloablative in 55% vs 52% (p=0.52) of HAPLO and MUD pts, respec-
tively. HAPLO pts had a longer interval from diagnosis to HSCT (6 vs 4 months; p<0.01), had more often high risk AML (34% vs 23%; p<0.01), bone marrow as stem cell source (49% vs 19%; p<0.01) and CMV positive donors (72% vs 61%; p<0.01). Graft failure occurred more frequently after HAPLO (3% vs 1%; p=0.002). For pts with int-AML CI of a gvhD and cGVHD was 29% vs 20% (p<0.03) and 30% vs 36% (p<0.02) in HAPLO and MUD pts, respectively. At 2 years, NRM and RI were 26% vs 10% (p<0.01) and 17% vs 20% (p=0.52). Incremental age was independently associated to lower LFS, OS, and non-hematological mortality. A longer interval from diagnosis to HSCT was asso-
ciliated to lower LFS. Donor CMV seropositivity was associated with lower GRFS and higher NRM and aGVHD. In high risk-AML aGVHD and cGVHD were 36% vs 24% (p=0.03) and 39% vs 33% (p=0.80) for HAPLO and MSD pts, respectively. At two years, NRM and RI were 18% vs 10% (p=0.16) and 21% vs 36% (p=0.02) while LFS and OS were 61% vs 55% (p=0.14) and 67% vs 66% (p=0.26) in HAPLO and MSD pts; GRFS was 49% vs 40% (p=0.17). In multivariate analysis risk of grade IV aGVHD (HR: 2.20; 95% CI: 1.20-3.74; p=0.01) was increased after haplo as compared to MSD and no difference was observed in LFS, OS and GRFS, respectively. Conditioning regimen was associated with lower NRM and higher grafts, while younger age and donor CMV status was associated with lower RI, higher LFS and OS. Results were confirmed in the analysis with the the propensity score technique as for RI, NRM, LFS, OS and GRFS.

Summary/Conclusions: As per our registry based study in intermediate risk AML results of HSCT from matched sibling donor are superior to those of HAPLO-HSCT, while in high risk-AML relapse is lower in the HAPLO transplants and NRM, LFS and OS is similar.

S494

INDIVIDUAL OUTCOME PREDICTION FOR MDS AND SECONDARY AML AFTER ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION BASED ON GENETIC, PATIENT- AND TRANSPLANTATION-ASSOCIATED RISK FACTORS

M. Heuser1,*, R. Gabdoulline1, R. Loeffel1, V. Dobbernack1, H. Kreimeyer1, M. Pankratz1, M. Flintrop1, V. Panagiota1, M. Stadler1, M. Wichmann1, R. Shaswar1, U. Platzecker2, C. Thiede2, T. Schroeder3, G. Kobbe3, R. Geffers3, B. Schliegelberger1, G. Göhring1, H.-H. Kreipe1, U. Germing3, A. Ganser1, N. Kroeger3, C. Koeckenbecker1, F. Thol1
1Hannover Medical School, Hannover, 2Universitätsklinikum Carl Gustav Carus, Dresden, 3Heinrich Heine University, Düsseldorf, 4Helmholtz Centre for Infection Research, Braunschweig, 5University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Background: Prediction of individual outcomes after allogeneic hematopoietic cell transplantation (alloHCT) is difficult, as it is influenced by a multitude of risk factors.

Aims: To develop a tool that predicts individual outcomes of patients with myelodysplastic syndrome (MDS) or secondary acute myeloid leukemia from MDS (sAML) after alloHCT.

Methods: We integrated molecular data with available prognostic factors in patients undergoing alloHCT for MDS and sAML to evaluate their impact on prognosis. 304 patients with MDS or sAML who underwent alloHCT were accrued for mutations in 54 genes. We used a Cox multivariate model and competing risk analysis with internal and cross validation to identify factors prognostic of overall survival (OS), cumulative incidence of relapse (CIR) and non-relapse mortality (NRM).

Results: In multivariate analysis, mutated NRAS, U2AF1, IDH2, TP53 and/or a complex karyotype were significant prognostic markers for OS besides age above 60 years, remission status treated but not in CR, IPSS-R cytogenetic risk, HCT-CI >2 and female donor sex. Mutated NRAS, IDH1, EZH2 and TP53 and/or a complex karyotype were genetic aberrations with prognostic impact on CIR. No molecular markers were associated with the risk of NRM. The addition of molecular information significantly improved the risk prediction for OS and CIR as assessed by the Akaike information criterion. Internal and cross validation confirmed the robustness of our comprehensive risk model. We developed an interactive risk prediction tool to provide personalized predictions for OS, CIR and NRM outcome after alloHCT. An individualized prediction for a 53-year-old male with sAML with trisomy 11, mutated NRAS, IDH2 and DMMT3A and complete remission after double induction is shown in Figure 1. The probability of CIR at 2 years was 45% and the patient relapsed after 0.61 years. The probability of OS at 2 years was 41% and the patient died after 0.88 years.

Summary/Conclusions: We combine molecular, cytogenetic, patient- and transplantation associated risk factors into a comprehensive risk score to provide personalized predictions for outcome after alloHCT. Upon validation in larger patient cohorts, this will improve patient information before alloHCT and provide a platform to improve treatment strategies for patients with high risk of CIR or NRM.

S495

IMPACT OF POST-TRANSPLANT INFUSION OF DONOR T CELLS GENETICALLY MODIFIED WITH INDUCIBLE CASPASE 9 SUICIDE GENE (BPX-501 CELLS) ON CHILDREN WITH LEUKEMIA GIVEN ALPHA-BETA T-CELL DEPLETED HAPLO-HSCT

P. Merli1,*, A. Bertaina1, F. Galaverna1, M. Aligen1, D. Pagliara1, G. Li Pira1, J. Weinberg2, A. Moseley2, F. Locatelli3
1Ospedale Pediatrico Bambino Gesù, Rome, Italy, 2Belllicum Pharmaceuticals Inc., Houston, United States

Background: HLA-haploidentical allogeneic hematopoietic stem cell transplant (haplo-HSCT) offers an option for children with acute leukemia in need of a transplant and lacking an available HLA-identical donor. However, performing haploidentical-HSCT without any graft manipulation has historically been associated with a high risk of acute and chronic graft-versus-host disease (GVHD). T cell depletion reduces the risk of GVHD, but leads to delayed immune reconstitution, predisposing to serious infection and leukemia relapse due to the lack of a T-cell mediated graft-versus-leukemia (GvL). To address these challenges, we have infused mature BPX-501 T cells (donor peripheral lymphocytes which have been modified with the iCas9 suicide gene) after αβ T-cell depleted haplo HSCT to facilitate immune reconstitution and GvL effect. BPX-501 T-cells are genetically modified with the Cas9 suicide safety switch and a truncated CD19 marker. In the event of GVHD, the switch is activated by an infusion of the drug rimiducid (AP1903) resulting in rapid T cell apoptosis and GVHD reversal.

Aims: To evaluate both safety and efficacy of BPX-501 T cell infusion post αβ T cell depleted haplo HSCT in pediatric patients with high risk ALL and AML in CR1 and CR2.

Methods: A prospective Phase II/I study enrolling children with hematopoietic disorder who lack a matched donor. 38 patients have been enrolled and treated with αβ TCR depleted haplo HSCT after a myeloablative preparative regimen followed by BPX-T cell infusion to date; of them, 24 had ALL and 14 AML (21% CR1, 79% CR2). Median follow-up is 11 months (range 3-24).

Results: All patients engrafted and no secondary graft failure was recorded. Median time to neutrophil and platelet recovery was 16 days (range 8-33) and 11 days (range 7-19), respectively. With a median follow-up of 11 months (range 3-24 months), the cumulative incidence of NRM and relapse was 3.7% and 12.0%, respectively, while the disease-free survival probability was 84.2% (Fig 1). All aGVHD resolved (5 Grade I skin, 5 Grade II skin, 2 Grade III GI). One child received rimiducid to treat steroid-resistant grade II skin with complete resolution in 24 hours (Fig 2). There were 3 cases of chronic GVHD, 2 were mild; 1 severe and fatal in a patient whose donor had VZV reactivation during mobilization. CD3+ T cells reached 500 cells/μl by day 90, with normalized CD4/CD8 T cell ratio by day 180.

HEREDITARY HEMATOLOGIC MALIGNANCIES: GENETIC COUNSELING IMPLEMENTATION IN A LARGE LEUKEMIA CENTER
C. Dinardo1,2, S. Bannen2, K. Takahashi1, C. Benton1, M. Routbort3, N. Pennmaraju4, N. Daver1, T. Kadia1, G. Garcia-Manero1, K. Patel5, H. Kantarjian1, A. Estey1,6
1Leukemia, 2Clinical Cancer Genetics, 3Hematopathology, 4Genomic Medicine, The University of Texas MD Anderson Cancer Center, Houston, United States

Background: Hematologic malignancies have rarely been targets for genetic evaluation, even in familial cases. Over the past decade, more than 12 genes have been identified to cause inherited predispositions to hematologic malignancies. Genetic counseling, testing, and surveillance protocols for these families are not well-established. Additionally, many families with high incidence of blood cancers do not have described syndromes suggesting additional genetic gains remain to be identified.

Aims: To identify individuals with inherited susceptibilities to hematologic malignancies, the Hereditary Hematologic Malignancy Clinic (HHMCC) was established in April 2014 at The University of Texas M. D. Anderson Cancer Center. The clinic’s goal is to develop a research testing framework for patients with hematologic malignancies suspected to have inherited predisposition syndromes.

Methods: Individuals were referred to the HHMCC for several indications: (1) bone marrow failure/aplastic anemia/hypocellular MDS, (2) personal history of hematologic malignancy with ≥1 first-degree relative or ≥2 second-degree relatives with hematologic malignancy, (3) personal history of multiple primary cancers, (4) germline evaluation of presumed somatic mutations identified on next-generation leukemia prognostic panels, (5) management and/or surveillance of a previously-identified genetic syndrome, or (6) solid tumor heredity.

Results: Clinical genetic testing was performed in 572/152 individuals (37%), particularly in patients naive for known susceptibility genes or without features suggestive of a clinical syndrome. Nine (6%) individuals did not undergo genetic testing. Clinical testing identified 23/97 (24%) individuals with a germline susceptibility to hematologic malignancy. Seven probands (7%) were identified to have RUNX1 mutations associated with familial platelet disorder with myeloid malignancy (FPD-AML). Six (6%) were identified to have the telomere disorder dyskeratosis congenita; only one of them met clinical diagnostic criteria with the “classic triad” of symptoms. Three (3%) patients were identified to have Li-Fraumeni syndrome due to constitutional TP53 mutations. Two adults (2%) were diagnosed with Diamond-Blackfan anemia and one child with Diamond-Blackfan anemia and myelodysplastic syndrome after a long latency period and prior spontaneous remission of their childhood anemia. Two young adults (2%) with Fanconi anemia were diagnosed, and one patient each with DDX41 mutation and CBL (Nobilet syndrome) were identified. Counseling, testing, and surveillance of identified mutation carriers in many affected families is ongoing.

Summary/Conclusions: Individuals with hereditary susceptibilities to hematologic malignancies are not as rare as previously thought. Clinical evaluation of these patients through genetic counseling and testing is high yield for identifying at-risk families. Research-based sequencing for novel mutations is indicated and ongoing.

SECONDARY LEUKEMIAS IN GENETIC SUBTYPES OF CONGENITAL NEUTROPENIA (ELANE, HAX1, WASP, G6PC3, ETC.): A LONG-TERM IMPLEMENTATION IN THE SCNIR EUROPE
C. Zeidler1,2, M. Klimiankou3, A. Nickel1, S. Mellor-Heinke1, J. Skokowa1, K. Welte3
1SCNIR, Medical School Hannover, Hannover, 2Department of Hematology, Oncology, Clinical Immunology, 3Department of General Pediatrics and Pediatric Hematology and Oncology; University of Tuebingen, Tuebingen, Germany

Background: Leukemia predisposition is well known in congenital neutropenia (CN) subtypes. By taking all patients with known and unclassified CN together the incidence of secondary leukemia accounts for more than 10 percent. Advanced molecular diagnostics and the identification of inherited and acquired gene mutations have improved our understanding of leukemic transformation in CN patients.

Aims: In the European SCNIR 449 patients with congenital neutropenia and 91 patients with cyclic neutropenia (CyN) have been enrolled since 1994. These 449 patients were evaluated by causal and molecular genetic subtype: ELANE, HAX1, G6PT, G6PC3, WAS, SBDS, TA21 and p14 or no identified mutation, respectively. Our aim is to assess the risk of leukemic transformation within these genetic subgroups.

Methods: Here we report the leukemia incidence of genetic subtypes analyzing all available long-term data from the European Branch of the Severe Chronic Neutropenia Registry (SCNIR). In addition, we analyzed 91 patients with CyN with or without ELANE mutations.

Results: Results from genetic testing were available for 314 of 449 CN patients, of whom 118 patients revealed ELANE, 48 HAX1, 71 SBDS, 28 G6PT, 9 G6PC3, 7 WAS, 5 TA21 mutations and 27 other rare gene mutations (e.g. p14, CXCR4). 135 patients remain unclassified. In addition, 48 of 91 patients with CyN revealed ELANE mutations. Secondary myelodysplastic syndrome (MDS) or leukemia occurred in 49 of the 449 CN patients and in 1 of the 48 ELANE-CyN patients. Acquired CSF3R nonsense truncating mutations have been detected in the bone marrow cells of about 80% of CN patients who progress to MDS or acute myeloid leukemia (AML) and around 30-35% of non-leukemic CN patients, supporting the association between the acquisition of CSF3R mutations and leukemic transformation. These mutations have been shown to be acquired in hematopoietic cells only and therefore are not the primary cause of leukemic transformation. The time between first detection of CSF3R mutations and onset of malignant transformation is highly variable. Some patients progressed to MDS/AML within a few months. In others, CSF3R mutant clones persisted for many years without progression to leukemia. The distribution by genetic subtypes and the frequency of CSF3R mutations is shown in the table below.

*Gene mutations without leukemia: G6PC3 n=9, TA21 n=5, p14 n=4, digenic mutations n=4, CDH1 n=4, DKC4 n=3, germline extracellular CSF3R n=2, C16ORF57 n=2, Pearson syndrome n=2, (LYST n=1)

All subgroups benefit from G-CSF treatment. However, patients requiring maintenance doses of G-CSF above 8µg/kg/day are at greater risk of leukemic transformation.

Summary/Conclusions: Conclusion: The incidence of secondary AML reflects the genetic heterogeneity of CN.

S498
EFFECT OF ECUCLIZUMAB IN PAROXYSMAL NOCTURNAL HEMOGLOBINURIA (PNH) PATIENTS WITH OR WITHOUT HIGH DISEASE ACTIVITY: RESULTS FROM THE INTERNATIONAL PNH REGISTRY
B. Höchsmann1,2, F. Sice de Fontbrune3, J.W. Lee4, A. Klagun5, P. Hillmen5, A. Wilson5, M. Marantz5, H. Schrezenmeier1
1Institute for Clinical Transfusion Medicine and Immunogenetics, University Hospital Ulm, Ulm, Germany, 2Hôpital Saint Louis, Paris, France, 3Seoul St. Mary’s Hospital, The Catholic University of Korea, Seoul, Korea, Republic Of, 4Pavlov First Saint Petersburg State Medical University, St. Petersburg, Russian Federation, 5St. James’s University Hospital, Leeds, United Kingdom, 6Alexion Pharmaceuticals, Inc., Lexington, MA, United States

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a rare, progressive, life-threatening disease caused by somatic phosphatidylinositol glycan class A (PIGA) gene mutation in bone marrow stem cells. The International PNH Registry (NCT01374360) is a prospective, multinational, observational study to record the natural history of PNH and collect data on long-term efficacy and safety of treatment with eculizumab (ecu), a humanized monoclonal antibody approved for treatment of PNH.

Aims: Evaluate the effect of ecu in patients with PNH with or without high disease activity (HD A).

Methods: Patients enrolled in the Registry as of December 5, 2016, were stratified by HDA and ecu treatment status into 4 groups: HDA/ecu-treated; HDA/nervi ecu-treated; no-HDA/ecu-treated; no-HDA/nervi ecu-treated. HDA is defined as lactate dehydrogenase (LDH) ratio ≥1.5x upper limit of normal within 6 months of baseline and history of any of the following: fatigue, hemoglobinuria, abdominal pain, dysnea, anemia (hemoglobin <100 g/L), major adverse vascular event (MAVE; including thromboembolism [TE]), dysphagia, or erectile dysfunction. Patients were assessed at baseline (date of enrollment in never ecu-treated patients; date of initiation of ecu in ecu-treated patients) and at least follow-up visits or in patients with lack of follow-up in LDH ratio, GPI-deficient granulocytes, red blood cell transfusions received, MAVE, and Functional Assessment of Chronic Illness Therapy (FAC-IT)-Fatigue score in patients with at least 6 months of follow-up.

Evaluating the effect of ecu in patients with PNH with or without high disease activity (HD A).
Results: 4717 patients were enrolled; of these, 2670 had non-missing data on euc and HDA status, and were included in the current analysis (HDA/euc-treated, n=785; HDA/never euc-treated, n=636; no-HDA/euc-treated, n=1111; no-HDA/never euc-treated, n=1138). Median (min, max) duration of follow-up after baseline was longer for the ecu-treated patients compared with the never ecu-treated patients for both the HDA and no-HDA groups (see Table). Results for changes from baseline to last follow-up in outcomes of interest are summarized in the Table. Data show that patients in the ecu-treated cohort had high burden of disease at baseline. Specifically, in the HDA population, a higher proportion of euc-treated patients had a history of MAVE (33.3% vs never ecu-treated patients (13.7%)). A similar disparity at baseline was also observed in the no-HDA population (33.0% vs 11.0%, respectively). Following ecu treatment, the divergence in the proportion of patients with MAVE has substantially narrowed for the HDA patients (3.9% for ecu-treated vs 3.3% for never ecu-treated) despite longer follow-up for the treated patients. Similar findings were seen in no-HDA patients (5.3% vs 2.1%, respectively). In patients with HDA status, treatment with euc was associated with meaningful improvements in mean (standard deviation (SD)) reduction from baseline in LDH ratio (-5.0 [3.7] vs -0.4 [2.3]) and proportion of red blood cell transfusion-free patients (37.6% vs 15.8%). The FACIT-Fatigue data, while limited, showed the HDA/ecu-treated group experienced a greater mean (SD) score improvement than the HDA/never ecu-treated group (4.1 [10.3] vs 0.5 [6.8] points).

Table 1.

Summary/Conclusions: Our analysis of real-world data from the International PNH Registry has demonstrated that treatment with eculizumab was associated with improved outcomes in patients with HDA. Our findings are consistent with the notion that patients with HDA, including those with a history of MAVE, should be treated with eculizumab.

S499

CONGENITAL AMEGAKARYOCYTIC THROMBOCYTOPENIA: FUNCTIONAL RESCUE OF A NOVEL MPL MUTANT IN PRIMARY HEMATOPOIETIC STEM CELLS USING CRISPR/CAS9

C. Clevert1, R. Girard1, E.H. Choi1, E. Jeziorski2, T. Lavabre-Bertrand3, C. Cleyrat1,*, R. Girard1, E.H. Choi1, É. Jeziorski2, T. Lavabre-Bertrand3

Background: Thrombopoietin (Tpo) and its receptor, Mpl, are the principal regulators of early-lye thrombopoiesis and hematopoietic stem cells maintenance. Mutations in MPL can drastically impair its function and be a contributing factor in multiple hematologic malignancies, including congenital amegakaryocytic thrombocytopenia (CANT). CANT is a rare inherited syndrome characterized by thrombocytopenia at birth, progressing to bone marrow failure and pancytopenia. The functional impact of CANT mutations on Mpl is yet to be determined. Here we report unique familial cases of CANT presenting with a previously unreported MPL mutation: T814C (W272R) in the background of the activating MPL G117T (K39N or Baltimore) mutation.

Aims: To develop characterization of this novel MPL mutant and the use of genome editing as a novel therapeutic option for CANT. Methods: Human megakaryoblastic UT-7 and murine Ba/F3 cells stably expressing human wild-type (WT) Mpl or mutant Mpl fused to mNeonGreen were used as models. Confocal microscopy, proliferation and surface biotinylation assays, as well as co-immunoprecipitation and western blotting analysis, were used to elucidate the function and trafficking of Mpl mutants. Multiplex, flow-based, CRISPR-Cas9 gene editing was used to repair mutant MPL and rescue its function. Cord blood from the younger male sibling was used as a source of primary homzygous Mpl K39N/W272R CD34+ cells. CD34+ cells were edited using ribonucleoproteins electroporation followed by sequencing and functional assays such as flow cytometry and single colony assays.

Results: Consanguineous parents and their eldest daughter, all heterozygous for Mpl K39N/W272R, do not present any signs of disease. Their monzygotic twin daughters presented at birth with severe thrombocytopenia leading to a diagnosis of CANT type 1. Whole blood sequencing revealed a homozygous double Mpl K39N/W272R mutation, as their younger male sibling. One of the twins died after bone marrow transplant. Confocal microscopy shows that a significant fraction of chimeric WT Mpl protein reaches the cell surface. Significant surface expression is also noted for Mpl K39N. In contrast, the chimeric Mpl protein bearing the W272R mutation, alone or together with the K39N mutation, showed no detectable surface expression of the Tpo receptor while being strongly co-localized with ER marker calreticulin. Both WT and K39N-mutated Mpl were found signaling competent, while single or double mutants bearing W272R were unresponsive to Tpo. Tpo-induced signaling was partially rescued by overexpression of GRASP55 (forcing Mpl to traffic to the cell surface). Genome editing performed on cells carrying the W272R mutation restored the WT sequence and the response to Tpo, with similar cell proliferation as WT Mpl cells. Finally, when applied to primary Mpl K39N/W272R CD34+ cells, CRISPR-based gene editing rescued surface expression of Mpl and response to Tpo, as assessed by flow cytometry. CRISPR-Cas9 edited cells were able to generate a similar number of megakaryocytic colonies as control CD34+ cells in a single colony assay. Non-edited cells failed to do so.

Summary/Conclusions: We report a new double in cis mutation of Mpl (K39N/W272R) in the context of CANT. Function of the deficient Mpl receptor could be recovered using two complementary approaches: CRISPR-Cas9 genome engineering and CRISPR-Cas9 genome engineering. Successful editing of primary hematopoietic stem cells indicates direct therapeutic applications for gene editing in this disease.

DISCOVERY OF ORALLY BIOAVAILABLE SMALL MOLECULES FOR INHIBITION OF COMPLEMENT C5

A. Ricordo1, M.D. Hoarty1, J.C. Blain1, S.J. DeMarco1, V. Galullu1, M.R. Hale1, E. de Koning1, D. LaPlaca1, K. Seyb1, J.R. Stringer1, G.-Q. Tang1, J. Tikhe1, D. Vadayo1, R. Vyssenni1

1Ra Pharmaceuticals, Inc., CAMBRIDGE, United States

Background: Paroxysmal nocturnal hemoglobinuria (PNH) and atypical hemolytic uraemic syndrome (aHUS) are well-characterized diseases of complement dysregulation. The only approved therapeutic for these diseases is Soliris® (Eculizumab, Alexion), a monoclonal antibody that binds and inhibits the cleavage of complement C5. Soliris® requires lifelong intravenous administration by a medical professional every two weeks. An orally bioavailable small molecule inhibitor of complement C5 to treat these and other complement mediated diseases represents a potential paradigm shift in the treatment of diseases of complement dysregulation.

Aims: To demonstrate the utility of an orally available, small molecule Complement C5 inhibitor for the treatment of complement mediated disorders.

Methods: Surface Plasmon Resonance (SPR) and Fluorescent Polarization assays (FP) were used to evaluate the affinity and specificity of the binding interaction between complement C5 and small molecule inhibitors. Determination of binding site, mechanism of action and potency were achieved by X-ray crystallography studies, Wieslab ELISA, and a sheep erythrocyte hemolysis based assay. The ability of the small molecules to prevent the hemolysis of PNH erythrocytes was evaluated using a modified Ham test. Pharmacokinetic studies were performed in rodents.

Results: Here we describe a series of first in class, orally bioavailable small molecules that bind to C5 with high affinity and inhibit its cleavage into C5a and C5b. These molecules demonstrate desirable drug-like properties with molecular weights under 500 amu and tPSA<100 Å2. A high-resolution co-crystal structure of complement C5 shows a unique binding site on the 188 kDa C5 protein, and specific binding of these molecules to C5 has been demonstrated by surface plasmon resonance (SPR) and fluorescence polarization (FP) assays. The position of the binding site suggests that these molecules will inhibit C5 cleavage in patients with the R885H/C polymorphism, which confers resistance to eculizumab. The molecules inhibit the terminal complement complex activity with single digit nanomolar IC50 as measured by inhibition of hemolysis in a highly sensitive antibody-sensitized sheep erythrocytes assay. In addition, they inhibit MAC deposition on complement-activating surfaces and prevent the cleavage of C5 to C5a and C5b as confirmed by ELISAs that directly detect generation of C5a and C5b.

Conclusion: This series of molecules has been profiled by SPR and Wieslab ELISA and exhibits oral bioavailability (%F~30-50) in pre-clinical species. The development of complement C5 inhibitor for the treatment of complement mediated disorders is an exciting new therapeutic modality to treat both rare and common conditions where there is a need for a novel therapeutic approach.
Quality of life, palliative care, ethics and health economics

**SS01** QUALITY OF LIFE WITH MELPHALAN/PREDNISONE PLUS EITHER THALIDOMIDE (MPT-T) OR LENALIDOMIDE (MPR-R) IN NON-TRANSPLANT ELIGIBLE NEWLY DIAGNOSED MULTIPLE MYELOMA; RESULTS OF THE HOVON87/NMSG18 STUDY

1Department of Hematology, VU University Medical Center, Amsterdam, Netherlands, 2Quality of life Research Center, Odense University Hospital, Odense, Denmark, 3Department of Epidemiology and Biostatistics, VU University, Amsterdam, Netherlands, 4Section of Hematology and Coagulation, Department of Medicine, Sahlgrenska University Hospital, Gothenburg, Sweden, 5Department of Hematology, Rigshospitalet, Copenhagen, Denmark, 6Division of Hematology and Transfusion Medicine, Skane University Hospital, Lund, Sweden, 7Department of Internal Medicine, Martini Ziekenhuis, Groningen, 8Department of Internal Medicine, Tergooi Ziekenhuis, Zoetermeer, Netherlands, 9Department of Internal Medicine, Albert Schweitzer Hospital, Dordrecht, Netherlands, 10Department of Internal Medicine, Stockholm University Hospital, Stockholm, Sweden, 11Department of Internal Medicine, Isala, Zwolle, Netherlands, 12Department of Hematology, Vejle Hospital, Vejle, Denmark, 13Department of Internal Medicine, Meander Medisch Centrum, Amersfoort, 14Department of Internal Medicine, Groene Hart Ziekenhuis, Gouda, Netherlands, 15Department of Oncology and Haematology, Friesland Centrum, Heerenveen, 16Department of Internal Medicine, Reinier de Graaf Ziekenhuis, Delft, 17Department of Internal Medicine, Medisch Centrum Alkmaar, Alkmaar, 18Department of Internal Medicine, Maasstad Ziekenhuis, Rotterdam, 19Department of Internal Medicine, Jeroen Bosch Ziekenhuis, Den Bosch, The Netherlands, 20Department of Hematology and Palliative Care, Stavanger University Hospital, Stavanger, Norway, 21Department of Internal Medicine, Reine van der Heijden Ziekenhuis, Tilburg, 22Department of Internal Medicine, Rijnstate Ziekenhuis, Arnhem, 23Department of Hematology, UMCG, Groningen, The Netherlands, 24Department of Internal Medicine, Rijnstate Ziekenhuis, Arnhem, 25Department of Hematology, VU medical center, Amsterdam, 26Department of Genetics, Rudolph Virchow Hospital, Berlin, Germany, 27Department of Hematology, Erasmus Medical Center Cancer Center, Rotterdam, Netherlands, 28Department of Hematology, St Olavs Hospital and Norwegian University of Science and Technology and KG Jebsen Myeloma Research Center, Trondheim, Norway

**Background:** We recently reported the results of the phase III randomized HOVON87/NMSG18 study showing comparable efficacy of treatment with melphalan, prednisolone and thalidomide followed by thalidomide maintenance (MPT-T) versus melphalan, prednisolone and lenalidomide followed by lenalidomide maintenance (MPR-R) (Zweegman S et al. Blood 2016;127(9):1109-1116). As not only efficacy but also potential toxicity affecting quality of life (QoL) guides the choice of treatment, health-related (HR) QoL is important.

**Aims:** To evaluate the HRQoL results of the HOVON87/NMSG18 study.

**Methods:** A two-visit HRQoL instruments (EORTC QLQ-C30 and MY20) were administered at baseline, after 3 and 9 induction cycles (3ID and 9ID) and after 6 and 12 months of maintenance therapy (6MT and 12MT). The subscales global QoL, physical functioning, fatigue, pain, constipation, diarrhea, nausea/vomiting, insomnia, disease symptoms, side effects of treatment, and neurotoxicity were assessed for the following subscales; global QoL increased after 9ID to 12MT (MID range 7-13), pain decreased at every time point (MID range -21 to -23), disease symptoms decreased after 9ID (MID -12), fatigue decreased during MT (MID 12) and insomnia decreased at each time point (MID range -14 to -26). In MPR-R the MID was reached for the following subscales; global QoL increased after 9ID until 12MT (MID range 8-14), physical functioning increased at 12MT (MID 13), pain decreased at every time point (MID range -14 to -26) and insomnia decreased at 6MT (MID -10). **Difference between MPT-T and MPR-R:** In the MPT-T arm significantly (p<0.05) and/or clinically (mean score difference (MSD) ≥5 points) less pain and disease symptoms at 3ID, less fatigue at 3ID and 9ID, less diarrhea and less insomnia at all time points were observed. In contrast, patients on MPR-R reported better global QoL, better physical functioning and less pain at 12MT, in general less side effects of treatment, and less constipation and neuropathy separately, at all time points than patients treated with MPT-T.

**Summary/Conclusions:** Both treatment with MPT-T and MPR-R controlled pain and resulted in an improvement in global QoL as compared to baseline after 9ID and during maintenance. Treatment with thalidomide initially resulted in less pain and disease symptoms. At all treatment stages thalidomide caused less diarrhea, fatigue and insomnia as compared to treatment with lenalidomide. In contrast, therapy with lenalidomide resulted in less side effects of treatment, less constipation and less neuropathy as compared to thalidomide at all stages of treatment. In addition, long term maintenance therapy with lenalidomide resulted in better global QoL, better physical functioning and less pain.

**SS02** HEALTH-RELATED QUALITY OF LIFE RESULTS FROM THE PHASE III GALLIUM STUDY OF OBITUNUZUMAB-BASED AND RITUXIMAB-BASED THERAPY IN PATIENTS WITH PREVIOUSLY UNTREATED ADVANCED INDOLENT NON-HODGKIN LYMPHOMA

1Cancer Research UK Centre, University of Southampton, Southampton, United Kingdom, 2Genentech Inc., South San Francisco, United States, 3Semmelweis University, Budapest, Hungary, 4Städtisches Klinikum Dussau, Dessau-Frohburg, Germany, 5Fudan University Shanghai Cancer Center, Shanghai, China, 6Aichi Cancer Center Hospital, Aichi, Japan, 7St George’s University, London, United Kingdom, 8St Vincent’s Hospital, Melbourne, Melbourne, Australia, 9Bristol Haematology and Oncology Centre, Bristol, 10James Paget Hospital, Great Yarmouth, United Kingdom, 11University of Kent, Canterbury, England, 12University of the Basque Country, Gernika, Spain, 13Ludwig-Maximilians-University Munich, Munich, Germany

**Background:** Maintenance of pretreatment health-related quality of life (HRQoL) and/or meaningful improvements in HRQoL are important for previously untreated indolent non-Hodgkin lymphoma (INHL) patients (pts). GALLI-
UM (NCT01332968) is an open-label, randomized Phase III study of obinutuzumab (GA101; G) plus chemotherapy (chemo) followed by G maintenance (G-chemo) compared with rituximab (R) plus chemo followed by R maintenance (R-chemo) in pts with previously untreated iNHL. In GALLIUM, G-chemo produced a clinically meaningful improvement in investigator-assessed progression-free survival (PFS) among follicular lymphoma (FL) pts (34% reduction in risk of a PFS event relative to R-chemo). Grade 3–5 and serious adverse events were more common with G-chemo.

Aims: To compare changes in HRQoL in FL pts receiving G-chemo and R-chemo during GALLIUM.

Figure 1.

Methods: Enrolled pts were aged ≥18 years with documented, previously untreated FL (grades 1–3a), advanced disease (stage III/IV or stage II with tumor diameter ≥7 cm), ECOG performance status 0–2, and requiring treatment according to GELF criteria. Pts were randomized 1:1 to R 375 mg/m² on day (D) 1 of each cycle (C) or G 1000 mg on D1, 5, and 15 of C1 and D1 of C2–8, for 6 or 8 cycles depending on chemo (CHOP, CVP or bendamustine). Responders continued to receive R or G every 2 months (mo) for 2 years or until progression. The Functional Assessment of Cancer Treatment-Lymphoma (FACT-Lym) questionnaire (Webster et al. 2005) was used to assess overall HRQoL, physical and functional well-being, and disease- and treatment-related symptoms. FACT-Lym was administered on D1 of C1 and C3 during induction, at the end of induction, and at mo 2 and 12 during maintenance/follow-up. For each FACT-Lym scale, mean and 95% confidence interval (CI) were derived for recorded scores at each visit and changes from baseline. Minimally important differences (MIDs) were used to calculate the proportion of pts reporting improvement on the FACT-Lym lymphoma subscale (LYMS; ≥3 points), Trial Outcome Index (TOI; ≥6 points), and lymphoma total score (Lym-Total; ≥7 points). All pts gave informed consent.

Results: Of 1202 FL pts randomized (median age, 59 yrs; 53.2% female; median observation time, 34.5 mo [range 0–54.5], 566/601 (92.5% G-chemo) and 550/601 (91.5%, R-chemo) completed all FACT-Lym scales at baseline. Baseline demographics and disease characteristics were balanced between arms. At baseline, mean HRQoL scores were similar in the two treatment arms, with all pts having some impairment of physical function, functional well-being, emotional and social function. Over the course of treatment, mean HRQoL was similar in the two treatment arms. From end of induction onwards, pts in both arms experienced clinically meaningful improvements from baseline in LYMS scores (Figure), and the summary scales that included this subscale (TOI, Lym-Total). On each summary scale, ≥50% of patients in each arm reported clinically meaningful improvements. There were no clear differences between arms in HRQoL scores over the course of therapy.

Summary/Conclusions: In previously untreated FL pts in GALLIUM, G-chemo and R-chemo produced similar improvements in HRQoL. These results suggest that lymphoma-related symptoms were reduced by both treatments and that the resulting improvements in well-being were not abrogated by treatment-related side effects. When viewed in the context of longer PFS, these results further support the benefit of G-chemo over R-chemo in GALLIUM.

S503

EFFECTIVE KEY WORKERS REDUCE THE NEED FOR CANCER SUPPORT GROUPS: RESULTS OF A POPULATION-BASED SURVEY FROM GREATER MANCHESTER CANCER PATHWAY BOARD (GMCPB)

J. Tomlins1, C. Wardley2, C. Quilliman3, J. Golding4, E. Cowell4, A. M. Kelly1, K. Bolton5, M. Dennis1, N. Remmington6

Background: Cancer patient support groups appear to provide an important source of support to many patients and carers. In recent years there has been an increasing focus in the UK for services to provide cancer support groups, however it is unclear what proportion of patients believe access to these support groups would improve their experience of living with and beyond cancer.

Aims: A patient experience survey was undertaken by the Haematology-Oncology GMCPB across 10 NHS hospital trusts, where there are a number of cancer support groups.

Methods: The sample for the survey included all adult (aged ≥16) patients with a confirmed diagnosis of a haematological cancer who attended a haematological oncology outpatient appointment during a 4 month period (June–September 2016). The survey was available for completion online and was completed anonymously. A translation/interpretation facility was not provided for patients whose first language was not English (due to funding restraints).

Results: 277 responses were returned with 1 response excluded (non-haematological malignancy). Haematological diagnoses included acute leukaemia (n = 40), chronic leukaemia (n = 35), lymphoma (n = 62), myeloma (n = 102), MDS (n = 15), MPD (n = 12), other (n = 2) and not specified (n = 7). 257 (93.1%) patients had received anttican therapy, 218 (78%) were receiving treatment at the time of survey and 54% had ongoing symptoms related to their treatment or cancer. 197 (71.4%) patients did not want access to a support group, 23 (19%) wanted access, 51 (8.3%) were not aware of the possibility and 6 (1.8%) did not respond. 51.8% of patients were aware of the existing support groups, 38.8% were not sure, 2.9% were not aware and 1.8% did not respond. The cohort of patients who did or did not want access to a support group was analysed further. 88% of patients had been given a key worker (either a specialist nurse, research nurse, advanced nurse practitioner or nurse clinician); of those the 88% were satisfied and 1% were partly satisfied with the support they had received with 11% not responding. 93% (n = 231) of patients were satisfied with the information they had received at diagnosis and 90% (n = 224) felt their diagnosis had been given sensitively. Only 20% of patients currently on treatment wanted access to a support group and 24% on treatment wanted access to a support group. Date of diagnosis was divided into three groups. Grp A: before 2005 (n = 15), Grp B: after 2006 (n = 229) and not stated (n = 14). There was no difference in the three groups when asked if they wanted access to support group (13%, 22%, 7% respectively; p = 0.3) or awareness that support group was available (40%, 57%, 50% respectively; p = 0.6). There were additional comments from patients that support from family and online forums in addition to key workers was extremely valuable to them. On univariate analysis patients who were satisfied with their key worker support did not want access to a support group (p = 0.04). There was no effect on wanting access to a support group and diagnosis (p = 0.67), treating hospital (p = 0.5), information given (p = 0.6), need for in-patient treatment (p = 0.3), quality of care (p = 0.8) or satisfaction with overall care (p = 0.8).

Summary/Conclusions: Our results suggest that a large majority of patients with haematological malignancy do not want access to a cancer support group but providing satisfactory support through key workers and other health care professionals is likely to achieve better patient experiences.

Acknowledgements: We would like to acknowledge the members of the GMCPB and patients for their contribution to the survey.
Methods: From April 2015 to February 2017, 152 consecutive patients with acute leukemia planned for remission induction chemotherapy were randomly assigned (1:1) to PICC (Arm A) or traditional CVC (Arm B) (Table 1). Inclusion criteria were age >18 years, expected survival >4 weeks, and need of central venous access (long-term >4 weeks). Exclusion criteria were ongoing uncontrolled systemic infection, presence of significant thrombosis/stenosis in arm or central veins, and inability to communicate and/or to sign informed consent. All insertions were followed by ultrasonography assessments and chest X-ray.

Results: 152 patients (130 AML and 22 ALL) with a median age of 47 years (range, 13-82), were randomized in the two arms. In the Arm A, 76 PICCs (power injectable PICCs, in new generation polyurethane, open-ended) were inserted in 76 patients. Double lumen PICCs (5 Fr) were inserted in 70 patients, single lumen PICCs (4 Fr) were inserted in 5 patients, and triple lumen PICC (6 Fr) was inserted in 1 patient. 68 PICCs were inserted in the right basilica vein, 5 PICCs were inserted in the left basilica vein and 3 PICCs were inserted in the left brachial vein. In Arm B, 76 traditional CVCs (untunneled heparin-coated Vialon CVC, Becton-Dickinson) were inserted by the Seldinger technique in other 76 patients. 45 CVCs were inserted in subclavian vein and 31 CVCs were inserted in internal jugular vein. Overall, the median duration of in situ catheter placement was 5 months: 6 months (range, 3-12) in the arm A vs. 3 months (range, 1-10) in the arm B. In the arm A, catheter-related thrombosis occurred in 8 patients (6 basilica veins, 2 brachial veins) and catheter-related bloodstream infections occurred in 4 patients (4 coagulase-negative staphylococci; of them, 2 meticillin-resistant). In the arm B, 20 cases of catheter-related thrombosis (7 subclavian veins, 13 internal jugular veins) and 15 cases of catheter-related bloodstream infections (10 enterobacteriaceae; 5 coagulase-negative staphylococci, and, of them, 3 meticillin-resistant) were observed. Thus, PICCs were significantly associated with fewer major complications than traditional CVCs (catheter-related thrombosis: 10.5% in the arm A vs. 26% in the arm B, p=0.01 by x2 test; catheter-related bloodstream infections: 5% in the arm A vs. 19% in the arm B, p=0.007 by x2 test) (Figure 1). Questionnaire covering activities of daily living confirmed improvement of quality of life.

19% in the arm B, = 0.01 by χ2 test; catheter-related bloodstream infections: 5% in the arm A vs. 26% in the arm B, p=0.01 by x2 test; rate and improvement of quality of life for patients with acute leukemia.

Summary/Conclusions: The preliminary observations of this ongoing Phase IV randomized study, focusing on front-line use of central venous access device in a high risk hematological population, suggest that the use of PICC represents an advance in terms of decrease of complication rate and improvement of quality of life for patients with acute leukemia.

SS05
THE SIMM STUDY: SURVEY OF INTEGRATIVE MEDICINE IN MYELOPROLIFERATIVE NEOPLASMS
K. Gowin1, D. Millstine2, H. Kosiorek2, B. Langlais3, J. Huberty4, R. Eckert4, R. Mesa5
1Hematology and Medical Oncology, 2Integrative Medicine Program, Department of Medicine, 3Department of Biostatistics, Mayo Clinic Arizona, 4School of Nutrition and Health Promotion, Arizona State University, 5Hematology, Mayo Clinic Arizona, Phoenix, United States

Background: Pharmacologic therapy stabilizes hematologic counts and splenomegaly in myeloproliferative neoplasms (MPN), however only partial symptom improvement typically occurs. Evidenced-based integrative care may address this need, however data is limited in patients with MPNs.

Aims: To investigate the association with symptom burden, quality of life, depression, and fatigue in MPN patients.

Methods: Patients were recruited via social media. Informed consent and online self-report surveys (Qualtrics) were completed capturing patient demographics, disease specific data, supportive care utilization, MPN symptom burden (MPN-SAF TSS), depression via Patient Health Questionnaire (PHQ-9), fatigue via Brief Fatigue Inventory (BFI) Usual, and an overall quality of life (QOL) single question assessment. ANOVA, chi square tests, and Wilcoxon rank sum tests methods were applied.

Results: Patients: A total of 1087 patient surveys were consented. Of these, 889 had 10 or more responses. There were 338 essential thrombocytosis (ET), 188 myelofibrosis (MF), 315 polycythemia vera (PV), and 17 other. In MF: DIPSS risk categories included low (8%), Int-1 (19%), Int-2 (29%), high (12%), and unknown (32%). Symptom association: Overall, patients had lower MPN related symptoms when participating in aerobic activity (p<0.001), massage (p=0.001), yoga (p=0.02), strength training (p<0.001), breathing exercises (p=0.001), and support groups (p=0.001). Overall quality of life was higher with aerobic activity (p<0.001), massage (p=0.02), yoga (p=0.02), strength training (p<0.001), breathing exercises (p=0.01), and support groups (p=0.001). Depression (PHQ-9 total >3 category) was lower in aerobic activity group (p=0.001), yoga (p=0.001), strength training (p=0.001), and meditation (p=0.2). Fatigue was lower in aerobic activity (p<0.001), massage (p=0.04), strength training (p<0.001), breathing exercises (p<0.001), and support groups (p=0.001). In subgroup analysis, ET and PV patients had lower symptom burden (MPN-SAF TSS) with aerobic activity (p<0.001, <0.001), massage (p=0.01, 0.02), and strength training (p<0.003, 0.02). Support groups were found to be associated with lower symptoms in ET patients (p=0.03). In MF, breathing exercises (p<0.001) and support groups (p=0.03) were associated with lower symptom burden. See Table #1.

Summary/Conclusions: Integrative therapies are associated with improved symptom burden, quality of life, depression, and fatigue in MPN patients. Interestingly, unique patterns were associated within MPN subtypes. Further studies are needed to understand the benefits of integrative therapies in MPN patients.
Acute lymphoblastic leukemia - Biology 2

T CELL EXHAUSTION CHARACTERIZED BY COMPROMISED MHC CLASS I AND II RESTRICTED CYTOTOXIC ACTIVITY ASSOCIATES WITH ACUTE B LYMWHOPLASTIC LEUKAEMIA RELAPSE AFTER ALLO-HSCT

L. Liu1*, Y. Zhang1, L. Xu1, X. Zhang1, Y. Wang1, K. Liu1, X. Huang1
1Peking University People’s Hospital & Peking University Institute of Hematology and Transplant Key Laboratory of Hematopoietic Stem Cell Transplantation, Beijing, China

Background: B cell acute lymphoblastic leukemia (B-ALL) relapse contributes to the predominant mortality after allogeneic hematopoietic stem cell transplant- tation (allo-HSCT). However, the mechanism of B-ALL relapse after allo-HSCT remains unknown. Eradication of leukemia in allo-HSCT settings largely relies on graft-versus-leukemia (GVL) effects mediated by donor T cells. T cell exhaustion characterized by increased expression of inhibitory receptors including PD-1 and Tim-3 and impaired function may blunt the GVL effects and was reported in acute myeloid leukemia relapse after allo-HSCT, whether T cell exhaustion is involved in B-ALL relapse after allo-HSCT remains unknown.

Aims: To evaluate whether T cell exhaustion is involved in B-ALL relapse after allo-HSCT, and investigate the correlation of inhibitory ligands on leukemic cells, leukemic load and T cell exhaustion, as well as the impact of treatment outcome on T cell exhaustion.

Methods: Our study enrolled 18 B-ALL patients who underwent first hematolog- ical relapse after allo-HSCT and 18 matched B-ALL patients in remission (without minimal residual disease MRD) and 14 healthy donors from April 2016 to November 2016 at the Peking University People’s Hospital. Patients were grouped by the Institute of Hematol- ogy, Transplant. Protocol and post-transplant time were matched in relapsed and non-relapsed patients. Post-transplant time were matched as follows: ±14days within 12 months ±1months from 12 to18months, ±3months from 18 to 36 months, ±12months over 3 years. Extra-medullary relapse were excluded in our study. All patients had achieved full donor chimerism before relapse or bone marrow collection. Peripheral blood (PB) were collected at the same day of bone marrow collection in relapsed patients. For patients who received induction therapy, we prospectively collected BM at least once after therapy. Sample collection was performed after patients was informed consent and approval by the institutional Human Ethics Review Committee of Peking Uni- versity People’s Hospital in accordance with the Declaration of Helsinki, phe- notypic and functional studies of T cells in those patients were performed using multi-color flow cytometry.

Results: In the current study, we observed that increased co-expression of PD-1 and Tim-3 was observed in both CD4+ and CD8+ T cells in relapse set- tings. Moreover, both CD4+ and CD8+ T cells exhibited compromised prolifer- ative capacity, cytokine production and cytotoxic potentials such as degranu- lation and granzyme B production (preferentially on CD4+T cells) in relapsed patients. In addition, T cells in the tumor were more easily exhausted than those in peripheral blood. Reversal of T cell exhaustion was associated with effective anti-leukemic response in relapsed patients who underwent re-induc- tion therapy.

Summary/Conclusions: In conclusion, our study suggested that T cells expe- rienced exhaustion comprehensively functional impairment in B-ALL relapse settings after allo-HSCT and reversal of T cell exhaustion was asso- ciated with effective anti-leukemic responses. These results also provide a foundation for the development of novel effective leukemia therapeutics, such as anti-PD-1 or PD-L1 therapy, by targeting T cell exhaustion

RUXOLITINIB/NILOTINIB COTREATMENT BETTER INHIBITS LEUKEMIA- PROPAGATING CELLS IN PHILADELPHIA CHROMOSOME-POSITIVE ALL

Y. Kong1,2, Y.-L. Wu1, Y. Song12, M.-M. Shi12, X.-N. Cao1, H.-Y. Zhao1, Y.-Z. Qin1, Y.-Y. Lai1, H. Jiang1, Q. Jiang1, X.-J. Huang1
1Department of Pediatrics and Adolescent Medicine, Ulm University Medical Center, Ulm, Germany, 2Department of Internal Medicine III, Ulm University Medical Center, Ulm, Germany

Background: B cell acute lymphoblastic leukemia (B-ALL) even in the modern era of tyrosine kinase inhibitors (TKIs). Relapse of Ph+ALL may result from the persistence of leukemia-propagating cells (LPCs), which are defined by their ability to initiate human leukemia and self- renew in immunocompromised mice. Using an anti-CD122-conditioned NOG/SCID xenograft mouse assay, LPCs were enriched and CD4+CD38-CD58- fraction in human Ph+ALL (Y.K., ..., X.J.H., Leukemia, 2014). Furthermore, a cohort study demonstrated that Ph+ALL patients with LPCs phenotype at diagnosis exhibited a significantly higher cumulative incidence of relapse than did the group with other phenotypes, even when receiving uniform front-line imatinib-based therapy pre- and post-allo-transplant (Y.K., ..., X.J.H., BMT, 2015). Therefore, it is imperative to identify novel therapeutic strategies based on LPCs to improve the prognosis of Ph+ALL patients.

Aims: To identify the potential molecular basis of LPC-mediated relapse, RNA sequencing/RNA-seq) and real-time reverse transcription-PCR (qRT-PCR) were performed to analyze gene expression profiles of LPCs and cells of other phenotypes from patients with de novo Ph+ALL. In order to assess the effects of the selective BCR-ABL and/or JAK2 inhibition therapy by the treatment with single agents or a combination of ruxolitinib and imatinib or nilotinib on Ph+ALL LPCs, drug-induced apoptosis of LPCs was investigated in vitro, as well as in vivo using sublethally irradiated and anti-CD122-conditioned NOG/SCID xenograft mouse assay. Moreover, western blot analyses were performed on the BM cells harvested from the different groups of recipient mice.

Methods: RNA-seq and qRT-PCR, we found that JAK2 was more highly expressed in the sorted LPCs than in the cells of other phenotypes in patients with de novo Ph+ALL in vitro study, cotreatment with nilotinib and ruxolitinib induced significantly higher levels of apoptosis in LPCs. In humanized Ph+ALL mice model, treatment with the nilotinib and ruxolitinib combination, compared with either ruxolitinib or TKIs alone, led to the most significant reduction in human Ph+ALL engraftment in the recipients. Further evidence that the most effective treatment with either nilotinib or ruxolitinib was achieved when the combination treatment was derived by the engulfment analysis of BCR/ABL expressing cells using a qRT-PCR assay and HE and IHC with anti-hcD19 staining. Moreover, the combination of nilotinib and ruxolitinib more effectively reduced the LPCs capacity through a lower expression of phospho-CrkL, JAK2 and STAT5 activities at the molecu- lar level.

Summary/Conclusions: JAK2 was more highly expressed in the sorted LPCs than in other cell phenotypes in patients with de novo Ph+ALL. Furthermore, selective BCR-ABL/JAK2 dual inhibition with nilotinib/ruxolitinib more effectively eliminated LPCs than either ruxolitinib or TKIs alone. Therefore, this pre-clinical study appears to provide scientific rationale for simultaneously targeting BCR- ABL and JAK2 activities, which represents a promising anti-LPCs therapeutic approach for patients with de novo Ph+ALL.

PREDICTING ANTI-LEUKAEMIA ACTIVITY OF THE B-2-SELECTIVE INHIBITOR ABT-199 IN BCP-ALL BY FUNCTIONAL ASSESSMENT OF APOPTOSIS SIGNALING

F. Seyfried1, S. Demiri2, R. Hör1, J. Ryan3, A. Scheffold3, M. Villalobos-Ortiz2, S. Kühler3, J. Zinngrebe1, S. Stilgenbauer3, A. Letai2, K.-M. Debatin1, L. H. Meyer1
1Department of Pediatrics and Adolescent Medicine, Ulm University Medical Center, Ulm, Germany, 2Dana-Farber Cancer Institute, Harvard Medical School, Boston, United States, 3Department of Internal Medicine III, Ulm University Medical Center, Ulm, Germany

Background: Although survival rates of pediatric BCP-ALL patients have con- tinuously improved during the past decades, therapy-related toxicity and relapse occurring in 10-20 % of patients are associated with poor outcome, clearly emphasizing the need of novel, targeted treatment strategies. Deregulated sur- vival pathways and cell death resistance contribute to treatment failure and reoccurrence of the disease. ABT-199 (venetoclax) is a small molecule inhibitor of BCL-2 demonstrating anti-cancer activity among different malignancies. How- ever, predictive biomarkers are required for up-front identification of patients who would benefit from BCL-2 directed therapies.

Aims: The aims of this study were to assess the efficacy of ABT-199 in BCP- ALL, to functionally evaluate factors mediating ABT-199 susceptibility or resist- ance and to identify markers indicative of favorable anti-leukemia activity.

Methods: The activity of ABT-199 was assessed by cell viability assays in BCP-ALL cell lines (N=6) and patient-derived xenograft (pdx) samples (N=27), analyzing half maximal effective concentrations (EC50). Expression of apo- tosis regulators was detected by western blot analysis. MCL-1 deficient cell lines were generated by CRISPR/Cas9 gene editing. BH3 profiling was used to measure the mitochondrial dependence of leukemia cells on anti-apoptotic BCL-2 family proteins. In vivo treatment of ABT-199 was performed in a set of three distinct ALL rpdx.

Results: Different sensitivities of ABT-199 were observed in a series of BCP- ALL pdx and cell lines with heterogeneous anti-leukemia activities upon drug exposure. The majority of BCP-ALL samples showed sensitivity to ABT-199- induced cell death in the nanomolar region (EC50 <1μM) with four out of six cell lines and 20 of 27 pdx, while ABT-199 insensitivities with EC50s of more than 1μM were identified in 26% of pdx leukemias. ABT-199 induces apoptosis based on its ability to form a sub-micron BCL-2/BAX complex, sequestering pro-apoptotic molecules; however, the sequestration of drug-released BIM by anti-apoptotic MCL-1 might lead to resistance. Therefore, we investigated protein expression of both regulators and found the ratio (BCL-2/MCL-1) to be cor-
related with ABT-199 sensitivity (t2 = 0.71, p = 0.006), highlighting the importance of
comprehensive assessment of the direct target molecule and additional resistance
mediating molecules. In line, MCL1 knockout in two ABT-199-resistant
cell lines led to sensitization towards ABT-199, however, resulted in different
effects of sensitization, emphasizing that ABT-199 resistance is determined by
the interplay of several apoptosis regulators. Therefore, we characterized the functional
dependence of pdx leukemias on anti-apoptotic BCL-2 family mem-
ers and BCL-2 gene expression profiling. Mitochondrial dependence on BCL-2 (mitochondrial prim-
ing by the BAD-peptide measuring BCL-2, BCL-XL and BCL-W, and subtracting
the response to the HRK-peptide measuring BCL-XL) was found to be tightly
correlated with ABT-199 sensitivity. In contrast, ABT-199-resistant samples
were characterized by low BCL-2-dependence and addiction to other BCL-2 family members,
including BCL-XL or MCL1. Finally, we evaluated prediction of in vivo ABT-199 sensitivity in a pre-clinical ALL pxd mouse model by func-
tional BH3 profiling. Strikingly, high mitochondrial BCL-2-dependency was clearly
associated with prolonged leukemia-free survival upon ABT-199-therapy (two pxd, log rank p = 0.0035 and <0.0001), in contrast to another leukemia
with low BCL-2-dependence and in vivo ABT-199 resistance (log rank p = 0.144).

Summary/Conclusions: SCP-ALL displays heterogeneous ABT-199 sensitivi-
ties characterized by the level of the target molecule but also other interacting
regulators. Functionally, mitochondrial BCL-2-dependence assessed by the BH3 profiling assay is clearly associated with ABT-199 sensitivity. Importantly,
in vivo anti-leukemia activity of ABT-199 therapy in individual pxd leukemias is predictable by mitochondrial BCL-2-dependence, emphasizing the utility of iden-
tification of patients and guidance of future clinical application by functional assessment of apoptosis signaling.

CD45RA- MEMORY T CELLS EXPRESSING AN NKGD2-CAR TARGET
PEDIATRIC ACUTE LEUKEMIA
L. Fernández1,*, J.-Y. Metais2, J. Valentín3, A. Escudero4, M. Vela5, A. Leivas1, J. Martínez1, W. Leung6, A. Pérez-Martínez6
1Clinical Research, CNIO, Madrid, Spain, 2Haematology, St.Jude Children's Research Hospital, Memphis, United States, 3Infectious diseases and Immuni-
ity, IdiPaz, 4Pediatric Oncology, INGEMM, Madrid, Spain, 5Clinical Development, Millenyi, Maryland, United States, 6Pediatric Hemato-Oncology, Hospital Universitario La Paz, Madrid, Spain

Background: Lymphoid and myeloid acute leukemia are the most frequent
type of cancer and the most frequent cause of cancer related death in children.
Relapse and refractory disease are the main clinical problems that current ther-
apieties are still unable to solve. One of the main NK cell activating receptors is
NKG2D. The role of NKG2D in leukemia cells was analyzed by flow cytometry
and could be

Aims: The aim of this study was to analyze the NKG2DL expression on pediatric acute leukemia cells and determine their susceptibility to an NKGD2 CAR
cell based immunotherapy.

Methods: The expression of NKGD2L was analyzed in Peripheral Blood
Mononuclear Cells (PBMCs) from patients suffering from acute leukemia, as
well as in leukemia cell lines, by flow cytometry (FCM) using specific monoc-
clonal antibodies directed against MICA, MICB, ULBP-1, ULBP-2, 4-1BB, CD3-z.

Summary/Conclusions: The expression of NKGD2L was significantly higher in
healthy donors compared with leukemia patients. The highest NKG2DL expres-
sion was observed in NKG2D CAR expressing T cells.

P510

A BILINEAL ACUTE LYMPHOBlastic LEUKEMIA ORIGINATING AT A
COMMON LYMPHODENDRITIC PROGENITOR
A. Gonzalez-Munillo1,*, C. Sánchez-Valdepeñas1, C. Robledo2, A. Castillo3, J. Abad-Cabezas4, C. Hernandez-Marcues1, D. Ruano1, L. Madero1, J. Alonso2, M. Ramirez1
1Pediatric Hematology & Oncology, Hospital Universitario Niño Jesús, Madrid, 2Instituto de Investigacion en Enfermedades Raras, Instituto de Salud Carlos III, Majadahonda, Spain

Background: Genetic mutations are crucial events during leukemogenesis and provide specific markers for backtracking the cellular origin of acute
leukemias up to immature uni- or multi-potent progenitor cells in the hierarchy of the hematopoietic system.

Aims: To characterize the clonal architecture and cell of origin in a case of
bilineal T- and B-ALL

Methods: Bone marrow cells obtained at diagnosis were used for all studies. Immunophenotyping was done by flow cytometry. T- and B-leukemic cell
purification was performed by immunomagnetics methods and DNA extracted after-
ward. TCR-gamma gene rearrangement was studied in T- and B-leukemic
cells independently by PCR spectratyping. Somatic mutations in purified T-
and B-leukemic cells were identified by deep-sequencing using a panel of 160
genes frequently mutated in cancer (Human comprehensive cancer panel, Qiajen). Mutations were validated by Sanger sequencing. Myeloid and ery-
thyroid clonogenic progenitors were isolated from myeloidcellular cultures,
DNA extracted, and assessed for the presence of the H3F3A p.K28N mutation by
Sanger sequencing.

Results: The patient was a 10 years old boy. At diagnosis, the bone marrow
was infiltrated by 60% leukemic cells, with 2 immunophenotypically different
populations: a common B-ALL (54%) and a pro-T-ALL (6%). The patient showed bone
marrow disease in an X-ray image and a mediastinal mass in the chest X-ray image.
Moreover, T-cell receptor (TCR) rearrangement was detected in purified (>95% true) T-ALL and B-ALL cells, suggesting a common origin for both leukemic subpopulations. The B-ALL cells presented a c.35G>A p.G12D mutation in the KRAS gene, absent in the T-
ALL. The T-ALL cells presented a c.35G>A (p.G12D) mutation in the NRAS
gene, absent in the B-ALL. A c.1126_1127insTAGA (p.P376fs*10) mutation in the WT1 gene was also detected only in the T-ALL. A c.849G>T (p.K28N)
mutation in the H3F3A gene was detected in both the B-ALL and T-ALL sub-
populations, confirming the involvement of a Common Lymphoid Progenitor in
the process of leukemogenesis. The presence of the H3F3A p.K28N mutation in
the myeloid compartment would point to a multistep myeloid-lymphoid rather than a lymphoid-restricted progenitor as the cell origin of the leukemia. Therefore, we cultured myeloid/erythroid-committed progenitor cells in clonogenic cultures and sequenced the H3F3A gene. None of the 122 myeloid or erythroid clonogenic progenitors (41 CFU-GM, 73 BFU-E and 8 CFU-GEMM) presented the p.K28N mutation in the H3F3A gene.

Summary/Conclusions: Our results indicate the involvement of a Common
Lymphoid Progenitor as the cell of origin in this case of bilineal ALL as well, as the crucial role of H3F3A and RAS family genes in the leukemogenesis process
coupled with B and T differentiation.

P511

CYSTEINE AND GLYCINE-RICH PROTEIN 2 (CSPG2) TRANSCRIPT LEVELS
CORRELATED WITH LEUKEMIA RELAPSE AND LEUKEMIA-FREE
SURVIVAL IN ADULT B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA WITH
NORMAL CYTOGENETICs
S.-J. Wang1,*, P.-Z. Wang2, R. Gale1, Y.-Z. Qin1, Y.-R. Liu1, Y.-Y. Lai1, H. Jiang1, Q. Jiang1, X.-H. Zhang1, B. Jiang1, L.-P. Xu1, X.-J. Huang4, K.-Y. Liu1, G.-R. Ruan1
1Peking University Peoples Hospital and Institute of Hematology, Beijing Key Laboratory of Hematopoietic Stem Cell Transplantation, 2Department of Immunology, School of Basic Medical Sciences, Peking University Health Science
Center., Beijing, China, 3Haematology Research Center, Division of Experimental Medicine, Department of Medicine, Imperial College London, London, United Kingdom, 4Peking University Peoples Hospital and Institute of Hematology, Beijing Key Laboratory of Hematopoietic Stem Cell Transplantation,Peking-Tsinghua Center for Life Sciences, Beijing, China

Background: Outcome of adults with B-cell acute lymphoblastic leukemia
(ALL) remains poor and relapse is the major cause of treatment-failure. CSPG2 is
upregulated in B-ALL compared with normal B-cells, suggesting a critical role in
leukemia cell proliferation and metastasis. However, its clinical significance and
biological function is unclear.

Methods: CSPG2 transcript levels were measured by qPCR in 122 samples of B-ALL patients. The samples were classified into two groups according to
whether they achieved complete remission (CR) or not. DNA extracted, and assessed for the presence of the H3F3A p.K28N mutation by
Sanger sequencing.

Summary/Conclusions: Our results show that CSPG2 transcript levels relate
with adult B-cell ALL survival in vitro and could be a promising and safe immunotherapeutic approach for pediatric acute leukemia patients.
Aims: To identify novel biomarkers in B-cell ALL based on bioinformatics analyses; to examine the expression and clinical significance of CSRP2 in adults with B-ALL; to explore effects of CSRP2 on biological function of B-cell ALL.

Methods: We did bio-informatics analyses to identify mRNA transcripts aberrantly-expressed in B-cell ALL. RT-qPCR (real-time quantitative polymerase chain reaction) was used to examine CSRP2 transcript levels in bone marrow samples from 236 adults with B-cell ALL compared with samples from normal. A prognostic value was assessed in 168 subjects. CSRP2-knockdown and CSRP2-over-expression cell models were constructed to study the biological function of CSRP2 in B-cell ALL.

Results: We selected 9 candidate genes for validation 7 of which proved significantly-associated with B-cell ALL. CSRP2 was the most differentially expressed gene in our validation studies. CSRP2 was over-expressed in 228 out of 236 adults (97%) with newly-diagnosed B-cell ALL. In subjects with normal cytogenetics, those with high CSRP2 transcript levels had a higher 5-year cumulative incidence of relapse (CIR) and worse relapse-free survival (RFS) compared to subjects with low transcript levels (56% [95% confidence interval 53-59%] vs 19% [18-20%]; P=0.011 and 41% [17-65%] vs 80% [86-96%]; P=0.007). In multivariate analyses a high CSRP2 transcript level was independently-associated with CIR (HR=5.32 [1.64-17.28]; P=0.005) and RFS (HR=5.56 [1.87-16.53]; P=0.002). Functional analyses indicated CSRP2 promoted cell proliferation, cell-cycle progression, in vitro colony formation and migration. Abnormal CSRP2 expression was associated with resistance to chemotherapy; sensitivity was restored by down-regulating CSRP2 expression. CSRP2 activated ERK1/2 signaling pathway, regulated cell-cycle related protein and activated CREB signaling pathway, whose activation was associated with poor prognosis in adults with B-cell ALL.

Summary/Conclusions: CSRP2 was widely over-expressed in adults with B-cell ALL. Determination of CSRP2 transcript levels in subjects with normal cytogenetics might inform therapy-decisions. Consideration could be given to down-regulating CSRP2 expression as a way to reverse drug resistance.

P512

THEРАЕUTIC TARGETING OF PRE-B CELL RECEPTOR SIGNALLING IN CHILDHOOD ACUTE LYMPHOBLASTIC LEUKAEMIA

A. Alhammer1,2,*, M. Case1, E. Matheson1, H. Blair1, J. Vormoor1, J. Irving1

1Newcastle University, Northern Institute for Cancer research, Newcastle upon Tyne, United Kingdom, 2Al-Nahrain University, Biotechnology research Center, Baghdad, Iraq

Background: Acute lymphoblastic leukaemia (ALL) is the most common malignancy in children and adolescents and relapsed ALL remains one of the leading causes of cancer-related deaths in children. Components of the precursor-B cell receptor (Pre-BCR) signalling pathway are hijacked in ALL cells and this dependence may be therapeutically targeted. A number of tyrosine kinase inhibitors (TKIs) targeting effectors of this signalling pathway are showing great promise in the clinic and warrant preclinical evaluation in paediatric ALL. They include Dasatinib (BCR-ABL SRC inhibitor), Fostamatinib R406 (SYK inhibitor), Ibrutinib (BTK inhibitor) and CAL-101 (PI3Kδ-8 inhibitor).

Aims: To preclinically evaluate these candidate TKIs, as novel, targeted drugs for otherwise-relapsed ALL.

Methods: ALL cell lines (Reh, Nalm-6, PreB 697 and its glucocorticoid resistant descendant, R3F9) and 36 primary-derived xenograft (PDX) cells from 16 ALL were used in the study. Cell viability was assessed by Resazurin. Pre-BCR expression (µHc, Vpreb and λ5) and functionality using a Calcium flux assay were detected by Flow cytometry. Intracellular phospho-flow cytometry was used to detect constitutive phosphorylation and activation in response to anti-Ig antibody, as well as drug pharmacodynamic measures (p-BTK, p-SYK, p- AKT, p-Erk, p-PLC-Y2, p-BLNK). Apoptosis and cell cycle were analysed by flow cytometry using Annexin V and Propidium Iodide. RQ-PCR was used to measure regulatory CSPR2 expression as a way to reverse drug resistance.

Results: ALL cell lines were modestly sensitive to Dasatinib (mean GI50 5.33 µM, range 2.45-12.5 µM) and R406 (mean GI50 4.32 µM, range 2.88 µM-5.83 µM). However, cells were resistant to Ibrutinib (mean GI50 15.9 µM, range 11.47 µM-18.3 µM) and CAL-101 (mean GI50 52.08 µM, range 25 µM-77.83 µM, range 2.45 µM-12.5 µM). Pre-BCR sensitivity was associated with Pre-BCR positive ALL and combination with Dexamethasone showed significant synergism in GC resistant cell lines and PDX samples. TKIs were also effective in some Pre-BCR negative ALL cells, however, predictive biomarkers need to be established. Confirmation of these data in preclinical models in vivo may define new therapies for high risk ALLs.

Summary/Conclusions: Significant sensitivity of TKIs targeting Pre-BCR signalling have been identified at clinically achievable concentrations. Dasatinib and R406 sensitivity was associated with Pre-BCR positive ALL and combination with Dexamethasone showed significant synergism in GC resistant cell lines and PDX samples. TKIs were also effective in some Pre-BCR negative ALL cells, however, predictive biomarkers need to be established. Confirmation of these data in preclinical models in vivo may define new therapies for high risk ALLs.
treat relapsed patients, there is still a need to develop new and effective targeted therapies. Previous evidence has shown IL-7 as a fundamental cytokine for normal T-ALL cell viability and homeostasis, as well as an important determinant for the T-ALL cell viability and proliferation in vitro and in vivo. Several strategies have been explored for the treatment of T-ALL, and targeting Interleukin 7 receptor alpha-chain (IL-7Rα) and downstream IL-7 signaling offers a potentially effective therapeutic strategy for T-ALL. The IL-7Rα is recruited and concentrated into lipid rafts thereby amplifying its downstream signaling pathway. The IL-7/STAT5 signaling pathway mediates downregulation of pro-apoptotic signals on human T-cells such as BAD and BIM. Moreover, we have previously reported that a new compound named Pyrido[4,3-b]Quinoxaline (PyQ) has an anti-tumoral effect on Acute Myeloblastic Leukemia (AML). It strongly interacts with the plasma membrane of AML cells and affects the positioning of the protein tyrosine phosphatase CD45, which is usually organized in microdomains into lipid rafts floating on the cell surface, and is delocalized by PyQ.

**Aims:** The aim of this study was to assess the anti-tumoral effect of PyQ on T-ALL cells and to identify which signaling pathway is affected by the compound.

**Methods:** We have 2 models of human T-ALL which can be studied in vitro when cocultured with murine stromal MS5 cells and in vivo when transplanted into immunodeficient NOD/SCID/γc−/− (NSG) mice. We also work on primary T-ALL blasts isolated from 10 patients suffering of T-ALL and maintained frozen in a biobank.

**Results:** In this study, we have shown that PyQ delocalizes the IL-7Rα away from lipid rafts from the surface of human T-ALL cells. We have also proved that localization of the IL-7Rα among lipid rafts plays a crucial role in human T-ALL maintenance. Its delocalization leads to IL-7 signaling pathway inactivation, upregulation of BAD and BIM genes involved in apoptosis and T-ALL cells apoptosis. We furthermore assessed effect of PyQ on 10 samples of primary T-ALL blasts. All of them were sensitive to IL-7-dependent cell survival and revealed a marked response to PyQ treatment (Mean IC_{50}=5.7 ng/mL). For this work, T-ALL cells were co-cultured on murine stromal MS5 cells and PyQ has affected mainly T-ALL cell growth. No effect was observed on the stromal feeder cells, suggesting that injection of PyQ in vivo would not impact the stromal microenvironment in bone marrow. Finally, we provided evidence that PyQ delayed T-ALL progression in vivo, after treatment of immunodeficient mice xenografted with T-ALL cells.

**Summary/Conclusions:** The findings of this study highlight the importance of the IL-7Rα localization in maintenance of T-ALL cells and may lead to the design of a new generation of anti-cancer drugs able to modulate the protein positioning into lipid rafts.
Background: Front-line imatinib (IM) plus chemotherapy followed by allogeneic hematopoietic stem cell transplantation (HSCT) is standard therapy for patients (pts.) with Ph+ ALL. Relapse after HSCT remains a major cause of treatment failure, and pts. in whom BCR-ABL transcripts are detectable after HSCT are at particular risk. Post-transplant maintenance using tyrosine kinase inhibitors (TKIs) to reduce the relapse rate remains a subject of uncertainty, as data from prospective studies are limited.

Aims: To determine the impact of IM administration after HSCT on patient outcome and to assess the predictive value of minimal residual disease (MRD) analysis by qRT-PCR of BCR-ABL1 transcripts.

Methods: In this prospective, multicentre trial by the GMALL study group, adult pts. (≥18 y) with Ph+ ALL in CR at HSCT were randomly assigned (1:1) to receive IM prophylactically after SCT or pre-emptively upon detection of MRD. Inclusion criteria included engraftment, sufficient hematopoietic and organ function, absence of infection, or immunosuppressive dose of IM was 600mg or 400mg recommended as starting dose. Primary endpoint was molecular or hematologic relapse, secondary endpoints included survival, DFS, severe toxicity and transplant-related mortality. All pts. were followed by frequent serial MRD analysis after HSCT. An interim analysis was reported previously. We here provide results of the final analysis of this trial, with long-term follow-up of up to 11 years after HSCT.

Results: 74 pts. were evaluable, 36 received prophylactic and 38 pts. pre-emptive IM. Median age was 41 y (18-89) and 44 y (19-68), respectively. Disease status at HSCT was CR1 (n=67), CR2 (n=5), n=1) (n=1), unknown (n=1). Most pts. received a PBS graft (n=61) and myeloablative TBI-based conditioning (n=65), 8 pts. underwent RIC with 2Gy or 4Gy TBI (n=6) or non-TBI RIC (n=2). Median time from HSCT to starting IM was 48d and 77d, respectively. IM dose was 600mg/d in 22% of pts., remaining pts. received 400mg. Treatment was prematurely discontinued in 56% and 59% of pts., median time to discontinuation was 92d (range, 0-111) and 71d (range, 0-786). 10y DFS of IM was 80.7% (95% CI: 75.1-85.8) and 71% with prophylactic and pre-emptive IM, respectively (p=ns). MRD levels were significantly predictive of relapse: BCR-ABL1/ABL1 (B/A) ratio ≥10-3 within 6 weeks prior to HSCT was associated with a higher cumulative incidence of relapse (CIR) (at 47.5% vs 10.6%, p=0.006) and inferior DFS (45% vs 79%, p=0.027) at 10y. B/A ratio ≤10-4 within 100d after HSCT was likewise associated with a higher CIR (21% vs 6%, p=0.018) and inferior DFS (55% vs 71% at 8y). An algorithm combining pre- and early (<100 days) post-transplant MRD levels (pre: ≥10-4; post: any positivity including below quantitative range) identified patients with a 60% vs 8.5% CIR at 10y.

Summary/Conclusions: Post-HSCT intervention with prophylactic or pre-emptive IM is associated with a low relapse risk and excellent long-term survival. A combination of pre- and post-transplant MRD analysis (10 deaths, 9 manufacturing failures, 3 adverse events [AEs], 4 pts. discontinued IM) is promising. 97 pts. received a single infusion of transduced CTL019 cells (median dose, 3.2×10^6 [range, 0.2-5.4×10^6] cells/kg). Median age was 12y (range, 3-25). During the first 8 wk after infusion, 98% of pts. experienced an AE of any grade (G), 82% experienced G3/4 AEs, and 72% experienced a serious AE (SAE). Common nonhematologic G3/4 AEs (≤10%) during the first 8 wk were cytokine release syndrome (CRS; ≤4%), hypotension (≤3%), decreased appetite (≤21%), increased AST (≤19%) and ALT (≤12%), hypoxia (≤16%), hypokalemia (≤13%), hypophosphatemia (≤11%), and pulmonary edema (≤10%). Rates of G3/4 AEs and SAEs decreased substantially >8 wk post infusion. 21 pts died post infusion: 16 (8.5%) from B-ALL (n=2), 320 days after infusion; n=14, >30 days); cerebral hemorrhage (n=1) and embryonic infectious stroke (n=1) (both ≤30 days); and infection (n=3, >30 days). Safety events were similar across pt subgroups based on age, sex, prior allogeneic stem cell transplant (alloSCT) (n=57), and Down syndrome (n=7). CRs were based on the IPSS scale, occurred in 81% of pts (Table 1). All CRS events occurred ≤8 wk post infusion. CRS was managed with supportive care, and 34% of pts were treated with anti-IL-6 agents. No deaths were attributed to CRS. Pts. with ≤50% bone marrow (BM) blasts at enrollment (n=68) were

Results: 123 pts were enrolled, 26 were not infused and not included in this analysis (10 deaths, 9 manufacturing failures, 3 adverse events [AEs], 4 pts. prematurely discontinued). 97 pts. received a single infusion of transduced CTL019 cells (median dose, 3.2×10^6 [range, 0.2-5.4×10^6] cells/kg). Median age was 12y (range, 3-25). During the first 8 wk after infusion, 98% of pts. experienced an AE of any grade (G), 82% experienced G3/4 AEs, and 72% experienced a serious AE (SAE). Common nonhematologic G3/4 AEs (≤10%) during the first 8 wk were cytokine release syndrome (CRS; ≤4%), hypotension (≤3%), decreased appetite (≤21%), increased AST (≤19%) and ALT (≤12%), hypoxia (≤16%), hypokalemia (≤13%), hypophosphatemia (≤11%), and pulmonary edema (≤10%). Rates of G3/4 AEs and SAEs decreased substantially >8 wk post infusion. 21 pts died post infusion: 16 (8.5%) from B-ALL (n=2), 320 days after infusion; n=14, >30 days); cerebral hemorrhage (n=1) and embryonic infectious stroke (n=1) (both ≤30 days); and infection (n=3, >30 days). Safety events were similar across pt subgroups based on age, sex, prior allogeneic stem cell transplant (alloSCT) (n=57), and Down syndrome (n=7). CRs were based on the IPSS scale, occurred in 81% of pts (Table 1). All CRS events occurred ≤8 wk post infusion. CRS was managed with supportive care, and 34% of pts were treated with anti-IL-6 agents. No deaths were attributed to CRS. Pts. with ≤50% bone marrow (BM) blasts at enrollment (n=68) were

Table 1.
twice as likely to develop G3/4 CRS than pts with <50% BM blasts (n=29) (53% vs 29%; P<0.0001). InO, more patients with diploid (≥20 metaphases) karyotype proceeded to stem cell transplant versus other cytogenetic subgroups. With InO, the duration of CR/CRi and OS did not differ according to whether ASCT was performed (P=0.5427). With InO, more patients with diploid (≥20 metaphases) karyotype proceeded to stem cell transplant versus other cytogenetic subgroups. With InO, the duration of remission (DoR) was significantly different between cytogenetic subgroups (P<0.0001), with diploid (≥20 metaphases) and other subgroups having the longest median DoR numerically and MLL subgroup having the shortest median DoR numerically; no significant differences in DoR were seen between cytogenetic subgroups with SC (P=0.7653). Significant differences in PFS were seen between cytogenetic subgroups with InO (P=0.0063); no significant differences were seen between cytogenetic subgroups with SC (P=0.5427). Within InO and SC arms, overall survival (OS) differences between cytogenetic subgroups were not significant (P=0.1629 and 0.3040, respectively); however, although not statistically significant based on 97.5% CI for hazard ratio (HR), OS was numerically longer (HR <1) with InO versus SC in diploid (≥20 metaphases), MLL, complex, other, and missing cytogenetic subgroups. Generally, adverse event profiles did not vary by cytogenetic subgroup.

Summary/Conclusions: In patients with diploid (≥20 metaphases), complex, other, and missing cytogenetic karyotypes, CR/CRi rates were significantly higher with InO versus SC (P<0.0001), with good OS in both. MLL, complex, other, and missing cytogenetic subgroups, OS favored InO versus SC, though not statistically significant. Safety profiles generally were similar to the overall study population.
A PHASE II STUDY WITH A SEQUENTIAL CLOFARABINE-CYCLOPHOSPHAMIDE COMBINATION SCHEDULE AS SALVAGE THERAPY FOR RELAPSED/REFRACTORY ACUTE LYMPHOBlastic LEUKEMIA (R/R) IN ADULT PATIENTS

1Department of Pediatrics, School of Medicine, Sapienza University, Rome, 2Department of Hematology, Ospedale Riuniti Villa Sofia-Cervello, Palermo, 3Department of Paediatric Haematology and Oncology, University Children’s Hospital, Vienna, Austria, 4Division of Pediatric Hematology and Oncology, University of Pennsylvania, Philadelphia, PA, USA, 5Medisch Centrum Haaglanden, Leiden, The Netherlands, 6Department of Pediatrics, University of Hong Kong, Hong Kong

Aims: To assess the activity and toxicity of the sequential clofarabine-cyclophosphamide regimen for adults with relapsed/refractory acute lymphoblastic leukemia.

Methods: An open-label, single-arm, phase II trial was conducted at six sites in Italy. Eligible patients aged 18-75 years with relapse or refractory AML or ALL were enrolled. The treatment consisted of a 5-day cycle of clofarabine 35 mg/m²/day, followed by cyclophosphamide 600 mg/m²/day. Two cycles were administered, with a 4-week interval between cycles.

Results: 15 patients were enrolled, with a median age of 52 years (range: 18-75). 14 patients (93%) had relapsed disease, and 1 patient (7%) had refractory disease. Complete response was achieved in 9 patients (60%) after 2 cycles of treatment. The median OS was 9 months (range: 1-124) and the median DFS was 6 months (range: 1-24). There were no grade 5 toxicities, and the most common grade 3/4 toxicities were febrile neutropenia (60%) and thrombocytopenia (40%). The overall response rate was 60%, with 0 CRs, 9 CRs, and 6 non-responders.

Summary/Conclusions: The sequential clofarabine-cyclophosphamide regimen showed acceptable activity and manageable toxicity in adults with relapsed/refractory AML or ALL. Further studies are needed to confirm these results and explore the potential benefits of this regimen in other settings.

BLINATUMOMAB USE IN PEDIATRIC AND ADULT PATIENTS WITH RELAPSED/REFRACTORY B-PRECURSOR ACUTE LYMPHOBlastic LEUKEMIA: AN OPEN-LABEL, MULTICENTER, EXPANDED ACCESS STUDY

F. Locatelli1,2,*, G. Zugaïner3, A. Vora4, C. Rossig5, C. Peters6, B. Breton7, M. O’Brien8, L. Belton9, R. Handgretinger10

1Hematology/Oncology, Children’s Hospital, University of Tübingen, Tübingen, Germany, 2Department of Hematology and Oncology, University Children’s Hospital, Munich, Germany, 3Department of Paediatric Hematology and Oncology, University Children’s Hospital, Vienna, Austria, 4Department of Pediatric Hematology and Oncology, University of Pennsylvania, Philadelphia, PA, USA, 5Department of Paediatric Haematology and Oncology, University Children’s Hospital, München, Münster, Germany

Aims: To evaluate the safety and efficacy of blinatumomab in adult and pediatric patients with relapsed/refractory B-precursor ALL enrolled in an expanded access study (NCT02187354).

Methods: Eligible patients (aged ≥18 years) with relapsed/refractory B-precursor ALL were treated with blinatumomab at a dose of 0.8 mg/m²/day for 3 weeks followed by 2 weeks off. The primary endpoint was the proportion of patients achieving complete response (CR) with or without CR with incomplete recovery (CRi) after 2-4 cycles of treatment. Efficacy endpoints included overall response rate (ORR) and duration of response.

Results: 21 patients were enrolled, with a median age of 24 years (range: 18-64). 10 patients achieved CR (45%) and 6 patients achieved CRi (28%). The median duration of response was 12.4 months (range: 2-50). The most common grade 3/4 adverse events were pyrexia (71%), cytokine release syndrome (23%), and neutropenia (21%). No grade 5 adverse events were reported.

Summary/Conclusions: Blinatumomab showed acceptable safety and efficacy in adult and pediatric patients with relapsed/refractory B-precursor ALL. Further studies are needed to confirm these results and explore the potential benefits of this regimen in other settings.
KTE-C19 CHIMERIC ANTIGEN RECEPTOR (CAR) T CELL THERAPY IN ADULTS WITH HIGH-BURDEN RELAPSED/REFRACTORY ACUTE LYMPHOBLASTIC LEUKEMIA (R/R ALL): UPDATED RESULTS FROM PHASE 1/2 OF ZUMA-3

1Department of Hematological Malignancies, H. Lee Moffitt Cancer Center, Tampa, Florida, United States, 2Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, Texas, 3David Geffen School of Medicine at UCLA, Los Angeles, California, 4Department of Medicine, The University of Chicago Medical Center, Chicago, Illinois, 5Department of Hematology, Moores UCSD Cancer Center, San Diego, California, 6Kite Pharma, Santa Monica, United States

Background: The incidence of acute lymphoblastic leukemia (ALL) is increasing, with nearly 6600 new diagnoses expected in 2016, of which >40% will affect children under the age of 10 years. Adult patients (pts) with B-ALL show high-risk disease biology, high rates of relapse, and poor survival (J Clin Oncol 2011;29:532; Blood 2012;119:34). Promising results have been observed with KTE-C19, an anti-CD19 chimeric antigen receptor (CAR) T cell therapy, in refractory, aggressive non-Hodgkin lymphoma (Blood 2016;128:LBA-6), and suggest an opportunity to improve outcomes in ALL. Here, we present updated results from phase 1 portion of ZUMA-3, a multi-center study of KTE-C19 in pts with high tumor burden ALL.

Aims: The goal of this study is to assess safety and efficacy of KTE-C19 in adult pts with relapsed/refractory ALL who have high disease burden.

Methods: Eligible pts were ≥18 years of age with relapsed/refractory ALL (Ph+ pts eligible), ≥25% bone marrow lymphoblasts, adequate organ function, and Eastern Cooperative Oncology Group status 0-1. Pts received 1 or 2 × 10⁶ CAR T cells/kg after conditioning with cyclophosphamide and fludarabine. The primary endpoint of phase 1 was incidence of dose-limiting toxicity (DLT). Secondary endpoints were efficacy outcomes of KTE-C19, including complete response (CR) rates and biomarker associations.

Results: As of Nov 1, 2016, 11 pts were enrolled, and 10 were treated with KTE-C19. One pt had a serious adverse event prior to dosing and was not treated. KTE-C19 was successfully manufactured in a centralized facility for all pts across a broad range of baseline absolute lymphocyte counts in 6 days, with a turnaround time of ~2 weeks. Pts were 60% men, with 1-4 prior lines of therapy and high disease burden (median, 81% bone marrow lymphoblasts). No pt (0/3) experienced a DLT at the 2 × 10⁶ dose, and phase 1 was then expanded to 6 pts at the 2 × 10⁶ dose. One pt experienced a grade 5 adverse event of multi-organ failure due to cytokine release syndrome (CRS), and subsequent pts (n=4) received 1 × 10⁶ CAR T cells/kg. Across all pts, the most common grade ≥3 adverse events were cytopenias (80%), febrile neutropenia (50%), pyrexia (40%), and transaminitis (40%). Grade ≥3 CRS and neurologic events were reported in 20% and 40% of pts, respectively. Cerebral edema was not observed. All CRS events resolved (except the grade 5 event); neurologic events resolved in 5 of 6 pts (1 grade 3 neurologic event ongoing at cut-off). Anti-CD19 CAR T cells achieved peak expansion within two weeks of infusion. Of the 8 efficacy evaluable pts, 6 (75%) achieved remission (including CR and CR with partial or incomplete hematopoietic recovery) by day 28 disease assessment or earlier. All remissions (100%) were minimal residual disease-negative. Of the 6 pts achieving minimal residual disease-negative CR, two eventually relapsed, one with CD19- disease and one with CD19+ disease. Safety and efficacy data were similar across KTE-C19 doses. Updated pt number, follow-up, and biomarker data will be presented.

Summary/Conclusions: No DLTs were observed with KTE-C19 in adult pts with high BM disease burden; one pt with high disease burden had grade 5 CRS after completion of the DLT cohort. Manufacturing was successful in all pts; most pts achieved a minimal residual disease-negative CR. These results demonstrate promising efficacy with a manageable safety profile. Based on these results, ZUMA-3 continues to enroll pts, adding measures to further enhance safety and with planned expansion to phase 2.

Impact: KTE-C19 demonstrates promising efficacy and manageable safety in a phase 1/2 study of pts with high burden ALL. The results support phase 2 expansion and enhanced safety measures to further improve outcomes in this difficult-to-treat ALL population.

EXPOSURE-ADJUSTED ADVERSE EVENTS COMPARING BLINATUMOMAB WITH STANDARD OF CARE CHEMOTHERAPY IN ADULTS WITH RELAPSED/REFRACTORY B-PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA FROM A RANDOMIZED PHASE 3 STUDY

M.S. Topp1,*, R.A. Larson2, A. Schuh3, W. Stevenson4, E. Lech-Maranda5, K. Nie6, Z. Zimmerman7, W. Kornamany8, A.S. Stein9

1Department of Medicine, Stanford University School of Medicine, Stanford, CA, United States, 2Department of Medicine, The University of Chicago Medicine, Chicago, IL, United States, 3Princess Margaret Cancer Centre, University Health Network, Toronto, Canada, 4Royal North Shore Hospital, University of Sydney, Sydney, Australia, 5Department of Hematology, Institute of Hematology and Transfusion Medicine and Centre of Postgraduate Medical Education, Warsaw, Poland, 6Global Biostatistical Sciences, 7Global Development, 8Global Safety, Amgen Inc, Thousand Oaks, CA, 9Gehr Family Center for Leukemia Research, City of Hope, Duarte, CA, United States

Background: Blinatumomab, a bispecific T-cell engager antibody construct, has shown improved overall survival vs standard of care (SOC) chemotherapy in patients with Philadelphia chromosome-negative relapsed/refractory B-precur sor acute lymphoblastic leukemia (ALL) in a randomized phase 3 study (N Engl J Med 2017;376:836-847).

Aims: We compared the incidence of adverse events (AEs) observed with blinatumomab vs SOC after adjusting for varying treatment exposure times for a more comprehensive evaluation of safety and tolerability.

Methods: Adults (aged ≥18 years) with relapsed/refractory B-precursor ALL (refractory to primary induction therapy or salvage therapy, first relapse <1 year, second or later relapse, or relapse after allogeneic hematopoietic stem cell transplantation) were randomized to receive either blinatumomab or SOC (1 of 4 predefined regimens). Blinatumomab was dosed by continuous intravenous infusion (4 weeks on/2 weeks off) for up to 5 induction cycles (9 µg/day on days 1−7 of cycle 1, 28 µg/day thereafter). Up to four maintenance cycles (1 of 4 predefined regimens). Blinatumomab was dosed by continuous intravenous infusion (4 weeks on/2 weeks off) for up to 12 months. Exposure-adjusted event rates were calculated as the number of events x 100/total exposure time (shown in the table).

Results: Median (range) number of cycles was 1 (1−4) for SOC and 2 (1−9) for blinatumomab. The highest exposure-adjusted event rates (per 100 patient-years) were for pyrexia (507 SOC vs 376 blinatumomab), anemia (987 vs 229), thrombocytopenia (750 vs 126), and neutropenia (351 vs 121), all of which were lower for blinatumomab than for SOC. Febrile neutropenia (365 vs 93) were lower for blinatumomab than for SOC after adjusting for varying treatment exposure times for a more comprehensive evaluation of safety and tolerability.

Impact: Blinatumomab was associated with a manageable safety profile. Based on these results, exposure-adjusted event rates can be used in clinical decision making or to aid in prioritization of future research.

Summary/Conclusions: In this study, blinatumomab showed an AE profile consistent with that previously reported for relapsed/refractory ALL, including similar rates of manageable CRS and neurologic events. Exposure-adjusted event rates were generally higher in SOC vs blinatumomab, including for cytopenias and infections.

DESIGNING THE NEXT GENERATION CD33-TARGETING ADC: IMGN779, SELECTED FOR POTENCY, NOVEL MECHANISM AND PRECLINICAL TOLERABILITY, WITH HIGH ACTIVITY IN DISSEMINATED AML MODELS AND IN MULTI-DOSE REGIMENS

S. Adams1, A. Wilhelm1, L. Harvey1, L. Flaherty1, K. Watkins1, S. Sikka1, P. Shah1, W. Li1, Y. Kouvatsi1, C. Sloss1, K. Lai1, M. Miller1, G. Payne1

1ImmunoGen, Waltham, United States

Background: Antibody-drug conjugates (ADCs) targeting CD33 are promising therapeutics in AML, where challenges are achieving efficacy while maintaining tolerability. Here, we report the payload/ linker design and selection resulting in a high-Therapeutic Index (TI) ADC with favorable preclinical toxicology profile across multiple species and preclinical activity in disseminated AML models and in multi-dose regimens. IMGN779, the final ADC design, is comprised of an indolino-benzodiazepine mono-imine DNA-alkylating payload, DGN462, coupled by a cleavable N-succinimidyl-4-(2-pyridyldithio)-2-sulfobutane (s-SPDB) linker to a CD33-targeting antibody.

Aims: Select the best ADC out of multiple preclinical anti-CD33 ADC candidates, and assess its activity in vitro and in vivo in AML models.

Methods: Unconjugated payloads were evaluated in vitro for cytotoxicity on human AML cell lines. Payloads were compared, as CD33-targeting conjugates, in vitro for cytotoxicity on human AML cell lines and in vivo for tolerability in mice and Ti in human AML xenografts. ADCs with cleavable and non-cleavable linkers were evaluated for cytotoxicity on MDR-positive and -negative AML cell lines, for tolerability in mice and Ti in AML xenografts. IMGN779, the final ADC design, was evaluated in vivo for toxicity in rats and cynomolgous monkeys. IMGN779’s antitumor activity was evaluated in disseminated models and in fractionated- and multi-dose models in AML xenografts.

Results: First, we selected a high affinity antibody to CD33 with retained ADC payload activity. Next, given concerns for long-term toxicity of DNA crosslinkers, we prepared DNA alkylating (single strand DNA damage) and DNA crosslinking (double strand DNA damage) versions of our novel IGN payload class. Both versions had comparable IC50 on human AML cell lines as free drugs (12-260 vs. 5-77 PM) and as CD33-targeting ADCs (0.7 vs. 0.5 PM). However, in vivo, the CD33-targeting DNA alkylating ADC had a 50%-higher MTD (maximally tolerated dose) in mice and 50% larger Ti in AML xenograft models (MTD 950 vs. 180 µg/kg, by payload, Ti of 95 vs. 19). In addition, the DNA crosslinking version led to delayed systemic toxicity at MTD, not seen in the DNA alkylating version even at its 5-fold higher MTD. Thus we selected the DNA alkylating version for further development. To determine the optimal linker design, we created ADCs with three different linkers, one non-cleavable and two cleavable, and based on improved in vitro efficacy (IC50) and in vivo safety/efficacy (MTD, Ti), the s-SPDB cleavable linker with the DNA alkylating payload was chosen as the lead clinical compound, and named IMGN779. In multiple species, IMGN779 had a consistent toxicity profile (mice, rats and monkeys), producing reversible cytopenias with no or minor changes in transaminases and without histologic evidence of hepatotoxicity. Importantly, IMGN779 was highly active at a single dose 10 µg/kg (payload) in an MV4-11 (FLT3-ITD+) disseminated AML xenograft model, producing a 90% increased life span, and was well-tolerated and highly active in repeat dosing regimens (10 or 30 µg/kg, qx 3 and q3dx 3) in a HL60 AML xenograft model. Similarly, in a MV4-11 xenograft model, a single dose of IMGN779 was highly active in single-dose (5 µg/kg, qx 3 or q4dx 3) and generated 33% more long-term tumor-free survivors compared to single-dose (10 µg/kg), demonstrating tolerability and enhanced efficacy in multi-dose and fractionated regimens.

Summary/Conclusions: IMGN779, designed as the next generation CD33-targeting ADC, utilizes a novel DNA alkylating DGN462 payload and a cleavable disulfide linker, selected to maximize anti-AML activity and preclinical safety. IMGN779 is highly active in multiple AML xenograft models, including models with poor prognostic factors, and is well-tolerated in preclinical repeat dosing regimens, where an additional benefit was achieved with a fractionating the dosing regimen over a single high dose. These results provide the foundation for the clinical evaluation of IMGN779 in AML.

P527

THE MIXED LINEAGE LEUKEMIA FUSION PARTNER ENL RECRUITS PAF1 TO CLEAR POLYCOMB-INDUCED TRANSCRIPTIONAL REPRESSION

K. Hetzner1, M. Garcia-Cuellar1, C. Bütter2, R. Slany1

1Biology, Institute of Genetics, 2Biology, Institute of Hum.Genetics, Friedrich Alexander University Erlangen-Nürnberg, Erlangen, Germany

Background: In mixed lineage leukemia ENL is frequently found juxtaposed to MLL creating MLL-ENL fusion proteins that initiate leukemogenic transfor- mation. Interestingly, murine ENL has also been shown to have oncogenic activity, a pediatric nephroblastoma. In its wild-type configuration ENL serves as scaf-olding factor in protein complexes that stimulate transcriptional elongation but, paradoxically, it also co-purifies with polycomb repressive complex 1 (PRC1).
Aims: This work examines how ENL influences PRC1 repressive activity. Methods: The effect of ENL on transcriptional activity of model promoters and endogenous transcriptional control elements was studied by biochemical and molecular biology methods. Results: Here we demonstrate that ENL overcomes polycomb induced silencing through recruitment of polymerase associated factor 1 (PAF1) and a chromatin rearrangement that enhances the ability to bind PAF1. This led to a significant and dose-dependent increase in mitochondrial-produced superoxides—a specific type of ROS. Moreover, we found that enforced expression of PFKcC can protect AML cells from lethal effects of superoxide-inducing agents 2-thienyltrifluoroacetone and Antimycin A. To identify potential ROS-regulatory enzymes downstream of PFKcC, we performed whole cell proteomics and found that the mitochondrial superoxide-neutralizing enzyme SOD2 is decreased in AML cells depleted of PFKcC. Similar to PFKcC inhibition, we also observed gene expression changes in cell lines and PD-AMLS in vitro as well as significantly extended the onset of MLL-AF9-driven AML in vivo (p=0.0042). Finally, we also found that enforced expression of SOD2 in tandem with another anti-oxidant enzyme Catalase, reverses the anti-leukemia effects of PFKcC inhibition confirming that PFKcC supports AML pathophysiology by maintaining mitochondrial redox homeostasis. Summary/Conclusions: Our results indicate that PFKcC and SOD2 regulate mitochondrial redox homeostasis to support AML cell survival and disease progression and thus may represent a foundation for designing and developing novel therapeutic strategies. P529 Abstract withdrawn.

P530 ROLE OF SHP2 IN A MOUSE MODEL OF AML CARRYING FLT3-ITD ALONG WITH LOSS OF TET2
R. Pandey1,*, B. Ramdas1, R. Chen1, R. Kapur1
1Indiana University School of Medicine, Indianapolis, United States

Background: SHP2, a protein tyrosine phosphatase coded by Ptpn11, is an essential protein that integrates signals from several different tyrosine kinase receptors with all the major intracellular signaling pathways such as ERK, PI3K and STAT pathways and regulates cell survival, proliferation and differentiation.

Methods: Aims: Inactivation of polycomb by ENL was accompanied by ubiquitination of histone H2B, the hallmark activity of PAF1 allied enzymes. On a global level, high resolution RNA-Seq demonstrated that MLL-ENL target genes stood out with a supraphysiological accumulation of H2B ubiquitination and H2B ubiquitination of Hox9a and Meis1, two sentinel loci for polycomb action. This was dependent on the conserved YEATS domain of ENL that operated as ‘switch’ binding either histone H3 or PAF1 thus effectively regulating ENL function as anti-repressor or elongation factor, respectively. With ENL silencing, transcriptional interaction with PAF1 and thus perturbed proper silencing. This effect was intensified in a MLL-ENL fusion where MLL itself provided a constitutive tether to PAF1 effectively creating a ‘super-transcription factor’ that constitutively combined anti-repression with elongation capabilities.

Summary/Conclusions: In summary, targeting histone ubiquitination may be an additional Achilles heel for mixed lineage leukemia that merits further investigation of therapeutic utility. P528

Background: Although numerous genetic mutations contribute to the etiology and pathophysiology of acute myeloid leukemia (AML), the molecular machinery that is not mutated but supports AML biology remains largely unknown. Several studies have shown that AML cells, irrespective of genetic sub-type, display an oxidized intracellular redox environment compared to their healthy counterparts. The redox environment of AML cells is largely due to the elevated reactive oxygen species (ROS) levels, which are a class of free radical molecules. Though ROS are by-products of several cellular processes, in excess, they can damage DNA and destroy organelles, resulting in the acquisition of genetic mutations or cell death. As a result, ROS homeostasis is tightly regulated by an array of molecular pathways. Although ROS is elevated in AML cells, the role of ROS and the identity of its regulators remain largely unknown. Here we report that the serine/threonine kinase, PKCε regulates the ROS-neutralizing enzyme SOD2 to support mitochondrial redox homeostasis and AML progression.

Aims: The goal of this study was to identify and subsequently assess how targeting key ROS-regulatory pathways impacts AML biology. Methods: Loss-of-function studies for PKCε and SOD2 were performed with recombinant lentiviruses expressing gene-targeting shRNAs. Recombinant retroviruses expressing either PKCε or SOD2/Catalase were used for gain-of-fusion assays. Cytoplasmic and mitochondrial superoxides and peroxides were measured using redox-sensitive GFP (roGFP) probes followed by flow cytometric analysis. Mitochondrial superoxides were also assessed by flow cytometric analysis of MitoSox stained cells. Proteomic analysis was achieved using nano LC-MS/MS. Annexin-V staining was analyzed by flow cytometry to measure apoptosis and in vitro and in vivo survival assays were performed to evaluate the ability of mice lacking PKCε or its FACS-based purification of shRNA-expressing cells followed either by: 1) growth in cytokine-enriched media or 2) transplantation into syngenic mice for cytometric analysis. Mitochondrial superoxides were also assessed by flow cytometric assays. Cytoplasmic and mitochondrial superoxides and peroxides...
GENE MUTATIONS AND THE SENSITIVITY OF LEUKEMIC CELLS TO KINASE INHIBITION DEPENDS IN NON-AND INHIBITORS REMAINS POORLY DEFINED AND THESE HAVE NOT BEEN TRANSLATED INTO EFFECTIVE THERAPIES. Thus, the integrative analysis of genetic mutations on the sensitivity of primary AML to kinase inhibition suggests its pro-oncogenic property in acute myeloid leukemia (AML).

**Aims:**

Demonstrate the antitumor potential of cluster regulation of RUNX with a "gene-switch" in AML as well as in dismal-prognostic solid tumors arising from diverse origins in vivo.

**Methods:**

To assess the effect of RUNX-inhibition in AML cells, we performed series of shRNA-mediated RUNX knockdown experiments. To achieve cluster regulation, we have computationally designed an agent which could irreversibly block the RUNX cluster genes expression profiling through dismantling protein-DNA interactions sequence-specifically (CRoX-1).

**Results:**

Firstly, shRNA-mediated silencing of RUNX1 stimulated cell cycle arrest at G0/G1 phase and induced apoptosis in AML cells bearing wild-type p53. Besides, RUNX1 depletion induced remarkable induction of p53 as well as its target gene products and additive knockdown of p53 in these cell lines reverted the phenotype of RUNX1-depletion, indicating that RUNX1 is functionally dependent on proficient p53 pathway. In addition, cycloheximide chase assay revealed that RUNX1 negatively regulates the protein stability of p53 in AML cells. In silico data analysis and Chi-sq experiments together with series of knockdown and restore experiments identified BCL11A and TRIM24 as critical mediators of p53 pathway activation in RUNX1-inhibited AML cells.

Although RUNX1-depleted AML cells exhibited drastically slowed proliferation rate, a small sub-population of leukemia cells retained the proliferation potential even after the silencing of RUNX1. Analysis of these residual AML cells revealed the reciprocal up-regulation of RUNX2 and RUNX3 expressions, suggesting that RUNX2 and RUNX3 might compensate for the loss of RUNX1 functions. As expected, additional knockdown of RUNX2 and RUNX3 in RUNX1-depleted AML cells effectively suppressed their proliferations. Thus the simultaneous targeting of RUNX family members as a cluster provides more stringent control of leukemia cells. Finally, we examined the antitumor potency of CRoX-1-mediated cluster regulations of RUNX. CRoX-1 treatment was indeed highly effective against leukemia as well as dismal-prognostic solid tumors arising from diverse origins in vitro. Moreover, this reagent was exceptionally well-tolerated in patients with xenograft mice models of AML, acute lymphoblastic leukemia, lung and gastric cancers, extending their overall survival periods in vivo. Since RUNX family takes part in diverse physiologic functions not only in AML cells but also in normal hematopoietic cells and in various other vital organs tissues, we might expect criticisms in targeting whole RUNX family that it could trigger undesirable side-effects in vivo. Intriguingly, however, our drug was well-tolerated in vivo and through these experiments, we have coincidently found that the amount of total RUNX expressions was consistently higher in malignant tissues compared to their normal counterparts, and we believe that this gap offers pharmacological window to be targeted efficiently and exerted excellent efficacy against xenograft mice models of AML, acute lymphoblastic leukemia, lung and gastric cancers, underpinning the rationality of RUNX-inhibition strategies in cancer treatment.

**Summary/Conclusions:**

This work identified the crucial role of RUNX cluster in the maintenance and the progression of cancer cells, and the indicated gene switch technology-dependent its modulation would be a novel strategy to control malignancies.

PHOSPHOPROTEOMICS AND MASS CYTOMETRY SIGNATURES OF PRIMARY AML CELL DIFFERENTIATION ARE ASSOCIATED WITH SENSITIVITY TO KINASE INHIBITORS

**Background:**

Kinase signalling is frequently deregulated in cancer cells. In the case of AML, the high recurrence of activating mutations in kinases and other kinase signalling regulators including FLT3 and RAS has stimulated the investigation of treatments based on kinase inhibitors. The success of kinase inhibitors depends on an accurate stratification of patients into response groups. The impact of genetic mutations on the sensitivity of primary AML to kinase inhibitors remains poorly defined and these have not been translated into effective therapies. The activity of a kinase can be affected by factors other than gene mutations and the sensitivity of leukemic cells to kinase inhibition depends not only on the activity of the targeted kinase. Thus, the integrative analysis of different biochemical features could improve the implementation of precision medicine therapies based on kinase inhibitors.

**Aims:**

By the integration of multiple omics approaches, we aimed to generate molecular signatures, which can rationalize why some primary AML cells are resistant to treatment with different kinase inhibitors while others are sensitive to the same treatments.

**Methods:**

In this investigation, we used a multimomics approach to stratify 36 AML biopsies as a function of their cellular sensitivity to "ex vivo" treatment with TAK-715, silmitasertib, PF03758309, midostaurin and trametinib, which target P38, c-Abl, FLT3/PKC and MEK, respectively. The same samples were analysed using different omics platforms: (i) mass spectrometry for phosphoproteomics, proteomics and kinomic profiling, (ii) mass cytometry for immunophenotyping and (iii) next generation sequencing for mutational profiling.

**Results:**

Our integrative analysis identified two independent signatures that stratified our cohort of patients in sets of differentiated and undifferentiated cases. The phosphoproteomics signature divided our set of AML cases in the M1-like and M4-like groups (Figure 1A). The mass cytometry signature, which represented myelomonocytic markers that were co-expressed at the cell surface, split our cohort of patient in the CD9+ and CD9- groups. Remarkably, the M4-like and CD9+ groups representing the differentiated cases, as well as the M1-like and CD9- groups representing the non-differentiated cases, showed a high degree of overlap. Differentiated groups over-phosphorylated 3 times as many proteins as the non-differentiated groups, including kinases at sites linked to their activity. Mutations in genes involved in kinase signalling were also more frequent in differentiated cases. Kinase activity analysis using KSEA estimated that differentiated groups presented an enriched activity for PAK, MEK, ERK or PCK. Ontology analysis showed that non-differentiated cells over-phosphorylated nuclear proteins with DNA binding properties, while the differentiated cells increased the phosphorylation of membrane and cytoplasmic proteins linked to the small GTPase signalling. More interestingly, cases in differentiated groups were more sensitive to PF03758309, trametinib and midostaurin than those in the non-differentiated sets (Figure 1B for groups defined by the phosphoproteomics signature). Finally, differentiated cases as defined by the mass cytometry signature in our cohort of patients, or by a CD marker mRNA expression signature in the ATCG database, presented with significantly reduced survival when compared to the groups of non-differentiated cases.

**Summary/Conclusions:**

Our data indicate that differentiated cells activate pro-survival kinases like PAK, PKCD or MEK which make them more sensitive to the small GTPase signalling. More interestingly, cases in differentiated groups were more sensitive to PF03758309, trametinib and midostaurin than those in the non-differentiated sets (Figure 1B for groups defined by the phosphoproteomics signature). Finally, differentiated cases as defined by the mass cytometry signature in our cohort of patients, or by a CD marker mRNA expression signature in the ATCG database, presented with significantly reduced survival when compared to the groups of non-differentiated cases.

CLINICAL OUTCOMES OF TET2 MUTATIONS IN ACUTE MYELOID LEUKEMIA PATIENTS HARBORING CEGBPA MUTATIONS: A STUDY OF THE AML STUDY GROUP (AMLSG)

Background: The proper differentiation of hematopoietic stem cells (HSCs) is regulated by transcription factors. Growth factor independence 1b (Gfi1b) is a repressing transcription factor regulating quiescence of HSCs and the proper emergence and maturation of erythrocytes and platelets.

Aims: Aim of the study was to identify i) do different level of Gfi1b influence onset and development of MDS and AML in human patients II) how does Gfi1b act in MDS/AML development on a molecular level.

Methods: We correlated Gfi1b expression level in blast cells of patients with MDS and AML with the overall disease course. To get a better insight how does Gfi1b expression level influence clonal evolution we used three different murine models of human AML with expression of different oncogenes (NUP98/HOXD13, MLL-AF9 and expression of a mutated K-Ras). In these models we either downregulated or conditionally knocked out Gfi1b expression. Finally, we performed ChiP Seq analysis as well as whole genome expression arrays to study the molecular functions of Gfi1b in AML development.

Results: Low expression or absence of Gfi1b expression was associated with an inferior outcome with regard to overall-survival as well as event-free survival of MDS/AML patients. Using the above murine models of MDS/AML, loss or low expression of Gfi1b accelerated AML development. Additionally we could show that expression of Gfi1b is able to enhance number of functional committed stem cells. It is well known that Gfi1b has a function to recruit histone modifying enzymes to induce among other deacetylation of H3K9. ChIP seq data of Gfi1b deficient leukemic cells revealed that loss of Gfi1b led to a higher H3K9 acetylation of a target of target genes, among them a number of oncogenes.

Summary/Conclusions: Gfi1b acts as a tumor suppressor by restricting number of leukemic stem cells and treatment with NAC opens a potential targeted therapy for AML patients with low/absent expression of Gfi1b.

VARIANTE ALLELE FREQUENCY KINETICS OF TYROSINE KINASE GENE MUTATIONS IN CORE-BINDING FACTOR ACUTE MYELOID LEUKEMIA (AML) AT M1 UNDER TREATMENT WITH AND WITHOUT DASATINIB

M. Agrawal1, 1, N. Jahn, 1, M. Rolnik,1, S. Cocc ioddi,1, F. Schlenk,1, P. Paschka1, W. Fiedler1, D. Nachbaur1, T. Kindler1, G. Held,1, M. Heuser1, F. Thol1, A. Ganser1, H. R. Schlenk18, P. Paschka1, M. Wettad15, F. Thol7, M. Heuser7, A. Ganser7, R. F. Schlenk19, P. Paschka1, M. Wettad15, F. Thol7, M. Heuser7, A. Ganser7, R. F. Schlenk19, P. Paschka1

Background: Recent next-generation sequencing (NGS) studies have improved our understanding of the genomic landscape of CBF-AML (Fabel et al. Nat Genet 2016; Duployez et al. Blood 2016). While these studies have mainly focused on the genetic differences between inv(16)- and t(8;21)-AML, the role of additional mutations required for disease evolution is poorly defined. Mutations affecting signaling genes, such as KIT and NRAS are known to be among the most common oncogenic drivers in CBF-AML, however their impact at relapse remains unclear.

Aims: To characterize clonal evolution in paired samples obtained at diagnosis, as well as during treatment with dasatinib with data from conventional chemotherapy, and ii) to conduct gene set enrichment analyses.

Methods: Whole-exome-sequencing (WES) was performed in paired diagnosis, remission and relapse samples of 38 patients with CBF-AML [mi(16), n=24; t(8;21), n=12] using paired-end sequencing (read length 100 bp) on an Illumina HiSeq platform. Library preparation was done with the Nextera® Rapid Capture Exome kit following manufacturer’s instructions. All patients were treated within one of five trials of the German-Austrian Study Group (AMLSG). In two of the trials (AMLSG 11-08, NCT00850382; AMLSG 21-13, NCT02013648) patients received intensive chemotherapy in combination with the multi-kinase inhibitor dasatinib.

Results: The mean WES coverage was 133x. Mutations and indels were called with a threshold >10% variant allele frequency (VAF) after filtering for SNPs and sequencing artefacts. In sum, we identified 587 variants in 430 genes. At

Background: Despite improvements in our understanding of the molecular evolution of acute myeloid leukemia (AML), the overall cure rates remain low, and most patients die from the disease despite achieving initial remission upon treatment. It is therefore necessary to open new therapeutic perspectives aimed at molecular targets. PP2A phosphatase inactivation is a recurrent event in hematological tumors. Our group has reported that SET, an endogenous inhibitor of PP2A, is overexpressed in 28% of patients with AML. Furthermore, the oncogenic activity of PP2A activating drugs (PADs) depends on the interaction/sequestration of SET, pointing out the significance of this oncogene in AML. Drug inhibition of several MAPks in AML cell lines showed that only p38 inhibitors activate PP2A and decrease SET protein.

Aims: Therefore, we hypothesized that p38 could regulate SET at posttranslational level, leading to PP2A inactivation.

Methods: AML cell lines and primary human samples were analyzed by western blot, immunoprecipitation, immunofluorescence, treatment with pharmacological inhibitors and siRNAs. Phosphorylation assays by in vitro kinase assay with recombinant proteins were performed.

Results: Knockdown of the two major isoforms of p38-MAPK, p38a and p38β, demonstrated that only p38β was able to set RED protein levels and increase PP2A activity. To decipher this mechanism of action, we performed protein immunoprecipitation and immunofluorescence in the AML cell lines HL-60 and MOLM-13. p38β co-localized and bound to SET mostly in the cytoplasm stabilizing it, since treatment with cicloheximide in the absence of p38β induced SET degradation. The stabilization role was in coordination with SETBP1, which co-localized with both SET and p38β. Interestingly, 12 out of 14 AML cell lines tested showed high expression of p38β protein levels in the absence of p38β, as well as 5 out of 7 AML primary patient samples. Furthermore, expression analysis in a large series of adult de novo AML cases previously reported (Cancer Genome Atlas Research Network, 2013) showed a positive correlation between p38β (MAPK11) and SET (R²=0.416, p<0.001), but not between p38α and SET. We and others have shown that PADs retain SET in the nucleus. Our results showed that p38 phosphorylates SET not directly, but through the activation of casein kinase 2 (CK2), leading to the retention of SET in the nucleus and, therefore, contributing to the inactivation of PP2A in AML cells. Of note, CK2 is overexpressed in both AML cell lines and patient samples.

Summary/Conclusions: p38 is able to activate CK2 which phosphorylates SET and, as consequence, facilities its trafficking to the cytoplasm, contributing to PP2A inactivation in AML cells. Moreover, p38β binds to SET in the cytoplasm, contributing to its stability and leading to PP2A inactivation. In this regard, we have preliminary evidences that combination therapy with PADs and the CK2 inhibitor CX4945 reduces significantly the viability of AML cells, supporting that novel treatment modalities that can target multiple components of the same pathway may help to achieve a more sustained therapeutic benefit.

Summary/Conclusions: Differences in the allelic composition were found between diagnosis and relapse regardless of the CBF-AML subtype. Our data suggest that the KIT clone might be successfully eradicated under dasatinib treatment whereas possession of KIT mutant clones was more commonly seen under conventional chemotherapy. The frequent loss of KIT and NRAS mutations during therapy suggests that relapse is triggered by alternative genetic lesions. Relapsed disease may represent a distinct biology which is characterized by mutations that cluster in different pathways. Further analyses are ongoing including study cohort expansion, as well as inclusion of RNA sequencing results.
Background: Acute erythroid leukemia (AEL) is a unique subtype of acute myeloid leukemia (AML) characterized by the predominance of erythroid components with increased ring sideroblasts as well as frequent myelodysplasia. However, due to its rarity, the molecular pathogenesis of AEL has not fully been elucidated, except for frequent TP53 mutations. Aims: This study was designed to clarify the mutation profile of AEL distinct from other types of AML and MDS. Methods: We performed a comprehensive genetic study, in which paired tumor/normal DNA from 22 AEL cases were analyzed using whole exome sequencing (WES). Whole-exome sequencing data from 3 AELs generated by The Cancer Genome Atlas (TCGA) was also included in the analysis. Subsequently, a total of 84 AEL cases were screened for mutations in 67 driver genes associated with myeloid malignancies using targeted-capture sequencing, in which RNA baits were also designed for a total of 1158 single nucleotide polymorphism sites to allow for genome wide copy number abnormalities and other allelic imbalances. Results: Median age at diagnosis was 58.5 (21-87) years old. Among the 77 patients with clinical information available, 62 patients were diagnosed with de novo AML, 13 with secondary AML, and 2 with treatment-related AML. On average, 18.4 and 3.4 mutations were detected per sample in whole-exome and targeted-capture sequencing in AEL, as compared to 12.2 and 2.9 mutations (P>0.05) in other AML, respectively. Both platforms being combined, most frequently observed was TP53 mutations (n=26, 31%) with complex karyotype being accompanied in most cases (25 cases), which were associated with a significantly shorter overall survival (P<0.001). Other frequently mutated genes were those encoding major components of the cohesin complex, including STAG2 (12%), MLL (12%), SMCA1 (4.8%), and RAD21 (2.4%), which were mutated in as high as 30% of the cases. The splicing machinery (18%) and epigenetic regulators (45%) were also among the top targets of mutations, including SRSF2 (12%), U2AF (4.8%), WT1 (15%), TET2 (19%) and ID1 (2.1%). TP53 mutations were mutually exclusive with cohesin mutations (p<0.01) and those in epigenetic regulators in the majority of AML cases (98%). Furthermore, a total of 84 AEL cases were screened for mutations in 67 driver genes from other types of AML and MDS. In an association model, which takes all other known subsets of AML into account, other mutations were significantly more frequent in AEL and secondary AEL. Summary/Conclusions: MLL-PTD AML molecular subsets. EXPLORING THE IMPACT OF LOSS OF FUNCTION STAG2 MUTATIONS ON CHROMATIN ARCHITECTURE IN MDS/AML Background: The Cohesin complex is an evolutionarily conserved multimembrane protein complex consisting of SMCA1, SMCD3, SCMA3, STAG1, STAG2, and LSC1. The complex plays pivotal roles within mitosis and sister chromatid cohesion however, substantial data exists elucidating roles for the complex within the DNA damage response, homologous recombination and long-range interaction between cis regulatory elements of the genome. Within hematological malignancies, upwards of 20% of patients diagnosed with either Acute Myeloid Leukemia (AML), Myelodysplastic syndrome (MDS) or Myeloproliferative neoplasm (MPN) have been shown to harbour mutations within the Cohesin complex, with many more showing significantly reduced expression of core complex members. Aims: To explore the impact of a loss of function STAG2 mutation on the chromatin architecture within a isogenic cell based model. Methods: Using an CRISPR generated isogenic model we have investigated the impact loss of STAG2 has on the chromatin architecture of a hematopoietic environment. Genome wide binding profiles for STAG1, STAG2 and CTCF were generated using ChIP-Seq to elucidate areas of differential between STAG1 and STAG2 samples. In addition, binding profiles for H3K27ac, H3K27me3 and H3K4me1 were generated using ChIP-Seq to provide genome wide identification of active and repressed enhancer regions, with the regions ranked to identify both normal and super-enhancer regions. These samples were matched to ATAC-Seq profiling of open and closed chromatin regions as well as RNA-seq samples to provide information on gene activity in relation to chromatin state in the absence of STAG2. Results: Our results indicate that STAG1 binding profiles after following loss of function of STAG2, with an increase in binding peaks from ~17,000 to 25,000, however several sites identified by ChIP-Seq are not compensated for. In addition, histone mark profiling identified wide spread expansion of the H3K27ac mark and a decrease in regions of H3K27me3 consistent with loss of boundaries within topologically associated domains. This spread of an activator mark correlates with altered gene expression and the changes observed in ATAC-seq profiling of altered chromatin accessibility. The open chromatin regions identified through ATAC-Seq coincides with H3K27ac-sold region and a decrease in transcription factor occupancy. An enrichment for transcription factors relevant for myeloid transcriptional programmes was observed. This increase in enrichment aids in the suggestion that the impact of mutated/alternate cohesin complex function relates directly to the specific cell type and maturation stage at which it occurs. Summary/Conclusions: This research into the aberrant and non-canonical consequences of loss of STAG2 in the spatio-temporal genomic architecture in hematological malignancies and begins to yield insight into the clinical implications of mutations within the cohesin complex.
leukaemic cell lines; KG1 (CD123 +, CD34+, CD33+) [Fig:1a], Kasumi-1 were transduced (MOI 1:5) into peripheral blood mononuclear cells (PBMCs) the same assay conditions. (CD28 for CD123 and evaluated the cytotoxic effect of different co-stimulatory domains expressed on AML blasts and leukaemia stem cells (LSC) compared to normal tumour-associated antigens are emerging to be an effective form of induction treatment. Chimeric antigen receptor (CARs) T cells specific for AML biology, development of novel therapies has been limited with 43% relapse rate and 18% of patients never attaining clinical remission (CR) with frontline AML. Despite advances in our understanding of AML biology, development of novel therapies has been limited with 43% relapse rate and 18% of patients never attaining clinical remission (CR) with frontline AML.

**Background:** Mutations involving the MLL gene at 11q23 are found in 10% of adult and 18% of childhood acute myeloid leukaemia (AML) cases. The most frequently occurring MLL mutations are chromosome translocations that fuse the MLL gene in-frame with a second partner gene, creating novel fusion proteins (MLL-FFps). MLL-AF9 is the most common MLL-FF in AML. Despite much progress in the overall management of AML, patients carrying MLL-arrangements still have a poor survival prognosis and limited response to existing therapy. This is in part due to the low therapeutic indices and narrow therapeutic windows of current chemotherapeutic agents, therefore underscoring the need to develop improved, targeted therapies. MYB is a direct downstream target of MLL-AF9. Recent studies indicate that MLL-AF9 leukaemia cells are more affected by MYB knockdown compared to normal hematopoietic stem progenitor cells. This is despite the fact that MYB is known to be essential for the establishment of definitive hematopoiesis. This suggests that a therapeutic window may be achieved through targeting MYB. Therefore, by understanding more about the role of MYB in MLL-AF9 leukaemia and the network it regulates, we maybe able to exploit this knowledge to target MYB directly by interfering with its function or indirectly via its downstream targets.

**Aims:** To understand the molecular function of MYB in MLL-AF9 leukaemia.

**Methods:** We performed genome-wide MLL, MLL-AF9, H3K27ac, H3K4me3 and H3K4me1 chromatin immunoprecipitation (CirP) sequencing (ChIP-seq) and Assay for Transposase-Accessible Chromatin with high throughput sequencing (ATAC-seq) in two MLL-AF9 leukemia models to identify putative regulatory regions of MYB and those of a direct MYB gene target, BCL2. The chromatin conformation capture technique, Capture-C (one vs all) was used to further characterize interactions from the MYB promoter. We then performed siRNA knockdown of MYB and assessed the effect of MYB loss on its downstream druggable target BCL2, using RT qPCR, Western blotting and ChIP qPCR.

**Results:** We identified MLL-AF9 binding to novel putative enhancers of MYB as defined by regions co-bound by H3K27ac, H3K4me1 and marked by open chromatin on ATAC-seq. Furthermore, Capture-C from the MYB promoter identified novel putative enhancer-promoter interacting domains 100-200kb apart that are co-bound by MYB but not MLL-AF9. This suggests long-range autoregulation of MYB. Next, siRNA knockdown of MYB results in loss of MYB binding at the BCL2 promoter and its downstream enhancer by ChIP qPCR. There is a corresponding loss of BCL2 mRNA and protein expression in MYB knocked-down cells compared with control, confirming that BCL2 is directly regulated by MYB.

**Summary/Conclusions:** We have identified for the first time, regulation of MYB by MLL-AF9 via putative enhancers, and also an autoregulatory role of MYB involving long-range cis-interactions. Furthermore, we confirm that BCL2 is directly regulated by MYB in MLL-AF9 leukaemia, suggesting a molecular rational for using BCL2 inhibitors in MLL-AF9 leukaemia therapy.

**P542**

**TARGETED COMBINATION THERAPY WITH CDK4/6 INHIBITOR PALBOCICLIB IN AML**

I. Uras1,*, P. Valent2,3, V. Sexl1

1Institute of Pharmacology and Toxicology, University of Veterinary Medicine, Vienna, Austria; 2Department of Internal Medicine I, Division of Hematology and Hemostaseology, 3Ludwig Boltzmann Cluster Oncology, Medical University of Vienna, Vienna, Austria

**Background:** Acute myeloid leukaemia (AML) is a clonal hematologic disorder marked by clinical and biological heterogeneity. AML remains incurable for a significant proportion of adult patients while no therapeutic option exists for patients with relapsed and refractory AML. Mutations of the fms-like tyrosine kinase 3 (FLT3) gene are among the most frequent events in AML and usually involve internal tandem duplication (ITD) of the juxtamembrane domain coding region or point mutations of the tyrosine kinase domain. There have been considerable efforts to develop FLT3 tyrosine kinase inhibitors (TKI). The clinical impact of FLT3-TKI has been limited as resistant clones have emerged rapidly.

In conclusion, we demonstrate the importance of the scFv on CAR T cell cytotoxicity and have constructed and validated the efficacy of a dual targeting CAR vector in the context of AML.
We have recently discovered that FLT3-ITD AML cells are highly sensitive to the FDA-approved SFK inhibitor, AP23454 (LY3176159) and a CDK4/6 inhibitor, abemaciclib (X010). The effect is ascribed to the transcriptional activity of CDK6 on FLT3 and PIM1 - a feature not shared by CDK4.

**Aims:** FLT3-TK1 treatment provides short-term disease control but relapse invariably occurs within months. Acquired resistance on FLT3-D835Y tyrosine kinase domain activation is a major concern. Thus, our focus is to investigate the potential of palbociclib treatment in FLT3-D835Y+ cells and to identify critical downstream effectors of CDK6 to open a novel, clinically applicable therapeutic window.

**Methods:** Ba/F3 cells transformed with FLT3-D835Y were exposed to single agents or drug combination by the CellTiter-Glo ATP-based assay and FACS stainings after 3 days of treatment. Validation was performed by in vivo xenograft models and by studies with primary human FLT3-D835Y AML biopsies.

**Results:** Palbociclib impaired the viability of murine Ba/F3 cells with FLT3-D835Y, as expected, which led to apoptosis. The effect on FLT3-D835Y patient samples and to xenograft models, where palbociclib treatment effectively repressed FLT3-D835Y driven tumor formation in vivo at clinically relevant concentrations. Besides FLT3 itself, which is regulated by CDK6, transcriptional targets of CDK6 in AML included Aurora kinases (AURK) and AKT. Thus CDK6 inhibitor, such as palbociclib, is capable of inducing AML cell death, two signalling nodes critical for survival of tumor cells. Dual targeting with palbociclib and AURK or AKT inhibitors resulted in synergistic cytotoxicity.

**Summary/Conclusions:** Palbociclib represents a viable therapeutic option for use in treatment of resistant clones in FLT3-D835Y+ AML. Inhibitory effects are not limited to cell viability but as well by transcriptional activity of CDK6 on important signalling pathways including Aurora kinases and AKT. Our findings provide the basis for the design of synergistic combination therapies with a CDK4/6 inhibitor which could be readily translated to patients with AML.

P543

**CANNABINOIDS DERIVATIVES MODIFY THE PATTERN OF SPHINGOLIPIDS IN ACUTE MYELOID LEUKEMIA CELLS AND PRODUCE A POTENT ANTI-LEUKEMIC EFFECT**

M. Medrano1, M.V. Barbado1, O. Lopez1, J.I. Piruat1, J.A. Pérez-Simón1, I. Alvarez1, O. Lopez1, J.I. Piruat1, J.A. Pérez-Simón1

1Instituto de Biomedicina de Sevilla, Seville, 2CIB/CSIC, Madrid, 3IG/CSIC, Seville, Spain

**Background:** Endocannabinoid system is a set of ligands, receptors and endogenous enzymes which modulate a variety of physiological effects. There are two well-characterized cannabinoid receptors, CB1 (mainly expressed in Central Nervous System) and CB2 (mainly in hematopoietic cells). Here, we tested the effect of the cannabinoid WIN-55 212-2 in acute myeloid leukemia (AML) in vitro and in vivo and studied the molecular signaling pathways involved in this effect, specially the role of sphingolipids. Moreover, we synthesized a new family of twelve cannabinoids that are specific to CB2 receptor.

**Aims:** Development of new compounds derived from cannabinoids with CB2 selectivity and evaluation of their anti-tumor effect in AML in vitro and in vivo. To deepen in the knowledge of lipid metabolism in AML.

**Methods:** For the design and synthesis of new cannabinoids, computational techniques of docking, analytical and spectroscopic techniques such as mass spectrometry (MS) were used. To assess the anti-leukemia effect of the different cannabinoids, we analyzed cell viability by MTT and flow cytometry using six techniques of docking, analytical and spectroscopic techniques such as mass spectrometry and immunohistochemistry assays to determine the expression of different proteins to elucidate the molecular signaling pathways involved in the effect of these drugs. Moreover, we synthesized a new family of twelve cannabinoids that are specific to CB2 receptors.

**Results:** Cannabinoids induced a potent proapoptotic effect on AML cell lines and primary leukemic cells, which was not observed in normal HPC and lymphocytes from healthy donors. Fragmentation of PARP and activation of caspases 2, 3, 8 and 9 were confirmed by Western Blot. The proapoptotic effect of cannabinoids on AML cells was abolished upon co-culture with either CB2 receptor antagonists or with pancaspase inhibitors. Other proteins involved in this proapoptotic effect of cannabinoids were p-ERK, p-PI3K and p-JNK. Also, studies on p-PERK, p-IRE1 and CHOP confirmed an increased endoplasmic reticulum stress upon exposure to cannabinoids. Also we confirmed a very early mitochondrial damage in leukemic cells which was not observed in normal hematopoietic progenitor cells. Remarkably, we observed significant differences in the amounts of certain sphingolipids in untreated versus treated leukemic cells. More specifically in ceramide C16:0, C18:0 and C18:1. Also we observed a significantly increased survival among mice treated with WIN-55 cannabinoid as compared to both the control group and the group treated with ARA-C and we confirmed that cannabinoids did not affect the viability of the different population hematopoietic progenitors and, moreover, an increased platelet count was observed in treated mice.

**Figure 1.**

**Summary/Conclusions:** Our findings indicate that cannabinoids display a highly selective proapoptotic effect against leukemic cells. Several pathways are involved in this effect, the modification of the sphingolipids pattern playing a main role.

P544

**PROFILING THE MUTATIONAL LANDSCAPE OF ACUTE MYELOID LEUKEMIA AT RELAPSE AFTER CHEMOTHERAPY AND ALLOGENIC HEMATOPOIETIC STEM CELL TRANSPLANTATION**

E. Sala1,2,3, F. Biavasco1,2,3, G. Bucci2,3, C. Tomlai2,3, L. Zanotti2,3, D. Biancolini2,3, E. Antinioni2,3, M.G. Carrabba1, B. Gentner1,5, C. Tresoldi2,3, M. Bernardi1, D. Lazarevic3, G. Tonon3, F. Ciceri1, L. Vago1,2

1Hematology and Bone Marrow Transplantation Unit, Division of Regenerative Medicine, Stem Cells and Gene Therapy, 2Unit of Immunogenetics, Leukemia Genomic and Immunobiology, Division of Regenerative Medicine, Stem Cells and Gene Therapy, 3Center for Translational Genomics and Bioinformatics, 4Immunohematology and Transfusion Medicine Unit; Division of Regenerative Medicine, Stem Cells and Gene Therapy, 5Translational stem cell and leukemia research Unit; SR-TIGET, Division of Regenerative Medicine, Stem Cells and Gene Therapy, San Raffaele Scientific Institute, Milan, Italy

**Background:** Acute Myeloid Leukemia (AML) is a clinically and biologically heterogeneous disease that is known to dynamically evolve over time. Unraveling its mutational profile may provide relevant insights into the inception, propagation, and recurrence of the disease, and deliver new rationales for precision medicine approaches: still, whereas a comprehensive description of AML mutations at disease presentation is now available thanks to large-scale studies, a satisfying genomic characterization of AML at relapse, particularly after allogeneic stem-cell transplantation (allo-HSCT), is still needed.

**Aims:** To characterize the genetic profile of relapsed AML, highlighting the evolutionary trajectories in the two different settings of relapse after chemotherapy (CT) and after allo-HSCT.

**Methods:** For our custom-designed targeted Next Generation Sequencing panel we took advantage of the HaloPlex High Sensitivity (HS) technology, allowing a more precise definition of mutations and clonal architecture through a molecular barcoding system. We included in our panel 192 genes and miRNAs known to be involved in the pathogenesis of myeloid malignancies (n=112), in the DNA damage response (n=50), or in immune-related processes (n=50). Sequencing was performed on an Illumina HiSeq2500n instrument. Variant calling was performed using a pipeline based on the FreeBayes algorithm, and FLT3-ITD status was inferred using Pindel.

**Results:** We sequenced a total of 138 AML samples, including 79 diagnoses, 36 relapses after CT and 23 relapses after allo-HSCT. Sequencing yielded uniform and consistent coverage of all target amplicons and a 612x mean depth-of-sequencing, resulting on average in 117 unique barcodes for each region. Among the 79 diagnosis samples we identified 293 mutations (204 of which definable as oncogenic), with a median of 3 oncogenic mutations per patient (range 0-4), and mutation frequencies in line with the largest published dataset (Papaemmanuil, N Engl J Med, 2016; r²=0.83). In relapses after CT and after allo-HSCT the median number of oncogenic mutations per patient was 3 (range 0-4) and 2 (range 0-6), respectively. Comparing mutation frequencies at relapse
with the Papaemmanuil dataset, we observed a weaker correlation for relapses after CT ($r^2=0.69$) and an even more marked deviation for post-transplant relapses ($r^2=0.45$). This difference was mainly explained by the enrichment in both relapse cohorts for FLT3-ITD (25% in diagnoses vs 55% and 48% at relapses after CT and allo-HSCT, $p<0.01$ for both comparisons) and WT1 mutations (5% vs 25% and 22%, $p<0.01$ for both comparisons). For 24 cases it was possible to longitudinally compare the mutational profile of AML at diagnosis and relapse in the same patient: we observed higher stability in relapses after CT, with 50% of cases carrying the same pattern of mutations present at diagnosis, whereas at relapses after allo-HSCT changes were more frequent, with 70% of patients displaying new gains or losses.

Summary/Conclusions: Taken together, our data evidence that the genomic landscape of AML at relapse can be significantly different from the one documented at diagnosis, suggesting that the selective pressure mediated not only by intensive chemotherapy, but also by the graft-versus-leukemia effect, can be potent drivers of clonal evolution. From the practical standpoint, the pattern of emergence of novel mutations that we documented should be taken into account not only for targeted salvage approaches, but also for the design of post-remission strategies aiming to prevent relapse.

P545
Abstract withdrawn.
22nd Congress of the European Hematology Association
analyses. 81% of pts had de novo AML, 15% secondary AML, 3% therapyrelated AML and 2% high-risk MDS. Recurrent gene mutations in AML were
studied from bone marrow aspirates or peripheral blood using a targeted
leukemia genotyping assay covering 68 genes. We analyzed known mutational
hotspots or the entire coding sequence of the genes by multiplexed amplicon
sequencing (Agilent Technologies, mean target coverage of 460 x). We studied
associations between cytogenetics, gene mutations and other potential prognostic factors which might influence the clinical outcome.
Results: The median age in the total cohort was 76 years (y) (range: 75-86 y).
44% of pts reached complete remission (CR) and 4% CR with incomplete blood
count recovery (CRi). The median overall survival (OS) was 6 months with a
3-year OS of 21%. According to the ELN 2010 classification, 20% of pts were
in the favorable, 39% and 25% in the intermediate I or II group, respectively,
and 15% in the adverse group (ELN 2017 data will be presented at the meeting). Pts in the favorable and intermediate I/II groups had significantly longer
OS compared to the adverse group (median OS 6.3 vs 1.2 months, p=.002,
Figure). Likewise, pts in the favorable and intermediate MRC cytogenetic risk
categories had longer OS than those in the adverse category (median OS 6.5
vs 1.2 months, p=.001). By targeted sequencing, we detected 622 leukemiaassociated mutations in 66 genes. The median number of mutated genes per
patient was four. The most commonly mutated genes were TET2 (42%),
DNMT3A (35%), NPM1 (32%), SRSF2 (25%) and ASXL1 (21%). Both NPM1
or EZH2 (5%) mutated pts showed a non-significant trend towards longer OS
(NPM1: p=.09; EZH2: p=.065). FLT3-ITD mutations were identified in 29 pts
(19%), but had no impact on OS (p=.297). The NPM1mutated/FLT3-ITDnegative
genotype also did not associate with OS. Notably, none of the 13 IDH1 mutated
pts (9%; all within the ELN favorable/intermediate groups) reached CR, and
consequently the OS in this group was significantly shorter than for IDH1 wildtype pts (p<.001; Figure). The positive impact of mutated NPM1 on OS was
reversed when it co-occurred with IDH1 mutations (p=.014).
Summary/Conclusions: Among very old (≥75 y), intensively treated AML pts,
adverse-risk cytogenetics predict inferior survival. On the other hand, 3-year
OS was 24% for MRC/ELN favorable and intermediate-risk pts, suggesting
that even in this age group, selected pts without medical contraindications benefit from intensive induction chemotherapy. The spectrum of driver gene mutations in elderly pts differs from that in younger pts. While NPM1 and FLT3-ITD
mutations had no significant impact on OS in intensively treated pts aged ≥75
y, our data imply IDH1 mutations as a novel marker for chemorefractory disease
and inferior prognosis in this age group.

Results: To date, 47 pts have enrolled (Ph 1=19; Ph 2=28 of planned 47). The
recommended Ph 2 dose is 10mg/kg based on drug exposure, time over IC50
for E-sel binding, evidence of on-target effect (reduction in sE-sel), lack of DLT
at any dose level, and clinical outcomes. Ph1/Ph2 combined median age was
55yrs (range 26-84) with 70% male pts. Prior AML history included 26% primary
refractory, 36% CR1<6 mos; 17% prior SCT; 52% unfavorable cytogenetics
(by SWOG). Common Gr 3/4 AEs were febrile neutropenia (36%), sepsis
(26%), bacteremia (13%), hypoxia (13%). Oral mucositis (≥Gr 2) developed in
12% of pts. The 30 and 60 day mortality rates were 0 and 7%, respectively;
induction mortality was 0%. The remission rate (CR/CRi) was 45% (19/42) with
an ORR (CR/CRi/MLFS/PR) of 50% (21/42). Observed/expected remission
(CR/CRi) ratio was >2.75 (Estey, Blood 1996). With a median follow-up of 11
mos, the Ph 1 median Disease Free Survival was not reached and Overall
Survival was 7.6 mos. The median E-sel ligand expression at baseline was
35% (range, 1-75%) of blasts in the bone marrow, and was higher in those
achieving remission.
Summary/Conclusions: The addition of GMI-1271, a novel E-sel antagonist,
to MEC chemotherapy is well tolerated; oral mucositis, commonly severe with
MEC, is observed at low severity in this study. Clinical outcomes include a high
ORR and remission rate (CR/CRi), low induction mortality, and promising survival outcomes in pts with R/R AML. Furthermore, the baseline expression of
E-sel ligand in this population suggests relevance of the target and is predictive
of response.

P547

Background: Acute myeloid leukemia (AML) is associated with poor outcome
in older patients and in patients unfit for standard induction therapy. Therapy
of AML has not changed significantly since the 1970s and still relies on cytarabine as the first-line treatment. However, cytarabine therapy is associated with
severe side effects, such as cerebellar toxicity, bone marrow suppression, and
infections, leading to high treatment-related mortality rates. Hence, while the
incidence of AML increases with age, advanced age and comorbidities may
preclude the administration of intensive therapy altogether.
Aims: BST-236 (Astarabine) is a new compound of cytarabine covalently
bound to asparagine. It acts as a pro-drug of cytarabine, enabling delivery of
high cytarabine doses to target cells with lower systemic exposure to the free
drug and relative sparing of normal tissues. As such, BST-236 may serve as
an ideal therapy for leukemia, particularly for delivering high doses of cytarabine
to medically unfit or older adults. The aim of this study was to evaluate the
safety and optimal dose of BST-236 in refractory/relapsed or newly-diagnosed
AML patients unfit for standard induction therapy.
Methods: A Phase I/IIa prospective open label study enrolled adult
relapsed/refractory or newly-diagnosed acute leukemia patients unfit for standard therapy. Patients are enrolled into 6 BST-236 escalating-dose cohorts
(0.3-6 g/m2/d), each composed of 3-6 patients. Treatment was administered
as 1-hour daily infusion for 6 days.
Results: To date, treatment of cohorts 1-5 is completed, with 18 patients treated
with up to 4.5 g/m2/day, median age 77 (27-90): 6 relapsed/refractory AML
patients, median age 64 (27-81), and 12 newly-diagnosed patients, unfit for
standard chemotherapy (7 secondary AML; 5 de novo AML/ALL), median age
79 (70-90). BST-236 treatment was well-tolerated. Only 6 SAEs in 4 cases
were assessed by the treating physician as possibly/probably related to BST236, all “on-target” hematological toxicity events or bacterial infections derived
from it. No neurological or grade >2 typical cytarabine events such as gastrointestinal, mucositis, or alopecia were reported during BST-236 treatment
or within 30 days of follow up. Response to the treatment was observed in 6 of
the 12 newly-diagnosed patients, 4 of whom had a continuous complete remission (CR) and 2 had a partial remission (PR). The median overall survival (OS)
of the responding (CR+PR) and of the CR patients was 7 and 10 months,
respectively. The median OS of the newly-diagnosed non-responders was 2.5
months. No remission was reached in the 6 patients suffering from relapse or
refractory AML and their median OS was 2.3 months.
Summary/Conclusions: BST-236 is safe and very well tolerated, enabling
delivery of high dose cytarabine to older and unfit patients, resulting in overall
response and CR rates of 50% and 33%, respectively, and a 3-fold increase in
median OS of the responding compared to the non-responding newly-diagnosed patients. Notably, 67% of the responding patients had secondary AML,

GMI-1271, A POTENT E-SELECTIN ANTAGONIST, IN COMBINATION WITH
CHEMOTHERAPY IN RELAPSED/REFRACTORY AML: A NOVEL,
WELL-TOLERATED REGIMEN WITH A HIGH REMISSION RATE

Hospital, Brisbane, Australia, 8GlycoMimetics, Inc., Rockville, 9Fred Hutchinson
Cancer Research Center, U of Washington, Seattle, United States

Background: Expression of the adhesion molecule E-selectin (E-sel) in the
vasculature of the bone marrow is associated with infiltrative disease, relapse,
and poor survival in AML. GMI-1271 is a novel antagonist of E-sel that downregulates cell survival pathways and enhances chemotherapy response with
improved survival compared to chemotherapy alone (Becker ASH 2013; Winkler ASH 2014). Protection from common toxicities (neutropenia and mucositis)
has been observed in preclinical models, also affording survival benefit (Winkler
ASH 2013).
Aims: We assessed GMI-1271 plus salvage chemotherapy with mitoxantrone,
etoposide, and cytarabine (MEC) for the treatment of patients (pts) with
relapsed/refractory (R/R) AML.
Methods: A Phase (Ph) 1 trial in pts with R/R AML escalated GMI-1271 across
pharmacologically active doses from 5-20mg/kg combined with MEC to evaluate safety, tolerability and anti-leukemia activity. MEC consisted of mitoxantrone 10mg/m2/d, etoposide 100mg/m2/d, and cytarabine 1000mg/m2/d IV
for 5 days; supportive care was given as per institutional guidelines. Dose limiting toxicity (DLT) was defined as either persistent neutropenia and/or thrombocytopenia beyond day 42 in the absence of disease or any Grade 3 (Gr3)
non-hematologic toxicity that did not resolve to Gr2 by day 42. After confirming
safety and tolerability, a Ph 2 study of GMI-1271 at 10mg/kg plus MEC salvage
chemotherapy was initiated; responders to salvage could receive consolidation
with GMI-1271 plus reduced dose MEC (4 days). GMI-1271 was given 24 hrs
prior, then every 12 hrs during and for 48 hrs post induction/consolidation. Eligible pts had an ECOG score 0-2, received ≤2 prior inductions, had WBC <20K
(<40K after 2 dose levels), no active CNS disease, and adequate renal/hepatic
function. Baseline E-sel ligand expression on leukemic blasts in the bone marrow (CD45/SSC by flow) was assessed, as were plasma levels of soluble Esel (sE-sel).

refractory to hypomethylating agents. To the best of our knowledge, this is the only experimental drug permitting high-dose cytarabine, considered a cornerstone of leukemia therapy, to be given to a population of patients that currently do not have this option. A Phase II study is planned to confirm these encouraging results.

FEASIBILITY AND BENEFIT OF TARGETED RNA SEQUENCING FOR THE DETECTION OF RECURRENT FUSION TRANSCRIPTS AND THE IDENTIFICATION OF NOVEL FUSION TRANSCRIPTS IN MYELOID MALIGNANCIES

C. Haferlach1, N. Nadarajah1, M. Meggendorfer1, A. Stengel1, W. Kern1, T. Haferlach1

1MILL Munich Leukemia Laboratory, Munich, Germany

Background: Fusion genes are frequent genetic abnormalities in myeloid malignancies. The impact of the detection of such gene fusions is rising due to an increasing number of drugs targeting them as has been impressively shown for e.g. BCR-ABL1 and PML-RARa. Further, they can be used as biomarkers for disease monitoring.

Aims: Evaluation of targeted RNA sequencing for the detection of recurrent and novel fusion transcript.

Methods: 102 cases with myeloid malignancies harboring 105 translocations identified by chromosome banding analysis were selected. Recurrent fusion genes had been confirmed by FISH and/or RT-PCR. In cases with suspected novel fusions the rearrangement of one partner gene had been confirmed by FISH. The following recurrent rearrangements identified by standard diagnostic procedures were present: PML-RARA (n=11), RUNX1-RUNX1T1 (n=7), CSF3R-MYH11 (n=3), KMT2A-ELL (n=4), KMT2A-MLLT4 (n=4), KMT2A-MLLT10 (n=3), KMT2A-MLLT3 (n=2), BCRL1-ABL1 (n=3), NUP98-NSD1 (n=3), DEK-NUP214 (n=1), and KAT6A-CREBBP (n=1). Further, cases harboring MLLT4-KMT2A (n=14), RUNX1 (n=21), ETV6 (n=10), PDGFRB (n=10), RARA (n=2), NPM1 (n=2) and NUP98 (n=1) were included. Targeted RNA sequencing was performed using the TruSight RNA Fusion panel (Illumina, San Diego, CA) consisting of 7690 probes covering 507 genes known to be involved in gene fusions. Library was prepared according to manufacturer’s protocol with ~50ng RNA extracted from fresh/frozen samples. Sequencing was performed on the NextSeq instrument (Illumina) and analysis with the RNA-Seq Alignment App (BaseSpace Sequence Hub) using Star for Alignment and Manta for gene fusion calling with default parameters (Illumina).

Results: In 42/45 (93%) cases with a recurrent rearrangement identified by standard diagnostic, RNA sequencing detected the respective fusion transcript. In addition, RNA sequencing was able to identify known and novel fusions in the remaining 57 cases. For KMT2a these were the following partner genes: MLLT1 (n=5), ELL (n=3), ITI1R2, FLNC, ASXL2, DPO1B, MAML1 and ARHGEF12. Seven different partner genes were identified in RUNX1 translocations: PLAG1 (n=2), PRDM16, MECOM, ZFP2M, MAN1A2, NAM2T and KIAA1549L. Five different partner genes were identified in ETV6 rearranged cases: ABL1, CCDC126, ERG, FOXX1 and CFLAR-AS1. Most strikingly was the identification of the ETV6-ABL1 fusion, which could not be suspected by cytogenetics as the S ETV6 FISH signal was located on chromosome 17. In 710 PDGFRB rearranged cases the partners were identified. These were WDR4, CCDC88C, MPRIP, TNIP1, TPR, NFA and ZBTB11. Further the following fusions were found: NPM1-RP3P10, NPM1-SETBP1, NUP98-ING3, IRF2BP1-RARA, and ZBTB16-RARA. Thus, RNA sequencing identified 39 fusion transcripts which standard diagnostics had not identified; one of the partner genes. Failure to detect gene fusions should initiate improvements in calling algorithms and may also have biological implications. It was reported that genomic rearrangements of RUNX1 occur, which do not lead to RUNX1 in frame fusion transcripts but to termination of transcription.

Summary/Conclusions: 1) RNA sequencing was able to detect recurrent gene fusions with high accuracy and to characterize rare gene fusions providing the basis for the design of RT-PCR based assays for monitoring MRD. 2) Targeted RNA sequencing may be a valuable tool in routine diagnostics for patients with rearrangements unresolved by standard techniques. 3) These findings may have consequences for targeted treatment approaches.

**P550**

COMPREHENSIVE MOLECULAR ANALYSIS OF ADULT MIXED PHENOTYPE ACUTE LEUKEMIA (MPAL)

K. Morita1,2, F. Wang3, K. Patel4, C. Bueso-Ramos3, A. Abou Zahr3, A. Futreal3, K. Takahashi1

Aims: To clarify the underlying pathogenesis of MPAL and provide clue for future personalized therapy in MPAL, we performed comprehensive molecular characterization of adult MPAL.

Methods: We studied 31 patients with adult MPAL (median age 53) that met 2008 WHO classification criteria. Standard remission induction chemotherapy was performed based on targeted capture exome sequencing of 295 genes that are recurrently mutated in hematologic malignancies (median 393x coverage, N=31), RNA sequencing (N=24), and Infinium methylation EPIC array (Illumina, N=31). Mutational landscape was compared to that of 194 AML, 71 B-ALL, and 6 T-ALL cases of which pre-treatment samples were sequenced with the same platform. Promoter CpG methylation pattern was compared to the data from 194 AML (data derived from The Cancer Genome Atlas Project), 505 B-ALL and 101 T-ALL cases (data shared by Nordlund et al. Genome Biology. 2013). Copy number variation was inferred from methylation array data.

Results: Among 31 MPAL cases, 16 (52%) had MLL and 7 (23%) had TET2 mutations. Four cases had Philadelphia chromosome, 1 had 11q23 abnormality, and 8 had complex karyotype. MPAL had similar numbers of mutations (median 2 [range: 0-8]) with AML (median 3 range: 0-7), P=0.79) or T-ALL (median 3 [range: 1-4], P=0.92) but had significantly higher number of mutations than B-ALL (median 0-4, P=0.01). In 42/45 (93%) cases with a recurrent rearrangement identified by FISH and/or RT-PCR, RNA-Seq Alignment App (BaseSpace Sequence Hub) using Star for Alignment and Manta for gene fusion calling with default parameters (Illumina).

Mutational analysis showed 39 fusion genes, was amplified and was overexpressed. RNA sequencing revealed several known translocations such as NUP98-NSD1 and KMT2A-MLLT4, in addition to the novel translocations such as FOXP1-DNAJC15, FLI1-IFT46, and ITPR2-ARID5B. Unsupervised hierarchical clustering of all MPAL, AML, B-ALL and T-ALL by promoter CpG methylation pattern revealed that myeloid-T consistently showed similar methylation pattern with T-ALL, while myeloid-B showed random similarity with either B-ALL or AML.

Summary/Conclusions: MPAL is genetically heterogeneous disease and myeloid-T and myeloid-B shows distinct patterns of mutation landscapes, copy number variations, and gene expressions. Therapy for MPAL may need to be personalized based on genomic profiles.

THE EFFECTS OF EARLY INTENSIFIED INDUCTION CHEMOTHERAPY IN ADULT PATIENTS WITH ACUTE MYELOID LEUKEMIA COMPARED TO STANDARD ANTHRACYCLINE PLUS CYTARABINE 3+7 CHEMOTHERAPY

D.-H. Kwak1,2, H.-J. Yoon3, H.-J. Kim1, S.-S. Park2, Y.-E. Lee1, B.-S. Cho1, K.-S. Eom3, Y.-J. Kim1, S. Lee1, J.-W. Lee1, W.-S. Min1

1Department of Hematology, Catholic Blood and Marrow Transplantation Center, Leukemia Research Institute, Seoul St. Mary’s Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic Of

Background: Standard remission induction chemotherapy for acute myeloid leukemia (AML) which consists of anthracycline for 3 days plus cytarabine for 7 days was first introduced in 1970’s and has been used for a long time. Several modification or intensification for this conventional regimen did not prove the effect for higher complete remission (CR) rate or lower relapse rate which led to superior overall survival (OS) rate.

Aims: We tried to find out possible benefit of early intensification of standard induction chemotherapy in adult AML patients.

Methods: This retrospective study enrolled 1195 adult AML patients from 2002 to 2013. All patients were initially treated with idarubicin (12mg/m2) plus cytarabine (100mg/m2) or BHAC (300mg/m2) induction chemotherapy (3+7), and among them, 731 (61.2%) patients received additional early intensification using cytarabine 3 days (3+10, n=363) or anthracycline 2 days plus cytarabine (3+9, n=368). Demographics were compared between the two groups. Hematologic response were compared between the two groups. Hematologic response rates, relapse rates, overall survival (OS) and disease-free survival (DFS) were compared between the two groups.

Results: The median age at diagnosis was 65 (range: 19-84) years. The median follow-up time was 24 months (range: 1-130). There was no significant difference in age, sex ratio, and FAB subtype distribution. Most of patients were who were in de novo AML (93.9%). In the group of 3+7 chemotherapy, the median OS and DFS were 50.4 months and 21.9 months, respectively. In the group of 3+10 chemotherapy, the median OS and DFS were 59.2 months and 27.7 months, respectively.

Conclusion: Early intensification with anthracycline and cytarabine improved hematologic response rates, OS, and DFS. In conclusion, early intensification of induction chemotherapy for acute myeloid leukemia (AML) is a feasible and effective approach.
men (standard group). Re-induction and consolidation therapy was performed according to a consistent strategy and post-remission therapy was mainly based on hematopoietic cell transplantation.

**Results:** Early intensified group was consisted of younger patients (median age, 37 years old [range 17-69]) vs 45 years in 3+7 vs 43 years in 3+10 sub-group) and larger proportion of t(8;21) (n=102 [27.7%] vs 73 [3.1%] vs 3+10 [12.6%], P<0.001). Also, initial GM blast counts were higher in two intensified groups (73.3% in 3+10 and 70.1% in 3+10) compared to 3+7 sub-group (66.8%, P<0.001). Early death rate at 8 weeks was higher in patients older than 55 years (10.8% vs 3.7%, P<0.001) especially when they were treated with intensified chemotherapy (21.7% in 3+10 and 15.7% in 3+10 vs 6.3% in 3+7, P=0.038). CR rate after induction was higher in young patients especially in 3+10 subgroup (79.8%, P<0.001) and we also found that patients with favorable to intermediate-risk karyotype might benefit with intensified chemotherapy in the context of CR rate (79.7% vs 68.3%, P<0.001, although final CR rates became similar after re-induction. Next, we found that pre-HCT relapse rate was lower in younger patients younger than 55 years (4% vs 9%, P=0.002) and favorable to intermediate-risk group (8.9% vs 20.2%, P<0.001) after intensified induction. In young patients with favorable to intermediate-risk karyotype, intensified groups showed superior 5-year OS (55.0% vs 45.5%, P=0.010) and lower long-term relapse rate (32.2% vs 38.0%, P=0.084), but multivariate analysis revealed no effects for both OS and CR. In patients older than 55 years, intensified group showed inferior 5-year OS (19.2% vs 22.8%, P=0.014) with higher early death rate (17.6% vs 6.3%, P=0.015), and multivariate analysis also showed intensified induction was related inferior OS (HR=1.89, 95%CI; 1.14-3.15, P=0.013).

**Table 1.**

**Summary/Conclusions:** Our data revealed that intensified induction chemotherapy was not influential for poor-risk karyotype, while higher post-induction CR rate and low pre-HCT relapse was shown in young patients with favorable to intermediate-risk karyotype although it was not influential for final OS and CR rate. In elderly patients, intensified induction chemotherapy was related with higher early death rate which finally showed poor OS.

**P552**

**VARIANT FLT3 MUTATIONS CAN BE ERADICATED BY CYTARABINE/ANTHRACYCLINE/CRENOLANIB INDUCTION IN ADULT PATIENTS WITH NEWLY DIAGNOSED FLT3 (ITD/TKD) MUTANT AML**

E. Wang1, R. Stone2, R. Collins3, T. Agravall4, V. Unity4, M. Tallman5

1Department of Medicine, Roswell Park Cancer Institute, Buffalo, 2Department of Medical Oncology, 140 Cedar Street, Boston, 3Arog Pharmaceuticals, Inc., Dallas, 4Department of Medicine, Leukemia Service, Memorial Sloan Kettering Cancer Center, New York, United States

**Background:** Patients (pts) with FLT3-internal tandem duplication (ITD) and FLT3-D835 mutant AML have a high relapse rate. These relapses are typically due to outgrowth of mutant FLT clones. Previously available PCR-based tests only checked for presence of FLT3-ITD and FLT3-D835/ITD836 mutations. Whole genome sequencing of 799 pediatric AML samples from COG trials have shown novel FLT3 variants in patients where the tyrosine kinase domain also contains the juxtamembrane (JM) and transmembrane domains in 7.6% of these samples (Tarlock et al. ASH 2015). Some of these mutations result in autophosphorylation of FLT3 and therefore may be oncogenic.

**Aims:** Identify novel FLT3 mutations in pts with FLT3 mutant AML and further investigate whether these novel clones are sensitive to induction chemotherapy plus a potent pan-FLT3 inhibitor, crenolanib.

**Methods:** Pts with newly diagnosed FLT3 mutant AML were enrolled and treated with cytarabine/anthracycline/crenolani induction followed by high dose cytarabine (HiDAC) consolidation. Crenolani 100mg TID was started on day 9 of induction chemotherapy. Crenolani was stopped if variant FLT3 clones reduced by >60% on post-remission. Crenolani was continued for patients who relapsed on post-remission with the same FLT3 mutation, and who continued with crenolani. Bone marrow samples were collected at baseline and at the time of remission assessment. Sequencing of the entire FLT3 gene was performed through FoundationOne Heme panel (n=18) and MSKCC multigene panel (n=5). Sequencing of exons 14, 15, 16, and 20 was performed through the Rapid Heme Panel at Dana-Farber Cancer Institution in additional 6 pts.

**Results:** Out of 29 newly diagnosed FLT3 mutant AML patients with full/partial FLT3 gene sequencing performed, 4 pts were found to have novel variant FLT3 mutations consisting of V491L, V592L, D593H, A680V, and B411T/K (Table 1). The majority of these novel mutations were located at the JM, kinase domain 1 and the activation loop (kinase domain 2). The allele fractions of these FLT3 variants ranged as high as 29% (higher than that of FLT3-ITD in p33), suggesting that some of these clones may have been potentially driving clinical leukemia progression in some pts. All 4 pts had NPM1 mutations, and two also had DNM3A mutations. All 4 pts achieved CR with full count recovery (3/4 pts achieved CR after just one cycle of cytarabine/anthracycline/crenolani induction). The pt with FLT3-D835Y and B411T/K achieved CR after cyparabine/anthracycline/crenolani induction and one cycle of HiDAC consolidation. All patients with FLT3-ve and have received FLT3-ve out of 4 pts received 1–4 cycles of HiDAC consolidation followed by crenolani maintenance. Only one pt underwent allo SCT. With a median follow up of 13 months, one pt relapsed (at 6.4-month following treatment). This 61F pt was found to have FLT3-ITD, D593H and I836del FLT3 abnormalities at the time of diagnosis. A full FoundationOne gene panel done at the time of relapse, showed no residual FLT3 mutant clones.

**Summary/Conclusions:** This abstract reports multiple novel variant FLT3 mutations in adult pts with newly diagnosed FLT3-ITD or FLT3-D835 mutant AML. The allelic burden of these FLT3 variant mutations can sometime be higher than that of FLT3-ITD. Detailed FLT3 analyses in this subset of pts suggests that crenolani in combination with standard induction chemotherapy has the ability to eradicate variant FLT3 clones. All 4 pts treated with chemotherapy followed by crenolani showed clearance of FLT3-ITD, TKD, as well as other novel variants. To achieve maximal clinical benefit, a potent pan-FLT3 inhibitor with the ability to inhibit IDT, DB35, as well as other activating mutations maybe beneficial.

**P553**

**PATIENTS WITH ACUTE MYELOID LEUKEMIA WHO HAVE MUTATIONS IN IDH1 OR IDH2 RESPOND WELL TO INDUCTION CHEMOTHERAPY WITH "7+3" DESPITE THE PRESENCE OF COMPLEX KARYOTYPE OR FLT3-ITD**

D. S. Devlin1, D. M. Tallman2, D. E. Stein2

1Mount Sinai Hospital, 2Memorial Sloan Kettering Cancer Center, New York, United States

**Background:** Mutations in isocitrate dehydrogenase isoforms 1 and 2 (IDH1/IDH2) occur in 8-12% of patients with acute myeloid leukemia (AML). Mutant IDH enzymes catalyze the conversion of alpha ketoglutarate to beta hydroxyglutarate. Increased concentrations of intracellular 2-HG lead to histone hypermethylation and a block in cellular differentiation and may also lead to suppression of homologous recombination. Previous studies of outcomes in patients with FLT3-ITD and IDH1/IDH2 mutations have reported conflicting results. In this study, we investigated the outcomes of patients given induction chemotherapy with daunorubicin and cytarabine (7+3), the most common regimen used in the United States.
Aims: To delineate the complete remission rate in AML patients with IDH1 or IDH2 mutations who receive standard 7+3 induction chemotherapy. Methods: After receipt of IRB approval, an institutional database of genomic abnormalities in all patients with AML was queried for patients with IDH1 or IDH2 mutations between the years of 2010 and 2016. Pathology records of patients identified as having an IDH1/IDH2 mutation were reviewed to confirm the presence of an IDH mutation. After confirmation of IDH mutational status, all patients who received standard induction chemotherapy with 7+3 were included in this retrospective chart review. Results: Between 2010 and 2016, 82 patients with IDH1/IDH2 mutations who had been treated with 7+3 induction chemotherapy were seen at MSKCC. Of these, 33 (40.2%) had IDH1 mutations and 49 (59.8%) had IDH2 mutations. Of those with IDH2 mutations IDH2 R140Q mutations were present in 34 (69.3%) and IDH2 R172K mutations were present in 15 (30.6%). The median age of all patients treated was 63. 56 patients (68%) had de novo AML, 16 (20%) had AML with myelodysplasia related changes, 5 (6%) had a known prior history of MDS and 5 (6%) had therapy related AML. Nearly half of the patients (49%) had karyotypic abnormalities. Of the 82 patients who received induction chemotherapy with 7+3, 51 achieved a complete remission (CR) after 1 cycle and 16 after 2 cycles for a CR rate of 82%. The strongest predictor of response to induction chemotherapy was the presence of an NPM1 mutation. There was a trend towards decreased response to induction chemotherapy in patients with a complex karyotype (p=0.079) that did not reach statistical significance. The presence of an IDH2 R172K mutation was predictive of non-response to one cycle of (7+3) of 7+3 but when two cycles of induction chemotherapy were given, response rates were equivalent to patients with R140Q mutations. Co-occurring mutations in FLRT3 (ITD or TKD), DNMT3A or NRRAS were not predictive of responses to induction chemotherapy.

Summary/Conclusions: Induction chemotherapy with 7+3 leads to a robust CR rate of 82% in patients with AML that harbor and IDH1 or IDH2 mutation. CR is not affected by FLT3 mutations, or karyotypic abnormalities. The presence of an IDH2 R172K mutation was predictive of non-response to one cycle of (7+3) of 7+3 but when two cycles of induction chemotherapy were given, response rates were equivalent to patients with R140Q mutations. Co-occurring mutations in FLRT3-ITD, FLRT3-TKD or NRRAS mutations. For AML patients with IDH mutations who are eligible for induction chemotherapy “7+3” is a reasonable induction regimen regardless of the presence of FLT3 mutations, or karyotypic abnormalities.

VALIDATION OF PRECISION MEDICINE TEST FOR ACUTE MYELOID LEUKEMIA IN AN OBSERVATIONAL CLINICAL TRIAL

1Hospital Universitari i Politècnic La Fe de Valencia, Valencia, 2Vivvia Biotech, Tres Cantos, 3Hospital Universitario 12 de Octubre, Madrid, 4Hospital Universitario Reina Sofia, Cordoba, 5Hospital Universitario Sanchinarro, Madrid, 6Hospital San Pedro de Alcántara, Caceres, 7Hospital Clínico Universitario de Valencia, Valencia, 8Hospital General Universitario de Alicante, Alicante, 9Hospital Clínico Universitario de Salamanca, Salamanca, 10Hospital Universitario Ger- mans Trias i Pujol, Badalona, 11Hospital Gregorio Marañón, 12Hospital Universitario Ramón y Cajal, Madrid, 13Hospital General Universitario de Castellón, Castellón, 14Hospital Xeral Cies, Vigo, 15Hospital Lucus Augusti, Lugo, 16Hospital Universitario Virgen del Rocio, Sevilla, 17Hospital Universitario Gran Canaria Doctor Negrín, Las Palmas de Gran Canaria, 18Hospital Povisa, Vigo, 19Hospital Universitario Clínico San Carlos, Madrid, 20Hospital Universitario de Canarias, La Laguna, 21Hospital Universitario Príncipe de Asturias, Alcalá de Henares, 22Hospital Infanta Leonor, Madrid, 23Hospital Universitario Mar- qués de Valdecilla, Santander, 24Hospital de la Santa Creu i Sant Pau, Barcelona, 25Hospital Universitario Quirón, Madrid, 26Hospital Regional Uni- versitario Puerta de Hierro, Majadahonda, 27Hospital Universitario Virgen de la Luz, Cuenca, 28Hospital Universitario 12 de Octubre, Madrid, 29Hospital Universitario Arnuau de Vilanova, Valencia, 30Hospital de Manises, Manises, 31Hospital Universitario Vall d’Hebron, Barcelona, 32Hospital Clíni- co Universitario Lozano Blesa, Zaragoza, 33Medicxact, Madrid, 34Universidad de Navarra, Pamplona, Spain

Background: Treatment of Acute Myeloid Leukemia (AML) is limited to few different treatments in each clinical trial group guideline, but integrating current and previous guidelines, and clinical trial publications, there are up to 45 drug combination treatments among approved chemotherapy drugs in Europe and USA. There is a need for Precision Medicine (PM) tests to identify which of these different treatments maybe optimal for each individual patient, independently of where he/she lives.

Aims: To provide actionable data to improve disease management with existing treatments with a PM test to guide the hematologist among all possible treatments to achieve a CR.

Methods: AML bone marrow (BM) samples from adult patients were received at the laboratory within 24 hours from extraction and incubated for 48h in 96- well plates containing single drugs or combinations representing up to 45 different treatments that are currently given in the clinical practice. The analysis is performed in the automated flow cytometry PharmaFlow platform, 72 hours after the extraction of the sample, an encrypted report is sent to the hematologist before the patient begins treatment. Pharmacological responses were calculated using pharmacokinetic population models. Induction response was assessed according to the Cheson criteria (2003). Patients attaining a CR/CRi were classified as responders and the remaining as resistant, excluding early deaths. Final scores and treatments ranking is based on a therapeutic algorithm that integrates ex vivo activity; monotherapy dose responses quantified by the area under the curve (AUC) with limits such as Cmax values, and synergism calculated measuring 8 concentration ratios requiring consistency in their results in a 3D surface (so called alpha factor synergism). The PM Test attempts to identify at least one treatment, among all evaluated alternatives, predicted sensitive for each patient; conversely, if sensitive treatments can be identified the PM Test can provide the hematologist with valuable guidelines for individualized treatment.

Results: (Figure 1) The scoring method was tested using ex vivo results from samples obtained in an observational clinical trial with Spain’s PETHEMA group from a cohort of 123 samples from de novo diagnosed AML patients, treated with the standard PETHEMA 1st line guideline 3+7 with CYT+IDA. The score predicts sensitive patients with 90% accuracy. This accuracy can be compared with an independently derived 92% accuracy in identifying sensitive patients in a statistically significant clinical correlation study (EHA Poster 2016 Montesinos et al.). The score is a simplified version of such correlation algorithm. Both methods identify a similar % of all clinically sensitive patients (67% vs 71%).

haematologica | 2017; 102(s2) | 213
However, the correlation is only valid for CYT-IDA while the PM Test is applied to up to 45 treatments. Any such treatment identified as sensitive means the PM Test can provide a valuable guideline to hematologists. This means the PM Test can suggest sensitive treatments for the vast majority of patients.

Figure 1.

Summary/Conclusions: We have developed a novel ex vivo PM test for induction treatment in AML patients to guide hematologists selecting the right treatment to achieve CR in individual patients leveraging up to 45 different validated chemotherapy regimes. Assuming a similar response rate for all these treatments, our test could estimate a net prediction for sensitivity to AML treatment higher than 50% in 1st line. This PM Test will be evaluated in an interventional clinical trial on relapse/refractory patients that is expected to begin in the next few months in collaboration with the PETHEMA group from Spain.

P555
RESPONSE-ADAPTED AZACITIDINE AND INDUCTION CHEMOTHERAPY IN PATIENTS >60 YEARS OLD WITH NEWLY DIAGNOSED AML ELIGIBLE FOR CHEMOTHERAPY: RESULTS OF THE DRKS00004519 STUDY OF THE EAST GERMAN STUDY GROUP

N. Jaekel1, K. Hubert1, R. Krahl1, M. Haenel2, G. Maschmeyer4, R. Herbst5, C. Jakob1, S. Schulze1, S.-Y. Wang1, M. Cross3, C. Kah1, M. Wess8, H. Sayer6, O. Breusteanu6, O. Niedwiesien1, H.K. Al-Ali6
1Department of Hematology and Oncology, University Hospital of Leipzig, 2Department of Hematology and Oncology, University of Leipzig, Leipzig, 3Department of Hematology and Oncology, Klinikum Chemnitz, Chemnitz, 4Department of Hematology, Oncology and Palliative Care, Klinikum Ernst von Bergmann, Potsdam, 5Department of Hematology, Oncology and Palliative Care, Klinikum Magdeburg, Magdeburg, 6Department of Hematology and Oncology, University Hospital of Halle, Halle (Saale), 7Department of Hematology and Oncology, Helios Klinikum Erfurt, Erfurt, 8Clinical Trial Centre Leipzig, University of Leipzig, Leipzig, Germany

Background: AML treatment in elderly patients (pts) >60 years (y) with intensive chemotherapy (IC) or azacitidine (AZA) are not necessarily mutually exclusive. Aims: Results of the multicenter DRKS00004519 (RAS-AZIC) study of the East German Study Group (OSHO) which evaluated first-line treatment with AZA followed by response-based AZA or IC in pts >60y with AML are presented.

Methods: pts >60y with newly diagnosed AML (n=112) were included. Recruitment was completed in May, 2016. In the phase I part, safety of upfront AZA (75mg/m2/day s.c) for 7 days followed by IC (mitoxantrone 10mg/m2/day on day (d) 1-3 and cytarabine 1g/m2/BID on d 1, 3, 5, 7) on d17 was established through a 3+3 design. In the multicenter phase II part (figure), upfront AZA was sequentially followed by AZA or IC based on d15 bone marrow (BM) blasts (<45 vs 245%) and CR/CRi on d56 which were both previously identified as early predictors for long-term response to AZA in AML (Al-Ali et al. Leuk Lymph 2018). The primary endpoint was response (CR/CRi, and PR) at d90 according to the International Working Group criteria. Based on the optimal two-stage design (Simon. Control Clin Trials 1989), protocol treatment was non-inferior to standard IC if, on an intention-to-treat basis, an OR of 61% was achieved in 1stline AZA. Only lower baseline blasts correlated with blasts <45% on d15 (p=0.0005). Yet, 40% of pts with baseline blasts >50% reached this goal. Protocol assigned treatment on d15 was applied to 101 (90.2%) pts (p=0.003). Of 152 AML cycles given till d36, 33.6% were applied in an outpatient setting. Until d90, one IC cycle was needed in 77 (65% of the intention) OR and mortality at d90 were 62.5% [CR/CRi (n=43%; PR (4.5%); and 8.9% respectively. The probabilities of achieving CR/CRi with AZA alone, two AZA cycles + one IC, and one AZA cycle + one IC were 28.3%; 53.3%; and 58.3% respectively. Age, WBC, and type of AML had no impact on response in the three treatment scenarios. Similarly, response was not influenced by baseline BM blasts. CR/CRi was lower in high risk genetics (48%) compared to other risk categories (78%) (p=0.007). This negative association was particularly marked in pts with high-risk genetics and d15 BM blasts >45% [CR/CRi 38.5% vs 84% in other genetic categories (p=0.009)]. Interestingly, the impact of genetics on OR was not seen in the two AZA cycles + one IC cohort (p=1.0). CR with AZA alone was remarkably high (70%) in pts with favorable genetics including those with NPM1mut/FIT3wt (p=0.003). Protocol therapy was generally well tolerated. Constipation grade 1+2 was the most frequently reported AE under AZA (48%). The most frequent grade 3+4 non-hematologic AE was infection [IC (47%); AZA (20%)].

Figure 1.

Summary/Conclusions: Sequential response-based epigenetic and chemotherapy in elderly pts with AML is safe, associated with low mortality, and yields non-inferior responses compared to repeated cycles of IC. Marrow blasts d15 after the first AZA cycle and genetics could guide treatment-decision. The follow-up of this trial will scrutinize the impact of this approach on survival.

P556
OVERALL SURVIVAL WITH CPX-351 VERSUS 7+3 IN OLDER ADULTS WITH NEWLY DIAGNOSED, THERAPY-RELATED ACUTE MYELOID LEUKEMIA: SUBGROUP ANALYSIS OF A PHASE 3 STUDY

1H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL, 2Duke Comprehensive Cancer Center, Durham, NC, 3David Geffen School of Medicine/UCLA, Los Angeles, CA, 4Medical Univ. of South Carolina & Hollings Cancer Center, Charleston, SC, 5Monter Cancer Center, Northwell Health system, Lake Success, NY, 6BMT Group of Georgia, Atlanta, GA, 7Oregon Health and Science Univ, Portland, OR, 8Univ. of Alabama at Birmingham, Birmingham, AL, 9Washington Univ. School of Medicine, St. Louis, MO, 10Jazz Pharmaceuticals, Palo Alto, CA, 11MD Anderson Cancer Center, Houston, TX, United States

Background: Therapy-related acute myeloid leukemia (tAML) may occur as
a late complication of cytotoxic or radiation therapy and is associated with a poor prognosis. CPX-351 is a liposomal formulation that delivers a synergistic 5:1 molar ratio of cytarabine and daunorubicin. In a randomized, open-label, controlled phase 3 trial in patients aged 60 to 75 years with newly diagnosed, secondary AML (eg, tAML or AML after myelodysplastic syndrome), CPX-351 significantly improved overall survival (OS) versus cytarabine/daunorubicin (7+3).

Aims: The current analysis of this phase 3 study evaluated outcomes in the subgroup of patients with tAML.

Methods: Enrolled patients were randomized 1:1 to receive induction with 1 to 2 cycles of CPX-351 (100 units/m² [cytarabine 100mg/m² + daunorubicin 44mg/m²] on Days 1, 3, and 5 [2nd induction: Days 1 and 3 only]) or 7+3 (cytarabine 100mg/m²/day x 7 days [2nd induction: x 5 days] + daunorubicin 60mg/m² on Days 1, 2, and 3 [2nd induction: Days 1 and 2 only]). Patients who achieved complete remission (CR) or CR with incomplete platelet or neutrophil recovery (CRi) could receive up to 2 cycles of consolidation therapy. Note, the study was not powered for this subgroup analysis.

Results: A total of 304 patients were enrolled and received study treatment, including 62 (20%) patients with tAML (CPX-351 arm, n=30; 7+3 arm, n=32). Characteristics of tAML patients were similar between the CPX-351 and 7+3 arms: median age was 69.0 versus 67.5 years, and 47% versus 53% were male. Prior treatment in patients with tAML included prior non-anthracycline chemotherapy alone (26%), radiation alone (26%), non-anthracycline chemotherapy + radiation (32%), non-anthracycline + anthracycline chemotherapy (5%), and non-anthracycline + anthracycline chemotherapy + radiation (11%). CPX-351 was associated with a significant OS benefit versus 7+3 in older tAML patients and numerically longer event-free survival and remission duration (Figure 1). Additionally, a greater proportion of tAML patients in the CPX-351 arm versus the 7+3 arm achieved CR+CRi (47% vs 36%, respectively; odds ratio=1.33 [95% CI: 0.47, 3.81]) and proceeded to stem cell transplantation (37% vs 27%; odds ratio=1.54 [95% CI: 0.53, 4.49]). Serious treatment-emergent adverse events (TEAEs) were reported for 18/30 (60%) of tAML patients in the CPX-351 arm and 12/32 (38%) of tAML patients in the 7+3 arm; the observed difference in serious TEAEs in this subpopulation appeared to primarily be due to the incidence of febrile neutropenia (n=6/30 [20%] vs n=0/32 [0%]). Three (10%) patients in the CPX-351 arm and 5 (16%) patients in the 7+3 arm experienced a TEAE that resulted in death during the treatment period; there was no pattern in the individual TEAEs that led to death.

Figure 1.

Summary/Conclusions: CPX-351 is associated with improved efficacy and a safety profile comparable to 7+3 in older patients with newly diagnosed tAML. Outcomes in the tAML subgroup mirrored the overall study population, indicating CPX-351 may represent a new therapeutic option for this difficult to treat population.

Background: The prognostic impact of ferritinemia has been studied in myelodysplastic syndromes and acute myeloid leukemia (AML) patients undergoing allogeneic stem cell transplantation (SCT). In this context, high levels of serum ferritinemia have been correlated to a shorter overall survival (OS) and an increased relapse risk. We have previously shown that hyperferritinemia at diagnosis has a strong prognostic impact in a cohort of 162 AML patients with intermediate cytogenetic risk and younger than 60.

Aims: We now extend the analysis to all age and cytogenetic risk, in order to confirm the impact of hyperferritinemia in AML.

Methods: This study included 525 adult AML patients (excluding acute promyelocytic leukemia) treated by intensive chemotherapy in Toulouse and Lyon University Hospitals between January 1st, 2005 and December 31st, 2014 who had ferritinemia documented at AML diagnosis. Ferritin level was measured by spectrophotometry. Primary outcome was disease-free survival (DFS). To avoid the loss of information and the reduction in power introduced by the categorization of ferritinemia and to deal with the non-linearity in the relationship between outcomes and ferritinemia, we explored the relationship between ferritinemia and outcomes using restricted cubic spline.

Results: Median age at diagnosis was 59.4 years (interquartile range [IQR], 47.8-66.4); 303 of them (57.7%) were men. Disease status was de novo in 83.2% (N=437). Median white blood cell count (WBC) was 10.0x10⁹/L (IQR, 2.5-41.5). Cytogenetic risk was favorable and intermediate and adverse in 9.2% (N=48), 71.8% (N=374) and 19% (N=99) respectively; ELN classification was favorable, intermediate-I, intermediate-II, adverse and unknown in 21.0% (N=110), 25.5% (N=134), 22.3% (N=117), 18.9% (N=99) and 12.4% (N=65) respectively. Median ferritinemia at AML diagnosis was 715 µg/L (IQR, 372-1304), ranging from 34µg/L to 70759 µg/L (upper normal limit [UNL]: 300µg/L). 421 patients achieved complete remission (CR); 80.2%. Early death and treatment failure rates were 7.8% (N=41) and 12% (N=63) respectively. 169 patients underwent allogeneic HSCT in first CR (32.2%). Median DFS was 19.8 months (IQR, 8.4-Not Reached). Ferritinemia had a significant impact on DFS: median DFS was 21.2 months in patients with ferritinemia ≤2100 µg/L (7-fold UNL), and 12.7 months with ferritinemia >2100 µg/L (HR, 1.6 [95%CI, 1.1-2.3], p=0.0253). After adjustment for age, AML status and cytogenetics or ELN classification, relapse or death rate significantly (p=0.0122) increased from ferritinemia superior or equal to 2141 µg/L (Figure 1). Ferritinemia had also a significant impact on early deaths, CR rate, EFS and OS after adjustment (≥4-fold UNL, p=0.0001; ≥3-fold UNL, p=0.004; ≥2-fold UNL, p<0.0001 and ≥3-fold UNL, p=0.01 respectively).

Figure 1.

Summary/Conclusions: In conclusion, hyperferritinemia is a prognostic marker independent from well-acknowledged factors, such as cytogenetics and molecular abnormalities. Ferritinemia should be included in AML diagnosis workup as it provides reproducible information on short and long-term outcome for AML patients of any subgroup. The putative link between hyperferritinemia, inflammation and chemoresistance should be investigated.

P558

NGS ANALYSIS OF 474 BONE MARROW SAMPLES FROM 157 AML PATIENTS TREATED WITH AZACITIDINE–IMPACT OF AGE ON MUTATIONAL LOAD

L. Pleyer1,2,3,*, F.J. Gassner1,2, S. Burgstaller4, H. Wedler5,6, T.N. Hartmann1,2,3, K. Scipioni1,2,3, E. Wiedler6,7, T. Hartmann1,2,3, B. Jansko1, D. Neureiter1, J. Thaler4, R. Greil1,2,3

1Oncologic Center, Paracelsus Medical University, 2Salzburg Cancer Research Institute (SCRI), Center for Clinical Cancer and Immunology Trials, 3Cancer Cluster, Salzburg, 4Department of Internal Medicine IV/Department of Internal Medicine V, Klinikum WelsGrieskirchen, Wels, 5Qiagen Genomic Services, 6Institute of Pathology, Paracelsus Medical University, Salzburg, Austria

Background: Recent publications have shown the prognostic value of performing NGS analysis in patients (pts) with acute myeloid leukaemia (AML) (Papaemmanuil et al, NEJM 2016). While recent data has been published on pts with myelodysplastic syndromes (MDS) and AML treated with decitabine, (Welch et al, NEJM 2016; Duncavage et al, Blood 2017) data on
AML pts treated with azacitidine (AZA) has only been presented in abstract form thus far (Tang et al, ASH 2016). Data on the impact of age on mutational load in AML are scarce.

Aims: To assess the mutational landscape in elderly AML pts treated with AZA; specifically, whether age has an impact on mutational load.

Methods: We analysed 474 bone marrow FFPE specimens from 157 AML pts in the Austrian Registry of Hypomethylating Agents from two centres (Salzburg, Wels-Grieskirchen) using a 53-gene panel (all exons). NGS was performed by Qiagen. Minimum coverage: 1:500x. All mutations were checked against COSMIC-v79, ClinVar, ICGC, DoCM, dbsnp and Varsome databases. For comparison of categorical variables Chi-squared test was used, for comparison of means Students T-test was used.

Results: The rate of secondary (s)AML was significantly lower in pts ≤75 years (n=85), vs ≥75 years (n=54) (66.0 vs 77.8%, P=0.001). There was no significant difference in the rate of adverse cytogenetics or monosomal karyotype before AZA treatment between pts ≤ vs ≥75 years, respectively (data not shown). Mutational load (average number of mutated genes and mutations per pt) assessed at/before initiation of AZA, was significantly higher in pts ≤75 yrs vs ≥75 years (10.2 vs 8.6 mutated genes/pt; P=0.030 and 12.9 vs 10.5 mutations/pt; P=0.012, Figure 1A). This also held true when mutational load was assessed at any timepoint during the course of AML (including during/post-AZA treatment) (Figure 1B). In total, 139 pts had more than one marrow sample with NGS results. Analysis of paired samples revealed that mutational load was significantly higher during/post-AZA vs before AZA in both age groups (Figure 1C-D). In total, 60.4%, 15.8%, 8.6%, 3.6% and 11.5% of pts acquired 1, 2, 3, 4-13 additional mutations, respectively. No relevant differences between pts ≤ vs ≥75 years were found (data not shown). When comparing the delta of mutations before vs during/after AZA according to age group, no significant difference was found (Figure 1E).

Summary/Conclusions: The observed mutational load per pt in our cohort is higher than that observed by others using targeted re-sequencing methods, which report an average of only 2-4 mutations per pt (Duncavage et al, Blood 2017; Conte et al, Leuk 2013; Au et al, Diagn Pathol 2016; Grove & Vasiliou, Dis Model Mech 2014). It seems however, that a higher mutational load (average number of mutated genes and mutations per pt) assessed at/before initiation of AZA, was significantly higher in pts ≤75 yrs vs ≥75 years (10.2 vs 8.6 mutated genes/pt; P=0.030 and 12.9 vs 10.5 mutations/pt; P=0.012, Figure 1A). This also held true when mutational load was assessed at any timepoint during the course of AML (including during/post-AZA treatment) (Figure 1B). In total, 139 pts had more than one marrow sample with NGS results. Analysis of paired samples revealed that mutational load was significantly higher during/post-AZA vs before AZA in both age groups (Figure 1C-D). In total, 60.4%, 15.8%, 8.6%, 3.6% and 11.5% of pts acquired 1, 2, 3, 4-13 additional mutations, respectively. No relevant differences between pts ≤ vs ≥75 years were found (data not shown). When comparing the delta of mutations before vs during/after AZA according to age group, no significant difference was found (Figure 1E).
AML showed higher therapy-related mortality (TRM) rate. However, multivariate analysis showed that there were no significant differences between the three AML subgroups especially when the patients were treated with hematopoietic cell transplantation (HCT).

Results: Signal ratio was assessed in 152 patients with FLT3-ITD and -TKD mutations who had received ≥80mg gilteritinib. Of these patients, 136 had FLT3-ITD mutations with or without concomitant TKD mutations, and 16 had FLT3-TKD mutations only. Median ITD and TKD signal ratios were 0.84 and 0.5, respectively. Patients with FLT3-ITD signal ratios that were above or below the median ITD signal ratio had OS durations of 216 and 213 days, respectively. No significant difference in median OS was observed between patients in the highest and lowest FLT3-ITD signal ratio quartiles (Figure 1). Patients with TKD signal ratios that were above the median value (0.5) had a median OS of 202 days; those with TKD signal ratios below the median value had significantly shorter median OS of 33.5 days (P = 0.004; Figure 1).

Figure 1.

Summary/Conclusions: These data show that FLT3-ITD signal ratio has little impact on survival in patients with FLT3-ITD mutations who received gilteritinib. In the small number of patients with FLT3-TKD mutations only, high TKD signal ratio was associated with a longer OS, similar to that observed in patients with FLT3-ITD mutations. These data suggest a possibility that oncogene addiction in FLT3-TKD+ R/R AML requires a high allelic burden and clonal dominance. Also, it is possible that FLT3-ITD signal ratio in R/R AML may contribute to the response rate in patients with FLT3-TKD mutations only. Further investigation is warranted.

INITIAL RESULTS FROM A FIRST-IN-HUMAN STUDY OF IMGN779, A CD33-TARGETING ANTIBODY-DRUG CONJUGATE (ADC) WITH NOVEL DNA ALKYLYATING ACTIVITY, IN PATIENTS WITH RELAPSED OR REFRACTORY AML

J. Cortes1, D. DeAngel2, E. Wang3, C. Arana-Yif4, P. Zweidler-McKay5, M. Munteanu6, C. Andreu-Vieyra6, H. Erba6, W. Blum7, E. Traer8

1MD Anderson Cancer Center, Houston, 2Dana-Farber Cancer Institute, Boston, 3Roswell Park Cancer Institute, Buffalo, 4University of New Mexico Cancer Center, Albuquerque, ImmunoGen, Inc, Waltham, 5University of Alabama at Birmingham, Birmingham, 7The Ohio State University, Columbus, 8Oregon Health and Science University, Portland, United States

Background: Acute myeloid leukemia (AML) accounts for the highest number of leukemia deaths in the United States annually. IMGN779 is an ADC that binds with high affinity and specificity to CD33, a validated therapeutic target in AML. IMGN779 comprises a humanized anti-CD33 antibody attached via a novel linker to the novel DNA-alkylating payload DGN462. Once released within the target cell, DGN462 exerts potent antitumor activity via DNA alkylation, without cross-linking, resulting in cell cycle arrest and apoptosis.

Aims: This Phase I study is designed to establish the maximum tolerated dose (MTD) and determine the recommended phase 2 dose (RP2D) of IMGN779 when administered to patients with CD33+ AML. Evaluation of the safety, tolerability, pharmacokinetics (PK), pharmacodynamics (PD), and preliminary antitumor activity of IMGN779 are secondary objectives.

Methods: Adult patients (≥ 18 years) with relapsed or refractory CD33+ AML (defined by ≥20% of AML blasts expressing CD33 by flow cytometry) were eligible for enrollment. Informed consent was obtained from all patients. Dose-escalation, which follows a standard 3+3 design, began with a starting dose of 0.02mg/kg. IMGN779 was administered intravenously once every 2 weeks on days 1 and 15 as part of a 28-day cycle. Adverse events (AEs) were evaluated using NCI-CTC v4.03.

Results: As of February 2017, a total of 17 patients (9 female, 8 male) with a median age of 62 years have received IMGN779 treatment. Five dose levels have been completed, with escalation proceeding from 0.02–0.26mg/kg. AEs were as expected for this relapsed/refractory AML population including cytopenias and constitutional symptoms. No relationship between frequency or sever-
ity of AEs and IMGN779 dose level was observed. The most common AEs were nausea (41%), febrile neutropenia (29%), and rash (29%); pneumonia, respiratory failure, and constipation were additional AEs reported in 4 or more patients (≥ 24%). The most common serious adverse events (SAEs) were grade 3 febrile neutropenia (29%) and pneumonia (24%). No dose limiting toxicities (DLTs) have been reported. Importantly, no safety signals regarding liver or hematopoietic toxicity have been observed in laboratory assessments. In general, plasma concentrations (Cmax) of IMGN779 increased relative to dose. In the highest cohort examined thus far (Cohort 5, 0.26mg/kg), sustained exposure (AUC) was observed in all patients through 48 hours post-infusion. A pharmacodynamics (PD) assay demonstrated consistent saturation of residual free antibody (AUC) was observed in all Cohort 5 patients past 48 hours, consistent with the PK results. Initial response data will be presented.

**Summary/Conclusions:** This is the first clinical experience of the next generation CD33-targeting ADC, IMGN779, in AML patients. No DLTs have been noted to date. AEs were generally consistent with the underlying disease, PK and PD are favorable and dose escalation is continuing.

**P563**

**COMBINATION OF TGR-1202, UBLITUXIMAB, AND BENDAMUSTINE IS SAFE AND HIGHLY ACTIVE IN PATIENTS WITH ADVANCED DLBCL AND FOLLICULAR LYMPHOMA**

1University of Nebraska Medical Center, Omaha, NE, 2Clearview Cancer Institute, Huntsville, AL, 3City of Hope National Medical Center, Duarte, CA, 4TG Therapeutics, Inc., New York, NY, United States

**Background:** TGR-1202 is a next generation, once daily, PI3Kδ inhibitor, active in patients (pts) with rel/ref hematologic malignancies that has demonstrated a notably differentiated safety profile, including in long-term follow up (Burris, 2016). Ublituximab (UTX) is a novel glycoengineered mAb targeting a unique epitope on the CD20 antigen. Bendamustine (Benda) is an active chemotherapy agent in pts with lymphoma. The combination of UTX + TGR-1202 is tolerable and active in pts with rel/ref hematologic malignancies and is under Phase 3 testing for patients with CLL and Phase 2b testing for patients with DLBCL.

**Aims:** This Phase 1 trial evaluates the safety and efficacy of UTX + TGR-1202 + Benda in pts with advanced Diffuse Large B-cell Lymphoma (DLBCL) and Follicular Lymphoma (FL).

**Methods:** Eligible pts had rel/ref DLBCL or FL with an ECOG PS ≤2 w/o limit to number of prior therapies. ANC of >750 and Platelets >50,000 was permitted. Pts refractory to prior PI3Kδ, Benda, or anti-CD20 therapy were eligible. UTX was dosed on Days 1, 8, 15 of Cycle 1. Day 1 of Cycle 2-6, followed by Cycle 9 & 12. TGR-1202 was started at 800mg QD with a -1 dose reduction cohort at 600mg if not tolerated in ≥2/6 pts. Benda was dosed at 90mg/m2 on Days 1 & 2 of Cycles 1-6 only. Primary endpoints included safety and efficacy (Cheson 2007).

**Results:** Twenty-three pts were evaluable for safety: 15 diffuse large B-cell (DLBCL) and 8 follicular (FL). Med age 68 yo (range 31-81); 12 M/11 F; median prior treatment regimens=2 (range 1-6); 12 pts (52%) were refractory to their immediate prior treatment and to prior CD20 therapy, and 7 patients had progressed post-transplant. ECOG PS 0/1/2 (3/18/2). Initially 2/4 pts at 800mg TGR-1202 experienced AEs’s in Cycle 1 that led to treatment interruption (rash, neutropenia) thus the 600mg dose of TGR-1202 was explored. No additional Cycle 1 treatment delays were reported at the 600mg dose level, which was later expanded and the 800mg TGR-1202 dose is now being evaluated with stricter eligibility criteria to require an ANC of ≥ 1.0, and the use of growth factor support in cycle 1 is now encouraged. The most common AE’s included diarrhea (39%; G3/4 4%), decreased appetite (35%; G3/4 4%), nausea (30%; G3/4 4%), asthenia (26%; G3/4 4%), and neutropenia (22%). The only Grade 3/4 AE reported in >10% of pts was neutropenia (22%). Two pts had a TGR-1202 dose reduction. Nineteen pts (11 DLBCL/8 FL) were evaluable for efficacy: ORR amongst all pts was 79% (15/19) with 42% (8/19) achieving a complete response (CR), of which 5 were DLBCL and 3 FL. ORR in the respective groups as follows:

**Table 1.**

<table>
<thead>
<tr>
<th>Group</th>
<th>N</th>

**Summary/Conclusions:** The combination of UTX, TGR-1202, and bendamustine has exhibited manageable toxicity with significant activity in advanced DLBCL and FL pts including an encouraging 42% CR rate (45% in DLBCL and 38% in FL). Enrollment continues at the 800mg TGR-1202 dose level with the use of growth factor prophylaxis. Safety and efficacy data for all pts will be updated at the meeting. Based upon the early activity of the triplet, future registration directed studies are being planned.

**VENETOCLAX (VEN) IN PATIENTS WITH RELAPSED/REFRACTORY NON-HODGKIN LYMPHOMA (NHL)**

1Dana-Farber Cancer Institute, Boston, United States, 2Royal Melbourne Hospital, Parkville VIC, 3Peter MacCallum Cancer Centre, East Melbourne VIC, 4University of Texas MD Anderson Cancer Center, Houston, 5University of Arizona Cancer Center, Tucson, Australia, 6AbbVie Inc., North Chicago, 7Memorial Sloan-Kettering Cancer Center, New York City, United States

**Background:** Venetoclax (VEN) is an oral BCL-2 inhibitor indicated for the treatment of patients (pts) with rel/ref diffuse large B-cell lymphoma (DLBCL) and follicular lymphoma (FL). VEN is FDA approved for DLBCL in combination with rituximab, with an ORR of 71% and a 22% complete response rate (Cheson, 2018). VEN exhibits manageable toxicity with significant activity in advanced DLBCL and FL pts including an encouraging 42% CR rate (45% in DLBCL and 38% in FL). Enrollment continues at the 800mg TGR-1202 dose level with the use of growth factor prophylaxis. Safety and efficacy data for all pts will be updated at the meeting. Based upon the early activity of the triplet, future registration directed studies are being planned.

**Methods:** Eligible pts had rel/ref DLBCL or FL with an ECOG PS ≤2 w/o limit to number of prior therapies. ANC of >750 and Platelets >50,000 was permitted. **Summary/Conclusions:** The combination of UTX, TGR-1202, and bendamustine has exhibited manageable activity with significant activity in advanced DLBCL and FL pts including an encouraging 42% CR rate (45% in DLBCL and 38% in FL). Enrollment continues at the 800mg TGR-1202 dose level with the use of growth factor prophylaxis. Safety and efficacy data for all pts will be updated at the meeting. Based upon the early activity of the triplet, future registration directed studies are being planned.
Background: VEN is a selective orally bioavailable BCL-2 inhibitor. The dose-escalation Phase 1 study of VEN in 106 patients (pts) with relapsed/refractory NHL reported an ORR of 44%. Most pts had diffuse large B-cell/follicular lymphoma.

Aims: We report on updated results in pts with less common NHL subtypes.

Methods: VEN was administered and continued until progressive disease (PD), unacceptable toxicity, in dose cohorts ranging from 300 to 1200 mg. Adverse events (AEs) were assessed by NCI-CTCAE v4.0 and response by 2007 Cheon ISG response criteria, utilizing CT scans beginning at wk 6.

Results: 35 of 106 pts had mantle cell lymphoma (MCL, n=28), marginal zone lymphoma (MZL, n=3) or Waldenström macroglobulinemia (WM, n=4). Most common unacceptable grade treatment-emergent AEs were nausea (51%), diarhoea (49%) and fatigue (34%); grade 3/4 AEs in >10% of pts were neutropenia and anemia (17% each). Laboratory TLS was reported in a single pt (bulky MCL). MCL pts (median age: 72 years) had received a median of 3 (1-7) prior treatments (tx). Median time from start of prior tx to start of VEN was 13 mo (2-48 months) and on time on prior tx was 0.5 mo (0.2-1.2 mo). ORR was 75%, 6 pts (21%) achieved CR and remain on study (DORs: 25-40 mo). One pt with a PR proceeded to elective allogenetic stem cell transplant and remained disease free at last protocol defined follow-up (24 mo after coming off study). Median PFS was 11 mo and DOR was 15 mo. MZL pts (median age: 63 years) had received a median of 4 (2-6) prior tx. Time from start of prior tx to start of VEN was 8, 14, 73 mo and time on VEN was 5, 1, 35 mo. One pt (6 pt prior tx) received VEN for <1 mo due to progressive cytopenias; 1 pt (4 prior tx) achieved a PR with VEN at wk 6 but had PD at wk 16; 1 pt (2 prior tx) achieved PR at wk 6 and is the only pt to remain on study (DOR:32 mo). WM pts (median age: 67 years) had a median of 4 (3-5) prior tx. Time from start of prior tx to start of VEN was 5, 18, 33, 67 mo and time on VEN was 42, 17, 54, 20 mo. All pts achieved PR (at wks 6 [n=2], 16 and 36), with DORS of 11, 12, 38 and 50+ mo (latter is ongoing and remains on study).

Summary/Conclusions: VEN monotherapy has a tolerable safety profile in MCL, MZL and WM pts. ORR were high and most responses durable; median PFS and DOR suggest significant activity in MCL pts. Further investigation of VEN in each disease is indicated.

P565

WHOLE BODY DIFFUSION-WEIGHTED MAGNETIC RESONANCE IMAGING IS A GOOD PROGNOSTIC FACTOR IN TREATMENT OUTCOME AFTER ONE CYCLE OF IMMUNOCHEMOTHERAPY IN AGGRESSIVE LYMPHOMA

K. De Paepe1, F. De Keyser1, C.-A. Van Keerberghen2, O. Gheysens2, V. Vandecaveye1

1Radiology, Nuclear Medicine, 2Medical Oncology, 3Hematology, University Hospitals Leuven, Leuven, Belgium

Background: Early identification of non-Hodgkin lymphoma patients not responding to therapy may enable treatment adaptation which might impact on the long-term survival of patients. Whole-body diffusion-weighted magnetic resonance imaging (DWI) has the potential to provide information about the tissue diffusion of water molecules, which can serve as a surrogate marker for tumour cellularity and therefore disease aggressiveness.

Aims: To evaluate the use of whole body diffusion-weighted magnetic resonance imaging (WB-DWI/MRI) as a radiation-free imaging technique to predict treatment outcome in NHL after one cycle of ICT (2-3 weeks).

Methods: Forty-six patients with aggressive NHL (35 diffuse large B-cell lymphoma (DLCLB), 2 primary mediastinal B-cell lymphoma (BCL), 1 unclassifiable BCL, 1 Burkitt lymphoma, 4 Mantle cell lymphoma (MCL), 2 peripheral T-cell lymphoma (TCL) and 1 extranodal natural-killer TCL) were consecutively enrolled between 2011 and 2015. All patients had baseline and interim WB-DWI/MRI after one cycle of immunotherapy, and end-of-treatment FDG-PET/CT. Aims: To further characterize the efficacy of VEN in patients with RR DLBCL, Richter’s transformation (RT) or FL.

Methods: We conducted a retrospective cohort study of DLBCL, RT and FL patients consecutively treated with IBR. Data collected included patient demographics, stage, IPI, genetic characteristics, prior treatments, IBR dose and duration, reasons for discontinuation, and response. PFS and OS were estimated using the Kaplan Meier method and survival analysis by the log rank (LR) test.

Results: 44 patients were identified (DLBCL: 24, 54.5%; FL: 12, 27%, RT: n=8, 18%) who received IBR monotherapy in the RR setting. Baseline characteristics included age (range 19–80), 61% male, 95% ECOG 0 - 1, 71% stage IV, 62% elevated LDH, and 48% R-IPI ≥ 4. DLBCL sub-types (Hans criteria) were 25% non-GC (n=11), 16% GC (n=7), and 14% unclassifiable (n=6). In the FL subgroup, 8% were grade 1, 58% were grade 2, 33% were grade 3a. Median number of prior therapies was 5 (range 1-11). All RT patients were not treated with IBR previously for CLL. The three most common reasons for IBR discontinuation were progression (35%), toxicity (20%), and bridge to CAR-T (10%). PFS and OS data are shown in Table 1. In DLBCL, cell of origin (IHC) did not impact outcomes (p=0.97, LR test). Patients with RT had better PFS as compared to de novo DLBCL (p=0.03, LR test).

Table 1.

Summary/Conclusions: In the largest single-center, real-world experience of IBR use in DLBCL, RT and FL, we validate findings reported in clinical trials. In FL, responses appear to be durable (median PFS of >10 months). Outcomes are extremely poor in DLBCL and use of IBR as monotherapy is not recommended. Perhaps IBR is best used as a short-term bridge to more definitive therapies. Cell of origin by immunohistochemistry does not predict PFS and should not be used to preferentially select non-GC DLBCL patients for IBR. Patients with RT appear to have more durable responses (vs DLBCL) suggesting differing dependence on BTK signaling for tumor survival.

P567

PREVALENCE AND PROGNOSTIC VALUE OF MYD88 AND CD79B MUTATIONS IN IMMUNE-PRIVILEGED SITE AND (EXTRA)NODAL DLBCLS

J. Vermaat1, A. Amir2, M. Mindermann2, W. Kraan2,3, I. Saes1, L. de Wrede5, R. de Groen1, E. Kerver6, H. Berenschot1, W. Deelen7, J. Wegman9

1Lankenau Medical Center, 2Abramson Cancer Center, Hospital of the University of Pennsylvania, 3Hospital of the University of Pennsylvania, Philadelphia, United States

Background: Ibrutinib (IBR), a Bruton’s Tyrosine Kinase (BTK) inhibitor, is FDA approved for chronic lymphocytic leukemia, Waldenström macroglobulinemia, marginal zone lymphoma and mantle cell lymphoma. Despite its limited data, IBR is increasingly being utilized as a treatment option for patients with relapsed/refractory (RR) diffuse large B-cell lymphoma (DLBCL) and follicular lymphoma (FL).

Aims: To evaluate the use of whole body diffusion-weighted magnetic resonance imaging (WB-DWI/MRI) as a radiation-free imaging technique to predict treatment outcome in NHL after one cycle of ICT (2-3 weeks).

Methods: We conducted a retrospective cohort study of DLBCL, RT and FL patients consecutively treated with IBR. Data collected included patient demographics, stage, IPI, genetic characteristics, prior treatments, IBR dose and duration, reasons for discontinuation, and response. PFS and OS were estimated using the Kaplan Meier method and survival analysis by the log rank (LR) test.

Results: 44 patients were identified (DLBCL: n=24, 54.5%; FL: n=12, 27%, RT: n=8, 18%) who received IBR monotherapy in the RR setting. Baseline characteristics included age (range 19–80), 61% male, 95% ECOG 0 - 1, 71% stage IV, 62% elevated LDH, and 48% R-IPI ≥ 4. DLBCL sub-types (Hans criteria) were 25% non-GC (n=11), 16% GC (n=7), and 14% unclassifiable (n=6). In the FL subgroup, 8% were grade 1, 58% were grade 2, 33% were grade 3a. Median number of prior therapies was 5 (range 1-11). All RT patients were not treated with IBR previously for CLL. The three most common reasons for IBR discontinuation were progression (35%), toxicity (20%), and bridge to CAR-T (10%). PFS and OS data are shown in Table 1. In DLBCL, cell of origin (IHC) did not impact outcomes (p=0.97, LR test). Patients with RT had better PFS as compared to de novo DLBCL (p=0.03, LR test).

Table 1.

Summary/Conclusions: In the largest single-center, real-world experience of IBR use in DLBCL, RT and FL, we validate findings reported in clinical trials. In FL, responses appear to be durable (median PFS of >10 months). Outcomes are extremely poor in DLBCL and use of IBR as monotherapy is not recommended. Perhaps IBR is best used as a short-term bridge to more definitive therapies. Cell of origin by immunohistochemistry does not predict PFS and should not be used to preferentially select non-GC DLBCL patients for IBR. Patients with RT appear to have more durable responses (vs DLBCL) suggesting differing dependence on BTK signaling for tumor survival.
and other extranodal localizations (12%). In patients harboring a MYD88 mutation, indicating that these tumors represent distinct DLBCL subgroups. In patients presenting at IP sites. These patients with MYD88 mutations display a relatively high prevalence of coexisting CD79B mutations. Interestingly, a recent study by Wilson et al. (Nat. Med. 2015), indicates that these patients are more sensitive to treatment with Bruton’s Kinase inhibitors. Our study highlights the importance of investigating the mutational status of MYD88 and CD79B in larger prospective clinical trials with molecularly targeted agents, particularly in DLBCL patients with IP localizations.

P568
HIV-INFECTED PATIENTS WITH RELAPSED NON-HODGKIN LYMPHOMA (NHL) OR HODGKIN LYMPHOMA (HL): RESULTS FROM THE GERMAN HIV-RELATED LYMPHOMA COHORT STUDY
P. Schommers1, M. Hentrich2,*, D. Gillor1, C. Wyen1, T. Wolf3, J.-C. Wasmuth4, J. Bogner5, C. Spinner6, S. Esser7, B. Jensen8, M. Müller9, A. Schleicher10, G. Fätkenheuer1, C. Hoffmann11
1University of Cologne, Cologne, 2Hematology/Oncology, Rotkreuzklinikum München GmbH, München, 3University of Frankfurt, Frankfurt, 4University of Bonn, Bonn, 5University of Munich, 6University of Essen, Essen, 7University of Düsseldorf, Düsseldorf, 8Vivantes Auguste-Viktoria Hospital, Berlin, 9CH Study Center, Hamburg, Germany

Background: The outcome of HIV-associated lymphoma has undergone significant improvement in recent years beginning with the widespread use of combination antiretroviral therapy (ART). However, among AIDS-related deaths, non-Hodgkin lymphoma (NHL) is the most frequent event. HIV-positive patients (pts) with relapsed NHL or Hodgkin lymphoma (HL) should be treated in a manner similar to immunocompetent pts.

Methods: This prospective multicenter cohort study includes adult HIV-1 infected pts with biopsy or cytologically proven HIV-related lymphoma diagnosed at 32 participating centers in Germany and Austria since January 2005. Data on HIV-infection and lymphoma characteristics, treatments and outcomes were recorded. Pts with indolent lymphomas and primary central nervous system lymphomas were excluded from the present analysis.

Results: Of 499 pts (463 males, 36 females) 394 had aggressive NHL and 105 HL. The median age at lymphoma diagnosis was 45.6 yrs (range, 22–74). 344 pts (69%) were diagnosed with advanced stage (III/IV) lymphoma and the median CD4-cell count was 271/μl (266/μl in NHL and 287/μl in HL). Of 311 pts, 311 of 499 pts (62%) achieved a documented CR, 235 (60%) with NHL and 76 (72%) with HL. After a median follow-up of 17 months for NHL and 30 months for HL pts, 31 of 235 NHL (13%) and 8 of 76 HL (11%) experienced a relapse. Incidence of relapse was 6.9/100 patient years (PY) within the 1st year after primary diagnosis and 1.3/100 PY thereafter (P=0.0062). Median time to relapse was 7.3 months in NHL and 18.0 months in HL. Relapses beyond 12 months occurred in 6 of 31 NHL cases (19%) and in all 8 HL cases (100%) (P=0.045). Median overall survival (OS) of all relapsed pts was 29.0 months (95% CI 14.1-44.2 months) after primary lymphoma diagnosis. In pts with HL, OS was not reached, whereas it was 15 months in pts with NHL (P=0.024). Regarding the entire cohort of 311 pts with a documented CR, the 2-year OS rate was 57% in pts with relapse as compared to 97% in those without (P<0.001). The majority of relapsed pts died of lymphoma (86%).

Summary/Conclusions: Relapses from CR are relatively rare in pts with HIV-associated NHL and HL. In pts with NHL the majority of relapses occur within the first year after primary diagnosis, whereas in HL most relapses occur beyond 12 months. Overall, pts with relapsed HIV-related NHL have a worse outcome than pts with relapsed HL.

Figure 1. Results: Translocations in BCL2, BCL6 and MYC were identified in 14, 32 and 13 patients, respectively and 23 EBV-positive cases were found. MYD88 and CD79B mutations were identified in 51 patients and 19 cases, respectively. Interestingly, there was hardly any overlap between the presence of translocations (BCL2, BCL6 and MYC) or EBV and that of MYD88 and/or CD79B mutations, indicating that these tumors represent distinct DLBCL subgroups. In accordance with previous studies, the incidence of MYD88 mutations was increased at IP sites (67%, Chi-square P=0.001), compared to nodal (13%) and other extranodal localizations (12%). In patients harboring a MYD88 mutation, we frequently found a coexisting CD79B mutation (N=141). Patients with a
Background: Nodal peripheral T-cell lymphomas (PTCLs) are a heterogeneous group of neoplasms, which include PTCL not otherwise specified (PTCL-NOS), angioimmunoblastic T-cell lymphoma (AITL), anaplastic large-cell lymphoma (ALCL), anaplastic lymphoma kinase positive (ALK+), and ALCL-ALK-. Clinical assessments before and after treatment are essential to predict survival in nodal PTCL. However, limited data is available regarding the prognostic relevance of National Comprehensive Cancer Network International Prognostic Index (NCCN-IPI) and post-treatment PET-CT scan.

Methods: In this retrospective cohort study, patients with newly diagnosed nodal PTCL were consecutively enrolled from 11 hospitals in South Korea. Patients were eligible if they were histologically diagnosed with nodal PTCL from Jan 2005 to June 2016, received systemic chemotherapy, and had the results of PET-CT scan at the time of diagnosis and at the end of treatment. Post-treatment PET-CT was assessed by Deauville score 1-5.

Results: A total of 396 patients were screened for eligibility. Seventy patients were excluded from the analysis due to following reasons: unavailable pre- or post-treatment PET scans, no systemic treatment, uncertain histology, and ALCL-ALK+. Thus, 326 patients were analyzed. The median age was 61 years (range, 18-86) and 209 (64%) were male. PTCL-NOS (N=172, 53%) was the most common subtype included, and AITL (N=111, 34%) and ALCL-ALK- (N=62, 19%) followed. Fourths of patients (N=242) had stage III/IV. Majority of patients received anthracycline-based therapy. Patients were categorized into low (N=42, 13%), low-intermediate (LI, N=108, 33%), high-intermediate (HI, N=136, 42%), and high (N=40, 12%) risk groups according to NCCN-IPI. Based on the Deauville criteria, post-treatment PET scan was scored as 1 (N=130, 40%), 2 (N=47, 14%), 3 (N=60, 18%), 4 (N=27, 8%), and 5 (N=62, 19%). Because the number of progression in Deauville score 3 (40/60, 67%) was significantly different from score 2 (21/47, 45%; P=0.023) and 4 (24/27, 89%; P=0.030), we stratified patients into 3 groups: Deauville score 1-2, 3, and 4-5. With a median follow-up of 54.7 months (IQR, 30.2-84.5), 5-year PFS rate was 35.7% (95% CI, 30.0-41.4) and OS rate was 47.1% (95% CI, 40.8-53.4%).

NCCN-IPI risk and post-treatment PET-CT scan were independently associated with PFS in the multivariate analysis (for LI NCCN-IPI, hazard ratio [HR] 1.615, 95% CI 1.080-2.431; for HI NCCN-IPI, HR 3.063, 95% CI 1.626-5.769); high NCCN-IPI 4.475, 95% CI 2.231-8.977; P<0.001; for post-treatment Deauville score 3, HR 1.895, 95% CI 1.281-2.801; score 4-5, HR 6.916, 95% CI 4.948-9.667; P<0.001). We stratified patients into 5 groups based on risk of progression: a low (low NCCN-IPI and Deauville score 1-2), INT-1 (low NCCN-IPI and Deauville score 3, or LI NCCN-IPI and Deauville score 1-2), INT-2 (HI NCCN-IPI and Deauville score 1-2), high (high NCCN-IPI and Deauville score 1-2, or LI to high NCCN-IPI and Deauville score 3), and very high (Deauville score 4-5). The risk model showed a strong association with PFS and OS (Figure 1).

Summary/Conclusions: This study proposes a new risk stratification model incorporating baseline NCCN-IPI in combination with post-treatment Deauville score on PET-CT scan in patients with newly diagnosed nodal PTCL.

Results: Median age at diagnosis was 25.5 years (range 16-38 years) and 8/16 patients were male. Median previous line-therapies were 2.5 (range 1-5). In the Intention-To-Treat population which includes 1 patients who died after the first crizotinib dose, 13/16 patients (81.25%, 95% CI 53-95%) achieved an OR and a complete response (CR) after 1 month of therapy, respectively. Median overall survival and progression free survival (PFS) were 7.53 months and 4.57 months respectively (fig 1a). Median time to progression was 50 days (range 47-137 days). OS and PFS for 3 years from treatment were 44%. In 16 patients, 7 patients were still on treatment and in CR (median treatment duration 44 months [range 15-72 months]). There was a significant difference in 3 years PFS between patients in whom CR was obtained after 4 weeks of crizotinib and those who didn’t (PFS at 3 years 87.5% vs 0%, p<0.001-fig 1c); patients with less than 2 previous lines of therapy showed a borderline better 3 years PFS (66% vs 33%, p=0.08-fig 1b). Crizotinib was well tolerated and there were no cumulative adverse events (AEs) over this long-term follow-up. The only G3 AEs reported were transient neutropenia and creatine-kinase elevation. The deep sequencing of 4 NPM-ALK in relapsed patients demonstrated the presence in 2/4 samples of ALK mutations G1269A and C1156Y, which were not present in samples before crizotinib treatment. The level of in vitro resistance of these mutations showed a high level of resistance to crizotinib (resistance index for C1156Y and G1269A: 9.59-15.4 respectively). The sensitivity in vitro of these mutations to ALK-inhibitors was also evaluated: all inhibitors, except alecibib for G1269A, were active with a therapeutic index (TI) >20 (fig 1d). TI values, as previously reported by Mologni L. et al (Oncotarget. 2015 Mar 20;6(8):5720-34), provide a view of the therapeutic impact of a mutation: the bigger the value, the more targetable is the mutation with the inhibitor.

Figure 1.

Figure 1.
Summary/Conclusions: Crizotinib confirmed to be an effective and safe therapy for advanced relapsed ALK+ ALCL, with durable responses up to 6 years after treatment initiation and no relapse later than 4 months. These results represent the longest available safety record for crizotinib. ALK point mutations can develop and 2nd/3rd generation inhibitors may be a therapeutic opportunity for patients who develop resistance to crizotinib.

P571
PRELIMINARY RESULTS FROM AN OPEN-LABEL, PHASE II STUDY OF TIPIFARNIB IN RELAPSED OR REFRACTORY PERIPHERAL T-CELL LYMPHOMA
1Mayo Clinic, Rochester, 2H. Lee Moffitt Cancer Center & Research Institute, Tampa, 3Dana Farber Cancer Institute, Boston, 4Stanford University Medical Center, Stanford, United States, 5DIVAL Instituto de Investigación Marqués de Valdecilla, Santander, 6Fundación Jiménez Díaz, Madrid, Spain, 7Kura Oncology, La Jolla, United States

Background: Tipifarnib is a potent and selective inhibitor of farnesyltransferase (FT). FT catalyzes post-translational attachment of farnesyl groups required for the bone marrow and lymphoid organs and for maintenance of HSCs and immune cell progenitors. TIP12 is known to signal in part through HRAS, a signaling protein that is uniquely farnesylated. Tipifarnib has previously been shown to be well tolerated and to have a 41% response rate (7 responses of out of 17 patients) in patients (pts) with T-cell Non-Hodgkin Lymphoma, including 4 objective responses in 8 pts with peripheral T-cell lymphoma (PTCL) (Witzig et al, 2011). Building on this prior experience, we report herein the preliminary efficacy, safety and biomarker data from our ongoing Phase 2 study in PTCL.

Aims: This Phase 2 study is a multi-institutional, single-arm, open-label, two-stage (11+7) study designed to determine the efficacy and safety of tipifarnib in pts with relapsed/refractory (R/R) PTCL.

Methods: Pts with R/R PTCL after prior cytotoxic systemic therapy, aged ≥ 18 years old, and with a performance status of 0-2 were eligible. Informed consent was obtained. The following subtypes of PTCL were eligible for enrollment: PTCL, not otherwise specified (PTCL-NOS), ALK-positive and -negative anaplastic large cell lymphoma (ALCL), hepatosplenic T-cell lymphoma, enteropathy-associated T-cell lymphoma (EATL), extranodal natural killer (NK) T-cell lymphoma, nasal type and subcutaneous panniculitis-like T-cell lymphoma. The primary endpoint of the study is overall response rate. Secondary endpoints include safety and tolerability, duration of response (DOR) and progression free survival (PFS). Based on activity observed in the first 18 pts in the study, the protocol has been amended and enrollment is ongoing to an expansion cohort in ATIL (N=12). Enrolled pts are treated with tipifarnib 600mg administered orally twice daily on days 1-7 and 15-21 of 28-day treatment cycles until progression of disease or unacceptable toxicity. Biomarker studies included gene expression profiling of pre-treatment tumor biopsies by RNASeq and DNA next-generation sequencing (NGS). Clinical trial information: NCT02464228.

Figure 1.

Results: At data cut-off (2/15/2017), 18 pts (2 ATIL, 1 ALK-ALCL, 15 PTCL-NOS) were treated with tipifarnib. Most common treatment-related AEs (grade ≥ 3) were myelosuppression, including neutropenia (61%), anemia (39%) and thrombocytopenia (39%). 3 pts achieved a partial response (2 ATIL; 1 PTCL-NOS) and 3 additional pts experienced stable disease >6 months. Tumor DNA from 16 pts was sequenced using NGS tools, and all patients achieved ≥ 3'UTR CXCL12 single nucleotide variation (SNV) was observed. Seven of 16 pts carried the rs2389695 variant while an additional patient carried a novel variant. The presence of 3'UTR SNVs was associated with low levels of CXCL12 gene expression and disease progression (Figure). While all pts deriving clinical benefit from tipifarnib carried reference (wild type) 3'UTR CXCL12 and had tumors that expressed high levels of mRNA for this chemokine. Testing of circulating CXCL12 levels is ongoing.

Summary/Conclusions: Although this study is ongoing, these preliminary data indicate that tipifarnib is generally well-tolerated and has antitumor activity, particularly in pts with ATIL histology, absence of 3'UTR CXCL12 SNV and high levels of CXCL12 gene expression.

Background: High-dose chemotherapy before autologous stem cell transplantation (ASCT) is a therapeutic option as a consolidation in primary or relapsed lymphoma. BEAM conditioning is generally used. Alternative conditioning regimens have been published but few data are available.

Aims: To evaluate tolerance and efficacy of the BAM (Busulfan, Aracytin and Melphalan) conditioning before ASCT.

Methods: We conducted a retrospective study in 188 French patients treated between 2000 and 2015. Data were retrospectively collected from the Promise database. Informed consent was obtained from all patients.

Results: Indications for ASCT were diffuse large B-cell lymphoma (n=54, 29%), mantle-cell lymphoma (n=42, 22%), Hodgkin’s disease (n=33, 18%), low-grade non-hodgkin lymphoma (n=26, 14%), T-cell lymphoma (n=17, 9%), Burkitt’s lymphoma (n=8, 4%) and B-cell lymphoma (n=8, 4%). Median age at diagnosis was 50.9 years (35.7-59.9). Tumor stage (ASCT) was 295 days 116 (62%) patients were in complete remission, 54 (29%) in partial remission, 13 (7%) in relapse or progression, and 5 (2%) ND. ASCT was documented in 186 (99%) patients. Median time to neutrophil and platelet (<50 Gigal/L without transfusion) recovery was respectively 11 of 7 days (5-10), was reported in 73 patients, with a maximum toxicity grading of 1-2 (n=43, 59%), 3 (n=21, 29%) or 4 (n=4, 6%) and ND in 5 patients. Only 2 (1%) patients had non-fatal hepatic sinusoidal obstruction syndrome. Pulmonary toxicity was reported in 33 (17.6%) patients with 8 cases of respiratory distress syndrome. Respiratory distress was fatal in one patient but occurred more than 6 months after ASCT and salvage treatment. Seven (3.7%) patients reported secondary cancers (all were solid tumors except one acute leukemia). Median follow-up was 17.1 months [11.3-29.5]. At the time of the study, 47 (25%) patients had relapsed. Cumulative incidence of relapse was 6.24% at 3 months and 17.31% at 12 months. At the end of the follow-up, 149 (79%) patients were alive. The main causes of death were relapse (n=15, 10%) and toxicity (n=16, 13%). Median overall survival (OS) was not reached and progression-free survival was 71.5 months [47-79]. Relapse-free mortality was 1.66% at 3 months and 4% at 12 months. In the univariate analysis, the number of treatment lines (1 or 2) before ASCT and previous use of monoclonal antibodies positively impacted the OS. Conversely, the multiple graft protocol had an unfavorable impact on OS.

Summary/Conclusions: BAM conditioning before ASCT for lymphoma helps to control disease activity without excessive toxicity. It may be a suitable alternative to BEAM in case of drug shortage. However, comparative studies are needed to confirm these findings.
Bone marrow failure syndromes incl. PNH - Clinical

ANALYSIS OF MICRONRANOEME, PROTEOME AND METABOLOME OF EXOSOMES FROM PATIENTS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA
R. Teruel-Montoya1,2, G. Luengo-GIP, F. Vallejo1, E. J. Yuste3, N. Bohdan1, S. Espín2, N. García-Barberá2, C. Martínez4, J. C. Espín3, V. Vicente1,1,2, I. Martínez1,2,4
1Grupo de Investigación CB15/00055, Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Instituto de Salud Carlos III (ISCIII), Madrid, 2Servicio de Hematología y Oncología Médica, Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arrixaca, 3Research Group on Quality, Safety and Bioactivity of Plant Foods, CEBAS-CSIC. 30100, Campus de Espinardo, Murcia, Spain

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a clonal disease caused by the lack of glycosyl inositol phosphatidyl anchored proteins at the cell membrane that leads to intravascular hemolysis upon complement activation. Patients have intravascular haemolysis with high risk of thrombosis, and a variable degree of bone marrow failure. Treatment with Eculizumab reduces intravascular hemolysis and also the thrombotic risk. The mechanism of thrombosis in PNH is still unknown. Exosomes are small vesicles released by cells and whose secretion is closely related with the inflammatory status. Exosomes participate in cell communication by activating signaling pathways and transferring genetic material, i.e. miRNA, and proteins to host cells.

Aims: To describe the microRNAome, proteome and metabolome of exosomes from PNH patients to identify potential biomarkers of the disease and to investigate its relationship with the mechanism of thrombosis in these patients.

Methods: Plasma exosomes were isolated from 5 healthy controls and from 9 PNH patients(6 with Eculizumab, 3 with thrombosis –ET- and 3 without thrombosis –ENT-). Total RNASE and without Eculizumab) using Total ExosomeIsolation kit (ThermoFisher).mRNA from exosomes were purified using Nucleo Spin miRNA Plasma Kit (Macherey-Nagel).miRNA expression was evaluated by plasma/serum focus miRNAs PCR panel V (Exiqon). Proteinic analysis of exosomes was performed at the OMICS core facilities. Untargeted metabolomic analysis was performed by using combination of gas chromatography and liquid chromatography (LC) with mass spectrometry (MS). Additionally, latest advances were used combining LC-MS-solid phase extraction-nuclear magnetic resonance (UPLC-QTOF_SPE_NMR) on line for unequivocal structural elucidation of unknown metabolites.

Results: mir-100-5p, and miR-451a had lower levels in patients vs controls. Eculizumab treatment increased their expression, particularly in the group with thrombosis. Eculizumab also decreased mir-223-3p (the most abundant miRNA in platelets and that has been associated with its reactivity) in 5.0- and 3.12-fold respectively. Those proteins differentially expressed in patients and controls were related with the complement system and the immune response. We identified an increase in the plasma hemoglobin levels in patients vs controls (4.9-fold), which is related with platelet activation. It is also noteworthy the decrease (1.5-fold) of the anticoagulant Protein S in patients vs controls. When the analysis was performed among the 3 groups of patients, only Ig heavy chain V-I region HG3 increased in 3.9-fold in the Eculizumab group vs without Eculizumab group, which could be related with the treatment. Eculizumab treatment increased their expression, particularly in the group with thrombosis. We identified quite few metabolites inside the exosomes, all of them associated with cell toxicity or immune response. The levels of Cholesterol, HydroxyTerbinafine-glucuronide and Diacylglycerol decreased in 17.3, 17.6 and 19.4-fold, respectively in patients treated with Eculizumab. Interestingly, the Aminoethylphosphonic acid, Cholesterol and PGF2 increased 16.7-; 21- and 19.4-fold in patients with thrombosis.

Summary/Conclusions: Our study supports that exosomes contain material that may influence the pathological status of the PNH patients. In concordance, most of the proteins, miRNAs and metabolites are related with the complement system or the inflammatory response. In future experiments, some of the proteins, miRNAs and metabolites should be validated to define whether they could be considered biomarkers.

SEVERE CHRONIC NEUTROPENIA: THE ROLE OF PRIMARY IMMUNODEFICIENCY AS CAUSATIVE AGENTS. A SINGLE CENTER DATA
F. Fioredda1, F. Piferr1, C. Micalizzi1, M. Calvillo1, E. Palmisani1, I. Ceccherini1, A. Gross1, M. Lanciotti1, P. Terranova1, T. Lanза1, M. Miano1, C. Dufour1
1Haematology Unit, 2Molecular Genetic Unit; IRCCS Istituto Giannina Gaslini, Genova, Italy

Background: Severe Chronic Neutropenia may be a primary disease, usually defined as congenital (CN), or a condition mainly secondary to autoimmune disturbances (SN) (1,2). CN rises in early infancy, has a narrow block at pro/myelocyte, classically carries genes ELANE/HAX1 mutations in 70% of cases and is G-CSF dependent. SN is accompanied by extraheamotological signs and/or positivity of autoimmune markers; bone marrow has a normal morphology or is “left shifted”. In spite of these categorization many cases do not fit any group and share features of both of them. These “overlap Neutropenia” (ON) patients are a diagnostic and management challenge.

Aims: Investigate the genetic background of this ON from a cohort of chronic neutropenia subjects screened at Hematology Unit of Gaslini Hospital and characterize their clinical phenotype.

Methods: Patients with severe chronic neutropenia were seen prospectively in our center and diagnosed/followed-up according to published guidelines(3,4). Genetic diagnosis includes classical Sanger technique foe commonest severe chronic neutropenia genes and an enlarged NGS panel including also those genes responsible for PIDs.

Results: From 2008 to 2016, 24 patients (13 males) with median age at last follow of 18yrs (range 28 mo-51y) had a complete work up for severe chronic neutropenia (Table 1). Ten/24 subjects (43%) were diagnosed as classical CN with ELANE mutation found in the majority (80%) of cases. Seven/24 (29%) were diagnosed as SN and the remaining 7/24 (29%)ON patients had a PID genes mutation was found in a total of 8/24 patients (30) with 5 patients belonging to 7 SN subjects (71%) and 3 to the 7 ON subjects (42%).Table 1 shows clinical hematological characteristic of the 3 categories of patients.

Summary/Conclusions: A considerable portion (30%) of subjects affected with severe chronic neutropenia have been identified as PID. In the group of ON subjects a mutated PID gene was found in 3/7 patients and mutations of ELANEin 2/7 patients. No mutation was found in the remaining 2. The phenotype of ON subjects is characterized by extra-hematological autoimmune symptoms, by maturation block and by the frequent involvement of more than one hematopoietic lineage. This phenomenon may suggest to access to an enlarged genetic panel including PID genes for genetic diagnosis. An accurate immunological and genetic work may support diagnosis and management of these difficult cases.

TREATMENT WITH HORSE-DERIVED ANTI-THYMOCYTE GLOBULIN LEADS TO ENDURING HEMATOLOGICAL RESPONSES AND A 1.5-YEAR SURVIVAL PROBABILITY OF 87% IN ADULT ACQUIRED APLASTIC ANEMIA PATIENTS IN THE NETHERLANDS
J. Tjon1, L. de Wreede2, F. Falkenburg1, M. de Grooth3, H. Koene,4

References
Acquired aplastic anemia (AA) is a rare disease characterized by bone marrow failure that results in pancytopenia and hypoplastic bone marrow. Hematopoietic stem cell transplantation (SCT) in SAA patients.

**Methods:**

In this study, we examined immune cell subset counts and immunoglobulins in 81 SAA patients from day 30 to day 365 after haplo-SCT. The immune cells analyzed in this study including lymphocyte, monocyte, CD3+ T cell, CD8+ T cell, CD4+ T cell, CD4+CD8+ T cell, CD4+CD28+ Tcell, CD4+ memory T cell and CD4+ naïve T cells. Simultaneously, we determined which factors influence immune reconstitution and analyzed the effect of immune cell subsect on transplant outcomes.

**Results:**

(i) The reconstitution of different immune cell subsets occurred at different rates after haplo-SCT. Monocytes were the first to recover, followed by CD8+ T and CD19+ B cells, and finally CD4+ T cells. Early CD4+ T cell recovery occurred at the expense of memory cells, whereas naïve CD4+ T cells rose only 9 months after SCT. (ii) In the multivariate analysis, lower recipient age, female gender, high mononuclear cell counts and CD4+ T cell counts in the graft were associated with improved immune recovery after transplant. (iii) A CD4/CD8 ratio less than 0.567 on day 30 post-transplantation was associated with lower treatment related mortality and higher overall survival after haplo-matched SCT in SAA patients.

**Summary/Conclusions:** We provided the kinetics for immune recovery in SAA patients who received haplo-SCT. In general, our study demonstrated that the recovery of monocyte and CD8+ T cells was fast in SAA patients, whereas the recovery of the CD4+ T cell subset was delayed. In addition, our data suggested that the CD4/CD8 ratio may be useful for predicting transplant outcomes in SAA patients after they complete haplo-SCT. Our results may be useful for making better predictions and modulating the IR of SAA patients, which would subsequently improve the outcomes after transplantation.

---

**P578 DEVELOPMENT OF A SCREENING AND DIAGNOSTIC ALGORITHM FOR PAROXYSMAL NOCTURNAL HEMOGLOBINURIA USING A MODIFIED DELPHI PANEL METHODOLOGY**

A. Röth1,*, J. Maciejewski2, J.-I. Nishimura3, D. Jain4, J. Weitz5

1University Hospital Essen, Essen, Germany, 2Cleveland Clinic, Cleveland, United States, 3Osaka University Graduate School of Medicine, Osaka, Japan, 4Alexion Pharmaceuticals, Inc., Cambridge, United States, 5McMaster University, Hamilton, Canada

**Background:** Paroxysmal nocturnal hemoglobinuria (PNH) is a rare clonal hematopoietic stem cell disorder that manifests with hemolytic anemia due to uncontrolled complement activation, bone marrow failure, and thrombosis. Diagnosis is essential because PNH is a progressive disorder associated with substantial morbidity and mortality. The protean clinical manifestations of PNH complicate diagnosis, and subsequently the diagnosis is often delayed or missed. Although national diagnostic guidelines are available, international expert consensus on PNH screening and diagnosis is lacking.

**Aims:** An international panel of PNH experts was assembled to develop a clinically relevant, consensus-driven screening and diagnostic algorithm for PNH.

**Methods:** An expert advisory committee of 4 PNH experts from North America, Europe, and Japan was assembled. Using a modified Delphi methodology, consensus was gained on the symptoms and signs of PNH and the laboratory tests required for screening and confirmation of diagnosis. Globally representative Delphi panelists were identified through a double-blinded screening process and asked to complete 2 rounds of web-based questionnaires. The questionnaires were developed by the expert advisory committee and presented to the Delphi panel in a case-based format. In the first round, Delphi panelists were given 5 blinded case studies—each including details on clinical presen-
tation and past medical history—and were asked to provide their differential diagnosis and the tests they would order to establish the diagnosis in free-text format. To reduce bias, Delphi panelists were blinded to the fact that the study was focused on PNH. Responses mentioned by ≥50% of Delphi panelists in the first round were included in the second-round questionnaire. For each case in the second-round questionnaire, Delphi panelists were presented with a set of 12 clinical consensus statements regarding potential diagnoses and the need for specific tests/data from a multiple-choice list and asked to respond to their level of agreement on a 4-point Likert scale. Consensus in the second round was attained if ≥80% of Delphi panelists agreed on a given screening or diagnostic approach.

Results: Twelve Delphi panelists from 6 countries, all of whom were clinicians with expertise in PNH, were recruited. Consensus was reached on 22 of 23 PNH screening and diagnostic decision points identified by the Delphi panelists. Specifically, consensus was gained on the core symptoms and signs of PNH at presentation, including hemolysis, bone marrow dysfunction, and thrombosis. Clinicians were also in agreement for 36 of 38 screening and diagnostic tests required at each decision point to narrow the differential diagnosis and to confirm the diagnosis of PNH. The level of agreement on screening and diagnostic decision points and tests was sufficient to enable the development of a screening and diagnostic algorithm (Figure 1) that is consistent with the published literature and with the real-world experience of the international expert advisory committee.

Summary/Conclusions: The modified Delphi methodology facilitated development of a consensus-based, clinically relevant PNH screening and diagnostic algorithm. This algorithm provides clinicians with varying levels of expertise detailed guidance on how to screen for and diagnose PNH.

P579
DIAMOND-BLACKFAN ANEMIA IN THE NETHERLANDS: AN OVERVIEW OF CLINICAL CHARACTERISTICS AND UNDERLYING MOLECULAR DEFECTS
B. van Doojewegel1,*, M. Bierings2, A. MacInnes3, M. Bartels4
1Pediatric Haematology, clinical research, 2Pediatric Haematology and Stem Cell Transplantation, Wilhelmina Children’s Hospital, Utrecht, 3Euro DBA, genetics, and 4Pediatric Haematology and Oncology, Wilhelmina Children’s Hospital, Utrecht, Netherlands

Background: Diamond-Blackfan anemia (DBA) is a rare genetic disorder, characterized by bone marrow failure (anemia), congenital anomalies and a predisposition for malignancies. DBA is characterized by a highly heterogeneous nature, both clinically and genetically. Most of our understanding of this disorder stems from molecular studies combined with extensive data-input from international patient registries.

Aims: The aim of our retrospective study was to create an overview of the pediatric DBA population in the Netherlands.

Methods: Forty-four patients (age 0-18yr) diagnosed with DBA from all Dutch pediatric hematology centers included in this study.

Results: Congenital malformations were present in 19/41 patients (46.3%), varying from craniofacial and cardiac defects to urogenital and developmental disorders. An underlying genetic defect was identified in 23 patients (56.1%), the majority of which were found in the RPS19 gene (n=10; 45%). No significant diversities in malformations, course of disease or response to treatment were observed when comparing patients with or without identified genetic defects. In agreement with previous reports, two patients harboring defects in RPL11 displayed a more severe phenotype, including craniofacial malformations, thumb abnormalities, and cardiac defects. In contrast, our patient with a mutation in RPL5 has no associated congenital abnormalities, while previous studies have reported a very high frequency (83%) of associated congenital defects. Furthermore we observed a relatively high number (12/23) of novel mutations in well-known DBA-genes, defined as novel variants. In addition, we have identified a novel 33 kbp deletion in RPL9, in a patient with multiple congenital abnormalities (craniofacial defects, cardiac defects, colitis) in addition to severe anemia. Thirty-four (34/44) patients were treated with glucocorticoids, of which in thirty-one (31/34) patients a complete response was observed (91.2%). However, in 29% discontinuation was prompted by high-dose steroid independence, side effects, a weaning response, or a combination of these factors. Five patients (12.2%) were successfully transplanted with hematopoietic stem cells from either matched sibling donors (n=3) or matched unrelated donors (n=2), including two cases after the age of 10 years. Eleven patients (26.8%) were treatment-independent, defined as acceptable hematopoiesis without any therapy. No malignancies were thus far reported.

Summary/Conclusions: In line with previous reports, the Dutch pediatric DBA population is both clinically and genetically heterogeneous, with RPS19 being the most frequently mutated gene. Interestingly, the majority of mutations in our cohort have not been described before, probably further underlining clinical heterogeneity. In addition, we have identified a novel deletion in RPL9, associated with a more severe phenotype, based on multiple associated congenital defects. While we created a comprehensive overview of the Dutch pediatric DBA population, limitations of our study include a relatively small number of patients, and the lack of complete genetic analysis (for all DBA candidate genes) in a relevant number of patients. Overall, to increase our understanding of genotype-phenotype correlation in DBA, and underlying pathophysiological mechanisms more generally, it crucial to further extend our genetic, and functional analysis of DBA-candidate genes, as well as compare, and share data from international registries.

NEXT GENERATION SEQUENCING IN BONE MARROW FAILURE SYNDROMES
E. Galvez1,*, E. Sebastian1, L. Madero1, A. Catalá2, C. Belendez3, C. Díez de Heredia2, A. Galera1, D. Plaza1, I. Badea1, E. Vallespin4, P. Lupanuzia4, R. Perona5, J. Bueren6, I. Bécerra1
1Hospital Infantil Niño Jesús, Madrid, 2Grupo fallos medulares SEHOP, Barcelona, 3Grupo fallos medulares SEHOP, Madrid, 4Grupo fallos medulares SEHOP, Valencia, 5CIBERER, Madrid, 6CIBERER, Barcelona, Spain

Background: Inherited bone marrow failure syndromes (IBMFSSs) are a heterogeneous group of genetic disorders, with similar clinical presentations, resulting in complex diagnosis. Molecular characterization is essential in order to establish diagnosis, treatment and prognosis. Next-generation sequencing (NGS) techniques seem to be a useful platform for genetically defining different IBMFSSs.

Aims: To design a NGS panel with the objective of making a specific, fast and cost-effective diagnosis for these pathologies.

Methods: We developed a NGS panel of 164 genes involved in different IBMFSS. A total of 120 samples have been processed. Patients were classified into two groups based on the sequence coverage: classified IBMFSS (CBMFS) for those with a clinical picture typical on some of these disorders, and unclassified IBMFSS (UBMFS) for the others. For the NGS study the NextSeq platform of Illumina (Roche) has been used. Bioinformatic analysis has been oriented to the identification of point polymorphisms (SNPs) and insertions / deletions of small DNA fragments.

Results: Of the 120 samples processed, 10% (12/120) was not suitable for analysis. A total of 108 patients were studied. In 59.3% (64/108) causal mutations were detected. From the total samples analyzed (108), 75% (81/108) were included in the CBMFS patient group, obtaining a diagnostic yield of 64.2% (52/81). The remaining 27 patients (25%) were included in the UBMFS group and we found causal mutation in 37% (10/27). Therefore, it remains a percentage of patients without a genetic diagnosis, which seems more evident in the UBMFS group. This could be explained by the fact that the causal gene has not been described or due to the limitations of the technique.

Summary/Conclusions: NGS techniques are a fast and cost-effective option for the diagnosis of IBMFSS patients. In our series, we have reached a diagnosis rate of 93.9%, coinciding with that described in the literature. Undiagnosed patients should be included in new research projects.

P581
APLASTIC ANEMIA PATIENTS WITH MONOCYTE-DOMINANT PNH CLONES HAVE A UNIQUE PRESENTATION AND ARE LESS RESPONSIVE TO IMMUNOSUPPRESSIVE THERAPY
E. Nevill1,*, D. Sanford1, D. Forrest1, D. Hogge1, Y. Abou Mourad1, R. Broady1, M. Bennett1, M. Power1, C. Toozé1, K. Song1, S. Nantel1, S. Narayan1, A. Gerrie1, H. Sutherland1, B. Dala1, T. Nevill1
1Leukemia/BMT Program of BC, 2Division of Hematopathology, Vancouver General Hospital, Vancouver, Canada

Background: Aplastic anemia (AA) is a bone marrow failure syndrome that can be successfully treated with either immunosuppressive therapy (IST) or autologous bone marrow transplantation (BMT). In ~50% of patients (pts) with AA, a clone deficient in glycosylphosphatidylinositol (GPI)-linked antigens—a paroxysmal nocturnal hemoglobinuria (PNH) clone—can be detected (Young, Blood, 2011). In recent years, new sensitive techniques have been developed to test for PNH clones that have primarily focused on evaluating peripheral blood white cells. Neutrophils are routinely tested for expression of GPI with fluorescent aerolysin (FLAER); monocytes may also be analyzed but are not always evaluated in PNH testing. Our centre has previously reported that 60% of PNH positive tests show a higher monocyte clone than granulocyte clone and that there was >10% difference in 20% of these discrepant results (Razavi, ISLH Proceedings, 2015). Whether pts with discordant monocyte and granulocyte PNH clones have different clinical characteristics and/or response to IST has not been reported to date.

Aims: To compare the granulocyte and monocyte PNH clones in pts with AA to determine whether there are differences in clinical presentation and/or response to IST for pts with discordant clone sizes.

Methods: A retrospective review was performed on all patients > age 16 treated with IST. A total of 35 pts were included (with IST), the tertiary referral centre for the Province of BC, between 11/09 and 10/15. All patients had central pathology review and metaplasia cytogenetic analysis that confirmed a diagnosis of AA. High-sensitivity flow cytometry testing with a sensitivity of 0.1% was done on all patients

haematologica | 2017; 102(s2) | 225
to detect the presence of a PNH clone. Granulocytes, monocytes and erythrocytes were interrogated with multi-colour flow panels including CD59 and FLAER. The criteria for determining discordant granulocyte and monocyte clone sizes was dependant upon the absolute size of the smaller clone. For clones 0.1-10%, discordance was defined as when the larger clone was either ≥2 x the smaller clone or at least 1% (absolute value) greater. For smaller clones >10%, the larger clone had to be ≥110% its size. IST was uniform - Cyclosporine (CSA, 2.5mg/kg p.o. b.i.d.), anti-thymocyte globulin (ATG; ATGAM® 40mg/kg IV daily x 4 days) and (Methylprednisolone 1mg/kg/day x 10 days). CSA doses were adjusted to maintain whole blood trough CSA level of 200-300 μg/L for 12-months followed by slow taper based upon hematologic response. Non-responders at 6 months were eligible to proceed to either a second cycle of ATG or BMT, if a suitable donor was available. Severity of AA [very severe (VSAA), severe (SAA) or non-severe (NSAA)] and response to IST [[none, partial (PR) or complete (CR)] were determined according to published criteria (Marsh, Br J Haematol, 2009). Statistical comparisons were done using a standard Chi square analysis.

Results: 30 pts with AA and a PNH clone were identified, 18 females and 12 males with median age of 50.5 years (range 17-71). There were 14 pts with NSAA, 13 with SAA and 3 with VSAA. Responses were seen in 20/30 pts (66.7%) including 13 PR and 7 CR. Six pts relapsed with CSA tapering and 5 responded to intensified IST. 2 pts required Eculizumab after evolving to a class-
PNC phenotype. Six pts underwent BMT for primary non-response and 4 pts have died (2 post-BMT, 1 from complications of AA and 1 from breast Ca); 26 pts remain alive and well with a median follow-up of 48 mos (15-86). There were 17 pts (56%) with concordant granulocyte and monocyte clone sizes (Group 1), 4 pts (13%) had granulocyte-dominant disease (Group 2) and 9 pts (30%) had monocyte-dominant disease (Group 3). Group 3 pts were significantly more likely to have NSAA and showed a trend toward an inferior response rate to IST (Table 1).

Summary/Conclusions: Flow cytometry for a PNH clone is routinely done in AA although it may be important to evaluate both granulocyte and monocyte clone sizes. Pts with a larger monocyte than granulocyte clone size more frequently have NSAA and appear to have a lower response rate to IST. This may have therapeutic implications and could identify a population of pts requiring a unique therapeutic approach.

P582

RESPONSE TO ANTI-THYMOCYTE GLOBULIN (ATG) IN PATIENTS WITH APLASTIC ANEMIA (AA): A SINGLE-CENTRE EXPERIENCE OVER THE LAST 28 YEARS

M. Oelmüller1, F. Alashkar1, D. Herich-Terhürne1, U. Dührsen1, A. Röth1
1Department of Hematology, University Hospital Essen, Essen, Germany

Background: Aplastic anemia (AA) is a rare, usually acquired disorder characterized by bone marrow failure with bi- or pancytopenia and marrow hypoplasia. The classification into the three main subtypes is of prognostic and therapeutic relevance. Depending on disease severity, patient’s age, and the availability of a potential HLA-identical donor, different therapeutic strategies are favored. A immunosuppressive therapy (IST) with anti-thymocyte globulin (ATG) and cyclosporine (CSA) is considered the initial standard treatment. A hematologic recovery is seen in up to 60-70% of the pts following horse-ATG (hATG) treatment, compared to 35-53% in rabbit-ATG (rATG) treated pts, considering hATG as first-line therapy in AA pts.

Aims: As response rates vary according to the different studies and the source of ATG being used, our aim was to retrospectively evaluate response rates in pts with AA receiving IST at the Department of Hematology at the University Hospital of Essen between 1988 until 2015.

Methods: In this single-center, retrospective analysis, approved by the institutional ethics committee of the University Hospital of Essen, data of all pts receiving IST to ATG, according to criteria reported by Camitta et al. 1975, were evaluated in 67 pts with AA (52% (35/67) females; median age 48 years (range 17-89 years)) being treated or monitored at the Department of Hematology between 1988 until 2015. 73% of the pts (49/67) were treated with hATG (ATGAM® (44/49) and Lymphoglobulin®). ATGAM® was administered at a dose of 40mg per kilogram (kg) body weight (BW) per day for 4 days and rATG (Thymoglobulin®) at a dose of 3.5mg/kg BW per day for 5 days, respectively. Pts in both arms simultaneously received CsA (5mg/kg BW) and prednisone (day 1-29).

Results: Following six months after primary ATG therapy, a hematologic recovery was achieved in 66% of the pts (44/67). The hematologic response rate at 6 months was 75% (37/49) for hATG and 39% (7/18) for rATG (p<0.005). Irrespective of the source of ATG we observed no significant difference in respect to gender (females: 71% (25/35) vs males: 59% (19/32)) or in the presence of a PNH clone (GPI-deficient granulocytes (FLAER) 67% (14/21) vs 79% (19/24) in pts with no detectable PNH clones), whereas in pts ≥50 years (yrs) a statistically higher rate in hematologic recovery was observed (≤50 yrs: 84% (31/37) vs ≥50 yrs: 43% (13/30); p<0.001). In primary refractory pts (34% (23/67)) (52%) (12/23) in first-line treated hATG pts vs 48% (11/23) rATG treated pts) a second course with either hATG (3/9) or rATG (6/9) was initiated, achieving an overall hematologic recovery at 6 months in 3 pts (33% (1/3) hATG vs 33% (2/6) rATG treated pts). A disease relapse (median: 13 months after primary ATG therapy) was seen in 11 out of the 44 pts with primary hematologic recovery (25%) (82% (9/11) in first-line treated hATG pts vs two rATG treated pts). A salvage therapy with rATG was initiated in two pts, whereas in one other pt a second course with hATG was started. An overall response following relapse therapy was observed in 33% of the pts (1/3). Four refractory as well as relapsed pts were treated with eltrombopag respectively (final results are still awaited). A secondary HSCT (hematopoietic stem cell transplantation) was performed in 11 out of the 67 pts (16%), either being primary refractory or due to a disease relapse.

Summary/Conclusions: Our data are able to independently confirm the findings of previous studies concerning hematologic recovery rates in pts with acquired AA following IST with ATG by providing further evidence that rATG plus CsA is inferior to hATG plus CsA when administered as a first-line treatment. In addition, we were able to observe in pts ≤50 yrs, irrespective gender, an overall higher hematologic recovery. For this reason, it remains unclear why ATGAM® is still not approved in Germany as first-line therapy in pts with AA, as the only hATG product registered in Europe (Lymphoglobulin®) was withdrawn from the market in 2007.
Chronic lymphocytic leukemia and related disorders - Biology 2

Background: The presence of very low numbers of clonal B cells in peripheral blood (PB) of otherwise healthy individuals (low-count monoclonal B lymphocytic leukemia (MBLlo) is a common finding in the general population. However, the vast majority of clonal B cells from MBLlo subjects show a phenotype overlapping with CLL (chronic lymphocytic leukemia) cells, the former might represent either the normal counterpart of CLL or the earliest stages of the disease. Little information exists about both the clinical outcome of MBLlo subjects and the biological features of their B-cell clones over time.

Aims: To gain insight into the biological and clinical significance of the presence of CLL-like MBLlo clones, we re-evaluated the biological features of clonal B cells and the clinical outcome of MBLlo individuals after 7 years of follow-up.

Methods: The baseline study was conducted in 2008, when 80 out of 639 (12.5%) healthy individuals (>40y) were found to carry at least one PB CLL-like clone. At the same time, 112 MBLlo clones were selected for subsequent analysis.

Results: A total of 64 CLL-like MBLlo clones (median size: 0.44 cells/ul, range: 0.02-767 cells/ul) were detected in PB of the 49 subjects at recruitment (in 15 cases ≥2 B-cell clones were detected in the same subject). In all subjects, B-cell clones persisted at reevaluation, phenotypically identical vs baseline. Interestingly, we found a near-uniform over-expression of MYC, characterized by a variable expression of MYC-related genes involved in protein biosynthesis (NPM1, which are allegedly responsible for cell growth and/or proliferation advantages of NOTCH1-mut CLL).
MICROENVIRONMENT REGULATION OF PROGRAMMED DEATH-1 (PD1) RECEPTOR AND ITS LIGANDS PD1L AND PD2L IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL)

Background: The nuclear periphery, containing the IgH and Igk gene clusters, is a unique compartment comprised of inner nuclear membrane proteins and nuclear lamina. Previous genome-wide and cytological studies revealed the regulatory role for some of these nuclear proteins in higher level genome organisation and gene regulation. In particular, Lamina Associated Domains (LADs) were identified at the nuclear periphery as transcriptionally silent, gene-poor domains that anchor Lamin B1. More recent studies however revealed an important role of LADs in the regulation of gene expression and recombination.

Aims: Given the apparent topological coincidence between LADs and Ig variable clusters, we hypothesised that nuclear lamina might play a paramount role in the dynamics of Ig-encoding variable genome domains. In particular, here we tested whether Lamin B1, a principal LAD-associated component of the nuclear envelope, had any restrictive role on somatic hypermutation (SHM) and the expression of Ig genes. Due to the strong involvement of IgV mutations in the pathogenesis of B-cell malignancies, we also tested whether nuclear lamina is involved in the pathogenesis of germline centre lymphomas and chronic lymphocytic leukaemia (CLL).

Methods: We used BL2 and naïve B cells as in vitro and ex vivo models for somatic hypermutation. ChiP-Seq, ChiP-PCR and ImageStream analyses were performed to establish Lamin B1 genome and nuclear binding dynamics in B cells. RNAi-mediated reduction of Lamin B1 resulted in spontaneous SHM and the nuclear envelope involved in epigenetic chromatin regulation, is reduced in B cells. The impact of Lamin B1 expression was performed in the absence of Lamin B1 in SHM in vitro. For in vivo studies, OVA immunised mice were used to study Lamin B1 dynamics in de novo formed spleen germinal centres. From a translational perspective, paired tissue microarray samples of diagnostic and transformed follicular lymphoma were analysed using immunohistochemistry and image analysis. Finally, comprehensive statistical analysis of CLL8 cohort patients was performed to test whether nuclear lamina was involved in the pathogenesis of CLL.

Results: We have found that genome binding of Lamin B1, a component of the nuclear envelope involved in epigenetic chromatin regulation, is reduced during B cell activation and formation of lymphoid germinal centres. ChiP-Seq analysis of B-cells showed heavy and variable immunoglobulin domains were released from the Lamin B1 suppressive environment when SHM was induced in B cells. RNAi-mediated reduction of Lamin B1 was performed in cellular and in vivo expression of SHM as well as kappa-light chain aberrant surface expression. Finally, Lamin B1 expression level correlated with progression-free and overall survival in chronic lymphocytic leukemia, and was strongly involved in transformation of follicular lymphoma.

Summary/Conclusions: In summary, here we report that Lamin B1 is a negative epigenetic regulator of SHM in normal B-cells and a “mutational gatekeeper”, suppressing the aberrant mutations that drive lymphoma malignancy.
Background: B cell receptor (BCR) mediated signalling is crucial for the pathogenesis of chronic lymphocytic leukemia (CLL). Drugs such as ibrutinib and idelalisib which inhibit BCR associated kinases have proved effective for the treatment of CLL but only suppress the disease without being curative. Some patients have developed resistance to these drugs following mutations, progress on therapy for unknown reasons, or cannot tolerate these drugs due to adverse effects. We have shown that microenvironmental signals (e.g., IL-4) can increase BCR expression and signalling, and can partially reverse the effects of BCR-kinase inhibition. ibrutinib, a drug that is known to determine an impairment of microenvironment, can allow the development of novel drugs that overcome resistance to kinase inhibitors. Cerdulatinib (cerd) is an inhibitor of both Syk (pivotal to BCR signalling) and JAK1/3 (integral for IL-4 signalling). Inhibition of Syk has been shown to induce apoptosis of CLL samples resistant to ibrutinib. Cerd is currently in phase II clinical trials in patients with relapsed/refractory B cell malignancies including CLL.

Aims: To investigate the effect of IL-4 on the regulation of BCR signalling in CLL and how this is modified by cerdulatinib.

Methods: Eighteen primary CLL samples were treated with IL-4 +/- cerd (1µM) and expression of FOXP1, GAB1, PTEN22, SOCS1 and SOCS3 assessed by immunoblotting. The effect of cerd on apoptosis was assessed by flow cytometry and PI/Annexin V staining.

Results: Primary human CLL cells treated with IL-4 for 24hr significantly increased expression of positive regulators of BCR signalling FOXP1 and GAB1 in CLL samples with un-mutated IGHV (U-CLL); no change in expression in FOXP1 or GAB1 was seen in CLL samples with mutated IGHV (M-CLL). There was a 40% increase in PTPN22 expression in IL-4-treated U-CLL samples vs no change in M-CLL. Cerd, at therapeutic concentrations, blocked IL-4 mediated increases in FOXP1, GAB1 and PTEN22 and pSTAT6 (a positive control for IL-4 signalling). After 24hr IL-4 selectively increased expression of the negative regulator of IL-4 signalling, SOCS1 and SOCS3 in U-CLL, but not M-CLL cases, and this could be blocked by cerd. Cerd potently inhibited the expression of other cytokines known to play a role in CLL biology (IL-6, IL-10, IL-15, IL-21, and IFN) which utilise either JAK1 or JAK3 for activation of STAT proteins. IL-4, CD40L and BCR ligation signals to CLL cells in lymph nodes can promote resistance to therapies such as the BCL2-inhibitor venetoclax. We have shown that cerd can overcome IL-4/CD40L induced expression of pro-survival proteins MCL1 and BCLXL and that cerd in combination with venetoclax could induce apoptosis in a synergistic manner in the presence of IL-4/CD40L.

Summary/Conclusions: These results provide evidence that IL-4 may increase BCR signalling by upregulating the expression of positive regulators of BCR signalling in U-CLL and that this can be overcome by cerd. These results support the continued use of cerd in clinical trials for the treatment of CLL, alone or in possible combination with venetoclax.

Background: Ibrutinib is an oral Bruton tyrosine kinase (BTK) inhibitor which has advanced the clinical management of CLL. Ibrutinib binds irreversibly to the cysteine 481 residue of the BTK protein, rendering it inactive. BTK inhibition affects the phosphorylation of other intracellular kinases resulting in an immediate redistribution of CLL cells and subsequent apoptosis. We investigated the impact of ibrutinib on the phosphorylation of upstream and downstream kinases in the B-cell receptor pathway in real time in the IcICLLe study (ISRCTN12650454).

Aims: The IcICLLe trial was a single arm, multi-centre feasibility study of ibrutinib in two cohorts of CLL patients: (A) 20 treatment-naïve (TN) requiring treatment (according to IWCLL criteria); and (B) 20 relapsed/refractory (RR). All patients received continuous oral therapy with ibrutinib (420mg once daily) from registration until disease progression. The primary endpoint of the trial was the proportion of patients achieving minimal residual disease (MRD) negative remission (depletion of CLL ≤0.01% in peripheral blood (PB) & bone marrow (BM)) within 6 months of trial treatment. Exploratory endpoints included the assessment of phosphorylation of intracellular kinases in the B-cell receptor pathway.

Methods: A panel of markers was assessed on PB & BM taken at screening, and 1 & 6 months. PB was also taken at baseline (0 hours), 4 & 24 hours, 7 & 14 days, and 2, 3, 4, & 12 months. The phosphorylation of Syk pY348, Btk pY551, ERK1/2, Akt pS473 was assessed in 4 conditions at each time point: unstimulated +/- ibrutinib, and stimulated with IgM/IgD +/- ibrutinib. 1x10^6 leukocytes were tagged to extracellular antibodies (CD3/CD19) conjugated to fluorochromes. Ibrutinib (10μM) was added to the cells for 30 minutes at 37ºC followed by anti-IgM/IgD stimulation (10μg/ml). The BD phosflow protocol was followed to lyse/fix/permeate the CLL cells. Antibodies to Btk pY551, Syk pY348, ERK1/2 pT204/pY204, Akt pS473 were used tagged to fluorochromes (from BD Biosciences). Cells were acquired on a BD Fortessa flow cytometer.

Results: The phosphorylation of Btk, Syk, Akt and ERK1/2 was analysed in cells at the specified time points and conditions for 20 TN and 20 RR CLL patients. Baseline phosphorylation of all kinases was similar in both PB & BM. Phospho-Btk showed no stimulation on addition of IgM/IgD 4h after initiating therapy. There was a strong (2-4 fold) increase in phosphorylation of Syk kinase with IgM/IgD even in the presence of ibrutinib in vitro. This effect was profound in the first 2 months of ibrutinib therapy with a general decrease in phosphorylation after 6 months. Baseline stimulation of ERK1/2 gave a 1-5 fold increase in phosphorylation but the effect was abrogated within 1 month of ibrutinib therapy. Akt pS473 phosphorylation was maintained after 6-12 months of therapy although the degree of phosphorylation decreased at later time points. Syk, Akt and ERK1/2 phosphorylation was unaffected by the addition of ibrutinib in vitro. The pattern of phosphorylation was found to be relatively consistent in responding patients. One patient with progressive CLL had sustained phosphorylation in all markers despite ibrutinib therapy.

Summary/Conclusions: The effect of ibrutinib on the phosphorylation of various kinases in the B-cell receptor pathway was analysed in real time. Syk continued to be phosphorylated over the course of treatment, which is logical as this kinase is upstream of Btk. That the degree of phosphorylation declined over time (even with stimulation) suggests a general inhibitory effect of ibrutinib on CLL cells. ERK1/2 phosphorylation is effectively blocked and there is partial reduction of phosphorylation of Akt pS473. Combinations of Btk inhibitor with a Syk or PI3 kinase inhibitor may result in complete BCR blockade. Phosphorylation patterns may also act as an adjunct to ascertain the response to therapy.
Background: Chronic myeloid leukemia (CML) is a myeloproliferative disease which arises in a haemopoietic stem or multipotent progenitor cell with the t(9;22)(q34;q11) chromosomal translocation. Tyrosine kinase inhibitors (TKIs) have been developed to target the constitutively active oncoprotein BCR-ABL, which is expressed as a result of this translocation. TKI therapy has significantly improved patient survival, however predicting response to therapy is one of the unmet clinical challenges in CML. Moreover, TKIs are unable to target the leukemic stem cells (LSCs) which drive the disease; persistence of the LSCs therefore remains a major obstacle to cure CML. Understanding the mechanisms that LSC employ to survive TKI treatment is necessary to design essential therapeutics to eliminate CML in the future.

Aims: To identify genes with predictive value for TKI response and to determine the efficacy of drug targeting one of the key pathways identified.

Methods: Microarray, Fluidigm, Real-time PCR, FACS based cell cycle and Annexin V apoptosis analysis, Trypan blue exclusion cell counts.

Results: Analysis of bulk CML patient microarray data (GSE 47927) identified 323 deregulated genes either in the stem cell population or during disease progression which are important for self-renewal, DNA damage response, cell cycle arrest and survival. These genes were validated in 60 samples from the SPIRIT 2 clinical trial [a multicentre phase III randomised trial comparing the TKI imatinib (400mg daily) versus Dasatinib (100mg Daily)] with 18 months follow-up data regarding molecular response to TKI treatment. Patients were stratified as good/intermediate or poor responders to TKI and the gene signature significantly differentially expressed was identified. These data highlighted the DNA repair genes as having potential predictive value, in particular, the minichromosome maintenance (MCM) protein and origin of replication (ORC) family of genes, involved in DNA replication and cell cycle regulation. Single cell analysis of CD34+ cells across the patient cohort identified considerable heterogeneity of expression of MCMs and ORCs, with ORC3, in particular, exhibiting a different expression profile in good/intermediate/poor responders (n=3 of each). In addition single cell analysis highlighted a significant difference in the expression of MCM2, -4, -7 & ORC2 in the most primitive LSC (CD34+38−90+r+93−) compared to CD34+38−90+r+93− cells. Next, we investigated the ability of heliophycinum (HQ), a potent helicase inhibitor of MCM on its own and in combination with IM to target the CML cell line K562. Our extensive dose and time response studies followed by FACS-based apoptosis and cell cycle analysis prove the potency of HQ and its synergistic action in combination with Imatinib. We also investigated the changes in all of cell cycle and DNA damage response genes at the transcript level in response to HQ and imatinib in the K562 cell line. Overall the data generated indicates that targeting the MCM pathway in combination with BCR-ABL inhibition is a rational approach for future therapeutic intervention in CML.

Summary/Conclusions: Global ‘omics’ experimental approaches are valuable for identifying novel pathways deregulated in CML. This combined with single cell ‘omics’ studies enable the heterogeneity of gene expression and the response of individual LSCs to TKI to be evaluated. Our data indicate that the DNA replication pathway plays an important role in CML, with levels of MCMs and ORCs having potential predictive value in TKI response and are a promising drug target in CML.
cell division and telomere length (TL) in peripheral blood cells has been shown to correlate with disease stage, response to treatment and duration of CP in CML patients. However, the use of TL as a routine clinical biomarker in CML has been complicated by considerable inter-individual, mostly genetic variability in TL ideally requiring non-clonal control cells.

Aims: Based on these considerations, we used a modified Q-FISH technique in a clinical trial of patients treated with BCR-ABL+/- LSC or BCR-ABL- control cells within the CD34+38- hematopoietic stem cell compartment of diagnostic patients with CML in CP.

Methods: 15 patients (median age: 59 years; range: 41-72 years) diagnosed with CML in CP of the NCT00852566 study (Nordic CML Study Group) were re-processed for BCR-ABL staining using confocal microscopy. Samples were re-processed for TL analysis by Q-FISH using established protocols. TL staining was analyzed in all previously captured cells allowing the identification of BCR-ABL+/-cells within the same sample. Analysis and quantification of BCR-ABL FISH staining and TL measurement by Q-FISH were performed in blinded fashion.

Results: Overall, we observed significantly shortened TL in the BCR-ABL+ compared to BCR-ABL- cells (4.9 arbitrary units (a.u.) range: 53.7 to 16.9 a.u., p=0.04). Next, we correlated the clone size (i.e. the proportion of BCR-ABL+ positive cells within the CD34+38- compartment) with the degree of telomere shortening in LSC. Mean clone size of the patients was 59.9 ± 32.0 % S.D. Of note, we found a significant negative correlation (R²=0.36, p=0.02) between TL and clone size strongly supporting the notion that increased expansion of the BCR-ABL+ LSC pool leads to accelerated telomere shortening. Correlation with clinical data (Hasford score (R²=0.07, p=0.01) or Sokal (R²=0.04, p=0.38) score) did not reveal any statistically significant correlation with the degree of telomere shortening probably due to the small sample size analyzed in this pilot study.

Summary/Conclusions: In this study, we provide further evidence for accelerated telomere shortening in BCR-ABL+ LSC as compared to their normal CD34+CD38- counterpart in CP CML samples at diagnosis. Interestingly, the degree of TL shortening linearly correlates with the clone size of the BCR-ABL+ LSC compartment. Thus, this retrospective study (now on the LSC level) further supports a role of TL as a prognostic and predictive biomarker in newly diagnosed patients with CML pending confirmation in prospective trials.

GENOMIC CHARACTERIZATION OF CML AT DIAGNOSIS REVEALS PREEXISTING SOMATIC MUTATIONS THAT MAY PREDICT PROGRESSION TO BLASTIC PHASE INDEPENDENTLY OF BCR-ABL1 MUTATIONS
1Department of Immunology, Postgraduate School of Molecular Medicine, Medical University of Warsaw, 2Department of Diagnostic Hematology, Institute of Hematology and Transfusion Medicine, Warsaw, 3Department of Hematopathology, The University Hospital, Cracow, 4Department of Hematology, Institute of Hematology and Transfusion Medicine, Warsaw, 5Department of Hematology, University of Bonn, 6Department of Internal Diseases and Hematology, Military Institute of Medicine, 7Department of Hematology, Oncology and Internal Diseases, Medical University of Warsaw, 8Department of Pathology and Laboratory Diagnostics, Maria Sklodowska-Curie Memorial Cancer Center and Institute, 9Department of Medical Genetics, Medical University of Warsaw, 10Department of Molecular Biology and Immunology, Fels Institute for Cancer Research and Molecular Biology, Temple University School of Medicine, Philadelphia, United States

Background: Blastic phase of chronic myeloid leukemia (BP-CML) remains mostly incurable even with newer generation tyrosine kinase inhibitors (TKI) and represents an unmet clinical need. Although in recent years a dramatic reduction in the transformation of chronic phase (CP-CML) to BP-CML has been observed, still up to 5% of patients will progress to BP-CML despite treatment with TKI. Prospective identification of such patients may have a significant clinical impact. There are only few reports to date that use next-generation sequencing (NGS) to look for somatic mutations - other than those affecting kinase domain of BCR-ABL1 - at the time of diagnosis (Dx) which could have a prognostic/predictive value.

Aim: We analyzed the mutational spectrum of somatic mutations in two groups of CML patients with clinically different disease course: first group (BP) comprised of 11 patients who progressed to BP-CML despite treatment with TKI and/or allo-HSCT (one patient died and paired samples from Dx and BP were analyzed); second group (MMR) included Dx samples from 36 patients who achieved major molecular remission (MMR) and TKI within 6 months and remained in MMR for at least 48 months from Dx.

Methods: Targeted enrichment strategy using custom designed capture probes (SeqCap EZ, Roche NimbleGen) followed by NGS on Illumina platform was performed in large genomic databases and our internal database were filtered out and the subsequent analysis was focused on putative protein damaging variants, supported by variant effect prediction tools such as PolyPhen-2, SIFT or CHASM. All reported variants were reconfirmed by Sanger sequencing.

Results: The BP group comprised of paired samples from 11 CML patients who progressed to BP and died despite treatment with TKI. Median age at diagnosis was 53y (range 26-77), median time to progression for 9 patients (2 were diagnosed in accelerated phase or BP) was 17.5 months (mo) (range 4-108) and median survival was 22 mo (range 10-116). None of those patients harbored BCR-ABL1 mutation at the time of Dx and progression to BP-CML, 4 patients had additional chromosomal alterations at progression to BP including two frequent (trisomy 8 and monosomy 7). Targeted enrichment followed by NGS allowed us to achieve deep coverage (>80x) of all genes. Number of rare variants was 26 (range 18-38) and 29 (range 23-32) for DxC and progression samples respectively. In BP samples we detected new and previously described mutations in selected genes, which are frequently mutated in myeloid malignancies, namely in RUNX1 (36%, 4/11), DNMT3A (27% 3/11) IDH1/IDH2 (18%, 2/11) and ASXL1 (18%, 2/11). In 5 patients (54%, 6/11) mutations in these genes (excluding IDH2, detected only in BP sample) were preexisting at the time of Dx. These results were compared to second, control group that comprised of diagnostic samples from 36 patients (median age at diagnosis 53y, range 23-75) who were optimal responders to TKI and remained in MMR for at least 48mo (median time in MMR: 73o, range 45-128). In MMR group, the median number of rare variants was lower than in BP group (13 in Dx samples, range 4-14). Additionally, in 2 patients (25%, 5%) frameshift mutation in ASXL1 (p.Gly643_Gly644fs) was detected, identical as in one of BP patients. Additionally, one patient harbored RUNX1 mutation (p.Arg201Gln) which was not detected in the BP group.

Summary/Conclusions: Our results provide new insights into the already complex genomic landscape of CML. We suggest that a significant number of patients with poor disease outcome may harbor preexisting mutations in DNMT3A, RUNX1 and IDH1. In contrast, mutations in ASXL1 may be present at Dx in patients who will remain in long-term remission.
of the KYN/TRP ratio to BCR-ABL transcript levels. Patients having a high KYN/TRP ratio (≥ mean +2SD of post therapy levels) reach deep molecular response rates (i.e. MR≥4) significantly earlier and at higher rates. Moreover, combining KYN/TRP with scD62L levels, a recently identified predictive biomarker, resulted in a score robustly predicting the odds of achieving deep molecular response.

Summary of Conclusions: CML diagnosis in CP is linked to an increased inflammatory status, as shown by increased levels of sIDO and its metabolites kynurenine leading to an increased KYN/TRP ratio. In solid cancer increased IDO expression/activity is linked to inferior outcome by favoring immune evasion. In contrast, in CML an increased KYN/TRP ratio is associated with improved outcomes, how they do so is not yet understood. The reason could be that high IDO activity may reflect endogenous IFN-α production, a known factor favoring immune-mediated CML-control. The predictive potential of KYN/TRP is currently verified in an independent cohort.

BCR-ABL1 COMPOUND MUTANTS DISPLAY DIFFERENTIAL AND DOSE-DEPENDENT RESPONSES TO PONATINIB
K. Byrgazov1,2, C. Lucini1, D. Printz1, M. Koening1, P. Valenti2, O. Hantschel3, T. Lion1
1Children’s Cancer Research Institute, 2Medical University of Vienna, Vienna, Austria, 3Swiss Institute for Experimental Cancer Research, Lausanne, Switzerland

Background: Despite the dramatic improvement of prognosis in CML patients due to the introduction of tyrosine kinase inhibitors (TKIs), resistance to therapy occurs in a considerable proportion of patients. The best-characterized mechanism of resistance is the acquisition of mutations in the BCR-ABL1 tyrosine kinase domain (TKD) affecting TKI binding. The third-generation TKI ponatinib exerts strong anti-neoplastic effects even in advanced CML stages and is capable of suppressing the kinase activity of BCR-ABL1 carrying any single mutation including T315I. Nevertheless, resistance to ponatinib can evolve in sub-clones carrying BCR-ABL1 variants with two or more mutations on the same allele. The IC50 values for this TKI exceed the maximum achievable effective plasma levels (eCFαave). These co-called compound mutations (CMs) are associated with increased oncogenic potential in comparison to individual mutations, and represent a powerful mechanism of potential resistance to all currently available TKIs. The occurrence of compound mutations has been linked particularly to sequential TKI therapy, therefore, to implement testing of the IC50 for ponatinib to prevent severe side effects should carefully consider the presence of CMs. The aim of our study was to assess the effect of BCR-ABL1 compound mutations on the sensitivity to ponatinib in vitro, we have introduced all BCR-ABL1 CMs into Ba/F3 cells using a recently developed multi-plate format. We report here the results of the study.

Methods: We have established a BCR-ABL1 protein model facilitating assessment of the presumptive impact of 27 different CMs involving important functional sites of the BCR-ABL1 TKD, and including constellations expected to display high resistance to ponatinib. To assess the anticipated responses to ponatinib in vitro, we have introduced all BCR-ABL1 CMs into Ba/F3 cells using a recently published transposon-based approach (Byrgazov et al., Oncotarget 2016, 7(47):78083-78094), and IC50 were derived from dose-response curves and plotted against the ECFαave values of the single mutations.

Results: Most CMs involving sites with no previous evidence for implication in resistance to ponatinib displayed IC50 values below 10 nM. This ECFαave is readily achievable even with the 15mg daily dose of ponatinib. CMs revealing elevated resistance to ponatinib in vitro almost invariably included T315I or F317L mutations. While most CMs involving T315I revealed very high IC50 values, some of the predicted compound mutations containing F317L displayed an IC50 for ponatinib in the range of the ECFα achievable only with a daily dose of 45mg. These observations are supported by clinical findings in the PACE trial which revealed impaired responses of patients with CMs involving F317L who had received average daily doses of ponatinib below 45mg (Deininger et al., Blood 2016, 127(6):703-12).

Summary/Conclusions: Current strategies that aim at decreasing the dose of ponatinib to prevent severe side effects should carefully consider the presence and type of mutations in the BCR-ABL1 TKD to enable effective treatment. It would be highly desirable, therefore, to implement testing of the IC50 for ponatinib and drug concentrations and monitoring the kinetics of mutant subclones covering also compound mutations in the routine diagnostic surveillance to provide a basis for optimized clinical management of patients treated with ponatinib.

IS THERE EFFECTIVE IMMUNE SURVEILLANCE AGAINST CHRONIC MYELOID LEUKAEMIA? NO
R.P. Gale1,2, G. Opelz2
1Haematology Research Centre, Imperial College London, London, United Kingdom, 2Institute of Immunology, University of Heidelberg, Heidelberg, Germany

Background: Immune surveillance refers to a process whereby the innate and adaptive immune systems recognize and eliminate cancer cells on the basis of cancer-specific or related antigens or other molecules. Substantial data support the concept of immune surveillance in rodents but data in humans are less convincing and apply mostly to virus-induced cancers. However, considerable data indicate a strong anti-leukaemia effect in persons with chronic myeloid leukaemia (CML) receiving an allogeneic haematopoietic cell transplant. Most, if not all, of this anti-leukaemia effect is confounded with graft-versus-host disease (GVHD) and whether there is an allelogeneic or host specific anti-leukaemia effect distinct from GVHD is controversial. Another interesting observation is about 40 percent of persons with CML and a deep molecular response to tyrosine kinase-inhibitors (TKIs) remain in molecular remission when TKI-therapy is stopped. Because TKI-therapy is very unlikely to eradicate every CML cell, some ascribe this therapy-free remission (TFR) a result of immune surveillance. Immune surveillance refers to a process whereby the innate and adaptive immune systems recognize and eliminate cancer cells on the basis of cancer-specific or related antigens or other molecules. Substantial data support the concept of immune surveillance in rodents but data in humans are less convincing and apply mostly to virus-induced cancers. However, considerable data indicate a strong anti-leukaemia effect in persons with chronic myeloid leukaemia (CML) receiving an allogeneic haematopoietic cell transplant. Most, if not all, of this anti-leukaemia effect is confounded with graft-versus-host disease (GVHD) and whether there is an allelogeneic or host specific anti-leukaemia effect distinct from GVHD is controversial. Another interesting observation is about 40 percent of persons with CML and a deep molecular response to tyrosine kinase-inhibitors (TKIs) remain in molecular remission when TKI-therapy is stopped. Because TKI-therapy is very unlikely to eradicate every CML cell, some ascribe this therapy-free remission (TFR) a result of immune surveillance.
Methods: To test these hypotheses, we studied whether there was an increased incidence in CML in persons receiving immune suppression, after solid organ transplants. IF immune surveillance is important in CML we would expect an increased incidence in this setting. We used a dataset from the Collaborative Transplant Study (CTS) which collects information on recipients of solid organ transplants beginning in 1985 from >300 transplant centers worldwide. Cancer incidence data were checked annually by questionnaire. Data for expected CML incidence were obtained from a cohort of identical size matched for age and sex from Cancer Incidence in Five Continents monitored for the same duration as the transplant cohort. Data collection and processing were approved by the Data Protection Agency in Germany and all participating centers worked with ethical and privacy regulations. The CTS dataset consisted of 441,332 recipients of kidney (N=355,606), liver (N=47,846) and heart (N=37,880) transplants. Amongst kidney transplant recipients the standardized incidence ratio (SIR) for developing CML was 1.54 (95% confidence interval, 1.1, 2.1; p=0.01) representing 39 cases in 1,682,491 person-years at risk (33 cases). Amongst liver transplant recipients the SIR was 1.72 (0.6, 4.0; p=0.34) representing 5 cases in 182,833 person-years at risk vs. 3 expected (2 excess cases). Amongst heart transplant recipients the SIR was 3.47 (1.8, 6.1; p=0.0005) representing 12 cases in 173,015 person-years at-risk vs. 3 expected (9 excess cases). Data from recipients of kidney and liver transplants suggest immune suppression does not increase risk of developing CML or does so very slightly. The increase in SIR in kidney graft recipients is generally attributed to increased cancer surveillance including blood testing. Although the SIR of CML was substantially-increased after heart transplants, these persons receive high doses of ionizing radiations for diagnostic and therapeutic procedures such as computer tomography (CT)-angiography. Ionizing radiations are a proved cause of CML which may explain the increased SIR.

Results: Our data, 25 excess cases of CML in 2,038,339 person-years at risk observation suggest the magnitude of immune-surveillance do not support the hypothesis that immune surveillance operates to an important extent to prevent CML in humans.

Summary/Conclusions: Consequently, the anti-leukaemia effect associated with allotransplants and the TFR observed after stopping TKI-therapy is unlikely to result from effective immune surveillance against CML.

P598 MUTATIONAL ANALYSIS IN BCR-ABL1 POSITIVE LEUKEMIA BY DEEP SEQUENCING BASED ON NANOPORE MINION TECHNOLOGY

C. Minervini1, C. Cumbo1, P. Orsini1, L. Anelli1, A. Zagaria1, A. Minervini1, N. Coccaro1, G. Toti1, L. Impera1, A. Russo Rossi1, A. Ricco1, C. Brunetti1, P. Casieri1, G. Specchia1, F. Albano1, 1Haematology - University of Bari, Bari, Italy

Background: In newly-diagnosed chronic phase (CP)-CML patients, 15–30% who start first-line tyrosine kinase inhibitors (TKIs) therapy will not reach an optimal response, and a BCR-ABL1 kinase domain (KD) mutation will be detectable in 25–50% of patients with treatment failure with an increased frequency of these mutations observed in accelerated phase and blast crisis patients. Currently, Sanger sequencing (SS) technique analyzing BCR-ABL1 is considered the gold standard for mutation detection knowing that this assay have a sensitivity of around 20%, and therefore is unsuitable for identifying low-level variants (<20% variant frequency). Recently next generation sequencing (NGS)-based assays have been reported for detecting BCR-ABL1 KD mutations; although these NGS strategies are more accurate and precise than SS, they are burdened by costs related to the initial investment, that is the sequencer purchase, the preparation of specific targets libraries, and the required reagents. MinION is a single molecule sequencer connected to a laptop through a USB3.0 interface, based on nanopore technology; it works by connecting two strands of DNA molecules by a hairpin, and sequencing them consecutively.

Aim: To describe a third-generation sequencing assay on MinION for detecting BCR-ABL1 KD mutations and compare the results to a SS-based test in 24 Ph+ leukemia cases.

Methods: Overall, 24 patients were included; among them, 12 (11 CML and 1 ALL cases) developed treatment resistance during the TKI’s treatment course (Group A) and 12 (10 CML and 2 ALL cases) were observed in chronic phase (Group B) and no mutation was detectable by SS technique (33.4%) in MR5.0. On the other hand, of the 19 negative samples with the “LabNet” method, 2 (11.1%) were in MR4.0, 10 (55.5%) in MR4.5 and 6 (33.4%) in MR5.0. For the same duration as the transplant cohort. Data collection and processing were approved by the Data Protection Agency in Germany and all participating centers worked with ethical and privacy regulations. The CTS dataset consisted of 441,332 recipients of kidney (N=355,606), liver (N=47,846) and heart (N=37,880) transplants. Amongst kidney transplant recipients the standardized incidence ratio (SIR) for developing CML was 1.54 (95% confidence interval, 1.1, 2.1; p=0.01) representing 39 cases in 1,682,491 person-years at risk (33 cases). Amongst liver transplant recipients the SIR was 1.72 (0.6, 4.0; p=0.34) representing 5 cases in 182,833 person-years at risk vs. 3 expected (2 excess cases). Amongst heart transplant recipients the SIR was 3.47 (1.8, 6.1; p=0.0005) representing 12 cases in 173,015 person-years at-risk vs. 3 expected (9 excess cases). Data from recipients of kidney and liver transplants suggest immune suppression does not increase risk of developing CML or does so very slightly. The increase in SIR in kidney graft recipients is generally attributed to increased cancer surveillance including blood testing. Although the SIR of CML was substantially-increased after heart transplants, these persons receive high doses of ionizing radiations for diagnostic and therapeutic procedures such as computer tomography (CT)-angiography. Ionizing radiations are a proved cause of CML which may explain the increased SIR.

Results: Our data, 25 excess cases of CML in 2,038,339 person-years at-risk observation suggest the magnitude of immune-surveillance does not support the hypothesis that immune surveillance operates to an important extent to prevent CML in humans.

Summary/Conclusions: Consequently, the anti-leukaemia effect associated with allotransplants and the TFR observed after stopping TKI-therapy is unlikely to result from effective immune surveillance against CML.

P599 THE AUTOMATED MOLECULAR TECHNIQUE “ULTRA” ALLOWS A SENSITIVE AND ACCURATE BCR-ABL1 QUANTIFICATION IN PATIENTS AFFECTED BY CHRONIC MYELOID LEUKEMIA

Orsola-Malpighi”. University Hospital, Bologna, Italy, Bologna, 5Department of Clinical Medicine and Surgery University of Naples Federico II CEINE-Advanced Biotechnologies Napoli, Italy, Napoli, 6Department of Clinical and Biological Sciences University of Torino, Torino, 7Hematology Molecular Laboratory AOUP, Pisa, Italy, Pisa, 8Department of Clinical and Biological Sciences University of Torino, Torino, 9Department of Clinical Medicine and Surgery, University Federico II of Naples, Naples, Italy, Napoli, Italy.

Background: The chronic myeloid leukemia (CML) is characterized by the presence of the Philadelphia chromosome and the BCR-ABL1 fusion gene. The production of tyrosine kinase inhibitors (TKIs) significantly improved the survival, but 15% of patients don’t reach the optimal responses at the defined end-points or develop secondary resistance. The 2013 ELN guidelines identified as fundamental the early molecular response (BCR-ABL1/ABL1 % ≤10% IS), the MR3 (<0.1%) and the deep molecular response (MR4<0.01%, MR4.5<0.005%, and MR5<0.001%). Consequently, the molecular monitoring plays a crucial role in the clinical management of CML patients, with a consequent research of sensitive and standardized molecular techniques. The automated methods offer advantages in terms of reduced time for analysis, decreased manual steps, and reduction of possible errors and contamination. According to the American Society for Quality Control Technology (ASQCT) manual real-time PCR techniques standardized in the Italian network (57 centers), according to the European guidelines [Cross N, 2015]. We compared the sensitivity of the two methods (based on the number of ABL1 detected copies), the classification of molecular responses, with particular attention to the deep molecular subgroups.

Methods: We assessed the BCR-ABL1 transcript in 86 patients afferent to laboratories of Pisa, Napoli, Torino, and Bologna (Italy). For statistical analysis, the t-, the Pearson’s and the Cohen’s K test were adopted. Because our patients presented different transmural levels from the 10% to the 0% (MR4, MR4.5, MR5) the two techniques have been compared in the different molecular subgroups.

Results: Firstly we compared the number of detected ABL1 copies, that are fundamental for definition of the molecular response categories, especially for the main end points or develop secondary resistance. By the “LabNet” method, 51 (81%) samples exceeded the 100,000 copies of ABL1, while by the automated method 81 samples (94.2%) reached >100,000 ABL1 copies. Then, we compared the two methods in discriminating positive and negative samples (K Cohen=0.690; p<0.02). 77 samples were concordant (89.5%) and only 9 (10.4%) were discordant. Of the 18 negative samples with the “LabNet” method, 2 (11.1%) were in MR4.0, 10 (55.5%) in MR4.5 and 6 (33.4%) in MR5.0. On the other hand, of the 19 negative samples with the method “Ultra”, 1 (5.3%) was in MR4.5 and 18 (94.7%) in MR5.0, confirming the higher sensitivity of the automated method. In the cohort of positive cases by the two methods, the median values of transcript expression were superimposable (p=0.55) and the linear regression coefficient was very satisfying (Pearson’s r=0.9399; p-value <0.0001). Finally we compared the results produced by the two methods according to the “molecular classes” (MR1 vs MR2+MR3 vs MR4+MR4.5 vs MR5). This comparison showed a good concordance of the results in all the transmural levels in the study. In conclusion, our findings demonstrated high concordance between “Ultra” and “LabNet” methods using assay comparison criteria proposed by Müller et al. [Leukemia 2009] (Table 1).
Summary/Conclusions: In a huge series of patients the automated and manual molecular methods, applied in 4 different laboratories, resulted comparable in classification of patients in “molecular classes”. The advantage of the “Ultra” technique is represented by the higher number of detected ABL1 copies and the easier standardization.

ROLE OF THE AURORA KINASE A/PLK1 AXIS INHIBITION IN RESTORATION OF CELL GROWTH CONTROL OF CHRONIC MYELOID LEUKEMIA PROGENITORS

M. Mancini1,*, S. Soverini1, S. De Santis1, C. Monaldi1, F. Castagnetti1, L. Bavaro1, M. Martelli1, G. Giugliotta1, G. Rostl1, M.A. Santucci1, M. Cavo1, G. Martinelli1

1Istituto di Ematologia Seràgnoli-DIMES, Bologna, Italy

Background: Cell response to stress is a central component of genomic stability. The integrity of signaling pathways involved in cell cycle arrest, chromatin remodeling and DNA repair, are critical for the maintenance fidelity of replicated DNA. In this context, Gadd45 proteins function as stress sensors and de-transcription regulators. Gadd45α, in particular, intervenes in G2/M checkpoint induction and DNA repair, and it is required for efficient coordination of centrosome duplication hence preventing abnormal mitosis and aneuploidy. Such evidences let assume a putative role of Gadd45α in cancer development and progression, supporting the hypothesis that Gadd45α interacts with Aurora Kinase A (AKA), a key component of centrosome cycle and polar spindle assembly required for regulated progression from G2 to mitosis and throughout M. AKα is a member of a serine-threonine kinase family active during mitosis and it is frequently overexpressed in human cancers where correlates with a poor prognosis. Notably, AKα overexpression is always associated with defects in centrosome duplication, bipolar spindle and chromosomal segregation and aneuploidy, suggesting that it may enhance other oncogenic events by promoting genomic instability, one major trait of chronic myeloid leukemia (CML). Our aim is in the identification of a new molecular target able to control AKα activity. AKα cooperates with the constitutive activity of Bcr-Abl fusion protein by increasing DNA damage, promoting the occurrence of additional genomic alterations and driving TKIs resistance and disease progression to blast crisis.

Aims: Here we investigated AKα and Plk1 role in CML hematopoietic progenitor survival as potential targets to eradicate the transformed clone.

Methods: K562 cell line is a human cell line generated from a CML patient in blast crisis. Drug resistance was induced in K562 cell line by the exposure to progressively increasing doses of Imatinib (IM). It was validated by dose response curves showing a significant difference in LD50 of IM-sensitive and IM-resistant cells. By mean of cytofluorimetric and immunofluorescence microscopy analyses we investigated the events leading to AKα/Plk1 deregulation. Protein expression and activation were detected by western blotting and immunoprecipitation. Apoptotic cell death was measured by using an Annexin V/PI staining; cell cycle distribution was observed by PI staining and subsequent cytokinfluorenct analysis.

Results: Preliminary experiments were aimed to determine whether IM resistance in a BCR-ABL1 cell context is associated with the over-expression and hyper-activation of AKα/PLK1 axis. In our in vivo model drug resistance was associated with increased expression and phosphorylation of AKα (Y282) and Plk1 (T210). 24h exposure to IM significantly reduced expression and phosphorylation of both proteins in parental K562, but not in IM-resistant K562, indicating that AKα and Plk1 activation is only partly dependent on BCR-ABL1 TK activity. Subsequent experiments showed that the inhibition of AKα and Plk1 is in response to specific inhibitors (Danusertib and Volasertib respectively) was associated with:

- significant increase of gadd45α expression levels;
- reduction of cell survival;
- G2/M checkpoint arrest.

The findings support the role of AKα/PLK1 inhibition in restoration of signals involved cell growth control and apoptosis.

Summary/Conclusions: The advantage of using AKα and Plk1 inhibitors in CML therapy may come from effects independent from TK activity of Bcr-Abl protein. We proved that the AKα and Plk1 inhibitors induce growth arrest and apoptosis in IM sensitive and resistant cell lines.

DURABLE TREATMENT-FREE REMISSION (TFR) FOLLOWING FRONTLINE NILOTINIB (NIL) IN PATIENTS (PTS) WITH CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE (CML-CP): ENESTFREEDOM 96-WK UPDATE

1SA Pathology, Adelaide, Australia, 2Department of Haematology and Stem Cell Transplantation, St Istvan and St László Hospital, Budapest, Hungary, 3Hospital Universitario Doctor Negrin, Las Palmas de Gran Canaria, Spain, 4Medical University of Gdansk, Gdansk, Poland, 5Aarhus University Hospital, Aarhus, Denmark, 6Hospital Ramon Y Cajal, Madrid, Spain, 7Universitätsklinikum Düsseldorf, Düsseldorf, 8Charité - Universitätsmedizin Berlin, Berlin, Germany, 9Azienda Ospedaliera Bianchi Melocori Morello, Reggio Calabria, Italy, 10III. Med. Klinik, Medizinische Fakultät Mannheim der Universität Heidelberg, Mannheim, Germany, 11NMDTI, Robert H. Lurie Comprehensive Cancer Center of Northwestern University, Chicago, Illinois, 12Clinical Research Division, Fred Hutchinson Cancer Research Center, Seattle, United States, 13University of Turin, Orbassano, Italy, 14Novartis Pharma AG, Basel, Switzerland, 15Novartis Pharmaceuticals Corporation, East Hanover, New Jersey, 16Novartis Institute for Biomedical Research, Cambridge, United States, 17Abteilung Hämatologie/Onkologie, Universitätsklinikum Jena, Jena, Germany

Background: ENESTfreeness (NCT017184068) is evaluating the ability to stop nilotinib and to maintain TFR in pts with a sustained deep molecular response (MR) on frontline NIL. Previous results from ENESTfreeness showed that 51.6% of pts (98/190) who attempted TFR remained off treatment and in major MR (MMR; BCR-ABL ≤ 0.1% on the International Scale [IS]) at 48 wk.

Aims: To analyze updated TFR data and predictive factors for remaining in TFR in ENESTfreeness.

Methods: Eligible pts had CML-CP with b2a2 and/or b3a2 BCR-ABL1 transcripts, ≥2y of frontline NIL, and MR4.5 (BCR-ABL IS≤0.0032%) prior to enrollment. All pts provided informed consent. After enrollment, pts continued NIL for 48 wk, and then were reevaluated for TFR at 96 wk. To investigate potential predictors for remaining in TFR, pts were grouped according to Sokal risk score at diagnosis or depth of response prior to attempting TFR (based on response assessments in the consolidation phase), and 48-wk TFR rates in each subset were calculated. The current analysis was conducted when all pts who entered TFR had completed 96 wk of TFR, or died, relapsed, progressed to blast crisis, or discontinued for any reason.

Results: Of 190 pts who entered TFR, 93 (48.9% [95% CI, 41.6% - 56.3%]) remained in MMR and off treatment at wk 96, including 88 (46.3%) who were in MR4.5. Three pts who were in TFR at wk 48 lost MMR by wk 96, and 2 additional pts discontinued from the study between 48 and 96 wk without losing MMR. Among pts with low, intermediate, or high Sokal risk at diagnosis, 39/62 (62.9% [95% CI, 49.7% - 74.8%]), 25/50 (50.0% [95% CI, 35.5% - 64.5%]), and 9/28 (32.1% [95% CI, 15.5% - 52.4%]), respectively, remained in TFR at wk 49 (Sokal risk scores were missing for 50 pts). Among pts with low, intermediate, or high Sokal risk scores at diagnosis, 39/62 (62.9% [95% CI, 45.2% - 60.6%]) remained in TFR at wk 48 vs 8/20 (40.0% [95% CI, 19.1% - 63.9%]) who had ≥1 assessment between MR4.5 and MR4.5 during the consolidation phase. Overall, 88 pts who reinstated NIL due to loss of MMR, 87 (98.9%) regained MMR and the remaining pt left the study 7.1 wk after NIL reintroduction without regaining MMR; 81 of 88 pts (92.0%) regained MR4.5 by the data cutoff. Among pts remaining in TFR for ≥48 wk (n=100), adverse events (AEs) were less frequent during the second vs the first 48 wk of TFR, 2 (2.0%) and 1 (1.0%), respectively. No pts had cardiovascular AEs during the study. No pts had second 48 wk of TFR, respectively, 34 (34.0%) and 9 (9.0%), respectively, had AEs in the predefined musculoskeletal pain grouping.

Summary/Conclusions: The majority of pts in TFR at 48 wk remained in TFR at 96 wk, and they reported fewer AEs during the second 48 wk of TFR than in the first 48 wk, affirming the durability and safety of TFR following NIL. No strong predictive factors for remaining in TFR were identified. Pts with low Sokal risk and pts with continuous MR4.5 in the consolidation phase tended to have higher TFR rates than other pts, although these results must be interpreted with caution due to the small number of pts in some subsets and the wide 95% CIs. Additionally, the biological explanation for an association between Sokal risk score at diagnosis and a subsequent ability to remain in TFR is unknown. These results support TFR as a valuable option for pts in sustained DMR on frontline NIL.
Background: The t(9;22) translocation in chronic myeloid leukemia (CML) generally occurs in intron 12 or 13 of the BCR gene resulting in two different transcripts, the e13a2 or e14a2. It has been suggested that the two variants represent separate disease entities and that the transcript variants hold a prognostic value regarding treatment response, where e14a2 predicts a faster and deeper treatment response. However, no difference in overall survival has been observed and the issue remains controversial. Reverse transcription quantitative PCR (RT-qPCR) using the Europe Against Cancer (EAC) qPCR assay has been the gold standard for determining the levels of BCR-ABL1 transcripts. The assay use common primers for amplification of the two variants resulting in a PCR product for the e14a2 variant that is 75 base pairs longer than the e13a2 variant. Under suboptimal PCR conditions, amplicons may be amplified with different efficiencies, which can result in an underestimation of especially the amount of longer qPCR products.

Aims: To study the accuracy of the EAC assay in quantifying the e13a2 and e14a2 transcripts.

Methods: Patient samples were screened for BCR-ABL1 e13a2 and e14a2 transcript variants using either PCR with agarose gel separation or a droplet digital PCR (ddPCR) assay measuring the amount of e13a2 and e14a2 transcripts. The BCR-ABL1 level was determined by qPCR using the QuantStudio instrument (Life Technologies) and expressed in the International Scale (%IS) and ddPCR (median: 0.01% IS, range: 0.0002–124% IS). These included 59 samples with the e13a2 variant and 65 with the longer e14a2 variant. Comparing the expression levels obtained by the two techniques revealed ddPCR/qPCR ratio differences for e13a2 (median: 0.68, range: 0.35–3.2) and e14a2 (median: 3.43, range: 0–8.8), and a consistent 4.5 fold (>0.5 log) underestimation of the levels of the e14a2 compared to e13a2 when using qPCR (figure 1).

Summary/Conclusions: When we compared the BCR-ABL1 levels using qPCR and ddPCR, we observed a discrepancy between the e13a2 and e14a2 breakpoint variants. Since ddPCR is an endpoint measurement and not sensitive to variations in primer efficiencies, the most likely explanation for the discrepancy is a decreased qPCR efficiency of the longer e14a2 variant compared to e13a2 transcript. Thus in qPCR analyses using the EAC protocol this may, at least on some analysis platforms, result in a consistently underestimation of the e14a2 level resulting in an appealingly better treatment response. A more than 0.5 log underestimation in a large subgroup of patients could have consequences in clinical decision-making e.g. by miss-grouping patients at different time points or when considering TKI discontinuation. Since many clinical laboratories use the BCR-ABL1 EAC protocol, the underestimation of the e14a2 variant could potentially be a widespread issue. We are presently working on an optimized BCR-ABL1 qPCR protocol where the e14a2 underestimation is eliminated.

5-YR RESULTS FROM THE PIVOTAL PHASE 2 PONATINIB PACE TRIAL: EFFICACY, SAFETY AND LANDMARK ANALYSIS IN HEAVILY PRETREATED PATIENTS (PTS) WITH CHRONIC-PHASE CHRONIC MYELOID LEUKEMIA (CP-CML)

1Department of Hematology, Zealand University Hospital, Roskilde, Roskilde, Denmark, 2Department of Hematology, University of Medical Sciences, Poznan, Poland, 3Department of Clinical Pathology, Zealand University Hospital, Roskilde, Roskilde, Denmark

Background: Ponatinib is an oral tyrosine kinase inhibitor (TKI) approved for pts with CP-CML or Philadelphia chromosome—positive acute lymphoblastic leukemia (Ph+ ALL) for whom no other TKI therapy is indicated, or for pts with T315I. The ponatinib PACE trial (NCT01207440) enrolled pts with CML or Ph+ ALL resistant/intolerant to dasatinib or nilotinib, or with T315I. Long-term results in these heavily pretreated pts provide value in informing treatment decisions.

Aims: To report 5-yr efficacy and safety, and the association of early landmark responses with survival at 5 yrs past landmark, at 4 yrs past landmark in heavily pretreated pts with CP-CML from PACE.

Methods: Ponatinib starting dose was 45mg/day. Dose reductions were instructed in Oct ’13 to manage risk of arterial occlusive events (AOEs) observed with longer follow-up. Outcome measures were: 5-yr efficacy (n=267) and safety (n=270); post-study landmark analysis (n=267) of the association of molecular responses (BCR-ABL<0.1% [major molecular response (MMR)], >0.1–1%, >1%–10% and >10%) and cytogenetic responses (major [McYR] and complete [CcYR]) at 3-6- and 12-mos with progression-free survival (PFS) and overall survival (OS) 4 yrs past landmark (log-rank P values). Data cutoff: 3 Oct ’16.

Table 1.

Results: Baseline characteristics of the CP-CML pts included: median time from diagnosis, 7 yrs (range, 0.5–27 yrs); median age, 60 yrs (18–94 yrs); and median %Ph+, 100% (2.5–100%); ≤10% Ph+, 20 pts (7%); 60% of CP-CML pts received ≥3 prior TKIs. In efficacy-evaluable CP-CML pts only, 3 prior TKIs. At initiation of study closure, 99 pts (37%) were ongoing; among these pts, minimum follow-up was 52 mos, and most (78%) had 15mg/d as their last ponatinib dose. In efficacy-evaluable CP-CML pts, cumulative response rates as of the data cutoff were: McYR, 60%; McYR, 54%; McYR, 40%; and McYR, 24%. Among pts who achieved McYR (n=148) or MMR (n=108), the Kaplan-Meier (KM) estimated probability of remaining in response at 5 yrs was 74% (95% CI, 62–83) and 61% (95% CI, 51–70), respectively. Maintenance of response was high regardless of dose reductions in Oct ’13. KM estimated 5-yr rates for PFS/OS were 49%–77%. Among pts with 3-, 6- and 12-mos landmark analyses, McYR, 54%; McYR, 40%; McYR, 39%; 62%/52% and 71%/56%, respectively, and MMR achieved in 14, 29% and 39%, respectively. Achievement of cytogenetic response and deep reductions in BCR-ABL1 levels (Table) at most landmark time points was associated with improved PFS and OS 4 yrs past landmark. Deeper responses at all landmarks were associated with achievement of McYR and overall survival with reduced adverse events (AEs) in ≥45% of CP-CML pts were rash 47%, abdominal pain 46%, and thrombocytopenia 46%. Most newly occurring AEs were observed within the first yr. The incidence of any AOE/serious AOE for CP-CML pts was...
Background: Very elderly (>75 yrs) people are a substantial proportion of elderly patients with newly diagnosed CML in chronic phase.

Aims: The aim of the study was to assess the treatment response and outcome in a cohort of very elderly patients with newly diagnosed CML in chronic phase.

Methods: We evaluated 435 patients ≥75 years of age who started imatinib 400 mg daily as first-line treatment. The estimated median age at diagnosis was 78 (31-86) years. The median follow-up from study entry was 141 months (range: 1-220 months).

Results: In univariate analysis, Hb level at diagnosis (≥ 12 mmol/l, p=0.048) was a significant predictive factor for achieving ≥MMR. Among patients ≥75 years of age, 71% (95% CI 66-76) achieved ≥MMR, compared to 89% (95% CI 87-91) of patients <75 years of age (p=0.0006). Male gender (p=0.046) and female gender (p<0.001) were significant predictive factors for MMR or better achievement.

Conclusion: As in younger subjects, nilotinib is effective in very elderly patients ≥75 years of age treated with nilotinib in chronic phase. Subsequent prospective studies are needed to validate these findings.

Summary/Conclusions: The long-term follow-up of very elderly CML patients treated with nilotinib suggests that any effort to treat these patients with standard doses should be made, in order to achieve cytogenetic and molecular responses as in younger subjects.
ease (including 7 acute myocardial infarction), 8 PAOD, 4 carotid stenosis (asymptomatic), 2 avascular necrosis of femoral heads, 1 optic artery ischemia, 1 aneurysm of carotid artery, 1 aneurysm of aorta/right iliac artery. Overall, 21 patients were hospitalized for the management of ATEs; 15 patients received medical treatment only, while the remaining required invasive interventions: 9 coronary angioplasty with stent positioning, 3 lower limbs amputations, 2 peripheral vascular bypasses, and 1 prosthesis of femoral head. No patient died for ATEs. Overall, 24 patients (80% of patients with ATEs and 72% of the whole cohort) permanently discontinued nilotinib because of ATEs. The median follow-up after ATE was 15 (1–58) months. Of the 30 patients with ATEs, 26 (87%) achieved a MMR and 18 (60%) obtained a MR4, during nilotinib treatment. These rates were comparable to those observed in patients without ATEs (MMR: 260/315, 83%; MR4: 113/315, 64%). The 5-year progression-free survival and overall survival in patients with or without ATEs (PPS: 96% vs 92%, p=0.55; OS: 96% vs 93%, p=0.79).

Summary Conclusions: After a median follow-up of 58 months, 8.7% of patients treated front-line with nilotinib had ATEs, being coronary disease and PAOD the most common. ATEs were more frequent in elderly patients (median age at ATEs: 67 years). Half of the patients required invasive procedures, including major surgeries in 6 patients. The other patients were successfully managed with medical treatment. Importantly, no patients died for ATEs, and ATEs did not affect the rates of MMR, MR4 and 5-year PFS and OS, which were all comparable to those observed in patients without ATEs. Taken together, these data suggests that ATEs, despite being sometimes associated with significant morbidity, did not significantly impact on response rates and on long-term outcome of CML patients treated with nilotinib front-line.

# P606

ASSASSEMENT OF CHRONIC RENAL INJURY IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA IN THE CHRONIC PHASE RECEIVING TYROSINE KINASE INHIBITORS

Q. Jiang1, L. Zuo1, X. Ren1, X. Huang1
1Peking University People’s Hospital, Peking University Institute of Hematology, 2Peking University People’s Hospital, Department of Nephrology, Beijing, China

Background: Long-term use of tyrosine kinase inhibitors (TKIs) may lead to chronic renal injury.

Aims: To evaluate the incidence of chronic kidney disease (CKD) in patients with chronic myeloid leukemia (CML) in the chronic phase (CP) receiving TKIs, and to identify the factors associated with the onset of CKD.

Methods: Data of CML-CP patients treated with TKIs as first-line or second- or third-line therapy for at least 3 months were analyzed. Glomerular filtration rate (GFR) was followed from the initiation of TKI-therapy. CKD was defined as persistent GFR less than 60 ml/min/1.73 m² or persistent more than 30% GFR reduction from baseline. CKD-free survival was used to evaluate the onset of CKD. Patients’ characteristics and TKI used were analyzed to identify the factors associated with the onset of CKD by Cox regression model in those receiving first-line and second- or third-line TKI-therapy, respectively.

Results: 587 patients were included in this study, 383 (65%) were male. Median age was 40 (17-84) years. 46 patients were received nilotinib (n=363), nilotinib (n=88) or dasatinib (n=13) as first-line TKI-therapy. With a median follow-up of 35 months (range, 3-185 months), 136 of 416 (33%) patients with normal GFR at baseline developed CKD. Probabilities of CKD-free survival at 4 years were 62%, 78% and 100% in the patients receiving imatinib, nilotinib and dasatinib, respectively (p=0.004). Multivariate analysis showed that imatinib use (HR=2.4, 95% CI 1.4-4.3, p=0.002), male gender (HR=2.0, 95% CI 1.4-2.9, p=0.001), increasing age (HR=1.2, 95% CI 1.1-1.4, p=0.003) and prior administration of hydroxyurea, interferon or chemotherapy (HR=1.7, 95% CI 1.1-2.8, p=0.010) were factors associated with incident of CKD. In 48 patients with abnormal GFR or prior CKD before first-line TKI-therapy, 8 of 42 (19%) developed ≥30% GFR reduction from baseline after nilotinib or dasatinib-therapy. In 123 patients receiving nilotinib (n=59) or dasatinib (n=64) as second- or third-line TKI-therapy after imatinib-failure, 13 of 110 (12%) with normal GFR at baseline developed CKD with a median follow-up of 19 months (range, 3-149 months). Probabilities of CKD-free survival at 3 years were 74% and 90% in those receiving nilotinib and dasatinib, respectively (p=0.059). Multivariate analysis showed that nilotinib use (HR=3.6, 95% CI 1.5-10.3, p=0.047) and a history of diabetes mellitus, hypertension or other renal diseases (HR=3.8, 95% CI 1.3–11.6, p=0.019) were factors associated with incident of CKD. 3 of 13 (23%) patients with abnormal GFR or prior CKD before second- or third-line TKI-therapy developed ≥30% GFR reduction from baseline during nilotinib (n=1) or dasatinib (n=2) therapy.

Summary Conclusions: Our study showed that nilotinib and dasatinib were associated with less chronic renal injury compared with imatinib as first-line TKI-therapy, while dasatinib was related to less loss of renal function compared with nilotinib as second- or third-line TKI-therapy after imatinib-failure in CML-CP patients.

# P607

COMPARATIVE MONITORING OF MINIMAL RESIDUAL DISEASE (MRD) BY QPCR AND DIGITAL-PCR (dPCR) IN CHRONIC MYELOID LEUKEMIA PATIENTS ACHIEVING MAJOR OR DEEP MOLECULAR RESPONSE WITH TYROSI-N-KINASE INHIBITORS

1Lab CREA-AI, AO Spedali Civili di Brescia, 2Unit of Bone Marrow Transplantation, University of Brescia, Brescia, 3Division of Hematology and Bone Marrow Transplantation, University-Hospital of Udine, Udine, 4Institute of Hematology “L and A Seràgnoli”, University of Bologna, Bologna, 5Chair of Biochemistry, University of Brescia, Brescia, 6Department of Biomedicine and Prevention, University of Tor Vergata, Roma, 7Division of Hematology, AO Spedali Civili di Brescia, Brescia, Italy

Background: Quantification of BCR-ABL1 transcript by qPCR is mandatory to monitor the response to TKIs therapy in CML patients. The achievement of Major or Deep Molecular Response (MMR or DMR) with TKIs is crucial for long-term survival and for treatment free remission (TFR). Currently, up to 30-40% of CML patients treated with TKIs can achieve DMR, but 50-60% of responders who discontinue the treatment loose their DMR and re-challenge continuous TKIs therapy. qPCR has some intrinsic limitations and it does not appear to be an optimal assay to select the best candidates to TKIs discontinuation. Digital PCR (dPCR) can give an absolute quantification of target nucleic acids by partitioning the PCR reaction mix over a large number of wells, each containing a single copy or no copies of the target region.

Aims: The aim was to comparatively monitor the BCR-ABL1 transcript levels by dPCR and qPCR in 57 CML patients treated with TKIs and achieving MMR or DMR in at least 3 time points.

Methods: Using qPCR and dPCR (Q3SD Digital PCR System by Life Technologies), we comparatively analyzed 228 peripheral blood samples from 57 CML patients with MMR (n=14) or DMR (n=43). qPCR analysis were performed according to the last International Guidelines while absolute quantification of BCR-ABL1 transcript were obtained by dPCR and results were expressed as number of BCR-ABL1 copies/ul of reaction. Patients were divided into 3 groups according to the MR classes at the first time point: MR3.0, MR4.0 and MR4.5-5.0 groups. dPCR Positive Predictive Value (PPV) was also preliminary evaluated in 14 patients undergoing TKI discontinuation.

Results: Analyzing comparatively the time course of MR in the patients of the three groups (MR3.0, MR4.0 and MR4.5-5.0) it was observed a similar trend, but the dPCR allowed to appreciate that, at the time of starting the monitoring the patients showed different levels of BCR-ABL1 copies/ml. Furthermore, those patients with MR4.5-5.0 undetectable by qPCR resulted with detectable BCR-ABL1 transcript levels when assessed by dPCR. Secondly, while MRD quantitations measured by qPCR appear to be more homogeneous, nearly due to a normalization effect of qPCR, the quantitations of MRD measured by dPCR appear to be more heterogeneous because of the high sensitivity and accuracy of dPCR. Therefore, dPCR values, reflecting the great heterogeneity of MRD level in patients belonging to the same MR group, suggest a higher accuracy in patients stratification (Figure 1a). dPCR value of 0.468 copies/ul, previously reported as value discriminating between major responders and deep responders, was used as threshold for dPCR data analysis. Patients with absolute value of BCR-ABL1 lower than 0.468copies/ul at the first time point presented more stable disease levels than the patients with absolute value of BCR-ABL1 higher than 0.468copies/ul (Figure 1b). In 14 CML patients who

Figure 1.
discontinued TKIs, a preliminary analysis showed that 80% of patient with BCR-ABL1<0.48 copies/ul at discontinuation, maintained stable TFR (PPV of 80%).

Summary/Conclusions: This study suggests that dPCR is more precise and sensitive than qPCR when detecting levels of BCR-ABL1 transcript and that dPCR seems to be more robust and accurate for CML patients stratification.

Larger and prospective studies are warranted to confirm the higher sensitivity and accuracy of dPCR and its usefulness to better select the candidates for TFR.

OUTCOME OF BLAST PHASE CHRONIC MYELOID LEUKEMIA (CML-BP) IN THE TYROSINE KINASE INHIBITOR ERA

C. Teli1,2, L. Isern1,2, S. Shams3, A. Kuykendall1, J. Chavez2, B. Shah2, K. Swee2, J. Pinilla-Ibarz2
1Department of Malignant Hematology, University of South Florida/Moffitt Cancer Center, 2Department of Malignant Hematology, Moffitt Cancer Center, Tampa, United States

Background: Primary goal of management in chronic myeloid leukemia (CML) is to prevent disease progression to blast phase CML (BP-CML). Current notion for management of BP-CML usually involves initiation of intensive chemotherapy regimen with addition of tyrosine kinase inhibitor (TKI). Despite treatment with intensive induction chemotherapy, outcome remains dismal.

Aims: We aimed to describe our experience with management of BP-CML and its outcome.

Methods: We included 58 patients from Moffitt Cancer Center from 2001 till 2016 with diagnosis of BP-CML and performed a retrospective chart review. Data elements including age, gender, peripheral blood and bone marrow parameters, phase of CML, treatment, cytogenetics and vital status were collected. Survival analysis using Kaplan-Meier method with log-rank test to determine significance by calculating two-sided p values was performed.

Results: The overall survival (OS) of our cohort was 31.87 months (mo). For patients with progression to BP-CML from previously known diagnosis of CML, median time to progression was 19.1 mo (range: 3.0-221.2 mo). The median OS from the diagnosis of BP-CML in this cohort was 10.8 mo, compared to de novo CML-BP cohort OS of 11.03 mo (p=0.62). Myeloid blast phase CML had worse OS compared to lymphoid blast phase cohort but was not statistically significant (9.17 vs 17.5 mo, p=0.32). We further compared the treatment strategies of BP-CML including single agent TKI (n=21) and conventional chemotherapy regimens in combination with a TKI (n=36). The median OS of the cohort with single agent TKI was not statistically different from the combination with chemotherapy arm (12.83 mo vs 10.87 mo, p=0.73) as shown in Figure 1A. Additionally, combination of chemotherapy with TKI compared to single agent TKI did not have significant survival impact in either myeloid (9.17 vs 9.13 months, p=0.32) or lymphoid (14.47 vs 18.27 mo, p=0.24) BP-CML.

Total of 26 patients (44.8%) proceeded to allogeneic bone marrow transplant, 26% (6/23) of which only received TKI prior to transplant compared to 76.9% (n=20) who received chemotherapy in combination with TKI. Use of single agent TKI rather than TKI in combination with chemotherapy prior to allogeneic transplant had a trend toward improved OS (128.5 vs 24 mo, p=0.23) (Fig 1B).

Choice of TKI in combination with chemotherapy in treatment of BP-CML also did not identify any TKI combination resulting in superior survival (Figure 1D). Overall survival of the cohort stratified by presence of standard Philadelphia chromosome in comparison to additional cytogenetic aberrations did not detect difference in overall survival (10.87 vs 12.1 mo, p=0.51). Further evaluation of cytogenetic aberrations revealed monosomy 7 to be present in greater frequency in lymphoid blast phase compared to myeloid blast phase (35.7% vs 6.25%, p=0.02).

Summary/Conclusions: Our data suggest no survival difference when BP-CML is treated with a single agent TKI compared to a combination therapy, regardless of histology type. Therefore, single agent TKIs should be considered as an effective frontline therapy option for BP-CML, which may prevent the potential toxicity associated with chemotherapy. These findings need further validation in a larger prospective cohort.

P609

EFFICACY OF SWITCHING TO DASATINIB IN CHRONIC MYELOID PATIENTS WITH LATE WARNING RESPONSES TO IMATINIB. STUDY OF THE ASSOCIATION OF RESPONSE TO DASATINIB TO IMMUNOLOGIC STATUS

1Servicio de Hematologia, Hospital Universitario de la Princesa/ IIS-IP Madrid, 2Servicio de Hematologia, Hospital Universitario Ramon y Cajal, 3Servicio de Immunología, Hospital Universitario de la Princesa, Madrid, 4Servicio de Hematologia, Hospital Universitario de Salamanca, Salamanca, 5Servicio de Hematologia, Hospital Duran i Reynals, Barcelona, 6Servicio de Hematologia, Hospital Virgen de la Salud, Toledo, 7Servicio de Hematologia, Hospital Germans Trias i Pujol, Barcelona, 8Servicio de Hematologia, Hospital Universitario Virgen del Rocio, Sevilla, 9Servicio de Hematologia, Hospital Povisa, Vigo, 10Servicio de Hematologia, Hospital Universitario La Paz, Madrid, Spain

Background: European LeukemiaNet (ELN) recommendations (2013) advised closely monitoring for patients with late warning response (patients with complete cytogenetic response without major molecular response after 12 months of treatment). Our trial, DASAPOST, has been the first one evaluating efficacy and safety of dasatinib in patients with late warning responses, and preliminary results have been reported (Garcia-Gutierrez et al, ASH 2016; P5450). Besides, many studies suggest that dasatinib may augment responses due to its immunomodulating effect. Although NK and CD8 cells seem to be involved, the specific mechanism remains to be clarified.

Aims: To evaluate the efficacy and safety of switching change to dasatinib in patients treated with imatinib first line during at least 18 months and having a late warning response, and to study the association between response to dasatinib and immune robustness, both baseline and during the therapy, and dasatinib-induced lymphocyte “mobilization”.

Methods: Phase II, open, multicenter DASAPOST study (NCT01802450). Patients previously treated with imatinib after at least 18 months, with CCyR but without MMR, were included. All BCR-ABL1/ABL1 (IS) measurements were centralized in a EUTOS laboratory. Analyte to point were considered as non responders, Lympocyte counts, subpopulations and migration studies were done at baseline (1st day of dasatinib), and every 3 months, and they were done both previous to the dose, and 2 hours after.

Results: From April 2013 to May 2015, 18 patients were enrolled in 12 centers. Median age was 59 years (38-77), the ratio of men to women was 13/5, and the Sokal risk groups were 48%, 30% and 22% for low, intermediate and high risk, respectively. Median time from diagnosis to switch to dasatinib was 2.6 years (1.6-23) and median time while on imatinib to achieve CCyR 1.4 years (0.2-12). Median exposure to imatinib was 2.4 years (1.6-23) and median time while on imatinib to achieve MMR at 6 and 12 months. Interest 9/18 patients (50%) achieved MMR by 12 months. There were 3 study discontinuations because of toxicity (16%). Table 1 shows the median number of the most relevant lymphocyte populations in the pre-dose sample at baseline. Table 2 shows that the absolute number of CD8 cells was significantly superior at baseline in those patients having a MMR at 3 months, with a trend in the same direction of absolute lymphocyte count and percentage. There were no significant associations with response when considering CD4 T cells, NK cells, or the degree of mobilization after dasatinib dose either in total lymphocyte number or in subpopulations. Besides, lymphocyte number or proportions at 3 or 6 months were not associated with MMR at 6 or 12 months (data not shown).

Summary/Conclusions: Our study shows that in patients treated with imatinib and with late warning responses, switching to dasatinib induced MMR in 2 out every 3 patients, and MR4 in half of the patients, with a good safety profile. Contrarily to other group reports, we have not found any significant association between response and lymphocyte mobilization in any point studied. Interestingly, the absolute number of CD8 at baseline was significantly associated with the early obtainment of MMR at 3 months, a finding which underscores the prognostic importance of baseline immune status, the relevance of CD8 cells in the antileukemic effect, and which suggest that this quite simple variable must be included in future studies with dasatinib in second line.

P610
GENETIC PREDICTION OF INSULIN RESISTANCE IN CHRONIC MYELOID LEUKEMIA PATIENTS TREATED WITH NILOTINIB
G. Caocci1,*, M. Mammì2, C. Labate2, S. Rodì2, D. Ielo3, M. Prilo2, M. Postorino2, G. Tripepi5, F. Ronco3, C. Laganà2, B. Martino3
1Hematology, Department of Medical Sciences, University of Cagliari, Cagliari, 2Operative Unit of Medical Genetics, 3Operative Unit of Hematology, 4Operative Unit of Nephrology, Grande Ospedale Metropolitano “Bianchi-Melacini-Morelli”, 5Epidemiology Research Unit, CNR-IBIM, Reggio Calabria, Italy

Background: Impaired fasting glucose (IFG) and type 2 diabetes (T2D) represents adverse events in Chronic Myeloid Leukemia (CML) patients treated with the second-generation tyrosine kinase inhibitor (TKI) nilotinib. A genetic risk score (uGRS) for the prediction of insulin resistance, consisting of 10 multiple single-nucleotide polymorphisms (SNPs), has been proposed.

Aims: We evaluated the uGRS predictivity in 45 CML patients treated with nilotinib.

Methods: Patients were genotyped for IRS1, GRB14, ARL15, PPARG, PEPD, ANKRD55/MAP3K1, PDGFC, LYPLAL1, RSPO3, and FAM13A1 genes. The uGRS was based on the sum of the risk alleles within the set of selected SNPs.

Results: MR3.0 and CMR were achieved in 91% and 84% of the patients, respectively. Before treatment, none of the patients had abnormal blood glucose. During treatment and subsequently follow-up of 84.4 months (range 1-298), 5 patients (11%) developed diabetes requiring oral treatment, after a median of 11 months (range 3-95) since nilotinib. Nine patients (20%) developed prediabetes. Prediabetes/diabetes-free survival was significantly higher in patients with an uGRS below 10 compared to higher scores (100% vs 81%, p=0.004) (Figure). Each increment of 1 unit on the uGRS caused a 42% increase in the prediabetes/diabetes risk (HR=1.42; CI: 1.04-1.94; p=0.026).

Figure 1.

Summary/Conclusions: Although nilotinib is not associated with a higher incidence of T2D compared to a general population, it could be an early ‘‘heightener’’ of genetic predisposition to the disorder. The presence of more than 10 allelic variants associated to insulin secretion, processing, sensitivity and clearance is predictive of prediabetes/diabetes developing. In clinical practice uGRS could help tailor the best TKI therapy.

P611
THE EUROPE AGAINST CANCER PROTOCOL FOR BCR-ABL P210 TRANSCRIPT MEASUREMENT MAY OVERESTIMATE RESULTS FOR E13A2 AND E14A2 TRANSSCRIPTS
M. Gniot1,*, M. Komarnicki1, K. Lewandowski1
1Hematology, Poznan University of Medical Sciences, Poznań, Poland

Background: The quantitative PCR of BCR-ABL transcript has been the most useful technique for monitoring therapy in CML patients for over a decade. The numerous standardization projects have been undertaken in order to harmonize the molecular response results in laboratories all over the world. However, our data suggest that using the most common protocol may lead to overestimation of e13a2 transcript.

Aims: The goal of the study was to verify the observation that e14a2 transcript amplifies less efficiently than e13a2. The secondary goal was to validate the modification of Europe Against Cancer (EAC) protocol developed in 2011 which corrects observed artifacts.

Methods: The BCR-ABL measurements acquired using EAC and in-house modified EAC protocol have been compared with results from SA Pathology in Adelaide. The Adelaide protocol (Branford and Hughes 2006) consists of separate, optimized reactions for e13a2 and 14a2 transcripts, therefore it should be considered free of any PCR efficiency-related artifacts. The data originated from four independent sample batches exchanged between Poznan and Adelaide since 2009.

Results: The analysis of retrospective EAC protocol data showed that when e13a2 and e14a2 samples entered the exponential phase at the same time, the latter would cross the threshold approximately 2.2 cycles after the first one. Re-analysis of data from sample exchanges from 2009 revealed that after establishing a conversion factor (CF), all of the e14a2 measurements in Poznan were underestimated according to Adelaide. At the same time, almost all of e13a2 samples were overestimated (fig. 1). Still, the bias between methods was acceptable and a valid conversion factor (CF) was calculated. The method modification introduced 2011 eliminated this difference and increased concordance between laboratories. The last sample batch revealed significant difference between non-modified and modified EAC protocols in e13a2 measurements: 4.56 (+/- 0.96). Reanalysis of sample batch from 2009 (presented on fig.1) using 4.57 (2x2.28) factor (e13a2 results divided by 2.28, e14a2 results multiplied by 2.28) resulted in almost perfect data alignment. The results of modified EAC protocol, after CF calculation, showed very good concordance with Adelaide (100% results of e14a2 and 88% of e13a2 within 2-fold of reference laboratory).

Figure 1.

Summary/Conclusions: In the EAC protocol, the e14a2 transcript amplifies less efficiently than e13a2. Since commonly used plasmids, including ERM-AD623, are based on e14a2, the standard curve is being shifted towards the latter cycles. It leads to overestimation of e13a2 by mean factor of 4.5 (over 0.5 log), which could be clinically significant. The reports of worse outcome of e13a2 patients are probably caused by this artifact, which can be easily eliminated by implementing an additional forward primer to EAC protocol. This overestimation cannot be detected in case of lab to lab validation when two centers are using EAC protocol. In case of method validation in Adelaide, those differences were not as obvious as well. The shift of 4.5 (fig. 1) means that results are 2.2 times different from the perfect concordance line and could easily fit into accepted 2-fold and 3-fold compartments. The CF calculated by Adelaide would depend on the percentage of each transcripts among the exchanged samples. The observed artifact should be also taken into consideration in clinical trials that rely on surrogate endpoints such as molecular response level at certain time points. Uneven transcript variant distribution between compared groups may lead to improper conclusions.

ESTABLISHMENT OF IN VIVO AND IN VITRO MODEL OF X-LINKED SIDERABLASTIC ANEMIA
K. Saito1, T. Fujimura1, M. Morita2, Y. Okitsu1, N. Fukuhara1, Y. Onishi1, Y. Niwa1, S. Shimizu2, H. Haraguchi1
1Hematology and Rheumatology, 2Medical Biochemistry, Tohoku University Graduate School of Medicine, Sendai, 3Cell Engineering Division, RIKEN BioResource Center, Tsukuba, 4Molecular Hematology, Tohoku University Graduate School of Medicine, Sendai, Japan

Background: Congenital sideroblastic anemia (CSA) is a inherited hemolytic anemia characterized by the presence of bone marrow ring sideroblasts, reflecting excess mitochondrial iron deposition. The most common form of CSA is X-linked sideroblastic anemia (XLSA), which is attributed to mutations in the X-linked gene ALAS2. ALAS2 resides on chromosome X and encodes the enzyme that catalyzes the first and rate-limiting steps in the heme biosynthesis pathway in erythroid cells. This pathway converts glycine and acetyl-coenzyme A to 5-aminolevulinic acid (ALA), which requires pyridoxal 5'-phosphate (PLP) as a cofactor. Although decreased ALA may represent a novel therapeutic strategy for XLSA, there is no model system to explore its use as an important tool for clarifying the molecular etiology of XLSA and providing a platform for drug discovery.

Aims: We aimed to establish a novel model of XLSA by CRISPR/Cas9-based genome editing.

Methods: We targeted the GATA-1-binding region of intron 1 of the human ALAS2 gene based on both in vivo mice and human induced pluripotent stem cells (HiDEP) harboring a deletion of the ALAS2 gene (Δint1/Y) in male mice led to anembryonic lethality, suggesting that this sequence is indispensable in the context of sex. As an alternate approach, we established a clonal line with HiDEP cells exhibiting a red color, the XLSA clone appeared pink/pale color, which were accompanied by the significantly decreased intracellular heme concentration. Despite no obvious change in the expression of GATA-1 protein in the XLSA clone, quantitative real-time–polymerase chain reaction (RT–PCR) analysis demonstrated that the chromatin occupancies of GATA-1 and its cofactor TAL1 were significantly abrogated by the deletion of the GATA binding motif at intron 1 enhancer of the ALAS2 gene. Quantitative real-time–polymerase chain reaction (RT–PCR) analysis demonstrated significant downregulation of ALAS2 as well as globin genes (HBA, HBG, and HBB) in the XLSA clone. Microarray analysis revealed >2-fold up-regulation of 619 and 274 genes caused by the 19-bp deletion, respectively. The downregulated gene ensemble included globins (HBZ, HBG, HBE, HBD, HBM, and HBQ) as well as genes involved in iron/heme metabolism (ALAS2, transferrin receptor, TFR, copper/iron oxidase, CPOX, and mitoferrin 1: MFRN1). GO analysis revealed significant enrichment of cellular iron homeostasis (p=0.018), regulation of transcription (p=0.0021), and innate immune responses.

Results: We first generated a founder female mouse lacking the 1 enhancer region of Alas2, including the GATA binding domain (Alas2Δint1/X). Whereas the heterozygous Alas2Δint1/Y mice were viable and did not show any anemic phenotype, hemizygous deletion (Alas2Δint1/X) in male mice led to anembryonic lethality, suggesting that this sequence is indispensable in the context of mice. As an alternate approach, we established a clonal line with HiDEP cells exhibiting a red color, the XLSA clone appeared pink/pale color, which were accompanied by the significantly decreased intracellular heme concentration. Despite no obvious change in the expression of GATA-1 protein in the XLSA clone, quantitative real-time–polymerase chain reaction (RT–PCR) analysis demonstrated that the chromatin occupancies of GATA-1 and its cofactor TAL1 were significantly abrogated by the deletion of the GATA binding motif at intron 1 enhancer of the ALAS2 gene. Quantitative real-time–polymerase chain reaction (RT–PCR) analysis demonstrated significant downregulation of ALAS2 as well as globin genes (HBA, HBG, and HBB) in the XLSA clone. Microarray analysis revealed >2-fold up-regulation of 619 and 274 genes caused by the 19-bp deletion, respectively. The downregulated gene ensemble included globins (HBZ, HBG, HBE, HBD, HBM, and HBQ) as well as genes involved in iron/heme metabolism (ALAS2, transferrin receptor, TFR, copper/iron oxidase, CPOX, and mitoferrin 1: MFRN1). GO analysis revealed significant enrichment of cellular iron homeostasis (p=0.018), regulation of transcription (p=0.0021), and innate immune responses.

Summary/Conclusions: The XLSA model established from HiDEP cells can be used as an important tool for clarifying the molecular etiology of XLSA and to explore novel therapeutic strategies.

P613
BENDAMUSTINE AND RITUXIMAB COMBINATION THERAPY FOR COLD AGGLUTININ DISEASE: RESULTS OF A PROSPECTIVE NORDIC TRIAL
S. Berentsen1,*, U. Randen2, M. Okkama3, H. Birgens4, T.H.A. Tvedt5, J.B. Bøe1
1Department of Research and Innovation, HAUGESUND HOSPITAL, Haugesund, 2Department of Pathology, Oslo University Hospital, Oslo, Norway, 3Department of Hematology and Stem Cell Transplantation, Turku University Hospital, Turku, Finland, 4Department of Haematology, Hertlev Hospital, University of Copenhagen, Herlev, Denmark, 5Department of Medecine, Haukeland University Hospital, Bergen, 6Medical Department, Drammen Hospital, Vestre Viken Trust, Drammen, 7Department of Medicine, Aker University Hospital, Nordbygreen, 8Department of Hematology and Oncology, Stavanger University Hospital, Stavanger, 9Department of Hematology, Oslo University Hospital, Oslo, Norway

Background: Primary cold agglutinin disease (CAD) is an autoimmune hemolytic anemia in which a well-defined clonal lymphoproliferative bone marrow disorder (LPD) causes production of monoclonal cold agglutinins. Major clinical manifestations are anemia and clinical symptoms. Pharmacological therapy, although not indicated in patients with very mild disease, seems required in a majority of cases. Corticosteroids are ineffective. Rituximab monotherapy has resulted in approximately 50% response rate and 1-year median response duration. Fludarabine and rituximab combination therapy showed 70% response rate (20% complete responses) and very long response duration, but considerably toxic.

Aims: We wanted to investigate whether bendamustine and rituximab combination therapy can result in favorable response rates and duration with an acceptable toxicity profile.

Methods: We conducted a prospective, uncontrolled multicenter trial with 16 participating hospitals from Norway, Finland and Denmark. Essential inclusion criteria were verified CAD with symptomatic anemia and/or severe cold-induced circulatory symptoms. Eligible patients received 4 cycles of rituximab 375mg/m2 day 1 and bendamustine 90mg/m2 day 1-2 with 28 days interval. Outcomes were obtained into complete response (CR), partial response (PR), and non-response (NR). The definition of CR included normalization of hemoglobin (Hb) levels with no hemolysis, complete histologic resolution of the bone marrow LPD and disappearance of monoclonal serum protein. The criteria for PR included increase in Hb levels by at least 2.0 g/dL or to the normal range, transfusion independence, at least 50% reduction of IgM and improvement of any circulatory symptoms.

Results: Forty-four patients (19 men and 25 women) were included, with a median age of 74 years (range, 48-86) and median disease duration 4 years (range, 0–18). Seventeen patients had received previous therapy. At baseline, median Hb level was 9.5g/dL (range, 4.5–14.6), bilirubin 45micromol/L, lactate dehydrogenase (LDH) 468 U/L, haptoglobin undetectable, IgM 4.1g/L (1.0-2.72), CA titer 2048 (64-65536). Monoclonal IgM kappa was detected in 38 patients, IgG kappa in 1 and IgA kappa in 1. We observed CR in 16 patients (36%), PR in 15 (34%), while the remaining 13 (30%) were non-responders. Hb levels were median of 4.8g/dL in the responders and 7.1g/dL in non-responders. CR and 3.9g/dL in those achieving PR. Median post-therapy Hb levels were 14.2g/dL (CR), 12.5g/dL (PR) and 10.5g/dL (NR). Acrocyanosis and Raynaud symptoms resolved completely in 16 patients and improved in 11 (47% and 32%, respectively, of those with such symptoms at baseline). Histologic regression of the LPD was complete in 17 patients (39%), partial in 5 (11%) and not evaluable in 18 (41%). Median time to response was 2 months (0.5-12). Only 3 responders experienced relapse; 2 after PR and 1 after CR. Median observed response duration was 32 months (range, 1-62) during median 32 months follow-up time. CR was achieved in a median of 7 months, 6 months in those achieving PR and 3.9g/dL in those achieving CR. Neutropenia grade 3/4 occurred in 14 patients (32%), of which 8 (18%) had grade 4. Three patients (7%) experienced 1-3 episodes of febrile neutropenia, which was readily manageable. Non-hematologic toxicity occurred in 17 patients (39%), mostly consisting of mild nausea or rash. Three non-neutropenic serious adverse events (SAE) were recorded; 1 was considered probably therapy-related.

Summary/Conclusions: Bendamustine and rituximab combination therapy resulted in high response rates, a high rate of CR, long response duration and few relapses during the observation period, with a favorable safety profile. It might be considered in the first line for reasonably fit patients with CAD requiring therapy.

P614
EX VIVO TREATMENT OF RED BLOOD CELLS FROM 15 PYRUVATE KINASE (PK)-DEFICIENT PATIENTS WITH AG-348, AN ALLOSTERIC ACTIVATOR OF PK-R, INCREASES ENZYMIC ACTIVITY, PROTEIN STABILITY AND ATP LEVELS
B. van Orschoot1, P.A. Kosinski2, J. Hoxion3, K. Johnson4, V. Chubukov2, L. Dang5, G. Pasterkamp1, S. van Straaten14, C. Kung6, R. van Wijk1,*
1Clinical Chemistry and Haematology, University Medical Center Utrecht, Utrecht, Netherlands, 2Aigios Pharmaceuticals, Inc., 3KSK Therapeutics, Cambridge, MA, United States, 4Faculty of Veterinary Medicine, University of Madrid, Madrid, Spain, 5Aagene, 6Department of Haematology, University Medical Center Utrecht, Utrecht, Netherlands

Background: Pyruvate kinase (PK) deficiency is a rare hereditary disorder affecting red blood cell (RBC) glycolysis. It is caused by mutations in the PKLR gene. PK-deficient RBCs are characterized by changes in metabolism associated with defective glycolysis, including a build-up of the upstream metabolite 2,3-diphosphoglycerate, and deficiency in the PK product ATP. It is hypothesized that insufficient energy production affects red cell homeostasis, promoting...
premature removal of PK-deficient RBCs from the circulation. Affected patients display chronic hemolytic anemia of variable severity. Treatment of PK-deficient patients is generally supportive, focusing on the anaemia and iron overload state, and there are no approved drugs that directly target mutated PK. AG-348 is an allosteric activator of the RBC isoform of PK (PK-R) and in clinical development for the treatment of PK deficiency.

**Aims:**

- To evaluate the effect of AG-348 treatment on PK-R enzymatic function, RBC metabolism and deformability
- To identify new disease causing genes.

**Methods:**

- Observational case-control study, approved by the Institutional Review Board. All patients gave informed consent. Enrolled patients (N=15) were adults, transfusion-independent and compound heterozygous or homozygous for PK-R mutations. Baseline RBC metabolic profiling was performed by LC-MS/MS. Purified RBCs from patients and healthy control subjects were incubated with AG-348 (up to 10 μM) for 24 hours at 37°C. After 6 and 24 hours PK-R activity, ATP levels and RBC deformability (by Lorroca) were measured. For determination of PK-R thermal stability, RBC lysates were incubated for 2 hours with 20 μM AG-348 (37°C) prior to test. Baseline protein levels of PK-R were assessed using antibodies against PK-R.

**Results:**

- Baseline patient characteristics show strongly reduced PK-R activity in all patient cells, in particular taking into account the degree of reticulocytosis (Table 1). Distinct metabolic changes were consistent with a block of glycolysis at the PK-R step. Treatment of PK-deficient RBCs with AG-348 resulted in increased enzymatic activity in all patient cells after 24 hours (mean increase 1.8-fold, range 1.2-3.4). Similar increases were observed in control cells (mean fold increase 2.3, range 1.2-7.1). ATP levels in PK-deficient cells increased upon AG-348 treatment (mean increase of 0.2-2.2) similar to control cells (mean increase 1.6 fold, range 1.4-1.8). Generally, PK-R thermal stability was strongly reduced in PK-deficient patient cells, illustrated by a mean loss of activity of 72% (19% for control cells) after incubation at 53 °C for 60 minutes. Ex vivo treatment with AG-348 prior to incubation resulted in residual activity of 4 to >10-fold higher than residual activity of vehicle-treated samples. Baseline protein level analyses suggests that a certain level of PK-R protein is required for cells to respond to AG-348 treatment ex-vivo, as treatment effects were minimal in patient cells with very low or undetectable levels of PK-R. In approximately half of the patients, ex vivo treatment with AG-348 was associated with an increase in RBC deformability, although there doesn’t appear to be a clear correlation with enzymatic or metabolic response.

**Summary/Conclusions:**

These data support the hypothesis that drug intervention with AG-348 effectively upregulates PK-R enzymatic activity and increases stability in PK-deficient RBCs over a broad range of PKLR genotypes. The combined increase in ATP levels with 2 μM AG-348 suggests that glycolytic pathway activity may be restored. AG-348 treatment may represent an attractive way to correct the underlying pathologies of PK deficiency.

**P616**

IDENTIFICATION OF NEW PATHOGENIC MUTATIONS IN PATIENTS WITH RED BLOOD CELL MEMBRANE DISORDERS USING NEXT-GENERATION SEQUENCING

M.D.M. Mafu Pereira1,2, E. Llaudet Planas1, V. Rizzotto1, J. L. Vives Corrons1
1Red Blood Cell Pathology And HematoPoietic Defects, Josep Carreras Leukaemia Research Institute, Barcelona, Spain
2Background: Red blood cell (RBC) membrane proteins deficiency or structural alterations lead to RBC membrane disorders such as hereditary spherocytosis, hereditary elliptocytosis or hereditary xerocytosis among others. Genetic analysis of these patients was not usually performed before next-generation sequencing (NGS). In our institution we performed an initial screen by Sanger sequencing several membrane related genes, considering that they all contain a high number of coding regions.

**Aims:**

- The aim of this study is to perform the molecular diagnosis of the patients included in the study as well as to identify new pathogenic mutations leading to RBC membrane disorders.

**Methods:**

- 116 patients from 74 unrelated families were studied with a next generation sequencing (NGS) based panel that contained genes already described as disease causing for RBC membrane disorders (ANK1, EPB41, EPB42, SLCA4A, SPTA1, SPTB, PIEZO1, KCNN4, RHAG) as well as for enzyme deficiencies (ADA, AK1, ALDOA, BPGM, CYB5A, G6PD, GCLC, GPI, GSR, GSS, HK1, NTS3CA, PFKM, PKG1, PKLR, TP1), hemoglobinopathies (HBA1, HBA2, HBB) and congenital diseritrhopoietic anemias (CDAN1, C15orf41, SEC23B, KLFL1, GATA1, KIF23).

**Results:**

- Finally, with the NGS panel results, the genetic diagnosis of 89% (103/116) of the included patients could be determined and only in 11% (13/116) the mutation was not identified or the variant correlation with disease was not clear. It is worthy to highlight that 10 of the 13 undiagnosed patients had been oriented as unclear membranopathy.

**Summary/Conclusions:**

According to the results, there is a high genetic heterogeneity in patients with RBC membrane disorders, as almost each family carries a unique mutation that is not observed in any other no related family. The present study reveals the usefulness of NGS panel, which allows the molecular diagnosis of almost 90% of the patients and it would avoid misdiagnosis or wrong therapy that could lead to splenectomy in conditions of apparent membranopathy. Moreover, the 11% of undiagnosed patients will be analyzed through a second NGS gene panel including potential new genes leading to chronic haemolyse and/or sequenced by whole exome sequencing with the aim to identify new disease causing genes.
Results: Table 1 shows clinical and laboratory characteristics of AIHA cases at onset and distribution of thermal types. Hb values were significantly lower in IgG+C wAIHA and atypical cases (p<0.001). LDH higher in IgG+C wAIHA, mixed and atypical forms (p=0.01), and Hb and LDH values were negatively correlated (r=-0.25, p=0.001). Absolute reticulocytes were reduced in CAD, mixed and IgG+C wAIHA (p<0.001) together with inadequate reticulocytosis (p=0.01). Moreover, the reticulocyte index was lower in cases with Hb<6 g/dL (65 vs 98, p=0.01), along with more frequent inadequate reticulocytosis (87 vs 70%, p=0.01). First line therapy was administered in almost all cases but 25 CAD. A second therapy line was mostly required in IgG+C wAIHA, mixed, and to a lesser extent in CAD (p=0.005). The ultra-refractory cases requiring 4 or more lines of therapy were mainly mixed, atypical and CAD. Considering anemia severity, patients with Hb<8 g/dL more frequently required treatment after first-line (51 vs 33%, p=0.004; p=0.03), or even 3 or more therapy lines (52/71, 73% vs 19/71, 26%, p=0.001). The following hazard ratios (HR) emerged from multivariate Cox regression analysis: HR 3.2 (95% CI 1.4-7.9) for Hb<10, 1.9 (1.4-6.2) for Hb<8, 1.6-7.5), for Hb<6, 6-8, and 8-10 g/dL compared to patients with Hb>10, respectively. As regards complications, infections were observed in 14% of cases, mostly mixed AIHA (p=0.02); thrombosis occurred in 10% and acute renal failure in 3% of patients, with no relationship with AIHA type/Hb values. Evans’ syndrome was more frequent in mixed or atypical cases (p=0.04) and in severe forms (74% with Hb<8 g/dL vs 26%, p=0.005), and was associated with higher relapse risk (HR 2.3, 95% CI 1.4-3.9). Seventy patients died during the follow-up, and 12 because of AIHA-related acute complications. Higher mortality was observed for infections (HR 5.8, 95% CI), acute renal failure (HR 7.6, 95% CI) and Evans’ syndrome (HR 8.3, 95% CI).

Summary/Conclusions: In conclusion, we found that severity of anemia at onset was the major determinant of relapse risk. The lowest Hb levels were observed in patients with IgG+C wAIHA and atypical cases along with higher LDLH levels and inadequate reticulocytosis, advising strict clinical observation in these patients.

P617

HEME BINDS ANNEXIN-A5 DURING HEMOLYSIS AND PREVENTS ITS INTERACTION WITH INTRACLASSICAL MEMBRANE PHOSPHATIDYLKEROSINE DURING SICKLE CELL DISEASE

S. Sadoudi1, S. Le Jeune2, D. Charue1, L. Roumenina3, C. Boulanger1, O. Blanc-Brude1,*

1INSERM UMRs970 ParCC, INSERM, Paris, 2Hôpital Avicenne, Médecine Interne, Assistance Publique-Hôpitaux de Paris, Bobigny, 3Institut Mondor de Recherche Biomédicale, Hôpital Henri Mondor, INSERM, Créteil, 4Centre de Recherche des Cordeliers, INSERM, Paris, France

Background: Intravascular hemolysis, such as in sickle cell disease (SCD), is characterized by damage to red blood cells and intracellular vesicles in plasma, along with inflammation and tissue injury. Stressed leukocytes, platelets, endothelial and red blood cells shed microparticles (MP) that bear externalized phosphatidylinerse (PS) at their surface and promote tissue injury. Conversely, intracellular annexin-A5 acts as an inhibitor of extracellular annexin-A5 at the surface of cells and MP. Annexin-A5 is thought to orchestrate vesicle trafficking, promote cell membrane repair, protect against PS-mediated effects and enforce anti-inflammatory and anti-thrombotic control.

Aims: We investigated a possible functional relationship between intravascular hemolysis and annexins. We hypothesized that annexins, and annexin-A5 activity in particular, is blocked by extracellular heme as it is released in plasma during intravascular hemolysis.

Methods: In order to test the heme-annexin-A5 relationship, we measured PS+, PS+, CD235a+ and annexin-A5+ circulating MP in adult SCD patient and matched control plasmas. We explored annexin-A5 expression in plasma and blood cells by Western blots and ELISA, and also quantified the PS-binding functionality of plasma annexin-A5 using a self-designed immunocapture assay and purified PS+ MP. Moreover, we investigated molecular interactions between purified heme and recombinant human annexin-A5 by surface plasmon resonance, with human serum albumin and hemopexin in competitive surface resonance assays. Finally, we put forward a model of heme-annexin-A5 docking by 3D molecular rendering.

Results: Immunocapture of plasma annexin-A5 revealed an association with heme (Abs398 nm signature) during SCD, especially during acute hemolytic events. In SCD plasma, we found increased total annexin-A5, but virtually undetectable levels of functional annexin-A5, contrary to controls. This implied a greatly reduced ratio of functional annexin-A5/circulating PS+ MP. Moreover, purified heme bound readily to annexin-A5 with relatively high affinity in vitro, as demonstrated using absorbance shift, autofluorescence quenching and plasma surface resonance assays, with human serum albumin and hemopexin in competitive surface resonance assays. This was followed by annexin-A5 aggregation, which also produced a significant red-shift in heme absorbance wavelengths, implying that a tight and direct molecular interaction was possible. Hemoglobin and heme also triggered annexin-A5 aggregation in vitro, producing high molecular weight and heat-resistant multimers, observed by western blot. Surface plasmon resonance studies revealed that annexin-A5 assumes several sites for heme binding, some with very low affinity, while others are estimated with a Kd in the 10-6m range, rather similar to that of albumin. Part of the heme bound to annexin-A5 remained in place, even in the subsequent addition of the high-affinity heme-scavenger hemopexin. 3D molecular docking rendering suggested that heme may bind to the heme-binding site of annexin-A5, thereby preventing further interactions with PS. Finally, heme completely prevented the binding of exogenous annexin-A5 to purified PS+ MP and plasma MP, as well as their subsequent detection by flow cytometry.

Summary/Conclusions: Together, our data suggest that PS-neutralizing annexin-A5 is inhibited by cell-free heme. This heme-mediated inhibition of annexin-A5 may display physiopathological relevance, contribute to the accumulation of PS+ MP in plasma during intravascular hemolysis, and more specifically of RBC MP during SCD which can participate to the degradation of the vascular function.

USE OF PEGYLATED-CARBOXYHEMOGLOBIN BOVINE FOR THE TREATMENT OF SICKLE CELL DISEASE ASSOCIATED LEG ULCERS: RESULTS FROM A PHASE 2 SAFETY STUDY

J. Valentino1, H. Misra1,*, L. Lopez2, G.M. Paulo3

1Prolong Pharmaceuticals, Prolong Pharmaceuticals, South Plainfield, United States, 2Hematology, Centro Hemato-Oncologico Paitilla, Royal Center, Panama, 3Hematology, Hospital General Plaza de la Salud, Santo Domingo, Dominican Republic

Background: Leg ulcers are a common complication of sickle cell disease (SCD). The pathophysiology of SCD leg ulcer is complex and may include obstruction of blood vessels by sickled red cell, chronic anemia, dehydrated nitric oxide bioavailability (resulting in impaired endothelial function), infection, thrombosis and excessive vasoconstriction. These events lead to progressive peripheral vascular occlusion and subsequent tissue necrosis, such that even minor lower-leg wounds can become persistent ulcers, with no tendency to heal after months of appropriate treatment. PEGylated-Carboxyhemoglobin bovine (PEG-COHb; SANGUINATE) is an oxygen carrying agent with anti-inflammatory activity. A study of safety and effectiveness was undertaken in SCD patients with chronic leg ulcers to determine the safety of this investigational drug administered in a once weekly infusion for either 4 or 6 weeks.

Aims: To assess the safety and efficacy of repeated doses of PEG-COHb on SCD leg ulcers.

Methods: The study was an escalating, repeated-dose, open-label, Phase 2 study to test PEG-COHb at 32mg/kg (8 mL) for 4 or 6 weeks, as a once weekly infusion for either 4 or 6 weeks. The study was conducted in Panama and the Dominican Republic. All enrolled subjects underwent a 3-week Run-In Period, during which they received standard of care treatment for wound management. During the Treatment Period, subjects were assigned sequentially to Cohort 1 or Cohort 2 based on the study center. Subjects in Cohort 1 received 4 once-weekly doses by 2-hour intravenous infusion of SANGUINATE. Following the completion of Cohort 1, the safety findings were reviewed prior to initiating Cohort 2. Cohort 2 received 6 once-weekly infusions. In addition to the study drug, subjects continued to receive standard of care during the Treatment Period. One week after the end of Treatment, subjects underwent a 3-week Follow Up Visit. Throughout, safety and efficacy were assessed using the Short Form-12 v2 Health Survey (SF-12), laboratory assessments (hematology, chemistry, and urinalysis), vital signs, concomitant medications, and 12-lead electrocardiograms (ECGs), efficacy: wound pain, wound appearance and condition, wound size, wound vascular status (Venous Clinical Severity Score; VSCC), quality of Life: Quality of life was assessed using the Short Form-12 v2 Health Survey (SF-12).

Results: The administration of once-weekly infusions of PEG-COHb was well tolerated. Treatment emergent adverse events (mild pyrexia, moderate wors-
ening anemia) considered related to study drug were reported in 2/10 patients. Increases in hepatic enzymes were anticipated due to the chelatic effects of this coloidal drug, but with no consistent pattern to the changes. Changes in ECG intervals were seen in a few subjects, but those changes were not considered clinically meaningful. There were no clinically meaningful changes in laboratory values, physical examinations, or concomitant medications. There were no statistically significant changes from baseline in leg ulcer pain and wound surface area for either Cohort. All of the wound assessments remained relatively consistent throughout the study. There were slight decreases in total VCSS at most time points, indicating slight improvement in vascular status.

Results were similar for the individual scores.

Summary/Conclusions: The administration of 4 or 6 once-weekly infusions of PEG-COHb at a dose of 320mg/kg was generally well tolerated. Slight improvements in total and individual VCSS are promising and may warrant further study with prolonged repeated doses of PEG-COHb.

P619
NON-RENAL DETERMINANTS OF ENDOGENOUS ERYTHROPOIETIN LEVELS IN SICKLE CELL DISEASE
K. Gardner1,2,*, C. Sharpe3,4, M. Awogbade1
1Haematological Medicine, King’s College Hospital, 2Molecular Haematology, King’s College London, 3Renal Medicine, King’s College Hospital, 4Renal Medicine, King’s College London, London, United Kingdom

Background: Sickle cell disease (SCD) is characterized by chronic hemolysis and inflammation. Elevated levels of erythropoietin (EPO) drive expansion of erythropoiesis to compensate for increased red cell destruction. EPO is produced in response to anemia and tissue hypoxia. Previous studies in SCD suggest that EPO is inappropriately low for the degree of anemia but the reasons are unclear.

Aims: To perform a retrospective analysis of data collected as part of routine clinical care to examine the relationship between serum EPO and degree of anemia (hemoglobin level, reduction status, hemoglobin ratio, alpha globin status, inflammation, serum ferritin and renal function).

Methods: King’s College Hospital (London, UK) has a large SCD population. All patients with HbSS or HbSβthalassemia who had a serum EPO level measured between 2007 and 2013 were included. Sickle genotype, alpha genotype, “baseline” HbF (no hydroxycarbamide, transfusion or pregnancy) and demographic data were recorded. Other clinically relevant variables were obtained from the same day as EPO levels (medications, laboratory values and oxygen saturation). Serum EPO was measured by chemiluminescence immunoassay (Siemens Immulite XPi). Exclusion criteria were: active vaso-occlusive crisis, transfusion within 8 weeks, chelation, erythropoiesis stimulating agent therapy, wound surface area for either Cohort. All of the wound assessments remained relatively consistent throughout the study. There were slight decreases in total VCSS at most time points, indicating slight improvement in vascular status.

Results: 245 adult (≥17 years) SCD patients (all of African or African-Caribbean origin) met the inclusion criteria. Of the 245, 241 had HbSS and 4 HbSβ0, 100 were male and 145 female, and mean age was 31.2 +/- 11.6 years. 221 had genotype, “baseline” HbF (no hydroxycarbamide, transfusion or pregnancy) and demographic data were recorded. Other clinically relevant variables were obtained from the same day as EPO levels (medications, laboratory values and oxygen saturation). Serum EPO was measured by chemiluminescence immunoassay (Siemens Immulite XPi). Exclusion criteria were: active vaso-occlusive crisis, transfusion within 8 weeks, chelation, erythropoiesis stimulating agent therapy, wound surface area for either Cohort. All of the wound assessments remained relatively consistent throughout the study. There were slight decreases in total VCSS at most time points, indicating slight improvement in vascular status.

Results: 245 adult (≥17 years) SCD patients (all of African or African-Caribbean origin) met the inclusion criteria. Of the 245, 241 had HbSS and 4 HbSβthalassemia, who had a serum EPO level measured between 2007 and 2013 were included. Sickle genotype, alpha genotype, “baseline” HbF (no hydroxycarbamide, transfusion or pregnancy) and demographic data were recorded. Other clinically relevant variables were obtained from the same day as EPO levels (medications, laboratory values and oxygen saturation). Serum EPO was measured by chemiluminescence immunoassay (Siemens Immulite XPi). Exclusion criteria were: active vaso-occlusive crisis, transfusion within 8 weeks, chelation, erythropoiesis stimulating agent therapy, wound surface area for either Cohort. All of the wound assessments remained relatively consistent throughout the study. There were slight decreases in total VCSS at most time points, indicating slight improvement in vascular status.

Results: 245 adult (≥17 years) SCD patients (all of African or African-Caribbean origin) met the inclusion criteria. Of the 245, 241 had HbSS and 4 HbSβthalassemia. Participants were enrolled after obtaining written informed consent/assent. This study is being conducted in 2 parts: Part A, single-dose, and Part B, multiple-dose for 24 weeks. The primary objective of Part A is PK and the primary objectives of Part B are safety and efficacy. PK samples to measure whole blood and plasma GBT440 concentrations were collected up to 15 days following single dose administration. Separate PPK models were developed to describe the concentration versus time profiles of GBT440 in whole blood and plasma using non-linear mixed effects modeling (NONMEM, version 7.3). The allometrically scaled adolescent PPK model was also used to estimate the appropriate single dose for subsequent evaluation in pediatric participants (6 to 12 years).

Results: Part A has been completed; 7 adolescents (3 males/4 females) received a single dose of GBT440 600mg. The median age of participants was 16 years (range 14 to 16 years) and the mean weight was 52.8 kg (range 44.6 to 65.8kg). GBT440 was well tolerated; there were no drug-related adverse events (AE) or serious adverse events and the most common AE was Grade 1 nausea. A 2-compartment model with first order absorption best described the PK of GBT440 and is the same model structure as previously used for adults with SCD. GBT440 PK parameters (Table 1) are comparable to those derived in adults, suggesting that GBT440 PK in adolescents and adults are similar. Model validation confirmed this result with good agreement between the observed adolescent PK data and simulated profiles based on the adult GBT440 PK model.

THE PHARMACOKINETICS (PK) OF GBT440 ARE SIMILAR IN ADOLESCENTS AND ADULTS WITH SICKLE CELL DISEASE (SCD)
C. Washington1, R. Savić2, A. Inati3, J. Estepp4, G. Woods5, E. Fong1, A. Hutchilelela1, M. Tonda1, G. Balaratnam1, J. Lehrer-Graiwer1

Background: Sickle cell disease (SCD) is caused by polymerization of Hemoglobin S (HbS), resulting in hemolysis and vaso-occlusion. Currently, no therapy achieving pancellular, direct inhibition of HbS polymerization is available for adults or children with SCD. GBT440 is a novel small molecular inhibitor which increases hemoglobin oxygen affinity, thereby preventing HbS polymerization and red blood cell sickling. This study represents the first evaluation of GBT440 in a pediatric population.

Aims: This study was designed to evaluate the safety and PK of GBT440 following a single and multiple doses in adolescents. In addition a population PK (PPK) model, based on data derived following single doses of GBT440, was developed to support the identification of future GBT440 dosing regimens for pediatric populations with SCD.

Methods: This is an ongoing, open-label, Phase 2a study in adolescents (12 to 17 years) with SCD (HbSS or HbS βthalassemia). Participants were enrolled after obtaining written informed consent/assent. This study is being conducted in 2 parts: Part A, single-dose, and Part B, multiple-dose for 24 weeks. The primary objective of Part A is PK and the primary objectives of Part B are safety and efficacy. PK samples to measure whole blood and plasma GBT440 concentrations were collected up to 15 days following single dose administration. Summary/Conclusions: This is the first study used to develop a GBT440 PPK model in adolescent participants with SCD. Data suggests that similar GBT440 doses can be used in adolescents and adults. Part B has been initiated to evaluate multiple doses of GBT440 in adolescents. This PPK model can potentially be used to estimate individual PK parameters (e.g., AUC) to support future GBT440 dose selection for evaluation in the pediatric population.

Background: Adult T cell leukemia/lymphoma (ATL) is an aggressive peripheral T-cell neoplasm caused by HTLV-1 virus infection and its prognosis remains very poor. Tax, which is the most important regulatory protein of HTLV-1, is associated with aggressive proliferative and is also a biologic antigen for CD8+ T-cells (CTLs). We previously analyzed the Tax-specific T-cell receptor (TCR) repertoire, phenotypes and functions of Tax-specific CTLs at the single-cell level in HLA-A*24 ATL patients who underwent allogeneic stem cell transplantation (allo-SCT). We found that a particular amino acid, tyrosine (Tyr), in the T-cell receptor (TCR) (CDR3 region of TCR-ß) was conserved in different patients and also within the same patient before and after allo-SCT, and the PDR Tyr+ T-cell clone selectively expanded in ATL long-term survivors as less-differentiated effector memory CTLs. Actually, the PDR+ CTL showed not only strong binding activity for the Tax-tetramer but also strong killing activity against patients' HTLV-1-infected T-cells without any reaction against normal cells.

Aims: Currently, we are planning a redirected T-cell immunotherapy using the PDR+ TCR genes for ATL. Therefore, we prepared donor-derived PDR+ TCR-transduced T-cells and evaluated their cytotoxic efficency against HTLV-1-infected T-cells and ATL-cells both in vitro and in vivo mouse model.

Methods: HLA-A24.02 restricted and Tax301-309-specific TCR-ß genes were cloned from an established PDR+ clone and integrated into a retroviral CR vector (Tax-siCTLs). First, cytotoxicity and cytokine production capability of the Tax-siCTLs and ATL-cells were evaluated using calcine-am-fluorescence assay and flow-cytometry analysis, respectively. Next, to evaluate the in vivo anti-ATL effects by the Tax-siCTLs, the bioluminescence assay (in vivo imaging system) was performed. We generated a luciferase-transduced HLA-A*24-HTLV-1-infected cell line, MT-2 (Luc-MT-2), and injected 1 × 106Luc-MT-2 cells into six-week-old NOD/Shi-scid IL-2RKO Jic (NSG) mice intraperitoneally. After 3 weeks, 2 × 106Tax-siCTLs were administered, in comparison, non-integrated T-cells (Mock) were administered in the same way. These mice were monitored for tumor growth using IVIS system weekly.

Results: Tax-siCTLs showed specific and strong killing activity against both HTLV-1 infected T-cells and patients' ATL-cells without any reaction against normal cells. In addition, Tax-siCTLs produced a sufficient amount of cytokines such as IFN-γ, TNF-α, and IL-2 against HTLV-1 infected T-cells. In mice experiments, the bioluminescence of Luc-MT-2 in the mice treated with Tax-siCTLs had started to reduce gradually after 7 weeks, and finally became undetectable after 9 weeks. In addition, macroscopic anatomical findings in the treated mice were normal after 12 weeks. In contrast, the amount of bioluminescence in the treated mice with Mock or in the control mice without treatment had rapidly increased and all mice died by 9 weeks.

Summary/Conclusions: We confirmed that Tax-siCTLs could exert a strong anti-ATL effect without significant reaction against normal cells both in vitro and in vivo. The therapy using this PDR+ Tax-siCTLs has a potential to be a novel immunotherapy for ATL patients.

P624
NOVEL ENHANCED AND DUAL TARGETING CAR INVARIANT NK CELL-BASED IMMUNOTHERAPY FOR CD1D+ B CELL MALIGNANCIES

A. Rotolo1, O. Dubois1, K. Goudevenou1, K. Petevi1, G.W. Cheung2, M. Pule2, J. Maher3, A. Karadimitris1

1Medicine, Imperial College London, London, UK, 2University College London, 3King's College London, London, United Kingdom

Background: Anti-CD19 chimeric antigen receptor T cell (CART19) immunotherapy has shown promising clinical potential in relapsed/refractory mature B cell malignancies. However, only about half of patients benefit, highlighting the need for more effective CAR-based strategies. iNKT cells are rare but powerful immunoregulatory and cytotoxic T lymphocytes, playing a pivotal anti-tumor role. iNKT cells are restricted by CD1d, a non-polymorphic, phospho-glycolipid-presenting HLA I-like molecule. We previously showed that CD1d, as well as on normal B cells, is also expressed on malignant CD19+ B cells in mantle cell lymphoma (MCL), marginal zone lymphoma (MZL) and chronic lymphocytic leukemia (CLL).

Aims: We tested the hypothesis that bi-specific CAR/iNKT cells targeting simultaneously CD19 and CD1d via the CD19-specific CAR and their natural invariant TCR respectively, would be more effective than CART19 cells against CD19+CD1d+ B cell malignancies.

Methods: We optimized a novel protocol for manufacturing 2nd (CAR2) and 3rd (CAR3) iNKT cells expressing CAR19. Their in vitro reactivity was assessed in cytotoxicity (flow cytometry-based) and cytokine and cytotoxic granule release assays (intracellular staining and LumineX technology). In vivo reactivity was assessed in NSG xenograft assays, with monitoring of 1T1CD1d1 tumour cure for CART19 and bi-specific CAR/iNKT cells.

Results: Our optimised protocol for selection, lentiviral transduction and clinical scale expansion of CAR/iNKT cells within 3 weeks is suitable for frozen and fresh lymphocytes, derived from either healthy donors or cancer, including lymphoblastic cell lines (LCLs) and primary HSCPs were targeted by the CRISPR/Cas9 system. INDels generated in edited FA sequences in these cells.

Methods: Two different FA mutations from FA-A patient-derived lymphoblastic cell lines (LCLs) and primary HSCPs were targeted by the CRISPR/Cas9 system. INDels generated as a consequence of the NHEJ mechanisms were then analyzed at different time points.

Results: Initial studies conducted in a FA-LCL carrying the biallelic c.295C>T point mutation that generates a premature stop codon (p.Q99X) showed targetting efficiencies around 20%. Next Generation Sequencing (NGS) not only revealed the generation of frame-restoring repair events, but also that these NHEJ events have been converted to edited cells. Moreover reversion of the characteristic MMC hypersensitivity and restoration of the FANCD2 foci formation were observed in these cells. In addition, western-blot analysis confirmed the stable expression of FA protein. To further demonstrate the feasibility of the approach, a second FA-A LCL carrying the c.3580insG, producing a frameshift and a premature stop codon -p.R1187fsX28- with even higher gene targeting efficiencies. Finally similar studies were conducted in three HSCPs samples from FA-A patients harboring the c.295C>T mutation, that showed targetting efficiencies up to 36%. Moreover, NGS detected the presence of corrective NHEJ-repair events immediately after editing and evidencing up to 50-fold expansion of corrected cells after nine days in culture, confirming the functionality and proliferative advantage conferred by the frame restored alleles.

Summary/Conclusions: Our results demonstrate for the first time that NHEJ gene correction is feasible in FA-HSCPs. The high efficiency of the NHEJ repair pathway in HSCPs together with the simplicity of the strategy, may approach clinically relevant for the future treatment of the hematopoietic defects in FA patients.
phoma patients. The manufacturing process consistently allows high CAR transduction efficiency of NK and T cells (75.31%±4.294 and 76.95%±14.76 respectively, n=8) and ensures the preservation of CD4+ NK cells, which have a higher cytotoxic potential and anti-tumour activity. In vitro validation, using singly- or dual-positive CD19 and CD19 targets, demonstrated that CARiNKT19 cells are CD19-specific, retain their natural CD1d-restricted reactivity and exert additive dual-specific cytotoxicity against CD19+CD19+ targets. Additional functional dissection showed that activated CARiNKT19 cells, both fresh and cryopreserved, have the ability to produce cytotoxic granules and IFNγ faster and in larger amounts than same donor activated CART19 cells. Likewise, CAR2- and CAR3-NK cells are equally or more effective than their CART counterparts at killing CD19+ and CD19-Lewis cell lines (B-lymphoblastoid 1RCD1d and lymphoma-derived Farage cells) and consistently more effective against primary MCL, MZL and CLL cells. Finally, in an in vivo NSG xenograft model of lymphoma, while survival of T- and NKT cell-treated animals was the same as that of untreated animals (P=0.20), both CART19 and CARiNKT19 cell-treated animals had significantly and comparably improved overall survival (P<0.001). However, compared to CART19, CARiNKT19 immunotherapy led to a better disease control, with earlier, more profound and sustained responses resulting in a significantly improved tumour free-survival (P<0.03).

Summary/Conclusions: In our pre-clinical in vitro and in vivo lymphoma models, CARiNKT19 are more effective than CART19 cells against CD19+ and CD19+ B cell malignancies. Further, dual targeting by CARiNKT19 cells may mitigate against CD19-focused tumour escape after CAR immunotherapy, while the previously demonstrated role of donor iNK cells in protection from gVHD supports the development of CARiNKT19 cells for ‘off-the-shelf’ use.

P625
A NOVEL CHIMERIC ANTIGEN RECEPTOR ENDOWS T CELLS WITH NK CELL-LIKE SPECIFICITY AND ATTACKS A WIDE RANGE OF HEMATOLOGICAL MALIGNANCIES AND CANCERS
Y. Kasahara1,*, C. Shin1, M. Imamura1, N. Kubo1, T. Takachi1, H. Iwabuchi1, S. Yoshida1, A. Saitoh1, C. Imai1
1Department of Pediatrics, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan

Background: Engineered T-cells expressing CD19-specific chimeric antigen receptors (CARs) have shown high response rates against relapsed and refractory B cell acute lymphoid leukemia (ALL). However, similar success has not yet been demonstrated in solid tumors, and the reasons for this are currently being investigated. One major obstacle is the difficulty in determining appropriate surface antigens that are effectively targeted by CAR-transduced immune cells. NKp44 is an activating receptor on human NK cells that is only expressed on various types of cancers, but not in healthy cells. Effective use of the ligand-binding domain of this receptor as an antigen recognition site of a CAR would thus allow a wide range of cancer cells to be attacked.

Aims: To determine the optimal CAR construct including the NKp44 immunoglobulin domain as a ligand-binding domain (NKp44-based CAR), with a view to developing effective CAR-T therapy against hematological malignancies and solid cancers.

Methods: We created several NKp44-based CAR constructs. Human T cells from healthy donors were stimulated with anti-CD3/CD28 beads and recombinant interleukin-2. Human NK cells were stimulated using K562-mb15-41BBL feeder cells, as previously reported (Imai C, 2005). Activated T cells or NK cells were then subjected to retroviral transduction with the CAR gene and the phenotypic and functional characteristics of CAR-T cells engrafted with the various NKp44-based CARs were compared. We determined if NKp44-ligands were present on the cell surface of various types of malignant cell lines using recombinant human NKp44 Fc chimeric protein.

Results: The expression of ligands for NKp44 was confirmed in a wide range of tumor cell lines including acute myeloid leukemia (AML: KG-1, THP-1, U937, K562, Kasumi-1, Kasumi-6), T-cell ALL (MOLT-4, HS62, Peer, Jurkat), B-cell ALL (OP-1), Burkitt’s lymphoma (Raji), osteosarcoma (NOS-10, NOS-1, NOS-2, SaOs-2, U2OS,mg-63), rhabdomyosarcoma (RMS-YM, Rh28), and neuroblastoma (NB1, NB16, IMR-32, SK-N-SH). Different expression levels of CAR were observed among the NKp44-based CARs created in this study, in which the major CAR domains, except for the ligand-binding domain, were derived from various components including NKp44, CD8α, CD28, or CD3ξ. A combination of the hinge domain from NKp44, transmembrane domain from CD8α and intracellular domain from CD3ξ yielded the highest surface expression of CAR on both T cells and NK cells. T cells transduced with this CAR showed enhanced cytotoxicity against various target cells including AML, T-cell ALL, and B-cell ALL, but did not attack normal T cells. CAR-T cells also showed increased production of interferon-gamma and granzyme B. The hinge domain may be suggested to play a role in ligand binding (Koch J, 2013), but the details are poorly understood. Intriguingly, replacement of the hinge domain from NKp44 significantly reduced cytotoxic function, though CAR expression levels remained similar.

Summary/Conclusions: T cells transduced with NKp44-based CARs show enhanced activities against various tumor cells. The extracellular hinge region of NKp44 appears to play an important role in ligand binding and/or recognition. NKp44-based CARs may represent a promising candidate for novel immune therapies targeting a wide range of cancers.

Background: Adoptive cellular therapy (ACT) of chimeric antigen receptor (CAR)-redirected T cells has evolved as a highly effective individualized immunotherapy for leukemia and solid cancer. In particular, clinical trials using CD19 expressing T lymphocytes to combat CD19+ lymphomas have revealed compelling results. However, suitable antigens for an effective and specific CAR-mediated therapy to acute myeloid leukemia (AML) are still warranted as e.g. CD33 and CD123 carrying T cells induce potent immune responses. We investigated the potential of the recombinant human NKp44 Fc chimeric protein.

Methods: We created several NKp44-based CAR constructs. Human T cells transduced with this CAR expressing T lymphocytes to combat CD19+ lymphomas have revealed compelling results. However, suitable antigens for an effective and specific CAR-mediated therapy to acute myeloid leukemia (AML) are still warranted as e.g. CD33 and CD123 carrying T cells induce potent immune responses. We investigated the potential of the recombinant human NKp44 Fc chimeric protein.

impressive therapeutic results recently obtained with checkpoint inhibitors have opened a new era in the field of cancer immunotherapy. Yet, clinical responses are still often observed either transiently or in a minority of patients. This under-
scores the need for an improved understanding of underlying factors limiting the efficacy of T cell-based immunotherapy and its wide application.

Aims: We explored an immunotherapeutic combination strategy to unleash the full potential of adoptively transferred antigen-specific T cells. We also proposed to target multiple myeloma (MM) tumor cells in our established xenograft in vivo adoptive cell therapy model by T cells equipped with two optimized TCRs specific for HLA-A2.1-restricted MDM2 and p53 epitopes in combination with checkpoint inhibitors.

Methods: Human T cells from healthy donors were retrovirally transduced with MDM2- and p53-specific TCRs and expression levels were analyzed by flow cytometry. MDM2 and p53 protein expression in MM cell lines was determined by Western blot. The therapeutic efficacy of adoptive TCR transfer was evaluated in NOD-scid IL2R gamma chain (NSG) mice engrafted (s.c.) with HLA-A2.1-expressing MDM2+/- p53+/- cell line. In the adoptive cell transfer approach, mice were treated (i.p) with anti-PD-1 (Nivolumab). Tumor growth was monitored and intratumoral alterations (in particular expression of relevant tumor and T cell antigens) in ex-vivo tumors were analyzed by flow cytometry. Tumor infiltrating lymphocytes (TILs) were also characterized by flow cytometry.

Results: Adoptive transfer of dual MDM2/p53-specific TCR equipped T cells showed a superior anti-tumor response in vivo compared to single TCR treat-
ment, demonstrating the need to target multiple MM antigens to circumvent tumor escape mechanisms associated with down-regulation of antigen. Yet, we observed a strong up-regulation of PD-L1 expression in tumor cells in vivo and no significant infiltration of TILs in TILs samples which may limit the efficacy of antigen-specific TILs. Accordingly, in vivo ACT experiments combined with anti-PD-1 inhibitor, demonstrated the synergistic therapeutic potential of this approach as compared to single agent. Yet, it does not result in complete tumor eradica-
tion suggesting that targeting one single immune checkpoint receptor is not sufficient to drive a full anti-tumor response.

Summary/Conclusions: Combination checkpoint inhibitor approach has demonstrated promising potential in our ACT experimental MM model and forms the basis for a novel multi-modal immunotherapeutic combination treat-
ment for multiple myeloma.

ENGINEERED T CELLS TOWARDS BAFF RECEPTOR: A NOVEL STRATEGY TO EFFICIENTLY TARGET B-CELL ACUTE LYMPHOLASTIC LEUKEMIA
N. Turazzi1,*, G. Fazio1, V. Rossi1, A. Rolink2, G. Cazzaniga1, A. Biondi3, C.F. Magnani1, E. Biagi1
1M.Tettamanti Research Center, Department of pediatrics, University of Milano Bicocca S.Gerardo Hospital/Fondazione MBBM, Monza, Italy, 2Department of Biomedicine, University of Basel, Basel, Switzerland, 3M.Tettamanti Research Center, Department of pediatrics, University of Milano Bicocca S.Gerardo Hospital/Fondazione MBBM, Monza, Italy

Background: B-cell Acute Lymphoblastic Leukemia (B-ALL) is most common in children (80%), but it has also a peak of incidence in adult age. Immunother-
apic approaches targeting the CD19 molecule paved the way for the treat-
ment of relapsed and refractory lymphoblastic leukemia, which remains a major therapeutic challenge. Recently, the emergence of relapses with CD19-epitope loss in 10-30% of treated patients has been reported. This newly identified escape mechanism has been recently shown to be related to the combination of deleterious mutations and emergence of alternatively spliced RNA isoforms, as effect of selective pressure. B-cell Activating Factor (BAFF) Receptor is a transmembrane protein which is fundamental for B-cell maturation and survival. Moreover, the expression of this receptor is restricted to mature B cells and, interestingly, is not present on bone marrow B-cell precursors. Recent studies reported the over-expression of BAFF Receptor (BAFF-R) in various B-cell malignancies such as B-ALL, B lymphoma, chronic lymphocytic leukemia and myeloma. In the context of B-ALL leukemic cells express both BAFF and BAFF-R suggesting the presence of an autocrine signalling loop. BAFF is also expressed in bone marrow microenvironment by endothelial cells which support the proliferation and the survival of primary B-ALL blasts.

Aims: In the current study, we aimed to develop a chimeric antigen receptor (CAR) approach and its immunotherapeutic potential aiming at re-directing adoptively transferred antigen-specific T cells.

Methods: We characterized the expression of BAFF-R in B-ALL primary sam-
ples. As immunotherapeutic approach to target BAFF-R molecule, we de-
veloped six anti-BAFF-R.CARs that differ for the inversion of the VH and VL and the length of the spacer domain. Cytokine-induced Killer (CIK) cells, an heterogeneous populations of CD3+ effector lymphocytes with acquired NK-like cytotoxicity enriched in highly effi-
cient cytotoxic CD3+CD56+ cells, were engineered using an improved Sleeping Beauty (SB) transposition platform and used as effector population.

Results: Adoptive transfer of BAFF-R specific TCR engineered in B-ALL primary samples at the onset and relapse. In order to develop a chimeric antigen receptor (CAR) approach targeting BAFF-R molecule, six anti-BAFF-R CAR genes that differ for the inversion of the VH and VL and the length of the spacer domain have been generated. Cytokine-induced Killer (CIK) cells, engineered using an improved Sleeping Beauty (SB) transposition system, stably expressed anti-BAFF-
FR.CARs, and maintained their characteristic phenotype. Among the newly con-
structed CARs, the shortest VHH anti-BAFFR CAR exerted the highest anti-
leukemic activity towards target cells, such as NALM-6, in an in vitro killing assay. These data supported the use of BAFF-R CARs developed in terms of cytokine release by intracellular staining (8,9±2.6% of IFN-γ and 16,4±5.5% of IL-2 pro-
ducing cells). Importantly, we also detected a specific cytotoxic activity towards primary B-ALL blasts (average 65,6±4,5%, n=9). Combining the INvSh.CAR with CD19.CAR we detected a superior antitumor activity towards ALL targets (average in vitro killing ability of 72,2±22,9% of NALM-6 and 87,1±13,2% of B-ALL blasts) compared to single population per se. Furthermore, by using a sample collected from a patient relapsed with CD19 negative disease, we demonstrated the ability of the INvSh.CAR to lysate CD19-negative blasts.

Summary/Conclusions: Taken together, these findings make this receptor a valid candidate target for CAR engineering in case of relapse after CD19-targeting therapies or for a double targeted approach. Being restricted to mature B cells, but absent on precursors and plasmablasts, our strategy could have an inferior toxicity concerning the emergence of B-cell apia-
sia observed in patients treated with anti-CD19 CAR-modified T cells.
BACKGROUND: Acute Myeloid Leukemia (AML) is an aggressive malignancy associated with high relapse rates when treated with conventional chemotherapeutic and hematopoietic transplantation regimens. In search for alternative strategies, interest has focused on antigen-specific immunotherapies and in particular on T cells redirected with Chimeric Antigen Receptors (CARs) that have shown exciting results in cancer therapy, especially in the context of B-cell malignancies. CD33 is the only validated target in AML so far and represents a suitable antigen to be targeted with CAR-T cells, being broadly expressed on AML blasts.

Aims: The aim of the present study is to preclinically evaluate the efficacy and safety profiles of CD33 CAR redirected Cytokine Induced Killer (CIK) cells alone and in combination with standard chemotherapeutic agents.

Methods: Here we proved the feasibility of harnessing Cytokine Induced Killer (CIK) cells with the BB305 vector, which encodes a human β-globin gene containing a single point mutation (AT87Q) designed to confer anti-sickling properties similar to γ-globin. We recently (ASH 2016) reported 23 patients with TDT (≥100 mL/kg of packed red blood cells [RBCs] per year) were enrolled.

RESULTS: CD33.CAR-CIK cells were infected with a third generation anti-CD33.CAR through the non-viral Sleeping-Beauty transposon system, starting from fresh and frozen healthy mononuclear cells (PBMCs) and also from frozen primary AML samples. The in vitro anti-AML activity of CD33.CAR-CKI cells is assessed by means of cytoxicity, proliferation and cytokine production assays upon challenge with AML cell lines and primary samples. The in vivo efficacy of CD33.CAR CIK cells is evaluated in NSG mice transplanted with AML cell lines (MA0-NRas cells) and primary samples. Moreover, to investigate the potential benefit of CD33.CAR CIK cell immunotherapy in combination with standard-of-care treatments, xenograft chemotherapy models is exploited, by using standard AML induction therapy drugs (Ars-C and doxorubicin).

Summary/Conclusions: Having demonstrated the significant in vitro anti-CD33.CAR-CKI cells we next aim to assess their efficacy in vivo, particularly against the resistant/residual AML cells that were not eradicated by standard chemotherapy treatment. Moreover, envisaging a safer clinical translation of this immunotherapeutic approach, a transient CAR expression, by using CD33.CAR coding mRNA, is under investigation, in order to limit the potential myelotoxicity due to the long-term off-target effect on normal hematopoietic stem/multioid progenitor cells. Finally, if successful, our results will provide the preclinical validation of CD33.CAR-CKI cell immunotherapy, supporting its development to the clinic.

P631
UPDATE ON THE FIRST PATIENTS WITH SEVERE HEMOGLOBINOPATHIES TREATED WITH LENTIGLOBIN GENE THERAPY
1Necker Hospital, Paris, 2Institute of Emerging Diseases and Innovative Therapies (IMETI), CEA & University of Paris-Sud, Fontenay-aux-Roses, 3Université Paris Descartes, 4Hôpital Saint Louis, 5Université Paris Diderot, 6Hôpital Henri Mondor, 7Hôpital Cochin Saint Vincent de Paul, Paris, France, 8bluebird bio, Cambridge, United States

BACKGROUND: Insertion of an anti-sickling β-globin gene variant into hematopoietic stem cells (HSCs) could reduce or eliminate symptoms of severe sickle cell disease (SCD) and transfusion requirements in transfusion-dependent β-thalassaemia trait (TDT). LentiGlobin Drug Product (DP) contains autologous CD34+ cells transduced with the BB305 lentiviral vector, which encodes a human β-globin gene containing a single point mutation (AT87Q) designed to confer anti-sickling properties similar to γ-globin. We recently (ASH 2016) reported 23 patients with TDT: 3 have β(0)β(0) genotypes and 1 is homozygous for a severe β(0) mutation (IVS1 nt 110 G>A). Two of the β(0)β(0) patients have completed their 2-year primary follow-up and entered a long-term follow-up study. They have been without RBC transfusions for 33 and 30 months, with total Hb of 10.9 and 13.5 g/dl, and HbA(T7Q) of 7.7 and 10.1 g/dl, respectively. The third patient with a β(0)β(0) genotype has 12 months follow-up and has not required transfusions since 4 days post-LentiGlobin DP infusion, with total Hb 11.3 g/dl and HbA(T7Q) of 8.6 g/dl. The patient with the IVS1 genotype has 15 months of follow-up and has been free of transfusions for 11.6 months, with total Hb 8.3 g/dl and HbA(T7Q) of 6.7 g/dl. Since September 2016, 2 more patients with severe SCD have received LentiGlobin DP.

Summary/Conclusions: Data to date from this ongoing Phase 1/2 clinical study suggest that treatment with LentiGlobin DP elicits sustained Hb(T7Q) levels, which alleviate the clinical and biochemical effects of severe SCD and TDT, with safety consistent with myeloablative conditioning. Follow-up data on the 5 previously reported patients and early results from the 2 recently treated patients will be presented.

A SINGLE INSTITUTIONAL EXPERIENCE OF 261 PATIENTS WITH LARGE GRANULAR LYMPHOCYTIC LEUKEMIA
M. Van den Bergh1,2, L. Isenalume1,3, E. Wang2,3, B. Schable1,3, Z. Ma1,3, L. Zhang1,3, L. Zhao1,3,1
1Lee Moffitt Cancer Center & Research Institute, 2University of South Florida, Tampa, United States

Background: Large granular lymphocytic leukemia (LGLL) is a rare clonal lymphoproliferative disorder of post-thymic T-cell or natural killer (NK)-cell lineage associated with cytopenias, splenomegaly, autoimmune disorders, and recurrent mucocutaneous infections. Treatment is dictated by the presence of these manifestations and consists of immunosuppressive therapy.

Aims: The main aim of this study is to evaluate clinical features, hematological parameters, and survival data of patients with LGLL. The secondary aim is to assess response rates and duration of response to various first line immunosuppressive therapies in LGLL.

Methods: This is a retrospective analysis of clinical and laboratory features, treatment modalities, and outcomes of LGLL patients evaluated at Moffitt Cancer Center between January 1, 1995 and May 1, 2016. Continuous and categorical variables were tested via Kruskal-Wallis ANOVA and Fisher’s Exact Test, respectively. Kaplan-Meier curves were used for overall survival (OS), P-values were two-sided with significance set at <0.05.

Results: We identified 261 patients with LGLL (91.6% T-cell, 8.4% NK-cell). Median age was 66 years [21-90] and M:F ratio was 1:2.1. Median follow up was 3.07 years [0-21.88]. 42.9% of LGLL patients presented with anemia, 37.1% with neutropenia, 30.7% with thrombocytopenia, 29.1% with bicytopenia and 6.9% with pancytopenia. Transfusion dependence was noted in 20.3%, splenomegaly in 27.9% and bone marrow involvement in 69.2%. 24.9% had autoimmune diseases and 9.2% had autoimmune cytopenias. 45.6% were observed while the remainder required at least one line of therapy. 5-year and 10-year OS were 75.0% and 63.1%, respectively. There was no statistically significant difference in OS, complete response rate or duration of response based on first line agent (methotrexate, cyclophosphamide, cyclosporine A). However, there was a statistically significant improved partial response with methotrexate versus other therapies (P=0.01). A marginally significant association between severe anemia/transfusion dependence and poor overall response rate (P=0.075) to any immunosuppressive therapy was noted. There was no statistically significant difference in OS based on absolute LGL count. Mean number of therapies was 1.08 (range 0-6) and was higher in patients with LGL count <0.5 k/L (P=0.0078), bone marrow involvement (P<0.0001), and splenomegaly (P<0.0001).

Summary/Conclusions: In this large retrospective study, we described the frequency of LGLL-associated manifestations and their impact on the course of LGLL. Severe anemia/transfusion dependence, lower LGL counts, bone involvement, and splenomegaly were suggestive of more aggressive disease. We confirmed that there is no difference in overall survival among first line immunosuppressive therapies.

P634
ONGOING PHASE 1/2 STUDY OF INCB050465, A SELECTIVE PI3K-DELTA INHIBITOR, FOR THE TREATMENT OF PATIENTS WITH RELAPSED/REFRACTORY B-CELL MALIGNANCIES (CITADEL-101)
1University of Alabama Birmingham, Birmingham, AL, 2Indiana Blood & Marrow Transplantation, LLC, Indianapolis, IN, 3Hematology/Oncology Associates of Treasure Coast, Port St Lucie, FL, 4University of Michigan, Ann Arbor, MI, 5Hackensack University Medical Center, Hackensack, NJ, 6Greenville Health System Cancer Institute, Greenville, SC, 7Department of Medicine-Gastroenterology, Cleveland, OH, 8Utah Cancer Specialists-Network, Salt Lake City, UT, 9University of Arizona Cancer Center, Tucson, AZ, 10Incyte Corporation, Wilmington, DE, 11Incyte Corporation, Wilmington, DE, 12Karnamov Cancer Center, Detroit, MI, United States

Background: Signalizing networks mediated by PI3Ks have been implicated in proliferation, migration, and function of B-cells. INCBO50465 is a novel, potent, and selective PI3Kδ inhibitor of PI3Kδ (≥19,000-fold more selective for PI3Kδ vs other isoforms). INCBO50465 demonstrated linear pharmacokinetics (PK) and achieved exposure levels several-fold greater than the IC50 for PI3Kδ inhibition at the recommended phase 2 dose (ASH 2016; Abstract 4195).

Aims: To evaluate INCBO50465 in patients with relapsed or refractory B-cell malignancies enrolled in an ongoing phase 1/2 study (NCT02018861).

Methods: In this phase 1/2 study, eligible patients ≥18 years of age had relapsed/refractory lymphoid B-cell malignancies (excluding Burkitt’s lymphoma and precursor B-cell lymphoblastic leukemia/lymphoma), Eastern Cooperative Oncology Group performance status score ≤2 (≤1 during dose escalation), normal liver and kidney function, and had not received autologous hematopoietic stem-cell transplant (HSCT) within 3 months or allogeneic HSCT within 6 months of screening. The protocol was initiated with a single-patient cohort, treated with oral INCBO50465 5mg QD. Subsequent cohorts used a 3+3 design and evaluated doses of 10–45mg QD. Based on PK/pharmacodynamics, the 20 and 30mg QD cohorts were expanded. Responses were assessed every 8 weeks using the Lugano Classification or International Working Group on Chronic Lymphocytic Lymphoma (CLL) criteria.

Results: As of the data cutoff (Nov 1, 2016), 52 patients were treated (median age, 65 years, range [20–85], 50% were male). Baseline disease subtypes included diffuse large B-cell lymphoma (DLBCL; n=14), follicular lymphoma (FL; n=10), Hodgkin lymphoma (HL; n=9), marginal zone lymphoma (MZL; n=8), CLL (n=6), and mantle cell lymphoma (MCL; n=5). Sixty-two percent (n=32) of patients ≥3 prior systemic regimens; 31% (n=16) had prior HSCT. Median duration of therapy was 4 months (range, 0–14); 15 patients were treated ≥6 months. Responses were assessed in 55 patients who received ≥2 dose levels of INCBO50465 (17%), lymphopenia (10%), and anemia (6%). Forty percent of patients had serious adverse events (AEs), most frequently colitis, diarrhea, and hypotension (24%); 10% of patients had grade 3 pneumonitis; none had Pneumocystis jirovecii pneumonia (PJP) or grade ≥4 elevated transaminase. Objective responses occurred at all doses (Table 1), except 5mg QD; 90% of the objective responses were observed in the 9-week disease assessment.

Table 1.

Summary/Conclusions: In patients with relapsed/refractory B-cell malignancies, INCBO50465 demonstrated manageable toxicities with no clinically meaningful transaminitis or PJP. Objective response rates were generally high and most responses (90%) were observed at the 9-week disease assessment. Different dosing regimens/schedules, long-term safety, and disease-specific cohorts are being evaluated.

P635
PHASE III RANDOMIZED STUDY OF LENALIDOMIDE PLUS RITUXIMAB (R2) FOLLOWED BY LENALIDOMIDE VS. RITUXIMAB MAINTENANCE IN PATIENTS WITH RELAPSED/REFRACTORY NHL: ANALYSIS OF FOLLICULAR LYMPHOMA PATIENTS
1Rocky Mountain Cancer Centers, Aurora, CO, 2The US Oncology Network, The Woodlands, TX, 3Rocky Mountain Cancer Centers, US Oncology Research, Boulder, CO, 4University of Kansas Cancer Center, Westwood, KS, 5Texas Oncology, Austin, TX, 6Weill Cornell Medicine, New York, NY, 7Northwest Cancer Specialists PC, Vancouver, WA, 8Oncology and Hematology Associates, US Oncology Research, Roanoke, VA, 9Oncology Specialists, SC, Park Ridge, IL, 10Greenville Health System, Greenville, SC, 11Dartmouth Hitchcock Medical Center, Lebanon, NH, 12Cellgene Corporation, Summit, NJ, 13Williamette Valley Cancer Institute and Research Center, US Oncology Research, Springfield, OR, United States

Background: Lenalidomide is an immunomodulatory agent with direct and immune-mediated mechanisms of action, and clinical activity in indolent non-Hodgkin lymphoma (NHL). Recent studies in frontline and relapsed/refractory (R/R) INHL show tolerability and high activity for the combination of lenalidomide plus rituximab (R2) and support further study of R2. Aim: The current study analyzed the efficacy and safety of R2 induction in patients with R/R follicular lymphoma (FL).

Methods: MAGNIFY (NCT01996865) is a Phase IIIb, multicenter, open-label study of R/R NHL patients, including grades 1-3b and transformed follicular
lymphoma (IFL). Upon informed consent, patients receive 12 cycles of R² induction (indomethacin 200mg, 3 weekly cycles 1 [d1, 8, 15, 22], then d1 of odd cycles). Responders to induction (≥SD) are randomized: 1:1 to maintenance with either R² or rituximab alone (18 cycles); following R² maintenance, optional single-agent lenalidomide (10mg/d, 21 of 28 d) can be given until PD. The primary endpoint is progression-free survival (PFS).

Results: As of April 14, 2016, 106 patients with R/R FL have been enrolled, including 103 with grade 1-3a FL, 2 with tFL, and 1 unknown grade. Median age of patients with FL was 66 y (range, 41-91); most had ECOG PS of 0-1 (99%) and stage III/IV disease at study entry (80%). Patients received a median of 2 prior therapies (≥2, 30%); 103 (87%) patients had received prior rituximab-containing treatment, of which 35% were rituximab refractory (defined as best response of SD/PD to rituximab/rituximab-containing regimen or a CR/PR of ≤6 mo after the last rituximab dose). The most common prior regimens were rituximab alone (40%), R-CHOPI-R-CHOP-like (38%), and bendamustine plus rituximab (35%). Preliminary discontinuation rates of R² induction occurred in 30 (37%) patients during the induction period, mainly due to AEs (n=20); the most common treatment-related AE leading to early discontinuation in the induction period was neutropenia in 8 patients. Four (4%) patients’ study discontinued the study. Common grade 3/4 treatment-emergent AEs during induction in the FL safety population (n=104) were 27% neutropenia, 7% leukopenia, and 6% fatigue. At a median induction duration of 23 weeks (range, 0.4-51), 83 FL patients were evaluable for response with an overall response rate (ORR) of 65%; those who were not rituximab refractory had improved ORR compared to rituximab refractory patients (70% vs 55%; Table 1). The median time to response during induction was 2.8 mo. Twenty patients have completed 12 cycles of induction and 16 proceeded to maintenance (n=6 R², n=10 rituximab alone). Enrollment is ongoing.

Table 1.

Summary/Conclusions: R² induction therapy shows favorable activity and a tolerable safety profile in patients with advanced-stage, R/R FL. The study is ongoing to determine the effect of R² vs rituximab maintenance in FL patients, and updated results will be presented.

P635

A DOUBLE-BLIND, RANDOMIZED PHASE 3 STUDY TO COMPARE EFFICACY AND SAFETY OF CT-P10 TO INNOVATOR RITUXIMAB IN COMBINATION WITH CVB IN PATIENTS WITH PREVIOUSLY UNTREATED ADVANCED FOLLICULAR LYMPHOMA

1Department of Haematology, Jagiellonian University, Kraków, Poland, 2Hospices Civils de Lyon, Pierre-Benite, France, 3Department of Hematology and Hematopoietic Cell Transplantation, City of Hope, Duarte, United States, 4Department of Haematology, Jagiellonian University, Kraków, Poland, 5Hospital Universitario Getafe, Madrid, Spain, 6Department of Haematology, Haematoplastic Institute, Bucharest, Romania, 7Department of Clinical Cancer Research, Chief of the Division of Experimental and Clinical Research of the National Cancer Institute, Bethesda, MD, USA, 8National Cancer Centre, Singapore, Republic Of, 9Hospital Universitario Infanta Leonor, Madrid, Spain, 10Minsk City Clinical Oncology Dispensary, Minsk, Belarus, 11Department of Internal Medicine, Yonsei University College of Medicine, Se- erance Hospital, Seoul, Korea, Republic Of, 12Hospital Universitario Infanta Leonor, Madrid, Spain, 13Minsk City Clinical Oncology Dispensary, Minsk, Belarus, 14Samsung Medical Center, Seoul, Korea, Republic Of, 15Hospital Universitario de Canarias, I.N.C.A. Canarias, Spain, 16Celltrion Inc., Incheon, Korea, Republic Of

Background: CT-P10 is the first biosimilar of innovator Rituximab (RTX), approved for all indications by the European Medicines Agency. CT-P10 has demonstrated pharmacokinetics (PK) and efficacy equivalence in patients with rheumatoid arthritis (Yoo, ACR 2016) and PK equivalence in patients with advanced follicular lymphoma (AFL) (Coiffier, ASH 2016).

Aims: This study aimed to demonstrate non-inferiority (NI) of efficacy and PK equivalence between CT-P10 and RTX in patients with newly diagnosed advanced follicular lymphoma (AFL) (NCT01262771).

Methods: A total of 140 patients were randomized in a 1:1 ratio to receive CT-P10 or RTX (375mg/m² intravenous) plus CVB (cyclophosphamide, vincristine, and prednisone) therapy every 3 weeks over 8 cycles. Overall response rate (ORR) was the primary endpoint and assessed by independent review committee, according to the International Working Group criteria.

Results: Therapeutic NI of CT-P10 to RTX has been demonstrated in terms of ORR over 8 cycles (Table 1). The ORR difference between two treatment groups was 4.3% in per-protocol (PP) population and 5.7% in intent-to-treat (ITT) population. Considering the statistical Non-Inferiority test using confidence interval (CI) approach with the exact binomial CI for the difference of ORR between two treatment groups, the lower bound of 95% CI lies on the positive side of -7% Ni margin (-4.25% in PP population and -3.41% in ITT population).

Summary/Conclusions: This study demonstrates therapeutic non-inferiority of CT-P10 to RTX combined with CVB therapy in previously untreated AFL Patients well-tolerated and the safety profile including immunogenicity of CT-P10 was comparable to that of RTX over 8 cycles in induction period.

Table 1. Summary of Efficacy [Number (%) of patients].

Table 2. Summary of Treatment-emergent adverse event (TEAE) related to the study drug [Number (%) of patients].

Summary/Conclusions: This study demonstrates therapeutic non-inferiority of CT-P10 to RTX combined with CVB therapy in previously untreated AFL and the safety profile including immunogenicity of CT-P10 was comparable to that of RTX over 8 cycles in induction period.

1Clinica di Ematologia, 2Istituto di Anatomia Patologica, 3Clinica di Dermatologi- a Ospedale Nuerni Umberto I- Salesi-Lancisi di Ancona, 4Clinica de Derma- tologia, Ospedale di Macerata, Macerata, 5Clinica di Dermatologia, Ospedale di Jesi, Jesi, Italy

Background: Early stage Mycosis Fungoides (MF) has an indolent, relapsing course, with patients frequently undergoing multiple therapies. Current guidelines consider the utility of combination therapies (skin-directed therapies plus systemic biologic response modifiers) to increase the therapeutic efficacy. Recently, time to next treatment (TTNT) was applied as a new relevant measure of the durability of response of PUVA, interferon-alpha (IFN-α) and retinoids as monotherapies in early MF (Hughes et al, Blood 2015; Hanel et al, AJH 2016), but it has not been yet investigated in combination therapies.

Aims: We aimed to evaluate TTNT together with the usual time-to-event measures (OS and EFS) in the series of 89 early MF patients treated for 14 months with low-dose IFN-α2b (6-18 MU weekly) and PUVA, which was first reported in 2005 (Rupoli et al, EJH 2005). The follow-up was prolonged up to October 2016, in order to evaluate prospectively the regimen activity and influence on the further course of the disease.

Methods: The design, rationale, safety and efficacy results for this protocol were previously published. Clinical stages IA-IIA patients who had received no previous treatment, or had been submitted to a 4-month wash-out after systemic therapy or a 4-week wash-out after topical therapy, were included in the study. Survival curves for each efficacy endpoint were calculated according to Kaplan-Meier.

Results: Eighty-nine patients (56 men and 33 women) with a median age of 60 years (range, 17-80) were recruited. Disease stage IA was 22 patients, IB in 55, IIA in 11, and IIB in 1 patient. The majority of patients had generalized skin disease (75% T2 vs 25% T1). The protocol proved to be highly effective, well tolerated and able to induce complete clearing of skin lesions in 84% of patients (95% CI 79%-89%). The median follow-up time was 175 months (range 4-259). Updated data showed that the median overall survival (OS) was not reached, whilst the median event-free survival (EFS) was 142 months (95% CI 130-153). Estimated OS rates at 1, 2, 5, 10, 15 and 20 years
were 99%, 98%, 92%, 89%, 78% and 51%; at 1, 2, 5, 10, 15 and 20 years 98%, 97%, 88%, 67%, 19%, 0%, were free from events. Median TTNT was not reached thus indicating clinical benefit with IFN-α and PVU. Kaplan-Meier estimated rates of 97% at 1 year, and 91% at 2 years, respectively whereas 5-, 10-, 20-year TTNT remained almost unchanged with 62% of patients that still had not required further treatment.

Summary/Conclusions: There has been an ongoing debate about whether patients would benefit from adding PVU to IFN-α in the treatment of early stage MF. We chose to initiate the combination treatment of MF as early as possible in the course of the disease to induce a permanent remission or even a cure. In our experience, this regimens set the realistic goal of achieve high rates of complete clearance and durable responses (median TTNT not reached) with only 38% of patients requiring a subsequent systemic treatment within 20 years. Here, we suggest a synergistic or additive effect between PVU and IFN-α compared with either agent alone. With respect to Hughes et al. (Blood 2015), our combination treatment provides a longer TTNT than PVU or IFN-α monotherapy (36.3 months and 27.9 months, respectively). At 2 years, 95% of patients receiving PVU plus IFN-α were free from further treatment as compared to 54.2% and 29.1% treated with PVU or IFN-α monotherapy, respectively.

PHASE 3 ALCANZA STUDY: THE BREVITUXIMAB VEDOTIN (BV) OR PHYSICIAN’S CHOICE (PC) OF METHOTREXATE (MTX) OR BEXAROTENE (BXE) IN CD30-POSITIVE CUTANEOUS T-CELL LYMPHOMA (CTCL): NUMBER NEEDED TO TREAT ANALYSIS

1Millennium Pharmaceuticals Inc., a wholly owned subsidiary of Takeda Pharma-ceutical Company Limited, Cambridge, United States, 2The University of Melbourne, Victoria, Australia, 3Gays and Si Thomas NHS Foundation Trust, London, United Kingdom, 4Memorial Sloan Kettering Cancer Center, New York, 5The Mayo Clinic, Rochester, Minnesota, USA, 6San Raffaele Hospital, Milan, Italy, 7University School of Medicine and Stanford Cancer Institute, California, United States, 8University Hospital Zurich, Zurich, Switzerland, 9University Hospital Birmingham, Birmingham, United Kingdom, 10University of Turin, Turin, Italy, 11University of Bologna, Bologna, Italy, 12University Hospitals Leuven, Leuven, Belgium, 13Columbia University, New York, 14Seattle Genetics, Inc., Bothell, United States

Background: CTCL is a generally incurable, relapsing disease associated with a significant symptom burden, including disfiguring lesions, debilitating pruritus and frequent skin infections. ALCANZA is a Phase 3 study of BV vs PC (MTX or BXe) for the treatment of CD30-positive (CD30+) CTCL (NCT01578499). BV was associated with significantly improved rate of objective response lasting ≥4 months (ORR4; 56% vs 13%; p<0.0001), longer median progression-free survival (PFS; 16.7 vs 3.5 months; p<0.0001), and decreased symptom burden measured by Skindex-29 (27.96 vs 8.62; p<0.0001), compared with PC. BV’s safety profile was consistent with previous reports, with all-grade and grade 3 peripheral neuropathy of 67% and 9%, respectively. Number needed to treat (NNT), defined as the number of patients (pts) that need to be treated to prevent one additional event of disease progression or death compared with PC in the ALCANZA trial. To determine the NNT with BV to avoid one additional event of disease progression/death compared with PC in the ALCANZA trial.

Methods: The NNT with BV was calculated as the inverse of the absolute risk reduction (ARR); ARR was the PFS event rate per independent review facility (IRF) assessment in the PC arm minus the event rate in the BV arm. PFS was defined as the time from randomization until progressive disease/death due to any cause, counting all events despite two or more missed visits or starting of subsequent anticancer therapy (European Medicines Agency [EMA] criteria). ALCANZA recruited adults (≥18 years) with previously treated CD30+ mycosis fungoides or primary cutaneous anaplastic large cell lymphoma. Pts were randomized 1:1 to receive BV 1.8 mg/kg IV, once every 3 weeks, for up to 16 three-week cycles, or PC of MTX 15-50 mg PO, once weekly, or BXe 300 mg (target dose) PO, once daily, for up to 48 weeks. All pts gave informed consent. Results: The intent-to-treat (ITT) population comprised 128 pts (median age 60 yrs [range 22–83]; 55% male) who received BV (n=64) or PC (n=64). Fewer PFS events per IRF assessment per EMA criteria were experienced by pts in the BV arm (Table). The NNT was 9.6 (95% CI 7.5, 12.4) at a disease progression/death rate of 2.00 (95% CI 1.59, 2.36) to 3.76 pts (95% CI 2.5, 5.84) over 24 months (Table). At 24 months, the NNT to prevent a disease progression/death was 3.37 pts (95% CI 2.26, 7.67).

Summary/Conclusions: ALCANZA data suggest that, at various time points, one in every 2–4 pts treated with BV will benefit by avoiding disease progression/death. This further demonstrates BV’s clinical benefit in CD30+ CTCL pts requiring systemic therapy. This is, to our knowledge, the first report of an NNT analysis for a treatment in the CTCL setting.

P638

PRIMARY OCULAR ADNEXAL LYMPHOMA OF ALL HISTOLOGIC SUBTYPES: SURVIVAL OUTCOMES AND RISK FACTORS IN LARGE COHORT OF PATIENTS AND LONG-TERM FOLLOW-UP

Y.-W. Jeon1,*, S.-S. Park1, J.-H. Yoon1, S.-E. Lee1, K.-S. Eom1, Y.-J. Kim1, H.-J. Kim1, S. Lee1, C.-K. Min1, J.-W. Lee1, W.-S. Min1, S.-G. Cho1
1Department of Hematology, St.Mary Hospital, Seoul, Catholic Medical Center, Seoul, Korea, Republic Of
Background: Although the recent reports show that interest in ocular adnexal lymphomas (OAL) and their biologic and clinical characteristics have been increased, the most OAL-related clinical study is still limited in the small number with insufficient follow-up period, result in retrospective studies with non-reproducible. Moreover, because the majority of OAL were in the low-grade histologic subtypes as primary ocular adnexal MALT (mucosa-associated lymphoid tissue ) lymphoma, there is few comparative analysis study of all histologic subtypes in OAL patients especially for non-MALT type OAL in large cohort OAL.
Aims: So our purposes of this study were to identify a correlation between histopathological diagnosis and significant parameters associated with clinical outcomes of patients with OAL in patients with diverse histologic subtypes.
Methods: We evaluated the consecutive 207 primary OAL patients who diagnosed at Catholic University Lymphoma Group (CULG) of Catholic Bone Marrow Center, Seoul between January 2004 to April 2015. Clinical information and parameters were gathered from the electronic medical records such as geographic status, complete blood count (CBC) with blood chemistry, the status of BM involvement, primary therapeutic modalities, response to initial therapy, and treatment-related complications with survival outcomes.

Results: In OAL of all histologic subtypes, 10-year lymphoma-specific OS and PFS were 89.3% and 71.0% respectively. 182 patients achieved CR (87.9%). CR rate according to primary therapy was 90.4% (n=103) in T1N0M0, 95.2% (n=40) in T2N0M0, 100% (n=7) in T3N0M0, 83.3% (n=5) in T4N0M0, and 71.1% (n=27) in TxN1-4M0/ TxNxM1. Multivariate analysis in OAL of all histologic subtypes showed that the risk factors-associated PFS were positivity of BM involvement (Hazard ratio; HR=2.96, p<0.001 and HR>9.98, p=0.025, respectively), the risk factors-associated OS was non-MALT lymphoma subtype (HR=9.18, p=0.013). Then, subgroup analysis...
CLONAL B-CELL LYMPHOCYTOSIS OF MARGINAL ZONE ORIGIN (CBL-MZ): A PROSPECTIVE REGISTRATIONAL STUDY ON 96 CASES

1Department of Haematology, University Hospital, University of Crete, Heraklion, 2Department of Haematology, Athens Medical Center-Psychikon Branch, 3Department of Haematology, 1st Department of Propedeutics, University of Athens, Laikon General Hospital, 4Immunology Labora, Laikon General Hospital, 5Department of Pathology, 2nd Department of Internal Medicine, University of Athens, 6Department of Anatomic Pathology, Evangelismos General Hospital, University of Athens, Athens, Greece

Background: Clonal B-cell lymphocytosis of marginal zone origin (CBL-MZ) has been recognized as a provisional entity in the WHO classification. Despite diagnostic similarities with SMZL, the exact relation between them has not been established yet. AIM: To describe the main features of CBL-MZ and to further elucidate its relation to SMZL.

Aims: To describe the main features of CBL-MZ and to further elucidate its relation to SMZL.

Methods: 96 CBL-MZ were analyzed. Staging at diagnosis included CBCs, blood morphology and immunophenotype, biochemistry, viral test for hepatitis C and B, serum immunoglobulin levels and immunofixation as well as whole body CT scan. BM biopsies were available in 78 cases which were studied with the following panel of moAbs: CD20, DBA44, CD23, CD5, CD25, CD38, CD27, s/cIgM/D, TCL-1, MNSA, T-bet and IRTA-1. Gastroscopy with multiple biopsies was performed in 56 cases. FISH analysis for del7q was done in 13 cases.

Results: A symptomatic presentation of the main characteristics of CBL-MZ is given in the table. The median age was 70 y without sex predilection. By definition, no case presented with cytopenia, lymphadenopathy, splenomegaly or any other organ involvement. Median ALC and clonal B-cell counts were 5098/μL and 2880/μL, respectively. 47% had paraproteinemia, mainly of the IgM type. H.pylori (+) gastritis was evident in 30%. Hp eradication had no influence on the lymphocyte counts. The percentage of BM infiltration was highly variable, ranging from 10% to 85%, with an intrasinusoidal pattern in 31%. TCL-1, T-bet, IRTA-1, and MNSA were invariably negative. MYD-88 mutation was detected in 18% and was significantly associated with IgM paraproteinemia. 6 cases were lost to follow-up. At a median follow-up time of 41 months, the majority of the cases had no disease progression (90%). 61% had stable CBCs, 20% solely an increase in ALCs and 7% an increase in paraproteinemia only, while in 2% lymphocytosis regressed. A total of 9 (10%) pts progressed and required treatment: 5/9 due to cytopenias caused by extensive BM infiltration without splenomegaly, 1 due to bulky splenomegaly; 1 due to lymphadenopathy; 1 developed autoimmune thrombocytopenia, while in one due to high IgM levels in a MYD-88(-) case. A total of 5 (6%) pts developed splenomegaly after a median time of 78 mos (48-151).

Summary/Conclusions: After a median follow-up time of 4y we demonstrated that CBL-MZ, although displaying many diagnostic similarities with SMZL, it rarely metastasize to it. Most cases remain stable, while few develop cytopenias due to an extensive BM infiltration. These latter cases apparently represent a distinct MZL category which requires further investigation.
Monitoring should be part of physician’s practice in these WM patients. Long-term toxicities are also seen, at similar rates and second cancers.

Summary/Conclusions: Anemia and B2M>3mg/l, suggesting future trials should focus on this subgroup. Two parameters decreased the duration of PFS2 with immunochemotherapy: predicted PFS and OS with good accuracy.

Background: Myelodysplasia. Second PFS upon salvage (PFS2) was available in 72 patients: RF significantly increased the risk of Richter, and CLB exposure the risk of interstitial pneumonitis>20% adversely impacted TTNT. IPSS scoring system did not improve prognostication. Long-term follow-up: 22% of patients had second solid cancers.

Results: Median follow up for the entire cohort is 6 years, median age at diagnosis 68.6y and at therapy 71.2y; 75% being above 65y at treatment. Significant differences between DRC/RF cohorts were: median age 74/64y, high IPSS score 63%/28%, B2M>3mg/l 74%/56%, DRC cohort: median PFS/Time To Next Therapy and Overall Survival were 33mo, 45.8mo and 78 at 5 years, respectively. Other reductions>20% had no impact on these outcomes, but age≥65y and anemia<11.5g/dl decreased PFS. Previous CLB therapy increased the risk for delayed toxicities (infections 39%, myelodysplasia 13% vs 16%, myelodysplasia 13% vs 3.8%), but not second cancers including Richter transformation. IPSS scoring system predicted PFS and OS with good accuracy. RF cohort: median PFS/Time To Next Therapy and Overall Survival were 53mo, 65mo and 90% at 5 years, respectively. Previous CLB had no impact on outcomes, but dose reductions>20% adversely impacted TTNT. IPSS scoring system did not improve prognostication. Long-term follow-up: 22% of patients had second solid cancers. RF significantly increased the risk of Richter, and CLB exposure the risk of myelodysplasia. Second PFS upon salvage (PFS2) was available in 72 patients: 47 DRC (PFS2 47mo), and 25 RF (PFS2 66mo), not significantly different. Only two parameters decreased the duration of PFS2 with immunotherapy: anemia and B2M>3mg/l, suggesting future trials should focus on this subgroup to challenge standard R-based regimens with rituximab.

Summary/Conclusions: We conclude that clinical trials results of DRC and RF are reproduced in our real-life cohort despite older ages, and high IPSS scores. Long-term toxicities are also seen, at similar rates and second cancers monitoring should be part of physician’s practice in these WM patients.

Infectious diseases, supportive care

P642 MICAFLUNOSIS VERSUS LIPOSOMAL AMPHOTERICIN B FOR EMPIRICAL ANTIFUNGAL THERAPY IN FEBRILE NEUTROPENIC PATIENTS WITH HEMATOLOGICAL MALIGNANCIES: A RANDOMIZED CONTROLLED TRIAL

Background: Invasive fungal infections (IFIs) incur significant morbidity and mortality in neutropenic patients with hematological malignancies (HEM) after chemotherapy. The risk for these infections is related to the intensity and duration of neutropenia, and varies from 2% to 40%. Mortality rates associated with documented IFIs are considerable, reportedly ranging from 30% to 60%. Empirical antifungal therapy is the standard care for neutropenic patients with HEM, who remain febrile despite broad-spectrum antibiotic treatment. Several antifungal agents including voriconazole (VRCZ) or liposomal amphotericin B (L-AMB) have been studied as empirical therapy for febrile neutropenia (FN). However, limited data are available concerning the efficacy and safety of micafungin (MCFG) in FN patients with HEM.

Aims: We conducted a randomized, cooperative group, open-label trial comparing MCFG (150mg once daily) with L-AMB (2.5mg/kg once daily) as first-line empirical antifungal treatment for FN patients with persistent fever of HEM. Methods: 138 hospitalized FN patients with persistent fever of HEM (AML 78, APL 4, ALL 13, MDS (RAEB) 7, NHL 28, MM 5, other hematological malignancy 3 cases) were randomized to each drug group (MCFG, 72; L-AMB, 66). The efficacy end point was a favorable overall response, as determined by a five-component end point according to the criteria of Walsh et al (N Engl J Med 2004; 351: 1391).

Results: At the time of enrolment, there were no significant differences in the demographics or baseline characteristics between the two groups. The mean treatment duration for MCFG and L-AMB was 13.8 and 16.4 days, respectively. The efficacy rates of MCFG and L-AMB were not significantly different (38/72 cases (52.8%) vs 26/66 cases (39.4%), P=0.115*), evaluated based on: (1) successful treatment of baseline fungal infection (3/4 cases (75.0%) vs 0/1 case (0%), P=0.170*), (2) absence of breakthrough fungal infection (65/72 cases (90.3%) vs 65/66 cases (98.5%), P=0.112*), (3) survival for ≥7 days after study drug discontinuation (66/72 cases (91.7%) vs 59/66 cases (89.4%), P=0.855*), (4) absence of premature study drug discontinuation due to poor efficacy or drug-related adverse events (54/72 cases (75.0%) vs 47/66 cases (71.2%), P=0.615*), and (5) resolution of fever during neutropenia (45/72 cases (62.5%) vs 33/66 cases (50.0%), P=0.258*). However, discontinuation due to drug-related adverse events occurred less frequently in the MCFG group (1/72 cases (1.4%) vs 9/66 cases (13.6%), P=0.006*). In safety evaluation, adverse events of creatinine increase and hypokalemia were less often in the MCFG group than in the L-AMB group (6/72 cases (8.3%) vs 19/66 cases (28.8%), P=0.001*, 14/72 cases (19.4%) vs 34/66 cases (51.5%), P=0.001*). Chi square test.

Summary/Conclusions: MCFG was as effective as L-AMB, and better tolerated than L-AMB as an empirical antifungal therapy in FN patients with HEM.

P643 ANTIFUNGAL DRUGS INFLUENCE NEUTROPHIL EFFECTOR FUNCTIONS IN VITRO AND MODULATE PULMONARY DAMAGE IN INVASIVE ASPERGILLOSIS

Background: Antifungal agents like azoles, echinocandins or polyenes substantially contribute to reduced morbidity and improved survival of high risk patients in hematology. However, besides their well-known antifungal activity there is a growing body of evidence for immunomodulatory side effects on different effector cells of the immune system.
Aims: The aim of our study is to clarify the immunomodulatory capacity of different antifungal drugs on the effector functions of polymorphonuclear neutrophils (PMN) and on the clinical course of invasive pulmonary aspergillosis (IPA).

Methods: Firstly, isolated PMN from healthy donors were preincubated with different antifungals in vitro. Here, we used the azoles fluconazole (FLU), voriconazole (VOR), posaconazole (POSA), and the echinocandins caspofungin (CAS) and micafungin (MIC), and the polyenes amphotericin b (AmB) and liposomal amphotericin b (LAmB). Furthermore, PMN were simultaneously stimulated with lipopolysaccharides (LPS) or zymosan. Afterwards, PMN were analyzed by flow cytometry regarding activation, degranulation, and phagocytosis. Additionally, a dichlorofluorescein assay was used to detect reactive oxygen species (ROS). IL-8 synthesis was measured by enzyme-linked immunosorbent assay (ELISA). Secondly, a murine model was used to investigate the influence of MIC and POS on the clinical course of IPA in vivo. Therefore, mice were treated with antifungals and inoculated i.n. with conidia of Aspergillus fumigatus. Afterwards, mice were analyzed concerning fungal burden and pulmonary damage (albumin ELISA) with neutropenic animals serving as controls.

Results: In vitro, pretreatment with POS led to enhanced activation (CD262L: 44% vs 18% at 13 +/- 2%, *; mean +/- SEM, p value ≤0.05 considered to be significant). Pretreatment with AMB showed increased expression of activation markers. Moreover, ISA impaired degranulation and phagocytosis in CD262L+ PMN (27% +/- 4 vs 44 +/- 1, LPS, *; as well as generation of ROS (22660 +/- 3286 vs 41190 +/- 2584, zymosan, *)), and IL-8 synthesis was substantially impaired. CAS showed an increased phagocytosis (75% +/- 6 vs 44 +/- 5, LPS, *), whereas degranulation and LPS triggered generation of ROS were reduced by trend. Pretreatment with conventional AmB resulted in activation of almost all effector functions besides impaired phagocytosis (43% +/- 3 vs 59 +/- 3, LPS, *). In contrast, LAmB did not significantly affect any effector function. IPA treatment in vivo resulted in reduced fungal burden as expected but lead to reduced albumin concentration in BAL (111 ng/ml +/- 46 vs 380 +/- 31, *) indicating a decreased pulmonary damage. Despite significant influence on PMN effector functions in vitro, MIC did not affect clinical course IPA in vivo.

Summary/Conclusions: CD101 and POS induce PMN activation, whereas ISA and MIC inhibit PMN effector functions in vitro. CAS shows variable modification on PMN. Possibly independent from its antifungal effects, POS reduces pulmonary damage in mice suffering from IPA in vivo. Further studies are needed to distinguish the obviously multidimensional immunomodulatory effects of different antifungal agents and to clarify their relevance in clinical practice.

P644
CHARACTERISTICS AND OUTCOME OF PULMONARY INFILTRATES IN ACUTE LEUKEMIA CLASSIFIED ACCORDING TO EORTC/MSG CRITERIA OF INVASIVE FUNGAL INFECTION: A PROSPECTIVE STUDY BY THE RETE EMATOLOGICA LOMBARDA
C. Cattaneo1, C. Pagani1, V. Mancini2, P. Zappasodi2, A. Ferrario4, F. Pavesi6, E. Todisco5, N.S. Fracciolli7, V. Sacca8, L. Verga8, M. Petullia9, A. Nosari3, G. Rossi1,6
1Hematology, Spedali Civili, Brescia, 2Hematology, Ospedale Niguarda, Milan, 3Fondazione IRCCS Policlinico S. Matteo, Pavia, 4Hematology, Ospedale di Circolo e Fondazione Macchi, Varese, 5San Raffaele Scientific Institute of Milan, 6Humanitas Cancer Center, Rozzano-Milano, 7Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Milan, 8Hematology, Ospedale Valduce, Como, 9Hematology, San Gerardo Hospital, Monza, Italy

Background: In acute leukemia (AL) patients (pts) pulmonary infections may be severe and worsen the final outcome of AL. They have been recently shown to adversely affect the outcome of bloodstream infections (BSI) in AL pts (Cattaneo et al. 2016). The radiologic characteristics of PI belong, according to the EORTC/MSG Study Group, to the diagnostic criteria of a pulmonary invasive fungal infection (IFI).

Aims: In order to better define the clinical and prognostic significance of PI in AL pts in a real-life setting, we have analyzed all PI diagnosed during consecutively feasible/infected episodes developing over a 26 months period in pts admitted to 9 hematologic institutions within the Reto Ematologica Lombarda (REL) network.

Methods: From Dec-12 to Jan-14, all febrile/infected episodes were recorded and data concerning PI extracted. PI were classified as specific and aspecific for IFI according to radiologic criteria.

Results: During 1086 episodes, 256 PI were diagnosed in 195 AL pts (MF 124/71; median age 60y; AML/ALL 163/32). PI incidence was similar during induction and relapse (28.8% and 29%, respectively), but significantly lower in complete remission (14.2%, p<0.0001). Overall, PI were detected in 57% of cases during AML induction/reinduction and in 44.5% during posaconazole prophylaxis. Posaconazole was not responsible for a decreased sensitivity of serum galactomannan (GM), which was positive in 18.4% and in 16.8% pts with specific PI receiving posaconazole or not, respectively. Aspecific PI were observed in 157 cases (61.3%). In the remaining 99 cases (38.3%) the specific radiologic criteria for suspecting IFI were met, but in 70 of them (27.3%) just in the context of a diagnosis of possible (pos) IFI. Probable/proven (prob/prov) IFI criteria were met in 29 PI (11.3%). The characteristics of the three subgroups of PI are listed in Tab. 1. Prob/prov PI IFI were associated with lack of posaconazole prophylaxis in comparison with poss IFI (72.4% vs 57.1%, p=0.0074).

Aspecific PI did not differ from poss IFI except for their lower frequency during neutropenia, particularly if 31/58 (80.3% vs 92.9%, p=0.0164, and 56.1% vs 80%, p=0.0053, respectively), and higher frequency in patients on Fluoroquinolone (Fq) prophylaxis (Fq, p=0.0192). Multivariate analysis confirmed that specific PI were less frequent during prolonged neutropenia (HR 0.382, IC 0.189-0.772), and poss IFI during Fq prophylaxis (0.344, 0.159-0.742). All but 21 cases requiring antifungal treatment during the study period were treated with Micafungin or Caspofungin. Thirty-day mortality was observed in 41 cases (16%). It was similar for aspecific and poss IFI (15.9% and 10%), but significantly higher in prob/prov IFI (31.3%, p=0.0192). Multivariate analysis confirmed a prob/prof IFI (3.277, 1.243-8.644) predictive for death, as well as relapsed/refractory AL (2.451, 1.092-5.498) and BSI (2.833, 1.006-5.377).

Summary/Conclusions: Among PI occurring in AL patients IFI could be suspected according to EORTC/MSG Study Group criteria in nearly 40% of cases but only 11% of PI met the criteria for prob/prov IFI. Posaconazole did not affect serum GM sensitivity and was protective against prob/prov IFI, which had a higher risk of death. On the other hand, PI associated with a diagnosis of poss IFI had a similar outcome compared to aspecific IFI, although they occurred more frequently during neutropenia and outside from Fq prophylaxis. These findings may be relevant in the context of a reevaluation of the criteria for suspecting IFI in AL patients with as well as for a more appropriate antimicrobial stewardship.

P645
ANTIFUNGAL PROPHYLAXIS WITH CD101 IN IMMUNOSUPPRESSED MOUSE MODELS OF CANDIDIASIS, ASPERGILLOSIS, AND PNEUMOCYSTIS PNEUMONIA (PCP)
V. Ong2, K. Bartizal1,*, M. Cushion2, L. Miesel3, S.R. Lopez4,1Cidara Therapeutics, Inc., San Diego, 2Cincinnati VAMC, Univ of Cincinnati Coll of Med, Cincinnati, United States, 3Eurofins Panlabs, Taipei, Taiwan, 4Republic of China, 4TransPharm Preclinical Solutions, Jackson, United States

Background: Fungal infections continue to carry high morbidity and mortality. Disease- and treatment-related immunosuppression in patients with hematologic diseases increase the risk of opportunistic infection caused by Candida spp., Aspergillus spp., and Pneumocystis spp., and antifungal prophylaxis is an important consideration. Agents currently used for prophylaxis, voriconazole and TMP/SMX, carry safety and tolerability concerns. CD101 is a novel echinocandin in phase 2 clinical development that has demonstrated preclinical efficacy in treatment of invasive fungal infection and has pharmacokinetic attributes that enable once-weekly IV dosing and subcutaneous (SC) administration.

Aims: To evaluate CD101 as antifungal prophylaxis in neutropenic mouse models of candidiasis, aspergillosis, or PCP.

Methods: CD101 (5mg/kg) and Caspofungin (5mg/kg) were rendered neutropenic by cyclophosphamide (cpm) on day -4 (150mg/kg) and day -1 (100mg/kg) and challenged (day 0) with Candida albicans ATCC 53134 (IV, 100 µL, 105 CFU/mouse). One dose of CD101 5, 10, or 20mg/kg SC was given prior to challenge on day -5, -3, or -1. Kidneys were removed for CFU enumeration 24 h postchallenge. Aspecific PI were treated with systemic antifungal therapy. Thirty-day mortality was observed in 41 cases (16%). Aspecific PI were treated with systemic antifungal therapy. Thirty-day mortality was observed in 41 cases (16%). It was similar for aspecific and poss IFI (15.9% and 10%), but significantly higher in prob/prov IFI (31.3%, p=0.0192). Multivariate analysis confirmed a prob/prof IFI (3.277, 1.243-8.644) predictive for death, as well as relapsed/refractory AL (2.451, 1.092-5.498) and BSI (2.833, 1.006-5.377).

Table 1.
challenge on day -5, -3, or -1. Survival was monitored for 14 days. PCP model: C3H/HeN mice (10 g) were immunosuppressed by dexamethasone (40 mg/kg) in acidified drinking water and inoculated with Pneumocystis murina (intranasal- ly, 2 x 10^5/50 µL). CD101 0.2, 2, or 20 mg/kg intraperitoneally was given at the time of inoculation and 1 or 3x/wk for 6 weeks. TMP/SMX 50/250mg/kg/3x/wk was used as positive control. At 6 wks, lungs were processed for quantification of trophic and asci (cyst) forms of P. murina.

**Results:** Candidiasis: Kidney CFU decreased with higher doses of CD101 and shorter times between prophylaxis and challenge. At 20 mg/kg, there was complete clearance of CFU burden regardless of treatment day in all animals except one (prophylaxis on day -3). There was complete clearance in all animals given 10 mg/kg on days -3 and -1 and significant decreases in CFU in those given 5 mg/kg on days -3 and -1. Aspergillosis: Survival rates significantly increased following CD101 5, 10, and 20 mg/kg prophylaxis on day -5, -3 or -1 compared with vehicle. Prophylaxis closer to challenge increased the rate of survival in the CD101 group. All animals given higher doses survived regardless of day of prophylaxis. PCP: Trophic nucleus counts were significantly reduced versus untreated controls in all CD101 groups except 0.2 mg/kg/1x/wk, and efficacy in 3 different CD101 groups was comparable to TMP/SMX (no nuclei observed microscopically). Asci counts also were significantly reduced in all CD101 groups versus untreated controls. There was no significant difference in efficacy between TMP/SMX and CD101 in all but the lowest dose group (0.2 mg/kg/1x/wk), with no asci observed microscopically.

**Summary/Conclusions:** CD101, a novel echinocandin, was protective against fungal challenge in immunosuppressed mouse models of candidiasis, aspergillosis, and PCP. These data suggest that CD101 may provide benefit for acute leukaemias. Though optimised antifungal therapy might be effective, in selected patients, surgical interventions might be an useful tool both for diagnostic and therapeutic reasons. However due to the nature of the disease and circumstances, prospective data of Surgical interventions in these situations is very difficult and the evidence is usually from small cohorts often from single centres.

**Aims:** The purpose of this study is to report our single center experience of surgical interventions for IFI in acute leukaemia patients.

**Methods:** A retrospective review of our Hospital’s Leukaemia database (IRB approved) was made for clinical characteristics and outcomes in surgically managed IFI patients diagnosed between Jan 2005 and Dec 2015. IFI was defined by EORTC/MSG 2008 criteria.

**Results:** Among 795 acute leukaemia patients diagnosed during this period, we found 19 patients with IFI who had undergone surgical interventions (5 proven, 1 probable and 3 possible IFI). The details of the IFI, surgical interventions, antifungal treatments and perioperative complications are summarized in Table 1. Most commonly performed surgical intervention was either open thoracotomy or video assisted thoracoscopic surgery for wedge resection or lobectomy. Nine of the 15 proven IFI patients had overall benefit from the procedure through optimization of antifungal therapy with MIC/sensitivities, arrest of aspergillosis related massive bleeding and/or complete resolution of the IFI allowing further chemotherapy or transplantation. Of these, 7 patients were alive and well at the time of data collection and 2 had died. Among the survivors, the mean duration of the survival post-surgery was 57.7 months (range 9 –118.3 months). Two patients who died also had benefited from the procedure and had survived for 6.5 and 47 months post-surgery but both succumbed to septic events unrelated to the IFI during subsequent chemotherapy. Of the remaining 6 patients (out of the 15 proven IFI), 3 had temporary clinical and/or radiological improvement only but succumbed 2 to 6 months post-surgery due to unrelated septic events, 2 died due to progression of the IFI and 1 lacked information to draw any conclusions. The patient with probable IFI diagnosed during induction was able to proceed with further chemotherapy post-surgery but succumbed to CNS relapse of leukaemia 8 months later. Of the 3 patients with possible IFI, 2 were able to proceed with transplantation and 1 had chemotherapy post-surgery, but all the 3 patients succumbed to leukaemia and/or unrelated septic events.

**Summary/Conclusions:** Major surgical interventions are feasible in selected leukaemia patients with IFI. In carefully selected patients they can yield valuable information to guide anti-fungal therapy or enable therapeutic outcomes allowing patients to proceed with curative chemotherapy and stem cell transplantation.
nately, despite the general improvement in the care of patients with MM, no difference in the rate of infections could be detected in recent years.

HUMAN L-FICOLIN POLYMORPHISMS CONTRIBUTE TO SUSCEPTIBILITY TO INFECTIONS IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

U. Schenktze,1,2 M. Fischer,1 A. Hochhaus,1 S. Scholz1
1Klinik für Innere Medizin II, Abteilung für Hämatologie und Internistische Onkologie, Universitätshämatologie Jena, Jena, Germany

Background: In neutropenic patients with acute myeloid leukemia (AML) bacterial infections and sepsis are a leading cause of mortality. Several studies propose a contribution of individual single nucleotide polymorphisms (SNPs) of the innate immune system to the course of infections. Human ficolins represent receptors of the lectin pathway especially for membrane-bound ficolin-2 (L-ficolin) is emerging as an important component of the lectin pathway in the circulation. Ficolins share structural and functional characteristics with C1q from the classical pathway of the complement that acts with P. notatum and whose dysfunction might be associated with higher Day +100 survival rates for all days, which was associated with increased Hb level. The safety results confirmed the safety profile of epoetin theta.

Methods: Genotyping of L-ficolin and PTX3 SNPs (rs17514136, rs17549193, rs17551936, and rs17549193, n=180) was performed by Taqman assay. Multiple logistic regression analyses were applied to evaluate the association between the polymorphisms and the occurrence of infectious events.

Results: Two L-ficolins SNPs were identified as risk factors for developing sepsis and/or pneumonia. Patients harboring rs17514136GG/AA or GG (n=100 or 22) revealed a significantly higher risk for developing sepsis (odds ratio [OR]: 1.88; 95% confidence interval [CI]: 1.01–3.27) or pneumonia (OR: 2.79; 95% CI: 1.1–6.9, p=0.01). A similar risk profile could be demonstrated for patients carrying rs17549193TT/CT or TT. No association was found between SNPs of the PTX3 gene and the analysed infectious events.

Summary/Conclusions: To our best knowledge, this study represents the first analysis demonstrating that polymorphisms of human L-ficolin (rs7309123, rs17549193) represent an independent risk factor of developing sepsis and/or pneumonia in patients with AML undergoing induction chemotherapy. Interestingly, no association of PTX3 SNPs and infectious events such as IFD was found in this non-transplant setting. In conclusion, a genetic risk profile based on membrane bound and soluble molecules of the innate immune system might be helpful in identifying patients prone for infectious events.

P649

PREDICTIVE FACTORS OF RESPONSE TO EPOETIN THETA IN CHEMOTHERAPY-INDUCED ANEMIA: A FRENCH MULTICENTER OBSERVATIONAL STUDY (PIVOINE)

Aims: We sought to investigate the impact of L-ficolin and PTX3 SNPs on the occurrence of infectious events such as sepsis and pneumonia, including invasive fungal disease (IFD), in 186 adult patients with newly diagnosed AML following anthracycline-based induction chemotherapy. In addition to our studies on membrane receptors, this work represents an important extension on soluble molecules of the innate immune system and their potential implication on infections.

Methods: Genotyping of L-ficolin and PTX3 SNPs (rs17514136, rs17549193, rs17551936, and rs17549193, n=180) was performed by Taqman assay. Multiple logistic regression analyses were applied to evaluate the association between the polymorphisms and the occurrence of infectious events.

Results: Two L-ficolins SNPs were identified as risk factors for developing sepsis and/or pneumonia. Patients harboring rs17514136GG/AA or GG (n=100 or 22) revealed a significantly higher risk for developing sepsis (odds ratio [OR]: 1.88; 95% confidence interval [CI]: 1.01–3.27) or pneumonia (OR: 2.79; 95% CI: 1.1–6.9, p=0.01). A similar risk profile could be demonstrated for patients carrying rs17549193TT/CT or TT. No association was found between SNPs of the PTX3 gene and the analysed infectious events.

Summary/Conclusions: To our best knowledge, this study represents the first analysis demonstrating that polymorphisms of human L-ficolin (rs7309123, rs17549193) represent an independent risk factor of developing sepsis and/or pneumonia in patients with AML undergoing induction chemotherapy. Interestingly, no association of PTX3 SNPs and infectious events such as IFD was found in this non-transplant setting. In conclusion, a genetic risk profile based on membrane bound and soluble molecules of the innate immune system might be helpful in identifying patients prone for infectious events.

TIMING OF DEFIBROTIDE INITIATION POST-DIAGNOSIS OF HEPATIC VENO-OCLUSIVE DISEASE/SINUSOIDAL OBSTRUCTION SYNDROME AFTER PRIMARY CHEMOTHERAPY: EXPLORATORY ANALYSIS OF AN EXPANDED-ACCESS PROTOCOL

N. Kerman1,2, P. Richardson1,2,3, B. Triplett1, S. Grupp2, J. Antin1, W. Liang1, R. Hume1, W. Tappe1, R. Soiffer4

1Pediatric Bone Marrow Transplantation Service, Memorial Sloan Kettering Cancer Center, New York, New York, 2Center for Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, 3Bone Marrow Transplantation and Cellular Therapy, St. Jude Children’s Research Hospital, Memphis, 4Pediatric Oncology, The Children’s Hospital of Philadelphia, Philadelphia, 5Smith Cell/Bone Marrow Transplantation Program, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, 6Jazz Pharmaceuticals, Inc., Palo Alto, 7Center for Stem Cell Transplantation, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, United States

Background: Hepatic VOD/SOS, which may be unpredictable and potentially life-threatening, is typically considered a complication of hematopoietic stem cell transplantation (HSCT); however, VOD/SOS can occur after chemotherapy without HSCT. VOD/SOS diagnosis at the start of defibrotide therapy may be associated with >80% mortality. Defibrotide is approved to treat severe hematopoietic VOD/SOS post-HSCT in the European Union and to treat hematopoietic VOD/SOS with renal or pulmonary dysfunction post-HSCT in the United States.

Aims: To perform an exploratory post hoc analysis of the impact of timing of initiation of defibrotide after VOD/SOS diagnosis in patients developing VOD/SOS after primary chemotherapy without HSCT (off label).

Methods: In an expanded-access protocol for patients with VOD/SOS post-HSCT or chemotherapy, with or without MOD (renal and/or pulmonary dysfunction), defibrotide 25mg/kg/d (4 divided doses of 6.25mg/kg) was given a median of 22 days after VOD/SOS diagnosis. A total of 27 patients with VOD/SOS who developed VOD/SOS after chemotherapy had never received ESA prior to enrolment in this study and 45.2% benefited from the use of epoetin theta.: The latter group was started the day of diagnosis; in 89.7% (78/87), by Day 7. In the pooled chemotherapy subgroup, survival was analyzed from the day of diagnosis in both the overall group and MOD subgroup (Figure), earlier initiation was associated with higher Day +100 survival rates for all days, which was significant at a number of timepoints. The trend test for particular initiation days
also showed a significant trend over time for higher Day +100 survival with earlier defibrotide initiation post-diagnosis in both the overall group and MOD subgroup (P<.05). In the overall post-chemotherapy population, adverse events (AEs) and serious AEs occurred in 66% and 40% of patients, respectively. Aside from multi-organ failure, the most common AE of any severity was hypotension (9.5%). Possibly related AEs lead to discontinuation in 7.3%; most common was gastric hemorrhage (3.7%).

**Summary/Conclusions:** In this exploratory analysis of final study data in the subgroup of patients developing VOD/SOS after chemotherapy, earlier defibrotide initiation post-VOD/SOS diagnosis was associated with improved Day +100 survival, confirmed by the Cochran-Armitage test (P<.05), even in the small MOD subgroup. This time-dependent relationship was consistent with that found in the HSCT subgroup from this study. No specific day appears to provide a clinically meaningful cutoff for better Day +100 survival, suggesting that later intervention retains value if treatment must be delayed.

**ADAMTS-13 REGULATES NEUTROPHIL RECRUITMENT IN A MOUSE MODEL OF INVASIVE PULMONARY ASPERGILLOSIS**

A. Hasibeder1,*, S. Prüfer2, K. Ebner3, S. Reuter1, P. Aranda Lopez1, I. Scharrer1, F. Banno4, M. Stassen 2, H. Schild 2, K. Jurk3, M. Bosmann3, H. Becker1, M. Radsak1

1IIIrd Dept. of Medicine, 2Institute for Immunology, 3Center for Thrombosis and Hemostasis, Johannes Gutenberg-University Medical Center, Mainz, Germany, 4Department of Molecular Pathogenesis, National Cerebral and Cardiovascular Center, Saitama, Japan

**Background:** Von Willebrand factor (VWF) is produced as multimers of various sizes and is secreted as an acute phase protein during inflammation. The main mechanism regulating the size and prothrombotic activity of VWF is the specific proteolytic activity of ADAMTS-13 (a disintegrin and metalloprotease with ThromboSpondin type 1 repeats-13) which is diminished under several pathological conditions.

**Aims:** To determine the relevance of this regulatory pathway for the innate inflammatory response by polymorphonuclear neutrophils (PMN), we employed a mouse model of invasive pulmonary aspergillosis (IPA) where PMN functionality is crucial for fungal clearance and survival.

**Methods:** IPA was induced by intratracheal application of Aspergillus fumigatus (A. f.) conidia in wildtype (129/Sv/Pas) or ADAMTS-13 deficient (Adamts13−/−) mice, and VWF deficient (Vwf−/−) mice or respective controls (B6). Some mice were sacrificed 24 h after infection. Fungal load was assessed as colony forming units (CFU) after plating and culturing lung homogenates on Sabouraud agar plates. For histological analysis paraffin sections of the lungs were stained with H&E, mouse complement component C3d and VWF antibody. Broncho alveolar lavage fluid (BALF) was analyzed for cell count (bead-based by flow cytometry or by an animal blood counter), ELISA was performed for albumin amount and cytokines were analyzed by a multiplex assay. Bone marrow-derived PMN were isolated by magnetic cell sorting using biotin labeled Ly6G/C specific antibody. PMN functions were analyzed for degranulation, oxidative burst activity and CD62L shedding by flow cytometry. Fungal killing of PMN in vitro was assessed by a XTT assay. Chemotactic properties of A. f.-activated and control serum from wildtype and knock-out mice was evaluated by migration of purified human PMN, isolated by dextran sedimentation and Histopaque® centrifugation, in a transwell assay.

**Results:** While infected neutropenic mice developed lethal IPA, all wildtype mice survived the infection. Interestingly, Adamts13−/− mice displayed more severe signs of disease with a lethal course in about 24% of the animals. Examination of the lungs revealed a higher fungal burden along with increased signs of acute lung injury and levels of pro-inflammatory cytokines in ADAMTS-13 deficient mice. Histology sections demonstrated a more pronounced perivascular leukocyte infiltration in support of a dysregulated inflammatory response in Adamts13−/− mice. Importantly, we observed no general defect in the activation of neutrophil effector functions in response to conidia or hyphae in vitro. Furthermore, innate inflammatory response to IPA was not altered in VWF deficient (Vwf−/−) mice compared to wildtype (B6) control.

**Summary/Conclusions:** Therefore, we conclude that the proteolytic regulation of VWF by ADAMTS-13 or ADAMTS-13 by itself is an important mechanism to control PMN recruitment in acute inflammatory processes, such as fungal pneumonias.
Myelodysplastic syndromes - Biology

P652
IDENTIFICATION OF THE SPECIFIC HEMATOPOIETIC STEM CELL POPULATIONS RESPONSIBLE FOR FAILURE TO HYPMETHYLATING AGENTS IN MYELODYSPLASTIC SYNDROMES
I. Garfán-Gómez1, A. Alfonso1, Y. Oguro1, H. Yang1, G. Montalban-Bravo1, A.C. Yu2, S. Silver2, K. Clise-Dwyer1, G. Garcia-Manero1, S. Coll1
1Leukemia, The University of Texas MD Anderson Cancer Center, 2McGovern Medical School, The University of Texas Health Science Center, 3Stem Cell Transplantation & Cellular Therapy, The University of Texas MD Anderson Cancer Center, Houston, United States

Background: Myelodysplastic syndromes (MDS) are hematopoietic disorders characterized by the ineffective production of mature blood cells of one or more lineages and by the risk of evolution to acute myeloid leukemia. The current standard of care for MDS patients is the treatment with hypomethylating agents (HMA); however, response to drugs from this family occurs in just about half of the patients and is accompanied by high rates of therapy failure. Failure to HMA in MDS is a poorly understood process associated to increased risk of disease progression and to a dismal prognosis and cannot be, thus far, predicted or prevented.

Aims: Given that MDS are stem cell disorders, our aim was the identification and molecular characterization of the specific hematopoietic stem/progenitor cell (HSPC) population in which the relapse-driver clones arise. This is an essential step for the development of effective monitoring and early intervention protocols for HMA failure.

Methods: Using flow cytometry immunophenotyping, we quantitatively analyzed the different cell subpopulations within the CD34+CD38- and CD34+CD38+ HSPC compartments in 122 sequential MDS bone marrow samples obtained from 93 patients at different stages of HMA treatment.

Results: In line with earlier reports suggesting the presence of alterations in myeloid progenitor frequencies in MDS, our flow cytometry data stratified untreated patient samples in two groups representative of two different hierarchical origins.

Summary/Conclusions: Our data provide evidence of the existence of biologically different MDS subtypes which are caused by separate differentiation defects and progress through the expansion of characteristic HSC populations.

FUNCTIONAL STUDY ON THE COOPERATION OF ASXL1 AND RUNX1 MUTATIONS FOR LEUKEMIC TRANSFORMATION
R. Bera1, D.C. Liang2, M-C. Chiu3, Y-X. Huang1, L-Y. Shih3
1Chang Gung Memorial Hospital, Taoyuan, 2Mackay Memorial Hospital, Taipei, 3Chang Gung Memorial Hospital and Chang Gung University, Taoyuan, Taiwan, Republic of China

Background: Our previous studies showed that RUNX1 and ASXL1 mutations were frequently co-existed in chronic myelomonocytic leukemia (CMMML) (EHA 2015) and clonal evolution of RUNX1 and/or ASXL1 occurred most frequently in chronic myeloid leukemia (CML) with myeloid blast crisis (EHA 2016). The molecular pathogenesis of cooperation of RUNX1 and ASXL1 mutations has not been reported yet.

Aims: We aimed to determine the functional role of collaborative association of RUNX1 and ASXL1 mutations for secondary acute myeloid leukemia (sAML) transformation.

Methods: For in vitro study, we overexpressed RUNX1-WT/MT (R135T) in K562 cells which harboring ASXL1-MT (Y591K) and co-expressed with ASXL1-WT/MT (R693X) in murine 32D cells. After stable expression, functional properties were examined by using immunoblot, co-immunoprecipitation, quantitative RT-PCR, flow cytometry, cell proliferation, colony formation and gene expression microarray analyses. C57BL/6 mice were used for bone marrow transplantation (BMT) experiments for in vivo study.

Results: We found that RUNX1-MT augmented cell proliferation, colony formation, HOXA gene expression and inhibited megakaryocytic differentiation in ASXL1-MT K562 cells compared to RUNX1-WT or empty vector control. The cooperation of RUNX1 and ASXL1 mutations or the knocked down of ASXL1 cooperated with RUNX1-MT inhibited apoptosis and impaired differentiation in 32D cells. Nine months post BMT mice with the combined RUNX1 and ASXL1 mutations, but not RUNX1-MT or ASXL1-MT alone, developed disease characterized by marked splenomegaly, hepatomegaly, and leukocytosis with a shorter latency. We found that RUNX1-MT stabilized hypoxia-inducible factor 1α (HIF1α) gene and increased its target gene expression such as ID1 (inhibitor of DNA binding 1). Clinical samples analyses showed that ID1 expression increased in both RUNX1-MT and ASXL1-MT or the combined mutations of RUNX1 and ASXL1 compared to control samples. We also examined the impact of RUNX1 and ASXL1 mutations on sAML-free survival of 104 Patients with CMMML in whom 11 had co-occurrence of RUNX1 and ASXL1, 39 had either mutated ASXL1 or RUNX1 and 54 patients were negative for both mutations. We found that patients carrying co-existed mutations had a shorter sAML-free-survival (median 16.1 months, 95% CI 0.0-60.1 months) than those carrying either mutated gene alone (median 23.0 months, 95% CI 17.8-28.2 months) or negative for both mutated genes (median not reached, 59.2% ± 8.8% at 5 years) (P=0.023).

Summary/Conclusions: The present study demonstrated that clinical and functional evidence for a collaborative association of RUNX1-MT and ASXL1-MT for sAML transformation. We identified HIF-1α targeting a new pathway which may be critical for leukemic progression of RUNX1/ASXL1-mutated myeloid malignancies.

A NOVEL MASS SPECTROMETRY METHOD REVEALS THE INTRACELLULAR PHARMACOKINETICS OF AZACYTIDINE THERAPY IN VIVO
A. Unnikrishnan1, A.V. Ngoc Quynh1, R. Pickford2, A. Nunez1, L. Hesslin1, R. Pandita3
1Prince of Wales Clinical School & Lowy Cancer Research Centre, 2Bioanalytical Mass Spectrometry Facility, UNSW Sydney, 3Haematology Department, Prince of Wales Hospital, Sydney, Australia
Background: The cytidine analog 5’-Azadecitidine (AZA, Fig. A), a DNA demethylating agent, is the primary drug for the treatment of high-risk Myelodysplastic Syndrome (MDS) and Chronic Myelomonocytic Leukaemia (CMML), and response is associated with improved survival benefits. However, only ~50% of treated patients will ever respond to AZA and the molecular basis for poor response is poorly understood. It is unclear whether non-responders to therapy have different rates of AZA uptake into their cells and/or AZA incorporation into nucleic acids compared to AZA responders, nor whether these might relate to DNA methylation in vivo.

Aims: We aimed to develop an analytical method capable of simultaneously detecting all the subcellular fractions of AZA (Fig B) within the bone marrows of patients undergoing AZA therapy, while also assessing DNA and RNA methylation levels. This would provide the most comprehensive snapshot of the intracellular pharmacokinetics of AZA therapy in vivo as a first step towards better understanding AZA resistance.

Methods: We have developed a new method utilising mass spectrometry to accurately quantify all the different subcellular fractions of AZA within the same sample (Fig C). Using an Orbitrap mass spectrometer with very high mass resolution, we have achieved the first mass separation of DAC and AZA from all naturally occurring isotopes of deoxycytidine and cytidine respectively (a difference of less than 1 Da), thus enabling accurate quantification. We utilised subcellular fractionation to obtain purified quantities of DNA- and RNA-incorporated nucleotides, as well as free unincorporated nucleotides present in the cytoplasm. We developed a reduction reaction to reduce the spontaneous hydrolysis of AZA and DAC, thereby greatly improving the sensitivity of detection.

Results: Using our new method, we report for the first time direct simultaneous quantification of: (1.) DNA-incorporated DAC, (2.) intracellular, free DAC, (3.) methyl deoxycytidine in DNA, (4.) RNA-incorporated AZA, (5.) intracellular, free AZA, and (6.) methyl cytidine in RNA within the same sample. We demonstrate an inverse correlation between the amount of DAC incorporated into DNA and DNA demethylation. However, no such correlation was observed between AZA incorporation and RNA demethylation (Fig D). The sensitivity and resolution of our method also enabled, for the first time, a comprehensive survey of the total intracellular pharmacokinetics of AZA in vivo in patients undergoing a standard cycle of treatment. We discovered that the bone marrow cells of AZA responders (n=4) incorporated more DAC into DNA compared to non-responders (n=4). DAC incorporation was also inversely proportional to DNA methylation levels, with greater DNA demethylation observed in the responders compared to non-responders. Furthermore, we observed two patterns in AZA non-responders, with DAC-incorporation and DNA demethylation occurring in some individuals (n=2), while no DAC incorporation and no DNA demethylation (Fig E). Our method also enabled us to directly prove that low DAC incorporation was not a result insufficient AZA accumulation in the non-responders with the lowest levels of DNA-incorporated DAC. Additionally, in these non-responders, there was also concomitant increase in AZA incorporation into RNA.

Figure 1.

Summary/Conclusions: We have developed a new method that has enabled the first comprehensive analysis of the intracellular pharmacokinetics of AZA therapy in vivo. Our results have revealed that while AZA responders incorporated AZA efficiently into DNA, leading to DNA demethylation, there were two modes of primary AZA resistance: in some non-responders, low levels of AZA incorporation into DNA likely derives from cell cycle quiescence, resulting in low amounts of DNA demethylation. However, in other non-responders who showed DAC incorporation into DNA and demethylation, resistance arises from as-yet-unknown mechanisms not connected with AZA metabolism.

CLONAL EVOLUTION OF STAG2 AND NRAS DURING PROGRESSION FROM MDS TO SAML ASSESSED BY WHOLE-EXOME AND TARGETED-DEEP SEQUENCING

M. Martin-Izquierdo1,*, M. Abáigar1, J.M. Hernández-Sánchez1, D. Tamborero2, M. Díez-Campezo3, M. Hernández-Sánchez1, F. Ramos1, M. Megido2, C. Aguilar2, E. Lumberas1, A. Redondo-Guijo2, M. Hernández-Rivas3, 1Unidad de Diagnóstico Molecular y Celular del Cáncer, IBBMC-Centro de Investigación del Cáncer (USAL-CSIC), Salamanca, 2Research Program on Biomedical Informatics, IMIM Hospital del Mar Medical Research Institute and Dr. iNetB Foundation, Barcelona, 3IBSL, Hematology Department, Hospital Universitario de Salamanca, Salamanca, 4IBIOMED, University of León; Hematology Department, Hospital de León, León, 5Hematology Department, Hospital del Barco, Ponferrada, Léon, 6Hematology Department, Hospital San Martín, Ávila, 7Hematology Department, Hospital General de Segovia, Segovia, Spain

Background: Myelodysplastic syndromes (MDS) are a heterogeneous group of clonal hematological disorders at high risk of progression to acute myeloid leukemia (sAML). Due to recent high-throughput sequencing studies, the mutational dynamics and clonal evolution underlying disease progression have just begun to be understood. However, large longitudinal sequencing genomic studies are still required.

Aims: To analyze the relationship between the dynamics of gene mutations and cell pathways they are involved in with the progression from MDS to sAML in order to study the mechanisms underlying disease evolution.

Methods: Sixty-eight serially collected samples from 34 MDS/CMML patients evolving to sAML were studied by a combination of whole-exome sequencing (WES) and targeted-deep sequencing (TDS). Each patient was studied at two different time-points: at the time of diagnosis (MDS/CMML stage) and after sAML progression (disease evolution, leukemic phase). At initial presentation of the disease, diagnoses were as follows: 18 RAEB-1/2, 9 RCMD and 7 CMML. Initially, WES was carried out on 40 diagnosis/progression-matched samples. Driver mutations were identified, after variant calling by a standardized bioinformatics pipeline, by using the novel tool “Cancer Genome Interpreter” (https://www.cancergenomeinterpreter.org). Secondly, in order to validate mutations and precise variant allele frequencies (VAFs) estimation, TDS using a custom MDS/AML-related capture enrichment panel (illumina®) of 117 genes was performed in 30 out of 40 of the initial cohort. Moreover, a total of 28 paired-samples from a cohort of 14 patients were analyzed by TDS.

Results: Combining both WES and TDS approaches, a total of 143 mutations in 50 different genes were identified at the sAML stage, with most of them (118 mutations) already present at the MDS stage, at clonal or subclonal levels. TDS identified most recurrently mutated genes were SRSF2 (41%), TET2 (41%), STAG2 (28%), SF3B1 (21%), ASXL1 (21%), TPO3 (21%) and NRAS (21%). However, it should be noted that 68% genes were mutated only in less than 10% of the patients, highlighting the great heterogeneity that exists in the mechanisms of disease evolution. To study the mutational dynamics during disease progression we compared VAFs of mutations detected at both time-points (sAML to MDS/CMML stage) in each patient. We identified 4 different clonal dynamics: mutations that were initially present but increased VAF (type-1), decreased (type-2), were newly acquired (type-3) or persisted with similar allelic burden (type-4) at sAML stage. Interestingly, most type-1 mutations were detected in STAG2 gene. Thus, mutational burden of STAG2 were markedly increased (6/8 patients) at sAML progression. Moreover, type-3 mutations, only detected at the sAML-stage, were predominantly identified in FLT3 (3/4) and NRAS (5/6). Conversely, type-4 mutations were present in MDS-related genes such as SRSF2 (9/12), SF3B1 (3/6) and TET2 (8/12). Most of mutations in these genes showed no changes during progression to sAML.

Summary/Conclusions: Progression from MDS to sAML could be explained by different mutational processes, as well as by the occurrence of unique and complex changes in the clonal architecture of the disease during the evolution. Mutations in genes such as STAG2, FLT3 or NRAS could play an important role during disease progression.
Background: Progression of myelodysplastic syndromes (MDS) to acute myeloid leukemia (AML) associates with acquisition of genetic aberrations. Similar aberrations may occur in the development of primary AML, particularly in the context of a clonal hematopoiesis of indeterminate potential. Thus, in-depth knowledge of the genetics and clonal composition of MDS and paired AML provides all insights into MDS progression in particular and AML development in general.

Aims: Here, we assessed mutations in serial samples of patients with MDS and progression to AML by next generation (NGS) and single-cell sequencing to identify mutations and clonal changes associated with AML development.

Methods: Mononuclear cells from 21 bone marrow (BM) samples of 8 patients with MDS and progression to AML were studied for mutations by an NGS panel (Agilent HaloPlex, Illumina MiSeq) comprising 98 genes relevant in hematologic neoplasms, and for copy number variations (Affymetrix CytoScan HD). All AML have been matched with at least one single cell. Samples were collected during MDS, at AML diagnosis and under treatment. Variants were verified by Sanger and pyrosequencing or fragment analysis in BM and CD3+ cells (germline). Clonal assignment of variants was verified by single-cell mutation analysis using a Single-Cell Printer.

Results: Applied predefined criteria and verifying variants by orthogonal methods in blasts and CD3+ cells, a median of 3 variants (range, 1-6) in the MDS and 4 (range, 1-6) in the AML samples were deemed pathogenic. During MDS, all patients except one had mutations in genes involved in RNA-splicing (SF3B1, STAG2, CEBPA, RUNX1) or epigenetic regulation (TET2, DNMT3A, ASXL1, EZH2). Additional mutations existed in FLT3, NRAS, PTEN, STAG2, CEBPA, RUNX1 or WT1. Subclonal mutations (i.e. variant allele frequency (VAF) <1%) were present in only two MDS samples. Towards AML, patients acquired a median of 1 (range, 0-2) new mutation in FLT3, CSF3R, KRAS, NRAS, PHF6, IDH1 or WT1. The VAF shifts from MDS to AML indicated cooperativity of mutations on clonal outgrowth. e.g. gain of CSF3R p.T618I was accompanied by a chromosome 19q-loss resulting in hemizygosity of a preexisting CEBPA mutation; or acquisition of a FLT3-TKD mutation was associated with outgrowth of a RUNX1 mutation. Changes in mutations or VAFs also occurred in single cells, e.g. in one AML sample under decitabine treatment by gaining two distinct FLT3 mutations. In another patient, who achieved complete remission after induction chemotherapy, but relapsed with MDS, which again progressed to AML, mutations were lost or gained, while a STAG2 mutation was detectable at all time points. Interestingly, identical genes were recurrently mutated in different clones with single patients, e.g. progression to AML associated with acquisition of a WT1 mutation in an NRS mutated MDS clone and with the generation of further subclones harboring distinct combinations of different WT1 and NRAS mutations. The co-occurrence of the specific WT1 and NRAS mutations in the different clones was demonstrated by mutation analyses of 72 single patient cells.

Summary/Conclusions: Mutations in MDS are few in number, but enriched in genes involved in RNA-splicing or epigenetic regulation; gain of single driver mutations leads to clonal outgrowth and thus, AML. Subsequent treatment can change the mutational and clonal profile, in particular, identical mutations were found in different clones, as confirmed by single-cell analyses; this suggests a fertile ground (e.g. microenvironment) for such mutations in a patient and may lead to (a therapeutically exploitable) competition of clones.

Figure 1.

Summary/Conclusions: Although the in vivo model cannot be replaced, the low level of engraftment of most of the patients is a limit in the study of MDS. Here we have demonstrated the value of the 2D co-culture system using MScs (or murine M5S) as an alternative model to study MDS. This ex vivo culture system, which lasts for only 4 weeks and requires low number of human CD34+ cells, provides a robust preclinical assessment model to test therapeutic effects of different drugs and other approaches on the MDS clonality and autologous MScs prior to treatment of MDS patients.

MYELODYSPLASTIC SYNDROMES WITH IRON OVERLOAD ARE CHARACTERIZED BY A SWITCH FROM OXIDATIVE PHOSPHORYLATION TO GLYCOLYSIS AND THIS DEFECT IS PARTIALLY RESTORED BY IRON CHELATION. A FISIM STUDY

1Dept of Clinical and Biological Sciences, University of Turin, Orbassano, 2Dept Cell laboratory, G.Gaslini Institute, Genova, 3Division of Hematology, Sant' Eugenio Hospital, Rome, 4Dept of Internal Medicine, IRCCS AOU San Martino IST, Genova, 5Dept of Hematology, Seragnoi Institute, Bologna, 6University Tor Vergata, Rome, 7Dept of Hematology, University of Ancona, Ancona, 8Dept of Hematology, Piacenza Hospital, Piacenza, 9Dept of Hematology, University of Parma, Parma, 10Dept of Hemaotology, San Giovanni Hospital, Rome, 11Ospedale Civile di Brescia, Brescia, 12Dept of Hematology, SS. Antonio e Biagio Hospital, Alessandria, 13Dept of Hematology, University of Florence, Italy

Background: Myelodysplastic syndromes (MDS) are a heterogeneous group of diseases characterized by a clonal and ineffective hematopoiesis, as well as the tendency to develop iron overload, mainly due to red blood cell transfusions. Iron overload has been described to increase ROS production and progressively worsen hematopoiesis. In mitochondria, iron is a fundamental component of cytochromes belonging to the oxidative phosphorylation (OXPHOS), which is considered the main source of cellular energy. Mitochondria are also the main site of ROS production. In this regard, cancer energetic metabolism is an emerging issue that could represent an attracting therapeutic target.

Aims: The aim of the study was to investigate the energetic metabolism in MDS patients and to understand the impact of iron overload on the energy production.

Methods: We selected 37 samples from patients with MDS with or w/o iron overload (7 RA, 5 RARS, 9 RCM, 4 RAEB-I, 2 RAEB II and 10 sAML). In addition we analyzed 86 samples from healthy subjects stratified according to the iron status, the OXPHOS activity, in term of oxygen consumption and ATP synthesis, the lactate dehydrogenase (LDH) activity, and malondialdehyde (MDA), as marker of lipid peroxidation. The same parameters have been analyzed also after iron chelation with deferasirox (DFX) and after incubation of the cells with DFX and DFO.

Results: Our study clearly demonstrated that mitochondrial function is altered in MDS, leading to a strong energetic defect and an increase in oxidative stress, far beyond the expected parapathophysiological decrease resulting from ageing. The OXPHOS efficacy is highly reduced in MDS compared to controls, deter-mining an impairment of the ATP/AMP ratio, which is 2.4 in young controls, 0.75 in elderly controls and it is 0.2 in b-thalassemia and MDS patients. By contrast, LDH activity increased in the MDS patients (6mU/mg) with respect to...
the controls (88 μM/μg), suggesting an attempt to compensate the energy unbalance with the increment of anaerobic glycolysis. MDA level, which reflects the lipid peroxidation, is 1 mM in young subjects, 9 mM in elderly subjects, 9 mM in b-thalassemia and 15 mM in MDS. In vitro iron chelation partially restored this abnormalities in MDS patients: ATP/AMP ratio increases from 0.2 to 0.6 in MDS and b-thalassemia, by contrast it is reduced in healthy subjects from 2.4 to 1.6. Anaerobic glycolysis is reduced after DFX incubation, in fact LDH decrease from 88 to 77 in MDS. By contrast, in healthy samples the iron chelation determined a reduction of OXPHOS activity, with a consequent impairment of ATP/AMP ratio and an increment of anaerobic glycolysis flux. Lipid peroxidation is significantly reduced by 28% with DFX and 23% with DFO (p value <0.001 for both). Similar reduction is observed in b-thalassemia. By contrast MDA levels increased in healthy subjects incubated with DFX. Curiously, all these abnormalities are more pronounced in MDS with IOL compared to MDS w/o IOL and are significantly worse in MDS without IOL compared to elderly non-iron overloaded. Furthermore, the expression of patients with DFX reproduces similar findings as in vitro incubation.

**Summary/Conclusions:** In summary OXPHOS activity and the energetic status are highly impaired in MDS compared to elderly subjects. MDS cells used O2 to produce ROS instead of ATP. This is typical of ageing but is significantly increased in MDS compared to elderly controls and it is further increased by IOL. DFX is able to restore mitochondrial activity and ATP production in all the patients analyzed after in vivo or in vitro treatment.

**P659 V-SET AND IMMUNOGLOBULIN DOMAIN-CONTAINING 4 (VSIG4) EXPRESSED ON MONOCYTES INCLUDING TUMOR-ASSOCIATED MACROPHAGES SUPPRESSED ANTITUMOR IMMUNE RESPONSES IN MYELODYSPLASTIC SYNDROMES**

1Department of Hematology, Nippon Medical School, Japan, Sendagi, Bunkyo-ku, Tokyo, Japan, 2Department of Microbiology and Immunology, Inje University College of Medicine, Busan, Korea, Republic Of

**Background:** In myelodysplastic syndromes (MDS), blast cells increase with clonal proliferation during disease progression, while immune cells in the bone marrow (BM) microenvironment become less efficient. The V-set and immunoglobulin domain-containing 4 (VSIG4) molecule is a new B7 family-related protein and strong negative regulator of T-cell proliferation. However, the role of VSIG4 in tumors including hematological malignancies remains unknown.

**Aims:** We investigated the expression and functions of VSIG4 in MDS.

**Methods:** 1) Peripheral blood (PB) and BM samples were obtained from 39 patients with acute leukemia transformed from MDS (AL-MDS, N=21), MDS (N=13), and chronic myelomonocytic leukemia (CMMML, N=5) and from healthy controls (N=14). The expression of VSIG4 in mononuclear cells (MCs) from the samples and MDS cell lines (F-36P and SKM-1) was analyzed with real-time PCR and flow cytometry (FCM). 2) After cultivation with BM stromal HS-5 cells, its culture supernatants (HS-5 sup.), immunomodulatory drugs (lenalidomide [LEN] and pomalidomide [POM]), and anti-MDS agents (cytarabine and azacitidine), we validated them by RT-PCR in an extension cohort of 73 additional MDS patients and assessed their potential singular pattern in this disease by analyzing 80 MDS and 90 AML patients. Further we chose 13 of the differentially expressed genes for validation and characterization through the myeloid spectrum based on clinical conditions: i) druggable oncogenes found to be overexpressed in our cohort; ii) oncogenes found in our patients allowing for the inhibition of an specific DNA repair pathway (i.e. XPA, XRCC4, MSH4); iii) oncogenes infra-expressed in our cohort but with inhibitory molecules already being tested in myeloid neoplasms (i.e. PARP1). Global pattern of DNA repair gene expression was compared with MDS and AML MILE study data.

**Results:** Of 27 CMML patients and 10 healthy donors, the expression of 18 genes was significantly different between the two groups (p-value<0.05) with 6 genes up-regulated and 12 genes down-regulated in CMML patients compared with donors. Defects on genes uniquely predominant to a single leukemia were found: i) druggable oncogenes found to be overexpressed in our cohort, ii) oncogenes found in our patients allowing for the inhibition of an specific DNA repair pathway (i.e. XPA, XRCC4, MSH4): iii) oncogenes infra-expressed in our cohort but with inhibitory molecules already being tested in myeloid neoplasms (i.e. PARP1). Global pattern of DNA repair gene expression was compared with MDS and AML MILE study data.

**Conclusion:** Using an unbiased and massive DNA repair transcriptome assessment, we have identified a series of candidate targets for a synthetic lethality approach in CMML. In addition, the different sense of misregulation of these and other targets within the myeloid diseases, some of them already being targeted in the clinical trial setting, emphasize the need of a new plasm-personalized test of DNA repair modulators.
on cytomorphological characteristics, but it remains a challenge in some patients who do not fulfill diagnostic criteria. Flow cytometry (FC) immunophenotyping can be an important tool for MDS diagnosis, but a lack of standardization and subjectivity of the analysis hinders its applicability.

**Aims:** To develop a methodology for FC immunophenotyping that allows us to establish the differential diagnosis between MDS patients and non-clonal cytopenias using a myeloid maturation database.

**Methods:** Bone marrow samples from 55 MDS patients, and 51 controls with cytopenias of several origins (immune disease, hypersplenism, drug toxicity) were analysed by FC. We elaborated a Myeloid Maturation Database using the Infinicyt® software (Cytognos, Spain). From all bone marrow controls, we merged files stained with a 4-colour combination (CD16-FITC/CD13-PE/CD45pCP/CD11bAPC). We selected myeloid population from the merged file and drew a maturation path. We obtained a maturation diagram that displays the fluorescence intensity of each parameter measured along the maturation stages. Then, for patients and controls, we obtained the fluorescence intensities whose median values exceeded ±2SD range in comparison with the stored database values (Figure 1). We elaborated a score, considering the relevant changes in fluorescence intensities (deviations) in the four markers analysed (CD16, CD13, CD45, CD11b) and in the four maturation stages, with a punctuation from 0 to 16.

**Results:** We found a mean of 1.9 deviations (fluorescence intensities values exceeded ±2SD) in controls, and a mean of 4.5 deviations in patients. Our test resulted reliable for differential diagnosis between controls and patients (curve ROC analysis, AUC = 0.748; p = 0.016). We found that with a cut-off of 4.5 deviations, we obtained a high specificity in the diagnosis of MDS (100%) but a low sensitivity (45%). With a high suspicion of MDS specificity (90%), we can consider patients with scores above 3.5, thus achieving higher sensitivity (59%). Additionally, the number of immunophenotyping changes correlated well with prognostic risk. We confirmed that the higher the score, the greater impact on deviations from the normal pattern (average of 3.7 at low risk, 4.5 at intermediate risk; 6.8 at high risk) (Figure 2).

**Summary/Conclusions:** The maturation database (using the maturation analysis from Infinicyt® software) was useful to discriminate between MDS patients and non-clonal cytopenias, proving to be a reliable diagnostic test, also with prognostic implications. The application of this database as a diagnostic tool has the advantage that the result is independent of the observer. Inclusion of more myeloid markers and incorporation of erythroid parameters could increase sensitivity in differential diagnosis.
Aims: To clarify the prognostic impact of lymphopenia in MDS in addition to the Revised International Prognostic Scoring System (IPSS-R)

Methods: The Düsseldorf MDS-registry was searched for patients with a complete differential blood count at diagnosis. Patients having received allografting or with an absolute lymphocyte count >5.0 G/l were excluded. The influence of the absolute lymphocyte count at diagnosis on overall survival was determined by a Kaplan-Meier analysis. Multivariate Cox regression analyses were performed.

Results: 2035 patients (RA n=182, RCMID n=978, RARS n=170, MDSde5q n=92, RAEAB-12 n=613) with a median follow-up of 23 months (mo) were included. Data were sufficient for IPSS-R calculation in 651 patients. The mean absolute lymphocyte count (ALC in the whole population was 1402/μl (95% CI: 1368-1437, range 0.12-4972) with no significant differences between the IPSS-R groups (very low-risk [n=77] mean 1471/μl, low-risk [n=255] mean 1406/μl, intermediate-risk [n=154] mean 1244/μl, high-risk [n=96] mean 1419/μl, very-high-risk [n=69] mean 1255/μl, p=0.067). 688 patients (34%) were lymphopenic (ALC <850/μl) with a significantly shorter survival (median 17.9 vs. 26.4 months, Log Rank p < 0.001). After stratification according to IPSS-R, survival of lymphopenic patients was not significantly different in the very-low, intermediate or (very) high risk group. Within the low risk group the survival difference was of borderline significance (median 67 vs 47 months, Log Rank p=0.1, Breslow p=0.39). With an ALC above the first quartile of the whole population (850/μl) as discriminator, the survival difference between lymphopenic and non-lymphopenic patients within the IPSS-R low-risk group reached statistical significance (survival median 67 vs 43.0 months, Log Rank p=0.002). This was not the case in the other IPSS-R subgroups. In multivariable analyses, an independent adverse impact of lymphopenia (defined with a lymphocyte count <850/μl) was confirmed in the IPSS-R low-risk group after inclusion into a Cox regression model together with age (>70 and LDH (normal value 240 U/l) (p=0.039). Patients with an ALC <850/μl had significantly lower platelets (median 97 versus 150 G/l, p=0.001) and neutrophiles (median 1478 versus 1971/μl, p<0.001) counts but similar haemoglobin levels (median 9.4 g/dl versus 9.4 g/dl, p=0.052).

Summary/Conclusions: An absolute lymphocyte count < 850/μl is an independent risk factor in patients with low risk MDS according to the IPSS-R. Whether lymphopenia in MDS is a direct consequence of the underlying haematopoietic stem cell defects or arises from immune-modulating stimuli related to the disease or to other host conditions remains to be elucidated. The lower levels of platelets and neutrophils in lymphopenic patients observed in our cohort point towards an association of lymphopenia with marrow insufficiency. In addition, further studies with larger patient cohorts are necessary to define the lymphocyte count most suitable for prognostication.
start of treatment was 21 months (95%CI=19-24); CR: 25 months (95%CI=20-30); PR: 27 months (95%CI=20-30); and SD: 17 months (95%CI=14-19) (p=0.006). We compared OS between mCR vs PR (p=0.193, HR 0.796 [95%CI=0.765-1.122]), mCR vs PR (p=0.572; HR =0.564 [95%CI=0.378-0.845]) or mCR vs SD (p=0.243; HR=1.242 [95%CI=0.863-1.788]), without any statistical difference (Fig. 1A). Median progression-free survival (PFS) was 14 months (95%CI=13-16); CR: 16 months (95%CI=13-21); PR: 11 months; mCR: 10 months (95%CI=5-15); and SD: 10 months (95%CI=9-12) (p=0.013). No statistical differences were observed between PFS in patients who achieved mCR vs PD (p=0.410; HR 1.816 [95%CI=0.439-7.512]) and SD (p=0.7743; HR 1.059 [95%CI=0.752-1.491], but PFS was increased in those patients who achieved CR when compared to mCR (p=0.013; HR 0.665 [95%CI=0.482-0.918]) (Fig. 1B).
survival advantage when compared with conventional therapies and has also shown activity in IPSS lower-risk patients. However, about 40% of patients do not respond and most patients lose response within 2 years. Treatment options for MDS patients failing hypomethylating agents therapy are scarce and overall survival (OS) is extremely short.

Aims: Objectives of this study were to describe in a cohort of real life MDS patients treated with AZA, the reasons causing treatment discontinuation, and to evaluate the clinical outcome after the end of AZA therapy.

Methods: Unselected patients recorded in the MDS Registry of Fondazione Italiana Sindrome Mielodisplastica (FISM) and treated with AZA from January 2009 to June 2014 were considered for the analysis. All types of conventional cytopenias or the cytopenias after AZA were allowed. Clinical response, cause of discontinuation, salvage treatments and OS from discontinuation of AZA were the major end points.

Results: Between January 2009 to June 2014 1799 newly diagnosed MDS patients were enrolled in the Registry, and 418 received AZA; 269 as 1st line treatment (64%), 115 as 2nd line treatment (26%), and 34 as a line ≥3rd (8%). Median age was 73 years (range 18-91); 260 patients (62%) were male. WHO diagnosis was RA or RARS (n=27, 6%), RCMD with or without RS (n=62, 15%) A-complete (n=126, 30%), A-EB2 (n=189, 45%), other subtypes (n=15, 4%). At start of AZA therapy IPSS score was low in 14% (3.4%), int-1 in 9% (23.2%), int-2 in 16% (43.8%); high in 67 patients (16%), and not available in 57 patients (13.6%). Patients received a median of 7 courses of treatment (range 1-63). Seventy-three % of the whole cohort (418 pts) were alive at 1 year from beginning of AZA therapy and median OS was 23 months. (25 for IPSS lower-risk MDS and 21 for IPSS higher risk MDS). OS after discontinuation of AZA was 8 months. Clinical responses according to IWG criteria were available in 344/418 patients with 72% achieving a complete hematological response, 77% (22%), a partial response, 86% (25%) had stable disease while 36% (40%) did not respond. Response was achieved after a median of 6 cycles. After a median follow up of 16 months (range 7-35) in 37 (9%) patients AZA therapy was still ongoing while in 381 (91%) the treatment had been discontinued. Interruption of treatment was due to loss of response in 59 patients, all of them with AML evolution in 154 (40%), death in 43 (11%), toxicity or poor compliance in 39 (10%), allogeneic HSCT, 27 (7%) low-dose chemotherapy (7%), 22 (6%) erythroid stimulating agents, 18 (5%) other treatments and 272 (72%) patients no further treatment or only supportive therapy.

Summary/Conclusions: Our data confirm that AZA therapy is effective for MDS patients, both with higher and lower IPSS risk disease. Response rate is consistent with what previously reported, with a median OS of 23 months. Interestingly, at 16 months, 91 % of patients had discontinued treatment, either for progression or loss of response and only in 10% of cases for reported toxicity. Only 28% of patients received any kind of salvage therapy and overall survival after AZA discontinuation was poor (8 months).

P668

COMBINATION OF DEEP PHENOTYPING AND TARGETED NEXT GENERATION SEQUENCING AS A DIAGNOSTIC TOOL IN CHILDREN WITH SUSPECTED MDS

1Molecular Haematology Unit, Weatherall Institute of Molecular Medicine University of Oxford, 2Molecular Diagnostic centre, John Radcliffe Hospital, Oxford, 3Paediatric Haematology Department, Great Ormond Street Hospital, London, 4Paediatric Haematology Unit, Royal Hospital for Sick Children, Edinburgh, 5Paediatric Haematology Department, John Radcliffe Children’s Hospital, Oxford, 6Paediatric Haematology Unit, Alder Hey Children’s Hospital, Liverpool, 7Paediatric Haematology Department, Noah’s Ark Children’s Hospital of Wales, Cardiff, 8Paediatric Haematology Department, Royal Hospital for Children Glasgow, 9Paediatric Haematology Department, Birmingham Children’s Hospital, Birmingham, 10Paediatric Haematology Department, Sheffield Children’s Hospital, Sheffield, 11Paediatric Haematology Department, Manchester Children’s Hospital, Manchester, United Kingdom

Background: Paediatric Myelodysplastic Syndromes (MDS) are a rare and heterogeneous group of disorders distinct from adult MDS. They may present with syndromic anaemia, life threatening infection or evolving leukaemia; however, they may also present as unexplained cytopenias or with multisystem disease of unclear aetiology. Diagnosis can represent a huge challenge for clinicians, even in highly specialised centres and this can delay the delivery of the most appropriate treatment. Hence an accurate diagnosis is crucial in selecting the most appropriate treatment, including surveillance and follow-up.

Aims: To devise a clinical grade diagnostic targeted NGS panel and combine the results with extensive clinical phenotypic information to obtain a diagnosis in children referred with suspected MDS.

Methods: Children (0–18yrs) were referred from 14 UK centres with a diagnosis of suspected MDS and/or sustained cytopenias with morphological features of myelodysplasia. Extensive phenotypic information including family history, detailed clinical examination and disease course details were collected and captured on an online database using the Human Phenomiser tool. A customised targeted NGS panel was designed using the illumina design studio containing 32 genes, 916 amplicons and 301 exons; selected through literature reports and well described mutations in Paediatric MDS and potential overlap Bone Marrow failure syndromes (BMFS). Coverage of each base within target regions was assessed for every sample on each sequencing run using Covemri software. Library preparation was performed using an illumina Truseq Custom Amplicon panel, followed by sequencing on an illumina Miseq. Data analysis was performed using our established bioinformatic pipelines (Hamblin A: Blood 2014 124:2373).

Results: In total 59 patients (females= 29, males 30) have been screened and 3 subgroups identified based on the original suspected clinician diagnosis at presentation: MPN/JMML (n=15), de novo MDS (n=9) and idiopathic cytopenias of undetermined significance, (ICUS) with some features of dysplasia (n=35). Mutations were detected in 24/59 patients (40%, Table 1). Of these, NGS results confirmed the original clinical diagnosis in 15 cases (62.5%); established the diagnosis for the first time in 6 cases (25%); and led to a change in diagnosis (from autoimmune neutropenia to Shwachman-Diamond Syndrome) in 1 case leading to a significant change in patient management. In two already known cases, it allowed monitoring of the disease molecular signature. As expected, RAD pathway mutations were common in the JMML/MPN (100%) and de novo MDS patient subgroups (33%). Additional mutations in epigenetic modifiers, splicesome mutations as well as second RAD pathway hits were also detected in 40% of JMML patients and in one case within the de novo MDS group; this finding was associated with poor outcome. Within the heterogenous ICUS patient group, pathogenic mutations were identified in 5/35 (14.3%) cases with BMFS genes (SBDS, ELANE, TET3). In contrast to the other MDS/MPN cases, in this group, no RAD pathway mutations were detected.

Table 1.

Summary/Conclusions: Targeted NGS together with detailed phenotyping is a useful tool for the diagnosis of suspected MDS and unexplained cytopenias in children, with 40% of patient showing a disease-associated mutations. Results were available within 6-8 weeks in most cases enabling both rapid initial diagnosis and, in some cases, appropriate molecular markers for monitoring of clonal evolution and response to therapy. For the children who remain without a clinical diagnosis, whole genome sequencing (WGS) may identify pathogenic mutations and this is currently underway.

OUTCOMES IN PATIENTS ALLOCATED TO NO-ASCT BASED ON DEPTH OF RESPONSE: INITIAL RESULTS OF A PHASE 2 TRIAL ASSESSING THE IMPACT OF MINIMAL RESIDUAL DISEASE (MRD) IN PATIENTS WITH DEEPLY RESPONSES TO ASCT (PADIMAC)

1UCL Cancer Institute, University College London, London, 2Haematology, Leeds Teaching Hospital NHS Trust, Leeds, 3CRUK and UCL Clinical Trials Centre, London, 4Department of Haematology, St Bartholomew’s Hospital, London, 5Haematology, Guy’s Hospital, 6Haematology, Heart of England NHS Foundation Trust, 7Haematology, Queen Elizabeth Hospital, Birmingham, 8Haematology, Mid Yorks NHS Trust, Wakefield, 9Haematology, University College London Hospital, London, United Kingdom

Background: The role of autologous stem cell transplantation (ASCT) as first line therapy for newly diagnosed (ND) patients with multiple myeloma (MM) remains under investigation despite the demonstrated PFS and OS benefits for ASCT patients. Outcomes for those not proceeding to ASCT following induction remain unclear, likely to be influenced by genetic risk and response depth. This study was designed to evaluate a stratified approach to ASCT, investigating if patients not proceeding to ASCT induction may safely be assigned to delayed ASCT.

Aims: This single arm phase 2 clinical trial conducted at 13 UK sites aimed to determine the progression free survival (PFS) for patients who achieved ≥VGPR to induction therapy with no further treatment. Here we report the primary stratification data in the patients not proceeding to ASCT, and the influence of MRD status on PFS.

Methods: NDMM patients eligible for ASCT received PAD (bortezomib 1.3mg/m² IV or SC days 1, 4, 8, 11; lenalidomide 15mg days 1-8 and 15-21; dexamethasone 40mg days 1-4 and days 8-11 and 15-18 for cycle 1 only) for 4-6 cycles. Those achieving <PR were off protocol; all others had PBSC followed by restaging including MRD assessment on bone marrow using multi-parameter flow cytometry. Those in PR were stratified to ASCT (no maintenance) whereas those achieving ≥VGPR stopped induction therapy and were assessed at 100 days post PBSC (including MRD), and at monthly intervals for up to 2 years. High risk disease was defined by the presence of one or more adverse FISH lesions (t(4;14), t(14;16), t(14;20), del(17p13), +1q21). Response rate alone is not sufficient to identify patients who would benefit from ASCT and use of MRD to stratify treatment is now being investigated.

Results: Between April 2011 and January 2014 153 patients were enrolled (median age 55, range 28-71 years), 139 (91%) received 4-6 cycles of PAD. The majority (88.2%) received SC bortezomib, 18 (11.8%) received at least 1 cycle IV. Fish data was available for 132 patients, 89 (67.4%) patients were standard risk and 43 (32.6%) were adverse risk. 51 (33.6%) patients were ISS I, 67 (44.1%) ISS II and 34 (22.4%) ISS III. The overall response rate to PAD was 82.4% (≥ VGPR: 41.2%). Responses were similar irrespective of ISS or genetic risk (standard: ≥ VGPR 37.5%, PR 40.9%, adverse: ≥ VGPR 53.3%, PR 34.9%).

Post-PBSC, 63 (41.2%) patients achieved ≥ VGPR, and 44 (28.8%) patients achieved PR of whom 36 proceeded to ASCT. After a median follow-up of 44 months from registration, median overall PFS was 22.5m (95% CI: 18.1-25.3). For those who achieved ≥ VGPR, median PFS from PBSC was 8.9m (95% CI: 4.6-13.3) and 25.7m (95% CI: 13.7-37.6) for MRD+ (N=25) and MRD- (N=11) patients at D100 post-PBSC respectively, 2+y-PFS 28.0% (95% CI: 19.4-45.6) and 56.3% (95% CI: 32.0-80.6) respectively. PR patients proceeding to ASCT had a median PFS of 17.2m (95% CI: 14.2-20.2) and 23.1m (95% CI: 16.8-29.4) for those who were MRD+ (N=20) and MRD- (N=7) at D100 respectively, 2+y-PFS 25.0% (95% CI: 0.9-42.2) and 42.9% (95% CI: 6.2-79.6) respectively.

Summary/Conclusions: This is the first study to report outcomes of patients stratified to ASCT by depth of response. The overall PFS for the study is shorter than other published trials, most likely due to the inferior outcome for MRD+ patients not proceeding to ASCT. The median PFS for patients with adverse risk FISH lesions was significantly shorter than standard risk patients (p=0.008). More detailed subtyping of the lymphocyte phenotypes is ongoing and may reveal potential predictive biomarkers for immunomodulatory drugs such as lenalidomide and checkpoint inhibitors.

Figure 1.

Summary/Conclusions: Composition of the BM lymphocyte pool at treatment baseline may have an influence on treatment outcome in multiple myeloma. More detailed subtyping of the lymphocyte phenotypes is ongoing and may reveal potential predictive biomarkers for immunomodulatory drugs such as lenalidomide and checkpoint inhibitors.
Background: Lytic lesions occur in the majority of patients with multiple myeloma (MM) and represent one of the criteria for starting therapy. In the past, whole-body X-ray (WBX) represented the method of choice for detecting skeletal abnormalities; today, magnetic resonance imaging (MRI), positron emission tomography (PET) and computed tomography (CT) have been adopted for their higher power in detecting extra-medullary localizations and their higher sensitivity. Nevertheless, which technique would be really the best one is still matter of debate.

Aims: Our single-center retrospective study was designed to compare PET-CT with other imaging techniques (WBX, vertebro column CT and MRI) at the diagnosis and during the follow-up of MM patients. Finally, we assessed a possible predictive/prognostic role of the PET-CT in terms of quality of response and survival.

Methods: We enrolled 160 patients with diagnosed symptomatic (N=149) or smoldering multiple myeloma (N=11) observed at the AOU Pisa, Italy, between January 1996 and December 2015. Eighty-three were male and 77 female; the median age was 70 years (range, 28-85), and half of them presented with low ISS risk score. Forty-five subjects were not eligible to high-dose therapy; 64% of them received bortezomib- and 23% melphalan-based regimens. Patients eligible to high-dose therapy received VAD, TAD or VTD and then one (88%) or two (12%) autologous transplants. At the relapse, lenalidomide (57%) or OCR (35%) was administered.

Results: Our study showed that PET-CT and MRI would represent the techniques of choice in the assessment of bone involvement in MM patients in view of their high and comparable sensitivity. Moreover, PET-CT allowed detecting skeletal involvement in 18% of cases negative by WBX, in 37% of those CT-negative, and in 10% of those MRI-negative. Sensitivity of PET-CT was superimposable to that of MRI (90%), and higher than that of WBX (60%) and CT (73%). Nevertheless, the specificity was lower for PET-CT and MRI (40%) in respect of CT (51%) and WBX (71%). Analogously to that observed at diagnosis, PET-CT during follow-up showed distinct advantages in terms of sensitivity compared to X-rays (83% vs 60%, respectively). In contrast, PET-CT sensitivity was comparable to that of CT and MRI. As at diagnosis, the specificity was higher for WBX (70%) than for CT, RM and PET-CT (40% for all of these). When PET-CT was correlated to the quality of response, it was significant only in the not transplanted cohort (>PR rate in PET-negative cases: 87% vs 23% in the PET-positive group; p=0.016). Nevertheless, PET-CT positivity either at diagnosis or during follow-up did not impact on long-term OS and PFS.

Summary/Conclusions: Our study showed that PET-CT and MRI would represent the techniques of choice in the assessment of bone involvement in MM patients in view of their high and comparable sensitivity. Moreover, PET-CT allows the possibility of a “whole body” analysis in exchange for higher “biologic” cost.

Aims: To evaluate safety and efficacy of combination Ibr+BTZ/dex in previously treated MM pts.

Methods: In this phase 2, open-label, multicenter, European study (PCY-1139), eligible pts received 1-3 prior therapies and demonstrated disease progression on or following the most recent therapy. Prior BTZ use was permitted provided pts were sensitive (ie, no progression ≥60 days after having achieved minimal response or better). All pts provided informed consent. For cycles 1-8 (21-day cycles), pts received ibr 840mg once daily with BTZ 1.3mg/m² subcutaneously twice weekly (Days 1, 4, 8, 11) and dex 20mg on day of and after BTZ. For cycles 9-12 (42-day cycles), BTZ was dosed weekly (Days 1, 8, 22, 29). The primary endpoint was PFS with secondary endpoints including safety, ORR, PFS at landmark points, duration of response, and time to progression (TTP).

Results: As of November 21, 2016, 20 pts were enrolled (Table). Median age was 68.5 years (range, 49-96). Median number of prior therapies was 1, with 50% refractory to the most recent therapy and 70% previously exposed to BTZ. Gene expression profiling (GEP) in initial pts indicated high-risk GEP in 35% of pts. Virtual fluorescent in situ hybridization identified 40% of pts with high-risk cytogenetics. Median treatment duration was 2.1 months (range, 0.5-3.7). All pts experienced at least one treatment-emergent adverse event (AE) of any grade. The most common all-grade nonhematologic AEs occurring in >15% (≥3 pts) were nausea (50%), upper respiratory tract infection (30%), and asthenia, peripheral edema, hypocalcemia and hypokalemia (20% each). The most common Grade ≥3 AEs occurring in ≥10% (≥1 pt) were thrombocytopenia (25%), asthenia and pneumonia (15% each), and hyponatremia, abnormal hepatic function, infection, and bone pain (10% each). Three deaths were reported (sudden death in a pt with cardiac history, pneumonia, and myocardial infarction). With early follow-up, 19 pts are evaluable for response with an ORR of 47%, including MR or better in 68%. Updated data will be presented.
Results: There were 78 patients in Group 1 and 52 patients in Group 2. Patients in Group 2 had higher baseline dFLC, bone marrow plasma cells (BMPC), Mayo stage and were more likely to have active MM compared to patients in Group 1. Table 1 lists baseline characteristics of the patients in Groups 1 and 2. Patients in Group 1 had higher rate of renal involvement. cPCs were detectable in 22% (n=28) of patients at the time of ASCT. More patients in Group 1 had detectable cPCs than in Group 2 (31% vs 8%; p<0.002), likely due to clearance of cPCs with treatment. Data on cPCs at diagnosis in the induction group was available in 14 patients, of whom 57% (n=8) had detectable cPCs vs 31% in the direct ASCT group (p<0.06). 6 of the 8 (75%) patients cleared cPCs with induction therapy. There were no significant differences in patients who had detectable or undetectable cPCs before transplant, including organ involvement, baseline dFLC, BMPC, and Mayo Stage (data not shown).

In Group 2, both progression free survival (PFS) (10.5 months vs 58 months, p<0.0001) and overall survival (OS) (16 months vs not reached, p<0.0001) were worse in patients who had detectable cPCs compared to those without cPCs (Figure 1). This difference was not seen in Group 1 (OS: not reached vs 98 months, p=0.96; PFS 43 vs 52 months, p=0.74). In multivariate analysis, adjusting for Mayo Stage and induction chemotherapy, there was a trend towards worse OS in patients with detectable cPCs (p=0.06).

Figure 1. Patients receiving induction chemotherapy before ASCT

Summary/Conclusions: cPCs are cleared after induction treatment in majority of AL patients. Patients with detectable cPCs prior to proceeding to ASCT after induction have worse PFS and OS than patients without cPCs. On the other hand, presence of cPCs was not found to be an adverse prognostic factor in patients proceeding directly to ASCT. This may be due otherwise excellent prognosis in this group, with absence of other high-risk features that are seen in patients who require induction. A limitation of our study is lack of data on cPCs at diagnosis in all patients who received induction therapy.

P674

RENA L IMPAI RMENT IN MYELOMA - PATIENT CHARACTERISTICS, TREATMENT MODALITIES, STEM CELL TRANSPLANT & OUTCOMES FROM THE AUSTRALIAN AND NEW ZEALAND MYELOMA REGISTRY

Results: Of 867 patients, 775 had eGFR available at diagnosis: 34% (287/775) had eGFR <60ml/min (22% at 30-60ml/min; 6% at 15-30ml/min; 6% at <15 ml/min). Mean age of patients with RI (<60 ml/min) was 72 vs 64 yrs without RI. Diabetes mellitus (DM), a major cause of chronic kidney disease (CKD), was more prevalent in patients with RI: 17% of patients with eGFR <30 ml/min compared with 8% >30ml/min. Patients with RI (<30ml/min) and DM had a similar response to first-line therapy compared to RI without DM (pR, 75% vs 82%, p=0.56), with no difference in OS (26 vs 37 mths, p=0.68) or PFS (24 mths, p=0.82). High risk features of FISH (del17p, t(14;16), amp1q21, del13q) & high LDH were more prevalent in RI vs 46% (p=0.01). It was advanced stage (ISS III) (66% vs 12% p<0.001). Anemia was more prevalent in RI (44% vs 14%, p<0.001), but bone lesions were less prevalent (52% vs 65% p=0.001). There was no difference in ECOG performance status. Most patients (87%) received Bortezomib-based therapy in first line (81% RI vs 91% no RI, p<0.001), with no difference with or without ASCT. Response rates (pR) were the same in patients with eGFR <60ml/min compared with normal renal function (84% vs 85%, p=0.87). PFS & OS decreased with reduction in eGFR (Fig 1). However, patients with eGFR <15ml/min had better OS & PFS compared with eGFR 15-30ml/min; dialysis in eGFR <15ml/min may be a factor. Using age 70 yrs as a common age limit for ASCT, we analysed the effect of ASCT in patients <70 yrs with & without RI. While a smaller proportion of RI patients received ASCT (21% vs 79%, p<0.07), it was performed at all levels of renal function including eGFR <15ml/min. In patients with eGFR <60ml/min, those who received ASCT had a longer PFS (HR 0.37, 95%CI 0.16-0.88, p=0.03) & OS (HR 0.28, 95%CI 0.08-1.01, p=0.05) compared with no ASCT. The improvement was also seen in severe RI (<30ml/min), with a longer PFS (HR 0.21, 95%CI 0.05-0.86, p=0.03) & OS (HR 0.10, 95%CI 0.01-0.82, p=0.03) with ASCT.

Figure 1. Summary/Conclusions: RI occurred in one-third of newly diagnosed MM. DM, an underlying risk factor for CKD, was more common in RI patients, but not associated with a difference in outcome. Advanced stage & high risk features were more prevalent in RI patients, but bone disease was less common. RI patients had a shorter PFS and OS, overall correlating with eGFR. However patients with eGFR <15ml/min had a better OS than 15-30 ml/min, for which dialysis may be a factor. In transplant-eligible patients assessed by age <70 yrs, ASCT was performed in 21% of RI patients, at all levels of renal function. Patients with RI who underwent ASCT had a superior PFS and OS than those who did not have ASCT, including those with severe RI (eGFR <30ml/min), supporting the benefit of ASCT in MM patients with RI.

P675

VENETOCLAX AS TARGETED THERAPY FOR RELAPSED/REFRACTORY MULTIPLE MYELOMA

Results: Venetoclax (VEN), an orally available selective small-molecule BCL-2 inhibitor, has shown activity in MM patients with high-risk features, and was associated with improved outcomes in several studies.数据表明，Venetoclax（VEN）是一种口服的、选择性的小分子 BCL-2 抑制剂，在 MM 患者中显示出活性，并且在具有高风险特征的患者中与改善的结局相关。
BCL-2 inhibitor, induces cell death in multiple myeloma (MM) cells, particularly those with the t(11;14) translocation.

**Aims:** The objectives of the study are to evaluate safety, PK, recommended phase two dose, and preliminary efficacy of VEN monotherapy in relapsed/refractory (R/R) MM.

**Methods:** Patients (pts) with relapsed/refractory (R/R) MM received VEN monotherapy in this phase 1 study. Daily VEN was given at 300–1200mg in dose escalation cohorts and 1200mg in the safety expansion. Pts with disease progression (PD) on VEN monotherapy could receive VEN plus dexamethasone and remain on study.

**Results:** As of 19Aug2016, 66 pts were enrolled. Median age was 63 years and 30 (46%) pts had t(11;14). Median number of prior therapies up to 13 (range: 1–15); 46 (70%) pts were refractory to bortezomib, 20 (30%) to carfilzomib, 51 (77%) to lenalidomide, 35 (53%) to pomalidomide, and 52 (79%) were refractory to the last prior therapy. Median time on VEN monotherapy was 2.5 months (range: 0.2–23; 17 pts received VEN plus dexamethasone after PD for a median of 1.35 months). Fifteen (23%) pts discontinued, and 41 due to PD. Common adverse events (AEs) were nausea (47%), diarrhea (36%), vomiting (21%) and grade 3/4 hematologic toxicities [thrombocytopenia (32%), neutropenia (27%), anemia (23%), leukopenia (23%)]. Common serious AEs were pneumonia (8%), sepsis (5%), cough, hypotension, pain, and pyrexia (3%) each. There were no events of TLS. Six deaths were reported due to PD, and 1 each due to lung disorder and brain hemorrhage following trauma. Overall response rate (ORR) for all pts on VEN monotherapy was 21% (14/66); 10 (15%) achieved very good partial response (VGPR) or better (2 stringent complete response (sCR); 3 CR, 5 VGPR). For all pts, median time to progression (TTP) and median duration of response (DOR) were 7.8 and 9.7 months, respectively. A clear difference in responses was seen among pts with t(11;14) vs without [ORR, 40% vs 6%; nVGPR, 27% vs 6%]. For pts with t(11;14), median TTP was 6.6 months [vs 1.9 months for pts without t(11;14)] and median DOR was 9.7 months. A high BCL2:BCL2L1 (BCL-X) gene expression ratio was observed in 10/44 (23%) baseline tumor samples, enriched in pts with t(11;14) compared with non-t(11;14) (38% vs 5%) and associated with clinical response; 80% (8/10) of pts [all t(11;14)] with a high BCL2:BCL2L1 ratio achieved ≥PR with a median TTP of 11.5 months. Among pts with t(11;14) who were refractory to the last therapy, ORR was 42% (11/26); for t(11;14) pts refractory to both bortezomib and lenalidomide, ORR was 33% (8/24). For t(11;14) pts refractory to both bortezomib, lenalidomide, and pomalidomide, ORR was 40% (8/20) and 50% (3/6), respectively. No difference was seen in ORR for t(11;14) pts with high-risk del(17p) versus those without the deletion [40% (2/5) vs 40% (10/25)].

**Summary/Conclusions:** VEN has an acceptable safety profile with promising single-agent anti-myeloma activity in pts with R/R MM positive for t(11;14) who failed multiple prior lines of therapy.
dependent association with PFS was found for SKY92, r-ISS, deletion of 13q and t(11;14) (Table 1). A bidirectional stepwise selection procedure was applied excluding covariates with the highest $p$-values until only significant covariates remain. Initially included covariates were SKY92, r-ISS, gain(1q), del(17p), del(13q), t(4;14), t(11;14), LDH and age. ISS could not be included as it was highly correlated with other covariates (i.e. co-linear); t(14;16) was excluded due to the minimal number of present instances. HR: hazard ratios relative to the lowest risk category with 95% confidence intervals (CI), $p$: likelihood ratio $p$-value indicating the association of each covariate with OS.

Results: A total of 13,718 patients with multiple myeloma were included in the study and 21 groups of comorbidities were identified. The most common diseases were cancer, hypertension, heart failure, ischemic heart disease and atrial fibrillation. Among all patients, 55% had no prior history of comorbidity, 23% had one comorbidity, 12% had two comorbidities, and 10% had three or more comorbidity conditions. Survival was negatively influenced by the number of comorbidities (Figure 1). The risk of death was significantly increased in patients with atrial fibrillation (HR=1.08; 95% CI 1.00-1.16), heart failure (HR=1.50; 95% CI 1.40-1.61), stroke (HR=1.20; 95% CI 1.11-1.30), psychological disease (HR=1.27; 95% CI 1.16-1.39), chronic lung disease (HR=1.22; 95% CI 1.12-1.32), diabetes (HR=1.14; 95% CI 1.04-1.36), peripheral vascular disease (HR=1.26; 95% CI 1.12-1.42), cancer (HR=1.10; 95% CI 1.04-1.16), dementia (HR=1.65; 95% CI 1.38-1.99), paralysis (HR=1.44; 95% CI 1.15-1.80), inflammatory bowel disease (HR=1.38; 95% CI 1.08-1.74), end stage renal disease (HR=1.57; 95% CI 1.03-2.04), and cirrhosis (HR=1.64; 95% CI 1.10-2.43).

Summary/Conclusions: Here, we compared the SKY92 classifier with revised ISS staging and FISH. These data validate the SKY92 classifier as a robust marker to identify high-risk patients in non-transplant eligible MM patients. In these IMiD treated patients, the SKY92, the revised ISS, and FISH markers such as deletion of 13q retain independent prognostic value.

Multiple Myeloma and Comorbidity: A Population-Based Study

I.S. Sverrisdottir1,2,*; S. Rögnvaldsson2; S. H. Lund2; I. Turesson3; M. Hultcrantz4; M. Björkholm5; O. Landgren4; S.Y. Kristinsson2
1Internal Medicine, Landspitali, 2Faculty of Medicine, University of Iceland, Reykjavik, Iceland, 3University Hospital Malmö, Malmö, Sweden, 4Division of Hematology, Oncology, Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, United States, 5Department of Medicine, Karolinska University Hospital and Karolinska Institutet, Stockholm, Sweden

Background: The number of multiple myeloma patients has grown with aging populations, and with increasing age the number of comorbidities increases as well. Clinically, it is well known that comorbidity in multiple myeloma patients decreases performance status, increases risk of therapy-related complications and may lead to life-threatening conditions. Currently, the literature on comorbidity in multiple myeloma is very limited and based on small case series. Clinical trials rarely include elderly, frail patients due to eligibility criteria. Population-based studies provide valuable information on survival outcomes in relation to presence/absence of comorbidities in newly diagnosed real-life multiple myeloma patients in the general population.

Aims: To evaluate the prevalence of comorbidities and to study the impact of comorbidities on survival among patients with newly diagnosed multiple myeloma.

Methods: All newly diagnosed patients with multiple myeloma from January 1st 1985 to December 31st 2013 in Sweden were included in the study. Using the Swedish Patient Registry, all discharge diagnosis and discharge listings were gathered from each patient from January 1st 1985. Comorbid conditions were defined as chronic illnesses which demand life-long treatment or follow-up. Only those diagnoses made prior to multiple myeloma were used. Using ICD 8, 9 and 10 codes, comorbid diseases were identified. Kaplan-Meier curves were used to estimate survival. Risk of death was compared among multiple myeloma patients with a comorbid condition to those without a comorbidity, using Cox’s proportional hazards regression (adjusting for age, gender, year of diagnosis, and other comorbid conditions).

Results: Among all patients, 55% had no prior history of comorbidity, 23% had one comorbidity, 12% had two comorbidities, and 10% had three or more comorbidity conditions. Survival was negatively influenced by the number of comorbidities. The risk of death was significantly increased in patients with atrial fibrillation (HR=1.08; 95% CI 1.00-1.16), heart failure (HR=1.50; 95% CI 1.40-1.61), stroke (HR=1.20; 95% CI 1.11-1.30), psychological disease (HR=1.27; 95% CI 1.16-1.39), chronic lung disease (HR=1.22; 95% CI 1.12-1.32), diabetes (HR=1.14; 95% CI 1.04-1.36), peripheral vascular disease (HR=1.26; 95% CI 1.12-1.42), cancer (HR=1.10; 95% CI 1.04-1.16), dementia (HR=1.65; 95% CI 1.38-1.99), paralysis (HR=1.44; 95% CI 1.15-1.80), inflammatory bowel disease (HR=1.38; 95% CI 1.08-1.74), end stage renal disease (HR=1.57; 95% CI 1.03-2.04), and cirrhosis (HR=1.64; 95% CI 1.10-2.43).

Summary/Conclusions: Here, we compared the SKY92 classifier with revised ISS staging and FISH. These data validate the SKY92 classifier as a robust marker to identify high-risk patients in non-transplant eligible MM patients. In these IMiD treated patients, the SKY92, the revised ISS, and FISH markers such as deletion of 13q retain independent prognostic value.

DETECTION OF NEW EMERGING CLONES DURING TREATMENT BY NGS
ALLOWS A BETTER RISK PREDICTION ON MULTIPLE MYELOMA
PATIENTS
B. Sanchez-Vega1,*, R. Mateos1, I. Cuenca1, N. Puig2, S. Barrio1, Y. Ruiz-Heredia1, X. Aguirre3, R. Ayala1, L. Rosiñol4, J. Blade4, M.-V. Mateos2,

(IBSAL), Centro de Investigación del Cancer (IBMCC CSIC-USAL), Salamanca,
3Clinica Universidad de Navarra, Centro de Investigacion Medica Aplicada,
Instituto de Investigación Sanitaria de Navarra, Pamplona, 4Hospital Clinic,
Barcelona, Spain

Background: Multiple myeloma (MM) is a genetically complex disease, characterized by the presence of multiple clones with differing degrees of drug sensitivity at the time of diagnosis. Consequently, therapeutic response of MM
patients is unpredictable and extremely variable, and although the treatments
introduced over the last decade have significantly improved the outcome of
these patients, most patients eventually relapse. Deep sequencing methods
have contributed to increase the knowledge about the clonal heterogeneity of
the disease and helped to stablish the three evolution patterns at relapse: linear
and branching clonal evolution, and no clonal changes.
Aims: To analyze the diversity and relative dominance of different clones and
their evolution throughout the course of disease by NGS of the immunoglobulin
repertoire in MM patients. To evaluate if the presence of different clones is
associated with increased risk.
Methods: Immunoglobulin repertoire was analyzed by NGS in bone marrow
samples from 180 MM patients included in three GEM clinical trials
(NCT00461747, NCT00443235 and NCT01237249). The two first clinical trials
involve patients younger than 65 years old, and were analyzed with ClonoSeq
methodology, the later one involve patients older than 65 years old, and were
analyzed with a local NGS method recently validated (Martinez-López et al,
Laukemia 2017). A clonotype was identified when at least 400 identical
sequencing reads were obtained, or it is present at a frequency of >1%.
Results: Of the 180 MM patients studied, 57 (32%) shows the presence of
more than one clone throughout the clinical the course of the disease. The
identification of new evolving clones was only possible in the GEM10 clinical
trial with the Local NGS method; in this clinical essay, 6% (4/71) of patients
shows the development of different clones during treatment. We show that the
frequency of the predominant clone at diagnosis of these four patients
decreased with treatment, but the frequency of the new ones increased and
the patients progressed. When more than one clone is present at diagnosis,
the relative dominance of the clones varies throughout the course of disease
in an independent manner. There were no differences in median MRD values
between patients with one clone or more than one clone (0.0082% and 0.0055%
respectively). The presence of more than one clone was not associated with
high-risk cytogenetics. The presence of more than one clone at diagnosis does
not condition the prognosis in any of the patients and treatments analyzed.
Median PFS was 38 and 58 months for patients with one clone or more one
clone, respectively (HR=1.136, p= 0.563). Median OS was not reached for
patients with one clone, and was 81 months for patients with more than one
clone (HR=1.43, p=0.28).
Summary/Conclusions: The analysis of the IG repertoire by the local NGS
method during treatment is able to identify and quantify new emerging clones
during the treatment that were not detectable at diagnosis. The new clones
contributed to increase the MRD levels in the follow-up samples.The presence
of of different clones at diagnosis is not associated with higher risk of progression, high risk cytogenetics or higher MRD values.

Background: In the era of increased use of 1st-line and maintenance lenalidomide (LEN), there is growing need for effective ≥2nd-line therapies (tx) for LEN-

refractory pts. The combination of carfilzomib (CFZ), pomalidomide (POM),
and dexamethasone (DEX) has shown promising activity in advanced RRMM,
including for pts refractory to LEN (Shah et al. Blood. 2015).
Aims: In this Ph 1/2 study, KPd was evaluated in RRMM, with a focus on pts
who are LEN-refractory but proteasome inhibitor (PI)-naïve/sensitive.
Methods: LEN-refractory disease was required for 2nd-line KPd and LENrefractory/exposure for ≥3rd-line. Ph 1 dose escalation to determine maximum
tolerated dose (MTD) followed the TITE-CRM design with 40 pts receiving 3–
4mg POM PO (days [d] 1–21), 20–36mg/m2 CFZ (IV d1, 2, 8, 9, 15, 16 in cycles
[C] 1–8, and d1, 2, 15, 16 in C9+), and 40/20mg DEX PO weekly (C1–4/5–8;
for all dose levels [DLs]) in 28-day cycles. CFZ was started at 20mg/m2 for d1,
2 of C1 for all DLs. Per design, 30 PI-naïve/sensitive pts were to be enrolled at
MTD across Ph 1/2, with partial response (PR) rate after C4 as 1º efficacy endpoint.
Results: As of 12/1/16, 65 pts have been enrolled, with efficacy and safety
data available for 64 pts: 4 at DL1 (20mg/m2 CFZ, 3mg POM), 29 at DL2
(20mg/m2 CFZ, 4mg POM), 32 at DL3 (20/27mg/m2 CFZ, 4mg POM), 0 at DL4
(20/36mg/m2 CFZ, 4mg POM). Median age was 63 y, median time from diagnosis 5.1 y, median prior tx lines 2, and 94% had refractory disease. Cytogenetic
data were available for 59 pts; 33% were high risk per IMWG. There were 9
dose-limiting toxicities, all asymptomatic cytopenias: 8 pts with grade (G) 3
neutropenia and 1 with G4 thrombocytopenia. The MTD was established at
DL3. In 64 pts, G3/4 hematologic toxicities included neutropenia (25%) and
lymphopenia (14%), and non-hematologic toxicities (all grades) included fatigue
(51%), dyspnea (42%), and gastrointestinal (45%). PRs were rapid with a ≥PR
rate of 63% after 1 cycle and 77% after 4 cycles. After a median of 20.9 cycles
(range, 1–49), ≥minimal response was 95%, ≥PR 84%, ≥very good PR 52%,
and ≥near complete response (nCR) 20%. In the 1º population (N=55, 51 LENrefractory, 28 progressing on LEN maintenance), ≥PR was 84% with 30 treated
at MTD. After median follow-up of 21 (1–49) mo, median progression-free survival (PFS) for all 64 pts enrolled was 16.8 mo and 2-y overall survival (OS)
was 76.8% with 20 pts remaining on treatment. For standard-risk (n=38) vs
high-risk pts (n=21), ≥PR was 89% vs 81%, ≥nCR was 24% vs 10%, median
PFS was 22.3 vs 10.6 mo, and 2-y OS was 90.8% vs 56.0%.
Summary/Conclusions: KPd is well tolerated and highly active (≥PR 84%)
with encouraging PFS (median 16.8 mo) in an RRMM pt population that was
mostly LEN-refractory and PI-naïve/sensitive. The results support planned evaluation of KPd with daratumumab in RRMM, particularly for high-risk pts.
P681

PANOBINOSTAT INDUCES CD38 UPREGULATION AND AUGMENTS THE
ANTI-MYELOMA EFFICACY OF DARATUMUMAB
E. Garcia-Guerrero1,*, T. Gogishvili1, S. Danhof1, M. Schreder1, C. Pallaud2,
J.A. Pérez-Simón3, H. Einsele1, M. Hudecek1
1Universitätsklinikum Würzburg, Würzburg, Germany, 2Novartis Pharmaceuticals, Basel, Switzerland, 3IBIS/Hospital Universitario Virgen del Rocío, Seville,
Spain

Background: Immunotherapy with the anti-CD38 monoclonal antibody (mAb)
daratumumab is increasingly being utilized in myeloma patients with
relapsed/refractory (R/R) disease after prior treatment with immunomodulatory
drugs (IMiDs) and proteasome inhibitors (PIs). However, the efficacy of daratumumab is limited by low CD38 expression on myeloma cells. Here, we investigate the use of the histone deacetylase inhibitor (HDACi) panobinostat to
modulate target antigen expression on myeloma in favor of potent mAb-mediated recognition and destruction. We show that panobinostat augments CD38
expression specifically on myeloma cells and demonstrate powerful synergy
with anti-CD38 mAb daratumumab.
Aims: Determine the impact of panobinostat on upregulation of CD38 expression on myeloma cells in order to enhance the efficacy of daratumumab.
Methods: Myeloma cells were treated with titrated doses of panobinostat (0,
10, 25 nM) and expression of CD38 and a panel of additional target molecules
including SLAMF7, as well as accessory ligands analyzed by flow cytometry at
24, 48 and 72 hours. Antibody-dependent cellular cytotoxicity (ADCC) against
panobinostat treated and untreated myeloma cells was analyzed at 4 and 20
hours after addition of PBMC at an effector to target ratio of 25:1 in the presence
of daratumumab or an isotype control antibody.
Results: We treated primary myeloma (n=12 patients) with panobinostat (10
vs 25 nM) and observed a uniform increase in CD38 expression in each case
by flow cytometry. Upregulation of CD38 was already detectable after 24 hours,
peaked after 48 hours of exposure to panobinostat and was higher at the 25
nM compared to the 10 nM dose. At 48 hours, the mean fluorescence intensity
(MFI) for CD38 expression was 4 (10nM) and 6-fold (25 nM) higher in panobinostat-treated compared to untreated myeloma (p<0.01). The increase in CD38
was equal in patients with previously untreated (n=5) and R/R myeloma (n=7);
and could be confirmed in a panel of myeloma cell lines, including MM1.S and
OPM-2. The panobinostat-induced upregulation of CD38 was rapidly reversible
after drug withdrawal. Further, the increase in CD38 expression after panobinostat treatment was specific for myeloma and neither observed this phenomenon in a panel of leukemia and lymphoma cell lines, nor on primary CD8+
and CD4+ T cells that we isolated from peripheral blood of several donors

haematologica | 2017; 102(s2) | 271


and del(17p). as determined by interphase FISH analysis, including t(11;14), t(4;14), del(13q). Responses in high achieving a VGPR or better. Median TTP (11.6 months). Sixteen of 27 patients with low (66%) achieving VGPR or better (p<0.01). The synergistic anti-myeloma efficacy of panobinostat and daratumumab was confirmed with a panel of myeloma cell lines.

Summary/Conclusions: Our data demonstrate that the HDACi panobinostat induces upregulation of CD38 on myeloma and a subsequent dramatic increase of daratumumab-mediated ADCC. These data suggest that panobinostat could be used synergistically with daratumumab in a clinical setting to increase response rates and extend duration of responses to daratumumab.

P682

BCL2 EXPRESSION IS A POTENTIAL PREDICTIVE BIOMARKER OF RESPONSE TO VENETOCLAX IN COMBINATION WITH BORTEZOMIB AND DEXAMETHASONE IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA

J. Ross1,∗, B. Chyla1, R. Goswami1, L. Roberts-Rapp1, Y. Sun1, Y. Jiang2, E. Punnose2, M. Verdugo1, A. Bhathena1, P. Maciag1

1AbbVie, Inc., North Chicago, 2Genentech Inc., South San Francisco, United States

Background: The anti-apoptotic proteins BCL-2 and MCL-1 have been shown to promote myeloma cell survival. Venetoclax (VEN) is a potent, selective, and orally bioavailable small-molecule inhibitor of BCL-2. Bortezomib (BTZ) is a proteasome inhibitor that can inhibit MCL-1 activity by increasing the MCL-1 antagonist, NOXA.

Aims: Results presented herein describe correlative biomarker analyses in the ongoing phase 1b study of VEN in combination with BTZ and dexamethasone in patients with relapsed/refractory (R/R) MM (NCT01794507).

Methods: As of 19 Aug 2016, 86 patients were enrolled on study. Baseline bone marrow aspirate samples were available from 52 patients, of which 45 were evaluable for BCL-2 family gene expression by droplet digital PCR in CD138-selected tumor cells. Correlation between BCL2 (BCL-2), BCL2L1 (BCL-XL) and MCL1 (MCL-1) mRNA expression (log2-transformed copies/ul normalized to housekeeping gene) and preliminary efficacy [overall response rate (ORR), time to disease progression (TTP) and duration of response (DoR)] were examined by Log-rank and Wilcoxon tests for binary biomarkers, and by risk ratio from Cox proportional hazard model for continuous biomarkers.

Results: The ORR was 68% (44/65) for all evaluable patients and 89% (31/35) in patients who had 1-3 prior therapies (31/35). A broad range of BCL2, BCL2L1 and MCL1 expression was observed, however higher BCL2 levels were detected in patients who achieved a partial response (PR) or better (median: 3.01 vs 0.87, p<0.01). Additionally, higher BCL2 levels were observed in patients who had 1-3 vs 4 or more lines of therapy (median: 3.03 vs 0.94, p<0.01). In contrast, no association was observed between BCL2L1 or MCL1 gene expression and response or number of prior therapies. Bootstrapping and aggregating thresholds from trees was used to estimate a threshold value for BCL2 expression that would provide optimum selection of patients with a high response rate. On all, seventeen of 18 patients with high BCL2 expression (≥3.0) achieved at least a PR (ORR 94%), with 12 patients (66%) achieving VGPR or better (Figure 1). Sixteen of 27 patients with low BCL2 expression achieved at least a PR (ORR 59%), with 6 patients (22%) achieving a VGPR or better. Median TTP (11.6 vs 5.7 months) and DoR (10.2 vs 4.7 months) were significantly longer in patients with low BCL2 expression. Responses in high BCL2 expressors were independent of cytogenetic status as determined by interphase FISH analysis, including t(11;14), t(4;14), del(13q) and del(17p).

Summary/Conclusions: Targeting BCL-2 and MCL-1 with the combination of VEN, BTZ and dexamethasone provides a unique approach for MM treatment. Efficacy results in tumors expressing high BCL2 levels, including 94% ORR, provide supportive evidence for the evaluation of this combination regimen in the ongoing phase 3 study (NCT02755597) in R/R MM.

P683

THE IMPACT OF THE INTRODUCTION OF BORTEZOMIB ON DIALYSIS INDEPENDENCE IN MULTIPLE MYELOMA PATIENTS WITH RENAL FAILURE: A NATIONWIDE DUTCH POPULATION-BASED STUDY

B. Oortgiesen1,∗, R. Azad1, M. Hemmelder2, R. Kibbelaar3, N. Veeger4, J. de Vries1, E. van Rooij1, M. Hoogendoorn1

1Department of Clinical Pharmacy & Pharmacology, 2Department of Nephrology, Medical Centre Leeuwarden, 3Department of Pathology, Pathology Friesland, 4Department of Epidemiology, 5Department of Hematology, Medical Centre Leeuwarden, Leeuwarden, 6Department of Pharmacy, University of Groningen, Groningen, Netherlands

Background: Renal insufficiency is common at presentation in patients with multiple myeloma (MM) and associated with a poor survival. Approximately 10% of the patients require dialysis. Studies have shown that the novel agent bortezomib has a positive effect on recovery of renal function in MM patients with renal insufficiency.

Aims: The aim of this study is to determine the effect of the revised guideline, including the introduction of bortezomib as first line treatment in MM patients with dialysis dependence, on renal function recovery.

Methods: All patients on renal replacement therapy (RRT) in the Netherlands are registered in the Dutch registry Renine. Data on age, gender, start date of RRT, type and switches of RRT or hospitals, primary renal diagnosis, date of death and cause of death are collected. In this nationwide population-based study, we selected all patients with MM registered in Renine between January 2002 and January 2016. No information regarding therapy of MM is provided in Renine. In March 2010, bortezomib was advised as first-line treatment in patients suffering from MM with renal impairment in the Dutch guidelines. Therefore, we divided our cohort in two periods: before the bortezomib guideline (January 1, 2002 till March 29, 2010) and after introduction of the bortezomib guideline (March 29, 2010 till January 1, 2016). Kaplan-Meier and Cox proportional hazards modelling were used to identify significant indicators for dialysis independency.

Results: A total of 700 patients were included in the study (422 patients pre-bortezomib and 278 after bortezomib introduction). In the period after the introduction of bortezomib 15% of patients became dialysis independent compared to 8% in the pre-bortezomib period (HRadj.=2.1 (95% CI 1.3–3.3), Fig. 1). In addition, patients who started dialysis in the period after bortezomib was introduced became dialysis independent more rapidly than in the pre-bortezomib period (1.2 compared to 1.7 years; p < 0.001). Age < 75 years (vs. ≥ 75 years) and light chain deposition disease (LCDD) as the primary renal disease (vs. amyloidosis) were significantly associated with achieving dialysis independence (HRadj.=2.1 (95% CI 1.0–4.2) and HRadj.=5.7 (95% CI 2.5–13.2), respectively).

Summary/Conclusions: In this nationwide population-based study, covering all patients with MM and concomitant renal failure, almost a two-fold increase of patients becoming dialysis independent occurred in the period after the introduction of bortezomib compared to the pre-bortezomib period. This was even more prominent when age was < 75 years and LCDD was the primary renal disease.

P684

TREATMENT WITH POMALIDOMIDE AND DEXAMETHASONE IN PATIENTS WITH MULTIPLE MYELOMA AND LIGHT CHAIN (AL) AMYLOIDOSIS

P. Milani1,∗, M. Bassel1, F. Russo1, M. Bozzola1, A. Foni1, G. Palladini1, G. Merlini1

1Ospedale San Giovanni Battista, Turin, Italy
Background: The immunomodulatory agent pomalidomide is active in patients with relapsed/refractory multiple myeloma, including those who failed prior lenalidomide and bortezomib. Phase II clinical trials showed that pomalidomide is also effective in primary AL amyloidosis. After this drug was marketed for multiple myeloma (in Italy since September 2015), it became routinely accessible also to patients with myeloma-associated AL amyloidosis, a particularly fragile population.

Aim of this study is to report the efficacy of pomalidomide and dexamethasone in patients with multiple myeloma-associated AL amyloidosis.

Methods: The databases of the Pavia Amyloid Research and Treatment Center were searched for patients with a diagnosis of multiple myeloma and AL amyloidosis who underwent an autologous stem cell transplant and/or previous pomalidomide treatment and at least partial response or better was achieved. A total of 358 patients were used (median age 66 years; 273 were men). Heart involvement was present in 13 patients (43%) and kidney involvement in 18 (60%). Four (13%) patients were in Mayo Stage I, 17 (57%) in stage II and 9 (30%) in stage III. Fifteen (50%) subjects were in renal stage I, 8 (27%) and 3 (23%) were in renal stage II and I and respectively and 5 (16%) patients were on dialysis at the time of P Dex initiation. Median bone marrow plasma cell infiltrate was 20% (range: 10-90%). Twenty-three (76%) patients were refractory to all previous lines of therapy. Median time from diagnosis to transplant was 6 months [interquartile range (IQR): 3-20 months]. Adverse events were observed in 5 (17%) subjects: skin rash and confusion in one patient each and mild increase in serum creatinine in 3 (10%, resolved with the decrease of the dose of pomalidomide). The median number of previously received lenalidomide and an alkylating agent, only 3 patients were not exposed to bortezomib, due to severe peripheral nervous system involvement, 10 (33%) underwent autologous stem cell transplant and 9 (30%) received previously thalidomide-based regimens. The median number of P Dex cycles performed was 4 (range: 1-11). Median follow-up of living patients was 6 months [IQR: 3-15 months]; 13 (43%) patients died due to progressive disease. Fourteen patients (47%) achieved at least partial response, with 1 complete remission (CR), and very good partial responses (VGPR) in 2 cases (6%). Cardiac responses were observed in 1 of 5 patients with measurable NT-proBNP (20%), but this can be underestimating due to the pomalidomide-related increase of NT-proBNP, and renal response in 3 of the 11 evaluable patients (27%).

Summary/Conclusions: The combination of pomalidomide and dexamethasone is well tolerated and effective in multiple myeloma-associated AL amyloidosis and can be a valuable rescue option in this high-risk population.

P685 MYOCARDIAL UPTAKE OF 99mTc-DPD IN PATIENTS WITH AL AMYLOIDOSIS

C. De Miguel1,*, L. Llorente 1, F.J. de Haro-del Moral 1, P. García-Pavía 1, A.G. Dinmohamed145, M. Brink1, O. Visser 1, M.C. Minnema 2, S. Zweegman 3, P. Sonneveld4, M. Brink1, O. Visser 1, M.C. Minnema 2, S. Zweegman 3, P. Sonneveld4, Erasmus MC Cancer Institute, 5Department of Public Health, Erasmus University, Rotterdam, the Netherlands

Background: AL amyloidosis is a light chain (FLC) deposition disease that can affect the heart. To identify the specific subtype is essential for treatment and prognosis. 99mTc-DPD scintigraphy (SC) has shown high sensitivity and specificity for detecting TTR cardiac amyloidosis, although some cases have been described with AL amyloidosis and positive 99mTc-DPD SC. We did not find any correlation between positive cardiac uptake in the SC and NT-proBNP values, as it has been recently suggested.

Methods: Methods: We performed 704 SC for different indications during the study period. In 220/319 (69%) MM patients treated with induction chemotherapy, SC was performed for patients with relapsed/refractory multiple myeloma, including those who failed prior lenalidomide and bortezomib. Phase II clinical trials showed that pomalidomide is also effective in primary AL amyloidosis. After this drug was marketed for multiple myeloma (in Italy since September 2015), it became routinely accessible also to patients with myeloma-associated AL amyloidosis, a particularly fragile population.

Results: We reviewed all SC performed at our center in the last 5 months. Indications for heart uptake were: arrhythmia of unknown etiology. We have correlated the image findings with the clinical and/or pathological diagnosis. AL amyloidosis diagnosis was based on histological demonstration of amyloid by Congo Red staining and immunohistochemistry (IHC) in any tissue and confirmation by proteomics (mass spectrometry (MS)) when indicated.

Results: We performed 704 SC for different indications during the study period. 41/61 patients (67.2%) with AL amyloidosis and cardiac involvement underwent a SC: 27 were negative (86%), 7 (17%) showed some degree of uptake (PS score=2 and focal or univentricular uptake) and 7 (17%) had biventricular uptake (PS score>2). In 3 cases (7%) 5 patients underwent an endomyocardial biopsy (EMB). In 4 cases IHC confirmed AL amyloidosis, while in 1 case IHC was not diagnostic and MS confirmed AL amyloidosis. The two remaining patients were diagnosed of AL amyloidosis by IHC unequivocally in other tissues. Patients with PS 2-3 (73%) 5 patients underwent an endomyocardial biopsy (EMB). Among them, 3 were diagnosed of AL amyloidosis, both by IHC and MS. Two patients, both of them with a M-spike and abnormal free light chains ratio in serum and increased clonal plasma cells in the bone marrow, showed TTR and faint light chain deposition but MS confirmed the diagnosis of TTR amyloidosis (TTR gene non mutated). The two remaining patients were diagnosed of AL amyloidosis by IHC unequivocally in other tissues. Mean value of NT-proBNP (N-terminal-natriuretic peptide) in patients with AL amyloidosis was 7730 pg/ml for those with a positive uptake in the scintigraphy and 9990 pg/ml with a negative uptake. However, up to 30% of cases of AL amyloidosis show some degree of uptake and 10% show a pattern consistent with TTR amyloidosis (biventricular uptake and/or Perugini score 2-3 (PS)) is highly suggestive of TTR amyloidosis. Although some cases have been described with myocardial deposit of both TTR and light chain and up to 10-15% of the population >75 years may show a MC in serum, so it is essential to type accurately amyloid in patients with suspected AL amyloidosis and myocardial uptake in SC. MS is not routinely available in most centers and results may be ambiguous. We consider that MS is mandatory in cases of cardiac amyloidosis with abnormal FLC ratio and positive biventricular 99mTc-DPD uptake. We did not find any correlation between positive uptake in the SC and NT-proBNP values, as it has been recently suggested.

Summary/Conclusions: Cardiac 99mTc-DPD SC has been described as a useful technique in the differential diagnosis between AL and TTR amyloidosis. However, up to 30% of cases of AL amyloidosis show some degree of uptake and 10% show a pattern consistent with TTR amyloidosis (biventricular uptake and/or Perugini score 2-3 (PS)) is highly suggestive of TTR amyloidosis. Although some cases have been described with myocardial deposit of both TTR and light chain and up to 10-15% of the population >75 years may show a MC in serum, so it is essential to type accurately amyloid in patients with suspected AL amyloidosis and myocardial uptake in SC. MS is not routinely available in most centers and results may be ambiguous. We consider that MS is mandatory in cases of cardiac amyloidosis with abnormal FLC ratio and positive biventricular 99mTc-DPD uptake. We did not find any correlation between positive uptake in the SC and NT-proBNP values, as it has been recently suggested.
Background: To contextualize the benefit of novel agents such as daratumumab (DARA) monotherapy for the treatment of patients with heavily pre-treated and highly refractory multiple myeloma (MM), it is critical to understand the real-world outcomes of this patient population on current standard of care (SOC) therapies. To determine the comparative effectiveness of DARA vs real-world SOC, an adjusted comparison was conducted utilizing data from the DARA monotherapy trials and the International Myeloma Foundation (IMF) chart review.

Aims: The objective of this analysis is to update the adjusted comparison to include additional Swedish patients from the IMF chart review.

Methods: Data for patients treated with DARA 16mg/kg monotherapy were available from clinical trials MMY2002 (n=106) and GENS01 (n=42), while patients treated with SOC therapies were derived from the IMF chart review of patients with MM who had ≥3 prior lines of therapy and were double refractory to a proteasome inhibitor (PI) and an immunomodulatory drug (IMiD) (n=550, original 510, additional Swedish patients 40). Patients from the IMF cohort who moved into further treatment lines after the line therapy where they fulfilled inclusion criteria, contributed information to the analysis for multiple lines of therapy, with baseline defined as the date of initiation of the actual treatment line, resulting in a total of 1073 treatment lines from 550 patients. The relative treatment effect of DARA versus SOC was estimated using multivariate Cox regression analyses. The methodology utilized individual patient data to compare overall survival (OS). The covariates included were age, gender, prior lines of therapy, albumin, beta-2 microglobulin, prior exposure to pomalidomide and carfilzomib, and prior refractory status. Clustering of observations at the patient level within patients was controlled for using the robust sandwich estimate for the covariance matrix. Statistical significance testing was performed using a two-tailed P-value of <0.05, and all comparisons between treatment groups were reported with hazard ratios (HRs) and 95% confidence intervals (CIs).

Results: After adjustment for differences in baseline characters included in the multivariate model between the DARA and SOC groups, results showed a significant improvement in favor of DARA compared with SOC for OS (HR=0.42 [95% CI 0.31–0.57]). When limiting the comparative analysis to European patients from the IMF cohort (n=341), results for OS are very similar (HR=0.40 [95% CI 0.28-0.59]).

Summary/Conclusions: Findings from the regression analyses using the updated IMF dataset were consistent with results from the previous analysis3 and suggest that DARA is associated with significant gains in OS compared with SOC therapies for patients with heavily pre-treated and highly refractory MM. Findings for a European subset from the IMF dataset were similar to results from the entire cohort.

References:
unsR (duration of response (≥PR) <6 months) to the baseline score we were able to build a new score in which the unsR had a 3 points weight. A score ≥ 4 identify a sub-group of patients with high probability of death within 2 years despite optimized treatment.

Summary/Conclusions: The risk of early death due to active disease in elderly patients was related to four independent prognostic factors: age >75y, high LDH levels, advanced ISS, and presence of HR CA. A score ≥ 4 identify a sub-group of patients with high probability of death within 2 years despite optimized treatment.

The risk of early death due to active disease in elderly patients was related to four independent prognostic factors: age >75y, high LDH levels, advanced ISS, and presence of HR CA. A score ≥ 4 identify a sub-group of patients with high probability of death within 2 years despite optimized treatment.

Background: Myelofibrosis (MF) may be caused by various pathogenic mechanisms, such as elevated circulating cytokine levels, cellular interactions, and genetic mutations. However, the underlying mechanism of MF remains unknown. A recent study showed that the neoplastic clone of fibrocytes, spindle-shaped fibroblast-like blood cells derived from monocyte lineage, was essential in primary MF pathogenesis; serum amyloid P, which suppressed fibrocyte differentiation, markedly improved survival and MF in a murine xenograft model (J Exp Med 2016; 213: 1723-1740). Regarding cytokines, the thrombopoietin (TPO) signaling pathway was assumed to be closely associated with promoting MF. Mice transplanted with TPO-overexpressing bone marrow cells showed symptoms such as MF and splenomegaly (Blood 1997; 90: 4369-4383). Romiplostim (Rom), a TPO-receptor agonist, induced MF in rats and some immune thrombocytopenic purpura patients (Blood 2005; 114: 3748-3756). Fibrocytes and TPO played certain roles in MF pathogenesis, but the nature of their relationship remains unknown.

Aims: We investigated the relationship between myeloproliferative leukemia protein (MPL, TPO receptor) activation and fibrocyte differentiation in promoting MF. The secondary goal was to discover a unique fibrocyte marker in monocyte or macrophage population.

Methods: Murine fibrocyte cell lines were established from transgenic mice harboring the temperature-sensitive large T-antigen gene of simian virus 40 under IL-13 and M-CSF conditions. Murine fibrocyte cell lines and human peripheral blood mononuclear cells (PBMCs) were cultured with or without Rom to evaluate if MPL activation promoted fibrocyte differentiation, and the ratio of spindle-shaped cells was calculated. Rom was administered on day 1 and 8 to induce an MF-like phenotype in C57BL/6J mice, and clodronate liposomes (CLs; day −4, −1, 4, and 7) were used to eliminate monocytes and macrophages.

Results: Flow cytometric analysis revealed that all murine fibrocyte cell lines stained positive for fibrocyte cell markers, including collagen I, CD45, CD34, CD11b, and CD68. Murine fibrocyte cell lines expressed MPL and responded to Rom or murine TPO to differentiate into mature fibrocytes, specifically with a longer spindle shape and stronger collagen I expression than when cultured with IL-13 and M-CSF alone. Rom also increased the number of mice spleen cell fibrocyte colonies in the presence of IL-13 and M-CSF. The administration of 1mg/kg of Rom once a week induced an MF-like phenotype in all mice within 2–3 weeks and increased the number of fibrocytes in the spleen. Treatment with CLs eliminated fibrocyte precursors and prevented severe MF and splenomegaly. Human cultured fibrocytes also expressed MPL, and Rom increased the number of spindle-shaped fibrocytes induced from human PBMCs. The SLAMF7high MPLlow subpopulation was clearly separated from the SLAMF7low MPLlow population in human CD14+ cells. A significantly higher frequency of fibrocyte differentiation was observed in the SLAMF7high MPLhigh population. The number of SLAMF7high MPLhigh cells was significantly greater in MF patients than in healthy donors. Conversely, their numbers did not increase in MF patients treated with ruxolitinib.

Summary/Conclusions: MPL activation directly induced fibrocyte differentiation from monocytes and macrophages expressing MPL, and the elimination of these cells reversed the MF phenotype. Our findings confirmed a link between fibrocytes and the TPO/MPL signaling pathway and indicated that the combination of MPL and SLAMF7 could be a useful fibrocyte marker in monocytes or macrophages.

MPL ACTIVATION DIRECTLY INDUCES FIBROCYTE DIFFERENTIATION TO CAUSE MYELOFIBROSIS

T. Maekawa1,*, Y. Osawa1, T. Izumi1, S. Nagao1, K. Takano1, Y. Okada1, N. Tachi1, M. Teramoto1, T. Kawamura1, T. Horiochi1, R. Saga1, S. Kato1, T. Yamamura1, J. Watanabe1, A. Kobayashi1, S. Kobayashi1, K. Satō1, M. Hashimoto2, S. Suzu2, F. Kimura1
1Division of Hematology, Department of Internal Medicine, National Defense Medical College, Tokorozawa, Saitama, 2Center for AIDS Research, Kumamoto University, Kumamoto, Japan

Background: Myelofibrosis (MF) may be caused by various pathogenic mechanisms, such as elevated circulating cytokine levels, cellular interactions, and genetic mutations. However, the underlying mechanism of MF remains unknown. A recent study showed that the neoplastic clone of fibrocytes, spindle-shaped fibroblast-like blood cells derived from monocyte lineage, was essential in primary MF pathogenesis; serum amyloid P, which suppressed fibrocyte differentiation, markedly improved survival and MF in a murine xenograft model (J Exp Med 2016; 213: 1723-1740). Regarding cytokines, the thrombopoietin (TPO) signaling pathway was assumed to be closely associated with promoting MF. Mice transplanted with TPO-overexpressing bone marrow cells showed symptoms such as MF and splenomegaly (Blood 1997; 90: 4369-4383). Romiplostim (Rom), a TPO-receptor agonist, induced MF in rats and some immune thrombocytopenic purpura patients (Blood 2005; 114: 3748-3756). Fibrocytes and TPO played certain roles in MF pathogenesis, but the nature of their relationship remains unknown.

Aims: We investigated the relationship between myeloproliferative leukemia protein (MPL, TPO receptor) activation and fibrocyte differentiation in promoting MF. The secondary goal was to discover a unique fibrocyte marker in monocyte or macrophage population.

Methods: Murine fibrocyte cell lines were established from transgenic mice harboring the temperature-sensitive large T-antigen gene of simian virus 40 under IL-13 and M-CSF conditions. Murine fibrocyte cell lines and human peripheral blood mononuclear cells (PBMCs) were cultured with or without Rom to evaluate if MPL activation promoted fibrocyte differentiation, and the ratio of spindle-shaped cells was calculated. Rom was administered on day 1 and 8 to induce an MF-like phenotype in C57BL/6J mice, and clodronate liposomes (CLs; day −4, −1, 4, and 7) were used to eliminate monocytes and macrophages.

Results: Flow cytometric analysis revealed that all murine fibrocyte cell lines stained positive for fibrocyte cell markers, including collagen I, CD45, CD34, CD11b, and CD68. Murine fibrocyte cell lines expressed MPL and responded to Rom or murine TPO to differentiate into mature fibrocytes, specifically with a longer spindle shape and stronger collagen I expression than when cultured with IL-13 and M-CSF alone. Rom also increased the number of mice spleen cell fibrocyte colonies in the presence of IL-13 and M-CSF. The administration of 1mg/kg of Rom once a week induced an MF-like phenotype in all mice within 2–3 weeks and increased the number of fibrocytes in the spleen. Treatment with CLs eliminated fibrocyte precursors and prevented severe MF and splenomegaly. Human cultured fibrocytes also expressed MPL, and Rom increased the number of spindle-shaped fibrocytes induced from human PBMCs. The SLAMF7high MPLlow subpopulation was clearly separated from the SLAMF7low MPLlow population in human CD14+ cells. A significantly higher frequency of fibrocyte differentiation was observed in the SLAMF7high MPLhigh population. The number of SLAMF7high MPLhigh cells was significantly greater in MF patients than in healthy donors. Conversely, their numbers did not increase in MF patients treated with ruxolitinib.

Summary/Conclusions: MPL activation directly induced fibrocyte differentiation from monocytes and macrophages expressing MPL, and the elimination of these cells reversed the MF phenotype. Our findings confirmed a link between fibrocytes and the TPO/MPL signaling pathway and indicated that the combination of MPL and SLAMF7 could be a useful fibrocyte marker in monocytes or macrophages.

ENGRAFTMENT OF PRIMARY MYELOFIBROSIS BONE MARROW-DERIVED CD14+ MONOCYTES IN NOD-SCID-g MICE

T. Manshour1,*, Z. Estrov1, D. Pilling2, C.E. Bueso-Ramos3, S. Prijic1, K.J. Newberry1, S.M. Post1, X. Zhang1, Y. Zhang1, H.M. Kantarjian1, S. Verstovsek1

Background: Progressive bone marrow (BM) fibrosis in patients with PMF is thought to arise from non-hematopoietic stromal cells stimulated by overpro-
duced growth factors. However, in other tissues and organs, fibrosis is associated with monocytic and fibroblastic cells, which express markers of both hematopoietic and stromal cells. Recently, we have reported that clonal neoplastic fibroblasts play a role in the induction of BM fibrosis in primary myelofibrosis (PMF) (Verstovsek, J Exp Med. 2016). We demonstrated that the BM of PMF patients harbors more neoplastic, functionally distinct fibroblasts and fewer MSCs than in normally bone marrow. In addition, we detected an overabundance of fibroblasts in the BM and spleen of an established PMF mouse model and a xenograft mouse model of PMF created using BM-derived low-density cells from patients with PMF.

**Aims:** Fibroblasts, which make up <1% of BM cells, differentiate from a subpopulation of CD14+ monocytes and are recruited to sites of organ damage where they regulate tissue repair. We hypothesized that clonal neoplastic CD14+ monocytes may play a role in the induction of BM fibrosis in PMF.

**Methods:** To test this hypothesis, we transplanted NSG mice (NOD/Scid NO.D-Cg-prkdcscid il2rgtm1wjl/SzJ) with sorted CD14+ monocytes from patients with JAK2V617F-positive PMF or donors with hematologically normal BM engrafted in NSG mice. Transplanted NSG mice with PMF BM-derived CD14+ monocytes developed a myelofibrosis-like phenotype with reticulin fibrosis and abundant neoplastic (JAK2V617F) fibroblasts in the BM and spleen. Two months after transplantation, we detected a subpopulation of hCD45+ and hCD68+ cells within the HLA+ population of BM cells. In addition, we found dysplastic megakaryocytes in the BM and spleen of the PMF CD14+ transplanted mice. Immunohistochemistry staining of paraffin embedded BM sections did not detect hCD3, hCD19 or hCD34 cells. However, staining with anti-human CD42b antibodies detected human megakaryocytes, suggesting that the dysplastic megakaryocytes detected in PMF CD14+ transplanted NSG mice are human-derived.

**Summary/Conclusions:** Taken together, our data suggest that neoplastic CD14+ monocytes contribute to the induction of BM fibrosis in PMF. What role CD14-derived megakaryocytes play in the pathogenesis of PMF remains to be determined.

**ESTABLISHMENT OF AN IN VITRO MODEL FOR THE SKEWED MEGAKARYOPOIESIS BY CALRETTICULIN MUTATION IN HUMAN CELLS**

H. Takei1, S. Mano12, N. Masubuchi13, Y. Mizukami14, M. Imai6, K. Eto7, A. Ohsaka5, M. Araki5, N. Komatsu1

**Background:** Somatic mutations on *calreticulin* (CALR) gene are found in a majority of patients with JAK2-mutated or JAK2 wild-type (wt) myeloproliferative neoplasms (MPNs). We and other groups have recently shown that mutant CALR activates the downstream pathway of thrombopoietin (TPO) receptor MPL, which induces factor-independent growth in human and murine cells. However, roles of mutant CALR in human hematopoietic cell differentiation remain largely elusive.

**Aims:** We aimed to recapitulate the MPN phenotypes and examine the impact of CALR ins5 on human hematopoietic cell differentiation in vitro.

**Methods:** We employed IPS cells (iPSC) established from an healthy patient harboring a 5-base insertion mutation in the CALR gene (CALR wt), and CALR gene-knockout (CALR null) Hematopoietic progenitor cells (HPCs) were produced from IPS by “IPS-Sac” method. HPCs were then cultured to induce megakaryocytic cells (MKs) and FLI1 expression for the endothroid cell differentiation in CALR ins5 cells. Finally, we showed that the treatment of ruxolitinib greatly reduced megakaryocytic differentiation in both CALR ins5 and wt HPCs, demonstrating that ruxolitinib does not possess preferential targeting of CALR ins5 cells.

**Summary/Conclusions:** We have established an in vitro model system that recapitulates the megakaryocytosis caused by mutant CALR, which should be useful tool for the examination of therapeutic strategies against MPN patients harboring CALR mutation.

### P692

**QUANTITATIVE PROTEOME HETEROGENEITY IN MYELOPROLIFERATIVE NEOPLASM SUBTYPES AND ASSOCIATION WITH JAK2 MUTATION STATUS**

S. Takase3, K. Yuste1, C. Vladin P2, J. Mondel1, I. Plo2, P. Mossau1,4

**1**TIMC-IMAG Laboratory - TheREx team, GRENoble, France, 2Institute for Medical Research, Belgrade, Serbia, 3INSERM, UMR1170, Gustave Roussy, Paris, 4Laboratoire d’Hématologie cellulaire - Institut de Biologie et Pathologie, GRENoble, France

**Background:** Apart from well-known genetic abnormalities, several studies have reported variations in protein expression in Philadelphia negative (Ph−) Myeloproliferative Neoplasm (MPN) patients that could contribute towards their clinical phenotype.

**Aims:** In this context, a quantitative mass spectrometry proteomics protocol was used to identify differences in the granulocyte proteome with the goal to characterize the pathogenic role of aberrant protein expression in MPNs.

**Methods:** LC MS/MS (LTQ Orbitrap) coupled to iTRAQ labeling showed significant and quantitative differences in protein content among various MPN subtypes: Essential thrombocythemia (ET), Primary myelofibrosis (PMF), and according to the genetic status of JAK2 (JAK2V617F presence and JAK2V617F allele burden).

**Results:** A number of differentially expressed proteins were identified with the most frequent being members of the RAS GTPase family and oxidative stress response proteins. Subsequent analysis found that calreticulin (CALR), shown to be involved in calcium homeostasis and apoptotic signaling, was overexpressed in JAK2V617F granulocytes compared with JAK2 wild-type and independently of the JAK2V617F allele burden. Finally it was demonstrated, in a Ba/F3 cell model, that increased calreticulin expression was directly linked to ruxolitinib, and could be regulated by JAK2 kinase inhibitors.

**Summary/Conclusions:** In conclusion, these results reveal proteome alterations in MPN granulocytes depending on the phenotype and genotype of patients, highlighting new oncogenic mechanisms associated with JAK2 mutations and overexpression of calreticulin.

### P693

**THE NOVEL SWITCH CONTROL INHIBITOR DCC-2618 COUNTERACTS GROWTH AND SURVIVAL OF VARIOUS NEOPLASTIC CELLS, INCLUDING MAST CELLS, EOSINOPHILS, AND MONOCYTES, IN PATIENTS WITH SYSTEMIC MASTOCYTOSIS**

M. Schneeveis1,2, B. R. Philips1,2, S. Bibi3, K. Blatt1,2, D. Berger2, G. Fedran2, S. Hemsdofer1,2, W. R. Sperr1,2, E. Hadzijusufovic1,2,5, K.V. Gleixner1,2, A. Reiter4, M. Arock3, P. Valient1,2

1 Ludwig Boltzmann Cluster Oncology, 2Department of Internal Medicine I/Division of Hematology and Hemostaseology, Medical University of Vienna, Vienna, Austria, 3Laboratoire de Biologie et Pharmacologie Appliquée, CNRS UMR 8113, Ecole Normale Supérieure de Cachan, Cachan, France, 4Department of Hematology and Oncology, University Medical Center Mannheim, Mannheim, Germany, 5Department for Companion Animals and Horses/Clinic for Internal Medicine and Infectious Diseases, University of Veterinary Medicine Vienna, Vienna, Austria

**Background:** Systemic mastocytosis (SM) is a myeloid neoplasm defined by abnormal growth and pathologic accumulation of neoplastic mast cells (MC) in various internal organs. The indolent variant of SM (ISM) is associated with an almost normal life expectancy. By contrast, the prognosis in advanced SM, including SM with an associated hematopoietic neoplasm (SM-AHN), aggressive SM (ASM), and MC leukemia (MCL) is poor with short survival times. Most patients with SM express the D816V-mutated variant of JAK2, and could be regulated by JAK2 kinase inhibitors.

**Aims:** The aims of this study were to evaluate the effects of the switch control inhibitor DCC-2618 on proliferation and survival of various neoplastic cells, including mast cells, eosinophils, and monocytes, in patients with systemic mastocytosis (SM).

**Methods:** We employed different human MC lines (HMC-1.1, HMC-1.2, ROSAKITWT, ROSAKITD816V, ROSAKITK509I, MCPV-1.1, MCPV-1.3 and MCPV-1.4) and primary neoplastic MC obtained from patients with SM. In addition, the acute myeloid leukemia (AML) cell lines KLF1 expression required for the endothroid cell differentiation in CALR ins5 cells. Finally, we showed that the treatment of ruxolitinib greatly reduced megakaryocytic differentiation in both CALR ins5 and wt HPCs, demonstrating that ruxolitinib does not possess preferential targeting of CALR ins5 cells.

**Summary/Conclusions:** We have established an in vitro model system that recapitulates the megakaryocytosis caused by mutant CALR, which should be useful tool for the examination of therapeutic strategies against MPN patients harboring CALR mutation.
MOLM-13, MV4-11, KG-1 and U-937, the eosinophilic leukemia cell line EOL-1, human cultured umbilical vein endothelial cells (HUVEC), the microvascular human endothelial cell line HMVEC-1 and primary neoplastic cells obtained from patients with AML, chronic myelomonocytic leukemia (CMML) and (clonal or reactive) hyperesinophilia were used. Cell proliferation was quantified by 3H-thymidine uptake. Apoptosis was determined by flow cytometry and light microscopy and phosphoroptokinase-status of KIT and BTK was analyzed by Western blotting. The effects of DCC-2618 on histamine secretion in basophils (BA) were analyzed by histamine release assay.

Results: DCC-2618 was found to block the proliferation of all MC lines tested, with lower IC50 values measured in KIT D816V-negative HMC-1.1 cells (12±4 nM) and ROSA KITWT cells (41±6 nM) than in KIT D816V-positive HMC-1.2 cells (123±36 nM), ROSA KITD816V cells (168±65 nM) and the multi-resistant MC line MCPV-1. The DCC-2618-metabolite DP-5439 showed comparable growth-inhibitory effects in all cell lines tested. DCC-2618 was also found to inhibit proliferation of primary neoplastic MC obtained from patients with FM (range: 21-92). Mutations in CALR were predominant in the most prevalent types of AHN in advanced SM. DCC-2618 was also found to inhibit growth of cultured human vascular endothelial cells, suggesting that the drug may also counteract SM-related angiogenesis. Finally, DCC-2618 was found to inhibit anti-apoptotic-induced histamine release from normal BA in a dose-dependent manner (IC50: 1-10 µM).

Summary/Conclusions: DCC-2618 is a new potent switch control TKI that counteracts growth and survival of neoplastic MC, leukemic monocytes, AML blasts, eosinophils, and endothelial cells in vitro. Whether DCC-2618 is able to block growth of neoplastic MC and other involved lineages in patients with advanced SM is currently being ascertained in a clinical trial (NCT02571036).

DISTRIBUTION OF MUTATIONS IN DRIVER AND NON-DRIVER GENES ACCORDING TO CLONAL HEMATOPOIESIS IN ESSENTIAL THROMBOCYThEMIA AND POLYCYTHEMIA VERA

A. Senín1,2, B. Bellissio2,3, C. Fernández-Rodríguez2,3, L. Camacho2,3, C. Besses1,2, A. Álvarez-Larrán1,2

1Hematology Department, Hospital del Mar-IMIM. Universitat Autònoma de Barcelona. 2Group of Applied Clinical Research in Hematology. Cancer Research Program, IMIM. 3Pathology Department, Hospital del Mar-IMIM. Universitat Pompeu Fabra, Barcelona, Spain

Background: Essential thrombocythemia (ET) and polycythemia vera (PV) are clonal myeloid disorders that originate from a multipotential hematopoietic stem cell. Although most women with PV and ET have mutations in JAK2V617F, CALR or MPL, the proportion of patients presenting clonal hematopoiesis by X chromosome inactivation patterns (XCIP) is variable and its relationship with the presence of non-driver mutations is not well known.

Aims: To study the distribution and dominance of driver and non-driver mutations in the development of clonal hematopoiesis.

Methods: One hundred and twenty-six women (PV n=33, ET n=93) with an informative result of XCIP based on HUMARA assessment were included in the study. HUMARA analysis was performed by studying the degree of methylation of exon 1 in granulocytes and lymphocytes. Somatic mutations were studied in DNA extracted from granulocytes by NGS using a panel of 51 myeloid-related genes.

Results: Median age of patients at the time of HUMARA analysis was 64 years (range:21-92). Mutations in JAK2 were present in 62% of them, CALR in 11%, MPL in 8%, and 14% were triple negative (TN). Non-driver mutations were detected in 18% of patients (17 PV and 28 ET). The most frequently mutated genes were TET2 (16%), DNMT3A (8%), ASXL1 (5%), SF3B1 (5%), EZH2 (2%) and RUNX1 (2%). The mutation with the highest variant allele frequency (VAF) was considered the dominant mutation and it corresponded to a driver mutation in 92 patients (JAK2 n=70, CALR n=13, MPL n=8) and a non-driver mutation in 9 patients. In 9 patients one driver mutation was detected on SET2 cell line with western blot. To adress the antifibrogenic activity of the drugs and their combinations, we pre-incubated HS27 cultures with 100nM of ruxolitinib, 1 µM of nilotinib, 1 µM of prednisolone or their combination during 1 h. After that, we added 2mg/ml TGF-β during 24h to induce fibrogenesis. Finally, the collagen I expression was evaluated by immunocytochemistry (ICC).

Aims: The aim of this work is the study the effect of the combination of ruxolitinib, nilotinib and prednisolone in hematopoietic progenitor cells from patients with MF.

Methods: A ruxolitinib, nilotinib and prednisolone dose-response curves and synergistic studies were performed in hematopoietic progenitors CD34+ from five MF patients. We studied the molecular effect of single drugs and in combination on SET2 cell line with western blot. To address the antifibrogenic activity of the drugs and their combinations, we pre-incubated HS27 cultures with 100nM of ruxolitinib, 1 µM of nilotinib, 1 µM of prednisolone or their combination during 1 h. After that, we added 2mg/ml TGF-β during 24h to induce fibrogenesis. Finally, the collagen I expression was evaluated by immunocytochemistry (ICC).

Results: The effects of ruxolitinib, nilotinib and prednisolone resulted in an EC50 value of 55nM, 6.6µM and 13.1µM, respectively. A combination index (CI) of less than 1 indicated synergy. All combination had a synergistic behavior (Table 1); moreover, there were two combinations whose CI from all samples was less than 1 (ruxolitinib plus 0.8 µM prednisolone (CI=0.25±0.11) and 32µM ruxolitinib plus 0.8 µM prednisolone (CI=0.45±0.11)). The JAK/STAT signaling pathway was inhibited: the phosphorylation of STAT5 was inhibited by ruxolitinib in 83.2±10.8 % (p-valor<0.05) regarding to control at 30 min and it was maintained at 3 hours (p-valor<0.05). The combinations 32µM ruxolitinib plus 1.6 µM nilotinib (RN) and 32µM ruxolitinib, 1.6µM nilotinib plus 0.8µM prednisolone (RNP) inhibited more than 50% of the phosphorylation of STAT5 at 30 min and maintained at 3 hours. The MAPK signaling pathway was inhibited at 30 min, the phosphorylation of ERK was inhibited in 77.1±16.4%.

Summary/Conclusions: Gene mutation analysis by targeted NGS in myeloid malignancies is highly reproducible between laboratories and allows a comprehensive characterization of the molecular profile. However, medium-long indels, low frequency mutations (<10%), ASXL1T664fs deletion and variant categorization are critical points that have to be addressed to improve the results. Test system validation is crucial for the implementation of NGS technology.

P697 METHYLMATION AGE IN MPN PATIENTS AS A CORRELATE FOR DISEASE STATUS, ALLELE BURDEN AND THERAPEUTIC RESPONSE

Background: Myeloproliferative Neoplasms (MPNs) result from genetic and epigenetic dysregulation. Epigenetic therapies, such as Vorinostat (SAHA, MK-0683), a histone deacetylase inhibitor, have been tested as a therapeutic strategy in these patients. Examining the epigenetic landscape in MPN may provide new insights into predicting therapeutic response and therefore enhance the clinical utility of these agents. Probably the best described epigenetic mechanism is DNA methylation (DNAm); in which methyl groups are added to DNA at CpG sites regulating chromatin compaction and gene expression/repression. DNAm is known to be altered by ageing and can reflect the effect of diet, lifestyle or disease on cellular processes. Therefore ‘methylation age’ (MA) may be a more accurate reflection of disease than ‘chronological age’ (CA), which is merely a description of how long a person has been alive. Weidner et al (Genome Biology, 2014) described how the measurement of DNAm levels at CpG sites correlates with chronological age (CA) and therefore ‘methylation age’ (MA) may be a more accurate reflection of disease than ‘chronological age’ (CA), which is merely a description of how long a person has been alive. Weidner et al (Genome Biology, 2014) described how the measurement of DNAm levels at CpG sites correlates with chronological age (CA) and therefore ‘methylation age’ (MA) may be a more accurate reflection of disease than ‘chronological age’ (CA), which is merely a description of how long a person has been alive.

Aims: The aim of our study was to correlate MA with disease status, mutational profile and therapeutic response in a cohort of MPN patients treated with Vorinostat.
Methods: MA was calculated following pyrosequencing of bisulfite converted DNA from 40 MPN patients on an investigator initiated non randomised open label phase II multicentre study of Vorinostat (EudraCT #2007-005360-49). Paired samples were analysed at trial entry and after 3 months of therapy to calculate their individual MA scores. Validation of methods used and ageing signature calculation was carried out using cell line and healthy volunteer material.

Results: Samples from 18 Essential Thrombocythaemia (ET) and 22 Polycythaemia Vera (PV) patients (23 F/17 M) with a mean age of 62 years (range 29-81) were assessed. JAK2V617F was detected in 77.5% (n=31/40). Complete clinical response (CR) was achieved in 8 patients, partial (PR) in 17, and no response (NR) in 15 patients. MA was on average 8.3 years younger than CA (range -43.4 to +41.6) at time of trial entry and 8.2 years younger (range -36.5 to +33.3) after therapy. This difference between MA and CA was greater in ET patients compared to PV, both at trial entry (-14.0 years vs -3.7) and after therapy (-13.0 years vs -4.3). A statistically significant link between JAK2 allele burden and MA was seen: compared to patients with low or no JAK2 allele burden, patients with high JAK2 (>80% at baseline) had an older MA at trial entry (64.2 years vs 44.5, p=0.0007) and after therapy (64.3 years vs 44.6, p=0.0015). This difference was also seen when PV or ET patients were examined separately. Patients with a high JAK2 allele burden tended to have a MA closer to their CA at trial entry (-0.8 years vs -15.3, p=0.0122) and after 3 months therapy (-0.5 years vs -12.2, p=0.0072). Although the cohort size was small, within the ET group, NR compared to PR was associated with a younger MA after therapy (41.4 years vs 56.3, p=0.0156). Within PV, NR compared to PR was associated with a MA that was older than CA both before (+9.2 years vs -14.2 years, p=0.0346) and after therapy (+7.4 years vs -13.9, p=0.0347).

Suggesions: A link between MA and JAK2 mutant allele burden in MPN patients, suggesting that allele burden not only has a role in clinical phenotype and disease evolution but in the overall methylation landscape of the mutated cells. However, the role of MA with respect to therapeutic response needs to be clarified with further studies required to show its full impact.

P698
ELUCIDATING THE AGE INDUCED HEMATOPOIETIC CELL-INNTRINSIC AND EXTRINSIC MECHANISMS IN MYELOPROLIFERATIVE NEOPLASMS INITIATION AND PROGRESSION
N. R. Tata 1*, S. Fatimah 2, M. Radek 3 1Department of Biomedicine, University Hospital Basel, Basel, Switzerland

Background: The number of detectable somatic mutations increase with age, but this increase is surpassed by the rise in the incidence of cancer in older people. The underlying mechanisms for this disparity remain to be elucidated. Myeloproliferative neoplasm (MPN) is an ideal malignancy model disease to study clonal hematopoiesis, disease initiation and progression during natural aging because the majority of the relevant mutations (such as JAK2 V617F) are catalogued, the disease evolves and progresses slowly allowing the collection of serial samples, and an inducible transgenic mouse models for the disease have been established. Nonetheless, the prevalent occurrence of such clonal events in aged individuals brings up the question, which age-associated disease have been established. Nonetheless, the prevalent occurrence of such clonal events in aged individuals brings up the question, which age-associated factors contribute to initiate hematologic malignancies and what are the rate limiting steps attributable for age-induced myeloid malignancies? We hypothesise that age induces different malignancies providing a context that favors a certain number of new mutations, selection for pre-malignant clones, and that activation of mutant JAK2 further augments these changes for increased MPN incidence in aged individuals. Thus, delineation of age associated cellular and molecular mechanisms attributable for increased prevalence of myeloid malignancies will be essential for the development of strategies for early detection and therapeutic targeting of myeloid malignancies.

Aims: The goal of this proposal is to identify age associated hematopoietic cell-intrinsic and cell-extrinsic factors that determine initiation and progression of MPN at young versus old age in mouse models carrying a JAK2-V617F or JAK2-V617F mutation.

Methods: To assess the effect of aging on MPN initiation and progression we studied the young and aged inducible transgenic mouse models of MPN. Integrated omics analysis was performed on MPN initiating stem and progenitor cells.

Results: Our results suggest that age related changes in expression patterns result in clones found in aged wildtype mice. The mutated profile in patients with pediatric MPN appear to be less complex than in older MPN patients. We are currently investigating the relative contributions and collaborations of age-associated cell intrinsic and extrinsic changes in HSCPs and BM niche in the course and severity of MPN in mouse models carrying a JAK2-V617F mutation, and in naturally aged donors and recipients of bone marrow transplantations.

Summary/Conclusions: Our study provided novel molecular and cellular mechanisms underlying increased incidence of MPN manifestation in old age. The implications of this work goes beyond the MPN malignancy and the comprehension of data sets generated in study will serve as a model to the wider scientific community to study other types of malignancies. This knowledge ultimately will help to define novel strategies to delay or target the onset of MPN in an aging individual.
Results: At BL, 59% of pts had anemia (hgb <10 g/dL); pts with BL anemia were more likely at BL to have platelet count <50,000/µL (51% vs 38%), pancytopeny MF (71% vs 57%), and high DI PSS score (41% vs 14%). For those with BL anemia regardless of whether RBC transfusion-dependent (TD), PAC did not worsen hgb levels and the rate of clinical improvement in hgb was higher for pts in the PAC BID arm (25% vs PAC QD (13%) or BID (12%) arms) (Table). Flow cytometry CAFRBC transfusion independence at 12 weeks (11%) at BL (30% in RUX) in RBC transfusion-dependency was achieved at higher rates with PAC QD (19%) and PAC BID (22%) vs BID (9%); 2 PAC and 0 BID pts achieved RBC-Tb by week 24. In PAC pts, SVR ≥35% and TSS reduction ≥50% were observed regardless of BL anemia or RBC-TD (Table). At BL, 16% of pts in the safety population had grade 3 anemia. Incidence of TE anemia was highest during the first 16 weeks of PAC (20% and 9% weeks 1-8, 13% and 9 weeks 13-18 weeks E and BID, respectively) and first 8 weeks of BID (10%). For pts with BL hgb <10 vs ≥10 g/dL, incidence of grade 3/4 TE anemia was similar with PAC QD (26% vs 28%, respectively), and lower in pts with BL hgb ≥10 g/dL with PAC BID (20%) vs BID (28%). In instances of SD plus clinical benefit, TE anemia with PAC or BID (Table) were in pts with BID hgb <10 g/dL. Dose modifications or discontinuations due to anemia were uncommon (Table). No exposure-response relationship was evident for grade ≥2 TE anemia. Summary/Conclusions: In pts with MF and BL thrombocytopenia, PAC treatment led to clinical improvement in hgb and reduction of RBC transfusion needs vs BID. Serious anemia, and dose modifications due to anemia were uncommon. PAC provides a treatment option for pts with MF, including those with BL thrombocytopenia and anemia, for whom available options are limited.

P700 COMBINATION THERAPY OF POMALIDOMIDE PLUS RUXITINIB IN MYELOFIBROSIS: RESULTS FROM COHORT 1 OF THE MPNSG-0212 TRIAL (NCT01644110)

1University Hospital of Ulm, Ulm, 2University of Bochum, Minden, 3RWTH Aachen University, University Medical Center, Aachen, 4Jena University Hospital, Jena, 5University Hospital of Freiburg, Freiburg, 6University Hospital of Mainz, Mainz, 7Stauferklinikum Mutlangen, Mutlangen, 8Hematology and Oncology Practice, Augsburg, 9University Medical Center Magdeburg, Magdeburg, 10University Tübingen, Tübingen, 11University of Cologne, Cologne, Germany

Background: Therapeutic options to address anemia in patients (pts) with Myelofibrosis (MF) are limited. In our MPNSG-00109 trial investigating pomalidomide (POM) in MF with cytopenia, anemia was improved in 14-29% of pts treated with 0.5-2.5mg POM once daily (QD) (Schränk FL, Steigmey F et al. Leukemia 2016). Aims: To evaluate synergistic effects of POM plus ruxitinib (RUX), we are currently investigating the combination therapy within the MPNSG-0212 trial (NCT01644110).

Methods: The MPNSG-0212 is designed as multicenter, single-arm phase-Ib/II trial with a target population of 38 pts in the first cohort. Primary endpoints are response rate after 12 cycles (28 days each) according to IWG-MRT (Tefferi et al., Blood 2006) and red blood cell (RBC) transfusion independence criteria (Gale et al., Leuk Res 2011). Secondary endpoints are safety, quality of life, progression-free, and overall survival. Main inclusion criterion is MF with anemia (hgb <10 g/dL) and/or RBC transfusion dependency. While POM is given at the fixed dosage of 0.5mg QD, RUX is started at 10mg twice daily (BID) from the first 16 weeks of PAC (20% and 9% weeks 1-8, 13% and 9 weeks 13-18 weeks E and BID, respectively) and first 8 weeks of BID (10%). For pts with BL hgb <10 vs ≥10 g/dL, incidence of grade 3/4 TE anemia was similar with PAC QD (26% vs 28%, respectively), and lower in pts with BL hgb ≥10 g/dL with PAC BID (20%) vs BID (28%). In instances of TE anemia with PAC or BID (Table) were in pts with BID hgb <10 g/dL. Dose modifications or discontinuations due to anemia were uncommon (Table). No exposure-response relationship was evident for grade ≥2 TE anemia. Summary/Conclusions: In pts with MF and BL thrombocytopenia, PAC treatment led to clinical improvement in hgb and reduction of RBC transfusion needs vs BID. Serious anemia, and dose modifications due to anemia were uncommon. PAC provides a treatment option for pts with MF, including those with BL thrombocytopenia and anemia, for whom available options are limited.

P701 PACRITINIB (PAC) VS BEST AVAILABLE THERAPY (BAT), IN PATIENTS WITH MF, Cytopenias and Splenomegaly: Results of the 24-week Phase 3 PACRITINIB (MF) and BASAL (BL) THROMBOCYTOPENIA: FOCUS ON RUXITINIB (RUX)-TREATED PATIENTS IN THE PHASE 3 PERSIST-2 TRIAL

1Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom, 2Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY, 3University of Michigan, Comprehensive Cancer Center, Ann Arbor, MI, 4Cleveland Clinic, Cleveland, OH, 5Northwestern University, Feinberg School of Medicine, Chicago, IL, 6University of Utah, Salt Lake City, UT, 7University of Toronto, Ontario, Canada, 8Albert Szent-Györgyi Central Clinical Center, University of Szeged, Szeged, Hungary, 9Beatson West of Scotland Cancer Centre, Glasgow, United Kingdom, 10Ryazan's Clinical Hospital, Ryazan, Russian Federation, 11VA Greater Los Angeles Healthcare System, West Los Angeles, CA, 12University of California-San Diego, La Jolla, CA

1Mayo Clinic, Scottsdale, AZ, 14MD Anderson Cancer Center, Houston, TX, United States

Background: MF is a life-threatening hematologic malignancy characterized by symptomatology, debilitating constitutional symptoms, and progressive cytopenias (anemia and thrombocytopenia). Currently, JAK1/2 inhibitor RUX is the only approved therapy for pts with MF. Although RUX has been shown to reduce splenomegaly and symptoms in pts with MF, it is associated with dose-limiting cytopenias and is not indicated for pts with platelets <50,000/µL. PAC is an oral kinase inhibitor with specificity for JAK2, FLT3, IAK1, and CSFIR. In the phase 3 PERSIST-2 study of PAC vs BAT (including RUX) in pts with MF and BL thrombocytopenia, PAC was significantly more effective in terms of spleen volume reduction (SVR; P=0.001) and appeared to have a better benefit/risk profile vs BAT.

Aims: This analysis examines outcomes for pts with MF treated with RUX in the phase 3 PERSIST-2 study.

Methods: Pts with MF and BL platelet count <100,000/µL were randomized (N=511) 1:1:1 to PAC 400mg once-daily (QD), PAC 200mg twice-daily (BID), or BAT. BAT included any physician-selected treatments for MF, as well as RUX due to RUX treatment. The co-primary endpoints were the rates of pts achieving ≥35% SVR (by MRI/CT) and ≥50% reduction in total symptom score (TSS; MPN-SAF TSS 2.0) at week 24. Efficacy analyses used the intent-to-treat efficacy (ITT-E) population, which included all pts with randomization date allowing them to contribute data for a week 24 endpoint. Crossover from BAT to PAC was allowed after week 24 or splenic progression.

Results: RUX was the most commonly received active BAT. 44 (45%) BAT pts received RUX (Figure) and 32 (33%) received only RUX. Of the 44 pts who received RUX on study, 17 (39%) had BL platelet counts <50,000/µL and would not have been candidates for RUX by approved indication (or study protocol).

Conclusions: This analysis examines outcomes for pts with MF treated with RUX in the phase 3 PERSIST-2 study.
SAFETY AND EFFICACY OF RUXOLITINIB (RUX) IN ELDERLY PATIENTS (≥75 YEARS) WITH MYELOFIBROSIS (MF): AN ANALYSIS FROM THE PHASE 3B, EXPANDED-ACCESS JUMP STUDY

1Rabin Medical Center, Petah Tikva, Israel, 2Princess Margaret Cancer Centre, Toronto, Ontario, Australia, 3Johannes Wesling Medical Center, University Hospital, Minden, Germany, 4University Hospital of Halle, Halle (Saale), Germany, 5Miguel Servet University Hospital and Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Zaragoza, Spain, 6CIRMM, Center for Research and Innovation of Myeloproliferative Neoplasms, AOU Careggi, Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy, 7St. Paul’s Hospital, University of British Columbia, Vancouver, British Columbia, Canada, 8Università Federale di Golina, Golina, Switzerland, 9Federal Almazov Medical Research Center of the Russian Ministry of Health, St. Petersburg, Russian Federation, 10Novartis Pharma AG, Basel, Switzerland, 11Novartis Healthcare Pvt. Ltd, Hyderabad, India, 12Azienda Ospedaliera Bianchi-Melacrinco-Morelli, Reggio Calabria, Italy

Background: RUX is a potent JAK1/JAK2 inhibitor that has led to reductions in splenomegaly and symptoms in patients (pts) with MF. Although few studies have assessed RUX in elderly pts, a recent analysis including 100 pts ≥75 y showed that RUX was safe and effective in these pts, with safety and efficacy outcomes similar to those in younger pts (Latagliata et al, Blood 2016;128:4251). JUMP, a large (N=2233), phase 3b, expanded-access trial, assessed safety and efficacy of RUX in pts with no access to RUX outside a clinical trial and included a cohort of pts ≥75 y.

Aims: To assess the safety and efficacy of RUX in pts aged ≥75 y.

Methods: Pts with high- or Int-2-MF, or Int-1-risk pts with a palpable (≥5 cm) spleen, were eligible. RUX starting doses were based on baseline platelet count (PLT) (counts (5mg bid [≥50 to <100x109/L], 15mg bid [100 to 200x109/L], or 20mg bid [≥200x109/L]). Pts were ≥18 y; there was no maximum age limit. The primary endpoint was safety and tolerability of RUX. Secondary endpoints included changes in spleen length and symptoms.

Results: This analysis includes 418 pts (primary MF, 66%) who were ≥75 y and started treatment ≥1 y before data cutoff (01 Jan 2016). Baseline characteristics (median) were age, 78 y (range, 75-89 y); male, 57%; spleen length, 10 cm (0-35 cm); blast count ≥1%, 30.3%; hemoglobin, 101 g/L (100-110 g/L); PLT count, 249x109/L (100-350x109/L); 6.3%). At data cutoff, more than half of pts remained on treatment or completed treatment per protocol (52.6%). As expected, a greater proportion of elderly pts discontinued RUX due to adverse events (AEs; 23.6%) or death (8.7%) than pts in the overall study (17.7% and 4.1%, respectively). Overall, 72.4% of pts had dose modifications (AEs, 58.4%), and 33.9% had an interruption (AEs, 31.5%). Safety of RUX in elderly pts was consistent with that in the overall population. Median exposure was 11 mo; mean daily dose was 26.8mg (SD, 10.6). The most common hematologic grade 3/4 AEs were anemia (43.8%; overall, 34.1%), and thrombocytopenia (22.1%; overall, 16.3%). AEs (all grade [grade 3/4]) in ≥10% of pts included asthenia (18.3% [2.6%]), pyrexia (18.0% [2.6%]), dyspnea (14.4% [4.3%]), diarrhea (13.5% [1.9%]), fatigue (11.8% [2.4%]), peripheral edema (10.8% [0.2%]), and pneumonia (10.1% [7.2%]). Infections in >5% of pts included pneumonia (10.1%), urinary tract infection (7.0%), and bronchitis (5.1%). Herpes zoster occurred in 3.9% of pts. At wk 24, 56.4% (124/220) of pts had a ≥50% reduction from baseline in spleen length (overall, 56.6%), and 19.1% (42/220) had ≥50% reductions (overall, 23.3%); rates were similar at wk 48 (54.6% [65/119] and 19.3% [23/119]; overall, 61.6% and 18.9%). Most pts (64.2%) achieved a ≥50% reduction at any time (Figure 1), similar to the overall population (70.2%). Pts also experienced significant improvements in symptoms. From wk 4 to 48, 42%-48% and 50%-57% of pts achieved a clinically meaningful response on the FACT-Lym and FACT-Fatigue, respectively.

Figure 1.
Summary/Conclusions: This analysis included the largest cohort of elderly pts with MF treated with RUX to date. Consistent with the study by Latagliata et al, RUX was safe and effective in pts ≥75 y, with pts achieving reductions in splenomegaly and symptoms similar to those in the overall population, with comparable rates of AEs. Additionally, findings from our study were consistent with those of the COMFORT studies, which included few pts ≥75 y. Overall, our study provides further evidence that RUX is safe and effective in elderly pts with MF.

Summary/Conclusions: This analysis included the largest cohort of elderly pts with MF treated with RUX to date. Consistent with the study by Latagliata et al, RUX was safe and effective in pts ≥75 y, with pts achieving reductions in splenomegaly and symptoms similar to those in the overall population, with comparable rates of AEs. Additionally, findings from our study were consistent with those of the COMFORT studies, which included few pts ≥75 y. Overall, our study provides further evidence that RUX is safe and effective in elderly pts with MF.
Background: Accurate disease risk stratification is crucial for transplant decision-making in idiopathic myelofibrosis (MF). Despite several prognostic models available, it is unknown if they are equivalent in the way they distribute patients into risk groups and in their discriminatory power to predict survival.

Aims: We have compared the performance of the International Prognostic Scoring System (IPSS), dynamic IPSS (DIPSS), DIPSS-plus, and Rumi’s score in a series of 544 MF patients aged 70 years or younger at time of diagnosis. Methods: The Spanish Registry of Myelofibrosis is a nationwide, longitudinal registry contributed by centers associated to the Grupo Español de Enfermedades Mieloproliferativas (GEMFIN). From January 2000 to January 2016, a total of 544 adult patients aged ≤70 years with primary MF (n=335) or secondary MF (n=209) had been included in the registry. Cases of the prefibrotic form of MF were not considered. Comparison of the relative power of each prognostic model to discriminate levels of risk was estimated by means of the Harrell’s concordance index (C-index) and the R² explained variation. All the statistical analyses were performed with IBM SPSS 22.0 and Stata 11.

Results: Median survival from diagnosis in diagnosis of de novo MF was 3.35 years, 177 patients (33%) had died, and the remaining were censored alive. Sixty-nine patients (13%) had been submitted to allogeneic stem cell transplantation, after a median time of 20 months from MF diagnosis. The median projected survival of the overall series was 9.46 years (95% confidence interval 7.44-11.48) and in the high risk group (very high risk in the Rumi’s score) was comparable in the four models. By contrast, the Rumi’s high risk group had a projected median survival of 9.2 years, whereas that of the intermediate-2 categories by the IPSS, DIPSS, and DIPSS-plus models was 6.6 years, 5.6 years, and 6.5 years, respectively. The number of patients in the intermediate-2 and high risk categories was smaller in the DIPSS than in the IPSS or the DIPSS-plus. Overall, the Rumi’s score yielded the highest power to discriminate between risk categories as measured by the C-index and the R² explained variation. However, the IPSS and DIPSS-plus were the best models to discriminate between the intermediate-1 and intermediate-2 risk categories, which is the critical cut-off point for patient selection to transplant.

Summary/Conclusions: In our contemporary series of MF patients only the high risk category of the current prognostication systems have a median survival below the 5-year threshold recommended for considering transplantation. Patient selection for transplantation is quite dependent on which prognostication model is used for disease risk stratification.

P704
LEUKEMIC TRANSFORMATION AND SECOND CANCERS IN 3649 HIGH RISK ET PATIENTS IN THE EXELS STUDY
G. Birgegård1,*, Y. Folkvaljon2, H. Garmo2, L. Holmberg3, C. Besses5, M. Griesshammer6, L. Gugliotta7, J. Wu8, H. Achenbach9, J.-J. Kiladjian10, N. Sgherza12, A. Tieghi13, G. Benevolo14, F. Cavazzini15, A. Isidori16, A. Ibatici17, M. D’Adda7, E. Abruzzese8, M. Tiribelli9, M. Spinsanti10, M. Bergamaschi11, M. Crugnola18, C. Bosi19, R. Latagliata5, D. Russo1, M. Cavo10, N. Vianelli10, 1Department of Haematology, Uppsala University, 2Regional Cancer Centre, Uppsala University Hospital, Uppsala, Sweden, 3King’s College London, Faculty of Life Sciences and Medicine, London, United Kingdom, 4Department of Surgical Sciences, Uppsala University, Uppsala, Sweden, 5Department of Haematology, Hospital del Mar-MIM, Barcelona, Spain, 6Hematology and Oncology, National Cancer Institute, NCI, Bethesda, USA, 7Department of Haematology, St Osrlos-Niipighi Hospital, Bologna, Italy, 8Global Biometrics, Shire Pharmaceuticals, Lexington, United States, 9Research & Development, Shire GmbH, Zug, Switzerland, 10APHP, Saint-Louis Hospital, Clinical Investigations Center, Paris, France, 11Department of Haematology, Guy’s and St Thomas’ NHS Foundation Trust, London, United Kingdom

Background: A common therapy for essential thrombocythemia (ET), hydroxy-ycarbamide (HC), has mutagenic properties and there is potential for leukemogenicity in patients with this condition. The EXELS study, we report here on 1,590 ET patients from 16 European Centres. Although leukemia (AML), and other malignancies in HC-treated patients compared with those treated with anagrelide (ANA). However, there were large age differences between groups. Here, we account for age differences by comparing standard incidence ratios (SIRs) using age-specific cancer registration data.

Aims: To assess the risk of AML and non-hematological malignancies in patients treated with HC or ANA in the EXELS study.

Methods: Previous exposure to ANA and HC was based on patient history. SIRs were calculated using background rates retrieved from Cancer Incidence in Five Continents (CI5). Risk of AML after study enrolment was estimated by cumulative incidence. Minimum exposure time of 180 days was used to account for disease progression as a confounding factor. Informed consent was obtained before the start of the study.

Results: Overall, 3460 patients were exposed to HC, ANA or both at registration, 481 patients had ANA treatment, 2305 had HC treatment and 674 had both exposures to both drugs. The median age in ANA patients was 51 years, and 71 years in HC patients. One hundred and seventy four cases of non-hematologic cancer, including 35 cases of skin cancer, were recorded. SIRs for all malignancies were close to 1 for all treatment groups, indicating similar risks to the background population. For all skin cancers, including melanoma, the SIR for patients with HC treatment was higher than expected, with 20 AML cases observed in the ANA-only group (person-years 8970, SIR 39.7), with another 20 AML cases in the group who switched from HC to ANA (person-years 2934, SIR 91.5). The risk ratio for AML developing in patients who switched from HC more than doubled (RR 2.30-2.52), irrespective of minimum exposure time. In contrast, no AML case was observed in the ANA-only group (person-years 1905, SIR 0) and there were only 3 AML cases in the group who switched from ANA to HC (person-years 802, SIR 68.5). Since the number of AML cases in the ANA group was 0, no statistical comparison could be made. Five AML cases were excluded from analysis since there was uncertainty about which drug was used first.

Table 1. Standardised incidence ratios (SIRs) with 95% confidence intervals (CIs).

Summary/Conclusions: ET patients have a substantially increased risk for AML development; the SIR for AML was 40-fold higher than expected with HC exposure. In patients who switched from HC to ANA the SIR was approximately 90-fold higher, with 20 AML cases observed versus the expected 0.22 cases. The number of AML cases was much lower (n=3) in patients who switched from ANA to HC. It has been proposed that exposure of ET patients failing HC therapy to a second potentially leukemogenic agent should be avoided; yet these data suggest that even after switching to a non-leukemogenic agent, HC-treated patients still have an over 90-fold increased risk of AML. Our data reinforces concerns of a leukemogenic effect of HC, with a markedly higher risk in patients failing HC and switching to another drug, even if that drug is ANA. The caution advocated in the use of HC seems well advised.

P705
EPIDEMIOLOGY, OUTCOME AND RISK FACTORS FOR INFECTIOUS COMPLICATIONS IN MF PATIENTS RECEIVING RUXOLITINIB. A MULTICENTER STUDY ON 373 PATIENTS
N. Polverelli1, G. Binotto2, G.A. Palumbo3, M. Bonifacio4, M. Breccia1, B. Martino5, D. Adda1, E. Abruzzese1, M. Spinsanti6, M. Bergamaschi7, N. Sgherza8, A. Tieghi9, G. Benevolo10, F. Summary/Conclusions: ET patients have a substantially increased risk for AML development; the SIR for AML was 40-fold higher than expected with HC exposure. In patients who switched from HC to ANA the SIR was approximately 90-fold higher, with 20 AML cases observed versus the expected 0.22 cases. The number of AML cases was much lower (n=3) in patients who switched from ANA to HC. It has been proposed that exposure of ET patients failing HC therapy to a second potentially leukemogenic agent should be avoided; yet these data suggest that even after switching to a non-leukemogenic agent, HC-treated patients still have an over 90-fold increased risk of AML. Our data reinforces concerns of a leukemogenic effect of HC, with a markedly higher risk in patients failing HC and switching to another drug, even if that drug is ANA. The caution advocated in the use of HC seems well advised.
Background: Infectious complications represent one of most frequent cause of morbidity and mortality in Myelofibrosis (MF), the most severe of myeloproliferative neoplasms. Ruxolitinib (RUX), the first approved JAK1/2 inhibitor, significantly ameliorates disease-related splenomegaly and constitutional symptoms. Prospective controlled studies observed a high rate of infectious complications including opportunistic and unusual infections, probably due to its immune-suppressant activity. However, risk factors for infections in MF patients (pts) treated with RUX are still to be investigated.

Aims: To evaluate characteristics, incidence and risk factors for infections in RUX-exposed MF pts.

Methods: Clinical and laboratory data of MF pts treated with RUX were retrospectively collected from the database of 21 Italian Hematology Centers. Infections were defined according to the CTCAE.

Results: At RUX start the clinical features were (median): age 68 years (27-89); ≥65y, 62%; male, 57%; Hb, 10.8g/dL (7-16.7); Hb <10g/dL, 40%; PLT, 246×10^9/L (33-1887); PLT <100×10^9/L, 10%; spleen enlargement, 97%; spleen length ≥10cm, 68%; constitutional symptoms, 52%. International Prognostic Score System (IPSS) was intermediate-1 (15%), intermediate-2 (46%), high (39%). JAKV617F mutation was detected in 255 out of 313 evaluated pts (81%). Karyotype was unfavorable in 15 out of 203 evaluable pts (7%). Previous infectious complications were recorded in 31 pts (8%). After a median RUX exposure of 20 months (range, 1-56), 101 pts (27%) experienced 129 infectious events (grade 3, 33%), for an incidence rate of 14.9 cases for 100 pts/year. The rate of infections tended to decrease over time: 54% occurred within 6 months of RUX start, 15% between 6 and 12 months, 9% between 12 and 18 months of infections tended to decrease over time, and were fatal in 11% of the cases. Advanced age, a previous infectious event and diagnosis of PMF seem to be the main contributors to infectious risk.
ET) chose watchful waiting to manage >25% of their pts at diagnosis; 22% of untreated pts had moderate to high (quartiles 3-4) overall symptom burden. Physicians primarily recommended treatment for pts experiencing severe symptoms (72% MF, 68% PV, 72% ET) or symptomatic splenomegaly (71% MF, 61% PV, 39% ET). PLB was mainly used to treat pts with PV. Of those who received PLB (n=155), 71% were very or somewhat satisfied; 25% were very or somewhat dissatisfied and 14% had a negative impact on their QOL. Similarly, 37% of physicians felt that PLB had a negative impact on pt QOL. PLB alone was insufficient for disease control in 38% of pts. Pts stopped PLB because physician deemed it no longer necessary (62%), pts felt worse after treatment (10%), and visit frequency was inconvenient (8%). Physician-reported reasons for stopping PLB were that visit frequency was inconvenient (38%), pts felt worse after treatment (35%), and lack of intravenous access (33%). HU use was assessed in pts with PV or ET. Of those who received HU (PV, n=95; ET, n=145), 78% and 74%, respectively, continued to receive HU; 19% and 22% were dissatisfied with HU therapy. Main reasons for stopping HU were lack of efficacy (29% PV, 13% ET) and toxicity (18% PV, 27% ET). Overall, 78% of physicians reported that up to 25% of their pts showed inadequate efficacy or intolerance of HU. Main measures of treatment success among pts were physician feedback (73% MF, 75% PV, 75% ET) and blood counts (72% MF, 67% PV, 74% ET). Lack of efficacy, side effects, and discontinue as key reasons for changing therapy.

Summary/Conclusions: Many pts with MPNs are managed with watchful waiting at diagnosis. Although most of these pts have a low symptom burden, 22% have a moderate to high burden, highlighting the need for proactive and standardized symptom assessments at diagnosis and over the course of treatment. Interestingly, a proportion of physicians and pts felt that phlebotomy had a high negative impact on pt QOL. Overall, pts consider physician feedback and blood counts to be important indicators of treatment success.

P707
SUCCESSFUL LONG-TERM MAINTENANCE OF PV PATIENTS WITH A MONTHLY SCHEDULE OF ROPEGINTERFERON ALFA-2b-AN UPDATE FROM THE PEGINIVERA STUDY

1Department of Medical Oncology and Hematology, 2Department of Biostatistics, 3Advanced Molecular Diagnostics Laboratory, Princess Margaret Cancer Centre, Toronto, Canada

Background: The outcome of patients with Philadelphia negative myeloproliferative neoplasms (MPN) who transform to acute leukemia is abysmal. There have been no advances in targeted therapy for this cohort of patients or individualized treatment based on genomic information. Furthermore, no large studies have investigated the impact of molecular profiling on clinical outcome in patients with accelerated or blast phase of MPN.

Aims: To describe the clinical outcomes of patients with MPN who transform to accelerated or blast phase and evaluate the impact of genomic alterations on outcomes.

Methods: Eligibility criteria included: Prior diagnosis of Philadelphia negative MPN according to WHO 2008 criteria; evidence of transformation to accelerated (10-19% blasts in peripheral blood or bone marrow) or blast phase (≥20% blasts) and seen at Princess Margaret Cancer Center between January 1998 and February 2017. The primary endpoint was overall survival (OS); defined as the time from transformation to death or last follow-up. Secondary endpoints included survival based on curative versus non-curative approach and treatment over time. In addition the impact of mutations will be correlated with clinical outcomes and survival.

Figure 1. Results: One hundred and eighty-seven patients who transformed to accelerated or blast phase with a prior diagnosis of MPN were identified at our institution.
tution. Twenty-nine patients were excluded: 17 for myelodysplastic/myeloproliferative overlap (MDS/MPN), six for insufficient information, five for not meeting criteria for accelerated or blast phase and one patient for a diagnosis of systemic mastocytosis. Of the 158 patients included in the study, the median age at the time of MPN diagnosis and leukemic transformation was 59 and 67 years respectively. Prior MPN diagnosis was: polycythemia vera (PV; n=25, 16%), essential thrombocythemia (ET; n=21, 13%), primary myelofibrosis (n=50, 32%), post ET myelofibrosis (PET MF; n=27, 17%), post PV myelofibrosis (PPV MF; n=24, 15%) and MPN-unclassifiable (n=11, 7%). One hundred and forty-two (93%) patients met the criteria for acute myeloid leukemia, thirteen (8%) had accelerated phase and 3 (2%) patients were diagnosed with myeloid sarcoma. Sixty-four (41%) patients were treated with curative intent including 27 (42%) patients who proceeded to hematopoietic cell transplantation, while 94 (59%) received non curative approach including low dose chemotherapy, hypomethylating agent, clinical trial or best supportive care. The median OS for the entire cohort was 6.5 months (95% CI: 5.06-8.01). In patients treated with curative intent median OS was 8.8 versus 3.2 months (p=0.003) for patients with non-curative intent. There was no difference in OS between historical controls treated between 1998 and 2011 when compared to a more recent cohort of patients (6.5 vs 7.3, p=0.34; see Figure 1). In 105 (67%) patients, NGS molecular profiling of 54 genes (39 hotspot region; 15 complete coding region coverage) was performed on peripheral blood or bone marrow samples using the TruSight Myeloid Sequencing Panel. Mutational data will be correlated with clinical outcomes and insights and clues as to how to develop an individualized treatment approach for this cohort of patients.

Summary/Conclusions: Despite advances in systemic therapies and supportive care, there has been no significant improvement in survival for MPN patients who transform to accelerated or blast phase, confirming that current treatment approaches are ineffective. Results of molecular profiling may provide valuable insights and clues as to how to develop an individualized treatment approach for this cohort of patients.

Other Non-malignant hematopoietic disorders

P709

MASITINIB FOR TREATMENT OF SEVERELY SYMPTOMATIC INDOLENT SYSTEMIC MSTACOTYSIS: ADDITIONAL EFFICACY ANALYSES FROM THE RANDOMIZED, PLACEBO-CONTROLLED, PHASE 3 STUDY AB06006

Background: Masitinib, a selective oral tyrosine kinase inhibitor targeting wild-type KIT, LYN and FYN, was the first drug to demonstrate efficacy in a phase 3 setting (study AB06006) for treatment of patients with severe indolent systemic mastocytosis (ISM) who are unresponsive to existing, optimal symptomatic treatments. In The Lancet (Feb 11;389(10069):612-620), Lortholary and colleagues reported a significant and clinically meaningful treatment benefit for masitinib (6mg/kg/day over 24-weeks) versus placebo, with primary analysis based on cumulative response (≥75% improvement from baseline, timeframe weeks 8-24, comprising 5 visits at 4-week intervals) in at least one of four severe baseline symptoms (pruritus, flushes, depression, or fatigue) using repeated measures methodology for rare diseases (i.e. a longitudinal analysis with respect to symptoms as opposed to patient response rate at a single point in time). Eligible patients were aged 18–75 years and had ISM according to WHO classification of Pathology Department, Université Paris Descartes, Paris Sorbonne Cité, Faculté de Médecine & APHP Necker-Enfants Malades, 1Service de médecine interne, Hôpital Tenon, Université Pierre et Marie Curie, Paris, France, 11Département de Pathologie, Harvard Medical School and Beth Israel Deaconess Medical Center, Boston, United States, 12Inserm U1068, CRCM (Signaling, Hematopoiesis and Mechanism of Oncogenesis), Inserm U1068, 13CNRS, UMR7258, Institut Paoli-Calmettes, Aix-Marseille Université, Marseille, 14Centre de Référence des Mastocytoses, 15Département of Infectious Diseases and Tropical Medicine and Centre d’Infectologie Necker-Pasteur, Hôpital Necker-Enfants-Malades, Université Paris Descartes, Paris Sorbonne Cité, 16Centre de Référence des Mastocytoses, Université Paris Descartes, Hôpital Necker Enfants Malades, Paris, France

Methods: Randomized, placebo-controlled, phase 3 study that included 135 severely symptomatic ISM patients, including the subvariant smoldering systemic mastocytosis (71 masitinib, 64 placebo). 80% of whom satisfied the WHO classification. Results: Masitinib showed a significant improvement over placebo according to its pre-specified primary endpoint (mITT population), with a cumulative response of 16.7% versus 7.4%, respectively, odds ratio (OR) of 3.6 [95%CI 1.2-10.8], P=0.008 (with re-randomization). This outcome was confirmed in the WHO patient subgroup: 17.8% versus 8.0%, respectively, OR=3.25 [0.97-10.88], P=0.0317. Computing the primary analysis (mITT) according to cumulative response per patient (GEE model) was also positive: 26.7% versus 12.8%, respectively, OR=2.48 [1.16-5.31], P=0.0212, as was analysis according to individual patient response (Pearson chi-square): 40.3% versus 24.2%, respectively, P=0.0062. Response (per patient) on all severe baseline symptoms for at least one visit was: 16.4% versus 7.6%, respectively, P=0.0062. Finally, analysis of sustained response in all severe baseline symptoms over multiple visits was highly discriminatory between treatment-arms: for patients with 3 severe baseline symptoms, masitinib generated a 12.5% response rate (≥75% improvement in each symptom) for 3 out of 5 visits, versus no response for placebo; and for patients with 2 severe baseline symptoms masitinib generated a response rate of 21.1%, 15.8% and 10.5% over at least 1, 2, and 3 visits, respectively, versus no response for placebo.

Summary/Conclusions: These post-hoc analyses confirm the clinical relevance, durability, and generalizability of the positive primary endpoint from study AB06006. Findings therefore support the conclusion that masitinib generates a significant therapeutic benefit in patients with severely symptomatic ISM who were unresponsive to optimal symptomatic treatments.

P710

THERAPY RESPONSE AND LONG-TERM OUTCOME OF 71 ADULT PATIENTS WITH HEMATOLOGICAL MALIGNANCY-ASSOCIATED HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS: A SINGLE INSTITUTION EXPERIENCE

M. Machaczka1,2,*, K. Kosior1, E. Pawlowicz2, M. Wolan2, M. Gajewski5, M. Klimkowska3

Background: Hematological malignancies are among the principal etiologies of hemophagocytic lymphohistiocytosis (HLH). The analysis of gene expression profiles in hematological malignancies has provided evidence for a subpopulation of patients with HLH associated with hematological malignancies (M-ALL). This subpopulation is characterized by a poor therapeutic response and increased mortality compared to non-M-ALL HLH. The aim of this study was to report the outcome of patients with M-ALL HLH in a single institution.

Methods: A retrospective analysis of 71 consecutive patients with M-ALL HLH was performed. The patients were treated with a combination of cyclosporine, dexamethasone, and an interleukin-1 receptor antagonist. The response was evaluated based on the International Pediatric HLH-2004 (IPAH-2004) criteria. The outcome was evaluated based on the Kaplan-Meier method.

Results: The median age of the patients was 43 years (range: 18-74). The median duration of therapy was 9 months (range: 1-36). The overall response rate was 75% (53/71). The median survival time was 18 months (range: 2-60). The median duration of remission was 12 months (range: 0-60). The 1-year survival rate was 78% (57/71). The 2-year survival rate was 72% (52/71). The 3-year survival rate was 68% (47/71). The 5-year survival rate was 63% (36/71). The median duration of remission was 12 months (range: 0-60). The median survival time was 18 months (range: 2-60).

Summary/Conclusions: The outcomes of patients with M-ALL HLH treated with a combination of cyclosporine, dexamethasone, and an interleukin-1 receptor antagonist were similar to those reported in other studies. The median duration of remission was 12 months (range: 0-60). The median survival time was 18 months (range: 2-60).

Other Non-malignant hematopoietic disorders
Background: Hemophagocytic lymphohistiocytosis (HLH) is a devastating disorder of uncontrolled immune activation characterized by clinicopathological evidence of extreme inflammation. Hematological malignancy-associated HLH (HM-HLH) has the worst outcome in comparison with any other form of HLH. HM-HLH can occur as the first manifestation of an occult malignancy, before start or during the treatment of known malignancy, or as the sign of a malignancy relapse or transformation to the more aggressive disease form.

Aims: The aim of the present study was to analyze the response to HLH therapy and overall survival of adult patients with HM-HLH.

Methods: From 2008 and onwards, data on adult patients referred to the Hematology Center Karolinska with suspected HLH were prospectively collected. Review concerned records of 142 adults with suspected HLH, hospitalized between Jan 2009 and Dec 2016. Of those, 71 patients with hematological malignancy were diagnosed with HLH and included to the present study. Hematological malignancy was defined as a neoplasm of lymphoid or myeloid origin. In all studied patients, the diagnosis of HLH was based on the HLH-2004 criteria. Infection as a possible additional trigger of HLH was carefully studied in all our HM-HLH patients. EBV and CMV DNA were routinely examined in whole blood, using RT quantitative PCR; other viruses (e.g. adenovirus, HSV, VZV, HHV6, influenza) were studied based on indications. Blood and urine cultures were performed in order to reveal any bacterial or fungal infections. Tests for fungal antigens, tuberculosis, parasitoid, and parasites were also performed if indicated. HLH treatment categories have included proapoptotic chemotherapy (etoposide) and immunosuppressive drugs, targeting hyperactivated macrophages (etoposide, corticosteroids, IVIG) and T cells (corticosteroids, cyclosporine A).

Results: Seventy-one adults, aged 22–84 years, were diagnosed with aggressive HM-HLH during the 8-year period. Lymphoid malignancy was diagnosed in 42 patients and myeloid malignancy in 29 patients. Fifty-four (76%) patients developed HLH as a first manifestation of underlying malignancy, during progression, or malignancy relapse. The remaining 24% patients developed HLH during chemotherapy. In 14 patients, HLH therapy started before confirmation of HLH diagnosis, based on suspicion of HLH (mean 6.7±8.4 days; range 0–2 days; range 1–31 days). Seventeen patients started HLH therapy at the day of HLH diagnosis. In 36 patients HLH therapy started after confirmation of HLH diagnosis (mean 15.9±4.13 days; median 5 days; range 1–242 days). Forty of 71 (56%) patients with active HLH died, of which 20 had signs of progressive malignancy, 16 patients had generalized infection (bacteraemia - 12 patients, viral - 3 patients, fungal - 4 patients; some patients had more than one source of infection). In 2 patients we observed central nervous system bleeding. Thirty-one (44%) patients responded to HLH therapy and achieved remission of HLH. However, only 13 of 71 (18%) patients with HM-HLH were still alive after a median follow-up time of 50 months, despite the attempted treatment in 67 (94%) cases. The probability of overall survival (OS) from 6, 12, 24 and 60 months after HLH diagnosis were 39, 20, 15 and 15%, respectively. The patients who developed HM-HLH with concomitant infection during chemotherapy had significantly longer OS (p=0.03) compared to patients who had HLH solely attributed to malignancy (Figure 1).

Summary/Conclusions: HLH in the context of malignancy is still considered a challenging adult hematology. HM-HLH is a highly lethal disorder in adults. The patients who develop HM-HLH with concomitant infection during chemotherapy show better survival than those who had HLH solely attributed to malignancy. Although poor outcome in some patients with HM-HLH is related to malignancy progression, in some patients the lack of effective M-HLH therapy may further impede adequate treatment of malignancy.

P711

WHOLE-EXOME SEQUENCING IN CHILDREN WITH IMMUNE CYTOPEnia: THE APPLICABILITY AND CLINICAL IMPACT

M. Svatoh1,2, V. Kanderová1, P. Cmišek3, L. Suková2, L. Šrámková2, J. Kaysersová1, J. Stuchlí1, M. Zálová1, L. Dušátková4, Š. Průhová5, M. Vlčková5, T. Freiberger5, D. Pospíšilová6, J. Blatný8, D. Procházková6, E. Mejstříková6, T. Kalina1, A. Sedvá1, J. Stary9, J. Trka1, E. Froliková1, F. Girodon1,2,*, M. Pacault3, F. Airaud4, C. Garrec4, S. Corbineau5, N. Casadevall6, F. Adeline3,4, C. Poiret5, S. Guérin6, F. Durand3, G. Pernollet5, J. Gérard7, D. Barret-Connor4, J. Courtin1,3.

Background: Whole-exome sequencing (WES) is widely used as a powerful tool for the identification of novel causal variants in primary immune dysregulation syndromes (PIDS). However, the clinical impact of these new causal variants remains uncertain. Our aim was to evaluate the impact and strategy of using WES in children with chronic early-onset autoimmune haemolytic anaemia (AHA), idiopathic thrombocytopenic purpura (ITP) and immune neutropenia, or their combination (Evans syndrome). Most of these patients presented with additional symptoms of immune dysregulation, e.g. common variable immunodeficiency (CVID), lymphoproliferative, autoimmune disorders (diabetes mellitus 1, thyroïditis).

Methods: 30 patients (age 0-39) were evaluated after an examination by a clinical hematologist and signature confirmed consensus. Genomic DNA were prepared from peripheral blood DNA using Agilent SureSelectXT Human All Exon V5/v6/UTR kit and sequenced with the Illumina NextSeq 500 system with a mean coverage of at least 30x.

Results: In 10 patients (33%) we were able to find likely causative mutations. In 3 patients (siblings) we identified a novel variant leading to CTLA4 deficiency, another novel variant in CTLA4 was identified together with an additional pathogenic variant in TSC1, causing a mixed phenotype. The genetic diagnosis of CTLA4 deficiency allowed for the use of CTLA4 agonist (Abatacept) treatment in 1 patient that led to improvement of his symptoms and disease stabilisation. However, after 6 months, the patient had developed agranulocytosis that led to hematopoietic stem cell transplantation. In 1 patient we were able to identify a gain-of-function variant in STAT3 that was recently described in immune dysregulation. In 3 patients we observed variants in genes typically described in connection with antibody deficiency (TACI, CD40L, and lKRBG). In 1 patient with chronic AHA and ITP we found a novel heterozygous variant in TERT gene related to dyskeratosis congenita. In 1 patient with multiple congenital abnormalities and Evans syndrome we discovered a heterozygous variant in KMT2D gene causing Kabuki syndrome. The remainder of our patients harboured variants that posed a diagnostic challenge. In 4 of these we identified variants in genes involved in the pathogenesis of immune dysregulation, which are observed at lower frequencies also in healthy people (CASP10, PIK3CD). 12 patients (36%) had either only one hit in the genes reported causal in autosomal recessive diseases (e.g. ITK, LRBA) or we have not yet found any relevant aberration. In 4 patients we were able to identify novel variants in genes related to immune dysregulation. However, these variants require extensive validation studies, using patients' primary cells or manipulating established in-vitro or animal models with gene editing techniques, in order to prove the causality.

Summary/Conclusions: WES is a highly useful method that helps to identify the genetic cause of the disease in approximately one third of patients and enables targeted therapy. While targeted sequencing can further reduce costs and make analysis more straightforward, gene panels are quickly becoming obsolete as new causal variants are discovered in the rapidly evolving field of primary immunodeficiencies. Because of the heterogeneity of genetic causes of immune cytopenias, we recommend to use WES over targeted gene panel sequencing.

P712

SEQUENCING OF THE HYPOXIA PATHWAY GENES IN PATIENTS WITH CONGENITAL ERYTHROCYTOPATHIES BY NEXT GENERATION SEQUENCING

F. Giordano1,2, M. Pacault3, F. Airaud4, C. Garrec4, S. Cortinovis5, N. Casadevall6,
Background: Erythrocytoses are characterized by an elevated red cell mass. The most widely studied disease is Polycythemia Vera (PV), however, other types of erythrocytoses can be either inherited (Congenital Erythrocytosis-CE) or acquired (Monocytic Erythrocytosis-ME). Aims: Mutation search in the hypoxia pathway.

Methods: We have performed secondary erythrocytosis related to lung, cardiac or renal disorder. Next generation sequencing (NGS) has been used to analyse the presence of mutations in patients suspected of CE.

Results: To date, samples from 140 patients have been recorded, among whom 46 have been analyzed using NGS approach, and 149 harbored the D816V mutation. Of the 14 patients [13 males and 1 female; median age 50 y. (12-71)] with unknown significance were detected, including 4 in PHD genes, 5 in HIF genes, 4 in LNK genes (SH2B3) and 1 in JAK2 gene. In patients with variants, a familial history of erythrocytosis was noted in 3. No independent thrombotic complication was reported in the 15 patients. In 2 patients (one with a JAK2 variant and one with a JAK2 variant), the erythropoietin was low, whereas for the others, the erythropoietin was normal. Of note, the median age of the patients was surprisingly high, suggesting that the diagnostic was not previously performed due to the absence of available tests. Functional studies were performed on PHD2 variants: a significant decrease in the hydroxylase activity was noted for one variant, but not for the others. On the other hand, a decrease in the stability along time of the PHD2 protein was observed for two variants, underscoring the different mechanisms involved in the impairment of the PHD2 activity.

Summary/Conclusions: NGS is a useful tool to explore mutations in CE, but identifies genetic variants in only 30% of patients with such disorder. Further, exomes including whole exome sequencing are planned to achieve a right diagnosis in the 70% remaining CE patients.

P713 CHARACTERIZATION OF CD34+ HEMATOPOIETIC PRECURSORS IN INDOLENT SYSTEMIC MASTOCYTOSIS AND THEIR POTENTIAL ROLE IN EARLY DISSEMINATION OF THE DISEASE

1. Cancer Research Centre (IBMC, USAL-CSIC), Cytometry Service (NULCEUS) and Department of Medicine, University of Salamanca, Salamanca, Spain; 2. Institute of Biomedical Research of Salamanca (IBSAL), Salamanca, Spain; 3. Department of Immunohematology and Blood Transfusion, Leiden University Medical Center, Leiden, Netherlands; 4. Sequencing DNA Service (NULCEUS), University of Salamanca, Salamanca, Spain; 5. Instituto de Estudios de Mastocitosis de Castilla La Mancha (CLMast), Hospital Virgen del Valle, Toledo, Spain

Background: Recent studies show that most systemic mastocytosis (SM) patients, including indolent SM (ISM) with (ISMs+) and without skin lesions (ISMs-), carry the KIT D816V mutation in PB leukocytes.

Aims: To investigate the potential association between the degree of involvement of BM hematopoiesis by the KIT D816V mutation and the distribution of different maturation-associated compartments of bone marrow (BM) and peripheral blood (PB) CD34+ hematopoietic precursors (HPC) in ISM, and identify the specific PB cell compartments that carry this mutation.

Methods: The distribution of different maturation-associated of BM and PB CD34+ HPC from 64 newly-diagnosed (KIT-mutated) ISM patients and 14 healthy controls was analyzed by flow cytometry. In 18 patients distinct FACS-purified PB cell compartments were also investigated for the KIT mutation.

Results: ISM patients showed higher percentages of both BM and PB MC-committed CD34+ HPC as controls, particularly among ISM cases with MC-restricted KIT mutation (ISMMC); this was associated with progressive blockade of maturation of CD34+ HPC to neutrophil lineage from ISMMC to multilineage KIT-mutated cases (ISMM). Regarding the frequency of KIT-mutated cases and cell populations in PB, variable patterns were observed, the percentage of KIT-mutated PB CD34+ HPC, eosinophils, neutrophils, monocytes and T-cells increasing from ISMsMC and ISMMMC to ISMM patients.

Summary/Conclusions: Positivity for the KIT D816V mutation in PB of ISM is associated with the accumulation of circulating myeloid and monocyte precursors, whereas in BM we observed a different pattern of KIT-mutated cell populations contributing to disease dissemination already at very early stages.
Background: Erythrocytosis, (i.e. increased levels of hemoglobin/hematocrit (Hb/Htc) >95 percentile for age and sex), is rarely found in pediatrics. Presence of familial cases, presentation at birth or presence of known mutations, as well as exclusion of secondary causes identifies primary (PE) or congenital secondary forms (CE). However, many cases still lack evident etiological definition (idiopathic E.). Moreover, natural course and treatment are still anecdotal reported.

Aims: We report a large and heterogeneous series of children with absolute erythrocytosis. The aims is to identify a possible clinical and diagnostic approach to children with erythrocytosis.

Methods: All children with E. who lacked evidence of reactive origin were consecutively referred to our laboratory for molecular evaluation. Molecular analysis of the main involved genes (VHL, HIF2A, EPOR, JAK2, PHD2) was performed by allele specific PCR, PCR on direct DNA sequencing. Erythropoietic Colony Essay (ECE) was performed on peripheral blood with and without cytokines. Clinical features and treatment choices were reported by referring clinicians (table 1).

Results: Patients were group according to the definitions of absolute Erythrocytosis. A total of 44 pediatric cases were identified (less than 18 years old). There were 7 families, where 5 adults were also found polyglobulic. However, in only 4 families a defect was identified (2 VHL, and 2 Hb variants). One Hb positive case was found sporadic. Most Hb variants were not symptomatic, while all other familiar cases had splenomegaly and vascular symptoms. Among non familial, non genetic cases, 5 children were affected by Down Syndrome; 4 children had severe renal or cerebral disease. In one 4 year old girl, with a polygenic VHL variant, who presented with arterial hypertension, a small size ganglioencephalocele was found after a 5%rs follow-up. In 21 cases non causes could be identified. They were mostly male (n=18); presented at adolescent age with advanced puberal status (n=17); many were symptomatic (6). Only one 9 year old girl was diagnosed with Polycytemia vera (JAK2V617F positive). Treatment varied according to physician decisions and presence of vascular symptoms, 6 children received ASA and 11 were phlebotomized. In two older year old girl was diagnosed with Polycytemia vera (JAK2V617F positive). Treatment varied according to physician decisions and presence of vascular symptoms. Among the 615 ITP, 181 ES), a significant neurological involvement was observed in 8 patients from 7 centers. With a median (range) follow-up of 12 years (6-26.5), 7 children had ES (including autoimmune neutropenia in 5) and 1 child had isolated ES. Median age at diagnosis was 11.5 years (1.8-15.8). At the last follow-up point, AIC were in partial or complete remission for all patients. Neurological symptoms appeared with a mean delay of 6 years (2.5-18) after AIC onset. The symptomatology was: seizures (n=4), cranial nerve palsy (n=2), Brown-Sequard syndrome (n=2) and/or sensory neuropathy (n=1). No infectious pathogens were identified. MRI showed multiple (n=6) or unique (n=2) inflammatory lesions with hypointense T2 signal in all patients, gadolinium-enhancing lesions in 7 and perilesional edema in 5. Five patients had a total of 8 biopsies, which confirmed the inflammatory process with macrophagic (n=3) or lymphoplasmocytic (n=5) infiltrates. In 4 cases, a lymphocytic meningitis was associated. Non-neurological organ involvement was present in all patients, mainly pulmonary nodules (n=6) and lymphoproliferation (n=4). All patients had an abnormal immunophenotype, with T-cell (n=7) or B-cell (n=3) deficiency and hypogammaglobulinemia was present in 7 of the 8 patients. PIDs have been given standard (n=6) or immunomodulatory treatment (n=2), or immunosuppressive treatment (n=3). Cisplatin, Methotrexate and Mofetil, improving symptomatology and MRI for all. Five patients relapsed and 3 patients had an asymptomatic radiological progression. At the last follow up point, all patients had neurological sequelae and 7 persisting radiological abnormalities. Four out of the 16 patients analyzed had a PID: 22q11.2 microdeletion (n=1), heterozygous C7A mutation (n=2) or homozygous LREA mutation (n=1).

Summary/Conclusions: Neurological involvement is rare and severe late event in the course of childhood ES, or exceptionally AHAi, that may reveal various underlying PID. Complete imaging and pathology examination highlight a causative immune dysregulation and could guide specific therapeutic strategies.

Background: The most frequent Autoimmune Neutropenia (AIN) in childhood is the primary type (p-AIN), whereas in adults AIN is mostly represented by secondary neutropenias, which can be associated to infection, drug adminis-

tration, immunodeficiency, neoplasms, bone marrow transplantation or other autoimmune disorders.

Aims: To describe clinic and laboratory findings in children affected by AIN secondary to other autoimmune diseases (s-AIN).

Methods: This registry study analyzes 26 patients affected by s-AIN enrolled in the Italian neutropenia registry of A.I.E.O.P. (Associazione Italiana di Onco-

Ematologia Pediatrica) over a 15-year time-span: this cohort, the largest ever described, was compared to 263 patients affected by p-AIN enrolled in the Registry in the same period.

Results: Specific characteristics of s-AIN patients are presented in Figure 1. The prevalence of former preterm babies among p-AIN (and not s-AIN) patients was significantly higher than in a cohort of 487 consecutively hospitalized chil-

dren (p=0.0009). The median age of onset of AIN was 0.77 year and 10.07 year in p-AIN and s-AIN respectively (p=0.002; p=0.03). The prevalence of IgA deficiency was 4% in p-AIN and 13.6% in s-AIN children: both prevalences were significantly higher than that (0.2%) presented in a group of 470 controls (p=0.0009). The median age of neutrophils was lower in p-AIN (0.45 x 10^9/L) than in s-AIN 0.63 x 10^9/L (p=0.03); median value of lym-

phocytes was significantly reduced (p=0.0001) in s-AIN 1.58 x 10^9/L vs p-

AIN (4.36 x 10^9/L) group. Leucopenia (p=0.0001) occurred more frequently in s-AIN; mononcytosis (p=0.03) and spontaneous remission (p=0.02) in p-AIN. GCSF was used in 9% of the p-AIN and 13% of the s-AIN patients (p=0.004). Neutropenia appeared con-

temporary to other autoimmune manifestations in 11/26 s-AIN patients (42.3%), appeared firstly in 8/26 patients (30.7%) (median and mean time of appearance of other autoimmune signs: 440 and 987 days respectively) and later in 7/26 patients (26.9%) (median and mean time of appearance of s-AIN: 566.5 and 866.3 days respectively). Evans Syndrome (ES) and autoimmune thyroiditis (AT) were the most common secondary autoimmune diseases (11 and 7 patients, respectively), whereas 7 s-AIN patients presented not previously reported associations: 3 with GH deficiency, 2 with coeliac disease (CD), 1 with autoimmune hepatitis (AH) and 1 with autoimmune encephalitis. In 6 children s-AIN was associated with more than one defined autoimmune disease and in 4 children with undefined autoimmune signs characterized by arthralgia and ANA positivity. Finally, only 2/26 patients presented spontaneous remission: a boy who recovered from ES and one patient, affected by both AT and CD who, after starting a gluten-free diet, recovered from s-AIN (and not from AT). A third girl suffering from both AH and bi-lineage ES (thrombocytopenia + AIN) has been maintained, 30 months after the stop therapy, a stable remission from AH and thrombocytopenia (but not from s-AIN).

Summary/Conclusions: p-AIN is in the vast majority of cases a benign and self-limiting disorder typically occurring under 2-3 years old whereas s-AIN is a more severe disease, usually appearing after the first 5 years of life, usually associated to lymphocytopenia and with a highly frequent tendency to become chronic.

P178 PAROSYMSMAL NOCTURNAL HEMOGLOBINURIA TREATMENT DURING PREGNANCY

tology, Moscow, Russian Federation

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a life-threatening disorder with a high risk of thrombosis. Targeted therapy radically changed the prognosis in PNH. Therefore issues of reproductive health in PNH patients are becoming very important. Recently the management of PNH during pregnancy has been challenging because of the high risk of maternal morbidity and fre-

quent pregnancy loss. The combination of targeted therapy with eculizumab and anticoagulants made it possible not only to increase the survival rate, but also to improve the quality of life.

Aims: We compared the pregnancy outcomes in PNH patients on eculizumab treatment and retrospective data of pregnancies on symptomatic therapy only.

Methods: Since 1999 we have analyzed 32 pregnancies in PNH patients. 17 patients (group 1) from 2013 exposed to eculizumab during pregnancy with anticoagulants. Other 15 women (group 2) received only symptomatic therapy. The median of PNH granulocyte clone at that time was 74.7% (23-99). PNH diagnosed before the pregnancy in all cases. 64.3% of them had previously received immunosuppressive treatment of aplastic anemia. 18.7% patients reg-

istered venous thromboses before conception. 92.9% of patients had been using eculizumab prior to becoming pregnant, mean duration of therapy was 21 months (4-44). Anticoagulation with low molecular weight heparin was used in 85.7% pregnancies.

Results: Clinical manifestations of hemolysis significantly regressed during eculizumab treatment: normalization of LDH was registered in 76.5% patients. Without eculizumab LDH level increased in all pregnant patients. No maternal death and thrombotic events have been observed. 42.9% of patients required a dose adjustment due to breakthrough hemolysis (a dose increase and/or more frequent use of eculizumab). Pregnancy complications were less frequent with eculizumab: abortion threat 35.3% vs 85.7%, fetal growth retardation syn-

drome 7.1% vs 21.4%, preeclampsia 5.9% vs 14.3%. Transfusion rate was higher without eculizumab (86.7% vs 41.2%). Pregnancies resulted in the birth in 100% patients exposed eculizumab and 42.9% on supportive treatment. Mean birth weight 2560 g (450-3550). Most of newborns (87.5%) are healthy, 83.3% of them received breastfeeding without complications both on eculizum-

ab and without it.

Summary/Conclusions: We can conclude that pregnancy outcomes in PNH patients with eculizumab are much better than with symptomatic therapy only. Our data demonstrate the possibility of safe therapy with eculizumab in pregn-

ant women. Pregnancy does not worsen the prognosis of PNH in the case of targeted and adequate supportive therapy. There is no difference in health between infants born by mothers with PNH and the newborns from general population.
Background: Gaucher disease type 1 (GD1), deficient lysosomal acid β-glucosidase activity leads to accumulation of glucosylceramide, primarily in macrophages (Gaucher cells), which deposit in the spleen, liver, and bone marrow, leading to thrombocytopenia, anemia, hepatosplenomegaly, and skeletal disease. Hematologists often identify and manage the disease. Intravenous enzyme replacement therapy (ERT) with recombinant acid β-glucosidase has been the mainstay of therapy for GD1. Eliglustat is an oral substrate reduction therapy approved as first-line treatment for adults with GD1 with poor, intermittent, or extensive CYP2D6-metabolizer phenotypes (>90% of patients). Phase 3 trials demonstrated safety and efficacy of eliglustat in naïve patients (Mistry et al. JAMA. 2015) and safety and stability in patients switching from long-term ERT (Cox et al. Blood. 2017). We report the final 5-year results of an open-label, Phase 2 trial (NCT00358150, Sanofi Genzyme) in previously untreated adults with GD1. These data build on 1-, 2-, and 4-year data showing sustained improvements in hematologic parameters, organ volumes, disease-related biomarkers, and measures of bone health (Lukina et al. Blood Cells Mol Dis. 2014).

Methods: Adult GD1 patients who had splenomegaly with thrombocytopenia and/or anemia received 50 or 100mg eliglustat tartrate (equivalent to 42 or 84mg eliglustat) twice daily, dosed by plasma trough levels. Efficacy outcomes included changes in hemoglobin, platelets, spleen and liver volumes, disease-related biomarker levels, skeletal manifestations, and achievement of therapeutic goals for anemia, thrombocytopenia, splenomegaly, and hepatomegaly (Pastores et al. Semin Hematol. 2004; Lukina et al. Blood. 2010).

Results: Of 26 enrolled patients, 19 completed the trial and 7 withdrew: 2 on the first day of treatment due to asymptomatic nonsustained ventricular tachycardia detected during the monitoring (plasma levels of eliglustat were undetectable); 1 after 1 year due to progression of a bone lesion (retrospectively identified at baseline); 1 chose to withdraw after 2 years; and 3 due to pregnancy. After 8 years of eliglustat, mean (±SD) hemoglobin level and platelet count increased by 2.1±1.7 g/dL (from 11.3±1.8 to 13.4±2.1 g/dL) and 110% (from 67.5±21.1 to 130.7±59.8 x10^9/L), respectively. Mean spleen and liver volumes (multiples of normal, MN) decreased by 68% (from 17.3±10.4 to 5.1±3.5 MN) and 31% (from 1.6±0.5 to 1.1±0.3 MN), respectively. All patients met ≥3 of 4 long-term therapeutic goals (spleen, 100% of patients; liver, 100%; hemoglobin, 93%; platelets, 53%) by 7-8 years. Median chitotriosidase levels decreased by 84%, CCL-18 by 82%, and glucosylsphingosine (Lyso GL-1) by 88%; plasma GL-1 normalized. Total mean lumbar spine bone mineral density increased by 0.12 g/cm²; mean Z-score increased by 0.88 (from -1.27±1.02 to -0.39±1.13) and mean T-score by 0.95 (from -1.64±1.07 to -0.69±1.31). Eliglustat was well-tolerated. All quality of life measures (SF-36, fatigue severity score, EORTC core and disease-specific score) showed improvement over time. Most adverse events in this long-term trial were mild or moderate in severity (98%, 342/348) and considered unrelated (94%, 328/348) to treatment.

Summary/Conclusions: After 8 years of treatment with eliglustat, clinically meaningful improvements in hematologic, visceral, biomarker, and bone parameters continued or were maintained among patients in this Phase 2 trial. No new safety concerns emerged.
Aims: The aim of this study was to analyze the biological features of ITP patients refractory to conventional therapies.

Methods: We performed a prospective study in 8 patients with primary ITP not responding to standard therapies (corticosteroids, IVIG and/or splenectomy) as well as in 8 patients with non-refractory ITP (control group). Mean platelet size, surface expression of platelet glycoprotein (GP) IIb and the activation marker CD62 were examined by flow cytometry (FC) analysis, as well as desialylation of platelet membrane receptors using fluorescein-conjugated Ricinus Communis Agglutinin I (RCA-1), a lectin that binds to galactose residues underlying sialic acids. Patients' sera was also incubated with normal human platelets to analyze their ability to induce desialylation in normal platelets. Analysis of desialylation of plasma proteins was performed by Western blot (FXI, FXII) and HPLC (trans-fucose). Patients' sera was also incubated with normal human platelets to analyze their ability to induce desialylation in normal platelets. Analysis of desialylation of plasma proteins was performed by Western blot (FXI, FXII) and HPLC (trans-fucose). Furthermore, TPO-RA refractory patients' sera desilylated normal platelets, but not plasma proteins. MACE assay revealed that unique positivity for anti-GPIbα (TPO-RA) (n=5) displayed higher platelet size and alpha-granule secretion. Recent studies have suggested a mechanism of Fcγ receptors' binding to TPO-RA mediated through receptor internalization and lysosomal digestion. In this study, we aimed to investigate the potential role of anti-GPIbα antibodies in TPO-RA refractoriness.

Results: The characteristics of the patients according to the response to conventional treatments (A: no responders; B: responders) are summarized in Table 1. Non responders exhibited lower platelet counts (p=0.006), higher expression of GPIIb (p=0.049) and loss of platelet sialic acids (p=0.005). Additionally, those who did not respond not only to traditional therapies (corticosteroids, IVIG and splenectomy) but also to thrombopoietin receptor agonists (TPO-RA) displayed higher platelet size and alpha-granule secretion. Furthermore, TPO-RA refractory patients' sera desilylated normal platelets, but not plasma proteins. MACE assay revealed that unique positivity for anti-GPIbα antibodies was only detected in those patients classified as non-responders to conventional ITP therapies, including TPO-RA. Summary/Conclusions: This study shows a significant higher platelet desialylation in ITP patients who are non-responders to conventional therapies, particularly if they are also refractory to TPO-RA. According to a previous study (1), these results seem to be associated to platelet activation mediated by anti-platelet specific antibodies.

Background: ITP is a disorder characterized by thrombocytopenia resulting from both increased immune-mediated platelet clearance and inappropriate thrombopoietin. TPO-RAs—romiplostim (R) and eltrombopag (E) - offer a new opportunity of treatment with high response rates. However, a small fraction of pts does not respond or loses response—i.e. desired platelet (plt) count achieved but not sustained over time— during long-term follow-up, which can not be resumed even if dosage is increased over time, or experience wide fluctuations in plt counts with either agent. Moreover, adverse events (AE) may necessitate treatment discontinuation. Finally, patient’s preference may be an important issue considering the different route and timing of administration of the two agents and the alimentary restrictions needed for proper E absorption. Availability of two TPO-RAs for clinical use, with different molecular structure and site of binding within the TPO receptor, has prompted trials of TPO-RA switching with the aim of overcoming treatment limitations of either agent resulting in increased overall response rates of approximately 80% in poor responders to 1st TPO-RA.

Aims: To present the results of a multicenter survey on TPO-RA switch policies and outcome.

Methods: Charts of ITP pts receiving TPO-RAs at 17 collaborating Haematology Centers were reviewed, including demographics and clinical data. Data were collected in a dedicated case report form. Pts were grouped and analyzed based on the clinical setting prompting the switch (Table 1). The study was approved by the Hospital Review Board of each participating Center.

Table 1.
Results: A total of 548 pts received either R or E between Dec 2009 and Dec 2015. Of these, 106 (19.4%) underwent TPO-RA switch. Table 1 summarizes outcome after switch. Overall 69/106 (65%) of pts achieved, regained or maintained response upon switching. Either one TPO-RA switch sequence was equally effective (p=0.882). Outcome was not associated with gender, age at 1st TPO-RA treatment, splenectomy status. However, number of lines of previous therapies correlated with lower response rate (p=0.020); escalation of line of therapy yielded a 30% increase in the odds of being a non responder; a trend toward lower probability of response was observed in pts with longer lasting disease before 1st TPO-RA administration (p=0.066). Adverse events (AE; 16/106 pts) were generally mild and reversible upon discontinuation of either one TPO-RA. One study with thrombopoietin receptor agonists produced severe (standard anticoagulation) thrombotic events were observed which did not recur after switching. AE were characteristic of older pts: each additional year increase in pts age determined a 5% increase in the odds of developing AE.

Summary/Conclusions: Approximately 20% of TPO-RA treated pts were felt by their attending physicians to potentially benefit from a switching policy. Exposure to the 2nd TPO-RA was more effective in pts who had lost response to 1st TPO-RA (80% responders) compared to those who were non responders to 1st TPO-RA (49% responders, p=0.001). It could be speculated that lack of response to either one of the two available TPO-RA identifies a subgroup of pts least likely to respond when switching to the second available TPO-RA. Pts switched for non-efficacy reasons are more likely to maintain a response upon switch (p=0.030). The so far unexplained and unprecedented phenomenon of wide plt fluctuation appears to be linked to the removal of the spleen, the physiological plt reservoir organ.

THROMBOEMBOLIC EVENT MANAGEMENT AND OUTCOMES IN PATIENTS WITH CHRONIC IMMUNE THROMBOCYTOPENIA (CITP) DURING TREATMENT WITH ELTROMBOPAG (EPAG): RESULTS FROM THE EXTEND STUDY
M.N. Saleh1,*, J.B. Busse8, R.S. Wong3, B. Meddeb4, A. Salama5, O. Ocak6, S. Atkinson6, E. Quebe-Fehling6, A. Khelif7
1Comprehensive Cancer Center, University of Alabama at Birmingham, Birmingham, 2Pediatric Hematology/Oncology, Wiel Cornelii Medicine, New York, United States, 3Sir YK Pao Centre for Cancer & Department of Medicine and Therapeutics, The Chinese University of Hong Kong, Hong Kong, 4Hôpital Aziza Othmana, Tunis, Tunisia, 5Charite-Universitaetsmedizin, Berlin, Germany, 6Novartis Pharma AG, Basel, Switzerland, 7Hôpital Farhat Hached, Sousse, Tunisia

Background: EPAG is an oral thrombopoiesis receptor agonist approved for treatment of previously treated patients (pts; eg corticosteroids, immunoglobulins) with cITP aged ≥1 yr. The EXTEND study, a global, open-label, extension study of pts with cITP who received EPAG or placebo in prior EPAG studies, evaluated long-term safety and tolerability of EPAG. In EXTEND, 19 (6.3%) pts receiving EPAG experienced a total of 24 thromboembolic events (TEEs; SAEs; Table 1). We analyzed the characteristics of pts treated with EPAG and any TEE (DVT, n=3; CI, n=3; MI, n=1; other, n=2) in the EXTEND study.

Methods: Adult pts with cITP received EPAG starting at 50mg/day, with titration to 25–75mg per day or less as required, based on individual platelet count responses (target range ≥50–200x10⁹/L). Maintenance dosing continued after minimization of concomitant ITP medication and optimization of EPAG dosing. Pts could remain on EPAG either for 2 yrs in countries where EPAG was commercially available, or for >2 yrs until EPAG became commercially available. The EXTEND primary objective included detection and documentation of AEs, and the EXTEND secondary objective was to evaluate long-term safety and tolerability of EPAG dosing. Pts whose treatment was interrupted had resolution of the event after medical/surgical treatment, most commonly anticoagulant therapy, regardless of whether EPAG was discontinued, interrupted or continued. The decision to restart EPAG following a TEE should be made on a case-by-case basis, with caution (including frequent platelet count monitoring) and only if the benefit is expected to outweigh any risk. If anticoagulation therapy is instituted (as in most cases), it is possible the bleeding risk may shift the risk-benefit to maintenance of EPAG treatment.

Summary/Conclusions: This analysis shows that most pts who experienced a TEE had resolution of the event after medical/surgical treatment, most commonly anticoagulant therapy, regardless of whether EPAG was discontinued, interrupted or continued. The decision to restart EPAG following a TEE should be made on a case-by-case basis, with caution (including frequent platelet count monitoring) and only if the benefit is expected to outweigh any risk. If anticoagulation therapy is instituted (as in most cases), it is possible the bleeding risk may shift the risk-benefit to maintenance of EPAG treatment.

SEVERE BLEEDING IN THE ELDERLY WITH PRIMARY IMMUNE THROMBOCYTOPENIA: CHARACTERISTICS, RESPONSE TO THERAPY AND LONG-TERM OUTCOME
M. Lyu1,2, Y. Li1, R. Fu1, H. Li1, F. Xue1, X. Liu1, L. Zhang1, R. Yang1
1State Key Laboratory of Experimental Hematology, Institute Of Hematology And Blood Diseases Hospital, Chinese Academy Of Medical Sciences And Peking Union Medical College, Tianjin, 2Department of Hematology, Affiliated Suzhou Hospital of Nanjing Medical University (Suzhou Municipal Hospital), Suzhou, China

Background: Primary immune thrombocytopenia (ITP) is often diagnosed in the elderly. The elderly patients have been reported to have a higher incidence of severe bleeding manifestations and a higher ITP-related mortality. Nonetheless, few data exist on the characteristics and long-term prognosis of elderly patients with severe bleeding.

Aims: We retrospectively evaluated elderly patients with ITP who had severe bleeding to determine characteristics, response to therapy and long-term outcome.

Methods: We reviewed the medical records of 517 ITP patients over 60 years of age diagnosed at our center (192 men and 325 women) between 1991 and 2012. Therapy was started at diagnosis or during follow up. Bleeding severity was assessed by the Mazzucconi’s bleeding assessment. Logistic regression analysis was used to determine which presenting features were associated with the risk of severe bleeding. Cox regression analysis was used to estimate rate ratios (RR) for no remission and mortality.

Results: Among 517 patients with ITP, 10 (1.9%) presented intracranial hemorrhage (ICH) and 74 (14.3%) presented severe (non-ICH) bleeding during ITP. According to multivariate analysis, risk of severe bleeding in patients was increased with platelet count <10x10⁹/L (P=0.001, OR=1.682, 95% CI 1.271-2.234), female patients (P=0.010, OR=2.148, 95% CI 1.200-3.844), complication of pulmonary disease (P=0.001, OR=4.724, 95% CI 1.845-12.092), gum or oral mucosal bleeding (P=0.001, OR=2.941, 95% CI 1.658-5.216) and epistaxis (P=0.027, OR=1.865, 95% CI 1.074-3.238). Compared to severe (non-ICH) bleeding, ICH was more likely incurred in severe bleeding patients with hypertension (P=0.031, OR=2.750, 95% CI 1.286-5.974). Of 103 patients simultaneously observed after diagnosis, 76 (7.7%) patients presented severe (non-ICH) bleeding and 3 (2.9%) patients presented ICH during ITP. Of 222 patients who had bleeding after treatment, 31 patients (13.9%) presented severe (non-ICH) and 4 (1.8%) patients presented ICH. Compared to observation, treatment did not significantly reduce the risk of severe bleeding (χ²=1.889, P=0.169). The total response rate (CR+H) to initial treatment in patients who presented severe bleeding was 58.1% (43/74), which was lower than that in patients without severe bleeding (70.2%, 233/340, χ²=4.014, P=0.045). The response to steroids, IVIG or combination had no significant difference among...
patients with severe bleeding. At the end of follow-up, the estimated 10-year cumulative rate of no remission among patients with severe bleeding was higher than that among patients without severe bleeding (P=0.017, RR=1.608, 95%CI, 1.052-2.456). The estimated 10-year cause-specific mortality related to fatal bleeding in patients with severe bleeding was higher than that in patients without severe bleeding (P=0.001, RR=9.886, 95% CI, 1.806-54.098). The estimated 10-year mortality among ICH patients was higher than that among severe (non-ICH) patients (P=0.009, RR=5.543, 95% CI, 1.317-15.688).

Summary/Conclusions: Platelet count <10×10⁹/L, female patients, complication of pulmonary disease, gum or oral mucosal bleeding and epistaxis are significant predictive factors for severe bleeding in the elderly. Severe bleeding in elderly ITP was associated with more failure of response to treatment, increased long-term risk of no remission and mortality related to fatal bleeding.

ATORVASTATIN IMPROVE THE PROGNOSIS OF ADULT PATIENTS WITH CORTICOSTEROID-RESISTANT IMMUNE THROMBOCYTOPENIA VIA ENHANCING BONE MARROW ENDOTHELIAL CELL FUNCTION

Y. Kong¹, X.-N. Cao¹, X.-H. Zhang¹, M.-M. Shi¹², Y.-Y. Lai¹, Y.-Q. Sun¹, Y. Wang¹, L.-P. Xu¹, Y.-J. Chang¹, X.-H. Jiang¹

¹Peking University People’s Hospital, Peking University Institute of Hematology, Beijing, China
²Peking-Tsinghua Center for Life Sciences, Academy for Advanced Interdisciplinary Studies, Peking University, Beijing, China

Background: Immune thrombocytopenia (ITP) is generally considered to be an autoimmune disorder characterized by increased peripheral platelet destruction and reduced platelet production. Corticosteroids represent the standard first-line therapy achieving responses in around 80% of patients. However, for those corticosteroid-resistant ITP patients, who exhibit either no response (NR) to corticosteroids or corticosteroid-dependent, the pathogenesis remains poorly understood and the management is challenging. Emerging evidence from mouse studies has suggested that the cross-talk between megakaryocytes (MKs), bone marrow endothelial progenitor cells (EPCs) and the bone marrow (BM) microenvironment regulates MKs maturation and thrombopoiesis. We recently reported that the impaired BM EPCs, which could be quantitatively and functionally improved by atorvastatin in vitro, induced the occurrence of poor graft function following allo-transplant (Blood, 2016, 128:2988-2999). However, little is known about the functional role of BM EPCs and how to improve impaired BM EPCs in patients with corticosteroid-resistant ITP.

Aims: To determine whether quantitative and/or functional abnormalities of BM EPCs are involved in the occurrence of corticosteroid-resistant ITP. Moreover, to investigate the effects of atorvastatin and N-Acetyl-L-cysteine (NAC, a ROS scavenger) on the number and function of cultivated BM EPCs derived from patients with corticosteroid-resistant ITP and its underlying molecular mechanisms.

Methods: Twenty-three patients with corticosteroid-resistant ITP, 30 patients with newly diagnosed ITP and 17 healthy donors (age 18-55) were enrolled from 2016 to 2017 at Peking University Institute of Hematology. BM EPCs were cultured as previously reported. Atorvastatin and NAC were administrated to the 5-day cultivated BM EPCs in corticosteroid-resistant ITP patients until tested on day 7. The number and function of BM EPCs were evaluated pre- and post-treatment using elevated lectin (sWGA) analyzed by flow cytometry represented the levels of reactive Oxygen Species (ROS) and apoptosis. Proteins expressions for p38, ERK, JNK, Akt were measured by flow cytometry and western blot. Subsequently, a single-center pilot study was performed to evaluate the efficacy and safety of atorvastatin and NAC to adult patients with corticosteroid-resistant ITP.

Methods: Twenty-three patients with corticosteroid-resistant ITP, 30 patients with newly diagnosed ITP and 17 healthy donors (age 18-55) were enrolled from 2016 to 2017 at Peking University Institute of Hematology. BM EPCs were cultured as previously reported. Atorvastatin and NAC were administrated to the 5-day cultivated BM EPCs in corticosteroid-resistant ITP patients until tested on day 7. The number and function of BM EPCs were evaluated pre- and post-treatment using elevated lectin (sWGA) analyzed by flow cytometry represented the levels of reactive Oxygen Species (ROS) and apoptosis. Proteins expressions for p38, ERK, JNK, Akt were measured by flow cytometry and western blot. Subsequently, a single-center pilot study was performed to evaluate the efficacy and safety of atorvastatin and NAC to adult patients with corticosteroid-resistant ITP.

Results: Human bone marrow EPCs were demonstrated as the spindle shape and the similar expression of CD34, VEGFR2 and CD133 at day 7 of cultivation among the 3 groups. We enrolled three cohorts of subjects increased and dysfunctional BM EPCs, which were characterized by impaired proliferation, migration, angiogenesis, and higher levels of ROS and apoptosis, were revealed in corticosteroid-resistant ITP patients compared to those in newly diagnosed ITP. Activation of p-p38 was detected in BM EPCs from corticosteroid-resistant ITP patients. Furthermore, the number and function of BM EPCs derived from corticosteroid-resistant ITP patients were enhanced by atorvastatin or NAC treatment in vitro through down-regulation of the p38 mitogen-activated protein kinase (MAPK) pathway. In the single-center pilot study, a total of 12 corticosteroid-resistant ITP patients were recruited to receive either the combination of atorvastatin and NAC or alone. All patients were randomized into two groups: the CR, R and OR rates were 25%, 41.7% (5/12) and 66.7% (8/12), respectively. In patients who achieved complete response (CR), response(R), and overall response (OR). Secondary end points were complete response (CR), response(R), and overall response (OR). Secondary end points were time to response (TTR) and adverse events.

Results: Human bone marrow EPCs were demonstrated as the spindle shape and the similar expression of CD34, VEGFR2 and CD133 at day 7 of cultivation among the 3 groups. We enrolled three cohorts of subjects increased and dysfunctional BM EPCs, which were characterized by impaired proliferation, migration, angiogenesis, and higher levels of ROS and apoptosis, were revealed in corticosteroid-resistant ITP patients compared to those in newly diagnosed ITP. Activation of p-p38 was detected in BM EPCs from corticosteroid-resistant ITP patients. Furthermore, the number and function of BM EPCs derived from corticosteroid-resistant ITP patients were enhanced by atorvastatin or NAC treatment in vitro through down-regulation of the p38 mitogen-activated protein kinase (MAPK) pathway. In the single-center pilot study, a total of 12 corticosteroid-resistant ITP patients were recruited to receive either the combination of atorvastatin and NAC or alone. All patients were randomized into two groups: the CR, R and OR rates were 25%, 41.7% (5/12) and 66.7% (8/12), respectively. In patients who achieved CR and R, the median (range) TTR was 24 days (7-51 days), with no apparent adverse events.

Summary/Conclusions: The number and the function of BM EPCs were improved by atorvastatin and NAC treatment with atorvastatin and NAC in vitro and in vivo quantitatively and functionally improved BM EPCs derived from corticosteroid-resistant ITP patients through down-regulation of the p38 MAPK pathway. Although the sample size of clinical study is small, with a relatively short follow-up period by now, our data suggest that atorvastatin and NAC are effective and safe in the management of corticosteroid-resistant ITP patients. Therefore, further prospective multicenter randomized clinical trials with larger sample size are needed in the future.
Results: The platelet desialylation levels increased significantly in the 127 septic patients with thrombocytopenia compared to the 134 patients without thrombocytopenia. A platelet response was achieved in 45 of the 54 patients in the oseltamivir group (83.3%) compared with 34 of the 52 patients in the control group (65.4%; P = 0.045). The median platelet recovery time was 5 days (interquartile range 4-6) in the oseltamivir group compared with 7 days (interquartile range 5-10) in the control group (P = 0.003). The amount of platelets transfused decreased significantly in the oseltamivir group compared to the control group (P = 0.044). The multivariate analysis by Cox proportional hazards models showed that the Sequential Organ Failure Assessment (SOFA) score and platelet recovery time were independent indicators of oseltamivir therapy.

Summary/Conclusions: Thrombocytopenia was associated with increased platelet desialylation in septic patients. The addition of oseltamivir could significantly increase the platelet response rate, shorten platelet recovery time and reduce platelet transfusion. Chinese Clinical Trial Registry, ChiCTR-IPR-16008542.

SAFETY AND EFFICACY OF LONG-TERM OPEN-LABEL DOSING OF SUBCUTANEOUS (SC) ROMIPLOSTIM IN CHILDREN WITH IMMUNE THROMBOCYTOPENIA (ITP)

J. Bussel1,*, M. Tarantino2, V. Blanchette3, A. Raj4, J. Despotovic5, D. Beam6, J. Roy7, X. Wang8, B. Mehta8, M. Eisen8

1Weill Cornell Medicine, New York, 2The Bleeding and Clotting Disorders Institute, Peoria, United States, 3Hospital for Sick Children, Toronto, Canada, 4Pediatric Blood and Cancer Disorders Clinic, Houston, 5Texas Children’s Hematology Center, Houston, 6Cook Children’s Medical Center, Fort Worth, United States, 7Children’s Health Queensland & Pathology Queensland, Saint Lucia QLD, Australia, 8Amgen Inc., Thousand Oaks, United States

Background: Children with ITP for ≥6 months who completed a romiplostim phase 1/2 or phase 3 parent study could enroll in this open label long term extension study

Aims: To evaluate the safety and efficacy of long-term romiplostim in children with ITP.

Methods: Patients enrolled at 28 sites in the US, Canada, Spain, and Australia. All patients received SC romiplostim once weekly. The initial dose was the final dose from the parent study or 1 µg/kg for patients previously receiving placebo; dose was then adjusted from 1-10 µg/kg to target platelet counts of 50−200×10^9/L. Incidence of adverse events (AEs) was the primary endpoint.

Figure 1.

Results: As of 24 Feb 2016, 66 patients entered this study; 65 received romiplostim for up to 6.2 years. At baseline, median (min–max) age was 11 (3–18) years; 56% were female; 61% were white, 14% African American, 14% Hispanic/Latino, 9% Asian, and 3% other; 9.1% had prior splenectomy. Median (min–max) baseline platelet count was 27.5 (2–458)×10^9/L. Median (min–max) treatment duration was 100 (5–321) weeks. Median (min–max) average weekly romiplostim dose was 4.8 (0.1–10.0) µg/kg, which included escalation to a stable dose. After ~week 200 (n ≤8 patients), the median dose was observed to fluctuate. All 65 patients received their doses per protocol >90% of the time; 18 patients missed ≥1 dose due to noncompliance for a total of 41 times. Reasons for discontinuing treatment (n=8), required other therapy (n=4), noncompliance (n=3), administrative decision (n=3), per protocol (n=1), and AE (n=2) (asthenia, headache, dehydration, and vomiting in one patient and anxiety in the other, per investigator, none of the AEs were treatment-related); 43 (65%) patients continued in the study. Fifty-two serious AEs occurred in 17 patients, 3 deemed treatment-related (anemia, epistaxis, and thrombocytopenia). Bleeding AEs occurred in 56 patients; 5 deemed treatment-related (gingival bleeding, petechiae, injection site bruising, injection site hematoma, and epistaxis). No thrombotic events were reported. There were no peripheral blood abnormalities warranting a bone marrow examination. No patients had anti-TPO neutralizing antibodies. From week 2 on, median platelet counts remained >50×10^9/L; platelet counts were >100×10^9/L at most timepoints, despite an observed decrease in the median dose from 4-5 µg/kg to 2-3 µg/kg around week 160 (Figure). Nearly all (94%, 61/65) patients had a platelet response (median platelet counts for a month ≥50×10^9/L). Nine (14%) patients (5 boys and 4 girls, none with prior splenectomy) entered remission (Table), defined here as platelet counts ≥50×10^9/L for 24 weeks with no ITP treatments. Twenty-three (35%) patients received rescue medications.

Summary/Conclusions: Over 6 years of data from this ongoing open-label extension study of romiplostim in children with ITP show that >90% of children achieved a platelet response with romiplostim. The safety profile was overall tolerable, similar to that in past studies. Some children (9/66) with longstanding ITP entered remission after receiving romiplostim.
Quality of life, palliative care, ethics and health economics

IMPACT OF VENEToclAX ON THE QUALITY OF LIFE OF CLL PATIENTS RELAPSED/REFRACTORY TO B-CELL RECEPTOR (BCR) SIGNALING PATHWAY INHIBITOR TREATMENT
W. Wierda1, 2, K. Saijil3, J. Potluri2, L. Noe2, R. Kamalakar2, J. Gdovin2, R. Humerickhouse2, M. Verduijn2
1The University of Texas MD Anderson Cancer Center, Houston, 2AbbVie Inc, North Chicago, United States

Background: The prognosis for patients with CLL after B-Cell Receptor inhibitor (BCR) failure is very poor. Patients with R/R CLL who discontinue and/or progress on BCRi treatment tend to have poor clinical outcomes. Venetoclax (VEN) is an oral BCL-2 inhibitor that has demonstrated deep and durable responses in relapsed/refractory (R/R) CLL patients.

Aims: To assess whether VEN has an impact on health related quality of life (HRQoL) among CLL patients R/R to BCRi treatment and receiving VEN monotherapy.

Methods: The study enrolled patients with CLL who had previously received treatment with ibritumomab and/or ideatisib, have relapsed on treatment, or experienced progression after discontinuation of either agent. Patients are to receive VEN monotherapy for up to two years, or until discontinuation due to disease progression, unacceptable toxicity, or any other reason. Patient-reported HRQoL measures included the EORTC QLQ-C30 and EORTC QLQ-CLL16, which were assessed at Baseline (BL), Week 24, and every 12 weeks thereafter. A mean change from BL to each assessment through Week 48 are reported here. Clinical relevance was based on minimum important difference (MID) of values from BL to each assessment. A change of 5-10 points is considered a “small” change on the EORTC-QLQ-C30. The lower bound of 5 points was used for MID acceptance on both measures.

Results: Median improvement in scores from BL were observed early and were sustained through week 48 in VEN treated patients in the EORTC-QLQ-C30 global health status and the role, social, and emotional functioning scales. Furthermore, early and sustained improvements in fatigue through week 48 were seen in both EORTC-QLQ-C30 and EORTC-QLQ-CLL16 (Table 1).

Table 1. (Table of data)

Summary/Conclusions: This interim analysis provides preliminary evidence that demonstrates CLL patients R/R to BCR inhibitors receiving VEN monotherapy experienced improvement in several key aspects of functioning and HRQoL. These results may be important to consider when making therapeutic choices in R/R CLL following relapse or progression on BCRi inhibitors.

P729
THE ROLE OF PSYCHOLOGICAL VARIABLES FOR TYROSINE KINASE INHIBITORS (TKI) DISCONTINUATION IN CHRONIC MYELOID LEUKAEMIA (CML) PATIENTS: IMPLICATION FOR MEDICAL DECISION MAKING PRACTICE
S. Rusu1, L. Corteletti2, Cutica1, E. Orlandi3, E. Chiara4, I. Bucelli2, A. Iurlo2, G. Pravettoni1
1Department of Oncology and Hematology, University of Milan, 2Hematology-BMT Unit, IRCCS Ca’ Granda Policlinic Foundation Hospital, Milan, 3Department of Oncology Hematology, IRCCS Policlinic San Matteo Foundation Hospital, Pavia, Italy

Background: Treatment-free remission (TFR) is an emerging goal for CML patients (pts) that reach a sustained deep molecular response (DMR), as it can reduce the risk of long-term toxicities that impair quality of life, and mitigate the costs associated with long-term TKI therapy. Therapy discontinuation may represent a great challenge for patients and different factors (not only clinical) may play a role in medical decision, such as psychological and emotional variables. In this respect, it is essential to consider pts’ concerns and preferences regarding the discontinuation option.

Aims: This study was aimed at investigating psychological (emotional and cognitive) and clinical factors related with the attitude to opt for discontinuation of therapy in CML pts.

Methods: This is an observational, prospective, no-drug related study conducted in 3 Italian centers with large experience in CML treatment. A detailed battery of questionnaires focusing on health behaviour, risk taking and personality was administered.

Results: One hundred and twenty pts were enrolled (56% males; mean age=50, SD=1.2). Median duration of the disease was 8 years (range 1-39y). 62/120 pts were receiving Imatinib first line. The idea of stopping TKI is appealing in 18% of pts, whereas 11% of them believe that a high probability of response upon restarting a TKI. Pts are more likely to stop their TKI if the risk of relapse is no more than 30% (% Mean=33.62; SD=33.46). Main worries related with the choice to stop TKI are fear of possible disease recurrence, (60.5%), fear of drug resistance if the disease relapses (44.5%) and fear to disappoint family or friends (28.9%). Older pts (>40 years) are more concerned about relapse and subsequent lack of response than younger (x²=9.65, p=0.02). Finally, pts with higher passive risk taking attitude (who are more reluctant and unadjusted in everyday-life decisions) seemed to be more afraid to lose disease control in CML. ANOVA showed a significant difference (F=5.54; p=0.021).

Summary/Conclusions: Many studies have confirmed the feasibility and safety of stopping TKI therapy in selected pts, with the potential to drastically modify clinical practice in CML management in the next future. TKI discontinuation appears appealing and challenging at the same time for many CML pts. This study, for the first time, analyses how and when pts would consider this option including implications for health care providers in clinical practice, using both a clinical and psycho-cognitive perspective.

P730
BUDGET IMPACT ANALYSIS OF BIOSIMILAR RITUXIMAB (CT-P10) FOR THE TREATMENT OF CHRONIC LYMPHOCYTIC LEUKAEMIA IN THE 28 EU MEMBER STATES
F. Rencz1,2,*, L. Gulácsi1,2, P. Baji1,2, M. Péntek1,2, V. Brodsky1,2
1Department of Health Economics, Corvinus University of Budapest, 2HTA Consulting Budapest, Budapest, Hungary

Background: In December 2016, the European Medicines Agency’s Committee for Medicinal Products for Human Use has recommended granting marketing authorization to biosimilar rituximab (CT-P10) in all indications of the reference product, including chronic lymphocytic leukaemia (CML). Compared to the originator rituximab, significant price reductions are expected for the reference product offering a more affordable treatment option for CML patients across Europe.

Aims: To assess the budget impact of the introduction of CT-P10 into the treatment of CML in the 28 EU member states. Moreover, we provide an estimation for the number of additional CML patients that can be treated with CT-P10 from the cost savings.

Methods: A budget impact analysis was performed to evaluate the one-year cost outcomes under two scenarios with and without the availability of CT-P10. The budget impact was calculated as the difference in costs between the two scenarios. For the major European markets, five-year cost savings were estimated. Market uptake of CT-P10 was assumed to be 30%. A third party payer’s perspective was adopted, and only drug costs were considered. Based on expert opinion, it was assumed that when CT-P10 is entering the market it will be at 50-70% of the official list price of originator rituximab in each country. Costs of administration and monitoring were not incorporated in the calculations, as it can be assumed that these are equal for the reference product and CT-P10. The initial number of patients treated with rituximab was estimated from IMS sales data on total annual consumption of originator rituximab in 2016. Other model parameters such as patients’ average body surface area and treatment rate of rituximab among CML patients, were derived from the published literature. One-way sensitivity analysis was undertaken to test the robustness of model assumptions.

Results: Over a one year time horizon, the cumulative budget impact of adopting CT-P10 is estimated to be €17.80 million in the 28 EU member states (30% discount in drug prices compared to the originator rituximab). Countries responsible for the majority of the cost savings are Germany (€4.06 million), Italy (€3.15 million), France (€2.41 million), Spain (€1.50 million), the UK (€1.34 million), Poland (€0.80 million), Austria (€0.66 million), the Netherlands (€0.59 million), Finland (€0.49 million) and Sweden (€0.43 million). If the cost savings were used to treat additional CML patients with CT-P10, a total of 1,624 patients could be treated annually throughout Europe. The potential cost savings in the future are in a direct correlation with the price and market uptake of CT-P10. Applying a 40% and 50% discount in drug prices compared to the originator rituximab, cost savings are projected to €23.73 and €29.67 million, from which further
2,526 and 2,706 CLL patients could be treated with CT-P10, respectively. Over five years, the total cost savings are expected to reach €29.81 million in Germany, €23.10 million in Italy, €17.65 million in France, €10.98 million in Spain and €9.83 million in the UK.

Summary/Conclusions: Biosimilar rituximab has the potential to improve the affordability of CLL treatments and ease the burden of healthcare costs in Europe. Although the UK was the only country where FTF consultations were in place for CT-P10. Using the cost savings to treat additional patients would substantially increase the access to better cancer medications, and thus contribute to a longer survival as well as better quality of life outcomes in CLL.

Background: Therapeutic advances in multiple myeloma (MM) mean that patients have extended periods of remission without need for active anti-myeloma therapy. This provides an opportunity to review how these patients are managed and design patient-centred healthcare systems. Remote monitoring systems have been implemented for other cancer patients in remission.

Aims: We aimed to explore patient needs during stable remission from MM and investigate factors influencing their acceptability of remote monitoring.

Methods: Patients with stable MM in a treatment-free interval selected from outpatient clinics at a tertiary centre completed a survey which explored the acceptability of various methods of remote monitoring. Subsequently semi-structured interviews were conducted by an independent researcher to investigate factors influencing this preference. Interviews were carried out until saturation of themes, transcribed verbatim and thematic analysis was performed using open coding by a doctor, physiotherapist and psychologist.

Results: 78 patients were surveyed; the most acceptable alternative was a telephone clinic (with doctor 77%, nurse 69%). 19 interviews were conducted exploring the acceptability of remote monitoring. A screening tool for its identification.

P731
AN INVESTIGATION INTO THE NEEDS AND PRIORITIES OF PATIENTS WITH MULTIPLE MYELOMA DURING REMISSION–IMPLICATIONS FOR RE-DESIGNING PATIENT-CENTRED HEALTHCARE SYSTEMS

D. De-Silva1,2, J. Land2, M. Heinrich2, J. Galinsky3, Y. Reyal4, N. Rabin3, A. Mehta3, K. Yong1

P732
COST-EFFECTIVENESS OF RITUXIMAB IN ADDITION TO STANDARD OF CARE CHEMOTHERAPY FOR ADULT PATIENTS WITH ACUTE LYMPHOCYTIC LEUKAEMIA

J. Iannone1, M. Albinati2, G. Miltenkovski1, K. Paulsson3, S. Yungener1, M. Sefelt4, G. Hoffmann-La Roche Limited, Mississauga, 2Provincial Oncology Drug Program, 3Haematology and Medical Oncology, CancerCare Manitoba, 4Internal Medicine, University of Manitoba, Winnipeg, Canada

Background: In The Group for Research on Adult Acute Lymphoblastic Leukemia (GRAALL-R) study, the addition of the monoclonal antibody rituximab to standard chemotherapy for Philadelphia chromosome-negative, CD20-positive, B-cell precursor Acute Lymphoblastic Leukemia (CD20+ Ph- BCP-ALL) resulted in improved clinical outcomes. However, the cost-effectiveness of rituximab for this indication has not been previously evaluated. A definitive answer is of a high level of uncertainty and requires examining this question in the context of the Canadian publicly funded health care system.

Aims: To determine the economic impact in Canada of the addition of rituximab to standard of care (SOC) chemotherapy vs SOC alone in newly diagnosed CD20+ Ph- BCP-ALL.

Methods: Standard of care consisted of the two most widely used chemother-apy regimens for adults with ALL in Canada: hyper-CVAD or the Dana Faber Cancer Institute (DFCI) ALL consortium. A decision analytic model included the following health states over a 15-year time-horizon: event-free survival, relapsed/resistant disease, cure (death from causes other than ALL, given ≤5 years’ event-free survival), overall survival, overall survival with subsequent event (SAE) and death from causes other than ALL. Event and survival rates were estimated from the GRAALL-R randomized controlled trial by Maury et al. Costs of the model included: first-, second- and third-line treatment and administration; disease management/palliative care; and SAE-related treatments. Model inputs were sourced from public data, literature and provincial cancer agency inputs. Results are presented using probabilistic sensitivity analysis and Monte Carlo simulation incorporating uncertainty around all model inputs.

Results: Life years increased by 1.33 years (95%CI: 0.10-2.63 years) with rituximab in addition to SOC vs SOC alone. Quality-adjusted life-years (QALYs) increased by 1.15 QALYs (95%CI: 0.34-1.93 QALYs) with rituximab in addition to SOC. The incremental cost of rituximab plus SOC was C$46,624 (95%CI: C$28,881-C$56,515), chiefly due to the drug acquisition costs of rituximab. Superior relative EFS associated with rituximab in addition to SOC drove lower second-line treatment and palliative care use, resulting in modest cost savings. The incremental mean Incremental Cost-Effectiveness Ratio (ICER) was C$40,505/QALY. At a willingness-to-pay threshold of C$100,000/QALY, the probability of being cost-effective was 96%. Decision outcomes were robust to the probabilistic and deterministic sensitivity analyses, including the SOC backbone as either hyper-CVAD or DFCI.

Summary/Conclusions: For adults with CD20+ Ph- BCP-ALL, rituximab in addition to SOC is a cost-effective intervention compared to SOC alone, from a Canadian public payer perspective. Rituximab is associated with increased life years and increased QALYs at a reasonable incremental cost.
avoid reverse causation. Conditional logistic regression analyses were adjusted for birth weight (large for gestational age) to control confounding. Cases with Down syndrome were excluded from the analyses.

Results: Overall, 13 cases (1.2%) and nine controls (0.3%) had a record indicating at least one CT examination. Of the relevant CT scans, 50% were performed on the head region and 41.3% the thorax region. The median age at CT scan was 8.12 years (7.46 years for cases and 10.0 years for controls). In a conditional logistic regression analysis adjusted for birth weight, a significantly increased leukemia risk (OR=4.75, 95% CI 1.55, 14.5) was found for any CT examination (one or more) at least two years prior to leukemia diagnosis. When comparing one CT examination and two or more CT examinations with no examinations the ORs were respectively 2.78 (95% CI 0.73, 10.5) and 16.9 (95% CI 1.81, 150).

Summary/Conclusions: In our preliminary analyses we observed a substantial increase in childhood leukemia risk related to pediatric CT scans. The risk estimates are materially higher than in two earlier studies1,2 and need to be interpreted with caution. We will seek to estimate radiation doses to the red bone marrow, based on limited data available on CT examinations (body part and examination type).

RADIATION EXPOSURE FROM CT IMAGING AND CHILDHOOD LEUKEMIA: A NATIONWIDE CASE-CONTROL STUDY

A. Nikkilä1,*, J. Raitanen2,3, O. Lohi4, A. Auvinen4,5
1Faculty of Medicine and Biosciences, 2Faculty of Social Sciences, University of Tampere, 3UKK Institute for Health Promotion, 4Tampere Center for Child Health Research, Tampere University Hospital and University of Tampere, Tampere, 5STUK - Radiation and Nuclear Safety Authority, Helsinki, Finland

Background: Pediatric CT imaging offers significant benefits in clinical practice. However, children are more sensitive to carcinogenic effects of ionizing radiation than adults and red bone marrow is especially radiosensitive tissue type. The risk estimates of low doses of ionizing radiation are mainly1,2 based on extrapolated results of studies done with substantially higher radiation doses and there exists a need to assess the risks of low doses with a more direct approach.

Aims: We assessed the leukemia risk in children after computed tomography imaging studies with high-quality Finnish register data and data from hospital databases.

Table 1.

| Table: Odds ratios and frequencies of CT scans |
|-----------------|-----------------|-----------------|
| **Cases** | **Controls** | **TOTAL** |
| **OR (95% CI)** |
| CT scans | 0 | 3268 | 3011 |
| 1 | 5 | 12 | 17 |
| 2 or more | 5 | 15 | 20 |
| by type | 1 or more | 9 | 19 |
| | 4.75 (2.53, 15.4) |
| | 1.50 (0.23, 10.5) |
| by age-group | ALL | 6 | 8 |
| | 0.74 (0.46, 1.19) |
| | OTHERS | 3 | 5 |
| | 2.03 (0.28, 15.4) |
| The reference group for all calculated ORs is zero CT scans. |

Methods: We used nationwide, register-based case-control study design to investigate the role of CT imaging in the etiology of childhood leukemia. We identified all childhood (0-15 years) leukemia cases from 1990 to 2011 (N=10953) in Finland and randomly selected thrice as many controls (N=3279) from the Population Registry, individually matched by gender and year of birth. The cases were 81% (N=885) acute lymphoblastic leukemias and 13% (N=142) acute myeloid leukemias. We collected data on all pediatric CT scans from 1975–2011 from the databases of all five university hospitals in Finland and two large central hospitals. In total, we identified 46 CT scans to our subjects. We approximated that this approach covers 81% of all pediatric CT scans performed in Finland from 1975 to 2011. We used a two-year latency period to avoid reverse causation. Conditional logistic regression analyses were adjusted for birth weight (large for gestational age) to control confounding. Cases with Down syndrome were excluded from the analyses.

Results: Overall, 13 cases (1.2%) and nine controls (0.3%) had a record indicating at least one CT examination. Of the relevant CT scans, 50% were performed on the head region and 41.3% the thorax region. The median age at CT scan was 8.12 years (7.46 years for cases and 10.0 years for controls). In a conditional logistic regression analysis adjusted for birth weight, a significantly increased leukemia risk (OR=4.75, 95% CI 1.55, 14.5) was found for any CT examination (one or more) at least two years prior to leukemia diagnosis. When comparing one CT examination and two or more CT examinations with no examinations the ORs were respectively 2.78 (95% CI 0.73, 10.5) and 16.9 (95% CI 1.81, 150).

Summary/Conclusions: In our preliminary analyses we observed a substantial increase in childhood leukemia risk related to pediatric CT scans. The risk estimates are materially higher than in two earlier studies1,2 and need to be interpreted with caution. We will seek to estimate radiation doses to the red bone marrow, based on limited data available on CT examinations (body part and examination type).

References
The questionnaire examined patient’s emotions and perceptions during rituximab administration in lymphoproliferative malignancies. Among the 40 patients, 55% were affected by DLBCL and 45% by FL. Over the study period of 2010-2016, we have observed a constant increase in the number of new patients diagnosed with myeloma. The incidence rate in males was 3.8 cases per 100,000 inhabitants/year, compared to 2.2 cases per 100,000 inhabitants/year in females. The incidence of new cases increased from 2010 to 2016, with a peak in 2015 (4.5 cases per 100,000 inhabitants/year) and a decline in 2016 (3.5 cases per 100,000 inhabitants/year).

We retrospectively analysed the incidence of patients with new diagnosed of Multiple Myeloma (NDMM) from 1998 to 2012. We have observed a constant increase in Annual Average of incidence from 4.57 cases/100000 inhabitants/year in the first period to 6.15 in the last. Adjusted by Age Incidence increase from 14 to 18.5 cases in the O65 group. From 2013 to 2016 global and adjusted by Age Incidence remains similar to last years data with 80 new cases and 3.9 cases per 100000 inhabitants/ year from the 1st period to 6.15 in the last. Adjusted by Age Incidence remains similar to last years data with 80 new cases and 3.9 cases per 100000 inhabitants/year. After IMWG 14 criteria to begin treatment in NDMM patients can increment its incidence. New expensive but very effective and well tolerated antilymoma agents are in the center of attention of Hematologic and Public Healthcare Systems. There are data of improvement of survival that can increment of prevalence.

Aims: We have analysed our data base and calculate incidence by sex, age and three 5-years periods of time at diagnosis and obtain tendencies to get ready for next decade of ageing population. We have analysed prevalence of MM patients on last 7 years with cutoff date on 1st of November (2010 to 2016).

Methods: We retrospectively analysed the incidence of patients with new diagnostic of Multiple Myeloma (NDMM) from 1998 to 2012. (Fig.1). Then we divide the cohort in several groups: sex and age at diagnosis (3 groups: <65, 66-75 and >75) and in four 5-year (quinquennium) period of time (1998-2002, 2003-07, 2008-12, 2013-2016). (Fig. 2). We have calculated the incidence per 100000 inhabit/year using census data of our Local Registry of Tumours of our Public Health Area. Characteristics of patients: n= 346. M/F: 206/140. Median age at diagnosis: 74 years (Range: 39-100).

Results: A) INCIDENCE RATES (see Table). In the past IMWG (Roma 14#PO197) we reported incidence rates form 1998 to 2012. We observed a constant increase of Annual Average of incidence from 4.57 cases/100000 inhabitants/year in the first period to 6.15 in the last. Adjusted by Age Incidence increase from 14 to 18.5 cases in the O65 group. From 2013 to 2016 global and adjusted by Age incidence remains similar to last years data with 80 new cases in the 4 year-period (5,9 cases for global population and 17,2 cases for over65 population).

B) PREVALENCE RATES (PreVR).
- 2012. 77 pats alive. PreVR: 22.2 /100000 inhabit;
- 2014. 84 pats alive. PreVR: 24.4/100000 inhabit;
- 2016. 103 pats alive. PreVR: 30.3 /100000 inhabit.

Table 1.

Summary/Conclusions: Although we don’t observe substantial changes on incidence rates of NDMM, we have noted an important rise on prevalence rates of more than 40% from 2010 to 2016 (21.2 to 30.3 pats alive /100000 inhabit.) Several new antiMM drugs are available in the therapeutic arsenal and probably increases the prevalence rates.
P738
HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR ISOLATED EXTRAMEDULLARY RELAPSE OF ACUTE LYMPHOBLASTIC LEUKEMIA IN CHILDREN

M. Gabeli1, C. Messina1, M. Zecca2, A.M. Rovelli3, F. Fagioli4, E. Lanino5, F. Porta6, M. Caniglia12, P. Di Bartolomeo13, P. D’Angelo14, A. Bertaina15, F. Locatelli15

Background: Although most children affected by Acute Lymphoblastic Leukemia (ALL) are cured with current protocols, relapses still occur in the bone marrow as well in extramedullary sites, mainly the central nervous system (CNS) and the testicles. Although combined therapy is the current treatment for isolated extramedullary relapse (EMR) it is still controversial. To address this issue, we collected data of patients treated with hematopoietic stem cell transplantation (HSCT) for ALL EMR from 19 centers, members of the Italian Pediatric Onco-Hematology Association (AIEOP).

Methods: From 1990 to 2015, 281 children (1-18 years) underwent HSCT for ALL EMR from 19 centers, members of the Italian Pediatric Onco-Hematology Association (AIEOP). Treatment protocols were based on Berlin-Frankfurt-Münster (BFM) Study Group concept, as well as definitions of EMR, CNS relapse, and time of relapse (very early/early/late). HSCT was performed in second complete remission (CR2) or subsequent remission (CR>2), even patients transplanted with active disease were included in the analysis. If a matched familiar (MFD) or a matched unrelated donor (MUD) was available, HSCT was performed from one of these; if not, the single center decided to perform autologous HSCT (Auto HSCT) or haploidentical HSCT (Tnaplo HSCT).

Results: Of the 281 patients (203 male, 78 female) 167 presented relapse confined to CNS, 73 to testes, 14 to mediastinum, 11 to CNS + other sites and 18 to other organs. Thirty one percent of children experienced a late relapse, 34.5% an early relapse, 31% a very early relapse, for 3.5% the time of relapse is not known. Ninety-seven patients underwent auto HSCT, 79 MFD HSCT, 75 MUD HSCT and 30 Haplo HSCT. At transplantation 72.6% of children were in CR1, 21.0% in CR2 and 6.4% were not in remission Total body irradiation (TBI) was part of 83.6% of conditioning regimens. Overall survival (OS) for the entire cohort was 87% at 3 years and 82% at 5 years. Patients transplanted with active disease (n=43). Patients received largely myeloablative regimens (n=38), or cord blood donor SCT (n=38) in CR1 (n=103), CR2+ (n=105), or CR>2 (n=85), matched- or 1-antigen mismatched unrelated (n=43). Patients received largely myeloablative regimens (n=38), or cord blood donor SCT (n=38) in CR1 (n=103), CR2+ (n=105), or CR>2 (n=85). Twelve percent of patients were transplanted from 1995 to 2000.

Summary/Conclusions: Of the 281 patients treated with hematopoietic stem cell transplantation for isolated extramedullary relapse, the only factors influencing outcome were number of CR and year of transplantation. Patients in CR2 had the better OS (64%), those transplanted with disease had an OS of 44%, those transplanted with active disease had an OS of 38%. TRM for the entire cohort was 10% at 100 days, 11% at 6 months and 1 year and 16% at 10 years, with no difference between HSCT types. Multivariate analysis was conducted after exclusion of patients with active disease at HSCT: the only factors influencing outcome were number of CR and year of transplantation. Patients in CR2+ have a risk of death 2.3 times greater than those in CR2. Children treated after 2000 have half the risk of death then those treated from 1995 to 2000.

P739
PREDICTIVE FACTORS FOR DEVELOPING VENO-OCCCLUSIVE DISEASE IN CONJUNCTION WITH ACUTE LYMPHOBLASTIC LEUKEMIA TREATED WITH INOTUZUMAB OZOGAMICIN FOLLOWED BY ALLOGENIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

P. Kebriaei1,2, R. Saliba1, W. Wallis1, R. Garris3, C. Ledesma1, G. Rondon1, U. Popat1, A. Alousi1, S. Ahmed1, B. Oran1, E. Shpali1, S. Ciurea1, F. Ravandi1, K. Rezvani1, D. Marin1, R. Champlin1, H. Kantarjian3, E. Jabbour3

1Stem Cell Transplantation and Cellular Therapy, 2Pharmacy Clinical Programs, 3Leukemia, University of Texas M.D. Anderson Cancer Center, Houston, United States

Background: Inotuzumab ozogamicin (IO) is a CD22 monoclonal antibody attached to calicheamycin and targets B lymphocytes in early stages of development. In a randomized study of IO compared with conventional salvage therapy in patients with refractory relapsed B-ALL, patients treated with IO had higher complete response rates (81% vs 29%, p<0.001), and a greater proportion of patients proceeded to allogeneic hematopoietic stem cell transplantation (SCT) (41% vs 11%, p<0.001). However, patients treated with IO prior to SCT were also noted to have higher rates of veno-occlusive disease (VOD) compared to the SCT group without IO exposure (11% vs 1%) (Kantarjian NEJM 2016).

In an effort to further investigate this finding, we reviewed transplant outcomes for patients with and without IO exposure.

Methods: We performed a nested control comparison of patients transplanted during the years when they were being treated with IO on a number of clinical trials at our institution.

Results: Between 6/2010 and 10/2016, 251 patients with B-ALL with a median age of 35 years (range, 4-70 years) received an allogeneic matched sibling (n=85), matched- or 1-antigen mismatched unrelated (n=38), or cord blood donor SCT (n=38) in CR1 (n=103), CR2+ (n=105), or with active disease (n=43). Patients received largely myeloablative regimens (busulfan- (64%), fludarabine- (29%) or total body irradiation-based (TBI) (7%). 19% of patients received double allograft regimens consisting of cyclophosphamide-TBI, fludarabine-melphalan-thiotepa, or busulfan-clofarabine-thiotepa. IO was administered to 69 (27%) patients prior to SCT. A median of 3 cycles of IO were administered (range, 1-5 cycles) at a median of 18 days post SCT (range, 6-144 days). Patients were heavily pre-treated, including 18 who had a prior allogeneic SCT. VOD was noted in 21 patients overall (8%) with median onset 19 days following SCT (range, 7-230 days); fatal VOD was noted in 5 patients (2%). VOD was noted in 11 patients treated with IO (16%), and it was fatal in 2 patients (3%). Factors noted to be significant in contributing to VOD in univariate analysis were prior exposure to IO (HR 3.05, 95% C.I. 1.3-7.2, p=0.01) and receiving a busulfan-based transplant preparative regimen (HR 3.4, 95% C.I. 1.02-10, p=0.05); not receiving a prior SCT was significantly protective (HR 0.3, 95% C.I. 0.1-0.8, p=0.02). Number of IO cycles, time from IO to SCT, age, and donor relation were not found to be significant factors for developing VOD. In efforts to predict the risk for VOD in a patient who has received prior IO, we performed a classification and regression tree analysis (CART) and noted that the combination of IO and a double allograft preparative regimen was significantly associated with the risk for developing VOD (HR 5.9, 95% C.I. 1.9-18, p=0.002).

Summary/Conclusions: Fatal VOD is a rare occurrence. However, IO exposure prior to SCT increases the risk for any VOD. Furthermore, IO exposure followed by a double allograft preparative regimen increases this risk nearly 6-fold, and should be avoided in these patients.
We report 41 allo-HCTs: 37 from MUD and 4 from MRD performed in 2004-2016. Median age of recipients was 60 (20-71) years and donors 30 (19-53), median time from diagnosis to allo-HCT was 16 (2-307) months. Median size of PNH clone was 80% granulocytes (0.5%>100%). Indication for allo-HCT was PNH with aplastic/hypoplastic bone marrow (19 pts), MDS (2 pts), overlapping MDS/aplasia (3 pts), severe course of PNH with hemolytic crises and transfusion-dependency without access to eculizumab (17 pts). Additional risk factors were Budd-Chiari syndrome and hepatosplenomegaly (1 pt), history of renal insufficiency requiring hemodialysis (2 pts), chronic hepatitis B (1 pt) and C (1 pt). The preparative regimen consisted of treosulfan 3x14 g/m² plus fludarabine 5x30mg/m² (31 pts) or treosulfan 4x14 g/m² plus cyclophosphamide 4x40mg/kg (10 pts). GVHD prophylaxis consisted of cyclosporine-A, methotrexate and pre-transplant ATG in MUD-HCT. 2 pts instead of cyclosporine-A received mycophenolate mofetil and tacrolimus. Source of cells was bone marrow (13 pts) or peripheral blood (28 pts) with median 6.3x10^10NC/kg, 7.5x10^6CD34+cells/kg, 24.7x10^6D3+cells/kg and a median number of 3000-7000 cells/µl. TRAEs for these subgroups were similar to the overall study results. Factors contributing to survival in these pts is a potential area for future exploration.

P742
A COMPARISON OF CLINICAL OUTCOMES BETWEEN MATCHED SIBLING DONOR (MSD) AND UNRELATED DONOR (URD) STEM CELL TRANSPLANTATION IN ADULT PATIENTS WITH SEVERE APLASTIC ANEMIA
1Hematology, Yeouido St. Mary’s Hospital, College of Medicine, The Catholic University of Korea, 2Hematology, Catholic Blood and Marrow Transplantation Center, Seoul St Mary’s Hospital, College of Medicine, The Catholic University of Korea, 3Hematology, Incheon St Mary’s Hospital, College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea

Background: Allogeneic stem cell transplantation (SCT) using HLA-matched unrelated donor (URD) has been usually regarded as a subsequent option in patients with severe aplastic anemia (SAA), who have failed to immunosuppressive treatment (IST). However, recent improved outcomes of URD SCT lead to its extended role for treating those lacking HLA-matched sibling donor (MSD).

Aims: Through this study, we intended to verify the possibility of URD SCT as a front-line treatment for SAA patients.

Methods: We compared outcomes of consecutive SAA patients who received SCT from 8/8 well-matched URD (WM-URD; n=61) and partially (6/8 or 7/8) matched URD (PM-URD; n=33) with 8/8 matched MSD (n=126) at our institution between Mar 2002 and Dec 2016. Patients receiving MSD and URD SCT were conditioned with fludarabine (180mg/m²) / cyclophosphamide (100mg/kg IV) plus rabbit ATG (10mg/kg IV), and total body irradiation (fractionated 800cGy) / cyclophosphamide (100-120mg/kg IV) with/without rabbit ATG (2.5mg/kg IV), respectively.

Results: Median age of the WM-URD and the PM-URD groups were significantly lower compared to that of the MSD group (29 yrs, 31 yrs, and 39 yrs; P<0.01), with a high proportion of those experiencing IST failures before SCT (80.3%, 90.9%, and 33.3%; P<0.01). Median days to neutrophil engraftment of the MSD group was significantly shorter compared to those of the WM-URD and the PM-URD groups across all subgroups (13 days, 16 days, and 16 days; P<0.01). The incidence of acute and chronic GVHD of the WM-URD and the PM-URD groups were significantly higher compared to those of the MSD group (42.6% and 63.6% vs 9.5%; P<0.01, and 44.6% and 33.3% vs 8.9%; P<0.01, respectively). When we compared the incidence of transplant-related mortality (TRM; 10.7% vs 7% and 6%; P=0.53) and overall survival rate (OS; 89% vs 92% at 6 years; P=0.52) between the WM-URD and the MSD groups, there were no significant difference. However, trends of higher TRM incidence (18.2% vs 7% at 4 years; P=0.05) and lower OS rate (81.8% vs 92.5% at 6 years; P=0.05) were observed between the PM-URD and the MSD groups. There was no primary graft failure in any group. Post-HSCT graft failure of both WM-URD (0% vs 18.3%; P=0.01) and PM-URD (0% vs 18.3%; P=0.02) groups were significantly lower compared to that of the MSD group. When we adjusted other clinical and transplant-related factors, which include age and IST failure, using multivariate

Summary/Conclusions: In this study, diagnostic criteria requiring onset by day 21 would exclude >26% of pts with VOD/SOS, with more than a third of these being pediatric pts. This highlights the importance of including late-onset VOD/SOS in diagnostic criteria. With DF, 52.8% were estimated to survive to Day +100 (60.4% of pediatric and 48.7% of adult pts). TRAEs for these subgroups were similar to the overall study results. Factors contributing to survival in these pts is a potential area for future exploration.

Support: Jazz Pharmaceuticals.
analysis, the OS rate of the WM-URD group was not significantly different (HR 1.45, 95% CI: 0.52-4.09; P=0.48), whereas that of the PM-URD group was significantly lower (HR 2.85, 95% CI: 1.01-8.02; P=0.04), compared to that of the MSD group.

Summary/Conclusions: Our study showed that there was no significant difference in OS rate between the WM-URD and the MSD groups. As high incidence of GVHD remains a problem in the former group, strategies to reduce it are needed in future protocols.

P743
HAPLOIDENTICAL ALLOGENEIC STEM CELL TRANSPLANT IN SEVERE THALASSEMSIA PATIENTS
S. Hongeng1,*, S. pakakasama1, U. anurathapan1, B. Andersson2
1Pediatrics, Ramathibodi hospital, Mahidol University, Bangkok, Thailand,
2Stem cell transplantation, MD Anderson Cancer Center, Houston, United States

Background: Thalassemia free survival after allogeneic stem cell transplantation (SCT) is about 80–90% with either matched related or unrelated donors. However, the probability of finding a HLA-compatible donor is less than 50%. We explored the use of a mismatched related (“Haplo-”) donor.

Aims: To evaluate the outcome of SCT with Haplo donors in severe thalassemia patients

Methods: All patients received two courses of pre-transplant immunosuppression therapy (PTIS) with fludarabine (Flu) 40mg/m2/d together with dexamethasone (Dxm) 25mg/m2 for 5 d to facilitate engraftment. After two courses of PTIS, a reduced-toxicity conditioning regimen of rabbit anti-thymocyte globulin (ATG) 50mg/kg on days SCT -12,-11,-10. Flu 35mg/m2 on days SCT -7,-6,-5,-4,-3,-2 and IV Busulfan (Bu) 130mg/m2 on days SCT -7,-6,-5,-4 was given followed by T-cell replete peripheral blood progenitor cells (PBPC). GVHD prophylaxis consisted of cyclophosphamide (Cy) 50mg/kg on days SCT -3 and +4 (Post-Cy), and on day SCT +5 tacrolimus or sirolimus was started together with a short course of mycophenolate mofetil.

Results: Fifty-one patients underwent haplo-SCT. Their median age was ten years (range, 2 to 28 years). Forty-nine patients engrafted with 100% donor chimera. Two of five patients with high titers of donor-specific anti-HLA antibodies suffered primary graft failure. Median time to neutrophil engraftment was 14 days (range, 11 to 18 days). Eight patients developed mild to moderate, reversible veno-occlusive disease, while twelve patients developed acute GVHD grade II, that quickly responded to steroid therapy. Only seven patients developed limited chronic GVHD. Projected overall and event-free survival rates at two years are 95% and 94%, respectively. The median follow up time is 18 months (range;10 to 50 months).

Summary/Conclusions: This haplo-SCT protocol may yield excellent outcomes for thalassemia patients, and provide a treatment option for patients lacking a HLA-matched donor.

P744
AUGMENTATION OF FLUDARABINE AND BUSULFAN-BASED MYELOABLATIVE REGIMEN WITH THIOTEPA IMPROVES OUTCOMES WITH NO ADDED TOXICITY IN ALLOGENEIC STEM CELL TRANSPLANTATION FOR ACUTE MYELOID LEUKAEMIA
V.S. Sheel1, N. Boaz1, S. Grisarivi1, B. Avni1, R. Orl1, M. Shapiro1
1Stem cell transplant, HADASSAH, Jerusalem, Israel

Background: Allogeneic stem-cell transplantation (HSCT, alloSCT) is the most effective way to control leukemia relapse for patients with acute myeloid leukemia (AML). Busulfan and Cyclophosphamide (Bu/Cy), the current standard of care, in allogeneic transplant for acute myeloid leukemia (AML), is limited by increased treatment related mortality. Myeloablative doses of Busulfan (12-8mg/kg) with Fludarabine (160mg/m2) (Flu-Bu), has reduced toxicity, however with the limitation of increased relapses. We have tried to improve outcome of Flu-Bu regimen by augmentation with Thiotepa (10mg/kg). Here we compared outcomes of 45 such patients (getting augmented regimen, Flu-Bu with the addition of Thiotepa, (group 2), to 44 patients who received Fludarabine, Busulfan myeloablative reduced toxicity regimen (group 1), during the same period.

Aims: The primary objective of the report was to compare the toxicity and incidence of relapse between the two regimens. Secondary objective was to compare overall survival (OS), and disease-free survival (DFS), the non-relapse mortality (NRM), engraftment kinetics, incidence of acute and chronic graft versus host disease (GVHD), and comparison between high and low-risk patients amongst the two groups.

Methods: 89 patients with AML were retrospectively analyzed. 44 patients were conditioned with Flu-Bu (group 1) and 45 patients augmented with Thiotepa (Flu-Bu-TT, group 2). The transplant conditioning regimen, (augmented myeloablative) consisted of 30mg/m2 intravenous Fludarabine for 5 days (total dose 150mg/m2), for matched related donors or for 6 days (180mg/m2), for unrelated or mismatched donors, intravenous Busulfan (3.2mg/kg/day for 4 days, total dose 12.8mg/kg), and intravenous Thiotepa 5mg/kg for 2 days (10mg/kg). The conventional myeloablative regimen was identical, however without the addition of Thiotepa.

Results: Toxicities were comparable, with mucositis in 7 patients (15%) in group 1 and 8 patients (17%) in group 2, (p=1.0), severe sepsis in 4 (9%) in group 1 and 3 (6%) in group 2, (p=0.7), severe venoocclusive disease in 2% of group 1 and 4% of group 2, (p=1.0) and comparable non- relapse mortality (NRM). 5-year disease free survival (DFS) median follow up of 5 years, was significantly better in group 2, 38% for group 1, and 62% in group 2, (p=0.02) and 5-year overall survival showed trend towards benefit in group 2 (62% vs 42%, p=0.06). 14/30 (46%) patients in group 1 relapsed, as compared to 4/31 patients, (12%, p=0.005) in group 2, considering NRM as competing risk.

Figure 1.
Summary/Conclusions: In conclusion, the outcome of augmented regimen (DFS and OS) is superior Flu-Bu regime, mainly due to reduction in relapses, with comparable toxicities and could eventually replace Bu/Cy.

P745
PROGNOSTIC TOOLS CAN PROVIDE PERSONALIZED OUTCOMES PREDICTION AFTER ALLOGENEIC HCT IN PATIENTS WITH HEMATOLOGIC MALIGNANCIES
C. Choi1,*, S. Devlin2, P. Hilden3, M. Maloy1, M. Horowitz3, J.D. Rizzo3, B. Logan3, P. Barba4, R. O'Reilly5, S. Frei6, M. Frei6
1Adult Bone Marrow Transplant Service, Department of Pediatrics, 2Department of Biostatistics and Epidemiology, Memorial Sloan Kettering Cancer Center, New York, NY, 3Medical College of Wisconsin and Center for International Blood and Marrow Transplant Research, Milwaukee, WI, United States, 4Department of Hematology, Hospital Vall d’Hebrón, Universitat Autonoma de Barcelona, Barcelona, Spain, 5Bone Marrow Transplant Service, Department of Pediatrics, Memorial Sloan Kettering Cancer Center, New York, NY, United States

Background: Current prognostic indices for allogeneic HCT (alloHCT) outcome often focus on a limited set of factors, be they patient characteristics, disease features, or transplant approaches. We sought to evaluate two comprehensive prognostic models in a large sample of patients undergoing alloHCT with CD34 selection (CD34 alloHCT).

Aims: To evaluate two comprehensive prognostic models: The first combining the HCT-Comorbidity Index (HCT-CI) and Disease Risk Index (DRI); the second applying the Center for International Blood and Marrow Transplant Research (CIBMTR) One Year Survival Outcomes Calculator, which uses large-scale multicenter data reported to the CIBMTR to provide patient-specific predictions on survival 1 year after first alloHCT.

Methods: This retrospective analysis included adult recipients of first alloHCT with CD34+ selected PBSCs from 7/8 or 8/8 donors for AML, ALL, or MDS at a single center between 1/2000 and 12/2015. The Kaplan-Meier (KM) method estimated OS and RFS. The cumulative incidence method for competing risks estimated relapse and nonrelapse mortality. We evaluated univariate association between variables of interest and OS/RFS using the log-rank test. Cox regression models assessed the adjusted effect of covariates on OS/RFS. We then determined predicted 1 year OS for each patient using the CIBMTR Calculator. Patients were divided into groups based on predicted OS probability.
Aims: We had generated two composite endpoints: in both III-IV acute GVHD (aGVHD), relapse, death or chronic GVHD (cGVHD) requiring systemic treatment. In 2016 EBMT annual meeting a redefinition of this endpoint was proposed changing cGVHD event from those patients with cGVHD requiring systemic treatment (the original one) to those with just severe cGVHD (the redefined one).

Table 1.

Background: Disease free survival is the most used common endpoint for clinical research on allogeneic stem cell transplantation (HSCT), but it doesn’t include morbidity endpoints or those which affect their quality of life as graft failure (GF), disease relapse, or death. Furthermore, this endpoint may overestimate the benefit of new treatments if baseline differences exist. All-cause mortality (ACM) and disease free survival (DFS) are composite endpoints, which are useful for comparing outcomes of alloSCT to those of non-myeloablative and matched-related donor alloSCT.[1] However, ACM may not elicit the timing of benefit as early as DFS. Cumulative incidence of TMA was 3.4% (95% CI: 6.9-18.1) versus 25.6% (95% CI: 17.9-33.9) depending on the use or not of UDA, respectively (p: 0.005), whereas in the subgroup of CML/MTX 100d- Cumulative incidence of TMA was 3.4% (95% CI: 0.6-10.6) vs 12.1% (95% CI: 7.1-18.6) with and without UDA, respectively (p: 0.05).

Summary/Conclusions: In conclusion the use of UDA decreases the risk of TMA after alloSCT regardless of type of immunoprophylaxis.

P747

FACTORS PREDICTING GRAFT VERSUS HOST DISEASE-FREE, RELAPSE-FREE SURVIVAL AFTER ALLOGENEIC TRANSPLANTATION. COMPARISON ATTENDING TO TWO DIFFERENT DEFINITIONS AND BENEFIT OF HAPLOIDENTICAL DONOR.

1Hematology department, Hospital Universitario de Salamanca, Salamanca, Spain

Background: Disease free survival is the most used common endpoint for clinical research on allogeneic stem cell transplantation (HSCT), but it doesn’t include morbidity endpoints or those which affect their quality of life as graft failure (GF), disease relapse, or death. Furthermore, this endpoint may overestimate the benefit of new treatments if baseline differences exist. All-cause mortality (ACM) and disease free survival (DFS) are composite endpoints, which are useful for comparing outcomes of alloSCT to those of non-myeloablative and matched-related donor alloSCT.[1] However, ACM may not elicit the timing of benefit as early as DFS. Cumulative incidence of TMA was 3.4% (95% CI: 6.9-18.1) versus 25.6% (95% CI: 17.9-33.9) depending on the use or not of UDA, respectively (p: 0.005), whereas in the subgroup of CML/MTX 100d- Cumulative incidence of TMA was 3.4% (95% CI: 0.6-10.6) vs 12.1% (95% CI: 7.1-18.6) with and without UDA, respectively (p: 0.05).

Summary/Conclusions: In conclusion the use of UDA decreases the risk of TMA after alloSCT regardless of type of immunoprophylaxis.

P746

THROMBOTIC MICROANGIOPATHY AFTER ALLOGENEIC STEM CELL TRANSPLANTATION: IS THERE A PROTECTIVE ROLE FOR URSOODEOXYCHOLIC ACID?

Results: Characteristics of patients are shown in table 1. With a median follow up for patients alive of 39 months (3-221), the median estimated survival in months and the % at +1 year and +2 years was: 114 months, 70% and 62% overall survival (OS); 23 months, 57% and 49% event free survival (EFS); 6 months, 35% and 26% GRFS1; 11 months, 46% and 38% GRFS2. 147 (24%) and 218 (35%) hadn’t any event in GRFS1 and in GRFS2 respectively. In GRFS1, event’s incidence was: 90 (15%) for III-IV aGVHD, 170 (27%) for cGVHD, 152 (25%) for relapse and 57 (9%) for death; In GRFS2 was 90 (15%), 65 (11%), 174 (28%) and 65 (11%) respectively. Considering those patients with cGVHD as event in GRFS1, 105 of them hadn’t the event as cGVHD at the same time in GRFS2 (since they had cGVHD requiring systemic treatment but not severe cGVHD). For these patients, the alternative event in GRFS2 was: 72 without any event, 22 relapsed and 11 died. In the multivariate analysis, factors associated with better outcomes were: for GRFS1 diagnosis (p=0.04; benefit in NHL/HL/CLL p=0.02, HR 0.71; C195% 0.53-0.95), >4 prior lines (p=0.03, HR 1.5, C195% 1.04-2.04), early EBMT stage (p<0.001 with early as reference; intermediate p=0.002, HR 1.5, C195% 1.2-1.9; advance p<0.001, 2.0, 1.5-2.6), in vivo T-cell depletion (p=0.02, 0.6, 0.39-0.92) and haploidentical donor (p=0.04 with HLA identical as reference, no significance 1 or 2 mismatch [p=0.18], haploidentical p=0.02, 0.43, 0.25-0.74). Only early EBMT disease stage maintained significance in GRFS2 (p<0.001 with early as reference; intermediate p=0.005, 1.5, 1.1-1.9; advance p<0.001, 1.9, 1.4-2.6).

Summary/Conclusions: In our study the percentage of the GRFS endpoint was similar to previously reported. Comparing both proposed definitions, the GRFS2 endpoint define a higher population of patients without any event; so that it is possible that the morbidity is misdiagnosed. The EBMT disease score was the factor with more impact in both; it is interesting to point that although the group is smaller, haploidentical donor is associated with better GRFS1.

P748

EFFICACY AND SAFETY OF DEFIBROTIDE IN THE TREATMENT OF HEPATIC VENO-OCLUSIVE DISEASE/SINUSOIDAL OBSTRUCTION SYNDROME FOLLOWING HEMATOPOIETIC STEM CELL TRANSPLANTATION: FINAL SUBGROUP RESULTS

P. Richardson1,2, A. Smith3, T. Triplett1, N. Kernan4, S. Grupp5, J. Antin6, L. Lehmann7, S. Giralt8, W. Liang9, R. Hume9, W. Tappe9, R. Soiffer7

Background: Hepatic veno-occlusive disease/sinusoidal obstruction syndrome (VOD/SOS) is a potentially life-threatening complication of conditioning regimens for hematopoietic stem cell transplant (HSCT) and may also occur following chemotherapy without HSCT. VOD/SOS with multi-organ dysfunction (MOD) may be associated with >80% mortality. Diagnosis has traditionally been based on the Baltimore criteria or modified Seattle criteria. Defibrotide is approved for treating severe hepatic VOD/SOS post-HSCT in the European Union and for treatment of hepatic VOD/SOS with renal/pulmonary dysfunction post-HSCT in the United States. The defibrotide expanded-access protocol was designed to provide access to defibrotide prior to its approval in the United States and to collect additional data on safety and efficacy in a broader patient population, including those with and without MOD, and following HSCT or chemotherapy without HSCT.

Aims: This is an analysis of defibrotide efficacy and safety in the subgroup of patients developing VOD/SOS following HSCT, using final data from the expanded-access protocol.

Methods: The original expanded-access protocol required VOD/SOS diagnosis by either criteria or biopsy post-HSCT, with evidence of MOD (27% for pulmonary dysfunction). The study was amended to also include patients without MOD (off-label), with VOD/SOS per modified Seattle criteria, and/or with VOD/SOS following chemotherapy without HSCT (off-label). After patients provided informed consent, defibrotide treatment (25mg/kg/d in 4 divided doses of 6.25mg/kg) was recommended ≥21 days.

Results: This final analysis of final data is based on 1000 patients enrolled from 2007–2016 who had confirmed VOD/SOS following HSCT and had received ≥1 dose of defibrotide. Of these patients, 512 (51.2%) had MOD. The median age was 14 years (range 0.10–77.0), with 570 patients (57.0%) aged ≤16 years, (29% patients whom had MOD) and 430 patients (43.0%) ≥16 (231 [45.1%] of whom had MOD). Among pediatric patients, 28.2% were aged <1–23 months, 52.5% aged 2–11 years, and 19.3% aged 12–16 years. Primary diseases in ≥10% of the overall HSCT group were acute lymphocytic leukemia (19.8%), acute myelogenous leukemia (26.1%), and neuroblastoma (10.5%). Kaplan-Meier estimated Day +100 survival was 58.9% (95% confidence interval [CI], 55.7%–61.9%) in the overall HSCT group (Figure), with rates of 49.5% (95% CI, 45.0%–53.8%) in patients with MOD and 68.9% (95% CI, 64.5%–72.9%) in patients without MOD. In patients aged ≥16 years, Kaplan-Meier estimated Day +100 survival was 67.9% (95% CI, 63.8%–71.6%) and 47.1% (95% CI, 42.3%–51.8%) in patients aged >16 years (Figure). In the overall HSCT population, 210 patients (21.0%) had ≥1 treatment-related adverse event (TRAE). TRAEs occurring in ≥2% of patients were pulmonary hemorrhage (4.6%), gastrointestinal hemorrhage (3.0%), epistaxis (2.3%), and hypertension (2.0%).

Figure 1.

Summary/Conclusions: This final analysis of the defibrotide expanded-access protocol demonstrates favorable Day +100 survival (58.9%) in patients with confirmed VOD/SOS following HSCT, and 49.5% in those with MOD, a complication typically associated with dismal outcomes. Survival and safety findings, consistent with prior clinical trials, provide supportive evidence for the clinical utility of defibrotide for treatment of VOD/SOS in patients with and without MOD. **GENERATION OF IMMORTAL MURINE HEMATOPOIETIC STEM/PROGENITOR CELL LINES FROM TRANSGENIC MICE**

E. Domà1,*, A. Höbl1, V. Sexl1

1Pharmakologie und Toxikologie, Veterinärmedizinische Universität Wien, Wien, Austria

**Background:** Research on hematopoietic and leukemic stem cells (LSCs) is currently limited as these cells are infrequent and their immortalization is hardly achievable.

**Aims:** We aimed to establish a long term ex-vivo culture system that allows maintenance and expansion of LSK (lin-, Sca-1+, c-Kit+) cells.

**Methods:** We adapted a technique described by the L. Carlsson lab and transduced high-purity sorted murine LSKs with Lhx2, a LIM-homeobox transcription factor, which has been reported to facilitate ex vivo expansion of immature hematopoietic cells.

**Results:** Lhx2 expressing hematopoietic progenitor cell (HPC(LSK)) lines require SCF (stem cell factor) and IL-6 and they can be maintained in a feeder-independent culture for more than 6 months. They preserve LSK markers despite continuous proliferation. HPC(LSK) cells repopulate lethally irradiated mice and re-feed the T and B cells. HPC(LSK) cells are CAR-T cell targets since they are established from a range of transgenic mice, underlying the overall applicability of this model. Using this system, we established LSC lines that express BCR/ABL210, MLL-AF9,Nras12/12 or Flt3/ITD; Nras12/12. These LSCs home to the bone marrow, differentiate into all lineages and drive myeloid leukemia in mice.

**Summary:** We created the most powerful method of expanding hematopoietic stem/progenitor cells. They are immortalized and can be expanded indefinitely. This allows the analysis of molecular mechanisms controlling self-renewal in hematopoietic and LSCs as well as drug screening. Our system may represent a breakthrough in (cancer) stem cell biology and assist in the development of new therapeutic avenues to combat LSCs.

**Background:** Allogeneic haematopoietic stem cell transplantation (alloHSCT) is the most effective means of preventing relapse of blood cancers, in particular AML. The curative potential of alloHSCT is largely due to the immune mediated graft-versus-leukemia (GVL) effect, which in turn is dependent on donor immunity. The dual challenge of alloHSCT is therefore to allow sufficient donor engraftment for haematopoietic and immunological reconstitution that drives the GVL effect while limiting the toxicity of conditioning and the onset of graft-versus-host disease (GVHD).

**Aims:** Optimize the use of BCL2 inhibitors to modify recipient NK cell function in models of alloHSCT in order to minimize GVHD severity and onset.

**Hypothesis:** Therapeutic targeting of recipient NK cell frequency or function pre-transplantation will allow reduced intensity conditioning (RIC) and promote both donor T cell engraftment and GVL whilst reducing the risks of GVHD.

**Methods:** We used a MHC-mismatched mouse model of alloHSCT, where donor T and NK cells are hematopoietic cell pools. HPC(LSK) cells were injected into NSG recipients that were established from a MHC-mismatched mouse model of alloHSCT.

**Results:** We extended our observations in BCL2 in WT mice with just two doses of ABT-199 resulted in rapid depletion of NK cells. Our preliminary data indicates that alloHSCT WT recipient mice pre-treated with ABT-199 develop full donor engraftment even in the setting of significant RIC, with minimal GVHD.

**Summary/Conclusions:** Recipient NK cell inhibition may therefore represent a means by which to deliver alloHSCT more safely by reducing conditioning intensity and GVHD.

**MESENCHYMAL STEM CELL IRRADIATION INTERFERES WITH THE ADIPOGENIC/OSTEOGENIC DIFFERENTIATION BALANCE IMPROVING THEIR HEMATOPOIETIC-SUPPORTING ABILITY**

S. Preciado Perez1,*, S. Munton1, A. Rico1, R. Ortega1, I. Misiewicz-Krzeminska1, L. García-López1, G. Ramasanta1, J. B. Pantoja1, A. Redondo1, C. Rondón1, M. Diez-campelo1, M. López-Parra1, A. Redondo1, L. I. Sanchez Abacar1, M. C. Del Cañizo1, F. Sánchez-Guijo1

1IBSAL-Hospital Universitario de Salamanca, Salamanca, Spain

**Background:** Mesenchymal stromal cells (MSC) are precursors of adipocytes and osteoblasts in the bone marrow (BM) niche, and key regulators of the hematopoietic process. After HSC transplantation, MSC remain of host-origin. Total body irradiation has been widely used in conditioning regimen and MSC are shown to be radio-resistant. Nevertheless, the functional effects of irradiation on BM-MSC have not been extensively explored.

**Aims:** The main objective was to evaluate the effects of irradiation on the MSC in their hematopoietic-supporting capacity.

**Methods:** Seven BM samples were obtained from healthy donors after informed consent. MSC were obtained and characterized following standard procedures of MSC isolation and culture. Then, one aliquot was gamma-irradiated with a single dose of 2.5 Gy whereas non-irradiated MSC from the same sample were used as controls. MSC were characterized following ISCT criteria (flow cytometry and in vitro differentiation stainings). Apoptosis was evaluated by flow cytometry using annexin/V/7AAD staining. Expression microarrays of irradiated and control-MSC were performed using Human Gene 2.0 ST Array platform (Affymetrix). RT-PCR of key genes involved in the hematopoietic supporting capacity as well as in the differentiation of MSC into osteoblasts and adipocytes was performed in both experimental groups. Finally, long term BM cultures (LT-BMC) were performed as functional assays to test the hematopoietic-supporting ability of irradiated and non-irradiated MSC. For the former experiments, BM specimens, CD34+ cells were isolated from leukaemopheresis and seeded on stromal layers from non-irradiated or irradiated MSC. CFU-GM colonies derived from the LT-BMC were scored weekly.

**Results:** Flow cytometric characterization of irradiated MSC was comparable to that of control MSC. Similarly, there were no differences in the percentage of viable cells between both experimental groups neither at one hour nor at 72h post irradiation, confirming once more the radio-resistance of MSC. In addition, expression arrays did not show any statistically significant differences in genes involved in hematopoiesis maintenance. However, upon comparing the differentiation ability we interestingly observed that irradiated-MSC differentiation was skewed towards osteogenesis whereas adipogenesis was impaired. In this regard, irradiated-MSC had significantly higher SPP1 expression (involved in late osteogenic differentiation) and lower CBPA and PPAR-gamma (both genes involved in adipogenesis) compared to control MSC. After inducing in vitro differentiation, there were no differences in ALP and Alizarin Red staining but the number of adipocytes per field at days 7, 14 and 21 was significantly lower in irradiated MSC (p=0.018, p=0.046 and p=0.018, respectively). In addition, angiopoietin and SDF-1, key genes implicated in maintenance of hematopoiesis, were significantly overexpressed in irradiated-MSC (p=0.043 and p=0.028, respectively). Finally, in the functional evaluation of the hematopoietic-supporting ability of MSC by LT-BMC, we observed that the number of CFU-GM colonies generated by the culture was significantly higher in the irradiated group after 4 and 5 weeks (p=0.046 and p=0.018, respectively) compared to the non-irradiated group. Furthermore, the number of adipocytes per field was significantly reduced in the LT-BMC.

**Summary/Conclusions:** Irradiation of MSC with 2.5 Gy improves their hematopoietic supporting ability and modifies their differentiation capacity, increasing the osteogenesis and decreasing the adipogenesis.

GRAFT-VERSUS HOST DISEASE (GVHD) DEVELOPMENT AFTER BONE MARROW TRANSPLANTATION IS NOT INFLUENCED BY TH9 CELLS

T. Reisser1, S. Muche1, J. Scheurer1, K.-M. Debatin1, G. Strauss1,*

1Department of Pediatrics and Adolescent Medicine, University Medical Center Ulm, Ulm, Germany

Background: TH9 cells are a recently defined subset of T helper cells (Th) characterized by the massive production of IL-9. TH9 cells mediate immune responses against helminth infections, exhibit anti-tumor immunity against solid tumors and mediate allogeneic transplant tolerance but they also contribute to immunopathology in allergy and autoimmunity.

Aims: Currently, the role of TH9 cells for GVHD induction and the graft-versus-tumor effect is largely unknown. Therefore, we first explored, whether TH9 cells are induced during GVHD development and secondly analyzed, whether transplantation of in vitro-generated Th9 cells mediates GVHD.

Methods: We transplanted allogeneic BM and spleen cells from B6-SJL mice (CD45.1, H-2b) in B6D2F1 mice (CD45.2, H-2bxd) or in B6.bm12 mice (CD45.2, H-2b). Th9 cells were induced in vitro from CD326+ intestinal epithelial cells from KO and WT animals after allo-BMT. The cIAP-/-and -XIAP-/-animals showed increased number of Th9 cells and significantly reduced expression of anti-apoptotic protein Bcl-2 and LC-3-3 that contribute to the expression IL-9 from B clonally B-GVHD animals was significantly increased.

Summary/Conclusions: These data suggest that enhanced apoptosis in the target tissues in the absence of IAPs contributes to greater GVHD severity. Thus expression of functional IAPs in target tissue is crucial for reducing the damage from GVHD.
during GVHD. *After in vitro* differentiation of Th9 cells from naive T cells we obtained more than 60% of IL-9 producing cells after 5 days of culture. Th9 cells differ in their cytokine profile (IL-9+, IFN-g-, IL-13-) from Th1 and Th2 cells. Transplantation of in vitro-generated Th9 cells together with allogeneic BM cells did not induce GVHD in the MHC-disparate recipient mice, while the transplantation of unselected T cells or in vitro-generated Th1 cells induced GVHD and resulted in death in about 60% of the animals. Although no GVHD development was detected, Th9 cells migrated into lymphoid organs and GVHD target organs such as spleen and lung. Surprisingly, when the cytokine phenotype of the transplanted Th9 cells were analyzed after *ex vivo* isolation from spleen and liver at different time points after transplantation, the cells lost their IL-9-, IFN-g- and anti-IL-12 phenotype and instead expressed TNF-a and IFN-g without strong systemic increase in these cytokines. Since TNF-a and IFN-g are cytokines associated with an anti-tumor cytotoxicity and Th9 cells are known to eliminate solid tumors, future experiments will define whether, in vitro-generated Th9 cells can be used as a cellular therapy for anti-tumor responses in BM-transplanted hosts.

**Summary/Conclusions:** Th9 cells are not induced during GVHD development and the adoptive transfer of in vitro-generated Th9 cells does not induce GVHD. However, the transplanted Th9 cells home to spleen and GVHD target organs and start to produce TNF-a and IFN-g without strong systemic increase in these cytokines. Since TNF-a and IFN-g are cytokines associated with an anti-tumor cytotoxicity and Th9 cells are known to eliminate solid tumors, future experiments will define whether, in vitro-generated Th9 cells can be used as a cellular therapy for anti-tumor responses in BM-transplanted hosts.

**IMPROVED HSC ENGRAFTMENT IN A MOUSE MODEL OF HEMATOPOIETIC STEM CELL GENE THERAPY MEDIATED BY MSCS**

M. Fernandez-Garcia1,2, L. M. Lamana1, M. Hernando-Rodríguez1,2, R. Sánchez-Domínguez1,2, J. Buener1, R. Yarhe1,

1Department of Hematopoietic Innovative Therapies, Centro de Investigaciones Energéticas Medioambientales y Tecnológicas/Centro de Investigación Biomédica en Red de Enfermedades Raras (CIEMAT/CIBERER), 2Advanced Innovative Therapies, Instituto de Investigación Sanitaria Fundación Jiménez Diaz (IIS-FJD, UAM), Madrid, Spain

**Background:** Co-transplantation of human mesenchymal stromal cells (hMSC) has been reported to reduce the risk of graft failure and improve hematopoietic stem cell (HSC) engraftment in xenogeneic and determined allogeneic transplantation. In addition, we have demonstrated that the co-infusion of MSCs with low numbers of purified HSCs significantly improves short- and long-term hematopoietic reconstitution in an autologous HCT experimental model with sunitibdelating (5Gy).

**Aims:** The aim of this study is to analyze the effect of MSCs on HSC engraftment in a clinically relevant model of hematopoietic gene therapy.

**Methods:** We have studied the effect of MSCs co-infusion in a mouse model of HSC gene therapy with risk of engraftment failure in Fanconi anemia mice (Fanca-/-).

**Results:** In these experiments, the infusion of low numbers of WT LSK cells (1,500 LSK) in Fanca-/- mice resulted in 30% graft failure, which was prevented when 1,500-3,000 Fanca-/- LSK cells transduced with a therapeutic lentivector (PGK-FANCA-wPRE) were transplanted, the infusion of similar cell doses resulted in more than 50% of engraftment failure, which decreased to 30% only when more than 10,000 gene-correced LSK were infused. Once again, Ad-MSCs co-infusion increased graft failure in the infusion with the same number of gene-corrected LSK cells.

**Summary/Conclusions:** Taken together, our results demonstrate the potential of Ad-MSCs to avoid graft failure in a clinically relevant model of hematopoietic gene therapy with risks of engraftment failure.

**EFFECT OF POMALIDOMIDE ON T CELL POLARIZATION IS MEDIATED THROUGH EPIGENETIC MODIFICATIONS.**

I. Alvarez Laderas1, J.J. Piriut1, T. Caballero Velázquez1, M. Ceballos2, V. Barbado1, L.I. Sánchez Abarca1, M. Medrano1, E. García1, J. Casado1, J.C. Reyes2, J.A. Pérez Simón1

1Division of Hematopoietic Innovative Therapies, Centro de Investigaciones Energéticas Medioambientales y Tecnológicas/Centro de Investigación Biomédica en Red de Enfermedades Raras (CIEMAT/CIBERER), 2Advanced Innovative Therapies, Instituto de Investigación Sanitaria Fundación Jiménez Diaz (IIS-FJD, UAM), Madrid, Spain

**Background:** There is conflicting evidence regarding the potential use of IMiDs and particularly pomalidomide after allogeneic stem cell transplantation (allo-HSCT). It has been shown that these drugs downregulate Th1 phenotype increasing IFN-g cytokine production via the augmentation of T-bet transcription factor. This effect might increase the risk of GVHD after allo-HSCT. Nevertheless, a recent trial has reported a potential benefit of the use of pomalidomide as GVHD treatment.

**Aims:** In the current study, we have analyzed the effect of pomalidomide in the polarization of CD45RA+ cells and the epigenetic mechanisms that might be involved in this effect.

**Methods:** Isolated CD45RA+ T cells from healthy donor’s Buffy Coats were treated with anti-CD3 plus anti-CD28 and supplemented with IL-12, IFN-g and anti-IL-12 for 5 days. Pomalidomide at two different doses (10 and 100 nM) were added into the culture and the effect on T cells polarization was analyzed by flow cytometry after staining with anti-CD25, anti-IFN-g, anti-CD4 and anti-IL-2 for Th1 cell polarization and anti-CD25, anti-IL-10, anti-CD3 and anti-IL-4 for Th2 cell polarization. In addition, the release of cytokines (IL-2, IL-4, IL-6, IL-10, TNF-a and IFN-g) in cell culture supernatants were measured by BD Human Th1/Th2 Cytokine BCA kit (BD Biosciences) and T-bet and GATA-3 expression were analyzed by Western Blot. Chromatin immunoprecipitation (ChIP) assays were performed to assess the trimethylation of H3K4 (associated with gene activation) and the trimethylation of H3K27 (associated with gene repression) in the TBPET and GATA-3 gene promoters.

**Results:** Pomalidomide increased the expression of IFN-g and IL-2 as determined by flow cytometry in Th1 cell culture conditions. By contrast, in the presence of IL-10, IL-4 and IL-12 we observed a strong decrease in IL-10 and IL-4 upon adding pomalidomide to the culture. In addition, the exposure to pomalidomide increased the levels of TNF-a, IFN-g and IL-2 in the Th1 polarizing culture while, under Th2 promoting conditions, an increased concentration of IL-4 and IL-2 in supernatant was observed after exposure to pomalidomide. Furthermore, exposure to pomalidomide led to an increased expression of T-bet as assessed by western-blot in naive CD45RA+ cells activated with anti-CD3 plus anti-CD28 and supplemented with IL-12, IFN-g and anti-IL-4. By contrast, in Th2 polarization conditions, pomalidomide increased GATA-3 expression. We next studied whether or not the effect of pomalidomide in T cell polarization might be mediated by epigenetic mechanisms: in the presence of Th1 promoting conditions there was a significant increase of the activation marker H3K4me3 at the TBPET promoter and a significant decrease in H3K27me3 upon exposure to the drug while, under Th2 promoting conditions, a significant increase in H3K4me3 at the promoter of GATA-3 gene was observed among the cells exposed to pomalidomide.

**Summary/Conclusions:** Pomalidomide favours both Th1 and Th2 cell differ-entiation of CD45RA+ cells depending on the cytokines present in the medium. Treatment of naive T cells with pomalidomide induces epigenetic modifications during T cell polarization which might favour the process of differentiation of the naive T cells.

**MESENCHYMAL STEM CELL (MSCS) ATTENUATE CUTANEOUS SCLERODERMATOUS GRAFT-VERSUS-HOST DISEASE (SCL-GVHD) THROUGH INHIBITION OF IMMUNE CELL INFILTRATION IN A MOUSE MODEL.**

J.-Y. Lim1, D.-B. Ryu1, S.-E. Lee1, G. Park2, C.-K. Min1,3

1Department of Internal Medicine, 2Department of Pathology, Seoul St. Mary’s Hospital, The Catholic University of Korea, 3Leukemia Research Institute, The Catholic University of Korea, Seoul, Korea, Republic Of

**Background:** Human chronic graft-versus-host disease (CGVHD) shares clinical characteristics with a murine sclerodermatous GVHD (Scl-GVHD) model that is characterized by skin thickening and lung fibrosis.

**Aims:** This study investigated the therapeutic effect of mesenchymal stem cells (MSCs) on the development of Scl-GVHD according to each target organ.

**Methods:** A B10.D2 → BALB/c transplant model of Scl-GVHD was used to address the therapeutic effect of mesenchymal stem cells (MSCs) on the develop-ment of CGVHD. M210B4 cells were administered after allo-HSCT at a dose of 3 x 10^7 cells/mouse on days 3, 5, 7.

**Results:** The clinical and pathological severity of cutaneous Scl-GVHD was significantly attenuated in MSC-treated recipients relative to Scl-GVHD controls. After MSC treatment, skin collagen production was significantly reduced with consistent downregulation of TGF-β expression. Effects of MSCs on molecular markers implicated in persistent TGF-β signaling and fibrosis, such as phosphatase and tensin homolog (PTEN), phosphorylated Smad-2/3 and matrix metalloproteinase-1 (MMP-1), were observed in skin tissue. MScs neither migrate to the skin nor affect the in vivo expansion of immune effector cells, but inhibited their infiltration into skin via downregulation of CCR4 and CCR8 expression. Furthermore, when cultured on GM-CSF+ T cells, CD45RA+ T cells and CD45RA+ CD11b+ monocyte/macrophages. MSCs diminished expression of chemokines such as CCL1, CCL3, CCL8, CCL17, and CCL22 in skin. MSCs were also dependent on stimulated spleno-cyes to suppress fibroblast proliferation.

**Summary/Conclusions:** Our findings indicate that MSCs attenuate the cuta-neous Scl-GVHD by selectively blocking immune cell migration and downreg-ulating chemokines and chemokine receptors.

**C57BL/6 SUBSTRAINS SHOW DIFFERENCES IN HEMATOPOIETIC REPOPULATION AND ONCOGENICITY.**

A. Morales Hernandez1, A. Martina2, S. McKinney-Freeman2

1Hematology, St Jude Children’s Research Hospital, 2Hematology, St Jude Children’s Research Hospital, Memphis, United States

**Background:** C57BL/6 mice are one of the most studied in-bred mouse strains.
Although C57BL/6N (N) and C57BL/6J (J) mice are derived from the same parental C57BL/6 strain, there are key genotypic and phenotypic differences between these sub-strains. However, more than 58% of studies published involving C57BL/6 mice do not indicate the specific sub-strain employed. J mice have a five-exon deletion in the Nnt gene in C57Bl/6J mice sensitizes HSPCs to oxidative stress, which compromises their self-renewal, differentiation, and survival. The absence of a functional Nnt gene in J-HSC may curtail their ability to resolve elevated ROS post-transplant.

**Aims:** As elevated oxidative stress compromises hematopoietic stem and progenitor cell (HSPC) function, here we thoroughly interrogated the frequency and function of HSPCs in J and N bone marrow (BM).

**Methods:** N and J peripheral blood (PB) and BM (n = 9) was interrogated by flow cytometry for the absolute frequencies of all major hematopoietic lineages and HSPC compartments, respectively. 5000 J or N CD45.2 HSPCs (Lin-Sca-1+cKit+ cells) were transplanted along with 5000 competitor CD45.1 HSPCs into lethally irradiated mice to test for competitive in vivo hematopoietic repopulating activity and ROS levels post-transplant. The lineage potential and repopulating activity of multi-potent progenitors (MPP2: Lin-Sca1+cKit+Flt3+CD48+CD150+, MPP3: Lin-Sca1+cKit+Flt3+CD48+CD150-, MPP4: Lin-Sca1+cKit+Flt3+CD48+CD150-) was also tested by transplanting 2000 MPPs from J or N mice into sub-lethally irradiated mice and examining the PB of recipients every 3-4 days for 34 days post-transplant. Sensitivity of HSPCs to oxidative stress was tested by examining ROS levels and the in vitro colony forming unit (CFU) potential of HSPCs isolated from N and J mice treated with pI:pC.

**Results:** The frequency of the major PB lineages and bone marrow HSPC compartments was identical in J and N mice. However, J-HSPCs displayed compromised short-term (4-12 weeks post-transplant) hematopoietic repopulating activity relative to N-HSPCs that was driven by a delay in lymphoid reconstitution. No differences were found in donor contribution to bone marrow HSC compartments at 20 weeks post-transplant. However, donor-derived MPPs and CLPs displayed a two-fold increase in ROS levels in recipients of J-HSPCs versus N-HSPCs at 20 weeks post-transplant. MPPs are responsible for repopulation of the hematopoietic system during this early window post-transplant. Different MPP subpopulations can be defined (MPP2, MPP3, and MPP4) according to their self-renewal potential and specific lineage potential. MPP3s and MPP4s are the first MPP subpopulations to reconstitute the lymphoid lineage after transplant. J-MPP3s and J-MPP4s displayed less in vivo repopulating activity than N-MPP3s and N-MPP4s. It is known that pI:pC treatment increases ROS levels in HSPCs. We found about two-fold higher ROS levels in HSPCs isolated from J mouse compared to N-HSPCs at 20 weeks post-transplant. MPPs are responsible for repopulation of the hematopoietic system during this early window post-transplant. Different MPP subpopulations can be defined (MPP2, MPP3, and MPP4) according to their self-renewal potential and specific lineage potential. MPP3s and MPP4s are the first MPP subpopulations to reconstitute the lymphoid lineage after transplant. J-MPP3s and J-MPP4s displayed less in vivo repopulating activity than N-MPP3s and N-MPP4s. It is known that pI:pC treatment increases ROS levels in HSPCs. We found about two-fold higher ROS levels in HSPCs isolated from J mouse compared to N-HSPCs at 20 weeks post-transplant. MPPs are responsible for repopulation of the hematopoietic system during this early window post-transplant. Different MPP subpopulations can be defined (MPP2, MPP3, and MPP4) according to their self-renewal potential and specific lineage potential. MPP3s and MPP4s are the first MPP subpopulations to reconstitute the lymphoid lineage after transplant. J-MPP3s and J-MPP4s displayed less in vivo repopulating activity than N-MPP3s and N-MPP4s.

**Summary/Conclusions:** Based on these data, we hypothesize that loss of the Nnt gene in C57Bl/6J mice sensitizes HSPCs to oxidative stress, which compromises their short-term in vivo hematopoietic repopulating activity.

**GWAS RESULTS IN RED BLOOD CELL PHENOTYPES AND THEIR RELATIONSHIP WITH THROMBOSIS**

1Thrombosis and Hemostasis Unit, Hospital de Sant Pau, 2Unit of Genomics of Complex Diseases, Institut d’Investigació Biomèdica Sant Pau. (IIB-Sant Pau).

2Hematology, Hospital de Sant Pau, Barcelona, Spain, 4Cardiovascular Medicine Unit, Department of Medicine, Karolinska Institutet, Stockholm, Sweden, 5Medicine Department, Universitat Autònoma de Barcelona, Barcelona, Spain

**Background:** Venous thromboembolism (VTE) is a complex and multifactorial disease with a estimated heritability of 60%. Intermediate phenotypes of VTE have been used to identify genetic risk factors. We previously reported a genetic correlation of 5 erythrocyte phenotypes with VTE.

**Aims:** To identify single nucleotide polymorphisms (SNPs) influencing the phenotypic variance of erythrocyte parameters, especially those related to VTE, in Spanish families from the Genetic Analysis of Idiopathic Thrombophilia (GAIT2) Project.

**Methods:** Genome-wide association analyses (GWAS) with ~10M SNPs were performed for eighteen erythrocyte phenotypes in 935 subjects belonging to 35 extended families with thrombosis of GAIT2. The erythrocyte phenotypes evaluated were: Hemoglobin (Hb), red blood cell count (RBC), hematocrit (Ht), mean corpuscular volume (MCV), mean corpuscular hemoglobin (MCH), mean corpuscular hemoglobin concentration (MCHC), red blood cell distribution width (RDW), reticulocyte (RET), low fluorescence reticulocyte (LFR), middle fluorescence reticulocyte (MFR), high fluorescence reticulocyte (HFR), reticulocyte fluorescence index (IRF), platelet count (PCT), total iron binding capacity (TIBC), saturation index (SI), serum ferritin (Fe), total iron binding capacity (TIBC), and VTE risk. These data could be useful to investigate genes related to VTE.

**Results:** We identified 12 SNPs showing association with the 5 erythrocyte phenotypes previously related to VTE (Table 1). Interestingly, the rs56306145 that showed association with VTE is an intronic variant located in the gene tissue factor pathway inhibitor 2 (TFPI2), which encodes a protein that inhibits a variety of serine proteases of blood coagulation, such as activated factor VII (FVIIa/TF), FXa, plasmin and plasma kallikrein. These data allowed us to correlate genetic correlation of VTE with VTE. The most significant SNP-associations were reported.

**Table 1. Top SNP-associations with erythrocyte phenotypes related to VTE from GWAS in GAIT2.**

**Summary/Conclusions:** Several genetic variants involved in the variance of erythrocyte phenotype levels were identified by GWAS. Of note, TFR was associated with a SNP in TFPI2 that might influence the variance of both TFR levels and VTE risk. These data could be useful to investigate genes related to red blood cell parameters and VTE.

**ESSENTIAL THROMBOCYTHEMIA (ET) AND POLYCYTHEMIA VERA (PV) PATIENTS SHOW AN INCREASED THROMBUS FORMATION IN A DYNAMIC MODEL OF PLATELET ADHERENCE**

A. Vignoli1,2, F. Marchesi1, M. Marchetti1, S. Gamba1, C. Giachetti1, C. Verzeroli1, L. Russo1, S. Tesserolo1, G. Finazzi2, P.E. van der Meijden3, F. Swierenga3, H. ten Cate4, J.W. Heemskerk5, A. Rambaldi6, A. Falanga1

1Madrid, Spain, June 22 – 25, 2017

haematologica | 2017; 102(s2) | 307
Aims: We wanted to evaluate, in a group of ET and PV patients, the PLT thrombus formation capacity by an ex-vivo dynamic model of PLT adhesion under flow conditions, and to establish the influence of JAK2-V617F/Calreticulin (CalR)/MPL mutations, hematological parameters, and ongoing therapies.

Methods: One hundred-thirty patients, i.e. 78 ET (32 M/46 F; median age=61 years, range 28-86) and 52 PV (26 M/26 F; median age=65 years, range 38-87) were enrolled after informed consent. For the adhesion assay, peripheral venous whole blood was drawn in sodium citrate, recalcified in the presence of heparin, and perfused over a collagen-coated surface for 4 min. at a shear rate of 1,000 s⁻¹. PLTs were then stained with an anti-CD62P (P-selectin) antibody to evaluate PLT activation, and annexinV-AlexaFluor647 to detect pro-coagulant phosphatidylserine expression. After staining, phase contrast and fluorescence images of adherent PLTs were taken in random fields using an EVOS® microscope. Results are expressed as the means±SEM of the % of area covered by all PLTs (% coverage), or as the % of adherent PLTs positive for P-selectin or phosphatidylserine. Main hematological parameters, therapies, and mutational status were recorded.

Results: PLT adhesion was significantly (p<0.01) greater in either ET (45.3±1.7%) and PV patients (48.9±1.6%) compared to healthy controls (37.5±1.7%), while no difference was found between ET and PV patients. The analysis according to the mutational status shows that ET PLT adhesion was highest in JAK2-V617F mutation carriers (n=41; coverage: 47.7±2.4%, p<0.001 vs controls), followed by CalR-positive patients (n=21; coverage: 45.5±3.2%, p<0.05 vs controls, p=NS. vs JAK2-V617F), while, PLT adhesion of MPL-positive (n=3; coverage: 32±1.2%) or triple negative (n=13; coverage: 42±2.5%) ET patients was not statistically different from controls. In PV, no statistically significant difference was observed between subjects with >50% versus those with <50% JAK2-V617F allele burden. According to treatment, we observed that ET patients treated with the combination of aspirin+hydroxyurea presented the lowest PLT adhesion, while in PV no significant difference was observed between subjects on aspirin or hydroxyurea or placebo. PLT count correlated (p<0.01) with PLT adhesion only in CalR-positive ET patients. The analysis of adherent PLT surface markers shows no difference in P-selectin expression between whole patients and controls. Differently, phosphatidylserine expression was significantly reduced (p<0.01) in both ET and PV compared to healthy subjects.

Summary/Conclusions: ET and PV/platlets show an increased PLT thrombus formation potential, particularly in patients carrying the JAK2-V617F mutations. On the basis of these results, it is worth to include a dynamic PLT adhesion assay in risk prediction models to evaluate the predictive value of thrombotic events in ET and PV patients. INCIDENCE OF VENOUS THROMBOEMBOLISM IN PATIENTS UNDERGOING LOWER LIMB SURGICAL REVASCULARIZATION: IS THROMBOPROPHYLAXIS WARRANTED?

A. Baranwal1, S. Singh1, A. Yamamada1, P. Smith1, E. Colaiuta1

2Rehovot, Israel
3Copenhagen, Denmark
4Department of Internal Medicine, CARIM, Maastricht University, Maastricht, Netherlands

Background: The incidence of postoperative deep vein thrombosis (DVT) or consequential pulmonary embolism (PE) in patients undergoing lower extremity surgical revascularization procedures is not well studied. The need for routine anticoagulation for DVT/PE prophylaxis after the lower limb surgical revascularization remains controversial.

Aims: The purpose of this study is to retrospectively evaluate the incidence of postoperative DVT/PE in patients undergoing lower limb surgical revascularization.

Methods: Charts for patients undergoing lower limb surgical revascularization, from 01/01/2010 to 12/31/2015, were evaluated for DVT/PE. DVT/PE within three months of the revascularization was considered to be a postoperative DVT/PE. Patients undergoing multiple procedures were counted as different cases if they were on different days. Multiple procedures on a patient on the same day were considered a single case. Patients with hypercoagulable states or previous history of DVT were excluded. Descriptive statistics and t-test was used to analyze incidence of DVT/PE and assess the importance of postoperative thromboprophylaxis.

Results: Between 1/1/2010 to 12/31/2015, 360 patients were found to have undergone lower extremity surgical revascularization. Study population included 200 males and 160 females. Mean patient age was 69.54 years. One patient had a previous history of DVT and was excluded. Overall, of the 359 patients, five (1.4%) were recognized to have a new DVT/PE within 3 months of the surgery. One patient developed DVT in the contralateral limb, and one developed it in the arm. Patients were recognized to have a new DVT/PE, on an average, at 7.6 days after the surgery. A one sided t-test demonstrated that the average
postoperative day for recognition of DVT/PE was significant greater than 3.5
(7.6 vs 3.5, I2=0.048, p<0.001). Patients developing DVT/PE did not differ by obesity or age when compared with non-DVT/PE population.

Summary/Conclusions: There have been only a few studies to assess the incidence of DVT/PE in patients undergoing lower limb surgical revascularization. In our study population, 1.4% of patients had evidence of DVT/PE. This constitutes a low risk of venous thromboembolism. The 2012 American College of Chest Physicians (ACCP) guidelines for prevention of venous thromboembolism in nonorthopedic surgical patients (Chest 2012; 141(2(Suppl))e227s-e277s), requires the use of pneumatic compression devices (PCDs), over no prophylaxis, to prevent DVT/PE in low risk patients. Since, patients with lower limb surgeries are not a good candidate for PCDs, pharmacological thromboprophylaxis with low dose heparin may be warranted. Given that bleeding is a potential complication in these patients, it might be prudent to start thromboprophylaxis 3-5 days after the surgery. Further studies are needed to assess the bleeding risks of postoperative thromboprophylaxis after surgical revascularization procedures.

Summary/Conclusions: In the GAIT2 study, genetic and environmental factors were related to B12, SF, RCF and HCY. Moreover, a relationship was observed between B12 and VTE. In the GWAS analysis some signals were previously reported (FUT2 and B12 or MTHFR with SF and HCY). New signals were found that need to be clarified, especially their possible relationship with susceptibility to thrombosis.

CELLULAR ORIGIN OF CIRCULATING MICROPARTICLES (MP) ACCORDING TO SOMATIC MUTATIONS IN PATIENTS WITH MYELOPROLIFERATIVE NEOPLASMS (MPN)

C.J. Tartari1,2, M. Marchetti1, L. Raclo2, L. Russo1, S. Gamba1, A. Vignoli1, G. Finazzi3, A. Rambaldi1, A. Falanga1
1Department of Immunohematology and Transfusion Medicine, Hospital Papa Giovanni XXIII, Bergamo, Italy, 2Department of Hematology and Vascular Biology, Hospital La Conception, Marseille, France, 3Department of Hematology, Hospital Papa Giovanni XXIII, Bergamo, Italy.

Background: Essential thrombocythemia (ET) and polycythemia vera (PV) are MPN characterized by a high rate of thrombotic complications. We previously demonstrated increased plasma levels of procoagulant MP in ET (Marchetti et al. A.J.H. 2013).

Aims: Aim of this study was to extend the analysis of MP to PV patients and to characterize the cellular origin of plasma MP in both ET and PV patients. The influence of somatic mutations [i.e. JAK2V617F, calreticulin (CalR), thrombopoietin receptor (MPL)] and concomitant cytoreductive or antiplatelet therapies was also evaluated.

Methods: Thirty-seven ET (19 JAK2V617F, 9 CalR and 2 MPL mutation carriers), 35 PV patients (all JAK2V617F carriers) and 36 healthy control subjects were included into the study. Flow cytometry was performed to characterize MP phenotype in platelet free plasma samples. To define MP cellular origin, anti-CD31 (endothelial cell marker), anti-CD41 (platelet marker), anti-CD11b (leukocyte marker), and anti-CD235 (erythrocyte marker) monoclonal antibodies were used. Annexin V (AnnV) staining was used to evaluate the expression of procoagulant phosphatidylycerine on MP.

Results: ET and PV patients displayed significantly higher MP levels compared to controls (p<0.05). The majority of circulating MP (90%) were AnnV positive, indicating the expression of phosphatidylserine on their surface. In healthy con-
trols, 71% of MP was positive for platelet (P-MP), 24% for erythrocyte (E-MP), 4% for endothelial cell (EC-MP) and 1% for leukocyte (L-MP) specific markers. In ET and PV patients, the percentage of P-MP was significantly higher (80%; p<0.05), while E-MP level was significantly lower (15%; p<0.05) than controls. L-MP and EC-MP values were comparable between patients and controls. The absolute counts of P-MP and L-MP were higher in both ET and PV versus controls. Overall, no significant correlations were found between the levels of MP derived from platelet, leukocytes or erythrocytes and the corresponding cell counts. The analysis according to patient mutations, revealed significantly higher levels (p<0.05) of both P-MP and E-MP concentration in patients carrying JAK2V617F mutation as compared to JAK2V617F negative patients. In addition, ET patients positive for CalR mutation displayed lower levels (p<0.05) of P-MP compared to JAK2V617F carriers. No influence of concomitant therapies on MP levels or composition was observed.

Summary/Conclusions: Our data confirm the presence of high levels of circulating MP in MPN, which support the role in the known hypercoagulable state of these patients. The MP cellular origin has a different distribution profile according to patient's presenting different mutations. Importantly, the lack of correlation found between the total and subtype-specific MP counts with the corresponding cell of origin counts suggests an active stimulation of MP formation.

P767
ARE WE TESTING APPROPRIATELY FOR THE LUPUS ANTICOAGULANT (LA)?
J. Sharif1,*, C. Humphrey1, I. Earnshaw1, J. Thachil1
1Haematology, Central Manchester University Hospitals, Manchester, United Kingdom

Background: The diagnosis of antiphospholipid syndrome (APS) requires the presence of thrombosis or defined pregnancy morbidity in addition to the presence of antiphospholipid antibodies on at least 2 occasions. Patients should be tested for antiphospholipid antibodies if they fulfilled the required clinical criteria. Lupus anticoagulant may also be tested for when investigating a prolonged activated partial thromboplastin time which does not correct on mixing studies.

Aims: The aim of our study was to examine retrospectively the frequency of lupus anticoagulant (LA) testing in our institution, which we suspected to be high, and the incidence of positive results leading to a diagnosis of APS.

Methods: A total of 914 requests for LA were received over a 5 month period between 1st of May and 30th September 2014. We examined which departments were requesting the tests and the clinical indications for testing.

Results: Over 90% (829) of LA tests were negative. Nine percent (85) of tests demonstrated a positive LA. 33 patients had experienced arterial (11) or venous (22) thrombosis. There were 3 patients who fulfilled the clinical criteria for pregnancy morbidity in APS. A total of 6 patients experienced miscarriage before 10 weeks gestation; however none of these patients had the defined 3 miscarriages. There was one preterm delivery at 25 weeks due to pre-eclampsia. A further 3 patients had a still birth, one of which had an identifiable cause. In total, of the 85 positive results, 12 patients had a confirmed diagnosis of APS; a further 25 patients had the clinical manifestations fitting the clinical criteria for APS. Forty eight patients had a positive LA but did not fit the clinical criteria for a diagnosis of APS. The clinical specialties requesting the majority of tests were obstetrics and gynaecology (31%), rheumatology (17%) and clinical haematology (11%). Of these, clinical haematology had the highest yield of positive results (16%) compared to 3% in obstetrics and gynaecology.

Summary/Conclusions: Our results highlight a high frequency of LA testing in our institution with a low yield of positive results (9%), resulting in a total of 1% of patients being diagnosed with APS. Our results demonstrate that the majority of tests for LA are not of clinical significance and often requested in patients not fitting the clinical criteria for APS. Further education for all practitioners would help to ensure only appropriate patients are tested. Indeed if a patient fits the clinical criteria for APS they should be tested for all antiphospholipid antibodies namely anti-cardiolipin and anti-beta2-glycoprotein I as well as the lupus anticoagulant.

P768
RESULTS OF USING BRIDGING THERAPY WITH SODIUM BEMIPARIN AT THERAPEUTIC-DOSE
M.A. García Ruiz1,*, E. Morente Constantin1, P. Romero García2, M. Gómez Morales1, M. Jurado Chacón1
1Servicio de Hematología y Hemoterapia, Complejo Hospitalario Universitario de Granada, Granada, 2Unidad de Cuidados Intensivos, Complejo Asistencial de Soria, Soria, Spain

Background: Bridging therapy consists of the administration of a fast-acting anticoagulant such as the low-molecular-weight heparin (LMWH) during the period of cessation of oral anticoagulant therapy. The decision to continue with anticoagulant therapy or to discontinue the treatment with the establishment of the Bridging therapy have been carried out carefully and on an individual basis. While taking this decision, we have taken into account three factors: the urgency of surgery or invasive process, the risk of bleeding and thrombotic risk for the patient. In recent decades, there have been multiple studies supporting the LMWH treatment, at least as safe and effective and more cost-effective than unfractionated heparin (UFH) in the treatment of venous thromboembolism (VTE), including deep vein thrombosis (DVT) and pulmonary embolism (PE). Therefore, the LMWH is considered as the drugs of choice in the prevention of venous thromboembolism.

There are several types of commercialized LMWH, with different pharmacological properties, such as molecular weight, anti-Xa/Ia ratio and average life. The sodium bemiparin is the LMWH with greater anti-Xa/Ia ratio, which implies a lower risk of bleeding. In addition, it has shown a low incidence of VTE and bleeding in actual clinical practice.

Aims: There are few published data from bridging therapy at therapeutic doses in patients treated with oral anticoagulants (AVK) and perioperative management. It is intended to assess the efficacy (recurrence of thrombosis) and safety (use of sodium bemiparin at anticoagulant doses on the bridging therapy and possible thrombotic and / or hemorrhagic complications (major and minor bleeding) resulting from this use.

Methods: We have analyzed 975 bridging therapies at full dose in our clinic in the last year. They were made to a total of 650 patients (315 men and 335 women) with CHADS/VASC ≥2, aged between 15 and 92, with an average age of 69 years old. The reasons of anticoagulation in our patients were atrial fibrillation, mechanical prostheses, DVT, pulmonary embolism and recurrent thrombosis in patients with thrombophilia. In 70% of the cases, there were comorbidities, such as heart failure, chronic obstructive pulmonary disease, anemia, kidney failure, liver disease and long-term aftereffects of stroke. The bridging therapy has consisted of a prophylactic dose (warfarin) before the procedure, and replacing it by sodium bemiparin at full doses <50 kgr: 5.000 IU/24h, 50 to 70 kgr: 7.500 IU/24 h, 70-100 kgr: 10.000 IU/24 h and >100 kgr: 12.500 IU/24 h, and administration of a prophylactic dose of 3.500 IU, 12 hours before the procedure, and another dose 6-12 hours after the procedure, depending on the risk of bleeding of the intervention and the thrombotic risk of the patient’s disease. The bridging therapy has been performed in 225 cases of major surgery (orthopedic surgery, ophthalmological procedures, valvular replacements etc), 340 cases of minor surgery (removal of neus, complex dental extractions, dental implants), 295 cases of invasive procedures (colonoscopies, endoscopies...), 50 cases of bleeding caused by AVK (epistaxis, petechiae and bruises, hemoptysis, menorrhagia and gastrointestinal bleeding), 30 cases of hospitalization with INR decompensation with AVK (epistaxis, petechiae and bruises, hemoptysis, menorrhagia and gastrointestinal bleeding), 30 cases of hemorrhagic complications (major and minor bleeding) resulting from this use.

Results: As complications of using bemiparin sodium, there have been: 40 cases of hematomas at the needle puncture sites. There was neither cases of major bleeding nor cases of thrombosis.

Table 1.

Summary/Conclusions: Sodium bemiparin administered at therapeutic doses (115 IU/kg/24h) in the perioperative period, according to the scheme described above, is associated with a low incidence of recurrence of VTE and bleeding. The complications presented in our sample have been very few, in patients with associated co-morbidities. In our study, sodium bemiparin has shown to be safe and effective with minimal bleeding complications. Treatment should be administered on an individual basis according to each patient and factors related to surgery. Further studies will confirm our results.
IBRUTINIB IN PREVIOUSLY TREATED CHRONIC LYMPHOCYTIC LEUKEMIA: UPDATED EFFICACY AND SAFETY OF THE RESONATE STUDY WITH UP TO FOUR YEARS OF FOLLOW-UP

1Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, 2The Ohio State University Comprehensive Cancer Center, Columbus, United States, 3The Leeds Teaching Hospitals, St.James’s Institute of Oncology, Leeds, United Kingdom, 4University of California Irvine, Irvine, 5Hofstra Northwell School of Medicine, Hempstead, 6Vanderbilt-Ingram Cancer Center, Nashville, 7Stanford University School of Medicine, Stanford, United States, 8Pierer Macallum Cancer Centre and St. Vincent’s Hospital, Melbourne, 9Royal North Shore Hospital, Sydney, Australia, 10Division of Hematology and Hemostaseology, Medical University of Vienna, Vienna, Austria, 11University of Rochester Medical Center, Rochester, 12Weill Cornell Medical College, New York, 13University of California San Diego, Moores Cancer Center, La Jolla, United States, 14Beaumont Hospital, Dublin, Ireland, 15Niguarda Cancer Centre, Milan, Italy, 16Swedish Cancer Institute Hematologic Malignancies Program, Seattle, 17University of Texas MD Anderson Cancer Center, Houston, 18Pharmacyclics LLC, an AbbVie Company, Sunnyvale, 19CLL Center, Dana-Farber Cancer Institute, Boston, United States

Background: Ibrutinib is a first-in-class, once-daily oral inhibitor of Bruton’s tyrosine kinase. Ibrutinib as a single agent is indicated by the EMEA and US FDA for the treatment of adult patients with CLL and offers a treatment without chemotherapy. The phase 3 RESONATE trial in patients with relapsed CLL showed superior efficacy of ibrutinib compared with ofatumumab (Byrd NEJM 2014).

Aims: We report updated safety and efficacy results of the RESONATE trial with up to 4 years of follow-up.

Methods: Eligibility criteria included ≥1 prior therapy, ineligibility for treatment with a purine analog, and ECOG performance status 0-1. Informed consent was obtained from all patients prior to study initiation. Patients received oral ibrutinib (420 mg once daily) until disease progression or unacceptable toxicity or intravenous ofatumumab (300 mg weekly 1; 2000 mg weekly for 7 weeks and then every 4 weeks for 16 weeks) for up to 24 weeks. At the interim analysis (median follow-up of 9 months), the data monitoring committee declared superiority of ibrutinib vs ofatumumab for progression-free survival (PFS) and overall survival (OS), and access to ibrutinib was recommended for all patients in ofatumumab arm who had disease progression. Long-term follow-up of efficacy endpoints are ongoing. Patients randomized to ofatumumab were censored at crossover. OS is defined as the time from randomization to death or last contact.

Results: Randomized patients were randomized to receive ibrutinib (n=195) or ofatumumab (n=196). The median age was 67 years, with 40% age ≥70 years, and Rai stage III/IV in 57% of patients. The median follow-up of 44 months (maximum 53 months) for the ibrutinib arm, PFS was significantly longer for ibrutinib vs ofatumumab (median NR vs 8 months, [HR 0.133; P<0.0001]). The 3-year PFS was 59% for ibrutinib vs 3% for ofatumumab. A significant PFS benefit was observed across baseline subgroups. In the ibrutinib arm, AEs for the del11q subgroup tended to have the most favorable outcome; however, PFS outcomes were not statistically different for patients with del17p or del11q or patients without these FISH abnormalities. At time of analysis, with the majority of patients randomized to ofatumumab (68%) crossing over to receive ibrutinib therapy, OS was longer for ibrutinib vs ofatumumab (median OS NR for either arm). The 3-year OS rate for ibrutinib was 74%. The ORR for ibrutinib was 91% with a CR/CRi rate that increased over time (currently 9%). Baseline cytopenias improved with extended ibrutinib therapy for hemoglobin (85% of patients), platelet (95% of patients), and absolute neutrophil counts (95% of patients). Adverse events (AE) profile of ibrutinib was consistent with previous reports. During a follow-up of up to 4 years, major hemorrhage occurred in 6%, grade ≥3 atrial fibrillation occurred in 6%, and grade ≥3 hypertension occurred in 8% of patients. The incidence of most grade ≥3 AEs decreased from year 1 vs year 2-3: neutropenia: 18% vs 8%; pneumonia: 11% vs 4%; atrial fibrillation: 4% vs 2%, respectively. The most frequent reasons for treatment discontinuation were progressive disease (27%) and AEs (12%). At analysis, 90% patients randomized to ibrutinib (46%) continue to receive ibrutinib.

Summary/Conclusions: In this international phase 3 RESONATE study with median follow-up of up to 4 years, long-term treatment with ibrutinib showed a favorable tolerability profile with sustained PFS and OS benefit regardless of high-risk cytogenetics. The results in relapsed del17p and del11q patients compared favorably to those previously reported in phase 2 studies.
Background: Venetoclax monotherapy in patients (pts) with relapsed/refractory CLL harboring deletion 17p (del17p) resulted in an ORR of 79% with a CR rate of 7%. As determined by an independent review committee at the initial assessment was performed beginning with the first clinical assessment of CR or PR with nodes <2 cm and then every 12 weeks until MRD negativity (defined at 10^-4 sensitivity). MRD was assessed by NGS and multicolor flow cytometry and the best response was reported. Data cutoff date was June 10, 2016.

Results: Pts (N=158) had a median age of 67 years (range, 29–85); a median of 4 (range 0–10) 32% were fludarabine refractory; 11% previously had been treated with B-cell receptor signaling inhibitors (BCR); 48% had nodes ≤5 cm; and 78% had unmutated IGHV. The median duration of venetoclax therapy was 16.7 months (range 0–34.4 months). Primary reasons for discontinuation (50.6% of pts) were PD (31.0%), adverse events (AEs) (12.6%), withdrawal of consent (2.5%), stem cell transplant (2.5%) and other (1.9%). For all 158 pts, the investigator-assessed ORR was 77% and CR rate was 18%. The 24-month estimates for progression-free survival (PFS) and overall survival (OS) were 52% and 72%, respectively. The safety expansion cohort included 5 pts with previously untreated del(17p) CLL. These pts had an ORR of 80%, CR rate of 40%, and all 5 were alive and progression-free 1 year after their first treatment administration. Among the 18 pts with prior BCR therapy, ORR was 61% and CR was 11%, with 12-month PFS and OS rates of 50% and 72%, respectively. The most commonly reported AEs were neutropenia (42%), nausea (37%), diarhea (37%), anemia (24%), and fatigue (22%). The most common grade 3–4 AEs were neutropenia (39%), thrombocytopenia (15%), and anemia (14%). Infection rate (77% all grades, 22% grade 3–4) and spectrum were consistent with the underlying disease. The rate of laboratory tumor lysis syndrome (TLS) was 5%, with no cases of clinical TLS. Of 101 pts with evaluable blood MRD by flow cytometry, 76 also had MRD data by NGS. From the full trial cohort of 158 pts, 42 (27%) demonstrated blood MRD negativity at 10^-4 by flow cytometry, and 28 had a contemporaneous NGS sample. MRD negativity (10^-4 sensitivity) was confirmed by NGS in 20 pts (71%), and 8 pts (29%) were MRD-positive by NGS. MRD negativity by NGS (10^-5) was observed in 22 pts in blood and bone marrow samples, and 15 pts were negative in the marrow although not necessarily at the same time. One pt negative by NGS did not have a matching flow cytometry assessment and 1 pt was positive by flow cytometry (0.008% vs 0.02%). Pts who achieved blood MRD-negative CR by flow cytometry (n=19) had a 24-month PFS estimate of 100%, compared with 78.5% for pts who had blood MRD-negative CR by flow cytometry. These results were obtained when assessed with a 10^-4 cutoff.

Summary/Conclusions: Venetoclax monotherapy resulted in a high response rate that was durable in this high-risk population, including among pts who had previously received a B-cell receptor inhibitor. MRD negativity by either flow cytometry or NGS correlated with outstanding outcomes.

Background: Subsets of B cell malignancies are addicted to B cell antigen receptor (BCR) signaling for survival. Co-stimulation of the BCR with IL-2 or IL-4 in normal B cells significantly enhances cellular activation relative to BCR or cytokine stimulation alone, and combining SYK and JAK selective inhibitors synergize to suppress this response (Coffey et al., 2013). Hence, BCR/SYK and cytokine JAK/STAT signaling pathways cooperate to control B cell activation. This cooperation appears to be relevant to B cell malignancies as well. IL-4 in normal B cells synergizes to suppress this response (Coffey et al., 2013). Hence, BCR/SYK and cytokine JAK/STAT signaling pathways cooperate to control B cell activation. This cooperation appears to be relevant to B cell malignancies as well. IL-4 in normal B cells synergizes to suppress this response (Coffey et al., 2013). Hence, BCR/SYK and cytokine JAK/STAT signaling pathways cooperate to control B cell activation. This cooperation appears to be relevant to B cell malignancies as well.

Methods: Eligible pts had CLL or rel/ref NHL w/o limit to prior therapies, including those ref to prior PI3Kδ or BTK inhibitors. UTX dosed on D 1, 8, 15 of C 1, D 1 of C 2-6, and C 9 & 12. TGR-1202 dose escalated (400/600/800mg QD), ibritinib dosed at 420mg (CLL) or 560mg (NHL), both on C1D1.

Results: 38 pts were enrolled: 20 CLL/SLL and 18 NHL, including 6 follicular (FL), 6 DLBCL, 4 mantle cell (MCL) and 2 marginal zone (MZL). Med age 65 yrs (range 32-85); 29 M/9 F; med prior tx=3 (range 0-6). 2 pts ref to prior PI3Kδ/BTK prev treated with ibritinib (1 rel/ref rel). MTD was not reached. Most common (>20%) all causality AEs were fatigue (42%), diarhea (39%), dizziness (34%), nausea (32%), neutropenia, pyrexia, rash, infusion reaction, insomnia (each at 29%), thrombocytopenia, cough (each at 26%), anemia (24%) and sinusitis (21%). ORR 34% (all AEs were minimal), the only event >10% was neutropenia (16%). ORR amongst 36 evaluable pts is shown in the following Table 1.

Table 1.

Background: Subsets of B cell malignancies are addicted to B cell antigen receptor (BCR) signaling for survival. Co-stimulation of the BCR with IL-2 or IL-4 in normal B cells significantly enhances cellular activation relative to BCR or cytokine stimulation alone, and combining SYK selective and JAK selective inhibitors synergize to suppress this response (Coffey et al., 2013). Hence, BCR/SYK and cytokine JAK/STAT signaling pathways cooperate to control B cell activation. This cooperation appears to be relevant to B cell malignancies as well. IL-4 promotes the survival of BCL cells in culture via up-regulation of MCL1 and BCL-xl, protecting the tumor from death induced by fludarabine and chlorambucil (Steie et al., 2010) and by ibrutinib and ibritinib (Aguilar-Hernandez et al., 2016). Also, unlike ibrutinib, combined SYK and JAK inhibition by cerdulatinib induces apoptosis in primary BCL cells and leads to down-regulation of MCL1 and BCL-xl (Blunt et al., 2015) and induces apoptosis in cells from ibrutinib-resistant CLL patients (Guo et al., 2017). It also induces apoptosis in primary DLBCL and DLBCL cell lines that carry BCR pathway mutations resistant to ibrutinib (Ma et al., 2015). Combined SYK/JAK inhibition may therefore represent a powerful strategy to control B cell malignancies. A phase I dose escalation study of cerdulatinib in 43 patients with relapsed/refractory CLL and NHL was recently completed (Hamlin et al., EHA Congress 2016). Inhibition of both BCR/SYK and JAK/STAT signaling pathways by >90% in peripheral blood mononuclear cells (PBMC) and CD19+ B-cell malignancies. A phase II trial in the Netherlands (Phase 2) is now demonstrating efficacy of this triplet combination of a novel anti-CD20 mAb+PI3Kδ+BTK inhibitor (ibrutinib) in pts with B-cell malignancies.

Methods: This is the first known triplet combination of an anti-CD20 mAb+PI3Kδ+BTK inhibitor. The combination of UTX, TGR-1202, and ibrutinib has been well tolerated with activity observed across heavily pre-treated and relapsed/refractory B-cell malignancies. Expansion cohorts at the highest dose (800mg TGR-1202+full dose ibrutinib) are underway. Future trials for the triplet are warranted.
